INSTRUCTIONS FOR USE

PLC Automation

Automation Builder, AC500

Automation Builder 2.5.0, AC500 V3, AC500-eCo V3, AC500-XC V3

Table of contents

1 PLC Automation with V3 CPUs

1.1 About this document

1.1.1 Documentation structure

↳ *Chapter 1.1.4 “Use the "magic button" to display your current position in the table of contents” on page 11.*

↳ *See also chapter " Your tasks - documentation from the user's point of view" on page 9.*

Table 1: Guidance for this documentation: Main chapters

Getting started Basic information to start with Automation Builder and AC500 PLC, e.g., licensing, GUI explanations, example projects.	↳ *Chapter 1.2 “Getting started” on page 11*
Automation Builder installation manager Add, remove or modify software packages in Automation Builder.	↳ *Chapter 1.3 “Automation Builder installation manager” on page 169*
Programming with CODESYS Information about IEC programming in Automation Builder, including description of CODESYS libraries.	↳ *Chapter 1.4 “Programming with CODESYS” on page 176*
Libraries and solutions ABB libraries. Overview and description of integrated standard libraries and solution libraries available as library packages. Explanation of the concept of solution libraries ("system technology"). Description of the library elements, like function blocks and functions.	↳ *AC500 V3 library descriptions: Chapter 1.5 " Libraries and solutions" on page 2146* ↳ *Chapter 1.10 “Reference, function blocks” on page 4292*
PLC integration (hardware) Hardware description and specifications. Overview on module variants, connections, technical data, order data, assembly of modules. Device configuration in Automation Builder. Explanation of system behavior ("system technology"), interaction between PLC behavior (firmware), configuration, programming and use cases.	↳ *Chapter 1.6 “PLC integration (hardware)” on page 2384*
Diagnosis and debugging Explanation of the diagnosis system in the PLC, the display of error messages at the CPU and in IEC applications. Online diagnosis in Automation Builder. List of diagnosis and error messages.	↳ *Chapter 1.7 “Diagnosis and debugging for AC500 V3 products” on page 4011*
Engineering interfaces and tools Information on add-on packages, e.g., for security static analysis or Project Version Control. Mainly for advanced users.	↳ *Chapter 1.8 “Engineering interfaces and tools” on page 4112*
Human machine interface (HMI) Information on HMI with Automation Builder. Configuration of HMI devices in Automation Builder.	↳ *Chapter 1.9 “Human machine interface” on page 4281*
Contact ABB Contact information about our sales and support teams.	↳ *Chapter 1.11 “Contact ABB” on page 4408*

1.1.2 Your tasks - documentation from the user's point of view

All information about **AC500**, **AC500-XC** and **AC500-eCo** is available in this manual.

All information about **AC500-S** and **AC500-S-XC** is available online in the *safety user manual*.

↳ *Chapter 1.1.4 “Use the "magic button" to display your current position in the table of contents” on page 11.*

↳ *See also chapter " Documentation structure" on page 8.*

As a mechanical/electrical designer

PLC system description	↳ *Chapter 1.6.2.7 “PLC system description” on page 2421*
Hardware descriptions	↳ *Chapter 1.6.3 “Device specifications” on page 2430*
Comparison of product features	● ↳ *Chapter 1.6.1 “Product overview and comparison” on page 2384* ● *via product catalog (online)*

1.1.4 Use the "magic button" to display your current position in the table of contents

☑ Documentation is opened in a PDF reader. PDF readers often provide a button to synchronize with the table of contents. Usually, you can find the "magic button" in the bookmarks tab. For example, it looks like this: /

▷ Select the "magic button".

⇨ Your current position will be highlighted in the bookmark tab.

1.2 Getting started

ABB Automation Builder - One holistic suite

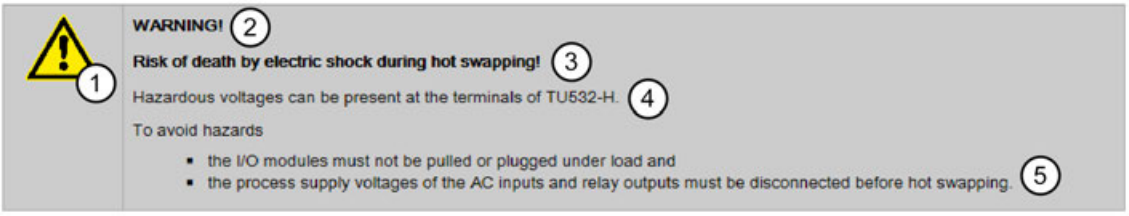
ABB Automation Builder is the integrated software suite for machine builders and system integrators wanting to automate their machines and systems in a productive way. Combining the tools required for configuring, programming, debugging and maintaining automation projects from a common intuitive interface, Automation Builder addresses the largest single cost element of most of today's industrial automation projects: software. ABB Automation Builder covers the engineering of ABB PLCs, Safety PLCs, control panels, drives, motion and robots.

Automation Builder ReadMe

Before starting Automation Builder configuration read the version specific information provided in the Automation Builder readme file. It describes new features and functions as well as workarounds on known problems. The readme file is stored in the installation directory of Automation Builder, however can be downloaded as well from ABB website http://new.abb.com/plc/automationbuilder.

1.2.1 Structure of safety notices

Throughout the documentation we use the following types of safety and information notices. They make you aware of safety considerations or give advice on AC500 products usage.



1 **Safety alert symbol** indicates the danger.
2 **Signal word** classifies the danger.
3 **Type and source of the risk** are mentioned.
4 **Possible consequences** of the risk are described.
5 **Measures to avoid these consequences** (enumerations).

Signal words

DANGER!
DANGER indicates a hazardous situation which, if not avoided, will result in death or serious injury.

Ensure to take measures to prevent the described impending danger.

WARNING!
WARNING indicates a hazardous situation which, if not avoided, could result in death or serious injury.

Ensure to take measures to prevent the described dangerous situation.

CAUTION!
CAUTION indicates a hazardous situation which, if not avoided, could result in minor or moderate injury.

Ensure to take measures to prevent the described dangerous situation.

NOTICE!
NOTICE is used to address practices not related to physical injury but might lead to property damage for example damage of the product.

Ensure to take measures to prevent the described dangerous situation.

NOTE provides additional information on the product, e.g., advices for configuration or best practice scenarios.

1.2.2 Cyber security

Cyber security disclaimer

This product is designed to be connected to and to communicate information and data via a network interface. It is your sole responsibility to provide and continuously ensure a secure connection between the product and your network or any other network (as the case may be). You shall establish and maintain any appropriate measures (such as but not limited to the installation of firewalls, application of authentication measures, encryption of data, installation of anti-virus programs, etc.) to protect the product, the network, its system and the interface against any kind of security breaches, unauthorized access, interference, intrusion, leakage and/or theft of data or information. ABB Ltd and its affiliates are not liable for damages and/or losses related to such security breaches, any unauthorized access, interference, intrusion, leakage and/or theft of data or information.

Although ABB provides functionality testing on the products and updates that we release, you should institute your own testing program for any product updates or other major system updates (to include but not limited to code changes, configuration file changes, third party software updates or patches, hardware exchanges, etc.) to ensure that the security measures that you have implemented have not been compromised and system functionality in your environment is as expected. This also applies to the operating system. Security measures (such as but not limited to the installation of latest patches, installation of firewalls, application of authentication measures, installation of anti-virus programs, etc.) are in your responsibility. You have to be aware that operating systems provide a considerable number of open ports that should be monitored carefully for any threats.

It has to be considered that online connections to any devices are not secured. It is your responsibility to assure that connections are established to the correct device (and e.g. not to an unknown device pretending to be a known device type). Furthermore you have to take care that confidential data exchanged with the PLC is either compiled or encrypted.

Security related deployment guidelines for industrial automation

Security details for industrial automation is provided in a *whitepaper* on ABB website.

Signed firmware updates

The firmware update files for the AC500 V3 PLC are digitally signed releases by ABB. During the update process, these signatures are validated by a hardware security component in the PLC. This way, the AC500 V3 PLC will only update with valid, authentic firmware, signed by ABB.

Open ports and services

As part of the ABB security concept the AC500 V3 PLC comes with minimal services opened by default. Only the services needed for initial setup and programming are open before any user application is downloaded *Chapter 1.6.1.3 “Ethernet protocols and ports for AC500 V3 products” on page 2389*.

Only used services/ports should be enabled (e.g. to enable the functionality of an FTPS server).

Secure communication

Whenever possible, use an encrypted communication between AC500 V3 devices and third party devices, such as HMI devices. This is necessary to protect passwords and other data.

Secure shell access for ABB service

The AC500 V3 PLC contains a secure shell service to access core logging data in case of problems which need a deeper analysis. This service is inactive by default, which means that no one can access this privileged shell in the normal operating state.

To activate this service, local access to the PLC is necessary and activation is only valid until the next power cycle of the PLC. Once activated, the service run on TCP port 22. Each PLC also protects the secure shell access by an individual password.

Frequently asked questions

For more information around cyber security please see our *FAQ*.

1.2.2.1 Defense in depth

The defense in depth approach implements multi-layer IT security measures. Each layer provides its special security measures. All deployed security mechanisms in the system must be updated regularly. It is also important to follow the system vendor's recommendations on how to configure and use these mechanisms. As a basis, the components must include security functions such as:

- Virus protection
- Firewall protection
- Strong and regularly changed passwords
- User management
- Using VPN tunnels for connections between networks

Additional security components such as routers and switches with integrated firewalls should be available. A defined user and rights concept managing access to the controllers and their networks is mandatory. Finally, the manufacturer of the components should be able to quickly discover weaknesses and provide patches.

Only used services/ports should be enabled (e.g. to enable the functionality of an FTPS server).

References: *CODESYS Security Whitepaper*

Security zones

IT resources vary in the extent to which they can be trusted. A common security architecture is therefore based on a layered approach that uses zones of trust to provide increasing levels of security according to increasing security needs. Less-trusted zones contain more-trusted zones and connections between the zones are only possible through secure interconnections such as firewallsFig. 1. All resources in the same zone must have the same minimum level of trust. The inner layers, where communication interaction needs to flow freely between nodes, must have the highest level of trust. This is the approach described in the IEC 62443 series of standards.

Firewalls, gateways, and proxies are used to control network traffic between zones of different security levels, and to filter out any undesirable or dangerous material. Traffic that is allowed to pass between zones should be limited to what is absolutely necessary because each type of service call or information exchange translates into a possible route that an intruder may be able to exploit. Different types of services represent different risks. Internet access, incoming e-mail and instant messaging, for example, represent very high risks.

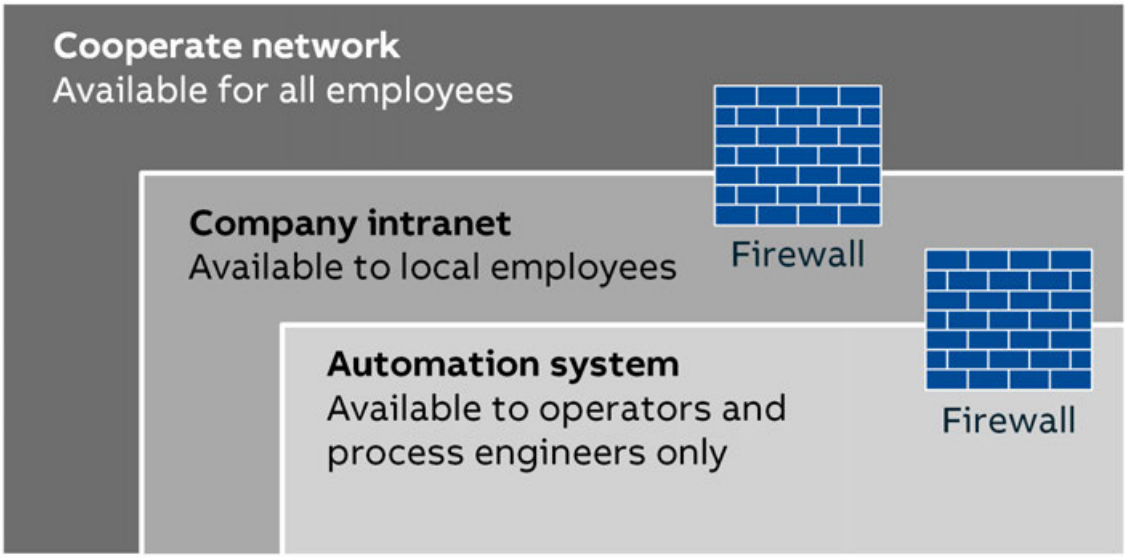


Fig. 1: Security zones

Fig. 1 shows three security zones, but the number of zones does not have to be as many or as few as three. The use of multiple zones allows access between zones of different trust levels to be controlled to protect a trusted resource from attack by a less trusted one.

High-security zones should be kept small and independent. They need to be physically protected, i.e. physical access to computers, network equipment and network cables must be limited by physical means to authorized persons only. A high-security zone should obviously not depend on resources in a less secure zone for its security. Therefore, it should form its own domain that is administered from the inside, and not depend on, e.g., a domain controller in a less secure network.

Even if a network zone is regarded as trusted, an attack is still possible: by a user or compromised resource that is inside the trusted zone, or by an outside user or resource that succeeds to penetrate the secure interconnection. Trust therefore depends also upon the types of measures taken to detect and prevent compromise of resources and violation of the security policy.

References: *Security for Industrial Automation and Control Systems*

1.2.2.2 Secure operation

The controller must be located in a protected environment in order to avoid accidental or intended access to the controller or the application.

A protected environment can be:

- Locked control cabinets without connection from outside
- No direct internet connection
- Use firewalls and VPN to separate different networks
- Separate different production areas with different access controls

To increase security, physical access protection measures such as fences, turnstiles, cameras or card readers can be added.

Follow these rules for the protected environment:

- Keep the trusted network as small as possible and independent from other networks.
- Protect the cross-communication of controllers and the communication between controllers and field devices via standard communication protocols (fieldbus systems) using appropriate measures.
- Protect such networks from unauthorized physical access.
- Use fieldbus systems only in protected environments. They are not protected by additional measures, such as encryption. Open physical or data access to fieldbus systems and their components is a serious security risk.

- Physically protect all equipment, i.e., ensure that physical access to computers, network equipment and cables, controllers, I/O systems, power supplies, etc., is limited to authorized persons
- When connecting a trusted network zone to outer networks, make sure that all connections are through properly configured secure interconnections only, such as a firewall or a system of firewalls, which is configured for “deny by default”, i.e., blocks everything except traffic that is explicitly needed to fulfill operational requirements.
- Allow only authorized users to log on to the system, and enforce strong passwords that are changed regularly.
- Continuously maintain the definitions of authorized users, user groups, and access rights, to properly reflect the current authorities and responsibilities of all individuals at all times. Users should not have more privileges than they need to do their job.
- Do not use the system for e-mail, instant messaging, or internet browsing. Use separate computers and networks for these functions if they are needed.
- Do not allow installation of any unauthorized software in the system.
- Restrict temporary connection of portable computers, USB memory sticks and other removable data carriers. Computers that can be physically accessed by regular users should have ports for removable data carriers disabled.
- If portable computers need to be connected, e.g., for service or maintenance purposes, they should be carefully scanned for viruses immediately before connection.
- All CDs, DVDs, USB memory sticks and other removable data carriers, and files with software or software updates, should also be checked for viruses before being introduced into the trusted zone.
- Continuously monitor the system for intrusion attempts.
- Define and maintain plans for incident response, including how to recover from potential disasters.
- Regularly review the organization as well as technical systems and installations with respect to compliance with security policies, procedures and practices.

A protected local control cabinet could look like in figure 2, page 16. This network is not connected to any external network. Security is primarily a matter of physically protecting the automation system and preventing unauthorized users from accessing the system and from connecting or installing unauthorized hardware and software.

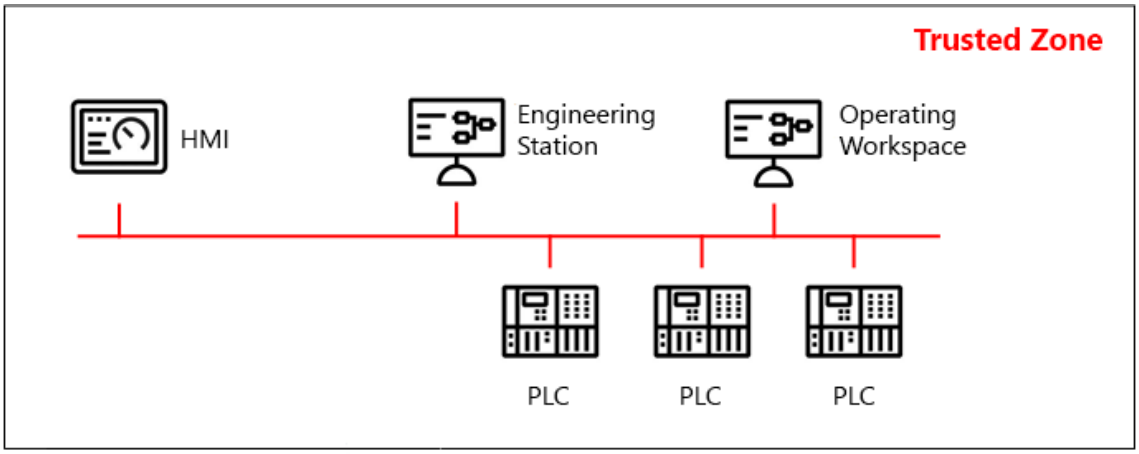

Fig. 2: Isolated automation system

Servers and workplaces that are not directly involved in the control and monitoring of the process should preferably be connected to a subnet that is separated from the automation system network by means of a router/firewall. This makes it possible to better control the network load and to limit access to certain servers on the automation system network. Note that servers and workplaces on this subnet are part of the trusted zone and thus need to be subject to the same security precautions as the nodes on the automation system network.

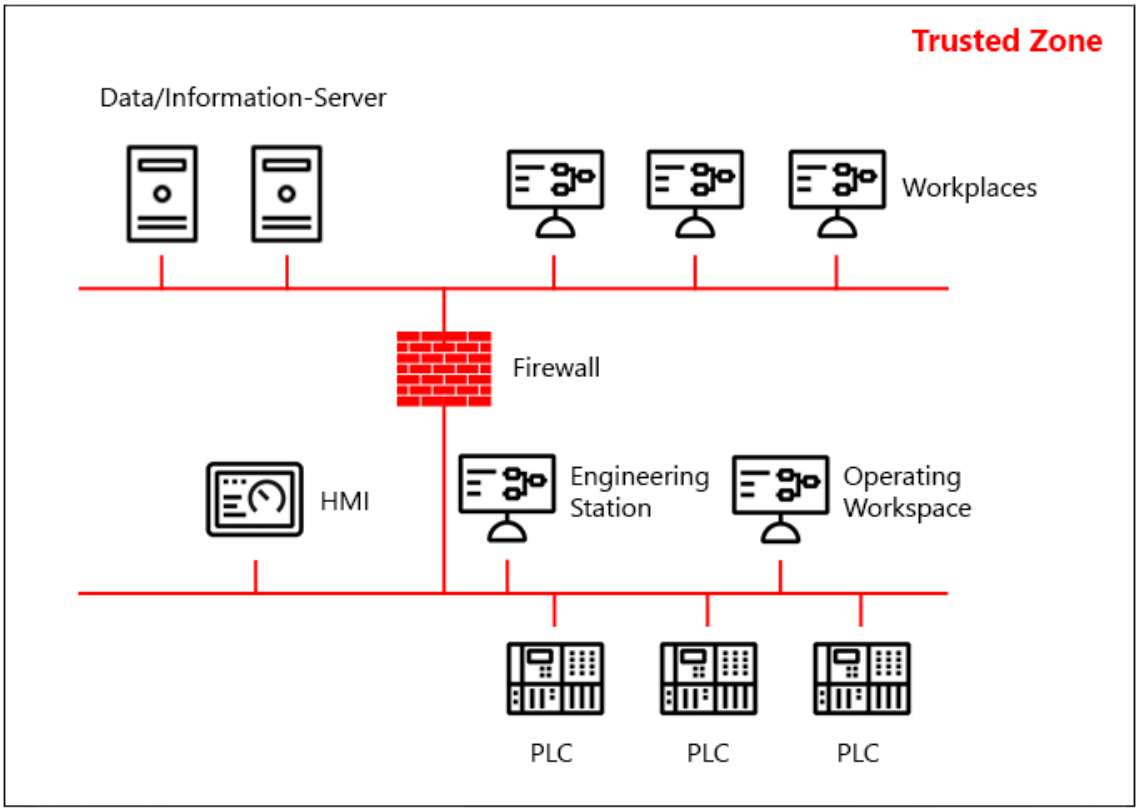

Fig. 3: Plant information network connected to an automation system

For the purposes of process control security, a general-purpose information system (IS) network should not be considered a trusted network, not the least since such networks are normally further connected to the Internet or other external networks. The IS network is therefore a different lower-security zone, and it should be separated from the automation system by means of a firewall. The IS and automation system networks should form separate domains.

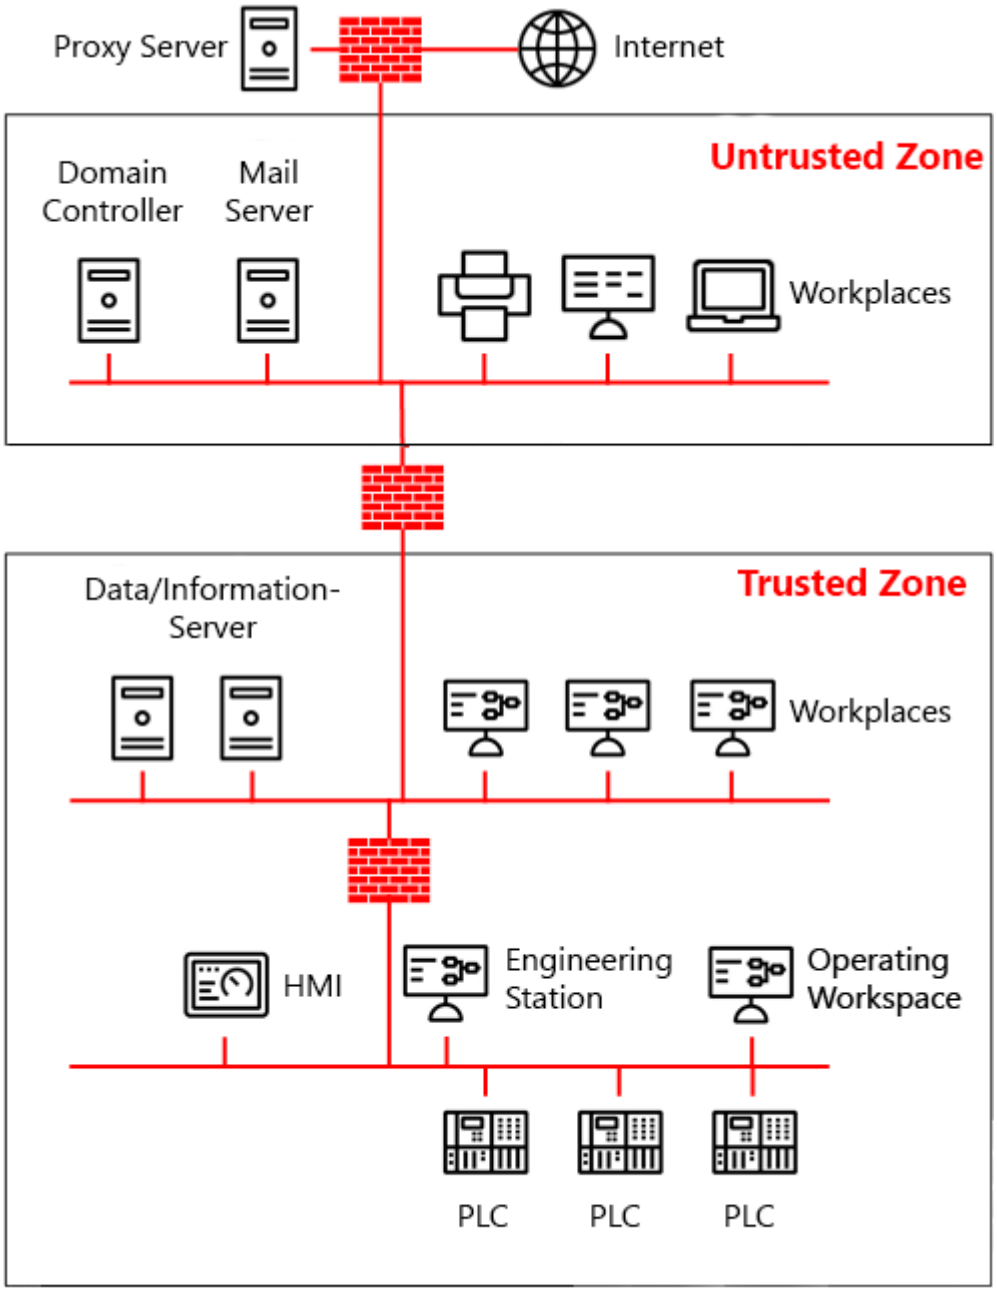

Fig. 4: Automation system and IS network

1.2.2.3 Hardening

System hardening means to eliminate as many security risks as possible. Hardening your system is an important step to protect your personal data and information. This process intends to eliminate attacks by patching vulnerabilities and turning off inessential services. Hardening a system involves several steps to form layers of protection.

Commissioning phase

- Protect the hardware from unauthorized access
- Be sure the hardware is based on a secure environment
- Disable unused software and services (network ports)
- Install firewalls
- Disallow file sharing among programs
- Install virus and spyware protection

- Use containers or virtual machines
- Create strong passwords by applying a strong password policy
- Create and keep backups
- Use encryption when possible
- Disable weak encryption algorithms
- Separate data and programs
- Enable and use disk quotas
- Strong logical access control
- Adjust default settings, especially passwords

Verification phase

- Verification of antivirus - Check antivirus is active and updated
- Verification of the identification - Check that test and unauthorized accounts are removed
- Verification of intrusion detection systems - Check malicious traffic is blocked
- Verification of audit logging - Check audit log is enabled
- You can use the checklist out of the *cyber security white paper*

Operation phase

- Keep software up-to-date, especially by applying security patches
- Keep antivirus up and running
- Keep antivirus definitions up-to-date
- Delete unused user accounts
- Lock an active session whenever it is unattended, e.g., lock the screen of the PC or of the control panel (HMI)

Decommissioning phase

- Delete all credentials stored in the device like certificates and user data *Chapter 1.6.4.4.6 “Decommissioning” on page 3351*.

References: *Hardening in Wikipedia (2021)*

1.2.2.4 Open Ports and Services

Overview of minimum cyber security requirements for open ports and services settings.

Port	Protocol	Description
1217	TCP	CODESYS Gateway V3
1210	TCP	CODESYS Gateway V2
1211	TCP	CODESYS Gateway V2
22350	TCP/UDP	CodeMeter License Server (runtime) – license
22352	HTTP	CodeMeter License Server (runtime) – WebAdmin
22353	HTTPS	CodeMeter License Server (runtime) – WebAdmin
11030	HTTP	Python editor server

1.2.3 Automation Builder update notification

A notification dialog will be shown if there are any updates available for the currently installed version on every launch of the Automation Builder.

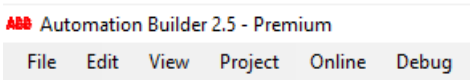
Chapter 1.3.3 “Automation Builder update notification” on page 172

1.2.4 Managing your licenses

After installing and licensing the Automation Builder you can manage your licenses in various ways.

1.2.4.1 Identifying the installed license

Since Automation Builder Version 1.1.1 the title bar or Automation Builder shows a license information:



Be aware of the following rule for this information:

The info in the menubar is taken in this order from the first found license

- local licenses (on PC)
- on dongle (USB key)
- network licenses (since AB1.2)

So if a local license is only basic and a dongle with premium is inserted:

- the information in the menubar is basic
- the functionality is premium (the highest available)

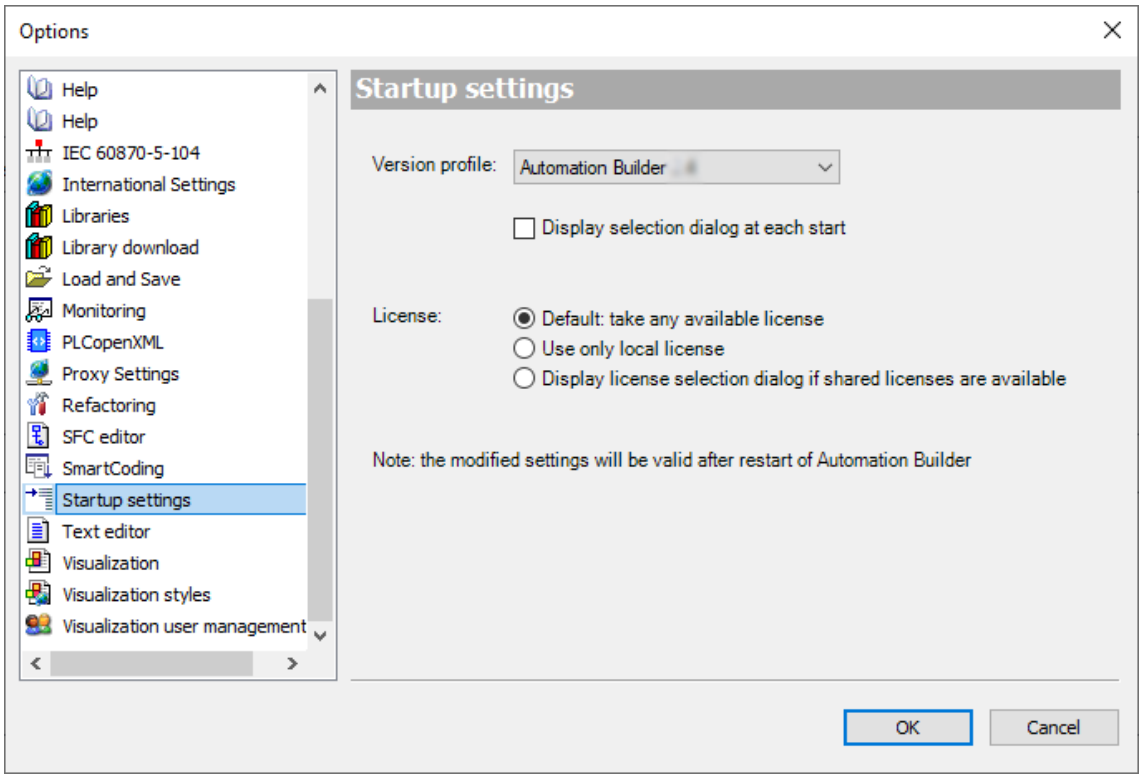
To check your installed licenses, the CodeMeter Control Center tool can be used ↳ *Chapter 1.2.4.3 “Checking licenses with CodeMeter control center” on page 22*.

1.2.4.2 Selecting the license used on Automation Builder startup

You can select, which license the Automation Builder should use on startup.

To select which license should be used:

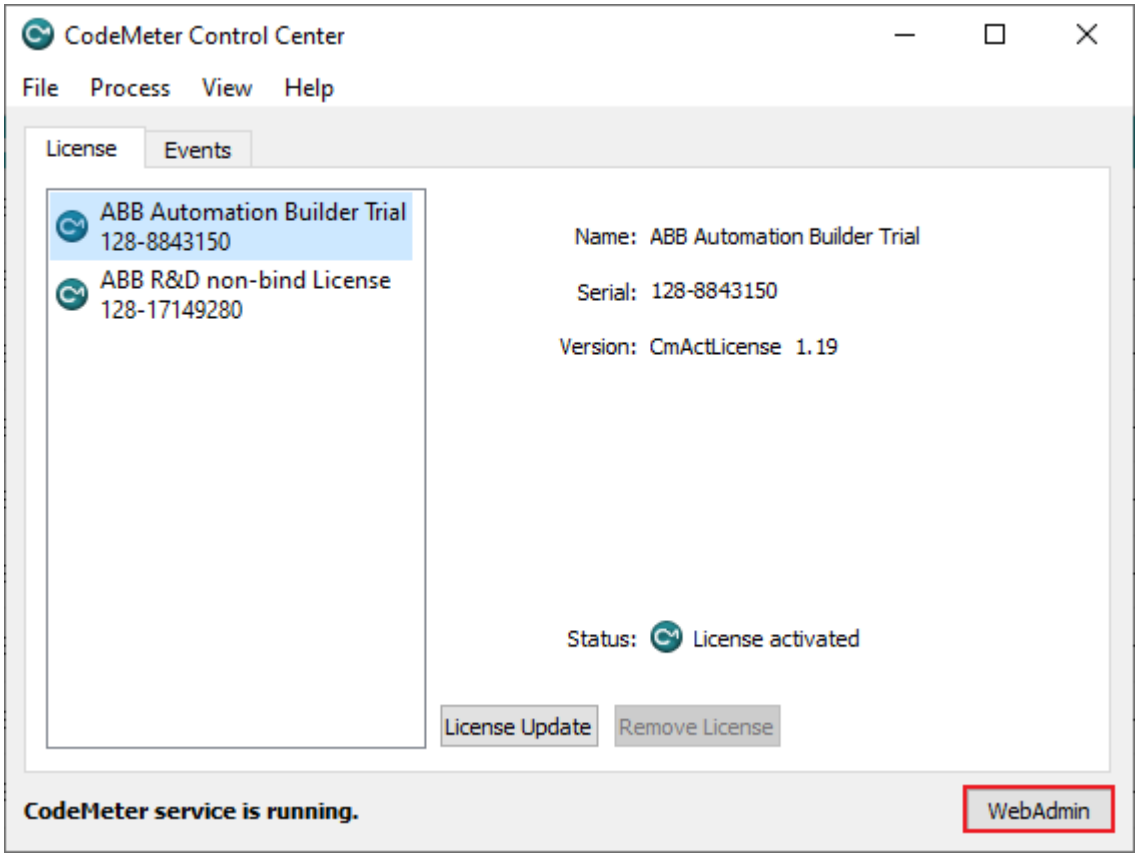
1. In the Automation Builder menu select *“Tools ➔ Options”*.
   ⇨ The Options window is opened.
2. In *“Startup settings”* under *“License”* select which license should be used.
   - Default: The most comprehensive available license will be selected
   - Use only local license: Network licenses will never be selected
   - Display licenses selection dialog if shared licenses are available: On every Automation Builder startup, you will be asked to select a license



3. To apply the setting select *“OK”*.

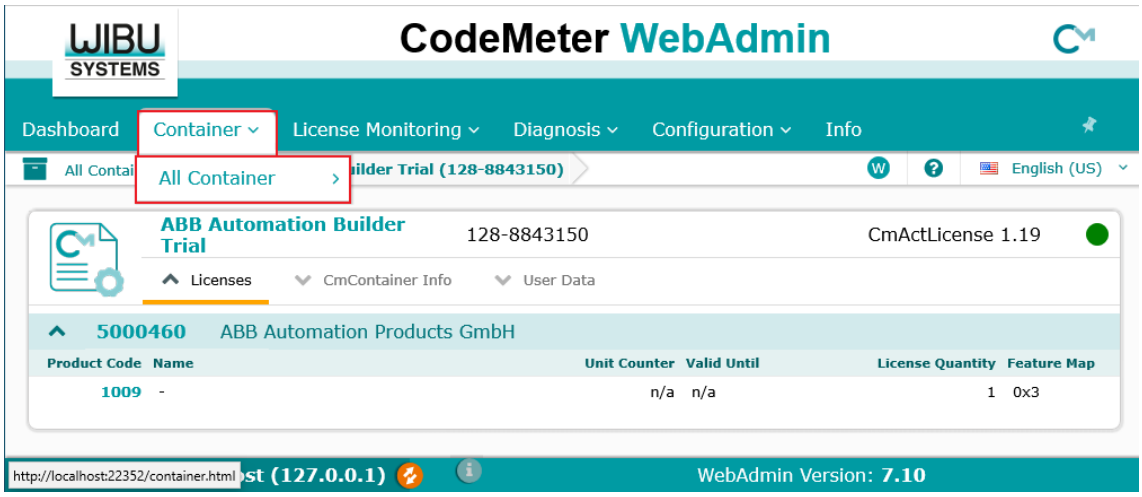
1.2.4.3 Checking licenses with CodeMeter control center

1. Open the CodeMeter Control Center via the *“Windows start menu ➔ CodeMeter ➔ CodeMeter Control Center”*.



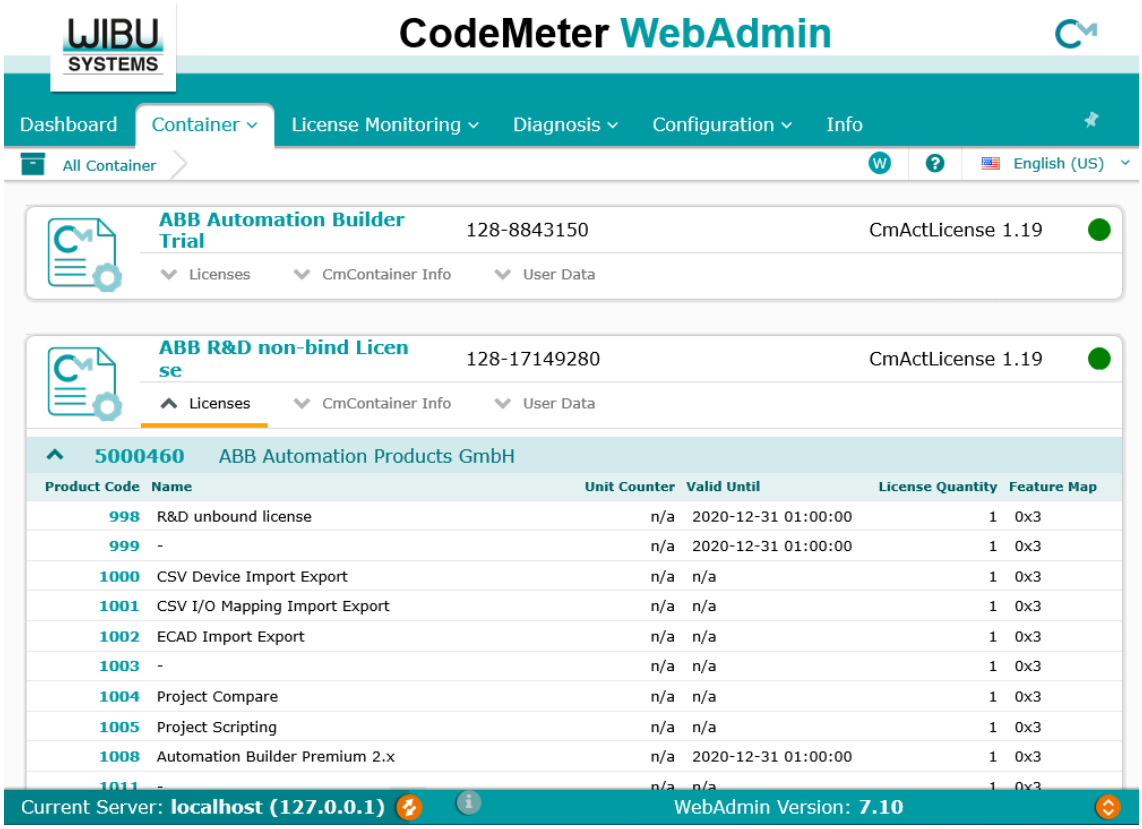
2. In the CodeMeter Control Center window you can see the different license “tickets” / “CmContainers” that are installed on your PC.

   To see more details, open the CodeMeter WebAdmin by selecting *“WebAdmin”*



3. Select *“Container ➔ All Container”*

   ⇨ Here the details of the license containers can be checked.

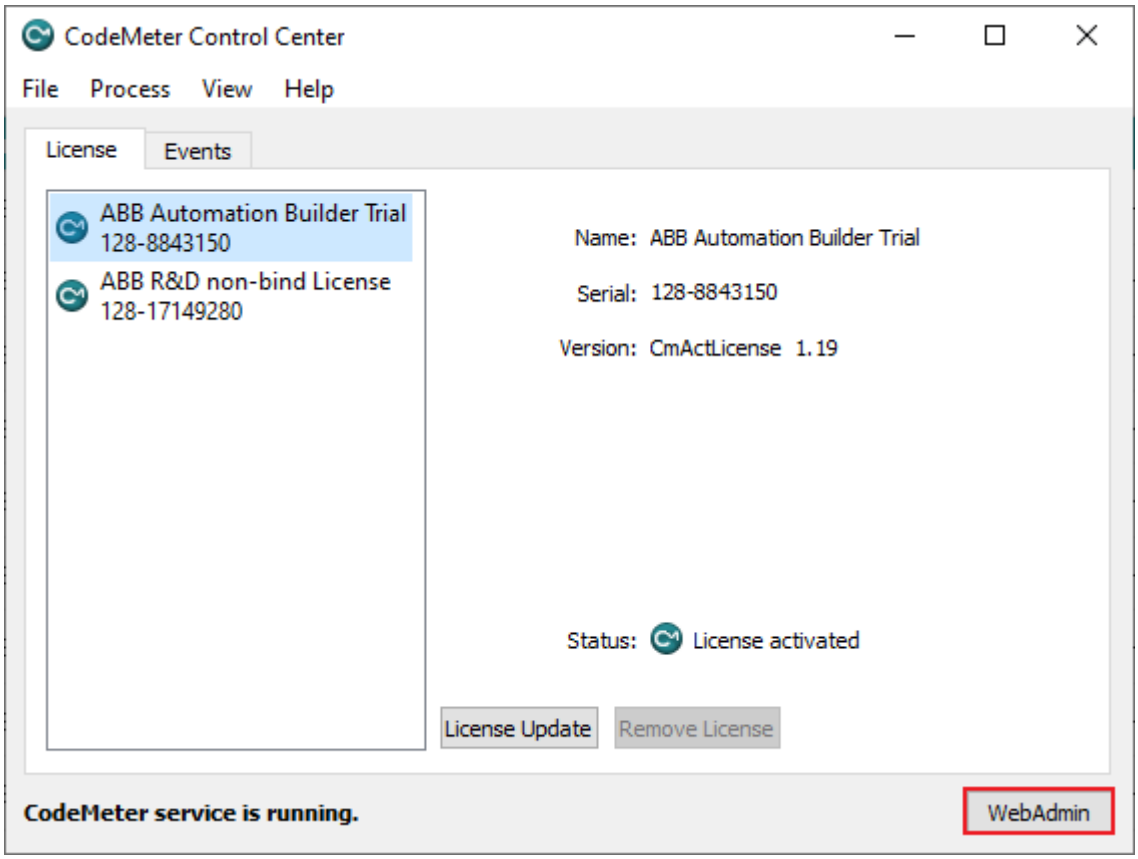


1.2.4.4 Setting dedicated network servers in search list

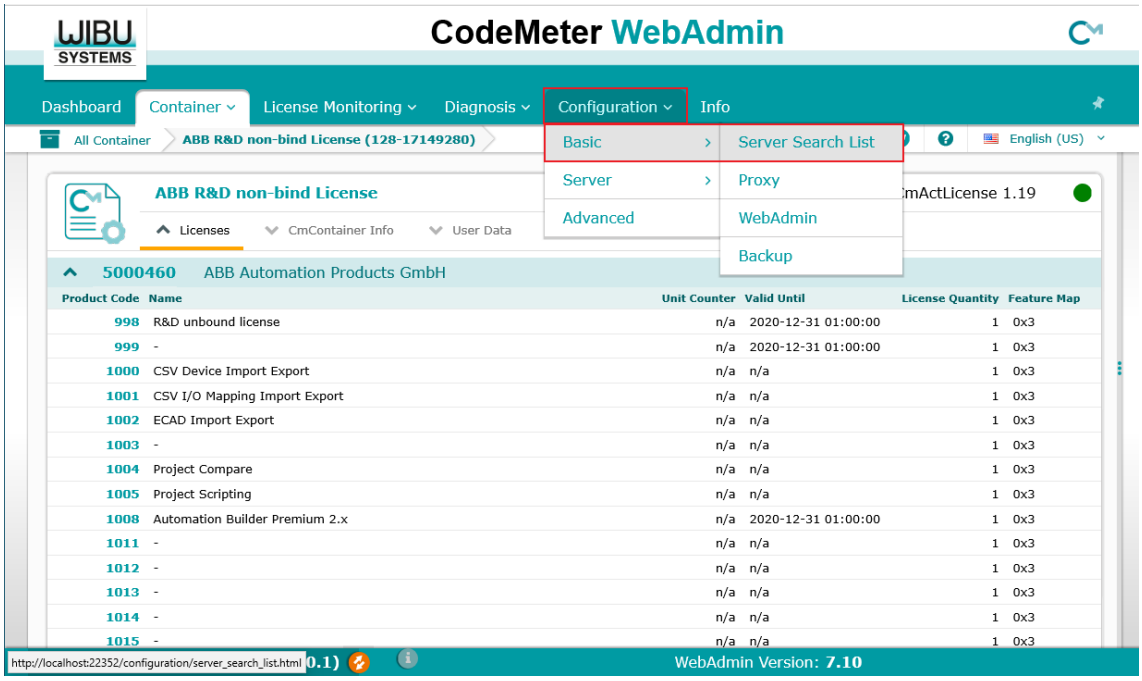
In case of a new installation CodeMeter will check for licenses also in the network. If there is a run-out or wrongly installed license found, the service is closed without any further hint. This looks like Automation Builder starts and closes after a few moments.

To set the search for licenses to your local machine only follow these steps:

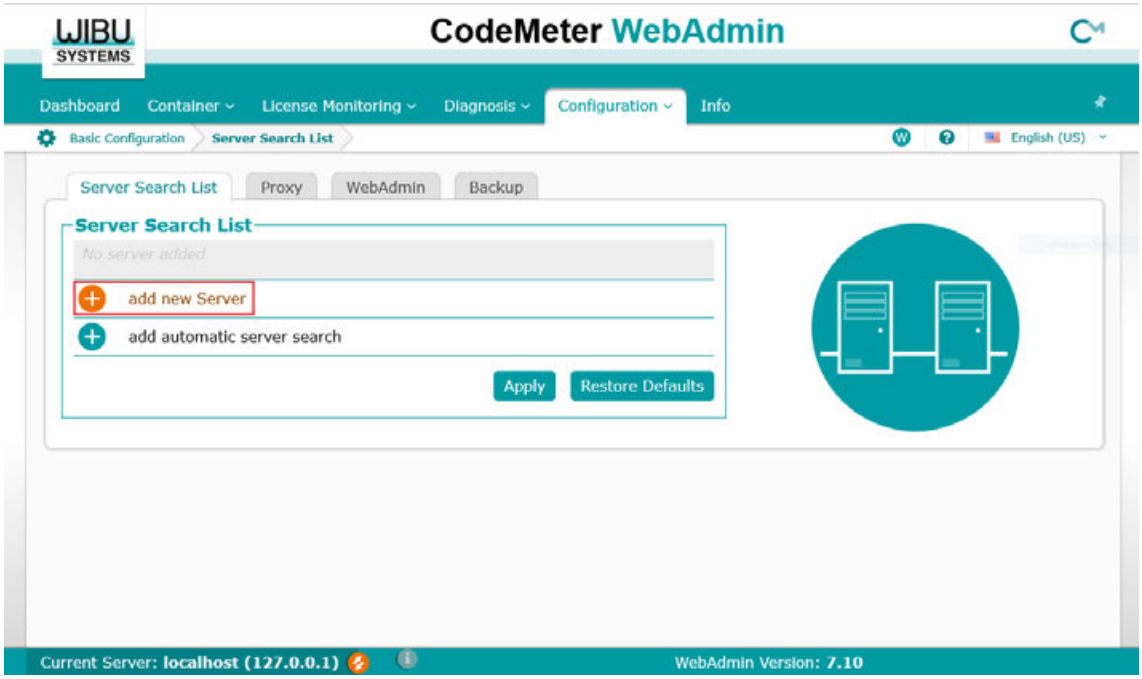
1. Open the CodeMeter Control Center. See ↬ *Chapter 1.2.4.3 “Checking licenses with CodeMeter control center” on page 22*
2. Open the CodeMeter WebAdmin by selecting *“WebAdmin”*



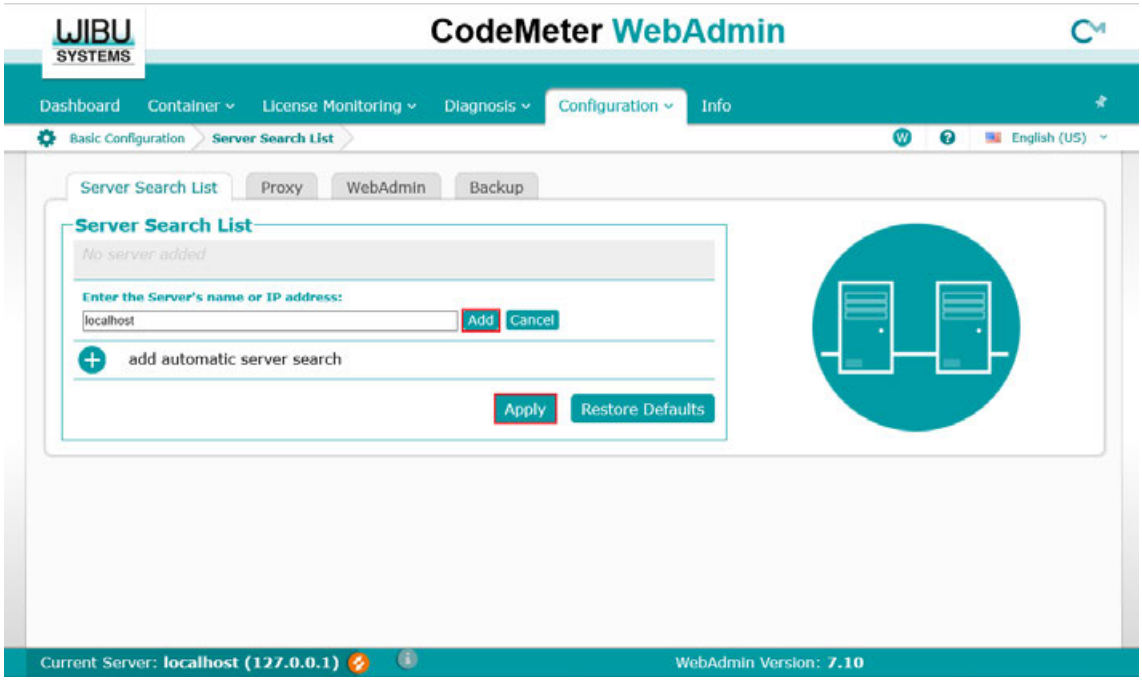
3. Select *"Configuration ➔ Basic ➔ Server Search List"*



4. Select *"add new Server"*



5. Enter "localhost" in the Server's names field
6. Select *“Add”*
7. Confirm by selecting *“Apply”*
   ⇨ The "localhost" is added to the Server Search List

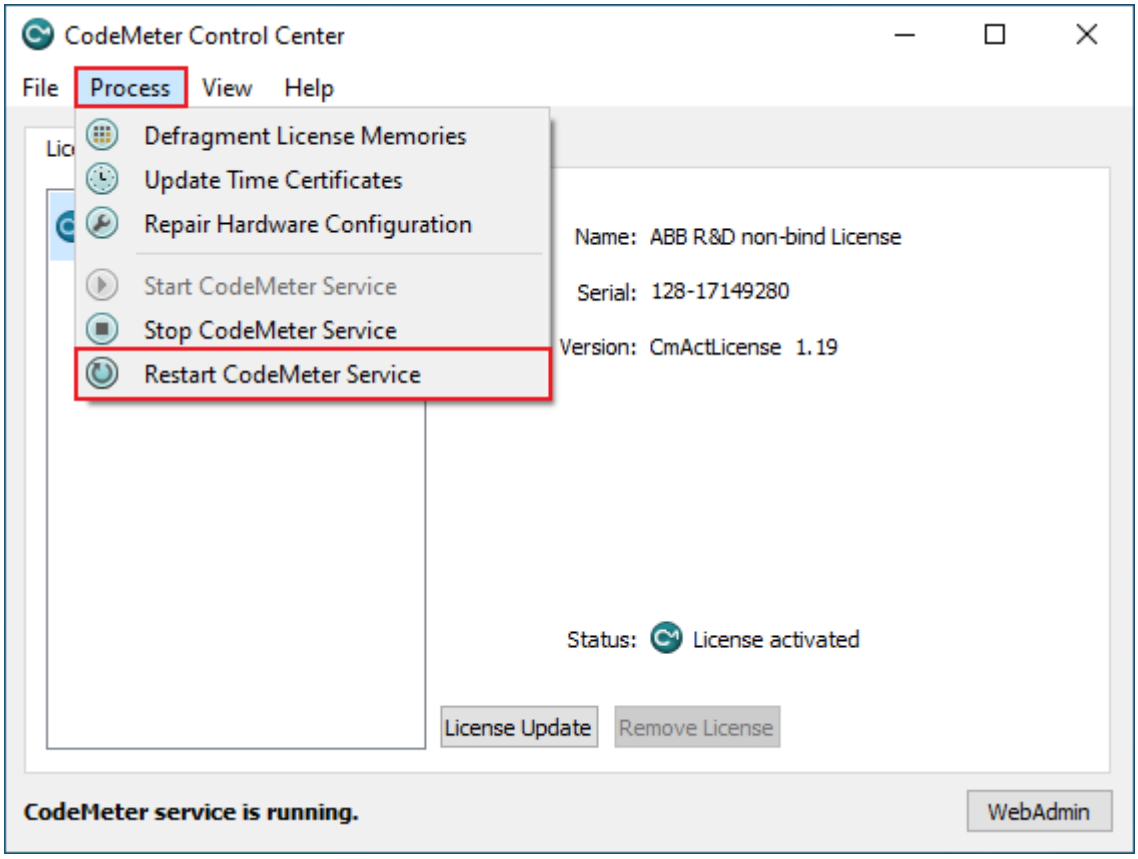


8. Restart the license check
9. Add more servers to the search list by entering the IP-Adress or name of the license servers you know.

1.2.4.5 Restarting license check with a dongle bound license

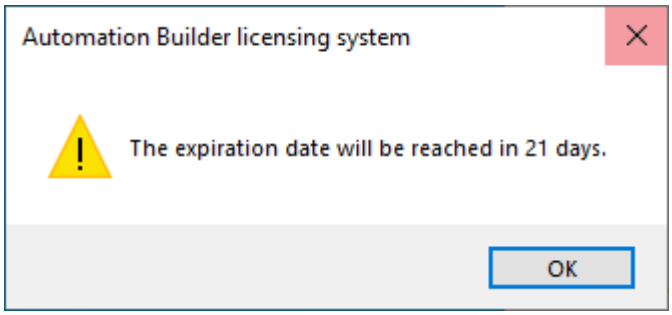
In case of using a dongle bound license it might be necessary to restart the check for license on the PC, e.g. if the dongle was removed and reinserted.

1. Open the CodeMeter Control Center. See *Chapter 1.2.4.3 “Checking licenses with CodeMeter control center” on page 22*
2. Select *“Process ➔ Restart CodeMeter Service”*



1.2.4.6 Removing trial license to remove expiring message

If an unlimited license is installed after having a trial license activated, the warning message for expiring date of the trial license still pops up at the Startup of the Automation Builder.

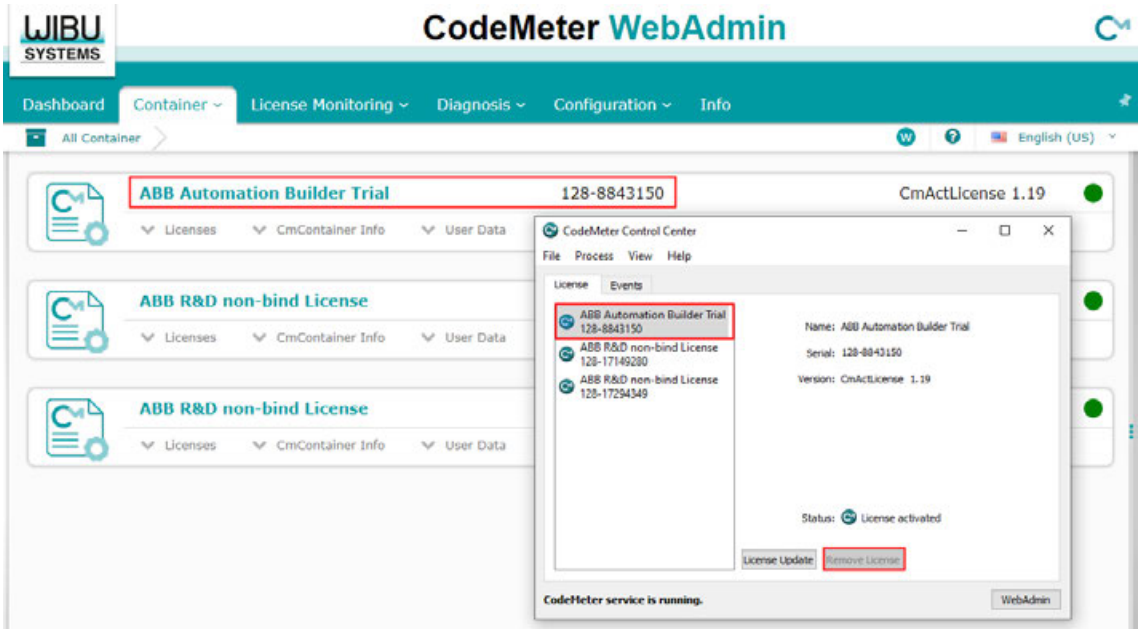


To avoid this message the trial license can be removed.

CAUTION!

- If you remove a license from your PC it will be permanently lost.
- Be aware that the trial license includes all premium functionalities, which will not be available any more if your unlimited license is not a premium license, e.g. standard.

1. Check for the Trial CmContainer number in CodeMeter WebAdmin InterfaceCheck for the Trial CmContainer number in CodeMeter WebAdmin Interface
2. Search CmContainer number in CodeMeter Control Center



3. Remove this selected license in CodeMeter Control Center

1.2.4.7 Network licenses

Starting from Automation Builder 1.2.0 network licenses can be used with Automation Builder.

This allows sharing of licenses between team members, easy switchover between several workstations with a single license and allows centralized administration (ordering, registration, activation).

The Automation Builder License Manager and CodeMeter need to be used to configure the Network server.

- *In a typical office LAN (Local Area Network) setup on Client side the default settings of the Automation Builder (and CodeMeter) are sufficient to get the Network Licenses working.*
- *If an opened Automation Builder is loosing contact to the network server (e.g. due to network problems) Automation Builder will prompt the user to restore the network. After 30 minutes without connection to the network server Automation Builder will fall back to basic edition. Opened editors for non-basic features stay open and usable. So your work will not be lost in case of troubles with the network.*

1.2.4.7.1 Setting up a network license

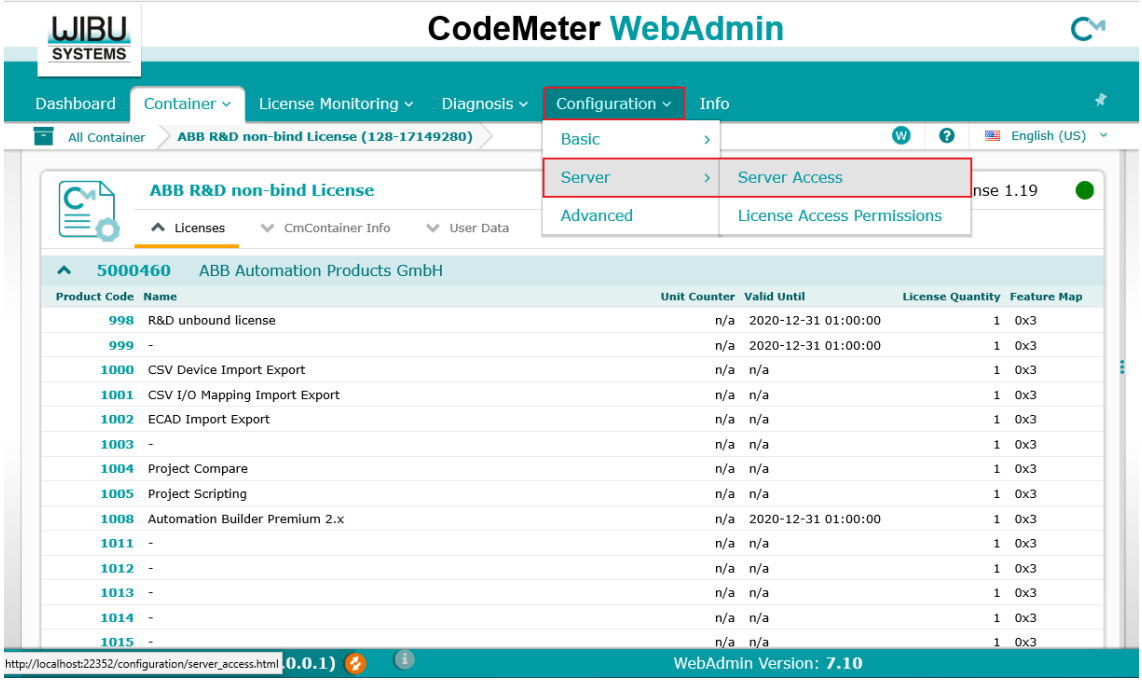
The following setup works in typical environments.

Configuring a network license server

☑ Network license must be registered.

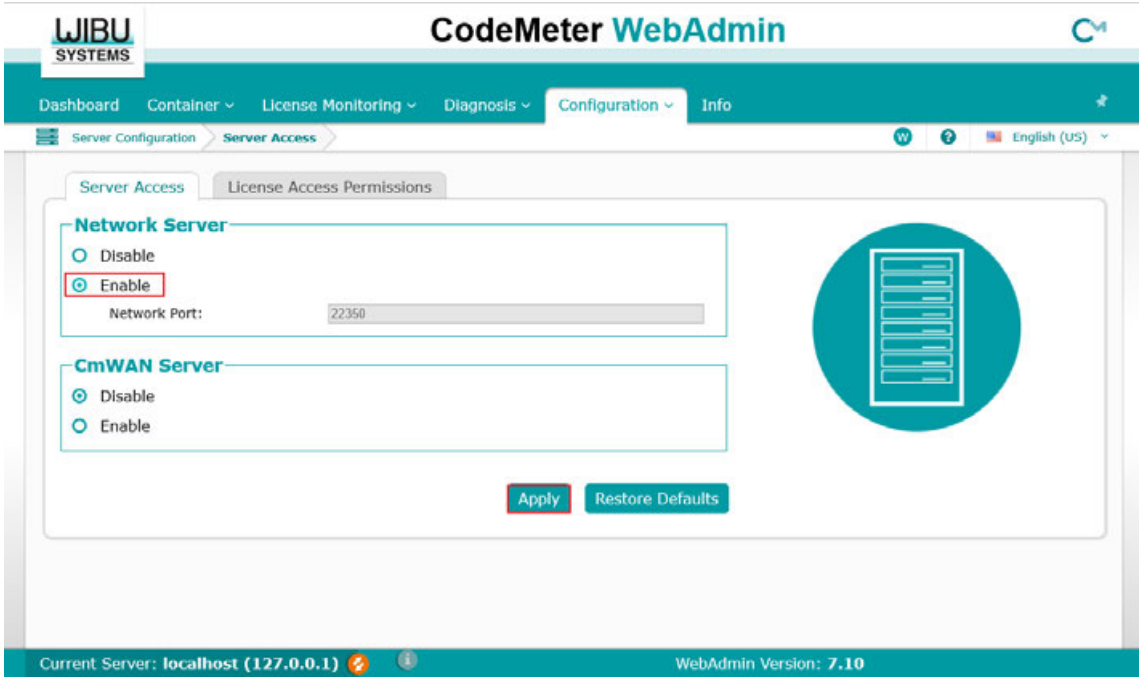
☑ Automation Builder license must be activated.

1. Launch CodeMeter WebAdmin as described in *Chapter 1.2.4 “Managing your licenses” on page 20*
2. Select *“Configuration ➔ Server ➔ Server Access”*



3. Enable Network Server

   Keep the default port settings. These should work in most cases.
4. Select *“Apply”*



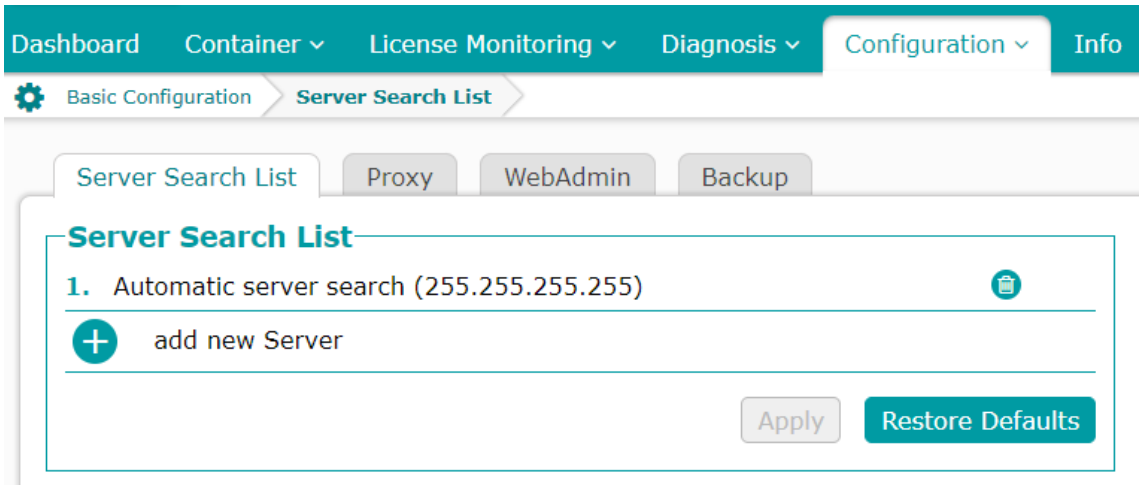
5. For the changes to take effect, restart CodeMeter Control Center see *Chapter 1.2.4.5 “Restarting license check with a dongle bound license” on page 25*

NOTICE!

- In case you want to control usage of network licenses please refer to
  ↳ *Chapter 1.2.4.7.3 “View network server license usage” on page 30*
- Activation keys for network licenses are valid for one network license each. This one license can be shared among many people but only one Automation Builder instance at the same time. If you want to run more than one Automation Builder instance at the same time you have to activate more than one network license. This means you have to purchase and enter more than one activation key (one per license).

Configuring the client side

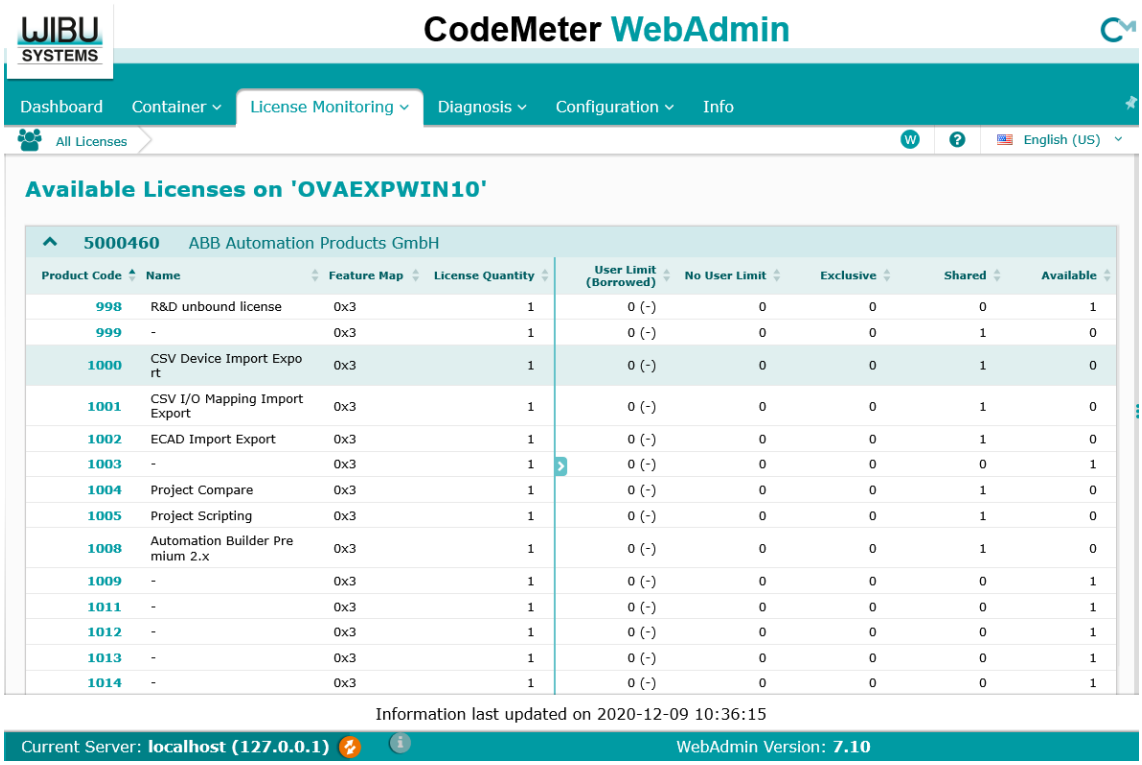
The default settings of Automation Builder and the CodeMeter (on client side) are sufficient in most cases to get the network licenses working. In case of problems accessing the network license, please set the server search list on the client side.



1.2.4.7.2 View network server licenses

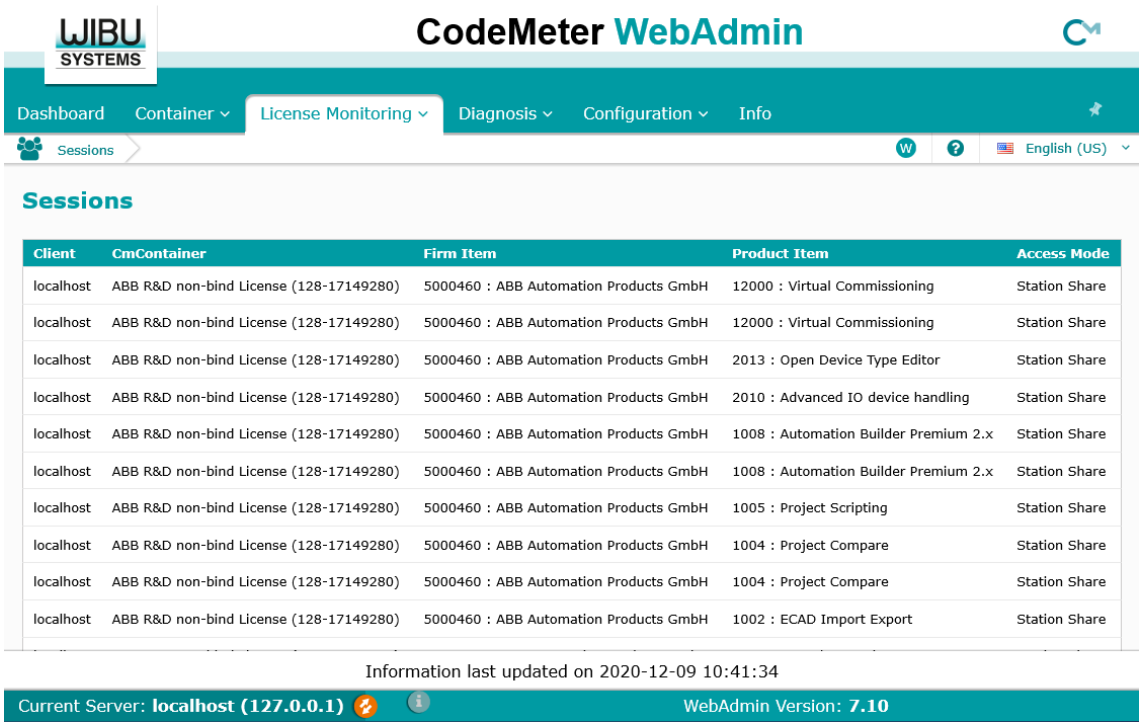
On the Network Server side you can find information on existing network licenses and their current allocation.

1. Launch CodeMeter WebAdmin. See ↳ *Chapter 1.2.4.3 "Checking licenses with CodeMeter control center" on page 22*
2. Select *"License Monitoring ➔ All Licenses "*



1.2.4.7.3 View network server license usage

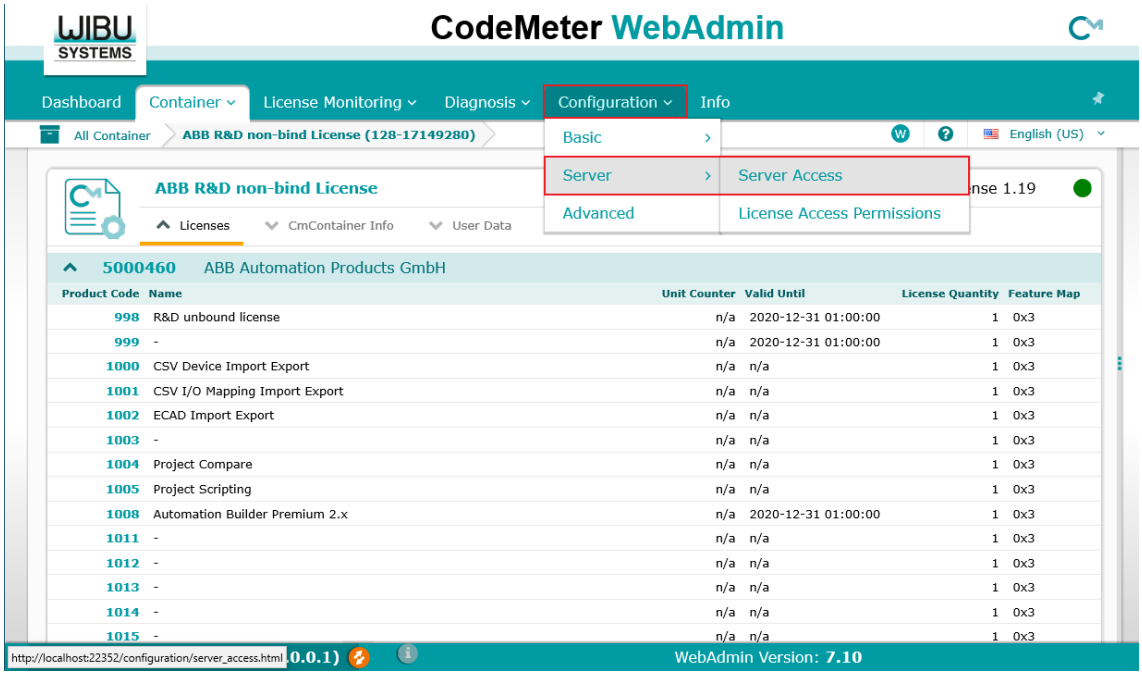
1. Launch CodeMeter WebAdmin. See ↳ *Chapter 1.2.4.3 "Checking licenses with CodeMeter control center" on page 22*
2. Select *"License Monitoring ➔ Sessions "*



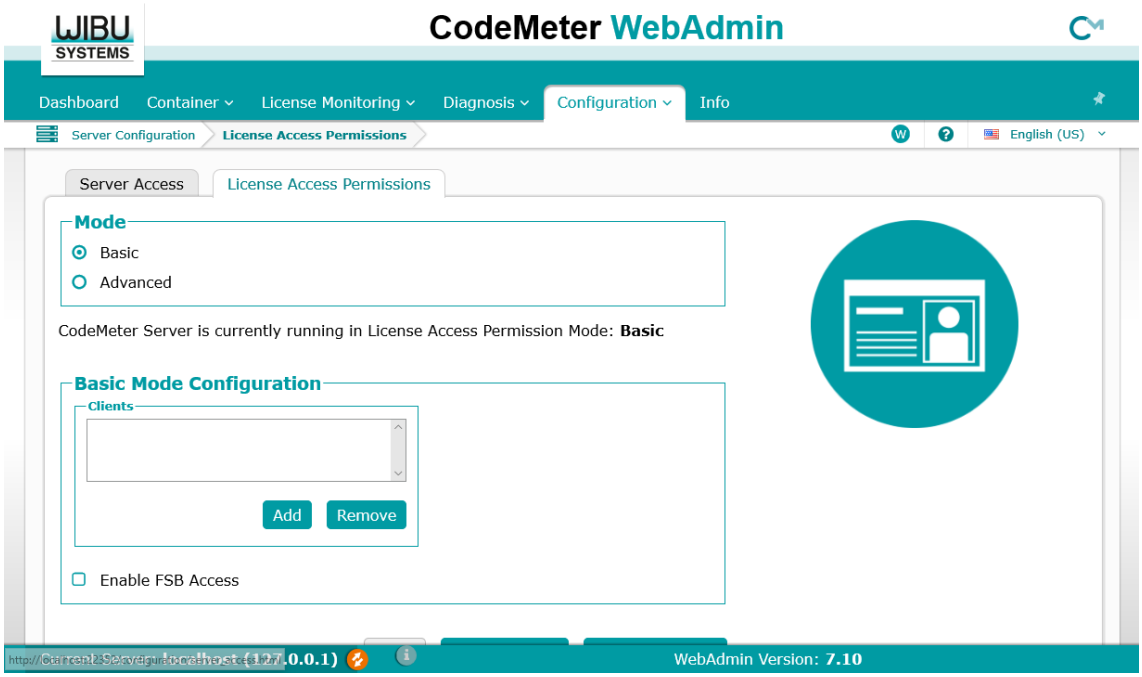
1.2.4.7.4 Controlling network server license usage

On the Network Server side you can define settings managing the client access to CodeMeter License Server on a network.

1. Launch CodeMeter WebAdmin. See *Chapter 1.2.4.3 "Checking licenses with CodeMeter control center" on page 22*
2. Select *"Configuration ➔ Server ➔ Server Access"*



3. Add entries of PCs you want to share licenses with by adding client computers and IP addresses for accessing CodeMeter License Server on a network.



1.2.4.8 License borrowing manager

The license borrowing manager allows you, to borrow a network license for offline use and return it.

> *The license borrowing manager is not part of the default software distribution, but will be handed out on request.*

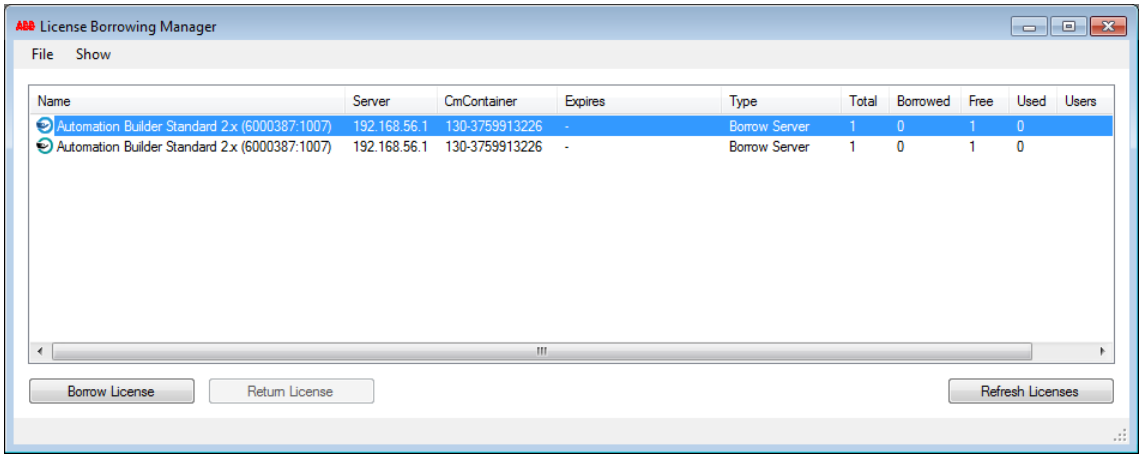
> *The license borrowing manager is only supported by Automation Builder 2.2.3 and later.*

1.2.4.8.1 Borrowing a network license

☑ Network access to the license server required.

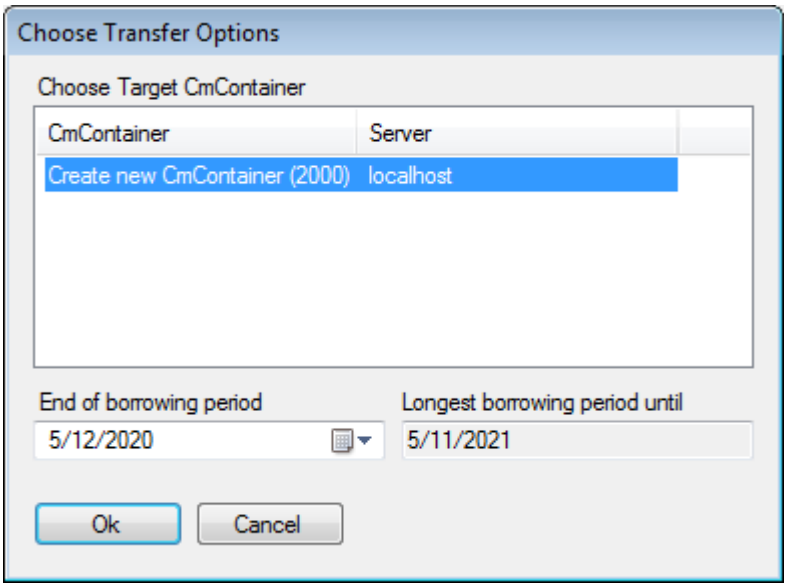
☑ Opened the license borrowing manager.

1. Select the license you want to borrow.



2. Select *“Borrow License”*.
3. Select the taget CmContainer.

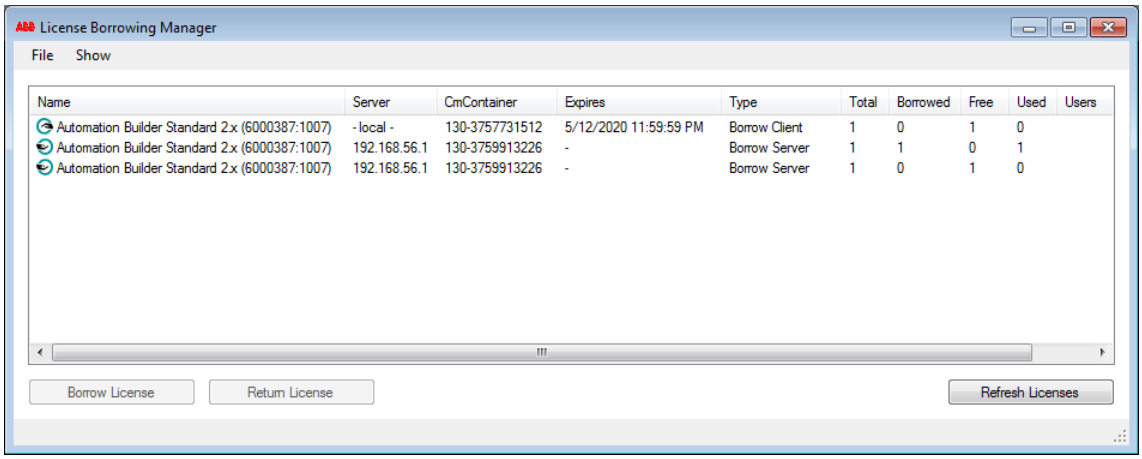
   Alternatively a new CmContainer can be created.
4. Select the end of the borrowing period.



5. Select *“OK”*.

   ⇨ The license has sucessfully been borrowed.

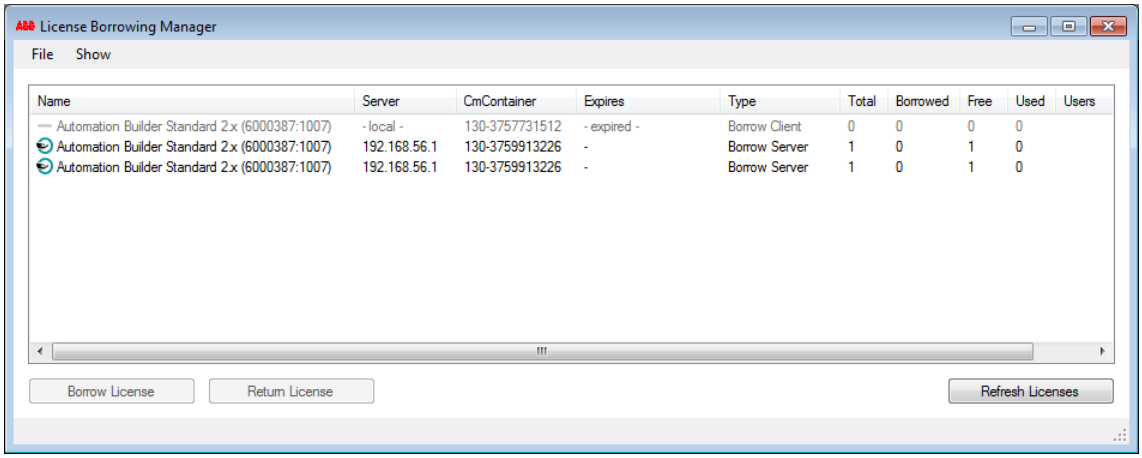
   The list of available licenses has been updated.



1.2.4.8.2 Returning a network license

Automatical return of a license

Network licenses will be returned automatically after the expiration of the maximum borrwoing period. No licenses server access is required.



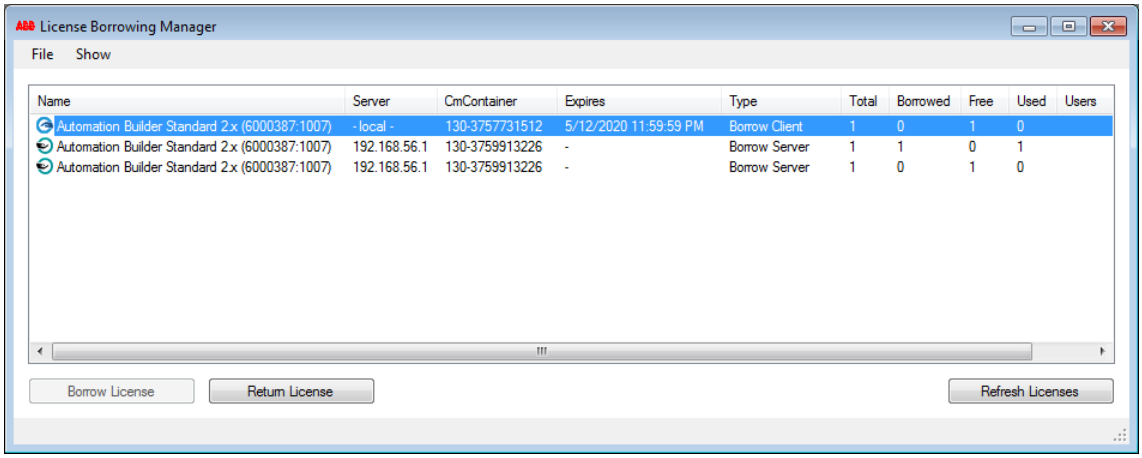
Manual return of a network license

Network licenses can be returned anytime manually.

☑ Network access to the license server required.

☑ Opened the license borrowing manager.

1. Select a borrowed license.



2. Select *“Return License”*

   ⇨ The license has sucessfully been returned.

1.2.4.9 Transfering an Automation Builder license

1.2.4.9.1 General

It is possible to transfer normal licenses from a PC to another PC or dongle (DM-Key).

This is not possible for ABB internal or temporary licenses, e.g. the 30 day Trial license.

The process consists of two main steps:

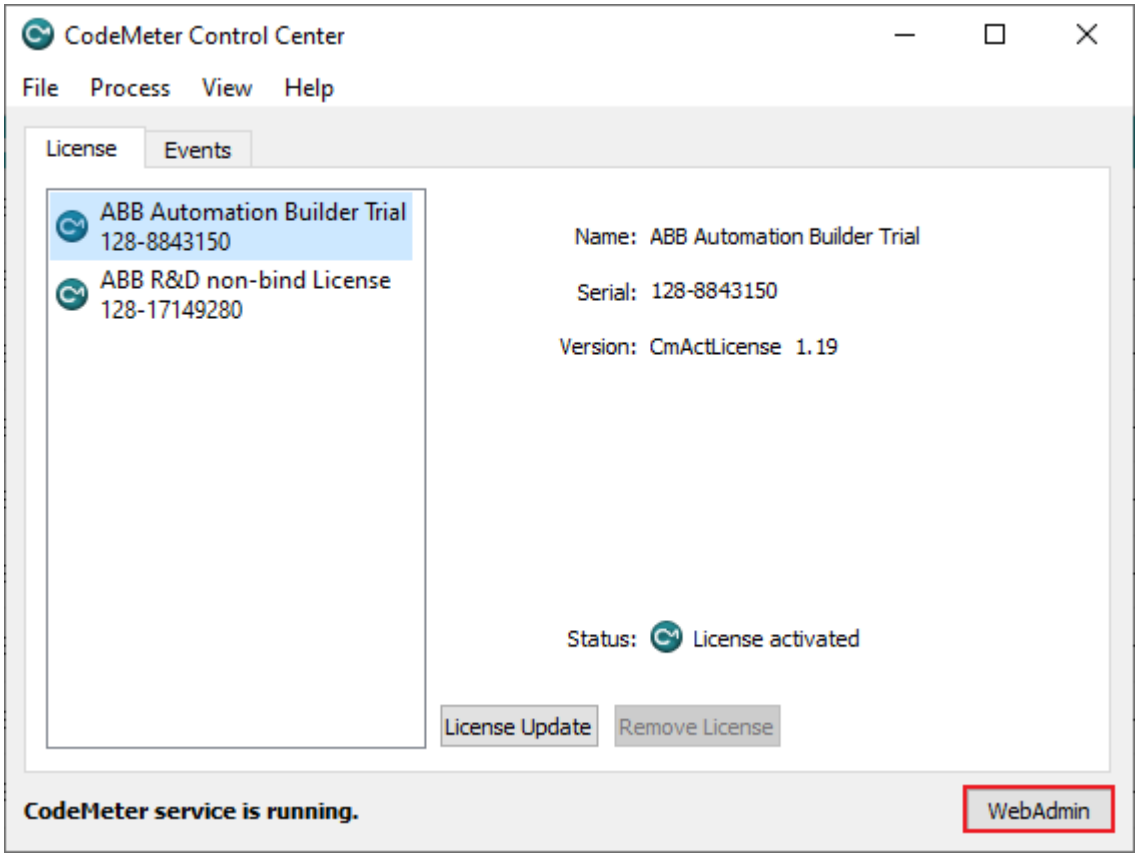
1. Return the actual license from the actual PC
2. Reactivate the license on the new PC

1.2.4.9.2 Getting activation code

For all license transfer processes the activation code is required. It is available from the license paper from purchasing the license.

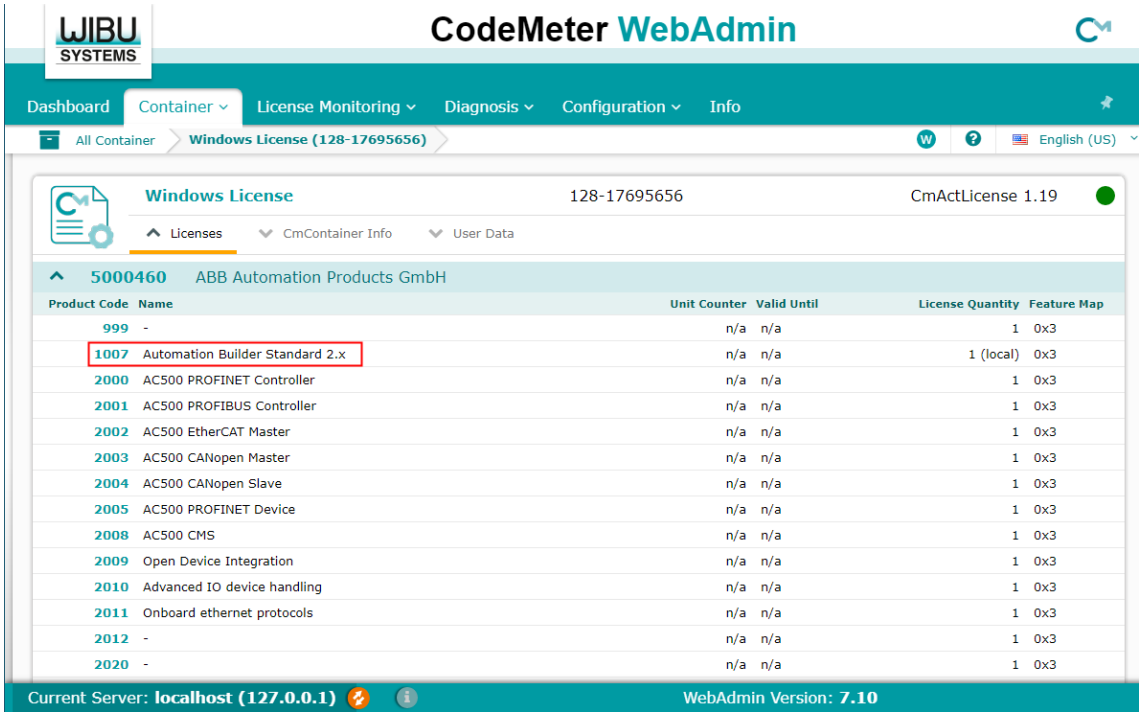
For Automation Builder licenses purchased April 2020 or later, the activation code is available from the activated license:

1. Open CodeMeter Control Center and navigate to the *"WebAdmin"*.

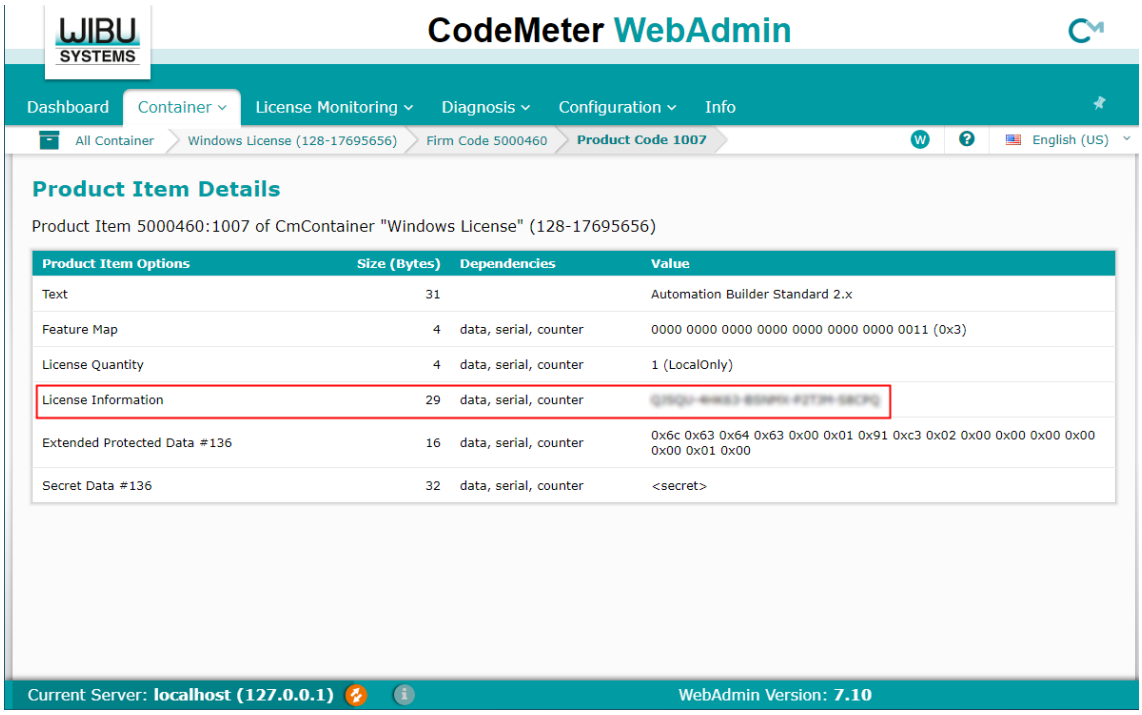


2. Identify the right product code.

   Automation Builder editions consist of multiple product codes. The activation ID is available from the product code containing the edition name, e.g. "Automation Builder Standard".



3. Select product code to access the product code details. Under *"License Information"* you can find the activation code.



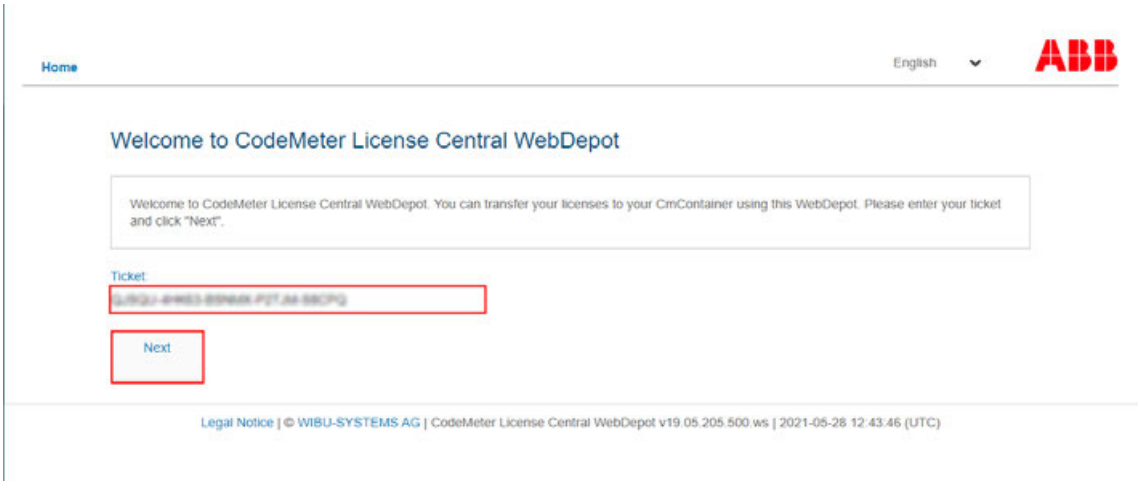
1.2.4.9.3 Returning an Automation Builder license

☑ You need the License Activation code of the license you want to return.

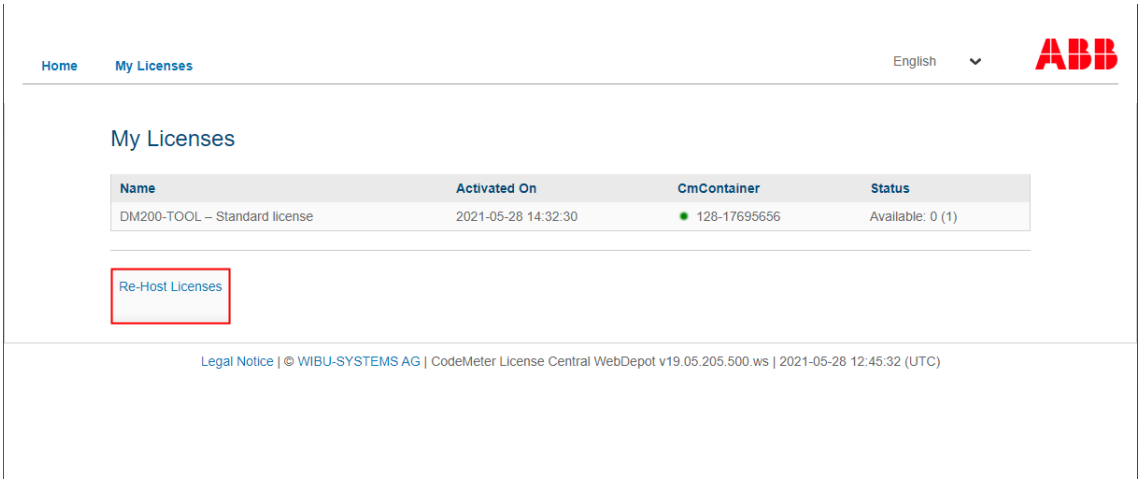
1. Go to the following website: *http://lc.codemeter.com/32838/depot-return/index.php*

> *The website is also availaible through the Automation Builder menu under "Help ➔ Return of Automation Builder license".*

2. Insert your Activation code in the field "Ticket"
3. Select *"Next"*



4. Select *“Re-Host License”*

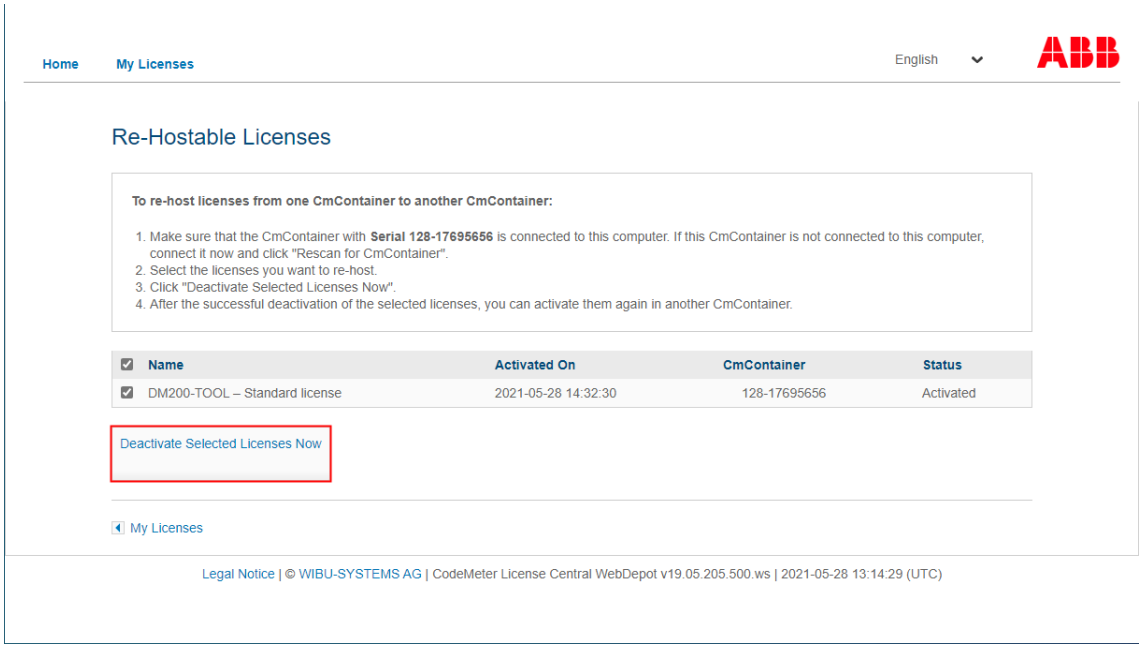


⇨ If the CmContainer is found, continue with Online licenses transfer ↯ *Chapter 1.2.4.9.3.1 “Online license transfer” on page 37*

⇨ If the CmContainer is not found, continue with Offline license transfer ↯ *Chapter 1.2.4.9.3.2 “Offline license transfer” on page 39*

Online license transfer

▷ Wait till the CmContainer is found, then select *“Deactivate Selected License Now”*



Home
My Licenses
English
Re-Hostable Licenses
To re-host licenses from one CmContainer to another CmContainer:
1. Make sure that the CmContainer with Serial 128-17695656 is connected to this computer. If this CmContainer is not connected to this computer, connect it now and click "Rescan for CmContainer".
2. Select the licenses you want to re-host.
3. Click "Deactivate Selected Licenses Now".
4. After the successful deactivation of the selected licenses, you can activate them again in another CmContainer.

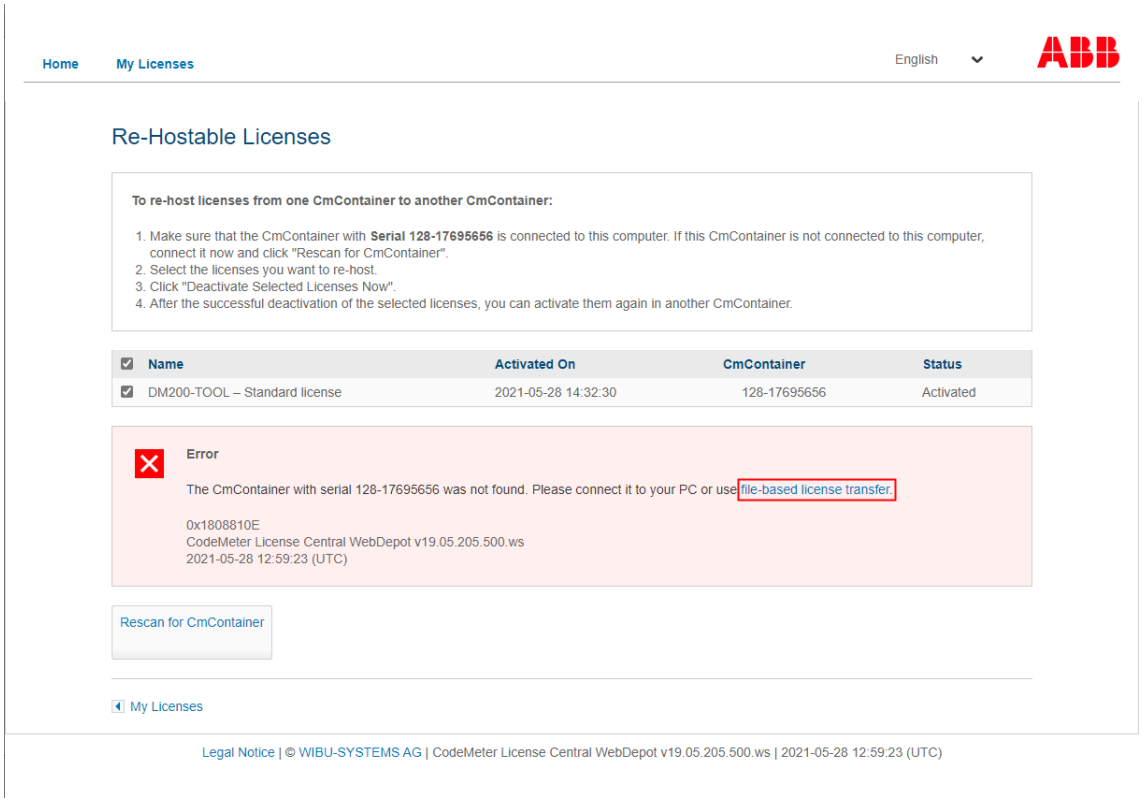
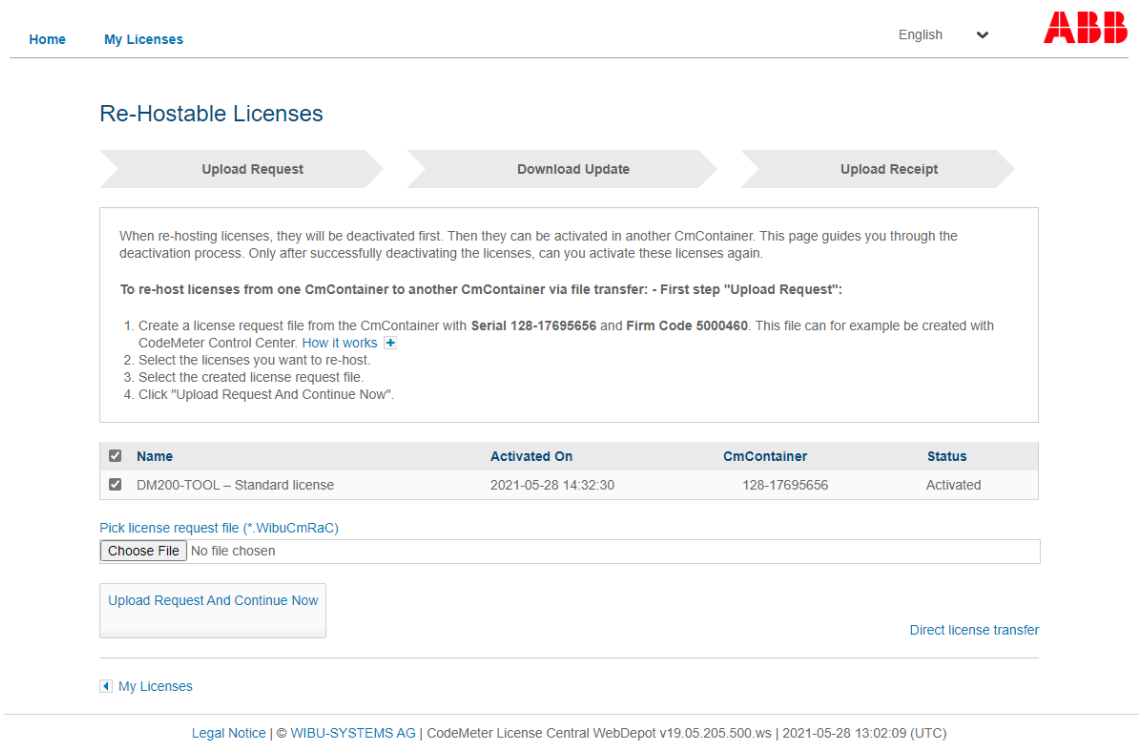
Online License Transfer
Starting license transfer.
Creating license request.
Downloading license update.
Importing license update to CmContainer.
Creating receipt.
Uploading receipt.
License transfer completed successfully!
OK

Offline license transfer

▷ If the CmContainer is not found on this PC, select file-based license transfer workflow.

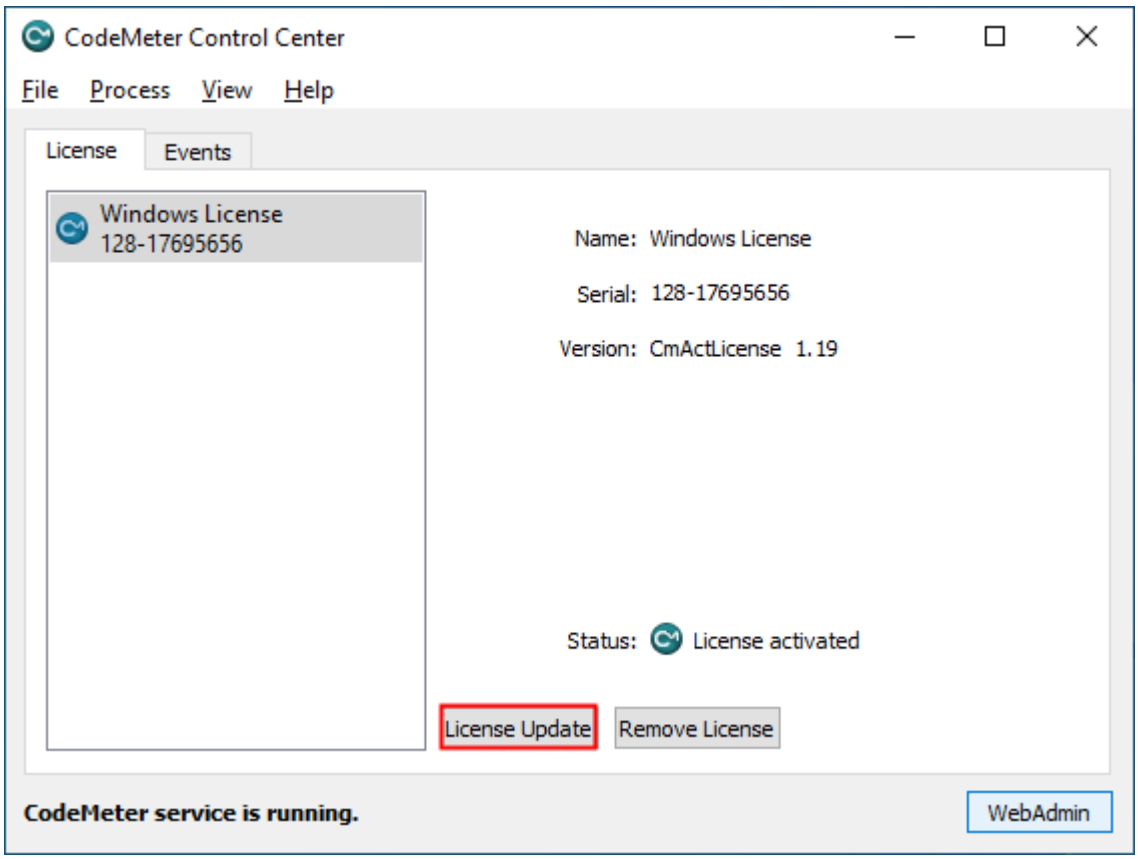


⇨ The following dialog opens

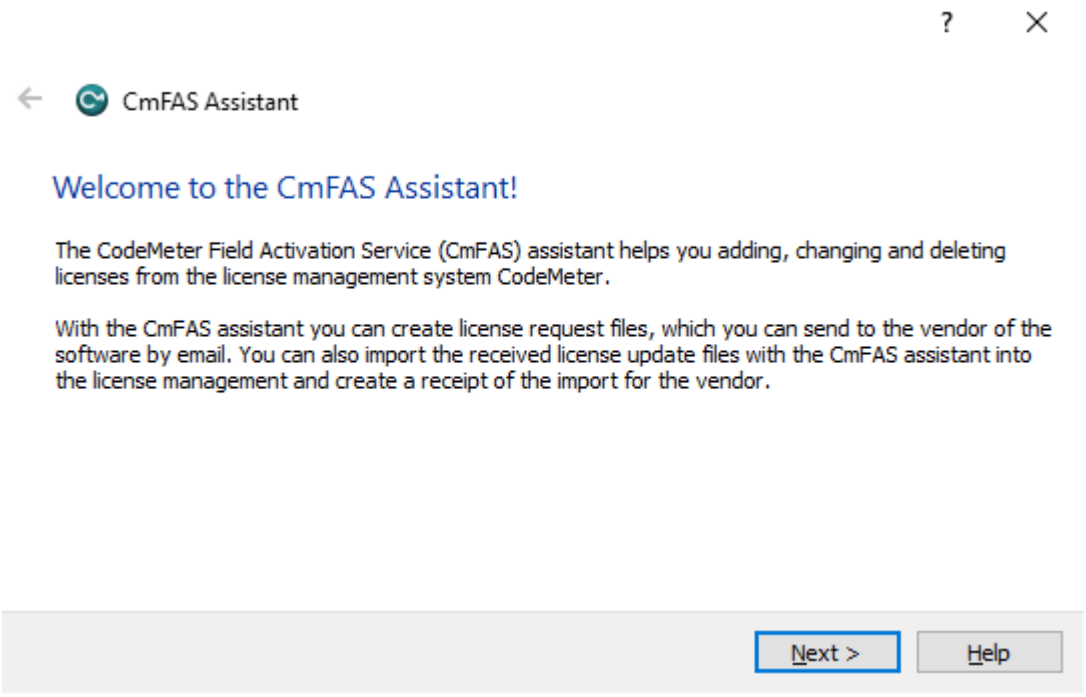


The instructions will lead you through the main steps of the offline license transfer:

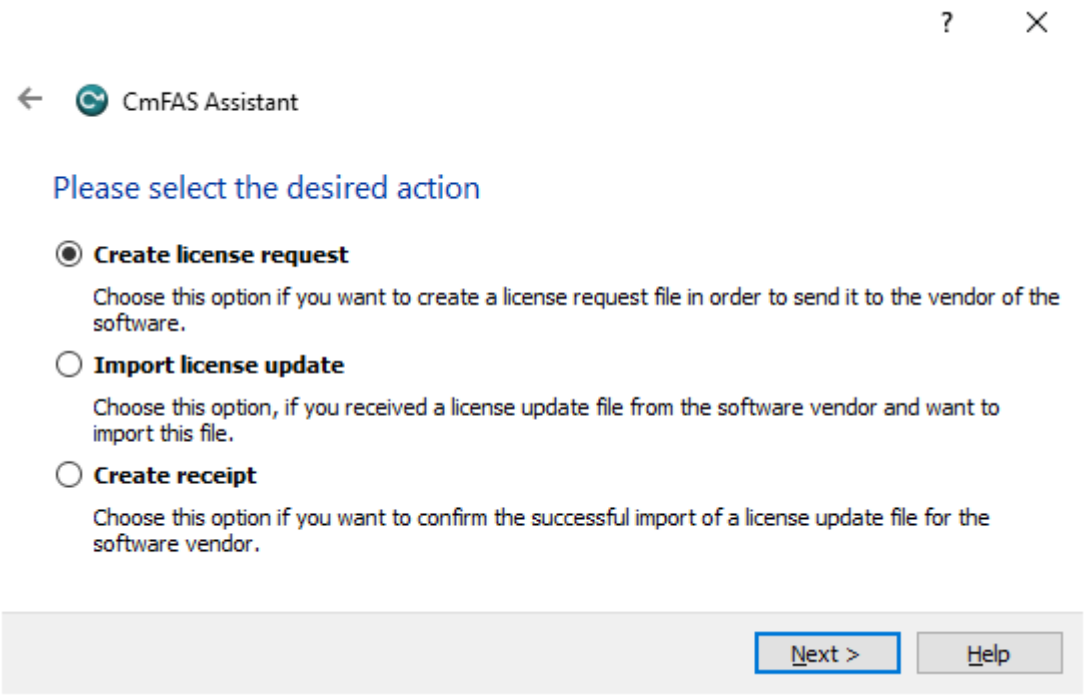
1. On the offline PC open the CodeMeter Control Center.
2. Select *“License Update”*.



⇨ The CmFAS Assistant opens.

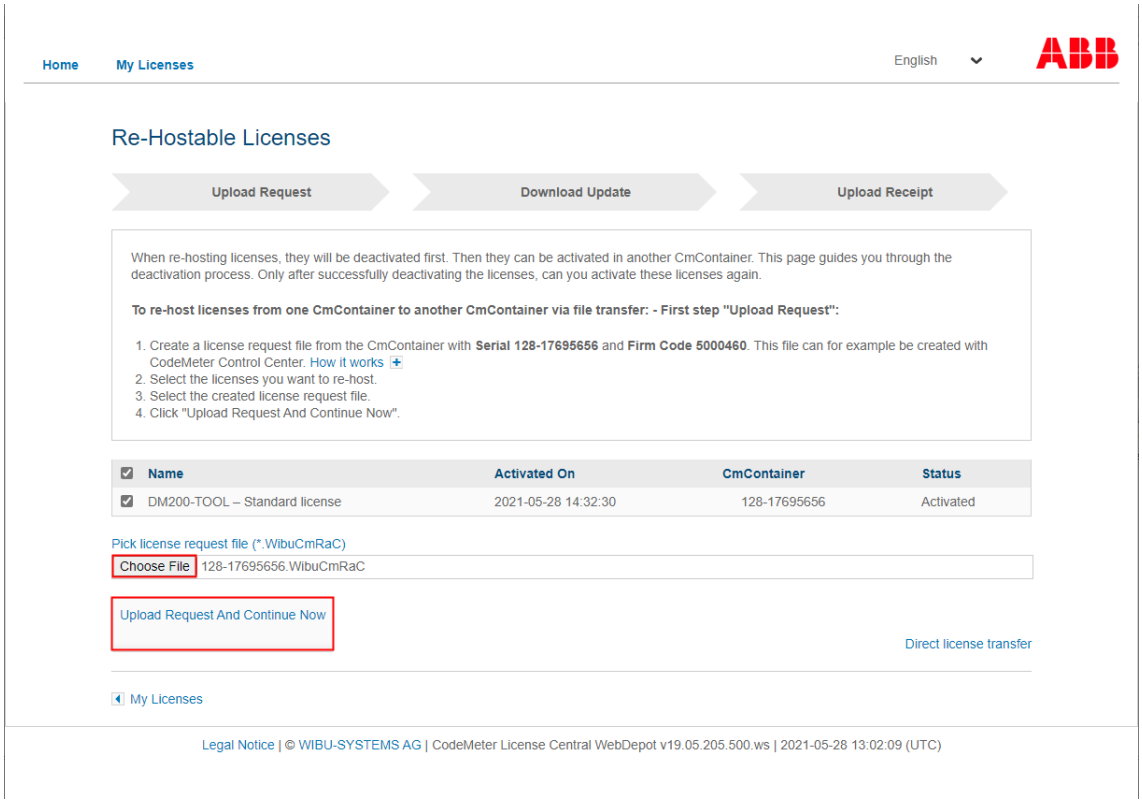


3. Select *“Create a license request file”*.

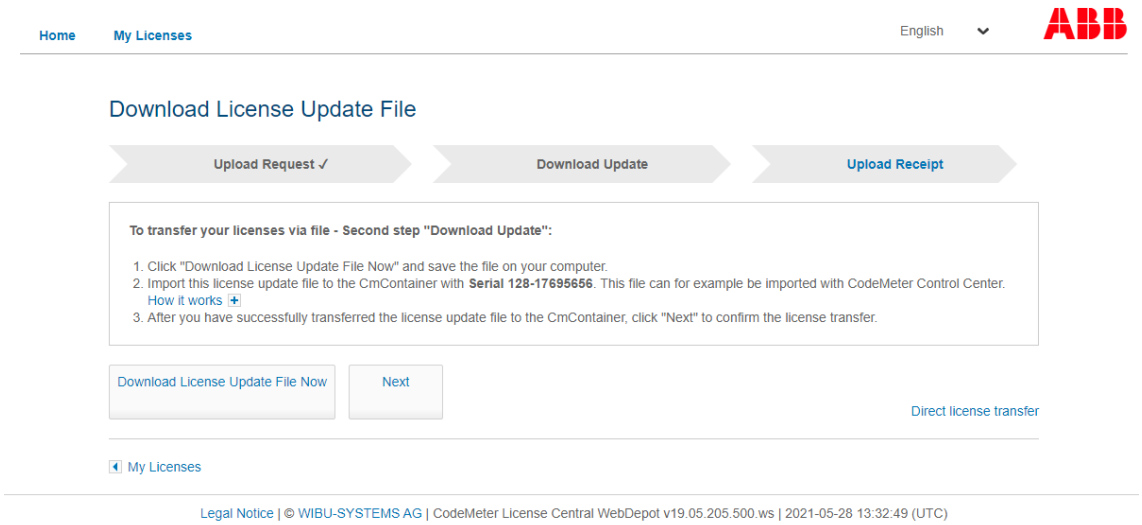


4. Select a location to store the license request file.
5. Transfer the license request file from the offline PC to an online PC.

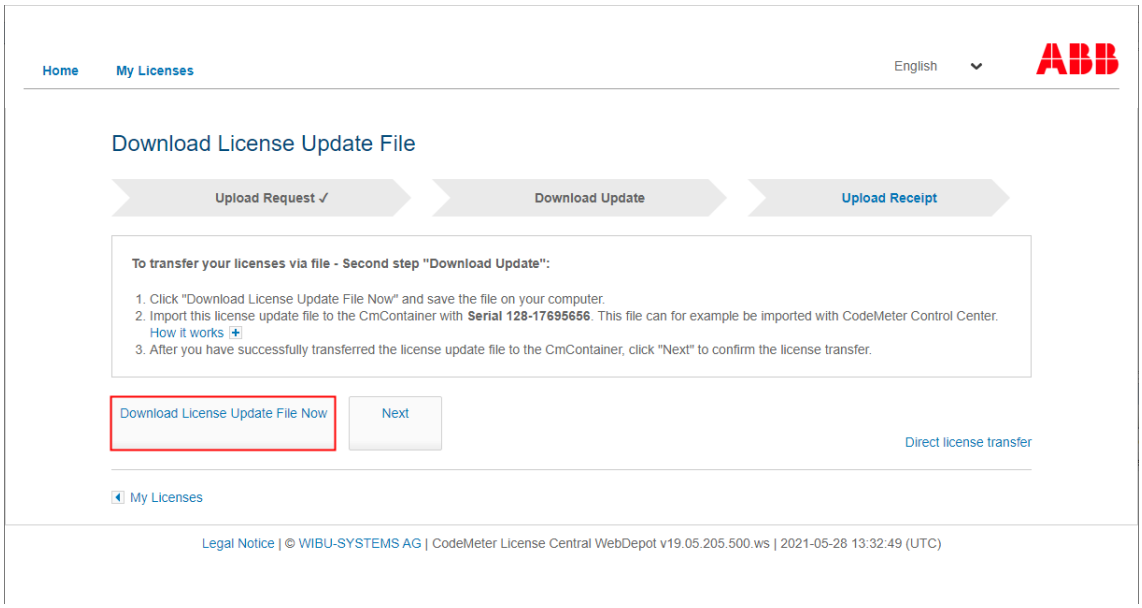
6. On the online PC choose the license request file and select *“Upload Request And Continue Now”*.



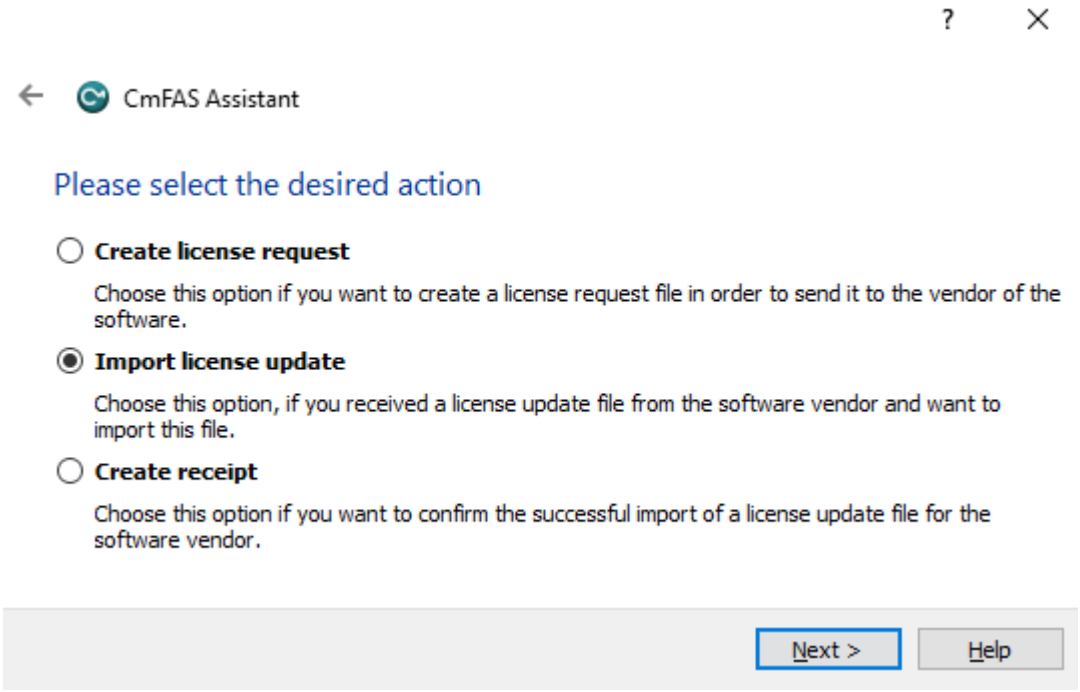
⇨ The next dialog is opened



7. Select *“Download License Update File Now”*.

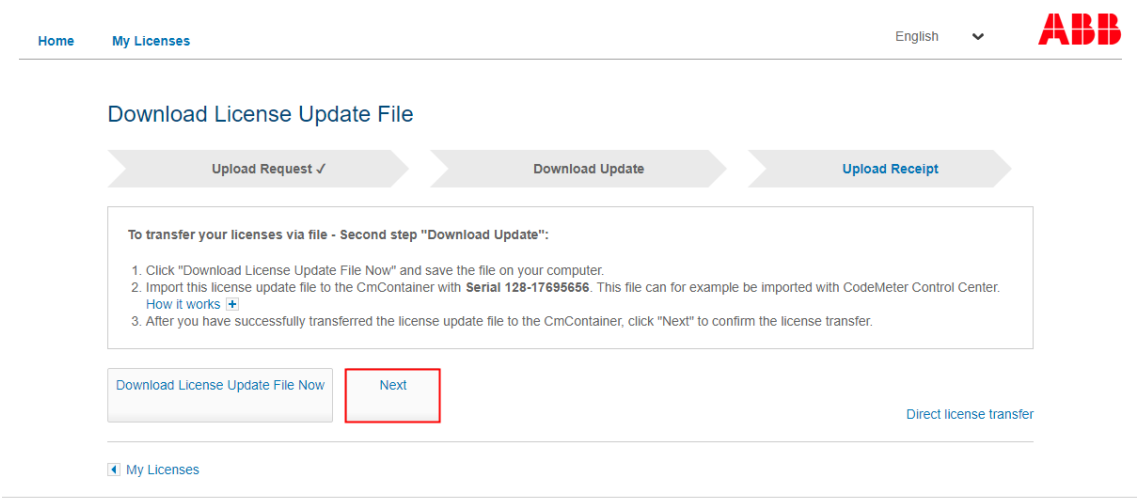


8. Save the license update file to a location on your computer.
9. Transfer the license upate file from the online PC to the offline PC.
10. On the offline PC open the CmFAS Assistant.
11. Select *“Import license update”*.

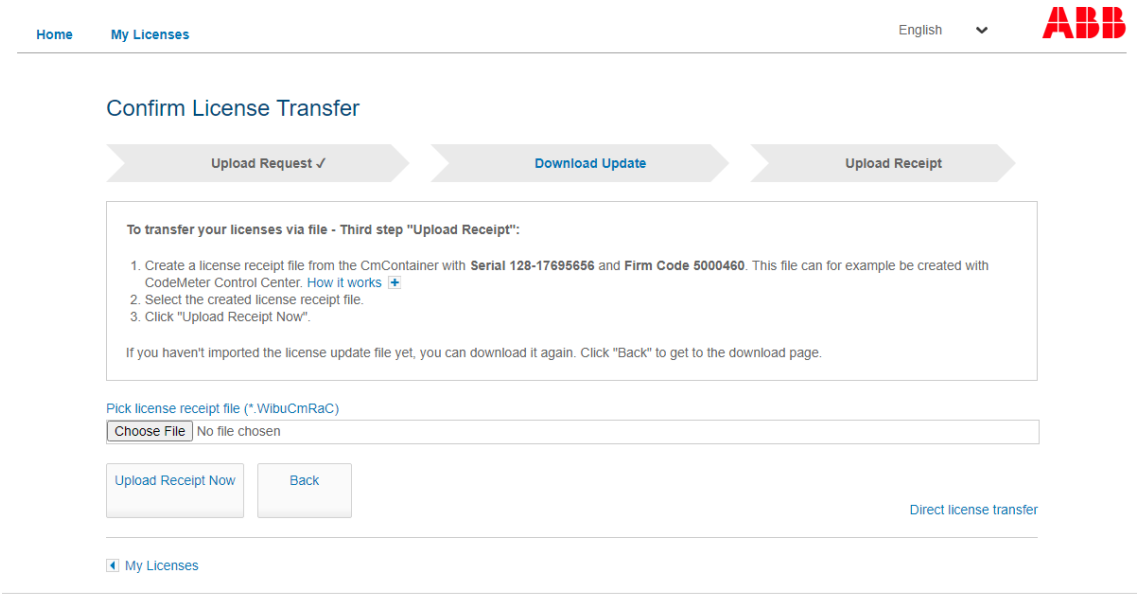


12. Select the license update file, to import the new license to the offline PC

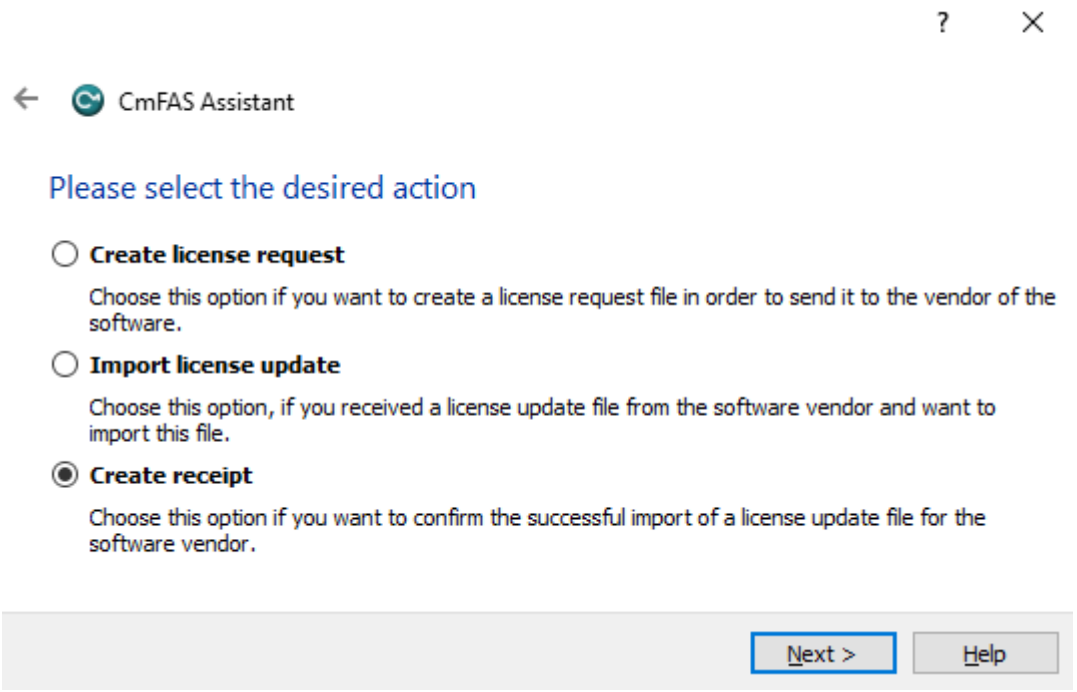
13. To confirm a succesful license transfer return to the online PC and select *“Next”*.



⇨ The last dialog is opened

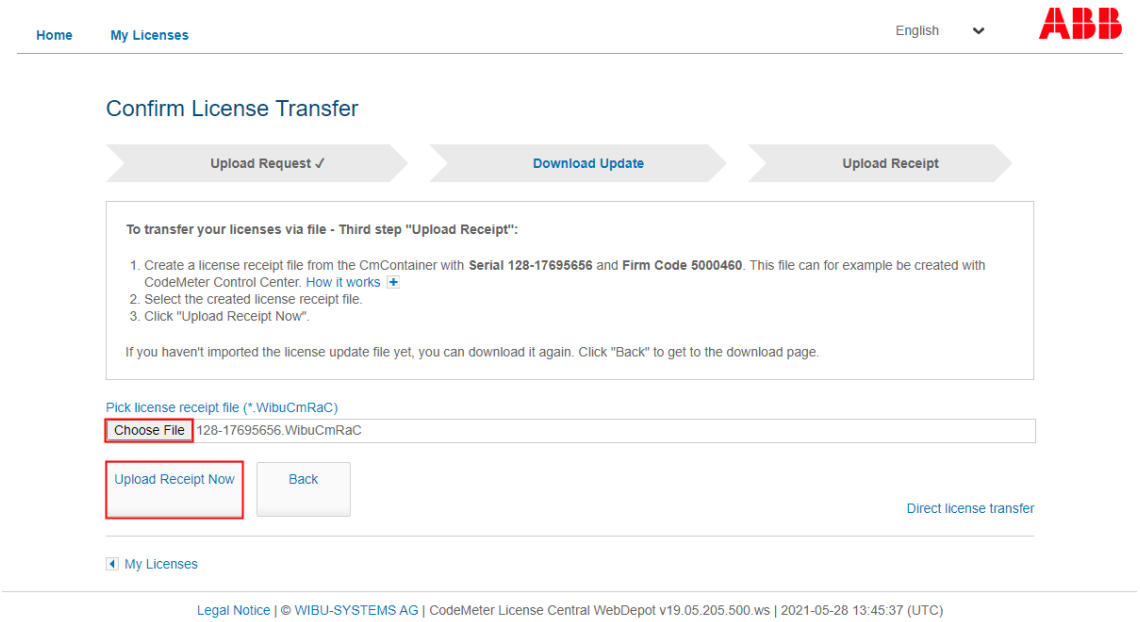


14. On the offline PC open the CmFAS Assistant.
15. Select *“Create receipt”*.

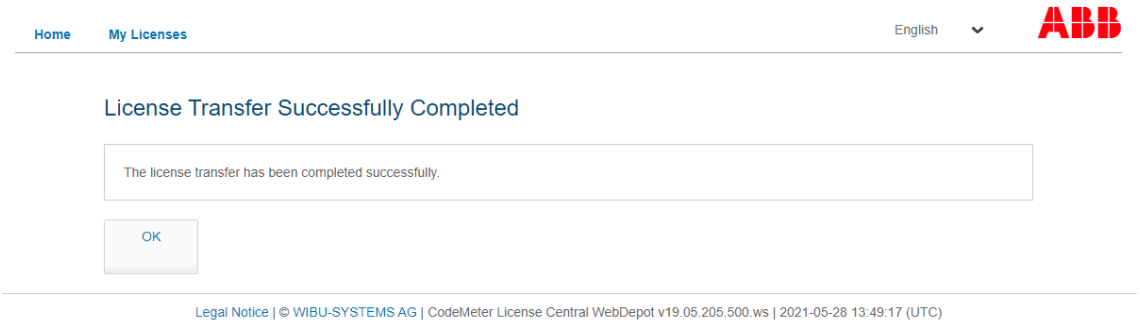


16. Choose a location to save the license receipt file.
17. Transfer the license receipt file from the offline PC to the online PC.

18. On the online PC choose the license receipt file and select *“Upload Receipt Now”*.



⇨ After a succesful license transfer you will receive the following message



1.2.4.10 Generating license information file for support

To create a license information file which includes all license information for the support:

1. Select *“Windows start menu* ➔ *CodeMeter* ➔ *Tools* ➔ *DmDust”*.
   ⇨ The explorer window opens and shows the folder where the created log file *“CmDust-Result.log”* is stored.
2. Please attach this file to any support request regarding your licenses.

1.2.4.10.1 Log files

Sometimes more detailed log files are needed to analyse a situation.

Then please also zip the following folder and attach it to your support request.

C:\ProgramData\CodeMeter\Logs

This folder includes

- CmActDiagLogyyyy-mm-dd-hhmmss.log
- CodeMeteryyyy-mm-dd-hhmmss.log

To make it easier to distinguish when the files were created, they are named as follows:

- yyyy – year, mm – month, hh – hour; mm – minutes, ss – seconds.

1.2.5 Set-up communication parameters in Windows

Set-up communication parameters

To set-up the communication between the PC and the PLC, e.g., for downloading the compiled program, you have to set-up the communication parameters.

The IP address of your PC must be in the same class as the IP address of the CPU.

The factory setting of the IP address of the CPU is 192.168.0.10.

The IP address of your PC should be 192.168.0.X. Avoid X = 10 in order to prevent an IP conflict with the CPU.

Subnet mask should be 255.255.255.0.

Change the IP address

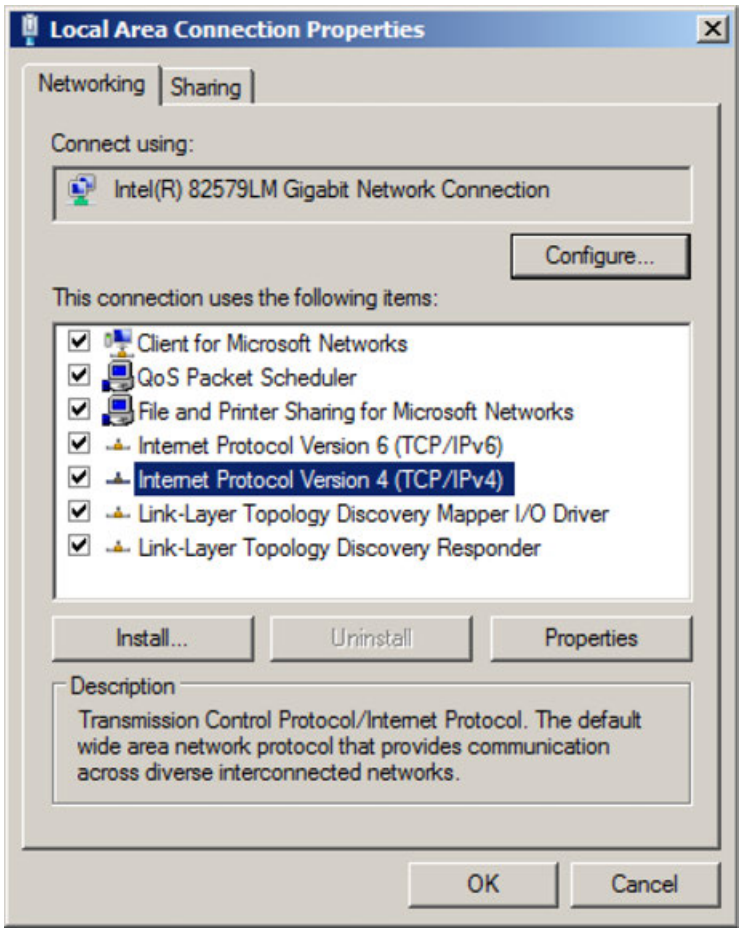
1. Open Windows **Control Panel**. Click *“Network and Internet ➔ Network and Sharing Center”*.
2. Click **Change adapter settings**.

   ⇨

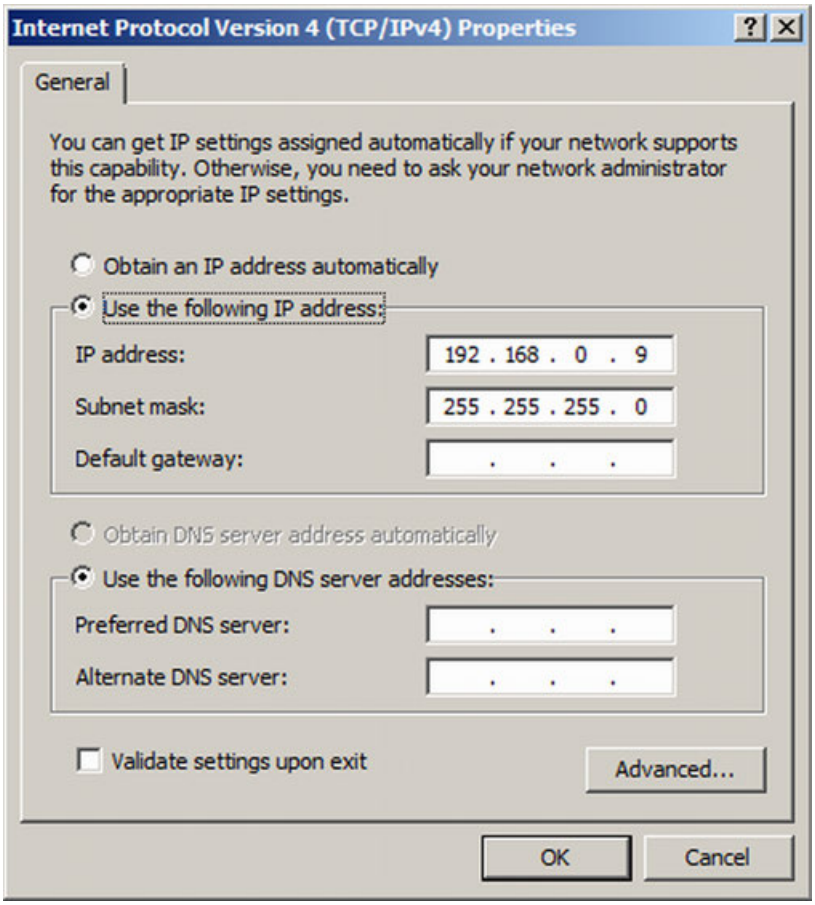
   

   If using existing network with several devices, please pay attention on given network rules or contact your system administrator.

3. Right-click **Local Area Connection (Ethernet)** and select **Properties**.



4. Double-click **Internet Protocol Version 4 (TCP/IPv4)**.



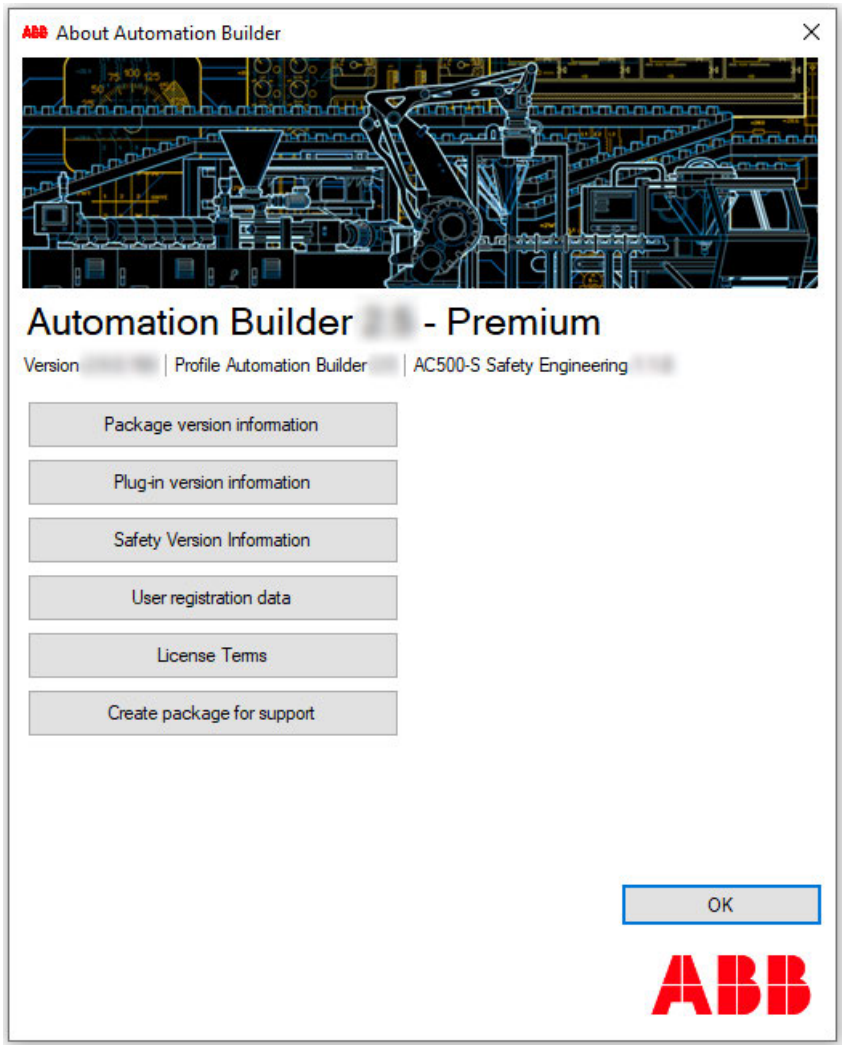
5. Enter your desired IP address and subnet mask.

1.2.6 Further information

Further information on the installed Automation Builder version such as installed packages or license terms can be found on the "About" page (help menu) and in ↳ *Chapter 1.4.1.20.4.13 “Dialog 'Options'” on page 1186*.

Safety Version is visible if safety option is installed. Safety Version Information shows the versions of all safety components.

- Package version information: Further information about all installed package versions is shown.
- Plug-in version infromation: Further information about all installed plug-in versions is shown.
- Safety version infromation: Further information about all safety component versions is shown.
- User registration data: Enter or change your registration data.
- License Terms: Information about the license terms.
- Create package for support: Creates a package which can be saved or sent to support ↳ *Chapter 1.2.8 “Create log files for support” on page 50*.



It is possible to either continue working with a project on an older Automation Builder version or to update a project to the latest Automation Builder version.

See

- *Chapter 1.4.1.20.4.13 “Dialog 'Options'” on page 1186*

1.2.7 PLC runtime and demo licensing

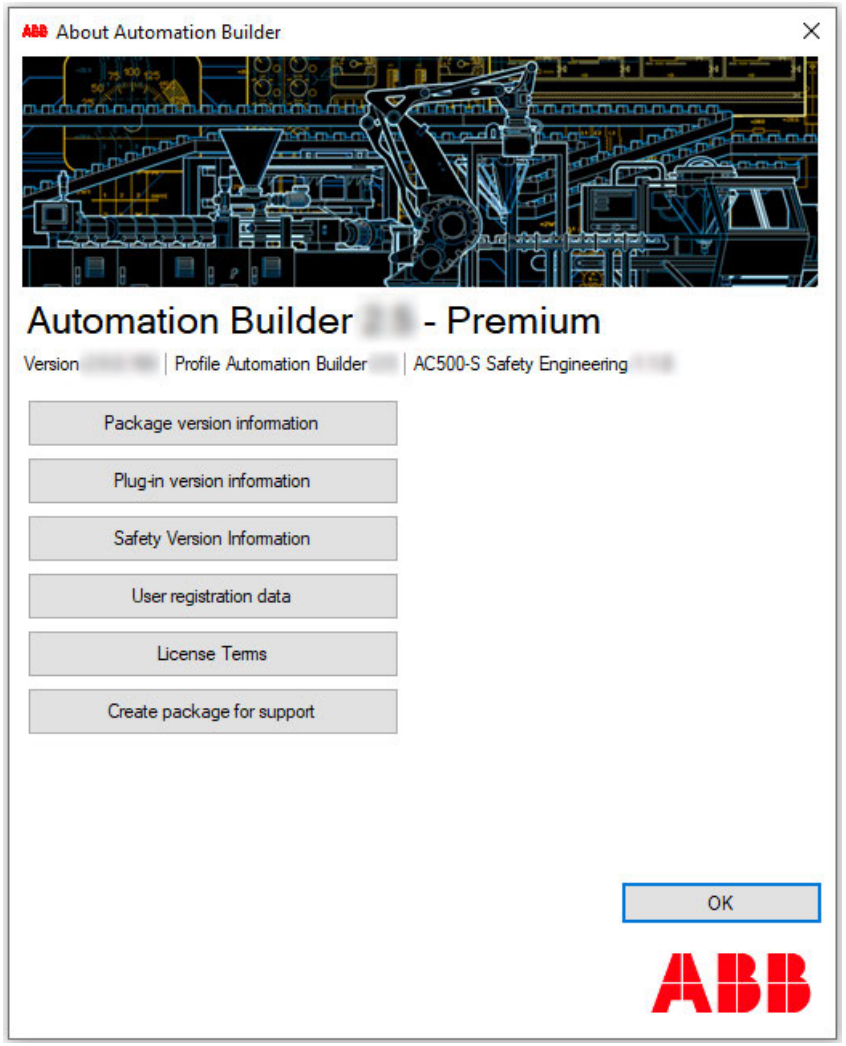
The use of some libraries and devices require the PLC to have a runtime license. Further it is possible to try out device features or library features by using a demo license *Chapter 1.6.6.2.2.2 “PLC runtime licensing” on page 3665*. .

1.2.8 Create log files for support

Professional support requires some information about the project and the devices.

To collect this information proceed as follows:

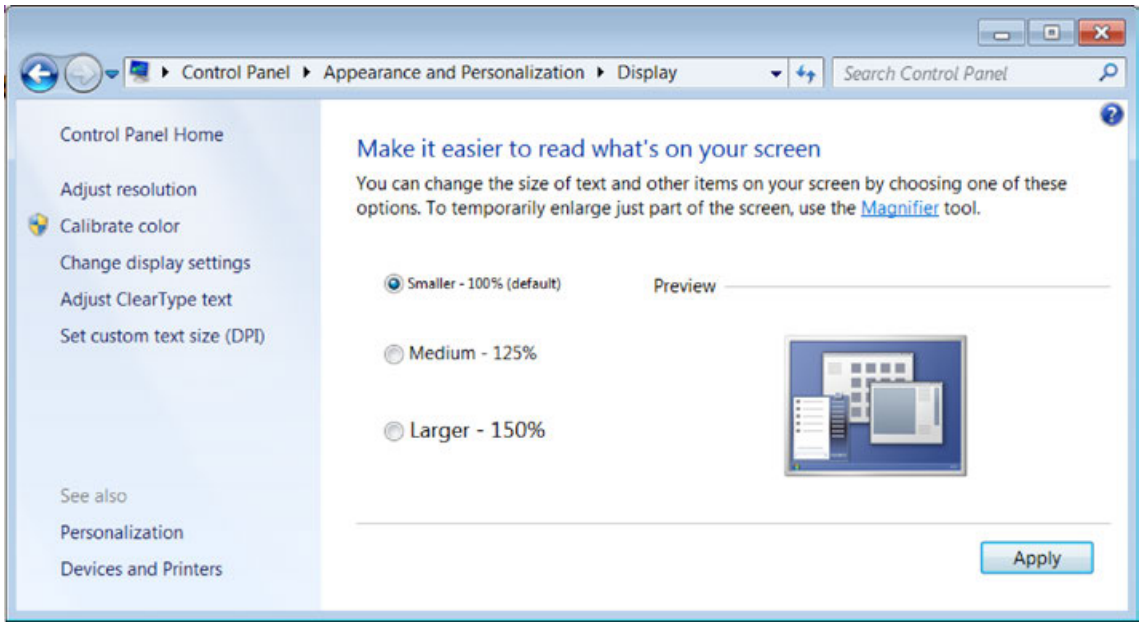
1. Click *"Help ➔ About"* in the main menu of Automation Builder.



2. Click *[Create package for support]* and wait until a list of log files is displayed.
3. Click *[Save package]* to store the zipped log files to your disk, or click *[Send package]* to send the zipped log files to ABB support.
4. Click *[OK]*.

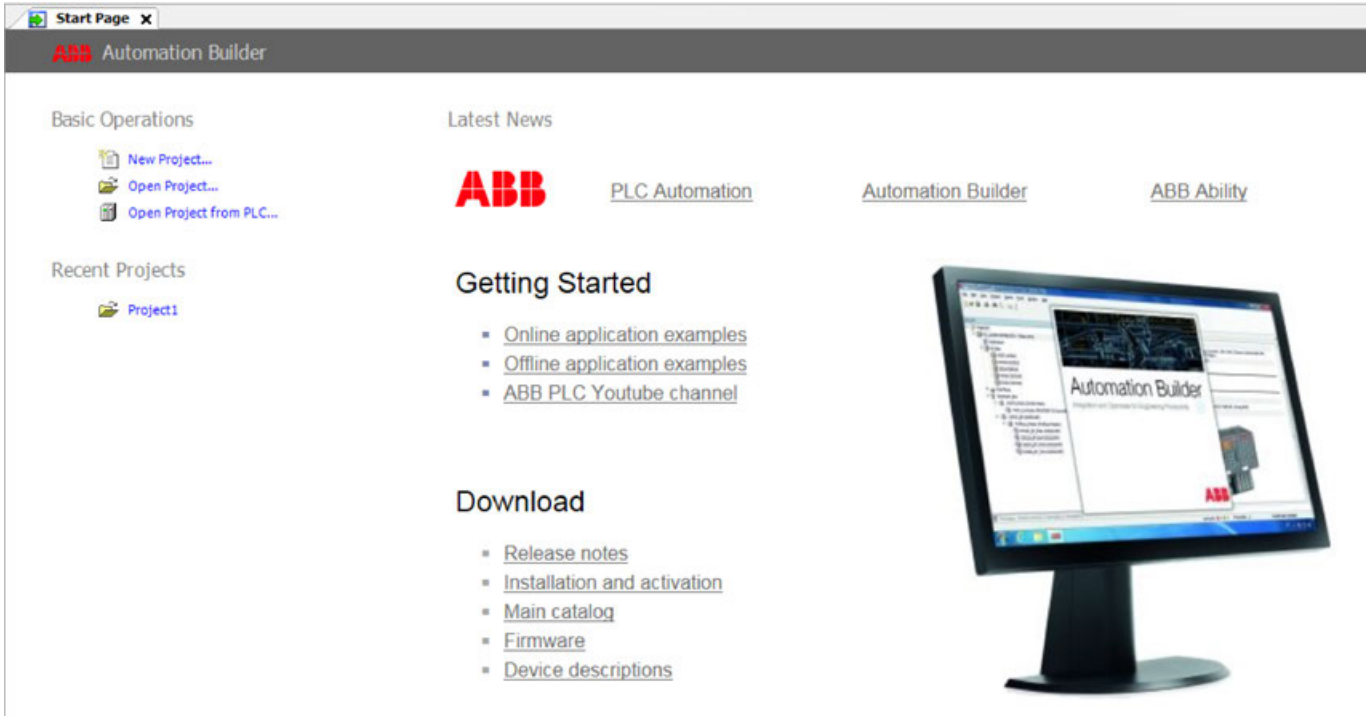
1.2.9 Menues, views, windows

Ensure the full display of Automation Builder editors by choosing the option Smaller - 100 % (default) in "Start ➔ Control Panel ➔ Appearance and Personalization ➔ Display".



1.2.9.1 Start page and menus

After start-up of Automation Builder software the start page is displayed.



All items of the Automation Builder user interface are described in the CODESYS documentation:

- *Chapter 1.4.1.20.3 “Menu Commands” on page 955*
- *Chapter 1.4.1.20.2 “Objects” on page 818*
- *Chapter 1.4.1.20.4 “Dialogs” on page 1149*

1.2.9.2 'All Messages' window

Errors, warning and success messages are written to the *“All messages”* window:

Chapter 1.4.1.20.3.3.5 “Command 'Messages'” on page 986

1.2.10 Device repository

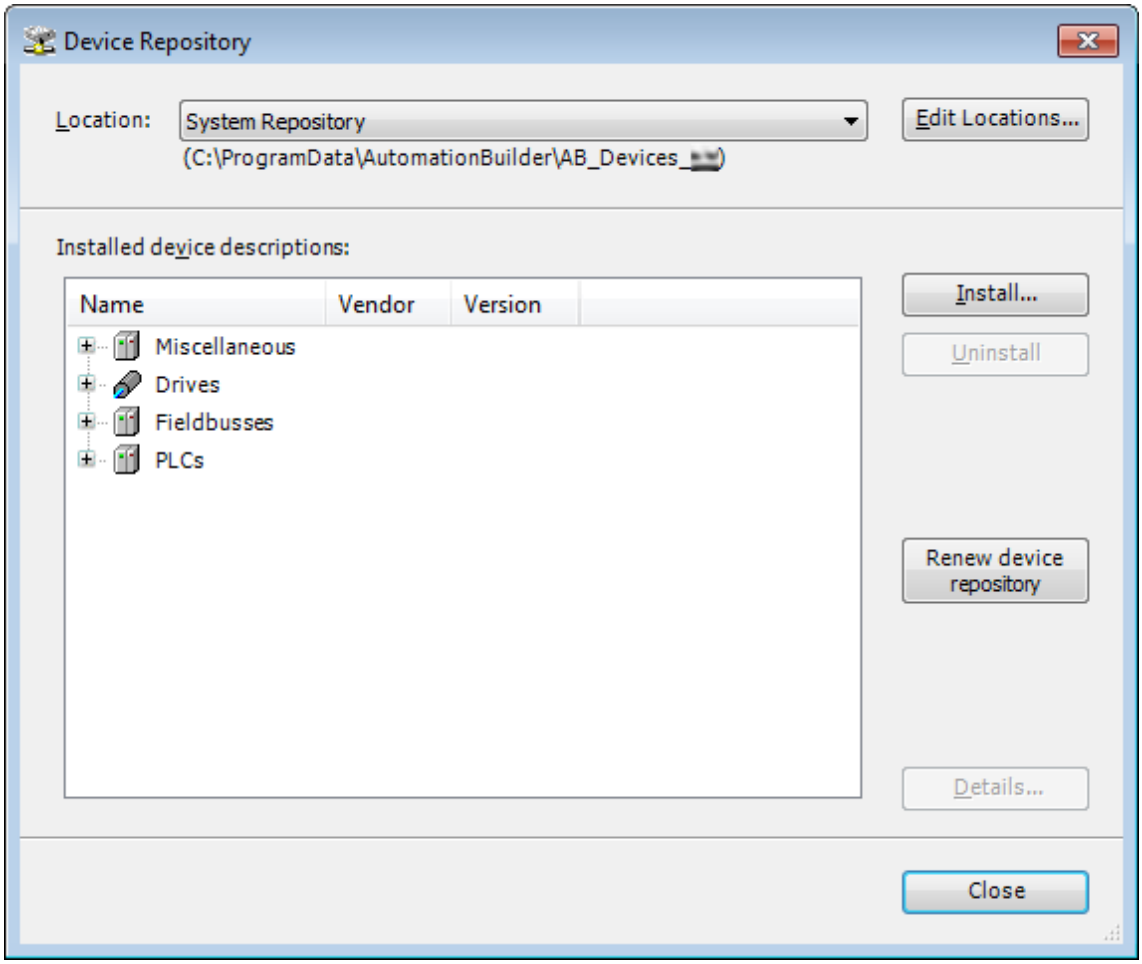
The Device Repository of Automation Builder manages the pool of devices that can be used in the PLC configuration.

You install or uninstall devices in the *“Device Repository”* dialog box. The system installs a device by reading the device description files, which define the device properties for configurability, programmability, and possible connections to other devices.

You can use the devices provided in the device repository by adding them to the device tree of your project.

Dialog device repository

1. Click *“Tools ➔ Device Repository”*.
   ⇨ The *“Device Repository”* dialog box opens.



[Edit Locations]: Changes the default repository location. The devices can be managed at different locations.

[Install] / *[Uninstall]*: Installs or uninstalls devices.

[Renew device repository]: Updates the device list, e.g. after uninstallation of a device.

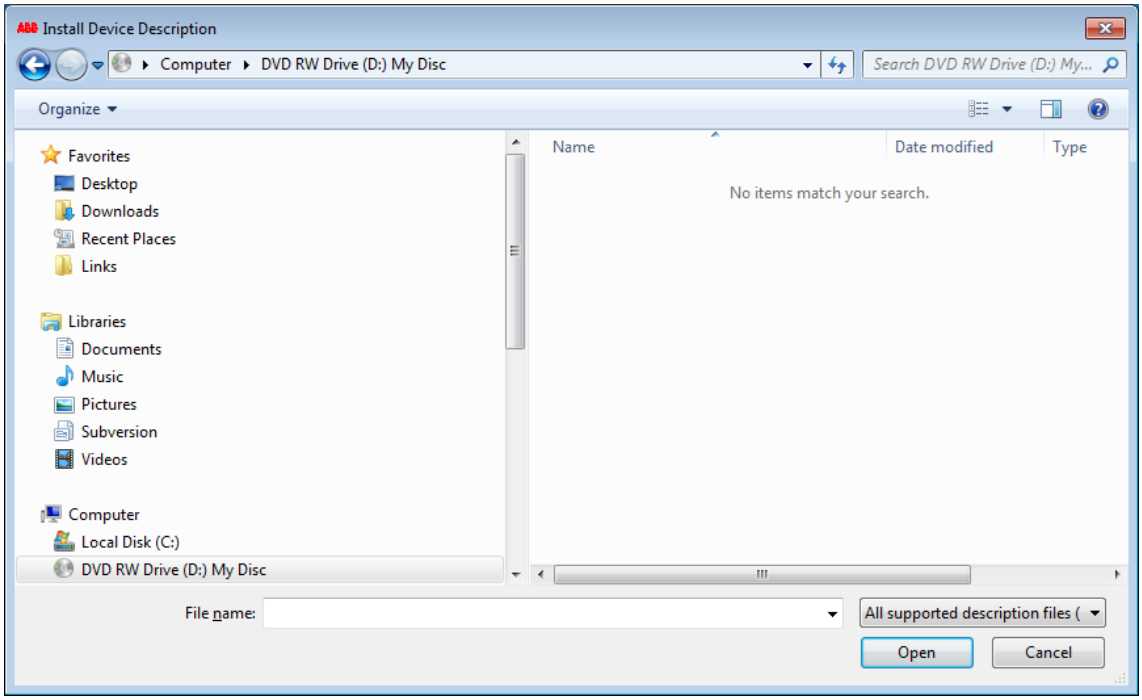
[Details]: Provides technical details on the selected device.

2. Select the install location. *“System Repository”* is set by default.

Installing devices

The device repository cannot be changed manually, e.g. by copying or deleting files. Use always the Device Repository dialog to add or remove devices.

1. Click *[Install]* and select the appropriate file format.
   ⇨ The *"Install Device Description"* dialog box opens.



2. Select the file path of the device description.
3. Select the file type filter of the required device description.
   ⇨ All device descriptions of the selected file type are listed.
4. Select the required device description and click *"Open"*.
   ⇨ Automation Builder adds the device description to the matching category of your device repository.

   If errors occur during installation (for example, missing files that are referenced by the device description), then Automation Builder displays them in the lower part of the device repository dialog box.

> *During the installation the device description files and all additional files referenced by that description will be copied to an internal location. Altering the original files will have no further effects to an internal location.*
>
> *The changes take only effect after reinstalling the corresponding device(s). The version number shown in the information section of the device should be verified.*

Uninstalling devices

Select the device you want to remove and click *[Uninstall]*.

The device is removed from the list.

> *Uninstalled devices which are used in existing projects are indicated by the symbol ❓. The device will not be configured properly.*

1.2.11 Creating and configuring projects

What is a project?

- A project contains the objects which are necessary to create a controller program ("application"):
  - Pure POUs, for example programs, function blocks, functions, and GVLs.
  - Objects that are also required to be able to run the application on a PLC. For example, task configuration, Library Manager, symbol configuration, device configuration, visualizations, and external files.
- In a project, you can program multiple applications and connect multiple controller devices.
- CODESYS manages device-specific and application-specific POUs in the *"Devices"* view ("device tree") and project-wide POUs in the *"POUs"* view.
- For the creation of projects, there are templates that already contain certain objects.
- Basic configurations and information for the project are defined in the *"Project Settings"* and *"Project Information"*. For example:
  - Compiler settings
  - User management
  - Author
  - Data about the project file

  There are settings for the version compatibility of the project in the configuration dialogs in the *"Project Environment"*.
- You save a project as a file in the file system. As an option, you can pack it together with project-relevant files and information into a project archive. It is also possible to save files in a source code management system such as SVN.
- Each project contains the information about the CODESYS version with which it was created. When you open it in another version, CODESYS will notify you about possible or necessary updates regarding file format, library versions, etc.
- You can compare, import/export projects, and create documentation for them.
- You can protect a project from being changed, or even completely protect it from being read. By using user management, you can selectively control the access to the project and even to individual objects in the project.

See also

- *Chapter 1.4.1.20.2.1 "Object 'Application'" on page 819*
- *Chapter 1.4.1.20.2 "Objects" on page 818*
- *Chapter 1.4.1.20.4 "Dialogs" on page 1149*
- *Chapter 1.4.1.20.3.4.13 "Command 'Project information'" on page 1007*
- *Chapter 1.4.1.5 "Protecting and Saving Projects" on page 197*

Handling of AC500 projects such as project creation, export/import, comparison of projects etc. is described in the sections for AC500 V3 products.

Chapter 1.6.6.1.1 "Project handling" on page 3632

1.2.12 Handling of AC500 projects

Handling of AC500 projects such as project creation, export/import, comparison of projects etc. is described in the sections for AC500 V3 products.

Chapter 1.6.6.1.1 "Project handling" on page 3632

Copy-and-paste from one project to another project in two different Automation Builder instances is possible. After copying parts of a project to a higher Automation Builder version the copied components have to be updated.

It is not possible to downgrade a project to an earlier Automation Builder version.

- *Import of export files is only allowed in the same profile version.*
- *Copy-and-paste of configurations must not be used to copy objects to an earlier version.*

Automation Builder performs an integrity check for the PLC configuration before generating the configuration.

Project archive Automation Builder supports the creation and the import of project archive files. Archive files contain all relevant project data including the PLC configuration, the CODESYS project files and all device descriptions. This allows exchanging Automation Builder projects without taking care of the target environment General Settings. ↳ *Chapter 1.6.6.1 “General settings” on page 3631*

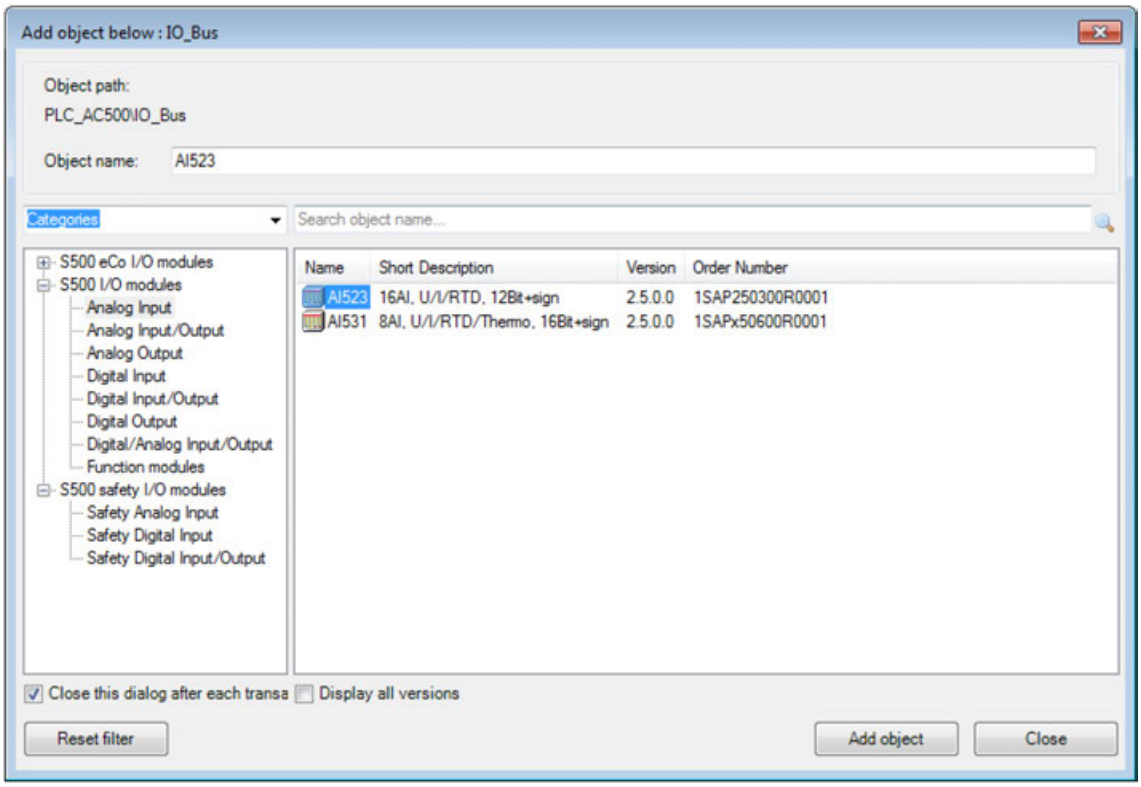
User and access rights of a project The 'User Management' provides functions for defining user accounts and configure the access rights within a project. The rights to access project objects via specified actions are assigned only to user groups, not to a single user account. So each user must be member of a group General Settings. ↳ *Chapter 1.6.6.1 “General settings” on page 3631*

1.2.13 Connection of devices

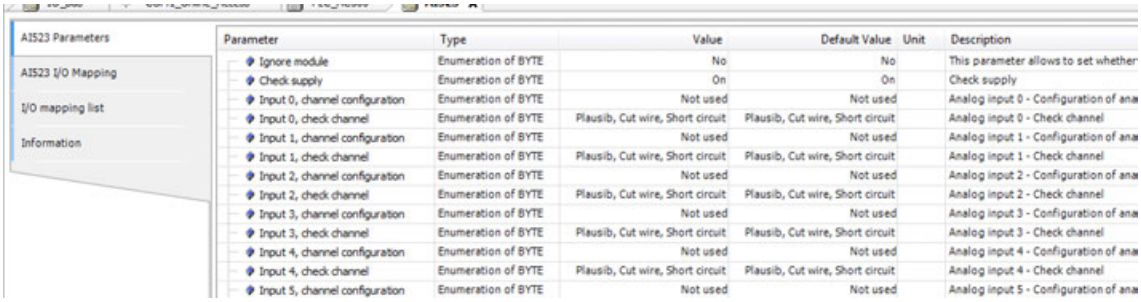
1.2.13.1 Configuring devices

Modify your Automation Builder project by adding device objects. Preset items can be replaced in the same way.

1. In the device tree, right-click an item node. Select *“Add object”*.



2. Select the desired object and click *[Add object]*.
3. Double-click the new object in the device tree to configure the device settings. Depending on the selected item different configuration tabs are available.



1.2.13.2 Symbolic names for variables, inputs and outputs

> *The IEC naming rules are not checked during input in Automation Builder.*

Input and output mapping

Devices with I/Os provide an I/O Mapping tab in their configuration editor where the available I/O channels can directly be mapped to a global variable.

The corresponding variable declarations are automatically available in the project.

All available I/O channels can easily be assigned to a variable.

Variable	Mapping	Channel	Address	Type	Default Value	Unit	Description
b_Input_IB0		Digital inputs I0 - I7	%IB0	BYTE			
x_Input_IB0_IX0		Digital input I0	%IX0.0	BOOL			
x_Input_IB0_IX1		Digital input I1	%IX0.1	BOOL			
x_Input_IB0_IX2		Digital input I2	%IX0.2	BOOL			
x_Input_IB0_IX3		Digital input I3	%IX0.3	BOOL			
x_Input_IB0_IX4		Digital input I4	%IX0.4	BOOL			
x_Input_IB0_IX5		Digital input I5	%IX0.5	BOOL			
x_Input_IB0_IX6		Digital input I6	%IX0.6	BOOL			
x_Input_IB0_IX7		Digital input I7	%IX0.7	BOOL			
		Digital inputs I8 - I15	%IB1	BYTE			
		Digital inputs I16 - I23	%IB2	BYTE			
		Digital inputs I24 - I31	%IB3	BYTE			
Fast counter							

AC500 uses Intel Byte Order (Little Endian).

Only entries with a data type set in column "Type" can be mapped. These entries can be expanded to show the available I/O channels.

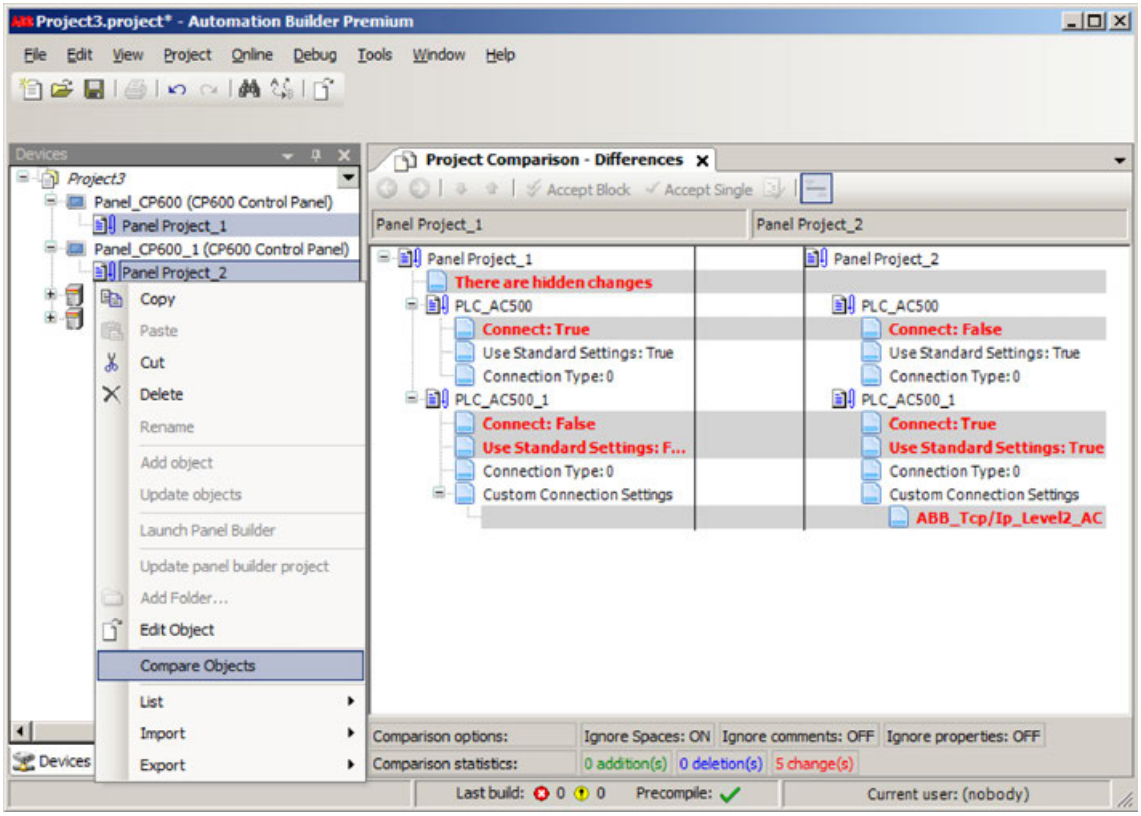
If the project has been imported from a previous Automation Builder version, all variables should be checked to avoid inconsistencies concerning the I/O mapping.

1.2.13.3 Update of AC500 devices

Perform a firmware update to update AC500 V3 devices. *Chapter 1.2.18.1.2.6 “ AC500 V3 firmware installation and update” on page 87*

1.2.13.4 Comparing objects

To compare similar objects within a project (such as the project configuration) select both objects. Right-click and select **Compare Objects** to see the differences.



1.2.14 Connection of serial interfaces

Depending on the device type, the configuration of serial interfaces is different.

AC500 V3 Products: *Chapter 1.6.6.2 “PLC devices and components” on page 3662*

1.2.14.1 Programming of applications

To create an application program which can be run on the controller, you fill POUs with declarations and implementation code (source code), establish the link from the controller I/Os to application variables, and configure the task assignment. After checking and debugging, the CODESYS compiler creates the application code which can be downloaded to the controller.

The programming of the application POUs is supported by the programming language editors and other features such as text lists, image pools, alarm configurations, pragmas, refactoring, and ready-to-use POUs from CODESYS Development System or libraries.

There are features for syntax checking and code analysis, for achieving data persistence, and for encrypting the application code which is downloaded to the controller.

1.2.15 I/O mapping

For all connected I/O devices perform an I/O Mapping.

Chapter 1.6.6.2.13.8 “I/O mapping list” on page 3777

1.2.16 AC500 PLC configuration

See Getting Started for AC500 V3 products. *Chapter 1.6.6.2.2 “PLC start-up” on page 3665*

1.2.17 Converting an AC500 V2 project to an AC500 V3 project

A project that has been configured for an AC500 V2 PLC can be converted to a project for an AC500 V3 PLC.

Essentially, the conversion is done in Automation Builder, however, some additional actions have to be executed manually. The complete procedure is described in the application example

Instructions on how to convert a V2 project to a V3 project and differences between V2 and V3.

1.2.18 Example projects

1.2.18.1 Example projects for AC500 V3

1.2.18.1.1 Hardware AC500 V3

Configuration for example projects

The example projects require a small PLC configuration with I/O devices, e.g., as available in the training case TA5450-CASE. *https://to.abb/AfO9-ftT*

Table 2: Modules for example projects to get started with AC500 V3 PLC

Product name	Type	First project ↳ *Chapter 1.2.18.1.2 “Example project for central I/O expansion” on page 63*	Second project ↳ *Chapter 1.2.18.1.3 “Example project for remote I/O expansion with PROFINET” on page 109*
PM5630- 2ETH	AC500 V3 CPU	x	x
TB5620-2ETH	terminal base for CPU	x	x
DA501	analog/digital mixed input/output (I/O) module	x	x
TU516-H	terminal unit for I/O module	x	x
CM579-PNIO	PROFINET communication module	--	x
CI502-PNIO	PROFINET communication interface module	--	x
TU508-ETH	terminal unit for communication interface module	--	x
TA524	blind cap for terminal base	x	x

Connections

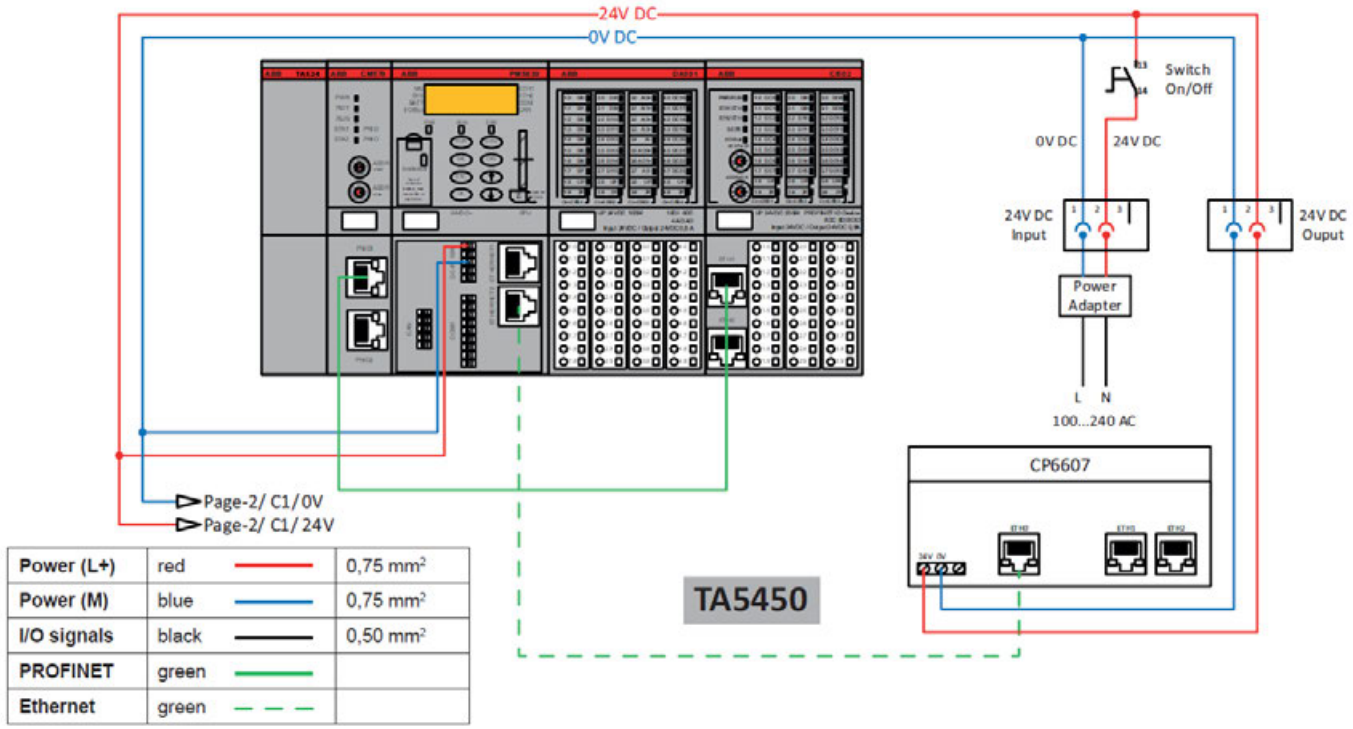


Fig. 5: Training case TA5450

> *In the training case, the control panel CP6607 is included. A control panel is not needed for the example projects.*

For testing the example project some inputs require to be connected as follows:

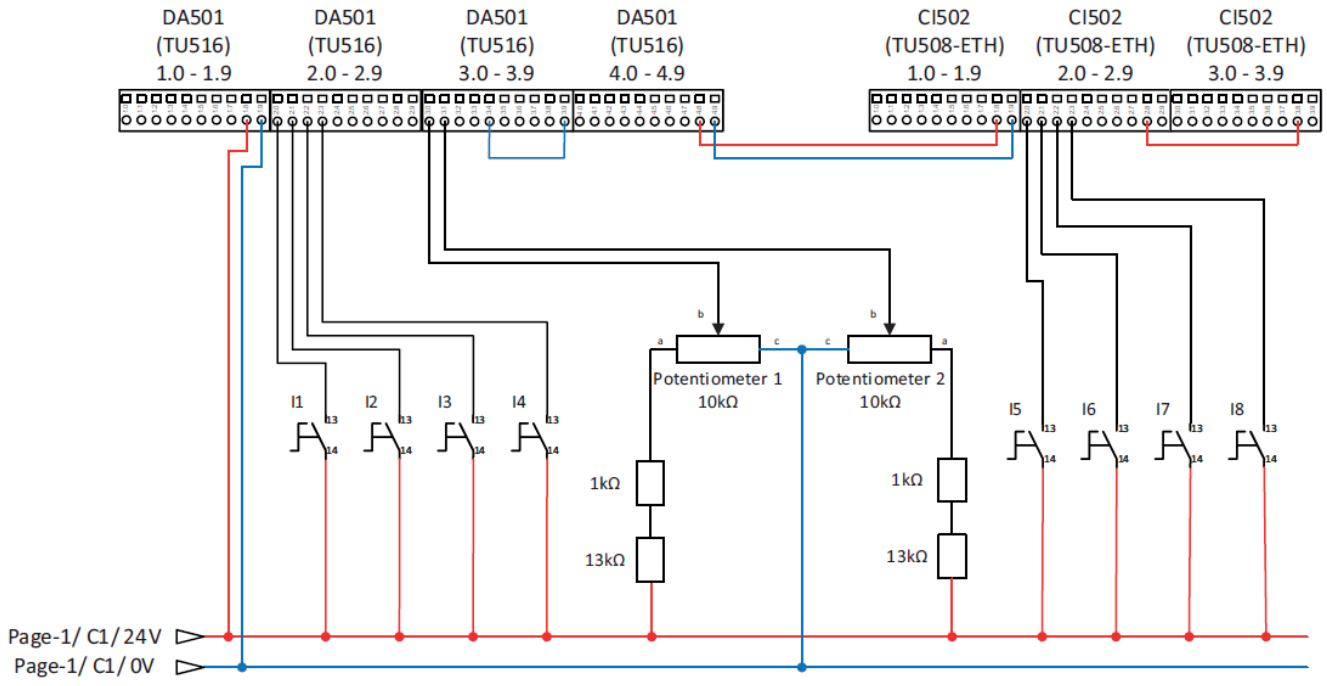

Fig. 6: Wiring of training case

For the example projects, not all input switches and none of the potentiometers included in training case are necessary.

You will need switch I1 for the example project for central I/O expansion.

You will need switch I5 for the example project for remote I/O expansion.

System assembly, construction and connection

NOTICE!

Avoidance of electrostatic charging

PLC devices and equipment are sensitive to electrostatic discharge, which can cause internal damage and affect normal operation. Observe the following rules when handling the system:

- Touch a grounded object to discharge potential static.
- Wear an approved grounding wrist strap.
- Do not touch connectors or pins on component boards.
- Do not touch circuit components inside the equipment.
- If available, use a static-safe workstation.
- When not in use, store the equipment in appropriate static-safe packaging.

You can mount AC500 PLC either to DIN rail or to a metal plate *Chapter 1.6.4.6.3 “Mounting and demounting” on page 3408*. Here, we recommend to mount on DIN rail.

1. Snap the terminal base onto DIN rail.
2. Snap the additional terminal units for I/O modules onto DIN rail.
3. Make the sensor/actuator wire connections according to the dedicated electronic module you want to use. Provide external process power supply as required.
4. If required, make the fieldbus connections according to the dedicated master communication module you want to use.
5. Plug the appropriate electronic and I/O modules in the correct locations (processor module, communication modules on terminal base, and eventually also communication interface modules and I/O modules onto dedicated terminal units).
6. Connect a programming cable (Ethernet cable between ETH port of CPU and PC with engineering software).

1.2.18.1.2 Example project for central I/O expansion

The following steps show how to set-up an application project and configure the hardware. A simple logic is used as example to introduce in programming and commissioning of the PLC. The workflow for creation of a visualization is explained, as well as how to set-up a web server for visualization.

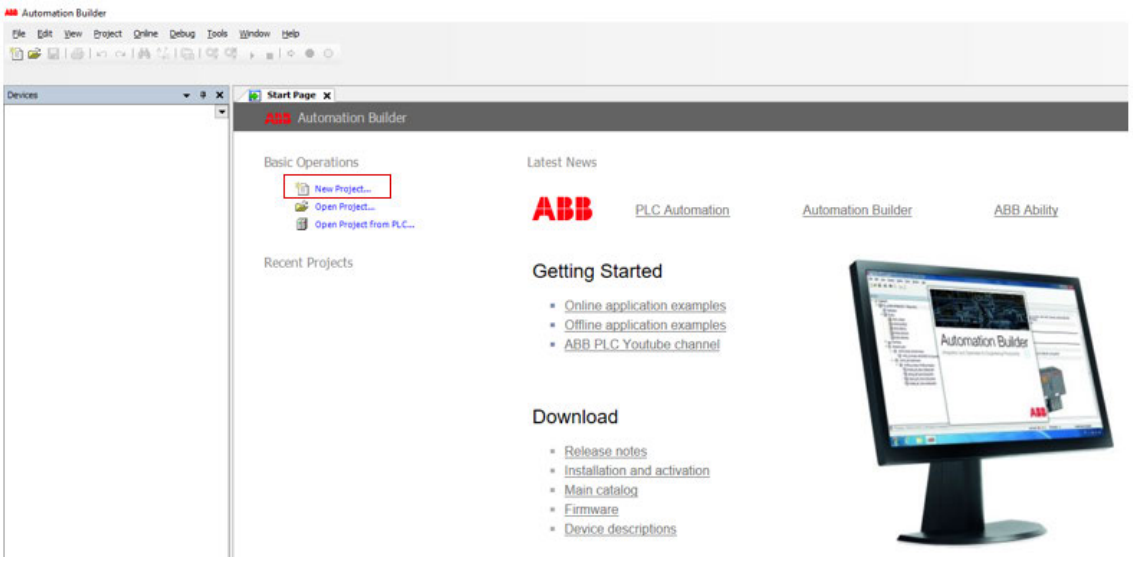
Preconditions

- Automation Builder is installed and licensed as, at least, basic edition *Chapter 1.2.4 “Managing your licenses” on page 20*.
- AC500 V3 CPU is assembled and connected to the PC *Chapter 1.2.18.1.1 “Hardware AC500 V3” on page 61*.

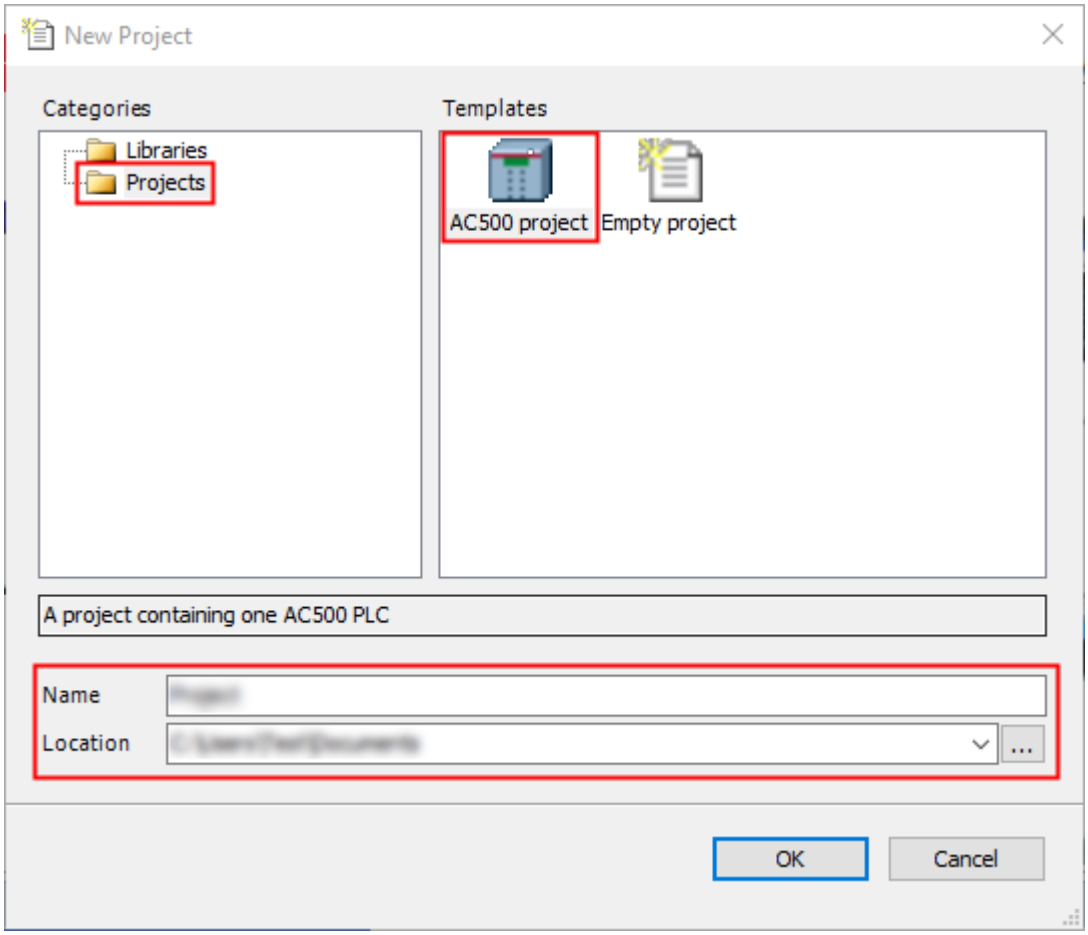
Create, set-up and save your AC500 V3 project

Create a project

1. Launch Automation Builder either out of the desktop icon or out of the Windows menu.

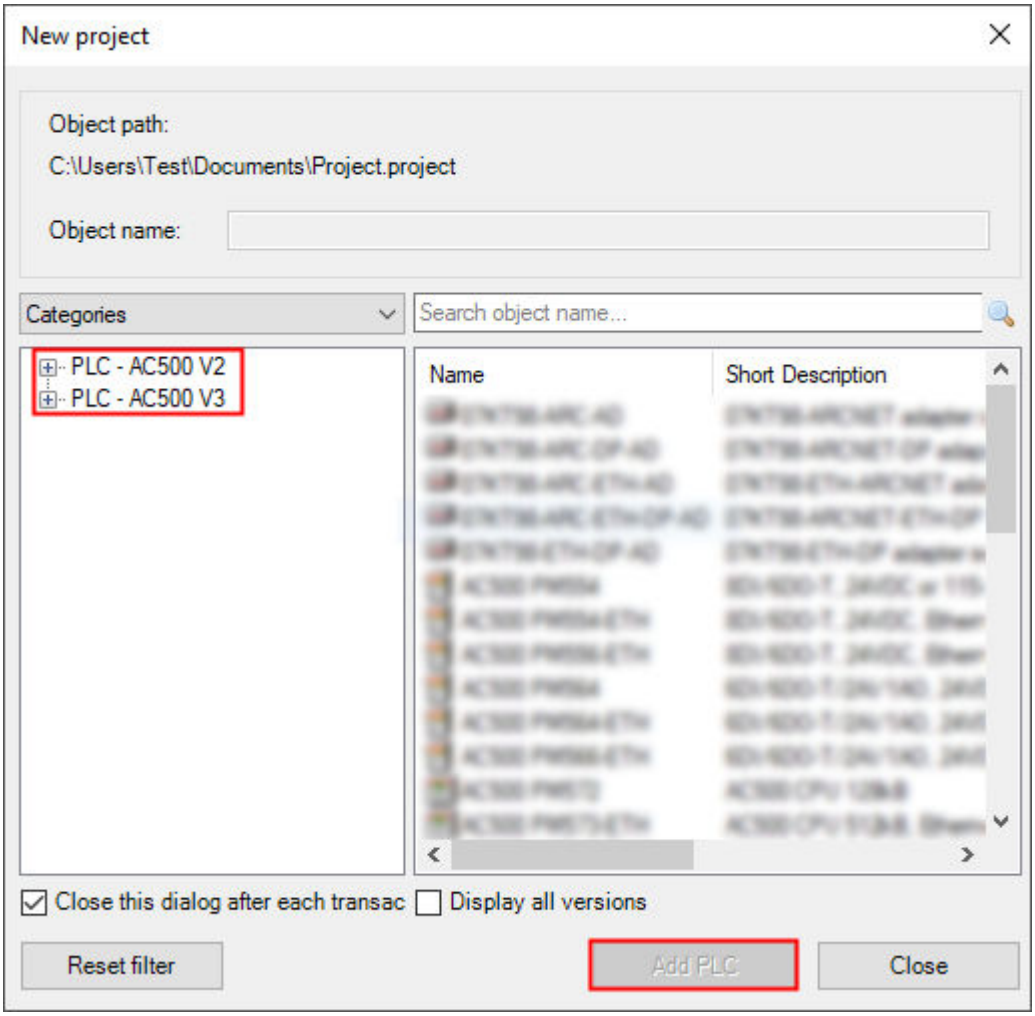


2. Select *"New Project"* or go to menu *"File ➔ New Project"*.



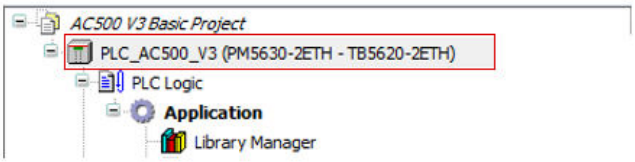
3. Select *"Projects"*.
4. Select *"AC500 project"*.
5. Fill in project name.
6. Choose a location to save the project to.

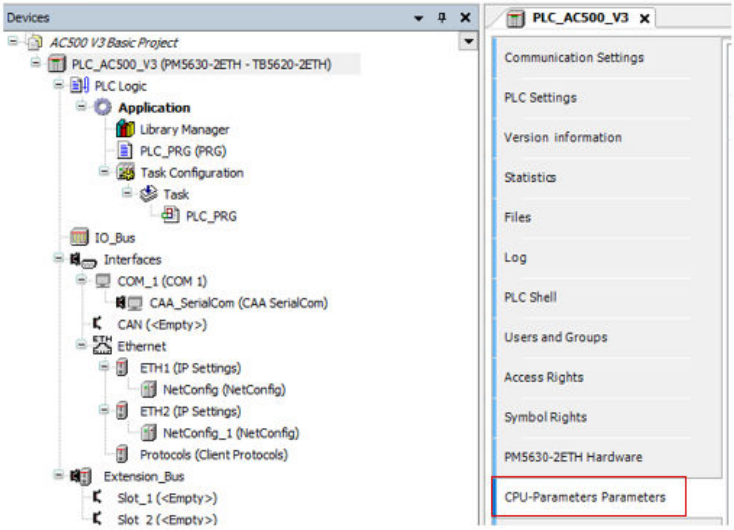
7. Select *“OK”*.
8. Select *“PLC - AC500 V3”*.
9. Select the CPU according to your hardware set-up.



10. Select *“Add PLC”* to add the CPU to your application.

Configure your CPU



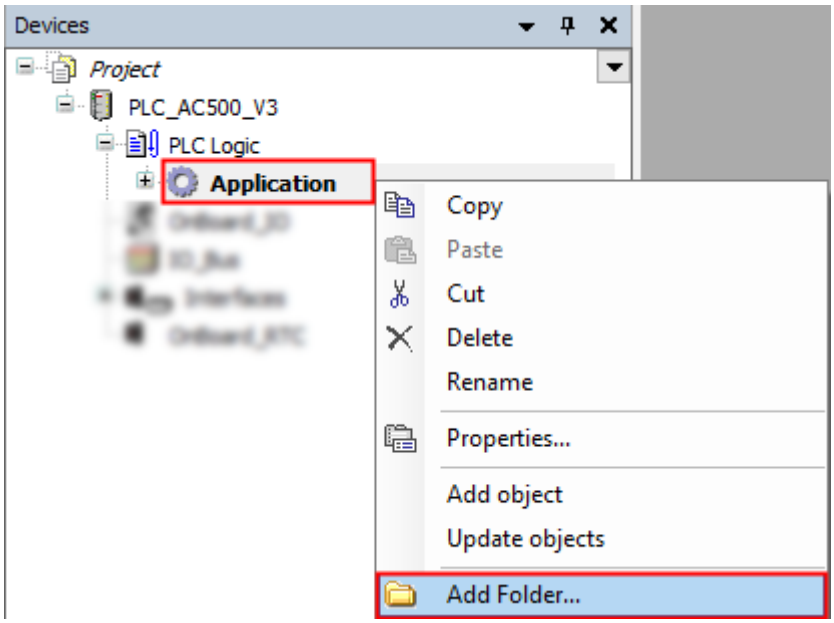


Parameter	Type	Value	Default Value
Error LED	Enumeration of BYTE	On	On
Check battery	Enumeration of BYTE	On	On
Stop on error class	Enumeration of BYTE	Diagnosis of at least error class 2	Diagnosis of at least error class 2

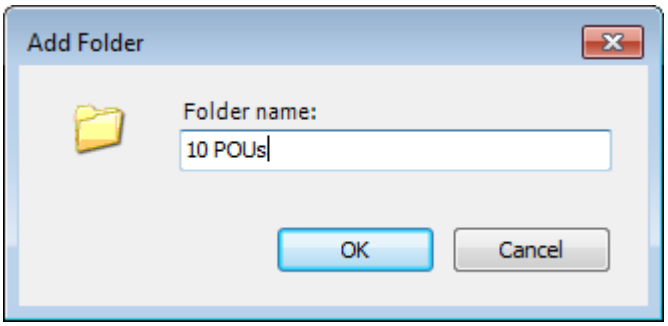
1. Double-click *“PLC_AC500_V3”*.
   ⇨ A tab opens in the editor view.
2. Select *“CPU-Parameters Parameters”*.
3. Under parameter *“Check battery”*, choose the value *“Off”* since there is no battery present inside the CPU module.
4. Keep the default values for all other parameters.

Create folders in the device tree

To optimize the project readability, you will create different folders to group similar objects. The folder names are exemplary. Because the device tree view follows an alphabetical order, we use number prefixes to determine the order.



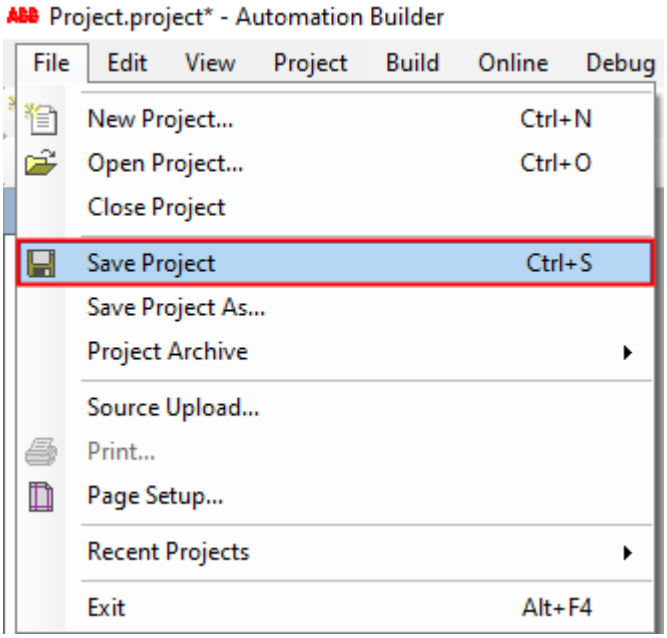
1. Right-click *“Application”*.
2. Select *“Add Folder”*.



3. Type in "10 POUs". This is a name example. Here, the intention is to see this folder as a last one.

   The folder "10 POUs" is for program organization units (POU). POUs are objects of type program, function or function block that are used to create a user program.

Save the project



▷ Select menu *"File ➔ Save Project"*.

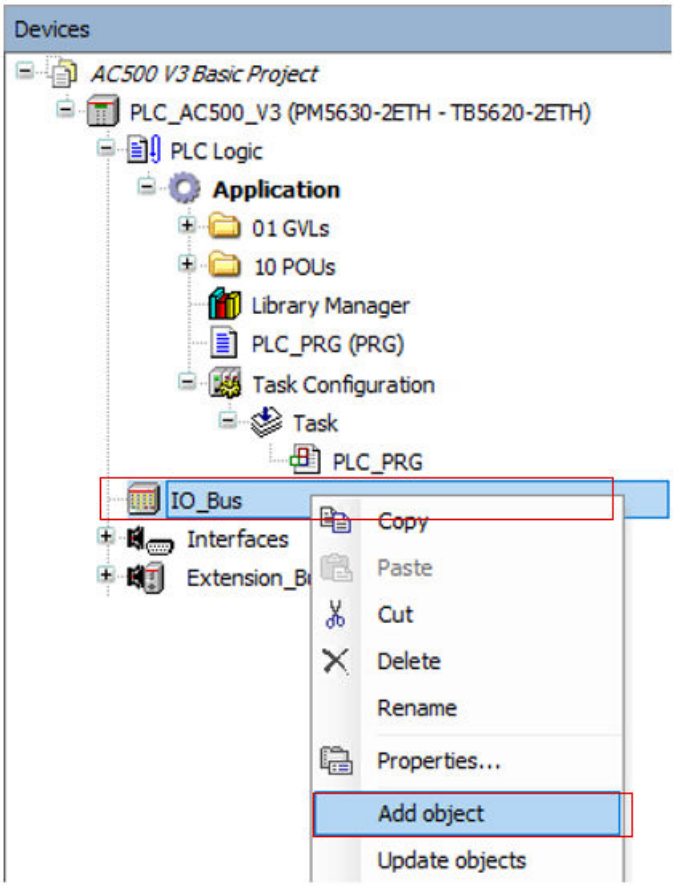
Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl]* + *[S]*.

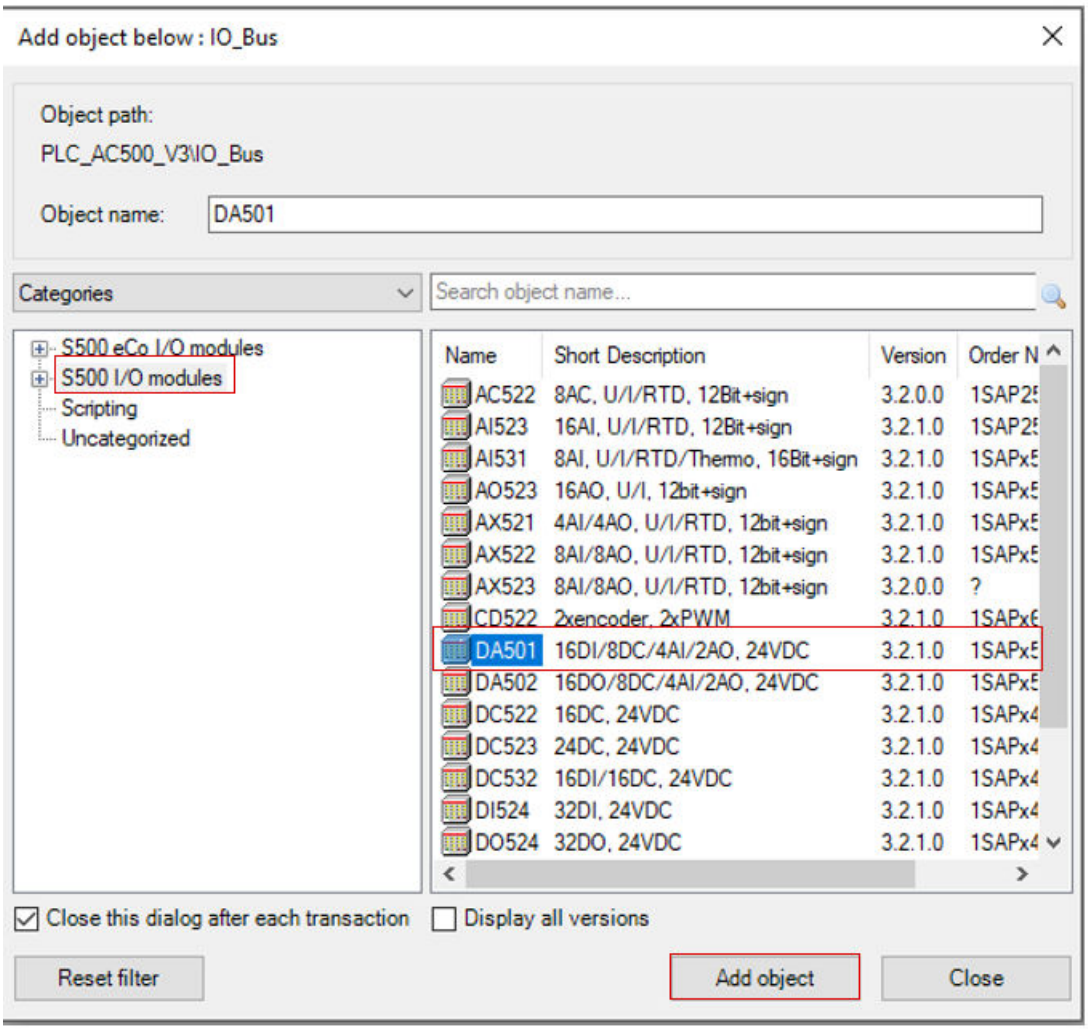
Configure the I/O module

- The types and order of modules in the Automation Builder project must match the real hardware configuration.
- The position of the modules in the device tree can be changed by drag and drop.

Add an I/O bus module

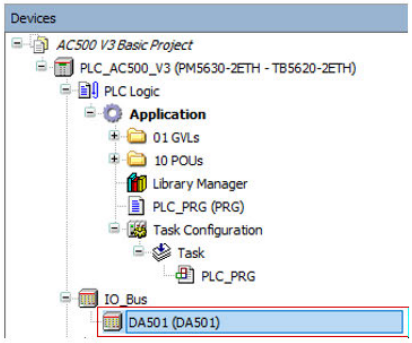


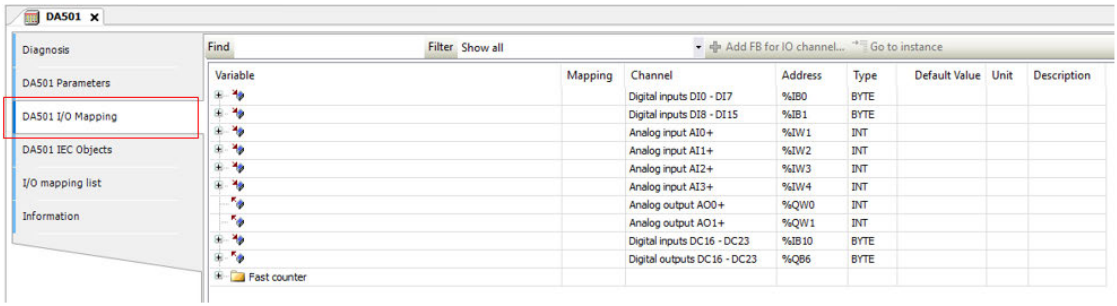
1. Right-click *"IO_Bus"* in the device tree.
2. Select *"Add object"*.



3. Select *“S500 I/O modules”*.
4. Select *“DA501”* module.
5. Select *“Add object”* to add the module to the I/O bus.

DA501 variable mapping

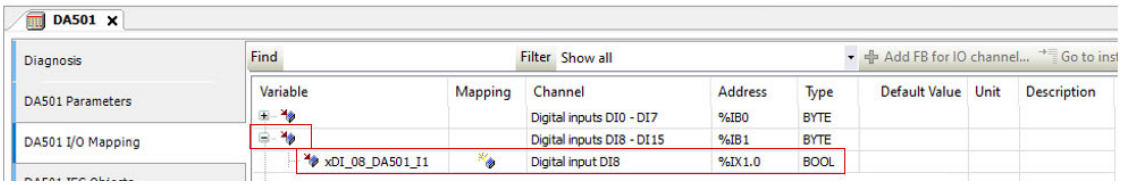




1. Double-click *“DA501”* in the device tree.
   ⇨ A tab opens in the editor view.
2. Select *“DA501 I/O Mapping”*
   ⇨ Here, you will map variable names (symbols) for the channels you will need in the program.

The suggested name convention is based on "Hungarian notation". A name prefix is describing variable type: e.g., "x" = variable of type BOOL, "w" = WORD, "i" = INT (integer) etc. This increases the code readability and is helpful for program analysis.

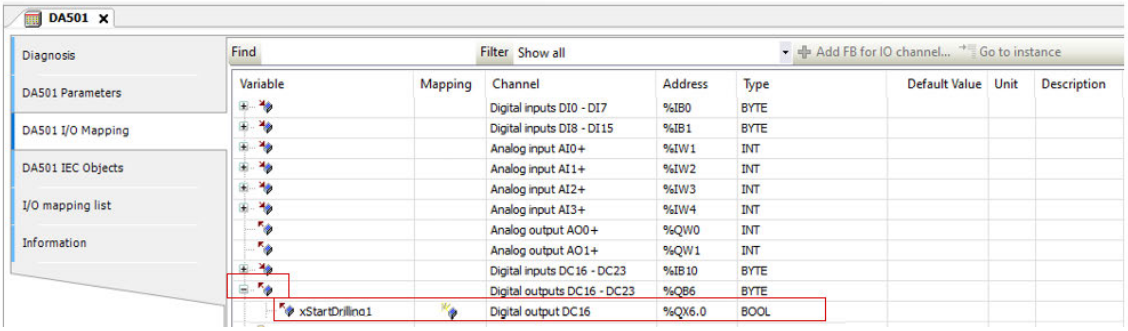
Handle the digital input variables



1. Open the list of the digital inputs.
2. Fill in the variable names:

Channel	Type	Variable
Digital input DI8	BOOL	xDI_08_DA501_I1

Handle the digital output variables



1. Open the list of the digital outputs.
2. Fill in the variable names:

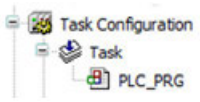
Channel	Type	Variable
Digital output DC16	BOOL	xStartDrilling1

Programming and compiling

Task configuration

A task is a time unit in the processing of a user program (IEC application), which defines by parameters the way and the speed the CPU is executing the user program.

For this project you will use only one cycling task.



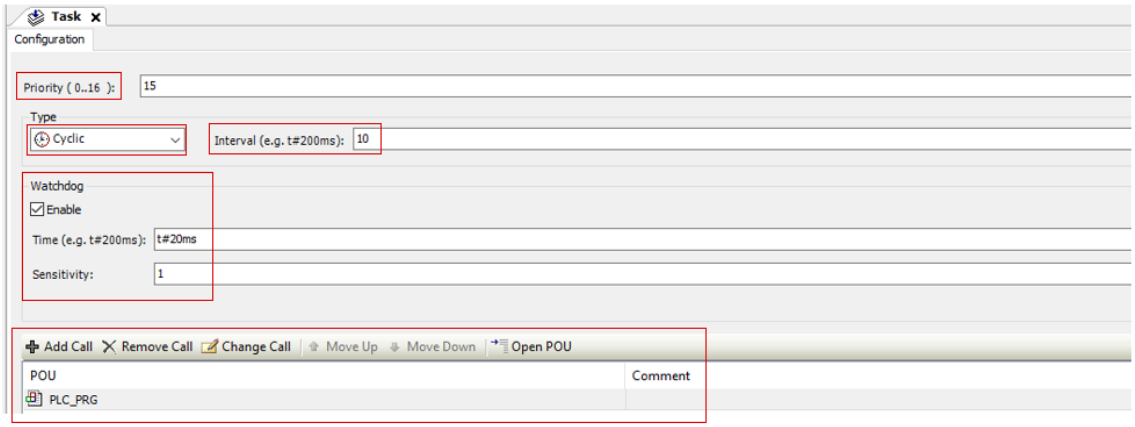
In the device tree, you see the objects *“Task configuration”* and *“Task”*. Both created automatically with the project.

For this project you will use only one cycling task.

▷ Double-click *“Task”* in the device tree.

⇨ A tab opens in the editor view.

For this project you will use only one cyclic task. Keep the default settings for the task.

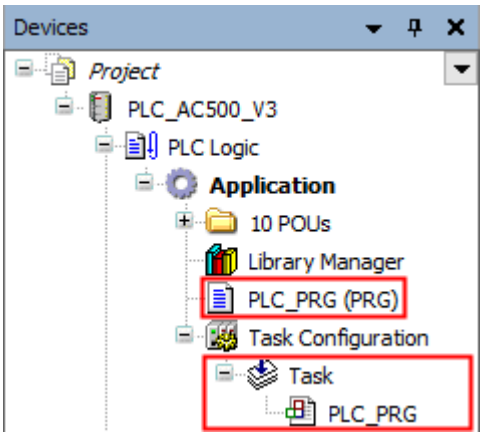


Priority	This is how the CPU prioritizes the task, when more than one task is defined. Priority 0...15 = real time tasks, priority 16 = non-real time task.
Type	In the CPU you can run tasks dependent on the demands of the process
Interval	For cyclic tasks you can set the cyclical execution time. It is usually set in milliseconds with IEC time syntax
Watchdog	To keep track of the time it takes to complete the task
Calls	You can call in one or more program POUs in one single task

Main program PLC_PRG

In the default task configuration ↳ *(shown in chapter 1.2.18.1.2.4.1 Task configuration on page 72)*, there is one call of a POU (program organization unit) i.e. "PLC_PRG".

In your project the "PLC_PRG" will become a main program containing calls to other programs (POUs) which you will create one by one.



The PLC_PRG POU has been defined by default in ST (Structured Text) editor. Keep this setting because of good visibility of the instructions at a glance and good handling for trouble-shooting.

To optimize the project readability, you will work with the previously created folder "10 POUs" and add the created subroutines (POUs) to this folder. The subroutines will be created in FBD (Function Block Diagram) editor.

Boolean logic "NOT"

Application example "driller"

Recognizing of a driller by a photo sensor. "TRUE" input signal from sensor indicates that a driller is broken. If driller has been found correct, then start drilling.

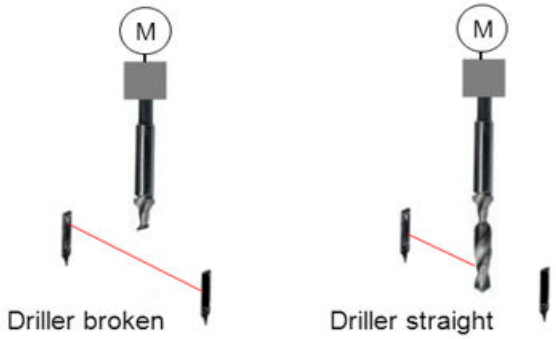


Table 3: Required behavior

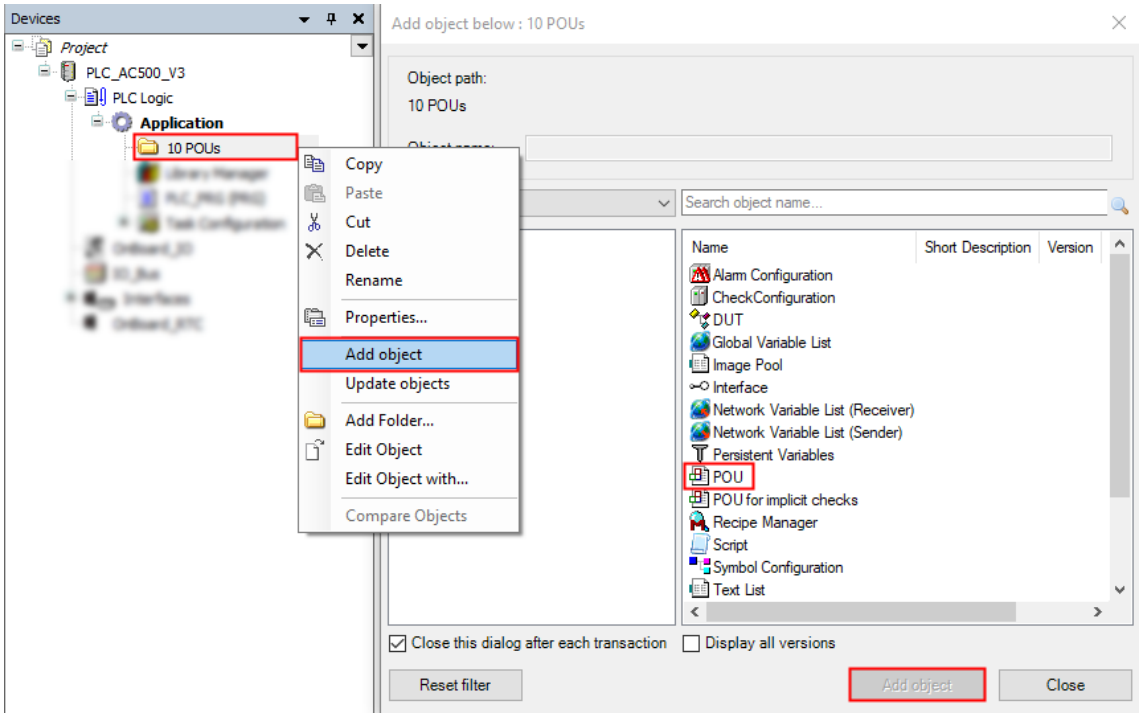
Signal from photo sensor	Required signal of motor ON
FALSE	TRUE
TRUE	FALSE

Table 4: Hardware set-up

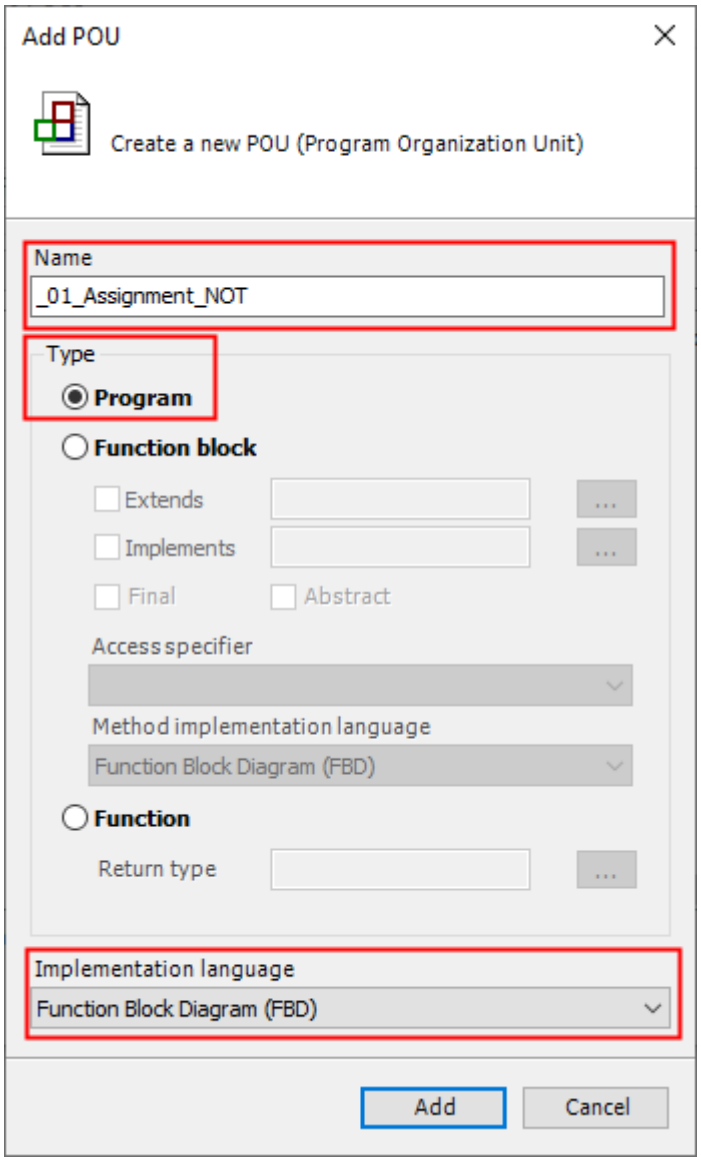
Element	HW channel	Symbol	Description
Switch I1	DA501 DI8	xDI_08_DA501_I1	Photo sensor
LED output DC16	DA501 DC16	xStartDrilling1	Motor on

Implementation

Create a new program POU in the project



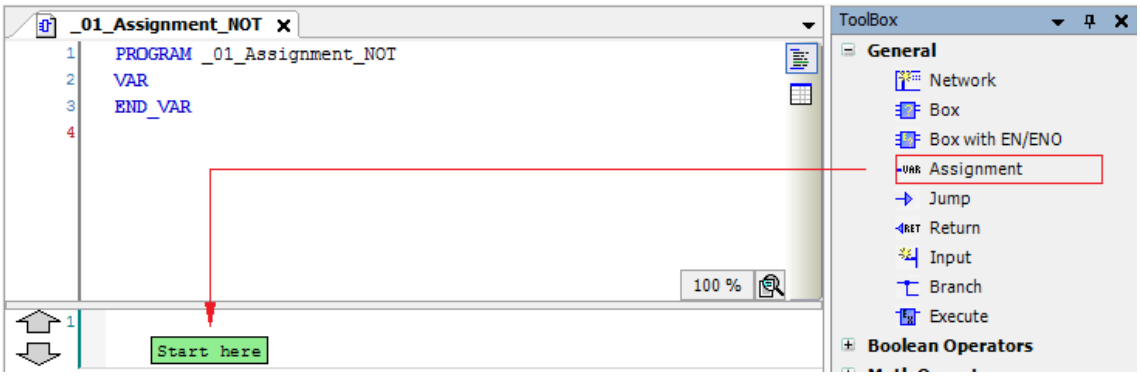
1. Right-click *“10 POUs”*.
2. Select *“Add object”*.
3. Select *“POU”*.
4. Select *“Add object”*.



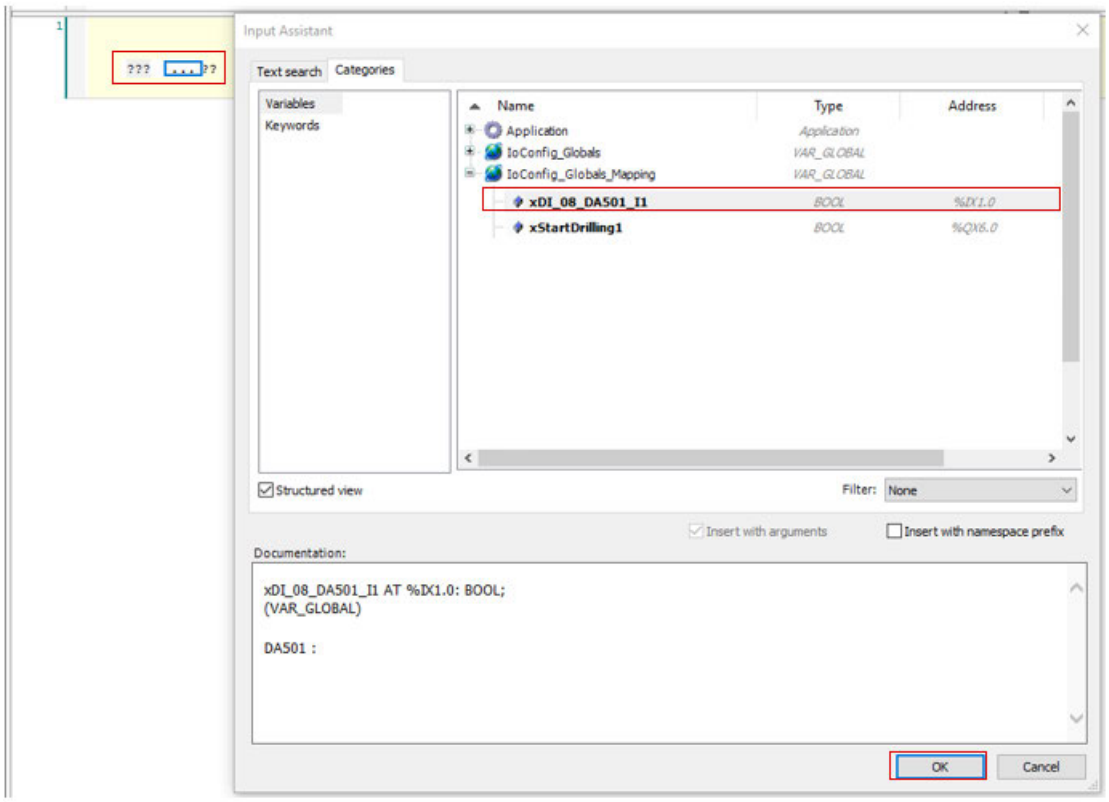
5. Enter *"_01_Assignment_NOT"*.
6. Select *"Program"*.
7. Select *"Function Block Diagram (FBD)"*.
8. Select *"Add"*.
   ⇨ POU has been added.

Assign the hardware DI signals to local variables

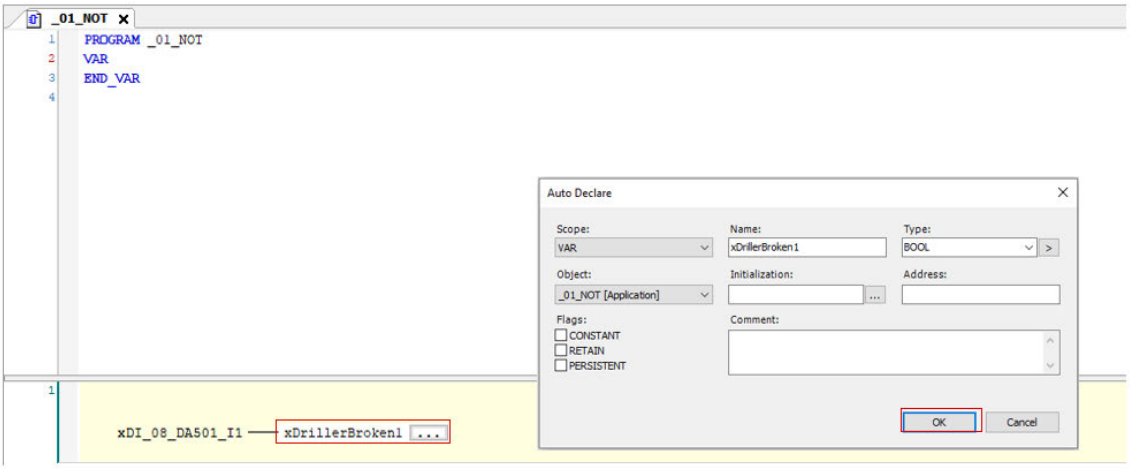
1. Double-click POU*"_01_Assignement_NOT"* in the device tree.



2. Select *"Assignment"* from the ToolBox.
3. Drag and drop *"Assignment"* into the "Start here" field in network *"1"*.

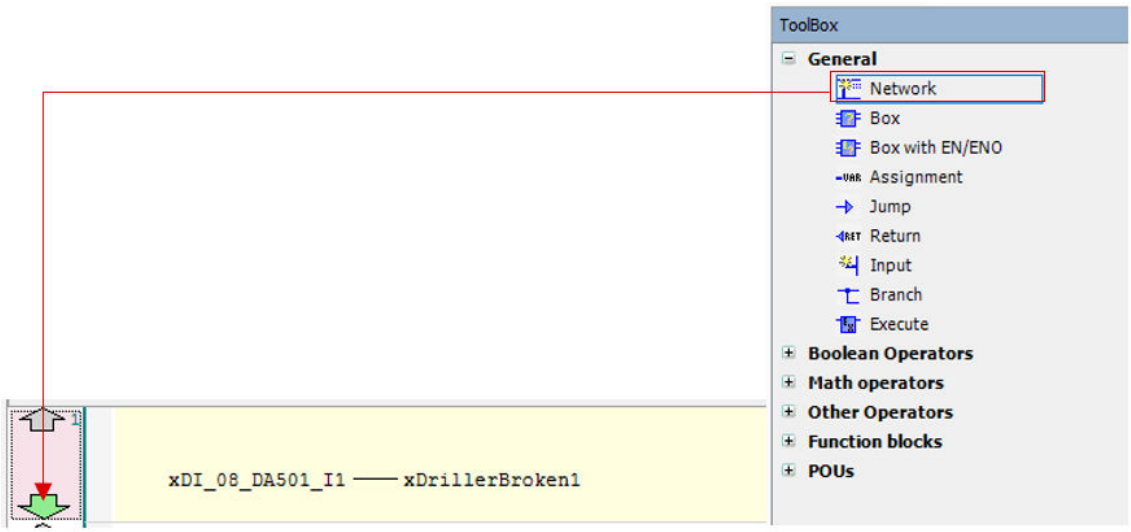


4. Select *"???"* on the left side of the assignment, then select *"..."*.
5. Open the *"Io Config_Globals_Mapping"* mapping list and select *"xDI_08_DA501_I1"*.
6. Select *"OK"* to add this variable to the left side of the assignment connector.



7. Select *"???"* on the right side of the assignment connector and mark the "???".
8. Create a new local variable by typing in "xDrillerBroken1" which will replace the "???".
9. Press *[Enter]*.
   ⇨ *"Auto Declare"* opens.

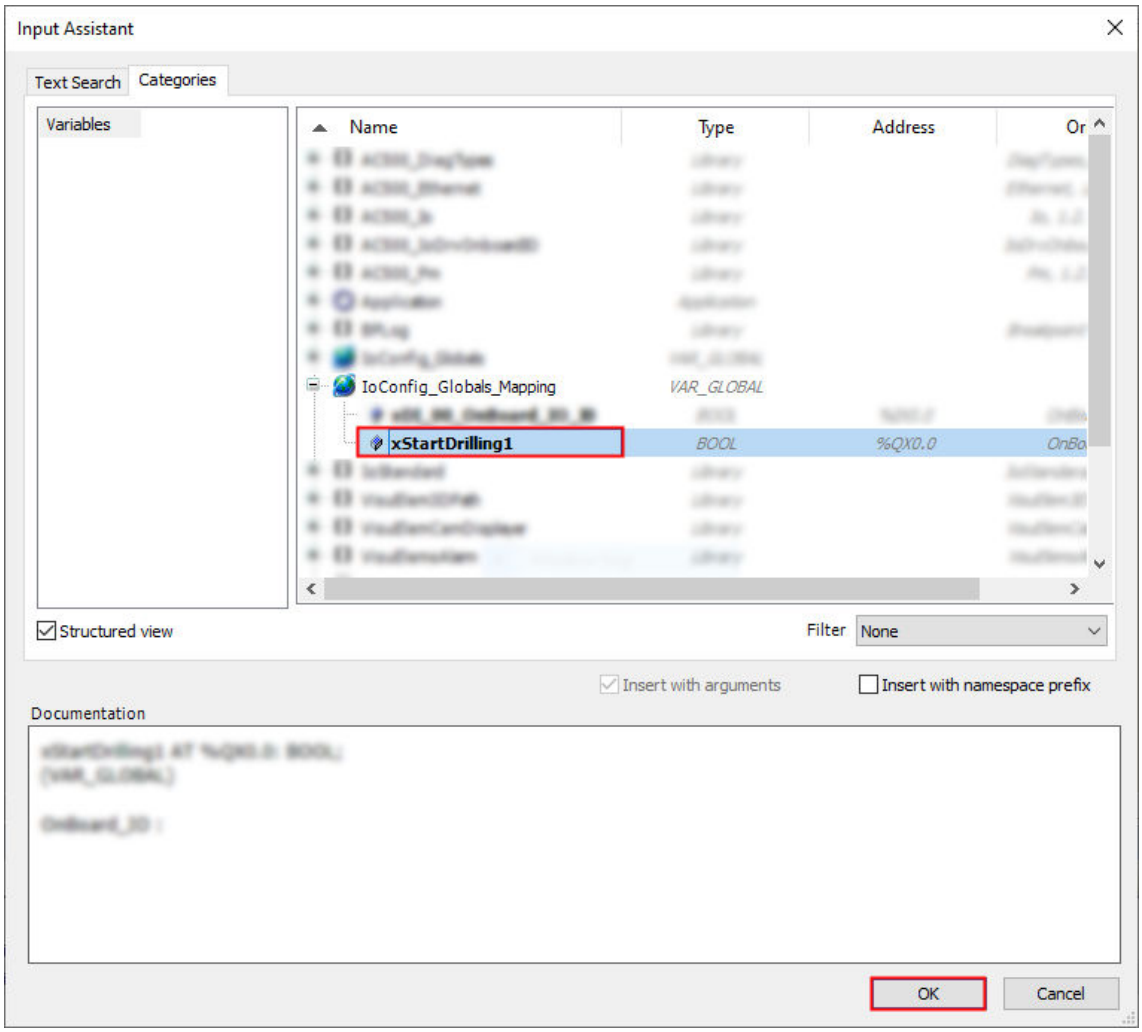
   You see the written variable name and the data type BOOL. The scope is "VAR". It means it is a local variable within this POU.
10. Select *"OK"* to accept the entries.



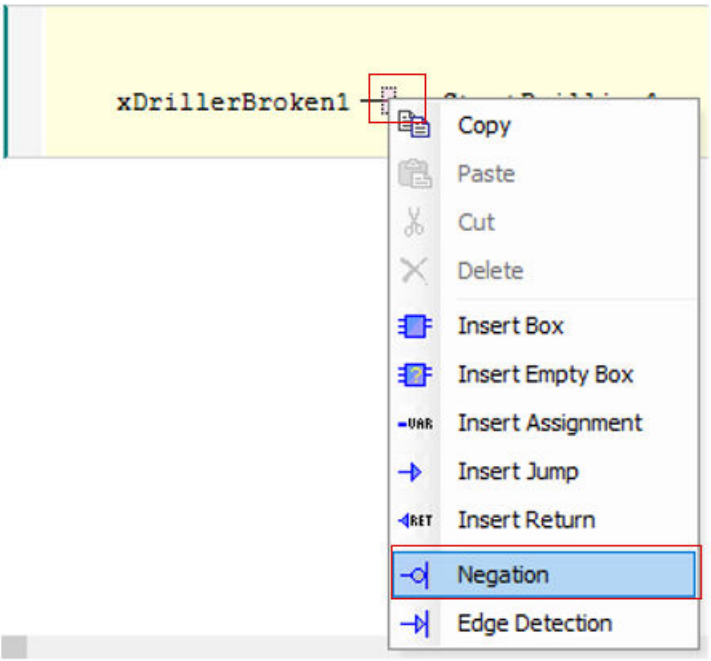
11. Drag and drop *"Network"* from the ToolBox to the down-arrow of network 1.
    ⇨ You added a network *"2"* below network 1.

Add assignments and a Boolean NOT to the DO signals

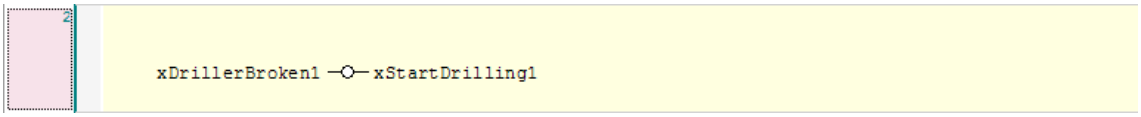
1. Add an assingment from the ToolBox.
2. Type in or copy & paste "xDrillerBroken1" to the left side of the instruction line.
3. Select *"???"* on the right side of the instruction line, then select *"..."*.
   ⇨ *"Input Assistant"* opens.



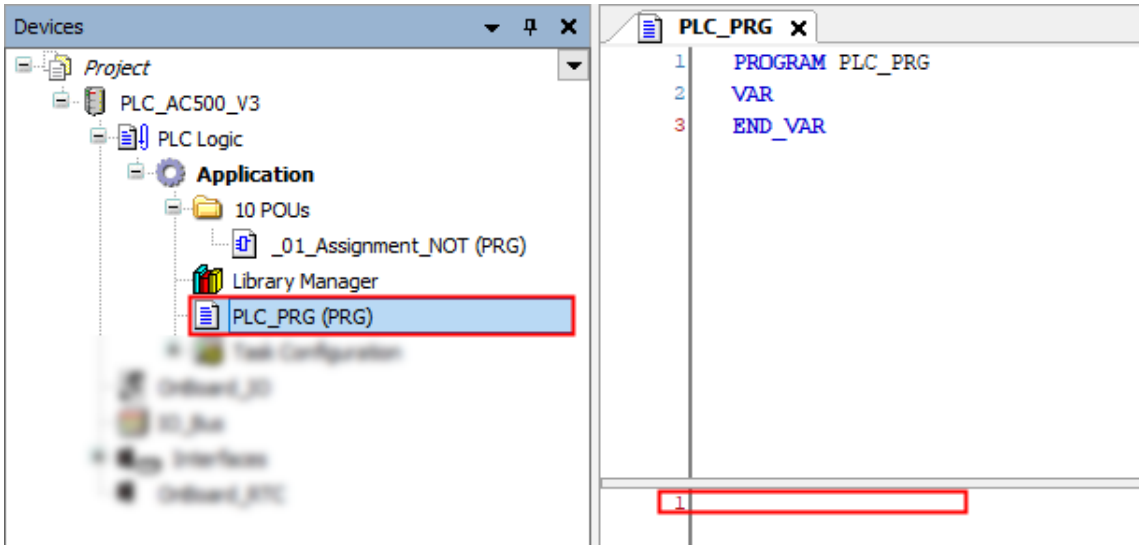
4. In the *"IoConfig_Globals_ Mapping"* variable list, select *"xStartDrilling1"*.
5. Select *"OK"* to close the dialog.



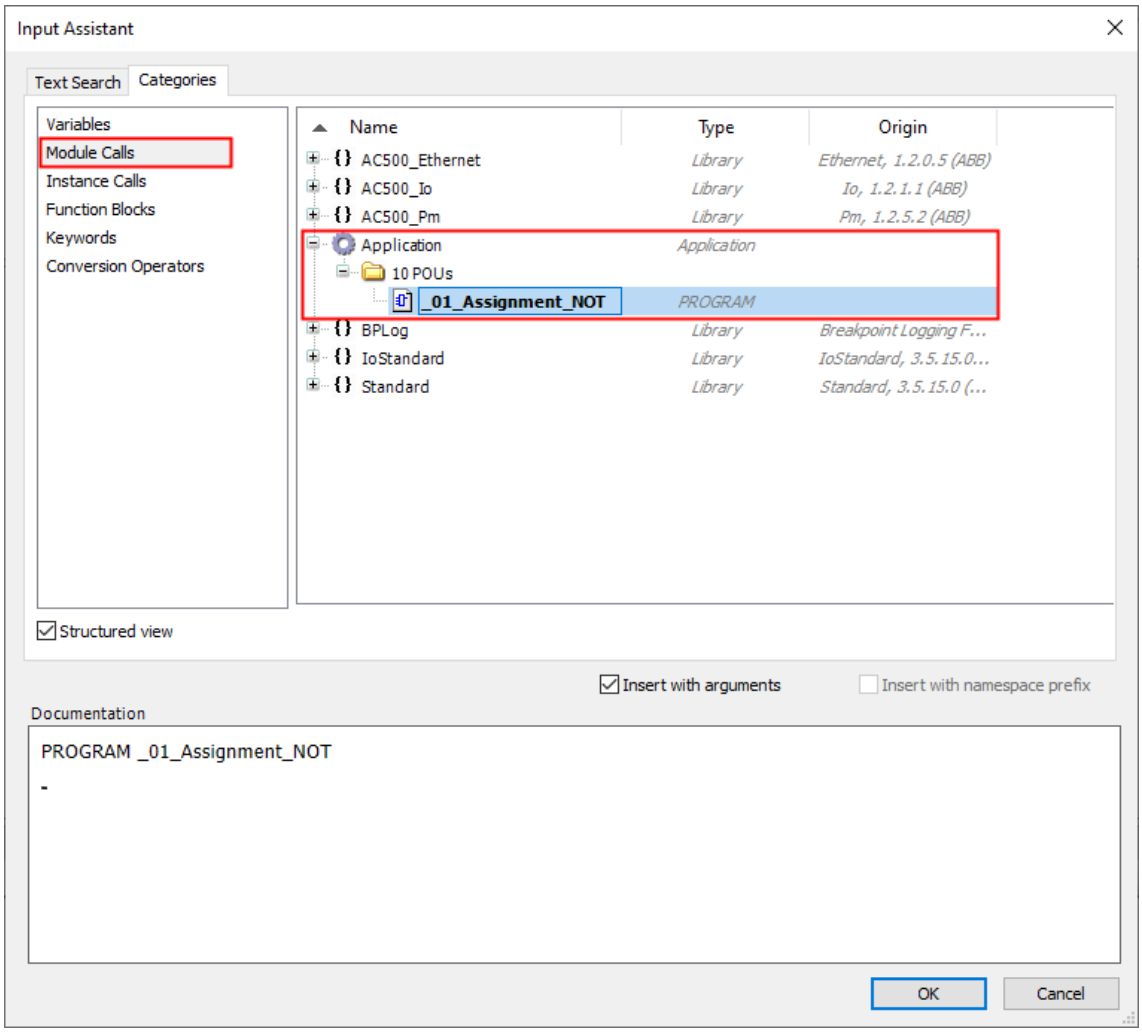
6. Right-click the center of assignment PIN.
7. Select *"Negation"* to add a negation to the assignment.



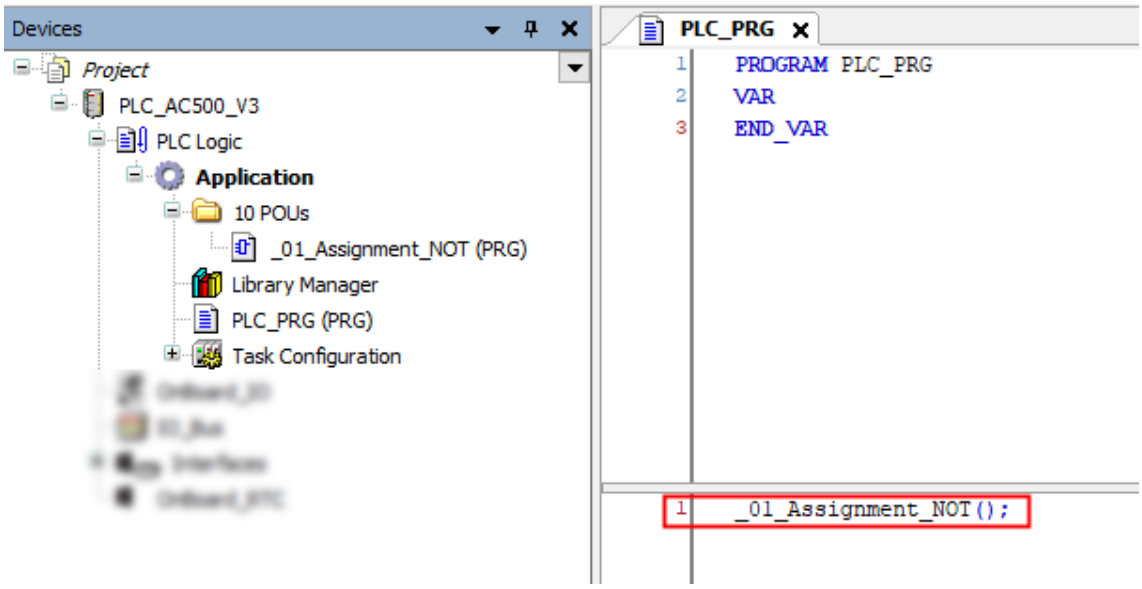
Call the POU in the PLC_PRG



1. Double-click *"PLC_PRG"*.
2. Select the first line in "PLC_PRG" and press *[F2]*.
   ⇨ *"Input Assistant"* opens.

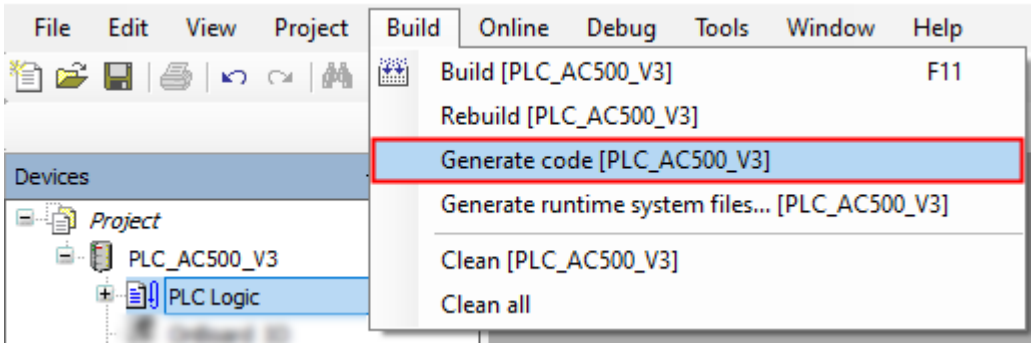


3. Select *“Module Calls”*.
4. Open *“Application”*.
5. Open *“10 POUs”* and select *“_01_Assignment_NOT”*.
6. Select *“OK”* to close the dialog.



Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

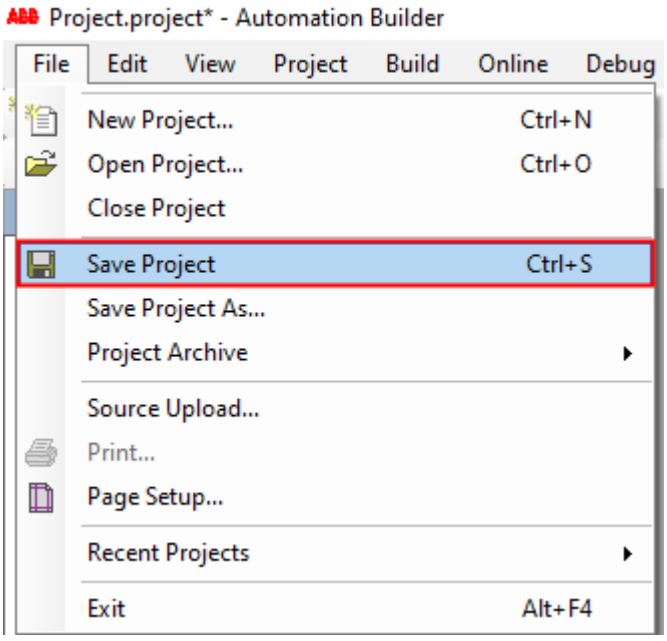


▷ Select menu *"Build ➔ Generate code"*.

⇨ The result of the compiling is shown in the *"Messages"* field at the bottom of the screen.

If you skip the compiling and select *"Login"*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save the project



▷ Select menu *"File ➔ Save Project"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl]* + *[S]*.

Set-up the communication gateway

Set-up communication parameters

To set-up the communication between the PC and the PLC, e.g., for downloading the compiled program, you have to set-up the communication parameters.

The IP address of your PC must be in the same class as the IP address of the CPU.

The factory setting of the IP address of the CPU is 192.168.0.10.

The IP address of your PC should be 192.168.0.X. Avoid X = 10 in order to prevent an IP conflict with the CPU.

Subnet mask should be 255.255.255.0.

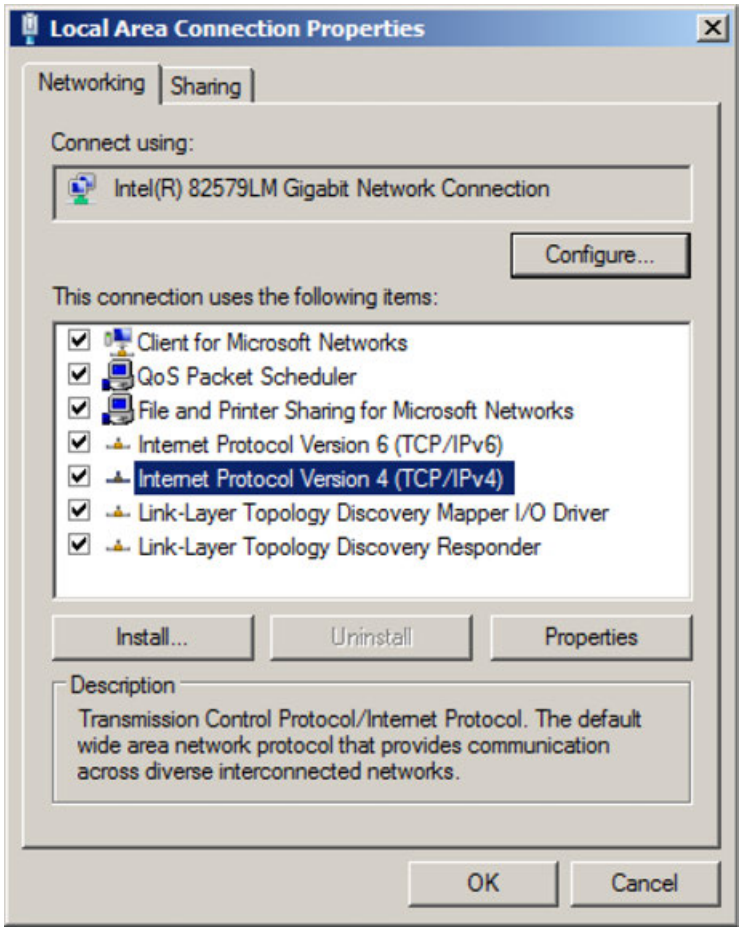
Change the IP address

1. Open Windows **Control Panel**. Click *"Network and Internet ➔ Network and Sharing Center"*.
2. Click **Change adapter settings**.

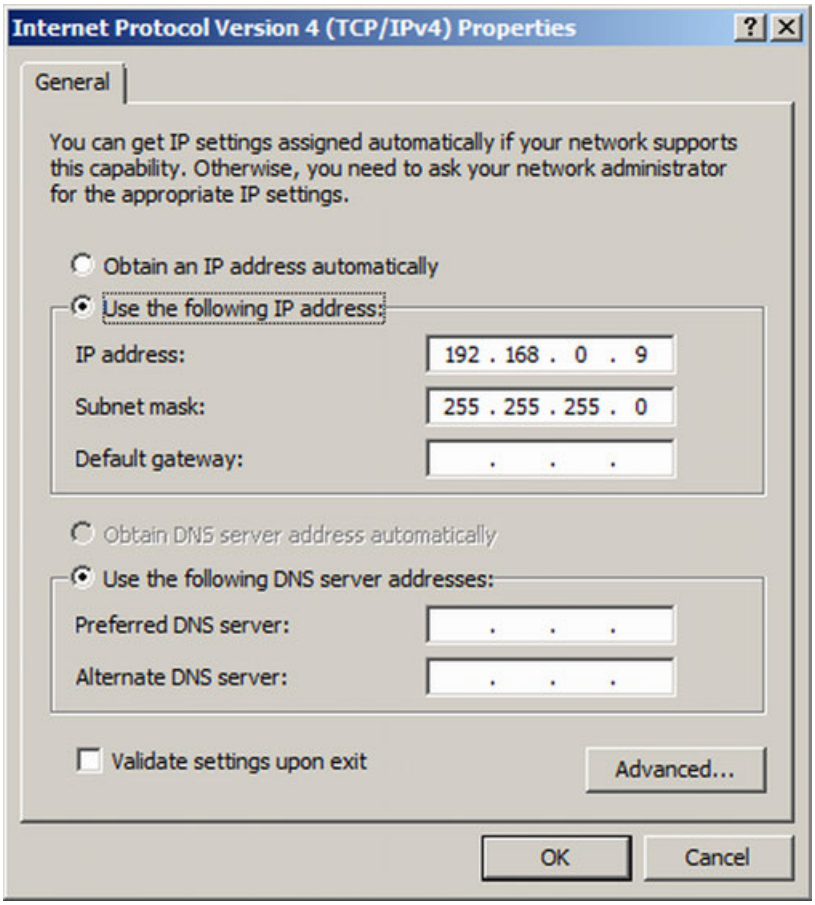
   ⇨

   If using existing network with several devices, please pay attention on given network rules or contact your system administrator.

3. Right-click **Local Area Connection (Ethernet)** and select **Properties**.



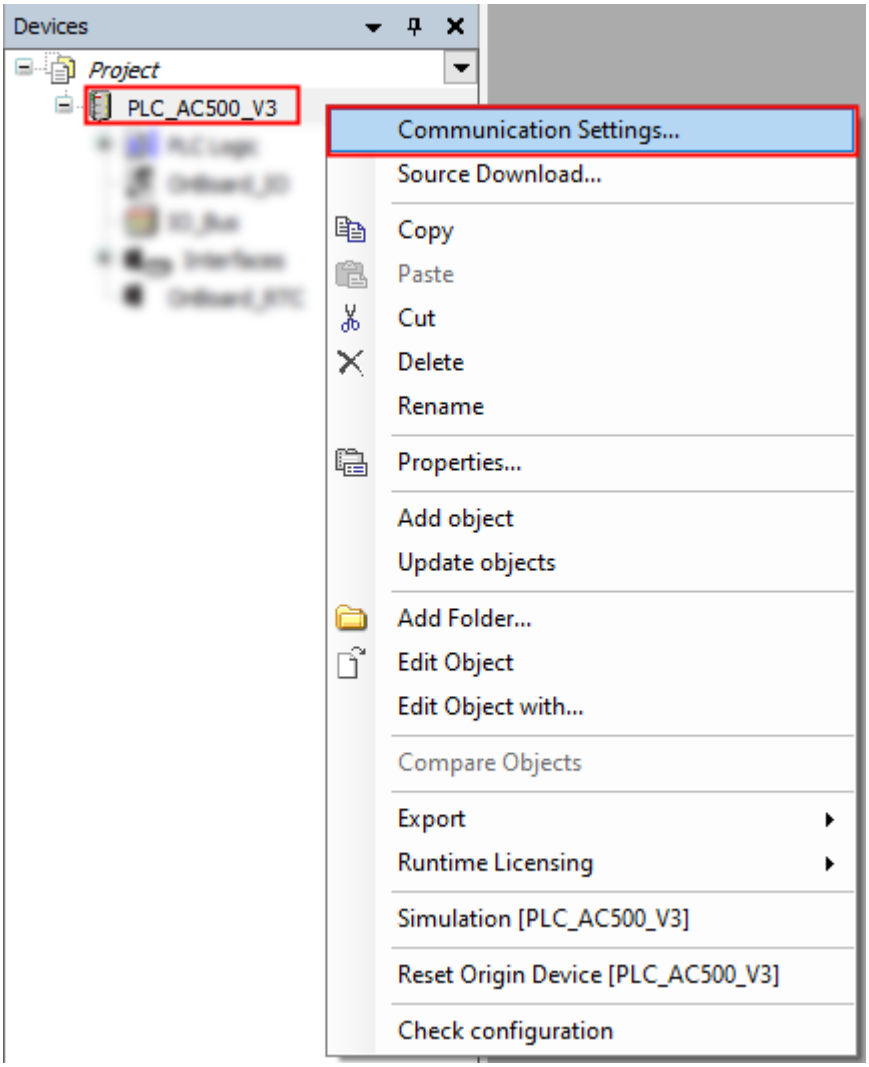
4. Double-click **Internet Protocol Version 4 (TCP/IPv4)**.



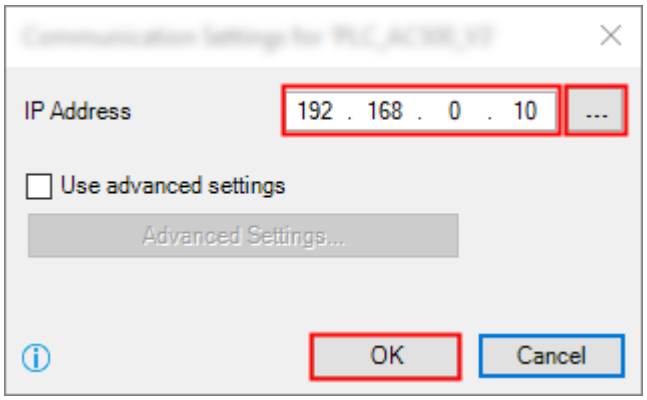
5. Enter your desired IP address and subnet mask.

Set-up the communication gateway

☑ CPU and PC are connected with an Ethernet cable.



1. In the Automation Builder device tree right-click *“PLC_AC500_V3”*.
2. Select *“Communication Settings”*.



3. Keep the default value in the IP address of the CPU or type in the current IP address, if differs.

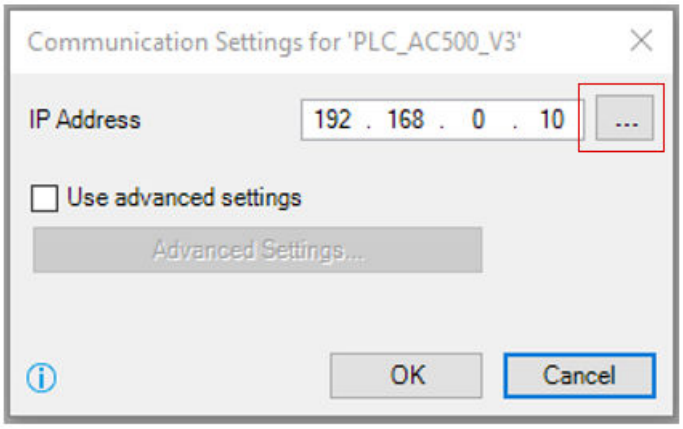
> *The standard (default) IP address of the port ETH1 is: 192.168.0.10*

4. Select *"OK"* to implement the IP address.

Network scan

If you need to scan the network for the CPU or if you have multiple CPUs on the same network.

1. Right-click *"PLC_AC500_V3"* in the device tree.
2. Select *"Communication Settings"*.



3. Select *"..."*.

   ⇨ *"Pick IP Address for "PLC_AC500_V3""* opens.

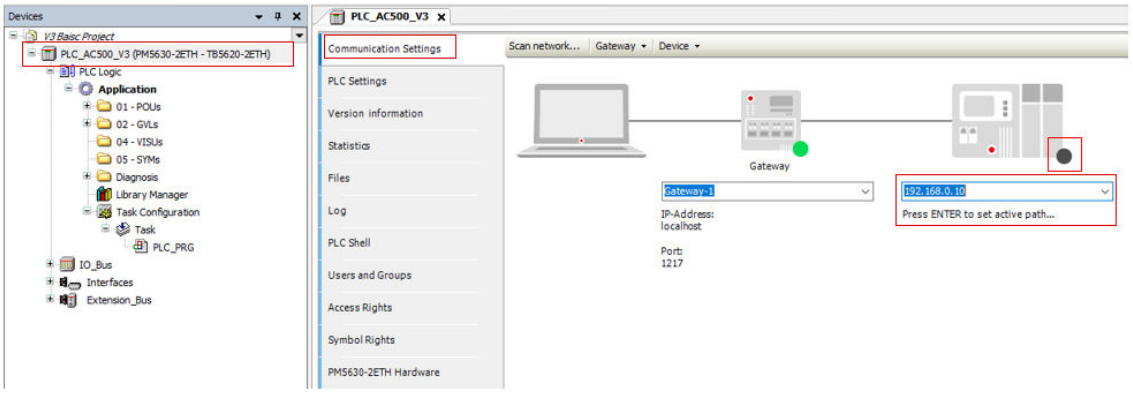
   The automatic scan runs.

   The results will appear in this field.

4. Select the CPU in the field and select *"OK"* to implement the needed communications gateway.

Check communication settings

If you need to check the communications settings or if you want to see more information about the current selected CPU.



1. Double-click *"PLC_AC500_V3"* in the device tree.

2. Select *“Communication Settings”*.
   ⇨ The selected IP address is shown.
3. If the IP address is not visible, enter the IP address manually.
4. To test the connection and/or to see the CPU information press *[Enter]* or click on the black dot next to the PLC figure.

AC500 V3 firmware installation and update

The PLC firmware can be updated via Automation Builder.

> *This is also necessary for commissioning V3 CPUs.*

A very new CPU has no pre-installed firmware. To guarantee the authenticity of delivered AC500 firmware, V3 CPUs are delivered with a boot loader only. You need to download a valid firmware to the CPU. After download, the functionality of the CPU is given.

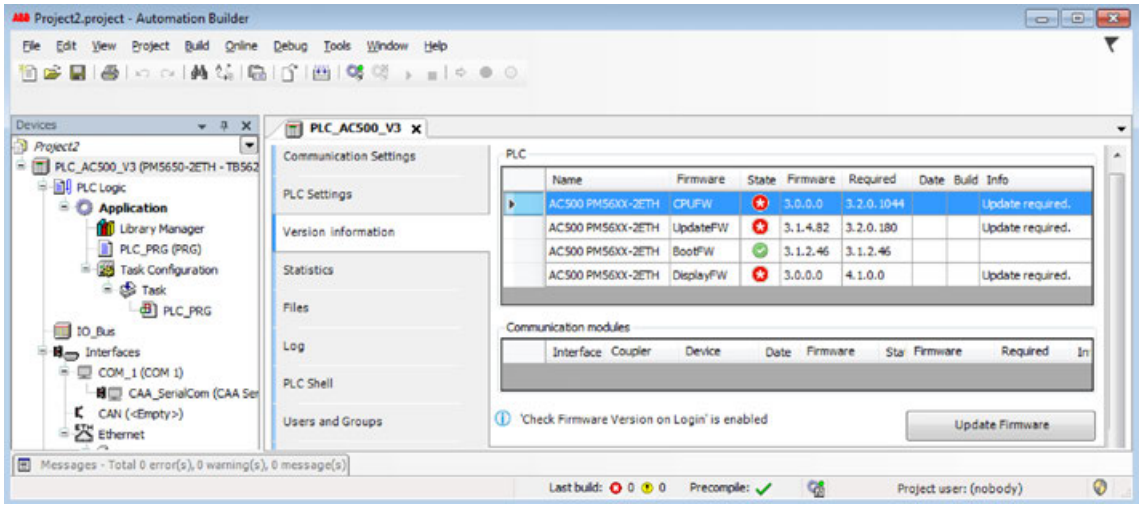
☑ An Automation Builder project with an AC500 V3 CPU is open.

☑ CPU is in "stop" mode or shows **uPdAtE** (update) on the display.

☑ After update the CPU shows either **donE** or **StoP** on the display

☑ For new modules: IP address is set. (The default IP address is 192.168.0.10)

1. Double-click CPU *“PLC_AC500_V3”*.
2. Select *“Version information”*.



3. Select *“Update Firmware”*.
   ⇨ While the update process is running, the RUN and ERR LEDs are toggling, i.e., they are flashing alternating.

4. Wait for the PLC to finish the update.

   A completed update is indicated by a message on the display. Either **donE**, or **StoP**.

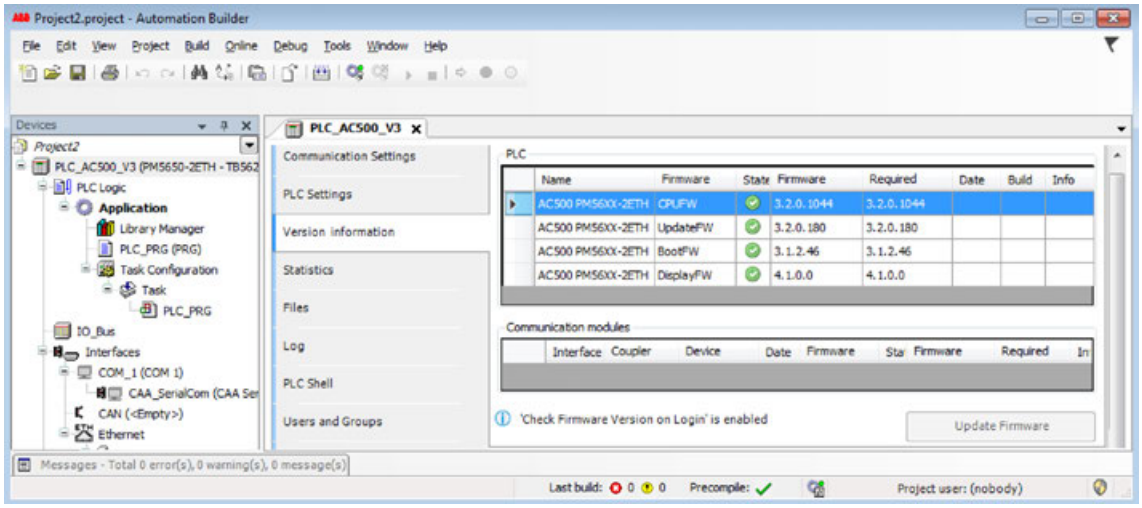
> **NOTICE!**
> Do not disconnect the power supply during the update process! The PLC could be damaged.

   ⇨ **StoP** indicates a restart has been performed by the CPU. When **donE** is displayed sometimes it is necessary to re-boot the CPU manually, e.g., by powering-off. Manual re-boot might be, e.g., for some older CPU versions or if downgrading to an older firmware version according to application settings.

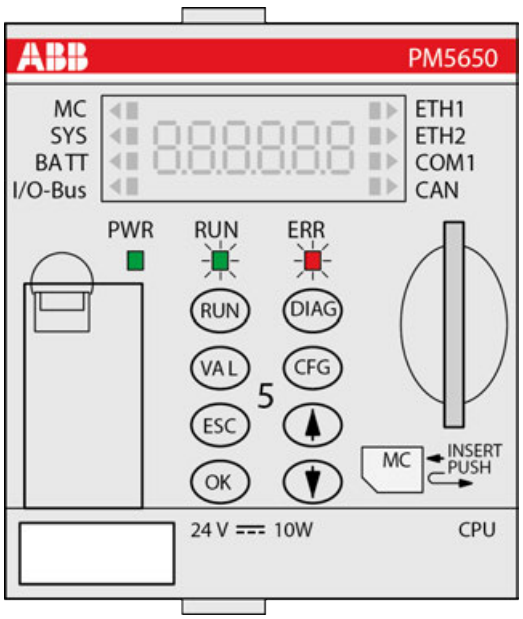
   The CPU display shows "stop" after re-boot. The update process is finished.

5. If necessary, refresh the version information by switching to another tab and back.

   ⇨ Successful firmware update:



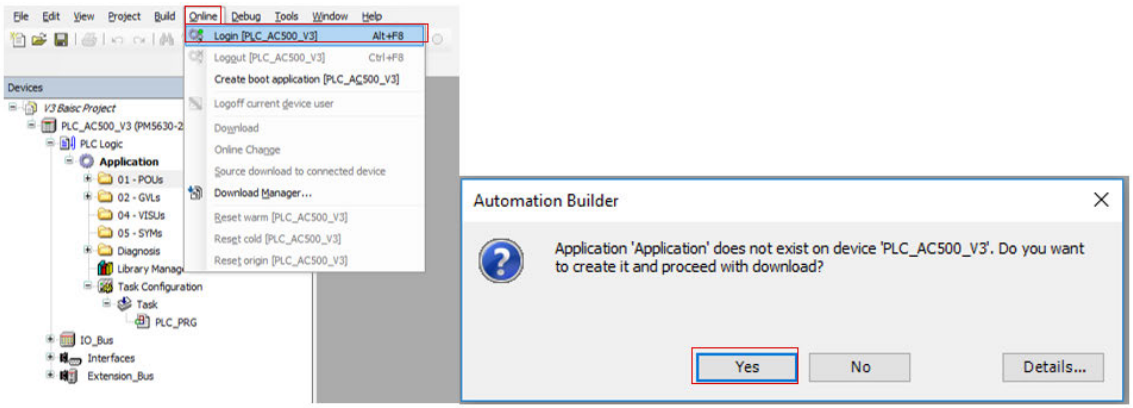
Behavior of LEDs during firmware update



LED	LED flashes	Status
RUN and ERR	Toggling	Update pending
RUN	Flashing slow	Done successful
ERR	Flashing slow	Done failed

Log-in to CPU and download the program

Logging-in to the CPU will load the project into the AC500 V3 CPU. The first log-in will also load the hardware set-up.

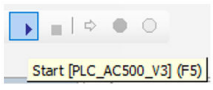


1. In the Automation Builder menu select *“Online ➔ Login [PLC_AC500_V3]”*.

   ⇨ A pop-up will appear.

2. Select *“Yes”* to download the application to the AC500V3 CPU.

   ⇨ PLC is in "stop" mode.



3. Start the PLC ↳ *Chapter 1.2.18.1.2.8.1 “Start the program execution” on page 90*.

Generally, if the CPU is in RUN mode, i.e. in program execution mode, a download will always cause the mode change to "stop". In stop mode the CPU is not controlling the system!

Always, after selecting the "Login" command, read carefully the dialog box text to ensure that you are aware of the CPU’s behavior after the command confirmation.

By default, a download generates following actions in the CPU:

- The project is stored in the RAM memory.
- The project is stored in the flash EEPROM, if boot application was created.

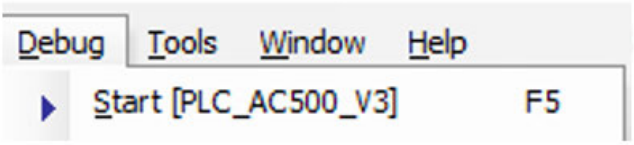
Test the program

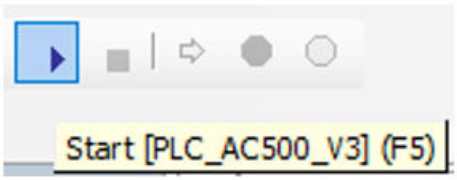
Start the program execution

☑ You are logged in the CPU.

☑ An executable project is loaded to the CPU.

☑ The CPU is in "stop" mode.





▷ Select menu *"Debug ➔ Start [PLC_AC500_V3]"*.

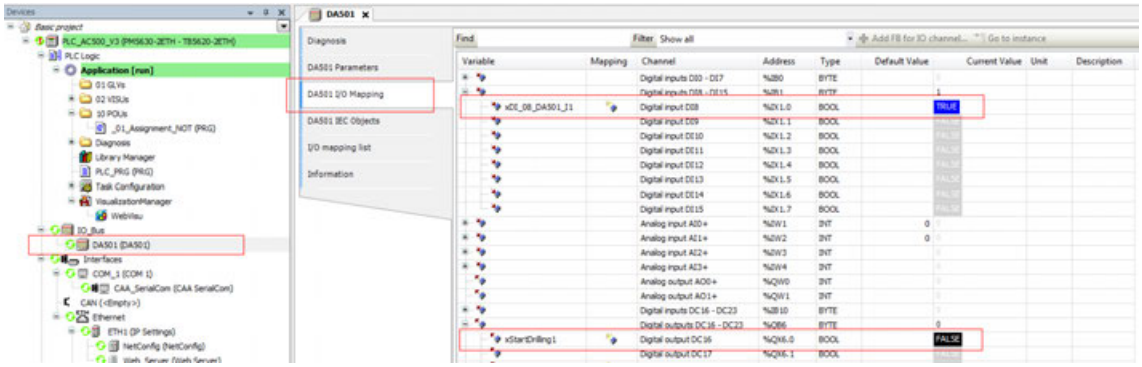
Alternatively, select the "start" icon in the tool bar.

Alternatively, press *[F5]*.

Test the function

▷ Operate the switch I1 and observe:

- The LEDs of the relevant DA501 inputs and outputs.
- The online status of inputs and outputs within the POU.

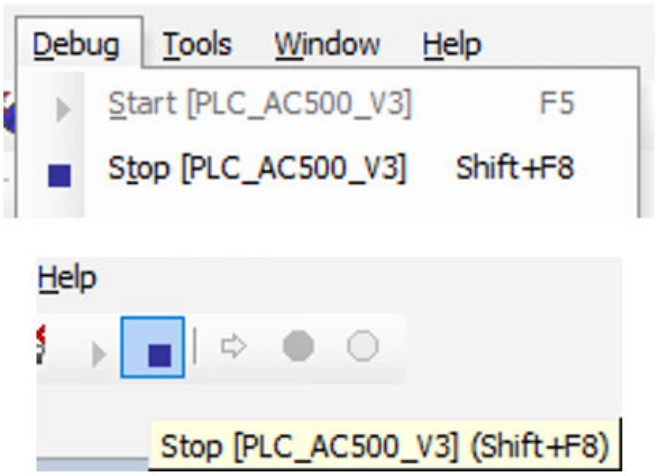


Stop the program execution

☑ You are logged in the CPU.

☑ An executable project is loaded to the CPU.

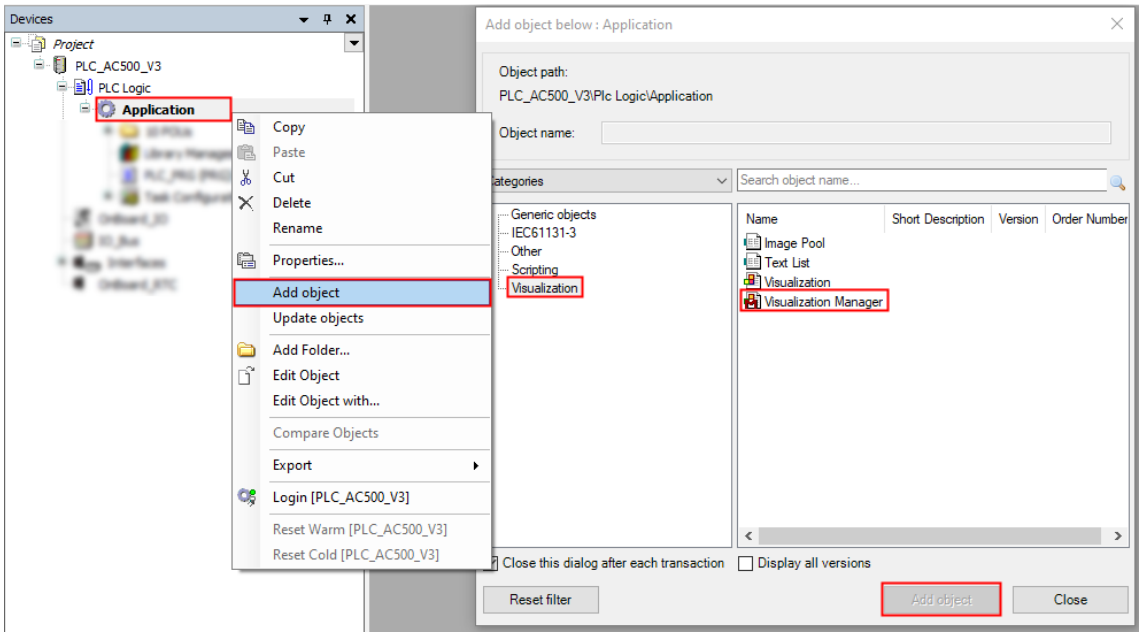
☑ The CPU is in RUN mode.



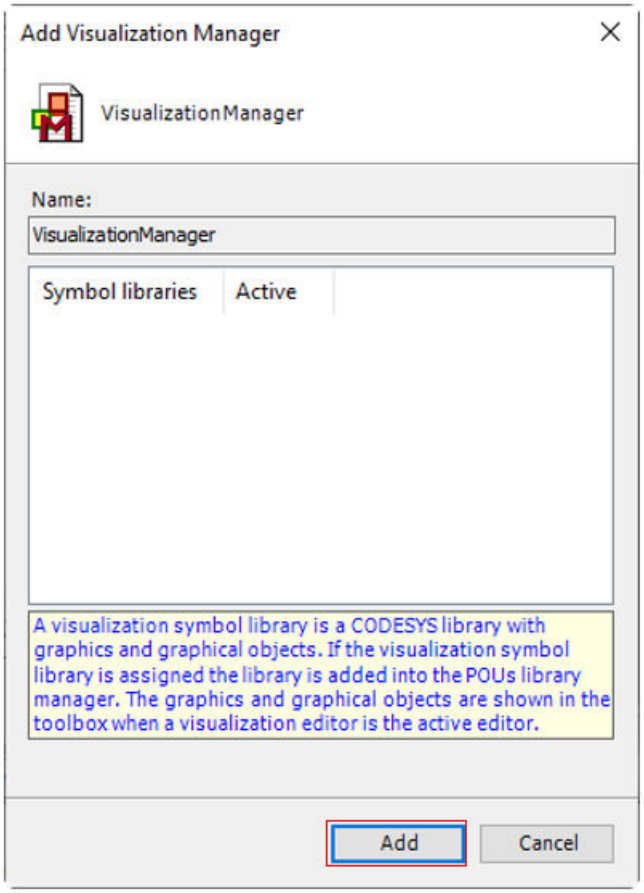
▷ Select menu *“Debug ➔ Stop [PLC_AC500_V3]”*
Alternatively, select the "stop” icon in the tool bar.
Alternatively, press *[Shift] + [F8]*.

Set-up visualization

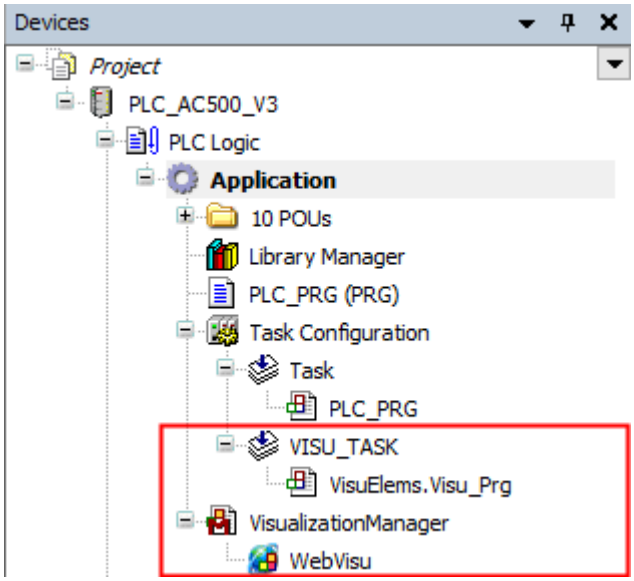
Add the VisualizationManager



1. Right-click *“Application”* in the device tree.
2. Select *“Add object”*.
3. Select *“VisualizationManager”*.
4. Select *“Add object”* to add the VisualizationManager to the project.
   ⇨ Dialog *“Add Visualization Manager”* opens.

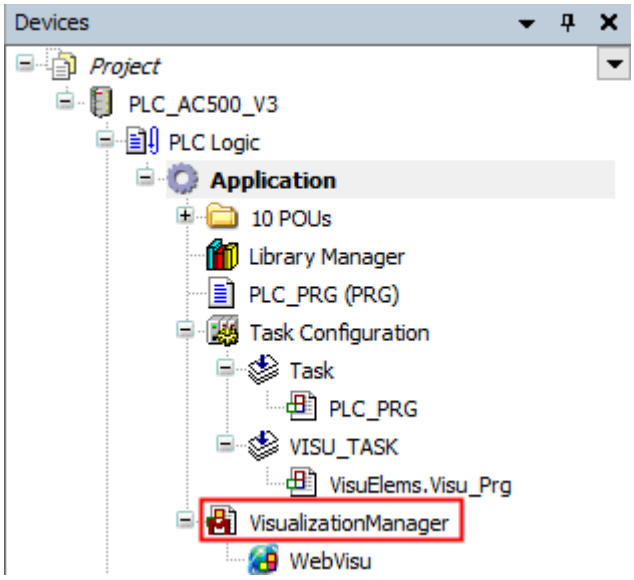


5. Select *“Add”*.

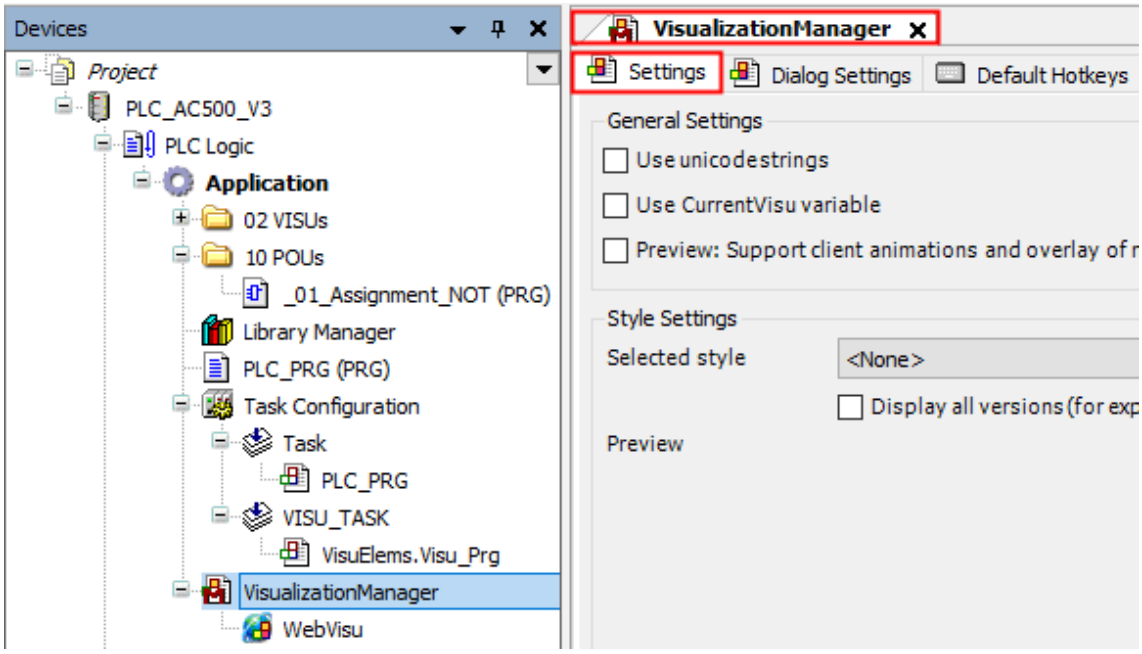


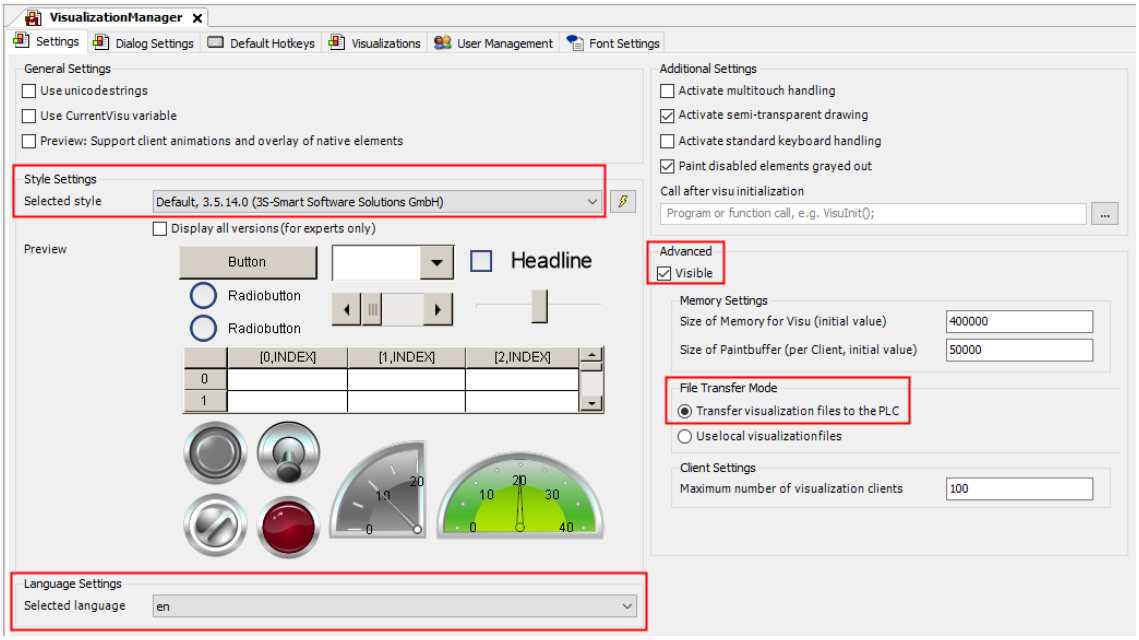
⇨ You added the objects *“VisualizationManager”* and *“VISU-TASK”* to the device tree.

Set-up the VisualizationManager



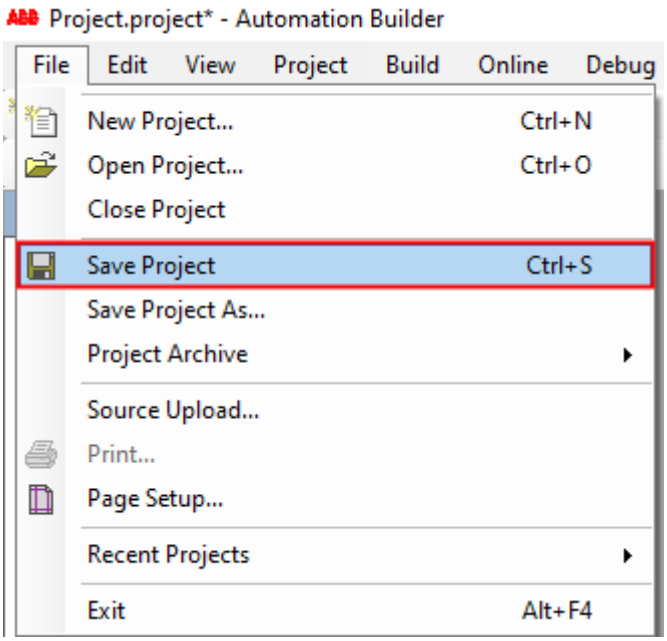
1. Double-click VisualizationManager in the device tree.
   ⇨ A tab opens in the editor view.





2. Select *“Settings”*.
3. Open the drop-down menu *“Selected style”*.
4. Select *“Default, x.x.x”* (exemplary).
5. Open the drop-down menu *“Selected language”*.
6. Select *“en”* for English language in the visualization.
7. Enable *“Visible”* for advanced settings.
8. Keep the file transfer to enable the visualization on the PLC (mandatory for web server function ↳ *Chapter 1.2.18.1.2.11 “Enable web visualization” on page 103*).

Save the project



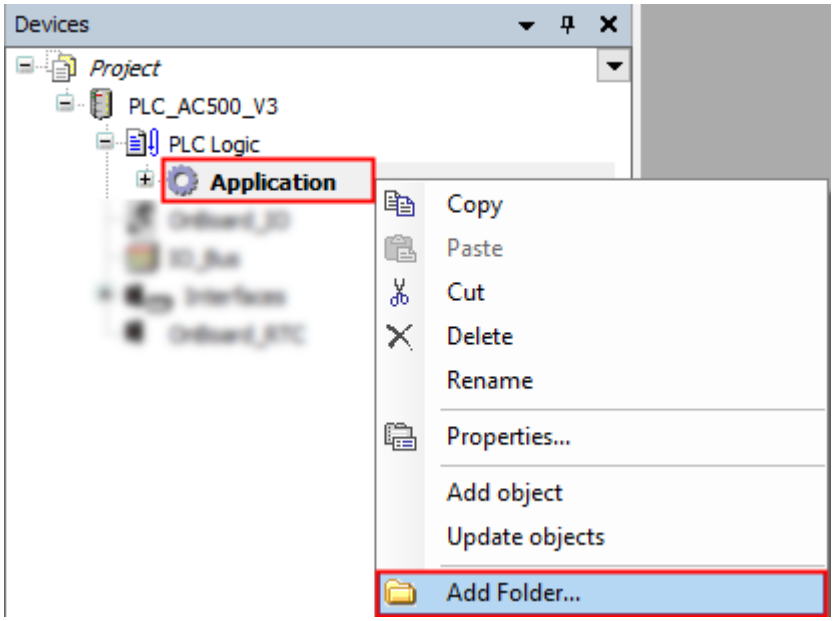
▷ Select menu *“File ➔ Save Project”*.

Alternatively, select the save icon in the tool bar.

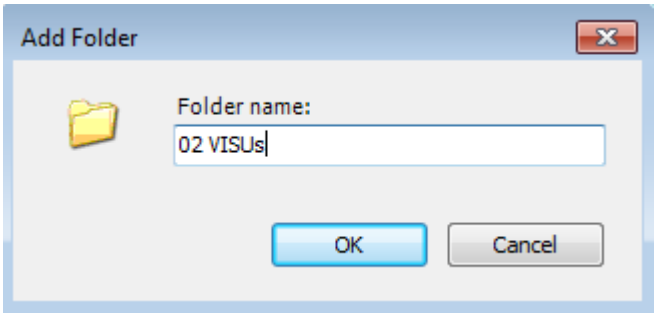
Alternatively, press *[Ctrl] + [S]*.

Create visualization

Add a folder for visualization screens

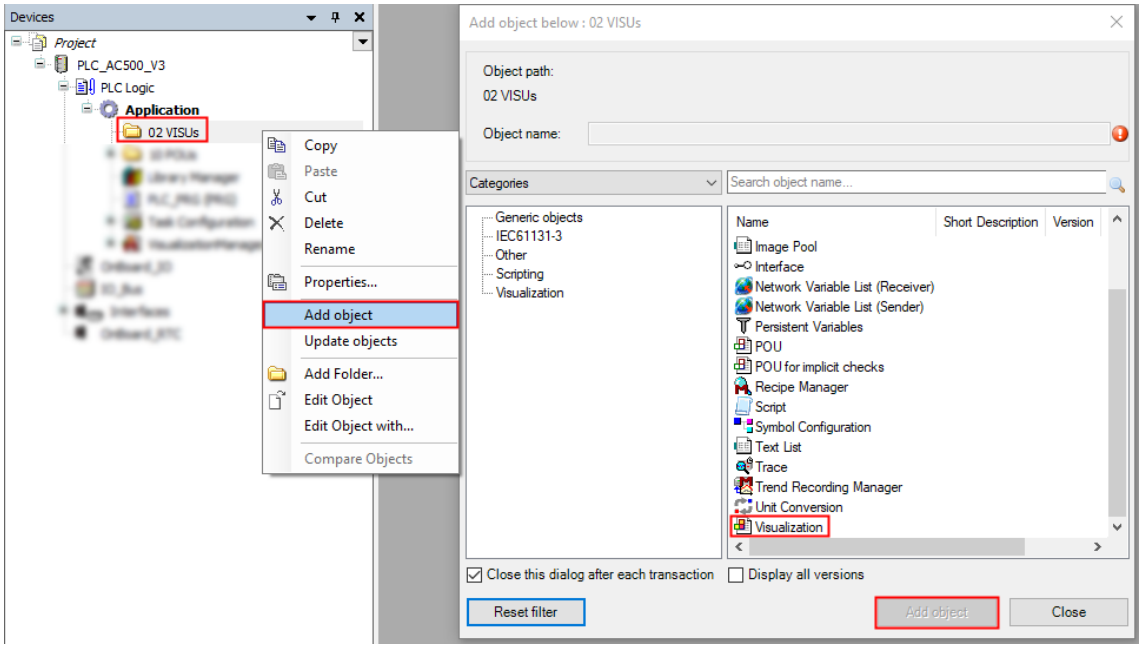


1. Right-click *“Application”* in the device tree.
2. Select *“Add Folder”*.

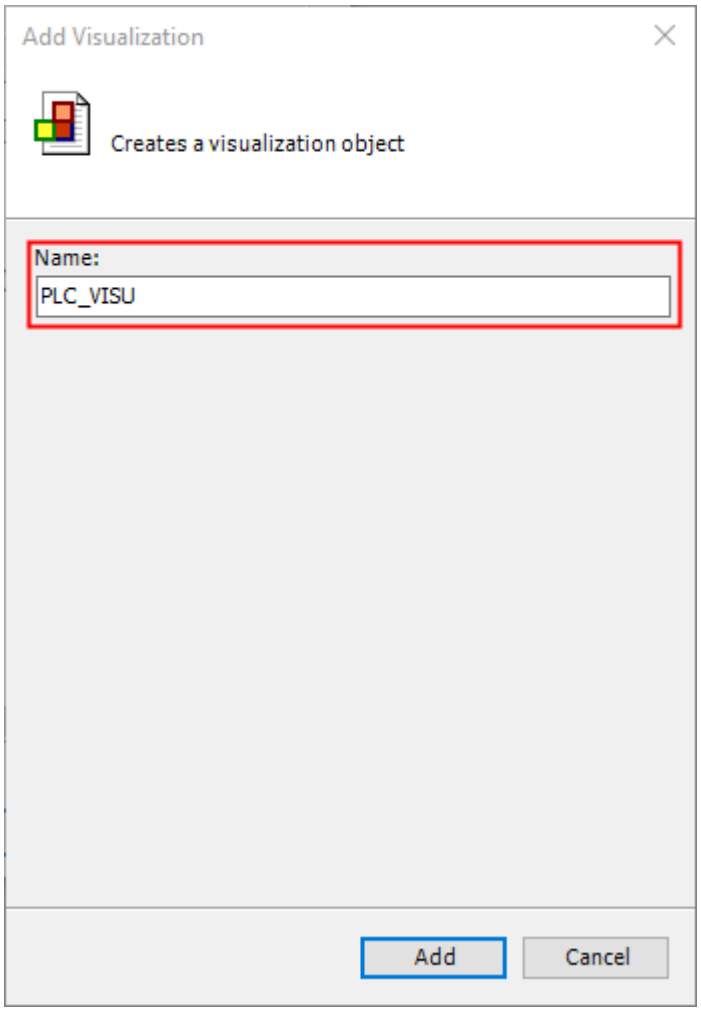


3. Type in "02 VISUs".
4. Select *“OK”* to add the folder.

Add a screen for "_01_Assignment_NOT" POU



1. Right-click *“02 VISUs”*.
2. Select *“Add object”*.
3. Select object *“Visualization”*.
4. Select *[OK]*.



5. Type in "PLC_VISU".
6. Select *“Add”*.
   ⇨ A tab opens in the editor view.

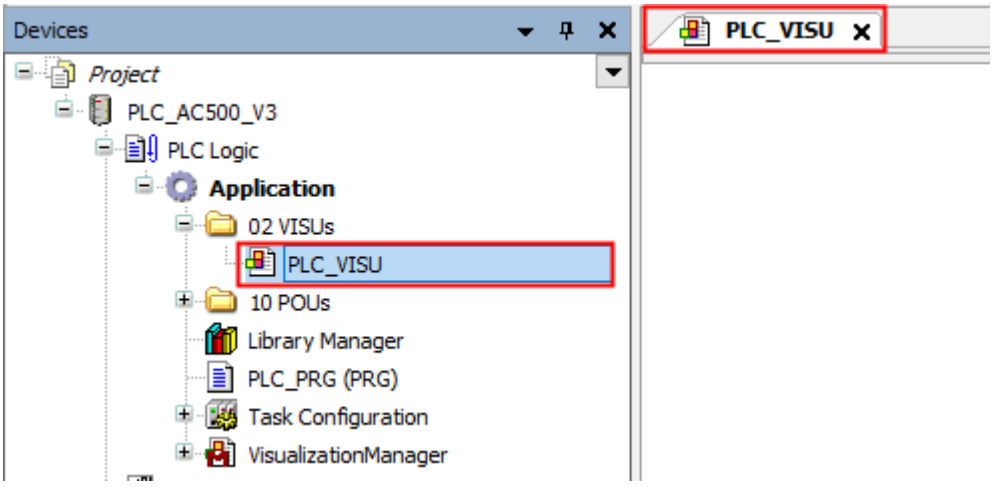


Fig. 7: PLC_VISU_tab

The name "PLC_VISU" has been chosen, because it is the default name for a home screen in a web visualization.

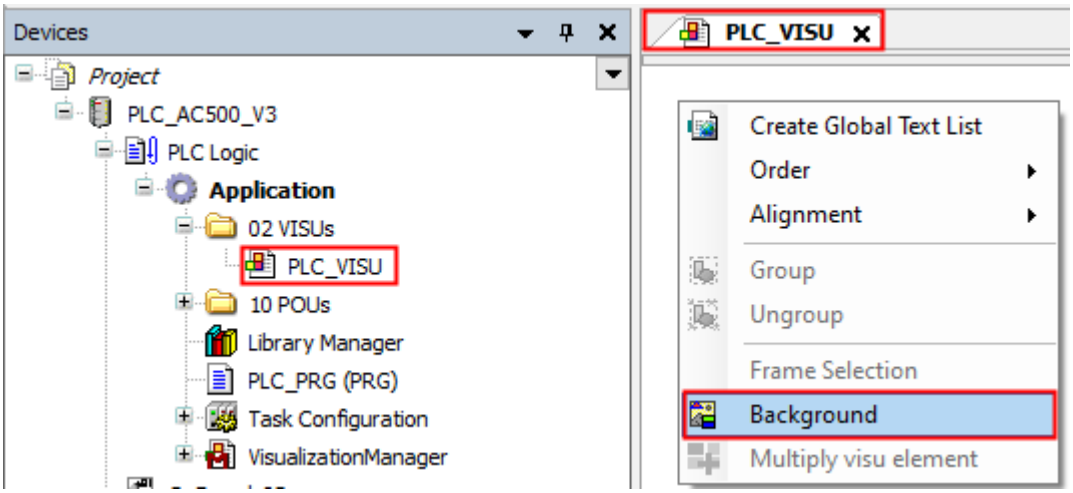
If you have more than one visualization object in your project, it will be useful to choose another name, e.g. "_01_Assignment_NOT_v". And to choose "PLC_VISU" as a home screen to access all available visualization screens.

The name of a visualization object can be modified afterwards.

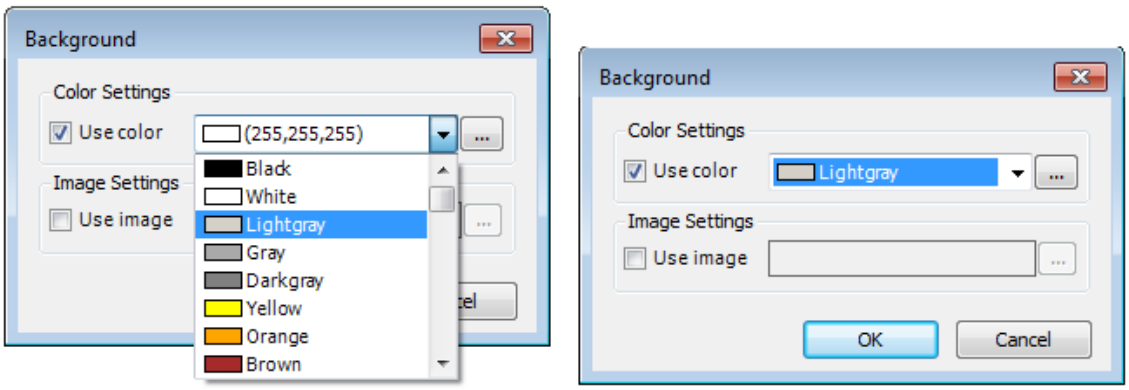
Creating and configuring of visualization

Change background color

1. Double-click *“PLC_VISU”* in the device tree.
   ⇨ A tab opens in the editor view.



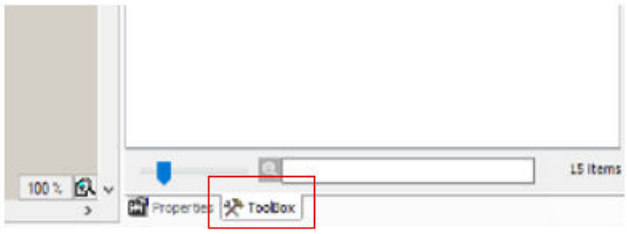
2. Right-click anywhere on the "PLC_VISU" editor page.
3. Select *“Background”*.



4. Enable the check box *“Use Color”*.
   ⇨ This enables the drop-down menu.
5. Select a color, e.g., *“Lightgray”*.
6. Select *[OK]* to add the color to "PLC_VISU".

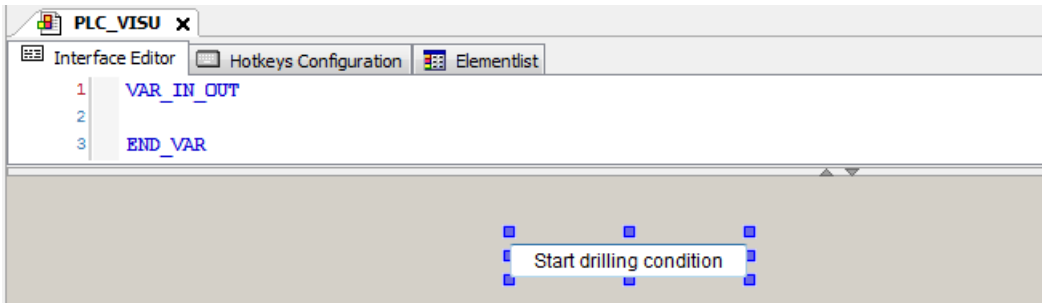
Add a screen title

1. Double-click on *"PLC_VISU"* in the device tree.



2. Select *"ToolBox"*.

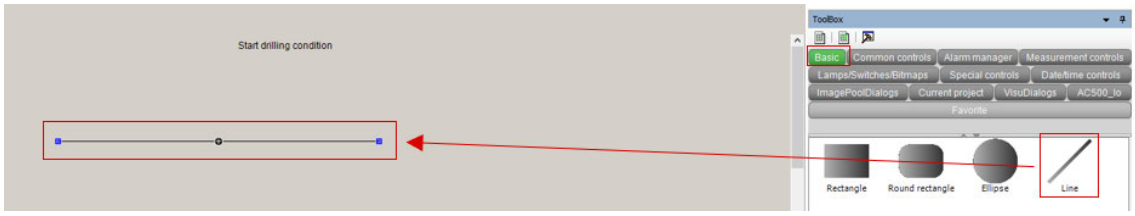
3. Select *"Common controls"*.
4. Drag and drop *"Label"* to the page.



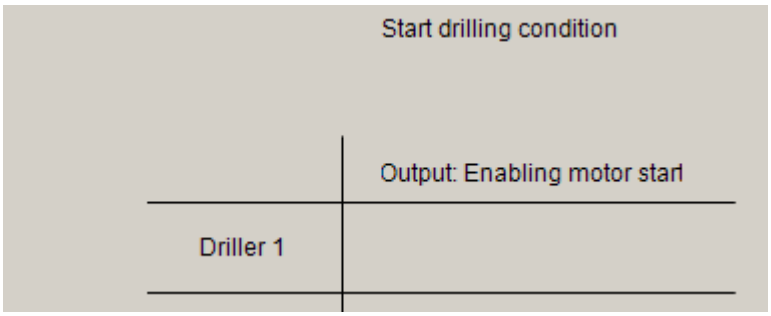
5. Type in "Start drilling condition".

Further lines and labels

1. Double-click on *"PLC_VISU"* in the device tree.



2. Select *"ToolBox"*.
3. Select *"Basic"*.
4. Drag and drop the line. Then drag the line to the needed length.

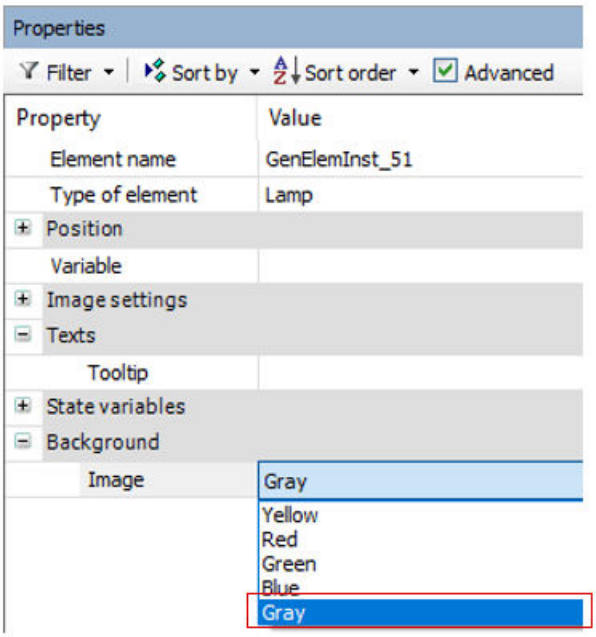


5. Follow the same procedure to create the other shapes and labels.

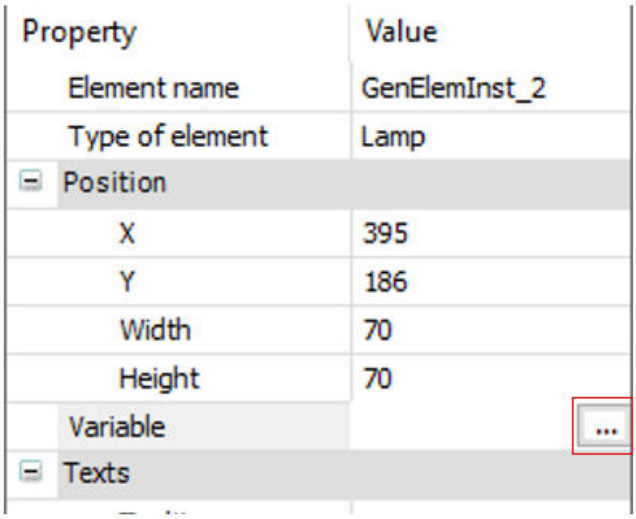
Lamp element for signal indication

1. Double-click on *“PLC_VISU”* in the device tree.

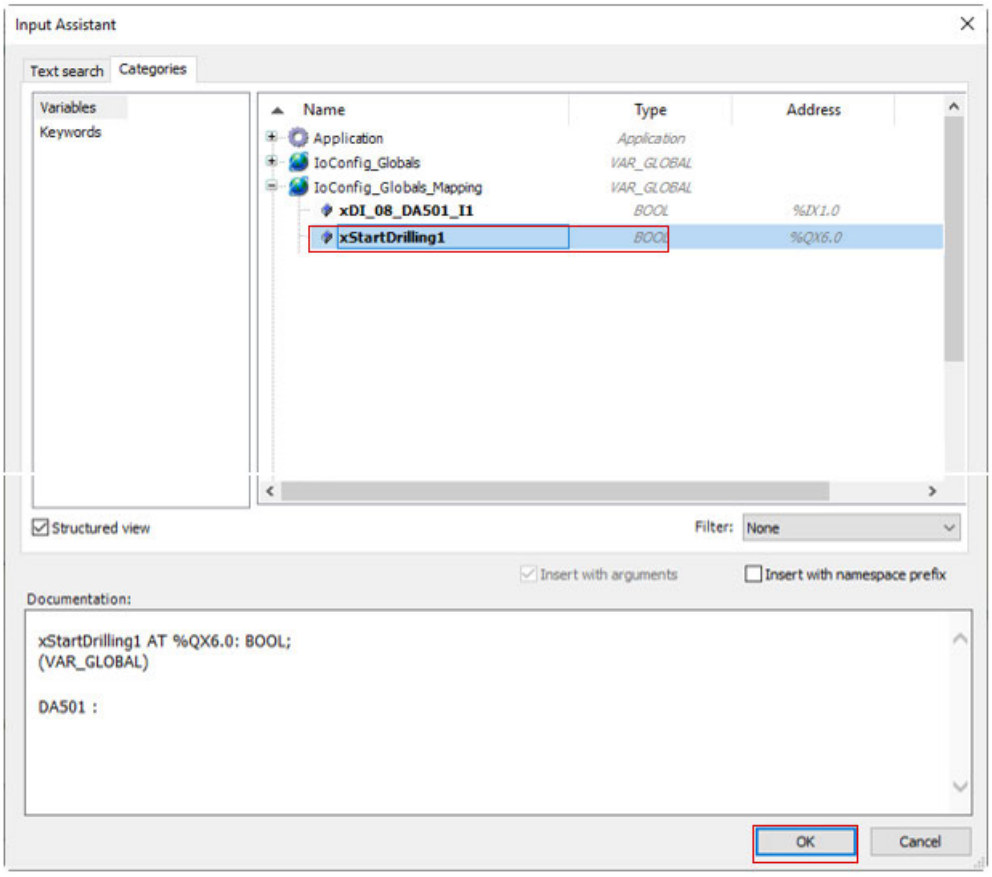
2. Select *“ToolBox”*.
3. Select *“Lamps/Switches/Bitmaps”*.
4. Drag and drop *“Lamp”* to the screen.
5. Adapt the size, if required.



6. Under *“Image”*, select *“Gray”*.



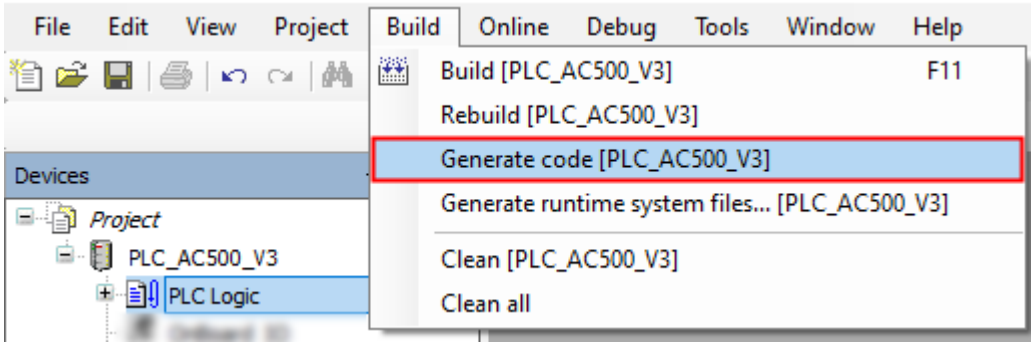
7. Double-click on *"Variable"* and select *"..."* to select a variable from the list.



8. Under *"IoConfig_Globals_Mapping"*, select *"xStartDrilling1"*.
9. Select *[OK]*.

Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

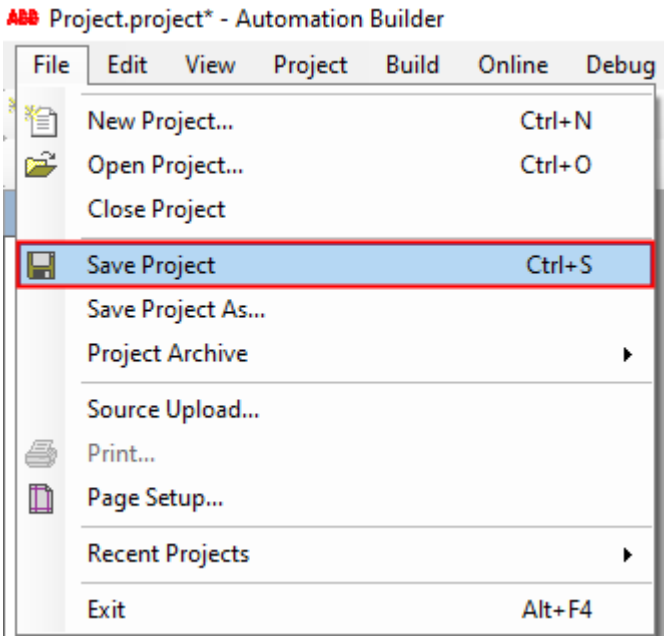


▷ Select menu *"Build ➔ Generate code"*.

⇨ The result of the compiling is shown in the *"Messages"* field at the bottom of the screen.

If you skip the compiling and select *"Login"*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save the project



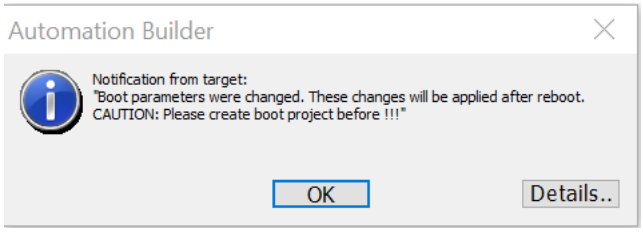
▷ Select menu *"File ➔ Save Project"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl] + [S]*.

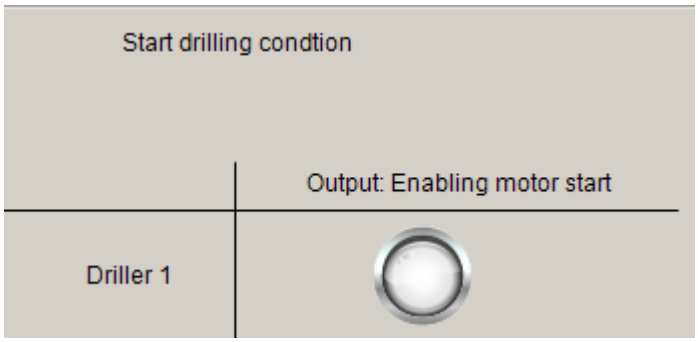
Loading the project to the CPU

1. Download the project to the CPU *as described in Chapter 1.2.18.1.2.7 , on page 89*.
2. Check the notification window at the end of the download. In case of message "Boot parameters were changed. These changes will be applied after reboot", a reboot of the CPU is required after creation of the boot project.



Test the program

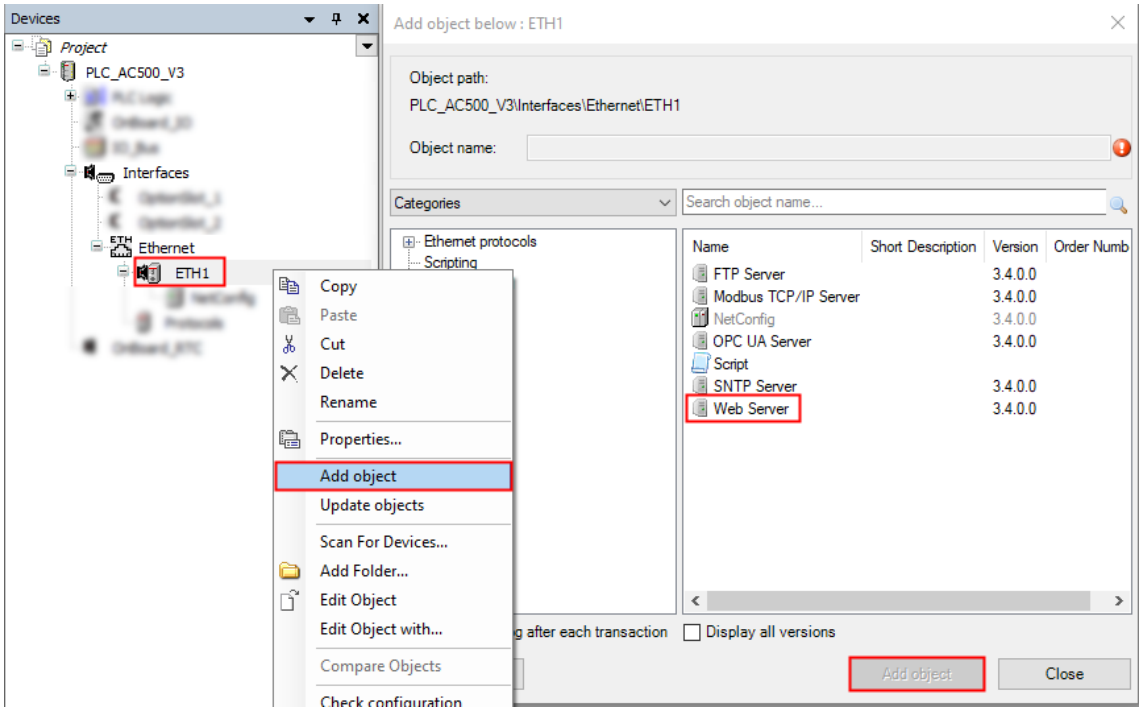
▷ Operate the switches and observe the visualization screen.



Enable web visualization

Add a web server object to the device tree

Ethernet ports can be configured for web server protocol. This description deals with ETH1 configuration for the web server

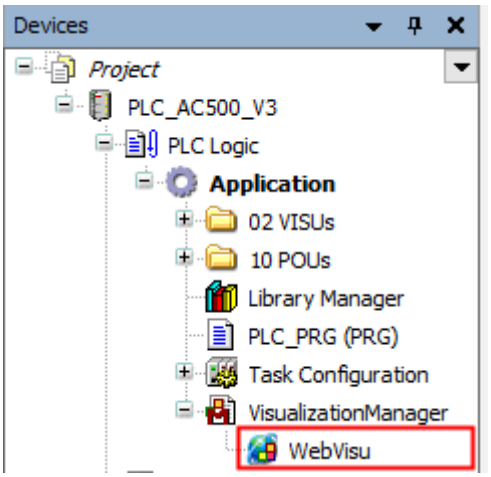


1. Right-click *“ETH1”* in the device tree.
2. Select *“Add object”*.
3. Select *“Web Server”*.

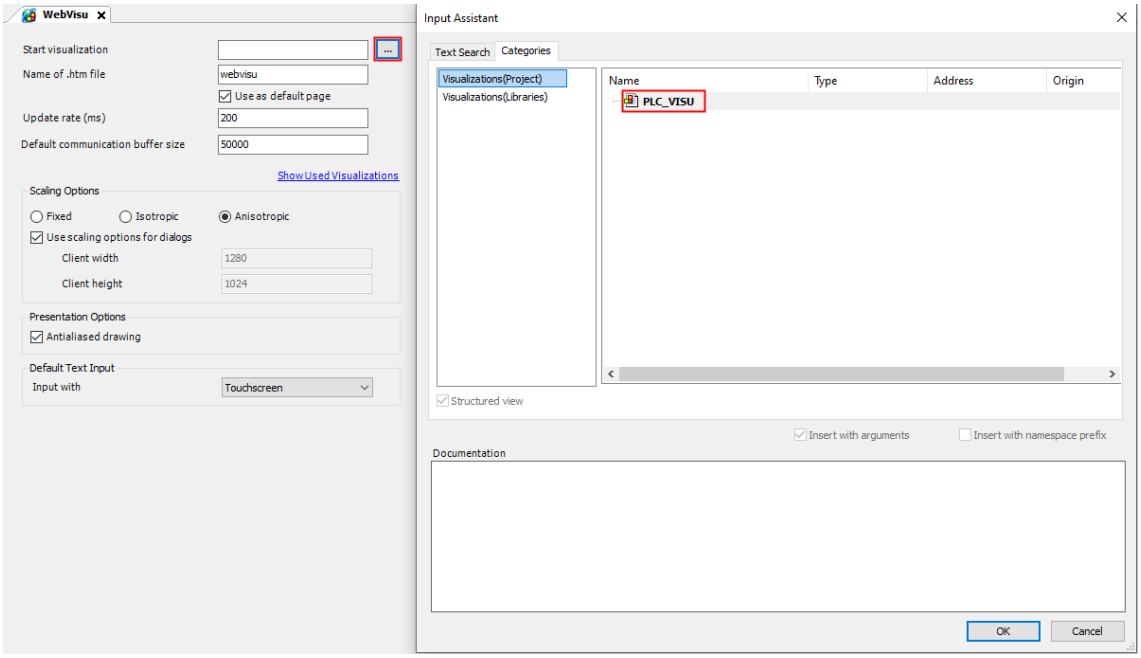
4. Select *“Add object”*.

   ⇨ You added and activated a web server on Ethernet port 1 on the AC500 V3 CPU.

Set-up the web server



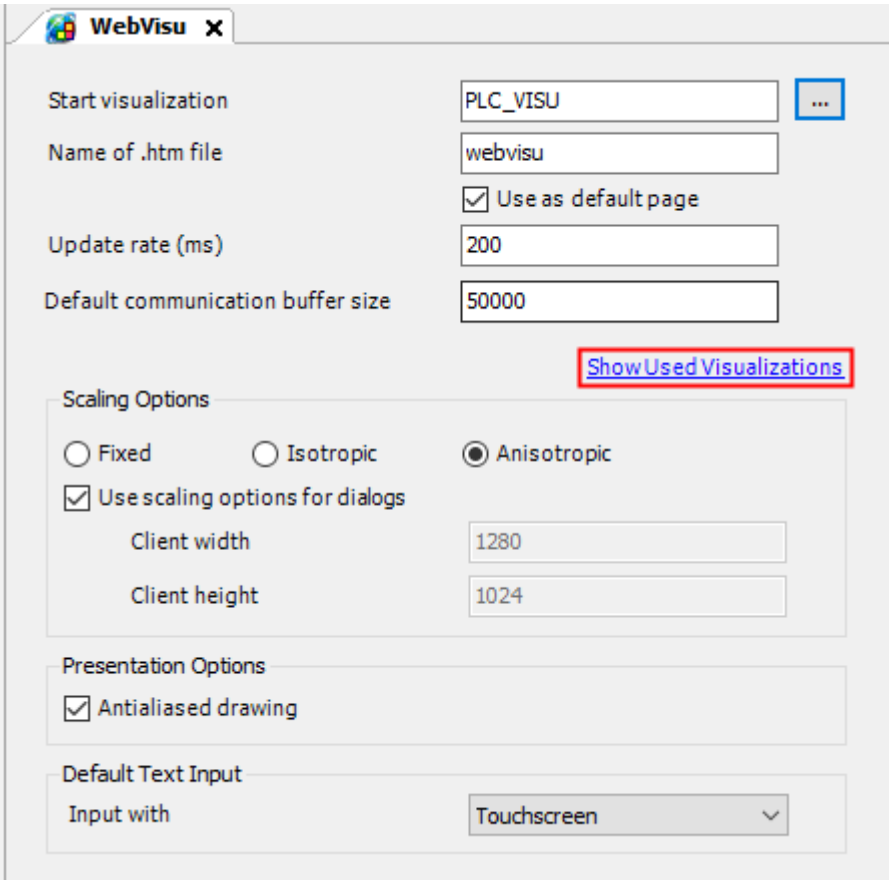
1. Double-click *“WebVisu”* in the device tree.



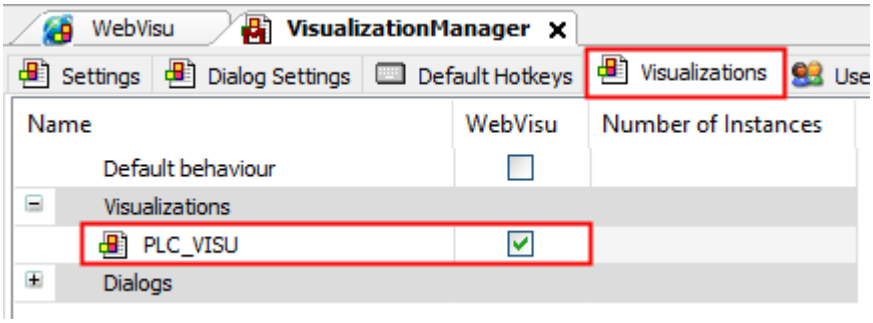
2. Under *“Start Visualization”*, select *“...”*.

   ⇨ A list opens.

3. Select the *“PLC_VISU”* screen from the list.
4. Keep all further settings with default values.



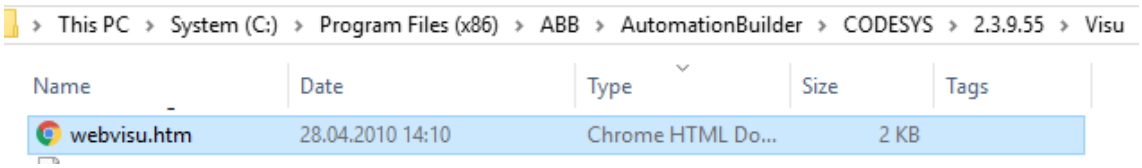
5. Select the link *"Show used visualizations"*.



⇨ The VisualizationManager editor and there the tab *"Visualizations"* opens. All screens and dialog elements created in the project are visible.

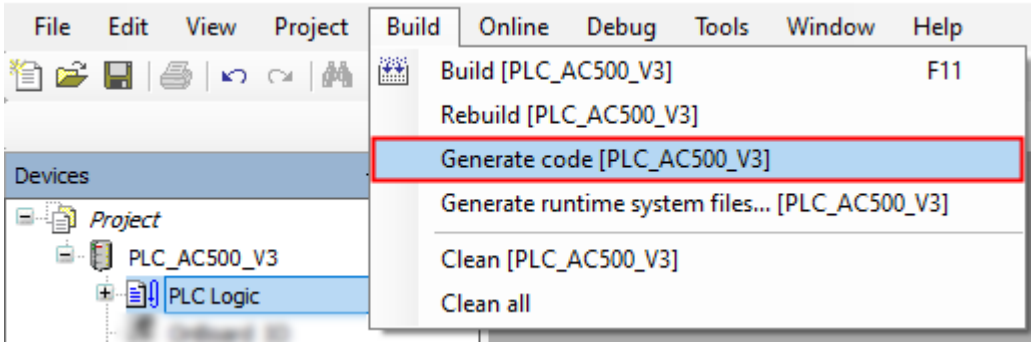
Here, you can select which screens are enabled or disabled for web visualization.

If you want to select another screen as a start visualization, you must modify the adequate parameter in the webvisu.htm file: `<param name="STARTVISU" value="PLC_VISU">`



Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

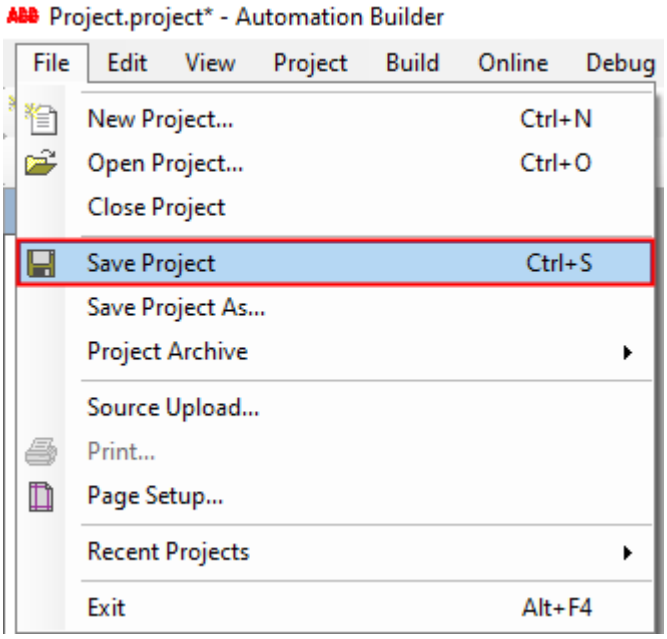


▷ Select menu *"Build ➔ Generate code"*.

⇨ The result of the compiling is shown in the *"Messages"* field at the bottom of the screen.

If you skip the compiling and select *"Login"*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save the project



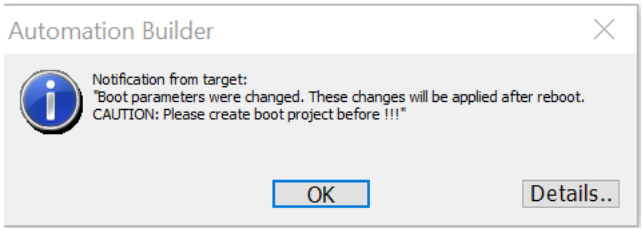
▷ Select menu *"File ➔ Save Project"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl] + [S]*.

Loading the project to the CPU

1. Download the project to the CPU *as described in Chapter 1.2.18.1.2.7 , on page 89*.
2. Check the notification window at the end of the download. In case of message "Boot parameters were changed. These changes will be applied after reboot", a reboot of the CPU is required after creation of the boot project.



Create a boot project

By default, after project download, the boot project is created automatically.

Rebooting the CPU

▷ Reboot the CPU by switching OFF and ON the power supply. (The parameter for web server activation is a boot pamater which is loaded during boot of the CPU)

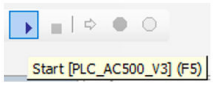
Test the web visualization

☑ You have downloaded the project and created the boot project.

☑ The CPU has been rebooted.

☑ You are logged in.

☑ CPU is in "stop" mode.



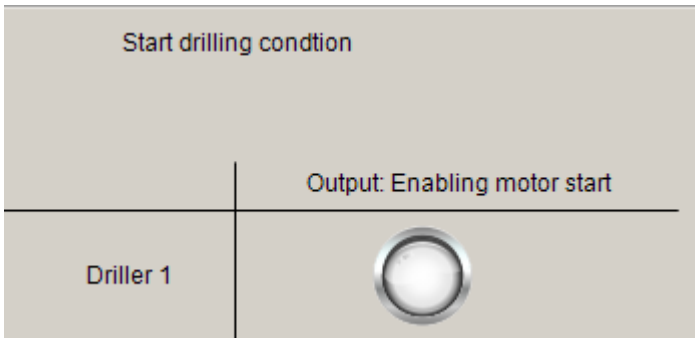
1. Start the project execution, e.g., from the tool bar.
2. Launch an internet browser.
3. Type in the URL field: *http://192.168.0.10/webvisu.htm*.

   192.168.0.10 is the IP address of CPU's ETH1 port.

   /webvisu.htm is the default htm file.

   ⇨ Web visualization will be loaded.

   The start screen "PLC_VISU" is displayed in a responsive view.



4. Test the function by operating switch I1.
5. Test the results for responsive view by changing the web browser window size.

Reset the CPU

Reset values and parameters

In some cases, it could be required to do a CPU reset, e.g., for resetting of counter values, parameters etc.

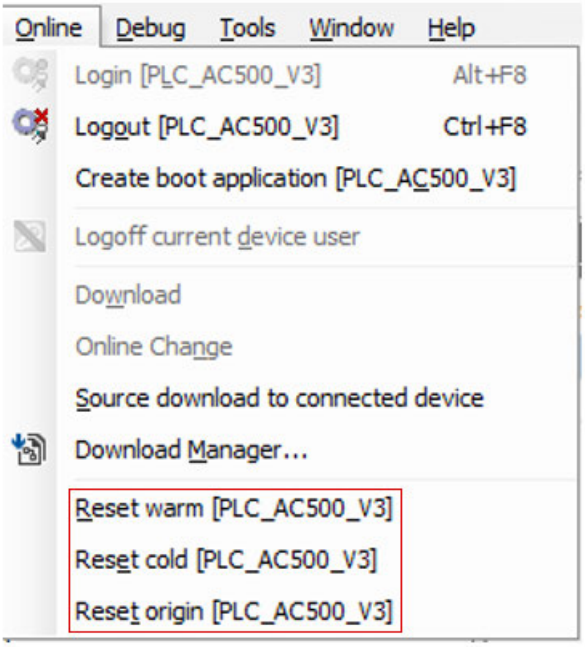


Fig. 8: Reset commands in "Online" menu

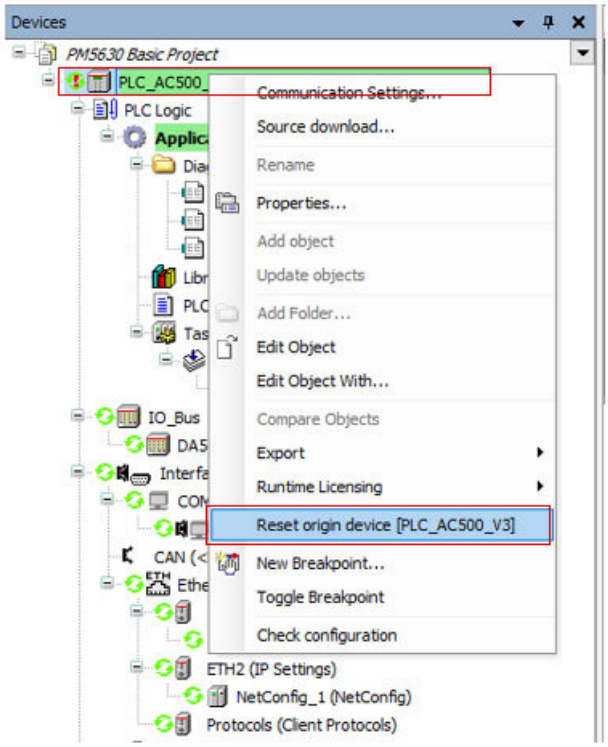
Reset warm	All variables are reset, except RETAIN PERSISTENT variables.
Reset cold	Causes initialization of all variables, except PERSISTENT variables. By recommended creation of remanent variables always with both properties: PERSISITENT and RETAIN, this command resets all variables, except PERSISTENT RETAIN variables.
Reset origin	All variables and the application project are reset.

Table 5: Behavior of variables of type VAR (local or global) and variables of type PERSISTENT RETAIN

	VAR	**VAR PERSISTENT RETAIN**
After online command 'Online change'	no change	no change
After online command 'Download'	initialization	no change
After online command 'Reset warm'	initialization	no change
After online command 'Reset cold'	initialization	no change
After online command 'Reset origin'	initialization	initialization
After power supply off	initialization	no change

Complete reset of the CPU

To do a complete reset of the CPU thereby erasing the application from the RAM and flash EEPROM do the following.



1. Right-click the station object *"PLC_AC500_V3"* in the device tree.
2. Select *"Reset origin device [station name]"*.
   ⇨ The application is completely erased from the CPU (complete project from all memory areas).

1.2.18.1.3 Example project for remote I/O expansion with PROFINET

This example introduces the configuration of the PLC with remote I/O. The use of I/O channels in a program and commissioning of the configuration is shown.

Preconditions

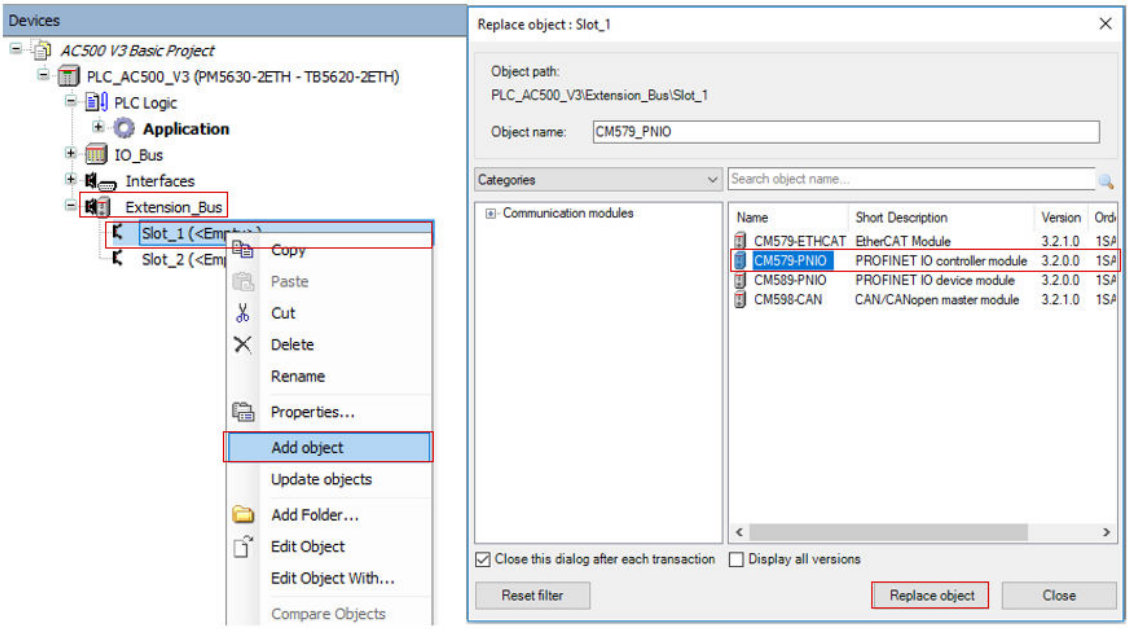
- Automation Builder is installed and licensed as, at least, standard edition ↳ *Chapter 1.2.4 "Managing your licenses" on page 20*.
- AC500 V3 CPU is assembled and connected to the PC ↳ *Chapter 1.2.18.1.1 "Hardware AC500 V3" on page 61*.
- Configuration and programming of this example project will be made in the existing example project for central I/O expansion ↳ *Chapter 1.2.18.1.2 "Example project for central I/O expansion" on page 63*.
- CM579-PNIO communication module is inserted in terminal base and connected to the PLC ↳ *Chapter 1.2.18.1.1 "Hardware AC500 V3" on page 61*.
- CI502-PNIO communication interface module is inserted in terminal unit and connected to the PLC ↳ *Chapter 1.2.18.1.1 "Hardware AC500 V3" on page 61*.

Set-up PROFINET controller

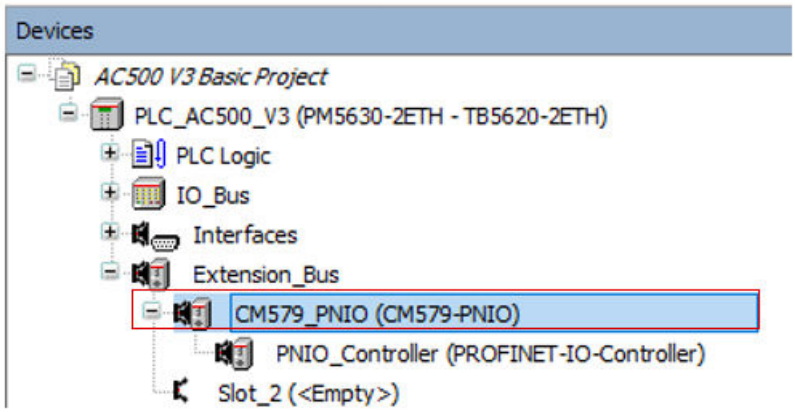
Add the CM579-PNIO to the device tree

1. In the Automation Builder device tree under *"Extension_Bus"*, right-click *"Slot_1"*.
2. Select *"Add object"*.

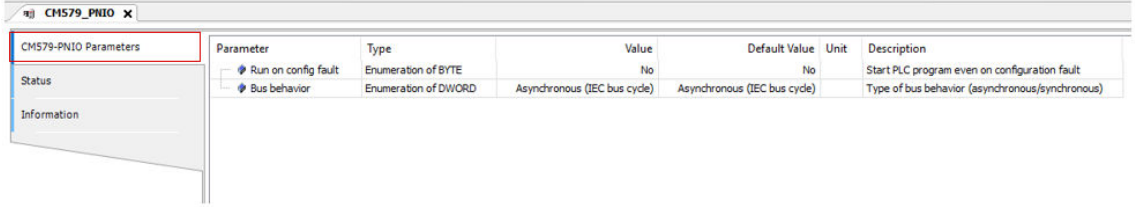
3. Select *“CM579-PNIO”*.
4. Select *“Replace object”* to add the CM579-PNIO.



Set-up the general behavior



1. Under *“Extension_Bus”*, double-click *“CM579_PNIO”* in the device tree.
   ⇨ A tab opens in the editor view.
2. Select *“CM579-PNIO Parameters”*.

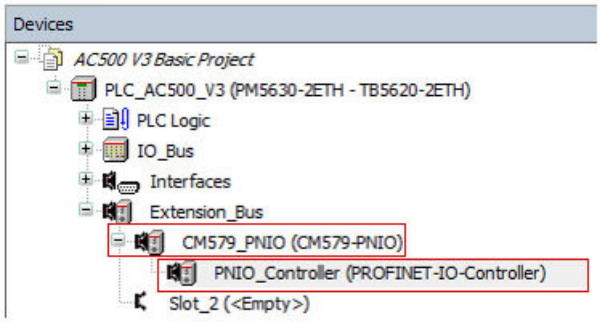


Run on configuration fault	This parameter will prohibit the PLC from running if the CM579-PNIO has a configuration error.
Bus behavior	This parameter sets how the data from the bus flows in/out of the CM579-PNIO.

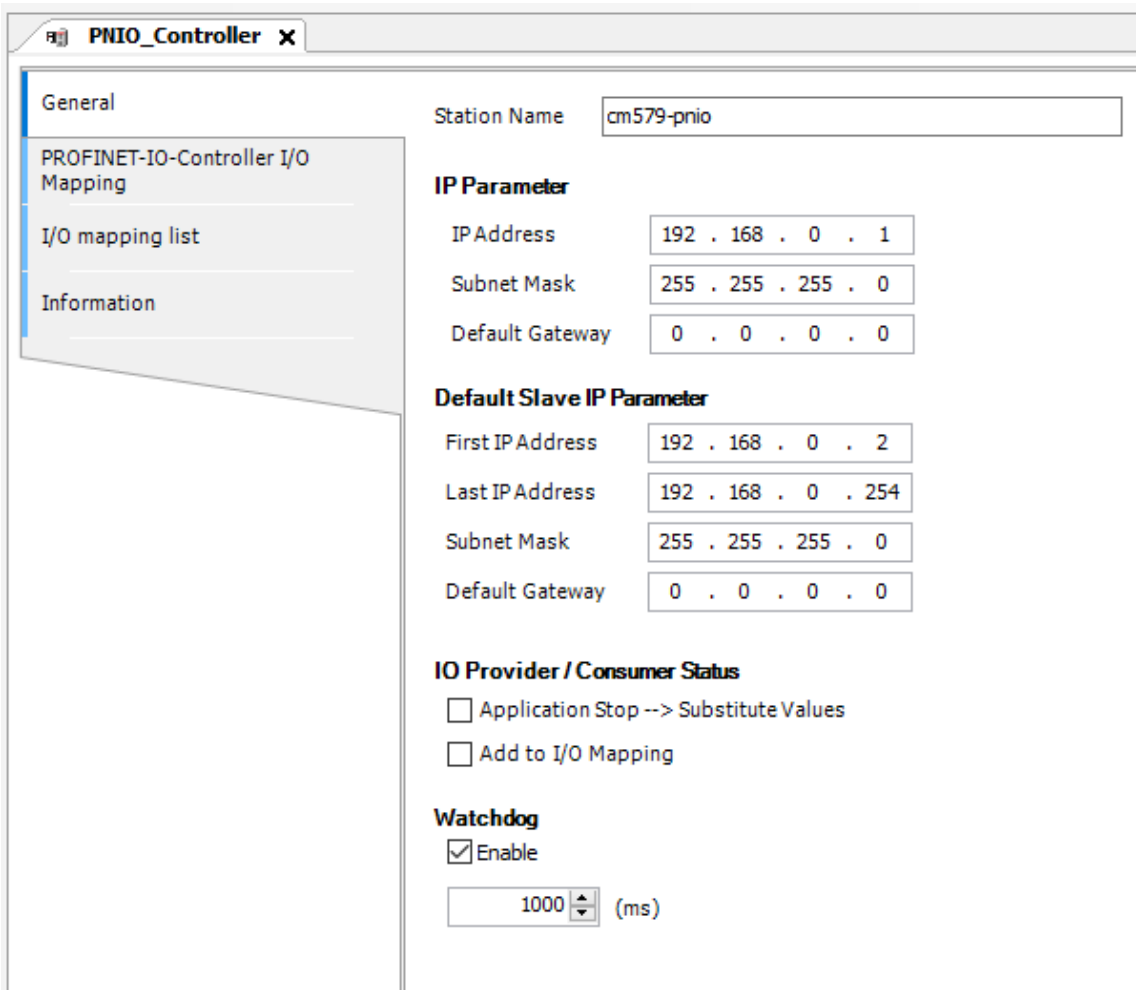
3. Select *“Status”*.
   ⇨ This opens the bus controller status and gives a basic status overview.
4. Select *“Information”*.
   ⇨ This page contains general information about the CM579-PNIO.
5. For the example project, you can keep the default settings.

Set-up the PROFINET IO controller

☑ To edit settings for the controller, you must not be logged-in to the PLC.



1. Under *“CM579_PNIO”*, double-click *“PNIO_Controller”* in the device tree.
   ⇨ A tab opens in the editor view.
2. Select *“PROFINET IO CONTROLLER”*



3. Select *“General”*.
4. Here, you can set-up the way, IP addresses are distributed out to the industrial bus network. You can even set, what IP-address and DNS name (station name) the PROFINET controller has.

   For the example project, keep the default settings.

Set-up PROFINET device

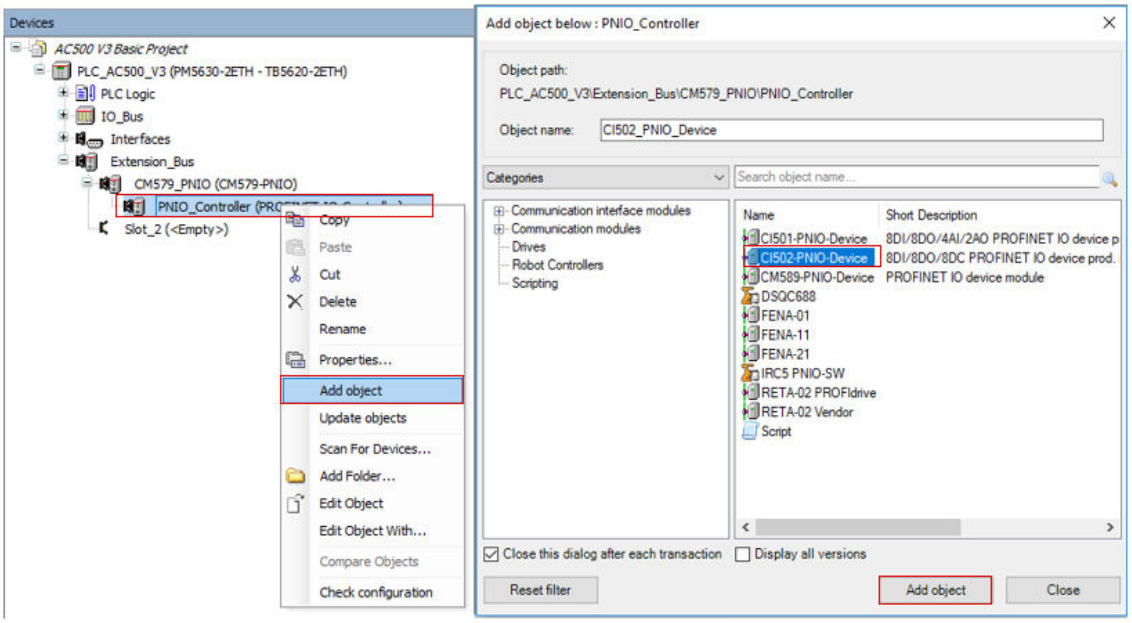
Hardware preparation

1. Switch off the power supply of your PLC.
2. Use a screw driver to set the CI502 module address to "02" by positioning of the upper rotary switch to "0" and lower switch to "2". Note, that the numbers have hexadecimal format.
3. Switch on the power supply.

Add the CI502-PNIO to the device tree

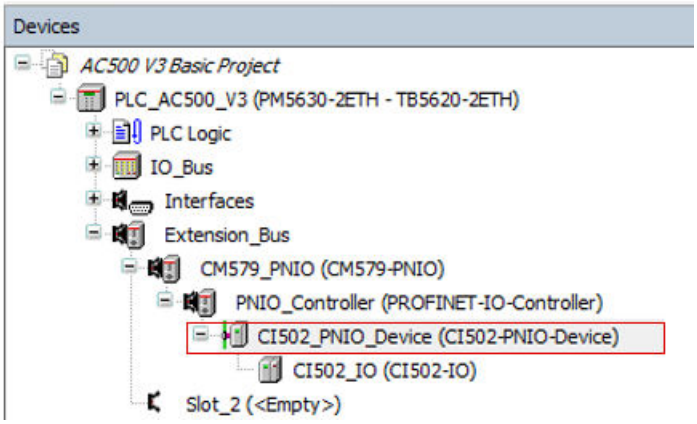
1. Right-click *“PNIO_Controller”* in the device tree.
2. Select *“Add object”*.
3. Select *“CI502-PNIO-Device”*.

4. Select *“Add object”* to add the device.



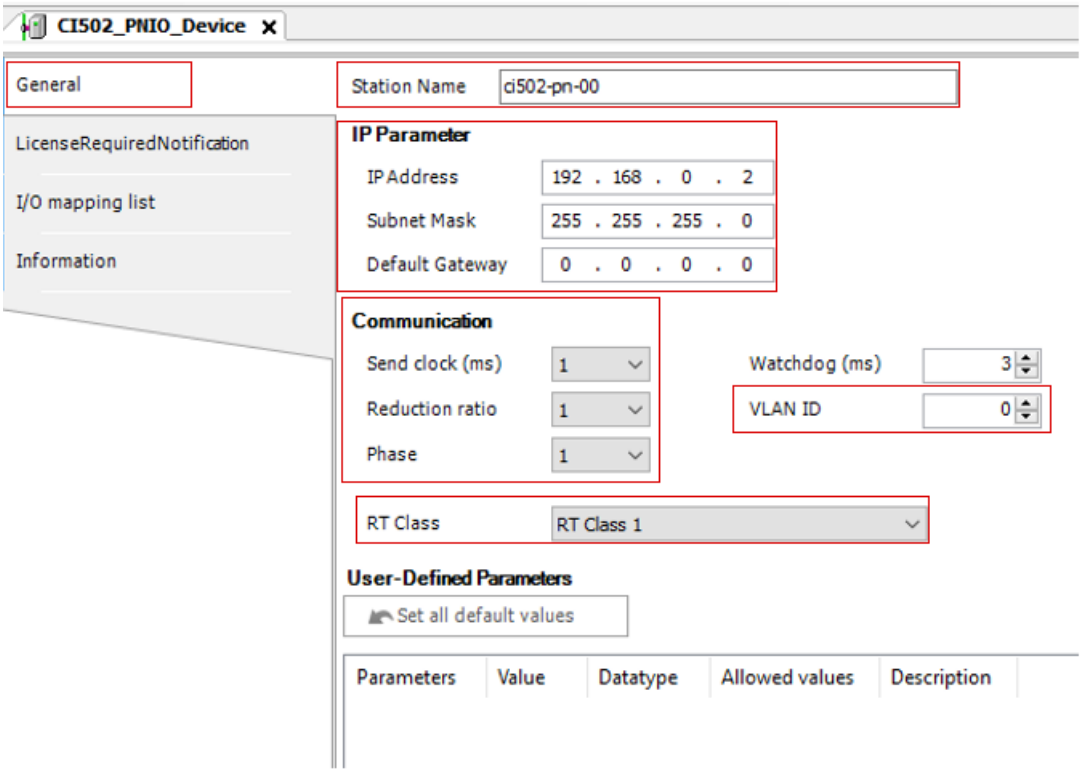
Configure the CI502-PNIO device

Configure the CI502-PNIO PROFINET IO device



1. Double-click *“CI502_PNIO_Device”*.
   ⇨ A tab opens in the editor view.

2. Select *“General”*.



Station name	Default station name
IP Parameter	IP-addressing parameters of the node. If modifications are required for *“IP Parameter”*, they must be done also for CM579-PNIO and all other devices in this PROFINET line.
Communication	Communication time set-up
VLAN	Virtual local area network ID
RT Class	PROFINET IO RT (real time) type settings

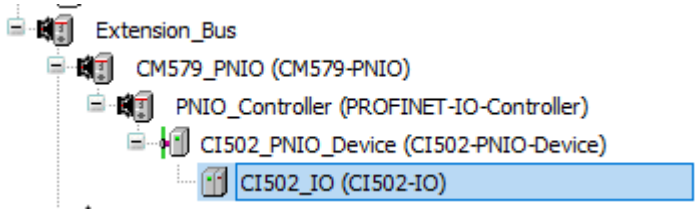
3. Set station name to "ci502-pn-02" according to hardware settings.

   For numbers greater than 09 always make sure, that the last two **decimal** digits of the node’s *“Station Name”* in Automation Builder correspond to the position of module’s rotary switches (**hexadecimal** values): e.g., "ci502-pn-10" <-> "0A" or "ci502-pn-16" <-> "10".

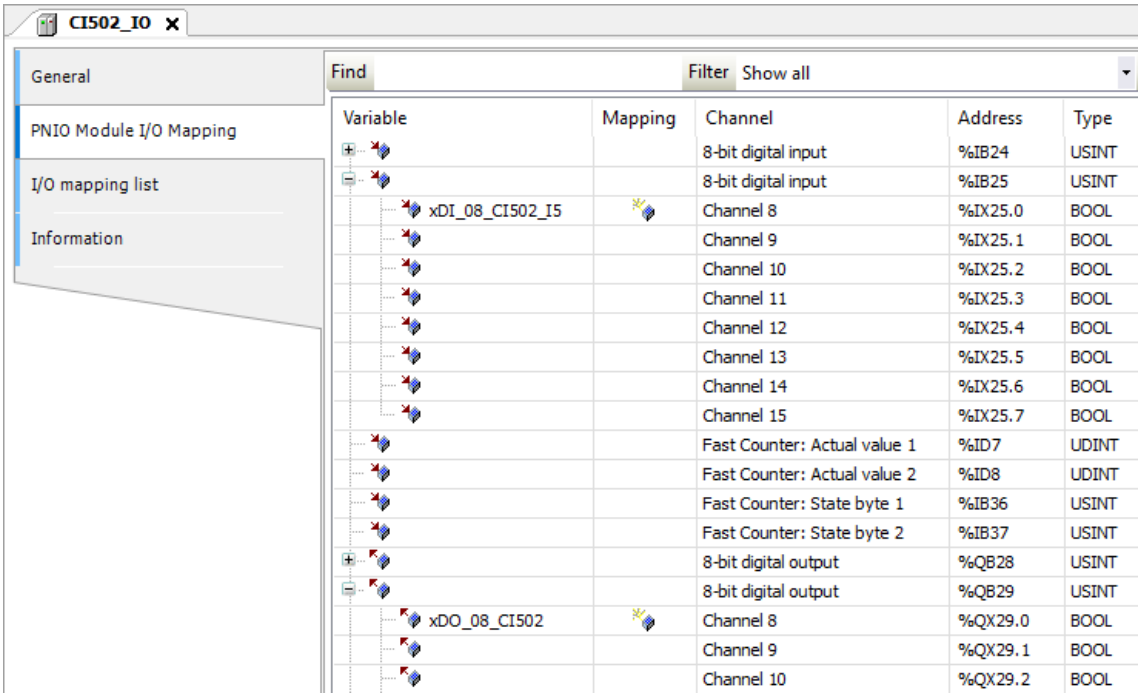
4. Leave the default settings for *“IP Parameter”*.
5. Adjust the communication time settings to get a Watchdog (ms) 24:
   - *“Send clock (ms)”*: 4
   - *“Reduction ratio”*: 2
   - *“Phase”*: 1
6. Leave the default settings for *“VLAN ID”*.
7. Leave the default settings for *“RT Class”*.

If the node has the same device address (the last two digits of the device name) as set by means of the rotary switches on the module, all the node parameters will be loaded automatically upon initialization scan of the CI50x module. This allows, e.g., the module exchange without an engineering tool.

Create CI502-PNIO I/O mapping to symbols



1. Double-click *"CI502_IO"*.

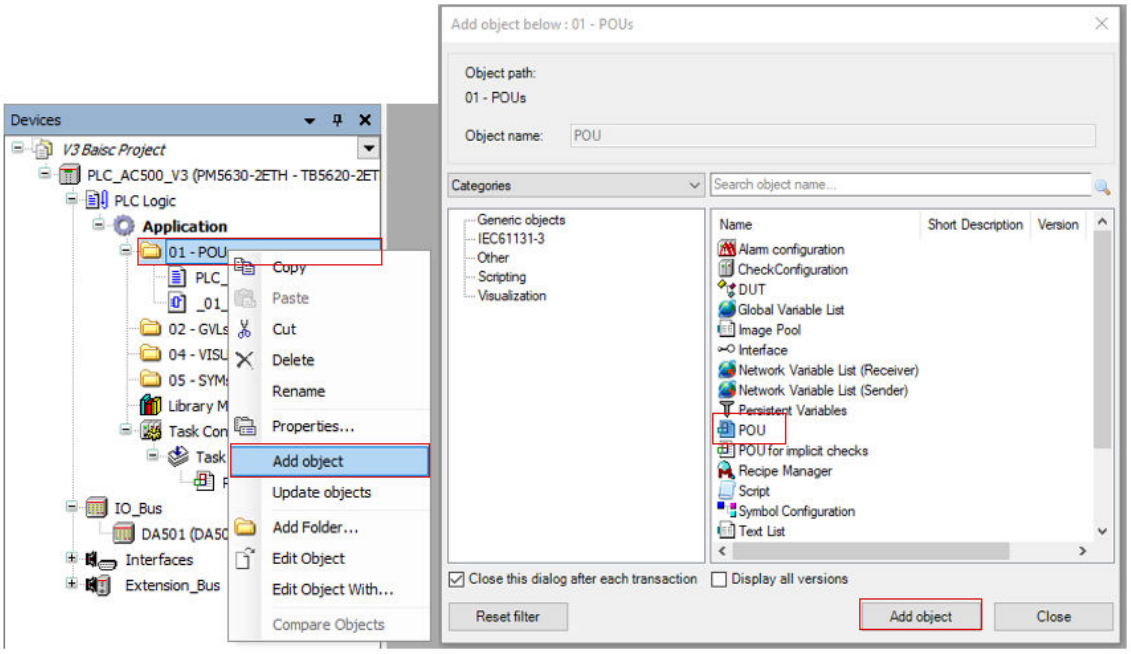


2. Select *"PNIO Module I/O Mapping"*.
3. Fill in the variable names:

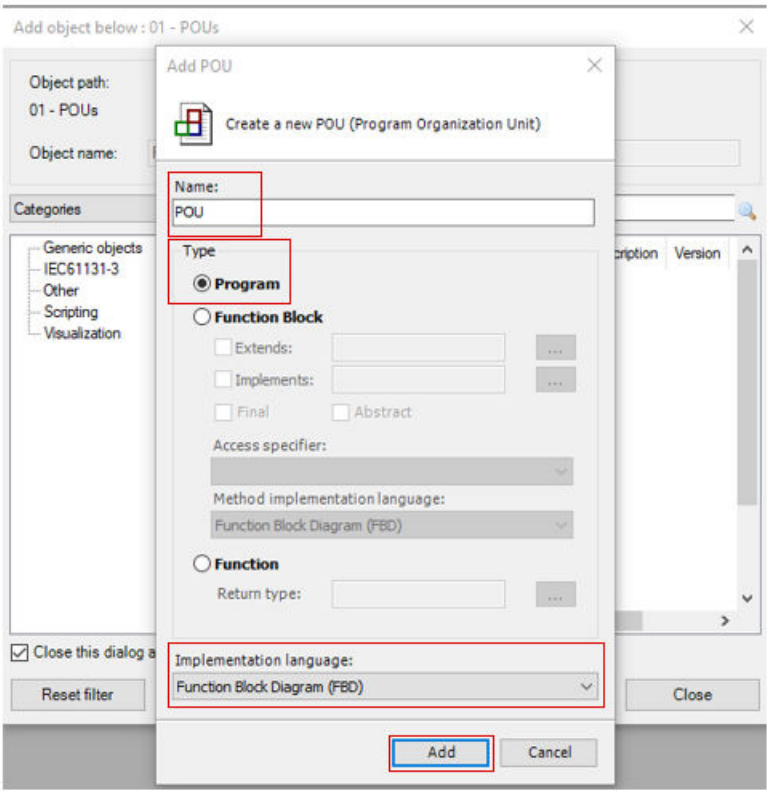
Element	Hardware channel	Symbol
Switch I5	CI502 DI8	xDI_08_CI502_I5
LED output DO8	CI502 DO 8	xDO_08_CI502

Add remote I/O expansion to project

Add a program POU to the project



1. Right-click *“01 - POUs”* in the device tree.
2. Select *“Add object”*.
3. Select *“POU”*.
4. Select *“Add object”*.

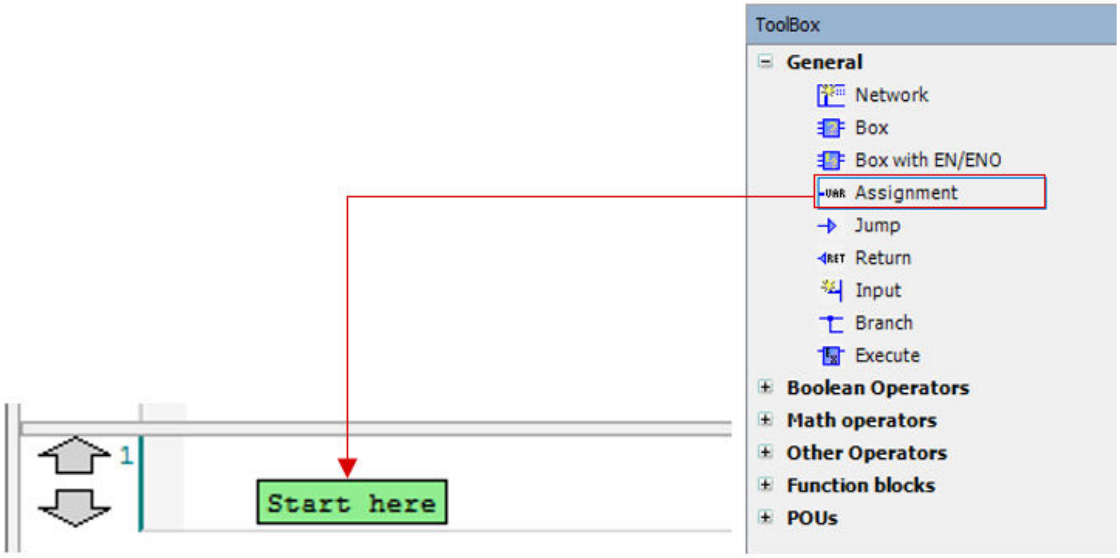


5. Fill in "_30_PNIO_test".
6. Select *“Program”*.
7. Select *“Function Block Diagram”*.

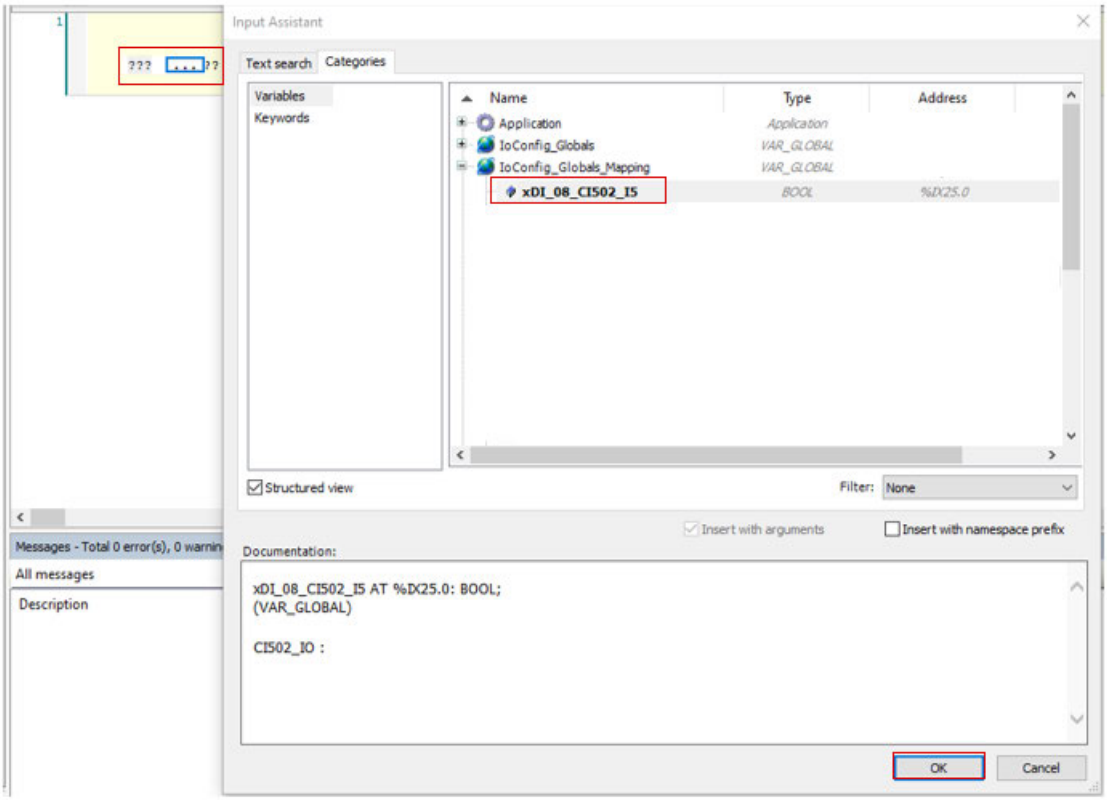
8. Select *[Add]* to add the POU.

Create a POU logic

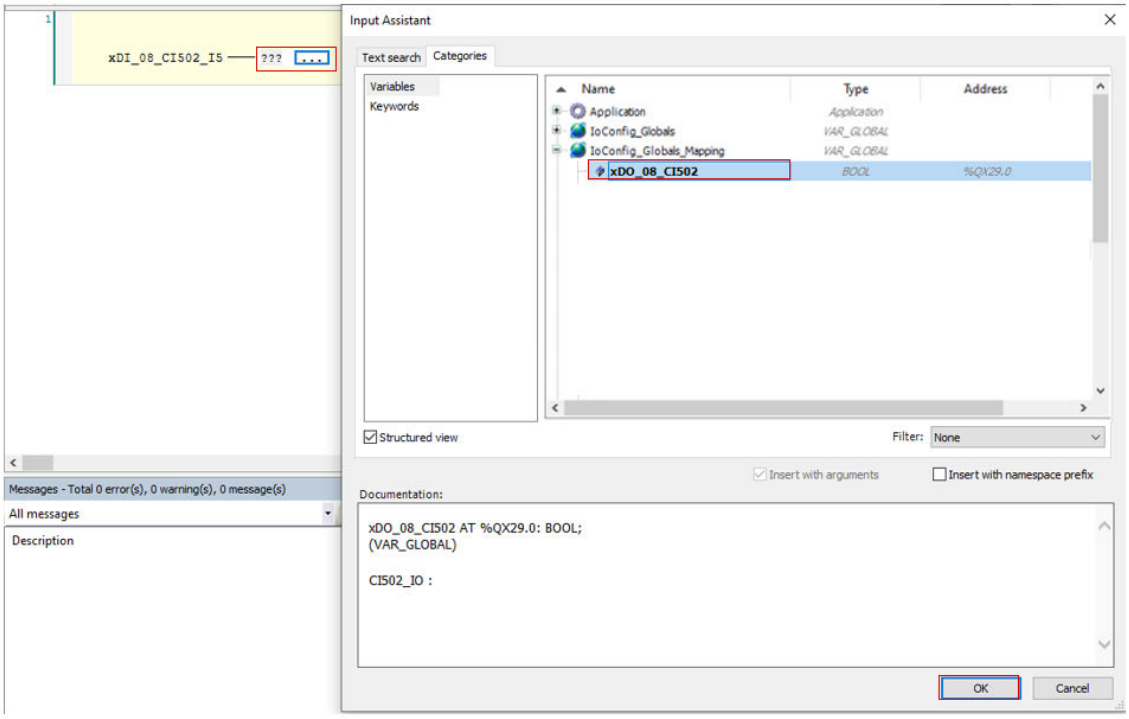
1. Double-click *“30_PNIO_test”* in the device tree.



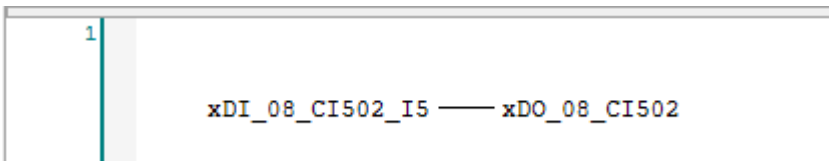
2. In the ToolBox, select *“Assignment”*.
3. Drag and drop *“Assignment”* into the "Start here" field in network "1".



4. Select *“???”* on the left side of the assignment, then select *“...”*.
5. In *“IoConfig_Globals_Mapping”* list, select *“xDI_08_CI502_I5”*.
6. Select *[OK]* to add this variable to the left side of the assignment connector.

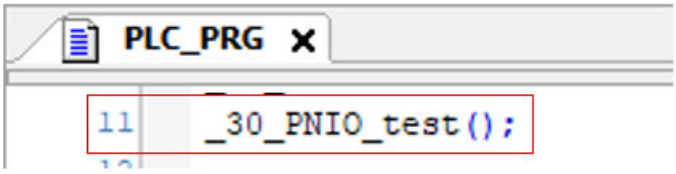


7. Select *"???"* on the right side of the assignment, then select *"..."*.
8. In *"IoConfig_Globals_Mapping"* list, select *"xDO_08_CI502"*.
9. Select *[OK]*.



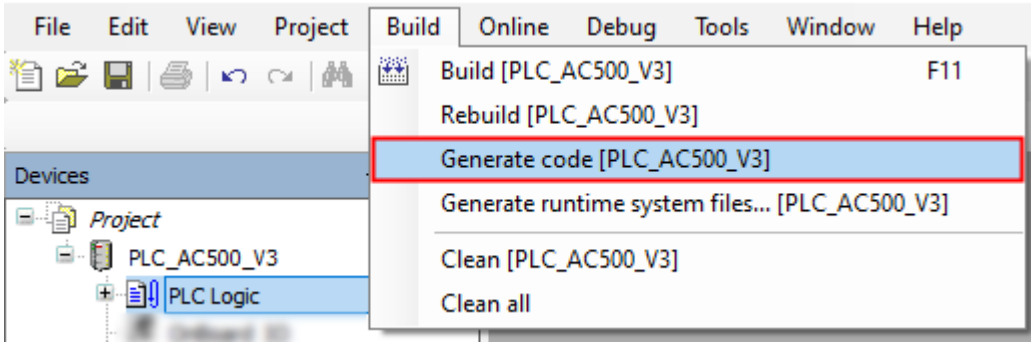
Call the POU in PLC_PRG

1. Double-click *"PLC_PRG"*.
2. Select the next free line in *"PLC_PRG"* and press *[F2]*.
   ⇨ *"Input Assistent"* opens.
3. Select *"Module Calls"*.
4. Open *"Application"*.
5. Open *"10 POUs"* and select *"_30_PNIO test"*.
6. Select *[OK]* to close the dialog.



Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

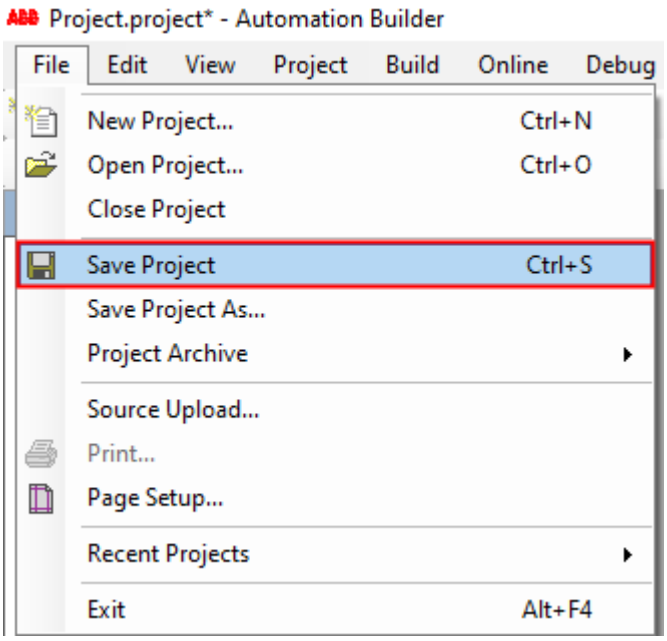


▷ Select menu *"Build ➔ Generate code"*.

⇨ The result of the compiling is shown in the *"Messages"* field at the bottom of the screen.

If you skip the compiling and select *"Login"*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save the project



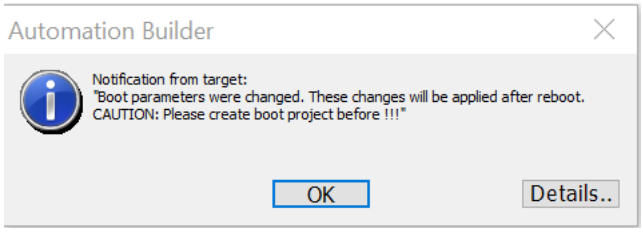
▷ Select menu *"File ➔ Save Project"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl] + [S]*.

Loading the project to the CPU

1. Download the project to the CPU ↬ *as described in Chapter 1.2.18.2.2.7 , on page 148*.
2. Check the notification window at the end of the download. In case of message "Boot parameters were changed. These changes will be applied after reboot", a reboot of the CPU is required after creation of the boot project.



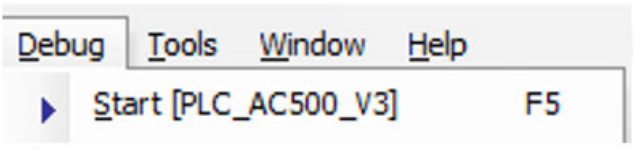
Test the program

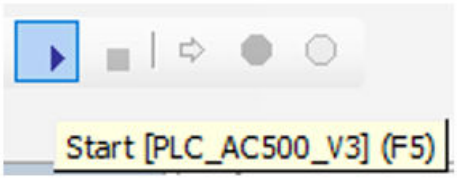
Start the program execution

☑ You are logged in the CPU.

☑ An executable project is loaded to the CPU.

☑ The CPU is in "stop" mode.





▷ Select menu *"Debug ➔ Start [PLC_AC500_V3]"*.

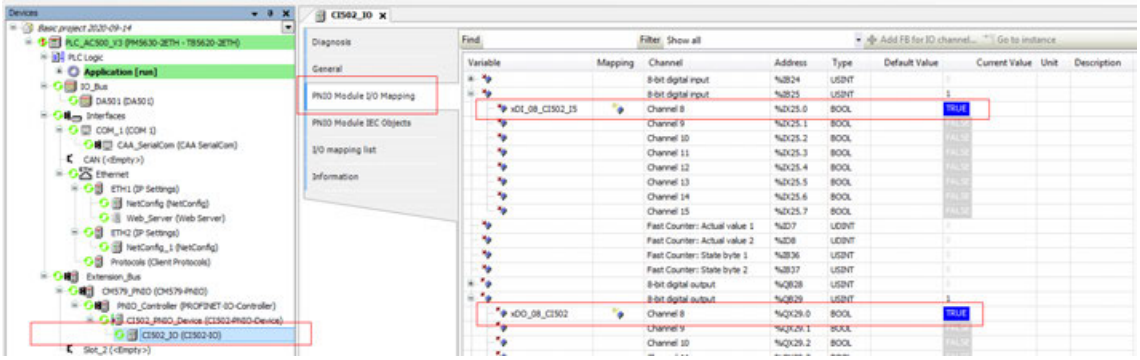
Alternatively, select the "start" icon in the tool bar.

Alternatively, press *[F5]*.

Test the function

▷ Operate the switch I5 and observe:

- The LEDs of the relevant CI502 inputs and outputs.
- The online status of inputs and outputs within the POU.



Reset the CPU

Reset values and parameters

In some cases, it could be required to do a CPU reset, e.g., for resetting of counter values, parameters etc.

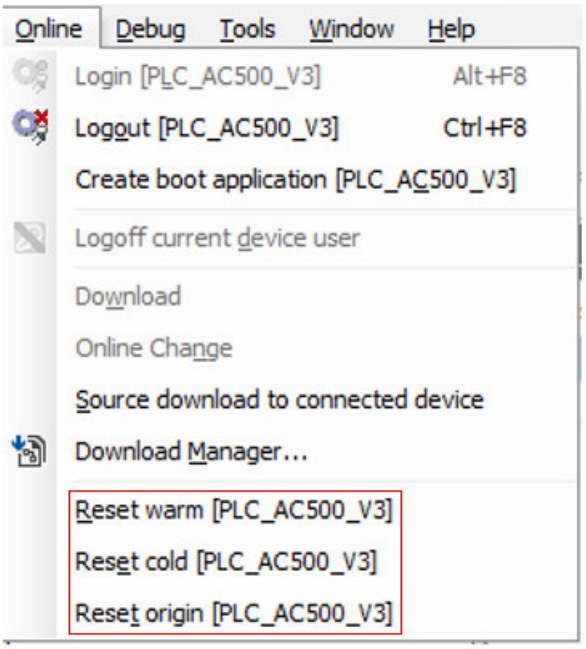


Fig. 9: Reset commands in “Online” menu

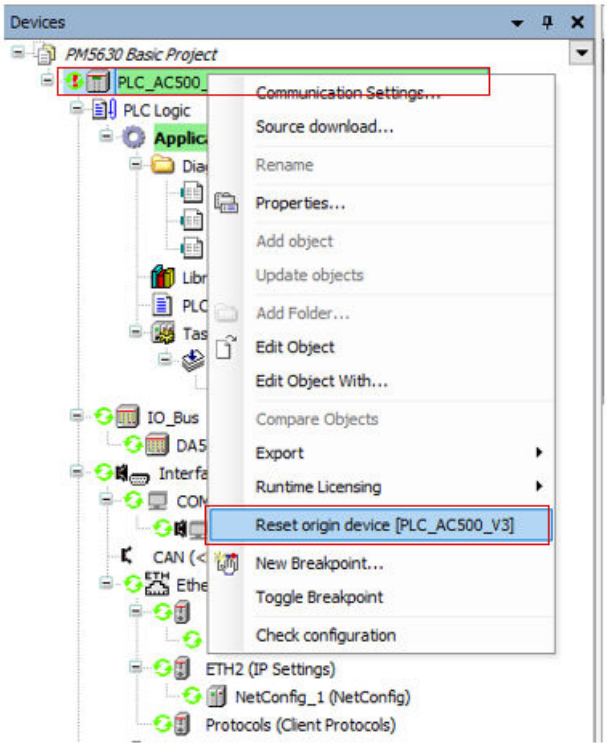
Reset warm	All variables are reset, except RETAIN PERSISTENT variables.
Reset cold	Causes initialization of all variables, except PERSISTENT variables. By recommended creation of remanent variables always with both properties: PERSISITENT and RETAIN, this command resets all variables, except PERSISTENT RETAIN variables.
Reset origin	All variables and the application project are reset.

Table 6: Behavior of variables of type VAR (local or global) and variables of type PERSISTENT RETAIN

	VAR	VAR PERSISTENT RETAIN
After online command 'Online change'	no change	no change
After online command 'Download'	initialization	no change
After online command 'Reset warm'	initialization	no change
After online command 'Reset cold'	initialization	no change
After online command 'Reset origin'	initialization	initialization
After power supply off	initialization	no change

Complete reset of the CPU

To do a complete reset of the CPU thereby erasing the application from the RAM and flash EEPROM do the following.



1. Right-click the station object *"PLC_AC500_V3"* in the device tree.
2. Select *"Reset origin device [station name]"*.
   ⇨ The application is completely erased from the CPU (complete project from all memory areas).

1.2.18.2 Example projects for AC500-eCo V3

1.2.18.2.1 Hardware AC500-eCo V3

Configuration for example projects

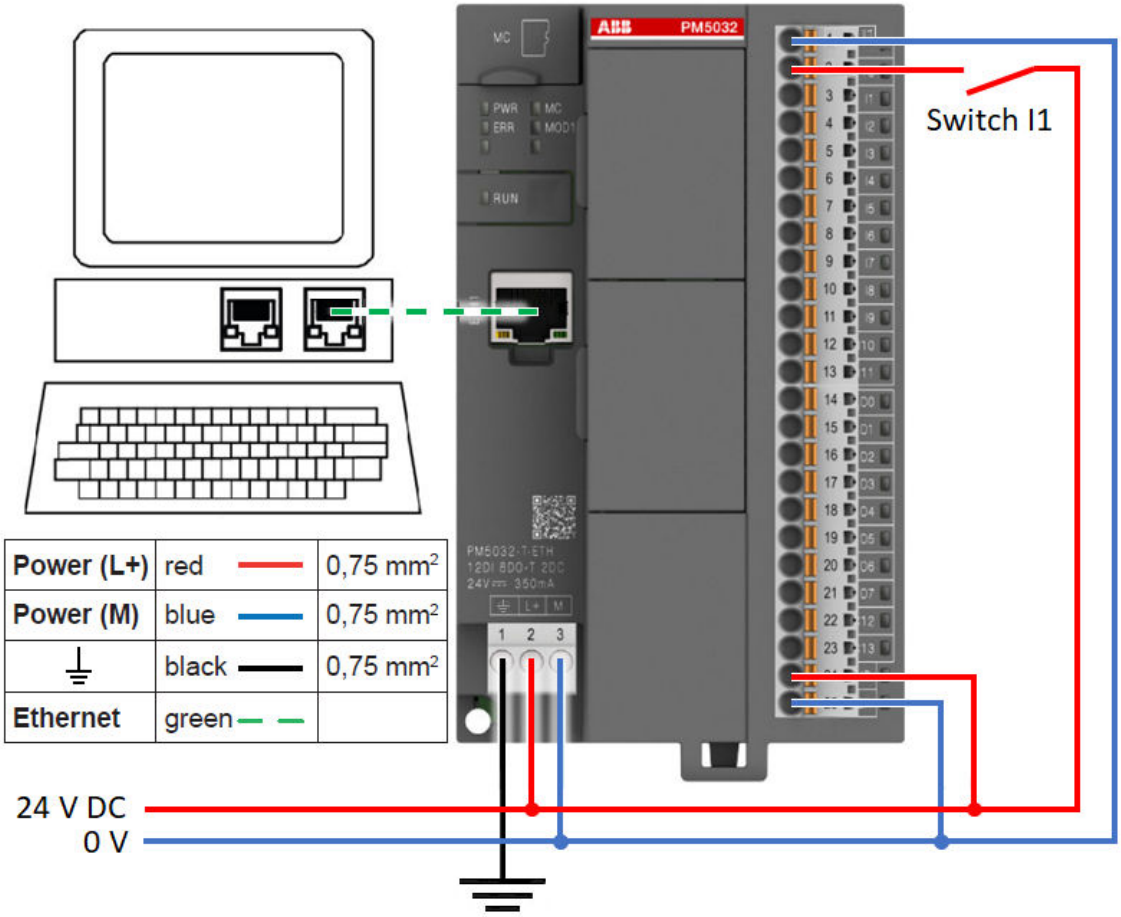
The example projects require a AC500-eCo V3 CPU. The onboard I/O channels are used.

The visualization example is running on CPUs as of PM5032-T-ETH.

Table 7: Modules for example projects to get started with AC500 V3 PLC

Product name	Type	First project
PM5032-T-ETH	CPU	x

Electrical connection



System assembly, construction and connection

NOTICE!

Avoidance of electrostatic charging

PLC devices and equipment are sensitive to electrostatic discharge, which can cause internal damage and affect normal operation. Observe the following rules when handling the system:

- Touch a grounded object to discharge potential static.
- Wear an approved grounding wrist strap.
- Do not touch connectors or pins on component boards.
- Do not touch circuit components inside the equipment.
- If available, use a static-safe workstation.
- When not in use, store the equipment in appropriate static-safe packaging.

You can mount AC500 PLC either to DIN rail or to a metal plate ↬ *Chapter 1.6.4.6.3 “Mounting and demounting” on page 3408*. Here, we recommend to mount on DIN rail.

1. Snap the terminal base onto DIN rail.
2. If needed, remove option board slot covers from the CPU and insert option boards.
3. If needed, snap the additional I/O modules onto DIN rail and slide them on the rail to establish the I/O bus connection.

4.

> *The terminal blocks are not included in the scope of delivery.*
>
> *The terminal blocks have to be ordered separetellly according to the CPU type and the type of terminal blocks needed (screw or spring technology).*

Insert terminal blocks for power and I/O connection to CPU, options and I/O modules.

5. Make the sensor/actuator wire connections according to the dedicated electronic module you want to use. Provide external process power supply as required.
6. Connect a programming cable (Ethernet cable between ETH port of CPU and PC with engineering software).

1.2.18.2.2 Example project

The following steps show how to set-up an application project and configure the hardware. A simple logic is used as example to introduce in programming and commissioning of the PLC. The workflow for creation of a visualization is explained, as well as how to set-up a web server for visualization.

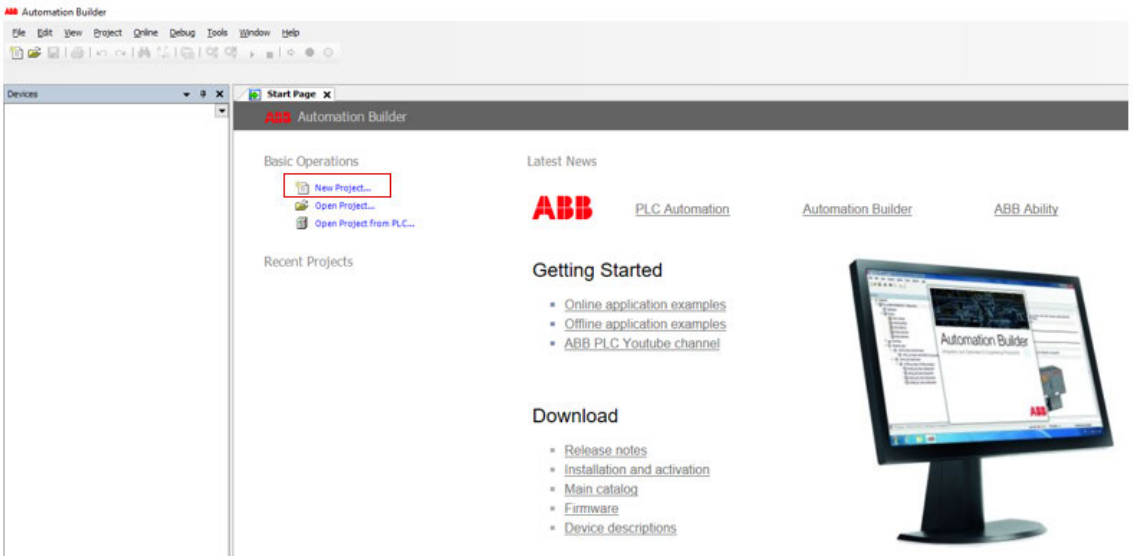
Preconditions

- Automation Builder is installed and licensed as, at least, basic edition ↬ *Chapter 1.2.4 “Managing your licenses” on page 20*.
- AC500 V3 CPU is assembled and connected to the PC ↬ *Chapter 1.2.18.2.1 “Hardware AC500-eCo V3” on page 122*.

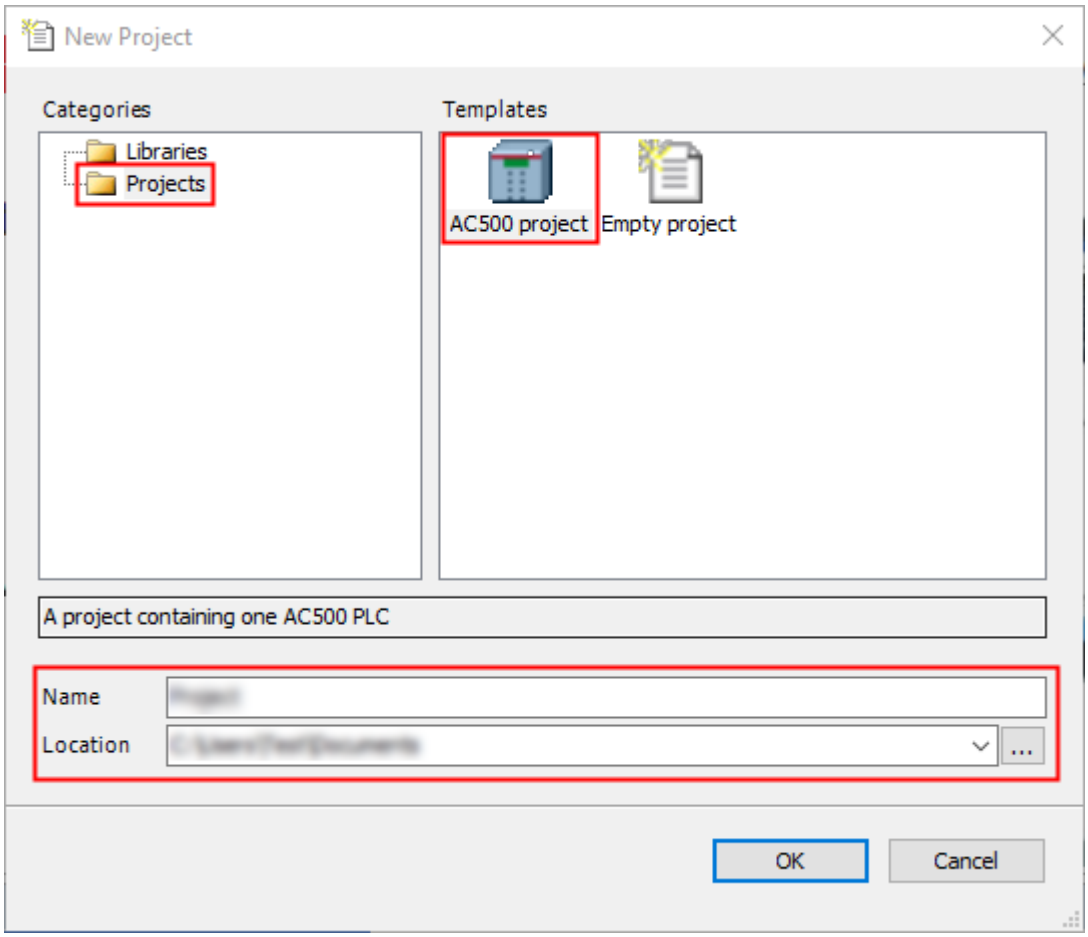
Create, set-up and save your AC500 V3 project

Create a project

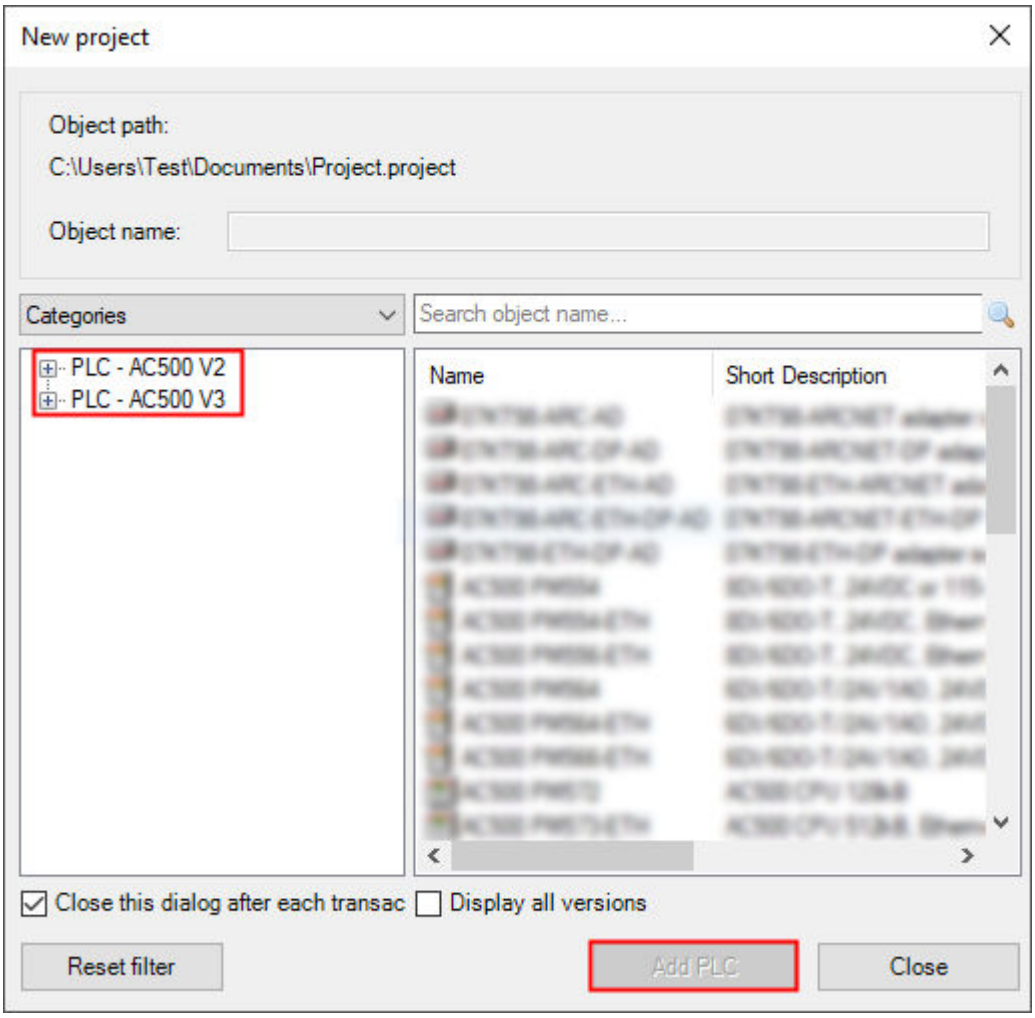
1. Launch Automation Builder either out of the desktop icon or out of the Windows menu.



2. Select *“New Project”* or go to menu *“File ➔ New Project”*.



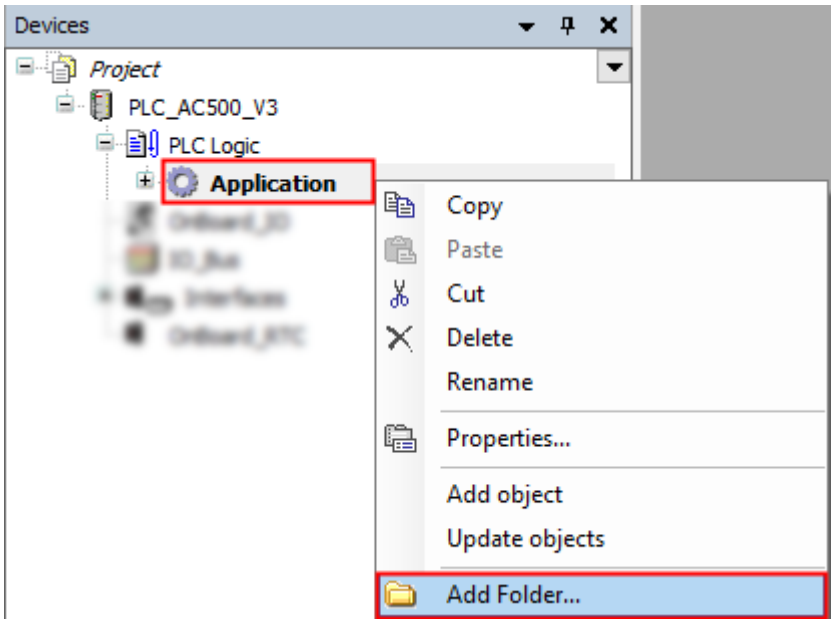
3. Select *“Projects”*.
4. Select *“AC500 project”*.
5. Fill in project name.
6. Choose a location to save the project to.
7. Select *“OK”*.
8. Select *“PLC - AC500 V3”*.
9. Select the CPU according to your hardware set-up.



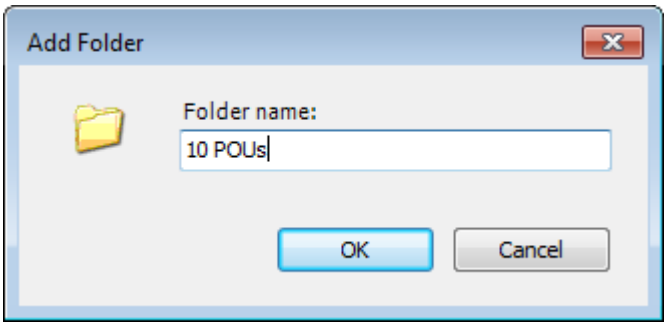
10. Select *"Add PLC"* to add the CPU to your application.

Create folders in the device tree

To optimize the project readability, you will create different folders to group similar objects. The folder names are exemplary. Because the device tree view follows an alphabetical order, we use number prefixes to determine the order.



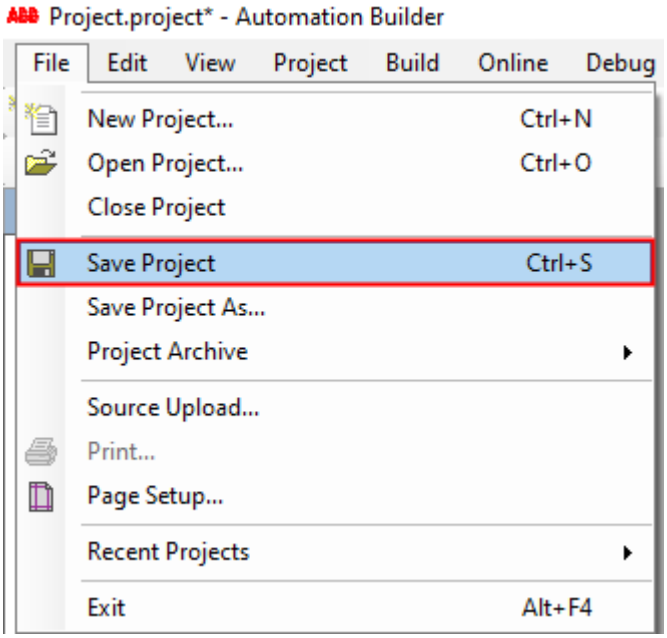
1. Right-click *“Application”*.
2. Select *“Add Folder”*.



3. Type in "10 POUs". This is a name example. Here, the intention is to see this folder as a last one.

   The folder "10 POUs" is for program organization units (POU). POUs are objects of type program, function or function block that are used to create a user program.

Save the project



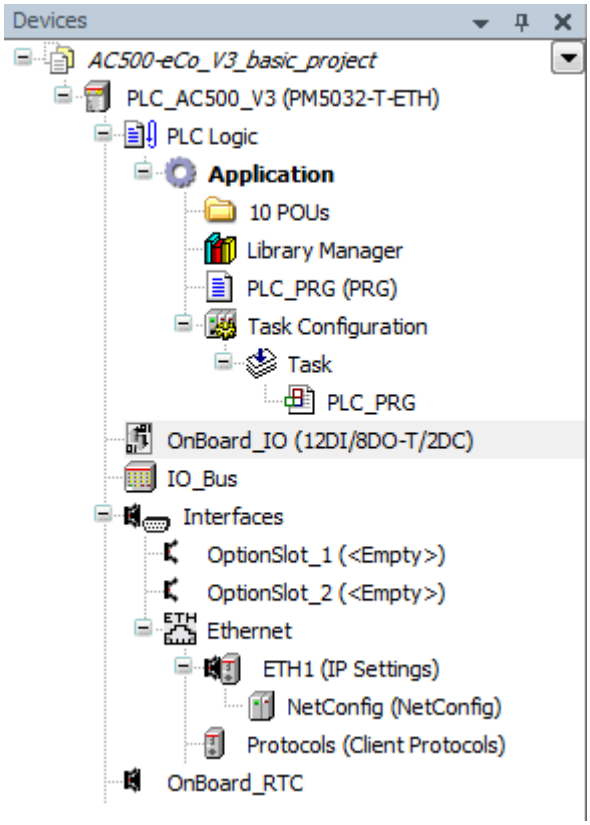
▷ Select menu *"File ➔ Save Project"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl]* + *[S]*.

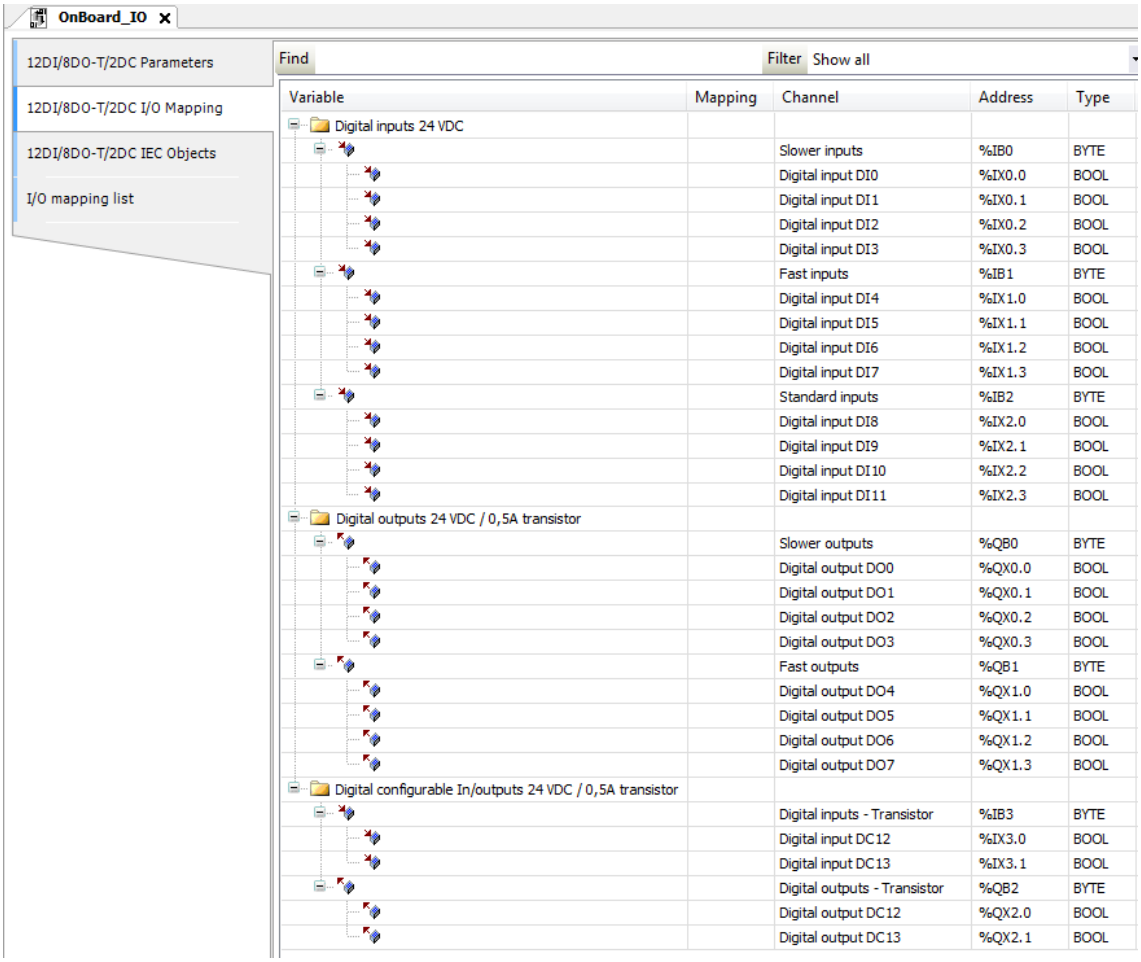
Configure the onboard I/O channels

Onboard I/O variable mapping



1. Double-click *“OnBoard_IO”* in the device tree.

⇨ A tab opens in the editor view.

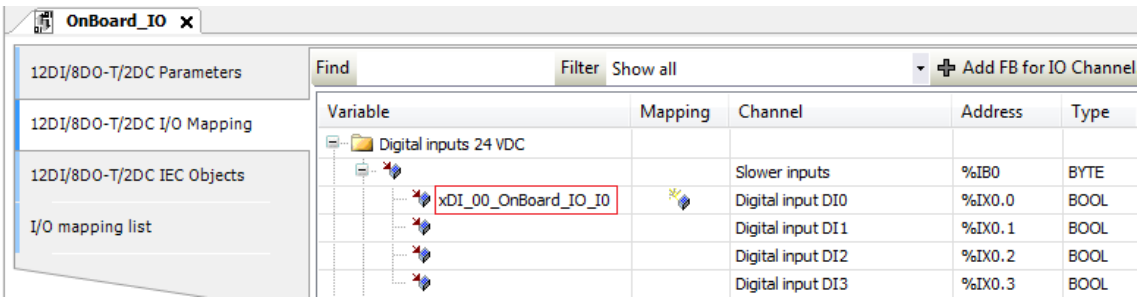


2. Select *“12DI/8DO-T/2DC I/O Mapping”*.

   ⇨ Here, you will map variable names (symbols) for the channels you will need in the program.

The suggested name convention is based on "Hungarian notation". A name prefix is describing variable type: e.g., "x" = variable of type BOOL, "w" = WORD, "i" = INT (integer) etc. This increases the code readability and is helpful for program analysis.

Handle the digital input variables

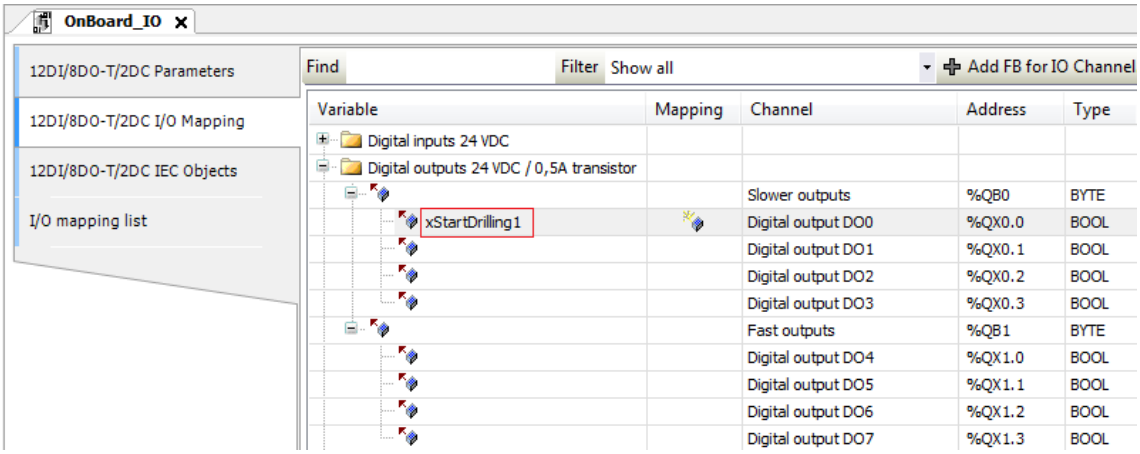


1. Open the list of the digital inputs.

2. Fill in the variable names:

Channel	Type	Variable
Digital input DI0	BOOL	xDI_00_OnBoard_IO_I0

Handle the digital output variables



1. Open the list of the digital outputs.
2. Fill in the variable names:

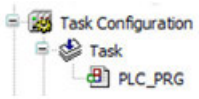
Channel	Type	Variable
Digital output DO0	BOOL	xStartDrilling1

Programming and compiling

Task configuration

A task is a time unit in the processing of a user program (IEC application), which defines by parameters the way and the speed the CPU is executing the user program.

For this project you will use only one cycling task.



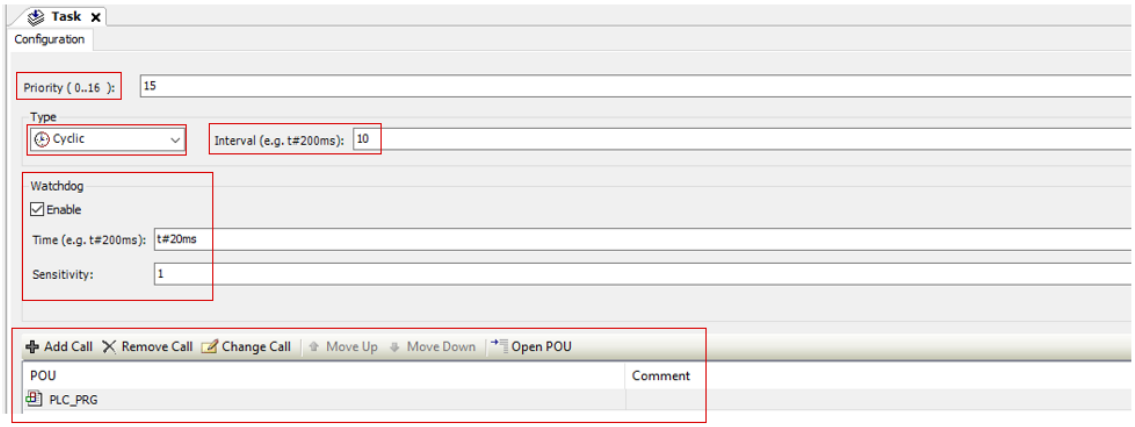
In the device tree, you see the objects *“Task configuration”* and *“Task”*. Both created automatically with the project.

For this project you will use only one cycling task.

▷ Double-click *"Task"* in the device tree.

⇨ A tab opens in the editor view.

For this project you will use only one cyclic task. Keep the default settings for the task.

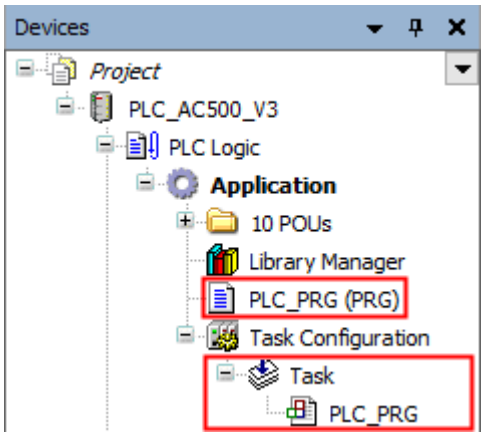


Priority	This is how the CPU prioritizes the task, when more than one task is defined. Priority 0...15 = real time tasks, priority 16 = non-real time task.
Type	In the CPU you can run tasks dependent on the demands of the process
Interval	For cyclic tasks you can set the cyclical execution time. It is usually set in milliseconds with IEC time syntax
Watchdog	To keep track of the time it takes to complete the task
Calls	You can call in one or more program POUs in one single task

Main program PLC_PRG

In the default task configuration ↬ *(shown in chapter 1.2.18.2.2.4.1 Task configuration on page 131)*, there is one call of a POU (program organization unit) i.e. "PLC_PRG".

In your project the "PLC_PRG" will become a main program containing calls to other programs (POUs) which you will create one by one.



The PLC_PRG POU has been defined by default in ST (Structured Text) editor. Keep this setting because of good visibility of the instructions at a glance and good handling for troubleshooting.

To optimize the project readability, you will work with the previously created folder "10 POUs" and add the created subroutines (POUs) to this folder. The subroutines will be created in FBD (Function Block Diagram) editor.

Boolean logic "NOT"

Application example "driller"

Recognizing of a driller by a photo sensor. "TRUE" input signal from sensor indicates that a driller is broken. If driller has been found correct, then start drilling.

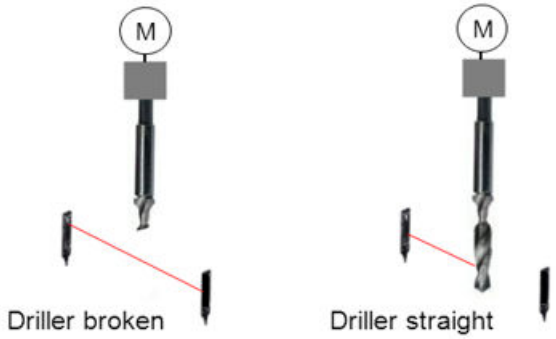


Table 8: Required behavior

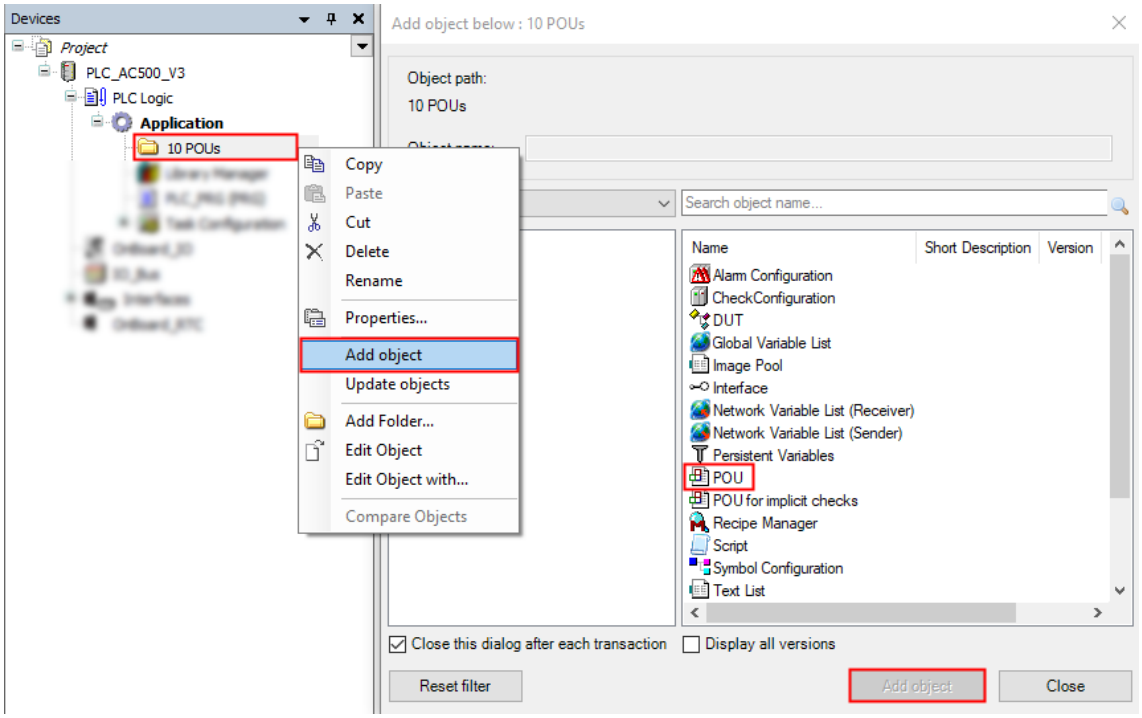
Signal from photo sensor	Required signal of motor ON
FALSE	TRUE
TRUE	FALSE

Table 9: Hardware set-up

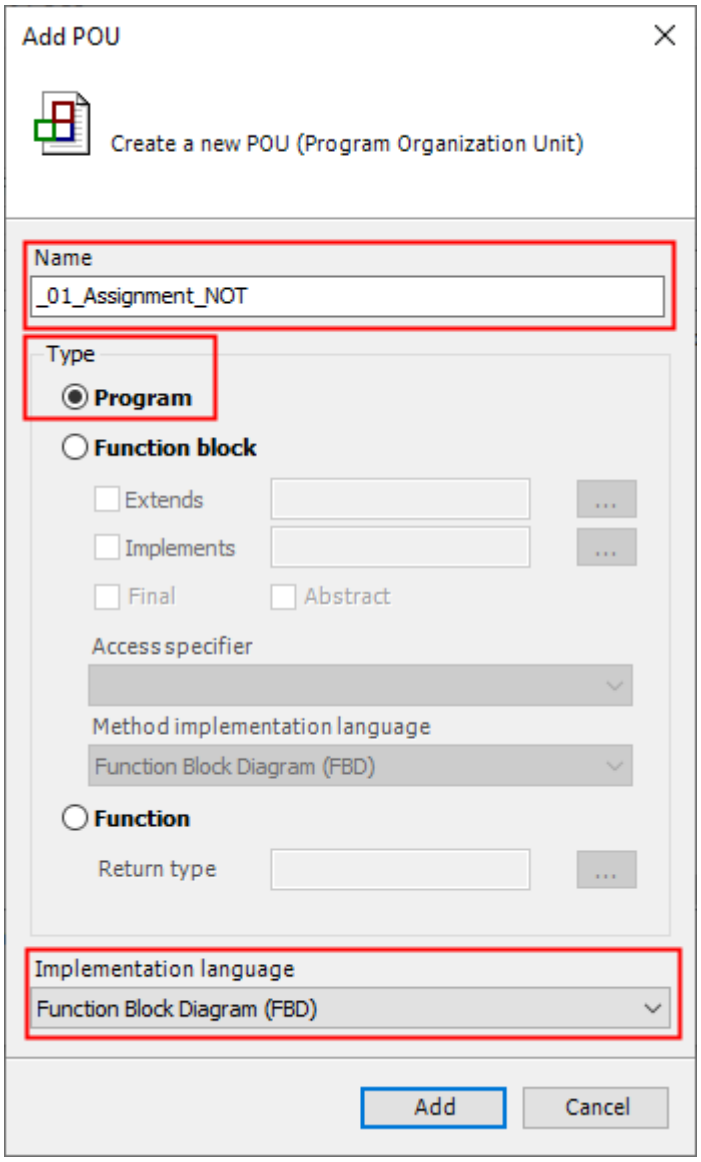
Element	HW channel	Symbol	Description
Switch I1	OnBoard_IO_I0	xDI_00_OnBoard_IO_I0	Photo sensor
LED output DO0	OnBoard_IO_O0	xStartDrilling1	Motor on

Implementation

Create a new program POU in the project



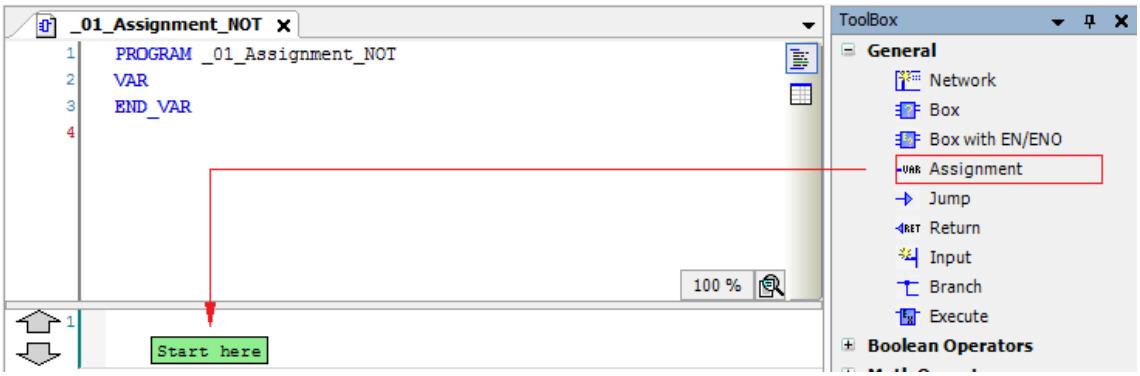
1. Right-click *“10 POUs”*.
2. Select *“Add object”*.
3. Select *“POU”*.
4. Select *“Add object”*.



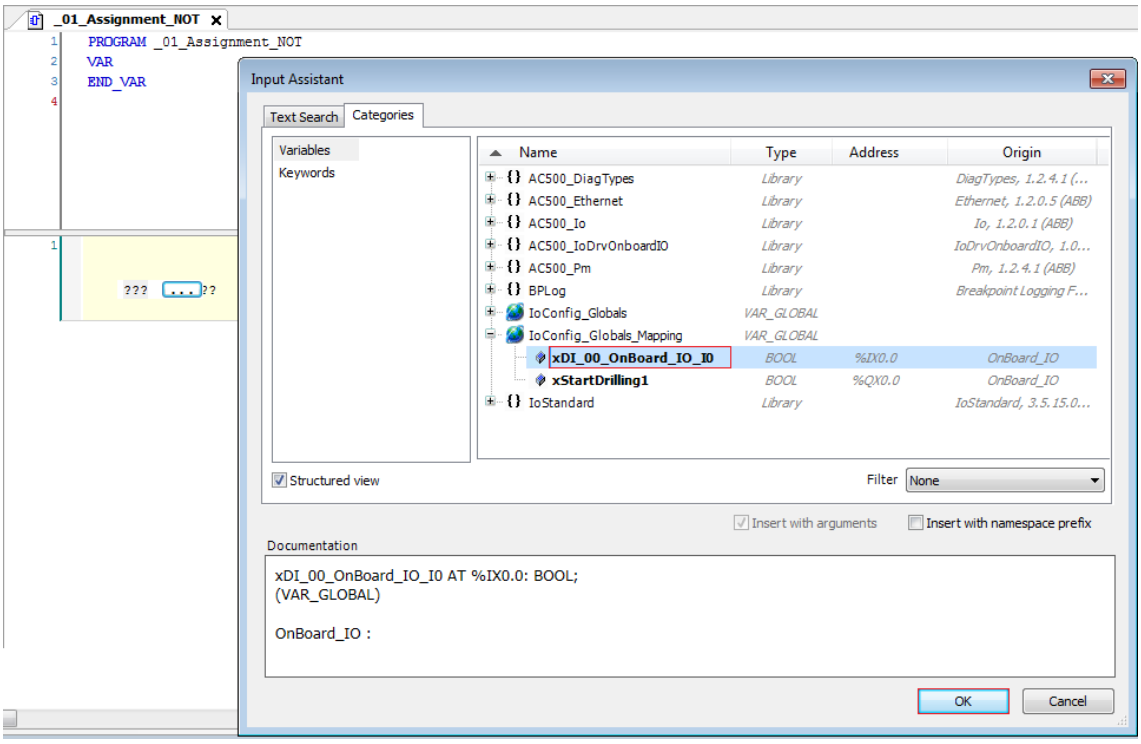
5. Enter *"_01_Assignment_NOT"*.
6. Select *"Program"*.
7. Select *"Function Block Diagram (FBD)"*.
8. Select *"Add"*.
   ⇨ POU has been added.

Assign the hardware DI signals to local variables

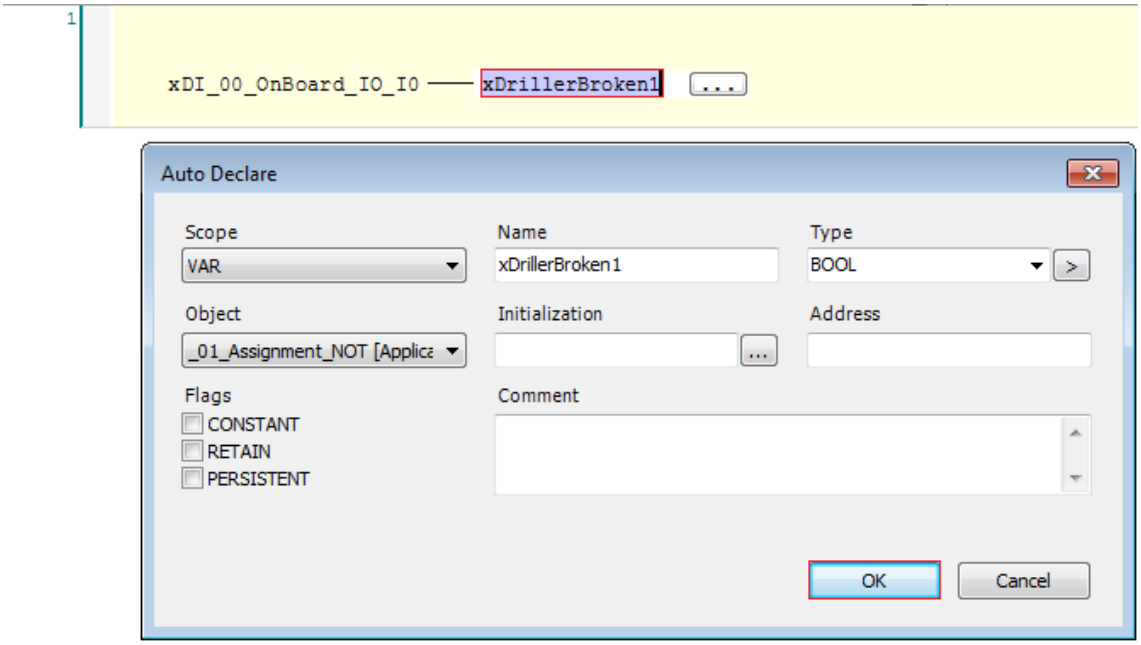
1. Double-click POU*"_01_Assignement_NOT"* in the device tree.



2. Select *"Assignment"* from the ToolBox.
3. Drag and drop *"Assignment"* into the "Start here" field in network *"1"*.



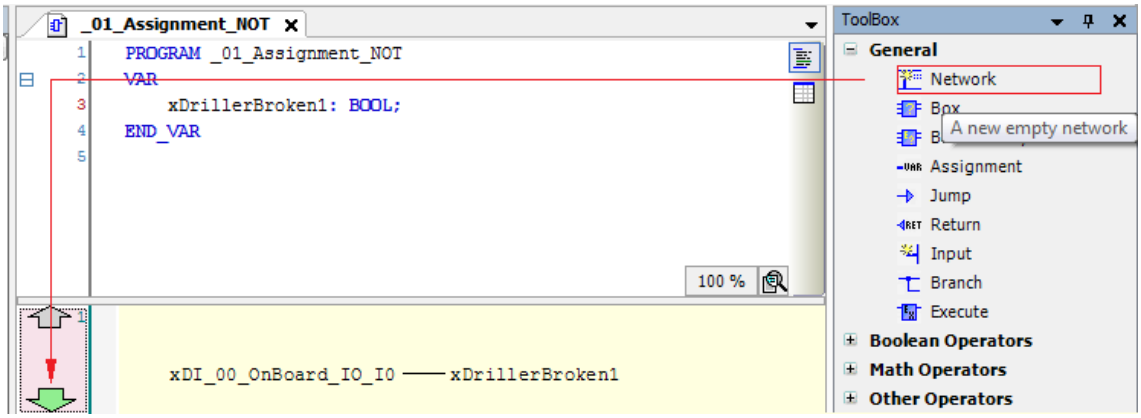
4. Select *"???"* on the left side of the assignment, then select *"..."*.
5. Open the *"Io Config_Globals_Mapping"* mapping list and select "xDI_00_OnBoard_IO_I0".
6. Select *"OK"* to add this variable to the left side of the assignment connector.



7. Select *"???"* on the right side of the assignment connector and mark the "???".
8. Create a new local variable by typing in "xDrillerBroken1" which will replace the "???".
9. Press *[Enter]*.

   ⇨ *"Auto Declare"* opens.

   You see the written variable name and the data type BOOL. The scope is "VAR". It means it is a local variable within this POU.
10. Select *"OK"* to accept the entries.



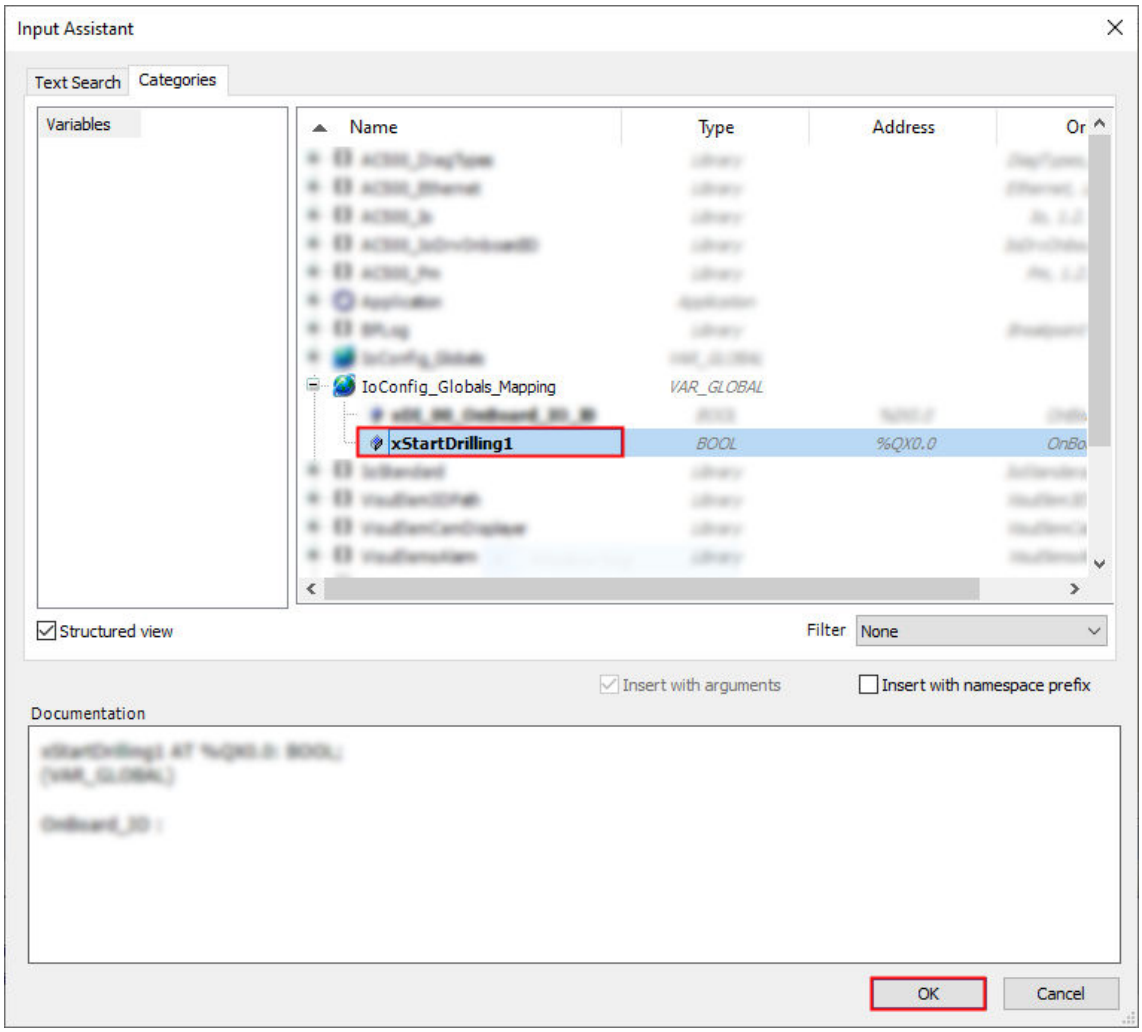
11. Drag and drop *"Network"* from the ToolBox to the down-arrow of network 1.

    ⇨ You added a network *"2"* below network 1.

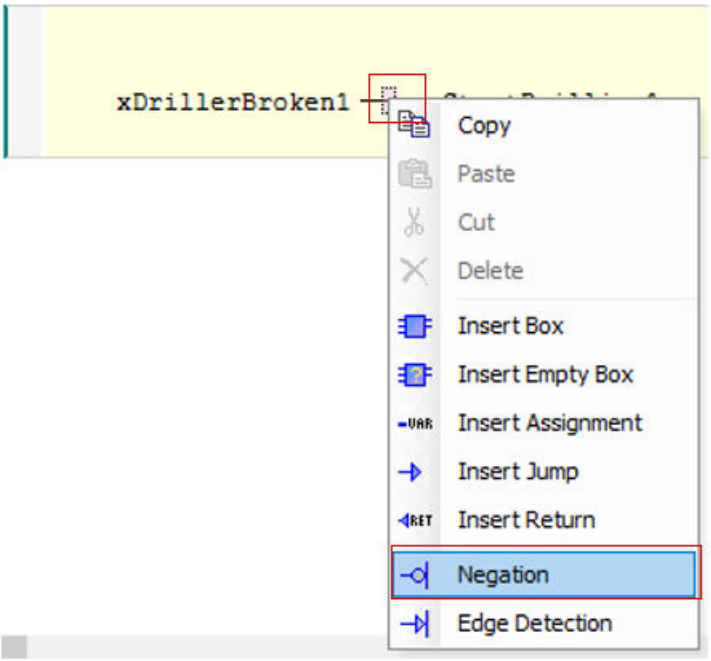
Add assignments and a Boolean NOT to the DO signals

1. Add an assingment from the ToolBox.
2. Type in or copy & paste "xDrillerBroken1" to the left side of the instruction line.
3. Select *"???"* on the right side of the instruction line, then select *"..."*.

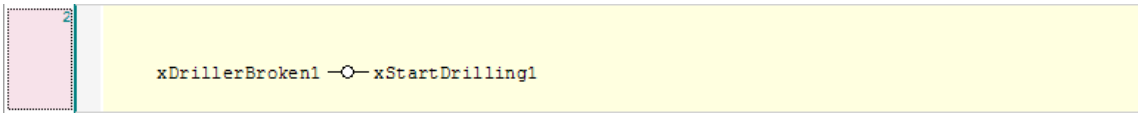
   ⇨ *"Input Assistant"* opens.



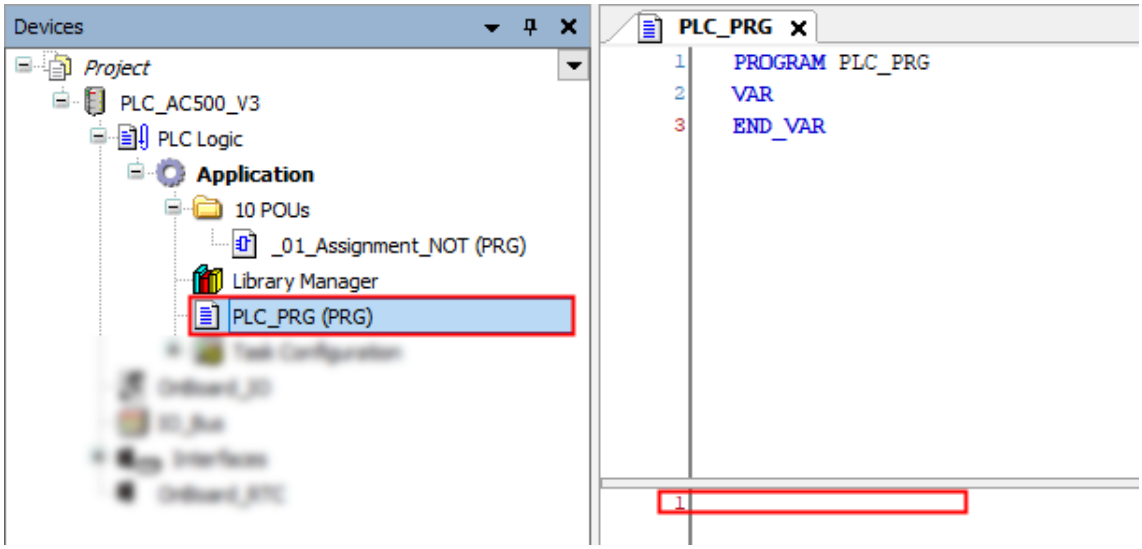
4. In the *"IoConfig_Globals_ Mapping"* variable list, select *"xStartDrilling1"*.
5. Select *"OK"* to close the dialog.



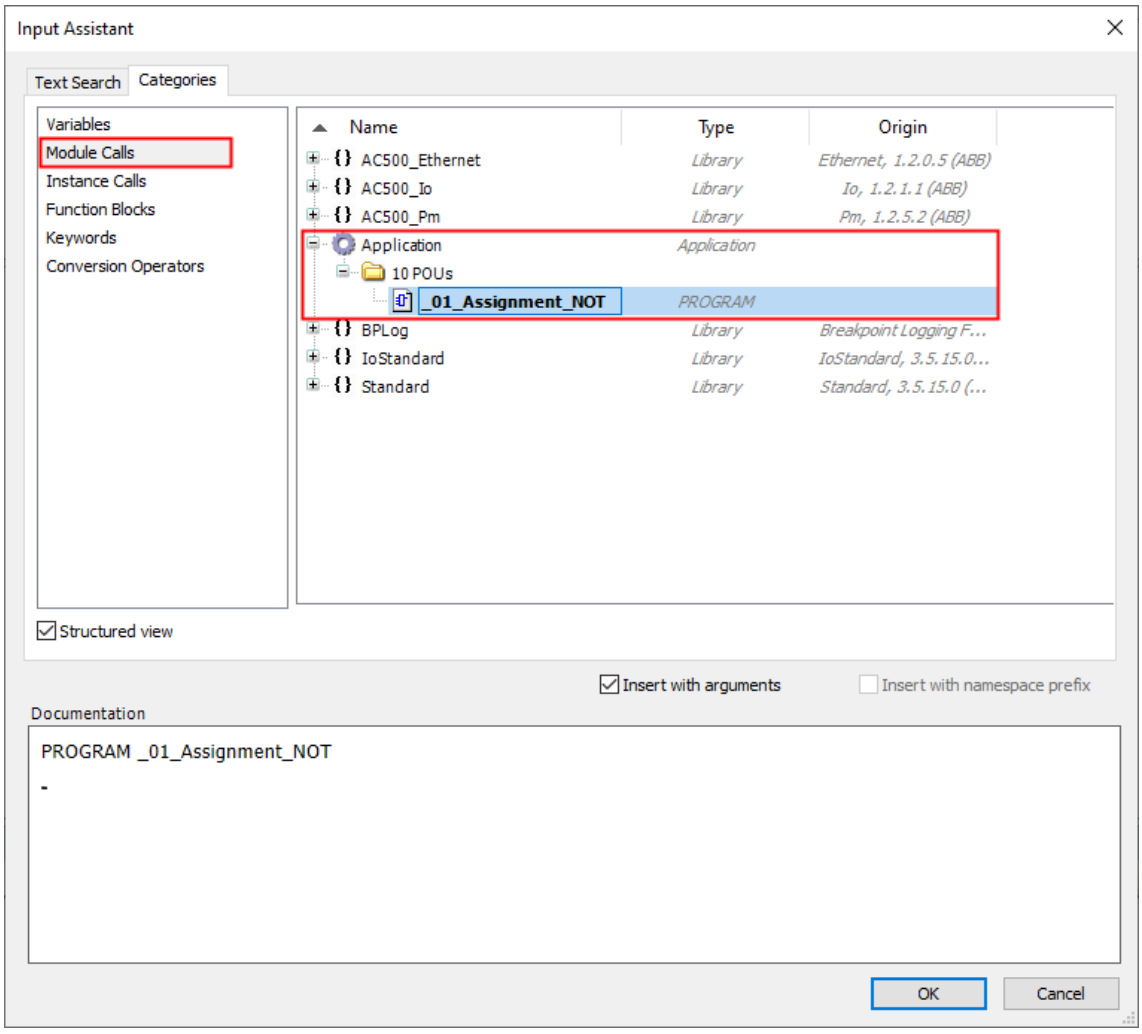
6. Right-click the center of assignment PIN.
7. Select *"Negation"* to add a negation to the assignment.



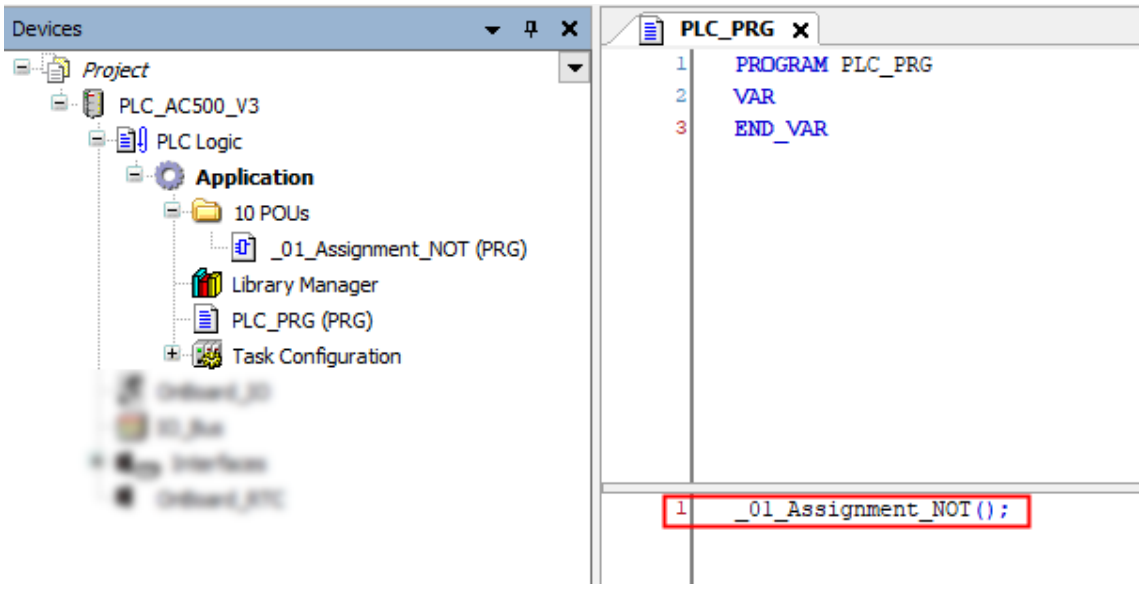
Call the POU in the PLC_PRG



1. Double-click *"PLC_PRG"*.
2. Select the first line in "PLC_PRG" and press *[F2]*.
   ⇨ *"Input Assistant"* opens.

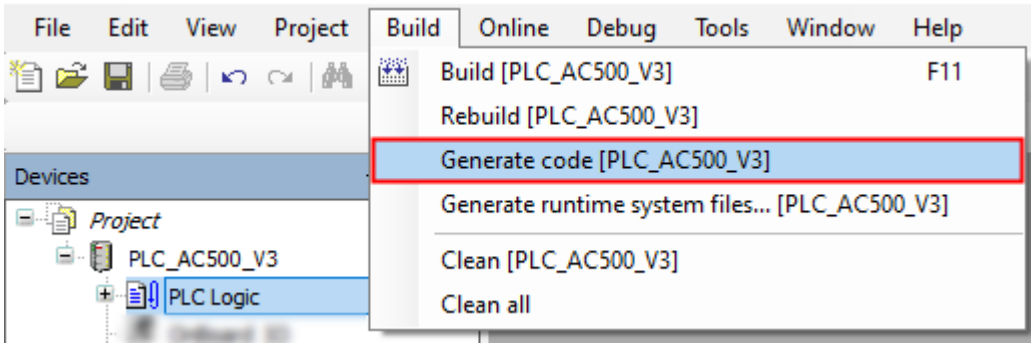


3. Select *“Module Calls”*.
4. Open *“Application”*.
5. Open *“10 POUs”* and select *“_01_Assignment_NOT”*.
6. Select *“OK”* to close the dialog.



Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

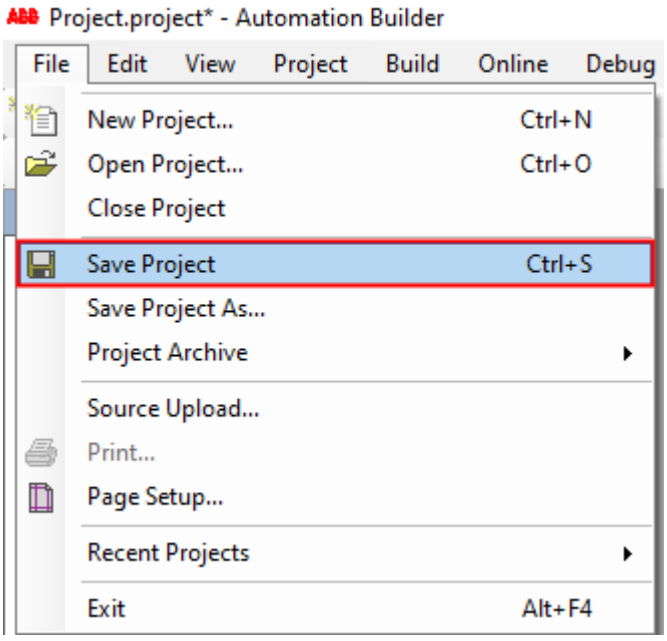


▷ Select menu *"Build ➔ Generate code"*.

⇨ The result of the compiling is shown in the *"Messages"* field at the bottom of the screen.

If you skip the compiling and select *"Login"*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save the project



▷ Select menu *"File ➔ Save Project"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl]* + *[S]*.

Set-up the communication gateway

Set-up communication parameters

To set-up the communication between the PC and the PLC, e.g., for downloading the compiled program, you have to set-up the communication parameters.

The IP address of your PC must be in the same class as the IP address of the CPU.

The factory setting of the IP address of the CPU is 192.168.0.10.

The IP address of your PC should be 192.168.0.X. Avoid X = 10 in order to prevent an IP conflict with the CPU.

Subnet mask should be 255.255.255.0.

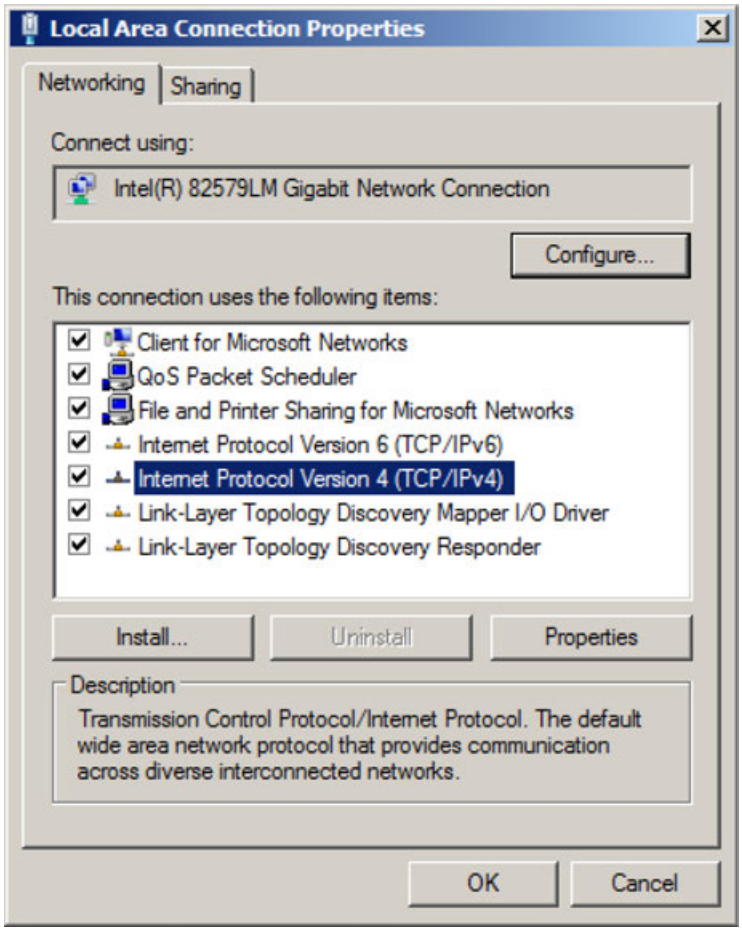
Change the IP address

1. Open Windows **Control Panel**. Click *"Network and Internet ➔ Network and Sharing Center"*.
2. Click **Change adapter settings**.

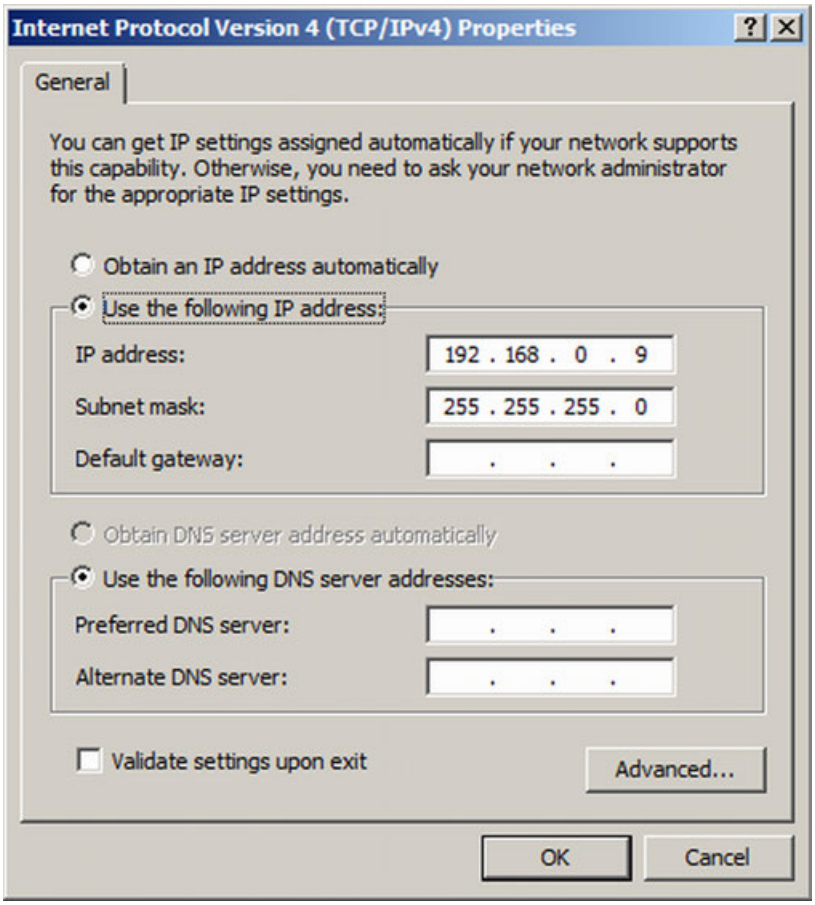
   ⇨

   If using existing network with several devices, please pay attention on given network rules or contact your system administrator.

3. Right-click **Local Area Connection (Ethernet)** and select **Properties**.



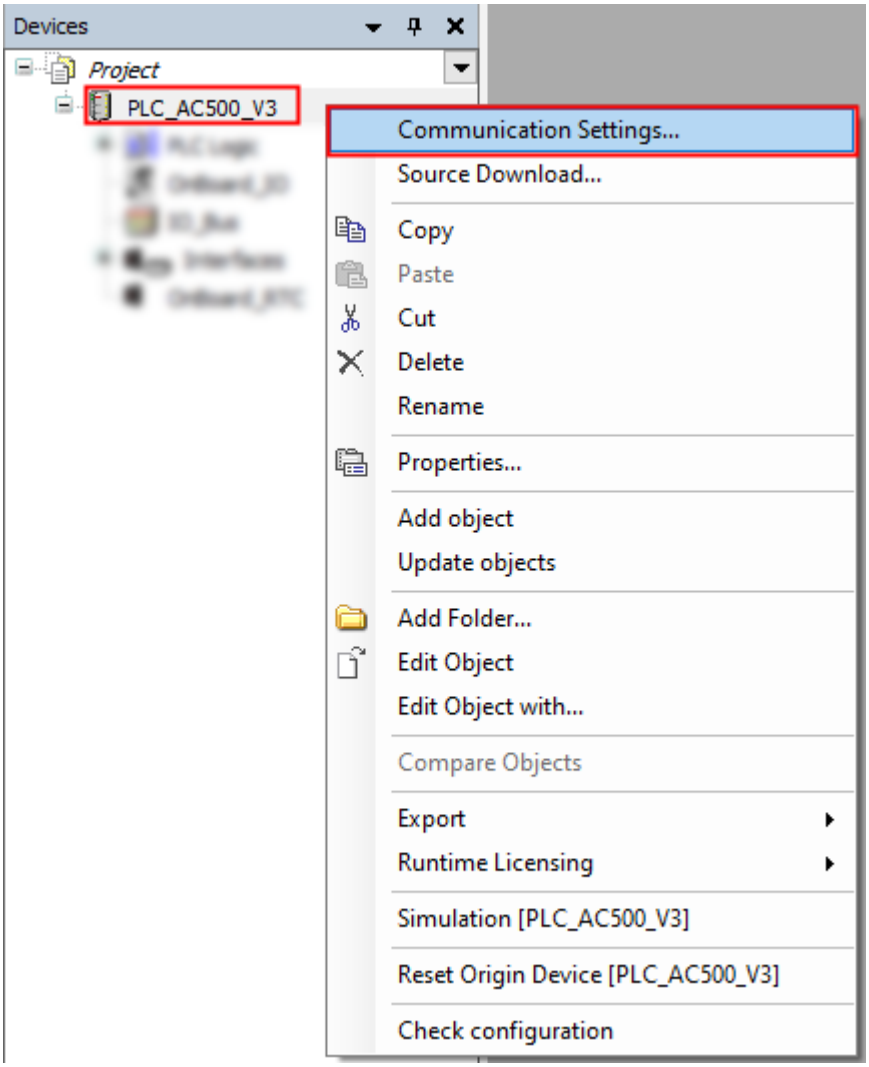
4. Double-click **Internet Protocol Version 4 (TCP/IPv4)**.



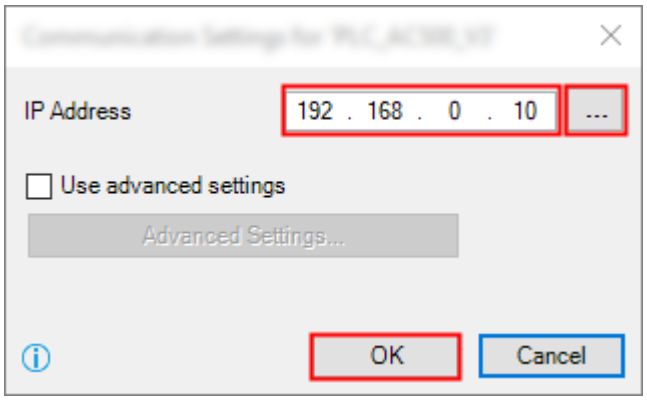
5. Enter your desired IP address and subnet mask.

Set-up the communication gateway

☑ CPU and PC are connected with an Ethernet cable.



1. In the Automation Builder device tree right-click *“PLC_AC500_V3”*.
2. Select *“Communication Settings”*.



3. Keep the default value in the IP address of the CPU or type in the current IP address, if differs.

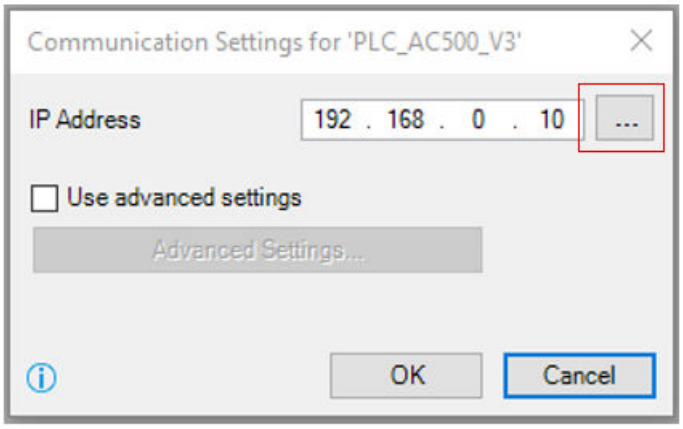
> *The standard (default) IP address of the port ETH1 is: 192.168.0.10*

4. Select *"OK"* to implement the IP address.

Network scan

If you need to scan the network for the CPU or if you have multiple CPUs on the same network.

1. Right-click *"PLC_AC500_V3"* in the device tree.
2. Select *"Communication Settings"*.



3. Select *"..."*.

   ⇨ *"Pick IP Address for "PLC_AC500_V3""* opens.

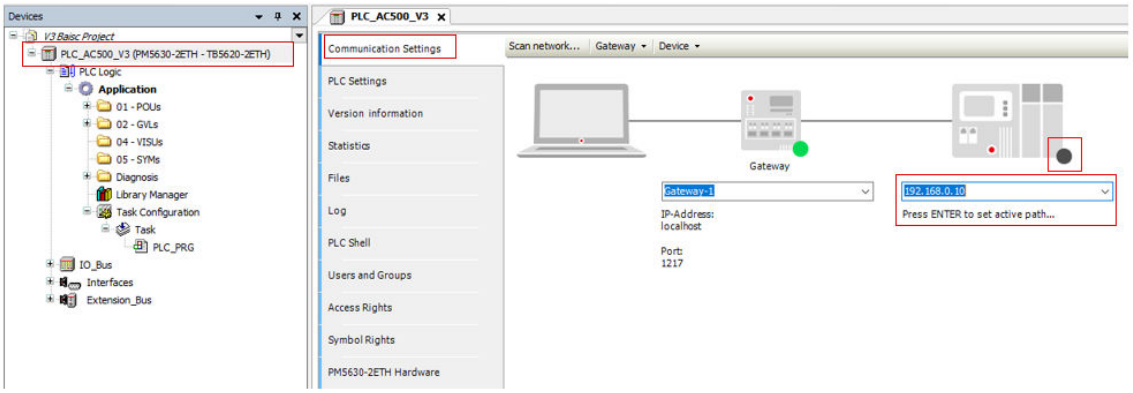
   The automatic scan runs.

   The results will appear in this field.

4. Select the CPU in the field and select *"OK"* to implement the needed communications gateway.

Check communication settings

If you need to check the communications settings or if you want to see more information about the current selected CPU.



1. Double-click *"PLC_AC500_V3"* in the device tree.

2. Select *“Communication Settings”*.

   ⇨ The selected IP address is shown.

3. If the IP address is not visible, enter the IP address manually.

4. To test the connection and/or to see the CPU information press *[Enter]* or click on the black dot next to the PLC figure.

AC500-eCo V3 firmware installation and update

The PLC firmware can be updated via Automation Builder.

> *This is also necessary for commissioning AC500-eCo V3 CPUs.*

A very new CPU has no pre-installed firmware. To guarantee the authenticity of delivered AC500-eCo firmware, V3 CPUs are delivered with a boot loader only. You need to download a valid firmware to the CPU. After download, the functionality of the CPU is given.

☑ An Automation Builder project with an AC500-eCo V3 CPU is open.

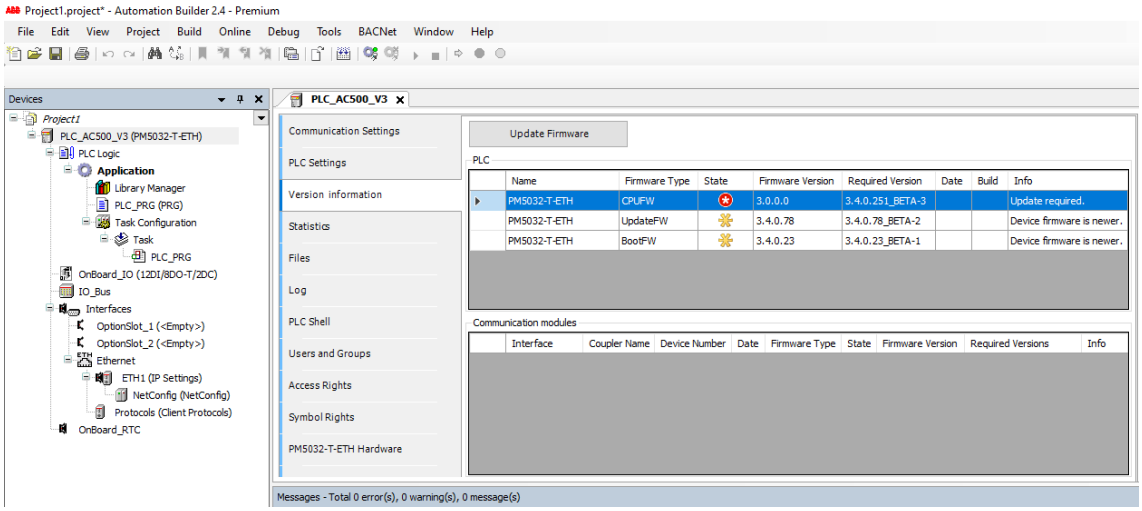
☑ CPU is in "stop" mode without firmware.

☑ The power LED is ON.

☑ For new modules: IP address is set. (The default IP address is 192.168.0.10)

1. Double-click CPU *“PLC_AC500_V3”*.

2. Select *“Version information”*.



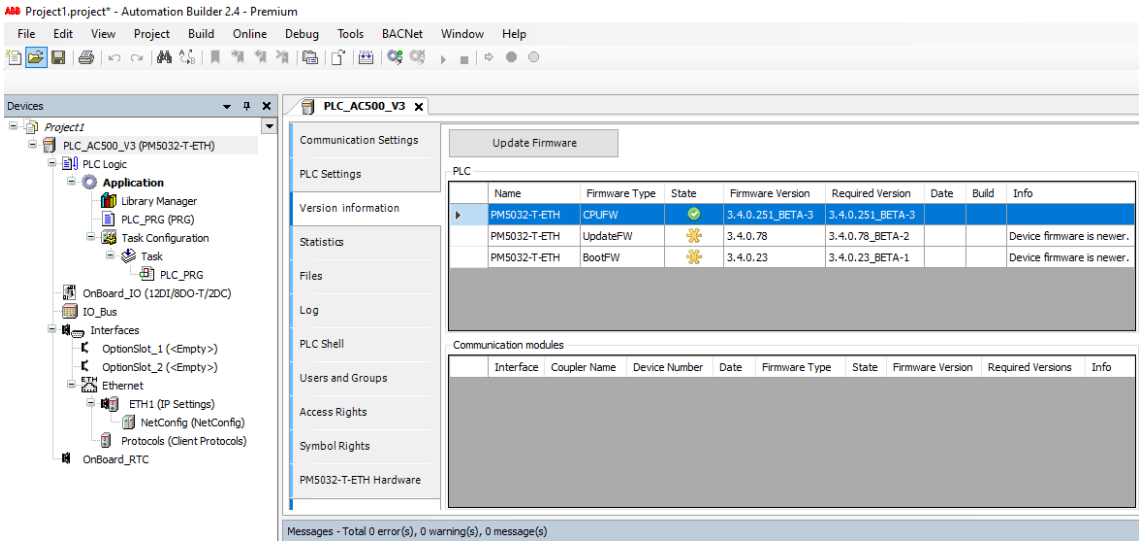
3. Select *[Update Firmware]*.

   ⇨ While the update process is running, the RUN and ERR LEDs are toggling, i.e., they are flashing alternating.

4. Wait for the PLC to finish the update.

> **NOTICE!**
> Do not disconnect the power supply during the update process! The PLC could be damaged.

5. If necessary, refresh the version information by switching to another tab and back.
   ⇨ Successful firmware update:



Behavior of LEDs during firmware update

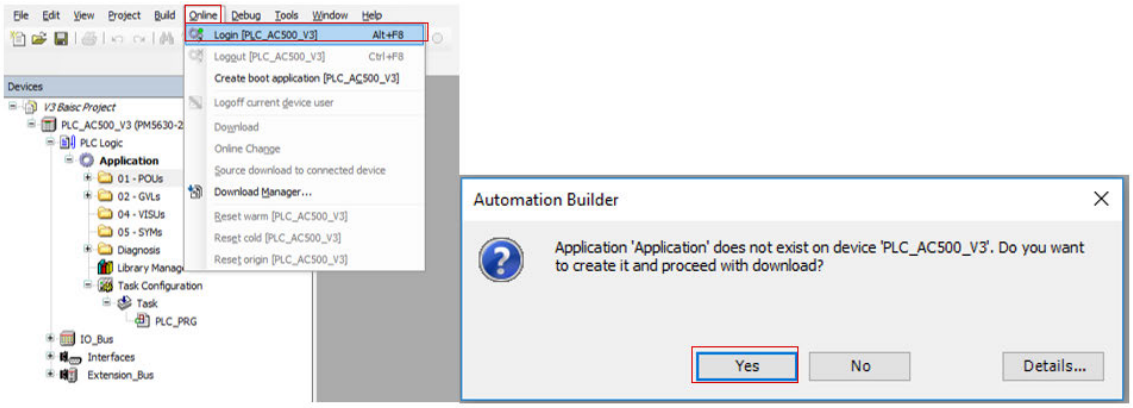
- CPU without firmware, only the power LED is on.
- While the firmware update process is running, the RUN and ERR LEDs are toggling, i.e., they are flashing alternating.

LED	LED flashes	Status
RUN and ERR	Toggling	Update pending
RUN	Flashing slow	Done successful
ERR	Flashing slow	Done failed

- CPU with installed firmware, only the power LED is on.
- If the CPU is running, then the RUN LED is on.
- If the CPU is in STOP mode, the RUN LED is off.

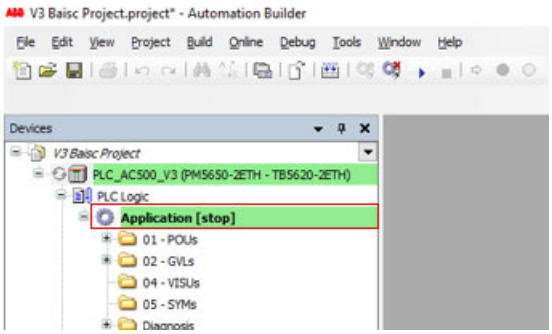
Log-in to CPU and download the program

Logging-in to the CPU will load the project into the AC500 V3 CPU. The first log-in will also load the hardware set-up.

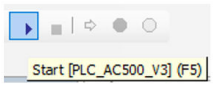


1. In the Automation Builder menu select *“Online ➔ Login [PLC_AC500_V3]”*.
   ⇨ A pop-up will appear.

2. Select *“Yes”* to download the application to the AC500V3 CPU.



⇨ PLC is in "stop" mode.



3. Start the PLC ↳ *Chapter 1.2.18.2.2.8.1 “Start the program execution” on page 149*.

> *Generally, if the CPU is in RUN mode, i.e. in program execution mode, a download will always cause the mode change to "stop". In stop mode the CPU is not controlling the system!*
>
> *Always, after selecting the "Login" command, read carefully the dialog box text to ensure that you are aware of the CPU’s behavior after the command confirmation.*

By default, a download generates following actions in the CPU:

- The project is stored in the RAM memory.
- The project is stored in the flash EEPROM, if boot application was created.

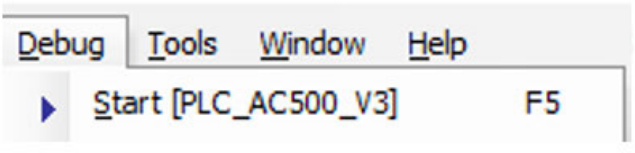
Test the program

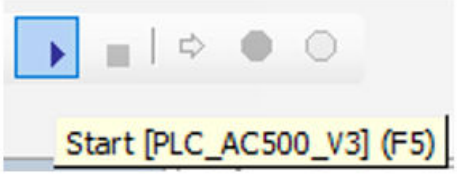
Start the program execution

☑ You are logged in the CPU.

☑ An executable project is loaded to the CPU.

☑ The CPU is in "stop" mode.





▷ Select menu *“Debug ➔ Start [PLC_AC500_V3]”*.

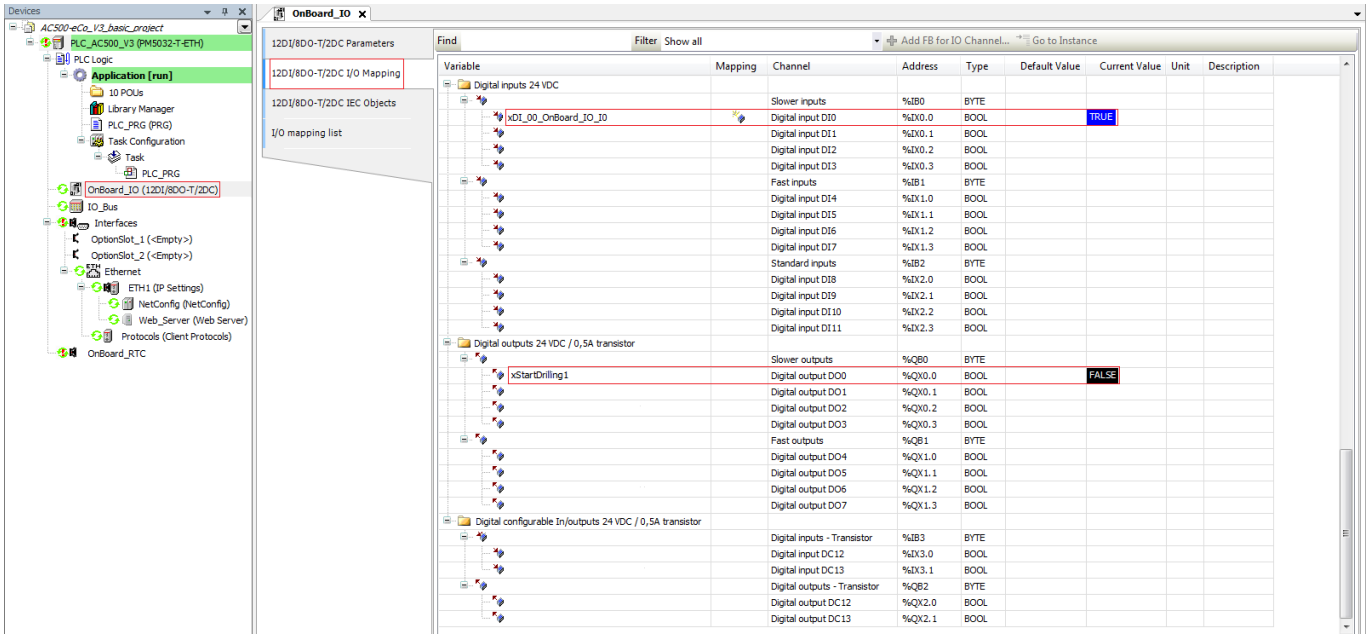
Alternatively, select the "start" icon in the tool bar.

Alternatively, press *[F5]*.

Test the function

▷ Operate the switch I1 and observe:

- The LEDs of the relevant onboard I/O inputs and outputs.
- The online status of inputs and outputs within the POU.

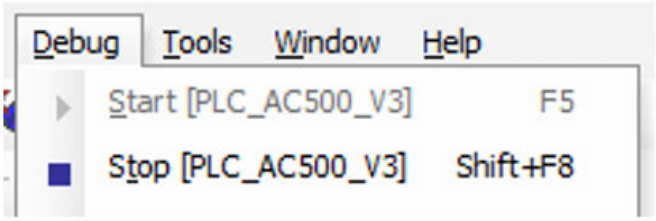


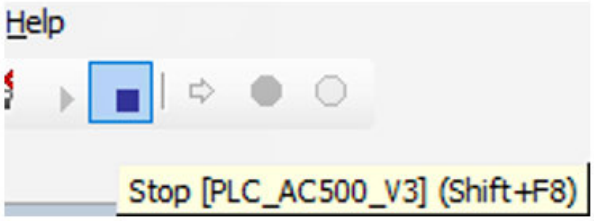
Stop the program execution

☑ You are logged in the CPU.

☑ An executable project is loaded to the CPU.

☑ The CPU is in RUN mode.





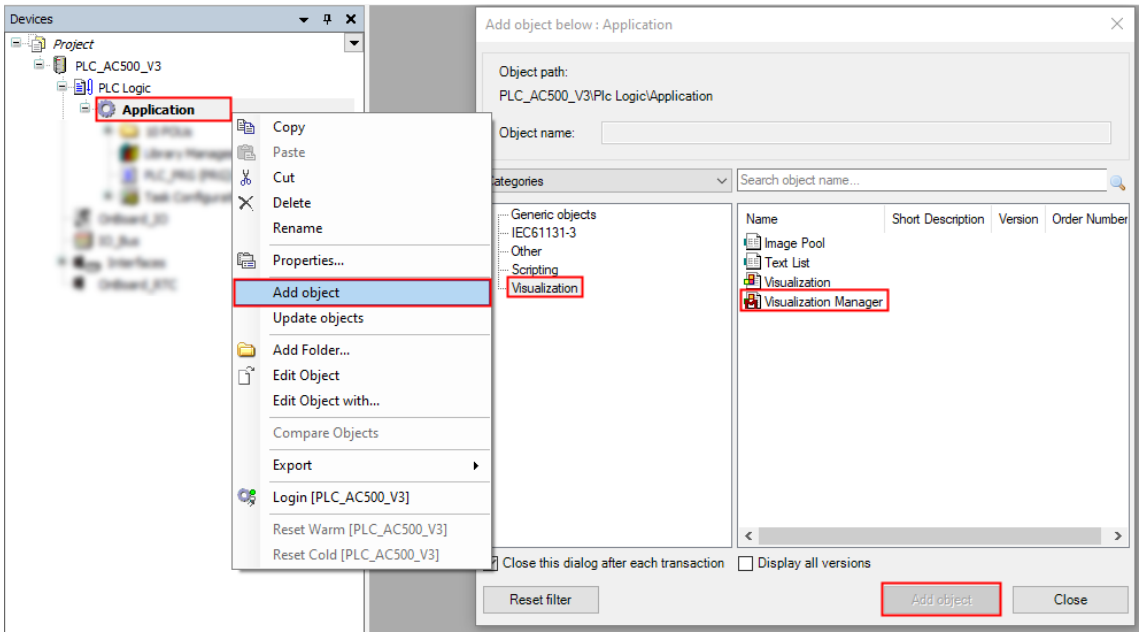
▷ Select menu *“Debug ➔ Stop [PLC_AC500_V3]”*

Alternatively, select the "stop” icon in the tool bar.

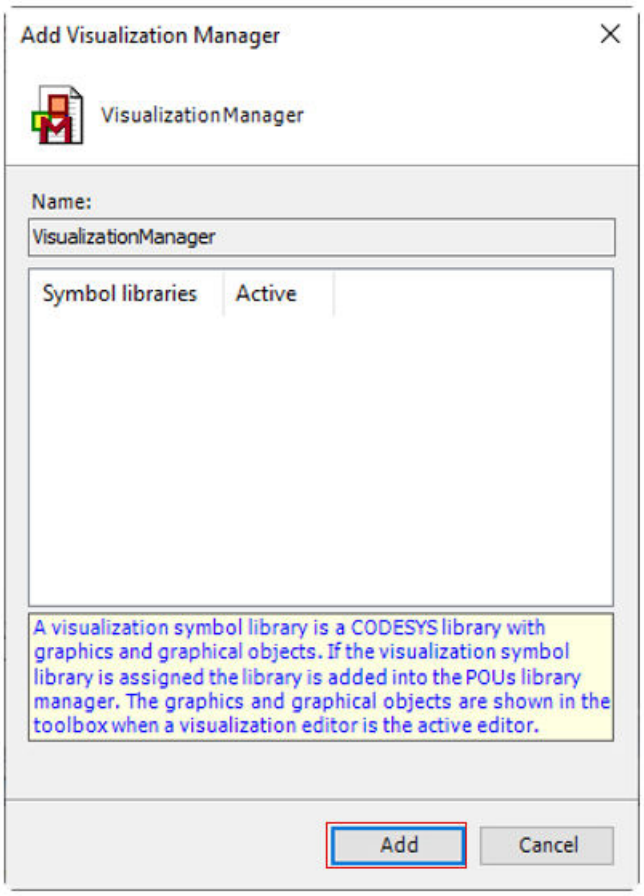
Alternatively, press *[Shift]* + *[F8]*.

Set-up visualization

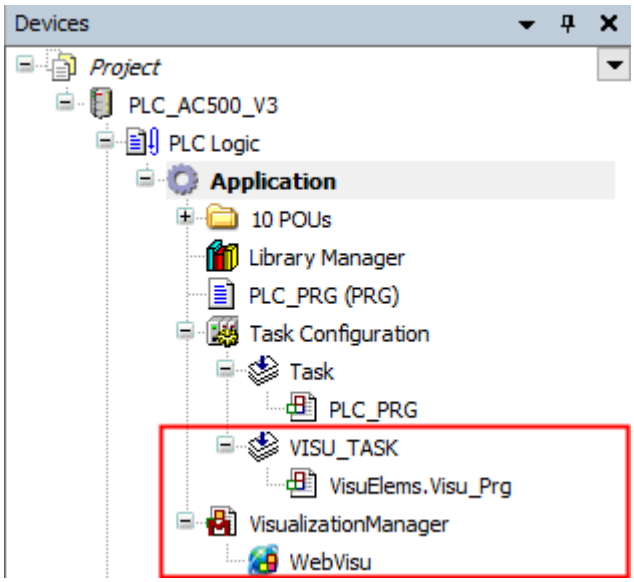
Add the VisualizationManager



1. Right-click *“Application”* in the device tree.
2. Select *“Add object”*.
3. Select *“VisualizationManager”*.
4. Select *“Add object”* to add the VisualizationManager to the project.
   ⇨ Dialog *“Add Visualization Manager”* opens.

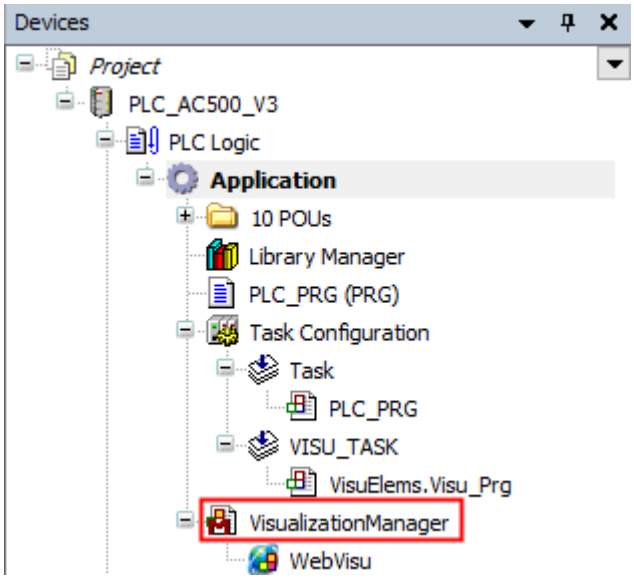


5. Select *“Add”*.

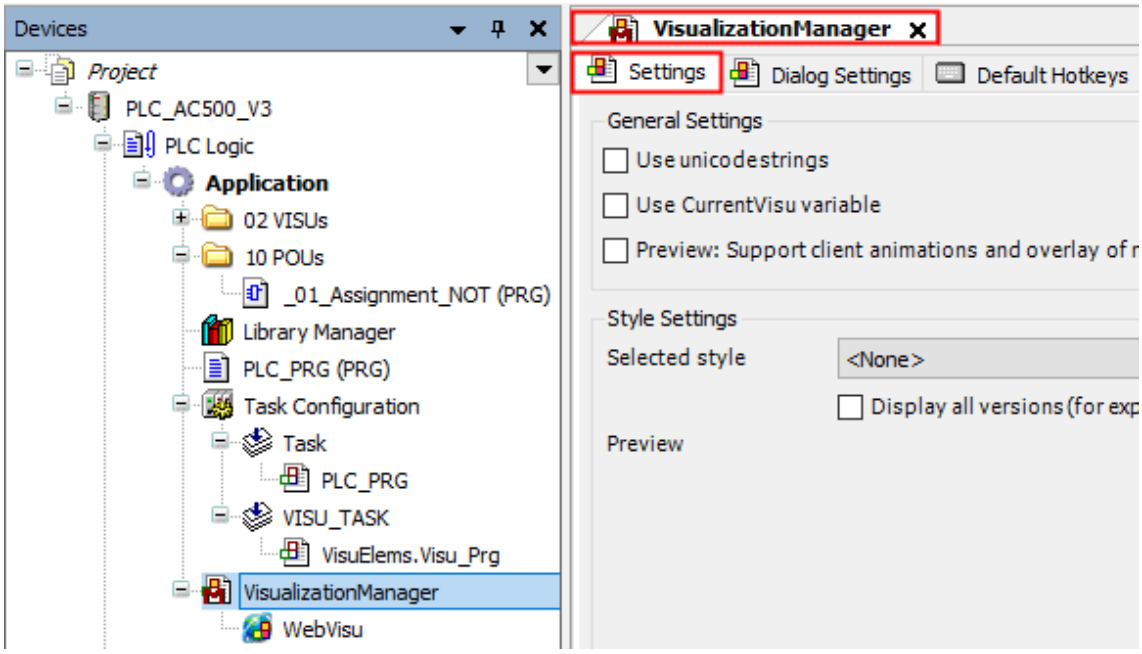


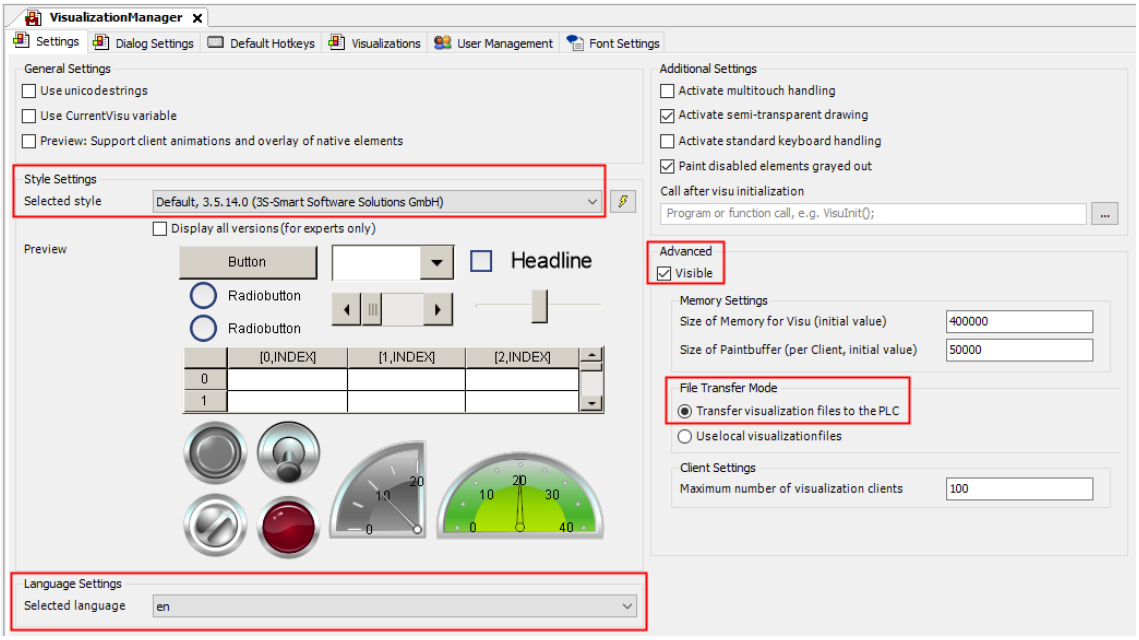
⇨ You added the objects *“VisualizationManager”* and *“VISU-TASK”* to the device tree.

Set-up the VisualizationManager



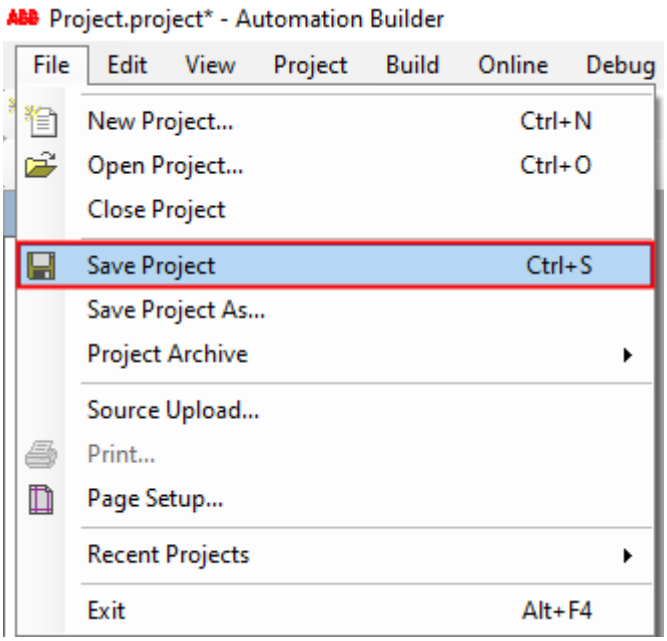
1. Double-click VisualizationManager in the device tree.
   ⇨ A tab opens in the editor view.





2. Select *“Settings”*.
3. Open the drop-down menu *“Selected style”*.
4. Select *“Default, x.x.x”* (exemplary).
5. Open the drop-down menu *“Selected language”*.
6. Select *“en”* for English language in the visualization.
7. Enable *“Visible”* for advanced settings.
8. Keep the file transfer to enable the visualization on the PLC (mandatory for web server function ↳ *Chapter 1.2.18.2.2.11 “Enable web visualization” on page 163*).

Save the project



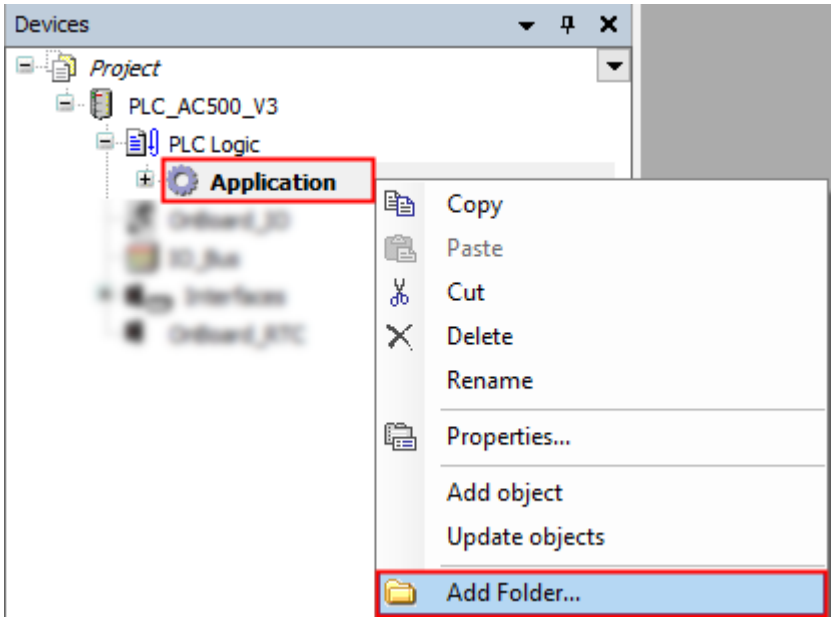
▷ Select menu *“File ➔ Save Project”*.

Alternatively, select the save icon in the tool bar.

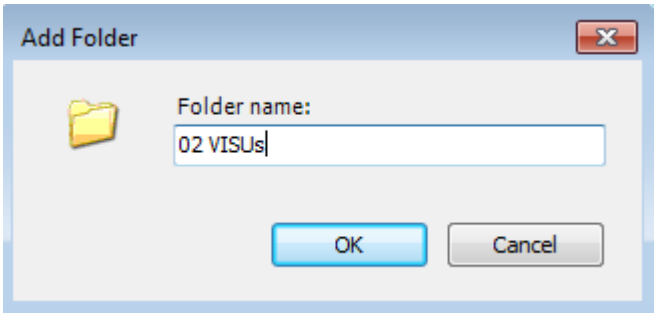
Alternatively, press *[Ctrl] + [S]*.

Create visualization

Add a folder for visualization screens

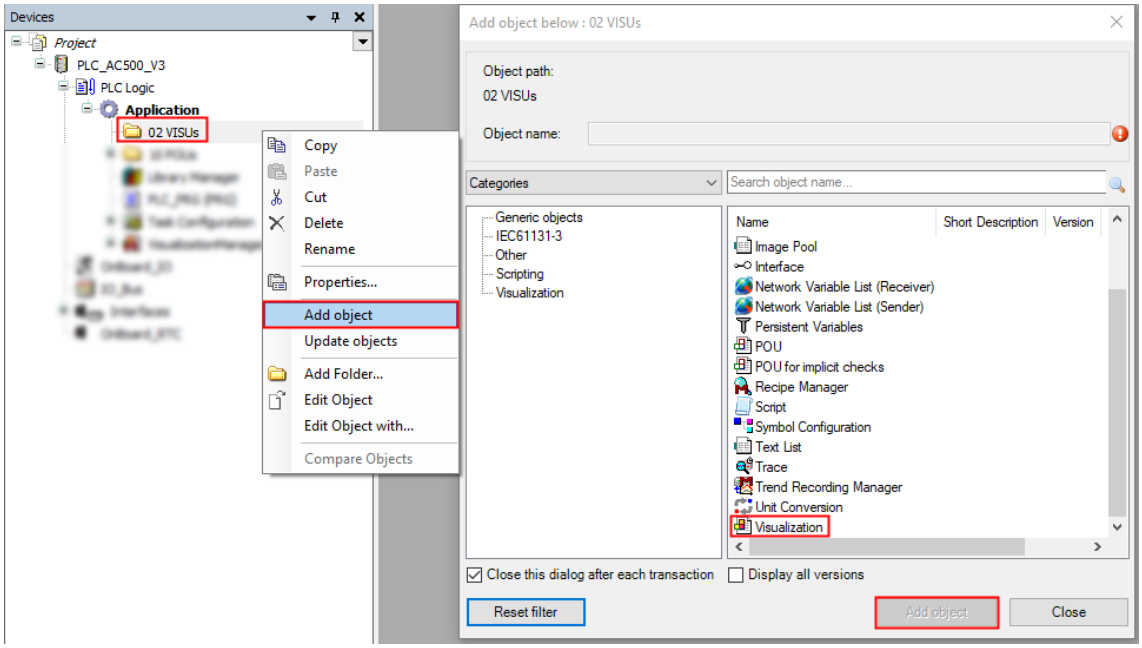


1. Right-click *“Application”* in the device tree.
2. Select *“Add Folder”*.

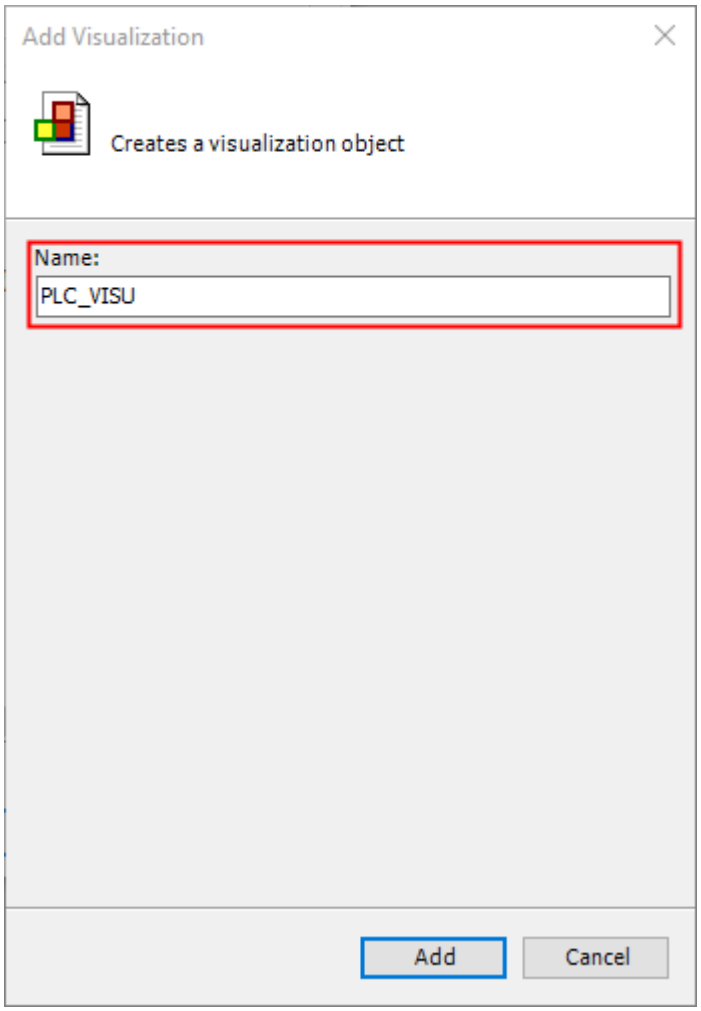


3. Type in "02 VISUs".
4. Select *“OK”* to add the folder.

Add a screen for "_01_Assignment_NOT" POU



1. Right-click *“02 VISUs”*.
2. Select *“Add object”*.
3. Select object *“Visualization”*.
4. Select *[OK]*.



5. Type in "PLC_VISU".
6. Select *“Add”*.
   ⇨ A tab opens in the editor view.

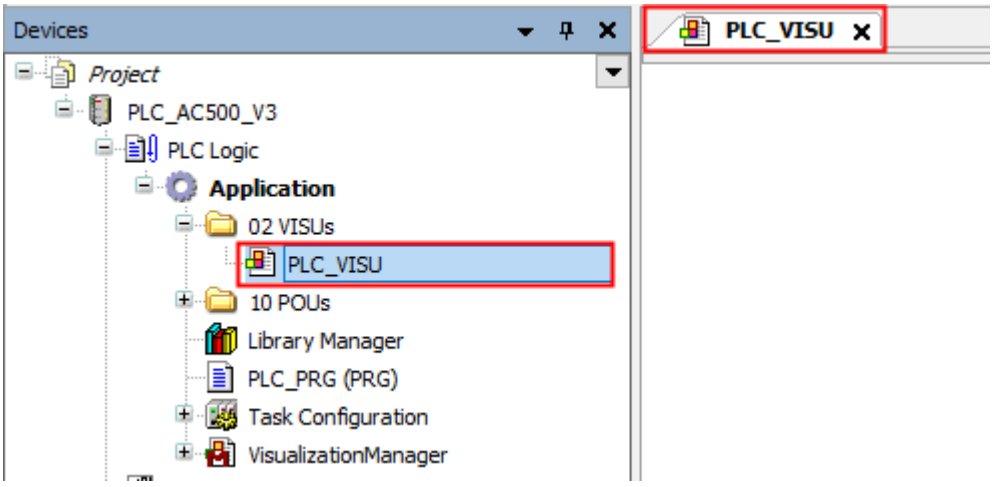


Fig. 10: PLC_VISU_tab

The name "PLC_VISU" has been chosen, because it is the default name for a home screen in a web visualization.

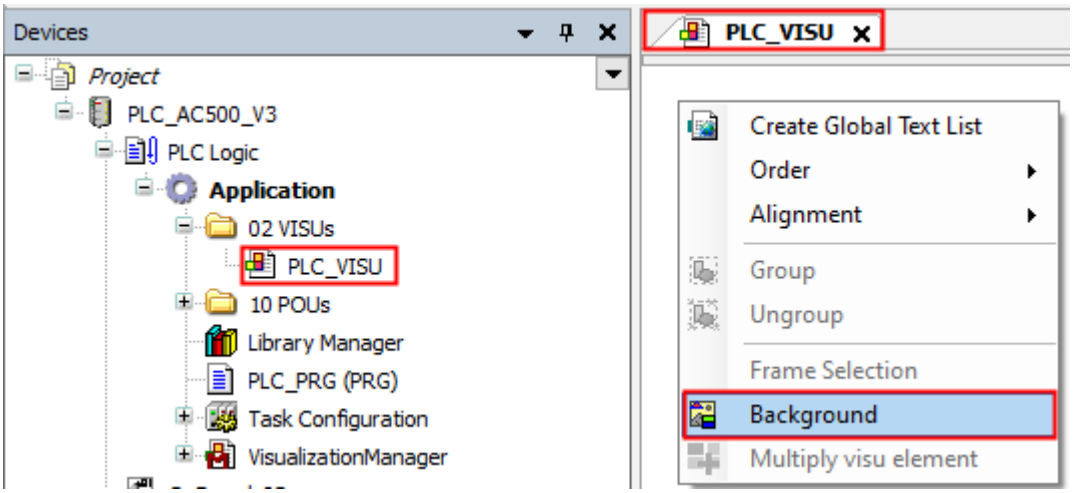
If you have more than one visualization object in your project, it will be useful to choose another name, e.g. "_01_Assignment_NOT_v". And to choose "PLC_VISU" as a home screen to access all available visualization screens.

The name of a visualization object can be modified afterwards.

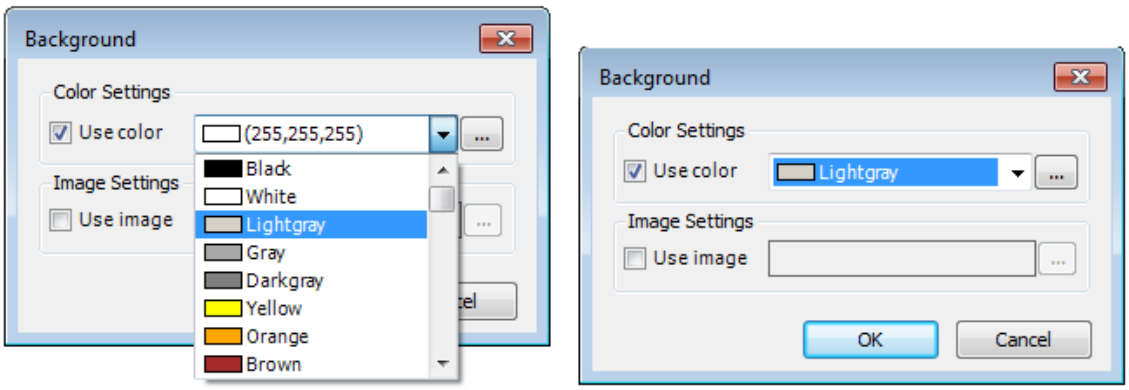
Creating and configuring of visualization

Change background color

1. Double-click *“PLC_VISU”* in the device tree.
   ⇨ A tab opens in the editor view.



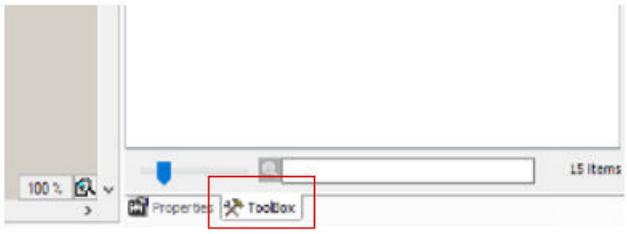
2. Right-click anywhere on the "PLC_VISU" editor page.
3. Select *“Background”*.



4. Enable the check box *“Use Color”*.
   ⇨ This enables the drop-down menu.
5. Select a color, e.g., *“Lightgray”*.
6. Select *[OK]* to add the color to "PLC_VISU".

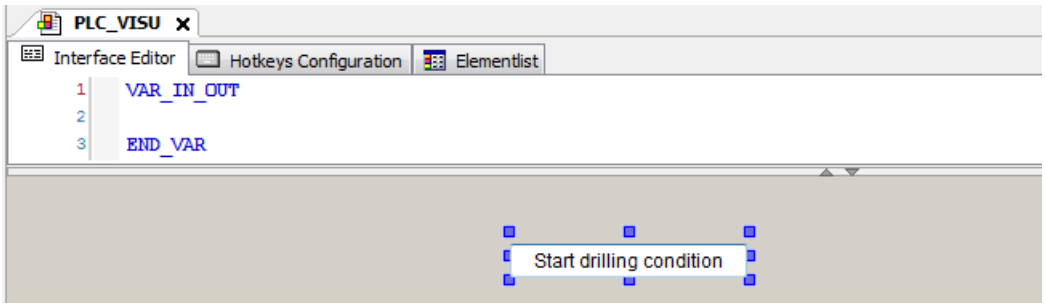
Add a screen title

1. Double-click on *“PLC_VISU”* in the device tree.



2. Select *“ToolBox”*.

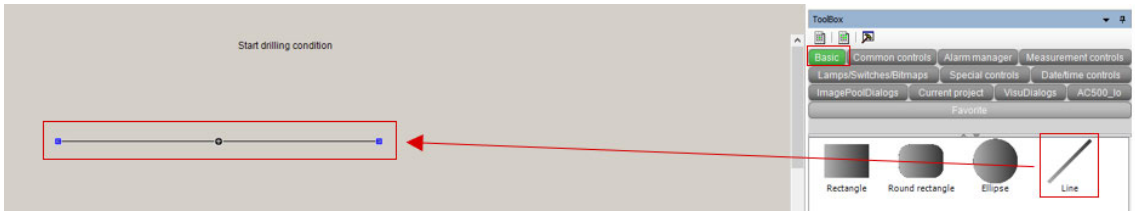
3. Select *“Common controls”*.
4. Drag and drop *“Label”* to the page.



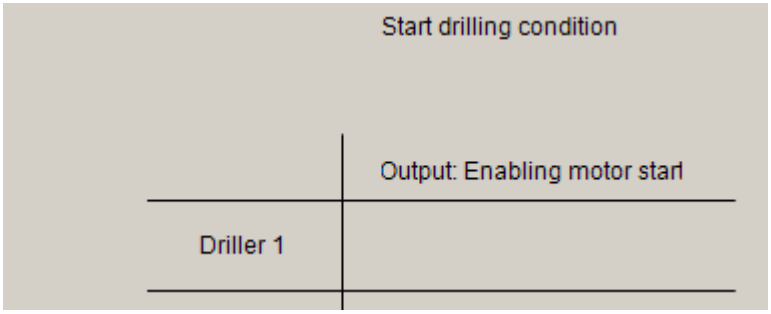
5. Type in "Start drilling condition".

Further lines and labels

1. Double-click on *“PLC_VISU”* in the device tree.



2. Select *“ToolBox”*.
3. Select *“Basic”*.
4. Drag and drop the line. Then drag the line to the needed length.

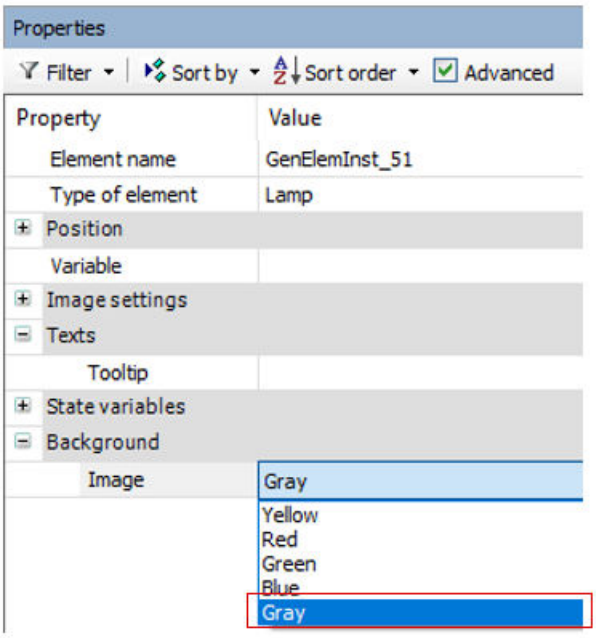


5. Follow the same procedure to create the other shapes and labels.

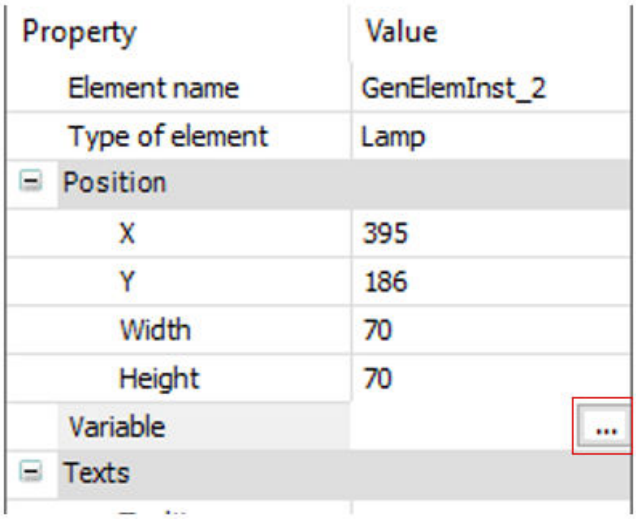
Lamp element for signal indication

1. Double-click on *“PLC_VISU”* in the device tree.

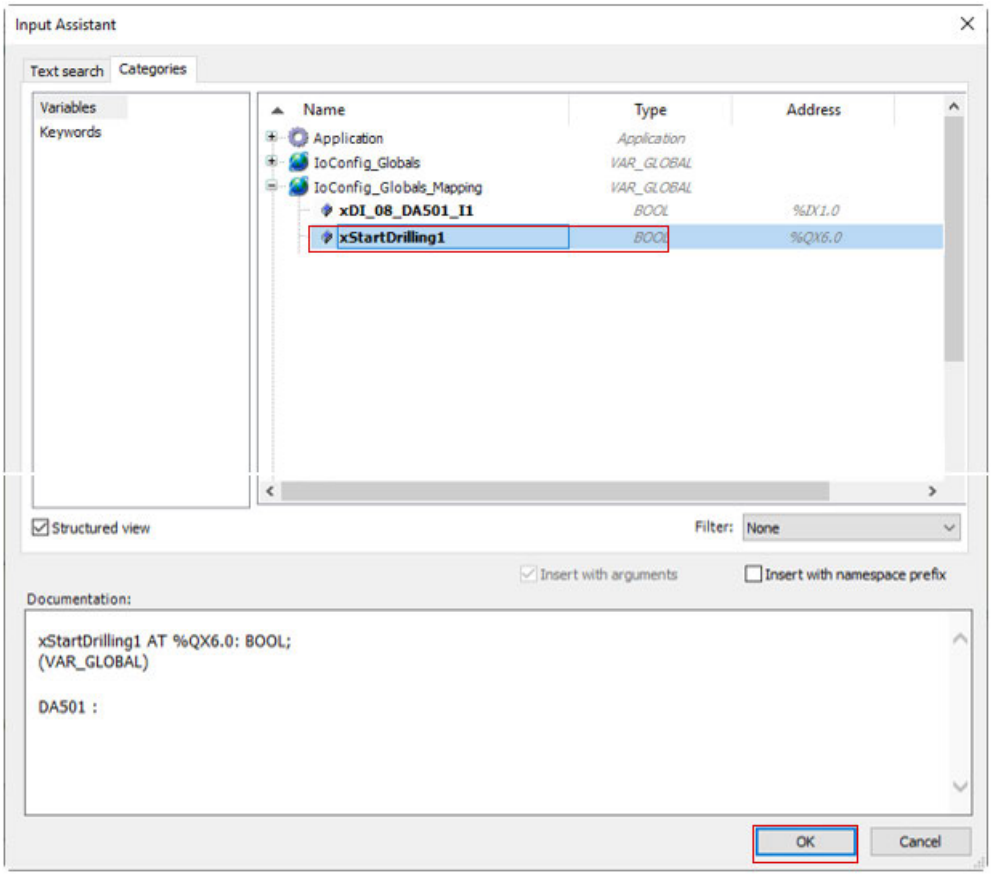
2. Select *“ToolBox”*.
3. Select *“Lamps/Switches/Bitmaps”*.
4. Drag and drop *“Lamp”* to the screen.
5. Adapt the size, if required.



6. Under *“Image”*, select *“Gray”*.



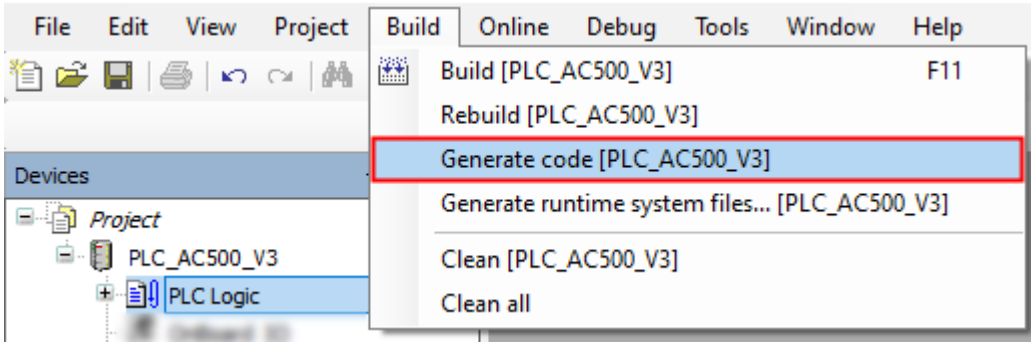
7. Double-click on *"Variable"* and select *"..."* to select a variable from the list.



8. Under *"IoConfig_Globals_Mapping"*, select *"xStartDrilling1"*.
9. Select *[OK]*.

Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

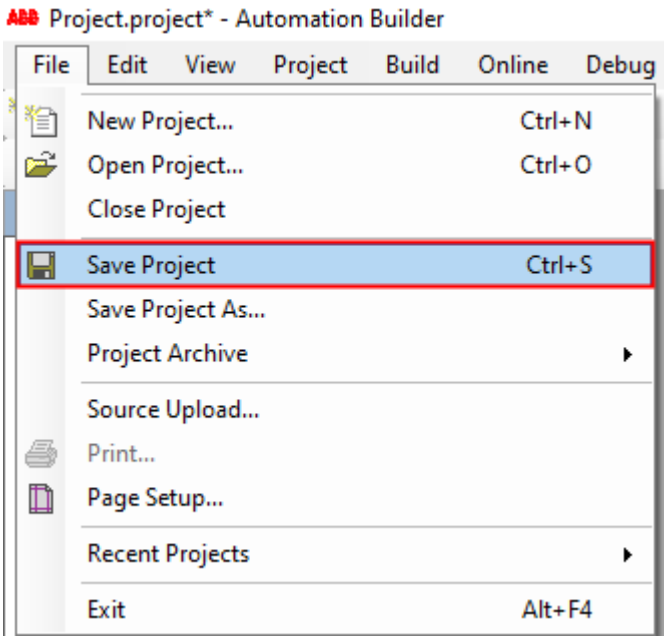


▷ Select menu *"Build ➔ Generate code"*.

⇨ The result of the compiling is shown in the *"Messages"* field at the bottom of the screen.

If you skip the compiling and select *"Login"*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save the project



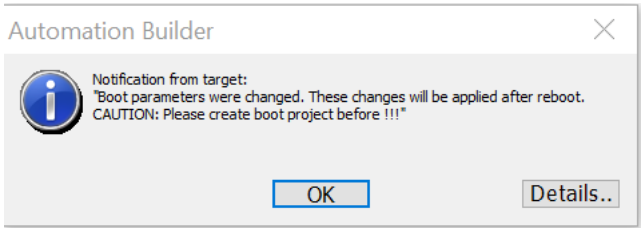
▷ Select menu *"File ➔ Save Project"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl] + [S]*.

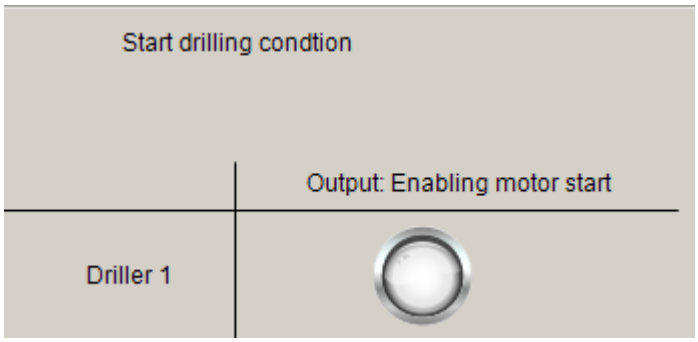
Loading the project to the CPU

1. Download the project to the CPU ↬ *as described in Chapter 1.2.18.2.2.7 , on page 148*.
2. Check the notification window at the end of the download. In case of message "Boot parameters were changed. These changes will be applied after reboot", a reboot of the CPU is required after creation of the boot project.



Test the program

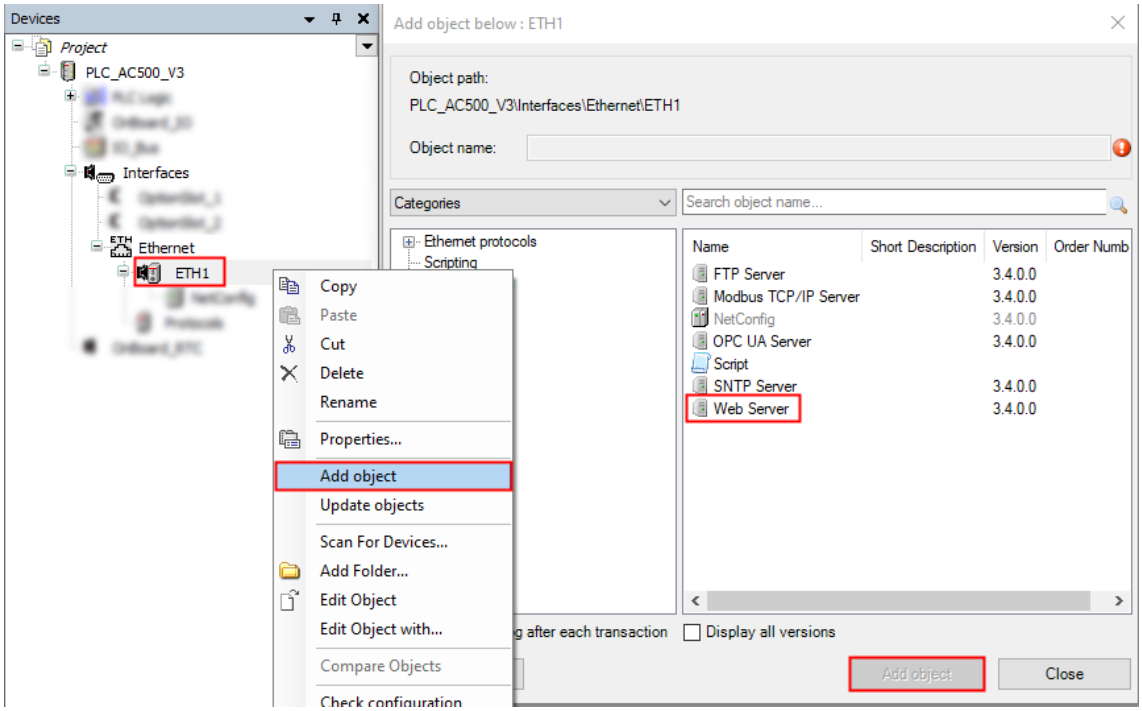
▷ Operate the switches and observe the visualization screen.



Enable web visualization

Add a web server object to the device tree

Ethernet ports can be configured for web server protocol. This description deals with ETH1 configuration for the web server

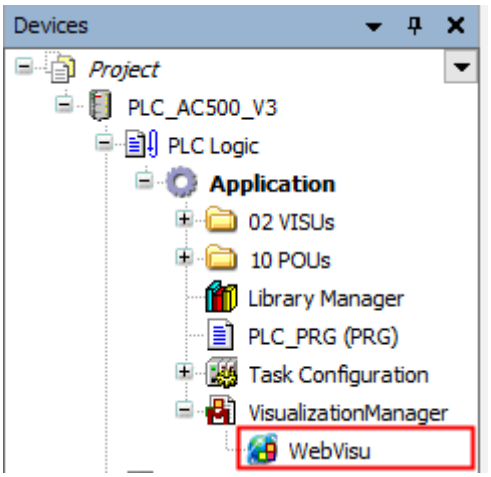


1. Right-click *“ETH1”* in the device tree.
2. Select *“Add object”*.
3. Select *“Web Server”*.

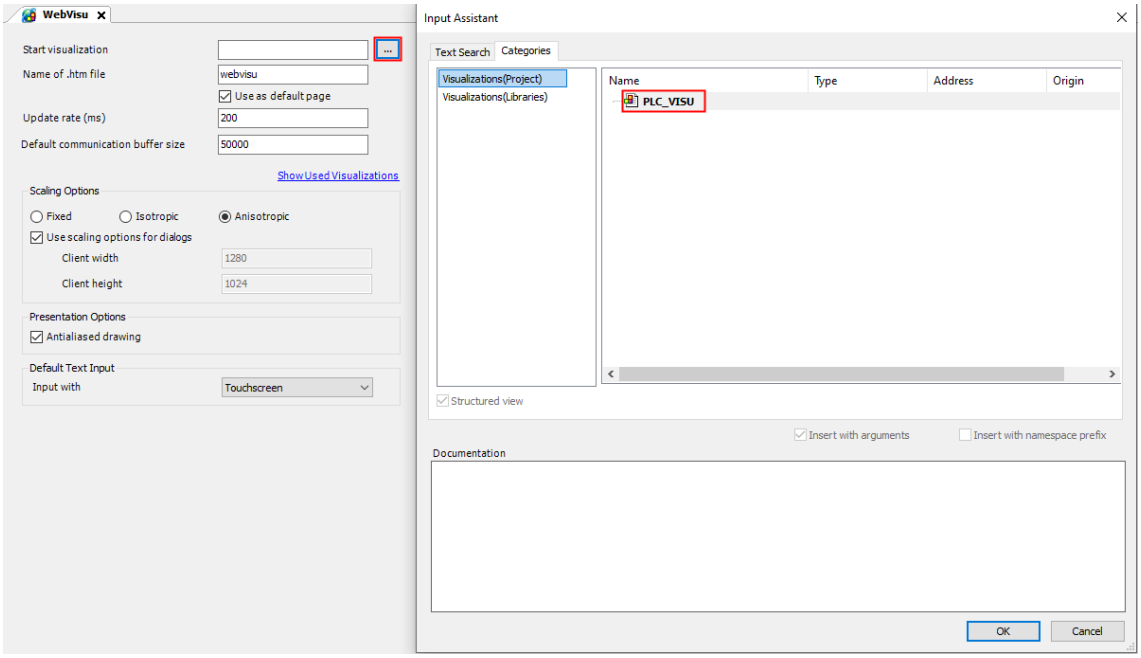
4. Select *“Add object”*.

   ⇨ You added and activated a web server on Ethernet port 1 on the AC500 V3 CPU.

Set-up the web server



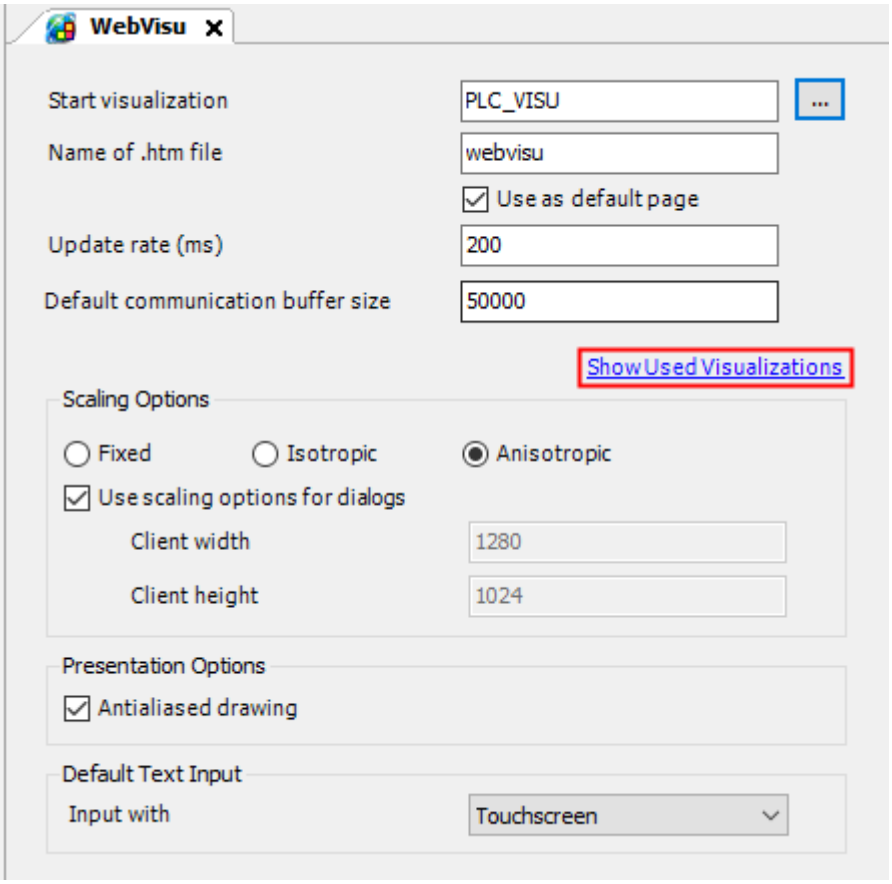
1. Double-click *“WebVisu”* in the device tree.



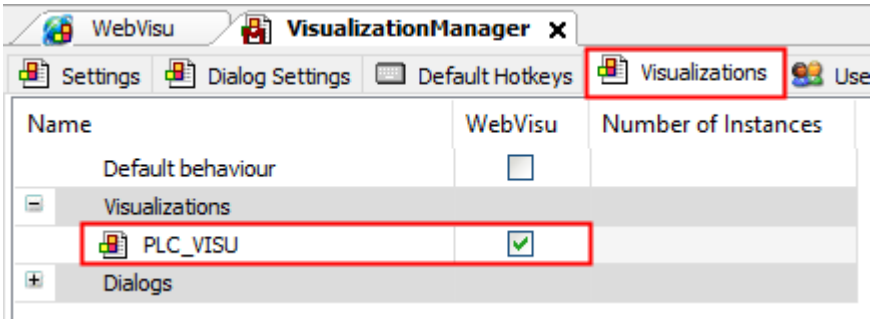
2. Under *“Start Visualization”*, select *“...”*.

   ⇨ A list opens.

3. Select the *“PLC_VISU”* screen from the list.
4. Keep all further settings with default values.



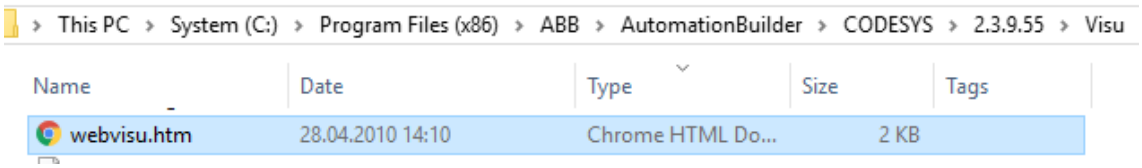
5. Select the link *"Show used visualizations"*.



⇨ The VisualizationManager editor and there the tab *"Visualizations"* opens. All screens and dialog elements created in the project are visible.

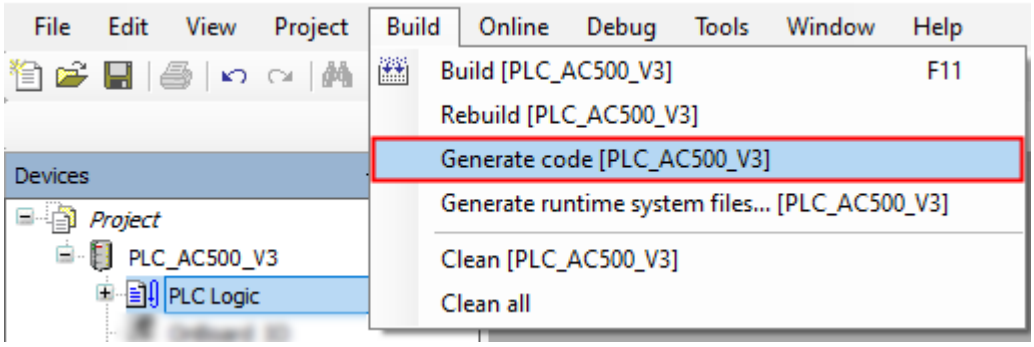
Here, you can select which screens are enabled or disabled for web visualization.

If you want to select another screen as a start visualization, you must modify the adequate parameter in the webvisu.htm file: `<param name="STARTVISU" value="PLC_VISU">`



Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

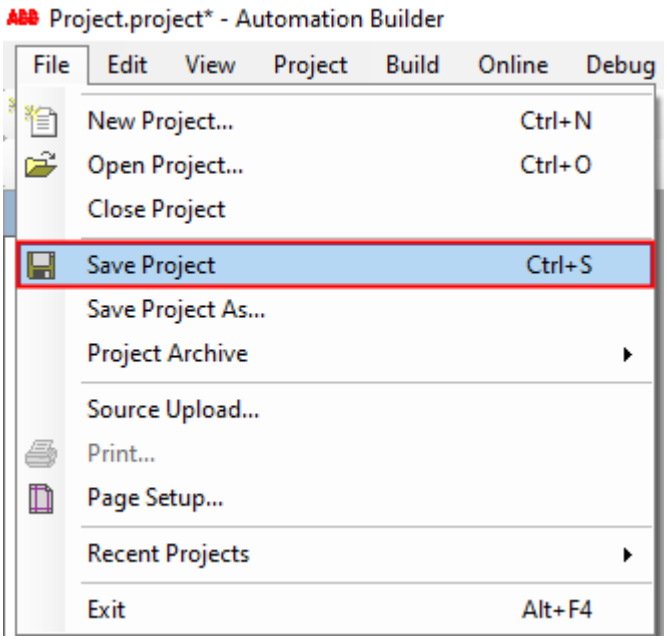


▷ Select menu *"Build ➔ Generate code"*.

⇨ The result of the compiling is shown in the *"Messages"* field at the bottom of the screen.

If you skip the compiling and select *"Login"*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save the project



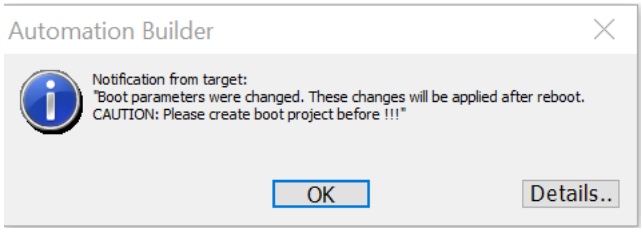
▷ Select menu *"File ➔ Save Project"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl] + [S]*.

Loading the project to the CPU

1. Download the project to the CPU ↬ *as described in Chapter 1.2.18.2.2.7 , on page 148*.
2. Check the notification window at the end of the download. In case of message "Boot parameters were changed. These changes will be applied after reboot", a reboot of the CPU is required after creation of the boot project.



Create a boot project

By default, after project download, the boot project is created automatically.

Rebooting the CPU

▷ Reboot the CPU by switching OFF and ON the power supply. (The parameter for web server activation is a boot pamater which is loaded during boot of the CPU)

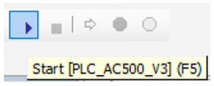
Test the web visualization

☑ You have downloaded the project and created the boot project.

☑ The CPU has been rebooted.

☑ You are logged in.

☑ CPU is in "stop" mode.



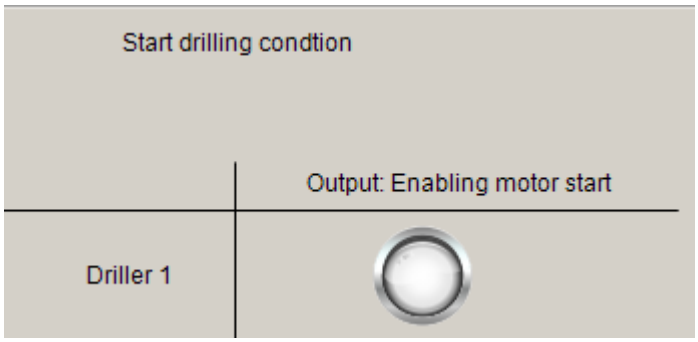
1. Start the project execution, e.g., from the tool bar.
2. Launch an internet browser.
3. Type in the URL field: *http://192.168.0.10/webvisu.htm*.

   192.168.0.10 is the IP address of CPU's ETH1 port.

   /webvisu.htm is the default htm file.

   ⇨ Web visualization will be loaded.

   The start screen "PLC_VISU" is displayed in a responsive view.



4. Test the function by operating switch I1.
5. Test the results for responsive view by changing the web browser window size.

Reset the CPU

Reset values and parameters

In some cases, it could be required to do a CPU reset, e.g., for resetting of counter values, parameters etc.

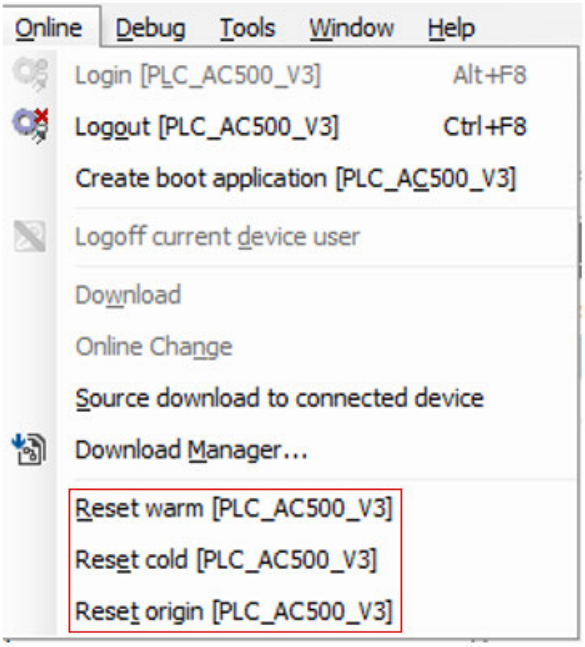


Fig. 11: Reset commands in “Online” menu

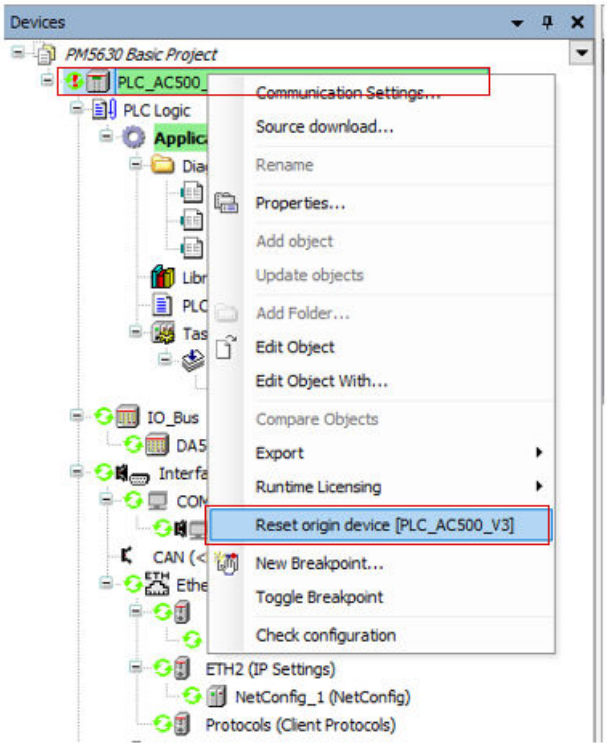
Reset warm	All variables are reset, except RETAIN PERSISTENT variables.
Reset cold	Causes initialization of all variables, except PERSISTENT variables. By recommended creation of remanent variables always with both properties: PERSISITENT and RETAIN, this command resets all variables, except PERSISTENT RETAIN variables.
Reset origin	All variables and the application project are reset.

Table 10: Behavior of variables of type VAR (local or global) and variables of type PERSISTENT RETAIN

	VAR	VAR PERSISTENT RETAIN
After online command 'Online change'	no change	no change
After online command 'Download'	initialization	no change
After online command 'Reset warm'	initialization	no change
After online command 'Reset cold'	initialization	no change
After online command 'Reset origin'	initialization	initialization
After power supply off	initialization	no change

Complete reset of the CPU

To do a complete reset of the CPU thereby erasing the application from the RAM and flash EEPROM do the following.



1. Right-click the station object *“PLC_AC500_V3”* in the device tree.
2. Select *“Reset origin device [station name]”*.
   ⇨ The application is completely erased from the CPU (complete project from all memory areas).

1.3 Automation Builder installation manager

Automation Builder installation manager allows you to install customer specific software packages, modify the existing installation, update installation information and to uninstall Automation Builder software packages in a comfortable and flexible way.

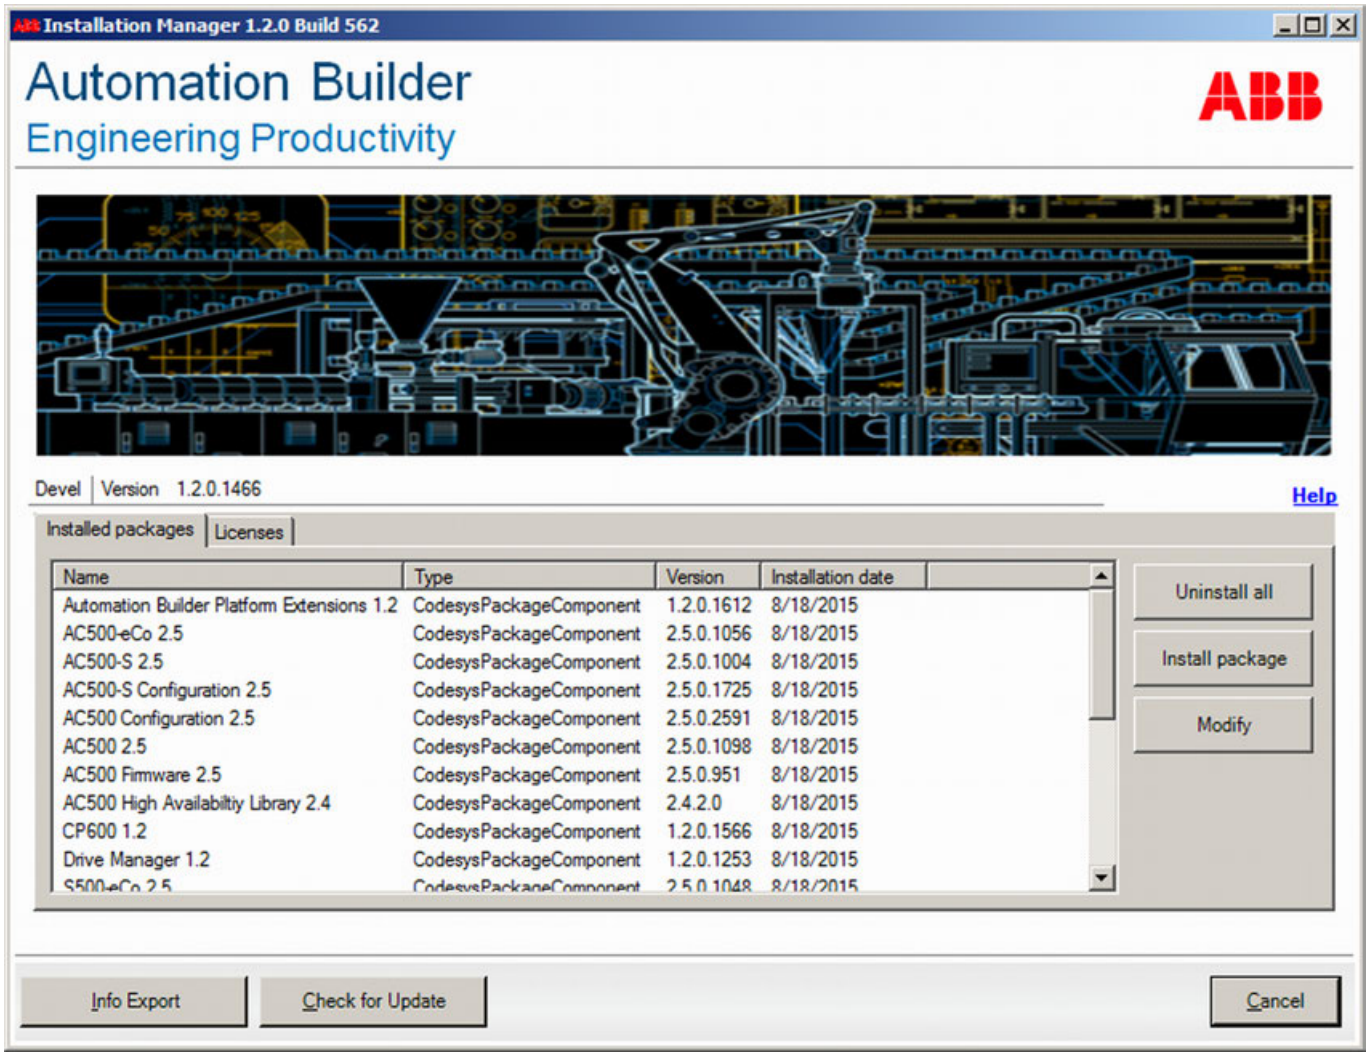
You can launch installation manager from the main menu of Automation Builder or from Windows start menu.

1. Open Automation Builder software.

   From the **Tools** menu, select **Installation Manager**.

2. As an alternative, launch installation manager from Windows start menu: *“Start menu ➔ All Programs ➔ ABB ➔ Automation Builder ➔ ABB Automation Builder Installation Manager”*.

   ⇨ Installation manager starts.



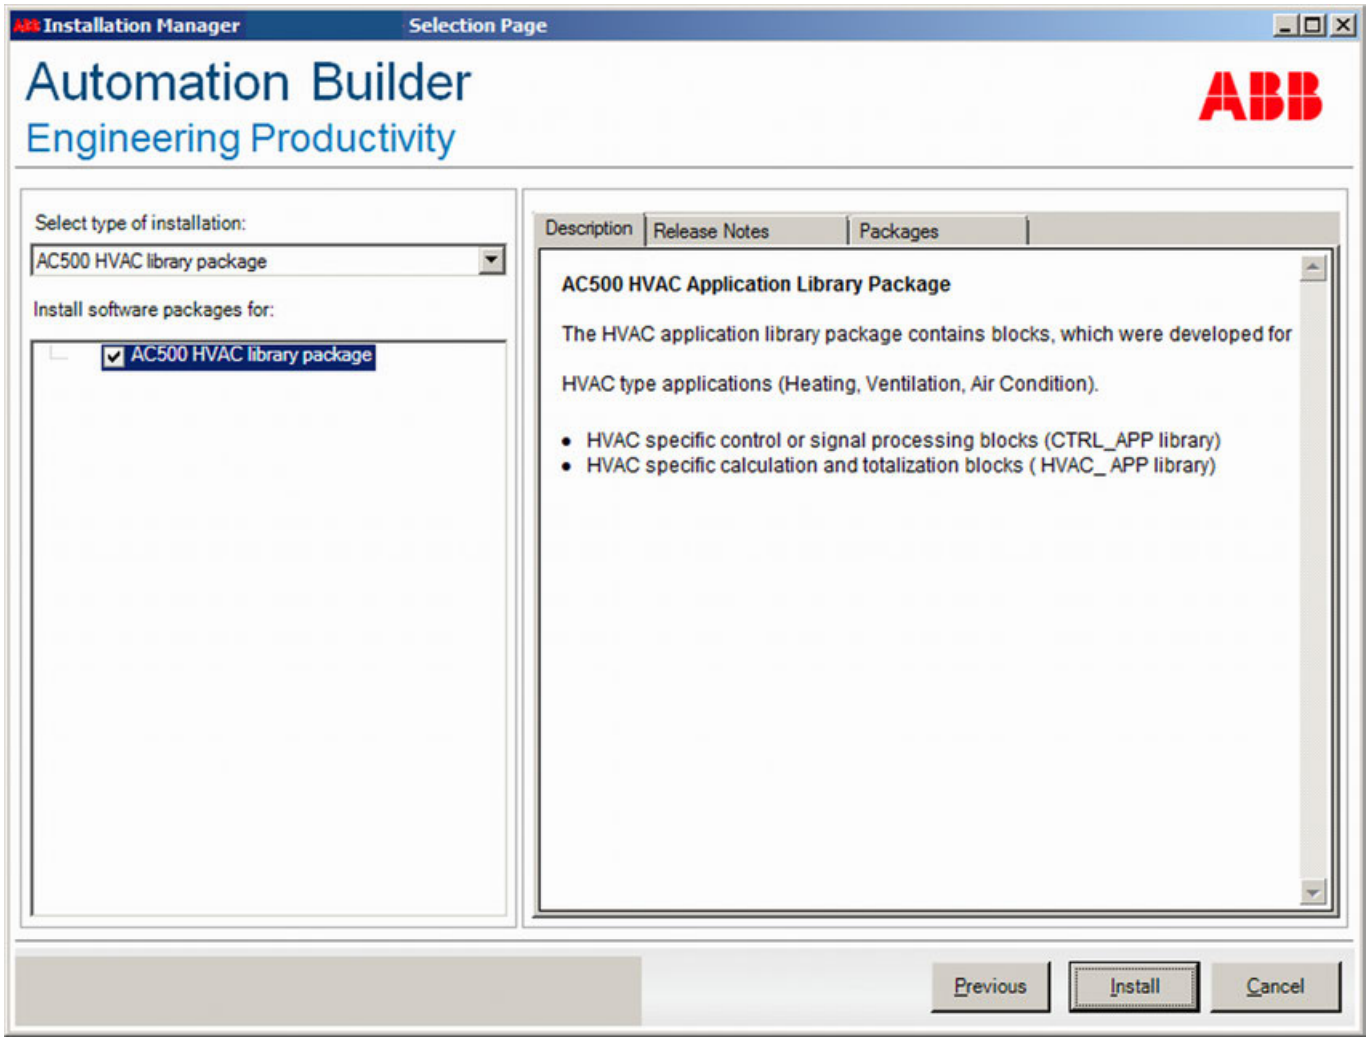
Options:

- **Installed packages**: Shows all installed packages of Automation Builder.
- **Licenses**: Displays the detailed license information of installed Automation Builder packages in the CodeMeter WebAdmin page. For more information, see *http://localhost:22350/$help/CmUserHelp/us/index.html?controlcenter.htm*.
- **Uninstall all**: Uninstalls the currently installed Automation Builder software.
- **Install Package**: Installs customer specific software packages.
- **Modify**: Adds or removes installed software packages.
- **Info Export**: Exports detailed information of installed packages in a notepad.
- **Check for Update**: Checks if your installed version of Automation Builder is up to date and checks for updates.

1.3.1 Installing customer specific package

Installation manager allows you to install customer specific software packages (CABPKG files). These packages are separately distributed to the customer based on the customer requirement.

1. In the installation manager, click **Install Package**.
2. Select the package to be installed (.cabpkg file) from the file system.



3. Select the components to be installed.
4. Click **Install**.

   ⇨ Data installation starts.
5. Successfully installed components are indicated with .

   Errors during data download are indicated with . Errors during download of any package component aborts the installation. In this case click **Show Log** and save the log data. Send the log file to ABB support team.

   Click **Finish** to end the wizard.

1.3.2 Adding or removing installed software packages

1. In the installation manager, click **Modify**.

   ⇨ The selection page opens.

   The selected software packages are installed already.

   The not selected software packages are not installed.

2. Select the software packages you want to install.

   Unselect the software packages you want to uninstall.

   > *You cannot unselect the main **ABB Automation Builder** software package.*

   If also an older Automation Builder version or Control Builder Plus version shall be installed for compatibility reasons, select the appropriate options under **Install also previous product versions**. This allows to open and edit a corresponding project in the original version without a previous project upgrade.

3. Click **Continue**.

   The following three cases are possible:

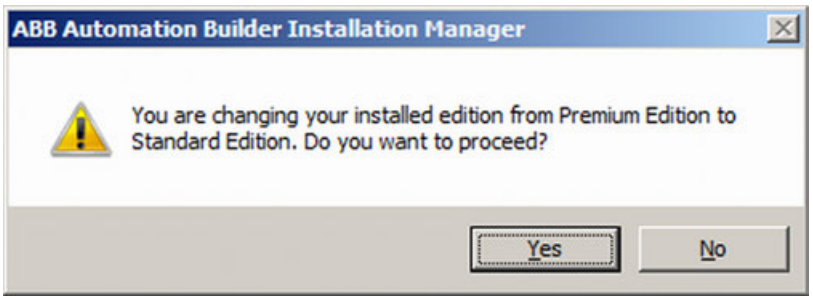
   - The selected software package starts downloading and installing.
   - The unselected software package will uninstall.
   - The unselected software package will uninstall first and then download and install the selected software package.

4. Successfully downloaded components are indicated with .

   Errors during data download are indicated with . Errors during download of any package component aborts the installation. In this case click **Show Log** and save the log data. Send the log file to ABB support team.

   Click **Finish** to end the wizard.

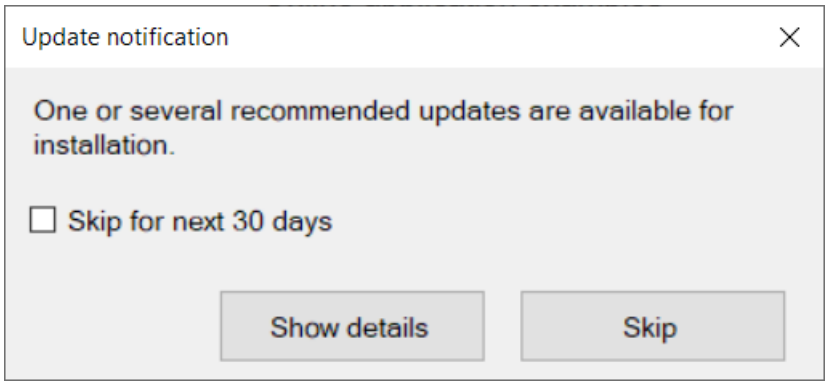
If you modify the type of installed edition, a warning message is displayed.



1.3.3 Automation Builder update notification

An update notification dialog will be shown during Automation Builder startup in case there are any updates available for the currently installed version.

- Notification on available major, minor, or service release version
- Notification on recommend software updates (Bug fixes, CM FW, V2 FW, LIB updates, documentation updates, ...), Automation Builder 2.5 and next future versions will show notification on updates.

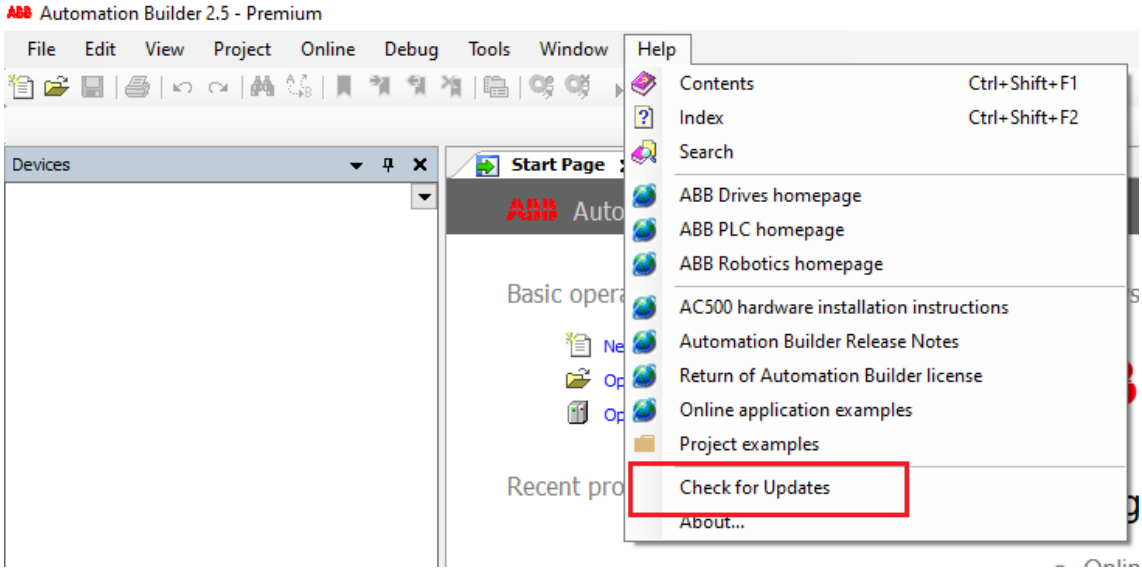


Skip of next 30 days + Skip:	Close the notification dialog. Notification dialog will not be shown for next 30 days.
Show details:	Show details will show the updates details page.
Skip:	Close the notification dialog. Next time launch of Automation Builder will show the notification dialog.

Update notifications will only be shown in the latest installed Automation Builder version profile.

"Help" - "Check for Updates" menu item

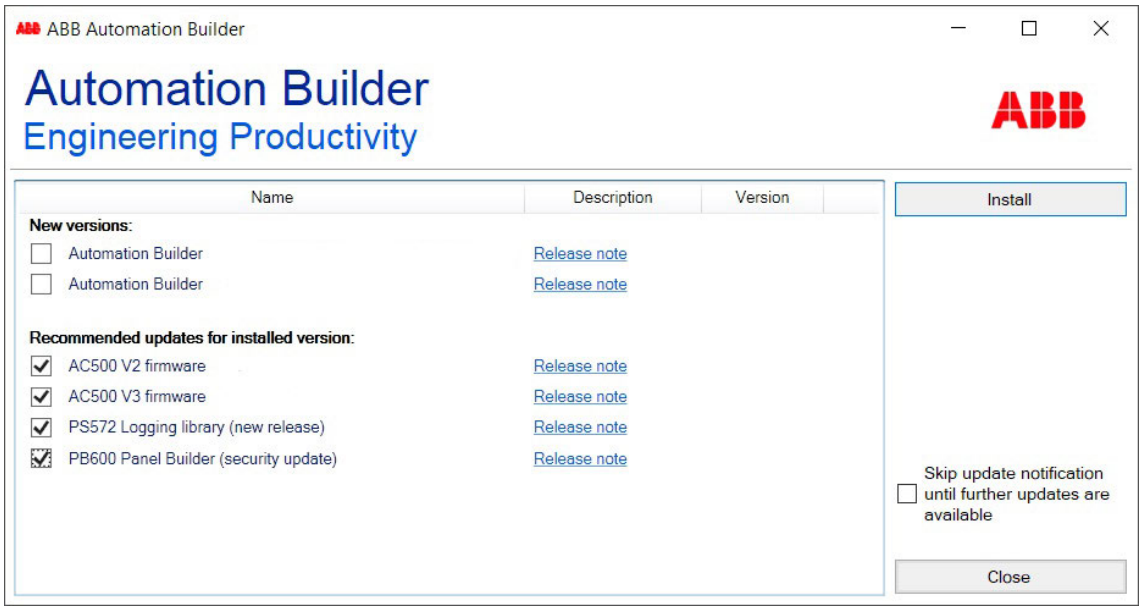
The *"Check for Updates"* menu item has been added to the *"Help"* menu. The user has the possibility to check for updates manually.



Check for Updates: Will launch the Automation Builder update details window.

Automation Builder update details window

The Automation Builder update window provides information about all available updates for the currently installed Automation Builder version and features. Detailed information is provided via the description links.



Skip update notification until further updates are available:	If this option is selected and the update details page is *"Close"*, no notification is displayed at startup until new updates are available.
New versions:	New releases of Automation Builder will be shown this section which will list hotfix version for the currently installed version or recent major version released, if any.
Recommended updates for installed version:	Updates for the currently installed options will be shown.

User can only select any one of the new versions and install.

Installed updates in the Installation Manager start page

All the installed updates will be shown in the Installation Manager start page in the *"Installed updates"* tab.

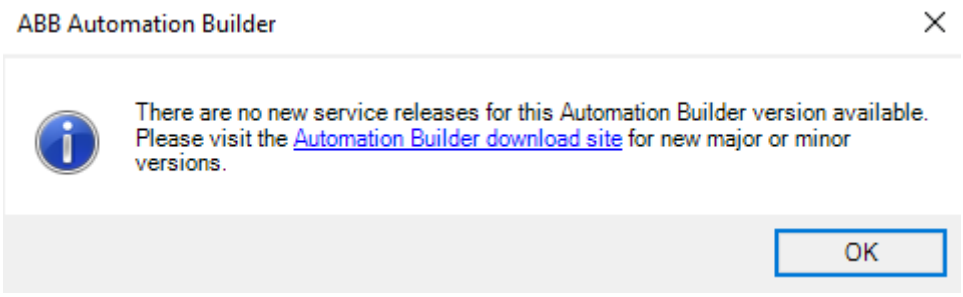
Installation Manager selection page

All the newly installed updates package version information will be updated and shown in the packages tab.

1.3.4 Checking for updates

▷ In the installation manager, click *“Check for new service release”*.

⇨ If the installed Automation Builder version is up-to-date, the following message will appear.



If a newer Automation Builder version is available, you will get an option to download and install the new version.

> *Create a project archive before updating Automation Builder. Project archives contain all project data, including data that is not stored with a *.project file, e.g. device description files for third party devices.*
>
> *Chapter 1.6.6.1.1.7.1 “Creation of an archive ” on page 3642*

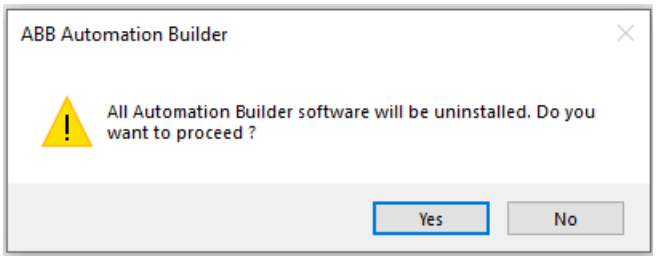
1.3.5 Uninstalling Automation Builder

Installation manager offers a comfortable way to uninstall Automation Builder software. This will uninstall all related packages of Automation Builder platform as well, such as Mint Plug-in, Automation Builder Extensions, Drive Manager etc.

1. In the installation manager, click *“Uninstall all”*.

⇨ A warning message is displayed to uninstall Automation Builder software.

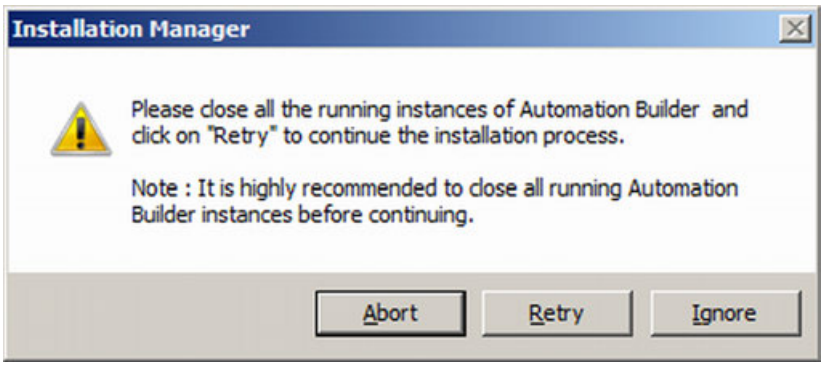
Click **Yes** to continue.



2. If Automation Builder instances are running, a warning message is displayed.

   Close running instances of Automation Builder and click **Retry** to continue uninstallation.

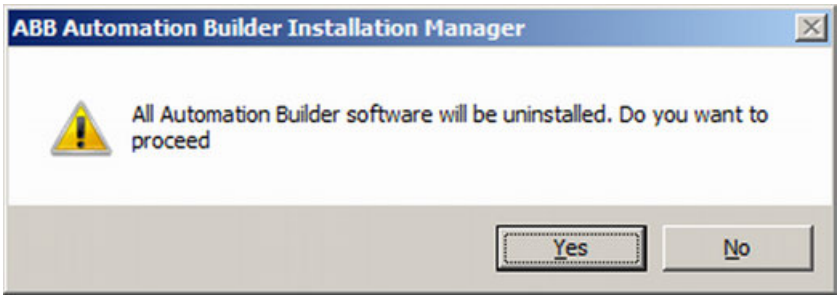
   With **Abort** uninstallation of the current package is stopped. Uninstallation is continued with the next package. With **Ignore**, uninstallation is forced. As this can lead to an erroneous uninstallation, we recommend you, *not* to use this option.



3. If installation manager was launched with *"Tools ➔ Installation Manager"*, the following message is displayed as Automation Builder is still running:

   With **Yes** Automation Builder software is closed to continue uninstallation procedure.

   With **No** uninstallation of the current package is stopped. Uninstallation is continued with the next package.



4. For each of the packages being uninstalled, system may prompt to continue uninstallation.
5. Successfully uninstalled components are indicated with ✔.

   Errors during uninstallation are indicated with ✖. Errors during uninstallation of any package component aborts the uninstallation. In this case click **Show Log** and save the log data. Send the log file to ABB support team.

   Click **Finish** to end the wizard.

1.4 Programming with CODESYS

1.4.1 CODESYS Development System

Using CODESYS help

CODESYS Help is intended to assist you in using the CODESYS Development System easily and successfully. You will find quick answers to questions and solutions to problems.

Each help component consists of a concept section and a reference section.

In the concept sections, we explain in detail all topics that are relevant for creating CODESYS projects. The concepts are supplemented with instructions that lead you step-by-step to the intended result.

In the reference sections, we provide complete reference works for the user interface and programming of CODESYS.

The following formats of CODESYS Help are provided:

- CODESYS Offline Help: CHM-based CODESYS Help
- CODESYS Online Help: Web-based CODESYS Help

In the CODESYS options, you determine whether to use CODESYS Offline Help or CODESYS Online Help.

You can call the context-sensitive help directly from the user interface of the CODESYS Development System. In CODESYS, when you position the cursor over an object, menu command, or programming element, and then press the *[F1]* key, the respective help page opens. As an alternative, you can use the commands in the *"Help"* menu. This is a full-text search. The index search is possible in CODESYS Offline Help only.

Search operators for the offline help

- `AND`
  Used automatically, for example the input of the search terms `Device Diagnosis` has the same results as the input of `Device AND Diagnosis`
- The `*` placeholder is used automatically. However, the `*` character must not be used as a wildcard because in this case the `*` character will be searched for specifically.

Search operators for the online help

- `AND`
- `OR`
- `NOT`
  Example: `abc NOT abcd`: The search result includes all help pages that contain `abc` and excludes the pages with `abcd`.
- `ANDNOT`
  `ANDNOT` is the combination of the search operators `AND` nd `NOT`.
- `ANDMAYBE`
  Example: The search for `abc ANDMAYBE xyz` finds the help pages that contain `abc` and `xyz`, and all pages that contain only the string `abc`.
- Placeholders
  – `*`: Replaces any number of characters
  – `?`: Replaces exactly one character

In the online help, you can use parentheses to group together multiple search operators for complex search queries. Example: `((profinet AND cycle) OR (Ethernet/IP AND cycle)) ANDNOT IRT`

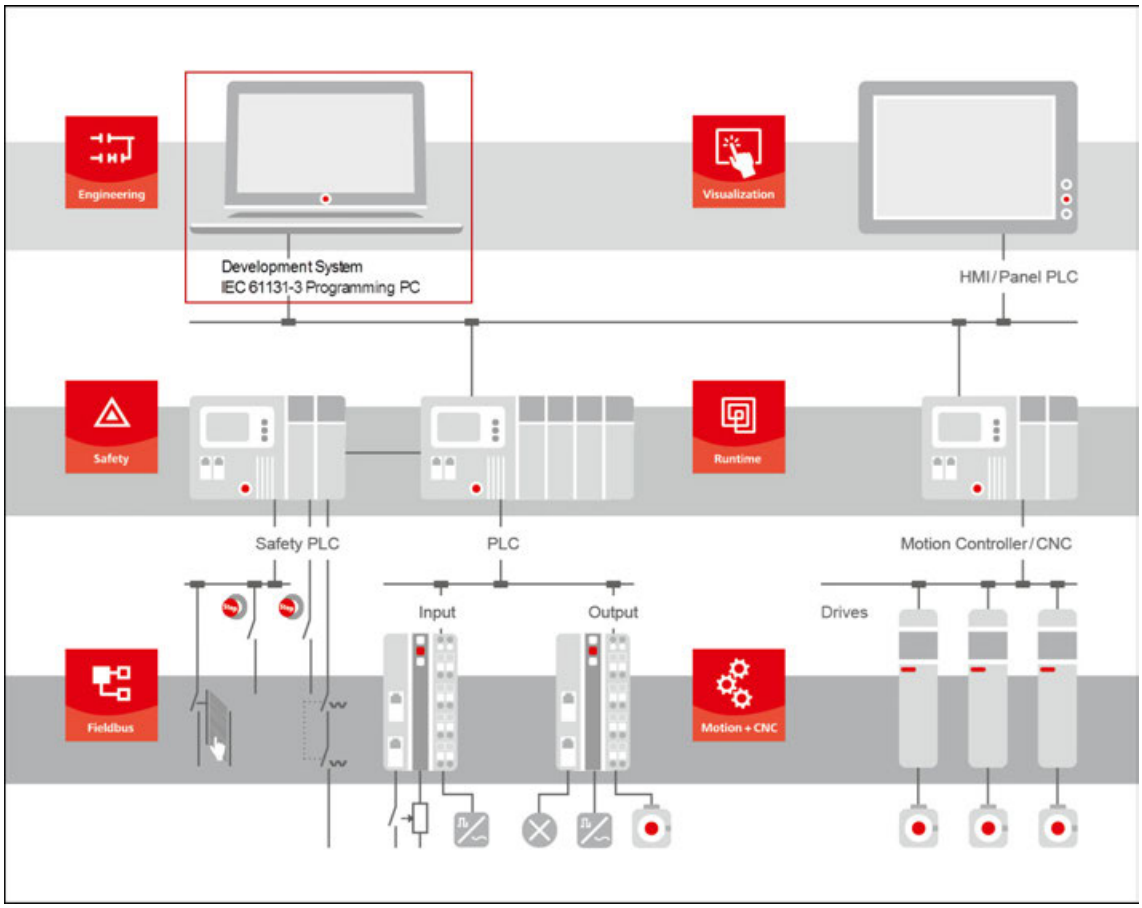
CODESYS System overview

The CODESYS Development System IEC 61131-3 programming tool forms the core of the CODESYS software platform for tasks in industrial automation technology. With additional, integrated solutions for motion control, visualizations, and fieldbus connections, the usual practical requirements are covered in one system.



Features

The free CODESYS Development System is a IEC 61131-3 programming platform for automation devices with control tasks. It provides diverse and comfortable engineering solutions to support you in your developing tasks:

	For this see in this Online Help:
Project configuration through wizards.	↳ *Chapter 1.4.1.2 “Creating and Configuring a Project” on page 186*
Adaptability of the user interface.	↳ *Chapter 1.4.1.1.2 “Customizing the user interface” on page 180*
Creation of professional IEC 61131-3 controller applications wit a host of standard features.	↳ *Chapter 1.4.1.8 “Programming of Applications” on page 222*
User-friendly programming with mouse and keyboard in all IEC 61131-3 languages. Appropriate editors for FBD, LD, IL, ST, SFC, additionally the variants CFC and Extended CFC.	↳ *Chapter 1.4.1.19.1 “Programming Languages and Editors” on page 460*
Input assistance for the input and configuration of data.	↳ *Chapter 1.4.1.8.5 “Using input assistance” on page 260*

	For this see in this Online Help:
Support of object-oriented programming. Real object-oriented programming (OOP) fully compliant with the IEC 61131-3 standard in all IEC 61131-3 languages, without any additional tools. Inheritance of POUS to similar application parts to reduce development time and errors. Object-orientation is not a must: Functional and object-oriented programming can be used and mixed as required.	*Chapter 1.4.1.8 “Programming of Applications” on page 222*
Comprehensive project comparison, also for graphic editors.	*Chapter 1.4.1.4 “Comparing projects” on page 195*
Library concept for an easy reutilization of application.	*Chapter 1.4.1.16 “Using Libraries” on page 448*
Debugging and online features for the fast optimization of the application code and to speed up testing and commissioning.	*Chapter 1.4.1.11 “Testing and Debugging” on page 394*
Integrated compilers for many different CPU platforms for optimizing the controller performance.	*Chapter 1.4.1.20.4.12.2 “Dialog 'Project Environment' - 'Compiler Version'” on page 1182* *Chapter 1.4.1.20.4.11.3 “Dialog Box 'Project Settings' - 'Compileoptions'” on page 1173*
Security features for the protection of the source code and the operation of the controller.	*Chapter 1.4.1.5 “Protecting and Saving Projects” on page 197* *Chapter 1.4.1.8.17 “Encrypting an application” on page 294* *Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385*
Field bus support and programming of devices from different manufacturers.	*Chapter 1.4.1.7 “Configuring I/O Links” on page 213*
Extensibility and adaptability without leaving the framework.	

Additionally:

Many seamlessly integrated tools for different kinds of automation tasks, for example CODESYS Visualization, CODESYS SoftMotion, CODESYS Application Composer.

Please always note the possibility to extend the functionalities by "AddOn"-Packages, provided in the CODESYS Store.

Customization of the user interface language

In the *“Option ➔ International Settings”* dialog you can customize the language of the user interface of the development system. This change will take effect the next time you start CODESYS. You can adjust the help language separately.

If you start CODESYS from the command line, you can add a parameter to adjust the user interface language.

See also

- *Chapter 1.4.1.20.4.13.13 “Dialog 'Options' – 'International Settings'” on page 1195*
- *Chapter 1.4.1.15 “Using the Command-Line Interface” on page 442*

1.4.1.1 Configuring CODESYS

CODESYS Development System allows to configure the behavior, the appearance, the content of the menus and the arrangement of the windows individually. In the *"Tools"* menu you find dialogs for customizing the user interface and to setup the CODESYS options.

See also

- *Chapter 1.4.1.20.4.14 "Dialog 'Customize'" on page 1205*
- *Chapter 1.4.1.20.4.13 "Dialog 'Options'" on page 1186*

1.4.1.1.1 Setting CODESYS options

You can configure the behavior and appearance of the CODESYS Development System in the different tabs of the *"Options"* dialog. The dialog opens by clicking *"Tools ➔ Options"*. Here you can configure the default settings for different editors and functionalities. These settings apply throughout CODESYS.

The settings are stored in your current user profile on your local system. For use on other systems, option settings, either user-specific or machine-specific (computer), can be exported to an XML file.

In V3.5 SP13 and later, CODESYS checks whether an older version is already installed when the development system is started for the first time. If this is the case, then the "Import Assistant" dialog opens for transferring the CODESYS options set with the older version.

- *Chapter 1.4.1.20.4.1 "Dialog 'Import Assistant'" on page 1149*
- *Chapter 1.4.1.1.2.1 "Customizing menus" on page 180*
- *Chapter 1.4.1.1.2.4 "Customizing keyboard shortcuts" on page 183*
- *Chapter 1.4.1.1.2.2 "Customizing toolbars" on page 182*

1.4.1.1.2 Customizing the user interface

In CODESYS, you can customize the user interface by changing the window layout as well as the appearance of menus and commands according to your requirements.

Customizing menus

You can customize the menu commands of the CODESYS user interface. In a configuration dialog, you can add or remove menus.

Removing menus and commands

1. Choose the command *"Tools ➔ Customize"*.
   ⇨ The *"Customize"* dialog box opens. The *"Menu"* tab is visible.

2. Select a menu in the menu tree or a command in a menu.
3. Click *“Delete”*.
   ⇨ The menu or command is deleted from the menu tree.
4. Click *“OK”*.
   ⇨ The dialog box closes and the menu is customized.

Adding menus

1. Choose the command *“Tools ➔ Customize”*.
   ⇨ The *“Customize”* dialog box opens. The *“Menu”* tab is visible.
2. Scroll to the end of the menu tree.
3. Select the blank symbol (□).
4. Click *“Add Popup Menu”*.
   ⇨ The *“Add Popup Menu”* dialog box opens.
5. Type a name for the new menu in the *“Default text”* field.
   If localization is unnecessary, then skip to step 9.
6. Click *“Add Language”*.
   ⇨ A drop-down list opens with available languages.
7. Choose the required language.
   ⇨ The language is added to the list of languages.
8. Click into the *“Text”* field and type the language-specific text.
9. Click *“OK”*.
   ⇨ The new menu is added at the bottom of the menu tree.
10. Change the menu order by clicking *“Move up”* and *“Move down”*. Click *“OK”* to close the *“Customize”* dialog box.

The new menu is displayed only when it contains a command.

Adding commands

1. Choose the command *“Tools ➔ Customize”*.
   ⇨ The *“Customize”* dialog box opens. The *“Menu”* tab is visible.
2. Expand the branch of the menu where the new command should be added.
3. Select the blank symbol (□).
4. Click *“Add Command”*.
   ⇨ The *“Add Command”* opens dialog box.
   The dialog box lists all commands grouped by category.
5. Select the command to be added. Click *“OK”*.
   ⇨ The new command is added to the menu tree.

6. Change the menu order by clicking *“Move up”* and *“Move down”*. Click *“Add separator”* to add a border between commands. Click `OK` to close the *“Customize”* dialog box.

   ⇨ The new command is now available in the menu.

See also

- *Chapter 1.4.1.20.4.14.1 “Dialog 'Customize' - 'Menu'” on page 1206*
- *Chapter 1.4.1.1.2.2 “Customizing toolbars” on page 182*

Customizing toolbars

You can customize the toolbars of the CODESYS user interface. In a configuration dialog, you can add or remove toolbars.

Removing toolbars and commands

1. Choose the command *“Tools ➔ Customize”*.

   ⇨ The *“Customize”* dialog box opens.

2. Choose the *“Toolbars”* tab.
3. Select a toolbar or a command from a toolbar tree.
4. Click *“Delete”*.

   ⇨ The toolbar or command is deleted.

5. Click *“OK”*.

   ⇨ The dialog box closes and the toolbar or command is removed.

Adding toolbars

1. Choose the command *“Tools ➔ Customize”*.

   ⇨ The *“Customize”* dialog box opens.

2. Choose the *“Toolbars”* tab.
3. Select the blank toolbar.
4. Click *“Add Toolbar”*.

   ⇨ The cursor blinks in the new toolbar.

5. Type a name.
6. Change the toolbar order by clicking *“Move up”* and *“Move down”*. Click *“OK”* to close the *“Customize”* dialog box.

CODESYS displays the new toolbar only when it contains a command.

Adding commands

1. Choose the command *“Tools ➔ Customize”*.

   ⇨ The *“Customize”* dialog box opens.

2. Choose the *“Toolbars”* tab.
3. Expand the tree of the toolbar where the new command should be added.
4. Select the blank symbol ( ).
5. Click *“Add Command”*.
   ⇨ The *“Add Command”* dialog box opens.
   The dialog box lists all commands grouped by category.
6. Select the command to be added. Click *“OK”*.
   ⇨ The new command is added to the toolbar tree.
7. Change the toolbar order by clicking *“Move up”* and *“Move down”*. Click *“Add separator”* to add a border between commands. Click *“OK”* to close the *“Customize”* dialog box.
   ⇨ The new command is available in the toolbar.

See also

- *Chapter 1.4.1.20.4.14.3 “Dialog 'Customize' - 'Toolbars'” on page 1207*
- *Chapter 1.4.1.1.2.1 “Customizing menus” on page 180*

Customize command icon

CODESYS provides the capability of assigning customized icons to commands.

1. Select the command *“Tools ➔ Customize”*.
   ⇨ The *“Customize”* dialog box opens.
2. Click the *“Command icons”* tab.
3. Select the category *“Help”* from the list on the left.
   ⇨ All commands in this category are listed on the right.
4. Select the command *“Information”*.
5. Click *“Assign”*.
   ⇨ A dialog box opens for selecting the icon file (*.ico).
6. Select an icon file.
7. Click the *“Open”* button.
   ⇨ The icon is assigned to the selected command.
8. Click *“OK”*.

See also

- *Chapter 1.4.1.20.4.14.2 “Dialog 'Customize' - 'Command Icons' ” on page 1206*

Customizing keyboard shortcuts

CODESYS provides the capability of executing commands directly via keyboard shortcuts. You can customize or extend predefined keyboard shortcuts.

1. Choose the command *“Tools ➔ Customize”*.
   ⇨ The *“Customize”* dialog box opens.

2. Choose the *“Keyboard”* tab.
3. Select the category *“Help”* from the list on the left.
   ⇨ All commands in this category are listed on the right.
4. Select the command *“Search”*.
5. Click into the field *“Press Shortcut Keys”*.
6. Press *[Ctrl]+[Shift]+[S]*.
   ⇨ CODESYS adds the key combination to the field.
7. Click *“Assign”*.
   ⇨ The keyboard shortcut is assigned to the command.
8. Click *“OK”*.
   ⇨ You can call the *“Search”* command by pressing *[Ctrl]+[Shift]+[S]*.

See also

- *Chapter 1.4.1.20.4.14.4 “Dialog Box 'Customize' - 'Keyboard' ” on page 1207*

Changing the window layout

In CODESYS, you can easily customize the layout of different views to your individual needs.

1. Drag the view by the caption bar or by the tab.
   ⇨ Arrows are shown to mark possible destinations. Example: 
2. Drag the view to one of the arrows.
   ⇨ The destination is displayed as a blue-shaded area.
3. Release the left mouse button.
   ⇨ The window is inserted into the selected destination.

The window can also be placed outside of the CODESYS programming interface.

See also

- *Chapter 1.4.1.1.2.6 “Resizing windows” on page 184*
- *Chapter 1.4.1.1.2.7 “Auto-hiding windows” on page 185*
- *Chapter 1.4.1.1.2.8 “Switching between windows” on page 185*

Resizing windows

1. Move the mouse pointer over the border between two windows or views.
   ⇨ The cursor becomes a left-right arrow.
2. Drag the border to another position.

You can resize detached views by moving the frame lines.

See also

- *Chapter 1.4.1.1.2.5 “Changing the window layout” on page 184*
- *Chapter 1.4.1.1.2.7 “Auto-hiding windows” on page 185*
- *Chapter 1.4.1.1.2.8 “Switching between windows” on page 185*

Auto-hiding windows

Hiding windows

When you hide a view, it is minimized to a tab in the frame of the user interface. When you move the pointer over the tab, the window is shown automatically.

1. Click into the window to be hidden.
2. Click *“Window ➔ Auto Hide”*.

   Or click the PIN symbol ( ) in the upper right corner of the view.

   ⇨ The window is hidden and only visible by a small tab on the edge of the main window.
3. Move the mouse pointer over the tab.

   ⇨ The window is shown as long as the mouse pointer hovers over the tab.

Showing windows

1. Click the tab of the hidden window.
2. Clear the check box *“Window ➔ Auto Hide”*.

   Or click the PIN symbol ( ) in the upper right corner of the view.

   ⇨ The window is permanently shown.

See also

- *Chapter 1.4.1.1.2.5 “Changing the window layout” on page 184*
- *Chapter 1.4.1.1.2.6 “Resizing windows” on page 184*
- *Chapter 1.4.1.1.2.8 “Switching between windows” on page 185*

Switching between windows

It is possible to switch directly between the currently opened views and the editor windows.

1. Press the keystroke combination *[Ctrl]+[Tab]*. Continue pressing the *[Ctrl]* key.

   ⇨ An overview opens with all active views and editors.
2. Continue pressing the *[Ctrl]* key and select a window using the arrow keys.
3. Release the *[Ctrl]* key.

   ⇨ The selected view or editor is activated.

- *Chapter 1.4.1.1.2.6 “Resizing windows” on page 184*
- *Chapter 1.4.1.1.2.7 “Auto-hiding windows” on page 185*

1.4.1.2 Creating and Configuring a Project

What is a project?

- A project contains the objects which are necessary to create a controller program ("application"):
  - Pure POUs, for example programs, function blocks, functions, and GVLs.
  - Objects that are also required to be able to run the application on a PLC. For example, task configuration, Library Manager, symbol configuration, device configuration, visualizations, and external files.
- In a project, you can program multiple applications and connect multiple controller devices.
- CODESYS manages device-specific and application-specific POUs in the *“Devices”* view ("device tree") and project-wide POUs in the *“POUs”* view.
- For the creation of projects, there are templates that already contain certain objects.
- Basic configurations and information for the project are defined in the *“Project Settings”* and *“Project Information”*. For example:
  - Compiler settings
  - User management
  - Author
  - Data about the project file

  There are settings for the version compatibility of the project in the configuration dialogs in the *“Project Environment”*.
- You save a project as a file in the file system. As an option, you can pack it together with project-relevant files and information into a project archive. It is also possible to save files in a source code management system such as SVN.
- Each project contains the information about the CODESYS version with which it was created. When you open it in another version, CODESYS will notify you about possible or necessary updates regarding file format, library versions, etc.
- You can compare, import/export projects, and create documentation for them.
- You can protect a project from being changed, or even completely protect it from being read. By using user management, you can selectively control the access to the project and even to individual objects in the project.

- *Chapter 1.4.1.5 “Protecting and Saving Projects” on page 197*

1.4.1.2.1 Opening a V3 Project

You can open projects, library projects, or project archives in CODESYS which have been created with different installations. When a project is opened, it is automatically checked whether or not the active installation is appropriate to load the project. At this time, deficiencies can be detected, such as missing add-ons or deprecated installations. You can correct these deficiencies. Then you can load the project with an appropriate installation.

The following actions are possible to correct deficiencies:

- Update existing add-ons and install missing add-ons
- Start another installation which is appropriate for the project
- Install an additional CODESYS version with the appropriate state

Loading a write-protected project

Moreover, you can load and read write-protected projects. You have to specify an appropriate location where you have the necessary write permissions only when you save the file.

Loading a project with access restrictions

You can load restricted projects only if you have the access credentials, such as user name and password.

Loading a project with a security key

You have selected a project which is protected by a security key. If the security key is not plugged into the computer, then you are prompted to plug it in. Otherwise CODESYS opens the project without any information about the protection.

Loading a backup of a project

Backups are created when the *"Automatically save"* project option is selected. When CODESYS is not ended properly after a change, the project is saved as a backup.

When you have selected a project, the *"Auto Save Backup"* dialog opens first when loading. There you can handle the backup.

- Help on CODESYS Installer

1.4.1.2.2 Opening a V2.3 project

A CoDeSys V2.3 project can be converted into a CODESYS V3 project only if the CODESYS V2.3 Converter package is installed in CODESYS V3. The package is available in the CODESYS Store.

Requirement: CODESYS is started (or a project is already open). You should be aware of the restrictions described below the following instructions.

1. Click *"File ➔ Open Project"*.
2. In the *"Open Project"* dialog, click any CoDeSys V2.3 project or project archive in the file system. For searching, you can set the file filter on the bottom right corner of the dialog.
   ⇨ If another project is still open, CODESYS instructs you to close it accordingly. After that the CoDeSys V2.3 converter automatically starts.
3. The V2.3 converter checks that the project can be compiled without errors. If so, then it processes the project automatically.
4. NOTE: If the project contains visualization objects with placeholder variables that the converter cannot resolve, the respective visualizations are shown as a group in place of the visualization references.
5. Device conversion: When a device (target system) is referenced in the project to be opened and no conversion rules are defined for the device, then the *"Device Conversion"* dialog opens. Specify here whether and how the converter should replace the previous device reference with a current one.
   ⇨ For replacement, the converter added the new device in the place of the old one in the device tree of the converted project.

6. Library conversion: if a library, for which no conversion rule has so far been defined, is referenced in the project to be opened, then the *“Conversion of Library Reference”* dialog opens. Specify here whether and how the converter should replace the existing library reference with a current one. If you select a library for which the project information is missing, then the *“Enter Project Information”* dialog opens in order to specify this information.

   ⇨ The converter loads the adapted project. Note: The redefined library references are to be found in the global Library Manager in the POUs view.

Restrictions when reusing a CoDeSys V2.3 project in CODESYS

Compilation:	The project has to be compilable without errors in CoDeSys V2.3. Note: CODESYS stills issues warnings in V3 when compiling. These are caused by implicit conversions, which can lead to a loss of information (for example through sign changes). CODESYS checks "case" statements against the switch variable: `CASE USINT OF INT` is not checked in CoDeSys V2.3, but it issues an error message when imported into V3.
Controller configuration:	The *“Controller Configuration”* of a CoDeSys V2.3 project cannot be imported into V3. You have to recreate the device configuration and re-declare the variables used in the controller configuration.
Network variables:	For network variables, CODESYS creates V3 GVL objects and imports the variable declarations. However, the network properties are not imported. See the description of the network variable exchange for this.
Libraries:	All variables and constants that are used in a library also have to be declared in the library. It must be possible to compile the library in CoDeSys V2.3 without errors.

Syntactic and semantic restrictions since CoDeSys V2.3:	● `FUNCTIONBLOCK` is not a valid keyword instead of `FUNCTION_BLOCK`.
	● `TYPE` (declaration of a structure) must be followed by a “:”.
	● `ARRAY` initialization** must have parentheses.
	● `INI` is no longer supported (you have to replace this in the code by the Init method).
	● In function calls it is no longer possible to mix explicit with implicit parameter assignments. Therefore the order of the parameter input assignments can be changed:
	`fun(formal1 := actual1, actual2); // -> error message`
	`fun(formal2 := actual2, formal1 := actual1); // same semantics as the following line:`
	`fun(formal1 := actual1, formal2 := actual2);`
	● CoDeSys V2.3 pragmas are not converted. They produce an warning in V3.
	● The `TRUNC` operator now converts to the data type `DINT` instead of `INT`. CODESYS automatically adds a corresponding type conversion for a CoDeSys V2.3 import.

Visualization:				
Placeholders and their replacement	Placeholders	VAR_INPUT	Usage	Replacement
	`PLC_PRG.$LocalVar$.aArr[0]`	`localVar: MyStruct;`	`localVar.aArr[0]`	`localVar := PLC_PRG.myStructVar`

	`$Var$.aArr[0]`	`Var : MyStruct;`	`Var.aArr[0]`	`Var := PLC_PRG.myStructVar`
	`PLC_PRG.myStructVar.aArr[$Index$]`	`Index : INT;`	`PLC_PRG.myStructVar.aArr[Index]`	`Index := 0`

Problematic placeholders	• Placeholders within a text:
	Text: `$axle$-Axis`
	Correction:
	`localVar : STRING;`
	Text: `%s-Axis`
	Text variable: `localVar`
	• Placeholder describes only one part of a variable name:
	`axis$axis$spur$spur$.fActPosition`
	Correction:
	Define only one placeholder for the `axis$axis$spur$spur$` placeholder.
	`axis_spur : MyFunctionBlock;`
	Then directly transfer the corresponding instance of the function block.
	`axis_spur := PLC_PRG.axis1spur2;`
	• Placeholder is replaced by an expression:
	`$Expression$ -> PLC_PRG.var1 + PLC_PRG.var2`
	Correction:
	You must transfer the expression to an auxiliary variable and then transfer this auxiliary variable as an instance.
	• The placeholder describes a program name: $Program$.bToggle -> PLC_PRG.bToggle D
	The converter cannot transfer this form of setting placeholders in V3. However, you will rarely use it in practice.
	• Placeholder is replaced by different types:
	`$Var$`
	-> replacement 1 : `PLC_PRG.n` (INT)
	-> replacement 2 : `PLC_PRG.st` (STRING)
	Correction:
	Define two different placeholders in the interface for this.
	• The visualization is located in a library. You replace the placeholder later from any desired project when you use the visualization there.
	Correction:
	Here you have to replace the `TYPE_NONE` data types manually. However, there is also the possibility for you to integrate the library in a project and the placeholder is correctly replaced. If you now import this project, the data type is also determined correctly in the library.			

Non-importable elements:	Trend, ActiveX – the import is not possible, because the implementation differs a great deal. In V3, a corresponding warning is issued and a corresponding manual reproduction is required.			
Programming languages	ST, IL, FBD:	No restrictions		

	LD:	CODESYS imports function blocks with parallel branches in such a way that the part before the branch is repeated for each branch. This corresponds to the generated code that CoDeSys V2.3 creates for parallel branches. 	SFC:	• Step variables explicitly declared by the user must be declared locally in the SFC editor. You may not declare them as VAR_INPUT, VAR_OUTPUT or VAR_INOUT, because CODESYS cannot automatically adapt the calls. Explanation: Steps no longer use Boolean variables for the management of the internal states in V3, but also structures of the type `SFCStepType`. • Identifier: the following identifiers may not begin with an underscore character: – Names of IEC actions in the tree – Variables that are called in an IEC association list – Names of transitions that have been programmed out Explanation: In V3 the implicit variables that CODESYS creates for actions are given an underscore character as prefix. An invalid identifier with a double underscore character would result.
	CFC:	• Large boxes: The layout of large boxes can lose quality due to an import. The boxes may overlap one another too much. (Correction planned). • Macros: Macros cannot be imported. (Correction planned).

1.4.1.2.3 Configuring a Project

You can configure your CODESYS project using the following dialogs:

- *“Project Settings”*: Basic settings on the behavour of editors and of the compiler, on user management etc.
- *“Project Information”*: Adding of individual and tagging information to the project
- *“Project Environment”*: Defining which versions of the external and internal modules should be used, with the aim of achieving up-to-dateness and compatibility with each other.

See also

- ↳ *Chapter 1.4.1.20.4.11 “Dialog 'Project Settings'” on page 1170*
- ↳ *Chapter 1.4.1.20.2.21 “Object 'Project Information'” on page 919*
- ↳ *Chapter 1.4.1.20.4.12 “Dialog 'Project Environment'” on page 1182*

Retrieving and Editing Project Information

You can use the *“Project Information”* object to retrieve information about your project and the associated file, and edit certain information.

The object contains information about

- File attributes
- Meta-information, such as manufacturer, title, or author
- Properties with keys
- Statistics
- Licensing
- Signing: This way of signing translated libraries is deprecated, and for security reasons should only be used if compatibility with older versions is required. If this method is used, then later you can use a public key token to verify that the library was last signed by the library vendor. As a library vendor, it is therefore crucial that you make the public key used available to the customer, for example in the documentation.

CODESYS saves the project information as an object within the project. When you transfer a project to another system, the *“Project Information”* object is transferred with it. There is no need for a project archive.

You can use property keys to access the project information externally via function blocks. For a library project, you can also query information about the licensing.

Editing meta-information

1. Click *“Project ➔ Project Information”*.
   ⇨ The *“Project Information”* dialog opens.
2. Click the *“Summary”* tab.
3. Specify your data in the input fields (example: `0.0.0.1` in the *“Version”* input field).
   ⇨ CODESYS creates a property with a key for each given value and manages them on the *“Properties”* tab. For a library project, CODESYS still uses the properties and sorts later in the library repository.

   If you select the option for CODESYS to create a functions block for these properties, then you can access the properties programmatically.

Creating functions for accessing properties

1. Click *“Project ➔ Project Information”*.
   ⇨ The *“Project Information”* dialog opens.
2. Select the *“Automatically generate 'Project Information' POUs”* option.

Example

Requirement: The following property is defined.

```
Key = nProp1
Type= number
Value= 333
```

1. Select the *“Automatically generate 'Project Information' POUs”* option.
2. Declare a property of the type `DINT`, for example `showprop : DINT;`.
3. Call the function `GetNumberProperty`: `showprop := GetNumberProperty("nProp1");`

   ⇨ You are granted access to the value in the application.

Note: The functions that are created with the “Automatically generate 'Project Information' POUs” option can be used only if the runtime supports the `WSTRING` data type. If this is not the case, then instead you can apply the “Automatically generate 'Library Information' POUs” option. You can use the functions created in this way at least in the application to access properties. These functions are not registered in the runtime.

Licensing library projects

If your project is a library project, then you can activate the library licensing in use here. The CODESYS Security Key is a dongle.

☑ Requirement: The project is a library project.

1. Click *“Project ➔ Project Information”*.

   ⇨ The *“Project Information”* dialog opens.
2. Click the *“Licensing”* tab.
3. Select the *“Activate dongle licensing”* option.
4. Specify the dongle data in *“Firm code”*, *“Product code”*, *“Activation URL”*, and *“Activation mail”*.

   ⇨ The library is licensed.

Creating private key files

1. Click *“Project ➔ Project Information”*.
2. Click the *“Signing”* tab.
3. Click the *“Create Private Key File”* button.

   ⇨ The *“Create Private Key File”* dialog opens.
4. Select a safe location, e.g. `D:\for lib developers only\mycomp_libkey.libpk` and exit the dialog with *“Save”*.

See also

- *Chapter 1.4.1.20.2.21 “Object 'Project Information'” on page 919*

Making project settings

You can configure settings that affect the behavior of CODESYS and that of certain editors in the *"Project Settings"* object. The settings are valid throughout the project and are applied immediately for active editors. You can also access the dialog boxes of the object with the command *"Project ➔ Project Settings"*.

CODESYS saves the project settings as an object directly in the project. If you then transfer a project to another system, the *"Project Settings"* object is also transferred with it, without a project archive being required.

1.4.1.3 Exporting and Transferring Projects

Export and import functions are available to you for the exchange of the data from CODESYS projects with other programs.

An exchange of CODESYS projects between CODESYS development systems takes place by way of a copy of the project file (*.project) or project archive (*.projectarchive).

See also

- *Chapter 1.4.1.3.1 "Exporting and importing projects" on page 193*
- *Chapter 1.4.1.3.2 "Transferring Projects" on page 194*

1.4.1.3.1 Exporting and importing projects

CODESYS offers commands for the export and import of objects to and from a file. Two possibilities are available to you here:

- Export to or import from a CODESYS XML file (*.export)
  This format is completely compatible with the CODESYS project format. The objects are saved in a machine-readable XML format.
- Export to or import from an XML file in the PLCopen format (*.xml)
  You can use this format to exchange information with other programs (for example program editors or documentation tools). PLCopen XML defines a subset of the elements known in CODESYS. 100% compatibility is thus not guaranteed.

Exporting projects

Requirement: A project is open in CODESYS.

1. Select the command *"Project ➔ Export…"* or *"Project ➔ Export PLCopenXML"*
2. Select the objects that you wish to export in the dialog box *"Export"* or *"Export PLCopenXML"*.
3. Click on *"OK"*.

4. Enter the file name and the location and click on *“Save”*.

Importing projects

Requirement: A project is open in CODESYS.

1. Select the command *“Project ➔ Import…”* or *“Project ➔ Import PLCopenXML”*.
2. In the dialog box *“Import”* or *“Import PLCopenXML”*, select the export file that you wish to import.
   ⇨ A dialog box opens and displays the objects in a tree structure, which can be inserted at this point.
3. Select the object in the object tree, under which the objects to be imported are to be inserted.
4. Select the objects and click *“OK”*.
   ⇨ The objects are added to the existing object tree.

1.4.1.3.2 Transferring Projects

If you wish to transfer a project to another computer and connect from there to the same PLC, without an online change or download being required, observe the following points.

- Make sure that the project requires only fixed versions of libraries (exception: interface libraries), visualization profile and compiler.
- Make sure that the boot application is up to date.

Then create a project archive, which you unpack on the other computer.

Transferring a project to another system

Requirement: A project is open on computer “PC1” that you transfer to another computer “PC2” and reconnect from there to the same controller.

1. Make sure that only libraries with fixed versions are integrated in the project, with the exception of pure interface libraries. To do this, open the *“Library Manager”* and check all entries that have a “*” instead of a fixed version specification.
2. Make sure that a fixed compiler version is set in the project settings. To check, select *“Project ➔ Project Settings”* and the *“Compiler Options”* category.
3. Make sure that a fixed visualization profile is defined in the project settings. To check, select *“Project ➔ Project Settings”* and the *“Visualization Profile”* category.

4. Make sure that the application that is presently open is the same as that which is presently in use on the PLC. This means that the “boot application” must be identical to the project in the programming system. To check, look at the project name in the title bar of the programming system window: If an asterisk is displayed behind the name, this means that the project has been modified, but not yet saved. It is then possible that the application and boot application do not correspond!

   In this case, first create a (new) boot application. It depends on the PLC and the application properties, whether this takes place automatically during the download of the application. For explicit creation, select the command *“Online ➔ Create boot application”*. Then execute a download with the help of the commands *“Online ➔ Login”* and *“Online ➔ Load”*.

   After that, start the application on the controller with the command *“Debug ➔ Start”*.

   ⇨ Now the desired application is running on the PLC, to which you wish to reconnect from the same project later on PC2.

5. Generate a project archive: Select *“File ➔ Project Archive ➔ Save/Send Archive”*. In the *“Project Archive”* dialog box, also select the following information:

   - *“Download information files”*
   - *“Library profile”*
   - *“Referenced devices”*
   - *“Referenced libraries”*
   - *“Visualization profile”*

   Save the project archive in a place that is accessible by PC2.

6. Log out from the controller: To do this, select *“Online ➔ Logout”*. You can stop and restart the PLC without reservations, before you reconnect from PC2.

7. Extract the project archive to PC2: Select *“File ➔ Project Archive ➔ Extract Archive”* and open the archive saved above. In the *“Extract Project Archive”* dialog box, activate the same information as described above when generating the archive.

8. Open the project and log in to PLC “xy” again.

   ⇨ CODESYS does not demand an online change or download; the project runs.

- *Chapter 1.4.1.20.3.1.8 “Command 'Save/Send Archive'” on page 960*

1.4.1.4 Comparing projects

You can compare the currently open project with another project – a reference project. The differences in contents, properties, or access rights are detected and shown in a comparison view.

Clicking *“Project ➔ Compare”* opens the *“Project Compare”* dialog for you to configure and run the comparison. Then the result is shown in the comparison view *“Project Compare - Differences”* where the objects are aligned in a tree structure. Objects that indicate differences from the respective reference object are identified by colors and symbols. This is how you detect whether or not the contents, properties, or access rights are different.

For differences in the contents, you can also open the detailed compare view *“Project Compare - <object name> Differences”* in order to zoom into the object. In the detailed compare view, the contents of the object and reference object are displayed or their source code aligned. The detected differences are marked. Previously opened views are not closed. In this way, you can have any number of comparison views open and read them, in addition to the project compare view.

You can accept the detected differences from the reference project into the current project. This is possible only from the reference project into the open project. To do this, you activate differences (for example in the code) that should be accepted in the current project with the commands , , or in the active comparison view for accepting. These positions are highlighted in yellow. Make sure that any other open compare views are inactive (write-protected, read-only). therefore, you can activate differences to be accepted in exactly one comparison view only. When exiting the active compare view, if you confirm that the differences that are activated for acceptance are actually accepted into the current project, then the current project is modified.

In order to exit the project comparison completely, close the project compare view.

1.4.1.4.1 Creating a comparison view

Requirement: You have made changes in your current project and wish, for example, to compare it with the last-saved version. In the meantime, for example, you have added further POUs, removed a POU, changed single lines of code or the object properties in function blocks.

1. Select the command *“Project ➔ Compare”*.

   ⇨ The *“Project Comparison”* dialog box opens.

2. Enter the path to the reference project, for example the path to the last-saved version of your current project.

3. Leave the activation of the comparison option *“Ignore Spaces”* as it is.

4. Click on *“OK”*.

   ⇨ The comparison view opens. Title: *“ Project Comparison – Differences”*. The Device trees of the current project and the reference project are displayed alongside each other and the changed objects are marked in color.

5. Select an object marked in blue in the tree of the reference project (right). The current project no longer contains this object.

   Click on *“Accept Single”*

   ⇨ The object is added to the tree of the current project (left). The line has a yellow background. appears in the middle column.

6. Select an object marked in green in the tree of the current project (left). The reference project does not contain this object.

   Click on *“Accept Single”*

   ⇨ The object is removed again from the tree of the current project (left). The line has a yellow background. appears in the middle column.

7. If changes are detected in the content of an object that is contained in both the current project and the reference project, this is indicated by red lettering. You can then switch to the detailed comparison view for the object by double-clicking on the object.

8. Close the comparison view and answer the query whether the changes made are to be saved with *“Yes”*.

   ⇨ The changes become effective in the project.

1.4.1.4.2 Opening the detailed compare view

Requirement: For example, a user modified the code in a POU of the current project. You have performed the project comparison by clicking *“Project ➔ Compare”*. The project compare view shows this POU highlighted in red in the aligned in the project tree.

1. Double-click the line of the aligned POU versions.

   ⇨ The compare view switches to the detailed compare view of the POU. The modified code lines are highlighted in gray and written in red.

2. Click .
   ⇨ Code lines with changes (red) are extended by two lines: an line with insert (left, green) and a line with delete (right, blue).
3. Click again.
   ⇨ The code line is marked again as modified.
4. Move the mouse pointer to the code line marked as modified and click *"Accept Single"*.
   ⇨ The code line from the reference project is activated for acceptance into the current project.
5. Click .
   ⇨ The project compare view opens for the entire project. It is write-protected (read-only) to prevent you from activating differences for acceptance. The link highlighted in yellow above the tree view also indicates this.
6. Click the link: *"Project compare view is read only because there are uncommitted changes in another view. Click here to switch to the modified view."*
   ⇨ The detailed compare view opens again. The unconfirmed changes are highlighted in yellow.
7. Click ✕ in the tab of the view and confirm that the changes should be saved.
   ⇨ The detail project view is closed and the POU is overwritten. Now it corresponds to the POU of the reference project. The project view is active again so that you can continue working with project compare.

If you do not click the link, but click ✕ instead to close the editor of the project compare view, then you will also confirm the acceptance of changes into the current project. The detail changes are accepted and then the project compare is closed completely.

1.4.1.5 Protecting and Saving Projects

General information about write and access protection

You can protect a project against unintentional changes by means of access and write protection. You can also provide it with read protection (knowledge protection).

Write protection:

The following options are available for providing the entire project with simple write protection:

- Select the *"Open Read-Only"* option when opening the project.
- You set the *"Released"* status in the *"Project Information"*.
- You select the "read-only" option in the properties of the project file in the local file system.

In order to protect only certain objects in a project against changes, or to allow access only to certain users, you can use a user and access rights management (see below). Some target devices similarly support user and rights management. The access of CODESYS to objects and files of the target device can thus be restricted.

However, write protection and access protection do not serve as protection of expertise of the POUs. Both CODESYS itself, automation platform plug-ins and persons with knowledge of the project file format can view or modify function blocks created with CODESYS.

Knowledge protection:

Knowledge protection of a project is done by encrypting the project file. Either with a project password, the CODESYS Security Key (dongle), or a certificate. We recommend protection by means of the key or the certificate because in this case no secret needs to be shared between authorized users. The desired type of project encryption is enabled in the project settings.

You can attain knowledge protection of a library by providing it as a target-system-independent "protected library" (`*.compiled-library`, `*.compiled-library-v3`). The library file no longer contains source code in this format, but only encrypted precompile context. The compiler is still able to interpret these data. Whether access by other CODESYS components or additional plug-ins is possible depends on their functionality and is to be observed in individual cases. Signing can increase protection even more.

Knowledge protection and copy protection of a boot application can be done by means of a runtime system dongle (simple or licensed) or encryption with a certificate. One of these options is enabled in the object properties of the application.

- *Chapter 1.4.1.5.2 “Assigning Passwords” on page 202*
- *Chapter 1.4.1.5.5 “Protecting Objects in the Project by Access Rights” on page 204*
- *Chapter 1.4.1.16.1 “Information for Library Developers” on page 449*
- *Chapter 1.4.1.8.17 “Encrypting an application” on page 294*

Encryption with certificates

In CODESYS, projects and applications can be encrypted with certificates and signed in order to protect them from unauthorized access.

To do this, you can configure specific security settings for each individual user profile. These settings are always used automatically when the user works with CODESYS projects. Therefore, they do not have to be redone for each project. The general configuration of the security features for a user profile is done in the *“Security Screen”* view of CODESYS. See the individual instructions below.

You can also encrypt a project file or an application for download or online change directly with a certificate:

- User-independent encryption for the current project is configured in the *“Security”* category of the *“Project Settings”*.
- User-independent encryption of the application is configured in the *“Properties”* dialog of the application object.

NOTICE!
When you encrypt a project, an application, or online code with a certificate, you will always require the certificate with a private key in order to open the object again.

If the CODESYS Security Agent add-on product is installed, then the “Security Screen” view provides an additional tab: “Devices”. This allows for the configuration of certificates for the encrypted communication with controllers.

Certificates, **Windows Certificate Store**

All available certificates are located in the Windows Certificate Store (*“certmgr”*) on your computer. There are two types of keys:

- Certificates with private keys
  - for file decryption
  - for digital signatures
- Certificates with public keys
  - for file encryption
  - for verifying digital signatures

The local Windows Certificate Store is usually filled with certificates by the IT administrator of the computer. Certificates are either created using special tools or the creation is requested by a trusted certification authority (CA).

If you receive a certificate file that you need to install yourself in the Windows Certificate Store, then double-click the file in the store directory. Depending on the type (certificate with private or public key only), the appropriate import wizard will appear.

- *Chapter 1.4.1.5.7 “Encrypting Projects with Certificates” on page 207*

User management and password manager

User accounts with different rights can be managed in CODESYS. For each account you can define the actions with which the user can access a project object.

The user management is configured in the *“Project settings”* in the category *“Users and Groups”*.

Before the creation of users and groups, please note the following:

- Rights can only be assigned to user groups. Therefore, you must assign each user to a group.
- There is automatically always a group 'Everyone' and by default every user and every other group is initially a member of this group. Thus each user account is automatically equipped with at least the defined standard rights.

  You cannot delete the group 'Everyone', you can only rename it, and you cannot remove members from this group.

  Caution: by default "Everyone" does not have the right to change the current user, group and rights configuration!
- There is automatically always a group 'Owner' containing a user 'Owner'. From V3.5 only the 'Owner' initially has the right to change the current user, group and rights configuration in a new project! Hence, only 'Owner' can assign this right to another group.

  Initially the 'Owner' can log in with user name 'Owner' and an empty password. You can add further users to the group 'Owner' or remove users from it, but at least one member must be retained. Like 'Everyone', you cannot delete the group 'Owner' and it always possesses all access rights. This prevents a project from being rendered unusable by denying all access rights to all groups.

  You can rename both the group 'Owner' and the user 'Owner'.
- If the programming system or a project is restarted, no user is initially logged in to the project. However, the user can then log in via a certain user account with user name and password in order to obtain the access rights defined for the account.
- Each project has its own user management! Therefore, in order to obtain certain access rights to a library integrated into the project, for example, the user must explicitly log in to the library project.

  Users and groups defined in different projects are not the same, even if they have the same names.
- A user management in a project only makes sense if it is connected with corresponding rights assignment for the access to project and objects. The project rights are generally managed in the dialog box *“Rights”* of the *“User Management”*. You can also change the access rights to an individual project object on the *“Access control”* tab of the *“Properties”* of the object.
- There are standard menu commands under *“Project ➔ User Management”* for logging into and out of a project as a defined user. A password manager permits the management of the login data on your computer.

From V3.5 only the 'Owner' initially has the right to change the current user, group and rights configuration in a new project! Hence, only 'Owner' can assign this right to another group.

NOTICE!
CODESYS stores the user passwords inaccessibly. If you forget a password, the user account becomes unusable. If you forget the 'Owner' password, the entire project may become unusable!

Password manager

The password manager enables you to save login data records that you enter during the login procedures for projects. It is accessible via a button in the login dialog box and offers fast access to the login data currently required. This can be helpful, for example, if you are working in parallel on several library projects that are protected by different passwords.

The password manager itself is protected by an individual master password. If you wish to use the password manager for the first time, CODESYS requests you to define this password in the password manager configuration dialog box. CODESYS notes the master password until you terminate the current CODESYS session. You must always input the password when you wish to log in to the password manager for the first time during a new session, or after you have changed it.

See also

- *Chapter 1.4.1.5.5 “Protecting Objects in the Project by Access Rights” on page 204*
- *Chapter 1.4.1.5.6 “Logging in via User Account and Password Manager” on page 205*
- *Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385*

Rights management

Rights management for access to a project and objects in a project is necessary in order to make a user management meaningful.

The rights for a project are generally managed in the *“Rights”* editor of the *“User Management”*. You can also change the access rights to an individual project object on the *“Access control”* tab of the *“Properties”* dialog box of the object.

Before assigning rights, please observe the following:

- In a new project CODESYS always sets all rights for the execution of actions on objects with the **default value** 'allowed' (standard right). The only exception to this is the right to change the current user, group and rights configuration. Initially only the 'Owner' group has this right.
- If you are member of a group that is permitted to change rights, you can do this at any time for each right when working further on a project. You change a right by switching between 'allowed' and 'forbidden' or by resetting to the default.

See also

- *Chapter 1.4.1.5.4 “Setting up a user management” on page 203*
- *Chapter 1.4.1.5.5 “Protecting Objects in the Project by Access Rights” on page 204*

Filing, saving

Provide the project file with the desired protection before saving it in the file system; see above. For a read-only project file you are given various options so that you can still save the file, depending on the type of write protection.

If the project is to be opened later in an older CODESYS version, it makes sense to save the project for precisely this version (file type), since CODESYS will also inform you immediately about possible losses of data in the course of saving it.

If you wish to save library projects, please observe the rules for the creation of libraries. Also consider the possibility of installing a library directly in a library repository.

If you wish to continue to use a project on another computer, it makes sense not only to save the project file, but also to create a project archive from all relevant auxiliary files.

You can make a setting so that a backup copy of this project is created each time the project is saved. In addition you can configure CODESYS so that projects are generally automatically saved at certain time intervals.

If you wish to keep projects in a source control system, observe the corresponding add-ons for CODESYS. For example, the link to SVN is supported.

- *Chapter 1.4.1.5.9 “Saving/Sending the project archive” on page 210*
- *Chapter 1.4.1.16.1 “Information for Library Developers” on page 449*
- *Chapter 1.4.1.5.10 “Linking a project to the source control system” on page 211*

1.4.1.5.1 Setting up write protection

A project can be protected against inadvertent changes by means of access and write protection. In addition, however, it can also be provided with read protection (know-how protection). You have the following options:

Open the project with write protection

Requirement: No project is opened.

1. Select *“File ➔ Open Project”*.
   ⇨ The dialog box *“Open project”* appears.
2. Select the project.
3. Click on the arrow button ▾ next to the *“Open”* button and select *“Open read-only”* from the menu.
   ⇨ CODESYS opens the project. At the top right in the main window a line appears *“'Project file cannot be saved…'”*. You must now select one of the offered options if you wish to save the project file.

See also

- *Chapter 1.4.1.2.1 “Opening a V3 Project” on page 186*

Providing projects with the attribute 'Released'

Requirement: project is opened.

1. Select *“Project ➔ Project Information”*, then the *“Summary”* tab.
2. Activate the option *“Released”*, confirm with *“OK”*.
3. Save the project, for example with *[Ctrl]+[S]*.
4. Open the project again with the command *“File ➔ Open Project”*.
   ⇨ CODESYS opens the project. At the top right in the main window a line appears *“'Project file cannot be saved…'”*. You can now directly remove the status *“Released”* again via the offered option if you wish to save the project file.

See also

- *Chapter 1.4.1.20.2.21 “Object 'Project Information'” on page 919*

Providing a project in the file system with the property 'Read-only'

▷ Provide the project file in its local file system with the property attribute 'Read-only'.

⇨ If you had already opened the project and you now attempt to save it under the same name, a dialog box appears informing you about the existent write protection. This dialog box provides you with the following options:

You can save the project under another name or another path using the button *“Save As…”*.

You can deliberately save the project under the same name and path and thus overwrite the existing version in the file system using the button *“Overwrite”*.

You can abort the saving procedure using the *“Cancel”* button, for example to remove the write protection on the disk.

If you re-open the project, a line appears at the top right in the main window `'The project cannot not be saved…'`. You must now select one of the offered options if you wish to save the project file.

See also

- ↳ *“General information about write and access protection” on page 197*

1.4.1.5.2 Assigning Passwords

Requirement: The project is open.

1. Click *“Project ➔ Project Settings”* and then select the *“Security”* category.
   ⇨ The dialog *“Project Settings / Security”* opens.
2. Select the *“Encryption”* option.
   ⇨ The option fields *“Password”*, *“Dongle”*, and *“Certificates”* are selectable.
3. Select the option *“Password”*.
   ⇨ The input fields for the encryption password appear.
4. Enter the encryption password in the input field *“New Password”*.
5. Enter the encryption password for confirmation in the input field *“Confirm new password”*.
6. Click *“OK”*.
   ⇨ CODESYS saves the encryption password for the project. You must enter this password in order to be able to open the project again, even if it is to be loaded as a library reference.

CAUTION!
If you no longer know the encryption password, you can no longer open or restore the project!

See also

- ↳ *Chapter 1.4.1.20.4.11.7 “Dialog 'Project Settings' - 'Security'” on page 1176*
- ↳ *Chapter 1.4.1.5 “Protecting and Saving Projects” on page 197*

1.4.1.5.3 Protecting Projects Using a Dongle

Requirement: The project is opened and you have connected the CODESYS Security Key (dongle) to your computer.

1. Click *“Project ➔ Project Settings”* and then select the *“Security”* category.
   ⇨ The dialog *“Project Settings / Security”* opens.
2. Select the *“Encryption”* option.
   ⇨ The option fields *“Password”*, *“Dongle”*, and *“Certificates”* are selectable.
3. Select the option *“Dongle”*.
   ⇨ The dialog with the drop-down list *“Registered Dongles”* and the buttons *“Add”*, *“Remove”*, *“Comment”* and *“Flash”* opens.
4. Click *“Add”*.
   ⇨ The *“Add Registered Dongle”* dialog opens.
5. Select the CODESYS Security Key (dongle) from the *“Dongle”* drop-down list and optionally enter a comment.
6. Click *“OK”*.
   ⇨ The added dongle is listed in the list *“Registered Dongles”*.
7. Click *“OK”*.
   ⇨ The dongle is registered for the project. You must connect the dongle to your computer in order to be able to open the project again, even if it is to be loaded as a library reference.

NOTICE!
If the CODESYS Security Key registered for the project is lost, you can no longer open the project or restore it.

See also

- *Chapter 1.4.1.20.4.11.7 “Dialog 'Project Settings' - 'Security'” on page 1176*
- *Chapter 1.4.1.5 “Protecting and Saving Projects” on page 197*

1.4.1.5.4 Setting up a user management

This concerns a user management for a CODESYS project file. Visualizations and devices can have their own user management.

The following guide describes how you can adapt the user management for the first time in a project. It deals with the definition of a user and a group to which he belongs.

Requirement: the project for which the user management is to be set up is opened. There is no adapted user configuration yet.

1. Select *“Project Settings ➔ Users and Groups”* and then the *“Users”* tab. The user `Owner` is already created by default.
2. Click on *“Add”*.
   ⇨ The dialog box *“Add User”* appears.

3. Enter a login name, for example 'Dev1', and a password. Leave the option *"Activated"* activated. Click on *"OK"*.

   ⇨ On creating a group for the first time, CODESYS now requests you to authenticate yourself to perform this action.

   In this case, enter 'Owner' as the *"current user"*. Do not enter a *"password"*, just click on *"OK"*.

   The user `Dev1` appears in the list and is automatically a `member of the group 'Everyone'.`

4. Change to the tab *"Groups"*, in order to add the user to a new group.

   ⇨ The groups `Everyone` and `Owner` have already been created.

5. Click on *"Add"* in order to open the dialog box *"Add Group"*.

6. Specify at least one name for the new group, for example 'Developers'. Activate the checkbox next to the entry *"User 'Dev1'"* in the field *"Members"*. Click on *"OK"*.

   ⇨ The group *"Developers"* now appears with `has user member 'Dev1'.`

7. Switch to the *"Users"* tab.

   ⇨ The user *"Dev1"* now appears as a member of the groups 'Everyone' and 'Developers'.

You can take over the user management configuration from another project by using the "Export/Import" functions in the dialog box "Project Settings", category "Users and Groups".

- *Chapter 1.4.1.10.3 "Handling of Device User Management" on page 385*

1.4.1.5.5 Protecting Objects in the Project by Access Rights

Protection of individual objects by setting access rights in the *"Rights"* editor

1. Select *"Project ➔ User Management ➔ Rights"*

   ⇨ The window of the *"Rights"* editor opens. On the left you can see the action categories, on the right the currently existing user groups.

2. Expand the relevant action category and below it the action for which you wish to change a right.

3. Select the goal of the action in the *"Actions"* window. In the *"Rights"* window, select the group for which you would like to change the right. Multiple selection is possible.

   ⇨ The buttons in the symbol bar are active.

4. Click on the appropriate button in order to change the right of the group for the action on the target object.

   ⇨ CODESYS updates the symbol in front of the group according to the new right. The right is immediately effective.

See also

- ↳ *Chapter 1.4.1.20.4.6 “Dialog 'Permissions'” on page 1152*

Protection of individual objects by setting access rights in the object properties

Here you can configure whether the members of a group have the right to view, edit or remove the object and to add/remove child objects to/from the object.

1. Select the object in the navigator tree.
2. In the context menu, select the command *“Properties”* and in the dialog box select the category *“Access Control”*.
3. In the table under *“Groups, Actions and Permissions”*, double-click on the symbol of the right that you wish to change.
   ⇨ A selection list of the possible rights appears: *“Grant”*, *“Deny”*, *“Clear”*.
4. Select the desired right and click on *“Accept”* or *“OK”*.
   ⇨ The right is immediately effective for the action and group. The symbol changes accordingly.

See also

- ↳ *Chapter 1.4.1.20.4.10.6 “Dialog 'Properties' - 'Access Control'” on page 1161*

1.4.1.5.6 Logging in via User Account and Password Manager

Logging in to a project without using the password manager functions

Requirement: A project is open. You wish to log in as a defined user for this project or for a library integrated in it in order to edit one or the other with certain rights. You have the required login data for the respective project or the library.

1. Select *“Project ➔ User Management ➔ User Logon”*.
   ⇨ The dialog box *“Logon”* opens.
2. Select the project file from *“Project/Library”* and enter the required access data *“User name”* and *“Password”*.
3. Log in with *“OK”*.
   ⇨ If another user is already logged in, this user will automatically be logged out by the new login.

Setting a master password for the password manager

Requirement: A project is open. The dialog box *“Login”* is open for you to log in as a defined user for a project or for a library integrated in the project. You wish to use the password manager in order to save login data in it.

1. Select *“Project ➔ User Management ➔ User Logon”*.
2. In the dialog box *“Logon”*, click on the button .
   ⇨ If you are working for the first time with the password manager, the dialog box *“Password Manager Configuration”* opens.

3. Enter a character string as the future master password. Confirm it in the second line and click on *“OK”*.

   ⇨ CODESYS notes the master password until you terminate the current CODESYS session. You must always input this password when you wish to log in to the password manager for the first time during a new session, or after you have changed it.

> **NOTICE!**
> If you have forgotten your master password, you no longer have any possibility to access the login data already saved! In this case you can only reset the password manager. After that you must start again to save passwords in the manager!

Saving login data in the password manager

Requirement: A project is open. You wish to log in as a defined user for this project or for a library integrated in it in order to edit one or the other with certain rights. You have the required login data for the respective project or the library. These login data have not yet been saved in the password manager.

1. Select *“Project ➔ User Management ➔ User Logon”*, in order to open the *“Logon”* dialog box.
2. Select the project file from *“Project/Library”*.
3. Enter the user name and password for the project or the library.
4. Click on the button .

   ⇨ If you are working for the first time with the password manager, you will be requested to define a master password. Refer to the above guide 'Setting a master password for the password manager' for this.

   When you call the password manager for the first time in this CODESYS session, you will be requested to enter the master password.
5. Enter the master password when requested to do so.

   ⇨ The password manager menu appears.
6. Select the option *“Save the credentials locally on this computer”*.

   ⇨ The login takes place. The data are saved in the password manager.

Getting the login data from the password manager

Requirement: A project is open. You wish to log in as a defined user for this project or for a library integrated in it in order to edit one or the other with certain rights. The login data required for this are already saved in the password manager.

1. Select *“Project ➔ User Management ➔ User Logon”* in order to open the *“Logon”* dialog box.
2. Click on the button .

   ⇨ If you are working for the first time with the password manager, you will be requested to define a master password. Refer to the above guide 'Setting a master password for the password manager' for this.

   When you call the password manager for the first time in this CODESYS session, you will be requested to enter the master password.
3. Enter the master password when requested to do so.

   ⇨ The password manager menu appears.
4. Select the appropriate entry *“Use the stored credentials for <user name>”*.

   ⇨ The login takes place automatically with the data read from the password manager.

Opening the password manager, changing the master password

Requirement: A project is open. You wish to open the password manager in order to view and/or edit the entries or to change the master password. You have already logged in once with the master password.

1. Select *"Project ➔ User Management ➔ User Logon"*, in order to open the *"Logon"* dialog box.
2. Click on the button .

   Select *"Open the Password Manager"*.

   ⇨ The password manager window opens.
3. Click on *"Change Master Password"* and make the change.

Logging out from the project

Requirement: A project is open. A user is logged in, which is recognizable by a name entry in the field *"Current User"* in the status bar.

▷ Select *"Project ➔ User Management ➔ User Logoff"*. Alternatively, double-click on the field *"Current User"* in the status bar.

⇨ If the user is logged in to only one project, he will now be logged out without further interaction. *"(nobody)"* appears again in the field *"Current User"* in the status bar

If the user is logged in to several projects, the dialog box *"Logoff"* opens. There, select the specific project or library project from which the user is to be logged out.

See also

- *"User management and password manager" on page 199*
- *Chapter 1.4.1.20.3.4.28 "Command 'User management' – 'Log in User'" on page 1016*
- *Chapter 1.4.1.5.4 "Setting up a user management" on page 203*

1.4.1.5.7 Encrypting Projects with Certificates

Configuring a certificate for project file encryption in a user profile

When a project is encrypted with a certificate, this certificate is needed for decryption to open the project. You can assign this certificate to specific user profiles. To do this, select the certificate from the Windows Certificate Store on the *"User"* tab of the *"Security Screen"*.

1. Double-click in the status bar or click *"View ➔ Security Screen"*.

   ⇨ The *"Security Screen"* view opens.
2. In the *"User"* tab, select the user profile for which the communication will be encrypted. By default, the specified user profile is the one you have used on your computer to sign into Windows. You can also create a new user profile with .
3. Click the button in the *"Project file decryption"* area.

   ⇨ The *"Certificate Selection"* dialog opens.
4. Select a certificate with a private key from the list *"Available certificates in the local Windows Certificate Store"*. Certificates with a private key are identified by the symbol.
5. Click .
6. The certificate is added to the upper part of the dialog.
7. Click *"OK"* to confirm your selection.

   ⇨ The selected certificate is displayed in the *"Security Screen"* in the *"Project file decryption"* area.

Encrypting a project with a certificate

A project encrypted with a certificate in connection with a user management allows you to restrict access to the project.

1. Click *"Project ➔ Project Settings"* and then select the *"Security"* category.
   ⇨ The *"Project Settings / Security"* dialog opens.
2. Select the *"Encryption"* option.
   ⇨ The option fields *"Password"*, *"Dongle"*, and *"Certificates"* are available.
3. Select the *"Encryption"* option.
   ⇨ The certificates available for project encryption are listed in the lower part of the dialog. If no certificate has been specified yet, then click to select a relevant certificate in the *"Certificate Selection"* dialog. Then return to the *"Project Settings"* dialog. Now the certificate is specified for encryption. Now the project can only be edited on computers of users who also have the certificate for file decryption.

Deleting a certificate in the user profile

You delete the certificate in the *"Security Screen"* view, either directly on the *"User"* tab or in the *"Certificate Selection"* dialog. The deletion will follow in the other dialog.

- Dialog *"Security Screen"*, tab *"User"*, *"Digital Signature"*, or *"Project Data Decryption"*: Select a certificate and click
- Dialog *"Certificate Selection"*: in the *"Security Screen"* dialog, click on the *"User"* tab. In the upper field of the *"Certificate Selection"* dialog, select the certificate to be deleted and click .

Configuring a certificate for the digital signature in a user profile

To ensure that the project is not only encrypted with a certificate, but also that its authorship and integrity can be verified, you can add a signature to the project:

1. Double-click in the status bar or click *"View ➔ Security Screen"*.
   ⇨ The *"Security Screen"* view opens.
2. In the *"User"* tab, select the user profile for which the digital signature will be created. By default, the specified user profile is the one you have used on your computer to sign into Windows. You can also create a new user profile with .
3. Click the button in the *"Digital signature"* area.
   ⇨ The *"Certificate Selection"* dialog opens.
4. Select a certificate with a private key from the list *"Available certificates in the local Windows Certificate Store"*. Certificates with a private key are identified by the symbol.
5. Click .
   ⇨ The certificate is added to the upper part of the dialog.
6. Click *"OK"* to confirm your selection.
   ⇨ The selected certificate is displayed in the *"Security Screen"* in the *"Digital signature"* area.

See also

- *"Encryption with certificates" on page 198*

- *Chapter 1.4.1.20.4.10.3 "Dialog 'Properties' - 'Encryption'" on page 1158*
- *Chapter 1.4.1.20.4.11.7 "Dialog 'Project Settings' - 'Security'" on page 1176*
- *Chapter 1.4.1.8.17 "Encrypting an application" on page 294*

1.4.1.5.8 Saving the Project

Saving a project under the same name

Requirement: The project is open. The project file is not write-protected.

▷ Select *“File ➔ Save”*.

⇨ CODESYS saves the project file with the current project name, which appears in the title bar of the main window. If the project has been changed since it was last saved, then the project name is provided with an asterisk. If this is set in the CODESYS options in the category *“Load and Save”*, then a backup copy will also be made.

Saving a project under a different name or format

Requirement: The project is open.

1. Select *“File ➔ Save Project as”*.

   ⇨ The *“Save Project”* dialog box opens.

2. Select a storage location in the file system and the desired *“File Type”* (project file or library file) and the desired storage version. If you want to open the project later in an older version, then it makes sense to save for precisely this version, as you will then be informed immediately in the message window about possible data loss.

   ⇨ If the project file is not write protected, then CODESYS saves it in the selected path. Otherwise you will be informed how to proceed.

3. If the current project contains add-ons that are not available in the selected memory format, then the *“Extend Profile”* dialog box opens.
4. Select the add-ons to extend the memory profile in order for the add-on data to be saved.
5. To save the memory profile permanently, click *“Save Profile”* and specify a name in the *“Enter profile name”* dialog box.
6. In the *“Extend Profile”* dialog box, select the *“Use saved profile”* option and click *“Yes”*.

   ⇨ CODESYS saves the project with the saved profile.

Saving a read-only project

Requirement: A read-only project is open.

▷ Select *“File ➔ Save”*.

If the write protection was assigned in CODESYS, then it will be displayed by a line in the top right corner of the main window. Depending on the current situation you will be offered one or more of the following actions so that you can still save the project:

- *“Save project under a different file name on the disk”*: Always appears and continues to the *“Save File”* dialog box, as for the *“Save File as”* command
- *“Exit read-only mode”*: Appears if the *“Open read-only”* option is selected when opening the project.
- *“Remove read-only attribute from the project on the disk”*: Appears if the project file was provided with the 'Read-only' property in the local file system at the time of opening.
- *“Remove identification 'Released' in the project information”*: Appears only if this attribute is currently set.

If the write protection was assigned outside of CODESYS in the properties of the project file in the file system, you will be offered the following options when you attempt to save under the same name and path:

- *“Save as”*: You can save under a different name as with the *“Save Project as”* command.
- *“Overwrite”*: The write protection is removed from the project file and the file is saved under its existing name.

1. Click on the line in the top right corner of the main window that indicates the write protection.
   ⇨ The current options with which you can still save the project appear in a selection menu.
2. Select one of the options offered and perform any necessary actions.
3. Click *"File ➔ Save"* or *"File ➔ Save as"*.
   ⇨ The project can be saved.

Saving of the project automatically; creating a backup copy

Requirement: The project is open.

1. Click *"Tools ➔ Options"* (category *"Load and Save"*.
   ⇨ The *"Load and Save"* dialog box opens.
2. Activate the *"Create backup files"* option.
3. Activate the *"Automatically save every … minutes"* option and select a time interval.
4. Click *"OK"* to close the *"Options"* dialog box.
   ⇨ Each time the project is saved, CODESYS also creates a backup copy `<project name>.backup`.

   CODESYS saves the project automatically at the specified time interval to a file `<project name>.autosave` in the project directory. If you open the project again after the development system was closed irregularly, then this file will be offered to you as an alternative to the file last saved by the user.

See also

- *Chapter 1.4.1.5 "Protecting and Saving Projects" on page 197*
- *Chapter 1.4.1.20.4.13.16 "Dialog 'Options' – 'Load and Save'" on page 1196*

1.4.1.5.9 Saving/Sending the project archive

You can configure a project archive and then save it in the file system or send it directly in an e-mail.

To send, follow the guide below as far as point 9. There, click on the button *"Send"* instead of *"Save"* in order to directly open the standard e-mail program, in which a new mail will automatically be created with the project archive file as an attachment.

Requirement: A project is opened.

1. Select *"File ➔ Project Archive ➔ Save/Send Archive"*.
   ⇨ The dialog box *"Project Archive"* appears.
2. Activate the checkbox next to each object that is to be saved in the archive.

In order to guarantee know-how protection,CODESYS will not automatically add unprotected libraries, not available as "compiled-library", to a project archive. If you explicitly select such a library in the list of additional files, you will get an appropriate warning.

3. If you want to pack further files in the archive, click on *"Additional Files"*.
   ⇨ The dialog box *"Additional Files"* opens.
4. Click on *"Add"*.

5. Select the files and click *“Open”*.
   ⇨ The files are added to the list of additional files.
6. Click on *“OK”*.
7. Click on *“Comment”*.
   ⇨ The dialog box *“Comment”* opens.
8. Enter a comment and click on *“OK”*.
9. Click on the button *“Save”*.
10. Select a storage location and a file name and click on *“Save”*.
    ⇨ The project archive is saved in the file directory.

See also

- *Chapter 1.4.1.20.3.1.4 “Command 'Save project'” on page 957*
- *Chapter 1.4.1.20.3.1.5 “Command 'Save Project as'” on page 958*

1.4.1.5.10 Linking a project to the source control system

To link your CODESYS projects to a source control system, check the following option:

The Professional Version Control add-on provides the capability of directly linking to an SVN database. You can get the package at the CODESYS Store and install it with the help of the Package Manager.

Refer to the corresponding help when using Professional Version Control.

1.4.1.6 Localizing projects

You can display your project in different languages when you create and link localization files. The localization files correspond to those of the `GNU gettext` system. The format of the localization template files is *.pot (Portable Object Template), from which localization files `*.po` (Portable Object) are generated after translation.

The project can be localized in different languages. However, editing is possible only in the original version.

You configure which categories of text information are localized in the project. Then you export these texts into a translation template. This template is a file in `*.pot` format (example: `project_1.pot`). You produce localization files in the format `*.po` (example: `de.po`, `en.po`, or `es.po`), either automatically with a corresponding external translation tool or manually with a neutral text editor. You can import the `*.po` files back into CODESYS and use them for localization.

The commands for using project localization are located in the menu *“Project ➔ Project localization”*.

See also

- *Chapter 1.4.1.20.3.4.16 “Command 'Project Localization' - 'Create Localization Template'” on page 1007*

Generating localization templates

Requirement: A project is open.

1. Click *"Project ➔ Project Localization ➔ Create Localization Template"*.
   ⇨ The *"Create Localization Template"* dialog box opens.
2. Activate the categories of text information that should be included in the localization template.
3. *"Position information"* can also be included in the template. For each text to be translated, specify its location in the project. Select the positions to be displayed in the translation template: only the first position found, all positions found, or none.
4. Click the *"Generate"* button.
   ⇨ The dialog box opens for saving a `*.pot` file to the file system. Save the localization template. Then you can process the file in a translation tool and generate localization files `<language>.po` in the required languages.

Format of the localization template: file `*.pot`

In the first line, the text categories are specified that were selected for the translation when generating the template:

Example: `#: Content:Comments|Identifiers|Names|Strings`: All four categories were selected.

Then each text to be translated is segmented in the form as in the following example:

Example

```
#: D:\Projects\p1.project\Project_Settings:1
msgid "Project Settings"
msgstr ""
```

Line 1: Position information displayed as source code reference. Displayed only if this has been configured when generating the translation file.

Line 2: Untranslated text as entry `msgid` (example: `msgid "Project settings"`).

Line 3: Placeholder for the translation: `msgstr ""`. Between the single straight quotation marks, the translation in the `*.po` file must be inserted in the respective language.

Format of the localization file: `*-<language>.po`

You can generate a `*.po` file with a translation tool or create one using a neutral text editor based on the `*.pot` file. For this purpose, you could change the file extension from `*.pot` to `*.po` and edit the according to `*.po` standard format.

It is imperative to specify the language in the form of the usual culture abbreviation in the metadata of the file (example: `"Language: de"` for German. Then you insert the translations of the individual texts between the straight quotation marks for the `msgstr ""` entries.

Example

```
"Language: de\n"
#: Content:Names
#: D:\projects\p1.project\Project_Settings:1
msgid "Project Settings"
msgstr "Projekteinstellungen"
```

Importing localization files / localizing projects

Requirement: For your project, localization files (`<language>.po`) were generated based on the translation template `*.pot`. The project is open.

1. Click *"Project ➔ Project Localization ➔ Manage Localizations"*.
2. Click on the *"Add"* button.
   ⇨ The *"Open Localization File"* dialog box appears for selecting a `*.po` file from the file system.

3. Select one of the localization files (example: `<project name>-de.po`).
   ⇨ The dialog box closes and the affected texts appear in the project in the respective language. For example, if you specify the translation `msgstr "Main program"` for the POU name "PLC_PRG" in the English localization file, then the object name "Main program" appears in the device tree.
4. In the same way, you import the localization files for other language targets.

Switching localization, adding and removing localization files

Requirement: All required language are stored in the project by importing the corresponding `*.po` file. The project is open.

1. Click *"Project ➔ Project Localization ➔ Manage Localization"*.
   ⇨ The *"Manage Localization"* dialog box opens. All stored localization files `*-<language>.po` appear in *"Files"*, as well as the entry *"<original version>"*.
2. Select the desired language and click the *"Switch Localization"* button.
   ⇨ The project appears in the selected language. When you select *"<original version>"*, the project is displayed in the original, unlocalized version and it cannot be edited.

Optional: Defining a default localization, toggling localizations

▷ Select one of the available localizations and activate the *"Default Localization"* option.
   ⇨ Click *"Project ➔ Project Localization ➔ Toggle Localization"* to toggle the localization between the default localization and original version. By default, this command is also available with the button on the toolbar.

1.4.1.7 Configuring I/O Links

With the help of device objects you can map hardware to be controlled in a tree structure in your CODESYS project. This makes the linking of hardware and application easy to handle.

In the configuration editors of the device objects, you can configure the settings for the communication between CODESYS and the controller, and above all for I/O mapping. The I/O mapping is the linking of the inputs and outputs of the controller with the variables of your application.

Access to control objects at runtime can be controlled, depending on the device, via an 'online user management', which you can edit – likewise depending on the device – in the CODESYS Development System. Moreover, communication with the controller depends on the current security settings.

See also

- *Chapter 1.4.1.7.1 "Configuring Devices and I/O Mapping" on page 213*

1.4.1.7.1 Configuring Devices and I/O Mapping

Configuring devices

You can configure the device objects inserted into the device tree in the associated device editor. The possibilities depend on the device description. The 'generic device editor' provides tabs that are supplemented as necessary by device-specific tabs.

Requirement: You have opened a standard project in whose device tree a standard PLC and below that a fieldbus device object are inserted.

1. Double-click the device object of the standard PLC in the device tree of your project.
   ⇨ The *“<device name>”* editor opens in the CODESYS main window. The *“Communication Settings”* tab is in the foreground. Change to the other tabs in order to make configuration settings for the controller. See the help pages for the generic device editor.
2. Double-click the fieldbus device object in the device tree of your project.
   ⇨ The *“<fieldbus device name>”* editor opens in the CODESYS main window. Specific tabs are available depending on the device. For the configuration options, see the help pages for the respective device editor. If the *“Show generic device configuration views”* option is selected in *“Tools ➔ Options”*, in the *“Device Editor”* category, then see also the tabs contributed by the generic device editor.

See also

- *Chapter 1.4.1.20.2.8.1 “Generic device editor” on page 839*

General information about I/O mapping

Whether or not you can configure an I/O mapping to project variables or even to the entire function blocks depends on the type of device. Configuring an I/O map means linking input and output channels of the device with variables of the project. We also use the term **'mapping'** for this.

Pay attention in general to the following for the mapping of inputs and outputs of a device to variables in CODESYS:

- You do not have write access to variables that are mapped to an input.
- You can map an existing variable to one input only.
- You can directly generate new global implicit variables in the I/O map and map them to a device channel.
- The memory layout of structures is specified by the device.
- You can change addresses and fix values in the I/O map.
- For each variable that is assigned to an I/O channel in the *“I/O Mapping”* dialog, you can cause 'force variables' to be generated during the compilation of the application (see further below). Using these variables you can, for example during the commissioning of a plant, force a value on the input or output via a visualization/HMI.
- Changes in the I/O map can be transferred to the controller with an online change.
- If a pointer to a device input is used, the access is considered to be a write access, for example `pTest := ADR(input);`. This leads to a compiler warning when the code is generated: "`...invalid assignment target`". If you require a construct of this kind, you have to first copy the input value `input` to a variable with write access.
- An I/O address can also be linked with a variable via the 'AT declaration' in the IEC code. Since a device configuration often changes again, however, we recommend that you make the assignments only in the device editor.

  If you use the AT declaration, note the following:
  – An AT declaration is permissible only with local or global variables, not with input or output variables of function blocks.
  – Implicit 'force variables' for I/Os (see below) cannot be generated for AT declarations.
  – If you use an AT declaration with structure variables or function block variables, all instances will access the same memory location. This then corresponds to the use of 'static variables' in classic programming languages such as 'C'.

NOTICE!

If a pointer to a device input is used, then the access (for example, `pTest := ADR(input);`) applies as write access. This leads to a compiler warning when the code is generated: "`...invalid assignment target`".

If you require a construct of this kind, you have to first copy the input value (`input`) to a variable with write access.

As an alternative, you can assign a variable to an address in the programming code using the AT declaration. In view of possible changes of the device configuration, however, we recommend that you make the assignments only in the device editor.

You can export the I/O mapping configuration of a device to a `csv` file or import it from such a file.

- *"Generating implicit variables for the forcing of I/Os" on page 221*

Linking a device input with an existing project variable ("mapping")

Requirement: A device that supports an I/O mapping configuration in CODESYS is inserted in the device tree of your project. On the *"I/O Mapping"* tab in the device editor you thus get a tabular display of the input and output channels of the device with specification of the addresses and data types.

NOTICE!

Mapping 'too large' data types

If a variable of a data type that is larger than a byte is mapped to a byte address, the value of the variable will be truncated to byte size there. For monitoring the variable value in the *"I/O Mapping"* dialog, this means that, in the root element of the address, the value is displayed which the variable currently has in the project. The current individual bit values of the byte are displayed in succession in the bit elements below that, but this may not be sufficient for the entire variable value.

If a UNION is represented by I/O channels in the mapping dialog, it depends on the device whether mapping to the root element is also possible.

1. In a POU, declare, for example, a variable `xBool4` of the type `BOOL` with which you want to access an input of the target device from the application.
2. To open the device editor, double-click the device object in the device tree, and then the *"<device name> I/O Mapping"* tab.
3. Observe the *"Variable"* column with the display of the device input channels and device output channels, which can still be sorted by organizational nodes, depending on the device. We assume that there is a device input of the type `BYTE`. It is displayed with its individual bit addresses (bit channels) below the `BYTE` node.

4. Note: When mapping structured variables, the editor prevents you from entering both the structure variable (example: `%QB0`) and individual structure elements (example: `%QB0.1` and `QB0.2`). Therefore, if there is a main entry with a subtree of bit channel entries in the mapping table, then the following applies: Then you can specify a variable either into the line of the main entry, or into the lines of the subelements (bit channels), but not into both.

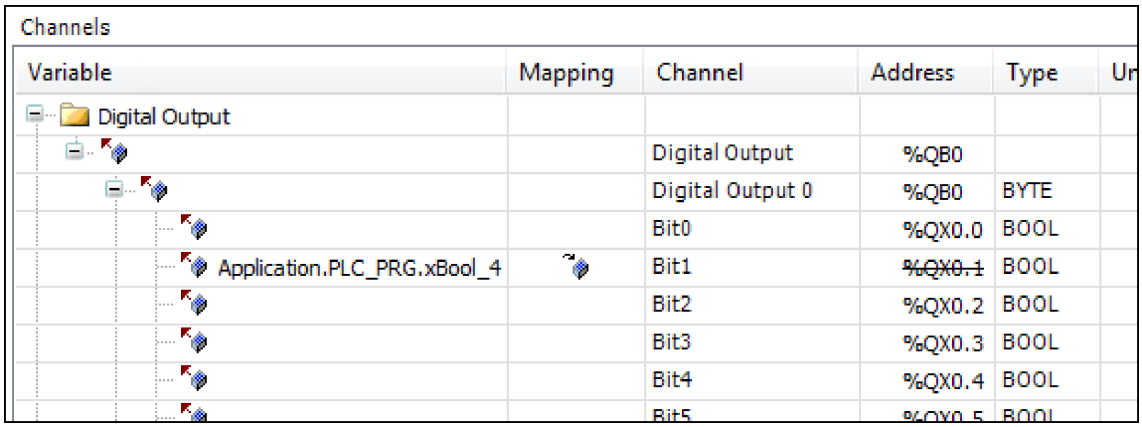
   You can now occupy either the entire channel with a variable of a suitable type OR its individual bit-channel addresses with suitable variables of the type `BOOL` or `BIT`. First of all, double-click a bit input channel in the *"Variables"* column.

   ⇨ An input field opens.

5. In order to place an existing variable on the channel, you have to enter the desired project variable with the complete path. Press ... to open the Input Assistant. Select, for example, the variable `Application.PLC_PRG.xBool4` declared in `PLC_PRG`.

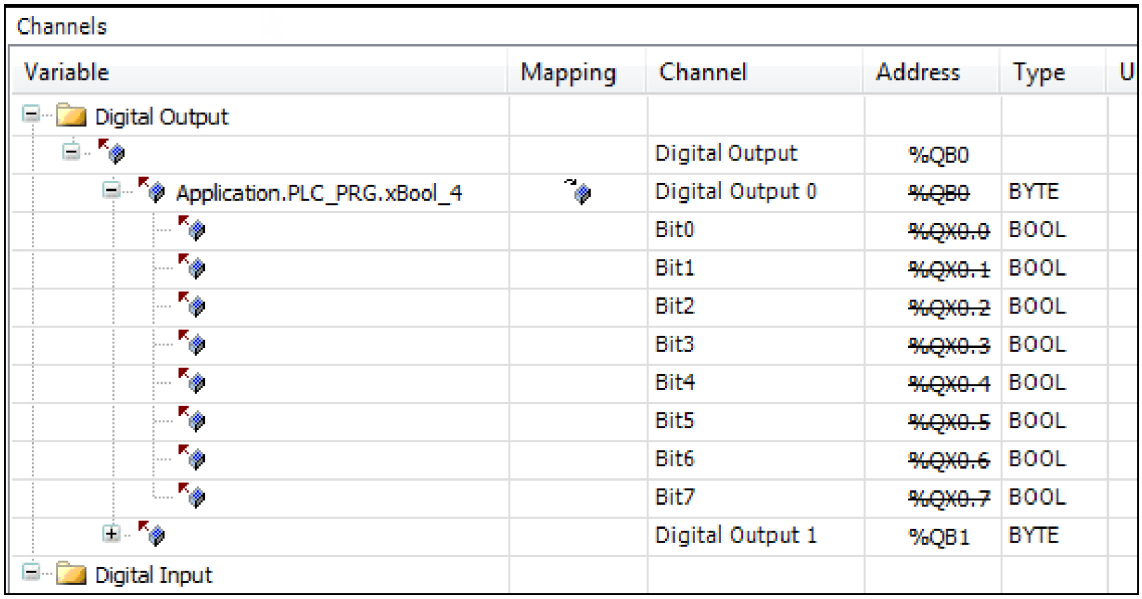
   ⇨ The variable is inserted. The HMI symbol ( ) is displayed in the *" Mapping"* column. The address is now struck through. That does not mean that the address is no longer available, because values of existing variables are managed at another memory space. But: in order to avoid ambiguities when writing the values, you should nevertheless not occupy the address with a further variable, especially in the case of outputs.

   Note: For compiler version V3.5 SP11 and higher, the initialization value of the variables is used automatically as the default value when mapping to an existing variable. You can edit the *"Default value"* field only if you map to a new created variable or if no mapping is specified. In older versions, users had to specify explicitly that the default value and initialization value were identical.



6. Delete the variable assignment again. Click the root of the channel, the `BYTE` node. Use the Input Assistant again to select the variable `Application.PLC_PRG.byte_gotodevice`.

   ⇨ The variable is inserted, all bit addresses of the main channel are struck through and you should not additionally occupy them.



See also

- *Chapter 1.4.1.20.2.8.11 “Tab '<device name> I/O Mapping'” on page 854*

Mapping a device input to a recently created project variable

In the following you will map a device output to a global implicit variable, which you recently create for this purpose directly in the *“I/O Mapping”* dialog.

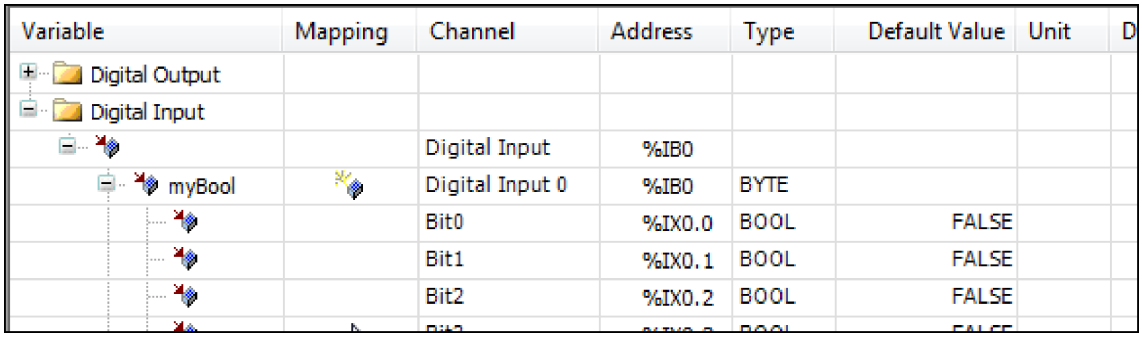
> *The “I/O Mapping” dialog is thus a further place for declaring a global variable.*

Requirement: A device that supports an I/O mapping configuration in CODESYS is inserted in the device tree of your project. On the *“I/O Mapping”* tab in the device editor you will thus see a tabular display of the input and output channels of the device with specification of the addresses and data types.

1. To open the device editor, double-click the device object in the device tree, and then the *“<device name> I/O Mapping”* tab.
2. Click in the mapping table on a channel entry in the *“Variable”* column in order to open an input field.

3. Enter a simple name (without '.') for a new variable (for example, `myBool`).

   ⇨ CODESYS creates the variable as an implicit global variable in the project and assigns it directly to the channel address. Therefore in this case the address does not appear struck through as in the case of mappings to existing variables.



Linking a device with a function block instance

If supported by the device, you can map entire function blocks to an input or output channel. This allows you to count the frequency of signal changes or scale a channel value for maintenance purposes, for example.

Here you will map a device output channel to a function block. In this example, the block scales the channel output value.

Requirement: A device with a digital output that supports FB mapping is linked in the project. There is a function block *"Scale_Output_Int"* with the following implementation. The attributes of the function block itself and before the output parameter with which the channel output is processed are important.

```
{attribute 'io_function_block'}
FUNCTION_BLOCK Scale_Output_Int
VAR_INPUT
    iInput : INT;
    iNumerator : INT;
    iDenominator : INT :=1;
    iOffset : INT := 0;
END_VAR
VAR_OUTPUT
 {attribute 'io_function_block_mapping'}
    iOutput : INT;
END_VAR
VAR
END_VAR
IF iDenominator <> 0 THEN
    iOutput := TO_INT(TO_DINT(iInput) * TO_DINT(iNumerator) /
TO_DINT(iDenominator)) + iOffset;
```

1. Open the *"<device name> I/O Mapping"* tab of the device editor. Double-click the output that should be connected to the function block. Click the button ✚ *"Add FB for IO channel"*.

   ⇨ The *"Select Function Block"* dialog opens. On the left side, you see at least the function block *"Scale_Output_int"* below the *"Application"* node. Libraries linked in the project that contain corresponding function blocks are also displayed for selection.

2. Select the POU `myScaleOutputInt`.

   ⇨ After clicking *"OK"*, the path of the function block parameter `iOutput` in the *"Variable"* is entered in the mapping dialog. The path comprises the application name, the device channel name, and the selected FB output (example: `App1.Out_4_Int_myScale_Output_Int_1.iOutput`).

3. Select the channel and click *"Go to Instance"*.

   ⇨ The focus switches to the *"<device name> IEC Objects"* tab and the created entry for the new IEC object `Out_4_Int_myScale_Output_Int_1`. In this view in online mode, you see the current value of the parameter `iOutput` for the channel `Out_4_Int` scaled by the FB. You can also write and force the value as in other monitoring views.

Changing and fixing an address value in the I/O map

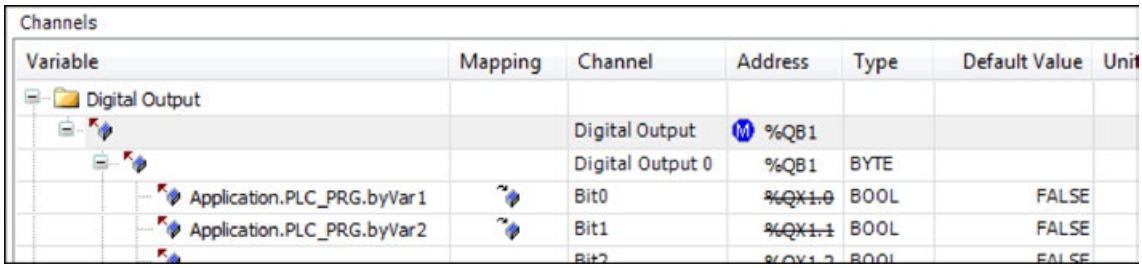
You can change the address value of an entire channel (but not that of an individual subelement of the channel!) in the mapping table of the *"<device name> I/O Mapping"* tab. This allows you to adapt the addressing to a specified machine configuration and to retain the address value even if the layout of the modules changes. By default, a change of the layout leads to an automatic adaptation of the address values.

Requirement: Your project has I/O mapping. See the corresponding sections of the help page above.

1. To open the device editor, double-click the device object in the device tree, and then the *"<device name> I/O Mapping"* tab.
2. Click in the mapping table on a channel entry in the *"Address"* column in order to open an input field. This is only possible for the 'root' address of a channel, not for a particular one of its subelements.

   Therefore, change the top address entry of a channel in the table, for example from `QB0` to `QB1`. Exit the input field.

   ⇨ The address value is changed. The symbol Ⓜ is displayed before the address. It indicates that the address is fixed. The addresses of the subelements of the channel are also changed accordingly. If you now change the position of the device object inside other device objects with input/output channels in the device tree, CODESYS does not adapt these addresses to the new order as would be the case without fixing.



3. In order to undo the manual change or fixing, open the input field of the address value again, delete the address entry and press the Enter key.

   ⇨ CODESYS resets the address and the subsequent addresses concerned to the values they had before the change and removes the symbol Ⓜ.

- *Chapter 1.4.1.20.2.8.11 "Tab '<device name> I/O Mapping'" on page 854*
- *Chapter 1.4.1.19.4.10 "Addresses" on page 643*

Configuration of the I/O variable update

Depending on the device that you link in the project, CODESYS updates the variables applied to its inputs and outputs in different ways. You can explicitly change the settings for this in the *"I/O Mapping"* dialog.

See also

- *Chapter 1.4.1.20.2.8.11 "Tab '<device name> I/O Mapping'" on page 854*

Monitoring of variables in the I/O map in online mode

Requirement: You have compiled an application with a device configuration containing I/O maps without error. The associated hardware and the bus system are running. You have connected to the controller by means of the *"Online ➔ Login"* command and have loaded and started the application.

1. Open the *"I/O Mapping"* tab of the PLC in the device editor. To open the editor, double-click the device object in the device tree.

   ⇨ The mapping table now additionally contains the *"Current Value"* and *"New Value"* columns.

   If a structure variable is mapped to the 'root' element of an address[1], CODESYS does not display a value in this line in online mode. If, for example, a `DWORD` variable is mapped to the address, however, the respective values are monitored both in the 'root' line and in the indented bit-channel lines below it.

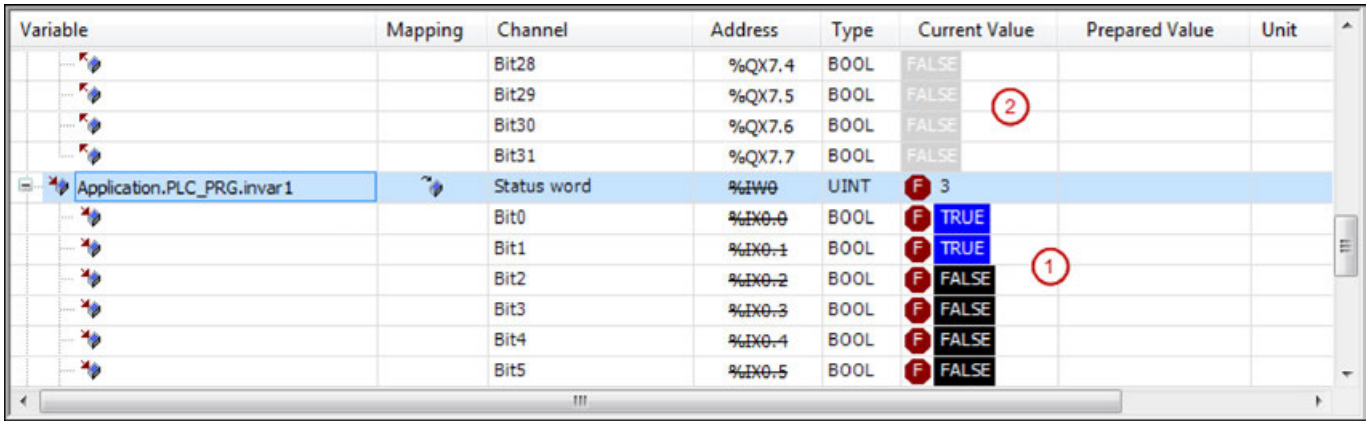
   As a matter of principle, the field in the 'root' line always remains empty if the value would be composed of several subelements.

   [1] 'root' = top element of this address in the Mapping dialog

2. Enter a certain variable value for an entry in the column *"New value"* and press *[F7]* to force or *[Ctrl]+[F7]* to write the value.

   ⇨ As in the case of monitoring in the declaration editor or in watch lists, the forced variable value is displayed in the column *"Current Value"* with a prefixed red F-symbol or the written value.

> **NOTICE!**
> Inputs and outputs that the PLC code does NOT use are not read by the PLC in online mode, as a result of which the displayed value could be incorrect. The *"Current Value"* of the variables concerned is displayed with a gray background.



(1) Forced values on the controller
(2) Values not used on the controller, value shown in gray

Generating implicit variables for the forcing of I/Os

During the commissioning of a plant or machine it may be necessary to 'force' the values applied at the inputs and outputs. If a device supports this you can cause special 'force variables' to be generated for this purpose and use them, for example, in an HMI visualization.

Requirement: The device supports the functionality. You have a project in which an I/O map is configured for the device and which contains a program object `PLC_PRG`.

1. Open the device editor, *"PLC Settings"* tab, by double-clicking the device object in the device tree.
2. Activate the option *"Generate force variables for IO mapping"*.
3. Press *[F11]* to compile the application.
   ⇨ Two variables are created for each I/O channel in accordance with the following syntax, in the process of which spaces in the channel name are replaced by underscores:

   `<device name>_<channel name>_<IEC address>_Force` of type `BOOL` for the activation and deactivation of forces.

   `<device name>_<channel name>_<IEC address>_Value` of the data type of the channel for defining the value that you want to force on the channel.

   These variables are available in the Input Assistant in the category *"Variables"* / *"IoConfig_Globals_Force_Variables."* You can use them in CODESYS in programming objects, in visualizations, in the symbol configuration, etc.
4. Open the function block *"PLC_PRG"*, set the focus in the implementation part and press *F2*.
   ⇨ The Input Assistant opens. The variables are available in the category *"Variables"* / *"IoConfig_Globals_Force_Variables"* as described above.

   A rising edge at the 'Force variable' input activates the forcing of the respective input or output with the value given by the 'Value variable'. A falling edge deactivates the forcing. Deactivation by resetting the 'Force' variable to `FALSE` is the requirement for being able to force a new value.

Take note of the following restrictions.

- Forcing via the implicit force variables is only possible for channels that are mapped in the *"I/O Mapping"* of the device to an existing or recently created variable.
- Forcing via the implicit force variables is not possible for unused inputs and outputs or those that are mapped to a variable via an AT declaration in an application program.
- I/O channels that you want to force via the mechanism have to be used by CODESYS in at least one task.
- CODESYS identifies forced inputs in the monitoring by the red Force symbol, but not forced input/outputs. The forced value is used only implicitly by the I/O driver for writing to the device.

See also

- *Chapter 1.4.1.20.2.8.9 "Tab 'PLC Settings'" on page 850*
- *Chapter 1.4.1.11.4 "Forcing and Writing of Variables" on page 401*

I/O mapping in one dialog for multiple devices

There is a table that displays the I/O map of a device plus the I/O maps of all subelements inserted below it in the device tree. There you can edit the I/O maps in exactly the same way as in the individual mapping tables of the respective device editors.

Requirement: In the device tree of your project there are several PLCs inserted that each enable an I/O mapping configuration.

1. Select the root node of the device tree and click *"Edit I/O Mapping"* in the context menu .
   ⇨ The *"Edit I/O Mapping"* dialog opens, in which the I/O mapping configurations of all devices inserted in the project are displayed in a table. You can edit the entries in the same way as in the *"I/O Mapping"* dialog of the associated device editor.

2. Now select one of the control objects in the device tree and select the *“Edit I/O Mapping”* command once again in the context menu.

   ⇨ The *“Edit I/O Mapping”* dialog now shows only the I/O table for the I/O mapping configurations found in and under the selected object.

3. Set a desired *“Filter”* in the bar above the table or enter a variable name in the *“Search for variable”* field in order to see the use of this variable in the mapping.

   ⇨ The method of working in this window is the same as that described for the *“<device name> I/O Mapping”* tab.

See also

- ↳ *Chapter 1.4.1.20.3.4.35 “Command 'Edit I/O Mapping'” on page 1018*

1.4.1.8 Programming of Applications

To create an application program which can be run on the controller, you fill POUs with declarations and implementation code (source code), establish the link from the controller I/Os to application variables, and configure the task assignment. After checking and debugging, the CODESYS compiler creates the application code which can be downloaded to the controller.

The programming of the application POUs is supported by the programming language editors and other features such as text lists, image pools, alarm configurations, pragmas, refactoring, and ready-to-use POUs from CODESYS Development System or libraries.

There are features for syntax checking and code analysis, for achieving data persistence, and for encrypting the application code which is downloaded to the controller.

1.4.1.8.1 Designating identifiers

Identifiers are names of variables and programming objects (for example programs, function blocks, and methods) and names of other objects of the application and project. There are rules that you must follow when assigning identifiers. Furthermore, there are also recommendations to help you designate uniform and expressive identifiers.

You designate variables identifiers in the variables declaration. These identifiers can e changed in the declaration section of the programming object. You designate identifiers for programming objects and other objects in the dialog box when adding the object. You can change the identifier of an existing object of the application or of the project in the properties dialog of the object. However, you cannot change the identifiers of objects that can be available only one time per application or project (for example, the *“Library Manager”* and *“ImagePool”* identifiers).

See also

- ↳ *Chapter 1.4.1.19.7 “Identifiers” on page 740*

1.4.1.8.2 Declaration of Variables

Variable declaration: Where and how?

You can declare variables at the following locations:

- Declaration part of a POU
  The *“Declare Variable”* dialog helps you with this.
  Hint: If you define a variable in the tabular declaration editor, the correct syntax is automatically produced.
- Declaration part of the GVL or NVL editor
- I/O mapping configuration of an I/O device object

Syntax

```
( <pragma> )*
<scope> ( <type qualifier> )?
    <identifier> (AT <address> )? : <data type> ( := <initial
value> )? ;
END_VAR
```

	Declaration	See also ● *Chapter 1.4.1.8.2.1 “Using the declaration editor” on page 226* ● *Chapter 1.4.1.8.2.2 “Using the 'Declare variable' dialog box” on page 227* ● *Chapter 1.4.1.20.3.2.32 “Command 'Auto Declare'” on page 975*
<pragma>	Pragma (none, one, or multiple) Note: By adding a pragma, you can affect the behavior and the properties of one or more variables.	See also ● *Chapter 1.4.1.8.6 “Using Pragmas” on page 263* ● *Chapter 1.4.1.19.6 “Pragmas” on page 683*
<scope>	Scope ● VAR ● VAR_CONFIG Note: If variables with incomplete address information are declared in function blocks (for example, AT %I*), then the variables in the variable declaration VAR_CONFIG have to be completely declared. You can access these variables in a local instance only when this is done. ● VAR_EXTERNAL ● VAR_GLOBAL ● VAR_INPUT ● VAR_INST ● VAR_IN_OUT ● VAR_OUTPUT ● VAR_STAT ● VAR_TEMP	See also ● *Chapter 1.4.1.19.2.1 “Local variables - VAR” on page 526* ● *Chapter 1.4.1.19.2.10 “Configuration variables - VAR_CONFIG” on page 534* ● *Chapter 1.4.1.19.2.8 “External variables - VAR_EXTERNAL” on page 533* ● *Chapter 1.4.1.19.2.5 “Global variables - VAR_GLOBAL” on page 531* *Chapter 1.4.1.20.2.10 “Object 'GVL' - Global Variable List” on page 871* ● *Chapter 1.4.1.19.2.2 “Input variables - VAR_INPUT” on page 526* ● *Chapter 1.4.1.19.2.9 “Instance variables - VAR_INST” on page 533* ● *Chapter 1.4.1.19.2.4 “Input/Output Variable (VAR_IN_OUT)” on page 527* ● *Chapter 1.4.1.19.2.3 “Output variables - VAR_OUTPUT” on page 527* ● *Chapter 1.4.1.19.2.7 “Static variables - VAR_STAT” on page 532* ● *Chapter 1.4.1.19.2.6 “Temporary variable - VAR_TEMP” on page 532*

    iTest: INT;
    fbDoItNow : FB_DoIt;
    iTest_200: INT;
    aData_Now : ARRAY[0..1] OF DATA_A := [(iA_1 := 1, iA_2 := 10,
dwA_3 := 16#00FF),(iA_1 := 2, iA_2 := 20, dwA_3 := 16#FF00)];
END_VAR

iTest := GVL.g_ciMAX_A;
iTest_200 :=  2 * GVL.g_ciMAX_A;
fbDoItNow(aData_A := aData_Now);
FOR iLoop := 0 TO GVL.g_ciSPECIAL DO
    ;
END_FOR
```

Variable initialization

The standard initialization value for all declarations is `0`. In the declaration part you can also specify user-defined initialization values for each variable and each data type.

The user-defined initialization starts with the assignment operator `:=` and consists of any valid expression of the programming language ST (structured text). You thus define the initialization value with the help of constants, other variables or functions. If you use a variable, you must also initialize it.

Examples

```
VAR

                var1:INT := 12;                 // initialization
value 12

                x : INT := 13 + 8;              // initalization
value defined by an expression of constants

                y : INT := x + fun(4);          // initialization
value defined by an expression,
                                                // that contains a
function call; notice the order!

                z : POINTER TO INT := ADR(y);   // not described in
the standard IEC61131-3:
                                                // initialization
value defined by an adress function;
                                                // Notice: In this
case the pointer will not be initialized
                                                // during an Online
Change *)
                END_VAR
```

Notes on the order of initialization

From compiler version 3.5.3.40, variables in a function block are initialized in the following order: firstly, all constants in accordance with the order of their declarations, then all other variables in accordance with the order of their declarations.

NOTICE!

From compiler version 3.3.2.0, variables from global variable lists are always initialized before the local variables of a POU.

- *Chapter 1.4.1.19.6.2.15 “Attribute 'global_init_slot'” on page 699*

Using the declaration editor

The declaration editor is used for declaring variables in the variable lists and POUs.

The declaration editor offers two possible views: textual and tabular.

in the dialog in *"Tools ➔ Options ➔ Declaration Editor"*, you define whether only the textual view or only the tabular view is available, or whether you can switch between both views by means of the buttons on the right side of the editor view.

If the declaration editor is used in conjunction with a programming language editor, it appears as the declaration part at the top of the window of a POU.

Declaring in the textual declaration editor

The behavior and the appearance of the textual editor are configured with the settings in the dialog *"Tools ➔ Options ➔ Text Editor"*. The settings concern colors, line numbers, tab widths, indentations etc. The usual Windows functions are available, plus the IntelliMouse functions if necessary.

Requirement: You have opened a programming object (POU, GVL or NVL) of a project. The textual declaration editor has the focus.

▷ Enter the variable declarations in correct syntax. With *[F2]* you can open the dialog *"Input Assistant"* for the selection of the data type or a keyword.

Declaring in the tabular declaration editor

In the tabular declaration editor, you add variable declarations to a table with the following columns: *"Scope"*, *"Name"*, *"Address"*, *"Data type"*, *"Initialization"*, *"Comment"*, and *"Attributes"* (pragmas).

Requirement: A programming object (POU or GVL) of a project is open. The tabular declaration editor has the focus.

1. Click the button in the declaration header or select the command *"Insert"* in the context menu.
   ⇨ CODESYS inserts a new row for a variable declaration and the input field for the variable name opens.
2. Specify a valid variable identifier.
3. Open the other fields of the declaration line as required with a double-click and select the desired specifications from the drop-down lists or with the help of the dialogs which appear.

See also

- *Chapter 1.4.1.19.1.1 "Declaration Editor" on page 461*
- *Chapter 1.4.1.20.3.2.32 "Command 'Auto Declare'" on page 975*
- *Chapter 1.4.1.8.2.2 "Using the 'Declare variable' dialog box" on page 227*
- *Chapter 1.4.1.20.3.16.2 "Command 'Edit Declaration Header'" on page 1121*
- *"Dialog 'Input Assistant' - Tab 'Categories'" on page 978*

Using the 'Declare variable' dialog box

Requirement: A programming object (POU or GVL) of a project is open.

1. Select the command *"Edit ➔ Auto Declare"*.
   ⇨ The dialog box *"Auto Declare"* opens.
2. Select the desired scope for the variable from the selection list *"Scope"*.
3. Enter a variable name in the input field *"Name"*.
4. Select the desired data type from the selection list *"Type"*.
5. If the initialization value deviates from the standard initialization value, enter an initialization value for the variable.
6. Complete your entries with a click on *"OK"*.
   ⇨ CODESYS lists the newly declared variable in the declaration part of your programming object.

With the help of pragmas in the declaration part you can affect the processing of the declaration by the compiler.

See also

- *Chapter 1.4.1.20.3.2.32 “Command 'Auto Declare'” on page 975*
- *Chapter 1.4.1.19.5 “Data Types” on page 646*
- *Chapter 1.4.1.8.6 “Using Pragmas” on page 263*

Declaring arrays

Requirement: A programming object (POU or GVL) of a project is open.

1. Click *“Edit ➔ Declare Variable”*.
   ⇨ The *“Declare Variable”* dialog opens.
2. Select the desired scope for the array from the drop-down list *“Scope”*.
3. Enter an identifier for the array in the *“Name”* input field.
4. Click the arrow button (>) next to the *“Data type”* input field and select the *“Array Assistant”* entry from the selection menu.
5. In the input fields *“Dimension 1”*, type in the lower and upper limit of the first dimension of the array (example: `1` and `3`).
   ⇨ The field *“Result”* displays the 1st dimension of the array (example: `ARRAY [1..3] OF ?`).
6. In the input field *“Basic type”*, type in the data type of the array or use the *“Input Assistant”* (>) or the *“Array Assistant”* (example: `DINT`).
   ⇨ The field *“Result”* displays the data type of the array now (example: `ARRAY [1..3] OF DINT`).
7. Define the second and third dimensions of the array according to steps 5 and 6 (example: Dimension 2: `1` and `4`, Dimension 3: `1` and `2`).
   ⇨ The *“Result”* field displays the array with the defined dimensions: `ARRAY [1..3, 1..4, 1..2] OF DINT`. The array consists of 3 * 4 * 2 = 24 elements.

   In an array of variable length, declare the dimension limits with an asterisk placeholder (`*`). Arrays of variable length are permitted to be used only in VAR_IN_OUT declarations of function blocks, methods, or functions.

   Example of a 2-dimensional array of variable length:
   `aiUnknownLengthData : ARRAY [*,*] OF INT;`
8. Click *“OK”*.
   ⇨ In the dialog *“Declare Variable”* the field *“Data type”* displays the array.
9. To modify the initialization values of the array, click the arrow button (...) next to the *“Initialization value”* input field.
   ⇨ The *“Initialization Value”* dialog opens.
10. Select the line of the array element whose initialization value you wish to modify. Example: Select array component [1, 1, 1].

11. Enter the desired initialization value in the input field below the list and click button *“Use value on selected lines”* (example: value `4`).

    ⇨ CODESYS displays the changed initialization value of the selected line.

12. Click *“OK”*.

    ⇨ In the *“Initialization value”* field of the *“Declare Variable”* dialog, CODESYS displays the initialization values of the array (example: `[4, 23(0)]`).

13. You can optionally enter a *“Comment”* in the input field.

14. Click *“OK”* in order to conclude the declaration of the array.

    ⇨ CODESYS adds the declaration of the array to the declaration part of the programming object.

See also

- *Chapter 1.4.1.20.3.2.32 “Command 'Auto Declare'” on page 975*
- *Chapter 1.4.1.19.5.14 “Data Type 'ARRAY'” on page 660*

Declaring global variables

Declaring global variables that are available within the application.

Requirement: A project is open.

1. In the Device tree of your project, select the application in which the global variables are to be valid.
2. Select the context menu command *“Add Object ➔ Global Variable List”*.

    ⇨ CODESYS inserts the *“GVL”* in the Device tree under the application and opens it in the editor.

3. Select the menu command *“Edit ➔ Auto Declare”*.

    ⇨ The dialog box *“Auto Declare”* opens.

4. In the selection list *“Scope”*, select the entry *“VAR_GLOBAL”*.
5. In the field *“Name”*, enter a name for the global variable.
6. Select a data type from the selection list *“Type”*.
7. If your variable is to have an initialization value other than the standard initialization value, click on  next to the field *“Initialization”*.

    ⇨ The dialog box *“Initialization Value”* opens.

8. Double-click on the cell *“Init value”* of your variable and enter the desired valid value.
9. Click on *“OK”*.

    ⇨ The initialization value is displayed in the dialog box *“Auto Declare”*.

10. Activate one of the *“Flags”* if necessary.
11. Confirm your entries by clicking on the button *“OK”*.

    ⇨ CODESYS inserts the declared variable in the GVL.

    The global variable is available in the total application of your project.

Declaring global variables that are available in the entire project.

1. Select the menu command *"View ➔ POUs"*.
   ⇨ The *"POUs"* view opens.
2. In the *"POUs"* view, select the uppermost node with the project name and select the context menu command *"Add Object ➔ Global Variable List"*.
   ⇨ CODESYS inserts the *"GVL"* in the *"POUs"* view and opens it in the editor.
3. Select the menu command *"Edit ➔ Auto Declare"*.
   ⇨ The dialog box *"Auto Declare"* opens.
4. In the selection list *"Scope"*, select the entry *"VAR_GLOBAL"*.
5. In the field *"Name"*, enter a name for the global variable.
6. Select a data type from the selection list *"Type"*.
7. If your variable is to have an initialization value other than the standard initialization value, enter it in the column *"Initialization"*.
8. Activate one of the *"Flags"* if necessary.
9. Confirm your entries by clicking on the button *"OK"*.
   ⇨ CODESYS inserts the declared variable in the GVL.

   The global variable is now available in the entire project.

Using Task-Local Variables

Task-local variables are cycle-consistent. In a task cycle, they are written only by a defined task, while all other tasks have read-only access. It is taken into account that tasks can be interrupted by other tasks or can run simultaneously. The cycle consistency also applies above all if the application is running on a system with a multicore processor.

Therefore, using task local global variable lists is one way to automatically achieve a synchronization (by the compiler) when multiple tasks are processing the same variables. This is not the case when using ordinary GVLs. Multiple tasks can write simultaneously to ordinary GVL variables during a cycle.

However, it is imperative to note: The synchronization of task-local variables requires a relatively large amount of time and memory and is not always the best solution for every application. For this reason, see below for more detailed technical information and best practice guidance to help you make the right decision.

In the CODESYS project, the *"Variable List (Task-Local)"* object is available for defining task-local variables. Syntactically, it corresponds to a normal GVL, but also contains the information of the task that has write access to the variables. Then all variables in such a GVL are not changed by another task during a cycle of a task.

The next section contains a simple example that demonstrates the principle and functionality of task-local variables. It includes a writing program and a reading program. The programs run in different tasks, but they access the same data that is stored in a task-local global variable list so that they are processed cycle-consistently.

Showing functionality in an example

See below for Instructions on reprogramming this sample application.

Sample application

```
(* task-local GVL, object name: "Tasklocals" *)
VAR_GLOBAL
    g_diaData : ARRAY [0..99] OF DINT;
END_VAR

PROGRAM ReadData
VAR
    diIndex : DINT;
    bTest : BOOL;
    diValue : DINT;
END_VAR
bTest := TRUE;
diValue := TaskLocals.g_diaData[0];
FOR diIndex := 0 TO 99 DO
    bTest := bTest AND (diValue = Tasklocals.g_diaData[diIndex]);
END_FOR

PROGRAM WriteData
VAR
    diIndex : DINT;
    diCounter : DINT;
END_VAR
diCounter := diCounter + 1;
FOR diCounter := 0 TO 99 DO
    Tasklocals.g_diaData[diIndex] := diCounter;
END_FOR
```

The programs *"WriteData"* and *"ReadData"* are called by different tasks.

In the program `WriteData`, the array `g_diaData` is populated with values. The program `ReadData` tests whether or not the values of the array are as expected. If so, then the variable `bTest` yields the result `TRUE`.

The array data that is tested is declared via the variable `g_diaData` in the object `Tasklocals` of type `Global Variable List (Task-Local)`. This synchronizes the data access in the compiler and guarantees cycle consistency, even when the accessing programs are called from different tasks. In the sample program, this means that the variable `test` is always `TRUE` in the program `ReadData`.

If the variable `g_diaData` were declared only as a global variable list in this example, then the test (the variable `test` in the program `ReadData`) would yield `FALSE` more often. In this case, this is because one of the two tasks in the `FOR` loop could be interrupted by the other task, or both tasks could run simultaneously (multicore controllers). And therefore the values could be changed by the writer while the reader reads the list.

Constraints in the declaration

NOTICE!
An online change of the application is not possible after changes in declarations in the list of task-local variables.

Note the following when declaring a global task-local variable list:

- Do not assign direct addresses by means of an AT declaration.
- Do not map to task-local variables in the controller configuration.
- Do not declare any pointers.
- Do not declare any references.

- Do not instantiate any function blocks.
- Do not declare any task-local variables as `PERSISTENT` and `RETAIN` at the same time.

The compiler reports write access in a task without write access as an error. However, not all write-access violations can be detected. The compiler can only assign static calls to a task. However, the call of a function block by means of a pointer or an interface is not assigned to a task, for example. As a result, any write access is not recorded there either. Moreover, pointers can point to task-local variables. Therefore, data can be manipulated in a read task. In this case, a runtime error is not issued. However, values that are modified by means of pointer access are not copied back in the shared reference of variables.

Properties of task-local global variables and possible behavior

The variables are located at a different address in the list for each task. For read access, this means: `ADR(variable name)` yields a different address in each task.

The synchronization mechanism guarantees the following:

- Cycle consistency
- Freedom from locked states: A task never waits for an action from another task at any time.

With this method, however, no time can be determined when a reading task securely receives a copy of the writing task. Fundamentally, the copies can deviate. In the example above, it cannot be concluded that each written copy is processed one time by the reader. For example, the reading task can edit the same array over multiple cycles, or the contents of the array can skip one or more values between two cycles. Both can occur and have to be considered.

The writing task can be paused for one cycle between two accesses to the shared reference by each reading task. This means that when `n` reading tasks exist, the writing task can have `n` cycles of delay until the next update of the shared reference.

In each task, the writing task can prevent a reading task from getting a reading copy. As a result, no maximum number of cycles can be specified after which a reading task will definitely receive a copy.

In particular, this can become problematic if very slow running tasks are involved. Assuming a task runs only every hour and cannot access the task-local variables during this time, then the task works with a very old copy of the list. Therefore, it can be useful to insert a time stamp in the task-local variables so that the reading tasks can at least determine whether or not the list is up-to-date. You can set a time stamp as follows: Add a variable of type `LTIME` to the list of task-local variables and add the following code to the writing task, for example: `tasklocal.g_timestamp := LTIME();`.

Best practice

Task-local variables are designed for the use case "Single writer - multiple readers". When you implement a code that is called by different tasks, using task-local variables is a significant advantage. For example, this is the case for the sample application `appTasklocal` as described above when it is extended by multiple reading tasks that all access the same array and use the same functions.

Task-local variables are especially useful on multicore systems. On these systems, you cannot synchronize tasks by priority. Then other synchronization mechanisms become necessary.

Do not use task-local variables when a reading task always has to work on the newest copy of the variable. Task-local variables are not suitable for this purpose.

A similar issue is the "Producer - Consumer" dilemma. This happens when a task produces data and another task processes the data. Choose another type of synchronization for this configuration. For example, the producer could use a flag to notify that a new date exists. Then the consumer can use a second flag to notify that it has processed its data and is waiting for new input. In this way, both can work on the same data. This removes the overhead for cyclic copying of data, and the consumer does not lose any data generated by the producer.

Monitoring

At runtime, multiple different copies of the task-local variable list may exist in memory. When monitoring a position, not all values can be displayed. Therefore, the values from the shared reference are displayed for inline monitoring, in the watch list, and in the visualization for a task-local variable.

When you set a breakpoint, the data of the task is displayed that ran to the breakpoint and was halted as a result. Meanwhile, the other tasks continue running. Under certain circumstances, the shared copy can be changed. In the context of the halted task, however, the values remain unchanged and are displayed as they are. You need to be aware of this.

Background: Technical implementation

For a list of task-local variables, the compiler creates a copy for each task, as well as a shared reference copy for all tasks. This creates a structure that contains the same variables as the list of task-local variables. Moreover, an array with this structure is created in which an array dimension is created for each task. As a result, an array element is indexed for each task. If a variable in the list is accessed now in the code, then the task-local copy of the list is actually accessed. Furthermore, it is determined in which task the block is currently running and the access is indexed accordingly.

For example, the line of code `diValue := TaskLocals.g_diaData[0];` from the above example is replaced by:

```
diValue := __TaskLocalVarsArray[__CURRENTTASK.TaskIndex].__g_diarr[0];
```

`__CURRENTTASK` is an operator that is available in CODESYS V3.5 SP13 and later in order to determine the current task index quickly.

At runtime, at the end of the writing task, the contents of the task-local list are written to the global list. For a reading task at the beginning, the contents of the shared reference are copied to the task-local copy. Therefore, for n tasks, there are n+1 copies of the list: One list serves as a shared reference and every task also has its own copy of the list.

A scheduler controls the time-based execution of multiple tasks and therefore also task switching. The strategy, which is tracked by the scheduler in order to control the allocation of the execution time, has the goal of preventing a task from being blocked. The synchronization mechanism is therefore optimized to the properties of task-local variables to prevent blocking states (lock states) and at no time does a task wait for the action of another task.

Synchronization strategy:

- As long as the writing task writes a copy back to the shared reference, none of the reading tasks gets a copy.
- As long as a reading task gets a copy of the common reference, the writing task does not write back a copy.

Instructions for creating the sample application as described above

Aim: With a program `ReadData`, you want to access the same data that is written by a program `WriteData`. Both programs should run in different tasks. You make the data available in a task-local variable list so that it is processed automatically in a cycle-consistent manner.

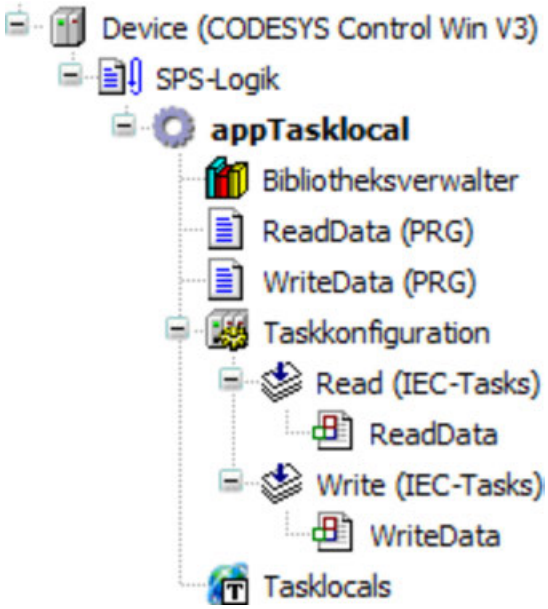
☑ Requirement: A brand new standard project is created and open in the editor.

1. Rename the application from `Application` to `appTasklocal`.
2. Below `appTasklocal`, add a program in ST named `ReadData`.
3. Below `appTasklocal`, add another program in ST named `WriteData`.
4. Below the object `Task Configuration`, rename the default task from `MainTask` to `Read`.
5. In the *“Configuration”* dialog of the task `Read`, click the *“Add Call”* button to call the program `ReadData`.
6. Below the *“Task Configuration”* object, add another task named `Write`, and add the call of the program `Write` to this task.

   ⇨ Now there are two tasks `Write` and `Read` in the task configuration which call the programs `WriteData` and `ReadData`, respectively.
7. Select the application `appTasklocal` and add an object of type *“Global Variable List (Task-Local)”*.

   ⇨ The *“Add Global Variable List (Task-Local)”* dialog opens.

8. Specify the name `Tasklocals`.
9. Select the `Write` task from the *“Task with write access”* list box.



⇨ The object structure for using task-local variables within an application is complete. Now you can code the objects as described in the example above.

1.4.1.8.3 Creating Source Code in IEC

Source code:

"Source code" is a term used for the implementation code, which you insert in the programming modules by using the appropriate programming language editors. The following programming module types are available for this purpose: POU (Program, Function, Function Block), Action, Method, Property, Interface.

Programming Language:

When creating a POU, you define, in which programming language the implementation should be inserted. Besides the IEC languages also CFC is available.

Programming Language:Editors:

You get a programming module editable in the corresponding programming language editor on a double-click on the programming module object. So, the module will appear either in the textual ST editor or in one of the graphical editors for FBD/LD/IL or CFC. Each editor consists of two windows: In the upper window you insert the declarations, in textual or tabular form, depending on the setting. In the lower window you insert the implementation code. The display and behaviour of each editor can be configured in the corresponding tab of the CODESYS *“Options”* dialog.

Regard the possibility to open a programming module for offline-editing even while the application is in online mode.

See also

- *Chapter 1.4.1.19.1 “Programming Languages and Editors” on page 460*
- *Chapter 1.4.1.20.3.4.11 “Command 'Edit Object (Offline)'” on page 1006*

FBD/LD/IL

A combined editor enables programming in the languages FBD (function block diagram), LD (ladder diagram) and IL (instruction list).

The basic unit of the FBD and LD programming is a network. Each network contains a structure that can represent the following: a logical or arithmetic expression, the call of a POU (function, function block, program etc.), a jump or a return instruction. IL actually requires no networks. In CODESYS, however , an IL program also consists of at least one network in order to support conversion to FBD or LD. In view of this you should also divide an IL program meaningfully into networks.

See also

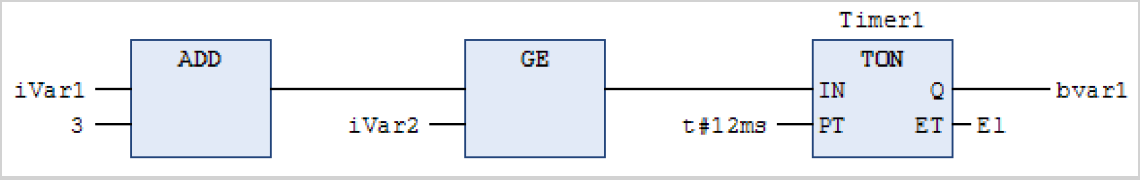
- *Chapter 1.4.1.19.1.5.1 “FBD/LD/IL Editor” on page 495*

Function block diagram (FBD)

The function block diagram is a graphically oriented IEC 61131 programming language. It works with a list of networks, where each network contains a structure that can contain logical and arithmetic expressions, calls of function blocks, a jump or a return instruction.

Boxes familiar from boolean algebra are used here. Boxes and variables are connected by connecting lines. The signal flow in the network runs from left to right. The signal flow in the editor runs from top to bottom, starting with network 1.

Example



CFC is also a programming language based on the same principle as FBD, but with the following differences:

- *The CFC editor is not network-oriented.*
- *You can freely place the elements in the CFC editor.*
- *Direct insertion of feedbacks is possible.*
- *The order of execution is determined by a list of currently inserted elements, which you can change.*

See also

- *Chapter 1.4.1.8.3.1.1 “Programming function block diagrams (FBD)” on page 237*
- *Chapter 1.4.1.20.3.13 “Menu 'FBD/LD/IL'” on page 1104*(commands)
- *Chapter 1.4.1.8.3.2 “Continuous Function Chart (CFC)” on page 241*

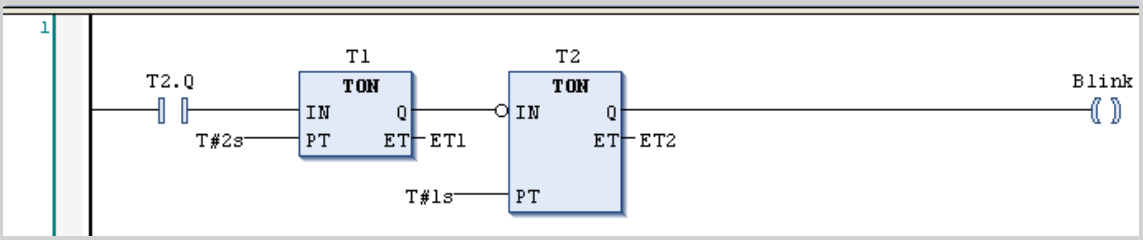
Ladder diagram (LD)

The ladder diagram (LD) is a graphically oriented programming language that approximates an electrical circuit diagram. On the one hand the ladder diagram is suitable for designing logical switching units, but on the other you can also create networks just as in FBD. Therefore you can use LD very well for controlling calls of other program blocks.

The ladder diagram consists of a series of networks. A network is bounded on the left side by a vertical line (bus bar). A network contains a circuit diagram of contacts, coils, optional boxes (POUs) and connecting lines. On the left side of a network there is a contact or a series of contacts that relay the ON or OFF state, which corresponds to the boolean values `TRUE` and `FALSE`, from left to right. A boolean variable is associated with each contact. If this variable is TRUE, the status is relayed from left to right via the connection line. Otherwise OFF is relayed. Thus the coil(s) in the right part of the network receive(s) the value ON and OFF coming from the left and the value TRUE or FALSE is written accordingly into the boolean variable assigned to them.

If the elements are connected in series, this means an AND operation. If they are connected in parallel, this means an OR operation. A line through an element means a negation of the element. The negation of an input or an output is indicated by a circle symbol.

Example



IEC 61131-3 defines a complete LD command set, consisting of different types of contacts and coils. Contacts conduct the current (according to their type) from left to right. Coils store the incoming value. Contacts and coils are assigned to boolean variables. You can supplement an LD network by jumps, returns, labels and comments.

See also

- *Chapter 1.4.1.8.3.1.2 “Programming ladder diagrams (LD)” on page 239*
- *Chapter 1.4.1.20.3.13 “Menu 'FBD/LD/IL'” on page 1104*(Befehle)

Instruction list (IL)

The instruction list is an assembler-like IEC 61131-compliant programming language. It supports accumulator-based programming.

An instruction list (IL) consists of a series of instructions. Each instruction starts in a new line and contains an operator and, depending on the type of operation, one or more operands separated by commas. A label, followed by a colon, can be placed in front of an instruction. It serves the identification of the instruction and you can use the label as a jump destination. A comment must be the last element in a line. Empty lines can be inserted between instructions.

All IEC 61131-3 operators are supported, as are multiple inputs, multiple outputs, negations, comments, set/reset of outputs and conditional/unconditional jumps.

Each instruction is based primarily on the loading of values into the accumulator (`LD` instruction). After that the corresponding operation is executed with the parameter from the accumulator. The result of the operation is written again into the accumulator, from where you should store it purposefully with the help of an `ST` instruction.

The instruction list supports comparison operators (EQ, GT, LT, GE, LE, NE) and jumps for programming of conditional executions or loops. Jumps can be unconditional (JMP) or conditional (JMPC / JMPCN). In the case of conditional jumps, a check is performed as to whether the value in the accumulator is `TRUE` or `FALSE`.

Example

```
1
LD      BVar1
ST      inst.IN     starts timer with rising e…
JMPC    mark1
CAL     inst(
        PT:=t1,                                 is True
        ET:=>t2)
LD      inst.Q      gets TRUE delay time after…
ST      inst2.IN    starts timer with rising e…
2

mark1:
LD      iVar2

- *Chapter 1.4.1.19.1.5.3 “Modifiers and operators in IL” on page 500*

Programming function block diagrams (FBD)

Creating a POU in the function block diagram (FBD) implementation language

1. Select an application in the device tree.
2. Select the command *“Project ➔ Add Object ➔ POU”*.
   ⇨ The dialog box *“Add POU”* opens.
3. Enter a name and select the implementation language *“Function Block Diagram (FBD)”*.
   Click on *“Add”*.
   ⇨ The POU is added to the device tree and opened in the editor. It consists of the declaration editor in the top part and the implementation part with an empty network in the lower part. The view *“ToolsBox”* is also automatically opened , in which the suitable elements, operators and function blocks for FBD programming are available.

See also

- *Chapter 1.4.1.20.2.18 “Object 'POU'” on page 881*
- *Chapter 1.4.1.8.3.1 “FBD/LD/IL” on page 235*

Programming a network

1. Click inside the automatically inserted empty network in the implementation part.
   ⇨ The network is given a yellow background and the area at the left-hand side with the network number is given a red background.

2. Open the context menu with the right mouse button.
   ⇨ You obtain amongst other things the insert commands for the elements that can be inserted at this point.
3. Insert the elements required for your programming using the menu commands or by dragging in the elements from the toolbox.
4. For example, select the command *“Insert Assignment”*.
   ⇨ An assignment line is inserted. In each case three question marks stand for assignment source and assignment target.
5. Select the question marks and replace them with the desired variable. Input assistance is available for this purpose.
6. Move the cursor over the assignment line.
   ⇨ The possible insertion positions for further elements are displayed as grey diamonds. A click on a diamond selects that position and the suitable insert commands are once again available.
7. Alternatively, you can drag an element with the mouse from the toolbox into the network. For example, click in the tool box on the box element, keep the mouse button pressed and move the cursor over the network.
   ⇨ Each possible insertion position lights up green.
8. Release the mouse button in order to insert the box.
   ⇨ The box is displayed in the network. The type of box on the inside and the instance name above the box, which is required in the case of a function block, are still kept free with three question marks.
9. Select the string `???` inside the box and replace it with the name of the box. Input assistance is available for this purpose.
   ⇨ The inputs and outputs of the selected box are displayed. They are still kept free with question marks, as is the instance name in the case of a function block.

- *Chapter 1.4.1.20.3.13 “Menu 'FBD/LD/IL'” on page 1104*
- *Chapter 1.4.1.8.3.1 “FBD/LD/IL” on page 235*

Programming line branches (subnetworks)

1. In the implementation part of your POU, insert a new network using the command *“FBD/LD/IL ➔ Insert network”* or drag it in from the tool box.
2. For example, drag an *“ADD”* operator into the empty network and replace the characters `???` with two variables of the type `INT`.
3. Drag the element *“Branch”* from the tool box into your implementation and release the mouse button at the green insertion position directly at the output of the operator.
   ⇨ The line branch splits the processing line at the output of the operator box into 2 subnetworks.
4. Further FBD elements and also further line branches can now be added to each of the two subnetworks.

- *Chapter 1.4.1.20.3.13.33 “Command 'Insert Branch'” on page 1113*

See also

- ↳ *Chapter 1.4.1.19.1.5.1 “FBD/LD/IL Editor” on page 495*

Programming ladder diagrams (LD)

Creating a POU in the ladder diagram (LD) implementation language

1. Select the application in the Device tree.
2. Select the command *“Project ➔ Add Object ➔ POU”*.
   ⇨ The dialog box *“Add POU”* opens.
3. Enter a name and select the implementation language *“Ladder Diagram (LD)”*.
   Click on *“Add”*.
   ⇨ CODESYS adds the POU to the Device tree and opens it in the editor. An empty network is inserted in the implementation part. The empty network is bounded on the left by a vertical line, which represents a bus bar. The view *“ToolBox”* is also automatically opened, in which the suitable elements, operators and function blocks for LD programming are available.

Adding a contact and a function block (TON)

☑ Requirement: a POU with the implementation language LD is opened in the editor and an empty network is inserted.

1. Click on the category *“Ladder Elements”* in the view *“ToolBox”*
2. Click on the *“Contact”* element, drag it into your network and release the mouse button at the insertion position *“Start here”*.
   ⇨ The contact is added on the left in the network directly against the vertical line.
3. Click on `???` and enter the identifier of a boolean variable. The input assistant is also available to you for this.
4. Click on the category *“Function Blocks”* in the view *“ToolBox”* and drag the function block *“TON”* onto an insertion position on the connecting line to the right of the inserted contact.
   ⇨ CODESYS inserts the box *“TON”* to the right of the contact. The contact is connected with the input `IN` of the TON box.
5. Enter a time constant at the input `PT`, for example `T#3s`.
   ⇨ If the variable of your contact goes `TRUE`, then the input `IN` of the TON box also goes `TRUE`. The TON box forwards the value `TRUE` to the output `Q` with a switch-on delay of `T#3s`, for example.

Inserting a closed line branch

Requirement: a POU with the implementation language LD is opened in the editor and an empty network is inserted.

1. Click inside the empty network and select the command *“FBD/LD/IL ➔ Insert Contact”*.
2. Select the connecting line to the left of the contact and select the command *“FBD/LD/IL ➔ Set Branch Start Point”*.
   ⇨ The starting point on the connecting line is marked by a red rectangle. CODESYS marks all possible end points of the branch with a blue rectangle.

3. Click on a blue rectangle in order to set the end point of your closed line branch.
   ⇨ CODESYS inserts the line branch between the starting and end points. The program flow will go through both branches up to the end point.

   If you insert the line branch at a box instead of at a contact, the box will only be called if none of the other branches is `TRUE`.

See also

- *Chapter 1.4.1.19.1.5.1 “FBD/LD/IL Editor” on page 495*
- *Chapter 1.4.1.19.1.5.4.14 “Closed branch” on page 509*
- *Chapter 1.4.1.19.1.5.4.11 “LD element 'Contact'” on page 507*

Programming in instruction list (IL)

If necessary, IL can be activated in the CODESYS options.

Creating POUs in the instruction list (IL) implementation language

1. Select the application in the device tree.
2. Click *“Project ➔ Add Object ➔ POU”*.
   ⇨ The *“Add POU”* dialog opens.
3. Enter a name and select the implementation language *“Instruction List (IL)”*.

   Click *“Add”*.
   ⇨ CODESYS adds the POU to the device tree and opens it in the editor. A network is already inserted in the implementation part.

Programming networks (example: ADD operation)

Requirement: A POU (IL) is opened in the editor and possesses an empty network.

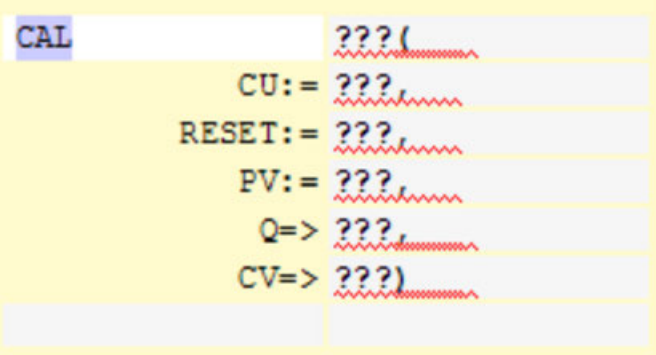
1. Click the line marked in color in the 1st column and enter the operator `LD`.
2. Press the *[Tab]* key.
   ⇨ The cursor jumps to the 2nd column
3. Enter the first summand of your ADD operation, for example `6`.
4. Press *[Ctrl]+[Enter]* or select the command *“FBD/LD/IL ➔ Insert IL Line After”*.
   ⇨ CODESYS inserts a new instruction line. The first column of this line has the focus.
5. Enter `ADD` and press *[Tab]*.
6. Enter the second summand of your ADD operation, for example `12`.
7. Press *[Ctrl]+[Enter]*
8. Enter the operator `ST` and press *[Tab]*.

9. Specify a variable of the data type `INT`, for example `iVar`.
   ⇨ The result – `16` in the example – is stored in the `iVar`.

Calling function blocks

Requirement: A POU (IL) is opened in the editor and possesses an empty network. A variable of the data type <function block> is declared in the declaration part (example: `C1:CTU;`).

1. Click the line marked in color in the 1st column and select the command *"FBD/LD/IL ➔ Insert Box"*.
   ⇨ The input assistant opens.
2. Select the desired function block in the category *"Function Blocks"* or *"Boxes"*, for example the *"CTU"* counter from the *"Standard"* library, and click *"OK"*.
   ⇨ CODESYS inserts the selected function block *"CTU"* as follows:



3. Replace the strings `???` with the variable name and the values or variables for the inputs/outputs of the function block.
4. As an alternative to inserting the function block via the input assistant, you can directly enter the call in the editor as shown in the picture at step 4.

See also

- *Chapter 1.4.1.19.1.5.1 "FBD/LD/IL Editor" on page 495*
- *Chapter 1.4.1.19.1.5.3 "Modifiers and operators in IL" on page 500*

Continuous Function Chart (CFC)

The *"Continuous Function Chart (CFC)"* implementation language is a graphical programming language which extends the standard languages of IEC 61131-3.

You can graphically program a system by means of a POU in CFC. You insert elements and position them freely. You insert connections and wire the elements to a network so that a well-structured function block diagram is created. You can also insert feedback. You can read function block diagrams like an circuit diagram or a block diagram.

The execution order of a function block diagram is based on data flow. Moreover, a POU can process multiple data flows. Then the data flows do not have any common data. In the editor, multiple networks do not have any connections to each other.

On the other hand, POUs in FBD, LD, or IL have a network-based execution order.

The *"Continuous Function Chart (CFC) - page-oriented"* implementation language is also a graphical programming language which extends the standard languages of IEC 61131-3.

In this language, you can graphically program large, complex function block diagrams. The same elements and commands are available as for *“Continuous Function Chart (CFC)”*. In addition, you can arrange the code on as many pages as you like. This allows you to create extensive function block diagrams that are still easy to print. Furthermore, each page has border areas. You can arrange inputs and sink connection marks on the left, and outputs and source connection marks on the right. This helps you to insert connecting lines and provides a better overview.

Unfortunately, it is not possible to switch a POU between the “Continuous Function Chart (CFC) - page-oriented” and “Continuous Function Chart (CFC)” implementation languages.

See also

- *Chapter 1.4.1.19.1.6.1 “CFC Editor” on page 511*
- *Chapter 1.4.1.19.1.6.2 “CFC editor, page-oriented” on page 514*
- *Chapter 1.4.1.20.3.12 “Menu 'CFC'” on page 1089*
- *Chapter 1.4.1.20.4.10.13 “Dialog 'Properties' - 'CFC Execution Order'” on page 1165*

Automatic Execution Order by Data Flow

The execution order in POUs is uniquely determined in text-based and network-based editors. In the CFC editor, however, you can position the elements freely, so the execution order is initially not unique. For this reason, CODESYS determines the execution order by data flow and, in the case of multiple networks, by the topological position of the elements. The elements are sorted from top to bottom and left to right. Now the execution order is unique and makes sure that the POU is processed while optimized by time and by cycle.

You can get information about the chronological order of the elements in the chart and temporarily display the execution order. When you program networks with feedback you can define an element as the starting point in the feedback loop.

You can also explicitly edit the processing order in a CFC object if necessary. To do this, switch the *“Auto Data Flow Mode”* property of the CFC object to *“Explicit Execution Order Mode”*. In this mode, you have the option of editing the execution order by means of menu commands.

Before CODESYS Development System V3.5 SP15, you had to define the execution order explicitly for each POU. The was no mode switching.

Data flow

In general, data flow is described as the chronological order in which data is read or written when and how in which programming objects. A POU can process any number of data flows, which can also be executed independently of each other.

Displaying the execution order

By default, the execution order of a CFC object is determined automatically. The *“Auto Data Flow Mode”* property is selected for this. You can temporarily display the automatically determined execution order in the CFC editor.

1. Create a new project using the *"Standard project"* template and specify the name `Minimal` for example.
2. Extend the application with the function block `FB_DOIt` in the *"ST"* implementation language with inputs and outputs.

   ⇨

```
FUNCTION_BLOCK FB_DoIt
VAR_INPUT
    iAlfa : INT;
    iBravo: INT;
    sCharlie : STRING := 'Charlie';
    xItem : BOOL;
END_VAR
VAR_OUTPUT
        iResult : INT;
        sResult : STRING;
        xResult : BOOL;
END_VAR
VAR
END_VAR

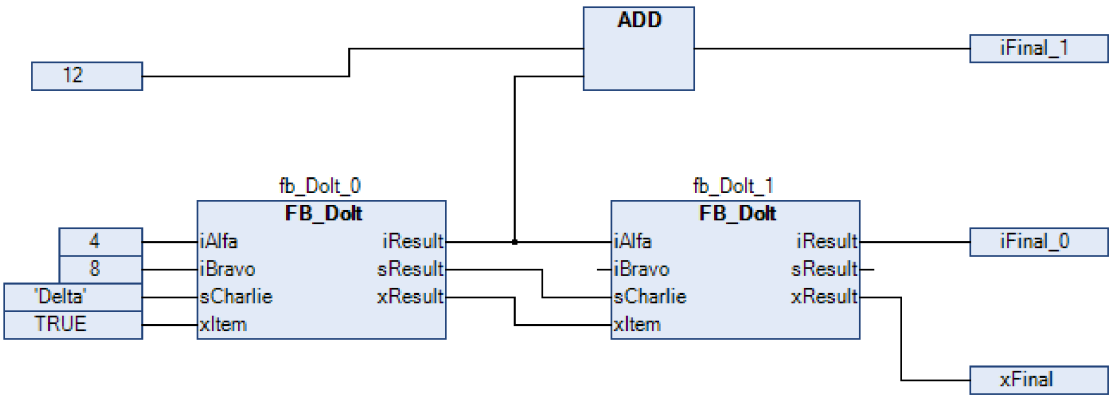
iResult := iAlfa + iBravo;

IF xItem = TRUE THEN
    xResult := TRUE;
END_IF
```

3. Create the function block `ExecuteCFC` in the *"CFC"* implementation language.

   ⇨

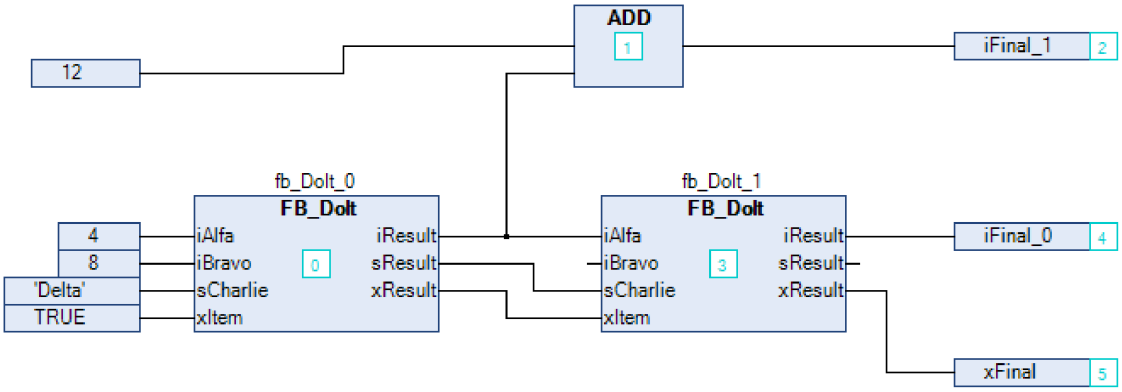
```
PROGRAM ExecuteCFC
VAR
    fb_DoIt_0: FB_DoIt;
    fb_DoIt_1: FB_DoIt;
    iFinal_1: INT;
    iFinal_0: INT;
    xFinal: BOOL;
END_VAR
```



Recently created programming objects in CFC have the Auto Data Flow Mode selected. The execution order of the programming object is optimally defined internally.

4. Click *“CFC ➔ Execution Order ➔ Display Execution Order”*.

   ⇨ The execution order of the object is shown. The boxes and inputs are numbered accordingly and reflect the chronological processing order. The numbering is hidden as soon as you click again in the CFC editor.

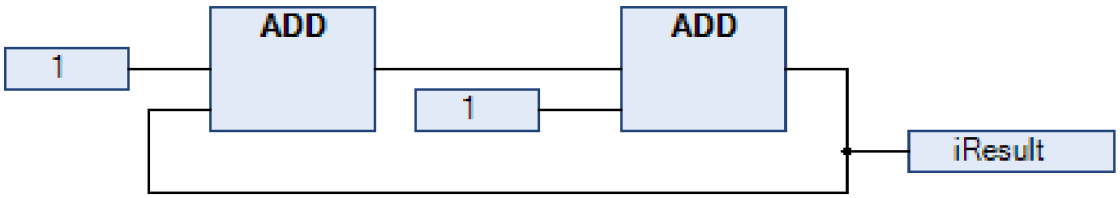


Determining the execution order in feedback networks

1. Create a CFC program with feedback.

   ⇨ The POU `PrgPositiveFeedback` counts.

```
PROGRAM PrgPositiveFeedback
VAR
    iResult: INT;
END_VAR
```



2. Select an element within the feedback.

   ⇨ The selected element is highlighted in red.

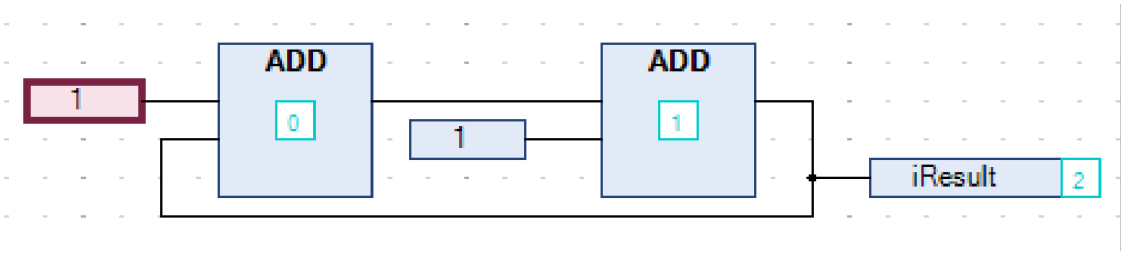
3. Click *“CFC ➔ Execution Order ➔ Set Start of Feedback”*.

   ⇨ At run time, this POU is processed first. The start POU of the feedback is defined and decorated with the ▶ symbol. The execution order is resorted and the selected element gets the number 0. (This is the lowest number of the feedback.)

4. Select the start POU again.

5. Click *"CFC ➔ Execution Order ➔ Set Start of Feedback"*.
   ⇨ The POU is not selected as the start POU.

   The execution order is defined internally.
6. Click *"CFC ➔ Execution Order ➔ Display Execution Order"*.
   ⇨ The execution order by data flow is displayed.



Defining the execution order explicitly

> *The automatically defined execution order by data flow results in time- and cycle-optimized execution of the POU. You do not need any information about the internally managed execution order during the development process.*
>
> *In "Explicit Execution Order Mode", it is your responsibility to adapt the execution order and to assess the consequences and impacts. This is another reason why the execution order is always displayed.*

You can change the automatically defined execution order of a CFC object explicitly when you select the *"Explicit Execution Order Mode"* option for the object.

1. In the *"Devices"* or *"POUs"* view, select a CFC object.
2. In he context menu, click *"Properties"*.
3. Click the *"CFC Execution Order"* tab.
   ⇨ The *"Execution order"* list box displays the currently selected mode.
4. In the *"Execution order"* list box, select *"Explicit Execution Order Mode"*.
5. Click *"OK"* to confirm the dialog.
   ⇨ The Explicit Execution Order Mode property is selected. The networks are numbered in the CFC editor, and the following commands are provided in the *"CFC ➔ Execution Order"* menu for editing the execution order.
6. Open a CFC object.
7. Select a numbered element and click *"CFC ➔ Execution Order ➔ Send to Front"*.
   ⇨ The execution order is resorted and the selected element has the number 0.

- *Chapter 1.4.1.19.1.6.2 "CFC editor, page-oriented" on page 514*
- *Chapter 1.4.1.20.3.12 "Menu 'CFC'" on page 1089*
- *Chapter 1.4.1.20.4.10.13 "Dialog 'Properties' - 'CFC Execution Order'" on page 1165*

Programming in the CFC editor

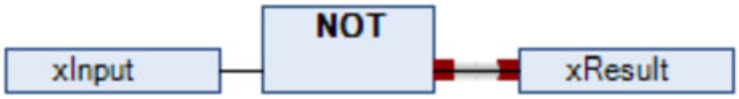
In the CFC editor, you can wire POUs to each other and create well-structured block diagrams.

The editor supports you in the following ways:

- Programming with elements and connecting lines
- Dragging instances and variables to the editing area
- Auto-routing the connecting lines
- Automatic linking
- Fixing of connecting lines by control points
- Collision detection
- Input assistance for connection marks
- Forcing and writing of values in online mode
- Movement of selection using arrow keys
- Reduced display of a POU without disconnected pins

Inserting elements and wiring with connecting lines

1. Drag a *“Box”* element and an *“Output”* element into the editor.
2. Click the output of the *“Box”* element.
   ⇨ The output is marked with a red box.
3. Drag a connecting line from the box output of the *“Box”* element to the box input of the *“Output”* element.
   ⇨ The cursor symbol changes when it reaches the box input.
4. Release the left mouse button.
   ⇨ The output pin of the box is wired to the input pin of the output.



You can also hold down the *[Ctrl]* key, select each pin, and then right-click *“Connected Selected Pins”*.

Calling of instances

1. Create a new project using the standard template and specify the name `First` for example.
   ⇨ The project `First.project` is created.

2. Extend the application with the function block `FB_DOIt` in the *"ST"* implementation language with inputs and outputs.

   ⇨
   ```
   FUNCTION_BLOCK FB_DoIt
   VAR_INPUT
       iAlfa : INT;
       iBravo: INT;
       sCharlie : STRING := 'Charlie';
       xItem : BOOL;
   END_VAR
   VAR_OUTPUT
           iResult : INT;
           sResult : STRING;
           xResult : BOOL;
   END_VAR
   VAR
   END_VAR

   iResult := iAlfa + iBravo;

   IF xItem = TRUE THEN
       xResult := TRUE;
   END_IF
   ```

3. Select the application and click *"Add Object ➔ POU"* in the context menu. Select the *"Continuous Function Chart (CFC)"* implementation language and the type `Program`. Specify the name `PrgFirst` for example.

   Click *"OK"* to confirm the dialog.

   ⇨ The program `PrgFirst` is created and it opens in the editor. It is still empty.

4. Instantiate function blocks and declare variables.

   ⇨
   ```
   PROGRAM PrgFirst
   VAR
       iCounter: INT;

       fbDoIt_1 : FB_DoIt;
       fbDoIt_2 : FB_DoIt;

       iOut : INT;
       sOut: STRING;
       xOut: BOOL;

   END_VAR
   ```

5. Drag a *"Box"* element from the *"ToolBox"* view into the editor.

6. Click the `???` field and type in `ADD`.

   ⇨ The box type is `ADD`. The box acts as an adder.

7. Click line 3 in the declaration editor.

   ⇨ The declaration line of `iCounter` is selected.

8. Click in the selection and drag the selected variable into the implementation. Focus there on an input of the `ADD` box.

   ⇨ An input has been created, declared, and connected to the box.

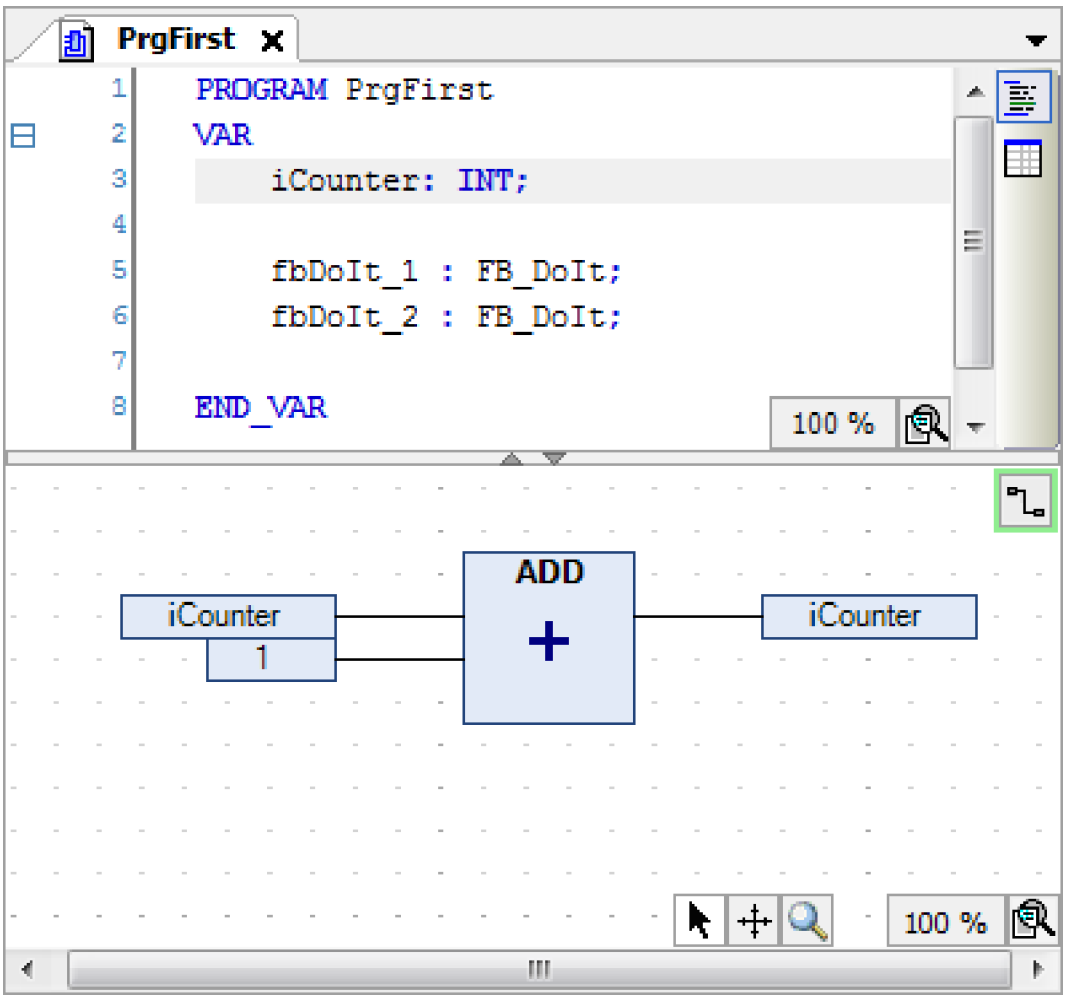
9. Click again in the selection and drag the variable to the output of the `ADD` box.

   ⇨ An output has been created, declared, and connected to the box.

10. Drag an *"Input"* element from the *"ToolBox"* view to the implementation. Click its `???` field and type in `1`.

11. Connect the `1` input to an input of the `ADD` box.

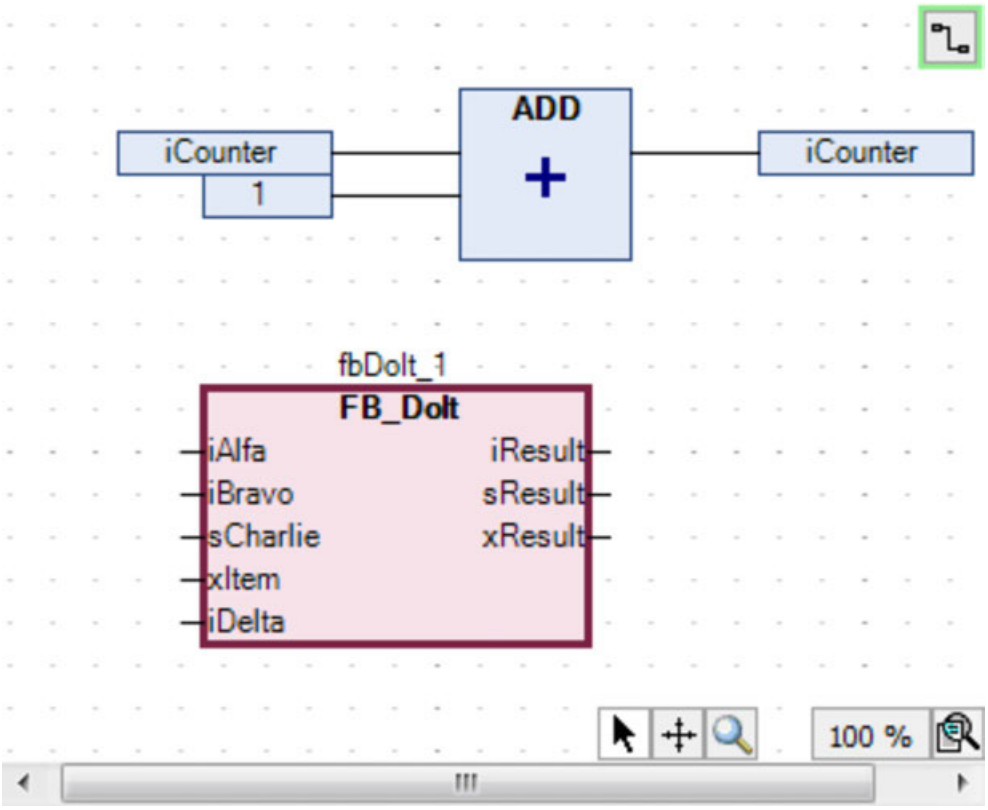
    ⇨ A network is programmed. At runtime, the network counts the bus cycles and stores the result in `iCounter`.



12. Click line 5 in the declaration editor.

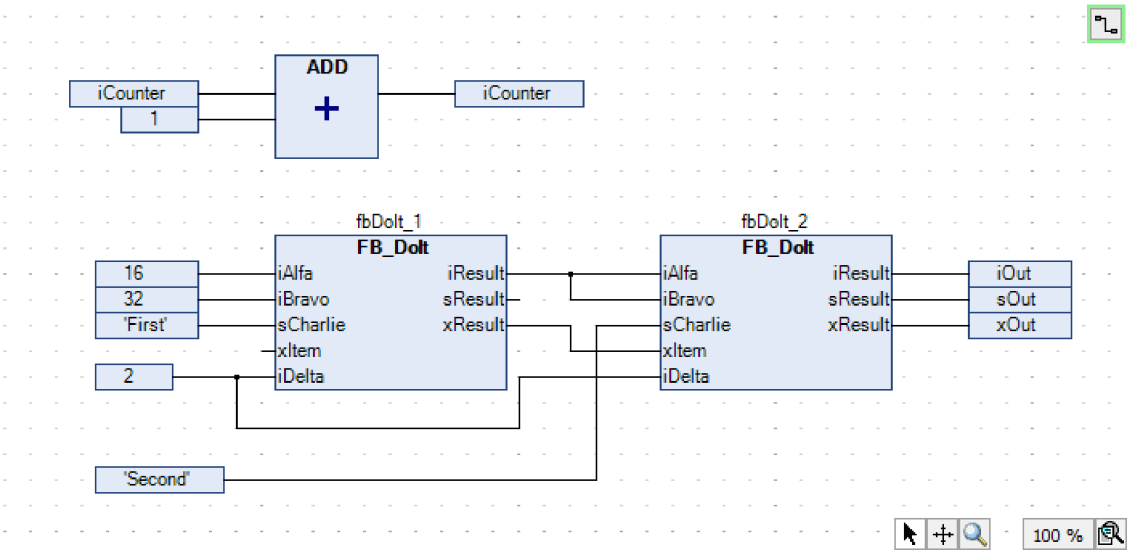
    ⇨ The line is selected.

13. Click in the selection and drag the selected instance into the implementation.
    ⇨ The instance appears as a POU in the editor. The type, name, and POU pins are displayed accordingly.



14. Drag the `fbDoIt_2` instance to the editor. Interconnect the instances to each other and to inputs and outputs.

    ⇨ Example:



A program in ST with the same functionality might look like this:

```
PROGRAM PrgFirstInSt
VAR
    iCounter: INT;

    fbDoIt_1 : FB_DoIt;
    fbDoIt_2 : FB_DoIt;

    iOut : INT;
    sOut: STRING;
    xOut: BOOL;

END_VAR
iCounter := iCounter + 1;
fbDoIt_1(iAlfa := 16, iBravo := 32, sCharlie := 'First',
xItem := TRUE, iDelta := 2, iResult => fbDoIt_2.iAlfa, xResult
=> fbDoIt_2.xItem);
fbDoIt_2(iBravo := fbDoIt_1.iResult, sCharlie := 'Second',
iDelta := 2, iResult => iOut , sResult=> sOut, xResult =>
xOut);
```

Creating connection marks

☑ Requirement: A CFC POU has connected elements.

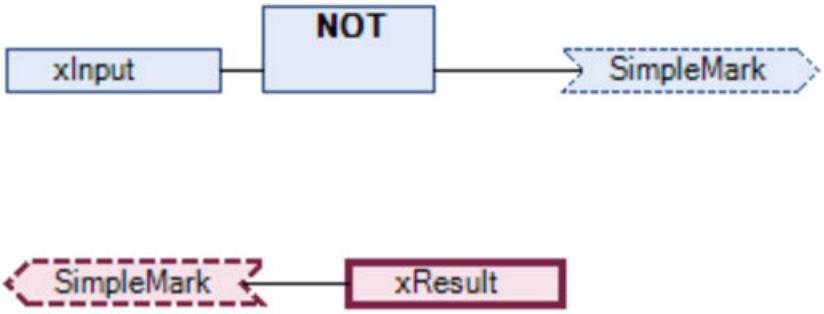
1. Select a connecting line between two elements.

   ⇨ The connecting line is displayed as selected. The ends of the connecting line are marked with red boxes (■).

2. Click *“CFC ➔ Connection Mark”*.

   ⇨ The connection is separated into a *“Connection Mark - Source”* and a *“Connection Mark - Sink”*. The name of the mark is generated automatically.

3. Click in the source connection marks.
   ⇨ You can edit the name.
4. Specify a name `SimpleMark` for the source connection mark.
   ⇨ The source connection mark and sink connection mark have the same name.

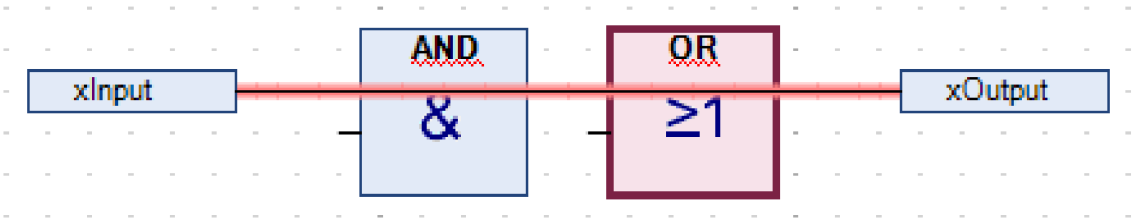


Resolving collisions and fixing connecting lines by means of control points

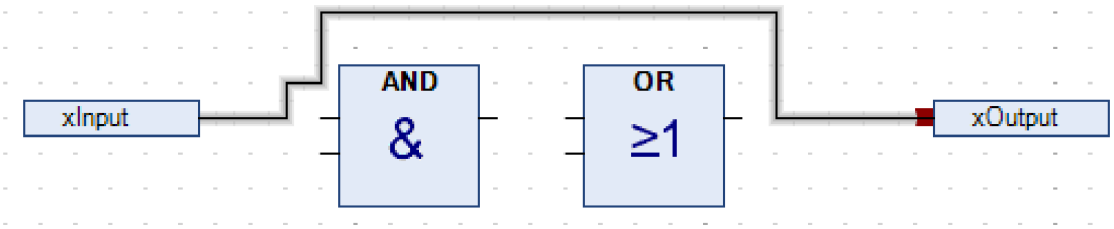
The following example shows how to use the *"Route All Connections"* command with control points.

1. Position the *"Input"* and *"Output"* elements. Connect the elements.

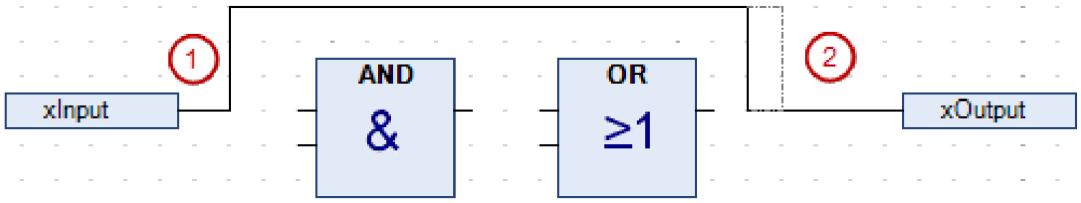
2. Position two *"Box"* elements on the line.
   ⇨ The connecting line and the boxes are marked red because of the collision.



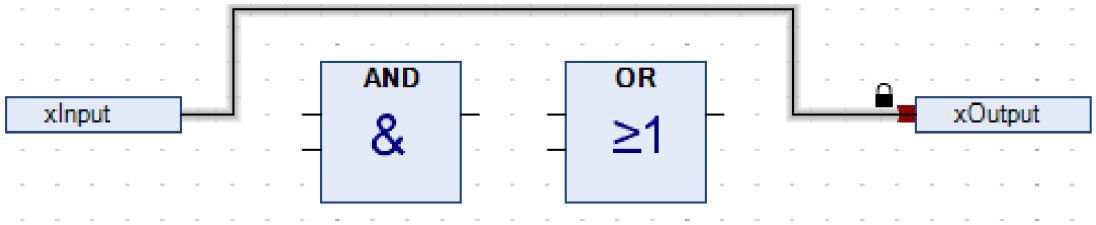
3. Click *"CFC ➔ Routing ➔ Route All Connections"*.
   ⇨ The collision is resolved.



4. Change the connecting lines gradually.

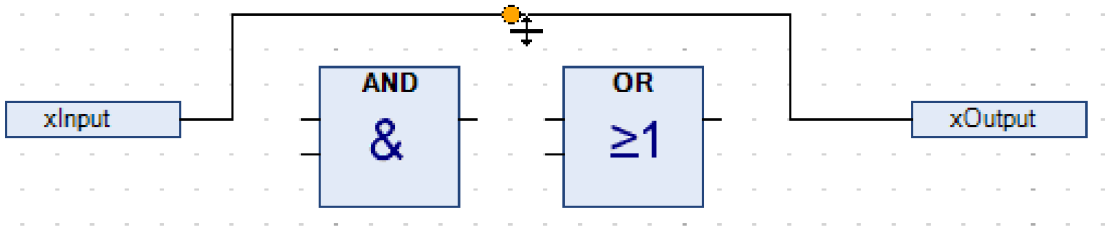


⇨ The connecting line has been changed manually and is now blocked for auto-routing. This is shown by a lock symbol at the end of the connection.



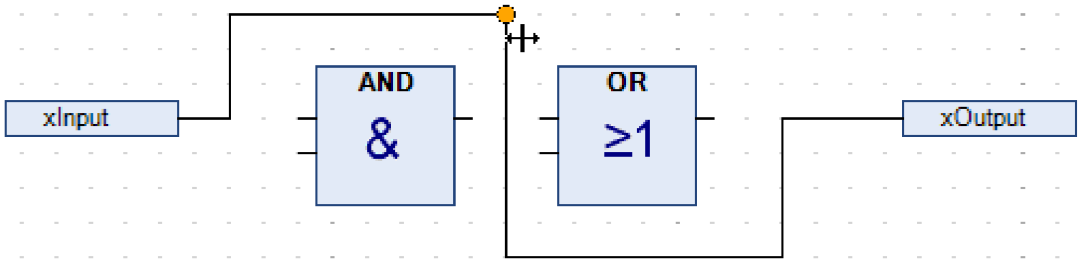
5. Select the connecting line and click *"CFC ➔ Routing ➔ Create Control Point"*.

⇨ A control point is created on the connecting line. The connecting line is fixed to the control point.



You can also drag a control point from the *"ToolBox"* view to a line.

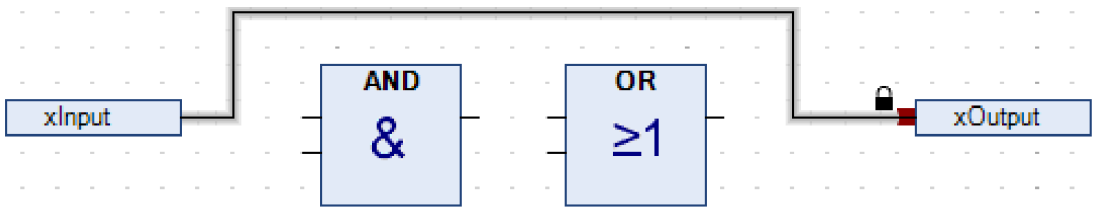
6. Change the connecting line as seen in the following example.



⇨ Use the control point for changing the connecting line according to your needs. You can set any number of control points.

7. In the context menu, click *"CFC ➔ Routing ➔ Remove Control Point"* to remove the control point.
8. Unlock the connection by clicking *"Unlock Connection"* or by clicking the lock symbol.
9. Select the connecting line and click *"Route All Connections"*.

⇨ The connecting line is routed automatically as seen in Step 3.



NOTICE!
Connections in a group are not auto-routed.

Reducing the display of a POU

☑ Requirement: A CFC POU is open. In the editor, its POUs with all declared pins are displayed.

1. Select a POU whose pins are partially disconnected.
   ⇨ Example: `fb_DoIt_1`

   The POU needs space for all of the pins.
2. Click *"CFC ➔ Pins ➔ Remove Unused Pins"*.
   ⇨ Now the POU needs less space and is displayed only with the functionally relevant pins.

Structured Text (ST), Extended Structured Text (ExST)

The ST editor is used for the programming of POUs in the IEC-61131-3 programming language Structured Text (ST) and Extended Structured Text. The Extended Structured Text offers some additional functions with regard to the IEC 61131-3 standard.

Structured Text is a programming language, comparable with other high-level languages such as C or PASCAL, which permits the development of complex algorithms. The program code consists of a combination of **expressions** and **instructions**, which can also be executed conditionally (IF… THEN… ELSE) or in loops (WHILE… DO).

An expression is a construct that returns a value following its evaluation. Expressions are also operators and operands together. You can also use assignments as expressions. An operand can be a constant, a variable, a function call or a further expression.

Instructions control how the expressions are to be processed.

For this text editor you can make various settings with regard to behavior, appearance and menus in the dialog boxes *"Options"* and *"Adapt"* in the *"Tools"* menu. The familiar Windows functions (for example IntelliMouse) are also available for this editor.

See also

- ↳ *Chapter 1.4.1.8.3.3.1 "Programming structured text (ST)" on page 254*
- ↳ *Chapter 1.4.1.20.4.13.25 "Dialog 'Options' - 'Text Editor'" on page 1203*
- ↳ *Chapter 1.4.1.20.4.14.1 "Dialog 'Customize' - 'Menu'" on page 1206*

ExST - Extended structured text

Extended Structured Text (ExST) is a CODESYS-specific extension of the IEC 61131-3 standard for Structured Text (ST).

- ↳ *Chapter 1.4.1.19.1.3.4.5 "ExST – Assignment as expression" on page 467*

Programming structured text (ST)

Principle

The programming languages 'Structured Text' and 'Extended Structured Text' are programmed in the ST editor. The program code consists of a combination of expressions and instructions, which can also be executed conditionally or in loops. You must conclude each instruction with a semicolon `;`.

The variables are declared in the declaration editor.

Creating a POU in the structured text (ST) implementation language

1. Select an application in the device tree.
2. Select the command *"Project ➔ Add Object ➔ POU"*.
   ⇨ The dialog box *"Add POU"* opens.
3. Enter a name and select the *"Implementation language""Structured Text (ST)"*. Click on *"Add"*.
   ⇨ The POU is added to the device tree and opened in the editor.

   Now insert the variable declarations in the upper part of the POU and enter the ST program code in the lower part of the POU.

Sequential Function Chart (SFC)

Use the SFC editor for programming POUs in the IEC 61131-3 compliant SFC implementation language. SFC is a graphical programming language for describing the chronological sequence of individual actions in a program. For this purpose, actions (discrete programming objects) are assigned to step elements. Transition elements control the processing order of steps.

- *Chapter 1.4.1.19.1.4.1 “SFC editor” on page 476*

Programming in SFC

Creating a POU in SFC

1. Select an application in the device tree.
2. Click *“Project ➔ Add Object ➔ POU”*.
   ⇨ The *“Add POU”* dialog opens.
3. Specify a name and select the *“Sequential Function Chart (SFC)”* implementation language.
   Click *“Add”*.
   ⇨ CODESYS adds the POU to the device tree and opens it in the editor.

Adding a step-transition

1. Select the transition after the initial step.
   ⇨ The transition is marked in red.
2. Click *“SFC ➔ Insert Step-Transition After”*.
   ⇨ CODESYS inserts the *“Step0”* step and the *“Trans0”* transition.
3. Select the *“Trans0”* transition and click *“SFC ➔ Insert Step-Transition”*.
   ⇨ CODESYS inserts the *“Trans1”* transition and the *“Step1”* step before the *“Trans0”* transition.

You can also drag the *“Step”* and *“Transition”* elements into the diagram from the *“Toolbox”* view.

See also

- *Chapter 1.4.1.19.1.4.8.1 “SFC elements 'Step' and 'Transition'” on page 486*
- *Chapter 1.4.1.20.3.11.6 “Command 'Insert Step-Transition'” on page 1081*
- *Chapter 1.4.1.20.3.11.7 “Command 'Insert Step-Transition After'” on page 1081*

Adding an entry action

1. Select the *“Step0”* step.
2. Click *“SFC ➔ Add Entry Action”*.
   ⇨ By default, you are prompted to select the duplication mode for the step actions. You decide whether the reference information about the existing step action objects is copied when the step is copied, or the objects are embedded. Embedding results in new step action objects being created when the step is copied. The duplication mode is defined in the *“Duplicate when copying”* step property. When this property is deactivated, the copied steps call the same actions as the current step.

   You can deactivate the prompt completely in the SFC properties.

   The display of embedded objects in the *“Devices”* and *“POUs”* views can be deactivated by means of a menu command.
3. For this example, accept the *“Copy reference”* default setting and click *“OK”* to confirm.
   ⇨ The *“Add Entry Action”* dialog opens.
4. Enter the name "Step0_entry" and select the *“Structured Text (ST)”* implementation language. Click *“Add”*.
   ⇨ CODESYS inserts the *“Step0_entry”* action below the POU in the device tree and opens the action in the editor.

   In the `Step0_entry` entry action, you program statements to be executed one time when the *“Step0”* step becomes active.
5. Close the editor of `Step0_entry`.
   ⇨ The *“Step0”* step is now marked with an *“E”* in the lower left corner. Double-click this marker to open the editor.

   
   The entry action `Step0_entry` is now available in the properties of the step in *“Entry action”*. Other actions can also be selected there as needed.
6. Select the *“Step0”* step. Press *[Ctrl]+[V]* to copy the step.
   ⇨ The same entry actions inserted above are available In the inserted copy of the step. The new step then calls the same exact action.

See also

- *Chapter 1.4.1.20.3.11.8 “Command 'Add Entry Action'” on page 1082*
- *“2. Step actions” on page 489*
- *Chapter 1.4.1.20.4.13.22 “ Dialog 'Options' - 'SFC Editor'” on page 1200*

Adding an exit action

1. Select the *“Step0”* step.
2. Click *“SFC ➔ Insert Exit Action”*.
   ⇨ By default, you are prompted to select the duplication mode for the step actions of the step. See above for adding an entry action. Then the *“Insert Exit Action”* dialog opens.

3. Enter the name "Step0_exit" and select the *"Structured Text (ST)"* implementation language. Click *"Add"*.
   ⇨ CODESYS inserts the *"Step0_exit"* action below the POU in the device tree and opens the action in the editor.
   In the `Step0_exit` exit action, you program statements to be executed one time before the *"Step0"* step becomes inactive.
4. Close the editor of `Step0_exit`.
   ⇨ The *"Step0"* step is now marked with an *"X"* in the lower right corner. Double-click this marker to open the editor.

You can define the exit action in the properties of the step in *"Exit action"*. Other actions can also be selected there.

See also

- *Chapter 1.4.1.20.3.11.9 "Command 'Add Exit Action'" on page 1082*
- *"2. Step actions" on page 489*

Adding an action

1. Double-click the *"Step0"* step.
   ⇨ By default, you are prompted to select the duplication mode for the step actions of the step. See above for adding an entry action. The *"Add Action"* dialog opens.
2. Type in the name "Step0_active" and select the *"Structured Text (ST)"* implementation language. Click *"Add"*.
   ⇨ CODESYS inserts the *"Step0_active"* action below the POU in the device tree and opens the action in the editor.
   In the `Step0_active` step action, you program statements to be executed as long as the step is active.
3. Close the editor of `Step0_active`.
   ⇨ The *"Step0"* step is now marked with a black triangle in the upper right corner.

You can define the action in the properties of the step in *"Step action"*. Other actions can also be selected there.

See also

- *"2. Step actions" on page 489*

Adding an alternative branch

1. Select the *“Step1”* step.
2. Click *“SFC ➔ Insert Branch Right”*.
   ⇨ CODESYS inserts the *“Step2”* step to the right of *“Step1”*. The steps are connected as a parallel branch signified by two pairs of double lines.
3. Select one of the double lines.
   ⇨ The double line is marked red.
4. Click *“SFC ➔ Alternative”*
   ⇨ CODESYS converts the branch into an alternative branch. The double lines change into a single line.

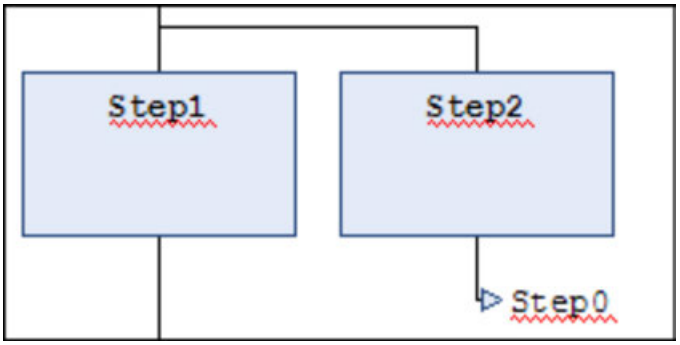
You can click *“SFC ➔ Parallel”* to convert an alternative branch into a parallel branch.

See also

- *Chapter 1.4.1.19.1.4.8.3 “SFC element 'Branch'” on page 491*
- *Chapter 1.4.1.20.3.11.10 “Command 'Parallel'” on page 1082*
- *Chapter 1.4.1.20.3.11.12 “Command 'Insert Branch'” on page 1083*
- *Chapter 1.4.1.20.3.11.13 “Command 'Insert Branch Right'” on page 1083*

Adding a jump

1. Select the *“Step2”* step.
2. Click *“SFC ➔ Insert Jump After”*.
   ⇨ CODESYS inserts the *“Step”* jump after the *“Step2”* step.
3. Select the *“Step”* jump destination.
   ⇨ You can type the jump destination manually or select it by using the Input Assistant [...]. Select `Step0`.



See also

- *Chapter 1.4.1.19.1.4.8.4 “SFC element 'Jump'” on page 492*
- *Chapter 1.4.1.20.3.11.16 “Command 'Insert Jump'” on page 1085*
- *Chapter 1.4.1.20.3.11.17 “Command 'Insert Jump After'” on page 1085*

Adding a macro

1. Select the *“Step1”* step.
2. Click *“SFC ➔ Insert Macro After”*.
   ⇨ CODESYS inserts the *“Macro0”* macro after the *“Step1”* step.

3. Double-click the *“Macro0”* element.
   ⇨ The macro opens in the implementation section of the editor. The name "Macro0" is displayed in the caption.
4. Click *“SFC ➔ Insert Step-Transition”*.
   ⇨ CODESYS inserts a step-transition combination.
5. Click *“SFC ➔ Zoom out of Macro”*.
   ⇨ The implementation section returns to the main diagram.

See also

- *Chapter 1.4.1.19.1.4.8.5 “SFC element 'Macro'” on page 492*
- *Chapter 1.4.1.20.3.11.18 “Command 'Insert Macro'” on page 1086*
- *Chapter 1.4.1.20.3.11.19 “Command 'Insert Macro After'” on page 1086*

Adding an association

1. Select the *“Step2”* step.
2. Click *“SFC ➔ Insert Action Association”*.
   ⇨ CODESYS inserts an association to the right of the *“Step2”* step.
3. Click in the left field of the association to select the qualifier.
   ⇨ You can enter the qualifier manually or use the Input Assistant ... . Select "P".
4. Click in the right field of the association to select the action.
   ⇨ You can type the action or select it by using the Input Assistant ... .

Using the library 'analyzation.library' for the analyzation of expressions

The library `analyzation.library` allows for the analyzation of expressions. It can be used, for example, in the SFC diagram to examine the result of the flag `SFCError`. This flag is used to monitor timeouts in the SFC diagram.

See also

- *Chapter 1.4.1.19.1.4.7 “Library "Analyzation"” on page 485*

See also

- *Chapter 1.4.1.19.1.4.1 “SFC editor” on page 476*

1.4.1.8.4 Function block — Calling functions or methods with external implementation

A runtime system can include the implementation of a function block, function, or method (for example, from a library). If you create a POU in your application with the same name by using the *"External implementation"* without an implementation, then you can execute the existing implementation. Please make sure that you declare local variables only in an external function block. External functions and methods must not contain local variables.

When the application is downloading, CODESYS searches for and links the associated implementation in the runtime system for each external POU.

Objects with the property "External implementation" are postfixed with `(EXT)` *after the object name in the "Devices" or "POUs" view.*

See also

- ↳ *Chapter 1.4.1.20.4.10.4 "Dialog 'Properties' - 'Build'" on page 1159*

Creating POUs with external implementation

1. Click *"Project ➔ Add Object ➔ POU"*.
2. Activate *"Function block"*, Method, or *"Function"* and specify the name of the associated implementation of the runtime system. Close the dialog box by clicking *"Add"*.
   ⇨ The runtime system POU is created in the *"POUs"* view. The name is postfixed with `(EXT)`.
3. Right-click the POU and select *"Properties"*.
   ⇨ The dialog box opens.
4. Click the *"Build"* tab.
5. Select the *"External implementation (Late link in the runtime system)"* check box.
   ⇨ The POU is declared and you can implement a POU call.

Creating methods with external implementation

1. Select a function block in the device tree or in the POUs view.
2. Select *"Add Object ➔ Method"* and type the name of the associated implementation of the runtime system. Click *"Add"* to close the dialog box.
   ⇨ The method is created.
3. Right-click the method and select *"Properties"*.
   ⇨ The dialog box opens.
4. Click the *"Build"* tab.
5. Select the *"External implementation (Late link in the runtime system)"* check box.
   ⇨ The method is declared and you can implement a method call. The method name is postfixed with `(EXT)` in the *"Devices"* or *"POUs"* view.

1.4.1.8.5 Using input assistance

CODESYS provides tools and features to help you code when creating programs.

Input assistant

The input assistant provides all program elements that you can insert at the current cursor position. Open the *“Input Assistant”* dialog by clicking *“Edit ➔ Input Assistant”* or by pressing *[F2]*.

See also

- *“Dialog 'Input Assistant' - Tab 'Categories'” on page 978*

Dialog 'Auto Declare'

This dialog supports the declaration of variables.

See also

- *Chapter 1.4.1.20.3.2.32 “Command 'Auto Declare'” on page 975*

"List components"

The "List components" function is an input tool in textual editors to help you input valid identifiers. Activate this function by clicking *“Tools ➔ Options”* and then the *“SmartCoding”* category. Select the *“List components after typing a dot (.)”* check box.

- If you type a dot (`.`) instead of a global variable, then a drop-down list opens with all available global variables. You insert the selected variable after the dot by double-clicking a variable in the drop-down list or by pressing *[Enter]*.
- If you type a dot (.) instead of a global variable after a function block instance variable or a structure variable, then CODESYS opens a drop-down list with all global variables, all input and output variables for the function block, or all structure members.

  You insert the selected variable after the dot by double-clicking a variable in the drop-down list or by pressing *[Enter]*.

  Note: When you also want to choose from the local variables of function block instances, select the *“Show all instance variables in input assistant”* option in the CODESYS options (SmartCoding category).
- If a component access (with a dot) for a drop-down list has already happened, then the last selected entry is preselected at the next component access.
- When you type any sequence of characters and then press *[Ctrl]+[Space]*, a drop-down list opens with all available POUs and global variables. The first element in this list that starts with the sequence of characters is selected by default and you can insert it by double-clicking it or by pressing *[Enter]*.

  Matches with the entered character string are highlighted in yellow in the drop-down list.

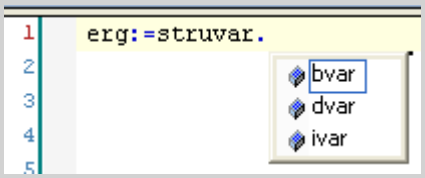
  If the entered character string is changed, then the displayed drop-down list is refreshed.
- In the ST editor, you can filter the displayed drop-down list by scopes:

  Depending on the displayed drop-down list, you can use the *[Arrow right]* and *[Arrow left]* keys to toggle between the following drop-down lists:
  - *“All items”*
  - *“Keywords”*
  - *“Global declarations”*
  - *“Local declarations”*
- CODESYS displays a tooltip if you type an opening parenthesis for a POU parameter when calling a function block, a method, or a function. This tooltip includes information about the parameters as they are declared in the POU. The tooltip remains open until you click to close it or you change the focus away from the current view. If you accidentally close the tooltip, then you can reopen it by pressing *[Ctrl]+[Shift]+[Space]*.

You can use the pragma attribute `'hide'` for excluding variables from the "List components" feature.

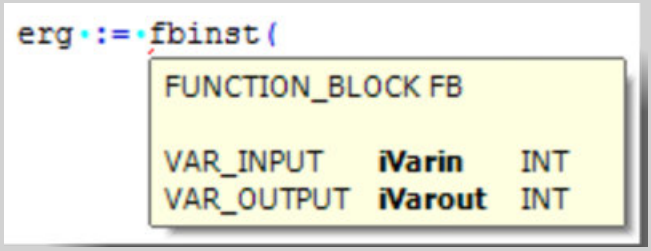
Examples

Typing structure variables:



list

Calling a function block:



See also

- *Chapter 1.4.1.20.4.13.23 “Dialog 'Options' - 'SmartCoding'” on page 1201*
- *Chapter 1.4.1.19.6.2.16 “Attribute 'hide'” on page 700*

Short form feature

The short form feature allows you to type abbreviated forms for variable declarations in the declaration editor and in textual editors where variables declarations are possible. Use this feature by pressing *[Ctrl]+[Enter]* to end a declaration line.

CODESYS supports the following short forms:

- All identifiers become variable identifiers except the last identifier of a line.
- The data type of the declaration is determined by the last identifier of the line. The following applies:
  - `B` or `BOOL` yields `BOOL`
  - `I` or `INT` yields `INT`
  - `R` or `BOOL` yields `BOOL`
  - `S` or `STRING` yields `STRING`
- If a data type is not defined using this rule, then the data type is automatically `BOOL`, and the last identifier is not used as the data type (see Example 1).
- Depending on the type of declaration, every defined constant becomes an initialization or string length definition (see Example 2 and 3).
- An address, such as `%MD12`, is automatically extended with the AT attribute (see Example 4).
- Any text after a semicolon (`;`) is converted into a comment (see Example 3).
- All other characters in the line are ignored (see exclamation mark in Example 5).

Examples

Example	Short Form	Resulting declaration
1	`A`	`A: BOOL`
2	`A B I 2`	`A, B: INT := 2;`
3	`ST S 2; A string`	`ST:STRING(2); (* A string *)`
4	`X %MD12 R 5 Real Number`	`X AT %MD12: REAL := 5.0;(* Real Number *)`
5	`B !`	`B: BOOL`

See also

- *Chapter 1.4.1.8.2 “Declaration of Variables ” on page 222*

Smart tag functions

Smart tags make it easier to write program code by suggest appropriate commands directly at the programming element. When you place the cursor over a programming element that has a smart tag function, the symbol appears. When you click the symbol, the commands that you can choose from are shown. Available smart tags:

- The smart tag function provides the *“Declare Variable”* command for undeclared variables in the implementation part of the ST editor.

See also

- *Chapter 1.4.1.20.3.2.32 “Command 'Auto Declare'” on page 975*

1.4.1.8.6 Using Pragmas

Pragma in CODESYS

A pragma is a text in the source code of the application that is enclosed in curly brackets. Pragmas are used to insert special statements in the code, which the compiler can evaluate. This allows a pragma to influence the properties of one or more variables with respect to precompilation or compilation (code generation). Pragmas that the compiler does not recognize are passed over as a comment.

The statement string of a pragma can also extend over multiple lines. For more details about the syntax, see the descriptions of the individual CODESYS pragmas.

There are different pragmas for different purposes (example: initialization of a variable, monitoring of a variable, adding a variable to the symbol configuration, forcing the display of messages during the compilation process, and behavior of a variable under certain conditions).

NOTICE!
Uppercase and lowercase characters have to be respected.

Examples

```
{warning 'This is not allowed'}

{attribute 'obsolete' := 'datatype fb1 not valid!'}

{attribute 'Test':='TestValue1;
                    TestValue2;
                    TestValue3'}
```

Possible insertion positions

NOTICE!
Pragmas in CODESYS are not one-to-one implementations of C preprocessor directives. You have to position a pragma like an ordinary statement. You must not use a pragma within an expression.

A pragma that the CODESYS compiler should evaluate can be inserted at the following positions:

- In the declaration part of a POU:
  - In the textual declaration editor, specify pragmas directly as line(s), either at the beginning of the POU or before a variable declaration.
  - In the tabular editor, you specify pragmas that should be located before the first declaration line in the *“Edit Declaration Part”* / *“Attributes”* dialog.
- In a global variable list
- In the implementation part of a POU:
  - The pragma has to be at a "statement position", meaning at the beginning of a POU on a separate line, or after a "`;`" or `END_IF`, `END_WHILE`, etc.
  - FBD/LD/IL editor: In networks of the FBD/LD/IL editor, you insert pragmas like a label by means of the *“FBD/LD/IL ➔ Insert Label”* command. Then, in the text field of the label with the corresponding pragma statement, replace the default text *“Label:”*. To use a pragma in addition to a label, you specify the pragma first and then the label.

Incorrect and correct positions for a conditional pragma

INCORRECT:

```
{IF defined(abc)}
IF x = abc THEN
{ELSE}
IF x = 12 THEN
{END_IF}
y := {IF defined(cde)} 12; {ELSE} 13; {END_IF}
END_IF
```

CORRECT:

```
{IF defined(abc)}
IF x = abc THEN
{IF defined(cde)}
    y := 12;
{ELSE}
   y := 13;
{END_IF}
END_IF
{ELSE}
IF x = 12 THEN
{IF defined(cde)}
    y := 12;
{ELSE}
   y := 13;
{END_IF}
END_IF
{END_IF}
```

In the “Properties” dialog (“Compile” category), you can specify "defines" that can be queried in pragmas.

Scope:

Depending on the type and contents of a pragma, it may influence the following:

- Subsequent declarations
- Exactly the next statement
- All subsequent statements until it is canceled by a corresponding pragma
- All subsequent statements until the same pragma is executed with other parameters or the end of the code is reached. In this context, "code" means the declaration part, implementation part, global variable list, and type declaration. Therefore, a pragma influences the entire object when the pragma is alone on the first line of the declaration part and is not superseded or canceled by another pragma.

Pragma categories in CODESYS

The CODESYS pragmas are divided into the following categories:

- Attribute pragmas (influence compiling and precompiling)
- Message pragmas (print user-defined messages when compiling)
- Conditional pragmas (influence code generation)
- User-defined pragmas

See also

1.4.1.8.7 Using Library POUs

Libraries are collections of objects that you can link to your application. You can use the objects contained in libraries in exactly the same way as objects that you have defined in the project.

Libraries can contain the following objects:

- POUs (for example function blocks, or functions)
- Interfaces and their methods and attributes
- Data types (for example enumerations, structures, aliases, and unions)
- Global variables, constants, and parameter lists
- Text lists, image pools, visualizations, and visual elements
- External files (for example, documentation)
- Cam plate tables

Libraries in a project are managed in the Library Manager. You use the dialog of the library repository to perform the previous installation of the library on the system.

For "visibility" of library POUs and namespaces of libraries, see also the help page for the library properties.

See also

- ↳ *Chapter 1.4.1.20.3.14.3 “Command 'Properties'” on page 1118*
- ↳ *Chapter 1.4.1.16 “Using Libraries” on page 448*
- ↳ *Chapter 1.4.1.20.3.14.3 “Command 'Properties'” on page 1118*

Using library POUs

The following instructions describe the example of how to insert the counter POU `CTUD` from the library `Standard` into your program.

1. Open a POU in the editor and place the cursor in the declaration part.
2. Specify the name for the function block instance, followed by a colon (example: `iCounter1:`).
3. Press *[F2]* to open the Input Assistant.
4. In the category *“Structured Types”*, select the `CTUD` function block from the `Standard` library (subfolder "Counter").

   Select the *“Insert with namespace prefix”* option.
5. Click *“OK”* to exit the dialog.

   ⇨ The function block is inserted with a namespace prefix into the declaration part: `iCounter1:Standard.CTUD`.

See also

- *Chapter 1.4.1.16 “Using Libraries” on page 448*

1.4.1.8.8 Managing text in text lists

Text lists are used for preparing visualization texts is multiple languages. You can specify the texts in Unicode format so that all languages and characters are possible. You can export text lists and then translate the texts outside of the current project.

CODESYS differentiates between static text (managed in the *“GlobalTextList”* object) and dynamic text (managed in objects of type *“TextList”*. Static texts exist in the visualization and can change only the displayed language while in runtime mode. The text ID stays the same. Dynamic texts can be controlled by means of an IEC variable that contains the text ID. In this way, you can display varying text in a visualization element in runtime mode. For example, you can configure a text field so that is shows an error text for an error number.

Both text list types include a table with text entries. An entry consists of an ID for identification, the output text, and its translation. In a text list or global text list, you can translate an output text in any number of languages. The translations are the basis for the language selection and the language switch in visualizations.

Adding a language and translating text

Requirement: A project is open with a text list or global text.

1. Double-click an object of type *“TextList”* or *“GlobalTextList”* in the device tree or POUs view.
   ⇨ The *“Textlist”* menu is shown in the menu bar and the text list opens in the editor.
2. Click *“Textlist ➔ Add Language”*.
3. Specify a name for the language (example: `en-US`). Click *“OK”* to close the dialog.
   ⇨ A column is displayed with the heading `en-US`.
4. Type in the translation of the source text into the column.

You can correct the name of a language in the table by means of the command “Rename Language” in the context menu of the text list.

Exporting a text list

☑ Requirement: A project is open with a text list or global text.

1. Double-click the object *“GlobalTextList”* or an object of type *“TextList”*.
   ⇨ The object opens.
2. Click *“Textlist ➔ Import/Export Text Lists”*.
   ⇨ The *“Import/Export”* dialog opens.
3. At *“Choose export file”*, click for more (...) and select the directory and file name (example: `Text_lists_exported`).
4. Select the *“Export”* option.

5. Click *"OK"* to close the *"Import/Export"* dialog.

   ⇨ CODESYS exports to a file the text list entries of all text lists of the project. The table contains a column with the text list names.

Example

Contents of the file `Text_lists_exported`

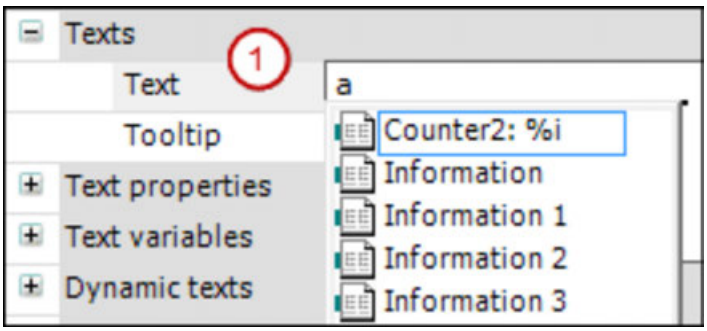
```
TextList    Id    Default    en_US
Text_list_A    A    Information A    Infrrmation A_en
Text_list_A    B    Information B: OK    Information B_en: OK
Text_list_A    C    Information C    Information C_en
Text_list_A    D    Information D    Information D_en
Text_list_A    E    Information E    Information E_en
Text_list_A    F    Information F    Information F_en
AlarmGroup    2    Warning 2
AlarmGroup    1    Warning 1
GlobalTextList        Information B    Information B_en
GlobalTextList        Information A    Information A_en
GlobalTextList        Switch    Switch
GlobalTextList        Counter: %i    Counter : %i
```

Preparing the exported file for input assistance

☑ Requirement: A file is created (example : `Text_lists_exported`) by means of the command *"Import/Export Text Lists"*. It contains the texts of the text lists of the project.

1. Click *"Tools* ➔ *Options"*, *"Visualization"* category, *"File Options"* tab.
2. Click … in *"Text file for textual "List components" "* and select a file (example: `Text_lists_exported`). Click *"OK"* to close the dialog.

   ⇨ When you specify a static text in the *"Texts"* property for an element in a visualization, CODESYS offers the source text of the file as input assistance when typing in the first letter.



(1): *"Texts"*, *"Text"*

See also

- ↳ *""List components"" on page 261*

Importing files with text list entries

A file to be imported has the `.csv` format. The first line is a header (example: `TextList Id Default en_US`). The other lines contain text list entries. You get this kind of file by exporting the text lists of the project to a file. There you can edit the text list entries and then import the file outside of CODESYS. When importing, CODESYS handles the text list entries differently for the `GlobalTextList` and for dynamic text lists.

`GlobalTextList`

- CODESYS does not create new text list entries for an unknown ID.
- CODESYS ignores changes that affect the ID or the source text.
- CODESYS accepts changes in the translations.

TextList

- For a new ID, CODESYS supplements the corresponding text list with a text list entry.
- For an existing ID that does not agree in the source text, the source text of the text list is overwritten with the source text of the file.
- CODESYS accepts changes in the translations.

Importing a file

☑ Requirement: A project is open with a text list or global text.

1. Double-click the object *"GlobalTextList"* or an object of type *"TextList"*.
   ⇨ The object opens.
2. Click *"Textlist ➔ Import/Export Text Lists"*.
   ⇨ The *"Import/Export"* dialog opens.
3. In the *"Choose file to compare or to import"* input field, click for more (...) and select the directory and file (example: `Text_lists_corrected.csv`).
4. Select the *"Import"* option.
5. Click *"OK"* to close the dialog.
   ⇨ CODESYS imports the text list entries of the file into the respective text lists.

Example

Contents of the file `Text_lists_corrected.csv`

```
TextList    Id    Default    en_US
Text_list_A    A    Information A    Information A2_en
Text_list_A    B    Information B: OK    Information B_en: OK
Text_list_A    C    Information C    Information C_en
Text_list_A    D    Information D    Information D_en
Text_list_A    E    Information E    Information E_en
Text_list_A    F    Information F    Information F_en
Text_list_A    G    Information G    Information G_en
AlarmGroup    2    Warning 2
AlarmGroup    1    Warning 1
GlobalTextList        Information B    Information B_en
GlobalTextList        Information A    Information A_en
GlobalTextList        Switch    Switch
GlobalTextList        Counter: %i    Counter : %i
```

These contents are applied to the text lists with the same name in the project.

See also

- *Chapter 1.4.1.20.3.20.6 "Command 'Import/Export Text Lists'" on page 1133*

Comparing text lists with a file and exporting differences

☑ Requirement: A project is open with a text list or global text.

1. Double-click the object *"GlobalTextList"* or an object of type *"TextList"*.
   ⇨ The object opens.

2. Click *"Textlist ➔ Import/Export Text Lists"* in the context menu.
   ⇨ The *"Import/Export"* dialog opens.
3. In the *"Choose file to compare or to import"* input field, click for more (...) and select the directory and file name of the comparison file (example: `Text_lists_corrected.csv`).
4. For *"Choose export file"*, click ... and select the directory and file that contains the comparison result.
5. Select the *"Export only text differences"* option.
6. Click *"OK"* to close the dialog.
   ⇨ CODESYS reads the import file and compares the text list entries that have the same ID. If they do not agree, then CODESYS writes the text list entries of the text list to the export file.

   For the global text list, CODESYS compares the translations of the same source texts. If they do not agree, then CODESYS writes the text list entries to the export file.

- *Chapter 1.4.1.20.3.20.7 "Command 'Remove Language'" on page 1134*
- *Chapter 1.4.1.20.2.24 "Object 'Text List'" on page 927*

Managing static text in global text lists

The global text list is the central location for texts that are displayed in the visualization.

When you configure a text for the first time in visualization element, CODESYS creates the global text list. CODESYS fills in the table as you create more texts. Therefore, the table includes all texts automatically that you create in the project visualizations. CODESYS assigns incremental IDs as integers, beginning at 0.

You can check, update, and compare the global text list with the static texts of the visualization. You cannot edit the source text or the ID directly in the table. However, you can replace a source text with another source text by creating and importing a replacement file. Menu commands are provided for this purpose.

Configuring visualization elements with static text

A text in a *"GlobalTextList"* can contain a format definition.

☑ Requirement: A project is open with a visualization. The *"GlobalTextList"* object contains the texts that are defined in the project visualizations.

1. Double-click the visualization.
   ⇨ The editor opens.
2. Select an element with the *"Text"* property (example: *"Text field"*).
3. Type in some text in the *"Text"* property (example: `Static Information A`).
   ⇨ CODESYS adds the text to the global text list in the POU view.

Checking the global text list

☑ Requirement: A project is open with a visualization. The *"GlobalTextList"* object contains the texts that are defined in the project visualizations.

1. Double-click the *"GlobalTextList"* object in the POUs tree.
   ⇨ The table opens with the static texts.
2. Click *"Text List ➔ Check Visualization Text IDs"*.
   ⇨ CODESYS reports when a source text of the text list does not match the static text that is identified by the ID. The source text in the global text list and the text in the visualization with the same ID do not match.

Updating IDs of the global text list

☑ Requirement: A project is open with a visualization. The *"GlobalTextList"* object contains the texts that are defined in the project visualizations.

1. Double-click the *"GlobalTextList"* object in the POUs tree.
   ⇨ The list opens with the text list entries.
2. Click *"Text List ➔ Update Visualization Text IDs"*.
   ⇨ CODESYS adds text to the global text list when a text in the *"Static Text"* property does not match the source text in the project visualizations.

Removing the global text list and creating current IDs again

☑ Requirement: A project is open with a visualization. The *"GlobalTextList"* object contains the texts that are defined in the project visualizations.

1. Right-click the *"GlobalTextList"* object in the POUs tree and select the *"Delete"* command.
   ⇨ The object is removed.
2. Open a visualization.
3. Click *"Visualization ➔ Create Global Text List"*.
   ⇨ In the POU view, a new *"GlobalTextList"* object is created. The global text list contains the static text from the existing project visualizations.

Removing IDs from the global text list

☑ Requirement: A project is open with a visualization. The *"GlobalTextList"* object contains the texts that were defined in the project visualizations.

1. Double-click the *"GlobalTextList"* object in the POUs tree.
   ⇨ The table opens with the texts.
2. Click *"Text List ➔ Remove Unused Text List Entries"*.
   ⇨ CODESYS removes the text list entries with IDs not referenced in the project visualizations.

Updating the global text list with a replacement file

A replacement file has the `CSV` format. The first row is a header: `defaultold defaultnew REPLACE`. The following rows contain the old source texts, the new source texts, and then the `REPLACE` command. Tabs, commas, and semicolons are permitted separators. A combination of separator characters in a file is not permitted.

Example (tab as separator character)

```
defaultold      defaultnew       REPLACE
Information A   Information A1   REPLACE
```

When you import a replacement file, CODESYS processes the replacement file row by row and performs the specified replacements in the *"GlobalTextList"*. In addition, CODESYS replaces the previous text with the replacement text in the visualizations. If the replacement text already exists as static text, then CODESYS recognizes this and harmonizes the static text and leaves only one text list entry.

☑ Requirement: A project is open with a text list or global text.

1. Double-click the *"GlobalTextList"* object.
   ⇨ The object opens.
2. Click *"Text List ➔ Import/Export Text Lists"*.
   ⇨ The *"Import/Export"* dialog opens.
3. At the *"Choose file to compare or to import"* input field, click for more (...) and select the directory and file (example: `ReplaceGlobalTextList.csv`).
4. Select the *"Import replacement file"* check box.
5. Click *"OK"* to close the dialog.
   ⇨ The texts in the text lists and the visualizations are replaced.

Example

The global text list contains the following source texts:

```
GlobalTextList        Counter: %i
GlobalTextList        Counter: %i
GlobalTextList        Information A
GlobalTextList        Information a
GlobalTextList        Information Aa
GlobalTextList        Switch
```

The replacement file contains the following replacements:

```
defaultold        defaultnew        REPLACE
Counter: %i        Counter2: %i    REPLACE
Counter:  %i        Counter2: %i    REPLACE
Information  A    Information A2    REPLACE
Information  a    Information A2    REPLACE
Information Aa    Information A2    REPLACE
Switch        Switch2            REPLACE
```

CODESYS detects duplicate text list entries and removes them. Afterwards, the global text list contains the following source texts:

5	Switch2
4	Counter2: %i
3	Information A2

The texts in the visualization have been replaced.

- *Chapter 1.4.1.20.3.20.11 “Command 'Update Visualization Text IDs'” on page 1135*
- *Chapter 1.4.1.20.2.9 “Object 'GlobalTextList'” on page 871*

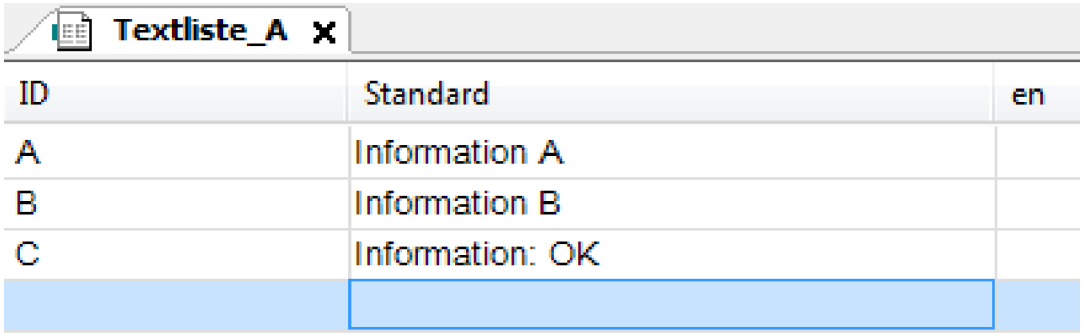
Managing dynamic text in text lists

You can create and translate texts in a text list for dynamic texts in order to show them dynamically in a visualization or in the alarm management. The object of type *"Text list"* can be located globally in the POUs view or below an application in the device tree. It contains a table with text list entries that you can edit and extend. A text list entry consists of an ID for identification, the output text, and its translation. You can add new text list entries to a text list. Menu commands are provided for this purpose.

Creating text lists for dynamic text output

Requirement: A project is open with a visualization.

1. Select an application in the POUs view or device tree and click *"Project ➔ Add Object"*.
2. Select *"Text list"*.
3. Type a name (example: `Textliste_A`). Click *"Add"* to close the dialog.
   ⇨ An object of type *"Text list"* is created.
4. Click below the *"Default"* column and open the input field. Type a text (example: `Information`).
   ⇨ The source text is created. It is used as a key in the table and as a source text for translations.
5. Type any string in the *"ID"* column (example: `A`).
   ⇨ A text list entry is defined with source text and ID. If you configure the *"Dynamic texts"* property of an element in a visualization, then you can select the text list `Textliste_A` and assign the ID `A`.
6. Double-click in the blank line at the end of the table below *"Default"* and type in more text list entries.



Displaying text dynamically

In a visualization, you can configure the dynamic output of texts that were created in a text list by configuring the *"Dynamic texts"* property of an element. You can directly assign a text list and an ID, as well as IEC variables, where you set the values programmatically.

☑ Requirement: A project with visualization is open and a text list is in the device tree.

1. Open the text list (example: `Text_list_A`).
2. Double-click the visualization.
   ⇨ The editor opens.
3. Drag an element to the visualization (example: a *"Text field"*).

4. Configure its *“Dynamic texts”* property by selecting one in the *“Text list”* property (example: `'Text_list_A'`) and add an ID from the text list into the *“Text index”* (example: `'A'`). **Pay attention to the single straight quotation marks**. You can also assign an IEC variable of type `STRING` for the text list name and ID.

   ⇨ The IEC variables allow for programmatic access to the texts of the text lists.

5. Build the application, download it to the controller, and start it.

   ⇨ The visualization shows the text from the text list in the text field : `Information A`.

- ↳ *Chapter 1.4.1.20.2.24 “Object 'Text List'” on page 927*

1.4.1.8.9 Using image pools

An image pool is a table of image files. CODESYS references image files for use in the project (for example, in a visualization) uniquely by the ID and name of the image pool. A project can include several image pools. You can create Image pools in the device tree below the application or in the POU pool. In a library project, you can use the object properties of an image pool to turn it into a symbol library for the visualization.

We recommend that you reduce the size of image files as much as possible integrating them. This will optimize the loading time of the visualization in every visualization type: TargetVisu, WebVisu and development system.

If you insert an image element into a visualization and enter an ID (*“Static ID”*) in the element properties, then CODESYS automatically creates a global image pool. CODESYS uses the default name *“GlobalImagePool”* for this.

Please note the following when the ID of an image file appears in several image pools.

- Search order: If you selected an image managed in *“GlobalImagePool”*, then you do not have to enter the name of the image pool. The search order for image files is as follows:
  - 1. GlobalImagePool
  - 2. Image pools assigned to the currently active application
  - 3. Image pools next to the GlobalImagePool in the POU window
  - 4. Image pools in libraries
- Unique access: You can reference a selected image directly and uniquely by appending the image ID to the name of the image pool in the following syntax "`<pool name>.<image ID>`.

See also

- ↳ *Chapter 1.4.1.20.2.13 “Object 'Image Pool'” on page 873*
- ↳ *Chapter 1.4.1.20.4.10.17 “Dialog 'Properties' - 'Image Pool'” on page 1168*

Creating image pools

1. Select the *“Application”* object in the device tree.

   Click *“Project ➔ Add Object ➔ Image Pool”*.

   ⇨ The *“Add Image Pool”* dialog box opens.

2. Type a name for the image pool (for example, "Images1") and click *“Add”*.

   ⇨ The image pool is added to the device tree.

3. Select the image pool object and open by choosing the command *“Project ➔ Edit Object”*.

4. Double-click the field in the *“ID”* column and assign an appropriate ID (for example, "Icon1").

   You can also add new images to the list by clicking *“Imagepool ➔ Add Image File”*.

5. Double-click the field in the *“File name”* column. Click for more settings (...).

   ⇨ The *“Select Image”* dialog box opens.

6. Click for more settings (...) and select the image file.

   ⇨ A thumbnail of the image file is displayed in the field of the column *“Image”*. The name of the file is displayed in the field of the column *“File name”*.

The image file can be references only by the name `Images1.Icon1`.

See also

- *Chapter 1.4.1.20.3.15.1 “Command 'Insert Image'” on page 1121*

Using image files in the 'Image' visualization element

When you insert an image element into a visualization, you can define the image type.

- Static image: Enter the image ID of the image file or the name of the image pool plus the image ID into the element configuration (property *“Static ID”*). Please note the comments for the search order and access.
- Dynamic image: Type the variable for defining the image file ID (for example, `PLC_PRG.imagevar`) in the element configuration (*“Bitmap ID variable”* property). You can exchange a dynamic element in online mode depending on a variable.

See also

- *Chapter 1.4.5.18.1.5 “Visualization Element 'Image'” on page 1418*

Using image files for the visualization background

You can set an image in the background definition of a visualization. You can define the image by the name of the image pool plus the filename, as described above for a visualization element.

See also

- *Chapter 1.4.5.19.2.10 “Command 'Background'” on page 1728*

1.4.1.8.10 Integrating C Modules

With the C code integration plugin, externally implemented C code files can be included in CODESYS projects and C stubs can be generated from IEC objects.

In CODESYS, the *“C Code Module”* object type is available for this purpose. The C code files and the used IEC objects are located below a *“C Code Module”*. A file directory on the hard disk with C code files is assigned to each C code module.

In the project, you can generate IEC objects from a C code file in the format *.h or *.hpp (header file) in order to use them in other POUs.

The generation of C-stubs is intended for the following use cases:

- A C code file accesses an IEC object: A C code file cannot access an IEC object directly. It can access only the C stub that was generated from the IEC object.
- Generation of precompiled modules that you can merge into a library project.

After being imported, the imported source code files are part of the CODESYS project and they are therefore decoupled from the original files on the disk.

During compilation, a dynamic module is generated from a C code module and saved as part of the project. Information, warnings, and errors are displayed in the message view in the *“C Code Module”* category.

All dynamic modules of an application are transferred and loaded to the runtime system during the download. The runtime system must support dynamic linking for this.

> ***License for the runtime system***
> *The runtime system requires a license that permits C modules to be loaded. Without this license, dynamic modules cannot be linked during the download, and therefore the download will be aborted.*

The dynamic modules are part of the boot application and they are reloaded and activated when the controller is restarted. The *"Reset Origin"* command unloads all C code modules in the application. The *"Reset Cold"* and *"Reset Warm"* commands do not lead to a repeated initialization of the C code modules.

> **NOTICE!**
> **No C code for simulation mode**
> In simulation mode, C code is not generated and loaded to the runtime system. To simulate the code contained in the C modules anyway, you can implement it for this purpose in the respective IEC objects of the C code module.

CODESYS does not support the monitoring of variables in C code files or the setting of breakpoints in C source code.

Precompiled module in a library:

C code integration provides the capability of assigning a precompiled runtime module (example: *.dll) in the library to a device and then to save it in the library. Then, these modules can be loaded dynamically.

See also

- *Chapter 1.4.1.10.3 "Handling of Device User Management" on page 385*

Configuring C code modules

Requirement: A project is open that already includes a C code module.

1. Click the object *"C Code Module"* in the device tree.
2. Select the command *"Properties"* in the context menu.
3. Open the *"Build"* tab in the *"Properties"* dialog.
4. Specify the file path of the Visual Studio installation on your computer. The input assistant (...) and the search tool (magnifying glass) are also available.
5. Specify the file path of the MS Windows SDK installation on your computer. The input assistant (...) and the search tool (magnifying glass) are also available.
6. Specify a file path for CODESYS to store the temporary compile files.

Importing folders with C source files from the file directory

Requirement: A project is open. The project controller supports the integration of C code.

1. Select *"Application"* in the device tree and click *"Project ➔ Add Object ➔ C Code Module"*.
2. If necessary, specify a new name for your C code module in the *"Add C Code Modules"* dialog. If you do not, then your object will be given the standard name *"C Code Module"*.
3. Click the symbol (...) next to the *"Source directory"* input field.
4. The *"Find Folder"* dialog opens.

5. In the *"Find Folder"* dialog, select the folder containing the C source files (`*.c`, `*.cpp`, `*.h`, or `*.hpp`).
6. When you select the *"Monitor folder for source code changes"* option, CODESYS displays a message when changes have been made to the C source files in the selected folder of the file system.
7. Click *"Add"*.
   ⇨ CODESYS inserts the C code module into the device tree with the folders *"Extensions"*, *"IEC interface"*, and *"Source Files"*.
8. In the device tree, click the plus symbol (*"+"*) of the *"Source Files"* folder.
   ⇨ The imported C source files are listed in the open folder.
9. If you double-click one of the C source files (), then the C code file opens in your editor.

Importing individual C code files

Requirement: A project is open that already includes a C code module.

1. Click the object *"C Code Module"* in the device tree.
2. Click *"Project ➔ Add Object ➔ C Code File"*.
3. In the *"Add C Code-File"* dialog, use the input assistant (...) to select a file in `*.c`, `*.cpp`, `*.h`, or `*.hpp` format, and then click *"Add"*.
   ⇨ CODESYS inserts the selected C code file into the device tree below the *"C Code Module"*.
4. If you double-click the new C code file () in the device tree, then it opens in the editor for modification.

Generating empty C code files

Requirement: A project is open that already includes a C code module.

1. Click the object *"C Code Module"* in the device tree.
2. Click *"Project ➔ Add Object ➔ C Code File"*.
3. In the *"Add C Code File"* dialog, specify the name for the new C code file with the appropriate file extension and click *"Add"*.
   ⇨ CODESYS inserts the selected C code file into the device tree below the *"C Code Module"*.
4. If you double-click the new C code file () in the device tree, then it opens in the editor for modification.

Converting C code files into IEC objects for use as programming objects in applications

Requirement: A project is open that includes a C code module and C code files. For example, the C code file contains the following C code: `int adder(int a, int b);`

1. Click a C code file with the file extension `*.h`. In this example, it is `test.h`.
2. Click *"Build ➔ C-Integration ➔ Create IEC Interface"*.
   ⇨ The dialog *"Create C Interface"* opens and lists the file `test.h` and its function `adder (int, int)`. Both are activated for the import.
3. Click *"Import"*.
4. CODESYS generates the *"adder (FUN)"* function and inserts it as an object in the *"IEC Interface"* folder in the device tree.

5. When you double-click the *"adder (FUN)"* object, it opens in the editor.
   ⇨ It contains the following declaration part:

```
{attribute 'C_SOURCE_EXPORT' := 'adder'}
{attribute 'external_name' := 'adder_CExt'}
FUNCTION adder : DINT
VAR_INPUT
  → a : DINT;
  → b : DINT;
END_VAR
VAR
END_VAR
```

6. You can now call the `adder` function in the implementation part of a POU (example: `adder (diVar1, diVar2);`).

Creating C stubs

Requirement: A project is open that includes a C code module. A POU is added to the C code module and this POU has implemented code.

▷ In the device tree, select the POU below the C code module and click *"C-Integration ➔ Create Stub Implementation in C"*.

⇨ CODESYS creates the objects *"iec_external.c"* and *"iec_external.h"* and adds them to the *"Extensions"* folder in the device tree.

In the message view (*"C Code module"* category), you will find a message that an m4 file has been successfully created.

> *When you click "Create Stub Implementation in C", the application is compiled automatically. If errors occur in the process, then these are indicated in the message view. In addition, please monitor the messages in the "C Code Module" category.*

Assigning pre-compiled run-time modules to devices and saving them in libraries

Requirement: A library (*.library) is open in CODESYS.

1. Click *"View ➔ POUs"*.
   ⇨ The *"POUs"* view opens and displays the library project and its objects.
2. Select the library project and click *"Project ➔ Add Object ➔ C-Implemented Library"*.
3. Click *"Add"* in the *"Add C-Implemented Library"* dialog.
   ⇨ CODESYS adds the object *"C Implemented Library"* to the *"POUs"* view.
4. Double-click the *"C Implemented Library"* object.
   ⇨ The object opens in its editor
5. Click *"Add"* in this editor.
   ⇨ The *"Select Device"* dialog opens.

6. In the *“Object file”* input field, specify the name of a dynamically loadable module in the format *.dll or *.so.

> **NOTICE!**
> The *.dll file must contain the title of the library project in its name. For example, if the library project is named XYlib, then the *“Object file”* must be called: `<Name>_XYlib.dll`.

7. In the *“Device”* window, select a device for assignment of the *“Object file”*.
8. Click *“Select Device”*.
   ⇨ CODESYS displays the created device file assignment in the editor on the tab *“Compiled Components”*.
9. Save the library project.

1.4.1.8.11 Programmatic Access to I/Os

CODESYS provides the following features for mapping project variables to input, output and memory addresses:

- Assignment of project variables to input, output and memory addresses in the *“I/O Mapping”* tab of the device editor
- Programmed access to I/Os
  – Variables configuration
  – AT declaration

> **NOTICE!**
> We recommend that you define the mapping of project variables to input, output and memory addresses in the *“I/O Mapping”* of the editor of the respective device.

See also

- *Chapter 1.4.1.7.1 “Configuring Devices and I/O Mapping” on page 213*

Variables configuration - VAR_CONFIG

Use the variables configuration for mapping variables of functions blocks to the process map. For declarations in the function block, assign the variables to the device inputs/outputs without providing the full address. Later, the exact address is provided centrally for all function block instances of the application in a global variable list including `VAR_CONFIG` declarations. This global variables list with the `VAR_CONFIG` declarations is termed the "variables configuration".

> **NOTICE!**
> For changes to variables that are assigned to I/O addresses, CODESYS displays them immediately In the process map. For changes to variables that are mapped by a variables configuration, CODESYS displays them not until the end of the responsible task.

Declaration of variables in functions blocks

When declaring variables in a function block, declare the variables between the keywords `VAR` and `END_VAR` and assign incomplete addresses to the variables. Mark these incomplete addresses with an asterisk (`*`).

Syntax:

```
<identifier> AT %<I|Q>*:<data type>;
```

Example

Define two local I/O variables: the input variable `xLocIn` and the output variable `xLocOut`.

```
FUNCTION_BLOCK locio
VAR
  xLocIn AT %I*: BOOL := TRUE;
  xLocOut AT %Q*: BOOL;
END_VAR
```

Final definition of addresses in the variables configuration of the global variables list

In the global variables list that you use as the variables configuration, define the variable declarations with the absolute addresses between the keywords `VAR_CONFIG` and `END_VAR`.

You must declare the `VAR_CONFIG` variables with the complete instance path, separating the individual POU and instance name by a dot (.). The declaration must include an address whose class (input/output) agrees with the class of the incomplete address (%I*, %Q*) in the function block. The data type must also agree.

Syntax:

```
<instance variable path> AT %<I|Q><location>: <data type>;
```

If the path instance does not exist, then an error is reported. CODESYS prints an error also if there is not an address configuration available for a variable that you declared with an incomplete address.

Example

The `locio` function block in the example above is used in a program as follows:

```
PROGRAM PLC_PRG
VAR
  locioVar1: locio;
  locioVar2: locio;
END_VAR
```

A correct variables configuration in a global variable list could then look like this:

```
VAR_CONFIG
  PLC_PRG.locioVar1.xLocIn AT %IX1.0 : BOOL;
  PLC_PRG.locioVar1.xLocOut AT %QX0.0 : BOOL;
  PLC_PRG.locioVar2.xLocIn AT %IX1.0 : BOOL;
  PLC_PRG.locioVar2.xLocOut AT %QX0.3 : BOOL;
END_VAR
```

See also

- *Chapter 1.4.1.19.2.10 “Configuration variables - VAR_CONFIG” on page 534*
- *Chapter 1.4.1.8.11.2 “AT declaration” on page 281*
- *Chapter 1.4.1.19.4.10 “Addresses” on page 643*

Creating a variables configuration

Requirement: You have a project open that includes a controller configuration with a field device. The project contains a program (e.g. `PLC_PRG`) and a function block (e.g. `func1`). The field device has inputs and outputs. The textual view is selected in the options for the declaration editor.

In the function block, assign variables to device I/Os with incomplete addresses and then create a variables configuration.

1. Double-click a function block in the device tree (e.g. `func1`).
   ⇨ The function block editor opens.
2. Type the following between the keywords `VAR` and `END_VAR`: `xLocIn AT %I*: BOOL := TRUE;` and `XLocOut AT %Q*:BOOL;` in the next line.
   ⇨ You have declared an input variable `xLocIn` and assigned it to the incomplete input address `%I*` of a field device. You have assigned the declared output variables have to the incomplete output address `%Q*`.

3. Click the `PLC_PRG` object in the device tree and add the following to the declaration section of the program between `VAR` and `END_VAR`:

   ```
   locioVar1: func;
   locioVar2: func;
   ```

4. Right-click the *"Application"* object in the device tree and click *"Add Object ➔ Global Variable List"* and then click *"Add"* in the *"Add Global Variable List"* dialog box.

   ⇨ The global variables list is added to the device tree and opens in the editor.

5. Change the keyword `VAR_GLOBAL` to `VAR_CONFIG`.

6. Click *"Declarations ➔ Add All Instance Paths"*.

   ⇨ The following instance paths are added:

   ```
   PLC_PRG.logioVar1.xLocIn AT %I*;
   PLC_PRG.logioVar2.xLocIn AT %I*;
   PLC_PRG.logioVar1.xLocOut AT %Q*;
   PLC_PRG.logioVar2.xLocOut AT %Q*;
   ```

7. Now, replace the incomplete addresses `%I*` and `%Q*` with the absolute, complete addresses.

See also

- *Chapter 1.4.1.20.3.17.4 "Command 'Add all instance paths'" on page 1124*

AT declaration

In the variables declaration, the code `AT` assigns a project variable to a specific input address, output address, or memory address of the PLC that is configured in the device tree. You can also define the assignment of variables to an address in the *"I/O Mapping"* dialog of the device in the PLC configuration.

Syntax

```
<variable name> AT <address> : <data type>;

<address> : %<memory area prefix> ( <size prefix> )? <memory position>
```

The AT declaration allows you to give the address a meaningful name. You can make any necessary changes for the input or output signals at just one location, for example in the declaration.

Examples

`VAR wInput AT %IW0 : WORD; END_VAR`	Variable declaration with address information of an input word
`VAR xActuator AT %QW0 : BOOL; END_VAR`	Boolean variable declaration Note: For Boolean variables, one byte is allocated internally if a single bit address is not specified. A change in the value of `xActuator` affects the range from `QX0.0` to `QX0.7`.
`VAR xSensor AT IX7.5 : BOOL; END_VAR`	Boolean variable declaration with explicit specification of a single bit address. On access, only the input bit 7.5 is read.
`VAR xSensor AT IX* : BOOL; END_VAR`	For the address specification, the placeholder `*` is given instead of the memory position. The final address specification is done in the variables configuration. Note: This is possible in function blocks.

If you assign a variable to an address, please note the following:

- You cannot write to variables that are placed at inputs. This will cause a compiler error.
- You can perform AT declarations only for local and global variables, not for input/output variables of POUs.
- Furthermore, AT declarations cannot be used in persistent variable lists.
- If you use AT declarations for structure components or function block variables, then all instances use the same memory. This is just like using static variables in classic programming languages, such as C.
- The memory layout of structures also depends on the target system.

NOTICE!
If you do not specify a single bit address explicitly, then Boolean variables are allocated byte-by-byte.

Example

```
PROGRAM PLC_PRG
VAR
    xVar AT %QW0 : BOOL;
END_VAR

xVar := TRUE;
```

When the variable `xVar` is written, the output memory range from `QX0.0` to `QX0.7` is affected.

1.4.1.8.12 Checking Syntax and Analyzing Code

CODESYS provides useful functions for detecting errors and assisting you while you create programs. The syntax check flags errors and prints them to the message view as early as the programming phase.

The static code analysis in CODESYS also assists you in complying with defined coding guidelines and detecting weak constructs.

See also

- *Chapter 1.4.1.8.12.1 “Checking Syntax” on page 283*
- *Chapter 1.4.1.8.12.2 “Analyzing code statically” on page 283*

Checking Syntax

When you input code, the precompile in CODESYS already runs some basic checks. Then, wavy underlines appear under buggy code in the editor and an error message is printed to the messages view.

CODESYS automatically generates the application code from the source code that was written in the development system. This is done automatically before downloading the application to the PLC. Before the application code is generated, a test is performed for checking the allocations, the data types, and the availability of libraries. Moreover, the memory addresses are allocated when the application code is generated. You can click *“Build ➔ Generate Code”* to execute this command explicitly, or press the *[F11]* key. This is useful for detecting any errors in your source code, even when the PLC is not connected yet.

CODESYS prints all errors and warnings to the "Build" category of the messages view. Double-clicking the error message opens the respective POU in the editor with the buggy code marked. As an alternative, you can also jump to the buggy code by right-clicking the error message.

Note the settings for this in the CODESYS options.

See also

- *Chapter 1.4.1.20.4.13.23 “Dialog 'Options' - 'SmartCoding'” on page 1201*

Analyzing code statically

You can subject your source code also to static analysis (lint) during the code generation. This determines whether or not your source code complies with the coding guidelines that you defined - according to the idea behind the lint analysis tool.

- You activate the rules to the checked in the *“Project Settings”* dialog in the *“Static Analysis Light”* category. The check itself is performed automatically each time code is generated, for example when you click *“Build ➔ Generate Code”*. If divergence from the rules is determined, then it is reported as an error message in the *“Build”* category of the message view. The reported errors have the prefix `SA<number>`.

NOTICE!

For static code analysis with *“Static Analysis Light”*, only the application code of the project is checked. Libraries are excluded from the check.

GVL variables in the *“POUs”* view are not necessarily checked: If you have a project with several applications, then only the objects in the active application are checked. If you have only one application, then the objects in the common POU pool are also checked.

“Static Analysis Light” includes only a reduced set of rules in the default development system. A larger set of rules, additional naming conventions, and metrics are available when you install the CODESYS Static Analysis add-on.

Deactivating lines of code in the implementations with pragmas from the static analysis

By means of the pragma `{analysis ...}`, you can mark code so that the specified rules are not checked. As a result, the marked lines of code are not subjected to static analysis. The marked code is ignored during the check.

Syntax:

`{analysis <sign><rule number>|,<other combinations of signs and rules, comma-separated>}`

`-<rule number>`: Deactivate the rule SA<rule number>.

`-<rule number>`: Activate the rule SA<rule number>.

Excluding implementation code

☑ Requirement: Rules are activated in the *"Project Settings"* dialog.

1. Add the pragma `{analysis -<number>}` above the line of code that contains code not to be checked first of all. For example, for the rule SA0024
   ⇨ The line of code is the first line of the code snippet that is not checked with rule 24.
2. Add the pragma `{analysis -<number>}` below the line of code that contains code not to be checked first of all. For example, for the rule SA0024
   ⇨ The line of code above is the last line of the code snippet that is not checked with rule 24.

Example: Ignore untyped literal

```
{analysis -24}
nTest := 99;
iVar := INT#2;
{analysis +24}
```

The rule *"SA0024: Untyped literals only"* is deactivated for two lines. An error is not issued although the code does not correct to: `nTest := DINT#99;`

Example: Ignore several rules

```
{analysis -10, -24, -18}
...
{analysis +10, +24, +18}
```

"SA0010: Arrays with only one component"

"SA0018: Unusual bit access"

"SA0024: Untyped literals only"

However, you cannot deactivate the rule `SA0004`: "Multiple Write Access on Output" with a pragma.

Excluding programming objects with pragmas from the static analysis

Syntax:

`{attribute 'analysis' := '-<rule number>[,<other negative rule numbers, comma-separated>]'}`

When you insert the attribute pragma in the declaration part of a programming object, the specified rules are excluded for the entire programming object. If multiple rules are excluded, then the rules are each comma-separated with a dash and a number. A pragma statement for activation is not required.

Example

```
{attribute 'analysis' := '-33, -31'}
TYPE LocalData :
STRUCT
    iLocal : INT;
    uiLocal : UINT;
    udiLocal : UDINT;
END_STRUCT
END_TYPE
```

The rules SA0033 and SA0031 are ignored for the structure `LocalData`.

```
{attribute 'analysis' := '-100'}
big: ARRAY[1..10000] OF DWORD;
```

The rule SA0100 is ignored for the array `big`.

1.4.1.8.13 Orientation and Navigation

Using the cross-reference list to find occurrences

The occurrences of symbols of a variable, a POU (program, function block, function), or a DUT can be displayed in a cross-reference list. Then you can jump from the list directly to the corresponding locations in the project.

There are two ways to search for occurrence locations of a symbol:

- Plain text search: You manually specify a text (symbol name, placeholder) in the *“Cross-Reference list”* view.
- Search for a specific declaration:
  - In the *“Cross-Reference List”* view, you select the declaration from the input assistant.
  - The focus is on a symbol name in the POU editor and you start the cross-reference search from the context menu.
  - The focus is on a symbol name in the POU editor, the *“Cross-Reference List”* view is open, and the cross-reference search executes automatically.
  - In the *“Cross-Reference List”* view which already lists occurrence locations for several declarations, you limit these results to a specific declaration.

Cross references with text search by symbol name

Requirement: The *“Cross-Reference List”* view is open.

1. Specify a string in the field next to the name, for example the identifier of the variable for which you want to find the occurrence location in the project. Example: "`iCounter`".

   For the text search, you can use the asterisk "`*`" (for any number of characters) or the question mark "`?`" (for an exact number of characters) combined with a substring of a variable identifier.

   Use the percent sign "`%`" to search for IEC addresses. Examples: "`%MW8`", "`%M*`".

2. Click the button to start a text search in the project.

   ⇨ The view *"Cross-Reference List"* opens and displays the occurrence locations for the `iCounter` variable. The declaration parts are always displayed in the project with the occurrence location indented.

3. Double-click an occurrence location in the cross-reference list.

   ⇨ The respective object opens in the editor with the marked occurrence location.

Cross-references for a specific symbol declaration

Requirement: A POU is open in the editor.

From the POU editor, with a menu command

1. Set the cursor at the identifier of the symbol (variable, POU) in the declaration part or implementation part.
2. Click *"Browse for Symbol ➔ Browse Cross-References"* in the context menu or *"Edit"* menu.

   ⇨ The *"Cross-Reference List"* view opens and shows the occurrence locations of the variables or POU.

If the *"Cross-Reference List"* view is already open, then you can also search the occurrence locations for a specific result as follows:

From the POU editor, automatic

▷ Select the *"Automatically list selection in cross reference view"* check box in *"Tools ➔ Options"* (*"SmartCoding"* category). Select the name of the symbol in the POU, or set the cursor in the name.

⇨ Depending on the position of the selection or cursor, the cross-reference list automatically shows the occurrence locations for the respective symbol.

In the cross-reference list view, with input assistance

▷ In the *"Cross-Reference List"* view, use the input assistant to specify a symbol name in the field next to *"By declaration"*.

⇨ The cross-reference list displays the occurrence locations for the symbol.

In the cross-reference list view, limited to a specific declaration

▷ If multiple declarations for a symbol are listed in the *"Cross-Reference List"* view, for example after a text search, then you can reduce the display to one result: Select the line with the desired declaration and click the button or click *"Limit Results to Current Declaration"* in the context menu.

⇨ the cross-reference list includes only the occurrence locations for the selected declaration.

See also

- *Chapter 1.4.1.20.3.3.13 "Command 'Cross Reference List'" on page 990*
- *Chapter 1.4.1.20.3.2.29 "Command 'Browse Cross References'" on page 974*
- *Chapter 1.4.1.20.4.13.23 "Dialog 'Options' - 'SmartCoding'" on page 1201*

Finding declarations

CODESYS provides the capability of searching the entire project for the definition location of a variable or function. The block that includes the definition opens in the editor with the marked declaration.

Finding the declaration of a variable

Requirement: You have opened a POU in the editor.

1. Set the cursor at an identifier in the implementation section.
2. Click *“Edit ➔ Browse ➔ Go to Definition”*.
   ⇨ The POU with the declaration opens in the editor with the variable definition marked. If the definition is located in a compiled library, then the respective block opens in the library manager.

You can execute this command in both online and offline mode.

Examples

The following block includes a function block definition (`fbinst`), a program call (`prog_y()`), and a function block call (`fbinst.out`):

```
VAR fbinst:fb1; ivar:INT; END_VAR prog_y(); ivar:=prog_y.y;
res1:=fbinst.out;
```

If the cursor is located at `prog_y`, then the command opens the program `prog_y` in the editor.

If the cursor is located at `fbinst`, then this command focuses in the declaration section at line `fbinst:fb1;`

If you set the cursor at `out`, then this command opens the function block `fb1` in its editor.

See also

- *Chapter 1.4.1.20.3.2.37 “Command 'Go to Definition'” on page 979*

Setting and using bookmarks

Bookmarks are used for easy navigation through long programs. You can use bookmarks in all implementation language editors, except SFC (sequential function chart). Commands help to navigate directly to the marked position in the program.

Setting and deleting bookmarks

Requirement: The POU is open in the editor.

1. Set the cursor at any program line.
2. Click *“Edit ➔ Bookmarks ➔ Toggle Bookmark”*.
   ⇨ A bookmark is set at this position in the program. This is marked by the bookmark symbol .
3. Set several bookmarks at different places in the program.
4. Set the cursor at a bookmarked program line.

5. Click *“Edit ➔ Bookmarks ➔ Toggle Bookmark”*.

   ⇨ The bookmark is removed. The bookmark symbol is deleted.

   As an alternative to this, you can delete one or more bookmarks in the *“Bookmarks”* view by clicking the button. For this purpose, the corresponding bookmarks have to be selected in the *“Bookmarks”* view.

> *Click “Edit ➔ Bookmarks ➔ Clear All Bookmarks (Active Editor)” to remove all bookmarks from the active POU.*

> *In order to delete all bookmarks in a project, click “Clear All Bookmarks”. However, for this command to be available, you first have to add it to a menu by means of the command “Tools ➔ Customize”.*

See also

- *Chapter 1.4.1.20.3.2.22 “Command 'Toggle Bookmark'” on page 972*
- *Chapter 1.4.1.20.3.2.27 “Command 'Clear All Bookmarks (Active Editor)'” on page 974*
- *Chapter 1.4.1.20.3.2.28 “Command 'Clear All Bookmarks'” on page 974*

Jumping to bookmarks within a POU

Requirement: The POU is open in the editor. Multiple bookmarks are set.

1. Click *“Edit ➔ Bookmarks ➔ Next Bookmark (Active Editor)”*.

   ⇨ Depending on the current cursor position, the cursor jumps to the next bookmark (see below).

2. Click *“Edit ➔ Bookmarks ➔ Previous Bookmark (Active Editor)”*.

   ⇨ Depending on the current cursor position, the cursor jumps to the previous bookmark (see above).

See also

- *Chapter 1.4.1.20.3.2.23 “Command 'Next Bookmark (Active Editor)'” on page 973*
- *Chapter 1.4.1.20.3.2.25 “Command 'Previous Bookmark (Active Editor)'” on page 973*

Jumping to bookmarks of different POUs in a project

A project is open with multiple POUs. Multiple bookmarks are set in different POUs.

1. Click *“View ➔ Bookmarks”*.

   ⇨ The *“Bookmarks”* view opens.

   All bookmarks in the project are listed in a table in the view.

2. Click the *“Next Bookmark”* button.

   ⇨ In the *“Bookmarks”* view, the bookmark in the row below the selected bookmark is selected.

   The POU with the recently selected bookmark in the table opens in the editor and the row with the bookmark is selected in the POU.

3. As in step 2, you can click the *"Previous Bookmark"* button to jump to the bookmark in the project that is displayed in the row above it in the *"Bookmarks"* view.

See also

- *Chapter 1.4.1.20.3.3.11 "Command 'Bookmarks'" on page 988*
- *Chapter 1.4.1.20.3.2.26 "Command 'Previous Bookmark'" on page 973*
- *Chapter 1.4.1.20.3.2.24 "Command 'Next Bookmark'" on page 973*

1.4.1.8.14 Searching and replacing in the entire project

In CODESYS you can search for strings in single objects or project-wide. If required, you can replace the string found.

1. Choose the command *"Search"* in the main menu *"Edit ➔ Search Replace"*.
   ⇨ The dialog *"Find"* opens.
2. Enter the string to be found in the field *"Find what"*.
3. Activate the search options
4. Define the objects to be searched by choosing an entry from the combobox *"Search"*.
5. Click on the button *"Find Next"*.
   ⇨ The first hit is displayed.
6. Click on the button *"Replace"* to replace the string found by a different one.
7. Click on the button *"Find All"* to get a list of all hits.

See also

- *Chapter 1.4.1.20.3.2.2 "Command 'Find', 'Find in Project'" on page 966*
- *Chapter 1.4.1.20.3.2.3 "Command 'Replace', 'Replace in Project'" on page 967*

1.4.1.8.15 Refactoring

In general, refactoring is a technique for improving the design of existing software code without changing the way it functions.

In CODESYS, refactoring provides functions for renaming objects and variables and updating referenced pins. You can display all occurrences of renamed objects and variables and then rename them all at once or individually. In *"Tools ➔ Options"*, you can also configure where CODESYS will prompt you for refactoring.

Renaming global variables

Requirement: A project is open that includes at least a function block *"FB"* and a global variable list. The global variable list *"GVL"* is open in the editor and contains a variable declaration (example: `iGlobal`). *"FB"* uses `iGlobal`.

Renaming global variables throughout the project

1. Select the global variable name `iGlobal`.
2. Right-click the variable and click *"Refactoring ➔ Rename iGlobal"*.
3. In the *"Rename"* dialog, type a name in the *"New name"* input field, for example `iGlobalOK`, and click *"OK"*.
   ⇨ The *"Refactoring"* dialog opens. In the device tree view on the left, the *"GVL"* and *"FB"* objects are highlighted in red and yellow. In the view on the right, *"FB"* in is open in its editor and `iGlobal` has already been renamed as `iGlobalOK`.
4. Click *"OK"*.
   ⇨ No global variable `iGlobal` is in your project. Now `iGlobalOK` is everywhere.

Renaming global variables throughout the project (except for a POU)

1. Select the global variable name `iGlobal`.
2. Right-click the variable and click *"Refactoring ➔ Rename iGlobal"*.
3. In the *"Rename"* dialog, type a name in the *"New name"* input field, for example `iGlobalTest`, and click *"OK"*.

   ⇨ The *"Refactoring"* dialog opens. In the device tree view on the left, the *"GVL"* and *"FB"* objects are highlighted in red and yellow. In the window on the right, the function block *"FB "* is open in its editor. `iGlobalTest` is listed instead of `iGlobal`.
4. Right-click in the view on the right.
5. Click *"Reject this Object"* and click *"OK"*.

   ⇨ The global variable `iGlobal` is available in *"FB"* in your project. The variable `iGlobalTest` is now specified in the objects where the previous variable occurred.

   The error message in the message view reports that the `iGlobal` identifier is not defined.

Adding and removing input variables

In the declaration part of blocks, you can add and delete input and output variables by using the refactoring commands. CODESYS performs updates at the occurrence locations and calling locations of the blocks. You can accept or reject these updates individually. The *"Refactoring"* dialog also opens for this purpose.

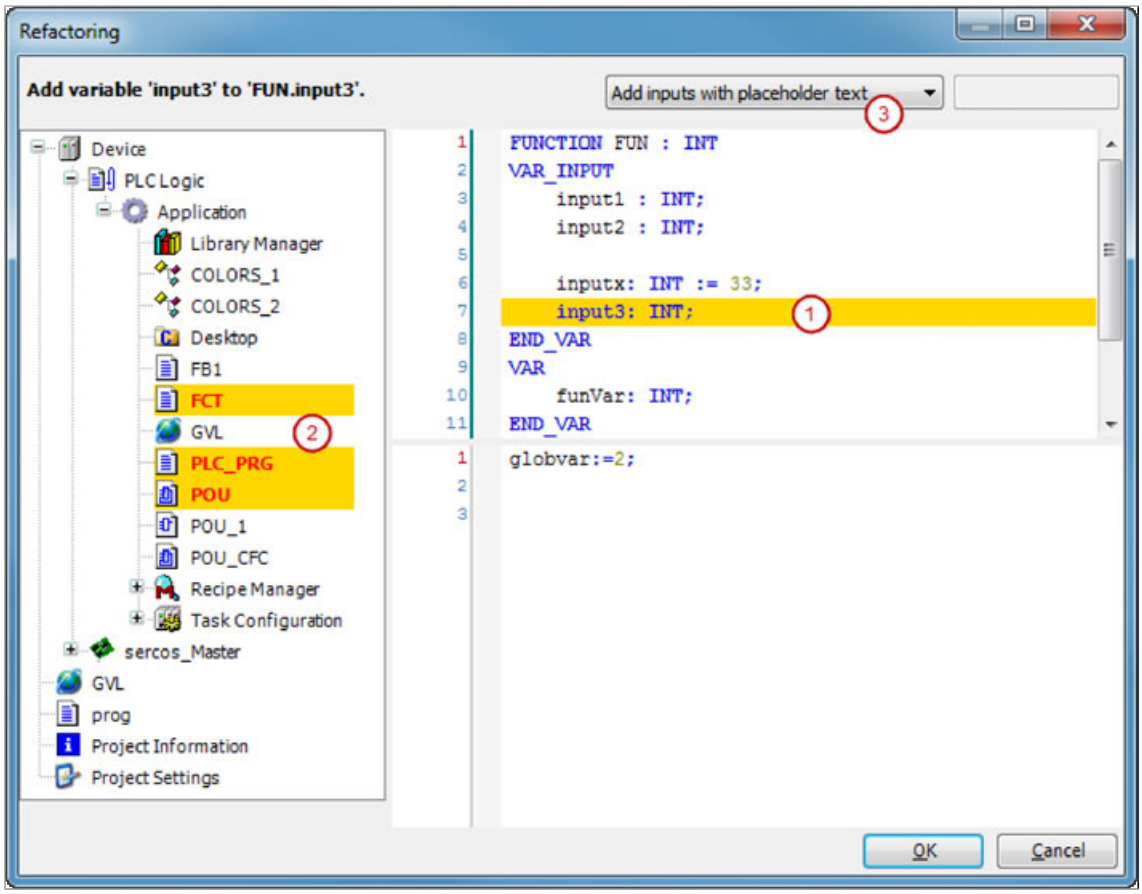
Requirement: The `FCT` (function type) POU is open in the editor. The function already contains the input variables `input1`, `input2`, and `inputx`. They are called in the `PLC_PRG` and `POU` programs.

1. Set the focus in the declaration part of the FCT function.
2. Click *"Refactoring ➔ Add Variable"*.

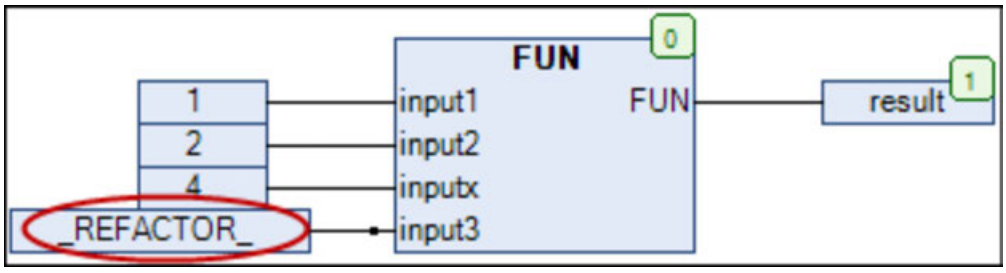
   ⇨ The default dialog opens for declaring variables.
3. Declare the variable `input_3` with the scope of `VAR_INPUT` and data type `INT`. Click *"OK"* to close the dialog.

   ⇨ The *"Refactoring"* dialog opens (see figure below). The affected locations are marked in yellow. (1)+(2)
4. In the upper right corner, select *"Add inputs with placeholder text"* from the drop-down list. (3).
5. In the left side of the window, click one of the highlighted objects (for example, `PLC_PRG`). Right-click and choose the *"Accept Whole Project"* command to add the new variable at the new location of use in `FCT` for the entire project.

   ⇨ You see the change in the implementation part of `PLC_PRG` in the view on the right: The placeholder `_REFACTOR_` appears at the location where the new variable was added.
6. Click *"OK"* to close the *"Refactoring"* dialog.
7. Click *"Edit ➔ Find"*. Search the project for "_REFACTOR_" to check and edit the affected locations.
8. Note: As an alternative, you can insert the new variable with another initialization value without working with a placeholder first. In this case, in Step 4 you select "Add inputs with the following value" and type the value in the field on the right side of the drop-down list.



Example of a new variable with placeholder text in a CFC block:



Please note that you can also remove variables with refactoring.

Reordering variables in the declaration

In the declaration part of function blocks, you can change the order of declarations by refactoring This is possible for declarations with scope `VAR_INPUT`, `VAR_OUTPUT`, or `VAR_IN_OUT`.

Requirement: The declaration part of a POU is open and includes declarations, for example:

```
VAR_INPUT
    invar2 : INT;
    invar1 : INT;
    in : DUT;
    bvar : BOOL;
    invar3 : INT;
END_VAR
```

1. Right-click in this declaration block to access the context menu.
2. Click *“Refactoring ➔ Reorder Variables”*.
   ⇨ The *“Reorder”* dialog opens with a list of `VAR_INPUT` variables.

3. Drag the *“invar1 : INT;”* entry to the position before the *“invar2.”* entry.
   ⇨ The `invar1` declaration is now at the top position.
4. Click *“OK”* to close the dialog.
   ⇨ The *“Refactoring”* dialog opens. The affected locations are marked in yellow (see figure above).
5. Click *“OK”* to accept the new order for the function block.

Changing a variable declaration and applying refactoring automatically

Refactoring helps you in the declaration when renaming variables (by means of "Auto declare").

☑ Requirement: Function block `fb_A`.

1. Click *“Tools ➔ Options”*.
   ⇨ The *“Options”* dialog opens.
2. Select the *“Refactoring”* category.
3. In *“Auto-Declare”*, activate the options *“On renaming variables”* and *“On adding or removing variables, or for changing the namespace”*.
4. Double-click the function block `fb_A`.
5. Select a variable in the declaration of `fb_A`, for example `iA`. As an alternative, you can set the cursor before or in the variable.
6. Specify *“Edit ➔ Declare variable”* (*[Shift]+[F2]*).
   ⇨ The *“Declare Variable”* dialog opens. The dialog includes the settings of `iA`.
7. Change the name of `iA` to `iCounter_A`.
8. The option *“Changes by means of refactoring”* appears and is activated.
9. Click *“OK”*.
   ⇨ The dialog *“Refactoring” “Renaming from iA to iCounterA”* opens. All locations affected by the variable renaming are marked there.
10. Click *“OK”* to close the dialog.
    ⇨ The changes are applied.

1.4.1.8.16 Task Configuration

In the task configuration, you define one or more tasks for controlling and executing the application program in the controller. Each application must include a *“Task Configuration”* object.

A task is a time-based flow unit of an IEC program. You define a task with a name, a priority, and a type, which determines which condition triggers the start of the task. You can define this condition either by time (cyclic-interval, freewheeling) or by the occurrence of an internal or external event to process the task. Examples of an event are the rising edge of a global project variable or an interrupt event of the controller.

A task calls one or more program blocks (POUs). These programs can be application-specific (objects below the application in the device tree) or project-specific (objects available in the POU window). In the case of a project-specific program, the application instances the project-global program. If CODESYS processes the task in the current cycle, then the programs are executed for the duration of a cycle.

With the combination of priority and condition, you define the order in which the tasks are processed. You can configure a watchdog for each task, and you can link a start, stop, and reset directly to the execution of the project block.

Rules for the processing order of the defined tasks:

- If the task condition is satisfied, then CODESYS processes the task.
- If several tasks satisfy the condition for processing at the same time, then CODESYS processes the tasks with the highest priority first.
- If several tasks with the same priority level satisfy the condition for processing at the same time, then CODESYS processes the longest waiting task first.
- The program calls are processed in the order they appear in the configuration dialog of the task.
- If a called program has the same name in the device tree of the application and in a library or project-global in the POU window, then the application program is used.

Attention

All tasks share one process map. The reason is as follows: When each task has its own individual process map, performance is compromised. However, the process map can be consistent only with one task. When you create a project, you must ensure that the application copies the input and output data to a safe location in case of conflicts. Modules, such as the library `SysSem`, provide the capability of solving consistency and synchronization problems.

Consistency problems can also occur when accessing other global objects, such as global variables or blocks. Consistency problems always occur if several tasks read and write to one variable. Modules, such as the library `SysSem`, are available as a solution.

Creating a task configuration

Requirement: The open project includes a program-type POU and a *“Task Configuration”* with a *“Task”* object has been inserted below *“Application”* in the device tree.

1. Double-click the task object below *“Task Configuration”* in the device tree.

   ⇨ The *“Configuration”* tab of the task object opens.

2. In the *“Type”* dropdown list., click *“Cyclic”*.

   ⇨ The *“Interval (e.g. t#200ms)”* input field appears.

3. Enter `t#300ms` in the *“Interval (e.g. t#200ms)”* input field.

4. Click *“Add Call”*.

   ⇨ The Input Assistant opens.

5. In *“Input Assistant ➔ Categories” -> “Programs”*, click the desired POU and then click *“OK”*.

   ⇨ CODESYS inserts the selected POU into the POU list of the *“Configuration”* tab and below the task object in the device tree.

   When the application is executed from the controller, CODESYS executes the selected POU in cyclical intervals of `300 ms`.

- ↳ *Chapter 1.4.1.20.2.27.1 “Tab 'Configuration'” on page 942*

Definitions of Jitter and Latency

In the *"Task Configuration"* object, on the *"Watchdog"* tab, you can monitor the periodic jitter values of the individual tasks at runtime. The periodic jitter is differentiated from latency-based release jitter. See the following definitions:

Periodic jitter

Periodic jitter (J_{per}) is the deviation of the cycle time of a task (T_{per}) from the desired task cycle time (T_0).

$J_{per} = T_{per} - T_0$

The desired (ideal) cycle time T_0 is specified in the configuration of the task as *"Interval"*.

You can monitor the current value, as well as the maximum and minimum value of the periodic jitter, on the *"Watchdog"* tab of the *"Task Configuration"*.

If the sum of all negative J_{per} values and the sum of all positive J_{per} values do not balance each other, then a drift results.

Latency

Latency is the delay between the invocation of a task and the actual start of its release.

Release jitter

The release jitter J_r is the difference between the maximum and the minimum latency (L) that has ever occurred.

$J_r = L_{max} - L_{min}$

In the case that $L_{max} = L_{min}$, a release jitter J_r of 0. results. This corresponds to a plain offset shift.

1.4.1.8.17 Encrypting an application

You achieve the know-how protection and copy protection of a boot application with the help of PLC -specific license management and its settings in the object properties of the application. In this case, the download code and boot application are encrypted.

Encryption with a dongle

Requirements: You have a project with an application that you want to download to the controller as an encrypted boot application. A security key for license management is connected to your computer.

1. Select the application in the device tree.
2. Select the *"Properties"* command in the context menu.
   ⇨ The *"Properties - <application name>"* dialog opens.
3. Click the *"Encryption"* tab.
4. For *"Encryption Technology"*, select the *"Simple Encryption"* option and type the *"Product Code"* that you received from the hardware manufacturer for the controller. Depending on the controller, it is protected either by a security key (firmcode is shown automatically) or by an integrated Wibu SD card for example.

5. Click *“Online ➔ Login”* and download the application.
   ⇨ If the matching security key and/or valid license is available, then you can download the application to the controller. By default, a boot application is automatically created at this time in the controller directory. The default setting is defined in the application *“Properties”*, in the *“Boot Application”* category.
6. Logout, change the application, and login again.
   ⇨ You are prompted to perform an online change. The dialog provides the option of updating the boot application on the PLC. If the security key and license match, then you can log in. If not, then you receive a corresponding message.

Encrypting with certificates

Requirements: You have a project with an application that you want to download to the controller as an encrypted boot application. In the Windows Certificate Store of your computer, you have a certificate of this controller for encrypting the application. Note: In case you want to download the application to different controllers, you will need the appropriate certificate for each controller.

1. Select the application in the device tree.
2. Select the *“Properties”* command in the context menu.
   ⇨ The *“Properties - <application name>”* dialog opens.
3. Click the *“Encryption”* tab.
4. On *“Encryption Technology”*, select the *“Encryption with certificates”* option.
   ⇨ The *“Certificates”* group is enabled.
5. If there are not any certificates listed in the table, then click the  button.
   ⇨ The *“Certificate Selection”* dialog opens for selecting a certificate from the local Windows Certificate Store.
6. In the lower area, select a certificate and add it to the upper area by clicking the  button, Click *“OK”* to confirm.
   ⇨ The certificate is shown in the *“Certificates”* group of the *“Encryption”* dialog.
7. Select the certificate and click *“Apply”* or *“OK”*.
   ⇨ The certificate is now used to encrypt the application. It can only be transferred to the controller on computers that have an corresponding key installed in the Windows Certificate Store.

Signing a boot application

1. Click  in the status bar of CODESYS to open the *“Security Screen”* view. Then select a certificate with a private key for a user profile for the *“Digital signature”*. The procedure is described in the instructions "Configuring a certificate for the digital signature in a user profile".
2. Double-click the certificate for the *“Digital signature”* in the *“User”* tab.
   ⇨ The *“Certificate”* dialog opens.
3. On the *“Details”* tab, click *“Copy to file”*.
   ⇨ The *“Certificate Export Wizard”* starts.

4. In the *“Export Private Key”* prompt, select the *“No, do not export the private key”* option.
5. For *“Export File Format”*, select the *“DER encoded binary X.509 (.CER)”* option.
6. In the next step, select a file name and the location for the certificate.
7. After the last step *“Finish”*, a message appears that the export was successful.
8. After successful export to CODESYS, open the device editor by double-clicking the controller in the device tree and selecting the *“Files”* tab for the file transfer.
9. Select the *“Path”* `cert/import` in the right side of the *“Runtime”* dialog.
10. On the left side of the dialog for *“Host”*, select the path in the file system where you saved the exported certificate and selected the certificate.
11. Click >>.
    ⇨ The certificate is copied to the `cert/import` folder.
12. Click the *“PLC Shell”* tab.
13. Type the command `cert-import trusted <file name of the certificate.cer>` in the input line of the tab and press the *[Enter]* key. Note that the file name is specified with the extension `.cer`; otherwise the certificate is not imported successfully.
    ⇨ The certificate is created on the controller under `trusted`. With this certificate, the controller can test the integrity of the boot application.
14. Open the *“Security Screen”* by double-clicking in the status bar.
15. If you want that downloads, online changes, and boot applications of your project are always encrypted, then select the *“Enforce signing of downloads, online changes and boot applications”* option in the *“Security level”* group on the *“User”* tab. To do this, the *“Enforce encryption of downloads, online changes and boot applications”* option also has to be selected.

Encrypting the download, online change, and boot application

Requirement: The CODESYS Security Agent add-on product is installed.

The *“Security Screen”* view provides an additional tab: *“Devices”*. This allows for the configuration of certificates for the encrypted communication with controllers. In this case, see the help for CODESYS Security Agent.

Alternatives:

If you the CODESYS Security Agent is not available to you, then you can proceed as follows by means of the PLC shell of the device editor:

In order to use certificates on the controller for the encryption of downloads, online changes, and boot applications, these certificates first have to be generated on the controller and loaded from the controller and installed in the Windows Certificate Store.

☑ Requirement: You are connected to the controller.

1. Open the device editor by double-clicking the controller in the device tree, and select the *“PLC Shell”* tab.
   ⇨ The tab appears with a blank display window. Below that is a command line.
2. Type `?` in the command line and press the *[Enter]* key.
   ⇨ All commands are listed in the display window.

3. Type the following command in the command line: `cert-getapplist`.
   ⇨ All used certificates are listed with information about components and availability with certificates.
4. If no certificate is available for the `CmpApp` component, then type the command `cert-genselfsigned <Number of the Component in the applist>`.
5. Click the *"Log"* tab and then the refresh button ().
   ⇨ The display shows whether or not the certificate was generated successfully.
6. Type in `cert-getcertlist` and press the *[Enter]* key.
   ⇨ Your own certificates are listed that can be used for encryption. The information `Number` and `Key usage(s)` are useful in the next step.

   `Number`: The number is specified as a parameter in the next step.

   `Key usage(s): Data encryption` means that this is a certificate of the controller for a download, online change, and boot application.
7. Export the required certificate by typing in the command `cert-export own 0` and press the *[Enter]* key. `0` is the `Number` of the certificate with `Key usage(s):Data encryption`.
   ⇨ The display shows that the certificate has been exported to a `cert` directory.
8. Click the *"Files"* tab of the device editor.
9. Click the refresh button () in the right part of the dialog in *"Runtime"*.
   ⇨ The list of files and directories is refreshed.
10. Open the *"cert"* folder in the list and then the *"export"* subfolder.
11. In the left part of the dialog in *"Host"*, open the directory where the certificate of the controller will be loaded.
12. In the right part of the dialog, select the certificate that you have exported and click  .
    ⇨ The certificate is copied to the selected directory.
13. In the file explorer, go to the directory where the certificate was copied and double-click the certificate.
    ⇨ The *"Certificate"* dialog opens and shows the information about this certificate.
14. On the *"General"* tab, click *"Install Certificate"*.
    ⇨ The *"Certificate Import Wizard"* starts.
15. In the *"Certificate Storage"* dialog, for *"Certificate Import Wizard"*, select the *"Store all certificates in the following store"* option and then select the *"Controller Certificates"* folder.
    ⇨ The controller certificate is imported into the Windows Certificate Store in the *"Controller Certificates"* folder. Now the certificate is available for the encryption of boot applications, downloads, and online changes.
16. Open the *"Security Screen"* by double-clicking  in the status bar.
17. If you want that downloads, online changes, and boot applications of your project are always encrypted, then select the *"Enforce encryption of downloads, online changes and boot applications"* option in the *"Security level"* group on the *"User"* tab.
18. Open the *"Project"* tab and double-click the application in the *"Encryption of boot application, download and online change"* area.
    ⇨ The properties dialog of the application opens.
19. Click the *"Encryption"* tab, select *"Encryption with certificates"* in the *"Encryption technology"* list box, and click  .

    If the *"Enforce encryption of downloads, online changes and boot applications"* option is selected in the *"Security Screen"*, then *"Encryption with certificates"* is already selected.

20. In the *“Certificate Selection”* dialog, select the respective certificate from the *“Controller Certificates”* folder and click .
21. Click *“OK”* to confirm the dialog.
    ⇨ The certificate is displayed in the properties dialog.
22. Confirm the properties dialog of the application.
    ⇨ The certificate is shown on the *“Project”* tab of the *“Security Screen”* in the *“Encryption of boot application, download and online change”* group.

    The boot application, download, and online change are encrypted.

Deleting a certificate for the encryption of boot application, download and, online change

Requirement: The CODESYS Security Agent add-on product is installed. A certificate with the information "Encrypted Application" is already installed on your computer.

1. In the *“Security Screen”* view, on the *“Project”* tab, in the bottom view, click the entry for the application.
   ⇨ The *“Properties”* dialog for the application opens with the *“Encryption”* tab.
2. For *“Encryption Technology”*, select *“Encryption with certificates”*. In the *“Certificates”* group, click .
3. In the *“Certificate Selection”* dialog, delete the certificate as described above.
4. Click *“OK”* to close the *“Certificate Selection”* dialog.
   ⇨ The certificate is no longer displayed in the *“Properties”* dialog.

1.4.1.8.18 Unit conversion

You define a conversion rule when you want to convert data for another system of units. This data is executed for a specific order of magnitude and unit of measure.

Conversion rules are defined in a *“Unit Conversion”* object. CODESYS automatically implements each conversion rule as a function block `<name>_Impl` and instances it as `<name>`. Each conversion rule includes `Convert` and `Reverse` methods for use as function blocks. Locations where you access a variable, you can link the variable to a conversion rule. The input assistant provides conversion rules in the *“Function Blocks”* and *“Instance Calls”* categories. After execution, the result is a converted value according to the conversion rule.

In a visualization, an IEC variable that is configured in an element property can also be linked to a conversion rules.

Defining unit conversions

1. Double-click a *“Unit conversion”* object in the device tree.
   ⇨ The respective editor opens with a table of the defined conversion rules. You edit a rule in *“Type setting”* and a respective condition in *“Condition setting”*.
2. Double-click the *“Add new entry”* field and type a name.
   ⇨ CODESYS implements the `<name>_Impl` function block and instances it as `<name>`.
3. Double-click the *“Type”* field and click a type from the drop-down list.
   ⇨ Input fields are displayed below the table for editing the conversion rule. The input fields vary according to selected type.
4. Change the conversion rule in the input fields.
   ⇨ The changes are displayed in the *“Setting”* category of the table.
5. Double-click the *“Condition”* field and click a condition type from the drop-down list.
   ⇨ Input fields are displayed below the *“Condition Setting”* category of the table to edit the condition. The input fields vary according to selected type.
6. Edit the condition.
   ⇨ The changes are displayed in the *“Condition Setting”* category of the table.

Defining switchable unit conversions

You can define which conversion rule is applied to a specific language or condition.

1. Double-click a *“Unit Conversion”* object in the device tree.
   ⇨ The respective editor opens with a table of the predefined conversion rules.
2. Click the *“Add new entry”* field and type a name.
   ⇨ Example: `Conv_A_LanguageDependent`
3. Double-click the *“Type”* field and click *“Switchable conversion”*. Double-click the *“Condition”* field and click *“Language”*.
   ⇨ Below the main table, the *“Switchable Conversion”* table is displayed with *“Condition setting”*.
4. In the *“Switchable Conversion”* table, double-click a predefined conversion rule from the drop-down list in the *“Switchable conversion name”* column, for example `Conv_AInInch`.

   In *“Condition Setting”*, type a value in the *“For condition 'Language'”* input field, for example `en`.
   ⇨ CODESYS executes the `Conv_AInInch` conversion rule only if the language set in the visualization manager is *“en ”*.
5. In the *“Switchable Conversion”* table, double-click a predefined conversion rule from the drop-down list in the *“Switchable conversion name”* column, for example `Conv_AInMM`.

   In *“Condition Setting”*, type a value in the *“For condition 'Language'”* input field, for example `de`.
   ⇨ CODESYS executes the `Conv_AInMM` conversion rule only if the language set in the visualization manager is *“de”*.
6. Apply the `Conv_A_LanguageDependent` conversion rule in the application or visualization.
   ⇨ If the set language in the visualization is English, then the application visualization apply the `Conv_AInInch` conversion rule. If the set language in the visualization is German, then the application visualization applies the `Conv_AInMM` conversion rule. The current visualization language is located in the `VisuElems.CurrentLanguage` variable.

Applying conversion rules

Add a conversion rule to objects that access IEC variables.

1. In the device tree, double-click an object that accesses IEC variables in order to link an IEC variable to a conversion rule at that location.
2. Declare a variable for the conversion result of the IEC variable.
   ⇨ ST sample code: `rConvertedA : REAL;`
3. Use the input assistant to apply the conversion rule with the `Convert` method and then assign the result to the variable.
   ⇨ ST sample code to link the IEC variable to the conversion rule: `rConvertedA := ConvRule_A.Convert(rA);`

Applying reverse conversion rules

1. In the device tree, double-click an object that accesses an IEC variable.
2. Declare a variable for the result of the conversion rule.
   ⇨ ST sample code: `rReverseA: REAL;`
3. Apply the reverse conversion rule with the `Reverse` method and then assign the result to the variable.
   ⇨ `rReverseA := ConvRule_A.Reverse(rConvertedA);`

Example

Requirement: The conversion rule is `Conv_XtoY`.

ST call

```
PROGRAM A_PRG
VAR
    rA : REAL;
    rConvertedA : REAL;
    rReverseToA : REAL;
END_VAR

rConvertedA := Conv_XtoY.Convert(rA);
rReverseToA := Conv_XtoY.Reverse(rConvertedA);
```

CFC call

In the CFC editor, define the instance name of the conversion rule via the block. Select the method in the block.

1.4.1.8.19 Data Persistence

The lifespan of a variable and its data begins at the time when the variable is created and ends at the time when the variable is deleted and its memory is freed. The time when the variable is created, initialized, or instantiated depends on the declared scope. The time when the memory is freed usually depends on the scope as well. For example, the memory of global variables is freed by exiting the application.

They can retain data longer than usual. The following mechanisms are provided for this purpose.

Mechanisms for data retention

- (A): Persistent global variable list with the keyword `PERSISTENT RETAIN`
  Persistent variables retain their values when the application is reloaded. Moreover, the values are restored after a download, warm start, or cold start.
- (B): Retain variables with the keyword `RETAIN`
  Retain variables retain their values after a warm start, but not after reloading the application, a download, or a cold start.
- (C): Variables of the Persistence Manager of the CODESYS Application Composer
  Variables of the Persistence Manager are stored in an external file.
- (D): Recipe variables
  Recipe variables and their values are stored in a recipe file.

Mechanisms in comparison

Which mechanism is suitable for which application? Some common use cases are considered in the table. The specific examples refer to a building control system.

Table 11: Comparison of mechanisms and use cases

	Uses case	**(A) Persistent variables**	**(B) Retain variables**	**(C) Variables of the Persistence Manager**	**(D) Recipe variables**
1	**The application must maintain device settings.** Example: After a power failure, the building control has to have information available about how long a window blind needs to be raised.	**Suitable**[1] Preferred use case In this case, you can also use retain variables instead of persistent variables. This is advantageous for variables whose declaration is often changed.	**Suitable** Preferred use case Retain variables are an advantage when their declarations are changed often.	**Suitable**[2] This is advantageous for controllers that do not have any hardware support. Special functionalities make this possible, such as double file buffering.	Possible, but very complicated and therefore not recommended.
2	**The application must maintain values also after program changes or extensions.**				
	2a: Rare extensions Example: An application programmer extends the program with a new switch and installs a new light. The building control must still have saved values available until then.	**Suitable**[1] Preferred use case	**Suitable**	**Suitable**[2]	Possible, but complicated.
	2b: Unrestricted changes, including deleting or changing the data type of variables The building control is running and is persistent. When an application programmer adds a new functionality to the controller and therefore adds another persistent variable to a function block, the values saved up to that point must be retained. For example, the program in an FB is extended with a variable that controls the automatic switching off of a previously uncontrolled lamp after a certain time. The building control must have the times of all controlled lamps available after the extension.	Not suitable	**Suitable** Data from retain variables are preserved as far as possible after an online change.	**Suitable** as far as possible [2] Preferred use case	Possible if textual, but complicated
	2c: The application must maintain values after a download.	**Suitable**	Not suitable	**Suitable**	**Suitable**

	Uses case	(A) Persistent variables	(B) Retain variables	(C) Variables of the Persistence Manager	(D) Recipe variables
3	**The application must be able to use different value sets.** Example: The operating settings for summer, winter, and holidays must be saved and imported when needed.	Not suitable	Not suitable	Not suitable	**Suitable** Preferred use case
4	**The application must be able to use settings from another system.** It must be possible to transfer settings to another plant using similar variables.	Not suitable	Not suitable	**Suitable**[2]	Suitable[3]
5	**The application must provide human readable data.** The user must be able to read, compare, and edit the data.	Not suitable	Not suitable	**Suitable**[2]	Suitable[3]

[1] Disadvantage: Only possible if the runtime system supports this mechanism and an NVRAM memory or UPS is available. Advantage: Speed; recommended application: 1 and 2a

[2] Disadvantage: In the case of large variable sets (> 10000), long delays during initialization and shutdown are to be expected. Advantage: No special memory is required; value retention exists even in case of changes, extensions, or deletions.

[3] Advantage: Editable remotely, transferable. Disadvantage: Complicated

Lifespan of variables when calling online commands

User input in the *"Online"* menu	Variable with usual lifespan
	Neither `RETAIN` nor `PERSISTENT`
		`RETAIN`	`PERSISTENT`
			`RETAIN PERSISTENT`
			`PERSISTENT RETAIN`

Command *"Online Change"*	x	x	x
Command *"Reset Warm"*	i	x	x
Command *"Reset Cold"*	i	i	x
Command *"Download"*	i	i	x [1]
Command *"Reset Origin"*	i	i	i

x : The variable retains its value.

i : The variable is initialized.

[1] Note: For the structure of persistent data, see the information in "Mechanism for downloading".

- *Chapter 1.4.1.20.3.6.5 "Command 'Load'" on page 1032*

Lifespan of variables when downloading a boot project

The values of ordinary variables lose their value and are reinitialized.

The values of persistent variables are protected when:

- The structure of the persistent variable in memory matches the structure in the persistent data list.

The values of retain variables are protected when:

- The structure of the persistent variable in memory matches the structure in the persistent data list.
- The persistent variables match the application (GUID has to agree).

A "Retain mismatch" occurs when the requirements for restoring the values of retain variables and persistent variables are not met when the application is booted. The response to this discrepancy is described in the documentation of the hardware manufacturer.

Note: For the structure of persistent data, refer to the information in "Mechanism for downloading".

See also

- *“Mechanism for downloading” on page 304*

Preserving data with persistent variables

Persistent variables retain their values after reloading the application, and after a download, warm start, or cold start.

A special non-volatile memory area on the controller, for example as NVRAM or UPS, is required to extend the lifespan. Securing the data in such a memory does not require any additional time, which is an advantage over data retention with the Persistence Manager. If the controller does not provide hardware support, then the data is usually stored in a file. Then the data will be retained if you shut down the controller correctly. In the event of a power failure or a pulled plug, however, data will be lost.

Behavior

Value retained for

- Uncontrolled exit
- Warm start by calling the *“Reset Warm”* command
- Cold start by calling the *“Reset Cold”* command
- Repeated download of the application

Reinitialization for

- Call of the *“Reset Origin”* command

Therefore, persistent variables are reinitialized only if you reset the controller to the factory settings (for example, when you click *“Online ➔ Reset Origin”*).

If, on the other hand, you download the application again, the persisted data is retained if possible. That depends on how profound the changes that led to the download were. Changing the application name always leads to a full reinitialization. Changes to the implementations never lead to a reinitialization: the data persistence is completely preserved. Changes to the declarations lead to an initialization of the new variables only if the existing variables are persistent, when you change the declarations so that the persistent variable list remains consistent. This is the case when you add a new variable or delete an existing one. Inconsistencies can occur if you edit and change the identifiers or data types of previously declared persistent variables.

Mechanism for downloading

Editing the variable list in the persistence editor causes the variable list to be edited automatically before it is saved, not to be saved as it is shown in the editor.

During post-processing, a variable that you have removed is replaced by a placeholder variable with the same memory requirement. As a result, the subsequent variables retain their addresses in the process image. Moreover, a variable you add is moved to the end of the list. Post-processing can neutralize changes that would lead to a loss of persistence. But you create gaps that use additional memory.

When downloading, the CRC value of the variable list and the length of the list (number of variables) are stored on the controller. When downloading again, the new test value is compared with the test value currently on the controller. Then the variable list is compared successively up to the specified length. If you have edited a declaration (for example, the name or data type), then the variable is reinitialized. Otherwise its value is retained. When the download is repeated, CODESYS checks whether the variable list declared in the persistence editor is still consistent with the variable list already on the controller.

The mechanism works well when the variables themselves are not modified significantly. Too extensive changes of the identifiers and the data types continue to lead to a reinitialization and the loss of persistence. If you anticipate frequent changes due to your application requirements, then this kind of a list is not recommended. Moreover, in an online change after a data type change, a persistent variable is less robust than a variable with a normal lifespan.

It is good practice to clear any gaps in the variable list after a while (command *“Reorder List and Clear Gaps”*). After cleaning, however, the list no longer matches the list on the controller and you have triggered an initialization of all persistent variables. The persistence of all variables is lost.

For versions before V3.5 SP1, changes in the persistence editor always lead to reinitialization.

Recovering data with the recipe manager

To clean up the global persistent variable list without losing persistence, you can save the data in a recipe using the Recipe Manager. This creates a list for all variables of the persistent variable list in the recipe manager, and at the same time its current values are stored by the controller as a recipe. Then execute the command *“Reorder List and Clear Gaps”* and perform a download again. Now when you execute the command *“Restore Values from Recipe”*, the values saved in the recipe are restored.

Changing an existing declaration in the persistent variable list

if you change the name or data type of a variable, this is interpreted as a new declaration and causes a re-initialization of the variables at the next online change or download. For complex data types, a change occurs when a new component is added, or when you change the type of a variable from `INT` to `UINT` in the depth of a used structure used, for example.

Basically, complex user-defined data types are not suitable for administration in a persistent variable list, because even small changes cause the variable to be initialized with all components.

Double allocation of memory in the case of instance paths

You can persist global variables or variables declared locally in a function block or program. To do this, add the keyword `PERSISTENT` to the declaration. In addition, you insert the instance path to this variable in the persistent global variable list. To do this, execute the *“Add All Instance Paths”* command in the persistence editor.

Persistence is guaranteed by the following mechanism:

- The cyclic tasks in which the variable is accessed are determined.
- At the end of the first cyclic task (in each cycle), the variable is copied to the persistent global variable list.
- After restarting the controller, the value of the persistent variable is copied to the ordinary variable.

The disadvantage of this mechanism is that memory is allocated both at the place of declaration and at the place of the instance path. This persistent variable has a **double** memory allocation. Moreover, the data is copied to both places in each cycle. This can be time consuming, especially when large structured values are involved.

Memory location in the case of persistent function block instances

A function block instance is always stored completely in memory. This is necessary so that the same code can work on different instances. If only one variable in a function block is marked with `PERSISTENT`, then the function block instance is stored completely with all variables in remanent memory, although only the one variable is treated as persistent. However, non-volatile memory is not available to the same extent as main memory.

A function block with a pointer to an instance in SRAM as a variable is not stored in the protected memory.

Importing from CoDeSys V2.3 projects

When you open a CoDeSys V2.3 project to import it into CODESYS V3, the declarations of persistent variables are not preserved. You have to revise the declarations and create then again in a separate persistent global variable list.

See also

- *Chapter 1.4.1.20.3.17.4 “Command 'Add all instance paths'” on page 1124*
- *Chapter 1.4.1.2.2 “Opening a V2.3 project” on page 187*

Preserving data with retain variables

Retain variables preserve their values after a warm start. However, the degree of value retention for persistent variables is higher.

A special non-volatile memory area on the controller, for example as NVRAM or UPS, is required to extend the lifespan. Securing the retain variables in such a memory does not require any additional time, which is an advantage over data retention with the Persistence Manager. If the controller does not provide hardware support, then the data is usually stored in a file. Then the data will be retained if you shut down the controller correctly. In the event of a power failure or a pulled plug, however, data will be lost.

Declaration

To declare a retain variable, add the `RETAIN` keyword to a variable declaration.

Behavior

Value retained for

- Uncontrolled exit
- Call of the *“Reset Warm”* command

Reinitialization for

- Repeated download of the application
- Call of the *“Reset Cold”* command (in contrast to persistent variables)
- Call of the *“Reset Origin”* command

When you restart an application, its variables are usually initialized with an explicitly preset initial value or with a default value. Variables marked with the `RETAIN` keyword are managed in a separate memory area depending on the target system and retain their value. Then the variables are protected from power failure, for example. This means that you can apply retain variables to a parts counter in a production line so that you can continue counting even after a power failure.

Memory location of persistent function block instances

Function block instances are stored as one block in memory. This is necessary so that the same code can work on different instances. If a variable is marked with `RETAIN` in a function block, then each instance of the function block is protected with all variables. This is also true for the variables of the function block that are not marked this way. However, non-volatile memory is not available to the same extent as main memory.

A function block with a pointer to an instance in SRAM as a variable is not stored in the protected memory.

Importing of CoDeSys V2.3 projects

When you open a CoDeSys V2.3 project to import it into CODESYS V3, the declarations of retain variables are preserved and remain effective as before.

See also

- *Chapter 1.4.1.19.2.13 “Retain Variable - RETAIN” on page 537*
- *Chapter 1.4.1.2.2 “Opening a V2.3 project” on page 187*

Retaining data with variables of the persistence manager

Persistent variables are managed in the Persistence Manager of the CODESYS Application Composer. The functionality of the *“Persistence Manager”* does not need any special memory on the controller in order to preserve values and data.

Declaration

In the declarations, the variables managed in the Persistence Manager are marked with the pragma `{attribute 'ac_persist'}`.

The pragma makes sure that the variable with this attribute is managed in the Persistence Manager of the Application Composer. The variable value is retained even if you change the declaration of the variable, delete a variable from the application, or add a new one. The value is retained even if you change the data type and use the appropriate conversions.

Mechanism

The variables of the Persistence Manager are stored with their values in an external archive file in TXT format.

The application code is extended with the code of the Persistence Manager, which leads to a greater memory requirement. This is at the expense of performance. Moreover, reading and especially writing a large number of persistent variables can take a long time. As a result, the executing task also blocks the execution for a long time.

Functionality

- You can load and edit the TXT file in an external editor such as Notepad++.
- You can use the persistent variables of the file in another application.
- You can configure the behavior of persistent variables by defining persistence groups, assigning variables to them, and configuring the groups with their own save and read behavior.

Preserving data with recipes

Variables are managed persistently in the Recipe Manager. The Recipe Manager does not need any special memory on the controller in order to preserve values and data.

Declaration

A recipe definition consists of a set of variables with values and is created and edited in the *“Recipe Manager”* object and saved to a file.

Functionality

- You can include a variable in multiple recipes, each with different values.
- In online mode, you can read in the actual values of the variables from the controller and save them as recipe values (specified value).
- You can use the `Recipe Management` library to programmatically implement the creation and editing of a recipe.
- You can save and backup a recipe as a recipe file.

- *Chapter 1.4.1.20.2.23 “Object 'Recipe Definition'” on page 926*

Declaring VAR PERSISTENT Variables

Below you will declare persistent variables in a persistent variable list and in a POU.

Requirement: A project is opened and contains a program POU. You have selected the option for the textual view in the *“Declaration Editor”* category of the options (menu command in *“Tools ➔ Options”*).

1. Add the *“Persistent Variables”* object to the application object with the menu command *“Project ➔ Add Object”*.
   ⇨ CODESYS adds the persistent variable list *“PersistentVars”* below the application object in the device tree and the editor opens.
2. In the editor, enter a variable declaration, for example `ivarpersist1 : INT;` between `VAR_GLOBAL PERSISTENT RETAIN` and `END_VAR`.
3. Double-click the POU in the device tree.
   ⇨ The editor of the POU opens.
4. Specify the following declaration in the declaration part:

   ```
   VAR PERSISTENT RETAIN
   ivarpersist2 : INT;
   END_VAR
   ```

5. Click *“Build ➔ Build”*.
   ⇨ The message view opens. If CODESYS has compiled the application without errors, then close the message window and continue with the next step. Otherwise, correct the error(s) and select the menu command *“Build ➔ Build”* again.
6. Set the focus in the *“PersistentVars”* editor. Click *“Declarations ➔ Add All Instance Paths”*
   ⇨ CODESYS adds the persistent variable from the persistent variable list *“PersistentVars”* to the POU:

   ```
   // instance path of the persistent variables created
   POU.IVARPERSIST2 : INT
   ```

See also

- *Chapter 1.4.1.20.2.12 “Object 'Persistent variable list'” on page 872*
- *Chapter 1.4.1.20.3.17.4 “Command 'Add all instance paths'” on page 1124*

Saving the values of a persistent variable list in a recipe

Requirement: a project is opened and a persistent variable list with declarations of persistent variables exists under an application object.

1. Double-click on the controller in the device tree and select the tab *“Communication Settings”*.
2. Select your gateway and click on the button *“Scan Network”*.
   ⇨ Your device is shown in bold in the tree view of the gateway.
3. Select your device and click on the button *“Set Active Path”*.
4. Select your application object in the device tree and select the context menu command *“Set Active Application”*.
   ⇨ The application object is displayed in bold.
5. Select the menu command *“Online ➔ Login”*
   ⇨ Your application is logged in to the controller and the controller and the application object in the device tree have a green background.
6. Double-click on the persistent variable list and select the command *“Declarations ➔ Save Current Values to Recipe”*.
   ⇨ CODESYS creates the objects *“Recipe Manager”* and *“PersistentVariables”* under the application object.
7. Select the menu command *“Online ➔ Logout”*.
   ⇨ The application is logged out from the controller.

See also

- *Chapter 1.4.1.20.3.17.2 “Command 'Save Current Values to Recipe'” on page 1123*

1.4.1.8.20 Alarm Management

For information about alarm management and alarm visualization, see the help for CODESYS Visualization.

1.4.1.8.21 Using POUs for implicit checks

CODESYS provides special POUs that implement implicit monitoring functions. At runtime, these functions check the array limits or subrange types, the validity of pointer addresses, or division by zero.

1. Select the *“Application”* object in the device tree.
   Click *“Project ➔ Add Object ➔ POU for Implicit Checks”*
   ⇨ The *“Add POU for Implicit Checks”* dialog box opens.
2. Select the desired functions.
3. Click *“Add”*.
   ⇨ The selected POUs are inserted below the *“Application”* in the device tree.
4. Open the POUs in the editor.

5. Adapt the implementation suggestion to your requirements.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

See also

- *Chapter 1.4.1.20.2.18 “Object 'POU'” on page 881*
- *Chapter 1.4.1.20.2.19 “Object 'POUs for Implicit Checks'” on page 904*

1.4.1.8.22 Object-Oriented Programming

CODESYS supports object oriented programming with function blocks and for this purpose provides the following features and objects:

- Methods
- Interfaces
- Properties
- Inheritance
- Method call, virtual function call
- Definition of function blocks as extensions of other function blocks

Basic information on dealing with object-oriented programming with AC500 V3 PLCs is given in the *application example*.

See also

- *Chapter 1.4.1.20.2.18.4 “Object 'Interface'” on page 888*

Extension of function blocks

The extension of a function block is based on the concept of inheritance in object-oriented programming. A derived function block thereby extends a basic function block and in doing so is given the properties of the basic function block in addition to its own properties.

The extension of a function block means:

- The inherited function block contains all data and methods that are defined by the basic function block. You can use an instance of the basic function block in every context in which CODESYS expects a function block of the type of the basic function block.
- The derived function block can overwrite the methods that you have defined in the base function block. This means that the inherited function block can define a method with the same name, the same inputs and the same output as is defined by the basic function block.
  Tip: You have the following support when overwriting methods, actions, attributes, and transitions that are inherited by the base block: When you insert a method, action, etc. below an inherited block, the *“Add Object”* dialog includes a combo box with a list of methods, actions, etc. used in the base block. You can accept these and adapt them accordingly.
- The derived function block may not contain function block variables with the same names as used by the basic function block. The compiler reports this as an error.
  The only exception: If you have declared a variable in the basic function block as `VAR_TEMP`, then the inherited function block may define a variable with the same name. In this case, the inherited function block can no longer access the variable of the basic function block.
- You can directly address the variables and methods of the basic function block within the scope of the inherited function block by using the `SUPER` pointer.

NOTICE!
Multiple inheritance is not permitted.

Exception: A function block can implement multiple interfaces, and an interface can extend other interfaces.

Extension of a basic function block by a new function block

Requirement: the currently opened project possesses a basic function block, for example *"POU_1(FB)"*, which is to be extended by a new function block.

1. Right-click the *"Application"* object in the device tree and select *"Project ➔ Add Object ➔ POU"*.
   ⇨ The *"Add POU"* dialog opens.
2. Type the name for the new POU in the *"Name"* input field, for example *"POU_Ex"*.
3. Select *"Function block"*.
4. Click *"Advanced"* and then the more button (...).
5. In the category *"Function blocks"* under *"Application"* in the input assistant, select the POU(FB) that is to serve as the basic function block, for example `POU_1`, and click *"OK"*.
6. As an option, you can select an *"Access modifier"* for the new function block from the drop-down list.
7. Select from the *"Implementation language"* combo box (example: *"Structured text (ST)"*.
8. Click *"Add"*.
   ⇨ CODESYS adds the `POU_Ex` function block to the device tree and opens the editor. The first line contains the text:

   ```
   FUNCTION_BLOCK POU_Ex EXTENDS POU_1
   ```

   The function block `POU_Ex` extends the basic function block `POU_1`.

Extension of a basic function block by an existing function block

Requirement: The open project possesses a base function block (example: `POU_1(FB)`) and another function block (example: `POU_Ex(FB)`). The function block `POU_Ex(FB)` is also to be given the properties of the basic function block. This means that `POU_Ex(FB)` should extend `POU_1(FB)`.

1. Double-click the function block `POU_Ex(FB)` in the device tree.
   ⇨ The function block editor opens.
2. Extend the existing entry in the top line `FUNCTION_BLOCK POU_Ex` with `EXTENDS POU_1`.
   ⇨ The function block POU_Ex extends the basic function block `POU_1`.

Implementing interfaces

Implementing interfaces is based on the concept of object-oriented programming. With common interfaces, you can use different but similar function blocks the same way.

A function block that implements an interface has to include all methods and attributes that are defined in that interface (interface methods and interface attributes). This means that the name and the inputs and outputs of the methods or attributes must be exactly the same. When you create a new function block that implements an interface, CODESYS adds all methods and attributes of the interface automatically to the tree below the new function block.

NOTICE!

If you add more interface methods afterwards, then CODESYS does not add these methods automatically to the affected function block. To perform this update, you must execute the *"Implement Interfaces"* command explicitly.

For inherited function blocks, you have to make sure that any methods or attributes that were derived through the inheritance of an interface also receive the appropriate implementation. Otherwise they should be deleted in case the implementation that was provided in the basis should be used. Respective compile error messages or warnings are displayed, prompted automatically by added pragma attributes. For more information, refer to the help page for the *"Implementing Interfaces"* command.

NOTICE!

- You must assign the interface of a function block to a variable of the interface type before a method can be called via the variable.
- A variable of the interface type is always a reference of the assigned function block instance.

A variable of the interface type is a reference to instances of function blocks. This kind of variable can refer to every function block that implements the interface. If there is no assignment to a variable, then the variable in online mode contains the value `0`.

Examples

The `I1` interface contains the `GetName` method.

```
METHOD GetName : STRING
```

The functions blocks `A` and `B` implements the interface `I1`:

```
FUNCTION_BLOCK A IMPLEMENTS I1
FUNCTION_BLOCK B IMPLEMENTS I1
```

For this reason, both function blocks must include a method named `GetName` and the return type `STRING`. Otherwise the compiler reports an error.

A function includes the declaration of a variable of interface `I1` type.

```
FUNCTION DeliverName : STRING
VAR_INPUT
    l_i : I1;
END_VAR
```

Function blocks that implement the `I1` interface can be assigned to these input variables.

Examples of function calls:

```
DeliverName(l_i := A_instance); // call with instance of type A
DeliverName(l_i := B_instance); // call with instance of type B
```

Calling of interface methods:

In this case, it depends on the actual type of `l_i` whether the application calls `A.GetName` or `B.GetName`.

```
DeliverName := l_i.GetName();
```

- ↳ *Chapter 1.4.1.20.3.22.2 “Command 'Implement Interfaces'” on page 1148*

Implementing an interface in a new function block

☑ Requirement: The open project has at least one interface object.

1. Right-click *“Application”* in the device tree and select *“Project ➔ Add Object ➔ POU”*.
   ⇨ The *“Add POU”* dialog box opens.
2. Type the name for the new POU in the *“Name”* input field, for example *“POU_Im”*.
3. Select *“Function block”*.
4. Click *“Implemented”* and then the more button (...).
5. In the input assistant, select the interface from the category *“Interfaces”*, for example `ITF1`, and click on *“OK”*.
6. To insert more interfaces, click ... and select a another interface.
7. As an option, you can select an *“Access modifier”* for the new function block from the selection list.
8. Select from the *“Implementation language”* combo box (example: *“Structured text (ST)”*.
9. Click *“Add”*.
   ⇨ CODESYS adds the *“POU_Ex”* function block to the device tree and opens the editor. The first line contains the text:

   ```
   FUNCTION_BLOCK POU_Im IMPLEMENTS ITF1
   ```

   The interface and its methods and properties are now inserted below the function block in the device tree. Now you can type program code into the implementation part of the interface and its methods.

Implementing an interface in an existing function block

☑ Requirement: The currently open project has a function block (example: *"POU_Im"*) and at least one interface object (example: *"ITF1"*).

1. Double-click the *"POU_Ex(FB)"* POU in the device tree.
   ⇨ The POU editor opens.
2. Extend the existing entry in the uppermost line `FUNCTION_BLOCK POU_Im` with `IMPLEMENTS ITF1`
   ⇨ The *"POU_Im"* function block implements the *"ITF1"* interface.

See also

- *Chapter 1.4.1.20.2.18.2 "Object 'Function Block'" on page 883*

Extending interfaces

You can extend interfaces just like function blocks. The interface is then also given the interface methods and interface properties of the basic interface in addition to its own.

Creation of an interface that extends another interface.

1. Select the object *"Application"* in the device tree.
2. Select the command *"Project ➔ Add Object ➔ Interface"*.
   ⇨ The dialog box *"Add Interface"* opens.
3. Enter a name for the new interface.
4. Activate the option *"Extended"* and click on the button ....
5. The input assistant opens.
6. From the category *"Interfaces"*, select the interface that is to be extended by the new interface.

- *Chapter 1.4.1.20.2.18.4 "Object 'Interface'" on page 888*

Calling methods

To implement a method call, the actual parameters (arguments) are passed to the interface variables. As an alternative, the parameter names can be omitted.

Depending on the declared access modifier, a method can be called only within its own name-space (`INTERNAL`), only within its own programming module and its derivatives (`PROTECTED`), or only within its own programming module (`PRIVATE`). For `PUBLIC`, the method can be called from anywhere.

Within the implementation, a method can call itself recursively, either directly by means of the `THIS` pointer, or by means of a local variable for the assigned function block.

Method call as a virtual function call

Virtual function calls can occur due to inheritance.

Virtual function calls enable one and the same call to call various methods in a program source code during the runtime.

In the following cases the method call is dynamically bound:

- You call a method via a pointer to a function block (for example `pfub^.method`).
  In this situation the pointer can point to instances of the type of the function block and to instances of all derived function blocks.
- You call the method of an interface variable (for example `interface1.method`).
  The interface can refer to all instances of function blocks that implement this interface.
- A method calls another method of the same function block. In this case the method can also call the method of a derived function block with the same name.
- The call of a method takes place by means of a reference to a function block. In this situation the reference can point to instances of the type of the function block and to instances of all derived function blocks.
- You assign `VAR_IN_OUT` variables of a basic function block type to an instance of a derived FB type.
  In this situation the variable can point to instances of the type of the function block and to instances of all derived function blocks.

Example

Overloading methods

The function blocks `fub1` and `fub2` extend the function block `fubbase` and implement the interface `interface1`. The methods `method1` and `method2` exist.

```
PROGRAM PLC_PRG
VAR_INPUT
  b : BOOL;
END_VAR

VAR  pInst : POINTER TO fubbase;
  instBase : fubbase;
  inst1 : fub1;
  inst2 : fub2;
  instRef : REFERENCE to fubbase;
END_VAR

IF b THEN
  instRef REF= inst1;            (* reference to fub1 *)
  pInst := ADR(instBase);
ELSE
  instRef REF= inst2;            (* reference to fub2  *)
  pInst := ADR(inst1);
END_IF
pInst^.method1();            (* If b is TRUE, fubbase.method1 will
be called, otherwise fub1.method1 is called *)
instRef.method1();        (* If b ist TRUE, fub1.method1 will be
called, otherwise fub2.method1 is called*)
```

On the assumption that `fubbase` in the above example contains two methods `method1` and `method2`, it overwrites `fub1 method2`, but not `method1`. The call of `method1` takes place as follows:

```
pInst^.method1();
```

If `b` is TRUE, then CODESYS calls `fubbase.method1`. If not, then `fub1.method1` is called.

Additional outputs

In accordance with the IEC 61131-3 standard, methods can have additional outputs declared, like normal functions. With the method call, you assign variables to the additional outputs.

Detailed information about this can be found in the topic “Function”.

Syntax for the call:

```
<function block name>.<method name>(<first input name> := <value> (,
<further input assignments>)+ , <first output name> => <first output
variable name> (,<further output assignments>)+ );
```

Example

Declaration

```
METHOD PUBLIC DoIt : BOOL
VAR_INPUT
    iInput_1 : DWORD;
    iInput_2 : DWORD;
END_VAR
VAR_OUTPUT
    iOutput_1 : INT;
    sOutput_2 : STRING;
ENDVAR
```

Call

```
fbInstance.DoIt(iInput_1 := 1, iInput_2 := 2, iOutput_1 =>
iLocal_1, sOUtput_2 => sLocal_2);
```

When the method is called, the values of the method outputs are written to the locally declared output variables.

Calling a method even if the application is in the STOP state

In the device description it is possible to define that a certain function block instance (of a library function block) always calls a certain method in each task cycle. If the method contains the input parameters of the following example, CODESYS processes the method even if the active application is presently in the STOP state:

Example

```
VAR_INPUT
    pTaskInfo : POINTER TO DWORD;
    pApplicationInfo: POINTER TO _IMPLICIT_APPLICATION_INFO;
END_VAR

(*Now the status of the application can be queried via
pApplicationInfo and the instructions can be implemented: *)
IF pApplicationInfo^.state = RUNNING THEN <instructions> END_IF;
```

Calling methods recursively

Use recursions mainly for processing recursive data types such as linked lists. Generally, we recommend that you be careful when using recursion. An unexpectedly deep recursion can lead to stack overflow and therefore to machine downtime.

Within their implementation, a method can call itself:

- Directly by means of the `THIS` pointer
- Indirectly by means of a local function block instance of the basic function block

Usually, a compiler warning is issued for such a recursive call. If the method is provided with the pragma `{attribute 'estimated-stack-usage' := '<sstimated_stack_size_in_bytes>'}`, then the compiler warning is suppressed. For an implementation example, refer to the section "Attribute 'estimated-stack-usage'".

1.4.1.8.23 Motion Solution

Basic Motion

Cams

The SoftMotion cam is integrated in the development interface of CODESYS. In the cam editor, cams and tappets can be implemented graphically or by means of tables. As soon as code is generated for the corresponding application, global data structures ("Cam Data") are created which the IEC program can access. For this purpose, the `SM3_Basic` is also linked automatically into the project when inserting a SoftMotion drive.

See also

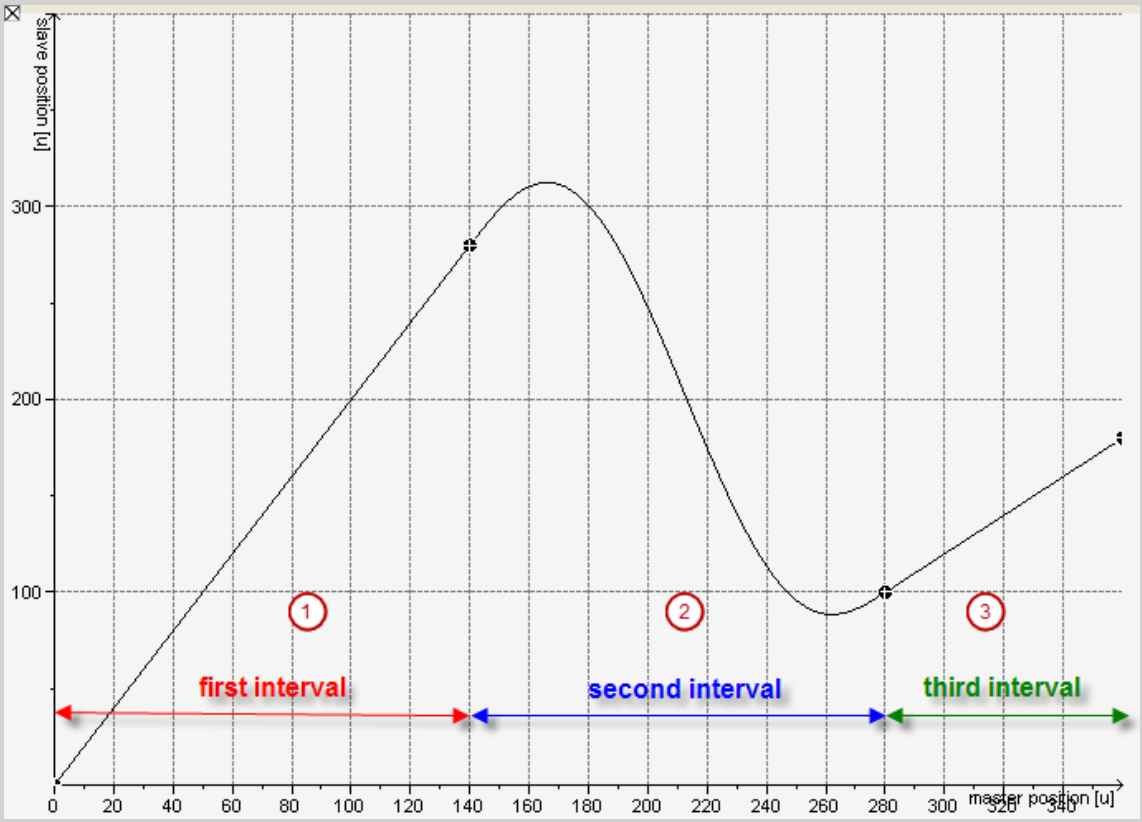
- *Chapter 1.4.1.8.23.1.1.1 “Definition of a SoftMotion Cam” on page 317*
- *Chapter 1.4.1.8.23.1.1.3 “Creating Cams” on page 319*

Definition of a SoftMotion Cam

A cam describes the functional dependency of one drive (slave) on another drive (master). The relationship is described by a continuous function (or curve) that maps a defined range of master values to slave values. To be more precise: After dividing the master axis into suitable segments, the graph of these functions can be represented on each of these intervals by a line or a 5th degree polynomial.

Example

The master values are applied to the horizontal axis and the slave values to the vertical axis in the cam graph.



In the example, the master values are between 0 and 360. This range is divided into three intervals:

- (1) First interval: [0, 140]
- (2) Second interval: [140, 280]
- (3) Third interval: [280, 360]

The function (graph) is linear in the first and third intervals and its graph is displayed as a line. As a result, its first derivative (slope) is constant and all higher derivatives are 0.

In the second interval, the graph is described by a 5th degree polynomial. Therefore, its first derivative is a 4th degree polynomial, its second derivative (curvature) is a 3rd degree polynomial, and its third derivative is a 2nd degree polynomial, etc.

When the function describes the movement of the slave depending on the position of the master, its first derivative corresponds to the velocity of the slave and the second derivative to its acceleration.

When you keep this physical interpretation in mind, it is obvious that the mapping has to be continuous. This means that its graph is not allowed to have any jumps. In particular, the continuity also has to be fulfilled at each point where two intervals meet. Furthermore, the continuity in general is also required by the first and second derivative. (In fact, these three continuity conditions at the start and end points of an interval determine the coefficients of the 5th degree polynomial inserted between two straight segments.

Moreover, you may add tappets (binary switches) to the cam at any position. In this way, you can create cam tables which contain tappets only. The slave position is then set to zero over the entire master value range.

Compiling cam definitions

At compile time, variables of type `MC_CAM_REF` are created for a cam. They include a description of each segment of the cam. Data structures of this kind are passed to the `MC_CamTableSelect` function block. The structure is part of the `SM3_Basic` library.

See also

- *MC_CAM_REF*
- *MC_CamTableSelect*

Structure of the Cam Editor

Open the cam editor by double-clicking the *“Cam”* object in the device tree.

The editor consists of the following tabs:

- Tab *“Cam”*: Includes a graphical editor for creating a cam path. Here, you can display and modify the slave position, slave velocity, slave acceleration, and slave jerk. In the graphical editor, you recognize very quickly when you program a movement with high acceleration.
- Tab *“Cam table”*: Includes an editor for listing base points in a table. Here, you can specify the exact positions and velocities.
- Tab *“Tappets”*: Includes an editor for programming tappets (switch points) in a diagram. This display provides a very good overview of the sequential order of the tappets.
- Tab *“Tappet table”*: Includes an editor for listing switch points in a table. Here, you can specify the exact switch points.

The tabs are split into an editor, as well as a *“ToolBox”* view and *“Properties”* view.

See also

- *Chapter 1.4.1.8.23.3.1.1.1.1 “Tab 'Cam'” on page 344*
- *Chapter 1.4.1.8.23.3.1.1.1.2 “Tab 'Cam table'” on page 345*
- *Chapter 1.4.1.8.23.3.1.1.1.3 “Tab 'Tappets'” on page 346*
- *Chapter 1.4.1.8.23.3.1.1.1.4 “Tab 'Tappet table'” on page 347*

Creating Cams

The steps for creating a cam are explained by means of a sample application that describes a rotary table with eight slots (45° division). Inside, there is a component that is fused ultrasonically. The welding tool is fed in by a linear drive after the rotary table has turned. After welding, the linear axis returns and the rotary table continues turning.

Work steps

- Rotary table turns 45° (duration: 400 ms).
- The welding head is moved down by a vertical axis of 250 mm (duration: 200 ms).
- Start welding (duration: 1200 ms).
- The welding head is moved up by a vertical axis of 250 mm (duration: 200 ms).

A cycle time of 2000 ms results from total times.

The application is implemented by means of a virtual master axis that runs continuously (modulo). The end value of the axis is projected according to the cycle time of 2000 ms. The rotary table is achieved as a cam (modulo; end value: 45°). The vertical axis is also achieved as a cam (restricted; end value: 300 mm). The welding process is controlled by a tappet.

Adding a cam to the device tree

Requirement: A SoftMotion controller is selected.

1. Select the *“Application”* object in the device tree.
2. Click *“Project ➔ Add object ➔ Cam table”*.
3. Specify the name *“Rotary table”* for the cam and click *“OK”*.
   ⇨ The object is inserted into the device tree. The cam editor opens.

4. Insert another cam named *“Vertical axis”*.

Setting the properties of the cam

1. Select the *“Rotary table”* cam in the device tree.
2. Click *“Properties”* in the *“View”* menu or in the context menu.
3. Select the *“Cam”* tab.
4. Specify the following values:
   - *“Master start position”*: 0
   - *“Master end position”*: 2000
   - *“Slave start position”*: 0
   - *“Slave end position”*: 45
   - *“Smooth transition”*: ☐ (deactivated)
5. Click *“OK”* to close the dialog. Confirm the dialog for changing the cam object.
6. Change the values for the *“Vertical axis”* cam in the same way:
   - *“Master start position”*: 0
   - *“Master end position”*: 2000
   - *“Slave start position”*: 0
   - *“Slave end position”*: 300
   - *“Smooth transition”*: ☑ (activated)
7. Click *“OK”* to close the dialog. Confirm the dialog for changing the cam object.

Changing the Cam Path

These instructions use the example from the section "Creating Cams" to demonstrate how to change a cam.

Changing the path with the graphical editor

1. Open the *“Rotary table”* cam in the editor.
   ⇨ The *“Cam”* tab is visible.
2. Select the point at 120 and delete it by pressing the delete key (*[Del]*). Also delete the point at 240.
3. Select the *“Add point”* tool from the *“ToolBox”* view.
   ⇨ The mouse pointer turns into crosshairs when you move it into the editor.
4. Click near *“Master position”* 400 and *“Slave position”* 45 in the upper graphs (slave position).
   ⇨ The curve of the slave position is changed. The curves of velocity, acceleration, and jerk also change.
5. Select the new inserted point by clicking it.
6. Drag the point to another position.
   ⇨ The curve of the slave position is adjusted accordingly.
7. Change the *“X”* and *“Y”* properties to the exact values of 400 and 45, respectively.
8. In the same way, change the x-value to 45 of the point at master position 2000.
9. Select the *“Select”* tool from the *“ToolBox”* view.

10. Select the second curve element (between 400 and 2000).
11. Change the *“Segment type”* property to *“Line”*.
12. Check the curve in the graphical editor.
    ⇨ Display:

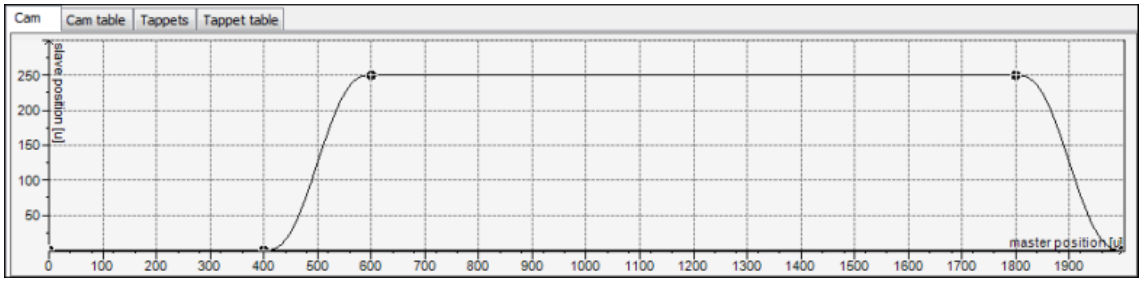
- ↳ *Chapter 1.4.1.8.23.3.1.1.1.1 “Tab 'Cam'” on page 344*

Changing the path with a cam table

1. Open the *“Vertical axis”* cam in the editor.
   ⇨ The *“Cam”* tab is visible.
2. Select the *“Cam table”* tab.
3. Delete the point at 120 by clicking the symbol. Also delete the point at 240.
4. Click the symbol.
   ⇨ A new point and a new segment are inserted at (1000/150).
5. Add two more points.
6. Change the values X / Y of the following points:
   - Point 1: `0 / 0`
   - Point 2: `400 / 0`
   - Point 3: `600 / 250`
   - Point 4: `1800 / 250`
   - Point 5: `2000 / 0`

   ⇨ The curve of the slave position is changed. The curves of velocity, acceleration, and jerk also change.
7. In the cam table, change the *“Segment type”* of the first and third segments to *“Line”*.
8. Check the curve in the graphical editor.
   ⇨ Display:



In practice, the curves of the different cams are defined frequently as overlapping in order to save on cycle time. In the example above, the vertical axis could already begin the movement while the rotary table is still in motion (for example, at X: 350).

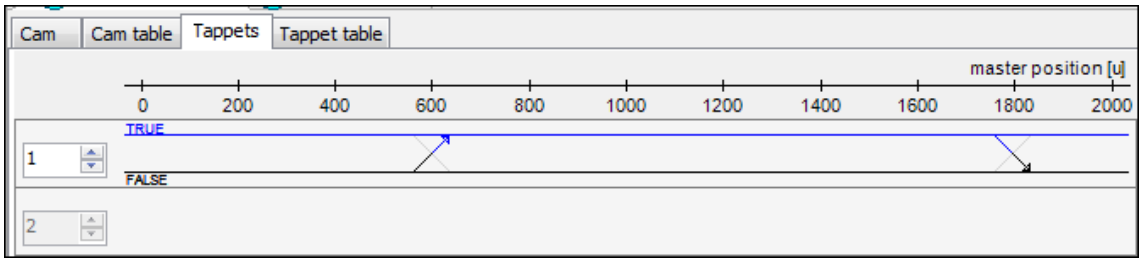
Defining Switch Points

Use switch points to trigger events depending on the master position. For example, this can be the setting of an output or the calling of a function block.

These instructions use the example from the section "Creating Cams" to demonstrate how to define switch points. In this example, the tappet starts and stops the welding process.

1. Open the *“Vertical axis”* cam in the editor.
   ⇨ The *“Cam”* tab is visible.
2. Select the *“Tappets”* tab.
3. Select the *“Add tappet”* tool from the *“ToolBox”* view.
   ⇨ The mouse pointer turns into crosshairs when you move it into the editor.
4. Click below the master position near position 600.
   ⇨ A tappet is inserted to the tappet path 1.
5. Select the tappet.

6. Change the values of the tappet in the *“Properties”* view.
   - *“X”*: 600
   - *“Positiver pass”*: *“Switch ON”*
   - *“Negative pass”*: *“No action”*
7. Insert another tappet to tappet path 1 at X: 1800.
   - *“X”*: 1800
   - *“Positiver pass”*: *“Switch OFF”*
   - *“Negative pass”*: *“No action”*
8. Check the result.



You can also change the values for “Positive pass” and “Negative pass” by clicking the respective end of the crosshairs (⌧).

Please note the possibility of also setting switch points in the “Tappet table” tab. This editor provides you with the same options, but in tabular form.

Important Cam Settings

The `SM3_Basic` library provides function blocks for handling cams. If you insert a SoftMotion drive into the device tree, then this library is included automatically into the project. You can also include this library manually by means of the *“Add Library”* command.

The following sections are intended to explain in detail the meaning of certain parameters (periodicity, offset, etc.), as well as the possibility of switching between different cams:

Periodic cam

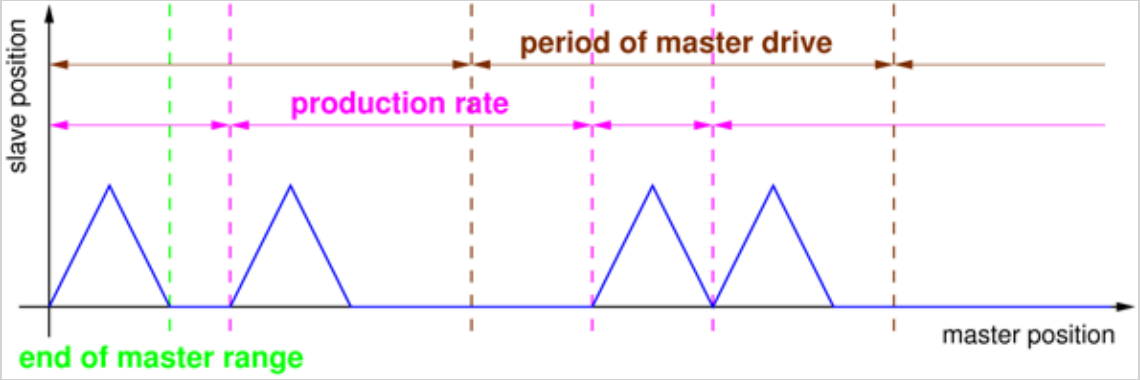
A cam can be run repeatedly when the `Periodic` input of the `MC_CamTableSelect` function block is set to TRUE. Then the cam is restarted automatically after reaching the end position. If this input is FALSE, then the `EndOfProfile` output variable of the `MC_CamIn` function block is set to `TRUE` when the end position of the master is reached. The slave pauses at its current position. Note that the cam activity does not stop after leaving the master value range. When entering the master drive again in the master value range, the slave drive is also checked by the cam.

Behavior in the case of `Slave.EndPosition` <> `Slave.StartPosition`: The function block `MC_CamIn` calculates an internal offset at the end of a period. In the subsequent period, the cam is shifted by this offset so that it continues at the current position of the slave and consequently prevents jumps.

For a periodic cam, you can activate the *“Smooth transition”* option in the cam properties. This is used for preventing jumps from occurring when transitioning from one period to another. Then the slave has the same velocity and acceleration at the end position as at the start position. The period and feed are measured in the units of slave scaling. Even if you do not activate *“Smooth transition”*, the cam can be operated continuously. In this case, your task is to make sure the consistency of the transitions are satisfied to a sufficient degree.

Example

The image below illustrates the differences between the occurring time spans. A practical use case is a conveyor belt that transports identical objects. A tool, such as a punch, is positioned above the conveyor belt and controlled by a slave drive (blue graph). The length of these objects is defined as the value range of the master. The tool runs travels within this range to and from the object.



Of course, the master value range of the cam (this is the range of defined positional values of the master) is not identical to the period of the master drive (in the example: one cycle of the conveyor belt). Therefore, the statement `'SlavePosition = CAM( MasterPosition )'` (the definition of the slave position as a function of the master position using the cam) is valid only for the first run of the cam.

When a new object arrives, a new cam cycle has to be started for controlling the tool. After the objects are placed on the conveyor belt with a specific, variable distance from one another, the production rate (the time span between successive starting of the cam) is not identical to the master value range of the cam.

- *MC_CamTableSelect*

Function block 'MC_CamTable-Select' and 'MC_CamIn'

- `MC_CamTableSelect.MasterAbsolute`:
  If the `MasterAbsolute` input is `TRUE`, then the cam is started at the current master position. This point may be at any position in the master value range of the cam. If the point is outside of the value range of the cam, then an error is issued.
  If the `MasterAbsolute` input is `FALSE`, then the cam is relocated to the current position. The zero point of the master is also shifted to the current master position. This mode is permitted only if the value 0 is in the master value range. Otherwise, an error is issued ("...master leaving specified range...").
- `MC_CamTableSelect.SlaveAbsolute`
  The parameter `CamTableSelect.SlaveAbsolute` influences the `StartMode` of the slave drive. This mode is defined by the `CamIn.StartMode` parameter. The following table documents the `StartMode` that results from the interaction of the two parameters.

- `MC_CamIn.StartMode`:
  - `absolute`: When starting a new cycle, the cam is evaluated independent of the current position of the slave. This can lead to jumps if the slave position to the master start position deviates from that of the master end position.
  - `relative`: The new cam is started allowing for the current slave position. The position that the slave has after the end of the previous cycle is added as a slave offset to the new evaluations of the cam. Jumps can also occur if the slave position at the master start position is not `0`.
  - `ramp_in`, `ramp_in_pos`, `ramp_in_neg`: `ramp_in`: When starting the cam, occurring jumps are prevented by compensating movements. Its dynamics values are limited by `VelocityDiff`, `Acceleration`, and `Deceleration`. If the slave drive is rotary, then the `ramp_in_pos` option compensates in the positive directions only, while `ramp_in_neg` compensates in the negative direction. For linear slave drives, the direction of the compensation is automatic, and `ramp_in_pos` and `ramp_in_neg` are interpreted like `ramp_in`.
- `MC_CamIn.MasterOffset`, `MC_CamIn.MasterScaling`:
  These parameters transform the master position according to the following formula: `X = MasterScaling*MasterPosition + MasterOffset`. The transformed position X is then used for evaluating the cam. In this way, the cam is run at a higher velocity when the value of `MasterScaling` is greater than `1`; on the other hand, the velocity is reduced for values less than `1`.
- `MC_CamIn.SlaveOffset`, `MC_CamIn.SlaveScaling`:
  This input moves or scales the graph of the cam function in the direction of the slave (vertical axis). First the cam is scaled and then moved according to the following formula: `Y = SlaveScaling*CAM( X ) + SlaveOffset`. A `SlaveScaling` > 1 magnifies the slave value range. Accordingly, a `SlaveScaling` < 1 reduces the magnification.

Table 12: Interaction of `MC_CamIn.StartMode` and `CamTableSelect.SlaveAbsolute`

`MC_CamIn.StartMode`	**`MC_CamTableSelect.SlaveAbsolute`**	**`MC_CamIn.StartMode`: New value**
`absolute`	`TRUE`	`absolute`
`absolute`	`FALSE`	`relative`
`relative`	`TRUE`	`relative`
`relative`	`FALSE`	`relative`
`ramp_in`	`TRUE`	`ramp_in absolute`
`ramp_in`	`FALSE`	`ramp_in relative`
`ramp_in_pos`	`TRUE`	`ramp_in_pos absolute`
`ramp_in_pos`	`FALSE`	`ramp_in_pos relative`
`ramp_in_neg`	`TRUE`	`ramp_in_neg absolute`
`ramp_in_neg`	`FALSE`	`ramp_in_neg relative`

Switching Between Cams

Basically, you can switch between different cams at any time. However, you should consider some points:

- In the cam editor, the position of the slave is defined uniquely as the function value of the cam function. This function is defined in the master value range and can be expressed as follows:
  `SlavePosition = CAM( MasterPosition )`
- Because the current position of the master drive usually deviates from the master value range, you must scale the master position in the definition range of the cam function in order to represent a valid argument:
  `SlavePosition = CAM( MasterScale*MasterPosition + MasterOffset )`
- In an analog way, you must scale the function value (the slave position) if the start of the cam in the mode `Absolute` would lead to a jump:
  `SlavePosition = SlaveScale*CAM( MasterPosition ) + SlaveOffset`
- You may have to apply both scaling values, which results in the following:
  `Slaveposition = SlaveScale*CAM( MasterScale*Masterposition + MasterOffset ) + SlaveOffset`
- The appropriate values for scaling and offset parameters can vary from period to period.
- Restarting the `MC_CamIn` function block deletes the corresponding memory area and also the values of scaling and offset. In this way, the cam function is applied in the original definition, which usually results in other values for the slave position. For this reason, it is recommended to restart the `MC_CamIn` function block to start another cam.

Example

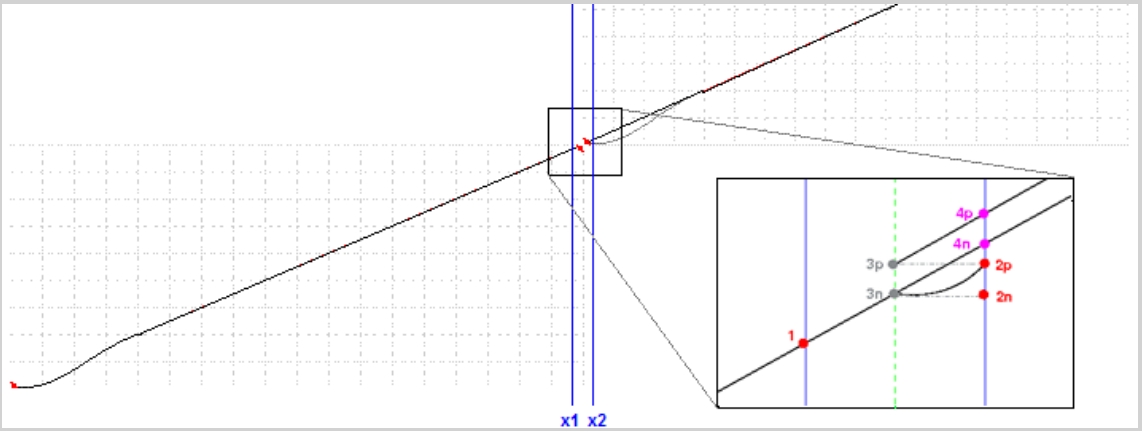
In the following example, it switches from `CAM1` to `CAM2`:

`CAM1` consists of a 5th order polynomial followed by two line segments.

`CAM2` consists of two line segments followed by one 5th order polynomial.

When switching between both cams, you should consider the following:

- To prevent jumps, the values of velocity and acceleration at the end point of the first cam should agree with the values at the start point of the second cam. In the example, this condition is fulfilled because the same velocity (=1) and acceleration (=0) is assigned to the end point of `CAM1` and the start point of `CAM2`.
- You can start the second cam in `Relative` mode when you have defined the start position of the slave as 0. However, the first cam must be running in `non-periodic` mode. Otherwise, if `CAM1` were periodic, then the `Relative` setting would result in a jump.



The magnification shows the transition from `CAM1` to `CAM2`. The blue lines marks the evaluations of the cam functions at the master positions `x1` and `x2`.

Now, we will look at the unfavorable case of `periodic`:

`MasterAbsolute := TRUE; SlaveAbsolute := FALSE;`	
`CAM(x1, CAM1, PERIODIC:=TRUE);`	The call starts an evaluation of the cam at the master position `x1`, which is less than the end position of the master of `CAM1`. Then `CAM1` is evaluated by default and yields point `1` as the position for the slave.
`CAM(x2, CAM1, PERIODIC:=TRUE);`	For the following call of the module, the master position `x2` is outside of the master value range of `CAM1`, whose limit is marked by the green dashed line and agrees with the horizontal axis of the point `3p`. Therefore, the `EndOfProfile` is set. Because `CAM1` was started in `periodic` mode, its restart occurs at the end of the value range, which finally yields the point `2p` as the result of the module call.
`CAM(EXECUTE:=FALSE);`	Switch to the new cam
`CAM(x2, CAM2, PERIODIC:=TRUE);`	Second evaluation at master position `x2`. This time, the new `CAM2` is evaluated. After `CAM2` is started in `Relative` mode, the current slave position (`2p`) is added as offset to the image of the cam function of `CAM2`. This moves the start point of its graph to the point `3p` and its evaluation at the master position `x2` yields the point `4p`, and therefore an unfavorable jump.

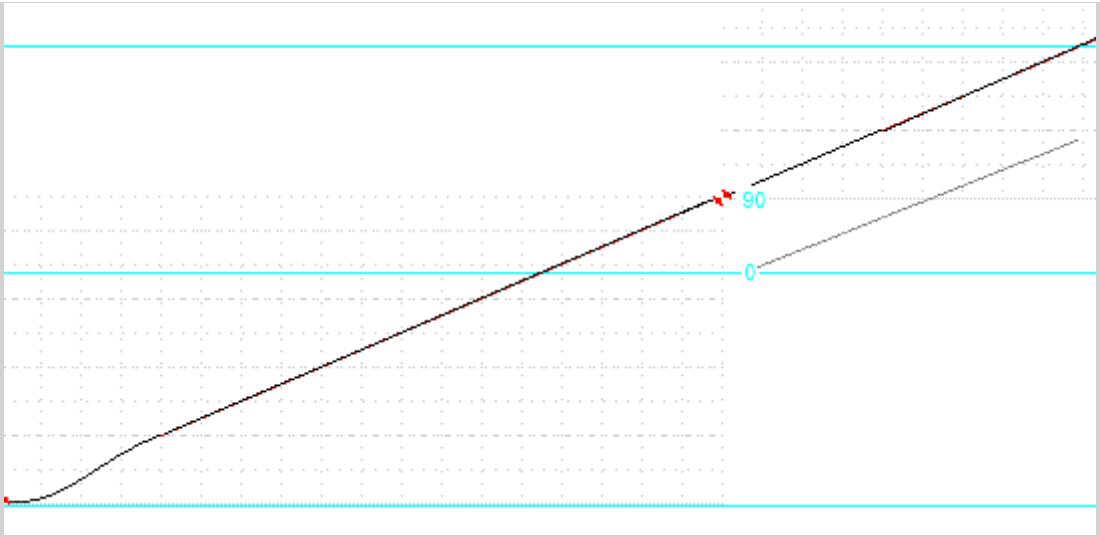
Select the `non-periodic` mode in order to prevent jumps:

`MasterAbsolute := TRUE; SlaveAbsolute := FALSE;`	
`CAM(x1, CAM1, PERIODIC:=FALSE);`	The call starts an evaluation of the cam at the master position `x1`, which is less than the end position of the master of `CAM1`. Then `CAM1` is evaluated by default and yields point 1 as the position for the slave.
`CAM(x2, CAM1, PERIODIC:=FALSE);`	For the following call of the module, the master position `x2` is outside of the master value range of `CAM1`, whose limit is marked by the green dashed line and agrees with the horizontal axis of the point `3n`. Therefore, the `EndOfProfile` is set. Because `CAM1` was started in `non-periodic` mode, slave position (`2n`) assigned to master position `x2` is identical to the position of the slave upon reaching the end of the value range of `CAM1` (`3n`).
`CAM(EXECUTE:=FALSE);`	Switch to new cam.
`CAM(x2, CAM2, PERIODIC:=FALSE);`	Second evaluation at master position `x2`.This time, the new `CAM2` is evaluated. After `CAM2` is started in `Relative` mode, the current slave position (`2n`) is added as offset to the image of the cam function of `CAM2`. This moves the start point of its graph to the point `3n` and its evaluation at the master position `x2` yields the point `4n`, which is on the specific line through the points `1` and `3n`.

To start the cam in `Absolute` mode, you have to make sure that the slave is in an appropriate start position. If the value range of the master agrees with the period of the slave, then switching between cams does not have any complications, regardless of whether the cams are periodic or not.

In the example above, you can start `CAM2` in `Absolute` mode when the periods of the master and slave agree with the master value range of `CAM2` (each is 360°).

If not, for example when the period of the slave is `270°` (indicated by the light blue line), then the `Absolute` option is not permitted without taking additional actions.



In this case, the slave is at 90° when switching from `CAM1` to `CAM2`. Starting `CAM2` in `Absolute` mode causes a jump to 0° (indicated by a gray line).

However, the jump can be prevented by setting the slave offset to the appropriate value of 90°.

Data Structure

Data structures of cams

On project compile, the created cam data is converted internally into a global variable list.

Each cam is represented by the data structure `MC_CAM_REF`. You can access this data structure by means of the IEC program or by preprocessing functions and function blocks. It is available by the `SM3_Basic` library.

A function block that describes a cam can also be generated or populated by the IEC program at runtime.

Example

Definition of the data structure:

```
TYPE mySMC_CAMTable_LREAL_10000_2 :
STRUCT
    Table: ARRAY[0..9999] OF ARRAY[0..1] OF LREAL;
    (* set all scaling definitions to 0 and 1
       result: all values of the table are not scaled *)
    fEditorMasterMin: REAL := 0;
    fEditorMasterMax: REAL := 1;
    fEditorSlaveMin: REAL := 0;
    fEditorSlaveMax: REAL := 1;
    fTableMasterMin: REAL := 0;
    fTableMasterMax: REAL := 1;
    fTableSlaveMin: REAL := 0;
    fTableSlaveMax: REAL := 1;
END_STRUCT
END_TYPE
```

Instantiating the data structure:

```
Cam: MC_CAM_REF;
Cam_PointArray : mySMC_CAMTable_LREAL_10000_2;
```

Calculating the cam:

```
Cam.byType:=2;
Cam.byVarType:=6;
Cam.nTappets:=0;
Cam.strCAMName:='myCAM';
Cam.pce:= ADR(CAM_PointArray);
FOR i:=0 TO 9999 DO
    (* example cam: master 0..360, slave 0..100,
       constant velocity *)
    Cam_PointArray.Table[i][0]:=UDINT_TO_LREAL(I)/10000 *
360;             (* X *)
    Cam_PointArray.Table[i][1]:=UDINT_TO_LREAL(I)/10000 *
100;             (* Y *)
END_FOR
Cam.nElements:=10000
Cam.xStart:=0.0;
Cam.xEnd:=360.0;
```

In order to allow for easy access to the function blocks, they are collected and listed in the `g_CAMManager` global variable with the `Count` property and the `GetCAM(int n)` method.

Example

Access to data objects of the MC_CAM_REF function block:

```
PROGRAM CAMManageRef
VAR
    pCAM_Ref: POINTER TO MC_CAM_REF;
    n: INT;
    i: INT;
END_VAR

n := g_CAMManager.Count;
FOR i:=0 TO n-1 DO
    pCAM_Ref := g_CAMManager.GetCAM(i); (* Processing pCAM_Ref*)
END_FOR
```

See also

- *MC_CAM_REF*

Manually generated cams A cam can be created in an IEC program without using the cam editor.

Example

Declaration:

```
VAR
i: INT;
CAM: MC_CAM_REF := (
    byType:=2, (* not-equidistant *)
    byVarType:=2, (* UINT *)
    nElements:=128,
    xStart:=0,
    xEnd:=360);
Table: SMC_CAMTable_UINT_128_2 := (
    fEditorMasterMin := 0, fEditorMasterMax := 360,
    fTableMasterMin := 0, fTableMasterMax := 6000,
    fEditorSlaveMin := 0, fEditorSlaveMax := 360,
    fTableSlaveMin := 0, fTableSlaveMax := 6000);
END_VAR
```

Implementation:

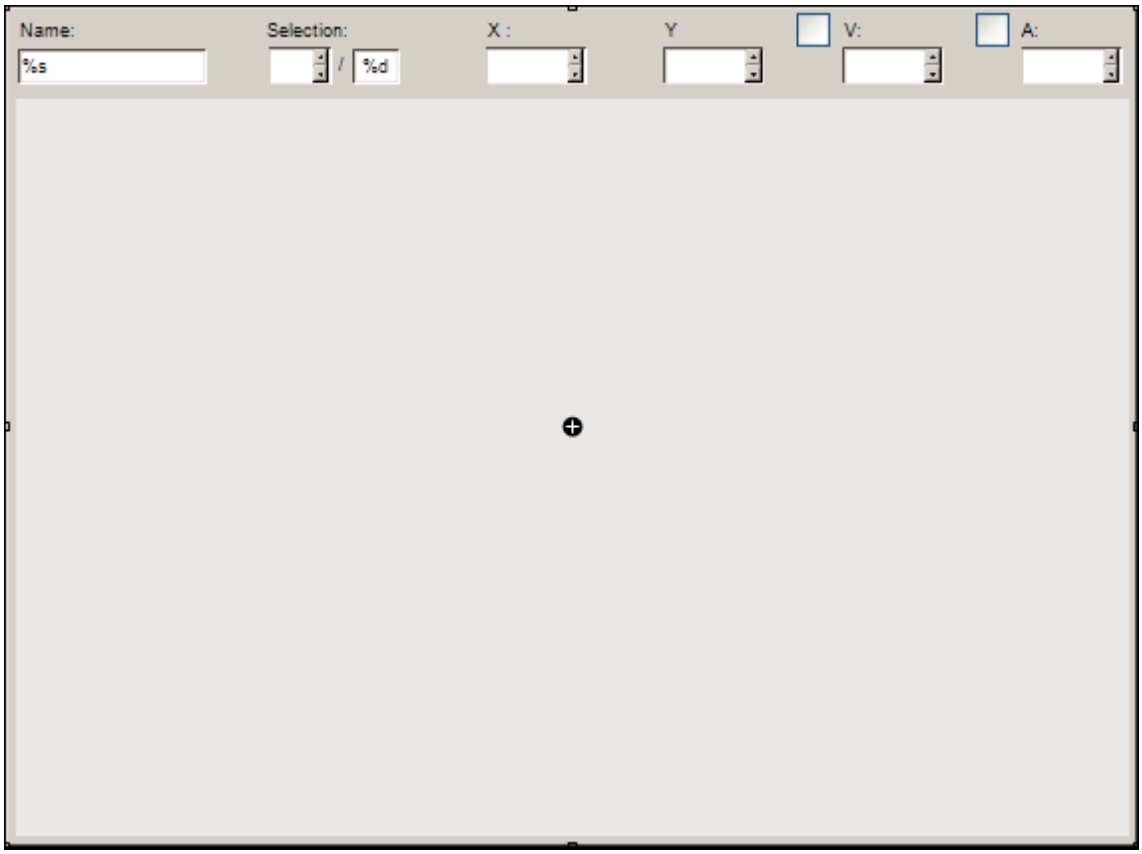
```
(* Generate cam (example: line); unique *)
FOR i:=0 TO 127 DO
    Table.Table[i][0] := Table.Table[i][1] := REAL_TO_UINT(i /
127.0 * 6000);
END_FOR
(* Link pointer; must be done in every cycle *)
CAM.pce := ADR(Table);
```

This generated cam can be specified in the `MC_CamTableSelect` function block and its output used again for `MC_CamIn`.

Visualization Element 'Online cam editor'

The online cam editor is a visualization template that displays a cam table in the visualization. With this element, you can modify the cam in online mode.

The visualization element is made available in a visualization template (*"SMC_VISU_CamEditor"*) of the `SM3_Basic` library. You find it in the visualization editor in the *"ToolBox"* view in the *"SM3_Basic"* tag. For more information about the "Frame" visualization element, refer to the CODESYS Visualization standard help.



In addition to the properties of the frame element, this template contains the following properties:

Property	Description
"xReadOnly"	If TRUE, then the cam cannot be modified.
"dIntervalX"	Step size for the X-value of the SpinControl element
"dIntervalY"	Step size for the Y-value of the SpinControl element
"dIntervalV"	Step size for the V-value (velocity) of the SpinControl element
"dIntervalA"	Step size for the A-value (acceleration) of the SpinControl element
"Editor"	Instance of the `SMC_CamEditor` function block

To visualize the cam, you must declare and call an instance of the `SMC_CamEditor` function block in your application.

```
PROGRAM PLC_PRG
VAR
    myCamEditor: SMC_CamEditor;
END_VAR
```

```
myCamEditor(cam := MyCam, bEnable :=TRUE);
```

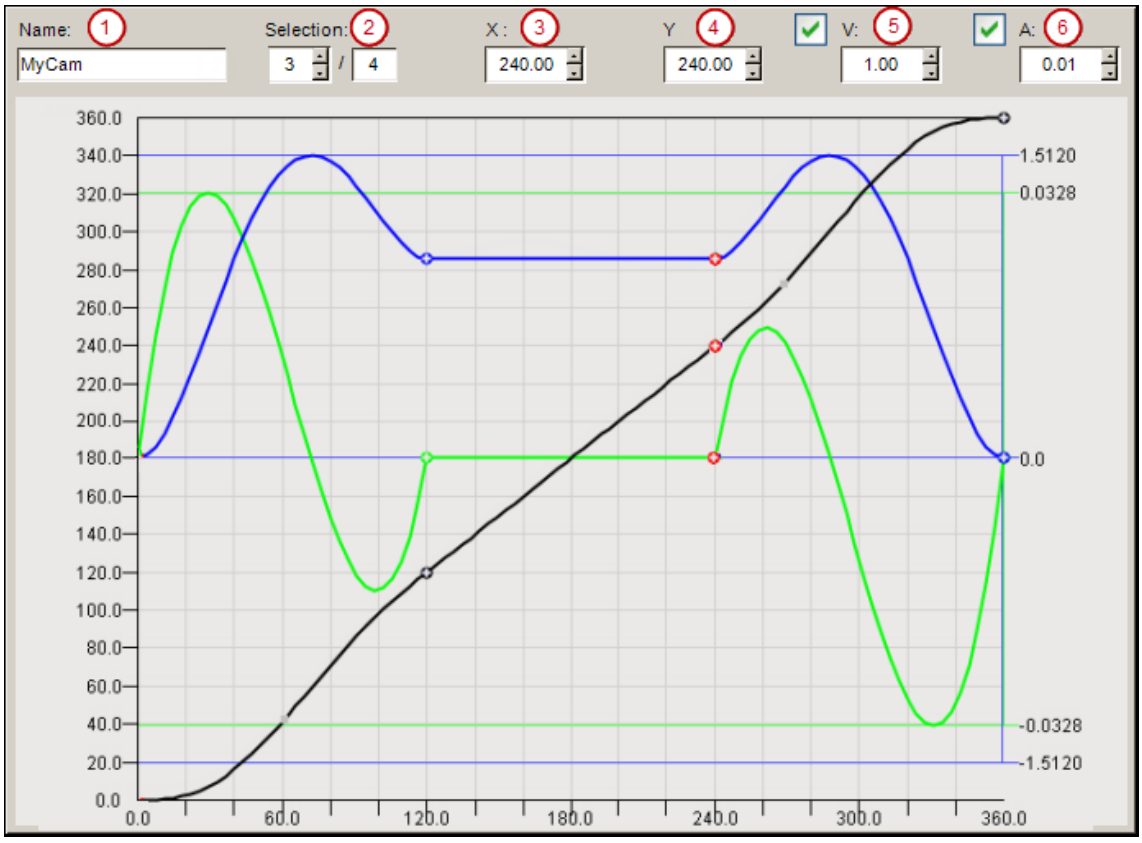
Cam editor in online mode

In online mode, the graphs of position (black), velocity (blue), and acceleration (green) are displayed.



(1) *“Name: ”*	Name of the curve table (read-only)
(3) *“Selection:”*	Selection of a curve point by mean of the SpinControl element. The selected point is displayed red.
(4) *“X:”*	Moves the curve point of the position in the X-direction (horizontal) by means of the SpinControl element or by specifying a value. The first and last points cannot be moved in the X-direction.
(5) *“Y:”*	Moves the curve point of the position in the Y-direction (vertical) by means of the SpinControl element or by specifying a value.
(6) *“V:”*	☑ Moves the curve point of the velocity by means of the SpinControl element or by specifying a value. The display of the velocity curve can be shown and hidden by means of a checkbox.
(7) *“A:”*	☑ Moves the curve point of the acceleration by means of the SpinControl element or by specifying a value. The display of the acceleration curve can be shown and hidden by means of a checkbox.

The cam tappets are displayed as small gray boxes.

It is also possible to move the curve points by dragging and dropping. To do this, the left mouse button must be pressed on the curve point longer than 500 ms. Then the curve point changes to a large red point.

BufferMode

Some function blocks have an input `BufferMode` which is used to control the chronological order of movements. The buffer mode defines whether the function block works in non-buffered mode ("Aborting", standard behavior) or in buffered mode ("Buffered"). The difference between these two modes is the time when they begin their actions:

- "Non-buffered Mode": The movement command is effective immediately, even if this interrupts another movement. The buffer of the commanded movements is deleted.
- "Buffered Mode": The movement command waits until the current function block sets its output `Done` (or `InPosition`, or `InVelocity`, etc.). The buffer modes are also used to define how the velocity curve should look at the transition of the movements.

Table 13: The input "BufferMode" is an ENUM of type MC_BUFFER_MODE.

Aborting	Default mode without buffering. The function block starts immediately and aborts an active movement. The command takes immediate effect on the axis.
Buffered	The function block starts as soon as the last commanded movement is terminated. No blending takes place here. The new movement starts at the velocity that the previous movement has when the end condition is reached (`Done`, `InVelocity`, `InEndVelocity`, `InGear`, `InSync`, `EndOfProfile`, etc.). If the previous movement was `MC_MoveAbsolute` or `MC_MoveRelative`, then the new movement starts at standstill.
BlendingLow	The function block starts as soon as the last commanded movement is terminated. The axis does not stop between movements, but passes through the end position of the first movement at the lower velocity of the two movement commands.
BlendingPrevious	The function block starts as soon as the last commanded movement is terminated. The axis does not stop between movements, but passes through the end position of the first movement at the velocity of the first movement command.
BlendingNext	The function block starts as soon as the last commanded movement is terminated. The axis does not stop between movements, but passes through the end position of the first movement at the velocity of the second movement command.
BlendingHigh	The function block starts as soon as the last commanded movement is terminated. The axis does not stop between movements, but passes through the end position of the first movement at the higher velocity of the two movement commands.

Supported Function Blocks

All function blocks that can be specified as buffered/blending commands have the following inputs and outputs:

- Input `BufferMode` (type `MC_BUFFER_MODE`)
- Output `Active` (type `BOOL`)

A command is accepted when the function block switches to the state `Busy` after a new movement has been commanded.

Function Block	Can be Defined as a Buffered/Blending Command	Can be Followed by a Buffered/Blending Command	Relevant Signal for Activating the Next Buffered/Blending FB
MC_Power	No	No	
MC_Home	No	No	
MC_Stop	No	No	
MC_Halt	No	No	
MC_MoveAbsolute MC_MoveRelative	Yes	Yes	Done
MC_MoveAdditive	No	Yes (Buffered only)	Done
MC_MoveSuperimposed	No	No (see chapter 'Behavior of MC_MoveSuperimposed')	
MC_MoveVelocity	Yes	Yes (Buffered only)	InVelocity
SMC_MoveContinuousAbsolute SMC_MoveContinuousRelative	No	Yes (Buffered only)	InEndVelocity
MC_PositionProfile MC_VelocityProfile MC_AccelerationProfile	No	Yes (Buffered only)	Done
MC_CamIn	No	Yes, also if periodic (only Buffered)	EndOfProfile
MC_CamOut	No	Yes (Buffered only)	Done
MC_GearIn	Yes (BlendingPrevious only)	Yes (Buffered only)	InGear
MC_GearOut	No	Yes (Buffered only)	Done
MC_GearInPos	Yes (BlendingPrevious only)	Yes (Buffered only)	InSync
SMC_FollowPosition SMC_FollowVelocity SMC_FollowPositionVelocity SMC_FollowSetValues	No	No	
SMC_SetTorque	No	No	
MC_Phasing	No	No	

Function Block	Can be Defined as a Buffered/Blending Command	Can be Followed by a Buffered/Blending Command	Relevant Signal for Activating the Next Buffered/Blending FB
MC_Jog SMC_Inch	No	No These function blocks should not be used when movements are commanded with buffer mode Buffered or Blending*. Jogging and the commanded movements could interrupt each other.	
SMC_BacklashCompensation	No	No	

Note for MC_GearInPos and MC_GearIn: The behavior of other buffer modes as BlendingPrevious is difficult to establish. The main problem is that the velocity of these function blocks can change at any time depending on the master axis. Because blending works best when the blending speed is known as early as possible, only BlendingPrevious is supported.

In the case of BlendingPrevious, the direction of the master axis can also change at any time. This means that the direction that the slave axis should have for MC_GearInPos is known only when the blending is complete. However, we need a direction for the blending movement right when the blending begins. This is why the first movement defines both the blending velocity and the direction, regardless of the direction defined by the subsequent MC_GearIn(Pos).

- *Chapter 1.4.1.8.23.1.2.8 “Behavior of MC_MoveSuperimposed” on page 340*

Buffering/Blending from Continuous or Synchronized Movement

According to PLCopen, the blending buffer mode determines the velocity at the end of the first movement.

In some cases, the velocity is already entirely determined by the first movement. This is the case when the first movement is of one of the following types:

- Continuous movement (MC_MoveVelocity, SMC_MoveContinuousRelative, or SMC_MoveContinuousAbsolute)
- Synchronized movement (MC_CamIn, MC_GearIn, or MC_GearInPos)

In these cases, Motion Solution supports only the buffer modes Buffered and Aborting. Using one of the blending buffer modes causes an FB error (SMC_BLENDING_NOT_SUPPORTED_BY_PREVIOUS_MOVEMENT).

When the subsequent buffered command becomes active, the output CommandAborted is set to TRUE for a previous movement command. In addition, the "Inxxx" outputs (for example, InVelocity for MC_MoveVelocity or InGear for MC_GearIn) and the output Busy are set for one cycle. This is in contrast to PLCopen, Section 2.4.1, in which CommandAborted and "Inxxx" as well as Busy are mutually exclusive.

See also

- linktarget [CODESYS_Softmotion] doesn't exist but @y.link.required='true'

Using One Function Block Instance to Control Multiple Movements

A single function block instance (for example, from `MC_MoveAbsolute`) cannot be used to control multiple buffered/blending movements as long as it is "Busy".

When a function block instance is `Busy`, the command for a new buffered or blended movement with this instance results in the error `SMC_MORE_THAN_ONE_MOVEMENT_PER_INSTANCE`.

To command multiple buffered or blended movements of the same type in a short order, multiple function module instances are required.

See also

- linktarget [CODESYS_Softmotion] doesn't exist but @y.link.required='true'

Behavior in Case of Error

If an axis error occurs (for example, the axis switches to the state `errorstop`), the active movement will report an error along with all other accepted movements.

If an FB error occurs in the function block of an active movement, then all movements accepted later also report an error. This is in contrast to PLCopen, Section 2.2.2, in which subsequent commands will continue the execution after an FB error.

See also

- linktarget [CODESYS_Softmotion] doesn't exist but @y.link.required='true'

Execution Order of Movement Function Blocks

When buffered movements or blending movements are commanded, the function block instance that commands the subsequent movement must not be executed earlier than the function block instance that commanded the previous movement.

If this order is violated, then the new error `SMC_MOVING_WITHOUT_ACTIVE_MOVEMENT` is reported and the axis switches to the state `Errorstop`.

See also

- linktarget [CODESYS_Softmotion] doesn't exist but @y.link.required='true'

Behavior in the Case of Buffered Movements

When a buffered movement is commanded after `MC_MoveAbsolute` or `MC_MoveRelative`, the buffered movement is active in the same cycle where the previous movement reports `Done` and reaches the velocity 0. However, the interpolation of the buffered movement does not start until the next cycle, so that the velocity of the axis at the end of the cycle is equal to 0.

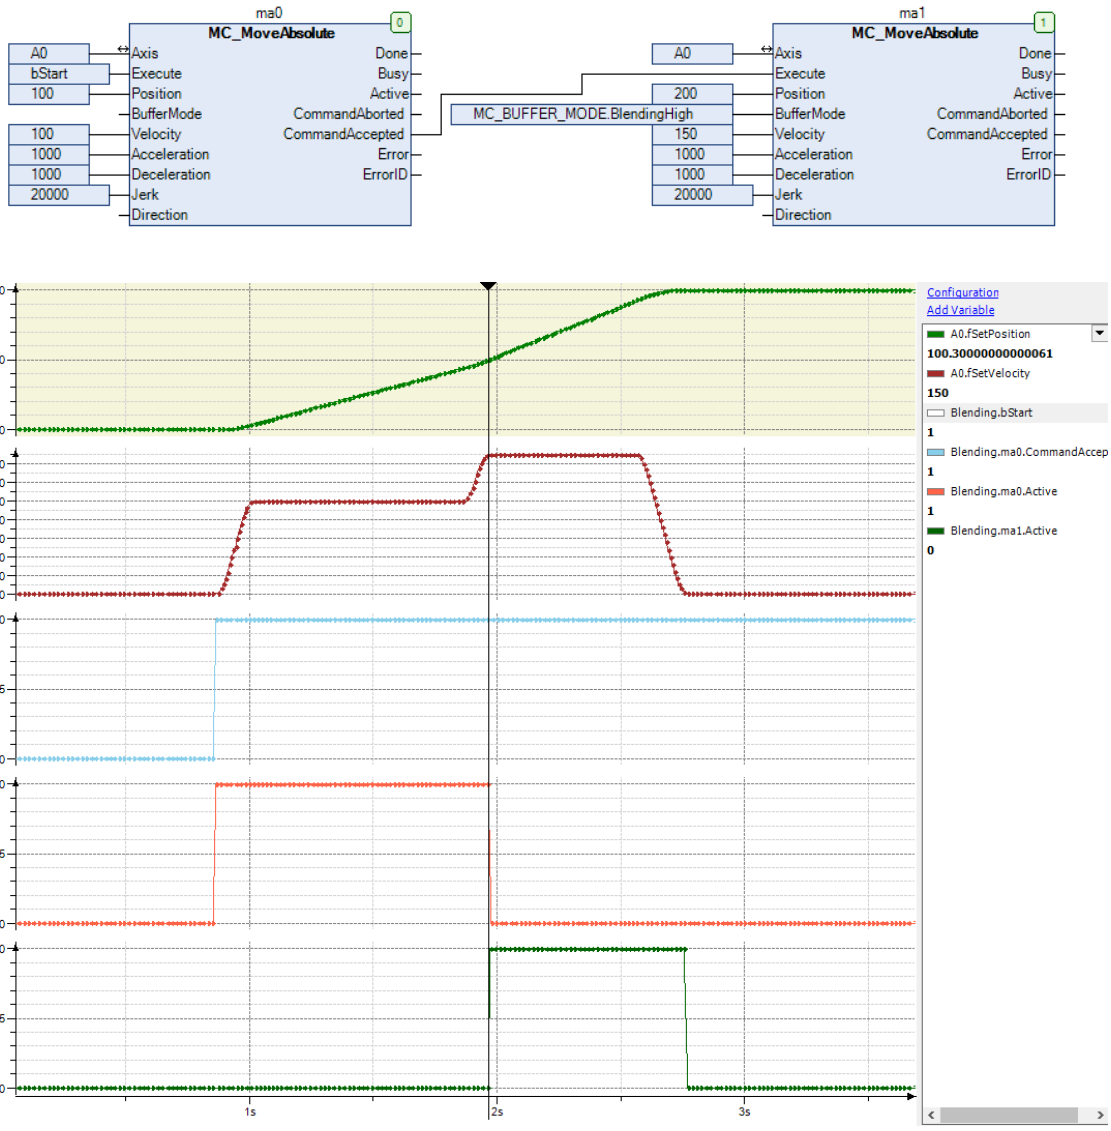
See also

- linktarget [CODESYS_Softmotion] doesn't exist but @y.link.required='true'

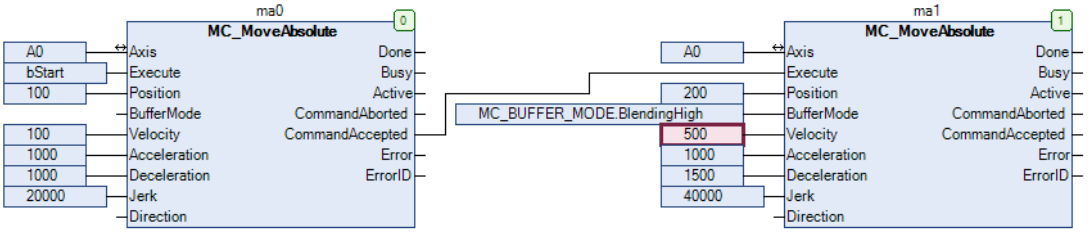
Behavior in the Case of Blending

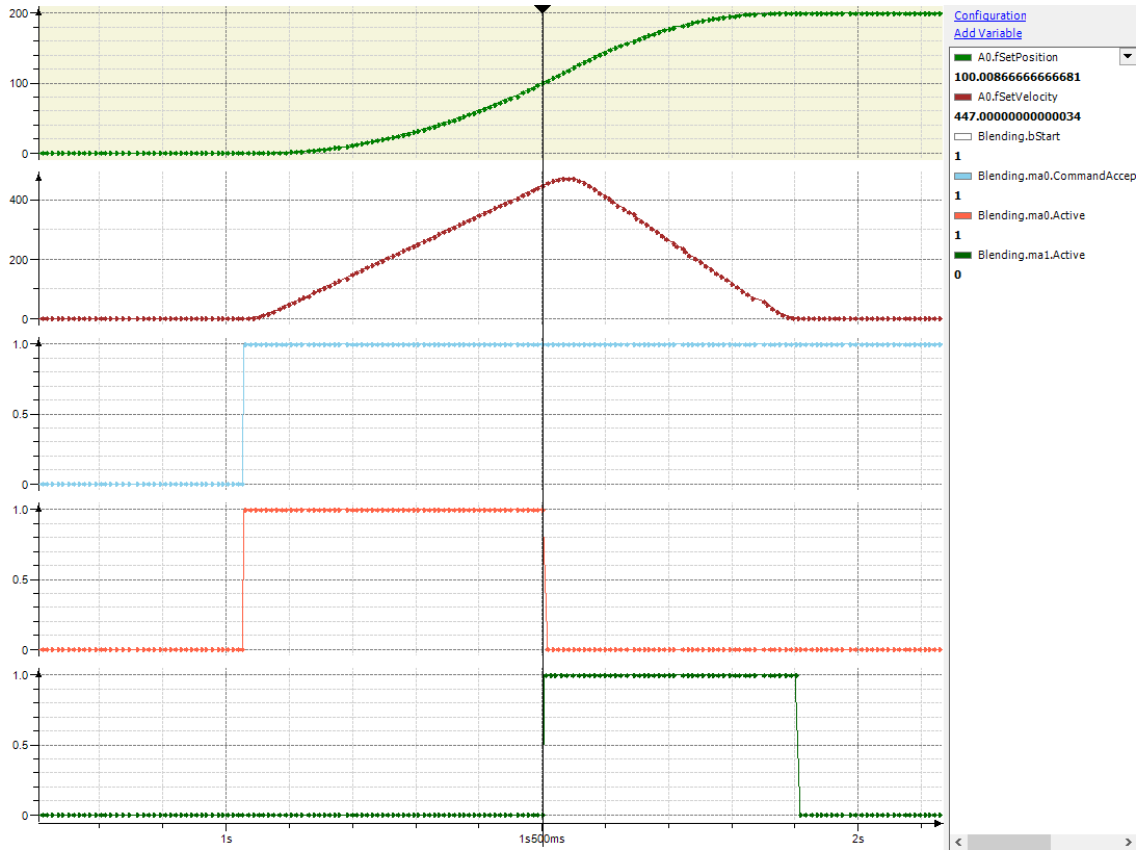
A basic property of the blending behavior of Motion Solution is that the axis moves along the same positions during blending as during a buffered movement. The only difference is the velocity along these positions.

This is obvious for simple cases. See the following example for this:



There are cases in which the property of traversing the same positions by the axis independently of the buffer mode influences the effective blending velocity between the two movements. This is the case, for example, if the above example is modified so that the maximum velocity of the second movement is so high that it cannot be reached at the blending position. According to the rules described in PLCopen, the blending velocity should be 500 u/s. However, to achieve this velocity at position 100 u, the axis would have to reverse, move in the negative direction to a position less than 0 u, and then accelerate to 500 u/s. Instead, in such cases the effective blending velocity is limited to the maximum velocity that can be achieved without reversal and position overshoot. In this example, the maximum velocity is 447 u/s.





The following rules for the effective blending velocity result from the property that the buffer mode does not change the driven positions:

- If the blending velocity cannot be reached without position overshoot, then the effective blending velocity is the next possible velocity that can be reached without overshoot (see example above).

  Note: The effective blending velocity can be higher or lower than the blending velocity.
- If the direction at the beginning of the second movement is opposite to the direction of the first movement, then the effective blending velocity is set to 0. This prevents the position from overshooting in the direction of the first movement beyond its target position.
- If the path of the second movement is too short to allow deceleration from the blending velocity to standstill, then the effective blending velocity is adjusted. It is set to the maximum velocity that allows for safe braking to a standstill on the path of the second movement.
- In the case of modulo axes, the effect of the input `Direction` of `MC_MoveAbsolute` is not affected by blending to a second movement. This means that the target position of the first movement is always in the same modulo period, regardless of whether or not a blending movement follows.
- In the case of modulo axes and a second movement of type `MC_MoveAbsolute`, the blending velocity does not affect the modulo period of the target position of the second movement when `Direction` = `fastest` is used. This means that the same target period is selected regardless of whether the second movement is commanded with `Buffered` or `Blending`.

See also

- **linktarget [CODESYS_Softmotion] doesn't exist but @y.link.required='true'**

Behavior of MC_MoveSuperimposed

If `MC_MoveSuperimposed` is active and the underlying movement is aborted, then `MC_MoveSuperimposed` is also aborted.

If the underlying movement is not aborted, but rather another movement is commanded with the mode `Buffered` or one of the modes of the blending buffer mode, then the behavior is as follows:`MC_MoveSuperimposed` is not aborted when the blending begins or the new movement is active. Instead, `MC_MoveSuperimposed` is continued in the background until it is done.

If an `MC_MoveAbsolute` assigned with buffered mode or a blending mode is commanded while an `MC_MoveSuperimposed` is active, then the resulting end position depends on the status of `MC_MoveSuperimposed` at the time when the `MC_MoveAbsolute` is active. If `MC_MoveSuperimposed` is still active at this time, then the resulting end position is the sum for the position of `MC_MoveAbsolute` and the path of `MC_MoveSuperimposed`. On the other hand, if `MC_MoveSuperimposed` is no longer active at this time, then the resulting end position is the position of `MC_MoveAbsolute` without the distance of `MC_MoveSuperimposed`. In a similar way, the resulting velocity of `MC_MoveVelocity` depends on the status of `MC_MoveSuperimposed` when `MC_MoveVelocity` is active.

The curve below shows an `MC_MoveSuperimposed` (*"sup"* function block) parallel to three absolute movements with blending buffer mode `BlendingHigh`. The first and second movements are commanded with a velocity of 100 u/s with the function blocks *"ma0"* and *"ma1"*. The function block *"ma2"* commands the third movement with a velocity of 120 u/s. The first target position is 10 u, the second is 25 u, and the third is 40 u. The velocity of the superimposed movement is 20, and the distance is 10. The resulting position is 50 u: the position of the last absolute movement plus the path of `MC_MoveSuperimposed`.

Examples of Use

Controlling a Cam Drive with a Virtual Time Axis

Refer to the sample project `PLCopenMulti.project` in the installation directory of CODESYS.

This example demonstrates how to implement a periodic cam on a linear drive. The example also demonstrates how to use the tappet function.

1. Insert a cam named `Example` in the device tree below *"Application"*. Open the cam in the editor.
2. Define a tappet in the *"Tappet"* tab.
   - *"X"*: `8.0`
   - *"Positive pass"*: `Invert`
   - *"Negative pass"*: `Invert`
3. Insert a virtual drive named `Drive` in the device tree below *"SoftMotion General Axis Pool"*. For this axis, select the axis type *"Modulo"* with a modulo value of `360`.
4. Insert another virtual drive named `Virtual`. For this axis, select the axis type *"Modulo"* with a modulo value of `10`.
5. Create a *"MOTION_PRG"* program in CFC.

```
PROGRAM MOTION_PRG
VAR
    power1, power2: MC_Power;
    TableSelect: MC_CamTableSelect;
    CamIn: MC_CamIn;
    Tappet: SMC_GetTappetValue;
    MoveVirtual: MC_MoveVelocity;
END_VAR
```

6. Insert a box element and assign the variable `power1` to it. The box element is used for switching on the `Drive`.

   Configure the inputs as follows:

   - *"Axis"*: `Drive`
   - *"Enable"*: `TRUE`
   - *"bRegulatorOn"*: `TRUE`
   - *"bDriveStart"* `TRUE`
7. Insert a box element and assign the variable `power2` to it. The box element is used for switching on the `Virtual` drive.

   Configure the inputs as follows:

   - *"Axis"*: `Virtual`
   - *"Enable"*: `TRUE`
   - *"bRegulatorOn"*: `TRUE`
   - *"bDriveStart"* `TRUE`
8. Insert a box element and assign the variable `MoveVirtual` to it. The box element is used for moving the virtual master.

   Configure the inputs as follows:

   - *"Axis"*: `Virtual`
   - *"Execute"*: `power2.Status`
   - *"Velocity"*: `2`
   - *"Acceleration"* `10`
   - *"Deceleration"* `10`
   - *"Direction"* `positive`

9. Insert a box element and assign the variable `TableSelect` to it. The box element is used for selecting a cam.

   Configure the inputs as follows:

   - *"Master"*: `Virtual`
   - *"Slave"*: `Drive`
   - *"CamTable"*: `Example`
   - *"Execute"* `TRUE`
   - *"Periodic"* `TRUE`
   - *"MasterAbsolute"* `TRUE`
   - *"SlaveAbsolute"* `TRUE`

10. Insert a box element and assign the variable `CamIn` to it. The box element implements the selected cam plate.

    Configure the inputs as follows:

    - *"Master"*: `Virtual`
    - *"Slave"*: `Drive`
    - *"Execute"* `power1.Status`
    - *"MasterOffset"*: `0`
    - *"SlaveOffset"*: `0`
    - *"MasterScaling"*: `1`
    - *"SlaveScaling"*: `1`
    - *"StartMode"*: `absolute`
    - *"CamTableID"*: `TableSelect.CamTableID`
    - *"VelocityDiff"*: `1`
    - *"Acceleration"*: `1`
    - *"Deceleration"*: `1`
    - *"TappetHysteresis"*: `1`

11. Insert a box element and assign the variable `Tappet` to it. The box element checks the setting of the cam switch.

    Configure the inputs as follows:

    - *"Tappets"*: `CamIn.Tappets`
    - *"iID"*: `1`
    - *"bInitValue"* `FALSE`
    - *"bSetInitValueAtReset"*: `FALSE`

    ⇨ The tappet is defined as an inverting tappet. For this reason, its value is changed every 10 seconds.

12. The sample project provides a visualization for checking the individual function blocks and the position of the axes.

13. Add the call of the `MOTION_PRG` program to the task *"MainTask"*.

14. Load the project to the controller and start it.

Alternating Cams

Refer to the sample project `PLCopenMultiCAM.project` in the installation directory of CODESYS.

This example demonstrates how a cam movement can be created with two alternating cams. The program is implemented in ST and executes the same actions as the sample "Cam Drive Control using a Virtual Time Axis". At the end of the first cam, the `MC_CamIn` function block sets the `EndOfProfile` output. In this way, the other curve table is assigned to `MC_CamTableSelect` and `MC_CamIn` is restarted.

Reference

User Interface

Objects

Object 'Cam Table'

Tab 'Cam'

In this graphical editor, the cam graphs are defined. You can switch between the graphical editor and the alternative tabular editor at any time (*"Cam table tab"* tab).

The editor window displays the curves of four graphs:

- Slave position (black)
- Slave velocity (blue)
- Slave acceleration (green)
- Slave jerk (yellow)

The horizontal axis of all four coordinate systems shows the range of the master values ([0,360]). The vertical axis in the position diagram shows the value range that is defined in the cam properties. The vertical axis of velocity, acceleration, and jerk is scaled automatically.

A new inserted cam is assigned with default values. It consists of four points that subdivide the graph into three sections: [0,120], [120,240], and [240,360]. Each of the interval parts of the cam graphs is type Poly5 (5th degree polynomial).

You can modify all curves, except the jerk curve. As velocity, acceleration, and jerk are derived curves, changes to one graph causes changes to the other graphs.

You change the height of the diagram by moving the horizontal separation bars.

Table 14: “View 'ToolBox'”

: *“Select”*	Select a line in the table by using this tool. Selected points are deleted by pressing the *[Del]* key.
“Add point”	Add new points with this tool. Click the insertion point in the diagram. The graph is then adapted automatically so that its curve runs through the new inserted point.

Table 15: “View 'Properties'”

X	X-position of the slave axis
Y	Y-position of the slave axis
V	Velocity of the slave axis
A	Acceleration of the slave axis
J	Jerk of the slave axis

- *Chapter 1.4.1.8.23.1.1.3 “Creating Cams” on page 319*

Tab 'Cam table'

The cam table is an alternative to the graphical editor for defining the cam graphs (*“Cam”* tab). You can switch between the table editor and the graphical editor at any time.

The first line of the table always contains the start position of the master (and the related slave values) and the last line is always the end position. The lines in-between alternately define segments and points.

Table 16

	Inserts a new line.
	Deletes the selected segment
“X”	X-position of the slave axis
“Y”	Y-position of the slave axis
“V”	Velocity of the slave axis
“A”	Acceleration of the slave axis
“J”	Jerk of the slave axis
“Segment type”	• *“Poly5”*: 5th degree polynomial • *“Line”* • Linear
The following values result from the values of the respective segment. They cannot be modified.	
min(Position)	Minimum value of the slave position
max(Position)	Maximum value of the slave position
max(Velocity)	Maximum value of the velocity of the slave, based on the master axis
max(Acceleration)	Maximum value of the acceleration of the slave, based on the master axis

Table 17: “View 'ToolBox'”

: *“Select”*	Select a line in the table by using this tool. Selected points are deleted by pressing the *[Del]* key.

Tab 'Tappets'

The tappet paths are defined in this table graphical editor. A tappet path defines one or more tappets depending on the master position. At the upper edge of the editor window, a horizontal axis approaches the range of the master positions. The individual tappet paths are defined below.

You can switch between the graphical editor and the alternative tabular editor at any time (*“Tappet table”* tab).

Table 18

1	Track ID of the tappet path All tappets of a tappet path refer to the same tappet switch (a variable of type BOOL).

Table 19: “View 'ToolBox'”

: *“Select”*	Select the tappets by means of this tool. You can drag the selected tappets to another position. You can modify the switch on/off attribute of a tappet by clicking the relevant end of the crossed line ( ). Delete the selected tappet by pressing the *[Del]* key.
	Add new tappets with this tool. Click the insertion point in the path.

Table 20: “View 'Properties'”

the tappet is assigned to a result, if it is passed from the position of the master axis in the positive (increasing master values) or negative direction.

Tab 'Tappet table'

This tabular editor is an alternative to the graphical editor for configuring the tappet paths (*“Tappets”* tab). A tappet path defines one or more tappets depending on the master position. In the table, the lines with the definitions of the associated tappets follow below each line that defines a tappet path.

You can switch between the table editor and the graphical editor at any time.

Table 22

	Inserts a new tappet.
	Deletes the tappet.
“Track ID”	ID of the tappet path All tappets of a tappet path refer to the same tappet switch (a variable of type BOOL).
“X”	Position of the tappet

“Positive pass”	Switch on/off attribute ● No action ● Switch to ON ● Switch to OFF ● Invert
“Negative pass”	Switch on/off attribute ● No action ● Switch to ON ● Switch to OFF ● Invert

Table 23: “View 'Properties'”

The tappet is assigned to a result, if it is passed from the position of the master axis in the positive (increasing master values) or negative direction.	
“X”	Position of the tappet
“Positive pass”	Switch on/off attribute ● No action ● Switch to ON ● Switch to OFF ● Invert
“Negative pass”	Switch on/off attribute ● No action ● Switch to ON ● Switch to OFF ● Invert

Dialog 'Properties - 'Cam'

Function: Use this dialog to define the global variables of the cam.

Table 24: “Dimensions”

“Master start/end position”	The start and end positions of the master define the range of the master values and therefore the scale of the horizontal axis of the cam. The default settings are given in angular degrees with 0 and 360 as limiting values.
“Slave start/end position”	The associated slave positions are determined by the graph type that is defined for the cam. However, the segment depicted by the curves (this is also the scale of the vertical axis) can be defined by the start and end positions of the slave that are given here.

Table 25: “Period”

These settings affect the work in the cam editor and cam table. Depending on these parameters, the slave start point is adjusted automatically when the end point is changed, as well as the other way around. This adjustment optimizes the period transition to be as smooth and jerk-free as possible.	
“Smooth transition”	☑: The values for position, velocity, and acceleration are adjusted automatically.
“Slave period”	Indicates when the slave period is repeated mechanically. Then the slave position at the start and end of the master period can deviate by one integer multiple of this value. This value is effective only if the *“Smooth transition”* check box is selected.

Table 26: “Continuity requirements”

Activation of these options for the continuity of the curve does not have any effect when editing the cam. It does, however, prompt a continuity check, which reports any violations to the message view (CAM). It is not possible to edit jumps in the position curve. The default setting also requires the continuity of velocity and acceleration. You can clear these options, for example in the special case of a curve that consists of only linear segments. However, this can lead to breaks in the position curve. By default, the jerk (4th derivative) is not tested for jumps.	
“Position”	☑: The entire curve is tested for jumps.
“Velocity”	
“Acceleration”	
“Jerk”	

Table 27: “Compile format”

When compiling, `MC_CAM_REF` structure variables are generated. A cam is described according to the following options:	
“Polynomial (XYVA)”	Polynomial description of the individual points, consisting of master position, slave position, slave velocity, and slave acceleration.
“One-dimensional point array”	1D table of slave positions
“Two-dimensional point array”	2D table of composite master/slave positions
“Elements”	Number of elements in the arrays. This array has already been created in SM3_Basic for the standard cases *“128”* and *“256”*. If you type in another value, you must create the structure in your application (see the following example).

Example of an array with 720 elements

```
TYPE SMC_CAMTable_LREAL_720_2 :
STRUCT
    Table: ARRAY[0..719] OF ARRAY[0..1] OF LREAL;
    fEditorMasterMin, fEditorMasterMax: REAL;
    fEditorSlaveMin, fEditorSlaveMax: REAL;
    fTableMasterMin, fTableMasterMax: REAL;
    fTableSlaveMin, fTableSlaveMax: REAL;
END_STRUCT
END_TYPE
```

- *Chapter 1.4.1.8.23.1.1.3 “Creating Cams” on page 319*

Commands

Cam

Command 'Display generated code'

Function: This command opens the *"Generated code"* dialog where the IEC initialization code of the represented cam is displayed.

Call: Menu bar: *"Cam"*.

Requirement: The cam editor is open and displays a cam.

Dialog 'Generated code'

Example: IEC initialization code

```
{attribute 'linkalways'}

VAR_GLOBAL
Cam_A: ARRAY[0..3] OF SMC_CAMXYVA := [
    (dX := 0, dY := 0, dV := 0, dA := 0),
    (dX := 120, dY := 120, dV := 1, dA := 0),
    (dX := 240, dY := 240, dV := 1, dA := 0),
    (dX := 360, dY := 360, dV := 0, dA := 0)];
Cam: MC_CAM_REF := (nElements := 4, byType := 3, xStart := 0,
xEnd := 360, nTappets := 0, strCAMName := 'Cam', pce := ADR(Cam_A),
xPartofLM := TRUE);
END_VAR
```

Command 'Read cam data from ASCII table'

Function: This command reads an `ASCII` file.

Call: Menu bar: *"Cam"*.

Requirement: The cam editor is open.

When being read, the file data is interpreted as the xy-values of a cam. The *"Number of points"* opens so that you can decrease the number of interpolation points. Then the determined points are interpolated to a cam and displayed in the editor.

The *"Write cam data to ASCII table"* commands creates an appropriate `TXT` file.

See also

- *Chapter 1.4.1.8.23.1.1.3 "Creating Cams" on page 319*
- *Chapter 1.4.1.8.23.3.1.2.1.4 "Command 'Write cam data to ASCII table'" on page 351*

Dialog Box 'Number of points'

"Number of points"	Number of points used for interpolation. Preset: According to the number of xy-values that are stored in the read file. Example: `256` You can decrease the preset value in order to determine the cam with fewer interpolation points. When determining the interpolation points, their x-values are distributed equidistantly.

As the cam is interpolated using a 5th degree polynomial, a larger number of interpolation points may cause oscillations.

Command 'Read cam online file'

Function: This command reads an external file with cam data. The file extension is `CAM`. The cam is displayed in the cam editor.

Call: Menu bar: *"Cam"*.

Requirement: The cam editor is open.

The *"Write cam online file"* command creates an appropriate file in `CAM` format.

Chapter 1.4.1.8.23.1.1.1 "Definition of a SoftMotion Cam" on page 317

Command 'Write cam data to ASCII table'

Function: This command creates an `ASCII` file (`TXT` extension) on the development system. A specified number of xy-values of the active cam is saved in this file. A standard dialog box opens first and then the *"Number of points"* dialog box.

Call: Menu bar: *"Cam"*.

Requirement: The cam editor is open and displays a cam.

See also

- *Chapter 1.4.1.8.23.3.1.2.1.2 "Command 'Read cam data from ASCII table'" on page 350*
- *Chapter 1.4.1.8.23.1.1.3 "Creating Cams" on page 319*

Dialog Box 'Number of points'

The ASCII table does not contain any information about cams.

"Number of points"	Number of xy-values that are saved in the file and represented in the curve shape. For this purpose, the x-curve is split equidistantly and the respective y-value is determined.

Command 'Write cam online file'

Function: This command creates a file (`CAM` extension). The file contains the data of the cam that is active in the editor.

Call: Menu bar: *"Cam"*.

Requirement: The cam editor is open and displays a cam.

The cam data is composed of a cam description and the positions and types of cams.

A `CAM` file can be read to the editor by means of the *"Read cam online file"* command.

In addition, an instance of the `SMC_ReadCAM` function block can read the file in order to load a cam table into the application at runtime.

1.4.1.9 Working with Controller Networks

With the following functionalities, CODESYS supports communication between controllers (PLC) and the insertion of a safety controller below a PLC:

- **Symbol Configuration**: CODESYS creates symbols with certain access rights for the variables in an application. With these symbols, you can access the variables from outside, for example from an OPC server.
- **Data Source Manager**: Manages the connection settings and the data transmission to remote devices (data sources). The transmitted data is mapped in data source variables that are accessed in the visualization or local application. An example of this is a control panel that controls remote devices and displays the state of the device as an HMI application.
- **Network Variables**: Network variables are variables whose values are accessible to different controllers in the network. The variables have to be defined in rigid, identical lists in both the transmitter device and the receiver device. These lists are assigned to applications, but can be located in different projects.
- A **safety controller** can be inserted below a PLC in the device tree. The communication links of the safety controller to the field devices, controller networks, and development system are routed through this controller.

The "DataServer" object is obsolete.

The data link with CODESYS DataServer has already been superseded with SP10 by a data link with data sources. With CODESYS 3.5 SP17, the functionality has now been completely removed.

In case you want to adapt an existing project with a "DataServer" object, you can do the following: Open the existing project with CODESYS V3.5 SP16, select the data server object, and click "Convert Data Server to Data Source Manager" in the context menu. After the conversion of the data link to a data source connection, you can open the project with a current CODESYS version.

1.4.1.9.1 Network and Addressing

Constructing a control network hierarchically, so that extensive self-configuration is possible.

In CODESYS the network topology is mapped to clear addresses and the routing algorithm is kept simple by structured addresses. There is direct and relative addressing and automatic address determination during the bootup of the system.

See also

- *Chapter 1.4.1.9.1.1 “Network topology” on page 353*
- *Chapter 1.4.1.9.1.2 “Addressing and Routing” on page 353*
- *Chapter 1.4.1.9.1.3 “Address Structures” on page 355*

Network topology

Information and recommendations for the topology of a control network

It is recommended to set up a network system so that the following are possible:

- Extensive self-configuration (address assignment)
- Transparent support for every communication medium
- Transport of data packets between different networks

The routing mechanism should be so simple that each network node can reroute data packets, even if it has a low memory capacity. Therefore, avoid extensive routing tables, complex calculations or queries at runtime.

Construct the control network hierarchically. Each node may possess a parent node and any number of child nodes. A node without a parent is a "top level" node. Cycles are not permitted, i.e. each control network has the structure of a tree.

Parent-child relationships results from the specification of certain network areas. A network area can be, for example, a local Ethernet or a serial point-to-point connection. We differentiate between the main network (mainnet) and the subnetworks (subnet). Each node belongs at the most to one main network, to which its parent node, if one exists, also belongs. For each node any desired number of subnets can be configured, for which the node acts in each case as a parent.

A network area may have only one parent node. Therefore, a configuration in which a network area is defined at the same time as a subnet of several nodes is invalid.

See also

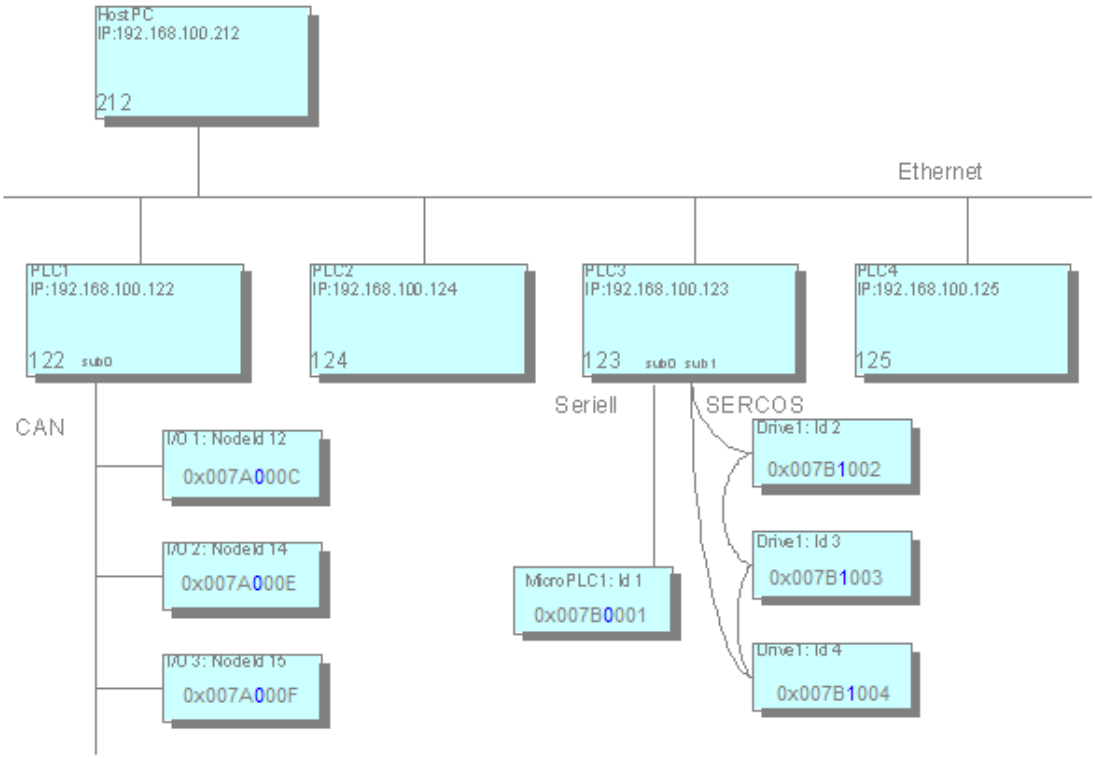
- *Chapter 1.4.1.9.1.2 “Addressing and Routing” on page 353*
- *Chapter 1.4.1.9.1.3 “Address Structures” on page 355*

Addressing and Routing

Addressing means: the topology of the control network is mapped to unique addresses.

A node address is composed hierarchically: for each network connection the associated block driver determines a local address, which uniquely identifies the node within the local network. The complete node address is formed as follows: The local address is placed in front of the subnet index of the local network assigned by the parent. In turn, the subnet index is placed in front of the node address of the parent. The length of the subnet index (in bits) is thereby determined by the device. The length of the local address, conversely, is determined by the type of network. A node without a main network is a top level node with address 0. A node with a main network that contains no parent is likewise a top level node. It is given the local address of the main network.

See an example of a control network here:



In the example the addresses of the nodes are represented in hexadecimal notation. The first 4 digits represent the address of the respective parent in the main network, for example `0x007A=122` for `PLC1`. The next byte (in blue lettering) is reserved for the subnet index and is followed by the local address, for example `C=12` for node ID `12`. The structuring of the addresses makes a lean routing algorithm possible. Routing tables, for example, are thus unnecessary. Information is queried only locally: via its own address and via the address of the parent node. On this basis a node can correctly process the data packets:

- If the destination address corresponds to the address of the current node, then this is meant to be the receiver.
- If the destination address starts with the address of the current node, then the data packet is either meant directly for a child or for a descendant of the node and must be forwarded.
- In all other cases the receiver is not a descendant of the current node and the data packet must be forwarded to its own parent.

Relative addressing is a special case: relative addresses do not contain the node number of the receiver, but directly describe the path from the sender to the receiver. The principle is similar to the relative path in the file system: the address consists of the number of steps via which the packet must be transported upwards. These are the steps to the corresponding parent and from the subsequent path downwards to the destination node.

The advantage of relative addressing is that two nodes in the same subtree can continue to communicate if the complete subtree is shifted to another place in the entire network. Whereas the absolute node addressing has to be modified due to this shift, the relative addressing is still valid.

Address determination

For a node to know its own address it must either know the address of its parent node or know that it is a top level node. For this purpose the node dispatches a message during the bootup to all network devices for address determination. As long as it receives no response to this message, the node considers itself to be a top level node, but continues to search for a possible parent. A parent node responds by announcing its address. The node will thus independently complete its address and will announce it to the subnets. An address determination can be accomplished during the bootup or at the request of the PC used for programming.

- *Chapter 1.4.1.9.1.3 “Address Structures” on page 355*

Address Structures

Network addresses

Network addresses represent a mapping of the addresses of the network type (for example IP) to logical addresses within a control network. This mapping is carried out by the corresponding block driver. The first three bytes of the IP address are identical for all network devices within an Ethernet network with "Class C" IP addresses. Consequently, the last 8 bits of the IP address suffice as network address, since they enable unambiguous mapping between the two addresses on the block driver.

A node has a different network address for each network connection. Different network connections can have the same network address, since each address need only be locally unique.

Terminology: the network address in the main network is usually designated as the network address of a node with no specification of the network connection.

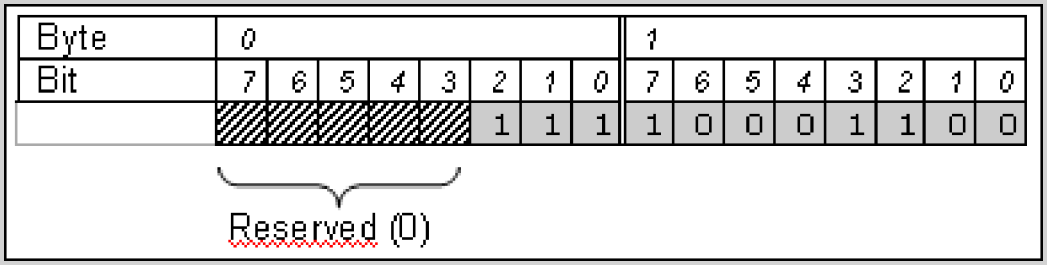
The length of a network address is specified in bits and can be chosen by the block driver as required. The same length must be used for all nodes within a network area. A network address is represented by an array of bytes in accordance with the following coding:

- Length of the network address: n bits
- Necessary bytes: b = (n + 7) DIV 8
- The (n MOD 8) bits of lowest rank of the first byte and all others (n DIV 8) are used for the network address.

Example of network address coding

Length: 11 bit

Address: 111 1000 1100



Node addresses

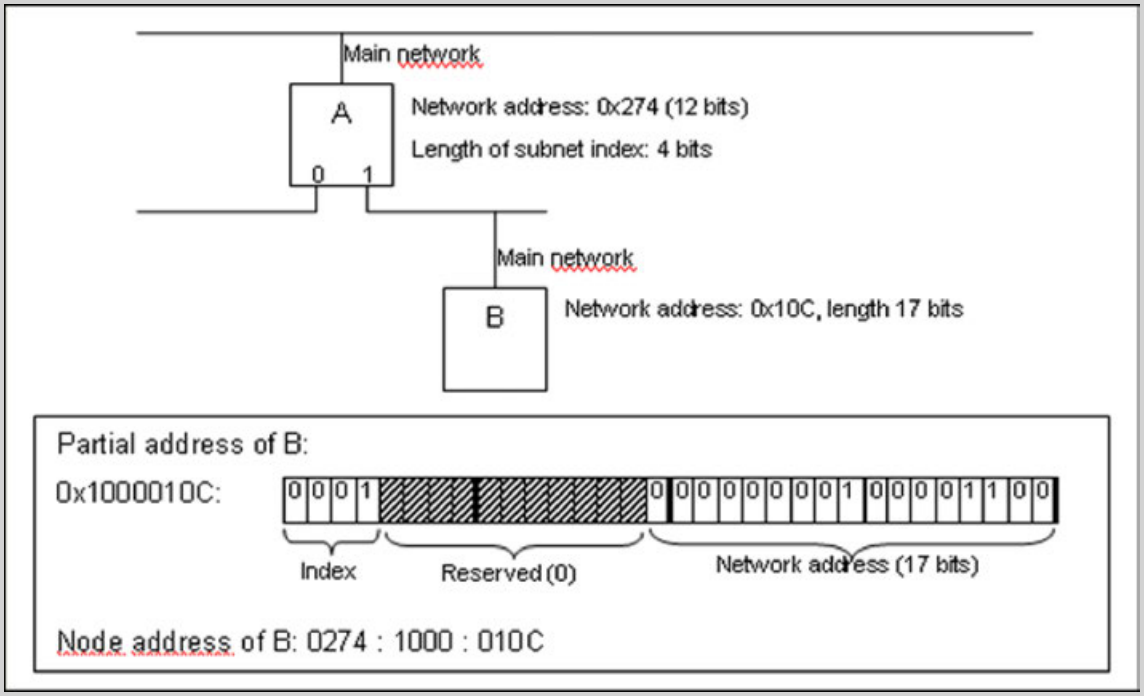
The node address indicates the absolute address of a node within a control network and is therefore unique within the whole "network tree". The address is composed of up to 15 address components, each of which occupies 2 bytes. The lower a node is located within the network hierarchy, the longer its address.

The complete node address consists of the partial addresses of all preceding nodes and the partial address of the node itself. Each partial address consists of one or more address components. The length is therefore always a multiple of 2 bytes. The partial address of a node is formed from the network address of the node in its main network and the subnet index of the main network in the case of the parent node. The bits required for the subindex are determined by the router of the parent node. Filler bits can be inserted between the subnet index and the network address in order to ensure that the length of the partial address is a multiple of 2 bytes.

Special cases:

- A node without a main network: this means that there is neither a subnet index nor a network address in the main network. In this case the address is set to 0x0000.
- A node in the main network without a parent: In this case a subnet index with the length 0 is assumed. The partial address corresponds to the network address, if necessary extended by filler bits.

Example of node addresses



The node address is always specified in hexadecimal. The individual address components (two bytes in each case) are separated by a colon ":". Since this represents an array of bytes and not a 16-bit value, the components are not displayed in the Intel format. For manually input addresses, missing parts in an address component are supplemented by leading zeros: "`274`" = "`0274`". In order to improve the legibility, the display should also always contain the leading zeros.

Absolute and relative addresses

Communication between two nodes can be based on relative or absolute addresses. Absolute addresses are identical to node addresses. Relative addresses specify a path from the sender to the receiver. They consist of an address offset and the descending path to the receiver.

The (negative) address offset describes the number of address components by which a packet must be passed upwards in the tree before it can be passed back down by the common parent node. Since nodes can use partial addresses that consist of more than one component, the number of parent components to be passed is always equal to the address offset. This means that the demarcation between the parent nodes is no longer clear. For that reason the common start of the address of the communication partners is used as the parent address. Each address component is counted as an upward step, independent of the current parent node. Each error resulting from this assumption can be detected by the corresponding parent node and must be handled by it accordingly.

After achieving the common parent node the relative path, as an array of address components, is followed downwards as usual. Formal: the node address of the receiver is formed by removing the last address offset components from the node address of the sender and by appending the relative path to the remaining address.

Example of the formation of node addresses

In the following example each address component is represented by a letter; in each case a dot separates nodes from each other. Since a node can carry several address components, there are some in the example that are represented with several letters.

Node A: `a.bc.d.ef.g`

Node B: `a.bc.i.j.kl.m`

- Address of the lowest common parent: `a.bc`
- Relative address from A to B: `-4/i.j.kl.m` (The number 4 results from the 4 components, `d`, `e`, `f` and `g`, which must pass on the data packet in the upward direction)

In order to guarantee correct operation of the routing, the relative address must be adapted each time it passes an intermediate node. It is sufficient to adapt the address offset. This is always done by the parent node: If a node receives a data packet from one of its subnets, the address offset is increased by the length of the address component of this subnet.

- If the new address offset is < 0, then the data packet must be passed further upward.
- If the address offset is >= 0, then the data packet must be passed on to the child node whose local address corresponds to the relative path, starting from the address offset. First of all, however, the address offset must be increased by the length of the local address of the child node, so that the child node sees the correct address.

A special situation results if the error mentioned above occurs during the determination of the common parent node. In this case the address offset of the actual parent node is negative, but this value is larger than the length of the partial address of the subnet from which the packet originated. So that the next node sees a correct relative address in this case, the node concerned must do the following: it must discover the error, calculate the local address of the child node on the basis of the address of the predecessor node and the length difference, and adapt the address offset accordingly. In this case, too, the address components as such remain unchanged; only the offset is changed.

Broadcast addresses

There are two types of broadcast - global and local. A global broadcast is sent to all the nodes in a network. The empty node address with a length of 0 is reserved for this purpose.

Local broadcasts are sent to all the devices in a network area. For this purpose, all the bits of the network address are set to 1. This is permissible both in relative and in absolute addresses.

A block driver must be able to process both kinds of broadcast addresses. This means: empty network addresses as well as network addresses whose bits were all set to 1 must be interpreted and sent to all devices concerned.

1.4.1.9.2 Symbol Configuration

Use the symbol configuration for preparing symbols with specific access rights for project variables. With these symbols, you can access the variables from outside, for example from an OPC server. When generating code, CODESYS also generates a symbol file (*.xml) that includes the description of the symbols.

The symbol file is stored in the project directory. The name of the symbol file is composed as follows: `<project name>.<device name>.<application name>.xml`

Example `proj_xy.PLC1.application.xml`

You can also generate the symbol file with the “Generate Code” command. This is very useful when downloading to the PLC is not possible.

The variables that you export as symbols can be bundled in the symbol configuration editor or defined in the variables declaration using the `{attribute 'symbol'}` pragma. Another option is using the element in the SFC editor, where you can define the implicitly generated element variables that should be exported to the symbol configuration.

The name of the symbol is generated in the symbol configuration in the following syntax: `<application name>.<POU name>.<variable name>`. When accessing the variable, you must always provide the complete symbol name in this syntax.

Example `MyApplication.PLC_PRG.a` or `MyApplication.SymFB.a`

As a rule, read-only access applies to symbols for input addresses and for variables that are mapped to input channels. Write access is possible for testing purposes in simulation mode only.

The symbol file is downloaded together with the application to the PLC. Depending on the device description, this file can be generated as an additional (child) application. This application is then listed on the *"Application"* tab of the device editor. Syntax: `<application name>._symbols`. The symbol application is regarded as a "normal" application with respect to the maximum number of applications on the PLC.

If your controller has a user management, then you can assign different access rights to a symbol to the individual user groups (clients). To do this, place the same symbol in different symbol sets and allow the individual user groups (clients) either to access a symbol set or not. An on-site operator or an operating data record, for example, receives more information and access to the same symbols as remote maintenance.

Creating a symbol configuration

Requirement: The project can be compiled without any errors.

1. Select the *"Application"* object in the device tree.
2. Click *"Project ➔ Add Object ➔ Symbol Configuration"*.
   ⇨ The *"Symbol Configuration"* object is added to the device tree and the objects editor opens.
3. Open the *"View"* menu of the editor and activate the categories of variables that should be provided in the configuration editor. Click *"Build"* in the symbol configuration editor.
   ⇨ All variables (according to the currently defined filter in the *"View"* menu) are displayed in a tree structure.
4. Select the check boxes of individual variables.

   Note: Pay attention to the current settings (see the *"Settings"* button in the menu bar of the editor).
   ⇨ In the field below the menu bar of the editor, information is provided about the current situation with accompanying instructions, as well as controls for corrective actions.

5. Follow the prompt in the field below the menu bar. In the following case, this should be only the information that the modified symbol configuration is transferred with the next download or online change.

   Click *"Build ➔ Generate Code"* on the CODESYS menu bar.

   ⇨ The `<project name>.<device name>.<application name>.xml` file is generated in the project directory.

CODESYS transmits the symbol configuration to the PLC for an application download or online change.

See also

- *Chapter 1.4.1.20.2.25 "Object 'Symbol Configuration'" on page 927*

Creating symbol sets with different access rights for different control clients

A symbol set is a defined set of symbols. If supported by the target device, you can combine different symbol sets from the symbols of the application in the symbol configuration editor. The information about the symbol sets is downloaded to the controller. Then you can define the user group that has access to each symbol set. Rights are assigned on the *"Symbol Rights"* tab of the device editor.

As a result, symbol sets allow different client-specific access rights to a symbol in the controller.

You can download changes to a symbol set definition to the controller in an online change. When the application is deleted on the controller, the symbol sets are also deleted. When building the application, you can create and save a symbol file in XML format for each symbol set.

In the following section, you will see an example of steps for creating symbol sets and the assignment of rights on the controller:

Requirements: The application has a defined symbol configuration in the project. The *"Enable symbol sets"* option is enabled in the settings of the symbol configuration. The controller has a user management. For the example here, there should be a user group that has the necessary rights for the servicing of the plant. By default, this type of user group, named "Service", is already created.

1. Define the connection to the controller in the *"Communication Settings"* of the device editor.
2. Click the button in the editor of the *"Symbol Configuration"* in order to create a new symbol set. Specify a name of the group ("Startup") in the *"Add New Symbol Set"* dialog.
3. Click the button (*"Build"*) in the toolbar of the dialog in order to display all symbols available in the project. Select the users who should belong to the group. Save the project.
4. Click the *"Configure Symbol Rights"* button.

   ⇨ The *"Symbol Rights"* tab of the device editor opens.
5. Click the button (*"Synchronization"*) to synchronize the display of the symbol sets with the device.

   ⇨ If you have not enabled user management on the controller yet, then you will see a dialog in the *"Users and Groups"* tab prompting you to do it.
6. Click *"OK"* in the dialog and click the *"Users and Groups"* tab.

   Click the button (*"Synchronization"*). Click *"Yes"* to confirm that user management should be enabled.

   ⇨ The *"Device User Logon"* dialog opens.
7. Sign in. If this is the first login, use "Administrator" as the user name and password, and then set a new password in the following dialog.

   ⇨ After the dialog is closed, the configurations of the device user management are displayed in the *"Users and Groups"* and *"Access Rights"* tabs.

8. Log in to the controller by clicking *“Online ➔ Login”*. Click *“Yes”* to the prompt of whether or not the application should be downloaded to the device.
9. After successful login, click the *“Symbol Rights”* tab. Click the *“Synchronization”* button.
   ⇨ In *“Symbol Sets”*, you see all sets that have currently been downloaded for the application (for this example, at least "startup"). In *“Rights”*, a table shows the user groups that are created in the user management of the controller. In the example, we assume that the default groups *“Administrator”* and *“Service”* have been created. When a symbol set is selected on the left, you see on the right the access rights of the individual user groups to this symbol set (: access granted; : access not granted). The possible type of access is already defined for each symbol in the symbol configuration (read, write, execute).
10. On the left, select the *“Startup”* symbol set and double-click the preset minus sign for "Administrator" as well as for "Service".
    ⇨ The symbol changes into a plus sign. The "Administrator" and "Service" now have access to the symbols in the *“Startup”* symbol set.

- *Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385*

1.4.1.9.3 Network Variables

The values of network variables can be exchanged between different PLCs in a network. The variables must be defined in strict, identical lists on both the sender device and receiver device, and only one device application defines the network variables. The lists can be in one or more projects.

The network variable list in the sender is a global variable list where specific log and transfer parameters are defined in their object properties. By adding these properties, you create a "network variable list (sender)" from an ordinary *“GVL”*. You can also insert a *“Network Variable List (Sender)”* object directly into the device tree when this object already has these parameters set.

The network variable list in the receiver is of type *“Network Variable List (Receiver)”*. When creating one, select the respective network variable list of the server. As an alternative, you can read this variable list from an export file that was generated from the sender list. An export file is required anyway for defining the sender list in another project.

The network variables are transmitted as broadcasting in one direction only: sender to receiver. However, it is also possible for a device to contain both sender and receiver lists.

For the `NetVarUdp` library version 3.5.7.0 and later, a receiver channel is no longer assigned when confirmed transfer is not selected. In this way, network variable exchange is also possible between two controllers on one hardware device .

NOTICE!

- If the exchanging devices should be senders and receivers, then the variable list identifiers must be unique in order to prevent abnormal operation. The variable list identifiers are defined in the *"Properties"* dialog of an object GVL.
- Data exchange via network variables is not possible when:
  - The device (target system) does not support it.
  - A firewall blocks the communication.
  - Another client or application is using the UDP port that is set in the properties of the network variable list.
  - More than one application per sender device and receiver device use network variable lists.
- Only arrays that have limits defined with a literal or constant are transmitted to the receiver application. Constant expressions are not permitted for this purpose.

  Example: "`arrVar : ARRAY[0..g_iArraySize-1] OF INT ;`" is not transmitted, but "`arrVar : ARRAY[0..10] OF INT ;`" is transmitted.
- The maximum size of a network variable is 255 bytes. The possible number of network variables is unlimited.
- If the size of the GVL exceeds the maximum length of the network telegram, then the data is split into multiple telegrams. Depending on the configuration, this can result in data inconsistencies.

Communication by means of network variables is also possible when the PLCs operated with applications from different versions of the development system (V2.3, V3). However, in this case, you cannot use the export/import mechanism for matching the variable lists exactly in the sender and receiver projects. The reason is that an variable export file (`*.exp`) that is generated from V2.3 does not include the required amount of information necessary for creating a receiving NVL in V3. There is no respective network parameter configuration as a GVL file, which you exported from the sender previously. To get this file, you must recreate the V2.3 NVL in V3 first. Then you can generate an export file and create a receiving NVL in V3 based on this.

An alternate to data exchange between PLCs is the use of data sources. As opposed to the broadcasting method for exchanging network variables, defined point-to-point connections are created between one application and a remote data source.

See also

- *Chapter 1.4.1.20.4.10.11 "Dialog 'Properties' - 'Network Variables'" on page 1163*
- *Chapter 1.4.1.20.2.10 "Object 'GVL' - Global Variable List" on page 871*

Configuring a Network Variable Exchange

The following steps are necessary for exchanging network variables between the sender device and receiver device.

1. Creating a network variable list in the sender device and generating an export file

Requirements: An application is inserted in the device tree of the PLC that has been employed as the sender device.

1. Select the application and insert a *“Network Variable List (Sender)”* object. Make the following settings in the *“Add Network Variable List (Sender)”* dialog: network type: `UDP`, example: "`NVL_Sender`".
2. Double-click the NVL object to open the respective editor and type the declarations of the network variables. Example:

```
VAR_GLOBAL
iglobvar:INT;
bglobvar:BOOL;
strglobvar:STRING;
END_VAR
```

3. Right-click the NVL object in the device tree to open the *“Properties”*. In the *“Properties”* dialog, open the *“Network Variables”* tab. This shows the following settings: Network type: UDP; List identifier: 1; Pack variables; Cyclic transmission: every 50 ms.
4. Note: You can also convert an existing GVL into a network variable list by configuring its network variable properties.
5. Click the *“Link to File”* tab.in the *“Properties”* dialog of the *“NVL_Sender”*. Define a file name `<export>.gvl` and a location in the file system for the export file of the GVL. Select the *“Export before compile”* option.
6. Click *“Build ➔ Generate Code”* to compile the application.

The export file for the network variable list is now located in the defined folder.

See also

- *Chapter 1.4.1.20.4.10.11 “Dialog 'Properties' - 'Network Variables'” on page 1163*

2. Creating an associated network variable list in the receiver device

Requirements: A sender device and a receiver device exist in the device tree. An application with a task configuration is inserted below the device. An NVL or a GVL is created below the sender device as network variable list to be sent.

1. Select the application of the receiver in the device tree and click *“Add Object ➔ Network Variable List (Receiver)”*.

   ⇨ The *“Add Network Variable List (Receiver)”* dialog opens.
2. In the dialog, select the previously created NVL of the sender device and type a name (for example, "NVL_Receiver"). CODESYS populates this receiver list automatically with the variable declarations from the sender list.

   Note: As an alternative, you can select the *“Import from file”* option and load the export file that was generated previously from the sender list.

3. Testing the network variable exchange

Requirements: A network variable list (sender) exists in the sender device, a network variable list (receiver) exists in the receiver device, and both lists have identical variable declarations.

1. Below the application in the sender device, create a program that increments a network variable. Example: `iglobvar:=iglobvar+1;`.
2. Configure the application task so that this program calls it.

3. Below the application in the receiver device, create a program that writes the value of this network variable to a local variable. Example: `ilocalvar:=iglobvar;`.
4. Configure the application task so that this program calls it.
5. Download both applications to the controllers and start them. (Set the application as active, login, download, and start.)
6. In the online views of the editors of both programs, check whether the values of `iglobvar` match in the receiver and the sender.

See also

- *Chapter 1.4.1.20.2.16 “Object 'Network Variable List (Sender)'” on page 880*
- *Chapter 1.4.1.20.2.17 “Object 'Network Variable List (Receiver)'” on page 880*

1.4.1.9.4 Data Link with Data Sources

In order to have read/write access to the remote devices and their running applications, you can add a data source manager to your application with one or more data sources.

The functionality of the data source manager allows for establishing connections and communication to remote devices, and it makes its data available through data source variables. At this time, the partners communicate by means of a point-to-point connection. Depending on the network where the controllers are located, a connection is established via the CODESYS data source types or CODESYS ApplicationV3.

Data source type CODESYS Symbolic

The data source type CODESYS Symbolic is available **only** together with a CODESYS HMI device. However, then it is advantageous to use this type.

Below a CODESYS HMI device, you can configure the data link either with data source type CODESYS Symbolic or with data source type CODESYS ApplicationV3. We recommend that you select the data source type CODESYS ApplicationV3 only when there are no resources for the symbol configuration available on the remote device. For example, this is the case with embedded or mini PLCs whose applications often do not contain a symbol configuration.

The requirement for a connection setup is that symbols have been configured in the remote device and as a result a symbol file exists. The application in the remote device has a symbol configuration. Then the data link can take place via symbolic monitoring.

In the case of symbolic monitoring, the symbol file on the remote device is read and the stored variable information is used for the data source variables and the data transfer. The advantage is that the application does not have to be updated in the local device when someone modifies the remote application without updating its symbol configuration. If the symbol file is also located on your development system (either a file or a symbol configuration object as part of your project), then the local symbol file can also be read. Then you can work offline during the development phase.

During the development phase, you can create a variable list offline by means of local symbol configuration files. In this way, you can develop a local application offline based on the symbol information without a connection to a data source.

The following connection types are possible:

- *“CODESYS V2”*:
  The devices exist in the same network. The V2 runtime on the remote PLC provides a communication interface.
- *“CODESYS V2 (Via gateway)”*
  The devices do not exist in the same network. They are connected via a V2 gateway.
  Note: For this connection, a *“CoDeSys V2.3 Gateway Server”* (V2 gateway) has to be installed on the development computer where CODESYS V3 is running.

- *“CODESYS V3”*
  The devices exist in the same network. The V3 runtime on the remote PLC provides a communication interface.
- *“CODESYS V3 (Via gateway)”*:
  The devices do not exist in the same network. They are connected via a V3 gateway.

Data source type CODESYS ApplicationV3

This data source type is available below all device types.

The data link with CODESYS ApplicationV3 data source type in done by means of address monitoring. This requires that the address information between the remote PLC and the local device match. The runtime system of the local application needs valid communication parameters in order to establish the connection.

The network scan function can support you when configuring the data source.

Disadvantage: If you modify the remote application, then you also have to update the local application afterwards (for example, the HMI application.

The advantage is that a symbol configuration is not required in the remote application.

Data transmission

At runtime of the local application, the data source variables that appear in the data source editor of the *“Variables”* tab are updated in configurable time intervals. The remote application is also executed at this time. Variables that are configured in the visualization, in the trend, as alarms, or for recipes are transferred and stored automatically. When a variable is accessed in IEC code only, the variable is not updated automatically. In this case, you have to select the *“Update always”* option in the data source editor of the *“Variables”* tab.

The data source types support the (read or write) data access to variables of the source PLC for the following data types:

- Scalar value at top level
  Example: `PLC_PRG.hugo`
- Property to a program or GVL by means of a call when it is marked with `{attribute monitoring := 'call'}`.
  Example: `PLC_PRG.PropertyCall`
- Variable which is mapped to bit addresses
  Example in `PLC_PRG`: `x AT %MX0.5 : BOOL;`
- Variable (type `BIT`) in a function block
  Example: Declaration in `DUT`: `x, y : BIT`, bit access: `PLC_PRG.dutInst.y`
- Structured obtainable variable
  Example: `PLC_PRG.outerInst.innerInst.dwVar`
- Property to POU instance when it is marked with `{attribute monitoring := 'call'}`.
  Example: `PLC_PRG.instance.PropertyCall`
- Property at top level and to an instance when it is marked with `{attribute monitoring := 'variable'}`.
  Note: This cannot be written by monitoring or by the data sources.
- Array access with literal index
  Example: `PLC_PRG.arrOfInts[3]`, `PLC_PRG.inst.arrOfBool[1]`
- Nested access (for example, array of structures or structure of arrays)

CAUTION!
Bit access used in visualizations that are transferred via a data source connection function only if they contain literal offset specifications. A visualization cannot process an offset specification by defined constants.

- *“Dialog 'Add Data Source'” on page 822*
- *Chapter 1.4.1.20.2.5 “Object 'Data Source'” on page 823*

Initially Adding a Data Source

For data exchange between your local device and a remote device, add a *“Data Source Manager”* object and then a *“Data Source”* below your application in the device tree. A wizard guides you through the configuration of the data source. Afterwards, you can change the settings at any time in the editor of the object. However, it is not possible to modify the data source type later.

Use the “CODESYS Symbolic” data source type unless there are no resources available in the remote PLC for a symbol configuration. As long as the symbol configuration in the remote device is not impacted by an application change, you have the advantage that the application in the local device does not have to be updated.

When adding a data source, select a data source type. Then specify the connection settings of the point-to-point connection to the remote device. Ideally, the remote device is running during this time and CODESYS can establish the connection to it immediately. Then all available data source variables from the remote PLC are displayed. Select the variables that should be transferred. You can also select all variables. Then the data source is initialized automatically, the data source variables are created below the *“DataSources_Objects”* folder, and another data source is added below the data source manager.

If the data is transferred using symbolic monitoring and the symbol file is stored on your development system, then you can read the variable information from the symbol file and work offline. The symbol file is stored either as a file on your development system or as a symbol configuration object as part of your project (in CODESYS).

The initial settings can be changed at any time in the data source editor.

Initially connecting devices symbolically via 'CODESYS V3'

A *“CODESYS Control Win V3”* is running on the remote device. Moreover, an application is running with a symbol configuration.

1. Below your application in the device tree, insert a *“Data Source Manager”* object.
2. Select the *“Data Source Manager”* object and click *“Add Object ➔ Data Source”*.
   ⇨ The *“Add Data Source”* dialog opens.
3. In the *“Name”* field, specify the data source name.
   ⇨ Example: `ds_Remote_Device`

4. As the data source type, select *“CODESYS Symbolic”*.
   ⇨ The data transfer is done via symbolic monitoring. The *“Initialize Data Source Wizard - Provider settings”* dialog opens.
5. As the connection type, select *“CODESYS V3”*.
6. For *“Type of name or address”*, select the *“Node name”* option.
7. In the *“Connection Settings”* group, specify the connection parameters for configuring the remote device. Example: *“[03A7)”*
   ⇨ The connection to the remote device is established and the application is read. The *“Initialize Data Source Wizard - Browse data items”* dialog also opens. The read remote control variables are displayed in the tree view on the *“Variables”* entry. The top node is the application, which is displayed with its remote application name.
8. In the tree view, select which control variables should be transferred. Then click *“Finish”*.
   ⇨ The data source is initially configured. The `ds_Remote_Device` object is added below the *“Data Source Manager”* node. The object is open, and on the *“Variables”* tab, the data source variables to be generated are displayed in the tree view. The GVL `ds_Remote_Device`, where the data source variables are declared, is located below the *“DataSource_Objects”* folder.

Initially connecting devices symbolically via 'CODESYS V3 (Via gateway)'

A *“CODESYS Control Win V3”* is running on the remote device. Moreover, an application is running with a symbol configuration. The remote device exists in another network so that the communication has to be routed via a gateway.

1. Below your application in the device tree, insert a *“Data Source Manager”* object.
2. Select the *“Data Source Manager”* object and click *“Add Object ➔ Data Source”*.
   ⇨ The *“Add Data Source”* dialog opens.
3. In the *“Name”* field, specify the data source name.
   ⇨ Example: `ds_Remote_Device`
4. As the data source type, select *“CODESYS Symbolic”*.
   ⇨ The data transfer is done via symbolic monitoring. The *“Initialize Data Source Wizard - Provider settings”* dialog opens.
5. As the connection type, select *“CODESYS V3 (Via gateway)”*.
   ⇨ You can also specify the communication parameters for the gateway.
6. For *“Type of name or address”*, select the *“Node name”* option.
7. In the *“Connection Settings”* group, specify the connection parameters for configuring the remote device. Example: *“[03A7)”*
   ⇨ The connection to the remote device is established and the application is read. The *“Initialize Data Source Wizard - Browse data items”* dialog also opens. The read remote control variables are displayed in the tree view on the *“Variables”* entry. The top node is the application, which is displayed with its remote application name.
8. In the tree view, select which control variables should be transferred. Then click *“Finish”*.
   ⇨ The data source is initially configured. The `ds_Remote_Device` object is added below the *“Data Source Manager”* node. The object is open, and on the *“Variables”* tab, the data source variables to be generated are displayed in the tree view. The GVL `ds_Remote_Device`, where the data source variables are declared, is located below the *“DataSource_Objects”* folder.

Initially connecting devices symbolically via 'CODESYS V2'

A *"CoDeSys V2.3 SP PLCWinNT V2.4"* is running on the remote device. Moreover, an application is running with a symbol configuration.

1. Below your application in the device tree, insert a *"Data Source Manager"* object.
2. Select the *"Data Source Manager"* object and click *"Add Object ➔ Data Source"*.
   ⇨ The *"Add Data Source"* dialog opens.
3. In the *"Name"* field, specify the data source name.
   ⇨ Example: `ds_Remote_Device`
4. As the data source type, select *"CODESYS Symbolic"*.
   ⇨ The data transfer is done via symbolic monitoring. The *"Initialize Data Source Wizard - Provider settings"* dialog opens.
5. As the connection type, select *"CODESYS V2"*.
6. In the *"Connection Settings"* group, specify the connection parameters for configuring the remote device.
   Example: driver type `TCP/IP (Level 2 Route)`, address `localhost`, port `1200`
   ⇨ The connection to the remote device is established and the application is read. The *"Initialize Data Source Wizard - Browse data items"* dialog also opens. The read remote control variables are displayed in the tree view on the *"Variables"* entry.
7. In the tree view, select which control variables should be transferred. Then click *"Finish"*.
   ⇨ The data source is initially configured. The `ds_Remote_Device` object is added below the *"Data Source Manager"* node. The object is open, and on the *"Variables"* tab, the data source variables to be generated are displayed in the tree view. The GVL `ds_Remote_Device`, where the data source variables are declared, is located below the *"DataSource_Objects"* folder.

Initially connecting devices symbolically via 'CODESYS V2 (Via gateway)'

A *"CoDeSys V2.3 SP PLCWinNT V2.4"* is running on the remote device. Moreover, an application is running with a symbol configuration. The remote device exists in another network so that the communication has to be routed via a gateway.

1. Below your application in the device tree, insert a *"Data Source Manager"* object.
2. Select the *"Data Source Manager"* object and click *"Add Object ➔ Data Source"*.
   ⇨ The *"Add Data Source"* dialog opens.
3. In the *"Name"* field, specify the data source name.
   ⇨ Example: `ds_Remote_Device`
4. As the data source type, select *"CODESYS Symbolic"*.
   ⇨ The data transfer is done via symbolic monitoring. The *"Initialize Data Source Wizard - Provider settings"* dialog opens.
5. As the connection type, select *"CODESYS V2 (Via gateway)"*.
   ⇨ You can also specify the communication parameters for the gateway.
6. In the *"Connection Settings"* group, specify the connection parameters for both the gateway and the device configuring the remote device.
   Example: driver type `TCP/IP (Level 2 Route)`, address `localhost`, port `1200`
   ⇨ The connection to the remote device is established and the application is read. The *"Initialize Data Source Wizard - Browse data items"* dialog opens. The remote control variables are displayed in the tree view on the *"Variables"* entry.

7. In the *“Connection Settings”* group, specify the connection parameters for configuring the remote device. Example: *“[03A7)”*

   ⇨ The connection to the remote device is established and the application is read. The *“Initialize Data Source Wizard - Browse data items”* dialog opens. The read remote control variables are displayed in the tree view on the *“Variables”* entry. The top node is the application, which is displayed with its remote application name.

8. In the tree view, select which control variables should be transferred. Then click *“Finish”*.

   ⇨ The data source is initially configured. The `ds_Remote_Device` object is added below the *“Data Source Manager”* node. The object is open, and on the *“Variables”* tab, the data source variables to be generated are displayed in the tree view. The GVL `ds_Remote_Device`, where the data source variables are declared, is located below the *“DataSource_Objects”* folder.

Initially adding data source variables from a symbol file

Ideally, the same symbol file on the remote device is saved on your development system.

1. Below your application in the device tree, insert a *“Data Source Manager”* object.
2. Select the *“Data Source Manager”* object and click *“Add Object ➔ Data Source”* in the context menu.

   ⇨ The *“Add Data Source”* dialog opens.

3. In the *“Name”* field, specify the data source name.

   ⇨ Example: `ds_Symbols`

4. As the data source type, select *“CODESYS Symbolic”*.

   ⇨ The data transfer is done via symbolic monitoring. The *“Initialize Data Source Wizard - Provider settings”* dialog opens.

5. In *“Variable information”*, click the *“From symbol file”* entry.
6. In *“Select symbol file”*, specify the location and the file name of the symbol file. When the code is generated, an XML symbol file is created in the project directory by default.

   ⇨ Example: `D:\Projects\V3.5 SP11\Project_A.Device.Application.xml`

   Hint: When a symbol file is specified, no additional connection settings have to be configured. A connection is not established. You are working offline. You have to configure the connection settings only when you need current data from the controller which is transferred online. In the *“Variable information”* settings, select the *“From connection settings”* option.

7. Click the *“Next”* button.

   ⇨ The *“Initialize Data Source Wizard - Browse data items”* dialog opens. The read symbols are displayed in the tree view on the *“Variables”* entry.

8. In the tree view, select the symbols to be transferred. Then click *“Finish”*.

   ⇨ The data source is initially configured. The `ds_Symbols` object is added below the *“Data Source Manager”* node. The object is open, and on the *“Variables”* tab, the data source variables that were generated based on the symbol file are displayed in the tree view. The GVL `ds_Symbols`, where the data source variables are declared, is located below the *“DataSource_Objects”* folder.

Initially adding data source variables from a symbol configuration

Your active project contains the control application for the remove device. The control application includes a symbol configuration with symbols that are added to your local application as data source variables.

1. Below your local application in the device tree, insert the *"Data Source Manager"* object.
2. Select the *"Data Source Manager"* object and click *"Add Object ➔ Data Source"*.
   ⇨ The *"Add Data Source"* dialog opens.
3. In the *"Name"* field, specify the data source name.
   ⇨ Example: `ds_Symbols`
4. As the data source type, select *"CODESYS Symbolic"*.
   ⇨ The data transfer is done via symbolic monitoring. The *"Initialize Data Source Wizard - Provider settings"* dialog opens.
5. In *"Variable information"*, select the *"<remote device>.<application>.symbol configuration"* entry.
   ⇨ Example: `Device.Application.Symbol Configuration`

   Hint: When a symbol file is specified, no additional connection settings have to be configured. A connection is not established. You are working offline.
6. Click the *"Next"* button.
   ⇨ The *"Initialize Data Source Wizard - Browse data items"* dialog opens. The read symbols are displayed in the tree view on the *"Variables"* entry.
7. In the tree view, select the symbols to be transferred. Click *"Finish"*.
   ⇨ The data source is initially configured. The `ds_Symbols` object is added below the *"Data Source Manager"* node. The object is open, and on the *"Variables"* tab, the data source variables that were generated based on the symbol configuration are displayed in the tree view. The GVL `ds_Symbols`, where the data source variables are declared, is located below the *"DataSource_Objects"* folder.

Initially connecting devices with address monitoring

A *"CODESYS Control Win V3"* is running on the remote device. The project of the remote device is located on your development computer. The engineered application there does not contain a symbol configuration.

Use this communication link only if there are no resources available in the remote PLC for a symbol configuration.

1. Below your application in the device tree, insert a *"Data Source Manager"* object.
2. Select the *"Data Source Manager"* object and click *"Add Object ➔ Data Source"*.
   ⇨ The *"Add Data Source"* dialog opens.
3. In the *"Name"* field, specify the data source name.
   ⇨ Example: `ds_Remote_Device`
4. As the data source type, select *"CODESYS ApplicationV3"*.
   ⇨ The data transfer is done by means of address monitoring. The *"Initialize Data Source Wizard - Provider settings"* dialog opens.
5. For *"Select the project type"*, select the *"Other Project"* option.
6. For *"Choose file"*, specify the file and location of the project on the remote device. Example: `C:\Data\Projects\PLC_A.project`.
   ⇨ The remote device is displayed in the tree view of the window below, and as a result the connection was established.
7. Click the *"From device"* link.
   ⇨ The connection parameters to the remote device are read and displayed in the dialog. The connection is configured.

8. Click *“Next>”*.

   ⇨ The *“Initialize Data Source Wizard - Browse data items”* dialog opens. The remote control variables are displayed in the tree view on the *“Variables”* entry.

9. In the tree view, select which control variables should be transferred. Then click *“Finish”*.

   ⇨ The data source is configured. A connection is established. The settings are stored in the object and can be modified in the editor of the object.

   The data source is initially configured. The `ds_Remote_Device` object is added below the *“Data Source Manager”* node. The object is open, and on the *“Variables”* tab, the data source variables to be generated are displayed in the tree view. The GVL `ds_Remote_Device`, where the data source variables are declared, is located below the *“DataSource_Objects”* folder.

- *Chapter 1.4.1.20.2.5.4 “Tab 'Communication' via CODESYS ApplicationV3” on page 831*

Editing data source variables

In runtime mode, the remote data is saved to the data source variables. The data source variables and their mapping to the remote variables are displayed in the data source editor below of the *“Variables”* tab. If the local and remote variables have the same names and the same data types, then the data is mapped 1:1. The variables and the data types are created automatically. That is the regular procedure.

You can also map to existing variables. This is necessary, for example, if a visualization includes a data type in an interface. Then the same data must be passed to this visualization. In this case, the declared local variable and the remote variable have the same data type, for example from one library. Moreover, you can map a local variable with a conforming data type to a remote variable. The data type can be created in the *“Type Mappings”* tab.

The specifically created variables and data types are declared in the *“DataSources_Objects”* folder. For each data source, a global variable list of the same name as the data source is declared there. Moreover, the data source variables usually have the identical or conforming data type as the remote control variable and they are declared as user-defined data types (DUT objects). Considering all data sources, multiple declaration of the same data types is avoided.

Do not edit the data interface in the *“DataSources_Objects”* folder manually. It is created initially when adding a data source. Changes can be made later in the editor of the data source.

See also

- *Chapter 1.4.1.9.4.4 “ Updating data interfaces” on page 373*
- *Chapter 1.4.1.20.2.5.1 “Tab 'Variables'” on page 824*

Selecting variables for data transfer

You can edit the selection of the data source variables.

☑ Requirement: The remote device and its application are running. A data source manager is already inserted below the local application with a data source.

1. Open the editor of the data source.
2. Select the *“Variables”* tab.
3. Click *“Update Variables”*.

   ⇨ The *“Browse Variables”* dialog opens.

4. Activate the variables that should be transferred and click *“OK”* to close the dialog.

   ⇨ The data source variables are modified according to the selection. The declaration of variables and data types is also modified.

   The *“Variables”* tab shows the modified selection. Moreover, the mapped remote variable is listed in the *“Remote variable”* column.

See also

- *Chapter 1.4.1.9 “Working with Controller Networks” on page 352*
- *Chapter 1.4.1.9.4.4 “ Updating data interfaces” on page 373*
- *Chapter 1.4.1.20.2.5.1 “Tab 'Variables'” on page 824*

Mapping remote variables to a new variables

You need to map a remote variable to a global implicit variable that is created new. That is the regular procedure for transposing data source to 1:1.

☑ Requirement: A project is open. A data source manager and a data source below it are located in the device tree of the local application.

1. Open the editor of the data source.
2. Select the *“Variables”* tab.

   ⇨ The data source variables are listed.
3. Select a variable and click the symbol in the *“Create or map”* column.
4. Specify a name in *“Local variable”*.

   ⇨ A variable is declared automatically and it contains the same value as the mapped remote variable.

Mapping remote variables to a existing variables

You need to map a remote variable to an existing variable.

☑ Requirement: A data source manager and a data source below it are located in the device tree of the local application. The remote data that should be transferred is displayed in the editor of the data source in the *“Variable”* tab

1. Open the editor of the data source.
2. Select the *“Variables”* tab.
3. Select a variable and click the symbol in the *“Create or map”* column.

   ⇨ A variable contains the same value as the mapped remote variable.

Mapping remote variables to local variables with a conforming data type

First, create a conforming data type and then use it for a variable.

☑ Requirement: A data source manager and a data source below it are located in the device tree of the local application. The remote data that should be transferred is displayed in the editor of the data source in the *“Variable”* tab

1. Open the editor of the data source.
2. Select the *“Type Mappings”* tab.

3. Select the data type in the list that you want to edit.
   ⇨ The elements of the data type are listed in the window below the data type list
4. Specify a name for the data type. Example: `DataType_A`. Select the name for the remote data types to which the local type should conform. Example: `Library1.DataType_A`.
5. Modify it in the window below the data type list and remove the elements that are not necessary for the data transfer.
6. Select the symbol for this data type in the *“Create or map”* column.
   ⇨ The data type `DataType_A` is declared in the *“DataSources_Objects”* folder.
7. Select the *“Variables”* tab.
8. Specify a name in the *“Local variable”* column. Example: `Var_A`
9. Select the symbol in the *“Create or map”* column.
10. Specify the data type `DataType_A` in the *“Mapping type”* column.
11. Select the remote variable with the data that should be transferred. Example: `appPLC_A.Data_A`. Use the input assistance for this.
    ⇨ A variable `Var_A` is declared automatically with the user-defined data type `DataType_A`. During data transfer, it receives the data of the mapped remote variables.

Example

Library `SnakeUtil`

The example demonstrates how variables of the data source are created. At this time, new variables are created, data is mapped to existing data types and their variables, and new data types are created with type-conforming mapping.

The remote PLC uses POU instances from the `SnakeUtil` library and the HMI device visualizes these POU instances. This is why the HMI application requires a variable in the operating interface that has a data type appropriate for a visualization template. As a result, the `SnakeUtil` library is linked integrated into the HMI application and the HMI variables instantiate the `SnakeUtil.SnakeVisu` visualization function block.

The following library function blocks from the `SnakeUtil` library are used in the remote PLC.

- Function block `SnakeUtil.Snake`: Equipped with much logic and calling from external functions.
- DUT `SnakeUtil.PositionInfo`: Two values (of the variables x and y)
- DUT: `SnakeUtil.DrawingInfo`: Image ID
- The `SnakeUtil.SnakeVisu` visualization function block with transfer parameter `SnakeUtil.Snake` visualizes the `Snake` function block.

The following settings are entered in the editor of the *“Type Mappings”* tab:

SnakeUtil.PositionInfo		PositionInfo	SnakeUtil.PositionInfo
GeneratedType_2		GeneratedType_2	GeneratedType_2
GeneratedType_3		GeneratedType_3	GeneratedType_3
Snake		Snake	SnakeUtil.Snake
SnakeUtil.DrawingInfo		DrawingInfo	SnakeUtil.DrawingInfo

In the visualization, a frame is inserted with a reference to `SnakeUtil.SnakeVisu`. This expects to have the type `SnakeUtil.Snake`.

The data types `SnakeUtil.PositionInfo` and `SnakeUtil.DrawingInfo` are mapped to existing data types (symbol in the *“Create or map”* column). The data types are small and contain data only.

The `SnakeUtil.Snake` function block is very complex and calls external functions that are not available in the HMI visualization. The function block with code is not required in the visualization. You need a less extensive but compatible and conforming type in the HMI visualization. Therefore, do not create the original data type directly. Instead, first modify the original data type and remove the unnecessary elements. Then create the new data type `Snake` by selecting the symbol in the *“Create or map”* column.

Editing Communication

You have added a *“Data Source Manager”* object and below it a *“Data Source”* object below your application in the device tree. The connection parameters are displayed in the data source editor of the *“Communication”* tab. You can modify it there.

The data source type and the current connection type are listed in the status bar. It is not possible to modify the data source type later.

See also

- *Chapter 1.4.1.9.4.1 “Initially Adding a Data Source” on page 365*
- *Chapter 1.4.1.20.2.5.3 “Tab 'Communication' via CODESYS Symbolic” on page 826*
- *Chapter 1.4.1.20.2.5.4 “Tab 'Communication' via CODESYS ApplicationV3” on page 831*

Updating data interfaces

The data source variables are updated cyclically in runtime mode. Only the data is updated that either is used in the current visualization or has the property *“Update always”*.

You can define the time interval. Moreover, you can define variables whose data is transferred in each update interval, and therefore they are always update. To update variables that are not used in the application code, you can implement an update programmatically with the help of interface functions from the data source manager.

> **NOTICE!**
> If data traffic between the remote and local device is too high, then the update rate is reduced automatically. This can lead to an incomplete transfer.

See also

- *Chapter 1.4.1.20.2.5.1 “Tab 'Variables'” on page 824*

Setting the update rate

1. Open the editor of the data source.
2. Click the *“General and Diagnosis”* tab.
3. Specify a value in the *“Update rate”* field.

   Example: `100`

   ⇨ The data from the remote device to the local device is transferred every 100 ms.

See also

- *Chapter 1.4.1.20.2.5.6 “Tab 'General and Diagnosis'” on page 834*

Selecting the variable for 'Update always'

> **NOTICE!**
> Avoid updating too many variables always. Each update produces additional data traffic at the connection between the remote and local devices. When data traffic is too high, the update rate is reduced automatically. This can lead to an incomplete transfer.

1. Open the editor of the data source.
2. Activate the option *“Update always”* for a variable.

   ⇨ The data of the variables is transferred at each update cycle, even when the data has not changed.

See also

- *Further information on page 824*

Updating data programmatically

The data source manager provides interface functions in the `Datasources` library. If a data source manager is integrated in the application code, then the global variable `g_Datasources` is instantiated automatically. This provides access to the interface functions.

Then you can update individual variables that are not called in the active visualization.

Example

The variable `ivar` is activated and deactivated by means of methods from the `Datasources` library so that its value is transferred. Furthermore, you can configure that the variable is updated only over a defined duration in order to save transfer capacity.

```
//Synchronize with DatasourcesTask and block until access is
possible
//Regard the feedback in ERR_OK or in ERR_DE_MULTITASKING_LOCKED
g_Datasources.BeginDataConfiguration(TRUE);
// Activate variable
g_DataServer.UseData(ADR('RemoteDevice.Application.PLC_PRG.iVar'));
// Deactivate variable
//
g_DataServer.ReleaseData(ADR('RemoteDevice.Application.PLC_PRG.iVar'
));
g_DataServer.EndDataConfiguration();
```

The data configuration is started with `BeginDataConfiguration(TRUE)`, thus initializing the synchronization of the task `DatasourceTask` with the application task. The value `TRUE` blocks the processing until the access to the variable is possible; `FALSE` repeats access attempts without blocking. The return values `ERR_OK` and `ERR_DS_MULTITASKING_LOCKED` provide feedback about the access attempts.

When synchronization is successful, the variable is activated by means of the `UseData` method. Then the data configuration is completed with the `EndDataConfiguration` method and the synchronization triggered again with the task `DatasourceTask`.

The `ReleaseData` method is used in the same way for deactivating the variable again at the desired processing time.

Using remote data

The variables that are listed in the data source editor of the *"Variables"* tab (and declared in the *"DataSources_Objects"* folder) can be used in your application like IEC variables. For example, you can visualize the variables.

If multiple data sources are available and therefore conflicts occur regarding unique variable names, then you must specify the data source name as the prefix. If no conflicts occur, then this is not necessary and you can map the variables without a data source prefix.

```
<data source name>.<function block name>.<variable name>
```

Displaying variable values from the remote device

You need to show the variable value `iTemp` of a remote device in a visualization element of a visualization in the local application (with the data source manager).

Initial situation: A data source `dsRemotePLC` is below the local data source manager where the connection to the remote device is configured. In addition, the variable `iTemp` is selected in the data source editor of the *"Variables"* tab.

1. Select the visualization element in the editor view. Select the properties *"Text variables"* - *"Text variable"* in the *"Properties"* view.
2. Select the `iTemp` variable.
   ⇨ The variable mapping is qualified. Example: `dsRemotePLC.PLC_PRG.iTemp`.
3. Select the *"Text"* property of the visualization element and type in the following: `Temperature: %s`
   ⇨ The value of the `iTemp` variable from the remote device `RemoteDevice` is displayed.
4. Download and start the remote application.
5. Download and start the local application.
   ⇨ The visualization starts and displays the actual value of `iTemp`.

NOTICE!
The visualization integrated in CODESYS does not display actual values of variables that are transferred by means of a data source connection. The integrated visualization displays only the initialization values or the last otherwise delivered values because they do not establish a connection to the data sources.

NOTICE!
If variables are used that are not called in the visualization code, then the variables must be updated in the application code by means of functions from the data source interface.

Establishing an Encrypted Connection of a Data Source OPC UA Client to an OPC UA Server

Requirement:

- An OPC UA Server is available. For a description of the OPC UA Server which is included in the standard installation CODESYS, see the chapter "OPC UA Server".
- You have installed the CODESYS Security Agent add-on in CODESYS.
- CODESYS is open.
- The *"Allow anonymous login"* option is selected for your controller in the *"Change Communication Policy"* dialog of the device editor (*"Communication Settings"* tab, *"Change Communication Policy"* command, *"Device"* menu). Or the user management has been explicitly disabled (for example, by switching to *"Optional user management"* in the *"Change Communication Policy"* dialog) and then *"Reset Origin"*.

1. Start the OPC UA Server.
2. Create a new CODESYS project.
3. Add a *"Data Source Manager"* object to the application.
4. Add a *"Data Source" "OPCUAClient"* to the *"Data Source Manager"*.
   ⇨ The *"Datasource"* dialog opens.
5. In the *"Datasource"* dialog, specify the URI of the started OPC UA Server and select the *"Information Model Source"*. When you select *"Online"* as the *"Information Model Source"*, the OPC UA Client connects to the OPC UA Server and reads the information about which variables and types exist. When you select *"Offline"*, the client reads the same information from an installed information model and does not require a running OPC UA Server to do this.
6. For *"Message Security Mode"*, select *"Sign and Encrypt"*.
   Note: You should use *"Message Security Mode"* = *"None"* only in closed networks.
7. Click *"Next"*.Now the client scans the OPC UA Server to find the variables and types of the OPC UA Server. The OPC UA Server has to be online to do this.
8. Now select one or more variables.
   ⇨ These variables can be exchanged later via encrypted communication between the OPC UA Client and the OPC UA Server. For the variables, components are created in the *"Devices"* view, in the *"DataSources_Objects"* folder. The variables can be used in the application.
9. In the next steps, you create a certificate for the encrypted communication from the OPC UA Client to the OPC UA Server.
10. Click *"View* ➔ *Security Screen"*.
11. Select the *"Devices"* tab.

12. Select the controller in the left view.
    ⇨ In the right view, all services of the controller are displayed which require a certificate.
13. Select the service *"CmpOPCUAClient"*.
14. Create a new certificate for the device. Click the  icon.
    ⇨ The *"Certificate Settings"* dialog opens.
15. Define the certificate parameters and click *"OK"* to close the dialog.
    ⇨ The certificate is created on the controller.
16. Click the  button and save the certificate to the local file directory of the OPC UA Server, in the folder `certs`.
    ⇨ Now when you restart the OPC UA Server, it will recognize the client certificate. The the server sends its certificate to the client. In the following steps, this certificate will be made "trusted" to the client.
17. To do this, in the *"Security Screen"* view, on the *"Devices"* tab, click the *"Certificates in Quarantine"* folder in the left area.
    ⇨ The certificate is displayed in the right area.
18. Drag this certificate to the *"Trusted Certificates"* folder.
    ⇨ Now the server certificate is "trusted" by the client.
19. Now when you connect to the controller and the application starts, the data source variables of the OPC UA Client can be exchanged with the OPC UA Server via the encrypted connection.

Establishing an Encrypted Connection of a Data Source OPC UA Client to an OPC UA Server

Requirement:

- An OPC UA Server is available. For a description of the OPC UA Server which is included in the standard installation CODESYS, see the chapter "OPC UA Server".
- You have installed the CODESYS Security Agent add-on in CODESYS.
- CODESYS is open.
- The *"Allow anonymous login"* option is selected for your controller in the *"Change Communication Policy"* dialog of the device editor (*"Communication Settings"* tab, *"Change Communication Policy"* command, *"Device"* menu). Or the user management has been explicitly disabled (for example, by switching to *"Optional user management"* in the *"Change Communication Policy"* dialog) and then *"Reset Origin"*.

1. Start the OPC UA Server.
2. Create a new CODESYS project.
3. Add a *"Data Source Manager"* object to the application.
4. Add a *"Data Source"* *"OPCUAClient"* to the *"Data Source Manager"*.
   ⇨ The *"Datasource"* dialog opens.
5. In the *"Datasource"* dialog, specify the URI of the started OPC UA Server and select the *"Information Model Source"*. When you select *"Online"* as the *"Information Model Source"*, the OPC UA Client connects to the OPC UA Server and reads the information about which variables and types exist. When you select *"Offline"*, the client reads the same information from an installed information model and does not require a running OPC UA Server to do this.

6. For *“Message Security Mode”*, select *“Sign and Encrypt”*.

   Note: You should use *“Message Security Mode”* = *“None”* only in closed networks.

7. Click *“Next”*.Now the client scans the OPC UA Server to find the variables and types of the OPC UA Server. The OPC UA Server has to be online to do this.

8. Now select one or more variables.

   ⇨ These variables can be exchanged later via encrypted communication between the OPC UA Client and the OPC UA Server. For the variables, components are created in the *“Devices”* view, in the *“DataSources_Objects”* folder. The variables can be used in the application.

9. In the next steps, you create a certificate for the encrypted communication from the OPC UA Client to the OPC UA Server.

10. Click *“View ➔ Security Screen”*.

11. Select the *“Devices”* tab.

12. Select the controller in the left view.

    ⇨ In the right view, all services of the controller are displayed which require a certificate.

13. Select the service *“CmpOPCUAClient”*.

14. Create a new certificate for the device. Click the  icon.

    ⇨ The *“Certificate Settings”* dialog opens.

15. Define the certificate parameters and click *“OK”* to close the dialog.

    ⇨ The certificate is created on the controller.

16. Click the  button and save the certificate to the local file directory of the OPC UA Server, in the folder `certs`.

    ⇨ Now when you restart the OPC UA Server, it will recognize the client certificate. The the server sends its certificate to the client. In the following steps, this certificate will be made "trusted" to the client.

17. To do this, in the *“Security Screen”* view, on the *“Devices”* tab, click the *“Certificates in Quarantine”* folder in the left area.

    ⇨ The certificate is displayed in the right area.

18. Drag this certificate to the *“Trusted Certificates”* folder.

    ⇨ Now the server certificate is "trusted" by the client.

19. Now when you connect to the controller and the application starts, the data source variables of the OPC UA Client can be exchanged with the OPC UA Server via the encrypted connection.

1.4.1.9.5 Subordinate safety controller

If a safety controller is below the standard controller, then the communication with the development system and the data exchange run via the standard controller. The communication links of the safety controller can interrupted the execution of commands that affect the standard controller. You find a notice about this for each these command.

Possible interruptions

- Temporary interruption: During the execution of the command (for example: download), the connections with the safety controller are interrupted first and then are automatically available again afterwards. If the interruption time is too long, then safety-oriented reactions can occur in the output devices and connected network variable receiver safety controllers. Then in the safety controller, the corresponding communication errors must be acknowledged (if not done automatically) in order to end the safety-oriented reactions. This affects the connection to their field devices and network variable receiver connections to other sender safety controllers. In the case of a connected safety controller with network variable senders, the communication errors must be acknowledged in the other safety controllers.
- Permanent interruption: The execution of commands (for example: delete) leads to an interruption that is ended again by another action (for example: download). As a result of the interruption, safety-oriented reactions can occur in the output devices and connected network variable receiver safety controllers. After ending the interruption, the corresponding communication errors must be acknowledged in the safety controller (if not done automatically) in order to end the safety-oriented reactions.

For a subordinate safety controller, the routing runs via *“<Name of SafetyApp>_Mapping”*. In some cases, it can happen that the user can see this application in the device tree.

CAUTION!
No commands may be executed in the application *“<Name of SafetyApp>_Mapping”*.

- *Chapter 1.4.1.9 “Working with Controller Networks” on page 352*

1.4.1.10 Downloading an Application to the PLC

In order to transfer your application to the PLC, the program has to be compiled without any errors and the connection settings for the PLC have to be set.

If the communication with the controller is encrypted and/or restricted to specific users, then you need the respective certificates and permissions. See here:

- *Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385*
- *Chapter 1.4.1.8.17 “Encrypting an application” on page 294*

You can edit the basic security policy for communication with the device in a dialog on the “Communication Settings” tab of the device editor. See here:

- *Chapter 1.4.1.10.2 “Encrypting Communication, Changing Security Settings” on page 381*

When these requirements are fulfilled, the application is downloaded to the PLC at login.

1.4.1.10.1 Configuring the Connection to the PLC

The connection to the controller is established by means of a gateway. This gateway can be your development computer or another network computer connected to the controller. The *“Communication Settings”* dialog is available for configuring the connection path. This dialog opens automatically when you attempt to log in, but the communication settings have not been configured yet.

> *If the communication with the controller is encrypted and secured by means of user management, then you need a corresponding certificate and credentials to establish the connection to the controller. In this case, see the relevant instructions on the "Encrypting communication and Changing Security Settings" help page.*

Requirement: The project can be compiled without any errors. A programmable logic controller (PLC) is inserted in the device tree. The use of a user management is required for the device, but it is not enabled.

1. In the device tree, select the PLC and click *“Project ➔ Edit Object”*.
   ⇨ The PLC opens in the editor.
2. Click the *“Communication Settings”* tab.
3. On the menu bar, click *“Scan Network”*.
   ⇨ The *“Select Device”* dialog opens. All available devices in the network are shown on the left side.
4. Select the desired device and click *“OK”*.
   ⇨ A dialog prompt is displayed with the notice that a user management is required for the device, but it is not enabled yet. You are prompted to enable the user management if you want. The notice is displayed that in this case you have to create a new administrator account and then log in as this user.
5. Click *“Yes”* to close the dialog prompt.
   ⇨ The *“Add Device User”* dialog opens to create an initial device administrator.
6. Define the credentials (*“Name”* and *“Password”*) for the device administrator. Select the *“Password can be changed by the user”* option.

   > **NOTICE!**
   > Remember the seriousness of the password: From within the development system, there is no way to access the controller again if you forget the password.

   Click *“OK”* to close the dialog.
   ⇨ The *“Device User Logon”* dialog opens.
7. Enter the credentials for the device administrator which you defined in the previous step.
   ⇨ The connection path for the PLC is set.

> *You can reset the communication settings view to the original view in the CODESYS options of the device editor.*

1.4.1.10.2 Encrypting Communication, Changing Security Settings

NOTICE!

Recommendations for data protection

In order to minimize the risk of data security violations, we recommend the following organizational and technical actions for the system where your applications are running. Whenever possible, avoid exposing the PLC and control networks to open networks and the Internet. Use additional data link layers for protection, such as a VPN for remote access. Install firewall mechanisms. Restrict access to authorized persons. Use high-strength passwords. Change any default passwords regularly before and after commissioning.

Use the security features supported by CODESYS and the respective controller, such as encryption of communication with the controller and intentionally restricted user access.

Communication with the device can be protected by means of encryption and user management on the device. You can change the current security preset on the *“Communication Settings”* tab of the device editor.

Establishing a connection to the controller, logging in, installing a trusted certificate for encrypted communication

☑ Requirement: Encrypted communication with the controller and user management are enforced on the controller. However, an individual password does not exist yet. A certificate has not been installed on your computer and the connection to the controller has not been configured yet.

1. In the device tree, double-click the controller.

   ⇨ The device editor opens.

2. Click the *“Communication Settings”* tab.
3. Click *“Scan Network”*.

4. Select a controller.

   ⇨ A dialog opens, informing you that the certificate of the device does not have a trusted signature for communication. You are prompted whether or not to install this certificate as trusted in the local "Controller Certificates" store on your computer, or accept a session only for this one.

   NOTICE!
   A controller certificate installed in this way is valid for only 30 days. This gives you time for the following long-term solutions:

   – Creation of an additional self-signed certificate with a longer term (for example, 365 days). You can do this on the security screen if you have installed the CODESYS Security Agent, even if a certificate already exists. Using the PLC shell of the device editor is not a convenient workaround.
     See below: "Configuring encrypted communication with a controller certificate with a more long-term validity period"
   – Importing a CA-signed certificate. This is currently only possible via the PLC shell commands of the runtime. Therefore, we recommend to use self-signed certificates first.

5. If you want to install the certificate, then select the first option and click *"OK"* to confirm the dialog prompt.

   ⇨ The certificate is listed as trusted. After accepting the self-signed certificate for the first time, you can establish an encrypted connection with the controller again and again without further prompts.

   A dialog prompt is displayed with the notice that a user management is required for the device, but it is not enabled yet. You are prompted to enable the user management if you want. The notice is displayed that in this case you have to create a new administrator account and then log in as this user.

6. Click *"Yes"* to close the dialog prompt.

   ⇨ The *"Add Device User"* dialog opens to create an initial device administrator.

7. Create a device user in order to edit the user management as this user. In this case, only the *"Administrator"* group is available. Specify a *"Name"* and *"Password"* for the user. The password strength is displayed. Note also the set options regarding a password change. By default, the password can be changed by the user at any time. Click *"OK"* to confirm.

   ⇨ The *"Device User Logon"* dialog opens.

8. Enter the credentials for the device administrator which you defined in the previous step.

   ⇨ You are logged in on the controller. On the *"Users and Groups"* tab, you can use the button to switch to synchronized mode. The device user management is displayed there and you can edit it.

   After you click *"OK"* to confirm, the device user management is displayed in the editor view. It contains the user of the *"Administrator"* group who you just defined. The name of this user is also displayed in the taskbar of the window as *"Device User"*.

9. All saved controller certificates (from Step 5) are stored in the local Windows Certificate Store on your computer. You can access this memory by means of the *"Execute"*, `certmgr.msc` command.

   ⇨ All registered certificates for encrypted communication with controllers are listed here in *"Controller Certificates"*.

Configuring a controller certificate with a more long-term validity period

Requirement: The CODESYS Security Agent add-on product is installed. You want to replace the temporary certificate (as described above) acquired the first time you connected to the protected controller with a certificate with a longer validity period.

for encrypted communication by means of CODESYS Security Agent (recommended)

In this case, the *"Security Screen"* view provides an additional tab: *"Devices"*. This allows for the simple configuration of certificates for the encrypted communication with controllers. For operation, see the help for CODESYS Security Agent: "Encrypted Communication with Devices via Controller Certificates".

Installing a controller certificate for encrypted communication via the PLC shell of the device editor

Choose this less convenient method when the CODESYS Security Agent is unavailable to you. In this case, you can set up a certificate with a more long-term validity period for communication encryption on the *"PLC Shell"* tab of the device editor.

☑ Requirement: You are connected to the controller.

1. At first, you check if a qualified certificate is already on the controller. If no certificate is available, then you create a new certificate.

   Open the device editor by double-clicking the controller in the device tree, and select the *"PLC Shell"* tab.

   ⇨ The tab appears with a blank display window. Below that is a command line.

2. Type the following command in the command line: `cert-getapplist`.

   ⇨ All used certificates are listed. The list includes information about the runtime component and whether or not the certificate is available.

3. If a certificate still does not exist for the component `CmpSecureChannel`, then type the following command in the input line:

   `cert-genselfsigned <number of the component in the applist>`

4. Click the *"Log"* tab and then the refresh button (🔄).

   ⇨ The display shows whether or not the certificate was generated successfully.

5. Change back again to the *"PLC Shell"* tab and type the command `cert-getapplist`.

   ⇨ The new certificate for the component `CmpSecureChannel` is displayed.

6. In the next two steps, activate encrypted communication in the security screen of CODESYS.

7. Open the *"Security Screen"* by double-clicking 🛡 in the status bar.

8. On the *"User"* tab, select the *"Enforce encrypted communication"* option in the *"Security Level"* group.

   ⇨ The communication to all controllers is encrypted. If there is not a certificate on a controller, then you cannot log in to it.

   The connecting line between the development system, the gateway, and the controller is displayed in yellow on the *"Communication Settings"* tab of the device editor of the controller.

9. As an alternative to the *"Enforce encrypted communication"* option which applies to all controllers, you can also define encrypted communication for specific controllers only. To do this, select the *"Communication Settings"* tab in the editor of the respective controller. Then click *"Encrypted Communication"* in the *"Device"* list box.

   ⇨ The communication with this controller is encrypted. If there is not a certificate on the controller, then you cannot log in to it.

   The connecting line between the development system, the gateway, and the controller is displayed in yellow on the *"Communication Settings"* tab of the device editor of the controller.

10. When you log in to the controller for the first time, a dialog opens with information that the certificate of the controller is not signed by a trustworthy authority. In addition, the dialog displays information about the certificate and prompts for you to install it as a trustworthy certificate in the local store in the *"Controller Certificates"* folder.

    When you confirm the dialog, the certificate is installed in the local store and you are logged in to the controller.

    In the future, communication with the controller will be encrypted automatically with this control certificate.

11. To increase security for key exchange for controllers < V3.5 13.0, you can generate Diffie-Hellman parameters on the controller. To do this, type the command `cert-gendhparams` in the input line.

    This is no longer required for controllers >= V3.5.13.0.

> **NOTICE!**
> Caution: Generating the Diffie-Hellman parameters can last for several minutes or even several hours. However, this process must be executed only one time for each controller. The Diffie-Hellman parameters increase security for key exchange and for future attacks against encrypted data recording.

Changing the communication policy (encryption, user management)

☑ Requirement: The connection to the device is established.

1. In the device tree, double-click the controller.

   ⇨ The device editor opens.

2. Click the *"Communication Settings"* tab.
3. Open the *"Device"* menu in the header of the editor. Click *"Change Communication Policy"*.

   ⇨ The *"Change Communication Policy"* dialog opens.

4. In the upper part of the dialog, you can toggle between the *"Optional encryption"*, *"Enforced encryption"*, and *"No encryption"* settings.
5. In the lower part of the dialog, you can toggle between the *"Optional user management"* and *"Enforced user management"* settings.

Enabling and disabling enforced encrypted communication

☑ Requirement: The device supports encrypted communication.

1. In the device tree, double-click the controller.

   ⇨ The device editor opens.

2. Click the *"Communication Settings"* tab.

3. Open the *"Device"* menu in the header of the editor. Click *"Encrypted Communication"*. The status toggles between enabled and disabled.

   ⇨ If the *"Encrypted communication"* option is selected, then the connection line between the development system, the gateway, and the device is highlighted in the editor in bold and in color in the graphical representation.

1.4.1.10.3 Handling of Device User Management

NOTICE!

Recommendations for data protection

In order to minimize the risk of data security violations, we recommend the following organizational and technical actions for the system where your applications are running. Whenever possible, avoid exposing the PLC and control networks to open networks and the Internet. Use additional data link layers for protection, such as a VPN for remote access. Install firewall mechanisms. Restrict access to authorized persons. Use high-strength passwords. Change any default passwords regularly before and after commissioning.

Use the security features supported by CODESYS and the respective controller, such as encryption of communication with the controller and intentionally restricted user access.

For devices that support a device user management, the device editor includes the *"Users and Groups"* tab and the *"Access Rights"*. When offered by the device, you can view the user management for the device here as well as edit it in synchronization mode (not in online mode). Here, you can grant or deny specific permissions on the controller to the defined user groups.

The device user management can already be set up in the device description.

Note the commands in the "Online ➔ Security" menu. You can easily add, edit, or remove a user account on the controller where you are currently logged in.

In order for the "Access Rights" tab to be available in the device editor, the corresponding CODESYS option must be selected in the device editor and unlocked in the device description. If the device editor is not available, then contact the manufacturer of the controller.

In order to grant access rights to a user group, first the users and user groups have to be configured on the *"Users and Groups"* tab of the device editor. User management first has to be set up on the controller before access rights can be configured on it. In case the user management of a device is not enabled yet, it can be enabled in the following way: Either by switching to the synchronized mode on the *"Users and Groups"* tab, or by adding a new user by means of the command *"Online ➔ Security ➔ Add Device User"*.

General information about device user management

For the CODESYS Control devices, a user management is enforced by default.

Access rights can be granted to groups only, not individual users. Therefore every user has to be a member of a group.

Access rights can be granted for the following actions which are executed on the individual objects of the controller:

- Add/Remove
- Modify
- View
- Execute

An object on the controller is usually assigned to just one controller component.

Each object can use all of the listed actions, but usually only the permissions for the following actions are needed on an object:

- *"View"*
- *"Modify"*

The objects are organized in a tree structure. There are two root objects for the two kinds of objects:

- *"Runtime objects ➔ Device"*: In these objects, all objects are managed that have online access in the controller and therefore have to control the access rights.
- *"File system objects ➔ /"*: In these objects, the permissions can be granted to folders of the current execution directory of the controller.

The child objects inherit the access rights from the root object (also *"Device"* or "*"/"*"). If a permission of a user group is denied or explicitly granted to a parent object, then this affects all child objects.

A single permission can be explicitly granted or denied (green plus sign or red minus sign), or remain "neutral" (light gray character). Neutral means that the permission has been neither explicitly granted nor denied. In this case, the permission of the parent object applies.

If no permission has been explicitly granted or denied in the entire hierarchy of the object, then it is by definition denied. As a result, all permissions are initially denied (exception: the access right for the *"View"* action). Initially, this permission is explicitly granted for every user group both on the *"Device"* runtime object as well as on the "*"/"*" file system object. This allows read access to all objects, unless it is explicitly denied in child objects.

For an overview table for the objects, see the "Tab 'Access Rights'" chapter.

See the following instructions for handling the editor for the device user management:

First-time login on the controller in order to edit or view its user management

Requirement: The connection to the controller is configured. The controller supports a device user management, but one is not active yet.

1. Double-click the controller device object in the device tree.
   ⇨ The device editor opens.
2. Click the *"Users and Groups"* tab.
3. Click  .
   ⇨ A dialog opens prompting whether the device user management should be activated.
4. Click *"Yes"* to acknowledge the dialog prompt.
   ⇨ The *"Add Device User"* dialog opens.

5. Now create a device user in order to edit the user management as this user. In this case, only the *"Administrator"* group is available. Specify a *"Name"* and *"Password"* for the user. The password strength is displayed. Note also the set options regarding a password change. By default, the password can be changed by the user at any time. Click *"OK"* to confirm.

   ⇨ The *"Device User Logon"* dialog opens.

6. Specify a *"User name"* and *"Password"* for the user who you just defined.

   ⇨ After you click *"OK"* to confirm, the device user management is displayed in the editor view. It contains the user of the administrator group who you just defined. The name of this user is also displayed in the taskbar of the window as *"Device User"*.

Setting up a new user in the user management of the controller

Requirement: The controller has a device user management. You have the corresponding access data.

1. Double-click the controller device object in the device tree.

   ⇨ The device editor opens.

2. Click the *"Users and Groups"* tab.

3. Click (Synchronization) to load the user management configuration from the controller to the editor. If you are not logged in to the device yet, then the *"Device User Logon"* dialog opens for entering the user name and password.

   ⇨ The user management configuration of the device is shown in the editor.

4. In the *"Users"* view, click *"Add"*.

   ⇨ The *"Add User"* dialog opens.

5. Specify the name of the new user and assign the user to a group. This counts as the user's minimum required default group. The user can be assigned to other groups later. Define and confirm a *"Password"* for the user. Define whether the user can change the password and whether the user has to change the password at the first login. Click *"OK"* to confirm.

   ⇨ The new user appears in the *"Users"* view as a new node and in the *"Groups"* view as a new subentry of the selected default group.

Changing of access rights to controller objects in the user management of the controller

Requirement: The controller has a device user management. You have the corresponding access data.

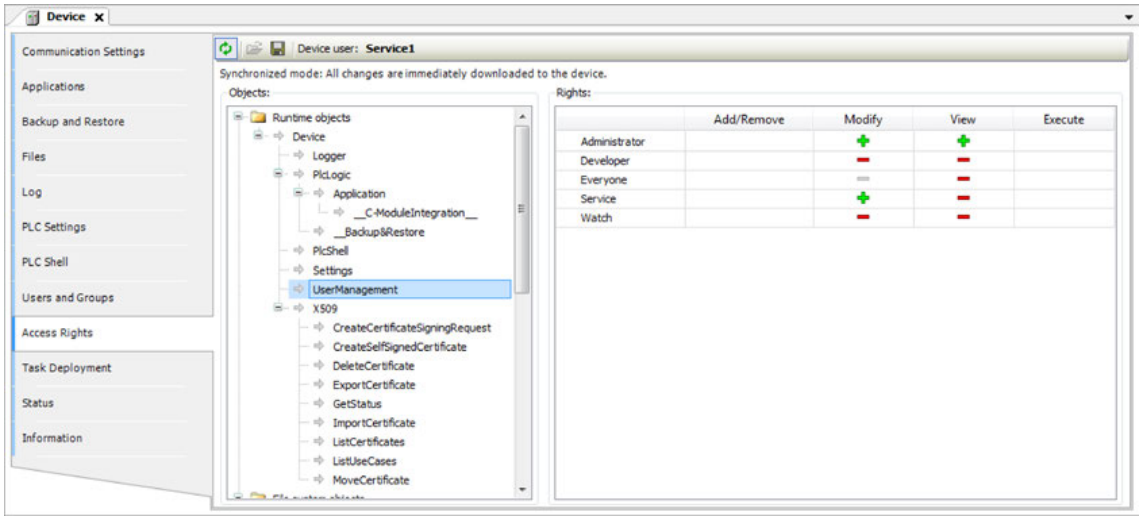
1. Double-click the controller device object in the device tree.

   ⇨ The device editor opens.

2. Click the *"Access Rights"* tab.

3. Click (Synchronization) to load the rights management configuration from the controller to the editor. If you are not logged in to the device yet, then the *"Device User Logon"* dialog opens for entering the access data.

   ⇨ The access rights management configuration of the device is shown in the editor.



4. Select the object whose access right you want to change to the left in the object tree.

   ⇨ In the *"Rights"* view, a table shows the access rights to this object for all configured user groups.

5. Double-click the right in the table that you want to change.

   ⇨ If the object has child objects, then a dialog prompts whether you want to modify the permissions for the child objects.

6. Click *"Yes"* or *"No"* to close the prompt.

   ⇨ The permissions are switched from "allowed" + to "not allowed" −, or the other way around. The symbol in the table cell changes accordingly. Explicitly set permissions appear in the table as green or red symbols. Rights that are inherited from a parent object appear as gray symbols.

Transferring and enabling a saved user management in offline mode from a DUM2 file to a controller

In V3.5 SP16 and higher, a file (.dum2) to be encrypted with a password is used for exporting a user management.*

1. Double-click the controller device object in the device tree.

   ⇨ The device editor opens.

2. Click the *"Users and Groups"* tab.

3. Click .

   ⇨ The dialog for selecting a file from the local file system opens.

4. Select the file (`<file name>.dum2`) with the desired user management from the local file system and click *"Open"* to confirm.

   ⇨ The *"Enter Password"* dialog opens.

5. Specify the password that was assigned when the user management file was exported (possible by means of the button).

   CAUTION: The import of a device user management by means of a `*.dum2` file completely overwrites the existing user management on the device. In order to log in to the device again afterwards, you need authentication data from the recently imported user management.

   ⇨ When the password is entered correctly, the configuration from the downloaded user management file is now displayed in the editor view.

6. Edit the configuration however you like. For example, change the user password or add a new user.

   ⇨ Every change is downloaded immediately to the device.

1.4.1.10.4 Generating Application Code

The application code is the machine code that a PLC executes when you start an application.

CODESYS automatically generates the application code from the source code that was written in the development system. This is done automatically before downloading the application to the PLC. Before the application code is generated, a test is performed for checking the allocations, the data types, and the availability of libraries. Moreover, the memory addresses are allocated when the application code is generated.

You can click *“Build ➔ Generate Code”* to execute this command explicitly. This is useful for detecting any errors in your source code, even when the PLC is not connected yet. The errors are output in the message view in the "Build" category.

NOTICE!
If you have encrypted the application, then consider the following information: If a (new) boot application is generated on request after an online change, then the boot application is formed in the RAM with the current code that is not encrypted.

Explicitly generating the application code

Requirement: The application can be compiled without any errors.

▷ Click *“Build ➔ Generate Code”*.

⇨ The application code is generated. Detailed information about memory allocation is output in the message view.

See also

- *Chapter 1.4.1.10.6 “Generating boot applications” on page 391*
- *Chapter 1.4.1.20.3.5.1 “Command 'Generate Code'” on page 1021*

Messages when generating the application code

When you generate the application code, CODESYS outputs information about memory allocation in the message view. Gaps form in the memory because reallocation is only for new and changed POUs and variables due to the incremental memory build. Online changes have the same effect. This fragmentation reduces the amount of available memory. However, you can completely reallocate the memory by clicking *“Clean”* and therefore increase the amount of free memory.

Syntax errors and bugs that CODESYS detects during the code generation and memory allocation are also output in the message view (*“Build”* category).

Output information about memory allocation:

- *“ Size of the generated code”* (in bytes): Sum of all code segments
- *“Size of global data”* (in bytes): Total memory used by the global variables. Inputs and outputs are not included unless inputs or outputs are mapped in the area of the global variables.
- *“Total allocated memory size for code and data”* (in bytes): The total allocated memory is composed of the already used memory areas plus the reserved, not yet used memory for incremental builds and online changes. After the first build, the already used memory is approximately equal to the highest used address (see below). The largest contiguous memory gap (see below) still corresponds approximately to the difference to the total allocated memory. However, as the number of incremental builds and online changes increases, the number of memory gaps also increases, and the largest contiguous memory gap becomes smaller.
- *“Memory area <n>”*: Contents of the individual reserved memory areas

  Background: It depends on the PLC which data and code is stored in which memory areas. For example, code and data are located in the same area on the CODESYS Control Win V3. For the addresses `%I`, `%M`, and `%Q`, memory is always reserved, even when a variable is not assigned to an address. After cleaning the application, the memory is reallocated completely. In this case, small gaps could result from the predefined alignment (normally 8). Larger gaps result from changing a date without cleaning, for example by increasing an array area. In this case, only the affected POUs are recompiled. Furthermore, in the case of an online change, the memory is used only for new variables and new code. Memory that was previously reserved by deleted variables and code is made available again. As a result, memory fragmentation can occur after many incremental builds and online changes. This creates many small gaps that might not be usable at all in some cases. To clarify how much memory is safely available, the "largest contiguous memory gap" of the memory area is output during code generation.
  - *“highest used address”* (Byte) : This is the highest reserved address in the entire allocated memory area. During the first build after a "Clean" operation, the memory addresses are output to variables in ascending order, taking into consideration the alignment (usually 8 bytes). As a result, the highest address used at this time corresponds approximately to the amount of memory used. The rest of the allocated memory area is still completely available for incremental builds and online changes.
  - *“Largest contiguous memory gap”* (in bytes): This is the memory size that is available for backup.

    Resulting gaps in the allocated memory are reused whenever possible for other changes. When, for example, a global variable of type `Byte` is added, it is placed in the first free byte of the memory. Even just a small gap is enough for this. However, an FB instance, a variable of the type structure or array, or the code for a POU has to be stored contiguously and therefore occupies more memory accordingly. As a result, they can be allocated only to the largest contiguous memory area. This is why during code generation the "largest contiguous memory gap" that is safely available is output (in bytes), as well as its percentage of the total memory.

Note the options for generating applications.

- *Chapter 1.4.1.20.4.10.9 “Dialog 'Properties - Application Build Options'” on page 1162*

Encrypting the application code

See also

- *Chapter 1.4.1.8.17 “Encrypting an application” on page 294*

1.4.1.10.5 Downloading the application code, logging in, and starting the PLC

In order to download the source code of your application to the PLC, you must log in to the PLC with application. If there are several applications in the project, then you must switch explicitly to the correct application first.

When you download an application to the PLC, CODESYS performs the following checks:

The list of applications on the PLC is compared with the applications available in the project. If they do not match, then you are prompted to download the application that is not on the PLC yet or delete existing applications.

For "externally implemented" blocks in the application to be downloaded, CODESYS checks whether these are available on the PLC. If they are not available, then the message "unresolved reference(s)" is printed to a dialog prompt and to the message view. Then CODESYS compares the parameters (variables) of the blocks in the application to be downloaded and the parameters of the same-named blocks in the application that exists on the PLC (signature check). If there are any discrepancies, then the message "invalid signature(s)" is printed to a dialog prompt and to the message view.

If the "Download Application Info" check box is selected in the application properties, then additional information about the application contents are downloaded to the PLC.

if multiple applications exist for the same device, then notice that the *“I/O Mapping”* dialog contains the definition for which of the applications is used for for the I/O mapping of the device.

See also

- *Chapter 1.4.1.20.2.1 “Object 'Application'” on page 819*

Transferring an application and starting the program

Requirement: The application contains no errors and the communication settings of the PLC are correct. The application does not exist yet on the PLC: The application and the communication with the controller are not encrypted.

1. Select the required application in the device tree. Skip to Step 3 if you have only one application.
2. Click *“Set Active Application”*.
   ⇨ The application name appears in bold typeface.
3. Click *“Online ➔ Login”*.
   ⇨ A dialog prompts you whether the application should be created on the PLC.
4. Click *“Yes”* to confirm.
   ⇨ The application is downloaded to the PLC.
5. Click *“Debug ➔ Start”* or press the *[F5]* key.
   ⇨ The application is running on the controller.

1.4.1.10.6 Generating boot applications

A boot application is the application that is started automatically when the controller is switched on or started. For this to happen, the application on the controller must exist as a file `<application name>.app`.

For each application that is running on the controller, a boot application can also be saved there.

By default, CODESYS generates the boot application automatically when an application is downloaded and transfers them to the PLC. The defaults for generating automatically are located in the *“Boot application”* category of the application *“Properties”*. When logging in with a changed application, you are still prompted whether or not to generate a new boot application.

In addition, you can create a (new) boot application at any time in online mode by clicking *“Online ➔ Create boot application”*.

You can create and save a local copy of a boot application in offline mode as well. Then, you can copy this application to the controller with external tools. In this way, you transfer an application to the controller, even when there is no connection to CODESYS.

Generating boot applications on the controller automatically and explicitly

Requirement: Offline mode; the application is compiled without errors. The connection to the controller is configured and the controller is running. The application is active. The following steps demonstrate the options:

1. Click *"Online ➔ Login"*.

   ⇨ The boot application file `<application name>.app` is created on the controller with the checksum of the boot application `<application name>.crc`.

2. Click *"Online ➔ Create Boot Application"* explicitly.

   ⇨ The files on the controller are replaced by new files.

3. Log out.
4. Change the application. Log back in to the controller.

   ⇨ You are prompted whether an online change should be performed. You see the *"Update boot application"* check box in the same dialog box. This is cleared by default, but this can be changed in the *"Boot Application"* category of the application *"Properties"*.

5. Keep the check box cleared and continue login.

   ⇨ A new boot application file is not created.

6. Log out. Close the project. Stop the controller. Restart the controller.

   ⇨ The boot application that was created above is running on the controller.

You can save the encrypted boot application on the controller. These settings are defined in the "Application Build Options" category of the application "Properties".

- *Chapter 1.4.1.20.4.10.2 "Dialog 'Properties' - 'Boot Application'" on page 1158*
- *Chapter 1.4.1.13.1 "Executing the online change" on page 439*
- *Chapter 1.4.1.20.3.6.4 "Command 'Create Boot Application'" on page 1032*

Creating boot applications in offline mode

Requirement: Offline mode; the application is compiled without errors. You want to generate a boot application for an application and save it in the file directory for copying it later to the controller by using external tools (without CODESYS).

1. Click *"Online ➔ Create Boot Application"*.

   ⇨ A dialog box opens for specifying a save location in the local file system.

2. Click a save path and then click *"Save"*.
3. If the application has changed since the last boot application was generated, then you are prompted to use a new code for the boot application. In this case, click *"Yes"*.

   ⇨ The *"Save as"* dialog box opens.

4. Select a directory and click *“Save”*.
   ⇨ The boot application file <application name>.app is created in the given path.

   You are prompted whether or not the build information for the boot application is saved.
5. Click *“Yes”*.
   ⇨ The build information is saved to the project directory as a file named `<application name>.compileinfo`. It is a requirement for a possible online change the next time the application is updated. Please note: Clicking *“Build ➔ Clean”* deletes this file.

See also

- *Chapter 1.4.1.20.3.6.4 “Command 'Create Boot Application'” on page 1032*

When using CODESYS Control Win V3

When using a CODESYS Control Win V3, the application name must also be included in the configuration file (`*.cfg`).

```
[CmpApp]
 Application.1=MyApplication
```

1.4.1.10.7 Downloading source code to and from the PLC

CODESYS provides the capability of loading project source code to a PLC as a project archive. You can then transfer this project archive back to the development system from the PLC as needed.

Requirement: The connection settings are configured for the affected controllers.

Downloading source code to the PLC

1. Choose the command *“File ➔ Source Download”*.
   ⇨ The dialog box *“Select Device”* opens.
2. Select the controller to receive the source code. Click *“OK”*.
   ⇨ CODESYS writes the archive file `Archiv.prj` to the controller.

By choosing the command “Online ➔ Source Download to Connected Device”, you can load the source code directly to the connected device.

See also

- *Chapter 1.4.1.20.3.1.11 “Command 'Source Download'” on page 963*
- *Chapter 1.4.1.20.3.6.7 “Command 'Source Download to Connected Device'” on page 1035*
- *Chapter 1.4.1.20.4.11.5 “Dialog 'Project Settings' – 'Source Download'” on page 1174*

Loading source code from the PLC

1. Choose the command *“File ➔ Source Upload”*.
   ⇨ The dialog box *“Select Device”* opens.
2. Select the controller to send the source code. Click *“OK”*.
   ⇨ The *“Extract Project”* dialog box opens.
3. Select the destination directory where you want to extract the project archive. Click *“Extract”*.
   ⇨ CODESYS extracts the project archive to the directory.
4. Then you are prompted to open the project archive. Click *“Yes”*.
   ⇨ The project opens.

See also

- *Chapter 1.4.1.20.3.1.10 “Command 'Source Upload'” on page 962*

1.4.1.11 Testing and Debugging

CODESYS provides various options for testing your application and detecting errors. You can start your application in simulation mode, even without connecting any hardware. Using breakpoints and stepping commands, you can examine specific parts of a program. By writing values to variables, you can influence the running program.

Commands are provided that reset your application in various different ways, from resetting only non-persistent variables to completely resetting the controller to factory settings.

See also

- *Chapter 1.4.1.11.2 “Using Breakpoints” on page 395*
- *Chapter 1.4.1.11.3 “Stepping Through a Program” on page 399*
- *Chapter 1.4.1.11.5 “Resetting applications” on page 404*

1.4.1.11.1 Testing in simulation mode

Use simulation mode for testing and debugging your program when you do not have a physical target device. In this mode, the application is started on a simulated device.

The command is available only when you are logged out.

Requirement: You program contains no errors (compiler error messages or compile errors) and you are not logged in.

1. Activate simulation mode as follows:
   - Click *“Online ➔ Simulation”*, or
   - Right-click the controller in the device tree and click *“Simulation”*.
   ⇨ The name of the controller in the device tree is displayed in italics. In the status line, "Simulation" appears highlighted in red. The *“Simulation”* command is selected in the main menu.
2. Click *“Online ➔ Login”*.
3. When logging in with the active application, you will be prompted whether the application "Sim.<device name>.<application name>" should be created and loaded. Click *“Yes”* to confirm.
   ⇨ The application is logged onto the PLC.

4. Now you can check and correct the program flow with the commands provided in the main menu in *“Debug”*.
5. Log out from the controller and end the simulation mode.

See also

- *Chapter 1.4.1.20.3.6.23 “Command 'Simulation” on page 1044*

Limitations

- The focus of the simulation mode is testing and debugging your program of the PLC. That means the functionality of the simulated PLC is limited. Keep in mind that some POUs have no function. They are not creating any compile or download errors, they will simple not work.
- Without an extra available “Virtual Commissioning” license the “Online mode” of the simulated PLC is limited to 2 hours. After 2 hours starting from the “Login”, the “Online mode” is automatically terminated and the PLC is logged out.
- It is not possible to create a “Boot Application” in the simulated PLC. Every “Login” starts with an empty simulated PLC and a download of the application is required.
- When logging in to a simulated PLC the first time a “Windows Security Alert” is displayed. Depending on the application, e.g. if any network communication is implemented, it might be necessary to allow the “Virtual AC500” to communicate on one or multiple network types.

1.4.1.11.2 Using Breakpoints

Breakpoints are commonly used for debugging programs. CODESYS supports breakpoints in all IEC editors.

You can set breakpoints at specific positions in the program to force an execution stop and to monitor variable values. You can set special data breakpoints to halt program execution when the value of a specific variable changes.

The halt at a breakpoint or data breakpoint can be linked to additional conditions. You can also redefine breakpoints and data breakpoints as execution points where specific code is executed instead of stopping the program.

The “Breakpoints” view provides an overview of all defined breakpoints. It also includes additional commands for processing batch changes to multiple breakpoints.

In the editor, the following symbols identify the status of a breakpoint or execution point:

- The breakpoint is enabled.
- The breakpoint is disabled.
- Breakpoint is set in another instance of the POU open in the editor.
- The program is halted at the breakpoint.
- The conditional breakpoint is enabled.
- The conditional breakpoint is disabled.
- The execution point is enabled.
- The execution point is disabled.
- The conditional execution point is enabled.
- The conditional execution point is disabled.
- The data breakpoint is enabled.
- The data breakpoint is disabled.
- Halt at data breakpoint
- The data execution point is enabled.
- The data execution point is disabled.
- Halt at data execution point

- The conditional data execution point is enabled.
- The conditional data breakpoint is enabled.

See also

- *Chapter 1.4.1.20.3.3.12 “Command 'Breakpoints'” on page 989*

Data breakpoints

The function of data breakpoints depends on the target system. Currently, data breakpoints are possible only with the CODESYS Control Win V3.

Program execution stops at a data breakpoint when the value of a particular variable or memory address changes. As with ordinary breakpoints, the halt can be linked to an additional condition, or specific code can be processed instead of the halt (converted to a data execution point).

You set a data breakpoint either by means of the *“New Data Breakpoint”* command in the *“Debug”* menu or by means of the *“New”* button in the *“Breakpoints”* view. You specify a qualified variable name or a memory address directly which is to be monitored for changes in its value.

Example

In the following sample code, the memory of the variable `iNumber` is overwritten unintentionally. However, a data breakpoint at the variable `iNumber` will detect when its value changes. The processing then stops with a corresponding message at the array access, which overwrites the variable value: `Idx` = `7`. See also below: "Setting a data breakpoint".

```
PROGRAM PLC_PRG
VAR
  Idx : INT;
  Ary : ARRAY[0..3] OF BYTE;
  iNumber : INT := 55;
END_VAR
FOR idx := 0 TO 6 DO
  Ary[idx] := 0;
END_FOR
```

Breakpoints in applications with multiple tasks

Basically, debugging is not possible for multiple tasks at the same time. While you are working on a task with breakpoints or stepping, breakpoints are ignored in other tasks.

If a POU containing a breakpoint is used by multiple tasks, then only the debug task is halted because it reaches the breakpoint first. All other tasks continue. The *“Call Stack”* dialog shows which task is currently halted.

If you need a breakpoint to affect only one specific task, then you can define this in the breakpoint properties.

Breakpoints operate separately for each application so that a "HALT ON BP" does not affect any other applications. This applies also to parent/child applications, even if the breakpoint is set in a block that is used by several applications and whose code is located only once on the PLC.

NOTICE!
The I/Os that are called by the debug task are not updated at a halt in the breakpoint, even if you select the *“Refresh I/Os in Stop”* check box in the PLC settings.

If the application stops at a breakpoint on the PLC, then an online change or download causes all tasks to halt which means the PLC will stop. In this case, CODESYS prompts you whether or not to continue with the login.

See also

- ↳ *Chapter 1.4.1.20.3.3.15 “Command 'Call Stack'” on page 993*

Setting a single breakpoint (example in ST editor)

Requirement: The application is in online mode and running. The operating mode is *“Debug”*.

1. In the editor, open a POU programmed in structured text (ST).
2. Place the cursor in the line where a breakpoint will be set.
3. Click *“Debug ➔ Toggle Breakpoint”* or press *[F9]*.
   ⇨ The line is marked in red and identified by the "breakpoint enabled" symbol (). If the program is halted at the breakpoint, then the line is marked by the "stop at breakpoint" symbol (). The processing of the program is stopped. This is identified in the status line by the `HALT ON BP` status highlighted in red.
4. Click *“Debug ➔ Start”* or press *[F5]*.
   ⇨ The program continues.
5. Set more breakpoints and check the variable values at the break position.
6. Place the cursor in the line where a breakpoint should be removed.
7. Click *“Debug ➔ Toggle Breakpoint”* or press *[F9]*.
   ⇨ The marking disappears. The breakpoint is deleted.

See also

- ↳ *Chapter 1.4.1.20.3.7.9 “Command 'Toggle Breakpoint'” on page 1050*

Defining a breakpoint condition (example in ST editor)

1. In the editor, open a POU programmed in structured text (ST).
2. Place the cursor in the line where a breakpoint will be set.
3. Click *“Debug ➔ New Breakpoint”*.
   ⇨ The *“Breakpoint Properties”* dialog opens.
4. Click the *“Condition”* tab.
5. Click *“Break when the hit count is a multiple of”* in the *“Hit Count”* list box.
   Specify the value "5" in the field to the right.
6. In addition, you can define a Boolean condition for when the breakpoint should be active. Select the *“Break, when true”* check box. Specify a Boolean variable in the text field to the right.
7. Select the *“Enable breakpoint immediately”* check box.
8. Close the dialog.
   ⇨ The line is marked red and identified by the "conditional breakpoint enabled" symbol ()

Monitor the running program. As long as the Boolean variable for the condition is `FALSE`, the breakpoint condition is not fulfilled and the program continues to run. If you set the variable to `TRUE`, then the condition is fulfilled and the program halts at the breakpoint every 5th pass.

See also

- *Chapter 1.4.1.20.4.5 "Dialog 'Breakpoint Properties'" on page 1151*

Defining an execution point (example in ST editor)

1. In the editor, open a POU programmed in structured text (ST).
2. Place the cursor at the position for an execution point.
3. Click *"Debug ➔ New Breakpoint"*.
   ⇨ The *"Breakpoint Properties"* dialog opens.
4. Click the *"Execution Point Settings"* tab.
5. Select the *"Execution point"* option.
   In the *"Execute the following code"* field, type the following statement: `iCounter := iCounter + 1;`
   In the *"Print a message in the device log"* field, type the following text: `Execution point reached {iCounter}`
6. Close the dialog.

When the program reaches the execution point, it does not halt, but executes the code defined above. In addition. a message is issued to the device log.

See also

- *Chapter 1.4.1.20.4.5 "Dialog 'Breakpoint Properties'" on page 1151*

Setting a data breakpoint

Requirement: The application is in online mode and running.

1. Click *"View ➔ Breakpoints"*.
2. Click *"Debug ➔ New Data Breakpoint"*.
3. Click the … button in the *"New breakpoint"* dialog (*"Data"* tab.
4. In the *"Input assistant"* dialog (*"Watch Variables"* tab), select the variables for which the program should halt when changed.
   As an alternative, specify the qualified name of the variable on the *"Data"* tab directly in the input line. Example: `PLC_PRG.iNumber`. The exact number of bytes to be monitored is specified as the *"Size"*. A value that corresponds to the data type is set here automatically by default. You can also specify fewer bytes to be monitored.
5. In the *"Breakpoints"* view, select the line with the data breakpoint and click the button.
   ⇨ The line is marked and identified by the "Data breakpoint enabled" symbol (●). When the program reaches the data breakpoint (meaning when the value of the selected variables changes), the program processing halts. In the implementation part of the POU, the next line is identified by an arrow. This is identified in the status line by the `HALT ON BP` status highlighted in red.
6. Click *"Debug ➔ Start"* or press *[F5]*.
   ⇨ The program continues running and halts again when the value of the variables changes again.

See also

- *Chapter 1.4.1.20.4.5 "Dialog 'Breakpoint Properties'" on page 1151*

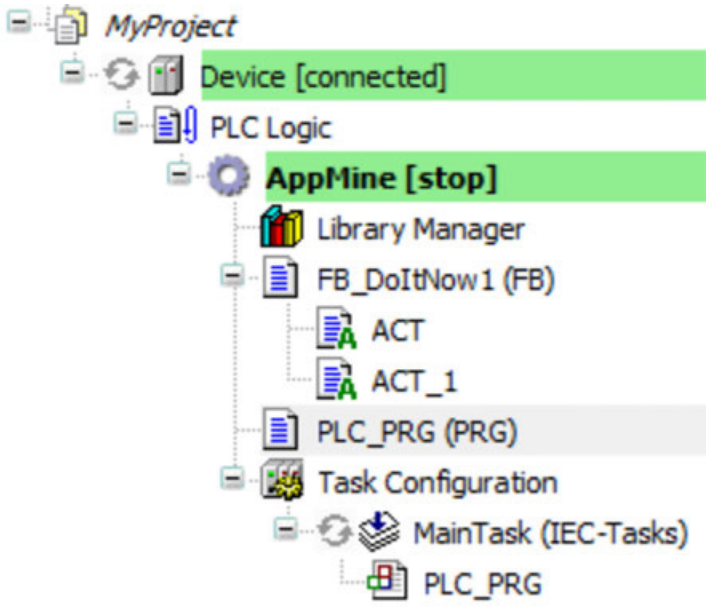
1.4.1.11.3 Stepping Through a Program

You can step through an application and navigate the code. This is useful to check the status of your code at runtime. You can examine the call process, track variable values, or locate errors.

Stepping commands are provided in the *"Debug"* menu for this purpose. The commands become available when you set breakpoints in online mode and then halt execution at a breakpoint: the application is in *"HALT ON BP"* state (debug mode). During debug mode, the current break position is highlighted in yellow and marked with the ➪ symbol in the text editors.

Switching to debug mode

1. Download your application to a controller.
   ⇨ The application is highlighted in green. CODESYS and the editors of the POUs are in online mode.



2. In the POUs, set breakpoints at the locations in the code that you want to examine.
   ⇨ All breakpoints are listed in the *"Breakpoints"* view.
3. Start the application.
   ⇨ The application starts and the code is processed until the first breakpoint.

   Now the application is in debug mode. In the device tree, the application is labeled with *"[halt on breakpoint]"*. The status bar provides information about the operating state:

   The editor was opened at the current break position. The line of code with an active breakpoint where program execution was halted is highlighted in yellow and marked by the ➪ symbol. This statement highlighted in yellow has not been executed yet.

   Now you can select the various stepping commands or display the call tree.

Alternatively, you can first start the application and then set a breakpoint.

Behavior of the stepping command in the 'Debug' menu

- Command *"Step Over"*
  The statement at the breakpoint position is executed. Program execution halts before the next statement in the POU.
  If the statement contains a call (from a program, function block instance, function, method, or action), then the subordinate POU is processed completely in one step.
- Command *"Step Into"*
  The statement at the breakpoint position is executed. Program execution halts before the next statement.
  If the statement contains a call (from a program, function block instance, function, method, or action), then the program execution jumps to this subordinate POU. The first statement there is executed and the program execution halts before the next statement. The new current breakpoint position is then in the called POU.
- Command *"Step Out"*
  The command executes the POU from the current breakpoint position to the end of the POU and then jumps back to the calling POU. Program execution halts at the calling position (in the line with the call).
  If the current breakpoint position is in the main program, then the POU is run through to the end. Then the program execution jumps back to the beginning (to the program start at the first line of code in the POU) and halts there.
- Command *"Run to Cursor"*
  First set the cursor at any line of code and then execute the command. The program is executed from the current breakpoint position and halts at the current cursor position without executing the code of this line.
- Command *"Set Next Statement"*
  First set the cursor at any line of code (also before the current breakpoint position) and then execute the command. The statement marked with the cursor is executed next. All statements in between are ignored and skipped.
- Command *"Show Next Statement"*
  If you do not see the current breakpoint position, then execute the command. Then the window with the current breakpoint position comes into focus and the breakpoint position is visible.

Click *"View ➔ Call Stack"* to completely show the previous call tree for the breakpoint position currently reached in the program processing.

The "Call Stack" view shows the location of the block in the call structure of the program at all times, even before compiling the application.

1.4.1.11.4 Forcing and Writing of Variables

CAUTION!

Unusual changes to variable values in an application currently running on the controller can lead to undesired behavior of the controlled machinery.

Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled machinery, the result may lead to damage to machinery and equipment or injury to health and life of personnel.

In CODESYS, variable values in the PLC can be changed in online mode. Here we make a distinction between forcing and writing a previously prepared value.

Writing is done with the *"Write Values"* command (*[Ctrl]+[F7]*) and sets the variable to the prepared value one time. In this way, the value can be overwritten again by the program at any time.

Forcing is done with the *"Force Values"* command (*[F7]*) and sets the prepared value permanently. For more information, see below.

The preparation of a value for forcing or writing is possible at different places:

- Declaration part: *"Prepared value"* field
- Implementation part of the FBD/LD/IL editor: inline monitoring field
- Watch view: *"Prepared value"* field

For instructions about this, see below. In the case that you want to prepare a value again for an already forced value, the *"Prepare Value"* dialog opens with options for handling the current force value.

Functionality of forcing

The prepared value is set to the respective variable at the beginning and end of a task cycle (or of a processing loop in the case of other task types).

The processing order in each cycle of a task is as follows:

1. Read the inputs

2. Force: Before the first program call, all prepared values are written to the variables by the runtime system, regardless of whether or not they are used by the task.

3. Process the IEC code

4. Force: After the last program call, all prepared values are written to the variables by the runtime system, regardless of whether or not they are used by the task.

5. Write the outputs

Note: It is possible that a forced variable temporarily gets a different value in the cycle while the code is being processed because the IEC code performs an assignment. Then the variable receives the forced value again only at the end of the cycle. The variable value can also be overwritten by the write access of a client to symbols of the application in mid-cycle. For this case, see the *"Access variables in sync with IEC tasks"* option in the *"Properties"* of the device object, or the *"Configure synchronization with IEC tasks"* setting in the symbol configuration. In this way, a PLC handler-supported synchronization of the write accesses by clients can be enabled with the task cycle.

NOTICE!

Forced values are marked with the F symbol. CODESYS does the forcing until the user lifts it explicitly by one of the following actions:

- Executing the *"Cancel forcing for all values"* command
- Lifting the force operation in the *"Prepare Value"* dialog
- Logging out of the application
  If forced variables still exist when logging out, then a dialog opens, prompting whether or not forcing should be lifted for all variables. If you respond by clicking *"No"*, then the forced values are applied again at the next login.

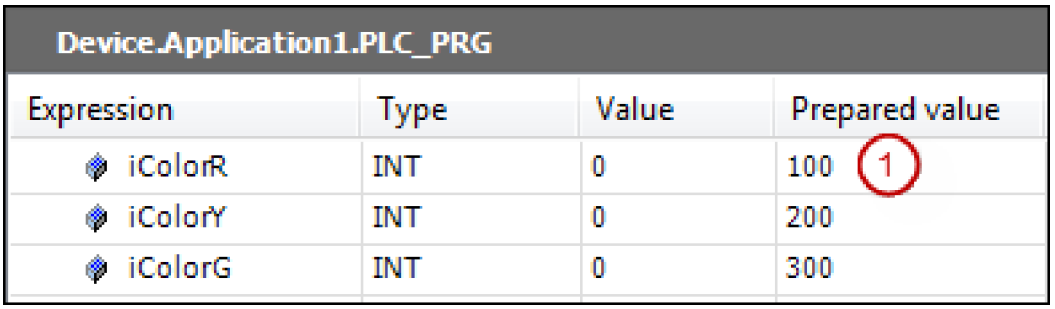
See also

- *Chapter 1.4.1.8.16 "Task Configuration" on page 292*
- *Chapter 1.4.1.20.4.10.19 "Dialog 'Properties' - 'Options'" on page 1169*
- *"Setting: Configure synchronization with IEC tasks" on page 932*

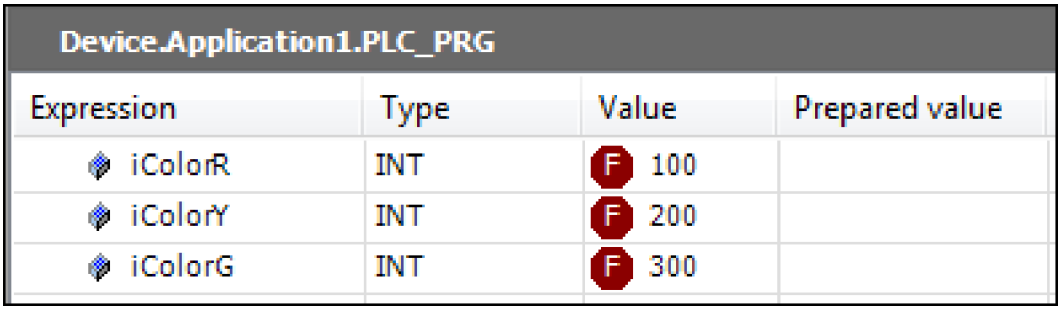
Forcing in the declaration part

Requirement: Your application includes a POU with declarations. The application is in online mode.

1. Open the POU in the editor by choosing the command *"Project ➔ Edit Object"*.
2. In the declaration part of the editor, double-click in column (1) *"Prepared Value"* of a variable.
   ⇨ The field can be edited and a value can be entered. When it is a Boolean value, you change the value by clicking in the field.



3. Perform Step 2 for other variables.
4. Click *"Debug ➔ Force Values"*.
   ⇨ The variable values are overwritten with the prepared values. The values are marked with the F symbol.



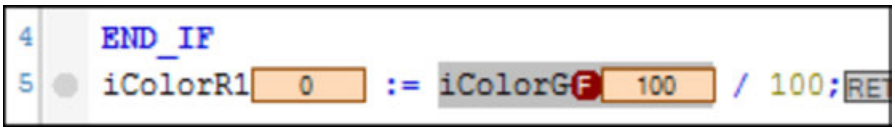
You can also force the variable values in the "Watch" view.

Forcing in the implementation part

Requirement: The application is in online mode.

1. Open the POU in the editor by choosing the command *"Project ➔ Edit Object"*.
2. In the implementation part of the editor, double-click an inline monitoring field (1).
   ⇨ The *"Prepare Value"* dialog opens.
3. Enter the new value in the field *"Prepare a new value for the next write or force operation"*.
   ⇨ The prepared value appears in the inline monitoring field.

4. Click *"Debug ➔ Force Values"*.
   ⇨ The value of the variables is overwritten with the prepared values. The values are marked with the F symbol.



Viewing and editing all forced variables one list

Requirement: The application is in online mode. Multiple variables are forced.

1. Click *"View ➔ Watch ➔ Watch all Forces"*.
   ⇨ The *"Watch all Forces"* view opens. It contains all currently forced variables of the application in the form of a watch list.
2. Select all lines in the list and click *"Unforce ➔ Unforce and Keep All Selected Values"* in the list box in the upper left part of the view.
   ⇨ The variables are unforced and they get the values that they had before forcing.

Forcing a function block input in CFC

Requirement: An application has a CFC POU that contains a function block, and the application is in offline mode.

NOTICE!
This kind of forcing uses a data breakpoint internally and is therefore different from forcing with the *"Force Values"* command or *[F7]*.

Values that were forced by the command *"Force FB Input"* do not respond to the commands *"Show All Forces"* or *"Unforce Values"*.

1. Open the editor of the CFC POU by double-clicking the object in the tree.
2. When using compiler version 3.5.11.x or 3.5.12.x, enable the "forceability" for the desired function block. Select the POU element in CFC and click *“CFC ➔ Prepare Box for Forcing”*.
3. Log in to the application on the target device. In CFC, select the input of the POU and click *“Force Function Block Input”* in the context menu.

   ⇨ The *“Force Value”* dialog opens.
4. Set a new value for the input. Example in the case of a `TON` POU: `FALSE` for the Boolean input `IN`, or `t#4s` for the `PT` input (TIME). Click *“OK”* to confirm.

   ⇨ The set value is forced immediately. A green circle is displayed at the upper left of the POU element and the name of the input in the element is highlighted in green. In the case of a Boolean value, a small monitoring view with the value also opens at the input. In the monitoring views, the forced value is displayed, for example in the *“Value”* column, as in the declaration part.
5. To remove the forced value, click *“Force Function Block Input”* again. In the *“Force Value”* dialog, select the *“Remove value”* option.

   ⇨ Forcing is canceled. The input gets the current value from the controller.

1.4.1.11.5 Resetting applications

Resetting the application stops the program and resets the variables to their initialization values. Depending on the type of reset, retain variables and persistent variables are also reset.

- Reset warm: All variables are reset, except `RETAIN` and `PERSISTENT` variables.
- Reset cold: All variables are reset, except `PERSISTENT` variables.
- Reset origin: All variables are reset.
- Reset origin device: All variables are reset and all applications are deleted.

The following sample program and statements clarify the functionality of the various resets.

See also

- *“Lifespan of variables when calling online commands” on page 303*

Sample program

Example

Declaration

```
VAR
    iVar: INT := 0;
END_VAR
VAR RETAIN
    iVarRetain: INT :=0;
END_VAR
VAR PERSISTENT
    iVarPersistent : INT:= 0;
END_VAR
```

Implementation

```
iVar := 100;
iVarRetain := 200;
iVarPersistent :=300;
```

1. Insert the *"Persistent Variables"* object below the application and open it in the editor.
2. Click *"Build ➔ Build"*.
3. Click *"Declare ➔ Add All Instance Paths"*.
   ⇨ The instance path of the persistent variables is inserted.
4. Download the application to the controller.

Executing a "Reset warm", "Reset cold", and "Reset origin"

Requirement: The sample program runs on the controller.

1. Click *"Online ➔ Login"* to switch to online mode.
2. Monitor the variables `iVar`, `iVarRetain`, and `iVarPersistent`.
3. Click *"Online ➔ Reset Warm"*.
   ⇨ You are prompted whether you really want to execute the command.
4. Click *"Yes"* to confirm the dialog.
   ⇨ The application is reset. The `iVar` variable is set to the initialization value 0. Both of the other variables retain their values.
5. Click *"Online ➔ Reset Cold"*.
   ⇨ You are prompted whether you really want to execute the command.
6. Click *"Yes"* to confirm the dialog.
   ⇨ The application is reset. The `iVar` and `iVarRetain` variables are set to the initialization value 0. The `iVarPersistent` variable retains its value.
7. Click *"Online ➔ Reset Origin"*.
   ⇨ You are prompted whether you really want to execute the command.
8. Click *"Yes"* to confirm the dialog.
   ⇨ The application is reset. All variables are reset to their initialization values.

See also

1.4.1.11.6 Flow Control

With flow control, you can monitor the processing of the application program. Flow control is provided for the ST, FBD, LD, and CFC language editors.

With an activated flow control, CODESYS displays the variable values and results from function calls and operations at the respective processing location and time. In this way, the exact lines of code and networks that process the current cycle are marked in colors. Compare this to standard monitoring, in which CODESYS delivers only the value that a variable has between two processing cycles.

Flow control works in all parts of the editor view that are currently visible. *“Flow control enabled”* is then displayed in the status line as long as the function is active and flow control positions (processed parts of code) are visible in an editor view.

You can write values in the declaration part and implementation part. Forcing is not possible.

NOTICE!
Values are written at the end of the current cycle.

NOTICE!
When you enable flow control, the cycle time of the application is prolonged.

When *“Confirmed Online Mode”* is selected in the communication settings, a dialog prompt appears when switching on the flow control to cancel the operation.

When flow control is enabled, it is not possible to use breakpoints or step through the program.

See also

- *Chapter 1.4.1.20.2.8.2 “Tab 'Communication Settings'” on page 840*
- *Chapter 1.4.1.20.3.7.22 “Command 'Flow Control'” on page 1056*

Display of the flow control in different language editors

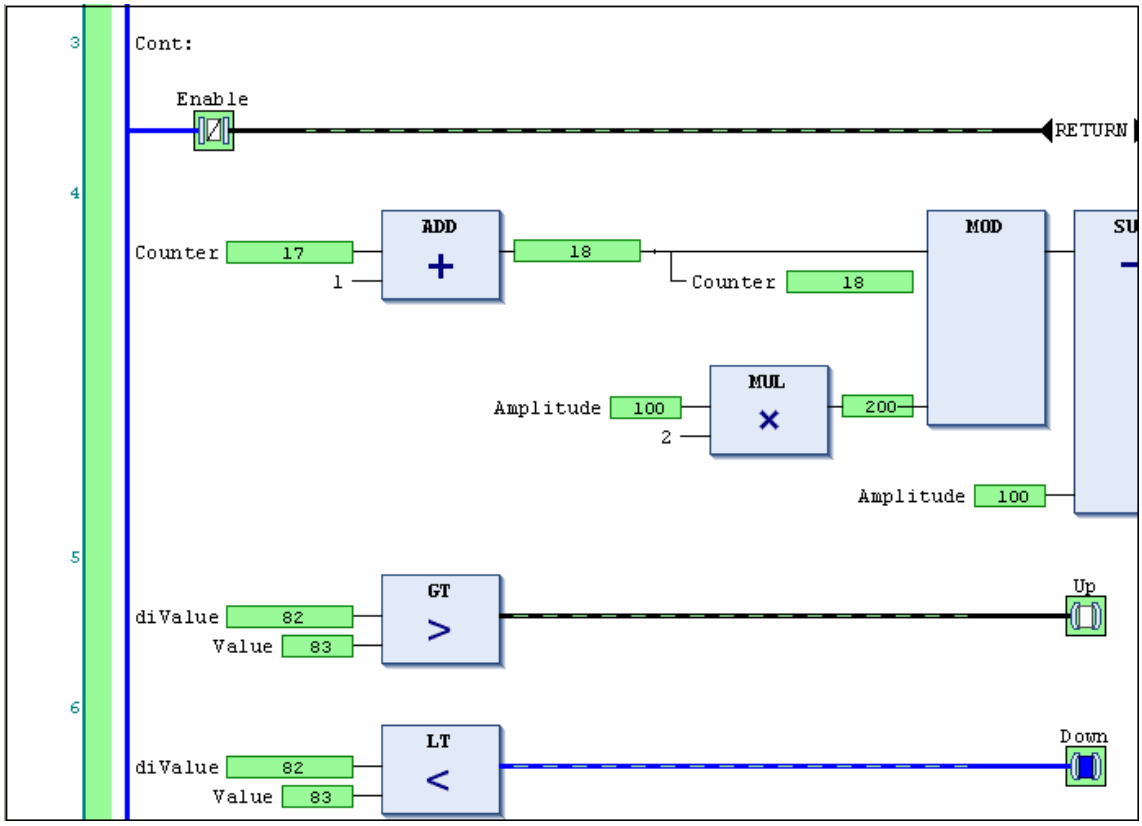
By default, CODESYS displays the flow control positions of the processed parts of code as green fields. Unprocessed parts of code are displayed in white.

Note that the displayed value of an unprocessed code position is an ordinary monitoring value. This is the value between two task cycles.

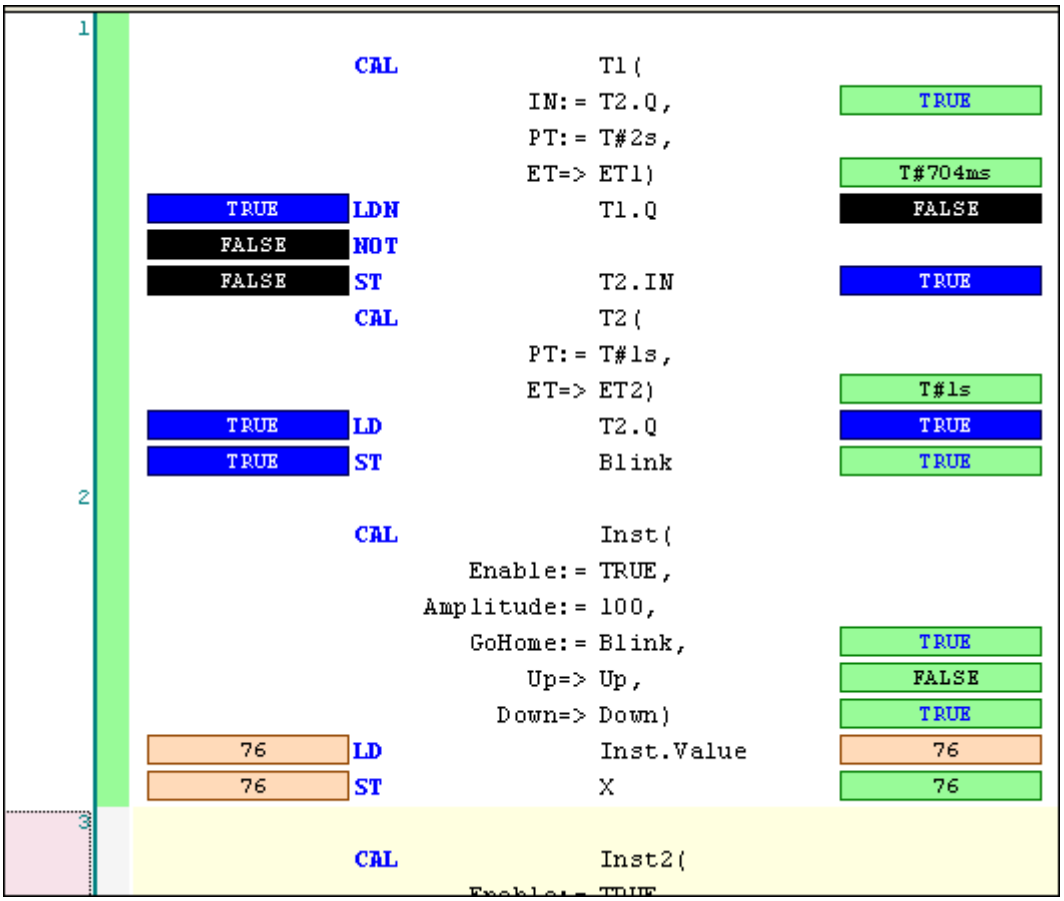
```
1  i 1619 := i 1619 + 1;
2  b 0 := NOT b 0;
3  IF str 'abcdefghij' = str1 '' THEN
4  fl2 1.5 := fl 1.23;
5  ELSE
6  fl2 1.5 :=1.5;
7  D 6.5E+04 :=B255*B255;
8  END_IF;
9  IF D 6.5E+04 <0.0 THEN
```

In network editors, CODESYS marks the processed networks with bars on the left edge in the flow control color.

In LD, CODESYS displays the currently processed connecting lines in green and all others in gray. The actual value of the connection is also displayed: `TRUE` by a bold blue line, `FALSE` by a bold black line, and unknown or analog values by thin black lines. Combinations of these lines are displayed as dashed lines.



In IL, for each statement CODESYS uses two fields for the display of the actual values. One is located to the left of the operator with the current accumulator value, and one is located to the right of the operand with the operand value.



1.4.1.11.7 Determining the current processing position with the call stack

You can use the call stack for determining the current position of the program flow. This function is very useful when stepping into programs.

Requirement: The application is in online mode. The program is halted at a breakpoint or you are stepping into it.

▷ Open the call stack by clicking *"View ➔ Call Stack"*.

⇨ The call stack opens. The list shows the current location with the complete call path.

The call stack is also available in offline mode and normal online mode (without using debugging functions). In this case, it receives the last displayed location during a stepped execution, but it is displayed in gray.

See also

- ↳ *Chapter 1.4.1.20.3.3.15 "Command 'Call Stack'" on page 993*
- ↳ *Chapter 1.4.1.11.3 "Stepping Through a Program" on page 399*

1.4.1.11.8 Checking the Task Deployment

The Tab *"Task Deployment"* of the device editor indicates in an overview the tasks that process the individual inputs and outputs of the I/O mapping of your application and the priority with which they do so. You can check here whether an unintentional overwriting of values is caused, which can lead to undefined values.

1. Generate code for the application: to do this select, for example, the command *“Build ➔ Generate Code”*.
2. Open the device editor by double-clicking on the device object in the device tree. Select the *“Task Deployment”* tab.
   ⇨ You obtain a display of the inputs and outputs of your application and the assignment of the tasks and their priorities. See the description of the *“Task Deployment”* tab for details.

See also

- *Chapter 1.4.1.20.2.8.17 “Tab 'Task deployment'” on page 869*
- *“General information about I/O mapping” on page 214*

1.4.1.12 Application at Runtime

When the application is running on the PLC, in the CODESYS Development System there are some features for monitoring and changing the values of the variables as well as for recording and storing the value charts.

Furthermore, you can poll some information from the PLC, you can have a look into the PLC-log, display a core dump and monitor the time behavior of the tasks.

Regard also the possibility to restrict the access on the running application in critical states of the machine via online commands provided by CODESYS Development System. For this purpose some system variables are available in a module of the `ComponentManager` library.

1.4.1.12.1 Monitoring of Values

In runtime mode, you can monitor the current variable values of a programming object at different places in a project. The following is what we refer to as monitoring:

- Online view of the programming editor of an object: inline monitoring
- Online view of the declaration editor of an object
- Object-independent, configurable watchlists

When you set the {attribute 'monitoring'...} pragma, you can monitor the results from function calls and the current variable values in property-type objects.

More options for recording current variable values:

– *Read and save recipes*
– *Record values on a timeline for displaying the history immediately or later: trace and trend features*

See also

- ↳ *Chapter 1.4.1.19.6.2.25 “Attribute 'monitoring'” on page 709*
- ↳ *Chapter 1.4.1.12.1.2 “Using watch lists” on page 416*
- ↳ *Chapter 1.4.1.12.2 “Changing Values with Recipes” on page 417*
- ↳ *Chapter 1.4.1.12.3 “Data Recording with Trace” on page 421*
- ↳ *Chapter 1.4.1.12.4 “Data Recording with Trend” on page 430*

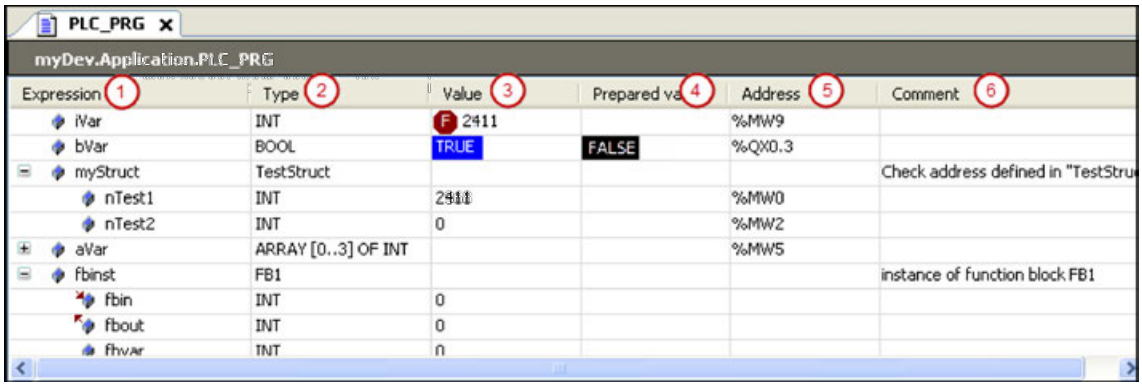
Calling of monitoring in programming objects

When an application is running on the controller, the actual values of variables are displayed in the editors of the POUs. This is how the values of variables are monitored.

☑ Requirement: The *“Enable inline monitoring”* option is activated in *“Tools* ➔ *Options”* in the *“Text Editor”* category on the *“Monitoring”* tab.

1. Download an application to the controller and start it.
2. Click *“Debug* ➔ *Display Mode* ➔ *Decimal”*.
   ⇨ The display format of the actual values is set.
3. Click a programming object in the *“Devices”* view or *“POUs”* view.
   ⇨ The respective editor opens. Actual values of the variables are refreshed continually for both the declaration and implementation.

Monitoring in the declaration editor



The actual value of an expression (1) is displayed in the *“Value”* column (3).

You can write and force a value in the *“Prepared Value”* (4) column. During the forcing, the actual value is decorated with a red symbol (F).

The expression of an interface reference can be expanded. If the interface points to a global instance, then this global instance is displayed as the first entry below the reference. Afterwards, if the interface reference changes, then the displayed reference is collapsed.

Monitoring in the implementation (inline monitoring)

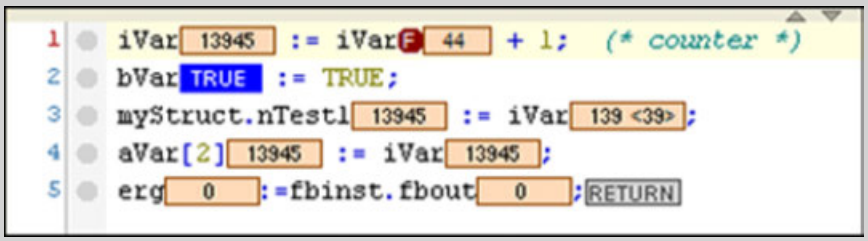
Inline monitoring is the display of the current variable value in the implementation.

Depending on the implementation language, the following displays are possible in the implementation part:

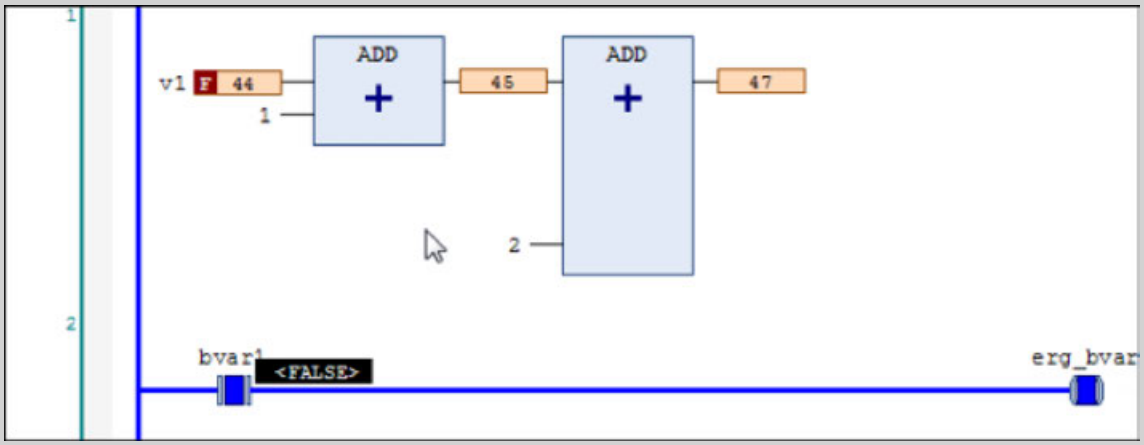
- Variables have a window with the current value displayed after their name: `nResult2` 17
  If you have prepared values for variables for forcing or writing, then they are displayed in angle brackets in the inline monitoring view after the current value.
  After forcing, the respective values are identified by the F symbol.
- Network editors and the CFC editor:
  Connecting lines are displayed in color according to their actual Boolean value (blue means `TRUE`, black means `FALSE`).

- LD editor:
  The contact and coil elements are also marked.
  For contacts and coils, a prepared value (`TRUE` or `FALSE`) is shown in a small view next to the element.
- SFC editor:
  Transitions with the value `TRUE` are displayed in color according to their actual Boolean value (blue means `TRUE`, black means `FALSE`).
  Active steps are displayed in blue.
  Forced transition values are displayed in red in the implementation.
- IL tabular editor:
  Current values are displayed in a separate column.

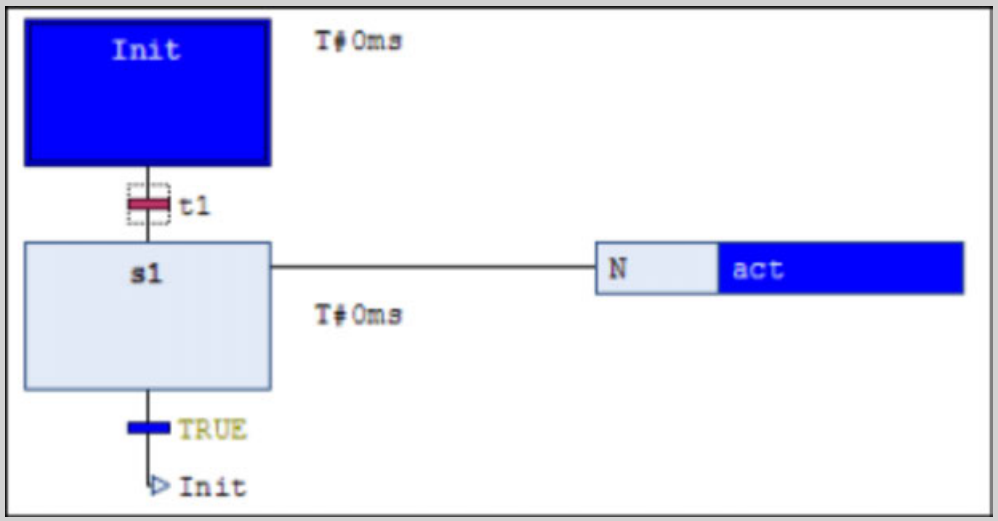
Monitoring in the ST editor



Monitoring in the LD editor



Monitoring in the SFC editor



> *You can deactivate the inline monitoring function in "Tools ➔ Options", in the "Text Editor" category on the "Monitoring" tab.*

See also

- *Chapter 1.4.1.19.1.3.1 "ST Editor" on page 463*
- *Chapter 1.4.1.19.1.3.2 "ST editor in online mode" on page 463*
- *Chapter 1.4.1.19.1.5.2 "FBD/LD/IL editor in online mode" on page 499*
- *Chapter 1.4.1.19.1.4.2 "SFC Editor in Online Mode" on page 476*
- *Chapter 1.4.1.19.1.6.4 "CFC Editor in Online Mode" on page 516*

Partial monitoring of an array

An expanded array shows the actual values for up to 1000 elements. However, this can be confusing. In addition, an array can contain more than 1000 elements. Then it is helpful to limit the range of displayed elements. You can do this in online mode in the following way.

Limiting the monitoring range

☑ Requirement: An application is running. It contains a multidimensional array variable with more than 1000 elements. Example: `arrBig : ARRAY [0..100, -9..10, -19..20] OF INT;`

1. Click in the field of the *"Data Type"* column for the `arrBig` variable.
   ⇨ The *"Monitoring Range"* dialog opens.
2. Specify the value `[1, -9, -19]` for *"Start"*.
3. Specify the value `[1, 10, 20]` for *"End"*.
   ⇨ The actual values of 800 array elements are displayed in the declaration editor. The range is limited to the elements of the index `[1, <i>, <j>]` with i from -9 to 10 and j from -19 to 20.

See also

- *Chapter 1.4.1.19.1.1 "Declaration Editor" on page 461*
- *Chapter 1.4.1.11.4 "Forcing and Writing of Variables" on page 401*
- *Chapter 1.4.1.20.4.9 "Dialog 'Monitoring Range'" on page 1156*

Monitoring a function block

When you double-click the editor view of a function block in online mode, a dialog opens where you can choose between viewing the basic implementation or a specific instance.

If you select the basic implementation, then the code is displayed in the editor without current values. Now set a breakpoint in the basic implementation. If the execution halts there, then the current values of the instance that is processed first in the program flow are displayed. Now you can step successively through all instances.

If you select one of the instances, then the editor opens with the code of the function block instance. The current values are displayed in the declaration and, if applicable, in the implementation, and are updated continuously.

See also

- *Chapter 1.4.1.20.2.18.2 "Object 'Function Block'" on page 883*
- *Chapter 1.4.1.11.2 "Using Breakpoints" on page 395*

Monitoring a property

You can monitor variables in a property object by setting a breakpoint in the function during online mode. When halted there, the current values are displayed.

In addition to your own values, the values of the variables of the superordinate instance are displayed automatically. In the declaration part of the property, the `THIS` pointer, which points to the superordinate instance, appears in the first line with the current data type information and values.

Example

Code

```
FUNCTION_BLOCK FB_BaseAlfa
VAR
    iBaseLocal : INT;
    sBaseLocal : STRING;
END_VAR
iBaseLocal := iBaseLocal + 1;
sBaseLocal := 'Testing Text';

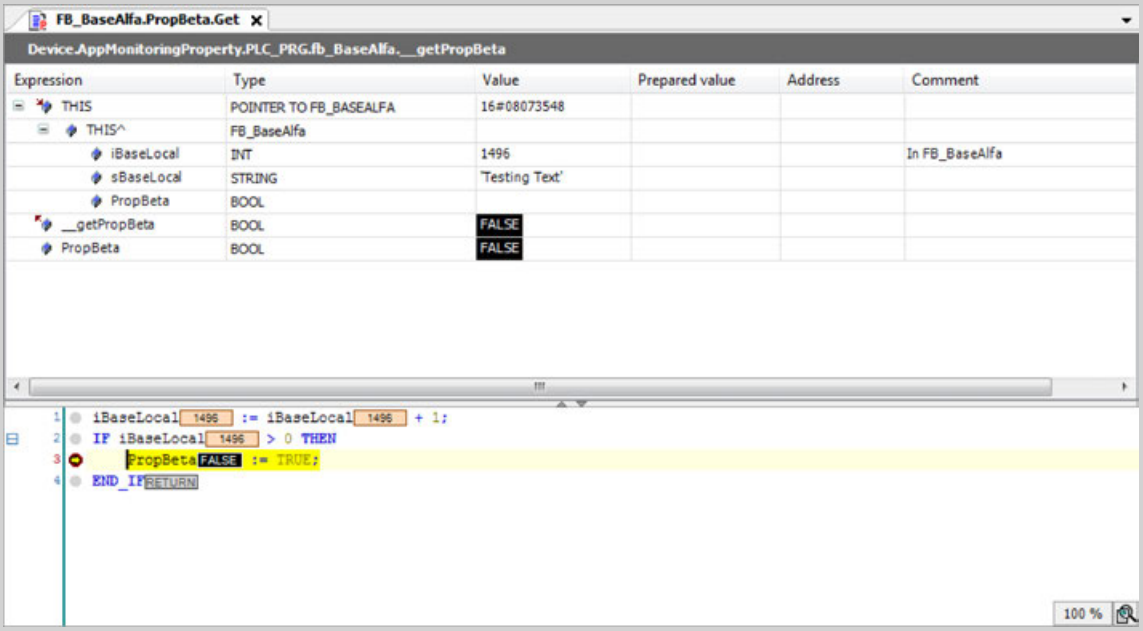
FB_BaseAlfa.PorpBeta.Get
iBaseLocal := iBaseLocal + 1;
IF iBaseLocal > 0 THEN
    PropBeta := TRUE;
END_IF

FB_BaseAlfa.PorpBeta.Set
IF PropBeta = TRUE THEN
    iBaseLocal := 0;
    sBaseLocal := 'Tested IF';
END_IF

PROGRAM PLC_PRG
VAR
    fb_BaseAlfa : FB_BaseAlfa;
END_VAR

fb_BaseAlfa();

IF fb_BaseAlfa.PropBeta = TRUE THEN
    xResult := TRUE;
END_IF
IF xReset THEN
    fb_BaseAlfa.PropBeta := TRUE;
    xReset := FALSE;
END_IF
```



See also

- *Chapter 1.4.1.20.2.18.8 “Object 'Property'” on page 897*

Monitoring of property access in the superordinate programming object

You can monitor the values of subordinate properties in a function block or program in addition to the variable values.

To do this, add either the pragma `{attribute 'monitoring' = 'variable'}` or `{attribute 'monitoring' = 'call'}` to the subordinate property object in the declaration. If you open the superordinate program instance or function block instance at runtime, then the current property values are displayed in the editor in addition to the current variable values.

See also

- *Chapter 1.4.1.20.2.18.8 “Object 'Property'” on page 897*
- *Chapter 1.4.1.19.6.2.25 “Attribute 'monitoring'” on page 709*

Monitoring a method

You can monitor variables in a method object by setting a breakpoint in the method during online mode. When halted there, the current values are displayed.

In addition to your own values, the values of the variables of the superordinate instance are displayed automatically. In the declaration part of the method, the `THIS` pointer, which points to the superordinate instance, appears in the first line with the current data type information and values.

Example

Code

```
FUNCTION_BLOCK FB_BaseAlfa
VAR
    iBaseLocal : INT;
    sBaseLocal : STRING;
END_VAR
iBaseLocal := iBaseLocal + 1;
sBaseLocal := 'Testing Text';

METHOD MethBaseAlfa : BOOL // Method of FB_BaseAlfa
VAR_INPUT
END_VAR
VAR
    iMethLocal : INT;
END_VAR
iMethLocal := iMethLocal + 1;

PROGRAM PLC_PRG
VAR
    fb_BaseAlfa : FB_BaseAlfa;
END_VAR
fb_BaseAlfa();
fb_BaseAlfa.MethBaseAlfa();
```

- *Chapter 1.4.1.20.2.18.5 “Object 'Method'” on page 889*

Monitoring a function

You can monitor variables in a function object by setting a breakpoint in the function during online mode. When halted there, the current values are displayed.

Monitoring the return value of a function call

In the ST editor of a POU, the current return value is displayed as inline monitoring at the position of the POU where a function is called.

The following conditions must be fulfilled:

- The value can be interpreted as a 4-byte numeric value. Example: `INT`, `SINT`, or `LINT`.
- The pragma `{attribute 'monitoring' := 'call'}` is inserted into the function.

See also

- *Chapter 1.4.1.20.2.18.3 “Object 'Function'” on page 886*
- *Chapter 1.4.1.19.6.2.25 “Attribute 'monitoring'” on page 709*

Using watch lists

What is a watch list?

A watch list is a user-defined list of project variables that are collected in one view for the purpose of monitoring their values. In online mode, you can write and force variable values in a watch list. Monitoring, writing, and forcing are handled the same way as the declaration editor in online mode. You can customize the format of the representation of floating-point values in the options for monitoring.

There are four, ready-to-use watch lists (`Watch <n>`) available in a project. Click *“View ➔ Watch”*.

> *If the expression is an interface reference, then it can be expanded. If the interface points to a global instance, then this global instance is displayed as the first entry below the reference. If the interface reference changes, then the displayed reference is collapsed.*

See also

- *Chapter 1.4.1.19.1.1 “Declaration Editor” on page 461*
- *Chapter 1.4.1.20.4.13.18 “Dialog 'Options' - 'Monitoring'” on page 1197*

Creating and editing a watch list (offline or online mode)

Requirement: The project is in either online or offline mode. It includes an application with declared variables that you want added to one of the four possible watch lists.

1. Click *“View ➔ Watch ➔ Watch <n>”*.

   ⇨ The `Watch <n>` view opens. It contains a blank table row.

2. Double-click the field in the *“Expression”* column and type a variable to monitor, either manually or with the input assistant.

   Syntax: <device name>.<application name>.<object name>.<variable name>

   Example: "`Dev1.App1.PLC_PRG.ivar`"

   If you type the name of a structured variable, then the individual components are displayed automatically in other lines in online mode.

3. Define all successive variables that will be monitored with this list. You can change the order by using drag and drop operations.

   ⇨ The *“Execution point”*, *“Type”*, *“Address”*, *“Comment”* fields are filled in automatically according to the variables declaration. The symbol before the expression indicates the type of variable: input variable (), output variable (), or ordinary variable ( ).

> *In online mode, you can also create or edit watch lists by right-clicking and choosing the “Add Watch” command.*

See also

- *Chapter 1.4.1.20.3.3.8 “Command 'Watch' - 'Watch <n>'” on page 987*

Adding variables by choosing the 'Add Watch' command (online mode)

Requirement: A project is open and running. It includes an application with declared variables that you want added to a possible watch list.

1. Click *“View ➔ Watch <n>”* to open the watch list.
2. Place the cursor on a variable in the declaration or implementation part of a POU and right-click to choose the *“Add Watch”* command.
   ⇨ This adds an entry to the list for the selected variable.
3. You can add other variables in this way or by typing directly into the list in the *“Expression”* field as described above.
   ⇨ The watch lists are updated immediately.

If a watch list is not open when you click “Add Watch” for a variable, then it is added automatically to the “Watch 1” list.

Writing and forcing variable values is also possible in the watch lists. In online mode, the “Prepared value” column is also available.

See also

- *Chapter 1.4.1.20.3.22.1 “Command 'Add Watch'” on page 1147*
- *Chapter 1.4.1.12.1.1 “Calling of monitoring in programming objects ” on page 410*
- *Chapter 1.4.1.11.4 “Forcing and Writing of Variables” on page 401*

1.4.1.12.2 Changing Values with Recipes

Use recipes to change or read recipes values for a specific set of variables (recipe definition) on the controller at the same time.

You define the basic settings for recipes, such as location and format, in the *“Recipe Manager”* object. Insert one or more recipe definitions below this object. A recipe definition is composed of one or more recipes for the contained variable. The recipe consists of specific variable values.

You can save a recipe to a file or write directly from files to the PLC.

Recipes can be loaded via the CODESYS development interface, the visualization element, or the application program.

Using recipes on remote devices

The variable values from recipes are transferred automatically to and from another controller when they are data source variables and a data source exchange is configured. Reading and writing occurs synchronously. Therefore, CODESYS updates all variables in a recipe at the same time. After reading or writing, you can use the call `g_RecipeManager.LastError` *to check whether or not the transfer was successful (*`g_RecipeManager.LastError = 0`*).*

See also

- *Chapter 1.4.1.20.2.22 “Object 'Recipe Manager'” on page 923*
- *Chapter 1.4.1.20.2.23 “Object 'Recipe Definition'” on page 926*
- *Chapter 1.4.1.9.4 “Data Link with Data Sources” on page 363*

Handling of recipes in the CODESYS user interface

The development interface of CODESYS provides commands for generating recipes as well as reading/writing in online mode.

See also

- *Chapter 1.4.1.20.3.19 “Menu 'Recipes'” on page 1127*

Using recipes in applications

At runtime, you can use recipes in the user program and visualization elements.

In the user program, you use the methods for the function block `RecipeManCommands` from the library `RecipeManagement`. In the visualization, you use recipes via the input configuration (internal command of visualization elements.

During the initialization process, the recipe management reads the values of the variables that are defined in the recipe definition. This operation takes place at the end of the initialization phase of the application. At this point, all initial values of the application variables are set. This is performed to initialize missing values from recipe files correctly.

See also

- *RecipeManCommands*
- *Input Configuration*

Creating a recipe

1. Select the *“Application”* object in the device tree.
2. Click *“Project ➔ Add Object ➔ Recipe Manager”*.
   ⇨ CODESYS adds the Recipe Manager to the device tree.
3. Select the *“Recipe Manager”* object in the device tree.
4. Click *“Project ➔ Add Object ➔ Recipe Definition”*.
   ⇨ CODESYS adds the recipe definition below the Recipe Manager.
5. Open the editor of the recipe definition by double-clicking the object.
6. Double-click the blank field below *“Variable”*. Specify the name of a variable that you will define a recipe. The Input Assistant can be used for this: [...] button.
7. Click *“Recipes ➔ Add New Recipe”* and specify a name for the new recipe.
   ⇨ A column with the new recipe name appears in the editor.
8. Enter the variable value for this recipe in this field.
9. Insert additional fields as needed.
10. Select a variable value for the recipe and click *“Recipes ➔ Save Recipe”*. Select a location and file name.
    ⇨ CODESYS saves the recipe in the format as defined in the Recipe Manager.

See also

- *Chapter 1.4.1.20.2.22 “Object 'Recipe Manager'” on page 923*
- *Chapter 1.4.1.20.2.23 “Object 'Recipe Definition'” on page 926*
- *Chapter 1.4.1.20.3.19 “Menu 'Recipes'” on page 1127*

Loading a recipe from a file

Requirement: A Recipe Manager is available in the application. In a recipe definition, there is a *“myRec”* recipe with variable values. A `myRec.txt` recipe file is located on the file system and contains the entries for this recipe.

Example of the recipe file:

```
PLC_PRG.bVar:=0
PLC_PRG.iVar:=2
PLC_PRG.dwVar:=35232
PLC_PRG.stVar:='first'
PLC_PRG.wstVar:='123443245'
```

1. Double-click the *“Recipe Definition”* object in the device tree to open the tabular editor for the definition of the individual recipes.
   ⇨ You see the `myRec` column with the current values for this recipe.
2. Edit the `myRec.txt` file in an external text editor and replace the variable values with other values that you want to load into the recipe definition in CODESYS. Save the file.
3. Click the *“myRec”* column in the recipe definition and click *“Load Recipe”* in the context menu.
   ⇨ A dialog prompt notifies you about the possibly needing to perform an online change when logging in again. An online change is necessary when you change the current values of the recipe variables by loading the recipe.
4. Click *“Yes”* to close the dialog and continue. Select the `myRec.txt` file from the file explorer for loading.
   ⇨ The recipe values in the recipe definition are updated according to the values read in the file.

If you want to overwrite only individual recipe variables with new values, then remove the values for the other variables before loading to the recipe file. Entries without value definitions are not read, and therefore updating leaves these variables unchanged on the PLC and in the project.

For values of the data type REAL/LREAL, the hexadecimal value is also written to the recipe file in some cases. This is necessary so that the exact identical value is restored when converting back. In this case, change the decimal value and delete the hexadecimal value.

- *Chapter 1.4.1.20.3.19.4 “Command ‘Load Recipe'” on page 1128*
- *Chapter 1.4.1.20.3.19.8 “Command 'Load and Write Recipe'” on page 1129*

Recipe management on the controller; memory usage

When you clear the *“Recipe management in the PLC”* option, the Recipe Manager and recipe definitions will not use any memory on the PLC.

If you select this option, then code is generated for the Recipe Manager and all recipe definitions, and this code is stored on the PLC. The size of the used memory primarily depends on the number pf recipes and their variables, as well as the data type of the variables. Whether or not the fields of the recipe definition are filled also has an effect. The memory usage of recipes cannot be calculated. It has to be determined by experimentation at the time it is needed. The following table merely provides some guiding principles.

	Code Size (bytes)	Data Size (bytes)	Total (bytes)
Recipe definition with 100 INT variables	194406	79400	267352
Recipe definition with 200 INT variables	238318	121284	459344
Recipe definition with 300 INT variables	282230	163084	543856
Recipe definition with 100 BOOL variables	192742	69884	343168
Recipe definition with 200 BOOL variables	235446	101568	436872
Recipe definition with 300 BOOL variables	278146	133284	510072
Recipe definition with 100 string variables	203278	870084	1154000
Recipe definition with 200 string variables	255570	1709784	2973296
Recipe definition with 300 string variables	307886	2549484	2964112

Loading recipe values from the controller

You can apply recipe values on the controller to recipe definitions in the project, even if these definitions have been modified in the project.

Requirement: The *“Recipe management in the PLC”* is option is selected in the Recipe Manager.

1. Create a recipe definition `RecDef1` in the project, containing the variables `PLC_PRG.ivar` and `PLC_PRG.bvar`. Insert a recipe *“R1”*: value for `PLC_PRG.ivar`: `33`; value for `PLC_PRG.bvar`: `TRUE`.
2. Log in to the controller and download the application.
   ⇨ The recipe file `R1.RecDef1.txtrecipe` is saved to the default directory of the controller ($PlcLogic$).
3. Logout and add another variable `PLC_PRG.dwvar` to the recipe definition in the project.
4. Edit the recipe definition file `R1.RecDef1.txtrecipe` on the device by changing the value for `PLC_PRG.ivar` from `33` to `34`.

   Moreover, add another recipe *“R2”* on the device. To do this, copy the `R1.RecDef1.txtrecipe` and rename it to `R2.RecDef1.txtrecipe`. Then edit this file and change the recipe values: `PLC_PRG.ivar`: `1`, `PLC_PRG.bvar`: `FALSE`.

   ⇨ Now two recipes *“R1”* and *“R2”* are available on the device. In the project, there is only *“R1”*, and it also contains other values than *“R1”* on the device.
5. Log in to the controller by means of an online change.
6. Click *“Load Recipes from Device”* from the context menu.
   ⇨ A dialog prompt notifies you that executing the command at the next login may trigger an online change, and that the recipes on the runtime system will overwrite the recipes of the current recipe definition.
7. Confirm that you want to continue.
   ⇨ A dialog prompt notifies you that the recipe for `PLC_PRG.dwvar` loaded on the device cannot yield a value from the controller.

8. Confirm that you want to continue.

   ⇨ The value of `PLC_PRG.ivar` in recipe *"R1"* of the recipe definition in the project changes to `34`. The recipe *"R2"* with the values `1` and `FALSE` is also listed in the recipe definition now. `PLC_PRG.dwvar` remains in the recipe definition.

1.4.1.12.3 Data Recording with Trace

You can use a *"Trace"* to follow the value history of variables on the controller in a similar way as a digital sampling oscilloscope. When the application is in runtime mode with trace, all statements are executed first within the task cycle. Then, data recording starts with value storage including time stamps. These time stamps are relative and refer to the start time of the data recording. The data yields a discrete time signal and CODESYS displays its course in the trace editor.

A sample (data record) is composed of the value and the time stamp. The runtime system writes the samples to a buffer with a definable size. CODESYS requests the data, saves it in the trace editor buffer, and displays it in the trace diagram as a function of time. You can monitor the value history of the configured variables continually because CODESYS displays the latest data.

You can trigger the data recording. When this happens, the application saves the data from the time of the trigger and CODESYS displays the data at the time of the trigger.

The configuration and the display of a trace are possible in the CODESYS project by means of trace objects in the trace editor. There are the following two object types:

- *"Trace"*: Inserted below the IEC application in the device tree. This kind of object always contains a purely application-specific trace configuration. You can download this trace configuration to the controller and run it with the application.
- *"DeviceTrace"*: Inserted below the device object in the device tree. If the PLC supports a trace manager, then you can use one or more *"DeviceTrace"* objects to access one or more traces that are running on the controller. These can be both application-specific or controller-specific traces. For example, a controller can support traces for recording the processor load. Menu commands allow for access from the CODESYS project to the trace manager in the device.

Access to the trace manager from IEC code is possible by means of the functions from the library `CmpTraceMgr.library`. For more information, refer to the library documentation.

NOTICE!
A running data recording with trace can lead to a significant increase in the cycle time of the IEC task.

NOTICE!
Data recording with trace also continues running after logging out of the device.

Runtime system component `CmpTraceMgr`, "Trace manager"

The device description of a runtime system with trace manager includes the `tracemanager` entry in the `TargetSettings` section.

In this case, CODESYS transfers only the trace configuration when downloading the application to the PLC. When you start the trace, the application interprets the configuration on the RTS by means of the trace manager, executes the data recording, and buffers the data sets on the PLC.

The `CmpTraceMgr` runtime system component provides extended functionality, as compared to data recording with IEC code.

Data recording is therefore possible as follows:

- Parameters on the PLC (for example, the processor load (cpuload, plcload), or the temperature curve of a CPU or a battery). The measurement of the processor load per CPU core (cpuload) is interesting for multicore controllers.
- Device signals (for example, the current path of a drive)
- System variables of another runtime system component

You can configure parameters like IEC variables in the *“Trace Configuration”* dialog of the *“Variable Settings”*.

The display of traces that run on the controller is possible in the trace editor of a DeviceTrace object.

See also

- *Chapter 1.4.1.12.3.4 “Accessing All Traces on the Controller” on page 428*
- *Chapter 1.4.1.20.2.29 “Object 'DeviceTrace'” on page 948*
- *Chapter 1.4.1.20.4.15.2 “Dialog 'Trace Configuration'” on page 1209*

Data recording after triggering

To monitor data that depends on an event or a condition, you can free the data recording that depends on a trigger. At runtime, the application checks whether the event has occurred or the the condition is fulfilled, and then it buffers the data accordingly.

The trace configuration enables triggering by:

- a trigger variable that maps the event
- a condition as expression
- a combination of trigger variable and condition

Saving samples to a file

You can save samples from the development system to a file. The file can also include the trace configuration.

Table 28: Possible file formats

File Extension	File type	Description
`*.trace`:	*“Trace file”*	Contains the samples and the trace configuration in XML format. You can execute the *“Load Trace”* command to load the file to the trace editor when offline and analyze the samples without a controller.
`*.txt`	*“Text File”*	Contains the samples in ASCII format. You can edit the file with an external tool.

File Extension	File type	Description
`*.trace.csv`	*"Trace dump"*	File in CSV format includes the trace configuration and optional samples. You can create the file by clicking *"Export Symbolic Trace Config"*. You can transfer the file to the controller and load it to the application. Then you can execute the *"Load Trace"* command in CODESYS to display this in the trace editor. You can also click *"Trace ➔ Save Trace"* and select the `*.trace.csv` file format. You can transfer the file to the controller and load it with an HMI for analysis.
`*.traceconfig`	*"Symbolic trace configuration"*	Contains the trace configuration CSV format. You can create the file by clicking *"Export Symbolic Trace Config"*. The `CmpTraceMgr` runtime system component can read the file.

See also

- ↳ *Chapter 1.4.1.20.2.28 "Object 'Trace'" on page 945*
- ↳ *Chapter 1.4.1.20.2.29 "Object 'DeviceTrace'" on page 948*

Getting started

Program

PLC_PRG

```
PROGRAM PLC_PRG
VAR
    iVar : INT;
    rSin : REAL;
    rVar : REAL;
END_VAR

iVar := iVar + 1;
iVar := iVar MOD 33;

rVar := rVar + 0.1;
rSin := 30 * SIN(rVar);
```

☑ Requirement: The application is running the `PLC_PRG` program on the controller.

1. In the device tree, select the application and add a new trace object by clicking *"Project ➔ Add Object"*.

   ⇨ The respective trace editor opens with the commands available in the *"Trace"* menu.

2. Click *"Trace ➔ Configuration"*.

   ⇨ The *"Trace Configuration"* dialog box opens.

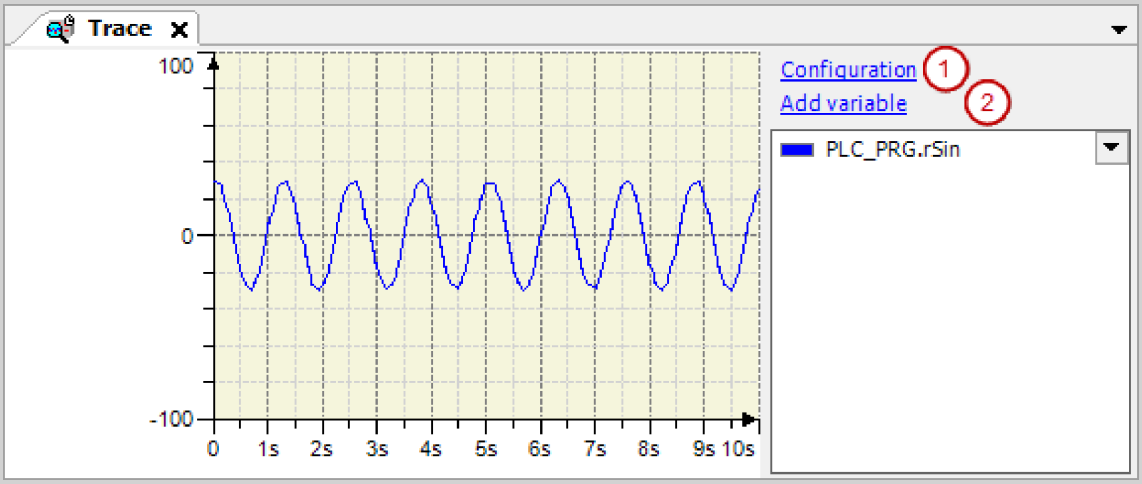
3. Select a task for running the trace feature. Normally this is the same task that is running in PLC_PRG.

4. Click *“Add Variable”* to add an entry to the tree view of the trace configuration and assign an IEC variable (for example, `PLC_PRG.rSin`).
5. Click *“Trace ➔ Download Trace”*.
   ⇨ CODESYS loads the trace configuration to the controller. The application starts recording data and transmits the data to CODESYS, where it is displayed in the trace diagram as a graph. Commands are provided for navigating through the samples and controlling the data recording.

Example

Trace the sine-shaped data of the IEC variable `PLC_PRG.rSin`

The `PLC_PRG` program is running on the controller. When you follow the instructions for "Getting Started", CODESYS displays the following trace diagram.



- (1) : *“Configuration”*
- (2) : *“Add Variable”*

See also

- *Chapter 1.4.1.20.2.28 “Object 'Trace'” on page 945*

Creating trace configuration

For a complete trace configuration, specify at least one task and one variable. In order to trigger the data recording, activate the trigger option and select a trigger variable or specify a recording condition.

See also

- *Chapter 1.4.1.20.4.15.1 “Dialog 'Advanced Trace Settings'” on page 1208*
- *Chapter 1.4.1.20.4.15.2 “Dialog 'Trace Configuration'” on page 1209*
- *Chapter 1.4.1.20.4.17 “Dialog Box 'Advanced Trend Settings'” on page 1214*
- *Chapter 1.4.1.12.4.2 “Configuring trend recording” on page 432*

Assigning a task

In this task, the data recording is executed in runtime mode. Usually the same task is selected where the variables are written.

1. Double-click the trace object.
   ⇨ The trace editor opens with the commands available in the *“Trace”* menu.

2. Click *“Trace ➔ Configuration”*.
   ⇨ The *“Trace Configuration”* dialog opens. In the tree view *“Trace Record”*, the top item is selected and the subdialog *“Record Settings”* is shown on the right.
3. Click the "arrow down" symbol (▼) in the *“Task”* drop-down list.
   ⇨ The drop-down list opens with all tasks that are available throughout the application.
4. Select a task for the trace.

See also

- *Chapter 1.4.1.20.4.15.2 “Dialog 'Trace Configuration'” on page 1209*

Configuring a trace variable

1. Double-click the trace object.
   ⇨ The trace editor opens. The commands of the *“Trace”* menu are available.
2. Click *“Add Variable”*.
   ⇨ The *“Trace Configuration”* dialog opens. The subdialog *“Variable Settings”* is displayed on the right.
3. Click … in the input field of the *“Variable”* setting and select a trace variable in the *“Input Assistant”* dialog.
   ⇨ The variable is configured for data recording. The trace record tree and the display tree were extended by the variable.
4. Click the *“Add Variable”* link.
   ⇨ The trace record tree and the display tree receive a new variable. The settings of the variables are available on the right.
5. Select a trace variable.
6. Click *“OK”* to close the dialog.
   ⇨ The variables are trace variables and are displayed in the trace variable list.

Deleting a trace variable

1. Double-click the trace object.
2. Click a variable in the trace record tree.
3. Click the *“Delete Variable”* command or press *[Del]*.
4. Click *“OK”* to close the dialog.
   ⇨ The variable is removed from the trace variable list.

Tracing a parameter

1. Double-click the trace object.
2. Click *“Add Variable”*.
   ⇨ The *“Trace Configuration”* dialog opens. The subdialog *“Variable Settings”* is displayed on the right.
3. Click ▼ (right of the *“Variable”* setting, left of the input field).
4. Select the *“Parameter”* option in the drop-down list.
5. Click … and select a parameter from the *“Input Assistant”* dialog.

6. Configure how the parameter is displayed.
7. Click *“OK”* to close the dialog.
   ⇨ The parameter will be traced and displayed in the trace variable list.

Configuring a trigger

1. Double-click the trace object.
   ⇨ The trace editor opens with the commands available in the *“Trace”* menu.
2. Click *“Trace ➔ Configuration”*.
   ⇨ The *“Trace Configuration”* dialog opens. The subdialog *“Record Settings”* is displayed on the right.
3. Select the *“Enable trigger”* check box.
4. Select the task in which the trend record is to be executed.
5. Select a variable from the *“Trigger Variable”* field.
6. Click *“OK”* to close the dialog.
   ⇨ The data recording will be triggered.

The trigger time is displayed as a black line in the diagram in runtime mode.

1. Download the application and start it.
2. Click *“Trace ➔ Download Trace”*.
   ⇨ The trace configuration is loaded. After triggering, the runtime system saves the value graph of the trace variables. The data is displayed in the trace editor. The trigger time is displayed as a black line in the diagram.

Configuring the display of the time axis

1. Double-click a trace object.
2. Click the *“Configuration”* link above the configuration tree.
   ⇨ The *“Trace Configuration”* dialog opens.
3. Select *“Time axis”* in the display tree (below *“Presentation (Diagrams)”*).
   ⇨ The display settings of the time axis are shown on the right.
4. Edit the presets and click the *“Preview”* link.
   ⇨ The changes are seen in the coordinate system preview.
5. Click *“Y-axis”* in the display tree. The *“Y-axis”* item is below every configured diagram. Therefore, the display of the value axis is set for each diagram.
   ⇨ The subdialog *“Display Settings”* of the selected axis is displayed on the right.
6. Change the preset value.
   ⇨ The changes are applied in the coordinate system preview.
7. Click OK to close the *“Trace Configuration”* dialog.
   ⇨ The display changes are visible in the affected diagrams.

Configuring the display of the trace variable

1. Double-click a trace object.
2. Click the *“Configuration”* link.
   ⇨ The *“Trace Configuration”* dialog opens.
3. Select a variable below *“Trace Record”*.
   ⇨ The subdialog *“Variable Settings”* of the selected variable is displayed on the right.
4. Change a setting, for example the *“Line type”*.
5. Click *“OK”* to close the dialog.
   ⇨ The display changes are visible in the affected diagrams.

Configuring the buffer for data on the runtime system

1. Double-click a trace object.
2. Click *“Trace ➔ Configuration”*.
   ⇨ The *“Trace Configuration”* dialog opens. The subdialog *“Record Settings”* is displayed on the right.
3. Click *“Advanced”*.
   ⇨ The *“Advanced Trace Settings”* dialog opens.
4. Change the setting *“Measure in every n-th cycle”* or *“Recommended runtime buffer size (samples)”*.
5. Click *“OK”* to close the dialog.
   ⇨ The buffer settings are reconfigured. It is applied after the trace configuration is loaded to the RTS the next time.

Editing the trace configuration in runtime mode

Requirement: The application is running on the controller and a trace configuration is loaded.

1. Double-click a variable in the trace record tree.
   ⇨ The *“Trace Configuration”* dialog opens.
2. Change the color, for example.
   ⇨ The variable is displayed in the new color in the affected diagrams without interrupting the execution of the application.

If you change essential settings, for example a trace variable, then you must download the trace configuration to the controller again.

Operating the data recording

Use menu commands for controlling how data is recorded.

Requirement: The application is loaded on the runtime system and a trace is configured.

Menu commands

- *“Trace ➔ Download Trace”*
- *“Trace ➔ Start Trace”*
- *“Trace ➔ Stop Trace”*
- *“Trace ➔ Reset Trigger”*

See also

- *Chapter 1.4.1.20.3.21.6 “Command 'Download Trace'” on page 1138*
- *Chapter 1.4.1.20.3.21.16 “Command 'Start Trace'” on page 1145*
- *Chapter 1.4.1.20.3.21.17 “Command 'Stop Trace'” on page 1145*
- *Chapter 1.4.1.20.3.21.13 “Command 'Reset Trigger'” on page 1144*

Accessing All Traces on the Controller

If the controller supports the runtime system component `CmpTraceMgr` (Trace Manager), then you can access all traces from a CODESYS project which are running on the controller. In addition to application-related traces that capture the values of IEC variables, these can also be entirely controller-specific traces (for example, for recording device signal values or the CPU load).

For each trace running on the controller that you want to present in your project, you have to insert an individual *“DeviceTrace”* object in the device tree.

In order to show a trace from the device in this object, the connection to the PLC has to be configured correctly (*“Communication Settings”*). Then use one of the following menu commands:

- *“Trace ➔ Upload Trace”*: Establishes the connection to the PLC and opens the *“Online List”* dialog for selecting a trace from the controller.
- *“Trace ➔ Online List”*: Available in online mode only: Also opens the *“Online List”* dialog.

Now the trace uploaded from the controller can be started and traced in the editor of the DeviceTrace object. The configuration of the presentation (colors, labels, etc.) is the same as with traces for application variables configured in the project.

> **NOTICE!**
>
> **Closing the DeviceTrace editor terminates the connection to the controller.**
>
> Please note that the connections to the controller is also terminated when the last open *“DeviceTrace”* editor is closed. In order for device traces to be displayed again in the project, you have to reload them into the *“DeviceTrace”* objects.
>
> At this time, closing the editor is also the recommended procedure for deliberately terminating the connection to the controller. Logging out is not enough for this.

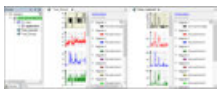
- *Chapter 1.4.1.20.2.29 “Object 'DeviceTrace'” on page 948*
- *Chapter 1.4.1.20.3.21.19 “ Command 'Upload Trace'” on page 1146*
- *Chapter 1.4.1.20.3.21.12 “Command 'Online List'” on page 1143*

Displaying the CPU load with DeviceTrace objects in the CODESYS project (example)

Requirement: The PLC device supports the Trace Manager. For the example described here, this is CODESYS Control Win V3. The device provides traces of the individual CPU loads (`CpuLoad`), as well as traces of the CPU load caused by the runtime system (`PlcLoad`). The possible display of the CPU load in the project can be helpful when using multicore functionality.

1. In the project, define the *"Communication Settings"* for the controller.
2. Select the PLC entry in the device tree and add a *"DeviceTrace"* object.
3. Rename *"DeviceTrace"* to "Trace_PlcLoad" (*"Properties"*).
4. Set the focus in the trace editor and click *"Trace ➔ Upload Trace"*.
   ⇨ The connection to the controller is established and the *"Online List"* dialog opens.
5. Select the *"PlcLoad"* entry in the dialog and click *"Upload"*. Click OK to close the dialog.
   ⇨ Multiple trace views open in the trace editor to show the CPU load in the runtime system. There are the traces for the particular CPUs and one trace for the average value. The following text appears for each: "No samples have been recorded."
6. Click *"Trace ➔ Start Trace"*.
   ⇨ The trace recording for the four parameters is displayed.
7. If you also want to display the traces for the `CpuLoad` per CPU with their average value in the project, then insert another *"DeviceTrace"* object into the device tree. Name it "Trace_CpuLoad" for example. Load and start the traces for *"CpuLoad"* in the editor as described above.
   ⇨ Now you can monitor all traces in the project:



8. If you want to change the appearance of the presentation, then click *"Configuration"* in the respective trace editor window to access the configuration dialogs. You can use these dialogs (except variable assignments) in the same way as for an IEC variable trace created in a project.
9. To disconnect from the controller, close all open DeviceTrace editor windows. If you are logged in to the device, then logging out is enough to terminate the connection.

Navigating into trace data

Use menu commands to navigate the data in the trace diagram.

Requirement: The application is in online mode.

Menu commands

- *"Trace ➔ Cursor"*
- *"Trace ➔ Mouse Zooming"*
- *"Trace ➔ Reset View"*
- *"Trace ➔ AutoFit"*
- *"Trace ➔ Compress"*
- *"Trace ➔ Stretch"*
- *"Trace ➔ Convert to Single-Channel"*
- *"Trace ➔ Convert to Multi-Channel"*

- *Chapter 1.4.1.20.3.21.11 “Command 'Convert to Single-Channel'” on page 1142*

Managing trace

Use menu commands to load and save traces in various formats.

Menu commands

- *“Trace ➔ Save Trace”*
- *“Trace ➔ Load Trace”*
- *“Trace ➔ Export Symbolic Trace Config”*

See also

- *Chapter 1.4.1.20.3.21.15 “Command 'Save Trace'” on page 1145*
- *Chapter 1.4.1.20.3.21.8 “Command 'Load Trace'” on page 1141*
- *Chapter 1.4.1.20.3.21.7 “Command 'Export Symbolic Trace Config'” on page 1139*

Showing statistics

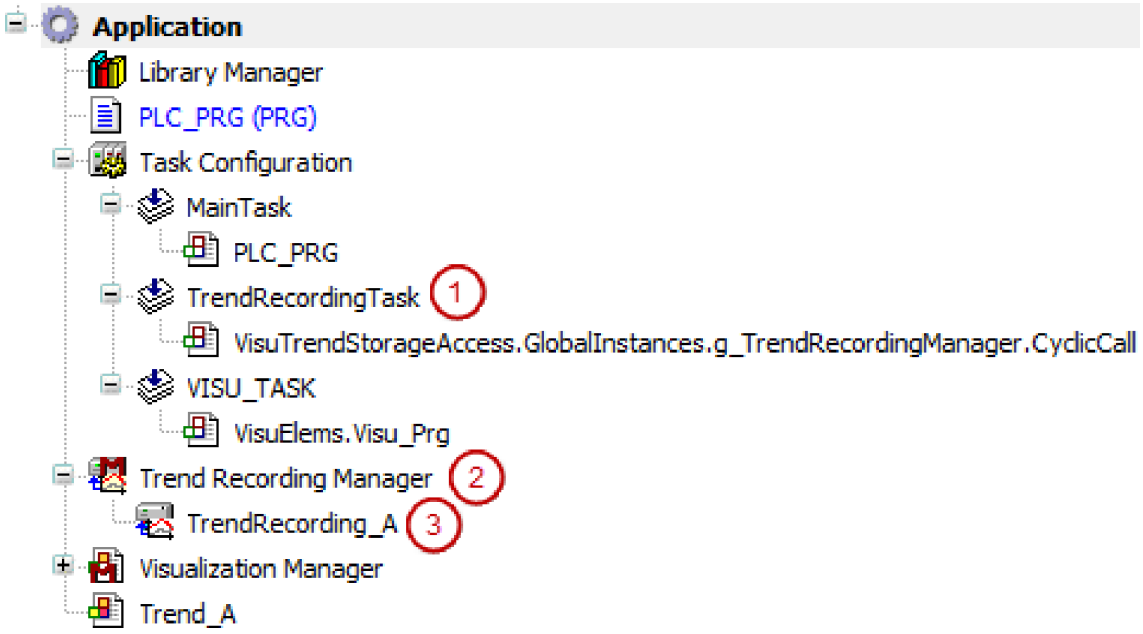
CODESYS evaluates and displays the recorded data with an option of saving the data to the clipboard. Click *“Trace ➔ Statistics”*.

See also

- *Chapter 1.4.1.20.3.21.20 “Command 'Statistics'” on page 1146*

1.4.1.12.4 Data Recording with Trend

When you want to monitor the development of data over a long period of time for the purpose of reading a trend, you can save the data with *“Trend Recording”*. You can configure any number of variables or parameters to save their values in a persistent database. This database is located on the PLC and is populated continually at runtime.



Trend recording comprises the following objects:

- (1):*"Trend recording task"* of type *"Task"*
- (2): Object of type *"Trend Recording Manager"*
- (3): Object of type *"Trend Recording"*

NOTICE!

Timeout for trend recording

During a trend recording, it can happen that the application task triggers a timeout that is caught with an exception when transitioning from *"Running"* to *"Stop"*. Causes can be that file operations with the SQLite database are taking too long or that too many variables are being recorded. This usually happens on a target device with weak performance.

You can avoid the occurrence of an exception:

– Configure the trend recording with less memory demand so that the amount of data that is stored is adapted to the target system.
– Reduce the number of variables.

To display the collected data, you design a visualization with a "Trend" element. This kind of visualization accesses the database for visualizing the data.

See also

- *Chapter 1.4.1.20.2.30 "Object 'Trend Recording Manager'" on page 949*
- *Chapter 1.4.1.20.2.31 "Object 'Trend Recording'" on page 949*
- *Chapter 1.4.1.20.2.32 "Object 'Trend Recording Task'" on page 952*

Getting started with trend recording

To execute trend recording on a runtime system, you need an application with a *"Trend Recording Manager"* object that contains at least one *"Trend Recording"* object. Then you can configure a database on the runtime system and the data buffering.

1. Add a *"Trend Recording Manager"* object below your application.
2. Select the *"Trend Recording Manager"* object and click *"Add Object ➔ Trend Recording"*. Type a name in the *"Add Trend Recording"* dialog box.
   ⇨ CODESYS creates the object. The editor opens.
3. Type a task in *"Record Settings"*.
4. Click *"Add Variable"*.
   ⇨ CODESYS adds another variables. The blank settings open in the *"Variable Settings"* to the right of the tree view.
5. Select a valid IEC variable from the *"Variable"* field.
   ⇨ The IEC variable is configured for trend recording.
6. Build the application.
7. Download the application to the controller and click *"Start"*.
   ⇨ The application records data in runtime mode and saves it to a database.

See also

- *Chapter 1.4.1.20.2.31 "Object 'Trend Recording'" on page 949*
- *Chapter 1.4.5.11.1 "Getting Started with Trend Visualization" on page 1309*

Configuring trend recording

You can configure a database on the runtime system and the data buffering.

NOTICE!
Timeout for trend recording
During a trend recording, it can happen that the application task triggers a timeout that is caught with an exception when transitioning from *"Running"* to *"Stop"*. Causes can be that file operations with the SQLite database are taking too long or that too many variables are being recorded. This usually happens on a target device with weak performance.

You can avoid the occurrence of an exception:

– Configure the trend recording with less memory demand so that the amount of data that is stored is adapted to the target system.
– Reduce the number of variables.

Assigning tasks

In this task, the runtime system records the trend.

In general, trend recording runs in the same task as the main program (for example, `PLC_PRG`).

1. Double-click a *"Trend Recording"* object in the device tree.
   ⇨ The respective editor opens. In the tree view of the trend configuration, the top entry is selected, and on the right you see the current configuration in *"Record Settings"*.
2. Click the "arrow down" symbol (▾) in the *"Task"* drop-down list.
   ⇨ The drop-down list opens with all tasks that are available throughout the application.
3. Select a task for trend recording.

See also

- ↳ *Chapter 1.4.1.20.2.31 “Object 'Trend Recording'” on page 949*

Adding IEC variables

> **NOTICE!**
> The number of variables is limited for trend recording. You can change this number in the *“Trend storage”* dialog.

1. Double-click a *“Trend Recording”* object in the device tree.
   ⇨ The respective editor opens. In the tree view of the trend configuration, the top entry is selected, and on the right you see the current configuration in *“Record Settings”*.
2. Right-click an entry in the tree view.
3. Click *“Add Variable”*.
   ⇨ CODESYS adds another variables. The blank settings open in the *“Variable Settings”* to the right of the tree view.
4. Select a valid IEC variable from the *“Variable”* field.
   ⇨ The IEC variable is configured for trend recording.
5. Configure how the variable is displayed in the trend diagram.
6. Configure how the alert color is displayed in the trend diagram.

See also

- ↳ *Chapter 1.4.1.20.2.31 “Object 'Trend Recording'” on page 949*
- ↳ *Chapter 1.4.1.20.4.16 “Dialog Box 'Trend storage'” on page 1214*

Removing variables from the configuration

1. Double-click a *“Trend Recording”* object in the device tree.
2. Click a variable in the tree view of the configuration.
3. Click *“Delete Variable”* or press *[Del]*.

Starting conditional trend recording

You can configure conditional trend recording for execution. Configuration is not possible when depending on triggering. For that you need a *“Trace”* object.

1. Double-click a *“Trend Recording”* object in the device tree.
2. Click the top node in the tree view of the trend configuration.
   ⇨ The name of the trend configuration is selected and on the right you see the current configuration in *“Record Settings”*.
3. Assign a Boolean variable, an access to a bit, or a property to the *“Record condition”* field.
   ⇨ When the application is in runtime mode, data is recorded only if the value is `TRUE`.

See also

- ↳ *Chapter 1.4.1.12.3 “Data Recording with Trace” on page 421*

Adding parameter

1. Double-click a *“Trend Recording”* object in the device tree.
   ⇨ The respective editor opens. In the tree view of the trend configuration, the top entry is selected, and on the right you see the current configuration in *“Record Settings”*.
2. Right-click an entry in the tree view.
3. Click *“Add Variable”*.
   ⇨ CODESYS inserts a new variable. The blank settings open in the *“Variable Settings”* to the right of the tree view.
4. Click the "down" symbol (▼) to the right of the *“Variable”* label.
5. Select *“Parameter”* from the drop-down list.
6. Click ... and select a parameter from the *“Input Assistant”* dialog.
7. Configure how the parameter is displayed in the trend diagram.
8. Configure how the alert color is displayed in the trend diagram.

See also

- *Chapter 1.4.1.20.2.31 “Object 'Trend Recording'” on page 949*

Configuring data buffering on the RTS

1. Double-click a *“Trend Recording”* object in the device tree.
   ⇨ The respective editor opens. In the tree view of the trend configuration, the top entry is selected, and on the right you see the current configuration in *“Record Settings”*.
2. Click *“Trend Storage”*.
   ⇨ The *“Trend Storage”* dialog opens.
3. Now you can change the settings.

See also

- *Chapter 1.4.1.20.4.16 “Dialog Box 'Trend storage'” on page 1214*

Configuring additional buffering

1. Double-click a *“Trend Recording”* object in the device tree.
   ⇨ The respective editor opens. In the tree view of the trend configuration, the top entry is selected, and on the right you see the current configuration in *“Record Settings”*.
2. Click *“Advanced”*.
   ⇨ The *“Advanced Trace Settings”* dialog opens.
3. Now you can change the settings.

See also

- *Chapter 1.4.1.20.4.17 “Dialog Box 'Advanced Trend Settings'” on page 1214*

See also

- *Chapter 1.4.1.12.3.2 “Creating trace configuration” on page 424*

1.4.1.12.5 Monitoring tasks

In online mode, you can display some statistical values of the tasks in the runtime system. This information is very useful for testing clock cycles or solving problems in the runtime performance.

1. Switch to online mode.
2. Select the *“Task Configuration”* object in the device tree.

   Click *“Project ➔ Edit Object”*.

   ⇨ The task configuration opens in the editor.
3. Click the *“Monitor”* tab.

See also

- *Chapter 1.4.1.20.2.26.3 “Tab 'Monitor'” on page 940*

1.4.1.12.6 Reading the PLC log

CODESYS provides the capability to display the events and error messages logged in the controller.

See also

- *Chapter 1.4.1.20.2.8.8 “Tab 'Log'” on page 848*

Reading the log

Requirement: The controller is running.

1. Select the controller in the device tree.
2. Choose the command *“Project ➔ Edit Object”*.

   ⇨ The device editor opens.
3. Choose the tab *“Log”*.
4. Click on to update the view.

   ⇨ A connection to the controller is established. The controller in the device tree is highlighted in green.

   All controller log information are displayed.
5. Click on to delete the current list.
6. Filter the view by clicking on the desired category (for example "Information").
7. Save the log entries. Click on and choose a file name.

See also

- *Chapter 1.4.1.20.2.8.8 “Tab 'Log'” on page 848*

1.4.1.12.7 Using PLC shell for requesting information

The "PLC shell" in CODESYS is a text-based control monitor (terminal) on a tab of the device editor. There you can enter commands for the request of specific information from the controller, as well as execute actions like starting, stopping or downloading applications. Also a description on the meaning and syntax of the possible commands you can get directly via the PLC shell.

Requesting information about the application on the controller

Requirement: Your project is connected with a controller; Example: CODESYS Control Win V3, on which an application `App1` is running.

1. Open the device editor double-clicking on the object CODESYS Control Win V3 in the device tree, and activate tab *"PLC Shell"*.
   ⇨ The tab shows an empty output data window. Below there is an entry field for a command.
2. Click button [...].
   ⇨ The *"Insert Standard Command"* dialog appears with a list of commands.
3. Choose command *"?"* and click button *"Execute"*.
   ⇨ The dialog closes and in the output data window you see a list of the supported commands and their possible parameters. Each the syntax for how to enter the command is displayed.
4. Click again [...] and choose command *"pid"*. In the input assistant supplement the command as follows: `pid App1`. Press the Enter key.
   ⇨ In the output data window the following gets displayed (the GUIDs are just exmples):

```
pid App1
Project Identification
Application: App1
Code GUID:0x08a893c0
Data GUID:0x762d0e90
```

5. Click button ▼ in the command line.
   ⇨ Command `pid App1` is added to the history of already entered commands.

See also

- *Chapter 1.4.1.20.2.8.10 "Tab 'PLC Shell'" on page 852*

1.4.1.12.8 PLC operation control via system variables

CAUTION!
You are responsible for runtime system services being enabled under safe application conditions and disabled only under critical conditions.

At runtime, the state of an application or facility can become sensitive and disruptive actions can endanger the entire machine or facility. However, in this state you can suppress certain commands and prevent dangerous actions. The *"PlcOperationControl"* function block and *"Component Manager"* library are provided for this purpose.

Examples of CODESYS commands that can suppress operations when executed:

- *“Online Change”*, *“Download”*
- *“Enable Breakpoint”*
- *“Reset Application”*, *“Stop Application”*
- *“Transmit Data”*
- *“Force Values”*, *“Write Values”*

In order that a backup solution is always in place, you are not permitted to suppress the *“Reset origin”* and *“Delete”* commands.

CODESYS will notify you if a currently disabled runtime system service is required when the application is in runtime mode. Then, you can respond with an appropriate countermeasure.

Function block `PlcOperationControl` for operation control

This function block is used for enabling and disabling operations.

Table 29: Property (`PROPERTY`)

Name	Data Type	Initial value	Description
`xDisableApplicationOnlineChange`	`BOOL`	`FALSE`	`TRUE`: Online change is suppressed.
`xDisableApplicationDownload`	`BOOL`	`FALSE`	`TRUE`: Download is suppressed.
`xDisableApplicationStop`	`BOOL`	`FALSE`	`TRUE`: Application stop is suppressed.
`xDisableApplicationBP`	`BOOL`	`FALSE`	`TRUE`: Setting breakpoints is suppressed.
`xDisableApplicationWrite`	`BOOL`	`FALSE`	`TRUE`: Writing variables is suppressed. This can also be suppressed via PLCHandler/IecVarAccess.
`xDisableApplicationForce`	`BOOL`	`FALSE`	`TRUE`: Forcing variables is suppressed.
`xDisableApplicationReset`	`BOOL`	`FALSE`	`TRUE`: Resetting the application (not "Reset origin") is suppressed.
`xDisableAll`	`BOOL`	`FALSE`	`TRUE`: All operations are suppressed.

Implementing operation control

Requirement

- Compiler version >= `3.4.3.0`
- In the device description, the PLC operation control is enabled by system variables.

1. Declare an instance of the `PlcOperationControl` function block (for example, `PlcOpCtrl_Inst`).

   ⇨ `PlcOpCtrl_Inst : PlcOperationControl;`

2. Suppress a command by assigning the respective `TRUE` property (for example, "Stop Application".

   ⇨ `PlcOpCtrl_Inst.xDIsableApplicationStop := TRUE;`

See also

- *Chapter 1.4.1.20.3.6.6 “Command 'Online Change'” on page 1033*
- *Chapter 1.4.1.20.3.7.16 “Command 'Force Values'” on page 1053*
  Chapter 1.4.1.11.4 “Forcing and Writing of Variables” on page 401

1.4.1.12.9 Backup and restore

CODESYS and the CODESYS standard runtime systems (with version 3.5.8.0 and later) support backing up application-specific files on the PLC. You can execute the required actions in the *“Backup and Restore”* tab of the generic device editor.

A backup consists of creating and saving a file in zip archive that contains the application-related files and an information file `meta.info`. This backup file has the extension `TBF` (="Target Backup File") and can be saved in the local file system or on the PLC.

The following applies when restoring the software status from the backup file:

- A dialog opens with a list of affected files on the PLC, and you can deactivate optional components.
- We highly recommend to set the application to STOP mode for backup or restore. A dialog prompt will open to warn you about this.
- The user interface is blocked when restoring to the PLC.
- Existing files are overwritten without warning.
- Existing boot applications are deactivated as soon as at least one new boot application is part of the restore.

See also

- *Chapter 1.4.1.20.2.8.5 “Tab 'Backup and Restore'” on page 846*

Creating backup files

Requirement: A project is open with an application that is running on the required device. In addition, for this example an external file `myExternalFile.txt` is inserted as an object below the application. This file is downloaded to the PLC implicitly when downloading the application.

1. Open the device editor by double-clicking the device entry in the device tree. Click the *“Backup and Restore”* tab.

   ⇨ The tab opens with a menu bar including the *“Backup”* and *“Restore”* menus.

2. In the *“Backup”* menu, select the *“Read Backup Information from Device”* item.

   ⇨ If the PLC is not connected at the moment, then CODESYS opens a temporary connection to the device and reads the relevant files from the `$PlcLogic$` directory of the PLC into a table in the lower part of the tabbed page. In this example, at least the following files will be listed: `$PlcLogic$/Application/Application.app`, `$PlcLogic$/Application/Application.crc`, and `$PlcLogic$/Application/myExternalFile.txt`. In addition, other external, project-dependent files are listed, which have been inserted below the application in the device tree. Furthermore, the source code archive file `$PlcLogic$/Archive.prj` is listed if you have set the project setting for this (*“Implicitly at program download and online change”*) as the loading time.

3. In the table, clear the check box for the `$PlcLogic$/Application//myExternalFile.txt` file in the *“Active”* column.

4. Select *“Save Backup File to Device”* in the *“Backup”* menu.

   ⇨ The *“Save as”* dialog opens. The file type is predefine as *“Backup files (*.tbf)”*.

5. Select a location for the backup file and click *“Save”*.

See also

- *Chapter 1.4.1.20.4.11.5 “Dialog 'Project Settings' – 'Source Download'” on page 1174*

Restoring from backup files

Requirement: A project is open with a PLC device connected. A backup file is saved to the local file system as described above.

1. Open the device editor by double-clicking the device entry in the device tree. Click the *"Backup and Restore"* tab.

   Click *"Restore ➔ Load Backup File from Disc"*.

   ⇨ The default prompt opens for selecting a backup file `tbf` in the local file system.

2. Select the backup file and click *"Open"*.

   ⇨ The files are read from the backup file and shown in the table of the dialog below. The file `$PlcLogic$/Application/myExternalFile.txt` that was excluded in the backup is missing.

3. Click *"Restore ➔ Restore Backup to Device"*.

   ⇨ A dialog prompt opens with information about the actions when restoring.

4. Click *"OK"* to start restoring the files to the PLC file system.

   ⇨ When restore is complete, you are prompted to restart the PLC in order to activate the loaded application.

1.4.1.13 Updating an Application on the PLC

CODESYS basically provides two options to transfer a modified application to the controller: download and online change.

A download results in a recompilation of the application. In that time, a syntax check is performed and application code is also created and downloaded to the controller. This leads to the running program being stopped. A download is the recommended method of data transfer because a defined starting state is always created due to the program stop and the reinitialization.

In the case of an online change, only the modified parts are downloaded again to the controller. A running program is not stopped for this. You should perform an online change only in the case of minor changes to the application. For extensive changes, the behavior of a program cannot be safely predicted. For more information, read the notes in the description of the *"Online Change"* command.

See also

- *Chapter 1.4.1.13.1 "Executing the online change" on page 439*
- *Chapter 1.4.1.13.2 "Execution of a download" on page 440*
- *Chapter 1.4.1.20.3.6.5 "Command 'Load'" on page 1032*
- *Chapter 1.4.1.20.3.6.6 "Command 'Online Change'" on page 1033*

1.4.1.13.1 Executing the online change

CODESYS automatically offers you an online change if you log in with an application that is already present on the controller, but has been changed since the last download in the programming system. With this procedure only the modified parts are reloaded to the controller. A running program on the controller is not stopped during the online change.

In the view *"Memory reserve for online change"*, you can configure memory reserves for the online change for function blocks of a project. In this way, instance variables do not have to be moved to the memory after changes are made to a function block for an online change.

NOTICE!

When carrying out the online change, pay attention to the notes in the description of the *"Online Change"* command.

See also

- ↳ *Chapter 1.4.1.20.3.6.6 “Command 'Online Change'” on page 1033*
- ↳ *Chapter 1.4.1.20.3.6.2 “Command 'Login'” on page 1028*
- ↳ *Chapter 1.4.1.10.4 “Generating Application Code” on page 389*

Executing the online change when logging in

Requirement: The connection settings of the controller are correctly set. The applications in the project and on the controller are identical. The project on the controller is running. The application is logged out.

1. Change your application.
2. Click *“Online ➔ Login”*.
   ⇨ A dialog appears with the information that the application has been changed since the last download.
3. Click the *“Details…”* button
4. Check the details in the *“Application information”* tab.
   If you have not generated any code since the last change, the command *“Application is not up to date. Generate code now?”* appears at the bottom edge of the dialog. In this case click this command.
   ⇨ You are shown a comparison view of the objects (objects marked red are different).
5. Close the dialog.
6. Select the option *“Login with Online Change”* and click *“OK”*.
   ⇨ The change is loaded to the controller. The running program on the controller is not stopped while doing this. The application is logged in.

See also

- ↳ *“View 'Project Comparison' - 'Differences'” on page 1011*

Execute online change in the logged-in state (online operation)

Requirement: The connection settings of the controller are correctly set. The applications in the project and on the controller are identical. The project on the controller is running. The application is logged in.

1. Select an object in the device tree. It is best to select a POU or a GVL here.
2. Click *“Project ➔ Edit Object (Offline)”*.
   ⇨ The object opens in the editor.
3. Change the object. For example, you can declare a new variable or change a value assignment here.
4. Click *“Online ➔ Online Change”*.
   ⇨ A query will appear, asking whether you really want to execute the online change.
5. Click *“Yes”* to confirm the dialog.
   ⇨ The change is loaded to the controller.

1.4.1.13.2 Execution of a download

A download of the application causes a compilation of the active application. In the process, a syntax check is performed and application code is also created and loaded to the controller. A program running on the controller is stopped during the download.

> **NOTICE!**
> During the download, pay attention to the notes in the description of the *"Download"* command.

See also

- ↳ *Chapter 1.4.1.20.3.6.5 "Command 'Load'" on page 1032*
- ↳ *Chapter 1.4.1.20.3.6.2 "Command 'Login'" on page 1028*
- ↳ *Chapter 1.4.1.10.4 "Generating Application Code" on page 389*

Downloading when logging in

Requirement: the connection settings of the controller are correctly set. The applications in the project and on the controller are identical. The project on the controller is running. The application is logged out.

1. Change your application.
2. Select the command *"Online ➔ Login"*
   ⇨ A dialog box appears with the information that the application has been changed since the last download.
3. Select the option *"Login with download"* and click on *"OK"*.
   ⇨ The running program on the controller is stopped and the change is loaded to the controller. The application is logged in.

Downloading in the logged-in state (online mode)

Requirement: the connection settings of the controller are correctly set. The applications in the project and on the controller are identical. The project on the controller is running. The application is logged in.

1. Select an object in the device tree. It is best to select a POU or a GVL here.
2. Select the command *"Project ➔ Edit Object (Offline)"*
   ⇨ The object opens in the editor.
3. Change the object. For example, you can declare a new variable or change a value assignment here.
4. Select the command *"Online ➔ Download"*.
   ⇨ A query will appear, asking whether you really want to execute the download.
5. Confirm the dialog box with *"Yes"*.
   ⇨ The running program on the controller is stopped and the change is loaded to the controller.

1.4.1.14 Copying files to/from PLC

In the generic *"Files"* tab of the device editor, you can copy files to and from the local file system and the controller.

Requirement: The vendor has unlocked the tab. In the device tree, the connection to the controller is configured. The device is running.

1. Double-click the PLC device object in the device tree to open the device editor.
2. Click the *"Files"* tab.

3. In *“Host”* | *“Location”* on the left part of the view, set the path in the local file system where files will be copied to and from. Example: `D:\FileTransferWithPLC`. If necessary, create a new directory by clicking the folder symbol ( ).

   ⇨ The files and directories are shown like in a file manager. Click the refresh symbol ( ) to update the display.

4. In *“Runtime”* on the right side of the view, set the required directory for the data transfer in the same way.

   ⇨ CODESYS shows the files on the controller.

5. Select the required files from the file system tree for the file transfer (multiple selection is possible). You can also select a directory for transferring all files in a folder.

6. Click the left and right arrow symbols (<< , >>) between the two parts of the view.

   ⇨ CODESYS copies the selected files to the other file system immediately. If a file is not already available in the target directory, then it is created. If it is already available and not write-protected, then it is overwritten. Otherwise a message is shown.

See also

- *Chapter 1.4.1.20.2.8.7 “Tab 'Files'” on page 848*

1.4.1.15 Using the Command-Line Interface

You can start the command line with the following options and arguments.

Syntax: `<folder>Automation Builder.exe --<option>`

> *Paths or option parameters must be written inside straight quotation marks when they contain spaces, dashes, or slash marks.*

Option `--culture` (language of the user interface)

CODESYS is started in the specified language.

Syntax: `--culture=<culture>`

`<Culture>`: Typical language codes are as follows: de, en, fr, it, es, zh-CHS.

Example Starting CODESYS with the user interface in English:

```
Automation Builder.exe --culture=en
```

See also

- *Chapter 1.4.1.20.4.13.13 “Dialog 'Options' – 'International Settings'” on page 1195*

Option `--profile` (CODESYS profile)

CODESYS is started directly with the specified profile. When you start CODESYS without this option, the *“Select Profile”* opens.

Syntax: `--profile="<profile name>"`

`<profile name>`: You have to specify the profile name exactly as it is displayed in the *“Help ➔ About”* splash screen of the development system or in the start menu on your computer.

Example

```
Automation Builder.exe --culture=de --profile="Automation Builder
2.5"
```

Option `--compare` (start project comparison)

After CODESYS is started, the comparison of two CODESYS projects is begun immediately. Type the path of the project file as arguments after the option and then the path of the reference project. CODESYS starts and opens the *"Project Comparison - Differences"* view.

Syntax:

```
--compare="<path of project file>" "<path of reference project file>"
```

Example

```
Automation Builder.exe --compare "D:\proj\project1.project"
"D:\proj\project2.project"
```

See also

- *Chapter 1.4.1.20.3.4.21 "Command 'Compare'" on page 1010*

Option `--project` (open CODESYS project)

CODESYS is started and the specified project is opened.

Syntax:

```
--project="<path of project file>"
```

`<path of project file>`: File path of project

Example

Open the `test` project:

```
Automation Builder.exe --culture=de --
project="D:\projects\test.project"
```

See also

- *Chapter 1.4.1.20.3.1.2 "Command 'Open Project'" on page 957*

Option `--projectarchive` (open CODESYS project archive)

CODESYS is started, the specified project archive is extracted, and the project is opened.

Syntax:

```
--projectarchive="<path of project archive file>"
```

`<path of project archive file>`: File path of project archive

Example

Extract the `test.projectarchive` and open the project in the development system:

```
Automation Builder.exe --
projectarchive="D:\projects\test.projectarchive"
```

See also

- *Chapter 1.4.1.20.3.1.9 "Command 'Extract Archive'" on page 961*

Option `--runscript` (run script) The specified script file is run by CODESYS.

Table 30: Command-line options for `--runscript`

`--runscript="<scriptfile>.py"`	CODESYS runs the `<scriptfile>.py` script file at startup. You have to provide the complete path of the script file.
`--scriptargs:'<arg1> <arg2> ... <argn>'`	Use this option with the `--runscript` option. As a result, the arguments <arg1> ... <argn> are passed to the script. The arguments are passed to the Python variable `sys.argv`.
`--noUI`	Use this option with the `--runscript` option. The CODESYS user interface is not opened. CODESYS prints all errors, warnings, compiler reports, and command-line messages generated from the script. The script messages (1: Severity Text) can be separated from other messages (2: Severity FatalError, Error, Warning, Information) with the ">" operator.
`--enablescripttracing`	Use this option with the `--runscript` option. As a result, each command of the script file is shown in the output.
`--textPrompts`	Use this option with the `--noUI` option. As a result, message service methods and default dialogs are output in the command line for user input. If you do not specify `--textPrompts`, then all message service prompts are confirmed automatically with default values.
`scriptdebugger {="<debugger>"}`	Use this option with the `--runscript` option. It sets IronPython in debug mode so that external debuggers can be used to debug Python scripts. The following values are defined for <debugger> (uppercase/lowercase is irrelevant). ● `auto`: Automatically detects if a debugger is included in every script for the current process. At this time, only .NET-based debuggers can be detected automatically. A detected debugger overwrites the `--enablescripttracing` flag. ● `.NET`: Activates debugging for .NET-based debuggers, such as "Python Tools for Visual Studio" (PTVS) and SharpDevelop. With this option, a debugger can also be included in running scripts, as opposed to "auto". Note: This is currently the default value when `--scriptdebugger` is used without providing a value. ● `disabled`: Deactivates debugging and automatic detection. ● `script`: Switches the IronPython script engine to debug mode for activating the debugging for set-trace debuggers. The script itself must connect to and disconnect from the debugger. ● `tracing`: Activates the simple integrated script tracing mode and deactivates the automatic detection (same as the option `--scripttracing`). ● `$absolute_path.py$`: Absolute path to a Python script that initiates the connection to a Python-based debugger. The IronPython script engine is switched to debug mode for allowing the debugging for set-trace debuggers. This script is run one time during the initialization and should define the following non-parameterized functions: `scriptdebuggersetup` is run immediately before running the user script to establish the connection to the debugger. `scriptdebuggershutdown` is called immediately after running the user script or when the script engine is downloaded and should close the connection to the debugger.

Examples of using transfer parameters in script files with 'sys.argv'

```
start /b /wait Automation Builder.exe
--runscript="D:\Script\ArgvAnd__main__Test.py"
--scriptargs:'username password 3.14 "path=\"C:\temp\\"'
```

Script file: `ArgvAnd__main__Test.py`

```
from __future__ import print_function
import sys
print("sys.argv: ", len(sys.argv), " elements:")

for arg in sys.argv:
    print(" - ", arg)
print()
print("__name__: ", __name__)
```

Output result: `stdout`:

```
sys.argv: 6 elements:
- D:\TestScripts\ArgvAnd__main__Test.py
- username
- password
- 3.14
- path= "C:temp"
__name__: __main__
```

For more information about the `__name__` global variable, see the Python documentation.

Examples of the message output

```
start /b /wait Automation Builder.exe --
runscript="D:\Script\AmpelTest.py" --noUI 1>ScriptMessages.txt
```

CODESYS passes all messages that are generated by the script to the `ScriptMessages.txt` file. Other messages are printed to the command line.

```
start /b /wait Automation Builder.exe --
runscript="D:\Script\AmpelTest.py" --noUI 2>NUL
```

CODESYS suppresses all messages, except for script messages. The script messages are printed to the command line.

Example of option --scriptdebugger

The following `initdebug.py` script was tested successfully with `pydevd`-based debuggers, such as PyDev / LiClipse and PyCharm. To use this script, start CODESYS with the following command line:

```
--profile="Fanta Development Build" --
scriptdebugger="D:\test\charmdebug\initdebug.py"
```

File: `initdebug.py`:

```
from _future_ import print_function
from _future_ import unicode_literals
import sys
sys.path.append(r"D:\test\Env2\Lib\site-packages\pycharm-debug.egg")
import pydevd
def scriptdebuggersetup():
pydevd.settrace('localhost', port=51234, stdoutToServer=True,
stderrToServer=True)
def scriptdebuggershutdown():
pydevd.stoptrace()
```

See also

- *http://docs.python.org/tutorial/modules.html*

Option `--ignorewhitespace` (ignore whitespace in project comparison)

If you add this option after the option `--compare <project1> <project2>`, then white-space is ignored in the project comparison. Note that semantically relevant spaces, for example in `STRING` literals, are still taken into account.

Syntax

```
--compare="<path of project file>" "<path of reference project file>"
--ignorewhitespace="true"|"false"
```

Example

```
Automation Builder.exe --compare "D:\proj\project1.project"
"D:\proj\project2.project" --ignorewhitespace="true"
```

See also

- *Chapter 1.4.1.20.3.4.21 “Command 'Compare'” on page 1010*

Option `--ignorecomments` (ignore comments in project comparison)

If you add this option after the option `--compare <project1> <project2>`, then comments are ignored in the project comparison.

Syntax:

```
--compare="<path of project file>" "<path of reference project file>"
--ignorecomments="true"|"false"
```

Example

```
Automation Builder.exe --compare "D:\proj\project1.project"
"D:\proj\project2.project" --ignorecomments="true"
```

See also

- *Chapter 1.4.1.20.3.4.21 “Command 'Compare'” on page 1010*

Option `--ignoreproperties` (ignore object properties in project comparison)

If you add this option after the option `--compare <project1> <project2>`, then object properties (permissions, compile settings, directories, bitmaps, etc.) are ignored in the project comparison.

Syntax:

```
--compare="<path of project file>" "<path of reference project file>"
--ignoreproperties="true"|"false"
```

Example

```
Automation Builder.exe --compare "D:\proj\project1.project"
"D:\proj\project2.project" --ignoreproperties="true"
```

See also

- *Chapter 1.4.1.20.3.4.21 “Command 'Compare'” on page 1010*

Option `--skipunlicensedplugins` (do not load components without a license)

CODESYS is started. In this case, the query as to whether unlicensed components should still be loaded is skipped. If so, then CODESYS does **not** load these components by implication.

Example

```
Automation Builder.exe --skipunlicensedplugins
```

Option `--signaturethumbprint` (thumbprint of the certificate which is used for signing compiled libraries)

If you add this option after the option `--project="<path of project file>"`, then the project is opened and the thumbprint of the certificate for signing compiled libraries is passed.

Syntax:

```
--signaturethumbprint="<thumbprint of digital signature>"
```

Example

```
Automation Builder.exe --project="D:\projects\test.project"
signaturethumbprint="3E96C9B61010CBDC3186021A1CAA64946DDCAAF3"
```

See also

- *Chapter 1.4.1.20.3.3.18 “Command 'Security Screen'” on page 995*

Option `--enforcesignedcompiledlibraries` (enforce signing of compiled libraries)

If you add this option after the option `--project="<path of project file>"`, then the *“Enforce signing of compiled libraries”* option is enabled in the project in the *“Security Screen”* on the *“User”* tab.

NOTICE!
When the *“Security Screen”* is opened and closed, the current settings are applied in the user options, even when no active changes have been made.

Syntax:

```
--enforcesignedcompiledlibraries="true"|"false"
```

Example

```
Automation Builder.exe --project="D:\projects\test.library" --
enforcesignedcompiledlibraries="true"
```

See also

- *Chapter 1.4.1.20.3.3.18 “Command 'Security Screen'” on page 995*

Option `--timestampingserverurl` (set the time stamp server address)

If you add this option after the option `--project="<path of project file>"`, then the Internet address of the RFC-3161 time stamp server (*“Timestamping server”*) is set in the project in the *“Security Screen”* on the *“User”* tab.

NOTICE!
When the *“Security Screen”* is opened and closed, the current settings are applied in the user options, even when no active changes have been made.

Syntax: `--timestampingserverurl="<URL of RFC-3161 timestamping server>"`

Example

```
Automation Builder.exe --timestampingserverurl="http://
timestamp.comodoca.com/rfc3161"
```

- *Chapter 1.4.1.20.3.3.18 “Command 'Security Screen'” on page 995*

1.4.1.16 Using Libraries

Library repository

The library repository is the storage location on the development system for libraries and associated metadata. You can link any installed the libraries into your project by means of a library manager. Moreover, the libraries are installed with version management for easy library updates.

You can create and edit more repositories in addition to the preinstalled `System` repository.

See also

- *Chapter 1.4.1.20.3.8.5 “Command 'Library Repository'” on page 1061*

Library Manager

In order to be able to use POUs, which are provided in a library POU, in the application, the library has to be integrated in the Library Manager in the project. The requirement for this is the installation of the library in the library repository.

The Library Manager displays all integrated libraries according to their library type and the respective properties. In the Library Manager, you can add more libraries from the library repository, remove libraries, and edit library properties.

The Library Manager can be inserted into the *“POUs”* view or the *“Devices”* view. As a result, a project can have a Library Manager for each application, as well as a Library Manager in the *“POUs”* view for use across all applications. The library POUs of the integrated libraries in the *“POUs”* view can be called regardless of the application. The library POUs of the integrated libraries in the *“Devices”* view can be called in the respective application code only. Furthermore, placeholder libraries behave differently when downloading depending on their positions.

Libraries that are integrated to a specific version in the project also have a placeholder for that version (placeholder library). You can define special placeholder resolutions. You can also use the placeholder resolution that is defined for a device in the device description or that is stored in the library repository for a library. The Library Manager notifies you about the actual placeholder resolution and shows the version that will be loaded when an application is downloaded (effective version).

When a Library Manager in the *“POUs”* view is integrated across all applications, you can access its contents globally. If placeholder libraries are integrated, then only the placeholder resolutions in the device description or library repository are checked.

A Library Manager is usually integrated in the *“Devices”* view. Then only the application code below it calls library POUs from it. Moreover, the special placeholder resolutions are checked first for placeholder libraries. Only after that are the placeholder resolutions checked that are in the device description or that originate from the library repository.

See also

- *Chapter 1.4.1.20.2.14 “Object 'Library Manager'” on page 874*
- *Chapter 1.4.1.8.7 “Using Library POUs” on page 265*

1.4.1.16.1 Information for Library Developers

In order to avoid consistency problems and to adequately support the user, be sure to adhere to certain rules for the creation, referencing, encryption, protection, and documentation of libraries.

The following description provides only an overview of the library development possibilities. For a more detailed description of these topics, see the "LibDev-Summary" guidelines for library development.

See also

- *Chapter 1.4.1.16 “Using Libraries” on page 448*

General

- You can define categories for libraries. The libraries are then displayed in the library repository below these categories.
- You can define a namespace for a library in order to enable unambiguous access to the integrated objects. The access becomes unambiguous by adding the namespace in front of the POU name:
  <namespace>.<variable name>
  Example: `AC.Module`
- You can open the POUs of unencrypted libraries (`*.library`) by double-clicking the respective entry in the Library Manager.

- You can create the following library types:
  - `*.library`: Implementation library (source code of the library)
  - `*.compiled-library`, `*.compiled-library-v3`: Protected library; source code no longer accessible.
  - `*_Itfs.library`: Interface library; contains only objects that are used for the interface definition of a component (for example, constants, structures, or interfaces) and do not generate any code.
  - `*_Cnt.library`: Container library; does not contain any POUs; instead contains exclusively other libraries; therefore used to conveniently integrate an entire set of libraries whose POUs are published on the top level of the container library.
- You can integrate external libraries into the application. External libraries are programmed outside of CODESYS in a different programming language, for example C.

Protection of libraries

- Source code protection:
  When a library is prepared in "compiled-library" format, the source code of the library POUs is no longer visible after the library is integrated into a project.
- Signing:
  In CODESYS V3 SP15 and higher, a certificate is always used for the signing of library projects (`*.compiled-library-v3`). The signing can be enforced by means of a setting in the security screen. Then for generating a compiled library, you need a certificate suitable for code signing in your user profile.
  For library projects that have to be compatible with CODESYS < V3 SP15 (`*.compiled-library`), only the less safe signing is possible with a private key and a corresponding token. These deprecated methods should only be used for reasons of compatibility. Settings are configured in the *“Project Information”* on the *“Signing”* tab.
  Note: For signing libraries, you should use compiler version 3.5.15.0 or higher because a better storage format is used.
- Licensing:
  You can protect libraries by means of a license (dongle or soft container). License-protected libraries can be installed in the library repository. However, for use in the project, the valid license has to exist on the computer. Licenses are managed in the License Manager.

Library versions

- You can have several versions of a library installed on the system at the same time.
- You can have several versions of a library integrated into your project at the same time. However, we do not recommend doing this. In this case, each of the libraries **must** be assigned a unique namespace and access to the symbols **must** be qualified. Examples: `V1.SendBlob`, `V2.SendBlob`

Referenced libraries

- You can integrate a library into other libraries (referenced libraries). The nesting can be of any depth.
- You can define whether referenced libraries should be visible in the Library Manager.
- You can integrate referenced libraries via library placeholders. This way you avoid the problems that could occur due to version dependencies or the necessity to use vendor-specific libraries.

See also

- *Chapter 1.4.1.2.3.1 “Retrieving and Editing Project Information” on page 191*

1.4.1.16.2 Adding a Library to the Application

The following instructions describe how to integrate for example the library `Util` into your application in order to use its library POUs.

1. Select the Library Manager and click *“Project ➔ Edit Object”* to open it in the editor.
   ⇨ The Library Manager opens in the editor.
2. Click *“Library ➔ Add Library”*.
   ⇨ The *“Add Library”* dialog opens.
3. Type the string "util" into the input field above to search the library.
   ⇨ The library `Util` is displayed in the library view.
4. Select the library `Util` and click *“OK”* to close the dialog.
   ⇨ The library `Util` is added to the Library Manager.

See also

- *Chapter 1.4.1.8.7 “Using Library POUs” on page 265*
- *Chapter 1.4.1.20.3.14.1 “Command 'Add Library'” on page 1116*
- *Chapter 1.4.1.16.3 “Adding a library to the repository” on page 451*

1.4.1.16.3 Adding a library to the repository

The following instructions describe how to install a library in the library repository.

1. Select the command *“Tools ➔ Library Repository”*.
   ⇨ The dialog box *“Library Repository”* opens.
2. Click on the *“Install”* button.
3. Select the library that you wish to install. You can set a file filter here.
   Click on *“Open”*.
   ⇨ The library is added to the repository. The library can now be added in the Library Manager.

See also

- *Chapter 1.4.1.16.2 “Adding a Library to the Application” on page 450*

1.4.1.16.4 Exporting library files

You can export a library from the library manager of a project or from the library repository and then save it as a file to the hard disk.

Export from the library manager

1. Open a library manager of an application in a project.
2. Select a library in the library manager.
3. Click the export command in the context menu.
   ⇨ The *“Export Library”* dialog box opens.
4. If the selected library is linked in the project not only as a compiled library, but also in source format, then both file types are in the drop-down list for *“File type”*. Otherwise, the filter automatically shows the available type: "`*.library` or `*.compiled-library`.
5. Select the file type and storage location and click *“Save”*.

Export from the library manager

1. Open the CODESYS library repository (*“Tools”* menu).
2. Select a library version in the window of the installed libraries.

3. Click the *“Export”* button.
   ⇨ The *“Export Library”* dialog box opens.
4. As step 4 and 5 for "Export from the library manager".

See also

- *Chapter 1.4.1.20.2.14 “Object 'Library Manager'” on page 874*
- *Chapter 1.4.1.20.3.8.5 “Command 'Library Repository'” on page 1061*

1.4.1.17 Managing devices

CODESYS manages the installed devices in the device repository. A device repository is a defined location in the file system. In the default CODESYS installation, it is defined with an absolute path as the system repository. You install or uninstall devices in the *“Device Repository”* dialog. The system installs a device by reading the device description file. The properties of a device are defined in these files regarding configurability, programmability, and possible connections to other devices.

You can use the devices provided in the device repository by adding them to the device tree of your project.

See also

- *Chapter 1.4.1.20.3.8.8 “Command 'Device Repository'” on page 1067*
- *Chapter 1.4.1.17.1 “Installing devices” on page 452*

1.4.1.17.1 Installing devices

Install a device in the device repository in order to include it in your project.

1. Click *“Tools ➔ Device Repository”*.
   ⇨ The *“Device Repository”* dialog box opens.
2. Select the install location. *“System Repository”* is set by default.
3. Click *“Install”*.
   ⇨ The *“Install Device Description”* dialog box opens.
4. Select the file path of the device description.
5. Select the file type filter of the required device description.
   ⇨ All device descriptions of the selected file type are listed.
6. Select the required device description and click *“Open”*.
   ⇨ CODESYS adds the device description to the matching category of your device repository.

   If errors occur during installation (for example, missing files that are referenced by the device description), then CODESYS displays them in the lower part of the device repository dialog box.

See also

- *Chapter 1.4.1.20.3.8.8 “Command 'Device Repository'” on page 1067*

1.4.1.18 Security

Due to the increased networking of controllers and plants, potential threats are also quickly rising. Therefore, you should carefully consider all possible security measures.

Security measures are absolutely necessary to protect data and communication channels from unauthorized access.

On the following help pages, you can learn more about the safety functions of CODESYS and the controller.

1.4.1.18.1 General Information

The following provides some general information about safety functions (security measures). This information applies regardless of the usage in CODESYS or one with a connection controller.

Access protection with user management

As a means of protecting against unauthorized access to data, it is necessary to configure user accounts with specific access rights. Only a user with the credentials has access to the data or functions.

Creating passwords according to the general recommendations for achieving a high password strength is a tremendous contribution to security.

The following types of user management are roughly distinguished as follows:

- Simple user management:
  To access data, only a password or the valid combination of user name and password has to be entered. This means that access can be only granted or denied. Graduated permissions cannot be configured.
- Group-based user management:
  The access rights are assigned to user groups. Users who belong to a group can access the data or functions after entering the credentials with precisely these assigned and different permissions.

Encryption, signature

Encryption:

Encryption of data means the following: Data is converted into an unreadable form and can only be made readable again with a matching key. In the simplest case, the key is a password or a key pair.

There are two types of encryption methods:

- Symmetric method: (the only type of encryption until the mid-1970s)
  Characteristic: Use of a secret key
  Advantages: Fast, simple encoding
  Disadvantages: The key has to be shared secretly.
- Asymmetric method:
  Characteristic: Use of a key pair (private/secret key and public key)
  Advantages: The public key can be made accessible to anyone, and authentication possible with it.
  Disadvantages: Slow (approx. 1,000 to 10,000 times slower than symmetric methods); complex encoding; long key lengths

Key exchange is usually performed by asymmetric methods; encryption and decryption by symmetric methods.

Signature:

In order for the irrefutable ownership and integrity of a message to be verifiable, it should be provided with a signature. These are usually the steps involved:

- Sender: Determines a unique hash value over the data (H)
- Sender: Encrypts the hash value with private key (He)
- Recipient: Also calculates the hash value and decrypts the He with the public key and compares the two values. This allows the sender to be identified uniquely and verifies that the sender owns the private key.

In the case of asymmetric encryption, a public key contained in a certificate is first exchanged between the sender and the recipient. In addition, each participant needs a private key with which they can decrypt the data if they have the certificate. So if you want to access a certificate, you need a certificate AND a private key.

Hash methods are necessary for this:

- Hash method:
  Characteristic: Unique thumbprint of the data (for example, checksum of the data)
  As low a collision as possible (it is very difficult to find / construct two different data for a single hash value)

Certificates

In order to assign the public key to an identity, it is usually embedded in a certificate.

In certificate-based systems, each user receives a digital certificate. The certificate is used for digital identification. It contains information about the identity and the public key of the user. Each certificate is authenticated by an issuing authority, which in turn may be authenticated by higher authorities. The trust system of this PKI (Public Key Infrastructure) is strictly hierarchical. The common trust anchor is a root certificate.

Contents of a certificate:

- Version
- Serial number
- Algorithm ID
- Issuer (authority or company)
- Validity from (not before) to (not after)
- Certificate owner (subject)
- Certificate owner key information (subject public key)
  - Public key algorithm
  - Public key of the certificate owner
- Unique ID of the issuer (optional)
- Unique ID of the owner (optional) The owner possess a private key matching the public key.
- Extensions
  - Purpose (extended key usage)
  - ...

The certificate consists of 2 parts/files:

- Public X.509 certificate (can be issued to anyone)
- Private key that matches the certificate or its public key only (has to be kept secret).

To manage the certificates in your local "Windows Certificate Store", see the following help page:

- *Chapter 1.4.1.5 “Protecting and Saving Projects” on page 197*

1.4.1.18.2 Security for the development system

In CODESYS, you can apply access protection to projects, libraries, as well as individual applications. In addition to a simple write protection for a project, a user management (credentials, access rights) and encryption using certificates should be used.

See current help:

- *Chapter 1.4.1.5 “Protecting and Saving Projects” on page 197*
- *Chapter 1.4.1.8.17 “Encrypting an application” on page 294*

1.4.1.18.3 Security for the Runtime/PLC

Communication with the controller connected in the CODESYS project should be protected against unauthorized access in the following ways:

- Enabling user management: simple or group-based
- Certificate-based encryption of communication with the controller

Enabling the security features

First switch the communication to encryption so that you do not reveal any credentials to other participants in the network when transferring the user management.

Enforcing encrypted communication

- On the controller:
  - Runtime version >= 3.5 SP14: Encryption can be enabled for *“Communication Policy”* and enforced for all clients.
- In CODESYS:
  - Encrypted communication can be selected as an option in the device editor on the *“Communication Settings”* tab (command or *“Change Communication Policy”* dialog) or in the *“Security Screen”* view.

    See the current help regarding this:

    Chapter 1.4.1.10.2 “Encrypting Communication, Changing Security Settings” on page 381

    If the CODESYS Security Agent is installed, then see the help for CODESYS Security Agent.

Enforcing a user management

- On the controller:
  - Runtime version >= 3.5 SP17: User management is enforced by default for *“Communication Policy”*.

    Note: For enabling the user management, at least a CODESYS development system V3.5 SP16 is necessary. This means that, in the case of enforced user management which has not been enabled yet, you cannot connect to an older development system.
- In CODESYS:
  - See the current help regarding this:

    Chapter 1.4.1.10.2 “Encrypting Communication, Changing Security Settings” on page 381

    Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385

1.4.1.18.4 Security for CODESYS WebVisu

Protect the connection between the web server of the controller and the visualization client with the following measures against unwanted access:

- Configure an HTTPS connection (encryption with SSL/TSL) between the visualization client and the web server.
- Restrict access to the visualization and configure a visualization user management.

Configure an encrypted connection.

An HTTPS connection between the web server and the visualization client requires authentication of the web server by means of a certificate. You can create a self-signed certificate in the *“Security Screen”*.

1. Click *“View ➔ Security Screen”*.
2. Create a certificate for the web server on your controller.
   ⇨ The certificate data for the web server is displayed.
3. **Stop your controller.**
4. Restart the controller.
   ⇨ The new certificate is active.
5. Download your application to the controller.
6. Open your browser and specify the URL address of your web server.
   The URL of a secure connection corresponds to the following format:
   `https:// <IP address/URL> :443/ <name of HTM file> .htm`.
   The HTML file name has to match the configured name as it is set in the *“Visualization Manager”* object below the WebVisu variant. You will find the IP address of the controller in the device editor when the a connection is active.
   ⇨ Example: `https://localhost:443/webvisu.htm`
   The browser establishes a connection. If the certificate is not rated as trusted, then a security notice appears.
7. Confirm that you know the risk and want to proceed.
   ⇨ You have created self-signed certificate and confirmed it as trusted.
   Now start the web application with the visualization. The lock symbol in the browser indicates secure communication.

See the chapter "Run as CODESYS WebVisu", which describes in detail how you use certificates in the security screen.

See also

- *Chapter "Run as CODESYS WebVisu"*
- *Chapter "User management of the visualization"*
- *Chapter 1.4.1.10.2 “Encrypting Communication, Changing Security Settings” on page 381*
- *Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385*

1.4.1.18.5 FAQ

Certificate expired

If the certificate from the controller for encrypted communication has expired (valid from "not before" until "not after"), you get a prompt with a corresponding message in CODESYS when you attempt to access the controller. For example, to renew the expired certificate, you can accept the expired certificate and connect to the controller.

You will see this message again every time you try to login until a valid certificate is installed on the controller.

If you have created or imported a new certificate on the controller, then this new certificate will be available for you to accept the next time you login.

See also

- *Chapter 1.4.1.10.2 “Encrypting Communication, Changing Security Settings” on page 381*

Other clients that communicate encrypted with the controller (for example, PLCHandler) will typically not accept an expired certificate. This means that no connection can be established here.

New certificate (while the current one is still valid)

A new certificate can be issued before the existing certificate expires. This makes it possible for the encrypted communication to continue seamlessly. As soon as a new certificate is available on the controller parallel to the one currently used, the new certificate will be offered by the controller at the next login attempt. All you have to do is accept it.

- *“Installing a controller certificate for encrypted communication via the PLC shell of the device editor” on page 383*

Client does not support security feature

User management

The following CODESYS clients do not support user management yet:

- WebServer < V3.5.14.0

In order for these clients to be able to establish a connection to the controller, the user management must not be enabled.

Encrypted communication

The following CODESYS clients do not support encrypted communication yet:

- Data servers with compiler version =< V3.5.9.0
- WebVisu < V3.5.14.0 or in the case of enabled file transfer
- WebServer < V3.5.14.0
- Remote TargetVisu
- Data source ApplicationV3
- OPC Server V3
- PLCHandler < V3.5.14.0

In order for these clients to be able to establish a connection to the controller, the encrypted communication can be set as optional. Therefore clients can establish either an encrypted or an unencrypted connection.

Do not use the same user or password for encrypted and unencrypted communication.

See also

- *Chapter 1.4.1.10.2 “Encrypting Communication, Changing Security Settings” on page 381*

CA-signed certificates preferred (PLC shell)

Using CA-signed certificates is not conveniently supported yet in CODESYS. However, you can still request and use these types of certificates. In the device editor, on the *“PLC Shell”* tab, you export the required CSR files to the file system and import from there the CER files sent from the certification authority.

Requesting and providing a CA-signed certificate

☑ You are connected to the controller.

1. First you generate certificate signing requests (CSR) of all server certificates.

   For this purpose, click the *“PLC Shell”* tab of the controller and type the command `cert-createcsr` in the input line.

2. Click the *“Log”* tab and then the refresh button (🔄).

   ⇨ In the log entries, you can see that the CSR files were generated.

3. Click the *“Files”* tab and open the file path `cert/export` in the right side of the *“Runtime”* dialog.

   ⇨ The `export` folder contains the generated CSR files, for example `0_CmpsecureChannl.csr, 1_CmpApp.csr, 2_CmpWebServer.csr`.

4. Select a file path where you wish to insert the CSR files in the left side of the *“Host”* dialog, mark the CSR files in the right side of the dialog, and click <<.

   ⇨ The CSR files are copied to the required folder.

5. These requests can be signed for certification signing by a certificate authority (CA), and then you receive a signed certificate from the certification authority.

6. In the steps that follow, you import these signed server certificates to your controller.

   NOTICE!
   Caution: Self-signed certificates of the server must be deleted before importing the CA-signed certificates.

7. Select the *“Path”* `cert/import` in the right side of the *“Runtime”* dialog.

8. In the left side of the *“Host”* dialog, select the path in the file system where you saved the signed certificates and selected the certificates.

9. Click >>.

   ⇨ The certificates are copied to the `cert/import` folder.

10. Click the *“PLC Shell”* tab.

11. Type the command `cert-import own <file name of the certificate.cer>` in the input line of the tab and press the *[Enter]* key.

    ⇨ The signed certificates are available to the runtime system servers.

- *Chapter 1.4.1.20.2.8.8 “Tab 'Log'” on page 848*
- *Chapter 1.4.1.20.2.8.7 “Tab 'Files'” on page 848*

Problems at login

If you have entered an incorrect password when logging in to the user management of the controller, then the login dialog reappears immediately afterwards. After three incorrect attempts, the controller is locked for a defined period of time. However, stricter policies on the controller can lead to the user being locked out and only authorized again by an administrator.

See also

- *Chapter 1.4.1.20.3.6.2 “Command 'Login'” on page 1028*

Disabling User Management

NOTICE!
After disabling the user management, your controller is accessible again for everyone in the network of the controller. Therefore, you should only do this in justified exceptional cases or if the clients used do not support any user management.

For enabling the user management, at least a CODESYS development system V3.5 SP16 is necessary. This means that, in the case of enforced user management which has not been enabled yet, you cannot connect to an older development system.

1. If the security policy for device user management is set to "Enforced", first set it back to "Optional".
2. Execute the *“Reset Origin Device”* command. This deletes the user management and you can then reconnect to the controller without having to enter user credentials. Note: In CODESYS Version 3.5 SP16 Patch 20 and higher, you can exclude the boot application from the delete operation when you execute *“Reset Origin Device”*.

See also

- *“Changing the communication policy (encryption, user management)” on page 384*
  Chapter 1.4.1.20.3.6.13 “Command 'Reset Origin Device'” on page 1040
- *Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385*
- *Chapter 1.4.1.5 “Protecting and Saving Projects” on page 197*

Permitting encrypted communication again

Remember that not every controller supports the deactivation of encrypted communication.

NOTICE!
We strongly advise against disabling encrypted communication. Especially in connection with an enabled user management, encrypted communication should be enabled so that credentials do not fall into the wrong hands.

To disable encrypted communication with the controller again, proceed as follows:

1. If the communication policy for encrypted communication is set to "Enforced", first set it back to "Optional".
2. In the device editor, on the *"Communication Settings"* tab in the *"Device"* menu, disable *"Encrypted communication"*. If you have installed the CODESYS Security Agent, then you can also change the setting in the *"Security Screen"*.
   ⇨ CODESYS establishes unencrypted communication again with the controller. Other clients can also communicate again without encryption.

1.4.1.19 Reference, Programming

1.4.1.19.1 Programming Languages and Editors

You program a POU in each case in the editor for the implementation language that you selected when creating the POU. CODESYS offers a text editor for ST and graphic editors for SFC, FBD/LD/IL and CFC.

The editor opens with a double-click on the POU in the device tree or in the *“POUs”* view.

Each of the programming language editors consists of two sub-windows:

- In the upper part you make declarations in the “declaration editor”, in text or tabular form depending on the setting.
- In the lower part you insert the implementation code in the respective language.

You can configure the display and the behavior of each editor project-wide on the associated tab of the CODESYS options.

Declaration Editor

In the declaration editor, you declare variables in variable lists and POUs.

If the declaration editor is used with an implementation language editor, then is opens in a view above the implementation language editor.

The declaration editor offers two possible views: textual and tabular. In the *“Tools ➔ Options ➔ Declaration Editor”* dialog, you define whether only the textual view or only the tabular view is available, or whether you can switch between both views by means of the buttons on the right side of the editor view.

A rectangle selection is possible in the textual view of the declaration editor. The key combinations for the rectangle selection are located on the help page for the ST editor.

See also

- *Chapter 1.4.1.8.2.1 “Using the declaration editor” on page 226*

- *Chapter 1.4.1.20.4.13.4 “Dialog 'Options' – 'Declaration Editor'” on page 1190*
- *Chapter 1.4.1.19.1.3.1 “ST Editor” on page 463*

Declaration editor in online mode

In online mode, you see the tabular view of the editor. The header always contains the current object path:`<device name>.<application name>.<object name>`. In contrast to offline mode, the table also contains the *“Value”* and *“Prepared Value”* columns.

The *“Value”* column shows the actual value on the PLC, offering monitoring functionality. If the expression is an array with more than 1,000 elements, then you can define the range of the array indices to monitor. To do this, double-click in the *“Data Type”* column to open the *“Monitoring Area”* dialog. In this dialog, the declared array range is specified as the *“Valid area”* for monitoring. A maximum of 20,000 elements can be monitored per array. You define the range of the array indices to be monitored by specifying the *“Start”* and *“End”* indices. In order to move this area more easily while maintaining the same size, the available scrollbars can be used coupled. Tot toggle between coupled and not coupled, click the symbol on the right of the bar. In non-coupled state, you can increase or decrease the size of the area to be monitored as desired.

The *“Prepared Value”* column contains the value that you prepared for forcing or writing.

If you double-click a *“Prepared value”* field, then you can specify a value explicitly for writing or forcing. In the case of enumerations, a combo box opens from which you can select a value. In the case of a Boolean variable you can toggle the prepared value with the help of the *[Enter]* key or the *[Space]* bar. If an expression (variable) is of a structured data type, for example the instance of a function block or an array variable, then a plus or a minus sign is placed in front.

You can customize the format of the representation of floating-point values in the options for monitoring.

Common functions in graphical editors

The implementation part of the graphical editors for FBD, LD, CFC, and SFC contains a toolbar in the lower right corner.

	Return to normal editing mode: The mouse pointer changes back to the shape of the default arrow. You can select and edit elements in the editor view.
	Panning tool: The mouse pointer changes to the shape of two crossed arrows. You can click and drag anywhere in the editor view to move the visible area of the FBD/LD/IL editor or also pivot a CFC chart.
	Magnification tool: A magnified window opens in the lower right corner of the editor view and the mouse pointer changes to the shape of a cross. As you move the mouse pointer over your diagram, the magnification tool shows the area of the diagram under the cross at 100% magnification. Note: If you click in the view, then the magnification tool closes and the part of the diagram that the tool contained is displayed at 100% magnification. If you want to retain the set zoom factor, then you should use the default arrow () for returning to the default editing mode.
	Zooming tool: This opens a drop-down list with a selection of zoom factors. Clicking more selections (. . .) will open the *“Zoom”* dialog for typing other values. The current zoom factor is always shown to the left of the symbol.

Zooming with the scroll wheel: By holding down the *[Ctrl]* key and moving the scroll wheel, you can change the zoom factor in steps of 10%.

Every graphical editor has its own *“ToolBox”* view that is located on the right of the editor view by default. The toolbox contains elements that you can drag to insertion points in the editor view. CODESYS highlights the insertion points with gray position flags in the shape of diamonds, triangles, or arrows. These flags are green when you move the mouse pointer over them. When you release the mouse button, CODESYS inserts the element at the selected position.

It is also possible to use the mouse for moving elements in the editor.

You can drag function block declarations in the FBD, LD, and CFC graphical editors to the editor view. To do this, select the full declaration (variable name and data type) and drag it to a suitable position in the editor view. In the ladder diagram, you can also drag Boolean declarations to the editor and insert them as contacts.

Structured Text and Extended Structured Text (ExST)

ST Editor

The ST editor is a textual editor used for the implementation of code in Structured Text (ST) and Extended Structured Text (ExST).

The line numbering is displayed on the left side of the editor. When inputing programming elements, the "List components" functionality (activated in the CODESYS options, *“SmartCoding”* category) and the Input Assistant *[F2]* are also useful. When the cursor is placed over a variable, CODESYS shows a tooltip with information for declaring variables.

The box selection can be made with the following key combinations:

- *[Shift]+[Alt]+[Arrow Right]*: The selected area is extended one position to the right.
- *[Shift]+[Alt]+[Arrow Left]*: The selected area is extended one position to the left.
- *[Shift]+[Alt]+[Arrow Up]*: The selected area is extended one position up.
- *[Shift]+[Alt]+[Arrow Down]*: The selected area is extended one position down.

The behavior (for example parentheses, mouse actions, tabs) and appearance of the editor are configured in the CODESYS options in the *“Text Editor”* category.

For an incremental search for strings in the editor, open an input field at the bottom edge of the editor by means of the key combination *[Ctrl]+[Shift]+[i]*. As soon as you start typing in characters, the corresponding search locations are highlighted in color in the editor. The number of found matches is shown to the right of the input field. You can set the cursor at the search location by using the arrow keys or the key combinations *[Alt]+[Page Up]* or *[Alt]+[Page Down]*.

When you place the cursor on a symbol name, all occurrence locations of the symbol within the editor are highlighted in color. The search locations correspond to the hits in the cross-reference list. For very large projects, this can cause input delays. In this case, you can disable the function in the options of the text editor.

CODESYS identifies syntax errors already when inputing in the editor and shows the corresponding messages in the message view (*“Precompile”* category). If the corresponding option is selected in the CODESYS options (*“SmartCoding”* category), then the error locations in the text are also underlined with a wavy red line.

The *“Format Document”* command provides an automatic formatting of syntactically correct ST code.

ST editor in online mode

In online mode CODESYS displays the variables and expressions in the ST editor. The writing and forcing of the variables and expressions as well as debugging functions (breakpoints, single step execution) are also possible.

If you use assignments as expressions in ST programming, no further breakpoint positions are created within a line.

ST expressions

An expression is a construct that returns a value following its evaluation.

Expressions are composed of operators and operands. In Extended Structured Text (ExST) you can also use assignments as expressions. An operand can be a constant, a variable, a function call or a further expression.

Examples

`2014`	`(* Constant *)`
`ivar`	`(* Variable *)`
`fct(a,b)`	`(* Function call *)`
`(x*y)/z`	`(* Expression *)`
`real_var2 := int.var;`	`(* in ExST: Assignment *) *)`

See also

- *“ExST - Extended structured text” on page 254*

Evaluation of expressions

The evaluation of an expression takes place by processing the operators according to certain rules of binding. CODESYS processes the operator with the strongest binding first. Operators with the same binding strength are processed from left to right.

Operation	Symbol	Binding strength
Parenthesize	(Expression)	Strongest binding
Function Call	Function name (parameter list) all operators with syntax: <operator> ()	
Exponentiate	`EXPT`	
Negate Complementation	`-` `NOT`	

Multiplication
Division
Modulo
	`*`
	`/`
	`MOD`	

Addition Subtraction	`+` `-`	
Comparison	<,>,<=,>=	

Operation	Symbol	Binding strength
Equality Inequality	= <>	
Bool AND	AND AND_THEN	
Bool XOR	XOR	
Bool OR	OR OR_ELSE	Weakest binding

See also

- *Chapter 1.4.1.19.3 “Operators” on page 542*

Assignments

ST assignment operator

Syntax:

<operand> := <expression>

This assignment operator executes the same function as the MOVE operator.

See also

- *Chapter 1.4.1.19.3.6 “Operator 'MOVE'” on page 550*

ST assignment operator for outputs

The assignment operator => assigns the output of a function, a function block, or a method to a variable. The position on the right side of the operator can also be blank.

Syntax

<output> => <variable>

Example

```
FBcomp_Output1 => bVar1;
FBcomp_Output2 => ;
```

FBcom_Output1 and FB_Output2 are outputs of a function block. The value of FBcom_Output1 is assigned to the variable bVar1.

ExST assignment 'S='

When the operand of the Set assignment switches to TRUE, then TRUE is assigned to the variable to the left of the operator. The variable is set.

```
<variable name> S= <operand name> ;
```

The variables and the operand have the data type `BOOL`.

Example

```
PROGRAM PLC_PRG
VAR
    xOperand: BOOL := FALSE;
    xSetVariable: BOOL := FALSE;
END_VAR

xSetVariable S= xOperand;
```

When the operand `xOperand` switches from `FALSE` to `TRUE`, then `TRUE` is also assigned to the variable `xSetVariable`. But then the variable keeps this state, even if the operand continues to change its state.

Multiple assignments

NOTICE!
In the case of multiple assignments within a code line, the individual assignments are not processed from right to left, but all assignments refer to the operands at the end of the code line.

Example

```
FUNCTION funCompute : BOOL
VAR_INPUT
    xIn : BOOL;
END_VAR
IF xIn = TRUE THEN
    funCompute := TRUE;
    RETURN;
END_IF

PROGRAM PLC_PRG
VAR
    xSetVariable: BOOL;
    xResetVariable: BOOL := TRUE;
    xVar: BOOL;
END_VAR
xSetVariable S= xResetVariable R= funCompute(xIn := xVar);
```

`xResetVariable` gets the `R=` assignment of the return value of `funCompute`.
`xSetVariable` gets the `S=` assignment of ht return value of `funCompute`, but not from `xResetVariable`.

See also

- *“ExST - Extended structured text” on page 254*
- *Chapter 1.4.1.19.1.3.4.4 “ExST assignment 'R='” on page 466*

ExST assignment 'R='

When the operand of the Reset assignment switches to `TRUE`, then `FALSE` is assigned to the variable to the left of the operator. The variable is reset.

```
<variable name> R= <operand name> ;
```

The variables and the operand have the data type `BOOL`.

Example

```
VAR
    xOperand: BOOL := FALSE;
    xResetVariable: BOOL := TRUE;
END_VAR

xResetVariable R= xOperand;
```

When the operand `xOperand` switches from `FALSE` to `TRUE`, then `FALSE` is also assigned to the variable `xResetVariable`. But then the variable keeps its state, even if the operand continues to change its state.

Multiple assignments

NOTICE!
In the case of multiple assignments within a code line, the individual assignments are not processed from right to left, but all assignments refer to the operands at the end of the code line.

Example

```
FUNCTION funCompute : BOOL
VAR_INPUT
    xIn : BOOL;
END_VAR
IF xIn = TRUE THEN
    funCompute := TRUE;
    RETURN;
END_IF

PROGRAM PLC_PRG
VAR
    xSetVariable: BOOL;
    xResetVariable: BOOL := TRUE;
    xVar: BOOL;
END_VAR
xSetVariable S= xResetVariable R= funCompute(xIn := xVar);
```

`xResetVariable` gets the `R=` assignment of the return value of `funCompute`.
`xSetVariable` gets the `S=` assignment of ht return value of `funCompute`, but not from `xResetVariable`.

See also

- *“ExST - Extended structured text” on page 254*
- *Chapter 1.4.1.19.1.3.4.3 “ExST assignment 'S='” on page 465*

ExST – Assignment as expression

In ExST, as an extension to the IEC 61131-3 standard, CODESYS permits the use of assignments as expressions.

Examples

`int_var1 := int_var2 := int_var3 + 9;`	(* `int_var1` and `int_var2` receive the value of `int_var3 + 9` *)
`real_var1 := real_var2 := int_var;`	(* `real_var1` and `real_var2` receive the value of `int_var` *)
`int_var := real_var1 := int_var;`	(* incorrect assignment, the data types do not correspond! *)

`IF b := (i = 1) THEN`
`i := i + 1;`
`END_IF`	

See also

- *“ExST - Extended structured text” on page 254*

Assignment Operator 'REF='

The operator generates a reference (pointer) to a value.

Syntax:

```
<variable name> REF= <variable name> ;
```

Example

```
refA : REFERENCE TO DUT;
B : DUT;
C : DUT;

A REF= B; // corresponds to A := ADR(B);
A := C; // corresponds to A^ := C;
```

See also

- *Chapter 1.4.1.19.5.13 “Reference” on page 658*
- *Chapter 1.4.1.20.3.12.8 “Command 'REF= (Reference Assignment)'” on page 1091*

Statements

ST statement 'IF'

The IF statement is used for checking a condition and, depending on this condition, for executing the subsequent statements.

A condition is coded as an expression that returns a Boolean value. If the expression returns TRUE, then the condition is fulfilled and the corresponding statements after THEN are executed. If the expression returns FALSE, then the following conditions, which are identified with ELSIF, are evaluated. If an ELSIF condition returns TRUE, then the statements are executed after the corresponding THEN. If all conditions return FALSE, then the statements after ELSE are executed.

Therefore, at most one branch of the IF statement is executed. ELSIF branches and the ELSE branch are optional.

Syntax

```
IF <condition> THEN
    <statements>
( ELSIF <condition> THEN
        <statements> )*
( ELSE
        <statements> )?
END_IF;
// ( ... )* None, once or several times
// ( ... )? Optional
```

Example

```
PROGRAM PLC_PRG
VAR
    iTemp: INT;
    xHeatingOn: BOOL;
    xOpenWindow: BOOL;
END_VAR

IF iTemp < 17 THEN
    xHeatingOn := TRUE;
ELSIF iTemp > 25 THEN
    xOpenWindow := TRUE;
ELSE xHeatingOn := FALSE;
END_IF;
```

The program is run as follows at runtime:

For the evaluation of the expression `iTemp < 17 = TRUE`, the subsequent statement is executed and the heating is switched on. For the evaluation of the expression `iTemp < 17 = FALSE`, the subsequent ELSIF condition `iTemp > 25` is evaluated. If this is true, then the statements in ELSIF are executed and the view is opened. If all conditions are FALSE, then the statement in ELSE is executed and the heating is switched off.

See also

- *Chapter 1.4.1.19.1.3.3 “ST expressions” on page 464*

ST instruction 'FOR'

The FOR loop is used to execute instructions with a certain number of repetitions.

Syntax:

```
FOR <counter> := <start value> TO <end value> {BY <increment> } DO
<instructions>
END_FOR;
```

The section inside the curly parentheses {} is optional.

CODESYS executes the `<instructions>` as long as the `<counter>` is not greater, or - in case of negative increment - is not smaller than the `<end value>`. This is checked before the execution of the `<instructions>`.

Every time the instructions `<instructions>` have been executed, the counter `<counter>` is automatically increased by the increment `<increment>`. The increment `<increment>` can have any integral value. If you do not specify an increment, the standard increment is `1`.

Example

```
FOR iCounter := 1 TO 5 BY 1 DO
iVar1 := iVar1*2;
END_FOR;
Erg := iVar1;
```

If you have pre-configured `iVar1` with `1`, `iVar1` has the value `32` after the FOR loop.

CAUTION!

The end value <end value> may not attain the same value as the upper limit of the data type of the counter.

If the end value of the counter is equal to the upper limit of the data type of the counter, an endless loop results. For example, an endless loop results in the above example if `iCounter` is of the data type `SINT` and the `<end value>` equals `127`, since the data type `SINT` has the upper limit `127`.

As an extension to the IEC 61131-3 standard you can use the `CONTINUE` instruction within the `FOR` loop.

See also

- *Chapter 1.4.1.19.5.2 “Integer data types” on page 647*
- *Chapter 1.4.1.19.1.3.5.9 “EXST Statement 'CONTINUE'” on page 474*

ST instruction 'CASE'

Use this dialog box for pooling several conditional instructions containing the same condition variable into a construct.

Syntax:

```
CASE <Var1> OF
<value1>:<instruction1>
<value2>:<instruction2>
<value3, value4, value5>:<instruction3>
<value6 ... value10>:<instruction4>
...
<value n>:<instruction n>

{ELSE <ELSE-instruction>}

END_CASE;
```

The section within the curly brackets `{}` is optional.

Processing scheme of a CASE instruction.

- If the value of the variable <Var1> is <value i>, then the instruction <instruction i> is executed.
- If the variable <Var1> has non of the given values, then the <ELSE-instruction> is executed.
- If the same instruction is executed for several values of the variable, then you can write the values in sequence, seperated by commas.

Example

```
CASE iVar OF
1, 5: bVar1 := TRUE;
      bVar3 := FALSE;

2: bVar2 := FALSE;
   bVar3 := TRUE;

10..20: bVar1 := TRUE;
        bVar3= TRUE;
ELSE
   bVar1 := NOT bVar1;
   bVar2 := bVar1 OR bVar2;
END_CASE;
```

ST instruction 'WHILE'

The WHILE loop is used like the FOR loop in order to execute instructions several times until the abort condition occurs. The abort condition of a WHILE loop is a boolean expression.

Syntax:

```
WHILE <boolean expression> DO
 <instructions>
 END_WHILE;
```

CODESYS repeatedly executes the <instructions> for as long as the <boolean expression> returns TRUE. If the boolean expression is already FALSE at the first evaluation, then CODESYS never executes the instructions. If the boolean expression never adopts the value FALSE, then the instructions are repeated endlessly, as a result of which a runtime error results.

Example

```
WHILE iCounter <> 0 DO
Var1 := Var1*2
iCounter := iCounter-1;
END_WHILE;
```

NOTICE!
You must ensure by programming means that no endless loops are caused.

In a certain sense the WHILE and REPEAT loops are more powerful than the FOR loop, since you don't need to already know the number of executions of the loop before its execution. In some cases it is thus only possible to work with these two kinds of loop. If the number of executions of the loop is clear, however, then a FOR loop is preferable in order to avoid endless loops.

As an extension to the IEC 61131-3 standard you can use the CONTINUE instruction within the WHILE loop.

See also

- *Chapter 1.4.1.19.1.3.5.2 “ST instruction 'FOR'” on page 469*
- *Chapter 1.4.1.19.1.3.5.9 “EXST Statement 'CONTINUE'” on page 474*

ST Statement 'REPEAT'

The `REPEAT` loop is used like the `WHILE` loop, but with the difference that CODESYS only checks the abort condition after the execution of the loop. The consequence of this behavior is that the `REPEAT` loop is executed at least once, regardless of the abort condition.

Syntax:

```
REPEAT
<instructions>
 UNTIL <boolean expression>
 END_REPEAT;
```

CODESYS executes the `<instructions>` until the `<boolean expression>` returns `TRUE`.

If the boolean expression already returns `TRUE` at the first evaluation, CODESYS executes the instructions precisely once. If the boolean expression never adopts the value `TRUE`, then the instructions are repeated endlessly, as a result of which a runtime error results.

Example

```
 REPEAT
 Var1 := Var1*2;
 iCounter := iCounter-1;
 UNTIL
 iCounter = 0
 END_REPEAT;
```

In a certain sense the `WHILE` and `REPEAT` loops are more powerful than the `FOR` loop, since the number of executions of the loop doesn't already need to be known before its execution. In some cases you can only work with these two kinds of loop. If the number of executions of the loop is clear, however, then a `FOR` loop is preferable in order to avoid endless loops.

As an extension to the IEC 61131-3 standard you can use the CONTINUE instruction within the `WHILE` loop.

See also

- *Chapter 1.4.1.19.1.3.5.4 “ST instruction 'WHILE'” on page 471*
- *Chapter 1.4.1.19.1.3.5.2 “ST instruction 'FOR'” on page 469*
- *Chapter 1.4.1.19.1.3.5.9 “EXST Statement 'CONTINUE'” on page 474*

ST statement 'RETURN'

Use the `RETURN` statement in order to exit from a function block. You can make this dependent on a condition, for example.

Example

```
IF xIsDone = TRUE THEN
    RETURN;
END_IF;

iCounter := iCounter + 1;
```

If the value of `xIsDone` is equal to `TRUE`, then the function block is exited immediately and the statement `iCounter := iCounter + 1;` is not executed.

See also

- *Chapter 1.4.1.19.1.3.5.1 “ST statement 'IF'” on page 469*

ST instruction 'JMP'

The `JMP` instruction is used to execute an unconditional jump to a program line that is marked by a jump label.

Syntax:

```
<label>: <instructions>
JMP <label>;
```

The jump label `<label>` is any unique identifier that you place at the beginning of a program line. On reaching the `JMP` instruction, a return to the program line with the `<label>` takes place.

Example

```
iVar1 := 0;
_label1: iVar1 := iVar1+1;
(*instructions*)

IF (iVar1 < 10) THEN
JMP _label1;
END_IF;
```

NOTICE!
You must ensure by programming means that no endless loops are caused. For example, you can make the jump conditional.

ST instruction 'EXIT'

The `EXIT` instruction is used in a `FOR`, `WHILE` or `REPEAT` loop in order to end the loop regardless of other abort conditions.

See also

- *Chapter 1.4.1.19.1.3.5.2 “ST instruction 'FOR'” on page 469*
- *Chapter 1.4.1.19.1.3.5.4 “ST instruction 'WHILE'” on page 471*
- *Chapter 1.4.1.19.1.3.5.5 “ST Statement 'REPEAT'” on page 472*

EXST Statement 'CONTINUE'

`CONTINUE` is an instruction of the Extended Structured Text (ExST).

The instruction is used inside `FOR`, `WHILE` and `REPEAT` loops in order to jump to the beginning of the next execution of the loop.

Example

```
FOR Counter:=1 TO 5 BY 1 DO
INT1:=INT1/2;
 IF INT1=0 THEN
  CONTINUE; (* to avoid a division by zero *)
 END_IF
Var1:=Var1/INT1; (* executed, if INT1 is not 0 *)
END_FOR;

Erg:=Var1;
```

See also

- *Chapter 1.4.1.19.1.3.5.2 “ST instruction 'FOR'” on page 469*
- *Chapter 1.4.1.19.1.3.5.4 “ST instruction 'WHILE'” on page 471*
- *Chapter 1.4.1.19.1.3.5.5 “ST Statement 'REPEAT'” on page 472*

ST function block call

Syntax

```
<FB-instance>(<FB input variable>:=<value or address>|, <other FB input variables>);
```

Example

```
  TMR:TON;

                    TMR (IN:=%OX5, PT:=T#300ms);
                    varA:=TMR.Q;
```

The timer function block `TON` is instanced in `TMR:TON` and called with assignments for the parameters `IN` and `PT`.

The output `Q` is addressed with `TMR.Q` and assigned to the variable `varA`.

See also

- *Chapter 1.4.1.20.2.18.2 “Object 'Function Block'” on page 883*

ST – Comments

Comment	Description	Example
Single-line	There are two ways of marking: ● Starts with `//` and ends at the end of the line ● Starts with `///` and ends at the end of the line In CODESYS, these comments are handled the same way. However, if library documentation is created using the LibDoc Scripting Collection, the following applies: ● When the property `LibDocContent = DocsOnly` is entered in the project information, only comments marked with `///` are processed into library documentation. See the example for this below the table. ● When `LibDocContent = CommentsAndDocs` (default setting) is defined, all comments are processed into library documentation.	`/// This is a comment.` `/// This is a comment.`
Multiline	Starts with `(*` and ends with `*)`.	`(* This is a multiline comment *)`
Nested	Starts with `(*` and ends with `*)`. Additional comments `(*....*)` can be contained within this comment.	`( * a:=inst.out; (* comment 1 *) b:=b+1; (* comment 2 *) *)`

Comments for tooltips and POU documentation

```
A tooltip in the header of a POU is defined by the following
comment:
    // tooltip text - line 1
    // tooltip text - line 2
    // tooltip text - line 3

    Afterwards the documentation is defined as follows:
    /// reStructuredText
```

Note: It is not recommended to mix the different comment types because this can cause unwanted side-effects when the documentation is generated.

Sequential Function Chart (SFC)

SFC editor

The SFC editor is graphical editor. A new SFC POU includes an Init step and a subsequent transition.

In the SFC editor, you can insert individual elements into the diagram by means of commands in the *“SFC”* menu, the context menu, or the *“ToolBox”* view.

When inserting by means of a menu command, the elements that can be inserted at the currently selected position are available.

Before inserting branches parallel to multiple actions and transitions, you must highlight these actions and transitions in a multiple selection.

You can also drag SFC elements from the *“ToolBox”* view to the diagram. When you drag an element over the editor, CODESYS marks all possible insertion points with gray boxes. If you move the mouse over a gray box, then the color of the box changes to green. When you release the mouse button, the object is inserted at that location.

If you drag a branch into the diagram, then you must set the beginning and the end of the branch using the mouse pointer. You set the beginning of the branch by releasing the mouse button at an insertion point. The color of the box then changes to red. You set the end of the branch by clicking the second insertion point. Then CODESYS inserts a branch around the objects between the beginning and end markers.

For copying step and transition elements that call action objects or transition objects, two different duplication modes can be set. Either the references are copied at the same time, or the referenced objects are embedded and duplicated when copying.

You define the look and feel of the editor in the CODESYS options (*“SFC Editor”*).

SFC Editor in Online Mode

In the SFC editor, the variables and expressions in use on the controller can be displayed at runtime. You can also write and force variables and expressions. Debugging functions, such as breakpoints and step-by-step execution, are not available yet.

In the SFC editor options, you can set the online representation of the SFC elements and attributes.

In the case that you have declared SFC flags explicitly, then they are displayed in the declaration part in online mode. They are not displayed in offline mode.

Note the processing order of elements in an SFC diagram.

In online mode, CODESYS displays active steps in blue.

Processing order in SFC

Basic element behavior

- Active step: An active step includes actions currently being executed. In online mode, CODESYS displays active steps in blue.
- Initial step: In the first cycle after calling a POU in SFC, the initial step is activated automatically and the step action is executed.
- CODESYS executes IEC actions at least two times: the first time is when the step is activated, and the second time when the step is deactivated (but not until the next cycle).
- Alternative branches: If the step before the branch is active, then CODESYS passes the first transition of each alternative branch line from left to right. CODESYS activates the subsequent step in the first branch line with a transition yielding `TRUE`.
- Parallel branches: If the step before the branch (horizontal double line) is active and the transition before the branch yields `TRUE`, then CODESYS activates the first steps in every branch line. The branch lines are then processed at the same time. The step after the end of the branch is activated when every last step in each branch line is active and the transition after the double line yields `TRUE`.

Processing order

1. **Reset IEC actions**

   CODESYS resets the internal action control flags of the action qualifiers (N, R, S, L, D, P, SD, DS, SL). These flags control IEC actions. However, flags are not reset when they are called within actions.

2. **Execute exit actions**

   CODESYS verifies whether all steps fulfill the condition for executing the exit action for each step. The order of verification follows the layout in the SFC diagram, from top to bottom and from left to right.

   CODESYS executes an exit action when the step is deactivated (after any entry and step actions have been executed in the preceding cycle and the condition for the subsequent step yields `TRUE`).

3. **Execute entry actions**

   CODESYS verifies whether all steps fulfill the condition for executing the entry action for each step. The order of verification follows the layout in the SFC diagram, from top to bottom and from left to right. If the conditions are fulfilled, then CODESYS executes the entry actions.

   CODESYS executes an entry action as soon as the transition of the preceding step has been processed and yields `TRUE`, thus indicating that the step has been activated.

4. **Time check / Execute step actions**

   CODESYS performs the following check for each step in the order of the SFC layout:

   - CODESYS copies the elapsed time of the active step to the respective implicit step variable `<step name>.t`. (not yet implemented)
   - If a timeout occurs, then CODESYS sets the respective error flags. (not yet implemented)
   - For non-IEC steps: CODESYS executes the step action.

5. **Execute IEC actions**

   CODESYS executes the IEC actions in alphabetical order, passing through the list of actions two times. In the first pass, CODESYS executes the IEC actions for each step that was deactivated in the preceding cycle. In the second pass, the IEC actions are executed for each active step.

6. **Transition check / Activate next steps**

   The transitions are passed as follows: If a step is active in the current cycle and the subsequent transition yields `TRUE` and any defined minimum time of the step has elapsed, then the subsequent step is activated.

NOTICE!

Please note when executing actions:

An action can be executed multiple times within the same cycle if you use it in multiple SFC diagrams. For example, if a sequential function chart includes two IEC actions A and B, both of which are programmed in SFC and call an IEC action C, then the IEC action C is called two times.

If you use the same IEC action at the same time in different levels of an SFC diagram, then this can lead to unpredictable results when processing. For this reason, CODESYS issues a corresponding error message. This error message can appear for projects that have been created in an earlier version of the development system.

Please note: It is possible to use implicit variables to monitor the processing status of steps and actions and to control processing.

See also

- *Chapter 1.4.1.19.1.4.5 “Implicit variables” on page 480*
- *Chapter 1.4.1.19.1.4.4 “Qualifiers for Actions in SFC” on page 479*

Qualifiers for Actions in SFC

You assign qualifiers to IEC steps. Qualifiers describe how a step action is processed.

Qualifiers are processed by the `SFCActionControl` function block in the library `IecSfc.library`. The library is automatically integrated into the project by the SFC plug-in.

Table 31: Available qualifiers

`N`	Non-stored	The action is active as long as the step.
`R`	overriding Reset	The action is deactivated.
`S`	Set (Stored)	CODESYS executes this action as soon as the step is active. The action execution is continued even when the step has been deactivated until it gets a reset.
`L`	time Limited	CODESYS executes this action as soon as the step is active. The action is executed until the step is deactivated or the given time span has elapsed.
`D`	time Delayed	CODESYS begins executing the action only after the given delay time has elapsed following step activation and the step is still active. The action is executed until the step is deactivated.
`P`	Pulse	CODESYS executes the action exactly two times: one time when the step is activated and one time when the step is deactivated.
`SD`	Stored and time Delayed	CODESYS begins executing the action only after the given delay time has elapsed following step activation. The action is executed until it gets a reset.
`DS`	Delayed and Stored	CODESYS begins executing the action only after the given delay time has elapsed following step activation and the step is still active. The action is executed until it gets a reset.
`SL`	Stored and time limited	CODESYS executes this action as soon as the step is activated. It is executed until the specified time has elapsed or it gets a reset.

You have to specify the times for the L, D, SD, DS, and SL qualifiers in the format of a TIME constant.

When an IEC action is deactivated, it is executed one more time. This means that CODESYS executes this kind of action at least two times. This also applies to actions with the `P` qualifier.

See also

- *Chapter 1.4.1.8.3.4.1 “Programming in SFC” on page 255*

Implicit variables

Every SFC object supplies implicit variables for you to monitor the status of steps and IEC actions at runtime. These implicit variables are declared automatically by CODESYS for each step and each IEC action.

The implicit variables are structure instances of the type `SFCStepType` for steps and type `SFCActionType` for actions. The variables have the same names as their elements, for example "step1" variable name for "step1" step name. The structure members describe the status of a step or action or the currently elapsed time in an active step.

In the element properties, you can define whether CODESYS should export a symbol definition for this flag to the symbol configuration.

See also

- *Chapter 1.4.1.19.1.4.8.6 “SFC element properties” on page 493*

Step and action status

Syntax for the implicit variable declaration:

```
<step name>:SFCStepType;
_<action name>:SFCActionType;
```

Table 32: The following implicit variables are available for step or IEC action status:

Step	
`<step name>.x`	Shows the activation status in the current cycle. When `<step name>.x = TRUE`, CODESYS processes the step in the current cycle.
`<step name>._x`	Shows the activation status for the next cycle. When `<step name>._x = TRUE` and `<step name>.x = FALSE`, CODESYS processes the step in the next cycle. This means that `<step name>._x` is copied to `<step name>.x` at the beginning of a cycle.
`<step name>.t`	The flag `t` yields the current elapsed time since the step was activated. This applies only to steps, regardless of whether a minimum time has been defined or not in the step properties. Also see SFC flag `SFCError`.
`<step name>._t`	For internal use only
IEC action	
`_<action name>.x`	`TRUE` when the action is being executed.
`_<action name>._x`	`TRUE` when the action is active.

NOTICE!
You can use the above variables to force a specific status value to a step (activate a step). However, note that this can cause an unstable status in the SFC.

See also

- *Chapter 1.4.1.19.1.4.6 “SFC Flags” on page 481*

Access to implicit variables

Syntax for access:

Assign the implicit variable directly in the POU: `<variable name>:=<step name>.<implicit variable>` or `<variable name>:=_<action name>.<implicit variable>`

Example

```
status:=step1._x;
```

From another POU, with the POU name: `<variable name>:=<POU name>.<step name>.<implicit variable>` or `<variable name>:=<POU name>._<action name>.<implicit variable>`

Example

```
status:=SFC_prog.step1._x;
```

Symbol generation

In the element properties of a step or action, you define whether CODESYS should add a symbol definition for the step or action flag. In the *"Properties"* view, you have to select the necessary access rights in the *"Symbol"* column.

See also

- *Chapter 1.4.1.19.1.4.8.6 "SFC element properties" on page 493*

SFC Flags

SFC flags are implicitly generated variables with predefined names. You can use them to influence the processing of an SFC diagram. You can use these flags, for example, to display timeouts or reset step chains. In addition, you can activate jogging mode specifically to activate transitions. You have to declare and activate these variables in order to have access to them.

SFC flags

Name	Data Type	Description
`SFCInit`	Bool	`TRUE`: CODESYS resets the sequence to the initial step. The other SFC flags are also reset (initialization). While the variable is `TRUE`, the initial step remains set (active), but its actions are not executed. Only when you set `SFCInit` again to `FALSE` is the POU further processed normally.
`SFCReset`	Bool	This function behaves similar to `SFCInit`. However, CODESYS continues processing after the initialization of the initial step. For example, in the initial step, you could immediately reset the `SFCReset` flag to `FALSE`.
`SFCError`	Bool	`TRUE` if a timeout occurs in an SFC diagram. If second timeout occurs in the program, it is not registered unless you previously reset the variable `SFCError`. The declaration of `SFCError` is a requirement for other flag variables to function for controlling the chronological sequence (*"SFCErrorStep"*, `SFCErrorPOU`, `SFCQuitError`).
`SFCEnableLimit`	Bool	Used specifically for activating (`TRUE`) and deactivating (`FALSE`) the timeout control in steps using `SFCError`. If you declare and activate this variable (SFC settings), then you must set it to `TRUE` for `SFCError` to work. If you do not, then the timeouts are ignored. The is useful, for example, at start-up or in manual operation. If you do not declare the variable, then `SFCError` will work automatically. The requirement is the declaration of `SFCError`.
`SFCErrorStep`	String	Stores the name of the step that caused a timeout, which was registered by `SFCError`. The name is kept until the registered step error is reset by means of `SFCQuitError` (FALSE -> TRUE). The requirement is the declaration of `SFCError`.

Name	Data Type	Description
SFCErrorPOU	String	Stores the name of the block in which a timeout occurred and was registered by SFCError. The name is saved until the timeout is reset by SFCQuitError. The requirement is the declaration of SFCError.
SFCQuitError	Bool	As long as this Boolean variable is TRUE, CODESYS pauses the processing of the SFC diagram and any timeout, saved in the variable SFCError, is reset. If you reset the variable to FALSE, then all previous times in the active steps are reset. The requirement is the declaration of SFCError.
SFCPause	Bool	As long as this variable is TRUE, CODESYS pauses the processing of the SFC diagram.
SFCTrans	Bool	TRUE if a transition is active.
SFCCurrentStep	String	Shows the name of the active step, regardless of the time monitoring. In parallel branches, the name of the step of the rightmost branch line is always stored.
SFCTip, SFCTipMode	Bool	Controls the jogging mode of the SFC block. If you enable this flag with SFCTipMode=TRUE, then you can activate the next step only by setting SFCTip to TRUE. While SFCTipMode is set to FALSE, transitions can also be used to continue activation.
SFCErrorAnalyzation,		Contains as string all variables that contribute to the total value TRUE of SFCError (timeout in one step). SFCError needs to be activated for this. SFCErrorAnalyzation implicitly uses the function of the POU AnalyzeExpression of the library Analyzation.
SFCErrorAnalyzationTable,		Contains in a table all variables that contribute to the total value TRUE of SFCError (timeout in one step). SFCError needs to be activated for this. SFCErrorAnalyzationTable implicitly uses the function of the POU AnalyzeExpressionTable of the library Analyzation.

Implicit generation of SFC flags

CODESYS declares SFC flags automatically when you activate the respective options. You can set this option in the *“SFC Settings”* tab of the properties dialog for each POU, or in the *“SFC”* project settings dialog for each SFC POU in the project.

The SFC settings for the SFC flags of individual POUs are effective only if you have not selected the “Use defaults” option. When you select this option, the settings apply that were defined in the project settings.

SFC flags that you declare in the SFC settings dialog are visible only in the online view of the SFC block.

See also

- *“Flag” on page 1166*

Explicit generation of SFC flags

Manual declaration, which was necessary in CoDeSys V2.3, is now only required to enable write access from another block. In this case, you should note that when you declare the flag in a global variable list, you must deactivate its *“Declare”* setting in the SFC settings dialog. If you do not do this, then a local SFC flag is implicitly declared that CODESYS uses instead of the global variable.

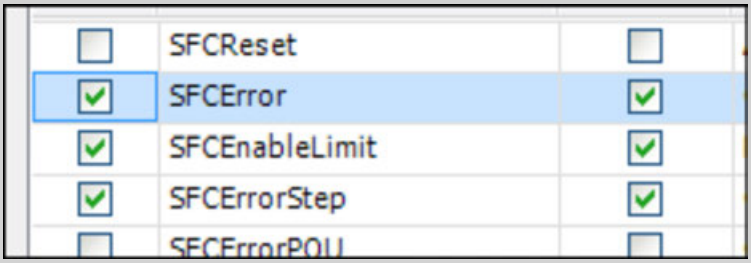
Application example for SFCError

Example

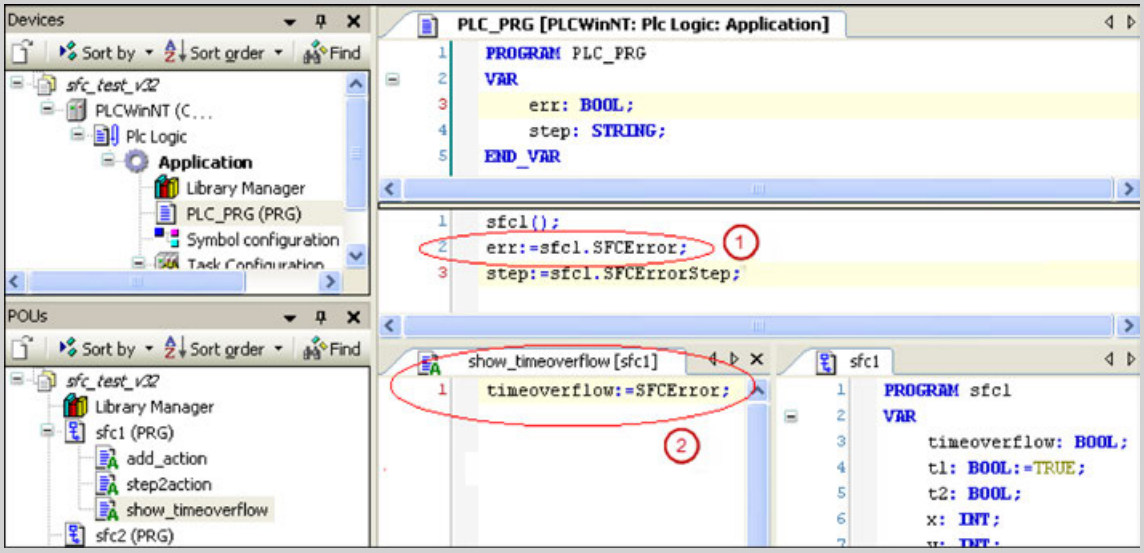
You have created an SFC block named `sfc1`, which contains the `s1` step. You have defined timeouts in the step properties. (See "Online view of SFC block `sfc1`" below.)

If for any reason the `s1` step remains active longer than its time properties have permitted (timeout), then CODESYS sets the `SFCError` flag to permit access by the application.

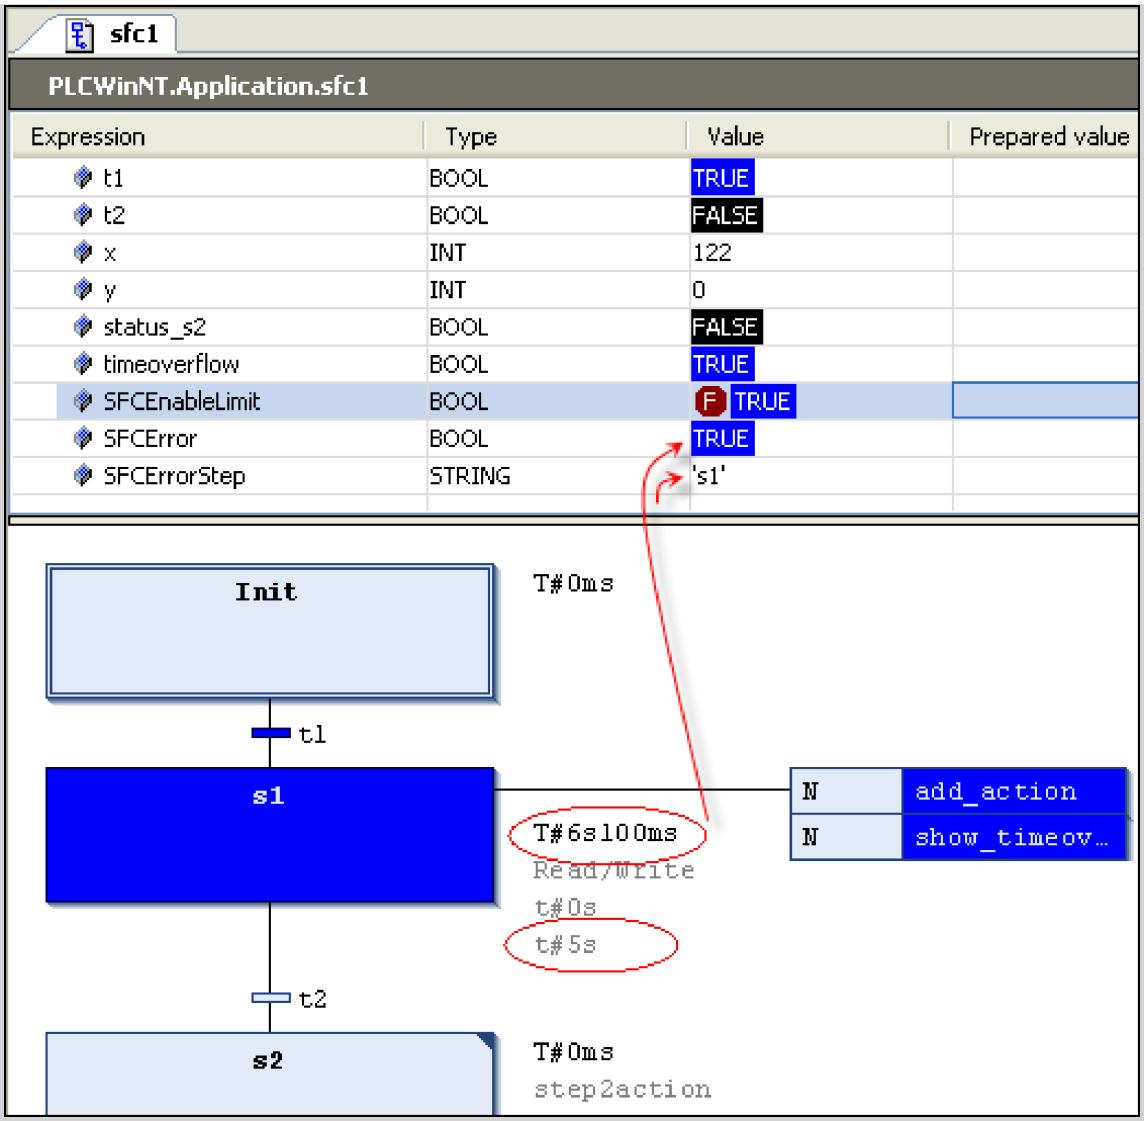
To permit access, you have to declare and activate the SFC flag in the SFC settings. If you have only declared it, then the SFC flag is only displayed in the online view of `sfc1` in the declaration part, but it has no function.



Now the SFC flag can be referenced within the POU, for example in an action (2) or outside of the block (1).



Online view of the SFC block `sfc1`



`SFCError` is `TRUE` as soon as a timeout occurs within `sfc2`.

Note that you can use the flags `SFCErrorAnalyzation` and `SFCErrorAnalyzationTable` to determine the components of the expression that contributes to the value `TRUE` of the `SFCError`.

See also

- *Chapter 1.4.1.19.1.4.7 “Library "Analyzation"” on page 485*

Access to the flags

Syntax for access:

You assign the flag directly within the POU: `<variable name>:=<SFC flag>`

Example

```
checkerror:=SFCerror;
```

From another POU with POU name: `<variable name>:=<POU name>.<SFC flag>`

Example:

```
checkerror:=SFC_prog.SFCerror;
```

If you need write access from another block, then you also have to declare the SFC flag explicitly as a VAR_INPUT variable in the SFC block or globally in a GVL.

Example

Local declaration:

```
PROGRAM SFC_prog
VAR_INPUT
  SFCinit:BOOL;
END_VAR
```

Global declaration in a global variable list:

```
VAR_GLOBAL
  SFCinit:BOOL;
END_VAR
```

```
PROGRAM PLC_PRG
VAR
  setinit: BOOL;
END_VAR
SFC_prog.SFCinit:=setinit;  // write access to SFCinit in SFC_prog
```

See also

- *Chapter 1.4.1.19.1.4.7 “Library "Analyzation"” on page 485*

Library "Analyzation"

This library contains POUs for the analysis of expressions. When a composite expression has the total value of `FALSE`, those of its components that contribute to this result can be determined. In the SFC editor, the flags `SFCErrorAnalyzation` and `SFCErrorAnalyzationTable` use these functions implicitly to examine the transition expressions. Then the flags provide the identifiers of the variables that contributed to a timeout error. They keep this information until they are reset explicitly by means of the SFC flag `SFCQuitError`.

An analysis POU cannot be called by means of a pointer. This kind of call is ignored. Call the POU as a single instance.

For a description of the library POUs and an example of how the SFC flags display the analysis results in CODESYS, see the documentation for the library (online help or directly in the Library Manager).

See also

- *Chapter 1.4.1.8.3.4.1 “Programming in SFC” on page 255*

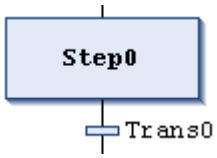
Elements

SFC elements 'Step' and 'Transition'

Step symbol ; Transition symbol

As a rule, CODESYS inserts steps and transitions as combinations. Inserting a step without a transition or a transition without a step causes an error when compiling. You can modify this by double-clicking the name.



NOTICE!
Step names must be unique within the scope of the parent block. Consider this especially when using actions that were also programmed in SFC.

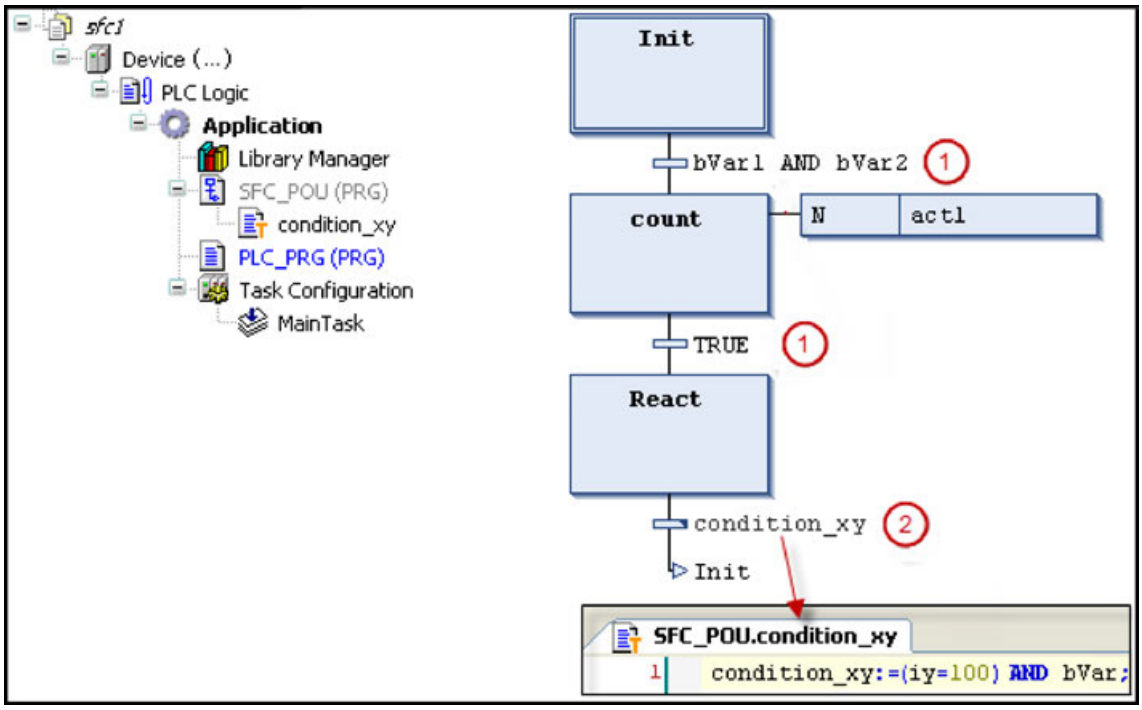
Please note that you can convert a step into an initial step by clicking *"Init step"* or by setting the respective property in the SFC properties.

All steps are defined by the step properties, which you can display and edit in the *"Properties"* view, depending on the set options.

You have to add those actions to the step which are to be executed when the step is active. A distinction is made between IEC actions and step actions. Details for this are found in the chapter about the SFC element "Action".

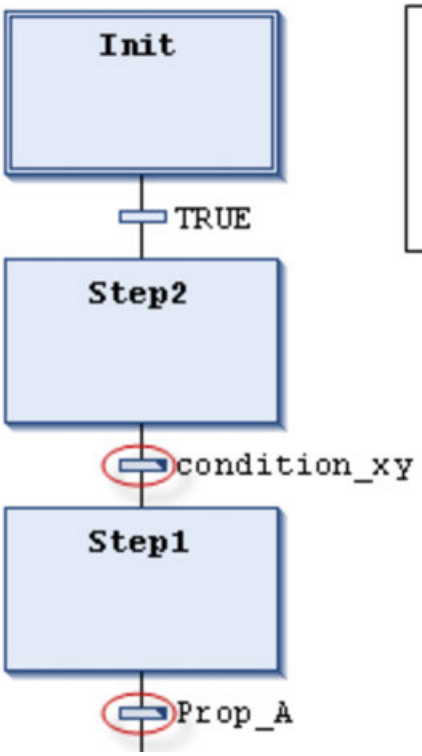
A transition must include the condition for the subsequent step to be active as soon as the value of the condition yields `TRUE`. Therefore, a transition condition must yield `TRUE` or `FALSE`. It can be defined in one of two ways:

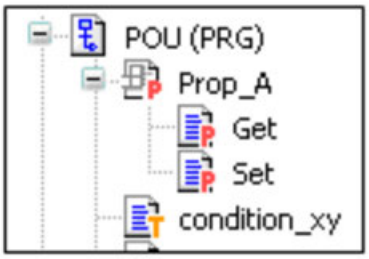
- (1) Inline condition (direct): You replace the default transition name with either the name of a Boolean variable, a Boolean address, a Boolean constant, or a statement with a Boolean result, for example `(i<100) AND b`. You cannot specify programs, function blocks, or assignments here.
- (2) Multi-use condition (separate transition or property object): You replace the default transition name with the name of a transition or property object (,). You create these objects by clicking *"Project ➔ Add Object"*. This allows multiple use of transitions, for example "condition_xy" in the figures below. Like an inline condition, the object can contain a Boolean variable, Boolean address, Boolean constant, or an statement with a Boolean result. In addition, it can also contain multiple statements with any code.



NOTICE!
The user is responsible for assigning the required expression to a transition variable if the transition includes multiple instructions.

Transitions that reference a transition or property object are marked with a small triangle in the upper right corner of the transition box.





As opposed to CoDeSys V2.3, now CODESYS treats a transition condition like a method call. The entry has the following syntax:

```
<transition name>:=<transition condition>
```

(for example `trans1:= a=100`)

or only

`<transition condition>`

(for example `a=100`)

You will find an example (condition_xy) in the figure above.

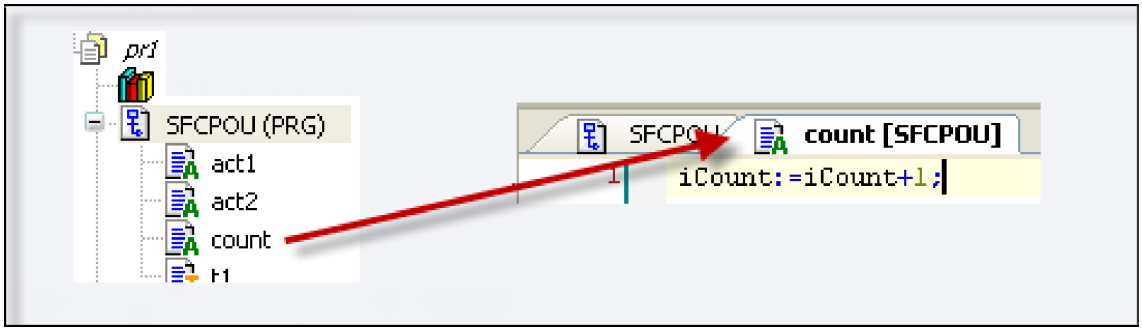
SFC Element 'Action'

Symbol: 

An action includes one or more statements in one of the valid implementation languages. You can assign an action to a step.

Actions that you use in SFC steps have to be created as POUs in the project.



Exception: In the case of IEC actions, which you add to a step as action association, you can also specify a Boolean variable instead of an action object. The value of these variables is switched between `FALSE` and `TRUE` each time the action is executed.

> **NOTICE!**
> You have to define unique step names within the scope of the parent block. An action written in SFC must not contain a step with a name identical to the step to which the action is assigned.

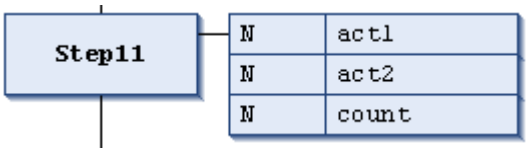
A distinction is made between IEC actions and step actions:

1. IEC actions

IEC actions comply with the IEC 61131-3 standard. They are executed according to their qualifiers.

IEC actions are executed two times: first when the step is activated and second when the step is deactivated. If you assign multiple actions to one step, then the action list is processed from top to bottom.

Each action box includes the qualifier in the first column and the action name in the second column. Both can be edited directly.



NOTICE!
When the same global Boolean variable is associated as an IEC action in different SFC POUs, unwanted overwriting can result.

In contrast to step actions, you can use different qualifiers for IEC actions. Moreover, each IEC action is provided with a control flag. This directs CODESYS to execute an action only one time at any moment, even if the action is called by another step at the same time. This cannot be guaranteed for step actions.

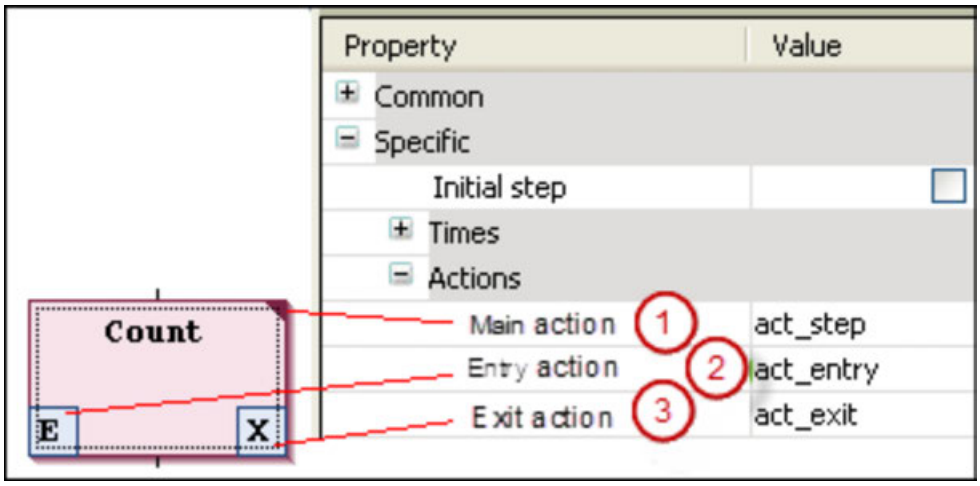
You assign IEC actions to steps by clicking *"SFC ➔ Insert Action Association"*.

See also

- *Chapter 1.4.1.20.3.11.14 "Command 'Insert Action Association'" on page 1084*
- *Chapter 1.4.1.19.1.4.4 "Qualifiers for Actions in SFC" on page 479*

2. Step actions These are actions that you can use to extend the IEC standard.

- **Entry action**:
  CODESYS executes this action after the step is activated and before the main action is executed.
  You reference a new action, or an action created below the SFC object, from a step by means of the *"Entry action"* element property (2). You can also add a new action to the step by means of the *"Add Entry Action"* command. The entry action is marked with an `E` in the lower left corner of the step box.
- **Main action**:
  CODESYS executes this action when the step is active and any entry actions have already been processed. However, in contrast to IEC actions (see above), these step actions are not executed a second time when the step is deactivated. Moreover, you cannot use qualifiers here.
  You add an existing action to a step by means of the *"Main action"* element property (1). You can create and add a new action by clicking the step element. A main action is marked with a filled triangle in the upper right corner of the step box.
- **Exit action**:
  CODESYS executes this action one time when the step is deactivated. However, note that an exit action is not executed in the same cycle, but at the beginning of the next cycle.
  You reference a new action, or an action created below the SFC object, from a step by means of the *"Exit action"* element property (3). You can also add a new action to the step by means of the *"Insert Exit Action"* command. The exit action is marked with an `X` in the lower right corner of the step box.



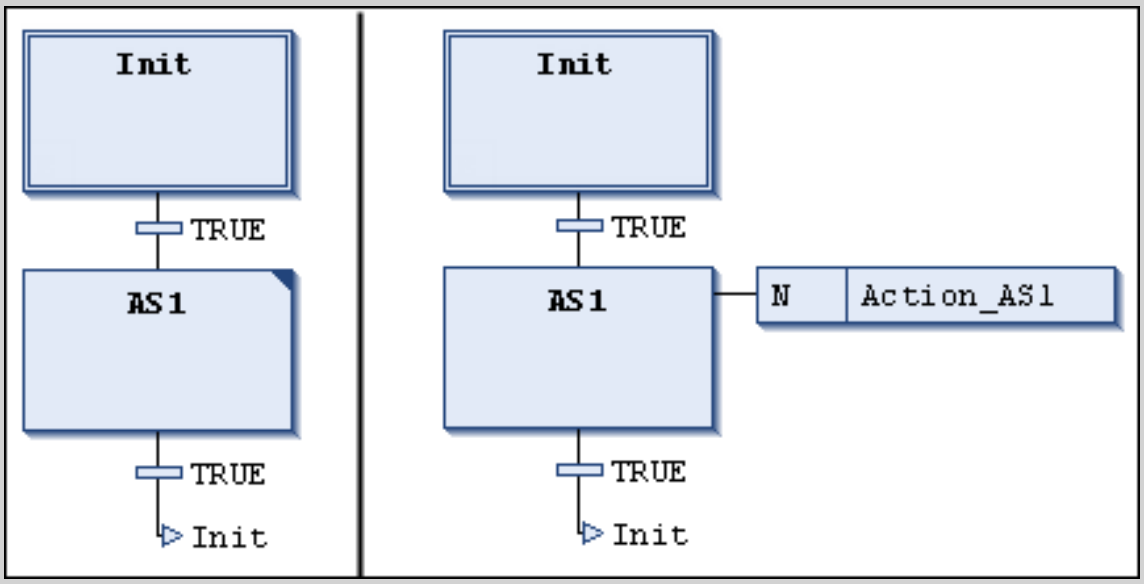
See also

- *Chapter 1.4.1.19.1.4.8.6 “SFC element properties” on page 493*

Difference between IEC actions and step actions

The main difference between step actions and IEC actions with a qualifier N is that an IEC action is always executed two times: when the step is activated and when the step is deactivated. See the following example:

Example



You have attached the `Action_AS1` action to the `AS1` step as a step action (left) and as an IEC action with qualifier N (right). Because two transitions are activated in each case, the time to reach the initial step again is two PLC cycles. This is true as long as the `iCounter` counter variable was initialized at 0 and then incremented in the `Action_AS1` action. After the `Init` step is reactivated, `iCounter` returns a value of 1 in the example on the left. In the example on the right, a value of 2 is returned because the IEC action is executed a second time due to the deactivation of `AS1`.

Another difference: Step actions can be pseudo-embedded. In this case, they can be called only from the related step. If you copy this step, CODESYS creates new action objects automatically and copies the respective implementation code. You define whether or not a step action is embedded, either when the first action is inserted into the step, or later in the *“Duplicate when copying”* element property. In general, this behavior can also be preset in the SFC options.

Moreover, for IEC actions, a Boolean variable can be specified instead of an action object. This is not possible for step actions.

SFC element 'Branch'

Symbol

Use branches to program parallel or alternative sequences in the sequential function chart.

For alternative branches, CODESYS processes just one of the branch lines at a time, depending on the preceding transition condition. Parallel branches are processed at the same time.

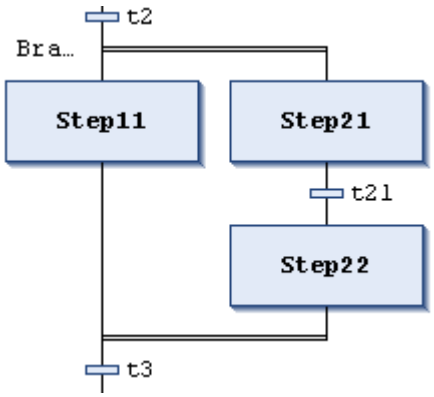
See also

- *Chapter 1.4.1.19.1.4.3 “Processing order in SFC” on page 477*
- *Chapter 1.4.1.8.3.4.1 “Programming in SFC” on page 255*
- *Chapter 1.4.1.20.3.11.13 “Command 'Insert Branch Right'” on page 1083*

Parallel branch

For parallel branches, the branch lines must begin and end with steps. Parallel branch lines can contain additional branches.

The horizontal lines before and after the branch are double lines.



Processing in online mode: If the preceding transition (t2 in the example) yields `TRUE`, then the first steps in all parallel branch lines are active (Step11 and Step21). CODESYS processes the individual branch lines at the same time and the subsequent transition is passed afterwards (t3).

The "Branch<n>" jump marker is added automatically to the horizontal line that indicates the beginning of a branch. You can define this marker as the jump destination.

Please note that you can convert a parallel branch into an alternative branch by clicking *“Alternative”*.

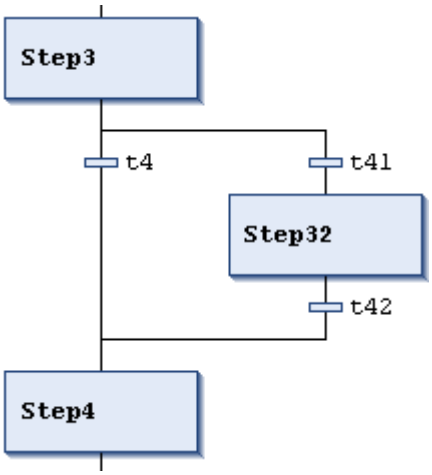
See also

- *Chapter 1.4.1.20.3.11.11 “Command 'Alternative'” on page 1083*

Alternative branch

The horizontal line before and after the branch is a single line.

In an alternative branch, the branch lines must begin and end with transitions. The branch lines can contain additional branches.



If the step before the branch is active, then CODESYS passes the first transition of each alternative branch line from left to right. For the first transition that yields `TRUE`, the associated branch line opens, thus activating the step following the transition.

Please note that you can convert an alternative branch into a parallel branch by clicking *“Parallel”*.

See also

- *Chapter 1.4.1.20.3.11.10 “Command 'Parallel'” on page 1082*

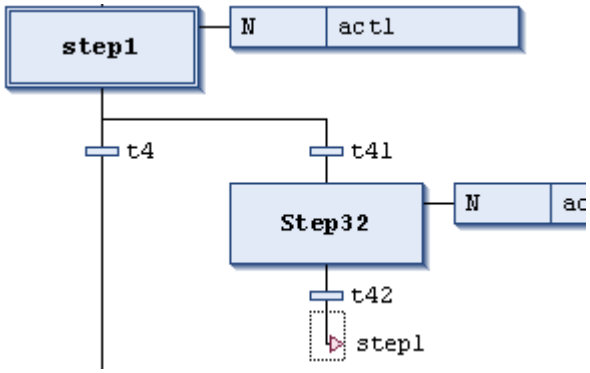
SFC element 'Jump'

Symbol

Use a jump to define which actions in a step should be executed next as soon as the transition preceding the jump is `TRUE`. Jumps may become necessary, as execution paths cannot cross or lead upwards.

Excluding the required jump at the end of a diagram, you can generally insert jumps only at the end of a branch.

The destination of a jump is defined by the added text string, which you can edit directly. The jump destination can be a step name or the marker for a parallel branch.



See also

- *Chapter 1.4.1.8.3.4.1 “Programming in SFC” on page 255*
- *Chapter 1.4.1.20.3.11.16 “Command 'Insert Jump'” on page 1085*

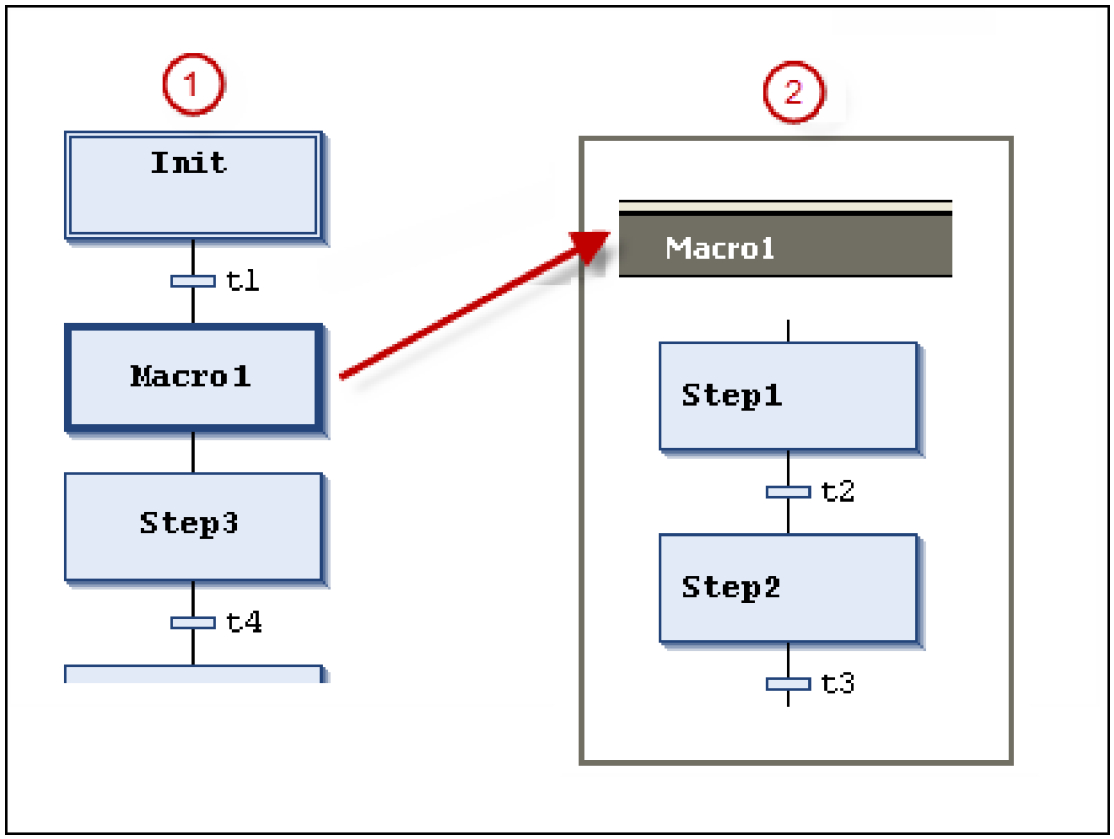
SFC element 'Macro'

Symbol

A macro includes part of the SFC diagram, but it is not displayed in detail in the main view of the editor.

Using macros does not influence the processing flow. Macros are used for hiding specific parts of the diagram, for example to increase overall clarity.

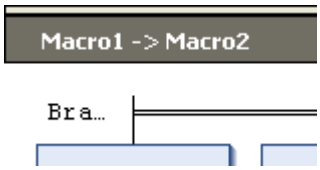
You open the macro editor by double-clicking the macro box or by clicking *"SFC ➔ Zoom Into Macro"*. You can program here just like in the main view of the SFC editor. To close the macro editor, click *"SFC ➔ Zoom Out of Macro"*.



① Main view in the SFC editor

② Macro editor view for Macro1

Macros can also include other macros. The caption of the macro editor always shows the path of the open macro within the diagram, for example:



See also

- *Chapter 1.4.1.8.3.4.1 "Programming in SFC" on page 255*
- *Chapter 1.4.1.20.3.11.20 "Command 'Zoom Into Macro'" on page 1086*
- *Chapter 1.4.1.20.3.11.21 "Command 'Zoom Out of Macro'" on page 1086*

SFC element properties

You edit the properties of an SFC element in the *"Properties"* view. Click *"View ➔ Element Properties"* to open this view. The properties to be displayed depend on the currently selected element.

The properties that are displayed in the SFC diagram next to the element depend on the settings in the “View” tab of the SFC editor options.

General

Property	Value description
“Name”	Element name, by default "<element><consecutive number>", for example step name "Step0", "Step1", branch name "Branch0”, etc.
“Comment”	Element comment in text, for example “counter reset”. You can insert line breaks by pressing *[Ctrl]+[Enter]*.
“Symbol”	For each SFC element, CODESYS declares an implicit variable with the same name as the element. The configuration determines whether this flag variable should be exported to the symbol configuration and which access rights for the symbol should be applied in the PLC. ● *“No access”*: The symbol is exported to the symbol configuration but cannot be accessed from the PLC. ● *“Read”*: The symbol is exported to the symbol configuration and can be read from the PLC. ● *“Write”*: The symbol is exported to the symbol configuration and can be written from the PLC. ● *“Read/Write”*: Combination of read and write. ● Empty: A symbol is not exported to the symbol configuration.

Specific

Property	Value description
“Init step”	☑: This option is activated only for the defined initial step. By default, this is the first step in an SFC diagram. Note: If you activate this property for another step, then it must be deactivated in the previous step to prevent compilation errors.
“Duplicate when copying”	This option is available for steps that contain a step action (entry action, main action, or exit action), and for transitions that are linked to a transition object. ☑: When copying the step or transition, a new object is created for each called action or transition. It contains a copy of the implementation code of the copied object. ☐: When copying a step or transition, the link to the called object is retained for the respective action or transition. No new objects are generated. The source and the copies of the step or transition call the same action or transition.

Property	Value description
"Times" ● *"Minimum active"* ● *"Maximum active"*	Minimum time that the step is active, even when the subsequent transition is TRUE. Maximum time that the step can be active. If this time is exceeded, then CODESYS sets the `SFCError` implicit variable to TRUE. Times according to IEC syntax (for example t#8s) or the TIME variable; default: t#0s.
"Actions" ● *"Entry action"* ● *"Step action"* ● *"Exit action"*	● *"Entry action"*: CODESYS executes these actions after activating the step. ● *"Step action"*: CODESYS executes this action when the step is active and any entry actions have already been processed. ● *"Exit action"*: CODESYS executes this action in the subsequent cycle when the step is deactivated. Please note the processing sequence.

When using the respective implicit SFC variables and flags, you receive information about the status of a step or an action or about timeouts.

Function Block Diagram / Ladder Diagram / Instruction List (FBD/LD/IL)

FBD/LD/IL Editor

The FBD/LD/IL editor is a combined editor of the programming languages FBD, LD and IL.

If necessary, IL can be activated in the CODESYS options.

There is a common set of commands and elements and CODESYS automatically converts the 3 programming languages into one another internally.

The code in the implementation part is structured in all three languages with the aid of networks.

The *"FBD/LD/IL"* menu provides the commands for working in the editor.

In offline and online modes, you can switch editors at any time by using the menu command in *"View"*.

The behavior of the FBD/LD/IL editor is defined by the settings in *"Tools ➔ Options"* (category *"FBD, LD and IL"*).

NOTICE!

There are some special elements that CODESYS cannot convert and thus it displays only in the applicable language. There are also constructs that are not clearly convertible between IL and FBD and are therefore 'normalized', i.e. nullified, when converted back to FBD. This concerns: negation of expressions and explicit/implicit assignment of function block inputs and outputs.

An error-free conversion between the languages requires syntactically correct code. Otherwise parts of the implementation can be lost.

See also

- *Chapter 1.4.1.20.3.13 “Menu 'FBD/LD/IL'” on page 1104* (commands)
- *Chapter 1.4.1.20.4.13.9 “Dialog 'Options' - 'FBD, LD, and IL'” on page 1192*
- *Chapter 1.4.1.19.1.2 “Common functions in graphical editors” on page 462*

FBD and LD editor

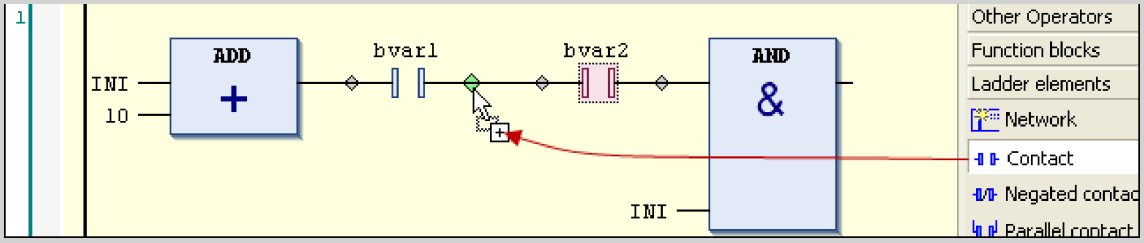
Inserting and arranging elements

You can drag elements with the mouse from the view *“Tools”* (toolbox) into the implementation part of the editor. Alternatively you can use the commands of the context menu or the *“FBD/LD/IL”* menu.

Settings for the display and interface are defined in the CODESYS options, category *“FBD/LD/IL”*.

If you drag an element with the mouse over a network in the editor, all possible insertion positions are displayed with gray diamond-shaped, triangular or arrow-shaped position marks. As soon as the mouse pointer is located over one of these marks, the mark turns green. If the mouse button is now released, CODESYS inserts the element at this position.

Example



If you drag a function block or an operator from the toolbox or a network at the left-hand side of the network onto one of the two arrows, then CODESYS automatically creates a new network and inserts the element there.

In order to replace an element, drag a suitable other element onto its position with the mouse. Elements that you can replace by the new element are marked by CODESYS in the editor with text fields, for example *“Replace”*, *“Attach input”*.

You can use the usual commands in the menu *“Edit”* for cutting, copying, pasting and deleting elements. Copying also works with drag-and-drop by holding down the *[Ctrl]* key.

NOTICE!

The operators with EN/ENO functionality can only be inserted in the FBD and IL editors.

Selecting elements

A box or a connecting line in the editor is selected by clicking on it with the mouse so that it has the focus. Multiple selection is possible by keeping the *[Ctrl]* key pressed. A selected element is shaded red.

Tooltip

If the cursor points to certain elements, for example to a variable or to an input, a tooltip appears showing information about this element.

In the case of elements underlined with a wavy red line, the tooltip shows the pre-compile error message of the error that occurs with this element.

Navigating in the editor

Table 33: Navigating in the editor

With the help of the keys and commands described below, you can place the focus within the editor on a different cursor position. The change between the positions is also network-spanning in function.	
[←] *[→]*	Change to the neighboring cursor position, along the signal flow, i.e. from left to right and vice versa.
[↑][↓] *[↓]*	Change to the next cursor position above or below the current position, if this neighboring position belongs to the same logical group. For example, all connections of a box form a logical group. If such a logical group does not exist: change to the first cursor position in the next higher or lower neighboring element. In the case of parallel-connected elements, navigation takes place along the first branch.
[Ctrl] + [Home]	Change to the first network; this will be selected.
[Ctrl] + [End]	Change to the last network; this will be selected.
[Page Up]	Scroll upwards by one page; the highest network on this page is selected.
[Page Down]	Scroll downwards by one page; the lowest network on this page is selected.
Command *“Go to…”*	Change to a certain network.

Opening function blocks

If a function block is inserted in the editor, then you can open its implementation by a double-click or with the context menu command *“Browse for symbol ➔ Go to Definition”*.

IL editor

Inserting and arranging elements:

You can insert elements with the help of the commands of the menu *“FBD/LD/IL”* in the context menu. You can also drag a new network from the tool box into the implementation part of the editor by drag-and-drop.

You can use the usual commands in the menu *“Edit”* for cutting, copying, pasting and deleting elements. Copying also works with drag-and-drop by holding down the *[Ctrl]* key.

NOTICE!
Please note that operators with EN/ENO functionality can only be inserted in the FBD and IL editors.

Each program line is entered in a table row.

Table 34: Structure of networks in the IL editor

1st line: Network title Requirement: The option is activated in the CODESYS options.		
2nd line: Network comment Requirement: The option is activated in the CODESYS options.		
3rd line and on:		
Column	**Contents**	**Description**
1	Operator	Contains the IL operator (LD, ST, CAL, AND, OR, etc.) or a function name. If you call a function block, you must additionally specify the corresponding parameters here; in the preceding field you must enter in this case := or =>.
2	Operand	Contains precisely one operand or the name of a jump label. In the case of several operands you must enter them in several rows and when doing so insert a comma directly behind the individual operands. (See example below)
3	Address	Contains the address of the operand as defined in its declaration. non-editable You can activate/deactivate the display via the option *"Display symbol address"*. To do this, select the command *"Tools ➔ Options"* and the *"General"* tab in the category *"FBD, LD and IL"*.
4	Symbol comment	Contains the comment that was specified for the operand if necessary in the declaration. non-editable You can activate/deactivate the display via the option *"Display symbol comment"* if you select the command *"Tools ➔ Options"* and the *"General"* tab in the category *"FBD, LD and IL"*.
5	Operand comment	Comment for the current program line. You can activate/deactivate the display via the option *"Operand comment"* if you select the command *"Tools ➔ Options"* and the *"General"* tab in the category *"FBD, LD and IL"*.

Example

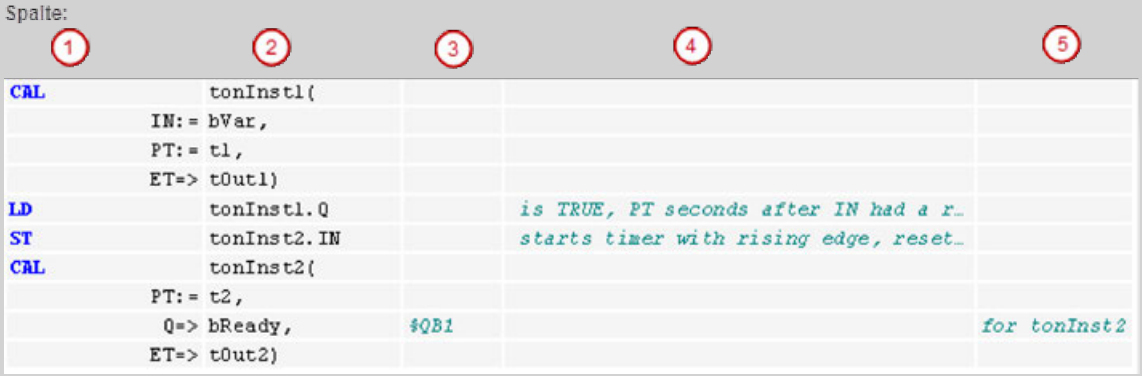

Table 35: Navigating in the editor

Key(s)/ command	Cursor movement
[↑] *[↓]*	Jumps to the field located above/below.
[Tab]	Jumps one field to the right within the row.
[Shift]+ [Tab]	Jumps to the left to the preceding field within the row
[Space]	Opens the editing frame for the selected field. Alternatively you can click with the mouse on the field. If applicable the button for the input assistant dialog box is available.
[Ctrl] + [Enter]	Inserts a new row below the current row.
[Del]	Deletes the current row.
[Ctrl] + [Home]	Sets the focus at the start of the document and marks the first network.
[Ctrl] + [End]	Sets the focus at the end of the document and marks the last network.
[Page Down]	Scrolls up by one page and marks the top rectangle.
[Page Up]	Scrolls down by one page and marks the top rectangle.

FBD/LD/IL editor in online mode

FBD/LD/IL editor in online mode

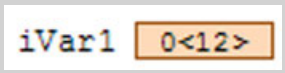
In online mode the current value of each variable is displayed behind the variable in the editor. Writing/forcing and the setting of breakpoints is possible.

If the variable is presently forced, this is indicated directly in front of the forced value by F. If a value has been prepared for writing or forcing, this value is displayed directly behind the current value in square brackets `<value>`.

Example

Forced variable:

Prepared value



In the online view of a ladder diagram (LD) the connecting lines are marked in color: connections with the value `TRUE` are displayed as a thick blue line, connections with the value `FALSE` as a thick black line. Conversely, connections with an unknown or analog value are displayed normally (thin black line).

NOTICE!
Note that values of the connections are calculated from the monitored variables. This is not a genuine flow control.

Breakpoints

Possible positions for breakpoints are in principle the positions at which values of variables can change (instructions), at which the program branches or at which another box is called.

Possible breakpoint positions:

- On the entire network: causes the breakpoint to be set at the first possible position in the network.
- On a box, if the box contains an assignment. Not possible with operator boxes, for example ADD, DIV.
- On assignments.
- At the end of the box at the position of the return to the calling box. In online mode an empty network automatically appears here; it is marked by 'RET' in place of a network number.

NOTICE!
At present you cannot directly set a breakpoint on the first box in the network. However, if you set a breakpoint on the entire network, this breakpoint marking is transferred automatically to the first box in online mode.

NOTICE!
Breakpoints in methods: CODESYS automatically sets a breakpoint in all methods that can be called. Therefore, if a method managed by an interface is called, breakpoints are set in all methods that occur in function blocks that implement this interface as well as in all derived function blocks that use the method. If a method is called by a pointer to a function block, CODESYS sets the breakpoints in the method of the function block and in all derived function blocks that use the method.

Modifiers and operators in IL

Table 36: Modifiers

Modifier	Combined with operator	Description
C	JMP, CAL, RET	The command is only executed if the result of the preceding expression is TRUE.
N	JMPC, CALC, RETC	The command is only executed if the result of the preceding expression is FALSE.
N	otherwise	negation of the operand (not of the accumulator).

Table 37: Operators with the possible modifiers

Operator	N	Meaning	Example
LD	N	Loads the (negated) the value of the operand into the accumulator.	LD ivar
ST	N	Stores the (negated) content of the accumulator in the operand.	ST iErg
S		Sets the operand (type BOOL) to TRUE if the content of the accumulator is TRUE.	S bVar1

Operator	N	Meaning	Example
R		Sets the operand (type BOOL) to FALSE if the content of the accumulator is TRUE.	R bVar1
AND	N, (	Bitwise AND of the accumulator value and (negated) operand	AND bVar2
OR	N, (	Bitwise OR of the accumulator value and (negated) operand	OR xVar
XOR	N, (	Bitwise exclusive OR of the accumulator value and (negated) operand	XOR N, (bVar1,bVar2)
NOT		Bitwise negation of the accumulator value	
ADD	(	Addition of the accumulator value and the operand; result is written into the accumulator.	ADD ivar1
SUB	(	Subtraction of the operand from the accumulator value; result is written into the accumulator.	SUB iVar2
MUL	(	Multiplication of accumulator value and operand; result is written into the accumulator.	MUL ivar2
DIV	(	Division of the accumulator value by the operand; result is written into the accumulator.	DIV 44
GT	(	Checks whether the accumulator value is greater than the operand value; result (BOOL) is written into the accumulator; >	GT 23
GE	(	Checks whether the accumulator value is greater than or equal to the operand value; result (BOOL) is written into the accumulator.	GE iVar2
EQ	(	Checks whether the accumulator value is equal to the operand value; result (BOOL) is written into the accumulator.	EQ iVar2
NE	(	Checks whether the accumulator value is not equal to the operand value; result (BOOL) is written into the accumulator;	NE iVar1
LE	(	Checks whether the accumulator value is smaller than or equal to the operand value; result (BOOL) is written into the accumulator.	LE 5
LT	(	Checks whether the accumulator value is smaller than the operand value; result (BOOL) is written into the accumulator.	LT cVar1
JMP	CN	Unconditional (conditional) jump to the specified jump label	JMPN next
CAL	CN	(Conditional) call of a program or a function block (if the accumulator value is TRUE)	CAL prog1
RET		Exit the box and return to the calling box.	RET
RET	C	If the accumulator value is TRUE: exit the box and return to the calling box.	RETC
RET	CN	If the accumulator value is FALSE: exit the box and return to the calling box.	RETCN
)		Evaluation of the reset operation	

Example

```
1
    AND     TRUE    load TRUE to accumulator
    ANDN    bVar1   execute AND with negated value of bVar1
    JMPC    m1      if accum. is TRUE, jump to label "m1"

    LDN     bVar2   store negated value of bVar2...
    ST      bRes    ... in bRes
2
    m1:

    LD      bVar2   store value of bVar2...
    ST      bRes    ... in bRes
```

Application	Description	Examples

Several operands for 1 operator	Options
	● You enter the operands into consecutive rows, separated by commas in the 2nd column.
	● You repeat the operator in consecutive rows.
		Variant 1 :
		`LD 2`
		`ADD 3,`
		`4,`
		`6`
		`ST iVAR`
		Variant 2 :
		`LD 2`
		`ADD 3`
		`ADD 4`
		`ADD 6`
		`ST iVAR`

Complex operands	For a complex operand, you enter the opening parenthesis (in the first column. You enter the closing parenthesis in the first column in a separate row following the operand entries of the following rows.	A string is rotated by a character each cycle:
		`LD stRotate`
		`RIGHT( stRotate`
		`LEN`
		`SUB 1`
		`)`
		`CONCAT( stRotate`
		`LEFT 1`
		`)`
		`ST stRotate`

Application	Description	Examples

Function block call, program call	Column 1: Operator `CAL` or `CALC`
	Column 2: Name of the function block instance or the program and opening parenthesis `(`. If no parameters follow, the closing parenthesis `)` is entered here.
	rows following that:
	Column 1: parameter name followed by `:=` for input parameter or `=>` for output parameter
	Column 2: parameter value followed by a comma `,` if further parameters follow. The closing parenthesis `)` is input after the last parameter.
	As a limitation according to the IEC standard, complex expressions cannot be used here. You must assign such constructs to the function block or the program before the call.
		`CAL POUToCall(`
		`iCounter:= 1,`
		`iDecrement:= 1000,`
		`wError=> wResult)`
		`LD POUToCall.bError`
		`ST bErr`

Function Call	Row 1: Column 1: `LD`
	Column 2: input variable
	Row 2: Column 1: Function name Column 2: further input parameters separated by commas.
	CODESYS writes the return value into the accumulator.
	Row 3: Column 1: `ST` Column 2: variable into which the return value is written
		`LD X7`
		`GeomAverage 25`
		`ST Ave`

Action call	Like function block call or program call. The action name is appended to the name of the FB instance or the program.	`CAL POU1.ResetAction`

Application	Description	Examples
Jump	Column 1: operator `JMP` or `JMPC`. Column 2: Name of the jump label of the destination network. In the case of an unconditional jump, the preceding instruction sequence must end with one of the following commands: `ST`, `STN`, `S`, `R`, `CAL`, `RET`, `JMP` In the case of a conditional jump the execution of the jump depends on the loaded value.	`LD BVar1` `JMPC Label1`

Elements

FBD/LD/IL element 'Network'

Symbol 

A network is the base unit of an FBD or LD program. In the FBD/LD/IL editor, the networks are arranged in a list. Each network is provided with a sequential network number on the left side and can include: logical and arithmetic expressions, program/function/function block calls, jumps, or return statements.

An IL program consists of at least one network. This network can include all IL statements of the program.

You can provide each network with a title, comment, or label. In the CODESYS options (category *“FBD, LD, and IL”*, you can define whether network title, comment, and separator between individual networks are displayed in the editor.

Click the first line of the network to enter a network title. Click the second line of the network to enter a network comment.

- *Chapter 1.4.1.20.3.13.1 “Command 'Insert Network'” on page 1104*

FBD/LD/IL element 'Box'

Symbol: 

A box and its call can represent additional functions, for example IEC function blocks, IEC functions, library function blocks, operators.

A box can have any number of inputs and outputs.

If the box also provides an image file, the box icon is displayed inside the box. The requirement is that the option *“Show box symbol”* is activated in the CODESYS options, category *“FBD, LD and IL”*.

If you have changed the box interfaces, you can update the box parameters with the command *“FBD/LD/IL ➔ Update Parameters”* without having to re-insert the box.

- *Chapter 1.4.1.20.3.13.38 “Command 'Update Parameters'” on page 1114*

FBD/LD/IL element 'Assignment'

Symbol:

The FBD editor shows a newly inserted assignment as a line with 3 question marks after it. The LD editor shows a newly inserted assignment as a coil with 3 question marks located above it.

After insertion you can replace the placeholder `???` by the name of the variable to which the signal coming from the left is to be assigned. The input assistant is available to you for this.

In IL an assignment is programmed via the operators `LD` and `ST`.

- *Chapter 1.4.1.19.1.5.1 “FBD/LD/IL Editor” on page 495*
- *Chapter 1.4.1.20.3.13.4 “Command 'Insert Assignment'” on page 1105*

FBD/LD/IL element 'Box with EN/ENO'

Symbol: 

The element is available only in the FBD and LD editors.

The box generally corresponds to the FBD/LD/IL element *“Box”*; however, this box additionally contains an EN input and an ENO output. EN and ENO have the data type `BOOL`.

Function of the `EN` input and `ENO` output: if the input `EN` has the value `FALSE` at the time of the calling the box, the operations defined in the box are not executed. Otherwise, i.e. if `EN` has the value `TRUE`, these operations are executed. The ENO output has the same value as the EN input.

See also

- *Chapter 1.4.1.20.3.13.6 “Command 'Insert Box with EN/ENO'” on page 1106*
- *Chapter 1.4.1.19.1.5.4.2 “FBD/LD/IL element 'Box'” on page 505*

FBD/LD/IL element 'Input'

Symbol: 

The maximum number of inputs depends on the type of box.

A newly added input is first marked with `???`. You can replace the string `???` by a variable or a constant.

See also

- *Chapter 1.4.1.20.3.13.13 “Command 'Insert Input'” on page 1107*
- *Chapter 1.4.1.19.1.5.1 “FBD/LD/IL Editor” on page 495*

FBD/LD/IL element 'Label'

The label is an optional identifier for a network in FBD and LD, which you can specify as a destination for a jump.

If you insert a jump label in a network, it will be added as an editable field *“Label:”* in the network.

See also

- *Chapter 1.4.1.19.1.5.1 “FBD/LD/IL Editor” on page 495*
- *Chapter 1.4.1.20.3.13.11 “Command 'Insert Label'” on page 1107*

FBD/LD/IL element 'Jump'

Symbol 

In FBD or LD a jump is inserted either directly before an input, directly after an output or at the end of the network, depending on the current cursor position.

You enter a jump label as the jump destination directly behind the jump element.

In IL you program a jump with the instruction `JMP`.

See also

- *Chapter 1.4.1.19.1.5.1 “FBD/LD/IL Editor” on page 495*
- *Chapter 1.4.1.20.3.13.10 “Command 'Insert Jump'” on page 1107*
- *Chapter 1.4.1.19.1.5.4.6 “FBD/LD/IL element 'Label'” on page 506*

FBD/LD/IL element 'Return'

This element immediately interrupts the execution of the box if the input of the `RETURN` element goes `TRUE`.

In an FBD or LD network you can place the Return instruction parallel to or after the preceding elements.

In IL the `RET` instruction is available to you for this purpose.

See also

- *Chapter 1.4.1.20.3.13.12 “Command 'Insert Return'” on page 1107*
- *Chapter 1.4.1.19.1.5.3 “Modifiers and operators in IL” on page 500*

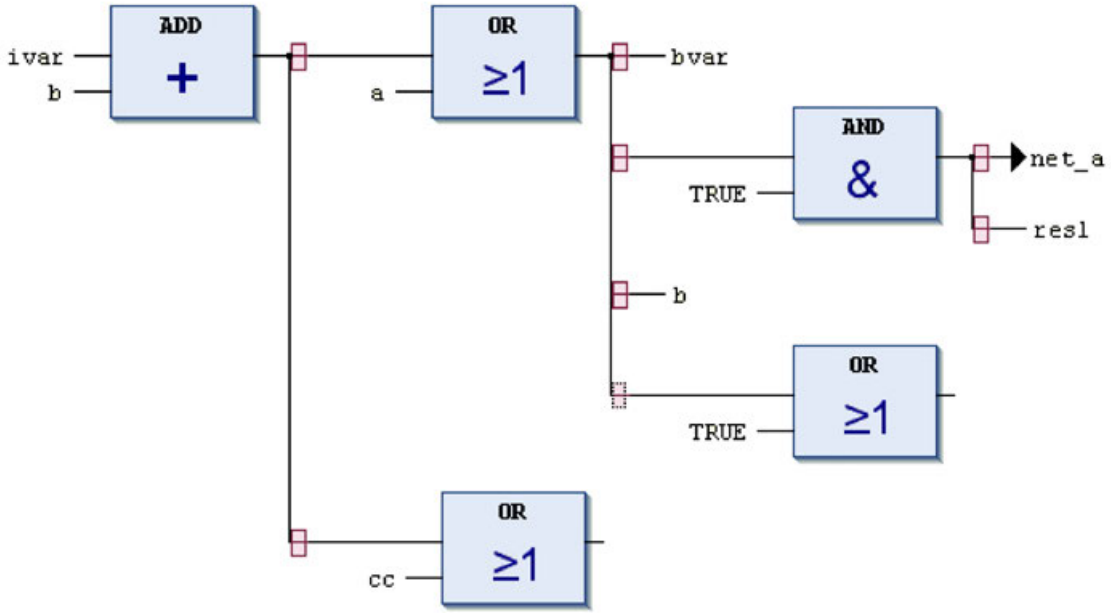
FBD/LD/IL element 'Branch'

Symbol: 

The element is available in the LD and FBD editor and represents an open line branch. A line branch splits the processing line from the current cursor position onwards into 2 subnetworks, which are executed in succession from top to bottom. You can branch each subnetwork further, as a result of which multiple branches are created within a network.

Each subnetwork is given a marker symbol (rectangle) at the branch point, which you can select in order to execute further commands.

> *The commands “Copy”, “Cut” and “Paste” are not available for subnetworks.*



In order to delete a subnetwork, you must first delete all elements of the network and then the marker symbol of the subnetwork.

See also

- *Chapter 1.4.1.20.3.13.33 “Command 'Insert Branch'” on page 1113*
- *Chapter 1.4.1.20.3.13.34 “Command 'Insert Branch Above'” on page 1113*
- *Chapter 1.4.1.20.3.13.35 “Command 'Insert Branch Below'” on page 1113*

FBD/LD/IL element 'Execute'

Symbol:

The element is a box that enables you to directly enter ST code in the FBD and LD editors.

You can drag the *“Execute”* element with the mouse from the *“Tools”* view into the implementation part of your POU. If you click on *“Enter ST code here...”*, an input field opens where you can input multiple-line ST code.

- *Chapter 1.4.1.19.1.5.1 “FBD/LD/IL Editor” on page 495*

LD element 'Contact'

Symbol: , in the editor

The element is available only in the LD editor.

A contact passes on the signal `TRUE` (ON) or `FALSE` (OFF) from left to right until the signal finally reaches a coil in the right-hand part of the network. For this purpose a boolean variable containing the signal is assigned to the contact. To do this, replace the placeholder `???` above the contact with the name of a boolean variable.

You can arrange several contacts both in series and in parallel. In the case of two parallel contacts, only one needs to obtain the value `TRUE` in order for ON to be passed on to the right. If contacts are connected in series, all of them must obtain the value `TRUE` in order for ON to be passed on to the right by the last contact in the series. Hence, you can program electrical parallel and series connections with LD.

A negated contact forwards the signal `TRUE` if the variable value is `FALSE`. You can negate an inserted contact with the help of the command *"FBD/LD/IL ➔ Negation"* or insert a negated contact from the *"Tools"* view.

If you place the mouse pointer on a contact with the left mouse button pressed and with a network selected, the button *"Convert to coil"* appears in the network. If you now move the mouse pointer onto this button, still with the mouse button pressed, and then release the mouse button over this button, CODESYS converts the contact into a coil.

See also

- *Chapter 1.4.1.19.1.5.1 "FBD/LD/IL Editor" on page 495*

LD element 'Coil'

Symbol: , in the editor

The element is available only in the LD editor.

A coil adopts the value supplied from the left and saves it in the boolean variable assigned to the coil. Its input can have the value `TRUE` (ON) or `FALSE` (OFF).

Several coils in a network can only be arranged in parallel.

In a negated coil the negated value of the incoming signal is stored in the boolean variable that is assigned to the coil.

Set coil, Reset coil

Symbol: , , in the editor: ,

Set coil: If the value `TRUE` arrives at a set coil, the coil retains the value `TRUE`. As long as the application is running, the value can no longer be overwritten here.

Reset coil: If the value `TRUE` arrives at a reset coil, the coil retains the value `FALSE`. As long as the application is running, the value can no longer be overwritten here.

You can define an inserted coil as a set or reset coil with the help of the command *"FBD/LD/IL ➔ Set/Reset"* or insert it as an element *"Set Coil"* and *"Reset Coil"* from the *"Tools"* view.

See also

- *Chapter 1.4.1.20.3.13.14 "Command 'Insert Coil'" on page 1108*
- *Chapter 1.4.1.20.3.13.16 "Command 'Insert Reset Coil'" on page 1108*

- *Chapter 1.4.1.20.3.13.31 "Command 'Set/Reset'" on page 1112*

LD element 'Branch Start/End'

Symbol:

The element serves the closed line branch.

See also

- *Chapter 1.4.1.19.1.5.4.14 “Closed branch” on page 509*
- *Chapter 1.4.1.19.1.5.1 “FBD/LD/IL Editor” on page 495*
- *Chapter 1.4.1.20.3.13.36 “Command 'Set Branch Start Point'” on page 1113*
- *Chapter 1.4.1.20.3.13.37 “Command 'Set Branch End Point'” on page 1114*

Closed branch

A closed branch is available in LD only, and it contains a starting point and an end point. It is used for implementing parallel analyses of logical elements.

Inserting a closed branch

- Command *“FBD/LD/IL ➔ Insert Contact Parallel (Below) ”*
- Command *“FBD/LD/IL ➔ Insert Contact Parallel (Above) ”*
- Command *“FBD/LD/IL ➔ Set Branch Start/End Point”*

Closed branch at a contact

When you select one or more contacts and then execute the command *“Insert Contact in Parallel”*, a parallel branch is added with a single vertical line. For this kind of branching, the signal flow passes through both branches. This is an OR construct of both branches.

Closed branch at a block, OR evaluation, or short-circuit evaluation

New: When you select a box and execute the command *“Insert Contact in Parallel”*, a parallel branch is inserted with a double vertical line. This indicates that a short-circuit evaluation (SCE) is implemented. SCE allows for the execution of a function block with a Boolean output to be bypassed if a specific condition is `TRUE`. The condition can be displayed in the LD editor as a branch connected parallel to the function block branch. The short circuit condition is defined by one or more contacts in this branch that are interconnected parallel or sequentially.

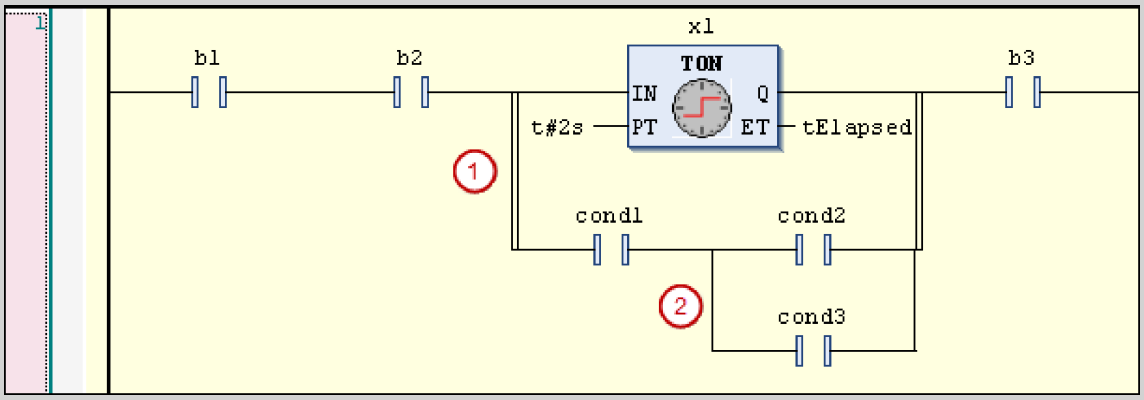
Functional principle:

The branches that do not include the function block are processed first. If CODESYS detects the value `TRUE` for one of these branches, then the function block is not called in the parallel branch. In this case, the value at the input of the function block is sent directly to the output. If CODESYS determines `FALSE` for the SCE condition, then the box will be called and the Boolean result of its processing is passed on. If all branches contain function blocks, they are analyzed from top to bottom and their outputs are logically ORed. If there are no branches with function blocks, normal OR operations are performed.

Example

The function block instance `x1` (TON) has a Boolean input and a Boolean output. The execution of `x1` is skipped if `TRUE` is determined for the condition in the parallel line branch. The condition value results from the OR and AND operations that connect contacts `cond1`, `cond2` and `cond3`.

`x1` is executed if the condition value from the connection of the contacts `cond1`, `cond2` and `cond3` is FALSE.



(1) Indicates from the double vertical connections that it is a construct subject to an SCE.

(2) Indicates from the single vertical connections that it is an OR construct.

The given LD example is shown below as ST code. `P_IN` and `P_OUT` are the Boolean values at the input (split point) and output (reunification point) of the parallel line branch.

```
P_IN := b1 AND b2;

IF ((P_IN AND cond1) AND (cond2 OR cond3)) THEN
   P_OUT := P_IN;
ELSE
   x1(IN := P_IN, PT := {p 10}t#2s);
   tElapsed := x1.ET;
   P_OUT := x1.Q;
END_IF
bRes := P_OUT AND b3;
```

Continuous Function Chart (CFC) and Page-Oriented CFC

From an external point of view, a Function Block Diagrams consists of inputs and outputs, with data being processed between them. From an internal point of view, a Function Block Diagrams consists of POUs and their connections which represent data (signals) and act as assignment operators in ST. The overall behavior is composed of the behavior of the inserted POUs which call other POUs or library POUs.

Code in the *"Continuous Function Chart (CFC)"* implementation language mainly illustrates the data flow through the system. Therefore, a continuous function chart is also referred to as a "signal flow chart".

In the page-oriented CFC editor, you can wire POUs to each other and create well-structured Function Block Diagrams distributed over multiple pages. The page-oriented editor behaves like the CFC editor, but provides the following functionality:

The page-oriented editor behaves like the CFC editor, but provides additional functionality.

The editor supports you with the following functions:

- Creating pages
- Setting the page size
- Copying and inserting pages in the page navigator
- Copying the implementation of a POU in the CFC implementation language and inserting into a page
- Well-structured and space-saving arranging of inputs, outputs, and connection marks in the border areas
- Connection over pages with connection marks

CFC Editor

Configuring the editor

You can configure the appearance, behavior, and printing for the entire project in the CODESYS options in the *"CFC Editor"* category. For example, on the *"View"* tab, you can configure the color of the connecting lines depending on the data type.

Editing

Cursor symbol:	Requirement: *"Pointer"* is selected in the *"Toolbox"* view. The symbol indicates that you can edit in the editor. Select elements or connections to move them or to execute commands.
Cursor symbol: +	Requirement: An element is selected in the *"Toolbox"* view. Clicking in the editor inserts the selected element. You can also drag an element to the editor.
Dragging a function block instance from the declaration to the editor	Requirement: A line is selected in the declaration of the CFC. The instance is inserted as a box with name, type, and all pins.
Dragging a variable from the declaration to a box pin to the editor	The variable is inserted as an input or output with a connection to the box pin in focus. Hint: The cursor indicates when your focused location is valid for a variable: 
Dragging a variable from the declaration part to the editor	Requirement: The respective element is selected in the declaration. ● Function block instance: A POU with the corresponding data type is created. ● Declaration of `VAR_INPUT` or `CONSTANT`: An input element is inserted. ● Declaration of `VAR_OUTPUT`: An output element is inserted. ● Declaration of `VAR`, `VAR_GLOBAL`: A window opens at the insert location, where you can select whether an input element or output element should be inserted. When a variable is dragged from the declaration part to an existing replaceable element, the existing element is replaced.
Dragging a function block or POU to the editor from the *"Devices"* view, *"POUs"* view, or from the Library Manager.	A box element with the corresponding type is inserted. ● When a box is dragged to an existing connecting line and both the input and output of the box are compatible with the data type of the line, the box is inserted in the line. Here its first matching input and output are connected to the elements that were previously connected by the connecting line. ● When a box is dragged to an existing box, the existing box is replaced.
Resorting the order of inputs and outputs within a function block by means of drag&drop	Requirement: The text field of the input or output, which should be resorted to another location, is selected.
[Ctrl] + click in the programing area	Requirement: An element is selected in the *"Toolbox"* view. As long as you hold down the *[Ctrl]* key, a selected element is created each time you click in the programming area.
[Ctrl]+[Right Arrow]	Requirement: In the CFC program, **exactly** one output pin is selected for an element. The selection is moved so that the input pin at the end of the connecting line is selected. In the case of multiple pins, all are selected. 
[Ctrl]+[Left Arrow]	Requirement: In the CFC program, **exactly** one input pin is selected for an element. The selection is moved so that the output pin at the beginning of the connecting line is selected. In the case of multiple pins, all are selected. Example: 
See also

- *Chapter 1.4.1.19.1.2 “Common functions in graphical editors” on page 462*

Connecting

You can insert connecting lines between element connections. Connecting lines are inserted by means of auto-routing so that connecting lines are automatically optimal and as short as possible. The connecting lines are checked for collisions.

Dragging a pin to another	A connecting line is inserted between the two element pins.
Dragging a pin to a function block	Dropping can be done on a pin or on the text field of a pin. In the case of extendable operators (example: ADD), dropping can also be done within the box. The following behavior applies for this: If there are still unconnected input pins, then the top free pin is connected. If there are no more unconnected input pins, then a new pin is automatically inserted below.
Command *“Connect Selected Pins”*	Requirement: Multiple pins are selected. The pins are marked in red.
Move an inserted element so that it touches the pin of another element.	Requirement: The *“Enable AutoConnect”* option is selected. The touching pins are connected automatically.
	The connection icon is located in the upper right corner of the editor. A green icon indicates collision-free connections. A red icon indicates collisions. Clicking the icon opens a menu with commands for collision processing, for example the *“Show Next Collision”* command.
	Requirement: A connection is selected and the *“Connection Mark”* command is executed. Instead of a long connecting line, a connection is represented by connection marks.

See also

- *Chapter 1.4.1.20.3.12.22 “Command 'Show Next Collision'” on page 1098*

Commands when editing

See also

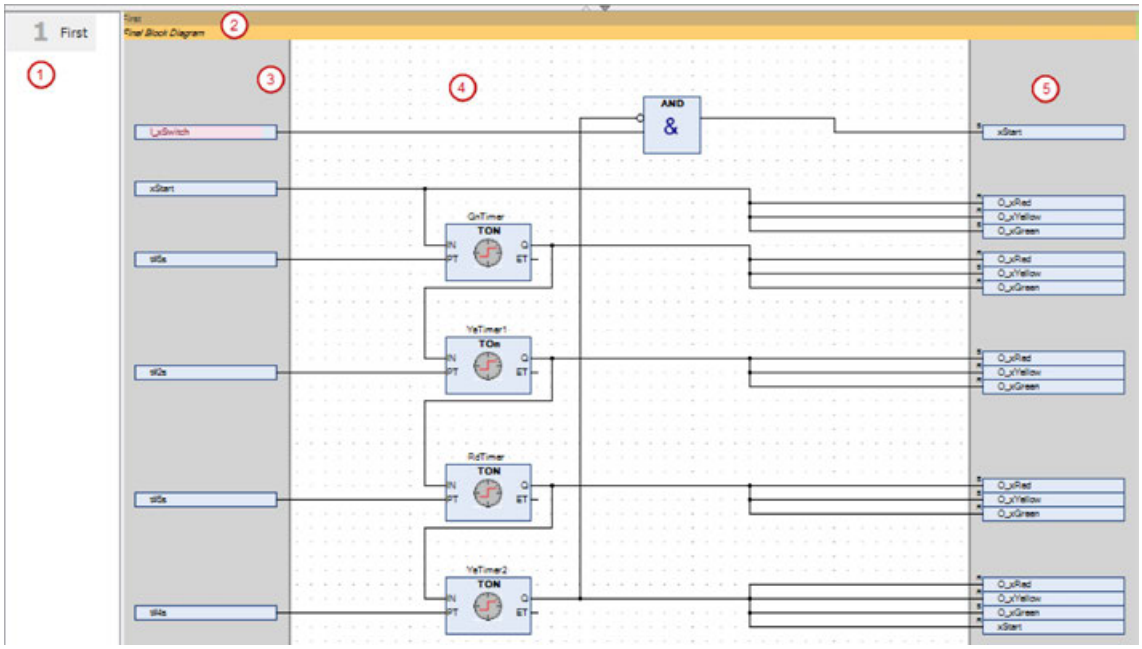
- *Chapter 1.4.1.20.3.12 “Menu 'CFC'” on page 1089*

See also

- *Chapter 1.4.1.19.1.2 “Common functions in graphical editors” on page 462*
- *Chapter 1.4.1.8.3.2.2 “ Programming in the CFC editor” on page 246*
- *Chapter 1.4.1.8.3.2.1 “Automatic Execution Order by Data Flow” on page 242*
- *Chapter 1.4.1.20.3.12 “Menu 'CFC'” on page 1089*
- *Chapter 1.4.1.20.4.10.13 “Dialog 'Properties' - 'CFC Execution Order'” on page 1165*

CFC editor, page-oriented

POUs generated in the “Continuous Function Chart (CFC) - page-oriented” cannot be converted into “Continuous Function Chart (CFC)” POUs or back.



- (1) Page navigator
- (2) Page header with name and description
- (3) Left border area reserved for inputs and sink connection marks
- (4) Program area
- (5) Right border area reserved for outputs and source connection marks

Editing

You can drag a *“Page”* element from the *“ToolBox”* view to the page navigation. Then an additional page is inserted.

You can select existing pages in the page navigation and duplicated them by clicking *“Edit ➔ Copy”* and *“Edit ➔ Paste”*.

The size of the page is changed by means of the *“Edit Page Size”* command.

Connections over multiple pages are established by means of the *“Connection Mark - Source”* and *“Connection Mark - Sink”* elements. When you drag a connecting line from an input pin or an output pin to the border area, a new connection mark is created automatically. The advantage is that the "List components" input assistance provides all previously defined connection mark sources.

If you have selected an element in the editor, then you can use the arrow keys to move the selection from one element to the next to navigate through the circuit. If you then select a connection mark and press another arrow key, even the corresponding connection mark of the next/previous page will be selected.

You can transfer networks from a CFC POU to the program area of a page-oriented CFC by clicking *“Edit ➔ Copy”* and *“Edit ➔ Paste”* (from the clipboard). You can also use drag&drop.

Execution order

The execution order is determined automatically according to the order of the pages as they are sorted in the page navigator of the editor. Within a page, a page-oriented CFC object behaves like a CFC object. Therefore, you can switch between *“Auto Data Flow Mode”* and *“Explicit Execution Order Mode”*.

Additional commands in *“CFC page-oriented”*

CFC Editor in Online Mode

In online mode, you can monitor and change variable values of the controller. In addition, debugging features are provided such as breakpoints and stepping.

Monitoring

As usual, you can monitor values in the declaration part as well as in the implementation part (with inline monitoring).

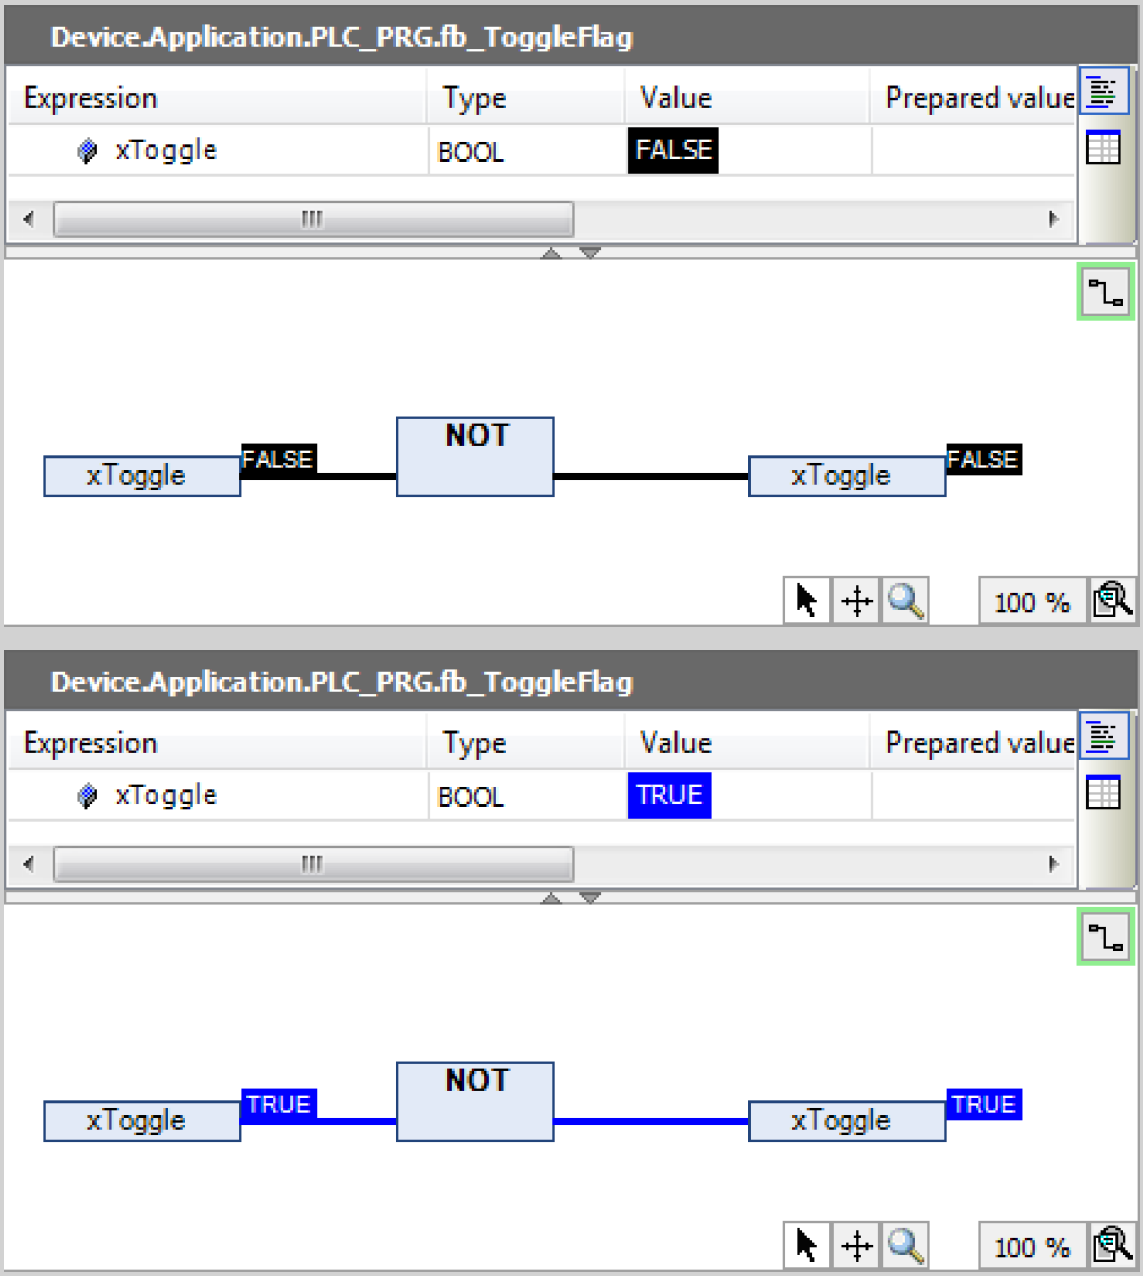
Inline monitoring of a function block is possible only when an instance of the function block is open. No values are displayed in the basic implementation view.

Monitoring a Boolean variable

The connections between Boolean variables are displayed in color according to their actual value: `TRUE` in blue and `FALSE` in black. The element pins are decorated with the actual value.

Example

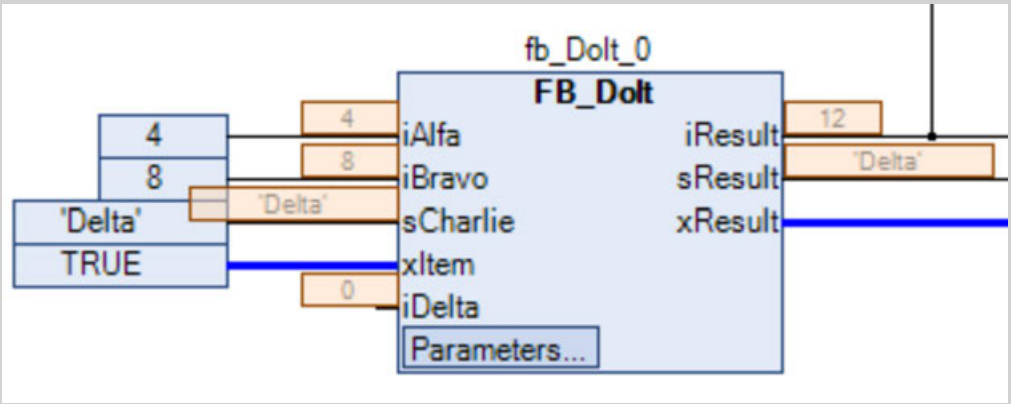
An application contains a CFC POU. An internal Boolean variable is switched there. With each cycle, the variable `iToggle` switches its state from `TRUE` to `FALSE`.



Monitoring a scalar variable

In the case of scalar variables, the element pins are decorated with the actual values.

Example



Forcing and writing of variables

In online mode in the declaration editor, you can prepare a value for forcing or writing a monitored variable.

When you select the *"Prepare values in implementation part"* check box in the *"CFC Editor"* category of the CODESYS options, you can also prepare values in the implementation part.

To do this, open the *"Prepare Value"* dialog by double-clicking an element or the monitoring box next to an element. No dialog appears for Boolean variables. However, with each mouse click on the value displayed next to the variable, the values `TRUE` and `FALSE` are toggled.

Prepared values are displayed in angle brackets. After executing a write or a force, a red "F" is shown in the monitoring box.

Changing of constant input parameters of function block instances

You can write input parameters of function block instances of type `VAR_INPUT CONSTANT` in online mode and modify the parameters in this way. After logging out, you save these parameters by clicking *"Save Prepared Parameters to Project"*.

☑ Requirement: A CFC editor is active. An instantiated function block has `VAR_INPUT CONSTANT` variables in its declaration.

1. In the editor, open the POU by calling the function block instance.

   ⇨

```
FUNCTION_BLOCK FB_DoIt
VAR_INPUT
    iAlfa : INT;
    iBravo: INT;
    sCharlie : STRING := 'Charlie';
    xItem : BOOL;
    iDelta : INT;
END_VAR
VAR_INPUT CONSTANT
    MAXIMUM : INT := 12;
END_VAR
VAR_OUTPUT
    iResult : INT;
    sResult : STRING;
    xResult : BOOL;
END_VAR
```

   The declaration of `FB_DOIt` has been supplemented by the constant `MAXIMUM`.

   The graphical representation of the function block instances contains the *"Parameters"* button.

2. Login to the controller.
3. Click the *"Parameters"* button of the function block instance.

   ⇨ The *"Edit Parameters"* dialog opens.

4. Click the *"Value"* column in an inline monitoring field of a parameter.

   ⇨ The *"Prepare Value"* dialog opens.

5. Type `20` in the *"Prepare a new value for the next write or force operation"* field.
6. Click *"OK"* to confirm the entry.

   ⇨ The prepared value is shown in angle brackets next to the current value (for example, `<20>`).

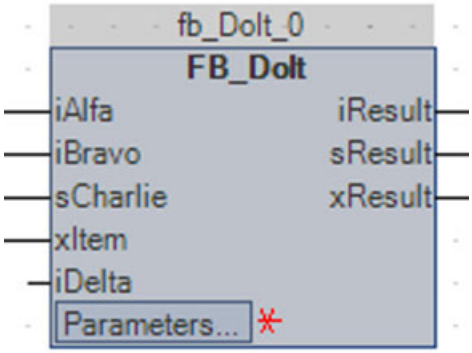
Parameter	Type	Value	Initial value	Min	Max	Unit	Description
MAXIMUM	INT	12 <20>	12				

7. Click *“Debug ➔ Write Values”*.

   ⇨ The prepared value is written. The parameter is changed and displayed in the project in brackets after the value.

Parameter	Type	Value	Initial value	Min	Max	Unit	Description
MAXIMUM	INT	[20] 20	12				

The difference between both values is shown by a red cross next to the parameter field of the function block instance.



8. Click *“Edit Parameters”* to close the dialog. Logout.
9. Click *“CFC ➔ Save Prepared Parameters to Project”*.

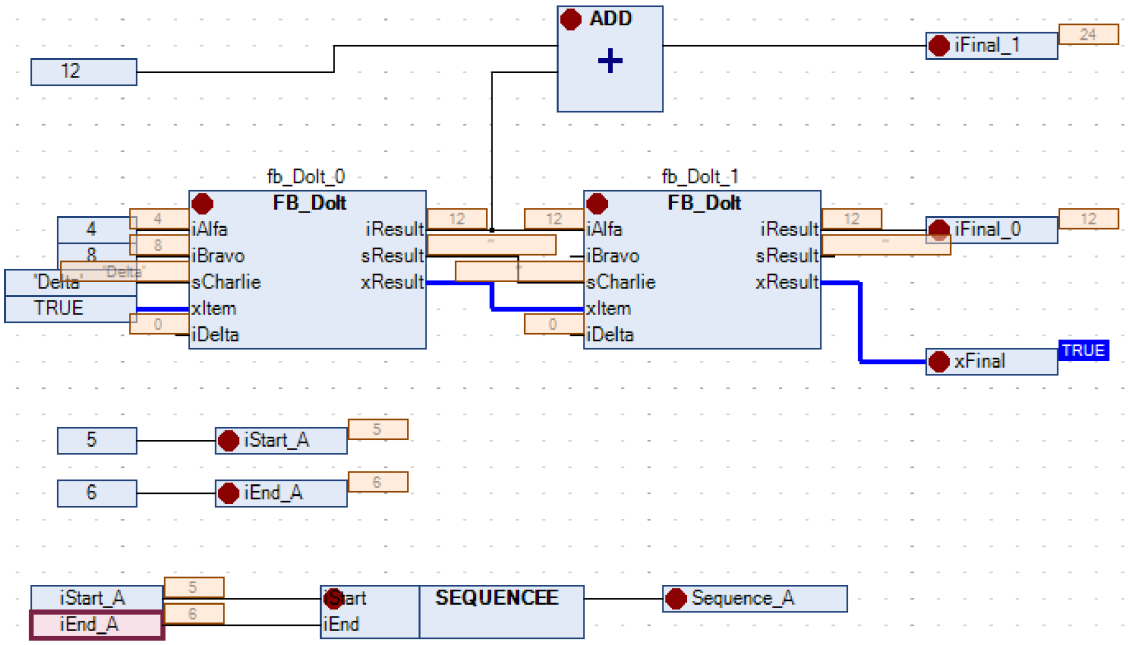
   ⇨ The change parameter values are saved to the project. The asterisk next to the parameter field disappears.

Breakpoint locations

Possible position of a breakpoint

- Element *“Output”*
  Variables are described.
- Element *“Box”*
  POUs are called.
- Element *“RETURN”*
  The program flow is branched.
- Element *“Selector”*
  Structure elements are described.

Click *“Debug ➔ Toggle Breakpoint”* to set a new breakpoint or delete an existing breakpoint. A red circle in the block diagram represents an active breakpoint.



> **NOTICE!**
>
> A breakpoint is set automatically in all methods that can be called.
>
> Therefore, if a method is called that is defined over an interface, then breakpoints are set in all methods of function blocks that implement this interface. This also applies to all inherited function blocks that define methods.

Stepping into a POU

You can process a POU in steps in debug mode. A called POU is supplemented internally by a `RETURN` at the beginning before the element with the number `0` and at the end after the last element. When stepping, these are started automatically.

Elements

CFC element 'Page'

Symbol: 

The element inserts a new page into the editor. It is available only in the page-oriented CFC editor. The number of the page is automatically assigned in accordance with its position. You can enter the name and the description of the page into the orange header. The page size is adapted with the *“Edit Page Size”* command.

See also

- *Chapter 1.4.1.20.3.12.2 “Command 'Edit Page Size'” on page 1090*

CFC element 'Control Point'

Symbol: 

Use a control point in order to fix points of a connection before you adapt the line routing. To do this, drag the element to the desired position on a connecting line. Connecting lines with control points are no longer routed automatically.

See also

- *Chapter 1.4.1.8.3.2.2 “ Programming in the CFC editor” on page 246*
- *Chapter 1.4.1.20.3.12.30 “Command 'Create Control Point'” on page 1100*
- *Chapter 1.4.1.20.3.12.29 “Command 'Remove Control Point'” on page 1099*

CFC Element 'Input'

Symbol:

Keyboard shortcuts for inserting the element: *[Ctrl]+[Q]*

By default, CODESYS inserts an input element with the text "???". You can edit this input field directly by clicking it and typing in a constant value or a variable name. Alternatively, you could click  to open the Input Assistant to select a variable.

CFC Element 'Output'

Symbol:

Keyboard shortcuts for inserting the element: *[Ctrl]+[A]*

By default, CODESYS inserts an output element with the text "???". You can edit this input field directly by clicking it and typing in a constant value or a variable name. Alternatively, you could click ... to open the Input Assistant to select a variable.

CFC Element 'Box'

Symbol:

Keyboard shortcuts for inserting the element

- *[Ctrl]+[B]*
- *[Ctrl]+[Shift]+[B]*: Empty box
- *[Ctrl]+[Shift]+[E]*: Box with EN/ENO

You use the element in order to insert an operator, a function, a function block, or a program. By default, CODESYS inserts the element with the name *“???”*. You can edit this field directly by clicking it and typing in a function block name. Alternatively, you could click ... to open the Input Assistant and select a function block

In the case of a function block, CODESYS also displays an input field (*“???”*) above the function block symbol. You have to replace this name with the name of the function block instance. If you instantiate a function block with constant input parameters, then the function block element displays the "Parameter..." field in the bottom left corner. You click on this field to edit the parameters.

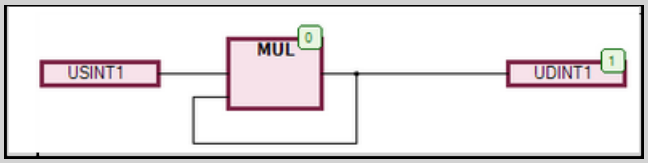
In order to replace an existing box, you replace only the currently inserted identifier with the new desired name. When you do this, note that CODESYS adapts the number of input and output pins according to the definition of the POU and that existing assignments may be deleted as a result.

NOTICE!

Because feedback is allowed in CFC, implicit variables with the data type of the input variable are created at the output of a box (in the example: `temp_USINT`). If the result of the operation of a function block is a value which exceeds the number range of the data type of the input variable, then the overflow is written to the implicit variable. The actual output variable gets the value of the implicit variable, thus the overflow and not the actual result of the operation (see example).

Example

Implicitly generated variables at the box output:



Implicitly generated code:

```
temp_USINT := USINT1 * temp_USINT;
UDINT1 := temp_USINT;
```

See also

- *Chapter 1.4.1.20.3.12.18 “Command 'Edit Parameters'” on page 1096*

CFC element 'Jump'

Symbol:

You use the element in order to define a position at which program execution is to continue. You must define this target position by a label. To do this, enter the name of the mark in the input field *“???”*. If you have already inserted the corresponding label, you can also select it via the input assistant (...).

See also

- *Chapter 1.4.1.19.1.6.5.7 “CFC element 'Label'” on page 524*

CFC element 'Label'

Symbol:

A label defines a position to which program execution jumps with the help of a jump element.

In online mode CODESYS automatically inserts a RETURN flag at the end of a CFC function block.

See also

- *Chapter 1.4.1.19.1.6.5.6 “CFC element 'Jump'” on page 523*

CFC element 'Return'

Symbol:

Use the element in order to exit the function block.

Please note that in online mode in the CFC editor a return element is automatically inserted before the first line and after the last element. In single-step execution CODESYS automatically jumps to the return element at the end before exiting the function block.

CFC element 'Composer'

Symbol:

The composer element is for handling structural components. The individual components of a structure are made available to you as an input. For this purpose you must name the composer element like the structure concerned (replace the *“???”*).

The composer element is the counterpart to the selector element.

See also

- *Chapter 1.4.1.19.1.6.5.10 “CFC element 'Selector'” on page 524*

CFC element 'Selector'

Symbol:

The selector element is for handling structural components. The individual components of a structure are made available to you as an output. For this purpose you must name the selector element like the structure concerned (replace the *“???”*)

The selector element is the counterpart to the composer element.

See also

- *Chapter 1.4.1.19.1.6.5.9 “CFC element 'Composer'” on page 524*

CFC element 'Comment'

Symbol:

With this element you input a comment in the CFC editor. Replace the placeholder text in the element by the comment text. A line break can be inserted with the aid of the shortcut *[Ctrl]* + *[Enter]*.

CFC element 'Connection Mark - Source/Sink'

Symbol: ,

You can use connection marks instead of a connecting line between elements. That helps you to display complex diagrams more clearly.

For a valid connection you must connect an element *“Connection Mark - Source”* with the output of an element and an element *“Connection Mark - Sink”* with the input of another element. Both marks must bear the same name. The names are not case-sensitive.

Notes on naming

- The standard name for connection marks is `C-<nr>`. `<nr>` is a sequential number starting with 1.
- You can rename the standard name. In doing so, you must make sure that the connection mark - source and connection mark - sink have the same name.
- If you change the name of the connection mark - source, the destination name is automatically renamed.
- If you change the name of the connection mark - sink, the source name is retained.

Observe the command “Connection Mark” for the automatic transformation of an existing connection.

See also

- *Chapter 1.4.1.20.3.12.31 “Command 'Connection Mark'” on page 1100*
- *Chapter 1.4.1.19.1.6.1 “CFC Editor” on page 511*

CFC element 'Input Pin'

Symbol: 

Depending on the type of function block you can add further inputs to an inserted function block element. To do this you must select the function block element and drag the function block input element onto the body of the function block.

Please note: You can drag an input or output connection to another position on the function block with the *[Ctrl]* key pressed.

See also

- *Chapter 1.4.1.19.1.6.5.14 “CFC element 'Output Pin'” on page 525*

CFC element 'Output Pin'

Symbol: 

Depending on the type of function block you can add further outputs to an inserted function block element. To do this you must select the function block element and drag the function block output element onto the body of the function block.

Please note: You can drag an input or output connection to another position on the function block with the *[Ctrl]* key pressed.

See also

- *Chapter 1.4.1.19.1.6.5.13 “CFC element 'Input Pin'” on page 525*

1.4.1.19.2 Variables

The scope of a variable defines how and where you can use a variable. You define the scope in the variable declaration.

Local variables - VAR

Local variables are declared between the keywords `VAR` and `END_VAR` in the declaration part of programming objects.

You have read-only access to local variables by using the instance path.

You can extend local variables with an attribute keyword.

Example

```
VAR
    iVar1 : INT;
END_VAR
```

See also

- ↳ *Chapter 1.4.1.8.19 “Data Persistence” on page 301*

Input variables - VAR_INPUT

Input variables are used at the inputs of function blocks.

`VAR_INPUT` variables are declared between the keywords `VAR_INPUT` and `END_VAR` in the declaration part of programming objects.

You can extend input variables with an attribute keyword.

Example

```
VAR_INPUT
    iIn1 : INT; (* 1st input variable *)
END_VAR
```

See also

- *Chapter 1.4.1.8.19 “Data Persistence” on page 301*

Output variables - VAR_OUTPUT

Output variables are used at the outputs of function blocks.

`VAR_OUTPUT` variables are declared between the keywords `VAR_OUTPUT` and `END_VAR` in the declaration part of programming objects. CODESYS returns the values of this variable to the calling POU. There you can retrieve the values and continue using them.

You can extend output variables with an attribute keyword.

Example

```
VAR_OUPUT
    iOut1 : INT; (*1st output variable *)
END_VAR
```

See also

- *Chapter 1.4.1.8.19 “Data Persistence” on page 301*

Output variables in functions and methods

According to the IEC 61131-3 standard, functions and methods have additional outputs. You have to assign these additional outputs when calling the function, as shown below.

Example

```
fun(iIn1 := 1, iIn2 := 2, iOut1 => iLoc1, iOut2 => iLoc2);
```

Input/Output Variable (VAR_IN_OUT)

A `VAR_IN_OUT` variable is an input/output variable, which is part of a POU interface and serves as a formal pass-by-reference parameter.

Syntax declaration

```
<keyword> <POU name>
VAR_IN_OUT
    <variable name> : <data type> ( := <initialization value> )? ;
END_VAR
<keyword> : FUNCTION | FUNCTION_BLOCK | METHOD | PRG
```

You can declare an input/output variable in the `VAR_IN_OUT` declaration section in the POUs `PRG`, `FUNCTION_BLOCK`, `METHOD`, or `FUNCTION`. As an option, a constant of the declared data type can be assigned as an initialization value. The `VAR_IN_OUT` variable can be read and written.

Usage

- **Call**: When a POU is called, the formal `VAR_IN_OUT` variable receives the actual variable (pass-by-reference variable) as the argument. At runtime, no copies are generated when parameters are passed. Instead, the formal variable receives a reference to the actual variable passed remotely. The referential variables contain a memory address internally as a value to the actual value (*pass as pointer*, *call-by reference*). It is not possible to specify a constant (literal) or a bit variable directly as an argument.
- **Read/write access within the POU**: If the variable is written to within the POU, then this affects the passed variable. When the POU is exited, any performed changes are retained. This means that a POU uses its `VAR_IN_OUT` variables just like the calling POU uses its variables. Read access is always permitted.

- **Read/write access remotely**: `VAR_IN_OUT` variables **cannot** be directly read or written remotely via `<function block instance name>.<variable name>`. This works only for `VAR_INPUT` and `VAR_OUTPUT` variables.
- **Passing string variables**: If a string variable is passed as an argument, then the actual variable and the formal variable should have the same length. Otherwise the passed string can be manipulated unintentionally. This problem does not occur in the case of `VAR_OUTPUT CONSTANT` parameters.
- **Passing bit variables**: A bit variable cannot be passed directly to a `VAR_IN_OUT` variable because it needs an intermediate variable.
- **Passing properties**: Not permitted.

If a string is passed as a variable or a constant to a formal `VAR_IN_OUT CONSTANT` variable, then the string is automatically passed completely. You do not have to check the string length.

See also

- Chapter *"Transfer variable `VAR_IN_OUT CONSTANT`" on page 530*

Example

Passing arrays

```
TYPE DUT_A :
STRUCT
    xA: BOOL;
    iB: INT;
END_STRUCT
END_TYPE

FUNCTION_BLOCK FB_SetArray
VAR_IN_OUT
    aData_A : ARRAY[0..1] OF DUT_A; // Formal variable
END_VAR
aData_A[0].xA := TRUE;
aData_A[0].iB := 100;

PROGRAM PLC_PRG
VAR
    fbSetA : FB_SetArray;
    aSpecialData : ARRAY[0..1] OF DUT_A; // Actual variable
END_VAR
fbSetA(aData_A := aSpecialData);
```

Expression	Type	Value	Prepared value	Address	Comment
fbSetA	FB_SetArray				
aSpecialData	ARRAY [0..1] OF DUT_A				Actual variable
aSpecialData[0]	DUT_A				
xA	BOOL	TRUE			
iB	INT	100			
aSpecialData[1]	DUT_A				
xA	BOOL	FALSE			
iB	INT	0			

Passing strings

```
{attribute 'qualified_only'}
VAR_GLOBAL
    g_sDEV_STATUS : STRING(25) := 'Device_A';
END_VAR

FUNCTION_BLOCK FB_SetStatus
VAR_IN_OUT
    sDeviceStatus : STRING(25); // Formal parameter
END_VAR
sDeviceStatus := CONCAT(sDeviceStatus, ' Activ');

PROGRAM PLC_PRG
VAR
    fbDoB : FB_SetStatus;
END_VAR
fbDoB(sDeviceStatus := GVL.g_sDEV_STATUS); //Call with actual
parameter
```

The variable `sDeviceStatus` is part of the POU interface of `FB_B`. When calling `fbDoB`, first a device name is assigned to the string and then the string is manipulated.

Passing bit variables

```
VAR_GLOBAL
    xBit0 AT %MX0.1 : BOOL;
    xTemp : BOOL;
END_VAR

FUNCTION_BLOCK FB_DoSomething
VAR_INPUT
```

```
    xIn : BOOL;
END_VAR
VAR_IN_OUT
    xInOut : BOOL;
END_VAR
IF xIn THEN
    xInOut := TRUE;
END_IF

PROGRAM PLC_PRG
VAR
    xIn : BOOL;
    DoSomething_1  : FB_DoSomething;
    DoSomething_2  : FB_DoSomething;
END_VAR

// The following line of code causes a compiler error:
// C0201: Typ 'BIT' is not equal to type 'BOOL' of VAR_IN_OUT
'xInOut'
DoSomething_1(xIn := xIn, xInOut := xBit0);

// Workaround
xTemp := xBit0;
DoSomething_2(xIn := xIn, xInOut := xTemp);
xBit0 := xTemp;
```

The program calls the function block instances `DoSomething_1` and `DoSomething_2`. As a result of the direct assignment of the bit variable `xBit0` to the `VAR_IN_OUT` input, a compiler error is generated when the `DoSomething_1` instance is called. In contrast, calling the `DoSomething_2` instance with the assignment of an intermediate variable is correct code.

Transfer variable VAR_IN_OUT CONSTANT

A `VAR_IN_OUT CONSTANT` variable serves as a constant pass-by-reference parameter, to which a `STRING` or `WSTRING` type variable or constant (literal) can be passed. The parameter can be read, but not written. Passing of properties is not permitted.

Syntax declaration

```
<keyword> <POU name>
VAR_IN_OUT CONSTANT
    <variable name> : <data type>; // formal parameter
END_VAR
<keyword> : FUNCTION | FUNCTION_BLOCK | METHOD | PRG
```

`VAR_IN_OUT CONSTANT` variables are declared without assigning an initialization value.

Usage

- When calling the POU, a `STRING` or `WSTRING` constant variable or literal can be passed. Consequently, write access is not permitted.
- Passing parameters of a string constant: The string length of the constants can be any size, and the string length does not depend on the string length of the `VAR_IN_OUT CONSTANT` variables.

If the “Replace constants” option is selected in “Project ➔ Project Settings” in the “Compile Options” category, then passing the parameters of a constant with basic data type or a constant variable with basic data type generates a compiler error.

The variable is supported in compiler version >= 3.5.2.0.

Example

Passing parameters of string constants and string variables

```
FUNCTION funManipulate : BOOL
VAR_IN_OUT
    sReadWrite : STRING(16); (* Can be read or written here in POU
*)
    dwVarReadWrite : DWORD; (* Can be read or written here in POU *)
END_VAR
VAR_IN_OUT CONSTANT
    c_sReadOnly : STRING(16); (* Constant string variable can only
be read here in POU *)
END_VAR

sReadWrite := 'String_from_POU';
dwVarReadWrite := STRING_TO_DWORD(c_sReadOnly);

PROGRAM PRG_A
VAR
    sVarFits : STRING(16);
    sValFits : STRING(16) := '1234567890123456';
    dwVar: DWORD;
END_VAR

// The following line of code causes the compiler error C0417:
// C0417: VAR_IN_OUT parameter 'sReadWrite' needs a variable with
write access as input.
funManipulate(sReadWrite:='1234567890123456',
c_sReadOnly:='1234567890123456', dwVarReadWrite := dwVar);

//  Correct code
funManipulate(sReadWrite := sValFits, c_sReadOnly := '23',
dwVarReadWrite := dwVar);
funManipulate(sReadWrite := sVarFits, c_sReadOnly := sValFits,
dwVarReadWrite := dwVar);
```

In the code, strings are passed to the `funManipulate` function via different `VAR_IN_OUT` variables. When passing a string literal, a compiler error is output to a `VAR_IN_OUT` variable. When passing a constant variable to a `VAR_IN_OUT CONSTANT` variable, correct code is generated even for passing string variables.

Global variables - VAR_GLOBAL

Global variables are ordinary variables, constants, external or remanent variables that are recognized within the entire project.

You declare global variables in global variable lists or in the declaration section of programming objects between the keywords `VAR_GLOBAL` and `END_VAR`.

The system recognizes a global variable when you prepend the variable name with a dot (for example, `.iGlobVar1`).

> **NOTICE!**
> If a local variable that is declared in a block has the same name as a global variable, then it has precedence within the block.

> **NOTICE!**
> For compiler version 3.2.0.0 and later, CODESYS always initializes global variables before the local POU variables.

Example

```
VAR_GLOBAL
    iVarGlob1 : INT;
END_VAR
```

See also

- *Chapter 1.4.1.20.2.10 “Object 'GVL' - Global Variable List” on page 871*
- *Chapter 1.4.1.19.3.69 “Operator - Global namespace” on page 629*

Temporary variable - VAR_TEMP

This function is an extension of the IEC 61131-3 standard.

You declare temporary variables locally between the keywords `VAR_TEMP` and `END_VAR`.

`VAR_TEMP` declarations are possible only in program blocks and function blocks.

CODESYS initializes temporary variables each time the block is called.

The application can access the temporary variables only in the implementation section of a program block or a function block.

Example

```
VAR_TEMP
        iVarTmp1 : INT; (*1st temporary variable *)
END_VAR
```

Static variables - VAR_STAT

This function is an extension of the IEC 61131-3 standard.

You declare static variables locally between the keywords `VAR_STAT` and `END_VAR`. CODESYS initializes static variables the first time each block is called.

You can access static variables only from within the namespace where the variables are declared (like static variables in C). But static variables retain their values when the application leaves the block. For example, you can use static variables as counters for function calls.

You can extend static variables with an attribute keyword.

Example

```
VAR_STAT
    iVarStat1 : INT;
END_VAR
```

See also

- *Chapter 1.4.1.8.19 “Data Persistence” on page 301*

External variables - VAR_EXTERNAL

External variables are global variables that are imported into a block.

You declare these variables between the keywords `VAR_EXTERNAL` and `END_VAR`. If the global variable does not exist, then an error message is printed.

> **NOTICE!**
> CODESYS does not require you to declare a global variable as external in order to use it in a POU. The keyword exists only for maintaining compliance with IEC 61131-3.

Syntax

```
<POU keyword> <POU name>
VAR_EXTERNAL
    <variable name> : <data type>;
END_VAR
```

Initialization is not permitted.

Example

```
FUNCTION_BLOCK FB_DoSomething
VAR_EXTERNAL
    iVarExt1 : INT; (* 1st external variable *)
END_VAR
```

See also

- *Chapter 1.4.1.20.2.10 “Object 'GVL' - Global Variable List” on page 871*

Instance variables - VAR_INST

CODESYS does not save a `VAR_INST` method variable in a method stack, but in the stack of the function block instance. This means that the `VAR_INST` variable functions like other Variables of the function block instance, and it is not reinitialized each time the method is called.

`VAR_INST` variables are permitted in methods only and you can access these variables only within the method. The variable values of instance variables are monitored in the declaration section of the method.

You can extend instance variable with an attribute keyword.

Example

```
METHOD meth_last : INT
VAR_INPUT
  iVar : INT;
END_VAR
VAR_INST
  iLast : INT := 0;
END_VAR
meth_last := iLast;
iLast := iVar;
```

Configuration variables - VAR_CONFIG

Use configuration variables for assigning complete addresses to variables that are declared in function blocks with incomplete addresses and will be mapped on device I/Os.

Declare the variables in a global variables list between `VAR_CONFIG` and `END_VAR`. The global variables list is termed "variables configuration", where you type the configuration variables with a complete instance path and the correct address.

Example

Declaration of the variable `xLocIn` with incomplete address `%I*` in a function block:

```
FUNCTION_BLOCK locio

VAR
    xLocIn AT %I* : BOOL := TRUE;
END_VAR
```

The `locio` function block is used in the `PLC_PRG` program:

```
PROGRAM PLC_PRG

VAR
    locioVar1 : locio;
END_VAR
```

The correct variables configuration in the global variable list is as follows:

```
VAR_CONFIG

  PLC_PRG.locioVar1.xLocIn AT %IX1.0 : BOOL;

END_VAR
```

See also

- ↳ *Chapter 1.4.1.8.11.1 “Variables configuration - VAR_CONFIG” on page 279*

Constant Variables - 'CONSTANT'

Constant variables are declared in global variable lists or in the declaration part of programming objects. In implementations, constant variables can be accessed as read-only via the instance path.

Syntax

```
<scope> CONSTANT
    <identifier> : <data type> := <initial value> ;
END_VAR

<scope> : VAR | VAR_INPUT | VAR_STAT | VAR_GLOBAL
<data type>: <elementary data type> | <user defined data type> |
<function block>
<initial value> : <literal value> | <identifier> | <expression>
```

Always assign an initialization value when declaring a constant variable. Then the constant cannot be written any more.

Example

Declaration

```
VAR CONSTANT
    c_rTAXFACTOR : REAL := 1.19;
END_VAR
```

Call

```
rPrice := rValue * c_rTAXFACTOR;
```

You have read-only access to constant variables in an implementation. Constant variables are located to the right of the assignment operator.

See also

- *Chapter 1.4.1.19.2.4 “Input/Output Variable (VAR_IN_OUT)” on page 527*
- *“Constants and literals” on page 632*

Persistent Variable - PERSISTENT

Persistent variables are declared in the declaration section `VAR_GLOBAL RETAIN PERSISTENT` in the persistent global variable list. For variables that are marked with the `PERSISTENT` keyword outside of the persistence editor, instance paths are added there.

As of CODESYS version 3.3.0.1, a variable declaration with `PERSISTENT RETAIN` has the same effect as with `RETAIN PERSISTENT` or `PERSISTENT`.

Syntax of the declaration in the global persistent variable list `PersistentVars`:

```
VAR_GLOBAL PERSISTENT RETAIN
    <identifier> : <data type> (:= <initialization>)?;
 <instance path to POU variable>
END_VAR
```

Syntax of the declaration in POUs

```
<scope> PERSISTENT RETAIN
    <identifier> : <data type> ( := <initialization> )?; //
( ... )? : Optional
END_VAR
<scope> : VAR | VAR_INPUT | VAR_OUTPUT | VAR_IN_OUT | VAR_STAT |
VAR_GLOBAL
```

An assignment of inputs, outputs, or memory addresses with the `AT` keyword is not permitted.

Never use the `POINTER TO` data type in persistent variable lists. If the application is downloaded again, their addresses could change. The corresponding compiler warnings are shown in the message window.

If you frequently change the names or data types of remanent variables, then it is better to declare them as retain variables with the `RETAIN` keyword only.

NOTICE!
Avoid inserting instance paths because in this case twice as much memory is used and a higher cycle time can occur. Instead, declare variables in the list of persistent variables.

Example

Declaration in the persistent variable list `PersistentVars`:

```
{attribute 'qualified_only'}
VAR_GLOBAL PERSISTENT RETAIN
    g_iCounter : INT;
    // Generated instance path of persistent variable
    PLC_PRG.fb_A.iPersistentCounter_A: INT;
END_VAR
```

Declaration in the function block `FB_A`:

```
FUNCTION_BLOCK FB_A
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR PERSISTENT
    iPersistentCounter_A : INT;
END_VAR
```

Declaration in the program `PLC_PRG`:

```
VAR
    fb_A1 : FB_A;
END_VAR
```

Possible declaration locations

Directly in the persistent global variable list	The variable is persistent and lies in the protected memory area.
Locally in a program with an instance path in the persistent variable list Locally in a function block with an instance path in the persistent variable list	The variable is persistent and located in the protected memory area and in the memory (double allocation).
Only locally in a program Only locally in a function block	This variable is not persistent. A warning is shown in the message window. Hint: Click *"Declarations ➔ Add All Instance Paths"* to import the variables into the persistent variable list.
Locally in a function	This declaration does not have any effect. The variable is not persistent.

In the persistence editor, click “Declarations ➔ Add All Instance Paths” if local variables are marked with `PERSISTENT`*.*

Whenever possible, avoid marking variables, which are declared in a function block, with `PERSISTENT`*. This is because the function block instance is stored entirely in remanent memory and not just the marked variable.*

See also

- *Chapter 1.4.1.8.19 “Data Persistence” on page 301*
- *Chapter 1.4.1.8.19.5 “Declaring VAR PERSISTENT Variables ” on page 308*
- *Chapter 1.4.1.20.3.17.4 “Command 'Add all instance paths'” on page 1124*
- *Chapter 1.4.1.8.19.1 “Preserving data with persistent variables” on page 304*

Retain Variable - RETAIN

Retain variables are declared by the keyword `RETAIN` is added in programming objects in the scope `VAR`, `VAR_INPUT`, `VAR_OUTPUT`, `VAR_IN_OUT`, `VAR_STAT`, or `VAR_GLOBAL`.

Syntax for the declaration

```
<scope> RETAIN
    <identifier>: <data type> ( := <initialization> )? // ( ... )? :
Optional
END_VAR
<scope> : VAR | VAR_INPUT | VAR_OUTPUT | VAR_IN_OUT | VAR_STAT |
VAR_GLOBAL
```

An assignment of inputs, outputs, or memory addresses with the `AT` keyword is not permitted.

Example

In a POU:

```
VAR RETAIN
    iVarRetain: INT;
END_VAR
```

In a GVL:

```
VAR_GLOBAL RETAIN
    g_iVarRetain: INT;
END_VAR
```

Possible declaration locations

Locally in a program	Only the variable is located in the retain memory area. Info: When using redundancy, the entire program with all of its data is located in the retain memory area.
Globally in a global variable list	Only the variable is located in the retain memory area. Info: When using redundancy, the entire global variable list with all of its data is located in the retain memory area.

Locally in a function block	The entire instance of the function block with all of its data is located in the retain memory area. Only the declared retain variable is protected.
Locally in a function	The variable is not located in the retain memory area. This declaration does not have any effect.
Locally and persistently in a function	The variable is not located in the retain memory area. This declaration does not have any effect.

Whenever possible, avoid using `RETAIN` to mark the variables of a function block.

- *Chapter 1.4.1.8.19.2 “Preserving data with retain variables” on page 306*

SUPER

`SUPER` is a special variable and is used for object-oriented programming.

`SUPER` is the pointer of a function block to the basic function block instance from which the function block was generated. The `SUPER` pointer thus also permits access to the implementation of the methods of the basic function block (basic class). A `SUPER` pointer is automatically available for each function block.

You can use `SUPER` only in methods and in the associated function block implementations.

Dereferencing of the pointer: `SUPER^`

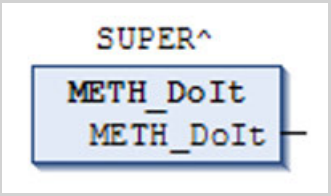
Use of the `SUPER` pointer: with the help of the keyword `SUPER` you call a method that is valid in the instance of the basic class or parent class.

Examples

ST:

```
SUPER^.METH_DoIt();
```

FBD/CFC/LD



`THIS` is not yet implemented for the instruction list (IL).

Examples

Use of `SUPER` and `THIS` pointers

```
FUNCTION_BLOCK FB_Base
VAR_OUTPUT
  iCnt : INT;
END_VAR

METHOD METH_DoIt : BOOL
 iCnt := -1;

METHOD METH_DoAlso : BOOL
 METH_DoAlso := TRUE;

FUNCTION_BLOCK FB_1 EXTENDS FB_Base
VAR_OUTPUT
 iBase : INT;
END_VAR

THIS^.METH_DoIt();  //Call of the methods of FB_1
THIS^.METH_DoAlso();

SUPER^.METH_DoIt();   //Call of the methods of FB_Base
SUPER^.METH_DoAlso();
iBase := SUPER^.iCnt;

METHOD METH_DoIt : BOOL
 iCnt := 1111;
 METH_DoIt := TRUE;

PROGRAM PLC_PRG
VAR
 myBase : FB_Base;
 myFB_1 : FB_1;
 iTHIS : INT;
 iBase : INT;
END_VAR

myBase();
iBase := myBase.iCnt;
myFB_1();
iTHIS := myFB_1.iCnt;
```

See also

- *Chapter 1.4.1.19.5 “Data Types” on page 646*
- *Chapter 1.4.1.19.2.15 “THIS” on page 539*

THIS

`THIS` is a special variable and is used for object-oriented programming.

`THIS` is the pointer of a function block to its own function block instance. A `THIS` pointer is automatically available for each function block.

You can use `THIS` only in methods and in function blocks. `THIS` is available for the implementation in the input assistant in the category *“Keywords”*.

Dereferencing of the pointer: `THIS^`

Use of the `THIS` pointer

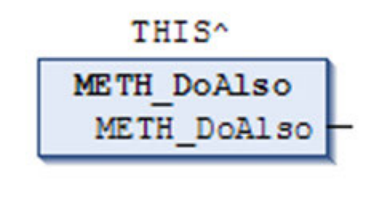
- If a local variable obscures a function block variable in a method, you can set the function block variable with the `THIS` pointer. See example below (1)
- If the pointer to the function block's own function block instance is referenced for use in a function. (See example below (2))

Examples

ST:

```
THIS^.METH_DoIt();
```

FBD/CFC/LD:



`THIS` is not yet implemented for the instruction list (IL).

Examples

(1) The local variable `iVarB` obscures the function block variable `iVarB`.

```
FUNCTION_BLOCK  fbA
VAR_INPUT
 iVarA: INT;
END_VAR
iVarA := 1;

FUNCTION_BLOCK fbB EXTENDS fbA
VAR_INPUT
 iVarB: INT := 0;
END_VAR
iVarA := 11;
iVarB := 2;

METHOD DoIt : BOOL
VAR_INPUT
END_VAR
VAR
 iVarB: INT;
END_VAR
iVarB := 22;    // The local variable iVarB is set.
THIS^.iVarB := 222;    // The function block variable iVarB is set
even though iVarB is obscured.

PROGRAM PLC_PRG
VAR
 MyfbB: fbB;
END_VAR

MyfbB(iVarA:=0, iVarB:= 0);
MyfbB.DoIt();
```

(2) A function call requires the reference to its own instance.

```
FUNCTION funA
VAR_INPUT
 pFB: fbA;
END_VAR
...;

FUNCTION_BLOCK  fbA
VAR_INPUT
 iVarA: INT;
END_VAR
...;

FUNCTION_BLOCK fbB EXTENDS fbA
VAR_INPUT
 iVarB: INT := 0;
END_VAR
iVarA := 11;
iVarB := 2;

METHOD DoIt : BOOL
VAR_INPUT
END_VAR
VAR
 iVarB: INT;
END_VAR
iVarB := 22;    //The local variable iVarB is set.
funA(pFB := THIS^);    //funA is called via THIS^.
PROGRAM PLC_PRG
```

```
VAR
 MyfbB: fbB;
END_VAR
MyfbB(iVarA:=0 , iVarB:= 0);
MyfbB.DoIt();
```

1.4.1.19.3 Operators

CODESYS V3 supports all IEC-61131-3 operators. These operators are recognized implicitly throughout the project. In addition to these IEC operators, CODESYS also supports some non-IEC 61131-3 operators.

Operators are used in blocks, such as functions.

For information about the processing order (binding strength) of the ST operators, please refer to the section on ST expressions.

CAUTION!
For operations with floating-point data types, the computational result depends on the applied target system hardware.

CAUTION!
For operations with overflow or underflow in the data type, the computational result depends on the applied target system hardware.

Overflow/underflow in the data type

The CODESYS compiler generates code for the target device and computes temporary results always with the native size that is defined by the target device. For example, computation is performed at least with 32-bit temporary values on x86 and ARM systems and always with 64-bit temporary values on x64 systems. This provides considerable advantages in the computation speed and often also produces the desired result. But this also means that an overflow or underflow in the data type is not truncated in some cases.

Examples

Example 1

The result of this addition is not truncated and the result in `dwVar` is `65536`.

```
VAR
wVar : WORD;
dwVar: DWORD;
END_VAR

wVar := 65535;
dwVar := wVar + 1;
```

Example 2

The overflow and underflow in the data type is not truncated and the results (`bVar1, bVar2`) of both comparisons are `FALSE` on 32-bit and 64-bit hardware.

```
VAR
wVar1 : WORD;
wVar2 : WORD;
bVar1 : BOOL;
bVar2 : BOOL;
END_VAR

wVar1 := 65535;
wVar2 := 0;
bVar1 := (wVar1 + 1) = wVar2;
bVar2 := (wVar2 - 1) = wVar1;
```

Example 3

By the assignment to `wVar3`, the value is truncated to the target data type `WORD` and the result `bvar1` is `TRUE`.

```
VAR
wVar1 : WORD;
wVar2 : WORD;
wVar3 : WORD;
bVar1 : BOOL;
END_VAR

wVar1 := 65535;
wVar2 := 0;
wVar3 := (wVar1 + 1);
bVar1 := wVar3 = wVar2;
```

Example 4

In order to force the compiler to truncate the temporary results, a conversion can be inserted.

The type conversion makes sure that both comparisons are 16-bit only and the results (`bVar1, bVar2`) of both comparisons are each `TRUE`.

```
VAR
wVar1 : WORD;
wVar2 : WORD;
bVar1 : BOOL;
bVar2 : BOOL;
END_VAR

wVar1 := 65535;
wVar2 := 0;
bVar1 := TO_WORD(wVar1 + 1) = wVar2;
bVar2 := TO_WORD(wVar2 - 1) = wVar1;
```

Call operators

↳ *Chapter 1.4.1.19.3.34 “Operator 'CAL'” on page 565*

Type conversion operators

You can explicitly call type conversion operators. The type conversion operators described below are available for typed conversions from one elementary type to another elementary type, as well as for overloading. Conversions from a larger type to a smaller type are also implicitly possible (for example, from `INT` to `BYTE` or from `DINT` to `WORD`).

Typed conversion: `<elementary data type> _TO_ <another elementary data type>`

Overloaded conversion: `TO_ <elementary data type>`

Elementary data types:

```
<elementary  data type> =
__UXINT | __XINT | __XWORD | BIT | BOOL | BYTE | DATE | DATE_AND_TIME
| DINT | DT | DWORD | INT | LDATE | LDATE_AND_TIME | LDT | LINT |
LREAL | LTIME | LTOD | LWORD | REAL | SINT | TIME | TOD | UDINT |
UINT | ULINT | USINT | WORD
```

The keywords `T`, `TIME_OF_DAY` and `DATE_AND_TIME` are alternative forms for the data types `TIME`, `TOD`, and `DT`. `T`, `TIME_OF_DAY` and `DATE_AND_TIME` are not represented as a type conversion command.

NOTICE!

If the operand value for a type conversion operator is outside of the value range of the target data type, then the result output depends on the processor type and is therefore undefined. This is the case, for example, when a negative operand value is converted from `LREAL` to the target data type `UINT`.

Information can be lost when converting from larger data types to smaller data types.

NOTICE!

String manipulation when converting to `STRING` or `WSTRING`

When converting the type to `STRING` or `WSTRING`, the typed value is left-aligned as a character string and truncated if it is too long. Therefore, declare the return variable for the type conversion operators `<>_TO_STRING` and `<>_TO_WSTRING` long enough that the character string has enough space without any manipulation.

Namespace operators

Namespace operators are extended from IEC 61131-3 operators. They make it possible for you to provided unique access to variables and modules, even when you use the same name multiple times for variables or modules in a project.

↳ *Chapter 1.4.1.19.3.69 “Operator - Global namespace” on page 629*

↳ *Chapter 1.4.1.19.3.70 “Operator - Namespace for global variables lists” on page 629*

↳ *Chapter 1.4.1.19.3.73 “Operator '__POOL'” on page 630*

Multicore operators

Working with different tasks requires the synchronization of these tasks. This is especially true when working on multicore platforms. Some special operators are provided in CODESYS to support this synchronization.

These operators are extensions of IEC-61131-3. The operators `TEST_AND_SET` and `__COMPARE_AND_SWAP` are used for similar tasks.

↳ *Chapter 1.4.1.19.3.68 “Operator 'TEST_AND_SET'” on page 628*

↳ *Chapter 1.4.1.19.3.64 “Operator '__COMPARE_AND_SWAP” on page 625*

↳ *Chapter 1.4.1.19.3.65 “Operator '__XADD'” on page 626*

Other operators

↳ *Chapter 1.4.1.19.3.56 “Operator '__DELETE'” on page 611*

↳ *Chapter 1.4.1.19.3.57 “Operator '__ISVALIDREF'” on page 614*

↳ *Chapter 1.4.1.19.3.74 “Operator 'INI'” on page 631*

↳ *Chapter 1.4.1.19.3.61 “Operators '__TRY', '__CATCH', '__FINALLY', '__ENDTRY'” on page 619*

↳ *Chapter 1.4.1.19.3.66 “Operator '__POSITION'” on page 627*

↳ *Chapter 1.4.1.19.3.67 “Operator '__POUNAME'” on page 627*

Operator 'ADD'

The IEC operator adds variables.

Permitted data types: `__UXINT | __XINT | __XWORD | BYTE | DATE | DATE_AND_TIME | DINT | DT | DWORD | INT | LDATE | LDATE_AND_TIME | LDT | LINT | LREAL | LTIME | LTOD | LWORD | REAL | SINT | TIME | TIME_OF_DAY | TOD | UDINT | UINT | ULINT | USINT | WORD`

Possible combinations for time data types:

- `TIME + TIME = TIME`
- `TIME + LTIME = LTIME`
- `LTIME + LTIME = LTIME`

Possible combinations for date and time data types:

- TOD + TIME = TOD
- DT + TIME = DT
- TOD + LTIME = LTOD
- DT + LTIME = LDT
- LTOD + TIME = LTOD
- LDT + LTIME = LDT
- LTOD +LTIME = LTOD
- LDT + LTIME = LDT

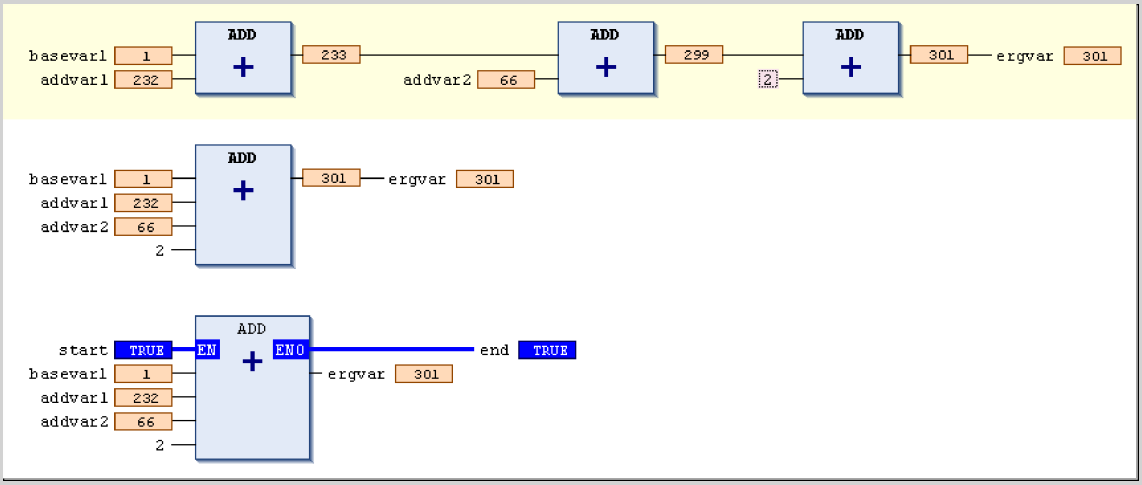
Feature in the FBD/LD editor: You can extend the ADD operator to function block inputs. The number of additional function block inputs is limited.

Examples

ST:

```
var1 := 7+2+4+7;
```

FBD:



Operator 'MUL'

This IEC operator is used for multiplying variables.

Permitted data types: BYTE, WORD, DWORD, LWORD, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, LREAL, TIME

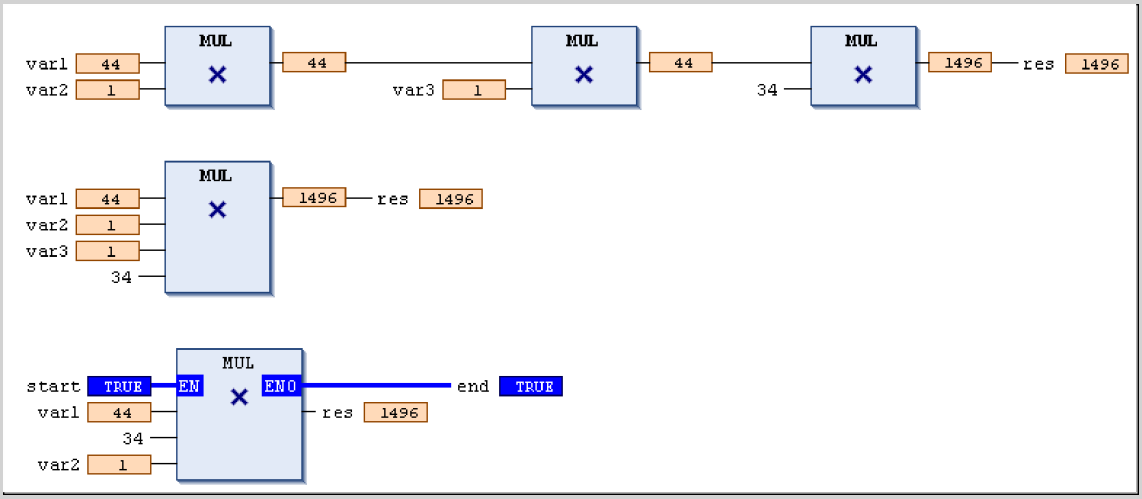
Feature in the FBD/LD editor: You can extend the MUL operator to additional function block inputs. The number of additional function block inputs is limited.

Examples

ST:

```
var1 := 7*2*4*7;
```

FBD:



Operator 'SUB'

The IEC operator subtracts variables.

Permitted data types: `BYTE`, `WORD`, `DWORD`, `LWORD`, `SINT`, `USINT`, `INT`, `UINT`, `DINT`, `UDINT`, `LINT`, `ULINT`, `REAL`, `LREAL`, `TIME`, `LTIME`, `TIME_OF_DAY (TOD)`, `LTIME_OF_DAY (LTOD)`, `DATE`, `LDATE`, `DATE_AND_TIME (DT)` `LDATE_AND_TIME (DT)`

Possible combinations for time data types:

- `TIME - TIME = TIME`
- `LTIME - LTIME = LTIME`

Possible combinations for date and time data types:

- `DATE - DATE = TIME`
- `LDATE - LDATE = LTIME`
- `TOD - TIME = TOD`
- `LTOD - LTIME = LTOD`
- `TOD - TOD = TIME`
- `LTOD - LTOD = LTIME`
- `DT - TIME = DT`
- `LDT - LTIME = LDT`
- `DT - DT = TIME`
- `LDT - LDT = LTIME`

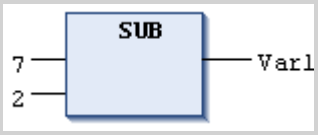
Negative `TIME/LTIME` values are undefined.

Examples

ST:

```
var1 := 7-2;
```

FBD:



Operator 'DIV'

This IEC operator is used for dividing variables.

Permitted data types: `BYTE`, `WORD`, `DWORD`, `LWORD`, `SINT`, `USINT`, `INT`, `UINT`, `DINT`, `UDINT`, `LINT`, `ULINT`, `REAL`, `LREAL`, `TIME`

NOTICE!
Division by zero may have different results depending on the target system.

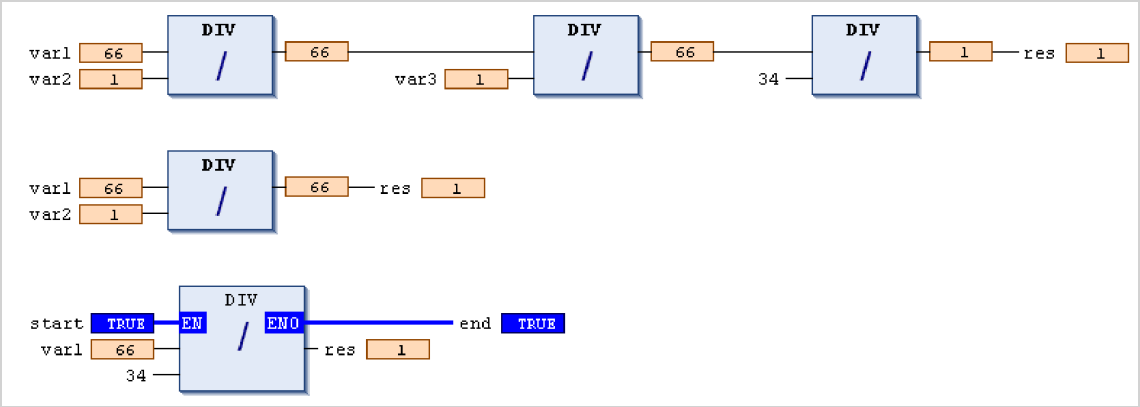
Examples

ST:

```
var1 := 8/2;
```

FBD:

1. Series of DIV blocks, 2. Single DIV block, 3. DIV blocks with EN/ENO parameters



Please note that it is possible to monitor division by zero at runtime by using the implicit monitoring functions `CheckDivInt`, `CheckDivLint`, `CheckDivReal`, and `CheckDivLReal`.

See also

- *Chapter 1.4.1.20.2.19.2 “POU 'CheckDivInt'” on page 909*
- *Chapter 1.4.1.20.2.19.3 “POU 'CheckDivLInt'” on page 909*
- *Chapter 1.4.1.20.2.19.4 “POU 'CheckDivReal'” on page 910*
- *Chapter 1.4.1.20.2.19.5 “POU 'CheckDivLReal'” on page 911*

Operator 'MOD'

This IEC operator is used for modulo division.

The result of the function is the integer remainder of division.

Permitted data types: `BYTE`, `WORD`, `DWORD`, `LWORD`, `SINT`, `USINT`, `INT`, `UINT`, `DINT`, `UDINT`, `LINT`, `ULINT`

> **NOTICE!**
> Division by zero may have different results depending on the target system.

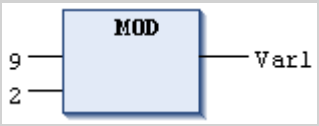
Examples

Result in Var1: 1

ST:

```
var1 := 9 MOD 2;
```

FBD:



Operator 'MOVE'

This IEC operator is used for assigning a variable to another variable of a corresponding type.

Because the `MOVE` block is available in the CFC, FBD, and LD editors, you can also use the EN/ENO functionality for variable assignment.

CFC with EN/ENO function:

CODESYS assigns the value of `var1` to `var2` only if "en_i" yields `TRUE`.

ST:

```
ivar2 := MOVE(ivar1);
```

This corresponds to:

```
ivar2 := ivar1;
```

Operator 'INDEXOF'

This operator is an extension of the IEC 61131-3 standard.

Instead of the `INDEXOF` operator, the `ADR` operator is provided in CODESYS V3 for obtaining a pointer at the index of a block.

See also

- *Chapter 1.4.1.19.3.31 “Operator 'ADR'” on page 563*

Operator 'SIZEOF'

The operator is an extension of the IEC 61131-3 standard.

The operator is used for defining the number of bytes that are required by the variable `x`. The operator `SIZEOF` always yields an unsigned value. The type of return variable adapts to the detected size of the variable `x`.

In compiler version 3.5.16.0 and higher, the operator `XSIZEOF` should be used instead of this operator.

Return value of `SIZEOF(x)`	Data type of the constant which CODESYS uses implicitly for the detected size.
0 <= size of x < 256	`USINT`
256 <= size of x < 65536	`UINT`
65536 <= size of x < 4294967296	`UDINT`
4294967296 <= size of x	`ULINT`

Examples

Result in `var1`: `10`.

ST:

```
arr1 : ARRAY[0..4] OF INT;
var1 : INT;

var1 := SIZEOF(arr1);  (* var1 := USINT#10; *)
```

See also

- *Chapter 1.4.1.19.3.9 “Operator 'XSIZEOF'” on page 551*

Operator 'XSIZEOF'

The operator is an extension of the IEC 61131-3 standard.

The operator is used for defining the number of bytes that are required by the variable x. The data type of the return value is `ULINT` on 64-bit platforms and `UDINT` on all other platforms.

The operator `XSIZEOF` should be used instead of the operator `SIZEOF`. Because the data type of the return value is fixed, problems do not occur for `XSIZEOF`, which do occur in the case of the operator `SIZEOF`.

Example

Variable udiVarX is

ST:

```
udiVarX : UDINT;  (* Data type for 64-bit platforms: ULINT *)

udiVarX := XSIZEOF(<variable>);
```

The variable udiVarX contains the number of bytes that the variable <variable> requires.

See also

- *Chapter 1.4.1.19.3.8 “Operator 'SIZEOF'” on page 551*

Operator 'NOT'

This IEC operator is used for the bitwise `NOT` of a bit operand.

When the respective input bit yields 0, the output bit also yields 1, and vice-versa.

Permitted data types: `BOOL`, `BYTE`, `WORD`, `DWORD`, `LWORD`

Examples

Result in `var1`: `2#0110_1100`

ST:

```
var1 := NOT 2#1001_0011;
```

FBD:

Operator 'AND'

This IEC operator is used for the bitwise `AND` of bit operands.

When the input bits all yield 1, the output bit also yields 1; otherwise 0.

Permitted data types: `BOOL`, `BYTE`, `WORD`, `DWORD`, `LWORD`

Examples

Result in `var1` ist `2#1000_0010`

ST:

```
var1 := 2#1001_0011 AND 2#1000_1010;
```

FBD:

Operator 'OR'

This IEC operator is used for the bitwise `OR` of bit operands.

When at least one of the input bits yields 1, the output bit also yields 1; otherwise 0.

Permitted data types: `BOOL`, `BYTE`, `WORD`, `DWORD`, `LWORD`

Examples

Result in `Var1` ist `2#1001_1011`

ST:

```
Var1 := 2#1001_0011 OR 2#1000_1010;
```

FBD:

Operator 'XOR'

This IEC operator is used for the bitwise XOR of bit operands.

When only one of the two input bits yields 1, the output bit also yields 1. When both inputs yield 1 or 0, then the output yields 0.

Permitted data types: BOOL, BYTE, WORD, DWORD, LWORD

> **NOTICE!**
> Please note the following behavior of the XOR block in extended form (more than two inputs): CODESYS compares the inputs in pairs and then the corresponding results (according to the standard, but not necessarily according to expectations).

Examples

Result in var1: 2#0001_1001

ST:

```
var1 := 2#1001_0011 XOR 2#1000_1010;
```

FBD:

Operator 'AND_THEN'

This operator is an extension of the IEC 61131-3 standard.

The AND_THEN operator is permitted only for programming in structured text with the AND operation of BOOL and BIT operands with short-circuit evaluation. This means that:

When all operands yield TRUE, the result of the operands also yield TRUE; otherwise FALSE.

However, CODESYS also executes the expressions on other operands only if the first operand of the AND_THEN operator is TRUE. This can prevent problems with null pointers, for example in conditions such as `IF (ptr <> 0 AND_THEN ptr^ = 99) THEN...`.

In contrast, CODESYS always evaluates all operands when using the AND IEC operator.

See also

- ↳ *Chapter 1.4.1.19.3.11 “Operator 'AND'” on page 552*

Operator 'OR_ELSE'

This operator is an extension of the IEC 61131-3 standard.

The OR_ELSE operator is permitted only for programming in structured text: OR operation of BOOL and BIT operands; with short-circuit evaluation. This means:

When at least one of the operands yields TRUE, the result of the operation also yields TRUE; otherwise FALSE.

In contrast to using the OR IEC operator, for OR_ELSE the expressions on all other operators are not evaluated as soon as one of the operands is evaluated as TRUE.

Example

```
VAR
    bEver: BOOL;
    bX: BOOL;
    dw: DWORD := 16#000000FF;
END_VAR
bEver := FALSE;
bX := dw.8 OR_ELSE dw.1 OR_ELSE dw.1 OR_ELSE (bEver := TRUE);
```

`dw.8` is `FALSE` and `dw.1` is `TRUE`; therefore `bX` is the result of the operation `TRUE`. However, the expression at the third input is not executed, and `bEver` remains `FALSE`. On the other hand, if the standard OR operation was used, `bEver` would be set to TRUE.

See also

- *Chapter 1.4.1.19.3.12 “Operator 'OR' ” on page 552*

Operator 'SHL'

This IEC operator is used for bitwise shift of an operand to the left.

`erg := SHL (in, n)`

`in`: Operand that is shifted to the left

`n`: Number of bits to shift `in` to the left

NOTICE!
If `n` overwrites the data type width, then it depends on the target system how the `BYTE`, `WORD`, `DWORD`, and `LWORD` operands are padded. The target systems cause padding with zeros or `n MOD <tab width>`.

NOTICE!
Please note the number of bits that CODESYS uses for this operation as defined by the data type of the input variable `in`.

Examples

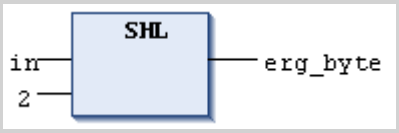
The results for `erg_byte` and `erg_word` are different, although the values of the `in_byte` and `in_word` input variables are the same and the data types of the input variables are different.

ST:

```
PROGRAM shl_st
VAR
 in_byte : BYTE := 16#45; (* 2#01000101 )
 in_word : WORD := 16#0045; (* 2#0000000001000101 )
 erg_byte : BYTE;
 erg_word : WORD;
 n: BYTE := 2;
END_VAR

erg_byte := SHL(in_byte,n); (* Result is 16#14, 2#00010100 *)
erg_word := SHL(in_word,n); (* Result is 16#0114,
2#0000000100010100 *)
```

FBD:



Operator 'SHR'

This IEC operator is used for bitwise shift of an operand to the right.

`erg := SHR (in, n)`

`in`: Operand that is shifted to the right

`n`: Number of bits for shifting `in` to the right

NOTICE!
If `n` overwrites the data type width, then it depends on the target system how the `BYTE`, `WORD`, `DWORD`, and `LWORD` operands are padded. The target systems cause padding with zeros or `n MOD <tab width>`.

Examples

ST:

```
PROGRAM shr_st
VAR
 in_byte : BYTE:=16#45; (* 2#01000101 )
 in_word : WORD:=16#0045; (* 2#0000000001000101 )
 erg_byte : BYTE;
 erg_word : WORD;
 n: BYTE :=2;
END_VAR

erg_byte := SHR(in_byte,n); (* Result is 16#11, 2#00010001 *)
erg_word := SHR(in_word,n); (* Result is 16#0011,
2#0000000000010001 *)
```

FBD:

Operator 'ROL'

This IEC operator is used for bitwise rotation of an operand to the left.

Permitted data types: `BYTE`, `WORD`, `DWORD`, `LWORD`

```
erg := ROL (in, n)
```

CODESYS moves `in` n-times one bit to the left and adds the bit to the leftmost position from the right.

NOTICE!
Please note the number of bits that CODESYS uses for this operation as defined by the data type of the input variable `in`. If this is a constant, then CODESYS uses the smallest possible data type. The data type of the output variables still does not influence this operation.

Examples

The results for `erg_byte` and `erg_word` are different depending on the data type of the input variables, although the values of the `in_byte` and `in_word` input variables are the same.

ST:

```
PROGRAM rol_st

VAR
 in_byte : BYTE := 16#45;
 in_word : WORD := 16#45;
 erg_byte : BYTE;
 erg_word : WORD;
 n: BYTE := 2;
END_VAR

erg_byte := ROL(in_byte,n); (* Result: 16#15 *)

erg_word := ROL(in_word,n); (* Result: 16#0114 *)
```

FBD:

IL:

```
LD    in_byte
ROL   n
ST    erg_byte
```

Operator 'ROR'

This IEC operator is used for bitwise rotation of an operand to the right.

Permitted data types: `BYTE`, `WORD`, `DWORD`, `LWORD`

```
erg := ROR(in,n)
```

CODESYS moves `in` n-times one bit to the right and adds the bit to the rightmost position from the left.

> *Please note the number of bits that CODESYS uses for this operation as defined by the data type of the input variable `in`. If this is a constant, then CODESYS uses the smallest possible data type. The data type of the output variables still does not influence this operation.*

Examples

The results for `erg_byte` and `erg_word` are different depending on the data type of the input variables, although the values of the `in_byte` and `in_word` input variables are the same.

ST:

```
PROGRAM ror_st

VAR
 in_byte : BYTE := 16#45;
 in_word : WORD := 16#45;
 erg_byte : BYTE;
 erg_word : WORD;
 n: BYTE := 2;
END_VAR

erg_byte := ROR(in_byte,n); (* Result: 16#51 *)

erg_word := ROR(in_word,n); (* Result: 16#4011 *)
```

FBD:

Operator 'SEL'

The IEC operator is used for bitwise selection.

`OUT := SEL(G, IN0, IN1)` means:

`OUT := IN0;` if `G = FALSE`

`OUT := IN1;` if `G = TRUE`

Permitted data types:

`IN0`, ..., `INn` and `OUT`: Any identical data type. Make sure that variables of the identical type are used at all three positions, especially when using user-defined data types. The compiler checks for type identity and returns any compile errors. The assignment of function block instances to interface variables is specifically not supported.

`G`: `BOOL`

NOTICE!

When `G` is TRUE, CODESYS does not compute an expression that precedes `IN0`.When `G` is `FALSE`, CODESYS does not compute an expression that precedes `IN1`.

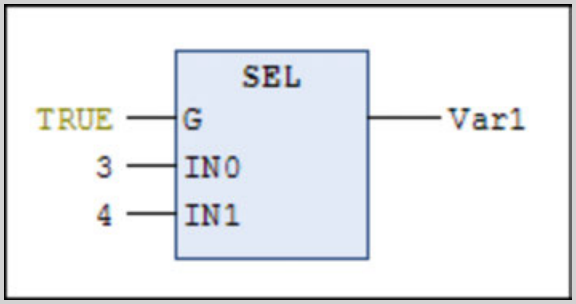
Caution: In the case of graphical programming languages, the expressions at `IN0` and `IN1` are computed independently of the `G` input when a *“Box”*, *“Jump”*, *“Return”*, *“Line Branch”*, or *“Edge Detection”* precedes.

Examples

ST:

```
Var1 := SEL(TRUE,3,4); (* Result: 4 *)
```

FBD:



Operator 'MAX'

This IEC operator is used for the maximum function. It yields the largest value of two values.

```
OUT := MAX(IN0, IN1)
```

Permitted data types: all

Examples

ST:

Result: 90

```
Var1 := MAX(30,40);
```

```
Var1 := MAX(40,MAX(90,30));
```

FBD:

Result: 90

Operator 'MIN'

This IEC operator is used for the minimum function. It yields the smallest value of two values.

```
OUT := MIN(IN0,IN1)
```

Permitted data types: all

Examples

Result: `30`

ST:

```
Var1:=MIN(90,30);

Var1 := MIN(MIN(90,30),40);
```

FBD:

Operator 'LIMIT'

This IEC selection operator is used for limiting.

`OUT := LIMIT(Min, IN, Max)`

Means: `OUT := MIN (MAX (IN, Min), Max)`

`Max` is the upper limit and `Min` is the lower limit for the result. If the `IN` value is above the `Max` upper limit, then LIMIT yields `Max`. If the value of `IN` is below the Min lower limit, then the result is `Min`.

Permitted data types for `IN` and `OUT`: all

Examples

Result in `Var1` is `80`

ST:

```
Var1 := LIMIT(30,90,80);
```

Operator 'MUX'

This IEC operator is used as a multiplexer.

`OUT := MUX(K, IN0,...,INn)`

Means: `OUT = IN_K`

Permitted data type for `K`: `BYTE`, `WORD`, `DWORD`, `LWORD`, `SINT`, `USINT`, `INT`, `UINT`, `DINT`, `LINT`, `ULINT`, o`UDINT`.

`IN0`, ..., `INn`, and `OUT`: Any identical data type. Make sure that variables of the identical type are used at all three positions, especially when using user-defined data types. The compiler checks for type identity and returns any compile errors. The assignment of function block instances to interface variables is specifically not supported.

`MUX` selects the K-th value from a set of values. The first value is K=0. If `K` is greater than the number of other inputs (n), then CODESYS passes on the last value (`INn`).

NOTICE!

For runtime optimization, CODESYS computes only the expression that precedes `IN_K`. However, CODESYS computes all branches in simulation mode.

Examples

Result in `Var1` is `30`.

ST:

```
Var1 := MUX(0,30,40,50,60,70,80);
```

Operator 'GT'

This IEC operator is used for the "greater than" function.

Permitted data types of the operands: any basic data type.

If the first operand is greater than the second operand, then the operator yields the result `TRUE`; otherwise `FALSE`.

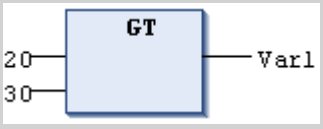
Examples

Result: FALSE

ST:

```
VAR1 := 20 > 30;
```

FBD:



Operator 'LT'

This IEC operator is used for the "less than" function.

Permitted data types of the operands: any basic data type.

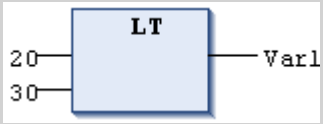
If the first operand is less than the second operand, then the operator yields the result `TRUE`; otherwise `FALSE`.

Examples

Result: `TRUE`

ST:

```
Var1 := 20 < 30;
```



Operator 'LE'

This IEC operator is used for the "less than or equal to" function.

Permitted data types of the operands: any basic data type.

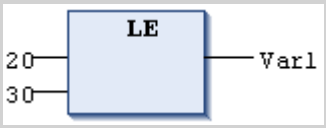
If the first operand is less than or equal to the second operand, then the operator yields the result `TRUE`; otherwise `FALSE`.

Examples

Result in `Var1`: `TRUE`

ST:

```
Var1 := 20 <= 30;
```



Operator 'GE'

This IEC operator is used for the "greater than or equal to" function.

Permitted data types of the operands: any basic data type.

If the first operand is greater than or equal to the second operand, then the operator yields the result `TRUE`; otherwise `FALSE`.

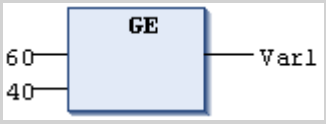
Examples

Result: `TRUE`

ST:

```
VAR1 := 60 >= 40;
```

FBD:



Operator 'EQ'

This IEC operator is used for the "equals" function.

Permitted data types of the operands: any basic data type, depending on target system and compiler version: structure data type.

If the operands are equal, then then the operator yields the result `TRUE`, otherwise `FALSE`.

Examples

Result: TRUE

ST:

```
VAR1 := 40 = 40;
```

FBD:

Operator 'NE'

This IEC operator is used for the "does not equal" function.

Permitted data types of the operands: any basic data type, depending on target system and compiler version: structure data type.

If the operands are not equal, then then the operator yields the result `TRUE`; otherwise `FALSE`.

If the target system supports the data type, then as from compiler version >= 3.5.7.0 also operands of type STRIUCT (structure) can be compared. Example: `IF (stStruct1 := stStruct2) THEN....`

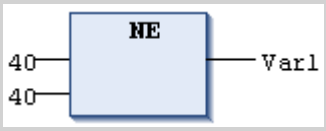
Examples

Result in `Var1` is `FALSE`

ST:

```
Var1 := 40 <> 40;
```

FBD:



Operator 'ADR'

The operator is an extension of the IEC 61131-3 standard.

`ADR` yields the 32-bit address (or the 64-bit address, if possible) of its argument. You can pass this address to the manufacturer functions or assign them to a pointer in the project.

Syntax

```
VAR
    <address name> : DWORD | LWORD | POINTER TO < basis data type>
END_VAR

<address name> := ADR( <variable name> );
```

Example

```
FUNCTION_BLOCK FB_Address
VAR
    piAddress1: POINTER TO INT;
    iNumber1: INT := 5;
    lwAddress2
    iNumber2: INT := 10;
END_VAR

piAddress1 := ADR(iNumber1); // piNumber is assigned to address of
iNumber1
lwAddress2 := ADR(iNumber2); // 64 bit runtime system
```

NOTICE!

In contrast to CoDeSys V2.3, you can use the `ADR` operator with function names, program names, function block names, and method names. Therefore, `ADR` replaces the `INDEXOF` operator.

When using function pointers, note that you can pass a function pointer to external libraries, but it is not possible to call a function pointer from within CODESYS. To enable a system call (runtime system), you must set the respective object property (*"Build"* tab) for the function object.

CAUTION!
When you use an online change, the contents of addresses can shift. As a result, `POINTER TO` variables could point to an invalid memory area. To avoid problems, you should make sure that the value of pointers is updated in every cycle.

CAUTION!
Do not return `Pointer-TO` variables of functions and methods to the caller or assign them to global variables.

See also

- *Chapter 1.4.1.19.5.12 “Pointers” on page 656*

Operator 'Content Operator'

This operator is an extension of the IEC 61131-3 standard.

You can use this operator to dereference pointers by appending the operator as `^` to the pointer identifier.

CAUTION!
When using pointers to addresses, please note that applying an online change can shift address contents.

Example

ST:

```
pt : POINTER TO INT;
var_int1 : INT;
var_int2 : INT;
pt := ADR(var_int1);
var_int2 := pt^;
```

Operator 'BITADR'

The operator is an extension of the IEC 61131-3 standard.

`BITADR` yields the bit offset within a segment in a `DWORD`.

NOTICE!
The offset depends on whether the "Byte addressing" option is selected or cleared in the target system settings.

The highest value nibble (4 bits) in this `DWORD` defines the memory range:

Marker `M`: `16#40000000`

Input `I`: `16#80000000`

Output `Q`: `16#C0000000`

CAUTION!
When using pointers to addresses, note that applying an online change can shift the contents of addresses.

Example **ST implementation language:**

```
VAR
    xVar AT %IX2.3 : BOOL;
    dwBitoffset : DWORD;
END_VAR

dwBitoffset := BITADR(xVar); (* If byte addressing = TRUE, result =
16#80000013; if byte addressing = FALSE, result =  16#80000023 *)
```

Operator 'CAL'

This IEC operator is used for calling function blocks.

In IL, `CAL` calls the instance of a function block.

```
CAL <function block> (<input variable1> := <value>,  <input
variableN> := <value>)
```

Example Call of the `Inst` instance of a function block with assignment of the input variables `Par1` and `Par2` with `0` or `TRUE`.

```
CAL Inst(Par1 := 0, Par2 := TRUE);
```

Overloading

NOTICE!
If the operand value for a type conversion operator is outside of the value range of the target data type, then the result output depends on the processor type and is therefore undefined. This is the case, for example, when a negative operand value is converted from `LREAL` to the target data type `UINT`.

Information can be lost when converting from larger data types to smaller data types.

NOTICE!
The rounding logic for borderline cases depends on the target system or the FPU (Floating Point Unit) of the target system. For example, a value of `-1.5` can be converted differently on different controllers.

Catch value ranges overflows across the application to program code-independent from the target system.

The IEC61131-3 specification does not provide for overloaded functions.

If you want to program strictly according to IEC61131-3, then you should use the operators of the syntax `<type> _TO_ <another type>` as described in the following sections.

The rules for typed conversions also apply here for overloading.

The operators convert values into other data types, explicitly specifying only a target data type and no initial data type (data type of the operands) ("overloaded conversion"). Overloading is not part of the IEC 61131-3 specification.

Call syntax

```
<variable name> := <TO operator> ( <operand> );
<operand> = <variable name> | <literal>
```

Operators

```
TO___UXINT
TO___XINT
TO___XWORD
TO_BIT
TO_BYTE
TO_BOOL
TO_DATE
TO_DINT
TO_DT
TO_DWORD
TO_INT
TO_LDATE
TO_LDT
TO_LINT
TO_LREAL
TO_LTIME
TO_LTOD
TO_LWORD
TO_REAL
TO_SINT
TO_STRING
TO_TIME
TO_TOD
TO_UDINT
TO_UINT
TO_ULINT
TO_USINT
TO_WORD
TO_WSTRING
```

Examples

ST implementation language:

```
VAR
    iNumber_1 : INT;
    rNumber_2 : REAL := 123.456;
    iNumber_2 : INT;
    xIsTrue : BOOL;
    sOutputText : STRING;
    sText : STRING := 'Hello World!';
    wsText: WSTRING;
    dateEvent : DATE := D#2019-9-3;
    uiEvent : UINT;
    uxiData : __UXINT;
END_VAR

iNumber_1 := TO_INT(4.22);            (* Result:  4 *)
iNumber_2 := TO_INT(rNumber_2);        (* Result:  123 *)
xIsTrue := TO_BOOL(1);                (* Result: TRUE *)
sOutputText := TO_STRING(342);        (* Result: '342' *)
wsText := TO_WSTRING(sText);        (* Result: "Hello World!" *)
uiEvent := TO_UINT(dateEvent);        (* Result:  44288 *)
uxiData := TO___UXINT(iNumber_2);    (* Result:  123 *)
```

Boolean Conversion

NOTICE!

String manipulation when converting to `STRING` or `WSTRING`

When converting the type to `STRING` or `WSTRING`, the typed value is left-aligned as a character string and truncated if it is too long. Therefore, declare the return variable for the type conversion operators `<>_TO_STRING` and `<>_TO_WSTRING` long enough that the character string has enough space without any manipulation.

The operators convert a Boolean value into the specified data types and return a type-converted value.

Call syntax

```
<variable name> := <BOOL to operator> ( <operand> );
<operand> = <variable name> | <literal>
```

Operators

```
BOOL_TO___UXINT
BOOL_TO___XINT
BOOL_TO___XWORD
BOOL_TO_BIT
BOOL_TO_BYTE
BOOL_TO_DATE
BOOL_TO_DINT
BOOL_TO_DT
BOOL_TO_DWORD
BOOL_TO_INT
BOOL_TO_LDATE
BOOL_TO_LDT
BOOL_TO_LINT
BOOL_TO_LREAL
BOOL_TO_LTIME
BOOL_TO_LTOD
BOOL_TO_LWORD
BOOL_TO_REAL
BOOL_TO_SINT
BOOL_TO_STRING
BOOL_TO_TIME
BOOL_TO_TOD
BOOL_TO_UDINT
BOOL_TO_UINT
BOOL_TO_ULINT
BOOL_TO_USINT
BOOL_TO_WORD
BOOL_TO_WSTRING
```

When the operand value is `TRUE`, the following typed values are returned:

- `BOOL_TO_DATE: D#1970-1-1 // The zeroth bit is set, but does not effect the display.`
- `BOOL_TO_DT: DT#1970-01-01-0:0:1`
- `BOOL_TO_LTIME: LTIME#1NS`
- `BOOL_TO_REAL: '1'`
- `BOOL_TO_STRING: 'TRUE'`
- `BOOL_TO_TOD: TOD#0:0:0.001`
- `BOOL_TO_TIME: T#1MS`
- `BOOL_TO_WSTRING: "TRUE"`

When the operand value is `FALSE`, the following typed values are returned:

- `BOOL_TO_DATE: D#1970-1-1`
- `BOOL_TO_DT: DT#1970-01-01-00:00:00`
- `BOOL_TO_LTIME: LTIME#0NS`
- `BOOL_TO_REAL: '0.0'`
- `BOOL_TO_STRING: 'FALSE'`
- `BOOL_TO_TOD: TOD#0:0:0`
- `BOOL_TO_TIME: T#0MS`
- `BOOL_TO_WSTRING: "FALSE"`

Integer Conversion

NOTICE!

If the operand value for a type conversion operator is outside of the value range of the target data type, then the result output depends on the processor type and is therefore undefined. This is the case, for example, when a negative operand value is converted from `LREAL` to the target data type `UINT`.

Information can be lost when converting from larger data types to smaller data types.

The operators convert an integer value into the specified data types and return this type-converted value. If the number to be converted exceeds the range limit, then the first bytes of the number are ignored.

Call syntax

```
<variable name> := <integer conversion type operator> ( <integer
operand> );

<integer conversion type operator> = <integer data type> _TO_ <data
type>
<integer operand> = <variable name> | <literal>

<integer data type> =
__UXINT | __XINT | __XWORD | BIT | BYTE | DINT | DWORD | INT | LINT |
LWORD | SINT | UDINT | UINT | ULINT | USINT | WORD
```

Converting to a string

NOTICE!

String manipulation when converting to `STRING` or `WSTRING`

When converting the type to `STRING` or `WSTRING`, the typed value is left-aligned as a character string and truncated if it is too long. Therefore, declare the return variable for the type conversion operators `<>_TO_STRING` and `<>_TO_WSTRING` long enough that the character string has enough space without any manipulation.

The operators that convert a value into a character string of type `STRING` or `WSTRING` require an operand that matches the target data type.

Example

FB_ConvertToWstrings

Device.App_ConvertStrings.PLC_PRG.fbConvertToWstrings

```
1  wstrReturn "255" := BYTE_TO_WSTRING(2#1111_1111);
2  wstrReturn_1 "D#1970-01- := DATE_TO_WSTRING(D#1970-1-1);
3  wstrReturn_2 "D#1970-01- := DATE_TO_WSTRING(D#1970-1-2);
4  wstrReturn_3 "D#1970-01- := DATE_TO_WSTRING(D#1970-1-1);
5  wstrReturn_4 "D#1970-01- := DATE_TO_WSTRING(DATE#1970-1-1);
6  wstrReturn_5 "DT#1970-01 := DT_TO_WSTRING(DT#1970-1-2-0:0:0);
7  wstrReturn_6 "65535" := DINT_TO_WSTRING(65535);
8  wstrReturn_7 "4294967295" := DWORD_TO_WSTRING(16#FFFF_FFFF);
9  wstrReturn_8 "-3276" := INT_TO_WSTRING(-3276);
10 wstrReturn_9 "0" := LINT_TO_WSTRING(0);
11 wstrReturn_10 "1.0e309" := LREAL_TO_WSTRING(1.7E+308);
12 wstrReturn_11 "1844674407 := LWORD_TO_WSTRING(16#FFFF_FFFF_FFFF_FFFF);
13 wstrReturn_12 "1.234" := REAL_TO_WSTRING(1.234);
14 wstrReturn_13 "127" := SINT_TO_WSTRING(127);
15 wstrReturn_14 "Hello" := STRING_TO_WSTRING('Hello');
16 wstrReturn_15 "TOD#01:01: := TOD_TO_WSTRING(TOD#1:1:1);
17 wstrReturn_16 "T#5d" := TIME_TO_WSTRING(T#5D);
18 wstrReturn_17 "4294967295" := UDINT_TO_WSTRING(4294967295);
19 wstrReturn_18 "65535" := UINT_TO_WSTRING(65535);
20 wstrReturn_19 "1" := ULINT_TO_WSTRING(1);
21 wstrReturn_20 "255" := USINT_TO_WSTRING(255);
22 wstrReturn_21 "65535" := WORD_TO_WSTRING(16#FFFF);
23
24 RETURN
```

100 %

Examples

ST implementation language

When a larger data type is converted to a smaller data type, the more high-order (front) bytes are truncated. When a smaller data type is converted to a larger data type, the more high-order bytes filled with zeros.

Floating-Point Number Conversion

NOTICE!
If the operand value for a type conversion operator is outside of the value range of the target data type, then the result output depends on the processor type and is therefore undefined. This is the case, for example, when a negative operand value is converted from `LREAL` to the target data type `UINT`.

Information can be lost when converting from larger data types to smaller data types.

NOTICE!
If the floating-point number is within the value range of the target data type, then the conversion operates the same way on all systems.

NOTICE!
If the floating-point number to be converted exceeds the range limit, then the first bytes of the number are ignored.

The operators convert a floating-point number into the specified data types and return a type-converted value. If applicable, the conversion is rounded.

Call

Syntax

```
<variable name> := <floating-point conversion operator> ( <floating-
point operand> );

<floating-point operand> = <variable name> | <literal>

<floating-point type> =
REAL |
LREAL
```

Operators

```

LREAL_TO_TIME
LREAL_TO_TOD
LREAL_TO_UDINT
LREAL_TO_UINT
LREAL_TO_ULINT
LREAL_TO_USINT
LREAL_TO_WORD
LREAL_TO_WSTRING
```

Rounding

When converting to an integer, the operand is rounded up or down to an integer value. For 1 to 4 after the decimal point, the number is rounded down. For 5 to 9, the number is rounded up. Then the rounded number is converted to the specified integer type. If the rounded value is outside of the integer value range, then an undefined, target system-dependent value is returned. An exception error is also possible then.

NOTICE!

The rounding logic for borderline cases depends on the target system or the FPU (Floating Point Unit) of the target system. For example, a value of `-1.5` can be converted differently on different controllers.

To program target system-independent code, you have to catch value range overflows across the application.

Converting to a string

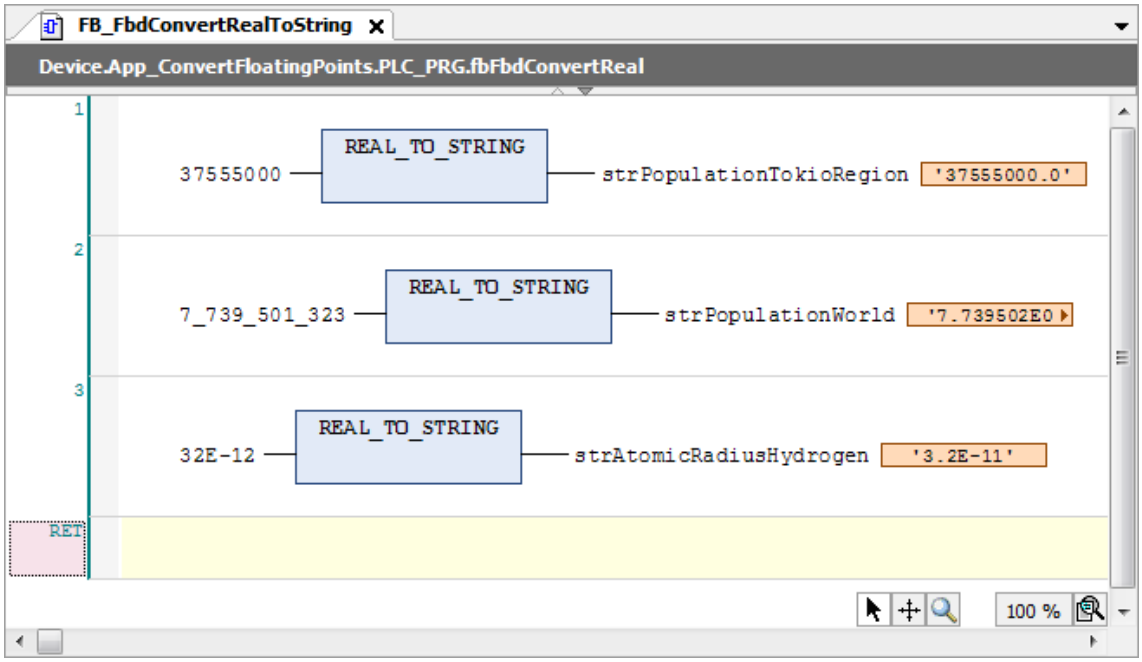
NOTICE!

String manipulation when converting to `STRING` or `WSTRING`

When converting the type to `STRING` or `WSTRING`, the typed value is left-aligned as a character string and truncated if it is too long. Therefore, declare the return variable for the type conversion operators `<>_TO_STRING` and `<>_TO_WSTRING` long enough that the character string has enough space without any manipulation.

For a floating-point number conversion to a string, the number of decimal places of the mantissa is limited to 6. If the number is < 1, then the mantissa is `1 <= m < 10`. If the mantissa has more digits after the comma, then it is rounded to the 6th digit and then converted.

The string variable may also be declared too short for the return value. In this case, the return string is truncated on the right.



Examples

ST implementation language

String Conversion

NOTICE!

If the operand value for a type conversion operator is outside of the value range of the target data type, then the result output depends on the processor type and is therefore undefined. This is the case, for example, when a negative operand value is converted from `LREAL` to the target data type `UINT`.

Information can be lost when converting from larger data types to smaller data types.

The operators convert a character string (`STRING` or `WSTRING`) into the specified target data type and return a type-converted value.

A conversion with a meaningful result is only possible when the operand matches the target data type according to the IEC 61131-3 standard. This is the case if the value of the operand corresponds to a valid constant (literal) of the target data type.

Convertible strings contain:

- Number with type prefix (example: `'16#FFFFFFFF'`)
- Number with grouping characters (example: `'2#1111_1111'`)
  Note: The international weight and measure grouping character (thin space) is not accepted. Only the underscore is accepted.
- Floating-point number, also in exponential notation (example: `'9.876'` or `'1.2E-34'`)
  Note: Floating-point numbers are not convertible. The comma is treated and truncated like a following character.
- Time, time of day, and date specification with prefix and size (example: `'T#2h'`, `'DT#2019-9-9-12:30:30.9'`)
- Infinite values (example: `'1.7E+400'`)
- Additional character **after** a number (example: `'2m'` or `'3.14'`). These are truncated. Additional characters **before** a number are not permitted.
- Spaces before (example: `' 3.14'`)

Call syntax

```
<variable name> := <string to operator> ( <operand> );

<operand> = <variable name> | <literal>
```

Converting to a Boolean value

Operator `STRING_TO_BOOL`: A value of `TRUE` is returned only if the operand value is `'TRUE'` or `'true'`. On the other hand, `FALSE` is returned for `'True'`.

Operator `WSTRING_TO_BOOL`: A value of `TRUE` is returned only if the operand value is `"TRUE"` or `"true"`. On the other hand, `FALSE` is returned for `"True"`.

Time Conversion

NOTICE!

If the operand value for a type conversion operator is outside of the value range of the target data type, then the result output depends on the processor type and is therefore undefined. This is the case, for example, when a negative operand value is converted from `LREAL` to the target data type `UINT`.

Information can be lost when converting from larger data types to smaller data types.

The operators convert time values (`TIME` or `LIME`) into the specified data types and return this type-converted value.

Call syntax

```
<variable name> := <time conversion operator> ( <operand> );

<operand> = <variable name> | <literal>
```

LTIME_TO_UINT
LTIME_TO_ULINT
LTIME_TO_USINT
LTIME_TO_WORD
LTIME_TO_WSTRING
```

Converting to Boolean values

The operator returns `FALSE` if and only if the operand value can be interpreted as "0".

`xTime := TIME_TO_BOOL(T#0MS);`	`xTime = FALSE`
`xLongTime := TIME_TO_BOOL(T#0NS);`	`xLongTime = FALSE`
`xTime := TIME_TO_BOOL(T#1MS);`	`xDate = TRUE`
`xLongTime := TIME_TO_BOOL(T#1NS);`	`xLongTime = TRUE`

Converting to a string

NOTICE!

String manipulation when converting to `STRING` or `WSTRING`

When converting the type to `STRING` or `WSTRING`, the typed value is left-aligned as a character string and truncated if it is too long. Therefore, declare the return variable for the type conversion operators `<>_TO_STRING` and `<>_TO_WSTRING` long enough that the character string has enough space without any manipulation.

`sTime := TIME_TO_STRING(T#0MS);`	`sTime = 'T#0MS'`
`wsLongTime := LTIME_TO_WSTRING(T#0US);`	`wsLongTime = "T#0US"`

Date and Time Conversion

NOTICE!

If the operand value for a type conversion operator is outside of the value range of the target data type, then the result output depends on the processor type and is therefore undefined. This is the case, for example, when a negative operand value is converted from `LREAL` to the target data type `UINT`.

Information can be lost when converting from larger data types to smaller data types.

The operators convert a date and time value into the specified data type and return a type-converted value.

Call syntax

```
<variable name> := <date and time conversion operator> ( <operand> );

<operand> = <variable name> | <literal>
```

The data types `DATE` and `DT` use the same memory format internally and are stored as `DWORD`. The resolution for `DATE` is 1 day. The resolution for `DT` is 1 second. Both begin at January 1, 1970.`TOD` is stored as `DWORD` with a resolution of 1 millisecond.

Converting to a Boolean value

The operator returns `FALSE` if and only if the operand value can be interpreted as "0".

`xDate := DATE_TO_BOOL(D#1970-1-1);`	`xDate = FALSE`
`xDateAndTime := DT_TO_BOOL(DT#1970-1-1-0:0:0);`	`xDateAndTime = FALSE`
`xTimeOfDay := TOD_TO_BOOL(TOD#0:0:0);`	`xTimeOfDay = FALSE`
`xDate := DATE_TO_BOOL(D#2019-9-1);`	`xDate = TRUE`
`xDateAndTime := DT_TO_BOOL(DT#2019-9-1-12:0:0);`	`xDateAndTime = TRUE`
`xTimeOfDay := TOD_TO_BOOL(TOD#12:0:0);`	`xTimeOfDay = TRUE`

Converting to an integer

The data types `DATE` and `DT` use the same memory format internally, namely a `DWORD`. The resolution for `DATE` is 1 day. The resolution for `DT` is 1 second. Both begin at January 1, 1970.

`TOD` is stored as `DWORD` with a resolution of 1 millisecond.

`diReturn_0 := DT_TO_DINT(DT#1970-1-1-0:0:0);`	`diReturn_0 = 0`
`diReturn_1 := DATE_TO_DINT(D#1970-1-1);`	`diReturn_1 = 0`
`diReturn_2 := TOD_TO_DINT(TOD#0:0:0);`	`diReturn_2 = 0`
`diReturn_1 := DT_TO_DINT(DT#1970-1-1-0:0:1);`	`diReturn_3 = 1`
`diReturn_3 := DATE_TO_DINT(D#1970-1-2);`	`diReturn_4 = 86400`
`diReturn_5 := DT_TO_DINT(DT#2019-9-1-12:0:0.0);`	`diReturn_5 = 1567339200`
`diReturn_6 := DATE_TO_DINT(D#2019-9-1);`	`diReturn_6 = 1567339200`
`diReturn_7 := TOD_TO_DINT(TOD#12:0:0);`	`diReturn_7 = 43200000`

Converting to a string

NOTICE!

String manipulation when converting to `STRING` or `WSTRING`

When converting the type to `STRING` or `WSTRING`, the typed value is left-aligned as a character string and truncated if it is too long. Therefore, declare the return variable for the type conversion operators `<>_TO_STRING` and `<>_TO_WSTRING` long enough that the character string has enough space without any manipulation.

The operands of type `DATE`, `DATE_AND_TIME`, `TIME_OF_DAY`, `DT`, or `TOD`, which are passed to an operator for a data and time conversion, are converted to their constant syntax (literal syntax). The generated string contains the keyword `D#`, `DT#` or `TOD#` and then the size with its data and time unit, as indicated in the IEC 61131-3 specification.

Examples

FB_ConvertToWstrings

Device.App_ConvertStrings.PLC_PRG.fbConvertToWstrings

```
1  wstrReturn "255" := BYTE_TO_WSTRING(2#1111_1111);

Operator 'TRUNC'

The IEC operator is used for converting the `REAL` data type into the `DINT` data type. CODESYS takes only the integer part of the number.

> *In CoDeSys V2.3, the `TRUNC` operator converts `REAL` into `INT`. If you import a V2.3 project, then CODESYS automatically replaces `TRUNC` with `TRUNC_INT`.*

If CODESYS cannot represent the input value by a `DINT` or `INT`, then the result of this function is undefined. The behavior of such input values is platform-dependent.

> **NOTICE!**
> If the operand value for a type conversion operator is outside of the value range of the target data type, then the result output depends on the processor type and is therefore undefined. This is the case, for example, when a negative operand value is converted from `LREAL` to the target data type `UINT`.
>
> Information can be lost when converting from larger data types to smaller data types.

Examples

Result in `diVar`: `1`

ST

```
diVar := TRUNC(1.9); (* Result: 1 *)

diVar := TRUNC(-1.4); (* Result: -1 *)
```

See also

- ↳ *"Type conversion operators" on page 545*

Operator 'TRUNC_INT'

The IEC operator is used for converting the `REAL` data type into the `INT` data type. CODESYS takes only the integer part of the number.

> *`TRUNC_INT` corresponds to the `TRUNC` operator in CoDeSys V2.3, and it is used automatically at this point when importing V2.3 projects. Note the change function of `TRUNC`.*

If CODESYS cannot represent the input value by a `DINT` or `INT`, then the result of this function is undefined. The behavior of such input values is platform-dependent.

> **NOTICE!**
> If the operand value for a type conversion operator is outside of the value range of the target data type, then the result output depends on the processor type and is therefore undefined. This is the case, for example, when a negative operand value is converted from `LREAL` to the target data type `UINT`.
>
> Information can be lost when converting from larger data types to smaller data types.

Examples

Result in `iVAR`: `1`

ST:

```
iVar := TRUNC_INT(1.9); (* Result: 1 *)

iVar := TRUNC_INT(-1.4); (* Result: -1 *)
```

See also

- *“Type conversion operators” on page 545*

Operator 'ABS'

This IEC operator yields the absolute value of a number.

Permitted data types for input and output variables and numeric constants: any numeric basic data type

Examples

Result in `i`: `2`

ST:

```
i := ABS(-2);
```

FBD:

Operator 'SQRT'

This IEC of course yields the square root of a number.

Permitted data types for input variables: any numeric basic data type

Permitted data types for output variables: `REAL` or `LREAL`

Examples

Result in `q`: `4`

ST:

```
q := SQRT(16);
```

FBD:

Operator 'LN'

This IEC operator yields the natural logarithm of a number.

Permitted data types for input variables: any numeric basic data type

Permitted data types for output variables: `REAL` and `LREAL`

Examples

Result: `3.80666`

ST:

```
q := LN(45);
```

FBD:

Operator 'LOG'

This IEC operator yields the base-10 logarithm of a number.

The input variable can be any numeric basic data type, but the output variable must be the data type `REAL` or `LREAL`.

Examples

Result in `q`: `2.49762`

ST:

```
q := LOG(314.5);
```

FBD:

Operator 'EXP'

This IEC operator yields the exponential function.

Permitted data types for input variables: any numeric basic data type

Permitted data types for output variables: `REAL` and `LREAL`

Examples

Result in `q`: `7.389056099`

ST:

```
q := EXP(2);
```

FBD:

Operator 'EXPT'

This IEC operator raises a number to a higher power and returns the power of the base raised to the exponent: `power = base`$^{\texttt{exponent}}$. The input values (parameters) are the base and the exponent. The power function is undefined if the base is zero and the exponent is negative. However, the behavior depends on the platform in this case.

Syntax:

```
EXPT(<base>,<exponent>)
```

Permitted data types for the input values: Numeric base data types (`SINT`, `USINT`, `INT`, `UINT`, `DINT`, `UDINT`, `LINT`, `ULINT`, `REAL`, `LREAL`, `BYTE`, `WORD`, `DWORD`, and `LWORD`)

Permitted data types for the return value: Floating-point number types (`REAL` and `LREAL`)

Example

Power function with literals

```
Var1 := EXPT(7,2);
```

FBD:

Return value: `Var1 = 49`

Example

Power function with variables

```
PROGRAM PLC_PRG
VAR
    lrPow : LREAL;
    iBase : INT := 2;
    iExponent : INT := 7;
END_VAR

lrPow := EXPT(iBase, iExponent);
```

Return value: `lrPow = 128`

Operator 'SIN'

The IEC operator yields the sine value of a number.

Permitted data types for input variables that measure the angle in radians: any numeric basic data type

Permitted data types for output variable: `REAL` and `LREAL`

The permitted range for the input value is -2^{63} to $+2^{63}$. On x86 and x64 systems: If the input value is outside of the permitted range, the function returns the input value

Examples

Result in `q`: `0.479426`

ST:

```
q := SIN (0.5);
```

FBD:

Operator 'COS'

The IEC operator yields the cosine value of a number.

Permitted data types for input variables that measure the angle in radians: any numeric basic data type

Permitted data types for output variables: `REAL` and `LREAL`

> *The permitted range for the input value is -2^{63} to $+2^{63}$. On x86 and x64 systems: If the input value is outside of the permitted range, the function returns the input value*

Examples

Result in `q`: `0.877583`

ST:

```
q := COS(0.5);
```

FBD:

Operator 'TAN'

This IEC operator yields the tangent value of a number.

Permitted data types for input variables that measure the angle in radians: any numeric basic data type

Permitted data types for output variables: `REAL` and `LREAL`

Examples

Result in `q`: `0.546302`

ST:

```
q := TAN(0.5);
```

FBD:

Operator 'ASIN'

This IEC operator yields the arcsine value of a number.

Permitted data types for input variables: any numeric basic data type

Permitted data types for output variables: `REAL` and `LREAL`

Examples

Result in q: `0.523599`

ST:

```
q := ASIN(0,5);
```

FBD:

Operator 'ACOS'

This IEC operator yields the arccosine value of a number. The value is computed in radians.

Permitted data types for input variables that measure the angle in radians: any numeric basic data type

Permitted data types for output variables: `REAL` and `LREAL`

Examples

Result in q: 1.0472

ST:

```
q := ACOS(0.5);
```

FBD:

Operator 'ATAN'

This IEC operator yields the arctangent value of a number. The value is computed in radians.

Permitted data types for input variables that measure the angle in radians: any numeric basic data type

Permitted data types for output variables: `REAL` and `LREAL`

Examples

Result in `q`: `0.463648`

ST:

```
q := ATAN(0.5);
```

FBD:

Operator '__DELETE'

This operator is an extension of the IEC 61131-3 standard.

> **NOTICE!**
> For compatibility, the compiler version must be >= 3.3.2.0.

The operator releases the memory of instances that the "__NEW" operator generated dynamically. The `__DELETE` operator does not have a return value and the operand is set to zero after this operation.

Requirement: In the properties dialog of the application, the *"Use dynamic memory allocation"* check box is selected in the *"Application Build Options"* tab.

```
__DELETE (<pointer>)
```

NOTICE!
Two tasks should not call __DELETE simultaneously. Either you use a semaphore (SysSemEnter) or comparable method to prevent any concurrent calling of __DELETE , or you use __DELETE in one tasks only (recommended).

You can use a semaphore (SysSemEnter) to prevent two tasks from allocating memory at the same time. As a consequence, the extensive use of `__DELETE` causes higher jitter.

If `Pointer` references a function block, then CODESYS calls the associated `FB_EXIT` method before the pointer is set to zero.

Examples

```
FUNCTION_BLOCK FBDynamic

VAR_INPUT
  in1, in2 : INT;
END_VAR

VAR_OUTPUT
  out : INT;
END_VAR

VAR
  test1 : INT := 1234;
  _inc : INT := 0;
  _dut : POINTER TO DUT;
  neu : BOOL;
END_VAR

out := in1 + in2;

METHOD FB_Exit : BOOL

VAR_INPUT
  bInCopyCode : BOOL;
END_VAR

__Delete(_dut);

METHOD FB_Init : BOOL

VAR_INPUT
    bInitRetains : BOOL;
    bInCopyCode : BOOL;
END_VAR

_dut := __NEW(DUT);

METHOD INC : INT

VAR_INPUT
END_VAR

_inc := _inc + 1;
INC := _inc;

PLC_PRG(PRG)

VAR
    pFB : POINTER TO FBDynamic;
    bInit: BOOL := TRUE;
    bDelete: BOOL;
    loc : INT;
END_VAR

IF (bInit) THEN
    pFB := __NEW(FBDynamic);
    bInit := FALSE;
END_IF
```

```
IF (pFB <> 0) THEN
    pFB^(in1 := 1, in2 := loc, out => loc);
    pFB^.INC();
END_IF

IF (bDelete) THEN
    __DELETE(pFB);
END_IF
```

Operator '__ISVALIDREF'

This operator is an extension of the IEC 61131-3 standard.

The operator is used for checking whether a reference refers to a valid value. For a description of use and an example, refer to the description for the `REFERENCE` data type.

See also

- ↳ *Chapter 1.4.1.19.5.13 “Reference” on page 658*

Operator '__NEW'

The operator is an extension of the IEC 61131-3 standard.

The `__NEW` operator reserves dynamic memory to instantiate function blocks, user-defined data types, or arrays of standard types. The operator returns a matching typed pointer.

Requirement: In the properties dialog of the parent application, on the *“Application Build Options”* tab, the *“Use dynamic memory allocation”* option is selected.

Syntax

```
<pointer name> := __NEW( <type> ( , <size> )? );
__DELETE( <pointer name> );

<type> : <function block> | <data unit type> | <standard data type>
```

The operator generates an instance of the type `<type>` and returns a pointer to this instance. Then the initialization of the instance is called. If `<type>` is a scalar standard data type, then the optional operand `<size>` is also evaluated. Then the operator generates an array of type `<standard data type>` and size `<size>`. If the attempt to allocate memory fails, then `__NEW` returns the value `0`.

Use the operator within the assignment "`:=`". Otherwise an error message is displayed.

A function block or a user-defined data type whose instance is created dynamically with `__NEW` uses a fixed memory area. Here it is required that you mark the objects with the pragma `{attribute 'enable_dynamic_creation'}`. It is not required for function blocks that are part of a library.

If you change the data layout of the function block in online mode, then you cannot execute a login with an online change afterwards. This is because the memory area of the function block instance has been invalidated. You change the data layout when you add new variables to the function block, delete existing variables, or change the data types of variables.

Example

Array (DWORD):

```
PROGRAM PLC_PRG
VAR
    pdwScalar : POINTER TO DWORD; //Typed pointer
    xInit : BOOL := TRUE;
    xDelete : BOOL;
END_VAR

IF (xInit) THEN
    pdwScalar := __NEW(DWORD, 16); // Allocates memory (16 dwords)
and assigns them to pointer pdwScalar
END_IF
IF (xDelete) THEN
    __DELETE(pdwScalar); // Frees memory of pointer
END_IF
```

Function block:

```
{attribute 'enable_dynamic_creation'}
FUNCTION_BLOCK FBComputeGamma
VAR_INPUT
    iAlpha : INT;
    iBeta : INT;
END_VAR
VAR_OUTPUT
    iGamma : INT;
END_VAR
VAR
END_VAR

iGamma := iAlpha + iBeta;

PROGRAM PLC_PRG
VAR
    pComputeGamma : POINTER TO FBComputeGamma;    // Typed pointer
    xInit : BOOL := TRUE;
    xDelete : BOOL;
    iResult : INT;
END_VAR

IF (xInit) THEN
    pComputeGamma := __NEW(FBComputeGamma); // Allocates memory
    xInit := FALSE;
END_IF
pComputeGamma^.iAlpha := (pComputeGamma^.iAlpha + 1)MOD 100; //
Sets first input of pComputeGamma
pComputeGamma^.iBeta := 10; // Sets second input of pComputeGamma
pComputeGamma^(); // Calls the FB pComputeGamma is pointing to
iResult := pComputeGamma^.iGamma; // Reads output of pComputeGamma
IF (xDelete) THEN
    __DELETE(pComputeGamma); // Frees memory
END_IF
```

User-defined data type (DUT):

```
{attribute 'enable_dynamic_creation'}
TYPE ABCDATA :
STRUCT
        iA, iB, iC, iD : INT;
END_STRUCT
END_TYPE

PROGRAM PLC_PRG
VAR
    pABCData : POINTER TO ABCDATA; // Typed pointer
    xInit : BOOL := TRUE;
```

```
    xDelete : BOOL;
END_VAR

IF (xInit) THEN
    pABCData := __NEW(ABCDATA); // Allocates memory
    xInit := FALSE;
END_IF
IF (xDelete) THEN
    __DELETE(pABCData); // Frees memory
END_IF
```

Array (BYTE):

```
PROGRAM PLC_PRG
VAR
    pbDataAlpha : POINTER TO BYTE;
    pbDataBeta : POINTER TO BYTE;
    xInit : BOOL := TRUE;
    xDelete : BOOL;
    usiCnt : USINT;
    bTestC: BYTE;
END_VAR

IF (xInit) THEN
    pbDataAlpha := __NEW(BYTE, 16); // Allocates 16 bytes for
pbDataAlpha
    pbDataBeta := __NEW(BYTE);  // Allocates memory for pbDataBeta
    xInit := FALSE;

    FOR usiCnt := 0 TO 15 DO
        pbDataAlpha[usiCnt] := usiCnt; // Writes to new array
    END_FOR
    pbDataBeta^:= 16#FF; // Writes to new data
END_IF

bTestC := pbDataAlpha[12];  // Reads new array by index access

IF (xDelete) THEN // Frees memory
    __DELETE(pbDataAlpha);
    __DELETE(pbDataBeta);
END_IF
```

NOTICE!

We do not recommend the simultaneous execution of two tasks that both call the `__NEW` operator. You use either a semaphore (`SysSemEnter`) or a comparable technique to prevent a concurrent call of `__NEW`. However, this results in a higher jitter when `__NEW` is applied extensively.

We recommend that you call `__NEW` operators in one task only.

Operator '__QUERYINTERFACE'

This operator is an extension of the IEC 61131-3 standard.

At runtime, the operator executes a type conversion of an interface reference into another type. The operator returns a `BOOL` result. `TRUE` means that CODESYS has performed the conversion successfully.

```
__QUERYINTERFACE(<ITF_Source>,<ITF_Dest>);
```

1.Operand: Interface reference or FB interface

2.Operand: Interface reference with required target type

The requirement for the explicit conversion is that both the ITF_Source and ITF_Dest are derived from `Interface __System.IQueryInterface`. This interface is implicitly available does not require a library.

Example

```
INTERFACE ItfBase EXTENDS __System.IQueryInterface
METHOD mbase : BOOL
END_METHOD

INTERFACE ItfDerived1 EXTENDS ItfBase
METHOD mderived1 : BOOL
END_METHOD

INTERFACE ItfDerived2 EXTENDS ItfBase
METHOD mderived2 : BOOL
END_METHOD

FUNCTION_BLOCK FB1 IMPLEMENTS ItfDerived1
METHOD mbase : BOOL
    mbase := TRUE;
END_METHOD
METHOD mderived1 : BOOL
    mderived1 := TRUE;
END_METHOD
END_FUNCTION_BLOCK

FUNCTION_BLOCK FB2 IMPLEMENTS ItfDerived2
METHOD mbase : BOOL
    mbase := FALSE;
END_METHOD
METHOD mderived2 : BOOL
    mderived2 := TRUE;
END_METHOD
END_FUNCTION_BLOCK

PROGRAMM POU
VAR
    inst1 : FB1;
    inst2 : FB2;
    itfbase1 : ItfBase := inst1;
    itfbase2 : ItfBase := inst2;
    itfderived1 : ItfDerived1 := 0;
    itfderived2 : ItfDerived2 := 0;
    xResult1, xResult2, xResult3, xResult4: BOOL;
END_VAR

xResult1 := __QUERYINTERFACE(itfbase1, itfderived1); // xResult =
TRUE, itfderivedi1 <>0
                                                     // references
the instance inst1
xResult2 := __QUERYINTERFACE(itfbase1, itfderived2); // xResult =
FALSE, itfderived2 = 0
xResult3 := __QUERYINTERFACE(itfbase2, itfderived1); // xResult =
FALSE, itfderived1 = 0
xResult4 := __QUERYINTERFACE(itfbase2, itfderived2); // xResult =
TRUE, itfderived2 <> 0
                                                     // references
the instance inst2
```

Operator '__QUERYPOINTER'

This operator is an extension of the IEC 61131-3 standard.

At runtime, the operator makes it possible to convert the type of an interface reference of a function block to a pointer. The operator returns a `BOOL` result. `TRUE` means that CODESYS has performed the conversion successfully.

> **NOTICE!**
> For compatibility, the definition of the pointer to be converted must be an extension of the base interface "__SYSTEM.IQueryInterface".

```
__QUERYPOINTER (<ITF_Source>, <Pointer_Dest>)
```

The operator receives an interface reference or a FB instance with the required target types as the first operand and a pointer as the second operand. After processing `__QUERYPOINTER`, Pointer_Dest receives the pointer to the reference or instance of a function block that the ITF_Source interface reference currently refers to. Pointer_Dest is not typed and can be cast to any type. You have to make sure of the type. For example, the interface could offer a method that returns a type code.

Operators '__TRY', '__CATCH', '__FINALLY', '__ENDTRY'

These operators are extended from the IEC 61131-3 standard and they are used for specific exception handling in IEC code.

Syntax

```
__TRY
    <statements_try>
__CATCH(exec)
    <statements_catch>
__FINALLY
    <statements_finally>
__ENDTRY
    <statements_next>
```

When a statement in the `__Try` operator throws an exception, the application does not stop. Instead, the application executes the statements in `__Catch`, starts the exception handling, and then executes the statements in `__FINALLY`. The exception handling ends with `__ENDTRY`, and the application executes the subsequent statements.

An IEC variable for an exception has the data type `__System.ExceptionCode`.

Example

If the statement in `__TRY` throws an exception, then program execution is not stopped. Instead, the statement in `__CATCH` is executed. Therefore, in this example, the application executes the `exc` function, then the statement in `__FINALLY`, and finally the statement in `__ENDTRY`.

```
FUNCTION Tester : UDINT
VAR_INPUT
    count : UDINT;
END_VAR
VAR_OUTPUT
    strExceptionText : STRING;
END_VAR
VAR
    exc : __SYSTEM.ExceptionCode;
END_VAR

__TRY
Tester := tryFun(count := count, testcase := g_testcase);  // This
statement is tested. If it throws an exception, then the statement
in __CATCH is executed first, and then the statement in __FINALLY.
__CATCH(exc)
HandleException(exc, strExceptionText => strExceptionText);
__FINALLY
GVL.g_count := GVL.g_count + 2;
__ENDTRY
```

RTSEXCPT_USER_EXCEPTION_BASE            := 16#00010000
) UDINT ;
END_TYPE
```

Operator '__VARINFO'

This operator is an extension of the IEC 61131-3 standard.

The operator yields information about a variable. You can save the information as data structure in a variable of data type `__SYSTEM.VAR_INFO`.

Syntax in the declaration:

```
<name of the info variable> : __SYSTEM.VAR_INFO; // Data structure
for info variable
```

Syntax for the call:

```
<name of the info variable> := __VARINFO( <variable name> ); // Call
of the operator
```

Example

```
FUNCTION_BLOCK FB_Velocity
VAR_INPUT
    rVelocity: REAL := 1.2;
END_VAR
VAR_OUTPUT
END_VAR
VAR
    infoVelocity: __SYSTEM.VAR_INFO; //Info of Velocity
END_VAR

infoVelocity := __VARINFO(rVelocity); // Gets the info of Velocity
locally

PROGRAM PLC_PRG
VAR
    iCounter : INT := 0; // Counts the calls
    infoCounter : __SYSTEM.VAR_INFO; //Info of Counter
    arrA : ARRAY [1..2, 1..2, 1..2] OF INT := [0, 1, 2, 3, 4, 5, 6,
7]; // Stores the A data
    infoA : __SYSTEM.VAR_INFO; //Info of A
    fbVel : FB_Velocity;
END_VAR

iCounter := iCounter + 1;
infoCounter := __VARINFO(iCounter);
infoA := __VARINFO(arrA);
fbVel();
```

The `iCounter` and `arrA` variables are recognized in the application code. The variable information is saved in the `infoCounter` and `infoA` variables. Moreover, the `FB_Velocity` function block is instantiated.

Data type `__SYSTEM.VAR_INFO`

Name	Data type	Initialization	Description
`ByteAddress`	`DWORD`	0	Address of the variable Example: `16#072E35EC` Note: For bit access of a variable `<variable name>.<bit index>`, the address of the variable that contains the bit is given.
`ByteOffset`	`DWORD`	0	Offset of the variable address (in bytes). Example: `13936` bytes. Note: If the variable is global, then the offset is relative to the beginning of the area. If the variable is a local variable in a function or method, then the offset is relative to the current stack frame. If the variable is a local variable in a function block, then the offset is relative to the function block instance.

Name	Data type	Initialization	Description
Area	DINT	0	Memory area number Area in the runtime system. Example: -1: Means that the variable is not global in the memory, but relative to an instance or on the stack. Note: The memory areas are device-dependent.
BitNr	INT	0	Number of bits (in bytes) Example: 16#00FF bytes Note: If the variable is **not** an integer data type, then: BitNr = -1 = 16#FFFF.
BitSize	INT	0	Memory size of the variable (in bits) Example: 16 bits
BitAddress	UDINT	0	Bit address of the variable Requirement: The variable is located in the input memory area I, output memory area Q, or marker memory area M. Otherwise the value is undefined.
TypeClass	TYPE_CLASS	TYPE_BOOL	Data type class of the variable Example: TYPE_INT, TYPE_ARRAY Note: For user-defined data types or function block instances, TYPE_USERDEF is output as the data type class.
TypeName	STRING(79)	''	Date type name of the variable as STRING(79) Note: For user-defined data types, the function block name or the DUT name is output. Example: 'INT', 'ARRAY'
NumElements	UDINT	0	Number of array elements Requirement: The variable has the data type ARRAY. Example: 8
BaseTypeClass	TYPE_CLASS	TYPE_BOOL	Elementary basic data type of the array elements. Requirement: The variable has the data type ARRAY. Example: TYPE_INT for arrA : ARRAY [1..2,1..2,1..2] OF INT;
ElemBitSize	UDINT	0	Memory size of the array element (in bits) Requirement: The variable has the data type ARRAY. Example: 16 bits for arrA : ARRAY [1..2,1..2,1..2] OF INT;

Name	Data type	Initialization	Description
MemoryArea	MEMORY_AREA	MEM_MEMORY	Information about the memory area ● MEM_GLOBAL: Global memory area For example in Area 0 ● MEM_LOCAL: Local memory area in Area -1 ● MEM_MEMORY: Marker memory area %M For example in 16#10 in Area 1 ● MEM_INPUT: Input memory area %I For example in 16#04 in Area 2 ● MEM_OUTPUT: Output memory area %Q For example in 16#08 in Area 3 ● MEM_RETAIN: Retain memory area For example in 16#20 in Area 0 Example: MEM_GLOBAL Note: The memory area configuration is device-dependent.
Symbol	STRING(39)	"	Variable name as STRING(39) Example: 'iCounter', 'arrA'
Comment	STRING(79)	"	Comment of the variable declaration Example: 'Counts the calls' or 'Stores the A data'

Operator '__CURRENTTASK'

This operator is an extension of the IEC 61131-3 standard.

In runtime mode, the operator provides information about the IEC task that is currently running.

The operator is supported only on target systems in which the target system setting `memory-layout\max-stack-size` is set to a value > 0.

The operator allows for access to a structure with two variables:

- TaskIndex: Zero-based index that identifies the task
- pTaskInfo: Detailed information about the currently running task. It can be assigned to a POINTER TO Task_Info2 from the library CmpIecTask.

The operator cannot be used in the declaration of a POU. This would result in an error message. If the current task cannot be determined, then the TaskIndex -1 and the pTaskInfo are zero.

Example

```
//Declaration
VAR
    idx : INT;
    pInfo : POINTER TO Task_Info2;
END_VAR

//Program code

idx := __CURRENTTASK.TaskIndex;
pInfo := __CURRENTTASK.pTaskInfo;
```

Operator '__COMPARE_AND_SWAP

The multicore operator is an extension of the IEC 61131-3 standard.

The operator can be used for implementing a semaphore, for example to guarantee exclusive access to a variable written to by different tasks.

`__COMPARE_AND_SWAP` gets a pointer to a data type `__XWORD` variable, an old value, and a new value as its input (example: `bMutex := __COMPARE_AND_SWAP(ADR(dwSynch), dwOld, dwNew);`). The old and new values can also be data type `__XWORD` variables. The referenced `__XWORD` variable is compared with the old value and if both are equal, then the new value is written. The result of the function is `TRUE` when the new value could be written.

The compiler automatically replaces the data type `__XWORD` with `DWORD` on 32-bit systems and `LWORD` on 64-bit systems.

This operation is atomic, so it cannot be interrupted by another task, even on multicore platforms.

Example

The following example shows a typical usage. Exclusive access to a type `STRING` variable, which is addressed via the `pstrOutput` pointer, should be implemented.

The access to a string is not atomic. If multiple tasks write to the same string at the same time, then the contents may be inconsistent.

With this function, it is now possible to write the same STRING variable in different tasks.

```
FUNCTION ExclusiveStringWrite : BOOL
VAR_INPUT
    strToWrite : STRING;
    pstrOutput : POINTER TO STRING;
END_VAR
VAR_STAT
  dwSynch : __XWORD;
END_VAR
VAR
    bMutex: BOOL;
END_VAR

bMutex:= __COMPARE_AND_SWAP(ADR(dwSynch), 0, 1);
(* compare with 0 and write 1 as atomic operation *)
IF bMutex THEN                          // bMutex is TRUE if write
could be done
    pstrOutput^ := strToWrite;          // Now you can write safely
on the string
    dwSynch := 0;                       // The __XWORD variable must
be reset.
    ExclusiveStringWrite := TRUE;          // Writing was successful
ELSE
    ExclusiveStringWrite := FALSE;      // Writing was not successful
END_IF
```

- *“Multicore operators” on page 546*
- *Chapter 1.4.1.19.3.68 “Operator 'TEST_AND_SET'” on page 628*

Operator '__XADD'

The multicore operator is an extension of the IEC 61131-3 standard.

The operator can be used for implementing an atomic counter. If an integer variable is incremented by means of ordinary addition, for example `iTest := iTest + 1;`, then this operation is not executed atomically. Another access to the variable could take place between reading and writing the variable.

If the counter is incremented in multiple tasks, then the counter result can be less than the number of counting cycles. So if two tasks execute the above code one time and the variable previously had the value `0`, then the variable can then have the value `1`. This is especially problematic if arrays are being processed in multiple tasks and a unique index is required for the array in each processing cycle.

When the `__XADD` operator is called, it gets a pointer to a type `DINT` variable as the first summand and a type `DINT` value as the second summand. `__XADD` returns the old value of the first summand and in the same step adds the second summand to the first summand.

For example, the function call can look like this: `diOld := __XADD(ADR(diVar), deAdd);`

Example

The following example shows a typical usage. An array should be populated from two tasks. In the process, all positions in the array should be used and no position should be overwritten.

With this function, multiple tasks can populate a Boolean array.

```
FUNCTION WriteToNextArrayPosition : BOOL
VAR_EXTERNAL
    g_diIndex : DINT;  // Index and array are globally defined and
used by multiple tasks
    g_boolArray : ARRAY [0..1000] OF BOOL;
END_VAR
VAR_INPUT
    bToWrite : BOOL;
END_VAR
VAR
    diIndex : DWORD;
END_VAR

diIndex := __XADD(ADR(g_diIndex), 1);        // Returns a unique
index
WriteToNextArrayPosition := FALSE;
IF (diIndex >= 0 AND diIndex <= 1000) THEN
    g_boolArray[diIndex] := bToWrite;         //Writes to unique
index
    WriteToNextArrayPosition := TRUE;         // TRUE: Array was
not full yet
END_IF
```

See also

- *“Multicore operators” on page 546*

Operator '__POSITION'

The operator is an extension of the IEC 61131-1 standard.

At runtime, the operator yields the position of a variable in the declaration part or in the implementation part of a POU. The operator has to be assigned the variables of type `STRING` in the declaration part or in the implementation part.

Result of `__POSITION`

- Declaration part: `'Line <line number> (Decl)'`
- Implementation part: `'Line <line number>, Column <column number> (Impl)'`

Example

```
PROGRAM PROG1
VAR
    strPOS : STRING := __POSITION();  //Yields the line number of
this declaration
    strlocalPOS : STRING;
END_VAR

    strlocalPOS := __POSITION();      //Yields the line and column
number of this assignment
```

Operator '__POUNAME'

The operator is an extension of the IEC 61131-1 standard.

At runtime, the operator yields the name of the POU that contains the operator `__POUNAME`. The result is of type `STRING`.

The result of `__POUNAME` depends where it is used:

- In a program: program name
- In a function name: function name
- In a function block: function block name
- In a method: the method name qualified with the FB name
- In a Get/Set accessor of a property: the property name + Get/Set qualified with the FB name
- In a GVL: GVL name
- In a structure: structure name
- In a data structure `UNION`: union name

Example

```
PROGRAM PROG1
VAR
    strPOU : STRING := __POUNAME();  //Yields 'PROG1'
    strlocalPOU : STRING;
END_VAR

    strlocalPOU := __POUNAME();     //Yields 'PROG1'
```

Operator 'TEST_AND_SET'

The multicore operator is an extension of the IEC 61131-3 standard.

The operator can be used for implementing a semaphore, for example to guarantee exclusive access to a variable written to by different tasks.

`TEST_AND_SET` gets a type `DWORD` variable as its input. Write access to this variable must be possible. The variable is set to `1` and the previous value is returned as the result.

The operation is atomic, which means that it cannot be interrupted by another task. This also applies to multicore platforms.

For example, the call in the program is `dwOldValue := TEST_AND_SET(dw);`, in which the variables `dwOldValue` and `dw` must be of data type `DWORD`.

Example

The following example shows a typical usage. Exclusive access to a type `STRING` variable, which is addressed via the `pstrOutput` pointer, should be implemented. The access to a string is not atomic. If multiple tasks write to the same string at the same time, then the contents may be inconsistent. With the `TEST_AND_SET` function, it is now possible to write the same `STRING` variable in different tasks.

```
FUNCTION ExclusiveStringWrite : BOOL
VAR_INPUT
    strToWrite : STRING;
    pstrOutput : POINTER TO STRING;
END_VAR
VAR_STAT
    dwSynch : DWORD;
END_VAR
VAR
    dwOldValue: DWORD;
END_VAR

dwOldValue := TEST_AND_SET(dwSynch);  // Write the 1 and read the
old value at the same time
IF dwOldValue = 0 THEN                // 0 means: no other task is
currently writing
   pstrOutput^ := strToWrite;         // Now you can write safely
on the string
   dwSynch := 0;                      // The DWORD must be reset
   ExclusiveStringWrite := TRUE;      // Writing was successful
ELSE
   ExclusiveStringWrite := FALSE;     // Writing was not successful
```

Operator - Global namespace

This operator is an extension of the IEC 61131-3 standard.

An instance path that begins with a dot (`.`) always opens a global namespace. If there is a local variable that has the same name `<varname>` as a global variable, then you refer to the global variable as `.<varname>`.

Operator - Namespace for global variables lists

This operator is an extension of the IEC 61131-3 standard.

You can use the name of a global variables list (GVL) as a namespace identifier for the variables that are defined in the list. This makes is possible to use variables with the same name in different global variables lists and still access specific variables uniquely. You use a dot (`.`) to prepend the name of the global variables list to the variable name.

```
<global variable list name>.<variable>
```

Example

```
globlist1.varx := globlist2.varx;
```

The `globlist1` and `globlist2` global variables lists each contain a `varx` variable. CODESYS copies the `varx` global variable from the `globlist2` list to `varx` in the `globlist1` list.

If you reference a variable that is declared in several global variables lists without referencing the prepended list name, then an error message is printed.

Operator - Library namespace

This operator is an extension of the IEC 61131-3 standard.

Syntax: `<library namespace>.<library identifier>`

Example: `LIB_A.FB_A`

A library module identifier is appended with the library namespace (as a prefix separated by a dot) for unique and qualified access to the library module. The namespace usually coincides with the library name.

Example

A library is included in a project and contains the module `FB_A`. However, the function block with the same name is already available locally in the project. Identify the library module as `LIB_A.FB_A` in order to access the library module, not the local function block.

```
var1 := FB_A(in := 12); // Call of the project function FB_A
var2 := LIB_A.FB_A(in := 22); // Call of the library function FB_A
```

You can define another identifier for the namespace. To do this, specify a namespace in the project information (library developers: when creating a library project). As an alternative, you can specify a specific namespace for a library in the library manager in the *“Properties”* dialog box (application developers: when creating an application).

- *Chapter 1.4.1.20.2.14 “Object 'Library Manager'” on page 874*

Operator - Enumeration namespace

This operator is an extension of the IEC 61131-3 standard.

You can use the TYPE name of an enumeration for unique access to an enumeration constant. In this way, you can use the same constant names in different enumerations.

The enumeration name is prepended to the constant name with a dot (`.`).

`<enumeration name>.<constant name>`

Example

The constant `Blue` is a component of both the enumeration `Colors` and the enumeration `Feelings`.

```
color := Colors.Blue;  // Access to component blue in enumeration
Colors

feeling := Feelings.Blue; // Access to component blue in
enumeration Feelings
```

Operator '__POOL'

The operator is an extension of the IEC 61131-3 standard.

The operator is used to reference objects which are managed in the global POU pool (in the *“POUs”* view). The operator directly accesses objects in the *“POUs”* view.

Example

```
PROGRAM PLC_PRG
VAR
    svar_pou : STRING;
END_VAR

svar_pou := __POOL.POU();
```

See also

- *Chapter 1.4.1.19.8 “Shadowing Rules” on page 745*

Operator 'INI'

> *The `INI` operator is a CoDeSys V2.3 operator. In CODESYS V3, the `FB_init` method replaces the `INI` operator. You can still use this operator in projects that are imported from CoDeSys V2.3.*

The `INI` operator is used for initializing retain variables of a function block instance used in a POU.

Assign the operator to a Boolean variable.

Syntax:

```
<Boolean variable name> := INI <FB instance name> , <Boolean value> );
<Boolean value> : TRUE | FALSE
```

If the second parameter of the operator yields `TRUE`, then CODESYS initializes all retain variables that are defined in the function block `<FB instance name>`.

Examples

`fbinst` is the instance of the function block `fb1`, where the retain variable `retvar` is defined.

ST:

```
Declaration in the block:

VAR
    fbinst : fb1;
    b : BOOL;
END_VAR

Program part:

b := INI(fbinst, TRUE);
ivar := fbinst.retvar; (* => retvar is initialized *)
```

FBD

1.4.1.19.4 Operands

Constants and literals

Constants are identifiers for unchangeable values. You can declare constants locally within a POU or globally within a global variable list. The declaration segment is extended with the keyword `CONSTANT`.

Constants are also character strings that represent the value of a base type, such as integers or floating-point numbers (for example, `16#FFFF_FFFF`, `T#5s`, or `-1.234 E-5`). To distinguish between them, these constants are also called literals, literal constants, or unnamed constants. There are logical (`TRUE`, `FALSE`) or numeric literals (`3.1415`, `T#5s`), but also character string literals (`'Hello world!'`, `"black"`).

Syntax declaration

```
<scope> CONSTANT
    <identifier> : <data type> := <initial value> ;
END_VAR

<scope> : VAR | VAR_INPUT | VAR_STAT | VAR_GLOBAL
<data type>: <elementary data type | user defined data type |
function block >
<initial value> : literal value | identifier | expression
```

Allowed initial values:

- Literal (example: `TRUE`, `FALSE`, `16#FFFF_FFFF`)
- Named constant that was declared at another location
- Simple expression composed of literals, also combined with simple operators, such as + - *

Inputs or function calls cannot be specified as an initial value.

Example

```
VAR_GLOBAL CONSTANT
    g_ciMAX_A : INT := 100;
    g_ciSPECIAL : INT := g_ciMAX_A - 10;
END_VAR
```

Constants are defined only for the declaration. The assignment of an initial value is required. Within an implementation, constants are only read and therefore always appear on the right of the assignment operator in a statement.

The constants are replaced with the initial value when the code is compiled. It also has to be possible to calculate the initial value at compile time.

Constants of structured or user-defined types are calculated not until runtime. Structured constants in programs or GVLs are calculated one time at program start. Structured constants in functions or methods are calculated every time the function or method is called. Therefore, the initialization of structured constants can depend on inputs or execute function calls.

Variables

You can declare variables as either local in the declaration part of a POU or in a global variable list. The allowed location of a variable depends on its data type.

See also

- *Chapter 1.4.1.19.2.11 “Constant Variables - 'CONSTANT'” on page 534*
- *Chapter 1.4.1.19.1.3.3 “ST expressions” on page 464*

BOOL constants

BOOL constants are the truth values `TRUE` (1) and `FALSE` (0).

See also

- *Chapter 1.4.1.19.5.1 “Data type 'BOOL'” on page 647*

Numeric constants

Numeric values can be binary, octal, decimal, and hexadecimal numbers. If an integer value is not a decimal number, then you must write its base followed by the number sign (#) before the integer constant. You enter the hexadecimal digit values for the numbers 10 to 15 as usual with the letters A-F.

You can use an underscore within a numeric value.

Examples:

`14`	decimal number
`2#1001_0011`	binary number
`8#67`	octal number
`16#A`	hexadecimal number
`DINT#16#A1`	typed data type `DINT#` and base `16#` combined

This type of numeric value can be `BYTE`, `WORD`, `DWORD`, `SINT`, `USINT`, `INT`, `UINT`, `DINT`, `UDINT`, `REAL`, or `LREAL`.

Implicit conversions from "larger" to "smaller" types are not permitted. You cannot simply use a DINT variable as an INT variable. For this, you have to use a type conversion function.

See also

- *Chapter 1.4.1.19.3 “Operators” on page 542*
- *Chapter 1.4.1.19.4.7 “Typed literals” on page 640*

As number constants basically are treated as integers, in divisions you must enter a constant in the format of a floating-point number in order not to loose the remainder. For example: Division `1/10` results in `0`, division `1.0/10` results in `0.1`.

REAL/LREAL constants

You can specify floating-point numbers as `REAL` and `LREAL` constants either in decimal notation or exponential notation with mantissa and exponent The decimal point serves as the decimal separator according to the International System of Units (English).

Syntax of exponential notation

```
<significand> e | E <exponent>

exponent : -44..38 // REAL
exponent : -324..308 // LREAL
```

Example

Table 38: `REAL` literal

7.4	Decimal number. 7,4 with a comma returns a compiler error
1/3.0	Decimal fraction for 0.333333343 Note: In the case of division of integer types, the result remains an integer type. In this case, the value is rounded. For example, 1/3 yields 0 as the result.
1.64e+009	Exponential notation
-3.402823e+38	Smallest number
-1E-44	Largest negative number
1.0E-44	Smallest positive number
3.402823e+38	Largest number

Table 39: `LREAL` literal

-1.7976931348623157E+308	Smallest number
-4.94065645841247E-324	Largest negative number
4.94065645841247E-324	Smallest positive number
1.7976931348623157E+308	Largest number

See also

- *Chapter 1.4.1.19.5.3 “Data type 'REAL' / 'LREAL'” on page 648*

String Constants

A string constant is a character string enclosed in single straight quotation marks. The characters are coded according to the character set specified in ISO/IEC 8859-1. Therefore, a string constant can include spaces and accented characters, as these belong to this character set. This is also referred to as a string literal, or simply a string.

Example: `'Hello world!'`

When a dollar sign ($) is in a string constant, the following two characters are interpreted as a hexadecimal code according to the coding in ISO/IEC 8859-1. The code also corresponds to ASCII code. In addition, please note the special cases.

Table 40: Hexadecimal code

String with $ code	Interpretation
`'$<8-bit code>'`	8-bit code: Two-digit hexadecimal number that is interpreted according to ISO/IEC 8859-1.
`'$41'`	A
`'$A9'`	©
`'$40'`	@
`'$0D'`	Control character: Line break (corresponds to '$R')
`'$0A'`	Control character: New line (corresponds to '$L' and '$N')

Table 41: Special cases

String with $ code	Interpretation
`'$L','$l'`	Control character: Line feed (corresponds to `'$0A'`)
`'$N','$n'`	Control character: New line (corresponds to `'$0A'`)
`'$P','$p'`	Control character: Form feed
`'$R','$r'`	Control character: Line break (corresponds to `'$0D'`)
`'$T','$t'`	Control character: Tab
`'$$'`	Dollar sign: $
`'$''`	Single straight quotation mark: '

Example Constant declaration

```
VAR CONSTANT
    constA : STRING := 'Hello world';
    constB : STRING := 'Hello world $21'; // Hello world!
END_VAR
```

TIME/LTIME Constant

You can use `TIME` constants to operate the standard timer modules. The constant has a size of 32 bits and a resolution in milliseconds.

In addition, the time constant `LTIME` is available as a time basis for high-resolution timers. The `LTIME` constant has a dimension of 64 bits and a resolution in nanoseconds.

TIME constant

Syntax

```
<time keyword> # <length of time>

<time keyword> : TIME | time | T | t
<length of time> : ( <number of days>d )? ( <number of hours>h )?
( <number of minutes>m )? ( <number of seconds>s )? (<number of
milliseconds>ms)? // ( ...)? Optional
```

The order of time units must not be changed. However, it is not required to specify all units. It is permitted to specify the units in uppercase.

Time units

- `D | d`: Days
- `H | h`: Hours
- `M | m`: Minutes
- `s | s`: Seconds
- `MS | ms`: Milliseconds

Examples

Correct time constants of an ST assignment

```
VAR
    timLength : TIME := T#14ms;
    timLength1 : TIME := T#100s12ms; // Overflow in the highest
unit is allowed.
    timLength2 : TIME := T#12h34m15s;
    timCompare : TIME;
    xIsOK: BOOL;

    timLongest := T#49D17H2M47S295MS; // 4294967295
END_VAR

IF timLength < T#15MS THEN
    IF timCompare < timLength1 THEN
        xIsOK := TRUE;
    END_IF;
END_IF
```

Table 42: Incorrect usage:

`timIncorrect := t#5m68s;`	Overflow at a lower position
`timIncorrect1 := 15ms;`	Time marker `T#` missing
`timIncorrect2 := t#4ms13d;`	Incorrect order of time units

LTIME constant

Syntax

```
<long time keyword> # <length of high resolution time>

<long time keyword> : LTIME | ltime
<length of high resolution time> : <length of time> ( <number of
microseconds>us )?  ( <number of nanoseconds>ns )? // ( ...)? Optional
```

You can use the same units for `LTIME` constants as for `TIME` constants. You can also specify microseconds and nanoseconds because the specified time is calculated in higher time resolution. `LTIME` literals are treated internally as data type `LWORD` and therefore the value resolved in nanoseconds.

Additional time units

- `US | us`: Microseconds
- `NS | ns`: Nanoseconds

Examples of correct usage of an ST assignment:

```
PROGRAM PLC_PRG
VAR
    ltimLength := LTIME#1000d15h23m12s34ms2us44ns;
    ltimLength1 := LTIME#3445343m3424732874823ns;
END_VAR
```

See also

- *Chapter 1.4.1.19.5.5 “Data Type 'TIME'” on page 649*
- *Chapter 1.4.1.19.4.6 “Date and Time Constants” on page 637*

Date and Time Constants

32-bit date specifications 'DATE'

Use the keyword `DATE` (`D`) to specify a date.

Syntax

```
<date keyword>#<year>-<month>-<day>

<date keyword> : DATE | date | D | d
<year> : 1970-2106
<month> : 1-12
<day> : 1-31
```

`DATE` literals are treated internally as data type `DWORD`, which corresponds to an upper limit of `DATE#2106-2-7`.

Example

```
PROGRAM PRG_Date
VAR
    dateStart : DATE := DATE#2018-8-8;
    dateEnd : DATE := D#2018-8-31;
    dateCompare: DATE := date#1996-05-06;
    xIsDuringTheTime: BOOL;

    dateEarliest : DATE := d#1970-1-1; // = 0
    dateLatest : DATE := DATE#2106-2-7; // = 4294967295
END_VAR

IF dateStart < dateCompare THEN
    IF dateCompare < dateEnd THEN
        xIsDuringTheTime := TRUE;
    END_IF;
END_IF
```

64-bit date specifications 'LDATE'

Use the keyword `LDATE` (`LD`) to specify a date.

Syntax

```
<date keyword>#<year>-<month>-<day>

<date keyword> : LDATE | ldate | LD | ld
<year> : 1970-2262
<month> : 1-12
<day> : 1-31
```

`LDATE` literals are treated internally as data type `LWORD`, which corresponds to an upper limit of `DATE#2554-7-21`.

Example

```
PROGRAM PRG_Ldate
VAR
    ldateStart : LDATE := LDATE#2018-8-8;
    ldateEnd : LDATE := ldate#2018-8-31;
    ldateCompare: LDATE := LD#1996-05-06;
    xIsDuringTheTime: BOOL;

    ldateEarliest : LDATE := ld#1970-1-1; // = 0
    ldateLatest : LDATE := LDATE#2262-4-10; // = 16#7FFF63888C620000

    lwValue: LWORD;
END_VAR

IF ldateStart < ldateCompare THEN
    IF ldateCompare < ldateEnd THEN
        xIsDuringTheTime := TRUE;
    END_IF;
END_IF
lwValue := LDATE_TO_LWORD(ldateCompare);
```

32-bit date and time specifications 'DATE_AND_TIME'

Use the keyword `DATE_AND_TIME` (`DT`) to specify a date and time.

Syntax

```
<date and time keyword>#<date and time value>

<date and time keyword> : DATE_AND_TIME | date_and_time | DT | dt
<date and time value> : <year>-<month>-<day>-<hour>:<minute>:<second>
<year> : 1970-2106
<month> : 1-12
<day> : 1-31
<hour> : 0-24
<minute> : 0-59
<second> : 0-59
```

`DATE_AND_TIME` literals are treated internally as data type `DWORD`. The time is processed in seconds and as a result can take on values from January 1, 1970 00:00 to February 7, 2106 06:28:15.

Example

```
PROGRAM PLC_PRG
VAR
    dtDate : DATE_AND_TIME := DATE_AND_TIME#1996-05-06-15:36:30;
    dtDate1: DATE_AND_TIME := DT#1972-03-29-00:00:00;
    dtDate2: DATE_AND_TIME := DT#2018-08-08-13:33:20.5;

    dtEarliest : DATE_AND_TIME :=
DATE_AND_TIME#1979-1-1-00:00:00; // 0
    dtLatest : DATE_AND_TIME := DATE_AND_TIME#2106-2-7-6:28:15; //
4294967295
END_VAR
```

64-bit date and time specifications 'LDATE_AND_TIME'

Use the keyword `LDATE_AND_TIME` (`LDT`) to specify a date and time.

Syntax

```
<date and time keyword>#<long date and time value>

<date and time keyword> : LDATE_AND_TIME | ldate_and_time | LDT | ldt
<date and time value> : <year>-<month>-<day>-<hour>:<minute>:<second>
<year> : 1970-2106
<month> : 1-12
<day> : 1-31
<hour> : 0-24
<minute> : 0-59
<second> : 0-59 LDATE_AND_TIME#2262-4-10-23:59:59.99999999
```

`DATE_AND_TIME` literals are treated internally as data type `LWORD`. The time is processed in seconds and as a result can take on values from January 1, 1970 00:00 to July 21, 2554 23:59:59.999999999.

Example

```
PROGRAM PLC_PRG
VAR
    ldtDate : LDATE_AND_TIME := LDATE_AND_TIME#1996-05-06-15:36:30;
    ldtDate1: LDATE_AND_TIME := LDT#1972-03-29-00:00:00;
    ldtDate2: LDATE_AND_TIME := LDT#2018-08-08-13:33:20.5;

    dtEarliest : LDT := LDT#1979-1-1-00:00:00; // 0
    dtLatest : LDT := LDT#2266-4-10-23:59:59; // =
16#7FFF63888C620000
END_VAR
```

32-bit time specifications 'TIME_OF_DAY'

Use the keyword `TIME_OF_DAY` (`TOD`) to specify a time.

Syntax

```
<time keyword>#<time value>

<time keyword> : TIME_OF_DAY | time_of_day | TOD | tod
<time value> : <hour>:<minute>:<second>
<hour> : 0-23
<minute> : 0-59
<second> : 0.000-59.999
```

You can also specify fractions of a second. `TIME_OF_DAY` literals are treated internally as `DWORD` and the value is resolved in milliseconds.

Examples

```
PROGRAM POU
VAR
    todClockTime : TIME_OF_DAY :=  TIME_OF_DAY#15:36:30.123;
    todEarliest : TIME_OF_DAY := TIME_OF_DAY#0:0:0.000;
    todLatest : TOD := TOD#23:59:59.999;
END_VAR
```

64-bit time specifications 'LTIME_OF_DAY'

Use the keyword `LTIME_OF_DAY` (`LTOD`) to specify a time.

Syntax

```
<time keyword>#<time value>

<time keyword> : LTIME_OF_DAY | ltime_of_day | LTOD | ltod
<time value> : <hour>:<minute>:<second>
<hour> : 0-23
<minute> : 0-59
<second> : 0.000-59.999999999
```

You can also specify fractions of a second. `LTIME_OF_DAY` literals are treated internally as `LWORD` and the value is resolved in nanoseconds.

Examples

```
PROGRAM POU
VAR
    ltodClockTime : LTIME_OF_DAY :=  TIME_OF_DAY#15:36:30.123456789;
    todEarliest : TIME_OF_DAY := TIME_OF_DAY#0:0:0;
    todLatest : TOD := TOD#23:59:59.999999999;
END_VAR
```

Typed literals

With the exception of REAL/LREAL constants (LREAL is always used here), CODESYS uses the smallest possible data type when calculating with IEC constants. If you want to use another data type, then you can use typed literals without having to declare the constants explicitly. When doing this, provide the constants with a prefix that indicates the type.

Syntax:

```
<type>#<literal>
```

<type> defines the desired data type; possible values: BOOL, SINT, USINT, BYTE, INT, UINT, WORD, DINT, UDINT, DWORD, REAL, LREAL. You must capitalize the entire type name.

<literal> defines the constants. The entry must match the data type defined in <Type>.

Example:

```
var1 := DINT#34;
```

If CODESYS cannot convert the constant into the target type without data loss, then an error message is issued.

You can use typed constants wherever you can use normal constants.

Access to Variables in Arrays, Structures, and Blocks

Syntax for access to

- Two-dimensional array component: <array name> [<1st dimension> , <2nd dimension>]
- Structural variable: <structure name> . <component name>
- Function block and program variable: <function block name> | <program name> . <variable name>

See also

- *Chapter 1.4.1.19.5.14 “Data Type 'ARRAY'” on page 660*
- *Chapter 1.4.1.19.5.16 “Structure” on page 674*
- *Chapter 1.4.1.20.2.18.2 “Object 'Function Block'” on page 883*
- *Chapter 1.4.1.20.2.18.1 “Object 'Program'” on page 882*

Bit Access in Variables

NOTICE!

Implement concurrent bit access by two tasks only if the processor can execute bit access directly on the memory. All x86 and x64 systems have commands for bit access in memory. Systems such as ARM and PPC cannot access bits directly in the memory.

If two tasks execute bit access simultaneously, even though the processor cannot perform bit access directly in the memory, then proceed as follows. Use a semaphore (SysSemEnter) or a similar technique to prevent competing bit access. However, it is best to execute the bit access within a task.

With index access, individual bits can be addressed in integer variables. Using a structure variable or a function block instance, individual bits can be addressed symbolically.

Index access to bits integer variables

You can address individual bits in integer variables. To do this, append the variable with a dot and the index of the addressed bit. The bit-index can be given by any constant. Indexing is 0-based.

Syntax

```
<integer variable name> . <index>
<integer data type> = BYTE | WORD | DWORD | LWORD | SINT | USINT |
INT | UINT | DINT | UDINT | LINT | ULINT
```

Example

In the program, the third bit of the variable `wA` is set to the value of variable `xB`. The constant `c_usiENABLE` acts as an index to access the third bit of the variable `iX`.

Index access

```
PROGRAM PLC_PRG
VAR
    wA : WORD := 16#FFFF;
    xB : BOOL := 0;
END_VAR

// Index access in an integer variable
wA.2 := xB;
```

Result: `wA = 2#1111_1111_1111_1011 = 16#FFFB`

Constant as index

```
// GVL declaration
VAR_GLOBAL CONSTANT
    gc_usiENABLE : USINT := 2;
END_VAR

PROGRAM PLC_PRG
VAR
    iX : INT := 0;
END_VAR

// Constant as index
iX.gc_usiENABLE :=  TRUE;     // Third bit in iX is set TRUE
```

Result: `iX = 4`

Symbolic bit access in structure variables

With the `BIT` data type, you can combine individual bits into a structure and then access them individually. Then the bit is addressed with the component name.

Example

Type declaration of the structure:

```
TYPE S_CONTROLLER :
STRUCT
    bitOperationEnabled : BIT;
    bitSwitchOnActive : BIT;
    bitEnableOperation : BIT;
    bitError : BIT;
    bitVoltageEnabled : BIT;
    bitQuickStop : BIT;
    bitSwitchOnLocked : BIT;
    bitWarning : BIT;
END_STRUCT
END_TYPE
```

Declaration and write access to a bit:

```
PROGRAM PLC_PRG
VAR
    ControlDriveA : S_CONTROLLER;
END_VAR

// Symbolic bit access to bitEnableOperation
ControlDriveA.bitEnableOperation := TRUE;
```

Symbolic bit access in function block instances

In function blocks, you can declare variables for individual bits.

Example

```
FUNCTION_BLOCK FB_Controller
VAR_INPUT
    bitSwitchOnActive : BIT;
    bitEnableOperation : BIT;
    bitVoltageEnabled : BIT;
    bitQuickStop : BIT;
    bitSwitchOnLocked : BIT;
END_VAR
VAR_OUTPUT
    bitOperationEnabled : BIT;
    bitError : BIT;
    bitWarning : BIT;
END_VAR
VAR
END_VAR
;

PROGRAM PLC_PRG
VAR
    fbController : FB_Controller;
END_VAR
// Symbolic bit access to bitSwitchOnActive
fbController(bitSwitchOnActive := TRUE);
```

Addresses

CAUTION!
If you use pointers to addresses, then the contents of addresses can be moved during an online change. If you use absolute addresses, then the contents of addresses does not change during an online change.

Syntax:

```
%<memory area prefix> ( <size prefix> )? <memory position>

<memory area prefix> : I | Q | M
<size prefix> : X | B | W | D
<memory position> : <number> ( .<number> )* // Depends on the target
system
```

When defining an address, you use specific character strings to express memory position and size. An address is marked with the percent sign (%), followed by the memory range prefix, the optional size prefix, and the memory range position. The numbering that you use for addressing the memory position depends on the target system.

Memory Range Prefix	
I	Input memory range for "Inputs" For physical inputs via input drivers, "Sensors"
Q	Output memory range for "Outputs" For physical outputs via output drivers, "Actuators"
M	Flag memory range

Size Prefix	Data Type	Data Width
No size prefix		Single bit
X		Single bit
B	BYTE	8 bits
W	WORD	16 bits
D	DWORD	32 bits

Examples

%QX7.5 %Q7.5	Single bit address of the output bit 7.5
%IW215	Word address of the input word 215
%QB7	Byte address of the output byte 7
%MD48	Address of a double word at memory position 48 in flag memory
%IW2.5.7.1	Word address of an input word; interpretation dependent on the current controller configuration
VAR wVar AT %IW0 : WORD; END_VAR	Variable declaration with address information of an input word
VAR xActuator AT %QW0 : BOOL; END_VAR	Boolean variable declaration Note: For Boolean variables, one byte is allocated internally if a single bit address is not specified. A change in the value of xActuator affects the range from QX0.0 to QX0.7.
VAR xSensor AT IX7.5 : BOOL; END_VAR	Boolean variable declaration with explicit specification of a single bit address. On access, only the input bit 7.5 is read.

Memory position

Make sure that the address is valid as follows:

To map a valid address in an application, you must know the required position (applicable memory range) in the process image: input memory range (I), output memory range (Q), and flag memory range (M) — see above. Furthermore, you have to specify the required size prefix: bit, BYTE, WORD, DWord (see above: X, B, W, D)

The current device configuration and device settings (hardware structure, device description, I/O settings) play a decisive part. Note specifically the differences in the interpretation of bit addresses for devices with "byte addressing mode" and devices with "word-oriented IEC addressing mode". For example, in a byte addressing device, the number before the point of bit address `%IX5.5` addresses byte 5. On the other hand, in a word-addressed device, it addresses word 5. In contrast, addressing with a word or byte address is independent of the device type: with `%IW5` always word 5 is addressed and with byte address `%IB5` always byte 5. Regardless of size and addressing mode, you can address different memory cells therefore with the same address information.

The following table shows the comparison of byte addressing and word-oriented IEC addressing for bits, bytes, words, and double words. It also shows the overlapping memory ranges that are present in the case of byte addressing (see also the example below the table).

Regarding syntax, note that the IEC addressing mode is always word-oriented. In this case, the word number is located before the point and the bit number ofter the point.

DWords / **W**ords				**B**ytes	**X** (bits)					
byte addressing		word oriented IEC addressing			byte addressing			word oriented IEC addressing		
D0	W0	D0	W0	B0	X0.7	...	X0.0	X0.7	...	X0.0
D1	W1			B1	X1.7	...	X1.0	X0.15	...	X0.8
...	W2		W1	B2	...			X1.7	...	X1.0
	W3			B3				X1.15	...	X1.8
	W4	D1	W2	B4						
	...			B5						
			W3	B6						
				B7						
		D2	W4	B8						
		...		...						
		...		...						
		...		...						
D(n-3)		D(n/4)	...							
	W(n-1)		W(n/2)							
				B**n**	Xn.7	...	Xn.0	X(n/2).15	...	X(n/2).8

n = byte number

Example of memory range overlapping in the case of the byte addressing mode

D0 contains B0 - B3, W0 contains B0 and B1, W1 contains B1 and B2, and W2 contains B2 and B3. Consequently, in order to avoid overlap, you must not use W1 (also D1, D2, and D3) for addressing.

See also

- *Chapter 1.4.1.8.11.2 “AT declaration” on page 281*

Functions

In ST, you can use a function call as an operand.

Example:

```
Result := Fct(7) + 3;
```

TIME() function

This function yields the time (in milliseconds) that has elapsed since system boot.

The data type is TIME.

Example in ST:

```
systime := TIME();
```

1.4.1.19.5 Data Types

In the programming, a variable is identified by its name and has an address in the memory of the target system. Accordingly, variable names are identifiers under which the allocated memory is addressed. The size of the variable is determined by its data type. This determines how much memory is reserved for the variable and how the values in memory are to be interpreted. The data type also determines which operators are allowed.

In CODESYS, there is also the capability of instantiating function blocks. Function block instances then use memory like variables do. The memory requirement is determined by the function block.

The following groups of data types are available.

Standard data types

A standard data type (or standard data type) is an elementary data type or a string data type.

```
<standard data type> : __UXINT | __XINT | __XWORD | BIT | BOOL |
BYTE | DATE | DATE_AND_TIME | DINT | DT | DWORD | INT | LDATE |
LDATE_AND_TIME | LDT | LINT | LREAL | LTIME | LTOD | LWORD | REAL |
SINT |STRING | TIME | TOD | TIME_OF_DAY | UDINT | UINT | ULINT | USINT
| WORD | WSTRING
```

User-defined data types

You can declare your own data types which are based on the default predefined data types or existing data types.

These kinds of data types are called user-defined or user-specific. The data types are either organized as its own DUT object or declared within the declaration part of a programming object. Moreover, they are differentiated according to their purpose and syntax.

User-Defined Data Type	Declaration	See also
Alias	DUT object	*Chapter 1.4.1.19.5.18 “Alias” on page 680*
Arrays	Programming object	*Chapter 1.4.1.19.5.14 “Data Type 'ARRAY'” on page 660*
Enumeration	DUT object, programming object	*Chapter 1.4.1.19.5.17 “Enumerations” on page 676*
Reference	Programming object	*Chapter 1.4.1.19.5.13 “Reference” on page 658*
Pointer	Programming object	*Chapter 1.4.1.19.5.12 “Pointers” on page 656*
Structure	DUT object	*Chapter 1.4.1.19.5.16 “Structure” on page 674*
Subrange type	Programming object	*Chapter 1.4.1.19.5.20 “Subrange types” on page 681*
Union	DUT object	*Chapter 1.4.1.19.5.19 “Data type 'UNION'” on page 681*
Vector	DUT object	*Chapter 1.4.1.19.5.15 “Data Type '__VECTOR'” on page 666*

NOTICE!
Note the recommendations for naming an identifier.

See also

- *Chapter 1.4.1.19.7 “Identifiers” on page 740*

Data type 'BOOL'

Data Type	Values	Memory
BOOL	TRUE (1), FALSE (0)	8 bit

See also

- *Chapter 1.4.1.19.4.1 “BOOL constants” on page 633*

Integer data types

CODESYS provides the following integer data types.

Data Type	Lower Limit	Upper Limit	Memory
BYTE	0	255	8 bit
WORD	0	65535	16 bit
DWORD	0	4294967295	32 bit
LWORD	0	2^{64}-1	64 bit
SINT	-128	127	8 bit
USINT	0	255	8 bit
INT	-32768	32767	16 bit

Data Type	Lower Limit	Upper Limit	Memory
UINT	0	65535	16 bit
DINT	-2147483648	2147483647	32 bit
UDINT	0	4294967295	32 bit
LINT	-2^{63}	$2^{63}-1$	64 bit
ULINT	0	$2^{64}-1$	64 bit

NOTICE!
Information can be lost when converting from larger to smaller types.

See also

- *Chapter 1.4.1.19.4.2 “Numeric constants” on page 633*

Data type 'REAL' / 'LREAL'

The data types `REAL` and `LREAL` are floating-point types according to IEEE 754. They are necessary when using decimal numbers and floating-point numbers in decimal notation or exponential notation.

Table 43: Target system: CODESYS Control Win V3

Data type	Smallest value number	Largest value number	Storage space
`REAL`	1.0E-44	3.402823E+38	32 bit
`LREAL`	4.94065645841247E-324	1.7976931348623157E+308	64 bit

Example

```
PROGRAM PLC_PRG
VAR
    rMax: REAL := 3.402823E+38; // Largest number
    rPosMin : REAL := 1.0E-44; // Smallest positive number
    rNegMax: REAL := -1.0E-44; // Largest negative number
    rMin: REAL := -3.402823E+38; // Smallest number

    lrMax: LREAL := 1.7976931348623157E+308; // Largest number
    lrPosMin : LREAL := 4.94065645841247E-324; // Smallest positve
number
    lNegMax: LREAL := -4.94065645841247E-324; // Largest negative
number
    lrMin: LREAL := -1.7976931348623157E+308; // Smallest number
END_VAR
```

NOTICE!
Support for the `LREAL` data type depends on the target device in use. Refer to the respective documentation as to whether or not the 64-bit type `LREAL` is converted to `REAL` or remains as `LREAL` when compiling the application. Conversion may result in the loss of information.

NOTICE!
If the value of the REAL/LREAL number is outside of the value range of the integer, then an undefined result is yielded from a data type conversion from REAL or LREAL to SINT, USINT, INT, UINT, DINT, UDINT, LINT, or ULINT. The result depends on the target system. An exception error is also possible. To get code that is independent of the target system, the application must catch value range violations.

If the REAL/LREAL number is within the value range of the integer data type, then the conversion operates the same way on all systems.

See also

- *Chapter 1.4.1.19.4.3 “REAL/LREAL constants” on page 634*

Data Type 'STRING'

A variable of data type STRING can have contain any character string. The amount of memory that is reserved during a declaration refers to characters and is shown in parentheses or brackets. If a size is not defined, then CODESYS allocates 80 characters by default.

As a rule, CODESYS does not limit the string length. However, the string function processes lengths of 1–255 only. If a variable is initialized with a string that is too long for the data type, then CODESYS truncates the string accordingly from the right.

NOTICE!
The memory required for a STRING variable is always one byte per character plus one additional byte (for example, 81 bytes for a "STRING(80)" declaration).

Example of a string declaration with 35 characters:

```
str : STRING(35):= 'This is a String';
```

See also

- *Chapter 1.4.1.19.4.4 “String Constants” on page 634*
- *Chapter 1.4.1.19.5.9 “Data type 'WSTRING'” on page 655*

Data Type 'TIME'

The data type is treated internally as DWORD. TIME is resolved in milliseconds.

Data type	Lower limit	Upper limit	Storage space	Resolution
TIME	T#0d0h0m0s0ms	T#49d17h2m47s295ms	32 bit	Milliseconds

See also

- *Chapter 1.4.1.19.5.6 “Data Type 'LTIME'” on page 650*
- *Chapter 1.4.1.19.4.5 “TIME/LTIME Constant” on page 635*
- *Chapter 1.4.1.19.4.6 “Date and Time Constants” on page 637*

Data Type 'LTIME'

Data Type 'LTIME'

You can use the data type LTIME as a time base for high-resolution timer. A high-resolution timer has a resolution in nanoseconds.

Data Type	Lower Limit	Upper Limit	Memory
LTIME	LTIME#0NS	LTIME#213503D23H34M33S709MS551US615NS	64 bits

Syntax:

```
LTIME#<long time declaration>
```

The time declaration can include units of time that apply for the TIME constant as well as:

- "US": microseconds
- "NS": nanoseconds

Example:

```
LTIME1 := LTIME#1000D15H23M12S34MS2US44NS
```

See also

- *Chapter 1.4.1.19.5.5 “Data Type 'TIME'” on page 649*
- *Chapter 1.4.1.19.3.40 “Time Conversion” on page 595*

Date and Time Data Types

The data types `DATE`, `DATE_AND_TIME` (`DT`), and `TIME_OF_DAY` (`TOD`) are handled internally like a `DWORD` (32-bit value).

The data types `LDATE`, `LDATE_AND_TIME` (`LDT`), and `LTIME_OF_DAY` (`LTOD`) are treated internally like an `LWORD` (64-bit value).

The values of these data types are measured in seconds, milliseconds, and nanoseconds since 01/01/1970.

Data Type	Lower Limit	Upper Limit	Memory	Resolution
`DATE`	`DATE#1970-01-01` `D#1970-01-01`	`DATE#2106-02-07` `D#2106-02-07`	32-bit	Seconds (although only the day is displayed)
`DATE_AND_TIME` `DT`	`DATE_AND_TIME#1970-1-1-0:0:0` `DT#1970-1-1-0:0:0`	`DATE_AND_TIME#2106-02-07-06:28:15` `DT#2106-02-07-06:28:15`	32-bit	Seconds
`TIME_OF_DAY` `TOD`	`TIME_OF_DAY#0:0:0` `TOD#0:0:0`	`TIME_OF_DAY#23:59:59.999` `TOD#23:59:59.999`	32-bit	Milliseconds

Data Type	Lower Limit	Upper Limit	Memory	Resolution
LDATE	LDATE#1970-1-1 LD#1970-1-1	LDATE#2554-7-21 LD#2554-7-21	64-bit	Nanosec-onds (although only the day is displayed)
LDATE_AND_TIME LDT	LDATE_AND_TIME#1970-1-1-0:0:0 LDT#1970-1-1-0:0:0	LDATE_AND_TIME#2554-7-21:23:59:59.999999999 LDT#2554-7-21-23:59:59.99999999	64-bit	Nanosec-onds
LTIME_OF_DAY LTOD	LTIME_OF_DAY#0:0:0 LTOD#0:0:0	LTIME_OF_DAY#23:59:59.999999999 LTOD#23:59:59.999999999	64-bit	Nanosec-onds

Example

```
VAR
    //Date
    dateBottom : DATE :=  DATE#1970-1-1;
    dateTop : DATE :=  DATE#2106-2-7;
    dateAppointment : DATE := D#2020-2-7; // D prohibited

    //Date and time
    dtBottom : DATE_AND_TIME :=  DATE_AND_TIME#1970-1-1-0:0:0;
    dtTop : DT :=  DATE_AND_TIME#2106-02-07-06:28:15;
    dtAppointment : DT := DT#2020-2-7-12:55:1.234;

    //Time of day
    todBottom : TIME_OF_DAY :=  TIME_OF_DAY#0:0:0;
    todTop : TOD :=  TIME_OF_DAY#23:59:59.999;
    todAppointment : TOD := TOD#12:3:4.567;

    // Long date
    ldateBottom : LDATE :=  LDATE#1970-1-1;
    ldateTop : LDATE :=  LDATE#2106-2-7;
    ldateAppointment : LDATE := LD#2020-2-7; // LD prohibited

    // Long date and time
    ldtBottom : LDATE_AND_TIME :=  LDATE_AND_TIME#1970-1-1-0:0:0;
    ldtTop : LDT :=  LDATE_AND_TIME#2262-4-10-23:59:59.99999999;
    ldtAppointment : LDT := LDT#2020-2-7-12:55:1.234567891;

    //Long time of day
    ltodBottom : LTIME_OF_DAY :=  LTIME_OF_DAY#0:0:0;
    ltodTop : LTOD :=  LTIME_OF_DAY#23:59:59.999999999 ;
    ltodAppointment : LTOD := LTOD#12:3:4.567890123;

END_VAR
```

Data Type 'ANY' and 'ANY_<type>'

The data types ANY or ANY_<type> are used in interfaces of functions, function blocks, or methods in order to type input parameters whose type is unknown or unspecified: The input variables (VAR_INPUT) have a generic data type.

The compiler replaces the type of input variable internally with the data structure described below, whereby the value is not passed directly. Instead, a pointer is passed to the actual value so only a variable can be passed. Therefore, the data type is only specified when it is called. As a result, calls of such POUs can be made using arguments which each have different data types.

*Literals, replaced constants, and results of function calls or expressions **cannot** be passed to input variables (`VAR_IN_OUT`).*

Internal data structure for 'ANY' and 'ANY_<type>'

When code is compiled, the input variables are typed **internally** with `ANY` data type by the following structure. When the POU is called (at runtime), the argument is passed to a reference parameter.

```
TYPE AnyType :
STRUCT
        // the type of the actual parameter
    typeclass : __SYSTEM.TYPE_CLASS ;
        // the pointer to the actual parameter
    pvalue : POINTER TO BYTE;
        // the size of the data, to which the pointer points
    diSize : DINT;
END_STRUCT
END_TYPE
```

You can access the input variable within the POU via this structure by means of this structure, and for example query the passed value.

Example This compares whether or not two input variables have the same type and the same value.

```
FUNCTION funGenericCompare : BOOL
VAR_INPUT
    any1 : ANY;
    any2 : ANY;
END_VAR
VAR
    pTest : POINTER TO ARRAY [0..100] OF POINTER TO DWORD;
    diCount: DINT;
END_VAR

pTest := ADR(any1);
Generic_Compare := FALSE;
IF any1.typeclass <> any2.typeclass THEN
    RETURN;
END_IF
IF any1.diSize <> any2.diSize THEN
    RETURN;
END_IF
// Byte comparison
FOR iCount := 0 TO any1.diSize-1 DO
    IF any1.pvalue[iCount] <> any2.pvalue[iCount] THEN
        RETURN;
    END_IF
END_FOR
Generic_Compare := TRUE;
RETURN;
// END_FUNCTION
```

Declaration Syntax The syntax descriptions refer to a POU with exactly one parameter (an input variable).

```
FUNCTION | FUNCTION_BLOCK | METHOD <POU name> ( : <return data
type> )?
VAR_INPUT
    <input variable name> : <generic data type>;
END_VAR

<generic data type> = ANY | ANY_BIT | ANY_DATE | ANY_NUM | ANY_REAL |
ANY_INT | ANY_STRING
```

Example

```
FUNCTION funComputeAny : BOOL
VAR_INPUT
        anyInput1 : ANY; // valid data type see table
END_VAR
// END_FUNCTION

FUNCTION_BLOCK FB_ComputeAny
VAR_INPUT
    anyInput1 : ANY;
END_VAR
// END_FUNCTION_BLOCK

FUNCTION_BLOCK FB_ComputeMethod
METHOD methComputeAnny : BOOL
VAR_INPUT
    anyInput1 : ANY_INT; // valid data types are SINT, INT, DINT,
LINT, USINT, UINT, UDINT, ULINT
END_VAR
//END_METHOD
```

With compiler versions > 3.5.1.0, the generic IEC data types in the table are supported.

The table represents the hierarchy of the generic data types and provides information as to which generic data type of the formal parameter (declaration) allows which elementary data types of the argument (call).

Generic data type in the case of a formal parameter			**Permitted elementary data type in the case of an actual parameter (argument)**
ANY	ANY_BIT		• BYTE • WORD • DWORD • LWORD
	ANY_DATE		• DATE • DATE_AND_TIME, DT • TIME_OF_DAY, TOD • LDATE • LDATE_AND_TIME, LDT • LTIME_OF_DAY, LTOD
	ANY_NUM	ANY_REAL	REAL, LREAL
		ANY_INT	USINT, UINT, UDINT, ULINT SINT, INT, DINT, LINT
	ANY_STRING		STRING, WSTRING

Call

The syntax descriptions refer to a POU with exactly one parameter, to which an argument is passed. As a result, the data type of the argument specifies the generic data type of the input variable. For example, arguments of the type `BYTE, WORD, DWORD, LWORD` can be passed to a type `ANY_BIT` input variable.

Syntax of function call

```
<variable name> := <function name> ( <argument name> );
<argument name> : variable with valid data type
```

Syntax of function block call

```
<function block name> ( <input variable name> := <argument name> );
```

Syntax of method call

```
<function block name> . <method name> ( <input variable name> :=
<argument name> );
```

Example

```
PROGRAM PLC_PRG
VAR
    byValue : BYTE := 16#AB;
    iValue : INT := -1234;
    xResultByte : BOOL;
    xResultInt : BOOL;

    fbComputeAnyByte : FB_ComputeAny;
    fbComputeAnyInt : FB_ComputeAny;

    fbComputeM1 : FB_ComputeMethod;
    fbComputeM2 : FB_ComputeMethod;

    byN : BYTE := 1;
    wBitField1 : WORD := 16#FFFF;
    wBitField2 : WORD := 16#0001;
    xInit : BOOL;
    xResult : BOOL;
END_VAR

xResultByte := funComputeAny(byValue);
xResultInt := funComputeAny(iValue);

xResult := funGenericCompare(wBitField1, wBitField2);

fbComputeAnyByte(anyInput1 := byValue);
fbComputeAnyInt(anyInput1 := iValue);

fbComputeM1.methComputeAnny(anyInput1 := byValue);
fbComputeM2.methComputeAnny(anyInput1 := iValue);
// END_PRG
```

Data type 'WSTRING'

The data type WSTRING is interpreted in Unicode format as opposed to the data type STRING (ASCII). As a result of this coding, the number of displayed characters for WSTRING depends on the characters. A length of 10 for WSTRING means that the length of the WSTRING can take a maximum of 10 WORDs. However, for some characters in Unicode, multiple WORDS are required for coding a character so that the number of characters do not have to correspond to the length of the WSTRING (10 in this case). The data type requires 1 WORD of memory per character plus 1 WORD of extra memory. Each STRING requires only 1 byte. The data type WSTRING is terminated with a `0`.

Example:

```
wstr : WSTRING := "This is a WString";
```

Data Type 'BIT'

The data type `BIT` is valid only in structures for the declaration of structure members or in a function block for the declaration of variables. A `BIT` variable can have the values `TRUE` (1) and `FALSE` (0). In this case, the variable requires exactly one bit of memory.

As a result, you can symbolically address individual bits by a name. `BIT` variables that are declared in succession are bundled in bytes. In this way, you can optimize memory use as opposed to `BOOL` types, which reserve 8 bits each. On the other hand, bit access is significantly more time-consuming. Therefore, you should use the `BIT` data type only when you need to define data in a predefined format.

Special Data Types '__UXINT', __XINT, and '__XWORD'

Variables with these data types are converted to a platform-compliant data type, depending on the target system.

CODESYS supports systems with address registers of 32-bit and 64-bit widths. For making the IEC code as independent from the target system as possible, you use the pseudo data types `__UXINT`, `__XINT`, and `__XWORD`. The compiler checks which target system types are current and then converts these data types into the appropriate standard data types.

Moreover, type conversion operators are provided for variables of these data types.

	Type conversion on 64-bit platforms	Type conversion on 32-bit platforms
`__UXINT`	`ULINT`	`UDINT`
`__XINT`	`LINT`	`DINT`
`__XWORD`	`LWORD`	`DWORD`

Pointers

A pointer stores the memory address of objects, such as variables or function block instances, at runtime.

Syntax of the pointer declaration:

```
<pointer name>: POINTER TO <data type | data unit type | function
block>;
```

Example

```
FUNCTION_BLOCK FB_Point
VAR
    piNumber: POINTER TO INT;
    iNumber1: INT := 5;
    iNumber2: INT;
END_VAR

piNumber := ADR(iNumber1); // piNumber is assigned to address of
iNumber1
iNumber2 := piNumber^; // value 5 of iNumber1 is assigned to
variable iNumber2 by dereferencing of pointer piNumber
```

Dereferencing a pointer means obtaining the value to which the pointer points. A pointer is dereferenced by appending the content operator `^` to the pointer identifier (for example, `piNumber^` in the example above). To assign the address of an object to a pointer, the address operator `ADR` is applied to the object: `ADR(iNumber1)`.

In online mode, you can click *"Edit ➔ Browse ➔ Go to Reference"* to jump from a pointer to the declaration location of the referenced variable.

NOTICE!

When a pointer points to an I/O input, write access applies. This leads to the compiler warning *"'<pointer name >' is not a valid assignment target"* when the code is generated. Example: `pwInput := ADR(wInput);`

If you require a construct of this kind, you have to first copy the input value (`wInput`) to a variable with write access.

Index access to pointers

CODESYS permits the index access `[]` to variables of type `POINTER TO`, as well as to the data types `STRING` or `WSTRING`.

The data, which the pointer points to, can also be accessed by appending the bracket operator `[]` to the pointer identifier(for example, `piData[i]`). The base data type of the pointer determines the data type and the size of the indexed component. In this case, the index access to the pointer is done arithmetically by adding the index dependent offset `i * SIZEOF( <base type> )` to the address of the pointer. The pointer is dereferenced implicitly at the same time.

Calculation: `piData[i] := (piData + i * SIZEOF(INT))^;`

This is **not**: `piData[i] != (piData + i)^`.

Index access `STRING`

When you use the index access with a variable of the type `STRING`, you get the character at the offset of the index expression. The result is of type `BYTE`. For example, `sData[i]` returns the i-th character of the character string `sData` as `SINT` (ASCII).

Index access `WSTRING`

When you use the index access with a variable of the type `WSTRING`, you get the character at the offset of the index expression. The result is of type `WORD`. For example, `wsData[i]` returns the i-th character of the character string as `INT` (Unicode).

Subtracting pointers

The result of the difference between two pointers is a value of type `DWORD`, even on 64-bit platforms when the pointers are 64-bit pointers.

Using references provides the advantage of guaranteeing type safety. That is not the case with pointers.

The memory access of pointers can be checked at runtime by the implicit monitoring function `CheckPointer`.

Reference

A reference implicitly refers to another object. When accessed, the reference is implicitly dereferenced, and therefore does not need a special content operator `^` such as a pointer.

Syntax

```
<identifier> : REFERENCE TO <data type> ;
<data type>: base type of the reference
```

Example

```
PROGRAM PLC_PRG
VAR
    rspeA : REFERENCE TO DUT_SPECIAL;
    pspeA : POINTER TO DUT_SPECIAL;
    speB : DUT_SPECIAL;
END_VAR

rspeA REF= speB; // Reference rspeA is alias for speB. The code
corresponds to pspeA := ADR(speB);
rspeA := speD; // The code corresponds to pspeA^ := speB;
```

The readability of a program is made difficult when the same memory cell is accessed simultaneously by means of an identifier and its alias (for example, `speB` and `rspeA`).

NOTICE!
With compiler version >= V3.3.0.0, references are initialized (at 0).

> **NOTICE!**
> If a reference refers to a device input, then the access (for example, `rInput REF= Input;`) is applies as write access. This leads to a compiler warning when the code is generated: "`...invalid assignment target`".
>
> If you require a construct of this kind, you have to first copy the input value (`rInput`) to a variable with write access.

Invalid declarations

```
ariTest : ARRAY[0..9] OF REFERENCE TO INT;
priTest : POINTER TO REFERENCE TO INT;
rriTest : REFERENCE TO REFERENCE TO INT;
rbitTest : REFERENCE TO BIT;
```

A reference type must not be used as the base type of an array, pointer, or reference. Furthermore, a reference must not refer to a bit variable. These kinds of constructs generate compiler errors.

Comparison of reference and pointer

A reference has the following advantages over a pointer:

- Easier to use:
  A reference can access the contents of the referenced object directly and without dereferencing.
- Finer and simpler syntax when passing values:
  Call of a function block which passes a reference without an address operator instead of a pointer
  Example: `fbDoIt(riInput:=iValue);`
  Instead of: `fbDoIt_1(piInput:=ADR(iValue));`
- Type safety:
  When assigning two references, the compiler checks whether their base types match. This is not checked in the case of pointers.

Testing the validity of a reference

You can use the operator `__ISVALIDREF` to check whether or not a reference points to a valid value (meaning a value not equal to 0).

Syntax

```
<Boolean variable name> := __ISVALIDREF( <reference name> );
```

`<reference name>`: Identifier declared with `REFERENCE TO`

The Boolean variable is `TRUE` when the reference points to a valid value. Otherwise it is `FALSE`.

Example

```
PROGRAM PLC_PRG
VAR
iAlfa : INT;
riBravo : REFERENCE TO INT;
riCharlie : REFERENCE TO INT;
bIsRef_Bravo : BOOL := FALSE;
bIsRef_Charlie : BOOL := FALSE;
END_VAR

iAlfa := iAlfa + 1;
riBravo REF= iAlfa;
riCharlie REF= 0;
bIsRef_Bravo := __ISVALIDREF(riBravo);  (* becomes TRUE,
because riBravo references to iAlfa, which is non-zero
*)
bIsRef_Charlie := __ISVALIDREF(riCharlie); (* becomes FALSE,
because riCharlie is set to 0 *)
```

In compiler version 3.5.7.40 and later, the implicit monitoring function "CheckPointer" acts on variables of type `REFERENCE TO` in the same way as for pointer variables.

Data Type 'ARRAY'

An array is a collection of data elements of the same data type. CODESYS supports one- and multi-dimensional arrays of fixed or variable length.

Array of fixed length

You can define arrays in the declaration part of a POU or in global variable lists.

Syntax of the declaration of a one-dimensional array

```
<variable name> :  ARRAY[ <dimension> ] OF <data type> ( :=
<initialization> )? ;

<dimension> :  <lower index bound>..<upper index bound>
<data type> : elementary data types | user defined data types |
function block types
// (...)? : Optional
```

Syntax of the declaration of a multi-dimensional array

```
<variable name> :  ARRAY[ <1st dimension> ( , <next dimension> )+ ]
OF <data type> ( := <initialization> )? ;

<1st dimension> :  <1st lower index bound>..<1st upper index bound>
<next dimension> : <next lower index bound>..<next upper index bound>
<data type> : elementary data types | user defined data types |
function block types
// (...)+ : One or more further dimensions
// (...)? : Optional
```

The index limits are integers; maximum of the data type `DINT`.

Syntax for data access

```
<variable name>[ <index of 1st dimension> ( , <index of next
dimension> )* ]
// (...)* : 0, one or more further dimensions
```

Note the capability of using the implicit monitoring function `CheckBounds()` to monitor the maintenance of the index limits at runtime.

Example

One-dimensional array of 10 integer elements

```
VAR
    aiCounter : ARRAY[0..9] OF INT;
END_VAR
```

Lower index limit: 0

Upper index limit: 9

Initialization

```
aiCounter : ARRAY[0..9] OF INT := [0, 10, 20, 30, 40, 50, 60, 70,
80, 90];
```

Data access

```
iLocalVariable := aiCounter[2];
```

The value 20 is assigned to the local variable.

Example

2-dimensional array

```
VAR
    aiCardGame : ARRAY[1..2, 3..4] OF INT;
END_VAR
```

1st dimension: 1 to 2

2nd dimension: 3 to 4

Initialization

```
aiCardGame : ARRAY[1..2, 3..4] OF INT := [2(10),2(20)]; // Short
notation for [10, 10, 20, 20]
```

Data access

```
iLocal_1 := aiCardGame[1, 3]; // Assignment of 10
iLocal_2 := aiCardGame[2, 4]; // Assignment of 20
```

Example

3-dimensional array

```
VAR
    aiCardGame : ARRAY[1..2, 3..4, 5..6] OF INT;
END_VAR
```

1st dimension: 1 to 2

2nd dimension: 3 to 4

3rd dimension: 5 to 6

2 * 2 * 2 = 8 array elements

Initialization

```
aiCardGame : ARRAY[1..2, 3..4, 5..6] OF INT := [10, 20, 30, 40, 50,
60, 70, 80];
```

Data access

```
iLocal_1 := aiCardGame[1, 3, 5]; // Assignment of 10
iLocal_2 := aiCardGame[2, 3, 5]; // Assignment of 20
iLocal_3 := aiCardGame[1, 4, 5]; // Assignment of 30
iLocal_4 := aiCardGame[2, 4, 5]; // Assignment of 40
iLocal_5 := aiCardGame[1, 3, 6]; // Assignment of 50
iLocal_6 := aiCardGame[2, 3, 6]; // Assignment of 60
iLocal_7 := aiCardGame[1, 4, 6]; // Assignment of 70
iLocal_8 := aiCardGame[2, 4, 6]; // Assignment of 80
```

Initialization

```
aiCardGame : ARRAY[1..2, 3..4, 5..6] OF INT := [2(10), 2(20),
2(30), 2(40)]; // Short notation for [10, 10, 20, 20, 30, 30, 40,
40]
```

Data access

```
iLocal_1 := aiCardGame[1, 3, 5]; // Assignment of 10
iLocal_2 := aiCardGame[2, 3, 5]; // Assignment of 10
iLocal_3 := aiCardGame[1, 4, 5]; // Assignment of 20
iLocal_4 := aiCardGame[2, 4, 5]; // Assignment of 20
iLocal_5 := aiCardGame[1, 3, 6]; // Assignment of 30
iLocal_6 := aiCardGame[2, 3, 6]; // Assignment of 30
iLocal_7 := aiCardGame[1, 4, 6]; // Assignment of 40
iLocal_8 := aiCardGame[2, 4, 6]; // Assignment of 40
```

Example

3-dimensional arrays of a user-defined structure

```
TYPE DATA_A
STRUCT
 iA_1 : INT;
 iA_2 : INT;
 dwA_3 : DWORD;
END_STRUCT
END_TYPE

PROGRAM PLC_PRG
VAR
    aData_A : ARRAY[1..3, 1..3, 1..10] OF DATA_A;
END_VAR
```

The array `aData_A` consists of a total of 3 * 3 * 10 = 90 array elements of data type `DATA_A`.

Initialize partially

```
aData_A : ARRAY[1..3, 1..3, 1..10] OF DATA_A := [(iA_1 := 1,
iA_2 := 10, dwA_3 := 16#00FF),(iA_1 := 2, iA_2 := 20, dwA_3 :=
16#FF00),(iA_1 := 3, iA_2 := 30, dwA_3 := 16#FFFF)];
```

In the example, only the first 3 elements are initialized explicitly. Elements to which no initialization value is assigned explicitly are initialized internally with the default value of the basic data type. This initializes the structure components at 0 starting with the element `aData_A[2, 1, 1]`.

Data access

```
iLocal_1 := aData_A[1,1,1].iA_1; // Assignment of 1
dwLocal_2 := aData_A[3,1,1].dwA_3; // Assignment of 16#FFFF
```

Example

Array of a function block

```
FUNCTION BLOCK FBObject_A
VAR
    iCounter : INT;
END_VAR
...

PROGRAM PLC_PRG
VAR
    aObject_A : ARRAY[1..4] OF FBObject_A;
END_VAR
```

The array `aObject_A` consists of 4 elements. Each element instantiates a `FBObject_A` function block.

Function call

```
aObject_A[2]();
```

Example

Implementation of `FB_Something` with method `FB_Init`

```
FUNCTION_BLOCK FB_Something
VAR
    _nId : INT;
    _lrIn : LREAL;
END_VAR
...

METHOD FB_Init : BOOL
VAR_INPUT
    bInitRetains : BOOL;
    bInCopyCode : BOOL;
    nId : INT;
    lrIn : LREAL;
END_VAR

_nId := nId;
_lrIn := lrIN;
```

The function block `FB_Something` has a method `FB_Init` that requires 2 parameters.

Instantiation of the array with initialization

```
PROGRAM PLC_PRG
VAR
    fb_Something_1 : FB_Something(nId := 11, lrIn := 33.44);
    a_Something : ARRAY[0..1, 0..1] OF FB_Something[(nId := 12,
lrIn := 11.22), (nId := 13, lrIn := 22.33), (nId := 14, lrIn :=
33.55),(nId := 15, lrIn := 11.22)];
END_VAR
```

Array of arrays

The declaration of an "array of arrays" is an alternative syntax for multidimensional arrays. A collection of elements is nested instead of dimensioning the elements. The nesting depth is unlimited.

Syntax for declaration

```
<variable name> :  ARRAY[<first>] ( OF ARRAY[<next>] )+ OF <data
type> ( := <initialization> )? ;

<first> :  <first lower index bound>..<first upper index bound>
<next> : <lower index bound>..<upper index bound> // one or more
arrays
<data type> : elementary data types | user defined data types |
function block types
// (...)+ : One or more further arrays
// (...)? : Optional
```

Syntax for data access

```
<variable name>[<index of first array>] ( [<index of next array>] )+ ;
// (...)* : 0, one or more further arrays
```

Example

```
PROGRAM PLC_PRG
VAR
    aiPoints : ARRAY[1..2,1..3] OF INT := [1,2,3,4,5,6];
    ai2Boxes : ARRAY[1..2] OF ARRAY[1..3] OF INT := [ [1, 2, 3],
[ 4, 5, 6]];
    ai3Boxes : ARRAY[1..2] OF ARRAY[1..3] OF ARRAY[1..4] OF INT :=
[ [ [1, 2, 3, 4], [5, 6, 7, 8 ], [9, 10, 11, 12] ], [ [13, 14, 15,
16], [ 17, 18, 19, 20], [21, 22, 23, 24] ] ];
    ai4Boxes : ARRAY[1..2] OF ARRAY[1..3] OF ARRAY[1..4] OF
ARRAY[1..5] OF INT;
END_VAR

aiPoints[1, 2] := 1200;
ai2Boxes[1][2] := 1200;
```

The variables `aiPoints` and `ai2Boxes` collect the same data elements, however the syntax for the declaration differs from that of the data access.

aiPoints	ARRAY [1..2, 1..3] OF INT	
aiPoints[1, 1]	INT	1
aiPoints[1, 2]	INT	1200
aiPoints[1, 3]	INT	3
aiPoints[2, 1]	INT	4
aiPoints[2, 2]	INT	5
aiPoints[2, 3]	INT	6

ai2Boxes	ARRAY [1..2] OF ARRAY [1..3] OF INT	
ai2Boxes[1]	ARRAY [1..3] OF INT	
ai2Boxes[1][1]	INT	1
ai2Boxes[1][2]	INT	1200
ai2Boxes[1][3]	INT	3
ai2Boxes[2]	ARRAY [1..3] OF INT	
ai2Boxes[2][1]	INT	4
ai2Boxes[2][2]	INT	5
ai2Boxes[2][3]	INT	6

Array of variable length

In function blocks, functions, or methods, you can declare arrays of variable length in the `VAR_IN_OUT` declaration section.

The `LOWER_BOUND` and `UPPER_BOUND` operators are provided for determining the index limits of the actual used array at runtime.

Only statically declared arrays (not arrays generated by means of the operator `__NEW`) may be passed to an array with variable length.

Syntax of the declaration of a one-dimensional array of variable length

```
<variable name> :  ARRAY[*] OF <data type> ( := <initialization> )? ;

<data type> : elementary data types | user defined data types |
function block types
// (...)? : Optional
```

Syntax of the declaration of a multi-dimensional array of variable length

```
<variable name> :  ARRAY[* ( , * )+ ] OF <data type> ( :=
<initialization> )? ;

<data type> : elementary data types | user defined data types |
function block types
// (...)+ : One or more further dimensions
// (...)? : Optional
```

Syntax of the operators for calculating the limit index

```
LOWER_BOUND( <variable name> , <dimension number> )
UPPER_BOUND( <variable name> , <dimension number> )
```

Example

The `SUM` function adds the integer values of the array elements and returns the calculated sum as a result. The sum is calculated across all array elements available at runtime. As the actual number of array elements will only be known at runtime, the local variable is declared as a one-dimensional array of variable length.

```
FUNCTION SUM: INT;
VAR_IN_OUT
    aiData : ARRAY[*] OF INT;
END_VAR
VAR
 diCounter, diResult : DINT;
END_VAR

diResult := 0;
FOR diCounter := LOWER_BOUND(aiData, 1) TO UPPER_BOUND(aiData, 1)
DO // Calculates the length of the current array
 diResult := diResult + A[i];
END_FOR;
SUM := diResult;
```

Data Type '__VECTOR'

Vector operations are supported natively only on 64-bit processors and offer a performance advantage only on these processors. The data sheet of the controller provides information about the processor used on the controller.

Currently, vector operations on the x86/64-bit platforms with SSE2 and ARM64 with NEON are supported natively. On all other platforms, vector operations are translated into individual statements. For example, vector addition is then executed with multiple single addition operations.

The command set extensions of the processors are SIMD extensions. SIMD (Single Instruction, Multiple Data) describes a computer architecture in which multiple data sets of the same type are processed simultaneously in parallel and therefore faster with one command call. In vector operations, for example, 4 pairs of numbers can then be added at the same time.

Syntax

```
<variable name> :  __VECTOR[ <vector size> ] OF <element type> ( :=
<initialization> )? ;

<vector size> : 1 |2 | 3 | 4 | 5| 6 | 7| 8
<element type> : REAL | LREAL
// (...)? : Optional
```

A vector data type is an array of floating-point numbers with a maximum of 8 elements. The operators `__vc<operator name>` are available for this data type. You can use these to implement vector operations without additional function calls.

Syntax for index access

```
<variable name>[ <index> ]
<index> : 0 | 1 | 2| 3 | 4 | 5| 6 | 7
```

When indexing a vector variable, you can access a single element of the vector. The index starts at 0 and goes until <vector size> - 1.

Example

```
PROGRAM PLC_PRG
VAR
    vcA : __VECTOR[3] OF REAL;
END_VAR

vcA[0] := 1.1;
vcA[1] := 2.2;
vcA[2] := 3.3;
```

Determining the optimal vector size

Use the optimal vector size depending on your target system as the vector size in order to program the most efficient code possible.

For target systems whose computer architecture is generally suitable for vector processing, we do not recommend using vectors of arbitrary size. There is an optimal vector size depending on the type of data processing of the processor. Vectors that are declared with this array size are processed as quickly as possible. Vectors that are declared as a larger array do not have an advantage in speed. Vectors that are declared as smaller arrays do not take full advantage of the processor's capabilities.

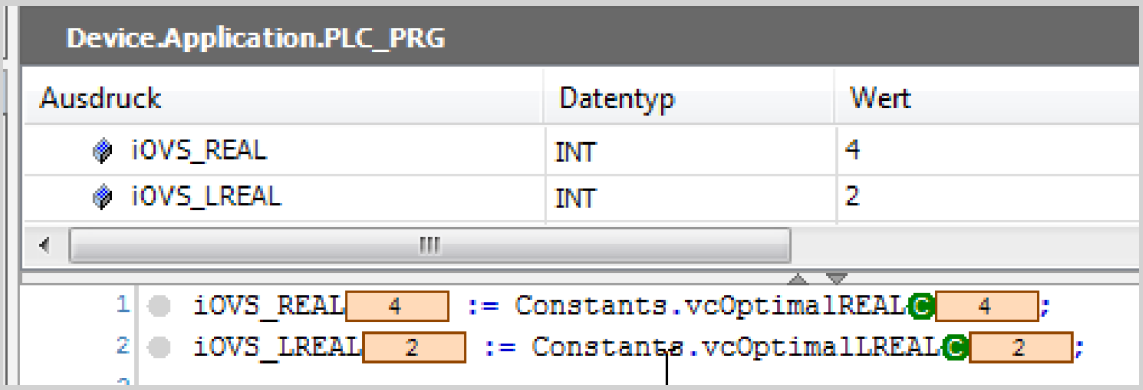
You can query the optimal size at runtime. You can find the information in the constants `Constants.vcOptimalREAL` (for vectors with `REAL` elements) and `Constants.vcOptimalLREAL` (for vectors with `LREAL` elements). The constants have the `LREAL` data type. If a constant returns the value `1` as the optimal value, then this means that accelerated vector processing is not available for the target system.

Example

```
PROGRAM PLC_PRG
VAR
    iOVS_REAL : INT; // Optimal vector size for REAL elements
    iOVS_LREAL : INT; // Optimal vector size for LREAL elements
END_VAR

iOVS_REAL := Constants.vcOptimalREAL;
iOVS_LREAL := Constants.vcOptimalLREAL;
```

An application that is loaded on the CODESYS Control Win V3 x64 target system returns the following values at runtime:



Operator __VCADD

The operator calculates the sum of two vectors.

Syntax

```
<vector variable> := <1st vector operand> __VCADD <2nd vector
operand>;
```

Example of addition

```
FUNCTION_BLOCK FB_ADD
VAR
    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
    vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 3);
    vcResult : __VECTOR[3] OF REAL;
END_VAR

vcResult := vcA __VCADD vcB;
```

Operator __VCSUB

The operator calculates the difference between two vectors.

Syntax

```
<vector variable> := <vector minuend> __VCSUB <vector subtrahend>;
```

Example of subtraction

```
FUNCTION_BLOCK FB_SUB
VAR
    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
    vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 3);
    vcResult0 : __VECTOR[3] OF REAL;
    vcResult1 : __VECTOR[3] OF REAL;
END_VAR

vcResult0 := vcA __VCSUB vcB;
vcResult1 := vcB __VCSUB vcA;
```

Operator __VCMUL

The operator calculates the product of two vectors or a scalar (floating-point number) and a vector.

Syntax

```
<vector variable> := <1st vector operand> __VCMUL <2nd vector
operand> | <scalar operand> __VCMUL <vector operand> | <vector
operand> __VCMUL <scalar operand> ;
```

Example of multiplication

```
FUNCTION_BLOCK FB_MUL
VAR
    rScalar : REAL := 1.1;
    vcA : __VECTOR[3] OF REAL;
    vcB : __VECTOR[3] OF REAL;
    vcResult0 : __VECTOR[3] OF REAL;
    vcResult1 : __VECTOR[3] OF REAL;
    vcResult2 : __VECTOR[3] OF REAL;
END_VAR

vcResult0 := vcA __VCMUL vcB;
vcResult1 := rScalar __VCMUL vcB;
vcResult2 := vcA __VCMUL 3.3;
```

Operator __VCDIV

The operator calculates the quotient of two vectors or a vector and a scalar.

Syntax

```
<vector variable> := <vector dividend> __VCDIV <vector divisor> | <
vector dividend> __VCMUL <scalar divisor> ;
```

Example of division

```
FUNCTION_BLOCK FB_DIV
VAR
    iScalar : INT := 3;
    rScalar : REAL := 1.5;
    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
    vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 3);
    vcResult0 : __VECTOR[3] OF REAL;
    vcResult1 : __VECTOR[3] OF REAL;
    vcResult2 : __VECTOR[3] OF REAL;
END_VAR

vcResult0 := vcA __VCDIV vcB;
// ERROR CODE vcResult1 := rScalar __VCDIV vcB;
// ERROR CODE vcResult1 := iScalar __VCDIV vcB;
// ERROR CODE vcResult1 := 3.3 __VCDIV vcB;
vcResult2 := vcA __VCDIV 1.5;
vcResult2 := vcA __VCDIV iScalar;
vcResult2 := vcA __VCDIV rScalar;
```

Operator __VCDOT

The operator calculates the dot product (scalar product) of two vectors.

Syntax

```
<scalar variable> := <1st vector operand> __VCDOT <2nd vector
operand> ;
```

Example of a dot product

```
FUNCTION_BLOCK FB_DOT
VAR
    rResult : REAL;
    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
    vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 3);
END_VAR

rResult := vcA __VCDOT vcB; // = 18
```

Operator __VCSQRT

The operator calculates the square root of each element in the vector.

Syntax

```
<vector variable> := __VCSQRT( <vector operand> );
```

Example of a square root

```
FUNCTION_BLOCK FB_SQRT
VAR
    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(4, 9, 16);
    vcResult0 : __VECTOR[3] OF REAL;
END_VAR

vcResult0 := __VCSQRT(vcA);
```

Operator __VCMAX

The operator calculates the maximum vector of two vectors. The maximum is determined element by element.

Syntax

```
<vector variable> := __VCMAX( <1st vector operand>, <2nd vector
operand>);
```

Example of a maximum vector

```
FUNCTION_BLOCK FB_MAX
VAR
    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
    vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 6);
    vcResult0 : __VECTOR[3] OF REAL;
END_VAR

vcResult0 := __VCMAX(vcA, vcB);
```

Operator __VCMIN

The operator calculates the minimum vector of two vectors. The minimum is determined element by element.

Syntax

```
<vector variable> := __VCMIN( <1st vector operand>, <2nd vector
operand>);
```

Example of a minimum vector

```
FUNCTION_BLOCK FB_MIN
VAR
    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
    vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 6);
    vcResult0 : __VECTOR[3] OF REAL;
END_VAR

vcResult0 := __VCMIN(vcA, vcB);
```

Operator __VCSET_REAL

The operator sets all elements of a vector in a statement. The elements have the `REAL` data type.

Syntax

```
<vector variable> := __VCSET_REAL( <first literal>, ( < next
literal> )+ ) ;
( ... )+ // number of elements have to match
```

Example

```
FUNCTION_BLOCK FB_SET
VAR
    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
    vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 3);
END_VAR

vcA := __VCSET_REAL(4, 4, 4);
vcB := __VCSET_REAL(1.1, 2.2, 3.3);
```

Operator __VCSET_LREAL

The operator sets all elements of a vector at once in a statement. The elements have the `LREAL` data type.

They can be used wherever variables are valid, such as in assignments in implementations or as parameters in function calls.

Syntax

```
<vector variable> := __VCSET_LREAL( <first literal>, ( < next
literal> )+ ) ;
( ... )+ // number of elements have to match
```

Example

```
FUNCTION_BLOCK FB_SET
VAR
    vclA : __VECTOR[3] OF LREAL := __VCSET_LREAL(3, 3, 3);
    vclB : __VECTOR[3] OF LREAL := __VCSET_LREAL(1, 2, 3);
END_VAR

vclA := __VCSET_LREAL(-1.7976931348623158E+308, 0.0,
1.7976931348623158E+308);
vclB := __VCSET_LREAL(-1.7976931348623158E+308, 0.0,
1.7976931348623158E+308);
```

Operator __VCLOAD_REAL

The operator interprets any arbitrary memory area as a vector. This is helpful for connecting vector variables to existing code. The operator requires 2 parameters. The first parameter indicates the number of vector elements. The second parameter is a pointer to the `REAL` data.

Syntax

```
<vector variable> := __VCLOAD_REAL( <vector size>, <pointer to data
of type REAL> ) ;
<vector size> : 2 | 3 | 4 | 5| 6 | 7| 8
```

Example of vectorization

```
FUNCTION_BLOCK FB_LOAD
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    rData0 : REAL := 1.234;
    rData1: REAL := 5.678;
    rData2 : REAL := 9.123;
    pData: POINTER TO REAL := ADR(rData0);

    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
END_VAR

vcA := __VCLOAD_REAL(3, pData);
```

Operator __VCLOAD_LREAL

The operator interprets any arbitrary memory area as a vector. This is helpful for connecting vector variables to existing code. The operator requires 2 parameters. The first parameter indicates the number of vector elements. The second parameter is a pointer to the `LREAL` data.

Syntax

```
<vector variable> := __VCLOAD_REAL( <vector size>, <pointer to data
of type LREAL> );
<number of vector elements> : 1 | 2 | 3 | 4 | 5| 6 | 7| 8
```

Example of vectorization

```
FUNCTION_BLOCK FB_LOAD
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    lrData0 : LREAL := -1.7976931348623158E+308;
    lrData1: LREAL := 1.6E+308;
    lrData2 : LREAL := 1.7E+308;
    lrData3 : LREAL := -1.6E+308;
    plData: POINTER TO LREAL := ADR(lrData0);

    vclA : __VECTOR[4] OF LREAL := __VCSET_LREAL(4, 4, 4, 4);
END_VAR
vclA := __VCLOAD_LREAL(4, plData);
```

Operator __VCSTORE

The operator saves/copies the contents of the vector to the specified memory address. The number and the types of elements are automatically applied from the vector variables.

Syntax

```
__VCSTORE( <pointer to data>, <vector variable> );
```

Example of storage

```
FUNCTION_BLOCK FB_STORE
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    rData0 : REAL := 3;
    rData1: REAL := 3;
    rData2 : REAL := 3;
    pData: POINTER TO REAL := ADR(rData0);

    lrData0 : LREAL := 4;
    lrData1: LREAL := 4;
    lrData2 : LREAL := 4;
    lrData3 : LREAL := 4;
    plData: POINTER TO LREAL := ADR(lrData0);

    vcA : __VECTOR[3] OF REAL := __VCSET_REAL( 1.234, 5.678, 9.123);
    vclA : __VECTOR[4] OF LREAL :=
__VCSET_LREAL(-1.7976931348623158E+308, 1.6E+308, 1.7E+308,
-1.6E+308);
END_VAR

__VCSTORE(pData, vcA);
__VCSTORE(plData, vclA);
```

Structure

A structure is a user-defined data type, which combines multiple variables of any data type into a logical unit. The variables declared within a structure are called members.

You make the type declaration of a structure in a *"DUT"* object which you create in the *"Project ➔ Add Object ➔ DUT"* menu or in the context menu of an application.

Syntax

```
TYPE <structure name> :
STRUCT
    ( <variable declaration optional with initialization> )+
END_STRUCT
END_TYPE
```

`<structure name>` is an identifier which is valid in the entire project so that you can use it like a standard data type. Moreover, you can declare any number of variables (at least one) which are supplemented optionally by an initialization.

Structures can also be nested. This means that you declare a structure member with an existing structure type. Then the only restriction is that you must not assign any address to the variable (structure member). (The AT declaration is not permitted here.)

Example

Type declaration

```
TYPE S_POLYGONLINE :
STRUCT
    aiStart : ARRAY[1..2] OF INT := [-99, -99];
    aiPoint1 : ARRAY[1..2] OF INT;
    aiPoint2 : ARRAY[1..2] OF INT;
    aiPoint3 : ARRAY[1..2] OF INT;
    aiPoint4 : ARRAY[1..2] OF INT;
    aiEnd : ARRAY[1..2] OF INT := [99, 99];
END_STRUCT
END_TYPE
```

Extension of a type declaration

An additional structure is declared from an existing structure. In addition to its own members, the extended structure also has the same structure members as the base structure.

Syntax

```
TYPE <structure name> EXTENDS <basis structure> :
STRUCT
    ( <variable declaration optional with initialization> )+
END_STRUCT
END_TYPE
```

Example

Type declaration

```
TYPE S_PENTAGON EXTENDS S_POLYGONLINE :
STRUCT
    aiPoint5 : ARRAY[1..2] OF INT;
END_STRUCT
END_TYPE
```

Declaration and initialization of structure variables

Example

```
PROGRAM progLine
VAR
    sPolygon : S_POLYGONLINE := (aiStart:=[1,1], aiPoint1:=[5,2],
aiPoint2:=[7,3], aiPoint3:=[8,5], aiPoint4:=[5,7], aiEnd:=[1,1]);
    sPentagon : S_PENTAGON := (aiStart:=[0,0], aiPoint1:=[1,1],
aiPoint2:=[2,2], aiPoint3:=[3,3], aiPoint4:=[4,4], aiPoint5:=[5,5],
aiEnd:=[0,0]);
END_VAR
```

You must not permitted to use initializations with variables. For an example of initializing an array of a structure, see the help page for the data type `ARRAY`.

Access to a structure member

You access structure members with the following syntax:

```
<variable name> . <component name>
```

Example

```
PROGRAM prog_Polygon
VAR
    sPolygon : S_POLYGONLINE := (aiStart:=[1,1], aiPoint1:=[5,2],
aiPoint2:=[7,3], aiPoint3:=[8,5], aiPoint4:=[5,7], aiEnd:=[1,1]);
    iPoint: INT;
END_VAR

// Assigns 5 to aiPoint
iPoint := sPolygon.aiPoint1[1];
```

Result: `iPoint = 5`

Symbolic bit access in structure variables

You can declare a structure with variables of data type `BIT` to combine individual bits into a logical unit. Then you can symbolically address individual bits by a name (instead of by a bit index).

Syntax declaration

```
TYPE <structure name> :
STRUCT
    ( <bit name> : BIT; )+
END_STRUCT
END_TYPE
```

Syntax of bit access

```
<structure name> . <bit name>
```

Example

Type declaration

```
TYPE S_CONTROL :
STRUCT
    bitOperationEnabled : BIT;
    bitSwitchOnActive : BIT;
    bitEnableOperation : BIT;
    bitError : BIT;
    bitVoltageEnabled : BIT;
    bitQuickStop : BIT;
    bitSwitchOnLocked : BIT;
    bitWarning : BIT;
END_STRUCT
END_TYPE
```

Bit access

```
FUNCTION_BLOCK FB_Controller
VAR_INPUT
        xStart : BOOL;
END_VAR
VAR_OUTPUT
END_VAR
VAR
    ControlDriveA : S_CONTROL;
END_VAR

IF xStart = TRUE THEN
    // Symbolic bit access
    ControlDriveA.bitEnableOperation := TRUE;
END_IF

PROGRAM PLC_PRG
VAR
    fbController : FB_Controller;
END_VAR

fbController();
fbController.xStart := TRUE;
```

*References and pointers to `BIT` variables are **invalid** declarations, as well as array elements with base type `BIT`.*

Enumerations

An enumeration is a user-defined data type composed of a series of comma-separated components (enumeration values) for declaring user-defined variables. Moreover, you can use the enumeration components like constants whose identifier `<enumeration name>.<component name>` is recognized globally in the project.

You declare an enumeration in a DUT object, which you have already created in the project by clicking *“Add Object”*.

Declaration

Syntax

```
( {attribute 'strict'} )? // Pragma optional but recommended
TYPE <enumeration name> :
(
    <first component declaration>,
    ( <component declaration> ,)+
    <last component declaration>
)( <basic data type> )? ( := <default variable initialization> )? ;
END_TYPE

( ... )? : Optional
<component declaration> : <component name> ( := <component
initialization> )?
<basic data type> : INT | UINT | SINT | USINT | DINT | UDINT | LINT |
ULINT | BYTE | WORD | DWORD | LWORD
<variable initialization> : <one of the component names>
```

In an enumeration declaration, at least 2 components are usually declared. However, you can declare as many as you want. Every single component can be assigned its own initialization. Enumerations automatically have the basic data type `INT`, but you can specify another basic data type. Moreover, you can specify a component in the declaration with which an enumeration variable is then initialized.

The pragma `{attribute 'strict'}` causes a strict type test to be performed as described below.

Example

```
{attribute 'qualified_only'}
{attribute 'strict'}
TYPE COLOR_BASIC :
(
    yellow,
    green,
    blue,
    black
)
; // Basic data type is INT, default initialization for all
COLOR_BASIC variables is yellow
END_TYPE
```

Enumeration with explicit basic data type

Extensions to the IEC 61131-3 standard

The basic data type for an enumeration declaration is `INT` by default. However, you can also declare enumerations that are based explicitly on another integer data type.

```
<basic data type> : INT | UINT | SINT | USINT | DINT | UDINT | LINT |
ULINT | BYTE | WORD | DWORD | LWORD
```

Example

Enumeration with basic data type DWORD

```
TYPE COLOR :
(
    white := 16#FFFFFF00,
    yellow := 16#FFFFFF00,
    green := 16#FF00FF00,
    blue := 16#FF0000FF,
    black := 16#88000000
) DWORD := black; // Basic data type is DWORD, default
initialization for all COLOR variables is black
END_TYPE
```

Strict programming rules

NOTICE!
In CODESYS V3.5 SP7 and later, the pragma `{attribute 'strict'}` is added automatically in the first line when declaring an enumeration.

The strict programming rules are activated when adding the pragma `{attribute 'strict'}`.

The following code is considered a compiler error:

- Arithmetic operations with enumeration components
  For example, an enumeration variable cannot be used as a counter variable in a `FOR` loop.
- Assignment of a constant value, which does not correspond to an enumeration value, to an enumeration component
- Assignment of a non-constant variable, which has another data type as the enumeration, to an enumeration component

Arithmetic operations can lead to undeclared values being assigned to enumeration components. A better programming style is to use `SWITCH`/`CASE` statements for processing component values.

Declaration and initialization of enumeration variables

Syntax

```
<variable name> : <enumeration name> ( := <initialization> )? ;
```

For a declaration of an enumeration variable with user-defined data type `<enumeration name>`, this can be initialized with an enumeration component.

Example

```
PROGRAM PLC_PRG
VAR
    colorCar: COLOR;
    colorTaxi : COLOR := COLOR.yellow;
END_VAR
```

The variable `colorCar` is initialized with `COLOR.black`. That is the default initialization for all enumeration variables of type `COLOR` and defined this way in the type declaration. The variable `colorTaxi` has its own initialization.

If no initializations are specified, then the initialization value is 0.

Example

```
PROGRAM PLC_PRG
VAR
    cbFlower : COLOR_BASIC;
    cbTree: COLOR_BASIC := COLOR_BASIC.green;
END_VAR
```

The variable `cbFlower` is initialized with `COLOR_BASIC.yellow`. That is the default initialization for all enumeration variables of type `COLOR_BASIC`. Because the enumeration declaration does not specify a component for initialization, the system automatically initializes with the component that has the value 0. This is usually the first of the enumeration components. However, it can also be another component that is not in the first position but explicitly initialized with 0.

The variable `cbTree` has an explicit initialization.

If no value is specified for both the type and the variable, then the following rule applies: If an enumeration contains a value for 0, then this value is the default initialization, and if not, then the first component in the list.

Example

Initialization with the 0 component

```
TYPE ENUM :
(
    e1 := 2,
    e2 := 0,
    e3
)
;
END_TYPE

PROGRAM PLC_PRG
VAR
    e : ENUM;
END_VAR
```

The variable `e` is initialized with `ENUM.e2`.

Initialization with the first component

```
TYPE ENUM2 :
(
    e1 := 3,
    e2 := 1,
    e3
)
;
END_TYPE

PROGRAM PLC_PRG
VAR
    e2 : ENUM2;
END_VAR
```

The variable `e2` is initialized with `ENUM.e1`.

Unique access to enumeration components

Extensions to the IEC 61131-3 standard

The enumeration components can also be used as constant variables with the identifier `<enumeration name>.<component name>`. Enumeration components are recognized globally in the project and access to them is unique. Therefore, a component name can be used in different enumerations.

Example

Component blue

```
PROGRAM PLC_PRG
VAR
    cbFlower : COLOR_BASIC;
    colorCar : COLOR;
END_VAR

(* unambiguous identifiers although the component names are
identical *)
cbFlower := COLOR_BASIC.blue;
colorCar := COLOR.blue;

(* invalid code *)
cbFlower := blue;
colorCar := blue;
```

See also

- *Chapter 1.4.1.19.3.72 “Operator - Enumeration namespace” on page 630*

Alias

An alias is a user-defined data type with which an alternative name for a basic type, data type, or function block is generated.

You make the type declaration of an alias in a *“DUT”* object which you create in the *“Project ➔ Add Object ➔ DUT”* menu or in the context menu of an application.

Syntax

```
TYPE <DUT name> : <basic type> | <data type> | <function block
name> ;
END_TYPE
```

Example

```
FUNCTION_BLOCK FB_Machine
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    iCounter : INT;
END_VAR
iCounter := iCounter + 1;

// Alias for FB_Machine
TYPE A_ROBOT : FB_Machine;
END_TYPE

PROGRAM prog_Robot
VAR
    fbRobot : A_ROBOT;
END_VAR
fbRobot();
```

Data type 'UNION'

A UNION is a data structure that usually contains different data types.

In a union, all components have the same offset and therefore the same amount of memory. In the following declaration example of a union, an assignment to `name.a` will also affect `name.b`.

Example

```
TYPE name:
UNION
    a : LREAL;
    b : LINT;
END_UNION
END_TYPE
```

Subrange types

A subrange type is a data type whose value range is a subset of a base type.

Syntax for the declaration:

```
<name> : <int type> (<lower limit>..<upper limit>);
```

`<name>`	valid IEC identifier
`<int type>`	data type of the subrange (SINT, USINT, INT, UINT, DINT, UDINT, BYTE, WORD, DWORD, LINT, ULINT, LWORD).
`<lower limit>`	Lower limit of the range: constants that have to be compatible with the basic data type. The lower limit is also included in this range.
`<upper limit>`	Upper limit of the range: constants that have to be compatible with the base data type. The upper limit is also included in this range.

Examples:

```
VAR
 i : INT (-4095..4095);
 ui : UINT (0..10000);
END_VAR
```

If you assign a value to a subrange type in the declaration or implementation section that is not within this range (example: i:=5000), then CODESYS issues an error message.

Please note: In runtime mode, it is possible to monitor the range limits of a subrange type by using the implicit monitoring functions `CheckRangeSigned` and `CheckRangeUnsigned`.

See also

- *Chapter 1.4.1.20.2.19.7 “POU 'CheckLRangeSigned'” on page 914*
- *Chapter 1.4.1.20.2.19.9 “POU 'CheckLRangeUnsigned'” on page 916*

Redundancy State

The library `Redundancy` provides the structure `RedundancyState` with the components describes below.

- By calling `GetRedundancyState(ADR(<RedundancyState name>));`, the state of the redundancy system is read and stored. As a result, you get programmatic access to the redundancy state and can display it, for example in a visualization.
- The redundancy state is also automatically displayed in the *"Redundancy Configuration"* editor, on the *"Redundancy State"* tab. There in the system graphic in the lower right corner of the respective PLC, the redundancy state is displayed symbolically by circle symbols. Moreover, the state is output as text below in the *"Redundancy State"* field. In this way, you can monitor the state of the redundancy system.

The following table compares these two options.

Circle Symbol	Output text under *"Redundancy State"*	`STRUCT RedundancyState`	Description
		`RS_START`	Initial state Tries (when configured correctly) to synchronize with the other PLC If not correctly configured, then the state is set to `RS_SIMULATION_START`.
		`RS_SYNCHRO`	Boot application downloaded, data synchronized, and task started Fieldbus deactivated
A	*"Active"*	`RS_CYCLE_ACTIVE`	Works in redundant synchronized mode as active PLC Fieldbus activated
P	*"Passive"*	`RS_CYCLE_STANDBY`	Works in redundant synchronized mode as passive PLC Fieldbus deactivated
S	*"Standalone"*	`RS_CYCLE_STANDALONE`	Works in standalone mode, not synchronized with the other PLC Fieldbus activated
E	*"Error"*	`RS_CYCLE_ERROR`	Fieldbus error, occurred in redundant synchronized mode as active PLC Fieldbus deactivated
Sim	*"Simulation"*	`RS_SIMULATION`	If not configured Works in standalone mode, not synchronized with the other PLC Fieldbus deactivated
		`RS_BOOTUP_ERROR`	If in state `RS_CYCLE_ACTIVE` The other PLC will become active because the PROFIBUS displays a problem with the active PLC (us). Fieldbus deactivated

Circle Symbol	Output text under *“Redundancy State”*	`STRUCT Redundancy State`	Description
		`RS_SHUTDOWN_ACTIVE`	Ends the runtime systems in state `RS_CYCLE_STANDALONE` Note: Leave the fieldbus activated on download.
		`RS_SHUTDOWN_STANDBY`	Ends the runtime systems in state `RS_CYCLE_STANDBY` Note: Deactivate the fieldbus on download.
		`RS_SYNCHRO_ERROR`	Error occurred during the state `RS_SYNCHRO` Fieldbus deactivated
		`RS_SIMULATION_START`	With setting `Simulation=1` Works in standalone mode after the start, not synchronized with the other PLC Fieldbus deactivated Note: A synchronization can be triggered later with library functions.
		`RS_NO_LICENCE`	If no license is installed and the demo time has expired. No operation
	*“Unknown”*	No assignment	Indicates that the connection to the PLC is not online

1.4.1.19.6 Pragmas

Pragma instructions affect the properties of one or more variables with regard to the compilation or pre-compilation process. Various categories of pragmas are available to you for this.

Message Pragmas

Message pragmas serve to force the display of messages in the Message window during the compilation process.

Insertion position: separate or already existing line in the text editor of a POU.

Table 44: 4 types of message pragmas

Pragma	Message type
`{text <'textstring'>}`	*"Text"*: display of <textstring>.
`{info <'textstring'>}`	*"Information "*: display of <textstring>.
`{warning <'textstring'>}`	*"Warning"*: display of <textstring>. Unlike the attribute pragma `'obsolete'`, you define the warning locally for the current position.
`{error <'textstring'>}`	*"Error "*: display of <textstring>.

In the CODESYS Message window you can jump with the help of the commands "Next Message" and "Previous Message" from a message of the category "Information", "Warning" and "Error" to the source position of the message. This means you jump to the position where the pragma is added in the source code.

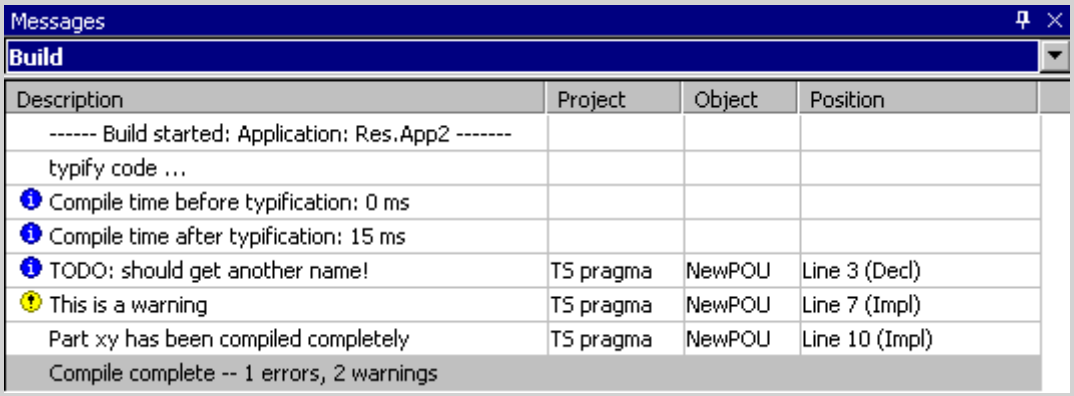
Example

```
VAR
    var : INT; {info 'TODO: should get another name'}
 bvar : BOOL;
 arrTest : ARRAY [0..10] OF INT;
 i:INT;

END_VAR
    arrTest[i] := arrTest[i]+1;
 ivar:=ivar+1;

 {warning 'This is a warning'}
 {text 'Part xy has been compiled completely'}
```

Display in the Message window:



See also

- *Chapter 1.4.1.19.6.3 "Conditional Pragmas" on page 732*

Attribute Pragmas

Attribute pragmas affect the compilation and the pre-compilation.

CODESYS supports a series of pre-defined attribute pragmas. In addition you can use user-defined pragmas, which you can query with the help of conditional pragmas before the compilation of the project.

Attributes are defined within the declaration part. Exception: For the objects Action and Transition, which have no own declaration part, you can define the attributes at the beginning of the implementation part

When you define own attributes, please make them unambiguous. Uniqueness can be reached for example by adding a prefix to the attribute name. OEMs can use the vendor prefix for this purpose.

User-defined attributes

User-defined attributes are any application-defined or user-defined attributes that you can apply to POUs, actions, data type definitions and variables. You can query a user-defined attribute with the help of conditional pragmas before the compilation of the application.

You can query user-defined attributes with conditional pragmas with the operator `hasattribute`*.*

More detailed information and examples can be found in the chapter 'Conditional pragmas'.

Syntax:

```
{attribute 'attribute'}
```

Example for POUs and actions

Attribute `'vision'` for function *"fun1"*

```
{attribute 'vision'}
FUNCTION fun1 : INT
VAR_INPUT
 i : INT;
END_VAR
```

Example for variables

Attribute `'DoCount'` for variable `ivar`:

```
PROGRAM PLC_PRG
VAR
 {attribute 'DoCount'};
 ivar:INT;
 bvar:BOOL;
END_VAR
```

Example for data types

Attribute `'aType'` for data type `DUT_1`:

```
{attribute 'aType'}
TYPE DUT_1 :
STRUCT
 a:INT;
 b:BOOL;
END_STRUCT
END_TYPE
```

See also

- *Chapter 1.4.1.19.6.3 “Conditional Pragmas” on page 732*

Attribute 'call_after_global_init_slot'

> **NOTICE!**
> `VAR_INPUT` declarations in functions or methods that use the attribute lead to compile errors. Reason: Input variables are unknown in this case at the time of the call, which occurs implicitly during the online change.

The effect of this pragma is that all functions and programs containing this attribute are called after the global initialization. You define the order of calling by means of the attribute value.

Syntax:

```
{attribute 'call_after_global_init_slot' := '<slot>'}
```

`<slot>`: Integer value that defines the ranking in the order of the calls; the lower the value, the earlier the call takes place. If several function blocks have the same ranking for the attribute, then the order of their calls remains indefinite.

Insert location: First line above the declaration part of functions and programs

If a method possesses the attribute, CODESYS determines all instances of the corresponding function block and calls all instances in the specified slot. In this case you have no influence on the order of the instances among themselves.

See also

- *Chapter 1.4.1.19.10 “Methods 'FB_Init', 'FB_Reinit', and 'FB_Exit'” on page 748*

Attribute 'call_after_init'

> **NOTICE!**
> `VAR_INPUT` declarations in functions or methods that use the attribute lead to compile errors. Reason: Input variables are unknown in this case at the time of the call, which occurs implicitly during the online change.

The effect of this pragma is that a method is called implicitly after the initialization of a function block instance. For reasons of performance you must add the attribute both to the function block and to the method in its own first line above the declaration part.

Syntax:

```
{attribute 'call_after_init'}
```

Call: First line above the declaration part of the method and the function block.

CODESYS calls the method after the method FB_init and after the variable values of an initialization expression in the instance declaration have become valid.

This functionality is supported from compiler version 3.4.1.0.

Example

Definition:

```
{attribute 'call_after_init'}
FUNCTION_BLOCK FB
... <function block definition>

{attribute 'call_after_init'}
METHOD FB_AfterInit
... <method definition>
```

The definition implements, for example, the following declaration in the subsequent code processing:

```
inst : FB := (in1 := 99);
```

Code processing:

```
inst.FB_Init();
inst.in1 := 99;
inst.FB_AfterInit();
```

This allows a reaction to the user-defined initialization in `FB_AfterInit`.

See also

- *Chapter 1.4.1.19.10 “Methods 'FB_Init', 'FB_Reinit', and 'FB_Exit'” on page 748*

Attribute 'call_after_online_change_slot'

> **NOTICE!**
> `VAR_INPUT` declarations in functions or methods that use the attribute lead to compile errors. Reason: Input variables are unknown in this case at the time of the call, which occurs implicitly during the online change.

The effect of this pragma is that all functions and programs containing this attribute are called after an online change. You define the order of calling by means of the attribute `<slot>`.

Syntax:

```
{attribute 'call_after_online_change_slot' := '<slot>'}
```

`<slot>`: Integer value that defines the ranking in the order of the calls; the lower the value, the earlier the call takes place. If several function blocks have the same ranking for the attribute, then the order of their calls remains indefinite.

Call: First line above the declaration part of functions and programs.

If a method possesses the attribute, then CODESYS determines all instances of the function block concerned. CODESYS calls all instances in the specified slot. In this case you have no influence on the order of the instances among themselves.

NOTICE!
Since the application cannot run during the online change, each code executed in this situation can lead to a jitter. Therefore, keep the extent of the executive code as small as possible.

See also

- *Chapter 1.4.1.20.3.6.6 “Command 'Online Change'” on page 1033*

Attribute 'call_before_global_exit_slot'

NOTICE!
`VAR_INPUT` declarations in functions or methods that use the attribute lead to compile errors. Reason: Input variables are unknown in this case at the time of the call, which occurs implicitly during the online change.

The effect of this pragma is that all functions and programs containing this attribute in a dedicated first line of their declaration are called before the GlobalExit. The GlobalExit takes place before a new download or a reset. Function blocks provided with an `FB_Exit` method are affected. The order of calling is defined by means of the attribute value.

Syntax:

```
{attribute 'call_before_global_exit_slot' := '<slot>'}
```

Insert location: First line above the declaration part of functions and programs.

`<slot>`: Integer value that defines the ranking in the order of the calls; the lower the value, the earlier the call takes place. If several function blocks have the same ranking for the attribute, then the order of their calls remains indefinite.

If a method possesses the attribute, then the method is called for all instances of the function block concerned. CODESYS calls all instances in the specified slot. In this case you have no influence on the order of the instances among themselves.

See also

- *Chapter 1.4.1.19.10 “Methods 'FB_Init', 'FB_Reinit', and 'FB_Exit'” on page 748*

Attribute 'call_on_type_change'

With this pragma, you can mark a method of a function block A that should be called when the data type changes for one or more function blocks B, C, etc. that are referenced by A. The referencing can be defined by a pointer variable or a `REFERENCE` variable.

Syntax:

```
{attribute 'call_on_type_change':= '<name of the first referenced
function block>|<name of the second referenced function block>|<name
of the ... referenced function block>'}
```

Insert location: Line above the first line in the method declaration.

Example

Function blocks with references

```
FUNCTION_BLOCK FB_A
...
VAR
    var_pt: POINTER TO FB_B;
    var_ref: REFERENCE TO FB_C;
END_VAR
...
```

Method for reaction to a type change in the references FB_B and FB_C

```
{attribute 'call_on_type_change' := 'FB_B, FB_C'}
METHOD METH_react_on_type_change : INT
VAR_INPUT
...
```

Attribute 'conditionalshow'

The pragma has the effect that the identifiers of an integrated compiled library `<library name> .compiled-library`, which are decorated with the pragma, are hidden before programming an application. The POUs can be called but the variables are invisible in the CODESYS user interface.

Affected features

- Library management
- Debugging
- Input Assistant
- Function "List components"
- Monitoring
- Symbol configuration

This is useful when you develop libraries. As the library developer, you decorate function blocks or variables with the pragma. As a result, you determine which identifiers are hidden in an application after integration. If you want to show the hidden identifiers later, for example for debugging or further development of the library, you can reactivate its visibility.

Syntax

```
{attribute 'conditionalshow' ( := ' <some text> ' )? }
```

`<some text>`: Optional string literal to control the visibility of the identifiers decorated with this kind of pragma by means of a command-line command and this literal. When the pragma is specified without a literal, the variables in the CODESYS development environment are always hidden, regardless of how CODESYS was started. For more help about this, see the document "Library Development Summary".

Insert location: Top line in the declaration part of a function block, above a variable

Example For more examples, see the document "Library Development Summary".

Hiding a variable

```
FUNCTION_BLOCK FB_DataManager
VAR
    {attribute 'conditionalshow' := 'Library_Developer'}
    iLocal : INT;
    iCounter : INT;
END_VAR
```

The variable `iLocal` is invisible.

Hiding a function block

```
{attribute 'conditionalshow' := 'Library_Developer'}
FUNCTION_BLOCK FB_DataManager
VAR
    iLocal : INT;
    iCounter : INT;
END_VAR
```

The identifiers `FB_DataManager`, `iLocal`, and `iCounter` are invisible.

Visibility in case of existing source code file

When the source code file `<library name> .library` from an integrated library also exists at the same memory location (repository), the identifiers are visible despite the pragmas. That is regardless of whether or not an attribute value has been specified in the declaration.

Command-line call to activate visibility

You can also enable the visibility of the hidden variable without a source code file by starting CODESYS with the command-line option `conditionalshowsymbols`. To enable the visibility, specify the attribute values of the pragma which are separated by commas.

Syntax

```
codesys.exe --conditionalshowsymbols=" <some text> ( ,<next text> )*
"
```

Example

```
codesys.exe --conditionalshowsymbols="Library_Developer"
codesys.exe --conditionalshowsymbols="Group_A,Group_B"
```

See also

- *Chapter 1.4.1.15 “Using the Command-Line Interface” on page 442*
- *Chapter 1.4.1.19.6.2.16 “Attribute 'hide'” on page 700*
- *Chapter 1.4.1.19.6.2.8 “Attribute 'conditionalshow_all_locals'” on page 691*
- "Library Development Summary", "Visibility Control" Chapter

Attribute 'conditionalshow_all_locals'

The pragma has the effect that **all local** variables of a library POU decorated with the pragma are hidden from application programmers. The POUs of an integrated compiled library `<library name> .compiled-library` can be called, but the variables are invisible in the CODESYS user interface.

Affects features:

- Library management
- Debugging
- Input Assistant
- Function "List components"
- Monitoring
- Symbol configuration

This is useful when you develop libraries. As the library developer, you decorate function blocks with the pragma. As a result, you determine that their identifiers are hidden in an application after integration. If you want to show these identifiers later, for example for debugging or further development of the library, you can reactivate its visibility.

Syntax

```
{attribute 'conditionalshow_all_locals' ( := ' <some text> ' )? }
```

`<some text>`: Optional string literal to control the visibility of the identifiers decorated with this kind of pragma by means of a command-line command and this literal. When the pragma is specified without a literal, the variables in the CODESYS development environment are always hidden, regardless of how CODESYS was started. For more help about this, see the document "Library Development Summary".

Insert location: Top line in the declaration part of the function block.

Example

Hiding all local variables

```
{attribute 'conditionalshow_all_locals' := 'Library_Developer'}
FUNCTION_BLOCK FB_DataManager
VAR
    iLocal : INT;
    iCounter : INT;
END_VAR
```

For more examples, see the document "Library Development Summary".

Visibility in case of existing source code file

When the source code file `<library name> .library` from an integrated library also exists at the same memory location (repository), the library POU variables are visible despite the pragmas. That is regardless of whether or not an attribute value has been specified in the declaration.

Command-line call to activate visibility

You can also enable the visibility of the hidden variable without a source code file by starting CODESYS with the command-line option `conditionalshowsymbols`. To enable the visibility, specify the attribute values of the pragma which are separated by commas.

Syntax

```
codesys.exe --conditionalshowsymbols=" <some text> ( ,<next text> )*
"
```

Example

```
codesys.exe --conditionalshowsymbols="Library_Developer"
codesys.exe --conditionalshowsymbols="Group_A,Group_B"
```

- *Chapter 1.4.1.19.6.2.7 “Attribute 'conditionalshow'” on page 690*
- "Library Development Summary", chapter "Visibility Control"

Attribute 'const_replaced', Attribute 'const_non_replaced'

The attribute `'const_replaced'` has the effect that the constant is replaced in the code, independently of the setting of the *“Replace constants”* compiler option. The attribute has an effect for variables of scalar types only, but not for compound types like arrays and structures.

You insert the pragma `{attribute 'const_non_replaced'}` accordingly in order to explicitly deactivate the *“Replace constants”* compiler option. This has the effect, for example in the symbol configuration, that the constant is available and can be exported despite the compiler option.

The *“Replace constants”* option in the *“Compile Options”* category of the *“Project Settings”* dialog is preset for the entire project, because replacing constants generally leads to faster code and less memory usage.

Syntax:

```
{attribute 'const_replaced'}
```

```
{attribute 'const_non_replaced'}
```

Insert location: Line above the declaration line of the global variables.

Example

The constants `iTestCon` and `xTestCon` are available in the symbol configuration because the *“Replace constants”* option deactivated.

```
{attribute 'qualified_only'}
VAR_GLOBAL CONSTANT
    {attribute 'const_non_replaced'}
    iTestCon    :    INT  := 12;
    {attribute 'const_non_replaced'}
    xTestCon    :    BOOL := TRUE;
    rTestCon    :    REAL := 1.5;
END_VAR

VAR_GLOBAL
    iTestVar    :    INT  := 12;
    xTestVar    :    BOOL := TRUE;
END_VAR
```

See also

- *Chapter 1.4.1.20.4.11.3 “Dialog Box 'Project Settings' - 'Compileoptions'” on page 1173*
- *Chapter 1.4.1.9.2 “Symbol Configuration” on page 357*

Attribute 'dataflow'

With this pragma you control the data flow in the processing of function blocks in the FBD/LD/IL editor. The attribute defines the input or output of a function block to which the continuing connection to the next or previous function block is connected.

You may provide only 1 input and 1 output with the attribute in the declaration of a function block.

Syntax:

```
{attribute 'dataflow'}
```

Insertion position: line above the line with the declaration of the corresponding variables.

In the case of function blocks without the attribute `'dataflow'`, CODESYS determines the data flow as follows: first of all the connection is placed between an output and an input of same data type. The highest input or output variable of the function blocks is always taken. If there are no variables of a corresponding data type, CODESYS connects the highest output with the highest input of the neighboring function blocks.

Example

The connection between `FB` and the preceding function block is established via the input variable `i1`. The connection between `FB` and the following function block is established via the output variable `outRes1`.

```
FUNCTION_BLOCK FB
VAR_INPUT
 r1 : REAL;
 {attribute 'dataflow'}
 i1 : INT;
 i2 : INT;
 r2 : REAL;
END_VAR

VAR_OUTPUT
{attribute 'dataflow'}
 outRes1 : REAL;
 out1 : INT;
 g1 : INT;
 g2 : REAL;
END_VAR
```

See also

- *Chapter 1.4.1.8.3.1.1 “Programming function block diagrams (FBD)” on page 237*

Attribute 'displaymode'

With this pragma you define the display mode of an individual variable. This definition overwrites the global setting for the display of the monitoring variable, which takes place via the commands in the menu *“Debug ➔ Display Mode”*.

Syntax:

```
{attribute 'displaymode':=<displaymode>}
```

The following definitions are possible

- Binary format
  - `{attribute 'displaymode':='bin'}`
  - `{attribute 'displaymode':='binary'}`
- Decimal format
  - `attribute 'displaymode':='dec'}`
  - `{attribute 'displaymode':='decimal'}`
- Hexadecimal format
  - `{attribute 'displaymode':='hex'}`
  - `attribute 'displaymode':='hexadecimal'}`

Insertion position: line above the line with the declaration of the corresponding variables.

Example

```
VAR
 {attribute 'displaymode':='hex'}
 dwVar1: DWORD;
END_VAR
```

See also

- *Chapter 1.4.1.20.3.7.24 “Command 'Display Mode' - 'Binary', 'Decimal', 'Hexadecimal'” on page 1058*

Attribute 'enable_dynamic_creation'

The pragma `enable_dynamic_creation` is needed for using the `__NEW` operator for function blocks.

Syntax:

```
{attribute 'enable_dynamic_creation'}
```

Insert location: First line in the declaration of the function block.

See also

- *Chapter 1.4.1.19.3.58 “Operator '__NEW'” on page 614*

Attribute 'estimated-stack-usage'

The pragma provides an estimated value for the stack size requirement.

Methods with recursive calls cannot pass a stack check because stack usage cannot be determined. As a result, a warning is issued. To prevent this warning, you can give the method an estimated value (in bytes) for the stack size requirement. Then the method passes the stack check successfully.

Syntax

```
{attribute 'estimated-stack-usage' := '<estimated stack size in bytes>'}
```

Example

```
{attribute 'estimated-stack-usage' := '127'} // 127 bytes
METHOD PUBLIC DoIt : BOOL
VAR_INPUT
END_VAR
```

Insert location: First line above the declaration part of the method.

The section "Method call" includes an example that uses this pragma.

Recursive method call

Within its implementation, a method can call itself, either directly by means of the `THIS` pointer, or by means of a local variable for the assigned function block.

Use recursions mainly for processing recursive data types such as linked lists. In general, we recommend to be careful when using recursion, as unexpectedly deep recursions can cause stack overflow and machine downtime.

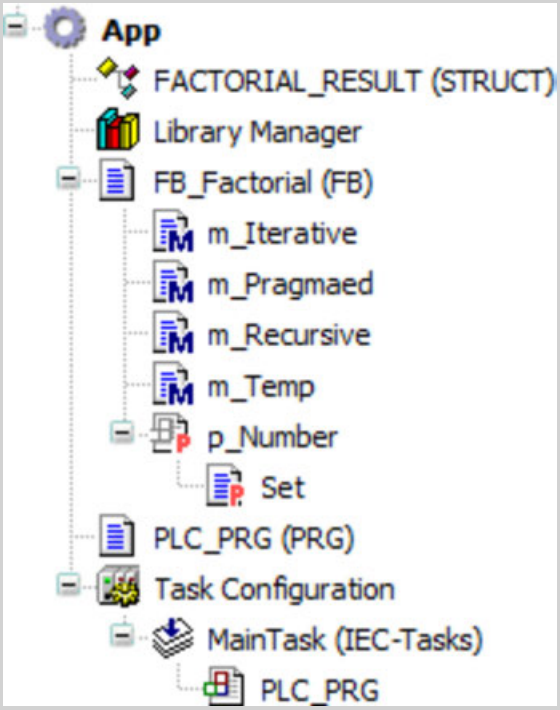
Example

Calculation of the factorial

The following program `PLC_PRG` calculates the factorial of a number in the `FB_Factorial` function block in a different way, each in its own method.

- Method `m_Iterative`: Iterative
- Method `m_Pragmaed`: Recursive with warning suppression
- Method `m_Recursive`: Recursive
- Method `m_Temp`: Temporary with warning suppression

A warning is issued for the `m_Recursive` method only.



```
// Contains the data  of the factorial calculation of uiNumber
TYPE FACTORIAL_RESULT :
STRUCT
    uiNumber : UINT;
    udiIterative : UDINT;
    udiRecursive : UDINT;
    udiPragmaed : UDINT;
    udiTemp : UDINT;
END_STRUCT
END_TYPE

PROGRAM PLC_PRG
VAR
    fb_Factorial_A : FB_Factorial;
    factorial_A : FACTORIAL_RESULT := (uiNumber := 9,
udiIterative := 0, udiRecursive := 0, udiPragmaed := 0 );
END_VAR
fb_Factorial_A.p_Number := factorial_A.uiNumber;
factorial_A.udiIterative := fb_Factorial_A.m_Iterative();
factorial_A.udiRecursive := fb_Factorial_A.m_Recursive(uiN :=
factorial_A.uiNumber);
factorial_A.udiPragmaed := fb_Factorial_A.m_Pragmaed(uiN :=
factorial_A.uiNumber);
factorial_A.udiTemp := fb_Factorial_A.m_Temp(uiN :=
factorial_A.uiNumber);
```

```
//Factorial calculation in different ways
FUNCTION_BLOCK FB_Factorial
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    uiN : UINT;
    udiIterative : UDINT;
    udiPragmaed : UDINT;
    udiRecursive : UDINT;
END_VAR

// Iterative calculation
METHOD PUBLIC m_Iterative : UDINT
VAR
    uiCnt : UINT;
END_VAR
m_Iterative := 1;
IF    uiN > 1 THEN
    FOR uiCnt := 1 TO uiN DO
        m_Iterative := m_Iterative * uiCnt;
    END_FOR;
    RETURN;
ELSE
    RETURN;
END_IF;

//Recursive calculation with suppressed warning
{attribute 'estimated-stack-usage' := '99'}
METHOD PUBLIC m_Pragmaed : UDINT
VAR_INPUT
    uiN : UINT;
END_VAR
VAR
END_VAR
m_Pragmaed := 1;
IF    uiN > 1 THEN
    m_Pragmaed := uiN * THIS^.m_Pragmaed(uiN := (uiN - 1));
    RETURN;
ELSE
    RETURN;
END_IF;

//Recursive calculation
METHOD PUBLIC m_Recursive : UDINT
VAR_INPUT
    uiN : UINT;
END_VAR
VAR
END_VAR
m_Recursive := 1;
IF    uiN > 1 THEN
    m_Recursive := uiN * THIS^.m_Recursive(uiN := (uiN - 1) );
    RETURN;
ELSE
    RETURN;
END_IF;

// Called by temporary FB instance
{attribute 'estimated-stack-usage' := '99'}
METHOD PUBLIC m_Temp : UDINT
VAR_INPUT
    uiN : UINT;
END_VAR
```

```
VAR
    fb_Temp : FB_Factorial;
END_VAR
m_Temp := 1;
IF    uiN > 1 THEN
    m_Temp := uiN * fb_Temp.m_Temp(uiN := (uiN - 1));
    RETURN;
ELSE
    RETURN;
END_IF;

PROPERTY p_Number : UINT
uiN := p_Number; //Setter method
```

Only the `m_Recursive` issues a warning when the program is executed.

Attribute 'ExpandFully'

The effect of this pragma is that the components of an array used as an input variable for referenced visualizations are made visible in the Properties dialog box of the visualization.

Syntax:

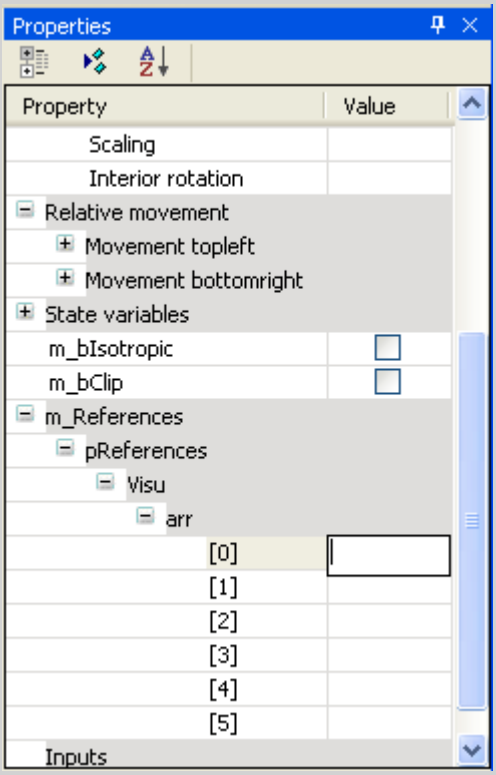
```
{attribute 'ExpandFully'}
```

Insertion position: the line above the line with the declaration of the array.

Example

The visualization *“visu”* is to be inserted into a frame inside the visualization *“visu_main”*. `arr` is defined as an input variable in the interface editor of *“visu”* and will thus be available later for assignments in the Properties dialog box of the frames in *“visu_main”*. In order to also make the individual components of `arr` available in this Properties dialog box, you must insert the attribute `'ExpandFully'` directly before `arr` in the interface editor of visu. Declaration in the interface editor of *“visu”*:

```
VAR_INPUT
 {attribute 'ExpandFully'}
 arr : ARRAY[0..5] OF INT;
END_VAR
```



Attribute 'global_init_slot'

The pragma defines the initialization order of programming blocks and global variable lists.

Variables in a list (GVL or POU) are initialized from top to bottom.

If there are several global variable lists, then the initialization order is not defined.

The initialization does not apply for the initialization of literal values, for example `1`, `'hello'`, `3.6`, or constants of base data types. However, you must define the initialization order yourself if there are dependencies between the lists. You can assign a defined initialization slot to a GVL or POU with the `'global_init_slot'` attribute.

Constants are initialized before the variables and in the same order as the variables. During initialization, the POUs are sorted according to the value for <slot>. Then the code for initializing the constants is generated and afterwards the code for initializing the variables.

Syntax:

```
{attribute 'global_init_slot' := '<slot>'}
```

`<slot>`: Integer value that defines the position in the call order. The default value for a POU (program, function block) is 50000. The default value for a GVL is 49990. A lower value means an earlier initialization. Caution: If several blocks or GVLs receive the same value for the `'global_init_slot'` attribute, then the initialization order remains undefined.

Insert location: The pragma always affects the entire GVL or POU and therefore it must be located above the `VAR_GLOBAL` or POU declaration.

If several programming blocks have got assigned the same value for the attribute `'global_init_slot'`, the order of their initialization remains undefined.

Example

The program includes two global variable lists `GVL_1` and `GVL_2`, as well as a `PLC_PRG` program that uses variables from both lists. `GVL_1` uses the variable `B` for initializing a variable `A`, which is initialized in `GVL_2` with a value of `1000`.

GVL_1

```
VAR_GLOBAL   //49990
 A : INT := GVL_2.B*100;
END_VAR
```

GVL_2

```
VAR_GLOBAL   //49990
 B : INT := 1000;
 C : INT := 10;
END_VAR
```

PLC_PRG

```
PROGRAM PLC_PRG  //50000
VAR
 ivar: INT := GVL_1.A;
 ivar2: INT;
END_VAR

ivar:=ivar+1;
ivar2:=GVL_2.C;
```

In this case, the compiler prints an error because `GVL_2.B` is used for initializing `GVL_1.A` before `GVL_2` has been initialized. You can prevent this by using the `global_init_slot` attribute to position `GVL_2` before `GVL_1` in the initialization sequence.

In this example, `GVL_1` must have at least one slot value of 49989 in order to achieve the earliest initialization within the program. Every lower value has the same effect:

GVL_2

```
{attribute 'global_init_slot' := '100'}
VAR_GLOBAL
  B : INT := 1000;
END_VAR
```

Using `GVL_2.C` in the implementation part of `PLC_PRG` is also not critical even without using a pragma because both GVLs are initialized before the program in either case.

Attribute 'hide'

Using the pragma `{attribute 'hide'}` to hide variables and POUs does not have the desired effect in most cases. Instead, you should use the pragma `{attribute 'conditionalshow'}`.

The pragma prevents the variables and POUs defined with it from being shown in the CODESYS user interface. As a result, you can intentionally hide these identifiers without restricting the access. This can be useful when you develop libraries.

Affected features:

- Library management
- Debugging
- Input Assistant
- Function "List components"

- Monitoring
- Symbol configuration

The variables or POUs defined with the pragma are neither visible in the Library Manager nor are they suggested in the Input Assistant or in the "List components" function. The pragma prevents those marked variables from being displayed in the symbol configuration. As a result, you cannot export these kinds of variables as symbols. The variables are also invisible in online mode, and therefore their values cannot be monitored. Moreover, you cannot use any debugging functionalities and you do not have any support when checking for bugs.

Syntax:

```
{attribute 'hide'}
```

Insert location: For variables, above the line with the declaration of the variables. For POUs, in the first line.

If you, the application developer, know the exact instance path of the hidden POUs and variables, then you can access them in the code.

Example of hidden variable

The function block `FB_MyA` contains the attribute pragma `{attribute 'hide'}` to hide the local variable `xInvisibleIn`.

```
FUNCTION_BLOCK FB_MyA
VAR_INPUT
    iInA : INT;
    {attribute 'hide'}
    xInvisibleIn : BOOL;
    xInit: BOOL;
END_VAR
VAR_OUTPUT
     iOutA : INT;
END_VAR
VAR
    iCounter : INT;
END_VAR
```

Two instances of the function block `FB_MyA` are defined in the main program.

```
PROGRAM PLC_PRG
VAR
    fbMyA1, fbMyA2 : FB_MyA;
    xVar2 : BOOL;
    iVar1 : INT;
    iVar2 : INT;
END_VAR
fbMyA1(iInA := 1, xInit := TRUE, xInvisibleIn := TRUE, iOutA =>
iVar1);
fbMyA2(iInA := 1, xInit := TRUE, iOutA => iVar2);
```

When the input value for `fbMyA1` is implemented, the "List components" function, which opens when you type `fbMyA1.` (in the implementation part of `PLC_PRG`), displays the variables `iInA`, `xInit`, and `iOutA`, but not the hidden variable `xInvisibleIn`.

Example of hidden library POU

`FB_A` is a function block of the library `HiddenFunctionality` with the default namespace `HIDDEN`. To hide the identifier and the POU code from application developers, begin the declaration of the POU with the attribute pragma `{attribute 'hide'}`. To hide the subordinate POUs (actions, methods, properties, and transitions) in the same way, also begin their declarations with `{attribute 'hide'}`.

```
{attribute 'hide'}
FUNCTION_BLOCK FB_A
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    iA : INT;
    iCount : INT;
    iInvisible : INT;
END_VAR

{attribute 'hide'}
METHOD METH_Count : INT
VAR_INPUT
END_VAR
iCount := iCount + 1;

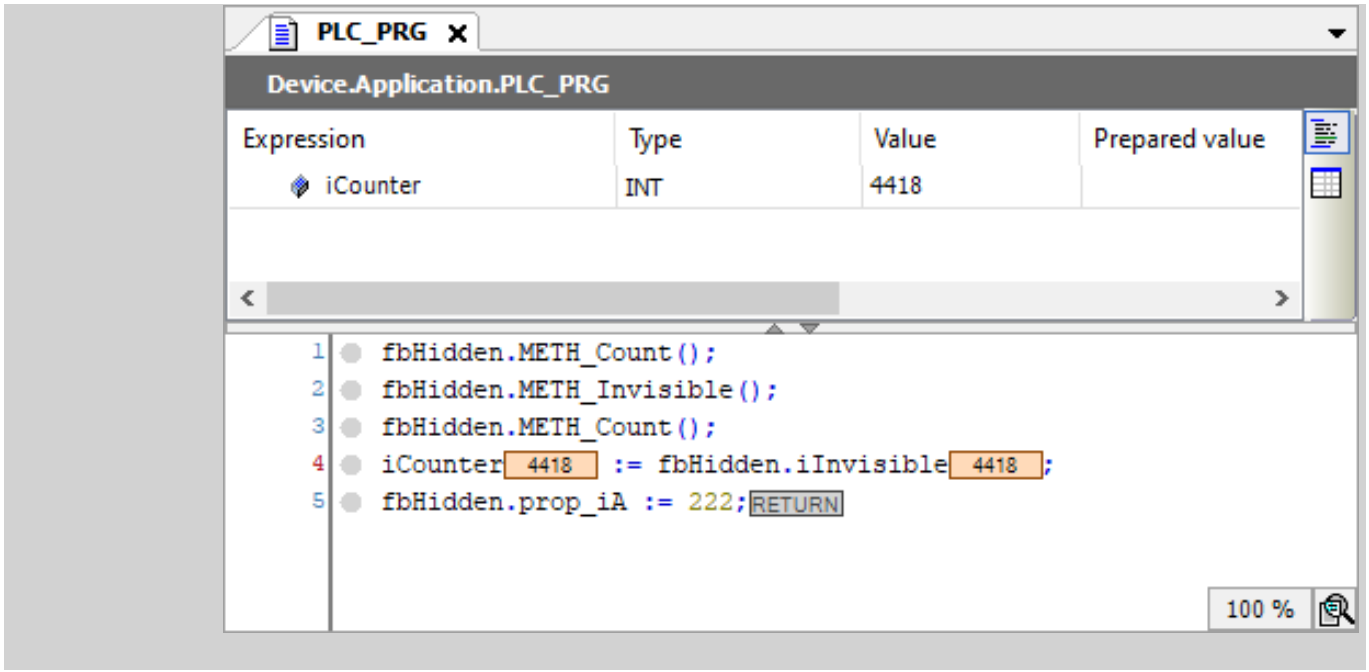
{attribute 'hide'}
METHOD METH_Invisible : BOOL
VAR_INPUT
END_VAR
iInvisible := iInvisible + 1;

{attribute 'hide'}
PROPERTY PUBLIC prop_iA : INT
```

For you as the application developer, all POUs are invisible. You can use them only if you know the instance path.

```
PROGRAM PLC_PRG
VAR
    fbHidden : HIDDEN.FB_A; // Hidden function block from library
HiddenFunctionality
    iCounter : INT;
END_VAR
fbHidden.METH_Invisible();
iCounter := fbHidden.iInvisible;
```

In online mode, no monitoring is performed.



With the pragma `hide_all_locals` you can hide all local variables of a POU.

See also

- *Chapter 1.4.1.19.6.2.17 “Attribute 'hide_all_locals'” on page 703*
- *Chapter 1.4.1.19.6.2.7 “Attribute 'conditionalshow'” on page 690*
- *Chapter 1.4.1.19.6.2.8 “Attribute 'conditionalshow_all_locals'” on page 691*

Attribute 'hide_all_locals'

The pragma prevents all local variables of a signature from being visible in the display of the 'List components' function, in the Input Assistant or in the declaration part in online mode. Moreover, these variables are hidden in the symbol configuration and therefore cannot be exported as symbols. The pragma is especially useful in library POUs to hide POU variables from users.

Affected features

- Library management
- Debugging
- Input Assistant
- Function "List components"
- Monitoring
- Symbol configuration

Syntax:

```
{attribute 'hide_all_locals'}
```

Insert location: First line above the declaration part of the POU

Example

The function block `FB_MyB` uses the attribute:

```
{attribute 'hide_all_locals'}
FUNCTION_BLOCK FB_MyB
VAR_INPUT
    iInB : INT;
    {attribute 'hide'}
    xInvisibleIn : BOOL;
    xInit: BOOL;
END_VAR
VAR_OUTPUT
     iOutB : INT;
END_VAR
VAR
    iCounter : INT;
    xVar : BOOL;
END_VAR
```

Two instances of the function block `FB_MyB` are defined in the main program.

```
PROGRAM PLC_PRG
VAR
    fbMyB1, fbMyB2: FB_MyB;
    iVar3: INT;
    iVar4: INT;
END_VAR

fbMyB1(iInB := 2, xInvisibleIn := TRUE, iOutB => iVar3);
fbMyB2(iInB := 2, iOutB => iVar4);
IF fbMyB2.iCounter > 100 THEN
    fbMyB2.xInit := TRUE;
END_IF
```

Now when you download the program to the controller, start it, and switch to online mode, the variables `iInB`, `xInit`, `iOutB`, and `xReset` are displayed in the declaration editor. However, the hidden local variables `iCounter` and `xVar` are not displayed.

See also

- *Chapter 1.4.1.19.6.2.16 “Attribute 'hide'” on page 700*

Attribute 'initialize_on_call'

The pragma causes input variables of a function block to be initialized on each call of the function block. If an input variable is affected which expects a pointer and this pointer has been removed during an online change, then the variable is initialized to `zero`.

Syntax:

```
{attribute 'initialize_on_call'}
```

Insert location: Always in the first line of the declaration part for the entire function block, and also in a line above the declaration of the individual input variable.

Example

```
{attribute 'initialize_on_call'}
FUNCTION_BLOCK fb
VAR_INPUT
                {attribute 'initialize_on_call'}
                pInt : POINTER TO INT := 0;
                {attribute 'initialize_on_call'}
                iVal : INT := 0;
END_VAR
```

Attribute 'init_namespace'

The effect of this pragma is that a variable of the type `STRING` or `WSTRING`, which is declared in a library function block with this pragma, is initialized when used in the project with the current namespace of the library.

Syntax

```
{attribute 'init_namespace'}
```

Insertion position: the line above the line with the declaration of the variables in a library function block.

Example

The function block *"POU"* is provided with the necessary attributes:

```
FUNCTION_BLOCK POU
VAR_OUTPUT
 {attribute 'init_namespace'}
 myStr: STRING;
END_VAR
```

An instance `fb` of the function block POU is defined within the main program PLC_PRG:

```
PROGRAM PLC_PRG
VAR
 fb:POU;
 newString: STRING;
END_VAR
 newString := fb.myStr;
```

The variable `myStr` is initialized with the current namespace, for example `MyLib`. This value is assigned to `newString` in the main program.

See also

- *Chapter 1.4.1.20.2.14 "Object 'Library Manager'" on page 874*

Attribute 'init_on_onlchange'

The effect of this pragma is that the variable to which the pragma is applied is initialized with each online change.

NOTICE!

For compiler version 3.5.0.0 and later, a fast online change is performed for minor changes. In this case, only the modified blocks are compiled and downloaded. In particular, no initialization code is generated. This means that also no code is generated when variables with the `init_on_onlchange` attribute are initialized. As a rule, this has no effect because the attribute is used primarily for initializing variables with addresses. However, it cannot happen that a variable changes its address during an online change.

To secure the effect of the `init_on_onlchange` attribute in the entire application code, you must deactivate the fast online change in general for the application by using the compiler definition `no_fast_online_change`. To do this, insert the definition in the application *"Properties"* (*"Build"* tab).

Syntax:

```
{attribute 'init_on_onlchange' }
```

Insert location: The line above the line with the declaration of the variables.

See also

- *Chapter 1.4.1.20.4.10.4 "Dialog 'Properties' - 'Build'" on page 1159*

Attribute 'instance-path'

This pragma can be applied to a local STRING variable and causes this local STRING variable to be initialized in sequence with the device tree path of the POU to which it belongs. This can be useful for error messages. The application of the pragma requires the application of the attribute `'reflection'` to the associated POU, as well as the application of the additional attribute `'noinit'` to the STRING variable.

Syntax:

```
{attribute 'instance-path'}
```

Insertion position: the line above the line with the declaration of the `STRING` variable.

Example

The following function block contains the attributes `'reflection'`, `'instance-path'` and `'noinit'`.

```
{attribute 'reflection'}
FUNCTION_BLOCK POU
VAR
 {attribute 'instance-path'}
 {attribute 'noinit'}
 str: STRING;
END_VAR
```

An instance *"myPOU"* of the function block *"POU"* is defined within the main program *"PLC_PRG"*:

```
PROGRAM PLC_PRG
VAR
 myPOU:POU;
 myString: STRING;
END_VAR
myPOU();
myString:=myPOU.str;
```

Following the initialization of the instance `myPOU`, the path of the instance myPOU is assigned to the string variable `str`, in the example `PLCWinNT.Application.PLC_PRG.myPOU`. This path is assigned in the main program to the variable `myString`.

NOTICE!
You can define the length of a string to be whatever you like (even >255), but you must consider that the string will be truncated at the end if it is assigned to a variable whose data type is too small for it.

See also

- *Chapter 1.4.1.19.6.2.39 “Attribute 'reflection'” on page 727*
- *Chapter 1.4.1.19.6.2.30 “Attribute 'noinit'” on page 713*

Attribute 'io_function_block', 'io_function_block_mapping'

With the `'io_function_block'` attribute, you mark a function block in order to prepare it for the assignment to a channel in the I/O mapping of the device configuration. Then it is shown in the *“Select function block”* dialog.

With the `'io_function_block_mapping'` attribute, you mark a parameter that should be used when mapping the FB to a device channel in this kind of function block. You can provide the attribute to multiple parameters of the function block. For I/O mapping, the first one is used automatically whose type matches the channel (input, output, data type).

Syntax:

```
{attribute 'io_function_block'}
{attribute 'io_function_block_mapping'}
```

Insert location: The line above the first line in the declaration of the function block, or the line above the parameter declaration.

Example

```
{attribute 'io_function_block'}
FUNCTION_BLOCK Scale_Output_Int
VAR_INPUT
    iInput : INT;
    iNumerator : INT;
    iDenominator : INT :=1;
    iOffset : INT := 0;
END_VAR
VAR_OUTPUT
 {attribute 'io_function_block_mapping'}
    iOutput : INT;
END_VAR
VAR
```

See also

- *Chapter 1.4.1.20.4.3 “Dialog 'Select Function Block'” on page 1150*
- *“Linking a device with a function block instance” on page 218*

Attribute 'is_connected'

You use the pragma `'is_connected'` to mark a Boolean function block variable which, when a function module instance is called, provides information about whether the associated input of the POU has an assignment.

The use of the pragma requires the use of the attribute `'reflection'` on the affected function block.

Syntax:

```
{attribute 'is_connected' := '<input variable>'}
```

Example

In the function block `FB`, a local variable is declared for each input variable (`in1` and `in2`) and the attribute `'is connected'` is prepended to it each time with the name of the input variable. The func itself gets the pragma attribute `'reflection'`.

When an instance of the function block is called, the local variable is `TRUE` in the case that the input assigned to it has received an assignment.

```
{attribute 'reflection'}
FUNCTION_BLOCK FB
VAR_INPUT
  in1: INT;
  in2: INT;
END_VAR
VAR
  {attribute 'is_connected' := 'in1'}
  in1_connection_info: BOOL;
  {attribute 'is_connected' := 'in2'}
  in2_connection_info: BOOL;
END_VAR
```

Assumption: When the function block instance is called, `in1` receives an external assignment and `in 2` does not receive an assignment. This results in the following code:

```
in1_connection_info := TRUE;
in2_connection_info := FALSE;
```

See also

- *Chapter 1.4.1.19.6.2.39 “Attribute 'reflection'” on page 727*
- *Chapter 1.4.1.20.2.18.2 “Object 'Function Block'” on page 883*

Attribute 'linkalways'

The pragma `{attribute 'linkalways'}` instructs the compiler to always include a POU or a library POU in the compile information. During the build, the POU is compiled and is part of the application code. During the download, the POU is downloaded to the PLC.

Syntax:

```
{attribute 'linkalways'}
```

Insertion location: The first line in the declaration part of the POU or library POU

The POU may be valid throughout the project (saved in the *“POUs”* view) or throughout the application (saved in the *“Devices”* view).

You can also select the “Link always” option in the “Build” tab of a POU's object properties.

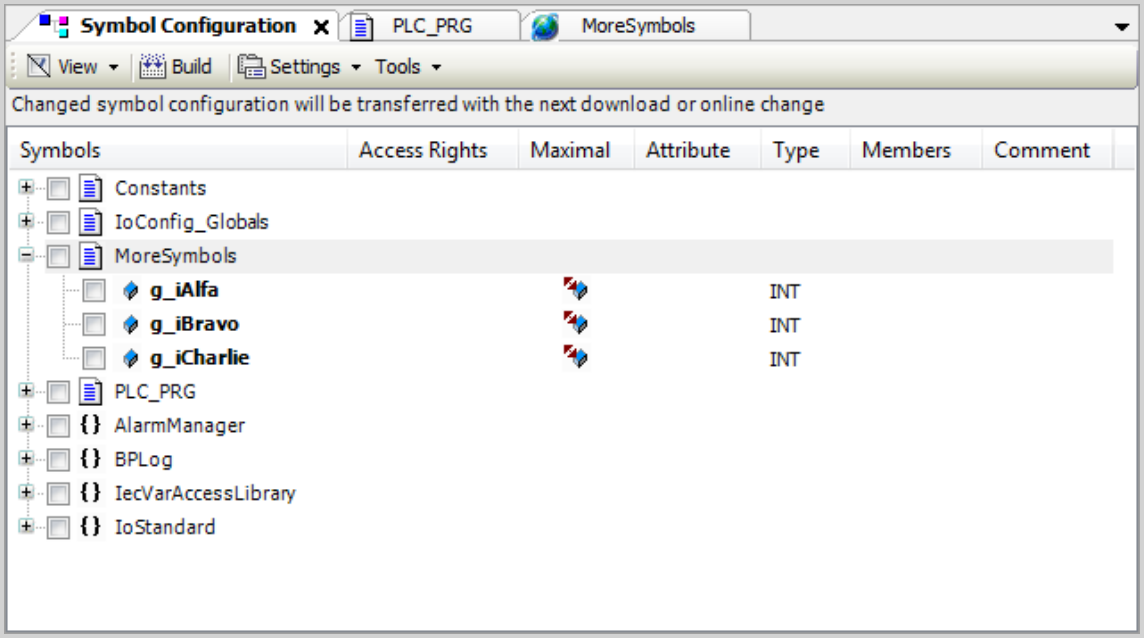
Example

The *"MoreSymbols"* GVL contains the pragma `{attribute 'linkalways'}`. The variables declared there are also part of the application code, regardless of any access.

GVL `MoreSymbols`

```
{attribute 'linkalways'}
VAR_GLOBAL
    g_iAlpha: INT;
    g_iBravo: INT;
    g_iCharlie: INT;
END_VAR
```

The symbol configuration also accesses the compile information. As a result, the variables of the `MoreSymbols` GVL are always provided for selection in the *"Symbol Configuration"* editor.



See also

- *Chapter 1.4.1.20.4.10.4 "Dialog 'Properties' - 'Build'" on page 1159*
- *Chapter 1.4.1.9.2 "Symbol Configuration" on page 357*

Attribute 'monitoring'

The effect of this pragma is that you can monitor values of properties or function calls in the online view of the IEC editor or in a watch list. There are two possible attribute values for this: `'variable'` and `'call'`

Syntax

```
{attribute 'monitoring' := 'variable'}
{attribute 'monitoring' := 'call'}
```

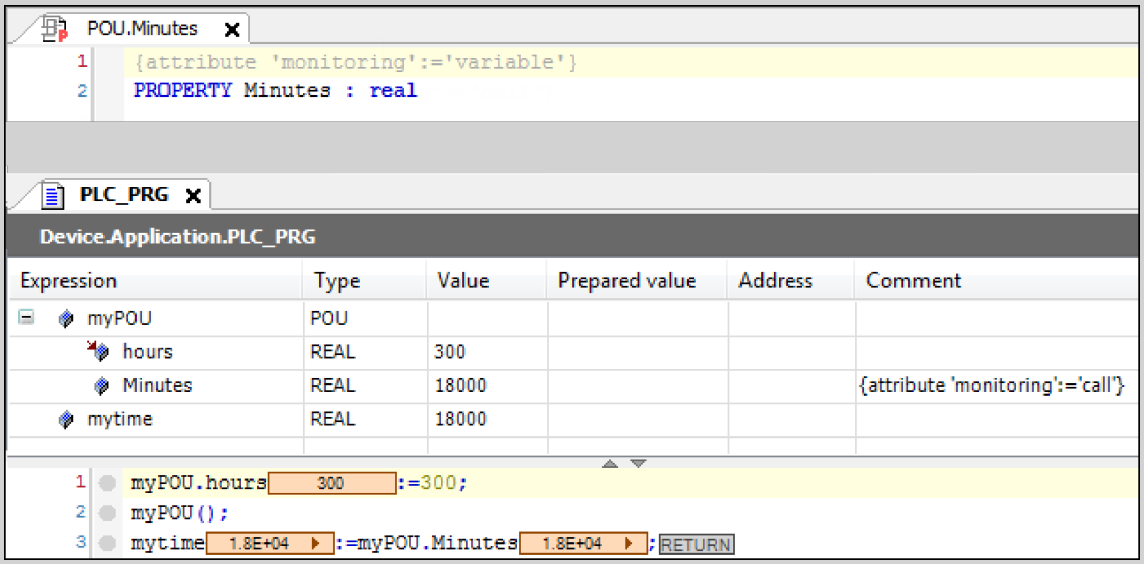
Monitoring of programming objects and their properties

In the online view of a function block or program, you can monitor the subordinate properties in addition to the local variables. This allows you to monitor the values of the `Get` and `Set` methods.

Insert either the pragma `{attribute 'monitoring' := 'variable'}` or `{attribute 'monitoring' := 'call'}` in the declaration of the property block. The current values of the property are then displayed automatically in the IEC editor or in a watch list.

Example

In online mode, the `PLC_PRG` object shows the value of the `Minutes` property at the call location inline in the ST editor. This is because the pragma `{attribute 'monitoring' := 'variable'}` is located in the declaration of the `Minutes` property.



Check carefully for each application which attribute pragma is suitable for displaying the desired value. This depends on whether further operations with the variables are implemented within the property.

1. Pragma `{attribute 'monitoring':='variable'}`:

An implicit variable is created for the property, which is then always given the current property value when the application calls the `Set` or `Get` method. The value stored last in this variable is displayed in the monitoring.

2. Pragma `{attribute 'monitoring':='call'}`:

You can use this attribute only for properties that return simple data types or pointers, but not for structured types. The value to be monitored is read or written by calling the property directly. This means that the monitoring service of the runtime executes the `Get` or `Set` method of the property.

NOTICE!
When you insert the pragma `{attribute 'monitoring':='call'}` for monitoring, you have to pay attention to possible side effects. These kinds of side effects can occur if additional operations are implemented in the property.

NOTICE!
The pragma `{attribute 'monitoring'}` is also evaluated for the symbol configuration. Only read access is possible for the value `'variable'`.

With the context menu command “Add Watch”, a variable on which the cursor is currently positioned is applied directly into the monitoring list in online mode.

The forcing or writing of functions is not supported. However, you can implicitly implement forcing by adding an additional input parameter for the respective function, which serves as an internal force flag.

Function monitoring is not possible in the compact runtime.

See also

- ↳ *Chapter 1.4.1.20.2.18.8 “Object 'Property'” on page 897*

Attribute 'no_assign', Attribute 'no_assign_warning'

The pragma `'no_assign'` results in compiler errors being displayed if an instance of the function block is assigned to another instance of the same function block. Such assignments are often to be avoided if the function block contains pointers and pointers lead to problems, because they are copied as well during the value assignment.

The pragma `'no_assign_warning'` results in the same as for the pragma `'no_assign'` with compiler warnings instead of compiler errors.

Syntax:

```
{attribute 'no_assign'}
```

Insert location: First line in the declaration part of a function block.

Example

Assignment of function block instances containing pointers.

In this example the value assignment of the function block instances will lead to problems during the execution of `fb_exit`:

```
VAR_GLOBAL
inst1 : TestFB;
  awsBufferLogFile : ARRAY [0..9] OF WSTRING(66);(* Area: 0,
Offset: 0x1304 (4868)*)
   LogFile : SEDL.LogRecord := (sFileName := 'LogFile.log',
pBuffer := ADR(awsBufferLogFile), udiMaxEntriesFile := UDINT#10000,
udiMaxBuffered := UDINT#10, uiLineSize := UINT#64, wsSep := " ",
xCircular := TRUE, siDateFormat := SINT#0, siTimeFormat := SINT#0);
END_VAR

 PROGRAM PLC_PRG
VAR
  inst2 : TestFB := inst1;
  LogFileNew
END_VAR
```

In this case `LogRecord` manages a list of pointers, for which various actions are executed in the case of `fb_exit`. Problems result due to the assignment, because `fb_exit` will be executed twice. You should prevent this by adding the attribute `'no_assign'` in the declaration of the function block *"TestFB"*:

```
{attribute 'no_assign'}
FUNCTION_BLOCK TestFB
VAR_INPUT
...
```

The following compiler errors are then displayed:

```
C0328: Assignment not allowed for type TestFB
C0328: Assignment not allowed for type LogRecord
```

If the pragma `no_assign_warning` is used instead of the pragma `no_assign` for the function block *"TestFB "*, then the `C0328` message is issued as compiler warning, not as a compiler error.

Attribute 'no_check'

This pragma prevents the check function being called for the POU (POUs for implicit checks). Since the check functions can affect the processing speed of the program, it can be useful to apply the attribute to function blocks that have already been checked or are frequently called.

You add the pragma to the declaration of a POU.

Syntax:

```
{attribute 'no_check'}
```

Insertion position: first line in the declaration part of the POU.

NOTICE!

The attribute also automatically affects the child objects of a POU!

Example: If the attribute is entered in a program, check functions will also not be carried out for actions that are assigned to this program.

Attribute 'no_copy'

In general an online change requires a re-allocation of instances, for example of a POU. In the process, the value of the variable contained in the instance is copied.

The pragma prevents the value of the variable contained in the instance from being copied in the course of an online change; instead, the variable is re-initialized in the course of an online change. This can be useful for a local pointer variable that points to a variable that has just been shifted by the online change and thus has a changed address.

You insert the attribute in the declaration part above the line of the declaration of the variables concerned.

Syntax:

```
{attribute 'no_copy'}
```

Attribute 'no-exit'

This attribute suppresses the call of the FB_exit method of a function block for a certain one of its instances. To do this you insert the attribute in the line before the declaration of the function block instance.

Syntax:

```
{attribute 'no-exit'}
```

Example

The method *“FB_exit”* is added to the function block *“POU_ex”*. Two instances of the function block *“POU_ex”* are created in the main program *“PLC_PRG”*.

```
PROGRAM PLC_PRG
VAR
 POU1 : POU_ex;
 {attribute 'no-exit'}
 POU2 : POU_ex;
END_VAR
```

POU1 is called, POU2 is not called.

See also

- *Chapter 1.4.1.19.10 “Methods 'FB_Init', 'FB_Reinit', and 'FB_Exit'” on page 748*

Attribute 'noinit'

This pragma is applied to variables that should not be implicitly initialized.

Syntax:

```
{attribute 'no_init'}
```

```
{attribute 'no-init'}
```

```
{attribute 'noinit'}
```

Insertion position: line above the declaration line of the variables concerned in the declaration part.

Example

```
PROGRAM PLC_PRG
VAR
 A : INT;

 {attribute 'no_init'}
 B : INT;
END_VAR
```

When the associated application is reset, the integer variable `A` is implicitly re-initialized with `0`, whereas the variable `B` retains its current value.

Attribute 'no_instance_in_retain'

You can use this pragma to prevent the instance of a function block from being stored in the retain memory.

Syntax:

```
{attribute 'no_instance_in_retain'}
```

Insert location:

Lines above the `FUNCTION_BLOCK` declaration in the declaration part of the function block.

Now when you declare an instance declaration of the function block as a `RETAIN` variable, an error message is issued.

See also

- *Chapter 1.4.1.8.19 “Data Persistence” on page 301*

Attribute 'no_virtual_actions'

The pragma is used for function blocks that are derived from a function block implemented in SFC and use the fundamental SFC sequence of this base class. The actions called from it exhibit the same virtual behavior as methods. This means that the implementations of the actions in the base class can be replaced by the derived class with its own specific implementations.

If you apply the pragma to the base class, then its actions are protected against overloading.

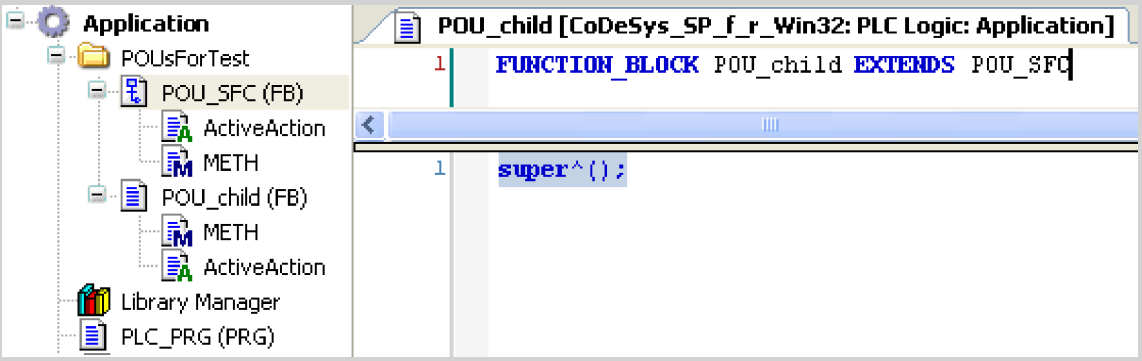
Syntax:

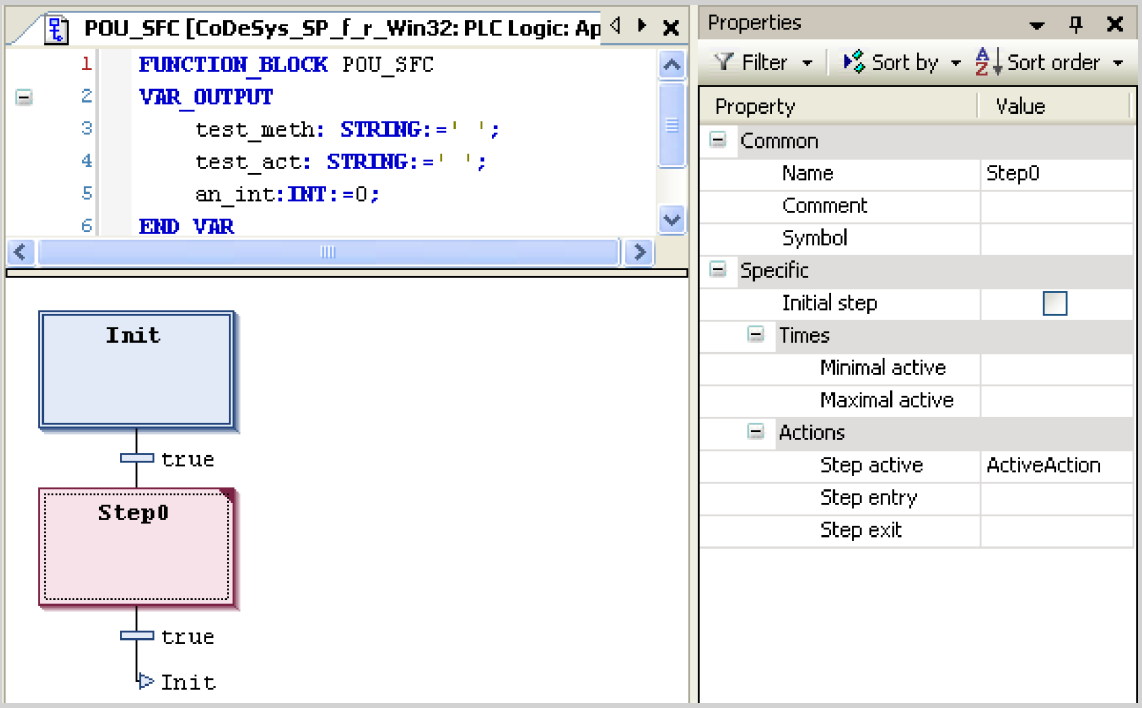
```
{attribute 'no_virtual_actions'}
```

Insert location: Top line in the declaration part of the function block

Example

The function block `POU_SFC` is the base class for the derived function block `POU_child`. The derived class `POU_child` calls the sequence of the base class written in SFC with the special variable `SUPER`.



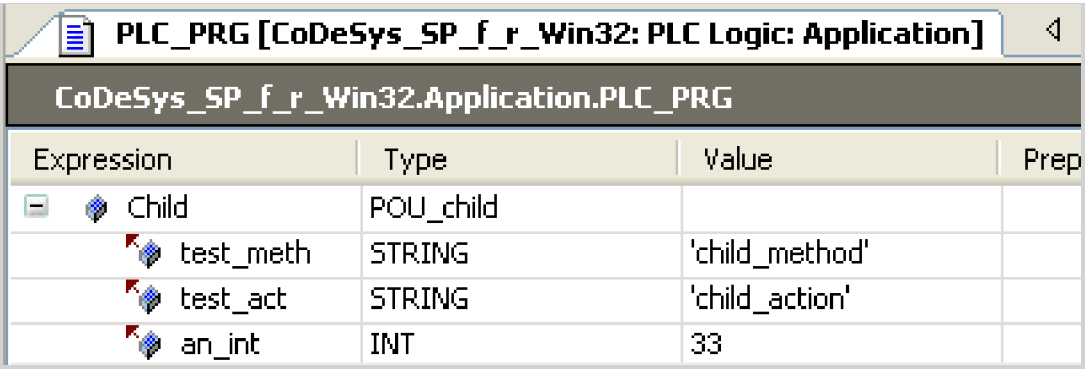


The exemplary implementation of this sequence is limited to the initial step, followed by a single step with a linked step action `ActiveAction`. This step with a linked step action takes care of the configuration of the output variables.

```
an_int:=an_int+1;     // Counting the action calls
test_act:='father_action';
METH();               // Call of the method METH in order to set the
string variable test_meth
```

In the case of the derived class `POU_child` the step action is replaced by a special implementation of `ActiveAction`. `Active Action` differs from the original only by the assignment of the string `'child_action'` in place of `'father_action'` at the variable `test_act`.

Likewise, the method `METH`, which assigns the string `'father_method'` to the variable `test_meth` in the base class, is overwritten so that `test_meth` now gets the value `'child_method'`. The main program `PLC_PRG` calls an instance of the function block `POU_child`, named `Child`. As expected, the value of the strings reflects the call of the action and method of the derived class:

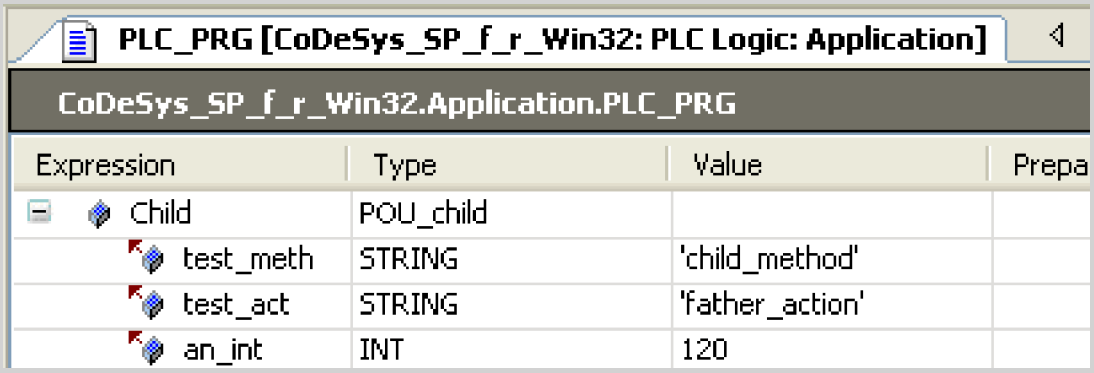


Now, however, you place the pragma `{attribute 'no_virtual_actions'}` in front of the base class:

```
{attribute 'no_virtual_actions'}

FUNCTION_BLOCK POU_SFC...
```

This changes the behavior: While the implementation of the derived class is still used for the method `METH`, the call of the step action now results in a call of the action `ActiveAction` of the base class. Therefore `test_act` is now given the value `'father_action'`:



Attribute 'pingroup'

The effect of this pragma is that the input pins or output pins (parameters) are grouped in the declaration of a function block. In the FBD/LD editor a pin group defined in this way can be displayed as an enlarged or reduced unit on the inserted function block. Several groups are possible and are distinguished by their names. CODESYS saves the respective state (reduced) per function block box with the project options.

Syntax:

```
{attribute 'pingroup' := '<group name>'}
```

Insertion position: line above the declaration of the input or output variables concerned in the declaration part of a function block.

Example Two groups are defined: `general (i1, out1)` and `group1 (i2, g1). r1, r2, outRes1` and `g2` are always displayed

```
FUNCTION_BLOCK FB
VAR_INPUT
 r1 : REAL;
 {attribute 'pingroup' := 'general'}
 i1 : INT;
 {attribute 'pingroup' := 'group1'}
 i2 : INT;
 r2 : REAL;
END_VAR

VAR_OUTPUT
 outRes1 : REAL;
 {attribute 'pingroup' := 'general'}
 out1 : INT;
    {attribute 'pingroup' := 'group1'}
 g1 : INT;
 g2 : REAL;
END_VAR
```

Attribute 'pin_presentation_order_inputs/outputs'

The pragmas are evaluated in the CFC, FBD, and LD graphical editors, causing the order of inputs/outputs of the affected function block to be displayed as specified. You program the order by assigning the names of the inputs/outputs to the attribute in the desired order.

Syntax

```
{attribute 'pin_presentation_order_inputs' := '<First_Input_Name>,
(<Next_Input_Name>, )* ( *, )? (<Next_Input_Name>,)*
<Last_Input_Name>'}
{attribute 'pin_presentation_order_outputs' := '<First_Output_Name>,
(<Next_Output_Name>,)* ( *, )? (<Next_Output_Name>,)*
<Last_Output_Name>'}
```

- `*`
  The terminal character serves as a wildcard for all inputs/outputs that are not specified in the display order. If the terminal character is missing, then the missing inputs/outputs are appended at the end.
- `( ... )?`
  The contents of the parentheses are optional.
- `( ... )*`
  The contents of the parentheses are optional again and can therefore occur not at all, one time, or several times.
- Insert location: First line in the declaration part of a function block.

> **NOTICE!**
> This pragma is not evaluated when pragma `{attribute 'pingroup' := '<Group_Name>'}` is used.

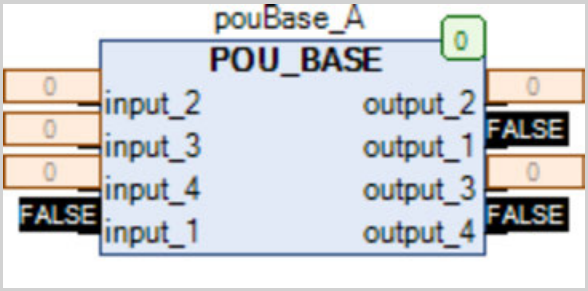
Example

```
{attribute 'pin_presentation_order_inputs' := 'input_2,*,input_1'}
{attribute 'pin_presentation_order_outputs' := 'output_2, output_1'}
FUNCTION_BLOCK POU_BASE
VAR_INPUT
    input_1 : BOOL;
    input_2 : INT;
    input_3 : INT;
    input_4 : INT;
END_VAR

VAR_OUTPUT
    output_1 : BOOL;
    output_2 : INT;
    output_3 : INT;
    output_4 : BOOL;
END_VAR

FUNCTION_BLOCK PLC_PRG
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    pouBase_A: POU_BASE;
END_VAR
```

In the representation of function module instance `pouBase_A`, the pragmas result in the following arrangement of input and output pins:



See also

- *Chapter 1.4.1.19.6.2.33 “Attribute 'pingroup'” on page 716*

Attribute 'obsolete'

The effect of this pragma is that a defined warning is displayed for a data type definition during compilation if the data type (structure, function block, etc.) is used in the project. This enables you, for example, to draw attention to the fact that a data type is no longer valid because, for example, an interface has changed and this should also be implemented in the project.

In contrast to a message pragma this warning is defined centrally for all instances of a data type.

Syntax:

```
{attribute 'obsolete' := 'user defined text'}
```

Insertion position: line of the data type definition or in a line above it.

Example The pragma is inserted in the definition function block `fb1`:

```
{attribute 'obsolete' := 'datatype fb1 not valid!'}
FUNCTION_BLOCK fb1
VAR_INPUT
 i:INT;
END_VAR
```

If you use fb1 as a data type, for example in `fbinst:fb1`, the following warning will be displayed when compiling the project: "datatype fb1 not valid".

See also

- *Chapter 1.4.1.19.6.1 “Message Pragmas” on page 683*

Attribute 'pack_mode'

The pragma defines how a data structure is packed during the allocation. The attribute has to be inserted above the data structure and affects the packing of the entire structure.

Syntax:

```
{attribute 'pack_mode' := ' <pack mode value>' }
```

Insert location: above the declaration of the data structure

Table 45: Possible values for <value>:

<pack mode value>	Associated packing method	Description
0	Aligned	All variables are allocated to byte addresses. There are no memory gaps.
1	1-byte-aligned	
2	2-byte-aligned	There are ● 1-byte variables at byte addresses ● 2-byte variables at addresses divisible by 2. A maximum gap of 1 byte results. ● 4-byte variables at addresses divisible by 2. A maximum gap of 1 byte results. ● 8-byte variables at addresses divisible by 2. A maximum gap of 1 byte results. ● Strings always at byte addresses. No gaps result.

<pack mode value>	Associated packing method	Description
4	4-byte-aligned	There are ● 1-byte variables at byte addresses ● 2-byte variables at addresses divisible by 2. A maximum gap of 1 byte results. ● 4 byte variables at addresses divisible by 4. A maximum gap of 3 byte results. ● 8-byte variables at addresses divisible by 4. A maximum gap of 3 byte results. ● Strings always at byte addresses. No gaps result.
8	8-byte-aligned	There are ● 1-byte variables at byte addresses ● 2-byte variables at addresses divisible by 2. A maximum gap of 1 byte results. ● 4 byte variables at addresses divisible by 4. A maximum gap of 3 byte results. ● 8 byte variables at addresses divisible by 8. A maximum gap of 7 byte results. ● Strings always at byte addresses. No gaps result.

Depending on the structure, there may be no difference in the memory mapping of the individual modes. Therefore, the memory allocation of a structure with `<pack mode value> = 4` *can correspond to that of* `<pack mode value> = 8`.

Arrays of structures: If the structures are combined in arrays, then bytes are added at the end of the structure so that the next structure is aligned.

NOTICE!
If the *"Compatibility layout"* option is selected in the symbol configuration and at the same time the attribute 'pack_mode' is used in the code, then problems can occur due to unintentional memory misalignment.

See also

- *Chapter 1.4.1.20.2.25 "Object 'Symbol Configuration'" on page 927*

Example 1

Example

```
{attribute 'pack_mode' := '1'}

TYPE myStruct:
STRUCT
  Enable: BOOL;
  Counter: INT;
  MaxSize: BOOL;
  MaxSizeReached: BOOL;
  END_STRUCT
END_TYPE
```

The memory range for a variable of the data type `myStruct` is allocated 'aligned'. If the storage address of its component `Enable` is `0x0100`, for example, then the component `Counter` follows at the address `0x0101`, `MaxSize` at address `0x0103` and `MaxSizeReached` at address `0x0104`. In the case of `'pack_mode':=2`, `Counter` would be at `0x0102`, `MaxSize` at `0x0104` and `MaxSizeReached` at `0x0106`.

Example 2

Example

```

Behavior without pack mode

If pack mode is not used, then the compiler typically uses pack mode 4 or 8, depending on the device description. In each case, a pack mode which is particularly beneficial for the processor is used so that memory access can be performed. This is also called natural alignment or a natural alignment of data.

Negative effects when using pack mode

Unaligned memory access can be the result of using the attribute `'pack_mode'`. This means, for example, that a data type with a size of 4 bytes is then located at an address which is not divisible by 4. Normally, on a 32-bit system a 32-bit data type can be read and written with a single memory access. On some platforms, for example on ARM platforms, this is possible only when this value is aligned in the memory. On other platforms, it can be that the access is possible but it is performed much more slowly.

Example

```
{attribute 'pack_mode':=1}

TYPE DUT
STRUCT
by1 : BYTE;
dw1 : DWORD;
END_STRUCT
END_TYPE
```

On an ARM platform, the value `dw1` cannot be read with a single access. When an attempt is made to access this element directly, the ARM processor will throw an exception.

Assumption: The following read access is performed: `dwTest := dut1.dw1;`

For this access to the `DWORD dw1`, four memory accesses are required because each byte is read, shifted, and disjuncted individually. The flow is somewhat the same as in the following example in which a `DWORD` is generated from an array of four bytes:

```
dwHelp := bytes[0];
dwResult := dwHelp;
dwHelp := bytes[1];
dwHelp := SHL(dwHelp, 8);
dwResult := dwResult OR dwHelp;
dwHelp := bytes[2];
dwHelp := SHL(dwHelp, 16);
dwResult := dwResult OR dwHelp;
dwHelp := bytes[3];
dwHelp := SHL(dwHelp, 24);
dwResult := dwResult OR dwHelp;
```

Obviously, this kind of access is much slower than access to a `DWORD`, which is aligned appropriately in the memory.

```
pdw := ADR(dut1.dw1);
dwTest := pdw^;
```

However, the compiler will not generate the access of the example when this kind of member is accessed by means of a pointer. This means that the following code results in an exception on an ARM platform.

```
pdw := ADR(dut1.dw1);
dwTest := pdw^;
```

For performance reasons, you should therefore avoid working with structures which are not naturally aligned.

A packed structure must not contain an unpacked structure.

Attribute 'ProcessValue'

With the `'ProcessValue'` attribute, you mark a component of a structure. In the CFC editor, you can then use the command *"Use attributed member as input"* in order to connect this structure to an input of scalar type.

Syntax:

```
{attribute 'ProcessValue'}
```

Insert location: Line above the affected structure variable.

Example

```
TYPE QINT :
STRUCT
    Status : STRING;
    {attribute 'ProcessValue'}
    Value1 : INT;
    Value2 : INT;
END_STRUCT
END_TYPE
```

See also

- *Chapter 1.4.1.20.3.12.36 "Command 'Use Attributed Member as Input'" on page 1102*

Attribute 'qualified_only'

The effect of this pragma is that variables of a global variable list are only addressed by specifying the global variable name, for example `gvl.g_var`. This also applies to variables of the type Enumeration and can be helpful in avoiding being mistaken for local variables.

Syntax:

{attribute 'qualified_only'}

Insertion position: line above `VAR_GLOBAL` in a GVL

Example Global Variable List *"GVL"*:

```
{attribute 'qualified_only'}
VAR_GLOBAL
 iVar:INT;
END_VAR
```

Within a POU, for example *"PLC_PRG"*, the global variable `iVar` can only be addressed using the prefix `GVL`:

```
GVL.iVar:=5;
```

Conversely, the following incomplete call of the variable will create an error:

```
iVar:=5;
```

Attribute 'reflection'

The pragma is used to identify POUs in which some variables require special treatment and are tagged with a specific attribute for this purpose. Currently, this applies to the attributes `'instance-path'` and `'is-connected'` for function block variables. The compiler searches only blocks marked with `'reflection'` for variables with these attributes and therefore needs less time.

Syntax:

```
{attribute 'reflection'}
```

For examples, see the description of the attributes `'instance-path'` and **'is-connected'**.

See also

- *Chapter 1.4.1.19.6.2.21 "Attribute 'instance-path'" on page 706*
- *Chapter 1.4.1.19.6.2.23 "Attribute 'is_connected'" on page 707*

Attribute 'subsequent'

The pragma is used to allocate consecutive variables in memory. When the list changes, the entire variable list is allocated to a new memory area. This pragma is used in programs and global variable lists.

Syntax:

```
{attribute 'subsequent'}
```

NOTICE!
`VAR_TEMP` in a program with attribute `'subsequent'` leads to a compiler error.

When a variable in the list is qualified with `RETAIN`, all variables of the declaration part are stored in the memory area for `RETAIN`.

Attribute 'symbol'

The pragma `{attribute 'symbol'}` defines which variables of a program or a global variable list are to be adopted into the symbol configuration. This means that the variables are exported as symbols to a symbol list. This symbol list is then available for external access both as an XML file in the project directory and as a file that is invisible to the user on the target system. For example, the symbol list is then available for access by an OPC server. The variables thus equipped with a symbol are loaded by CODESYS to the controller, even if they are not explicitly configured or visible in the editor of the symbol configuration.

In any case, however, an object *"Symbol configuration"* must be created below the application concerned in the device tree.

Syntax:

```
{attribute 'symbol' := '<access possibilities>'}
```

`<access possibilities>`: `none`, `read`, `write`, `readwrite`. The default value `readwrite` applies if no parameter is specified.

Insertion position:

- in order to affect only an individual variable, you must place the pragma in the line before the variable declaration.
- In order to be effective for all variables in the declaration part of a program, you must place the pragma in the first line of the declaration editor. In this case, too, you can still set instructions for individual variables explicitly in the respective line.

Example

With the following configuration the variables `A` and `B` are exported with read and write permission. Variable `D` is exported with read permission.

```
{attribute 'symbol' := 'readwrite'}
PROGRAM PLC_PRG
VAR
 A : INT;
 B : INT;
{attribute 'symbol' := 'none'}
 C : INT;
{attribute 'symbol' := 'read'}
 D : INT;
END_VAR
```

See also

- ↳ *Chapter 1.4.1.8.6 "Using Pragmas" on page 263*
- ↳ *Chapter 1.4.1.9.2 "Symbol Configuration" on page 357*

Attribute 'to_string'

The pragma affects how the result of converting an enumeration component with the `TO_STRING` operator is output. If the enumeration declaration has the pragma, then the name of the enumeration component appears as a string instead of the numeric value.

Syntax:

```
{attribute 'to_string'}
```

Insert location: First line above the declaration part of the enumeration.

Example

Declaration of the enumeration `color`:

```
{attribute 'to_string'}
TYPE color :
(
    red := 0,
    blue := 1,
    green := 2
);
END_TYPE
```

Conversion with `TO_STRING`:

```
PROGRAM PLC_PRG
VAR
    i_color: Color;
    s_show_color: STRING;
END_VAR
i_color := 1;
s_show_color := TO_STRING(i_color);
```

In this case, `str_show_color` gets the value `'blue'` instead of `'1'` as the conversion result.

See also

- *Chapter 1.4.1.19.5.17 “Enumerations” on page 676*

Attribute 'warning disable', attribute 'warning restore'

This pragma causes certain warnings to be suppressed. The `warning restore` pragma causes a suppressed message to be reactivated.

Syntax:

```
{warning disable <compiler ID>}
```

```
{warning restore <compiler ID>}
```

`<compiler ID>`: ID located at the beginning of an error or a warning message.

Example

Compiler message:

```
typify code ...
C0196: Implicit conversion from unsigned Type 'UINT' to signed Type
'INT' : possible change of sign
Compile complete -- 0 errors
```

Applying the pragma to a variable declaration:

```
VAR
 {warning disable C0195}
 test1 : UINT := -1;
 {warning restore C0195}
 test2 : UINT := -1;
END_VAR
```

`test1` does not generate an error message, `test2` generates an error message.

Effects of Pragmas on Symbols

POUs and variables can change their behavior with respect to the symbol configuration as a result of pragmas. A detailed description can be found on the help page of each pragma.

Pragma with attribute	Effect	See also
`{attribute 'call_after_global_init_slot' := ' <slot> '}`	None

Conditional Pragmas

The purpose of conditional pragmas is to influence the generation of code in the pre-compilation process or the compilation process. The ST implementation language supports these pragmas.

NOTICE!
They use conditional pragmas in the implementations of POUs. CODESYS does not evaluate these conditional pragmas if you use them in the declaration part.

With conditional pragmas you affect whether implementation code is taken into account for the compilation. For example, you can make this dependent on whether a certain variable is declared, whether a certain function block exists, etc.

Pragma	Description
`{define <identifier>}`	The value can be queried and compared later with `hasvalue`.
`{undefine <identifier>}`	The `{define}` statement of the identifier `<identifier>` is canceled, and the identifier is 'undefined' again from now on. The pragma is ignored if the specified identifier is not defined at all.

`{IF <expr>}...`
`{ELSIF <expr>}...`
`{ELSE}...`
`END_IF}`
	These are pragmas for the conditional compilation.
	The specified expressions `<expr>` must be constant at the time of compilation; they are evaluated in the order in which they appear here until one of the expressions indicates a non-zero value. The text linked to the instruction is compiled; the other lines are ignored. The order of the sections is fixed. The `ELSIF` and `ELSE` sections are optional. The `ELSIF`-segments may occur any number of times. You can use several conditional compilation operators within the constants `<expr>`.

`<expr>`	You can use one or more **operators** within the constant expression `<expr>` within the conditional compilation pragma `{IF}` or `{ELSIF}` .

You can enter expressions and `define` definitions as “compiler definitions” in the “Compile” tab in the Properties dialog of POUs. If you enter `define` definitions in the properties dialog, you must omit the term `{define}`, contrary to the definition in the implementation code. In addition, you can specify several `define` definitions in the properties dialog, separated by commas.

See also

- *Chapter 1.4.1.8.3.3 “Structured Text (ST), Extended Structured Text (ExST)” on page 253*

Operator `defined (<identifier>)`

This operator causes the expression to be given the value `TRUE`. The requirement is that the identifier `<identifier>` was defined with the help of a `{define}` instruction and not undefined again afterwards with an `{undefine}` instruction; otherwise `FALSE` is returned.

Example

Requirement: The applications `App1` and `App2` exist. The variable `pdef1` is defined by a `{define}` statement in `App1`, but not in `App2`.

```
{IF defined (pdef1)}
(* This code is processed in App1 *)
{info 'pdef1 defined'}
    hugo := hugo + SINT#1;
{ELSE}
(* the following code is only processed in App2 *)
{info 'pdef1 not defined'}
    hugo := hugo - SINT#1;
{END_IF}
```

This also contains an example of a message pragma: Only the message `pdef1 defined` is displayed in the message view when the application is compiled, because `pdef1` is actually defined. The message `pdef1 not defined` is displayed if `pdef1` is not defined.

Operator `defined (variable: <variable>)`

This operator causes the expression to be given the value `TRUE` if the variable `<variable>` is declared within the current scope; otherwise `FALSE` is returned.

Example

Requirement: The two applications `App1` and `App2` exist. The variable `g_bTest` is declared in `App1`, but not in `App2`.

```
{IF defined (variable: g_bTest)}
(* the following code is only processed in App2*)
    g_bTest := x > 300;
{END_IF}
```

Operator `defined (type: <identifier>)`

The operator causes the expression to be given the value `TRUE` if a data type is declared with the identifier `<identifier>`; otherwise `FALSE` is returned.

Example

Requirement: The two applications `App1` and `App2` exist. The data type `DUT` is declared in `App1`, but not in `App2`.

```
{IF defined (type: DUT)}
(* the following code is only processed in App1*)
    bDutDefined := TRUE;
{END_IF}
```

Operator `defined (pou: <pou name>)`

The operator causes the expression to be given the value `TRUE` if a function block or an action with name `<pou-name>` exists; otherwise `FALSE` is returned.

Example

Requirement: The two applications `App1` and `App2` exist. The function block `CheckBounds` exists in `App1`, but not in `App2`.

```
{IF defined (pou: CheckBounds)}
(* the following code is only processed in App1 *)
    arrTest[CheckBounds(0,i,10)] := arrTest[CheckBounds(0,i,10)] +
1;
{ELSE}
(* the following code is only processed in App2 *)
    arrTest[i] := arrTest[i]+1;
{END_IF}
```

Operator `defined (task: <identifier>)`

Not yet implemented!

The operator causes the expression to be given the value `TRUE` if a task is defined with the name `<identifier>`; otherwise `FALSE` is returned.

Example

Requirement: The two applications `App1` and `App2` exist. The task `PLC_PRG_Task` is defined in `App1`, but not in `App2`.

```
IF defined (task: PLC_PRG_Task)}
(* the following code is only processed in App1 *)
    erg := plc_prg.x;
{ELSE}
(* the following code is only processed in App2 *)
    erg := prog.x;
{END_IF}
```

Operator `defined (resource: <identifier>)`

Not yet implemented!

The operator causes the expression to be given the value `TRUE` if a resource object with the name `<identifier>` exists for the application; otherwise `FALSE` is returned.

Example

Requirement: The two applications `App1` and `App2` exist. A resource object `glob_var1` of the global variable list exists for `App1`, but not for `App2`.

```
{IF defined (resource:glob_var1)}
(* the following code is only processed in App1 *)
    gvar_x := gvar_x + ivar;
{ELSE}
(* the following code is only processed in App2 *)
    x := x + ivar;
{END_IF}
```

Operator `defined (IsSimulationMode)`

The operator causes the expression to be given the value `TRUE` if the application runs on a simulated device, i.e. in simulation mode.

See also

- *Chapter 1.4.1.11.1 “Testing in simulation mode” on page 394*

Operator defined (IsLittleEndian)

The operator causes the expression to be given the value `FALSE`, if the CPU memory is organized in Big Endian (Motorola byte order).

Operator defined (IsFPUSupported)

If the expression returns the value `TRUE`, then the code generator produces an FPU code (for the floating-point unit processor) when calculating with `REAL` values. Otherwise CODESYS emulates FPU operations, which is much slower.

Operator hasvalue (RegisterSize, '<register size>')

`<register size>`: Size of a CPU register in bits

This operator causes the expression to return the value `TRUE` if the size of a CPU register is equal to `<register size>`.

Possible values for `<register size>`

- `16` for C16x,
- `64` for X86-64 bit
- `32` for X86-32 Bit

Operator hasvalue (PackMode, '<pack mode value>')

The checked pack mode depends on the device description, not on the pragma that can be specified for individual DUTs.

Operator hasattribute (pou: <pou name>, '<attribute>')

This operator causes the expression to be given the value `TRUE` if the attribute `<attribute>` is specified in the first line of the declaration part of the function block `<pou name>`; otherwise `FALSE` is returned.

Example

Requirement: The two applications `App1` and `App2` exist. The function `fun1` is declared in `App1` and `App2`. However, in `App1` it is also provided with the pragma `{attribute 'vision'}`.

In App1:

```
{attribute 'vision'}
FUNCTION fun1 : INT
VAR_INPUT
    i : INT;
END_VAR
VAR
END_VAR
```

In App2:

```
FUNCTION fun1 : INT
VAR_INPUT
    i : INT;
END_VAR
VAR
END_VAR
```

Pragma instruction:

```
{IF hasattribute (pou: fun1, 'vision')}
(* the following code is only processed in App1 *)
    ergvar := fun1(ivar);
{END_IF}
```

See also

- ↳ *Chapter 1.4.1.19.6.2.1 “User-defined attributes” on page 686*

Operator `hasattribute (variable: <variable>, '<attribute>')`

This operator causes the expression to be given the value `TRUE` if the pragma `{attribute '<attribute>'}` is assigned to the variable in the line before the variable declaration; otherwise `FALSE` is returned.

Example

Requirement: The two applications `App1` and `App2` exist. The variable `g_globalInt` is used in `App1` and `App2`, but in `App1` the attribute `'DoCount'` is assigned to it in addition.

Declaration of `g_GlobalInt` in `App1`

```
VAR_GLOBAL
    {attribute 'DoCount'}
    g_globalInt : INT;
    g_multiType : STRING;
END_VAR
```

Declaration `g_GlobalInt` in `App2`:

```
VAR_GLOBAL
    g_globalInt : INT;
    g_multiType : STRING;
END_VAR
```

Pragma instruction:

```
{IF hasattribute (variable: g_globalInt, 'DoCount')}
    (* the following code is only processed in App1 *)
    g_globalInt := g_globalInt + 1;
{END_IF}
```

See also

- ↳ *Chapter 1.4.1.19.6.2.1 “User-defined attributes” on page 686*

Operator `hastype (variable: <variable>, <type-spec>)`

This operator causes the expression to be given the value `TRUE` if the variable `<variable>` is of the data type `<type-spec>`; otherwise `FALSE` is returned.

Possible data types for `<type-spec>`:

- `BOOL`
- `BYTE`
- `DATE`
- `DATE_AND_TIME (DT)`
- `DINT`
- `DWORD`
- `INT`
- `LDATE`
- `LDATE_AND_TIME (LDT)`
- `LINT`
- `LREAL`
- `LTIME`
- `LTIME_OF_DAY (LTOD)`
- `LWORD`
- `REAL`
- `SINT`
- `STRING`
- `TIME`
- `TIME_OF_DAY (TOD)`
- `ULINT`

- UDINT
- UINT
- USINT
- WORD
- WSTRING

Example

Requirement: The two applications App1 and App2 exist. The variable g_multitype is declared in App1 with data type LREAL, in App2 with data type STRING.

```
{IF (hastype (variable: g_multitype, LREAL))}
(*  the following code is only processed in App1 *)
    g_multitype := (0.9 + g_multitype) * 1.1;
{ELSIF (hastype (variable: g_multitype, STRING))}
(* the following code is only processed in App2 *)
    g_multitype := 'this is a multitalent';
{END_IF}
```

Operator hasvalue (<define-ident>, '<char-string>')

This operator causes the expression to be given the value TRUE if a variable is defined with the identifier <define-ident> and has the value <char-string>; otherwise FALSE is returned.

Example

Requirement: The two applications App1 and App2 exist. The variable test is used in the applications App1 and App2; in App1 it is given the value 1, in App2 the value 2.

```
{IF hasvalue(test,'1')}
(*  the following code is only processed in App1 *)
x := x + 1;
{ELSIF hasvalue(test,'2')}
(*  the following code is only processed in App2 *)
    x := x + 2;
{END_IF}
```

Operator hasconstantvalue(<variable>, <literal expression>)

You can use this operator to query the declared value of a constant.

Example

Requirement:

```
{IF hasconstantvalue(test,'1')}
(*  the following code is only processed in App1 *)
    x := x + 1;
{ELSIF hasconstantvalue(test,'2')}
(*  the following code is only processed in App2 *)
    x := x + 2;
{END_IF}
```

Operator NOT <operator>

The expression is given the value TRUE if the reverse value of <operator> returns the value TRUE. <operator> can be one of the operators described in this chapter.

Example

Requirement: The two applications `App1` and `App2` exist.`PLC_PRG1` exists in `App1` and `App2`, and the POU `CheckBounds` exists only in `App1`.

```
{IF defined (pou: PLC_PRG1) AND NOT (defined (pou: CheckBounds))}
(* the following code is only processed in App2 *)
    bANDNotTest := TRUE;
{END_IF}
```

Operator <operator> AND <operator>

The expression is given the value `TRUE` if the two specified operators return `TRUE`. `<operator>` can be one of the operators described in this chapter.

Example

Requirement: The applications `App1` and `App2` exist.`PLC_PRG1` exists in `App1` and `App2`, the POU `CheckBounds` only in `App1`.

```
{IF defined (pou: PLC_PRG1) AND (defined (pou: CheckBounds))}
    (* the following code is only processed in App1 *)
    bANDTest := TRUE;
{END_IF}
```

Operator <operator> OR <operator>

The expression returns `TRUE` if one of the two specified operators returns `TRUE`. `<operator>` can be one of the operators described in this chapter.

Example

Requirement: The two applications `App1` and `App2` exist. The POU `PLC_PRG1` exists in `App1` and `App2`, and the POU `CheckBounds` exists only in `App1`.

```
{IF defined (pou: PLC_PRG1) OR (defined (pou: CheckBounds))}
(* the following code is only processed in App1 and in App2 *)
    bORTest := TRUE;
{END_IF}
```

Operator (<operator>)

`()` parenthesizes the operators.

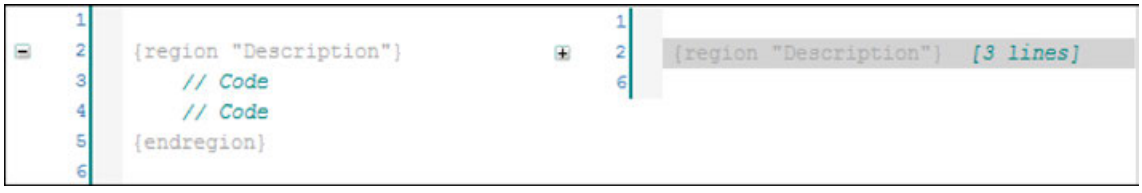
Region Pragma

This pragma is used for grouping several lines into one block in a text editor. The block can be named. Region pragmas can also be nested.

Code with region pragma: Expanded and collapsed views



The pragma can be used in the ST editor and all declaration editors. Syntax highlighting can be customized in the options.

1.4.1.19.7 Identifiers

Rules for identifier designation

Rules for identifiers of variables

- An identifier must not contain spaces or special characters.
- Capitalization is ignored. For example, `VAR1` and `var1` refer to the same variable.
- The underscore is recognized. For example, `A_BCD` and `AB_CD` are treated as two different identifiers. Multiple consecutive underscores are not permitted.
- The length of an identifier is unrestricted.

Rules for multiple use of identifiers (namespaces)

- An identifier must not be declared two times locally.
- An identifier can be used more than one time globally. If a local variable has the same name as a global variable, then the local variable has priority within the POU.
- An identifier must not be identical to a keyword, such as the scope `VAR_Global`.
- A variable that is declared in a global variable list can have the same name as a variable defined in another GVL. CODESYS provides features that extend the standard for the namespace or scope of variables:
  - Global namespace operator:
    An instance path that begins with a dot always opens a global namespace. If there is a local variable (for example, `ivar`) that has the same name as a global variable, then you refer to the global variable as `.ivar`.
  - The name of a global variable list can define the namespace uniquely for the include variables. Therefore, you can declare variables with the same name in different global variables list and still uniquely reference by prepending the list name.
    For example, `globlist1.ivar := globlist2.ivar; (* ivar from GVL globlist2 is copied to ivar in GVL globlist1 *).`
  - Variables that are defined in the global variable list of a library included in the project can be addressed uniquely according to the following syntax:
    `<name scope library>.< GVL name>.<variable name>`
    For example, `globlist1.ivar := lib1.globlist1.ivar (* ivar from GVL globlist1 in library lib1 is copied to ivar in GVL globlist1 *).`
- When inserting a library, you also use the Library Manager to define a namespace. In this way, you can make unique references to a library block or library variable by `<namespace library>.<block name|variable name>`. Note that when libraries are nested, you have to reference the namespaces of all libraries are in succession
  Example: If `Lib1` is referenced by `Lib0`, then the POU `func` in `Lib1` is addressed by `Lib0.Lib1.fun`: `ivar := Lib0.Lib1.fun(4, 5); (* return value from func is copied to variable ivar in the project *)`

We recommend that you apply the following rules in addition to the items that you have to consider specifically for variables declaration. By doing this, you get the best possible harmonization when assigning names.

Recommendations for variable names

Whenever possible, you should name variables in Hungarian notation in applications and libraries. Find a meaningful, short, English name for each variable as a base name, which can consist of several words. Write the first letter of each word in uppercase, the remaining letters in lowercase. In front of the base name, append a prefix in lowercase to indicate the data type of the variable.

Example: `iFileSize : INT;`

Data Type	Prefix	Description
BOOL	x	We expressly recommend x as the prefix for Boolean variables in order to distinguish them from identifiers of the data type BYTE. The prefix indicates the view of an IEC programmer.
	b	Reserved
BYTE	by	Bit string; not for arithmetic operations
WORD	w	Bit string; not for arithmetic operations
DWORD	dw	Bit string; not for arithmetic operations
LWORD	lw	Bit string; not for arithmetic operations
SINT	si	Arithmetic integer data type, 8-bit
USINT	usi	Arithmetic integer data type, 8-bit
INT	i	Arithmetic integer data type, 16-bit
UINT	ui	Arithmetic integer data type, 16-bit
DINT	di	Arithmetic integer data type, 32-bit
UDINT	udi	Arithmetic integer data type, 32-bit
LINT	li	Arithmetic integer data type, 64-bit
ULINT	uli	Arithmetic integer data type, 64-bit
REAL	r	Arithmetic floating-point data type, 32-bit
LREAL	lr	Arithmetic floating-point data type, 64-bit
STRING	s	Single-byte character string of variable length (default setting: 80 characters)
WSTRING	ws	Double-byte character string of variable length (default setting: 80 characters)
TIME	tim	Time duration, 32-bit
LTIME	ltim	Time duration, 64-bit
• TIME_OF_DAY • TOD	tod	Time of day, 32-bit
• LTIME_OF_DAY • LTOD	ltod	Time of day, 64-bit
• DATE_AND_TIME • DT	dt	Date and time
• LDATE_AND_TIME • LDT	ldt	
DATE	• dat • d	Calender date
LDATE	• ldat • ld	Calender date

Data Type	Prefix	Description
POINTER	p	
ARRAY	a	
Enumeration	e	

Example

```
VAR
    bySubIndix: BYTE;
    xFlag: BOOL;
    udiCounter: UDINT;
END_VAR
```

Identifier	Description	Example
Nested declaration	Prefixes are attached successively in the order of declaration.	pabyTelegramData: POINTER TO ARRAY [0..7] OF BYTE;
Function block instance Variable of user-defined data type	Prefix: Abbreviation for the name of the function block or data type	cansdoReceivedTelegram: CAN_SDOTelegram; TYPE CAN_SDOTelegram : (* prefix: sdo *) STRUCT wIndex: WORD; bySubIndex:BYTE; byLen:BYTE; aby: ARRAY [0..3] OF BYTE; END_STRUCT END_TYPE
Local constant Local constant variable	Prefix: c_, followed by the type prefix and the variable name	VAR CONSTANT c_uiSyncID: UINT := 16#80; END_VAR
Global variable	An additional prefix is appended to the library prefix. g_	VAR_GLOBAL CAN_g_iTest: INT; END_VAR
Global constants Global constant variable	An additional prefix is appended to the library prefix. gc_	VAR_GLOBAL CONSTANT CAN_gc_dwExample: DWORD; END_VAR

Recommendations for variable names CODESYS V3.x libraries

Identifier	Description	Example

Variable	Corresponds to the description for variable names, with the exception that global variables and constants do not require library prefixes because the namespace replaces the function.	`g_iTest: INT; // Declaration`
		`CAN.g_iTest; // Implementation; call in the program`

Recommendations for identifiers for user-defined data types (DUT)

Identifier for	Description	Example

Structures	Library prefix followed by an underscore and a short, informative description of the structure. The associated prefix for created variables of this structure should follow the colon as a comment.	`TYPE CAN_SDOTelegram : (* prefix: sdo *)`
		`STRUCT`
		`wIndex : WORD;`
		`bySubIndex : BYTE;`
		`byLen : BYTE;`
		`abyData: ARRAY [0..3] OF BYTE;`
		`END_STRUCT`
		`END_TYPE`

Enumerations	Library prefix followed by an underscore and the identifier in uppercase.
	Note: In past CODESYS versions, enumeration values > 16#7FFF caused errors because they were not automatically converted to `INT`. For this reason, enumerations should always be declared with correct `INT` values.
		`TYPE CAL_Day :`
		`(`
		`CAL_MONDAY,`
		`CAL_TUESDAY,`
		`CAL_WEDNESDAY,`
		`CAL_THURSDAY,`
		`CAL_FRIDAY,`
		`CAL_SATURDAY,`
		`CAL_SUNDAY`
		`);`
		Declaration:
		`eToday: CAL_Day;`

Recommendations for identifiers for user-defined data types (DUT) in CODESYS V3 libraries

Identifier for	Description	Example

DUT names in CODESYS V3 libraries	The namespace replaces the need for the library prefix. Therefore, it is omitted. Enumeration values are also defined without a library prefix.	Library with namespace `CAL`
		`TYPE DAY :`
		`(`
		`□MONDAY`
		`□TUESDAY,`
		`□WEDNESDAY,`
		`□THURSDAY,`
		`□FRIDAY,`
		`□SATURDAY,`
		`□SUNDAY`
		`);`
		Declaration:
		`eToday: CAL.Day;`
		Usage in the application
		`IF eToday = CAL.Day.MONDAY THEN`

Recommendations for identifiers for POUs, functions, function blocks, programs

Identifier for	Description	Example
POUs: Functions, function blocks, programs	Library prefix followed by an underscore and a short, informative POU name. Like for variables, the first letter of each word is uppercase and all other letters are lowercase. We recommend that you compose the POU name from a verb and a noun. For function blocks, the associated prefix for created instances should follow the name as a comment.	`FUNCTION_BLOCK CAN_SendTelegram (* prefix: canst *)`
Actions	Only actions that the block itself calls, beginning with `prv_`. Otherwise, actions do not have a prefix.	

Recommendations for identifiers for POUs in CODESYS V3 libraries

Identifier for	Description	Example
POU	The library prefix is omitted because the name-space replaces the function of the library prefix.	`FUNCTION_BLOCK SendTelegram (* prefix: canst *)`
Method	Only methods that the block itself calls, beginning with `prv_`. Otherwise, methods do not have a prefix.	
Interface Interface	`I`	`ICANDevice`

Recommendations for identifiers for visualizations

NOTICE!
Note that a visualization is not named the same as another block in the project because this may cause problems when changing visualizations.

- *Chapter 1.4.1.19.5 “Data Types” on page 646*
- *Chapter 1.4.1.19.2 “Variables” on page 526*

1.4.1.19.8 Shadowing Rules

In CODESYS, you are generally allowed to use the same identifier for different elements. For example, a POU and a variable can be named the same. However, you should avoid this practice in order to prevent confusion.

Negative example: In the following code snippet, a local function block instance has the same name as a function:

Example

```
FUNCTION YYY : INT
;
END_FUNCTION

FUNCTION_BLOCK XXX
;
END_FUNCTION_BLOCK

PROGRAM PLC_PRG
VAR
    YYY : XXX;
END_VAR
YYY();
END_PROGRAM
```

In such a case as this, it is unclear whether the instance or the function is called in the program.

To make sure that names are always unique, you should follow naming conventions, such as certain prefixes for variables. Rules for assigning identifiers can be found in the "Identifiers" chapter of the help.

Naming conventions can be checked automatically using the static code analysis of CODESYS. Static code analysis could also detect the duplicate use of the name `YYY` and report it as an error.

The consistent use of the attribute `qualified_only` for enumerations and global variable lists and the use of qualified libraries can also prevent ambiguous situations.

To make sure that a POU of the same name in the *"Devices"* view is not called when a POU in the *"POUs"* view is called, the operator `__POOL` should be prepended (for example, `svar_pou := __POOL.POU();`) when the name of the POU is called.

Shadowing: The compiler does not report any errors or warnings if the same identifier is used for different elements. Instead, the compiler searches the code in a specific order for the declaration of the identifier. If a declaration is found, then the compiler does not search for any other declarations elsewhere. If other declarations do exist, then they are "shadowed" for the compiler. The following section describes the shadowing rules (that is, the search order that the compiler uses when searching for the declaration for identifiers). The section "Ambiguous access and qualified access" provides ways to prevent ambiguous access and bypass shadowing rules.

Search order in the application

When the compiler encounters a single identifier in the code of an application, it searches for the corresponding declaration in the following order:

1. Local variables of a method
2. Local variables in the function block, program, or function, and in any base function blocks
3. Local methods of the POU
4. Global variables in the application, if the `qualified_only` attribute is not set in the variable list where the global variables are declared
5. Global variables in a parent application, if the `qualified_only` attribute is not set in the variable list where the global variables are declared
6. Global variables in referred libraries when neither the library nor the variable list requires qualified access
7. POU or type names from the application (that is, names of global variable lists, function blocks, and so on)
8. POU or type names from a parent application
9. POU or type names from a library
10. Namespaces of locally referred libraries and libraries that are published by libraries
11. Global variables in the *"POUs"* view, unless the `qualified_only` attribute is set in the variable list where they are declared
12. POU or type names from the *"POUs"* view (that is, names of global variable lists, function blocks, and so on)

Libraries that are inserted in the Library Manager of the "POUs" view are mirrored in the Library Manager in all applications in the project with the appropriate placeholder resolution. These libraries then form a common namespace with the libraries in the application. Therefore, there is no shadowing of libraries in the pool by libraries in the application.

Search order in the library

When the compiler encounters a single identifier in the code of a library, it searches for the corresponding declaration in the following order:

1. Local variables of a method
2. Local variables in the function block, program, or function, and in any base function blocks
3. Local methods of the POU
4. Global variables in the local library, if the `qualified_only` attribute is not set in the variable list where the global variables are declared
5. Global variables in referred libraries when neither the library nor the variable list requires qualified access

6. POU or type names from the local library (that is, names of global variable lists, function blocks, and so on)

7. POU or type names from a referred library

8. Namespaces of locally referred libraries and libraries that are published by locally refereed libraries

Ambiguous access and qualified access

Despite these search orders, ambiguous access can still occur. For example, this is the case when a variable with the same name exists in two global variable lists that do not require qualified access. Such a case is reported by the compiler as an error (for example: `ambiguous use of the name XXX`).

This kind of ambiguous usage can be made unique by means of qualified access, for example by accessing via the name of the global variable list (example: `GVL.XXX`).

Qualified access can also always be used to avoid shadowing rules.

- The name of the global variable list can be used to uniquely access a variable in the list.
- The name of a library can be used to uniquely access elements in the library.
- The `THIS` pointer be used to uniquely access variables in a function block, even if a local variable with the same name exists in a method of the function block.

To find the declaration location of an identifier at any time, use the command *"Edit ➔ Browse ➔ Go to Definition"*. This can be especially helpful if the compiler produces an apparently obscure error message.

Searching in instance paths

The search orders described above do not apply to identifiers that exist as components in an instance path or to identifiers that are used as inputs in calls.

For access of the following type `yy.component`, it depends on the entity described by `yy` where the declaration of `component` is searched for.

If `yy` denotes a variable with a structured data type (that is, type `STRUCT` or `UNION`), then `component` is searched for in the following order:

- Local variables of the function block
- Local variables of the base function block
- Methods of the function block
- Methods of the base function block

If `yy` denotes a global variable list or a program, then `component` is searched for in this list only.

If `yy` denotes a namespace of a library, then `component` is searched for in this library exactly as described in the section above "Search order in the library".

Only in the second instance does the compiler decide whether access to the found element is granted (that is, whether the variable is only locally accessible, or whether a method is private). If access is not allowed, an error is issued.

1.4.1.19.9 Keywords

In all editors, you must capitalize keywords that for example denote scopes, data types, or operators.

Keywords cannot be used as variable names.

Examples

```
VAR
END_VAR
BOOL_TO_INT
IF
THEN
ELSE
LTIME
MUL
XOR
PERSISTENT
PROGRAM
```

CODESYS checks the correct use of keywords automatically and highlights errors immediately during input with a wavy underline.

When CODESYS creates implicit code, variables and functions are generally given a name that is prepended with two underscores (__). The use of double underscores in the implementation code is prevented automatically. This eliminates conflicts between internal system identifiers and identifiers assigned by the programmer.

The following keywords are used in the CODESYS export format. Therefore, you may not use them as identifiers:

- ACTION
- END_ACTION
- END_FUNCTION
- END_FUNCTION_BLOCK
- END_PROGRAM

Other valid keywords:

- VAR_ACCESS
- READ_ONLY
- READ_WRITE
- PARAMS

1.4.1.19.10 Methods 'FB_Init', 'FB_Reinit', and 'FB_Exit'

You can declare the methods explicitly in order to influence the initialization of function block variables, as well as the behavior when exiting function blocks.

The type of the return value for the implicit methods is `BOOL`. The value is not evaluated by the system, but the type should not be changed.

`FB_Init` is always available implicitly and it is used primarily for initialization. For a specific influence, you can also declare the methods explicitly and provide additional code there with the standard initialization code.

`FB_Reinit` must be implemented explicitly. If this method exists, then it is called after the instance of the affected function block is **copied**. That happens during an online change after changes to the function block declaration (signature change) in order to reinitialize the new instance module. To reinitialize the basic implementation of the function block, you must call `FB_Reinit` explicitly.

`FB_Exit` must be implemented explicitly. If there is an implementation, then the method is called before the controller removes the code of the function block instance (implicit call).

The following shows some use cases of these methods for different operating conditions.

Operating condition "First download"

When downloading an application to a PLC with factory settings, the memory of all variables must be offset to the required initial state. In this way, the data areas of function block instances are assigned the required values. By the explicit implementation of `FB_Init` for function blocks, you can react specifically to this situation in the application code. By evaluating the method parameters `bInCopyCode` (`FALSE`) and `bInitRetains` (`TRUE`), you can detect this operating condition clearly. (See "Operating condition "Online Change"" and "Operating condition "Re-download"".)

Operating condition "Online Change"

Within the scope of the online change, you can influence the initialization of function block instances by means of the methods `FB_Exit`, `FB_Init`, and `FB_Reinit`. During the online change, the changes to the application that were made in offline mode are applied in the running PLC. This is the reason that the old instances of the function blocks are replaced by new instances as much as possible without incident. If no changes were made to the declaration part of a function block in the application before login, but in the implementation only, then the data areas are not replaced. Only code blocks are replaced. Then the methods `FB_Exit` , `FB_Init`, and `FB_Reinit` are not called.

If you have made changes to the declaration of a function block that lead to the copying operation described above, then you receive a message during the online change about possible unintended effects. In the “Details” of the message view, you see a list of all instances to be copied.

In the code of the `FB_Init` method, the parameter `bInCopyCode` (`TRUE`) can be evaluated to detect whether or not an online change is being executed.

The following calls occur in succession during an online change:

1. `FB_Exit`

   ```
   old_inst.FB_Exit(bInCopyCode := TRUE);
   ```

   You can call `FB_Exit` when exiting the old instance in order to trigger specific cleanup tasks **before the copy operation**. In this way, you can prepare the data for the following copy operation and influence the state of the new instance. You can notify other parts of the application about the pending change in location in the memory. Pay special attention to the variables of type `POINTER` and `REFERENCE`. These may no longer refer to the required memory locations after the online change. Interface variables (`INTERFACE`) are handled separately by the compiler and they are adapted accordingly during the online change. External resources such as sockets, files, or other handles can be applied by the new instance, in some case unchanged. Often they do not have to be treated specially during an online change. (See "Operating condition "Re-download"")

2. `FB_Init`

   ```
   new_inst.FB_Init(bInitRetains := FALSE, bInCopyCode := TRUE);
   ```

   `FB_Init` is called before the copy operation and can be used in order to execute specific operations for the online change. For example, you can initialize variables accordingly at the new location in the memory, or notify other parts of the application about the new location of specific variables in the memory.

3. Copy operation: `copy`

   ```
   copy(&old_inst, &new_inst);
   ```

   Existing values remain unchanged. For this purpose, they are copied from the old instance into the new instance.

4. `FB_Reinit`

   ```
   new_inst.FB_Reinit();
   ```

   This method is called after the copy operation and should set defined values for the variables of the instance. For example, you can initialize variables accordingly at the new location in the memory, or notify other parts of the application about the new location of specific variables in the memory. Design the implementation independent of the online change. The method can also be called from the application at any time in order to reset a function block instance to its original state.

With the `{attribute 'no_copy'}` attribute, you can prevent that this is copied during the online change for a single variable of the function block. It always retains the initial value.

See also

- *Chapter 1.4.1.20.3.3.19 “Command 'Settings of Memory Reserve for Online Change' ” on page 998*

Operating condition "New download"

When downloading an application, an existing application may be replaced on the PLC. Therefore, the provision of memory for the present function blocks must be regulated. You can use the `FB_Exit` method for implementing the required steps for this. For example, you can offset external resources (with socket and file handles) in a defined state.

You can detect this operating condition by checking whether or not the parameter `bInCopyCode = FALSE` for the `FB_Exit` method.

Operating condition "Start of application"

The initial assignments are processed before the first cycle of the application tasks.

Example

```
T1 : TON := (PT:=t#500ms);
```

These kinds of assignments are executed only after calling `FB_Init`. In order to control the effects of these assignments, you can provide a function block or a method of a function block with the `{attribute 'call_after_init'}` attribute. You must add the attribute above the declaration part of the function block body and above the declaration part of the corresponding method. A POU that extends another POU which uses the `{attribute 'call_after_init'}` attribute must also have the attribute. For the benefit of clarity, we recommend that the corresponding methods are overwritten with the same name, the same signature, and the same attribute. This requires calling `SUPER^.MyInit`. The name of the method can be chosen without restriction. (Exceptions: `FB_Init`, `FB_Reinit`, and `FB_Exit`). The method is called after processing the initial assignments and before starting the application tasks. Therefore, the method can react to user input.

When using `FB_Init` or `{attribute 'call_after_init'}`, remember that detecting errors in the `FB_Init` method or in methods decorated with the `{attribute 'call_after_init'}` attribute is tedious, because the setting of breakpoints may not have the expected effect.

NOTICE!
If the explicitly defined initialization code is reached during execution, then the function block instance is already completely initialized via the implicit initialization code. Therefore, there must not be a `SUPER^.FB_Init` call.

NOTICE!

`FB_Init` replaces the `INI` operator used in CoDeSys V2.3. The methods cannot be compared to the design of a constructor, such as in C#, C++, or Java. This has consequences for function blocks that extend other function blocks. (See below: "Derived function blocks")

Interface of method `FB_Init`

```
METHOD FB_Init : BOOL
VAR_INPUT
  bInitRetains : BOOL; // TRUE: the retain variables are initialized
(reset warm / reset cold)
  bInCopyCode : BOOL;  // TRUE: the instance will be copied to the
copy code afterward (online change)
END_VAR
```

You can declare additional function block inputs in an `FB_init` method. Then you have to set these inputs in the declaration of the function block instance.

Example

Method `FB_Init` for the `serialdevice` function block

```
METHOD PUBLIC FB_Init : BOOL
VAR_INPUT
    bInitRetains : BOOL; // initializing of retain variable
    bInCopyCode : BOOL; // instance is copied to copy code
    iCOMnum : INT; // additional input: number of the COM
interface, that is to be observed
END_VAR
```

Instantiation of the `serialdevice` function block:

```
com1: serialdevice(iCOMnum:=1);
com0: serialdevice(iCOMnum:=0);
```

Interface of method `FB_Reinit`

```
METHOD FB_Reinit : BOOL
```

Interface of method `FB_Exit`

There is the mandatory parameter `bInCopyCode`.

```
METHOD FB_Exit : BOOL
VAR_INPUT
 bInCopyCode : BOOL; // TRUE: the exit method is called in order to
leave the instance which will be copied afterwards (online change).
END_VAR
```

Behavior for derived function blocks

If a function block is derived from another function block, then the `FB_Init` method of the derived function block must define the same parameters as the `FB_Init` method of the basic function block. However, you can add further parameters in order to set up a special initialization for the instance.

Example

The function blocks `MainFB`, `SubFB`, and `SubSubFB` are derived from each other. Therefore, `SubFB EXTENDS MainFB` and `SubSubFB EXTENDS SubFB` apply.

Calling order of methods `FB_Exit` and `FB_Init`:

1. `fbSubSubFb.FB_Exit(...);`
2. `fbSubFb.FB_Exit(...);`
3. `fbMainFb.FB_Exit(...);`
4. `fbMainFb.FB_Init(...);`
5. `fbSubFb.FB_Init(...);`
6. `fbSubSubFb.FB_Init(...);`

1.4.1.19.11 Error Messages and Warnings

Compiler error C0001

Message: Constant '<constant value>' too large for type '<data type>'

Possible error cause: A typed constant is too large for the given data type or a constant is too large for each possible data type.

Error correction: Use smaller constants or an appropriate data type for a typed constant.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    test1: INT;
    test2: INT;
    test3: LREAL;
END_VAR

test1 := 12345678912345566991923939292939911;
test2 := INT#123456;
test3 := 10E500;

--> C0001: Constant '12345678912345566991923939292939911' too large
for type 'ANY_INT'
--> C0001: Constant 'INT#123456' too large for type 'INT'
--> C0001: Constant '10E500' too large for type 'ANY_REAL'
```

Compiler error C0002

Message: '<operator 1>' or '<operator 2>' expected instead of '<tag>'

Possible error cause: Syntax error

Error correction: Use the correct syntax.

Example of the error:

```
PROGRAM PLC_PRG
Fun(1;

--> C0002:  ',' or ')' expected instead of ';'
```

Compiler error C0003

Message: '<value>' is not a valid bit number for '<variable>'

Possible error cause: Attempted access to a bit that is outside of the range for a data type.

Error correction: Use a bit value for the bit access that is lower than the number of bits in the data type of the variable.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    test1: WORD;
    test2: BOOL;
END_VAR

test1 := test2.17;

--> C0003:  '17' is not a valid bit number for 'w'
```

Compiler Error C0004

Message: '<variable>' is not a component of '<structure>'

Possible error cause: Component access with "." to a variable that is not a structured value or does not exist as a component of the structure.

Error correction: Access a defined component, or change the definition of the component in the data type. The input assistance "List components" provides all valid access to this position.

Example of the error:

```
TYPE DUT:
STRUCT
    x, y : INT;
END_STRUCT
END_TYPE

PROGRAM PLC_PRG
VAR
    test1 : DUT;
    test2 : INT;
END_VAR

test2 := test1.z;

--> C0032:  Type 'Unknown type: 'test1.z'' cannot be converted to
type 'INT'
--> C0004:  'z' is to a component of 'DUT'
```

Compiler error C0005

Message: Constant overflow in address '<address>'

Possible error cause: At least one component in the address does not fit into a 32-bit integer value.

Error correction: Use a valid address expression.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    X: BYTE;
END_VAR

X := %QB5555555555;

--> C0005: Constant overflow in address '%??'
```

Compiler error C0006

Message: '<operator>' expected instead of '<token>'

Possible error cause: Syntax error

Error correction: Use the correct syntax.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    x: INT;
    bTest : BOOL;
END_VAR

IF bTest
    x := 9;
END_IF

--> C0006:  'THEN' expected instead of 'x'
```

Compiler error C0007

Message: Expression expected instead of '<token>'

Possible error cause: Syntax error

Error correction: Use the correct syntax.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    x: INT;
    bTest : BOOL;
END_VAR

IF THEN
    x := 9;
END_IF

--> C0007: Expression expected instead of 'THEN'
```

Compiler error C0008

Message: Unexpected end-of-file found: '<operator 1>', '<operator 2>', or '<operator 3>' expected

Possible error cause: Syntax error

Error correction: Use the correct syntax.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    x: INT;
    bTest : BOOL;
END_VAR

IF bTest THEN
    x := 9;

--> C0008: Unexpected end-of-file found: 'ELSIF', 'ELSE' or 'END_IF'
expected
```

Compiler error C0009

Message: Unexpected token '<token>' found

Possible error cause: Syntax error

Error correction: Use the correct syntax.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

END_FOR;

--> C0009: Unexpected token 'END_FOR' found
```

Compiler error C0010

Message: Unexpected end-of-file found: '<token>' expected

Possible error cause: Syntax error

Error correction: Use the correct syntax.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i: INT;
END_VAR

FOR i := 0 TO 2 DO
;

--> C0010: Unexpected end-of-file 'END_FOR' found
```

Compiler error C0011

Message: No 'CASE' label found

Possible error cause: Syntax error in a CASE statement. A statement in a CASE statement is not assigned to a CASE label.

Error correction: Add a CASE label.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i: INT;
    x: INT;
END_VAR

CASE i OF
    x := 9;
END_CASE

--> C0011: No 'CASE' label found
```

Error correction:

```
CASE i OF
0:
    x := 9;
END_CASE
```

Compiler error C0013

Message: At least one statement is expected.

Possible error cause: At least one statement is expected at some positions in the code. For example, in the THEN and ELSE part of an IF statement, or in the body of a FOR loop.

Error correction: Add at least one statement at the selected position. It is enough to write a blank statement ";".

Example of the error:

```
PROGRAM PLC_PRG
VAR
    bTest: BOOL;
END_VAR

IF bTest THEN
END_IF

--> C0013: At least one statement is expected
```

Compiler error C0016

Message: Counter initialization expected

Possible error cause: Syntax error in a FOR loop. The counter variable is not initialized correctly.

Error correction: Pay attention to the correct syntax of the FOR loop.

```
FOR i := 0 TO 10 DO
    ;
END_FOR
```

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i: INT;
END_VAR

FOR i TO 10 DO
    ;
END_FOR

--> C0015: Counter initialization expected
```

Error correction:

```
FOR i := 0 TO 10 DO
    ;
END_FOR
```

Compiler error C0018

Message: <expression> is not a valid assignment target

Possible error cause: An expression with no write permission is on the left side of an assignment. Example: a constant.

Error correction: Assign only to variables that have write access.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i: INT;
END_VAR
VAR CONSTANT
```

```
    j: INT := 0;
END_VAR

j := i;

--> C0018:  'j' is not a valid assignment target
```

Compiler error C0020

Message: '<statement>' is no valid statement

Possible error cause: Syntax error (for example, too few or too many characters)

Error correction: Make sure that the syntax is correct.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    x : INT;
END_VAR

x = 2;

--> C0020: '(x = 2); ' is no valid statement
```

Error correction:

```
Example:
x := 2;
```

Compiler error C0022

Message: '<operator>' needs exactly '<number of operands>' operands

Possible error cause: Too many or too few operands are assigned to an operator.

Error correction: Assign the required number of operands to the operator.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    pt: POINTER TO INT;
END_VAR

pt := ADR(i,1);

--> C0022: 'ADR' needs exactly '1' operands
```

Error correction:

```
Example:
pt := ADR(i);
```

Compiler error C0023

Message: '<operator>' needs at least '<number of operands>' operands

Possible error cause: Too few operands are assigned to an operator.

Error correction: Assign the required number of operands to the operator.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR

i := MUX(30,40);

--> C0023: 'MUX' needs at least '3' operands
```

Error correction:

```
Example:
i := MUX(30,40,50);
```

Compiler error C0026

Message: Identifier expected instead of '<invalid identifier>'

Possible error cause: An invalid identifier is passed to a method.

Error correction: Use valid identifiers.

Example of the error:

```
METHOD 123
VAR_INPUT
END_VAR

--> C0243: The name used in the signature is not identical to the
object name
--> C0026: Identifier expected instead of '123'
```

Error correction:

```
Example:
METHOD METH123
```

Compiler error C0027

Message: size of string expected after '('

Possible error cause: The length of the string is not specified.

Error correction: Specify a string length between the parentheses.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     str : STRING();
END_VAR

--> C0027: size of string expected after '('
--> C0006: ';, :=, REF=, ( or [' expected instead of ')'
```

Error correction:

```
Example:
str : STRING(100);
```

Compiler error C0030

Message: Direct Address expected after 'AT' instead of '<identifier>'

Possible error cause: Either an invalid address or no address is assigned after 'AT'.

Error correction: Specify a valid address.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     i AT ABC : INT;
END_VAR

--> C0030: Direct Address expected after 'AT' instead of 'ABC'
```

Error correction:

```
Example:
i AT %IW0 : INT;
```

Compiler error C0031

Message: Type definition expected instead of '<no data type>'

Possible error cause: An invalid type definition is assigned to the identifier.

Error correction: Specify a valid type definition.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     i : 0;
END_VAR

--> C0031: Type definition expected instead of '0'
```

Error correction:

```
Example:
i : INT;
```

Compiler error C0032

Message: Type '<type 1>' can not be converted to type '<type 2>'

Possible error cause: A variable is assigned to another variable with an incompatible type.

Error correction: Use a type conversion.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    test1: INT;
    test2: STRING;
END_VAR

test1 := test2;

-->C0032: Type 'STRING' cannot be converted to type 'INT'
```

Error correction:

```
Example:
test1 := TO_INT(test2);
```

Compiler Error C0033

Message: Type '<pointer type>' possibly not convertible to type '<data type>' .

Possible error cause: This error occurs only when checking pool objects. An attempt was made to convert a pointer to an integer. Because the size of pointers in a library is unknown, errors may occur when using the library.

Error correction: Use the type `__UXINT` or `__XWORD` for platform-independent calculations with pointers.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    ptr : POINTER TO INT;
    dw : DWORD;
END_VAR
    dw := ptr;

--> C0033: Type 'POINTER TO INT‘ possibly not convertible to type
'DWORD‘.
```

Compiler error C0035

Message: Program name, function or function block instance expected instead of '<invalid function>'

Possible error cause: A function is called that does not exist.

Error correction: Make sure that only program names, functions, and function Block Instances that exist are called.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

PLC_PRG.METH1();

METHOD METH
VAR_INPUT
END_VAR

--> C0004: 'METH1' is no component of 'PLC_PRG'
--> C0035: Program name, function or function block instance expected
instead of 'PLC_PRG.METH1'
```

Error correction:

```
Example:
PLC_PRG.METH();
```

Compiler Error C0036

Message: Cannot call object of type <type>

Possible error cause: An attempt has been made to call an object that does not support any calls.

Error correction: Only functions, function blocks, programs, methods, and actions can be called.

Example of the error:

```
VAR_GLOBAL GVL
    value : INT;
END_VAR
PROGRAM PLC_PRG
GVL();

--> C0036: Cannot call object of type 'VAR_GLOBAL‘.
```

Compiler error C0037

Message: '<invalid input>' is no input of '<function name>'

Possible error cause: A local variable is defined in a function call.

Error correction: Declare the variable as an input parameter.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     i : INT;
END_VAR
i := TEST(iVar := 1);

FUNCTION TEST : INT
VAR
    iVar : INT;
END_VAR

--> C0037: 'iVar' is no input of 'TEST'
```

Error correction:

```
Example:
VAR_INPUT
    iVar : INT;
END_VAR
```

Compiler error C0038

Message: '<invalid output>' is no output of '<function name>'

Possible error cause: A local variable is handled as an output in a function call.

Error correction: Declare the variable as an output parameter.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     i : INT;
     x : INT;
END_VAR
i := TEST(iVar => x);

FUNCTION TEST : INT
VAR
    iVar : INT;
END_VAR

--> C0038: 'iVar' is no output of 'TEST'
```

Error correction:

```
Example:
VAR_OUTPUT
    iVar : INT;
END_VAR
```

Compiler error C0039

Message: VAR_IN_OUT '<invalid variable>' must be assigned in call of '<function block name>'

Possible error cause: An IN_OUT variable is not passed to a function block that requires an IN_OUT variable.

Error correction: Assign the IN_OUT variable.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR
inst();

FUNCTION_BLOCK FB
VAR_IN_OUT
    inout : INT;
END_VAR

--> C0039: VAR_IN_OUT 'inout' must be assigned in call of 'FB'
```

Error correction:

```
Example:
inst(inout := i);
```

Compiler error C0040

Message: Function '<function name>' requires exactly '<number of inputs>' input

Possible error cause: Too many or too few parameters are passed to the called function.

Error correction: Pass exactly as many parameters to the function as are expected.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     i : INT;
END_VAR
i := TEST(1,2);

FUNCTION TEST : INT
VAR_INPUT
    IN: INT;
END_VAR

--> C0040: Function 'TEST' requires exactly '1' inputs
```

Error correction:

```
Example:
i := Test(1);
```

Compiler error C0041

Message: VAR_IN_OUT parameter '<parameter name>' of '<function name>' needs variable with write access as input

Possible error cause: The passed parameter is not a variable with write access (but a constant for example).

Error correction: Pass a VAR_IN_OUT parameter with write access to the function.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     i : INT;
     x : INT;
END_VAR
i := Test(31415);

FUNCTION TEST : INT
```

```
VAR_IN_OUT
    in_out: INT;
END_VAR

--> C0041: VAR_IN_OUT' parameter 'in_out' of 'TEST' needs variable
with write access as input
```

Error correction:

```
Example:
i := Test(x);
```

Compiler Error C0042 (Compiler Version <= 3.4.10)

Message: Either all or none formal parameter have to be denoted in function call

Possible error cause: The parameters are explicitly assigned to the function in the wrong order.

Error correction: Use uniform formal parameters or implicit parameters.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     i : INT;
END_VAR
 i := Test(iPar1:=2, 5);

FUNCTION Test : INT
VAR_INPUT
    iPar1 : INT;
    iPar2 : INT;
END_VAR

--> Either all or none formal parameter have to be denoted in
function call
```

Compiler error C0043

Message: Wrong formal parameter: '<parameter name>' expected in this place

Possible error cause: The parameters are assigned to the function explicitly in the wrong order.

Error correction: Specify the parameters in the correct order.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     i : INT;
END_VAR
i := Test(iPar2 := 2, 5);

FUNCTION Test : INT
VAR_INPUT
    iPar1 : INT;
    iPar2 : INT;
END_VAR

--> C0043: Wrong formal parameter: 'iPar1' expected in this place
--> C0412: Multiple input assignments for parameter ''
```

Error correction:

```
Example:
i := Test(5, iPar2 := 2);
```

Compiler error C0044

Message: Assignment to input missing for parameter '<input variable name>' in call of '<function block name>'

Possible error cause: A parameter is passed although an input variable is not declared.

Error correction: Declare an input variable.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR
inst(1);

FUNCTION_BLOCK FB
VAR_INPUT

END_VAR

--> C0044: Assignment to input missing for parameter '1' in call of
'FB'
```

Error correction:

```
Example:
VAR_INPUT
    in : INT;
END_VAR
```

Compiler error C0045

Message: Use of 'THIS' is not allowed in this context

Possible error cause: In order to be assigned to the current instance, THIS can be used only in a method, action, transition, or in the body of a function block. This error message appears for all other positions.

Error correction: Use THIS in an allowed context only.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    test1: INT;
END_VAR

THIS^.test1 := 19;

--> C0018: 'THIS^.test1' is not a valid assignment target
--> C0062: 'THIS^' is not a structure variable
--> C0045: Use of 'THIS' is not allowed in this context
```

Compiler error C0046

Message: Identifier '<identifier name>' not defined

Possible error cause: An identifier is used that is not declared.

Error correction: Declare the variables that you want to use.

Example of the error:

```
PROGRAM PLC_PRG
VAR

END_VAR

i := 1;

--> C0018: 'i' is no valid assignment target
--> C0046: Identifier 'i' not defined
```

Error correction:

```
Example:
VAR
    i : INT;
END_VAR
```

Compiler error C0047

Message: Cannot apply indexing with '[]' to an expression of type '<data type>'

Possible error cause: A data type that is not an array is indexed with '[]'.

Error correction: Index data types with '[]' only if they are declared as arrays.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR
i[1];

--> C0047: Cannot apply indexing with '[]' to an expression of type
'INT'
```

Compiler error C0048

Message: Array requires exactly '<number>' indexes

Possible error cause: Too many or too few indexes are specified when using an array.

Error correction: Specify as many indexes as there are dimensions assigned to the array.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    arr1 : ARRAY[1..2,1..3] OF INT;
END_VAR
arr1[1] := 5;

--> C0048: Array requires exactly 2 indexes
```

Error correction:

```
Example:
arr1[1,2] := 5;
```

Compiler error C0049

Message: The constant index '<index value>' is not within the range from '<start index>' to '<end index>'

Possible error cause: An index is specified that is outside the size of the array.

Error correction: Use only indexes that are within the size of he array.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    arr1 : ARRAY[1..2] OF INT;
END_VAR
arr1[3] := 1;

--> C0049: The constant index '3' is not within the range from '1' to
'2'
```

Error correction:

```
Example:
arr1[2] := 1;
```

Compiler error C0050

Message: Bitaccess requires literal or symbolic integer constant

Possible error cause: No literal or an integer constant is specified in a bit access.

Error correction: Use a literal or an integer constant.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    x : INT;
END_VAR

i.x := FALSE;

--> C0018: 'i.x' is no valid assignment target
--> C0050: Bitaccess requires literal or symbolic integer constant
```

Error correction:

```
Example:
i := Test(x);
```

Compiler Error C0051

Message: Single byte string expected for an attribute value instead of '<value>‘.

Possible error cause: A character string does not appear at the displayed location as expected.

Error correction: Replace the current value with a string.

Example of the error:

```
PROGRAM PLC_PRG
{IF hasattribute(pou: MyPOU, MyAttribute)}
{END_IF}

--> C0051: Single byte string expected for an attribute value instead
of 'MyAttribute'.
```

Error correction:

```
PROGRAM PLC_PRG
{IF hasattribute(pou: MyPOU, 'MyAttribute')}
{END_IF}
```

Compiler Error C0053

Message: Compiler version <version> has been withdrawn. Please use a higher compiler version instead.

Possible error cause: The current compiler version cannot ne used.

Error correction: Adapt the current compiler version in the project (Project Environment, Project Settings).

Compiler error C0061

Message: Bitaccess on function call is not allowed

Possible error cause: Bit access is performed on a function.

Error correction: Use bit access only for supported data types.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

Test().2;

FUNCTION Test : INT
VAR_INPUT

END_VAR

--> C0061: Bitaccess on function call is not allowed
```

Compiler error C0062

Message: '<variable name>' is no structured variable

Possible error cause: A variable that is not a structure variable is treated like a structure variable.

Error correction: Make sure that the variable is a structure variable.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    pt : PUNKT;
    i : INT;
END_VAR

i.x := 1024;

TYPE Punkt :
STRUCT
    x : REAL;
    y : REAL;
END_STRUCT
```

```
END_TYPE

--> C0018: 'i.x' is no valid assignment target
--> C0062: 'Variable' is no structured variable
```

Error correction:

```
Example:
pt.x := 1024;
```

Compiler error C0064

Message: Dereferencing requires a pointer

Possible error cause: A variable that is not a pointer variable is dereferenced.

Error correction: Dereference only variables that are pointer variables.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    pi : POINTER TO INT;
END_VAR
i^:=1;

--> C0018: 'i^' not a valid assignment target
--> C0064: Dereferencing requires a pointer
```

Error correction:

```
Example:
pi := ADR(i);
pi^ := 1;
```

Compiler Error C0065

Message: There is no global definition for '<name>'.

Possible error cause: The value searched for is not a global variable, global POU, or other value that can be accessed globally.

Error correction: Declare '<name>' as a global variable.

Example of the error:

```
PROGRAM PLC_PRG
.someValue := 5;

--> C0065: There is no global definition for 'someValue‘
```

Error correction:

```
Example:
VAR_GLOBAL
    someValue : INT;
END_VAR
```

Compiler error C0066

Message: Cannot compare type '<data type>' with type '<data type>'

Possible error cause: Two data types are compared which cannot be compared with each other.

Error correction: Compare only data types that can be compared with each other.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    re : REAL;
    str: STRING;
    b : BOOL;
END_VAR

b := i > str;

--> C0066: Cannot compare type 'INT' with type 'STRING'
```

Error correction:

```
Example:
b := i > re;
```

Compiler error C0068

Message: Compare not possible on objects of type '<data type>'

Possible error cause: Objects are being compared in which a comparison is not possible.

Error correction: Compare only data types in which a comparison is possible (INT, REAL, etc.).

Example of the error:

```
PROGRAM PLC_PRG
VAR
    b : BOOL;
    arr1 : ARRAY [1..2] OF INT;
    arr2 : ARRAY [1..2] OF INT;
END_VAR

b := arr1 > arr2;

--> C0068: Compare not possible on objects of type 'ARRAY [1..2]'
```

Compiler error C0069

Message: Compare not possible on objects of type '<data type>' or '<data type>'

Possible error cause: Two different objects are being compared in which a comparison is not possible.

Error correction: Compare only data types in which a comparison is possible (INT, REAL, etc.).

Example of the error:

```
PROGRAM PLC_PRG
VAR
    b : BOOL;
    arr1 : ARRAY [1..2] OF INT;
    arr2 : ARRAY [1..3] OF INT;
END_VAR

b := arr1 > arr2;

--> C0069: Compare not possible on objects of type 'ARRAY [1..2]' or
'ARRAY [1..3]'
```

Compiler error C0070

Message: 'INI' operator needs function block instance or data unit type instance

Possible error cause: Neither a function block instance nor a DUT instance is applied to the INI operator.

Error correction: Pass only function block instances or DUT instances to the INI operator.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    b : BOOL;
    inst : FB;
END_VAR

b := INI(b, TRUE);

FUNCTION_BLOCK FB
VAR
END_VAR

--> C0070: 'INI' operator needs function block instance or data unit
type instance
```

Error correction:

```
Example:
b := INI(inst, TRUE);
```

Compiler error C0072

Message: Operator <operator name>' is not possible on type '<data type>'

Possible error cause: An operator is applied to an incompatible type.

Error correction: Apply operators only on compatible types.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    str : STRING;
END_VAR

str := ABS(str);

--> C0072: Operator 'Abs' is not possible on type 'STRING'
```

Error correction:

```
Example:
i := ABS(i);
```

Compiler error C0074

Message: Unexpected array initialisation

Possible error cause: Syntax error in the array initialization

Error correction: Correct the syntax

Example of the error:

```
PROGRAM PLC_PRG
VAR
    arr1 : INT := [1,2,3,4,5,6];
END_VAR
```

```
--> C0074: Unexpected array initialisation
--> C0032: Cannot convert type 'Unknown type: [1,2,3,4,5,6]' to type
'INT'
```

Error correction:

```
Example:
arr1 : ARRAY [1..6] OF INT := [1,2,3,4,5,6];
```

Compiler error C0075

Message: Too many initializers for array

Possible error cause: Too many values are specified for the size of the array.

Error correction: The number of assigned values must correspond to the size of the array.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    arr1 : ARRAY [1..5] OF INT := [1,2,3,4,5,6];
END_VAR
```

```
--> C0075: Unexpected array initialisation
```

Error correction:

```
Example:
arr1 : ARRAY [1..6] OF INT := [1,2,3,4,5,6];
```

Compiler error C0076

Message:Unexpected structure initialisation

Possible error cause: Syntax error in the structure initialization

Error correction: Make sure that the syntax is correct.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    st1 : INT := (p1 := 1);
END_VAR
```

```
--> C0076: Unexpected structure initialisation
--> C0032: Cannot convert type 'STRUCT(p1:=1)' to type 'INT'
--> C0046: Identifier 'p1' not defined
--> C0018: 'p1' is no valid assignment target
```

Error correction:

```
Example:
st1 : STRUCT1 := (p1:=1,p2:=10);
```

Compiler error C0077

Message: Unknown type: '<data type>'

Possible error cause: Invalid data type in the declaration (maybe a syntax error)

Error correction: Specify valid data types only.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INTEGER;
END_VAR

--> C0077: Unknown type: 'INTEGER'
```

Error correction:

```
Example:
arr1 : ARRAY[1..2] OF STRUCT1 := (p1:=1,p2:=10);
```

Compiler Error C0078

Message: Unsupported type: '<data type>'

Possible error cause: The used type is not supported by the current device and therefore cannot be used.

Error correction: If possible, use a different type. For example, `REAL` instead of `LREAL`.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    value : LREAL;
END_VAR

--> C0078: Unsupported type: 'LREAL‘
```

Error correction:

```
Example:
PROGRAM PLC_PRG
VAR
    value : REAL;
END_VAR
```

Compiler error C0080

Message: Functionblock '<function block name>' must be instantiated to be accessed

Possible error cause: Missing function Block Instantiation

Error correction: Instantiate the function block.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

FB();

FUNCTION_BLOCK FB
VAR
END_VAR

--> C0080: Functionblock 'FB' must be instantiated to be accessed
```

Error correction:

```
Example:
VAR
    inst : FB;
END_VAR
inst();
```

Compiler error C0081

Message: Unexpected Pragma: '<pragma name>' found without matching 'if'

Possible error cause: The IF condition is missing when using the pragma.

Error correction: Complete the IF condition of the pragma.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR

i := 5;
{END_IF}

--> C0081: Unexpected Pragma: 'END_IF' found without matching 'if'
```

Error correction:

```
Example:
{IF <expression>}
i := 5;
{END_IF}
```

Compiler error C0082

Message: '<invalid pragma>' is no valid condition for pragma

Possible error cause: When using a pragma, an invalid expression is used in the IF condition.

Error correction: Use valid pragma conditions.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR

{IF abc}
i := 5;
{END_IF}

--> C0082: '!!!ERROR!!!' is no valid condition for pragma
```

Error correction:

```
Example:
{IF defined (abc)}
```

Compiler error C0084

Message: '<pragma operand>' is no valid operand for pragma

Possible error cause: Syntax error

Error correction: Use valid pragma operands.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

{IF defined(0)}
{END_IF}

--> C0084: 'defined(null)' is no valid operand for pragma
```

Error correction:

```
Example:
{IF defined (abc)}
```

Compiler Error C0085

Message: Define value expected instead of '<value>‘.

Possible error cause: A string is expected instead of the current value at the displayed location of the pragma.

Error correction: Replace the current value with a string.

Example of the error:

```
PROGRAM PLC_PRG

{IF hasvalue(define, defineValue)}
{END_IF}

--> C0086: C:0085: Define value expected instead of 'defineValue‘
```

Error correction:

```
Example:
PROGRAM PLC_PRG

{IF hasvalue(define, '120')}
{END_IF}
```

Compiler error C0086

Message: No definition found for interface '<interface name>'

Possible error cause: An undefined interface is used.

Error correction: Define the interface.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     inst : FB;
END_VAR

FUNCTION_BLOCK FB IMPLEMENTS XY
VAR
END_VAR

--> C0086: No definition found for interface 'XY'
```

Error correction:

```
Example:
INTERFACE XY
```

Compiler error C0087

Message: There is no implementation for method '<method name>' defined in interface '<interface name>'.

Possible error cause: One of the methods specified by the interface has not be provided by the implemented function block.

Error correction: Implement all methods that are specified by the interface.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     inst : FB;
END_VAR

INTERFACE XY
METHOD METH1
VAR_INPUT
END_VAR

FUNCTION_BLOCK FB IMPLEMENTS XY
VAR
END_VAR
METHOD METH2
VAR_INPUT
END_VAR

--> C0087: There is no implementation for method 'METH1' defined in
interface 'XY'
```

Compiler error C0089

Message: Interface of overridden method '{0}' of interface '{1}' does not match declaration

Possible error cause: The signature of the implemented method does not match the signature of the method in the interface.

Error correction: Make sure that the same return types and parameters are declared.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     inst : FB;
END_VAR

INTERFACE XY
METHOD METH1
VAR_INPUT
    iPar : INT;
END_VAR

FUNCTION_BLOCK FB IMPLEMENTS XY
VAR
END_VAR
METHOD METH1
VAR_INPUT
```

```
END_VAR

--> C0089: Interface of overridden method 'METH1' of interface 'XY'
does not match declaration
```

Compiler error C0090

Message: No definition found for base class '<function name>'

Possible error cause: The function block specified as the base does not exist or is not a function block.

Error correction: Use a function block as the base.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     inst : FB;
END_VAR

FUNCTION_BLOCK FB EXTENDS POU
VAR
END_VAR

FUNCTION POU
VAR
END_VAR

--> C00090: No definition found for base class 'POU'
```

Compiler error C0091

Message: Recursion in base function block list: <function name>

Possible error cause: A base function block is extended by itself.

Error correction: Recursion in base function block lists is not possible.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     inst : FB;
END_VAR

FUNCTION_BLOCK FB EXTENDS FB
VAR
END_VAR

--> C00091: Recursion in base function block list: FB -> FB
```

Compiler error C0094

Message: Interface of overridden method '<method name>' of interface '<function block name>' doesn't match declaration

Possible error cause: The signature of the method of the first interface does not match the signature of the method in the second interface, which is extended by the first.

Error correction: Align the signatures.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     xyz : XY2;
END_VAR

FUNCTION_BLOCK XY
METHOD METH1
VAR_INPUT
END_VAR

FUNCTION_BLOCK XY2 EXTENDS XY
METHOD METH1
VAR_INPUT
    iPar : BOOL;
END_VAR

--> C00094: Interface of the overridden method METH1 of interface XY
doesn't match declaration
```

Compiler error C0096

Message: Only one base function block may be defined in EXTENDS-list.

Possible error cause: Two or more base function blocks are defined in the EXTENDS list.

Error correction: Define only one base function block in the EXTENDS list.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    fb : FB;
END_VAR

FUNCTION_BLOCK FB EXTENDS FB2, FB3
VAR
END_VAR

FUNCTION_BLOCK FB2
VAR
END_VAR

FUNCTION_BLOCK FB3
VAR
END_VAR

--> C00096: Only one base function block may be defined in EXTENDS-
list
```

Compiler error C0097

Message: Duplicate definition of variable '<variable name>' in function block '<function block name>' and in base '<base function block name>'

Possible error cause: A variable is declared with the same name in a function block and its base.

Error correction: Use different variable names.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    fb : FB;
END_VAR

FUNCTION_BLOCK FB EXTENDS FB2
VAR
    i : INT;
END_VAR

FUNCTION_BLOCK FB2
VAR
    i : INT;
END_VAR

--> C00097: Duplicate definition of variable 'i' in function block
'FB' and in base 'FB2'
```

Compiler error C0098

Message: The keyword "FUNCTIONBLOCK" is no longer supported. Use "FUNCTION_BLOCK" instead.

Possible cause of error: Syntax error

Error correction: Use the keyword "FUNCTION_BLOCK".

Example of the error:

```
PROGRAM PLC_PRG
VAR
     inst : FB;
END_VAR

FUNCTIONBLOCK FB
VAR
END_VAR

--> C00098: The keyword "FUNCTIONBLOCK" is no longer supported. Use
"FUNCTION_BLOCK" instead. Use "FUNCTION_BLOCK" instead.
```

Compiler Error C0099 (Compiler Version < 3.5.7.0)

Message: Local defined enumeration are no longer supported. Use datatype definition instead.

Possible error cause: A local enumeration declaration was used together with a compiler version that does not support this.

Error correction: Use a later compiler version, or define the enumeration in a DUT.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    localEnumVar : (RED, GREEN, BLUE) := RED;
END_VAR

--> C0099: Local defined enumeration are no longer supported. Use
datatype definition instead.
```

Compiler error C0101

Message: Data Recursion: '<recursion>'

Possible error cause: Recursive data initialization over two function blocks

Error correction: Avoid recursions for data initialization.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst0 : FB1;
END_VAR

FUNCTION_BLOCK FB1
VAR
    inst1 : FB2;
END_VAR

FUNCTION_BLOCK FB2
VAR
    inst2 : FB1;
END_VAR

--> C0101: Data Recursion: FB1->FB2->FB1
```

Compiler error C0102

Message: Out of retain memory: Variable '<variable name>', <byte size> bytes.

Possible error cause: More retain memory is used than is available on the PLC. It is also possible that the retain memory is too fragmented due to incremental builds.

Error correction: Use the *“Clean”* for fragmenting the memory. This will force the reallocation of all data at the next build.

Compiler error C0104

Message: 'Out of global data memory: Variable '<variable name>', <byte size> bytes.

Possible error cause: More memory for data is used than is available on the PLC. It is also possible that the memory is too fragmented due to incremental builds.

Error correction: Use the *“Clean”* for fragmenting the memory. This will force the reallocation of all data at the next build.

Compiler error C0114

Message: Invalid destination <jump label> for 'JMP'

Possible error cause: Syntax error or typographical error in the JMP destination

Error correction: Correct the typographical or syntax error.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR
JMP 0;

--> C0114: Invalid destination 0 for 'JMP'
```

Compiler Error C0115

Message: The second parameter of a conditional call (????ALWAYS CALC????) has to be a valid call statement.

Error correction: Specify the call of a function, method, or function block in the second parameter of the conditional ????CALC??? call.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    condition : BOOL;
END_VAR
CALC(condition, 1+2);

--> C0115: The second parameter of a conditional call has to be a
valid call statement.
```

Error correction:

```
Example:
CALC(condition, MyFunction(1,2))
```

Compiler error C0116

Message: The label '<jump label>' is a duplicate

Possible error cause: A label is defined multiple times.

Error correction: Define each label one time only.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR
JMP label;
label:

label:

--> C0116: The label 'LABEL' is a duplicate
```

Compiler error C0117

Message: No such label '<jump label>' within the scope of the 'JMP' statement

Possible error cause: A jump is made to a label that does not exist.

Error correction: Define the label that you specify as the destination.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR
JMP A;

--> C0117: No such label 'A' within the scope of the 'JMP' statement
```

Compiler error C0118

Message: The label '<jump label>' has not been referenced.

Possible error cause: A jump label is defined that is not referenced.

Error correction: Remove the unused jump labels.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR
LABEL:

--> C0118: The label ' LABEL' has not been referenced
```

Compiler error C0119

Message: An 'FB_init'-Method of a functionblock or struct needs two inputs 'bInitRetains' and 'bInCopyCode' of type BOOL

Possible error cause: One or both of the inputs 'bInitRetains' and 'bInCopyCode' of type BOOL is missing.

Error correction: Define the missing inputs.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR

FUNCTION_BLOCK FB
METHOD FB_init
VAR_INPUT
END_VAR

--> C0119: An 'FB_init'-Method of a functionblock or struct needs two
inputs 'bInitRetains' and 'bInCopyCode' of type BOOL
```

Error correction:

```
Example:
METHOD FB_init
VAR_INPUT
    bInitRetains : BOOL;
    bInCopyCode : BOOL;
END_VAR
```

Compiler error C0120

Message: An 'FB_Exit'-Method of a functionblock or struct needs an input 'bInCopyCode' of type BOOL.

Possible error cause: The input 'bInCopyCode' of type BOOL is missing.

Error correction: Define the input.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR

FUNCTION_BLOCK FB
```

```
METHOD FB_exit
VAR_INPUT
END_VAR

--> C0120: An 'FB_Exit'-Method of a functionblock or struct needs an
input 'bInCopyCode' of type BOOL.
```

Error correction:

```
Example:
METHOD FB_exit
VAR_INPUT
    bInCopyCode : BOOL;
END_VAR
```

Compiler error C0122

Message: Expression 'SUPER' is not allowed in this context

Possible error cause: "SUPER^" is used outside of derived function blocks.

Error correction: Use "SUPER^" in function blocks only.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

SUPER^.METH(TRUE, TRUE);

--> C0122: Expression 'SUPER' is not allowed in this context
```

Compiler error C0124

Message: 'Initialization' is no valid initialization for an enumeration

Possible error cause: A data type that is not ANY_INT is used for the enum initialization.

Error correction: Use only ANY_INT for enum initializations.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : DUT;
END_VAR

TYPE DUT :
(
  enum_member := 1.5
) DWORD;
END_TYPE

--> C0032: Cannot convert type 'LREAL' to type 'DUT'
--> C0124: 'Initialization' is no valid initialization for an
enumeration
```

Compiler error C0125

Message: The constant <constant value> is assigned to more than one enumeration.

Possible error cause: The same value is assigned to two or more enumerations.

Error correction: Assign different values to the enumerations.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : DUT;
END_VAR

TYPE DUT :
(
    enum_member := 0,
    enum_member2 := 0
);
END_TYPE

--> C0125: The constant 0 is assigned to more than one enumeration
```

Compiler error C0126

Message: Variable of type '<data type>' requires exactly 1 Index

Possible error cause: Multiple indexes are assigned to a variable with one index.

Error correction: Assign only one index.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    pi : POINTER TO INT;
END_VAR
pi[0,1] := 0;

--> C0126: Variable of type 'POINTER TO INT' requires exactly 1 Index
```

Error correction:

```
Example:
pi[0] := 0;
```

Compiler error C0130

Message: <object> '<object name>' referenced without parentheses '()'

Possible error cause: A method is referenced without parentheses.

Error correction: Always reference methods by means of parentheses.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR
inst.METH1

--> C0130: METHOD 'METH1' referenced without parentheses '()'
```

Error correction:

```
Example:
inst.METH1();
```

Compiler error C0131

Message: '<value>' is not allowed as operand for 'ADR'

Possible error cause: A constant is passed as an operand to the operator ADR.

Error correction: Use only valid operands for ADR.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    pt : POINTER TO INT;
END_VAR

pt := ADR(1);

--> C0131: '1' is not allowed as operand for 'ADR'
```

Error correction:

```
Example:
pt := ADR(i);
```

Compiler error C0132

Message: No enclosing loop of which to EXIT

Possible error cause: EXIT is used outside of a loop.

Error correction: Use EXIT inside of a loop only.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

EXIT
;

--> C0132: No enclosing loop of which to EXIT
```

Compiler error C0136

Message: ambiguous use of name '<variable name>'

Possible error cause: A variable is declared in multiple GVLs.

Error correction: Qualify the variable with the desired GVL.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    j : INT := g_i;
END_VAR

GVL1:
VAR_GLOBAL
    g_i : INT;
END_VAR

GVL2:
```

```
VAR_GLOBAL
    g_i : INT;
END_VAR

--> C0136: ambiguous use of name 'g_i'
```

Error correction:

```
Example:
j : INT := GVL1.g_i;
```

Compiler Error C0138

Message: No matching 'FB_Init' method found for instantiation of POU.

Possible error cause: No `FB_Init` method exists that accepts the passed parameters.

Error correction: Check which arguments `FB_Init` has to receive and adjust the passed arguments.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    myPOU : POU(arg1 := 1, arg2 := 2);
END_VAR

--> C0138: No matching 'FB_Init‘ method found for instantiation of
POU.
```

Compiler error C0139

Message: The code <code> has no effect. Is this the intent?

Possible error cause: The written code is syntactically correct but does not do anything.

Error correction: Write code that has a purpose.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR

i;

--> C0139: The code 'i;' has no effect. Is this the intent?
```

Compiler error C0140

Message: Reference assign is only allowed to variables of Reference type

Possible error cause: An attempt is made to assign a reference value to a variable not defined as a reference type.

Error correction: Define the variable as a reference type.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    I_r : INT;
END_VAR
```

```
I_r REF= i;

--> C0140: Reference assign is only allowed to variables of Reference
type
```

Error correction:

```
Example:
I_r : REFERENCE TO INT;
```

Compiler error C0141

Message: Reference assign needs variable with write access

Possible error cause: A constant is assigned to the reference assignment.

Error correction: Assign a writable variable.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    I_r : REFERENCE TO INT;
END_VAR

I_r REF= 314;

--> C0141: Reference assign needs variable with write access
```

Error correction:

```
Example:
I_r REF= i;
```

Compiler error C0142

Message: A local variable named '<variable name>' is already defined in '<pou name>'

Possible error cause: The same variable name is used two times.

Error correction: Use different variable names.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    i : INT;
END_VAR

--> C0142: A local variable named 'i' is already defined in 'PLC_PRG'
```

Compiler error C0143

Message: The property '<property name>' cannot be used in this context because it lacks the get accessor

Possible error cause: The property does not have Get access.

Error correction: Make sure that the property has a Get access definition.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    inst: FB;
END_VAR

i := inst.Prop;

FUNCTION_BLOCK FB
VAR
END_VAR

PROPERTY Prop : INT
Set;

--> C0143: The property 'Prop' cannot be used in this context because
it lacks the get accessor
```

Compiler error C0144

Message: Inheritance only allowed in Functionblocks, Interfaces and Structures

Possible error cause: An attempt is made to use inheritance in an object that does not permit inheritance.

Error correction: Use `EXTENDS` in function blocks, interfaces, and structures only.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : DUT_1;
END_VAR

TYPE DUT:
(
    enum_member := 0
);
END_TYPE

TYPE DUT_1 EXTENDS DUT:
(
    enum_memberX := 0
);
END_TYPE

--> C0144: Inheritance only allowed in Functionblocks, Interfaces and
Structures
```

Compiler error C0145

Message: Interfaces can only be implemented by Functionblocks

Possible error cause: An attempt is made to implement an interface outside of a function block.

Error correction: Implement interfaces only in function blocks.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

POU();

FUNCTION POU IMPLEMENTS ITF
VAR
END_VAR

--> C0145: Interfaces can only be implemented by Functionblocks
```

Compiler error C0149

Message: Variable declarations are not allowed in interfaces

Possible error cause: An attempt is made to define a variable in an interface.

Error correction: Do not define variables in interfaces.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : ITF;
END_VAR

INTERFACE ITF
VAR_INPUT
    i : INT;
END_VAR

--> C0149: Variable declarations are not allowed in interfaces
```

Compiler error C0161

Message: Border <array bound> of array is no constant value

Possible error cause: A variable is specified as an array bound.

Error correction: Use constants for the array bounds.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT := 3;
    arr1 : ARRAY[1..i] OF INT;
END_VAR

--> C0161: Border 'i' of array is no constant value
```

Error correction:

```
Example:
arr1 : ARRAY[1..3] OF INT;
```

Compiler error C0162

Message: Number <number of array values> of array initialisations is no constant value

Possible error cause: The initialization `[Wert1,AnzahlWert2(Wert2)]` works only with a constant for `AnzahlWert2`.

Error correction: Use constants only.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT := 3;
    arr1 : ARRAY[1..4] OF INT := [1,i(7)];
END_VAR

--> C0162: Number 'i' of array initialisations is no constant value
```

Error correction:

```
Example:
arr1 : ARRAY[1..4] OF INT := [1,3(7)];
```

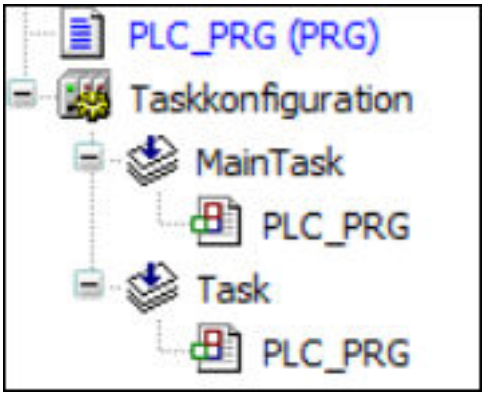
Compiler Error C0164

Message: POU <name> writes to output <name> and is called in several tasks.

Possible error cause: The device setting `codegenerator\check-multiple-task-output-write` is set and multiple tasks access the same output.

Error correction: Do not call a program that changes outputs in multiple tasks.

Example of the error:



```
PROGRAM PLC_PRG
VAR
    Output AT %QB7 : BYTE
END_VAR

Output := 0;

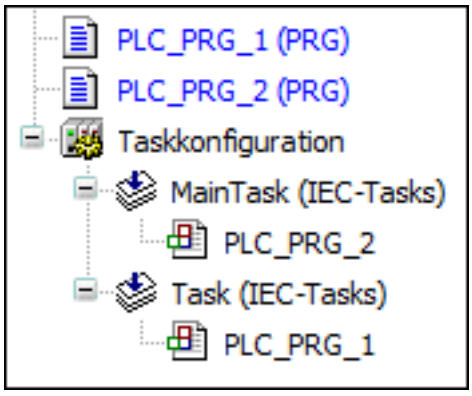
--> C0164: POU 'PLC_PRG' writes to output 'QB7' and is called in
several tasks
```

Compiler Error C0165

Message: Variable '<variable name>‘, which is mapped on address '<address>‘ is written in different tasks.

Possible error cause: The device setting `codegenerator\check-multiple-task-output-write` is set and multiple tasks access the same output.

Error correction: Write an output in one fixed task only. If multiple tasks need to calculate data for one output, then you should try to transfer this information by means of global variables to one fixed task, which then writes the data to one output.



Example of the error:

```
PROGRAM PLC_PRG_1
VAR
    Output AT %QB7 : BYTE;
END_VAR
Output := 0;

PROGRAM PLC_PRG_2
VAR
    Output AT %QB7 : BYTE;
END_VAR
Output := 1;

--> C0165: Variable 'Output', which is mapped on address 'QB7' is
written in different tasks.
```

Compiler error C0168

Message: 'VAR_CONFIG' declaration only allowed in VAR_CONFIG - list

Possible error cause: 'VAR_CONFIG' is used outside of a VAR_CONFIG list.

Error correction: Use 'VAR_CONFIG' only in VAR_CONFIG lists.

Example of the error:

```
PROGRAM PLC_PRG
VAR_CONFIG
    i : INT;
END_VAR

--> C0168: 'VAR_CONFIG' declaration only allowed in VAR_CONFIG - list
```

Compiler error C0169

Message: 'VAR_GLOBAL' declaration only allowed in Global variable list

Possible error cause: 'VAR_GLOBAL' is used outside of global variable lists.

Error correction: Use 'VAR_GLOBAL' in global variable lists only.

Example of the error:

```
PROGRAM PLC_PRG
VAR_GLOBAL
    i : INT;
END_VAR

--> C0169: 'VAR_GLOBAL' declaration only allowed in Global variable
list
```

Compiler Error C0173

Message: '<keyword>' not allowed in this place

Possible error cause: A declaration keyword (example: `VAR_INPUT`, `VAR_OUTPUT`, or `VAR`) is not allowed at this location.

Error correction: Correct the declaration: Inputs and outputs are not useful or necessary in type definitions or global variable lists.

```
TYPE DUT :
STRUCT
    member : INT;
END_STRUCT
END_TYPE
```

Example of the error:

```
TYPE DUT :
STRUCT
    VAR_INPUT
        member : INT;
    END_VAR
END_STRUCT
END_TYPE

--> C0173: 'VAR_INPUT' not allowed in this place.
```

Error correction

```
Example:
TYPE DUT :
STRUCT
    member : INT;
END_STRUCT
END_TYPE
```

Compiler error C0174

Message: 'VAR_TEMP' declaration not allowed in this place

Possible error cause: 'VAR_TEMP' is used outside of a program or function block.

Error correction: Use 'VAR_TEMP' inside of programs and function blocks only.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

FUN();

FUNCTION FUN
VAR_TEMP
END_VAR

--> C0174: 'VAR_TEMP' declaration not allowed in this place
```

Compiler error C0175

Message: 'RETAIN' or 'PERSISTENT' not allowed in this place

Possible error cause: 'RETAIN' or 'PERSISTENT' is used in a function.

Error correction: Use 'RETAIN' or 'PERSISTENT' at the intended locations.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

POU_1();

FUNCTION POU_1
VAR RETAIN
END_VAR

--> C0175: 'RETAIN' or 'PERSISTENT' not allowed in this place
```

- *Chapter 1.4.1.19.2.13 “Retain Variable - RETAIN” on page 537*

Compiler error C0177

Message: '<object>' is of type 'type' and cannot be instantiated

Possible error cause: An attempt is made to instantiate a function.

Error correction: Instantiate only objects that can be instantiated.

Example of the error:

```
PROGRAM PLC_PRG
VAR
     inst : POU;
END_VAR

FUNCTION POU
VAR
END_VAR

--> C0177: 'POU' is of type 'FUNCTION' and cannot be instantiated
```

Compiler error C0178

Message: No external access to 'VAR_IN_OUT' parameter '<parameter name>' of '<object name>'

Possible error cause: An attempt is made to remotely access a 'VAR_IN_OUT' parameter.

Error correction: Do not remotely access 'VAR_IN_OUT' parameters.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : FB;
    i : INT;
END_VAR
i := inst.in_out;

FUNCTION_BLOCK FB
VAR_IN_OUT
    in_out : INT;
END_VAR

--> C0178: No external access to 'VAR_IN_OUT' parameter 'in_out' of
'FB'
```

Compiler Error C0179

Message: '<identifier>' is no output of 'Function block'

Possible error cause: The initialization of a function block instance must not contain `VAR_IN_OUT` variables.

Error correction: Use `VAR_IN_OUT` variables in function block calls only. When initializing a function block instance, only assign the inputs of a function block.

Example of the error:

```
Example:
FUNCTION_BLOCK MyFB
VAR_IN_OUT
    inOut : INT;
END_VAR

PROGRAM PLC_PRG
VAR
    iValue : INT;
    fb : MyFB := (inOut := iValue);
END_VAR

--> C0179: 'inOut' is no output of 'MyFB'
```

Compiler Error C0180

Message: Ambiguous namespace '<library 1>' defined by library '<library 2>'

Possible error cause: The namespace of the library <library 1> is not unique. It is already used for <library 2>.

Error correction: Change the namespace of the library accordingly (*"Properties"* button in the Library Manager).

Example of the error:

```
--> C0180: Ambiguous namespace 'STANDARD' defined by library
'Standard, 3.5.15.0 (System)'
```

Compiler error C0182

Message: Return type is only possible for POUs of Type FUNCTION and METHOD

Possible error cause: An attempt is made to define a return value in a program.

Error correction: Define a return value only in methods and functions.

Example of the error:

```
PROGRAM PLC_PRG : BOOL
VAR
END_VAR

--> C0182: Return type is only possible for POUs of Type FUNCTION and
METHOD
```

Compiler Error C0183

Message: Global scope operation '.' is not valid on expression '<expression>'

Possible error cause: The '.' operator is used to access a global variable. However, at this location it is not followed by a valid IEC identifier, but for example a character such as ";" or a reserved identifier such as `FUNCTION`, or an operator such as `TO_STRING`.

Error correction: Use a valid IEC identifier for a global variable.

Example of the error:

```
PROGRAM PLC_PRG
...

iVar := .FUNCTION;// ERROR: C0183 because ; is not a valid identifier
strVar := .TO_STRING;
-->  C0183: Global scope operation '.' is not valid on expression
'<expression>'
```

Error correction

```
Example: globalValue is declared in a GVL.
PROGRAM PLC_PRG
iVar := .globalValue;
```

Compiler error C0185

Message: It is not possible to perform component access '.', index access '[]' or call '()' on result of function call. Assign result to help variable first.

Possible error cause: Component or index access to the result of a function call is performed.

Error correction: Assign the result to a variable in order to access.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    it : ITF;
END_VAR

POU_1()[0].METH1();

FUNCTION POU_1 : ARRAY[0..0] OF ITF

INTERFACE ITF

METHOD METH1

--> C0185: It is not possible to perform component access '.', index
access '[]' or call '()' on result of function call. Assign result to
help variable first.
```

Compiler Error C0186

Message: It is not possible to compare interface that is return value of call. Assign to variable first.

Possible error cause: A comparison operation is applied to an interface that is returned by a function.

Error correction: First assign the result of the function call to a variable and then compare the value of the variable. This will also reduce the number of function calls that are required.

Example of the error:

```
INTERFACE MyInterface

FUNCTION GetInterface : MyInterface

PROGRAM PLC_PRG
IF GetInterface() <> 0 THEN
    // ...
END_IF

--> C0186: It is not possible to compare interface that is return
value of call. Assign to variable first.
```

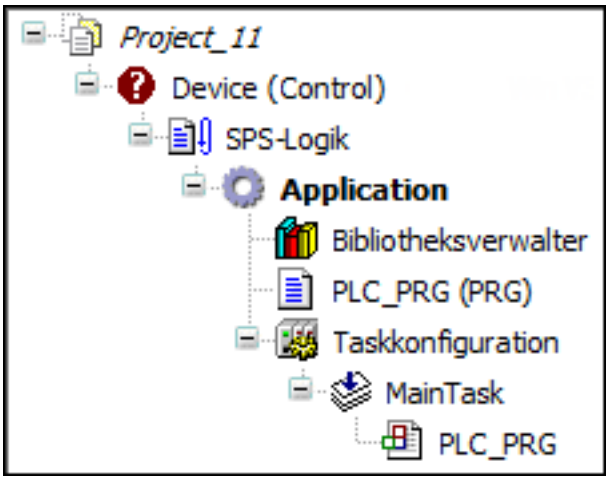
Error correction:

```
Example:
PROGRAM PLC_PRG
VAR_TEMP
    tempInterface : MyInterface;
END_VAR
tempInterface := GetInterface();
IF tempInterface <> 0 THEN
    // ...
END_IF
```

Compiler Error C0188

Message: Device not installed to the system. No code generation possible.

Possible error cause: The desired device is not installed.



Error correction: Install the missing device in the device repository, or replace the existing device already inserted in the device tree with another existing device (*"Update Device"*).

Compiler error C0189

Message: ';' expected instead of '<token>'

Possible error cause: Syntax error

Error correction: Make sure that the syntax is correct.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    INT
END_VAR

--> C0009: Unexpected Token '<Token>' found
--> C0189: ';' expected instead of 'INT'
```

Compiler error C0190

Message: ';' expected instead of end of POU

Possible error cause: Syntax error in the POU

Error correction: Make sure that the syntax is correct.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR
i := 5

--> C0190: ';' expected instead of end of POU
```

Compiler error C0191

Message: The operator 'INDEXOF' is no longer supported. Use ADR instead. ADR on a POU-Name returns a Pointer to a Pointer to the function code.

Possible error cause: The outdated operator 'INDEXOF' is used.

Error correction: Use the operator 'ADR'.

Compiler error C0195

Message: Implicit conversion from signed Type '<data type 1>' to unsigned Type '<data type 2>' : possible change of sign

Possible error cause: A sign conflict may have been missed in the implicit conversion.

Error correction: Convert only data types with the same sign implicitly.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    b : UINT;
END_VAR

b := i;

--> C0195: Implicit conversion from signed Type 'INT' to unsigned
Type 'UINT' : possible change of sign
```

Compiler error C0196

Message: Implicit conversion from unsigned Type '<data type 1>' to signed type '<data type 2>' : possible change of sign

Possible error cause: A sign conflict may have been missed in the implicit conversion.

Error correction: Use explicit conversions.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    b : UINT;
END_VAR

i := b;

--> C0196: Implicit conversion from unsigned Type 'UINT' to signed
type 'INT' : possible change of sign
```

Compiler error C0197

Message: Implicit conversion from '<data type 1>' to '<data type 2>': possible loss of information

Possible error cause: An attempt is made to convert a variable from data type DINT or LINT to data type REAL.

Error correction: For DINT, use the data type LREAL, and when converting from LINT to LREAL make sure that the value of LINT does not exceed the capacity of LREAL.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : DINT;
    b : REAL;
END_VAR
b := i;

--> C0197: Implicit conversion from 'DINT' to 'REAL': possible loss
of information
```

Compiler error C0198

Message: String constant '<string value>' too long for destination type '<data type>'

Possible error cause: The string constant has too many characters.

Error correction: Use shorter string constants or declare larger strings.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    str : STRING(4) := '12345';
END_VAR

--> C0198: String constant '12345' too long for destination type
'STRING(4)'
```

Compiler error C0199

Message: Interface '<interface name>' must be instantiated to be accessed

Possible error cause: An attempt is made to access an interface method without the interface being instantiated.

Error correction: Instantiate the interface.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

ITF.METH();

INTERFACE ITF

METHOD METH
VAR_INPUT
END_VAR

--> C0199: Interface 'ITF' must be instantiated to be accessed
```

Error correction:

```
Example:
itest: ITF;
```

Compiler error C0201

Message: Type '<data type 1>' is not equal to type '<data type 2>' of VAR_IN_OUT 'Variable'

Possible error cause: The data type that is passed to the function as a VAR_IN_OUT parameter does not match the data type defined in it.

Error correction: Pass a variable with the correct data type.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    Inst: POU;
    b : BOOL;
END_VAR

inst(in_out := b);

FUNCTION_BLOCK POU
VAR_IN_OUT
    in_out : INT;
END_VAR

--> C0201: Type 'BOOL' is not equal to type 'INT' of VAR_IN_OUT
'Variable'
```

Compiler error C0203

Message: Only Structures and Function Blocks can contain variables of type BIT.

Possible error cause: An attempt is made to declare a variable of type BIT outside of structures and function blocks.

Error correction: Declare variables of type BIT only in structures and function blocks.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    b : BIT;
END_VAR

--> C0203: Only Structures and Function Blocks can contain variables
of type BIT.
```

Compiler error C0204

Message: Variables of type BIT must be declared within a VAR_INPUT-, VAR_OUTPUT or VAR-block

Possible error cause: An attempt is made to define a variable of type BIT or as a VAR_IN_OUT parameter.

Error correction: Define variables of type BIT only within a VAR_INPUT, VAR_OUTPUT or VAR block.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR

FUNCTION_BLOCK FB
VAR_IN_OUT
    b : BIT;
END_VAR

--> C0204: Variables of type BIT must be declared within a
VAR_INPUT-, VAR_OUTPUT or VAR-block
```

Compiler error C0205

Message: POINTER TO BIT is not allowed

Possible error cause: An attempt is made to declare a POINTER TO BIT.

Error correction: Do not declare POINTER TO BIT.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    pt : POINTER TO BIT;
END_VAR

--> C0205: POINTER TO BIT is not allowed
```

Compiler error C0206

Message: BIT is not allowed as base type of an array

Possible error cause: An attempt is made to declare a BIT array.

Error correction: Do not declare BIT arrays.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    arr : ARRAY[1..2] OF BIT;
END_VAR

--> C0206: BIT is not allowed as base type of an array
```

Compiler Error C0207

Message: There is no system definition for '<identifier>'

Possible error cause: An attempt was made to access a variable in `__SYSTEM` that does not exist.

Error correction: Check and correct the specified identifier of the respective variable.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    Value : INT;
END_VAR
Value := __SYSTEM.UnknownVariable;

--> C0207: There is no system definition for 'UnkownVariable'
```

Compiler error C0208

Message: 'MOD' is not defined for 'REAL'

Possible error cause: An attempt is made to perform a modulo operation with a variable of type `REAL`.

Error correction: Modulo operations are only possible with variables of type `ANY_INT`.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    r1 : REAL;
END_VAR
r1 := r1 MOD 2;

--> C0208: 'MOD' is not defined for 'REAL'
```

Compiler Error C0209

Message: You have defined '<number>' applications for device '<device name>'. The maximum number is '<number>'. So you will not be able to download all applications.

Possible error cause: Some devices only support a specific number of applications (device description). If a project contains more applications, then not all will be downloaded to the device.

Error correction: Remove applications from your project or use another device.

Compiler error C0211

Message: Variable declaration expected instead of <expression>

Possible error cause: Syntax error

Error correction: Make sure that the syntax is correct.

Example of the error:

```
PROGRAM PLC_PRG
VAR
   VAR

   END_VAR
END_VAR

--> C0211: Variable declaration expected instead of VAR END_VAR
```

Compiler error C0212

Message: VAR, VAR_INPUT, VAR_OUTPUT or VAR_INOUT expected instead of <expression>

Possible error cause: Syntax error

Error correction: Make sure that the syntax is correct.

Example of the error:

```
PROGRAM PLC_PRG
i : INT;

--> C0212: VAR, VAR_INPUT, VAR_OUTPUT or VAR_INOUT expected instead
of i : INT;
```

Compiler Error C0215

Message: Direct address declaration is not possible in persistent list

Possible error cause: Persistent variables are not allowed to have a direct address.

Error correction: Remove the direct address assignment in the persistent variable list.

Example of the error:

```
VAR_GLOBAL PERSISTENT RETAIN
    directAddressVar AT %QB7 : BYTE;
END_VAR

--> C0215: Direct address declaration is not possible in persistent
list.
```

Compiler error C0216

Message: Case label duplicate

Possible error cause: A CASE label is used multiple times.

Error correction: Use each CASE label only one time.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR

CASE i OF
  1: i := i+1;
  1: i := i+2;
ELSE
  i := i+10;
END_CASE;

--> C0216: Case label duplicate
```

Compiler error C0217

Message: Case label <case label> also contained in range <case range begin> .. <case range end>

Possible error cause: A CASE label is part of the range of another CASE label.

Error correction: Make sure that there is no intersecting.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR
CASE i OF
  3..5: i := i+2;
  4: i := i+2;
ELSE
  i := i+10;
END_CASE;

--> C0217: Case label 4 also contained in range 3 .. 5
```

Compiler error C0218

Message: Case label requires literal or symbolic integer constant

Possible error cause: An attempt is made to use a variable as a CASE label.

Error correction: Use only literals and symbolic integer constants.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
    a : INT := 2;
END_VAR

CASE i OF
  1: i := i+1;
  a: i := i+2;
ELSE
  i := i+10;
END_CASE;

--> C0218: Case label requires literal or symbolic integer constant
```

Compiler error C0219

Message: Case contains overlapping range <case range 1 begin> .. <case range 1 end> and <case range 2 begin> .. <case range 2 end>

Possible error cause: Two branches of CASE markers have the same elements or subsets.

Error correction: Make sure that there is no intersecting.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR
CASE i OF
  3..5: i := i+2;
  1..4: i := i+2;
ELSE
  i := i+10;
END_CASE;

--> C0219: Case contains overlapping range 1 .. 4 and 3 .. 5
```

Compiler error C0221

Message: Direct Address '<address>' malformed

Possible error cause: An address is not displayed completely.

Error correction: Make sure that the address is displayed correctly.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    xVar : BOOL;
END_VAR;
xVar := %IX0;

--> C0221: Direct Address '%IXO' malformed
```

Error correction:

```
Example:
xVar := %IX0.2;
```

Compiler error C0222

Message: Outputs can't be of type 'REFERENCE TO'

Possible error cause: An attempt is made to define `REFERNCE TO` as an output parameter.

Error correction: Do not use `REFERENCE TO` as an output parameter.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR

FUNCTION_BLOCK FB
VAR_OUTPUT
    re : REFERENCE TO INT;
END_VAR

--> C0222: Outputs can't be of type 'REFERENCE TO'
```

Compiler error C0224

Message: Call Recursion: <recursion>

Possible error cause: A function calls itself.

Error correction: Make sure that functions are not recursive.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

POU();

FUNCTION POU
VAR
END_VAR

POU();

--> C0224: Call Recursion: POU -> POU
```

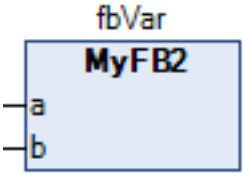
Compiler Error C0225

Message: '<name>' is not an instance of '<name>'

Possible error cause: A function block in a graphical programming language has been assigned with an explicitly specified type that does not match the declared type.

Error correction: Replace the explicit type with the one used in the declaration part, or remove the specification of the explicit type from the POU.

Example of the error:

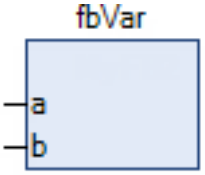


```
PROGRAM PLC_PRG
VAR
    fbVar : MyFB;
END_VAR
```

```
--> C0225: 'fbVar‘ is not an instance of 'MyFB2‘
```

Error correction:

or



Compiler error C0227

Message: Initialisation of constant variable <constant name> not constant

Possible error cause: A constant is initialized with a variable.

Error correction: Initialize constants only with constant values.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR
VAR CONSTANT
    k : INT := i;
END_VAR
```

```
--> C0227: Initialisation of constant variable 'k' not constant
```

Compiler error C0228

Message: No initial value for constant variable '<constant name>'

Possible error cause: A constant is not initialized.

Error correction: Initialize the constants.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR
VAR CONSTANT
    k : INT;
END_VAR

--> C0228: No initial value for constant variable 'k'
```

Error correction:

```
Example:
k : INT := 1;
```

Compiler Error C0230

Message: Type name '<data type>' not expected in this place

Possible error cause: The data type name of an enumeration is used at an invalid position.

Error correction: Check whether the data type name is used correctly at this location. Maybe there is a spelling error.

Example of the error:

```
TYPE MyEnum :
(
    enum_member := 0
);
END_TYPE

PROGRAM PLC_PRG
VAR
    value : INT;
END_VAR
value := MyEnum;
MyEnum := value;

--> For PLC_PRG, the error message is issued 2x:
C0230:  Type name 'MyEnum' not expected in this place
```

Error correction:

```
Example:
value := MyEnum.enum_member;
MyEnum.enum_member := value;
```

Compiler Error C0232

Message: Array initialisation expected

Possible error cause: An array of arrays is initialized, but the initialization values are not nested.

Error correction: Use a nested array initialization as shown in the example below.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    value : ARRAY[0..2] OF ARRAY[0..2]  OF INT := [1,2,3];
END_VAR

--> C0232: Array initialisation expected
```

Error correction:

```
Example:
value : ARRAY[0..2] OF ARRAY[0..2]  OF INT := [
[1,2,3],
[4,5,6],
[7,8,9]];
```

Compiler Error C0233

Message: Initialisation list for {0} <data type> expected

Possible error cause: An array of the type of a structure is initialized with elements that are not structure initializations or variables.

Error correction: As shown in the example below, use structure initializations or existing variables to initialize arrays of structures.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    values : ARRAY[0..2] OF COLOR := [1,2,3];
END_VAR

--> C0233: Initialisation list for COLOR expected
```

Error correction:

```
Example:
PROGRAM PLC_PRG
VAR
      colorVariable : COLOR := (red:=0, green:=0, blue:=255);
      value : ARRAY[0..2] OF COLOR := [
            colorVariable,
            (red:=255, green:=0, blue:=0),
            (red:=0, green:=255, blue:=0)];
END_VAR
```

Compiler error C0234

Message: First Operand of __QueryInterface must be an interface reference or the instance of a function block

Possible error cause: Incorrect operands are passed to the operator `__QueryInterface`.

Error correction: Pass an interface reference or the instance of a function block.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    a : INT;
    ITFref, ITFref2 : ITF;
    ITFref2 : ITF2;
END_VAR

__QueryInterface(a ,ITFref);
```

```
INTERFACE ITF EXTENDS __SYSTEM.IQueryInterface
INTERFACE ITF2 EXTENDS ITF

--> C0234: First Operand of __QueryInterface must be an interface
reference or the instance of a function block
```

Error correction:

```
Example:
__QueryInterface(ITFref2, ITFref);
```

Compiler error C0235

Message: Second Operand of __QueryInterface must be an interface reference

Possible error cause: Incorrect operands are passed to the operator `__QueryInterface`.

Error correction: Pass an interface reference.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    a : INT;
    ITFref, ITFref2 : ITF;
    ITFref2 : ITF2;
END_VAR

__QueryInterface(ITFref2, a);

INTERFACE ITF EXTENDS __SYSTEM.IQueryInterface
INTERFACE ITF2 EXTENDS ITF

--> C0235: Second Operand of __QueryInterface must be an interface
reference
```

Error correction:

```
Example:
__QueryInterface(ITFref2, ITFref);
```

Compiler error C0236

Message: Wrong type definition for VAR_EXTERNAL <variable name>

Possible error cause: The variable is declared in `VAR_GLOBAL` / `VAR_EXTERNAL` as different types.

Error correction: Use the same type definition in `VAR_GLOBAL` and `VAR_EXTERNAL`.

Example of the error:

```
PROGRAM PLC_PRG
VAR_EXTERNAL
    ig : STRING;
END_VAR

VAR_GLOBAL
    ig : INT;
END_VAR

--> C0236: Wrong type definition for VAR_EXTERNAL ig
```

Compiler error C0237

Message: No global definition found for VAR_EXTERNAL '<variable name>'

Possible error cause: An attempt is made to declare a variable in `VAR_EXTERNAL` which does not exist in `VAR_GLOBAL`.

Error correction: Make sure that the identifiers match.

Example of the error:

```
PROGRAM PLC_PRG
VAR_EXTERNAL
    i : INT;
END_VAR

VAR_GLOBAL
    ig : INT;
END_VAR

--> C0237: No global definition found for VAR_EXTERNAL 'i'
```

Compiler error C0238

Message: No initial value allowed for VAR_EXTERNAL <variable name>

Possible error cause: An attempt is made to initialize a variable in `VAR_EXTERNAL`.

Error correction: Do not initialize variables in `VAR_EXTERNAL`.

Example of the error:

```
PROGRAM PLC_PRG
VAR_EXTERNAL
    ig : INT := 2;
END_VAR

VAR_GLOBAL
    ig : INT;
END_VAR

--> C0238: No initial value allowed for VAR_EXTERNAL ig
```

Compiler error C0239

Message: Interface <interface name 1> does not extend <interface name 2>

Possible error cause: The used interface does not extend another interface.

Error correction: Extend the interface.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    ITFref : ITF;
    ITFref2 : ITF2;
END_VAR

__QueryInterface(ITFref2,ITFref);

INTERFACE ITF
INTERFACE ITF2 EXTENDS ITF

--> C0239: Interface ITF__Union does not extend
__System.IQueryInterface
```

Error correction:

```
Example:
INTERFACE ITF EXTENDS __System.IQueryInterface
```

Compiler error C0240

Message: First Operand of __QueryPointer must be an interface reference or the instance of a function block

Possible error cause: Incorrect operands are passed to the operator `__QueryPointer`.

Error correction: Pass an interface reference or the instance of a function block.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    a : INT;
    ITFref : ITF;
    pt : POINTER TO FB;
END_VAR

__QueryPointer(a,pt);

--> C0240: First Operand of __QueryPointer must be an interface
reference or the instance of a function block
```

Error correction:

```
Example:
__QueryPointer (ITFref, pt);
```

Compiler error C0241

Message: Second Operand of __QueryPointer must be pointer

Possible error cause: Incorrect operands are passed to the operator `__QueryPointer`.

Error correction: Pass a pointer.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    b : INT;
    ITFref : ITF;
    pt : POINTER TO FB;
END_VAR

__QueryPointer(ITFref,b);

INTERFACE ITF EXTENDS __System.IQueryInterface

--> C0241:  Second Operand of __QueryPointer must be pointer
```

Error correction:

```
Example:
__QueryPointer (ITFref, pt);
```

Compiler error C0242

Message: Operand of __DELETE must be pointer

Possible error cause: An incorrect operand is passed to the operator `__DELETE`.

Error correction: Pass a pointer.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    a : INT;
    pt : POINTER TO INT;
END_VAR

__DELETE(a);

--> C0242: Operand of __DELETE must be pointer
```

Error correction:

```
Example:
__DELETE (pt);
```

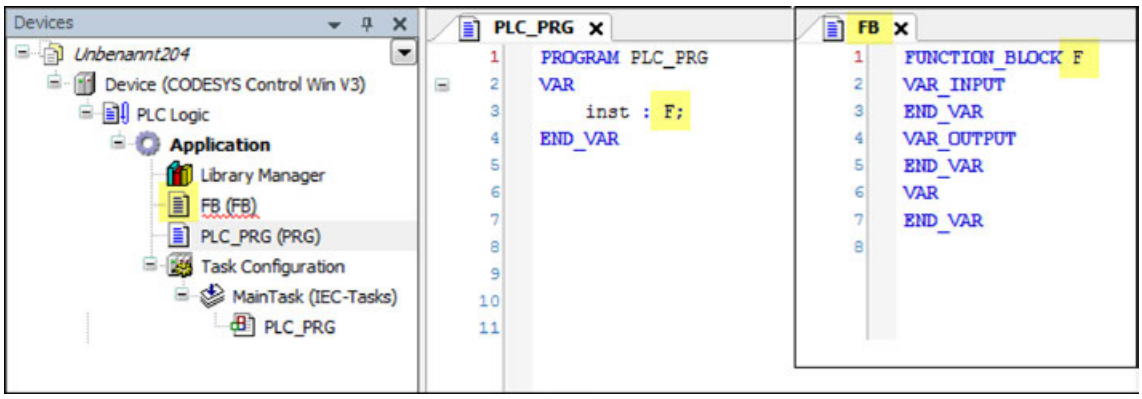
Compiler error C0243

Message: The name used in the signature is not identical to the object name

Possible error cause: The object name differs from the name used in the code.

Error correction: make sure that the names are the same.

Example of the error:



Compiler Error C0380

Message: The Operators LOWER_BOUND and UPPER_BOUND are only supported for arrays of variable length.

Possible error cause: One of the two operators LOWER_BOUND or UPPER_BOUND is not used for an array of variable length.

Error correction: Use the operators LOWER_BOUND and UPPER_BOUND only for an array of variable length.

> *For compiler version 3.5.14.0 and higher, the operators can also be used for static arrays. As a result, the error C0380 occurs only in the case of earlier compiler versions.*

Example of the error:

```
FUNCTION_BLOCK POU
VAR_IN_OUT
    arrin : ARRAY [*] OF INT;
END_VAR
VAR
    arrtest : ARRAY [0..5] OF INT;
    test1: DINT;
    test2: DINT;
```

```
END_VAR

test1 := UPPER_BOUND(arrin, 1);
test2 := UPPER_BOUND(arrtest, 1);

--> C0380: The operators LOWER_BOUND and UPPER_BOUND are supported
only for arrays with variable length.
```

Compiler error C0509

Message: Multiple assignments for operator '__New' not allowed

Possible error cause: In one line of code, the assignment operator ":=" is called a multiple number of times with the `__New` operator.

Error correction: Program the memory allocation with the `__New` operator in a separate line of code for each pointer that points to dynamically allocated memory.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    pbAlpha : POINTER TO BYTE; // Typed pointer to Alpha
    pbBeta: POINTER TO BYTE;    // Typed pointer to Beta
    xInit : BOOL := TRUE;
    xDelete : BOOL;
END_VAR

IF (xInit) THEN
    pbBeta := pbAlpha := __NEW(BYTE); // Incorrect code for memory
allocation
END_IF

pbBeta := pbAlpha := 16#01;

IF (xDelete) THEN
    __DELETE(pbAlpha); // Frees memory of pointer
END_IF

--> C0509: Multiple assignments for operator '__New' not allowed
```

Error correction:

```
PROGRAM PLC_PRG
VAR
    pbAlpha : POINTER TO BYTE; // Pointer to Alpha
    pbBeta: POINTER TO BYTE;    // Pointer to Beta
    xInit : BOOL := TRUE;
    xDelete : BOOL;
END_VAR

IF (xInit) THEN
    pbAlpha := __NEW(BYTE); // Allocates memory for Alpha
    pbBeta :=  __NEW(BYTE); // Allocates memory for Beta
END_IF

pbBeta := pbAlpha := 16#01; // Multiple assignment

IF (xDelete) THEN
    __DELETE(pbAlpha); // Frees memory of pointer
END_IF
```

Compiler error C0511

Message: The function block '<function block name>' is ABSTRACT and cannot be used as a target for an assignment.

Possible error cause: A value was assigned to an abstract function block. The concrete function blocks may have different types and therefore cannot be copied.

Error correction: In order to copy the data of the function block, concrete function blocks have to be used.

Example of the error:

```
PROGRAM PLC_PRG
VAR
refAbstract1 : REFERENCE TO AbstractPOU;
refAbstract2 : REFERENCE TO AbstractPOU;
END_VAR

refAbstract1 := refAbstract2;
--> C0511: The function block 'refAbstract1' is ABSTRACT and cannot
be used as a target for an assignment.
```

Error correction:

Use the reference assignment `REF=` to assign the reference `refAbstract1` to the same function block as `refAbstract2`.

Compiler Error C0542

Message: Inheritance is not intended for the data type "UNION" <data type name>.

Possible error cause: A structured data type (`DUT`) is derived from a `UNION` by extending with `EXTENDS`, or a `UNION` is derived from a `DUT`. This kind of derivation is not permitted. However, for reasons of compatibility only a warning is issued.

Example of the error

```
TYPE U_StringExt EXTENDS U_StringBase :
UNION
    str10 : STRING(10);
END_UNION
END_TYPE TYPE U_StringBase :
UNION
    str20 : STRING(20);
END_UNION
END_TYPE PROGRAM PLC_PRG
VAR
    uStringExt : U_StringExt;
END_VAR

uStringExt.str20 := 'a234567890b234567890'; -> C0542
```

Compiler Error C0543

Message: The name <keyword> is a reserved keyword in the IEC 1131-3 standard. An error will be issued in future versions.

Possible error cause: A reserved keyword was assigned as the name of a variable.

Error correction: Rename the variable.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    char : BYTE;
END_VAR
```

```
--> C0543: The name 'char' is a reserved keyword in the IEC 1131-3
standard. An error will be issued in future versions.
```

Note: For violations in compiled libraries, only a text message (information) will be issued instead of a warning.

The following keywords are reserved:

- CHAR
- WCHAR
- ANY_DERIVED
- ANY_ELEMENTARY
- ANY_MAGNITUDE
- ANY_SIGNED
- ANY_DURATION
- ANY_CHARS
- ANY_CHARS
- CHAR_TO
- TO_CHAR
- WCHAR_TO
- TO_WCHAR
- ATAN2
- USING
- CLASS

1.4.1.20 Reference, User Interface

1.4.1.20.1 Notifications

Notifications inform you about important information, such as available updates or security notices.

To open the *“Notifications”* view, click the icon in the upper right corner of the frame window of CODESYS. All received notifications are displayed in this view. Notifications marked as *“read”* are deleted from the list the next time CODESYS is started.

The red icon 3 indicates that new notifications are available, as well as how many.

1.4.1.20.2 Objects

Objects in CODESYS provide special functionalities to create applications. Examples: Application, program, function, Library Manager, devices, image pool. Objects are managed in tree structures in the views *“Devices”*, *“POUs”* and *“Modules”*.

You can add an object to the belonging "tree" by use of the command *“Project ➔ Add Object”*. The possible insert positions depends on the position within the tree.

Each object provides properties, which can be viewed and accessed with the command from the context menu of the object.

See also

- *Chapter 1.4.1.20.3.3.22 “Command 'Properties'” on page 1000*

Object 'Application'

Symbol:

The object is displayed as a node in the device tree. It comprises the objects which are required for a controller program to run.

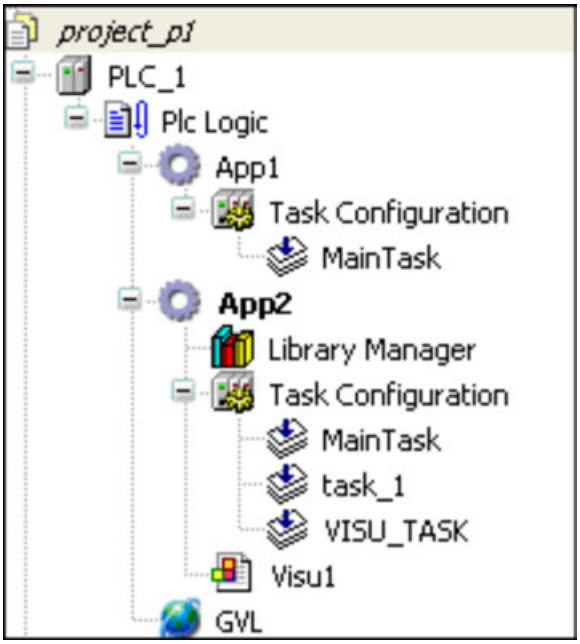
You can insert an application object below a *"PLC Logic"* node (below a programmable device) or as a child application below an existing application (parent application).

Below each application, there has to be a *"Task Configuration"* where you configure which program of the application will be called by which task and using which settings.

Furthermore, you insert the POUs of your controller program below an application, for example POUs, global variables lists, and the Library Manager. These POUs are available only for this application and its child applications.

In addition, the application can also use instances of project-global POUs. You manage project-global POUs in the *"POUs"* view. The use of these kinds of instances follows the thinking behind object-oriented programming.

Multiple applications can be inserted below a PLC device object. To do this, they have to have unique names.



NOTICE!
An online change after a changing the parent application will remove the child application from the PLC.

When multiple applications are directly below a device object, for the I/O handling of the device you have to define the application whose variables CODESYS should use for communication with the target system. The settings are configured on the *"PLC Settings"* tab of the device editor.

The application that you want to work with in online mode has to be set as the "active application" (see *"App2"* in the figure above).

You can set special properties for an application on the *"Application Build Options"* tab of the *"Properties"* dialog of the application object. Example: Activation of dynamic memory allocation.

When downloading the application to the PLC, you can include information about the application contents. This is also a setting on the *"Application Build Options"* tab. Then later you can compare the application on the controller with the active application in CODESYS.

If you want to add individual information about the author, version, and an individual short description, you can modify the information in the general *“Project Information”* on the *“Information”* tab of the *“Properties”* dialog.

When you want to log in to the target system (PLC or simulation) with an application, it will first be checked which applications are currently on the PLC and whether or not the application parameters on the controller match those in the project configuration. Corresponding messages will notify you about mismatches and possible options for further action. In this step, you can also delete applications from the PLC.

On the *“Application”* tab of the device editor, you can see which applications currently exist on the device. There you can also delete applications from the target system. It is possible that you also see additional applications which are not represented by a separate object in the device tree, for example the `<application>_symbols.app`, which contains a symbol list created for the application (see “Symbol Configuration”).

Object 'POU Locations'

This object is available only for specific controllers. It is displayed automatically in the device tree. The object cannot be added or removed manually. The object can be used for mapping the executable code of an application in different code areas on the controller. Specifically small controllers often have limited internal code areas (flash memory). If one or more additional code areas (for example, external flash memory) are available on the controller, then the location of the code POUs of an application can be changed specifically.

If there are no specific requirements, then the code POUs are stored sequentially in the code areas (*“default”*). This means that the next code POUs are stored in the next areas only when the first code area is filled. In the *“POU Locations”* editor, you will see the current location of the POUs in the memory areas and you can change them specifically.

Editor 'POU Locations'

Double-clicking the *“POU Locations”* object in the device tree of the controller opens the editor. Then it receives the entry *“<application>”*. After a code generation, all program blocks of the application are displayed with the respective object type, current location in the memory, and code size.

In the *“Configured Location”* column, you can set one of the memory areas other than the *“Current Location”* for each POU or library.

In order to move the POUs to the recently configured memory locations, you first have to *“Clean”* and then *“Generate Code”* again.

Make sure to pay attention to the messages in the category “POU Locations”. This also shows when a code POU cannot be moved as expected.

"Clean"	Deletion of the compile information for the application. Corresponds to the menu command *"Build ➔ Clean"*. Requirement for moving the POUs to the configured memory locations.
"Generate code"	Starting of the code generation for the application. Corresponds to the menu command *"Build ➔ Generate Code"*. Requirement for moving the POUs to the configured memory locations.
"Objects"	Objects of the application, including the objects from the referenced libraries
"Type"	Object type; examples: *"Function block"*, *"Method"*, *"Library"*
"Current location"	Current memory location of the POU: `area_<n>`.
"Configured location"	Configured memory location where the POU is moved at the next code generation. Possible values: ● *"default"*: Automatically assigned area. ● *"area_<n>"*: Explicitly assigned memory area (n=number)
"Code size"	Code size of the POU (in bytes)

- *Chapter 1.4.1.20.3.5.2 "Command 'Clean'" on page 1021*
- *Chapter 1.4.1.20.3.5.1 "Command 'Generate Code'" on page 1021*

Objects for Alarm Management

The help pages for alarm management are summarized in the help for CODESYS Visualization. So please see there for help on the following objects::

- Object *"Alarm Configuration"*
- Object *"Alarm Class"*
- Object *"Alarm Group"*
- Object *"Alarm Storage"*
- Object *"Remote Alarms"*

Object 'Data Source Manager'

Symbol: 

The object is used as a node for data sources below it. At least one data source has to exist. An application with the data source manager communicates with remote devices.

See also

- *Chapter 1.4.1.9.4 "Data Link with Data Sources" on page 363*

Command 'Add Object' > 'Data Source'

Function: The command opens the *"Add Data Source"* dialog.

Call

- Menu bar: *"Project"*
- Context menu in the *"Devices"* view of the CODESYSperspective
- Context menu in the *"Data Sources"* view of the *"HMI"* perspective

Requirement: The *"Data Source Manager"* object is selected that should have an additional data source.

Dialog 'Add Data Source'

"Name"	Example: `Data_Source_A`
"Select data source type"	Data source type that matches the controller configuration in order to establish communication. ● *"CODESYS Symbolic"*: Requirement: The local device is a CODESYS HMI. The data is transmitted by means of symbolic monitoring. This requires that symbols are configured in the symbol configuration of the remote PLC application. Note: As long as the symbol configuration is not impacted by an application change, you have the advantage that the application in the local device does not have to be updated. Hint: Use this communication connection unless there are no resources available in the remote PLC for a symbol configuration. ● *"CODESYS ApplicationV3"*: The data is transmitted via the CODESYS address protocol. This requires that the address information between the remote PLC and the local device match. Otherwise a connection cannot be established. Advantage: A symbol configuration is not required in the remote application. Note: For changes to the remote application, the local application has to be updated (for example, the HMI application). Hint: Use this communication for embedded or mini PLCs when there are no available resources for the symbol configuration. ● *"OPC UA Server"*: Data is transferred from an OPC UA server to the local controller via a TCP connection.
"Add"	Opens the *"Initialize Data Source - Provider settings"* dialog. The contents of the dialog depend on the selected data source type.

NOTICE!
The remote PLC should be running and the remote PLC application loaded and started.

See also

- *Chapter 1.4.1.20.2.4 "Object 'Data Source Manager'" on page 821*
- *Chapter 1.4.1.20.2.5.1 "Tab 'Variables'" on page 824*

Dialog 'Initialize Data Source Wizard - Provider settings' (for 'CODESYS Symbolic')

The settings of this dialog are described in the following chapter: Object 'Data Source' - Tab 'Communication".

The dialog is used to configure the connection initially when you have selected *"CODESYS Symbolic"* as the data source type. The communication is done by means of symbolic monitoring. The configuration can be modified later in the editor of the data source on the *"Communication"* tab.

See also

- *Chapter 1.4.1.20.2.5.3 "Tab 'Communication' via CODESYS Symbolic" on page 826*

Dialog 'Initialize Data Source Wizard - Provider settings' (for 'CODESYS ApplicationV3')

The settings of this dialog are described in the following chapter: Object 'Data Source' - Tab 'Communication".

The dialog is used to configure the connection initially when you have selected *“CODESYS ApplicationV3”* as the data source type. The communication is done by means of address monitoring.

See also

- *Chapter 1.4.1.20.2.5.4 “Tab 'Communication' via CODESYS ApplicationV3” on page 831*

Dialog 'Initialize Data Source Wizard - Provider settings' (for 'OPC UA Server')

The settings of this dialog are described in the following chapter: Object 'Data Source' - Tab 'Communication".

The dialog is used to configure the connection initially when you have selected *“OPC UA Server”* as the data source type. The communication takes place over a TCP connection.

See also

- *Chapter 1.4.1.20.2.5.5 “Tab 'Communication' via OPC UA Server” on page 834*

Dialog 'Initialize Data Source Wizard - Browse data items'

The settings of this dialog are described in the following chapter: Object 'Data Source' - Dialog 'Choose Variables'.

Function: You can select the variables for data transmission from the variables of the remote PLC. By clicking *“Finish”*, the data source is initialized and the data types and variables (data interface) are declared below the folder *“DataSources_Objects”*. You can modify the settings in the editor of the data source object.

Call: Automatic

See also

- *“Dialog 'Choose Variables'” on page 824*

Object 'Data Source'

Symbol: 

In the editor (object type *“Data Source”*), the access to the data of a remote device is managed on the *“Variables”*, *“Type Mappings”*, *“Communication”*, and *“General and Diagnosis”* tabs.

Status bar

The status bar which is always visible notifies you about the data source type and the most important communication settings. When the communication is established by means of the data source type CODESYS Symbolic, the name of the data source type, the connection type, and the network name of the remote device are displayed. When the communication is established by means of data source type CODESYS ApplicationV3 , then the name of the data source type, the location of the remote project, and the instance name of the remote application.

Example:

```
CODESYS Symbolic (CODESYS V3): PLC_Name
CODESYS ApplicationV3 (D:\Projects\Project_A): Project_A.App_A
```

See also

- *Chapter 1.4.1.9 “Working with Controller Networks” on page 352*

Tab 'Variables'

The variables for the data originating from the remote source are declared in the global variable list `<name of data source>`. The global variable list acts as a data interface to the remote PLC. The object is located below the application and below the *“DataSources_Objects”* folder.

“Update variables”	Establishes a connection to the remote device and opens the *“Choose Variables”* dialog.

“Local variable”	Variable in the local application. Contains the remote data.
“Access rights”	Access rights of the variables. The respective remote variable has the same access rights. ● : Write access. Every time the values changes, the variable is updated on the controller. ● : Read access. Every time the values changes on the controller, the variable is updated in the application. ● : Read/Write access Note: If you change the access rights, then a download is required for the change to go into effect.
“Update always”	: The controller data is updated automatically (via the data source). A variable is updated automatically if it is used in the visualization, trend, recipe, or as an alarm. Note: This is the recommended setting type. : The variable is updated in each cycle. Note: Select the option only when the variable is used exclusively in IEC code. If a variable is used in the visualization code, then it is updated automatically. Note: When an instance of a function block or a data type is updated in this way, the instance is always transferred completely.
“Create or map”	Mapping type for how the remote variable is mapped to the local variable. ● : Mapping to a specific created variable with the data type of the remote variable. The control data is mapped 1:1. That is the recommended mapping type. The variable is declared in the GVL `<name of data source>`. ● : Mapping to an existing variable. This requires that the existing variable has the same data type. ● : Mapping to a specific created variable with type-conforming data type to the remote data type: remote and local data types are not the same, but compatible. For example, a type-conforming data type can be available in a library. The variable is declared in the GVL `<name of data source>`.
“Type mapping”	Data type of the remote variable. If the variable is not a scalar type, then the type is listed on the *“Type Mappings”* tab.
“Remote variable”	Variable in the remote PLC

Dialog 'Choose Variables'

Symbol:

Function: The dialog lists the remote variables that are accessed by means of the configured connection.

Call: *“Update variables”* command on the *“Variables”* tab.

Requirement: The remote PLC is running. The control application is downloaded.

“Variables”	The remote variables are listed in the tree view. The top node is identified by the remote application name. Its variables are listed below that. Structured data is listed with all of its subordinate elements. Example: `appControl_A` ☑: The variable is selected for transferring to the local device. When the variable is structured, it is applied with all subelements. If the variables themselves are subelements, then only this subelement is applied without accepting the structure completely. Red font: When a variable is displayed in a red font, the variable is not available (anymore) in the remote PLC. Note: You can click *“Uncheck unavailable variables”* to remove the variable from the list. ☐: The variable is not selected for the transfer.
⊞	The variable has expandable elements. By clicking the symbol, the variable is extended by their elements.
“Insert the items structured”	☑: The selected variables are transferred with this structure if they are structured. ☐: The variable is transferred unstructured with a scalar data type.
“Uncheck unavailable variables”	Requirement: The link is visible when previously are no longer available in the variable available on the remote PLC. These variables are marked in red in the window above. The symbol configuration or the application presumably changed in the remote PLC. By clicking the command, the red variables are removed from the list box.

Tab 'Type Mappings'

The tab lists the non-scalar data types as they are currently available in the *“DataSources_Objects”* folder. You can edit or delete the data type declaration by selecting a data type and then the declared elements in the lower window. Moreover, you can modify the name, reset access rights, map another type, or select another remote variable.

Tab 'Type Mappings'

“Local type”	Data type in the local application
“Create or map”	• : Mapping to a new created data type. Declared in the *“DataSources_Objects”* folder. • : Mapping to an existing data type • : Mapping to a type-conforming data type. Declared in the *“DataSources_Objects”* folder.
“Mapping name”	Name of the data type
“Remote type”	Data type of the remote PLC

List with the subordinate elements of the selected data type.	
“Local variable”	Local variable name of the element of the selected data type
“Access right”	Access rights to the element

“Type mapping”	Data type of the element
“Remote variable”	Remote variable name of the element of the selected data type

[Del]	Removes the selected element

See also

- *Chapter 1.4.1.9.4.2 “Editing data source variables” on page 370*

Tab 'Communication' via CODESYS Symbolic

The tab includes the communication settings via CODESYS Symbolic for the remote data source.

When initially adding a data source, you have selected the *“CODESYS Symbolic”* data source type, and depending on that the communication settings to the data source were configured. Afterwards, the communication settings are outdated on this tab. You can only initially set the *“Data source type”* setting.

CODESYS Symbolic means that in the case of an active connection the communication is done via symbolic monitoring. This kind of symbolic access is possibly for CODESYS V2 and CODESYS V3 controller variants. In addition, the runtime system has to support the symbol configuration.

You can develop a local application offline based on the symbol information without a connection to the data source. To do this, you refer to a symbol file in the configuration settings in which all required variable information has been stored. Then no active connection is established.

Tab 'Communication' via CODESYS Symbolic

"Variable information"	Source of the variable information ● *"From connection settings"* A connection is established actively according to the communication settings specified below (*"Connection type"* and *"Connection Settings"*). The variable information is read from the remote controller application. ● *"<device name>.<application name>.symbol configuration"* The variable information is read from the symbol configuration. The symbol configuration is part of the active project and located in the device tree at the object of the remote controller below the application. An active connection is not established to the controller. ● *"From symbol file"* The variable information is read from a symbol configuration file that is stored on the development system. In the *"Choose symbol file"* field, specify this data. An active connection is not established to the controller.
"Choose symbol file"	The path of the symbol file for the *"Variable information"* selection is *"From symbol file"*. The symbol file is stored on the development system and contains the required variable information. By default, a symbol file path is created in the project directory in the following structure: `<project folder>\<project name>.<device name>.<application name>.xml`. Example: `D:\Projects\Project_A\VisualizeWithHMI.Device.Application.xml` Note: If the *"Alarm Table"* element or *"Trend"* element is used in the visualization, then the symbol file required for symbolic access and the respective project **must** both be saved in the same folder. The project contains the configuration for the alarm table element or the trend recording for the trend element. This is the default case for automatically generated symbol files. Example: `D:\Projects\Project_A\VisualizeWithHMI.project`

"Connection type"	Connection type between the remote PLC and the local device. Depending on the selected connection type, the following settings below change. Note: Whenever possible, avoid a direct connection without a gateway. ● *"CODESYS V2"* The devices exist in the same network. The V2 runtime on the remote PLC provides a communication interface. ● *"CODESYS V2 (Via gateway)"* The devices do not exist in the same network. They are connected via a V2 gateway. ● *"CODESYS V3"* The devices exist in the same network. The V3 runtime on the remote PLC provides a communication interface. ● *"CODESYS V3 (Via gateway)"* The devices do not exist in the same network. They are connected via a V3 gateway.

Connection settings for connection type 'CODESYS V2'

"PLC"	
"Driver type"	● *"Tcp/Ip (Level 2 Route)"* ● *"Tcp/Ip (Level 2)"* ● *"Tcp/Ip"*
"Address"	Example: `localhost` (for the currently used system on your computer)
"Port"	Example: `1200`
"Block size"	Example: `128` Requirement: The driver type is *"Tcp/Ip (Level 2)"*.
"Target ID"	Example: `0` Requirement: The driver type is *"Tcp/Ip (Level 2 Route)"*.
"Motorola byte order"	☑: Byte order on the PLC in big endian (Motorola format) ☐: Byte order in little endian (Intel format)

Connection settings for connection type 'CODESYS V2 (Via gateway)'

"Gateway"	The gateway settings are configured in addition to the PLC settings. Note: For this connection, a *"CoDeSys V2.3 Gateway Server"* (V2 Gateway) also has to be installed on the development computer where CODESYS V3 is running.
"IP address"	Example: `localhost`
"Port"	Example: `1217`

Connection settings for connection type 'CODESYS V3'

"PLC"	
"Name or address of device"	The setting that you make here varies according to the selection in the *"Type of name or address"* list box. For options that are derived automatically, you do not have to specify the setting here. The setting can remain empty. Example: Nothing specified for *"...(automatically derived)"* Example: `PLC_A` for *"Node name"* Example: `[ABCD]` for *"Node address"* Example: `192.168.1.5:11741` for *"IP address"* Example: `POU.dssCommVar` with data type `DatasourceSym.ConnectionSetup` for *"Dynamic from variable"* Hint: …: Opens the input to select the program variables for dynamic configuration. This variable has to be the data type `DatasourceSym.ConnectionSetup`.

"Type of name or address"	● *"Node name (automatically derived)"* ● *"Node address (automatically derived)"* ● *"IP address (automatically derived)"* ● *"Node name"* ● *"Node address"* ● *"IP address"* ● *"Dynamic from variable"*
"Dynamic from variable"	The device name or address is configured dynamically at runtime by means of an IEC variable of data type `DatasourceSym.ConnectionSetup`. The data type `DatasourceSym.ConnectionSetup` (`STRUCT`) is defined in the `Datasource Symbolic Access` library. For the configuration, the structure member `xDataValid` first has to be set to `FALSE`. If the address data has been specified, then `xDataValid` has to be set back to `TRUE`. Use case: The device name or address is not available when a project is being created. The dynamic configuration can also be used to change the settings at runtime without restarting the HMI application. Note: For this connection type, the connection is also not done dynamically via gateway.

Connection settings for connection type 'CODESYS V3 (Via gateway)'

"Gateway"	The gateway settings are configured in addition to the PLC settings.
"IP address"	Example: `localhost`
"Port"	Example: `1217`

Extending the communication settings for the PLCHandler interface

NOTICE!
It is not recommended to configure the PLCHandler manually.

The connection to the controller is established via the CODESYS PLCHandler communication interface. In this case, the configuration is performed in the PLCHandler INI format and allows for advanced parameterization.

"Advanced"	
"Used as"	● *"Don't use"* Recommended setting The *"INI content"* property as well as any specified configuration settings there are ignored. ● *"Extend the configuration by the following content"* As a rule, the configuration settings are used which are specified in the *"Connection Settings for CODESYS V3 (Via gateway)"* property. Moreover, the configuration settings are used in the *"INI content"* property. ● *"Configure completely with the following content"* The configuration settings of the *"Configuration Settings for CODESYS V3 (Via gateway)"* property are ignored. Instead, only the configuration settings are used in the *"INI content"* property.

"INI content"	Requirement: *"Used as"* is set to *"Extend the configuration by the following content"*.
	Example:
	`logfilter=16#000000FF`
	Example:
	`parameter0=EncryptCommunication`
	`value0=1`
	Note: If the parameters are generic, then they can be specified as 0-based (`parameter0` and `value0`). When extending, the numbering is automatically adjusted so that the extended parameters connect to the existing ones. The number of parameters (`parameters=<n>`) is also set to the correct value.

"INI content"	Requirement: *"Used as"* is set to *"Configure completely with the following content"*.
	Example:
	`[PLC:PLC_IdArti]`
	`interfacetype=ARTI`
	`active=1`
	`logevents=1`
	`motorola=0`
	`nologin=0`
	`timeout=10000`
	`precheckidentity=0`
	`tries=3`
	`waittime=12`
	`reconnecttime=10`
	`buffersize=0`
	`device=Tcp/Ip (Level 2 Route)`
	`instance=PLCWinNT_TCPIP_L2Route`
	`parameters=4`
	`parameter0=Address`
	`value0=localhost`
	`parameter1=Port`
	`value1=1200`
	`parameter2=TargetId`
	`value2=0`
	`parameter3=Motorola byteorder`
	`value3=No`

Communication settings for controllers with visualization user management

"Login Configuration"	If a visualization user management is configured on the remote device, then valid credentials are required at login.
"Type"	Defines how the visualization user management gets credentials ● *"Login using the following credentials"* The credentials are hard-coded into the *"User name"* and *"Password"* settings. They are used each time a connection is attempted. ● *"Login using the credentials determined at runtime"* At runtime, a dialog opens and prompts the user to specify a user name and password. Hard-coded credentials, which have nonetheless been specified in *"User name"* and *"Password"*, are ignored.

“User name”	Example: `max.smith`
“Password”	Example: •••

- *Chapter 1.4.1.20.2.4 “Object 'Data Source Manager'” on page 821*

Tab 'Communication' via CODESYS ApplicationV3

The tab includes the communication settings for a remote data source.

When initially adding a data source, you have selected the CODESYS ApplicationV3 data source type, and depending on that the communication settings to the data source were configured. Afterwards, the communication settings are outdated on this tab. You can only initially set the *“Data source type”* and *“Select the project type”* settings.

CODESYS ApplicationV3 means that in the case of an active connection the communication is done via address monitoring. In this case, the remote PLC is configured by directly specifying the device address or automatically via network scan.

Tab 'Communication' via CODESYS ApplicationV3

“Select the project type”	The project type indicates where the controller is configured: in the same project as the HMI application or in a separate project. ● *“Current project”* The control application is part of the currently open project. The communication settings can be updated automatically or manually. ● *“Other Project”* The control application is part of a separate project whose location is specified in *“Choose file”*. The communication settings are done manually. In the initial setting of the data source object, this option is fixed and influences which settings are available for *“Target device”*.
“Choose file”	Name and path of the project that contains the control application (source project) Example: `D:\PLCs\PLC_A.project` Requirement: The *“Select the project type”* is *“Other Project”*.
Window area for controllers of the project	Controllers and their subordinate applications, read from the selected project Example: 
Settings for 'Select the project type' == 'Current project'

"Target device"	Note: The following settings are available when *"Select the project type"* is set to *"Current project"*.
"Automatic configuration"	: The configuration is read automatically from the source project. This is the recommended setting. Example: *"[DEVICE_A]"* Example: *"[undetermined]"*: No configuration can be read. Note: Make sure that the application is running on the controller and the network path is active. The communication settings of the controller are applied only then. These are the communication settings that were configured in the source project in the device editor on the *"Communication Settings"* tab.
"Manual configuration"	: More configuration settings are displayed. See "Manual configuration" below.

Settings for 'Select the project type' == 'Other Project'

The communication setting is done only manually.

See "Manual configuration" below.

Manual configuration

"Dynamic from variable"	: The communication parameters are configured at application runtime by means of an IEC variable of data type `DatasourceAppV3.ConnectionSetup`. ...: Opens the input for selecting the IEC variables for a dynamic configuration. The data type `DatasourceAppV3.ConnectionSetup` (`STRUCT`) is defined in the `Datasource ApplicationV3 Access` library. For the configuration, the structure member `xDataValid` first has to be set to `FALSE`. If the address data has been specified, then `xDataValid` has to be set back to `TRUE`. Use case: The communication parameters are not available yet when a project is being created.
"Use device address"	: The communication is done via the address specified here. Example: `0101` Hint: Click *"From device"* for an automatic address setting.
"From device"	The data of the currently connected data source device is read automatically and specified in *"Use device address"*. The address corresponds to the setting of the device in the device editor in *"Communication Settings"*.
"Search for the target device using the network scan"	: The data source manager starts the network scan for devices in the network. The scan is successfully when controllers are found whose communication settings match the selected search criteria. The result is displayed in the input fields.
"Node name"	: Search for the specified node name Example: `WST06`
"Target type"	: Search for the specified target type Example. `4096`
"Target ID"	: Search for the specified target ID Example: `0000 0001`
"Target version"	: Search for the specified target version Example: `1.0.0.0`

"Network location"	● *"Direct child of the data sources PLC"*: The scanned remote PLC has an address that is running with the address of the local controller (of the data source manager). Example: Data sources PLC: `0000.0001`; remote source PLC: `0000.0001.0001` ● *"Direct child of node with address"*: Specify the address of the parent node ● *"Direct child of the data source PLC or of the node with address"*: Combination of both options above.
"Search type"	● *"First found device"*: The first controller in the device tree is selected that fulfills the specified criteria. ● *"Exactly found device"*: The controller is selected that fulfills the specified criteria exactly. Note: The data source manager waits until the network scan is complete. This usually takes about 10 seconds.

Communication settings for controllers with visualization user management

"Login Configuration"	If a visualization user management is configured on the remote device, then valid credentials are required at login.
"Type"	Defines how the visualization user management gets credentials ● *"Login using the following credentials"* The credentials are hard-coded into the *"User name"* and *"Password"* settings. They are used each time a connection is attempted. ● *"Login using the credentials determined at runtime"* At runtime, a dialog opens and prompts the user to specify a user name and password. Hard-coded credentials, which have nonetheless been specified in *"User name"* and *"Password"*, are ignored.
"User name"	Example: `max.smith`
"Password"	Example: ●●●

Specific settings of the communication buffer

"Advanced"	☑: The subsequent settings are changed.
"Default communication buffer size"	Default setting: `50000`

Tab 'Communication' via OPC UA Server

“Server URI”	URI of the OPC UA Server Editable
“Information Model Source ” The information model defines how the data is structured and organized on the OPC UA Server.	
“ Online”	The client connects to the server and detects the existing variables and types. Requirement: There exists an unencrypted connection to the server.
“Offline”	The client reads the variables and types from the information model. A connection to the server is not required. The list box includes the OPC UA information models which are installed in the *“OPC UA Information Model Repository”*.
“Security”	
“Messages Security Mode”	Type of encryption ● *“None”*: No encryption and no signing Note: if you select this option, there can be no guarantee who receives the data. Therefore, *“None”* should be used exclusively in closed networks. ● *“Sign and Encrypt”*: The transferred data will be signed and encrypted. Signing makes sure that the data is not manipulated and the receiver is correct. ● *“Sign”*: The transferred data will be signed. Signing and encryption work only for certificates.
“Security Policy”	List box for the encryption method to be used: ● Basic256sha256 Requirement: Either *“Sign and Encrypt”* or *“Sign”* was selected for *“Messages Security Mode”*.

- ↳ *Chapter 1.4.1.20.2.4 “Object 'Data Source Manager'” on page 821*

Tab 'General and Diagnosis'

The *“General and Diagnosis”* tab provides information about the status of the data source communication.

“Update Configuration”	
“Update rate (ms)”	Example: `200`

“Connection Information”	
“Connection status”	Example: `online`
“Error information”	Example: `OK`

See also

- ↳ *Chapter 1.4.1.9.4.4 “ Updating data interfaces” on page 373*

Object 'DUT'

Symbol:

- for a DUT without text list support
- for an enumeration data type with text list support

A DUT (Data Unit Type) declares a user-specific data type.

You can add this kind of object below the application or in the *“POUs”* view. When the object is created, the *“Add DUT”* dialog opens. There you select among the *“Structure”*, *“Enumeration”*, *“Alias”*, or *“Union”* data types.

Moreover, enumerations can have a text list stored to localize the enumeration values. Then the object also has a localization view.

Syntax

```
TYPE <identifier> : <data type declaration with optional
initialization>
END_TYPE
```

How the data type declaration has to be done syntactically depends in detail on the selected data type.

Examples

Declaration of a structure

```
TYPE S_POLYGONLINE :
STRUCT
    aiStart : ARRAY[1..2] OF INT := [-99, -99];
    aiPoint1 : ARRAY[1..2] OF INT;
    aiPoint2 : ARRAY[1..2] OF INT;
    aiPoint3 : ARRAY[1..2] OF INT;
    aiPoint4 : ARRAY[1..2] OF INT;
    aiEnd : ARRAY[1..2] OF INT := [99, 99];
END_STRUCT
END_TYPE
```

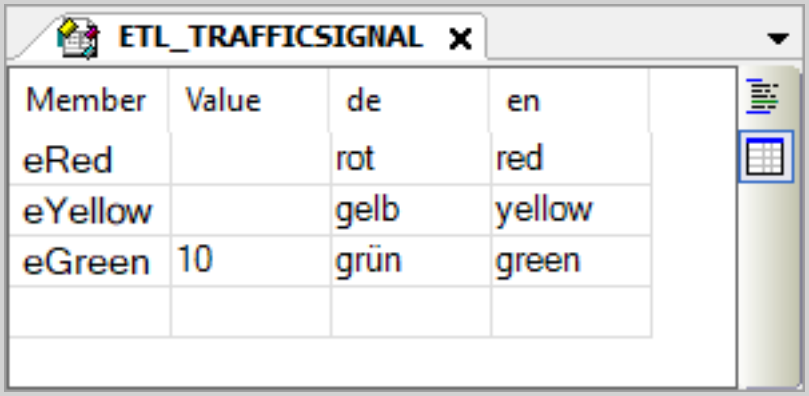
Extension of a structure

```
TYPE S_PENTAGON EXTENDS S_POLYGONLINE :
STRUCT
    aiPoint5     : ARRAY[1..2] OF INT;
END_STRUCT
END_TYPE
```

Declaration of an enumeration

```
{attribute 'qualified_only'}
{attribute 'strict'}
TYPE E_TRAFFICSIGNAL :
(
    eRed,
    eYellow,
    eGreen := 10
);
END_TYPE
```

Enumeration with text list support in the localization view



The *"Textual View"* and *"Localization View"* buttons are located on the right edge of the editor. Click the buttons to toggle between the views.

Declaration of an alias

```
TYPE A_MESSAGE : STRING[50];
END_TYPE
```

Declaration of a union of components with different data types

```
TYPE U_DATA :
UNION
    lrA : LREAL;
    liA : LINT;
    dwA : DWORD;
END_UNION
END_TYPE
```

Dialog 'Add DUT'

Function: The dialog is used to configure a new DUT (Data Unit Type).

Call: Menu bar: *"Project ➔ Add Object ➔ DUT"*; context menu of the application object.

“Name”	Name of the new DUT data type Example: `S_POLYGONLINE`

Table 46: “Type”

“Structure”	Creates an object which declares a structure that combines multiple variables with different data types into a logical unit. The variables declared within the structure are called members. Example: `S_POLYGONLINE`
“Extends”	☑: Extends an existing structure by more members. In the input field, specify an existing structure. The members of the existing structure are automatically available in the new structure. Example: `S_PENTAGON`
“Enumeration”	Creates an object which declares an enumeration that combines multiple integer constants into a logical unit. The constants declared within an enumeration are also called enumeration values. Example: `E_TRAFFICSIGNAL`
“Add Text List Support”	☐: Enumeration that does not have any text list support ☑: Enumeration with additionally stored text list for the enumeration values. The text list allows you to localize the names of the enumeration values. Example: `ETL_TRAFFICSIGNAL` Note: In the case of an existing enumeration type, text list support can be added or removed at any time. As a result, the *“Add Text List Support”* and *“Remove Text List Support”* commands are provided in the context menu of the object. Hint: The localized texts can be displayed, for example, in a visualization. In this case, the text output of a visualization element displays the symbolic enumeration values in the current language instead of the numeric enumeration values. When an enumeration with text list support is specified in the *“Text variable”* property of a visualization element, it gets the additional property `< < enumeration name> >`. Example: In a visualization, you use the variable `PLC_PRG.eTrafficLight` of type `ETL_TRAFFICSIGNAL`. `ETL_TRAFFICSIGNAL` is an enumeration with text list support. Then the entry in the properties editor of the visualization element looks like this: `PLC_PRG.eTrafficLight <ETL_TRAFFICSIGNAL>`. Hint: When you edit the enumeration type in the application, a prompt opens when you close the application and asks whether the affected visualizations should be updated automatically. See also: Help for "Enumerations" with information about the declaration syntax
“Alias”	Creates an object which declares an alias with which an alternative name is declared for a base type, data type, or function block
“Union”	Creates an object which declares a union that combines multiple members with mostly different data types into a logical unit. All members have the same offset so that they are occupy the same memory. The memory requirement of a union is determined by the memory requirement of its "largest" component.
“Add”	Closes the dialog and creates the new object The object is displayed with the symbol in the device tree or in the *“POUs”* view. When a text list is also stored for the object, the symbol is displayed.

Object 'External File'

An *“External File”* is any file that you add to the project in the *“POUs”* view or *“Devices”* view. Click *“Project ➔ Add Object”* to open the *“Add External File”* dialog and define how the file belongs to the project.

An external file which was inserted in the *“POUs”* view is never downloaded to the controller.

An external file which was added in the *“Devices”* view is always downloaded to the controller when an online change or a download is performed due to an IEC code change.

When an external file is downloaded to the controller, it is not updated in the project.

Dialog 'Add External File'

“File path”	The ... button opens a dialog for selecting a file in the local file system.
“Name”	Object name for the file in CODESYS. If you do not type anything, the file will have its previous name.

Table 47: “File Handling”

“Remember the link”	The file is available in the project only as long as it exists in the defined file path.
“Remember the link and embed into project”	CODESYS saves an internal copy of the file in the project, as well as the link to the defined file path. The update option selected below applies as long as the external file exists there. Otherwise CODESYS uses the version saved in the project.
“Embed into project”	CODESYS saves only one copy of the file in the project. There is no longer a link to the external file.

Table 48: “Change Tracking”

“Reload the file automatically”	If the external file changes, then CODESYS updates the file in the project.
“Prompt whether to reload the file”	If the external file changes, then a dialog prompt opens whether CODESYS should also update the file in the project.
“ Do nothing”	The file remains unchanged in the project, even if the external file changes.

“Display File Properties”	Clicking this button opens the default *“Properties of <file name>”* dialog, which you can also open in the Windows file system by right-clicking the file.
“Open”	The file object is inserted into the device tree (*“Devices”* or *“POUs”* view) and opened in the editor for the matching file format.

- *Chapter 1.4.1.20.3.4.1 “Command ‘Add Object’” on page 1001*
- *Chapter 1.4.1.20.4.10.7 “Dialog 'Properties' - 'External file'” on page 1161*

Object 'Device' and Generic Device Editor

Symbol: 

A device object represents a type of hardware; examples: control device, fieldbus node, bus node, drive, I/O module, monitor. The arrangement of the device objects in the device tree, that is the view *“Devices”* in CODESYS, maps the hardware structure. In the device object configuration editors inter alia you connect the controller I/Os with project variables.

Use command *“Add Device”* or *“Insert Device”* to insert a device object in the device tree. Depending on the insert position CODESYS always offers the currently matching devices.

A double-click on a device object in the device tree opens the associated device editor. The editor provides generic and device-specific tabs for the device configuration.

See also

- *Chapter 1.4.1.20.2.8.1 “Generic device editor” on page 839*

Generic device editor

The generic device editor contains tabs for the configuration of a PLC device in CODESYS. Additionally there are device-specific tabs, so that the configuration editor consists of many different dialogs, depending on the device.

The editor opens after a double-click the device object in the device tree (*“Devices”* view).

You can make general settings for a device editor in the CODESYS *“Options”* in the *“Device Editor”* category. For example, you can show and hide the tabs of the generic device editor.

A device editor is given the name of the device. The following tabs of the generic device editor can be included:

- *“Communication”*: Configuration of the connection between the development system and a programmable device (PLC). Not available in the case of pure I/O devices.
- *“Applications”*: List of the applications on the controller.
- *“<device> Parameters”*: Display and configuration of device parameters.
- *“Files”*: Configuration of the file transfers between a host file system and the device.
- *“Log”*: Display of the PLC log file.
- *“PLC Settings”*: Configuration of the handling of the I/Os: which application, behavior in the stop state, updating, bus cycle options, etc.
- *“PLC Shell”*: Text-based control monitor for interrogating certain information from the controller.
- *“Users and Groups”*: User management with regard to the device at runtime.
- *“Access Rights”*: Rights for access to objects and files on the device.
- *“Symbol Rights”*: Access rights of individual user groups to symbols (symbol sets) on the device.
- *“Task List”*: Overview of all inputs and outputs, which are assigned to tasks – useful for troubleshooting.
- *“Status”*: Device-specific status and diagnostic messages.
- *“Information”*: General information about the device (name, vendor, version etc.)

See also

- *Chapter 1.4.1.7 “Configuring I/O Links” on page 213*

Tab 'Communication Settings'

On this tab of the generic device editor, you define the connection between CODESYS and the device on which your application(s) should run.

If you prefer the classic mode of display for the dialog, then select it in the CODESYS “Options” (“Device Editor” category).

You select a gateway and a target device from the list boxes. The possible selections depend on the entries in the *“Manage Gateways”* and *“Manage Favorite Devices”* dialogs (see the *“Gateway”* menu).

You can also specify the target directly with the IP address (example: "192.168.101.109"), device address (example: "[056D]"), or device name (example: "MyDevice"). After the device is entered, CODESYS searches for the device in the network of the gateway.

The option of searching by device name requires unique device names in the network.

The solid circle on the lower right corner of the gateway symbol provides information about the connection status:

- Red: CODESYS cannot establish the connection.
- Green: The connection is established.
- Black: The connection status is unknown.

Some communication protocols allow regular checking of the gateway so that the status cannot be displayed.

Clicking the solid circle of the target device starts a network scan for the device. This works only if the network is not already being scanned.

“Scan Network”	This button opens the *“Select Device”* dialog. It lists all configured gateways with the associated devices. You can select one target device from this list. If the name of the selected device is unique, then the name will be used in the connection settings. Otherwise, the unique device address is applied. For details about this dialog, see the description of the classic view below.
“Gateway ”	This menu includes the following commands: ● *“Add New Gateway”*: Opens the *“Gateway”* dialog for defining a new gateway channel. ● *“Manage Gateways”*: Opens the *“Manage Gateways”* dialog with an overview of all gateways. You can add or delete entries here or change their order. ● *“Configure Local Gateway”*: Opens the *“Gateway Configuration”* dialog. You can configure the block drivers for the local gateway.
“ Device”	This menu includes the following commands: ● *“Add Current Device to Favorites”*: Adds the currently set device to the list of favorite devices. ● *“Manage Favorite Devices”*: Opens the favorites dialog with a list of all preferred devices. In this dialog, you can add or delete entries or change their order. The top device is the default. ● *“Rename Active Device”*: Opens the *“Change Device Name”* dialog. ● *“Wink Current Device”*: Devices that support this function illuminate a flashing signal. ● *“Send Echo Service”*: CODESYS sends five echo services to the controller. These are used to test the network connection, similar to the ping function. The services are sent first without a payload and then with a payload. The scope of the payload depends on the communication buffer of the PLC. A message view opens with information about the average echo service delay and the scope of the sent payload. ● *“Store Communication Settings in Project”*: ☑: CODESYS saves the communication settings in the project for reuse on the same computer. Note: If you use the project on another computer, then you have to reset the active path. ☐: CODESYS saves the communication settings in the options of the local installation for reuse on the same computer. Note: When using CODESYS SVN, the option should be cleared in order to prevent blocking the device object. ● *“Confirmed Online Mode”*: ☑: For security reasons, CODESYS requires you to confirm the following when calling the following online commands: Force Values, Write Values, Multiple Loading, Release Force List, Single Cycle, Start, Stop. ● *“Filter Network Scans by Target ID”*: ☑: The display is limited on the devices that have the same target ID as the current device configured in the project. ● *“Encrypted Communication”*: ☑: The communication to this controller is encrypted. A certificate of the controller is required in order to log in to the controller. If the certificate is not available, then an error message opens prompting whether or not the certificate should be displayed and installed. If the *“Enforce encrypted communication”* option is selected as *“Security level”* in the *“Security Screen”* view, then the *“Encrypted Communication”* command is disabled here. ● *“Change Communication Policy”* Opens the *“Change Communication Policy”* dialog for changing the device setting for the encryption of communication.

Table 49: Dialog “Change Communication Policy”

If a new communication policy is selected in this dialog, then the configuration on the controller is changed.	
“Communication Settings”	
“Current policy”	Shows the currently selected policy for the encryption of communication
“New policy”	List box for the new policy for encryption ● *“No encryption”*: The controller does not support encrypted communication. ● *“Optional encryption”*: The controller supports encrypted and unencrypted communication. ● *“Enforced encryption”*: The controller supports encrypted communication only.
“Device User Management”	
“Current policy”	Shows the currently selected policy for user management
“New policy”	List box for the new policy for user management ● *“Optional user management”*: It is the responsibility of the user to enable user management on the device or leave the device unprotected. ● *“Enforced user management”*: The user management on the device is enabled and cannot be disabled by the user.
“Allow anonymous login”	☑: Specific registered components (for example, OPC UA) can connect to the controller without the providing any credentials. Even if anonymous access to the OPC UA is permitted, the created device user management for the controller remains active.

Communication Settings - Classic Mode

In the CODESYS options, you can activate the classic mode of the dialog (*“Tools ➔ Options”*, "Device Editor" category).

“Select the network path to the controller”	Gateway channel for the connection. Select the channel from the lower part of the view.

Table 50: "View displaying configured gateway channels and network devices"

Left side of view	Tree structure of the configured gateway channels with the connected devices in the local network:  Note: CODESYS saves these entries on the local system, not in the project. The device entries are preceded by a device symbol ( ). Entries with a target ID that are different from those currently configured in the project are displayed in gray. Click *"Scan Network"* to refresh the list. Note: If you created the first project on the local system, then the local gateway is listed as an entry in the tree by default. CODESYS starts this gateway automatically on system boot. The solid circle on the lower right corner of the gateway symbol provides information about the connection status: ● Red: CODESYS Development System cannot establish the connection. ● Green: The connection is established:  ● Black: The connection status is unknown. Note: Some communication protocols allow regular checking of the gateway so that the status cannot be displayed. Each of the device entries in the tree consists of a symbol followed by the *"Device name"*> [*"Device address"*]. On the right side of the view, you also see the *"Target ID"*, *"Target Name"*, *"Target Type, Target Vendor"*, and *"Target Version"*.
Right side of view	Information about the gateway channel of device selected on the left side of the view. When a gateway channel is selected in the left view, the following information is displayed: *"Device name"*, *"IP address"*, *"Port"*, *"Driver"* When a device is selected in the left view, the following information is displayed (depending of the device): *"Device name"*, *"Device address"*, *"Number of channels"*, *"Block driver"*, *"Serial number"*, *"Encrypted communication"*, *"Target vendor"*, *"Target ID"*, *"Target name"*, *"Target type"*,*" Target version"*.

Table 51: "Filter and sorting functions on the right side of the dialog"

"Filter"	You can reduce the displayed list of devices that have the same *"Target ID"* as the current device configured in the project.
"Sorting order"	You can sort the list by *"Name"* or *"Device Address"* in alphabetical or ascending order.

Table 52: Command buttons on the right side of the dialog

"Set Active Path"	The command sets the selected communications channel as active. Double-clicking the entry in the channel tree achieves the same result.
"Add Gateway"	The command opens the *"Gateway"* dialog where you can define a gateway that CODESYS should add to the current configuration.
"Add Device"	The command opens the *"Add Device"* dialog. Here you can manually define a device that is to be inserted under the gateway entry currently selected in the tree. Note the functionality of *"Scan Network"* as well.
"Scan Network"	The command starts a search for available devices in the local network. The configuration tree of the gateway is refreshed accordingly.

Table 53: “Commands in the context menu of the gateway tree and device tree in the dialog”

“Scan for Device by Address”	The command searches the network for devices with a unique address as given in the configuration tree. CODESYS displays the detected devices with the given address below the gateway. The search always applies to the devices below the selected gateway or below the selected entry.
“Scan for Device by Name”	The command searches the network for devices with the same name as given in the configuration tree. Capitalization is ignored. CODESYS displays the detected devices below the gateway with the given name together with its unique device address. The search always applies to the devices below the selected gateway or below the selected entry.
“Scan for Device by IP Address”	The command searches the network for devices with a unique IP address as given in the configuration tree. CODESYS displays the detected devices with the given address below the gateway together with its name. The search always applies to the devices below the selected gateway or below the selected entry.
“Send Echo Service”	CODESYS sends five echo services to the controller. These are used to test the network connection, similar to the ping function. The services are sent first without a payload and then with a payload. The scope of the payload depends on the communication buffer of the PLC. A message view opens with information about the average echo service delay and the scope of the sent payload.
“Delete Selected Device”	The command deletes the selected device from the channel tree.
“Edit Gateway”	The command opens the *“Gateway”* dialog for editing the settings for the selected gateway.
“Configure the Local Gateway”	The command opens a dialog for configuring a local gateway. This provides an alternative to manually editing the `Gateway.cfg` file.

Table 54: Options in the lower part of the dialog

“Don't store communication settings in project”	• ☑: CODESYS saves the communication settings in the options of the local installation for reuse on the same computer. Note: When using CODESYS SVN, the option should be selected in order to prevent blocking the device object. • ☐: CODESYS saves the communication settings in the project for reuse on the same computer. Note: If you use the project on another computer, then you have to reset the active path.
“Confirmed Online Mode”	☑: For security reasons, CODESYS requires you to confirm the following when calling the following online commands: *“Force Values”*, *“Write Values”*, *“Multiple Loading”*, *“Release Force List”*, *“Single Cycle”*, *“Start”*, *“Stop”*.

Tab 'Parameters'

This dialog is intended for test purposes. Its values should be changed only by experts.

The device-specific parameters are displayed in a table on this tab of the generic device editor. The device description defines which parameters you can edit in this dialog.

You can sort the entries in alphabetically ascending or descending order or in the default order by clicking the column header.

“Parameter”	Parameter name, not editable
“Type”	Data type of the parameter, not editable
“ Value”	Initially displays the default value of the parameter, directly or the corresponding symbol name. Non-editable parameters are displayed in light-gray. If the parameter is editable you can open an input field, a drop-down list or a file selection dialog with a double-click the table field and use it to change the value.
“Default value”	Default value of the parameter defined by the device description, not editable
“Unit”	Unit of measure for the value (example: "ms" for milliseconds; not editable)
“Description”	Short description of the parameter specified by the device description, not editable

Tab 'Applications'

On this tab of the generic device editor you can see which applications exist on the device. Depending on the system you can delete the applications from the device or retrieve detailed information about the application.

“Applications on the PLC”	List of the applications found via *“Refresh list”* during the last scan of the control device.
“Delete” *“Delete All”*	Deletes the application selected in the list or all listed applications on the controller Note: If a safety controller is inserted below a PLC, then this command can **permanently** interrupt the communication links of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system. The safe field devices and the other safety controller can enter the safe state as a reaction. The connection to the development system is affected only in the case of a safety controller that is connected to the main controller via a fieldbus. For more information, refer to the section "Subordinate Safety Controller".
“Details”	Opens the dialog box *“Details”*. It displays information defined for the application on the *“Information”* tab of the dialog box *“Properties”*.
“ Contents”	Requirement: The *“Download the application info”* option is activated in the *“Properties”* of the application object on the *“Application generation options”* tab. This causes information about the contents of the application to be additionally loaded to the PLC. The *“Contents”* button opens a dialog box with additional information about the differences between the latest generated code and the application code that exists on the controller. The different modules are displayed in a comparison view.
“Refresh List”	The controller is scanned for applications and the list is refreshed accordingly

You can configure the commands “Remove Application from Device” and “Remove Applications from Device” by means of the dialog box form “Tools ➔ Customize”. These commands correspond to the “Delete” and “Delete All” buttons.

Tab 'Backup and Restore'

In this tabbed page of the generic device editor, you can backup and restore the application-specific file on the PLC by saving and reading a zip archive.

Requirement: The communication settings are correct for connection to the device. The application for backup is available on the PLC.

Table 55: Menu Bar

“Backup”	This button opens a menu with the following commands: ● *“Read Backup Information from Device”*: This command searches for application-specific files from the `$PlcLogic$` directory of the PLC and lists them in a table in the lower part of the tabbed page. ● *“Create Backup File and Save to Disk”*: Requirement: The *“Read Backup Information from Device”* command was used for determining the backup-related files. These files are located in the table in the lower part of the tabbed page. This command compresses the files in the table set as *“Active”* and the `meta.info` information file into a backup zip file. The file extension is `tbf` (="Target Backup File"). ● *“Save Backup File to Device”*: Requirement: The backup file has been saved to the disk. This command saves the backup file to the `TBF` directory of the PLC.
“Restore”	This button opens a menu with the following commands: ● *“Load Backup File from Disk”*: This command opens the *“Open”* dialog box for navigating the file system for a saved backup file. The included files are listed in a table in the lower part of the tabbed page. ● *“Load Backup File from Device”*: This command generates a list of all backup files found on the PLC. Select one of these files to view its contents in a table on the tabbed page. For the restore operation, you can deactivate optional components and edit the comments. ● *“Restore on Device”*: This command is available if at least one component of the backup file that is currently loaded in the tabbed page is set to active. It prompts for restoring the application status on the device. The user interface is blocked during restore. You can cancel the operation.

Table 56: “Target Information”

“ID”	ID of the PLC (example: `0000 0001`)
“Type”	Device type (example: `4096`)
“Version”	Device version (example: `3.5.8.0`)

Table 57: “Backup Information”

“File name”	Storage path of the backup file. Clicking the symbol () opens the file system dialog box. Example: `PlcLogic$/Application/Application.crc`
“Size of active files”	(in kilobytes) Total size of the files set as active in the table (example: `206 KB (210965 bytes)`).
“Mode”	Defines the scope of the backup: *“Application”*. The application-related files are added to the archive.
“Comment”	Optional entry for comments to be saved in the `meta.info` file of the backup and reading when the files are restored.

Table 58: Table of files for backup

“Active”	: Optional files can be deactivated here for exclusion in the backup file. Required components are shown here with a green check mark (no check box).
“Component”	Affected components (example: `file system`)
“File”	Name of the component file to back up (example: `$PlcLogic$/Application/Application.app`)
“Size”	File size in bytes (example: `43280`)
“Requires STOP”	 : For components, the application must be stopped before backup and restore. A dialog prompt will open to warn you of any backup or restore conflicts.

See also

- *Chapter 1.4.1.12.9 “Backup and restore” on page 438*

Tab 'Synchronized Files'

The tab of the generic device editor lists the files that are downloaded to the PLC when the application is downloaded. For example, these are external files that were added to an application.

Implicit files, such as the source code archive file, are displayed here only if their time of download is configured for this and the *“Show implicit files for application download on the editor of a PLC”* option is activated in the CODESYS options (*“Device Editor”* category).

“Refresh”	Refreshes the view
“Download 'on-demand' files”	For internal use only.
“File Name”	Name of the file below the application, or direct name of the implicitly transferred file (example: `archive.prj`). Double-click the file name to open the file.
“Host Path”	Location or original location of the file (example: `D:\Proj1\Files`). Double-click the path to open the directory in the file explorer.
“Timing”	Time interval of the file update on the PLC (example: *“After application download/online change”*).
“Information”	Object-dependent additional information (example: *“Object: External File”*).
“Provider”	General origin type of the file (example: *“External File Objects”*, *“Source code download provider”*).

See also

- *Chapter 1.4.1.20.4.13.6 “Dialog 'Options' - 'Device Editor'” on page 1190*
- *Chapter 1.4.1.20.2.7 “Object 'External File'” on page 838*

Tab 'Files'

In this tab of the generic device editor, you can transfer files between CODESYS (host) and the PLC. If the communication settings are correct and the PLC is online, then CODESYS establishes the connection automatically to the PLC for the duration of the file transfer.

Table 59: “Host” / “Runtime”

	Access to the file system of the host with the functionalities of a standard file manager
“Location”	Current directory for the file transfer on the host side
	Opens a dialog to create a new directory in the set path
 “”	Deletes the selected files or directories
	Updates the list of files and directories there for the set location
	Copies the selected files and directories to the respective other file system from the host and runtime system If a file is not already available in the target directory, then it is created. If it is already available and not write-protected, then it is overwritten. Then a corresponding message is displayed.  corresponds to the *“Write File to Controller”* command.  corresponds to the *“Write File from Controller”* command.

By default, the “Write File to Controller” and “Write File from Controller” commands are not included in any menu. You can add it to a menu by means of the “Tools ➔ Customize” dialog, in the “Online” command category.

- *Chapter 1.4.1.14 “Copying files to/from PLC” on page 441*

Tab 'Log'

You can view the PLC log on this tab of the generic device editor. It lists the events that were recorded on the target system. This concerns the following:

- Events during the startup and shutdown of the system (components loaded, with version)
- Application download and loading of the boot application
- Custom entries
- Log entries from I/O drivers
- Log entries from data sources

The “Log” tab also opens when you click “Open Log Page”. You can configure this as a menu command in the “Customize” dialog.

Table 60: Menu bar

	Refreshes the list of log events for all runtime system component
"Components"	Filters the display of log events by the runtime system components selected in the list box Example: `CmpApp` displays all events which occur in these components, for example "`Application [ <name> ] loaded via [OnlineChange]`". *"<all components>"*: Displays the reported events of all components
	Loads the next page with newer log messages
	Loads the previous page with older log messages
	Loads the page with the newest log entries and enables automatic scrolling
	 : Indicates that there are new log messages which have not been displayed yet. Hint: This is also displayed on the status bar as *"Auto-Scroll: ON"*.
	Loads the page with oldest log messages
	Filters events with the severity *"Warning"* and notifies about how many Blue-outlined button: Warnings are displayed.
	Filters events with the severity *"Error"* and notifies about how many Blue-outlined button: Errors are displayed.
	Filters events with the severity *"Exception"* and notifies about how many Blue-outlined button: Exceptions are displayed.
	Filters events with the severity *"Information"* and notifies about how many Blue-outlined button: Information is displayed.
	Filters events with the severity *"Debug"* and notifies about how many Blue-outlined button: Debug messages are displayed.
Logger	Enables a logger for displaying its recorded events By default, the `<default logger>` defined by the system is set. For example, that is the logger `PlcLog` for a CODESYS Control Win V3 runtime system.
"UTC time"	 : Converts the times displayed below *"Timestamp"* to the local time of the development system. The conversion is based on the time zone of the operating system where the CODESYS is running. (default setting)  : Displays the original time stamp of the runtime system If you change the option, then the displayed time stamp is converted automatically.
	Exports the list contents to an xml file. You can select the file name and location.
	Imports an XML file with log messages stored in the file system . A separate window opens to display the log messages.

Table 61: Display window with log file

Tabular display of the log messages Ten thousand log messages are displayed per page.	
"Severity"	• : Warning • : Error • : Exception • : Information • : Debug message
"Time Stamp"	Date and time of the development system or of the runtime system) Example: `01/12/07 09:48`
"Description"	Description of the event Example: `PLC started`
"Component"	Runtime component where the reported event occurred

Table 62: Status bar

"Auto-Scroll"	Displays whether auto-scrolling is enabled (*"ON"*) or disabled (*"OFF"*) Hint: Click the button to enable *"Auto-Scroll"*. • *"ON"*: The log list is refreshed automatically when changes occur. • *"OFF"*: When a new log event occurs, it is displayed next to *"Off"*. Moreover, the button is decorated on the menu bar: .

Note for error checking

For exceptions with the description `*SOURCEPOSITION*`, the affected function opens in the editor by double-clicking it or by means of the "Display Source Code in Editor" command in the context menu. The cursor jumps to the line that is causing the error. You can also perform this diagnosis when you have the CODESYS project archive, including the download information files and the exported log file. When the affected function is protected, then the following message appears: "`The source code is not available for <function name>`".

If a `VendorException` is reported, then a manufacturer-specific exception error has occurred in the CODESYS runtime. Contact the PLC manufacturer for more information.

- *Chapter 1.4.1.20.2.8 "Object 'Device' and Generic Device Editor" on page 839*
- *Chapter 1.4.1.12.6 "Reading the PLC log" on page 435*
- *Chapter 1.4.1.20.4.14.1 "Dialog 'Customize' - 'Menu'" on page 1206*

Tab 'PLC Settings'

On this tab of the generic device editor you make the basic settings for the configuration of the PLC, for example the handling of inputs and outputs and the bus cycle task.

“Application for I/O handling”	Application that is responsible for the I/O handling.

Table 63: “PLC Settings”

“Update IO while in stop”	☑: CODESYS refreshes the values of the input and output channels even if the PLC is in the stop state. If the watchdog detects a malfunction, the outputs are set to the predefined default values. ☐: CODESYS does not refresh the values of the input and output channels when the PLC is in the stop state.
“Behavior for outputs in stop”	Handling of the output channels when the controller enters the stop state: ● *“Keep current values”*: The current values are retained. ● *“Set all outputs to default”*: The default values resulting from the I/O mapping are assigned. ● *“Execute program”*: You can control the handling of the output values via a program contained in the project, which CODESYS executes at "STOP". Enter the name of the program in the field on the right.
“Always update variables”	Global setting that defines whether or not CODESYS updates the I/O variables in the bus cycle task. This setting is effective for I/O variables of the slaves and modules only if 'deactivated' is defined in their update settings. ● *“Disabled (update only if used in a task)”*: CODESYS updates the I/O variables only if they are used in a task. ● *“Enabled 1 (use bus cycle task if not used in any task)”*: CODESYS updates the I/O variables in the bus cycle task if they are not used in any other task. ● *“Enabled 2 (always in bus cycle task)”*: CODESYS updates all variables in each cycle of the bus cycle task, regardless of whether they are used and whether they are mapped to an input or output channel.

Table 64: “Bus Cycle Options”

“Bus cycle task”	Task that controls the bus cycle. By default the task defined by the device description is entered. By default the bus cycle setting of the superordinate bus device (use cycle settings of the superordinate bus) applies, i.e. the device tree is scanned upwards for the next valid bus cycle task definition. Pay strict attention to the following notes!

NOTICE!
Before you select the *“<unspecified>”* setting for the bus cycle task, you should be aware that "<unspecified>" means that the default setting given in the device description goes into effects. You should therefore check this description. Use of the task with the shortest cycle time may be defined as the default there, but use of the task with the longest cycle time could equally well be defined!

NOTICE!
For fieldbuses, a fixed cycle matrix is necessary to assure a determined behavior. Therefore, do not use the type 'free-running' for a bus cycle task.

Table 65: “Additional Settings”

“Generate force variables for IO mapping ”	This setting is available only if it is supported by the device. ☑: When compiling the application CODESYS creates two global variables for each I/O channel that is mapped to a variable in the dialog *“I/O Mapping”*. You can use these variables for the forcing of the input or output value on this channel, for example via an HMI visualization.
“Enable Diagnosis for devices”	☑: CODESYS automatically integrates the library `CAA Device Diagnosis` in the project and creates an implicit function block for each device. If there is already a function block for the device, then either an extended FB is used (for example with EtherCAT) or a further FB instance is added. This then contains a general implementation of the device diagnostics. By means of the FB instances you can determine the status of all devices in the application and evaluate errors. In addition, the library contains functions for the programmatic editing of the device tree. Example: Scanning of all children of a bus system, jumping to the parent element.
“Create additional parameters”	This setting is available only if it is supported by the device. Create additional parameters.
“ Show I/O warnings as errors ”	Warnings concerning the I/O configuration are displayed as errors.

Tab 'PLC Shell'

This tab of the generic device editor includes a text-based control monitor for querying specific information from the controller. You can specify device-dependent commands for this and receive the response from the controller in a result window.

Table 66: ABB AG standard commands

Command with Possible Parameters	Description
?	List of available PLC shell commands with possible parameters and short description
`getcmdlist`	List of names of available PLC shell commands
`mem <memory address> [<size>]`	Provides a hex dump of the defined memory range. The size parameter is optional and describes the number of bytes that are output. Default value: 16 Example: `mem 16x0422139C 8`
`reflect`	Repeats the given command (for testing the connection)
`applist`	Provides a list of all loaded applications The order in the list defines the application index beginning with `0`.
`pid [<application name>| <application index>]` *	Provides the GUID (application index) of one or all loaded applications
`pinf [<application name>| <application index>]` *	Provides the contents of the following fields from the project information: title, version, author, and description. Requirement: The option *“Create POU for properties access automatically”* in the *“Project Information”* dialog is activated.

Command with Possible Parameters	Description
`startprg [<application name>|<application index>]` *	Starts the given application, or all loaded applications if no application is given
`stopprg [<application name>|<application index>]` *	Stops the given application, or all loaded applications if no application is given
`resetprg [<application name>|<application index>]` *	Resets the given application, or all loaded applications if no application is given
`resetprgcold [<application name>|<application index>]` *	Executes a cold boot of the given application, or all loaded applications if no application is given
`reload[<application name>|<application index>]` *	Loads the boot application of the given application, or the boot projects of all loaded applications if no application is given
`getprgstat [<application name>|<application index>]` *	Provides the program status of the given application, or the program status of all loaded applications if no application is given
`plcload`	Shows the processor load of the controller (in percent)
`rtsinfo`	Provides information about the runtime system, for example the processor and version of the runtime system
`channelinfo`	Provides information about the communication channel
`rtc-get`	Provides the universal time (UTC) via the `DataTime` string
`rtc-set`	Sets the universal time (UTC) via the `DataTime` string (see ISO 8601)
`listpcicards [<VendorID>]`	Provides a list of PCI adapters (all or by <VendorID>)
`gettaskgroups`	Provides a list of all task groups, their tasks, and the CPU core binding
`cert-getapplist`	Provides all registered and used certificates (ID of the component and usage).
`cert-genselfsigned [<number for search result by "cert-getapplist"> <expdays=>]`	Generates self-signed certificates The validity period of the certificate can be specified by means of `expdays=`. Default value: 365 days
`cert-gendhparams [length in bits]`	Generates the parameters for the Diffie-Hellman key exchange Caution: This operation can take several minutes to complete.
`cert-getcertlist [<trust level>]`	Lists all certificates of the specified trust level If a trust level is not given, then all certificates are listed. Possible trust levels • `untrusted`: Untrustworthy certificates • `trusted`: Trustworthy certificates • `own`: Certificate of the controller • `quarantine`: Certificates whose trust level (trusted, untrusted) cannot be determined by validation. Incoming connections were therefore denied.
`cert-createcsr [<number for search result by "cert-getapplist">]`	Generates CSR files for all applications
`cert-import <trust level> <file name.cer>`	Imports the specified certificate
`cert-export <trust level> [<number for search result by "cert-getcertlist">]`	Exports the specified certificate

Command with Possible Parameters	Description
`cert-remove <trust level> <number for search result by "cert-getcertlist" or "all">`	Removes the specified certificate
`cpuload`	Shows the processor load of the CPU (for multicore, each processor core)
`gettaskgroups`	Provides a list of defined task groups The assigned tasks are shown for each task group.
`getmulticoreinfo`	Shows whether or not multicore is supported and the number of available processor cores
`sessinfo-list`	Provides a list of all currently logged in clients/users
`sessinfo-getcnt`	Provides the number of currently logged in clients/users

* Application name: Name of the application in the device tree

Application index: Results from the list of all applications on the controller that you can call with the *"applist"* command. Index `0` stands for the first application in the list, `1` for the second, and so on.

Tab '<device name> I/O Mapping'

Devices with I/O channels

This tab is displayed in device editors for devices with I/O channels. It shows the available channels and allows for the mapping of input, output, and memory addresses of the controller to variables or entire function blocks of the application. In this way, you create the 'I/O Mapping'.

The application that is to take care of the I/O handling is defined on the *"PLC Settings"* tab.

You can use the "Online Configuration Mode" if the device supports it. In this mode, you can access the I/Os of the hardware without having to download an actual application to the device beforehand.

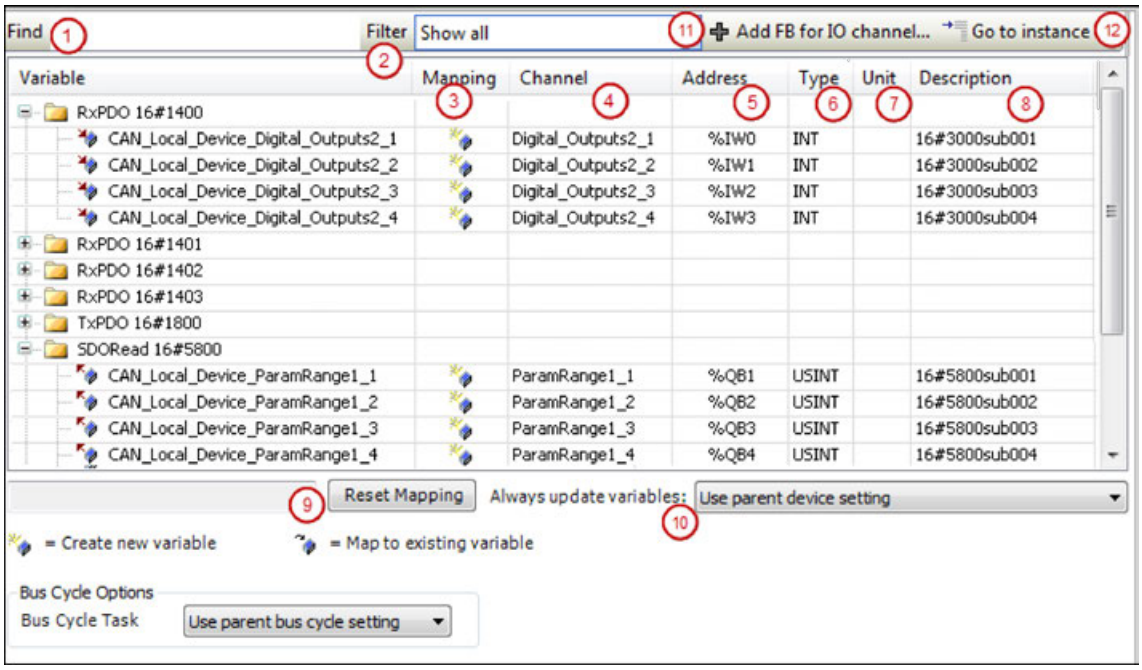
You can also create the I/O mapping in the "Edit I/O Mapping" dialog. Here you get a mapping list with search and filter functions for an entire device tree.

NOTICE!

Mapping 'too large' data types

If a variable of a data type that is larger than a byte is mapped to a byte address, the value of the variable will be truncated to byte size there. For monitoring the variable value in the *"I/O Mapping"* dialog, this means that, in the root element of the address, the value is displayed which the variable currently has in the project. The current individual bit values of the byte are displayed in succession in the bit elements below that, but this may not be sufficient for the entire variable value.

Example of the *"<device name> I/O Mapping"* tab for a CAN bus slave:



The tab contains a table for editing the I/O mapping. The information displayed for the inputs and outputs originates from the device description.

"Find" (1)	Input field for a search string for the mapping table. The search results are marked in yellow.
"Filter" (2)	List box with filters for the I/O mappings displayed in the mapping table: ● *"Show all"* ● *"Show only outputs"* ● *"Show only inputs"* ● *"Show only unmapped variables"* ● *"Show only mapped variables"* ● *"Show only mapping to existing variables"* ● *" Show only mapping to new variables"*
"Add FB for IO channel" (11)	Depending on the device, available if the channel entry is selected in the mapping table. Opens the *"Select Function Block"* dialog for selecting the function block that should be linked directly to the channel.
"Go to instance" (12)	Available if the entry is selected in the mapping table. Jumps to the corresponding entry on the *"<device name> IEC Objects"* tab.

"Variable"	Depending on the device, the inputs and outputs of the device are displayed as nodes and below them, indented, the associated channels or, depending on the device, only the implicitly created device instance. The symbol indicates the type of channel: : Input : Output Double-click the cell to open an input field. ● Option 1: The variable already exists; specify complete path: <application name>.<module name>.<variable name>; example: `app1.plc_prg.ivar`; input assistance via ... ● Option 2: The variable does not exist yet; enter a simple name; automatically created internally as a global variable. Depending on the device, inputs or outputs can be linked directly to a function block. In this case, the *"Add FB for IO channel"* button can be clicked. See above.
"Mapping" (3)	Type of mapping: ● : Existing variable ● : New variable ● : Mapping to function block instance
" Channel" (4)	Symbolic name of the channel.
"Address" (5)	Address of the channel (example: `%IW0`). Address strikethrough: Indicates that you should not assign any more variables to this address. Reason: Although the variable specified here is managed – as an existing variable –at a different memory location, ambiguity could result when the values are written, particularly with outputs. : Indicates that this address has been edited and fixed. If the arrangement of the device objects in the device tree changes, then CODESYS does not adapt this address automatically.
"Type" (6)	Data type of the channel (example: `BOOL`). Structures or bit fields defined in the device description are displayed only if they are part of the IEC standard and are identified as IEC data types in the device description. Otherwise the table cell remains empty. When mapping structured variables, the editor prevents you from specifying both the structure variable (example: `%QB0`) and individual structure elements (example: `%QB0.1` and `QB0.2`). Therefore, if there is a main entry with a subtree of bit channel entries in the mapping table, then the following applies: You can input a variable either into the line of the main entry, or into the lines of the subelements (bit channels), but not into both.
"Default value"	Default value of the parameter that applies to the channel: Appears only if the option *"Set all outputs to default"* is selected in the *"PLC Settings"* for the behavior of the outputs at stop. Note: For compiler version V3.5 SP11 and higher, the initialization value of the variables is used automatically as the default value when mapping to an existing variable. You can edit the *"Default value"* field only if you map to a new created variable or if no mapping is specified. In older versions, users had to specify explicitly that the default value and initialization value were identical.
"Unit" (7)	Unit for the parameter value (example: `ms` for milliseconds).
"Description" (8)	Short description of the parameter.
"Current value"	Actual value of the parameter applied to the channel; displayed in online mode only.

The change of the default value by an online change is allowed, however the value is applied only after a "Reset cold" or "Reset warm".

"Reset Mapping" (9)	CODESYS resets the mapping settings to the default values as defined in the device description file.
"Always update variables" (10)	Definition for the device object about updating I/O variables. The default value is defined in the device description: ● *"Use parent device setting"*: Update according to the setting of the superordinate device. ● *"Enabled 1 (use bus cycle task if not used in any task)"*: CODESYS updates the I/O variables in the bus cycle task if they are not used in any other task. ● *"Enabled 2 (always in bus cycle task)"*: CODESYS updates all variables in each cycle of the bus cycle task, regardless of whether they are used and whether they are mapped to an input or output channel.

If a UNION is represented by I/O channels in the mapping dialog, it depends on the device whether mapping to the root element is also possible.

Devices with I/O drivers

For devices with I/O drivers, you can set the bus cycle task here in the *"I/O Mapping"* tab if the general settings should not be used (*"PLC Settings"* tab).

Table 67: Bus Cycle Options

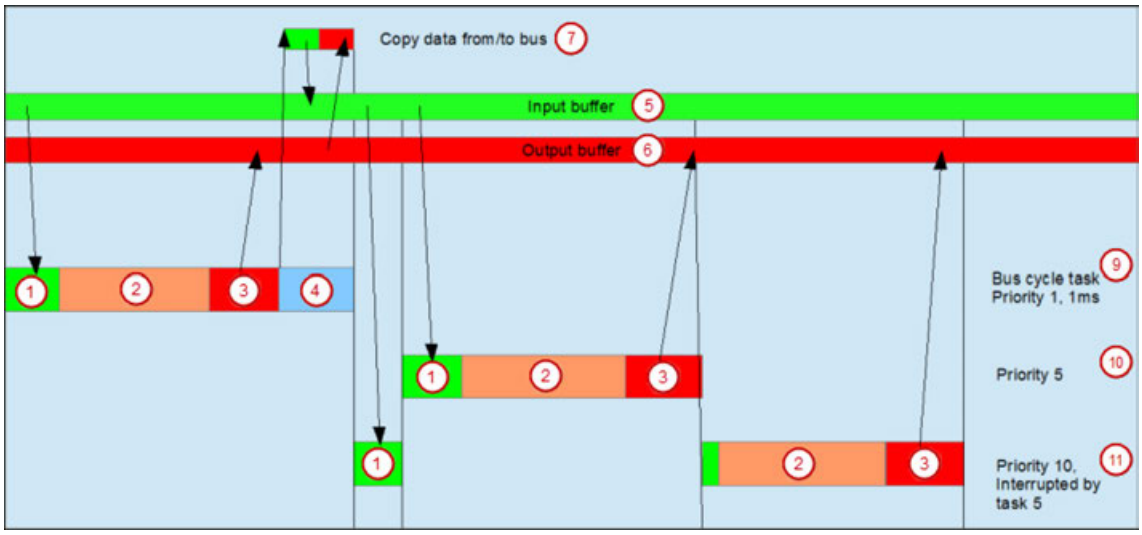
"Bus Cycle Task "	The list box provides all tasks which are defined in the task configuration of the active application (example: *"MainTask"*. In case of *"Use parent bus cycle setting"*, the settings of the parent node will be used.

General information about the bus cycle task

Generally, for each IEC task, the used input data is read at the start of each task (1) and the written output data is transferred to the I/O driver at the end of the task (3). The implementation in the I/O driver is decisive for additional transfer of the I/O data. It is responsible for the time frame and time point that the actual transfer to the corresponding bus system occurs.

The bus cycle task of the PLC can be defined globally for all fieldbuses in the PLC settings. For some fieldbuses, however, you can change this independent of the global setting. The task with the shortest cycle time is used as the bus cycle task (setting: *"unspecified"* in the PLC settings). The messages are normally sent on the bus in this task.

Other tasks copy only the I/O data from an internal buffer that is exchanged only with the physical hardware in the bus cycle task.



(1) Read inputs from input buffer (2) IEC task
(3) Write outputs to output buffer (4) Bus cycle
(5) Input buffer (6) Output buffer
(7) Copy data to/from bus
(9) Bus cycle task, priority 1, 1 ms
(10) Bus cycle task, priority 5
(11) Bus cycle task, priority 10, interrupted by task 5

Task usage

The *"Task Deployment"* tab provides an overview of used I/O channels, the set bus cycle task, and the usage of channels.

WARNING!
If an output is written in various tasks, then the status is undefined, as this can be overwritten in each case.

If the same inputs are used in various tasks, then it is possible for the input to change during the processing of a task. This happens when the task is interrupted by a task with a higher priority and causes the process image to be read again. Solution: At the beginning of the IEC task, copy the input variables to variables and then work only with the local variables in the rest of the code.

Conclusion: Using the same inputs and outputs in several tasks does not make any sense and can lead to unexpected reactions in some cases.

Tab '<device name> IEC Objects'

> **NOTICE!**
> Please note that manually creating another instance of the device object can lead to malfunctions.

In this tab of the generic device editor, "objects" are listed that allow for access to the device from the IEC application. In online mode, this is used as the monitoring view.

For devices for which a function block instance is created implicitly, at least this instance is listed as an object here in the table. This instance can be used, for example, in order to restart a bus or to query information from the application. The device type determines whether this kind of device instance is available and which access options it has. Please refer to the help for the special device configuration.

Instances of function blocks that are linked with inputs or outputs of the device are also displayed here. The mapping of a function block to a channel is defined in the *"<device name> I/O Mapping"* tab. The *"Go to Instance"* command takes you directly to the affected object from there.

In addition, you can create more objects in the table here that are not yet linked with a device channel.

In online mode, you can use the table of IEC objects as a monitoring view. It also shows the current value, the address, and the comment for the function block variable at the channel. Finally, it provides the capability of writing and forcing values.

"Add" *"Edit"*	Opens the *"Select Function Block"* dialog for creating a new instance or for editing the instance selected in the table.
"Delete"	Deletes the selected entry.
"Go to Variable"	Jumps from the selected entry directly to the corresponding mapping in the *"<device name> I/O Mapping"* tab.
"Variable"	The object name comprises the device name and the function block name. Example: `EL2004_Relay`. Changing the device name has an immediate effect. The part of the name after the device name is editable here.
"Mapping"	Mapping type, as in the *"<device name> I/O Mapping"* tab
"Type"	Data type: Here it is the name of the function block.
"Value" *"Prepared value"* *"Address "* *" Comment"*	In online mode only: Display of the current value, the address, and the comment for the variable at the channel. Moreover, the option of specifying a value for writing or forcing the variable.

Tab 'Users and Groups'

NOTICE!

Recommendations regarding data security

In order to minimize the risk of data security violations, we recommend the following organizational and technical actions for the system where your applications are running. Whenever possible, avoid exposing the PLC and control networks to open networks and the Internet. Use additional data link layers for protection, such as a VPN for teleaccess, and install firewall mechanisms. Restrict access to authorized persons only, and change any existing default passwords during the initial commissioning, and change them regularly.

On this tab of the generic device editor, you edit the device user management of the PLC.

Depending on how it is supported by the device, you can define user accounts and user groups. In combination with the configuration on the *“Access Rights”* tab, you thus control access to control objects and files at runtime.

Requirements: The controller has a user management and allows it to be edited. You have login data in order to be able to log in to the controller.

It is possible to apply user account definitions from the project user management into the device user management (see below: “Import” button).

Table 68: Toolbar of the tab

Synchronization	Switches on and off the synchronization between the editor and the user management on the device. If the button is not pressed, then the editor is blank or it contains a configuration that you loaded from the hard disk. When the button is pressed, CODESYS synchronizes the display in the editor continuously with the current user management on the connected device. When you enable the synchronization while the editor contains a user configuration that is not synchronized with the device yet, you are prompted what should happen to the editor contents. Options: ● *"Upload from the device and overwrite the editor content"*: The configuration on the device is loaded into the editor, overwriting the current contents. ● *"Download the editor content to the device and overwrite the user management there"*: The configuration in the editor is transferred to the device and applied there.
Import from disk	CAUTION: The import of a device user management by means of a `*.dum2` file completely overwrites the existing user management on the device. In order to log in to the device again afterwards, you need authentication data from the new user management. This means that you have to log in as a user from the imported user management after the import. ● When you click the button on the *"Users and Groups"* tab to import a *"Device user management file *.dum2"*, the default dialog for selecting a file opens to select a device user management file from the hard drive. After you select the file, the *"Enter Password"* dialog opens. You have to specify the password that was assigned when the file was exported. Then the user management is enabled. Note: Before V3.5 SP16, the *"Device user management files (*.dum)"* file type was used which did not require any encryption. ● When you click the button on the *"Access Rights"* tab to import a *"Device rights management file *.drm"*, the default dialog for selecting a file opens to select a corresponding file from the hard drive. The existing configuration in the dialog is overwritten by the imported file.
Export to disk	● When you click the button on the *"Users and Groups"* tab, first the *"Enter Password"* dialog opens for assigning a password to the device user management file. Note: This password has to be repeated later when this file is imported to enable this user management on the controller. After the password assignment dialog is closed, the default dialog for selecting and importing a user management configuration from the hard disk opens. In this case, the file type is *"Device user management files (*.dum2)"*. Note: Before V3.5 SP16, the *"Device user management files (*.dum)"* file type was used which did not require any encryption. ● When you click the button on the *"Access Rights"* tab, the file type is *"Device rights management files (*.drm)"*. In this case, a password does not have to be assigned for the file before saving.
"Device user"	User name of the user currently logged in on the device

Table 69: "User"

All currently defined users, and below them their memberships of user groups, are listed in a tree structure.	
"Add"	Opens the *"Add User"* dialog for creating a new user account.
"Import"	Opens the *"Import User"* dialog. It displays all the user accounts defined in the project user management. Select the desired entries and click *"OK"* in order to import them into the device user management. CAUTION: The passwords are NOT applied.

“Edit”	Opens the *“Edit User <user name>”* dialog. It corresponds to the *“Add User”* dialog and you can change the settings of the user account.
“Delete”	Deletes the account of the currently selected user.

Table 70: “Groups”

All currently defined groups, and below them the users assigned to them, are listed in a tree structure.	
“Add”	Opens the *“Add Group”* dialog. Define a new group name. From the list of defined users, select those that are to belong to the group. Click *“OK”* to confirm the selection. The group is displayed in the tree.
“Import”	Opens the *“Import User”* dialog. It displays all the user groups defined in the project user management. Select the desired entries and click *“OK”* in order to import them into the device user management.
“Edit”	Opens the *“Edit Group <group name>”* dialog. It corresponds to the *“Add Group”* dialog where you can change the group definition.
“Delete”	Deletes the currently selected group.

Table 71: “Add Dialog 'Add User'”

“Name”	Name of the new user
“Default group”	List box with all configured user groups. Every user has to belong to at least one group. You define this here as a default group.
“ Password”	
“Confirm password”	
“Password strength”	Password security in a range from *“Very weak”* to *“Very good”*.
“Hide password”	☑: The password is shown only with asterisks **"*"** when it is typed in.
“Password can be changed by the user”	
“Password must be changed at first login”

Tab 'Access Rights'

NOTICE!

Recommendations regarding data security

In order to minimize the risk of data security violations, we recommend the following organizational and technical actions for the system where your applications are running. Whenever possible, avoid exposing the PLC and control networks to open networks and the Internet. Use additional data link layers for protection, such as a VPN for teleaccess, and install firewall mechanisms. Restrict access to authorized persons only, and change any existing default passwords during the initial commissioning, and change them regularly.

NOTICE!

Detailed information on the concept and use of device user management is provided in "Handling of Device User Management".

There you will also find the following instructions on how to use the editor:

- First-time login to the controller for editing and viewing its user management
- Setting up a new user in the user management of the controller
- Changing of access rights to controller objects in the user management of the controller
- Loading user management from a *.dum file, modifying it, and downloading it to the controller in offline mode

On this tab of the device editor, you define the device access rights of device users to objects on the controller. As in the project user management, users must be members of at least one user group and only user groups can be granted certain access rights.

Requirements for the *“Access Rights”* tab to be displayed:

- In the CODESYS options, in the *“Device Editor”* category, the *“Show access rights page”* option has to be selected.
  Note that this CODESYS option can be overwritten by the device description.

Requirements for the access rights to be granted to user groups

- A component for the user management has to be available on the controller. That is the primary requirement.
- Users and user groups have to be configured on the *“Users and Groups”* tab.

Table 72: Toolbar of the tab

Synchronization	Switches on and off the synchronization between the editor and the user management on the device. If the button is not pressed, then the editor is blank or it contains a configuration that you loaded from the hard disk. When the button is pressed, CODESYS synchronizes the display in the editor continuously with the current user management on the connected device. When you enable the synchronization while the editor contains a user configuration that is not synchronized with the device yet, you are prompted what should happen to the editor contents. Options: ● *"Upload from the device and overwrite the editor content"*: The configuration on the device is loaded into the editor, overwriting the current contents. ● *"Download the editor content to the device and overwrite the user management there"*: The configuration in the editor is transferred to the device and applied there.
Import from disk	CAUTION: The import of a device user management by means of a `*.dum2` file completely overwrites the existing user management on the device. In order to log in to the device again afterwards, you need authentication data from the new user management. This means that you have to log in as a user from the imported user management after the import. ● When you click the button on the *"Users and Groups"* tab to import a *"Device user management file *.dum2"*, the default dialog for selecting a file opens to select a device user management file from the hard drive. After you select the file, the *"Enter Password"* dialog opens. You have to specify the password that was assigned when the file was exported. Then the user management is enabled. Note: Before V3.5 SP16, the *"Device user management files (*.dum)"* file type was used which did not require any encryption. ● When you click the button on the *"Access Rights"* tab to import a *"Device rights management file *.drm"*, the default dialog for selecting a file opens to select a corresponding file from the hard drive. The existing configuration in the dialog is overwritten by the imported file.
Export to disk	● When you click the button on the *"Users and Groups"* tab, first the *"Enter Password"* dialog opens for assigning a password to the device user management file. Note: This password has to be repeated later when this file is imported to enable this user management on the controller. After the password assignment dialog is closed, the default dialog for selecting and importing a user management configuration from the hard disk opens. In this case, the file type is *"Device user management files (*.dum2)"*. Note: Before V3.5 SP16, the *"Device user management files (*.dum)"* file type was used which did not require any encryption. ● When you click the button on the *"Access Rights"* tab, the file type is *"Device rights management files (*.drm)"*. In this case, a password does not have to be assigned for the file before saving.
"Device user"	User name of the user currently logged in on the device

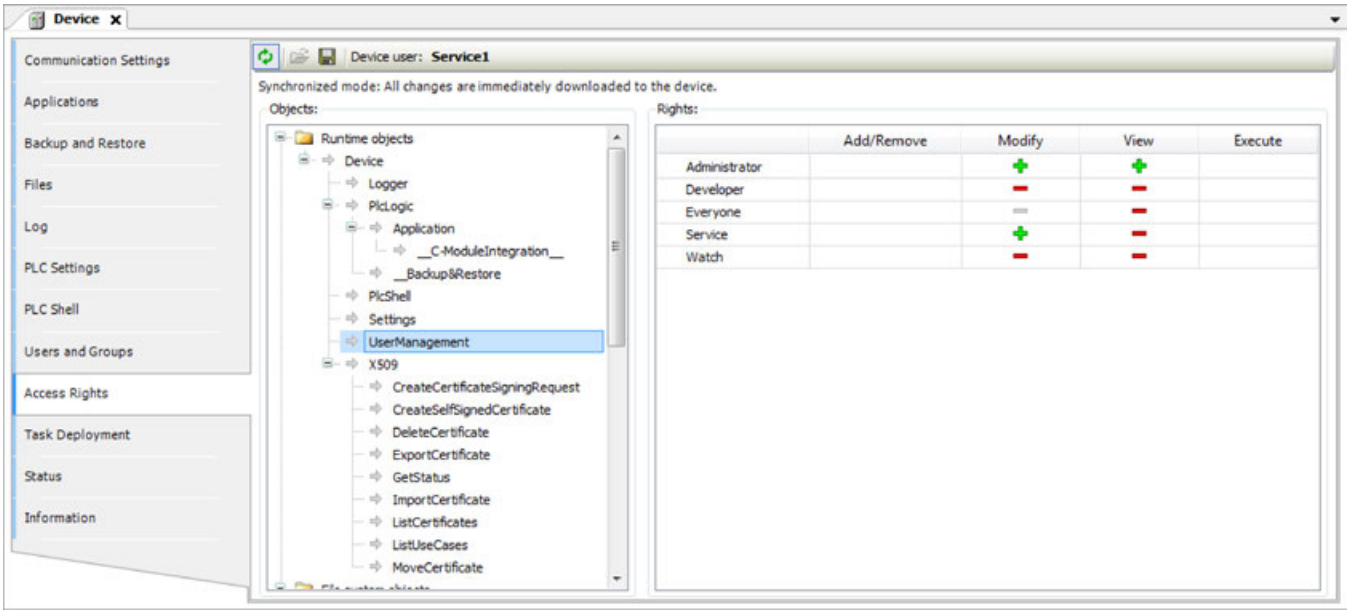
Table 73: “Objects”

In the tree structure, the objects are listed to which actions can be executed at runtime. The objects are each assigned by their object source and partially sorted in object groups. In the *“Rights”* view, you can configure the access options for a user group to a selected object.
Object source (root node) ● *“File system objects ➔ Device”*: In these objects, the rights can be granted to folders of the current execution directory of the controller. ● *“Runtime objects ➔ /”*: In these objects, all objects are managed that have online access in the controller and therefore have to control the access rights. A description of the objects is located in the table. *“Overview of the objects” on page 867*
Object groups and objects (indented) Example: *“Device”* with child nodes *“Logger”*, *“PlcLogic”*, *“Settings”*, *“UserManagement”*.

Table 74: “Rights”

In general, the access rights are inherited from the root object (also *“Device”* or *“/”* to the subobjects. This means that if a permission of a user group is denied or explicitly granted to a parent object, then this first affects all child objects.

The table applies for the object that is currently selected in the tree. For every user group, it shows the rights currently configured for the possible actions on this object.



Possible actions on the object:

- *“Add/Remove”*
- *“Modify”*
- *“View”*
- *“Execute”*

When an object is clicked, a table on the right side shows the access rights of the available user groups for the selected object.

This allows you to quickly see:

- Which access rights are evaluated by an object
- Which user group has which effective rights to which object

Meanings of the symbols

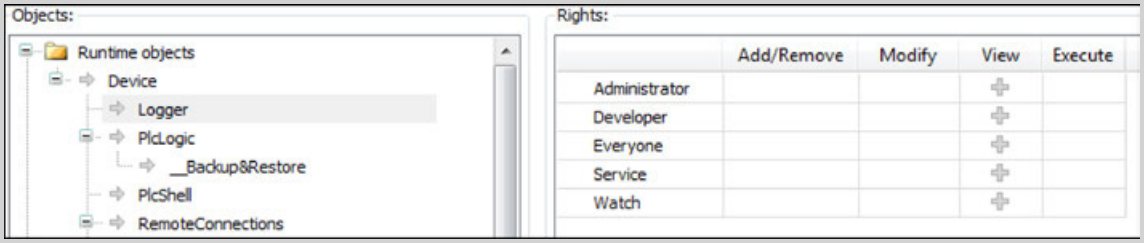
- ✚: Access right granted explicitly
- ━: Access right denied explicitly
- ✚: Access right granted through inheritance
- ━: Access right denied through inheritance
- ✖: The access right was not granted or denied explicitly and also not inherited by the parent object. Access is not possible.
- No symbol: Multiple objects are selected that have different access rights.

Change the permission by clicking the symbol.

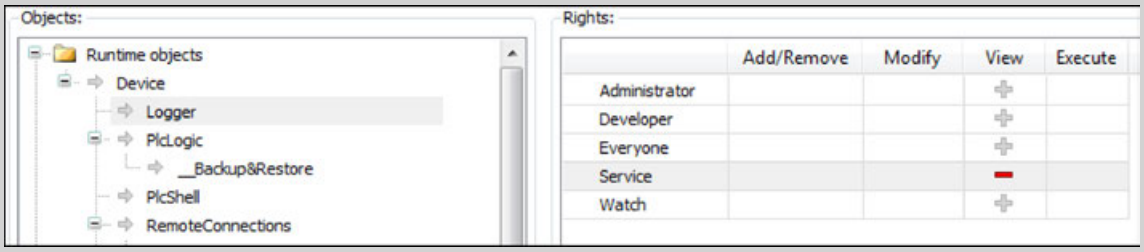
Example

The *"Logger"* object on the *"Access Rights"* tab was created by the "Logger" component and controls its access rights. It is located directly below the *"Device"* runtime object.

The possible access rights for this object can be granted only for the *"View"* action.



Initially, each object has a read access. This means that every user can read the "Logger" of a controller. If this access right should be denied for a single user group (*"Service"* in the example), then the read access to the logger object has to be denied explicitly.



Overview of the objects

"Runtime objects ➔ Device"						
"Logger"	Online access to the logger is read only. Therefore, only the *"View"* access right can be granted or denied here.					
"PlcLogic"	All IEC applications are inserted here automatically as child objects during download. When an application is deleted, it is removed automatically. This allows specific control of online access to the application. Access rights can be assigned centrally over all applications in the *"PlcLogic"* The *"Administrator"* and *"Developer"* user groups have full access to the IEC applications. The *"Service"* and *"Watch"* user groups only have read access (for example for read-only monitoring of values).					
	The following table shows which action is affected in particular when a specific access right is granted for an IEC application. **x** : The right has to be set explicitly. **–** : The right is not relevant.					
	"Application"	**Operation**	**Access Rights**			
			"Add/ Remove"	*"Execute"*	*"Modify"*	*"View"*
		Login	–	–	–	x
		Create	x	–	–	–
		Create child object	x	–	–	–
		Delete	x	–	–	–
		Download / online change	x	–	–	–
		Create Boot Application	x	–	–	–

		Read variable	–	–	–	x
		Write Variable	–	–	x	x
		Force variable	–	–	x	x
		Set and delete break-point	–	x	x	–
		Set Next Statement	–	x	x	–
		Read call stack	–	–	–	x
		Single cycle	–	x	–	–
		Switch on flow control	–	x	x	–
		Start / Stop	–	x	–	–
		Reset	–	x	–	–
		Restore retain variables	–	x	–	–
		Save retain variables	–	–	–	x
“PlcShell”	Only the *“Modify”* permission is evaluated at this time. This means that only when the *“Modify”* permission has been granted to a user group can PLC shell commands also be evaluated.					
“RemoteConnections”	Additional external connections to the controller can be configured below this node. Currently, access to the CODESYS OPC UA server can be configured here.					
“Settings”	This is the online access to the configuration settings of a controller. By default, access to *“Modify”* is granted only to the administrator.					
“UserManagement”	This is the online access to the user management of a controller. By default, read/write access is granted only to the administrator.					
“X509”	This controls the online access to the X.509 certificates. Two types of access are distinguished here: ● Read (*“View”*) ● Write (*“Modify”*) Every operation is assigned to one of these two access rights. Each operation is inserted as a child object below X509. Therefore, access per operation can now be fine-tuned even more.					
“File system objects ➔ /”						
	All folders from the execution path of the controller are inserted below the "*“/”*" file system object. This allows you to grant specific rights to each folder of the file system.

Tab 'Symbol Rights'

In this tab of the generic device editor, you define the access rights of different user groups (clients) to the individual symbol sets available on the controller.

Requirement: User management must be set up on the PLC. An application was downloaded to the controller for which symbol sets were defined in the CODESYS project. They have access data for logging in to the controller.

In the *“Symbol Sets”* view, all symbol sets are listed below the *“Application”* node whose definition was downloaded with the application to the controller.

In the *“Rights”* view, the user groups defined in the user management of the controller are listed in a table. When a symbol set is selected, you see the access rights of the corresponding user group to the symbols of this set. : Access granted; : Access not granted. You can change the access rights by double-clicking the symbol.

Click the button to save the current access configuration to an XML file The file type is *“Device symbol management files (*.dsm)”*. Click the button to read a file like this from the hard drive.

- *Chapter 1.4.1.20.2.8.13 “Tab 'Users and Groups'” on page 860*

Tab 'Licensed Software Metrics'

The tab of the device editor displays the code sizes of the applications of the open project in a tree structure. The display is refreshed when you click *“Build ➔ Generate Code”* or *“Online ➔ Login”* for the active application. When the compile information is deleted, the displayed code size of the corresponding application is reset.

“Metric”	Applications of the open project
“Size”	● *“Size of User Code”*: Sum of the displayed code sizes of the applications listed below ● Code size of the respective application
“ Unit”	Unit in which the *“Size”* is displayed
“Max. Allowed”	Not implemented yet

Tab 'Task deployment'

This sub-dialog box of the device editor displays a table of inputs and outputs as well as their assignment to the defined tasks.

The information only becomes visible after code has been generated for the application. It is used for troubleshooting, because it shows where inputs or outputs are used in several tasks with different priorities. Multiple use can lead to undefined values through overwriting.

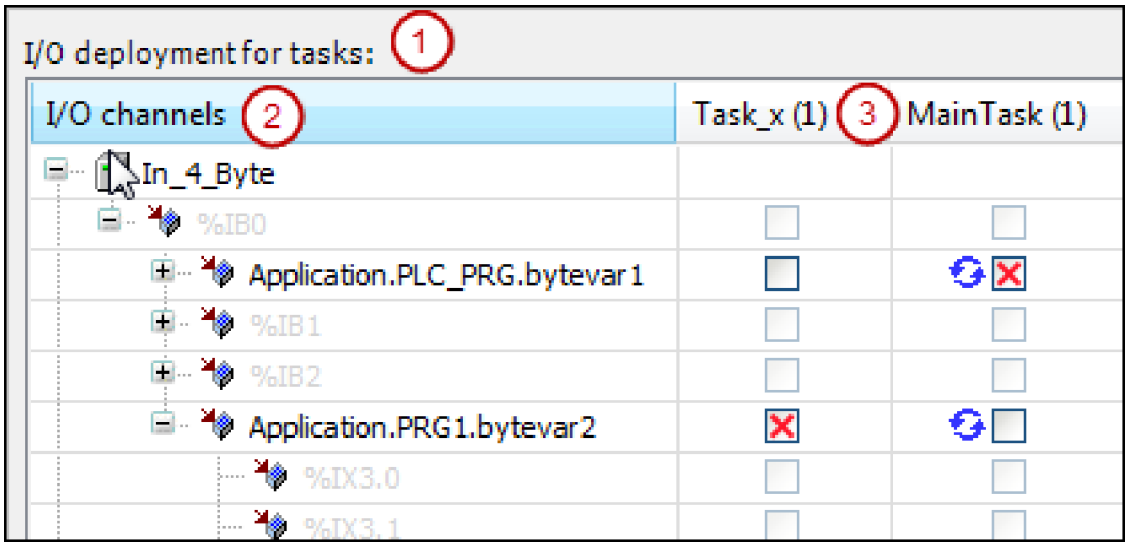

Table 75: "I/O Deployment for Tasks" (1)

"I/O Channels" (2)	All inputs and outputs of the linked devices. The display corresponds to that in the dialog box *"I/O Mapping"* of the device editor. By double-clicking on an input or output you can open the associated I/O mapping editor.
"<task name>" (3)	A column appears for every task defined in the task configuration. The title contains the task name and priority. The priority of the tasks decreases from first to the last column. A red cross appears in the box for inputs and outputs that are written or read by a task: ☒. In addition, the task defined as a *"Bus cycle task"* in the *"PLC Settings"* of the device editor is marked at these points with a blue double arrow symbol ⟳. Following a mouse-click on the title cell, only the I/Os assigned to this task are displayed. Following a mouse-click on the *"I/O Channels"* cell, all channels are shown again.

- *Chapter 1.4.1.20.2.8.11 "Tab '<device name> I/O Mapping'" on page 854*
- *Chapter 1.4.1.20.2.8.9 "Tab 'PLC Settings'" on page 850*
- *Chapter 1.4.1.8.16.1 "Creating a task configuration" on page 293*

Tab 'Status'

This tab of the generic device editor displays status information, for example 'Running' or 'Stopped', and specific diagnostic messages from the respective device, also information about the card used and the internal bus system.

See also

- *Chapter 1.4.1.20.2.8.1 "Generic device editor" on page 839*

Tab 'Information'

This tab of the generic device editor displays general information that originates from the device description file: name, vendor, categories, version, order number, description, if necessary an illustration.

See also

- *Chapter 1.4.1.20.2.8.1 “Generic device editor” on page 839*

Object 'GlobalTextList'

Symbol: 

This object is for the management and translation of texts that are written as static text in visualizations in the project. It contains a table with these texts. If you write a text in a visualization in an element under the property *“Texts”*, CODESYS automatically adds a line in the table. You cannot write any new text here, you can only edit an existing text.

In addition CODESYS makes the following commands available, in order to consolidate the *“GlobalTextList”*:

- *“Check Visualization Text IDs”*
- *“Update Visualization Text IDs”*
- *“Remove Unused Text List Entries”*

The object is located in the POUs view and exists once at the most

“ID”	Unambiguous identifier of the text
“Default”	Source text as a character string with one formatting specification at the most, for example `Information A: %i possibilities`. If no translation is written under a language column , CODESYS uses this text. Double-click in the field in order to edit the text.
The table contains as many language columns as you have added. A language column is named with a language code that you entered when creating the column with the command *“Insert Language”*.	
“<Language code>”	Name of the language as a language code, for example `en-US`. This column contains the translation of the text that is written under *“Standard”*. If the language code is selected as a language in the visualization manager, a visualization displays the translation during operation. A running visualization can switch over during operation to another language at the request of a user. Double-click in the field in order to edit the text.

Object 'GVL' - Global Variable List

Symbol: 

A global variable list is used for the declaration, editing and display of global variables.

A GVL is added to the application or the project with the command *“Project ➔ Add Object ➔ Global Variable List”*.

If you insert a GVL under an application in the Device tree, the variables are valid within this application. If you add a GVL in the `POUs` view, the variables are valid for the entire project.

You can apply settings for the editor of the object in the dialog *"Tools ➔ Options"* in the categories *"Declaration Editor"* and *"Text Editor"*.

If the target system supports network functionality, you can convert the variables of a GVL into network variables and thus use them for data exchange with other devices in the network. To do this you must define corresponding properties for the GVL in the *"Network Variables"* tab of the *"Properties"* dialog.

See also

- *Chapter 1.4.1.8 "Programming of Applications" on page 222*
- *Chapter 1.4.1.20.4.10.11 "Dialog 'Properties' - 'Network Variables'" on page 1163*
- *Chapter 1.4.1.20.4.13 "Dialog 'Options'" on page 1186*

Object 'GVL' - Global Variable List (task-local)

Symbol: 

A global variable list (task-local) is used for the declaration, editing and display of global variables. For this special global variable list, the declared variables in the list can be written by one task only. All other tasks have only read-only access. This makes sure that the values of these variables are always consistent, even for multicore projects.

The object is available for compiler version 3.5.13.0 with the corresponding device description.

"Task with write access"	Task that has exclusive write access to the variables.

See also

- *Chapter 1.4.1.8.2.5 "Using Task-Local Variables" on page 230*
- *Chapter 1.4.1.8.2.4 "Declaring global variables" on page 229*

- *Chapter 1.4.1.20.2.26.5 "Tab 'Task Groups'" on page 941*

Object 'Persistent variable list'

Symbol: 

The object contains the declaration of global persistent variables in the declaration section `VAR_GLOBAL PERSISTENT RETAIN .. END_VAR`. The variables are stored in special non-volatile memory.

The persistence editor shows the variables as a list in the usual way. The displayed list does not influence the persistence behavior of the variables, but only the list stored internally in the process image. The list there contains all variables ever declared in chronological order. Variables that you have removed are marked with a placeholder and continue to exist as a gap.

The declaration section can also contain instance paths, which refer to locally declared persistent variables and were created with the command *"Declarations ➔ Add All Instance Paths"*.

NOTICE!
Before you decide how to set up persistence for an application, it would be helpful for you to be familiar with the use cases described in the *"Data Persistence"* section. Moreover, it is helpful if you can differentiate between the mechanisms of persistent variables, retain variables, variables of the Persistence Manager, and recipe variables.

Commands

The following commands are provided in the persistence editor:

- Command *“Declarations ➔ Add All Instance Paths”*
- Command *“Declarations ➔ Reorder List and Clear Gaps”*

See also

- TODO
- *Chapter 1.4.1.20.3.17.1 “Command 'Reorder List and Clean Gaps'” on page 1123*
- *Chapter 1.4.1.8.19.1 “Preserving data with persistent variables” on page 304*
- *Chapter 1.4.1.8.19.2 “Preserving data with retain variables” on page 306*
- *Chapter 1.4.1.20.3.17.4 “Command 'Add all instance paths'” on page 1124*

Object 'Image Pool'

The *“Image Pool”* object contains a table with image ID assignments.

“ID”	ID of the image; you reference this ID, for example in the visualization of the image.
“File name”	File path of the image; if you click for more settings (...), the *“Select Image”* dialog box opens.
“Image”	Show a thumbnail of the image.
“Link type”	Opens the *“Select Image”* dialog box, where you define the link type.

Dialog box 'Select Image'

“Image file”	Name and directory of the image file (example: "C:\Programme\images\logo.bmp") CODESYS supports the following image formats: BMP, EMF, GIF, ICO, JPG, PNG, SVG, and TIFF. Please note that a controller may not support all formats. Whether or not you can use images formatted as scalable vector graphics (*.svg) depends on the operating system. Any necessary information is located in the device description of the hardware vendor.

Table 76: “File Handling”

“Remember the link”	CODESYS saves only the link. CODESYS automatically updates any changes to an image file in the image pool. You must ensure that the path of the image file does not change. When saving the project as an archive, CODESYS embeds the image file in the project archive.
“Remember the link and embed into project”	CODESYS copies the image to the image pool and the link information is retained. In this way, CODESYS recognizes any changes to the image file and then update the image pool can as needed. This behavior is controlled with the options in the next table. Embedded image files increase the memory requirement of the project.
“Embed into project”	CODESYS copies the image to the image pool. If the image file is changed again afterwards, then it is not updated in the project. For libraries, you must embed the image in the project. Embedded image files increase the memory requirement of the project.

Table 77: “Change Tracking”

These options are available only if you have selected the *“Remember the link and embed into project”* check box as described above.	
“Reload the file automatically”	CODESYS automatically updates the image file in the project without prompting.
“Prompt whether to reload the file”	If the image file has changed, you may be prompted whether or not the image file should be updated.
“Do nothing”	CODESYS does not update the image file in the image pool.

See also

- *Chapter 1.4.1.8.9 “Using image pools” on page 274*

Object 'Library Manager'

Symbol: 

The Library Manager lists all libraries that were integrated in the project for creating applications. It provides information about the type of library, its properties, and its contents.

You can expand or collapse the list of integrated libraries, as well as edit library properties for non-dependent libraries.

The Library Manager consists of three views:

- Upper view: List of integrated libraries
- Lower left view: Tree structure with all modules of the library selected in the upper view
- Lower right view: Documentation for the module selected in the tree

See also

- *Chapter 1.4.1.16 “Using Libraries” on page 448*

List of integrated libraries List of all libraries integrated in the project. If a library depends on other libraries, then these referenced libraries are automatically integrated.

Displayed in gray fonts	The library was added to the project automatically by means of a plug-in.
Displayed in black fonts	The library was added to the project automatically by means of the *“Add Library”* command.
“Name”	Display of the integrated library in the following syntax: *“<placeholder name> = <library name>, <version> (<company>)”*: *“<placeholder name>”*: If it is a placeholder library for a library, then the placeholder name is before a *“ = ”*. *“<library name>”*: Name of the library that is used for management in the library repository. *“<version>”*: Version that was referenced at the first time it was integrated. *“ (<company>)”*: Vendor (optional)

"Namespace"	Namespace for unique access to the contents of the library. It is prepended to a module identifier for this purpose: <namespace>.<library module identifier> The namespace usually coincides with the library name. Note: If the library has the property `LanguageModelAttribute "qualified-access-only"`, then you **must** access the library module in the application code by means of the namespace. Qualified (unique) access is enforced. You can modify the standard namespace for local use (within the project) in the *"Properties"* dialog.
" Effective version"	Version of the library after the resolution. This version is used in the project. Requirement: The Library Manager exists in the *"Devices"* view and a placeholder library is selected. Example: `3.5.10.0` A placeholder library that is integrated below an application is resolved by assigning a special resolution to the placeholder library in the *"Placeholders"* dialog. Then the selected library is loaded. Other resolutions are ignored. If no special resolution is given, then a check is performed as to whether or not a resolution is specified in the device description and library profile of the application. The first search hit is applied.
	Symbol with tooltip to notify about the current device-dependent resolution of the selected library. Example when the Library Manager is in the *"Devices"* view: *"This placeholder is explicitly redirected to this version (see the Placeholders dialog)"* Example when the Library Manager is in the *"POUs"* view: *"In the 'Device_1' device, the placeholder is resolved to 'VisuElemsAlarms, 1.0.0.0 (System)"* A placeholder library that is integrated in the *"POUs"* view is resolved by checking depending on the application whether or not a resolution is specified in the device description. Afterwards, the library profile is checked. The first detected resolution is used. If you have assigned a special resolution to the placeholder library in the *"Placeholders"* dialog, then this will **always be ignored**. The result is shown in the tooltip of the symbol.
	Library that is signed with a trusted certificate (compatible with CODESYS >= V3 SP15)
	Library that is signed with a trusted certificate, but references at least one unsigned library
	Library that is signed with a private key and token (compatible with CODESYS < V3 SP15)
	Library that is not signed, or signed with an untrusted or expired certificate. In the case of an untrusted certificate, the *"Trust Certificate"* command is provided in the context menu.
	Library that is defined as optional and not currently available
	Library whose status is being determined
	Licensed library for which no valid license is currently available
	Library symbol for a library that cannot be loaded because its signature (encryption) could not be verified

Table 78: Commands in the Library Manager

"Add Library"	Opens the dialog for selecting a library. All libraries installed in the library repository are offered.
"Delete Library"	Removes the presently selected library from the project
"Properties"	Opens the dialog for the display and editing of the properties of the presently selected library
"Details"	Opens a dialog with details for the presently selected library (general information, contents, properties, license information)
"Try to Reload Library"	If you select a library marked as not found, you can attempt to load it into the project again using this command.
"Download Missing Libraries"	CODESYS scans for the missing libraries in the download servers specified in the project options. After that you can download and install the library.
"Placeholders"	The *"Placeholders"* dialog opens. The current resolution is displayed there and you can edit it.
"Library Repository"	Opens the *"Library Repository"* dialog for installing and uninstalling libraries and for defining library locations
"Icon legend"	Opens the *"Information"* dialog with a legend of the icons that display the current status of a library in the list of integrated libraries (see above)
"Summary"	Opens the *"Library Summary"* dialog. All libraries referenced in the project are displayed in a tree structure in the dialog, and those libraries which reference these libraries. ● Command *"Display all occurrences in library hierarchy and close dialog"*: In the editor of the Library Manager, the libraries in the open tree structure are marked which reference or use this library. Requirement: A library is selected. The *"Information"* dialog is then closed. This command is also executed when you double-click a library. Display of the libraries ● *"Managed Library"*: Name and version of the library ● *"Number of Occurrences"*: Number of locations where this library is referenced by other libraries. When you click *"+"* for a library, the libraries, which reference this library, are displayed in the next level down.

"Trust Certificate"	Only in the context menu of a library selected in the Library Manager, in which the library has been signed with an untrusted certificate. The command turns the untrusted certificate into a trusted certificate and the prepended icon changes from to .
"Export Library"	Only in the context menu of a library selected in the Library Manager: Opens the default dialog for saving the library file in the file system

- *Chapter 1.4.1.20.2.21 "Object 'Project Information'" on page 919*

Tree structure of all modules of a selected library

All library modules that were integrated with the library are listed in the tree structure.

Requirement: A library is selected in the upper view.

The usual sorting and search functions are available in the menu bar.

Documentation for the library module selected in the lower left view

Tab *“Inputs/Outputs”*	Interface (inputs/outputs) of the library module
Tab *“Graphical”*	Graphical display of the module
Tab *“Documentation”*	Documentation for the library module. Note: As a library developer, you have to follow the rules for documentation inclusion in 'Guidelines for library development'.
Tab *“Parameter List”*	Requirement: The library project contains a parameter list. You can change the values of these parameters in the column *“Value (editable)”*.

See also

- *Chapter 1.4.1.16.1 “Information for Library Developers” on page 449*

Object 'OPC UA Information Model'

Symbol:

The *“OPC UA Information Model”* object is added to the *“Communication Manager”* in the application. When added, an OPC UA publishing object and below that an information model object as a child object are also added.

In the *“Add OPC UA Information Model”* dialog, specify a name for the information model and select the OPC UA information model. The selection includes the OPC UA information models which are installed in the *“OPC UA Information Model Repository”*.

OPC UA information model editor

Symbol:

The editor is used to select the object types and data types of the OPC UA information model which you want to use in the open CODESYS project. The selected OPC UA types are converted to IEC types in the editor.

“Browse Information Model ”	List box The currently used information model and the information models which are referenced by the current model are displayed. The dependencies depend on the respective information model. The OPC UA base model is always displayed.
“Generate IEC declarations ”	Generates an IEC declaration for all OPC UA types converted into an IEC type. The generated IEC types are saved in a folder (example: *“OPC Objects”*) in the *“Devices”* view and can be used in the implementation of the IEC code. When implementing the CODESYS project, you can select them in the *“Input Assistant”* dialog. When the IEC declarations are generated, the appropriate attributes are automatically added to the generated POUs (example: `'opcua.mapping.type','opcua.mapping.member.accesslevel'`). Note: The attributes added by the system should not be changed by the user. When the IEC type cannot be created, the entry `UNKNOWN_TYPE` is displayed in the declaration instead of the data type. The user should delete this variable because in this case it is almost always an OPC UA feature which is not supported yet. OPC UA features which are not supported yet are grayed out in the left area.
“Data Model”	
Left area: OPC UA data model	
“Types”	Display of the OPC UA data types and object types in a tree structure When you drag an OPC UA type to the right area, CODESYS converts the OPC UA type into the corresponding IEC type which can be used in the implementation of the CODESYS project. In this case, only the root node of an OPC UA type can be dragged to the right area. For a detailed description of the assignment of individual OPC UA types to the corresponding IEC types in the mapping operation, see the chapters "Mapping of OPC UA Types to IEC Types" and "Mapping of Reference Types".
“Element Type”	OPC UA element type
“Reference Type”	OPC UA reference types Example: `HasComponent`, `HasProperty` For a description of these reference types, see the chapter "Mapping of OPC UA Types to IEC Types".
“Modelling Rule”	● *“Mandatory”*: For the corresponding OPC UA type, the respective members are generated in the project when the *“Generate IEC declarations”* command is executed. In the right area, the *“Generate member”* field is activated and cannot be deactivated. ● *“Optional”*: Generating an IEC member for this OPC UA type is optional. ● *“Optional placeholder”*: in the right, you can drag another IEC type for this placeholder. For an example as a screenshot, see the chapter "Using OPC UA Companion Information Models".
Right area: Object types and data types of the OPC UA information model which are mapped to IEC types	
“Name”	Name of the IEC POU or data type in the project By default, the name of the type is displayed in the OPC UA information model. OPC UA also supports names which are invalid in IEC. In these cases, CODESYS automatically generates a valid IEC name. You can change the name.
“IEC Type”	IEC type to which the OPC UA type was mapped (example: `BOOL`, *“Method”*).

"OPC UA Type"	Corresponds to the *"Element Type"* displayed in the left area
"Generate member"	● ☑: When the *"Generate IEC declarations"* command is executed, a corresponding member or a placeholder is generated in the project. Only the interfaces are automatically generated here. The implementation still has to be manually created later in a POU. When the *"Modelling Rule"* is *"Mandatory"* for the OPC UA type in the right area, this option cannot be deactivated. ● ☐: When the *"Generate IEC declarations"* command is executed, a corresponding member is not generated in the project. Click this option to activate it.

OPC UA publishing editor

Symbol:

In the editor, the instances (OPC UA objects) of the OPC UA types are configured which should be available to the OPC UA Clients via the controller

"Search for Mapped Instances"	Searches in GVLs and PRGs below the current application for instances of the mapped OPC UA types which have already been declared. The search result is displayed in the list. Note: Instances in the *"POUs"* view and in libraries are not taken into consideration.
"Create New Instance"	Opens the *"Create New Instance"* dialog to select the IEC type for which a new instance should be generated. Instances can be generated for the POUs which have been created in the OPC UA information model editor from OPC UA types. These instances can be used in POUs in the application. Requirement: In the OPC UA information model editor, the *"Generate IEC declarations"* command has been executed after mapping the OPC UA types to the IEC types.
"Root Node"	Selection of directories or the object instance of the server which is displayed on the OPC UA Client for publishing the instances. The list box depends on the applied OPC UA companion specification.
Tabular list of generated instances:	
"OPC UA Variable"	Variable which has been generated as an instance of an OPC UA type. This variable can be published in an OPC UA Client. You can edit the displayed name.
"OPC UA Type"	OPC UA type of the *"OPC UA Variable"*
"Map or Generate"	● : The *"OPC UA Variable"* has been mapped to an existing variable. ● : The *"OPC UA Variable"* has been generated as a new instance.
"IEC Variable"	Full variable name
"IEC Type"	IEC type of the IEC variable
"Access Rights"	Note that an OPC UA Client may have read/write access the OPC UA variable. In the function blocks, the access rights to the variables can be changed by attributes which can also be read from the XML file if necessary. Reading and writing
"Maximal"	Maximum possible permissions for the OPC UA variable

- *Chapter 1.4.1.20.3.8.12 "Command 'OPC UA Information Model Repository'" on page 1069*

Object 'Network Variable List (Sender)'

Symbol: 

A network variable list (sender) is used for declaring and listing global variables that should be sent to network variable lists (receiver) of other devices or network projects.

You add the object to the device tree by clicking *"Add Object ➔ Network Variable List (Sender)"* of an application.

You can configure the protocol and transfer parameters in the *"Add Network Variable List (Sender)"* dialog box or *"Properties"* dialog box of the object in the *"Network Variables"* tab.

Dialog Box 'Add Network Variable List (Sender)'

Function: This dialog box defines the network properties for the sender NVL. When you close the dialog box, CODESYS adds the sender NVL of the application to the device tree.

Call: Main menu *"Project ➔ Add Object ➔ Network Variable List (Sender)"* while the application is selected in the device tree.

This dialog box corresponds to the *"Network Variables"* tab in the *"Properties"* of the network variable list object.

See also

- *Chapter 1.4.1.20.4.10.11 "Dialog 'Properties' - 'Network Variables'" on page 1163*
- *Chapter 1.4.1.20.2.17 "Object 'Network Variable List (Receiver)'" on page 880*
- *Chapter 1.4.1.9.3.1 "Configuring a Network Variable Exchange" on page 361*

Object 'Network Variable List (Receiver)'

Symbol: 

The object is used for listing the received network variables and displaying the information: network and transmit information and sender.

You add the object to an application by clicking *"Add Object ➔ Network Variable List (Receiver)"*.

The network variable list (receiver) shows the received network variables, which were declared in network variable list (sender) of another device or project. You cannot change the network variables in the object editor.

The object editor consists of two parts:

- Information about the sender and transfer log of the list
- List of declarations of network variables

Dialog Box 'Add Network Variable List (Receiver)'

Function: This dialog box defines the receiver NVL to a sender NVL and adds the receiver NVL to the application object in the device tree.

Call: Main menu *"Project ➔ Add Object ➔ Network Variable List (Receiver)"* (when the application object is selected).

"Task"	Task of the current application that controls the variables to be received.
"Sender"	Drop-down list ● Available sender NVLs of another device in the project ● *"Import from file"*: Required if the necessary sender NVL is defined in another project. For this, the necessary sender NVL must have been generated in another project as *"GVL export file *.gvl"* in the properties dialog of the NVL in the *"Link To File"* tab.
"Import from file"	File name in *"GVL export file *.gvl"* format if you have selected *"Import from file"* for *"Sender "*.

See also

- *Chapter 1.4.1.9.3.1 “Configuring a Network Variable Exchange” on page 361*
- *Chapter 1.4.1.20.2.16 “Object 'Network Variable List (Sender)'” on page 880*

Object 'POU'

Symbol: 

An object of the type *“POU”* is a Program Organization Unit in a CODESYS project. You write source code for your controller program in POUs.

There are the following types of POUs:

- Program
- Function
- Function block

A *“POU”* object is inserted by using the command *“Project ➔ Add Object”* in the Device tree or in the *“POUs”* view. When adding a POU you define the POU type and the implementation language.

You can also add other programming objects (method, action, etc.) to these objects.

Calling POUs

Certain POUs can call other POUs. Recursions are not permitted.

When calling POUs via the namespace, CODESYS browses the project for the POU to be called in accordance with the following order:

1. Current application
2. *“Library Manager”* of the current application
3. *“POUs”* view
4. *“Library Manager”* in the *“POUs”* view

If you want to call a POU that exists with the same name in a library used in the application and as an object in the “POUs” view, note the following: There is no syntax that allows you to call the POU in the “POUs” view only by its name. In this case you must shift the library from the application's library manager to the project's library manager (in the “POUs” view). After that you can call the POU object in the “POUs” view purely by its name. If you add the namespace to the library, you can call the POU of the library.

The term “POU” is also used in CODESYS for the “POUs” view in which CODESYS manages the global objects in the project.

See also

- *Chapter 1.4.1.20.2.18 “Object 'POU'” on page 881*
- *Chapter 1.4.1.20.4.10 “Dialog 'Properties'” on page 1157*

Dialog 'Add POU'

Function: The dialog is used to configure a new POU according to the IEC 61131-3 standard. This means that a POU can be a program, a function, or a function block.

Call: *“Project ➔ Add Object”* menu; context menu in the *“Devices”* view when an application is selected; context menu in the *“POUs”* view

"Name"	Name of POU

Table 79: "Type"

"Program"	
"Function Block"	● ☑ *"Extends"*: Specification or selection of a base function module in the sense of object-oriented programming. Specified with the EXTENDS keyword in the function block declaration ● ☑ *"Implements"*: Specification or selection of an interface in the sense of object-oriented programming. Specified with the IMPLEMENTS keyword in the function block declaration. When the POU is created, all methods are created which are defined via the interface. ● ☑ *"Final"*: Derived access is not allowed. This means that you cannot extend the function block with another function block. This allows for optimized code generation. ● ☑ *"Abstract"*: Identifies that the function block has a missing or incomplete implementation and cannot be instantiated. Abstract FBs are used exclusively as base function blocks and the implementation typically occurs in a derived FB. If a non-abstract function block is created, which in turn extends an abstract function block, then all abstract methods of the abstract basic function block are added to the new function block as (non-abstract) methods. ● *"Access specifier"* – *"PUBLIC"*: Corresponds to the specification of no access specifier. – *"INTERNAL"*: Access to the function block is restricted to the namespace (library). ● *"Method implementation language"*: When you select the *"Implements"* option, you can select an implementation language here for all method objects that CODESYS generates by means of the implementation of the interface. The *"Method implementation language"* does not depend on the implementation language of the function block.
"Function"	Note: Not available when *"Sequential Function Chart (SFC)"* is selected as the *"Implementation language"*. *"Return type:"*: Data type of the return value
"Implementation language"	Implementation language of the POU

Object 'Program'

A program is a POU that supplies one or more values during execution. After execution of the program, all values are retained until the next execution. The order of calling the programs within an application is defined in task objects.

A program is added to the application or the project using the command *"Project ➔ Add Object ➔ POU"*. In the Device tree and in the *"POUs"* view the program POUs have the suffix *"(PRG)"*.

The editor of a program consists of the declaration part and the implementation part.

The uppermost line of the declaration part contains the following declaration:

```
PROGRAM <program>
```

Calling a program

Programs and function blocks can call a program. A program call is not permitted in a function. There are no instances of programs.

If a POU calls a program and values of the program change as a result, these changes are retained until the next program call. The values of the program are also retained even if the repeat call takes place by another POU. This differs from the call of a function block. When calling a function block only the values of the respective instance of the function block change. The changes only need to be observed if a POU calls the same instance again.

You can also set the input or output parameters for a program directly when calling.

Syntax: `<program>(<input variable> := <value>, <output value> => <value>):`

If you insert a program call via the input assistant and the *"Insert with arguments"* option in the input assistant is activated at the same time, CODESYS adds input and/or output parameters to the program call in accordance with the syntax.

Examples

Calls:

IL:

```
CAL      PLC_PRG(
         in1:= 2)
LD       PLC_PRG.out2
ST       erg
```

With assignment of the parameters:

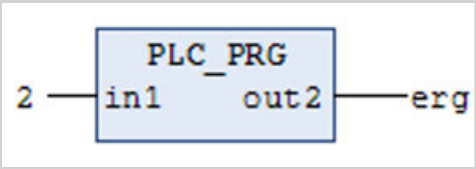
```
CAL      PLC_PRG(
         in1:= 2,
         out2=> erg)
```

ST:

```
PLC_PRG()
                    erg := PLC_PRG.out2;
```

With assignment of the parameters:

```
PLC_PRG(in1:=2, out1=>erg);
```



See also

- *Chapter 1.4.1.20.2.18 "Object 'POU'" on page 881*
- *Chapter 1.4.1.8.16 "Task Configuration" on page 292*

Object 'Function Block'

A function block is a POU that yields one or more values when executed.

The object is added to the application or the project by clicking *"Project ➔ Add Object ➔ POU"*. In the device tree or in the *"POUs"* view, function block POUs have the *"(FB)"* suffix.

It always calls a function block by means of an instance that is a copy of the function block.

The editor of a function block consists of the declaration part and the implementation part.

The values of the output variables and the internal variables remain unchanged after execution until the next execution. This means that the function block does not necessarily return the same output values for multiple calls with the same input variables.

In addition to the functionality described in IEC 61131-3, you can also use function blocks in CODESYS for the following functionalities of object-oriented programming:

- Extension of a function block
- Implementation of interfaces
- Methods
- Properties

The top line of the declaration part contains the following declaration:

```
FUNCTION_BLOCK <access specifier> <function block> | EXTENDS <function block> | IMPLEMENTS <comma-separated list of interfaces>
```

Calling a function block

The call is always made by means of an instance of the function block. When a function block is called, only the values of the respective instance change.

Declaration of the instance:

```
<instance> : <function block>;
```

You access a variable of the function block in the implementation part as follows:

```
<instance> . <variable>
```

NOTICE!

Note the following:

- You can access only input and output variables of a function block from outside the function block instance, not the internal variables.
- Access to a function block instance is restricted to the POU in which the instance is declared, unless you have declared the instance globally.
- You can assign the desired values to the function block variables when you call the instance.

Example

Access to function block variables:

The function block `FB1` has the input variable `iVar1` of type `INT` and the output variable `out1`. In the following, the variable `iVar1` is called from the program `Prog`.

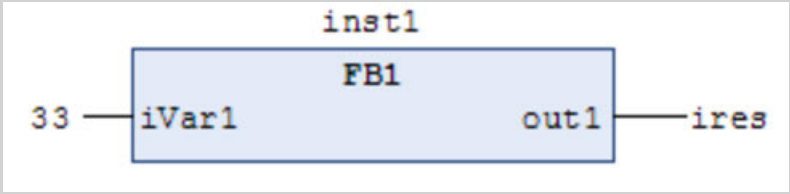
```
PROGRAM Prog
VAR
inst1:FB1;
END_VAR

inst1.iVar1 := 33;  (* FB1 is called and the value 33 is assigned
to the variable iVar1 *)

inst1();            (* FB1 is called, that's necessary for the
following access to the output variable *)

ires := inst1.out1  (* the output variable out1 of the FB1 is read
*)
```

In FBD:



Assigning variable values when calling:

In the textual languages IL and ST, you can assign values directly to input and/or output variables when you call the function block.

A value is assigned to an input variable with `:=` .

A value is assigned to an output variable with `=>` .

Example

The instance `CMD_TMR` of the timer function block is called with assignments for the input variables `IN` and `PT`. Then the output variable `Q` of the timer is assigned to the variable `A`.

```
PROGRAM PLC_PRG
VAR
    CMD_TMR : TOF;
END_VAR

CMD_TMR(IN := %IX5.1, PT := T#100MS);
A := CMD_TMR.Q;
```

When you insert a function block instance by means of the “Input Assistant” and select the “Insert with arguments” option in the “Input Assistant” dialog, CODESYS inserts the call with all input and output variables. Then you only have to insert the desired value assignment. In the example above, CODESYS inserts the call as follows: `CMD_TMR (IN:= ,PT:= , Q=> ).`

You can use the attribute `'is_connected'` *and a local variable to determine at the time of the call in the function block instance whether or not a specific input receives an external assignment.*

See also

- *Chapter 1.4.1.20.2.18 “Object 'POU'” on page 881*

- *Chapter 1.4.1.20.2.18.8 “Object 'Property'” on page 897*
- *Chapter 1.4.1.19.6.2.23 “Attribute 'is_connected'” on page 707*

Object 'Function'

A function is a POU that supplies precisely one data element when executed and whose call in textual languages can occur as an operator in expressions. The data element can also be an array or a structure.

The object is added to the application or the project by clicking *“Project ➔ Add Object ➔ POU”*. In the device tree or in the *“POUs”* view, function POUs have the *“(FUN)”* suffix.

NOTICE!
Functions have no internal status information, which means that functions do not save the values of their variables until the next call. Calls of a function with the same input variable values always supply the same output value. Therefore, functions must not use global variables and addresses!

The editor of a function consists of the declaration part and the implementation part.

The top line of the declaration part contains the following declaration:

```
FUNCTION <function> : <data type>
```

Below that, you declare the input and function variables.

The output variable of a function is the function name.

NOTICE!
If you declare a local variable in a function as `RETAIN`, this has no effect. In this case, CODESYS issues a compiler error.

NOTICE!
You cannot mix explicit and implicit parameter assignments in function calls in CODESYS V3. This means that you have to use either only explicit or only implicit parameter assignments in function calls. The order of the parameter assignments when calling a function is arbitrary.

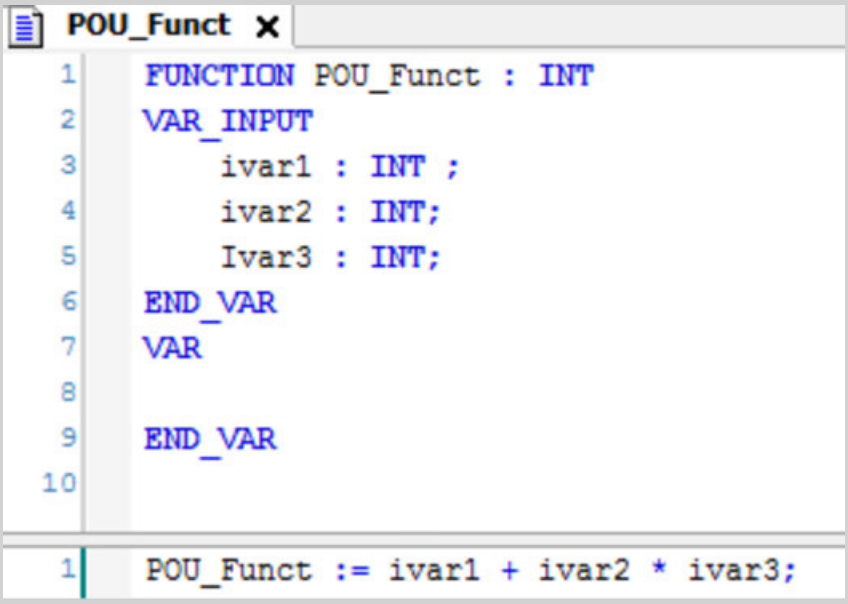
Calling a function

In ST, you can use the call of a function as an operand in expressions.

In SFC, you can use a function call only within step actions or transitions.

Examples

Function with declaration part and a line implementation code



Function calls:

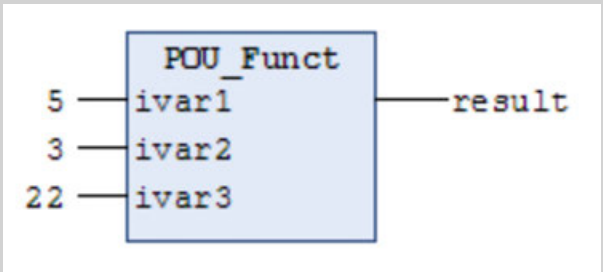
ST:

```
result := POU_Funct(5,3,22);
```

AWL:

LD	5
POU_Funct	3
	22
ST	result

FBD:



Functions with additional outputs

According to the IEC 61131-3 standard, functions can have additional outputs. You declare the additional outputs in the function between the keywords `VAR_OUTPUT` and `END_VAR`. The function is called according to the following syntax:

```
<function> (<function output variable1> => <output variable 1>,
<function output variable n> => <output variable n>)
```

Example

The `fun` function is defined with two input variables `in1` and `in2`. The output variable of the `fun` function is written to the locally declared output variables `loc1` and `loc2`.

```
fun(in1 := 1, in2 := 2, out1 => loc1, out2 => loc2);
```

See also

- *Chapter 1.4.1.20.2.18 “Object 'POU'” on page 881*

Object 'Interface'

Symbol:

Keyword: `INTERFACE`

An interface is a means of object-oriented programming. The object `ITF` describes a set of method and property prototypes. In this context, prototype means that the methods and properties contain only declarations and no implementation.

This allows different function blocks having common properties to be used in the same way. An object *“ITF”* is added to the application or the project with the command *“Project ➔ Add Object ➔ Interface”*.

Table 80: “Adding an interface”

“Inheritance”	
“Name”	Interface name
“Extends”	: Extends the interface that you enter in the input field or via the input assistant . This means that all methods of the interface that extend the new interface are also available in the new interface.

You can add the objects *“Interface property”* and *“Interface Method”* to the object *“ITF”*. Interface methods may contain only the declarations of input, output and input/output variables, but no implementation.

So that you can also use an interface in the program, there must be a function block that implements this interface.

This means:

- the function block contains the interface in its IMPLEMENTS list in its declaration part
- the function block contains an implementation for all methods and property prototypes of the interface

A function block can implement one or more interfaces. You can use the same method with identical parameters, but different implementation code in different function blocks.

Please note the following:

- You may not define variables within an interface. An interface has no implementation part and no actions. Only a collection of methods is defined, in which you may define only input, output and input/output variables.
- CODESYS always treats variables declared with the type of an interface as references.
- A function block that implements an interface must contain implementation code for the methods of the interface. You have named the methods exactly as in the interface and the methods contain the same input, output and input/output variables as in the interface.

NOTICE!

Interface references and online change

The following can happen with a compiler version < 3.4.1.0: if a function block changes its data because variables are added or deleted, or because the type of variables changes, then CODESYS copies all instances of the function block to a new memory location. In this case, however, an interface reference refers not to the new memory location, but still to the old one.

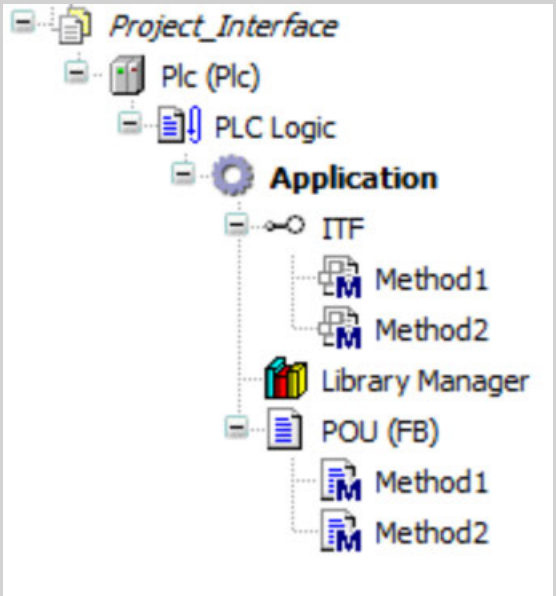
In case of compiler versions >= 3.4.1.0, CODESYS automatically re-addresses the interface references so that CODESYS also references the correct interface in case of an online change. CODESYS requires additional code and more time for this, so that jitter problems can occur depending on the number of objects concerned. Therefore, CODESYS displays the number of variables and interface references concerned before the execution of the online change and you can then decide whether the online change should be executed or aborted.

Example

Definition of an interface and its use in a function block

You have inserted the interface *"ITF"* below the application. The interface contains the methods *"Method1"* and *"Method2"*. *"ITF"*, *"Method1"* and *"Method2"* contain no implementation code. You insert the required variable declarations only in the declaration part of the methods.

If you subsequently insert a function block in the device tree that implements the interface *"ITF"*, CODESYS automatically also inserts the methods *"Method1"* and *"Method2"* under the function block. Here you can implement function-block-specific code in the methods.



- *Chapter 1.4.1.8.22.2 "Implementing interfaces" on page 312*
- *Chapter 1.4.1.8.22.3 "Extending interfaces" on page 314*

Object 'Method'

Symbol:

Keyword: `METHOD`

Methods are an extension of the IEC 61131-3 standard and a tool for object-oriented programming which is used for data encapsulation. A method contains a declaration and an implementation. However, unlike a function, a method is not an independent POU, and it is subordinated to a function block or program. A method can access all valid variables of the superordinate POU.

You can use interfaces for the organization of methods.

You can add a method below a program or a function block. Click *“Project ➔ Add Object ➔ Method”* to open the *“Add Method”* dialog.

Declaration

- The variables of a method contain temporary data that are valid only during the execution of the method (stack variables). All variables that are declared and implemented in a method are reinitialized each time the method is called.
- Like functions, methods can have additional outputs. You have to assign these additional outputs in the method call.
- Depending on the declared access specifier, a method can be called only within its own namespace (`INTERNAL`), only within its own POU and its derivatives (`PROTECTED`), or only within its own POU (`PRIVATE`). For `PUBLIC`, the method can be called from anywhere.

Interface methods can have declared input, output, and `VAR_IN_OUT` variables, but do not contain an implementation.

See also

- *Chapter 1.4.1.20.2.18.6 “Object 'Interface Method'” on page 894*

Implementation

- Access to function block instances or program variables is allowed in the implementation of the method.
- The `THIS` pointer allows for access to its own function block instance. Therefore, the pointer is allowed only in methods that are assigned to a function block.
- A method cannot access `VAR_TEMP` variables of the function block.
- A method can call itself recursively.

NOTICE!
When you copy a method below a POU and add it below an interface, or move the method there, the contained implementation is removed automatically.

Calling a method

Syntax for calls:

```
<return value variable> := <POU name> . <method name> ( <method input
name> := <variable name> (, <further method input name> := <variable
name> )* );
```

For the method call, you assign transfer parameters to the input variables of the method. Respect the declaration when doing this. It is enough to specify the names of the input variables without paying attention to their order in the declaration.

Example

Declaration

```
METHOD PUBLIC DoIt : BOOL
VAR_INPUT
    iInput_1 : DWORD;
    iInput_2 : DWORD;
    sInput_3 : STRING(12);
END_VAR
```

Call

```
bFinishedMethod := fbInstance.DoIt(sInput_3 := 'Hello World ',
iInput_2 := 16#FFFF, iInput_1 := 16);
```

When the method is called, the return value of the method is assigned, for example, to variables declared locally. When you omit the names of the input variables, you have to pay attention to the declaration order.

Example

Declaration

```
METHOD PUBLIC DoIt : BOOL
VAR_INPUT
    iInput_1 : DWORD;
    iInput_2 : DWORD;
    sInput_3 : STRING(12);
END_VAR
```

Call

```
bFinishedMethod := fbInstance.DoIt( 16, 16#FFFF,'Hello World ');
```

Recursive method call

Within the implementation, a method can call itself, either directly by means of the `THIS` pointer, or by means of a local variable for the assigned function block.

- `THIS^. <method name> ( <parameter transfer of all input and output variables> )`
  Direct call of the relevant function block instance with the `THIS` pointer
- `VAR fb_Temp : <function block name>; END_VAR`
  Call by means of a local variable of the method that temporarily instantiates the relevant function block

A compiler warning is issued for a recursive call. If the method is provided with the pragma `{attribute 'estimated-stack-usage' := '<sstimated_stack_size_in_bytes>'}`, then the compiler warning is suppressed. For an implementation example, see the "Attribute 'estimated-stack-usage'" chapter.

To call methods recursively, it is not enough to specify only the method name. If only the method name is specified, then a compiler error is issued: *“Program name, function or function block instance expected instead of”*

See also

- *Chapter 1.4.1.8.22.4 “Calling methods” on page 314*
- *Chapter 1.4.1.19.6.2.13 “Attribute 'estimated-stack-usage'” on page 695*
- *Chapter 1.4.1.19.2.15 “THIS” on page 539*

Special methods of a function block

FB_Init	Declarations automatically implicit, but explicit declaration also possible Contains initialization code for the function block, as is defined in the declaration part of the function block
FB_Reinit	Explicit declaration is necessary. Call after the instance of the function block was copied (as during an online change). It reinitializes the new instance module.
FB_Exit	Explicit declaration is necessary. Call for each instance of the function block before a new download or a reset or during an online change for all shifted or deleted instances.
Properties	Provides Set and/or Get accessor methods.

See also

- *Chapter 1.4.1.19.10 “Methods 'FB_Init', 'FB_Reinit', and 'FB_Exit'” on page 748*
- *Chapter 1.4.1.20.2.18.8 “Object 'Property'” on page 897*
- *Chapter 1.4.1.20.2.18.7 “Object 'Interface Property'” on page 894*

Dialog 'Add Method'

Function: Defines a method below the selected POU when the dialog is closed.

Call: Menu bar: *“Project ➔ Add Object ➔ Method”*; context menu

Requirement: A program (PRG) or a function block (FUNCTION_BLOCK) is selected in the *“POUs”* view or the *“Devices”* view.

The interface of a method inserted below a basic function block is copied when a method with the same name is inserted below a derived function block.

“Name”	Example: meth_DoIt. The standard methods FB_Init and FB_Exit are offered in a list box if they are not already inserted below the POU. If it is a derived function block, then the list box also offers all of the methods of the basic function block.
“Return type”	Default data type or structured data type of return value Example: BOOL
“Implementation language”	Example: *“Structured Text (ST)”*
“Access specifier”	Controls access to data. ● *“PUBLIC”* or not specified: Access is not restricted. ● *“PRIVATE”*: Access is restricted to the program, function block, or GVL. The object is marked as (private) in the POU or device view. The declaration contains the keyword PRIVATE. ● *“PROTECTED”*: Access is restricted to the program, function block, or GVL with its derivations. The declaration contains the keyword PROTECTED. The object is marked as (protected) in the POU or device view. ● *“INTERNAL”*: Access to the method is restricted to the namespace (library). The object is marked as (internal) in the POU or device view. The declaration contains the keyword INTERNAL.
“Abstract”	☑: Identifies that the method does not have an implementation and the implementation is provided by the derived FB
“Add”	Adds a new method below the selected object.

Input support when generating inheriting POUs

When you doing object-oriented programming and using the inheritance (keyword `EXTENDS`) of POUs, you can get support as follows:

When you insert an action, a property, a method, or a transition below a POU derived from a base POU, the *"Add …"* dialog opens. Then the input field for the name extends to a list box. The list box contains a valid selection from the actions, properties, methods, or transitions available in the base POU. Now you can, for example, easily accept a method of the base POU and then adapt it to the derived function of the POU.

Methods and properties with the access modifier `PRIVATE` are not listed here because they are also not inherited. Methods and properties with the access modifier `PUBLIC` automatically get a blank access modifier field when accepting into the derived POU, which means the same thing functionally.

Example

Object 'Interface Method'

Symbol: 

This object is used for object-oriented programming.

The object *“Interface Method”* is added to an interface via the command *“Project ➔ Add Object”*.

If a method is inserted underneath an interface, you can add and instance only variable declarations (input, output and input/output variables) in this method.

You can only add program code to the method if a function block 'implements' the interface to which the method belongs. CODESYS then inserts the method underneath the function block.

See also

- *Chapter 1.4.1.20.2.18.4 “Object 'Interface'” on page 888*
- *Chapter 1.4.1.20.2.18.5 “Object 'Method'” on page 889*
- *Chapter 1.4.1.8.22.2 “Implementing interfaces” on page 312*

Object 'Interface Property'

Symbol: 

Interface properties are an extension of the IEC 61131-3 standard and a tool for object-oriented programming. An interface property declares the accessor methods `Get` and `Set` (no implementation code). Therefore, a function block that implements an interface also inherits their interface properties.

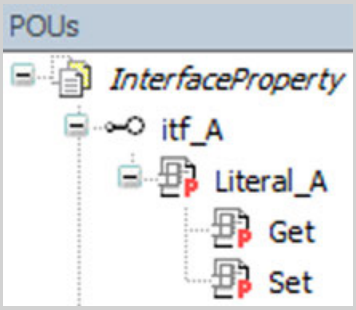
You can add an interface property to the device tree for an interface. Then an interface is extended with the accessor methods `Get` and `Set`. The `Get` accessor is for read access. The `Set` accessor is for write access. You can delete an unneeded accessor. Click *“Project ➔ Add Object ➔ Interface Property”* to add an accessor. The *“Add Interface Property”* dialog opens.

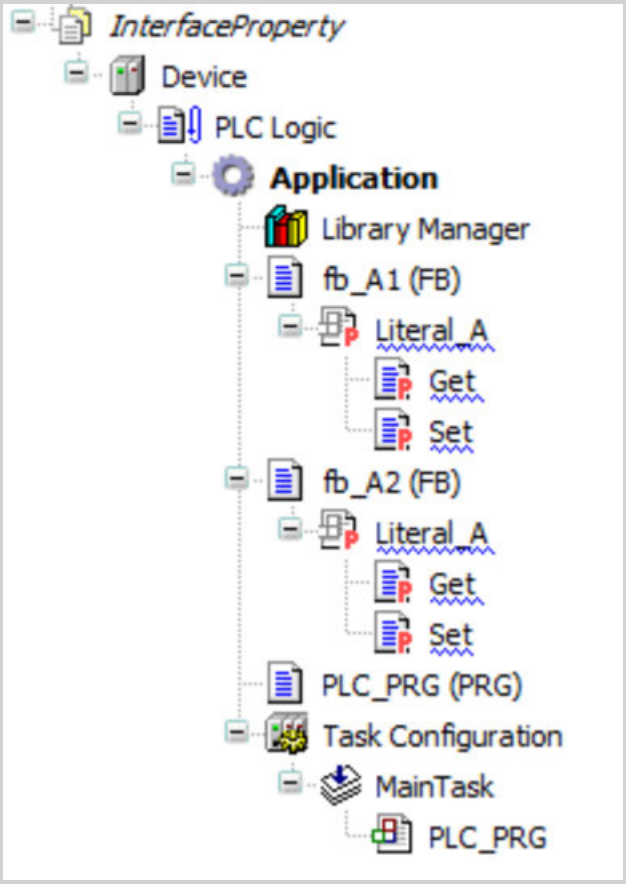
See also

- *Chapter 1.4.1.20.2.18.4 “Object 'Interface'” on page 888*
- *Chapter 1.4.1.20.2.18.8 “Object 'Property'” on page 897*

Example

Declaration and implementation of the interface property `Literal_A`





This interface `itf_A` has the property `Literal_A` with the accessor methods `Get` and `Set`.

The function blocks `fb_A1` and `fb_A2` implement the interface `itf_A` and therefore inherit its interface property. Each FB has its own implementation.

Interface `itf_A`

```
INTERFACE itf_A
VAR
END_VAR
PROPERTY Literal_A : STRING
```

FB `fb_A1`

```
FUNCTION_BLOCK fb_A1 IMPLEMENTS itf_A
VAR
    str_1 : STRING;
    str_2 : STRING;
    iCnt : INT;
END_VAR
iCnt := iCnt + 1;

str_1 := 'Function block A1';
```

Accessor fb_A1.Literal_A.Get

```
VAR
END_VAR
Literal_A := CONCAT (str_1,' and property.');
```

Accessor fb_A1.Literal_A.Set

```
VAR
END_VAR
str_2 := Literal_A;
```

FB fb_A2

```
FUNCTION_BLOCK fb_A2 IMPLEMENTS itf_A
VAR
    str_1 : STRING;
    str_2 : STRING;
    iCnt : INT;
END_VAR

iCnt := iCnt + 1;
str_1 := 'Function block A2';
```

Accessor fb_A2.Literal_A.Get

```
VAR
END_VAR
Literal_A := str_1;
```

Accessor fb_A2.Literal_A.Set

```
VAR
END_VAR
str_2 := Literal_A;
```

Program PLC_PRG

```
PROGRAM PLC_PRG
VAR
    iCnt : INT;
    my_1 : fb_A1;
    my_2 : fb_A2;
    strName_1 : STRING;
    strName_2: STRING;
END_VAR

iCnt := iCnt + 1;
my_1();
my_2();
strName_1:= my_1.Literal_A;
strName_2:= my_2.Literal_A;
my_1.Literal_A := 'Hello 1';
my_2.Literal_A := 'World 2';
```

This leads to the following monitoring of `PLC_PRG` when the application is in runtime mode:

Expression	Type	Value
iCnt	INT	-25848
my_1	fb_A1	
str_1	STRING	'Function block A1'
str_2	STRING	'Hello 1'
my_2	fb_A2	
str_1	STRING	'Function block A2'
str_2	STRING	'World 2'
iCnt	INT	-31303
strName_1	STRING	'Function block A1 and property.'
strName_2	STRING	'Function block A2'

Object 'Property'

Symbol:

Keyword: `PROPERTY`

Properties are an extension of the IEC 61131-3 standard and a tool for object-oriented programming.

Properties are used for data encapsulation because they allow for external access to data and act as filters at the same time. For this purpose, a property provides the accessor methods `Get` and `Set` which allows for read and write access to the data of the instance below the property.

You can add a property with accessor methods below a program, a function block, or a global variable list. Click *"Project ➔ Add Object ➔ Property"* to open the *"Add Property"* dialog.

> *You can add an interface property below an interface.*
>
> *When you copy a property that is inserted below a POU and add it below an interface, or if you move the property there, the included implementations are removed automatically.*

See also

- *Chapter 1.4.1.20.2.18.7 "Object 'Interface Property'" on page 894*

Dialog 'Add Property'

Function: Creates a new property below the selected POU when the dialog is closed.

Call: Menu bar: *"Project ➔ Add Object ➔ Property"*; context menu

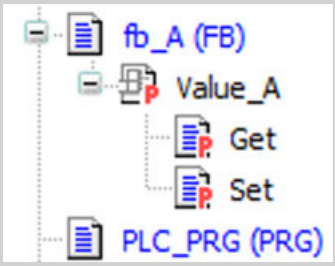
Requirement: A program (`PRG`), a function block (`FUNCTION_BLOCK`), or a global variable list (`GVL`) is selected in the *"POUs"* view or the *"Devices"* view.

"Name"	Name (identifier) of the property Example: `prop_iA`
"Return type"	Default type or structured type of return value Example: `INT`
"Implementation language"	Example: *"Structured Text (ST)"*

“Access specifier”	Controls access to data
“PUBLIC” or unspecified	Access is not restricted.
“PRIVATE”	Access is restricted to the program, function block, or GVL. The object is marked as `(private)` in the POU or device view. The declaration contains the keyword `PRIVATE`.
“PROTECTED”	Access is restricted to the program, function block, or GVL with its derivations. The object is marked as `(protected)` in the POU or device view. The declaration contains the keyword `PROTECTED`.
“INTERNAL”	Access is restricted to the namespace (library). The object is marked as `(internal)` in the POU or device view. The declaration contains the keyword `INTERNAL`.
“Abstract”	☑: Identifies that the property does not have an implementation and the implementation is provided by the derived FB
“Add”	Adds a new property be low the selected object and below that the accessor methods `Get` and `Set` Note: When you select a property, you can also add a previously removed accessor explicitly by clicking *“Add Object”*.

Editor 'Property' You can program the data access in the editor. The code can contain additional local variables. However, it must not contain any additional input variables or (as opposed to a function or method) output variables.

Example



Function block FB_A

```
FUNCTION_BLOCK FB_A
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    iA : INT;
END_VAR

iA := iA + 1;
```

Property `prop_iA`

```
PROPERTY PUBLIC prop_iA : INT
```

Accessor method FB_A.prop_iA. Get

```
prop_iA := iA;
```

Accessor method FB_A.prop_iA. Set

```
iA := prop_iA;
```

```
PROGRAM PLC_PRG
VAR
    fbA : FB_A;
    iVar: INT;
END_VAR

fbA();
IF fbA.prop_iA > 500 THEN
    fbA.prop_iA := 0;
END_IF
iVar := fbA.prop_iA;
```

`Get` and `Set` accessors

The call of the `Set` accessor is written to the property. Then it is used in the same way as an input parameter. When the Get accessor is called, the property is read. It is used in the same way as an output parameter. Access is restricted in each case by means of access modifiers (qualifiers). As a result, the objects are identified accordingly.

When a property is accessed as read only or write only, you can delete the unneeded accessors.

You can add accessors explicitly by selecting a property and clicking *“Add Object”*. A dialog opens, either *“Add Get accessor”* or *“Add Set accessor”*. There you can set the implementation language and the access.

Table 81: Dialog “Add Get (Set) Accessor”

“Implementation language”	Example: *“Structured Text (ST)”*

"Access specifier"	Qualifier for the declaration part
`PUBLIC` or unspecified	Access is not restricted.
`PRIVATE`	Access is restricted to the program, function block, or GVL. The object is marked as `(private)` in the POU or device view. The declaration contains the keyword.
`PROTECTED`	Access to the property is restricted to the program, function block, or GVL and its derivations. The declaration contains the keyword. The object is marked as `(protected)` in the POU or device view.
`INTERNAL`	Access to the method is restricted to the namespace (the library). The object is marked as `(internal)` in the POU or device view. The declaration contains the keyword.
"Add"	Adds the accessor methods `Get` or `Set` below the selected property.

Monitoring of properties in online mode

The following pragmas are provided for the monitoring of properties in online mode. You insert them at the top position of the property definition:

- `{attribute 'monitoring' := 'variable'}`
  Each time the property is accessed, CODESYS saves the actual value to a variable and displays the value of this variable. This value can become outdated if no more access to the property takes place in the code.
- `{attribute 'monitoring' := 'call'}`
  Each time the value is displayed, CODESYS calls the code of the `Get` accessor. If this code contains a side effect, then the monitoring executes the side effect.

You can monitor a property with the help of the following functions.

- Inline monitoring
  Requirement: The *"Enable inline monitoring"* option is selected in the *"Text Editor"* category of the *"Options"* dialog.
- Watch List

Input support when generating inheriting POUs

When you doing object-oriented programming and using the inheritance (keyword `EXTENDS`) of POUs, you can get support as follows:

When you insert an action, a property, a method, or a transition below a POU derived from a base POU, the *"Add …"* dialog opens. Then the input field for the name extends to a list box. The list box contains a valid selection from the actions, properties, methods, or transitions available in the base POU. Now you can, for example, easily accept a method of the base POU and then adapt it to the derived function of the POU.

Methods and properties with the access modifier `PRIVATE` are not listed here because they are also not inherited. Methods and properties with the access modifier `PUBLIC` automatically get a blank access modifier field when accepting into the derived POU, which means the same thing functionally.

Example

- *Chapter 1.4.1.20.2.18.10 “Object 'Transition'” on page 903*

Object 'Action'

Symbol:

Implement more program code in an action. You can implement this program code as the base implementation in another language. The base implementation is a function block or a program where you inserted the action.

An action does not have its own declaration and it works with the data from the base implementation. This means that the action uses the input and output variables and the local variables from its base implementation.

Add an *“Action”* to a function block or program by clicking *“Project ➔ Add Object ➔ Action”*.

Table 82: “Add Action”

“Name”	Name of the action
“Implementation language”	List box of implementation language

Input support when generating inheriting POUs

When you doing object-oriented programming and using the inheritance (keyword `EXTENDS`) of POUs, you can get support as follows:

When you insert an action, a property, a method, or a transition below a POU derived from a base POU, the *“Add …”* dialog opens. Then the input field for the name extends to a list box. The list box contains a valid selection from the actions, properties, methods, or transitions available in the base POU. Now you can, for example, easily accept a method of the base POU and then adapt it to the derived function of the POU.

Methods and properties with the access modifier `PRIVATE` are not listed here because they are also not inherited. Methods and properties with the access modifier `PUBLIC` automatically get a blank access modifier field when accepting into the derived POU, which means the same thing functionally.

Calling an action

Syntax:

`<program>.<action>` or `<FB instance>.<action>`

To call an action from only within the base implementation, you only have to provide the action name.

Examples

Calling a *"Reset"* action from another POU The call is not executed from the base implementation.

Declaration:

```
PROGRAM PLC_PRG
VAR
    Inst : Counter;
END_VAR
```

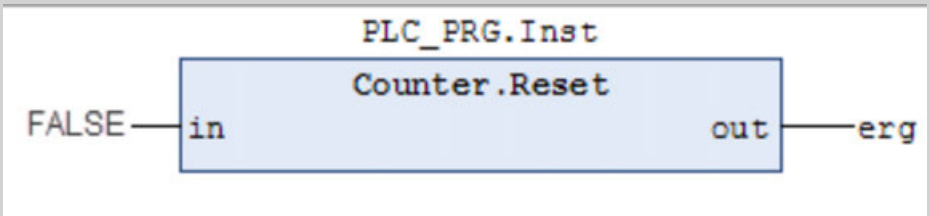
Calling a *"Reset"* action from an IL POU

```
CAL Inst.Reset(In := FALSE)
LD Inst.Out
ST ERG
```

Calling a *"Reset"* action from an ST POU

```
Inst.Reset(In := FALSE);
Erg := Inst.out;
```

Calling a *"Reset"* action from an FBD POU



Actions are used frequently in the SFC implementation language.

Object 'POUs for Implicit Checks'

You can add these special POUs to an application to equip them with implicit monitoring functions. At runtime, these functions check the limits of arrays or subrange types, the validity of pointer addresses, and division by zero. Please note: This option can be disabled for devices that are already equipped with these kinds of monitoring blocks by a special implicit library.

The command *“Add Object ➔ POU for Implicit Checks”* is used for adding to the application. The command opens the *“Add POU for Implicit Checks”* dialog where you can select a monitoring function type (see table below). Depending on the monitoring function, you have to adapt the implementation code or create it yourself from scratch.

To prevent multiple inclusions, monitoring functions that have already been inserted are disabled in the *“Add POU for Implicit Checks”* dialog.

NOTICE!

To get the feature for monitoring functions, do not edit their declaration part. However, you are permitted to add local variables.

After removing an implicit monitoring function (example: `Check Bounds`) from the project, only a download is possible, not an online change. A corresponding message is issued.

By default, CODESYS does not run implicit checks for function blocks from libraries used in the application. However, you can extend the check to the libraries by opening the “Properties” dialog of the application and specifying the compiler definition `checks_in_libs` in the “Compiler-Defines” field in the “Build” tab. This definition affects implementation libraries (`*.library`) only, not protected libraries (`*.compiled-library`).

You can use the "no_check" attribute to deactivate the check for special POUs in the project.

Table 83: “Available Functions”

Monitoring function	Type
“Check Bounds”	*“Bound Checks”* Appropriate handling of bound violations; such handling includes setting flags or changing field indices.
“CheckDivDInt”	*“Division checks”*: Monitors the divisor value to avoid division by zero.
“CheckDivLInt”	
“CheckDivReal”	
“CheckDivLReal”	
“CheckRangeSigned”	*“Range checks”*: Monitors the range limit of a subrange type in runtime mode. Valid for data types `DINT`/`UDINT`.
“CheckRangeUnsigned”	
“CheckLRangeSigned”	*“L-range checks”*: Monitors the range limit of a subrange type in runtime mode. Valid for data types `LINT`/`ULINT`.
“CheckLRangeUnsigned”	
“CheckPointer”	*“Pointer checks”* You are responsible for filling in this function completely with implementation code. Refer to the help page for "POU 'CheckPointer'". The function should monitor whether the passed pointer reference a valid memory address, and whether the orientation of the referenced memory area matches the variable type to which the pointer refers. If both conditions are fulfilled, then the pointer is returned. If not, then `CheckPointer` should complete an appropriate error handling. `CheckPointer` monitors the same way as variables of type `REFERENCE TO`.

POU 'CheckBounds'

Functions for Bound Checks: CheckBounds

The task of this monitoring function is to handle bound violations appropriately. Examples of reactions to violations include setting error flags and changing the value of the array index. The check is performed only for one variable array index. An incorrect constant array index causes a compiler error. CODESYS calls the function implicitly when values are assigned to an `ARRAY` variable.

After inserting the function, you receive automatically generated code in the declaration and implementation parts. See below.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration part. However, you are permitted to add local variables.

Declaration part

```
// Automatically generated code: DO NOT EDIT
FUNCTION CheckBounds : DINT
VAR_INPUT
      index, lower, upper: DINT;
END_VAR
```

Implementation

```
// This automatically generated code is a suggested implementation.
IF  index < lower THEN
      CheckBounds := lower;
ELSIF  index > upper THEN
      CheckBounds := upper;
ELSE
      CheckBounds := index;
END_IF

(* It is also possible to set a breakpoint, log messages or e.g. to
halt on an exception:
Add CmpApp.library, SysExcept.library and SysTypes2_Itf as newest.
Declaration:
VAR
    _pApp : POINTER TO CmpApp.APPLICATION;
    _result   : SysTypes.RTS_IEC_RESULT;
END_VAR

Implementation:
_pApp := AppGetCurrent(pResult:=_result);
IF  index < lower THEN
        CheckBounds := lower;
        IF _pApp <> 0 THEN
                AppGenerateException(pApp:=_pApp,
ulException:=RtsExceptions.RTSEXCPT_ARRAYBOUNDS);
        END_IF
ELSIF  index > upper THEN
        CheckBounds := upper;
        IF _pApp <> 0 THEN
                AppGenerateException(pApp:=_pApp,
```

```
ulException:=RtsExceptions.RTSEXCPT_ARRAYBOUNDS);
        END_IF
ELSE
        CheckBounds := index;
END_IF
*)
```

When the *"CheckBounds"* function is called, it receives the following input parameters:

- `index`: Index of the array element
- `lower`: Lower limit of the array range
- `upper`: Upper limit of the array range

The return value is the index of the array element, as long as it is within a valid range. If not, then the CODESYS returns either the upper or lower limit, depending on which threshold was violated.

Example: Correction of the access to an array outside the defined array bounds

In the sample program below, the index falls short of the defined lower limit of the `a` array.

```
PROGRAM PLC_PRG
VAR
 a: ARRAY[0..7] OF BOOL;
    b: INT:=10;
END_VAR

a[b]:=TRUE;
```

In this example, the `CheckBounds` function causes `a` to change the upper limit of the array range index to `10`. The value `TRUE` is assigned then to the element `a[7]`. In this way, the function corrects array access outside of the valid array range.

Example: Output of an exception when array limits are violated.

Add the following libraries in the library manager of the application:

- `CmpApp.library` and `SysExcept.library` as placeholder libraries
- `SysTypes2_Itfs.library` with *"Newest version always"*

Add a *"CheckBounds"* object below the application and modify the specified code as shown below.

Declaration part

```
FUNCTION CheckBounds : DINT
VAR_INPUT
    index, lower, upper: DINT;
END_VAR
VAR
    _pApp : POINTER TO CmpApp.APPLICATION;
    _Result   : ISystypes2.RTS_IEC_RESULT;
END_VAR
```

Implementation part

```
// This automatically generated code is a suggested implementation.
_pApp := AppGetCurrent(pResult := _Result);
IF  index < lower THEN
    CheckBounds := lower;
    IF _pApp <> 0 THEN
        AppGenerateException(pApp := _pApp, ulException :=
RtsExceptions.RTSEXCPT_ARRAYBOUNDS);
    END_IF
ELSIF  index > upper THEN
    CheckBounds := upper;
    IF _pApp <> 0 THEN
       AppGenerateException(pApp:=_pApp,
ulException:=RtsExceptions.RTSEXCPT_ARRAYBOUNDS);
    END_IF
ELSE
    CheckBounds := index;
END_IF
```

Program a *"MAIN_PRG"* object below the application with the contents shown below.

```
PROGRAM MAIN_PRG
VAR
    xInit    : BOOL;
    arData   : ARRAY[0..7] OF BYTE;
    i        : INT;
    dwAdr       : DWORD;
END_VAR

IF NOT xInit THEN
    // Required for CheckBounds
    xInit  := TRUE;
END_IF

// Set i to a value > 7 or < 0
// Generates an exception in CheckBounds, user-defined
arData[i] := 11;
```

When you load and start this application, an exception will be thrown when array bounds are violated. Processing stops in *"CheckBounds"* so that the type of error can be detected.

See also

POU 'CheckDivInt'

Functions for preventing division by zero: CheckDivInt, CheckDivLint, CheckDivReal, and CheckDivLReal

To prevent division by zero, you can use the functions `CheckDivInt`, `CheckDivLint`, `CheckDivReal`, and `CheckDivLReal`. If you include these functions in the application, then they are called before each division operation in the code.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

The default implementation of CheckDivReal:

Declaration section:

```
// This is automatically generated code: DO NOT EDIT
FUNCTION CheckDivReal : REAL
VAR_INPUT
    divisor:REAL;
END_VAR
```

Implementation section:

```
// This automatically generated code is a suggested implementation.
IF divisor = 0 THEN
    CheckDivReal:=1;
ELSE
    CheckDivReal:=divisor;
END_IF;
```

The `DIV` operator uses the output of the `CheckDivReal` function as a divisor. In the sample program below, `CheckDivReal` prevents division by `0` by changing the implicit value of the divisor `d` from "0" to `1` before the division operation is executed. Therefore, the division result is `799`.

```
PROGRAM PLC_PRG
VAR
 erg:REAL;
 v1:REAL:=799;
 d:REAL:=0;
END_VAR
erg:= v1 / d;
```

See also

- *Chapter 1.4.1.8.21 “Using POUs for implicit checks” on page 309*

POU 'CheckDivLInt'

Functions for preventing division by zero: CheckDivInt, CheckDivLint, CheckDivReal, and CheckDivLReal

To prevent division by zero, you can use the functions `CheckDivInt`, `CheckDivLint`, `CheckDivReal`, and `CheckDivLReal`. If you include these functions in the application, then they are called before each division operation in the code.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

The default implementation of CheckDivReal:

Declaration section:

```
// This is automatically generated code: DO NOT EDIT
FUNCTION CheckDivReal : REAL
VAR_INPUT
    divisor:REAL;
END_VAR
```

Implementation section:

```
// This automatically generated code is a suggested implementation.
IF divisor = 0 THEN
    CheckDivReal:=1;
ELSE
    CheckDivReal:=divisor;
END_IF;
```

The `DIV` operator uses the output of the `CheckDivReal` function as a divisor. In the sample program below, `CheckDivReal` prevents division by `0` by changing the implicit value of the divisor `d` from "0" to `1` before the division operation is executed. Therefore, the division result is `799`.

```
PROGRAM PLC_PRG
VAR
 erg:REAL;
 v1:REAL:=799;
 d:REAL:=0;
END_VAR
erg:= v1 / d;
```

POU 'CheckDivReal'

Functions for preventing division by zero: `CheckDivInt`, `CheckDivLint`, `CheckDivReal`, and `CheckDivLReal`

To prevent division by zero, you can use the functions `CheckDivInt`, `CheckDivLint`, `CheckDivReal`, and `CheckDivLReal`. If you include these functions in the application, then they are called before each division operation in the code.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

The default implementation of CheckDiv-Real:

Declaration section:

```
// This is automatically generated code: DO NOT EDIT
FUNCTION CheckDivReal : REAL
VAR_INPUT
    divisor:REAL;
END_VAR
```

Implementation section:

```
// This automatically generated code is a suggested implementation.
IF divisor = 0 THEN
    CheckDivReal:=1;
ELSE
    CheckDivReal:=divisor;
END_IF;
```

The `DIV` operator uses the output of the `CheckDivReal` function as a divisor. In the sample program below, `CheckDivReal` prevents division by `0` by changing the implicit value of the divisor `d` from "0" to `1` before the division operation is executed. Therefore, the division result is `799`.

```
PROGRAM PLC_PRG
VAR
 erg:REAL;
 v1:REAL:=799;
 d:REAL:=0;
END_VAR
erg:= v1 / d;
```

POU 'CheckDivLReal'

Functions for preventing division by zero: `CheckDivInt`, `CheckDivLint`, `CheckDivReal`, and `CheckDivLReal`

To prevent division by zero, you can use the functions `CheckDivInt`, `CheckDivLint`, `CheckDivReal`, and `CheckDivLReal`. If you include these functions in the application, then they are called before each division operation in the code.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

The default implementation of CheckDiv-Real:

Declaration section:

```
// This is automatically generated code: DO NOT EDIT
FUNCTION CheckDivReal : REAL
VAR_INPUT
    divisor:REAL;
END_VAR
```

Implementation section:

```
// This automatically generated code is a suggested implementation.
IF divisor = 0 THEN
    CheckDivReal:=1;
ELSE
    CheckDivReal:=divisor;
END_IF;
```

The `DIV` operator uses the output of the `CheckDivReal` function as a divisor. In the sample program below, `CheckDivReal` prevents division by `0` by changing the implicit value of the divisor `d` from "0" to `1` before the division operation is executed. Therefore, the division result is `799`.

```
PROGRAM PLC_PRG
VAR
 erg:REAL;
 v1:REAL:=799;
 d:REAL:=0;
END_VAR
erg:= v1 / d;
```

POU 'CheckRangeSigned'

Function for monitoring the range limits of a subrange type of type DINT.

This monitoring function is responsible for the appropriate handling violations to range limits. Examples of reactions to violations include setting error flags and changing values. The functions are called implicitly when a value is assigned to a subrange type variable.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

When the function is called, it receives the following input parameters:

- `value`: Value that should be assigned to the subrange type variables
- `lower`: Lower range limit
- `upper`: Upper range limit

The return value is the assignment value as long as it is within the valid range. If not, then either the upper or lower limit is returned, depending on which threshold was violated.

For example, the assignment `i := 10*y` is replaced implicitly by `i := CheckRangeSigned(10*y, -4095, 4095);`

If `y` is "1000", then "10*1000=10000" is not assigned to `i` like in the original code. Instead, the upper range limit of "4095" is assigned.

The same is true for `CheckRangeUnsigned` function.

NOTICE!
If functions are not available, then the subrange is not checked for the respective variables at runtime. In this case, you can assign any value between -2147483648 and +2147483648 (or between 0 and 4294967295) to a variable of subrange type DINT/UDINT. You can assign any value between -9223372036854775808 and +9223372036854775807 (or between 0 and 18446744073709551615) to a variable of a subrange type LINT/ULINT.

CAUTION!
Linking area monitoring functions can lead to endless loops. For example, an endless loop can occur if the counter variable of a FOR loop is a subrange type and the counting range for the loop exits the defined subrange.

Example of an endless loop:

```
VAR
    ui : UINT (0..10000);
 ...
END_VAR

FOR ui:=0 TO 10000 DO
    ...
END_FOR
```

The program never exits the FOR loop because the `CheckRangeSigned` monitoring function prevents `ui` from being set to a value greater than 10000.

Example for `CheckRangeSigned`

The assignment of a value to a DINT variable of a signed subrange type is a condition for automatically calling the `CheckRangeSigned`. This function restricts the assignment value to the subrange as defined in the variables declaration. The default implementation of the function in ST is as follows:

Declaration section:

```
// This is automatically generated code: DO NOT EDIT
FUNCTION CheckRangeSigned : DINT
VAR_INPUT
    value, lower, upper: DINT;
END_VAR
```

Implementation:

```
// This automatically generated code is a suggested implementation.
IF (value < lower) THEN
    CheckRangeSigned := lower;
    ELSEIF(value > upper) THEN
    CheckRangeSigned := upper;
ELSE
    CheckRangeSigned := value;
END_VAR
```

See also

- *Chapter 1.4.1.8.21 “Using POUs for implicit checks” on page 309*

POU 'CheckLRangeSigned'

Function for monitoring the range limits of a subrange type of type LINT.

For an implementation example of range monitoring, refer to the help page for the `CheckRangeSigned` function.

This monitoring function is responsible for the appropriate handling violations to range limits. Examples of reactions to violations include setting error flags and changing values. The functions are called implicitly when a value is assigned to a subrange type variable.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

When the function is called, it receives the following input parameters:

- `value`: Value that should be assigned to the subrange type variables
- `lower`: Lower range limit
- `upper`: Upper range limit

The return value is the assignment value as long as it is within the valid range. If not, then either the upper or lower limit is returned, depending on which threshold was violated.

For example, the assignment `i := 10*y` is replaced implicitly by `i := CheckRangeSigned(10*y, -4095, 4095);`

If `y` is "1000", then "10*1000=10000" is not assigned to `i` like in the original code. Instead, the upper range limit of "4095" is assigned.

The same is true for `CheckRangeUnsigned` function.

NOTICE!
If functions are not available, then the subrange is not checked for the respective variables at runtime. In this case, you can assign any value between -2147483648 and +2147483648 (or between 0 and 4294967295) to a variable of subrange type DINT/UDINT. You can assign any value between -9223372036854775808 and +9223372036854775807 (or between 0 and 18446744073709551615) to a variable of a subrange type LINT/ULINT.

CAUTION!
Linking area monitoring functions can lead to endless loops. For example, an endless loop can occur if the counter variable of a FOR loop is a subrange type and the counting range for the loop exits the defined subrange.

Example of an endless loop:

```
VAR
    ui : UINT (0..10000);
 ...
END_VAR

FOR ui:=0 TO 10000 DO
    ...
END_FOR
```

The program never exits the FOR loop because the `CheckRangeSigned` monitoring function prevents `ui` from being set to a value greater than 10000.

- *Chapter 1.4.1.20.2.19.6 “POU 'CheckRangeSigned'” on page 912*

POU 'CheckRangeUnsigned'

Function for monitoring the range limits of a subrange type of type UDINT.

For an implementation example of range monitoring, refer to the help page for the `CheckRangeSigned` function.

This monitoring function is responsible for the appropriate handling violations to range limits. Examples of reactions to violations include setting error flags and changing values. The functions are called implicitly when a value is assigned to a subrange type variable.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

When the function is called, it receives the following input parameters:

- `value`: Value that should be assigned to the subrange type variables
- `lower`: Lower range limit
- `upper`: Upper range limit

The return value is the assignment value as long as it is within the valid range. If not, then either the upper or lower limit is returned, depending on which threshold was violated.

For example, the assignment `i := 10*y` is replaced implicitly by `i := CheckRangeSigned(10*y, -4095, 4095);`

If `y` is "1000", then "10*1000=10000" is not assigned to `i` like in the original code. Instead, the upper range limit of "4095" is assigned.

The same is true for `CheckRangeUnsigned` function.

NOTICE!
If functions are not available, then the subrange is not checked for the respective variables at runtime. In this case, you can assign any value between -2147483648 and +2147483648 (or between 0 and 4294967295) to a variable of subrange type DINT/UDINT. You can assign any value between -9223372036854775808 and +9223372036854775807 (or between 0 and 18446744073709551615) to a variable of a subrange type LINT/ULINT.

CAUTION!
Linking area monitoring functions can lead to endless loops. For example, an endless loop can occur if the counter variable of a FOR loop is a subrange type and the counting range for the loop exits the defined subrange.

Example of an endless loop:

```
VAR
    ui : UINT (0..10000);
 ...
END_VAR

FOR ui:=0 TO 10000 DO
    ...
END_FOR
```

The program never exits the FOR loop because the `CheckRangeSigned` monitoring function prevents `ui` from being set to a value greater than 10000.

POU 'CheckLRangeUnsigned'

Function for monitoring the range limits of a subrange type of type ULINT.

For an implementation example of range monitoring, refer to the help page for the `CheckRangeSigned` function.

This monitoring function is responsible for the appropriate handling violations to range limits. Examples of reactions to violations include setting error flags and changing values. The functions are called implicitly when a value is assigned to a subrange type variable.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

When the function is called, it receives the following input parameters:

- `value`: Value that should be assigned to the subrange type variables
- `lower`: Lower range limit
- `upper`: Upper range limit

The return value is the assignment value as long as it is within the valid range. If not, then either the upper or lower limit is returned, depending on which threshold was violated.

For example, the assignment `i := 10*y` is replaced implicitly by `i := CheckRangeSigned(10*y, -4095, 4095);`

If `y` is "1000", then "10*1000=10000" is not assigned to `i` like in the original code. Instead, the upper range limit of "4095" is assigned.

The same is true for `CheckRangeUnsigned` function.

NOTICE!
If functions are not available, then the subrange is not checked for the respective variables at runtime. In this case, you can assign any value between -2147483648 and +2147483648 (or between 0 and 4294967295) to a variable of subrange type DINT/UDINT. You can assign any value between -9223372036854775808 and +9223372036854775807 (or between 0 and 18446744073709551615) to a variable of a subrange type LINT/ULINT.

CAUTION!
Linking area monitoring functions can lead to endless loops. For example, an endless loop can occur if the counter variable of a FOR loop is a subrange type and the counting range for the loop exits the defined subrange.

Example of an endless loop:

```
VAR
    ui : UINT (0..10000);
 ...
END_VAR

FOR ui:=0 TO 10000 DO
    ...
END_FOR
```

The program never exits the FOR loop because the `CheckRangeSigned` monitoring function prevents `ui` from being set to a value greater than 10000.

POU 'CheckPointer'

Monitoring function for pointers (Checkpointer)

Use this function to monitor the memory access of pointers in runtime mode. As opposed to other monitoring functions, a standard suggestion does not exist for the implementation of `CheckPointer`. You must define an implementation according to your own requirements.

The `CheckPointer` function should check whether the returned pointer references a valid memory address; monitors whether the orientation of the referenced memory range matches the variable type that the pointer refers to. If both conditions are fulfilled, then the pointer is returned. If not, then the function should complete an appropriate error handling.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

NOTICE!
An implicit monitoring function call does not occur for THIS pointer and SUPER pointer.

NOTICE!
For complier version 3.5.7.40 and later, the implicit check function *"Checkpointer"* also acts on `REFERENCE` variables in the same way as on pointer variables.

Model

Declaration:

```
// Automatically generated code: DO NOT EDIT
FUNCTION CheckPointer : POINTER TO BYTE
VAR_INPUT
    ptToTest : POINTER TO BYTE;
    iSize : DINT;
    iGran : DINT;
    bWrite: BOOL;
END_VAR
```

Implementation: (incomplete)

```
// Not a standard implementation. Please add your own code here.
CheckPointer := ptToTest;
```

When the function is called, CODESYS provides the following input parameters:

- `ptToTest`: Target address of the pointer
- `iSize`: Size of the referenced variable; the data type of `iSize` must be compatible with `INT` and cover the dimensional scope of the variables.
- `iGran`: Granularity of the referenced size; this is the largest non-structured data type contained in the referenced variables; the data type of `iGran` must be compatible with `INT`
- `bWrite`: Access type (`TRUE` = write access, `FALSE` = read access); the data type of `bWrite` must be `BOOL`

When the result of the check is positive, the unchanged pointer is returned (`ptToTest`).

Object 'Project Settings'

Symbol: 

Function: This object contains the configuration of the project.

Call:

- *"Project ➔ Project Settings"*
- Double-click on the object in the device tree

CODESYS saves the project settings directly in the project. If, for example, you transfer a project to another system, the *"Project Settings"* object is also transferred with it without a project archive being required.

The project settings are valid project-wide and offer setting possibilities for various categories such as *"AS"* or *"Users and Groups"*. The available categories vary, depending on which software packages you have installed via the package manager.

- *Chapter 1.4.1.20.4.11.10 “Dialog 'Project Settings' - 'Visualization Profile'” on page 1181*

Object 'Project Information'

Symbol: 

Function: The object contains the properties, meta-information, and project information. With this, you can check the authorship and integrity of the project.

Call

- Double-click the object in the device tree
- Menu bar: *“Project ➔ Project Information”*

Requirement: CODESYS creates the object when you click *“Project ➔ Project Information”*, and the dialog opens.

CODESYS saves the project information directly in the project. For example, if you transfer a project to another system, then the *“Project Information”* object is also transferred. You do not need a project archive.

Tab 'File'

The tab displays the properties of the project file and their attributes. You cannot edit these attributes. They correspond to the file properties of Windows Explorer.

Tab 'Summary'

The tab contains general information and meta-information of the project file. CODESYS uses this information to create keys on the *“Properties”* tab. For example, if the name `Company_A` is specified in *“Company”*, then the `Company` key with the value `Company_A` is provided on the *“Properties”* tab.

NOTICE!
If you save your project as a library project, then you should pay attention to the guidelines for library developers (Library Development Summary).

For a library project, a *“Company”*, a *“Title”*, and a *“Version”* must be specified to install the library.	
“Company”	Name of the company (example: `Company_A`).
“Title”	Title of the project (example `Automation_A`).
“Version”	Version of the project (example: `0.0.0.1`).
“Released”	 : Activates protection from modification. Result: If you edit the project now, then a dialog prompt opens to confirm whether you really want to change the project. If you reply to this prompt one time by clicking *“Yes”*, then no additional prompts appear for more editing actions.

"Categories"	Categories of the library project, according to which you can sort in the *"Library Repository"* dialog. If no category is specified, then the category *"Other"* is assigned to the library. The categories originate from one or more external description files in XML format. However, they can also originate from a library project that has already been created. Requirement: The project is a library project. ...: The *"Library Categories"* dialog opens where you can add library categories.
"Default namespace"	If you do not define a standard namespace here, then the name of the library file is applied automatically as the namespace.
"Author"	Author of the project (example: `Arnold Best`).
"Description"	Example: `For internal use only`

- *Chapter 1.4.1.20.3.1.7 "Command 'Save Project as Compiled Library'" on page 960*
- *Chapter 1.4.1.16.1 "Information for Library Developers" on page 449*

Table 84: Dialog "Library Categories"

List of categories	List of the categories that are assigned to the library project. They can originate from several sources. After you specify all desired categories, click *"OK"* to confirm.
Button *"Add"*	The *"From Description File"* and *"From Other Library"* commands appear.
Button *"Remove"*	CODESYS removes the selected category.
Command *"From Description File"*	The *"Select Description File"* dialog opens for you select a description file (`*.libcat.xml`). The file contains command categories. When you click *"Open"*, CODESYS accepts the categories.
Command *"From Other Library"*	The *"Select Library"* dialog opens, where you select a library with command categories to be accepted. When you click *"Open"*, CODESYS accepts the categories.
Button *"OK"*	CODESYS provides the categories as project information and displays it in the *"Library Categories"* field.

See also

- *Chapter 1.4.4.1 "Guidelines for creating libraries" on page 1249*
- *Chapter 1.4.1.20.3.8.5 "Command 'Library Repository'" on page 1061*

Tab 'Properties' On this tab, you can define keys that you can control externally from user-specific programs.

NOTICE!
If you have opened a library project, then note the description of the relevant keys in the guidelines for library developers (Library Development Summary).

If you have opened a symbol library as a project, then the key `VisuSymbolLibrary = TRUE` must be defined. It identifies the library as a symbol library.

"Key"	Name of the key. Specify any string of text for the new key, or select an existing key from the *"Properties"* table.
"Type"	Data type of the key. Possible types: *"Text"*, *"Date"*, *"Number"*, *"Boolean"*, *"Version"*.

"Value"	Value of the key in permitted format ● *"Text"*: Any character string ● *"Date"*: Example: `Friday, January 1, 2016 00:00:00`. Minimum entry for the date: `1.1` ● *"Number"*: Integer in Integer32 format with or without a sign (example: `-32500`). ● *"Boolean"*: `True` or `False`, capitalization irrelevant. ● *"Version"*: Examples: `1.1`, `1.0.1.0`, maximum four figures.
"Add"	Adds the new defined key to the *"Properties"* table.
"Modify"	Saves the change made for the key selected in the *"Properties"* table.
"Remove"	Removes the key selected in the *"Properties"* table.

"Properties"	List of the properties that are defined as keys. CODESYS creates keys automatically for the information in the *"Summary"* tab. Click a key to edit it in the input fields above the list.

See also

- *Chapter 1.4.4.1 "Guidelines for creating libraries" on page 1249*
- *Using the Symbol Library in the Visualization*
- *Chapter 1.4.1.20.4.10.17 "Dialog 'Properties' - 'Image Pool'" on page 1168*

Tab 'Statistics' The dialog provides statistical information about the number of objects of the individual type or use in the project.

Tab 'Licensing' The dialog is for the license protection of libraries.

CAUTION!
You can protect only compiled libraries in this way.

Table 85: "Variables"

"Activate dongle licensing"	☑: The library requires a dongle with a license to use it.
"Firm code"	License information that must be supplied from the dongle for using the library later.
"Product code"	
"Activation URL"	
"Activation mail"	

See also

- *Chapter 1.4.4.1 "Guidelines for creating libraries" on page 1249*

Tab 'Signing' This tab is displayed only for existing libraries whose signing has been created with this tab. This tab is no longer visible for newly generated libraries.

When a certificate-signed library is created (possible as of CODESYS V3 SP15) and library compatibility with CODESYS < V3 SP15 is not set, the settings on this tab are disabled. In this case, the signing is done by means of a certificate that has to be assigned to the user profile in the security screen.

One method, which is not recommended but may be necessary in some case for compatibility with versions < V3 SP15, is the less secure signing of a library by means of a vendor-specific, one-time key in this dialog. Requirement: This key is available as a private key file (`*.libpk`) with an associated token. The user of the library also has to obtain this key in order to be able to check whether the last signing was actually performed by the library vendor.

"Activate signing"	☑: CODESYS signs the library project with a single-use, manufacturer-specific key.
"Private key file"	Location of the private key file `*.libpk` (example: `D:\for lib developers only\mycomp_libkey.libpk`).
"Public key token"	Example: `427A5701DA3CF3CF` Requirement: A private key file is specified, and CODESYS has read and entered the token.
"Create Private Key File"	CODESYS creates a new private key file.

- *Chapter 1.4.1.20.3.3.18 "Command 'Security Screen'" on page 995*

Options for creating blocks for accessing project information

"Automatically generate 'Project Information' POUs"	Note: The functions that are created with this option can be used only if the runtime supports the `WSTRING` data type. If this is not the case, then you can use the functions that were created automatically for the with the individual items of the project information, at least in the application for accessing properties. These functions are not registered in the runtime. ☑: CODESYS creates POUs of the `FUNCTION` type in the *"POUs"* view, allowing programmatic access to the project properties in the application. The function blocks `GetCompany`, `GetTitle` and `GetVersion` are created for the properties *"Company"*, *"Title"* and *"Version"*. The following function blocks are available for user-defined properties: • `GetBooleanProperty`: BOOL (TRUE/FALSE) • `GetNumberProperty`: DINT (numeric value) • `GetTextProperty`: WSTRING (character string) • `GetTextProperty2`: POINTER TO WSTRING (unlimited length) • `GetVersionProperty`: VERSION (version number as character string) Note: Do not activate this option for standard libraries, because this can cause problems on smaller systems due to the additional memory requirements. Note: If a library also contains this project information POU, then you should use the operator `__POOL` to make sure that this POU is accessed.
"Automatically generate 'Library Information' POUs"	☑: CODESYS creates POUs of the `FUNCTION` type in the *"POUs"* view, allowing programmatic access to the project properties in the application. For the *"Version"* and *"Released"* properties, the following functions are created: `GetLibVersion` (version number as character string), `GetLibVersionNumber` (version number as numeric value), and `IsLibReleased` (TRUE/FALSE). Note: These functions are not registered in the runtime. The option is available as an alternative solution is the runtime does not support the `WSTRING` data type, therefore not permitting you to use the functions created with the *"Automatically generate 'Project Information' POUs"* option.

- *Chapter 1.4.1.19.3.73 “Operator '__POOL'” on page 630*

Object 'Recipe Manager'

Tab 'Storage' The recipe manager provides functions for maintaining user-defined variable lists, known as recipe definitions. The recipe definitions can be stored in recipe files on the PLC.

“Storage Type”	*“Textual”*: CODESYS saves the recipe in a readable Format with the configured columns and delimiters. *“Binary”*: CODESYS saves the recipe in a non-readable binary format. This format requires less storage space. Note: You can read binary recipes again only if you have not changed the variable lists.
“File path”	`<directory name>\` Example: `AllRecipes\` Path on the runtime system Notes: ● The path has to end with a backslash ("\"). ● The path is usually a relative path on the target system in the directory of the runtime files (`PlcLogic`). ● Access to paths outside of the directory `PlcLogic` is not permitted on every controller. An absolute path for Windows systems can be selected by pressing the ... button. Example of the file path in the runtime system: `PlcLogic/AllRecipes` CODESYS saves a file in this directory for each recipe when downloading to the PLC. The requirement is that you select the *“Recipe management in the PLC”* option. The files are loaded to the recipe manager each time the application is restarted.
“File extension”	File extension for the recipe file in the format `.<file extension>` The resulting default name for recipe files is in the form `<recipe>.<recipe definition>.<file extension>`.
“Separator”	Delimiters between the individual values in the saved file
“Available Columns” *“ Selected Columns”*	Defines the information that is saved and in which order in the recipe file
“Save as Default”	CODESYS uses the settings on the tab throughout the entire project for all other recipe managers.

Tab 'General'

“Recipe management in the PLC”	☑: Has to be selected for the user program or visualization elements to load recipes at runtime. If you transfer recipes to the PLC exclusively via the CODESYS program interface, then you can clear this option.

Table 86: “Save Recipe”

“Save recipe changes to recipe files automatically”	When *“Recipe management in the PLC”* is selected, there is the following option for saving the recipe: ☑: We recommend this option because it helps the recipe manager operate "normally". The recipe files on the PLC are updated automatically at runtime whenever a recipe is changed.

Table 87: “Load Recipe”

When *“Recipe management in the PLC”* is selected, there are the following two options for downloading from the PLC:	
“Download only for exact match of the variable list”	◉: The recipe is only downloaded if the file on the PLC contains all variables from the variable list of the recipe definition of the application and these are sorted in the same order. Additional entries at the end are ignored. If the required match does not exist, then the error status `ERR_RECIPE_MISMATCH` is set (`RecipeManCommands.GetLastError`).
“Download variables with matching names”	◉: The recipe values are downloaded only for those variables that have the same name in the recipe definition of the application as in the recipe file on the PLC. If the variable lists differ in composition and sorting, then no error status is set. In this way, recipe files can also be downloaded if variables in the file or in the recipe definition have been deleted.

“Overwrite existing recipes on download”	☑: If recipe files with the same name exist on the controller, then they are overwritten with the configured values from the project when the application is started. If the values from the existing recipe files should be loaded instead, then this option has to be disabled. Requirement: The *“Storage Type”* is *“Textual”* and the *“Save recipe changes to recipe files automatically”* option is selected.

Table 88: “Write Recipe”

The following options are available for writing recipe values to the variables on the PLC:	
“Limit the variable to min/max when recipe value is out of the range”	◉: If the recipe contains a value that is outside of the range of values specified in the definition, then the defined minimum or maximum value is written to the PLC variable instead of this value.
“Do not write to a variable when the recipe value is out of the min/max range”	◉: If the recipe contains a value that is outside of the range of values specified in the definition, then no value is written to the PLC variable. It retains its current value.

Table 89: “Read Recipe”

The following option is available for reading recipe values from the PLC into the recipe in the project:	
“Check recipe for changes”	Always use the function block `RecipeManCommands` from `RecipeManagement.library` to read recipes. Never call the method cyclically. This is because each call can be written to the file system, which is time-intensive and burdens the controller. For example, a Raspberry protocol interpreter has a limited number of write cycles. ☑: With each method call, the current PLC variable values are first read into the recipe. Then the system checks whether the values have changed. Only if the values have changed is the recipe saved. This means that the recipe file is overwritten with the current recipes. The option can be used in order to update the recipe file in the local file system only if recipe values have changed on the PLC. However, it affects performance because it generates additional code for checking. ☐: With each method call, the current PLC variable values are first read into the recipe. Then the recipe is written to the recipe file in the local file system. Note: As the file system is written to each call, the controller can be very burdened.

Recipes during online mode

Table 90: Option “Save recipe changes to recipe files automatically” is selected.

Menu commands	**Behavior of the recipes defined in the project**	**Behavior of the defined recipes at runtime**
“Online ➔ Reset Warm” *“Online ➔ Reset Cold”* *“Online ➔ Download”*	The recipes of all recipe definitions are downloaded with the values from the current projects.	Dynamically generated recipes remain unchanged.
“Online ➔ Reset Origin”	The application is removed from the PLC. If a download is done again afterwards, then the recipes are restored as for an online reset warm.	
Shutdown and restart of the PLC	After a restart, the recipes are downloaded again from the automatically created files. This will restore the same state as before shutdown.	
“Online ➔ Online Change”	The recipe values remain unchanged. In runtime mode, a recipe can be changed only via the function block command `RecipeManCommands`.	
“Debug ➔ Stop” *“Debug ➔ Start”*	The recipes remain unchanged when the PLC is stopped or started.	

Table 91: Option “Save recipe changes to recipe files automatically” is not selected.

Actions	**Recipes defined in the project**	**Recipes defined at runtime**
“Online ➔ Reset Warm” *“Online ➔ Reset Cold”* *“Online ➔ Download”*	The recipes of all recipe definitions are downloaded with the values from the current projects. However, these are set in the memory only. To save recipes to a file, you have to run the *“Save Recipe”* command explicitly.	Dynamically generated recipes are lost.
“Online ➔ Reset Origin”	The application is removed from the PLC. When a download is performed afterwards, the recipes are restored.	Dynamically generated recipes are lost.

Actions	Recipes defined in the project	Recipes defined at runtime
Shutdown and restart of the PLC	After the restart, the recipes are downloaded again from the automatically created files. This will restore the same state as before shutdown.	
“Online ➔ Online Change”	The recipe values remain unchanged. In runtime mode, a recipe can be changed only via the function block command `RecipeManCommands`.	
“Debug ➔ Stop” *“Debug ➔ Start”*	The recipes remain unchanged when the PLC is stopped or started.

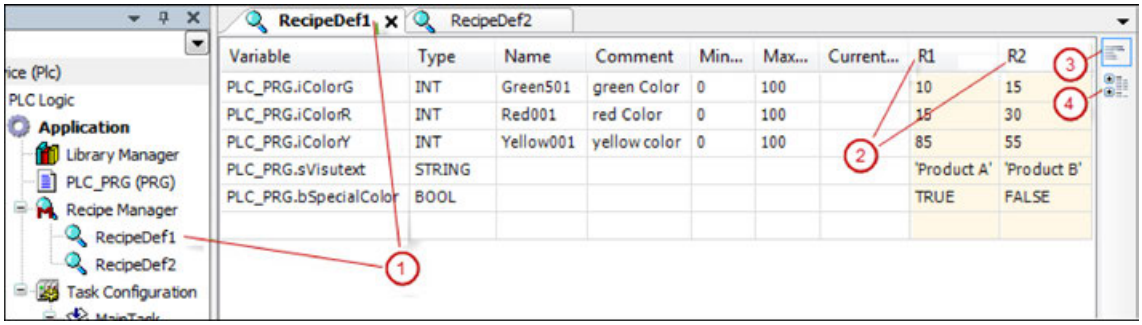
- *Method Calls of the 'Recipe Management' Library*

Object 'Recipe Definition'

In the recipe definition (1), you define different data sets for the variables, which are termed recipes (2).

You can toggle the display of the recipe definition between the flat list view (3) and the structured view (4). In the structured view, CODESYS groups variables according to structure.



“Type”	Entered automatically
“Name”	Optional
“Minimal Value” *“Maximal Value”*	If the variable value is less than the *“Minimal Value”* or greater than the *“Maximal Value”*, then CODESYS sets the value to the *“Minimal Value”* or *“Maximal Value”*.
“Comment”	Additional information, for example the unit of the value.
“Current Value”	Current variable value; not shown in online mode

Table 92: “Additional commands in the context menu in the structured view”

“Add Sibling”	Adds a sibling variable to the recipe definition.
“Add Child”	Adds a child variable to the recipe definition.

See also

- *Chapter 1.4.1.12.2 “Changing Values with Recipes” on page 417*

Object 'Text List'

Symbol: 

This object is used to create, manage, and translate texts. It contains a table with texts where you can add new texts. You can select a text which you have composed here can be selected in a visualization in the *"Dynamic texts"* property of an element. In runtime mode, the visualization displays this text dynamically in the selected language.

When the object is assigned to an alarm group and is located below the *"Alarm Configuration"* object, CODESYS adds the texts of the alarm group to the table. You can also add texts.

"ID"	Unique identifier of the text
"Standard":	Source text as character string (example: `Information A: %i options`). Use the keyboard shortcut *[Ctrl]+[Enter]* to add a line break. Double-click in the field to edit the text.
The table contains as many language columns as you want to add. A language column is named with a language code that you specified when you created the column by means of the *"Insert Language"* command.	
"<language code>"	Name of the language as a language code. Example: `en-US`. This column contains the translation of the text which is composed under *"Standard"*. Under the condition that the language code is selected as the language in the visualization manager, a visualization displays the translated text in runtime mode. If a translation has not been composed, then CODESYS uses the text under *"Standard"*. A visualization in runtime mode can also change the language if requested by a user.
Blank line	Edit the line to add your own text.

Object 'Symbol Configuration'

You can use the symbol configuration for creating symbol descriptions for project variables. Click *"Project ➔ Add Object"* to add a symbol configuration object to the device tree. Then define specific presets. See dialog below: *"Add Symbol Configuration"*.

Double-click the *"Symbol Configuration"* object to open the symbol configuration editor.

Dialog 'Add Symbol Configuration'

Function: This dialog is used to define the defaults for a *"Symbol Configuration"* object.

Call: *"Project ➔ Add Object ➔ Symbol Configuration"* menu; context menu of the application object.

"Include comments in XML"	Exports the symbol file with the comments assigned to the variables.
"Support OPC UA features"	Note: Availability and editability of this option depend on the device. ☑: When downloading the symbol configuration, additional information is also downloaded to the controller. The information below is necessary for operating the OPC UA server. ● Base types of inherited function blocks ● Contents of attributes that were assigned via compiler pragmas ● Scopes (example: `VAR_INPUT`, `VAR_OUTPUT`, `VAR_IN_OUT`)

Table 93: “Client-Side Data Layout”

For detailed information and examples of layout options, see the next section "Symbol Configuration Editor".	
“Compatibility layout”	This setting is used for the compatibility of old projects. The data layout created for the client is matched as much as possible to the layout created internally by the compiler.
“Optimized layout”	Recommended for new projects. Calculates the output layout in optimized form detached from the internal compiler layout. Does not generate any gaps for unpublished elements and strictly fulfills the requirements for memory alignment of the data types. Requires compiler version 3.5.7.0 or higher.

Symbol configuration editor The editor includes a table with selected variables and a menu bar for editing.

Table 94: Menu bar

“View”	You can use this button for activating and deactivating the following categories of variables used in the configuration editor: ● *“Unconfigured from Project”*: Variables that have not been added to the symbol configuration, but are provided in the project. ● *“Unconfigured from Libraries”*: Variables that have not been added to the symbol configuration, but are provided in the project. ● *“Symbols Exported via Attribute”*: This filter also lists the variables that have already been marked for export in the symbol file by means of the `{attribute 'symbol' := 'read'}` pragma. These symbols are displayed in gray. The *“Attribute”* column shows which access rights are set by the pragma.
“Build”	Compiles the project. Requirement for current preparation of variables in the configuration editor.

"Settings"	• *"Support OPC UA features"*: Note: Availability and editability of this option depend on the device. ☑: When downloading the symbol configuration, additional information is also downloaded to the controller. The information below is necessary for operating the OPC UA server. This currently includes the following information: – Base types of inherited function blocks – Contents of attributes that were assigned via compiler pragmas – Scopes (example: `VAR_INPUT`, `VAR_OUTPUT`, `VAR_IN_OUT`) • <!> *"Include comments in XML"* ☑: Exports the symbol file with the comments assigned to the variables. • *"Include Node Flags in XML"* ☑: The namespace node flags provide additional information about the origin of a node in the namespace. The node flags always in the symbol table when OPC UA is activated. However, its inclusion in the XML file can be deactivated as some defective parsers have problems with it. • *"Configure Comments and Attributes"* Opens the *"Comments and Attributes"* dialog. Here you configure the details of what should be included in the symbol configuration and XML file with respect to comments and attributes. • *"Configure synchronization with IEC tasks"*: Opens the *"Properties - <device name>"* dialog, *"Options"* tab. This setting allows for the symbolic clients (e.g. visualizations or database links based on the PLCHandler) to have consistent read/write access synchronized with the IEC tasks. For a detailed description of this setting, see the "Setting: Configure synchronization with IEC tasks" section below. Note: Variable access which is synchronous with the IEC tasks can increase the jitter for all IEC applications on this device. Synchronized consistent access can interrupt the real-time capability. • List box for defining the data layout type for the client of the symbol configuration: Note: See the "Example of data layout types" section at the end of this help page. – *"Optimized layout"*: Recommend for new projects. Calculates the output layout in optimized form detached from the internal compiler layout. Does not generate any gaps for unpublished elements and strictly fulfills the requirements for memory alignment of the data types. Requires compiler version 3.5.7.0 or higher. – *"Compatibility layout"*: This setting is used for the compatibility of old projects. The data layout created for the client is matched as much as possible to the layout created internally by the compiler. Due to the configuration possibilities of the symbol configuration which have grown over time, problematic offsets can still result. Causes of offsets Memory gaps due to internal pointers or references in function blocks and structure components that are not released for symbol configuration. Memory gaps that occur differently in 32-bit and 64-bit systems depending on the data type, such as `__XINT` / `__XWORD` . Fields that are at uneven addresses. Some clients are not set up for this. Unintentional memory misalignment, which occurs when using the attributes `'pack_mode'` or `'relative_offset'`. • *"Use Empty Namespaces by Default (V2 Compatibility)"*: Required when using a CODESYS V2-compatible OPC server configuration. ☑: Behavior same as in CODESYS V2.3. – Program variables are exported without an application name (`Application.PLC_PRG.MyVar` --> `PLC_PRG.MyVar` – Global variables are exported additionally without the GVL name (`Application.GVL.MyGlobVar` --> `.MyGlobVar`

	• *“Enable Direct I/O Access”*: This feature is potentially dangerous and **not intended for operation in production**. Activate only for error checking and tests, or when commissioning the machinery (for example, for checking cables connections). ☑: In the symbol configuration, you can also use access to direct I/O addresses that correspond to IEC syntax (for example, "%IX0.0"). Access to input addresses (I) is read-only*. Access to output addresses (Q) and memory addresses (M) can be read-write. *Information: In simulation mode, write access to symbols is also possible for input addresses. Because external clients for protocols such as OPC or OPC UA do not always support IEC syntax for direct addresses, access is also provided using an array syntax in the namespace __MIO of the implicit code. For example, you can also access __MIO.MIO_IX[2].x3 instead of %IX2.3. However, the symbols for array access are hidden in browsers because some clients cannot handle the large number of nodes (several thousand depending on the size of the I/O ranges). • *“Support Calls of Functions, FBs, Methods, and Programs”*: Note: Availability and editability of this option depend on the device. ☑: The access rights *“execute”* can be set in the symbol table for symbols of POUs of type function, function block, method, or program. The *“Support OPC UA features”* option also has to be selected in the *“Settings”*. • *“Include Call information in XML”*: ☑: The information about called functions, function blocks, methods, or programs is also listed in the XML file of the symbol configuration. The option is enabled only if the *“Support calls of functions, FBs, methods, and programs”* option is supported by the device. • *“Enable Symbol Sets”*: ☑: A toolbar with buttons and a list box is displayed above the symbol table. You can use this to configure symbol sets for client-specific assignment of access rights to the controller. See "Toolbar for symbol set configuration" below.
“Download”	If you use a device that supports its own application file for the symbol configuration, then this button is also available in the toolbar. If you change the symbol configuration in online mode, then you can load the new `<application name>._symbols` file immediately to the PLC.
“Tools”	*“Save XSD Scheme File”*: This command opens the standard dialog for saving a file in the file system. With this command, you can prepare the XSD format of the symbol file, for example for use in external programs.

Table 95: Symbol table

“Access Rights”	You can change the access rights for a symbol by clicking the symbol in the *“Access Rights”* column. Icons for access rights (in ascending order) • : Read only • : Write only • : Read and write • : Execute This permission allow for execute access to functions, function blocks, methods, and programs. Requirements for the assignment: The device provides the *“Support calls of functions, FBs, methods, and programs”* and *“Support OPC UA features”* options. Both options are activated in the *“Settings”*. Note: In case the controller has a user management, you can use symbol sets to define client-specific access rights to the same symbols.
“Maximal”	Maximum access rights for this symbol

"Attribute"	If the access right was assigned by attribute, then a corresponding icon is displayed here.
"Type"	Alias data types are also displayed In CODESYS V3.5 SP6 and higher. Example: `MY_INT : INT` for a variable declared with the data type `MY_INT` (type `INT`).
"Members"	You can add variables of a structured data type also by selecting a check box for symbol configuration in the *"Symbols"* column. This causes CODESYS to export all member variable symbols. However, in the *"Members"* column, you can click the ellipsis button (...) to select only specific structural components. Note: This selection applies to all instances of this data type for which symbols are exported. If a member of a structured type cannot be selected, then an asterisk (*) is displayed in the check boxes of the members to indicate that all exportable members of that type are exported.

Table 96: Toolbar for symbol set configuration

"List box"	Already defined symbol sets
"Add New Symbol Set"	Opens the *"Add New Symbol Set"* dialog for specifying a name for this set
"Add Duplicate from Selected Symbol Set"	Opens the *"Add Duplicate from Selected Symbol Set"* dialog. A copy is created for the set selected in the list box. You can change the default name (`<group name>_duplicate`).
"Rename Selected Symbol Set"	Opens the *"Rename Selected Symbol Set"* dialog for specifying another name for the set selected in list box.
"Delete selected Symbol Set"	Opens a dialog prompting whether or not the symbol set selected in the list box should be deleted.
"Configure Symbol Rights"	Opens the *"Symbol Rights"* tab of the device editor. When logged in there, you can assign different access rights for each user group (client) to the symbol set selected in the list box.

Dialog 'Comments and Attributes'

Table 97: "Symbol Table Contents"

"Enable extended OPC UA information"	Note: Availability and editability of this option depend on the device. ☑: Additional information that can be evaluated by OPC UA servers is included in the symbol table. This includes inheritance information of user-defined data types and the namespace node flags. Additional information, such as comments and attributes, can also be included if the OPC UA setting is active. When the OPC UA setting is enabled, attributes are included in the symbol table according to the following rule: ● In compiler versions V3.5.5.0 to V3.5.7.X, all attributes are included according to the *"Match simple identifiers"* setting. ● In compiler version V3.5.8.X, all attributes are included according to the setting *"Include all attributes"*. ● In compiler version V3.5.9.0 and higher, you can customize the attributes that are included.
"Include comments"	Requirement: *"Enable extended OPC UA information"* is activated. ☑: Comments and attributes are also saved in the symbol table.

“Include attributes”	
“Also include comments and attributes for type nodes”	Requirement: *“Include comments”* is activated. ☑: The information for type nodes is also included (user-defined types, such as `STRUCT` and `ENUM` elements). ☐: Only directly exported variables have comments and attributes.

Table 98: “XML symbol file contents”

“Include namespace node flags”	☑: The namespace node flags provide additional information about the origin of a node in the namespace. The node flags always in the symbol table when OPC UA is activated. However, its inclusion in the XML file can be deactivated as some defective parsers have problems with it.
“Include comments”	☑: Comments can also be saved in the XML file. In compiler versions V3.5.5.x to V3.5.8.0, this includes the setting *“Prefer docu-comments”*.
“Include attributes”	☑: Attributes can also be saved in the symbol file.
“Also include comments and attributes for type nodes”	Requirement: *“Include comments”* is activated. ☑: The information for type nodes is also included (user-defined types, such as `STRUCT` and `ENUM` elements). ☐: Only directly exported variables have comments and attributes.

Table 99: “Select Comments”

Requirement: *“Include comments”* is activated.	
“Include docu comments” *“Include normal comments ”* *“Always include both types of comments”* *“Prefer docu comments, fallback to normal ones”* *“Prefer normal comments, fallback to docu comments”*	The options determines the comments that are saved in the symbol configuration.

Table 100: “Filter Attributes (Case-Insensitive)”

Requirement: *“Include attributes”* is activated.	
“Include all attributes” *“Include attributes starting with”* *“Filter attributes with regular expression”*	Defines the attributes that are saved in the symbol configuration.
“Match simple identifiers”	Exists primarily due to the backward compatibility to older versions in order to emulate the old behavior.

Setting: Configure synchronization with IEC tasks

For synchronously consistent access, the symbolic client waits in the runtime when processing a read or write request until a time is found when no IEC task is executed. When this gap is detected, restarting the IEC tasks is prevented until all values of the variable list have been copied. Then the IEC tasks are planned again as usual. Synchronized access can cause a delayed starting of IEC tasks, which is shown as increased jitter. As all applications in the runtime are managed by a common scheduler, this potential impairment of the real-time behavior

affects all applications on the device. All applications of the device are affected, regardless of whether or not they include a symbol configuration or they have been downloaded to the controller from one or more CODESYS projects. Therefore, the runtime permits synchronized consist access only if this it allows all applications that are downloaded to the controller at the time of access.

The setting is located in the editor of the symbol configuration of the “Settings” menu. In addition, the setting is also located in the context menu of the controller when you click the “Properties” command and then select the “Options” tab in the opened dialog.

For applications without symbol configuration, the setting can only be found in the properties dialog.

NOTICE!

After changing the setting, all applications downloaded to the device by means of a download or online change have to be reloaded and all boot applications updated.

In which cases is synchronized consistent access necessary?

As a rule, there is no need for consistent values for displayed values because it is mostly irrelevant from which IEC task cycle the changed values originate. It is completely irrelevant for seldom changed values. Even when writing there are almost no hard consistency demands because typically the machine must be in a kind of standby mode (for example when writing recipes) in which there is no direct access to the values written as recipes.

In contrast, consistent values are particularly necessary for database links to save production data. For clocked machines, however, these values must be synchronous with the production timing (one value set per produced product) and not consistent with reference to one or more IEC tasks. With reference to the machine clocking, the consistency must be already ensured by the IEC application. For this purpose, the values that arise during a production cycle are typically collected in a global variable list. At the end of the cycle, the symbolic client is notified by means of an additional variable (`BOOL` or counter) that the machine cycle has ended and the values are valid. Now the client has the chance to archive the values from the production cycle. Depending on necessity, the successful reading can also be displayed in the opposite direction by means of a released variable, so that the production can also be halted in case the production data cannot be archived. Synchronized consistent access is not necessary and helpful for this use case because the synchronization takes place at the application level.

In contrast, synchronized consistent access by symbolic clients is typically applied in the process industry with continuously running systems without production clocking when, for example when process values are written consistently and cyclically in a fixed time frame of 60s. This can take place either by synchronization on the application level similar to clocked machines (see above) or by synchronization of the synchronized consistent symbolic access. The advantage of the latter is that no logic has to be implemented in the IEC program and access is controlled entirely by the client.

CAUTION!

Due to the increased jitter, the synchronized consistent monitoring is not suitable for motion or real-time critical applications. For these reasons, synchronized consistent access should be released and used only if it is absolutely necessary.

If a client uses synchronous consistent access released by this setting, then it has and effect on the client. Depending on the scheduler of the runtime, the response time can jitter more here for read/write access because the system might still have to wait for an execution gap of the IEC tasks. Read and/or write access can still fail when IEC tasks run for a long time (in the range of several 100 ms) or the CPU load is close to 100% for an extended period of time with one or more IEC tasks (in the range of several 100 ms). Therefore, the availability of the values also depends on the load of the controller by the IEC application.

Moreover, the client can minimize the effects on itself and on the runtime if it observes the following in the definition of the variable lists to be read or written:

- Synchronized consistent access only to those variables that are absolutely and consistently required.
- Separate variable lists for variables that have to be consistent and for variables that could be inconsistent.
- Divide variable lists with several consistent variables into several smaller lists.
- Select read intervals for cyclic reading of values as large as possible.

Support for the current configuration and possible corrective actions

Entries marked in red in the symbol table show variables that they are configured for export to the symbol file but are currently invalid in the application. The cause for this can be that the declaration has been removed from the block.

In version 3.5.8.0 and higher, a warning appears in the editor if variables that have configured symbols are not used in the IEC code or are not mapped in the case of I/O variables. In addition, the compiler indicates variables that are referenced from outdated library versions n the symbol configuration.

NOTICE!

Object variables that are not used in the program code remain uncompiled by default and are therefore not available in the symbol configuration.

However, CODESYS provides variables from uncompiled objects in the symbol configuration when one of the following conditions is met:

– The *“Link always”* POU property is selected.
– The `{attribute 'linkalways'}` pragma is used.

Example for the data layout types

Examples for the layout types

The following examples from an IEC application will show how gaps can result in the client-side memory layout caused by unpublished symbols, internal "invisible" pointers, or a "pack mode" definition in the device description. With the *"Optimized layout"* setting, the gaps are avoided. The symbol file contains different information about the size and offset of memory locations, depending on the selected layout setting.

Example: Large structure

```
// Example of a big structure, where not all members get published :
STRUCT
    {attribute 'symbol':='readwrite'}
    PublicNumber : INT;

    {attribute 'symbol':='none'}
    InternalData : ARRAY[0..100] OF BYTE;

    {attribute 'symbol':='readwrite'}
    SecondNumber : INT;

    {attribute 'symbol':='none'}
    MoreData : ARRAY[0..100] OF BYTE;
END_STRUCT
END_TYPE
```

Resulting entries in the symbol file; pay attention to "size" and "byteoffset":

Symbol file, large structure, compatibility layout option

```
<TypeUserDef name="T_LargeStructure" size="208" nativesize="208"
typeclass="Userdef" pouclass="STRUCTURE" iecname="LargeStructure">

<UserDefElement iecname="PublicNumber" type="T_INT" byteoffset="0"
vartype="VAR" />

<UserDefElement iecname="SecondNumber" type="T_INT"
byteoffset="104" vartype="VAR" />

</TypeUserDef>
```

Symbol file, large structure, optimized layout option

```
<TypeUserDef name="T_LargeStructure" size="4" nativesize="208"
typeclass="Userdef" pouclass="STRUCTURE" iecname="LargeStructure">

<UserDefElement iecname="PublicNumber" type="T_INT" byteoffset="0"
vartype="VAR" />

<UserDefElement iecname="SecondNumber" type="T_INT" byteoffset="2"
vartype="VAR" />

</TypeUserDef>
```

Example: Structure with uneven addresses

```
// The following mechanisms can cause memory misalignment:
// - {attribute 'relative_offset':='…'} at a member
// - {attribute 'pack_mode':='…'} at a structure declaration
// - target setting 'memory-layout\pack-mode' in the device
description

{attribute 'pack_mode':='1'}
TYPE UnevenAddresses:
STRUCT
    {attribute 'relative_offset':='3'}
    {attribute 'symbol':='readwrite'}
    PublicNumber : INT;
```

```
    {attribute 'symbol':='readwrite'}
    PublicValue : LREAL;
END_STRUCT
END_TYPE
```

Resulting entries in the symbol file; pay attention to "size" and "byteoffset":

Symbol file, structure with uneven addresses, compatibility layout option

```
<TypeUserDef name="T_UnevenAddresses" size="13" nativesize="13"
typeclass="Userdef" pouclass="STRUCTURE" iecname="UnevenAddresses">

<UserDefElement iecname="PublicNumber" type="T_INT" byteoffset="3"
vartype="VAR" />

<UserDefElement iecname="PublicValue" type="T_LREAL" byteoffset="5"
vartype="VAR" />

</TypeUserDef>
```

Symbol file, structure with uneven addresses, optimized layout option

```
<TypeUserDef name="T_UnevenAddresses" size="16" nativesize="13"
typeclass="Userdef" pouclass="STRUCTURE" iecname="UnevenAddresses">

<UserDefElement iecname="PublicNumber" type="T_INT" byteoffset="0"
vartype="VAR" />

<UserDefElement iecname="PublicValue" type="T_LREAL" byteoffset="8"
vartype="VAR" />

</TypeUserDef>
```

Example: Function block

```
// Each POU contains some implicit variables, which do not get
published. Depending on the data type these might cause memory gaps
of different sizes.
FUNCTION_BLOCK POU IMPLEMENTS SomeInterface
VAR_INPUT
    in : INT;
END_VAR
VAR_OUTPUT
    out : INT;
END_VAR
VAR
END_VAR
```

Each POU contains some implicit variables, which do not get published. If it is a data type such as `__XWORD`, then different sizes of memory gaps result in the client-side data layout, depending on whether the system is 64-bit or 32-bit.

Resulting entries in the symbol file for 64-bit and 32-bit; pay attention to "size" and "byteoffset":

Symbol file, function block, compatibility layout option, 64-bit

```
<TypeUserDef name="T_POU" size="24" nativesize="24"
typeclass="Userdef" pouclass="FUNCTION_BLOCK" iecname="POU">

<UserDefElement iecname="in" type="T_INT" byteoffset="16"
vartype="VAR_INPUT" />

<UserDefElement iecname="out" type="T_INT" byteoffset="18"
vartype="VAR_OUTPUT" />

</TypeUserDef>
```

Symbol file, function block, optimized layout option, 64-bit

```
<TypeUserDef name="T_POU" size="4" nativesize="24"
typeclass="Userdef" pouclass="FUNCTION_BLOCK" iecname="POU">

<UserDefElement iecname="in" type="T_INT" byteoffset="0"
vartype="VAR_INPUT" />
```

```
                <UserDefElement iecname="out" type="T_INT" byteoffset="2"
                vartype="VAR_OUTPUT" />

                </TypeUserDef>
```

Symbol file, function block, compatibility layout option, 32-bit

```
                <TypeUserDef name="T_POU" size="12" nativesize="12"
                typeclass="Userdef" pouclass="FUNCTION_BLOCK" iecname="POU">

                <UserDefElement iecname="in" type="T_INT" byteoffset="8"
                vartype="VAR_INPUT" />

                <UserDefElement iecname="out" type="T_INT" byteoffset="10"
                vartype="VAR_OUTPUT" />

                </TypeUserDef>
```

Symbol file, function block, optimized layout option, 32-bit

```
                <TypeUserDef name="T_POU" size="4" nativesize="12"
                typeclass="Userdef" pouclass="FUNCTION_BLOCK" iecname="POU">

                <UserDefElement iecname="in" type="T_INT" byteoffset="0"
                vartype="VAR_INPUT" />

                <UserDefElement iecname="out" type="T_INT" byteoffset="2"
                vartype="VAR_OUTPUT" />

                </TypeUserDef>
```

Object 'Task Configuration'

Symbol:

The object is used to define and display the basic settings for the task configuration.

The *“Task Configuration”* object must be included exactly one time in each application.

“Task Configuration” tabs and functions

- *“Properties”*: Display of the basic settings
- *“System Events”*: Linking of POU calls with system events
- *“Monitor”*: Display of the status and current statistics for the cycles times in online mode
- *“Variable Usage”*: Overview of the tasks that access the variables and how they do it
- *“Task Groups”*: Definitions of the tasks groups and their assignment to CPUs
- *“CPU Load”*: Graphical representation of the CPU load in online mode

Tab 'Properties'

Object: *“Task Configuration”*

In this tab, you define the basic settings of the task configuration as predefined by the target system, such as the maximum values for tasks and watchdog parameters.

Tab 'System Events'

Object: *“Task Configuration”*

On the *“System Events”* tab, you define which event calls which function and whether or not the configuration is currently activated. You use this tab when a system event (instead of a task) should call a project function.

“Add Event Handler”	Opens the *“Add Event Handler”* dialog
“Remove Event Handler”	Deletes the selected list assignment
“Event Info”	Shows information from the corresponding event library
“Open Event Function”	Opens the editor of the new function for the selected assignment You have selected the implementation language of the new function in the *“Add Event Handler”* dialog.
Assignment of functions to call for events with: *“Name”*,*“Description”*, *“Function to call”*, and *“Active”* (activate/deactivate configuration).	

Table 101: “Add Event Handler”

Adds a new assignment "Event – Function to call" to the list	
“Event”	The possible selection depends on the target device. CODESYS marks unavailable events with a red symbol in front of the name. A list of all possible system events is located at the end of this section.
“Function to call”	Function name (*“POU”*, type *“FUNCTION”*) You have to specify the name of the **new** function. CODESYS inserts the function to the device tree after you confirm the dialog.
“Scope”	● *“Application”*: The function is available to the application. ● *“POUs”*: The function is available to the entire project.
“Implementation language”	Implementation language for the new function
“Description”	Short description of the selected event

Features in *“Online Mode”*

The list of assignments from called functions to events also includes the following information: *“Event Status”*, *“Call Count”*, and the *“Online Reset”* button.

“Event Status”	`0`: No error has occurred. Does not equal `0`: Error. You need to consult the respective runtime system documentation.
“Call Count”	Displays how often the event has occurred or the associated function has been called.
“Online Reset”	CODESYS reinitializes the event lists and resets the counter for the events/function calls. Incorrectly initialized events are displayed with a red status cell.

Possible system events

Event	Description	Task	Debugging
PrepareStart	Call before starting the application	Communication task	No
StartDone	Call after starting the application	Communication task	No
PrepareStop	Call before stopping the application	Communication task	No
StopDone	Call after stopping the application	Communication task	No
PrepareReset	Call before resetting the application	Communication task	No
ResetDone	Call after resetting the application	Communication task	No
PrepareOnline-Change	Call before online change of the application	Communication task	No
OnlineChangeDone	Call after online change of the application	Communication task	No
PrepareDownload	Call before downloading the application	Communication task	No
DownloadDone	Call after downloading the application	Communication task	No
PrepareDelete	Call before deleting the application	Communication task	No
DeleteDone	Call after deleting the application	Communication task	No
PrepareExit	Call before exiting the application	Communication task	No
ExitDone	Call after exiting the application	Communication task	No
CodeInitDone	Event is sent after Code Init. Called within the task safe section and only for an online change change (for example, the copy code for online change is executed here).	Communication task	No
Exception	The event is sent if an exception has occurred in the context of an application.	Exception handling task of the runtime, or the task itself if the runtime does not support exception handling	Depends on the task
Login	Login of a client to this application	Communication task	No
Logout	Logout of a client from this application	Communication task	No
BeforeReadingInputs	Call before reading the inputs	IEC task	Yes
AfterReadingInputs	Call after reading the inputs	IEC task	Yes

Event	Description	Task	Debugging
BeforeWritingOutputs	Call before writing the outputs	IEC task	Yes
AfterWritingOutputs	Call after writing the outputs	IEC task	Yes
DebugLoop	Event is sent in cycles to the debug loop if the IEC task stops at a breakpoint.	Communication task	No
PrepareShutdown	Event is sent immediately before the runtime system is downloaded.	Runtime main loop	No
PrepareExitComm	Event is sent during download before exiting the communication server.	Runtime main loop	No
PrepareExitTasks	Event is sent during download before exiting all tasks.	Runtime main loop	No

Tab 'Monitor'

Object: *"Task Configuration"*

In online mode, the tab shows the status of the tasks of the task configuration, as well as some current measurements of the cycles and cycle times. CODESYS updates the values in the same time interval as for the monitoring of values from the PLC.

The displayed values can be reset to `0` by means of the *"Reset"* context menu command.

"Task"	Task name (as defined in the task configuration)
"Status"	● *"Not created"*: The task has not been started since the last update (especially for event tasks). ● *"Generated"*: The task is recognized in the runtime system, but not yet in operation. ● *"Valid"*: The task is operating normally. ● *"Exception"*: The task has produced an exception status.
"IEC-Cycle Count"	Number of cycles executed since starting the application where the IEC code was executed (`0` if the target system does not support the counter function)
"Cycle Count"	Number of executed cycles since logging in to the PLC It depends on the target system whether cycles are also counted where the application is not running. In these cases, the *"Cycle Count"* may be greater than the *"IEC-Cycle Count"*.
"Last Cycle Time (µs)"	Last measured cycle time [µs]
"Average Cycle Time (µs)"	Average cycle time over all cycles [µs]
"Max. Cycle Time (µs)"	Maximum measured cycle time over all cycles [µs]
"Min. Cycle Time (µs)"	Minimum measured cycle time over all cycles [µs]
"Jitter (µs)"	Current value of the periodic jitter [µs] Note: From CODESYS 3.5 SP11 to SP15, the peak-peak value of the periodic jitter is displayed. In earlier versions and in SP16 and later, the current value of the periodic jitter is displayed.

“Min. Jitter (µs)”	Minimum measured periodic jitter [µs]
“Max. Jitter (µs)”	Maximum measured periodic jitter [µs]
“Core”	Number of the processor core where the task is currently running Example: `2` Requirement: The controller is equipped with a multicore processor. If the CPU is not a multicore CPU, then the value `-1` is displayed here.

See also

- *Chapter 1.4.1.8.16.2 “Definitions of Jitter and Latency” on page 294*
- *Chapter 1.4.1.8.16 “Task Configuration” on page 292*

Tab 'Variable Usage'

Object: *“Task Configuration”*

The *“Variable Usage”* tab provides an overview of all variables and their usage. There you can see the tasks where variables are accessed.

When using multicore, write access (w) to a variable should take place only in a task because otherwise it can cause inconsistencies.

In the context menu, you can hide individual tasks and show the cross-reference list to variables.

“Variables”	Name of the variable
“Type”	Data type
“Number”	Number of tasks that access these variables.
“<task name>”	Access to the variable (r: read, w: write, rw: read/write)

See also

- *Chapter 1.4.1.8.16 “Task Configuration” on page 292*

Tab 'Task Groups'

Object: *“Task Configuration”*

You define task groups on the *“Task Groups”* tab. Task groups can be distributed over the individual processor cores in multicore systems. The tasks of a task group are bound to the processor cores according to the strategy defined in the *“Core”* field.

“Add Group”	The button adds a new task group named `NewGroup_<no>`.
“Remove Group”	Deletes the selected task group.

“Group Name”	The name can be changed by double-clicking in the field.
“Core”	Determines the processor core for process the tasks of this group. ● *“Free floating”*: All tasks are bound dynamically to different processor cores. The user does not have any influence over this. The operating system is responsible for the distribution. ● *“Sequentially pinned”*: All tasks are bound and fixed to different processor cores. The user does not have any influence over this. ● *“Fixed pinned”*: All tasks are bound to one processor core. By default, the runtime system determines the processor core. ● *“<core number>”*: Fixed defined processor core. If the processor core is not available, then an error message is issued.

See also

- *Chapter 1.4.1.8.16 “Task Configuration” on page 292*

Tab 'CPU Load'

Object: *“Task Configuration”*

The *“CPU Load”* tab is available in online mode for multicore devices only. The load of the individual CPUs is presented in the trace editor.

You open the trace configuration by double-clicking the legend in the window on the right side. Adding more variables is not possible here.

See also

- *“Displaying the CPU load with DeviceTrace objects in the CODESYS project (example)” on page 429*

Object 'Task'

Symbol: 

In this object, you define the conditions for starting and calling the task.

You insert the object below *“Task Configuration”* in the device tree.

Tab 'Configuration'

Object: *“Task”*

“Priority”	Possible values: 0..31, where 0 is the highest priority
“Task group”	Assigned task group. This assignment is shown in parentheses in the device tree. Task groups can be assigned to specific processor cores in multicore. The task group is shown in parentheses after the task in the device tree.

Table 102: “Type”

“Cyclic”	CODESYS processes the task in cycles. The cycle time of the task is defined in the input field *“Interval”*.
“Event”	CODESYS starts processing the task as soon as the global variable defined in the input field *“Event”* contains a rising edge.
“Freewheeling”	CODESYS starts processing the task again automatically in a continuous loop at program start and at the end of a complete pass. The cycle time is not defined.

“Status”	CODESYS starts task processing as soon as the variable defined in the *“Event”* input field yields the Boolean value `TRUE`.
“External”	CODESYS starts processing the task as soon as the event defined in the *“Event”* input field occurs. The target system determines which events are supported and offered in the list box. (Not to be confused with system events).
“Interval”	Task-cycle time Required for the types *“Cyclic”* or *“External Event”* when the event requires a given time. Time span after which the task should be restarted. If you enter a number here, then you can select the desired unit in the list box after the input field. When you select *“ms”*, an entry is automatically displayed in TIME format, for example `t#200ms`, as soon as the window is in focus again. You can also enter the task cycle time directly in TIME format. Entries in [µs] format are always displayed as a pure number. Deviations of the task from this desired task cycle time are displayed at runtime as periodic jitter on the *“Watchdog”* tab.

NOTICE!
For fieldbuses, a fixed cycle matrix is necessary to assure a determined behavior. Therefore, you should not use *“Type” “Freewheeling”* for a bus cycle task.

NOTICE!
Note the following difference between the processing types *“Status ”* and *“Event”*. If the given event yields `TRUE`, then the start condition of a task of type *“Status”* is fulfilled. In contrast, the start of a task of type *“Event”* requires a switch of the event from `FALSE` to `TRUE`. If the sampling rate of the task scheduler is too low, then the rising edge of the event can remain unnoticed.

NOTICE!
When setting the task cycle time, you have to identify which bus system is currently being used. For example, the task cycle time in a CAN bus system must match the currently set baud rate and the number of frames used in the bus. In addition, the times set for heartbeat, node guarding, and sync should always be a multiple of the task cycle time. If not, then CAN frames can be lost.

Table 103: “Watchdog”

Defines the time monitoring for a task. If the target system supports an advanced watchdog configuration, then the following settings may be predefined in the device description. ● Upper and lower limit ● Default watchdog time ● Time specified as percentage The default watchdog settings depend on the device.	
“Enable”	The watchdog is active. If the task exceeds the currently set *“Time”* of the watchdog, then the task is halted with an error status (exception). The application in whose task the error occurred and its child applications are also halted. In this way, all tasks of the affected applications are also halted. Then the currently defined *“Sensitivity”* is also taken into account. If you activate the option *“Update I/Os”* in the *“PLC Settings”* of the PLC, then CODESYS resets the outputs to the defined default values. Possible cases: ● Multiple consecutive timeouts: Sensitivity: 0, 1 - exception in cycle 1 Sensitivity: 2 - exception in cycle 2 Sensitivity: n - exception in cycle n ● Single timeout: Exception if the cycle time of the current cycle is longer than (time * sensitivity). Example: Time=t#10ms, Sensitivity=5 (i.e., exception as soon as the one-time task runs longer than 50 ms)
“Time (e.g. t#200ms)”	Watchdog time Defines (together with *“Sensitivity”*) the watchdog for a task; description as for *“Enable”*. Depending on the target system, the monitoring time span is given as a percentage of the task interval if possible. In this case, the list box for the unit is disabled and displays *“%”*.
“Sensitivity”	Number Defines (together with the watchdog) the watchdog for a task; description as for *“Enable”*.

Using the functions from the library `CmpIecTask.library`, you can deactivate a watchdog for specific PLC cycles. This is useful for cycles that demand more time due to initialization.

Example Deactivating/reactivating the watchdog:

```
hIecTask := RTS_IEC_HANDLE //Declaration of the variable hIecTask
hIecTask := IecTaskGetCurrent(0);
IecTaskDisableWatchdog(hIecTask); // Watchdog disabled
...
IecTaskEnableWatchdog(hIecTask); Watchdog enabled
```

List of *“POU”*s that the task calls The calling order corresponds to the POU order in the list (from top to bottom).	
“Add Call”	Defines a new program call

“ Open POU”	Opens the selected POU
“Move Up” *“Move Down”*	Changes the calling order

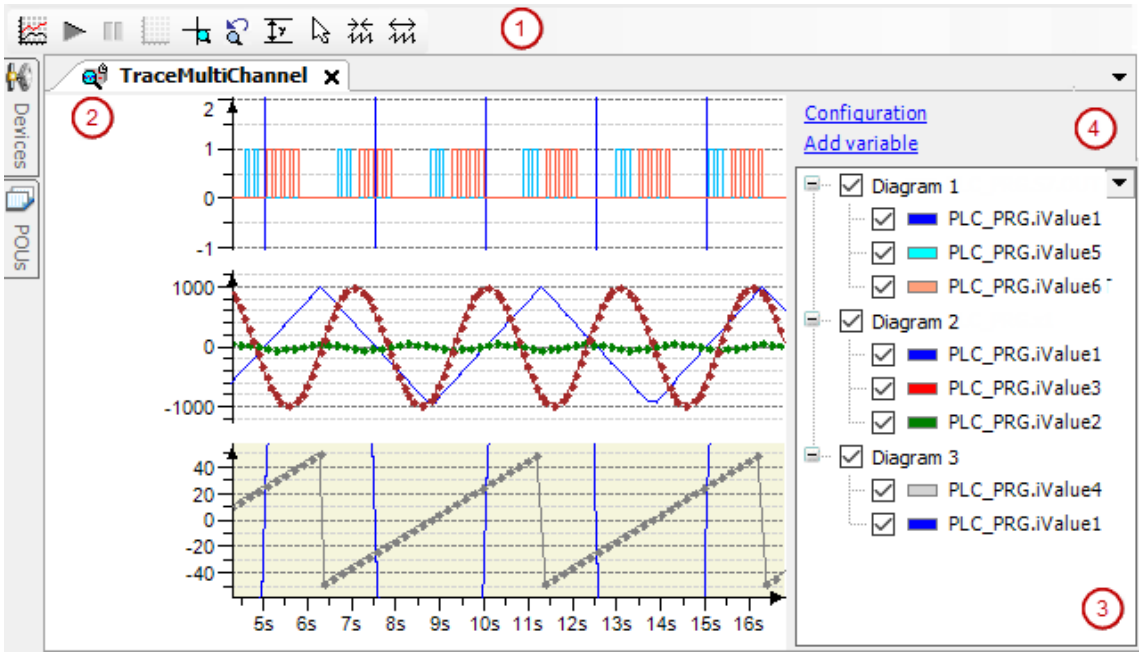
Object 'Trace'

Symbol:

An object of type *“Trace”* is used for configuring and displaying application-specific trace data in one or more charts. At application runtime, value curves of trace variables, which you can monitor in the trace editor in CODESYS, are recorded on the controller. Requirements are that a trace configuration has been configured transferred to the controller, and the trace recording has been started. The recorded data is transferred to the development system and displayed in diagrams according to the configuration. You can navigate through the data when tracing.

> *If the controller supports a Trace Manager, then you can use the 'DeviceTrace' object type in the Trace Manager to access all traces that are running on the controller.*

Double clicking the trace object opens the trace editor. The corresponding toolbar contains the most important trace commands. The trace variable list shows the variable whose value curve is recorded.



- (1): Toolbar of the trace editor
- (2): Trace editor
- (3): Trace variable list
- (4): Links for trace configuration
  “Configuration”
  “Add Variable”

Trace editor

At application runtime, the runtime system buffer of the trace component is filled with the recorded samples. The data is transferred to the development system and stored in its trace editor buffer. The trace editor accesses this data and displays it in diagrams as a graph over time. When you close the trace editor, the trace editor buffer will be freed.

Use menu commands for controlling the trace. In addition, you can use menu commands, keyboard shortcuts, and mouse input for navigating through the data.

Trace variable list

The trace variable list provides an overview of the current trace configuration. In the list, all charts with the respective trace variables are displayed in a table. When you double-click a trace variable, the *“Trace Configuration”* dialog also opens with the variable settings.

	A list box opens by means of the *“Hide Instance Paths”* command.
“Hide Instance Paths”	Display of the variable name in the list ●  : Variable name with full instance path Example: `PLC_PRG.iCounter`

Table 104: Charts

Tabular display of the charts:	
“Name”	List of charts with the respective variables ● *“Chart <n>”*☑: The chart is displayed. The chart name can be changed by clicking the selected name. ● *“<variable>”*☑: The variable is displayed. The variable name can be changed by clicking the selected name in the line editor. When you select a *“Chart <n>”* in the table, the corresponding chart is also selected in the editor. This also works the other way around.
“Cursor <n>”	Y-value at the cursor position
“Delta”	Delta of the Y-value from *“Cursor 2”* to *“Cursor 1”*

> *You can drag the charts and variables to sort them or move them to other diagrams. When the [Ctrl] key is pressed, the variable is copied. This is also possible in online mode.*

Table 105: Context menu in the trace variable list

"Add Variable"	Adds a new trace variable and opens the *"Trace Configuration"* dialog with its variable settings. Select a variable in the input field of the *"Variable"* setting to trace its value curve.
"Visible"	Toggles the visibility of the graph (value curve or trace variable) in the corresponding diagrams: ● : Visible. ● : Invisible.
"Display Mode"	Opens the *"Trace Configuration"* dialog. Select a configuration item in the *"Trace Record"* tree view or *"Presentation (Diagrams)"*.
"Configuration"	Opens the *"Trace Configuration"* dialog. The *"Variable Settings"* are displayed on the right.

Navigating in the diagram

Table 106: With mouse input

User input with the mouse	**Mouse cursor symbol during user input**	**Effect**
Drag the graph along the X-axis.		Scrolls trace graphs of all diagrams at the same time along the time axis (X-axis).
Hold down the *[Ctrl]* key and drag the graphs along the Y-axis.		Scrolls the trace graphs of the selected diagrams along the Y-axis.
Roll the mouse wheel backwards.		Compressed time axis (like the symbol).
Roll the mouse wheel forwards.		Stretches time axis (like the symbol).
Press and hold down the *[Ctrl]* key and roll the mouse wheel backwards.		Compresses the Y-axis.
Press and hold down the *[Ctrl]* key and roll the mouse wheel forwards.		Stretches the Y-axis.
Requirement: One or two trace cursors are activated. Drag the triangle of a trace cursor to another position along the time axis.		Refreshes the Y-values in the trace variable list at the same time ● First value: Y-value at the position of the left cursor. ● Second value: Y-value at the position of the right cursor. ● Third value: Difference between both values.
Requirement: *"Mouse zooming"* is activated ( ). Stretch a rectangle.		Zooms the trace graphs of all diagrams to the rectangle.

Table 107: With keyboard shortcuts

Shortcut	Effect
Requirement: No trace cursor is activated. *[Arrow Left]* *[Arrow Right]*	Scrolls trace graphs of all diagrams at the same time along the time axis.
[Arrow Up] *[Arrow Down]*	Scrolls the trace graphs of the selected diagrams along the Y-axis.
Requirement: One or two trace cursors are activated. *[Alt]+[Arrow Left]* *[Alt]+[Arrow Right]*	Scrolls trace graphs of all diagrams at the same time along the time axis.
[-]	Compressed time axis (like the symbol).
[+]	Stretches the X-axis (like the symbol).
[Ctrl]+[-]	Compresses the Y-axis of the selected diagram.
[Ctrl]+[+]	Stretches the Y-axis of the selected diagram.
[Tab]	Selects the next lower diagram.
Requirement: One or two trace cursors are activated. *[Arrow Left]* *[Arrow Right]*	Moves the black trace cursor.
Requirement: Two trace cursors are activated. *[Shift]+[Arrow Left]* *[Shift]+[Arrow Right]*	Moves the gray trace cursor.

- *Chapter 1.4.1.12 “Application at Runtime” on page 409*

Object 'DeviceTrace'

Symbol:

A *“DeviceTrace”* object shows trace data in one or more diagrams, as does a *“Trace”* object.

The difference is that a *“DeviceTrace”* directly accesses traces that are running on the controller. The object is inserted below the device in the device tree. Therefore there is no immediate dependency on the applications in the CODESYS project.

You can use the DeviceTrace for visualizing the processor load of a multicore controller.

For more information about the editor and its operation, refer to the help page for the *“Trace”* object.

See also

- *Chapter 1.4.1.20.2.28 “Object 'Trace'” on page 945*
- *“Runtime system component `CmpTraceMgr`, "Trace manager"” on page 421*
- *Chapter 1.4.1.12.3.4 “Accessing All Traces on the Controller” on page 428*

Object 'Trend Recording Manager'

Symbol 

A *“Trend Recording Manager”* object makes it possible to save data at runtime in a database for a long period of time. This data is recorded with the *“CmpTraceMgr”* runtime system component. In the device tree, this object is used as a node for trend recordings that are created below an application. It is available below an application only one time.

See also

- *Chapter 1.4.1.12.4 “Data Recording with Trend” on page 430*
- *Chapter 1.4.1.20.3.4.1 “Command ‘Add Object’” on page 1001*
- *Chapter 1.4.1.20.2.31 “Object 'Trend Recording'” on page 949*

Object 'Trend Recording'

Symbol: 

A *“Trend Recording”* object is always located below a *“Trend Recording Manager”* and enables editing of the trace configuration. At runtime, CODESYS transfers the configuration that is available to the runtime system component `CmpTraceMgr`. You can configure an application with any number of trend recordings.

NOTICE!

Timeout for trend recording

During a trend recording, it can happen that the application task triggers a timeout that is caught with an exception when transitioning from *“Running”* to *“Stop”*. Causes can be that file operations with the SQLite database are taking too long or that too many variables are being recorded. This usually happens on a target device with weak performance.

You can avoid the occurrence of an exception:

– Configure the trend recording with less memory demand so that the amount of data that is stored is adapted to the target system.
– Reduce the number of variables.

The editor includes the configuration for trend recording. The tree view shows the trend configuration and enables navigation there.

The top entry contains the trend name. When this entry is selected, the *“Record Settings”* are displayed next to it. An entry is located here for each variable whose data was recorded continuously. When a variable is selected, the *“Variable Settings”* are displayed next to it.

“Add Variable”	When you click the link, a new entry is displayed in the trend configuration with its blank configuration below the *“Variable Settings”* group.
“Delete Variable”	The selected variable is removed. Requirement: A variable is selected.

See also

- *Command 'Edit Trend Recording'*

'Recording Settings'

The data is recorded in the runtime system component by means of the functionality which is also used for the trace. The settings that appear here are the same. The options that are not required here are deactivated.

The settings that affect the trigger are deactivated. Only a trace configuration for a trace editor can configure triggering.	
“Task”	Task where data was recorded. Click ▼ to open a list box with all tasks available in the project. In general, the trend recording runs in the same task as the main program. For example: `MainTask`
“Recording condition”	Condition under which the application records data: ● IEC variable of type `INT`. The condition is fulfilled for `TRUE`. ● Bit access to an integer variable. The condition is fulfilled for `1`. As read access to a property. The contents of a pointer are not permitted. Note: If no condition is defined, then the recording starts automatically.
“Comment”	Comment (example: `Data recording of sensor A`)
“Resolution”	Resolution that the application saves the time stamp Note: If the task where the trend object is executed has a cycle time of 1 ms or less, then you should set the resolution of the time stamp to *“1 µs”*.
“Trend Storage”	The *“Trend Storage”* dialog opens.
“Advanced”	The *“Advanced Trend Settings”* dialog opens.

See also

- *Chapter 1.4.1.20.4.16 “Dialog Box 'Trend storage'” on page 1214*
- *Chapter 1.4.1.20.4.17 “Dialog Box 'Advanced Trend Settings'” on page 1214*

'Variable Settings'

“Variable”	Variable for recorded value. ● IEC variable with valid data type ● Property ● Reference ● Contents of the pointer ● Array element of a valid data type ● Enumeration of a valid data type Valid data types are all standard types, **except** `STRING`, `WSTRING`, and `ARRAY`.
“Parameter”	Parameter for the recorded value The *“Input Assistant”* dialog lists all valid system parameters in the *“Parameters”* category of the *“Categories”* tab.
	Click the symbol to toggle between *“Variable”* and *“Parameter”*.
“Recording condition”	Condition under which the application records the data of these *“Variables”*: ● IEC variable of type `INT`. The condition is fulfilled for `TRUE`. ● Bit access to an integer variable. The condition is fulfilled for `1`. As read access to a property The contents of a pointer are not permitted. Note: If no condition is defined, then the recording starts automatically.
“Attached y axis”	Y-axis of the trend diagram that displays the *“Variable”*. The list box provides the standard Y-axis and the configured Y-axes. Requirement: This option is visible only when the *“Trend”* visualization element has configured additional Y-axes in the *“Edit Display Settings”* dialog.

"Display variable name"	☑: The visualization shows the name of the IEC variable in the trend diagram at runtime. Either alone or in parentheses after the *"Description"* ☐: The name of the IEC variable is shown and does not appear in parentheses after the *"Description"*. Requirement: If any text is typed in *"Description"*, then you can disable the option.
"Description"	Text for the tooltip (example: `Sensor A`): When a visualization user focuses on the variable in the trend diagram, the visualization shows the text as a tooltip. The text is typed into the *"GlobalTextList"* object and can be localized there. When the *"Display Variable Name"* property is activated, then the text is supplemented with the variable name in parentheses. Example: `Sensor A (PLC_PRG.iSensor_A)` If *"Description"* does not contain any text, then *"Display Variable Name"* is enabled. The name is then alone without parentheses (for example, `PLC_PRG.iSensor_A`). If a legend is assigned to the trend, then the trend variable is labeled in the legend and shown like the trend is configured here.
"Curve type"	● *"Line"* ● *"Area"*:
"Graph color"	Color of the curve in the trend diagram
"Line type"	● *"Line"*: Values are linked to form a line. ● *"Step"*: Values are linked in the form of steps. ● *"None"*: Values are not linked. Requirement: The *"Curve type"* is *"Line"*.
"Filling type"	● *"No filling"* ● *"Plain color"*: ● *"Gradient"* Requirement: The *"Curve type"* is *"Area"*.
"Filling color"	☑: The area is filled with the selected color. Requirement: The *"Curve type"* is *"Area"*.
"Transparency"	Value (0 to 255) for defining the transparency of the selected color Example `255`: The color is opaque. `0`: The color is completely transparent Requirement: The *"Curve type"* is *"Area"*.
"Line width"	Value (in pixels) Example: `1`
"Line style"	The display of the line is solid, dash, dot, dash-dot, or dash-dot-dot.
"Point type"	Display as scatter chart ● *"Dot"*: Value as a dot. ● *"Cross"*: Value as a cross. ● *"None"*: No dot display Hint: Select *"None"* for larger size data.
"Activate minimum warning"	☑: Warning when below the lower limit.
"Critical lower limit"	If the variable value is below the limit, then the variables are displayed with the alert color in the trend diagram.
"Color"	Warning color on falling below the limit
"Activate maximum warning"	☑: A warning is issued if the upper limit is exceeded.

“Critical upper limit”	If the variable value exceeds the limit, then the variables are displayed with the alert color in the trend diagram.
“Color”	Warning color on exceeding the limit

Object 'Trend Recording Task'

Symbol 

If you design a visualization with a *“Trend”* element, then CODESYS automatically extends the *“Task Configuration”* with a *“Trend Recording Task”*. The task is below an application one time at most and calls the `VisuTrendStorageAccess.GlobalInstances.g_TrendRecordingManager.CyclicCall` program to run the trend recording manager.

See also

- *Chapter 1.4.1.20.3.4.1 “Command ‘Add Object’” on page 1001*
- *Chapter 1.4.1.12.4 “Data Recording with Trend” on page 430*

Object 'Unit Conversion'

Symbol 

A *“Unit Conversion”* object is used to define a conversion rule. The following table lists all defined conversion rules. You can edit a conversion rule in the input fields listed below the table.

Table of conversion rules

“Name”	`<name> : <name>_Impl` is the name of the conversion rule. CODESYS automatically implements the entry as a function block `<name>_Impl` and instances it as `<name>`.
“Type”	Type of conversion rule ● *“Single scaling (offset)”*: adds an offset to the input variable. `Result := Input + Offset` ● *“Single scaling (factor)”*: multiplies the input variable by a factor. `Result := Input * Factor` ● *“Linear scaling 1 (factor and offset)”*: converts the input variable with a factor and offset. `Result := Input * Factor + Offset` ● *“Linear scaling 2 (Base and target range)”*: converts the input variable for the output value to be within a target range. CODESYS calculates the functional linear equation internally. ● *“User defined conversion”*: configures a user-defined conversion rule with IEC operators. The input variable is `rValue`. ● *“Switchable conversion”*: defines a conversion rule that CODESYS executes independent of any specified language or variable.
“Setting”	Displays the configured conversion rule.
“Condition”	● *“TRUE”*: CODESYS always executes the conversion. ● *“Language”* If the language in the visualization is the language defined here, then CODESYS executes the conversion. The current visualization language is located in the `VisuElems.CurrentLanguage` variable. ● *“Variable”*: If the comparison is TRUE, then CODESYS executes the conversion rule. CODESYS can pass the comparison for a constant, variable, or IEC expression. You can edit the comparison below the table in the *“Condition Setting”*.
“Condition Setting”	If you select *“TRUE”* as the *“Condition”*, then the field is hidden. If you configure *“Language”* as the *“Condition”*, then the field shows the current configuration, for example `en,de`. If you select *“Variable”* as the *“Condition”*, then the field shows the current configuration, for example `PLC_PRG.bActual=PLC_PRG.bSet`. You can edit the current condition setting below the table in the input fields for *“Condition Setting”*.

Input field 'Single scaling (offset)'

The input variable is added with an offset.

“Offset”	● as a number, including `REAL` ● as an IEC variable

Input field 'Single scaling (factor)'

The input variable is multiplied by the factor.

“Factor”	● as a number, including `REAL` ● as an IEC variable

Input field 'Linear scaling 1 (factor and offset)'

The input variable is converted with the linear equation defined below.

“Factor”	● as a number, including `REAL` ● as an IEC variable
“Offset”	● as a number, including `REAL` ● as an IEC variable

Input field 'Linear scaling 2 (Base and target range)'

The input variable is converted to be within a target range. CODESYS internally creates a linear equation from the following input values.

“Base start value”	Lowest possible value for the input variable. ● as a number, including `REAL` ● as an IEC variable
“Base end value”	Highest possible value for the input variable. ● as a number, including `REAL` ● as an IEC variable
“Target start value”	Lowest possible value for the output variable. ● as a number, including `REAL` ● as an IEC variable
“Target end value”	Highest possible value for the output variable. ● as a number, including `REAL` ● as an IEC variable

Example Conversion of electric current from a 10-bit input signal to an amperage range of 4-20 mA

“Base start value”	`0`
“Base end value”	`1024`
“Target start value”	`4.0`
“Target end value”	`20.0`

Input field 'User defined conversion'

“Convert :=”	Conversion rule as mathematical function of `rValue` The input variable is `rValue`.
“Reverse :=”	Reverse function of the function defined in *“Convert”*

Input field 'Switchable conversion'

Use this conversion rule when you want to apply a conversion that is language-specific or variable-dependent.

“Switchable conversion name”	Selected from a list of predefined conversion rules. Double-click directly into the field for editing.
“Condition setting”“”	Configured condition. Click into the input fields in *“Condition setting”* to edit the condition.

Example

The `Conv_A_LanguageDependent` conversion rule that defines which conversion rule is executed for the English or German language.

"Name"	*"Type"*	*"Setting"*	*"Condition"*	*"Condition setting"*
`Conv_A_LanguageDependent`	*"Switchable conversion"*	`Conv_AInInch, Conv_AInMM`	*"Language"*	

"Switchable conversion name"	*"Condition setting"*
`Conv_AInInch`	`en`
`Conv_AInMM`	`de`

1.4.1.20.3 Menu Commands

By default the most important commands are already provided in the CODESYS user interface. If you want to customize the menu configuration individually, choose command *"Tools ➔ Customize ➔ Menu"*.

When you have installed any packages or add-ons, additional menus and commands might be available.

Menu 'File'

Command 'New Project'

Symbol:  , Shortcut: *[Ctrl]* + *[N]*

Function: This command opens the *"New Project"* dialog box for the creation of a new project file.

Call: *"File"* menu

'New Project' dialog box

Function: Selection of a project category and a project template.

Call: *"File ➔ New Project"*

Depending on the template, you obtain a project that is automatically equipped with a certain range of objects.

Table 108: "Categories"

"Libraries"	
"Projects"	

Table 109: "Templates"

"Projects" category::	
"Empty project"	Contains only the *"Project Settings"* object
"Standard project"	Contains a basic range of objects and libraries. A wizard assists with the creation – see below.
"Standard project with Application Composer"	Contains a basic range of objects and libraries for working with the Application Composer. A wizard assists with the creation.
"Libraries" category:	
"CODESYS container library "	Library that contains only further libraries, but no function blocks of its own.
"CODESYS interface library "	Library only for the definition of the interface of a software component. Thus contains only objects that do not generate any code (constants, structures, interfaces, etc.).
"Empty library"	Contains only the *"Project Settings"* object
" External CODESYS library "	Target-system-specific library which is implemented as part of the runtime system (in ANSI C or C++).
"Name"	Name of the project to be created. Depending on the template, a standard name appears. The numerical suffix ensures the uniqueness of the name in the file system. You can change the file name, taking into consideration the file path conventions of the operating system. Periods are not permitted in names. CODESYS automatically adds the appropriate file extension to the selected template.
"Location"	Location for the new project file. ... opens a dialog box for browsing the file system. ▼ displays the history of previously entered paths
"OK"	CODESYS opens a new project. An error symbol ⓘ next to the input field draws attention to missing specifications. If you place the mouse pointer on it, a tooltip appears, informing you what to do.

***"Standard Project"* dialog box**

Function: Wizard for the creation of a standard project.

Call: Command *"File ➔ New Project"*; in the *"New Project"* dialog box, select the *"Projects"* category and the *"Standard project"* template and click on *"OK"*.

“Device”	Selection list with PLC devices. The selected device is inserted as an object in the Devices view below the root node
“PLC_PRG in”	Selection list with the programming languages. The automatically inserted program PLC_PRG is created in the selected language.

Command 'Open Project'

Symbol:  ; shortcut: *[Ctrl]+[O]*

Function: The command opens the default dialog for loading a project. You can search for a CODESYS project in the file system and open it in the development system.

Call: Menu bar: *“File”*

Dialog 'Open Project'

“File type”	Type of the CODESYS project to be loaded to the development system
“All supported files”	Filters by all projects which CODESYS can load Hint: For example, you can select `PRO` projects which have been created with CoDeSys V2.3. These kinds of projects are also converted.
File extension `project`	Filters by projects which have been created with CODESYS V3
File extension `projectarchive`	Filters by project archives which have been created with CODESYS V3
File extension `library`	Filters by library projects which have been created with CODESYS V3
“Open”	Loads the project you selected to CODESYS Note: Depending on the state of your CODESYS installation, it may be necessary to update or supplement the installation. If this is the case, then first open another *“Open Project”* dialog with options for installation management.

See also

- *Chapter 1.4.1.2.1 “Opening a V3 Project” on page 186*
- *Chapter 1.4.1.2.2 “Opening a V2.3 project” on page 187*

Command ‘Close Project’

Function: This command closes the currently opened project. CODESYS remains opened.

Call: *“File”* menu. In addition implicitly when opening a new/other project, while another project is still open.

If the project contains unsaved changes, a query appears, asking whether the project should be saved.

If you have not yet explicitly saved the project, a query appears asking whether you wish to delete the project files.

Command 'Save project'

Symbol:  , shortcut *[Ctrl]* + *[S]*

Function: this command saves the project file.

Call: *"File"* menu

This command saves the project file with the current project name, which appears in the title bar of the main window. If the project has been changed since it was last saved, the project name is given an asterisk.

The command is not available if the project is read-only.

Write protection exists if

- the project is identified in the project information (summary) as 'Released'
- the option *"Open read-only"* was selected in the dialog box *"Open Project"* when opening the project

Write protection is indicated by a line in the top right corner of the main window. A mouse-click on this line brings up a menu with commands for the possible actions:

- *"Save project under a different file name on the disk"*: a mouse-click on this option leads to 'Save file as…'
- *"Exit read-only mode"*: appears only if the option *"Open read-only"* was selected when opening the project.
- *"Remove read-only attribute from the project on the disk"*: appears only if the project file had been provided with the property 'Read-only' on the disk at the time of opening.
- *"Remove identification 'Released' in the project information"*: appears only if this attribute is currently set.

Backup copy

Optionally a backup copy of the project file can be created. If the option *"Create backup copy"* is activated in the option dialog box 'Load and Save', the project is additionally copied to a file `<projectname.backup>` each time the project is saved.

See also

- *Chapter 1.4.1.20.3.1.5 "Command 'Save Project as'" on page 958*
- *Chapter 1.4.1.5.8 "Saving the Project" on page 209*
- *Chapter 1.4.1.20.4.13.16 "Dialog 'Options' – 'Load and Save'" on page 1196*

Command 'Save Project as'

This command opens the standard Windows dialog box for saving a file. The project can be stored with the desired location and file type.

"File type"	For both normal projects and library projects, this drop-down list contains the respective versions of the development system for which the project can be saved. If the current project contains add-ons that are not available in the selected memory format (profile), then the *"Extend Profile"* dialog box opens. ● *"Project files (CODESYS v<version>) (*.project)"*: The project is saved as a CODESYS project file "<project name>.project " for the currently used or selected version of the development system. ● *"Library files (CODESYS v<version>) (*.library)"*: The project is saved as a CODESYS library file "<project name>.library" for the currently used or selected version of the development system. If the project should be opened later in an older version, then it makes sense to save for precisely this version, as you will then be informed immediately about possible data loss.

Before saving a project as a library:

- Make sure that the rules for creating libraries have been followed.
- If it is to be possible to configure global constants provided by the library at a later time in an application, then you must define them in a parameter list. A parameter list is a special type of global variable list.
- When saving the project, no automatic check for errors is performed.
- Unlike CoDeSys V2.3, there is no distinction between 'external' and 'internal' libraries. Now you can define in the properties of each individual project object whether or not it should be treated as 'external'.
- Consider whether the library created is to be installed in the system library repository immediately. If so, then use the command 'Save project and install in the library repository'.
- If you want to protect the library project from later changes, then set the *"Released"* attribute in the *"Project Information"* dialog box. At the next attempt to save the project, a corresponding message will be displayed and the user must respond to the write protection with deliberate actions.
- If you save the project as a version of the development system other than the one currently in use, then you will be informed first about possible data loss.

Dialog box 'Extend Profile'

In this dialog box, the selected profile (memory format) can be extended by the add-ons that are contained in the current project. The profile is saved temporarily and then deleted after being saved or exported.

"Add to profile"	☑: The current profile is extended by the add-on so that the add-on data of the current project is also saved.
"Add-on"	The add-on of the current project that is not contained in the selected memory format.
"Version"	Version of the *"Add-on"* included in the current profile. If several versions are installed, then the version can be selected.
"Save profile"	Opens the *"Enter Profile Name"* dialog box. In this dialog box, specify the name for the new profile. The new profile is saved permanently at `$ProgramData$/$PRODUCT$/CustomInformationalProfiles`.
"Use saved profile"	The profile which was permanently saved in *"Save profile"* is used for saving or exporting the current project.

- *Chapter 1.4.1.20.3.1.6 "Command 'Save Project and Install into Library Repository'" on page 959*

Command 'Save Project and Install into Library Repository'

Function: this command saves the project as a library in the 'system' library repository.

Call: Main menu *"File"*.

With this command CODESYS saves the project as a library in the 'system' library repository. This is an extension to the saving of a project as a library file using the *"Save Project as"* command. The library is installed on the local system and is immediately available for insertion into a project.

See also

- *Chapter 1.4.1.20.3.1.5 "Command 'Save Project as'" on page 958*

Command 'Save Project as Compiled Library'

Function: The command saves a library project in encrypted form.

Call: Menu bar: *"File"*

The command opens the default dialog for saving a file in the file system. The *"Compiled CODESYS Libraries"* file type is already preset. The file extension is `.compiled-library-v3` or `.compiled-library` (CODESYS < SP15). In this format, then source code of the library POU is not visible when the library is used in a project.

If the *"Enforce signing of compiled libraries"* option is selected in the *"Security Screen"* view on the *"User"* tab, then a library project has to be provided with a digital certificate-based signature when being saved. When a suitable certificate is available, it is provided in the *"Security Screen"* on the *"User"* tab in the *"Digital Signature"* section. In the *"Project Information"*, on the *"Summary"* tab, a *"Library compatibility"* with a CODESYS version >= V3 SP15 is set by default. In this case, the project file is stored with the file extension `.compiled-library-v3` when being saved as a compiled and signed library. If you still have not specified a suitable valid certificate for your user profile in the *"Security Screen"*, then a dialog prompt opens next for you to do this. Afterwards, you can execute the save command again.

In all other respects, compiled library files behave just like `*.library` files, and therefore they can be installed and referenced with the same steps.

We recommend the use of compiled libraries signed with certificates. Besides the protection of the source code and the unauthorized use of a library, less memory is also used which therefore results in shorter loading times.

If you have the corresponding help files with translations, then as of CODESYS V3 SP15 you can extend the library documentation with the translation into other languages. This is done as follows:

Place the files created for the new languages `__lmd__<language>.aux` in a directory `<library name>.lmd` parallel to the library project `<library name>.compiled-library-v3`. If the files are correct, then they are included in the compiled library file when saving the library project by means of the "Save Project as Compiled Library" command.

Example: The directory `standard.lmd` is exists parallel to the library file `standard.compiled-library-v3` and contains the file `__lmd__fr.aux` with the French translation of the library documentation. After the compiled library is saved, the French version of the documentation is also available in the Library Manager.

Command 'Save/Send Archive'

Function: This command opens the dialog *"Project Archive"* for the configuration of project archives.

Call: Menu bar: *"File ➔ Project Archive"*

An archive file (*.projectarchive) contains all files contained and referenced in the currently opened project. It can either be saved or dispatched as an e-mail attachment. The dispatch by email is very helpful for providing an employee with all project-relevant files. The file can be simply unpacked again with the command *"Extract Archive"*.

NOTICE!
The archiving function is not intended for the storage of a project, but rather for the simple summarizing of all project-relevant files.

See also

- *Chapter 1.4.1.5.9 “Saving/Sending the project archive” on page 210*
- *Chapter 1.4.1.20.3.1.9 “Command 'Extract Archive'” on page 961*

Dialog 'Project Archive'

The dialog displays all the categories that can be added to the project archive. In this dialog, complete categories or individual objects from the categories can be added to the project archive by setting a check mark (☑).

Entries that are display as red in the list require your attention. Move the mouse pointer over this library for more information.

“Additional Files”	Opens the dialog *“Additional Files”*. Here, further files can be added to the archive with the *“Add”* button.
“Comment”	Opens the "Comment" dialog. Here, comments can be added to the archive.
“Save”	Creates the archive file and saves it. The storage location and the archive name are specified in the subsequent dialog
“Send”	Creates a temporary archive file that is attached to an empty e-mail. A correct installation of the MAPI (Messaging Application Programming Interface) is required for the successful execution of this operation. Failure is documented by the display of a corresponding error message. The temporary archive is automatically deleted after sending the e-mail.

Command 'Extract Archive'

Function: The command extracts a project archive, that was created with the command *“Save/Send Archive”*. You have to configure which objects of the archive CODESYS shall extract and in which directory of the file system they will be copied.

Call: Main menu *“File ➔ Project Archive”*

The file extension of an archive is `.projectarchive`.

After the archive is selected, the dialog *“Extract Project Archive”* opens to configure the extract parameters.

Dialog Box 'Extract Project Archive'

This dialog box shows the contents of the project archive. You can exclude complete categories or single objects from categories by clearing the check boxes (☑) from the extraction.

Table 110: “Locations”

“Extract into the same folder where the archive is located”	The archive is extracted to the same directory.
“Extract into the following folder”	The contents of the archive are extracted to the given path.
“Advanced”	Opens the *“Advanced”* dialog box for you to define where special and additional files from the archive are extracted.

Table 111: “Contents”

“Items”	Shows the contents of the archive structured in object categories. ☑: The object is extracted. ☐: The object is not extracted.
“Comment”	Comment that was entered when creating the project archive

“Extract”	If an extracted file has the same name as an existing file in the target directory, then a dialog box opens, prompting whether the local file should be replaced. The decision can be applied automatically to any additional conflicting names. In this case, you have to select the ☑ *“Apply to all objects and files”* check box.

Dialog 'Advanced'

Table 112: “Repositories”

“Install devices into”	Drop-down list with currently available repositories. Select the repositories, in which CODESYS shall install the devices and the libraries of the archive.
“Install libraries into”	

Table 113: “Additional Files”

By default the "additional files" are set to *“Do not extract”*. Select the entries in the table and chose one of the following options:	
“Extract into project folder”	Folder of the project file
“Extract into folder”	User defined folder
“Do not extract”	Default

See also

- *Chapter 1.4.1.20.3.1.8 “Command 'Save/Send Archive'” on page 960*

Command 'Source Upload'

Function: This command loads the project source code (as project archive) from the controller.

Call: Main menu *“File”*.

Requirement: The network path for the controller must be configured.

After you execute the command, an overview opens with all devices in the network. Select a controller from this overview. The dialog box *“Extract Project Archive”* then opens with export settings.

See also

- *Chapter 1.4.1.10.7 “Downloading source code to and from the PLC” on page 393*
- *Chapter 1.4.1.20.3.1.11 “Command 'Source Download'” on page 963*

Dialog Box 'Extract Project Archive'

This dialog box shows the contents of the project archive. You can exclude complete categories or single objects from categories by clearing the check boxes (☑) from the extraction.

Table 114: “Locations”

“Extract into the same folder where the archive is located”	The archive is extracted to the same directory.
“Extract into the following folder”	The contents of the archive are extracted to the given path.
“Advanced”	Opens the *“Advanced”* dialog box for you to define where special and additional files from the archive are extracted.

Table 115: “Contents”

“Items”	Shows the contents of the archive structured in object categories. ☑: The object is extracted. ☐: The object is not extracted.
“Comment”	Comment that was entered when creating the project archive

“Extract”	If an extracted file has the same name as an existing file in the target directory, then a dialog box opens, prompting whether the local file should be replaced. The decision can be applied automatically to any additional conflicting names. In this case, you have to select the ☑ *“Apply to all objects and files”* check box.

Command 'Source Download'

Function: This command loads the project source code (as project archive) to the controller.

Call: Main menu *“File”*.

Requirement: The network path for the controller must be configured.

After you execute the command, an overview opens with all devices in the network. Select a controller from this overview. Then the `Archiv.prj` project archive is downloaded to this controller. You can click *“Source Upload”* to upload the complete source code to the CODESYS development system at a later time.

If you are already connected to a controller (in online mode), then the *“Source Download to Connected Device”* command is also available for this process.

See also

- *Chapter 1.4.1.10.7 “Downloading source code to and from the PLC” on page 393*
- *Chapter 1.4.1.20.3.1.10 “Command 'Source Upload'” on page 962*
- *Chapter 1.4.1.20.3.6.7 “Command 'Source Download to Connected Device'” on page 1035*

Command 'Print'

Symbol: 

Function: This command opens the default Windows dialog box for printing documents.

Call: Main menu *“File”*

See also

- *Chapter 1.4.1.20.4.11.6 “Dialog 'Project Settings' - 'Page Setup'” on page 1175*

Command 'Print Preview'

Function: This command opens a print preview for the currently open element.

Call: Main menu *“File”*

Requirement: An object is open in the editor.

See also

- *Chapter 1.4.1.20.4.11.6 “Dialog 'Project Settings' - 'Page Setup'” on page 1175*
- *Chapter 1.4.1.20.3.1.12 “Command 'Print'” on page 963*

Command 'Page Setup'

Symbol: 

Function: This command opens the *“Page Setup”* dialog box for configuring the layout of the printed version of the project contents.

Call: Main menu *“File ➔ Page Setup”*

See also

- *Chapter 1.4.1.20.4.11.6 “Dialog 'Project Settings' - 'Page Setup'” on page 1175*
- *Chapter 1.4.1.20.3.1.12 “Command 'Print'” on page 963*

Command ‘Recent Projects’

Function: Opens the list of the projects used recently, from which you can select a project to open.

Call: *“File”* menu

Command 'Exit'

Shortcut: *[<Alt>]+[<F4>]*

Function: this command exits from the programming system. If a project is currently opened that has been changed since it was last saved, a dialog box opens asking whether the project should be saved.

Call: *“File”* menu

Menu 'Edit'

Standard Commands

CODESYS provides the following standard commands:

- Undo: , shortcut: *[Ctrl]* + *[Z]*
- Redo: , shortcut: *[Ctrl]* + *[Y]*
- Cut: , shortcut: *[Ctrl]* + *[X]*
- Copy: , shortcut: *[Ctrl]* + *[C]*
- Paste: , shortcut: *[Ctrl]* + *[V]*
- Delete: , shortcut: *[Ctrl]*
- Select all: shortcut: *[Ctrl]* + *[Ctrl]*

Not all editors support the *"Insert"* command. In some editors it can be used with limitations. Graphical editors only support the command if the pasted elements will create a valid construct.

In object trees like POUs or device view the command refers to the currently selected object. Multi selection is possible.

Command 'Find', 'Find in Project'

Symbol ; keyboard shortcut: *[Ctrl]+[F]*

Symbol , keyboard shortcut *[Ctrl]+[Shift]+[F]*

Function: These commands scan the project or parts of it for a specified character string.

Call: Menu bar: *"Edit* ➔ *Find Replace"*

This command opens the *"Find"* dialog where the searched character string is specified and the search options are defined.

Dialog 'Find'

"Search for"	Character string to be searched.
"Match case":	: The search considers uppercase and lowercase.
"Match whole word":	: Only character strings are found that exact matches.
"Search up":	: The specified search range runs upwards. : The specified search range runs downwards.
"Use regular expressions":	Use the > button to receive support when specifying regular expressions.
"Search in"	: Drop-down list with the areas of the project to be searched: ● *"Active editor"* ● *"All open editors"* ● *"Selected objects & Subobjects"* ● *"Entire project"* ● *"Entire project & Uncompiled libraries"* ● *"Selection only"* ...: Opens a dialog where you set the areas of the project to be searched (see below)
"Find next"	Start the search
"Find all"	All search results are listed in the message view with their object path, project name, object name, and object position. Possible additional information for position: *"(Decl)"* = Declaration part of the object; *"(Impl)"* = Implementation part of the object Double-clicking the entry in the list opens the match position in the respective object editor.
"Replace"	Switches to the *"Replace"* dialog

The color of the search result markings can be customized in the options of the text editor. This is done by means of the parameter "Selection color" - "Inactive" in the "Text Area" tab.

See also

- *"Tab 'Text Area'" on page 1204*

Dialog for setting the objects to be searched

"Entire project"	All editable positions in all objects of the project are searched.
"Entire project and all uncompiled libraries"	All editable positions in all objects of the project, including integrated uncompiled libraries, are searched.
"Within the following objects"	Only the editable positions within the objects defined here are searched:
	• *"Scheme"*: The *"Save"* command saves the current search configuration by the specified name. All saved schemes are available in the drop-down list ( ). • *"Object types"*: : The object is searched. • *"Name filter"*: Name filter for the searched objects. The placeholder "*" can be used. Example: Filter "*CAN*": All objects are searched that have "CAN" in the name.
"All open editors"	All editors are searched that are currently open in a window.
"Active editor"	Only the editor is searched where the cursor currently is.
"Selection only"	Only the text is searched that is currently selected in an object.

See also

- *Chapter 1.4.1.20.3.2.3 "Command 'Replace', 'Replace in Project'" on page 967*
- *Chapter 1.4.1.8.14 "Searching and replacing in the entire project" on page 289*

Command 'Replace', 'Replace in Project'

Symbol ; keyboard shortcut: *[Ctrl]+[H]*

Symbol , keyboard shortcut *[Ctrl]+[Shift]+[H]*

Function: These commands scan the project or parts of it for a specified character string and replaces it.

Call: Menu bar: *"Edit ➔ Find Replace"*

Requirement: The application is in online mode.

This command opens the *"Replace"* dialog where the search and replace character strings are specified and the search options are defined.

Table 116: In addition to the options of the "Search" dialog, the following settings are still possible:

"Replace with"	Input field for the new character string.
"Replace"	Each next found string is highlighted in the editor and replaced (step-by-step replace).

“Replace all”	All found strings are replaced at one time without them being displayed in the editors.
“Leave changed objects open after "Replace all"”	The editors of the found objects remain open.

Replacement in referenced libraries is not possible.

- *Chapter 1.4.1.8.14 “Searching and replacing in the entire project” on page 289*

Command 'Find Next'

Symbol  ,keyboard shortcut *[F3]*

Function: During the search for a certain string within the project, this command selects the next match at its position in the respective editor.

Call: Menu *“Edit ➔ Search Replace”*

Requirement: You have already started searching the project for a certain string by using the commands *“Find”* or *“Replace”*.

See also

- *Chapter 1.4.1.20.3.2.2 “Command 'Find', 'Find in Project'” on page 966*

- *Chapter 1.4.1.8.14 “Searching and replacing in the entire project” on page 289*

Command 'Find Next (Selection)'

Keyboard shortcut *[Ctrl]* + *[F3]*

Function: The command searches the project for the next string matching the string which is currently selected or in which you have currently placed the cursor.

Call: Menu *“Edit ➔ Find Replace”*

Requirement: You have the cursor placed in an editable string in your project, or you have selected an editable string.

See also

- *Chapter 1.4.1.20.3.2.2 “Command 'Find', 'Find in Project'” on page 966*

- *Chapter 1.4.1.8.14 “Searching and replacing in the entire project” on page 289*

Command 'Insert File as Text'

Function: This command copies the contents of a text file to the active editor as the current cursor position.

Call: The command is not in any menu by default. You can add it to a menu by using the dialog box from *“Tools ➔ Customize”* (command category *“Text Editor”*).

Requirement: The file must have the extension `.txt`. The command is available in a text editor only.

Many development environments and text processing applications provide the option of exporting code and text as a plain text file. This command can copy the contents of this file to the editor.

See also

- *Chapter 1.4.1.20.4.13.25 “Dialog 'Options' - 'Text Editor'” on page 1203*

Command 'Overwrite Mode'

Shortcut: *[Insert]*

Function: This command activates the overwrite mode.

Call: Menu *“Edit ➔ Advanced”*

Requirement: A text editor is opened.

If the overwrite mode is activated, characters in front of the cursor are overwritten when entering new characters. If the overwrite mode is deactivated, characters are inserted and existing characters in front of the cursor are retained.

See also

- *Chapter 1.4.1.20.4.13.25 “Dialog 'Options' - 'Text Editor'” on page 1203*

Command 'View Whitespace'

Symbol: 

Function: This command causes control characters for spaces and tabs to be shown.

Call: Menu *“Edit ➔ Advanced”*

Requirement: A text editor is opened.

CODESYS visualizes spaces by a period and tabs by an arrow.

See also

- ↳ *Chapter 1.4.1.20.4.13.25 “Dialog 'Options' - 'Text Editor'” on page 1203*

Command 'View Indentation Guides'

Function: This command activates the indentation help lines.

Call: Menu *“Edit ➔ Extended”*

Requirement: A text editor is opened.

If the indentation help lines are activated, a broken line is inserted for each manual indentation in the code. This facilitates the overview of the different levels in the code. You can insert manual indentations with the *[Tab]* key.

See also

- ↳ *Chapter 1.4.1.20.4.13.25 “Dialog 'Options' - 'Text Editor'” on page 1203*

Command 'Go to Line'

Function: With this command the cursor jumps to a defined line in the code.

Call: Menu *“Edit ➔ Extended”*

Requirement: A text editor is opened.

This command opens a dialog box with an input field *“Line number”*.

See also

- ↳ *Chapter 1.4.1.20.4.13.25 “Dialog 'Options' - 'Text Editor'” on page 1203*

Command 'Make Uppercase'

Shortcut: *[Ctrl]+[Shift]+[U]*

Function: This command converts all lowercase letters in the selected code into uppercase letters.

Call: Menu *“Edit ➔ Advanced”*

Requirement: A text editor is opened and code is selected, or the declaration editor is opened and variable declarations are selected.

See also

- ↳ *Chapter 1.4.1.20.4.13.25 “Dialog 'Options' - 'Text Editor'” on page 1203*

Command 'Make Lowercase'

Shortcut: *[Ctrl]+[U]*

Function: This command converts all uppercase letters in the selected code into lowercase letters.

Call: Menu *“Edit ➔ Advanced”*

Requirement: a text editor is opened and code is selected, or the declaration editor is opened and variable declarations are selected.

See also

- *Chapter 1.4.1.20.4.13.25 “Dialog 'Options' - 'Text Editor'” on page 1203*

Command 'Go to Matching Bracket'

Function: This command makes the cursor jump to the other part of the selected code parenthesis.

Call: Menu *“Edit ➔ Advanced”*

Requirement: A text editor is opened and the cursor is positioned at an opening or closing code parenthesis. If you position the cursor at a code parenthesis, CODESYS displays the corresponding parenthesis in color, provided you have activated the option *“Associated parentheses”* in the CODESYS options in the *“Text Editor”* category, *“Text Area”* tab.

See also

- *“Tab 'Text Area'” on page 1204*

Command 'Select to Matching Bracket'

Function: This command selects the entire code section within the currently selected code parentheses.

Call: Menu *“Edit ➔ Extended”*

Requirement: A text editor is opened and the cursor is positioned at an opening or closing code parenthesis. If you position the cursor at a code parenthesis, CODESYS displays the corresponding parenthesis in color, provided you have activated the option *“Associated parentheses”* in the project options in the *“Text Editor”* category, *“Text Area”* tab.

See also

- *Chapter 1.4.1.20.4.13.25 “Dialog 'Options' - 'Text Editor'” on page 1203*

Command 'Expand All Folds'

Function: This command expands all collapsed code segments in the textual editor or result locations in the cross-reference list so that the code and all search locations are displayed in full again.

Requirement: A textual editor is active and indentation is activated in the *“Options”* (*“Text Editor”* category); or the cross-reference list is active.

Call: Textual editors: main menu*“Edit ➔ Advanced”*, or right-click. In the cross-reference list: right-click.

See also

- *Chapter 1.4.1.20.4.13.25 “Dialog 'Options' - 'Text Editor'” on page 1203*
- *Chapter 1.4.1.20.3.2.18 “Command 'Collapse All Folds'” on page 971*
- *“Right-click commands in the cross-reference list” on page 992*

Command 'Collapse All Folds'

Function: This command collapses all expanded code segments in the textual editor or result locations in the cross-reference list. In this way, only the uppermost level of code and only the root node of the result locations displayed.

Requirement: A textual editor is active and indentation is activated in the *"Options"* (*"Text Editor"* category); or the cross-reference list is active.

Call: In textual editors: main menu *"Edit ➔ Advanced"*, or right-click. In the cross-reference list: right-click.

See also

- *Chapter 1.4.1.20.4.13.25 "Dialog 'Options' - 'Text Editor'" on page 1203*
- *Chapter 1.4.1.20.3.2.17 "Command 'Expand All Folds'" on page 971*
- *"Right-click commands in the cross-reference list" on page 992*

Command 'Comment Out Selected Lines'

Symbol ; keyboard shortcut: *[Ctrl]+[O]*

Function: The command inserts comment marks ('//') at the beginning of the selected lines.

Call: Menu bar: *"Edit ➔ Advanced"*; context menu

Requirement: In the ST editor, either the cursor is located in a line of the implementation or multiple lines are selected.

See also

- *Chapter 1.4.1.20.3.2.20 "Command 'Uncomment Selected Lines'" on page 972*

Command 'Uncomment Selected Lines'

Symbol ; keyboard shortcut: *[Ctrl]+[I]*

Function: The command removes any comment marks ('//') at the beginning of the selected lines.

Call: Menu bar: *"Edit ➔ Advanced"*; context menu

Requirement: In the ST editor, either the cursor is located in a line of the implementation or multiple lines are selected.

See also

- *Chapter 1.4.1.20.3.2.19 "Command 'Comment Out Selected Lines'" on page 972*

Command 'Enable Inline Monitoring'

Function: This command enables or disables the inline monitoring function. This works the same way as the check box with the same name in the CODESYS options (*"Text Editor"* category).

Requirement: A text editor is active.

Call: Context menu of the text editor in the *"Advanced"* submenu.

See also

- *"Tab 'Monitoring'" on page 1205*
- *Chapter 1.4.1.12.1 "Monitoring of Values" on page 409*

Command 'Toggle Bookmark'

Symbol  , keyboard shortcut *[Ctrl]+[F12]*

Function: The command sets or removes a bookmark at the current position.

Call: Menu bar: *"Edit ➔ Bookmarks"*

Requirement: A POU is open in the editor and the cursor is at a program line.

See also

- *Chapter 1.4.1.8.13.3 “Setting and using bookmarks” on page 287*

Command 'Next Bookmark (Active Editor)'

Symbol: ; keyboard shortcut: *[F12]*

Function: The command jumps to the next bookmark in the active editor.

Call: Menu bar: *“Edit ➔ Bookmarks”*

Requirement: A POU is open in the editor and the cursor is positioned in the POU.

See also

- *Chapter 1.4.1.20.3.2.24 “Command 'Next Bookmark'” on page 973*
- *Chapter 1.4.1.8.13.3 “Setting and using bookmarks” on page 287*

Command 'Next Bookmark'

Symbol:

Function: The command jumps to the next bookmark in the *“Bookmarks”* view and in the project, and opens the respective POU. The order of jumping to bookmarks corresponds to the order of bookmarks in the table of the *“Bookmarks”* view.

Call:

- *“Next Bookmark”* button in the *“Bookmarks”* view
- The command is not in any menu by default. You can add it to a menu by using the dialog from *“Tools ➔ Customize”* (command category *“Bookmarks”*).

Requirement:

- A project is open.
- The *“Bookmarks”* view is open.

See also

- *Chapter 1.4.1.20.3.2.23 “Command 'Next Bookmark (Active Editor)'” on page 973*

Command 'Previous Bookmark (Active Editor)'

Symbol: ; keyboard shortcut: *[Shift]+[F12]*

Function: The command jumps to the previous bookmark in the active editor.

Call: Menu bar: *“Edit ➔ Bookmarks”*

A POU is open in the editor and the cursor is positioned in the POU.

See also

- *Chapter 1.4.1.20.3.2.26 “Command 'Previous Bookmark'” on page 973*
- *Chapter 1.4.1.8.13.3 “Setting and using bookmarks” on page 287*

Command 'Previous Bookmark'

Symbol:

Function: The command jumps to the previous bookmark in the *“Bookmarks”* view and in the project, and opens the respective POU. The order of jumping to bookmarks corresponds to the order of bookmarks in the table of the *“Bookmarks”* view.

Call:

- *"Next Bookmark"* button in the *"Bookmarks"* view
- The command is not in any menu by default. You can add it to a menu by using the dialog from *"Tools ➔ Customize"* (command category *"Bookmarks"*).

Requirement:

- A project is open.
- The *"Bookmarks"* view is open.

See also

- *Chapter 1.4.1.20.3.2.25 "Command 'Previous Bookmark (Active Editor)'" on page 973*
- *Chapter 1.4.1.8.13.3 "Setting and using bookmarks" on page 287*

Command 'Clear All Bookmarks (Active Editor)'

Symbol:

Function: The command deletes all bookmarks in the active editor.

Call: Menu bar: *"Bookmarks"*

Requirement: A POU is open in the editor and the cursor is positioned in the POU.

See also

- *Chapter 1.4.1.20.3.2.28 "Command 'Clear All Bookmarks'" on page 974*
- *Chapter 1.4.1.8.13.3 "Setting and using bookmarks" on page 287*

Command 'Clear All Bookmarks'

Symbol:

Function: The command deletes all bookmarks in the open project.

Call: The command is not in any menu by default. You can add it to a menu by using the dialog from *"Tools ➔ Customize"* (command category *"Bookmarks"*).

Requirement: A POU is open in the editor and the cursor is positioned in the POU.

See also

- *Chapter 1.4.1.20.3.2.27 "Command 'Clear All Bookmarks (Active Editor)'" on page 974*
- *Chapter 1.4.1.8.13.3 "Setting and using bookmarks" on page 287*

Command 'Browse Cross References'

Symbol:

Function: The command shows all occurrences of a variable in the *"Cross Reference List"* view.

Call: Menu bar: *"Edit ➔ Browse"*; cross reference view: toolbar

Requirement: A POU is open in the editor and the cursor is set at a variable. Or the *"Cross Reference List"* view is open and a variable is specified in the *"Name"* field.

See also

- *Chapter 1.4.1.8.13.1 "Using the cross-reference list to find occurrences" on page 285*
- *Chapter 1.4.1.20.3.2.30 "Command 'Browse Global Cross References'" on page 975*

Command 'Browse Global Cross References'

Symbol: 

Function: The command shows all occurrences of all variables with the same name in the *"Cross Reference List"* view. In contrast to the *"Browse Cross References"* command, these can be different variables.

Call: Menu bar: *"Edit ➔ Browse"*; cross reference view: toolbar

Requirement: A POU is open in the editor and the cursor is set at a variable. Or the *"Cross Reference List"* view is open and a variable is specified in the *"Name"* field.

See also

- *Chapter 1.4.1.8.13.1 "Using the cross-reference list to find occurrences" on page 285*
- *Chapter 1.4.1.20.3.2.29 "Command 'Browse Cross References'" on page 974*

Command 'Browse Call Tree'

Symbol: 

Function: The command opens the view *"Call Tree"*, which displays the calls of a module and also its callers.

Call:

- Menu *"Edit ➔ Browse"*
- Context menu, see below: Requirement

Requirement: A module is opened in the editor and the cursor is placed in a variable, or a module is selected in the *"Devices"* view or in the *"POUs"* view.

See also

- *Chapter 1.4.1.20.3.3.16 "Command 'Call tree'" on page 993*

Command 'Auto Declare'

Keyboard shortcut: *[Shift]+[F2]*

Function: The command opens the *"Auto Declare"* dialog, which supports the declaration of a variable.

Call: Menu bar: *"Edit"*

Requirement: An object or a device of the project is opened in the editor.

With the auto-declaration function, the *"Auto Declare"* dialog also appears when the cursor is located in the implementation part of a POU in a line containing the name of an undeclared variable. The requirement for this is that you must have clicked *"Tools ➔ Options"* and enabled the *"Declare unknown variables automatically (AutoDeclare)"* option in the *"SmartCoding"* category.

With the smart tag function, the *"Auto Declare"* command also appears when you place the cursor over an undeclared variable in the implementation part of the ST editor and then click  .

Dialog 'Auto Declare'

"Scope"	Scope of the variable that is not declared yet. Example: `VAR` (default setting for local variables)
"Name"	Variable name not declared yet Example: `bIsValid`

"Type"	Example: `BOOL` ● ▼: Lists the standard data types. ● >: – *"Input Assistant"*: Opens the *"Input Assistant"* dialog – *"Array Assistant"*: Opens the *"Array"* dialog
"Object"	Object where the new variable is declared. By default, the object that you are editing now. Example: `fbA` ▼: Lists that objects where the variable can be declared. If no objects are available for the selected *"Scope"*, the entry *"<create object>"* appears. When you select the *"<create object>"* entry, the *"Add Object"* dialog opens for generating a suitable object.
"Initialization"	Example: `FALSE` If you do not specify an initialization value, then the variable is initialized automatically. ...: Opens the *"Initialization Value"* dialog. This procedure is helpful for the initialization of structured variables.
"Address"	Memory address of the application for the variable that is not declared yet. Example: `%IX1.0` Note: Possible only for the following scopes: ● Local variable (`VAR`) ● Global variable (`VAR_GLOBAL`) ● Or for a persistent variable (`PERSISTENT`).
"Flags"	Attribute keywords ● `CONSTANT`: Keyword for a constant. ● `RETAIN`: Keyword for a remanent variable. ● `PERSISTENT`: Keyword for a persistent variable (stricter than `RETAIN`). The selected attribute keyword is added to the variable declaration.
"Comment"	Example: `New input In1` In the tabular declaration editor, the comment entered is displayed in the *"Comment"* column, while in the textual declaration editor it is displayed above the variable declaration.
"Apply changes using refactoring"	☑: When you exit the dialog, the variable is not declared yet, but then it opens the *"Refactoring"* dialog. You can continue editing your changes here. The option appears for the following scopes: ● Input variable (`VAR_INPUT`) ● Output variable (`VAR_OUTPUT`) ● `VAR_IN_OUT` variables (input variable and output variable)

"OK"	The variable is declared and appears in the declaration.
	Example:
	`VAR RETAIN`
	`    // New input In1`
	`    xIn1 AT %IX1.0: BOOL := FALSE;`
	`END_VAR`

Dialog 'Array'

"Ranks and base type specification"	Definition of the field sizes (*"Dimension"*) by entering the lower and upper limits and the *"Base type"* of the array. You can enter the basic type directly or with the help of the *"Input Assistant"* or *"Array"* dialogs when you click the > button.
"Result"	Display of the defined array

NOTICE!
CODESYS reinitializes variables only if you have modified the initialization values of the variables.

Dialog 'Initialization Value'

List of the variables with name (*"Expression"*), *"Initialization Value"* and *"Data Type"*. Modified initialization values are displayed in bold fonts.	
Input field below the list	Input of an initialization value for the selected variable(s)
"Apply value to selected lines"	Change of the initialization value of the selected line(s) according to the value of the input field
"Reset selected lines to default values"	Resets the default initialization values
"OK"	CODESYS applies the initialization values in the *"Auto Declare"* dialog.

In the case that the variable to be initialized by means of this dialog is a function block instance with an extended FB_Init method, an additional table is displayed above the *"Initialization Value"* table. The additional FB_Init parameters are listed in this table. The meaning and operation essentially correspond to the lower table with the following differences:

- All variables have to be assigned with initialization values. Otherwise *"OK"* remains disabled.
- For complex data types (structures, arrays), no components contained within are displayed (type cannot be expanded). In this case, the complex type has to be initialized with a corresponding variable.

For FB_Init parameters configure this way, a corresponding symbol is displayed after the initialization value in the *"Auto Declare"* dialog.

Command 'Input Assistant'

Symbol: ; keyboard shortcut: *[F2]*

Function: This command opens the *“Input Assistant”* dialog which helps you to select one of the possible programming elements at the current cursor position.

Call: Menu bar: *“Edit”*; context menu.

Requirement: A POU is open in the editor and the cursor is at a program line.

Dialog 'Input Assistant' - Tab 'Categories'

The input assistant provides all program elements that you can insert at the current cursor position in the editor.

The elements are sorted by *“Categories”*. In the category *“Variables”*, you can also set a *“Filter”* for the scope, for example *“Local variables”*, *“Global variables”*, or *“Constants”*.

“Structured view”	☑: The elements are displayed in a structure tree. You can show/hide the columns *“Type”*, *“Address”*, and *“Origin”* by right-clicking the column title and selecting/clearing the column name in the dropdown list. ☐: The elements are displayed in a flat structure.
“Show documentation”	☑: The dialog is extended with the *“Documentation”* field.
“Insert with arguments”	☑: Elements that include arguments (for example, functions) also insert with these arguments at the cursor position. Example: If you insert the function block `fb1`, which contains an input variable `fb1_in` and an output variable `fb1_out`, "with arguments", then this appears in the editor as follows: `fb1(fb1_in:= , fb1_out=> ).`
“Insert with namespace prefix”	☑: Inserts the selected element with the appended namespace. In the case of library modules, the check box remains disabled if the requirement for a namespace has been defined in the library properties.

If you create objects with the same name in the same category, whether globally (“POUs” view) or assigned to an application (“Devices” view), then only one entry appears in the input assistant. The usage conforms to the usual call priority (application assigned before global).

Dialog 'Input Assistant' - Tab 'Text Search'

This tab allows you to search for specific objects. When you begin typing a search string into the search field, the names of all objects are listed whose names include the search string. Double-click an object to insert it at the current cursor position in the editor.

“Filters”	Limits the search to a specific variable category

- *Chapter 1.4.1.20.3.2.33 “Command 'Input Assistant'” on page 977*

Command 'Go to Source Position'

Function: The command sets the cursor to the position in the source code that causes the message.

Call: Main menu *“Edit”*, context menu of the message in the message view.

Requirements: A message is selected in the message view.

Use the command *“Next Message”* or *“Previous Message”* to display the source code position of the next or previous message.

See also

- *Chapter 1.4.1.20.3.2.35 “Command 'Next Message'” on page 979*
- *Chapter 1.4.1.20.3.2.36 “Command 'Previous Message'” on page 979*
- *Chapter 1.4.1.20.3.3.5 “Command 'Messages'” on page 986*

Command 'Next Message'

Keyboard shortcut: *[F4]*

Function: This command selects the next message in the messages view.

Call: Main menu *“Edit”*.

If the last message in the list has been reached, then the marking jumps to the beginning.

See also

- *Chapter 1.4.1.20.3.2.36 “Command 'Previous Message'” on page 979*

Command 'Previous Message'

Keyboard shortcut: *[Shift]+[F4]*

Function: This command selects the previous message in the messages view.

Call: Main menu *“Edit”*

If the first message in the list has been reached, then the marking jumps to the end.

See also

- *Chapter 1.4.1.20.3.2.35 “Command 'Next Message'” on page 979*

Command 'Go to Definition'

Symbol: 

Function: This command shows the definition locations of a variable or function.

Call: Main menu *“Edit ➔ Browse”*

Requirement: A POU is open in the editor and the cursor is at a variable or function.

See also

- *Chapter 1.4.1.8.13.2 “Finding declarations” on page 287*

Command 'Go To Reference'

Symbol: 

Function: The command opens the declaration location of the variable that is referenced by the pointer currently in focus in online mode.

Call:

- Context menu in the declaration part or implementation code
- Menu bar: *“Edit ➔ Browse”*

Requirement: Online mode. A POU is open in the editor and the cursor is at a pointer. The referenced variable is stored in static memory.

If the pointer does not point exactly to the beginning of the variable, then a corresponding message is displayed when you switch to the variable declaration.

See also

- *Chapter 1.4.1.19.5.12 “Pointers” on page 656*

Command 'Go to Instance'

Symbol:

Function: This command opens the instance of a function block in a new window.

Call: Menu bar: *“Edit ➔ Browse for Symbol”*

Requirement: The application is in online mode. A POU is open in the editor and the cursor is at an instance of a function block.

The command is not available for temporary instances or instances from compiled libraries.

See also

- *Chapter 1.4.1.8.13.2 “Finding declarations” on page 287*

Command 'Refactoring' - 'Rename <...>'

Function: This command opens a dialog box for renaming an object or variable across the project.

Call: Main menu *“Edit ➔ Refactoring”* or right-click.

Requirement: An object is selected in the device tree or in the *“POUs”* view, or the cursor is placed before or on a variable identifier in the declaration section of a programming object.

You can rename the following:

- Variables
- POUs
- GVLs
- Methods
- Properties
- Devices
- Variables and unit conversions in the unit conversion edit

Dialog box 'Rename'

“Current name”	Name of the object or variable
“New name”	Input field for a new name. If the name already exists, then CODESYS reports this directly below this input field.
“OK”	Can be activated if you have typed a valid name in *“New name”*. Opens the *“Refactoring”* dialog box. The affected objects and occurrences are highlighted in both views. You can determine how to handle the occurrences in each view by right-clicking the occurrences and clicking the available commands.

Dialog box 'Re-factoring'

This dialog box displays all occurrences in the project. The affected objects and occurrences are highlighted in both views.	
Right view	Displays the occurrence within an object where *"Current name"* occurs.
Left view	Device tree of the project with the object.
You can determine how to handle the occurrences in each view by right-clicking the occurrences and clicking the available commands.	
"Reject this change"	Reject the single change in view on the right.
"Accept this object"	Accept all changes in the affected object.
"Reject this object"	Reject all changes in the affected object.
"Accept whole project"	Accept all changes in the project.
"Reject whole project"	Reject all changes in the project.
CODESYS highlights the accepted changes in yellow and the rejected changes in gray.	

See also

- *Chapter 1.4.1.8.15 "Refactoring" on page 289*

Command 'Refactoring' - 'Update Referenced Pins'

> **NOTICE!**
> Currently, this command applies only to the CFC, FBD, LD, and IL editors. It is a combination of the *"Reset Pins"* and *"Update Parameters"* commands.

Function: This command modifies the pins according to the latest block declaration in all affected occurrences of the block.

Call: Main menu *"Edit ➔ Refactoring"* or right-click.

Requirement: The cursor is placed in the name of the block in the first line of the block declaration or in the device tree.

See also

- *Chapter 1.4.1.8.15 "Refactoring" on page 289*
- *Chapter 1.4.1.20.3.12.24 "Command 'Reset Pins'" on page 1098*
- *Chapter 1.4.1.20.3.13.38 "Command 'Update Parameters'" on page 1114*

Command 'Refactoring' - 'Add Variable'

Symbol: 

Function: This command enables the declaration of variables in a POU, as well as the automatic update to the occurrence of the POU.

Call: Main menu *"Edit ➔ Refactoring"*, or right-click.

Requirements: The declaration part is in focus.

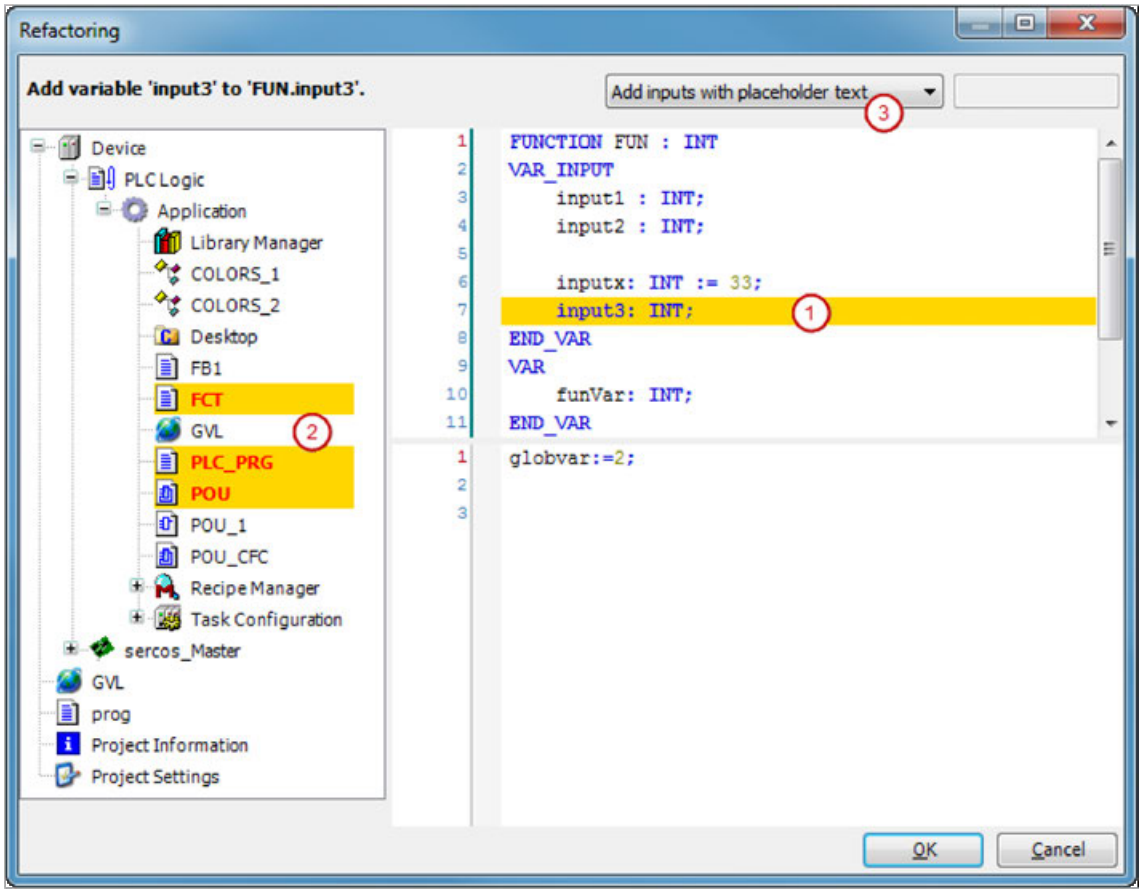
The command opens the default dialog box for declaring variables.

See also

- *"Dialog 'Auto Declare'" on page 975*

Dialog box 'Refactoring'

After clicking *"OK"* to close the declaration dialog, the *"Refactoring"* dialog box opens with two frames.



"Right dialog frame "	Declaration part and implementation of the POU where the variable is added. Colored highlighting of changed locations: New added declarations have a blue font and are highlighted in yellow (1).
"Left dialog frame "	Device tree or POUs tree of the project. Colored highlighting of blocks where the POU is used: red font and yellow highlight (2). After you double-click the POU object, the detail view opens.

Before you decide which changes to accept at which locations, select the required option from the drop-down list (3) at the upper right part of the window:

"Add inputs with placeholder text"	Default placeholder text: `_REFACTOR_`; editable The placeholder text defined here is used at the occurrence locations of the new added variables in the implementation code. This is used for searching for the affected locations.
"Add inputs with the following value"	Initialization value for the new variable.

You can accept or reject changes by right-clicking the changed locations or by executing commands in the left or right area of the dialog box. Refer to the description of the *"Refactoring ➔ Rename"* command.

Examples

1. By refactoring, the `fun` block receives a new input variable `input3` with the initialization value `1`. The change has the following effect:

Before:

```
fun(a + b, 3, TRUE);
fun(input1:= a + b , input2 :=3 , inputx := TRUE);
```

After:

```
fun(a + b, 3, 1, TRUE);
fun(input1:= a + b , input2 :=3 , _REFACTOR_, inputx := TRUE);
```

2. By refactoring, the "fun" block receives a new input variable `input3` with the placeholder text "_REFACTOR_":

Before:

```
inst(input1 := a + b, input2 := 3, inputx := TRUE);
fun(a + b, 3, TRUE);
```

After:

```
inst(input1 := a + b, input2 := 3, input3 := _REFACTOR_, inputx
:= TRUE);
fun(a + b, 3, _REFACTOR_, TRUE);
```

- *Chapter 1.4.1.8.15 “Refactoring” on page 289*
- *Chapter 1.4.1.20.3.2.40 “Command 'Refactoring' - 'Rename <...>'” on page 980*

Command 'Refactoring' - 'Remove <variable>'

Symbol: 

Function: This command removes an input or output variable from the POU and all occurrences of the POU.

Call: Main menu *“Edit ➔ Refactoring”*, or right-click.

Requirements: In the declaration part of the POU, the cursor is located in the identifier of the variable to be removed.

Then, the command opens a dialog box with information about the removal. After you confirm this, the *“Refactoring”* dialog box opens. For a description of the *“Refactoring”* dialog box, refer to the *“Edit ➔ Refactoring ➔ Rename”* help page.

When you accept the changes in the *“Refactoring”* dialog box, the respective input and output parameters are deleted at the occurrence locations of the affected POU.

In CFC, only the connection is removed between the removed input or output to the block. The input or output itself remains in the chart.

Example in ST

In a POU, refactoring removes the `input4` input variable. The occurrences are updated automatically:

Before removal:

```
inst(input1 := a + b, input2 := 3, input4 := 1, input5 := TRUE);
fun(a + b, 3, 1, TRUE);
```

After removal:

```
inst(input1 := a + b, input2 := 3, input5 := TRUE);
fun(a + b, 3, TRUE);
```

- *Chapter 1.4.1.8.15 “Refactoring” on page 289*
- *Chapter 1.4.1.20.3.2.40 “Command 'Refactoring' - 'Rename <...>'” on page 980*

Command 'Refactoring' - 'Reorder Variables'

Symbol: 

Function: This command allows changing the order of variables in the declaration editor for the selected scope: `VAR_INPUT`, `VAR_OUTPUT`, or `VAR_IN_OUT`.

Call: *“Edit ➔ Refactoring”*; context menu of the focused scope in the declaration editor.

Requirement: One of the above scopes is selected in the declaration, and more than one variable is declared in it.

The command opens the *“Reorder”* dialog box with a list of all declarations of the selected scope. You can drag a selected declaration up or down to another position.

See also

- *Chapter 1.4.1.8.15 “Refactoring” on page 289*

Command 'Advanced' - 'Format Document'

Symbol: 

Function: The command starts an automatic formatting of the code in the open ST editor.

Call: Menu bar: *“Edit ➔ Advanced”*; context menu of the window in focus in the ST editor

Requirement: The focus is in the ST editor. The syntax of the ST code does not contain any errors.

The following formatting is performed automatically:

- Keywords are converted to uppercase letters.
- Spacing is standardized.
- Indentations are changed according to syntax.
- Long lines are wrapped in sensible places.

- *Chapter 1.4.1.19.1.3.1 “ST Editor” on page 463*

Menu 'View'

Standard Menu in View 'Devices', 'POUs', 'Modules'

The views *“Devices”*, *“POUs”* and *“Modules”* provide the button in the top right corner to open a menu with the following commands:

- *“Open in editor”*: Opens the selected object in the corresponding editor.
- *“Find object”*: Opens the dialog *“Find Object”* for the object tree. Starting to enter a search string all matching objects will be displayed with their path. Use the button *“Open”* to open the selected search result in the editor.
- *“Sort by type”*: Sorts the objects in the view alphabetic by type.
- *“Sort by name”*: Sorts the objects in the view alphabetic by name.
- *“Sort ascending”*: Displays the chosen sorting in ascending order.
- *“Sort descending”*: Displays the chosen sorting in descending order.
- *“Track active editor”*: CODESYS selects the object, that is opened in the active editor, in the device tree of the view.

See also

- *Chapter 1.4.1.20.3.3.2 “Command 'Devices'” on page 985*
- *Chapter 1.4.1.20.3.3.3 “Command ‘POUs’” on page 986*
- *Chapter 1.4.1.20.3.3.4 “Command 'Modules'” on page 986*

Command 'Devices'

Symbol: , view: *[Alt]* + *[0]*

Function: The command opens the view *“Devices”* in the CODESYS main window. The view contains the project's "device tree", where you configure your applications

Button opens the standard menu for navigating in the tree view.

Call: Menu *“View”*

See also

- *Chapter 1.4.1.20.3.3.3 “Command ‘POUs’” on page 986*
- *Chapter 1.4.1.20.3.3.1 “Standard Menu in View 'Devices', 'POUs', 'Modules'” on page 985*

Command ‘POUs’

Symbol: , Shortcut: *[Alt]* + *[1]*

Function: This command opens the *“POUs”* view in the CODESYS main window. POUs located here are available in the entire project.

Call: Menu *“View”*

See also

- *Chapter 1.4.1.20.3.3.1 “Standard Menu in View 'Devices', 'POUs', 'Modules'” on page 985*

Command 'Modules'

Symbol:

Function: This command opens the *“Modules”* view and shows the modules of the application composer in a tree structure.

Call: Main menu *“View”*

See also

- *Chapter 1.4.1.20.3.3.1 “Standard Menu in View 'Devices', 'POUs', 'Modules'” on page 985*

Command 'Messages'

Symbol:

Function: This command opens the *“Messages”* view.

Call: Menu bar: *“View”*.

View 'Messages'

Message category	The messages are categorized by component or functionality for selection from a drop-down list. Filter the message display by selecting a category.
Message type	Click the symbol of the message type to show or hide messages. CODESYS displays the number of messages next to each symbol. ● : Error ● : Warning ● : Message
	Deletes all messages in the selected message category.
	Deletes all messages in all message categories.
“Description”	Message text with the reported object and the location in the object. Double-click a message in the table to jump to the source text location.
“Project”	
“Object”	
“Position”	

Table 117: "Commands in the context menu"

"Next Message"	The source text position of the next message is displayed.
"Previous Message"	The source text position of the previous message is displayed.
"Go to Source Position"	The source position of the selected message is displayed.

Command 'Element properties'

Symbol: 

Function: This command opens the *"Element Properties"* view.

Call: Main menu *"View"*

This command opens the properties view for the open object. This view is available only for a few objects, for example visualization and POU (SFC).

The properties are displayed in a structured table. You change the property values by clicking into the value fields. You can filter or sort the properties view.

Command 'ToolBox'

Symbol: 

Function: This command opens the *"ToolBox"* view.

Call: Main menu *"View"*

This command opens the toolbox view for the open object. By default, this view is available for graphical editors and visualizations. It includes the graphical programming elements that you can drag into the editor.

Command 'Watch' - 'Watch <n>'

Symbol: 

Function: This command opens the "Watch <n>" view. You can populate a watchlist with variables from your project in order to monitor, force, or write these variable values in an individual view in online mode. The value "n" can be 1, 2, 3, or 4 for a total of up to four watchlists.

Call: Main menu *"View"*

See also

- *Chapter 1.4.1.12.1.2 "Using watch lists" on page 416*

Command 'Watch' - 'Watch All Forces'

Symbol: 

Function: The command opens the *"Watch All Forces"* view, which is a special kind of watch list.

Call: Menu bar: *"View* ➔ *Watch* ➔ *Watch All Forces"*

Requirement: A project is in offline mode or online mode.

The view contains all variables currently prepared for forcing, and all forced variables of the application in one list. Actions are possible in the list which are also possible in other watch lists. Moreover, the following commands are available in the *"Unforce"* list box of the view:

Table 118: “Watch All Forces”

Tabular view of all forced variables of the application, including variables prepared for forcing	
“Expression”	Variable name
“Data Type”	Data type of the variable
“Value”	Currently forced value of the variable
“Prepared Value”	Value prepared for forcing
“Overwritten value at start of cycle”	For inputs, the actual value is already overwritten by the force value before the application code is executed. As a result, this is the forced value. For outputs, this is the forced value.
“Overwritten value at end of cycle”	For outputs, this is the value which is calculated in the cycle. However, this value is overwritten by the force value at the end of the cycle. For inputs, this is the forced value.

- *“Unforce and Keep All Selected Values”*: For all selected entries in the list, the variables will be set to the forced value and the forcing will be lifted
- *“Unforce and Restore All Selected Values”*: For all selected entries in the list, the variables will be reset to the values they had before they were forced, and the forcing will be lifted.

See also

- *Chapter 1.4.1.11.4 “Forcing and Writing of Variables” on page 401*
- *Chapter 1.4.1.12.1.2 “Using watch lists” on page 416*

Command 'Add All Forces to Watchlist'

Function: The command adds all variables of the active application, which are currently prepared for forcing, or which are already forced, to the watchlist. Please regard, that this works only for docked watch list views.

Call: Context menu of view *“Watch”*

Requirement: Online mode, a watch list view is active.

There is a special watch list: “Watch All Forces”. This view shows automatically all variables currently prepared for forcing or already being forced. It provides additional commands for releasing any forces.

See also

- *Chapter 1.4.1.20.3.3.8 “Command 'Watch' - 'Watch <n>'” on page 987*
- *Chapter 1.4.1.20.3.3.9 “Command 'Watch' - 'Watch All Forces'” on page 987*
- *Chapter 1.4.1.11.4 “Forcing and Writing of Variables” on page 401*

Command 'Bookmarks'

Symbol:

Function: This command opens the *“Bookmarks”* view.

Call: Menu bar: *“View”*.

"Previous Bookmark"	Jumps to the bookmark that above the selected bookmark in the table and opens the respective POU in the editor.
"Next Bookmark"	Jumps to the bookmark that below the selected bookmark in the table and opens the respective POU in the editor.
	Deletes the selected bookmark from the table and in the respective POU.
List of bookmarks in the project with the following information: *"Bookmark"*, *"Object"*, and *"Position"*. You can edit the bookmark order per drag&drop. When you double-click a row, CODESYS opens the respective *"Object"* in the editor and jumps to this bookmark.	
"Bookmark"	Name of the bookmark as assigned by CODESYS in ascending numerical order: *"Bookmark_0"*, *"Bookmark_2"* etc. If the bookmark is selected and you click in the field, then it is editable and you can modify the bookmark name.
"Object"	Name and project path of the POU where the bookmark is set Example: `POU_Add [PLC_1: SPS-Logic: Application]`
"Position"	Position of the bookmark in the POU Example: `Row 3, Column 1 (Impl)` `(Impl)`: in the implementation part of the POU `(Decl)`: in the declaration part of the POU

See also

- *Chapter 1.4.1.8.13.3 "Setting and using bookmarks" on page 287*
- *Chapter 1.4.1.20.3.2.24 "Command 'Next Bookmark'" on page 973*
- *Chapter 1.4.1.20.3.2.26 "Command 'Previous Bookmark'" on page 973*

Command 'Breakpoints'

Symbol:

Function: This command opens the *"Breakpoints"* view.

Call: Menu bar: *"View"*.

This view shows an overview of all defined breakpoints for an application. You have access to all breakpoint commands within this view.

Table 119: Table of current breakpoints

"Application"	Select the required application from the list.
"POU"	Name of the function block that will receive the breakpoint
"Location"	Location of the breakpoint in the POU ● Text editor: Line number and column number ● Graphical editor: Network number or element number For function blocks, "(Impl)" indicates that the breakpoint is located in the implementation of the function block, not in an instance.
"Instance Path"	Complete object path of the breakpoint location.
"Tasks"	Names of tasks that will be effective when the breakpoint is executed. If there are no restrictions, then "(all)" is displayed here.

"Condition"	• *"Break always"*: No additional enable condition defined; the breakpoint is always enabled. • Boolean expression. The expression must yield `TRUE` for the breakpoint to be enabled.
"Hit Count Condition"	When the breakpoint should be in effect (depending on the hit count)
"Current Hit Count"	How often the breakpoint has already been reached up to now during the execution

Table 120: Toolbar

	*"New Breakpoint"*	This command opens the *"Breakpoint Properties"* dialog.
	"New Data Breakpoint"	This command opens the *"New Breakpoint"* dialog.
	*"Clear Breakpoint"*	Removes the breakpoint (not the same as disable)
	*"Enable/Disable Breakpoint"*	Toggles the status of the breakpoint or execution point between "enabled" and "disabled" • Breakpoint enabled • Breakpoint disabled • Execution point enabled • Execution point disabled • Data breakpoint enabled • Data breakpoint disabled • Data execution point enabled • Data execution point disabled As opposed to "Clear breakpoint", a disabled breakpoint remains in the list and can be enabled again.
	*"Properties"*	The *"Breakpoint Properties"* dialog opens for editing the breakpoint parameters. This dialog is the same as *"New Breakpoint"*. In online mode, you can change the breakpoint into an execution point.
	*"Go to Source Position"*	Opens the online view of the affected block. The cursor is set at the breakpoint location.
	*"Clear All Breakpoints"*	Deletes all breakpoints and execution points in the application. The list is cleared. Not to be confused with "deactivate".
	*"Enable All Breakpoints"*	Enables all currently disabled breakpoints and execution points.
	*"Disable All Breakpoints"*	Disables all currently enabled breakpoints and execution points. The points remain in the list and can be enabled again.

Command 'Cross Reference List'

Symbol: 

Function: This command opens the *"Cross Reference List"* view.

Call: Menu bar: *"View"*, or *"Edit ➔ Browse ➔ Browse Cross References"*.

This view shows a list of cross-references for a symbol in the project. The symbol can be a variable, a POU (program, function block, function), or a user-specific data type (DUT). The cross-reference list offer two basic types of searches:

- Text search: By specifying a symbol name, the cross-references of all symbols in the project are displayed with their names. If multiple symbols with the same are found, then the display can be limited to individual declarations by means of the context menu.
- Declaration search: The symbol can be selected by means of the input assistant or by specifying a qualified path (for example, `Device.Application.PLC_PRG.i` or `__POOL.POU.a`). Then only the occurrence locations of this symbol are displayed, even if there exist other symbols with the same name.

Input field	Symbol name (variable name, POU name, DUT name). Input options: ● Selection of a declared symbol by means of the input assistant (button). ● Manual input of the symbol name. Triggering of the search by pressing the button or the *[Enter]* key. For the text search, you can use the placeholders "`*`" (any number of characters) or "`?`" (exactly any one character) in combination with a partial string of a variable identifier. Use the percent sign "`%`" to search for IEC addresses. Examples: "`%MW8`", "`%M*`". More options outside of cross-reference list view: ● Use the command *"Browse for Symbol ➔ Browse Cross References"* if the name of a declared symbol is selected in an editor, or if the cursor is in the name field. A search is also possible if the object is selected in the device tree or POU pool. ● Automatic if the name of a declared symbol is selected in an editor, or if the cursor is in the name field. A automatic search is also possible if the object is selected in the device tree or POU pool. Requirement: CODESYS option *"Automatically list selection in cross reference view"* is activated (category *"SmartCoding"*. The following input is valid: ● Variable name, simple or qualified. Examples: "`iVar`", "`PLC_PRG.iVar`". ● POU name: Examples: "`PLC_PRG`", "`myFB`". ● DUT name: Example: "`mySTRUCT`". ● Strings combined with placeholders: asterisk (*) for any character or question mark (?) for exactly one characters). Example: "`iVar*`" applies to `iVar1`, `iVar_glob2`, `iVar45`, etc. "`iVar?`" refers to `iVar1`, `iVar2`, `iVarX`, and so on, but not `iVar_glob2`, `iVar45` and so on... ● "`%<IEC address>`": CODESYS searches for variables that are assigned to this address and direct memory access. Example: "`%QB0`", `%Q0 := 2`.
	Open input assistant for selecting a symbol
	Perform a search
	Define columns to search for the string.
Input field	String that is searched for in the selected columns. The result locations are marked in yellow. Cross references without this string are hidden.
	Show source position of previous cross-reference, *[Shift]+[F4]*
	Show source position of next cross-reference, *[F4]*
	Limit results to current declaration: Available if multiple declarations are found for a symbol. Limits the display to the declaration that you have selected in the list.

	Show source position of selected cross-reference: The focus jumps to the occurrence location of the symbol.
	Print cross-reference list: The default dialog opens for setting up a print job.
The cross references are displayed with the following information:	
“Symbol”	The result locations for the symbols (variables, POUs, or DUTs) are grouped by declaration. The declaration occurrence comprises the root node and the occurrence locations in the project are indented below. The precise expression is displayed that has the symbol at the occurrence location. Example: If there is a global variable `i` in the project and a local declared variable `i` in a POU, then two root node entries will be listed after a text search for cross-references with the occurrences of the variable `i` below each.
“POU”	Block name; also a task name if a block call in the task configuration.
“Variable”	Only the variable name (for example, `iVar`)
“Access”	Type of access to the variable at the occurrence location: *“Declaration”* / *“Read”* / *“Write”* / *“Call”*. Special case for pointers: An assignment type `p := ADR(var1)` is displayed as `write | address` when searching for `var1`. The reason for this: Any write access to `p` is not displayed when searching for `var1`. Write access is also possible by means of pointer variables.
“Type”	Data type of the variable
“Address”	IEC address if variables are assigned Example: "`AT %QB0`".
“Position”	Location of the occurrence in the POU editor, for example line number, network number, declaration part, or implementation part. Example: "`line 1, column 1 (Impl)`".
“Object”	POU name plus complete path of the occurrence location in brackets (if this is found in the *“Devices”* view). Example: "`PLC_PRG [Device:Plc Logic:Application]`"
“Comment”	Comments if available in the declaration of the variable

The search yields all result locations in the project and in included, uncompiled libraries.

Right-click commands in the cross-reference list

“Show source position”: Opens the respective POU and marks the occurrence: for root entries, the declaration, and for subordinate entries, the respective occurrence location. As an alternative, you can double-click a line.

“Limit Results to Selected Declaration”: Limits the display of results to the selected symbol declaration if multiple declarations are found.

“Expand All”: In the list, every single result location is shown.

“Collapse All”: In the list, only the root nodes of the result locations are shown.

See also

- *Chapter 1.4.1.20.3.2.29 “Command 'Browse Cross References'” on page 974*
- *Chapter 1.4.1.8.13.1 “Using the cross-reference list to find occurrences” on page 285*
- *Chapter 1.4.1.20.3.22.3 “Command 'Limit Results to Current Declaration'” on page 1148*
- *Chapter 1.4.1.20.3.2.18 “Command 'Collapse All Folds'” on page 971*
- *Chapter 1.4.1.20.3.2.17 “Command 'Expand All Folds'” on page 971*

Command 'Browse Cross References in Classic View'

Symbol 

Function: This command opens the *“Classic Cross Reference List”* view.

Call: The command is not in any menu by default. You can add it to a menu by using the dialog box from *“Tools ➔ Customize”* (command category *“Browse Project”*).

The view corresponds to the *“Cross Reference List”* view before CODESYS V3.5 SP6.

Command 'Call Stack'

Symbol: 

Function: This command opens the *“Call Stack”* view.

Call: Main menu *“Debug”*.

This view is very useful when you want to step into programs. It shows the current location with the complete call path.

“Application”	Name of the active application that controls the current POU
“Task”	Name of the task that controls the current POU
“POU”	Name of the POU where program execution has halted The first line in the list describes the current execution location (marked with a yellow arrow). If this location is in a block that is called by another block, then the call location is described in the second line. In turn, if the caller is called by yet another block, then that call location is described in the third line, and so on.
“Location”	Position within the POU where program execution has halted ● Line and column numbers for textual editors ● Network or element numbers for graphical editors
“Instance path”	Instance where program execution has halted

The call stack is also available in offline mode and normal online mode when you are not currently using any debugging functions). In this case, it receives the last displayed location during a stepped execution, but it is displayed in gray.

The “Call Tree” view, in contrast to the “Call Stack”, at any time provides information on the calls of a POU.

See also

- *Chapter 1.4.1.11.2 “Using Breakpoints” on page 395*
Chapter 1.4.1.20.3.3.16 “Command 'Call tree'” on page 993

Command 'Call tree'

Symbol: 

Function: This command opens the *“Call Tree”* view.

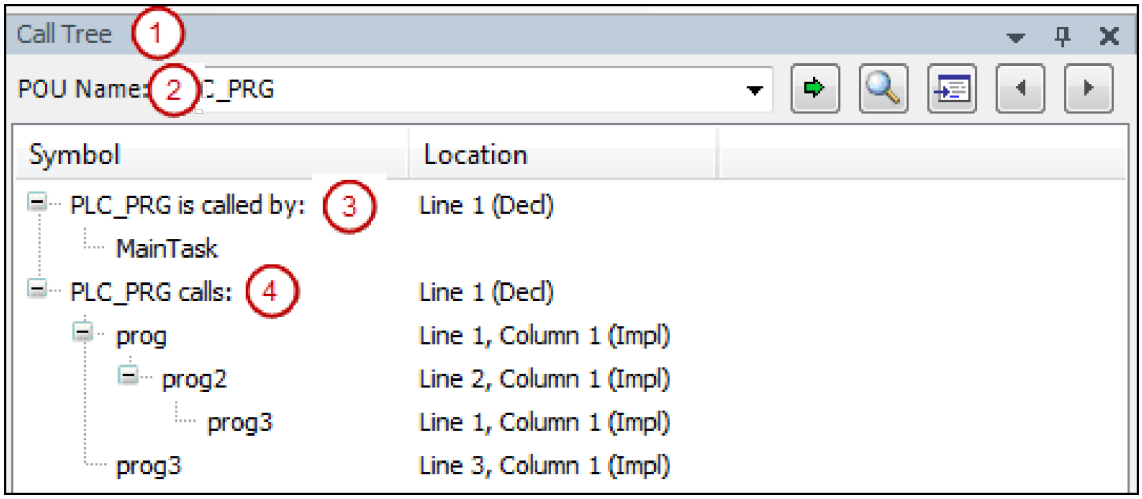
Call:

- *“View”* menu
- Context menu of a callable block in the *“Devices”* or *“POUs”* view.

View 'Call tree'

The call tree is available at all times, even before compiling the application. It is a static representation of the caller and the calls of the block that you specify explicitly. Therefore, the tree always contains two root nodes above the respective call order is displayed as successive indented entries. Recursive calls are detected quickly in this tree representation.

Example of a call tree (1) for the (2) PLC_PRG block:



- (3) Node *"<block name> is called by:"*
- (4) Node *"<block name> calls:"*

"Block name"	Name of the program block; specified manually, by dragging from another view, or by means of the button . The drop-down list includes the last specified block names.
Toolbar and keyboard usage	
: Find block	CODESYS searches for the block specified in *"Block name"* and displays its caller and calls.
: Use block from the input assistant	The *"Input Assistant"* dialog box opens for selecting a block call or instance call. The call tree is refreshed automatically after the selection.
: Show source code position of the selected block	CODESYS jumps to the occurrence location of the block in the source code of the program.
[F4]: Show source code position of the next block *[Shift]+[F4]*: Show source code position of the previous block	The selection in the call tree jumps to the next or previous block in the call structure. At the same time, the associated source code position is opened in the respective editor. Note: Double-clicking an entry in the call tree also opens the associated source code position.
Display of the call tree:	
"Symbol"	*"<block name> is called by"*: The call order is displayed for below this node. The bottom entry in this tree structure shows the start of the calls. *"<block name> calls"*: The calls from this block are displayed below this node. The bottom entry in this tree structure shows the end of the call chain.
"Position"	For the root node in the call tree: Line numbers of the declaration (*"Decl"*) of the block. For the caller or calls below the root node: Line number, column number, and network number of the position, depending on the implementation language.
Context menu for the entry selected in the tree:	
"Collapse All"	The expanded entries in the call tree are collapsed, except for the two root nodes.

"Show Source Position"	CODESYS jumps to the occurrence location of the block in the source code of the program.
"Set as New Root Node"	The entry selected in the call tree is displayed in *"Block name"*. The tree is refreshed automatically for the new root nodes.

The "Call list" view is provided for immediate information when stepping through a program, as opposed to the static call tree that provides call information about a block. The call list always shows the full call path of the current position that is reached.

See also

- *Chapter 1.4.1.11.3 "Stepping Through a Program" on page 399*
- *Chapter 1.4.1.20.3.3.15 "Command 'Call Stack'" on page 993*
- *Chapter 1.4.1.20.3.2.31 "Command 'Browse Call Tree'" on page 975*

Command 'Memory'

Symbol:

Function: In CODESYS V3.5 version earlier than SP11, the command opens the *"Memory"* view.

Call: Menu bar: *"View* ➔ *Memory"*.

As of SP11, the command provides the notice that you must install the CODESYS Memory Tools package (available in the CODESYS Store) in order to use the memory view. After installation, you can open the *"Memory"* view by clicking *"View* ➔ *Show Memory View"*.

Command 'Security Screen'

Symbol:

Function: The command opens the *"Security Screen"* view.

Call:

- *"View"* menu
- icon or in the status bar
  The icon is displayed in blue when a valid certificate is specified for the digital signature. When only one client certificate is specified for the encrypted communication, the icon remains gray, resulting in the client certificate providing no increased security for the user.

The following security features of CODESYS are configured and displayed in the view:

- Personal user certificate
- Encrypted communication
- Encryption and signatures of IEC projects
- Encryption and signature of download, online change, and boot application
- Security level

NOTICE!
When the *"Security Screen"* is opened and closed, the current settings are applied in the user options, even when no active changes have been made.

If the CODESYS Security Agent add-on product is installed, then the "Security Screen" view provides an additional "Devices" tab. This allows for the configuration of certificates for the encrypted communication with controllers.

Tab 'User'

On this tab, certificates are configured that are required for the encrypted communication and the digital signature of the user. Only certificates with private keys can be specified here. The user profile is saved as an XML file in the user options.

"User Profile and Certificate Selection"	By default, the login name for Windows is specified as the user profile.
List box with existing user profiles	: Opens the *"User Profiles"* dialog. Here you specify the name for a new user profile. : Deletes the selected user profile. This user profile is no longer displayed in the list box.
"Digital Signature"	: Opens the *"Certificate Selection"* dialog for selecting the certificate for the digital signature. One certificate can be selected. The certificate has to have a private key. : Deletes the displayed certificate. One certificate can be selected. The certificate has to have a private key.
"Project File Decryption"	: Opens the *"Certificate Selection"* dialog for selecting the certificate for decrypting project files. One certificate can be selected. The certificate has to have a private key. : Deletes the displayed certificate.

See also

- *Chapter 1.4.1.20.4.18 "Dialog 'Certificate Selection'" on page 1215*

Table 121: "Security Level"

"Activate the Use of Certificates for Enhanced Security"	
"Enforce encrypted communication"	: When the user communicates with the controller, the server certificate of the controller is used for establishing an encrypted connection. Then the entire communication is encrypted.
"Enforce encryption of project files"	: All project files of the user are encrypted with a certificate. When the project is saved, it is encrypted with the certificate specified in the project settings (*"Project Settings ➔ Security"* dialog). The selected certificate is displayed on the *"Project"* tab in the *"Project file encryption"* group. To open this project, the certificate to be encrypted has to be specified in *"Project file decryption"* with a private key.
"Enforce signing of project files"	: All project files of the user are signed with a certificate. In *"Digital Signature"*, a certificate has to be specified with a private key. When a project is saved, a signature file `<project name>.project.p7s` is generated in the project directory containing the signature.

"Enforce encryption of downloads, online changes and boot applications"	☑: The data that is downloaded to the controller has to be encrypted with a controller certificate. This certificate is defined directly either in the properties dialog of the application on the *"Encryption"* tab, or in the security screen, on the *"Project"* tab, in the *"Encryption of Boot Application, Download and Online Change"* group. Controller certificates are located in the local Windows Certificate Store in the *"PLC Certificates"* directory. If the certificates of your controller are not available in the directory, then they first have to be loaded from the controller and installed to the directory. For instructions, see the "*"Controller Certificates"*" chapter.
"Enforce signing of downloads, online changes and boot applications"	☑: The online code (downloads, online changes, and boot applications) have to be signed with a certificate with a personal key. The certificate is selected from the *"Digital Signature"* area. Requirement: The *"Encryption of boot application, download and online change"* option is selected.
"Enforce signing of compiled libraries"	☑: The *"File ➔ Save Project as Compiled Library"* command generates a signed library `<library name>.compiled-library-v3`. Requirements ● A certificate with a private key that supports code signing is available. ● A library compatibility >= CODESYS V3 SP15 is set in the project information. *"Enforce timestamping of signed compiled libraries"*: ☑: The URL of the time stamp server which created the time stamp has to be entered in the *"Timestamping server"* field. Example: `timestamp.comodoca.com/rfc3161`.

- *Chapter 1.4.1.16.1 "Information for Library Developers" on page 449*

Tab 'Project'

All project-specific settings are configured on this tab. These elements are active only when a primary project is loaded.

"Project file encryption"	
"Technology"	☑: Opens the *"Project Settings ➔ Security"* dialog When you select the *"Encryption"* project setting and then *"Certificates"* in the dialog, you can choose a corresponding certificate by clicking ☑. For more information, see the description of the "Project Settings: Security" dialog.
"Certificates of Users Sharing this Project"	Area for listing the certificates that encrypt the project file.

“Encryption of Boot Application, Download and Online Change”	
List of the applications of the controller	Double-clicking an application in the list opens the *“Properties ➔ Encryption”* dialog. Depending on the settings of the *“Security Level”* on the *“User”* tab of the *“Security Screen”*, the following fields are available in the open properties dialog: ● *“Encryption”* tab with active *“Certificates”* area ● *“Encryption”* tab with *“Encryption Technology”* list box. In the *“Properties ➔ Encryption”* dialog, click the button to select the controller certificate for *“Encryption of Boot Application, Download and Online Change”*. For more information, see the description of the "Properties: Encryption" dialog. Controller certificates are located in the local Windows Certificate Store in the *“PLC Certificates”* directory. If the certificates of your controller are not available in the directory, then they first have to be loaded from the controller and installed to the directory. For instructions, see the "Protecting and Saving a Project" - " Encryption with Certificates" chapter.

Tab 'Devices'

This tab is available only after you have installed the CODESYS Security Agent add-on. For a description of this tab, see the help for the CODESYS Security Agent.

Command 'Settings of Memory Reserve for Online Change'

Function: This command opens the *“ Online Change Memory Reserve”* view.

Call: Menu bar: *“View”*.

In the view, memory reserves are configured for the function blocks during the online change.

“Scan Application”	● Searches the selected application for function blocks and displays them in the *“Function blocks”* area ● Updates the *“Function blocks”* area after the application is built again. ● Updates the *“Function blocks”* area after an online change.
Drop-down list with the applications of the open project	Selection of the application whose function blocks should be displayed and/or edited in this view.

Table 122: “Function Blocks”

“All”	All function blocks of the selected application are displayed.
“Pool”	All function blocks of the *“POUs”* view that are displayed which are referenced in the application.
“No memory-reserve”	All function blocks with a memory reserve of 0 bytes are displayed.
“<memory reserve> bytes”	Display of all function blocks with the number of bytes is displayed that is defined in *“Memory reserve”*.
Information about the function blocks Multiple selection is also possible when selecting a POU for the configuration of the memory reserve.	

“Function block”	Name of the function block
“Size”	Size of the function block Size of an instance of a function block Specified in bytes
“Number of instances ”	Number of instances of a function block in the project
“Memory reserve”	Display of the memory reserve for each instance of the function block
“Additional memory for all instances”	Product of *“Number of instances”* and *“Memory reserve”*
“Remaining memory reserve”	Number of bytes that are available as reserve.

Table 123: “Settings”

“Memory reserve (in bytes)”	Input field for the memory reserve for the selected function block. Specified in bytes Requirement: the application is not located on the controller yet or you have allowed the memory reserve to be changed by clicking the *“Edit”* button in the *“Allow editing”* area.
“Apply for Selection”	The *“Memory reserve (in bytes)”* is assigned to the function block and the table column *“Memory Reserve”* is updated. In multiple selection, the specified value is assigned to each function block. In order to update the columns *“Size”*, *“Number of Instances”*, *“Additional Memory for All Instances”*, and *“Remaining Size of the Memory Reserve”*, click *“Build ➔ Build”*, and then click the *“Scan Application”* button.

Table 124: “Enable Editing”

“Enable”	The input field *“Memory reserve (in bytes)”* is editable. This button is modified in *“Editable”*.

Table 125: “Information”

“Number of FBs”	Total number of function blocks in the application
“Additional memory for all instances”	Sum of the memory reserves of all function block instances of the application. Specified in bytes

See also

- *Chapter 1.4.1.20.3.6.6 “Command 'Online Change'” on page 1033*

Command 'Start Page'

Symbol: 

Function: This command opens the *“Start Page”* view.

Call: Main menu *“View”*

The view includes some basic commands and a list of recently opened projects. In addition, the CODESYS homepage is displayed.

If you access the Internet through a proxy, then you can save the authentication data in the project options (“Proxy Settings”) so you do not have to provide this data every time you use this command.

By moving the mouse pointer over the list of recently opened projects, you can remove or pin individual projects in the list. Pinned projects remain in this list until you remove the pin.

In the project options (*“Load and Save”*), you can configure whether this start page should open automatically when you start CODESYS.

See also

- *Chapter 1.4.1.20.4.13.16 “Dialog 'Options' – 'Load and Save'” on page 1196*
- *Chapter 1.4.1.20.4.13.20 “Dialog 'Options' - 'Proxy Settings'” on page 1198*

Command 'Full Screen'

Symbol: , keyboard shortcut *[Ctrl]+[Shift]+[F12]*

Function: This command switches the CODESYS display to full screen mode.

Call: Main menu *“View”*

Choosing this command displays the main window of the CODESYS user interface in full-screen mode. You can return to the previous setting by choosing the command again or with the keyboard shortcut *[Ctrl]+[Shift]+[F12]*.

Command 'Properties'

Symbol:

Function: This command opens the properties of the currently selected object in the POUs tree or device tree.

Call: Main menu *“View”*

Menu 'Project'

Command ‘Add Object’

Symbol: 

Function: This command opens a submenu with objects that contain all objects that can be inserted, depending on the current position in the *“Devices”* or *“POUs”* view.

Call: *“Project”* menu, context menu in the *“Devices”* or *“POUs”* view.

Requirement: If CODESYS is to insert the object in the device tree, select an already existing object under which the new one is can be inserted indented. If CODESYS is to insert the object in the POUs tree, set the focus in any free place in the CODESYS window.

Command ‘Add Folder’

Symbol: 

Function: This command opens a dialog box for defining a new folder in the Devices or POUs view.

Call: *“Project”* menu, context menu in the Devices or POUs view

> *You cannot structure the arrangement of device nodes and device objects through folders that you have created yourself.*

This command inserts the folder below the object that has just been selected in the tree. If no object is selected, CODESYS inserts the folder right at the top in the tree directly under the root node.

Command 'Insert Device'

Function: this command opens the dialog box *“Add Device”* for the selection of a device object that is to be inserted in the device tree below the currently selected object.

Call: Context menu of a device object in the device tree.

Requirement: An object is selected in the device tree below which a device object can be inserted.

See also

- *Chapter 1.4.1.7 “Configuring I/O Links” on page 213*

Dialog box 'Add device'

Function: Depending on the currently selected position in the device tree, the dialog box offers a selection of the devices that can be inserted at this point. In addition, it contains the commands also available in the context menu: *“Insert Device”*, *“Add Device”*, *“Plug Device”*, *“Update Device”*.

Requirement: The devices are installed in the device repository on the local system.

> *If you have opened the dialog box, it always displays the selection to suit the object currently selected in the device tree until you click “Close”.*

“Name”	Name with which the device is to appear in the device tree. Must be a valid IEC identifier.

Table 126: “action”

“Add device”	CODESYS inserts the selected device indented below the selected object in the device tree.
“Insert device”	CODESYS inserts the selected device at the same level as the selected object below it in the device tree.

“Plug device”	CODESYS inserts the selected device in the selected slot. If the slot is already occupied, the existing module is replaced by the new one.
“Update device”	CODESYS replaces the device selected in the device tree by the one selected. Please note: Depending on the device, this may cause the configuration already done in the device editor to be overwritten with the default values!

“String for the full text search”	This field is editable after clicking in it. For any character string entered, only those devices that include the character string are displayed in the lower view. The matched string is highlighted in yellow for these devices.
“Vendor:”	Drop-down list with manufacturers whose available devices are displayed.
“Group by category”	☑: The available devices (newest version) are sorted by category. The category is defined in the device description file. ☐: The available devices appear flat and alphabetically sorted.
“Display all versions (for experts only)”	☑: In addition, all other available versions of the devices can also be selected. ☐: Only the newest version of each device is available for selection
“Display outdated versions”	☑: In addition, outdated versions of the devices can also be selected. Outdated versions result, for example, from the update of plug-ins. ☐: Outdated device versions are not displayed.

The information provided by the device description file is displayed: device name, vendor, categories, version, order number and a short description, device-specific bitmap.

- *Chapter 1.4.1.20.3.4.4 “Command 'Plug Device'” on page 1003*
- *Chapter 1.4.1.20.3.4.6 “Command 'Update Device'” on page 1005*

Command 'Plug Device'

Function: Like the command *“Add Device”*, this command opens the dialog box *“Add Device”* for the selection of a device object that is to be inserted in the device tree in the currently selected slot.

Call: Context menu of the slot of a device object in the device tree.

Requirement: The slot of a device object is selected in the device tree.

An empty slot is identified by the symbol and the entry "<empty> (<empty>)". An occupied slot is given the symbol and the name of the device.

In the case of an occupied slot, this command replaces the existing module with the new one.

- *Chapter 1.4.1.7 “Configuring I/O Links” on page 213*

Command 'Scan for Devices'

Function: The command establishes a brief connection to the hardware and determines the devices in the network. Then you can apply the devices found into the device tree of your project.

Call: Menu bar: *“Project”*; context menu of a device object in the device tree

Requirement: The communication settings to the controller are correct. The gateway and the PLC are started. The device supports the scan function.

The following devices provide the scan function: EtherCAT master, EtherNet/IP Scanner (IEC), Sercos master, CANopen Manager, CANopen Manager SIL2, PROFINET controller und PROFIBUS DP master.

You can perform the device scan immediately if the scan function is permanently implemented in the PLC. When scan function is implemented in a library, you have to log in only one time to download the library to the controller.

The command refers to the master controller selected in the device tree. For example, an already inserted PROFINET IO controller can be selected and the command used to determine the I/O devices and I/O modules assigned to it.

After performing the scan operation, the *“Scan Devices”* dialog opens and displays the found devices.

Dialog 'Scan Devices'

Table 127: “Scanned Devices”

“Device name, Device type, Address, Station name, etc.”	Data about the scanned device depending on network type. When you change a value in the list of scanned devices, the value is shown in italics. This indicates that the new value has been changed in the editor in CODESYS, but not in the device. When you download the value to the device, it is shown normally. Value that indicate differences between the project and the scanned device are shown in orange. If multiple device descriptions are available for the scanned device, then the name is displayed in bold. The selection of the matching device description is resolved differently for different fieldbuses. For more detailed information, see the corresponding fieldbus chapters. If a device description cannot be found, then the following message is shown: "Attention! The device was not found in the repository." Depending on the bus system, additional information is displayed, such as manufacturer number and product number. The device cannot be inserted into the project without the installed device description.
“Show differences to project”	☑: The table in the dialog also shows additional configured devices (in the device tree of the project). ☐: The table shows all scanned devices. The configured devices are not shown.
“Scan for Devices”	Starts a new search.
“Copy All Devices to Project”	The device that is selected in the table is inserted into the device tree in the project. If nothing is selected, then all scanned devices are shown.

NOTICE!

If you insert devices, which are available in the device tree, to the device tree with *“Copy All Devices to Project”*, then the following should be noted. The data of the *“Process Data”* and *“<...> I/O Mapping”* tabs of the existing devices can be overwritten with the data of the recently inserted devices.

Table 128: “Configured Devices”

This part of the dialog is visible only when you select the *“Show differences to project”* option. Differences between the scanned and configured devices are color-coded. Devices displayed in green are identical on both sides. Devices displayed in red are available only in the view of the scanned or configured devices.	
	If you have selected a device in both views, then the scanned devices are inserted above the selected configured device.
	If you have selected a device in both views, then the scanned devices are inserted below the selected configured device.
	If you have selected a device in both views, then the configured devices are replaced by the selected scanned device.
	All scanned devices are copied to the project.
	Deletes the selected configure device.

The dialogs for the scan differ depending on the type of device. See the help pages for the respective device editor.

Command 'Update Device'

Function: Like the command *“Add Device”*, this command opens the dialog box *“Add Device”* for the selection of a device object. This object is inserted in the device tree in place of the currently selected object.

Call: Context menu of a device object in the device tree.

Requirement: An object is selected in the device tree below which a device object can be inserted.

With this command you can insert either a different version of a device or a different type of device in place of the previous one.

The symbolic device name used in the device tree is retained, but the device type specified in parentheses behind it changes if a different type has been selected. Thus if only the device version is changed, the object entry appears unchanged.

If the device type does not change, the configuration tree indented below the device entry concerned is retained. In this case the configuration settings also remain the same. Inconsistencies in the configuration resulting from the device update are reported by CODESYS at the next compilation of the application. This also concerns implicitly inserted libraries, which CODESYS does not remove accordingly during a device update.

- *Chapter 1.4.1.7 “Configuring I/O Links” on page 213*
- *Chapter 1.4.1.20.3.4.3 “Command 'Insert Device'” on page 1002*

Command 'Acknowledge Diagnosis', 'Acknowledge Diagnosis for Subtree'

Function: The command acknowledges a diagnosis message.

Call: Context menu of a device object in the device tree

Requirement: The project is in online mode.

The *“Acknowledge diagnosis”* command acknowledges the diagnosis messages of an individual device. The *“Acknowledge Diagnosis for Subtree”* command also acknowledges the diagnosis messages of all subordinate devices. The diagnosis message of a pending malfunction is indicated by a red exclamation mark at the device object. The diagnosis message of a corrected malfunction is indicated by a gray exclamation mark.

Command 'Edit Object'

Function: This command opens the object in its editor.

Call: Main menu *“Project”*, context menu.

Requirement: An object is selected in the device tree or in the *“POUs”* view.

Command 'Edit Object with'

Function: When multiple objects are available for an object, this command opens a dialog box for selecting an editor.

If only one editor is available for an object, then this command opens the object in that editor.

Call: Main menu *“Project”* or shortcut menu (right-click)

Requirement: An object is selected in the device tree or in the *“POUs”* view.

In the standard installation of CODESYS, there is no object that has multiple available editors.

Command 'Check integrity'

Function: Automation Builder checks the project integrity for the complete project ("Project integrity" checks if all devices in the device tree are installed in the device repository).

Call: Main menu *“Project”*, Context menu.

Requirement: A project is open.

Command 'Edit Object (Offline)'

Function: The command opens the object offline in the editor.

Call: Main menu *“Project”*, Context menu

Requirement: The application is in online mode. An object is selected in the device tree or in the *“POUs”* view.

The command allows you to edit objects in online mode. After editing you transfer the changes to the controller by use of the command *“Online ➔ Online Change”* or *“Online ➔ Load”*.

See also

- *Chapter 1.4.1.20.3.6.6 “Command 'Online Change'” on page 1033*
- *Chapter 1.4.1.20.3.6.5 “Command 'Load'” on page 1032*

Command 'Set Active Application'

Function: This command sets the selected application as the active application.

Call: Main menu *“Project”*, or right-click the *“Application”* object.

Requirement: The project has at least two applications. The selected application is not active.

Online actions apply only to the active application. The name of an active application is displayed in bold typeface in the device tree.

Command 'Project information'

Symbol: 

Function: This command opens the dialog box *“Project Information”*.

Call: Main menu*“Project”*

When you execute the command in the project for the first time, CODESYS creates the *“Project Information”* object.

See also

Command 'Project Settings'

Symbol: 

Function: This command opens the *“Project Settings”* dialog box.

Call: *“Project”* menu or double-click on the object *“Project Settings”* in the *“POUs”* view

Requirement: A project is open.

See also

- *Chapter 1.4.1.2.3.2 “Making project settings” on page 193*
- *Chapter 1.4.1.20.4.11 “Dialog 'Project Settings'” on page 1170*

Command 'Project Environment'

Function: This command opens the *“Project Environment”* dialog box.

Call: *“Project”* menu

Requirement: A project is open.

this command is for checking the currentness of software and files integrated in the project and enables them to be updated.

See also

Command 'Project Localization' - 'Create Localization Template'

Function: This command opens the *“Create Localization Template”* dialog. Define here which information should be exported from the project to a translation template (`*.pot` file).

Call: Menu bar: *“Project ➔ Project Localization”*.

Requirement: A project is open.

Dialog 'Create Localization Template'

This dialog is used for selecting the textual information that should be used in the localization template.

Table 129: "Include the Following Information"

"Names"	Texts, such as dialog captions and object names in the device tree
"Identifier"	Variable identifier (example: `Counter`)
" Strings"	Example: `'count'` in the following declaration: `strVar: STRING := 'count';`
"Comments"	Comment texts in the POUs

"Position information"	Selection of which positions of the selected text categories in the project should be included in the translation file. The position information is located in the first line(s) of a segment for a translation. Example:
	`#: D:\Proj1.project\Project_Settings:1`
	`msgid "Project settings"`
	`msgstr ""`
	● *"All"*: All detected positions of the text are listed.
	● *"First appearance"*: In the translation file, the position is included in the project where the text to be translated appears for the first time.
	● *"None"*

"Generate"	This button opens the dialog for saving a file. The translation template is created in a text file of type `*.pot` (portable object template). Each further generation creates a completely new template file.

See also

- Help about CODESYS Visualization: Multi-language capability

Command 'Project Localization' - 'Manage Localizations'

Function: This command opens the *"Manage localizations"* dialog. Select the desired localization language in the dialog or the original version of the project. You can still accept the localization files `*.<language>.po` into the project or remove them.

Call: Menu bar: *"Project ➔ Project localization"*.

Requirement: A project is open.

Dialog 'Manage localizations'

"Available Localizations"	List of the localization files available in the project. Example:
	`proj1-de.po`
	`proj1-en.po`
	`<original version>`
	The original version is always available. The project can be edited only in the original version.

"Add"	This button opens the dialog for selecting an additional `po` file from the file system.
"Remove"	This button removes the `po` file, which is selected on the left side, from the project.
"Default localization"	☑: The selected localization is for the default localization. The entry is display in bold.

“Switch Localization”	Use this button to switch to the selected localization.
“OK”	The project is displayed in the language that is provided by the file selected below the files. If you select *“<original version>”*, then the project appears in the editable non-localized version.

See also

- *Chapter 1.4.5.6 “Setting Up Multiple Languages” on page 1286*

Command 'Project Localization' - 'Toggle Localization'

Symbol: 

Function: This command switches between the currently set project localization and the <original version>.

Call: Menu bar: *“Project ➔ Project Localization”*; button in the *“Manage Localizations”* dialog;  button on the toolbar.

Requirement: A project is open. A default localization for the project is defined in the *“Manage Localizations”* dialog.

See also

- Help about CODESYS Visualization: Multi-language capability
- *Chapter 1.4.1.20.3.4.17 “Command 'Project Localization' - 'Manage Localizations'” on page 1008*

Command 'Document'

Symbol: 

Function: This command opens the *“Document Project”* dialog box, where you can define the project documentation. This includes the selection of objects in the open project that you want to print.

Call: Main menu *“Project”*

Table 130: “Document Project” dialog box

“Please select the objects which are to be printed”	Project tree view In this view, you can select or clear objects for printing. All objects are selected by default.
“Title page”	CODESYS creates a title page named "Project Documentation" with the following information: ● File: project file name ● Date: Creation date of the project documentation ● Profile: CODESYS profile of the project
“Table of contents”	CODESYS creates a table of contents for the project documentation.
“Preview”	CODESYS creates and opens a print preview of the project documentation.
“Select”	CODESYS opens a drop-down list of all or single object types for the project documentation.
“Deselect”	CODESYS opens a drop-down list of all or single object types that should be excluded from the project documentation.
“OK”	The *“Print”* dialog box opens.

See also

- *Chapter 1.4.1.20.4.11.6 “Dialog 'Project Settings' - 'Page Setup'” on page 1175*
- *Chapter 1.4.1.20.3.1.12 “Command 'Print'” on page 963*

Command 'Compare objects'

Function: To compare similar objects within a project.

Call: Main menu *“Project”*, Context menu.

Requirement: Both projects have to be open.

Chapter 1.2.13.4 “Comparing objects” on page 59

Command 'Compare'

Symbol: 

Function: This command opens the *“Project Comparison”* dialog. In this dialog, you define the reference project to compare with the current project. You configure the comparison process by means of options. When the dialog is exited, the comparison starts and the result is shown in the view *“Project Compare - Differences”*.

Call: Menu bar: *“Project ➔ Compare”*.

Requirement: A project is open.

See also

- *Chapter 1.4.1.4 “Comparing projects” on page 195*
- *Chapter 1.4.1.20.3.4.22 “Command 'Commit Accepted Changes'” on page 1014*

Dialog 'Project Comparison'

Table 131: “Compare the currently open project with:”

“Project on disk”	Path of the reference project on the file system.
“Project in a source control database”	*“Host”*: Name of the host where the source code management is located. *“Port”*: Number of the port for connecting to the source code management. *“Location”*: Path of the reference project. Requirement: The project is linked to source code management (for example, Professional Version Control).

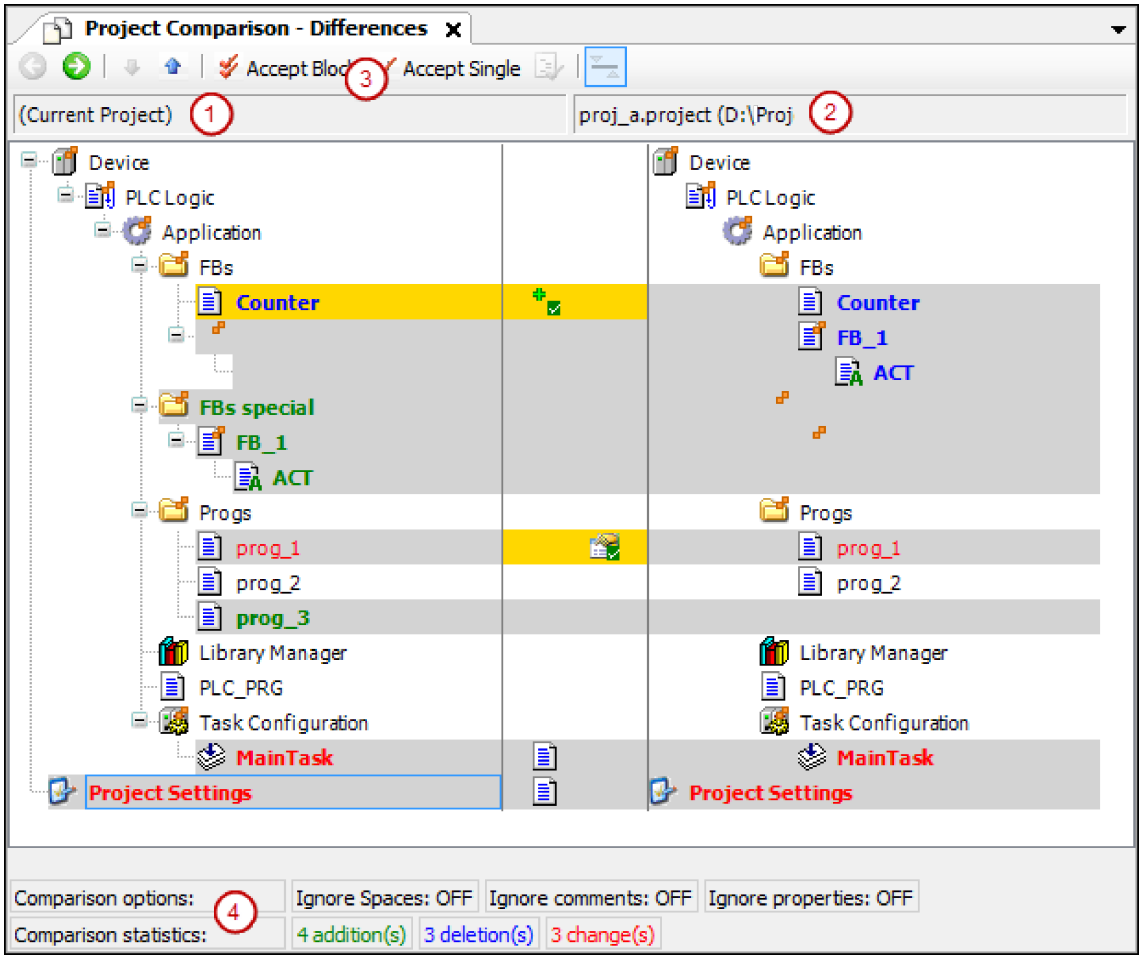
Table 132: “Compare Options”

“Ignore whitespace”	☑: Whitespace differences between the current project and the reference project are ignored.
“Ignore comments”	☑: Comments in the programming code are excluded from the comparison.
“Ignore properties”	☑: Object properties are excluded from the comparison.

“OK”	Starts the project compare and displays the result in the view *“Project compare - Differences”*.

View 'Project Comparison' - 'Differences'

The project compare view opens when you click *"OK"* to close the *"Project Compare"* dialog.



```
(1) Object tree of the current project
(2) Object tree of the reference project
(3) Command 'Accept Block', command 'Accept Single'
(4) Compare options, configured in 'Project Compare' dialog
    Compare statistics: added, deleted, and changed objects
```

Table 133: Toolbar

	Switches to the detailed compare view *"Project Comparison' - '<object name> Differences"* for the object selected in the tree. Alternative: Double-click the object.
	Selects the next bottom object in the device tree where differences were detected.
	Selects the next top object in the device tree where differences were detected.
"Accept Block"	The block (selected object with all subordinate objects and units) is selected for acceptance from the reference block to the current block. Repeated clicking of *"Accept Block"* undoes the effects of its last change.
"Accept Single"	The object is selected in the current object for acceptance from the reference line.
	Requirement: The properties, access rights, or contents of the objects selected in the object tree are different. Opens the *"Accept"* dialog.

Table 134: Display of differences with colors, and symbols

Black font	Objects are identical.
Object name with	Child objects of the object are different
Gray highlight	Objects are different.
Gray highlight + bold blue font	Object is only in the reference project.
Gray highlight + bold green font	Object is only in the open project (not in reference project).
Gray highlight + red font +	Object has different properties.
Gray highlight + red font +	Access rights of object and reference object are different.
Gray highlight + bold red font +	Implementation of objects is different. Double-click the line to display the object-specific compare view.
Yellow highlight	Object is activated for acceptance.
Yellow highlight +	Adding the reference object to the open project is activated.
Yellow highlight +	Deleting the object (in the open project) is activated.
Yellow highlight +	Acceptance of the properties of the reference project is activated.
Yellow highlight + red font +	Acceptance of the access rights of the reference project is activated.
Gray highlight + bold red font +	Acceptance of the implementation of the reference project is activated.
"Compare options"	Defined comparison options in the *"Project Comparison"* dialog.
"Compare statistics"	Number of additions, deletions, and changes in the current project, as compared to the reference project. *"Change"* means differences of an object available in both projects.
×	The dialog prompt opens: *"Do you want to commit the changes which you made in the diff view?"* *"Yes"*: The contents, properties, or access rights of the objects highlighted in yellow are modified in the project. Now they correspond to the reference project. Then the project compare view is closed completely.

View 'Project Comparison' - '<object name> Differences'

Function: Detail compare view

Call in the project compare view:

- Select an object that is identified as having different contents which you need to view in detail. Click .
- Double-click the object.

Table 135: Toolbar

	Switch back to the project compare view.
	Selects the next line below in the code where differences were detected.

	Selects the next line above in the code where differences were detected.
"Accept Block"[2]	The block (with all subordinate lines) is selected for acceptance of the reference blocks into the current project. A block in the detailed compare view consists of the unit where the cursor is located and all corresponding units that have the same difference markers. A unit is a line, network, or element. Subsequent lines of a line are examples of corresponding units. Repeated clicking of *"Accept Block"* undoes the effects of its last change.
"Accept Single"	The line is selected in the current object for acceptance of the reference line.
	Switches between the default display where different units (lines, networks, elements) are displayed in red and another display: The units are displayed as recently added in the open project. In the reference project, they are displayed as deleted. Available within the detailed compare view only. Note: Depending on the display, detected differences in the statistics are counted as changed, inserted, or deleted.

Table 136: Display of differences with colors, and symbols

Black font	Objects are identical.
Gray highlight + bold blue font	Code is only in the reference project.
Gray highlight + bold green font	Code is only in the current project (not in reference project).
Yellow highlight	The object is activated for acceptance.
×	The dialog prompt opens: *"Do you want to commit the changes which you made in the diff view?"* *"Yes"*: The code highlighted in yellow is accepted into the project. The code corresponds to the reference project. Then the detailed view is closed and the project view is displayed. You can continue working with project compare.

Dialog 'Accept'

Table 137: "Which meta data should be accepted?"

"Access rights"	☑: Access rights that are selected for acceptance.
"Accepted groups"	Grouping with access rights accepted by the reference project. A group is accepted if it is present in both projects with different access rights. Example: `Group_A`
"Unaccepted groups (missing in a project) "	The group is not accepted if it is not present in one of the two projects.
"Properties"	☑: Properties activated for accept Requirement: The properties of the reference object and object are different.

"OK"	Settings are accepted.

Command 'Commit Accepted Changes'

Symbol:

Function: This command commits the accepted differences from the project comparison to the current project.

Call: *"Project ➔ Commit Accepted Changes"*.

Requirement: Changes from the project comparison have been accepted.

> *The changes are only copied to the project. This command does not save them to the hard disk.*

See also

- *Chapter 1.4.1.4.2 "Opening the detailed compare view" on page 196*

Command 'Map pool devices'

Symbol:

Function: Maps imported devices from the device pool to already configured devices below a PLC.

Call: Main menu *"Project"*, Context menu.

Requirement: A project is open.

Chapter 1.8.1.1.7 "Arrange or map devices imported to the device pool" on page 4115

Command 'Export'

Function: This command opens a dialog box for exporting objects from a project to an XML file.

Call: Menu bar: *"Project"*.

Dialog 'Export' This dialog box lists all objects from the device tree, POU tree, and module tree that CODESYS can export.

One file per subtree	☑: CODESYS generates a separate export file for each subtree that is located directly under the root node and includes selected files. ☐: CODESYS generates one export file for all selected objects.
"Saved version"	This version should correspond to the target version where the export file will later be imported. If the current project contains plug-ins or add-ons that are not available in the selected memory format (profile), then the *"Extend Profile"* dialog box opens. In this dialog box, the selected profile can be extended with the add-ons.

See also

- *Chapter 1.4.1.20.3.1.5 "Command 'Save Project as'" on page 958*
- *Chapter 1.4.1.20.3.4.25 "Command 'Import'" on page 1015*
- *Chapter 1.4.1.3.1 "Exporting and importing projects" on page 193*

Command 'Import'

Function: This command opens a dialog box for importing objects from an XML file.

Call: Menu *“Project”*

Requirement: A project is open.

Dialog box 'Import'

The dialog box lists all objects from the export file that CODESYS can import at this point.

“Currently selected target objects”	Object that is selected in the Device tree
“Insertable items”	Displays all objects of the export file that CODESYS can insert below the selected object.
“Show contents”	Displays the contents of the export file in a tree structure

Command 'Export PLCopenXML'

Function: This command opens a dialog box for exporting objects from a project into an XML file in the PLCopen format.

Call: Menu *“Project”*

Dialog box 'Export PLCopenXML'

The dialog box lists all objects from the Device tree that CODESYS can export into an XML file in accordance with the PLCopen format.

The PLCopenXML scheme does not permit VAR_GLOBAL and VAR_GLOBAL CONSTANT POUs to be in the same variable list. Therefore, if you wish to export both, you must first divide the variables into two separate variable lists.

See also

- *Chapter 1.4.1.20.3.4.27 “Command 'Import PLCopenXML'” on page 1015*

Command 'Import PLCopenXML'

Function: This command opens a dialog box for importing objects from an XML file in PLCopen format.

Call: Menu *“Project”*

Requirement: A project is open.

Dialog box 'Import PLCopenXML'

The dialog box lists all objects from the PLCopen export file that CODESYS can import at this point.

“Currently selected target object”	Object that is selected in the Device tree
“Insertable items”	Displays all objects of the export file that CODESYS can insert below the selected object.

The PLCopenXML scheme does not permit VAR_GLOBAL and VAR_GLOBAL CONSTANT POUs to be in the same variable list. Therefore, if you wish to export both, the variables must first be divided into two separate variable lists.

Command 'User management' – 'Log in User'

Symbol: 

This command opens the dialog box *"Login"*. Here you specify the project that you wish to edit and enter the login data for a user account with the corresponding rights. In addition, you can open the password manager from this dialog box.

The command is available in the menu *"Project ➔ User Management"*.

See also

- *Chapter 1.4.1.5.6 "Logging in via User Account and Password Manager" on page 205*

Command 'User management' – 'Log out User'

Symbol: 

The user currently logged in to the project is logged out again with this command. This takes place without a dialog box or message, unless no user is currently logged in.

The command is available in the menu *"Project ➔ User Management"*.

If the user is currently logged in to several projects or to libraries integrated in them (it does not have to be the same user account), then the dialog box *"Logout"* opens, in which the specific project or library project can be selected from which the current user is to be logged out.

The status bar always displays the user who is currently logged into the project.

A double-click on the field *"Current user"* in the status bar enables quick access to the *"Login"* or *"Logout"* dialog box.

See also

- *Chapter 1.4.1.5.6 "Logging in via User Account and Password Manager" on page 205*
- *Chapter 1.4.1.20.3.4.28 "Command 'User management' – 'Log in User'" on page 1016*

Command 'User management' – 'Rights…'

This command opens the dialog box *"Rights"*, in which you define the actions that may be carried out, the user groups that may carry them out and the project objects on which they may be carried out.

The command is available in the menu *"Project ➔ User Management"*.

See also

- *Chapter 1.4.1.5.5 "Protecting Objects in the Project by Access Rights" on page 204*

Command 'Insert Device'

Function: Like the command *“Add Device”*, this command opens a dialog box *“Insert Device”* for the selection of a device object. This object is inserted in the device tree at the same level as the currently selected object.

Call: Context menu of a device object in the device tree.

Requirement: An object is selected in the device tree below which a device object can be inserted at the same level.

See also

- *Chapter 1.4.1.7 “Configuring I/O Links” on page 213*
- *Chapter 1.4.1.20.3.4.3 “Command 'Insert Device'” on page 1002*

Command 'Generate EtherCAT XML'

The command is not integrated in the standard main menu. You can add it via the dialog box “Tools ➔ Customize” from the category “Devices”.

Function: This command opens the standard dialog box for saving a file in the local file system. You can define a name and a storage location for an xml file, in which CODESYS is to store the EtherCAT configuration of the EtherCAT master currently selected in the device tree. This may be necessary in order to operate an external EtherCAT stack.

Call: Context menu of an EtherCAT master device object in the device tree.

See also

- *Chapter 1.4.1.7 “Configuring I/O Links” on page 213*

Command 'Generate Sercos SCI XML'

The command is not integrated in the standard menu. You can add it via the dialog box “Tools ➔ Customize” from the category “Devices”.

Function: This command opens the standard dialog box for saving a file in the local file system. You can define a name and a location for an xml file in which CODESYS then stores the configuration data of the sercos master currently selected in the device tree. This may be necessary in order to operate an external sercos stack.

Call: Context menu of a sercos master device object in the device tree.

See also

- *Chapter 1.4.1.7 “Configuring I/O Links” on page 213*
- *Chapter 1.4.1.1.2.1 “Customizing menus” on page 180*

Command 'Disable Device' – 'Enable Device'

Function: This command switches back and forth between the enabled (activated) and disabled (deactivated) states of a device in the bus system.

Call: Context menu of a device object in the device tree.

Requirement: The project is in offline mode. The bus driver must support the function.

A disabled device is not taken into account and is not addressed. Note that with some bus systems the deactivation of a node can lead to the master stopping.

The entry of a disabled device in the tree appears in light-gray lettering. When logging in, disabled devices are additionally marked with a red triangle.

See also

- *Chapter 1.4.1.7 “Configuring I/O Links” on page 213*

Command 'Edit I/O Mapping'

Function: This command opens the *“Edit I/O Mapping”* dialog box. This displays all I/O mappings of the currently selected device object, including I/O mappings of all additional device objects that are inserted in the device tree below this object.

Call: Context menu of a device object in the device tree.

Dialog box 'Edit I/O mapping'

You can edit the I/O mapping in this dialog box in exactly the same way as in the dialog box *“I/O mapping”* of the individual device editors. The respective other dialog boxes are directly updated accordingly.

“Search”	Input field for a search string for the mapping table. The search results are marked in yellow.
“Filter”	Drop-down list for filtering I/O assignments displayed listed in the mapping table: ● *“Show all”* ● *“Show outputs only”* ● *“Show inputs only”* ● *“Show unmapped variables only”* ● *“Show mapped variables only”* ● *“Show mappings to existing variables only”* ● *“ Show mappings to new variables only”*

In the context menu you will find among other things the following commands:

“Export Mappings to CSV”: Stores the mappings of a device and its sub-devices in an external file. To do this you select the device in the device tree or in the mapping list.

“Import Mappings from CSV”: Inserts mappings from a file created beforehand by export.

See also

- *Chapter 1.4.1.7 “Configuring I/O Links” on page 213*
- *Chapter 1.4.1.20.3.4.35 “Command 'Edit I/O Mapping'” on page 1018*
- *Chapter 1.4.1.20.3.4.37 “Command 'Export Mappings to CSV'” on page 1019*
- *Chapter 1.4.1.20.3.4.36 “Command 'Import Mappings from CSV'” on page 1018*

Command 'Import Mappings from CSV'

Function: The command opens the default dialog for opening a file in the local file system. The filter is set to the file format `CSV` in order to import the I/O mapping configuration of a device from the file which was exported previously by means of the *“Export Mappings to CSV”* command. CODESYS writes the configuration to the selected device.

Call: Context menu of a device object in the *“Devices”* view.

Requirement: A project is open with a device and an I/O mapping configuration. The device matches the exported `CSV` file.

NOTICE!

I/O mapping configurations are stored in `CSV` files with the semicolon separator. These files can be edited manually. If the files are edited manually, then it is imperative that this format is retained in order to import successfully. Note: The entries of the file to the I/O mapping of the device are assigned by the device name and the parameter name. Parameter names that are not unique are numbered sequentially in this file (@<n>).

Fields without contents in the `CSV` file are ignored at import. To remove an existing entry in the I/O mapping by importing, you have to add a space in the respective field in the `CSV` file.

See also

- *Chapter 1.4.1.20.3.4.37 “Command 'Export Mappings to CSV'” on page 1019*
- *Chapter 1.4.1.7.1 “Configuring Devices and I/O Mapping” on page 213*

Command 'Export Mappings to CSV'

Function: The command opens the default dialog for saving a file to the local file system. The filter is set to file format `CSV`. After specifying a name and a location, CODESYS stores the I/O mapping configuration in a `CSV` file with the semicolon separator.

Call: Context menu of a device object in the *“Devices”* view.

Requirement: A device object with an I/O mapping configuration is selected in the device tree.

Parameter names that are not unique are numbered sequentially in this file (@<n>).

See also

- *Chapter 1.4.1.20.3.4.36 “Command 'Import Mappings from CSV'” on page 1018*
- *Chapter 1.4.1.7.1 “Configuring Devices and I/O Mapping” on page 213*

Command 'Read PLC Parameter File to Configuration'

Function: This command reads the configuration file `IoConfig.par` of the PLC and stores the values in the project. Such a file is created if the parameters of the PLC have been changed by another device, for example via a visualization. Then these parameters are changed only in the memory of the PLC, but not in the configuration of the project.

Call: Context menu of the PLC device object

Requirement: You have made the command available using the dialog in *“Tools ➔ Customize”*.

Command 'Online Config Mode'

Function: This command is for switching the online configuration mode on and off. At switch-on it establishes a connection to the PLC and loads an implicitly created application *“HiddenOnlineConfigModeApp”* to the PLC. Depending on the device, CODESYS goes into simple online configuration mode or a dialog box appears for selecting between simple and advanced online configuration mode.

Call: Context menu of the PLC object in the device tree

Requirement: The communication settings for the PLC device are correctly set.

Simple online configuration mode:

This command creates the implicit application `HiddenOnlineConfigModeApp` and loads it to the controller. The application automatically initializes all inputs and outputs of the controller once. After that you can access the I/Os as follows:

- Read I/Os
- Write outputs
- Diagnosis (in the device tree and on the *"Status"* tab of the device editor)
- Scan (of the current hardware)
- Interactive online functions, if supported (for example, writing asynchronous messages)

Advanced online configuration mode (parameter mode):

If there are already applications on the PLC and the controller supports it, the command first opens the dialog box *"Devices"*, which displays the applications existing on the controller. From this dialog you can connect via the button *"Parameter mode"* to the PLC and then access the values of the device parameters without having to log in with a real application.

Writing and forcing in the I/O mapping

In online configuration mode the writing and forcing of values on the "I/O Mapping" tab works differently to the way it works in real online mode. The outputs are written immediately after insertion into the table. There is no "Prepared Value" column; instead, the initial values can be changed directly after a double-click on the column "Current Value".

Dialog box 'Config application mode'

This dialog box appears after the command *"Online Config Mode"* if the device supports the advanced online configuration mode and there are already real applications on the controller.

"Parameter mode"	The controller configuration in the project is compared with that on the device. If they correspond, CODESYS establishes a connection to the PLC. Unlike the simple online configuration mode it permits the reading and – if supported by the driver – the writing of parameters in the generic device editor. The applications already loaded to the device remain unchanged in this case!
"Config application mode"	CODESYS switches to the 'simple online configuration mode'.

Command 'Runtime licensing'

Symbol: 

Function: Management of runtime licenses on the PLC. The use of some libraries and devices require the PLC to have a runtime license.

Call: Main menu *"Project"*, Context menu. Displayed only offline.

Requirement: A project is open. Log-in required for managing runtime licenses without need for memory card.

The license status of a PLC can be displayed at any time ↳ *Chapter 1.6.6.2.2.5 "View license information" on page 3672*.

Menu 'Build'

Command 'Generate Code'

Symbol  ; shortcut: *[F11]*

Function: The command starts the code generation for the active application.

Call: Menu bar: *“Build”*

When generating code with this command, code is generated as when downloading the application to the PLC, but the code is not transferred to the PLC. At this time, other source code tests are performed As a result, you can check the code for bugs that were not detected by the compiler and for fixing any bugs before the code is used in online mode.

See also

- *Chapter 1.4.1.10.4 “Generating Application Code” on page 389*

Command 'Clean'

Function: This command deletes the build information for the active application.

Call: Main menu *“Build”*.

During the last download, the build information was created and saved to a file (*.compileinfo).

After a cleaning process, an online change is no longer possible for the affected application. The application must be fully downloaded to the controller again.

See also

- *Chapter 1.4.1.20.3.5.3 “Command 'Clean All'” on page 1021*

Command 'Clean All'

Function: This command deletes the build information for all applications in the project.

Call: Main menu *“Build”*.

During the last download, the build information was created in the local file system and saved to a file (*.compileinfo).

This command requires a download before another login An online change is no longer possible. As compared to the *“Clean”* command (only the active application), CODESYS regenerates the language model for all objects, which is very time-consuming.

NOTICE!
Reconsider carefully whether or not executing this command is really necessary. If you only want to rebuild and download the active application, then execute the *“Clean”* command.

See also

- *Chapter 1.4.1.20.3.5.2 “Command 'Clean'” on page 1021*

Command 'Build'

Function: The command starts the build operation for the active application.

Call: The command is not in any menu by default. You can add it to a menu by using the dialog from *“Tools ➔ Customize”* (command category *“Build”*).

During the build operation, CODESYS performs a syntactic validation of all objects in the application. However, code is not generated like at log in to the target system or download of the application. The build operation is always performed automatically when you log in with a changed program.

When the check is complete, CODESYS displays any error messages or warnings in the message view (*“Build”* category).

If the program has not been changed since it was compiled without errors the last time, then it is not recompiled. The message "The application is current" appears. If the syntactic validation is repeated, then you must execute the *“Rebuild”* command.

See also

- *Chapter 1.4.1.20.3.5.5 “Command 'Rebuild'” on page 1022*

Command 'Rebuild'

Function: The command starts the build operation for the active application, even if the last build contained errors.

Call: The command is not in any menu by default. You can add it to a menu by using the dialog from *“Tools ➔ Customize”* (command category *“Build”*).

See also

- *Chapter 1.4.1.20.3.5.4 “Command 'Build'” on page 1022*

Command 'Generate Runtime System Files'

Function: The command generates a C stub file and an M4 interface file from the current library project. These files are used as the basis for creating an external library file.

Call: Menu bar: *“Build”*

Requirement: A library project is open.

The command opens the *“Generate Files for Runtime System”* dialog.

"Output directory"	Directory where CODESYS creates the runtime system files. Click the ... button to open the default dialog for browsing the file system.
"Component names"	Name of the library project
"Which files do you want to create?"	
"M4 interface file"	☑: Interface file <project name>Itf.m4 with definitions. Example of m4 file:
"C stub file"	☑: Stub file for reprogramming the library in C. Example of stub file:
"Options"

Command 'Check all Pool Objects'

Symbol ; shortcut: *[F11]*

Function: The command starts a build operation (a syntax check) for all pool objects that are managed in the POU view and as a result are available throughout the project. First and foremost, this is useful when creating libraries.

Call: Menu bar: *“Build”*

Requirement: A library project is open.

> **NOTICE!**
> The command does not result in code generation. In addition, no file is created in the project directory with information about the build operation.

See also

- *Chapter 1.4.1.20.4.14.1 “Dialog 'Customize' - 'Menu'” on page 1206*
- *Chapter 1.4.1.16.1 “Information for Library Developers” on page 449*

Command 'Generate Code for Active Application'

Function: The command generates the code for the application of a library project.

Call: Menu bar: *“Build”*

Requirement: The project contains an application.

- A library project is open.
- The library project contains an application.

When generating code with this command, code is generated as when downloading the application to the PLC, but the code is not transferred to the PLC. At this time, other source code tests are performed As a result, you can check the code for bugs that were not detected by the compiler and for fixing any bugs before the code is used in online mode.

See also

- *Chapter 1.4.1.20.3.5.6 “Command 'Generate Runtime System Files'” on page 1022*

Command 'Check All Application Objects'

Function: This command starts a build operation for all objects of the active application, even for the POUs that are not used by the application. After the build operation, the errors that were found in the unused objects are also displayed in the message window.

Call: The command is not in any menu by default. You can add it to a menu by using the dialog from *“Tools ➔ Customize”* (command category *“Build”*).

Requirement: An application of the open project is active.

> **NOTICE!**
> The command does not result in code generation. In addition, no file is created in the project directory with information about the build operation.

See also

- *Chapter 1.4.1.20.4.14.1 “Dialog 'Customize' - 'Menu'” on page 1206*

Command 'Check Library Compatibility'

Function: The command triggers a check whether the currently opened library project is compatible with the last installed version of this library (next lower version number) .

Call: By default the command is not available in any menu. You can add it to a menu by using the *“Tools ➔ Customize”* dialog, command category *“Build”*.

Requirement: A library project is opened.

The check regards differences in the implemented interfaces of a method. So, after the check you will get displayed error messages in the messages window in the following cases:

- Adding or removing inputs or outputs of function blocks, functions or methods
- Changing the data type of inputs or outputs
- Modifying the implemented interfaces of a method

See also

- *Chapter 1.4.1.20.4.14.1 “Dialog 'Customize' - 'Menu'” on page 1206*
- *Chapter 1.4.1.16.1 “Information for Library Developers” on page 449*

Command 'C Integration' - 'Update C Sources'

Function: this command opens the dialog *“Update C Sources”* for updating the objects in the project that have changed in the source directory on the disk.

Call: Menu bar: *“Build”*; context menu.

Requirement: An object *“C Code Module”* or *“C Implemented Library”* is selected. When adding the C-code module in the dialog *“Add C Code Module”*, you have activated the option *“Check folder for source code changes”*.

“File”	File that has changed on the disk.
“Action”	Action that is executed in CODESYS if you click *“Update”*.
“Update options”	● *“Remove IEC interfaces due to changed header files”* ● *“Export source files to the monitored project folder”*
“Refresh”	CODESYS updates the listed files.

See also

- *Chapter 1.4.1.20.3.5.12 “Command 'C Integration – Open in IDE'” on page 1025*
- *Chapter 1.4.1.8.10 “Integrating C Modules” on page 275*

Command 'C Integration – Open in IDE'

Function: The command opens the *“C Code Module”* in the associated IDE (Integrated Development Environment).

Call: Main menu *“Create”*, context menu

Requirement: You have opened an object *“C Code Module”* and the associated IDE is not opened.

If the IDE is closed, CODESYS checks whether the files have been changed and, in such a case, a dialog box appears for confirming the update of the C-code module in CODESYS.

See also

- *Chapter 1.4.1.20.4.10.5 “Dialog 'Properties' – 'Build' (C-integration)” on page 1160*
- *Chapter 1.4.1.20.3.5.11 “Command 'C Integration' - 'Update C Sources'” on page 1025*
- *Chapter 1.4.1.8.10 “Integrating C Modules” on page 275*

Command 'C Integration' - 'Export C sSurces'

Function: The command exports all C-code files of a C-code module and saves them in the folder that you select in the dialog *“Find Folder”*.

Call: Menu bar: *“Build”*; context menu.

Requirement: A C code module is selected in the device tree.

See also

- *Chapter 1.4.1.8.10 “Integrating C Modules” on page 275*

Command 'C Integration – Create Stub Implementation in C'

Function: This command creates C-stubs for the selected POU and stores them in the *“Extensions”* folder in the objects *“iec_external.c”* and *“iec_external.h”*.

Call: Main menu *“Build”*, context menu

Requirement: A POU that is inserted under the object of the type *“C Code Module”* is selected in the device tree. The application has been compiled without errors.

See also

- *Chapter 1.4.1.8.10 “Integrating C Modules” on page 275*

Command 'Create IEC Interface'

Function: The command creates corresponding IEC objects from the selected file with the format `*.h` or `*.hhp` and stores these IEC objects in the folder *“IEC interface”*.

Call: Main menu *“Build”*, context menu

Requirement: You have selected an imported C-code file of the format `*.h` or `*.hpp` in the device tree below the object *“C Code Module”*.

If you select the command and the header file is free of errors, the dialog box *“C Functions”* opens with a list of the functions of the file that is to be exported.

Dialog box 'Create IEC interface'

“Function”	List of the functions You select the functions for which a corresponding IEC object is to be created.
“Import”	CODESYS generates corresponding IEC objects for the selected C-functions and stores them in the folder *“IEC interface”* below the object *“C Code Module”*.

See also

- *Chapter 1.4.1.8.10 “Integrating C Modules” on page 275*

Command 'Generate Disassembly File'

Function: This command generates a disassembly file `<project name>.asm` from the current project and saves it in the file directory in the project folder.

Call: The command is not in any menu by default. You can add it to a menu by using the dialog box from *"Tools ➔ Customize"* (command category *"Build"*).

See also

- *Chapter 1.4.1.20.4.14.1 "Dialog 'Customize' - 'Menu'" on page 1206*

Menu 'Online'

Command 'Choose Active Application'

Symbol: 

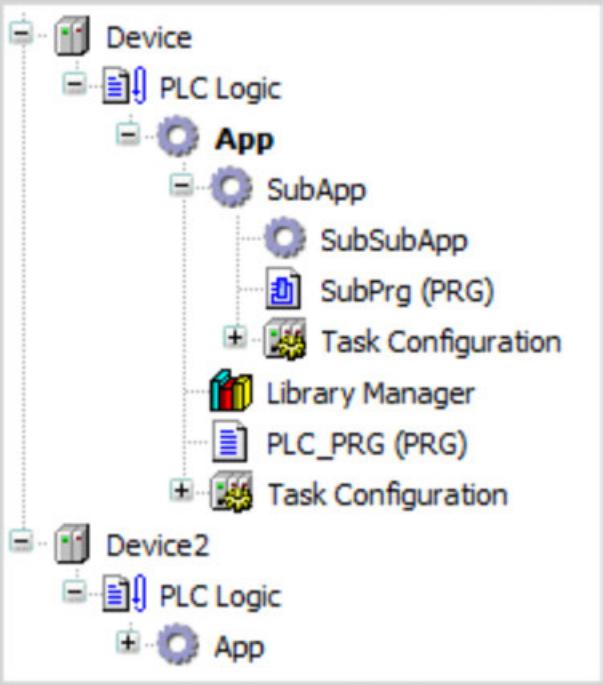
The command is implemented as a list box from which you can set an application active. By default, the list box is located on the toolbar.

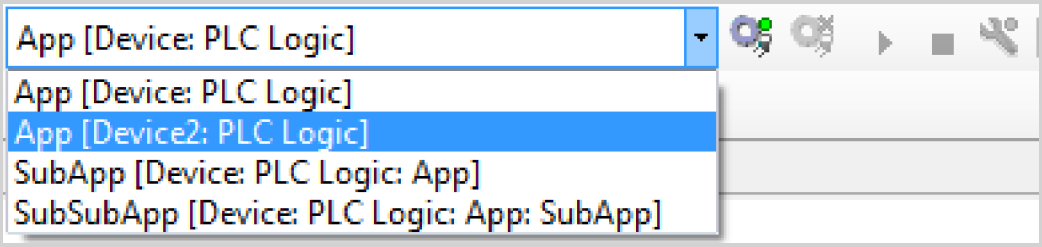
Function: The list box displays the currently active application with its device path.

Call: The list box contains all applications that are organized in the *"Devices"* view. By clicking an entry in the list box, you activate the selected application.

Requirement: The project has multiple applications.

Example





When you call commands in the “Build” oder “Online” menus, these commands are applied to the active application. This is displayed in the list box, and also displayed in bold in the device tree. In particular, this applies to the “Build ➔ Build” and “Online ➔ Login” commands.

You can also access these commands using the command icons on the toolbar where the list box is located. When the command icons are called, they are also applied to the active application.

However, if you call a command from the context menu of a device object in the device tree, then the command is applied to the corresponding object. For example, by calling , you can establish a connection to an application on the device which is not active.

See also

- *Chapter 1.4.1.20.3.4.12 “Command 'Set Active Application'” on page 1006*
- *Chapter 1.4.1.20.3.5.4 “Command 'Build'” on page 1022*
- *Chapter 1.4.1.20.3.6.2 “Command 'Login'” on page 1028*

Command 'Login'

Symbol: ; shortcut: *[Alt]+[F8]*.

Function: The command connects the application to the target system (PLC to simulated device) and starts the online mode.

Call: Menu bar: *“Online”*; context menu of an *“Application”* object

Requirement: The application contains no errors and the communication settings are configured.

A dialog prompt opens if the communication settings are incorrect. You can then switch directly to the *“Communication Settings”* of the PLC.

If you click *“Login”* from the online menu, then the currently active application is connected to the target system. If you choose this command from the context menu (right-click) while an application is selected in the device tree, then that application is logged in, even if it is not set as the active application.

If an online user management is configured on the target device, then you are prompted for user data when you log in. The *“Device User Login”* dialog opens for this.

CAUTION!

Check controller accessibility

For security reasons, controllers should not be accessible from the Internet or untrusted Networks under any circumstances! In particular, the TCP/IP programming ports (usually UDP-Ports 1740..1743 and TCP-Ports 1217 + 11740 or the controller specific ports) should not be accessible from the internet without protection. In case Internet access to the controller is needed, using a a safe mechanism is absolutely mandatory, such as VPN and password protection of the controller.

see also: *Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385*

NOTICE!

If a safety controller is inserted below a controller, then this command can interrupt the communication connections **temporarily**.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the "Subordinate Safety Controllers" chapter.

Possible situations when logging in:

- A later version of the device description (than in the project) is on the PLC. A warning prompt is displayed with the option to cancel the process.
- The application does not exist on the PLC: You are prompted to confirm the download.
- The application is already on the PLC and has not been changed since the last download. The login continues without any more prompts.
- The application exists on the PLC, but it has been changed since the last download.
  You are prompted to select one of the following options:
  – Login with online change (Note the information about online changes in the help page "Command 'Online Change' ".)
  – Login with download
  – Login without any change

  The position also provides the option of updating the boot application on the PLC.
- An unknown version of the application exists on the PLC. CODESYS prompts you to replace it.

- A version of the application exists on the PLC and is running. CODESYS prompts you to log in anyway and overwrite the currently running application.
- The application on the PLC is currently halted at a breakpoint. You are logged out and the program has been changed: CODESYS prompts you with a warning that the PLC will be stopped completely if an online change or download occurs. This happens also if several tasks exist and the breakpoint affects only one of them.

Click *"Details"* in the dialogs above to open the *"Application Information"* dialog.

> *In CODESYS V3.5 SP17 and higher, only exactly one CODESYS instance can ever be logged in to an application of a controller. If a second CODESYS instance wants to log in to the same application of the same controller, then an error message is displayed.*

See also

- *Chapter 1.4.1.20.3.6.6 "Command 'Online Change'" on page 1033*
- *Chapter 1.4.1.9.5 "Subordinate safety controller" on page 378*

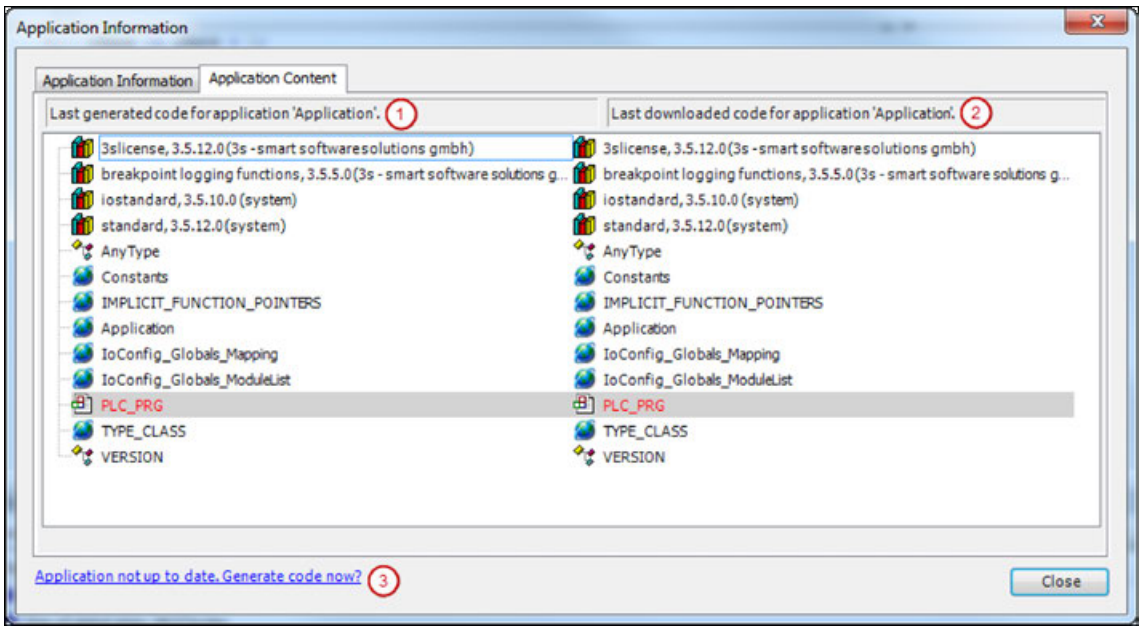
Dialog 'Application Information' (Details)

The dialog provides two tabs with comparative information about the application changed in the development system and its previous version currently located on the PLC. There are two tabs:

- *"Application information"*: The application properties of the *"Application in the IDE"* (Integrated Development Environment) are compared with those of the *"Application in the PLC"*: Project name, Last modification, IDE version, Author, Description. In addition, CODESYS shows the objects that have changed since the last download.
- *"Application contents"*: When the *"Download application info"* is selected, the contents of the applications on both the (1) development system and (2) PLC can be compared. The *"Download application info"* option is located on the *"Application Build Options"* tab of the application properties.

  If the code in the development system is not current, then (3) *"Application not up to date. Generate code now?"* appears at the bottom left of the dialog. Execute this command to update the application source code.

  This detailed information can help you to better assess the effects of login in the current situation and to make a decision about downloading the new application.



The comparison can also be displayed in the device editor (“Applications” tab) by clicking “Content”.

See also

- *Chapter 1.4.1.20.2.8.4 “Tab 'Applications'” on page 845*
- *Chapter 1.4.1.4 “Comparing projects” on page 195*

Unknown applications on the PLC

If one or more applications are already on the PLC, but are not in the project, then CODESYS opens a dialog with a list of these applications. You can then define whether an application should be deleted before loading the current application from the PLC. This also applies to child applications that are on the PLC, but have been deleted from the project in the meantime.

Compiling the project before login

If an application program has not been compiled since the last change, then CODESYS compiles the project before login. This operation is the same as the *“Generate Code”* command when logged out.

If compile errors occur, then a dialog prompt opens. The errors are displayed in the message view in the *“Build”* category. You can then decide whether or not you log in without downloading the program to the PLC.

See also

- *Chapter 1.4.1.20.3.5.4 “Command 'Build'” on page 1022*

Error at login

If an error occurs when logging in to the PLC, then CODESYS cancels the loading operation with an error message. The error dialog gives you the options of showing the error details. If an exception was thrown and the text *SOURCEPOSITION* is included in the log, then you can display the affected function in the editor by clicking *“Show in Editor”*. The cursor jumps to the line containing the error.

Messages during the download operation

If CODESYS downloads the project to the PLC at login, then the following information is printed to the message view:

- Generated code size
- Size of the global data
- Resulting memory requirement on the PLC
- List of the affected blocks (for online change)

In online mode, you cannot change the settings of the devices or modules. You have to logout of the application for changing device parameters. Depending on the bus system, there may be some special parameters that you can also change in online mode.

CODESYS saves the view configuration separately in online and offline mode. In addition, views are closed that cannot be used in any operating mode. For this reason, the view can change automatically at login.

Command 'Logout'

Symbol:  , keyboard shortcut: *[Ctrl]+[F8]*.

Function: This command disconnects the application from the target system (controller or simulated device) and returns to offline mode.

Call: Main menu *“Online”*, or context menu of the *“Application”* object.

Command 'Create Boot Application'

Function: This command generates a boot application.

Call: Main menu *“Online”*.

A boot application is the application that is started automatically when the controller is switched on or started.

In offline mode, you can save the boot application in any directory. In online mode, CODESYS save the boot application to the target device. The file name is `<application name>.app`.

See also

- *Chapter 1.4.1.10.6 “Generating boot applications” on page 391*
- *Chapter 1.4.1.20.2.1 “Object 'Application'” on page 819*

Command 'Load'

Function: This command causes a compilation of the active application with subsequent download to the controller.

Call: Menu bar: *“Online”*.

Requirement: The application is in online mode.

When you execute this command, CODESYS performs a syntax check and generates the application code. This code is downloaded to the PLC. Furthermore, CODESYS generates the build log `<project name>.<device name>.<application ID>.compile info` in the project directory.

NOTICE!
During loading all variables are re-initialized with the exception of persistent variables.

NOTICE!
If a safety controller is inserted below a controller, then this command can interrupt the communication connections **temporarily**.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the "Subordinate Safety Controllers" chapter.

The description of the *“Login”* command describes the possible situations when logging in and loading.

If you attempt to download an application when the same version of the application is already on the PLC, then you get the message: "Program is unchanged. Application was not downloaded". CODESYS downloads the application to the PLC.

During loading a record of the actions being executed (generation of code, execution of initialization, etc.) appears in the Message window in the message category *“Compile”*. Furthermore, information is displayed regarding the memory ranges, the size of the code, the global data and the allocated memory. For the purpose of clarity, as opposed to the online change, the modified function blocks are no longer listed.

See also

- *Chapter 1.4.1.20.3.6.2 “Command 'Login'” on page 1028*
- *Chapter 1.4.1.9.5 “Subordinate safety controller” on page 378*

Command 'Online Change'

Function: The command is used for initiating an online change on the current application. When this is done, CODESYS re-downloads only the changed parts of an application that is already running on the PLC.

Call: Menu bar: *“Online”*; context menu of an *“Application”* object

Requirement: The application is in online mode.

The command is available in the context menu if an application is selected in the device tree. In this way, you can perform an online change just for one application, even if that application is not currently active.

CAUTION!

An online change modifies the running application program and does not cause a restart.

Make sure that the new application code still has the required effect on the controlled system.

Depending on the controlled plant, the plant and workpieces may be damaged or the health and life of persons could be endangered.

NOTICE!

1. When an online change is performed, the application-specific initializations (example: homing) are not executed because the machine retains its status. For this reason, the new program code may not have the intended effect.

2. Pointer variables retain their value from the last cycle. When a pointer refers to a variable whose value was changed in an online change, the variable no longer yields the correct value. Make sure that the pointers are re-assigned in each cycle.

3. After the parent application has been changed, a child application is removed from the controller when an online change is performed.

NOTICE!

For compiler version >= 3.5.0.0, a fast online change is performed for minor changes. In this case, only the modified blocks are compiled and downloaded. In particular, no initialization code is generated. This means that also no code is generated when variables with the `init_on_onlchange` attribute are initialized. As a rule, this has no effect because the attribute is used primarily for initializing variables with addresses. However, it cannot happen that a variable changes its address during an online change.

To secure the effect of the `init_on_onlchange` attribute in the entire application code, you must deactivate the fast online change in general for the application by using the compiler definition `no_fast_online_change`. To do this, insert the definition in the application *"Properties"* (*"Build"* tab).

At the time of download, CODESYS also lists the changed interfaces, affected variables, and all blocks with new generated code in the *"Build"* category of the message view. If memory locations change, a dialog will inform you of possible problems in conjunction with pointers.

In the "Online Change Memory Reserve" view, memory reserves can be configured for the online change so that instance variables do not have to be moved in the memory when changing a function block in an online change.

What prevents an online change?

There are actions in CODESYS after which an online change on a controller is no longer possible. Afterwards, the application always has to be completely recompiled. A typical case is the *"Clean All"* action which deletes the compile information stored at the last download. However, these kind of actions typically generate a warning which you have to acknowledge.

But there are also "normal" editing actions that result in an online change not being possible at the next login. Therefore, pay attention to the following symbol in the status bar when editing in the program POUs: . When this symbol turns red in color (), only a full download to the controller can be performed. Double-clicking the symbol opens the *"Application Information"* dialog with a list of differences to the last download. In the dialog, you also find information about which of the changes prevent an online change.

Actions and changes in different areas of an application that prevent an online change:

Check functions	Activation or removal of a check function (`CheckBounds`, `CheckRange`, `CheckDiv`, etc.) Change in an interface of a check function (also the insertion and deletion of local variables)
Task configuration	Change in the configuration settings
Project settings	Change of the *"Compile Options"* in the *"Settings"* section (Unicode, replace constants, logging in, breakpoints) Change in the *"Compiler defines"*
Application properties	Change of the *"Target system memory settings"* (*"Build"* tab)
POU properties	Change of the *"External implementation"* option (*"Build"* tab)
Task-local global variable list	All changes

Function block	Change of the base POU of a function block (`EXTENDS FBbase`), also the insertion or deletion of such a base POU Change in the interface list (`IMPLEMENTS ITF`). Exception: Adding a new interface at the end of a list
Data type	Change of the data type of a variable from a user-defined data type to another user-defined data type (for example, from `TON` to `TOF`) Change of the data type from a user-defined data type to a base type (for example, from `TON` to `TIME`) Note: As a workaround, you should always change the name of the variable together with the data type. Then the variable is initialized as a new variable and the old one is removed. Then an online change is possible.
Alarm configuration	Change in the alarm database configuration Change of the number of latch variables (also has an effect on the memory format in the database) Change to the configuration of the distributed alarms
Data source	All changes in the configuration
Device configuration	Change in the device tree (also by the *“Update Device”* command) Change in a device configuration: By default, changes to device parameters are not capable of online change. However, exceptions can be configured in the device description. Note: I/O mapping to variables is possible by online change.
Visualization	Toggling of the overlay function Before V3.5 SP6: Change in the configuration of the trace element Note: In V3.5 SP6 and higher, the following applies: For online changes that affect visualizations or affect the data of the application (for example, a new variable is inserted), the visualization is completely reinitialized. For TargetVisu, for example, this means that the visualization closes and reopens with the start page. For WebVisu, the visualization also restarts with the start visualization after a short waiting period.
Unit conversion	Insertion or removal of objects for unit conversion
Trend	Change of the number of variables or maximum number of variables. Change of the number of variables with a description or special line settings

Command 'Source Download to Connected Device'

Function: This command loads the project source code (as project archive) to the controller currently connected.

Call: Main menu *“Online”*.

Requirement: The application is in online mode.

See also

- *Chapter 1.4.1.20.3.1.10 “Command 'Source Upload'” on page 962*
- *Chapter 1.4.1.20.3.1.11 “Command 'Source Download'” on page 963*

Command 'Download Manager'

Symbol:

Function: Download or create a boot project from the project devices or update the firmware oft he device.

Call: Main menu *“Online”*, Context menu.

Requirement: A project is open.

Command 'Multiple Download'

Function: The command causes the code generation of the applications contained in the project as well as the loading of the applications to the corresponding controllers.

Call: Menu bar: *“Online”*

The command opens a dialog with a list of the applications. In this dialog, select the applications that are to be loaded. Then, CODESYS performs the syntax check of these applications and generates the respective code. The code is then downloaded to the respective PLC.
For each selected application, CODESYS generates a build log with the name `<project name>.<device name>.<application ID>.compileinfo` in the project directory.

NOTICE!

If a safety controller is inserted below a controller, then this command can interrupt the communication connections **temporarily**.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the "Subordinate Safety Controllers" chapter.

Dialog 'Multiple Download'

“Please select the items to be downloaded”	: Selection of the applications. The applications are thereby also loaded to different controllers.
“Move Up”, *“Move Down”*	Change of the order of download of the applications. The applications are downloaded to the PLCs in the order of this list. By default, this list is alphabetically sorted. Parent-child relationships of applications are thereby taken into account.
“OK”	Checks the syntax of all selected applications. Afterwards, the communication with the associated controller is verified for each application before the download takes place.

Table 138: “Online Change Options”

If an earlier version already exists on the PLC and is different from the current version, then the following options are provided:	
“Try to perform an online change. If this is not possible, perform a full download.”	Activated by default. If an online change cannot be executed for one of the applications, then a download is performed.
“ Force an online change. If this is not possible, cancel the operation.”	If an online change cannot be performed for (at least) one of the applications, then no download is performed and the online change is terminated (for example, if you have executed the command *“Clean All”* beforehand).
“Always perform a full download.”	Downloads all parts of the applications to the PLC, regardless of any existing versions.

For selected applications that do not exist on the PLC yet, CODESYS performs a download automatically to the PLC.

Table 139: “Other Options”

“Delete all applications on the PLC which are not part of the project. ”	☑: Corresponding applications are deleted
“Start all applications after download or online change”	☑: The applications are started after the download or online change.
“Do not release forced variables”	☑: If an application with forced variables exists on the controller, and if the implementation of this application has been changed, then no download is performed for this application. The message *“Error: Skipped because one or more variables have been forced”* appears for this application in the window *“Multiple Download - Result”*.

Note that variables with the key attribute `PERSISTENT RETAIN` are not generally initialized. If you change the data layout, however, the persistent variables are automatically re-initialized.

After completion of the download a listing of all selected applications appears in the download order that you configured. In addition, you are shown information on the success of the download for each application in the *“Multiple Download - Result”* dialog:

- *“Created”*: A new application has been created and downloaded to the controller.
- *“Not changed”*: The application which exists on the controller has not been changed.
- *“Online changed”*: The application which exists on the controller has been modified by an online change.
- *“Downloaded”*: The application which exists on the controller has been replaced by a new created application.
- *“Skipped due to impossible online change”*: An online change could not be performed for the application. The application was not changed.
- *“Error”*: An error has occurred for this application during download. More details may be displayed.
- *“Cancelled by user”*: The operation has been aborted by the user.

Command 'Reset Cold'

Function: The command results in a cold start of the active application on the controller.

Call: Menu bar: *"Online"*

Requirement: The application is in online mode.

> **NOTICE!**
> If a safety controller is inserted below a controller, then this command can interrupt the communication connections **temporarily**.
>
> Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.
>
> For more information, see the "Subordinate Safety Controllers" chapter.

After restarting with *"Reset Cold"*, the following happens:

- Application code is retained on the controller.
- Variables are initialized (with the initialization value or the default initialization value 0), and the previous values are lost.
- Retain variables are initialized, and the previous values are lost.
- Persistent variables are retained with values.
- Breakpoints that were set in the code are retained with their status (for example, activated or deactivated).
- The application goes into the *"STOP"* state.

You can also select the command while debugging the application when it halts at a breakpoint in the *"HALT ON BP"* state. Then either the warm start is executed immediately, or the remaining statements of the current cycle are processed. Therefore, a message window opens for you to select the next action. However, the message window opens only if the runtime system is capable of restarting the cycle without terminating it first.

After the reset, you can run the application as usual and, for example, start the execution by clicking *"Debug ➔ Start"*.

- *Chapter 1.4.1.20.3.6.12 "Command 'Reset Origin'" on page 1039*

Command 'Reset Warm'

Function: The command results in a warm start of the active application on the controller.

Call: Menu bar: *"Online"*

Requirement: The application is in online mode.

NOTICE!

If a safety controller is inserted below a controller, then this command can interrupt the communication connections **temporarily**.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the "Subordinate Safety Controllers" chapter.

After restarting with *“Reset Warm”*, the following happens:

- Application code remains loaded on the controller.
- Variables are initialized (with the initialization value or the default initialization value 0).
- Retain variables are retained with values.
- Persistent variables are retained with values.
- Breakpoints that were set in the code are retained with their status (for example, activated or deactivated).
- The application goes into the *“STOP”* state.

You can also select the command while debugging the application when it halts at a breakpoint in the *“HALT ON BP”* state. Then either the warm start is executed immediately, or the remaining statements of the current cycle are processed. Therefore, a message window opens for you to select the next action. However, the message window opens only if the runtime system is capable of restarting the cycle without terminating it first.

After the reset, you can run the application as usual and, for example, start the execution by clicking *“Debug ➔ Start”*.

- *Chapter 1.4.1.20.3.6.12 “Command 'Reset Origin'” on page 1039*

Command 'Reset Origin'

Function: The command results in a reset origin of the active application on the controller.

Call: Menu bar: *“Online”*

Requirement: The application is in online mode.

NOTICE!

If a safety controller is inserted below a controller, then this command can interrupt the communication connections **permanently**.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the "Subordinate Safety Controllers" chapter.

After restarting with *"Reset Origin"*, the following happens:

- The application code is deleted, and as a result the application has no state.
- Variables are deleted, and the values are lost.
- Retain variables are deleted, and the values are lost.
- Persistent variables are deleted, and the values are lost.
- Breakpoints that were set in the code are lost.

- *Chapter 1.4.1.20.3.6.10 "Command 'Reset Cold'" on page 1038*

Command 'Reset Origin Device'

Function: The command opens a dialog to reset the device to its factory settings. All applications, boot applications, and remanent variables will be deleted from the device. Depending on the version of the device, a selection of the elements to be deleted can be made in this dialog. When these elements are unselected in the dialog, they are not deleted during the reset and remain on the controller. By default, all elements are selected and everything is deleted. Elements that are not available for selection are generally also deleted.

Call: Right-click a programmable device in the device tree.

NOTICE!

If a safety controller is inserted below a controller, then this command can interrupt the communication connections **permanently**.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the "Subordinate Safety Controllers" chapter.

After restarting with *"Reset Origin Device"*, the following happens:

- All applications are reset as with the *"Reset Origin"* command.
- All files, which are not deleted by the *"Reset Origin"* command, are deleted (for example, files from visualization, alarms, and recipes).

- The user management is deleted.
- All certificates which are currently managed by the runtime system are deleted.

Note: When resetting the device, the objects selected in this dialog are also deleted. If not all displayed objects are selected in this dialog, then possibly other objects can no longer be used or they are also deleted. .	
"Delete"	☑: The object is deleted when the *"Reset Origin Device"* command is executed.
"Object"	Objects that can be excluded from *"Delete"*. The listed objects depend on the version of the controller. In version 3.5.16.20 and higher, the following objects can be excluded from the delete operation. ● *"User Management"* ● *"PLC Logic"* ● *"Certificates"*

Command 'Logoff Current Device User'

Symbol: 

Function: This command logs out the user currently logged in to the controller (device). If CODESYS still has a connection to the controller, then it will be disconnected.

Call: Main menu *"Online"*.

Requirement: The application is in online mode.

You can manage the device user management in the "Users and Groups" tab and "Access control" of the device editor. The commands in the "Online ➔ Security" menu provide another simple option for protecting access to the target device.

See also

- *Chapter 1.4.1.20.2.8.13 "Tab 'Users and Groups'" on page 860*
- *Chapter 1.4.1.10.3 "Handling of Device User Management" on page 385*

Command 'Download'

Function: This command loads the compiled project in the PLC.

Call: Main menu *"Online"*, Context menu.

Requirement: A project is open. Log-in required for download.

Command 'Add Device User'

Symbol: 

Function: This command configures a new device user and adds this user to the administrator group.

Call: Menu bar: *“Online ➔ Security”*

Requirement: The device supports a device user management. You are logged in to the device as a user.

You can manage the device user management in the “Users and Groups” tab and “Access control” of the device editor. The commands in the “Online ➔ Security” menu provide another simple option for protecting access to the target device.

See also

- *Chapter 1.4.1.20.2.8.13 “Tab 'Users and Groups'” on page 860*
- *Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385*

This command opens the *“Add Device User”* dialog. Here you define the access data of the new user.

The dialog corresponds to the dialog in the *“Users and Groups”* tab of the device editor for adding a new user.

Please use a strong password as follows:

- Password length >= 8 characters (best >= 12)
- Use uppercase and lowercase
- Include numbers
- Use special characters
- Do not use existing names or sequence of characters that are easy to guess (for example, “123”, “abc”, “qwerty”)

CAUTION!
After performing this action, you can no longer use a blank username and password to log in. You must remember your password.

See also

- *Chapter 1.4.1.20.3.6.17 “Command 'Remove Device User'” on page 1042*
- *Chapter 1.4.1.20.3.6.18 “Command 'Change Password Device User'” on page 1043*

Command 'Remove Device User'

Symbol: 

Function: This command removes a user from the user management on the target system (device).

Call: Menu bar: *“Online ➔ Security”*

Requirement: You are logged in to the device as a user.

You can manage the device user management in the “Users and Groups” tab and “Access control” of the device editor. The commands in the “Online ➔ Security” menu provide another simple option for protecting access to the target device.

See also

- *Chapter 1.4.1.20.2.8.13 “Tab 'Users and Groups'” on page 860*
- *Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385*

This command opens the *“Remove Device User”* dialog. Specify the user name and password of the user to be removed and click *“OK”* to confirm.

CAUTION!
After performing this action, you can no longer use this removed user account to log in. If this user is the only one on the target system, then a dialog prompt notifies you that this user cannot be removed.

See also

- *Chapter 1.4.1.20.3.6.16 “Command 'Add Device User'” on page 1041*
- *Chapter 1.4.1.20.3.6.18 “Command 'Change Password Device User'” on page 1043*

Command 'Change Password Device User'

Symbol:

Function: The command changes the password for the user who is currently logged on the PLC.

Call: *“Online* ➔ *Security”* menu

Requirement: You are logged in to the device as a user.

The command opens the *“Change Password for Device User”* dialog for defining a new password. You have to specify the old password again.

NOTICE!
After performing this action, you can no longer use the previous password to log in.

Make sure that you use a strong password. Note the following:

- Password length >= 8 characters (best >= 12)
- Use uppercase and lowercase
- Include numbers
- Use special characters
- Do not use existing names or sequence of characters that are easy to guess (for example, "123", "abc", "qwerty")

- *Chapter 1.4.1.10.3 “Handling of Device User Management” on page 385*

Command 'Stop Execution on Handled Exceptions'

Function: This command halts the application where the error is located despite a programmed exception handling.

Call: This command is not available by default, but it can be configured from the *“Tools* ➔ *Customize”*, *“Add Command”* dialog box (*“Online”* category).

Requirement: The application is in online mode and contains a programmed exception handling with the `__TRY` and `__CATCH` operators.

If you have configured this command from the *“Online”* menu and you call it from there, then the currently active application is affected. Furthermore, this command can help you to detect errors.

See also

- *Chapter 1.4.1.19.3.61 “Operators '__TRY', '__CATCH', '__FINALLY', '__ENDTRY'” on page 619*
- *“Adding commands” on page 181*
- *Chapter 1.4.1.20.3.8.16 “Command 'Customize'” on page 1071*

Command 'Connect to Device'

Function: The command establishes a connection to the device currently selected in the device tree.

Call: Context menu of the device.

Requirements: A device is selected in the device tree. The communication settings are configured correctly.

See also

- *Chapter 1.4.1.20.3.6.21 “Command 'Disconnect from Device'” on page 1044*

Command 'Disconnect from Device'

Function: The command disconnects the connection from a device.

Call: Context menu of the device.

Requirements: A device is selected in the device tree.

See also

- *Chapter 1.4.1.20.3.6.20 “Command 'Connect to Device'” on page 1044*

Command 'Wink'

Symbol: 

Function: The command causes an LED of a connected controller to blink. As a result, the hardware can be identified clearly.

Call: The command is not in any menu by default. You can add it to a menu by means of the *“Tools ➔ Customize”* dialog, in the *“Online”* command category.

Requirement: The controller supports this function and the connection parameters are configured correctly.

Command 'Simulation

Function: The command switches the development system to simulation mode.

Call: Menu bar: *“Online”*

In simulation mode, you can start and debug the active application an on a simulated target device. A physical target device is not necessary for testing the online behavior of an application. When logging in for the first time, you are prompted whether the application should be created or loaded. For a simulated device, you do not have to configure the communication settings. In CODESYS simulation mode, the entry of the controller in the device tree is displayed in italics.

NOTICE!

No C code for simulation mode

In simulation mode, C code is not generated and loaded to the runtime system. To simulate the code contained in the C modules anyway, you can implement it for this purpose in the respective IEC objects of the C code module.

After successful login, the red triangle symbol (⚠) in the device tree indicates simulation mode. You can use the corresponding online commands for testing the application.

To switch off simulation mode, log out of the controller and execute the *"Simulation"* command again.

The command affects the active application only.

Differences between simulation mode and operation with a physical controller

	Simulation	Physical Controller
Real-time behavior / multicore	● Runs in the CODESYS process with normal priority ● Single-core --> Worse real-time behavior	● Real-time operating system ● Single-core or multicore
Architecture scope	● Simulation 64-bit (depends on the CODESYS installation): --> Possible compile error in the IEC application if the application has been previously run only as 32-bit (for example, use of `DWORD` as POINTER)	● Controller 32-bit
FPU (rounding error)	● Uses FPU of the PC ● Different configuration of the FPU exceptions	● Uses FPU of the controller or FPU emulation ● Different configuration of the FPU exceptions
Handling of exceptions	● Exception handling of the Windows Runtime System	● Exception handling of the controller

	Simulation	Physical Controller
External libraries (Cmp/Sys/CAA/OEM/…)	● Only a few external Cmp/SysLibs are physically available. As compared to embedded, more SysLibs could also be available. ● Other implementation/behavior of the SysLibs (Windows in contrast to the OS of the controller) ● "Unresolved Reference error“ on download is ignored. The application can still be downloaded to the controller and started. If the missing functions are actually called, they return nonsense values. Therefore, an IEC implementation can also be specified for external POUs. This substitute IEC code is then executed in the simulation.	● "Unresolved Reference error" on download when external libraries do not exist in the controller
I/O drivers	● I/O configuration is generated but not evaluated. ● Fieldbus stacks are not evaluated. ● I/O channels are not updated and no bus telegrams are sent.	● Mostly no restriction, but depends on the capabilities of the controller
SoftMotion drivers	● All SoftMotion axes are set to virtual and therefore simulated.	● Mostly no restriction, but depends on the capabilities of the controller

See also

- *Chapter 1.4.1.11.1 “Testing in simulation mode” on page 394*

Command 'Operating Mode'

Function: The commands set the controller to a state which prevents accidental change to the project.

Call: Menu bar: *“Online ➔ Operating Mode”*

You can use these commands, for example, to lock the state of a controller in order to prevent the controller from switching to another state while you program another controller.

When programming is complete, the controller should then be switched to a defined and externally visible state that is set exactly the same way after restarting.

The , , and symbols in the status bar indicate the current operating mode. Double-clicking one of these symbols opens a help window.

If it supports the controller, then you can switch the controller to the following operating modes:

- *“Debug”*: No restrictions
- *“Locked”*: The current state of debugging is locked on the application. No additional breakpoints can be set and no additional variables can be forced. Writing variables is still possible and breakpoints which are already set remain active.
  Only the "RUN" state of an application is preserved in *“Locked”* operating mode even if the controller is restarted.
  With this operating mode, a developer can prevent himself or another developer from changing the application on the controller, for example by setting or deleting a breakpoint, by forcing, or by making changes to the file system. This operating mode is helpful to prevent a download to an incorrect controller when, for example, multiple controllers of a plant are programmed.
- *“Operational”*:
  This operating mode makes sure that the controller reloads the same applications after a restart and that no debug features are active anymore. The operating mode is set when a controller is completely programmed and should be accepted or already is.
  Conditions for activating the *“Operational”* mode
  – A boot application for each application has to exist on the controller.
  – There must not be any active breakpoints set.
  – All applications have to be running.
  – There must not exist any forced values.
  – Furthermore, the device can define more of its own restrictions.

The *“Locked”* and *“Operational”* operating modes are different in the use cases and in the requirements for activating the operating mode. However, for both operating modes the runtime system prevents the following actions:

- Regarding the application
  – Download of an application
  – Online change
  – Force variables
  – Set breakpoints
  – Stop application
  – Reset application
  – Start application
  – Delete application
- Regarding the file transfer of the controller
  – Download of a file to the controller
  – Delete a file on the controller
  – Rename a file on the controller
  – Create a directory on the controller
  – Delete a directory on the controller
  – Rename a directory on the controller

You cannot switch the operating mode between “Locked” and “Operational”.

Command 'Virtual mode'

Function: *“Virtual Mode”* option enables virtual mode for Automation Builder.

Call: Main menu *“Online”*, Context menue

Requirement: A project is open. Command is only available, if a license for advanced simulation support is acitvated.

Command 'Virtual system testing'

Function: The *“Virtual system testing”* editor contains settings for the virtual devices and the simulation set-up and control.

Call: Main menu *“Online”*, Context menu

Requirement: A project is open. Command is only available, if a license for advanced simulation support is acitvated.

Menu 'Debug'

Command 'Start'

Symbol: ; keyboard shortcut: *[F5]*

Function: This command starts the application (status: *“RUN”*).

Call: Menu bar: *“Debug”*; context menu of object: *“Application”*

Requirement: The application is in online mode and its status is *“STOP”*.

Executing this command from the *“Debug”* menu will affect the application that is currently in focus.

See also

- *Chapter 1.4.1.10.5 “Downloading the application code, logging in, and starting the PLC” on page 391*

Command 'Stop'

Symbol: ; keyboard shortcut: *[Shift]+[F8]*

Function: This command stops the application (status: *"STOP"*).

Call: Menu bar: *"Debug"*; context menu of object: *"Application"*

Requirement: The application is in offline mode and its status is *"RUN"*.

Executing this command from the *"Debug"* menu will affect the application that is currently in focus.

Command 'Single Cycle'

Keyboard shortcut *[Ctrl]+[F5]*

Function: This command executes the active application for one cycle.

Call: Main menu *"Debug"*.

Requirement: The application is in online mode and the program is halted at a program step.

Command 'New Breakpoint'

Symbol: , keyboard shortcut *[Alt]+[F7]*.

Function: This command opens the *"Breakpoint Properties"* dialog box.

Call: Main menu *"Debug"*.

Requirement: The application must be in online mode.

With the "Toggle Breakpoint" command, you can set a new breakpoint directly at the current cursor position in online mode.

See also

- *Chapter 1.4.1.11.2 "Using Breakpoints" on page 395*

Command 'New Data Breakpoint'

Symbol:

Function: The command opens the *"New breakpoint"* dialog.

Call: Menu bar: *"Debug"*

Requirement:

- The application is in online mode.
- The device description file of the target device contains the entries for the "data breakpoints" functionality. Currently, data breakpoints are possible only with the CODESYS Control Win V3.

See also

- *Chapter 1.4.1.20.4.8 "Dialog 'New Breakpoint'" on page 1154*
- *Chapter 1.4.1.11.2 "Using Breakpoints" on page 395*

Command 'Edit Breakpoint'

Symbol:

Function: This command opens the *“Breakpoint Properties”* dialog box.

Call: Main menu *“Debug”*.

Requirement: The application is in online mode and the cursor is halted at a breakpoint.

See also

- *Chapter 1.4.1.11.2 “Using Breakpoints” on page 395*

Command 'Enable Breakpoint'

Function: This command enables a disabled breakpoint.

Call: Main menu *“Debug”*.

Requirement: The application is in online mode and the cursor is halted at a disabled breakpoint.

See also

- *Chapter 1.4.1.11.2 “Using Breakpoints” on page 395*

Command 'Disable Breakpoint'

Function: This command disables an enabled breakpoint.

Call: Main menu *“Debug”*.

Requirement: The application is in online mode and the cursor is halted at an enabled breakpoint.

See also

- *Chapter 1.4.1.11.2 “Using Breakpoints” on page 395*

Command 'Toggle Breakpoint'

Keyboard shortcut *[F9]*

Function: This command sets a breakpoint or clears an existing breakpoint.

Call: Main menu *“Debug”*.

Requirement: The application is in online mode. The cursor is positioned at a breakpoint.

See also

- *Chapter 1.4.1.11.2 “Using Breakpoints” on page 395*

Command 'Step Over'

Symbol  , shortcut *[F10]*

Function: The command executes the statement where the program is currently located and halts before the next statement in the POU.

Call: Menu bar: *“Debug”*

Requirement: The application is in online mode and the program is halted at the current break position (debug mode).

If the executed statement contains a call (from a program, function block instance, function, method, or action), then the subordinate POU is processed completely in one step and returned to the call. Then it halts before the next statement (in the next line of code).

Click “Step Into” to jump to a subordinate POU and process it in single steps.

See also

- *Chapter 1.4.1.11.3 “Stepping Through a Program” on page 399*
- *Chapter 1.4.1.20.3.7.11 “Command 'Step Into'” on page 1051*

Command 'Step Into'

Symbol , shortcut *[F11]*

Function: The command executes the statement where the program is currently located and halts before the next statement.

Call: Menu bar: *“Debug”*

Requirement: The application is in online mode and the program is halted at the current break position (debug mode).

If the executed statement contains a call (from a program, function block instance, function, method, or action), then the program execution jumps to this subordinate POU. Its code opens in a separate editor. The first statement there is executed and the program execution halts before the next statement. The new current breakpoint position is then in the called POU.

Click “Step Over” to remain in the currently active POU and execute the call in one step.

See also

- *Chapter 1.4.1.11.3 “Stepping Through a Program” on page 399*
- *Chapter 1.4.1.20.3.7.10 “Command 'Step Over'” on page 1050*

Command 'Step Out'

Symbol , shortcut *[Ctrl]+[F11]*

Function: The command executes the program until the next return and halts afterwards.

Call: Menu bar: *“Debug”*

Requirement: The application is in online mode and the program is halted at the current break position (debug mode).

If the current breakpoint position is in a subordinate POU, then this is run through to the end. Then the program execution jumps back to the calling point in the calling POU and halts there (in the line with the call).

If the current breakpoint position is in the main program, then the POU is run through to the end. Then the program execution jumps back to the beginning (to the program start at the first line of code in the POU) and halts there.

See also

- *Chapter 1.4.1.11.3 “Stepping Through a Program” on page 399*

Command 'Run to Cursor'

Symbol: 

Function: The command executes a program until a specified position as marked by the cursor.

Call: Menu bar: *“Debug”*

Requirement: The application is in online mode and the program is halted at the current break position (debug mode). Moreover, you have marked any line of code in any POU with the cursor.

The statements between the current breakpoint position and the cursor position are executed in one step. Then the execution halts at the cursor position, which then becomes the next breakpoint position. Remember that the line of code where you placed the cursor is reached but not executed.

See also

- *Chapter 1.4.1.11.3 “Stepping Through a Program” on page 399*

Command 'Set Next Statement'

Symbol: 

Function: The command determines which statement is executed next.

Call: Menu bar: *“Debug”*

Requirement: The application is in online mode and the program is halted at the current break position (debug mode). Moreover, you have marked any line of code in any POU with the cursor.

The line of code marked with the cursor becomes the current breakpoint position without executing the statements in between or the statement that jumped to it.

See also

- *Chapter 1.4.1.11.3 “Stepping Through a Program” on page 399*

Command 'Show Next Statement'

Symbol: 

Function: The command displays the program statement that is processed in the next step.

Call: Menu bar: *“Debug”*

Requirement: The application is in online mode and the program is halted at the current break position (debug mode). The break position is in a line of code that you cannot see.

The command makes the window with the current breakpoint position active (in the code highlighted in yellow and marked with the symbol) and makes the breakpoint position to become visible. This is useful if you have multiple editors open and the breakpoint position is hidden in an inactive editor.

See also

- *Chapter 1.4.1.11.3 “Stepping Through a Program” on page 399*

Command 'Force Values'

Keyboard shortcut: *[F7]*

Function: The command sets a permanent predefined value to a variable on the controller.

Call: Menu bar: *“Debug”*

Requirement: The application is in online mode.

CAUTION!
Unusual changes to variable values in an application currently running on the controller can lead to undesired behavior of the controlled machinery.
Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled machinery, the result may lead to damage to machinery and equipment or injury to health and life of personnel.

With this command, CODESYS permanently sets one or more variables of the active application to defined values on the PLC.

A forced value is marked with the forced symbol ( ).

For more information about the functionality of forcing and the p of values, see the "Forcing and Writing of Variables" help page.

By default, the “Force Values [All Applications]” command, which applies to all application in the project, and is not included in a menu.

See also

- *Chapter 1.4.1.11.4 “Forcing and Writing of Variables” on page 401*
- *Chapter 1.4.1.20.4.7 “Dialog Box 'Prepare Value'” on page 1153*
- *Chapter 1.4.1.20.3.7.18 “Command 'Unforce Values'” on page 1054*

Command 'Write Values'

Keyboard shortcut *[Ctrl]-[F7]*

Function: This command sets a predefined value to a variable on the controller one time.

Call: Main menu *“Debug”*.

Requirement: The application is in online mode.

CAUTION!
Unusual changes to variable values in an application currently running on the controller can lead to undesired behavior of the controlled machinery.
Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled machinery, the result may lead to damage to machinery and equipment or injury to health and life of personnel.

With this command, one or more variables of the **active application** are set to defined values on the controller one time. Writing is done one time at the beginning of the next cycle.

Values are prepared by

- Clicking in the field *“Prepared value”* in the declaration section
- Clicking in the inline monitoring field in the implementation section
- Clicking in the field *“Prepared value”* in the watch window

The command “Write Values [All Applications]” affects all application in the project and is not included in a menu by default.

See also

- *Chapter 1.4.1.20.3.7.16 “Command 'Force Values'” on page 1053*
- *Chapter 1.4.1.11.4 “Forcing and Writing of Variables” on page 401*

Command 'Unforce Values'

Keyboard shortcut *[Alt]+[F7]*

Function: This command resets the forcing of all variables. The variables receive their current values from the PLC.

Call: *“Debug”*.

Requirement: The application is in online mode.

The *“Remove Force List”* command has the same functionality as this command with one difference. If the *“Remove Force List”* command cannot be executed for all forced values, then no message is displayed.

CAUTION!

Unusual changes to variable values in an application currently running on the PLC can lead to undesired behavior of the controlled machinery.

Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled system, the result may lead to damage to machinery and equipment or injury to health and life of personnel.

The command “Force Values [All Applications]” affects all application in the project and is not included in a menu by default.

See also

- *Chapter 1.4.1.20.3.7.16 “Command 'Force Values'” on page 1053*
- *Chapter 1.4.1.11.4 “Forcing and Writing of Variables” on page 401*

Command 'Force All Values from <Device.Application>'

Function: This command resets all values of variables from the selection <Device.Application> to predefined values permanently.

Call:

- Context menu of the application in the device tree
- Context menu in the editor of a POU from the selected application

Requirement: The application is in online mode.

CAUTION!
Unusual changes to variable values in an application currently running on the controller can lead to undesired behavior of the controlled machinery.
Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled machinery, the result may lead to damage to machinery and equipment or injury to health and life of personnel.

With this command, CODESYS permanently sets one or more variables of the active application to defined values on the PLC. This is done at the beginning and end of a processing cycle. Order of processing: 1) read inputs, 2) force values, 3) process code, 4) force values, 5) write outputs.

You can prepare values as follows:

- Click in the *“Prepared value”* field in the declaration part and type in the value. For Boolean variables, you change the value by clicking the field.
- Click in the inline monitoring field in the implementation part of the FBD/LD/IL editor
- Click in the *“Prepared value”* field in the monitoring view and type in the value.

A forced value is marked with the forced symbol ( ).

CODESYS forces the value until you explicitly lift it by

- Clicking *“Unforce Values”*
- Clicking *“Unforce All Values from <Device.Application>”*
- Lifting the force in the *“Prepare Value”* dialog
- Logging out of the application

The command “Force Values [All Applications]” affects all application in the project and is not included in a menu by default.

See also

- *Chapter 1.4.1.20.4.7 “Dialog Box 'Prepare Value'” on page 1153*

- *Chapter 1.4.1.20.3.7.21 “Command 'Unforce All Values from <Device.Application>'” on page 1056*

Command 'Write All Values from <Device.Application>'

Function: This command resets all values of variables from the selection <Device.Application> to predefined values one time.

Call:

- Context menu of the application in the device tree
- Context menu in the editor of a POU from the selected application

Requirement: The application is in online mode.

CAUTION!
Unusual changes to variable values in an application currently running on the controller can lead to undesired behavior of the controlled machinery.
Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled machinery, the result may lead to damage to machinery and equipment or injury to health and life of personnel.

With this command, one or more variables of the selected <Device.Application> are set to defined values on the PLC one time. Writing is done one time at the beginning of the next cycle.

You can prepare values as follows:

- Click in the "Prepared value" field in the declaration part and type in the value. For Boolean variables, you change the value by clicking the field.
- Click in the inline monitoring field in the implementation part of the FBD/LD/IL editor
- Click in the "Prepared value" field in the monitoring view and type in the value.

- *Chapter 1.4.1.20.3.7.17 “Command 'Write Values'” on page 1053*
- *Chapter 1.4.1.20.3.7.19 “Command 'Force All Values from <Device.Application>'” on page 1054*
- *Chapter 1.4.1.11.4 “Forcing and Writing of Variables” on page 401*

Command 'Unforce All Values from <Device.Application>'

Function: This command resets the forcing of all values of the variables from the selected <Device.Application>. The variables receive their current values from the PLC.

Call:

- Context menu of the application in the device tree
- Context menu in the editor of a POU from the selected application

Requirement: The application is in online mode.

CAUTION!

Unusual changes to variable values in an application currently running on the controller can lead to undesired behavior of the controlled machinery.

Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled machinery, the result may lead to damage to machinery and equipment or injury to health and life of personnel.

See also

- *Chapter 1.4.1.20.3.7.19 “Command 'Force All Values from <Device.Application>'” on page 1054*
- *Chapter 1.4.1.20.3.7.18 “Command 'Unforce Values'” on page 1054*

Command 'Flow Control'

Function: This command activates and deactivates the flow control.

Call: Menu*“Debug”*

Requirement: The application is in online mode.

NOTICE!

An active flow control extends application runtime.

When *“Confirmed Online Mode”* is activated in the communication settings, a dialog prompt appears when switching on the flow control to cancel the process.

When flow control is activated, it is not possible to use breakpoints or step through the program.

See also

- *Chapter 1.4.1.11.6 “Flow Control” on page 406*

Menu 'Core Dump'

Command 'Load Core Dump'

Function: CODESYS scans the project directory for core dump files. When a new core dump is forced with the *"Create Core Dump"* command, the dump file is automatically loaded from the controller to the project directory. If multiple core dump files are available, then CODESYS prompts you to choose whether the latest file should be opened in the project. You can also select one of the other files.

When a file is loaded into the project, an online view of the application appears with state of the application at the time when the core dump was generated. You can then view the variable values afterwards. Finally, the call tree is also available.

Call: Main menu *"Debug ➔ Core Dump"*.

Requirement: The application is in offline mode.

> **NOTICE!**
> You can close the core dump view only by clicking *"Close Core Dump"*. The *"Logout"* command has no effect in this view.

See also

- *Chapter 1.4.1.20.3.7.23.2 "Command 'Create Core Dump'" on page 1057*
- *Chapter 1.4.1.20.3.7.23.3 "Command 'Close Core Dump'" on page 1058*

Command 'Create Core Dump'

Function: This command causes CODESYS to check whether a core dump file is already available on the controller.

If a core dump file is available, then CODESYS prompts you to load this file to the project directory.

With the following requirements, CODESYS generates a new dump file with the current application data:

- A core dump file is still not available or CODESYS has rejected a core dump file from being loaded.
- The application is currently stopped at breakpoint or an exception has occurred.

The generated core dump file is saved directly to the project directory: `<project name>.<device name>.<application name>.<application Guid>.core`. You can cancel the file generation by clicking the button in the status bar.

The amount of detail in the dump depends on the support from the runtime system. Runtime systems that are appropriate for this purpose generate just one dump in the case of an exception error. The core dump output from clicking *"Load Core Dump"* can therefore be used for error analysis.

Call: Main menu *"Debug ➔ Core Dump"*.

Requirement: The application is in online mode.

See also

- *Chapter 1.4.1.20.3.7.23.1 "Command 'Load Core Dump'" on page 1057*

Command 'Close Core Dump'

Function: This command closes the core dump view of the application that is open in the project.

Call: Main menu *“Debug ➔ Core Dump”*.

Requirement: The application is in offline mode and you have loaded a core dump file to the project from the controller.

Command 'Load Device Log from Core Dump'

Function: This command imports the controller log list that was saved with the last generated core dump. The log list is displayed in the same view as in online mode in the *“Log”* tab of the device editor.

Call: Main menu *“Debug ➔ Core Dump”*.

Requirement: The application is in offline mode and a core dump is open in the project.

See also

- *Chapter 1.4.1.20.2.8.8 “Tab 'Log'” on page 848*

Command 'Display Mode' - 'Binary', 'Decimal', 'Hexadecimal'

Function: These commands in the *“Display Mode”* submenu are used for setting the format of values in the display mode when monitoring in online mode.

Call: Main menu *“Debug”*.

Requirement: The project is in either online or offline mode.

The "Binary" and "Hexadecimal" display modes are unsigned, and "Decimal" is signed.

See also

- *Chapter 1.4.1.12.1.1 “Calling of monitoring in programming objects ” on page 410*

Menu 'Tools'

Command 'IP-Configuration'

Function: Scan the project for IP address, device ID and other Informations.

Call: Main menu *“Tools”*, Context menu

Requirement: -

Chapter 1.6.6.2.2.4.2 “Configuration of the IP settings with the IP configuration tool” on page 3675

Command 'Install additional licence'

Function: Installs additional engineering license.

Call: Main menu *“Tools”*, Context menu

Requirement: -

Command 'Migrate third party devices'

Function: After a selection of a previous version profile, all the third party devices which have been installed inside this version profile are listed and can migrated.

Call: Main menu *“Tools”*, Context menu

Requirement: -

Chapter 1.6.6.1.5 “Migration of third party devices” on page 3658

Command 'Package Manager'

Symbol: 

Function: The command opens the *“Package Manager”* dialog where you install, uninstall, and manage packages.

Call: Menu bar: *“Tools”*

You can also call the Package Manager as a standalone application from the command line.

Table 140: “Currently Installed Packages”

List of installed packages with *“Name”*, *“Version”*,*“Installation date”*, *“Update info”*, *“License info”* If a package originates from the CODESYS Store, then CODESYS identifies it with the red package symbol instead of the yellow symbol. When an update is available, CODESYS indicates this with an entry in the *“Update info”* column and with the symbol.	
“Refresh”	Refreshes the list
“Install”	Opens the standard dialog for finding a file in the file system. By default, the file type is *.package. You can also install two versions of a package. After you select the package, the *“Check package signatures”* dialog opens. ● In the dialog, the package is displayed with the information about signing. Detailed information about signing is displayed in the tooltip and also in a dialog which opens when you double-click a package. ● *“Allow unsigned and self-signed packages”* : The package should be installed although it is unsigned or self-signed. After the package is selected, the installation wizard opens with the dialogs: ● *“Installation - License Agreement”* In this dialog, CODESYS also displays the *“Checksum”* of the package. Displayed only when the package has a license agreement. ● *“Choose Setup Type”* The options are package-dependent. – *“Complete setup”*: CODESYS installs all components – *“Typical setup”*: CODESYS installs a standard set of components as defined in the package – *“Custom setup”*: CODESYS installs those components which are selected in a dialog ● *“Installation - Target Versions”*: You select which of the existing target versions should be updated by the package installation. You have to select at least one version profile. When this dialog is successfully completed, the selected package is ready for installation. You have to close all CODESYS instances in order for the package installation to be automatically started and run.
“Uninstall ”	Uninstalls the selected package ● When the *“Display versions”* option is not selected, CODESYS uninstalls all versions of the selected package. ● When the *“Display versions”* option is selected and you have selected a package node on the top level, CODESYS uninstalls all versions of the selected package. ● When the *“Display versions”* option is selected and you have selected an individual package version, CODESYS uninstalls exactly this version. When this dialog is closed, all CODESYS instances have to be closed in order for the package uninstallation to start.

"Details"	Opens the *"Details"* dialog for the selected package with the following tabs: ● *"Package Details"* – *"Name"*: Package name – *"Version"* – *"Checksum"*: SHA-1 checksum of the package – *"Vendor"* – *"Copyright"* – *"Description"* – *"Installation date"* ● *"License Agreement"* ● *"Installations Log"*
"Search updates in background"	☑: CODESYS automatically searches for updates every time the programming system is started and then one time every hour.
"Display versions"	☑: Displays all versions of the installed package.

You can compare the "Checksum" with the package checksum from the package vendor. CODESYS displays this checksum in the "Details" dialog and in the "Installation - License Agreement" dialog of the installation wizard. You do this to make sure that you have installed an original package.

If you have installed a newer version of the programming system in the same installation directory as the previous version, the license information about the previously installed package remains unchanged and CODESYS displays the information in the "Package Manager" dialog.

Table 141: "Updates"

"Search Updates"	Searches for the selected package on your system and in the CODESYS Store Updates. CODESYS displays the found updates in the *"Update Info"* column of the package list.
"Download"	Installs the update package from the *"Download Package"* dialog. In the *"Download Package"* dialog, click the *"Download and Installation"* button for this.

Table 142: "CODESYS Store"

"Rating"	Give an rating of the package
"CODESYS Store"	Link to the homepage of the Store

Command 'Library Repository'

Symbol:

Function: The command opens the *"Library Repository"* dialog. In this dialog you define which libraries are installed on the local system and are thus available for your application.

Call: Menu bar: *"Tools"*

Dialog 'Library Repository'

Table 143: “Location”

Display of the directory on the local system in which the library files are located. The libraries in this *“Location”* are listed in the *“Installed libraries”* area.	
“Edit Locations”	Opens the *“Edit Repository Locations”* dialog.

1. *You can only use empty directories for new repositories.*
2. *You can also use existing repositories as locations.*
3. *The "System" repository is not editable; CODESYS indicates this by the italic lettering of the entry.*

Table 144: Dialog “Edit Repository Locations”

List of the repositories with *“Location”* and *“Name”*	
“Add”	Creates a new repository. Opens the *“Repository Location”* dialog. The selected directory (*“Location”* input field) has to be either empty or an existing valid repository. *“Name”* is the input field for a symbolic repository name.
“Edit”	Opens the *“Repository Location”* dialog (see *“Add”*)
“Remove ”	A dialog box open, asking whether only the entry should be removed from the list of repositories, or whether the directory with the library files should be deleted from the file system. If you want to delete the directory, you have to confirm this.

Table 145: “Installed libraries”

List of the libraries in a tree structure. Display of each library with category, name, company and version. The icon to the left of the name indicates whether the library is digitally signed or unsigned.	
“Company ”	List box for filtering the displayed libraries.
“Install”	Opens the *“Select Library”* dialog. Possible filters: ● *“Compiled CODESYS library files (* .compiled-library)”*. ● *“Compiled CODESYS library files (* .compiled-library-v3)”* ab V3 SP15 ● *“Library files (*.library)”* for still uncompiled library projects ● *“All files (*.*)”*
“Uninstall”	Uninstalls the selected library.
“Export”	Opens the default dialog for saving the library project to the local file system. The file type is `Library files (*.library)`, `Compiled library files (*.compiled-library)`, or `Compiled library files (*.compiled-library-v3)`.
“Find”	Searches for libraries and function blocks. Opens the *“Find Library”* dialog. When you enter a string in the input field, CODESYS displays the libraries that it finds with a corresponding string.
“Details”	Opens the *“Details”* dialog with details from the project information of the library for the selected version of a library. You find the following information by clicking *“More”* in the *“Details”* dialog: ● *“Size”*: Specified in bytes ● *“Created”*: Creation date ● *“Changed”*: Date of the last change ● *“Last access”*: Date ● *“Attributes”* ● *“Properties”*

“Dependencies”	For the selected library, the *“Dependencies”* dialog opens, showing the dependencies on other libraries. *“Title”*, *“Version”* and *“Company”* are shown for each library reference. References that function via placeholders are displayed according to the syntax: #<placeholder name>.
“Group by category”	● ☑: Grouping by library category ● ☐: Alphabetical sorting The categories are defined by external description files '*.libcat.xml'.

Table 146: “Library Profiles”

A library profile defines the library version with which CODESYS resolves a library placeholder if a certain compiler version is set in the project.	
“Import”	Imports a `*.libraryprofile` file. If the import already contains existing placeholder entries, a query appears asking whether CODESYS should overwrite it.
“Export”	Exports an xml file with the extension `*.libraryprofile` with the assignments of the selected placeholder entries; you can only select a single entry of a *“Compiler version”*.

Placeholder resolutions can also be defined in the target device currently in use and even by a specific local specification in the Placeholders dialog in the Library Manager.

Command 'License Manager'

Symbol: 

Function: This command opens the wizard for configuring licenses for CODESYS add-on products. The wizard starts with the *“License Manager - Select target”* dialog.

Call: Menu bar: *“Tools”*.

The License Manager can handle licenses for CODESYS add-on products on the local computer, as well as licenses for RTS add-on products on devices. It supports both the installation in a soft container and on a dongle.

Dialog 'License Manager - Select Target'

This is the start dialog of the License Manager wizard. Here you decide where the license will be installed.

“Workstation”	Local computer
“Device”	Controller. The connection to this device must be configured correctly in order to license (*“Communication Settings”* tab of the device editor).

After clicking *“Next”*, you decide the container where you want to manage the licenses.

Dialog 'License Manager - Select container'

“Dongle”	A corresponding dongle must be connected to the computer or device. Not all devices support dongles.
“Soft container”	"CODESYS Security Key. A corresponding soft container must be registered in the CodeMeter Control Center. The CODESYS installation provides an existing soft container.

If you are installing a product on your local computer (*“Workstation”*), then the *“License Manager”* opens immediately for the specific selection of the dongle or soft container, and the next actions. This happens after you choose the container type and click *“Next >”*.

If you are licensing the add-on product for a controller, then first the dialog opens for selecting the device in the network after you click *“Next >”*. This dialog corresponds to the classic view of the *“Communication Settings”* tab of the device editor.

Dialog 'License Manager'

“Container”	Depending on whether *“Dongle”* or *“Soft container”* was selected: Drop-down list of all CODESYS dongles or soft containers that were found on the computer or device.
“Products”	List of all installed products that are subject to licensing. A prepended symbol indicates the existence and validity of the license. On the right side of the window, the following information is displayed for the selected product and corresponding licenses: *“Name”* *“Company”* *“Unit counter”* *“License quantity”* *“Usage period”* *“Feature map”* *“Activation time”* *“Expiration time”* *“Firm code”* *“Product code”* *“Description”*

“Install Licenses”	Opens the dialog *“Install licenses on <computer> - Select Operation”*: ● *“Activate license”*: Opens the dialog *“Install licenses on <computer> - Activate License”* (see more below) ● *“Request license”*: Opens the dialog *“Install licenses on <computer> - Request License”* (see more below) ● *“Install license”*: Opens the dialog *“Install licenses on <computer> - Install License”* (see more below)
“Additional Functions”	Opens the menu with the following actions: ● *“Return license”*: Opens the *“Return Licenses”* (see more below) ● *“Restore license”*: This function is available in the case of device licensing only. Opens the *“Restore Licenses”* dialog (see more below)

Table 147: “Install Licenses on <computer> - Activate License”

This is the recommended way to activate a license available via the License Server when you have an Internet connection. Requirement: The computer has an Internet connection.	
“Ticket ID”	Input field for the ticket ID that you received from the software vendor. The ticket ID consists of five sets of five alphanumerical characters (for example: `LYSQ3-ZU93K-24LWC-XGWJ8-5AY7H`).
“License server”	Drop-down list of the license server that provides the license for activating the product. You receive the server URL from the software vendor.
“Select Ticket from Repository”	Opens the *“License Repository”* dialog.
“Next”	CODESYS connects to the license server. ● If the specified ticket contains only one license, then a dialog opens to confirm the successful activation after completion of the server action. ● If the specified ticket contains multiple licenses, then the dialog *“Install licenses - Select Licenses”* opens with a list of these licenses (see description below).

Table 148: “Install Licenses - Select Licenses”

Selection of the licenses to be activated for the ticket which you specified in the dialog *“Install Licenses - Activate License”*.	
“Name”	Product name
“Available”	Number of available licenses
“Used”	Number of used licenses
Total	Sum of all used and available licenses
Next	CODESYS connects to the license server. After successful completion of the server action, a dialog opens with the confirmation of the activation.

Table 149: “Install Licenses on <computer> - Request License”

If the computer does not have an Internet connection, then you can generate a context file from this dialog. The file "WibuCmRaC" is then transmitted to the license server via an Internet-enabled computer. When activation is complete, a license update file "WibuCmRaU" is provided for download.	
“Software vendor”	Input field for firm codes from the software vendor that provided the license for activating the product. As an alternative, you can select the software vendor from the drop-down list.
“Context file”	Location and name

Table 150: “Install Licenses on <computer> - Install License”

If you downloaded a license update file from the Internet during software activation, then you can use this dialog to install the license on your dongle. To do this, specify the path of the license update file in the input field.

Table 151: “Return License”

If the license permits, you can return it in order to reactivate it later on another computer.	
“Ticket ID”	Field for specifying the ticket ID that was used for licensing.
“License server”	Drop-down list for selecting the license server that provides the license for activating the product. You receive the server URL from the software vendor.
“Load License(s)”	Button for showing all current licenses installed for the given ticket ID on the server in the *“Licenses”* window.

“Licenses”	List of licenses available on the server for the given ticket ID. The following information for the selected license is displayed next to the window on the right: ● *“Name”* ● *“Number of activations”* ● *“Return allowed”* ● *“Activation type”* ● *“Activation date”* ● *“Firm code”* ● *“Comment”*
“Return License(s)”	Button for returning the selected license(s). These can be reactivated later on another system.

Table 152: “Install Licenses - Restore Licenses”

When activated, device licenses are saved to a file (`*.WibuCmRau`) on the local computer and in the "CODESYS Central License Server". If lost, they can be restored from this file to the identical device.	
“Ticket ID”	Field for specifying the ticket ID that was used for licensing that has already occurred.
“Restore”	If a corresponding license backup file is found, then the license is reactivated in the device.

See also

- *Chapter 1.4.1.20.2.8.2 “Tab 'Communication Settings'” on page 840*
- *Chapter 1.4.1.20.3.8.7 “Command ‘License Repository’” on page 1066*

Command ‘License Repository’

Symbol: 

Function: This command opens the dialog box *“License Repository”* for viewing information about the individual licenses.

Call: Main menu *“Tools”*

Requirements: CODESYS is in offline or online mode.

In the license repository, after entering the ticket number, you can obtain information about the licenses concerned from the central license server.

To do this you can paste the ticket number(s) from the clipboard or import it/them from a text file.

Table 153: “Tickets”

<List of the ticket IDs imported into the repository for components requiring licenses>	
“Licenses”	If you select an entry in the list of tickets, the name and the status of the licensed component are displayed here. : License available and valid : License found, but invalid : License not found In the right-hand part of the dialog box you will then receive then the following information about this license:
	“Name”: name of the product to be licensed *“Item number”*: item number in the license server. *“Return allowed”*: It is possible to have this license deactivated so that it can be re-activated on another system. *“Can be activated”*: you can have the license activated via the license manager. *“Activation quantitiy”*: number of activations that have taken place so far. *“Activation date”*: date of the current activation *“Container serial ”* *“Firm codes”* *“Comment”*

“Import Tickets”	The standard dialog box for browsing the local file system appears. If you open a text file containing one or more “tickets”, i.e. license numbers, these are imported into the repository. Alternatively you can also insert the numbers from the clipboard into the list.

Command 'Device Repository'

Symbol:

Function: This command opens the *“Device Repository”* dialog. This dialog is used for managing the devices that are installed on the local system and can be integrated into CODESYS projects.

Call: Menu bar: *“Tools”*.

Dialog 'Device Repository'

CAUTION!

Do not change the internal device repository manually. Do not copy any files to or from the repository. Always use the device repository dialog to install or uninstall devices.

Table 154

“Location”	Shows the device repository directory on the local system. The list box shows the currently set save locations. By default, CODESYS creates the system repository during installation. The devices of the selected location are listed in the *“Installed device descriptions”* field.
“Edit Locations”	Opens the *“Edit Repository Locations”* dialog.

Table 155: Dialog 'Edit Repository Locations'

List of the repositories with *“Location”* and *“Name”*.	
“Add”	Creates a new repository. Opens the *“Repository Location”* dialog. The selected directory (*“Location”* input field) must be empty or it must be a valid repository.
“Edit”	Opens the *“Repository Location”* dialog (see *“Add”*).
“Remove ”	A dialog prompt opens for you to decide whether the respective directory should also be deleted from the hard disk.

Table 156: “Installed Device Descriptions”

List of device descriptions in multilevel tree structure. Shows all device descriptions with *“Name”*, *“Vendor”*, and *“Version”*. The top nodes represent device categories, for example PLCs, fieldbuses, and logical devices.	
“String for full-text search in all devices”	This field is editable after clicking in it. For any character string entered, only those devices that include the character string are displayed in the lower view. The matched string is highlighted in yellow for these devices.
“Vendor”	Drop-down list with manufacturers whose available devices are displayed.
“Install”	Opens the *“Install Device Description”* dialog. For the default devices with file type "*.devdesc.xml". You can also select manufacturer-specific description files, such as "*.gsd" files for PROFIBUS DP modules, "*.eds" and "*.dcf" files for CAN devices. When you click *“OK”* to confirm the selection, CODESYS inserts the new device into the device repository. If an error occurs during installation (for example, missing files that are referenced by the device description), then CODESYS reports the error to the lower part of the device repository dialog.
“Uninstall”	Removes the selected device. If you delete the device from the device repository, then it is no longer available for use in the programming system.
“Renew Device Repository”	Updates all devices in the device repository. When new versions of import plug-ins are available, some device descriptions may be outdated. The affected devices are marked with a warning symbol (⚠). This command opens a dialog to confirm the update.
“Download Missing Device Descriptions”	Opens when you use devices in your project that are not available in the device repository. When you execute this command, a list of missing devices is displayed. There you can select the corresponding devices for download.
“Details”	Opens the *“Details”* dialog for the selected device description. This dialog provides additional information from the device description file.

NOTICE!
During installation, CODESYS copies the device description files and all additional reference files to an internal location. Therefore, any changes to the original files no longer influence the installed devices. You must reinstall the devices to make any changes effective. We recommended that you change the internal version number of a device description after a modification.

- *Chapter 1.4.1.20.4.13.5 “Dialog 'Options' – 'Device Description Download'” on page 1190*

Command 'Create Device list CSV'

Symbol:

Function: MS Excel template of device list for device import is opened.

Call: Main menu *“Tools”*, Context menu

Requirement: -

Chapter 1.8.1.3.2 “Creating CSV device list” on page 4119

Command 'Multi Online Change'

Function: The MultiOnlineChange tool/plug-in for Automation Builder enables firmware update, download and online change of the same project to several AC500 V2 PLCs.

Call: Main menu *“Tools”*, Context menu

Requirement: -

Command 'Device ECAD data'

Function: Automation Builder provides an ECAD interface for exchanging the PLC configuration data with EPLAN Electric P8 and Zuken E3. This feature removes double data entry between electrical engineering in the ECAD tool and the control logic programming in Automation Builder by synchronizing the PLC hardware including topology and I/O signals between these tools.

Call: Main menu *“Tools”*, Context menu

Requirement: A project is open.

Chapter 1.8.1.1 “Exporting and importing ECAD data (PBF)” on page 4112

Command 'OPC UA Information Model Repository'

Function: The command opens the *“OPC UA Information Model”* dialog. The OPC UA information models, which are installed on the local system and can be integrated in CODESYS projects, are managed in the dialog.

Call: Menu bar: *“Tools”*

Table 157: Dialog 'OPC UA Information Model'

"Location"	Displays the OPC UA information model directories on the local system. The list box shows the currently set locations. By default, CODESYS creates the system repository during installation. The information models of the selected location are listed in the *"Installed OPC UA information models"* area.
"Edit Locations"	Opens the *"Edit Repository Locations"* dialog.
"Installed OPC UA information models"	
List of installed information models. Double-click to open installed information model documentation. Note: The information models of this repository can also be added to project archives.	
"Install "	Opens the *"Select Installed OPC UA Information Model(s)"* dialog. ● File type: OPC UA Information Models `*NodeSet2.xml` (example: *"Informationmodel.NodeSet2.xml"*. When you click *"Open"*, the selected information model is inserted in the repository. ● File type: All files `*.*`: You can select an OPC UA documentation, for example, in PDF or Word format. When you click *"Open"*, the *"Assign Documentation OPC UA Information Models"* opens. For a description of the dialog, see below.
"Uninstall"	Uninstalls the selected OPC UA information model. When you delete the information model from the repository, it is no longer available in the development system for use in the CODESYS Development System.
"Details"	Opens the *"Details"* dialog for the selected information model. The dialog includes additional information about the information model. In *"Alias"*, you can specify an alias name for the URI. Moreover, information is displayed as to whether or not a documentation for the information model is available. ● *"Model URI"* ● *"Publication date"* ● *"Publisher"* ● *"Repository"* ● *"Alias"* ● *"Documentation available"*: – *"Yes"*: The *"Uninstall documentation"* button is available. – *"No"*: The *"Install documentation"* button is available. ● *"Install documentation"*: Opens the *"Select OPC UA Information Model Documentation"* dialog. The data type `OPC UA Information Model Documentation (*.pdf)` is set as default in the dialog.
"Documentation"	Opens the installed documentation for the selected information model. If no documentation is installed for the selected information model, then the command is disabled.
"Display all versions"	All installed versions of the information model are displayed in a tree structure.

Command 'Scripting' - 'Execute Script File'

Symbol: 

Function: This command opens a dialog for selecting and then executing the script file (*.py).

Call: Menu bar: *"Tools ➔ Scripting"*.

Command 'Scripting' - 'Enable Script Tracing'

Symbol: 

Function: This command makes CODESYS print all commands from the script file to the message view. Use this command for monitoring and debugging scripts. A blue frame around the symbol indicates that the option is active.

Call: Main menu *“Tools ➔ Scripting”*.

Command 'Scripting' - 'Scripts'

Function: This command executes a script that is stored in the `ScriptDir` folder.

Call: Menu bar: *“Tools ➔ Scripting ➔ Scripts”*.

Requirement: The `ScriptDir` folder exists in the CODESYS installation directory. Python scripts are stored in this folder with the file extension `.py`.

All scripts that are contained in the `ScriptDir` folder are executable as menu commands and are sorted alphabetically by file name.

Command 'Customize'

Function: This command opens the *“Customize”* dialog box, where you can customize the menus, toolbars, and keyboard shortcuts according to your individual requirements.

Call: Main menu *“Tools”*

Command 'Options'

Function: The command opens the dialog box *“Options”* for the configuration of the CODESYS options. These options define the behavior and appearance of the CODESYS user interface. CODESYS saves the settings in your current user profile on your local system. The current profile specifies the standard settings.

Call: *“Tools”* menu

Command 'Import and Export Options'

Function: This command opens the *"Import and Export Options"* dialog. Here you can configure the export and import of selected settings of the CODESYS options. The settings are saved to an XML file with the default extension (`options.xml`).

Call: Menu bar: *"Tools"*.

Dialog 'Import and Export Options'

"Export selected options"	*"Select options"*: In the table, you can select the categories of options, either user-specific or machine-specific (computer), whose current settings are to be exported to the XML file. *"File"*: Path of the export file in the local file system. Example: `D:\system1.options.xml`. Button ...: Opens the default dialog to search for an existing file in the local file system, or to create one. The *"File type"* `option export (*.options.xml)` is preset.
"Import selected options"	*"File"*: Path of the options export file whose contents are to be imported. Button ...: Opens the default dialog to search for an existing file of type `option export (*.options.xml)` in the local file system. After you click *"OK"* to close the dialog, the settings described in the file are applied to the project.

See also

- *Chapter 1.4.1.1.1 "Setting CODESYS options" on page 180*

Command 'Device Reader'

Function: The command opens the standard *"Select Device"* dialog and reads the license and product information of the selected controller. This license and product information is displayed in the *"Device Reader"* dialog.

Call: Menu bar: *"Tools"*

Requirement: No applications exist on the controller.

> *If the command is selected although an application exists on the controller, then a dialog prompts the user whether or not all applications should be removed from the controller. When the user click "No" to this dialog, the "Device Reader" command is aborted.*

Table 158: Dialog "Device Reader"

"Status of Available Device Features"	
"Product"	CODESYS product (example: `SoftMotion`)
"Feature"	Feature of *"Product"* Example: `CNC` is a *"Feature"* of `SoftMotion`.
"License Active/Count "	`Yes`: A license exists for the feature. `No`: A license does not exist for the feature. *"Count"*: Number of licenses

Menu 'Window'

Command 'Next Editor'

Keyboard shortcut: *[Ctrl]+[F6]*

Function: This command switches focus from the currently active view to the next view. The next view is identified by the tab to the right of the currently active tab.

Call: Main menu *“Window”*

Requirement: At least one object is open.

See also

- *Chapter 1.4.1.20.3.9.2 “Command 'Previous Editor'” on page 1073*

Command 'Previous Editor'

Keyboard shortcut: *[Shift]+[Ctrl]+[F6]*

Function: This command switches focus from the currently active view to the previous view. The previous view is identified by the tab to the left of the currently active tab.

Call: Main menu *“Window”*

Requirement: At least one object is open.

See also

- *Chapter 1.4.1.20.3.9.1 “Command 'Next Editor'” on page 1073*

Command 'Close All Editors'

Symbol: 

Function: This command closes all currently open editor views.

Call: Main menu *“Window”*

Requirement: At least one editor is open.

See also

- *Chapter 1.4.1.20.3.9.4 “Command 'Close All Editors of Inactive Applications'” on page 1074*
- *Chapter 1.4.1.20.3.9.16 “Command 'Close All Editors But This'” on page 1077*

Command 'Close All Editors of Inactive Applications'

Function: This command closes all editor views for objects that are located directly below a currently inactive application. Object editors in the POU view remain open.

Call: Main menu *“Window”*

Requirement: At least one object of an inactive application is open.

See also

- *Chapter 1.4.1.20.3.9.3 “Command 'Close All Editors'” on page 1073*
- *Chapter 1.4.1.20.3.9.16 “Command 'Close All Editors But This'” on page 1077*

Command 'Reset Window Layout'

Function: This command resets all currently open windows and views to their default positions. You are prompted for a confirmation before the command is executed.

Call: Main menu *“Tools”*

Command 'New Horizontal Tab Group'

Symbol: 

Function: This command moves the currently active view to a new, separate tab group below the existing one.

Call: Main menu *“Window”* or context menu of the tab

Requirement: Several editor views are open as tabs next to each other.

If you open another object in the editor, then this is automatically included in the tab group that is currently in focus.

See also

- *Chapter 1.4.1.20.3.9.7 “Command 'New Vertical Tab Group'” on page 1074*

Command 'New Vertical Tab Group'

Symbol: 

Function: This command moves the currently active view to a new, separate tab group to the right of the existing one.

Call: Main menu *“Window”* or context menu of the tab

Requirement: Several editor views are open as tabs next to each other.

If you open another object in the editor, then this is automatically included in the tab group that is currently in focus.

See also

- *Chapter 1.4.1.20.3.9.6 “Command 'New Horizontal Tab Group'” on page 1074*

Command 'Float'

Function: This command releases a docked view from its frame in the user interface and repositions it on the screen as a floating window.

Call: Main menu *"Window"*

Requirement: The application is in online mode.

This window can then be positioned outside of the user interface. Use the *"Dock"* command to return a floating window to the frame of the user interface.

See also

- *Chapter 1.4.1.20.3.9.9 "Command 'Dock'" on page 1075*

Command 'Dock'

Function: This command returns a floating window, which was released by the *"Float"* command, to the frame of the user interface.

Call: Main menu *"Window"*

See also

- *Chapter 1.4.1.20.3.9.8 "Command 'Float'" on page 1075*

Command 'Auto Hide'

Keyboard shortcut: *[F7]*

Function: This command shows or hides a view.

Call: Main menu *"Window"*

Hide simply means that CODESYS minimizes the view to a tab at the bottom of the user interface which is visible only when you move the mouse over the tab. The command functions like a check box. When a window is hidden, the check box is selected in the menu. When you click the command again, the checkbox is cleared and the window is shown.

Command 'Next Pane'

Keyboard shortcut: *[F6]*

Function: This command sets the focus on the next pane.

Call: Main menu *"Window"*

Requirement: An object is open that contains two or more panes.

Example: If an object is open in the ST editor and the cursor is currently in the declaration section, then command sets the focus to implementation section.

See also

- *Chapter 1.4.1.20.3.9.12 "Command 'Previous Pane'" on page 1075*

Command 'Previous Pane'

Keyboard shortcut: *[Shift]+[F6]*

Function: This command sets the focus on the previous pane.

Call: Main menu *"Window"*

Requirement: An object is open that contains two or more panes.

Example: If an object is open in the ST editor and the cursor is currently in the declaration section, then command sets the focus to implementation section.

See also

- *Chapter 1.4.1.20.3.9.11 “Command 'Next Pane'” on page 1075*

Command 'Toggle First Pane'

Keyboard shortcut *[Alt]+[F6]*

Function: This command shows and hides the declaration view.

Call: *“Window”*.

Requirement: The cursor is positioned in the editor of one of the following objects:

- POU
- Transition
- Method
- Get accessor method of a property
- Set accessor method of a property
- Visualization

You can also toggle the subviews by means of the buttons.

See also

- *Chapter 1.4.1.20.3.9.14 “Command 'Toggle Second Pane'” on page 1076*

Command 'Toggle Second Pane'

Function: This command shows and hides the implementation view.

Call: *“Window”*.

Requirement: The cursor is positioned in the editor of one of the following objects:

- POU
- Transition
- Method
- Get accessor method of a property
- Set accessor method of a property
- visualization

You can also toggle the subviews by means of the buttons.

See also

- *Chapter 1.4.1.20.3.9.13 “Command 'Toggle First Pane'” on page 1076*

Command 'Windows'

Function: This command opens the *“Windows”* dialog box, which lists all open objects. You can then activate or close any of the listed views.

Call: Main menu *“Window”*

Command 'Close All Editors But This'

Function: This command closes all editor views except the currently open one.

Call: Right-click the tab

Requirement: At least two objects are open.

See also

- *Chapter 1.4.1.20.3.9.3 “Command 'Close All Editors'” on page 1073*
- *Chapter 1.4.1.20.3.9.4 “Command 'Close All Editors of Inactive Applications'” on page 1074*

Command 'Select Object in Navigator'

Function: This command selects the object of the active editor in the device tree.

Call: Right-click the tab

Requirement: At least one object is open.

This command is executed automatically when you select the “Track active editor” option for the device tree.

See also

- *Chapter 1.4.1.20.3.9.18 “Command 'Select Parent Object in Navigator'” on page 1077*

Command 'Select Parent Object in Navigator'

Function: This command selects the parent object in the device tree.

Call: Right-click the tab

Requirement: At least one object is open.

See also

- *Chapter 1.4.1.20.3.9.17 “Command 'Select Object in Navigator'” on page 1077*

Commands of the Submenu 'Window'

Function: The command activates the selected window.

Call: Main menu *“Window”*

For each opened editor window the menu *“Window”* contains a command *“<n><object name>”*. Choosing this command activates the corresponding window. In offline mode CODESYS adds the extension *“(Offline)”*. To differentiate between the implementation or the instances of a function block the extension *“(Impl)”* or *“<instance path>”* is added.

Menu 'Help'

Command 'Contents'

Symbol:  ; keyboard shortcut: *[Ctrl]+[Shift]+[F1]*

Function: This command opens the CODESYS help.

Call: Menu bar: *“Help”*.

Command 'Index'

Symbol:  ; keyboard shortcut: *[Ctrl]+[Shift]+[F2]*

Function: This command opens the CODESYS help.

Call: Menu bar: *“Help”*.

An index search is not possible in the online help. The *“Index”* tab opens in the offline help.

All index entries of the help are listed alphabetically in the index view.

“ Look for ”	As you type letters into the input field, CODESYS searches automatically for matches in the index list.
“Display”	Opens the help page for the highlighted index entry in the list and displays the title of the help page and location of the help file (*.chm) in the *“Index results for <index entry>”* view. When several pages are found and then displayed in this view, then you view a specific help page by clicking its entry in the list. Clicking an entry in the index list achieves the same result.

Command 'Find'

Symbol: 

Function: This command opens the CODESYS help.

Call: Menu bar: *“Help”*.

In the online help, you can run a full-text search from the input field on the top right of the help page. The *“Find”* tab opens in the offline help.

Table 159: Tab 'Search'

“Search for”	Combo box for defining the search term or for selecting the 25 most recent search terms.
“ Search in titles only”	The search is performed only in the titles of the help pages.
“Display partial matches”	Displays terms also as search results that include the search term.
“Limit to .... matches ”	Limits the number of search results. Maximum value: 1000
“Find”	Starts the full-text search.

Command 'About'

Function: This command opens a splash screen with information about the CODESYS version and copyright. In addition, buttons are available for detailed information about the version, license, and acknowledgments.

Call: Main menu *"Help"*.

"Version Info"	Opens the *"Detailed Version Information"* dialog box with a list of CODESYS components and information about the operating system. *"Export"*: Exports the detailed version information as a *.txt file or in any other format.
"License Info"	Opens the *"License Information"* dialog box. ● *"Plug-in"*: Drop-down list for the plug-in to display the license information ● *"Software License"*: License information about selected *"Plug-in"*
"Acknowledgments"	

Menu 'SFC'

Command 'Init Step'

Symbol: 

Function: This command converts the selected step into an initial step.

Call: Main menu *"SFC"*

After you choose this command, the borders of the step element change to a double line. The previous initial step is automatically displayed as a normal step with a single-line border.

You can also activate and deactivate the property *“Init step”* in the properties dialog of a step. However, CODESYS does not automatically adjust the settings of other steps.

This command is useful if you want to convert a diagram. When you create a new SFC object, it automatically includes an initial step followed by a transition (TRUE) and a jump back to the initial step.

Please note: In online mode, it is possible to reset the diagram to the initial step using the `SFCInit` and `SFCReset` flags.

See also

- *Chapter 1.4.1.19.1.4.6 “SFC Flags” on page 481*
- *Chapter 1.4.1.19.1.4.8.6 “SFC element properties” on page 493*

Command 'Insert Step'

Symbol:

Function: This command inserts a step before the selected point.

Call: Menu bar *“SFC”*; context menu in SFC editor

The new step is named `Step<n>` by default, where `n` is an incremental number starting at `0` for the first step that is inserted in addition to the initial step. The name can be edited by clicking on it.

See also

- *Chapter 1.4.1.20.3.11.7 “Command 'Insert Step-Transition After'” on page 1081*
- *Chapter 1.4.1.20.3.11.1 “Command 'Init Step'” on page 1079*
- *Chapter 1.4.1.19.1.4.8.1 “SFC elements 'Step' and 'Transition'” on page 486*

Command 'Insert Step After'

Symbol:

Function: This command inserts a step after the selected point.

Call: Menu bar *“SFC”*; context menu in SFC editor

The new step is named `Step<n>` by default, where `n` is an incremental number starting at `0` for the first step that is inserted in addition to the initial step. The name can be edited by clicking on it.

See also

- *Chapter 1.4.1.20.3.11.7 “Command 'Insert Step-Transition After'” on page 1081*
- *Chapter 1.4.1.20.3.11.1 “Command 'Init Step'” on page 1079*
- *Chapter 1.4.1.19.1.4.8.1 “SFC elements 'Step' and 'Transition'” on page 486*

Command 'Insert Transition After'

Symbol:

Function: This command inserts a transition after the selected point.

Call: Menu bar *“SFC”*; context menu in SFC editor

The new transition is named `Trans<n>` by default, where `n` is an incremental number beginning at `0` for the first transition. The name can be edited by clicking on it.

See also

- *Chapter 1.4.1.20.3.11.7 “Command 'Insert Step-Transition After'” on page 1081*
- *Chapter 1.4.1.19.1.4.8.1 “SFC elements 'Step' and 'Transition'” on page 486*

Command 'Insert Transition'

Symbol:

Function: This command inserts a transition before the selected point.

Call: Menu bar *“SFC”*; context menu in SFC editor

The new transition is named `Trans<n>` by default, where `n` is an incremental number beginning at `0` for the first transition. The name can be edited by clicking on it.

See also

- *Chapter 1.4.1.20.3.11.7 “Command 'Insert Step-Transition After'” on page 1081*
- *Chapter 1.4.1.19.1.4.8.1 “SFC elements 'Step' and 'Transition'” on page 486*

Command 'Insert Step-Transition'

Symbol: 

Function: This command inserts a step and a transition before the selected point.

Call: Main menu *“SFC”*

If you have selected a step, then CODESYS inserts a new step-transition combination. If you have selected a transition, then a new transition-step combination is inserted.

The new step is named `Step<n>` by default, where `n` is an incremental number beginning at `0` for the first step that was inserted in addition to the initial step. The new transition is named `Trans<n>` by default. You can edit the default names directly by clicking the names.

See also

- *Chapter 1.4.1.20.3.11.7 “Command 'Insert Step-Transition After'” on page 1081*
- *Chapter 1.4.1.20.3.11.1 “Command 'Init Step'” on page 1079*
- *Chapter 1.4.1.19.1.4.8.1 “SFC elements 'Step' and 'Transition'” on page 486*

Command 'Insert Step-Transition After'

Symbol: 

Function: This command inserts a step and a transition after the selected point.

Call: Main menu *“SFC”*

If you have selected a step, then CODESYS inserts a new transition-step combination. If you have selected a transition, then a new step-transition combination is inserted.

The new step is named `Step<n>` by default, where `n` is an incremental number beginning at `0` for the first step that was inserted in addition to the initial step. The new transition is named `Trans<n>` by default. You can edit the default names directly by clicking the names.

See also

- *Chapter 1.4.1.20.3.11.6 “Command 'Insert Step-Transition'” on page 1081*

Command 'Add Entry Action'

Symbol: 

Function: This command opens the *“Add Entry Action”* dialog box where you define a new entry action. Depending on the SFC options, a dialog prompt may open for selecting the duplication mode for the new step action.

Call: Menu bar: *“SFC”*; context menu of the selected step element.

Requirement: A step element in SFC is selected.

The entry action is opened automatically in the ST editor. The step element contains an `E` in the lower left corner.

Confirmation prompt for selecting the duplication mode

Options:

- *“Copy reference: A new step will call the same actions”*: If the step is copied in SFC, the link to the step action(s) is also copied. The steps copied by each other will therefore call the same actions.
- *“Copy implementation: New action objects are created for a new step.”*: This means that the step actions for a copied step are embedded. By default, the generated action objects appear below an SFC box in the device tree or *“POUs”* view. These objects contains a copy of the original implementation code of the respective action.

  The display of the embedded objects can be activated and deactivated in the tree by means of the *“Show Embedded Objects”* and *“Hide Embedded Objects”* commands in the context menu of an SFC object.

- *Chapter 1.4.1.20.3.11.25 “Command 'Do Not Display Embedded Objects'” on page 1088*

Command 'Add Exit Action'

Symbol: 

Function: This command opens the *“Add Exit Action”* dialog box where you define a new exit action. Depending on the SFC options, a dialog prompt may open for selecting the duplication mode for the new step action. For more information, refer to the help page for the *“Add Exit Action”* command.

Call: Menu bar: *“SFC”*; context menu of the selected step element.

Requirement: A step element in SFC is selected.

See also

- *Chapter 1.4.1.20.3.11.8 “Command 'Add Entry Action'” on page 1082*

- *Chapter 1.4.1.20.3.11.25 “Command 'Do Not Display Embedded Objects'” on page 1088*

Command 'Parallel'

Symbol: 

Function: This command converts the selected alternative branch into a parallel branch.

Call: Main menu *“SFC”*

Requirement: The horizontal connecting line of a branch is selected.

Please note that after you convert a branch, you must check and modify the layout of the steps and transitions before and after the branch.

See also

- *Chapter 1.4.1.20.3.11.11 “Command 'Alternative'” on page 1083*

Command 'Alternative'

Symbol: 

Function: This command converts the selected parallel branch into an alternative branch.

Call: Main menu *“SFC”*

Requirement: The horizontal connecting line of a branch is selected.

Please note that after you convert a branch, you must check and modify the layout of the steps and transitions before and after the branch.

See also

- *Chapter 1.4.1.20.3.11.10 “Command 'Parallel'” on page 1082*

Command 'Insert Branch'

Symbol: 

Function: This command inserts a branch to the left of the selected point.

Call: Main menu *“SFC”*

This command functions similar to the *“Insert Branch Right”* command.

See also

- *Chapter 1.4.1.19.1.4.8.3 “SFC element 'Branch'” on page 491*
- *Chapter 1.4.1.20.3.11.13 “Command 'Insert Branch Right'” on page 1083*

Command 'Insert Branch Right'

Symbol: 

Function: This command inserts a branch to the right of the selected point.

Call: Main menu *“SFC”*

The type of inserted branch depends on the selected element.

- If the uppermost element of the selected elements is a transition or an alternative branch, then CODESYS inserts an alternative branch.
- If the uppermost element of the selected elements is a step, a macro, a jump, or a parallel branch, then CODESYS inserts a parallel branch with the `Branch<x>` jump marker, where `x` is an incremental number. You can edit the default name of the jump marker or define the jump marker as a jump destination.
- If a common element of an existing branch (horizontal line) is selected, then CODESYS inserts the new branch line as a branch line on the far right. If an entire branch line of an existing branch is selected, then CODESYS inserts the new branch line directly to the right as a new branch line.

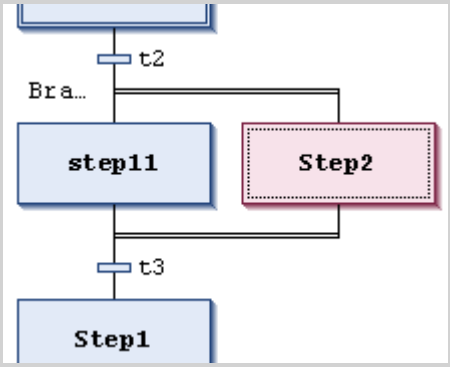
Please note: You can convert a branch into another type with the “Alternative” and “Parallel” commands.

Example of parallel branch

The following image shows a new inserted parallel branch generated by the *"Insert Branch Right"* command while the `Step11` step was selected. CODESYS automatically inserts a step (`Step2` in the example).

Processing in online mode: If `t2` yields TRUE, then CODESYS executes `Step2` immediately after `step11` and before `t3` is passed.

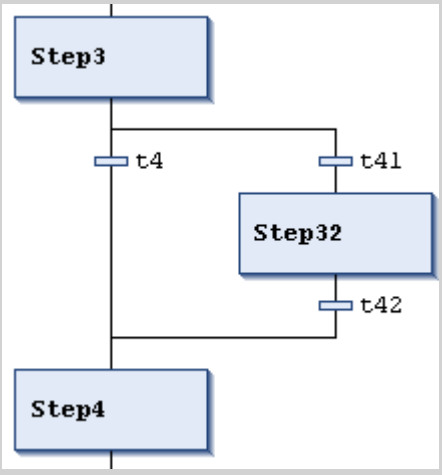
Thus, CODESYS processes both branch lines as opposed to alternative branches.



Example of alternative branch

The following image shows a new inserted alternative branch generated by the *"Insert Branch Right"* command while the `t4` transition was selected. CODESYS automatically inserts a step (`Step32` in the example), a preceding transition, and a subsequent transition (`t41, t42`).

Processing in online mode: If `Step3` is active, then CODESYS passes the subsequent transitions (`t4, t41`) from left to right. The first branch line of the main branch with the first transition yielding `TRUE` is passed. Therefore, only one branch line is processed as opposed to with a parallel branch.



See also

- *Chapter 1.4.1.19.1.4.8.3 "SFC element 'Branch'" on page 491*
- *Chapter 1.4.1.20.3.11.12 "Command 'Insert Branch'" on page 1083*
- *Chapter 1.4.1.20.3.11.10 "Command 'Parallel'" on page 1082*
- *Chapter 1.4.1.20.3.11.11 "Command 'Alternative'" on page 1083*

Command 'Insert Action Association'

Symbol:

Function: This command assigns an IEC action to a step.

Call: Main menu *"SFC"*

Requirement: A step is selected.

CODESYS inserts the action element to the right of the selected step element.

If you have already assigned one or more actions to the step, they are displayed in an action list. The new action is then inserted as follows:

- If you selected the step element, the action is inserted as the first action of the step at first position of the action list.
- If you selected one of the available actions in the action list, then the action is inserted directly above the selected action.

The left section of the action element includes the qualifier (`N` by default). You enter the action name in the right section. To set this value, click in the box to obtain an editing frame. You must have already created this action as a POU in the project.

You can also edit the qualifier. Valid qualifiers are described in the chapter “Qualifiers for Actions in SFC".

See also

- *Chapter 1.4.1.20.3.11.15 “Command 'Insert Action Association After'” on page 1085*
- *Chapter 1.4.1.19.1.4.4 “Qualifiers for Actions in SFC” on page 479*

Command 'Insert Action Association After'

Symbol: 

Function: This command assigns an IEC action to a step.

Call: Main menu *“SFC”*

Requirement: A step is selected.

This command functions similar to the *“Insert Action Association”* command. The difference between the two commands is that CODESYS inserts the new action in the last position of the action list, not the first position. If you select an action in the action list, then CODESYS inserts the new action at the bottom of the list, not at the top.

See also

- *Chapter 1.4.1.20.3.11.14 “Command 'Insert Action Association'” on page 1084*
- *Chapter 1.4.1.19.1.4.4 “Qualifiers for Actions in SFC” on page 479*

Command 'Insert Jump'

Symbol: 

Function: This command inserts a jump element before the selected element.

Call: Main menu *“SFC”*

Requirement: A step is selected.

CODESYS automatically inserts the jump with the `Step` destination. Then, you still have to replace this jump destination with an actual destination by using the input assistant.

See also

- *Chapter 1.4.1.19.1.4.8.4 “SFC element 'Jump'” on page 492*
- *Chapter 1.4.1.20.3.11.17 “Command 'Insert Jump After'” on page 1085*

Command 'Insert Jump After'

Symbol: 

Function: This command inserts a jump element after the selected element.

Call: Main menu *“SFC”*

CODESYS automatically inserts the jump with the `Step` destination. Then, you still have to replace this jump destination with an actual destination by using the input assistant.

See also

- *Chapter 1.4.1.19.1.4.8.4 “SFC element 'Jump'” on page 492*
- *Chapter 1.4.1.20.3.11.16 “Command 'Insert Jump'” on page 1085*

Command 'Insert Macro'

Symbol:

Function: This command inserts a macro element before the selected element.

Call: Main menu *“SFC”*

The new macro is named `Macro<x>` by default, where `x` is an incremental number beginning at `0` for the first macro. You can edit the default name directly by clicking the name.

To edit the macro, click *“Zoom Into Macro”* in the macro editor.

See also

- *Chapter 1.4.1.20.3.11.20 “Command 'Zoom Into Macro'” on page 1086*
- *Chapter 1.4.1.20.3.11.19 “Command 'Insert Macro After'” on page 1086*

Command 'Insert Macro After'

Symbol:

Function: This command inserts a macro element after the selected element.

Call: Main menu *“SFC”*

This command functions similar to the *“Insert Macro”* command.

See also

- *Chapter 1.4.1.20.3.11.20 “Command 'Zoom Into Macro'” on page 1086*
- *Chapter 1.4.1.20.3.11.18 “Command 'Insert Macro'” on page 1086*

Command 'Zoom Into Macro'

Symbol:

Function: This command opens a macro for editing in the macro editor.

Call: Main menu *“SFC”*

Requirement: A macro is selected.

By choosing this command, CODESYS closes the main view of the SFC editor and opens the macro editor. This is also an SFC editor for editing the section of the SFC diagram that is displayed as a macro box in the main view.

Click *“Zoom Out of Macro”* to return to the main view.

See also

- *Chapter 1.4.1.20.3.11.21 “Command 'Zoom Out of Macro'” on page 1086*

Command 'Zoom Out of Macro'

Symbol:

Function: This command closes the macro editor and returns to the main view of the SFC editor.

Call: Main menu *“SFC”*

Requirement: A macro is open in the macro editor.

See also

- *Chapter 1.4.1.20.3.11.20 “Command 'Zoom Into Macro'” on page 1086*

Command 'Paste After'

Symbol: 

Function: This command pastes the elements from the clipboard after the selected position.

Call: Main menu *“SFC”*.

Command 'Change Duplication' - 'Set'

Function: This command embeds every step action or transition, which is called by a step or transition in the SFC box, with the caller. In this way, the action or transition object can be called only from exactly this caller (pseudo-embedding). The result is that copying step and transition elements that call cations or transitions automatically creates new action or transition objects. the implementation code is also copied.

Call: Menu bar: *“SFC”*.

For more details about duplication mode, refer to the help page for the SFC element properties and the instructions for adding step actions.

Pseudo-embedded objects can be hidden in the “Devices” or “POUs” view by means of a command.

See also

- *Chapter 1.4.1.19.1.4.8.6 “SFC element properties” on page 493*
- *Chapter 1.4.1.8.3.4.1 “Programming in SFC” on page 255*

Command 'Change Duplication' - 'Remove'

Function: This command removes the embedding of action, transition, and property objects by a step or transition that calls it for the entire SFC box. In this way, the pseudo-embedding of the action, transition, or property objects is removed. If step or transition elements are copied, which call actions, transitions, or properties, then the copying calls the same actions and transitions as the source.

Call: Menu bar: *“SFC”*.

For more details about duplication mode, refer to the help page for the SFC element properties and the instructions for adding step actions.

Pseudo-embedded objects can be hidden in the “Devices” or “POUs” view by means of a command.

See also

- *Chapter 1.4.1.19.1.4.8.6 “SFC element properties” on page 493*
- *Chapter 1.4.1.8.3.4.1 “Programming in SFC” on page 255*
- *Chapter 1.4.1.20.3.11.25 “Command 'Do Not Display Embedded Objects'” on page 1088*

Command 'Do Not Display Embedded Objects'

Function: This command causes action and transition objects, which are embedded in an SFC box by a step or transition, do not appear in the tree.

Call: Context menu of an SFC box in the *“Devices”* or *“POUs”* view.

Menu 'CFC'

Command 'Edit Worksheet'

Function: This command opens the *“Edit Worksheet”* dialog box in which you set the size of the worksheet.

Call: Main menu *“CFC”*

Requirements: A CFC editor is active.

Dialog box 'Edit worksheet'

“Use following dimensions”	Here is where you set the size of the worksheet. Your change is only accepted if the size is sufficient for the existing program.
“Adapt the dimensions automatically”	Automatically adapts the size of the worksheet to the size of your program.
“Move the working sheet origin relatively”	Shifts the worksheet along the x or y axis. The input of negative numbers is permitted.

Command 'Edit Page Size’
