Use and installation instructions for LoPak1 Pre-applied Thermal Interface Material (TIM)

This application note provides some basic guidelines for installing and using the LoPak1 modules in a range of environments. Following these guidelines ensures safe mechanical, electrical and thermal connections that are crucial for reliable operation of these power modules.

1. General
The descriptions and recommendations in this document cannot replace an accurate assessment and evaluation of all aspects of the application related to the intended use of the device. All LoPak1 modules undergo a final test according to IEC60747-9 and IEC60747-15 before delivery.

2. ESD considerations
IGBTs are sensitive to electrostatic discharge (ESD). All LoPak1 modules are ESD protected during transportation and storage. When handling the modules, the gate and auxiliary terminals of both switches should be short-circuited with the ESD protection cap provided or with a metal strip to prevent damage by static charges (IEC60747-1, chap. VIII). A conductive-grounded wrist strap and a conductive-grounded work station are strongly recommended during assembly.

3. Climatic conditions, storage and transportation
During transportation and storage of the modules, extreme forces such as shock or vibration should be avoided as well as environmental conditions exceeding the recommended limits. The maximum storage time is 12 months.

4. Climatic conditions during active, current carrying operation of LoPak1 modules
The LoPak1 modules are not hermetically sealed. The housings and the molding compound, used for the electrical isolation within the housing, are permeable by humidity and gases in both directions. Humidity differences will therefore be equalized. The climate conditions for LoPak1 modules in active, current carrying operation are specified according to Environmental Specification 5SZK 9118. In the case of a humid atmosphere that causes condensation, or operation in climatic conditions surpassing class 3K3 of EN60721-3-3, appropriate measures must be taken to avoid liquid droplet depositions under all circumstances.
5. Terminals
The connection between gate-drive circuit and the control terminals of the LoPak1 module should be as short as possible. Coaxial cables, twisted wires or mounting of the gate-drive PCB directly on the auxiliary terminals are highly recommended to prevent any electro-magnetic interference (EMI) from the power circuitry to the gate signals. Figure 1 shows the circuit diagram of the device with all internal and external connections in the phase-leg configuration. A low inductance symmetrical copper busbar, mounted directly on top of the module, is highly recommended for all LoPak1 modules.

6. Safe operating area / Voltage rating
The peak turn-off over-voltage ($V_{CEM}$) must be kept below the maximum rated collector-emitter voltage ($V_{CES}$) for each switch in the LoPak1 module. Therefore, it is important to use a busbar with low inductance $L_s$. Please refer to the module data sheet for the internal module stray inductance ($L_{in}$).

$$V_{CEM} = |di/dt| \cdot (L_{in} + L_s) + V_{DC} \leq V_{CES} \quad \text{Eq. 1}$$

The “Turn-off safe operating area (RBSOA)” graph in the module data sheet shows the maximum allowed operating conditions with the peak turn-off over-voltage measured at the module power terminals and at the chip (figure 2). There are several factors limiting the voltage class and operating range of the device when used at altitudes higher than 2000 m above sea level. The lower air pressure will affect the cooling performance, the changed dielectric strength of the air will reduce the clearance distance of the device and the statistical failure rate due to higher cosmic radiation levels will also impact the maximum operating voltage. All these factors should be carefully analyzed in the design phase. The LoPak1 application notes provide data to optimize use of the device for the appropriate application conditions (see also application support).

7. Gate drive
It is recommended the LoPak1 modules are operated with a turn-on gate voltage of +15 volts (V) for low on-state losses and good short-circuit ruggedness. Turn-on gate-voltages of more than +15 V result in slightly lower on-state losses but reduce short-circuit ruggedness. A turn-off gate voltage of -5 to -15 V is recommended for low turn-off losses and high dv/dt immunity. The gate driver can be mounted or fixed either by using the press fit pins or soldering pins.
8. Heat sink specification
The mounting area on the heat sink and the module must be clean and free of particles to obtain the maximum thermal conductivity between the module and the heat sink. In addition, ridges with more than 10 µm height, or particles, can lead to deformation of the Cu baseplate and cracks in the ceramic, so must be avoided. The mechanical specification of the mounting surface is:
- Flatness: 30 micrometer (µm) over entire contact area
- Roughness: Rz - 15 µm, no ridge larger than 10 µm

9. Thermal Interface Material (TIM) information
TIM is applied in a paste form using automatic stencil printing during module fabrication, but it transforms into a solid during a curing / drying process performed after coating. The TIM layer remains solid at room temperature, reducing the potential for damage to the print pattern by accidental contact. Module handling and installation is also made easier for the customer. The TIM becomes viscous during module operation when it is heated to temperatures above 45°C by the transistors on the semiconductor chips in the module, allowing it to spread out evenly across the interface during thermal cycling to provide a homogeneous coating across the base plate/heat sink interface.
11. Mounting of the busbar and auxiliary connections

The busbars must be mounted onto the collector and emitter power terminals with the recommended torque given in table 1. It is important that the mounting torque is above the minimum requirement and it is better close to the maximum recommended value to allow good electrical and thermal contact. The cross sections of the busbars must be sufficiently large to avoid heating of the module by busbar resistive losses. Permanent mechanical stress to the power and auxiliary terminals, for example by rotating forces, must be avoided. Special attention must be paid to avoiding forces caused by shock and vibration as well as forces due to thermal expansion of the busbar during operation.

Supporting the busbar could be done using fixing posts close to the modules on each side, an example of which is shown in figure 13.

If soldering pins are used, the auxiliary pins must be connected by plugs according to an appropriate standard such as DIN 46245, while observing the ESD guidelines. If an external driver board is used, it is recommended that the contact areas be mechanically relieved after soldering by mounting the PCB onto the module using the four PCB mounting stand-offs.

If press fit pins are used, a reasonable amount of contact area between the PCB hole and press fit pin should be left in the PCB design and the appropriate mounting tools should be used. Also note that the auxiliary emitter and collector terminals are not designed to carry any load current.

Maximum forces at the terminals during the assembly process are shown in figures 6 and 7. Connecting parts, such as the busbar and gate-unit, must be designed and assembled in a way that those forces are not exceeded.

Important notes:

- Impact wrenches can damage the module or cause jamming of the screw and are not recommended.
- Do not use too fast screwing speed as this might result in excessive torque values or jamming of the screw.
- The use of washers and lock- or spring washers is recommended.

Table 01 Recommended mounting torques

The two-step procedure must be followed to allow the module baseplate to relax and conform to the heat sink. It is strongly recommended to recheck the torque after 15 - 30 minutes and retorque to the final torque value if necessary, following the sequence shown in figure 5.
To avoid the screws jamming, always use screw material that matches the material of the thread: for example threads in the heat sink or the terminal nuts. The module’s terminal nuts are made from 10B21 carbon steel.

The screw lengths must be selected to ensure the maximum tightening depth of the main connections is not exceeded.

12. Cleaning during replacement
The heat sink must be cleaned to remove any remaining debris when replacing the power semiconductor module. Removing the paste creates no special industrial safety demands. A lint free cloth can be used for cleaning, and the surface of the heat sink must not be damaged during this process.

Step 1: Remove module from the heat sink
Step 2: Clean off coarse particles
Step 3: Complete a final wipe-down
Small particles will be left behind in the microstructure of the heat sink surface. They should not cause an issue for the mounting of another module with applied TIM, provided the TIM on the replacement module is identical to the remaining TIM from the module that was removed. If the mounting position to be used has been previously coated with another heat conducting media, a thorough cleaning using approved solvents or alcohol is required.
