RELION® 670 SERIES
Bay control REC670
Version 2.1 ANSI
Commissioning manual
Copyright

This document and parts thereof must not be reproduced or copied without written permission from ABB, and the contents thereof must not be imparted to a third party, nor used for any unauthorized purpose.

The software and hardware described in this document is furnished under a license and may be used or disclosed only in accordance with the terms of such license.

This product includes software developed by the OpenSSL Project for use in the OpenSSL Toolkit. (http://www.openssl.org/) This product includes cryptographic software written/developed by: Eric Young (eay@cryptsoft.com) and Tim Hudson (tjh@cryptsoft.com).

Trademarks

ABB and Relion are registered trademarks of the ABB Group. All other brand or product names mentioned in this document may be trademarks or registered trademarks of their respective holders.

Warranty

Please inquire about the terms of warranty from your nearest ABB representative.
Disclaimer

The data, examples and diagrams in this manual are included solely for the concept or product description and are not to be deemed as a statement of guaranteed properties. All persons responsible for applying the equipment addressed in this manual must satisfy themselves that each intended application is suitable and acceptable, including that any applicable safety or other operational requirements are complied with. In particular, any risks in applications where a system failure and/or product failure would create a risk for harm to property or persons (including but not limited to personal injuries or death) shall be the sole responsibility of the person or entity applying the equipment, and those so responsible are hereby requested to ensure that all measures are taken to exclude or mitigate such risks.

This document has been carefully checked by ABB but deviations cannot be completely ruled out. In case any errors are detected, the reader is kindly requested to notify the manufacturer. Other than under explicit contractual commitments, in no event shall ABB be responsible or liable for any loss or damage resulting from the use of this manual or the application of the equipment.
Conformity

This product complies with the directive of the Council of the European Communities on the approximation of the laws of the Member States relating to electromagnetic compatibility (EMC Directive 2004/108/EC) and concerning electrical equipment for use within specified voltage limits (Low-voltage directive 2006/95/EC). This conformity is the result of tests conducted by ABB in accordance with the product standard EN 60255-26 for the EMC directive, and with the product standards EN 60255-1 and EN 60255-27 for the low voltage directive. The product is designed in accordance with the international standards of the IEC 60255 series and ANSI C37.90.

Section 10 Testing functionality by secondary injection

10.1 Testing disturbance report

10.1.1 Introduction

10.1.2 Disturbance report settings

10.1.3 Disturbance recorder (DR)

10.1.4 Event recorder (ER) and Event list (EL)

10.2 Identifying the function to test in the technical reference manual

10.3 Differential protection

10.4 Current protection

10.4.1 Instantaneous phase overcurrent protection 3-phase output PHPIOC (50)

10.4.1.1 Measuring the trip limit of set values

10.4.1.2 Completing the test

10.4.2 Four step phase overcurrent protection 3-phase output OC4PTOC (51_67)

10.4.2.1 Verifying the settings

10.4.2.2 Completing the test

10.4.3 Instantaneous residual overcurrent protection EFPIOC (50N)

10.4.3.1 Measuring the trip limit of set values

10.4.3.2 Completing the test

10.4.4 Four step residual overcurrent protection, (Zero sequence or negative sequence directionality) EF4PTOC (51N/67N)

10.4.4.1 Four step directional ground fault protection

10.4.4.2 Four step non-directional ground fault protection

10.4.4.3 Completing the test

10.4.5 Four step negative sequence overcurrent protection NS4PTOC (46I2)

10.4.5.1 Completing the test

10.4.6 Sensitive directional residual overcurrent and power protection SDEPSDE (67N)

10.4.6.1 Measuring the trip and time limit for set values

10.4.6.2 Completing the test

10.4.7 Thermal overload protection, one time constant, Fahrenheit/Celsius LFPTTR/LCPTTR (26)

10.4.7.1 Measuring the trip and time limit of set values

Section 1    Introduction

1.1 This manual

The commissioning manual contains instructions on how to commission the IED. The manual can also be used by system engineers and maintenance personnel for assistance during the testing phase. The manual provides procedures for the checking of external circuitry and energizing the IED, parameter setting and configuration as well as verifying settings by secondary injection. The manual describes the process of testing an IED in a substation which is not in service. The chapters are organized in the chronological order in which the IED should be commissioned. The relevant procedures may be followed also during the service and maintenance activities.

1.2 Intended audience

This manual addresses the personnel responsible for commissioning, maintenance and taking the IED in and out of normal service.

The commissioning personnel must have a basic knowledge of handling electronic equipment. The commissioning and maintenance personnel must be well experienced in using protection equipment, test equipment, protection functions and the configured functional logics in the IED.
1.3 Product documentation

1.3.1 Product documentation set

Figure 1: The intended use of manuals throughout the product lifecycle

The engineering manual contains instructions on how to engineer the IEDs using the various tools available within the PCM600 software. The manual provides instructions on how to set up a PCM600 project and insert IEDs to the project structure. The manual also recommends a sequence for the engineering of protection and control functions, LHMI functions as well as communication engineering for IEC 60870-5-103, IEC 61850, DNP3, LON and SPA.

The installation manual contains instructions on how to install the IED. The manual provides procedures for mechanical and electrical installation. The chapters are organized in the chronological order in which the IED should be installed.

The commissioning manual contains instructions on how to commission the IED. The manual can also be used by system engineers and maintenance personnel for assistance during the testing phase. The manual provides procedures for the checking of external circuitry and energizing the IED, parameter setting and configuration as well as verifying settings by secondary injection. The manual describes the process of testing an IED in a substation which is not in service. The chapters are organized in the chronological order in which the IED should be commissioned. The relevant procedures may be followed also during the service and maintenance activities.
The operation manual contains instructions on how to operate the IED once it has been commissioned. The manual provides instructions for the monitoring, controlling and setting of the IED. The manual also describes how to identify disturbances and how to view calculated and measured power grid data to determine the cause of a fault.

The application manual contains application descriptions and setting guidelines sorted per function. The manual can be used to find out when and for what purpose a typical protection function can be used. The manual can also provide assistance for calculating settings.

The technical manual contains operation principle descriptions, and lists function blocks, logic diagrams, input and output signals, setting parameters and technical data, sorted per function. The manual can be used as a technical reference during the engineering phase, installation and commissioning phase, and during normal service.

The communication protocol manual describes the communication protocols supported by the IED. The manual concentrates on the vendor-specific implementations.

The point list manual describes the outlook and properties of the data points specific to the IED. The manual should be used in conjunction with the corresponding communication protocol manual.

The cyber security deployment guideline describes the process for handling cyber security when communicating with the IED. Certification, Authorization with role based access control, and product engineering for cyber security related events are described and sorted by function. The guideline can be used as a technical reference during the engineering phase, installation and commissioning phase, and during normal service.

1.4 Document symbols and conventions

1.4.1 Symbols

The electrical warning icon indicates the presence of a hazard which could result in electrical shock.

The warning icon indicates the presence of a hazard which could result in personal injury.

The caution hot surface icon indicates important information or warning about the temperature of product surfaces.

Class 1 Laser product. Take adequate measures to protect the eyes and do not view directly with optical instruments.

The caution icon indicates important information or warning related to the concept discussed in the text. It might indicate the presence of a hazard which could result in corruption of software or damage to equipment or property.

The information icon alerts the reader of important facts and conditions.

The tip icon indicates advice on, for example, how to design your project or how to use a certain function.

Although warning hazards are related to personal injury, it is necessary to understand that under certain operational conditions, operation of damaged equipment may result in degraded process...
performance leading to personal injury or death. It is important that the user fully complies with all warning and cautionary notices.

1.4.2 Document conventions

- Abbreviations and acronyms in this manual are spelled out in the glossary. The glossary also contains definitions of important terms.
- Push button navigation in the LHMI menu structure is presented by using the push button icons. For example, to navigate between the options, use ↑ and ↓.
- HMI menu paths are presented in bold. For example, select Main menu/Settings.
- LHMI messages are shown in Courier font. For example, to save the changes in non-volatile memory, select Yes and press ←.
- Parameter names are shown in italics. For example, the function can be enabled and disabled with the Operation setting.
- Each function block symbol shows the available input/output signal.
  - the character ^ in front of an input/output signal name indicates that the signal name may be customized using the PCM600 software.
  - the character * after an input signal name indicates that the signal must be connected to another function block in the application configuration to achieve a valid application configuration.
- Dimensions are provided both in inches and millimeters. If it is not specifically mentioned then the dimension is in millimeters.

Section 2  Safety information

2.1  Symbols on the product

All warnings must be observed.

Read the entire manual before doing installation or any maintenance work on the product. All warnings must be observed.

Class 1 Laser product. Take adequate measures to protect your eyes and do not view directly with optical instruments.

Do not touch the unit in operation. The installation shall take into account the worst case temperature.

2.2  Warnings

Observe the warnings during all types of work related to the product.

Only electrically skilled persons with the proper authorization and knowledge of any safety hazards are allowed to carry out the electrical installation.

National and local electrical safety regulations must always be followed. Working in a high voltage environment requires serious approach to avoid human injuries and damage to equipment.

Do not touch circuitry during operation. Potentially lethal voltages and currents are present.
Always use suitable isolated test pins when measuring signals in open circuitry. Potentially lethal voltages and currents are present.

Never connect or disconnect a wire and/or a connector to or from an IED during normal operation. Hazardous voltages and currents are present that may be lethal. Operation may be disrupted and IED and measuring circuitry may be damaged.

Dangerous voltages can occur on the connectors, even though the auxiliary voltage has been disconnected.

Always connect the IED to protective ground, regardless of the operating conditions. This also applies to special occasions such as bench testing, demonstrations and off-site configuration. This is class 1 equipment that shall be grounded.

Never disconnect the secondary connection of current transformer circuit without short-circuiting the transformer’s secondary winding. Operating a current transformer with the secondary winding open will cause a massive potential build-up that may damage the transformer and may cause injuries to humans.

Never remove any screw from a powered IED or from an IED connected to powered circuitry. Potentially lethal voltages and currents are present.

Take adequate measures to protect the eyes. Never look into the laser beam.

The IED with accessories should be mounted in a cubicle in a restricted access area within a power station, substation or industrial or retail environment.

2.3 Caution signs

Whenever changes are made in the IED, measures should be taken to avoid inadvertent tripping.
The IED contains components which are sensitive to electrostatic discharge. ESD precautions shall always be observed prior to touching components.

Always transport PCBs (modules) using certified conductive bags.

Do not connect live wires to the IED. Internal circuitry may be damaged.

Always use a conductive wrist strap connected to protective ground when replacing modules. Electrostatic discharge (ESD) may damage the module and IED circuitry.

Take care to avoid electrical shock during installation and commissioning.

Changing the active setting group will inevitably change the IEDs operation. Be careful and check regulations before making the change.

2.4 Note signs

Observe the maximum allowed continuous current for the different current transformer inputs of the IED. See technical data.

Section 4  Starting up

4.1  Factory and site acceptance testing

Testing the proper IED operation is carried out at different occasions, for example:

- Acceptance testing
- Commissioning testing
- Maintenance testing

This manual describes the workflow and the steps to carry out the commissioning testing.

Factory acceptance testing (FAT) is typically done to verify that the IED and its corresponding configuration meet the requirements of the utility or industry. This test is the most complex and in depth, as it is done to familiarize the user with a new product or to verify a new configuration. The complexity of this testing depends on several factors, such as:

- New IED type
- New configuration
- Modified configuration

Site acceptance testing (SAT or commissioning testing) is typically done to verify that the installed IED is correctly set and connected to the power system. SAT requires that the acceptance testing has been performed and that the application configuration is verified.

Maintenance testing is a periodic verification that the IED is healthy and has correct settings, depending on changes in the power system. There are also other types of maintenance testing.

4.2  Commissioning checklist

Before starting up commissioning at site, check that the following items are available:

- Single line diagram
- Protection block diagram
- Circuit diagram
- Setting list and configuration
- RJ-45 Ethernet cable (CAT 5)
- Three-phase test kit or other test equipment depending on the complexity of the configuration and functions to be tested.
- PC with PCM600 installed along with the connectivity packages corresponding to the IEDs to be tested.
- Administration rights on the PC, to set up IP addresses
4.3 Checking the power supply

Do not insert anything else to the female connector but the corresponding male connector. Inserting anything else (such as a measurement probe) may damage the female connector and prevent a proper electrical contact between the printed circuit board and the external wiring connected to the screw terminal block.

Check that the auxiliary supply voltage remains within the permissible input voltage range under all operating conditions. Check that the polarity is correct before energizing the IED.

4.4 Energizing the IED

4.4.1 Checking the IED operation

Check all connections to external circuitry to ensure correct installation, before energizing the IED and carrying out the commissioning procedures.

Energize the power supply of the IED to pickup. Keep the DC power supply on until the Root menu or the selected default screen is shown on the HMI before interrupting the DC power supply again. The energization could be done in a number of ways, from energizing a whole cubicle with many IEDs to energizing each single IED one by one.

If HW (i.e. I/O and/or communication boards etc.) have been changed (i.e. removed, replaced, or added), the user should re-configure the IED by navigating in the local HMI menu to: Main menu/Configuration/Reconfigure HW modules to activate the changed hardware modules in order to enable the self-supervision function to detect possible hardware errors.

Check also the self-supervision function in Main menu/Diagnostics/IED status/General menu in local HMI to verify that the IED operates properly.

Set the IED time if no time synchronization source is configured.

To ensure that the IED is according to the delivery and ordering specifications documents delivered together with each IED, the user should also after start-up use the built in HMI to check the IED's:

- Software version, Main menu/Diagnostics/IED status/Product identifiers.
- Serial number, Main menu/Diagnostics/IED status/Product identifiers.
- Installed modules and their ordering number, Main menu/Diagnostics/IED status/Installed HW.

4.4.2 IED start-up sequence

When the IED is energized, the green LED starts flashing instantly. After approximately 55 seconds the window lights up and the window displays 'IED Startup'. The main menu is displayed and the upper row should indicate 'Available' after about 90 seconds. A steady green light indicates a successful startup.
**Figure 2:** Typical IED start-up sequence

1. IED energized. Green LED instantly starts flashing
2. LCD lights up and “IED startup” is displayed
3. The main menu is displayed. A steady green light indicates a successful startup.

If the upper row in the window indicates ‘Fail’ instead of ‘Available’ and the green LED flashes, an internal failure in the IED has been detected. See section [Checking the self supervision function](#) to investigate the fault.

### 4.5 Setting up communication between PCM600 and the IED

The communication between the IED and PCM600 is independent of the communication protocol used within the substation or to the NCC.

The communication media is always Ethernet and the used protocol is TCP/IP.

Each IED has an RJ-45 Ethernet interface connector on the front. The front Ethernet connector shall be used for communication with PCM600.

When an Ethernet-based station protocol is used, PCM600 communication can use the same Ethernet port and IP address.

To connect PCM600 to the IED, two basic variants must be considered.

- Direct point-to-point link between PCM600 and the IED front port. The front port can be seen as a service port.
- Indirect link via a station LAN or from remote via a network.

The physical connection and the IP address must be configured in both cases to enable communication.

The communication procedures are the same in both cases.

1. If needed, set the IP address for the IEDs.
2. Set up the PC or workstation for a direct link (point-to-point), or
3. Connect the PC or workstation to the LAN/WAN network.
4. Configure the IED IP addresses in the PCM600 project for each IED to match the IP addresses of the physical IEDs.

**Setting up IP addresses**

The IP address and the corresponding communication subnetwork mask must be set via the LHMI for each available Ethernet interface in the IED. Each Ethernet interface has a default factory IP
address when the IED is delivered. The IP address and the subnetwork mask might have to be reset when an additional Ethernet interface is installed or an interface is replaced.

- The default IP address for the IED front port is 10.1.150.3 and the corresponding subnetwork mask is 255.255.255.0, which can be set via the local HMI path Main menu/Configuration/Communication/Ethernet configuration/Front:1.

Setting up the PC or workstation for point-to-point access to IEDs front port

An ethernet cable (max 2 m length) with RJ-45 connectors is needed to connect two physical Ethernet interfaces together without a hub, router, bridge or switch in between.

![Figure 3: Point-to-point link between IED and PCM600](IEC09000096-2-en.vsd)

The following description is an example valid for standard PCs using Microsoft Windows operating system. The example is taken from a Laptop with one Ethernet interface.

Administrator rights are required to change the PC communication setup. It is automatically detected that Tx signals from the IED are received on the Tx pin on the PC. Thus, a straight (standard) Ethernet cable can be used.

1. Select **Search programs and files** in the **Start menu** in Windows.
Figure 4: Select: Search programs and files

2. Type **View network connections** and click on the **View network connections** icon.
Figure 5: Click View network connections

3. Right-click and select **Properties**.

Figure 6: Right-click Local Area Connection and select **Properties**

4. Select the TCP/IPv4 protocol from the list of configured components using this connection and click **Properties**.
Figure 7: Select the TCP/IPv4 protocol and open Properties

5. Select **Use the following IP address** and define **IP address** and **Subnet mask** if the front port is used and if the **IP address** is not set to be obtained automatically by the IED, see Figure 8. The IP address must be different from the IP address chosen for the IED.

Figure 8: Select: Use the following IP address

6. Use the **ping** command to verify connectivity with the IED.
7. Close all open windows and start PCM600.
The PC and IED must belong to the same subnetwork for this set-up to work.

**Setting up the PC to access the IED via a network**

The same method is used as for connecting to the front port.

The PC and IED must belong to the same subnetwork for this set-up to work.

### 4.6 Writing an application configuration to the IED

When writing a configuration to the IED with PCM600, the IED is automatically set in configuration mode. When the IED is set in configuration mode, all functions are blocked. The red LED on the IED flashes, and the green LED is lit while the IED is in the configuration mode.

When the configuration is written and completed, the IED is automatically set into normal mode. For further instructions please refer to the users manuals for PCM600.

### 4.7 Checking CT circuits

Check that the wiring is in strict accordance with the supplied connection diagram.

The CTs must be connected in accordance with the circuit diagram provided with the IED, both with regards to phases and polarity. The following tests shall be performed on every primary CT connected to the IED:

- Primary injection test to verify the current ratio of the CT, the correct wiring up to the protection IED and correct phase sequence connection (that is A, B, C.)
- Polarity check to prove that the predicted direction of secondary current flow is correct for a given direction of primary current flow. This is an essential test for the proper operation of the differential function and directional protection functions.
- CT secondary loop resistance measurement to confirm that the current transformer secondary loop DC resistance is within the specification for the connected protection functions. When the measured loop resistance is near the calculated value for maximum DC resistance, perform a complete burden test.
- CT excitation test in order to confirm that the current transformer is of the correct accuracy rating and that there are no shorted turns in the current transformer windings. Manufacturer's design curves must be available for the current transformer to compare the actual results.
- Grounding check of the individual CT secondary circuits to verify that each three-phase set of main CTs is properly connected to the station ground and only at one electrical point.
- Insulation resistance check.
While the CT primary is energized, the secondary circuit shall never be open
circuited because extremely dangerous high voltages may arise.

Both the primary and the secondary sides must be disconnected from the line and
the IED when plotting the excitation characteristics.

If the CT secondary circuit ground connection is removed without the current
transformer primary being de-energized, dangerous voltages may result in the
secondary CT circuits.

4.8 Checking VT circuits

Check that the wiring is in strict accordance with the supplied connection diagram.

Correct possible errors before continuing to test the circuitry.

Test the circuitry.

• Polarity check when applicable; this test is often omitted for CVTs
• VT circuit voltage measurement (primary injection test)
• Grounding check
• Phase relationship
• Insulation resistance check

The primary injection test verifies the VT ratio and the wiring all the way from the primary system
to the IED. Injection must be performed for each phase-to-neutral circuit.

While testing VT secondary circuit and associated secondary equipment, care shall
be exercised to isolate the VT from the circuit being tested to avoid backcharging
the VT from the secondary side.

4.9 Using the RTXP test switch

The RTXP test switch is designed to provide the means of safe testing of the IED. This is achieved
by the electromechanical design of the test switch and test plug handle. When the test plug handle
is inserted, it first blocks the trip and alarm circuits then it short circuits the CT secondary circuit
and opens the VT secondary circuits making the IED available for secondary injection.

When pulled out, the test handle is mechanically stopped in half withdrawn position. In this
position, the current and voltage enter the protection, but the alarm and trip circuits are still
isolated and the IED is in test mode. Before removing the test handle, check the measured values in the IED.

Not until the test handle is completely removed, the trip and alarm circuits are restored for operation.

Verify that the contact sockets have been crimped correctly and that they are fully inserted by tugging on the wires. Never do this with current circuits in service.

Current circuit
1. Verify that the contacts are of current circuit type.
2. Verify that the short circuit jumpers are located in the correct slots.

Voltage circuit
1. Verify that the contacts are of voltage circuit type.
2. Check that no short circuit jumpers are located in the slots dedicated for voltage.

Trip and alarm circuits
1. Check that the correct types of contacts are used.

### 4.10 Checking the binary I/O circuits

Do not insert anything else to the female connector but the corresponding male connector. Inserting anything else (such as a measurement probe) may damage the female connector and prevent a proper electrical contact between the printed circuit board and the external wiring connected to the screw terminal block.

#### 4.10.1 Binary input circuits

Preferably, disconnect the binary input connector from the binary input cards. Check all connected signals so that both input level and polarity are in accordance with the IED specifications.

#### 4.10.2 Binary output circuits

Preferably, disconnect the binary output connector from the binary output cards. Check all connected signals so that both load and polarity are in accordance with IED specifications.

### 4.11 Checking optical connections

Check that the Tx and Rx optical connections are correct.
An IED equipped with optical connections has a minimum space requirement of 180 mm (7.2 inches) for plastic fiber cables and 275 mm (10.9 inches) for glass fiber cables. Check the allowed minimum bending radius from the optical cable manufacturer.
Section 5 Configuring the IED and changing settings

5.1 Overview

The customer specific values for each setting parameter and a configuration file have to be available before the IED can be set and configured, if the IED is not delivered with a configuration.

Use the configuration tools in PCM600 to verify that the IED has the expected configuration.

Each function included in the IED has several setting parameters, which have to be set in order to make the IED behave as intended. A factory default value is provided for each parameter. The Parameter Setting Tool in PCM600 is used when changing setting parameters.

All settings can be

• Entered manually through the local HMI.
• Written from a PC, either locally or remotely using PCM600. Front or rear port communication has to be established before the settings can be written to the IED.

Make sure that the DC supply is not turned off when the IED saves the written configuration.

The IED uses a FLASH disk for storing configuration data and process data like counters, object states, Local/Remote switch position etc. Since FLASH memory is used, measures have been taken in software to make sure that the FLASH disk is not worn out by too intensive storing of data.

This means, that to be absolutely sure that all data have been saved to FLASH, it is necessary to leave the IED with auxiliary power connected after all the commissioning is done (including setting the Local/Remote switch to the desired position) for at least one hour after the last commissioning action performed on the IED.

After that time has elapsed, it will be safe to turn the IED off, no data will be lost.

5.2 Configuring analog CT inputs

The analog input channels must be configured to get correct measurement results as well as correct protection functionality. Because all protection algorithms in the IED utilize the primary system quantities, it is extremely important to make sure that connected current transformer settings are done properly. These data are calculated by the system engineer and normally set by the commissioning personnel from the local HMI or from PCM600.

The analog inputs on the transformer input module are dimensioned for either 1A or 5A. Each transformer input module has a unique combination of current and voltage inputs. Make sure the input current rating is correct and that it matches the order documentation.
The primary CT data are entered via the HMI menu under **Main menu/Configurations/Analog modules**

The following parameter shall be set for every current transformer connected to the IED:

### Table 8: CT configuration

<table>
<thead>
<tr>
<th>Parameter description</th>
<th>Parameter name</th>
<th>Range</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rated CT primary current in A, n = channel number</td>
<td>CTPRIMn</td>
<td>from 0 to 99999</td>
<td>3000</td>
</tr>
</tbody>
</table>

This parameter defines the primary rated current of the CT. For two sets of CTs with ratio 1000/1 and 1000/5 this parameter is set to the same value of 1000 for both CT inputs. The parameter *CTStarPoint* can be used in order to reverse the direction of the CT. This might be necessary if two sets of CTs have different neutral (WYE) point locations in relation to the protected busbar.

For main CTs with 2A rated secondary current, it is recommended to connect the secondary wiring to the 1A input.

Take the rated permissive overload values for the current inputs into consideration.

### 5.3 Reconfiguring the IED

I/O modules configured with PCM600 (BIM, BOM or IOM) are supervised.

I/O modules that are not configured are not supervised.

Each logical I/O module has an error flag that indicates signal or module failure. The error flag is also set when the physical I/O module of the correct type is not detected in the connected slot.
Section 6 Establishing connection and verifying the SPA/IEC communication

6.1 Entering settings

If the IED is connected to a monitoring or control system via the rear SPA/IEC port, the SPA/IEC port has to be set either for SPA or IEC use.

6.1.1 Entering SPA settings

The SPA/IEC port is located on the rear side of the IED. Two types of interfaces can be used:

- for plastic fibers with connector type HFBR
- for glass fibers with connectors type ST

When using the SPA protocol, the rear SPA/IEC port must be set for SPA use.

Procedure

1. Set the operation of the rear optical SPA/IEC port to “SPA”.
   The operation of the rear SPA port can be found on the local HMI under Main menu/Configuration/Communication/Station communication/Port configuration/SLM optical serial port/PROTOCOL:1
   When the setting is entered the IED restarts automatically. After the restart the SPA/IEC port operates as a SPA port.
2. Set the slave number and baud rate for the rear SPA port
   The slave number and baud rate can be found on the local HMI under Main menu/Configuration/Communication/SPA/SPA:1
   Set the same slave number and baud rate as set in the SMS system for the IED.

6.1.2 Entering IEC settings

When using the IEC protocol, the rear SPA/IEC port must be set for IEC use.

Two types of interfaces can be used:

- for plastic fibers with connector type HFBR
- for glass fibers with connectors type ST

Procedure

1. Set the operation of the rear SPA/IEC port to “IEC”.
   The operation of the rear SPA/IEC port can be found on the local HMI under Main menu/Configuration/Communication/SLM configuration/Rear optical SPA-IEC-DNP port/PROTOCOL:1
When the setting is entered the IED restarts automatically. After the restart the selected IEC port operates as an IEC port.

2. Set the slave number and baud rate for the rear IEC port.
The slave number and baud rate can be found on the local HMI under **Main menu/Configuration/Communication/SLM configuration/Rear optical SPA-IEC-DNP port/IEC60870–5–103**
Set the same slave number and baud rate as set in the IEC master system for the IED.

### 6.2 Verifying the communication

To verify that the rear communication with the SMS/SCS system is working, there are some different methods. Choose one of the following.

#### 6.2.1 Verifying SPA communication

**Procedure**

1. Use a SPA-emulator and send “RF” to the IED. The answer from the IED should be the type and version of it, for example, “REL670 2.1...”.
2. Generate one binary event by activating a function, which is configured to an event block where the used input is set to generate events on SPA. The configuration must be made with the PCM600 software. Verify that the event is presented in the SMS/SCS system.

During the following tests of the different functions in the IED, verify that the events and indications in the SMS/SCS system are as expected.

#### 6.2.2 Verifying IEC communication

To verify that the IEC communication with the IEC master system is working, there are some different methods. Choose one of the following.

**Procedure**

1. Check that the master system time-out for response from the IED, for example after a setting change, is > 40 seconds.
2. Use a protocol analyzer and record the communication between the IED and the IEC master. Check in the protocol analyzer’s log that the IED answers the master messages.
3. Generate one binary event by activating a function that is configured to an event block where the used input is set to generate events on IEC. The configuration must be made with the PCM600 software. Verify that the event is presented in the IEC master system.

During the following tests of the different functions in the IED, verify that the events and indications in the IEC master system are as expected.

### 6.3 fiber optic loop

The SPA communication is mainly used for SMS. It can include different numerical IEDs with remote communication possibilities. The fiber optic loop can contain < 20-30 IEDs depending on requirements on response time. Connection to a personal computer (PC) can be made directly (if
the PC is located in the substation) or by telephone modem through a telephone network with ITU (CCITT) characteristics.

Section 7  Establishing connection and verifying the LON communication

7.1  Communication via the rear ports

7.1.1  LON communication

LON communication is normally used in substation automation systems. Optical fiber is used within the substation as the physical communication link.

The test can only be carried out when the whole communication system is installed. Thus, the test is a system test and is not dealt with here.

![Diagram of LON communication structure](IEC05000663-1-en.vsd)

Figure 9:  Example of LON communication structure for a substation automation system

An optical network can be used within the substation automation system. This enables communication with the IEDs through the LON bus from the operator’s workplace, from the control center and also from other IEDs via bay-to-bay horizontal communication.

The fiber optic LON bus is implemented using either glass core or plastic core fiber optic cables.
Table 11: Specification of the fiber optic connectors

7.1.2 The LON Protocol

The LON protocol is specified in the LonTalkProtocol Specification Version 3 from Echelon Corporation. This protocol is designed for communication in control networks and is a peer-to-peer protocol where all the devices connected to the network can communicate with each other directly. For more information of the bay-to-bay communication, refer to the section Multiple command function.

7.1.3 Hardware and software modules

The hardware needed for applying LON communication depends on the application, but one very central unit needed is the LON Star Coupler and optical fibers connecting the star coupler to the IEDs. To interface the IEDs from the MicroSCADA with Classic Monitor, application library LIB520 is required.

The HV Control 670 software module is included in the LIB520 high-voltage process package, which is a part of the Application Software Library in MicroSCADA applications.

The HV Control 670 software module is used for control functions in the IEDs. The module contains a process picture, dialogues and a tool to generate a process database for the control application in MicroSCADA.

When using MicroSCADA Monitor Pro instead of the Classic Monitor, SA LIB is used together with 670 series Object Type files.

Use the LON Network Tool (LNT) to set the LON communication. This is a software tool applied as one node on the LON bus. To communicate via LON, the IEDs need to know

- The node addresses of the other connected IEDs.
- The network variable selectors to be used.

This is organized by LNT.

The node address is transferred to LNT via the local HMI by setting the parameter ServicePinMsg = Yes. The node address is sent to LNT via the LON bus, or LNT can scan the network for new nodes.
The communication speed of the LON bus is set to the default of 1.25 Mbit/s. This can be changed by LNT.

The setting parameters for the LON communication are set via the local HMI. Refer to the technical manual for setting parameters specifications.

The path to LON settings in the local HMI is Main menu/Configuration/Communication/SLM configuration/Rear optical LON port

If the LON communication from the IED stops, caused by setting of illegal communication parameters (outside the setting range) or by another disturbance, it is possible to reset the LON port of the IED.

Path in the local HMI under Main menu/Configuration/Communication/SLM configuration/Rear optical LON port

These parameters can only be set with the LON Network Tool (LNT).

Section 8       Establishing connection and verifying the IEC 61850 communication

8.1 Overview

The rear OEM ports are used for:

- process bus (IEC 61850-9-2LE) communication
- substation bus (IEC 61850-8-1) communication.

For IEC 61850-8-1 redundant communication, both rear OEM ports are utilized. In this case IEC 61850-9-2LE communication can not be used.

IEC 61850-9-2LE process bus communication is not supported in the IED.

8.2 Setting the station communication

To enable IEC 61850 communication the corresponding OEM ports must be activated. The rear OEM port AB and CD is used for IEC 61850-8-1 communication. The rear OEM port CD is used for IEC 61850-9-2LE communication. For IEC 61850-8-1 redundant communication, both OEM port AB and CD are used exclusively.

IEC 61850-9-2LE communication can only be used on OEM rear port X311:C, D.

To enable IEC 61850 station communication:

1. Enable IEC 61850-8-1 (substation bus) communication for port AB.
   1.1. Set values for the rear ports AB.
   Navigate to: Main menu/Configuration/Communication/Ethernet configuration/LANAB:1
   Set values for Mode, IPAddress and IPMask. Mode must be set to Normal.
   Check that the correct IP address is assigned to the port.
   1.2. Enable IEC 61850-8-1 communication.
   Navigate to: Main menu/Configuration/Communication/Station communication/IEC61850-8-1/IEC61850-8–1:1
   Set Operation to Enabled, PortSelGOOSE and PortSelMMS to the port used (for example LANAB).

2. Enable redundant IEC 61850-8-1 communication for port AB and CD
2.1. Enable redundant communication.
   Navigate to: **Main menu/Configuration/Communication/Ethernet configuration/PRP:1**
   Set values for *Operation*, *IPAddress* and *IPMask*. *Operation* must be set to *Enabled*.
   The IED will restart after confirmation. Menu items **LANAB:1** and **LANCD:1** are hidden in local HMI after restart but are visible in PST where the values for parameter *Mode* is set to *Duo*.

3. Enable IEC 61850-9-2LE (process bus) communication for port CD.

3.1. Set values for the rear port CD.
   Navigate to: **Main menu/Configuration/Communication/Ethernet configuration/LANCD:1**
   Set values for *Mode*, *IPAddress* and *IPMask*. *Mode* must be set to *IEC9-2*.

There are no settings needed for the IEC 61850-9-2LE communication in the local HMI branch **Station communication**. Make sure that the optical fibers are connected correctly.
Communication is enabled whenever the merging unit starts sending data.

### 8.3 Verifying the communication

To verify that the communication is working a test/analyzing tool, for example ITT600, can be used.

**Verifying redundant IEC 61850-8-1 communication**

Ensure that the IED receives IEC 61850-8-1 data on both port AB and CD. Browse in the local HMI to **Main menu/Diagnostics/Communication/Redundant PRP** and check that both signals LAN-A-STATUS and LAN-B-STATUS are shown as *Ok*. Remove the optical connection to one of the ports AB or CD. Verify that either signal LAN-A-STATUS or LAN-B-STATUS (depending on which connection that was removed) are shown as *Error* and the that other signal is shown as *Ok*. Be sure to re-connect the removed connection after completed verification.
Section 9  Testing IED operation

9.1  Preparing for test

9.1.1  Requirements

IED test requirements:

- Calculated settings
- Application configuration diagram
- Signal matrix (SMT) configuration
- Terminal connection diagram
- Technical manual
- Three-phase test equipment
- Process bus, IEC61850-9-2LE, MU test simulator, if IEC 61850-9-2LE process bus communication is used.
- PCM600

The setting and configuration of the IED must be completed before the testing can start.

The terminal diagram, available in the technical reference manual, is a general diagram of the IED.

Note that the same diagram is not always applicable to each specific delivery (especially for the configuration of all the binary inputs and outputs).

Therefore, before testing, check that the available terminal diagram corresponds to the IED.

The technical manual contains application and functionality summaries, function blocks, logic diagrams, input and output signals, setting parameters and technical data sorted per function.

The test equipment should be able to provide a three-phase supply of voltages and currents. The magnitude of voltage and current as well as the phase angle between voltage and current must be variable. The voltages and currents from the test equipment must be obtained from the same source and they must have minimal harmonic content. If the test equipment cannot indicate the phase angle, a separate phase-angle measuring instrument is necessary.

Prepare the IED for test before testing a particular function. Consider the logic diagram of the tested protection function when performing the test. All included functions in the IED are tested according to the corresponding test instructions in this chapter. The functions can be tested in any order according to user preferences. Only the functions that are used (Operation is set to Enabled) should be tested.

The response from a test can be viewed in different ways:

- Binary outputs signals
- Service values on the local HMI (logical signals or phasors)
- A PC with PCM600 application configuration software in work online mode
All setting groups that are used should be tested.

- This IED is designed for a maximum continuous current of four times the rated current.

- All references to CT and VT must be interpreted as analog values received from merging units (MU) via IEC 61850-9-2LE communication protocol, analog values received from the transformer input module, or analog values received from the LDCM.

- When using a MU test simulator, make sure it is set to the correct SVID and that the system frequency is set to the same as in the IED.

- Please observe the measuring accuracy of the IED, the test equipment and the angular accuracy for both of them.

- Please consider the configured logic from the function block to the output contacts when measuring the trip time.

- After intense testing, it is important that the IED is not immediately restarted, which might cause a faulty trip due to flash memory restrictions. Some time must pass before the IED is restarted. For more information about the flash memory, refer to section “Configuring the IED and changing settings”.

### 9.1.2 Preparing the IED to verify settings

If a test switch is included, start preparation by making the necessary connections to the test switch. This means connecting the test equipment according to a specific and designated IED terminal diagram.

Put the IED into the test mode to facilitate the test of individual functions and prevent unwanted operation caused by other functions. The busbar differential protection is not included in the test mode and is not prevented to trip during the test operations. The test switch should then be connected to the IED.

Verify that analog input signals from the analog input module are measured and recorded correctly by injecting currents and voltages required by the specific IED.

To make testing even more effective, use PCM600. PCM600 includes the Signal monitoring tool, which is useful in reading the individual currents and voltages, their amplitudes and phase angles. In addition, PCM600 contains the Disturbance handling tool. The content of reports generated by the Disturbance handling tool can be configured which makes the work more efficient. For
example, the tool may be configured to only show time tagged events and to exclude analog information and so on.

Check the disturbance report settings to ensure that the indications are correct.

For information about the functions to test, for example signal or parameter names, see the technical manual. The correct initiation of the disturbance recorder is made on pickup and/or release or trip from a function. Also check that the wanted recordings of analog (real and calculated) and binary signals are achieved.

Parameters can be entered into different setting groups. Make sure to test functions for the same parameter setting group. If needed, repeat the tests for all different setting groups used. The difference between testing the first parameter setting group and the remaining is that there is no need for testing the connections.

During testing, observe that the right testing method, that corresponds to the actual parameters set in the activated parameter setting group, is used.

Set and configure the function(s) before testing. Most functions are highly flexible and permit a choice of functional and tripping modes. The various modes are checked at the factory as part of the design verification. In certain cases, only modes with a high probability of coming into operation need to be checked when commissioned to verify the configuration and settings.

9.2 Activating the test mode

Put the IED into the test mode before testing. The test mode blocks all protection functions and some of the control functions in the IED, and the individual functions to be tested can be unblocked to prevent unwanted operation caused by other functions. In this way, it is possible to test slower back-up measuring functions without the interference from faster measuring functions. The test switch should then be connected to the IED. Test mode is indicated when the yellow PickupLED flashes.

It is important that the IED function to be tested is put into test mode, even if the MU is sending data marked as "test". The IED will interpret these data as valid if it is not in test mode.

1. Browse to the **TestMode** menu and press *E*. The **TestMode** menu is found on the local HMI under **Main menu/Test/IED test mode/TestMode**.
2. Use the up and down arrows to choose **Enabled** and press *E*.
3. Press the left arrow to exit the menu. The dialog box **Save changes** appears.
4. Choose **Yes**, press *E* and exit the menu. The yellow pickupLED above the LCD will start flashing when the IED is in test mode.

9.3 Preparing the connection to the test equipment

The IED can be equipped with a test switch of type RTXP8, RTXP18 or RTXP24 or FT. The test switch and its associated test plug handles are a part of the COMBITEST or FT system of ABB, which provides secure and convenient testing of the IED.
When using the COMBITEST, preparations for testing are automatically carried out in the proper sequence, that is, for example, blocking of tripping circuits, short circuiting of CTs, opening of voltage circuits, making IED terminals available for secondary injection. Terminals 1 and 8, 1 and 18 as well as 1 and 12 of the test switches RTXP8, RTXP18 and RTXP24 respectively are not disconnected as they supply DC power to the protection IED. When FT switch is used for testing, care shall be exercised to open the tripping circuit, ahead of manipulating the CT fingers.

The RTXH test-plug handle leads may be connected to any type of test equipment or instrument. When a number of protection IEDs of the same type are tested, the test-plug handle only needs to be moved from the test switch of one protection IED to the test switch of the other, without altering the previous connections.

Use COMBITEST test system to prevent unwanted tripping when the handle is withdrawn, since latches on the handle secure it in the half withdrawn position. In this position, all voltages and currents are restored and any re-energizing transients are given a chance to decay before the trip circuits are restored. When the latches are released, the handle can be completely withdrawn from the test switch, restoring the trip circuits to the protection IED.

If a test switch is not used, perform measurement according to the provided circuit diagrams.

![Warning]

Never disconnect the secondary connection of a current transformer circuit without first short-circuiting the transformer’s secondary winding. Operating a current transformer with the secondary winding open will cause a massive potential build up that may damage the transformer and cause personal injury.

### 9.4 Connecting the test equipment to the IED

Connect the test equipment according to the IED specific connection diagram and the needed input and output signals for the function under test. An example of a connection is shown in figure 10.

Connect the current and voltage terminals. Pay attention to the current polarity. Make sure that the connection of input and output current terminals and the connection of the residual current conductor is correct. Check that the input and output logical signals in the logic diagram for the function under test are connected to the corresponding binary inputs and outputs of the IED under test.

The MU test equipment must be connected to the CD port on the OEM module when process bus IEC61850-9-2LE communication is used.

To ensure correct results, make sure that the IED as well as the test equipment are properly grounded before testing.
9.5 Releasing the function to be tested

Release or unblock the function to be tested. This is done to ensure that only the function or the chain of functions to be tested are in operation and that other functions are prevented from operating. Release the tested function(s) by setting the corresponding Blocked parameter under Function test modes to No in the local HMI.

When testing a function in this blocking feature, remember that not only the actual function must be activated, but the whole sequence of interconnected functions (from measuring inputs to binary output contacts), including logic must be activated. Before starting a new test mode session, scroll through every function to ensure that only the function to be tested (and the interconnected ones) have the parameters Blocked and eventually EvDisable set to No and Yes respectively. Remember that a function is also blocked if the BLOCK input signal on the corresponding function block is active, which depends on the configuration. Ensure that the logical status of the BLOCK input signal is equal to 0 for the function to be tested. Event function blocks can also be individually blocked to ensure that no events are reported to a remote station during the test. This is done by setting the parameter EvDisable to Yes.

Any function is blocked if the corresponding setting in the local HMI under Main menu/Test/Function test modes menu remains Enabled, that is, the parameter Blocked is set to Yes and the parameter TestMode under Main menu/Test/IED test mode remains active. All functions that were blocked or released in a previous test mode session, that is, the parameter Test mode is set to Enabled, are reset when a new test mode session is started.

Procedure
1. Click the **Function test modes** menu.  
The Function test modes menu is located in the local HMI under **Main menu/Test/Function test modes**.
2. Browse to the function instance that needs to be released.
3. Set parameter *Blocked* for the selected function to *No*.

### 9.6 Verifying analog primary and secondary measurement

Verify that the connections are correct and that measuring and scaling is done correctly. This is done by injecting current and voltage to the IED.

Besides verifying analog input values from the merging unit via the IEC/UCA 61850-9-2LE process bus, analog values from the transformer input module can be verified as follows.

Apply input signals as needed according to the actual hardware and the application configuration.

1. Inject a symmetrical three-phase voltage and current at rated value.
2. Compare the injected value with the measured values.  
The voltage and current phasor menu in the local HMI is located under **Main menu/Measurements/Analog primary values** and **Main menu/Measurements/Analog secondary values**.
3. Compare the frequency reading with the set frequency and the direction of the power.  
The frequency and active power are located under **Main menu/Measurements/Monitoring/ServiceValues(MMXN)/CVMMXN:x**. Then navigate to the bottom of the list to find the frequency.
4. Inject an unsymmetrical three-phase voltage and current, to verify that phases are correctly connected.

If some setting deviates, check the analog input settings under **Main menu/Configuration/Analog modules**.

If the IEC/UCA 61850-9-2LE communication is interrupted during current injection, the report tool in PCM600 will display the current that was injected before the interruption.
9.7 Testing the protection functionality

Each protection function must be tested individually by secondary injection.

- Verify operating levels (trip) and timers.
- Verify alarm and blocking signals.
- Use the disturbance handling tool in PCM600 to evaluate that the protection function has received the correct data and responded correctly (signaling and timing).
- Use the event viewer tool in PCM600 to check that only expected events have occurred.

9.8 Forcing of binary I/O signals for testing

9.8.1 Forcing concept

Forcing of binary inputs and outputs is a convenient way to test wiring in substations as well as testing configuration logic in the IEDs. Basically it means that all binary inputs and outputs on the IED I/O modules (BOM, BIM, IOM & SOM) can be set to a value (i.e. active or not-active), selected by the user, while the IED is in test mode. For inputs, this is true regardless of the actual signal voltage present on the input. For outputs, any output relay can be forced to be active or not, regardless of the current requested state of the output in the IED logic configuration.
Be observant that forcing of binary inputs and outputs on an IED, with inappropriate setup, can result in potential danger.

9.8.2 How to enable forcing

To enable forcing, the IED must first be put into IED test mode. While the IED is not in test mode, the LHMI/PCM600 menus that relate to forcing will not have any effect on the input/output status due to safety reasons.

9.8.2.1 Enable forcing by using LHMI

1. Enable IED Testmode by setting `IEDTestMode` to `On` under **Main menu/Test/IED test mode TESTMODE:1**.

   ![IED Testmode Configuration][1]

2. Exit back to the root menu.
3. Select *Yes* in the save dialogue box.
   Once the IED is in test mode the yellow Start LED starts to blink.

9.8.2.2 Enable forcing using TESTMODE function block

- Use the TESTMODE function block, appropriately configured in PCM600/ACT.

It may be convenient to control the input on mentioned component from, for example, an LHMI function key or similar during commissioning to quickly and easily enter IED test mode.

9.8.3 How to change binary input/output signals using forcing

Once the IED is in IED test mode, the LHMI/PCM600 menus can be used to control input/output signals freely.
### 9.8.3.1 Forcing by using LHMI

#### Editing a signal value directly

- Edit the input/output value directly to select the desired logical level, by doing following:
  1. Select the value line of the desired signal, see figure 12.
  2. Press the Enter key to edit the value.

![Figure 12: Value line of the desired signal](image)

3. Use the up/down arrows on the LHMI to change the signal value or the appropriate menu in PCM600.
   The status of the signal changes automatically to Forced (i.e. there is no need to set the status to Forced manually).

On the LHMI, these edit changes have immediate effect. This means that the value changes directly when the up/down arrow is pressed (i.e. there is no need to press the Enter key to effectuate the change).

When navigating away from a LHMI forcing menu for an I/O board, the user is prompted to either leave the signals forced, or to revert all of them back to the unforced state.
It is possible to power-cycle the IED in this state without losing the forcing states and values. This means that once a signal is forced, and the IED remains in IED test mode, the input or output will appear “frozen” at the value selected by the user, even if the IED is switched off and back on again.

Freezing a signal value without changing it

- Set the status of a signal to Forced, in the forcing menu that corresponds to the I/O card in question. See example of LHMI menu in figure 13

![LHMI menu example](image)

**Figure 13:** Example of LHMI menu using BIM3

The signal “freezes” and will not change value even if, for example, a binary input signal voltage changes level, or if a binary output is activated as the result of a protection function block activating.

9.8.3.2 Forcing by using PCM600

In PCM600 the concept is a bit different compared to LHMI. The forcing is accomplished by entering a forcing session. Within such a session, multiple signals on multiple I/O boards may be edited and changed at the same time and has no effect on the IED. Once the user is satisfied with the forcing setup, then all the changes can be effectuated simultaneously towards the IED, potentially changing inputs and outputs on multiple I/O boards at the same time. It is also possible to abort this operation (described in step 6 below) and to undo all forcing.

1. Right click on the IED in the plant structure and select **Signal Monitoring**.
2. Click on the **List View** tab.
3. Click **Forcing Session** in the menu **IED/Start Forcing**.

![PCM600 forcing session](image)

4. Click **Start editing signal value for forcing** on the tool bar.
The Signal Monitoring menu changes and indicates the forcing values that can be edited.

</tbody>
</table>

5. Select and edit the values.
6. Click **Acknowledge and send**.

This commits the values to the IED and exits the editing session.

7. Click **Cancel** to abort the changes and revert back to actual IED values.

Regardless if the forcing changes are committed or canceled, the forcing is still active.

To force more signals, click the button **Start editing signal value for forcing** again.
9.8.4  How to undo forcing changes and return the IED to normal operation

Regardless of which input/output signals have been forced, all forced signals will return to their normal states immediately when the IED is taken out of test mode.

When the forcing is removed by exiting from IED test mode, both input and output signals may change values. This means that logic input signals may activate functions in the IED and that output relays may change state, which can be potentially dangerous.

9.8.4.1 Undo forcing by using TestMode component

- If the IED test mode was entered through the test mode function block:
  1. Deactivate the control input on that block.

  This immediately undoes all forcing, regardless of how it was accomplished and disabled all the way to force signals.

9.8.4.2 Undo forcing by using LHMI

- If the IED test mode was enabled to using the LHMI:
  1. Set IEDTestMode to Off in the LHMI menu.
  2. Exit from the menu and click Yes in the Save dialogue box.

  This immediately undoes all forcing, regardless of how it was accomplished and disabled.

9.8.4.3 Undo forcing by using PCM600

1. Uncheck Forcing Session under the menu IED.

2. Click Yes in the confirmation dialogue box.

PCM600 will revert all forced signals back to unforced and the real signal values will immediately take effect again.
This may change both binary input values and output relay states and will undo any forcing done by using the LHMI.
If the IED is left in test mode, then it is still possible to perform new forcing operations, both from LHMI and from PCM600.
Section 10 Testing functionality by secondary injection

10.1 Testing disturbance report

10.1.1 Introduction

The following sub-functions are included in the disturbance report function:

- Disturbance recorder
- Event list
- Event recorder
- Fault locator
- Trip value recorder
- Indications

If the disturbance report is enabled, then its sub-functions are also set up and so it is not possible to only disable these sub-functions. The disturbance report function is disabled (parameter *Operation = Disabled*) in PCM600 or the local HMI under *Main menu/Settings/IED Settings/Monitoring/Disturbance report/DRPRDRE:1*.

10.1.2 Disturbance report settings

When the IED is in test mode, the disturbance report can be made active or inactive. If the disturbance recorder is turned on during test mode, recordings will be made. When test mode is switched off all recordings made during the test session are cleared.

Setting *OpModeTest* for the control of the disturbance recorder during test mode are located on the local HMI under *Main menu/Settings/IED Settings/Monitoring/Disturbance report/DRPRDRE:1*.

10.1.3 Disturbance recorder (DR)

A *Manual Trig* can be started at any time. This results in a recording of the actual values from all recorded channels.

The *Manual Trig* can be started in two ways:

1. From the local HMI under *Main menu/Disturbance records*.
   1.1. Enter on the row at the bottom of the HMI called *Manual trig*. A new recording begins. The view is updated if you leave the menu and return.
   1.2. Navigate to *General information* or to *Trip values* to obtain more detailed information.
2. Open the Disturbance handling tool for the IED in the plant structure in PCM600.
2.1. Right-click and select Execute manual Trig in the window Available recordings in IED.
2.2. Read the required recordings from the IED.
2.3. Refresh the window Recordings and select a recording.
2.4. Right-click and select Create Report or Open With to export the recordings to any disturbance analyzing tool that can handle Comtrade formatted files.

Evaluation of the results from the disturbance recording function requires access to a PC either permanently connected to the IED or temporarily connected to the Ethernet port (RJ-45) on the front. The PCM600 software package must be installed in the PC.

Disturbance upload can be performed by the use of PCM600 or by any third party tool with IEC 61850 protocol. Reports can automatically be generated from PCM600. Disturbance files can be analyzed by any tool reading Comtrade formatted disturbance files.

It could be useful to have a printer for hard copies. The correct start criteria and behavior of the disturbance recording function can be checked when IED protective functions are tested.

When the IED is brought into normal service it is recommended to delete all recordings, made during commissioning to avoid confusion in future fault analysis.

All recordings in the IED can be deleted in two ways:
1. in the local HMI under Main menu/Clear/Reset disturbances, or
2. in the Disturbance handling tool in PCM600 by selecting Delete all recordings in the IED... in the window Available Recordings in IED.

10.1.4 Event recorder (ER) and Event list (EL)

The result from the event recorder and event list can be viewed on the local HMI or, after upload, in PCM600 as follows:

1. on the local HMI under Main menu/Events, or in more details via
2. the Event Viewer in PCM600.
   The internal FIFO register of all events will appear when the event viewer is launched.

When the IED is brought into normal service it is recommended to delete all events resulting from commissioning tests to avoid confusion in future fault analysis. All events in the IED can be cleared in the local HMI under Main Menu//Clear/Clear internal event list or Main menu/Clear/Clear process event list. It is not possible to clear the event lists from PCM600.

When testing binary inputs, the event list (EL) might be used instead. No uploading or analyzing of registrations is then needed since the event list keeps running, independent of start of disturbance registration.

10.2 Identifying the function to test in the technical reference manual

Use the technical manual to identify function blocks, logic diagrams, input and output signals, setting parameters and technical data.
10.3 Differential protection

10.3.1 High impedance differential protection HZPDIF (87)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.3.1.1 Verifying the settings

1. Connect single-phase or three-phase test set to inject the operating voltage. The injection is done across the measuring branch.

The required trip and alarm voltage, as well as the used stabilizing resistance value must be set in the function. Note as well that used CT input in the IED must have ratio set as 1:1. This is essential for the measurement of the expected value. Normally a slightly higher operating value is no problem as the sensitivity is not influenced much.

2. Increase the voltage and make note of the trip value Pickup. This is done by manual testing and without trip of the test set.

3. Connect the trip contact to the test set to stop the test set for measurement of trip times below.

4. Reduce the voltage slowly and make note of the reset value. The reset value must be high for this function.

5. Check the operating time by injecting a voltage corresponding to 1.2 * Pickup level. Make note of the measured trip time.

6. If required, verify the trip time at another voltage. Normally 2 * Pickup is selected.

7. If used, measure the alarm level operating value. Increase the voltage and make note of the trip value AlarmPickup. This is done with manual test and without trip of the test set.

8. Measure the operating time on the alarm output by connecting the stop of the test set to an output from tAlarm. Inject a voltage 1.2 * AlarmPickup and measure the alarm time.

9. Check that trip and alarm outputs trip according to the configuration logic.

10. Finally check that pickup and alarm information is stored in the event menu and if a serial connection to the SA is available verify that the correct and only the required signals are presented on the local HMI and on the SCADA system.

Information on how to use the event menu is found in the operator's manual.

10.3.1.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.
10.4 Current protection

10.4.1 Instantaneous phase overcurrent protection 3-phase output PHPIOC (50)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

To verify the settings the following fault type should be tested:

- Phase-to-ground fault

Ensure that the maximum continuous current, supplied from the current source used for the test of the IED, does not exceed four times the rated current value of the IED.

10.4.1.1 Measuring the trip limit of set values

1. Inject a phase current into the IED with an initial value below that of the setting.
2. Set the operation mode to 1 out of 3.
3. Increase the injected current in the Ln phase until the TR_A (TR_B or TR_C) signal appears.
4. Switch the fault current off.

Observe: Do not exceed the maximum permitted overloading of the current circuits in the IED.

5. Compare the measured operating current with the set value.
6. Set the operation mode to 2 out of 3 and inject current into one of the phases. Check - no operation.

10.4.1.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.4.2 Four step phase overcurrent protection 3-phase output OC4PTOC (51_67)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.
10.4.2.1 Verifying the settings

Verification of the non-directional phase overcurrent function is done as instructed below, without applying any polarizing voltage.

1. Connect the test set for current injection to the appropriate IED phases.
   If there is any configuration logic that is used to enable or block any of the four available overcurrent steps, make sure that the step under test is enabled (for example, end fault protection).
   If 1 out of 3 currents for operation is chosen: Connect the injection current to phases A and neutral.
   If 2 out of 3 currents for operation is chosen: Connect the injection current into phase A and out from phase B.
   If 3 out of 3 currents for operation is chosen: Connect the symmetrical three-phase injection current into phases A, B and C.

2. Connect the test set for the appropriate three-phase voltage injection to the IED phases A, B and C. The protection shall be fed with a symmetrical three-phase voltage.

3. Block higher set stages when testing lower set stages by following the procedure described below:
   3.1. Set the injected polarizing voltage slightly larger than the set minimum polarizing voltage (default is 5% of VBase) and set the injection current to lag the appropriate voltage by an angle of about 80° if forward directional function is selected.
      If 1 out of 3 currents for operation is chosen: The voltage angle of phase A is the reference.
      If 2 out of 3 currents for operation is chosen: The voltage angle of phase A – the voltage angle of B is the reference.
      If 3 out of 3 currents for operation is chosen: The voltage angle of phase A is the reference.
      If reverse directional function is selected, set the injection current to lag the polarizing voltage by an angle equal to 260° (equal to 80° + 180°).
   3.2. Increase the injected current, note the trip value of the tested step of the function and compare it to the set value.
   3.3. Decrease the current slowly, note the reset value and compare it to the reset ratio 95%.

4. If the test has been performed by injection of current in phase A, repeat the test, injecting current into phases B and C with polarizing voltage connected to phases B, respectively C (1 out of 3 currents for operation).

5. If the test has been performed by injection of current in phases AB, repeat the test, injecting current into phases BC and CA with the appropriate phase angle of injected currents.

6. Connect a trip output contact to a timer.

7. Set the injected current to 200% of the trip level of the tested stage, switch on the current and check the time delay.
   For inverse time curves, check the trip time at a current equal to 110% of the trip current for \( txMin \).

8. Check that all trip and pickup contacts trip according to the configuration (signal matrixes).

9. Reverse the direction of the injected current and check that the protection does not trip.

10. If 2 out of 3 or 3 out of 3 currents for operation is chosen: Check that the function will not trip with current in one phase only.

11. Repeat the above described tests for the higher set stages.

12. Check that pickup and trip information is stored in the event menu.
10.4.2.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.4.3 Instantaneous residual overcurrent protection EFPIOC (50N)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

To verify the settings the following fault type should be tested:

- Phase-to-ground fault

Ensure that the maximum continuous current, supplied from the current source used for the test of the IED, does not exceed four times the rated current value of the IED.

10.4.3.1 Measuring the trip limit of set values

1. Inject a phase current into the IED with an initial value below that of the setting.
2. Increase the injected current in the Ln or in the neutral (summated current input) phase until the TRIP signal appears.
3. Disable the fault current
   Observe to not exceed the maximum permitted overloading of the current circuits in the IED.
4. Compare the measured operating current with the set value.

10.4.3.2Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.4.4 Four step residual overcurrent protection, (Zero sequence or negative sequence directionality) EF4PTOC (51N/67N)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.4.4.1 Four step directional ground fault protection

1. Connect the test set for single current injection to the appropriate IED terminals.
   Connect the injection current to terminals A and neutral.
2. Set the injected polarizing voltage slightly larger than the set minimum polarizing voltage (default 5% of Vn) and set the injection current to lag the voltage by an angle equal to the set reference characteristic angle (AngleRCA), if the forward directional function is selected.
If reverse directional function is selected, set the injection current to lag the polarizing voltage by an angle equal to \( RCA + 180^\circ \).
3. Increase the injected current and note the value at which the studied step of the function trips.
4. Decrease the current slowly and note the reset value.
5. If the test has been performed by injection of current in phase A, repeat the test, injecting current into terminals B and C with a polarizing voltage connected to terminals B, respectively C.
6. Block lower set steps when testing higher set steps according to the instructions that follow.
7. Connect a trip output contact to a timer.
8. Set the injected current to 200\% of the trip level of the tested step, switch on the current and check the time delay.
   For inverse time curves, check the trip time at a current equal to 110\% of the trip current for \( txMin \).
9. Check that all trip and pickup contacts trip according to the configuration (signal matrixes)
10. Reverse the direction of the injected current and check that the step does not trip.
11. Check that the protection does not trip when the polarizing voltage is zero.
12. Repeat the above described tests for the higher set steps.
13. Finally, check that pickup and trip information is stored in the event menu.

10.4.4.2 Four step non-directional ground fault protection

1. Do as described in "Four step directional ground fault protection", but without applying any polarizing voltage.

10.4.4.3 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.4.5 Four step negative sequence overcurrent protection NS4PTOC (46I2)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

When inverse time overcurrent characteristic is selected, the trip time of the stage will be the sum of the inverse time delay and the set definite time delay. Thus, if only the inverse time delay is required, it is important to set the definite time delay for that stage to zero.

Procedure

1. Connect the test set for injection of three-phase currents and voltages to the appropriate CT and VT inputs of the IED.
2. Inject pure negative sequence current, that is, phase currents with exactly same magnitude, reversed sequence and exactly 120\° phase displaced into the IED with an initial value below
negative sequence current pickup level. No output signals should be activated. Check under NS4PTOC function Service Values that correct I2 magnitude is measured by the function.

3. Set the injected negative sequence polarizing voltage slightly larger than the set minimum polarizing voltage (default 5 % of Vn) and set the injection current to lag the voltage by an angle equal to the set reference characteristic angle (180° - AngleRCA) if the forward directional function is selected.
   If reverse directional function is selected, set the injection current to lag the polarizing voltage by an angle equal to RCA.

4. Increase the injected current and note the value at which the studied step of the function trip.

5. Decrease the current slowly and note the reset value.

6. Block lower set steps when testing higher set steps according to the instructions that follow.

7. Connect a trip output contact to a timer.

8. Set the injected current to 200% of the trip level of the tested step, switch on the current and check the time delay.
   For inverse time curves, check the trip time at a current equal to 110% of the trip current in order to test parameter txmin.

9. Check that all trip and pickup contacts trip according to the configuration (signal matrixes)

10. Reverse the direction of the injected current and check that the step does not trip.

11. Check that the protection does not trip when the polarizing voltage is zero.

12. Repeat the above-described tests for the higher set steps.

13. Finally, check that pickup and trip information is stored in the event menu.

### 10.4.5.1 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

### 10.4.6 Sensitive directional residual overcurrent and power protection SDEPSDE (67N)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.
### 10.4.6.1 Measuring the trip and time limit for set values

**Operation mode $3I_0 \cdot \cos \phi$**

**Procedure**

1. Set the polarizing voltage to $1.2 \cdot VN_{RelPU}$ and set the phase angle between voltage and current to the set characteristic angle ($RCADir$). Note that the current lagging the voltage.
   
   Take setting $RCAComp$ into consideration if not equal to 0.

2. Inject current until the function picks up, and make sure that the trip current of the set directional element is equal to the $INcosPhiPU$ setting.
   
   The I Dir ($3I_0 \cdot \cos \phi$) function activates the PICKUP and PUNDIN output.

3. Assume that $\phi'$ is the phase angle between injected voltage ($3V_0$) and current ($3I_0$) i.e. $\phi' = RCADir - \phi$. Change $\phi'$ to for example 45 degrees. Increase the injected current until the function trips.

4. Compare the result with the set value and make sure that the new injected $3I_0 \cdot \cos \phi$ is equal to the setting $INcosPhiPU$.
   
   Take the set characteristic into consideration, see Figure 15 and Figure 16.

5. Measure the trip time of the timer by injecting a current two times the set $INcosPhiPU$ value and the polarizing voltage $1.2 \cdot VN_{RelPU}$. 

---

**Figure 14: Principle connection of the test set**

Values of the logical signals belonging to the sensitive directional residual overcurrent and power protection are available on the local HMI under **Main menu/Test/Function status/Current protection/SensDirResOvCurr(67N,IN>)/SDEPSDE(67N,IN>):x**
6. Compare the result with the expected value. 
The expected value depends on whether definite or inverse time was selected.
7. Set the polarizing voltage to zero and increase until the boolean output signal UNREL is activated, which is visible in the Application Configuration in PCM600 when the IED is in online mode. Compare the voltage with the set value \( VNRelPU \).
8. Continue to test another function or complete the test by setting the test mode to Disabled.

\[ Tinv = \frac{TDSN \cdot SRef}{3I_0 \cdot 3V_{test} \cdot \cos(\varphi)} \]

(Equation 1)

Figure 15: Characteristic with ROAdir restriction
Figure 16: Explanation of RCAcomp

**Operation mode 3I₀ · 3V₀ · cos φ**

1. Set the polarizing voltage to 1.2 · VNRelPU and set the phase angle between voltage and current to the set characteristic angle (RCADir). Note that the current lagging the voltage.
2. Inject current until the function picks up, and make sure that the trip power is equal to the SN_PU setting for the set directional element. 
   Note that for pick-up, both the injected current and voltage must be greater than the set values INRelPU and VNRelPU respectively. 
   The function activates the PICKUP and PUDIRIN outputs.
3. Assume that φ’ is the phase angle between injected voltage (3V₀) and current (3I₀) i.e. φ’ = RCADir-φ. Change φ’ to for example 45 degrees. Increase the injected current until the function trips.
4. Compare the result with the set value and make sure that the new injected 3I₀ · 3V₀ · cos φ is equal to the setting SN_PU. Take the set characteristic into consideration, see figure 15 and figure 16.
5. Measure the trip time of the timer by injecting 1.2 · VNRelPU and a current to get two times the set SN_PU trip value.
\[ T_{inv} = \frac{TDSN \cdot SRef}{3I_{0\text{test}} \cdot 3V_{0\text{test}} \cdot \cos(\phi)} \]  
(Equation 2)

6. Compare the result with the expected value. The expected value depends on whether definite or inverse time was selected.

7. Continue to test another function or complete the test by setting the test mode to Disabled.

**Operation mode \(3I_0\) and \(\phi\)**

1. Set the polarizing voltage to \(1.2 \cdot VN_{ReIPU}\) and set the phase angle between voltage and current to the set characteristic angle \((RCADir)\). Note that the current lagging the voltage.

2. Inject current until the function picks up, and make sure that the trip current is equal to the \(IN_{ReIPU}\) setting for the set directional element.

   Note that for pickup, both the injected current and voltage must be greater than the set values \(IN_{ReIPU}\) and \(VN_{ReIPU}\) respectively.

   The function activates the PICKUP and PUDIRIN output.

3. Measure with angles \(\phi\) around \(RCADir \pm ROADir\).

4. Compare the result with the set values, refer to figure 17 for example characteristic.

5. Measure the trip time of the timer by injecting a current to get two times the set \(SN_{PU}\) trip value.

\[ T_{inv} = \frac{TDSN \cdot SRef}{3I_{0\text{test}} \cdot 3V_{0\text{test}} \cdot \cos(\phi)} \]  
(Equation 3)

6. Compare the result with the expected value. The expected value depends on whether definite or inverse time was selected.

7. Continue to test another function or complete the test by setting the test mode to Disabled.
Non-directional ground fault current protection

Procedure

1. Measure that the trip current is equal to the INNonDirPU setting. The function activates the PICKUP and PUDIRIN output.
2. Measure the trip time of the timer by injecting a current of 200% of the trip value.
3. Compare the result with the expected value. The expected value depends on whether definite time tINNonDir or inverse time was selected.
4. Continue to test another function or complete the test by setting the test mode to Disabled.

Residual overvoltage release and protection

Procedure

1. Measure that the trip voltage is equal to the VN PU setting. The function activates the PICKUP and PUVN signals.
2. Measure the trip time by injecting a voltage 1.2 times set VN PU trip value.
3. Compare the result with the set tVN trip value.
4. Inject a voltage $0.8 \cdot VNRelPU$ and a current high enough to trip the directional function at the chosen angle.
5. Increase the voltage until the directional function is released.
6. Compare the measured value with the set VNRelPU trip value.

10.4.6.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.
10.4.7 Thermal overload protection, one time constant, Fahrenheit/Celsius LFPTTR/LCPTTR (26)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

Check that the input logical signal BLOCK is logical zero and that on the local HMI, the logical signal TRIP, PICKUP and ALARM are equal to logical zero.

10.4.7.1 Measuring the trip and time limit of set values

Testing the protection without external temperature compensation (NonComp)

1. Quickly set the measured current (fault current) in one phase to about 300% of $i_{Ref}$ (to minimise the trip time), and switch the current off.
2. Reset the thermal memory on the local HMI under Main menu/Reset/Reset temperature/ThermalOverload1TimeConst(PTRR,26)/LFPTTR:x, Main menu/Reset/Reset temperature/ThermalOverload1TimeConst(PTRR,26)/LCPTTR:x.
3. Switch the fault current on and take note of the temperature, available on the local HMI under Main menu/Test/Function status/Current protection/ThermOverLoad1TimeConst(PTRR,26)/LFPTTR:x/TEMP, Main menu/Test/Function status/Current protection/ThermOverLoad1TimeConst(PTRR,26)/LCPTTR:x/TEMP.
4. Check the time until the actual temperature TEMP has reached the AlarmTemp level during injection.
   Monitor the signal ALARM until it appears on the corresponding binary output or on the local HMI.
5. Measure the LFPTTR/LCPTTR (26) protection trip time.
   Use the TRIP signal from the configured binary output to stop the timer.
6. Take the TEMP readings.
   Compare with the setting of TripTemp.
7. Activate the BLOCK binary input.
   The signals ALARM, PICKUP and TRIP should disappear.
8. Reset the BLOCK binary input.
9. Check the reset limit (TdReset).
   Monitor the signal PICKUP until it disappears on the corresponding binary output or on the local HMI, take the TEMP readings and compare with the setting of ReclTemp.
10. Compare the measured trip time with the setting according to the formula.
11. Reset the thermal memory.
12. Continue to test another function or end the test by changing the test mode setting to Disabled.

10.4.7.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.
10.4.8 Thermal overload protection, two time constants TRPTTR (49)

Prepare the IED for verification of settings as outlined in section “Requirements” and section “Preparing for test” in this chapter.

10.4.8.1 Checking trip and reset values

1. Connect symmetrical three-phase currents to the appropriate current terminals of the IED.
2. Set the Time constant 1 (Tau1) and Time Constant 2 (Tau2) temporarily to 1 minute.
3. Set the three-phase injection currents slightly lower than the set trip value of stage IBase1, increase the current in phase A until stage IBase1 trips and note the trip value.

Observe the maximum permitted overloading of the current circuits in the IED.

4. Decrease the current slowly and note the reset value.
5. Activate the cooling input signal, thus switching to base current IBase2.
6. Check the trip and reset values (for all three phases) for IBase2 in the same way as described above for stage IBase1.
7. Deactivate the input signal for stage IBase2.
8. Set the time constant for IBase1 in accordance with the setting plan.
9. Set the injection current for phase A to 1.50 · IBase1.
10. Connect a trip output contact to the timer and monitor the output of contacts ALARM1 and ALARM2 to digital inputs in test equipment.
Read the heat content in the thermal protection from the local HMI and wait until the content is zero.
11. Switch on the injection current and check that ALARM1 and ALARM2 contacts trip at the set percentage level and that the trip time for tripping is in accordance with the set Time Constant 1 (Tau1).

With setting Itr = 101%IBase1 and injection current 1.50 · IBase1, the trip time from zero content in the memory shall be 0.60 · Time Constant 1 (Tau1).
12. Check that all trip and alarm contacts trip according to the configuration logic.
13. Switch off the injection current and check from the service menu readings of thermal status and LOCKOUT that the lockout resets at the set percentage of heat content.
14. Activate the cooling input signal to switch over to base current IBase2.
Wait 5 minutes to empty the thermal memory and set Time Constant 2 (Tau2) in accordance with the setting plan.
15. Test with injection current 1.50 · IBase2 the thermal alarm level, the trip time for tripping and the lockout reset in the same way as described for stage IBase1.
16. Finally check that pickup and trip information is stored in the event menu.

10.4.8.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.
10.4.9 Breaker failure protection, phase segregated activation and output CCRBRF (50BF)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

The Breaker failure protection, 3-phase activation and output function CCRBRF (50BF) should normally be tested in conjunction with some other function that provides an initiate signal. An external BFI_3P signal can also be used.

To verify the settings in the most common back-up trip mode 1 out of 3, it is sufficient to test phase-to-ground faults.

At mode 2 out of 4 the phase current setting, Pickup_PH can be checked by single-phase injection where the return current is connected to the summated current input. The value of residual (ground fault) current IN set lower than Pickup_PH is easiest checked in back-up trip mode 1 out of 4.

10.4.9.1 Checking the phase current trip value, Pickup_PH

The check of the Pickup_PH current level is best made in FunctionMode = Current and BuTripMode = 1 out of 3 or 2 out of 4.

1. Apply the fault condition, including BFI_3P of CCRBRF (50BF), with a current below set Pickup_PH.
2. Repeat the fault condition and increase the current in steps until a trip occurs.
3. Compare the result with the set Pickup_PH.
4. Disconnect AC and BFI_3P input signals.

Note! If No CBPos Check or Retrip off is set, only back-up trip can be used to check set IP>.

10.4.9.2 Checking the residual (ground fault) current trip value Pickup_N set below Pickup_PH

Check the low set Pickup_N current where setting FunctionMode = Current and setting BuTripMode = 1 out of 4.

1. Apply the fault condition, including BFI_3P of CCRBRF (50BF), with a current just below set Pickup_N.
2. Repeat the fault condition and increase the current in steps until trip appears.
3. Compare the result with the set Pickup_N.
4. Disconnect AC and BFI_3P input signals.

10.4.9.3 Checking the re-trip and back-up times

The check of the set times can be made in connection with the check of trip values above.
Choose the applicable function and trip mode, such as FunctionMode = Current and RetripMode = CB Pos Check.

1. Apply the fault condition, including initiation of CCRBRF (50BF), well above the set current value. Measure time from BFI_3P of CCRBRF (50BF).
2. Check the re-trip t1 and back-up trip times t2 and t3.
   In applicable cases, the back-up trip for multi-phase pickup t2MPh and back-up trip 2, t2 and t3 can also be checked. To check t2MPh, a two-phase or three-phase initiation shall be applied.
3. Disconnect AC and BFI_3P input signals.

10.4.9.4 Verifying the re-trip mode

Choose the mode below, which corresponds to the actual case.

In the cases below it is assumed that FunctionMode = Current is selected.

Checking the case without re-trip, RetripMode = Retrip Off

1. Set RetripMode = Retrip Off.
2. Apply the fault condition, including initiation of CCRBRF (50BF), well above the set current value.
3. Verify that no re-trip, but back-up trip is achieved after set time.
4. Disconnect AC and BFI_3P input signals.

Checking the re-trip with current check, RetripMode = CB Pos Check

1. Set RetripMode = CB Pos Check.
2. Apply the fault condition, including initiation of CCRBRF (50BF), well above the set current value.
3. Verify that re-trip is achieved after set time t1 and back-up trip after time t2.
4. Apply the fault condition, including initiation of CCRBRF (50BF), with current below set current value.
5. Verify that no re-trip, and no back-up trip is obtained.
6. Disconnect AC and BFI_3P input signals.

Checking re-trip without current check

1. Set RetripMode = No CBPos Check.
2. Apply the fault condition, including initiation of CCRBRF (50BF), well above the set current value.
3. Verify that re-trip is achieved after the set time t1, and the back-up trip after time t2.
4. Apply the fault condition, including initiation of CCRBRF (50BF), with current below set current value.
5. Verify that re-trip is achieved after set time t1, but no back-up trip is obtained.
6. Disconnect AC and BFI_3P input signals.

10.4.9.5 Verifying the back-up trip mode

In the cases below it is assumed that FunctionMode = Current is selected.
Checking that back-up tripping is not achieved at normal CB tripping

Use the actual tripping modes. The case below applies to re-trip with current check.

1. Apply the fault condition, including initiation of CCRBRF (50BF), with phase current well above set value Pickup_PH.
2. Interrupt the current, with a margin before back-up trip time, \( t_2 \). It may be made at issue of re-trip command.
3. Check that re-trip is achieved, if selected, but no back-up trip is obtained.
4. Disconnect AC and BFI_3P input signals.

The normal mode \( BuTripMode = 1 \text{ out of 3} \) should have been verified in the tests above. In applicable cases the modes 1 out of 4 and 2 out of 4 can be checked. Choose the mode below, which corresponds to the actual case.

Checking the case \( BuTripMode = 1 \text{ out of 4} \)

It is assumed that the ground-fault current setting Pickup_N is below phase current setting Pickup_PH.

1. Set \( BuTripMode = 1 \text{ out of 4} \).
2. Apply the fault condition, including initiation of CCRBRF (50BF), with one-phase current below set Pickup_PH but above Pickup_N. The residual ground-fault should then be above set Pickup_N.
3. Verify that back-up trip is achieved after set time. If selected, re-trip should also appear.
4. Disconnect AC and BFI_3P input signals.

Checking the case \( BuTripMode = 2 \text{ out of 4} \)

The ground-fault current setting Pickup_N may be equal to or below phase-current setting Pickup_PH.

1. Set \( BuTripMode = 2 \text{ out of 4} \).
2. Apply the fault condition, including initiation of CCRBRF (50BF), with one-phase current above set Pickup_PH and residual (ground fault) above set Pickup_N.
3. Verify that back-up trip is achieved after set time. If selected, re-trip should also appear.
4. Apply the fault condition, including initiation of CCRBRF (50BF), with at least one-phase current below set Pickup_PH and residual (ground fault) above set Pickup_N. The current may be arranged by feeding three- (or two-) phase currents with equal phase angle \( (I_0\text{-component}) \) below Pickup_PH, but of such value that the residual (ground fault) current \( (3I_0) \) will be above set value Pickup_N.
5. Verify that back-up trip is not achieved.
6. Disconnect AC and BFI_3P input signals.

10.4.9.6 Verifying instantaneous back-up trip at CB faulty condition

Applies in a case where a signal from CB supervision function regarding CB being faulty and unable to trip is connected to input 52FAIL.
1. Repeat the check of back-up trip time. Disconnect current and input signals.
2. Activate the input 52FAIL. The output CBALARM (CB faulty alarm) should appear after set time \( t_{CBAlarm} \). Keep the input activated.
3. Apply the fault condition, including initiation of CCRBRF (50BF), with current above set current value.
4. Verify that back-up trip is obtained without intentional delay, for example within 20ms from application of initiation.
5. Disconnect injected AC and BFI_3P input signals.

### 10.4.9.7 Verifying the case \( \text{RetripMode} = \text{Contact} \)

It is assumed that re-trip without current check is selected, \( \text{RetripMode} = \text{Contact} \).

1. Set \( \text{FunctionMode} = \text{Contact} \).
2. Apply input signal for CB closed to relevant input or inputs 52a_A (B or C).
3. Apply input signal, or signals for initiation of CCRBRF (50BF).
4. Verify that phase selection re-trip and back-up trip are achieved after set times.
5. Disconnect the trip signal(s). Keep the CB closed signal(s).
6. 
7. Apply input signal(s), for initiation of CCRBRF (50BF).
8. Arrange disconnection of CB closed signal(s) well before set back-up trip time \( t_2 \).
9. Verify that back-up trip is not achieved.
10. Disconnect injected AC and BFI_3P input signals.

### 10.4.9.8 Verifying the function mode \( \text{Current&Contact} \)

To be made only when \( \text{FunctionMode} = \text{Current&Contact} \) is selected. It is suggested to make the tests in one phase only, or at three-pole trip applications for just three-pole tripping.

**Checking the case with fault current above set value \( \text{Pickup\_PH} \)**

The operation shall be as in \( \text{FunctionMode} = \text{Current} \).

1. Set \( \text{FunctionMode} = \text{Current&Contact} \).
2. Leave the inputs for CB close inactivated. These signals should not influence.
3. Apply the fault condition, including initiation of CCRBRF (50BF), with current above the set \( \text{Pickup\_PH} \) value.
4. Check that the re-trip, if selected, and back-up trip commands are achieved.
5. Disconnect the AC and the BFI_3P signal(s).

**Checking the case with fault current below set value \( \text{Pickup\_BlkCont} \)**

The case shall simulate a case where the fault current is very low and operation will depend on CB position signal from CB auxiliary contact. It is suggested that re-trip without current check is used, setting \( \text{RetripMode} = \text{No CBPos Check} \).

1. Set \( \text{FunctionMode} = \text{Current&Contact} \).
2. Apply input signal for CB closed to relevant input or inputs 52a_A (B or C)
3. Apply the fault condition with input signal(s) for initiation of CCRBRF (50BF). The value of current should be below the set value \( \text{Pickup\_BlkCont} \).
4. Verify that phase selection re-trip (if selected) and back-up trip are achieved after set times. Failure to trip is simulated by keeping the signal(s) CB closed activated.
5. Disconnect the AC and the BFI_3P signal(s). Keep the CB closed signal(s).
6. Apply the fault and the initiation again. The value of current should be below the set value `Pickup_BlkCont`.
7. Arrange disconnection of BC closed signal(s) well before set back-up trip time \( t_2 \). It simulates a correct CB tripping.
8. Verify that back-up trip is not achieved. Re-trip can appear for example, due to selection "Re-trip without current check".
9. Disconnect injected AC and BFI_3P input signals.

10.4.9.9 Completing the test

Continue to test another function or end the test by changing the `TestMode` setting to `Disabled`. Restore connections and settings to their original values, if they were changed for testing purposes.

10.4.10 Stub protection STBPTOC (50STB)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

Logical signals for STBPTOC (50STB) protection are available on the local HMI under `Main menu/Settings/Setting group N/Current protection/Stub(PTOC,50STB)/STBPTOC:x`

10.4.10.1 Measuring the trip limit of set values

1. Check that the input logical signals BLOCK and ENABLE and the output logical signal TRIP are all logical zero.
2. Activate the input ENABLE on the STBPTOC (50STB) function block.
3. For a short while inject a current (fault current) in one phase to about 110% of the set operating current, and switch the current off. Observe to not exceed the maximum permitted overloading of the current circuits in the IED.
4. Switch the fault current on and measure the operating time of STBPTOC (50STB). Use the TRIP signal from the configured binary output to stop the timer. The operation should be instantaneously.
5. Activate the input BLOCK on the STBPTOC (50STB) function block.
6. Switch on the fault current (110% of the setting). No TRIP signal should appear.
7. Switch off the fault current.
8. For a short while inject a current (fault current) in same phase to about 90% of the set operating current, and switch the current off.
9. Switch the fault current on. No TRIP signal should appear.
10. Switch off the fault current.
11. Reset the ENABLE binary input.
12. Switch the fault current on. No TRIP signal should appear.
13. Disable the fault current.
10.4.10.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.4.11 Pole discrepancy protection CCPDSC (52PD)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.4.11.1 Verifying the settings

1. External detection logic, Contact function selection = ContactSel setting equals CCPDSC (52PD) signal from CB. Activate the EXTPDIND binary input, and measure the operating time of CCPDSC (52PD). Use the TRIP signal from the configured binary output to stop the timer.
2. Compare the measured time with the set value tTrip.
3. Reset the EXTPDIND input.
4. Activate the BLKDBYAR binary input.
   This test should be performed together with Autorecloser SMBRREC (79).
5. Activate the EXTPDIND binary input.
   No TRIP signal should appear.
6. Reset both BLKDBYAR and EXTPDIND binary inputs.
7. Activate the BLOCK binary input.
8. Activate EXTPDIND binary input.
   NO TRIP signal should appear.
9. Reset both BLOCK and EXTPDIND binary inputs.
10. If Internal detection logic Contact function selection = ContactSel setting equals Pole position from auxiliary contacts. Then set inputs 52b_A...52a_C in a status that activates the pole discordance logic and repeats step 2 to step 6.
11. Unsymmetrical current detection with CB monitoring: Set measured current in one phase to 110% of current release level. Activate CLOSECMD and measure the operating time of the CCPDSC (52PD) protection. Use the TRIP signal from the configured binary output to stop the timer.
12. Deactivate the CLOSECMD: Set measured current in one phase to 90% of Current Release level. Activate CLOSECMD.
    NO TRIP signal should appear.
13. Repeat the previous two steps using OPENCMD instead of CLOSECMD. Asymmetry current detection with CB monitoring: Set all three currents to 110% of Current Release level. Activate CLOSECMD.
    NO TRIP signal should appear due to symmetrical condition.
14. Deactivate the CLOSECMD. Decrease one current with 120% of the current unsymmetrical level compared to the other two phases. Activate CLOSECMD and measure the operating time of the CCPDSC (52PD) protection.
    Use the TRIP signal from the configured binary output to stop the timer.
15. Deactivate the CLOSECMD. Decrease one current with 80% of the current unsymmetrical level compared to the other two phases. Activate CLOSECMD.
    NO TRIP signal should appear.
10.4.11.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.4.12 Directional underpower protection GUPPDUP (37)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.4.12.1 Verifying the settings

The underpower protection shall be set to values according to the real set values to be used.

The test is made by means of injection of voltage and current where the amplitude of both current and voltage and the phase angle between the voltage and current can be controlled. During the test, the analog outputs of active and reactive power shall be monitored.

1. Connect the test set for injection of voltage and current corresponding to the mode to be used in the application. If a three-phase test set is available this could be used for all the modes. If a single-phase current/voltage test set is available the test set should be connected to a selected input for one-phase current and voltage.

| C    | $\mathbf{\bar{S}} = 3 \cdot \bar{V}_C \cdot \bar{I}_C^*$ | (Equation 12) |

2. Adjust the injected current and voltage to the set values in % of $I_{Base}$ and $V_{Base}$ (converted to secondary current and voltage). The angle between the injected current and voltage shall be set equal to the set direction $Angle1$, angle for stage 1 (equal to 0° for low forward power protection and equal to 180° for reverse power protection). Check that the monitored active power is equal to 100% of rated power and that the reactive power is equal to 0% of rated power.

3. Change the angle between the injected current and voltage to $Angle1 + 90^\circ$. Check that the monitored active power is equal to 0% of rated power and that the reactive power is equal to 100% of rated power.

4. Change the angle between the injected current and voltage back to 0°. Decrease the current slowly until the PICKUP1 signal, pickup of stage 1, is activated.

5. Increase the current to 100% of $I_{Base}$.

6. Switch the current off and measure the time for activation of TRIP1, trip of stage 1.

7. If a second stage is used, repeat steps 2 to 6 for the second stage.

#### 10.4.12.2 Completing the test

Continue to test another function or end the test by changing the $TestMode$ setting to $Disabled$. Restore connections and settings to their original values, if they were changed for testing purposes.

#### 10.4.13 Directional overpower protection GOPPDOP (32)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

#### 10.4.13.1 Verifying the settings

The overpower protection shall be set to values according to the real set values to be used. The test is made by means of injection of voltage and current where the amplitude of both current and voltage and the phase angle between the voltage and current can be controlled. During the test the analog outputs of active and reactive power shall be monitored.
1. Connect the test set for injection of voltage and current corresponding to the mode to be used in the application. If a three phase test set is available this could be used for all the modes. If a single phase current/voltage test set is available the test set should be connected to a selected input for one phase current and voltage.

2. Adjust the injected current and voltage to the set rated values in % of IBase and VBase (converted to secondary current and voltage). The angle between the injected current and voltage shall be set equal to the set direction Angle1, angle for stage 1 (equal to 0° for low forward power protection and equal to 180° for reverse power protection). Check that the monitored active power is equal to 100% of rated power and that the reactive power is equal to 0% of rated power.

3. Change the angle between the injected current and voltage to Angle1 + 90°. Check that the monitored active power is equal to 0% of rated power and that the reactive power is equal to 100% of rated power.

4. Change the angle between the injected current and voltage back to Angle1 value. Increase the current slowly from 0 until the PICKUP1 signal, pickup of stage 1, is activated. Check the injected power and compare it to the set value Power1, power setting for stage 1 in % of Sbase.

5. Increase the current to 100% of IBase and switch the current off.

6. Switch the current on and measure the time for activation of TRIP1, trip of stage 1.

7. If a second stage is used, repeat steps 2 to 6 for the second stage.

### 10.4.13.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

### 10.4.14 Broken conductor check BRCPTOC (46)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

#### 10.4.14.1 Measuring the trip and time limit of set values

1. Check that the input logical signal BLOCK to the BRCPTOC (46) function block is logical zero and note on the local HMI that the output signal TRIP from the BRCPTOC (46) function block is equal to the logical 0.

2. Set the measured current (fault current) in one phase to about 110% of the set operating current Pickup_PH. Observe to not exceed the maximum permitted overloading of the current circuits in the terminal.

3. Switch on the fault current and measure the operating time of BRCPTOC (46). TRIP is controlled by Gate 13 in the configuration. Use the TRIP signal from the configured binary output to stop the timer.

4. Compare the measured time with the set value tOper.

5. Activate the BLOCK binary input.

6. Switch on the fault current (110% of the setting) and wait longer than the set value tOper. No TRIP signal should appear.

7. Switch off the fault current.
8. Set the measured current (fault current) in same phase to about 90% of the set operating current $\text{Pickup}_\text{PH}$. Switch off the current.
9. Switch on the fault current and wait longer than the set value $t_{\text{Oper}}$. No TRIP signal should appear.
10. Switch off the fault current.

10.4.14.2 Completing the test

Continue to test another function or end the test by changing the $TestMode$ setting to $Disabled$. Restore connections and settings to their original values, if they were changed for testing purposes.

10.4.15 Capacitor bank protection CBPGAPC

Prepare the IED for verification of settings as outlined in section “Preparing for test” in this chapter.

In this section it is shown how to test the capacitor bank protection function CBPGAPC for application on a 60Hz, 200MVAr, 400kV SCB with 500/5A ratio CT.

Note that such SCB is shown in the application manual for this function. The same procedure can be used to test SCB with some other rating and different CT ratio.

As calculated in the application manual the base current for this particular SCB will be 289A on the primary side and 0.578A on the CT secondary side. Before any testing is commenced make sure that setting $IBase$ for this function is set to 289A (that is, setting for the base current corresponds to the rated current of the protected SCB). It will be also assumed that all other settings have values as shown in the setting example in the application manual for this SCB.

Test equipment

Connect the secondary test set to the CT inputs on the IED dedicated for the SCB currents. Single- or three-phase test equipment can be used but it may be required to have facility to vary the frequency of the injected current signal(s).

10.4.15.1 Verifying the settings and operation of the function

Reconnection inhibit feature

1. Inject SCB rated current (that is, 0.587A at 50Hz for this SCB) in at least one phase (preferably perform this test with three phase injection).
2. After couple of seconds stop injection of all currents (that is, set all currents back to 0A).
3. Check that function binary output signal $RECNINH$ is set to logical 1 and that only resets after the set time under parameter $t_{ReconnInhibit}$ (for example 300s for this SCB) has expired.
4. If this binary signal is used to prevent CB closing make sure that it is properly connected/wired into the CB closing circuit.
Overcurrent feature

Note that during testing the overcurrent feature the harmonic voltage overload feature or reactive power overload feature may also give pickup and trip signals depending on their actual settings. Therefore it is best to switch them off during this test.

1. Inject current 20% bigger than the set overcurrent pickup level under setting parameter \textit{PU 51} (for example, 1.2 \cdot 1.35 \cdot 0.587A = 0.951A at 50Hz for this SCB) in phase A only.
2. Check that function binary output signals PU_51_A and PU_OC are set to one.
3. Check that function binary output signals TROC and TRIP are set to one after the set time under parameter \textit{tOC} (that is, 30s for this SCB) has expired.
4. If any of these signals are used for tripping, signaling and/or local/remote indication check that all relevant contacts and LEDs have operated and that all relevant GOOSE messages have been sent.
5. Check that service value from the function for current in phase A, on the local HMI under \textbf{Main menu/Test} is approximately 476A (that is, 0.951A \cdot (500/1) = 476A).
6. Stop injection of all currents (that is, set all currents back to 0A).
7. Check that all above mentioned function binary output signals now have logical value zero.
8. Repeat above steps 1-7 for phase B and phase C.

Note that the operation of this feature is based on current peak value. That means that this overcurrent function is also able to trip for the same current magnitude but for different injected frequencies. If required repeat this injection procedure for example for the 3rd harmonic by just simply injecting 3 \cdot 50 = 150Hz currents with the same magnitude. Obtain results shall be the same.

Undercurrent feature

1. Inject SCB rated current (that is, 0.587A at 50Hz for this SCB) in all three phases.
2. Lower phase A current 10% under the set value for setting parameter \textit{PU 37} (that is, 0.9 \cdot 0.7 \cdot 0.587A = 0.370A at 50Hz for this SCB).
3. Check that function binary output signals PU_37_A and PU_UC are set to one.
4. Check that function binary output signals TRUC and TRIP are set to one after the set time under parameter \textit{tUC} (for example, 5s for this SCB) has expired.
5. If any of these signals are used for tripping, signaling and/or local/remote indication check that all relevant contacts and LEDs have operated and that all relevant GOOSE messages have been sent.
6. Check that service value from the function for current in phase A, on the local HMI under \textbf{Main menu/Test} is approximately 185A (that is, 0.370A \cdot (500/1) = 185A).
7. Stop injection of all currents (that is, set all currents back to 0A).
8. Check that all above mentioned function binary output signals now have logical value zero because they will be automatically blocked by operation of built-in reconnection inhibit feature.
9. Repeat above steps 1-8 for phase B and phase C.
Reactive power overload feature

Note that during testing the reactive power overload feature the harmonic voltage overload feature or overcurrent feature may also give pickup and trip signals depending on their actual settings. Therefore it is recommended to switch them off during this test.

1. Inject current equal to the set reactive power overload pickup level under setting parameter UP_QOL (that is, $1.3 \cdot 0.587A = 0.763A$ at 50Hz for this SCB) in phase A only.
2. Check that function binary output signals PU_QOL_A and PU_QOL are set to one.
3. Check that function binary output signals TRQOL and TRIP are set to one after the set time under parameter tQOL (for example, 60s for this SCB) has expired.
4. If any of these signals are used for tripping, signaling and/or local/remote indication check that all relevant contacts and LEDs have operated and that all relevant GOOSE messages have been sent.
5. Check that service value from the function for current in phase A, on the local HMI under Main menu/Test is approximately 382A (that is, $0.763A \cdot (500/1) = 382A$).
6. Check that service value from the function for reactive power in phase A, on the local HMI under Main menu/Test is approximately 169% (that is, $1.3 \cdot 1.3 = 1.69pu = 169\%$).

Note that operation of this feature is based on injected current and internally calculated true RMS values. That means that this feature is also able to trip for current signals with varying frequency. However due to relatively complex calculation procedure it is recommended to do secondary tests only with fundamental frequency current signals.

The following formula can be used to calculate SCB reactive power in per-unit system when current with different frequency from the rated frequency is injected.

$$Q[pu] = \frac{f_{\text{rated}}}{f_{\text{injected}}} \cdot I^2[pu]$$

(Equation 13)

Harmonic voltage overload feature

Note that during testing the harmonic voltage overload feature the reactive power overload feature or overcurrent feature may also give pickup and trip signals depending on their actual settings. Therefore it is recommended to switch them off during this test.

Procedure to test inverse time delayed step:

The following points on the inverse curve are defined per relevant IEC/ANSI standards for time multiplier value set to $k_{HOL\_IDMT}=1.0$.
<table>
<thead>
<tr>
<th>U_{\text{peak RMS [pu]}}</th>
<th>1.15</th>
<th>1.2</th>
<th>1.3</th>
<th>1.4</th>
<th>1.7</th>
<th>2.0</th>
<th>2.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time [s]</td>
<td>1800</td>
<td>300</td>
<td>60</td>
<td>15</td>
<td>1</td>
<td>0.3</td>
<td>0.12</td>
</tr>
</tbody>
</table>

Note that operation of this feature is based on internally calculated voltage peak RMS value. That means that this feature is also able to trip for current signals with varying frequency.

Here will be shown how to test the fourth point from the above table. Other points can be tested in the similar way:

1. Inject 140% of the base current (that is, $1.4 \times 0.587\, \text{A} = 0.822\, \text{A}$ at 50Hz for this SCB) in phase A only.
2. Check that function binary output signals PU_HOL_IDMT_A and PU_HOL are set to one.
3. Check that function binary output signals TRHOL and TRIP are set to one after the expected time (for example, 15s for this voltage level in accordance with the above table) has expired.
4. If any of these signals are used for tripping, signaling and/or local/remote indication, check that all relevant contacts and LEDs have operated and that all relevant GOOSE messages have been sent.
5. Check that service value for current in phase A, on the local HMI under Main menu/Test is approximately 411A (that is, $0.822\, \text{A} \times (500/1) = 411\, \text{A}$).
6. Check that service value for voltage across SCB in phase A, on the local HMI under Main menu/Test is approximately 140%.
7. Stop injection of all currents (that is, set all currents back to 0A).
8. Check that all above mentioned function binary output signals now have logical value zero.
9. Repeat above steps 1 - 8 for phase B and phase C.
10. Repeat above steps 1 - 8 to test different points from the above table.

Operation of this feature is based on internally calculated peak RMS voltage value. That means that this feature is also able to trip for current signals with varying frequency. Note that for the fundamental frequency injection, internally calculated voltage in percent corresponds directly to the injected current value given in percent. However if it is required to test IDMT characteristic with a varying frequency, the magnitude of the injected current must be adjusted accordingly. The following formula can be used to calculate required current RMS value in percent at the desired injection frequency in order to archive voltage percentage value given in the above table:

$$I_{\text{f}_{\text{inj}}} = \frac{I_{\text{f}_{\text{inj}}}}{I_{\text{f}_{\text{rated}}}} \times V_{\%}$$

(Equation 14)

Note that it is recommended to test IDMT operating times by injected current with the rated frequency.

Above procedure can also be used to test definite time step. Pay attention that IDMT step can also trip during such injection. Therefore make sure that appropriate settings are entered in order to insure correct test results for definite time step.
10.4.15.2 Completing the test

Continue to test another functions or end the test by changing the Test mode setting to *Disabled*. Restore connections and settings to their original values, if they were changed for testing purposes. Make sure that all built-in features for this function, which shall be in operation, are enabled and with correct settings.

10.4.16 Voltage-restrained time overcurrent protection VRPVOC(51V)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.4.16.1 Verifying the settings

Verifying settings by secondary injection

1. Connect the test set for three-phase current injection and three-phase voltage injection to the appropriate IED terminals.
2. Go to Main menu/Settings/IED Settings/Current protection/VoltageRestOverCurr (51V,2(I>/V<))/VRPVOC (51V,2(I>/V<)):1/General and make sure that the function is enabled, that is, Operation is set to *Enabled*.
3. The test of the function may be performed by injecting restrain voltage and increasing the injected current(s). Note the value at which the PICKUP and STOC signals are set.

In the following equations, restrain voltage is the magnitude of the minimum phase-to-phase voltage in secondary volts.

The set trip value in secondary amperes is calculated according to the following equations:

First part of the characteristic (Restrain voltage ≤ 25% of *VBase*):

\[
\frac{\text{Pickup Curr}}{100} \times \frac{\text{IBase}}{\text{CT}} \times \frac{\text{sec}}{\text{CTprim}} \times \frac{\text{VDepFact}}{100}
\]

(Equation 15)

Second part of the characteristic (25% of *VBase* ≤ Restrain voltage ≤ *VHighLimit/100* *VBase*), valid when setting parameter *VDepMode* = *Slope*:

\[
\left\{ \frac{\text{Pickup Curr}}{100} \times \frac{\text{IBase}}{\text{CT}} \times \frac{\text{sec}}{\text{CTprim}} \times \frac{1}{\text{VDepFact}} \times \frac{\text{VBase}}{\text{VTprim}} \times \left( \frac{\text{Restrain Voltage} - 25}{100} \times \frac{\text{VBase}}{\text{VT}} \right) \right\} 
\]

(Equation 16)

Third part of the characteristic (*VHighLimit/100* *VBase* ≤ Restrain voltage):

\[
\frac{\text{Pickup Curr}}{100} \times \frac{\text{IBase}}{\text{CT}} \times \frac{\text{sec}}{\text{CTprim}} \times \frac{\text{VDepFact}}{100}
\]

(Equation 17)

Example (rated secondary current = 5A):
CT ratio | 10 000/5A
---|---
VT ratio | 10 kV/100 V
Pickup_Curr | 100%
VDepFact | 25%
VHighLimit | 100%
IBase | 10 000 A
VBase | 10 kV

A test for each section of the characteristic of the function VRPVOC may be performed; that may be achieved by applying the following voltages:

First section of the characteristic:
If \( VDepMode = \) Slope, the minimum measured phase-to-phase voltage is lower than 0,25\( \times \) \( VBase \); if \( VDepMode = \) Step, the minimum measured phase-to-phase voltage is lower than \( VHighLimit/100\times VBase \):
- VA: Ampl = 10 / \( \sqrt{3} \); Angle = 0°
- VB: Ampl = 10 / \( \sqrt{3} \); Angle = 240°
- VC: Ampl = 100 / \( \sqrt{3} \); Angle = 120°

Second section of the characteristic only:
If \( VDepMode = \) Slope, the minimum measured phase-to-phase voltage is between 0,25\( \times \) \( VBase \) and \( VHighLimit/100\times VBase \):
- VA: Ampl = 50 / \( \sqrt{3} \); Angle = 0°
- VB: Ampl = 50 / \( \sqrt{3} \); Angle = 240°
- VC: Ampl = 100 / \( \sqrt{3} \); Angle = 120°

Last section of the characteristic:
If \( VDepMode = \) either Slope or Step, the minimum measured phase-to-phase voltage is higher than \( VHighLimit/100\times VBase \):
- VA: Ampl = 105 / \( \sqrt{3} \); Angle = 0°
- VB: Ampl = 105 / \( \sqrt{3} \); Angle = 240°
- VC: Ampl = 105 / \( \sqrt{3} \); Angle = 120°

4. Inject the voltages that are related to the first part of the characteristic, and then slowly increase the phase current \( IA \) from 0.0 A up to the value the function trips. The PICKUP and STOC signals must be activated when the amplitude of the phase current \( IA \) is slightly above 0.25 A on the secondary side. The corresponding trip signals TROC and TRIP will be activated after the pre-set time delay has expired.

5. Decrease the current \( IA \) slowly and note the reset value.

6. Repeat steps 4 and 5 applying voltages that are related to the second and the last section of the characteristic; the function trips when \( IA \) is slightly higher than: 0.5 A in the second section; 5A in the last section.

7. Connect the trip output contact to the input channel of the test set in order to stop the injection and measure the trip time.

8. If definite time delay is used for the overcurrent step, set the setting \( Characterist = ANSI Def. Time \). Apply the voltages related to the last part of the characteristic and inject a current \( IA \) 200% higher than the set tripping level, and check the definite time delay for trip (the signals TROC and TRIP of the protection function VRPVOC are active in trip condition).

9. If inverse time delay is used for the overcurrent step, the parameter setting \( Characterist \) shall be properly set; we can refer, for example, to the setting \( IEC Very inv. \); If the IEC Very inverse time characteristic is selected, the trip signals TROC and TRIP will trip after a time defined by the equation:
\[ t[s] = \frac{13.5 + k}{I/Pickup\_Curr} - 1 \]

(Equation 18)

where:
- \( t \) Trip time in seconds
- \( I \) Measured value (for example, phase current)
- \( Pickup\_Curr \) Set trip value

This means that if the measured phase current jumps from 0 to 2 times the set trip level and time multiplier \( k \) is set to 1.0 s (default value), then the TROC and TRIP signals will trip after a time delay equal to 13.5 s ± tolerance.

Taking into account the above explanation, inject the voltages related to the last part of the characteristic and inject a current \( I_a \) 200% higher than the set operation level, and check the trip time delay.

If \( t_{Def\_OC} \) is set to a value different from 0 s, then this time delay is added to the one that is defined by the IDMT characteristic.

10. Check the pickup and trip information that are stored in the event menu.
11. The previous step 8 or 9 may be repeated also for the first and second section of the characteristic.
12. Supply the IED with symmetric three-phase voltages at their rated values. Go to Main menu/Settings/IED Settings/Current protection/VoltageRestOverCurr(51V,2(/>\text{V}<))/VRPVOC(51V,2(/>\text{V}<)):1/Undervoltage and set the setting \( \text{Operation\_UV = Enabled} \) to activate the undervoltage stage.
13. Slowly decrease the voltage in two phases simultaneously, until the STUV and PICKUP signals appear.
14. Note the trip value. The set trip value in secondary volts is calculated according to the following equation:

\[ Pickup\_Volt = \frac{V_{Base} \times VT_{sec} \times VT_{prim}}{100 \times \sqrt{3}} \]

(Equation 19)

If the VRPVOC function is used as an overcurrent protection with undervoltage seal-in, it is necessary to first inject sufficient current to activate the STOC signal before the under-voltage step is allowed to trip. In order to achieve that, apply symmetric three-phase voltages at their rated value and then inject a current \( I_a \) that is 200% higher than the set tripping level. Then slowly decrease the voltage in two phases simultaneously, until the STUV and PICKUP signals appear.

15. Increase slowly the applied voltages of the previous two phases and note the reset value.
16. Check that the trip output of the relay is connected to the input channel of the test in order to stop the injection and measure the trip time.
17. Inject symmetric three-phase voltages at their rated value and check that the STUV and PICKUP signals reset as well as the trip signals of the function block (TRIP and TRUV).
18. Instantaneously decrease the voltage in two phases simultaneously to a value 20% lower than the set trip value (take into account the previous note if VRPVOC is configured in ACT with the undervoltage seal-in feature).
19. Measure the definite time delay for the TRUV and TRIP signals and compare it with the set value \( t_{Def, UV} \).
20. Check that pickup and trip information is stored in the event menu.

10.4.16.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.5 Voltage protection

10.5.1 Two step undervoltage protection UV2PTUV (27)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.5.1.1 Verifying the settings

Verification of PICKUP value and time delay to trip for Step 1

1. Check that the IED settings are appropriate, especially the PICKUP value, the definite time delay and the 1 out of 3 operation mode.
2. Supply the IED with three-phase voltages at their rated values.
3. Slowly decrease the voltage in one of the phases, until the PICKUP signal appears.
4. Note the trip value and compare it with the set value.

The trip value in secondary volts is calculated according to the following equations:

For phase-to-ground measurement:

\[
\frac{V_{pickup}}{100} < \frac{V_{Base}}{\sqrt{3}} \times \frac{VT_{sec}}{VT_{prim}}
\]

(Equation 20)

For phase-to-phase measurement:

\[
\frac{V_{pickup}}{100} \times V_{Base} \times \frac{VT_{sec}}{VT_{prim}}
\]

(Equation 21)

5. Increase the measured voltage to rated load conditions.
6. Check that the PICKUP signal resets.
7. Instantaneously decrease the voltage in one phase to a value about 20% lower than the measured trip value.
8. Measure the time delay for the TRIP signal, and compare it with the set value.
9. Check the inverse time delay by injecting a voltage corresponding to $0.8 \times V_{\text{pickup}}$.

   For example, if the inverse time curve A is selected, the trip signals TRST1 and TRIP trip after a time corresponding to the equation:

   \[
   t(s) = \left( \frac{TD1}{V} \right) \left( 1 - \frac{V}{V_{\text{pickup}}} < \right)
   \]

   (Equation 22)

   where:
   - $t(s)$: Trip time in seconds
   - $TD1$: Settable time multiplier of the function for step 1
   - $V$: Measured voltage
   - $V_{\text{pickup}}$: Set pickup voltage for step 1

   For example, if the measured voltage jumps from the rated value to 0.8 times the set pickup voltage level and time multiplier $TD1$ is set to 0.05 s (default value), then the TRST1 and TRIP signals trip at a time equal to 0.250 s ± tolerance.
10. The test above can be repeated to check the inverse time characteristic at different voltage levels.
11. Repeat the above-described steps for Step 2 of the function.

**Extended testing**
The tests above can be repeated for 2 out of 3 and for 3 out of 3 operation mode.

10.5.2.1 Completing the test
Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.5.2 Two step overvoltage protection OV2PTOV (59)
Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.5.2.1 Verifying the settings

Verification of single-phase voltage and time delay to trip for Step 1
1. Apply single-phase voltage below the set value Pickup1.
2. Slowly increase the voltage until the PU_ST1 signal appears.
3. Note the trip value and compare it with the set value Pickup1.

The trip value in secondary volts is calculated according to the following equations:

For phase-to-ground measurement:

\[
\frac{V_{\text{pickup}}}{100} \times \frac{V_{\text{Base}}}{\sqrt{3}} \times \frac{VT_{\text{sec}}}{VT_{\text{prim}}}
\]

(Equation 23)

For phase-to-phase measurement:

\[
\frac{V_{\text{pickup}}}{100} \times V_{\text{Base}} \times \frac{VT_{\text{sec}}}{VT_{\text{prim}}}
\]

(Equation 24)

4. Decrease the voltage slowly and note the reset value.
5. Set and apply about 20% higher voltage than the measured trip value for one phase.
6. Measure the time delay for the TRST1 signal and compare it with the set value.
7. Check the inverse time delay by injecting a voltage corresponding to 1.2 × Vpickup.
8. Repeat the test to check the inverse time characteristic at different over-voltage levels.
9. Repeat the above-described steps for Step 2 of the function.

10.5.2.2 Extended testing

1. The tests above can be repeated for 2 out of 3 and for 3 out of 3 operation mode.

10.5.3 Two step residual overvoltage protection ROV2PTOV (59N)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.5.3.1 Verifying the settings
1. Apply a single-phase voltage either to a single-phase voltage input or to a residual voltage input with the pickup value below the set value Pickup1.
2. Slowly increase the value until PU_ST1 appears.
3. Note the trip value and compare it with the set value.
4. Decrease the voltage slowly and note the reset value.
5. Set and apply a 20% higher voltage than the measured trip value for one phase.
6. Measure the time delay for the TRST1 signal and compare it with the set value.
7. Check the inverse time delay by injecting a voltage corresponding to 1.2 × Vpickup>.

For example, if the inverse time curve A is selected, the trip signals TRST1 and TRIP trip after a time corresponding to the equation:

\[
t(s) = \frac{k_1}{\left(\frac{U}{U_{1 >}} - 1\right)}
\]

(Equation 25)

\[
t(s) = \frac{TD_1}{\left(\frac{V}{V_{\text{pickup} >}} - 1\right)}
\]

(Equation 26)

where:
- \(t(s)\) Trip time in seconds
- \(TD_1\) Settable time multiplier of the function for step 1
- \(V\) Measured voltage
- \(V_{\text{pickup} >}\) Set pickup voltage for step 1

For example, if the measured voltage jumps from 0 to 1.2 times the set pickup voltage level and time multiplier \(TD_1\) is set to 0.05 s (default value), then the TRST1 and TRIP signals trip at a time equal to 0.250 s ± tolerance.
8. Repeat the test for Step 2 of the function.

10.5.3.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.5.4 Voltage differential protection VDCPTOV (60)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.
10.5.4.1 Check of undervoltage levels

This test is relevant if the setting BlkDiffAtVLow = Yes.

Check of V1Low

Procedure

1. Connect voltages to the IED according to valid connection diagram and figure 18.
2. Apply voltage higher than the highest set value of VDTrip, V1Low and V2Low to the V1 three-phase inputs and to one phase of the V2 inputs according to figure 18. The voltage differential PICKUP signal is set.

3. Decrease slowly the voltage in phase VA of the test set until the PICKUP signal resets.
4. Check V1 blocking level by comparing the voltage level at reset with the set undervoltage blocking V1Low.
5. Repeat steps 2 to 4 to check V1Low for the other phases.

The connections to V1 must be shifted to test another phase. (VA to VB, VB to VC, VC to VA)

Check of V2Low

Procedure
1. Connect voltages to the IED according to valid connection diagram and figure 19.

![Connection Diagram](ANSI07000107-1-en.vsd)

Figure 19: Connection of the test set to the IED for test of V2 block level

where:
1. is three-phase voltage group1 (V1)
2. is three-phase voltage group2 (V2)

2. Apply voltage higher than the highest set value of \( VD_{Trip} \), \( V1_{Low} \), and \( V2_{Low} \) to the V1 three-phase inputs and to one phase of the V2 inputs according to figure 19. The voltage differential PICKUP signal is set.

3. Decrease slowly the voltage in phase VC of the test set until the PICKUP signal resets.

4. Check V2 blocking level by comparing the voltage level at reset with the set undervoltage blocking \( V2_{Low} \).

10.5.4.2 Check of voltage differential trip and alarm levels

Procedure

1. Connect voltages to the IED according to valid connection diagram and figure 20.
Figure 20: Connection of the test set to the IED for test of alarm levels, trip levels and trip timer

where:
1. is three-phase voltage group 1 (V1)
2. is three-phase voltage group 2 (V2)

2. Apply 1.2 · Vn (rated voltage) to the V1 and V2 inputs.
3. Decrease slowly the voltage of in phase VA of the test set until the ALARM signal is activated.

   The ALARM signal is delayed with timer \( t_{Alarm} \)

4. Check the alarm operation level by comparing the differential voltage level at ALARM with the set alarm level \( V_{DAlarm} \).
5. Continue to slowly decrease the voltage until PICKUP signal is activated.
6. Check the differential voltage operation level by comparing the differential voltage level at PICKUP with the set trip level \( V_{DTrip} \).
7. Repeat steps 1 to 6 to check the other phases.
   Observe that the connections to V1 must be shifted to test another phase. (VA to VB, VB to VC, VC to VA)

10.5.4.3 Check of trip and trip reset timers

Procedure
1. Connect voltages to the IED according to valid connection diagram and figure 20.
2. Set Vn (rated voltage) to the V1 inputs and increase V2 voltage until differential voltage is 1.5 \cdot operating level (VDTrip).
3. Switch on the test set. Measure the time from activation of the PICKUP signal until TRIP signal is activated.
4. Check the measured time by comparing it to the set trip time \( t_{Trip} \).
5. Increase the voltage until PICKUP signal resets. Measure the time from reset of PICKUP signal to reset of TRIP signal.
6. Check the measured time by comparing it to the set trip reset time \( t_{Reset} \).

10.5.4.4 Final adjustment of compensation for VT ratio differences

Procedure

1. With the protection in test mode, view the differential voltage service values in each phase on the local HMI under Main menu/Test/Function status/Voltage protection/VoltageDiff(PTOV,60)/VDCPTOV:x.

   The IED voltage inputs should be connected to the VTs according to valid connection diagram.

2. Record the differential voltages.
3. Calculate the compensation factor \( RF_x \) for each phase.
   For information about calculation of the compensation factor, see the application manual.
4. Set the compensation factors on the local HMI under Main menu/Settings/Settings group N/Voltage protection/VoltageDiff(PTOV,60)/VDCPTOV:x
5. Check that the differential voltages are close to zero.

10.5.4.5 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.5.5 Loss of voltage check LOVPTUV (27)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.5.5.1 Measuring the trip limit of set values

1. Check that the input logical signals BLOCK, CBOPEN and BLKU are logical zero.
2. Supply a three-phase rated voltage in all three phases and note on the local HMI that the TRIP logical signal is equal to the logical 0.
3. Switch off the voltage in all three phases. After set \( t_{Trip} \) time a TRIP signal appears on the corresponding binary output or on the local HMI.
Note that TRIP at this time is a pulse signal, duration should be according to set tPulse.

4. Inject the measured voltages at rated values for at least set tRestore time.
5. Activate the CBOPEN binary input.
6. Simultaneously disconnect all the three-phase voltages from the IED. No TRIP signal should appear.
7. Inject the measured voltages at rated values for at least set tRestore time.
8. Activate the BLKU binary input.
9. Simultaneously disconnect all the three-phase voltages from the IED. No TRIP signal should appear.
10. Reset the BLKU binary input.
11. Inject the measured voltages at rated values for at least set tRestore time.
12. Activate the BLOCK binary input.
13. Simultaneously disconnect all the three-phase voltages from the IED. No TRIP signal should appear.
14. Reset the BLOCK binary input.

10.5.5.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.6 Frequency protection

10.6.1 Underfrequency protection SAPTUF (81)

Prepare the IED for verification of settings as outlined in section “Requirements” and section “Preparing for test” in this chapter.

10.6.1.1 Verifying the settings

Verification of PICKUP value and time delay to trip

1. Check that the IED settings are appropriate, for example the PICKUP value and the time delay.
2. Supply the IED with three-phase voltages at their rated values.
3. Slowly decrease the frequency of the applied voltage, until the PICKUP signal appears.
4. Note the operate value and compare it with the set value.
5. Note the trip value and compare it with the set value.
6. Increase the frequency until rated operating levels are reached.
7. Check that the PICKUP signal resets.
8. Instantaneously decrease the frequency of the applied voltage to a value about 1% lower than the trip value (a step change more than 2% will increase the time delay).
9. Measure the time delay of the TRIP signal, and compare it with the set value. Note that the measured time consists of the set value for time delay plus minimum trip time of the pickup start function (80 - 90 ms).
Extended testing

1. The test above can be repeated to check the time to reset.
2. The tests above can be repeated to test the frequency dependent inverse time characteristic.

Verification of the low voltage magnitude blocking

1. Check that the IED settings are appropriate, for example the PUFrequency, VMin, and the tDelay.
2. Supply the IED with three-phase voltages at rated values.
3. Slowly decrease the magnitude of the applied voltage, until the BLKDMAGN signal appears.
4. Note the voltage magnitude value and compare it with the set value VMin.
5. Slowly decrease the frequency of the applied voltage, to a value below PUFrequency.
6. Check that the PICKUP signal does not appear.
7. Wait for a time corresponding to tDelay, make sure that the TRIP signal does not appear.

10.6.1.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.6.2 Overfrequency protection SAPTOF (81)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.6.2.1 Verifying the settings

Verification of PICKUP value and time delay to trip

1. Check that the settings in the IED are appropriate, for example the PICKUP value and the time delay.
2. Supply the IED with three-phase voltages at their rated values.
3. Slowly increase the frequency of the applied voltage, until the PICKUP signal appears.
4. Note the trip value and compare it with the set value.
5. Decrease the frequency to rated operating conditions.
6. Check that the PICKUP signal resets.
7. Instantaneously increase the frequency of the applied voltage to a value about 1% lower than the trip value (a step change more than 2% will increase the time delay).
8. Measure the time delay for the TRIP signal, and compare it with the set value. Note that the measured time consists of the set value for time delay plus minimum trip time of the pickup function (80 - 90 ms).

Extended testing

1. The test above can be repeated to check the time to reset.

Verification of the low voltage magnitude blocking
1. Check that the settings in the IED are appropriate, for example the \textit{PUF}requency, \textit{VMin}, and the \textit{tDelay}.
2. Supply the IED with three-phase voltages at their rated values.
3. Slowly decrease the magnitude of the applied voltage, until the BLKDMAGN signal appears.
4. Note the voltage magnitude value and compare it with the set value, \textit{VMin}.
5. Slowly increase the frequency of the applied voltage, to a value above \textit{PUF}requency.
6. Check that the PICKUP signal does not appear.
7. Wait for a time corresponding to \textit{tDelay}, make sure that the TRIP signal does not appear.

10.6.2.2 \textbf{Completing the test}

Continue to test another function or end the test by changing the \textit{TestMode} setting to \textit{Disabled}. Restore connections and settings to their original values, if they were changed for testing purposes.

10.6.3 \textbf{Rate-of-change frequency protection SAPFRC (81)}

Prepare the IED for verification of settings as outlined in section \textit{"Requirements"} and section \textit{"Preparing for test"} in this chapter.

10.6.3.1 \textbf{Verifying the settings}

\textbf{PICKUP value and time delay to trip}

1. Check that the settings in the IED are appropriate, especially the PICKUP value and the definite time delay. Set \textit{PickupFreqGrad}, to a rather small negative value.
2. Supply the IED with three-phase voltages at their rated values.
3. Slowly decrease the frequency of the applied voltage, with an increasing rate-of-change that finally exceeds the setting of \textit{PickupFreqGrad}, and check that the PICKUP signal appears.
4. Note the trip value and compare it with the set value.
5. Increase the frequency to rated operating conditions, and zero rate-of-change.
6. Check that the PICKUP signal resets.
7. Instantaneously decrease the frequency of the applied voltage to a value about 20\% lower than the nominal value.
8. Measure the time delay for the TRIP signal, and compare it with the set value.

\textbf{Extended testing}

1. The test above can be repeated to check a positive setting of \textit{PickupFreqGrad}.
2. The tests above can be repeated to check the time to reset.
3. The tests above can be repeated to test the RESTORE signal, when the frequency recovers from a low value.

10.6.3.2 \textbf{Completing the test}

Continue to test another function or end the test by changing the \textit{TestMode} setting to \textit{Disabled}. Restore connections and settings to their original values, if they were changed for testing purposes.
10.6.4 Frequency time accumulation protection function FTAQFVR (81A)

Prepare the IED for verification of settings as outlined in section “Overview” and section “Preparing for test” in this chapter.

10.6.4.1 Verifying the settings

Time measurement and the injection of current and voltage can be done using a common test equipment.

**Verification of the PICKUP value and time delay to trip**

1. Connect the test set for the injection of three-phase currents and three-phase voltages to the appropriate current and voltage terminals of the IED.
2. Ensure that the settings in the IED are appropriate, especially the PickupCurrentLevel, FreqHighLimit, FreqLowLimit, VHighLimit and VLowLimit setting.
3. Supply the IED with three-phase currents and voltages at their rated value.
4. Slowly decrease the frequency of the applied voltage until it crosses the frequency high limit and the BFI_3P signal appears.
5. Check that the FREQOK signal appears.
6. Compare the trip value to the set frequency high limit value.
7. Decrease the frequency of the applied voltage until it crosses the frequency low limit and the BFI_3P signal disappears.
8. Check that the FREQOK signal disappears.
9. Compare the reset value to the set frequency low limit value.
10. Readjust the frequency of the applied voltage (with steps of 0.001 Hz/s) to a value within the set frequency band limit.
11. Ensure that the BFI_3P signal reappears.
12. Wait for a time corresponding to tCont and ensure that the TRIP and TRIPCONT signals are generated.
13. Measure the time delay for the TRIP signal and compare it to the set value.

**Verification of the ACCALARM value and time delay to trip**

1. Connect the test set for the injection of three-phase currents and three-phase voltages to the appropriate current and voltage terminals of the IED.
2. Ensure that the settings in the IED are appropriate for the default settings, especially the PickupCurrentLevel, FreqHighLimit, FreqLowLimit, VHighLimit and VLowLimit setting.
3. Supply the IED with three-phase currents and voltages at their rated value.
4. Slowly decrease the frequency of the applied voltage until it crosses the frequency high limit and the BFI_3P signal appears.
5. Continuously change the frequency of the applied voltage, so that for a certain time the frequency is outside the set band limit and falls gradually within the band limit.
6. Count only the time when the frequency lies within the set frequency band limit. Wait for a time corresponding to tAccLimit and ensure that the ACCALARM signal appears.
7. Measure the time delay for the ACCALARM signal and compare it to the set value.

**Extended testing**

1. To check the value of TRIPACC, repeat the above test case in such a way that the frequency of the applied voltage is within the set frequency band when time approaches the tAccLimit setting value.
Verification of generator start and stop logic

1. Ensure that the settings in the IED are appropriate to the default settings, especially the PickupCurrentLevel, FreqHighLimit, FreqLowLimit, VHighLimit and VLowLimit.
2. Ensure that the setting CBCheck is enabled.
3. Supply the IED with three-phase currents and voltages at their rated values.
4. Slowly decrease the frequency of the applied voltage until the BFI_3P signal appears.
5. Activate the CBOPEN input signal.
6. Slowly decrease the injected current below the PickupCurrentLevel value until the BFI_3P signal disappears.
7. Compare the current magnitude value to the set value.

Verification of voltage band limit check logic

1. Ensure that the settings in the IED are appropriate to the default settings, especially the PickupCurrentLevel, FreqHighLimit, FreqLowLimit, VHighLimit and VLowLimit settings.
2. Ensure that the EnaVoltCheck is enabled.
3. Supply the IED with three-phase currents and voltages at their rated values.
4. Check that the VOLTOK signal appears.
5. Slowly decrease the frequency of the applied voltage until the BFI_3P signal appears.
6. Slowly decrease the positive-sequence voltage of the injected voltage below the VLowLimit value until the BFI_3P signal disappears.
7. Check that the VOLTOK signal disappears.
8. Compare the reset value to the set voltage low limit value.
9. Readjust the positive-sequence voltage of the applied voltage to a value within the set voltage band limits.
10. Check that the BFI_3P signal reappears.
11. Slowly increase the positive-sequence voltage of the injected voltage above the VUHighLimit value until the BFI_3P signal disappears.
12. Compare the reset value to the set voltage high limit value.

10.6.4.2 Completing the test

- Continue to test another function or end the test by changing the Test mode setting to Disabled.
- Restore connections and settings to their original values if they were changed for testing purposes.

10.7 Multipurpose protection

10.7.1 General current and voltage protection CVGAPC

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

One of the new facilities within the general current and voltage protection function CVGAPC is that the value, which is processed and used for evaluation in the function, can be chosen in many different ways by the setting parameters CurrentInput and VoltageInput.

These setting parameters decide what kind of preprocessing the connected three-phase CT and VT inputs shall be subjected to. That is, for example, single-phase quantities, phase-to-phase...
quantities, positive sequence quantities, negative sequence quantities, maximum quantity from the three-phase group, minimum quantity from the three-phase group, difference between maximum and minimum quantities (unbalance) can be derived and then used in the function.

Due to the versatile possibilities of CVGAPC itself, but also the possibilities of logic combinations in the application configuration of outputs from more than one CVGAPC function block, it is hardly possible to define a fully covering general commissioning test.

10.7.1.1  **Built-in overcurrent feature (non-directional)**

Procedure

1. Go to **Main menu/Test/Function test modes/Multipurpose protection/GeneralCurrentVoltage(GAPC)/CVGAPC:x** and make sure that CVGAPC to be tested is unblocked and other functions that might disturb the evaluation of the test are blocked.
2. Connect the test set for injection of three-phase currents to the appropriate current terminals of the IED.
3. Inject current(s) in a way that relevant measured current (according to setting parameter **CurrentInput**) is created from the test set. Increase the current(s) until the low set stage trips and check against the set trip value.
4. Decrease the current slowly and check the reset value.
5. Block high set stage if the injection current will activate the high set stage when testing the low set stage according to below.
6. Connect a TRIP output contact to the timer.
7. Set the current to 200% of the trip value of low set stage, switch on the current and check the time delay.
   For inverse time curves, check the trip time at a current equal to 110% of the trip current at **t_MinTripDelay**.
8. Check that TRIP and PICKUP contacts trip according to the configuration logic.
9. Release the blocking of the high set stage and check the trip and reset value and the time delay for the high set stage in the same way as for the low set stage.
10. Finally check that PICKUP and TRIP information is stored in the event menu.

   Information on how to use the event menu is found in the operator's manual.

10.7.1.2  **Overcurrent feature with current restraint**

The current restraining value has also to be measured or calculated and the influence on the operation has to be calculated when the testing of the trip value is done.

Procedure

1. Trip value measurement
   The current restraining value has also to be measured or calculated and the influence on the operation has to be calculated when the testing of the trip value is done.
10.7.1.3 Overcurrent feature with voltage restraint

Proceedure

1. Connect the test set for injection of three-phase currents and three-phase voltages to the appropriate current and voltage terminals of the IED.
2. Inject current(s) and voltage(s) in a way that relevant measured (according to setting parameter CurrentInput and VoltageInput) currents and voltages are created from the test set.
   Overall check in principal as above (non-directional overcurrent feature)
3. Trip value measurement
   The relevant voltage restraining value (according to setting parameter VoltageInput) has also to be injected from the test set and the influence on the trip value has to be calculated when testing of the trip value is done.
4. Trip time measurement
   Definite times may be tested as above (non-directional overcurrent feature). For inverse time characteristics the PICKUP value (to which the overcurrent ratio has to be calculated) is the actual pickup value as got with actual restraining from the voltage restraining quantity.

10.7.1.4 Overcurrent feature with directionality

Please note that the directional characteristic can be set in two different ways either just dependent on the angle between current and polarizing voltage (setting parameter DirPrinc_OC1 or DirPrinc_OC2 set to or in a way that the trip value also is dependent on the angle between current and polarizing voltage according to the I \cdot \cos(\Phi) law (setting parameter DirPrinc_OC1 or DirPrinc_OC2 set to I \cdot \cos(\Phi)). This has to be known if a more detailed measurement of the directional characteristic is made, than the one described below.

Proceedure

1. Connect the test set for injection of three-phase currents and three-phase voltages to the appropriate current and voltage terminals of the IED.
2. Inject current(s) and voltage(s) in a way that relevant measured (according to setting parameter CurrentInput and VoltageInput) currents and voltages are created from the test set.
3. Set the relevant measuring quantity current to lag or lead (lag for negative RCA angle and lead for positive RCA angle) the relevant polarizing quantity voltage by an angle equal to the set IED characteristic angle (rca-dir) when forward directional feature is selected and the CTWYEpont configuration parameter is set to ToObject.
   If reverse directional feature is selected or CTWYEpont configuration parameter is set to FromObject, the angle between current and polarizing voltage shall be set equal to rca-dir +180°.
4. Overall check in principal as above (non-directional overcurrent feature)
5. Reverse the direction of the injection current and check that the protection does not trip.
6. Check with low polarization voltage that the feature becomes non-directional, blocked or with memory according to the setting.

10.7.1.5 Over/Undervoltage feature

Proceedure
1. Connect the test set for injection three-phase voltages to the appropriate voltage terminals of the IED.
2. Inject voltage(s) in a way that relevant measured (according to setting parameter `VoltageInput`) voltages are created from the test set.
3. Overall check in principal as above (non-directional overcurrent feature) and correspondingly for the undervoltage feature.

### 10.7.1.6 Completing the test

Continue to test another function or end the test by changing the `TestMode` setting to `Disabled`. Restore connections and settings to their original values, if they were changed for testing purposes.

### 10.8 Secondary system supervision

#### 10.8.1 Current circuit supervision CCSSPVC (87)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

The Current circuit supervision function CCSSPVC (87) is conveniently tested with the same three-phase test set as used when testing the measuring functions in the IED.

The condition for this procedure is that the setting of `IMinOp` is lower than the setting of `Pickup_Block`.

#### 10.8.1.1 Verifying the settings

1. Check the input circuits and the trip value of the `IMinOp` current level detector by injecting current, one phase at a time.
2. Check the phase current blocking function for all three phases by injecting current, one phase at a time. The output signals shall reset with a delay of 1 second when the current exceeds 1.5 \( \cdot I_{\text{Base}} \).
3. Inject a current 0.1 \( \cdot I_{\text{Base}} \) to the reference current input Analogue channel ID current input 5.
4. Increase slowly the current in one of the phases current input and check that FAIL output is obtained when the current is about 0.9 \( \cdot I_{\text{Base}} \).

#### 10.8.1.2 Completing the test

Continue to test another function or end the test by changing the `TestMode` setting to `Disabled`. Restore connections and settings to their original values, if they were changed for testing purposes.

#### 10.8.2 Fuse failure supervision FUFSPVC

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.
The verification is divided in two main parts. The first part is common to all fuse failure supervision options, and checks that binary inputs and outputs trip as expected according to actual configuration. In the second part the relevant set trip values are measured.

### 10.8.2.1 Checking that the binary inputs and outputs trip as expected

1. Simulate normal operating conditions with the three-phase currents in phase with their corresponding phase voltages and with all of them equal to their rated values.
2. Connect the nominal dc voltage to the 89bS binary input.
   - The signal BLKV should appear with almost no time delay.
   - The signals BLKZ and 3PH should not appear on the IED.
   - Only the distance protection function can trip.
   - Undervoltage-dependent functions must not trip.
3. Disconnect the dc voltage from the 89b binary input terminal.
4. Connect the nominal dc voltage to the MCBOP binary input.
   - BLKV and BLKZ signals should appear without any time delay.
   - All undervoltage-dependent functions must be blocked.
5. Disconnect the dc voltage from the MCBOP binary input terminal.
6. Disconnect one of the phase voltages and observe the logical output signals on the binary outputs of the IED.
   - BLKV and BLKZ signals should appear simultaneously whether the BLKV and BLKZ reset depends on the setting Seal/In “on” or “off”. If “on” no reset, if “off” reset.
7. After more than 5 seconds disconnect the remaining two-phase voltages and all three currents.
   - There should be no change in the high status of the output signals BLKV and BLKZ.
   - The signal 3PH will appear.
8. Establish normal voltage and current operating conditions simultaneously and observe the corresponding output signals. They should change to logical 0 as follows:
   - Signal 3PH after about 25ms
   - Signal BLKV after about 50ms
   - Signal BLKZ after about 200ms

### 10.8.2.2 Measuring the trip value for the negative sequence function

Measure the trip value for the negative sequence function, if included in the IED.

1. Simulate normal operating conditions with the three-phase currents in phase with their corresponding phase voltages and with all of them equal to their rated values.
2. Slowly decrease the measured voltage in one phase until the BLKV signal appears.
3. Record the measured voltage and calculate the corresponding negative-sequence voltage according to the equation (observe that the voltages in the equation are phasors):
\[ 3 \cdot V_2 = V_A + a^2 \cdot V_B + a \cdot V_C \]

(Equation 27)

Where:

\[ V_A, V_B, \text{and } V_C \]

are the measured phase voltages

\[ a = 1 \cdot e^{\frac{2\pi}{3}} = -0.5 + j\frac{\sqrt{3}}{2} \]

4. Compare the result with the set value of the negative-sequence operating voltage (consider that the set value \(3V_{2PU}\) is in percentage of the base voltage \(V_{Base}\)).

5. Repeat steps 1 and 2. Then slowly increase the measured current in one phase until the BLKV signal disappears.

6. Record the measured current and calculate the corresponding negative-sequence current according to the equation (observe that the currents in the equation are phasors):

\[ 3 \cdot I_2 = I_A + a^2 \cdot I_B + a \cdot I_C \]

(Equation 30)

Where:

\[ I_A, I_B, \text{and } I_C \]

are the measured phase currents

\[ a = 1 \cdot e^{\frac{2\pi}{3}} = -0.5 + j\frac{\sqrt{3}}{2} \]

7. Compare the result with the set value of the negative-sequence operating current. Consider that the set value \(3I_{2<}\) is in percentage of the base current \(I_{Base}\).

### 10.8.2.3 Measuring the trip value for the zero-sequence function

Measure the trip value for the zero-sequence function, if included in the IED.

1. Simulate normal operating conditions with the three-phase currents in phase with their corresponding phase voltages and with all of them equal to their rated values.

2. Slowly decrease the measured voltage in one phase until the BLKV signal appears.

3. Record the measured voltage and calculate the corresponding zero-sequence voltage according to the equation (observe that the voltages in the equation are phasors):

\[ 3 \cdot V_0 = V_A + V_B + V_C \]

(Equation 33)

Where:

\[ V_A, V_B, \text{and } V_C \]

are the measured phase voltages
4. Compare the result with the set value of the zero-sequence tripping voltage (consider that the set value $3V0\text{Pickup}$ is in percentage of the base voltage.)

5. Repeat steps 1 and 2. Then slowly increase the measured current in one phase until the BLKV signal disappears.

6. Record the measured current and calculate the corresponding zero-sequence current according to the equation (observe that the currents in the equation are phasors):

$$3V_0 = V_A + V_B + V_C$$

(Equation 35)

Where:

$V_A$, $V_B$ and $V_C$ are the measured phase voltages.

7. Compare the result with the set value of the zero-sequence trip current. Consider that the set value $3I0< is in percentage of the base current $I_{Base}$.

10.8.2.4 Measuring the trip value for the dead line detection function

1. Apply three-phase voltages with their rated value and zero currents.

2. Decrease the measured voltage in one phase until the DLD1PH signal appears.

3. This is the point at which the dead line condition is detected. Check the value of the decreased voltage with the set value $VDLDPU$ ($VDLDPU$ is in percentage of the base voltage $V_{Base}$).

4. Apply three-phase currents with their rated value and zero voltages.

5. Decrease the measured current in one phase until the DLD1PH signal appears.

6. This is the point at which the dead line condition is detected. Check the value of the decreased current with the set value $IDLDPU$ ($IDLDPU$ is in percentage of the base current $I_{Base}$).

10.8.2.5 Checking the operation of the $dv/dt$ and $di/dt$ based function

Check the operation of the $dv/dt$ and $di/dt$ based function if included in the IED.

1. Simulate normal operating conditions with the three-phase currents in phase with their corresponding phase voltages and with all of them equal to their rated values.

2. Change the voltages and currents in all three phases simultaneously. The voltage change must be higher than the set value $DVPu$ and the current change must be lower than the set value $DIPu$.

   - The BLKV and BLKZ signals appear without any time delay. The BLKZ signal will be activated only if the internal deadline detection is not activated at the same time.
   - $3PH$ should appear after 5 seconds, if the remaining voltage levels are lower than the set $VDLDPU$ of the dead line detection function.

3. Apply normal conditions as in step 1. The BLKV, BLKZ and $3PH$ signals should reset, if activated, see step 1 and 2.

4. Change the voltages and currents in all three phases simultaneously. The voltage change must be higher than the set value $DVPu$ and the current change must be higher than the set value $DIPu$. 
The BLKV, BLKZ and 3PH signals should not appear.

5. Repeat step 2.
6. Connect the nominal voltages in all three phases and feed a current below the trip level in all three phases.
7. Keep the current constant. Disconnect the voltage in all three phases simultaneously. The BLKV, BLKZ and 3PH signals should not appear.
8. Change the magnitude of the voltage and current for phase 1 to a value higher than the set value $DVPU$ and $DIPU$.
9. Check that the pickup output signals PU_DV_A and PU_DI_A and the general pickup signals PU_DV or PU_DI are activated.
10. Check that the pickup output signals for the current and voltage phases 2 and 3 are activated by changing the magnitude of the voltage and current for phases 2 and 3.

10.8.2.6 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.8.3 Fuse failure supervision

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

Checking the operation of binary input and output

1. Simulate normal operation conditions with three-phase voltage on the main fuse group and the pilot fuse group. Ensure the values are equal to their rated values.
2. Disconnect one of the phase voltage from the main fuse group or the pilot fuse group. Observe the binary outputs of the IED. The MAINFUF or the PILOTFUF signals are simultaneously activated. Only the output circuit related to the open phase will be active i.e either MAINFUF or PILOTFUF.
3. Establish a normal voltage operating condition and observe the corresponding output signals. MAINFUF or PILOTFUF should change to 0 in about 27 ms.
4. Set normal conditions as mentioned in step 1.
5. Enable the BLOCK binary input and repeat step 2. MAINFUF or PILOTFUF should not appear.

Checking the operation of MAINFUF and PILOTFUF

1. Simulate normal operation conditions with three-phase voltage on the main fuse group and the pilot fuse group. Ensure the values are equal to their rated values.
2. Decrease one of the three-phase voltages on main fuse group or pilot fuse group. The voltage change must be greater than the set value for $Vdif \text{ Main block}$ or $Vdif \text{ Pilot alarm}$. MAINFUF or PILOTFUF signals are activated without any time delay.
3. Set normal conditions as mentioned in step 1. MAINFUF or PILOTFUF signals should reset.
4. Set SealIn to On, $Vdif \text{ Main block}$ to 20% of $VBase$ and $VSealIn$ to 70% of $VBase$.
5. Apply three-phase voltages with the value slightly below $VSealIn$ level.
6. Decrease one of the three-phase voltages on main fuse group. The voltage change must be greater than the set value for $Vdif \text{ Main block}$. MAINFUF signal is activated.
7. After more than 5 seconds increase the measured voltage back to the value slightly below \( V_{SealIn} \) level. MAINFUF signal should not reset.
8. Slowly increase measured voltage to the value slightly above \( V_{SealIn} \) until MAINFUF signal resets.
9. Record the measured voltage and compare with the set value \( V_{SealIn} \).

10.8.3.1 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.9 Control

10.9.1 Synchrocheck, energizing check, and synchronizing SESRSYN (25)

This section contains instructions on how to test the synchrocheck synchronism check, energizing check, and synchronizing function SESRSYN (25) for single, double and breaker-and-a-half arrangements.

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

At commissioning and periodical checks, the functions shall be tested with the used settings. To test a specific function, it might be necessary to change some setting parameters, for example:

- \( \text{AutoEnerg} = \text{Disabled/ DLLB/ DBLL/ Both} \)
- \( \text{ManEnerg} = \text{Disabled} \)
- \( \text{Operation} = \text{Disabled/ Enabled} \)
- Activation of the voltage selection function if applicable

The tests explained in the test procedures below describe the settings, which can be used as references during testing before the final settings are specified. After testing, restore the equipment to the normal or desired settings.

A secondary injection test set with the possibility to alter the phase angle and amplitude of the voltage is needed. The test set must also be able to generate different frequencies on different outputs.

The description below applies for a system with a nominal frequency of 60 Hz but can be directly applicable to 50 Hz. SESRSYN (25) can be set to use different phases, phase to ground or phase to phase. Use the set voltages instead of what is indicated below.

Figure 21 shows the general test connection principle, which can be used during testing. This description describes the test of the version intended for one bay.

Figure 22 shows the general test connection for a breaker-and-a-half diameter with one-phase voltage connected to the line side.
Figure 21: General test connection with three-phase voltage connected to the line side

Figure 22: General test connection for a breaker-and-a-half diameter with one-phase voltage connected to the line side

10.9.1.1 Testing the synchronizing function

The voltage inputs used are:
Testing the frequency difference
The frequency difference test should verify that operation is achieved when the frequency difference between bus and line is less than set value of $F_{reqDiffMax}$ and above set value of $F_{reqDiffMin}$. The test procedure below will depend on the settings used. Input STARTSYN must be activated during the test.

$F_{reqDiffMax} = 50.2$ Hz

$F_{reqDiffMin} = 50.01$ Hz

t_breaker = 0.080 s

1. Apply voltages
   1.1. V-Line = 100% $V_{BaseLine}$ and f-Line = 60.0 Hz
   1.2. V-Bus = 100% $V_{BaseBus}$ and f-Bus = 60.15 Hz

2. Check that a closing pulse is submitted at a closing angle equal to calculated phase angle value from the formula below. Modern test sets will evaluate this automatically.
   \[
   \text{Closing Angle} = |( (f_{Bus} - f_{Line}) \times t_{Breaker} \times 360 \text{ degrees}) |
   \]
   \[f_{Bus} = \text{Bus frequency}\]
   \[f_{Line} = \text{Line frequency}\]
   \[t_{Breaker} = \text{Set closing time of the breaker}\]

3. Repeat with
   3.1. V-Bus = 100% $V_{BaseBus}$ and f-bus = 60.25 Hz, to verify that the function does not trip when frequency difference is above limit.

4. Verify that the closing command is not issued when the frequency difference is less than the set value $F_{reqDiffMin}$.

10.9.1.2 Testing the synchrocheck check

During the test of SESRSYN (25) for a single bay arrangement, these voltage inputs are used:

V-Line VA, VB or VC line 1 voltage input on the IED according to the connection in SMT
V-Bus V5 voltage input on the IED according to the connection in SMT

Testing the voltage difference
Set the voltage difference to 0.15 p.u. on the local HMI, and the test should check that operation is achieved when the voltage difference $V_{DiffSC}$ is lower than 0.15 p.u.

The settings used in the test shall be final settings. The test shall be adapted to site setting values instead of values in the example below.

Test with no voltage difference between the inputs.

Test with a voltage difference higher than the set $V_{DiffSC}$. 

Commissioning manual
1. **Apply voltages V-Line (for example) = 80% GblBaseSelLine and V-Bus = 80% GblBaseSelBusGblBaseSelBus with the same phase-angle and frequency.**
2. **Check that the AUTOSYOK and MANSYOK outputs are activated.**
3. The test can be repeated with different voltage values to verify that the function trips within the set VDiffSC. Check with both V-Line and V-Bus respectively lower than the other.
4. Increase the V-Bus to 110% GblBaseSelBus, and the V-Line = 90% GblBaseSelLine and also the opposite condition.
5. **Check that the two outputs for manual and auto synchronism are not activated.**

**Testing the phase angle difference**

The phase angle differences PhaseDiffM and PhaseDiffA respectively are set to their final settings and the test should verify that operation is achieved when the phase angle difference is lower than this value both leading and lagging.

Test with no voltage difference.

1. **Apply voltages V-Line (for example) = 100% GblBaseSelLine and V-Bus = 100% GblBaseSelBus, with a phase difference equal to 0 degrees and a frequency difference lower than FreqDiffA and FreqDiffM.**
2. **Check that the AUTOSYOK and MANSYOK outputs are activated.**

The test can be repeated with other phase difference values to verify that the function trips for values lower than the set ones, PhaseDiffM and PhaseDiffA. By changing the phase angle on the voltage connected to V-Bus, between ± dφ degrees, the user can check that the two outputs are activated for a phase difference lower than the set value. It should not trip for other values. See figure 23.

![Phase angle difference diagram](en05000551_ansi.vsd)

**Figure 23: Test of phase difference**

3. Change the phase angle between +dφ and -dφ and verify that the two outputs are activated for phase differences between these values but not for phase differences outside, see figure 23.

**Testing the frequency difference**

The frequency difference test should verify that operation is achieved when the FreqDiffA and FreqDiffM frequency difference is lower than the set value for manual and auto synchronizing check, FreqDiffA and FreqDiffM respectively and that operation is blocked when the frequency difference is greater.

Test with frequency difference = 0 mHz
Test with a frequency difference outside the set limits for manual and auto synchronizing check respectively.

1. Apply voltages V-Line equal to 100% $GblBaseSelLine$ and V-Bus equal to 100% $GblBaseSelBus$, with a frequency difference equal to 0 mHz and a phase difference lower than the set value.
2. Check that the AUTOSYOK and MANSYOK outputs are activated.
3. Apply voltage to the V-Line equal to 100% $GblBaseSelLine$ with a frequency equal to 50 Hz and voltage V-Bus equal to 100% $GblBaseSelBus$, with a frequency outside the set limit.
4. Check that the two outputs are not activated. The test can be repeated with different frequency values to verify that the function trips for values lower than the set ones. If a modern test set is used, the frequency can be changed continuously.

**Testing the reference voltage**

1. Use the same basic test connection as in figure 21. The voltage difference between the voltage connected to V-Bus and V-Line should be 0%, so that the AUTOSYOK and MANSYOK outputs are activated first.
2. Change the V-Line voltage connection to V-Line2 without changing the setting on the local HMI. Check that the two outputs are not activated.

**10.9.1.3 Testing the energizing check**

During the test of the energizing check function for a single bay arrangement, these voltage inputs are used:

- **V-Line**: VA, VB or VC line1 voltage inputs on the IED
- **V-Bus**: Bus voltage input on the IED

**General**

When testing the energizing check function for the applicable bus, arrangement shall be done for the energizing check functions. The voltage is selected by activation of different inputs in the voltage selection logic.

Live voltage level is fixed to 80% $VBase$ and dead voltage level to fixed 40% $VBase$.

The test shall be performed according to the settings for the station. Test the alternatives below that are applicable.

**Testing the dead line live bus (DLLB)**

The test should verify that the energizing check function trips for a low voltage on the V-Line and for a high voltage on the V-Bus. This corresponds to the energizing of a dead line to a live bus.

1. Apply a single-phase voltage 100% $GblBaseSelBus$ to the V-Bus, and a single-phase voltage 30% $GblBaseSelLine$ to the V-Line.
2. Check that the AUTOENOK and MANENOK outputs are activated after set $tAutoEnerg$ respectively $tManEnerg$.
3. Increase the V-Line to 60% $GblBaseSelLine$ and V-Bus to be equal to 100% $GblBaseSelBus$. The outputs should not be activated.
4. The test can be repeated with different values on the V-Bus and the V-Line.
Testing the dead bus live line (DBLL)
The test should verify that the energizing check function trips for a low voltage on the V-Bus and for a high voltage on the V-Line. This corresponds to an energizing of a dead bus to a live line.

1. Verify the settings AutoEnerg or ManEnerg to be DBLL.
2. Apply a single-phase voltage of 30% GblBaseSelBus to the V-Bus and a single-phase voltage of 100% GblBaseSelLine to the V-Line.
3. Check that the AUTOENOK and MANENOK outputs are activated after set tAutoEnerg respectively tManEnerg.
4. Decrease the V-Line to 60% GblBaseSelLine and keep the V-Bus equal to 30% GblBaseSelBus. The outputs should not be activated.
5. The test can be repeated with different values on the V-Bus and the V-Line.

Testing both directions (DLLB or DBLL)

1. Verify the local HMI settings AutoEnerg or ManEnerg to be Both.
2. Apply a single-phase voltage of 30% GblBaseSelLine to the V-Line and a single-phase voltage of 100% GblBaseSelBus to the V-Bus.
3. Check that the AUTOENOK and MANENOK outputs are activated after set tAutoEnerg respectively tManEnerg.
4. Change the connection so that the V-Line is equal to 100% GblBaseSelLine and the V-Bus is equal to 30% GblBaseSelBus. The outputs should still be activated.
5. The test can be repeated with different values on the V-Bus and the V-Line.

Testing the dead bus dead line (DBDL)
The test should verify that the energizing check function trips for a low voltage on both the V-Bus and the V-Line, that is, closing of the breaker in a non-energized system. Test is valid only when this function is used.

1. Verify the local HMI setting AutoEnerg to be Disabled and ManEnerg to be DBLL.
2. Set the parameter ManEnergDBDL to Enabled.
3. Apply a single-phase voltage of 30% GblBaseSelBus to the V-Bus and a single-phase voltage of 30% GblBaseSelLine to the V-Line.
4. Check that the MANENOK output is activated after set tManEnerg.
5. Increase the V-Bus to 80% GblBaseSelBus and keep the V-Line equal to 30% GblBaseSelLine. The outputs should not be activated.
6. Repeat the test with ManEnerg set to DLLB with different values on the V-Bus and the V-Line voltage.

10.9.1.4 Testing the voltage selection

Testing the voltage selection for single CB arrangements
This test should verify that the correct voltage is selected for the measurement in the SESRSYN function used in a double-bus arrangement. Apply a single-phase voltage of 100% GblBaseSelLine to the V-Line and a single-phase voltage of 100% GblBaseSelBus to the V-Bus.

If the VB1/2OK inputs for the fuse failure are used, they must be activated, during tests below. Also verify that deactivation prevents operation and gives an alarm.
1. Connect the signals above to binary inputs and binary outputs.
2. Connect the voltage inputs to the analog inputs used for each bus or line depending of the type of busbar arrangement and verify that correct output signals are generated.

**Testing the voltage selection for double breaker**

This test should verify that correct voltage is selected for the measurement in the SESRSYN function used for a diameter in a Breaker-and-a-half arrangement. Apply a single-phase voltage of 100% GblBaseSelLine to the V-Line and a single-phase voltage of 100% GblBaseSelBus to the V-Bus. Verify that correct output signals are generated.

1. Connect the analog signals to the voltage inputs, in pair of two for V1 and V2. (Inputs V3PB1, V3PB2, V3PL1, V3PL2)
2. Activate the binary signals according to the used alternative. Verify the measuring voltage on the synchronizing check function SESRSYN (25). Normally it can be good to verify synchronizing check with the same voltages and phase angles on both voltages. The voltages should be verified to be available when selected and not available when another input is activated so connect only one voltage transformer reference at each time.
3. Record the voltage selection tests in a matrix table showing read values and AUTOSYOK/MANSYOK signals to document the test performed.

**Testing the voltage selection for 1 1/2 CB arrangements**

At test of the SESRSYN (25) function for a breaker-and-a-half diameter the following alternative voltage inputs can be used for the three SESRSYN (SESRSYN 1, SESRSYN 2, SESRSYN 3) functions. These three SESRSYN functions can either be in one, two or three different IEDs. Table 18 describes the scenario when SESRSYN 1, SESRSYN 2 and SESRSYN 3 all are in the same IED. If SESRSYN 3 is in another IED, WA1 will be considered as WA2 and LINE2 as LINE1. The voltage is selected by activation of different inputs in the voltage selection logic as shown in table 18 and figure 24.

**10.9.1.5 Completing the test**

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

**10.9.2 Autorecloser for 1/2/3-phase operation SMBRREG (79)**

Verification of the Autorecloser for 1/2/3-phase operation function SMBRREC (79) for single-phase, two-phase or three-phase reclosing attempts can be considered to consist of two parts.
• One part to verify the internal logic and timing of the function
• One part to verify its interaction with the protection system

This section deals with verification of SMBRREC (79) itself. However, it is practical to initiate SMBRREC (79) by activating a protection function, for example, by secondary injection tests.

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

The purpose of verification before commissioning is to check that entered selections, setting parameters and configuration render the intended result. The function is flexible with many options and facilities. At commissioning only the selections and settings intended for use are verified. If one chooses to reduce some time settings in order to speed up verification, be careful to set the parameters at intended operational values at the end of the verification procedure. One such parameter is the $t_{Reset}$ time that must be timed out before a new test sequence can be performed.

The verification test is performed together with protection and trip functions. Figure 25 illustrates a suggested testing arrangement, where the circuit-breaker (CB) is simulated by an external bi-stable relay (BR), for example a relay type RXMVB2 or RXMD or Breaker Simulator of ABB. The following manual switches are used:

• Switch or push-button to close (SC)
• Switch or push-button to trip (ST)
• Switch for CB ready condition (SRY)

If no bi-stable relay or breaker simulator is available, replace it with two self-reset auxiliary relays and use a self-holding connection.

Use a secondary injection IED test set to trip the protection function. The test set shall be switched off when a trip signal is given or when the BR comes to open position to simulate real conditions.

The CB simulation can be made more elaborate, including simulation of the operating gear condition, CBREADY of either the type ready for a Close-Open (CO) cycle, or the type ready for an Open-Close -Open (OCO) cycle.

The CB condition CBREADY of a type, CO, shall be high (true) until a closing operation is performed. It then goes low (false) for a recharging time of about 5 - 10s. After that it is high again.

A CB condition CBREADY of a type, OCO shall be high (true) before and during tripping (Initiate reclosing). During tripping it goes low for a recharging time, for example, 10s. It may thus be low at the instant of reclosing. After each Open or Close operation it may need a recharging period before it goes high again.

In the example of CB simulation arrangement, the CBREADY condition is simulated by a manual switch, SRY.

Information and material for the verification:

• Protection or control unit, IED, configured and with settings entered.
• Configuration diagram for the IED
• Terminal diagram for the IED, or plant circuit diagram including the IED
• Technical reference manual for the IED
• IED test set for secondary injection
- Means to indicate, measure and record operation and times, for example an event recording facility
- A bi-stable relay (BR) or two auxiliary relays to simulate a CB
- Two push-buttons (SC, ST) to operate the BR and a change-over switch (SRY) to simulate CBREADY
- Possibly a switch simulation the synchronizing check SESRSYN (25) condition

Figure 25: Simulating the CB operation by a bi-stable relay/breaker simulator and manual switches

10.9.2.1 Preparation of the verification

1. Check the function settings on the local HMI under **Main menu/Settings/Setting group N/Control/Autorecloser79.5(0→1)/SMBRREC**:x
If any timer settings are reduced to speed up or facilitate the testing, they shall be set to normal after testing. A temporary label on the IED can be a reminder to restore normal settings after which a verification test should be performed.

2. Decide if a synchronizing check function SESRSYN (25) shall be included in the test. If SESRSYN (25) as an internal function or external device is not operated by the injection, input signal SYNC must be connected as a permanent high signal or controlled by a switch.

3. Read and make notes of the reclosing operation counters on the local HMI under Main menu/Test/Function status/Control/AutoRecloser79,5(0->1)/SMBRREC:x Possibly reset the counters to Zero. Counters are reset in the reset menu.

4. Make arrangements for the simulation of the CB, for example as in figure 25.

5. Make arrangements for indication, recording and time measurements. The signals for ,52a, RI, CLOSECMD, READY and other relevant signals should preferably be arranged for event recording with time tagging. If that is not possible, other means of time measurement and recording should be arranged.

10.9.2.2 Switching the autorecloser for 1/2/3-phase operation function to Enabled and Disabled

1. Set the Operation setting to Disabled and check the state.
2. Set the Operation setting to Enabled and check the state, including SETON and READY. The CB should be closed and ready.
3. If external control inputs OFF/ON are used, check that they work. Set ExternalCtrl = On and use the control inputs to switch On and Off, and check the state of the function.

10.9.2.3 Verifying the autorecloser function SMBRREC (79)

Select the test cases to be run according to what is applicable to the particular application. It can be, for example,

- three-phase single-shot reclosing
- two-shot reclosing
- single-phase and three-phase single-shot reclosing

Below, a case with single-phase and three-phase single-shot reclosing is described.

1. Set Operation = Enabled.
2. If the synchronizing check SESRSYN (25) is not to be operated, ensure that the signal SYNC input is activated. If SESRSYN (25) is to be included, ensure that it is supplied with the appropriate AC quantities.
3. Simulate CB closed position by closing switch SC to make the BR relay pick-up.
4. Simulate CBREADY by closing the switch SRY, and leave it closed.
5. Inject AC quantities to give a trip, for example, a one-pole trip, to the BR and to the RI input. Observe and preferably record the operation. The BR relay shall trip and reclose (pick-up). After reclosing, the SRY switch can be opened for about 5s and then closed again. The autoreclosing open time and the sequence should be checked, for example in the event recording. Check also the operation indications (disturbance report) and the operation counters on the local HMI under Main menu/Test/Function status/Control/AutoRecloser79,5(0->1)/SMBRREC:x

Should the operation not be as expected, this should be investigated. It could be caused by an inappropriate setting or missing condition such as CBREADY.
6. Repeat the sequence by simulating a permanent fault.
Shortly after the reclosing shot, a new fault is applied. If a single-shot reclosing program is selected, there shall be one reclosing operation and then blocking of SMBREC (79) for the set Reset time.
Before a new reclosing sequence can be run, the CBREADY and 52a (CB closed) must be set manually.

7. Repeat the sequence by simulating a three-phase transient and permanent faults, and other applicable cases, such as signal to RI_HS and high-speed reclosing.
   If just single-phase reclosing is selected, FirstShot = 1ph, a check can be run to make sure that a three-pole trip does not result in any reclosing. Other similar cases can be checked as required.

10.9.2.4 Checking the reclosing conditions

When checking the influence of a releasing condition it is suggested to first run a sequence with the condition fulfilled. When the condition signal is removed, and a new sequence is run, it indicates that the result was due to the changed condition. In case of a blocking signal the procedure should be similar. Start without the blocking or inhibit signal, and then run a sequence with the blocking or inhibit signal added.

Checking the influence of the INHIBIT signal

1. Check that the autorecloser function SMBREC (79) is operative, for example, by making a reclosing shot without the INHIBIT signal.
2. Apply a fault and thereby a RI signal. At the same time, or during the open time, apply a signal to the input INHIBIT.
3. Check that the reclosing sequence is interrupted and no reclosing takes place.

Check closing onto a fault

1. Check that the autorecloser function SMBREC (79) is operative, for example by making a reclosing shot. Keep the CBREADY signal high.
2. Set the breaker simulating relay BR in Open position.
3. Close the BR relay and apply immediately a fault and thereby a RI signal.
4. Check that no reclosing takes place.

Checking the influence of CB not ready for reclosing

1. Check that the autorecloser function SMBREC (79) is operative, for example by making a reclosing shot. Keep the CB simulator BR closed. Remove the CBREADY signal by opening SRY.
2. Apply a fault and thereby a RI signal.
3. Check that no reclosing takes place.

Checking the influence of synchronizing check (at three-pole reclosing)

1. Check that the autorecloser function SMBREC (79) is operative, for example, by making a three-pole reclosing shot with the SESRSYN (25)synchronizing check condition. Set the SESRSYN (25) function to Off to eliminate the signal connected to input signalSYNC.
2. Apply a fault causing three-phase trip and thereby a RI and a TR3P signal.
3. Wait for the tSync time-out limit.
   Check that no reclosing is made.
**Checking the response when autoreclosing is Off**

*Procedure*

1. Check that the autorecloser function SMBRREC (79) is operative, for example by making a reclosing shot.
   Set the autoreclosing operation to *Off*, for example by external control.
   The output READY shall be low, and PREP3P shall be high.
2. Apply a single phase fault and thereby a RI signal.
3. Check that a definitive three phase trip and no reclosing takes place.

**Testing autoreclosing in a multi-breaker arrangement**

The usual arrangement is to have an autorecloser function SMBRREC (79) per circuit-breaker. They can be in different CB related IEDs or in a common IED.

- A master SMBRREC (79) function is set with *Priority = High*.
- A slave SMBRREC (79) function is set with *Priority = Low*.

See the application manual for an illustration of typical interconnections.

The two functions can be checked individually by carefully applying RI, WAIT, and INHIBIT signals.

It is also possible to verify the two functions together by using CB simulating equipment for two CB circuits. There should be interconnections from the master to the slave function, WFMASTER - WAIT, and UNSUCCCL - INHIBIT, as shown in the illustration referred to above.

**Restoring equipment**

After the tests, restore the equipment to normal or desired state. Check the following items in particular:

1. Check the operation counters.
   Reset the counters to zero, if that is the user’s preference. The counter reset function is found on the local HMI under **Main menu/Reset/Reset counters/AutoRecloser79,5(0-->1)/SMBRREC:**
2. Restore settings that may have been modified for the tests back to normal.
3. Disconnect the test switch, CB simulating arrangement and test circuits.
   Reconnect any links or connection terminals, which may have been opened for the tests.
4. Reset indications, alarms and disturbance recordings.
   Clearing of the disturbance report can be done via the Disturbance Handling in PCM600 or the local HMI.

**10.9.2.5 Completing the test**

Continue to test another function or end the test by changing the *TestMode* setting to *Disabled*. Restore connections and settings to their original values, if they were changed for testing purposes.
10.9.3 Apparatus control APC

The apparatus control function consists of four types of function blocks, which are connected in a delivery-specific way between bays and to the station level. For that reason, test the total function in a system, that is, either in a complete delivery system as an acceptance test (FAT/SAT) or as parts of that system.

If a block/unblock command is sent from remote to function, while the IED is shut down, this command will not be recognized after the start up, thus the command that was sent prior to the shut down is used. In such cases, where there is a mismatch, the user is advised to make a complete cycle of block/unblock operations to align the statuses.

10.9.4 Voltage control TR1ATCC, TR8ATCC, TCMYLTC, TCLYLTC

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

The automatic voltage control for tap changer, single control TR1ATCC (90) is based on a transformer configuration that consists of one tap changer on a single two-winding power transformer.

The automatic voltage control for tap changer, parallel control TR8ATCC (90), if installed, may be set to operate in Master Follower (MF) mode, or Minimise Circulating Current (MCC) mode. The commissioning tests for each parallel control mode are addressed separately in the following procedure.

Secondary injection of load current \(I_L\) and secondary bus voltage \(U_B\) equivalent quantities are required during installation and commissioning tests. The test consists mainly of:

1. Increasing or decreasing the injected voltage or current at the analogue inputs of the IED.
2. Checking that the corresponding commands (Lower or Raise) are issued by the voltage control function.

Setting confirmation is an important step for voltage control in the installation and commissioning phase to ensure consistency of power systems base quantities, alarm/blocking conditions and parallel control settings for each transformer control function.

Before starting any test, verify the following settings in PCM600 or the local HMI for TR1ATCC (90), TR8ATCC (90) and TCMYLTC (84) and TCLYLTC (84).

- Confirm power system base quantities \(I1Base, I2Base, VBase\).

Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/General

and

Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x
• Confirm that the setting for short circuit impedance $X_{r2}$ for TR1ATCC (90) or TR8ATCC (90) is in accordance with transformer data:
  - Short circuit impedance, available on the local HMI under Main menu/Settings/IED settings/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/$X_{r2}$.

• Confirm that the setting for TCMYLTC (84) or TCLYLTC (84) is in accordance with transformer data:
  - Tap change timeout duration - effectively the maximum transformer tap change time, $t_{TCTimeout}$, available on the local HMI under Main menu/Settings/IED Settings/Control/TransformerTapControl(YLTC,84)/TCMYLTC:x/TCLYLTC:x/$t_{TCTimeout}$.
  - Load tap changer pulse duration - required length of pulse from IED to load tap changer, $t_{PulseDur}$, available on the local HMI under Main menu/Settings/IED Settings/Control/TransformerTapControl(YLTC,84)/TCMYLTC:x/TCLYLTC:x/$t_{PulseDur}$.
  - Transformer tap range, $LowVoltTap$ and $HighVoltTap$, available on the local HMI under Main menu/Settings/IED Settings/Control/TransformerTapControl(YLTC,84)/TCMYLTC:x/TCLYLTC:x/$LowVoltTap$ and $HighVoltTap$.
  - Load tap changer code type - method for digital feedback of tap position, $CodeType$, available on the local HMI under Main menu/Settings/IED settings/Control/TransformerTapControl(YLTC,84)/TCMYLTC:x/TCLYLTC:x/$CodeType$.

During the installation and commissioning, the behavior of the voltage control functions for different tests may be governed by a parameter group, available on the local HMI under Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x. These parameter settings can cause a Total Block, Automatic Block or Alarm for a variety of system conditions including over and under voltage, over current and tap changer failure. It is important to review these settings and confirm the intended response of the voltage control function for different secondary injection tests.

**Terminology**

The busbar voltage $V_B$ is a shorter notation for the measured voltages $V_a$, $V_b$, $V_c$ or $V_{ij}$, where $V_{ij}$ is the phase-phase voltage, $V_{ij} = V_i - V_j$, or $V_i$, where $V_i$ is one single-phase-to-ground voltage.

$I_L$ is a shorter notation for the measured load current; it is to be used instead of the three-phase quantities $I_a$, $I_b$, $I_c$ or the two-phase quantities $I_i$ and $I_j$, or single-phase current $I_i$.

Also note that for simplicity, the Parameter Setting menu structures included in the following procedure are referred to universally as VCP1, for example, Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/Time/t1 and t2l.

For cases where single-mode voltage control is implemented, the Parameter Setting menu structure includes TR1ATCC:1 instead of the parallel designator TR8ATCC:1.

**10.9.4.1 Secondary test**

The voltage control function performs basic voltage regulation by comparing a calculated load voltage ($V_L$) against a voltage range defined by setting $V_{Deadband}$ (with upper and lower limits $V_2$ and $V_1$ respectively). The calculated load voltage $V_L$ represents the secondary transformer bus voltage $V_B$ adjusted for Load drop compensation (LDC) where enabled in settings.
Note that when LDC is disabled, \( V_B \) equals \( V_L \).

When the load voltage \( V_L \) stays within the interval between \( V1 \) and \( V2 \), no action will be taken.

If \( V_L < V1 \) or \( V_L > V2 \), a command timer will pickup, which is constant time or inverse time defined by setting \( t1 \) and \( t1Use \). The command timer will trip while the measured voltage stays outside the inner deadband (defined by setting \( VDeadbandInner \)).

If \( V_L \) remains outside of the voltage range defined by \( VDeadband \) and the command timer expires, the voltage control will execute a raise or lower command to the transformer tap changer. This command sequence will be repeated until \( V_L \) is brought back within the inner deadband range.

### 10.9.4.2 Check the activation of the voltage control operation

1. **Confirm Transformer Tap Control = Enable and Transformer Voltage Control = Enable**
   - Direct tap change control
     
     Main menu/Settings/IED Settings/Control/TransformerTapChanger(YLTC,84)/TCMYLTxC:TCLYLTC:x/Operation
   - Automatic transformer voltage control
     
     Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/General/Operation
   - Enable Tap Command
     
     Main menu/Settings/IED Settings/Control/TransformerTapChanger(YLTC,84)/TCMYLTxC:TCLYLTC:x/EnabTapCmd

   While the test set is connected to the IED but no voltage is applied, the voltage control functions will detect an undervoltage condition that may result in an alarm or blocking of the voltage-control operation. These conditions will be shown on the local HMI.

2. **Apply the corresponding voltage**
   
   Confirm the analog measuring mode prior to undertaking secondary injection (positive sequence, phase-to-phase, or phase-to-ground). This measuring mode is defined in the local HMI under **Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/General/MeasMode**

   The application of nominal voltage \( VSet \) according to set **MeasMode** to the IEDs should cause the alarm or blocking condition for undervoltage to reset.

### 10.9.4.3 Check the normal voltage regulation function
1. Review the settings for $V_{\text{Deadband}}$ (based on percentage of nominal bus voltage) and calculate the upper ($V_2$) and lower ($V_1$) voltage regulation limits for which a tap change command will be issued.

2. Review the expected time for first ($t_1$) and subsequent ($t_2$) tap change commands from the voltage control function on the local HMI under Main menu/Settings/Setting Group N/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/Time/t1 and t2!

3. Lower the voltage $1\%$ below $V_1$ and wait for the issue of a Raise command from the voltage control after the expiry of a constant or inverse time delay set by $t_1$. Detection of this command will involve locating the allocated binary output for a raise pulse command in the Signal Matrix in PCM600 and monitoring a positive from this output.

4. After the issue of the raise command, return the applied voltage to $V_{\text{Set}}$ (nominal value).

5. Raise the voltage $1\%$ above the upper deadband limit $V_2$ and wait for the issue of a lower command from the voltage control after the expiry of a constant or inverse time delay set by $t_1$. Detection of this command will involve locating the allocated binary output for a low pulse command in the Signal Matrix in PCM600 and monitoring a positive from this output.

6. Return the applied voltage to $V_{\text{Set}}$.

### 10.9.4.4 Check the undervoltage block function

1. Confirm the setting for $V_{\text{block}}$, nominally at $80\%$ of rated voltage.

2. Confirm the voltage control function response to an applied voltage below $V_{\text{block}}$, by reviewing the setting in the local HMI under Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/UVBk that may cause an alarm, total or automatic block of the voltage control function to be displayed on the local HMI.

3. Apply a voltage slightly below $V_{\text{block}}$ and confirm the response of the voltage control function.

### 10.9.4.5 Check the upper and lower busbar voltage limit

1. Confirm the settings for $V_{\text{min}}$ and $V_{\text{max}}$ in the local HMI under Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/Voltage/Um or Umin and Main menu/Settings/IED Settings/Control/TR8ATCC (90)/TR8ATCC:n/Voltage/Umax

2. Confirm the voltage control function response to an applied voltage below $V_{\text{min}}$ and above $V_{\text{max}}$, by reviewing the settings in the local HMI under Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/UVPartBk and Main menu/IED Settings/Control/TransformerVoltageControl/TR1ATCC:x/TR8ATCC:x/OVPartBk. These conditions may cause an alarm or total block of the voltage control function to be displayed on the local HMI.

3. Decrease the injected voltage slightly below the $V_{\text{min}}$ value and check for the corresponding blocking or alarm condition on the local HMI. For an alarm condition, the voltage regulation function is not blocked and a raise command should be issued from the IED.

4. Increase the applied voltage slightly above the $V_{\text{max}}$ value and check for the corresponding blocking or alarm condition on the local HMI. For an alarm condition, the voltage regulation function is not blocked and a lower command should be issued from the IED.

### 10.9.4.6 Check the overcurrent block function
1. Confirm the setting for \( I_{block} \) in the local HMI under **Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,91)/TR1ATCC:x/TR8ATCC:x/TCCtrl/Iblock**

2. Confirm the voltage control function response to an applied current above \( I_{block} \), by reviewing the settings in the local HMI under **Main menu/Settings/IED Settings/Control/TransformerVoltageControl(ATCC,91)/TR1ATCC:x/TR8ATCC:x/OVPartBk**. This condition may cause an alarm or total block of the voltage control function to be displayed on the local HMI.

3. Inject a current higher than the \( I_{block} \) setting and confirm the alarm or blocking condition is present on the local HMI. If an automatic or total blocking condition occurs, change the applied secondary voltage and confirm that no tap change commands are issued from the associated binary outputs. This situation can also be confirmed through reviewing the disturbance and service reports on the local HMI.

### 10.9.4.7 Single transformer

#### Load drop compensation

1. Confirm that \( OperationLDC \) is set to **Enabled**.
2. Confirm settings for \( R_{line} \) and \( X_{line} \).
3. Calculate the expected load voltage \( V_L \) (displayed as a measured value on the local HMI) based on secondary injection of transformer secondary voltage \( (V_B = V_{Set}) \) and rated load current \( (I_L = I_{1Base}) \), in accordance with equation 37.

\[
V_L = V_B - (R_{line} + jX_{line}) \cdot I_L
\]

(Equation 37)

where:

\( V_L, I_L = \text{Re}(I_L) + j\text{Im}(I_L) \) are complex phase quantities

When all secondary phase-to-ground voltages are available, use the positive-sequence components of voltage and current. By separation of real and imaginary parts:

\[
V_L = v_L, \text{re} = v_B, \text{re} - r_{line} \cdot i_L, \text{re} + x_{line} \cdot i_L, \text{re}
\]

(Equation 38)

\[
V_L, \text{im} = v_L, \text{im} - x_{line} \cdot i_L, \text{re} - r_{line} \cdot i_L, \text{im}
\]

(Equation 39)

where:

\( v_B \) is the complex value of the busbar voltage

\( i_L \) is the complex value of the line current (secondary side)

\( r_{line} \) is the value of the line resistance

\( x_{line} \) is the value of the line reactance
For comparison with the set-point value, the modulus of $U_L$ are according to equation 40.

\[ |V_L| = \sqrt{(v_L, re)^2 + (v_L, im)^2} \]

(Equation 40)

4. Inject voltage for $V_B$ equal to setting $V_{Set}$.
5. Inject current equal to rated current $I_{2Base}$.
6. Confirm on the local HMI that service values for bus voltage and load current are equal to injected quantities.
7. Confirm that the calculated value for load voltage, displayed on the local HMI, is equal to that derived through hand calculations.
8. When setting $OperationLDC$ set to Enabled, the voltage regulation algorithm uses the calculated value for load voltage as the regulating quantity to compare against $V_{Set}$ and the voltage deadband limits $V_{Deadband}$ and $V_{DeadbandInner}$.
9. While injecting rated current $I_{2Base}$ into the IED, inject a quantity for $V_B$ that is slightly higher than $V_{Set} + |(R_{line} + jX_{Line}) \cdot I_L|$. This will ensure that the regulating voltage $V_L$ is higher than $V_{Set}$, and hence no tap change command should be issued from the IED.
10. Reduce the injected voltage for $V_B$ slightly below $V_{Set} + |(R_{line} + jX_{Line}) \cdot I_L|$ and confirm that the calculated value for load voltage is below $V_{Set}$ and a tap change command is issued from the IED.

10.9.4.8 Parallel voltage regulation

Master follower voltage regulation

1. For the transformers connected in the parallel group, confirm that $OperationPAR$ is set to $MF$.
2. For parallel operation, it is also recommended to confirm for parallel group membership, defined by setting $TnRXOP$ in the local HMI under Main menu/Settings/Setting group N/Control/TransformerVoltageControl(ATCC,90)/TR8ATCC:x/ParCtrl

The general parallel arrangement of transformers are defined by setting $TnRXOP$ to $Enabled$ or $Disabled$. The following rules are applicable on the settings $T1RXOP$ – $T4RXOP$.

If IED $T1$ and $T2$ are connected,
- $T1RXOP$ shall be set to $Enabled$ in instance 2 of TR8ATCC (90),
- $T2RXOP$ shall be set to $Enabled$ in instance 3 of TR8ATCC (90),
- $T2RXOP$ and $T3RXOP$ shall be set to $Enabled$ in instance 1 of TR8ATCC (90), and so on.

The parameter corresponding to the own IED must not be set. $T1RXOP$ should thus not be set in IED $T1$, $T2RXOP$ not in IED $T2$, and so on.

3. The lowest transformer number in the parallel group is by default set as the Master – confirm that this is the case by reviewing the setting in the local HMI.
4. Review the settings for $V_{Deadband}$ (based on percentage of nominal bus voltage) and calculate the upper ($V2$) and lower ($V1$) voltage regulation limits for which a tap change command will be issued from the master transformer in the group.
5. Review the expected time for first ($t_1$) and subsequent ($t_2$) tap change commands from the master transformer in the local HMI under Main menu/Settings/Setting group N/Control/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/Time/t1 and t2
6. Apply a voltage 1% below $V1$ and wait for the issue of a raise command from the voltage control after the expiry of a constant or inverse time delay set by $t_1$. Detection of this
command will involve locating the allocated binary output for a raise command in the Signal Matrix in PCM600 and monitoring a positive from this output. Confirm the timing of this command correlates with the setting $t_1$.

7. After the issue of the raise command, confirm that all follower transformers in the group change tap in accordance with the command issued from the master transformer.

8. Inject a voltage $V_B$ for the master transformer that is 1% above the upper deadband limit $V_2$ and wait for the issue of a lower command from the voltage control after the expiry of a constant or inverse time delay set by $t_2$.

9. Confirm that all follower transformers in the group change tap in accordance with this command.

**Circulating current voltage regulation**

This instruction for confirmation of circulating current voltage regulation assumes two transformers in the parallel group. Setting confirmation through secondary injection requires calculation of circulating currents for each transformer based on impedance values and respective compensating factors, and is therefore more complex for greater than two transformers.

1. Confirm that OperationPAR is set to CC for the transformers in the parallel group.

2. For parallel operation, it is also recommended that settings be confirmed for parallel group membership, governed by setting $TrRXOP$ in the local HMI under **Main menu/Settings/Setting group N/Control/TransformerVoltageControl(ATCC,90)/TR8ATCC:x/ParCtrl**

   The general parallel arrangement of transformers are defined by setting $TrRXOP$ to Enabled or Disabled. The following rules are applicable on the settings $T1RXOP$ - $T4RXOP$.

   If IED $T1$ and $T2$ are connected,
   - $T1RXOP$ shall be set to Enabled in instance 2 of TR8ATCC (90), and
   - $T2RXOP$ shall be set to Enabled in instance 1 of TR8ATCC (90).

   If $T1$ - $T3$ are available,
   - $T1RXOP$ and $T2RXOP$ shall be set to Enabled in instance 3 of TR8ATCC (90),
   - $T2RXOP$ and $T3RXOP$ shall be set to Enabled in instance 1 of TR8ATCC (90) and so on.

   The parameter corresponding to the own IED must not be set. $T1RXOP$ should thus not be set in IED $T1$, $T2RXOP$ in IED $T2$ and so on.

3. Review the settings for $VDeadband$ (based on percentage of nominal bus voltage) and calculate the upper ($V2$) and lower ($V1$) voltage regulation limits for which a tap change command will be issued from the master transformer in the group.

4. Review the expected time for first ($t_1$) and subsequent ($t_2$) tap change commands from the master transformer in the local HMI under **Main menu/Settings/Setting group N/TransformerVoltageControl(ATCC,90)/TR1ATCC:x/TR8ATCC:x/Time/t1 and t2**

5. Inject a voltage $V_B$ equal to $VSet$ for each transformer.

6. Inject a load current for Transformer 1 that is equal to rated load current $I2Base$ and a load current for Transformer 2 that is equal to 95% of rated load current $I2Base$. This will have the effect of producing a calculated circulating current that flows from HV to LV side for Transformer 1 and LV to HV side for Transformer 2.

7. Confirm that a circulating current is measured on the local HMI that is equal in magnitude to 5% of $I2Base$, with polarity as discussed in step 6.

8. Confirm the settings for $C_i$ (Compensation Factor) and $X_i$ (Transformer Short Circuit Impedance). Using these setting values and the measured quantity of circulating current from the local HMI ($I_{cc_i}$), calculate the value for circulating current voltage adjustment $Vci$. 

\[ Vdi = Ci \cdot Icc_i \cdot Xi \]  
(Equation 41)

The voltage regulation algorithm then increases (for transformer T2) or decreases (for transformer T1) the measured voltage by Vdi and compares Vi against the voltage deadband limits V1 and V2 for the purposes of voltage regulation.

\[ Vi = VB + Vdi \]  
(Equation 42)

9. To cause a tap change, the calculated value for circulating current voltage adjustment must offset the injected quantity for bus voltage VB so that Vi is outside the voltage deadband created by setting VDeadband. Expressed by equation 43 and equation 44.

\[ Vdi > V2 - VB \]  
(Equation 43)

\[ VB = Vset \]  
(for the purposes of this test procedure)  
(Equation 44)

Therefore:

\[ Ci \cdot Icc_i \cdot Xi > V2 - Vset \]  
(Equation 45)

\[ |Icc_i| \frac{(V2 - Vset)}{(Ci \cdot Xi)} \]  
(Equation 46)

10. Using the settings for VSet, VDeadband, C (Compensating factor) and \( Xr2 \) (transformer short circuit impedance) calculate the magnitude of ICC_i necessary to cause a tap change command.

11. Inject current equal to I2Base for Transformer 1 and \( (I2Base - |Icc_i|) \) for Transformer 2 so that the magnitude of calculated circulating current will cause a raise command to be issued for Transformer 2 and a lower command for Transformer 1. Magnitude and direction of circulating currents measured for each transformer can be observed as service values on the local HMI and raise/lower commands detected from the binary output mapped in the Signal Matrix.
The voltage injection equal to $V_{Set}$ is required for both transformers during this test.

12. Confirm that a tap change command is issued from the voltage control function to compensate for the circulating current.
13. Injected currents can be reversed such that the direction of calculated circulating currents change polarity, which will cause a lower command for Transformer 2 and a raise command for Transformer 1.

Circulating current limit

1. Confirm that $\text{OperationPAR}$ is set to $\text{CC}$ for each transformer in the parallel group.
2. Confirm that $\text{OperCCBlock}$ is set to $\text{Enable}$ for each transformer in the parallel group.
3. Review the setting for $\text{CircCurrLimit}$.
4. Review the setting for $\text{CircCurrBk}$ to confirm whether a circulating current limit will result in an $\text{Alarm}$ state, $\text{Auto Block}$ or $\text{Auto&Man Block}$ of the automatic voltage control for tap changer, for parallel control function TR8ATCC (90).
5. Inject a voltage $V_b$ equal to $V_{Set}$ for each transformer.
6. Inject a load current for Transformer 1 that is equal to rated load current $I_{2\text{Base}}$ and a load current for Transformer 2 that is 1% less than $(I_{2\text{Base}} - (I_{2\text{Base}} \cdot \text{CircCurrLimit}))$.
7. Confirm that the automatic voltage control for tap changer, for parallel control function TR8ATCC (90) responds in accordance with the setting for $\text{CircCurrBk}$. Alarm and blocking conditions can be confirmed through interrogation of the event menu or the control menu on the local HMI.

$V_{T\text{mismatch}}$ during parallel operation

1. Confirm that $\text{OperationPAR}$ is set to $\text{MF}$ for each transformer in the parallel group.
2. Review the setting for $\text{V\_T\text{mismatch}}$ and $\text{t\_V\text{\_mismatch}}$.
3. Inject a voltage $V_b$ equal to $V_{Set}$ for Transformer 1 and a voltage less than $(V_{Set} - (V_{\text{T\_mismatch}} \cdot V_{Set}))$ for Transformer 2.
4. This condition should result in a $V\_\text{mismatch}$ which will mutually block the operation of the automatic voltage control for tap changer, parallel control function TR8ATCC (90) for all transformers connected in the parallel group, which can be confirmed through interrogation of the local HMI.
5. Confirm that the automatic voltage control for tap changer, parallel control function TR8ATCC (90) responds in accordance with the setting for $\text{CircCurrBk}$.

10.9.4.9 Completing the test

Continue to test another function or end the test by changing the $\text{TestMode}$ setting to $\text{Disabled}$. Restore connections and settings to their original values, if they were changed for testing purposes.

10.9.5 Single command, 16 signals $\text{SINGLECMD}$

For the single command function block, it is necessary to configure the output signal to corresponding binary output of the IED. The operation of the single command function ($\text{SINGLECMD}$) is then checked from the local HMI by applying the commands with $\text{Mode} = \text{Off}$, $\text{Steady}$ or $\text{Pulse}$, and by observing the logic statuses of the corresponding binary output.
Command control functions included in the operation of different built-in functions must be tested at the same time as their corresponding functions.

### 10.9.6 Interlocking

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

Values of the logical signals are available on the local HMI under Main menu/Tests/Function status/Control/Apparatus control/Interlocking. The Signal Monitoring in PCM600 shows the same signals that are available on the local HMI.

The interlocking function consists of a bay-level part and a station-level part. The interlocking is delivery specific and is realized by bay-to-bay communication over the station bus. For that reason, test the function in a system, that is, either in a complete delivery system as an acceptance test (FAT/SAT) or as parts of that system.

### 10.10 Scheme communication

#### 10.10.1 Scheme communication logic for distance or overcurrent protection ZCPSCH (85)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

Check the scheme logic during the secondary injection test of the impedance or overcurrent protection functions.

Activation of the different zones verifies that the CS signal is issued from the intended zones. The CS signal from the independent tripping zone must have a $t_{SendMin}$ minimum time.

Check the tripping function by activating the CR and CR_GUARD inputs with the overreaching zone used to achieve the PLTR_CRD signal.

It is sufficient to activate the zones with only one type of fault with the secondary injection.

#### 10.10.1.1 Testing permissive underreaching

1. Activate the receive (CR) signal in the IED.
2. Apply healthy normal load conditions to the IED for at least two seconds.
3. Apply a fault condition within the permissive zone.
4. Check that correct trip outputs, external signals, and indications are obtained for the actual type of fault generated.
5. Check that other zones operate according to their zone timers and that the send (CS) signal is obtained only for the zone configured to generate the actual signal.
6. Deactivate the receive (CR) signal in the IED.
7. Check that the trip time complies with the zone timers and that correct trip outputs, external signals, and indications are obtained for the actual type of fault generated.
10.10.1.2 Testing permissive overreaching

1. Activate the receive (CR) signal in the IED.
2. Apply healthy normal load conditions to the IED for at least two seconds.
3. Apply a fault condition within the permissive zone.
4. Check that correct trip outputs, external signals, and indication are obtained for the actual type of fault generated.
5. Check that the other zones operate according to their zone timer and that the send (CS) signal is obtained only for the zones that are configured to give the actual signal. Also the zone connected to CS underreach is giving CS in this mode.
6. Deactivate the IED receive (CR) signal.
7. Apply healthy normal load conditions to the IED for at least two seconds.
8. Apply a fault condition within the permissive zone.
9. Check that trip time complies with the zone timers and that correct trip outputs, external signals, and indications are obtained for the actual type of fault generated.

10.10.1.3 Testing blocking scheme

1. Deactivate the receive (CR) signal of the IED.
2. Apply healthy normal load conditions to the IED for at least two seconds.
3. Apply a fault condition within the forward directed zone used for scheme communication tripping.
4. Check that correct trip outputs and external signals are obtained for the type of fault generated and that the trip time complies with the \( t_{Coord} \) timer (plus relay measuring time).
5. Check that the other zones trip according to their zone times and that a send (CS) signal is only obtained for the reverse zone.
6. Activate the IED receive (CR) signal.
7. Apply a fault condition in the forward directed zone used for scheme communication tripping.
8. Check that the no trip from scheme communication occurs.
9. Check that the trip time from the forward directed zone used for scheme communication tripping complies with the zone timer and that correct trip outputs, external signals, and indications are obtained for the actual type of fault generated.

10.10.1.4 Testing delta blocking scheme

1. Deactivate the receive (CR) signal of the IED.
2. Apply healthy normal load conditions to the IED for at least two seconds.
3. Apply a fault condition within the forward directed zone used for scheme communication tripping.
4. Check that correct trip outputs and external signals are obtained for the type of fault generated and that the trip time complies with the \( t_{Coord} \) timer (plus relay measuring time).
5. Check that the other zones trip according to their zone times and that a send (CS) signal is only obtained for the reverse zone.
6. Check that for a forward fault, carrier send (CS) signal is first obtained from the delta based fault inception detection (as it is not directional), and immediately inhibited by the forward zone.
7. Activate the IED receive (CR) signal.
8. Apply a fault condition in the forward directed zone used for scheme communication tripping.
9. Check that the no trip from scheme communication occurs.
10. Check that the trip time from the forward directed zone used for scheme communication tripping complies with the zone timer and that correct trip outputs, external signals, and indications are obtained for the actual type of fault generated.

10.10.5 Checking of unblocking logic

Check the unblocking function (if the function is required) when checking the communication scheme.

Command function with continuous unblocking \((Unblock = 1)\)

Procedure

1. Activate the guard input signal (CR_GUARD) of the IED.
2. Using the scheme selected, check that a signal accelerated trip (TRIP) is obtained when the guard signal is deactivated.

10.10.6 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.10.2 Current reversal and Weak-end infeed logic for distance protection 3-phase ZCRWPSCH (85)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

Values of the logical signals for ZCRWPSCH are available on the local HMI under Main menu/Tests/Function status / Scheme communication / ZCRWPSCH(85) /ZCRWPSCH:1.

The Signal Monitoring in PCM600 shows signals that are available on the Local HMI.

The current reversal logic and the weak-end infeed functions are tested during the secondary-injection test of the impedance or overcurrent protection zones together with the scheme communication logic for the distance protection function ZCPSCH (85).

10.10.2.1 Current reversal logic

It is possible to check the delay of the CS send signal with \(t\text{DelayRev}\) by changing from a reverse to a forward fault.

By continuously activating the CR input and changing from a reverse to a forward fault, the delay \(t\text{DelayRev}\) can be checked.
Checking of current reversal

The reverse zone timer must not operate before the forward zone fault is applied. The user might need to block the reverse zone timer setting during testing of current reversal.

The forward zone timer must be set longer than the $t_{DelayRev}$ set value.

1. Activate the receive (CRL) signal.
2. Set the healthy condition to an impedance at 50% of the reach of the reverse zone connected to IRV.
3. After the pickup condition is obtained for reverse zone, apply a fault at 50% of the reach of the forward zone connected to WEIBLK2.
4. Check that correct trip outputs and external signals are obtained for the type of fault generated. The operation time should be about the $t_{DelayRev}$ setting longer than the carrier accelerated trip (TRIP) recorded for the permissive overreach scheme communication.
5. Restore the forward and reverse zone timer to its original setting.

10.10.2.2 Weak end infeed logic

Weak-end infeed logic at permissive overreach schemes

1. Check the blocking of the echo with the injection of a CRL signal >40ms after a reverse fault is applied.
2. Measure the duration of the echoed CS signal by applying a CRL receive signal.
3. Check the trip functions and the voltage level for trip by reducing a phase voltage and applying a CRL receive signal.

Testing conditions
Only one type of fault is sufficient, with the current reversal and weak-end infeed logic for distance protection function ZCRWPSCH (85). Apply three faults (one in each phase). For phase A-G fault, set these parameters:

<table>
<thead>
<tr>
<th>Phase</th>
<th>I (Amps)</th>
<th>Phase-angle (Deg)</th>
<th>V (Volts)</th>
<th>Phase-angle (Deg)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0</td>
<td>0</td>
<td>Set less than $\frac{UPN}{PLU27PN}$</td>
<td>0</td>
</tr>
<tr>
<td>B</td>
<td>0</td>
<td>240</td>
<td>69.3</td>
<td>240</td>
</tr>
<tr>
<td>C</td>
<td>0</td>
<td>120</td>
<td>69.3</td>
<td>120</td>
</tr>
</tbody>
</table>

If wanted, change all settings cyclically for other faults (BG and CG).
The setting parameter WEI is set to *Echo & Trip*.

1. Apply input signals according Table 19.
2. Activate the receive (CR) signal.
3. After the IED has operated, turn off the input signals.
4. Check that trip, send signal, and indication are obtained.

The ECHO output gives only a 200 ms pulse.

### 10.10.2.3 Completing the test

Continue to test another function or end the test by changing the *TestMode* setting to *Disabled*. Restore connections and settings to their original values, if they were changed for testing purposes.

### 10.10.3 Local acceleration logic ZCLCP SCH

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

The logic is checked during the secondary injection test of the impedance measuring zones.

#### 10.10.3.1 Verifying the settings

1. Provide the IED with conditions equivalent to normal load for at least two seconds.
2. Deactivate the conditions for accelerated function.
3. Apply a phase-to-ground fault at 100% of line impedance.
4. Check that the fault is tripped with the second zone time delay.
5. Provide the IED with conditions equivalent to normal load for at least two seconds.
6. Activate the condition for accelerated function either by the autorecloser or by the loss-of-load.
7. Apply a phase-to-ground fault at 100% of line impedance.
8. Check that the fault is tripped instantaneously.

#### 10.10.3.2 Completing the test

Continue to test another function or end the test by changing the *TestMode* setting to *Disabled*. Restore connections and settings to their original values, if they were changed for testing purposes.

### 10.10.4 Scheme communication logic for residual overcurrent protection ECPSCH (85)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.
Before testing the communication logic for residual overcurrent protection function ECPSCH (85), the four step residual overcurrent protection function EF4PTOC (51N/67N) has to be tested according to the corresponding instruction. Once this is done, continue with the instructions below.

If the current reversal and weak-end infeed logic for ground-fault protection is included, proceed with the testing according to the corresponding instruction after the testing the communication logic for residual overcurrent protection. The current reversal and weak-end-infeed functions shall be tested together with the permissive scheme.

### 10.10.4.1 Testing the directional comparison logic function

#### Blocking scheme

1. Inject the polarizing voltage 3V0 at 5% of $V_{base}$ (EF4PTOC, 51N67N) where the current is lagging the voltage by 65°.
2. Inject current (65° lagging the voltage) in one phase at about 110% of the set operating current, and switch the current off with the switch.
3. Switch the fault current on and measure the operating time of the communication logic. Use the TRIP signal from the configured binary output to stop the timer.
4. Compare the measured time with the set value $t_{Coord}$.
5. Activate the CR binary input.
6. Check that the CRL output is activated when the CR input is activated.
7. Switch the fault current on (110% of the set operating current) and wait longer than the set value $t_{Coord}$.

   ![Info](image)

   **No TRIP signal should appear.**

8. Switch the fault current off.
9. Reset the CR binary input.
10. Activate the BLOCK digital input.
11. Switch the fault current on (110% of the set operating current) and wait for a period longer than the set value $t_{Coord}$.

   ![Info](image)

   **No TRIP signal should appear.**

12. Switch the fault current and the polarizing voltage off.
13. Reset the BLOCK digital input.

#### Permissive scheme

1. Inject the polarizing voltage 3V0, which is 5% of $V_{base}$ (EF4PTOC, 51N67N) where the current is lagging the voltage by 65°.
2. Inject current (65° lagging the voltage) into one phase at about 110% of the set operating current, and switch the current off with the switch.
3. Switch the fault current on, (110% of the set operating current) and wait longer than the set value $t_{Coord}$. 

Commissioning manual 153
No TRIP signal should appear, and the CS binary output should be activated.

4. Switch the fault current off.
5. Activate the CR binary input.
6. Switch the fault current on (110% of the set operating current) and measure the operating time of the ECP SCH (85) logic. Use the TRIP signal from the configured binary output to stop the timer.
7. Compare the measured time with the setting for \textit{tCoord}.
8. Activate the BLOCK digital input.
9. Switch the fault current on (110% of the set operating current) and wait for a period longer than the set value \textit{tCoord}.

No TRIP signal should appear.

10. Switch the fault current and the polarizing voltage off.
11. Reset the CR binary input and the BLOCK digital input.

10.10.4.2 Completing the test

Continue to test another function or end the test by changing the \textit{TestMode} setting to \textit{Disabled}. Restore connections and settings to their original values, if they were changed for testing purposes.

10.10.5 Current reversal and weak-end infeed logic for residual overcurrent protection ECRWPSCH (85)

Prepare the IED for verification of settings as outlined in the section "Preparing for test" in this chapter.

Values of the logical signals for ECRWPSCH are available on the Local HMI under Main menu/Tests/Function status/Scheme communication/ECRWPSCH(85)/ECRWPSCH:1. The Signal Monitoring in PCM600 shows service values that are available on the Local HMI as well.

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

First, test the four step residual overcurrent protection function EF4PTOC (51N/67N) and then the current reversal and weak-end infeed logic according to the corresponding instructions. Then continue with the instructions below.

10.10.5.1 Testing the current reversal logic
1. Inject the polarizing voltage 3V0 to 5% of $V_{\text{Base}}$ and the phase angle between voltage and current to 155°, the current leads the voltage.
2. Inject current ($180^\circ - \text{AngleRCA}$) in one phase to about 110% of the set operating current of the four step residual overcurrent protection ($\text{INDir}$).
3. Check that the IRVL output is activated in the disturbance recorder after the set time $t_{\text{PickUpRev}}$.
4. Abruptly reverse the current to $\text{AngleRCA}$ setting lagging the voltage, to operate the forward directional element.
5. Check that the IRVL output still is activated after the reversal with a time delay that complies with the setting $t_{\text{DelayRev}}$.
6. Switch off the polarizing voltage and the current.

10.10.5.2 Testing the weak-end infeed logic

If setting $\text{WEI} = \text{Echo}$

1. Inject the polarizing voltage 3V0 to ($180^\circ - \text{AngleRCA}$) of $V_{\text{Base}}$ and the phase angle between voltage and current to 155°, the current leads the voltage.
2. Inject current ($180^\circ - \text{AngleRCA}$) in one phase to about 110% of the setting operating current ($\text{INDir}$).
3. Activate the CRL binary input.
   
   No ECHO and CS should appear.
4. Abruptly reverse the current to the setting of $\text{AngleRCA}$ setup lagging the voltage, to operate the forward directional element.
   
   No ECHO and CS should appear.
5. Switch off the current and check that the ECHO and CS appear on the corresponding binary output during 200ms after resetting the directional element.
6. Switch off the CRL binary input.
7. Activate the BLOCK binary input.
8. Activate the CRL binary input.
   
   No ECHO and CS should appear.
9. Switch off the polarizing voltage and reset the BLOCK and CRL binary input.

If setting $\text{WEI} = \text{Echo & Trip}$

1. Inject the polarizing voltage 3V0 to about 90% of the setting ($3V_{\text{OPU}}$) operating voltage.
2. Activate the CRL binary input.
No ECHO, CS and TRWEI outputs should appear.

3. Increase the injected voltage to about 110% of the setting \(3V_{OPL}\) operating voltage.
4. Activate the CRL binary input.
5. Check that the ECHO, CS and TRWEI appear on the corresponding binary output or on the local HMI.
6. Reset the CRL binary input.
7. Activate the BLOCK binary input.
8. Activate the CRL binary input.

No ECHO, CS and TRWEI outputs should appear.

9. Reset the CRL and BLOCK binary input.
10. Inject the polarizing voltage \(3V_0\) to about 110% of the setting \(3V_{OPL}\) and adjust the phase angle between the voltage and current to \((180° - \text{AngRCA})\) setting, the current leads the voltage.
11. Inject current in one phase to about 110% of the set trip current \(I_{NDir}\).
12. Activate the CRL binary input.

No ECHO and TRWEI should appear.

13. Abruptly reverse the current to 65° lagging the voltage to trip the forward directional element.

No ECHO and TRWEI should appear.

14. Switch the current off and check that the ECHO, CS and TRWEI appear on the corresponding binary output during 200ms after resetting the directional element. If EF4PTOC also trips in forward direction, CS should be obtained.
15. Switch the polarizing voltage off and reset the CRL binary input.

10.10.5.3 Completing the test

Continue to test another function or end the test by changing the \(TestMode\) setting to \(Disabled\). Restore connections and settings to their original values, if they were changed for testing purposes.

10.11 Logic

10.11.1 Tripping logic, common 3-phase output SMPPTRC (94)

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.
This function is functionality tested together with other protection functions (line differential protection, ground-fault overcurrent protection, and so on) within the IED. It is recommended that the function is tested together with the autorecloser function, when built into the IED or when a separate external unit is used for reclosing purposes. The instances of SMPPTRC (94) are identical except for the name of the function block SMPPTRC (94). The testing is preferably done in conjunction with the protection system and autoreclosing function.

### 10.11.1 Three-phase operating mode

1. Check that AutoLock and TripLockout are both set to Disabled.
2. Initiate a three-phase fault. An adequate time interval between the faults should be considered, to overcome a reset time caused by the possible activation of the Autorecloser function SMBRREC (79). The function must issue a three-pole trip in all cases, when trip is initiated by any protection or some other built-in or external function. The following functional output signals must always appear simultaneously: TRIP, TR_A, TR_B, TR_C and TR3P.

### 10.11.2 1ph/3ph operating mode

In addition to various other tests, the following tests should be performed. They depend on the complete configuration of an IED:

**Procedure**

1. Make sure that TripLockout and AutoLock are both set to Disabled.
2. Initiate different single-phase-to-ground faults one at a time.
3. Initiate different phase-to-phase and three-phase faults. Consider using an adequate time interval between faults, to overcome a reset time, which is activated by SMBRREC (79). A three-pole trip should occur for each separate fault and all of the trips. Functional outputs TRIP, all TR_A, TR_B, TR_C and TR3P should be active at each fault.

   No other outputs should be active.

4. Initiate a single phase-to-ground fault and switch it off immediately when the trip signal is issued for the corresponding phase. Initiate the same fault once again within the reset time of the used SMBRREC (79).
5. Initiate a single phase-to-ground fault and switch it off immediately when the trip signal is issued for the corresponding phase. Initiate the second single phase-to-ground fault in one of the remaining phases within the time interval, shorter than tEvolvingFault (default setting 2.0s) and shorter than the dead-time of SMBRREC (79), when included in the protection scheme. Check that the second trip is a three-pole trip and that a three-phase autoreclosing attempt is given after the three-phase dead time. Functional outputs TRIP, TR_A, TR_B, TR_C and TR1P should be active during the first fault. No other outputs should be active. Functional outputs TRIP, all TR_A, TR_B, TR_C and TR3P should be active during second fault.
10.11.1.3 1ph/2ph/3ph operating mode

In addition to other tests, the following tests, which depend on the complete configuration of an IED, should be carried out.

Procedure

1. Make sure that AutoLock and TripLockout are both set to Disabled.
2. Initiate different single-phase-to-ground faults one at a time.
   Take an adequate time interval between faults into consideration, to overcome a reset time, which is activated by the autorecloser function SMBRREC (79). Only a single-pole trip should occur for each separate fault and only one of the trip outputs (TR_A, TR_B, TR_C) should be activated at a time. Functional outputs TRIP and TR1P should be active at each fault. No other outputs should be active.
3. Initiate different phase-to-phase faults one at a time.
   Take an adequate time interval between faults into consideration, to overcome a reset time which is activated by SMBRREC (79). Only a two-phase trip should occur for each separate fault and only corresponding two trip outputs (TR_A, TR_B, TR_C) should be activated at a time. Functional outputs TRIP and TR2P should be active at each fault. No other outputs should be active.
4. Initiate a three-phase fault.
5. Initiate a single-phase-to-ground fault and switch it off immediately when the trip signal is issued for the corresponding phase. Initiate the same fault once again within the reset time of the used SMBRREC (79).
   A single-phase fault shall be given at the first fault. A three-pole trip must be initiated for the second fault. Check that the corresponding trip signals appear after both faults. Functional outputs TRIP, TR_A, TR_B, TR_C and TR1P should be active during first fault. No other outputs should be active. Functional outputs TRIP, all TR_A, TR_B, TR_C and TR3P should be active during second fault.
6. Initiate a single phase-to-ground fault and switch it off immediately when the trip signal is generated for the corresponding phase. Initiate the second single-phase-to-ground fault in one of the remaining phases within the time interval, shorter than tEvolvingFault (default setting 2.0s) and shorter than the dead-time of SMBRREC (79), when included in the protection scheme.
7. Check, that the output signals, issued for the first fault, correspond to a two-phase trip for included phases. The output signals generated by the second fault must correspond to the three-phase tripping action.

10.11.1.4 Circuit breaker lockout

The following tests should be carried out when the built-in lockout function is used in addition to possible other tests, which depends on the complete configuration of an IED.

1. Check that AutoLock and TripLockout are both set to Disabled.
2. Activate shortly the set lockout (SETLKOUT) signal in the IED.
3. Check that the circuit breaker lockout (CLLKOUT) signal is set.
4. Activate shortly thereafter, the reset lockout (RSTLKOUT) signal in the IED.
5. Check that the circuit breaker lockout (CLLKOUT) signal is reset.
6. Initiate a three-phase fault.
   A three- trip should occur and all trip outputs TR_A, TR_B, TR_C should be activated.
   Functional outputs TRIP and TR3P should be active at each fault. The output CLLKOUT should not be set.
7. Activate the automatic lockout function, set AutoLock = Enabled and repeat.
Besides the TRIP outputs, CLLKOUT should be set.
8. Reset the lockout signal by activating the reset lockout (RSTLKOUT) signal.
9. Activate the trip signal lockout function, set \textit{TripLockout} = \textit{Enabled} and repeat. All trip outputs (TR_A, TR_B, TR_C) and functional outputs TRIP and TR3P must be active and stay active after each fault, CLLKOUT should be set.
10. Reset the lockout.
   All functional outputs should reset.
11. Deactivate the TRIP signal lockout function, set \textit{TripLockout} = \textit{Disabled} and the automatic lockout function, set \textit{AutoLock} = \textit{Disabled}.

10.11.5 Completing the test

Continue to test another function or end the test by changing the \textit{TestMode} setting to \textit{Disabled}. Restore connections and settings to their original values, if they were changed for testing purposes.

10.12 Monitoring

10.12.1 Gas medium supervision SSIMG

Prepare the IED for verification of settings as outlined in section "Testing the liquid medium supervision for alarm and lock out conditions" and section "Completing the test" in this chapter.

Check that the input logical signal \textit{BLOCK} is logical zero and that on the local HMI, the logical signals \textit{PRES\_ALM}, \textit{PRES\_LO}, \textit{TEMP\_ALM} and \textit{TEMP\_LO} are equal to logical zero.

10.12.1.1 Testing the liquid medium supervision for alarm and lock out conditions

1. Connect binary inputs to consider gas pressure and gas density to initiate the alarms.
2. Consider the analogue pressure input \textit{PRESSURE} to initiate the alarms.
3. Gas pressure lock out input can be used to set \textit{PRES\_LO} signal, check the signal status in local HMI under \textit{Main menu/Test/Function status/Monitoring/Gas medium supervision SSIMG/PRES\_LO}
4. Reduce the pressure level input below \textit{PresAlmLimit}, check for \textit{PRES\_ALM} signal status in local HMI under \textit{Main menu/Test/Function status/Monitoring/Gas medium supervision SSIMG/PRES\_ALM}
5. Activate \textit{BLOCK} binary input, the signals \textit{PRES\_ALM}, \textit{PRES\_LO} should disappear.
6. Reset the \textit{BLOCK} binary input.
7. Check for reset lock out input \textit{RESET\_LO} to reset \textit{PRES\_LO} lock out signal.
8. Conduct these steps for temperature input as well to detect and reset \textit{TEMP\_ALM} and \textit{TEMP\_LO} signals.
9. Continue to test another function or end the test by changing the \textit{TestMode} setting to \textit{off}.

10.12.1.2 Completing the test

Continue to test another function or end the test by changing the \textit{TestMode} setting to \textit{Off}. Restore connections and settings to their original values, if they were changed for testing purposes.
10.12.2 **Liquid medium supervision SSIML**

Prepare the IED for verification of settings as outlined in section "Liquid medium supervision SSIML" and section "Completing the test" in this chapter.

Check that the input logical signal BLOCK is logical zero and that on the local HMI, the logical signals LVL_ALM, LVL_LO, TEMP_ALM and TEMP_LO are equal to logical zero.

### 10.12.2.1 Testing the liquid medium supervision for alarm and lock out conditions

1. Connect the binary inputs to consider liquid level to initiate the alarms.
2. Consider the analogue level input LEVEL to initiate the alarms.
3. Liquid level lock out input can be used to set LVL_LO signal, check the signal status in local HMI under Main menu/Test/Function status/Monitoring/Liquid medium supervision SSIML/LVL_LO
4. Reduce the liquid level input below LevelAlmLimit, check for LVL_ALM signal status in local HMI under Main menu/Test/Function status/Monitoring/Liquid medium supervision SSIML/LVL_ALM
5. Activate BLOCK binary input, the signals LVL_ALM, LVL_LO should disappear.
6. Reset the BLOCK binary input.
7. Check for reset lock out input RESET_LO to reset the LVL_LO lock out signal.
8. Conduct these steps for temperature input as well to detect and reset TEMP_ALM and TEMP_LO signals.
9. Continue to test another function or end the test by changing the TestMode setting to Off.

### 10.12.2.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Off. Restore connections and settings to their original values, if they were changed for testing purposes.

### 10.12.3 **Breaker monitoring SSCBR**

Prepare the IED for verification of settings outlined in section "Testing the IED operation".

The Signal Monitoring tool in PCM600 shows the service values that are available on the Local HMI as well.

Values of the logical signals belong to the breaker monitoring are available on the local HMI under: Main menu/Test/Function status/Monitoring/BreakerMonitoring/SSCBR:x

### 10.12.3.1 Verifying the settings

1. Connect the test set for the injection of a three-phase current to the appropriate current terminals of the IED.
2. If current need to be injected for a particular test, it should be done in the phase selected by the PhSel/parameter.
3. Follow the sequence for positioning the auxiliary contacts before testing:

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSCLOSE</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>POSOPEN</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
4. Test of CB contact travel time
   4.1. Test the set timing defined by OpenTimeCorr, CloseTimeCorr, tTrOpenAlm and tTrCloseAlm.
   4.2. Change the status of the auxiliary contacts such that travel time to open TTRVOP and travel time to close TTRVCL exceed the respective set values (tTrOpenAlm and tTrCloseAlm). The measured travel time for opening and closing is shown on TTRVOP and TTRVCL respectively.
   4.3. Check that TRVTOPAL and TRVTCLAL are activated.

5. Test of CB status
   5.1. Test the set current level defined by AccStopCurr.
   5.2. Check the CLOSEPOS output by changing the POSOPEN to 0 and POSCLOSE to 1.
   5.3. Check the OPENPOS output by changing the POSOPEN to 1 and POSCLOSE to 0 and also inject the current in the selected phase slightly lower and higher than AccStopCurr set value. Only for a current lower than set AccStopCurr should activate the output POSOPEN.
   5.4. Check the circuit breaker is in INVDPOS if auxiliary contacts read same value or CB is open and inject the current in selected phase more than AccStopCurr set value.

6. Test of remaining life of CB
   6.1. Test the set timing defined by RatedOperCurr, RatedFltCurr, OperNoRated, OperNoFault, DirCoef, CBLifeAlmLevel.
   6.2. Vary the phase current in the selected phase from below rated operated current, RatedOperCurr to above rated fault current, RatedFltCurr of a breaker.
   6.3. The remaining life of CB output CBLIFEPH is estimated when the CB is changed from closed to open position. Check that the output CBLIFEPH is decreased with a value that corresponds to the injected current.
   6.4. CBLIFEAL is activated as soon as CBLIFEPH is below the set CBLifeAlmLevel value.

7. Test of accumulated energy
   7.1. Test the actual set values defined by AccSelCal to Aux Contact, ContTrCorr and AlmAccCurrPwr.
   7.2. Inject phase current in the selected phase such that its value is greater than set AccStopCurr value.
   7.3. When the breaker goes to open position, accumulated energy IPOWPH is calculated. The calculated value can be seen on the output IPOWPH.
   7.4. Alarm signal IPOWALPH appears when IPOWPH is greater than set AlmAccCurrPwr value.
   7.5. Lockout signal IPOWLOPH appears if IPOWPH exceeds further to the threshold value LOAccCurrPwr.
   7.6. Calculation of accumulated energy IPOWPH is stopped when injected current is lower than set AccStopCurr value.

8. Test of CB operation cycles
   8.1. Test the actual set values defined by OperAlmLevel and OperLOLevel.
   8.2. The operation counter, NOOPER is updated for every close-open sequence of the breaker by changing the position of auxiliary contacts POSCLOSE and POSOPEN.
   8.3. OPERALM is activated when NOOPER value exceeds the set OperAlmLevel value. The actual value can be read on the output NOOPER.
   8.4. OPERLO is activated when NOOPER value exceeds the set OperLOLevel value.

9. Test of CB spring charge monitoring
   9.1. Test the actual set value defined by SpChAlmTime.
   9.2. Enable SPRCHRST input. Also activate SPRCHRD after a time greater than set time SpChAlmTime.
   9.3. At this condition, SPCHALM is activated.

10. Test of CB gas pressure indication
10.1. Test the actual set value defined by $tDGасPresAlm$ and $tDGасPresLO$.

10.2. The output $GPRESALM$ is activated after a time greater than set time of $tDGасPresAlm$ value if the input $PRESALM$ is enabled.

10.3. The output $GPRESLO$ is activated after a set time of $tDGасPresLO$ value if the input $PRESLO$ is enabled.

### 10.12.3.2 Completing the test

1. Continue to test another function or end the test by changing the *Test mode* setting to *Disabled*.
2. Restore connections and settings to their original values if they were changed for testing purposes.

### 10.12.4 Event function EVENT

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

During testing, the IED can be set when in test mode from PST. The functionality of the event reporting during test mode is set in the Parameter Setting tool in PCM600.

- Use event masks
- Report no events
- Report all events

In test mode, individual event blocks can be blocked from PCM600.

### 10.12.5 Fault locator LMBRFLO

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

The Fault locator function LMBRFLO depends on other functions to work properly, that is, phase selection information from distance protection function and analog information supplied by the trip value recorder function. Check that proper binary initiate (pickup or tripping) and phase selection signals are connected and voltage and current signals are configured (parameter settings).

The result is displayed on the local HMI or via PCM600. Distances to faults for the last 100 recorded disturbances can be found on the local HMI under **Main menu/Disturbance Records/Disturbance #n(n = 1–100)/General Information**

If PCM600 is used, the result is displayed on the recording list after upload, including loop selection information.
Table 20: Test settings

</tr>
</tbody>
</table>

10.12.5.1 Measuring the operate limit

1. Set the test point ($|Z|$ fault impedance and $Z\Phi$ impedance phase angle) for a condition that meets the requirements in table 20.
2. Subject the IED to healthy normal load conditions for at least two seconds.
3. Apply a fault condition.
   Check that the distance-to-fault value displayed on the HMI complies with equations 47, 48 and 49

\[
p = \frac{Z_x}{X1} \cdot 100
\]  
(Equation 47)

in % for two- and three-pole faults

\[
p = \frac{3 \cdot Z_x}{X0 + 2 \cdot X1} \cdot 100
\]  
(Equation 48)

in % for single-phase-to-ground faults

\[
p = \frac{3 \cdot Z_x}{X0 + 2 \cdot X1 \cdot XM} \cdot 100
\]  
(Equation 49)

in % for single-phase-to-ground faults with mutual zero sequence current.

Where:
\[
p = \text{the expected value of a distance to fault in percent}
\]
\[
Z_x = \text{set test point on the test set}
\]

Table continues on next page
10.12.5.2 Completing the test

Continue to test another function or end the test by changing the TestMode setting to Disabled. Restore connections and settings to their original values, if they were changed for testing purposes.

10.12.6 Limit counter L4UFCNT

The Limit counter function L4UFCNT can be tested by connecting a binary input to the counter and applying pulses to the counter. The speed of the pulses must not exceed the cycle time of the function. Normally the counter will be tested when testing the function that the counter is connected to, such as the trip function. When the function is configured, test it together with the function that operates it. Trig the function and check that the counter result corresponds to the number of operations.

10.12.6.1 Completing the test

Continue to test another function or end the test by changing the Test mode setting to Off. Restore connections and settings to their original values, if they were changed for testing purposes.

10.13 Metering

10.13.1 Pulse-counter logic PCFCNT

The test of the Pulse-counter logic function PCFCNT requires the Parameter Setting tool in PCM600 or an appropriate connection to the local HMI with the necessary functionality. A known number of pulses with different frequencies are connected to the pulse counter input. The test should be performed with settings Operation = Enable or Operation = Disable and the function blocked or unblocked. The pulse counter value is then checked in PCM600 or on the local HMI.

10.13.2 Function for energy calculation and demand handling ETPMMTR

Prepare the IED for verification of settings as outlined in section "Overview “ and section "Preparing for test“ in this chapter.

10.13.2.1 Verifying the settings

Common test equipment can be used to determine the injection of current and voltage and time measurement.

Verification of EAFACC & ERFACC output
1. Connect the test set for injection of three-phase currents and three phase voltage to the appropriate current and voltage terminals of the IED.
2. Ensure the instantaneous values of active and reactive power from CVMMXN function block are connected to ETPMMTR function block active and reactive power inputs.
3. Enable the EnaAcc setting and set tEnergy as 1 minute.
4. Activate the STARTACC input and supply the IED with three phase currents and voltages at their rated value.
5. Check that the ACCINPRG signal appears continuously.
6. Note the EAFACC and ERFACC value after 1 minute and compare it with calculated energy value.
7. Similarly check after each 1 minute whether the calculated integrated energy value and EAFACC and ERFACC outputs are matching.
8. After some time (multiple of minute) remove the current and voltage input from CVMMXN function block.
9. Check the EAFACC and ERFACC output in the next 1 minute cycle for the retaining the same value.
10. Activate STOPACC input after some time and supply the IED with same current and voltage.
11. Check that the ACCINPRG signal disappears immediately and EAFACC and ERFACC outputs also stop updating.
12. Similarly the testing can be done for EAFACC and ERFACC outputs by changing the power inputs directions through direction settings.

Verification of MAXPAFD & MAXPRFD outputs

1. Repeat the above test steps 1 to 2.
2. Set tEnergy setting as 1 minute and supply the IED with three phase currents and voltages at their rated value till 1 minute.
3. Check the MAXPAFD and MAXPRFD outputs after 1 minute and compare it with last 1 minute average power values.
4. Increase either three phase current or voltage above the last 1 minute value.
5. After 1 minute check the MAXPAFD and MAXPRFD whether it is showing the last 1 minute average power value as maximum.
6. Next 1 minute cycle reduce the current or voltage below previous value.
7. Check after 1 minute whether the MAXPAFD and MAXPRFD outputs are retaining the old maximum value.
8. Similarly the testing can be done for MAXPAFD and MAXPRFD outputs by changing the power inputs directions through direction settings.

Verification of EAFALM & ERFALM outputs

1. Repeat the above test steps 1 to 2.
2. Set tEnergy setting as 1 minute and supply the IED with three phase currents and voltages at their rated value till 1 minute.
3. Ensure that the active and reactive energy values are less than the EALim and ERLim setting default values respectively.
4. Check that EAFALM and ERFALM are low.
5. Increase the supply currents or voltage in next 1 minute cycle such that the active or reactive energy values are greater than the EALim and ERLim setting default values respectively.
6. Check that EAFALM and ERFALM are high after 1 minute.
7. Similarly the testing can be done for EAFALM and ERFALM outputs by changing the power inputs directions through direction settings.
10.13.2.2 Completing the test

Continue to test another function or end the test by changing the *TestMode* setting to *Disabled*. Restore connections and settings to their original values, if they were changed for testing purposes.

10.14 Station communication

10.14.1 Multiple command and transmit MULTICMDRCV / MULTICMDSND

The multiple command and transmit function (MULTICMDRCV / MULTICMDSND) is only applicable for horizontal communication.

Test of the multiple command function block and multiple transmit is recommended to be performed in a system, that is, either in a complete delivery system as an acceptance test (FAT/SAT) or as parts of that system, because the command function blocks are connected in a delivery-specific way between bays and the station level and transmit.

Command and transmit function blocks included in the operation of different built-in functions must be tested at the same time as their corresponding functions.

10.15 Remote communication

10.15.1 Binary signal transfer BinSignReceive, BinSignTransm

Prepare the IED for verification of settings as outlined in section "Preparing the IED to verify settings".

To perform a test of Binary signal transfer function (BinSignReceive/BinSignTransm), the hardware (LDCM) and binary input and output signals to transfer must be configured as required by the application.

There are two types of internal self supervision of BinSignReceive/BinSignTransm

- The I/O-circuit board is supervised as an I/O module. For example it generates FAIL if the board is not inserted. I/O-modules not configured are not supervised.
- The communication is supervised and the signal COMFAIL is generated if a communication error is detected.

Status for inputs and outputs as well as self-supervision status are available from the local HMI under

- Self-supervision status: Main menu/Diagnostics/Internal events
- Status for inputs and outputs: Main menu/Test/Function status, browse to the function group of interest.
- Remote communication related signals: Main menu/Test/Function status/Communication/Remote communication

Test the correct functionality by simulating different kind of faults. Also check that sent and received data is correctly transmitted and read.
A test connection is shown in figure 26. A binary input signal (BI) at End1 is configured to be transferred through the communication link to End2. At End2 the received signal is configured to control a binary output (BO). Check at End2 that the BI signal is received and the BO operates.

Repeat the test for all the signals configured to be transmitted over the communication link.

10.16 Basic IED functions

10.16.1 Parameter setting group handling SETGRPS

Prepare the IED for verification of settings as outlined in section "Requirements" and section "Preparing for test" in this chapter.

10.16.1.1 Verifying the settings

1. Check the configuration of binary inputs that control the selection of the active setting group.
2. Browse to the ActiveGroup menu to achieve information about the active setting group.
The **ActiveGroup** menu is located on the local HMI under **Main menu/Test/Function status/Setting groups/ActiveGroup**

3. Connect the appropriate dc voltage to the corresponding binary input of the IED and observe the information presented on the local HMI.
   The displayed information must always correspond to the activated input.
4. Check that the corresponding output indicates the active group.
   Operating procedures for the PC aided methods of changing the active setting groups are described in the corresponding PCM600 documents and instructions for the operators within the SCS are included in the SCS documentation.

### 10.16.1.2 Completing the test

Continue to test another function or end the test by changing the **TestMode** setting to **Disabled**. Restore connections and settings to their original values, if they were changed for testing purposes.

### 10.17 Exit test mode

The following procedure is used to return to normal operation.

> After exiting the IED test mode, make sure that the MU is returned to normal mode.

1. Navigate to the test mode folder.
2. Change the **Enable** setting to **Disable**. Press the 'E' key and the left arrow key.
3. Answer **YES**, press the 'E' key and exit the menus.
Section 11 Primary injection testing

Whenever it becomes necessary to work on primary equipment, it is essential that all the necessary switching, locking, grounding and safety procedures are observed and obeyed in a rigid and formalized manner. Operating and testing procedures should be strictly followed in order to avoid exposure to live equipment.

A test with primary current through the protected zone is usually a final check that the current circuits are correctly connected to the IED protection scheme. It is important to have an appropriate source, which is able to inject sufficient current in the primary circuit in order to distinguish between noise and real injected current. Therefore it is recommended that the injection current should be at least 10% of rated CT primary current.

11.1 Transformer Voltage Control ATCC

11.1.1 Load drop compensation function, LDC

The load drop compensation function can be tested directly with operational currents, in other words, with the power transformer in service and loaded.

When the system is carrying load there is a difference between the busbar voltage (VB) and the voltage at the load point (VL). This difference is load dependent and can be compensated by the ATCC function.

The load current is fed into the ATCC function where parameters corresponding to the line data for resistance and inductance are set. The voltage drop calculated by the LDC is proportional to the voltage drop in the system up to the load point.

In the IED, this voltage is subtracted from the measured busbar voltage (VB) and the result, corresponding to the voltage at the load point (UL) is presented to the ATCC function for the purposes of voltage regulation. This voltage will be lower (if resistive or inductive load current is applied) than the Vset voltage and ATCC increases the voltage in order to achieve the correct system voltage at the load point.

1. Confirm the PST settings for Rline and Xline. If the function LDC is set to Zero, this test is omitted.
2. Open the voltage control display on the LHMI in Main Menu/Control/Commands/TransformerVoltageControl (ATCC, 90).
3. In this view, check the following settings:

3.1. Check that Control Mode is set to Manual.
3.2. Operate the tap changer so that the Load Voltage corresponds to the Voltage Set Point.
3.3. Check that neither the Raise or the Lower command are operating. Voltage Deviation should be less than 100%.
3.4. Compare the values of Bus Voltage and Load Voltage.

UL can be obtained by a vector calculation where IL is the load current and values for RL and XL are the settings given in primary system ohms.

For inductive load, the Bus Voltage should be higher than the Load Voltage. If not, current circuits are incorrect and must be reversed. Incorrect current polarity may be an issue with physical wiring or the current direction convention selected for the CT analogue input as part of the setting in the PST setting.

### 11.1.2 Voltage control of Parallel Transformers

In parallel operation, each transformer protection IED must be connected to the station communication bus for data exchange. The following procedure assumes that the necessary pre-configuration in the Parameter Setting tool and the Signal Matrix tool has been performed and
tested to enable data exchange between IEDs or between instances of voltage control in the same IED.

For parallel operation, it is also recommended to confirm the setting for the general parallel arrangement of transformers in Main menu/Settings/Setting group N/Control/TransformerVoltageControl(ATCC,90)/TR8ATCC:x/ParCtrl. General parallel arrangement of transformers are defined by setting TnRXOP to On or Off. The following rules are applicable for the settings of T1RXOP – T8RXOP.

- In each instance of TR8ATCC, set all TnRXOP parameters corresponding to the connected IEDs to Enabled except the parameter corresponding to the IED itself. For example, do not set T1RXOP to Enabled in IED T1 or T2RXOP to Enabled in IED T2.

For example, if IEDs T1, T2 and T3 are connected,

- In instance 1 of TR8ATCC (90), set T2RXOP and T3RXOP to Enabled.
- In instance 2 of TR8ATCC (90), set T1RXOP and T3RXOP to Enabled.
- In instance 3 of TR8ATCC (90), set T1RXOP and T2RXOP to Enabled.

### 11.1.3 Minimum Circulating Current (MCC) method

Voltage control of parallel transformers with the circulating current method means minimizing the circulating current at a given voltage target value. The busbar voltage (VB) is measured individually for each transformer in the parallel group by its associated TR8ATCC function. These measured values are then exchanged between the transformers, and in each TR8ATCC block, the mean value of all VB values is calculated. The resulting value VBmean is then used in each IED instead of VB for the voltage regulation.

1. Check the overcurrent blocking level (Iblock) in Main menu/Settings/General settings/Control/TransformerVoltageControl(ATCC,90)/TR8ATCC:x/TCCtrl/Iblock.
2. Check that the circulating current blocking (OperCCBlock) is set On, and the check the correct settings for circulating current limit (CircCurLimit) in Main menu/Settings/General settings/Control/TransformerVoltageControl(ATCC,90)/TR8ATCC:x/ParCtrl/CircCurrLimit.

3. Connect all transformers in the parallel group to the same busbar on the secondary side.
4. Open the test display for Transformer Voltage Control on the LHMI in **Main menu/Test/Function status/Control/TransformerVoltageControl(ATCC,90)**.
5. Manually execute Raise commands to step up the tap changer for transformer T1 to two steps above the setting for the other transformers in the parallel group.
6. Check that the value of $I_PRI\text{MI}$ is below the overcurrent blocking level ($I_{\text{block}}$).
7. Check that the value of $I_{\text{CIRCUL}}$ is below the circulating current limit ($C_{\text{CIRCUL}}$).
8. Set the control mode to **Automatic** for all transformers.
9. For transformer T1, adjust the parameter Comp on the local HMI in **Main menu/Settings/Setting group N/Control/TransformerVoltageControl(ATCC,90)/TR8ATCC:x/ParCtrl/Comp** so that the LOWER output is activated due to circulating current. Comp is a setting for circulating current Compensating Factor, and it is effectively a multiplier value to change the sensitivity of the voltage regulation function to measured values of circulating current. A nominal value of 200 for Comp should be appropriate to achieve sensitive voltage regulation. Smaller values may lead to a normal state where tap changers for parallel transformers are well out of step, and values significantly higher will cause over-sensitivity in the voltage control function and tap changer hunting behavior. It is an important outcome of the testing process that the compensating factor is checked for each transformer to ensure sensitive but stable operation for circulating currents. For example, if there are three transformers connected in parallel, and the tap changer of transformer T1 is two steps over the tap changer of T2 and T3, the circulating current detected by the VCTR for T1 will be the sum (with opposite sign) of the current measured at T2 and T3. The currents measured at T2 and T3 will ideally be about the same values. If the voltage is close to the upper limit of the $V_{\text{Deadband}}$, the tap changer of T1 will try to decrease the controlled voltage. In the opposite case, that is, the voltage is close to the lower limit of $V_{\text{Deadband}}$, the tap changer at T1 will not try to decrease the controlled voltage. The tap changer for T2 and T3 will not operate due to the fact that the detected circulating current will be half of the current detected at T1. The setting of the parameter Comp then might need to be increased a little. At least one tap changer step difference between the different transformers should be allowed in order to avoid the tap changers to operate too often. If the allowed difference is, for example, two steps, the tap changer shall be stepped up three steps when setting the parameter Comp.
10. Set the Comp parameter for T2 and T3 in the same manner as for T1. According to the described procedure when the tap changer of one transformer is two steps above the others, it shall automatically step down. When there are only two transformers in the group either shall one step down or the other step up depending on the voltage level at the ATCC.

### 11.1.4 Master Follower (MF) method

The Master Follower method requires a Master to be nominated in a parallel group. It is responsible for measuring secondary bus voltage and executing commands to raise and lower tap changers, which are repeated by Follower transformers in the group.

1. Confirm the voltage blocking levels $OV_{\text{ParBK}}$ and $UV_{\text{ParBK}}$ in **Main menu/Settings/General settings/Control/TransformerVoltageControl(ATCC,90)/TR8ATCC:x/Voltage/U_{\text{max}},U_{\text{min}}**.
2. Check that MFMode is set to **Follow Tap** or **Follow Cmd** in **Main menu/Settings/General settings/Control/TransformerVoltageControl(ATCC,90)/TR8ATCC:x/MFMode**. If this setting is **Follow Tap**, all Follower transformers shall match the actual tap setting of the Master, while **Follow Cmd** requires that Follower transformers follow the RAISE and LOWER commands executed by the Master.
3. Confirm the maximum difference in tap positions for parallel transformers. The number of taps is determined by the setting in the Parameter Setting tool under **Main menu/Settings/Setting group N/Control/TransformerVoltageControl(ATCC,90)/TR8ATCC:x/ParCtrl/MF\text{Pos}Di\text{ff}Li\text{m}**.
4. Connect all transformers in the parallel group to the same busbar on both the primary and secondary sides.

5. Set the control mode to Manual for each transformer in the parallel control group.

6. Open the test display for Transformer Voltage Control on the LHMI in Main menu/Test/Function status/Control/TransformerVoltageControl (ATCC, 90).

7. Manually execute Raise commands to step up the tap changer one step for all transformers in the parallel group.

8. Check that the value of BUSVOLT is below overvoltage blocking level OVPartBK and above the undervoltage blocking level UVPartBK.

9. Set the control mode to Auto for each transformer in the parallel control group.

10. Set Transformer 2 to Master of the parallel group and T1 to Follower (in that order) and repeat steps 7 to 10. Undertake this same test by setting each Transformer in turn to Master.

11. Note that voltage regulation will be mutually blocked if no transformer is set to Master in the parallel group. To confirm this function, set T1 as Master and the other transformers in the parallel group as Follower. Without allocating a new Master, set T1 to Follower and note the Automatic block state on the local HMI for all parallel transformers.

12. Restore T1 to Master of the parallel transformer group and ensure that control mode for each transformer is Automatic.

### 11.1.5 Completing the test

After the test is completed and relevant disturbance records are saved to document the test, go to Main menu/Clear on the local HMI and clear all LEDs, the process eventlist and disturbances from the IED.
Section 12  Commissioning and maintenance of the fault clearing system

12.1 Commissioning tests

During commissioning all protection functions shall be verified with the setting values used at each plant. The commissioning tests must include verification of all circuits by highlighting the circuit diagrams and the configuration diagrams for the used functions.

Further, the settings for protection functions are tested and recorded carefully as outlined for the future periodic maintenance tests.

The final testing includes primary verification of all directional functions where load currents is checked on the local HMI and in PCM600. The magnitudes and angles of all currents and voltages should be checked and the symmetry verified.

Directional functions have information about the measured direction and, for example, measured impedance. These values must be checked and verified as correct with the export or import of power available.

Finally, final trip tests must be performed. This involves activation of protection functions or tripping outputs with the circuit breaker closed and the tripping of the breaker verified. When several breakers are involved, each breaker must be checked individually and it must be verified that the other involved breakers are not tripped at the same time.

12.2 Periodic maintenance tests

The periodicity of all tests depends on several factors, for example the importance of the installation, environmental conditions, simple or complex equipment, static or electromechanical IEDs, and so on.

The normal maintenance practices of the user should be followed. However, ABB's recommendation is as follows:

Every second to third year

- Visual inspection of all equipment.
- Removal of dust on ventilation louvres and IEDs if necessary.
- Periodic maintenance test for protection IEDs of object where no redundant protections are provided.

Every four to six years

- Periodic maintenance test for protection IEDs of objects with redundant protection system.
First maintenance test should always be carried out after the first half year of service.

When protection IEDs are combined with built-in control, the test interval can be increased drastically, up to for instance 15 years, because the IED continuously reads service values, operates the breakers, and so on.

12.2.1 Visual inspection

Prior to testing, the protection IEDs should be inspected to detect any visible damage that may have occurred (for example, dirt or moisture deposits, overheating).

Make sure that all IEDs are equipped with covers.

12.2.2 Maintenance tests

To be made after the first half year of service, then with the cycle as proposed above and after any suspected maloperation or change of the IED setting.

Testing of protection IEDs shall preferably be made with the primary circuit de-energized. The IED cannot protect the circuit during testing. Trained personnel may test one IED at a time on live circuits where redundant protection is installed and de-energization of the primary circuit is not allowed.

ABB protection IEDs are preferably tested by aid of components from the COMBITEST testing system or FT test systems described in information B03-9510 E. Main components are RTXP 8/18/24 test switch usually located to the left in each protection IED and RTXH 8/18/24 test handle, which is inserted in test switch at secondary testing. All necessary operations such as opening of trip circuits, short-circuiting of current circuits and opening of voltage circuits are automatically performed in the right order to allow for simple and safe secondary testing even with the object in service.

Important components of FT test system are FT1, FTx, FT19, FT19RS, FR19RX switches and assemblies as well as FT-1 test plug.

12.2.2.1 Preparation

Before starting maintenance testing, the test engineers should scrutinize applicable circuit diagrams and have the following documentation available:

- Test instructions for protection IEDs to be tested
- Test records from previous commissioning and maintenance tests
- List of valid settings
- Blank test records to fill in measured values
12.2.2 Recording

It is of utmost importance to carefully record the test results. Special test sheets covering the frequency of test, date of test and achieved test values should be used. IED setting list and protocols from previous tests should be available and all results should be compared for differences. At component failures, spare equipment is used and set to the requested value. A note of the exchange is made and the new measured values are recorded. Test records for several years of testing should be stored in a common file for a station, or a part of a station, to give a simple overview of the period of testing and achieved test values. These test records are valuable when analysis of service disturbances shall be done.

12.2.3 Secondary injection

The periodic maintenance test is done by secondary injection from a portable test set. Each protection shall be tested according to the secondary injection test information for the specific protection IED. Only the setting values adopted shall be checked for each protection function. If the discrepancy between obtained value and requested set value is too big the setting should be adjusted, the new value recorded and a note should be made in the test record.

12.2.4 Alarm test

When inserting the test handle of RTXP or using FT plugs, the alarm and event signalling is normally blocked. This is done in the IED by setting the event reporting to Disabled during the test. This can be done when the test handle is inserted or the IED is set to test mode from the local HMI. At the end of the secondary injection test it should be checked that the event and alarm signalling is correct by activating the events and performing some selected tests.

12.2.5 Self supervision check

Once secondary testing has been completed, it should be checked that no self-supervision signals are activated continuously or sporadically. Especially check the time synchronization system, GPS or other, and communication signals, both station communication and remote communication.

12.2.6 Trip circuit check

When the protection IED undergoes an operational check, a tripping pulse is normally obtained on one or more of the output contacts and preferably on the test switch. The healthy circuit is of utmost importance for the protection operation. If the circuit is not provided with a continuous trip-circuit supervision, it is possible to check that circuit is really closed when the test-plug handle has been removed by using a high-ohmic voltmeter and measuring between the plus and the trip output on the panel. The measurement is then done through the trip coil of the circuit breaker and therefore the complete trip circuit is checked.

Note that the breaker must be closed.
Please observe that the test system does not provide built-in security during this test. If the instrument should be set on Amp instead of Volts, the circuit breaker naturally is tripped, therefore, great care is necessary.

Trip circuit from trip IEDs to circuit breaker is often supervised by trip-circuit supervision. It can then be checked that a circuit is healthy by opening tripping output terminals in the cubicle. When the terminal is opened, an alarm shall be achieved on the signal system after a delay of some seconds.

Remember to close the circuit directly after the test and tighten the terminal carefully.

12.2.2.7 Measurement of service currents

After a maintenance test it is recommended to measure the service currents and service voltages recorded by the protection IED. The service values are checked on the local HMI or in PCM600. Ensure that the correct values and angles between voltages and currents are recorded. Also check the direction of directional functions such as Distance and directional overcurrent functions.

For transformer differential protection, the achieved differential current value is dependent on the tap changer position and can vary between less than 1% up to perhaps 10% of rated current. For line differential functions, the capacitive charging currents can normally be recorded as a differential current.

The zero-sequence current to ground-fault protection IEDs should be measured. The current amounts normally very small but normally it is possible to see if the current circuit is "alive".

The neutral-point voltage to an ground-fault protection IED is checked. The voltage is normally 0.1 to 1V secondary. However, voltage can be considerably higher due to harmonics. Normally a CVT secondary can have around 2.5 - 3% third-harmonic voltage.

12.2.2.8 Restoring

Maintenance is very important to improve the availability of the protection system by detecting failures before the protection is required to operate. There is however little point in testing healthy equipment and then putting it back into service with an open terminal, with a removed fuse or open miniature circuit breaker with an open connection, wrong setting, and so on.

Thus a list should be prepared of all items disturbed during test so that all can be put back into service quickly and without overlooking something. It should be put back into service item by item and signed by the responsible engineer.
Section 13  Troubleshooting

13.1  Checking the self supervision signals

13.1.1  Checking the self supervision function

13.1.1.1  Determine the cause of an internal failure

This procedure describes how to navigate the menus in order to find the cause of an internal failure when indicated by the flashing green LED on the HMI module.

Procedure

1. Display the general diagnostics menu. Navigate the menus to: Diagnostics/IED status/General

2. Scroll the supervision values to identify the reason for the failure. Use the arrow buttons to scroll between values.

13.1.2  Self supervision HMI data

13.1.2.1  General IED status

The following table shows the general IED status signals.

Table 21: Signals from the General menu in the diagnostics tree.

<table>
<thead>
<tr>
<th>Indicated result</th>
<th>Possible reason</th>
<th>Proposed action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internal fail Off</td>
<td>No problem detected.</td>
<td>None.</td>
</tr>
<tr>
<td>Internal fail On</td>
<td>A failure has occurred.</td>
<td>Check the rest of the indicated results to find the fault.</td>
</tr>
<tr>
<td>Internal warning Off</td>
<td>No problem detected.</td>
<td>None.</td>
</tr>
<tr>
<td>Internal warning On</td>
<td>A warning has been issued.</td>
<td>Check the rest of the indicated results to find the fault.</td>
</tr>
<tr>
<td>Time synch Ready</td>
<td>No problem detected.</td>
<td>None.</td>
</tr>
<tr>
<td>Time synch Fail</td>
<td>No time synchronization.</td>
<td>Check the synchronization source for problems. If the problem persists, contact your ABB representative for service.</td>
</tr>
<tr>

</table>

Table continues on next page
## 13.2 Fault tracing

### 13.2.1 Internal fault indications

If an internal fault has occurred, the local HMI displays information under **Main menu/Diagnostics/IED status/General**

Under the Diagnostics menus, indications of a possible internal failure (serious fault) or internal warning (minor problem) are listed.

Indications regarding the faulty unit are outlined in table 22.

**Table 22: Self-supervision signals on the local HMI**

<table>
<thead>
<tr>
<th>HMI Signal Name</th>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT Fail</td>
<td>OFF / ON</td>
<td>This signal will be active if one or more of the following internal signals are active; INT--LMDError, INT--WATCHDOG, INT--APPERROR, INT--RTEERROR, or any of the HW dependent signals</td>
</tr>
<tr>
<td>INT Warning</td>
<td>OFF / ON</td>
<td>This signal will be active if one or more of the following internal signals are active; INT--RTCERROR, INT--IEC61850ERROR, INT--TIMESYNCHERROR</td>
</tr>
<tr>
<td>ADMnn</td>
<td>READY / FAIL</td>
<td>Analog input module n failed. Signal activation will reset the IED</td>
</tr>
<tr>

<td>READY / FAIL</td>
<td>BIM error. Binary input module Error status. Signal activation will reset the IED</td>
</tr>
<tr>
<td>BOMn</td>
<td>READY / FAIL</td>
<td>BOM error. Binary output module Error status.</td>
</tr>
<tr>
<td>IOMn</td>
<td>READY / FAIL</td>
<td>IOM-error. Input/Output Module Error status.</td>
</tr>
<tr>
<td>MIMn</td>
<td>READY / FAIL</td>
<td>mA input module MIM1 failed. Signal activation will reset the IED</td>
</tr>
<tr>
<td>RTC</td>
<td>READY / FAIL</td>
<td>This signal will be active when there is a hardware error with the real time clock.</td>
</tr>
</tbody>
</table>

Table continues on next page
### HMI Signal Name | Status | Description
--- | --- | ---
Time Sync | READY / FAIL | This signal will be active when the source of the time synchronization is lost, or when the time system has to make a time reset.

Application | READY / FAIL | This signal will be active if one or more of the application threads are not in the state that Runtime Engine expects. The states can be CREATED, INITIALIZED, RUNNING, etc.

RTE | READY / FAIL | This signal will be active if the Runtime Engine failed to do some actions with the application threads. The actions can be loading of settings or parameters for components, changing of setting groups, loading or unloading of application threads.

IEC61850 | READY / FAIL | This signal will be active if the IEC 61850 stack did not succeed in some actions like reading IEC 61850 configuration, startup etc.

LMD | READY / FAIL | LON network interface, MIP/DPS, is in an unrecoverable error state.

LDCMxxx | READY / FAIL | Line Differential Communication Error status

OEM | READY / FAIL | Optical Ethernet Module error status

Also the internal signals, such as INT--FAIL and INT--WARNING can be connected to binary output contacts for signalling to a control room.

In the IED Status - Information, the present information from the self-supervision function can be viewed. Indications of failure or warnings for each hardware module are provided, as well as information about the external time synchronization and the internal clock. All according to table 22. Loss of time synchronization can be considered as a warning only. The IED has full functionality without time synchronization.

When settings are changed in the IED, the protection and control applications restart in order to take effect of the changes. During restart, internal events get generated and Runtime App error will be displayed. These events are only indications and will be for short duration during the restart.

**IED will not be operational during applications restart.**

### 13.2.2 Using front-connected PC

When an internal fault has occurred, extensive information about the fault can be retrieved from the list of internal events available in the SMS part:

**TRM-STAT TermStatus - Internal Events**
The list of internal events provides valuable information, which can be used during commissioning and fault tracing.

The internal events are time tagged with a resolution of 1ms and stored in a list. The list can store up to 40 events. The list is based on the FIFO principle, when it is full, the oldest event is overwritten. The list cannot be cleared and its content cannot be erased.

The internal events in this list not only refer to faults in the IED, but also to other activities, such as change of settings, clearing of disturbance reports, and loss of external time synchronization.

The information can only be retrieved from the Parameter Setting software package. The PC can be connected either to the port at the front or at the rear of the IED.

These events are logged as internal events.

**Table 23: Events available for the internal event list in the IED**

<table>
<thead>
<tr>
<th>Event message:</th>
<th>Description</th>
<th>Generating signal:</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT--FAIL Off</td>
<td>Internal fail status</td>
<td>INT--FAIL (reset event)</td>
</tr>
<tr>
<td>INT--FAIL</td>
<td></td>
<td>INT--FAIL (set event)</td>
</tr>
<tr>
<td>INT--WARNING Off</td>
<td>Internal warning status</td>
<td>INT--WARNING (reset event)</td>
</tr>
<tr>
<td>INT--WARNING</td>
<td></td>
<td>INT--WARNING (set event)</td>
</tr>
<tr>
<td>IOn--Error Off</td>
<td>In/Out module No. n status</td>
<td>IOn--Error (reset event)</td>
</tr>
<tr>
<td>IOn--Error</td>
<td></td>
<td>IOn--Error (set event)</td>
</tr>
<tr>
<td>ADMn-Error Off</td>
<td>Analog/Digital module No. n status</td>
<td>ADMn-Error (reset event)</td>
</tr>
<tr>
<td>ADMn-Error</td>
<td></td>
<td>ADMn-Error (set event)</td>
</tr>
<tr>
<td>MIM1-Error Off</td>
<td>mA-input module status</td>
<td>MIM1-Error (reset event)</td>
</tr>
<tr>
<td>MIM1-Error</td>
<td></td>
<td>MIM1-Error (set event)</td>
</tr>
<tr>
<td>INT--RTC Off</td>
<td>Real Time Clock (RTC) status</td>
<td>INT--RTC (reset event)</td>
</tr>
<tr>
<td>INT--RTC</td>
<td></td>
<td>INT--RTC (set event)</td>
</tr>
<tr>
<td>INT--TSYNC Off</td>
<td>External time synchronization status</td>
<td>INT--TSYNC (reset event)</td>
</tr>
<tr>
<td>INT--TSYNC</td>
<td></td>
<td>INT--TSYNC (set event)</td>
</tr>
<tr>
<td>INT--SETCHGD</td>
<td>Any settings in IED changed</td>
<td></td>
</tr>
<tr>
<td>DRPC-CLEARED</td>
<td>All disturbances in Disturbance report cleared</td>
<td></td>
</tr>
</tbody>
</table>

The events in the internal event list are time tagged with a resolution of 1ms.

This means that, when using the PC for fault tracing, it provides information on the:

- Module that should be changed.
- Sequence of faults, if more than one unit is faulty.
- Exact time when the fault occurred.
13.2.3 Diagnosing the IED status via the LHMI hint menu

In order to help the user, there is an LHMI page labeled ‘Hints’. This page is located under Main menu/Diagnostics/IED status/Hints. For each activated hint there is a headline. From the headline view, an explanation page can be entered, giving the user more information and hints about the particular topic.

For example, if there is a configuration to use IEC 61850 9–2 analog data, but no data arrives on the access point, then the IED will use substituted data and most protection functions will be blocked. This condition will be indicated with a sub-menu under Hints, where details about this condition are shown. The Hint menu is a way to assist the user in troubleshooting.

The Hint menu is currently only available in English. All the entries are in English, regardless of which language is selected.

The supported list of hints are as follows:

<table>
<thead>
<tr>
<th>Headline</th>
<th>Explanation</th>
</tr>
</thead>
</table>
| Incorrect setting of SyncLostMode | There are two explanations possible:  
  * SyncLostMode is set to Block, no time source is configured to achieve the required accuracy. Unless a high accuracy time source is selected, the function dependent on high time accuracy will be blocked.  
  * SyncLostMode is set to BlockOnLostUTC, but there is no UTC capable synch source (GPS, IRIG-B) used. Unless a UTC capable time source is selected, the function dependent on high time accuracy will be blocked. |
| Sampled value substituted | <Access Point><Hardware Module Identifier><svID>  
  Where the Hardware Module Identifier is the same as given in PCM600, e.g. AP1: MU1_9201 svID: <ABB_MU0101> |
| Time diff: IED vs Sampled value | <Access Point><Hardware Module Identifier><svID>  
  Where the Hardware Module Identifier is the same as given in PCM600, e.g. AP1: MU1_9201 svID: <ABB_MU0101> |
| Frequency diff: IED vs Sampled value | <Access Point><Hardware Module Identifier><svID>  
  Where the Hardware Module Identifier is the same as given in PCM600, e.g. AP1: MU1_9201 svID: <ABB_MU0101> |
| Wrong cycle time for PMU report | Wrong cycle time on SMAI or 3PHSUM block connected to Phasor Report block. The SMAI or 3PHSUM block should have the same cycle time as that of Phasor Report. |
| PMU not connected to 3ph output | The PMU phasor report input(s) must be connected to the 3ph output of SMAI or 3PHSU. |

Table continues on next page
<table>
<thead>
<tr>
<th>Headline</th>
<th>Explanation</th>
</tr>
</thead>
</table>
| **Invalid value set for PMU Parameters** | There are two explanations possible:  
- Check if the following parameters are set correctly on PMUREPORT: ReportRate or SvcClass or parameter PRIMVAL:1.FrequencySel is not set as 50Hz / 60Hz.  
- Check if the following parameters are set correctly on PMUREPORT: ReportRate or SvcClass or RptTimetag or parameter PRIMVAL:1.FrequencySel is not set as 50Hz / 60Hz. |
| **Invalid phase angle reference** | The selected PhaseAngleRef corresponds to an analog channel that is not configured. Please configure a valid reference channel. |
| **GOOSE is configured on a disabled port** | At least one of the access points configured for GOOSE is disabled. The port can be disabled either through changing the access point operation to off or by unchecking the GOOSE protocol from the access point in the Ethernet configuration in PCM600 or LHMI. Please enable GOOSE on access points: AP_FRONT, AP_1 |
| **LDCM not running the application image** | <slot number> is running the factory image instead of the application image. The factory image is older and does not contain the latest updates and fixes. Please reboot the IED. If the problem persists update the LDCM firmware or replace the board. |
| **LDCM version is not accepted** | <device name> firmware version <version string> is not accepted. The minimum accepted version is <version string>. Please update the LDCM firmware or replace the board. |
| **OEM not running the application image** | OEM in slot <slot number> is running the factory image instead of the application image. The factory image is older and does not contain the latest updates and fixes. Please reboot the IED. If the problem persists, update the OEM firmware or replace the board. |
| **SFP unplugged from the slot** | SFP has been unplugged from the slot. Please check the connection. Corresponding hardware(s) is set to fail. |
| **SFP replaced with other type** | Configured and the detected SFP(s) are different. Corresponding hardware(s) is set to fail. Please restart IED and consider Reconfigure HW modules to get updated hardware list. |
| **Non ABB vendor SFP detected** | Non ABB vendor SFP detected. Corresponding hardware(s) is set to fail. Please use ABB approved SFP’s. |

### 13.2.4 Hardware re-configuration

When adding, removing or moving a hardware modules in an IED (for example, I/O modules, communication modules or time synchronization modules) a set of procedures must be followed.

**Adding a new module in to an IED**

Procedure:
1. Switch the IED off and insert the new module.
2. Switch the IED on, wait for it to start, and then perform a HW reconfig.
3. Perform a license update in PCM600.

The new module is now available in PCM600 and is ready to be configured.

**Removing a module from an IED**

Procedure:

1. Remove all existing configuration for the module in PCM, and write that configuration to the IED.
2. Switch the IED off and remove the HW module.
3. Switch the IED on, wait for it to start, and then perform a HW reconfig.
4. Perform a license update in PCM 600.

If any configuration that makes the module needed remains, then the HW reconfig will not remove the module.
The module will still be needed. An error indication for the module will appear, if the module is physically removed from the IED and the IED is restarted with some part of the configuration still requiring the module.

**Moving a module in an IED from one position to another**

Procedure:

1. Remove all existing configuration for the module in PCM, and write that configuration to the IED.
2. Switch the IED off and move the HW module.
3. Switch the IED on, wait for it to start, and then perform a HW reconfig.
4. Perform a license update in PCM600.

The new module is now available in PCM600 at the new position and is ready to be configured.

**13.3 Repair instruction**

- Never disconnect the secondary connection of a current transformer circuit without short-circuiting the transformer’s secondary winding. Operating a current transformer with the secondary winding open will cause a massive potential buildup that may damage the transformer and may cause injuries to humans.

- Never connect or disconnect a wire and/or a connector to or from a IED during normal service. Hazardous voltages and currents are present that may be lethal. Operation may be disrupted and IED and measuring circuitry may be damaged.
An alternative is to open the IED and send only the faulty circuit board to ABB for repair. When a printed circuit board is sent to ABB, it must always be placed in a metallic, ESD-proof, protection bag. The user can also purchase separate replacement modules.

Strictly follow the company and country safety regulations.

Most electronic components are sensitive to electrostatic discharge and latent damage may occur. Please observe usual procedures for handling electronics and also use an ESD wrist strap. A semi-conducting layer must be placed on the workbench and connected to ground.

Disassemble and reassemble the IED accordingly:

1. Switch off the dc supply.
2. Short-circuit the current transformers and disconnect all current and voltage connections from the IED.
3. Disconnect all signal wires by removing the female connectors.
4. Disconnect the optical fibers.
5. Unscrew the main back plate of the IED.
6. If the transformer module is to be changed:
   • Remove the IED from the panel if necessary.
   • Remove the rear plate of the IED.
   • Remove the front plate.
   • Remove the screws of the transformer input module, both front and rear.
7. Pull out the faulty module.
8. Check that the new module has a correct identity number.
9. Check that the springs on the card rail are connected to the corresponding metallic area on the circuit board when the new module is inserted.
10. Reassemble the IED.

If the IED has been calibrated with the system inputs, the calibration procedure must be performed again to maintain the total system accuracy.

13.4 Repair support

If an IED needs to be repaired, the whole IED must be removed and sent to an ABB Logistic Center. Please contact the local ABB representative to get more details.

13.5 Maintenance

The IED is self-supervised. No special maintenance is required.

Instructions from the power network company and other maintenance directives valid for maintenance of the power system must be followed.
Section 14  Glossary

AC  Alternating current
ACC  Actual channel
ACT  Application configuration tool within PCM600
A/D converter  Analog-to-digital converter

IDBS
Integrating deadband supervision

IEC
International Electrical Committee

IEC 60044-6
IEC Standard, Instrument transformers – Part 6: Requirements for protective current transformers for transient performance

IEC 60870-5-103
Communication standard for protection equipment. A serial master/slave protocol for point-to-point communication

IEC 61850
Substation automation communication standard

IEC 61850–8–1
Communication protocol standard

IEEE
Institute of Electrical and Electronics Engineers

IEEE 802.12
A network technology standard that provides 100 Mbits/s on twisted-pair or optical fiber cable

IEEE P1386.1
PCI Mezzanine Card (PMC) standard for local bus modules. References the CMC (IEEE P1386, also known as Common Mezzanine Card) standard for the mechanics and the PCI specifications from the PCI SIG (Special Interest Group) for the electrical EMF (Electromotive force).

IEEE 1686
Standard for Substation Intelligent Electronic Devices (IEDs) Cyber Security Capabilities

IED
Intelligent electronic device

IET600
Integrated engineering tool

I-GIS
Intelligent gas-insulated switchgear

IOM
Binary input/output module

Instance
When several occurrences of the same function are available in the IED, they are referred to as instances of that function. One instance of a function is identical to another of the same kind but has a different number in the IED user interfaces. The word “instance” is sometimes defined as an item of information that is representative of a type. In the same way an instance of a function in the IED is representative of a type of function.

IP
1. Internet protocol. The network layer for the TCP/IP protocol suite widely used on Ethernet networks. IP is a connectionless, best-effort packet-switching protocol. It provides packet routing, fragmentation and reassembly through the data link layer.
2. Ingression protection, according to IEC 60529

IP 20
Ingression protection, according to IEC 60529, level IP20- Protected against solid foreign objects of 12.5mm diameter and greater.

IP 40
Ingression protection, according to IEC 60529, level IP40-Protected against solid foreign objects of 1mm diameter and greater.

IP 54
Ingression protection, according to IEC 60529, level IP54-Dust-protected, protected against splashing water.

IRF
Internal failure signal

IRIG-B:
InterRange Instrumentation Group Time code format B, standard 200
