ABB's synchronous generators for diesel and gas engines, type AMG 0710, 0900, 1120, 1250 and 1600, can be retrofitted with sensors to monitor vibration levels on the generator. The sensors are fitted on the bearing shield, using an adapter, to monitor the velocity of movement in the vertical and horizontal directions.

Monitoring the generator’s vibration levels is especially useful for detecting bearing wear and other possible problems in the generator. Increasing vibration levels can be an early warning of bearing problems, as well as providing additional information when existing issues are investigated.

The vibration monitoring system is easily installed and does not require any internal changes to the generator. ABB supplies all the necessary materials and documentation. For the best possible results, ABB service engineers are available to provide on-site installation assistance.

Benefits
• Improved generator condition monitoring
• Additional information for maintenance and troubleshooting
• Supports move from reactive to predictive maintenance
• System is easy to install and maintain
• Full manufacturer support
