This document presents details how an encoderless safe maximum speed (SMS) safety function can be designed and implemented using an ACS880-01 industrial drive and a safety functions module together with other ABB safety devices. The safety function is implemented according to EN/IEC 62061, EN ISO 13849-1, EN/IEC 60204-1 and EN/IEC 61800-5-2 machinery standards. Necessary SIL/PL calculations are presented using ABB’s Functional safety design tool.

Safer machines with drive-based functional safety
Drive-based safety functions are used in applications that require risk reduction from eg. unexpected and hazardous movement. The aim is to design machines that are safe to use. This safety function example can be implemented with ACS880 series drives only.

ACS880-01 industrial drives, together with the safety functions module, provides the encoderless safe maximum speed (SMS) safety function. The function ensures that the motor speed does not exceed the specified maximum speed limit, safeguarding a machine. SMS safety function is pre-programmed in the safety functions module. Only application specific parameter configuration is necessary to commission the function.
Effective and reliable encoderless safe maximum speed function for drive applications

**Overview of the safety function**

The SMS safety function ensures that motor speed does not exceed a specified maximum speed limit. SMS does not need a separate activation switch since it is permanently activated in the safety functions module configuration. The SMS safety function is suitable for eg. making sure that the protection of the structural speed of a machine is not exceeded.

**Operation of the safety function**

The SMS safety function continuously monitors the speed of the drives output when the drive is operational. If motor speed exceeds above the specified speed limit, the safety functions module activates the emergency stop function (stop category 0 or 1 depending on configuration) in order to stop the motor.

If the SMS safety function trips (activates the STO due to overspeed), drive system requires a reboot.

**Ensuring the required safety performance**

The safety function has to fulfil the required safety performance determined by a risk assessment. ABB’s Functional safety design tool (FSDT-01) is used to design the desired safety function. This is carried out according to the following steps:

1. **Evaluate the risks** to establish target safety performance (SIL/PL level) for the safety function.

2. **Design** the safety function loop and **verify** the achieved performance level (PL) or safety integrity level (SIL) for the safety function loop (according to EN ISO 13849-1 or EN IEC 62061, respectively), utilizing the device safety data and the application specific characteristics.

General considerations
Achieving machinery safety requires a systematic approach beyond the physical implementation of a safety function. The overall machinery safety generally covers the following areas:

- **Planning** for and managing functional safety during the lifecycle of the machine
- **Assuring compliance** to local laws and requirements (such as the Machinery directive/CE marking)
- **Assessing machine risks** (analysis and evaluation)
- **Planning the risk reduction** and establishing safety requirements
- **Designing** the safety functions
- **Implementing and verifying** the safety functions
- **Validating** the safety functions
- **Documenting** the implemented functions and results of risk assessment, verification and validation

Finally, the implemented safety function is validated against the risk assessment to ensure that the implemented safety function actually reduces the targeted risk.
