Before putting protective relays into service, remove all blocking which may have been inserted for the purpose of securing the parts during shipment. Make sure that all moving parts operate freely. Inspect the contacts to see that they are clean and close properly. Operate the relay to check the settings and electrical connections.

1. APPLICATION
These relays have been specially designed and tested to establish their suitability for class 1E applications in accordance with the ABB Power T&D Company program for class 1E Qualification Testing as detailed in bulletin STR-1.

“Class 1E” is the safety classification of the electric equipment and systems in nuclear power generating stations that are essential to emergency shutdown of the reactor, containment isolation, cooling of the reactor, and heat removal from the containment and reactor, or otherwise are essential in preventing significant release of radioactive material to the environment.

The type CO-4 relay is used in applications that require a step-type current vs. time characteristics. A typical application is as an overcurrent relay that is to coordinate with a type DS circuit breaker or a circuit breaker with similar tripping characteristics.

2. CONSTRUCTION AND OPERATION
The type CO-4 relay consists of an overcurrent unit (CO-5), an indicating instantaneous trip (IIT) mounted on the left hand pedestal, and a timer (T) which is activated by a current operated instantaneous trip (IT). See figure 1. Internal schematic, figure 2, shows the relationships of these units.

2.1 ELECTROMAGNET
The electromagnet of the overcurrent unit has a main tapped coil located on the center leg of an “E” type laminated structure that produces a flux which divides and returns through the outer legs. A shading coil causes the flux through the left leg to lag the main pole flux. The out-of-phase fluxes thus produced in the air gap cause a contact closing torque.

2.2 INDICATING CONTACTOR SWITCH UNIT (ICS)
The dc indicating contactor switch is a small clapper type device. A magnetic armature, to which leaf-spring mounted contacts are attached is attached to the magnetic core upon energizing of the switch. When the switch closes, the moving contacts bridge two stationary contacts, completing the trip circuit. Also during this operation two fingers on the armature deflect a spring located on the front of the switch, which allows the operation indicator target to drop.

With the timer (T) set for not less than 70 cycles, the type CO-4 relay has a seismic Zero Period Acceleration (ZPA) rating greater than 5.7 g as defined in IEEE standard C37.98 for broad-band multi-frequency fragility testing.

All possible contingencies which may arise during installation, operation or maintenance, and all details and variations of this equipment do not purport to be covered by these instructions. If further information is desired by purchaser regarding this particular installation, operation or maintenance of this equipment, the local ABB Power T&D Co. Inc. representative should be contacted.
The front spring, in addition to holding the target, provides restraint for the armature and thus controls the pickup value of the switch.

2.3 INDICATING INSTANTANEOUS TRIP UNIT (IIT)
The instantaneous trip unit is a small ac operated clapper type device. A magnetic armature, to which leaf-spring mounted contacts are attached, is attracted to the magnetic core upon energization of the switch. When the switch closes, the moving contacts bridge two stationary contacts completing the trip circuit. Also during the operation, two fingers on the armature deflect a spring located on the front of the switch which allows the operation indicator target to drop.

A core screw accessible from the top of the switch and taps on the coil provides the adjustable pickup range.

The indicating instantaneous trip contacts will close 30 amperes at 250 volts dc, and will carry this current long enough to trip a breaker.

2.4 TIMER (T)
The timer is a solid-state type. It consists of a printed circuit board with an output telephone relay, a rectifier, two operational amplifiers and several associated components.

2.5 INSTANTANEOUS TRIP UNIT (IT)
The instantaneous trip unit is a small ac operated clapper type device. A magnetic armature, to which leaf-spring mounted contacts are attached, is attracted to the magnetic core upon energization of the switch. When the switch closes, the moving contacts bridge two stationary contacts completing the timer circuit.

A core screw accessible from the top of the switch and taps on the coil provides the adjustable pickup range.

The IT contacts are connected in a series with the timer to allow an adjustable time delay after the IT picks up.

3. CHARACTERISTICS
They typical current ranges of the unit of the type CO-4 relay are as follows:

CO-5 type long time overcurrent nit 4 to 12 amperes with taps at 4-5-6-7-8-10 and 12 amperes. The tap value is the minimum current required to just close the relay contacts.

IIT instantaneous unit has an adjustable range of 6 to 144 amperes.

The IT instantaneous unit has an adjustable range of 6 to 144 amperes. However, the usable range of the device is 10 to 100 amperes. This range restriction is due to the timer (T) which is activated by the IT device. The range of the timer is 10 to 100 amperes and 0.25 to 3 seconds for the solid-state unit.

The typical operating curves of the CO-5 unit are shown by figure 4. The time dial indicates starting position of the moving contact over a 270° range. Indexes from 1 (minimum time) to 11 (maximum time).

The typical band curves of the overall operating characteristic of the type CO-4 relay are shown by figure 4.

3.1 TRIP CIRCUIT
All tripping contacts are connected in parallel which allows tripping by the CO-5 long time unit. IT plus time delay or IIT instantaneously, depending on the relative unit settings and current magnitude.

The main contacts will close 30 amperes at 250 volts dc and the seal-in contacts of the indicating contractor switch will carry this current long enough to trip a circuit breaker.

4. SETTINGS

The setting are made to obtain an operating characteristic similar to that indicated by the example curve of figure 4.

4.1 CO UNIT

The overcurrent unit settings can be defined either by tap setting and time dial position or by tap setting and a specific time of operation at some current multiple of the tap setting (e.g., 4 tap setting, 2 time dial position or 4 tap setting, 6.0 seconds at 4 times tap value current).

To provide selective circuit breaker operation, a minimum coordinating time of 0.3 seconds plus circuit breaker time is recommended between the relay being set and the relays with which coordination is to be effected.

The connector screw on the terminal plate above the time dial makes connections to various turns on the operating coil. By placing the screw in the various terminal plate holes, the relay will respond to multiples of tap value currents in accordance with the various typical time-current curves.

4.1.1 Instantaneous Reclosing

The factory adjustment of the CO unit contact provides a contact follow. When instantaneous circuit breaker reclosing will be initiated upon the closure of the CO contact, this contact follow must be eliminated by loosening the stationary contact mounting screw, removing the contact plate and then replacing the plate with the bent end resting against the contact spring. With this change and the contact mounting screw tightened, the stationary contact will rest solidly against its backstop.

4.1.2 INDICATING CONTACTOR SWITCH (ICS)

There are no settings to make on the indicating contactor switch (ICS).

4.2 INDICATING INSTANTANEOUS TRIP (IIT)

The proper tap must be selected and the core screw must be adjusted to the value of pick-up current desired.

The nameplate data will furnish the actual current range that may be obtained from the IIT unit. It is recommended that the IIT be set on the higher tap where there is a choice of tap settings. For example, for a 20 ampere setting use the 20 to 50 tap rather than the 6 to 20 tap.

4.3 INSTANTANEOUS TRIP UNIT (IT)

The proper tap must be selected and the core screw must be adjusted to the value of pick-up current desired.

The nameplate data will furnish the actual current range that may be obtained from the IT unit. It is recommended where there is a choice of tap settings that the IT unit be set on the higher tap setting. For example, for a 20 ampere setting use the 20 to 50 tap rather than the 6 to 20 tap.

4.3.1 TIMER (T)

The solid-state timer uses a trimpot P1 which controls the time delay from 0.25 to 3.0 seconds. This range is marked on the PC board. (See figure 5) The time delay is proportional to the time constant produced by P1, R7, C2 and C3 as shown in figure 6. The first op-amp is used as a voltage follower and the second one is used as a voltage level detector. As the voltage across the capacitor C2 exceeds the voltage level at pin 6 of IC2, the output telephone relay picks up to close the T contacts.

Since the tap block connector screw carries operating current, be sure the screw is turned tight.

In order to avoid opening current transformer circuits when changing taps under load, the relay must be first removed from the case. Chassis operating shorting switches on the case will short the secondary of the current transformer. The taps should then be changed with the relay outside of the case and then re-inserted into the case.
5. INSTALLATION
The relay should be mounted on switchboard panels or their equivalent in a location free from dirt, moisture, excessive vibration and heat. Mount the relay vertically by means of the four mounting holes on the flange for the semi-flush type FT case. The mounting screws may be utilized for grounding the relay. External toothed washers are provided for use in the locations shown on the outline and drilling plan to facilitate making a good electrical connection between the relay case, its mounting screws and the relay panel. Ground wires should be affixed to the mounting screws as required for poorly grounded or insulating panels. Other electrical connections may be made directly to the terminals by means of screws for steel panel mounting.

For detail information on the FT case refer to IL 41-076 for semi-flush mounting.

6. ADJUSTMENTS AND MAINTENANCE
Proper adjustments have been made at the factory. Upon receipt of the relay no customer adjustments, other than those covered under “SETTINGS” should be required.

6.1 PERFORMANCE CHECK
1. Contact
The index mark on the movement frame will coincide with the “O” mark on the time dial when the stationary contact has moved through approximately one-half of its normal deflection. Therefore, with the stationary contact resting against the backstop, the index mark is offset for the right of the “O” mark by approximately .020”. The placement of the various time dial positions in line with the index mark will give operating times as shown on the respective timecurrent curves.

2. Minimum Trip Current
Set the time dial to position 6. Alternately apply tap value current plus 3% and tap value current minus 3%. The moving contact should leave the backstop at tap value current plus 3% and should return to the backstop at tap value current minus 3%.

3. Time Curve
Table 1 shows the time curve calibration points. With the time dial set to the indicated position, apply the currents specified by Table 1 and measure the operating time of the relay. The operating times should equal those of Table 1 plus or minus 5%.

<th>Timer</th>
</tr>
</thead>
</table>

The burden of the timer and auxiliary transformer at 5 amperes 60 Hertz is as follows:

- IT contact open 0.7 VA at 80 lag.
- IT contact close 1.7 VA at 50 lag.
4. Indicating Instantaneous Trip (IIT)
The core screw which is adjustable from the to of the trip unit and
the tap located on the top of the IIT determines the pickup value.
The trip unit has a nominal ratio of adjustment of 1 to 24.

Apply sufficient current to operate the IIT. The operation indicator
target should drop freely.

5. Indicating Contactor Switch (ICS)
Close the main relay contacts and pass sufficient dc current
through the trip current to close the contacts of the ICS. This value
of current should not be greater than the particular ICS nameplate
rating. The indicator target should drop freely.

Repeat above except pass 85% of ICS nameplate rating current.
Contacts should not pick up and target should not drop.

6. Instantaneous Trip Unit (IT)
The core screw which is adjustable from the top of the trip unit and
the tap located on the side of the IT determines the pickup value,
The unit has a nominal ratio of adjustment of 1 to 24 but its range
is limited from 10 amperes to 100 amperes.

Apply sufficient current to operate the IT.

7. Timer (T)
Energize the IT circuit at 150% of the IT setting to check the timer
setting. The time delay of the solid-state timer is adjusted by a
trimpot P1. A small arrow on the trimpot indicates the setting
position which is marked on the PC boards. The timer is factory
calibrated and set for a time delay of 2.5 seconds.

7.1 CO UNIT
1. Contacts
The index mark on the movement frame will coincide with the
"0" mark on the time dial when the stationary contact has moved
through approximately one-half of its normal deflection. Therefore,
with the stationary contact resting against the backstop, the index
mark is offset to the right of the "0" mark by approximately .020".
The placement of the various time dial positions in line with the
index mark will give operating times as shown on the respective
time-current curves.

2. Minimum Trip Current
The adjustment of the spring tension in setting the minimum trip
current value of the relay is most conveniently made with the
damping magnet removed.

With the time dial set on "0, wind up the spiral spring by means of
the spring adjuster until approximately 6-2/4 convolutions show.

The spiral can be adjusted with the spring shield in place as
follows. One slot of the spring adjuster will be available for a
screwdriver in one window of the front barrier of the spring shield.
By adjusting this slot until a barrier of the spring shield prevents
further adjustment, a second slot of the spring adjuster will appear
in the window the other side of the spring shield barrier. Adjusting
the second slot in a similar manner will reveal a third slot in the
opposite window of the spring shield.
Set the relay on the minimum tap setting, the time dial to position 6.

Adjust the control spring tension so that the moving contact will leave the backstop at tap value current +1.0% and will return to the backstop at tap value current -1.9%.

3. Time Curve Calibration
Install the permanent magnet.

Apply the indicated current per Table 1 for permanent magnet adjustment and measure the operating time. Adjust the permanent magnet keeper until the operating time corresponds to the value of Table 1.

Apply the indicated current per Table 1 for the electromagnet plug adjustment and measure the operating time. Adjust the proper plug until the operating time corresponds to the value in Table 1 (Withdrawing the left-hand plug, front view, increases the operating time and withdrawing the right-hand plug, front view decreases the operating time.) In adjusting the plugs, one plug should be screwed in completely and the other plug run in or out until the proper operating time has been obtained.

Recheck the permanent magnet adjustment. If the operating time for this calibration point has changed, readjust the permanent magnet and then recheck the plug adjustment.

7.2 INDICATING CONTACTOR SWITCH (ICS)
Initially adjust unit on the pedestal so that armature fingers do not touch the yoke in the resent position. (Viewed from top of switch between cover and frame.) This can be done by loosening the mounting screw in the molded pedestal and moving the ICS in the downward position.

a) Contact Wipe – Adjust the stationary contact so that both stationary contacts make with the moving contacts simultaneously and wipe 1/64” to 3/64” when the armature is against the core.

b) Target – Manually raise the moving contacts and check to see that the target drops at the same time as the contacts make or 1/16” ahead. The cover may be removed and the tab holding the target reformed slightly if necessary. However, care should be exercised so that the target will not drop with a slight jar.

If the pickup is low the front cover must be removed and the leaf spring bent outward equally.

7.3 INDICATING INSTANTANEOUS TRIP (IIT)
Initially adjust unit on the pedestal so that armature fingers do not touch the yoke in the resent position. (Viewed from top of switch between cover and frame.) This can be done by loosening the mounting screw in the molded pedestal and moving the IIT in the downward position.

a) Contact Wipe – Adjust the stationary contacts so that both stationary contacts make with the moving contacts simultaneously and wipe 1/64” to 3/64” when the armature is against the core. This can be accomplished by inserting a .0125 thickness gauge between the armature and core and adjusting the stationary contacts until they must touch the moving contacts.

b) Target – Manually raise the moving contacts and check to see that the target drops at the same time as the contacts make. The cover may be removed and the tab holding the target reformed slightly if necessary. However, care should be exercised so that the target will not drop with a slight jar.

c) Pickup – Place tap screw in the 6 to 20 tap and turn the core screw all the way in. Contacts should pickup at less than 6.0 amps, but not lower than 5.1 amperes. If pickup is above this range it may be reduced by using a tweezer or similar tool and squeezing each leaf spring approximately equally by applying the tweezer between the leaf spring and the front surface of the cover at the bottom of the lower window. If the pickup is below this range it may be increased by removing the front cover and bending the leaf spring outward equally. An approximate adjustment would be where the end of the leaf spring is in line with the edge of the molded cover.

The desired pickup is obtained by setting the tap screw in the proper range and adjusting the core screw.
7.4 INSTANTANEOUS TRIP (IT)
Initially adjust unit on the pedestal so that armature fingers do not touch the yoke in the resent position. (Viewed from top of switch between cover and frame.) This can be done by loosening the mounting screw in the molded pedestal and moving the IT in the downward position.

a) Contact Wipe – Adjust the stationary contacts so that both stationary contacts make with the moving contacts simultaneously and wipe 1/64" to 3/64" when the armature is against the core.

This can be accomplished by inserting a .0125 thickness gauge between the armature and core and adjusting the stationary contacts until they just touch the moving contacts.

b) Pickup – Place tap screw in the 6 to 20 tap and turn the core screw all the way in. Contacts should pickup at less than 6.0 amp, but not lower than 5.1 amperes. If pickup is above this range it may be reduced by using a tweezer or similar tool and squeezing each leaf spring approximately equal by applying the tweezer between the leaf spring and the front surface of the cover at the bottom of the lower window. If the pickup is below this range it may be increased by removing the front cover and bending the leaf spring outward equally. An approximate adjustment would be where the end of the leaf spring is in line with the edge of the molded cover.

The desired pickup is obtained by setting the tap screw in the proper range and adjusting the core screw.

7.5 TIMER (T)
Apply 150% of the minimum pickup current for the IT and note the time of operation of the timer with a setting of 2.5 seconds. The operating time should be within 5% of indicated value. If time is not within limits, the time for a given P1 setting can be increased by adjusting multi-turn pot P2 in the clockwise direction. Conversely, the time can be decreased by counterclockwise direction P2.

8. ROUTINE MAINTENANCE
All relays should be inspected periodically. They should receive a “Performance Check” at least once every year or at such other time intervals as may be dictated by experience to be suitable to the particular application. A minimum suggested check on the relay system is to close the contacts manually so that the breaker trips and the target drops. Then release the contacts and observe that the reset is smooth and positive.

If an additional time check is desired, pass test current through the relay and check the time of operation. It is preferable to make this at several times pick-up current at an expected operating point for the particular application.

All contacts should be checked and cleaned if necessary. A contact burnisher Style number 182A836H01 is recommended for this purpose. The use of abrasive material for cleaning contacts is not recommended, because of the danger of embedding small particles on the face of the soft silver and thus impairing the contact.

9. RENEWAL PARTS
Repair work can be done most satisfactorily at the factory. However, interchangeable parts can be furnished to customers who are equipped for doing repair work. However, installation of an interchangeable part is the responsibility of those performing the work. When ordering parts, always give the complete nameplate data.
