INSTRUCTIONS FOR USE

PLC Automation

Automation Builder, AC500

Automation Builder 2.4.0, AC500 V3
Table of contents

1 PLC Automation with V3 CPUs
   1.1 Getting started
      1.1.1 Introduction
      1.1.2 Cyber security in AC500 V3 products
         1.1.2.1 Defense in depth
         1.1.2.2 Secure operation
      1.1.3 Installing Automation Builder
      1.1.4 Licensing procedure
         1.1.4.1 Activating Automation Builder license
         1.1.4.2 Activation of Automation Builder licensing
         1.1.4.3 Online activation
         1.1.4.4 Offline activation
         1.1.4.5 Activating PLC application library license
         1.1.4.6 Installing an additional license
         1.1.4.7 Activating the stand-alone tool
      1.1.5 Set-up communication parameters in windows
      1.1.6 Information on the installed version
      1.1.7 PLC runtime and demo licensing
      1.1.8 Menues, views, windows
         1.1.8.1 Start page and menus
         1.1.8.2 'All Messages' window
      1.1.9 Device repository
      1.1.10 Creating and configuring projects
      1.1.11 Handling of AC500 projects
      1.1.12 Connection of devices
         1.1.12.1 Configuring devices
         1.1.12.2 Symbolic names for variables, inputs and outputs
         1.1.12.3 Update of AC500 devices
         1.1.12.4 Comparing objects
      1.1.13 Connection of serial interfaces
         1.1.13.1 Programming of applications
      1.1.14 I/O mapping
      1.1.15 AC500 PLC configuration
      1.1.16 Convert an AC500 V2 project to an AC500 V3 project
      1.1.17 Example projects
         1.1.17.1 Hardware AC500 V3
         1.1.17.2 Example project for central I/O expansion
            1.1.17.2.1 Preconditions
            1.1.17.2.2 Create, set-up and save your AC500 V3 project
            1.1.17.2.3 Configure the I/O module
            1.1.17.2.4 Programming and compiling
            1.1.17.2.5 Set-up the communication gateway
            1.1.17.2.6 AC500 V3 firmware installation and update
            1.1.17.2.7 Log-in to CPU and download the program
# Table of contents

1.1.17.2.8 Test the program................................................................. 62
1.1.17.2.9 Set-up visualization............................................................ 64
1.1.17.2.10 Create visualization......................................................... 68
1.1.17.2.11 Enable web visualization................................................ 75
1.1.17.2.12 Reset the CPU................................................................. 80
1.1.17.3 Example project for remote I/O expansion with PROFINET.............................................................................. 81
1.1.17.3.1 Preconditions.................................................................. 81
1.1.17.3.2 Set-up PROFINET controller........................................... 82
1.1.17.3.3 Set-up PROFINET device................................................ 84
1.1.17.3.4 Add remote I/O expansion to project......................... 88
1.1.17.3.5 Test the program.............................................................. 91
1.1.17.3.6 Reset the CPU................................................................. 92
1.2 Automation Builder installation manager.......................................... 94
1.2.1 Installing customer specific package..................................... 95
1.2.2 Adding or removing installed software packages................. 96
1.2.3 Checking for updates.............................................................. 97
1.2.4 Uninstalling Automation Builder.......................................... 98
1.3 Programming with IEC 61131-3 editor.............................................. 99
  1.3.1 CODESYS Development System............................................. 99
    1.3.1.1 Configuring CODESYS.................................................. 102
    1.3.1.1.1 Setting CODESYS options...................................... 102
    1.3.1.1.2 Customizing the user interface............................... 102
    1.3.1.2 Your first CODESYS program.................................... 108
    1.3.1.3 Creating and configuring a project................................. 124
    1.3.1.3.1 Creating standard projects.................................. 124
    1.3.1.3.2 Adding objects....................................................... 125
    1.3.1.3.3 Changing the compiler version............................... 126
    1.3.1.3.4 Opening a V3 project............................................ 127
    1.3.1.3.5 Opening a V2.3 project.......................................... 128
    1.3.1.3.6 Configuring a project............................................ 131
    1.3.1.4 Exporting and transferring a project............................. 135
    1.3.1.4.1 Exporting and importing projects.......................... 135
    1.3.1.4.2 Transferring projects............................................ 136
    1.3.1.5 Comparing projects....................................................... 137
    1.3.1.5.1 Creating a comparison view.................................. 137
    1.3.1.5.2 Opening the Detailed Compare View............... 138
    1.3.1.6 Protecting and saving a project..................................... 139
    1.3.1.6.1 Setting up write protection.................................. 142
    1.3.1.6.2 Assigning passwords............................................. 143
    1.3.1.6.3 Protecting projects using a dongle.......................... 144
    1.3.1.6.4 Setting up a user management................................ 145
    1.3.1.6.5 Protecting objects in the project by access rights..... 146
    1.3.1.6.6 Logging in via user account and password manager... 147
    1.3.1.6.7 Encrypting projects with certificates..................... 149
    1.3.1.6.8 Save project....................................................... 150
    1.3.1.6.9 Saving/Sending the project archive......................... 152
    1.3.1.6.10 Linking a project to the source control system..... 152
    1.3.1.7 Localizing projects...................................................... 153
    1.3.1.8 Configuring I/O links................................................... 155
      1.3.1.8.1 Device tree and device editor............................ 155
      1.3.1.8.2 Mapping a hardware structure in the device tree..... 159

1 PLC Automation with V3 CPUs
1.1 Getting started
1.1.1 Introduction

ABB Automation Builder is the integrated software suite for machine builders and system integrators wanting to automate their machines and systems in a productive way. Combining the tools required for configuring, programming, debugging and maintaining automation projects from a common intuitive interface, Automation Builder addresses the largest single cost element of most of today's industrial automation projects: software. ABB Automation Builder covers the engineering of ABB PLCs, Safety PLCs, control panels, drives, motion and robots.

Before starting Automation Builder configuration read the version specific information provided in the Automation Builder ReadMe file. It describes new features and functions as well as workarounds on known problems. The ReadMe file is stored in the installation directory of Automation Builder, however can be downloaded as well from ABB website http://new.abb.com/plc/automationbuilder.

1.1.1.1 Cyber security in Automation Builder

This product is designed to be connected to and to communicate information and data via a network interface. It is your sole responsibility to provide and continuously ensure a secure connection between the product and your network or any other network (as the case may be). You shall establish and maintain any appropriate measures (such as but not limited to the installation of firewalls, application of authentication measures, encryption of data, installation of anti-virus programs, etc.) to protect the product, the network, its system and the interface against any kind of security breaches, unauthorized access, interference, intrusion, leakage and/or theft of data or information. ABB Ltd and its affiliates are not liable for damages and/or losses related to such security breaches, any unauthorized access, interference, intrusion, leakage and/or theft of data or information.

Although ABB provides functionality testing on the products and updates that we release, you should institute your own testing program for any product updates or other major system updates (to include but not limited to code changes, configuration file changes, third party software updates or patches, hardware exchanges, etc.) to ensure that the security measures that you have implemented have not been compromised and system functionality in your environment is as expected. This also applies to the operating system. Security measures (such as but not limited to the installation of latest patches, installation of firewalls, application of authentication measures, installation of anti-virus programs, etc.) are in your responsibility. You have to be aware that operating systems provide a considerable number of open ports that should be monitored carefully for any threats.

It has to be considered that online connections to any devices are not secured. It is your responsibility to assure that connections are established to the correct device (and e.g. not to an unknown device pretending to be a known device type). Furthermore you have to take care that confidential data exchanged with the PLC is either compiled or encrypted.

1.1.1.2 Cyber security in AC500 V3 products

This product is designed to be connected to and to communicate information and data via a network interface. It is your sole responsibility to provide and continuously ensure a secure connection between the product and your network or any other network (as the case may be). You shall establish and maintain any appropriate measures (such as but not limited to the installation of firewalls, application of authentication measures, encryption of data, installation of anti-virus programs, etc.) to protect the product, the network, its system and the interface against any kind of security breaches, unauthorized access, interference, intrusion, leakage and/or theft of data or information. ABB Ltd and its affiliates are not liable for damages and/or losses related to such security breaches, any unauthorized access, interference, intrusion, leakage and/or theft of data or information.

Although ABB provides functionality testing on the products and updates that we release, you should institute your own testing program for any product updates or other major system updates (to include but not limited to code changes, configuration file changes, third party software updates or patches, hardware exchanges, etc.) to ensure that the security measures that you have implemented have not been compromised and system functionality in your environment is as expected. This also applies to the operating system. Security measures (such as but not limited to the installation of latest patches, installation of firewalls, application of authentication measures, installation of anti-virus programs, etc.) are in your responsibility. You have to be aware that operating systems provide a considerable number of open ports that should be monitored carefully for any threats.

It has to be considered that online connections to any devices are not secured. It is your responsibility to assure that connections are established to the correct device (and e.g. not to an unknown device pretending to be a known device type). Furthermore you have to take care that confidential data exchanged with the PLC is either compiled or encrypted.
programs, etc.) to protect the product, the network, its system and the interface against any kind of security breaches, unauthorized access, interference, intrusion, leakage and/or theft of data or information. ABB Ltd and its affiliates are not liable for damages and/or losses related to such security breaches, any unauthorized access, interference, intrusion, leakage and/or theft of data or information.

The firmware update files for the AC500 V3 PLC are digitally signed releases by ABB. During the update process, these signatures are validated by a hardware security component in the PLC. This way, the AC500 V3 PLC will only update with valid, authentic firmware, signed by ABB.

The AC500 V3 PLC comes with minimal services opened by default. Only the services needed for initial setup and programming are open before any user application is downloaded.

Details

Chapter 1.5.1.3 “Ethernet protocols and ports for AC500 V3 products” on page 2224.

The AC500 V3 PLC contains a secure shell service to access core logging data in case of problems which need a deeper analysis. This service is inactive by default, which means that no one can access this privileged shell in the normal operating state.

To activate this service, local access to the PLC is necessary and activation is only valid until the next power cycle of the PLC. Once activated, the service run on TCP port 22. Each PLC also protects the secure shell access by an individual password.

1.1.1.2.1 Defense in depth

The defense in depth approach implements multi-layer IT security measures. Each layer provides its special security measures. All deployed security mechanisms in the system must be updated regularly. It is also important to follow the system vendor’s recommendations on how to configure and use these mechanisms. As a basis, the components must include security functions such as:

- Virus protection
- Firewall protection
- Strong and regularly changed passwords
- User management
- Using VPN tunnels for connections between networks

Additional security components such as routers and switches with integrated firewalls should be available. A defined user and rights concept managing access to the controllers and their networks is mandatory. Finally, the manufacturer of the components should be able to quickly discover weaknesses and provide patches.

References: CODESYS Security Whitepaper

Security zones

IT resources vary in the extent to which they can be trusted. A common security architecture is therefore based on a layered approach that uses zones of trust to provide increasing levels of security according to increasing security needs. Less-trusted zones contain more-trusted zones and connections between the zones are only possible through secure interconnections such as firewalls. Fig. 1. All resources in the same zone must have the same minimum level of trust. The inner layers, where communication interaction needs to flow freely between nodes, must have the highest level of trust. This is the approach described in the IEC 62443 series of standards.
Firewalls, gateways, and proxies are used to control network traffic between zones of different security levels, and to filter out any undesirable or dangerous material. Traffic that is allowed to pass between zones should be limited to what is absolutely necessary because each type of service call or information exchange translates into a possible route that an intruder may be able to exploit. Different types of services represent different risks. Internet access, incoming e-mail and instant messaging, for example, represent very high risks.

![Cooperate network](image)

**Fig. 1: Security zones**

Fig. 1 shows three security zones, but the number of zones does not have to be as many or as few as three. The use of multiple zones allows access between zones of different trust levels to be controlled to protect a trusted resource from attack by a less trusted one.

High-security zones should be kept small and independent. They need to be physically protected, i.e. physical access to computers, network equipment and network cables must be limited by physical means to authorized persons only. A high-security zone should obviously not depend on resources in a less secure zone for its security. Therefore, it should form its own domain that is administered from the inside, and not depend on, e.g., a domain controller in a less secure network.

Even if a network zone is regarded as trusted, an attack is still possible: by a user or compromised resource that is inside the trusted zone, or by an outside user or resource that succeeds to penetrate the secure interconnection. Trust therefore depends also upon the types of measures taken to detect and prevent compromise of resources and violation of the security policy.

References: *Security for Industrial Automation and Control Systems*

### 1.1.2 Secure operation

The controller must be located in a protected environment in order to avoid accidental or intended access to the controller or the application.

A protected environment can be:

- Locked control cabinets without connection from outside
- No direct internet connection
- Use firewalls and VPN to separate different networks
- Separate different production areas with different access controls

To increase security, physical access protection measures such as fences, turnstiles, cameras or card readers can be added.
Follow these rules for the protected environment:

- Keep the trusted network as small as possible and independent from other networks.
- Protect the cross-communication of controllers and the communication between controllers and field devices via standard communication protocols (fieldbus systems) using appropriate measures.
- Protect such networks from unauthorized physical access.
- Use fieldbus systems only in protected environments. They are not protected by additional measures, such as encryption. Open physical or data access to fieldbus systems and their components is a serious security risk.
- Physically protect all equipment, i.e., ensure that physical access to computers, network equipment and cables, controllers, I/O systems, power supplies, etc., is limited to authorized persons.
- When connecting a trusted network zone to outer networks, make sure that all connections are through properly configured secure interconnections only, such as a firewall or a system of firewalls, which is configured for “deny by default”, i.e., blocks everything except traffic that is explicitly needed to fulfill operational requirements.
- Allow only authorized users to log on to the system, and enforce strong passwords that are changed regularly.
- Continuously maintain the definitions of authorized users, user groups, and access rights, to properly reflect the current authorities and responsibilities of all individuals at all times. Users should not have more privileges than they need to do their job.
- Do not use the system for e-mail, instant messaging, or internet browsing. Use separate computers and networks for these functions if they are needed.
- Do not allow installation of any unauthorized software in the system.
- Restrict temporary connection of portable computers, USB memory sticks and other removable data carriers. Computers that can be physically accessed by regular users should have ports for removable data carriers disabled.
- If portable computers need to be connected, e.g., for service or maintenance purposes, they should be carefully scanned for viruses immediately before connection.
- All CDs, DVDs, USB memory sticks and other removable data carriers, and files with software or software updates, should also be checked for viruses before being introduced into the trusted zone.
- Continuously monitor the system for intrusion attempts.
- Define and maintain plans for incident response, including how to recover from potential disasters.
- Regularly review the organization as well as technical systems and installations with respect to compliance with security policies, procedures and practices.

A protected local control cabinet could look like in picture 2, page 17. This network is not connected to any external network. Security is primarily a matter of physically protecting the automation system and preventing unauthorized users from accessing the system and from connecting or installing unauthorized hardware and software.

![Diagram of Trusted Zone and Isolated Automation Network]

**Fig. 2: Isolated automation system**
Servers and workplaces that are not directly involved in the control and supervision of the process should preferably be connected to a subnet that is separated from the automation system network by means of a router/firewall. This makes it possible to better control the network load and to limit access to certain servers on the automation system network. Note that servers and workplaces on this subnet are part of the trusted zone and thus need to be subject to the same security precautions as the nodes on the automation system network.

Fig. 3: Plant information network connected to an automation system

For the purposes of process control security, a general-purpose information system (IS) network should not be considered a trusted network, not the least since such networks are normally further connected to the Internet or other external networks. The IS network is therefore a different lower-security zone, and it should be separated from the automation system by means of a firewall. The IS and automation system networks should form separate domains.
1.1.2 Installing Automation Builder

**Preconditions**  You must have administrator rights on your PC to install Automation Builder.

**Installation**

1. Go to [abb.com/automationbuilder](http://abb.com/automationbuilder) to access the homepage of Automation Builder.
2. In the “Downloads” section, select “Download Automation Builder”.
3. In the “Latest Automation Builder” section, select “Automation Builder x.x. Download” (x.x = latest version). This downloads the installer on your PC.
4. Open the downloaded installer and follow the instructions of the installation manager.
5. Keep the default type of installation to “Premium Edition”.
6. Select software packages to be installed:
   Enable the check box “PLC - AC500 V3” to activate installation of all options for AC500 V3.
7. Click “Download and install” and follow the instructions of the setup.

1.1.3 Licensing procedure

1.1.3.1 Activating Automation Builder license

1. Automation Builder software must be installed successfully.
2. Start Automation Builder.
   A licensing wizard starts and guides you through the licensing procedure.
3. Enter user information and select [OK].
   In case of future support requests, your registration details enable ABB support team to handle your questions quickly.
4. If you purchase a license that is locked to a flash drive, plug in the device and select [Next].
**Fig. 5: Activation mode**

- **Activation key**: Enable this option and enter the key. For further information on how to receive this key, contact ABB sales team.
- **Trial license**: You can test Automation Builder software with a trial version in Premium Edition. In this case no activation key is required.
- **Basic license**: You can install Automation Builder software in Basic Edition. In this case no activation key is required.
- **Offline activation**: This is required in case of unavailability of internet on the PC. See Chapter 1.1.3.4 “Offline activation” on page 23.

4. Choose an activation mode and select [Next].
5. Select the license lock mode according to your purchased license and select [Next].
   - If you hold a single PC license, choose PC locked option to license and lock Automation Builder software to the current PC.
   - If you hold a license for portable Automation Builder software, plug a USB drive, enable Portable option and choose your USB drive from the drop-down list. With this, a portable Automation Builder license is created, which allows to operate Automation Builder software on any PC.

6. Select the activation mode and select [Next].
   - Select “Online Activation” in Chapter 1.1.3.3 “Online activation” on page 23 if the PC contains internet access or select “Offline Activation” in Chapter 1.1.3.4 “Offline activation” on page 23.
1.1.3.2 Automation Builder licensing

Automation Builder requires a valid license. Depending on the required functionality, Automation Builder can be licensed in Basic, Standard or Premium edition.

For license validation, use CodeMeter licensing server from WIBUS system. Generally, licensing mechanism is automatic without further user action. However, you can set up and use your own licensing server. For further information on setting up this server, see the manufacturer documentation (http://www.wibu.com/en/manuals-guides.html).

Part of Automation Builder licensing is registration and activation (usually with an activation key).

For testing purpose, Automation Builder can be installed as a trial version (Premium Edition). The trial version expires after 30 days and then the Automation Builder requires an appropriate license.

1.1.3.3 Online activation

The activation data can be sent to ABB License server if the current PC contains internet access.

1. Enable “Online Activation” and select [Next].
   - Activation procedure starts. A successfully ended licensing procedure ends with a success message.
2. Select [OK] to end the wizard.
   - Automation Builder license is activated and starts.

1.1.3.4 Offline activation

The activation data cannot be sent to the licensing server if the PC does not have internet access. In this case, the offline activation file is created. This file can be used to transfer activation data to the licensing server from another PC with internet access.

1. Enable “Offline Activation” and select [Next].
2. From the file system choose a shareable location (e.g., a shared folder or a USB drive).
   ● Enter a file name and select [Save]. An activation file is created and stored to the selected directory.
   ● Do not close (Cancel) or proceed (Next) the wizard. The license activation is made from a PC with internet availability.
3. Upload the activation file to the licensing website (http://lc.codemeter.com/32838/depot).
   - Follow the instructions.
   - Default language can be changed with the drop-down menu on the right side of the screen.
     ⇒ You will receive an activation response file.

4. Store the file to a shareable location (e.g. a shared folder or a USB drive).

5. Return to your original PC.

6. Select [Browse] and select the activation response file from the shareable location.
   ⇒ Due to security reasons an activation receipt file is created.

7. Enter a file name and store the activation receipt file to a shareable location (e.g. a shared folder or a USB drive).

8. Move to a PC with internet availability and upload the activation receipt file from the shareable location to the registration website (http://lc.codemeter.com/32838/depot).

### 1.1.3.5 Activating PLC application library license

The PLC application library can be activated using Automation Builder License Manager in online and offline modes.

- “Automation Builder License Manager” is installed.

1. Start “Automation Builder License Manager”.
   - Go to “Start ➔ All Programs ➔ ABB ➔ Automation Builder ➔ Automation Builder License Manager”.

---

**Fig. 8: Licensing website**

- Upload activation request
- Download activation response
- Upload activation receipt

Activating your licenses offline - First step “Upload activation request”:
1. Create an activation request file with the Automation Builder Activation Wizard.
2. Pick the created activation request file.
3. Click “Upload request and continue”.

Pick activation request file (*.xml)

Choose File  No file chosen

Upload request and continue

---

PLC Automation with V3 CPUs
Getting started > Licensing procedure
2. Choose an activation mode and click “Next”.
   - **Activation key**: For information on how to receive an activation key, contact the ABB sales team.
   - **Offline activation**: This is required in case of unavailability of internet access.

3. Follow step 5 and 6 in Chapter 1.1.3.1 “Activating Automation Builder license” on page 20 to proceed further.

For an online or offline activation of a PLC application library license, see Chapter 1.1.3.3 “Online activation” on page 23 and Chapter 1.1.3.4 “Offline activation” on page 23.

### 1.1.3.6 Installing an additional license

The additional feature or software which need additional license other than Automation Builder license can be activated in an easy way. You can activate additional license using online and offline modes.

1. In Automation Builder, go to “Tools ⇒ Install additional license”.
2. Choose activation mode and select [Next].
   - **Online activation**: Activate the license in online mode using activation key Chapter 1.1.3.3 “Online activation” on page 23.
   - **Offline activation**: Activate the license in offline mode using activation file Chapter 1.1.3.4 “Offline activation” on page 23.

   For information on how to receive online activation key and offline activation file, contact ABB sales team.

3. After installing additional license, restart Automation Builder to enable the new feature or software.

### 1.1.3.7 Activating the stand-alone tool

Automation Builder License Manager is a stand-alone tool which is used for registration and license activation.

In case, if the user need to install stand-alone tool using **Install Additional Tools** without Automation Builder installation, the stand-alone tool must be activated using Automation Builder license key. The user can launch the tool manually from start menu and do the registration and license activation same as Automation Builder license activation. For further information, see section Chapter 1.1.3.1 “Activating Automation Builder license” on page 20.

### 1.1.4 Set-up communication parameters in windows

To set-up the communication between the PC and the PLC, e.g., for downloading the compiled program, you have to set-up the communication parameters.

The IP address of your PC must be in the same class as the IP address of the CPU.

The factory setting of the IP address of the CPU is 192.168.0.10.

The IP address of your PC should be 192.168.0.X. Avoid X = 10 in order to prevent an IP conflict with the CPU.

Subnet mask should be 255.255.255.0.
Change the IP address

1. Open Windows Control Panel. Click “Network and Internet ➔ Network and Sharing Center”.

2. Click Change adapter settings.

   If using existing network with several devices, please pay attention on given network rules or contact your system administrator.

3. Right-click Local Area Connection (Ethernet) and select Properties.

5. Enter your desired IP address and subnet mask.

1.1.5 Information on the installed version

Further information on the installed Automation Builder version such as installed packages or license terms can be found on the "About" page (help menu) and in startupsettings. Safety Version is visible if safety option is installed. Safety Version Information shows the versions of all safety components.
It is possible to either continue working with a project on an older Automation Builder version or to update a project to the latest Automation Builder version (see also startupsettings).

### 1.1.6 PLC runtime and demo licensing

The use of some libraries and devices require the PLC to have a runtime license. Further it is possible to try out device features or library features by using a demo license \ Chapter 1.5.6.2.2.2 “PLC runtime licensing” on page 3258. See PLC Runtime Licensing.

### 1.1.7 Create log files for support

Professional support requires some information about the project and the devices. To collect this information proceed as follows:
1. Click “Help ➔ About” in the main menu of Automation Builder.

2. Click [Create package for support] and wait until a list of log files is displayed.

3. Click [Save package] to store the zipped log files to your disk, or click [Send package] to send the zipped log files to ABB support.

4. Click [OK].

1.1.8 Menues, views, windows

Ensure the full display of Automation Builder editors by choosing the option Smaller - 100 % (default) in “Start ➔ Control Panel ➔ Appearance and Personalization ➔ Display”. 
1.1.8.1 Start page and menus

After start-up of Automation Builder software the start page is displayed.

All items of the Automation Builder user interface are described in the CODESYS documentation:

- **Commands** ➧ Chapter 1.3.1.25.2 “Menu Commands” on page 852
- **Objects** ➧ Chapter 1.3.1.25.1 “Objects” on page 710
- **Dialog Boxes** ➧ Chapter 1.3.1.25.3 “Dialogs” on page 1039

1.1.8.2 'All Messages' window

Errors, warning and success messages are written to the “All messages” window:
1.1.9 Device repository

The Device Repository of Automation Builder manages the pool of devices that can be used in the PLC configuration.

You install or uninstall devices in the “Device Repository” dialog box. The system installs a device by reading the device description files, which define the device properties for configurability, programmability, and possible connections to other devices.

You can use the devices provided in the device repository by adding them to the device tree of your project.
Dialog device repository

1. Click "Tools ➔ Device Repository".
   ➔ The “Device Repository” dialog box opens.

   ![Device Repository dialog box]

   - [Edit Locations]: Changes the default repository location. The devices can be managed at different locations.
   - [Install] / [Uninstall]: Installs or uninstalls devices.
   - [Renew device repository]: Updates the device list, e.g. after uninstallation of a device.
   - [Details]: Provides technical details on the selected device.

2. Select the install location. “System Repository” is set by default.

Installing devices

The device repository cannot be changed manually, e.g. by copying or deleting files. Use always the Device Repository dialog to add or remove devices.
1. Click [Install] and select the appropriate file format.
   ⇒ The “Install Device Description” dialog box opens.

2. Select the file path of the device description.
3. Select the file type filter of the required device description.
   ⇒ All device descriptions of the selected file type are listed.
4. Select the required device description and click “Open”.
   ⇒ Automation Builder adds the device description to the matching category of your device repository.

   If errors occur during installation (for example, missing files that are referenced by the device description), then Automation Builder displays them in the lower part of the device repository dialog box.

   During the installation the device description files and all additional files referenced by that description will be copied to an internal location. Altering the original files will have no further effects to an internal location.

   The changes take only effect after reinstalling the corresponding device(s). The version number shown in the information section of the device should be verified.

Uninstalling devices
Select the device you want to remove and click [Uninstall].
The device is removed from the list.

Uninstalled devices which are used in existing projects are indicated by the symbol 🝦. The device will not be configured properly.
1.1.10 Creating and configuring projects

What is a project?

- A project contains the objects that are necessary for the creation of a control program ('application'):
  - Pure POUs, for example programs, function blocks, functions, GVLs.
  - Objects that are additionally required in order to be able to execute the application on a PLC. For example, task configuration, library manager, symbol configuration, device configuration, visualizations, external files.
- You can program several applications and connect several control devices in a project.
- CODESYS manages device-specific and application-specific POUs in the "Devices" view ('Device tree'), project-wide available POUs in the "POUs" view.
- For the creation of projects there are templates that already contain certain objects.
- Basic configurations and information for the project are defined in the "Project Settings" and the "Project Information". For example:
  - Compiler settings
  - User management
  - Author
  - Data for the project file.

There are settings for the version compatibility of the project in the configuration dialog boxes for the "Project Environment".

- You save a project as a file in the file system. Optionally you can pack it together with project-relevant files and information in a project archive. Saving in a source control system such as SVN is also possible
- Each project contains the information regarding the CODESYS version with which it was created. If you open it in another version, CODESYS will draw your attention to possible or necessary updates with regard to file format, library versions, etc.
- You can compare, export or import projects and create documentation for them.
- You can protect a project against change and completely, i.e. also against reading. By using a user management system you can purposefully control access to the project and even to individual objects in the project.

Handling of AC500 projects such as project creation, export/import, comparison of projects etc. is described in the sections for AC500 V3 products Chapter 1.5.6.1.1 "Project handling" on page 3228

1.1.11 Handling of AC500 projects

Handling of AC500 projects such as project creation, export/import, comparison of projects etc. is described in the sections for AC500 V3 products Chapter 1.5.6.1.1 "Project handling" on page 3228

Copy-and-paste from one project to another project in two different Automation Builder instances is possible. After copying parts of a project to a higher Automation Builder version the copied components have to be updated.

It is not possible to downgrade a project to an earlier Automation Builderversion.

- Import of export files is only allowed in the same profile version.
- Copy-and-paste of configurations must not be used to copy objects to an earlier version.
Automation Builder performs an integrity check for the PLC configuration before generating the configuration.

Project archive
Automation Builder supports the creation and the import of project archive files. Archive files contain all relevant project data including the PLC configuration, the CODESYS project files and all device descriptions. This allows exchanging Automation Builder projects without taking care of the target environment General Settings % Chapter 1.5.6.1 “General settings” on page 3228.

User and access rights of a project
The ‘User Management’ provides functions for defining user accounts and configure the access rights within a project. The rights to access project objects via specified actions are assigned only to user groups, not to a single user account. So each user must be member of a group General Settings % Chapter 1.5.6.1 “General settings” on page 3228.

1.1.12 Connection of devices
1.1.12.1 Configuring devices
Modify your Automation Builder project by adding device objects. Preset items can be replaced in the same way.

1. In the device tree, right-click an item node. Select “Add object”.

2. Select the desired object and click [Add object].
3. Double-click the new object in the device tree to configure the device settings. Depending on the selected item different configuration tabs are available.

1.1.12.2 Symbolic names for variables, inputs and outputs

The IEC naming rules are not checked during input in Automation Builder.

Input and output mapping

Devices with I/Os provide an I/O Mapping tab in their configuration editor where the available I/O channels can directly be mapped to a global variable.

The corresponding variable declarations are automatically available in the project.

All available I/O channels can easily be assigned to a variable.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Mapping</th>
<th>Channel</th>
<th>Address</th>
<th>Type</th>
<th>Default Value</th>
<th>Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b_Input_180</td>
<td></td>
<td>Digital inputs 10 - 17</td>
<td>%I0.0</td>
<td>BYTE</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>x_Input_180_I00</td>
<td></td>
<td>Digital input 10</td>
<td>%I0.0</td>
<td>BOOL</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>x_Input_180_I01</td>
<td></td>
<td>Digital input 11</td>
<td>%I0.1</td>
<td>BOOL</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>x_Input_180_I02</td>
<td></td>
<td>Digital input 12</td>
<td>%I0.2</td>
<td>BOOL</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>x_Input_180_I03</td>
<td></td>
<td>Digital input 13</td>
<td>%I0.3</td>
<td>BOOL</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>x_Input_180_I04</td>
<td></td>
<td>Digital input 14</td>
<td>%I0.4</td>

<td>Digital input 16</td>
<td>%I0.6</td>
<td>BOOL</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>x_Input_180_I07</td>
<td></td>
<td>Digital input 17</td>
<td>%I0.7</td>
<td>BOOL</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Digital inputs 10 - 115</td>
<td>%I1</td>
<td>BYTE</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Digital inputs 116 - 123</td>
<td>%I2</td>
<td>BYTE</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Digital inputs 124 - 131</td>
<td>%I3</td>
<td>BYTE</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

AC500 uses Intel Byte Order (Little Endian).

Only entries with a data type set in column "Type" can be mapped. These entries can be expanded to show the available I/O channels.

If the project has been imported from a previous Automation Builder version, all variables should be checked to avoid inconsistencies concerning the I/O mapping.
1.1.12.3 Update of AC500 devices

Perform a **firmware update** to update AC500 V3 devices. Chapter 1.1.17.2.6 “AC500 V3 firmware installation and update” on page 59.

1.1.12.4 Comparing objects

To compare similar objects within a project (such as the project configuration) select both objects. Right-click and select **Compare Objects** to see the differences.

![Image of compare objects](image)

1.1.13 Connection of serial interfaces

Depending on the device type, the configuration of serial interfaces is different.

AC500 V3 Products: **Configuration of serial interfaces** Chapter 1.5.6.2 “PLC devices and components” on page 3254

1.1.13.1 Programming of applications

For creating an application program which is executable on the PLC, you fill POUs with declarations and implementation code (source code), you define the mapping of the hardware I/Os on application variables, and you configure the task handling. After having checked and debugged your implementation, the CODESYS compiler will generate the application code which can be downloaded to the PLC.

The programming of the application POUs will be supported by the programming language editors and further features like for example textlists, image pools, alarm configuration, pragmas, refactoring and usage of ready modules provided by CODESYS Development System or by libraries.
1.1.14 I/O mapping

For all connected I/O devices perform an I/O Mapping.

AC500 V3 Products § Chapter 1.5.6.2.9.7 “I/O mapping list” on page 3309

1.1.15 AC500 PLC configuration

See Getting Started for AC500 V3 Products § Chapter 1.5.6.2.2 “PLC start-up” on page 3257.

1.1.16 Convert an AC500 V2 project to an AC500 V3 project

Instructions on how to convert a V2 project to a V3 project and differences between V2 and V3.

Keywords: Migration, conversion, V2, V3, differences between V2 and V3, application example, checkbox “Change to AC500 V3 PLC”

1.1.17 Example projects

1.1.17.1 Hardware AC500 V3

1.1.17.1.1 Configuration for example projects

The example projects require a small PLC configuration with I/O devices, e.g., as available in the training case TA5450-CASE. https://to.abb/AfO9-ftT

Table 1: Modules for example projects to get started with AC500 V3 PLC

Electrical connection

In the training case, the control panel CP6607 is included. A control panel is not needed for the example projects.

For testing the example project some inputs require to be connected as follows:

Fig. 9: Training case TA5450

Fig. 10: Wiring of training case
For the example projects, not all input switches and none of the potentiometers included in training case are necessary.

You will need switch I1 for the example project for central I/O expansion.

You will need switch I5 for the example project for remote I/O expansion.

### 1.1.17.2 System assembly, construction and connection

**NOTICE!**

**Avoidance of electrostatic charging**

PLC devices and equipment is sensitive to electrostatic discharge, which can cause internal damage and affect normal operation. Observe the following rules when handling the system:

- Touch a grounded object to discharge potential static.
- Wear an approved grounding wrist strap.
- Do not touch connectors or pins on component boards.
- Do not touch circuit components inside the equipment.
- If available, use a static-safe workstation.
- When not in use, store the equipment in appropriate static-safe packaging.

You can mount AC500 PLC either to DIN rail or to a metal plate. Chapter 1.5.4.5.3 “Mounting and demounting” on page 3068. Here, we recommend to mount on DIN rail.

1. Snap the terminal base onto DIN rail.
2. Snap the additional terminal units for I/O modules onto DIN rail.
3. Make the sensor/actuator wire connections according to the dedicated electronic module you want to use. Provide external process power supply as required.
4. If required, make the fieldbus connections according to the dedicated master communication module you want to use.
5. Plug the appropriate electronic and I/O modules in the correct locations (processor module, communication modules on terminal base, and eventually also communication interface modules and I/O modules onto dedicated terminal units).
6. Connect a programming cable (Ethernet cable between ETH port of CPU and PC with engineering software).

### 1.1.17.2 Example project for central I/O expansion

The following steps show how to set-up an application project and configure the hardware. A simple logic is used as example to introduce in programming and commissioning of the PLC. The workflow for creation of a visualization is explained, as well as how to set-up a webserver for visualization.

#### 1.1.17.2.1 Preconditions

- Automation Builder is installed and licensed as, at least, basic edition.
- AC500 V3 CPU is assembled and connected to the PC.
1.1.17.2 Create, set-up and save your AC500 V3 project

Create a project

1. Launch Automation Builder either out of the desktop icon or out of the Windows menu.

2. Select “New Project” or go to menu “File ➔ New Project”.

3. Select “Projects”.
4. Select “AC500 project”.
5. Fill in project name and choose a location to save the project to.
6. Select “OK”.

7. Select “PLC - AC500 V3”.
8. Select the CPU according to your hardware set-up.
9. Select “Add PLC” to add the CPU to your application.
Configure your CPU

1. Double-click “PLC_AC500_V3”.
   - A tab opens in the editor view.
2. Select “CPU-Parameters Parameters”.
3. Under parameter “Check battery”, choose the value “Off” since there is no battery present inside the CPU module.
4. Keep the default values for all other parameters.

Create folders in the device tree

To optimize the project readability, you will create different folders to group similar objects. The folder names are exemplary. Because the device tree view follows an alphabetical order, we use number prefixes to determine the order.
1. Right-click “Application”.
2. Select “Add Folder”.
3. Type in "10 POUs". This is a name example. Here, the intension is to see this folder as a last one.
   The folder "10 POUs" is for program organization units (POU). POUs are objects of type program, function or function block that are used to create a user program.

Save the project

Select menu “File ➔ Save Project”.
Alternatively, select the "save" icon in the tool bar.
Alternatively, press [STRG] + [S].

1.1.17.3 Configure the I/O module

- The types and order of modules in the Automation Builder project must match the real hardware configuration.
- The position of the modules in the device tree can be changed by drag and drop.
Add an I/O bus module

1. Right-click "IO_Bus" in the device tree.
2. Select "Add object".
3. Select “S500 I/O modules”.
5. Select “Add object” to add the module to the I/O bus.
DA501 variable mapping

1. Double-click “DA501” in the device tree.
   ⇒ A tab opens in the editor view.
2. Select “DA501 I/O Mapping”.
   ⇒ Here, you will map variable names (symbols) for the channels you will need in the program.

The suggested name convention is based on "Hungarian notation". A name prefix is describing variable type: e.g., "x" = variable of type BOOL, "w" = WORD, "i" = INT (integer) etc. This increases the code readability and is helpful for program analysis.

Handle the digital input variables

1. Open the list of the digital inputs.
2. Fill in the variable names:

<table>
<thead>
<tr>
<th>Channel</th>
<th>Type</th>
<th>Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digital input DI8</td>
<td>BOOL</td>
<td>xDI_08_DA501_I1</td>
</tr>
</tbody>
</table>
Handle the digital output variables

1. Open the list of the digital outputs.
2. Fill in the variable names:

<table>
<thead>
<tr>
<th>Channel</th>
<th>Type</th>
<th>Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digital output DC16</td>
<td>BOOL</td>
<td>xStartDrilling1</td>
</tr>
</tbody>
</table>

1.17.2.4 Programming and compiling

Task configuration

A task is a time unit in the processing of a user program (IEC application), which defines by parameters the way and the speed the CPU is executing the user program.

In the device tree, you see the objects “Task configuration” and “Task”. Both created automatically with the project.

Double-click “Task” in the device tree.

⇒ A tab opens in the editor view.

For this project you will use only one cyclic task. Keep the default settings for the task.

Priority

This is how the CPU prioritizes the task, when more than one task is defined. Priority 0...15 = realtime tasks, priority 16 = non-realtime task.

Type

In the CPU you can run tasks dependent on the demands of the process

Interval

For cyclic tasks you can set the cyclical execution time. It is usually set in milliseconds with IEC time syntax

Watchdog

To keep track of the time it takes to complete the task

Calls

You can call in one or more program POUs in one single task
Main program PLC_PRG

In the default task configuration \( \infty \) (shown in chapter 1.1.17.2.4.1 Task configuration on page 48), there is one call of a POU (program organization unit) i.e. "PLC_PRG". In your project the "PLC_PRG" will become a main program containing calls to other programs (POUs) which you will create one by one.

![Diagram of PLC_PRG POU](image)

The PLC_PRG POU has been defined by default in ST (structured text) editor. Keep this setting because of good visibility of the instructions at a glance and good handling for troubleshooting.

To optimize the project readability, you will work with the previously created folder "10 POUs" and add the created subroutines (POUs) to this folder. The subroutines will be created in FBD (function block diagram) editor.

Boolean logic "NOT"

Application example "driller"

Recognizing of a driller by a photo sensor. "TRUE" input signal from sensor indicates that a driller is broken. If driller has been found correct, then start drilling.

![Diagram of driller](image)

Table 2: Required behavior

<table>
<thead>
<tr>
<th>Signal from photo sensor</th>
<th>Required signal of motor ON</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
<td>TRUE</td>
</tr>
<tr>
<td>TRUE</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
Table 3: Hardware set-up

<table>
<thead>
<tr>
<th>Element</th>
<th>HW channel</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch I1</td>
<td>DA501 DI8</td>
<td>xDI_08_DA501_I1</td>
<td>Photo sensor</td>
</tr>
<tr>
<td>LED output DC16</td>
<td>DA501 DC16</td>
<td>xStartDrilling1</td>
<td>Motor on</td>
</tr>
</tbody>
</table>

Implementation

Create a new program POU in the project

1. Right-click “10 POUs”.
2. Select “Add object”.
3. Select “POU”.
4. Select “Add object”.

PLC Automation with V3 CPUs
Getting started > Example projects

2020/12/10 ADR010583, 1, en_US
5. Fill in "_01_Assignment_NOT".
6. Select "Program".
7. Select "Function Block Diagram (FBD)".
8. Select [Add] to add the POU.

Assign the hardware DI signals to local variables
1. Double-click POU "_01_Assignment_NOT" in the device tree.
2. Select "Assignment" from the ToolBox.
3. Drag and drop "Assignment" into the "Start here" field in network "1".
4. Select “???” on the left side of the assignment, then select “…”

5. Open the “Io Config_Globals_Mapping” mapping list and select “xDI_08_DA501_I1”.

6. Select [OK] to add this variable to the left side of the assignment connector.

7. Select “???” on the right side of the assignment connector and mark the “???”.

8. Create a new local variable by typing in "xDrillerBroken1" which will replace the “???”.

9. Press [Enter].

   “Auto Declare” opens.

   You see the written variable name and the data type BOOL. The scope is "VAR". It means it is a local variable within this POU.

10. Select [OK] to accept the entries.
11. Drag and drop “Network” from the ToolBox to the down-arrow of network 1.
   ⇒ You added a network “2” below network 1.

Add assignments and a Boolean NOT to the DO signals

1. Add an assingment from the ToolBox.
2. Type in or copy & paste "xDrillerBroken1" to the left side of the instruction line.
3. Select “???” on the right side of the instruction line, then select “...”.
   ⇒ “Input Assistant” opens.

4. In the “IoConfig_Globals_Mapping” variable list, select “xStartDrilling1”.
5. Select [OK] to close the dialog.

6. Right-click the center of assignment pin.

7. Select “Negation” to add a negation to the assignment.
Call the POU in the PLC_PRG

1. Double-click “PLC_PRG”.
2. Select the first line in “PLC_PRG” and press [F2].
   → “Input Assistant” opens.
3. Select “Module Calls”.
4. Open “Application”.
5. Open “10 POUs” and select “_01_Assignment_NOT”.

![Image of PLC_PRG call process](image-url)
6. Select [OK] to close the dialog.

Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

Select menu “Build ➔ Generate code”.

The result of the compiling is shown in the “Messages” field at the bottom of the screen.

If you skip the compiling and select “Login”, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save the project

Select menu “File ➔ Save Project”.

Alternatively, select the "save” icon in the tool bar.

Alternatively, press [STRG] + [S].

1.1.17.2.5 Set-up the communication gateway

IP is configured properly ➔ Chapter 1.1.4 “Set-up communication parameters in windows” on page 25.
CPU and PC are connected with an Ethernet cable.

1. Right-click “PLC_AC500_V3” in the device tree.
2. Select “Communication Settings”.
3. Keep the default value in the IP address of the CPU or type in the current IP address, if differs.

The standard (default) IP address of the port ETH1 is: 192.168.0.10
The standard (default) IP address of the port ETH2 is: 192.168.1.10
4. Select “OK” to implement the IP address.

**Network scan**

If you need to scan the network for the CPU or if you have multiple CPUs on the same network.

1. Right-click “PLC_AC500_V3” in the device tree.
2. Select “Communication Settings”.

   ![Communication Settings](image)

3. Select “...”.
   - “Pick IP Address for “PLC_AC500_V3”” opens.

   ![Pick IP Address](image)

The automatic scan runs.

The results will appear in this field.

4. Select the CPU in the field and select [OK] to implement the needed communications gateway.

**Check communication settings**

If you need to check the communications settings or if you want to see more information about the current selected CPU.
1. Double-click “PLC_AC500_V3” in the device tree.
2. Select “Communication Settings”.
   - The selected IP address is shown.
3. If the IP address is not visible, enter the IP address manually.
4. To test the connection and/or to see the CPU information press [Enter] or click on the black dot next to the PLC picture.

### 1.17.2.6 AC500 V3 firmware installation and update

The PLC firmware can be updated via Automation Builder.

> This is also necessary for commissioning V3 CPUs.

A very new CPU has no pre-installed firmware. To guarantee the authenticity of delivered AC500 firmware, V3 CPUs are delivered with a boot loader only. You need to download a valid firmware to the CPU. After download, the functionality of the CPU is given.

- An Automation Builder project with an AC500 V3 CPU is open.
- CPU is in "stop" mode or shows uPdAtE (update) on the display.
- After update the CPU shows either donE or StoP on the display.
For new modules: IP address is set. (The default IP address is 192.168.0.10)

1. Double-click CPU “PLC_AC500_V3”.
2. Select “Version information”.
3. Select [Update Firmware].
   - While the update process is running, the RUN and ERR LEDs are toggling, i.e., they are flashing alternating.
4. Wait for the PLC to finish the update.
   A completed update is indicated by a message on the display. Either done, or Stop.

**NOTICE!**
Do not disconnect the power supply during the update process! The PLC could be damaged.

- Stop indicates a restart has been performed by the CPU. When done is displayed sometimes it is necessary to re-boot the CPU manually, e.g., by powering-off. Manual re-boot might be, e.g., for some older CPU versions or if downgrading to an older firmware version according to application settings.

The CPU display shows "stop" after re-boot. The update process is finished.
5. If necessary, refresh the version information by switching to another tab and back.

⇒ Successful firmware update:

<table>
<thead>
<tr>
<th>LED</th>
<th>LED flashes</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>RUN and ERR</td>
<td>Toggling</td>
<td>Update pending</td>
</tr>
<tr>
<td>RUN</td>
<td>Flashing slow</td>
<td>Done successful</td>
</tr>
<tr>
<td>ERR</td>
<td>Flashing slow</td>
<td>Done failed</td>
</tr>
</tbody>
</table>

**Behavior of LEDs during firmware update**

**Log-in to CPU and download the program**

Logging-in to the CPU will load the project into the AC500 V3 CPU. The first log-in will also load the hardware set-up.
1. Select menu “Online → Login [PLC_AC500_V3]”.  
   ➤ A pop-up will appear.
2. Select “Yes” to download the application to the AC500V3 CPU.
   ➤ PLC is in "stop" mode.
3. Start the PLC  
   Chapter 1.1.17.2.8.1 “Start the program execution” on page 62.

By default, a download generates following actions in the CPU:

- The project is stored in the RAM memory.
- The project is stored in the flash EEPROM, if boot application was created.

**1.1.17.2.8 Test the program**

**Start the program execution**

- You are logged in the CPU.
- An executable project is loaded to the CPU.
The CPU is in "stop" mode.

Select menu ""Debug ➔ Start [PLC_AC500_V3]"". Alternatively, select the "start" icon in the tool bar. Alternatively, press [F5].

Test the function

Operate the switch I1 and observe:
- The LEDs of the relevant DA501 inputs and outputs.
- The online status of inputs and outputs within the POU.

Stop the program execution

You are logged in the CPU.
☑️ An executable project is loaded to the CPU.
☑️ The CPU is in "run" mode.

Select menu ""Online ➔ Stop [PLC_AC500_V3]""
Select menu "Debug ➔ Stop [PLC_AC500_V3]"
Alternatively, select the "stop" icon in the tool bar.
Alternatively, press [Shift] + [F8].
1.1.17.2.9 Set-up visualization

Add the VisualizationManager

1. Right-click “Application” in the device tree.
2. Select “Add object”.
3. Select “VisualizationManager”.
4. Select [Add object] to add the VisualizationManager to the project.
   ➞ Dialog “Add Visualization Manager” opens.
5. Select [Add].

⇒ You added the objects “VisualizationManager” and “VISU-TASK” to the device tree.
Set-up the VisualizationManager

1. Double-click VisualizationManager in the device tree.
   ⇒ A tab opens in the editor view.

2. Select “Settings”.

3. Open the drop-down menu “Selected style”.

4. Select “Default, x.x.x” (exemplary).
5. Open the drop-down menu “Selected language”.

8. Keep the file transfer to enable the visualization on the PLC (mandatory for web server function © Chapter 1.1.17.2.11 “Enable web visualization” on page 75).
Save the project

[Diagram of project saving process]

- Select menu “File ➔ Save Project”.
- Alternatively, select the "save" icon in the tool bar.
- Alternatively, press [STRG] + [S].

1.1.17.2.10 Create visualization

Add a folder for visualization screens

1. Right-click “Application” in the device tree.
2. Select “Add Folder”.
3. Type in "02 VISUs".
4. Select [OK] to add the folder.
Add a screen for "_01_Assignment_NOT" POU

1. Right-click "02 VISUs".
2. Select "Add object".
3. Select object "Visualization".
4. Select [OK].
5. Type in "PLC_VISU".
6. Select [Add].

⇒ A tab opens in the editor view.
The name "PLC_VISU" has been chosen, because it is the default name for a home screen in a web visualization.

If you have more than one visualization object in your project, it will be useful to choose another name, e.g. "_01_Assignment_NOT_v". And to choose "PLC_VISU" as a home screen to access all available visualization screens.

The name of a visualization object can be modified afterwards.

Creating and configuring of visualization

Change background color

1. Double-click “PLC_VISU” in the device tree.
   ⇒ A tab opens in the editor view.

2. Right-click anywhere on the "PLC_VISU" editor page.

3. Select "Background".

4. Enable the check box “Use Color”.
   ⇒ This enables the drop-down menu.

5. Select a color, e.g., “Lightgray”.

6. Select [OK] to add the color to "PLC_VISU".
Add a screen title

1. Double-click on “PLC_VISU” in the device tree.

2. Select “ToolBox”.

3. Select “Common controls”.

4. Drag and drop “Label” to the page.

5. Type in "Start drilling condition".

Further lines and labels

1. Double-click on “PLC_VISU” in the device tree.

2. Select “ToolBox”.

3. Select “Basic”.

4. Drag and drop the line. Then drag the line to the needed length.
5. Follow the same procedure to create the other shapes and labels.

**Lamp element for signal indication**

1. Double-click on “PLC_VISU” in the device tree.
2. Select “ToolBox”.
3. Select “Lamps/Switches/Bitmaps”.
4. Drag and drop “Lamp” to the screen.
5. Adapt the size, if required.

7. Double-click on “Variable” and select “...” to select a variable from the list.

8. Under “IoConfig_Globals_Mapping”, select “xStartDrilling1”.

9. Select [OK].

**Compile the project**

Before logging-in to the CPU, you need to compile the complete code without any errors.
Select menu “Build ➔ Generate code”.

The result of the compiling is shown in the “Messages” field at the bottom of the screen.

If you skip the compiling and select “Login”, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save the project

Select menu “File ➔ Save Project”. Alternatively, select the “save” icon in the tool bar. Alternatively, press [STRG] + [S].

Loading the project to the CPU

1. Download the project to the CPU as described in Chapter 1.1.17.2.7, on page 61.
2. Check the notification window at the end of the download. In case of message "Boot parameters were changed. These changes will be applied after reboot", a reboot of the CPU is required after creation of the boot project.
Test the program

1.1.17.2.11 Enable web visualization

Add a web server object to the device tree

Both Ethernet ports can be configured for web server protocol each. This description deals with ETH1 configuration for the web server.
1. Right-click “Protocols” in the device tree.
   Right-click “ETH1” in the device tree.
2. Select “Add object”.
3. Select “Web Server”.
4. Select “Add object”.
   ⇒ You added and activated a web server on Ethernet port 1 on the AC500 V3 CPU.

**Set-up the web server**

1. Double-click “WebVisu” in the device tree.
2. Under “Start Visualization”, select “…”.
   ⇒ A list opens.

3. Select the “PLC_VISU” screen from the list.

4. Keep all further settings with default values.
5. Select the link “Show used visualizations”.

The VisualizationManager editor and there the tab “Visualizations” opens. All screens and dialog elements created in the project are visible. Here, you can select which screens are enabled or disabled for web visualization.

If you want to select another screen as a start visualization, you must modify the adequate parameter in the webvisu.htm file:

```html
<param name="STARTVISU" value="PLC_VISU">
```

Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

Select menu “Build ➔ Generate code”.

The result of the compiling is shown in the “Messages” field at the bottom of the screen.

If you skip the compiling and select “Login”, the Automation Builder will automatically trigger compiling in advance to logging-in.
Save the project

Select menu “File ➔ Save Project”. Alternatively, select the "save" icon in the tool bar. Alternatively, press [STRG] + [S].

Loading the project to the CPU

1. Download the project to the CPU as described in Chapter 1.1.17.2.7, on page 61.
2. Check the notification window at the end of the download. In case of message "Boot parameters were changed. These changes will be applied after reboot", a reboot of the CPU is required after creation of the boot project.

Create a boot project

By default, after project download, the boot project is created automatically.

Rebooting the CPU

Reboot the CPU by switching OFF and ON the power supply. (The parameter for webserver activation is a boot parameter which is loaded during boot of the CPU)

Test the web visualization

☑ You have downloaded the project and created the boot project.
☑ The CPU has been rebooted.
☑ You are logged in.
☑ CPU is in "stop" mode.
1. Start the project execution, e.g., from the tool bar.
2. Launch an internet browser.
   192.168.0.10 is the IP address of CPU’s ETH1 port.
   /webvisu.htm is the default htm file.
   Web visualization will be loaded.

   The start screen “PLC_VISU” is displayed in a responsive view.

4. Test the function by operating switch I1.
5. Test the results for responsive view by changing the web browser window size.

1.17.2.12  Reset the CPU

**Reset values and parameters**
In some cases, it could be required to do a CPU reset, e.g., for resetting of counter values, parameters etc.

![Reset commands in “Online” menu](image)

*Fig. 11: Reset commands in “Online” menu*

- **Reset warm**
  - All variables are reset, except RETAIN PERSISTENT variables.

- **Reset cold**
  - Causes initialization of all variables, except PERSISTENT variables. By recommended creation of remanent variables always with both properties: PERSISTENT and RETAIN, this command resets all variables, except PERSISTENT RETAIN variables.

- **Reset origin**
  - All variables and the application project are reset.
Table 4: Behavior of variables of type VAR (local or global) and variables of type PERSISTENT RETAIN

<table>

</tr>
</tbody>
</table>

Complete reset of the CPU

To do a complete reset of the CPU thereby erasing the application from the RAM and flash EEPROM do the following.

1. Right-click the station object “PLC_AC500_V3” in the device tree.
2. Select “Reset origin device [station name]”.  
   ⇒ The application is completely erased from the CPU (complete project from all memory areas).

1.1.17.3 Example project for remote I/O expansion with PROFINET

This example introduces the configuration of the PLC with remote I/O. The use of I/O channels in a program and commissioning of the configuration is shown.

1.1.17.3.1 Preconditions

- Automation Builder is installed and licensed as, at least, standard edition.
- AC500 V3 CPU is assembled and connected to the PC.
● Configuration and programming of this example project will be made in the existing example project for central I/O expansion "Chapter 1.1.17.2 “Example project for central I/O expansion” on page 40.

● CM579-PNIO communication module is inserted in terminal base and connected to the PLC.

● CI502-PNIO communication interface module is inserted in terminal unit and connected to the PLC.

1.1.17.3.2 Set-up PROFINET controller

Add the CM579-PNIO to the device tree

1. Under “Extension_Bus”, right-click “Slot_1” in the device tree.
2. Select “Add object”.
3. Select “CM579-PNIO”.
4. Select “Replace object” to add the CM579-PNIO.

Set-up the general behavior

   ⇒ A tab opens in the editor view.
2. Select “CM579-PNIO Parameters”.

Run on configuration fault
This parameter will prohibit the PLC from running if the CM579-PNIO has a configuration error/fault.

Bus behavior
This parameter sets how the data from the bus flows in/out of the CM579-PNIO.

3. Select “Status”.
⇒ This opens the bus controller status and gives a basic status overview.

4. Select “Information”.
⇒ This page contains general information about the CM579-PNIO.

5. For the example project, you can keep the default settings.

Set-up the PROFINET IO controller

To edit settings for the controller, you must not be logged-in to the PLC.

⇒ A tab opens in the editor view.

2. Select “PROFINET IO CONTROLLER”
3. Select "General".

4. Here, you can set-up the way, IP addresses are distributed out to the industrial bus network. You can even set, what IP-address and DNS name (station name) the PROFINET controller has.

   For the example project, keep the default settings.

### 1.1.17.3.3 Set-up PROFINET device

#### Hardware preparation

1. Switch off the power supply of your PLC.

2. Use a screw driver to set the CI502 module address to "02" by positioning of the upper rotary switch to "0" and lower switch to "2". Note, that the numbers have hexadecimal format.

3. Switch on the power supply.
Add the CI502-PNIO to the device tree

1. Right-click “PNIO_Controller” in the device tree.
2. Select “Add object”.
3. Select “CI502-PNIO-Device”.
4. Select “Add object” to add the device.

Configure the CI502-PNIO device

Configure the CI502-PNIO PROFINET IO device

1. Double-click “CI502_PNIO_Device”.
   ⇒ A tab opens in the editor view.
2. Select "PROFINET IO Device".
   Select “General”.

   ![Image of PROFINET IO Device configuration panel]

   Station name: Default station name
   IP Parameter: IP-addressing parameters of the node. If modifications are required for "IP Parameter", they must be done also for CM579-PNIO and all other devices in this PROFINET line.
   Communication: Communication time set-up
   VLAN: virtual local area network ID
   RT Class: PROFINET IO RT (real time) type settings

3. Set station name to "ci502-pn-02" according to hardware settings.

   For numbers greater than 09 always make sure, that the last two decimal digits of the node’s "Station Name" in Automation Builder correspond to the position of module’s rotary switches (hexadecimal values): e.g., "ci502-pn-10" <-> "0A" or "ci502-pn-16" <-> "10".

4. Leave the default settings for "IP Parameter".

5. Adjust the communication time settings to get a Watchdog (ms) 24:
   - "Send clock (ms)": 4
   - "Reduction ratio": 2
   - "Phase": 1

6. Leave the default settings for "VLAN ID".

7. Leave the default settings for "RT Class".

   ![Information icon]

   If the node has the same device address (the last two digits of the device name) as set by means of the rotary switches on the module, all the node parameters will be loaded automatically upon initialization scan of the CI50x module. This allows, e.g., the module exchange without an engineering tool.
Create CI502-PNIO I/O mapping to symbols

1. Double-click “CI502_IO”.

2. Select “PNIO Module I/O Mapping”.

3. Fill in the variable names:

<table>
<thead>
<tr>
<th>Element</th>
<th>Hardware channel</th>
<th>Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch I5</td>
<td>CI502 DI8</td>
<td>xDI_08_CI502_I5</td>
</tr>
<tr>
<td>LED output DO8</td>
<td>CI502 DO 8</td>
<td>xDO_08_CI502</td>
</tr>
</tbody>
</table>
Add remote I/O expansion to project

Add a program POU to the project

1. Right-click “01 - POUs” in the device tree.
2. Select “Add object”.
3. Select “POU”.
4. Select “Add object”.
5. Fill in "_30_PNIO_test".
6. Select “Program”.
7. Select “Function Block Diagram”.
8. Select [Add] to add the POU.

Create a POU logic

1. Double-click “30_PNIO_test” in the device tree.

2. In the ToolBox, select “Assignment”.
3. Drag and drop “Assignment” into the "Start here" field in network "1".

4. Select “???” on the left side of the assignment, then select “...”.
5. In “IoConfig_Globals_Mapping” list, select “xDI_08_CI502_I5”.
6. Select [OK] to add this variable to the left side of the assignment connector.
7. Select “???” on the right side of the assignment, then select “...”.
8. In “IoConfig_Globals_Mapping” list, select “xDO_08_CI502”.
9. Select [OK].

Call the POU in PLC_PRG
1. Double-click “PLC_PRG”.
2. Select the next free line in “PLC_PRG” and press [F2].
   ⇒ “Input Assistent” opens.
3. Select “Module Calls”.
4. Open “Application”.
5. Open “10 POUs” and select “_30_PNIO test”.
6. Select [OK] to close the dialog.

Compile the project
Before logging-in to the CPU, you need to compile the complete code without any errors.
Select menu “Build ➔ Generate code”.

The result of the compiling is shown in the “Messages” field at the bottom of the screen.

If you skip the compiling and select “Login”, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save the project

Select menu “File ➔ Save Project”. Alternatively, select the "save" icon in the tool bar. Alternatively, press [STRG] + [S].

Loading the project to the CPU

1. Download the project to the CPU as described in Chapter 1.1.17.2.7 , on page 61.
2. Check the notification window at the end of the download. In case of message "Boot parameters were changed. These changes will be applied after reboot", a reboot of the CPU is required after creation of the boot project.
The CPU is in "stop" mode.

Select menu "Debug ➔ Start [PLC_AC500_V3]". Alternatively, select the "start" icon in the tool bar. Alternatively, press [F5].

Test the function

Operate the switch I5 and observe:

- The LEDs of the relevant CI502 inputs and outputs.
- The online status of inputs and outputs within the POU.

1.1.17.3.6 Reset the CPU

Reset values and parameters

In some cases, it could be required to do a CPU reset, e.g., for resetting of counter values, parameters etc.
Fig. 12: Reset commands in “Online” menu

<table>
<thead>
<tr>
<th>Reset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>warm</td>
<td>All variables are reset, except RETAIN PERSISTENT variables.</td>

</tr>
</tbody>
</table>

Complete reset of the CPU

To do a complete reset of the CPU thereby erasing the application from the RAM and flash EEPROM do the following.
1. Right-click the station object “PLC_AC500_V3” in the device tree.
2. Select “Reset origin device [station name]”.
   ⇒ The application is completely erased from the CPU (complete project from all memory areas).

1.2 Automation Builder installation manager

Automation Builder installation manager allows you to install customer specific software packages, modify the existing installation, update installation information and to uninstall Automation Builder software packages in a comfortable and flexible way.

You can launch installation manager from the main menu of Automation Builder or from Windows start menu.
1. Open Automation Builder software.
   From the Tools menu, select Installation Manager.
2. As an alternative, launch installation manager from Windows start menu: “Start menu ➔ All Programs ➔ ABB ➔ Automation Builder ➔ ABB Automation Builder Installation Manager”. Installation manager starts.

Options:

- **Installed packages**: Shows all installed packages of Automation Builder.
- **Uninstall all**: Uninstalls the currently installed Automation Builder software.
- **Install Package**: Installs customer specific software packages.
- **Modify**: Adds or removes installed software packages.
- **Info Export**: Exports detailed information of installed packages in a notepad.
- **Check for Update**: Checks if your installed version of Automation Builder is up to date and checks for updates.

### 1.2.1 Installing customer specific package

Installation manager allows you to install customer specific software packages (CABPKG files). These packages are separately distributed to the customer based on the customer requirement.
1. In the installation manager, click **Install Package**.
2. Select the package to be installed (.cabpkg file) from the file system.
3. Select the components to be installed.
4. Click **Install**.
   > Data installation starts.
5. Successfully installed components are indicated with ✅.
   Errors during data download are indicated with ⚠️. Errors during download of any package component aborts the installation. In this case click **Show Log** and save the log data.
   Send the log file to ABB support team.
   Click **Finish** to end the wizard.

### 1.2.2 Adding or removing installed software packages

1. In the installation manager, click **Modify**.
   > The selection page opens.
   The selected software packages are installed already.
   The not selected software packages are not installed.
2. Select the software packages you want to install.
Unselect the software packages you want to uninstall.

You cannot unselect the main **ABB Automation Builder** software package.

If also an older Automation Builder version or Control Builder Plus version shall be installed for compatibility reasons, select the appropriate options under **Install also previous product versions**. This allows to open and edit a corresponding project in the original version without a previous project upgrade.

3. Click **Continue**.
The following three cases are possible:
- The selected software package starts downloading and installing.
- The unselected software package will uninstall.
- The unselected software package will uninstall first and then download and install the selected software package.

4. Successfully downloaded components are indicated with ☑.
Errors during data download are indicated with ☢. Errors during download of any package component aborts the installation. In this case click **Show Log** and save the log data. Send the log file to ABB support team.
Click **Finish** to end the wizard.

If you modify the type of installed edition, a warning message is displayed.

1.2.3 Checking for updates

In the installation manager, click **Check for Updates**.

If the installed Automation Builder version is up-to-date, the following message will appear.

If a newer Automation Builder version is available, you will get an option to download and install the new version.
1.2.4 Uninstalling Automation Builder

Installation manager offers a comfortable way to uninstall Automation Builder software. This will uninstall all related packages of Automation Builder platform as well, such as Mint Plugin, Automation Builder Extensions, Drive Manager etc.

1. In the installation manager, click **Uninstall all**.
   - A warning message is displayed to uninstall Automation Builder software.
     - Click **Yes** to continue.

2. If Automation Builder instances are running, a warning message is displayed. Close running instances of Automation Builder and click **Retry** to continue uninstallation.
   - With **Abort** uninstallation of the current package is stopped. Uninstallation is continued with the next package. With **Ignore**, uninstallation is forced. As this can lead to an erroneous uninstallation, we recommend you, *not* to use this option.

3. If installation manager was launched with “**Tools** ➤ **Installation Manager**”, the following message is displayed as Automation Builder is still running:
   - With **Yes** Automation Builder software is closed to continue uninstallation procedure.
   - With **No** uninstallation of the current package is stopped. Uninstallation is continued with the next package.

4. For each of the packages being uninstalled, system may prompt to continue uninstallation.
5. Successfully uninstalled components are indicated with 🔄. Errors during uninstallation are indicated with 🚨. Errors during uninstallation of any package component aborts the uninstallation. In this case click **Show Log** and save the log data. Send the log file to ABB support team.

Click **Finish** to end the wizard.

### 1.3 Programming with IEC 61131-3 editor

#### 1.3.1 CODESYS Development System

**Using CODESYS help**

CODESYS Help is intended to assist you in using the CODESYS Development System easily and successfully. You will find quick answers to questions and solutions to problems.

Each help component consists of a concept section and a reference section.

In the concept sections, we explain in detail all topics that are relevant for creating CODESYS projects. The concepts are supplemented with instructions that lead you step-by-step to the intended result.

In the reference sections, we provide complete reference works for the user interface and programming of CODESYS.

The following formats of CODESYS Help are provided:

- CODESYS Offline Help: CHM-based CODESYS Help
- CODESYS Online Help: Web-based CODESYS Help

In the CODESYS options, you determine whether to use CODESYS Offline Help or CODESYS Online Help.

You can call the context-sensitive help directly from the user interface of the CODESYS Development System. In CODESYS, when you position the cursor over an object, menu command, or programming element, and then press the [F1] key, the respective help page opens. As an alternative, you can use the commands in the "Help" menu. This is a full-text search. The index search is possible in CODESYS Offline Help only.

**Search operators for the offline help**

- **AND**
  - Used automatically, for example the input of the search terms Device Diagnosis has the same results as the input of *Device AND Diagnosis*
  - The * placeholder is used automatically. However, the * character must not be used as a wildcard because in this case the * character will be searched for specifically.

**Search operators for the online help**

- **AND**
- **OR**
- **NOT**
  - Example: abc NOT abcd: The search result includes all help pages that contain abc and excludes the pages with abcd.
- **ANDNOT**
  - ANDNOT is the combination of the search operators AND nd NOT.
- **ANDMAYBE**
  - Example: The search for abc ANDMAYBE xyz finds the help pages that contain abc and xyz, and all pages that contain only the string abc.
- **Placeholders**
  - *: Replaces any number of characters
  - ?: Replaces exactly one character

In the online help, you can use parentheses to group together multiple search operators for complex search queries. Example: ((profinet AND cycle) OR (Ethernet/IP AND cycle)) ANDNOT IRT
The CODESYS Development System IEC 61131-3 programming tool forms the core of the CODESYS software platform for tasks in industrial automation technology. With additional, integrated solutions for motion control, visualizations, and fieldbus connections, the usual practical requirements are covered in one system.

The free CODESYS Development System is a IEC 61131-3 programming platform for automation devices with control tasks. It provides diverse and comfortable engineering solutions to support you in your developing tasks:

- **Features**
  - Project configuration through wizards.  
    For this see in this Online Help:

Customization of the user interface language

In the “Option ➤ International Settings” dialog you can customize the language of the user interface of the development system. This change will take effect the next time you start CODESYS. You can adjust the help language separately.
If you start CODESYS from the command line, you can add a parameter to adjust the user interface language.

See also

- Chapter 1.3.1.25.3.13.12 “Dialog ‘Options’ – ‘International Settings’” on page 1083
- Chapter 1.3.1.18 “Using the command-line interface” on page 366

1.3.1.1 Configuring CODESYS

CODESYS Development System allows to configure the behavior, the appearance, the content of the menus and the arrangement of the windows individually. In the “Tools” menu you find dialogs for customizing the user interface and to setup the CODESYS options.

See also

- Chapter 1.3.1.25.3.14 “Dialog ‘Customize’” on page 1089
- Chapter 1.3.1.25.3.13 “Dialog ‘Options’” on page 1073

1.3.1.1.1 Setting CODESYS options

You can configure the behavior and appearance of the CODESYS Development System in the different tabs of the “Options” dialog. The dialog opens by clicking “Tools ➔ Options”. Here you can configure the default settings for different editors and functionalities. These settings apply throughout CODESYS.

The settings are stored in your current user profile on your local system. For use on other systems, option settings, either user-specific or machine-specific (computer), can be exported to an XML file.

In V3.5 SP13 and later, CODESYS checks whether an older version is already installed when the development system is started for the first time. If this is the case, then the “Import Assistant” dialog opens for transferring the CODESYS options set with the older version.

- Chapter 1.3.1.1.2.2 “Customizing toolbars” on page 104

1.3.1.1.2 Customizing the user interface

In CODESYS, you can customize the user interface by changing the window layout as well as the appearance of menus and commands according to your requirements.
**Customizing menus**

You can customize the menu commands of the CODESYS user interface. In a configuration dialog, you can add or remove menus.

**Removing menus and commands**

1. Choose the command “Tools ➔ Customize”.
   ⇒ The “Customize” dialog box opens. The “Menu” tab is visible.
2. Select a menu in the menu tree or a command in a menu.
3. Click “Delete”.
   ⇒ The menu or command is deleted from the menu tree.
4. Click “OK”.
   ⇒ The dialog box closes and the menu is customized.

**Adding menus**

1. Choose the command “Tools ➔ Customize”.
   ⇒ The “Customize” dialog box opens. The “Menu” tab is visible.
2. Scroll to the end of the menu tree.
3. Select the blank symbol ( ).
4. Click “Add Popup Menu”.
   ⇒ The “Add Popup Menu” dialog box opens.
5. Type a name for the new menu in the “Default text” field.
   If localization is unnecessary, then skip to step 9.
6. Click “Add Language”.
   ⇒ A drop-down list opens with available languages.
7. Choose the required language.
   ⇒ The language is added to the list of languages.
8. Click into the “Text” field and type the language-specific text.
9. Click “OK”.
   ⇒ The new menu is added at the bottom of the menu tree.
10. Change the menu order by clicking “Move up” and “Move down”. Click “OK” to close the “Customize” dialog box.

   *The new menu is displayed only when it contains a command.*

**Adding commands**

1. Choose the command “Tools ➔ Customize”.
   ⇒ The “Customize” dialog box opens. The “Menu” tab is visible.
2. Expand the branch of the menu where the new command should be added.
3. Select the blank symbol (□).
4. Click “Add Command”.
   ⇒ The “Add Command” opens dialog box.
      The dialog box lists all commands grouped by category.
5. Select the command to be added. Click “OK”.
   ⇒ The new command is added to the menu tree.
6. Change the menu order by clicking “Move up” and “Move down”. Click “Add separator” to add a border between commands. Click OK to close the “Customize” dialog box.
   ⇒ The new command is now available in the menu.

See also
● § Chapter 1.3.1.25.3.14.1 “Dialog ‘Customize’ - ‘Menu’” on page 1089
● § Chapter 1.3.1.1.2.2 “Customizing toolbars” on page 104

Customizing toolbars
You can customize the toolbars of the CODESYS user interface. In a configuration dialog, you can add or remove toolbars.

Removing toolbars and commands
1. Choose the command “Tools ➤ Customize”.
   ⇒ The “Customize” dialog box opens.
2. Choose the “Toolbars” tab.
3. Select a toolbar or a command from a toolbar tree.
4. Click “Delete”.
   ⇒ The toolbar or command is deleted.
5. Click “OK”.
   ⇒ The dialog box closes and the toolbar or command is removed.

Adding toolbars
1. Choose the command “Tools ➤ Customize”.
   ⇒ The “Customize” dialog box opens.
2. Choose the “Toolbars” tab.
3. Select the blank toolbar.
4. Click “Add Toolbar”.
   ⇒ The cursor blinks in the new toolbar.
5. Type a name.
6. Change the toolbar order by clicking “Move up” and “Move down”. Click “OK” to close the “Customize” dialog box.

CODESYS displays the new toolbar only when it contains a command.

Adding commands

1. Choose the command “Tools → Customize”.
   - The “Customize” dialog box opens.
2. Choose the “Toolbars” tab.
3. Expand the tree of the toolbar where the new command should be added.
4. Select the blank symbol (□).
5. Click “Add Command”.
   - The “Add Command” dialog box opens.
   - The dialog box lists all commands grouped by category.
6. Select the command to be added. Click “OK”.
   - The new command is added to the toolbar tree.
7. Change the toolbar order by clicking “Move up” and “Move down”. Click “Add separator” to add a border between commands. Click “OK” to close the “Customize” dialog box.
   - The new command is available in the toolbar.

See also
- § Chapter 1.3.1.25.3.14.3 “Dialog 'Customize' - 'Toolbars'” on page 1090
- § Chapter 1.3.1.1.2.1 “Customizing menus” on page 103

Customize command icon

CODESYS provides the capability of assigning customized icons to commands.

1. Select the command “Tools → Customize”.
   - The “Customize” dialog box opens.
2. Click the “Command icons” tab.
3. Select the category “Help” from the list on the left.
   - All commands in this category are listed on the right.
4. Select the command “Information”.
5. Click “Assign”.
   - A dialog box opens for selecting the icon file (*.ico).
7. Click the “Open” button.
   - The icon is assigned to the selected command.
8. Click “OK”.
Customizing keyboard shortcuts

CODESYS provides the capability of executing commands directly via keyboard shortcuts. You can customize or extend predefined keyboard shortcuts.

1. Choose the command “Tools ➔ Customize”.
   ⇒ The “Customize” dialog box opens.
2. Choose the “Keyboard” tab.
3. Select the category “Help” from the list on the left.
   ⇒ All commands in this category are listed on the right.
4. Select the command “Search”.
5. Click into the field “Press Shortcut Keys”.
6. Press `[Ctrl]+[Shift]+[S]`.
   ⇒ CODESYS adds the key combination to the field.
7. Click “Assign”.
   ⇒ The keyboard shortcut is assigned to the command.
8. Click “OK”.
   ⇒ You can call the “Search” command by pressing `[Ctrl]+[Shift]+[S]`.

See also
● Chapter 1.3.1.25.3.14.4 “Dialog Box ‘Customize’ - ‘Keyboard’ ” on page 1091

Changing the window layout

In CODESYS, you can easily customize the layout of different views to your individual needs.

1. Drag the view by the caption bar or by the tab.
   ⇒ Arrows are shown to mark possible destinations. Example: △
2. Drag the view to one of the arrows.
   ⇒ The destination is displayed as a blue-shaded area.
3. Release the left mouse button.
   ⇒ The window is inserted into the selected destination.

The window can also be placed outside of the CODESYS programming interface.
Resizing windows

1. Move the mouse pointer over the border between two windows or views.
   ⇒ The cursor becomes a left-right arrow.
2. Drag the border to another position.

   You can resize detached views by moving the frame lines.

See also

- Chapter 1.3.1.1.2.6 “Resizing windows” on page 107
- Chapter 1.3.1.1.2.7 “Auto-hiding windows” on page 107
- Chapter 1.3.1.1.2.8 “Switching between windows” on page 108

Auto-hiding windows

Hiding windows  When you hide a view, it is minimized to a tab in the frame of the user interface. When you move the pointer over the tab, the window is shown automatically.

1. Click into the window to be hidden.
2. Click “Window ➔ Auto Hide”.
   Or click the pin symbol (マーク) in the upper right corner of the view.
   ⇒ The window is hidden and only visible by a small tab on the edge of the main window.
3. Move the mouse pointer over the tab.
   ⇒ The window is shown as long as the mouse pointer hovers over the tab.

Showing windows

1. Click the tab of the hidden window.
2. Clear the check box “Window ➔ Auto Hide”.
   Or click the pin symbol (マーク) in the upper right corner of the view.
   ⇒ The window is permanently shown.

- Chapter 1.3.1.1.2.5 “Changing the window layout” on page 106
- Chapter 1.3.1.1.2.7 “Auto-hiding windows” on page 107
- Chapter 1.3.1.1.2.8 “Switching between windows” on page 108
Switching between windows

It is possible to switch directly between the currently opened views and the editor windows.

1. Press the keystroke combination $\text{[Ctrl]}+\text{[Tab]}$. Continue pressing the $\text{[Ctrl]}$ key.
   - An overview opens with all active views and editors.
2. Continue pressing the $\text{[Ctrl]}$ key and select a window using the arrow keys.
3. Release the $\text{[Ctrl]}$ key.
   - The selected view or editor is activated.

- Chapter 1.3.1.1.2.7 “Auto-hiding windows” on page 107

1.3.1.2 Your first CODESYS program

Data security: In order to minimize the risk of data security breaches, we recommend the following organizational and technical measures:

- Avoid access to the PLC and control networks from open networks and the Internet.
- Use a VPN for remote access.
- Install a firewall.
- If you want to publish your visualization on the web, then set a password to prevent unauthorized access.
- Use the latest versions of gateway servers and web servers.

Install CODESYS

The installation includes the development system and the CODESYS Gateway and CODESYS Control Win V3, whose services are accessible in the Windows taskbar. These three programs are necessary in order to simulate a controller on your computer.

Contents of your first project

In this tutorial, you will program a simple refrigerator controller. The finished project RefrigeratorControl.project_archive can be found in the CODESYS installation directory in the Projects directory. In addition to the sample project, which you will create here step by step, the finished project contains a complete visualization with operation and diagnosis.

- As with a conventional refrigerator, the temperature is specified by the user via a rotary control.
- The refrigerator determines the actual temperature using a sensor. When it is too high, the refrigerator starts the compressor with an adjustable delay.
- The compressor cools until the desired temperature is reached, minus a hysteresis of 1 degree. The hysteresis is intended to prevent the actual temperature from fluctuating too much around the set temperature, which would result in the compressor constantly switching itself off and on.
- When the door is open, a lamp lights up inside the refrigerator. When the door is open too long, a beeping acoustic signal sounds.
- If the compressor does not reach the set temperature despite activity of the motor over a long period of time, then the buzzer emits a steady acoustic signal.

Engineering:
The cooling activity is controlled in the main program of the application. The signal management is controlled in another POU. The required standard function blocks are available in the Standard library. Because no physical temperature sensors and no physical actuators are connected in this sample project, you will also write a program to simulate the increase and decrease of the temperature. This will allow you to monitor the operation of the refrigerator controller afterwards in online mode.

Variables that are to be used by all POUs need to be defined in a global variable list.

**Preparation**

You have installed the CODESYS Development System and launched it with the default profile "CODESYS V<current version>". The frame window of the development system opens with the standard menu bar: No project is open yet.

**Creating the project and selecting the PLC device**

1. Click “File ➔ New Project”.
2. In the “Templates” view, select the “Standard project” template.
3. Specify a name and a storage location for the project and click “OK”.
   ⇨ The “Standard Project” dialog opens for entering the device type and the implementation language of the main program.
4. In the “Device” list box, select “CODESYS Control Win V3”.
5. In the “PLC_PRG in” list box, select “Continuous Function Chart (CFC)” and click “OK”.
   ⇨ The project opens in the CODESYS frame window.

On the left-hand side of the frame window, in the “Devices” view, you will see the device tree (“Devices” view). The previously selected PLC device is displayed with the default name “Device”.

The “Application” object for the application that you will program already exists below the “PLC Logic” object.

“Application” already contains an object for the main program PLC_PRG and the “Library Manager”.

The “Library Manager” already contains the libraries IoStandard and Standard. The library IoStandard is required for I/O configurations. The library Standard contains all functions and function blocks that are described by the IEC 61131-3 standard.

The “Task Configuration” object is located at the bottom of the device tree with the MainTask, which controls the processing of PLC_PRG. Visualization objects, for example, can be inserted below the “Task Configuration” at a later time.

In addition to the libraries IoStandard and Standard, you need the library Util for this sample project:

1. Double-click the “Library Manager” object in the device tree.
   ⇨ The Library Manager opens in its editor.
2. In the header bar of the editor, click “Add Library”. In the “Add Library” dialog, select the library Util.
   Click “OK” to confirm the selection.
   ⇨ The library Util is added to the Library Manager, and the POUs from the library are available for use in the project.
To program the control application in the project, see the following sections:

**Declaring the global variables**

First, declare the variables that you want to use across the entire application. To do this, create a global variable list below “Application”:

1. Select **Application** and click “Add Object ➔ Global Variable List” in the context menu. Change the default name GVL to Glob_Var and click “Add” to confirm.
   - The **Glob_Var** object appears below **Application**. The GVL editor opens to the right of the device tree.

2. When the textual view opens, it already contains the keywords **VAR_GLOBAL** and **END_VAR**. For our example, click **VAR_GLOBAL** in the right sidebar of the editor to activate the tabular view.
   - An empty row appears. The cursor is in the “Name” column.

3. In the context menu, click “Insert”.
   - An input field opens. At the same time, the “Scope” **VAR_GLOBAL** and the “Data type” **BOOL** are entered in the line automatically.

4. Specify rTempActual in the “Name” field.
5. Double-click in the field of the “Data Type” column.
   - Now the field can be edited and the button appears.

6. Click and then select “Input Assistant”.
   - The “Input Assistant” dialog opens.

7. Select the data type **REAL** and click “OK”.
8. Enter a numerical value in the “Initialization” column (example: 8.0).

Declare the following variables in the same way:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data type</th>
<th>Initialization</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>rTempActual</td>
<td>REAL</td>
<td>1.0</td>
<td>Actual temperature</td>
</tr>
<tr>
<td>rTempSet</td>
<td>REAL</td>
<td>8.0</td>
<td>Set temperature</td>
</tr>
<tr>
<td>xDoorOpen</td>
<td>BOOL</td>
<td>FALSE</td>
<td>Status of door</td>
</tr>
<tr>
<td>timAlarmThreshold</td>
<td>TIME</td>
<td>T#30S</td>
<td>Time after compressor runs that a signal sounds</td>
</tr>
<tr>
<td>timDoorOpenThreshold</td>
<td>TIME</td>
<td>T#10S</td>
<td>Time after opening the door that a signal sounds</td>
</tr>
<tr>
<td>xCompressor</td>
<td>BOOL</td>
<td>FALSE</td>
<td>Control signal</td>
</tr>
<tr>
<td>xSignal</td>
<td>BOOL</td>
<td>FALSE</td>
<td>Control signal</td>
</tr>
<tr>
<td>xLamp</td>
<td>BOOL</td>
<td>FALSE</td>
<td>Status message</td>
</tr>
</tbody>
</table>

You will now describe the main function of the application program in the main POU **PLC_PRG**, which is created by default. The compressor is activated and cools when the actual temperature is higher than the set temperature plus a hysteresis. The compressor switches off when the actual temperature is less than the set temperature minus the hysteresis.

To describe this functionality in the CFC implementation language, follow the steps below:
1. Double-click **PLC_PRG** in the device tree.
   - The CFC editor opens in the **PLC_PRG** tab. The declaration editor appears above the graphical editor area in textual or tabular form. The “**ToolBox**” view is on the right side.

2. In the “**ToolBox**” view, select the “**Input**” element and drag it to a point in the CFC editor.
   - The nameless entry ??? was inserted.

3. In the CFC editor, click ??? for the input. Then click to open the input assistance. In the “**Variables**” category, select the variable rTempActual below “**Application**” -> **Glob_Var**. This is how to reference the global variable rTempActual here.
   - The input name is **Glob_Var.rTempActual**.

4. As in Step 3, create another input with the name of the global variable **Glob_Var.rTempSet**.

5. Create another input, and then click ??? and replace them with the name **rHysteresis**.
   - Because this is not the name of a known variable, the “**Declare Variable**” dialog opens. The name is already used in the dialog.

6. In the “**Declare Variable**” dialog, specify “**Data Type**” with **REAL** and “**Initialization value**” with **1**. Click “**OK**”.
   - The variable **rHysteresis** appears in the declaration editor.

7. In the “**ToolBox**” view, select “**Box**” element and drag it to a point in the CFC editor.
   - The POU opens in the CFC Editor.

8. Replace ??? with **ADD**.
   - The POU adds all inputs that are connected to it.

9. Connect the **Glob_Var.rTempSet** input to the **ADD** POU. To do this, click the output pin of the input and drag it to the upper input pin of the **ADD** POU.

10. In the same way, connect the input **rHysteresis** with the lower input of the **ADD** POU.
    - The two inputs **rHysteresis** and **Glob_Var.rTempSet** are now added by **ADD**.

11. To move an element in the editor, click an empty space in the element or click the the frame, so that the element is selected (red border, red highlight). Drag the element to the desired position.

12. Create another POU to the right of the **ADD** POU. Its purpose is to compare **Glob_Var.rTempActual** with the sum of **Glob_Var.rTempSet** and **rHysteresis**. Assign the **GT** function (greater than) to the POU. 
    - The **GT** POU works as follows: IF (upper input > lower input) THEN
    - output := **TRUE**;

13. Connect the input **Glob_Var.rTempActual** to the upper input of the **GT** POU.

14. Connect the output of the **ADD** POU to the lower input of the **GT** POU.

15. Now create a function block to the right of the **GT** POU that starts and stops the cooling compressor depending on the input conditions (Set – Reset). Specify the name **SR** in the ??? field. Press the enter key to close the open input field above the POU (**SR_0**).
    - The “**Declare Variable**” dialog opens.

16. Declare the variable with the name **SR_0** and the data type **SR**. Click “**OK**”.
    - The **SR** POU from the **Standard** library is instantiated. **SR** is used for the definition of **THEN** at the output of the **GT** POU. The inputs **SET1** and **RESET** appear.
17. Connect the output pin on the right of the GT POU to the SET1 input of the SR_0 POU.
   ✓ SR can set a Boolean variable from FALSE to TRUE and back again. When the condition at the input SET1 is satisfied, the Boolean variable is set to TRUE. The variable is reset again when the condition at RESET is satisfied. The Boolean (global) variable in our example is Glob_Var.xCompressor.

18. Create an “Output” element and assign it to the global variable Glob_Var.xCompressor. Drag a connecting line between Glob_Var.xCompressor and the output pin Q1 of SR.

Now specify the condition under which the compressor should switch off again (in this case, the RESET input of the SR POU gets a TRUE signal). To do this, formulate the opposite condition to that above. Use the SUB (subtraction) and LT (less than) POUs to do this.

The result is the following CFC chart:

Creating a POU for signal management in the ladder diagram editor

In another POU, you will now implement the signal management for the alarm buzzer and for switching the lamp on and off. The ladder diagram (LD) implementation language is suitable for this.

Handle each of the following signals in their own networks:

- When the compressor runs too long because the temperature is too high, a continuous acoustic signal sounds.
- When the door is open too long, an intermittent signal sounds.
- The light is on as long as the door is open.

1. Below the Application in the device tree, create a POU object of type “Program” using the “Ladder Diagram (LD)” implementation language. Specify the name Signals for the program.

   ✓ Signals is listed in the device tree next to PLC_PRG. The ladder diagram editor opens in the Signals tab. The declaration editor appears in the upper part, the “ToolBox” view to the right. The LD contains an empty network.

2. Create a program in the network so that an acoustic signal sounds when the compressor runs too long without reaching the temperature setpoint. To do this, insert a TON timer POU. It switches a Boolean signal to TRUE only after a specified time. Select a TON below “Function Blocks” in the “ToolBox” view and drag it to the empty network and to the “Start here” box which appears. Release the mouse button when the field turns green.

   ✓ The POU appears as a box with inputs and outputs and is automatically assigned the instance name TON_0. The line editor is open and the cursor is blinking there.
   ⊳ You have confirmed the instance name. The “Declare Variable” dialog opens.

4. Click “OK” to confirm the dialog.
   ⊳ Now the inserted POU `TON` is instantiated with the name `TON_0`. Moreover, the top input is displayed by default as a contact preceding the POU.

   To read the help for the function block `TON`, place the cursor in/on the POU in the "TON" string and press [F1].

5. Now you program so that the function block is activated as soon as the cooling compressor starts to run. For this purpose, name the contact at the upper input of the POU `Glob_Var.xCompressor`. You have already declared this Boolean variable in the GVL `Glob_Var`.

   When you begin to type a variable name at the input position, you automatically get a list of all variables with names that begin with the typed characters and can be used at this point. This assistance is a default setting in the CODESYS options for SmartCoding.

6. Insert the signal that is to be activated. To do this, drag a “Coil” from the “Ladder Diagram Elements” toolbox category to the output `Q` of the `TON` POU. Specify the name `Glob_Var.xSignal` for the coil.

7. Define the time period from the activation of the POU `TON_0` until the signal should sound. This definition takes place via the variable `Glob_Var.timAlarmThreshold`, which you insert for this purpose at the input `PT` of `TON_0`. To do this, click the fine-edged box to right of the input pin and enter the variable name.

8. Select the POU `TON` and click “Remove unused FB call parameters in the context menu”.
   ⊳ The unused output `ET` is removed.

9. In the second network of the LD, program so that the signal sounds intermittently when the door is open too long.
   In the editor window, click below the first network. In the context menu, click “Insert network”.
   ⊳ An empty network with the number “2” appears.

10. As in the first network, implement a POU `TON` for time-controlled activation of the signal. This time it is triggered by the global variable `Glob_Var.xDoorOpen` at the input `IN`. At the input `PT`, add the global variable `Glob_Var.timDoorOpenThreshold`.

11. In addition, from the library `Util`, add a POU `BLINK` at the output `Q` of the POU `TON` in this network and instantiate it as `Blink_0`.

12. The POU `BLINK_0` clocks the signal forwarding `Q` and therefore `Glob_Var.xSignal`.
    First, drag two “Contact” elements from the “ToolBox” view to the `OUT` output of the POU. Assign the variable `TON_1.Q` to the contact directly after the output `Q` and the global variable `Glob_Var.xDoorOpen` to the second contact.

13. Insert a “Coil” element after the two contacts and assign the global variable `Glob_Var.xSignal` to it.

14. To do this, declare the local variable `timSignalTime : TIME := T#1S;` and insert this variable at the inputs `TIMELOW` and `TIMEHIGH`. The cycle time is 1 second for `TRUE` and 1 second for `FALSE`.

15. Select the POU `TON` and click “Remove unused FB call parameters in the context menu”.
   ⊳ The unused output `ET` was removed.
16. In the third network of the LD, program so that the lamp lights up as long as the door is open. To do this, insert another network. In that network on the left, insert a contact `GlobVar.xDoorOpen`, which leads directly to an inserted coil `Glob_Var.xLamp`.

17. CODESYS processes the networks of an LD in succession. Now install a jump to Network 3 at the end of Network 1 in order to ensure that either only Network 1 or only Network 2 is executed:

   Select Network 3 by clicking in the network or in the field with the network number. In the context menu, click “Insert Label”. Replace the text Label: in the upper left part of the network with `DoorIsOpen`:

   Select Network 1. In the “ToolBox” view, in the “Common” category, drag the “Jump” element to the network. Place it on the “Add output or jump here” box which appears.

   ↩️ The jump element appears. The jump destination is still specified as `???`.

18. Select `???` and click ⬅️. Select `DoorIsOpen` from the possible label identifiers and click “OK” to confirm.

   ↩️ The label to Network 3 is implemented.

The LD program now looks like this:

![LD program image]

Calling the Signals program in the main program

In our program sample, the main program PLC_PRG should call the Signals program for signal processing.
1. In the device tree, double-click **PLC_PRG**.
   - The **PLC_PRG** program opens in the editor.
2. In the “ToolBox” view, drag a “Box” element to the editor of **PLC_PRG**.
3. Using the Input Assistant, add this POU from the “POU Calls” category to the call of the Signals program.

**Creating an ST POU for a simulation**

Because the application in this example project is not linked to physical sensors and actuators, you also need to write a program for the simulation of increase and decrease in temperature. This will allow you to monitor the operation of the refrigerator controller afterwards in online mode.

You create the simulation program in structured text.

The program increases the temperature until the main program **PLC_PRG** determines that the set temperature has been exceeded. Then the program activates the cooling compressor. Then the simulation program decreases the temperature until the main program deactivates the compressor again.
1. Below the application, insert a POU of type “Program” in the “ST” implementation language. Specify the name Simulation.

2. Implement the following code in the ST editor:

```plaintext
PROGRAM Simulation
VAR
    TON_1: TON;                            //The temperature is decreased on a time delay, when the compressor has been activated
    P_Cooling: TIME:=T#500MS;
    xReduceTemp: BOOL;                  //Signal for decreasing
    TON_2: TON;                            //The temperature is increased on a time delay, when the compressor has been activated
    P_Environment: TIME:=T#2S;          //Delay time when the door is closed
    P_EnvironmentDoorOpen: TIME:=T#1S;  //Delay time when the door is open
    xRaiseTemp: BOOL;                   //Signal for increasing
    timTemp: TIME;                      //Delay time
    iCounter: INT;
END_VAR

iCounter := iCounter + 1;       // No function, just for demonstration purposes.

// After the compressor has been activated due to TempActual being too high, the temperature decreases.
// The temperature is decremented by 0.1°C per cycle after a delay of P_Cooling
IF Glob_VAR.xCompressor THEN
    TON_1(IN:= Glob_Var.xCompressor, PT:= P_Cooling, Q=>xReduceTemp);
    IF xReduceTemp THEN
        Glob_Var.rTempActual := Glob_Var.rTempActual-0.1;
    TON_1(IN:=FALSE);
END_IF
END_IF

//If the door is open, the warming occurs faster; SEL selects P_EnvironmentDoorOpen
timTemp:=SEL(Glob_Var.xDoorOpen, P_Environment, P_EnvironmentDoorOpen);

//If the compressor is not in operation, then the cooling chamber becomes warmer.
//The temperature is incremented by 0.1°C per cycle after a delay of timTemp
TON_2(IN:= TRUE, PT:= timTemp, Q=>xRaiseTemp);
IF xRaiseTemp THEN
    Glob_Var.rTempActual := Glob_Var.rTempActual + 0.1;
    TON_2(IN:=FALSE);
END_IF
```

PLC Automation with V3 CPUs
Programming with IEC 61131-3 editor > CODESYS Development System

2020/12/10
3ADR010583, 1, en_US
116
We recommend that you use a visualization for convenient operation and monitoring of the entire control program. A visualization created with CODESYS is installed in the completed sample project for this tutorial, which is provided with the standard CODESYS Visualization installation (Projects directory). You can download this project to the controller and start it to see it working together with the visualization. When started, the Live_Visu begins with a representation of the refrigerator which reproduces the operation of the simulation program without you having to input any data. However, you can open and close the door by clicking the on/off switch. It is possible to adjust the default temperature by means of the needle of the rotary control. We will not cover the creation of the visualization in this tutorial. An corresponding tutorial is planned in the help for CODESYS Visualization.

Defining the programs to be executed in the task configuration

The default task configuration contains the call for the main program PLC_PRG. For our sample project, you also need to add the call for the Simulation program.

1. In the device tree, drag the Simulation entry to MainTask below the “Task Configuration”:
   - The Simulation program is inserted into the task configuration.

2. To view the task configuration, double-click the MainTask entry to open the editor.
   - In the table in the lower part of the editor, you see the POUs that are called by the task: PLC_PRG (entered by default) and Simulation. The call type of the task is “Cyclic” at intervals of 20 milliseconds. In online mode, the task will execute the two POUs one time per cycle.

Defining the "active application" for the communication with the PLC

The name of the Application is displayed in bold fonts in the “Devices” view. This means that this application is set as the "active application". The communication with the controller then refers to this application.

When there is only one application in a project, it automatically becomes the active application. If your application is not active yet, then activate it as follows:

▷ In the context menu of Application, click “Set Active Application”.
   - “Application” is now displayed in bold in the “Devices” view.

Debugging the application program

When you are inputting the code, CODESYS immediately alerts you to syntax errors by means of a wavy red underline below the text in question. Press [F11] to check the syntax of the entire application. The result of the check is shown in the message view. If necessary, click “View Messages” to open the message view. Then you can select a message and press the [F4] key to jump to the corresponding point in the code.

Afterwards, only an error-free application can be downloaded to the controller.
Starting the gateway server and PLC

CAUTION!
Check controller accessibility
For security reasons, controllers should not be accessible from the Internet or untrusted Networks under any circumstances! In particular, the TCP/IP programming ports (usually UDP-Ports 1740..1743 and TCP-Ports 1217 + 11740 or the controller specific ports) should not be accessible from the internet without protection. In case Internet access to the controller is needed, using a a safe mechanism is absolutely mandatory, such as VPN and password protection of the controller.

see also: Chapter 1.3.1.11.3 “Handling of device user management” on page 300

Starting the gateway server:
The program GatewaySysTray is installed as standard with CODESYS. You can communicate with the gateway server by means of this program. The gateway server is started automatically as a service when the system starts. Check that the Windows taskbar contains the program icon . When the gateway server is not running, the icon looks like this: . In this case, you can click the icon to open the gateway menu and click “Start Gateway”.

Starting the PLC:
The program CODESYSControlSysTray is installed by default with CODESYS. You can communicate with the CODESYS Control Service by means of this program. In CODESYS V3.5 SP2 and later, the control service is no longer automatically started on starting up the system. This is to protect against unauthorized access. Start the PLC as follows: In the Windows taskbar, click to open the PLC menu. Then click “Start PLC”. If the PLC is running, then the icon changes to . A dialog that appears at startup indicates that the started PLC allows programming access. Pay attention to the security notice above.

In the very first communication configuration: Adding the gateway

▷ In the “Devices” view, double-click Device (CODESYS Control Win V3).

◇ The “Communication Settings” tab opens in the Device editor.

If this is your first communication configuration with CODESYS V3, then now you need to define the local gateway server. If you have already defined the gateway server, then it will be shown on the “Communication Settings” tab. In this case, you can now continue to " Defining the communication channel" on page 120".

The gateway server is provided with the CODESYS installation.
1. Click “Gateway ➔ Add New Gateway”.
   ⇒ The “Gateway” dialog opens.

2. In the “Name” input field, specify a symbolic name for the gateway.
3. In the “Drivers” list box, select “TCP/IP”.
4. Double-click the right column of the “IP address” row and specify localhost in the input field.
5. Click “OK”.

⇒ The gateway is entered on the “Communication Settings” tab (1) of the device editor. When the gateway is running correctly, a filled green circle appears on the graphic of the gateway:

![Gateway graphic with green circle]

Defining the communication channel

Now define the communication channel to the device, which is then used via the gateway that you have set. To do this, double-click “Device” in the device tree to open the “Communication Settings” tab of the device editor.

1. Click “Scan Network” to search the local network for all available devices.

⇒ The “Select Device” dialog (1) appears with a list of all devices with which you can establish a connection.

![Select Device dialog]

2. Select the tree entry with the name of your computer.
3. Click “OK”.
   ⇒ The channel is now active and the associated information appears below the device graphic on the “Communication Settings” tab.

All communication actions now refer exactly to this channel. Remember this later if you have multiple communication channels in the project.

For the application on the PLC, see the following sections:

**Downloading the application to the PLC**

Requirement: The application has been compiled without errors. See "Debugging the application program" on page 117.

1. Click “Online ➔ Login”.
   ⇒ A dialog prompt opens to ask whether or not the application should be downloaded to the controller.
2. Click “Yes”.
   ⇒ The application is downloaded to the controller. The entries for the controller and the application in the “Devices” view are highlighted in green. Stop appears after the “Application” object. The current status of the controller appears in the taskbar:

   ![Stop](image)

   Run appears after the “Application” object.

Starting the application

If you have followed this tutorial precisely up until now, then you can use the “Application” on the PLC “Device (CODESYS Control Win V3”).

   ⇒ In the “Devices” view, in the context menu of the “Application” object, click “Start”.

   ⇒ The program starts running. The entries for the controller and the application in the “Devices” view are highlighted in green. Run appears after the “Application” object. The current status of the controller appears in the taskbar:

   ![Run](image)

**Monitoring and one-time writing of variable values at runtime**

In the following section, you can view the "monitoring" of the variable values in the various POUs, and you can set a specific variable value on the controller one time only from CODESYS.

You can see the actual values of the application variables in the online views of the POU editors or in monitoring lists. In the example here, we will focus on monitoring in the POU editor.

Requirement: The application is running on the controller.
1. In the device tree, double-click the objects PLC_PRG, Signals, Simulation, and Glob_Var to open the online views of the editors.

In the declaration part of each view, the actual value of the variable (1) on the controller appears in the table of expressions in the “Value” column (3) (see figure).

Monitoring in the implementation part depends on the implementation language. In the case of non-Boolean variables, the value is always located in a rectangular field to the right of the identifier. In the ST editor, this also applies to Boolean variables. We call this display "Inline monitoring". In the graphical editors, the value of a Boolean variable is shown by the color of the output connecting line (black for FALSE and blue for TRUE):
2. Observe how the variable values change in the various POUs. For example, you can see in the GVL Glob_Var how the values of rTempActual and xCompressor change due to the processing of the simulation program.

One-time setting of variable values on the controller:
1. Set the focus in the online view of the GVL Glob_Var.
2. To set a new specified value, double-click in the “Prepared Value” column (2) next to the expression rTempSet.
   ⇒ An input field opens.
3. Specify the value 9 and exit the input field.
4. To specify an open door, click once in the “Prepared Value” field next to the expression xDoorOpen. The value TRUE is specified. Click three more times to see that you can toggle the prepared value between TRUE, FALSE, and empty.
5. To write the prepared value TRUE one time only to the variable, press [Ctrl]+[F7].
   ⇒ The two values are each transferred to the “Value” column (3). Now the variable xDoorOpen no longer changes its value and the set temperature is 9 degrees. The variable timTemp changes to the value 1s because the refrigerator door is now “open” and the heating due to the Simulation should be faster than before (2s).

Setting of breakpoints and stepping at runtime

Debugging: For troubleshooting purposes, you need to check the variable values at certain points in the code. You can define breakpoints for the execution and initiate a step-by-step execution of the statements.

Requirement: The application has been downloaded to the controller and is running.
1. Double-click Simulation to open the program in the editor.
2. Place the cursor in the code line iCounter := iCoutner + 1; and press [F9].
   ⇒ The symbol ● is displayed before the line of code. It indicates that a breakpoint is set on this line. The symbol changes immediately to ●. The yellow arrow always points to the next statement to be processed. HALT ON BP. appears in the taskbar instead of RUN.
3. Observe the value of the variable iCounter in the inline monitoring or in the declaration part of the Simulation program.
   ⇒ The value of the variable no longer changes. The processing was stopped at the breakpoint.
4. Press [F5] to restart the processing.
   ⇒ After one cycle, the program stops again at the breakpoint. iCounter was incremented by 1.
5. Press [F8] to execute the next processing step.
   ⇒ The “RETURN” at the end of the line iCounter := iCounter + 1; statement is highlighted in yellow.
6. Press [F8] again to execute the next processing step.
   ⇒ The processing jumps to the editor of PLC_PRG. Repeatedly pressing [F8] shows how the program is executed step-by-step. The statement to execute is once again marked each time with a yellow arrow.
7. To disable the breakpoint and return to normal processing, set the cursor back in the code line and press [F9]. Then press [F5] to set the application back to RUN mode.
Requirement: The application has been downloaded to the controller and is running.

1. As above when stepping, monitor the line `iCounter := iCounter + 1;` in the Simulation program.

2. Press `[Ctrl]+[F5]` or click “Debug ➔ Single Cycle” to run a single cycle.
   ➔ The processing runs through one cycle and stops at the breakpoint again. `iCounter` was incremented by 1.

   ➔ The program runs again without stopping and without forced values. The `temp` variable has the value 1s again. RUN is displayed again in the status bar.

### Creating and configuring a project

#### What is a project?

- A project contains the objects that are necessary for the creation of a control program (`application`):
  - Pure POUs, for example programs, function blocks, functions, GVLs.
  - Objects that are additionally required in order to be able to execute the application on a PLC. For example, task configuration, library manager, symbol configuration, device configuration, visualizations, external files.
- You can program several applications and connect several control devices in a project.
- CODESYS manages device-specific and application-specific POUs in the “Devices” view (‘Device tree’), project-wide available POUs in the “POUs” view.
- For the creation of projects there are templates that already contain certain objects.
- Basic configurations and information for the project are defined in the “Project Settings” and the “Project Information”. For example:
  - Compiler settings
  - User management
  - Author
  - Data for the project file.

There are settings for the version compatibility of the project in the configuration dialog boxes for the “Project Environment”.

- You save a project as a file in the file system. Optionally you can pack it together with project-relevant files and information in a project archive. Saving in a source control system such as SVN is also possible
- Each project contains the information regarding the CODESYS version with which it was created. If you open it in another version, CODESYS will draw your attention to possible or necessary updates with regard to file format, library versions, etc.
- You can compare, export or import projects and create documentation for them.
- You can protect a project against change and completely, i.e. also against reading. By using a user management system you can purposefully control access to the project and even to individual objects in the project.

### Creating standard projects

1. Click “File ➔ New Project” and then the template “Projects ➔ Standard project”. Specify a name (example: `myProject`) and a location in the file system.
   ➔ The “Standard Project” dialog opens.
2. Select one of the standard devices CODESYS Control Win V3 from the "Device" list, and select "Structured Text (ST)" from the "PLC_PRG in" list. Then click "OK".

⇒ The project name myProject is listed in the title bar of the main window of the development system. The following structure is created in the device tree ("Devices" view).

![Device Tree Diagram]

Depending on the selected PLC, additional device nodes may also be shown.

The PLC is always displayed automatically with a "PLC Logic" subnode. The base objects below it are: an application with a "Library Manager" and a "Task Configuration". The task configuration defines the MainTask for processing the standard POU "PLC_PRG".

The library manager already contains Standard.library with base POUs (for example, counters, timers, and string functions) that can be used later when programming.

Now when you fill "PLC_PRG" with error-free code, you can download it to the controller and execute it without requiring any further programming objects.

In SP13 and later, the project setting "Integrity check" in "Project → Project Settings → Security" is activated automatically for a new created standard project. For detailed information on how to protect your project, please refer to the section "Protecting and Saving a Project".

- Chapter 1.3.1.25.3.11.7 “Dialog 'Project Settings' - 'Security'” on page 1064

1.3.1.3.2 Adding objects

Requirement: A project is open. At least the highest node "<project name>" is shown in the "Devices" view ("Device tree") and in the "POUs" view.

The following instructions indicate a few possibilities when creating objects in the project.
1. Select an entry in the Device tree or in the POUs tree, for example the “Application” object.
2. Select the command “Project ➔ Add Object”.
   ⇒ Depending on the selected entry in the tree, CODESYS offers the suitable objects for selection.
3. For example, select the object “POU” and, in the dialog box “Add POU” which then appears, select the type “Program” with implementation language “Structured Text (ST)” and name “prog”.
   ⇒ After clicking on “Add”, CODESYS inserts a program object “prog” in the device tree below “Application”.
4. Select an object in the tree and select the command “Properties” in the context menu.
   ⇒ The dialog box “Properties” appears with the object-relevant categories. If you use a user management system you can, for example, restrict access to the object here.
5. Select an entry in the tree under which you would like to create a folder in order to collect certain objects in it. Please note: you cannot structure the arrangement of device nodes and device objects through folders that you have created yourself.
6. Select the command “Add Folder” in the context menu and, in the dialog box that appears, define a name for the new folder. Click on “OK”.
   ⇒ The folder appears in the tree.
7. Select an object in the tree and shift it by dragging it with the mouse within the tree to another position, for example into the folder.
8. Do not select an object in the Device tree; instead, set the focus on any desired free position in the CODESYS interface. Select the command “Project ➔ Add Object” and then, for example, the object “TextList”.
   ⇒ The object “Text List” is inserted in the “POUs” view!

- § Chapter 1.3.1.25.2.3.22 “Command ‘Properties’” on page 896

### 1.3.1.3.3 Changing the compiler version

The version of the compiler with which code is generated in the current project for use on the target device is defined in the project settings.

The compiler version is independent of the CODESYS version. Hence, constant application code is created from the source code when the compiler version is set the same, even if this takes place from different CODESYS versions.

**NOTICE!**

Pay attention to the setting “Do not update” on the “Compiler Version” tab in the “Project Environment” dialog box: if this is activated and you open an older project, for which the “Newest” compiler version is still set, then CODESYS will continue to use the compiler version used last in the old project. This also applies if a different "current" version is defined in the new environment!
If you open a project in which the newest compiler version is not set, the “Project Environment” dialog box appears with a corresponding note and the possibility to update directly.

Requirement: A project is open.
1. Select the command “Project ➔ Project Settings” and then the “Compile Options” tab.
2. Select the desired “Fix Version” and click on “OK”.
   ⇒ The change is immediately effective.

● § Chapter 1.3.1.25.3.12.2 “Dialog ‘Project Environment’ - ‘Compiler Version’” on page 1070

1.3.1.3.4 Opening a V3 project

Requirement: CODESYS is started (or a project is already open).
1. Click “File ➔ Open Project”.
2. In the “Open project” dialog, click any V3 project or project archive in the file system. A file filter is located in the lower right corner of the dialog. Note: If necessary, you can open the project as write protected in order to prevent any accidental changes to the existing project file.

If no other project is open, then the following cases are possible:

- You have selected a project that was saved with a later CODESYS version.
  This kind of project may include data that cannot be loaded. You can still open the project, but you have to understand that the project can behave unexpectedly because it cannot be interpreted completely. Objects that CODESYS could not load, either partially or completely, are highlighted in red in the device tree with the text “[unknown]” or “[incomplete]”. CODESYS cannot display objects in the editor that are unknown to the current version. CODESYS displays incomplete objects in the editor with a warning that the displayed contents may not correspond to the original. CODESYS cannot save incomplete projects as their original names. This is displayed by a write protection note in the upper right corner. You can save the file as another name.
- You have selected a project that CODESYS did not save properly after the last change, but the project option “Auto Save” was activated: The dialog “Auto Save Backup” opens for handling the backup.
- You have selected a project that is write-protected: You can either open the project in write-protected mode or remove the write protection.
- You have selected a project that is password-protected. You are prompted for the password.
- You have selected a project that is protected by a security key. If the security key is not plugged into the computer, then you are prompted to plug it in. Otherwise CODESYS opens the project without any information about the protection.
- You have selected a project that contains a package (add-on) or plug-in specific POU. In addition, the project was saved with a CODESYS installation that also had the relevant add-ons and plug-ins installed. However, the add-ons and plug-ins are not installed in the current CODESYS installation.
  A dialog opens with information that the project cannot be loaded with all POUs. The missing add-ons and plug-ins are listed with the version information. You can cancel opening the project and then perform an installation.
  ⇒ The “Project Environment” dialog opens.
3. Check the updates provided in the “Project Environment” dialog. For projects that were created with very old V3 versions, information may be displayed how to replace specific objects in order to continue using the project. Depending on whether you leave the project as it is or continue development under up-to-date conditions, you perform updates or you do not. After each update, a login without download or online change is no longer possible.

⇒ The project opens.

- Chapter 1.3.1.3.5 “Opening a V2.3 project” on page 128
- Chapter 1.3.1.25.3.13.13 “Dialog ‘Options’ – ‘Load and Save’” on page 1083
- Chapter 1.3.1.6.1 “Setting up write protection” on page 142
- Chapter 1.3.1.6.2 “Assigning passwords” on page 143
- Chapter 1.3.1.25.2.1.2 “Command ‘Open Project’” on page 853

1.3.1.3.5 Opening a V2.3 project

A CoDeSys V2.3 project can be converted into a CODESYS V3 project only if the CODESYS V2.3 Converter package is installed in CODESYS V3. The package is available in the CODESYS Store.

Requirement: CODESYS is started (or a project is already open). You should be aware of the restrictions described below the following instructions.

1. Click “File ➔ Open Project”.

2. In the “Open Project” dialog, click any CoDeSys V2.3 project or project archive in the file system. For searching, you can set the file filter on the bottom right corner of the dialog.

⇒ If another project is still open, CODESYS instructs you to close it accordingly. After that the CoDeSys V2.3 converter automatically starts.

3. The V2.3 converter checks that the project can be compiled without errors. If so, then it processes the project automatically.

4. NOTE: If the project contains visualization objects with placeholder variables that the converter cannot resolve, the respective visualizations are shown as a group in place of the visualization references.

5. Device conversion: When a device (target system) is referenced in the project to be opened and no conversion rules are defined for the device, then the “Device Conversion” dialog opens. Specify here whether and how the converter should replace the previous device reference with a current one.

⇒ For replacement, the converter added the new device in the place of the old one in the device tree of the converted project.

6. Library conversion: if a library, for which no conversion rule has so far been defined, is referenced in the project to be opened, then the “Conversion of Library Reference” dialog opens. Specify here whether and how the converter should replace the existing library reference with a current one. If you select a library for which the project information is missing, then the “Enter Project Information” dialog opens in order to specify this information.

⇒ The converter loads the adapted project. Note: The redefined library references are to be found in the global Library Manager in the POUs view.
### Restrictions when reusing a CoDeSys V2.3 project in CODESYS

<table>
<thead>
<tr>
<th>Compilation:</th>
<th>The project has to be compilable without errors in CoDeSys V2.3. Note: CODESYS still issues warnings in V3 when compiling. These are caused by implicit conversions, which can lead to a loss of information (for example through sign changes). CODESYS checks &quot;case&quot; statements against the switch variable: CASE USINT OF INT is not checked in CoDeSys V2.3, but it issues an error message when imported into V3.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Controller configuration:</td>
<td>The &quot;Controller Configuration&quot; of a CoDeSys V2.3 project cannot be imported into V3. You have to recreate the device configuration and re-declare the variables used in the controller configuration.</td>
</tr>
<tr>
<td>Network variables:</td>
<td>For network variables, CODESYS creates V3 GVL objects and imports the variable declarations. However, the network properties are not imported. See the description of the network variable exchange for this.</td>
</tr>
<tr>
<td>Libraries:</td>
<td>All variables and constants that are used in a library also have to be declared in the library. It must be possible to compile the library in CoDeSys V2.3 without errors.</td>
</tr>
</tbody>
</table>
| Syntax and semantic restrictions since CoDeSys V2.3: | - FUNCTIONBLOCK is not a valid keyword instead of FUNCTION_BLOCK.  
- TYPE (declaration of a structure) must be followed by a ":".  
- ARRAY initialization** must have parentheses.  
- INI is no longer supported (you have to replace this in the code by the Init method).  
- In function calls it is no longer possible to mix explicit with implicit parameter assignments. Therefore the order of the parameter input assignments can be changed:  
  `fun(formal1 := actual1, actual2);`  // -> error message  
  `fun(formal2 := actual2, formal1 := actual1);`  // same semantics as the following line:  
  `fun(formal1 := actual1, formal2 := actual2);`  
- CoDeSys V2.3 pragmas are not converted. They produce an warning in V3.  
- The TRUNC operator now converts to the data type DINT instead of INT. CODESYS automatically adds a corresponding type conversion for a CoDeSys V2.3 import. |

### Visualization:

<table>
<thead>
<tr>
<th>Placeholders and their replacement</th>
<th>VAR_INPUT</th>
<th>Usage</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Placeholders</td>
<td>VAR_INPUT</td>
<td>Usage</td>
<td>Replacement</td>
</tr>
<tr>
<td>PLC_PRG.$Local Var$.aArr[0] localVar: MyStruct; localVar.aArr[0] localVar := PLC_PRG.myStruc tVar</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$Var$.aArr[0] Var : MyStruct; Var.aArr[0] Var := PLC_PRG.myStruc tVar</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>PLC_PRG.myStruc tVar.aArr[$Index$] Index : INT; PLC_PRG.myStruc tVar.aArr[Index] Index := 0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Problematic placeholders

- **Placeholders within a text:**
  - Text: `$axle$-Axis`
  - Correction: `localVar : STRING;`
  - Text: `%s-Axis`
  - Text variable: `localVar`

- **Placeholder describes only one part of a variable name:**
  - Text: `axis$axis$spur$spur$.fActPosition`
  - Correction: Define only one placeholder for the `axis$axis$spur$spur$` placeholder.
  - axis_spur : MyFunctionBlock;
  - Then directly transfer the corresponding instance of the function block.
  - axis_spur := PLC_PRG.axis1spur2;

- **Placeholder is replaced by an expression:**
  - Text: `$Expression$ -> PLC_PRG.var1 + PLC_PRG.var2`
  - Correction: You must transfer the expression to an auxiliary variable and then transfer this auxiliary variable as an instance.

- **The placeholder describes a program name:** `$Program$.bToggle -> PLC_PRG.bToggle D`
  - The converter cannot transfer this form of setting placeholders in V3. However, you will rarely use it in practice.

- **Placeholder is replaced by different types:**
  - Text: `$Var$
  - Correction: Define two different placeholders in the interface for this.

- **The visualization is located in a library. You replace the placeholder later from any desired project when you use the visualization there.**
  - Correction: Here you have to replace the `TYPE.NONE` data types manually. However, there is also the possibility for you to integrate the library in a project and the placeholder is correctly replaced. If you now import this project, the data type is also determined correctly in the library.

### Non-importable elements:

- Trend, ActiveX – the import is not possible, because the implementation differs a great deal. In V3, a corresponding warning is issued and a corresponding manual reproduction is required.

### Programming languages

| ST, IL, FBD: | No restrictions |
CODESYS imports function blocks with parallel branches in such a way that the part before the branch is repeated for each branch. This corresponds to the generated code that CoDeSys V2.3 creates for parallel branches.

- **SFC:**
  - Step variables explicitly declared by the user must be declared locally in the SFC editor. You may not declare them as VAR_INPUT, VAR_OUTPUT or VAR_INOUT, because CODESYS cannot automatically adapt the calls. Explanation: Steps no longer use Boolean variables for the management of the internal states in V3, but also structures of the type SFCStepType.
  - Identifier: the following identifiers may not begin with an underscore character:
    - Names of IEC actions in the tree
    - Variables that are called in an IEC association list
    - Names of transitions that have been programmed out
  - Explanation: In V3 the implicit variables that CODESYS creates for actions are given an underscore character as prefix. An invalid identifier with a double underscore character would result.

- **CFC:**
  - Large boxes: The layout of large boxes can lose quality due to an import. The boxes may overlap one another too much. (Correction planned).
  - Macros: Macros cannot be imported. (Correction planned).

- Chapter 1.3.1.25.3.2 “Dialog ‘Library Reference Conversion’” on page 1040

### 1.3.1.3.6 Configuring a project

You can configure your CODESYS project using the following dialogs:
- "Project Settings": Basic settings on the behaviour of editors and of the compiler, on user management etc.
- "Project Information": Adding of individual and tagging information to the project
- "Project Environment": Defining which versions of the external and internal modules should be used, with the aim of achieving up-to-dateness and compatibility with each other.
Retrieving and editing project information

You can use the “Project Information” object to retrieve information about your project and the associated file, and edit certain information.

The object contains information about

- File attributes
- Meta-information, such as manufacturer, title, or author
- Properties with keys
- Statistics
- Licensing
- Signing: This way of signing translated libraries is deprecated, and for security reasons should only be used if compatibility with older versions is required. If this method is used, then later you can use a public key token to verify that the library was last signed by the library vendor. As a library vendor, it is therefore crucial that you make the public key used available to the customer, for example in the documentation.

CODESYS saves the project information as an object within the project. When you transfer a project to another system, the “Project Information” object is transferred with it. There is no need for a project archive.

You can use property keys to access the project information externally via function blocks. For a library project, you can also query information about the licensing.

Editing meta-information

1. Click “Project ➔ Project Information”.
2. The “Project Information” dialog opens.
3. Select the “Summary” tab.
4. Specify your data in the input fields (example: 0.0.0.1 in the “Version” input field).

   CODESYS creates a property with a key for each given value and manages them on the “Properties” tab. For a library project, CODESYS still uses the properties and sorts later in the library repository.

   If you select the option for CODESYS to create a functions block for these properties, then you can access the properties programmatically.

Creating functions for accessing properties

1. Click “Project ➔ Project Information”.
2. The “Project Information” dialog opens.
3. Select the “Automatically generate ’Project Information’ POUs” option.
Example

Requirement: The following property is defined.

```
Key = nProp1
Type= number
Value= 333
```

1. Select the “Automatically generate ’Project Information’ POUs” option.
2. Declare a property of the type DINT, for example `showprop : DINT;`.
3. Call the function `GetNumberProperty`: `showprop := GetNumberProperty("nProp1");`
   ⇒ You are granted access to the value in the application.

Note: The functions that are created with the “Automatically generate ’Project Information’ POUs” option can be used only if the runtime system supports the WSTRING data type. If this is not the case, then instead you can apply the “Automatically generate ’Library Information’ POUs” option. You can use the functions created in this way at least in the application to access properties. These functions are not registered in the runtime system.

Licensing library projects

If your project is a library project, then you can activate the library licensing in use here. The CODESYS Security Key is a dongle.

- Requirement: The project is a library project.
  1. Click “Project ➤ Project Information”.
     ⇒ The “Project Information” dialog opens.
  2. Click the “Licensing” tab.
  3. Select the “Activate dongle licensing” option.
  4. Specify the dongle data in “Firm code”, “Product code”, “Activation URL”, and “Activation mail”.
     ⇒ The library is licensed.

Deprecated: Signing a library project (only for version compatibility with CODESYS < SP15)

In CODESYS V3 SP15 and later, library signing is always certificate-based and can be executed by means of the “File ➤ Save Project as Compiled Library” command. In contrast to deprecated signing by using the settings in the “Project Information” - “Signing” dialog, the entire library is signed with the certificate.

In case you still have to sign a library project for a CODESYS version < V3 V3 SP15 for reasons of compatibility, then proceed as described below.

- Requirement: You have an available private key file with an associated token. In the project information of the library project, on the “Summary” tab, a library compatibility with a CODESYS version < V3 V3 SP15 is set
  1. Click “Project ➤ Project Information”.
     ⇒ The “Project Information” dialog opens.
  2. Click the “Signing” tab.
  3. Select the “Activate signing” option.
4. Specify the memory location of your private key file.
   ⇒ CODESYS enters the token automatically in “Public key token” (example: 427A5701DA3CF3CF).

5. Click “File ➔ Save Project as Compiled Library”.
   ⇒ The library project is saved as a files with the extension *.library. You will see the
token in the library repository or Library Manager in the library details and can com-
pare it with the library vendor's published token. In this way, you can check whether
the library actually originates from the intended vendor.

See also
● § Chapter 1.3.1.25.2.1.7 “Command ‘Save Project as Compiled Library’” on page 856

Creating private
key files

1. Click “Project ➔ Project Information”.
2. Click the “Signing” tab.
3. Click the “Create Private Key File” button.
   ⇒ The “Create Private Key File” dialog opens.
4. Select a safe location, e.g. D:\for lib developers only\mycomp_libkey.libpk
   and exit the dialog with “Save”.

See also
● § Chapter 1.3.1.25.1.31 “Object ‘Project Information’” on page 811

Making project settings

You can configure settings that affect the behavior of CODESYS and that of certain editors in
the “Project Settings” object. The settings are valid throughout the project and are applied
immediately for active editors. You can also access the dialog boxes of the object with the com-
mand “Project ➔ Project Settings”.

CODESYS saves the project settings as an object directly in the project. If you then transfer a
project to another system, the “Project Settings” object is also transferred with it, without a
project archive being required.

1.3.1.4 Exporting and transferring a project

Export and import functions are available to you for the exchange of the data from CODESYS projects with other programs.

An exchange of CODESYS projects between CODESYS development systems takes place by way of a copy of the project file (*.project) or project archive (*.projectarchive).

See also
- Chapter 1.3.1.4.1 “Exporting and importing projects” on page 135
- Chapter 1.3.1.4.2 “Transferring projects” on page 136

1.3.1.4.1 Exporting and importing projects

CODESYS offers commands for the export and import of objects to and from a file. Two possibilities are available to you here:

- Export to or import from a CODESYS XML file (*.export)
  This format is completely compatible with the CODESYS project format. The objects are saved in a machine-readable XML format.
- Export to or import from an XML file in the PLCopen format (*.xml)
  You can use this format to exchange information with other programs (for example program editors or documentation tools). PLCopen XML defines a subset of the elements known in CODESYS. 100% compatibility is thus not guaranteed.

Exporting projects

Requirement: A project is open in CODESYS.

1. Select the command “Project ➔ Export…” or “Project ➔ Export PLCopenXML”.
2. Select the objects that you wish to export in the dialog box “Export” or “Export PLCopenXML”.
3. Click on “OK”.
4. Enter the file name and the location and click on “Save”.

Importing projects

Requirement: A project is open in CODESYS.

1. Select the command “Project ➔ Import…” or “Project ➔ Import PLCopenXML”.
2. In the dialog box “Import” or “Import PLCopenXML”, select the export file that you wish to import.
   ➔ A dialog box opens and displays the objects in a tree structure, which can be inserted at this point.
3. Select the object in the object tree, under which the objects to be imported are to be inserted.
4. Select the objects and click “OK”.
   ➔ The objects are added to the existing object tree.

1.3.1.4.2 Transferring projects

If you wish to transfer a project to another computer and connect from there to the same PLC, without an online change or download being required, observe the following points.

- Make sure that the project requires only fixed versions of libraries (exception: interface libraries), visualization profile and compiler.
- Make sure that the boot application is up to date.

Then create a project archive, which you unpack on the other computer.

Transferring a project to another system

Requirement: A project is open on computer “PC1” that you transfer to another computer “PC2” and reconnect from there to the same controller.

1. Make sure that only libraries with fixed versions are integrated in the project, with the exception of pure interface libraries. To do this, open the “Library Manager” and check all entries that have a “*” instead of a fixed version specification.
2. Make sure that a fixed compiler version is set in the project settings. To check, select “Project ➔ Project Settings” and the “Compiler Options” category.
3. Make sure that a fixed visualization profile is defined in the project settings. To check, select “Project ➔ Project Settings” and the “Visualization Profile” category.
4. Make sure that the application that is presently open is the same as that which is presently in use on the PLC. This means that the “boot application” must be identical to the project in the programming system. To check, look at the project name in the title bar of the programming system window: If an asterisk is displayed behind the name, this means that the project has been modified, but not yet saved. It is then possible that the application and boot application do not correspond!

In this case, first create a (new) boot application. It depends on the PLC and the application properties, whether this takes place automatically during the download of the application. For explicit creation, select the command “Online ➔ Create boot application”. Then execute a download with the help of the commands “Online ➔ Login” and “Online ➔ Load”.

After that, start the application on the controller with the command “Debug ➔ Start”.

⇒ Now the desired application is running on the PLC, to which you wish to reconnect from the same project later on PC2.

5. Generate a project archive: Select “File ➔ Project Archive ➔ Save/Send Archive”. In the “Project Archive” dialog box, also select the following information:
   - “Download information files”
   - “Library profile”
   - “Referenced devices”
   - “Referenced libraries”
   - “Visualization profile”

Save the project archive in a place that is accessible by PC2.

6. Log out from the controller: To do this, select “Online ➔ Logout”. You can stop and restart the PLC without reservations, before you reconnect from PC2.

7. Extract the project archive to PC2: Select “File ➔ Project Archive ➔ Extract Archive” and open the archive saved above. In the “Extract Project Archive” dialog box, activate the same information as described above when generating the archive.

8. Open the project and log in to PLC “xy” again.

⇒ CODESYS does not demand an online change or download; the project runs.
1.3.1.5 Comparing projects

You can compare the currently open project with another project – a reference project. The differences in contents, properties, or access rights are detected and shown in a comparison view.

Clicking “Project ➤ Compare” opens the “Project Compare” dialog for you to configure and run the comparison. Then the result is shown in the comparison view “Project Compare - Differences” where the objects are aligned in a tree structure. Objects that indicate differences from the respective reference object are identified by colors and symbols. This is how you detect whether or not the contents, properties, or access rights are different.

For differences in the contents, you can also open the detailed compare view “Project Compare - <object name> Differences” in order to zoom into the object. In the detailed compare view, the contents of the object and reference object are displayed or their source code aligned. The detected differences are marked. Previously opened views are not closed. In this way, you can have any number of comparison views open and read them, in addition to the project compare view.

You can accept the detected differences from the reference project into the current project. This is possible only from the reference project into the open project. To do this, you activate differences (for example in the code) that should be accepted in the current project with the commands ✓, ✗, or ✕ in the active comparison view for accepting. These positions are highlighted in yellow. Make sure that any other open compare views are inactive (write-protected, read-only), therefore, you can activate differences to be accepted in exactly one comparison view only. When exiting the active compare view, if you confirm that the differences that are activated for acceptance are actually accepted into the current project, then the current project is modified.

In order to exit the project comparison completely, close the project compare view.

1.3.1.5.1 Creating a comparison view

Requirement: You have made changes in your current project and wish, for example, to compare it with the last-saved version. In the meantime, for example, you have added further POU's, removed a POU, changed single lines of code or the object properties in function blocks.

1. Select the command “Project ➤ Compare”.
   ➤ The “Project Comparison” dialog box opens.

2. Enter the path to the reference project, for example the path to the last-saved version of your current project.

3. Leave the activation of the comparison option “Ignore Spaces” as it is.

4. Click on “OK”.
   ➤ CODESYS opens the comparison view. Title: “Project Comparison – Differences”. The Device trees of the current project and the reference project are displayed alongside each other and the changed objects are marked in color.

5. Select an object marked in blue in the tree of the reference project (right). The current project no longer contains this object.

   Click on ✓ “Accept Single”
   ➤ CODESYS adds the object to the tree of the current project (left). The line has a yellow background. ✗ appears in the middle column.
6. Select an object marked in green in the tree of the current project (left). The reference project does not contain this object.

   Click on "Accept Single"
   ⇐ CODESYS removes the object again from the tree of the current project (left). The line has a yellow background. 🟢 appears in the middle column.

7. If CODESYS detects changes in the content of an object that is contained in both the current project and the reference project, this is indicated by red lettering. You can then switch to the detailed comparison view for the object by double-clicking on the object.

8. Close the comparison view and answer the query whether the changes made are to be saved with "Yes".
   ⇐ The changes become effective in the project.

1.3.1.5.2 Opening the Detailed Compare View

Requirement: For example, a user modified the code in a POU of the current project. You have performed the project comparison by clicking "Project ➔ Compare". The project compare view shows this POU highlighted in red in the aligned in the project tree.

1. Double-click the line of the aligned POU versions.
   ⇐ The compare view switches to the detailed compare view of the POU. The modified code lines are highlighted in gray and written in red.

2. Click ☑.
   ⇐ Code lines with changes (red) are extended by two lines: an line with insert (left, green) and a line with delete (right, blue).

3. Click ✗ again.
   ⇐ The code line is marked again as modified.

4. Move the mouse pointer to the code line marked as modified and click "Accept Single".
   ⇐ The code line from the reference project is activated for acceptance into the current project.

5. Click ☑.
   ⇐ The project compare view opens for the entire project. It is write-protected (read-only) to prevent you from activating differences for acceptance. The link highlighted in yellow above the tree view also indicates this.

6. Click the link: "Project compare view is read only because there are uncommitted changes in another view. Click here to switch to the modified view."
   ⇐ The detailed compare view opens again. The unconfirmed changes are highlighted in yellow.

7. Click ✗ in the tab of the view and confirm that the changes should be saved.
   ⇐ The detail project view is closed and the POU is overwritten. Now it corresponds to the POU of the reference project. The project view is active again so that you can continue working with project compare.

---

If you do not click the link, but click ✗ instead to close the editor of the project compare view, then you will also confirm the acceptance of changes into the current project. The detail changes are accepted and then the project compare is closed completely.
You can protect a project against unintentional changes by means of access and write protection. You can also provide it with read protection (knowledge protection).

Write protection:
The following options are available for providing the entire project with simple write protection:

- Select the "Open Read-Only" option when opening the project.
- You set the "Released" status in the "Project Information".
- You select the "read-only" option in the properties of the project file in the local file system.

In order to protect only certain objects in a project against changes, or to allow access only to certain users, you can use a user and access rights management (see below). Some target devices similarly support user and rights management. The access of CODESYS to objects and files of the target device can thus be restricted.

However, write protection and access protection do not serve as protection of expertise of the POU.s. Both CODESYS itself, automation platform plug-ins and persons with knowledge of the project file format can view or modify function blocks created with CODESYS.

Knowledge protection:
Knowledge protection of a project is done by encrypting the project file. Either with a project password, the CODESYS Security Key (dongle), or a certificate. We recommend protection by means of the key or the certificate because in this case no secret needs to be shared between authorized users. The desired type of project encryption is enabled in the project settings.

You can attain knowledge protection of a library by providing it as a target-system-independent "protected library" (*.compiled-library, *.compiled-library-v3). The library file no longer contains source code in this format, but only encrypted precompile context. The compiler is still able to interpret these data. Whether access by other CODESYS components or additional plug-ins is possible depends on their functionality and is to be observed in individual cases. Signing can increase protection even more.

Knowledge protection and copy protection of a boot application can be done by means of a run-time system dongle (simple or licensed) or encryption with a certificate. One of these options is enabled in the object properties of the application.

- Chapter 1.3.1.9.18 “Encrypting an application” on page 242

Encryption with certificates

In CODESYS, projects and applications can be encrypted with certificates and signed in order to protect them from unauthorized access.

To do this, you can configure specific security settings for each individual user profile. These settings are always used automatically when the user works with CODESYS projects. Therefore, they do not have to be redone for each project. The general configuration of the security features for a user profile is done in the "Security Screen" view of CODESYS. See the individual instructions below.

You can also encrypt a project file or an application for download or online change directly with a certificate:
● User-independent encryption for the current project is configured in the “Security” category of the “Project Settings”.
● User-independent encryption of the application is configured in the “Properties” dialog of the application object.

**NOTICE!**
When you encrypt a project, an application, or online code with a certificate, you will always require the certificate with a private key in order to open the object again.

If the CODESYS Security Agent add-on product is installed, then the “Security Screen” view provides an additional tab: “Devices”. This allows for the configuration of certificates for the encrypted communication with controllers.

**Certificates, Windows Certificate Store**
All available certificates are located in the Windows Certificate Store (“certmgr”) on your computer. There are two types of keys:

- Certificates with private keys
  - for file decryption
  - for digital signatures
- Certificates with public keys
  - for file encryption
  - for verifying digital signatures

The local Windows Certificate Store is usually filled with certificates by the IT administrator of the computer. Certificates are either created using special tools or the creation is requested by a trusted certification authority (CA).

If you receive a certificate file that you need to install yourself in the Windows Certificate Store, then double-click the file in the store directory. Depending on the type (certificate with private or public key only), the appropriate import wizard will appear.

- § Chapter 1.3.1.6.7 “Encrypting projects with certificates” on page 149

**User management and password manager**
User accounts with different rights can be managed in CODESYS. For each account you can define the actions with which the user can access a project object.

The user management is configured in the “Project settings” in the category “Users and Groups”.

Before the creation of users and groups, please note the following:

- Rights can only be assigned to user groups. Therefore, you must assign each user to a group.
- There is automatically always a group ‘Everyone’ and by default every user and every other group is initially a member of this group. Thus each user account is automatically equipped with at least the defined standard rights.
- You cannot delete the group 'Everyone’, you can only rename it, and you cannot remove members from this group.
- Caution: by default "Everyone" does not have the right to change the current user, group and rights configuration!
● There is automatically always a group ‘Owner’ containing a user ‘Owner’. From V3.5 only the ‘Owner’ initially has the right to change the current user, group and rights configuration in a new project! Hence, only ‘Owner’ can assign this right to another group.

Initially the ‘Owner’ can log in with user name ‘Owner’ and an empty password. You can add further users to the group ‘Owner’ or remove users from it, but at least one member must be retained. Like ‘Everyone’, you cannot delete the group ‘Owner’ and it always possesses all access rights. This prevents a project from being rendered unusable by denying all access rights to all groups.

You can rename both the group ‘Owner’ and the user ‘Owner’.

● If the programming system or a project is restarted, no user is initially logged in to the project. However, the user can then log in via a certain user account with user name and password in order to obtain the access rights defined for the account.

● Each project has its own user management! Therefore, in order to obtain certain access rights to a library integrated into the project, for example, the user must explicitly log in to the library project.

Users and groups defined in different projects are not the same, even if they have the same names.

● A user management in a project only makes sense if it is connected with corresponding rights assignment for the access to project and objects. The project rights are generally managed in the dialog box “Rights” of the “User Management”. You can also change the access rights to an individual project object on the “Access control” tab of the “Properties” of the object.

● There are standard menu commands under “Project ➔ User Management” for logging into and out of a project as a defined user. A password manager permits the management of the login data on your computer.

From V3.5 only the ‘Owner’ initially has the right to change the current user, group and rights configuration in a new project! Hence, only ‘Owner’ can assign this right to another group.

NOTICE!
CODESYS stores the user passwords inaccessibly. If you forget a password, the user account becomes unusable. If you forget the ‘Owner’ password, the entire project may become unusable!

Password manager

The password manager enables you to save login data records that you enter during the login procedures for projects. It is accessible via a button in the login dialog box and offers fast access to the login data currently required. This can be helpful, for example, if you are working in parallel on several library projects that are protected by different passwords.

The password manager itself is protected by an individual master password. If you wish to use the password manager for the first time, CODESYS requests you to define this password in the password manager configuration dialog box. CODESYS notes the master password until you terminate the current CODESYS session. You must always input the password when you wish to log in to the password manager for the first time during a new session, or after you have changed it.

● § Chapter 1.3.1.6.6 “Logging in via user account and password manager” on page 147
● § Chapter 1.3.1.11.3 “Handling of device user management” on page 300

Rights management

Rights management for access to a project and objects in a project is necessary in order to make a user management meaningful.
The rights for a project are generally managed in the “Rights” editor of the “User Management”. You can also change the access rights to an individual project object on the “Access control” tab of the “Properties” dialog box of the object.

Before assigning rights, please observe the following:

- In a new project CODESYS always sets all rights for the execution of actions on objects with the default value ‘allowed’ (standard right). The only exception to this is the right to change the current user, group and rights configuration. Initially only the ‘Owner’ group has this right.
- If you are member of a group that is permitted to change rights, you can do this at any time for each right when working further on a project. You change a right by switching between ‘allowed’ and ‘forbidden’ or by resetting to the default.

- Chapter 1.3.1.6.4 “Setting up a user management” on page 145
- Chapter 1.3.1.6.5 “Protecting objects in the project by access rights” on page 146

Filing, saving

Provide the project file with the desired protection before saving it in the file system; see above. For a read-only project file you are given various options so that you can still save the file, depending on the type of write protection.

If the project is to be opened later in an older CODESYS version, it makes sense to save the project for precisely this version (file type), since CODESYS will also inform you immediately about possible losses of data in the course of saving it.

If you wish to save library projects, please observe the rules for the creation of libraries. Also consider the possibility of installing a library directly in a library repository.

If you wish to continue to use a project on another computer, it makes sense not only to save the project file, but also to create a project archive from all relevant auxiliary files.

You can make a setting so that a backup copy of this project is created each time the project is saved. In addition you can configure CODESYS so that projects are generally automatically saved at certain time intervals.

If you wish to keep projects in a source control system, observe the corresponding add-ons for CODESYS. For example, the link to SVN is supported.

- Chapter 1.3.1.6.10 “Linking a project to the source control system” on page 152

1.3.1.6.1 Setting up write protection

A project can be protected against inadvertent changes by means of access and write protection. In addition, however, it can also be provided with read protection (know-how protection). You have the following options:

Open the project with write protection

Requirement: No project is opened.

1. Select “File ➔ Open Project”.
   ⇔ The dialog box “Open project” appears.

2. Select the project.
3. Click on the arrow button ☰ next to the “Open” button and select “Open read-only” from the menu.

 CODESYS opens the project. At the top right in the main window a line appears “Project file cannot be saved...”. You must now select one of the offered options if you wish to save the project file.

See also
● Chapter 1.3.1.3.4 “Opening a V3 project” on page 127

Providing projects with the attribute 'Released'

Requirement: project is opened.

1. Select “Project ➔ Project Information”, then the “Summary” tab.
2. Activate the option “Released”, confirm with “OK”.
3. Save the project, for example with [Ctrl]+[S].
4. Open the project again with the command “File ➔ Open Project”.

 CODESYS opens the project. At the top right in the main window a line appears “Project file cannot be saved...”. You can now directly remove the status “Released” again via the offered option if you wish to save the project file.

See also
● Chapter 1.3.1.25.1.31 “Object ‘Project Information’” on page 811

Providing a project in the file system with the property 'Read-only'

Provide the project file in its local file system with the property attribute ‘Read-only’.

 If you had already opened the project and you now attempt to save it under the same name, a dialog box appears informing you about the existent write protection. This dialog box provides you with the following options:

 You can save the project under another name or another path using the button “Save As...”.

 You can deliberately save the project under the same name and path and thus overwrite the existing version in the file system using the button “Overwrite”.

 You can abort the saving procedure using the “Cancel” button, for example to remove the write protection on the disk.

 If you re-open the project, a line appears at the top right in the main window 'The project cannot not be saved...'. You must now select one of the offered options if you wish to save the project file.

See also
● “General information about write and access protection” on page 139

1.3.1.6.2 Assigning passwords

Requirement: The project is open.
1. Click “Project ➤ Project Settings” and then select the “Security” category.
   ⇒ The dialog “Project Settings / Security” opens.
2. Select the “Encryption” option.
   ⇒ The option fields “Password”, “Dongle”, and “Certificates” are selectable.
3. Select the option “Password”.
   ⇒ The input fields for the encryption password appear.
4. Enter the encryption password in the input field “New password”.
5. Enter the encryption password for confirmation in the input field “Confirm new password”.
6. Click “OK”.
   ⇒ CODESYS saves the encryption password for the project. You must enter this password in order to be able to open the project again, even if it is to be loaded as a library reference.

CAUTION!
If you no longer know the encryption password, you can no longer open or restore the project!

See also
● § Chapter 1.3.1.25.3.11.7 “Dialog ‘Project Settings’ - ‘Security’” on page 1064
● § Chapter 1.3.1.6 “Protecting and saving a project” on page 139

1.3.1.6.3 Protecting projects using a dongle

Requirement: The project is opened and you have connected the CODESYS Security Key (dongle) to your computer.

1. Click “Project ➤ Project Settings” and then select the “Security” category.
   ⇒ The dialog “Project Settings / Security” opens.
2. Select the “Encryption” option.
   ⇒ The option fields “Password”, “Dongle”, and “Certificates” are selectable.
3. Select the option “Dongle”.
   ⇒ The dialog with the drop-down list “Registered Dongles” and the buttons “Add”, “Remove”, “Comment” and “Flash” opens.
4. Click “Add”.
   ⇒ The “Add registered dongle” dialog opens.
5. Select the CODESYS Security Key (dongle) from the “Dongle” drop-down list and optionally enter a comment.
6. Click “OK”.
   ⇒ The added dongle is listed in the list “Registered Dongles”.
7. Click “OK”.
   ⇒ The dongle is registered for the project. You must connect the dongle to your computer in order to be able to open the project again, even if it is to be loaded as a library reference.
NOTICE!
If the CODESYS Security Key registered for the project is lost, you can no longer open the project or restore it.

1.3.1.6.4 Setting up a user management

This concerns a user management for a CODESYS project file. Visualizations and devices can have their own user management.

The following guide describes how you can adapt the user management for the first time in a project. It deals with the definition of a user and a group to which he belongs.

Requirement: the project for which the user management is to be set up is opened. There is no adapted user configuration yet.

1. Select “Project Settings ➔ Users and Groups” and then the “Users” tab. The user Owner is already created by default.

2. Click on “Add”.
   ⇒ The dialog box “Add User” appears.

3. Enter a login name, for example 'Dev1', and a password. Leave the option “Activated” activated. Click on “OK”.
   ⇒ On creating a group for the first time, CODESYS now requests you to authenticate yourself to perform this action.

   In this case, enter 'Owner' as the “current user”. Do not enter a “password”, just click on “OK”.

   The user Dev1 appears in the list and is automatically a member of the group 'Everyone'.

4. Change to the tab “Groups”, in order to add the user to a new group.
   ⇒ The groups Everyone and Owner have already been created.

5. Click on “Add” in order to open the dialog box “Add Group”.

6. Specify at least one name for the new group, for example 'Developers'. Activate the checkbox next to the entry “User 'Dev1'” in the field “Members”. Click on “OK”.

   ⇒ The group “Developers” now appears with has user member 'Dev1'.

7. Switch to the “Users” tab.

   ⇒ The user “Dev1” now appears as a member of the groups 'Everyone' and 'Developers'.

You can take over the user management configuration from another project by using the “Export/Import” functions in the dialog box “Project Settings”, category “Users and Groups”.

1.3.1.6.5 Protecting objects in the project by access rights

Protection of individual objects by setting access rights in the “Rights” editor

1. Select “Project ➤ User Management ➤ Rights”
   ⇒ The window of the “Rights” editor opens. On the left you can see the action categories, on the right the currently existing user groups.

2. Expand the relevant action category and below it the action for which you wish to change the right.

3. Select the goal of the action in the “Actions” window. In the “Rights” window, select the group for which you would like to change the right. Multiple selection is possible.
   ⇒ The buttons in the symbol bar are active.

4. Click on the appropriate button in order to change the right of the group for the action on the target object.
   ⇒ CODESYS updates the symbol in front of the group according to the new right. The right is immediately effective.

See also

● Chapter 1.3.1.25.3.6 “Dialog ‘Permissions’” on page 1042

Protection of individual objects by setting access rights in the object properties

Here you can configure whether the members of a group have the right to view, edit or remove the object and to add/remove child objects to/from the object.

1. Select the object in the navigator tree.

2. In the context menu, select the command “Properties” and in the dialog box select the category “Access Control”.

3. In the table under “Groups, actions and permissions”, double-click on the symbol of the right that you wish to change.
   ⇒ A selection list of the possible rights appears: “Grant”, “Deny”, “Clear”.

4. Select the desired right and click on “Accept” or “OK”.
   ⇒ The right is immediately effective for the action and group. The symbol changes accordingly.

● Chapter 1.3.1.25.3.10.6 “Dialog ‘Properties’ - ‘Access Control’” on page 1050
1.3.1.6.6 Logging in via user account and password manager

Logging in to a project without using the password manager functions

Requirement: A project is open. You wish to log in as a defined user for this project or for a library integrated in it in order to edit one or the other with certain rights. You have the required login data for the respective project or the library.

1. Select “Project ➔ User Management ➔ User Logon”.
   ⇒ The dialog box “Logon” opens.
2. Select the project file from “Project/Library” and enter the required access data “User name” and “Password”.
3. Log in with “OK”.
   ⇒ If another user is already logged in, this user will automatically be logged out by the new login.

Setting a master password for the password manager

Requirement: A project is open. The dialog box “Login” is open for you to log in as a defined user for a project or for a library integrated in the project. You wish to use the password manager in order to save login data in it.

1. Select “Project ➔ User Management ➔ User Logon”.
2. In the dialog box “Logon”, click on the button.
   ⇒ If you are working for the first time with the password manager, the dialog box “Password Manager Configuration” opens.
3. Enter a character string as the future master password. Confirm it in the second line and click on “OK”.
   ⇒ CODESYS notes the master password until you terminate the current CODESYS session. You must always input this password when you wish to log in to the password manager for the first time during a new session, or after you have changed it.

NOTICE!
If you have forgotten your master password, you no longer have any possibility to access the login data already saved! In this case you can only reset the password manager. After that you must start again to save passwords in the manager!

Saving login data in the password manager

Requirement: A project is open. You wish to log in as a defined user for this project or for a library integrated in it in order to edit one or the other with certain rights. You have the required login data for the respective project or the library. These login data have not yet been saved in the password manager.

1. Select “Project ➔ User Management ➔ User Logon”, in order to open the “Logon” dialog box.
2. Select the project file from “Project/Library”.
3. Enter the user name and password for the project or the library.
4. Click on the button.
   ⇒ If you are working for the first time with the password manager, you will be requested to define a master password. Refer to the above guide ‘Setting a master password for the password manager’ for this.

When you call the password manager for the first time in this CODESYS session, you will be requested to enter the master password.
5. Enter the master password when requested to do so.
   ⇒ The password manager menu appears.

6. Select the option “Save the credentials locally on this computer”.
   ⇒ The login takes place. The data are saved in the password manager.

Getting the login data from the password manager

Requirement: A project is open. You wish to log in as a defined user for this project or for a library integrated in it in order to edit one or the other with certain rights. The login data required for this are already saved in the password manager.

1. Select “Project ➔ User Management ➔ User Logon” in order to open the “Logon” dialog box.
2. Click on the button.
   ⇒ If you are working for the first time with the password manager, you will be requested to define a master password. Refer to the above guide ‘Setting a master password for the password manager’ for this.
   When you call the password manager for the first time in this CODESYS session, you will be requested to enter the master password.
3. Enter the master password when requested to do so.
   ⇒ The password manager menu appears.
4. Select the appropriate entry “Use the stored credentials for <user name>”.
   ⇒ The login takes place automatically with the data read from the password manager.

Opening the password manager, changing the master password

Requirement: A project is open. You wish to open the password manager in order to view and/or edit the entries or to change the master password. You have already logged in once with the master password.

1. Select “Project ➔ User Management ➔ User Logon”, in order to open the “Logon” dialog box.
2. Click on the button.
   Select “Open the Password Manager”.
   ⇒ The password manager window opens.
3. Click on “Change master password” and make the change.

Logging out from the project

Requirement: A project is open. A user is logged in, which is recognizable by a name entry in the field “Current User” in the status bar.

⇒ Select “Project ➔ User Management ➔ User Logoff”. Alternatively, double-click on the field “Current User” in the status bar.
   ⇒ If the user is logged in to only one project, he will now be logged out without further interaction. “(nobody)” appears again in the field “Current User” in the status bar
   If the user is logged in to several projects, the dialog box “Logoff” opens. There, select the specific project or library project from which the user is to be logged out.

- Chapter 1.3.1.6.4 “Setting up a user management” on page 145
1.3.1.6.7 Encrypting projects with certificates

**Configuring a certificate for project file encryption in a user profile**

When a project is encrypted with a certificate, this certificate is needed for decryption to open the project. You can assign this certificate to specific user profiles. To do this, select the certificate from the Windows Certificate Store on the “User” tab of the “Security Screen”.

1. Double-click 🖼 in the status bar or click “View ➔ Security Screen”.
   ↩️ The “Security Screen” view opens.
2. In the “User” tab, select the user profile for which the communication will be encrypted. By default, the specified user profile is the one you have used on your computer to sign into Windows. You can also create a new user profile with 📦.
3. Click the button in the “Project file decryption” area.
   ↩️ The “Certificate Selection” dialog opens.
4. Select a certificate with a private key from the list “Available certificates in the local Windows Certificate Store”. Certificates with a private key are identified by the 🗝️ symbol.
5. Click 🖼.
6. The certificate is added to the upper part of the dialog.
7. Click “OK” to confirm your selection.
   ↩️ The selected certificate is displayed in the “Security Screen” in the “Project file decryption” area.

**Encrypting a project with a certificate**

A project encrypted with a certificate in connection with a user management allows you to restrict access to the project.

1. Click “Project ➔ Project Settings” and then select the “Security” category.
   ↩️ The “Project Settings / Security” dialog opens.
2. Select the “Encryption” option.
   ↩️ The option fields “Password”, “Dongle”, and “Certificates” are available.
3. Select the “Encryption” option.
   ↩️ The certificates available for project encryption are listed in the lower part of the dialog. If no certificate has been specified yet, then click 🖼 to select a relevant certificate in the “Certificate Selection” dialog. Then return to the “Project Settings” dialog. Now the certificate is specified for encryption. Now the project can only be edited on computers of users who also have the certificate for file decryption.

**Deleting a certificate in the user profile**

You delete the certificate in the “Security Screen” view, either directly on the “User” tab or in the “Certificate Selection” dialog. The deletion will follow in the other dialog.

- Dialog “Security Screen”, tab “User”, “Digital signature”, or “Project data decryption”: Select a certificate and click 🗝️
- Dialog “Certificate Selection”: in the “Security Screen” dialog, click 🖼 on the “User” tab. In the upper field of the “Certificate Selection” dialog, select the certificate to be deleted and click 🗝️

**Configuring a certificate for the digital signature in a user profile**

To ensure that the project is not only encrypted with a certificate, but also that its authorship and integrity can be verified, you can add a signature to the project:
1. Double-click 🖼 in the status bar or click “View ➔ Security Screen”.
   ➞ The “Security Screen” view opens.
2. In the “User” tab, select the user profile for which the digital signature will be created. By default, the specified user profile is the one you have used on your computer to sign into Windows. You can also create a new user profile with ⬆.
3. Click the button in the “Digital signature” area.
   ➞ The “Certificate Selection” dialog opens.
4. Select a certificate with a private key from the list “Available certificates in the local Windows Certificate Store”. Certificates with a private key are identified by the 📜 symbol.
5. Click 📜. The certificate is added to the upper part of the dialog.
6. Click “OK” to confirm your selection.
   ➞ The selected certificate is displayed in the “Security Screen” in the “Digital signature” area.

1.3.1.6.8 Save project
Saving a project under the same name
Requirement: The project is open. The project file is not write-protected.

▷ Select “File ➔ Save”.
   ➞ CODESYS saves the project file with the current project name, which appears in the title bar of the main window. If the project has been changed since it was last saved, then the project name is provided with an asterisk. If this is set in the CODESYS options in the category “Load and save”, then a backup copy will also be made.

Saving a project under a different name or format
Requirement: The project is open.

1. Select “File ➔ Save Project As”.
   ➞ The “Save Project” dialog box opens.
2. Select a storage location in the file system and the desired “File Type” (project file or library file) and the desired storage version. If you want to open the project later in an older version, then it makes sense to save for precisely this version, as you will then be informed immediately in the message window about possible data loss.
   ➞ If the project file is not write protected, then CODESYS saves it in the selected path. Otherwise you will be informed how to proceed.
3. If the current project contains add-ons that are not available in the selected memory format, then the “Extend Profile” dialog box opens.
4. Select the add-ons to extend the memory profile in order for the add-on data to be saved.
5. To save the memory profile permanently, click “Save Profile” and specify a name in the “Enter profile name” dialog box.

6. In the “Extend Profile” dialog box, select the “Use saved profile” option and click “Yes”.
   - CODESYS saves the project with the saved profile.

**Saving a read-only project**

Requirement: A read-only project is open.

- Select “File ➔ Save”.

If the write protection was assigned in CODESYS, then it will be displayed by a line in the top right corner of the main window. Depending on the current situation you will be offered one or more of the following actions so that you can still save the project:

- “Save project under a different file name on the disk”: Always appears and continues to the “Save File” dialog box, as for the “Save File As” command.
- “Exit read-only mode”: Appears if the “Open read-only” option is selected when opening the project.
- “Remove read-only attribute from the project on the disk”: Appears if the project file was provided with the 'Read-only' property in the local file system at the time of opening.
- “Remove identification ‘Released’ in the project information”: Appears only if this attribute is currently set.

If the write protection was assigned outside of CODESYS in the properties of the project file in the file system, you will be offered the following options when you attempt to save under the same name and path:

- “Save As”: You can save under a different name as with the “Save Project As” command.
- “Overwrite”: The write protection is removed from the project file and the file is saved under its existing name.

1. Click on the line in the top right corner of the main window that indicates the write protection.
   - The current options with which you can still save the project appear in a selection menu.

2. Select one of the options offered and perform any necessary actions.

3. Click “File ➔ Save” or “File ➔ Save As”.
   - The project can be saved.

**Saving of the project automatically; creating a backup copy**

Requirement: The project is open.

1. Click “Tools ➔ Options” (category “Load and Save”).
   - The “Load and Save” dialog box opens.

2. Activate the “Create backup files” option.

3. Activate the “Automatically save every … minute(s)” option and select a time interval.

4. Click “OK” to close the “Options” dialog box.
   - Each time the project is saved, CODESYS also creates a backup copy <project name>.backup.

CODESYS saves the project automatically at the specified time interval to a file <project name>.autosave in the project directory. If you open the project again after the development system was closed irregularly, then this file will be offered to you as an alternative to the file last saved by the user.
1.3.1.6.9 Saving/Sending the project archive

You can configure a project archive and then save it in the file system or send it directly in an e-mail.

To send, follow the guide below as far as point 9. There, click on the button “Send” instead of “Save” in order to directly open the standard e-mail program, in which a new mail will automatically be created with the project archive file as an attachment.

Requirement: A project is opened.

1. Select “File ➔ Project Archive ➔ Save/Send Archive”.
   ⇒ The dialog box “Project Archive” appears.

2. Activate the checkbox next to each object that is to be saved in the archive.

   In order to guarantee know-how protection, CODESYS will not automatically add unprotected libraries, not available as “compiled-library”, to a project archive. If you explicitly select such a library in the list of additional files, you will get an appropriate warning.

3. If you want to pack further files in the archive, click on “Additional Files”.
   ⇒ The dialog box “Additional Files” opens.

4. Click on “Add”.

5. Select the files and click “Open”.
   ⇒ The files are added to the list of additional files.

6. Click on “OK”.

7. Click on “Comment”.
   ⇒ The dialog box “Comment” opens.

8. Enter a comment and click on “OK”.

9. Click on the button “Save”.

10. Select a storage location and a file name and click on “Save”.
    ⇒ The project archive is saved in the file directory.

1.3.1.6.10 Linking a project to the source control system

To link your CODESYS projects to a source control system, check the following option:

The CODESYS SVN add-on provides the capability of directly linking to an SVN database. You can get the package at the CODESYS Store and install it with the help of the Package Manager. Refer to the corresponding help when using CODESYS SVN.
1.3.1.7 Localizing projects

You can display your project in different languages when you create and link localization files. The localization files correspond to those of the GNU gettext system. The format of the localization template files is *.pot (Portable Object Template), from which localization files *.po (Portable Object) are generated after translation.

You configure which categories of text information are localized in the project. Then you export these texts into a translation template. This template is a file in *.pot format (example: project_1.pot). You produce localization files in the format *.po (example: de.po, en.po, or es.po), either automatically with a corresponding external translation tool or manually with a neutral text editor. You can import the *.po files back into CODESYS and use them for localization.

The commands for using project localization are located in the menu “Project ➔ Project localization”.

See also
- § Chapter 1.3.1.25.2.4.14 “Command 'Project Localization' - 'Create Localization Template’” on page 903

Generating localization templates

Requirement: A project is open.

1. Click “Project ➔ Project Localization ➔ Create Localization Template”.
   ➔ The “Create Localization Template” dialog box opens.

2. Activate the categories of text information that should be included in the localization template.

3. “Position information” can also be included in the template. For each text to be translated, specify its location in the project. Select the positions to be displayed in the translation template: only the first position found, all positions found, or none.

4. Click the “Generate” button.
   ➔ The dialog box opens for saving a *.pot file to the file system. Save the localization template. Then you can process the file in a translation tool and generate localization files <language>.po in the required languages.

Format of the localization template: file *.pot

In the first line, the text categories are specified that were selected for the translation when generating the template:

Example: #: Content:Comments|Identifiers|Names|Strings: All four categories were selected.

Then each text to be translated is segmented in the form as in the following example:
Example

```plaintext
#: D:\Projects\pl1.project\Project_Settings:1
msgid "Project Settings"
msgstr ""
Line 1: Position information displayed as source code reference. Displayed only if this has
been configured when generating the translation file.

Line 2: Untranslated text as entry msgid (example: msgid "Project settings").

Line 3: Placeholder for the translation: msgstr "". Between the single straight quotation
marks, the translation in the *.po file must be inserted in the respective language.
```

Format of the localization file:  

*-  
<language>.po

You can generate a *.po file with a translation tool or create one using a neutral text editor
based on the *.pot file. For this purpose, you could change the file extension from *.pot to
*.po and edit the according to *.po standard format.

It is imperative to specify the language in the form of the usual culture abbreviation in the meta-
data of the file (example: "Language: de" for German. Then you insert the translations of the
individual texts between the straight quotation marks for the msgstr "" entries.

Example

```plaintext
"Language: de\\n"  
#: Content:Names  
#: D:\projects\pl1.project\Project_Settings:1  
msgid "Project Settings"  
msgstr "Projekteinstellungen"
```

Importing localization files / localizing projects

Requirement: For your project, localization files (<language>.po) were generated based on
the translation template *.pot. The project is open.

1. Click “Project ➔ Project Localization ➔ Manage Localizations”.
2. Click on the “Add” button.
   - The “Open Localization File” dialog box appears for selecting a *.po file from the file
     system.
3. Select one of the localization files (example: <project name>-de.po).
   - The dialog box closes and the affected texts appear in the project in the respective
     language. For example, if you specify the translation msgstr "Main program" for
     the POU name "PLC_PRG" in the English localization file, then the object name "Main
     program" appears in the device tree.
4. In the same way, you import the localization files for other language targets.

Switching localization, adding and removing localization files

Requirement: All required language are stored in the project by importing the corresponding
*.po file. The project is open.

1. Click “Project ➔ Project Localization ➔ Manage Localization”.
   - The “Manage Localization” dialog box opens. All stored localization files *-<language>.po appear in “Files”, as well as the entry “<original version>”.
2. Select the desired language and click the “Switch Localization” button.
   - The project appears in the selected language. When you select “<original version>”,
     the project is displayed in the original, unlocalized version and it cannot be edited.
Optional: Defining a default localization, toggling localizations

Select one of the available localizations and activate the “Default Localization” option.

Click “Project ➔ Project Localization ➔ Toggle Localization” to toggle the localization between the default localization and original version. By default, this command is also available with the button on the toolbar.

1.3.1.8 Configuring I/O links

With the help of device objects, you can map hardware to be controlled in a tree structure in your CODESYS project. This makes for easy handling of the linking of hardware and application.

In the configuration editors of the device objects, you can configure the settings for the communication between CODESYS and the controller, and above all for I/O mapping. I/O mapping is the linking of the inputs and outputs of the controller with the variables of your application.

Depending on the device, access to controller objects at runtime can be regulated by means of an editable online user management in the CODESYS Development System. Moreover, communication with the controller depends on the current security settings.

- Chapter 1.3.1.16 “Using device applications” on page 358

1.3.1.8.1 Device tree and device editor

Device tree

In the “Devices” view (also called the device tree), you organize applications according to target device. In this view, you can see the PLC hardware and fieldbus systems, configure the hardware communication, and assign applications.

The root node of the device tree is a symbolic node entry: “<project name>”.

You insert device objects below this node for one or more PLCs, also referred to as target systems. Each device object represents a specific hardware component, for example a controller, fieldbus, bus coupler, drive, I/O module, or monitor. When you add objects, an add assistant helps you by offering all possible devices from your local device repository.

If you are already connected to a controller network, then you can scan the hardware for available devices and save them to the device tree in the current configuration.

For creating device objects in the device tree (mapping to the controlling hardware environment), specific rules apply (see below). The hierarchical layout of application objects and device objects defined the scope of other objects, such as libraries and GVLs.

There are programmable devices and parameterizable devices. The device type defines the possible insertion point in the device tree and the selection of objects that you can insert below the device. Programmable devices automatically get an additional “PLC Logic” node below the device object, which is merely for organizational purposes. Below this node, you insert the objects that are required for programming the device (this means the application(s) and GVLs or text lists, for example). An alternative to this concept is the use of a device application if the device supports this functionality. A device application combines the global data for all applications of a controller so that the applications can focus exclusively on control tasks.
Each device is defined by a device description and must be installed on the local system in order to be inserted into the device tree. The device description file defines the device properties for configurability, programmability, and possible connections to other devices.

The “POUs” view includes objects that can be used throughout the project. Programming objects that are intended for a specific application must be inserted below the application object in the “Devices” view (device tree).

Note the option of letting the active application run on a simulated device, which is provided by default within the development system. Currently, this simulation option is available for the CODESYS Control Win V3 target system. In simulation mode, you can also test the online functionality of the application without hardware. Click “Online ➔ Simulation” to activate simulation mode.

Note the option of establishing a connection to the device by means of the “Online Config Mode” command for an application, without having to load the application beforehand. This is useful for the initial commissioning of an I/O system because you can reference and test the I/Os with it in the PLC configuration, before you have programmed and downloaded the actual application.

Example of a device tree:
A device entry in the device tree consists of a symbol, the symbolic device name that is editable in the tree, and the device type (device name as defined in the device description).

You configure device communication, parameters, and IO mappings in the device editor dialogs. Open this editor by double-clicking the device object.

See also

- Chapter 1.3.1.16 “Using device applications” on page 358
- Chapter 1.3.1.25.2.4.35 “Command ‘Online Config Mode’” on page 915
- Chapter 1.3.1.25.2.4.31 “Command ‘Edit I/O Mapping’” on page 914
- Chapter 1.3.1.25.1.19 “Object ‘Device’ and generic device editor” on page 740
- Chapter 1.3.1.25.1.1 “Object ‘Application’” on page 710
Rules and procedures for arranging and configuring objects in the device tree

- **Insert objects**: To insert a device object, click “Add Device” or “Insert Device” by right-clicking in the device tree. For other objects, click “Add Object”. CODESYS always offers the appropriate objects at the currently selected position in the tree. Example: Modules for a PROFIBUS DP slave can be inserted only below a respective slave object, and applications inserted only below programmable devices. The selection of device objects also depends on which devices are installed in the device repository.

- You can only **insert device objects** on the level directly below the “<project name>” root node. If you select another object type, such as a text list, then CODESYS inserts this into the “POUs” view (project-global pool) automatically.

- **Insert applications**: A distinction is made here between the usual device tree structure with a “PLC Logic” node and the use of a “Device Application”. The following applies for the usual structure (for the device application, see the that chapter of the help).

You can insert an “Application” object only below the “PLC Logic” node (a programmable device). All applications must be named uniquely for each device. Below each application, you can insert more objects that are required for programming, such as POUs, DUTs, GVLs, or visualizations.

Below each application, you must insert a task configuration and configure the respective program calls (from application-specific POUs, or POU instances from the “POUs” view).

If multiple applications exist directly below a device, then you will need to define settings for the I/O processing of the device. This includes the variables of the application that CODESYS uses for communication with the target system. The settings are configured on the “PLC Settings” tab of the device editor.

Hierarchical layout of applications and scopes: You can add an application below another application. We refer to the resulting construct as the parent application and child application. In this case, the following applies: The child application can access objects in the parent application, but not the other direction. The reason for this is that a child application should always be removable or exchangeable without affecting the parent application.

**NOTICE**: After the parent application has been changed, the PLC removes a child application when an online change is performed.

- **Insert devices**: CODESYS inserts a device object in the tree as a node. If nodes are defined in the device description, then they are inserted automatically. A subnode can also represent a programmable device. Order of device objects in the tree (from top to bottom): For each level, the programmable devices (PLC Logic) are listed first and then the other types in alphabetical order.

- **Update devices**: A device that has been inserted into the device tree can be replaced using device applications, 5, en_USed by another version of the same device or by a device of another type (“Update devices”). A configuration tree below the device is available when possible.

- **Moving and deleting objects**: You can use the standard commands “Cut”, “Copy”, “Paste”, and “Delete” on objects, or drag an object to another position. When you copy objects, the new object gets the same name with an incremented number.

- **Network scan of the current hardware**: By default, creating the PLC configuration in the device tree is supported by the device editors with scan functionality. The current hardware environment is scanned and the detected modules are displayed in a dialog. From there, you can save the required device directly to the device tree. See the “Scan Devices” command.

- % Chapter 1.3.1.8.2 “Mapping a hardware structure in the device tree” on page 159
- % Chapter 1.3.1.16 “Using device applications” on page 358
- % Chapter 1.3.1.25.2.4.6 “Command ‘Update Device’” on page 901

Device tree in online mode

In online mode, a symbol before a device entry indicates the device status:

- 📄: The PLC is connected, the application is running, the device is in operation, and data is being exchanged. The “Refresh I/Os in stop” check box on the “PLC Settings” tab can be selected or cleared.

- 📄: The PLC is connected and in “STOP”; and the “Refresh I/Os in stop” check box on the “PLC Settings” tab is cleared.

- 📄: The PLC is connected and the application is running. Diagnostic information is available.
The device is in preoperative mode and is not running yet. Diagnostic information is available.

⚠️: The device is not exchanging data; bus error, no configuration, or simulation mode.

💡: The device is running in demo mode for 30 minutes. When this time has elapsed, demo mode will expire and the fieldbus will end the data exchange.

⚠️: The device is configured, but not fully operational. No data is exchanged. Example case: CANopen devices when booting and in preoperative mode.

⚠️: Redundancy mode is active. The fieldbus master is not sending any data because another master is active.

❓: The device description could not be found in the device repository.

❓: The device itself is running, but a child device is not running. The child device is not visible due to a collapsed device tree.

The names of all connected devices and applications are highlighted in green.

The names of devices that are running in simulation mode are displayed in italics.

Additional diagnostic information is located on the “Status” tab of the respective device editor.

If you login while the device description on the target device is more recent than in the project, then a warning prompt opens with the possibility to cancel the process.

See also
- % Chapter 1.3.1.25.1.19 “Object 'Device' and generic device editor” on page 740
- % Chapter 1.3.1.8.3 “Configuring devices and I/O mapping” on page 162

Device editor

You can configure the settings for communication between CODESYS and the target device on the tabs of the device editor. Double-click the device object in the device tree to open the editor. The editor includes generic as well as specific tabs. Its title contains the device name.

See also
- % Chapter 1.3.1.25.1.19 “Object 'Device' and generic device editor” on page 740
- % Chapter 1.3.1.8.3 “Configuring devices and I/O mapping” on page 162

1.3.1.8.2 Mapping a hardware structure in the device tree

You map the hardware that you control with your application in the “Devices” view (device tree). To do this, insert device objects into this tree structure which represent physical devices in the network until the hierarchy reflects the controller network. Device objects are, for example, a PLC object, a fieldbus object, or a logical device.

Mapping a standard controller with fieldbus in the device tree

Below you will map hardware containing a standard PLC and a standard fieldbus.

1. Click “File ➔ New Project”.
2. In the “New Project” dialog, select the “Standard project” template.
3. In the “Standard Project” dialog, select the “CODESYS Control Win V3” device.

CODESYS inserts the Device “(CODESYS Control Win V3)” object in the device tree under the root node and below it the “PLC Logic” node, which always provides a programmable device object. An “Application” object exists below that, and the “Library Manager”, “PLC_PRG”, and “Task Configuration” objects exist below that.

4. Select the Device entry and click “Add Device” in the context menu.

The “Add Device” dialog provides a selection of the devices installed on your system. 'Installed on the system' means that CODESYS has received a device description for the respective hardware. You can thus use the device object and the associated configuration editor in the project.

5. Select one of the provided PLCs (example: “CAN-bus”) and click the “Add Device” button.

The “CAN-Bus” object appears in the device tree indented below Device “(CODESYS Control Win V3)”. The “Add Device” dialog remains open. If you now select the new “CAN-bus” entry, it automatically offers the objects that are insertable under it.

6. For example, select the “CANopen Device” from the “Local Device” category.

“CANopen_Device” is inserted indented under “CAN-bus” in the device tree.

7. Do you want to add a different device to the one you added before? Select the device entry and click “Update Device” in the context menu.

The “Update Device” dialog opens. It corresponds to the “Add Device” dialog used previously. You can select another device, which is then inserted in the tree in place of the previous one.

See also
- § Chapter 1.3.1.25.2.4.3 “Command 'Insert Device’” on page 898
- § Chapter 1.3.1.25.2.4.6 “Command 'Update Device’” on page 901

You can determine the devices in the network of the hardware environment (scan) and apply the devices found into the device tree of your project. If the scan function is permanently implemented in the PLC, you can perform the scan without further preparations. For this purpose, CODESYS establishes a brief connection to the controller. If the scan function is provided in a library, the device that includes the library must be inserted in the device tree and a login to the controller executed. Only then can the library be placed on the controller, making scanning possible.

Scanning is started by means of the “Scan for Devices” command. It refers to the controller that is currently selected in the device tree and linked to the project. For example, you can select an inserted PROFINET IO controller and use the command to determine the I/O devices and I/O modules assigned to it.

Requirement: Your project has a device configuration. The communication settings are correct. Gateways and hardware are running.
1. Select a PLC object in the device tree.
2. Click “Scan for Devices” in the context menu.
   ⇒ CODESYS establishes the connection to the hardware. The dialog “Scan for Devices” appears. Depending on the type of device it offers different functions. However, a table always appears, showing the devices found in the hardware: device name, type of device, station name, etc. Regarding this, see the help for the respective device editor.
3. So that the list displays only devices found that you do not yet have in the device configuration of your project, activate the “Show differences to project” option.
4. In order to apply a device into the device tree of the project, select the entry in the table and click the button “Copy to project”. All devices found are applied if you do not select an entry.
   ⇒ The corresponding entries are inserted in the device tree.

Checking the controller configuration with the help of the ‘Online Config Mode’ command

With CODESYS you can test the correct wiring of the I/Os and the fieldbus of your target system, without having to develop a real application for the controller and loading it to the controller beforehand. This is interesting for the initial commissioning phase. Use the ‘Simple online configuration mode’ for this. If there is already an application on the controller, you can optionally also use the ‘Advanced online configuration mode’ if the device supports this. This allows you to read device parameters without having to login with the application concerned from CODESYS.

Simple online configuration mode

You create an implicit application by means of the “Online Config Mode” command in the context menu of the PLC object in the device tree. CODESYS automatically loads the application to the PLC and, via the application, automatically initializes all I/Os once. The application is called “HiddenOnlineConfigModeApp”. It is displayed in the device editor of the PLC on the “Applications” tab. You can use it to operate the I/Os with the following functions as in normal online mode:

- Read I/Os
- Write outputs
- Diagnosis (in the tree and on the status page)
- Scan (of the current hardware)
- Interactive online functions, if supported (for example, writing asynchronous messages)

Writing and forcing in the I/O mapping

In online configuration mode, the writing and forcing of values in the “I/O Mapping” dialog works differently to the way it works in real online mode. CODESYS writes the outputs into the I/O mapping table immediately after insertion. There is no “Prepared Value” column. Instead, you change the initial values directly after you double-click the “Current Value” column.

Testing the I/O access with the help of the simple online configuration mode:

Requirement: You have created a standard project with a device configuration in which you have configured an I/O mapping. In a program block you make read or write accesses to inputs or outputs of the hardware in order to check their wiring. The connection to the PLC of the hardware is configured in the communication settings. The PLC is running.

1. Select the PLC object in the device tree.
   ⇒ For example, the CODESYS Control Win V3 device is selected in the device tree.
2. Click “Online Config Mode” in the context menu.
   - CODESYS connects to the controller and the PLC object in the tree is given a green background.

3. Double-click the PLC object in the device tree in order to open the device editor. Select the tab “Applications”.

4. Click the “Update list” button.
   - The application HiddenOnlineConfigModeApp appears in the window “Applications on the controller”.

5. Start your program and check the behavior of the inputs and outputs.

Advanced online configuration mode (parameter mode)

If there is already a ‘real’ application on the controller and the device supports the ‘Advanced online configuration mode’, you can also optionally select the ‘Parameter mode’ after the command “Online configuration mode”. Then you can read the parameters of the real application on the controller without having to perform a standard login and – if compilation information is missing – having to download this application again. You can see the parameters on the “Configuration” tab of the device editor. The parameter mode prevents the inadvertent changing of the data on the controller; the applications remain untouched. Writing of the parameters is possible only if the driver supports it.

Setting up parameter mode for reading the device parameters:

Requirement: There are already one or more applications on the target device. The target device supports the advanced online configuration mode. You have opened the project containing these applications. You wish to look at the device parameters without having to login to the controller. The connection to the PLC of the hardware is configured in the communication settings. The PLC is running.

1. Select the PLC object in the device tree.
2. Click “Online Config Mode” in the context menu.
   - CODESYS connects to the controller and the PLC object in the tree is given a green background. The dialog “Select configuration mode” appears with a display of the application(s) on the PLC.

3. Select the desired application and click the “Parameter mode” button.
   - CODESYS checks whether the application in the project corresponds to the application on the PLC.

4. If CODESYS does not signal an error regarding the correspondence of the applications to each other, open the “Configuration” tab of the PLC device editor.
   - You can read the device parameters.

1.3.1.8.3 Configuring devices and I/O mapping

Configuring devices

You can configure the device objects inserted into the device tree in the associated device editor. The possibilities depend on the device description. The ‘generic device editor’ provides tabs that are supplemented as necessary by device-specific tabs.

Requirement: You have opened a standard project in whose device tree a standard PLC and below that a fieldbus device object are inserted.
1. Double-click the device object of the standard PLC in the device tree of your project.
   - The “<device name>” editor opens in the CODESYS main window. The “Communication Settings” tab is in the foreground. Change to the other tabs in order to make configuration settings for the controller. See the help pages for the generic device editor.

2. Double-click the fieldbus device object in the device tree of your project.
   - The “<fieldbus device name>” editor opens in the CODESYS main window. Specific tabs are available depending on the device. For the configuration options, see the help pages for the respective device editor. If the “Show generic device configuration views” option is selected in “Tools ➔ Options”, in the “Device Editor” category, then see also the tabs contributed by the generic device editor.

See also
- Chapter 1.3.1.25.1.19.1 “Generic device editor” on page 741

Read PLC parameter file to configuration

If the configuration parameters of the PLC have been changed by another device, for example via a visualization, a configuration file IoConfig.par is created on the controller. Depending on the device, a button may be in the parameter dialog of the device editor in online mode for writing the current parameters to such a file. In order to update the changed parameters inside your project as well, you can read in the parameter file in online mode.

Requirement: You have a standard project with a device tree in which the hardware environment is mapped with a PLC and a parameterizable device in the device tree. On the controller there is a file IoConfig.par, in which the device parameters were previously saved with the current values.

1. Add the “Read PLC parameter file to configuration” command from the “Devices” category in the “Tools ➔ Customize” dialog to an interface menu.
2. Select the PLC device object in the device tree and open the context menu.
3. Click “Read PLC parameter file to configuration”.
   - CODESYS automatically establishes a connection to the controller and reads in the parameters from the par-file. These are updated accordingly on the tab with the device parameters.

See also
- Chapter 1.3.1.25.2.4.34 “Command ‘Read PLC Parameter File to Configuration’” on page 915
- Chapter 1.3.1.25.3.14.1 “Dialog ‘Customize’ - ‘Menu’” on page 1089

General information about I/O mapping

Whether or not you can configure an I/O mapping to project variables or even to the entire function blocks depends on the type of device. Configuring an I/O map means linking input and output channels of the device with variables of the project. We also use the term ‘mapping’ for this.

Pay attention in general to the following for the mapping of inputs and outputs of a device to variables in CODESYS:
- You do not have write access to variables that are mapped to an input.
- You can map an existing variable to one input only.
- You can directly generate new global implicit variables in the I/O map and map them to a device channel.
- The memory layout of structures is specified by the device.
- You can change addresses and fix values in the I/O map.
● For each variable that is assigned to an I/O channel in the "I/O Mapping" dialog, you can cause 'force variables' to be generated during the compilation of the application (see further below). Using these variables you can, for example during the commissioning of a plant, force a value on the input or output via a visualization/HMI.

● Changes in the I/O map can be transferred to the controller with an online change.

● If a pointer to a device input is used, the access is considered to be a write access, for example `pTest := ADR(input);`. This leads to a compiler warning when code is generated: "...invalid assignment target". If you require a construct of this kind, you must first copy the input value `input` to a variable with write access.

● An I/O address can also be linked with a variable via the 'AT declaration' in the IEC code. Since a device configuration often changes again, however, we recommend that you make the assignments only in the device editor.

  If you use the AT declaration, note the following:
  - An AT declaration is permissible only with local or global variables, not with input or output variables of function blocks.
  - Implicit 'force variables' for I/Os (see below) cannot be generated for AT declarations.
  - If you use an AT declaration with structure variables or function block variables, all instances will access the same memory location. This then corresponds to the use of 'static variables' in classic programming languages such as 'C'.

<table>
<thead>
<tr>
<th>NOTICE!</th>
</tr>
</thead>
<tbody>
<tr>
<td>If a pointer to a device input is used, then the access (for example <code>pTest := ADR(input);</code>) is considered to be a write access. This leads to a compiler warning when code is generated: &quot;...invalid assignment target&quot;.</td>
</tr>
</tbody>
</table>

If you require a construct of this kind, you must first copy the input value (`input`) to a variable with write access.

As an alternative, you can assign a variable to an address in the programming code using the AT declaration. In view of possible changes of the device configuration, however, we recommend that you make the assignments only in the device editor.

You can export the I/O mapping configuration of a device to a csv file or import it from such a file.

● § “Generating implicit variables for the forcing of I/Os” on page 170

Linking a device input with an existing project variable ("mapping")

Requirement: A device that supports an I/O mapping configuration in CODESYS is inserted in the device tree of your project. On the "I/O Mapping" tab in the device editor you thus get a tabular display of the input and output channels of the device with specification of the addresses and data types.
NOTICE!

Mapping 'too large' data types

If a variable of a data type that is larger than a byte is mapped to a byte address, the value of the variable will be truncated to byte size there. For monitoring the variable value in the "I/O Mapping" dialog, this means the following: In the root element of the address, the value is displayed that the variable currently has in the project. The current individual bit values of the byte are displayed in succession in the bit elements below that, but this may not be sufficient for the entire variable value.

If a UNION is represented by I/O channels in the mapping dialog, it depends on the device whether mapping to the "root" element is also possible.

1. In a POU, declare, for example, a variable xBool4 of the type BOOL with which you wish to access an input of the target device from the application.
2. To open the device editor, double-click the device object in the device tree, and then the "<device name> I/O Mapping" tab.
3. Observe the “Variable” column with the display of the device input channels 🔄 and device output channels 🔄, which can still be sorted by organizational nodes 🗄, depending on the device. We assume that there is a device input of the type BYTE. It is displayed with its individual bit addresses (bit channels) below the BYTE node.
4. Note: When mapping structured variables, the editor prevents you from entering both the structure variable (example: %QB0) and individual structure elements (example: %QB0.1 and %QB0.2). Therefore, if there is a main entry with a subtree of bit channel entries in the mapping table, then the following applies: Then you can specify a variable either into the line of the main entry, or into the lines of the subelements (bit channels), but not into both. You can now occupy either the entire channel with a variable of a suitable type OR its individual bit-channel addresses with suitable variables of the type BOOL or BIT. First of all, double-click a bit input channel in the “Variables” column.

▷ An input field opens.
5. In order to place an existing variable on the channel, you must enter the desired project variable with the complete path. Press \( \text{ } \) to open the Input Assistant. Select, for example, the variable `Application.PLC_PRG.xBool4` declared in `PLC_PRG`.

The variable is inserted. The HMI symbol (\( \text{ } \)) is displayed in the “Mapping” column. The address is now struck through. That does not mean that the address is no longer available, because values of existing variables are managed at another memory space. But: in order to avoid ambiguities when writing the values, you should nevertheless not occupy the address with a further variable, especially in the case of outputs.

Note: For compiler version V3.5 SP11 and later, the initialization value of the variables is used automatically as the default value when mapping to an existing variable. You can edit the “Default value” field only if you map to a new created variable or if no mapping is specified. In older versions, users had to specify explicitly that the default value and initialization value were identical.

6. Delete the variable assignment again. Click the root of the channel, the `BYTE` node. Use the Input Assistant again to select the variable `Application.PLC_PRG.byte_gotodevice`.

The variable is inserted, all bit addresses of the main channel are struck through and you should not additionally occupy them.

See also
- Chapter 1.3.1.25.1.19.11 “Tab ‘<device name> I/O Mapping’” on page 755
In the following you will map a device output to a global implicit variable, which you recently create for this purpose directly in the “I/O Mapping” dialog.

The “I/O Mapping” dialog is thus a further place for declaring a global variable.

Requirement: A device that supports an I/O mapping configuration in CODESYS is inserted in the device tree of your project. On the “I/O Mapping” tab in the device editor you will thus see a tabular display of the input and output channels of the device with specification of the addresses and data types.

1. To open the device editor, double-click the device object in the device tree, and then the “<device name> I/O Mapping” tab.
2. Click in the mapping table on a channel entry in the “Variable” column in order to open an input field.
3. Enter a simple name (without ‘.’) for a new variable (for example, myBool).

   CODESYS creates the variable as an implicit global variable in the project and assigns it directly to the channel address. Therefore in this case the address does not appear struck through as in the case of mappings to existing variables.

Mapping a device input to a recently created project variable

Linking a device with a function block instance

If supported by the device, you can map entire function blocks to an input or output channel. This allows you to count the frequency of signal changes or scale a channel value for maintenance purposes, for example.

Here you will map a device output channel to a function block. In this example, the block scales the channel output value.

Requirement: A device with a digital output that supports FB mapping is linked in the project. There is a function block “Scale_Output_Int” with the following implementation. The attributes of the function block itself and before the output parameter with which the channel output is processed are important.

```plaintext
{attribute 'io_function_block'}
FUNCTION_BLOCK Scale_Output_Int
VAR_INPUT
  iInput : INT;
  iNumerator : INT;
  iDenominator : INT :=1;
  iOffset : INT := 0;
END_VAR
VAR_OUTPUT
{attribute 'io_function_block_mapping'}
iOutput : INT;
END_VAR
VAR
END_VAR
IF iDenominator <> 0 THEN
  iOutput := TO_INT(TO_DINT(iInput) * TO_DINT(iNumerator) / TO_DINT(iDenominator)) + iOffset;
END_IF
```

2020/12/10 3ADR010583, 1, en_US

167
1. Open the "<device name> I/O Mapping" tab of the device editor. Double-click the output that should be connected to the function block. Click the button "Add FB for IO channel".

   ⇒ The "Select Function Block" dialog opens. On the left side, you see at least the function block "Scale_Output_int" below the "Application" node. Libraries linked in the project that contain corresponding function blocks are also displayed for selection.

2. Select the POU myScaleOutputInt.

   ⇒ After clicking "OK", the path of the function block parameter iOutput in the "Variable" is entered in the mapping dialog. The path comprises the application name, the device channel name, and the selected FB output (example: Appl.Out_4_Int_myScale_Output_Int_1.iOutput).

3. Select the channel and click "Go to Instance".

   ⇒ The focus switches to the "<device name> IEC Objects" tab and the created entry for the new IEC object Out_4_Int myScale_Output_Int_1. In this view in online mode, you see the current value of the parameter iOutput for the channel Out_4_Int scaled by the FB. You can also write and force the value as in other monitoring views.

Changing and fixing an address value in the I/O map

You can change the address value of an entire channel (but not that of an individual subelement of the channel!) in the mapping table of the "<device name> I/O Mapping" tab. This allows you to adapt the addressing to a specified machine configuration and to retain the address value even if the layout of the modules changes. By default, a change of the layout leads to an automatic adaptation of the address values.

Requirement: Your project has I/O mapping. See the corresponding sections of the help page above.

1. To open the device editor, double-click the device object in the device tree, and then the "<device name> I/O Mapping" tab.

2. Click in the mapping table on a channel entry in the “Address” column in order to open an input field. This is only possible for the 'root' address of a channel, not for a particular one of its subelements.

   Therefore, change the top address entry of a channel in the table, for example from QB0 to QB1. Exit the input field.

   ⇒ The address value is changed. The symbol is displayed before the address. It indicates that the address is fixed. The addresses of the subelements of the channel are also changed accordingly. If you now change the position of the device object inside other device objects with input/output channels in the device tree, CODESYS does not adapt these addresses to the new order as would be the case without fixing.
3. In order to undo the manual change or fixing, open the input field of the address value again, delete the address entry and press the Enter key.

⇒ CODESYS resets the address and the subsequent addresses concerned to the values they had before the change and removes the symbol 🗑.

See also
- § Chapter 1.3.1.25.1.19.11 “Tab `<device name> I/O Mapping’” on page 755
- § Chapter 1.3.1.24.4.12 “Addresses” on page 566

Configuration of the I/O variable update

Depending on the device that you link in the project, CODESYS updates the variables applied to its inputs and outputs in different ways. You can explicitly change the settings for this in the “I/O Mapping” dialog.

See also
- § Chapter 1.3.1.25.1.19.11 “Tab `<device name> I/O Mapping’” on page 755

Monitoring of variables in the I/O map in online mode

Requirement: You have compiled an application with a device configuration containing I/O maps without error. The associated hardware and the bus system are running. You have connected to the controller by means of the “Online ➤ Login” command and have loaded and started the application.

1. Open the “I/O Mapping” tab of the PLC in the device editor. To open the editor, double-click the device object in the device tree.

⇒ The mapping table now additionally contains the “Current Value” and “New Value” columns.

   If a structure variable is mapped to the ‘root’ element of an address¹, CODESYS does not display a value in this line in online mode. If, for example, a DWORD variable is mapped to the address, however, the respective values are monitored both in the ‘root’ line and in the indented bit-channel lines below it.

   As a matter of principle, the field in the ‘root’ line always remains empty if the value would be composed of several subelements.

¹ ‘root’ = top element of this address in the Mapping dialog

2. Enter a certain variable value for an entry in the column “New value” and press [F7] to force or [Ctrl]+[F7] to write the value.

⇒ As in the case of monitoring in the declaration editor or in watch lists, the forced variable value is displayed in the column “Current Value” with a prefixed red F-symbol or the written value.

NOTICE!

Inputs and outputs that the PLC code does NOT use are not read by the PLC in online mode, as a result of which the displayed value could be incorrect. The “Current Value” of the variables concerned is displayed with a gray background.
Forced values on the controller

Values not used on the controller, value shown in gray

During the commissioning of a plant or machine it may be necessary to 'force' the values applied at the inputs and outputs. If a device supports this you can cause special 'force variables' to be generated for this purpose and use them, for example, in an HMI visualization.

Requirement: The device supports the functionality. You have a project in which an I/O map is configured for the device and which contains a program object PLC_PRG.

1. Open the device editor, "PLC Settings" tab, by double-clicking the device object in the device tree.
2. Activate the option “Generate force variables for IO mapping”.

Two variables are created for each I/O channel in accordance with the following syntax, in the process of which spaces in the channel name are replaced by underscores:

<device name>_<channel name>_<IEC address>_Force of type BOOL for the activation and deactivation of forces.

<device name>_<channel name>_<IEC address>_Value of the data type of the channel for defining the value that you wish to force on the channel.

These variables are available in the Input Assistant in the category "Variables" / "IoConfig_Globals_Force_Variables." You can use them in CODESYS in programming objects, in visualizations, in the symbol configuration, etc.

4. Open the function block “PLC_PRG”, set the focus in the implementation part and press F2.

The Input Assistant opens. The variables are available in the category "Variables" / "IoConfig_Globals_Force_Variables" as described above.

A rising edge at the 'Force variable' input activates the forcing of the respective input or output with the value given by the 'Value variable'. A falling edge deactivates the forcing. Deactivation by resetting the 'Force' variable to FALSE is the requirement for being able to force a new value.

Take note of the following restrictions.

- Forcing via the implicit force variables is only possible for channels that are mapped in the "I/O Mapping" of the device to an existing or recently created variable.
- Forcing via the implicit force variables is not possible for unused inputs and outputs or those that are mapped to a variable via an AT declaration in an application program.
- I/O channels that you wish to force via the mechanism have to be used by CODESYS in at least one task.
- CODESYS identifies forced inputs in the monitoring by the red Force symbol, but not forced input/outputs! The forced value is used only implicitly by the I/O driver for writing to the device.

- Chapter 1.3.1.12.4 “Forcing and writing variables” on page 315

I/O mapping in one dialog for multiple devices

There is a table that displays the I/O map of a device plus the I/O maps of all subelements inserted below it in the device tree. There you can edit the I/O maps in exactly the same way as in the individual mapping tables of the respective device editors.

Requirement: In the device tree of your project there are several PLCs inserted that each enable an I/O mapping configuration.

1. Select the root node of the device tree and click “Edit I/O Mapping” in the context menu.
   - The “Edit I/O Mapping” dialog opens, in which the I/O mapping configurations of all devices inserted in the project are displayed in a table. You can edit the entries in the same way as in the “I/O Mapping” dialog of the associated device editor.

2. Now select one of the control objects in the device tree and select the “Edit I/O Mapping” command once again in the context menu.
   - The “Edit I/O Mapping” dialog now shows only the I/O table for the I/O mapping configurations found in and under the selected object.

3. Set a desired “Filter” in the bar above the table or enter a variable name in the “Search for variable” field in order to see the use of this variable in the mapping.
   - The method of working in this window is the same as that described for the “<device name> I/O Mapping” tab.

See also
- Chapter 1.3.1.25.2.4.31 “Command ‘Edit I/O Mapping’” on page 914

1.3.1.9 Programming of applications

For creating an application program which is executable on the PLC, you fill POUs with declarations and implementation code (source code), you define the mapping of the hardware I/Os on application variables, and you configure the task handling. After having checked and debugged your implementation, the CODESYS compiler will generate the application code which can be downloaded to the PLC.

The programming of the application POUs will be supported by the programming language editors and further features like for example textlists, image pools, alarm configuration, pragmas, refactoring and usage of ready modules provided by CODESYS Development System or by libraries.

1.3.1.9.1 Designating identifiers

Identifiers are names of variables and programming objects (for example programs, function blocks, and methods) and names of other objects of the application and project. There are rules that you must follow when assigning identifiers. Furthermore, there are also recommendations to help you designate uniform and expressive identifiers.

You designate variables identifiers in the variables declaration. These identifiers can e changed in the declaration section of the programming object. You designate identifiers for programming objects and other objects in the dialog box when adding the object. You can change the identifier of an existing object of the application or of the project in the properties dialog of the object. However, you cannot change the identifiers of objects that can be available only one time per application or project (for example, the “Library Manager” and “ImagePool” identifiers).

See also
- Chapter 1.3.1.24.7 “Identifiers” on page 644
1.3.1.9.2 Declaration of variables

Variable declaration: where and how

In CODESYS projects you can declare variables in the following places:

- Declaration part of a POU
- Dialog box “Auto Declare”, if a POU has the focus
- DUT, GVL or NVL editor
- I/O mapping configuration of an I/O device object

The variable declarations in global variable lists (GVL, NVL) and in the declaration part of POUs are carried out in the declaration editor. Special editors or dialog boxes are available for all other variants.

NOTICE!

By adding pragmas you can affect the behavior and the properties of one or more variables. More precise information can be found in the chapter "Use of pragmas".

Syntax for the variable declaration in POUs or global variable lists, if textual display is selected for the declaration editor:

```
<identifier> {AT <address>}:<data type> {:=<initialisation>};
```

- `<identifier>`: Name of the variable. The rules listed in the chapter "Identifiers" must be followed without exception when assigning an identifier. In addition, this chapter contains recommendations for standardizing the assignment of names.
- `{AT <address>}` (optional): You can directly bind a variable to a certain address with the help of the keyword AT.
- `<data type>`
- `{:=<initialisation>}` (optional)

In function blocks you can also declare variables with incomplete address specifications. In order to be able to use such a variable in a local instance, however, there must be a corresponding entry for this variable in the "variable configuration".

If you define a variable in the tabular declaration editor, the correct syntax is automatically produced.

- Chapter 1.3.1.9.2.2 “Using the ‘Declare variable’ dialog box” on page 174

Variable initialization

The standard initialization value for all declarations is 0. In the declaration part you can also specify user-defined initialization values for each variable and each data type.

The user-defined initialization starts with the assignment operator `:=` and consists of any valid expression of the programming language ST (structured text). You thus define the initialization value with the help of constants, other variables or functions. If you use a variable, you must also initialize it.
VAR

  var1: INT := 12;                 (* initialization value 12*)

  x : INT := 13 + 8;              (* initialzation value defined by an expression of constants*)

  y : INT := x + fun(4);          (* initialization value defined by an expression, that contains a function call; notice the order! *)

  z : POINTER TO INT := ADR(y);   (* not described in the standard IEC61131-3; initialization value defined by an adress function; Notice: the pointer will not be initialized during an Online Change *)

END_VAR

Examples

Notes on the order of initialization

From compiler version 3.5.3.40, variables in a function block are initialized in the following order: firstly, all constants in accordance with the order of their declarations, then all other variables in accordance with the order of their declarations.

NOTICE!

From compiler version 3.3.2.0, variables from global variable lists are always initialized before the local variables of a POU.

● § Chapter 1.3.1.24.5.14 “Data type `ARRAY’” on page 581
● § “Initializing structures” on page 594
● § Chapter 1.3.1.24.5 “Data types” on page 569

Using the declaration editor

The declaration editor is used for declaring variables in the variable lists and POUs. The declaration editor offers two possible views: textual and tabular.

in the dialog in “Tools -> Options -> Declaration Editor”, you define whether only the textual view or only the tabular view is available, or whether you can switch between both views by means of the buttons on the right side of the editor view.

If the declaration editor is used in conjunction with a programming language editor, it appears as the declaration part at the top of the window of a POU.

Declaring in the textual declaration editor

The behavior and the appearance of the textual editor are configured with the settings in the dialog “Tools -> Options -> Text Editor”. The settings concern colors, line numbers, tab widths, indentations etc. The usual Windows functions are available, plus the IntelliMouse functions if necessary.

Requirement: You have opened a programming object (POU, GVL or NVL) of a project. The textual declaration editor has the focus.
Enter the variable declarations in correct syntax. With [F2] you can open the dialog "Input Assistant" for the selection of the data type or a keyword.

Declaring in the tabular declaration editor

In the tabular declaration editor, you add variable declarations to a table with the following columns: "Scope", "Name", "Address", "Data type", "Initialization", "Comment", and "Attributes" (pragmas).

Requirement: A programming object (POU or GVL) of a project is open. The tabular declaration editor has the focus.

1. Click the button in the declaration header or select the command "Insert" in the context menu.
   - CODESYS inserts a new row for a variable declaration and the input field for the variable name opens.
2. Specify a valid variable identifier.
3. Open the other fields of the declaration line as required with a double-click and select the desired specifications from the drop-down lists or with the help of the dialogs which appear.

- “Dialog ‘Input Assistant’ - Tab ‘Categories’” on page 874

Using the ‘Declare variable’ dialog box

Requirement: A programming object (POU or GVL) of a project is open.

1. Select the command “Edit ➔ Auto Declare”.
   - The dialog box “Auto Declare” opens.
2. Select the desired scope for the variable from the selection list “Scope”.
3. Enter a variable name in the input field “Name”.
4. Select the desired data type from the selection list “Type”.
5. If the initialization value deviates from the standard initialization value, enter an initialization value for the variable.
6. Complete your entries with a click on “OK”.
   - CODESYS lists the newly declared variable in the declaration part of your programming object.

With the help of pragmas in the declaration part you can affect the processing of the declaration by the compiler.

Declaring arrays

Requirement: A programming object (POU or GVL) of a project is open.

1. Click “Edit ➔ Declare Variable”.
   ⇒ The “Declare Variable” dialog opens.
2. Select the desired scope for the array from the drop-down list “Scope”.
3. Enter an identifier for the array in the “Name” input field.
4. Click the arrow button (>>) next to the “Data type” input field and select the “Array Assistant” entry from the selection menu.
5. In the input fields “Dimension 1”, type in the lower and upper limit of the first dimension of the array (example: 1 and 3).
   ⇒ The field “Result” displays the 1st dimension of the array (example: ARRAY [1..3] OF ?).
6. In the input field “Basic type”, type in the data type of the array or use the “Input Assistant” ( ) or the “Array Assistant” (example: DINT).
   ⇒ The field “Result” displays the data type of the array now (example: ARRAY [1..3] OF DINT).
7. Define the second and third dimensions of the array according to steps 5 and 6 (example: Dimension 2: 1 and 4, Dimension 3: 1 and 2).
   ⇒ The “Result” field displays the array with the defined dimensions: ARRAY [1..3, 1..4, 1..2] OF DINT. The array consists of 3 * 4 * 2 = 24 elements.

In an array of variable length, declare the dimension limits with an asterisk placeholder (*). Arrays of variable length are permitted to be used only in VAR_IN_OUT declarations of function blocks, methods, or functions.

Example of a 2-dimensional array of variable length:
aiUnknownLengthData : ARRAY [*,*] OF INT;

8. Click “OK”.
   ⇒ In the dialog “Declare Variable” the field “Data type” displays the array.
9. To modify the initialization values of the array, click the arrow button (<<) next to the “Initialization value” input field.
   ⇒ The “Initialization Value” dialog opens.
10. Select the line of the array element whose initialization value you wish to modify. Example: Select array component [1, 1, 1].
11. Enter the desired initialization value in the input field below the list and click button “Use value on selected lines” (example: value 4).
   ⇒ CODESYS displays the changed initialization value of the selected line.
12. Click “OK”.
   ⇒ In the “Initialization value” field of the “Declare Variable” dialog, CODESYS displays the initialization values of the array (example: (4, 23(0))).
13. You can optionally enter a “Comment” in the input field.
14. Click “OK” in order to conclude the declaration of the array.
   ⇒ CODESYS adds the declaration of the array to the declaration part of the programming object.
Declaring global variables

Declaring global variables that are available within the application.

1. In the Device tree of your project, select the application in which the global variables are to be valid.
2. Select the context menu command “Add Object ➤ Global Variable List”.
   ⇒ CODESYS inserts the “GVL” in the Device tree under the application and opens it in the editor.
3. Select the menu command “Edit ➤ Auto Declare”.
   ⇒ The dialog box “Auto Declare” opens.
4. In the selection list “Scope”, select the entry “VAR_GLOBAL”.
5. In the field “Name”, enter a name for the global variable.
6. Select a data type from the selection list “Type”.
7. If your variable is to have an initialization value other than the standard initialization value, click on next to the field “Initialization”.
   ⇒ The dialog box “Initialization Value” opens.
8. Double-click on the cell “Init value” of your variable and enter the desired valid value.
9. Click on “OK”.
   ⇒ The initialization value is displayed in the dialog box “Auto Declare”.
10. Activate one of the “Flags” if necessary.
11. Confirm your entries by clicking on the button “OK”.
   ⇒ CODESYS inserts the declared variable in the GVL.

   The global variable is available in the total application of your project.

Declaring global variables that are available in the entire project.

1. Select the menu command “View ➤ POU’s”.
   ⇒ The “POUs” view opens.
2. In the “POUs” view, select the uppermost node with the project name and select the context menu command “Add Object ➤ Global Variable List”.
   ⇒ CODESYS inserts the “GVL” in the “POUs” view and opens it in the editor.
3. Select the menu command “Edit ➤ Auto Declare”.
   ⇒ The dialog box “Auto Declare” opens.
4. In the selection list “Scope”, select the entry “VAR_GLOBAL”.
5. In the field “Name”, enter a name for the global variable.
6. Select a data type from the selection list “Type”.
7. If your variable is to have an initialization value other than the standard initialization value, enter it in the column “Initialization”.
8. Activate one of the “Flags” if necessary.
9. Confirm your entries by clicking on the button “OK”.
   ⇒ CODESYS inserts the declared variable in the GVL.
   The global variable is now available in the entire project.

Using task-local global variable lists

You can insert task-local global variable lists in the project in order to synchronize variables over multiple tasks. A task-local global variable list is cycle-consistent. The contents of the list are modified by only one task during a task cycle. Only this task writes to the variables in the list. All other tasks have read-only access to the list.

You declare task-local variables in the object ☞ “Global Variable List (task-local)” as a list, which syntactically is the same as a global variable list. There you also determine the task that has write access.

Implementing an application

☐ Requirement: CODESYS is open and a new standard project is created.
1. Select the “PLC Logic” node in the “Devices” view. Click “Add Object ➔ Application” in the context menu.
   ⇒ The “Add Application” dialog opens.
2. Specify the name appTasklocal.
3. Select the application and click “Add Object ➔ POU” in the context menu.
   ⇒ The “Add POU” dialog opens.
4. Specify the name ReadDate. Select “Program” as the type. Select “Structured Text” as the implementation language. Click “Add” to close the dialog.
   ⇒ The program ReadData is created.
5. Select the application again and click “Add Object ➔ POU” in the context menu.
6. Specify the name WriteData. Select the “Program” options as the type. Select “Structured Text” as the implementation language. Click “Add” to close the dialog.
   ⇒ The program WriteData is created.
7. Select the application and click “Add Object ➔ Task Configuration” in the context menu.
   ⇒ The task configuration is created with the standard task Task.
8. Select the standard task and click “Properties” in the context menu.
9. Specify the name Read in the input field.
   ⇒ The task is renamed. Moreover, the “Configuration” tab is open in the editor.
10. Click “Add Call” in the editor.
    ⇒ The “Input assistant” dialog opens.
11. Select the “ReadData” program in the configuration tree. Click “OK” to close the dialog.
   ✐ The Read task calls the ReadData program at runtime.

12. Select the task configuration and click “Add Object ➔ Task” in the context menu.
   ✐ The “Add Task” dialog opens.

13. Specify the name Write in the input field. Click “Add” to close the dialog.
   ✐ The Write task is created. The “Configuration” tab is opened in the editor.

14. Click “Add Call” in the editor.
   ✐ The “Input Assistant” dialog opens.

15. Select the “WriteData” program in the configuration tree. Click “OK” to close the dialog.
   ✐ The Write task calls the WriteData program at runtime.

16. Select the appTasklocal application and click “Add Object ➔ Global Variable List (Task-Local)” in the context menu.
   ✐ The “Add Global Variable List (Task-Local)” dialog opens.

17. Specify the name Tasklocals.

18. Select the Write task from the “Task with write access” drop-down list.

   ✐ The object structure for using task-local variables within an application is complete.

   Now you can code the objects.

   The application contains a task responsible for writing the data and a task responsible for reading the data.
The `diaData` array is populated with values in the `WriteData` program. The `ReadData` program tests whether or not the values of the array are as expected. If so, then the `bTest` variable yields the result `TRUE`.

The tested data is declared in the variable `g_diaData` as task-local GVL. This causes data access to be synchronized in the computer. In turn, this guarantees that the data is with cycle consistency even if the accessing programs are called from different tasks. It is taken into account that tasks can be interrupted by other tasks or can run simultaneously. The guarantee also applies above all if the application is running on a system with a multicore processor.

If the variable `g_diaData` is declared as a global variable list only and the `WriteData` and `ReadData` programs are called from different tasks, then the test will yield `FALSE` more often. Because then for example the values in `WriteData` can be changed while the values in `ReadData` are being read.

When using task-local variables, the compiler synchronizes the data of the variables, which takes a lot of time and memory. The synchronization is a complex task that is suitable above all for multicore operation. Select this data type only if sufficient resources are available. Then having this kind of data consistency is a convenient option for you without worrying about data synchronization. You can concentrate on the actual task of implementing the functionality.

Restrictions in the declaration

In the global task-local variable list, pay attention to the following:

- Do not assign direct addresses.
- Do not map direct addresses.
- Do not declare pointers.
- Do not declare references.
Do not instantiate function blocks.

Do not declare remanent variables as PERSISTENT and RETAIN at the same time.

Example:

```
VAR_GLOBAL RETAIN g_RemenantData END_VAR
```

When you edit the declaration in the list of task-local variables, you cannot login to the application afterwards with an online change.

Data access

Compiler errors:
The compiler reports write access in a task without write access as an error. However, not all write-access violations can be detected. The compiler can only assign static calls to a task. The call of a function block by means of a pointer or an interface is not assigned to a task, for example. Therefore, no write access is recorded there either. Moreover, pointers can point to task-local variables. Therefore, data can be manipulated in a read task. In this case, a runtime error is not issued. However, values that are modified by means of pointer access are not copied back in the shared reference of variables.

Read access:
Task-local variables are located at a different address in the list for each task. As a result, the ADR operator applied for a task-local variable yields another address in each task.

Controlling the task execution

A scheduler controls the time-based execution of multiple tasks and therefore also task switching. The strategy, which is tracked by the scheduler in order to control the allocation of the execution time, has the goal of preventing a task from being blocked. The synchronization mechanism is optimized to prevent blocking states (lock states) and at no time does a task wait for the action of another task.

Scheduling strategy:
- As long as the writing task saves a copy back to the shared reference, none of the reading tasks gets a copy.
- As long as a reading task gets a copy of the common reference, the writing task does not write back a copy.

Due to the scheduling method, no time can be determined when a reading task securely receives a copy of the writing task. In principle, the copies can run apart from one another. During the runtime of the sample application `appTasklocal`, you cannot expect each written copy to be edited once by the reader. For example, the reading task can edit the same array over multiple cycles, or the contents of the array can skip one or more values between two cycles. Pay attention to these effects of task switching.

For task-local variables on the other hand, it is guaranteed that task switching runs with cycle consistency.

A task with write access is halted for example between two accesses to the shared reference by a reading task for the duration of one cycle. Therefore, if n reading tasks exist, then the writing task can have n cycles of delay until the next update of the shared reference.

A writing task can also prevent a reading task from getting a reading copy in each cycle. Consequently, no upper limit can be specified for the number of cycles after which a reading task will definitely receive a copy. This can lead to problems especially when the reading task runs very slowly. For example, if a task runs only every hour and cannot access the task-local variables during this time, then the task works with a very old copy of the list.

You can remedy this by adding a time stamp for each task-local variable. In this way, you can at least determine whether the reading tasks access a current list. For example, add a variable of data type LTIME to the list of task-local variables and add the following code to the writing task:

```
tasklocal.g_ltimStamp := LTIME();
```
The compiler creates a copy for a list of task-local variables for each task. This creates a structure with the same variables as those in the list of task-local variables. Moreover, an array with this structure is created in which a dimension is created for each task. As a result, an array element is indexed for each task. If a variable in the list is accessed now in the code, then the task-local copy of the list is actually accessed. Furthermore, it is determined in which task the block is currently running and then the access is indexed accordingly.

For example, the line of code `diValue := TaskLocals.g_diaData[0];` from the above example is replaced by:

```c
diValue := __TaskLocalVarsArray[__CURRENTTASK.TaskIndex].__g_diarr[0];
```

`__CURRENTTASK` is an operator that is available in CODESYS V3.5 SP13 and later in order to determine the current task index quickly.

At runtime for the writing task at the end, the contents of the task-local list are written to the global list. For a reading task at the beginning, the contents of the global list are copied to the task-local copy. Therefore, for n tasks, there are n+1 copies of the list: One list serves as a shared reference and every task also has its own copy of the list. In addition, copying to or from the shared reference is also synchronized.

---

When deciding whether or not synchronization is the appropriate technique for your system, consider that the technical implementation requires more effort.

---

Task-local variables are designed for the use case "Single writer - multiple readers". When you implement a code that is called by different tasks, using task-local variables is a significant advantage. For example, this is the case for the sample application appTasklocal when it is extended by multiple reading tasks that all access the same array and use the same functions.

Task-local variables are especially useful on multicore systems. On these systems, you cannot synchronize tasks by priority. Then other synchronization mechanisms become necessary.

Do not use task-local variables when a reading task always works on the newest copy of the variable. Task-local variables are not suitable for this purpose.

A similar issue is the "Producer - Consumer" dilemma. This happens when a task produces data and another task processes the data. Choose another type of synchronization for this configuration. For example, the producer could use a flag to notify that a new date is present. Then the consumer uses a second flag to notify that it has processed its data and is waiting for new input. In this way, both can work on the same data. This removes the overhead for cyclic copying of data, and the consumer does not lose any data generated by the producer.

---

At runtime, there may exist multiple different copies of the task-local variable list in memory. When monitoring a position, not all values can be displayed. Therefore, the values from the shared reference are displayed for inline monitoring, in the monitoring list, and in the visualization for a task-local variable.

If you set a breakpoint, then the data of the task is displayed that ran to the breakpoint and was halted as a result. Meanwhile, the other tasks continue running. Under certain circumstances, the shared copy can be changed. In the context of the halted task, however, the values remain unchanged and are displayed as they are. You must be aware of this.

---

1.3.1.9.3 Creating source code in IEC

Source code:

"Source code" is a term used for the implementation code, which you insert in the programming modules by using the appropriate programming language editors. The following programming module types are available for this purpose: POU (Program, Function, Function Block), Action, Method, Property, Interface.

Programming Language:

When creating a POU, you define, in which programming language the implementation should be inserted. Besides the IEC languages also CFC is available.

Programming Language:Editors:

You get a programming module editable in the corresponding programming language editor on a double-click on the programming module object. So, the module will appear either in the textual ST editor or in one of the graphical editors for FBD/LD/IL or CFC. Each editor consists of two windows: In the upper window you insert the declarations, in textual or tabular form, depending on the setting. In the lower window you insert the implementation code. The display and behaviour of each editor can be configured in the corresponding tab of the CODESYS "Options" dialog.

Regard the possibility to open a programming module for offline-editing even while the application is in online mode.

● Chapter 1.3.1.25.2.4.9 “Command ‘Edit Object (Offline)’” on page 902

FBD/LD/IL

A combined editor enables programming in the languages FBD (function block diagram), LD (ladder diagram) and IL (instruction list).

The basic unit of the FBD and LD programming is a network. Each network contains a structure that can represent the following: a logical or arithmetic expression, the call of a POU (function, function block, program etc.), a jump or a return instruction. IL actually requires no networks. In CODESYS, however, an IL program also consists of at least one network in order to support conversion to FBD or LD. In view of this you should also divide an IL program meaningfully into networks.

See also

● Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Function block diagram (FBD)

The function block diagram is a graphically oriented IEC 61131 programming language. It works with a list of networks, where each network contains a structure that can contain logical and arithmetic expressions, calls of function blocks, a jump or a return instruction.

Boxes familiar from boolean algebra are used here. Boxes and variables are connected by connecting lines. The signal flow in the network runs from left to right. The signal flow in the editor runs from top to bottom, starting with network 1.

Example
CFC is also a programming language based on the same principle as FBD, but with the following differences:

– The CFC editor is not network-oriented.
– You can freely place the elements in the CFC editor.
– Direct insertion of feedbacks is possible.
– The order of execution is determined by a list of currently inserted elements, which you can change.

See also

● § Chapter 1.3.1.9.3.1.1 “Programming function block diagrams (FBD)” on page 184
● § Chapter 1.3.1.25.2.13 “Menu ‘FBD/LD/IL’” on page 992

Ladder diagram (LD)

The ladder diagram (LD) is a graphically oriented programming language that approximates an electrical circuit diagram. On the one hand the ladder diagram is suitable for designing logical switching units, but on the other you can also create networks just as in FBD. Therefore you can use LD very well for controlling calls of other program blocks.

The ladder diagram consists of a series of networks. A network is bounded on the left side by a vertical line (bus bar). A network contains a circuit diagram of contacts, coils, optional boxes (POUs) and connecting lines. On the left side of a network there is a contact or a series of contacts that relay the ON or OFF state, which corresponds to the boolean values TRUE and FALSE, from left to right. A boolean variable is associated with each contact. If this variable is TRUE, the status is relayed from left to right via the connection line. Otherwise OFF is relayed. Thus the coil(s) in the right part of the network receive(s) the value ON and OFF coming from the left and the value TRUE or FALSE is written accordingly into the boolean variable assigned to them.

If the elements are connected in series, this means an AND operation. If they are connected in parallel, this means an OR operation. A line through an element means a negation of the element. The negation of an input or an output is indicated by a circle symbol.

Example

IEC 61131-3 defines a complete LD command set, consisting of different types of contacts and coils. Contacts conduct the current (according to their type) from left to right. Coils store the incoming value. Contacts and coils are assigned to boolean variables. You can supplement an LD network by jumps, returns, labels and comments.

See also

● § Chapter 1.3.1.9.3.1.2 “Programming ladder diagrams (LD)” on page 186
● § Chapter 1.3.1.25.2.13 “Menu ‘FBD/LD/IL’” on page 992

Instruction list (IL)

The instruction list is an assembler-like IEC 61131-compliant programming language. It supports accumulator-based programming.

An instruction list (IL) consists of a series of instructions. Each instruction starts in a new line and contains an operator and, depending on the type of operation, one or more operands separated by commas. A label, followed by a colon, can be placed in front of an instruction. It serves the identification of the instruction and you can use the label as a jump destination. A comment must be the last element in a line. Empty lines can be inserted between instructions.
All IEC 61131-3 operators are supported, as are multiple inputs, multiple outputs, negations, comments, set/reset of outputs and conditional/unconditional jumps.

Each instruction is based primarily on the loading of values into the accumulator (LD instruction). After that the corresponding operation is executed with the parameter from the accumulator. The result of the operation is written again into the accumulator, from where you should store it purposefully with the help of an ST instruction.

The instruction list supports comparison operators (EQ, GT, LT, GE, LE, NE) and jumps for programming of conditional executions or loops. Jumps can be unconditional (JMP) or conditional (JMPC / JMPCN). In the case of conditional jumps, a check is performed as to whether the value in the accumulator is TRUE or FALSE.

Example

![Example Image]

Programming function block diagrams (FBD)

Creating a POU in the function block diagram (FBD) implementation language

1. Select an application in the device tree.
2. Select the command “Project ➔ Add Object ➔ POU”.
   ⇢ The dialog box “Add POU” opens.
3. Enter a name and select the implementation language “Function Block Diagram (FBD)”. Click on “Add”.
   ⇢ The POU is added to the device tree and opened in the editor. It consists of the declaration editor in the top part and the implementation part with an empty network in the lower part. The view “ToolsBox” is also automatically opened, in which the suitable elements, operators and function blocks for FBD programming are available.
Programming a network

1. Click inside the automatically inserted empty network in the implementation part.
   ⇒ The network is given a yellow background and the area at the left-hand side with the network number is given a red background.
2. Open the context menu with the right mouse button.
   ⇒ You obtain amongst other things the insert commands for the elements that can be inserted at this point.
3. Insert the elements required for your programming using the menu commands or by dragging in the elements from the toolbox.
4. For example, select the command “Insert Assignment”.
   ⇒ An assignment line is inserted. In each case three question marks stand for assignment source and assignment target.
5. Select the question marks and replace them with the desired variable. Input assistance is available for this purpose.
6. Move the cursor over the assignment line.
   ⇒ The possible insertion positions for further elements are displayed as grey diamonds. A click on a diamond selects that position and the suitable insert commands are once again available.
7. Alternatively, you can drag an element with the mouse from the toolbox into the network. For example, click in the tool box on the box element, keep the mouse button pressed and move the cursor over the network.
   ⇒ Each possible insertion position lights up green.
8. Release the mouse button in order to insert the box.
   ⇒ The box is displayed in the network. The type of box on the inside and the instance name above the box, which is required in the case of a function block, are still kept free with three question marks.
9. Select the string ??? inside the box and replace it with the name of the box. Input assistance is available for this purpose.
   ⇒ The inputs and outputs of the selected box are displayed. They are still kept free with question marks, as is the instance name in the case of a function block.

- Chapter 1.3.1.9.3.1 “FBD/LD/IL” on page 182

Programming line branches (subnetworks)

1. In the implementation part of your POU, insert a new network using the command “FBD/LD/IL ➔ Insert network” or drag it in from the tool box.
2. For example, drag an “ADD” operator into the empty network and replace the characters ??? with two variables of the type INT.
3. Drag the element “Branch” from the tool box into your implementation and release the mouse button at the green insertion position directly at the output of the operator.
   ⇒ The line branch splits the processing line at the output of the operator box into 2 sub-networks.

4. Further FBD elements and also further line branches can now be added to each of the two subnetworks.

---

**Programming ladder diagrams (LD)**

**Creating a POU in the ladder diagram (LD) implementation language**

1. Select the application in the Device tree.
2. Select the command “Project ➔ Add Object ➔ POU”.
   ⇒ The dialog box “Add POU” opens.
3. Enter a name and select the implementation language “Ladder Diagram (LD)”.
   Click on “Add”.
   ⇒ CODESYS adds the POU to the Device tree and opens it in the editor. An empty network is inserted in the implementation part. The empty network is bounded on the left by a vertical line, which represents a bus bar. The view “ToolBox” is also automatically opened, in which the suitable elements, operators and function blocks for LD programming are available.

**Adding a contact and a function block (TON)**

☑ Requirement: a POU with the implementation language LD is opened in the editor and an empty network is inserted.

1. Click on the category “Ladder Elements” in the view “ToolBox”
2. Click on the “Contact” element, drag it into your network and release the mouse button at the insertion position “Start here”.
   ⇒ The contact is added on the left in the network directly against the vertical line.
3. Click on ??? and enter the identifier of a boolean variable. The input assistant is also available to you for this.
4. Click on “Function Blocks” in the view “ToolBox” and drag the function block “TON” onto an insertion position on the connecting line to the right of the inserted contact.
   ⇒ CODESYS inserts the box “TON” to the right of the contact. The contact is connected with the input IN of the TON box.
5. Enter a time constant at the input PT, for example T#3s.
   ⇔ If the variable of your contact goes TRUE, then the input IN of the TON box also goes TRUE. The TON box forwards the value TRUE to the output Q with a switch-on delay of T#3s, for example.

Inserting a closed line branch

Requirement: a POU with the implementation language LD is opened in the editor and an empty network is inserted.

1. Click inside the empty network and select the command “FBD/LD/IL ➔ Insert Contact”.
2. Select the connecting line to the left of the contact and select the command “FBD/LD/IL ➔ Set Branch Start Point”.
   ⇔ The starting point on the connecting line is marked by a red rectangle. CODESYS marks all possible end points of the branch with a blue rectangle.
3. Click on a blue rectangle in order to set the end point of your closed line branch.
   ⇔ CODESYS inserts the line branch between the starting and end points. The program flow will go through both branches up to the end point.

If you insert the line branch at a box instead of at a contact, the box will only be called if none of the other branches is TRUE.

- Section 1.3.1.24.1.5.4.14 “Closed branch” on page 475
- Section 1.3.1.24.1.5.4.11 “LD element ‘Contact’” on page 473

Programming in instruction list (IL)

If necessary, IL can be activated in the CODESYS options.

Creating POUs in the instruction list (IL) implementation language

1. Select the application in the device tree.
2. Click “Project ➔ Add Object ➔ POU”.
   ⇔ The “Add POU” dialog opens.
3. Enter a name and select the implementation language “Instruction List (IL)”.
   Click “Add”.
   ⇔ CODESYS adds the POU to the device tree and opens it in the editor. A network is already inserted in the implementation part.

Programming networks (example: ADD operation)

Requirement: A POU (IL) is opened in the editor and possesses an empty network.
1. Click the line marked in color in the 1st column and enter the operator LD.
2. Press the [Tab] key.
   ⇒ The cursor jumps to the 2nd column
3. Enter the first summand of your ADD operation, for example 6.
4. Press [Ctrl]+[Enter] or select the command “FBD/LD/IL Insert IL Line After”.
   ⇒ CODESYS inserts a new instruction line. The first column of this line has the focus.
5. Enter ADD and press [Tab].
6. Enter the second summand of your ADD operation, for example 12.
7. Press [Ctrl]+[Enter]
8. Enter the operator ST and press [Tab].
9. Specify a variable of the data type INT, for example iVar.
   ⇒ The result – 16 in the example – is stored in the iVar.

**Calling function blocks**

Requirement: A POU (IL) is opened in the editor and possesses an empty network. A variable of the data type <function block> is declared in the declaration part (example: Cl:CTU;).

1. Click the line marked in color in the 1st column and select the command “FBD/LD/IL Insert Box”.
   ⇒ The input assistant opens.
2. Select the desired function block in the category “Function Blocks” or “Boxes”, for example the “CTU” counter from the “Standard” library, and click “OK”.
   ⇒ CODESYS inserts the selected function block “CTU” as follows:

   ![Function Block Example](image)

   3. Replace the strings ??? with the variable name and the values or variables for the inputs/ outputs of the function block.
4. As an alternative to inserting the function block via the input assistant, you can directly enter the call in the editor as shown in the picture at step 4.

**Continuous function chart (CFC)**

The “Continuous Function Chart (CFC)” implementation language is a graphical programming language which extends the standard languages of IEC 61131-3.
You can graphically program a system by means of a POU in CFC. You insert elements and position them freely. You insert connections and wire the elements to a network so that a well-structured function block diagram is created. You can also insert feedback. You can read function block diagrams like an circuit diagram or a block diagram.

The execution order of a function block diagram is based on data flow. Moreover, a POU can process multiple data flows. Then the data flows do not have any common data. In the editor, multiple networks do not have any connections to each other.

On the other hand, POUs in FBD, LD, or IL have a network-based execution order.

The “Continuous Function Chart (CFC) - page-oriented” implementation language is also a graphical programming language which extends the standard languages of IEC 61131-3.

In this language, you can graphically program large, complex function block diagrams. The same elements and commands are available as for “Continuous Function Chart (CFC)”. In addition, you can arrange the code on as many pages as you like. This allows you to create extensive function block diagrams that are still easy to print. Furthermore, each page has border areas. You can arrange inputs and sink connection marks on the left, and outputs and source connection marks on the right. This helps you to insert connecting lines and provides a better overview.

Unfortunately, it is not possible to switch a POU between the “Continuous Function Chart (CFC) - page-oriented” and “Continuous Function Chart (CFC)” implementation languages.

Automatic execution order by data flow

The execution order in POUs is uniquely determined in text-based and network-based editors. In the CFC editor, however, you can position the elements freely, so the execution order is initially not unique. For this reason, CODESYS determines the execution order by data flow and, in the case of multiple networks, by the topological position of the elements. The elements are sorted from top to bottom and left to right. Now the execution order is unique and makes sure that the POU is processed while optimized by time and by cycle.

You can get information about the chronological order of the elements in the chart and temporarily display the execution order. When you program networks with feedback you can define an element as the starting point in the feedback loop.

You can also explicitly edit the processing order in a CFC object if necessary. To do this, switch the “Auto Data Flow Mode” property of the CFC object to “Explicit Execution Order Mode”. In this mode, you have the option of editing the execution order by means of menu commands.

Before CODESYS Development System V3.5 SP15, you had to define the execution order explicitly for each POU. The was no mode switching.

Data flow

In general, data flow is described as the chronological order in which data is read or written when and how in which programming objects. A POU can process any number of data flows, which can also be executed independently of each other.
**Displaying the execution order**

By default, the execution order of a CFC object is determined automatically. The “Auto Data Flow Mode” property is selected for this. You can temporarily display the automatically determined execution order in the CFC editor.

1. Create a new project using the “Standard project” template and specify the name *Minimal* for example.

2. Extend the application with the function block `FB_DoIt` in the “ST” implementation language with inputs and outputs.

```plaintext
FUNCTION_BLOCK FB_DoIt
  VAR_INPUT
    iAlfa : INT;
    iBravo: INT;
    sCharlie : STRING := 'Charlie';
    xItem : BOOL;
  END_VAR
  VAR_OUTPUT
    iResult : INT;
    sResult : STRING;
    xResult : BOOL;
  END_VAR
  VAR
  END_VAR
  iResult := iAlfa + iBravo;
  IF xItem = TRUE THEN
    xResult := TRUE;
  END_IF
END_FUNCTION_BLOCK
```

3. Create the function block `ExecuteCFC` in the “CFC” implementation language.

```plaintext
PROGRAM ExecuteCFC
  VAR
    fb_DoIt_0: FB_DoIt;
    fb_DoIt_1: FB_DoIt;
    iFinal_1: INT;
    iFinal_0: INT;
    xFinal: BOOL;
  END_VAR
```

Recently created programming objects in CFC have the Auto Data Flow Mode selected. The execution order of the programming object is optimally defined internally.
4. Click “CFC ➔ Execution Order ➔ Display Execution Order”. 
   ⇒ The execution order of the object is shown. The boxes and inputs are numbered accordingly and reflect the chronological processing order. The numbering is hidden as soon as you click again in the CFC editor.

![Diagram showing execution order with boxes and numbers]

Determining the execution order in feedback networks

1. Create a CFC program with feedback.
   ⇒ The POU PrgPositiveFeedback counts.

   ```plaintext
   PROGRAM PrgPositiveFeedback
   VAR
   iResult: INT;
   END_VAR
   ```

2. Select an element within the feedback.
   ⇒ The selected element is highlighted in red.

3. Click “CFC ➔ Execution Order ➔ Set Start of Feedback”.
   ⇒ At runtime, this POU is processed first. The start POU of the feedback is defined and decorated with the ▶ symbol. The execution order is resorted and the selected element gets the number 0. (This is the lowest number of the feedback.)

4. Select the start POU again.
5. Click “CFC ➔ Execution Order ➔ Set Start of Feedback”.  
   ⇒ The POU is not selected as the start POU.

The execution order is defined internally.

6. Click “CFC ➔ Execution Order ➔ Display Execution Order”.  
   ⇒ The execution order by data flow is displayed.

The automatically defined execution order by data flow results in time- and cycle-optimized execution of the POU. You do not need any information about the internally managed execution order during the development process.  

In “Explicit Execution Order Mode”, it is your responsibility to adapt the execution order and to assess the consequences and impacts. This is another reason why the execution order is always displayed.

You can change the automatically defined execution order of a CFC object explicitly when you select the “Explicit Execution Order Mode” option for the object.

1. In the “Devices” or “POUs” view, select a CFC object.
2. In the context menu, click “Properties”.
3. Click the “CFC Execution Order” tab.  
   ⇒ The “Execution order” list box displays the currently selected mode.
4. In the “Execution order” list box, select “Explicit Execution Order Mode”.
5. Click “OK” to confirm the dialog.  
   ⇒ The Explicit Execution Order Mode property is selected. The networks are numbered in the CFC editor, and the following commands are provided in the “CFC ➔ Execution Order” menu for editing the execution order.
6. Open a CFC object.
7. Select a numbered element and click “CFC ➔ Execution Order ➔ Send to Front”.  
   ⇒ The execution order is resorted and the selected element has the number 0.

Programming in the CFC editor

In the CFC editor, you can wire POUs to each other and create well-structured block diagrams.

The editor supports you in the following ways:

- Programming with elements and connecting lines
- Dragging instances and variables to the editing area
- Auto-routing the connecting lines
- Automatic linking
- Fixing of connecting lines by control points
- Collision detection
- Input assistance for connection marks
- Forcing and writing of values in online mode
- Movement of selection using arrow keys
- Reduced display of a POU without disconnected pins

Inserting elements and wiring with connecting lines

1. Drag a “Box” element and an “Output” element into the editor.
2. Click the output of the “Box” element.
   ⇨ The output is marked with a red box.
3. Drag a connecting line from the box output of the “Box” element to the box input of the “Output” element.
   ⇨ The cursor symbol changes when it reaches the box input.
4. Release the left mouse button.
   ⇨ The output pin of the box is wired to the input pin of the output.

You can also hold down the [Ctrl] key, select each pin, and then right-click “Connected Selected Pins”.

Calling of instances

1. Create a new project using the standard template and specify the name First for example.
   ⇨ The project First.project is created.
2. Extend the application with the function block `FB_DoIt` in the “ST” implementation language with inputs and outputs.

   ```
   FUNCTION_BLOCK FB_DoIt
   VAR_INPUT
     iAlfa : INT;
     iBravo: INT;
     sCharlie : STRING := 'Charlie';
     xItem : BOOL;
   END_VAR
   VAR_OUTPUT
     iResult : INT;
     sResult : STRING;
     xResult : BOOL;
   END_VAR
   VAR
     END_VAR
   iResult := iAlfa + iBravo;
   IF xItem = TRUE THEN
     xResult := TRUE;
   END_IF
   ```

3. Select the application and click “Add Object ➔ POU” in the context menu. Select the “Continuous Function Chart (CFC)” implementation language and the type Program. Specify the name `PrgFirst` for example.

   Click “OK” to confirm the dialog.

   The program `PrgFirst` is created and it opens in the editor. It is still empty.

4. Instantiate function blocks and declare variables.

   ```
   PROGRAM PrgFirst
   VAR
     iCounter: INT;
     fbDoIt_1 : FB_DoIt;
     fbDoIt_2 : FB_DoIt;
     iOut : INT;
     sOut: STRING;
     xOut: BOOL;
   END_VAR
   ```

5. Drag a “Box” element from the “ToolBox” view into the editor.

6. Click the ??? field and type in ADD.

   The box type is ADD. The box acts as an adder.

7. Click line 3 in the declaration editor.

   The declaration line of `iCounter` is selected.

8. Click in the selection and drag the selected variable into the implementation. Focus there on an input of the ADD box.

   An input has been created, declared, and connected to the box.

9. Click again in the selection and drag the variable to the output of the ADD box.

   An output has been created, declared, and connected to the box.

10. Drag an “Input” element from the “ToolBox” view to the implementation. Click its ??? field and type in 1.
11. Connect the 1 input to an input of the ADD box.
   ⇒ A network is programmed. At runtime, the network counts the bus cycles and stores the result in iCounter.

12. Click line 5 in the declaration editor.
   ⇒ The line is selected.
13. Click in the selection and drag the selected instance into the implementation.

⇒ The instance appears as a POU in the editor. The type, name, and POU pins are displayed accordingly.
14. Drag the `fbDoIt_2` instance to the editor. Interconnect the instances to each other and to inputs and outputs.

Example:

A program in ST with the same functionality might look like this:

```plaintext
PROGRAM PrgFirstInSt
VAR
  iCounter: INT;
  fbDoIt_1 : FB_DoIt;
  fbDoIt_2 : FB_DoIt;
  iOut : INT;
  sOut: STRING;
  xOut: BOOL;
END_VAR

iCounter := iCounter + 1;
fbDoIt_1(iAlfa := 16, iBravo := 32, sCharlie := 'First',
          xItem := TRUE, iDelta := 2, iResult => fbDoIt_2.iAlfa, xResult
          => fbDoIt_2.xItem);
fbDoIt_2(iBravo := fbDoIt_1.iResult, sCharlie := 'Second',
          iDelta := 2, iResult => iOut , sResult=> sOut, xResult =>
          xOut);
```

Creating connection marks

- Requirement: A CFC POU has connected elements.
- 1. Select a connecting line between two elements.
  - The connecting line is displayed as selected. The ends of the connecting line are marked with red boxes ( ).
- 2. Click “CFC ➜ Connection Mark”.
  - The connection is separated into a “Connection Mark - Source” and a “Connection Mark - Sink”. The name of the mark is generated automatically.
3. Click in the source connection marks.
   ➔ You can edit the name.

4. Specify a name SimpleMark for the source connection mark.
   ➔ The source connection mark and sink connection mark have the same name.

The following example shows how to use the “Route All Connections” command with control points.

1. Position the “Input” and “Output” elements. Connect the elements.

2. Position two “Box” elements on the line.
   ➔ The connecting line and the boxes are marked red because of the collision.

3. Click “CFC ➔ Routing ➔ Route All Connections”.
   ➔ The collision is resolved.
4. Change the connecting lines gradually.

5. Select the connecting line and click “CFC ➔ Routing ➔ Create Control Point”.

6. Change the connecting line as seen in the following example.

7. In the context menu, click “CFC ➔ Routing ➔ Remove Control Point” to remove the control point.

8. Unlock the connection by clicking “Unlock Connection” or by clicking the lock symbol.

9. Select the connecting line and click “Route All Connections”.

⇒ The connecting line has been changed manually and is now blocked for auto-routing. This is shown by a lock symbol at the end of the connection.

⇒ A control point is created on the connecting line. The connecting line is fixed to the control point.

⇒ You can also drag a control point from the “ToolBox” view to a line.

⇒ Use the control point for changing the connecting line according to your needs. You can set any number of control points.

⇒ The connecting line is routed automatically as seen in Step 3.
NOTICE!
Connections in a group are not auto-routed.

Reducing the display of a POU

- Requirement: A CFC POU is open. In the editor, its POUs with all declared pins are displayed.

1. Select a POU whose pins are partially disconnected.
   - Example: fb_DoIt_1

The POU needs space for all of the pins.

2. Click “CFC ➔ Pins ➔ Remove Unused Pins”.
   - Now the POU needs less space and is displayed only with the functionally relevant pins.

Structured text (ST), extended structured ext (ExST)

The ST editor is used for the programming of POUs in the IEC-61131-3 programming language Structured Text (ST) and Extended Structured Text. The Extended Structured Text offers some additional functions with regard to the IEC 61131-3 standard.
Structured Text is a programming language, comparable with other high-level languages such as C or PASCAL, which permits the development of complex algorithms. The program code consists of a combination of expressions and instructions, which can also be executed conditionally (IF... THEN... ELSE) or in loops (WHILE... DO).

An expression is a construct that returns a value following its evaluation. Expressions are also operators and operands together. You can also use assignments as expressions. An operand can be a constant, a variable, a function call or a further expression.

Instructions control how the expressions are to be processed.

For this text editor you can make various settings with regard to behavior, appearance and menus in the dialog boxes “Options” and “Adapt” in the “Tools” menu. The familiar Windows functions (for example IntelliMouse) are also available for this editor.

See also
- Chapter 1.3.1.9.3.3.1 “Programming structured text (ST)” on page 201
- Chapter 1.3.1.25.3.13.20 “Dialog ‘Options’ - ‘Text Editor’” on page 1086
- Chapter 1.3.1.25.3.14.1 “Dialog ‘Customize’ - ‘Menu’” on page 1089

ExST - Extended structured text

Extended Structured Text (ExST) is a CODESYS-specific extension of the IEC 61131-3 standard for Structured Text (ST).

See also
- Chapter 1.3.1.24.1.3.4.4 “ExST assignment ‘R’=” on page 434
- Chapter 1.3.1.24.1.3.4.3 “ExST assignment ‘S’=” on page 433
- Chapter 1.3.1.24.1.3.4.5 “ExST – Assignment as expression” on page 435

Programming structured text (ST)

Principle

The programming languages 'Structured Text' and 'Extended Structured Text' are programmed in the ST editor. The program code consists of a combination of expressions and instructions, which can also be executed conditionally or in loops. You must conclude each instruction with a semicolon ;.

The variables are declared in the declaration editor.

Creating a POU in the structured text (ST) implementation language

1. Select an application in the device tree.
2. Select the command “Project ➔ Add Object ➔ POU”.
   - The dialog box “Add POU” opens.
3. Enter a name and select the “Implementation language” “Structured Text (ST)”. Click on “Add”.
   - The POU is added to the device tree and opened in the editor.
   - Now insert the variable declarations in the upper part of the POU and enter the ST program code in the lower part of the POU.

See also
- Chapter 1.3.1.24.1.3.3 “ST expressions” on page 431
- Chapter 1.3.1.24.1.3 “Structured text and extended structured text (ExST)” on page 430
- Chapter 1.3.1.24.1.3.5.10 “ST function block call” on page 441
Sequential function chart (SFC)

Use the SFC editor for programming POUs in the IEC 61131-3 compliant SFC implementation language. SFC is a graphical programming language for describing the chronological sequence of individual actions in a program. For this purpose, actions (discrete programming objects) are assigned to step elements. Transition elements control the processing order of steps.

See also
- Chapter 1.3.1.24.1.4.1 “SFC editor” on page 442

Programming the sequential function chart (SFC)

Creating POUs in the SFC implementation language

1. Select an application in the device tree.
2. Click “Project ➔ Add Object ➔ POU”.
   ⇒ The dialog box “Add POU” opens.
3. Enter a name and select the implementation language “Sequential Function Chart (SFC)”. Click “Add”.
   ⇒ CODESYS adds the POU to the device tree and opens it in the editor.

Adding step-transitions

1. Select the transition after the initial step.
   ⇒ The transition is marked red.
2. Click “SFC ➔ Insert step-transition after”.
   ⇒ CODESYS inserts the “Step0” step and the “Trans0” transition.
3. Select the “Trans0” transition and click “SFC ➔ Insert Step-Transition”.
   ⇒ CODESYS inserts the “Trans1” transition and the “Step1” step before the “Trans0” transition.

You can also drag the “Step” and “Transition” elements into the diagram from the “Toolbox” view.

See also
- Chapter 1.3.1.24.1.4.7.1 “SFC elements 'Step' and 'Transition’” on page 452
- Chapter 1.3.1.25.2.11.6 “Command 'Insert Step-Transition’” on page 969
- Chapter 1.3.1.25.2.11.7 “Command 'Insert Step-Transition After’” on page 969
Adding entry actions

1. Select “Step0”.
2. Click “SFC ➯ Add entry action”.
   - By default, you are prompted to select the duplication mode for the step actions. You decide whether the reference to the existing step action objects is copied when the step is copied, or the objects are embedded. Embedding results in new step action objects being created when the step is copied. The duplication mode is defined in the “Duplicate when copying” step property. When it is deactivated, the copied steps call the same actions as the current step.
   - You can deactivate the prompt completely in the SFC properties.
   - The display of embedded objects in the “Devices” and “POUs” views can be deactivated by means of a menu command.
3. For this example, accept the default setting “Copy reference” and confirm by clicking “OK”.
   - The “Add Entry Action” dialog box opens.
4. Type the name "Step0_entry" and select “Structured Text (ST)” as the implementation language. Click “Add”.
   - CODESYS inserts the “Step0_entry” action below the POU in the device tree and opens the action in the editor.
   - In the "Step0_entry" entry action, you program statements to be executed one time when the “Step0” step becomes active.
5. Close the "Step0_entry" editor.
   - The “Step0” step is now marked with an “E” in the lower left corner. Double-clicking this marker opens the editor.
   ![Step0 Editor](image)
   - The entry action Step0_entry is now available in the properties of the step in “Entry action”. Other actions can also be selected there as needed.
6. Select Step0. Press [Ctrl]+[V] to copy the step.
   - The same entry actions inserted above are available in the inserted copy of the step. The new step then calls the same exact action.

See also
- Chapter 1.3.1.25.2.11.8 “Command ‘Add Entry Action’” on page 970
- Chapter 1.3.1.24.1.4.7.2 “SFC element ‘Action’” on page 454
- Chapter 1.3.1.25.3.13.1 “Dialog ‘Options’ - ‘SFC Editor’” on page 1074

Adding exit actions

1. Select “Step0”.
2. Click “SFC ➯ Add Exit Action”.
   - By default, you are prompted to select the duplication mode for the step actions of the step. See above for adding entry actions. Then the “Add Exit Action” dialog box opens.
3. Specify the name "Step0_exit" and select the implementation language "Structured Text (ST)". Click "Add".
   ⇒ CODESYS inserts the "Step0_exit" action below the POU in the device tree and opens the action in the editor.
   In the "Step0_exit" exit action, you program statements to be executed one time before the "Step0" step becomes inactive.
4. Close the "Step0_exit" editor.
   ⇒ The “Step0” step is now marked with an “X” in the lower right corner. Double-clicking this marker opens the editor.

![Step0]

You can define the exit action in the step properties of “Exit action”, as well as select other actions as needed.

See also
- Chapter 1.3.1.25.2.11.9 “Command 'Add Exit Action’” on page 970
- “2. Step actions” on page 455

Adding actions

1. Double-click the “Step0” step.
   ⇒ By default, you are prompted to select the duplication mode for the step actions of the step. See above for adding entry actions. The “Add Action” dialog box opens.
2. Type the name "Step0_active" and select the implementation language "Structured Text (ST)". Click "Add".
   ⇒ CODESYS inserts the “Step0_active” action below the POU in the device tree and opens the action in the editor.
   In the Step0_active step action, you program statements to be executed as long as the step is active.
3. Close the "Step0_active" editor.
   ⇒ The “Step0” step is now marked with a black triangle in the upper right corner.

![Step0]

You can define the action in the step properties of “Step action”, as well as select other actions as needed.

See also
- “2. Step actions” on page 455
Adding alternative branches

1. Select “Step1”.
2. Click “SFC ➔ Insert Branch Right”.
   ⇒ CODESYS inserts the “Step2” step to the right of “Step1”. The steps are connected as a parallel branch signified by two pairs of double lines.
3. Select one of the double lines.
   ⇒ The double line is marked red.
4. Click “SFC ➔ Alternative”
   ⇒ CODESYS converts the branch into an alternative branch. The double lines change into a single line.

You can convert an alternative branch into a parallel branch by clicking “SFC ➔ Parallel”.

See also
- Chapter 1.3.1.24.1.4.7.3 “SFC element 'Branch'” on page 457
- Chapter 1.3.1.25.2.11.10 “Command 'Parallel'” on page 970
- Chapter 1.3.1.25.2.11.12 “Command 'Insert Branch'” on page 971
- Chapter 1.3.1.25.2.11.13 “Command 'Insert Branch Right'” on page 971

Adding jumps

1. Select “Step2”.
2. Click “SFC ➔ Insert Jump After”.
   ⇒ CODESYS inserts the “Step” jump after the “Step2” step.
3. Select the “Step” jump destination.
   ⇒ You can type the jump destination manually or select it by using the input assistant. Select Step0.

See also
- Chapter 1.3.1.24.1.4.7.4 “SFC element 'Jump'” on page 458
- Chapter 1.3.1.25.2.11.16 “Command 'Insert Jump'” on page 973
- Chapter 1.3.1.25.2.11.17 “Command 'Insert Jump After'” on page 973

Adding macros

1. Select “Step1”.
2. Click “SFC ➔ Insert macro after”.
   ⇒ CODESYS inserts the “Macro0” macro after the “Step1” step.
3. Double-click the “Macro0” element.
   ⇒ The macro opens in the implementation section of the editor. The name "Macro0" is displayed in the caption.

4. Click “SFC ➔ Insert step-transition”.
   ⇒ CODESYS inserts a step-transition combination.

5. Click “SFC ➔ Zoom out of macro”.
   ⇒ The implementation section returns to the main diagram.

-  “Chapter 1.3.1.25.2.11.19 “Command 'Insert Macro After’’” on page 974

Adding associations

1. Select “Step2”.

2. Click “SFC ➔ Insert Action Association”.
   ⇒ CODESYS inserts an association to the right of the “Step2” step.

3. Click in the left field of the association to select the qualifier.
   ⇒ You can enter the qualifier manually or use the input assistant. Select "P".

4. Click in the right field of the association to select the action.
   ⇒ You can type the action or select it by using the input assistant.

1.3.1.9.4 Configuring the memory reserve for an online change

You can configure a function block with a memory reserve to prevent its function block instances from having to be copied to new memory locations during an online change. This can happen when you make declaration changes for example adding variables to the function block. With memory reserves, this kind of online change runs faster and fewer problems occur. When the memory reserve is depleted, a message is displayed before the online change is performed.
NOTICE!
The memory reserve for a function block is best configured before downloading the application to the controller for the first time. If the memory reserve is configured when the application exists on the controller, then a more complicated online change is necessary.

In the future, bigger changes are made to a function block of a project, which could result in function block instances being copied to other memory locations in an online change.

- Requirement: The open project is not located on the controller yet.
  1. Click “View ➔ Online Change Memory Reserve Settings”.
     ⇒ The “Online Change Memory Reserve” view opens.
  2. Select the application of the project from the list box.
  3. Click “Build ➔ Build”.
  4. Click the “Scan Application” button.
  5. Select the “All” entry in the “Function blocks” area.
     ⇒ All function blocks of the application are displayed in the view.
  6. Select the corresponding function block for which you want to configure a memory reserve.
     ⇒ If the application is not on the controller yet, then the “Memory reserve” input field is editable.
  7. If the application is already on the controller, then click the “Enabled” button in the “Enable Editing” area.
     Note that if you modify the memory reserve of an application that is already on the controller, then the instances of all affected function blocks have to be copied to the memory.
  8. Specify the size of the memory reserve (in bytes) and click “Apply for Selection”.
     ⇒ The given number of bytes is shown in the “Memory reserve” field in the table.
  9. Click “Build ➔ Build” and then click “Scan Application”.
     ⇒ The following information is updated in the function block list for the configured function block: “Size”, “Instance count”, “Additional memory for all instances”, and “Remaining size of the memory reserve”.

Now when you download the application to the controller, the function block instances occupy the required memory and also the memory reserve. In the future, bigger changes of the function block can be downloaded to the controller with the online change without having to copy all function block instances to memory.

See also
- § Chapter 1.3.1.25.2.3.19 “Command ‘Settings of Memory Reserve for Online Change’” on page 894
- § Chapter 1.3.1.25.2.6.6 “Command ‘Online Change’” on page 928
1.3.1.9.5 Function block — Calling functions or methods with external implementation

A runtime system can include the implementation of a function block, function, or method (for example, from a library). If you create a POU in your application with the same name by using the “External implementation” without an implementation, then you can execute the existing implementation. Please make sure that you declare local variables only in an external function block. External functions and methods must not contain local variables.

When the application is downloading, CODESYS searches for and links the associated implementation in the runtime system for each external POU.

Objects with the property “External implementation” are postfixed with (EXT) after the object name in the “Devices” or “POUs” view.

See also

● Chapter 1.3.1.25.3.10.4 “Dialog ’Properties’ - ’Build’” on page 1048

Creating POUs with external implementation

1. Click “Project ➔ Add Object ➔ POU”.
2. Activate “Function block”, Method, or “Function” and specify the name of the associated implementation of the runtime system. Close the dialog box by clicking “Add”.
   ➔ The runtime system POU is created in the “POUs” view. The name is postfixed with (EXT).
3. Right-click the POU and select “Properties”.
   ➔ The dialog box opens.
4. Click the “Build” tab.
5. Select the “External implementation (Late link in the runtime system)” check box.
   ➔ The POU is declared and you can implement a POU call.

Creating methods with external implementation

1. Select a function block in the device tree or in the POUs view.
2. Select “Add Object ➔ Method” and type the name of the associated implementation of the runtime system. Click “Add” to close the dialog box.
   ➔ The method is created.
3. Right-click the method and select “Properties”.
   ➔ The dialog box opens.
4. Click the “Build” tab.
5. Select the “External implementation (Late link in the runtime system)” check box.
   ➔ The method is declared and you can implement a method call. The method name is postfixed with (EXT) in the “Devices” or “POUs” view.

1.3.1.9.6 Using input assistance

CODESYS provides tools and features to help you code when creating programs.
**Input assistant**
The input assistant provides all program elements that you can insert at the current cursor position. Open the “Input Assistant” dialog by clicking “Edit ➔ Input Assistant” or by pressing [F2].

See also
- “Dialog 'Input Assistant' - Tab 'Categories’” on page 874

**Dialog 'Auto Declare’**
This dialog supports the declaration of variables.

See also
- “Chapter 1.3.1.25.2.2.31 “Command 'Auto Declare’” on page 872

**"List components"**
The "List components" function is an input tool in textual editors to help you input valid identifiers. Activate this function by clicking “Tools ➔ Options” and then the “SmartCoding” category. Select the “List components after typing a dot (.)” check box.

- If you type a dot (.) instead of a global variable, then a drop-down list opens with all available global variables. You insert the selected variable after the dot by double-clicking a variable in the drop-down list or by pressing [Enter].
- If you type a dot (.) instead of a global variable after a function block instance variable or a structure variable, then CODESYS opens a drop-down list with all global variables, all input and output variables for the function block, or all structure members. You insert the selected variable after the dot by double-clicking a variable in the drop-down list or by pressing [Enter].
  
  Note: When you also want to choose from the local variables of function block instances, select the “Show all instance variables in input assistant” option in the CODESYS options (SmartCoding category).
- If a component access (with a dot) for a drop-down list has already happened, then the last selected entry is preselected at the next component access.
- When you type any sequence of characters and then press [Ctrl]+[Space], a drop-down list opens with all available POU’s and global variables. The first element in this list that starts with the sequence of characters is selected by default and you can insert it by double-clicking it or by pressing [Enter].
  
  Matches with the entered character string are highlighted in yellow in the drop-down list.
  
  If the entered character string is changed, then the displayed drop-down list is refreshed.
- In the ST editor, you can filter the displayed drop-down list by scopes:
  
  Depending on the displayed drop-down list, you can use the [Arrow right] and [Arrow left] keys to toggle between the following drop-down lists:
  - “All items”
  - “Keywords”
  - “Global declarations”
  - “Local declarations”
- CODESYS displays a tooltip if you type an opening parenthesis for a POU parameter when calling a function block, a method, or a function. This tooltip includes information about the parameters as they are declared in the POU. The tooltip remains open until you click to close it or you change the focus away from the current view. If you accidentally close the tooltip, then you can reopen it by pressing [Ctrl]+[Shift]+[Space].

You can use the pragma attribute ‘hide’ for excluding variables from the "List components" feature.
Examples

Typing structure variables:

Calling a function block:

See also

- Chapter 1.3.1.25.3.13.11 “Dialog ‘Options’ - ‘SmartCoding’” on page 1082
- Chapter 1.3.1.24.6.2.13 “Attribute ‘hide’” on page 613

Short form feature

The short form feature allows you to type abbreviated forms for variable declarations in the declaration editor and in textual editors where variables declarations are possible. Use this feature by pressing [Ctrl]+[Enter] to end a declaration line.

CODESYS supports the following short forms:

- All identifiers become variable identifiers except the last identifier of a line.
- The data type of the declaration is determined by the last identifier of the line. The following applies:
  - B or BOOL yields BOOL
  - I or INT yields INT
  - R or BOOL yields BOOL
  - S or STRING yields STRING
- If a data type is not defined using this rule, then the data type is automatically BOOL, and the last identifier is not used as the data type (see Example 1).
- Depending on the type of declaration, every defined constant becomes an initialization or string length definition (see Example 2 and 3).
- An address, such as %MD12, is automatically extended with the AT attribute (see Example 4).
- Any text after a semicolon (;) is converted into a comment (see Example 3).
- All other characters in the line are ignored (see exclamation mark in Example 5).

Examples

<table>
<thead>
<tr>
<th>Example</th>
<th>Short Form</th>
<th>Resulting declaration</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>A</td>
<td>A: BOOL</td>
</tr>
<tr>
<td>2</td>
<td>A B I 2</td>
<td>A, B: INT := 2;</td>
</tr>
<tr>
<td>3</td>
<td>ST S 2; A string</td>
<td>ST:STRING(2); (* A string *)</td>
</tr>
<tr>
<td>4</td>
<td>X %MD12 R 5 Real Number</td>
<td>X AT %MD12: REAL := 5.0;(* Real Number *)</td>
</tr>
<tr>
<td>5</td>
<td>B !</td>
<td>B: BOOL</td>
</tr>
</tbody>
</table>
See also
- Chapter 1.3.1.9.2 “Declaration of variables ” on page 172

Smart tag functions
Smart tags make it easier to write program code by suggest appropriate commands directly at the programming element. When you place the cursor over a programming element that has a smart tag function, the symbol appears. When you click the symbol, the commands that you can choose from are shown. Available smart tags:
- The smart tag function provides the “Declare Variable” command for undeclared variables in the implementation part of the ST editor.

See also
- Chapter 1.3.1.25.2.2.31 “Command ‘Auto Declare’” on page 872

1.3.1.9.7 Using pragmas

What is a pragma in CODESYS?
A pragma is a special statement in the source code of an application that influences the properties of variables when precompiling or compiling (code generation).

There are different pragmas for different purposes (example: initialization of a variable, monitoring of a variable, adding a variable to the symbol configuration, forcing the display of messages during the compilation process, and behavior of a variable under certain conditions).

NOTICE!
Uppercase and lowercase characters must be maintained

How and where to insert a pragma?
A pragma statement is specified in braces. Attributes and texts used within the statement are enclosed in single straight quotation marks. The opening brace may follow immediately after a variable name. Opening and closing braces must be located on the same line.

Examples

{warning 'This is not allowed'}
{attribute 'obsolete' := 'datatype fb1 not valid!'}

Possible insertion points:
- Declaration part of a POU
  In the textual declaration editor, you specify pragmas directly as a line. In the tabular editor, you specify pragmas that must be located before the first declaration line in the dialog box “Edit Declaration Part” / “Attributes”.
- Global variable list
- Implementation part of a POU (on a separate line or on a line with code text)
  FBD/LD/IL: Pragmas in networks of the FBD/LD/IL editor are entered as a label. Click the command “FBD/LD/IL ➔ Add Label” and replace the default text “Label:” in the text field with the appropriate pragma statement. To use a pragma in addition to a label, you specify the pragma first and then the label.

NOTICE!
Pragmas in CODESYS are not one-to-one implementations of C preprocessor directives. You must position a pragma like an ordinary statement. It must not be used within an expression.
Incorrect and correct positions for a conditional pragma

**INCORRECT:**

{IF defined(abc)}
IF x = abc THEN
(ELSE)
IF x = 12 THEN
(END_IF)
y := {IF defined(cde)} 12; {ELSE} 13; {END_IF}
END_IF

**CORRECT:**

{IF defined(abc)}
IF x = abc THEN
(IF defined(cde))
y := 12;
(ELSE)
y := 13;
(END_IF)
END_IF
ELSE
IF x = 12 THEN
(IF defined(cde))
y := 12;
(ELSE)
y := 13;
(END_IF)
END_IF

In the “Properties” dialog box (“Compile” category), you can specify "defines" that can be queried in pragmas.

Scope:
Depending on the type and contents of a pragma, it may influence the following:

- subsequent declarations
- the next statement only
- all subsequent statements until it is canceled by a corresponding pragma
- all subsequent statements until the same pragma is executed with other parameters or the end of the code is reached. In this context, "code" means the declaration part, implementation part, global variable list, and type declaration. Therefore, a pragma influences the entire object when the pragma is alone on the first line of the declaration part and is not superseded or canceled by another pragma.

What kinds of pragmas are there?
The CODESYS pragmas are divided into the following categories:

- Attribute pragmas (influence compiling and precompiling)
- Message pragmas (print user-defined messages when compiling)
- Conditional pragmas (influence code generation)
- User-defined pragmas

See also

- % Chapter 1.3.1.9.2.2 “Using the 'Declare variable' dialog box” on page 174
- % Chapter 1.3.1.24.6.2 “Attribute pragmas” on page 601
1.3.1.8 Using library POUs

Libraries are collections of objects that you can link to your application. You can use the objects contained in libraries in exactly the same way as objects that you have defined in the project.

Libraries can contain:

- POUs, such as function blocks or functions
- Interfaces and their methods and attributes
- Data types, such as enumerations, structures, aliases, and unions
- Global variables, constants, parameter lists
- Text lists, image collections, visualizations, and visual elements
- External files, such as documentation
- Cam plate tables

The library manager is used for managing libraries in a project. You use the library repository dialog box for installing the library in advance onto the system.

See also

- Chapter 1.3.1.19 “Using libraries” on page 371

Using library POUs

The following instructions describe how to insert the counter module CTUD from the Standard library into your program.

1. Open a POU in the editor and place the cursor in the declaration part.
2. Specify the name for the function block instance, followed by a colon (example: iCounter1:).
4. In the category “Structured Types”, select the CTUD function block from the Standard library (subfolder “Counter”).
   
   Activate the option “Insert with namespace prefix”.
5. Click “OK” to close the dialog box.

   The function block is inserted with a namespace prefix into the declaration part: iCounter1:Standard.CTUD.

See also

- Chapter 1.3.1.19 “Using libraries” on page 371

1.3.1.9 Managing text in text lists

Text lists are used for preparing visualization texts in multiple languages. You can specify the texts in Unicode format so that all languages and characters are possible. You can export text lists and then translate the texts outside of the current project.

CODESYS differentiates between static text (managed in the “GlobalTextList” object) and dynamic text (managed in objects of type “TextList”). Static texts exist in the visualization and can change only the displayed language while in runtime mode. The text ID stays the same. Dynamic texts can be controlled by means of an IEC variable that contains the text ID. In this way, you can display varying text in a visualization element in runtime mode. For example, you can configure a text field so that is shows an error text for an error number.
Both text list types include a table with text entries. An entry consists of an ID for identification, the output text, and its translation. In a text list or global text list, you can translate an output text in any number of languages. The translations are the basis for the language selection and the language switch in visualizations.

**Adding a language and translating text**

Requirement: A project is open with a text list or global text.

1. Double-click an object of type “TextList” or “GlobalTextList” in the device tree or POUs view.  
   ⇒ The “Textlist” menu is shown in the menu bar and the text list opens in the editor.
2. Click “Textlist ➔ Add Language”.
3. Specify a name for the language (example: en-US). Click “OK” to close the dialog.
   ⇒ A column is displayed with the heading en-US.
4. Type in the translation of the source text into the column.

You can correct the name of a language in the table by means of the command “Rename Language” in the context menu of the text list.

**Exporting a text list**

.Requirement: A project is open with a text list or global text.

1. Double-click the object “GlobalTextList” or an object of type “TextList”.  
   ⇒ The object opens.
2. Click “Textlist ➔ Import/Export Text Lists”.
   ⇒ The “Import/Export” dialog opens.
3. At “Choose export file”, click for more (….) and select the directory and file name (example: Text_lists_exported).
4. Select the “Export” option.
5. Click “OK” to close the “Import/Export” dialog.
   ⇒ CODESYS exports to a file the text list entries of all text lists of the project. The table contains a column with the text list names.
Example

Contents of the file

<table>
<thead>
<tr>
<th>TextList</th>
<th>Id</th>
<th>Default</th>
<th>en_US</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text_list_A</td>
<td>A</td>
<td>Information A</td>
<td>Information A_en</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>B</td>
<td>Information B: OK</td>
<td>Information B_en: OK</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>C</td>
<td>Information C</td>
<td>Information C_en</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>D</td>
<td>Information D</td>
<td>Information D_en</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>E</td>
<td>Information E</td>
<td>Information E_en</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>F</td>
<td>Information F</td>
<td>Information F_en</td>
</tr>
<tr>
<td>AlarmGroup</td>
<td>2</td>
<td>Warning 2</td>
<td></td>
</tr>
<tr>
<td>AlarmGroup</td>
<td>1</td>
<td>Warning 1</td>
<td></td>
</tr>
<tr>
<td>GlobalTextList</td>
<td></td>
<td>Information B</td>
<td>Information B_en</td>
</tr>
<tr>
<td>GlobalTextList</td>
<td></td>
<td>Information A</td>
<td>Information A_en</td>
</tr>
<tr>
<td>GlobalTextList</td>
<td></td>
<td>Switch</td>
<td>Switch</td>
</tr>
<tr>
<td>GlobalTextList</td>
<td></td>
<td>Counter: %i</td>
<td>Counter: %i</td>
</tr>
</tbody>
</table>

Preparing the exported file for input assistance

- Requirement: A file is created (example: Text_lists_exported) by means of the command “Import/Export Text Lists”. It contains the texts of the text lists of the project.
  2. Click in “Text file for textual "List components" ” and select a file (example: Text_lists_exported). Click “OK” to close the dialog.

(1): “Texts”, “Text”

See also
- “List components” on page 209

Importing files with text list entries

A file to be imported has the .csv format. The first line is a header (example: TextList Id Default en_US). The other lines contain text list entries. You get this kind of file by exporting the text lists of the project to a file. There you can edit the text list entries and then import the file outside of CODESYS. When importing, CODESYS handles the text list entries differently for the GlobalTextList and for dynamic text lists.

- CODESYS does not create new text list entries for an unknown ID.
- CODESYS ignores changes that affect the ID or the source text.
- CODESYS accepts changes in the translations.
TextList

- For a new ID, CODESYS supplements the corresponding text list with a text list entry.
- For an existing ID that does not agree in the source text, the source text of the text list is overwritten with the source text of the file.
- CODESYS accepts changes in the translations.

Importing a file

Requirement: A project is open with a text list or global text.
1. Double-click the object “GlobalTextList” or an object of type “TextList”.
   ⇒ The object opens.
2. Click “Textlist ➔ Import/Export Text Lists”.
   ⇒ The “Import/Export” dialog opens.
3. In the “Choose file to compare or to import” input field, click for more (…) and select the directory and file (example: Text_lists_corrected.csv).
4. Select the “Import” option.
5. Click “OK” to close the dialog.
   ⇒ CODESYS imports the text list entries of the file into the respective text lists.

Example Contents of the file

<table>
<thead>
<tr>
<th>TextList</th>
<th>Id</th>
<th>Default</th>
<th>en_US</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text_list_A</td>
<td>A</td>
<td>Information A</td>
<td>Information A_en</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>B</td>
<td>Information B: OK</td>
<td>Information B_en: OK</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>C</td>
<td>Information C</td>
<td>Information C_en</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>D</td>
<td>Information D</td>
<td>Information D_en</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>E</td>
<td>Information E</td>
<td>Information E_en</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>F</td>
<td>Information F</td>
<td>Information F_en</td>
</tr>
<tr>
<td>Text_list_A</td>
<td>G</td>
<td>Information G</td>
<td>Information G_en</td>
</tr>
<tr>
<td>AlarmGroup</td>
<td>2</td>
<td>Warning 2</td>
<td></td>
</tr>
<tr>
<td>AlarmGroup</td>
<td>1</td>
<td>Warning 1</td>
<td></td>
</tr>
<tr>
<td>GlobalTextList</td>
<td></td>
<td>Information B</td>
<td>Information B_en</td>
</tr>
<tr>
<td>GlobalTextList</td>
<td></td>
<td>Information A</td>
<td>Information A_en</td>
</tr>
<tr>
<td>GlobalTextList</td>
<td></td>
<td>Switch</td>
<td>Switch</td>
</tr>
<tr>
<td>GlobalTextList</td>
<td></td>
<td>Counter: %i</td>
<td>Counter: %i</td>
</tr>
</tbody>
</table>

These contents are applied to the text lists with the same name in the project.

- ¶ Chapter 1.3.1.25.2.20.6 “Command ‘Import/Export Text Lists’” on page 1021

Comparing text lists with a file and exporting differences

Requirement: A project is open with a text list or global text.
1. Double-click the object “GlobalTextList” or an object of type “TextList”.
   ⇒ The object opens.
2. Click “Textlist ➔ Import/Export Text Lists” in the context menu.
   ⇒ The “Import/Export” dialog opens.
3. In the “Choose file to compare or to import” input field, click for more (…) and select the directory and file name of the comparison file (example: Text_lists_corrected.csv).
4. For “Choose export file”, click […] and select the directory and file that contains the comparison result.
5. Select the “Export only text differences” option.
6. Click “OK” to close the dialog.

   CODESYS reads the import file and compares the text list entries that have the same ID. If they do not agree, then CODESYS writes the text list entries of the text list to the export file. 

   For the global text list, CODESYS compares the translations of the same source texts. If they do not agree, then CODESYS writes the text list entries to the export file.

- Chapter 1.3.1.25.2.20.7 “Command ‘Remove Language’” on page 1022
- Chapter 1.3.1.25.1.35 “Object ‘TextList’” on page 823

Managing static text in global text lists

The global text list is the central location for texts that are displayed in the visualization.

When you configure a text for the first time in visualization element, CODESYS creates the global text list. CODESYS fills in the table as you create more texts. Therefore, the table includes all texts automatically that you create in the project visualizations. CODESYS assigns incremental IDs as integers, beginning at 0.

You can check, update, and compare the global text list with the static texts of the visualization. You cannot edit the source text or the ID directly in the table. However, you can replace a source text with another source text by creating and importing a replacement file. Menu commands are provided for this purpose.

Configuring visualization elements with static text

A text in a “GlobalTextList” can contain a format definition.

☐ Requirement: A project is open with a visualization. The “GlobalTextList” object contains the texts that are defined in the project visualizations.

1. Double-click the visualization.

   ⇒ The editor opens.

2. Select an element with the “Text” property (example: “Text field”).

3. Type in some text in the “Text” property (example: Static Information A).

   ⇒ CODESYS adds the text to the global text list in the POU view.

Checking the global text list

☐ Requirement: A project is open with a visualization. The “GlobalTextList” object contains the texts that are defined in the project visualizations.

1. Double-click the “GlobalTextList” object in the POUs tree.

   ⇒ The table opens with the static texts.

2. Click “Text List ➤ Check Visualization Text IDs”.

   ⇒ CODESYS reports when a source text of the text list does not match the static text that is identified by the ID. The source text in the global text list and the text in the visualization with the same ID do not match.
Updating IDs of the global text list

☐ Requirement: A project is open with a visualization. The “GlobalTextList” object contains the texts that are defined in the project visualizations.
1. Double-click the “GlobalTextList” object in the POUs tree.
   ⇒ The list opens with the text list entries.
2. Click “Text List ➤ Update Visualization Text IDs”.
   ⇒ CODESYS adds text to the global text list when a text in the “Static Text” property does not match the source text in the project visualizations.

Removing the global text list and creating current IDs again

☐ Requirement: A project is open with a visualization. The “GlobalTextList” object contains the texts that are defined in the project visualizations.
1. Right-click the “GlobalTextList” object in the POUs tree and select the “Delete” command.
   ⇒ The object is removed.
2. Open a visualization.
3. Click “Visualization ➤ Create Global Text List”.
   ⇒ In the POU view, a new “GlobalTextList” object is created. The global text list contains the static text from the existing project visualizations.

Removing IDs from the global text list

☐ Requirement: A project is open with a visualization. The “GlobalTextList” object contains the texts that were defined in the project visualizations.
1. Double-click the “GlobalTextList” object in the POUs tree.
   ⇒ The table opens with the texts.
2. Click “Text List ➤ Remove Unused Text List Entries”.
   ⇒ CODESYS removes the text list entries with IDs not referenced in the project visualizations.

Updating the global text list with a replacement file

A replacement file has the CSV format. The first row is a header: defaultold defaultnew REPLACE. The following rows contain the old source texts, the new source texts, and then the REPLACE command. Tabs, commas, and semicolons are permitted separators. A combination of separator characters in a file is not permitted.

defaultold  defaultnew  REPLACE
Information A  Information A1  REPLACE

When you import a replacement file, CODESYS processes the replacement file row by row and performs the specified replacements in the “GlobalTextList”. In addition, CODESYS replaces the previous text with the replacement text in the visualizations. If the replacement text already exists as static text, then CODESYS recognizes this and harmonizes the static text and leaves only one text list entry.
Requirement: A project is open with a text list or global text.

1. Double-click the “GlobalTextList” object.
   ⇒ The object opens.

2. Click “Text List ➔ Import/Export Text Lists”.
   ⇒ The “Import/Export” dialog opens.

3. At the “Choose file to compare or to import” input field, click for more (…) and select the directory and file (example: ReplaceGlobalTextList.csv).

4. Select the “Import replacement file” check box.

5. Click “OK” to close the dialog.
   ⇒ The texts in the text lists and the visualizations are replaced.

**Example**

The global text list contains the following source texts:

- GlobalTextList Counter: %i
- GlobalTextList Counter: %i
- GlobalTextList Information A
- GlobalTextList Information a
- GlobalTextList Information Aa
- GlobalTextList Switch

The replacement file contains the following replacements:

- defaultold defaultnew REPLACE
- Counter: %i Counter2: %i REPLACE
- Counter: %i Counter2: %i REPLACE
- Information A Information A2 REPLACE
- Information a Information A2 REPLACE
- Information Aa Information A2 REPLACE
- Switch Switch2 REPLACE

CODESYS detects duplicate text list entries and removes them. Afterwards, the global text list contains the following source texts:

```
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Switch2</td>
</tr>
<tr>
<td>4</td>
<td>Counter2: %i</td>
</tr>
<tr>
<td>3</td>
<td>Information A2</td>
</tr>
</tbody>
</table>
```

The texts in the visualization have been replaced.
Managing dynamic text in text lists

You can create and translate texts in a text list for dynamic texts in order to show them dynamically in a visualization or in the alarm management. The object of type “Text list” can be located globally in the POUs view or below an application in the device tree. It contains a table with text list entries that you can edit and extend. A text list entry consists of an ID for identification, the output text, and its translation. You can add new text list entries to a text list. Menu commands are provided for this purpose.

Creating text lists for dynamic text output

Requirement: A project is open with a visualization.

1. Select an application in the POUs view or device tree and click “Project ➔ Add Object”.
2. Select “Text list”.
3. Type a name (example: Textliste_A). Click “Add” to close the dialog.
   ➔ An object of type “Text list” is created.
4. Click below the “Default” column and open the input field. Type a text (example: Information).
   ➔ The source text is created. It is used as a key in the table and as a source text for translations.
5. Type any string in the “ID” column (example: A).
   ➔ A text list entry is defined with source text and ID. If you configure the “Dynamic texts” property of an element in a visualization, then you can select the text list Textliste_A and assign the ID A.
6. Double-click in the blank line at the end of the table below “Default” and type in more text list entries.

Displaying text dynamically

In a visualization, you can configure the dynamic output of texts that were created in a text list by configuring the “Dynamic texts” property of an element. You can directly assign a text list and an ID, as well as IEC variables, where you set the values programmatically.
Requirement: A project with visualization is open and a text list is in the device tree.

1. Open the text list (example: `Text_list_A`).
2. Double-click the visualization.
   - The editor opens.
3. Drag an element to the visualization (example: a “Text field”).
4. Configure its “Dynamic texts” property by selecting one in the “Text list” property (example: `Text_list_A`) and add an ID from the text list into the “Text index” (example: ‘A’).
   - Pay attention to the single straight quotation marks. You can also assign an IEC variable of type `STRING` for the text list name and ID.
   - The IEC variables allow for programmatic access to the texts of the text lists.
5. Build the application, download it to the controller, and start it.
   - The visualization shows the text from the text list in the text field: Information A.

1.3.1.9.10 Using image pools

An image pool is a table of image files. CODESYS references image files for use in the project (for example, in a visualization) uniquely by the ID and name of the image pool. A project can include several image pools. You can create Image pools in the device tree below the application or in the POU pool. In a library project, you can use the object properties of an image pool to turn it into a symbol library for the visualization.

We recommend that you reduce the size of image files as much as possible integrating them. This will optimize the loading time of the visualization in every visualization type: TargetVisu, WebVisu and development system.

If you insert an image element into a visualization and enter an ID (“Static ID”) in the element properties, then CODESYS automatically creates a global image pool. CODESYS uses the default name “GlobalImagePool” for this.

Please note the following when the ID of an image file appears in several image pools.
- Search order: If you selected an image managed in “GlobalImagePool”, then you do not have to enter the name of the image pool. The search order for image files is as follows:
  - 1. GlobalImagePool
  - 2. Image pools assigned to the currently active application
  - 3. Image pools next to the GlobalImagePool in the POU window
  - 4. Image pools in libraries
- Unique access: You can reference a selected image directly and uniquely by appending the image ID to the name of the image pool in the following syntax “<pool name>.<image ID>”.

See also
- © Chapter 1.3.1.25.1.24 “Object ‘Image Pool’” on page 770
- © Chapter 1.3.1.25.3.10.16 “Dialog ‘Properties’ - ‘Image Pool’” on page 1057
Creating image pools

1. Select the “Application” object in the device tree.
   Click “Project ➔ Add Object ➔ Image Pool”.
   > The “Add Image Pool” dialog box opens.
2. Type a name for the image pool (for example, "Images1") and click “Add”.
   > The image pool is added to the device tree.
3. Select the image pool object and open by choosing the command “Project ➔ Edit Object”.
4. Double-click the field in the “ID” column and assign an appropriate ID (for example, "Icon1").
   You can also add new images to the list by clicking “Imagepool ➔ Add Image File”.
5. Double-click the field in the “File name” column. Click for more settings (…).
   > The “Select Image” dialog box opens.
6. Click for more settings (…) and select the image file.
   > A thumbnail of the image file is displayed in the field of the column “Image”. The name of the file is displayed in the field of the column “File name”.

The image file can be references only by the name Images1.Icon1.

See also
- Chapter 1.3.1.25.2.15.1 “Command 'Insert Image’” on page 1009

Using image files in the 'Image' visualization element

When you insert an image element into a visualization, you can define the image type.
- Static image: Enter the image ID of the image file or the name of the image pool plus the image ID into the element configuration (property “Static ID”). Please note the comments for the search order and access.
- Dynamic image: Type the variable for defining the image file ID (for example, PLC_PRG.imagevar) in the element configuration (“Bitmap ID variable” property). You can exchange a dynamic element in online mode depending on a variable.

See also
- Visualization element 'Image' Chapter 1.3.5.18.1.5 “Visualization element 'Image’” on page 1272

Using image files for the visualization background

You can set an image in the background definition of a visualization. You can define the image by the name of the image pool plus the filename, as described above for a visualization element.

- Command ‘Background’ Chapter 1.3.5.19.2.10 “Command ‘Background’” on page 1565

1.3.1.9.11 Integrating C Modules

With the C code integration plugin, externally implemented C code files can be included in CODESYS projects and C stubs can be generated from IEC objects.

In CODESYS, the “C Code Module” object type is available for this purpose. The C code files and the used IEC objects are located below a “C Code Module”. A file directory on the hard disk with C code files is assigned to each C code module.

In the project, you can generate IEC objects from a C code file in the format *.h or *.hpp (header file) in order to use them in other POUs.
The generation of C-stubs is intended for the following use cases:

- A C code file accesses an IEC object: A C code file cannot access an IEC object directly. It can access only the C stub that was generated from the IEC object.
- Generation of precompiled modules that you can merge into a library project.

After being imported, the imported source code files are part of the CODESYS project and they are therefore decoupled from the original files on the disk.

During compilation, a dynamic module is generated from a C code module and saved as part of the project. Information, warnings, and errors are displayed in the message view in the "C Code Module" category.

All dynamic modules of an application are transferred and loaded to the runtime system during the download. The runtime system must support dynamic linking for this.

---

**License for the runtime system**

The runtime system requires a license that permits C modules to be loaded. Without this license, dynamic modules cannot be linked during the download, and therefore the download will be aborted.

---

The dynamic modules are part of the boot application and they are reloaded and activated when the controller is restarted. The "Reset Origin" command unloads all C code modules in the application. The "Reset Cold" and "Reset Warm" commands do not lead to a repeated initialization of the C code modules.

---

**NOTICE!**

- **No C code for simulation mode**
  
  In simulation mode, C code is not generated and loaded to the runtime system. To simulate the code contained in the C modules anyway, you can implement it for this purpose in the respective IEC objects of the C code module.

---

CODESYS does not support the monitoring of variables in C code files or the setting of breakpoints in C source code.

**Precompiled module in a library:**

C code integration provides the capability of assigning a precompiled runtime module (example: ".dll") in the library to a device and then to save it in the library. Then, these modules can be loaded dynamically.

- Chapter 1.3.1.11.3 "Handling of device user management" on page 300

---

**Configuring C code modules**

Requirement: A project is open that already includes a C code module.

1. Click the object "C Code Module" in the device tree.
2. Select the command “Properties” in the context menu.
3. Open the “Build” tab in the “Properties” dialog.
4. Specify the file path of the Visual Studio installation on your computer. The input assistant and the search tool (magnifying glass) are also available.
5. Specify the file path of the MS Windows SDK installation on your computer. The input assistant and the search tool (magnifying glass) are also available.
6. Specify a file path for CODESYS to store the temporary compile files.
Importing folders with C source files from the file directory

Requirement: A project is open. The project controller supports the integration of C code.

1. Select “Application” in the device tree and click “Project ➔ Add Object ➔ C Code Module”.
2. If necessary, specify a new name for your C code module in the “Add C Code Modules” dialog. If you do not, then your object will be given the standard name “C Code Module”.
3. Click the symbol (…) next to the “Source directory” input field.
4. The “Find Folder” dialog opens.
5. In the “Find Folder” dialog, select the folder containing the C source files (*.c, *.cpp, *.h, or *.hpp).
6. When you select the “Monitor folder for source code changes” option, CODESYS displays a message when changes have been made to the C source files in the selected folder of the file system.
7. Click “Add”.
   ⇒ CODESYS inserts the C code module into the device tree with the folders “Extensions”, “IEC interface”, and “Source Files”.
8. In the device tree, click the plus symbol (+) of the “Source Files” folder.
   ⇒ The imported C source files are listed in the open folder.
9. If you double-click one of the C source files (éd), then the C code file opens in your editor.

Importing individual C code files

Requirement: A project is open that already includes a C code module.

1. Click the object “C Code Module” in the device tree.
2. Click “Project ➔ Add Object ➔ C Code File”.
3. In the “Add C Code-File” dialog, use the input assistant (…) to select a file in *.c, *.cpp, *.h, or *.hpp format, and then click “Add”.
   ⇒ CODESYS inserts the selected C code file into the device tree below the “C Code Module”.
4. If you double-click the new C code file (éd) in the device tree, then it opens in the editor for modification.

Generating empty C code files

Requirement: A project is open that already includes a C code module.

1. Click the object “C Code Module” in the device tree.
2. Click “Project ➔ Add Object ➔ C Code File”.
3. In the “Add C Code File” dialog, specify the name for the new C code file with the appropriate file extension and click “Add”.
   ⇒ CODESYS inserts the selected C code file into the device tree below the “C Code Module”.
4. If you double-click the new C code file (éd) in the device tree, then it opens in the editor for modification.
Converting C code files into IEC objects for use as programming objects in applications

Requirement: A project is open that includes a C code module and C code files. For example, the C code file contains the following C code:

```c
int adder(int a, int b);
```

1. Click a C code file with the file extension *.h. In this example, it is test.h.
2. Click “Build ➤ C-Integration ➤ Create IEC Interface”.
   - The dialog “Create C Interface” opens and lists the file test.h and its function adder (int, int). Both are activated for the import.
3. Click “Import”.
4. CODESYS generates the “adder (FUN)” function and inserts it as an object in the “IEC Interface” folder in the device tree.
5. When you double-click the “adder (FUN)” object, it opens in the editor.
   - It contains the following declaration part:

```c
FUNCTION adder::DINT
VAR_INPUT
   → a::DINT;
   → b::DINT;
END_VAR
VAR
END_VAR
```
6. You can now call the adder function in the implementation part of a POU (example: adder (diVar1, diVar2);).

Creating C stubs

Requirement: A project is open that includes a C code module. A POU is added to the C code module and this POU has implemented code.

- In the device tree, select the POU below the C code module and click “C-Integration ➤ Create Stub Implementation in C”.
- CODESYS creates the objects “iec_external.c” and “iec_external.h” and adds them to the “Extensions” folder in the device tree.
- In the message view (“C Code module” category), you will find a message that an m4 file has been successfully created.

When you click “Create Stub Implementation in C”, the application is compiled automatically. If errors occur in the process, then these are indicated in the message view. In addition, please monitor the messages in the “C Code Module” category.

Assigning pre-compiled runtime modules to devices and saving them in libraries

Requirement: A library (*.library) is open in CODESYS.
1. Click “View ➔ POUs”.
   ⇒ The “POUs” view opens and displays the library project and its objects.
2. Select the library project and click “Project ➔ Add Object ➔ C-Implemented Library”.
3. Click “Add” in the “Add C-Implemented Library” dialog.
   ⇒ CODESYS adds the object “C Implemented Library” to the “POUs” view.
4. Double-click the “C Implemented Library” object.
   ⇒ The object opens in its editor
5. Click “Add” in this editor.
   ⇒ The “Select Device” dialog opens.
6. In the “Object file” input field, specify the name of a dynamically loadable module in the format *.dll or *.so.

   ![NOTICE!]
   The *.dll file must contain the title of the library project in its name. For example, if the library project is named XYlib, then the “Object file” must be called: <Name>_XYlib.dll.

7. In the “Device” window, select a device for assignment of the “Object file”.
8. Click “Select Device”.
   ⇒ CODESYS displays the created device file assignment in the editor on the tab “Compiled Components”.
9. Save the library project.

See also
- § Chapter 1.3.1.25.1.18 “Object 'C Implemented Library'” on page 739

### 1.3.1.9.12 Programmatic access to I/Os

CODESYS provides the following features for mapping project variables to input, output and memory addresses:

- Assignment of project variables to input, output and memory addresses in the “I/O Mapping” tab of the device editor
- Programmed access to I/Os
  - Variables configuration
  - AT declaration

   ![NOTICE!]
   We recommend that you define the mapping of project variables to input, output and memory addresses in the “I/O Mapping” of the editor of the respective device.

See also
- § Chapter 1.3.1.8.3 “Configuring devices and I/O mapping” on page 162
Variables configuration - VAR_CONFIG

Use the variables configuration for mapping variables of functions blocks to the process map. For declarations in the function block, assign the variables to the device inputs/outputs without providing the full address. Later, the exact address is provided centrally for all function block instances of the application in a global variable list including VAR_CONFIG declarations. This global variables list with the VAR_CONFIG declarations is termed the "variables configuration".

NOTICE!
For changes to variables that are assigned to I/O addresses, CODESYS displays them immediately in the process map. For changes to variables that are mapped by a variables configuration, CODESYS displays them not until the end of the responsible task.

Declaration of variables in functions blocks

When declaring variables in a function block, declare the variables between the keywords VAR and END_VAR and assign incomplete addresses to the variables. Mark these incomplete addresses with an asterisk (*).

Syntax:
<identifier> AT %<I|Q>*: <data type>;

Example
Define two local I/O variables: the input variable xLocIn and the output variable xLocOut.

FUNCTION_BLOCK locio
VAR
  xLocIn AT %I*: BOOL := TRUE;
  xLocOut AT %Q*: BOOL;
END_VAR

Final definition of addresses in the variables configuration of the global variables list

In the global variables list that you use as the variables configuration, define the variable declarations with the absolute addresses between the keywords VAR_CONFIG and END_VAR.

You must declare the VAR_CONFIG variables with the complete instance path, separating the individual POU and instance name by a dot (.). The declaration must include an address whose class (input/output) agrees with the class of the incomplete address (%I*, %Q*) in the function block. The data type must also agree.

Syntax:
<instance variable path> AT %<I|Q><location>: <data type>;

If the path instance does not exist, then an error is reported. CODESYS prints an error also if there is not an address configuration available for a variable that you declared with an incomplete address.

Example
The locio function block in the example above is used in a program as follows:

PROGRAM PLC_PRG
VAR
  locioVar1: locio;
  locioVar2: locio;
END_VAR

A correct variables configuration in a global variable list could then look like this:

VAR_CONFIG
  PLC_PRG.locioVar1.xLocIn AT %IX1.0 : BOOL;
  PLC_PRG.locioVar1.xLocOut AT %QX0.0 : BOOL;
  PLC_PRG.locioVar2.xLocIn AT %IX1.0 : BOOL;
  PLC_PRG.locioVar2.xLocOut AT %QX0.3 : BOOL;
END_VAR
Creating a variables configuration

Requirement: You have a project open that includes a controller configuration with a field device. The project contains a program (e.g. PLC_PRG) and a function block (e.g. func1). The field device has inputs and outputs. The textual view is selected in the options for the declaration editor.

1. Double-click a function block in the device tree (e.g. func1).
   ⇒ The function block editor opens.
2. Type the following between the keywords VAR and END_VAR:
   xLocIn AT %I*: BOOL := TRUE;
   and
   XLocOut AT %Q*: BOOL; in the next line.
   ⇒ You have declared an input variable xLocIn and assigned it to the incomplete input address %I* of a field device. You have assigned the declared output variables have to the incomplete output address %Q*.
3. Click the PLC_PRG object in the device tree and add the following to the declaration section of the program between VAR and END_VAR:

   locioVar1: func;
   locioVar2: func;
4. Right-click the “Application” object in the device tree and click “Add Object,” “Global Variable List” and then click “Add” in the “Add Global Variable List” dialog box.
   ⇒ The global variables list is added to the device tree and opens in the editor.
5. Change the keyword VAR_GLOBAL to VAR_CONFIG.
6. Click “Declarations,” “Add All Instance Paths”.
   ⇒ The following instance paths are added:

   PLC_PRG.logioVar1.xLocIn AT %I*;
   PLC_PRG.logioVar2.xLocIn AT %I*;
   PLC_PRG.logioVar1.xLocOut AT %Q*;
   PLC_PRG.logioVar2.xLocOut AT %Q*;
7. Now, replace the incomplete addresses %I* and %Q* with the absolute, complete addresses.

See also
● Chapter 1.3.1.24.2.10 “Configuration variables - VAR_CONFIG” on page 497
● Chapter 1.3.1.9.12.2 “AT declaration” on page 228
● Chapter 1.3.1.24.4.12 “Addresses” on page 566

AT declaration

In the variables declaration, the code AT assigns a project variable to a specific input address, output address, or memory address of the PLC that is configured in the device tree. You can also define the assignment of variables to an address in the “I/O Mapping” dialog of the device in the PLC configuration.

Syntax

<variable name> AT <address> : <data type>;

<address> : %<memory area prefix> ( <size prefix> )? <memory position>
The AT declaration allows you to give the address a meaningful name. You can make any necessary changes for the input or output signals at just one location, for example in the declaration.

### Examples

<table>
<thead>
<tr>
<th>Declaration</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VAR wInput AT %IW0 : WORD; END_VAR</td>
<td>Variable declaration with address information of an input word</td>
</tr>
<tr>
<td>VAR xActuator AT %QW0 : BOOL; END_VAR</td>
<td>Boolean variable declaration</td>
</tr>
<tr>
<td>Note: For Boolean variables, one byte is allocated internally if a single bit address is not specified. A change in the value of <code>xActuator</code> affects the range from <code>QX0.0</code> to <code>QX0.7</code>.</td>
<td></td>
</tr>
<tr>
<td>VAR xSensor AT IX7.5 : BOOL; END_VAR</td>
<td>Boolean variable declaration with explicit specification of a single bit address. On access, only the input bit 7.5 is read.</td>
</tr>
<tr>
<td>VAR xSensor AT IX* : BOOL; END_VAR</td>
<td>For the address specification, the placeholder <code>*</code> is given instead of the memory position. The final address specification is done in the variables configuration.</td>
</tr>
<tr>
<td>Note: This is possible in function blocks.</td>
<td></td>
</tr>
</tbody>
</table>

If you assign a variable to an address, please note the following:

- You cannot write to variables that are placed at inputs. This will cause a compiler error.
- You can perform AT declarations only for local and global variables, not for input/output variables of POUs.
- Furthermore, AT declarations cannot be used in persistent variable lists.
- If you use AT declarations for structure components or function block variables, then all instances use the same memory. This is just like using static variables in classic programming languages, such as C.
- The memory layout of structures also depends on the target system.

---

**NOTICE!**

If you do not specify a single bit address explicitly, then Boolean variables are allocated byte-by-byte.

### Example

```plaintext
PROGRAM PLC_PRG
VAR
  xVar AT %QW0 : BOOL;
END_VAR

xVar := TRUE;
```

When the variable `xVar` is written, the output memory range from `QX0.0` to `QX0.7` is affected.

- § Chapter 1.3.1.24.4.12 “Addresses” on page 566
1.3.1.9.13 Checking syntax and analyzing code

CODESYS provides useful functions for detecting errors and assisting you while you create programs. The syntax check flags errors and prints them to the message view as early as the programming phase.

The static code analysis in CODESYS also assists you in complying with defined coding guidelines and detecting weak constructs.

See also

- Chapter 1.3.1.9.13.1 “Checking syntax” on page 230
- Chapter 1.3.1.9.13.2 “Analyzing code statically” on page 230

Checking syntax

When you input code, the precompile in CODESYS already runs some basic checks. Then, wavy underlines appear under buggy code in the editor and an error message is printed to the messages view.

After programming, you must check the syntax of the application by clicking “Build ➔ Build” or by pressing [F11]. In this step, the compiler checks the program and prints any other errors.

CODESYS automatically generates the application code from the source code that was written in the development system. This is done automatically before downloading the application to the controller. Before the application code is generated, a test is performed for checking the assignments, the data types, and library availability. In addition, the memory addresses are allocated when the application code is generated. You can execute this command explicitly by clicking “Build ➔ Generate Code”. This is useful for detecting any errors in your source code, even when the controller is not connected yet.

CODESYS prints all errors and warnings to the "Build" category of the messages view. Double-clicking the error message opens the respective POU in the editor with the buggy code marked. As an alternative, you can also jump to the buggy code by right-clicking the error message.

Please note the settings for this in the CODESYS options.

See also

- Chapter 1.3.1.25.3.13.11 “Dialog 'Options' - 'SmartCoding’” on page 1082

Analyzing code statically

You can subject your source code also to static analysis (lint) during the code generation. This determines whether or not your source code complies with the coding guidelines that you defined - according to the idea behind the lint analysis tool.

- You activate the rules to the checked in the “Project Settings” dialog in the “Static Analysis Light” category. The check itself is performed automatically each time code is generated, for example when you click “Build ➔ Generate Code”. If divergence from the rules is determined, then it is reported as an error message in the “Build” category of the message view. The reported errors have the prefix SA<number>.

![NOTICE!]

For static code analysis with “Static Analysis Light”, only the application code of the project is checked. Libraries are excluded from the check.

GVL variables in the “POUs” view are not necessarily checked: If you have a project with several applications, then only the objects in the active application are checked. If you have only one application, then the objects in the common POU pool are also checked.
"Static Analysis Light" includes only a reduced set of rules in the default development system. A larger set of rules, additional naming conventions, and metrics are available when you install the CODESYS Static Analysis add-on.

**Deactivating lines of code in the implementations with pragmas from the static analysis**

By means of the pragma `{analysis ...}`, you can mark code so that the specified rules are not checked. As a result, the marked lines of code are not subjected to static analysis. The marked code is ignored during the check.

**Syntax:**

```
{analysis <sign><rule number>|,<other combinations of signs and rules, comma-separated>}
```

- `<rule number>`: Deactivate the rule SA<rule number>.
- `<rule number>`: Activate the rule SA<rule number>.

**Requirement:** Rules are activated in the “Project Settings” dialog.

1. Add the pragma `{analysis -<number>}` above the line of code that contains code not to be checked first of all. For example, for the rule SA0024:
   - The line of code is the first line of the code snippet that is not checked with rule 24.
2. Add the pragma `{analysis -<number>}` below the line of code that contains code not to be checked first of all. For example, for the rule SA0024:
   - The line of code above is the last line of the code snippet that is not checked with rule 24.

**Example:**

**Ignore untyped literal**

```plaintext
{analysis -24)
nTest := 99;
iVar := INT#2;
{analysis +24)
```

The rule “SA0024: Untyped literals only” is deactivated for two lines. An error is not issued although the code does not correct to: `nTest := DINT#99;`

**Example:**

**Ignore several rules**

```plaintext
{analysis -10, -24, -18)
...
{analysis +10, +24, +18)
```

“SA0010: Arrays with only one component”
“SA0018: Unusual bit access”
“SA0024: Untyped literals only”

**However, you cannot deactivate the rule SA0004: “Multiple Write Access on Output” with a pragma.**
Excluding programming objects with pragmas from the static analysis

Syntax:
{attribute 'analysis' := '-<rule number>[,<other negative rule numbers, comma-separated>]'}

When you insert the attribute pragma in the declaration part of a programming object, the specified rules are excluded for the entire programming object. If multiple rules are excluded, then the rules are each comma-separated with a dash and a number. A pragma statement for activation is not required.

Example

{attribute 'analysis' := '-33, -31'}
TYPE LocalData :
STRUCT
  iLocal : INT;
  uiLocal : UINT;
  udiLocal : UDINT;
END_STRUCT
END_TYPE

The rules SA0033 and SA0031 are ignored for the structure LocalData.

{attribute 'analysis' := '-100'}
big: ARRAY[1..10000] OF DWORD;

The rule SA0100 is ignored for the array big.

1.3.1.9.14 Orientation and navigation

Using the cross-reference list to find occurrences

The occurrences of symbols of a variable, a POU (program, function block, function), or a DUT can be displayed in a cross reference list. Then you can jump from the list directly to the corresponding locations in the project.

There are two ways to search for occurrence locations of a symbol:

- Plain text search: You manually specify a text (symbol name, placeholder) in the “Cross Reference List” view.
- Search for a specific declaration:
  - In the “Cross-Reference List” view, you select the declaration from the input assistant.
  - The focus is on a symbol name in the POU editor and you start the cross-reference search from the context menu.
  - The focus is on a symbol name in the POU editor, the “Cross-Reference List” view is open, and the cross-reference search executes automatically.
  - In the “Cross-Reference List” view which already lists occurrence locations for several declarations, you limit these results to a specific declaration.

Cross references with text search by symbol name

Requirement: The “Cross-Reference List” view is open.
1. Specify a string in the field next to the name, for example the identifier of the variable for which you want to find the occurrence location in the project. Example: "iCounter".
   
   For the text search, you can use the asterisk "*" (for any number of characters) or the question mark "?" (for an exact number of characters) combined with a substring of a variable identifier.
   
   Use the percent sign "%" to search for IEC addresses. Examples: "%MW8", "%M?".

2. Click the button to start a text search in the project.
   
   The view "Cross-Reference List" opens and displays the occurrence locations for the iCounter variable. The declaration parts are always displayed in the project with the occurrence location indented.

3. Double-click an occurrence location in the cross-reference list.
   
   The respective object opens in the editor with the marked occurrence location.

Requirement: A POU is open in the editor.

Cross-references for a specific symbol declaration

From the POU editor, with a menu command

1. Set the cursor at the identifier of the symbol (variable, POU) in the declaration part or implementation part.
2. Click “Browse for Symbol ➔ Browse Cross-References” in the context menu or “Edit” menu.
   
   The “Cross-Reference List” view opens and shows the occurrence locations of the variables or POU.

If the “Cross-Reference List” view is already open, then you can also search the occurrence locations for a specific result as follows:

From the POU editor, automatic

Select the “Automatically list selection in cross reference view” check box in “Tools ➔ Options” (“SmartCoding” category). Select the name of the symbol in the POU, or set the cursor in the name.

Depending on the position of the selection or cursor, the cross-reference list automatically shows the occurrence locations for the respective symbol.

In the cross-reference list view, with input assistance

In the “Cross-Reference List” view, use the input assistant 📅 to specify a symbol name in the field next to “By declaration”.

The cross reference list displays the occurrence locations for the symbol.

In the cross-reference list view, limited to a specific declaration

If multiple declarations for a symbol are listed in the “Cross-Reference List” view, for example after a text search, then you can reduce the display to one result: Select the line with the desired declaration and click the button or click “Limit Results to Current Declaration” in the context menu.

The cross-reference list includes only the occurrence locations for the selected declaration.

- Chapter 1.3.1.25.2.2.29 “Command ‘Browse Cross-References’” on page 871
- Chapter 1.3.1.25.3.13.11 “Dialog ‘Options’ - ‘SmartCoding’” on page 1082
Finding declarations

CODESYS provides the capability of searching the entire project for the definition location of a variable or function. The block that includes the definition opens in the editor with the marked declaration.

Finding the declaration of a variable

Requirement: You have opened a POU in the editor.

1. Set the cursor at an identifier in the implementation section.
2. Click “Edit ➔ Browse ➔ Go to Definition”.
   ⇒ The POU with the declaration opens in the editor with the variable definition marked. If the definition is located in a compiled library, then the respective block opens in the library manager.

> You can execute this command in both online and offline mode.

Examples

The following block includes a function block definition (fbinst), a program call (prog_y()), and a function block call (fbinst.out):

```
VAR fbinst:fb1; ivar:INT; END_VAR prog_y(); ivar:=prog_y.y;
res1:=fbinst.out;
```

If the cursor is located at prog_y, then the command opens the program prog_y in the editor.
If the cursor is located at fbinst, then this command focuses in the declaration section at line fbinst:fb1;
If you set the cursor at out, then this command opens the function block fb1 in its editor.

● Chapter 1.3.1.25.2.2.36 “Command ‘Go to Definition’” on page 875

Setting and using bookmarks

Bookmarks are used for easy navigation through long programs. You can use bookmarks in all implementation language editors, except SFC (sequential function chart). Commands help to navigate directly to the marked position in the program.

Setting and deleting bookmarks

Requirement: The POU is open in the editor.

1. Set the cursor at any program line.
2. Click “Edit ➔ Bookmarks ➔ Toggle Bookmark”.
   ⇒ A bookmark is set at this position in the program. This is marked by the bookmark symbol ☐.
3. Set several bookmarks at different places in the program.
4. Set the cursor at a bookmarked program line.
5. Click “Edit ➔ Bookmarks ➔ Toggle Bookmark”.  
⇒ The bookmark is removed. The bookmark symbol □ is deleted.

As an alternative to this, you can delete one or more bookmarks in the “Bookmarks” view by clicking the ✗ button. For this purpose, the corresponding bookmarks have to be selected in the “Bookmarks” view.

```
Click “Edit ➔ Bookmarks ➔ Clear All Bookmarks (Active Editor)” to remove all bookmarks from the active POU.
```

```
In order to delete all bookmarks in a project, click “Clear All Bookmarks”. However, for this command to be available, you first have to add it to a menu by means of the command “Tools ➔ Customize”.
```

- % Chapter 1.3.1.25.2.2.28 “Command ‘Clear All Bookmarks’” on page 871

Jumping to bookmarks within a POU

Requirement: The POU is open in the editor. Multiple bookmarks are set.

1. Click “Edit ➔ Bookmarks ➔ Next Bookmark (Active Editor)”.  
⇒ Depending on the current cursor position, the cursor jumps to the next bookmark (see below).

2. Click “Edit ➔ Bookmarks ➔ Previous Bookmark (Active Editor)”.  
⇒ Depending on the current cursor position, the cursor jumps to the previous bookmark (see above).

See also
- % Chapter 1.3.1.25.2.2.23 “Command ‘Next Bookmark (Active Editor)’” on page 870
- % Chapter 1.3.1.25.2.2.25 “Command ‘Previous Bookmark (Active Editor)’” on page 870

Jumping to bookmarks of different POUs in a project

A project is open with multiple POUs. Multiple bookmarks are set in different POUs.

1. Click “View ➔ Bookmarks”.  
⇒ The “Bookmarks” view opens.

All bookmarks in the project are listed in a table in the view.

2. Click the ✳ “Next Bookmark” button.  
⇒ In the “Bookmarks” view, the bookmark in the row below the selected bookmark is selected.

The POU with the recently selected bookmark in the table opens in the editor and the row with the bookmark is selected in the POU.
3. As in step 2, you can click the ‘Previous Bookmark’ button to jump to the bookmark in the project that is displayed in the row above it in the “Bookmarks” view.

- Chapter 1.3.1.25.2.2.24 “Command 'Next Bookmark’” on page 870

1.3.1.9.15 Searching and replacing in the entire project

In CODESYS you can search for strings in single objects or project-wide. If required, you can replace the string found.

1. Choose the command “Search” in the main menu “Edit ➔ Search Replace”.
   - The dialog “Find” opens.
2. Enter the string to be found in the field “Find what”.
3. Activate the search options
4. Define the objects to be searched by choosing an entry from the combobox “Search”.
5. Click on the button “Find Next”.
   - The first hit is displayed.
6. Click on the button “Replace” to replace the string found by a different one.
7. Click on the button “Find All” to get a list of all hits.

See also
- Chapter 1.3.1.25.2.2.2 “Command 'Find', 'Find in Project’” on page 863
- Chapter 1.3.1.25.2.2.3 “Command 'Replace', 'Replace in Project’” on page 864

1.3.1.9.16 Refactoring

In general, refactoring is a technique for improving the design of existing software code without changing the way it functions.

In CODESYS, refactoring provides functions for renaming objects and variables and updating referenced pins. You can display all occurrences of renamed objects and variables and then rename them all at once or individually. In “Tools ➔ Options”, you can also configure where CODESYS will prompt you for refactoring.

Renaming global variables

Requirement: A project is open that includes at least a function block “FB” and a global variable list. The global variable list “GVL” is open in the editor and contains a variable declaration (example: iGlobal). “FB” uses iGlobal.

1. Select the global variable name iGlobal.
2. Right-click the variable and click “Refactoring ➔ Rename iGlobal”.
3. In the “Rename” dialog, type a name in the “New name” input field, for example iGlobalOK, and click “OK”.
   - The “Refactoring” dialog opens. In the device tree view on the left, the “GVL” and “FB” objects are highlighted in red and yellow. In the view on the right, “FB” in is open in its editor and iGlobal has already been renamed as iGlobalOK.
4. Click “OK”.
   - No global variable iGlobal is in your project. Now iGlobalOK is everywhere.
1. Select the global variable name iGlobal.

2. Right-click the variable and click “Refactoring ➔ Rename iGlobal”.

3. In the “Rename” dialog, type a name in the “New name” input field, for example iGlobalTest, and click “OK”.
   ⇒ The “Refactoring” dialog opens. In the device tree view on the left, the “GVL” and “FB” objects are highlighted in red and yellow. In the window on the right, the function block “FB” is open in its editor. iGlobalTest is listed instead of iGlobal.

4. Right-click in the view on the right.

5. Click “Reject this Object” and click “OK”.
   ⇒ The global variable iGlobal is available in “FB” in your project. The variable iGlobalTest is now specified in the objects where the previous variable occurred.

In the declaration part of blocks, you can add and delete input and output variables by using the refactoring commands. CODESYS performs updates at the occurrence locations and calling locations of the blocks. You can accept or reject these updates individually. The “Refactoring” dialog also opens for this purpose.

Requirement: The FCT (function type) POU is open in the editor. The function already contains the input variables input1, input2, and inputx. They are called in the PLC_PRG and POU programs.

1. Set the focus in the declaration part of the FCT function.

2. Click “Refactoring ➔ Add Variable”.
   ⇒ The default dialog opens for declaring variables.

3. Declare the variable input_3 with the scope of VAR_INPUT and data type INT. Click “OK” to close the dialog.
   ⇒ The “Refactoring” dialog opens (see figure below). The affected locations are marked in yellow. (1)+(2)

4. In the upper right corner, select “Add inputs with placeholder text” from the drop-down list. (3).

5. In the left side of the window, click one of the highlighted objects (for example, PLC_PRG). Right-click and choose the “Accept Whole Project” command to add the new variable at the new location of use in FCT for the entire project.
   ⇒ You see the change in the implementation part of PLC_PRG in the view on the right: The placeholder _REFACTOR_ appears at the location where the new variable was added.

6. Click “OK” to close the “Refactoring” dialog.

7. Click “Edit ➔ Find”. Search the project for “_REFACTOR_” to check and edit the affected locations.

8. Note: As an alternative, you can insert the new variable with another initialization value without working with a placeholder first. In this case, in Step 4 you select “Add inputs with the following value” and type the value in the field on the right side of the drop-down list.
Example of a new variable with placeholder text in a CFC block:

Please note that you can also remove variables with refactoring.

**Reordering variables in the declaration**

In the declaration part of function blocks, you can change the order of declarations by refactoring. This is possible for declarations with scope `VAR_INPUT`, `VAR_OUTPUT`, or `VAR_IN_OUT`.

**Requirement:** The declaration part of a POU is open and includes declarations, for example:

```plaintext
VAR_INPUT
  invar2 : INT;
  invar1 : INT;
  in : DUT;
  bvar : BOOL;
  invar3 : INT;
END_VAR
```

1. Right-click in this declaration block to access the context menu.
2. Click “Refactoring ➔ Reorder Variables”.
   - The “Reorder” dialog opens with a list of `VAR_INPUT` variables.
3. Drag the "invar1 : INT;" entry to the position before the "invar2." entry.
   ⇒ The invar1 declaration is now at the top position.
4. Click “OK” to close the dialog.
   ⇒ The “Refactoring” dialog opens. The affected locations are marked in yellow (see figure above).
5. Click “OK” to accept the new order for the function block.

Changing a variable declaration and applying refactoring automatically

Refactoring helps you in the declaration when renaming variables (by means of "Auto declare").

- Requirement: Function block fb_A.
  1. Click “Tools ➔ Options”.
     ⇒ The “Options” dialog opens.
  2. Select the “Refactoring” category.
  3. In “Auto-Declare”, activate the options “On renaming variables” and “On adding or removing variables, or for changing the namespace”.
  4. Double-click the function block fb_A.
  5. Select a variable in the declaration of fb_A, for example iA. As an alternative, you can set the cursor before or in the variable.
  6. Specify “Edit ➔ Declare variable” ([Shift]+[F2]).
     ⇒ The “Declare Variable” dialog opens. The dialog includes the settings of iA.
  7. Change the name of iA to iCounter_A.
  8. The option “Changes by means of refactoring” appears and is activated.
  9. Click “OK”.
     ⇒ The dialog “Refactoring” “Renaming from iA to iCounter_A” opens. All locations affected by the variable renaming are marked there.
10. Click “OK” to close the dialog.
     ⇒ The changes are applied.

1.3.1.9.17 Task configuration

In the task configuration, you define one or more tasks for controlling and executing the application program in the controller. Each application must include a “Task Configuration” object.

A task is a time-based flow unit of an IEC program. You define a task with a name, a priority, and a type, which determines which condition triggers the start of the task. You can define this condition either by time (cyclic-interval, freewheeling) or by the occurrence of an internal or external event to process the task. Examples of an event are the rising edge of a global project variable or an interrupt event of the controller.
A task calls one or more program blocks (POUs). These programs can be application-specific (objects below the application in the device tree) or project-specific (objects available in the POU window). In the case of a project-specific program, the application instances the project-global program. If CODESYS processes the task in the current cycle, then the programs are executed for the duration of a cycle.

With the combination of priority and condition, you define the order in which the tasks are processed. You can configure a watchdog for each task, and you can link a start, stop, and reset directly to the execution of the project block.

Rules for the processing order of the defined tasks:

- If the task condition is satisfied, then CODESYS processes the task.
- If several tasks satisfy the condition for processing at the same time, then CODESYS processes the tasks with the highest priority first.
- If several tasks with the same priority level satisfy the condition for processing at the same time, then CODESYS processes the longest waiting task first.
- The program calls are processed in the order they appear in the configuration dialog of the task.
- If a called program has the same name in the device tree of the application and in a library or project-global in the POU window, then the application program is used.

Attention

All tasks share one process map. The reason is as follows: When each task has its own individual process map, performance is compromised. However, the process map can be consistent only with one task. When you create a project, you must ensure that the application copies the input and output data to a safe location in case of conflicts. Modules, such as the library SysSem, provide the capability of solving consistency and synchronization problems.

Consistency problems can also occur when accessing other global objects, such as global variables or blocks. Consistency problems always occur if several tasks read and write to one variable. Modules, such as the library SysSem, are available as a solution.

Creating a task configuration

Requirement: The open project includes a program-type POU and a “Task Configuration” with a “Task” object has been inserted below “Application” in the device tree.

1. Double-click the task object below “Task Configuration” in the device tree.
   - The “Configuration” tab of the task object opens.
2. In the “Type” dropdown list., click “Cyclic”.
   - The “Interval (e.g. t#200ms)” input field appears.
3. Enter t#300ms in the “Interval (e.g. t#200ms)” input field.
4. Click “Add Call”.
   - The Input Assistant opens.
5. In “Input Assistant ➔ Categories” ➔ “Programs”, click the desired POU and then click “OK”.
   - CODESYS inserts the selected POU into the POU list of the “Configuration” tab and below the task object in the device tree.
   - When the application is executed from the controller, CODESYS executes the selected POU in cyclical intervals of 300 ms.

- Chapter 1.3.1.25.1.38.1 “Tab 'Configuration’” on page 839
Multicore

Object: “Task Configuration”

More and more of today's controllers have processors with multiple CPU cores. In order to take advantage of this for the IEC program and improve performance, CODESYS provides options for distributing the IEC tasks over these CPU cores. In order to benefit from a multicore processor as well, the IEC program has to be distributed into multiple tasks.

There are two basic different strategies in CODESYS for distributing IEC tasks over CPU cores:

- Fixed linking of an IEC task to a CPU core:
  The task is always executed on this specific CPU core. In this case, multiple tasks can also be bundled to one and the same CPU core if the IEC program is not yet able to be executed on multiple CPU cores at the same time.

- The IEC task is executed on all CPU cores:
  The operating system takes control of distributing the task on the CPU cores.

**NOTICE!**

When the IEC tasks are distributed over CPU cores, some changes result in the behavior in the IEC program, which have to be considered:

- The processing of IEC tasks by priority is no longer a given. They are processed by priority only if the tasks are bundled together to one CPU core.
- The cycle consistency of the data in the IEC task with the highest priority is no longer a given. Therefore, the data has to be copied locally at the beginning of the IEC task cycle if the values should not change during the cycle.
- For consistent counters (incrementer, decrementer), the atomic external library function `SysCpuAtomicAdd()` should always be used (for more details, see `SysCpuHandling.library`).

**NOTICE!**

Data consistency

- Bit access (data type `BIT`) is not processed consistently on marker CPUs in the IEC program. For this we recommend that you use the external library function `SysCpuTestAndSetBit()` (for more details, see `SysCpuHandling.library`).
- Simple data types up to a width of 32 bits (`BIT, BYTE, WORD/INT, DWORD/DINT, etc.`) are processed consistently in the IEC program on marker CPUs as well.
- Data types with 64 bits (`LINT, LWORD, LREAL`) are processed consistently in the IEC program on marker CPUs only. You do not have to do anything explicit in this case.
- To access complex data types (`STRINGs, FBs, STRUCTs, ARRAYs`), you have to make arrangements yourself for the synchronization/consistency.
- In the task configuration in the “Variable Usage” tab, you can define whether a date in IEC has read or write access.
- On multicore systems, a memory reordering effect can occur. For more information, see `__MemoryBarrier()` IEC-Operator.

- ¶ “Multicore operators” on page 509
Distributing tasks over multiple processor cores

Requirement: At least two tasks are defined in your application, for example “MainTask (IEC task)” and “LowTask (IEC task)”.

1. Open the “Task Configuration” object in the editor.
2. Switch to the “Task Groups” tab.
   - The overview shows a “IEC-Tasks” task group.
3. Add a new task group by clicking the “Add Group” button.
   - The group “NewGroup” is added.
4. Double-click the group name “NewGroup” and change it to “LowGroup”.
5. Select an assignment in “Core”, for example “1”.
6. Open the task “LowTask (IEC task)” in the editor.
7. Select the new group “LowGroup” in “Task Group”.
   - The task “LowTask” is processed now by processor core 1 due to its group membership in “LowGroup”.

See also
- Chapter 1.3.1.25.1.37.5 “Tab ‘Task Groups’” on page 838
- Chapter 1.3.1.25.1.38.1 “Tab ‘Configuration’” on page 839

Display the processor load in the trace for each processor core

In CODESYS, you can visualize the processor load in a “DeviceTrace” object. For more information, refer to the following help section about displaying device traces in the project:

See also
- Chapter 1.3.1.13.3.4 “Accessing all traces on the controller” on page 342

1.3.1.9.18 Encrypting an application

You achieve the know-how protection and copy protection of a boot application with the help of PLC-specific license management and its settings in the object properties of the application. In this case, the download code and boot application are encrypted.

Encryption with a dongle

Requirements: You have a project with an application that you want to download to the controller as an encrypted boot application. A security key for license management is connected to your computer.

1. Select the application in the device tree.
2. Select the “Properties” command in the context menu.
   - The “Properties - <application name>” dialog opens.
3. Click the “Encryption” tab.
4. For “Encryption Technology”, select the “Simple Encryption” option and type the “Product Code” that you received from the hardware manufacturer for the controller. Depending on the controller, it is protected either by a security key (firmcode is shown automatically) or by an integrated Wibu SD card for example.
5. Click “Online ➔ Login” and download the application.
   - If the matching security key and/or valid license is available, then you can download the application to the controller. By default, a boot application is automatically created at this time in the controller directory. The default setting is defined in the application “Properties”, in the “Boot Application” category.
6. Logout, change the application, and login again.
   ⇒ You are prompted to perform an online change. The dialog provides the option of
   updating the boot application on the PLC. If the security key and license match, then
   you can log in. If not, then you receive a corresponding message.

**Encrypting with certificates**

Requirements: You have a project with an application that you want to download to the con-
troller as an encrypted boot application. In the Windows Certificate Store of your computer, you
have a certificate of this controller for encrypting the application. Note: In case you want to
download the application to different controllers, you will need the appropriate certificate for
each controller.

1. Select the application in the device tree.
2. Select the “Properties” command in the context menu.
   ⇒ The “Properties - <application name>” dialog opens.
3. Click the “Encryption” tab.
   ⇒ The “Certificates” group is enabled.
5. If there are not any certificates listed in the table, then click the button.
   ⇒ The “Certificate Selection” dialog opens for selecting a certificate from the local Win-
dows Certificate Store.
6. In the lower area, select a certificate and add it to the upper area by clicking the button,
   Click “OK” to confirm.
   ⇒ The certificate is shown in the “Certificates” group of the “Encryption” dialog.
7. Select the certificate and click “Apply” or “OK”.
   ⇒ The certificate is now used to encrypt the application. It can only be transferred to the
   controller on computers that have an corresponding key installed in the Windows Cer-
tificate Store.

**Signing a boot application**

1. Click in the status bar of CODESYS to open the “Security Screen” view. Then select a
   certificate with a private key for a user profile for the “Digital signature”. The procedure is
described in the instructions "Configuring a certificate for the digital signature in a user
profile".
2. Double-click the certificate for the “Digital signature” in the “User” tab.
   ⇒ The “Certificate” dialog opens.
3. On the “Details” tab, click “Copy to file”.
   ⇒ The “Certificate Export Wizard” starts.
4. In the “Export Private Key” prompt, select the “No, do not export the private key” option.
5. For “Export File Format”, select the “DER encoded binary X.509 (.CER)” option.
6. In the next step, select a file name and the location for the certificate.
7. After the last step “Finish”, a message appears that the export was successful.
8. After successful export to CODESYS, open the device editor by double-clicking the controller in the device tree and selecting the “Files” tab for the file transfer.

9. Select the “Path” cert/import in the right side of the “Runtime” dialog.

10. On the left side of the dialog for “Host”, select the path in the file system where you saved the exported certificate and selected the certificate.

11. Click ➤. The certificate is copied to the cert/import folder.

12. Click the “PLC Shell” tab.

13. Type the command cert-import trusted <file name of the certificate.cer> in the input line of the tab and press the [Enter] key. Note that the file name is specified with the extension .cer; otherwise the certificate is not imported successfully.
   ➤ The certificate is created on the controller under trusted. With this certificate, the controller can test the integrity of the boot application.

14. Open the “Security Screen” by double-clicking ✨ in the status bar.

15. If you want that downloads, online changes, and boot applications of your project are always encrypted, then select the “Enforce signing of downloads, online changes and boot applications” option in the “Security level” group on the “User” tab. To do this, the “Enforce encryption of downloads, online changes and boot applications” option also has to be selected.

- “Encryption, signature” on page 421
- Chapter 1.3.1.25.2.3.18 “Command ‘Security Screen’” on page 891
- Chapter 1.3.1.25.3.10.3 “Dialog ‘Properties’ - ‘Encryption’” on page 1047

Encryption the download, online change, and boot application

Requirement: The CODESYS Security Agent add-on product is installed.

The “Security Screen” view provides an additional tab: “Devices”. This allows for the configuration of certificates for the encrypted communication with controllers. In this case, see the help for CODESYS Security Agent.

Alternatives:

If you the CODESYS Security Agent is not available to you, then you can proceed as follows by means of the PLC shell of the device editor:

In order to use certificates on the controller for the encryption of downloads, online changes, and boot applications, these certificates first have to be generated on the controller and loaded from the controller and installed in the Windows Certificate Store.

- Requirement: You are connected to the controller.

1. Open the device editor by double-clicking the controller in the device tree, and select the “PLC Shell” tab.
   ➤ The tab appears with a blank display window. Below that is a command line.

2. Type ? in the command line and press the [Enter] key.
   ➤ All commands are listed in the display window.

3. Type the following command in the command line: cert-getapplist.
   ➤ All used certificates are listed with information about components and availability with certificates.

4. If no certificate is available for the CmpApp component, then type the command cert-genselfsigned <Number of the Component in the applist>.
5. Click the “Log” tab and then the refresh button ( הראשי).
   ➤ The display shows whether or not the certificate was generated successfully.

6. Type in `cert-getcertlist` and press the [Enter] key.
   ➤ Your own certificates are listed that can be used for encryption. The information
     Number and Key usage(s) are useful in the next step.
     Number: The number is specified as a parameter in the next step.
     Key usage(s): Data encryption means that this is a certificate of the controller
     for a download, online change, and boot application.

7. Export the required certificate by typing in the command `cert-export own 0` and press
   the [Enter] key.
   ➤ The display shows that the certificate has been exported to a cert directory.

8. Click the “Files” tab of the device editor.

9. Click the refresh button ( הראשי) in the right part of the dialog in “Runtime”.
   ➤ The list of files and directories is refreshed.

10. Open the “cert” folder in the list and then the “export” subfolder.

11. In the left part of the dialog in “Host”, open the directory where the certificate of the con-
    troller will be loaded.

12. In the right part of the dialog, select the certificate that you have exported and click
    ➤ The certificate is copied to the selected directory.

13. In the file explorer, go to the directory where the certificate was copied and double-click
    the certificate.
   ➤ The “Certificate” dialog opens and shows the information about this certificate.

14. On the “General” tab, click “Install Certificate”.
   ➤ The “Certificate Import Wizard” starts.

15. In the “Certificate Storage” dialog, for “Certificate Import Wizard”, select the “Store all
certificates in the following store” option and then select the “Controller Certificates” folder.
   ➤ The controller certificate is imported into the Windows Certificate Store in the
   “Controller Certificates” folder. Now the certificate is available for the encryption of
   boot applications, downloads, and online changes.

16. Open the “Security Screen” by double-clicking in the status bar.

17. If you want that downloads, online changes, and boot applications of your project are
    always encrypted, then select the “Enforce encryption of downloads, online changes and
    boot applications” option in the “Security level” group on the “User” tab.

18. Open the “Project” tab and double-click the application in the “Encryption of boot
application, download and online change” area.
   ➤ The properties dialog of the application opens.

19. Click the “Encryption” tab, select “Encryption with certificates” in the “Encryption
technology” list box, and click
   If the “Enforce encryption of downloads, online changes and boot applications” option
   is selected in the “Security Screen”, then “Encryption with certificates” is already selected.

20. In the “Certificate Selection” dialog, select the respective certificate from the “Controller
    Certificates” folder and click

21. Click “OK” to confirm the dialog.
   ➤ The certificate is displayed in the properties dialog.
22. Confirm the properties dialog of the application.
   ⇒ The certificate is shown on the “Project” tab of the “Security Screen” in the “Encryption of boot application, download and online change” group.
   The boot application, download, and online change are encrypted.

- Chapter 1.3.1.25.2.3.18 “Command ‘Security Screen’” on page 891

Deleting a certificate for the encryption of boot application, download and, online change

Requirement: The CODESYS Security Agent add-on product is installed. A certificate with the information “Encrypted Application” is already installed on your computer.

1. In the “Security Screen” view, on the “Project” tab, in the bottom view, click the entry for the application.
   ⇒ The “Properties” dialog for the application opens with the “Encryption” tab.
2. For “Encryption Technology”, select “Encryption with certificates”. In the “Certificates” group, click .
3. In the “Certificate Selection” dialog, delete the certificate as described above.
4. Click “OK” to close the “Certificate Selection” dialog.
   ⇒ The certificate is no longer displayed in the “Properties” dialog.

1.3.1.9.19 Unit conversion

You define a conversion rule when you want to convert data for another system of units. This data is executed for a specific order of magnitude and unit of measure.

Conversion rules are defined in a “Unit Conversion” object. CODESYS automatically implements each conversion rule as a function block <name>_Impl and instances it as <name>.
Each conversion rule includes Convert and Reverse methods for use as function blocks.
Locations where you access a variable, you can link the variable to a conversion rule. The input assistant provides conversion rules in the “Function Blocks” and “Instance Calls” categories.
After execution, the result is a converted value according to the conversion rule.
In a visualization, an IEC variable that is configured in an element property can also be linked to a conversion rules.

Defining unit conversions

1. Double-click a “Unit conversion” object in the device tree.
   ⇒ The respective editor opens with a table of the defined conversion rules. You edit a rule in “Type setting” and a respective condition in “Condition setting”.

246
3ADR010583, 1, en_US
2020/12/10
2. Double-click the “Add new entry” field and type a name.
   ⇒ CODESYS implements the <name>_Impl function block and instances it as <name>.
3. Double-click the “Type” field and click a type from the drop-down list.
   ⇒ Input fields are displayed below the table for editing the conversion rule. The input fields vary according to selected type.
4. Change the conversion rule in the input fields.
   ⇒ The changes are displayed in the “Setting” category of the table.
5. Double-click the “Condition” field and click a condition type from the drop-down list.
   ⇒ Input fields are displayed below the “Condition Setting” category of the table to edit the condition. The input fields vary according to selected type.
6. Edit the condition.
   ⇒ The changes are displayed in the “Condition Setting” category of the table.

**Defining switchable unit conversions**

You can define which conversion rule is applied to a specific language or condition.

1. Double-click a “Unit Conversion” object in the device tree.
   ⇒ The respective editor opens with a table of the predefined conversion rules.
2. Click the “Add new entry” field and type a name.
   ⇒ Example: Conv_A_LanguageDependent
3. Double-click the “Type” field and click “Switchable conversion”. Double-click the “Condition” field and click “Language”.
   ⇒ Below the main table, the “Switchable Conversion” table is displayed with “Condition setting”.
4. In the “Switchable Conversion” table, double-click a predefined conversion rule from the drop-down list in the “Switchable conversion name” column, for example Conv_AInInch. In “Condition Setting”, type a value in the “For condition 'Language'” input field, for example en.
   ⇒ CODESYS executes the Conv_AInInch conversion rule only if the language set in the visualization manager is “en”.
5. In the “Switchable Conversion” table, double-click a predefined conversion rule from the drop-down list in the “Switchable conversion name” column, for example Conv_AInMM. In “Condition Setting”, type a value in the “For condition 'Language'” input field, for example de.
   ⇒ CODESYS executes the Conv_AInMM conversion rule only if the language set in the visualization manager is “de”.
6. Apply the Conv_A_LanguageDependent conversion rule in the application or visualization.
   ⇒ If the set language in the visualization is English, then the application visualization applies the Conv_AInInch conversion rule. If the set language in the visualization is German, then the application visualization applies the Conv_AInMM conversion rule. The current visualization language is located in the VisuElems.CurrentLanguage variable.

**Applying conversion rules**

Add a conversion rule to objects that access IEC variables.
1. In the device tree, double-click an object that accesses IEC variables in order to link an IEC variable to a conversion rule at that location.

2. Declare a variable for the conversion result of the IEC variable.

   ST sample code: rConvertedA : REAL;

3. Use the input assistant to apply the conversion rule with the `Convert` method and then assign the result to the variable.

   ST sample code to link the IEC variable to the conversion rule: rConvertedA := ConvRule_A.Convert(rA);

Applying reverse conversion rules

1. In the device tree, double-click an object that accesses an IEC variable.

2. Declare a variable for the result of the conversion rule.

   ST sample code: rReverseA: REAL;

3. Apply the reverse conversion rule with the `Reverse` method and then assign the result to the variable.

   rReverseA := ConvRule_A.Reverse(rConvertedA);

Example

Requirement: The conversion rule is Conv_XtoY.

ST call

```st
PROGRAM A_PRG
VAR
  rA : REAL;
  rConvertedA : REAL;
  rReverseToA : REAL;
END_VAR
rConvertedA := Conv_XtoY.Convert(rA);
rReverseToA := Conv_XtoY.Reverse(rConvertedA);
```

CFC call

In the CFC editor, define the instance name of the conversion rule via the block. Select the method in the block.

1.3.1.20 Data persistence

The lifespan of a variable and its data begins at the time when the variable is created and ends
at the time when the variable is deleted and its memory is freed. The time when the variable is
created, initialized, or instantiated depends on the declared scope. The time when the memory
is freed usually depends on the scope as well. For example, the memory of global variables is
freed by exiting the application.

They can retain data longer than usual. The following mechanisms are provided for this pur-
pose.

Mechanisms for data retention

- (A): Persistent global variable list with the keyword PERSISTENT RETAIN
  Persistent variables retain their values when the application is reloaded. Moreover, the
  values are restored after a download, warm start, or cold start.
- (B): Retain variables with the keyword RETAIN
  Retain variables retain their values after a warm start, but not after reloading the application,
  a download, or a cold start.
- (C): Variables of the Persistence Manager of the CODESYS Application Composer
  Variables of the Persistence Manager are stored in an external file.
- (D): Recipe variables
  Recipe variables and their values are stored in a recipe file.

Mechanisms in comparison

Which mechanism is suitable for which application? Some common use cases are considered
in the table. The specific examples refer to a building control system.
<table>
<thead>
<tr>
<th>Uses case</th>
<th>(A) Persistent variables</th>
<th>(B) Retain variables</th>
<th>(C) Variables of the Persistence Manager</th>
<th>(D) Recipe variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The application must maintain device settings. Example: After a power failure, the building control has to have information available about how long a window blind needs to be raised.</td>
<td>Suitable(^1) Preferred use case In this case, you can also use retain variables instead of persistent variables. This is advantageous for variables whose declaration is often changed.</td>
<td>Suitable Preferred use case Retain variables are an advantage when their declarations are changed often.</td>
<td>Suitable(^2) This is advantageous for controllers that do not have any hardware support. Special functionalities make this possible, such as double file buffering.</td>
</tr>
<tr>
<td>2</td>
<td>The application must maintain values also after program changes or extensions.</td>
<td>Suitable(^1) Preferred use case</td>
<td>Suitable</td>
<td>Suitable(^2) Possible, but complicated.</td>
</tr>
<tr>
<td>2a: Rare extensions Example: An application programmer extends the program with a new switch and installs a new light. The building control must still have saved values available until then.</td>
<td>Suitable</td>
<td>Suitable</td>
<td>Suitable(^2) Possible, but complicated.</td>
<td></td>
</tr>
<tr>
<td>2b: Unrestricted changes, including deleting or changing the data type of variables The building control is running and is persistent. When an application programmer adds a new functionality to the controller and therefore adds another persistent variable to a function block, the values saved up to that point must be retained. For example, the program in an FB is extended with a variable that controls the automatic switching off of a previously uncontrolled lamp after a certain time. The building control must have the times of all controlled lamps available after the extension.</td>
<td>Not suitable</td>
<td>Suitable Data from retain variables are preserved as far as possible after an online change.</td>
<td>Suitable as far as possible(^2) Preferred use case</td>
<td></td>
</tr>
<tr>

<td>Suitable^3</td>
</tr>
<tr>
<td>The user must be able to read, compare, and edit the data.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1 Disadvantage: Only possible if the runtime system supports this mechanism and an NVRAM memory or UPS is available. Advantage: Speed; recommended application: 1 and 2a

2 Disadvantage: In the case of large variable sets (> 10000), long delays during initialization and shutdown are to be expected. Advantage: No special memory is required; value retention exists even in case of changes, extensions, or deletions.

3 Advantage: Editable remotely, transferable. Disadvantage: Complicated

- ≈ Chapter 1.3.1.25.2.6.11 “Command ‘Reset Origin’” on page 932
Lifespan of variables when downloading a boot project

The values of ordinary variables lose their value and are reinitialized.

The values of persistent variables are protected when:

- The structure of the persistent variable in memory matches the structure in the persistent data list.

The values of retain variables are protected when:

- The structure of the persistent variable in memory matches the structure in the persistent data list.
- The persistent variables match the application (GUID has to agree).

A "Retain mismatch" occurs when the requirements for restoring the values of retain variables and persistent variables are not met when the application is booted. The response to this discrepancy is described in the documentation of the hardware manufacturer.

Note: For the structure of persistent data, refer to the information in "Mechanism for downloading".

See also

- “Mechanism for downloading” on page 252

Preserving data with persistent variables

Persistent variables retain their values after reloading the application, and after a download, warm start, or cold start.

A special non-volatile memory area on the controller, for example as NVRAM or UPS, is required to extend the lifespan. Securing the data in such a memory does not require any additional time, which is an advantage over data retention with the Persistence Manager. If the controller does not provide hardware support, then the data is usually stored in a file. Then the data will be retained if you shut down the controller correctly. In the event of a power failure or a pulled plug, however, data will be lost.

Behavior

Value retained for

- Uncontrolled exit
- Warm start by calling the "Reset Warm" command
- Cold start by calling the "Reset Cold" command
- Repeated download of the application

Reinitialization for

- Call of the "Reset Origin" command

Therefore, persistent variables are reinitialized only if you reset the controller to the factory settings (for example, when you click “Online ➔ Reset Origin”).

If, on the other hand, you download the application again, the persisted data is retained if possible. That depends on how profound the changes that led to the download were. Changing the application name always leads to a full reinitialization. Changes to the implementations never lead to a reinitialization: the data persistence is completely preserved. Changes to the declarations lead to an initialization of the new variables only if the existing variables are persistent, when you change the declarations so that the persistent variable list remains consistent. This is the case when you add a new variable or delete an existing one. Inconsistencies can occur if you edit and change the identifiers or data types of previously declared persistent variables.

Mechanism for downloading

Editing the variable list in the persistence editor causes the variable list to be edited automatically before it is saved, not to be saved as it is shown in the editor.
During post-processing, a variable that you have removed is replaced by a placeholder variable with the same memory requirement. As a result, the subsequent variables retain their addresses in the process image. Moreover, a variable you add is moved to the end of the list. Post-processing can neutralize changes that would lead to a loss of persistence. But you create gaps that use additional memory.

When downloading, the CRC value of the variable list and the length of the list (number of variables) are stored on the controller. When downloading again, the new test value is compared with the test value currently on the controller. Then the variable list is compared successively up to the specified length. If you have edited a declaration (for example, the name or data type), then the variable is reinitialized. Otherwise its value is retained. When the download is repeated, CODESYS checks whether the variable list declared in the persistence editor is still consistent with the variable list already on the controller.

The mechanism works well when the variables themselves are not modified significantly. Too extensive changes of the identifiers and the data types continue to lead to a reinitialization and the loss of persistence. If you anticipate frequent changes due to your application requirements, then this kind of a list is not recommended. Moreover, in an online change after a data type change, a persistent variable is less robust than a variable with a normal lifespan.

It is good practice to clear any gaps in the variable list after a while (command “Reorder List and Clear Gaps”). After cleaning, however, the list no longer matches the list on the controller and you have triggered an initialization of all persistent variables. The persistence of all variables is lost.

For versions before V3.5 SP1, changes in the persistence editor always lead to reinitialization.

Recovering data with the recipe manager

To clean up the global persistent variable list without losing persistence, you can save the data in a recipe using the Recipe Manager. This creates a list for all variables of the persistent variable list in the recipe manager, and at the same time its current values are stored by the controller as a recipe. Then execute the command “Reorder List and Clear Gaps” and perform a download again. Now when you execute the command “Restore Values from Recipe”, the values saved in the recipe are restored.

Changing an existing declaration in the persistent variable list

If you change the name or data type of a variable, this is interpreted as a new declaration and causes a re-initialization of the variables at the next online change or download. For complex data types, a change occurs when a new component is added, or when you change the type of a variable from INT to UINT in the depth of a used structure used, for example.

Basically, complex user-defined data types are not suitable for administration in a persistent variable list, because even small changes cause the variable to be initialized with all components.

Double allocation of memory in the case of instance paths

You can persist global variables or variables declared locally in a function block or program. To do this, add the keyword PERSISTENT to the declaration. In addition, you insert the instance path to this variable in the persistent global variable list. To do this, execute the “Add All Instance Paths” command in the persistence editor.

Persistence is guaranteed by the following mechanism:

- The cyclic tasks in which the variable is accessed are determined.
- At the end of the first cyclic task (in each cycle), the variable is copied to the persistent global variable list.
- After restarting the controller, the value of the persistent variable is copied to the ordinary variable.
The disadvantage of this mechanism is that memory is allocated both at the place of declaration and at the place of the instance path. This persistent variable has a double memory allocation. Moreover, the data is copied to both places in each cycle. This can be time consuming, especially when large structured values are involved.

**Memory location in the case of persistent function block instances**

A function block instance is always stored completely in memory. This is necessary so that the same code can work on different instances. If only one variable in a function block is marked with PERSISTENT, then the function block instance is stored completely with all variables in remanent memory, although only the one variable is treated as persistent. However, non-volatile memory is not available to the same extent as main memory.

A function block with a pointer to an instance in SRAM as a variable is not stored in the protected memory.

**Importing from CoDeSys V2.3 projects**

When you open a CoDeSys V2.3 project to import it into CODESYS V3, the declarations of persistent variables are not preserved. You have to revise the declarations and create them again in a separate persistent global variable list.

See also

- § Chapter 1.3.1.24.2.12 “Persistent variable - PERSISTENT” on page 498
- § Chapter 1.3.1.25.2.17.4 “Command ‘Add all instance paths”’ on page 1012
- § Chapter 1.3.1.3.5 “Opening a V2.3 project” on page 128

**Preserving data with retain variables**

Retain variables preserve their values after a warm start. However, the degree of value retention for persistent variables is higher.

A special non-volatile memory area on the controller, for example as NVRAM or UPS, is required to extend the lifespan. Securing the retain variables in such a memory does not require any additional time, which is an advantage over data retention with the Persistence Manager. If the controller does not provide hardware support, then the data is usually stored in a file. Then the data will be retained if you shut down the controller correctly. In the event of a power failure or a pulled plug, however, data will be lost.

**Declaration**

To declare a retain variable, add the RETAIN keyword to a variable declaration.

**Behavior**

Value retained for

- Uncontrolled exit
- Call of the "Reset Warm" command

Reinitialization for

- Repeated download of the application
- Call of the "Reset Cold" command (in contrast to persistent variables)
- Call of the "Reset Origin" command

When you restart an application, its variables are usually initialized with an explicitly preset initial value or with a default value. Variables marked with the RETAIN keyword are managed in a separate memory area depending on the target system and retain their value. Then the variables are protected from power failure, for example. This means that you can apply retain variables to a parts counter in a production line so that you can continue counting even after a power failure.
Function block instances are stored as one block in memory. This is necessary so that the same code can work on different instances. If a variable is marked with `RETAIN` in a function block, then each instance of the function block is protected with all variables. This is also true for the variables of the function block that are not marked this way. However, non-volatile memory is not available to the same extent as main memory.

A function block with a pointer to an instance in SRAM as a variable is not stored in the protected memory.

When you open a CoDeSys V2.3 project to import it into CODESYS V3, the declarations of retain variables are preserved and remain effective as before.

See also
- Chapter 1.3.1.24.2.13 “Retain variable - RETAIN” on page 500
- Chapter 1.3.1.3.5 “Opening a V2.3 project” on page 128

Persistent variables are managed in the Persistence Manager of the CODESYS Application Composer. The functionality of the “Persistence Manager” does not need any special memory on the controller in order to preserve values and data.

In the declarations, the variables managed in the Persistence Manager are marked with the pragma `{attribute 'ac_persist'}`.

The pragma makes sure that the variable with this attribute is managed in the Persistence Manager of the Application Composer. The variable value is retained even if you change the declaration of the variable, delete a variable from the application, or add a new one. The value is retained even if you change the data type and use the appropriate conversions.

The variables of the Persistence Manager are stored with their values in an external archive file in TXT format.

The application code is extended with the code of the Persistence Manager, which leads to a greater memory requirement. This is at the expense of performance. Moreover, reading and especially writing a large number of persistent variables can take a long time. As a result, the executing task also blocks the execution for a long time.

- You can load and edit the TXT file in an external editor such as Notepad++.
- You can use the persistent variables of the file in another application.
- You can configure the behavior of persistent variables by defining persistence groups, assigning variables to them, and configuring the groups with their own save and read behavior.

See also
- Persistence Manager

Variables are managed persistently in the Recipe Manager. The Recipe Manager does not need any special memory on the controller in order to preserve values and data.
Declaration

A recipe definition consists of a set of variables with values and is created and edited in the "Recipe Manager" object and saved to a file.

Functionality

- You can include a variable in multiple recipes, each with different values.
- In online mode, you can read in the actual values of the variables from the controller and save them as recipe values (specified value).
- You can use the Recipe Management library to programmatically implement the creation and editing of a recipe.
- You can save and backup a recipe as a recipe file.

Declaring VAR PERSISTENT variables

Below you will declare persistent variables in a persistent variable list and in a POU.

Requirement: A project is opened and contains a program POU. You have enabled the option for the textual view in the "Declaration Editor" category of the options (menu command “Tools ➔ Options”).

1. Add the “Persistent Variables” object to the application object with the menu command “Project ➔ Add Object”.

   ⇒ CODESYS adds the persistent variable list “PersistentVars” below the application object in the device tree and the editor opens.

2. In the editor, enter a variable declaration, for example

   ivarpersist1 : INT; between VAR_GLOBAL PERSISTENT RETAIN and END_VAR.

3. Double-click the POU in the device tree.

   ⇒ The editor of the POU opens.

4. Specify the following declaration in the declaration part:

   VAR PERSISTENT
   ivarpersist2 : INT;
   END_VAR

5. Click “Build ➔ Build”.

   ⇒ The message view opens. If CODESYS has compiled the application without errors, then close the message window and continue with the next step. Otherwise, correct the error(s) and select the menu command “Build ➔ Build” again.

6. Click the tab “PersistentVars” to select the persistent variable list as the active editor and select the menu command “Declarations ➔ Add All Instance Paths”.

   ⇒ CODESYS adds the persistent variable from the persistent variable list “PersistentVars” to the POU:

   // instance path of the persistent variables created
   POU.IVARPERSIST2 : INT
Saving the values of a persistent variable list in a recipe

Requirement: a project is opened and a persistent variable list with declarations of persistent variables exists under an application object.

1. Double-click on the controller in the device tree and select the tab “Communication Settings”.
2. Select your gateway and click on the button “Scan Network”.
   ⇒ Your device is shown in bold in the tree view of the gateway.
3. Select your device and click on the button “Set Active Path”.
4. Select your application object in the device tree and select the context menu command “Set Active Application”.
   ⇒ The application object is displayed in bold.
5. Select the menu command “Online ➔ Login”.
   ⇒ Your application is logged in to the controller and the controller and the application object in the device tree have a green background.
6. Double-click on the persistent variable list and select the command “Declarations ➔ Save Current Values to Recipe”.
   ⇒ CODESYS creates the objects “Recipe Manager” and “PersistentVariables” under the application object.
7. Select the menu command “Online ➔ Logout”.
   ⇒ The application is logged out from the controller.

1.3.1.9.21 Alarm management

You can use the alarm management as part of an application in order to determine and record critical process states and to display them with the help of visualization elements. You can take notice of alarms via the application or user inputs in the visualization and react accordingly with acknowledgment and subsequent actions. CODESYS provides special visualization elements and a library for this.

An alarm management consists of the following elements

- **Alarm class**: an alarm class serves the typifying of alarms, i.e. it defines a basic parameter set for an alarm. You must specify the class when creating an alarm. For example, it defines how an alarm must be confirmed, whether it is to be recorded and displayed, or whether it is to be written to a file.

- **Alarm group**: an alarm group is for the concrete configuration of one or more alarms. In the alarm group you define the conditions for the individual alarms and assign the alarms to the alarm classes. Furthermore you define there whether the alarms of this group are archived.

- **Alarm storage**: an alarm storage is for defining the parameters for the archiving of the alarms that occur.
The visualization of CODESYS offers the elements “Alarm Table” and “Alarm Banner” for displaying the alarm messages.

So that you have access to the alarms from the application, the library AlarmManager.library offers certain functions and interfaces.

- Visualization Element ‘Alarm banner’ Chapter 1.3.5.18.1.23 “Visualization element ‘Alarm banner’” on page 1402

Defining alarms

For alarm management in CODESYS the following definitions apply to an alarm. An alarm definition consists in principle of
- a general description (ID, message text, etc.)
- a description of the cause of the alarm (expression to be monitored, limits, min. pending time, etc.)
- a description of the effects of the alarm (actions, display properties, confirmation method etc.).

Acknowledgement of alarms: the main reason for the use of alarms is to inform the user about an alarm situation. In order to ensure that the user has taken notice of the information, CODESYS provides you with various actions that you define in the alarm class. The user must acknowledge the alarm in order to delete it from the alarm list. The special types of alarm acknowledgment are described in the status diagrams as status transitions.

Alarm event: an alarm event is linked to an alarm condition. While an alarm condition can exist over a lengthy period, the alarm event describes the momentary occurrence of a change, for example the change from the normal state to the alarm state. In the CODESYS alarm configuration the same names (Active, ACK, Inactive) are used for the three types of events and the associated alarm status.

The following features are supported in CODESYS:
- Deactivation of the alarm generation for simple alarms as well as for alarm groups
- Selection of the alarms that are to be displayed, by definition of alarm groups and priorities
- Display of all alarm events in an alarm table
- Visualization elements “Alarm Table” and “Alarm Banner” in the CODESYS visualization

Configuring the alarm management

Creating alarm configurations

1. Select an application in the device tree.
2. Click “Project ➔ Add Object ➔ Alarm configuration”.
   ➔ The “Add Alarm Configuration” dialog box opens.
3. Click “Add”.
   ⇒ CODESYS adds the “Alarm Configuration” to the device tree below the application.
   In addition, CODESYS inserts the predefined alarm classes (“Error”, “Info”, and “Warning”) and the alarm storage “AlarmStorage” below the alarm configuration. The predefined objects are available to you if you need them.

### Configuring alarm classes

1. Select the “Alarm Configuration” object in the device tree.
2. Click “Project ➔ Add Object ➔ Alarm Class”.
   Type in a name (example: "PartsDeficit") and click “Add”
   ⇒ The “PartsDeficit” alarm class is added to the device tree. The object opens in the editor.
3. Set the following parameters for the class. These apply to all alarms that belong to this class group:
   - “Priority”: 10
   - “Archiving”
   - “Acknowledgment method”: REP_ACK
   - “acknowledge separately”:

4. In the following, you define that the bPartsDeficit variable has the value TRUE when alarm messages occur: Double-click the “Action” column in the “Notification actions” group.
   Select the “Variable” action.
   Press the [Enter] key.
   ⇒ The action is added and all options are activated.
5. Select the “Activate” check box, and clear the “Deactivate” and “Confirm” check boxes.
6. Click inside the input field “Variable” and enter bPartsDeficit or select the variable with the help of the input assistant
   Enter the value TRUE into the right field.
   ⇒ The ...bPartsDeficit := TRUE statement is displayed in the “Details” column.
7. Select the “Background color” "Red" in the “Active” row of the “Display Options” group.
   Select the “Background color” "Yellow" in the “Wait for confirmation” row in the “Presentation Options” group.

All messages in the “PartsDeficit” class set the variable bPartsDeficit to TRUE. Active messages are highlighted in red in the "Alarm table" visualization element. Deactivated messages that are not acknowledged are highlighted in yellow.

- Visualization Element Alarm table ➔ Chapter 1.3.5.18.1.22 “Visualization element ‘Alarm table’” on page 1395
- Visualization Element Alarm banner ➔ Chapter 1.3.5.18.1.23 “Visualization element ‘Alarm banner’” on page 1402

### Configuring alarm groups

In the following, you define an alarm group with an alarm for monitoring PartsDeficit. You have already created the applicable alarm class above.
1. Select the “Alarm Configuration” object in the device tree.

2. Click “Project ➔ Add Object ➔ Alarm Group”.
   Type in the name “PartsDeficit” and click “Add”
   ⇒ The “PartsDeficit” alarm group is added to the device tree. The object opens in the editor.
   CODESYS creates the text list “PartsDeficit”.

3. Set the following parameters:
   ● “Archiving”: (none)

4. Double-click in the “Observation type” field.
   Select the “Digital” monitoring type.

5. Configure the alarm as follows:
   ● “Class”: PartsDeficit
   ● “Message”: PartsDeficit at Station 1 - level: <LATCH1> ("<LATCH1>" is a placeholder for latch variable 1.)
   ● “Min. pend. time”: t#5s
   ● “Latch var 1”: ...iFuellstand

6. In the “Digital” group, click the “Expression” field and type in bPart1Empty or select the variable by using the input assistant.
   Type in the value TRUE in the right field.
   ⇒ The ...bTeil1Leer = TRUE statement is displayed in the “Details” column.

If the bTeil1Leer variable switches to TRUE, then CODESYS triggers a message. The value of the iFuellstand variable is printed with the message. The acknowledgment response and the display are executed according to the “PartsDeficit” alarm class. The alarm is not archived.

See also
●  Chapter 1.3.1.25.1.7 “Object ‘Alarm Group’” on page 718

Configuring alarm storage

1. Select the “Alarm Storage” object in the device tree.

2. To change the name, select the “Properties” command in the context menu.
   Change the name from "AlarmStorage" (example: "DatabaseFileAlarmStorage") and click “OK”.

3. Double-click the “DatabaseFileAlarmStorage” object in the device tree to open the editor.

4. Configure as follows:
   ● “Subdirectory”: Leave this field blank. Specifying a directory is optional only on the PLC where the alarm storage file will be saved.
   ● “Limit” group: Select the “No limit” check box.
   ⇒ The alarm storage is configured. In this case, CODESYS saves the alarms internally in an unlimited buffer.

See also
●  Chapter 1.3.1.25.1.8 “Object ‘Alarm Storage’” on page 721
Calling event alarms in the program

You define the alarms in the object Alarm Group. The monitoring type “Event” is thereby available. Contrary to the other monitoring types, which trigger the alarm depending on a condition, you can trigger the alarm with the type “Event” via a function block call.

Defining the event alarm in the alarm group

1. Create an alarm group.
2. Define an alarm of the monitoring type “Event” in the alarm group.
3. In the column “Class”, select an alarm class with the acknowledgement method “ACK” or create a new alarm class.

See also
● “Configuring alarm classes” on page 259

Program call for triggering the event alarm

1. Set the cursor at the program position at which the function-block call is to take place.
2. Use the RaiseEvent function from the AlarmManager library:
   Enter 'AlarmManager', followed by a period.
   ⇒ A window opens containing a list of all insertable elements (function 'List components').
3. Select AlarmGlobals and enter a period.
4. In the same way, insert the elements g_AlarmHandler and RaiseEvent.
   ⇒ You get the following line:
   Alarmmanager.AlarmGlobals.g_AlarmHandler.RaiseEvent.
5. Now define the transfer variables AlarmGroup_ID and “Alarm_ID”. To do this, enter an opening parenthesis.
   ⇒ A tooltip appears, showing information about the transfer variables
6. Press [F2]
   ⇒ The input assistant opens
7. On the “Categories” tab (3), select the category “Variables” (4).

8. Select the desired group ID variable (1).
   ➞ The variable is applied into the program line.

9. Enter a comma and insert the desired alarm ID variable (2) in the same way as in step 7.
   Input a closing parenthesis and a semicolon.
   ➞ You get the following program line:
     
     ```
     Alarmmanager.AlarmGlobals.g_AlarmHandler.RaiseEvent(Alm_AlarmConfiguration.Alarmgroup_IDs.ID_AlarmGroup1,
     Alm_AlarmGroup1_Alarm_IDs.ID_0);
     ```

1.3.1.9.22 Using POUs for implicit checks

CODESYS provides special POUs that implement implicit monitoring functions. At runtime, these functions check the array limits or subrange types, the validity of pointer addresses, or division by zero.

1. Select the “Application” object in the device tree.
   Click “Project ➔ Add Object ➔ POU for Implicit Checks”
   ➞ The “Add POU for Implicit Checks” dialog box opens.

2. Select the desired functions.

3. Click “Add”.
   ➞ The selected POUs are inserted below the “Application” in the device tree.

4. Open the POUs in the editor.
5. Adapt the implementation suggestion to your requirements.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

See also
● Chapter 1.3.1.25.1.28 “Object ‘POU’” on page 775

1.3.1.9.23 Object-oriented programming
CODESYS supports object oriented programming with function blocks and for this purpose provides the following features and objects:

● Methods
● Interfaces
● Properties
● Inheritance
● Method call, virtual function call
● Definition of function blocks as extensions of other function blocks

See also
● Chapter 1.3.1.25.1.28.4 “Object ‘Interface’” on page 783

Extension of function blocks
The extension of a function block is based on the concept of inheritance in object-oriented programming. A derived function block thereby extends a basic function block and in doing so is given the properties of the basic function block in addition to its own properties.

The extension of a function block means:

● The inherited function block contains all data and methods that are defined by the basic function block. You can use an instance of the basic function block in every context in which CODESYS expects a function block of the type of the basic function block.

● The derived function block can overwrite the methods that you have defined in the base function block. This means that the inherited function block can define a method with the same name, the same inputs and the same output as is defined by the basic function block. Tip: You have the following support when overwriting methods, actions, attributes, and transitions that are inherited by the base block: When you insert a method, action, etc. below an inherited block, the “Add Object” dialog includes a combo box with a list of methods, actions, etc. used in the base block. You can accept these and adapt them accordingly.

● The derived function block may not contain function block variables with the same names as used by the basic function block. The compiler reports this as an error. The only exception: If you have declared a variable in the basic function block as VAR_TEMP, then the inherited function block may define a variable with the same name. In this case, the inherited function block can no longer access the variable of the basic function block.

● You can directly address the variables and methods of the basic function block within the scope of the inherited function block by using the SUPER pointer.
NOTICE!
Multiple inheritance is not permitted.
Exception: A function block can implement multiple interfaces, and an interface can extend other interfaces.

Extension of a basic function block by a new function block

Requirement: the currently opened project possesses a basic function block, for example “POU_1(FB)”, which is to be extended by a new function block.

1. Right-click the “Application” object in the device tree and select “Project ➔ Add Object ➔ POU”.
   ⇒ The “Add POU” dialog opens.
2. Type the name for the new POU in the “Name” input field, for example “POU_Ex”.
3. Select “Function block”.
4. Click “Advanced” and then the more button (≡).
5. In the category “Function blocks” under “Application” in the input assistant, select the POU(FB) that is to serve as the basic function block, for example POU_1, and click “OK”.
6. As an option, you can select an “Access modifier” for the new function block from the drop-down list.
7. Select from the “Implementation language” combo box (example: “Structured text (ST)”).
8. Click “Add”.
   ⇒ CODESYS adds the POU_Ex function block to the device tree and opens the editor.
   The first line contains the text:
   ```
   FUNCTION_BLOCK POU_Ex EXTENDS POU_1
   ```
   The function block POU_Ex extends the basic function block POU_1.

Extension of a basic function block by an existing function block

Requirement: The open project possesses a base function block (example: POU_1(FB)) and another function block (example: POU_Ex(FB)). The function block POU_Ex(FB) is also to be given the properties of the basic function block. This means that POU_Ex(FB) should extend POU_1(FB).

1. Double-click the function block POU_Ex(FB) in the device tree.
   ⇒ The function block editor opens.
2. Extend the existing entry in the top line FUNCTION_BLOCK POU_Ex with EXTENDS POU_1.
   ⇒ The function block POU_Ex extends the basic function block POU_1.

Implementing interfaces

Implementing interfaces is based on the concept of object-oriented programming. With common interfaces, you can use different but similar function blocks the same way.

A function block that implements an interface has to include all methods and attributes that are defined in that interface (interface methods and interface attributes). This means that the name and the inputs and outputs of the methods or attributes must be exactly the same. When you create a new function block that implements an interface, CODESYS adds all methods and attributes of the interface automatically to the tree below the new function block.

**NOTICE!**
If you add more interface methods afterwards, then CODESYS does not add these methods automatically to the affected function block. To perform this update, you must execute the "Implement Interfaces" command explicitly.

For inherited function blocks, you have to make sure that any methods or attributes that were derived through the inheritance of an interface also receive the appropriate implementation. Otherwise they should be deleted in case the implementation that was provided in the basis should be used. Respective compile error messages or warnings are displayed, prompted automatically by added pragma attributes. For more information, refer to the help page for the "Implementing Interfaces" command.

**NOTICE!**

- You must assign the interface of a function block to a variable of the interface type before a method can be called via the variable.
- A variable of the interface type is always a reference of the assigned function block instance.

A variable of the interface type is a reference to instances of function blocks. This kind of variable can refer to every function block that implements the interface. If there is no assignment to a variable, then the variable in online mode contains the value 0.
The interface contains the `GetName` method.

```plaintext
METHOD GetName : STRING
```

The functions blocks A and B implements the interface I1:

```plaintext
FUNCTION_BLOCK A IMPLEMENTS I1
FUNCTION_BLOCK B IMPLEMENTS I1
```

For this reason, both function blocks must include a method named `GetName` and the return type `STRING`. Otherwise the compiler reports an error.

A function includes the declaration of a variable of interface I1 type.

```plaintext
FUNCTION DeliverName : STRING
VAR_INPUT
  l_i : I1;
END_VAR
```

Function blocks that implement the I1 interface can be assigned to these input variables.

Examples of function calls:

```plaintext
DeliverName(l_i := A_instance); // call with instance of type A
DeliverName(l_i := B_instance); // call with instance of type B
```

Calling of interface methods:

In this case, it depends on the actual type of `l_i` whether the application calls `A.GetName` or `B.GetName`.

```plaintext
DeliverName := l_i.GetName();
```

---

### Implementing an interface in a new function block

- Requirement: The open project has at least one interface object.

1. Right-click “Application” in the device tree and select “Project ➔ Add Object ➔ POU”.
   - The “Add POU” dialog box opens.
2. Type the name for the new POU in the “Name” input field, for example “POU_Im”.
3. Select “Function block”.
4. Click “Implemented” and then the more button ().
5. In the input assistant, select the interface from the category “Interfaces”, for example ITF1, and click on “OK”.
6. To insert more interfaces, click ( ) and select a another interface.
7. As an option, you can select an “Access modifier” for the new function block from the selection list.
8. Select from the “Implementation language” combo box (example: “Structured text (ST)”).
9. Click “Add”.
   - CODESYS adds the “POU_Ex” function block to the device tree and opens the editor.
   - The first line contains the text:
     ```plaintext
     FUNCTION_BLOCK POU_Im IMPLEMENTS ITF1
     ```
   - The interface and its methods and properties are now inserted below the function block in the device tree. Now you can type program code into the implementation part of the interface and its methods.

---

Examples

- Chapter 1.3.1.25.2.23.2 “Command ‘Implement Interfaces’” on page 1038
Implementing an interface in an existing function block

- Requirement: The currently open project has a function block (example: “POU_Im”) and at least one interface object (example: “ITF1”).

1. Double-click the “POU_Ex(FB)” POU in the device tree.
   - The POU editor opens.
2. Extend the existing entry in the uppermost line `FUNCTION_BLOCK POU_Im with IMPLEMENTS ITF1`.
   - The “POU_Im” function block implements the “ITF1” interface.

See also
- “Chapter 1.3.1.25.1.28.2 “Object ‘Function Block’” on page 778

Extending interfaces

You can extend interfaces just like function blocks. The interface is then also given the interface methods and interface properties of the basic interface in addition to its own.

1. Select the object “Application” in the device tree.
2. Select the command “Project ➔ Add Object ➔ Interface”.
   - The dialog box “Add Interface” opens.
3. Enter a name for the new interface.
4. Activate the option “Extended” and click on the button 
5. The input assistant opens.
6. From the category “Interfaces”, select the interface that is to be extended by the new interface.

- “Chapter 1.3.1.25.1.28.4 “Object ‘Interface’” on page 783

Calling methods

To implement a method call, the actual parameters (arguments) are passed to the interface variables. As an alternative, the parameter names can be omitted.

Depending on the declared access modifier, a method can be called only within its own namespace (INTERNAL), only within its own programming module and its derivatives (PROTECTED), or only within its own programming module (PRIVATE). For PUBLIC, the method can be called from anywhere.

Within the implementation, a method can call itself recursively, either directly by means of the THIS pointer, or by means of a local variable for the assigned function block.

Method call as a virtual function call

Virtual function calls can occur due to inheritance.

Virtual function calls enable one and the same call to call various methods in a program source code during the runtime.
In the following cases the method call is dynamically bound:

- You call a method via a pointer to a function block (for example `pfub^.method`).
  In this situation the pointer can point to instances of the type of the function block and to instances of all derived function blocks.
- You call the method of an interface variable (for example `interface1.method`).
  The interface can refer to all instances of function blocks that implement this interface.
- A method calls another method of the same function block. In this case the method can also call the method of a derived function block with the same name.
- The call of a method takes place by means of a reference to a function block. In this situation the reference can point to instances of the type of the function block and to instances of all derived function blocks.
- You assign `VAR_IN_OUT` variables of a basic function block type to an instance of a derived FB type.
  In this situation the variable can point to instances of the type of the function block and to instances of all derived function blocks.

**Example**

<table>
<thead>
<tr>
<th>Overloading methods</th>
<th>The function blocks <code>fub1</code> and <code>fub2</code> extend the function block <code>fubbase</code> and implement the interface <code>interface1</code>. The methods <code>method1</code> and <code>method2</code> exist.</th>
</tr>
</thead>
</table>
| PROGRAM PLC_PRG     | **VAR_INPUT**  
|                     | `b : BOOL;`  
| END_VAR             | **VAR**  
|                     | `pInst : POINTER TO fubbase;`  
|                     | `instBase : fubbase;`  
|                     | `inst1 : fub1;`  
|                     | `inst2 : fub2;`  
|                     | `instRef : REFERENCE to fubbase;`  
| END_VAR             |
| IF `b` THEN         | `instRef REF= inst1;`  
|                     | (* reference to fub1 *)  
|                     | `pInst := ADR(instBase);`  
| ELSE                | `instRef REF= inst2;`  
|                     | (* reference to fub2 *)  
|                     | `pInst := ADR(inst1);`  
| END IF              |
| `pInst^.method1();` | (* If `b` is TRUE, `fubbase.method1` will be called, otherwise `fub1.method1` is called *)  
| `instRef.method1();` | (* If `b` is TRUE, `fub1.method1` will be called, otherwise `fub2.method1` is called*)  

On the assumption that `fubbase` in the above example contains two methods `method1` and `method2`, it overwrites `fub1.method2`, but not `method1`. The call of `method1` takes place as follows:

- `pInst^.method1();`
- If `b` is TRUE, then CODESYS calls `fubbase.method1`. If not, then `fub1.method1` is called.

**Additional outputs**

In accordance with the IEC 61131-3 standard, methods can have additional outputs declared, like normal functions. With the method call, you assign variables to the additional outputs.

Detailed information about this can be found in the topic “Function”.

---

3ADR010583, 1, en_US
Syntax for the call:

\[
\text{<function block name>.<method name>(<first input name> := <value> (, <further input assignments>)+, <first output name> => <first output variable name> (,<further output assignments>)+ )};
\]

Example

Declaration

\[
\text{METHOD PUBLIC DoIt : BOOL}
\text{VAR_INPUT}
\quad \text{iInput_1 : DWORD;}
\quad \text{iInput_2 : DWORD;}
\text{END_VAR}
\text{VAR_OUTPUT}
\quad \text{iOutput_1 : INT;}
\quad \text{sOutput_2 : STRING;}
\text{ENDVAR}
\]

Call

\[
\text{fbInstance.DoIt(iInput_1 := 1, iInput_2 := 2, iOutput_1 => iLocal_1, sOutput_2 => sLocal_2);}
\]

When the method is called, the values of the method outputs are written to the locally declared output variables.

Calling a method even if the application is in the STOP state

In the device description it is possible to define that a certain function block instance (of a library function block) always calls a certain method in each task cycle. If the method contains the input parameters of the following example, CODESYS processes the method even if the active application is presently in the STOP state:

Example

\[
\text{VAR_INPUT}
\quad \text{pTaskInfo : POINTER TO DWORD;}
\quad \text{pApplicationInfo: POINTER TO _IMPLICIT_APPLICATION_INFO;}
\text{END_VAR}
\]

\[
\text{(*Now the status of the application can be queried via}
\text{pApplicationInfo and the instructions can be implemented: *)}
\text{IF pApplicationInfo^.state = RUNNING THEN <instructions> END_IF;}
\]

Calling methods recursively

Use recursions mainly for processing recursive data types such as linked lists. Generally, we recommend that you be careful when using recursion. An unexpectedly deep recursion can lead to stack overflow and therefore to machine downtime.

Within their implementation, a method can call itself:

- Directly by means of the THIS pointer
- Indirectly by means of a local function block instance of the basic function block

Usually, a compiler warning is issued for such a recursive call. If the method is provided with the pragma \{attribute 'estimated-stack-usage' := '<estimated_stack_size_in_bytes>'\}, then the compiler warning is suppressed. For an implementation example, refer to the section "Attribute 'estimated-stack-usage". 
1.3.1.10 Working with control networks

With the following functionalities, CODESYS supports communication between controllers (PLC) and the insertion of a safety device below a PLC:

- **Symbol configuration**: CODESYS creates symbols with certain access rights for the variables in an application. With these symbols, you can access the variables from outside, for example from an OPC server.

- **Data source manager**: Manages the connection settings and the data transmission to remote devices (data sources). The transmitted data is mapped in data source variables that are accessed in the visualization or local application. An example of this is a control panel that controls remote devices and visualizes the state of the device as an HMI application.

- **Network variables**: Network variables are variables whose values are accessible to different controllers in the network. The variables must be defined in rigid, identical lists in both the transmitter device and the receiver device. These lists are assigned to applications, but can be located in different projects.

- **A safety device** can be inserted below a PLC in the device tree. The communications links of the safety devices to the field devices, controller networks, and development system are routed via this controller.

1.3.1.10.1 Network and addressing

Constructing a control network hierarchically, so that extensive self-configuration is possible. In CODESYS the network topology is mapped to clear addresses and the routing algorithm is kept simple by structured addresses. There is direct and relative addressing and automatic address determination during the bootup of the system.

Network topology

It is recommended to set up a network system so that the following are possible:

- Extensive self-configuration (address assignment)
- Transparent support for every communication medium
- Transport of data packets between different networks
The routing mechanism should be so simple that each network node can reroute data packets, even if it has a low memory capacity. Therefore, avoid extensive routing tables, complex calculations or queries at runtime.

Construct the control network hierarchically. Each node may possess a parent node and any number of child nodes. A node without a parent is a "top level" node. Cycles are not permitted, i.e. each control network has the structure of a tree.

Parent-child relationships result from the specification of certain network areas. A network area can be, for example, a local Ethernet or a serial point-to-point connection. We differentiate between the main network (mainnet) and the subnetworks (subnet). Each node belongs at the most to one main network, to which its parent node, if one exists, also belongs. For each node any desired number of subnets can be configured, for which the node acts in each case as a parent.

A network area may have only one parent node. Therefore, a configuration in which a network area is defined at the same time as a subnet of several nodes is invalid.

- Chapter 1.3.1.10.1.3 “Address structures” on page 272

### Addressing and routing

Addressing means: the topology of the control network is mapped to unique addresses.

A node address is composed hierarchically: for each network connection the associated block driver determines a local address, which uniquely identifies the node within the local network. The complete node address is formed as follows: The local address is placed in front of the subnet index of the local network assigned by the parent. In turn, the subnet index is placed in front of the node address of the parent. The length of the subnet index (in bits) is thereby determined by the device. The length of the local address, conversely, is determined by the type of network. A node without a main network is a top level node with address 0. A node with a main network that contains no parent is likewise a top level node. It is given the local address of the main network.

See an example of a control network here:
In the example the addresses of the nodes are represented in hexadecimal notation. The first 4 digits represent the address of the respective parent in the main network, for example 0x007A=122 for PLC1. The next byte (in blue lettering) is reserved for the subnet index and is followed by the local address, for example C=12 for node ID 12. The structuring of the addresses makes a lean routing algorithm possible. Routing tables, for example, are thus unnecessary. Information is queried only locally: via its own address and via the address of the parent node. On this basis a node can correctly process the data packets:

- If the destination address corresponds to the address of the current node, then this is meant to be the receiver.
- If the destination address starts with the address of the current node, then the data packet is either meant directly for a child or for a descendant of the node and must be forwarded.
- In all other cases the receiver is not a descendant of the current node and the data packet must be forwarded to its own parent.

Relative addressing is a special case: relative addresses do not contain the node number of the receiver, but directly describe the path from the sender to the receiver. The principle is similar to the relative path in the file system: the address consists of the number of steps via which the packet must be transported upwards. These are the steps to the corresponding parent and from the subsequent path downwards to the destination node.

The advantage of relative addressing is that two nodes in the same subtree can continue to communicate if the complete subtree is shifted to another place in the entire network. Whereas the absolute node addressing has to be modified due to this shift, the relative addressing is still valid.

Address determination

For a node to know its own address it must either know the address of its parent node or know that it is a top level node. For this purpose the node dispatches a message during the bootup to all network devices for address determination. As long as it receives no response to this message, the node considers itself to be a top level node, but continues to search for a possible parent. A parent node responds by announcing its address. The node will thus independently complete its address and will announce it to the subnets. An address determination can be accomplished during the bootup or at the request of the PC used for programming.

**Node addresses**

The node address indicates the absolute address of a node within a control network and is therefore unique within the whole "network tree". The address is composed of up to 15 address components, each of which occupies 2 bytes. The lower a node is located within the network hierarchy, the longer its address.

The complete node address consists of the partial addresses of all preceding nodes and the partial address of the node itself. Each partial address consists of one or more address components. The length is therefore always a multiple of 2 bytes. The partial address of a node is formed from the network address of the node in its main network and the subnet index of the main network in the case of the parent node. The bits required for the subindex are determined by the router of the parent node. Filler bits can be inserted between the subnet index and the network address in order to ensure that the length of the partial address is a multiple of 2 bytes.

**Special cases:**

- A node without a main network: this means that there is neither a subnet index nor a network address in the main network. In this case the address is set to 0x0000.
- A node in the main network without a parent: In this case a subnet index with the length 0 is assumed. The partial address corresponds to the network address, if necessary extended by filler bits.

---

**Example of node addresses**

**Main network**

- Network address: 0x274 (12 bits)
- Length of subnet index: 4 bits

**Partial address of B:**

- 0x1000010C:
  - 0\_0\_0\_1\_0\_0\_0\_0\_0\_0\_1\_0\_0\_0\_1\_1\_0

- Node address of B: 0274 : 1000 : 010C
The node address is always specified in hexadecimal. The individual address components (two bytes in each case) are separated by a colon ":". Since this represents an array of bytes and not a 16-bit value, the components are not displayed in the Intel format. For manually input addresses, missing parts in an address component are supplemented by leading zeros: "274" = "0274". In order to improve the legibility, the display should also always contain the leading zeros.

**Absolute and relative addresses**

Communication between two nodes can be based on relative or absolute addresses. Absolute addresses are identical to node addresses. Relative addresses specify a path from the sender to the receiver. They consist of an address offset and the descending path to the receiver.

The (negative) address offset describes the number of address components by which a packet must be passed upwards in the tree before it can be passed back down by the common parent node. Since nodes can use partial addresses that consist of more than one component, the number of parent components to be passed is always equal to the address offset. This means that the demarcation between the parent nodes is no longer clear. For that reason the common start of the address of the communication partners is used as the parent address. Each address component is counted as an upward step, independent of the current parent node. Each error resulting from this assumption can be detected by the corresponding parent node and must be handled by it accordingly.

After achieving the common parent node the relative path, as an array of address components, is followed downwards as usual. Formal: the node address of the receiver is formed by removing the last address offset components from the node address of the sender and by appending the relative path to the remaining address.

**Example of the formation of node addresses**

In the following example each address component is represented by a letter; in each case a dot separates nodes from each other. Since a node can carry several address components, there are some in the example that are represented with several letters.

Node A: a.bc.d.ef.g

Node B: a.bc.i.j.kl.m

- Address of the lowest common parent: a.bc
- Relative address from A to B: -4/i.j.kl.m (The number 4 results from the 4 components, d, e, f and g, which must pass on the data packet in the upward direction)

In order to guarantee correct operation of the routing, the relative address must be adapted each time it passes an intermediate node. It is sufficient to adapt the address offset. This is always done by the parent node: If a node receives a data packet from one of its subnets, the address offset is increased by the length of the address component of this subnet.

- If the new address offset is < 0, then the data packet must be passed further upward.
- If the address offset is >= 0, then the data packet must be passed on to the child node whose local address corresponds to the relative path, starting from the address offset. First of all, however, the address offset must be increased by the length of the local address of the child node, so that the child node sees the correct address.

A special situation results if the error mentioned above occurs during the determination of the common parent node. In this case the address offset of the actual parent node is negative, but this value is larger than the length of the partial address of the subnet from which the packet originated. So that the next node sees a correct relative address in this case, the node concerned must do the following: it must discover the error, calculate the local address of the child node on the basis of the address of the predecessor node and the length difference, and adapt the address offset accordingly. In this case, too, the address components as such remain unchanged; only the offset is changed.

**Broadcast addresses**

There are two types of broadcast - global and local. A global broadcast is sent to all the nodes in a network. The empty node address with a length of 0 is reserved for this purpose.

Local broadcasts are sent to all the devices in a network area. For this purpose, all the bits of the network address are set to 1. This is permissible both in relative and in absolute addresses.
A block driver must be able to process both kinds of broadcast addresses. This means: empty network addresses as well as network addresses whose bits were all set to 1 must be interpreted and sent to all devices concerned.

### 1.3.1.10.2 Symbol configuration

Use the symbol configuration for preparing symbols with specific access rights for project variables. With these symbols, you can access the variables from outside, for example from an OPC server. When generating code, CODESYS also generates a symbol file (*.xml) that includes the description of the symbols.

The symbol file is stored in the project directory. The name of the symbol file is composed as follows: `<project name>..<device name>..<application name>.xml`

**Example**

`proj_xy.PLC1.application.xml`

You can also generate the symbol file with the “Generate Code” command. This is very useful when downloading to the PLC is not possible.

The variables that you export as symbols can be bundled in the symbol configuration editor or defined in the variables declaration using the `attribute 'symbol'` pragma. Another option is using the element in the SFC editor, where you can define the implicitly generated element variables that should be exported to the symbol configuration.

The name of the symbol is generated in the symbol configuration in the following syntax: `<application name>..<POU name>..<variable name>`. When accessing the variable, you must always provide the complete symbol name in this syntax.

**Example**

`MyApplication.PLC_PRG.a` or `MyApplication.SymFB.a`

As a rule, read-only access applies to symbols for input addresses and for variables that are mapped to input channels. Write access is possible for testing purposes in simulation mode only.

The symbol file is loaded with the application to the PLC. Depending on the device description, this file can be generated as an additional (child) application. This application is then listed in the “Application” tab of the device editor. Syntax: `<application name>..symbols`. The symbol application is regarded as a "normal" application with respect to the maximum number of applications on the PLC.

If your controller has a user management, then you can assign different access rights to a symbol to the individual user groups (clients). To do this, place the same symbol in different symbol sets and allow the individual user groups (clients) either to access a symbol set or not. An on-site operator or an operating data record, for example, receives more information and access to the same symbols as telemaintenance.

Creating a symbol configuration

Requirement: The project can be compiled without any errors.

1. Select the “Application” object in the device tree.
2. Click “Project ➔ Add Object ➔ Symbol Configuration”.
   ⇒ The “Symbol Configuration” object is added to the device tree and the objects editor opens.
3. Open the “View” menu of the editor and activate the categories of variables that should be provided in the configuration editor. Click “Build” in the symbol configuration editor.
   ⇒ All variables (according to the currently defined filter in the “View” menu) are displayed in a tree structure.
4. Select the check boxes of individual variables.
   Note: Pay attention to the current settings (see the “Settings” button in the menu bar of the editor).
   ⇒ In the field below the menu bar of the editor, information is provided about the current situation with accompanying instructions, as well as controls for corrective actions.
5. Follow the prompt in the field below the menu bar. In the following case, this should be only the information that the modified symbol configuration is transferred with the next download or online change.
   Click “Build ➔ Generate Code” in the CODESYS main menu.
   ⇒ The <project name>.<device name>.<application name>.xml file is generated in the project directory.

CODESYS transmits the symbol configuration to the PLC for an application download or online change.

● § Chapter 1.3.1.25.1.36 “Object 'Symbol Configuration'” on page 824

Creating symbol sets with different access rights for different control clients

A symbol set is a defined set of symbols. If supported by the target device, you can combine different symbol sets from the symbols of the application in the symbol configuration editor. The information about the symbol sets is downloaded to the controller. Then you can define the user group that has access to each symbol set. Rights are assigned in the “Symbol Rights” tab of the device editor.

As a result, symbol sets allow different client-specific access rights to a symbol in the controller.

You can download changes to a symbol set definition to the controller in an online change. When the application is deleted on the controller, the symbol sets are also deleted. When building the application, you can create and save a symbol file in XML format for each symbol set.

In the following section, you will see an example of steps for creating symbol sets and the assignment of rights on the controller:

Requirements: The application has a defined symbol configuration in the project. The “Enable symbol sets” option is enabled in the settings of the symbol configuration. The controller has a user management. For the example here, there should be a user group that has the necessary rights for the servicing of the plant. By default, this type of user group, named “Service”, is already created.

1. Define the connection to the controller in the “Communication Settings” of the device editor.
2. Click the button in the editor of the “Symbol Configuration” in order to create a new symbol set. Specify a name of the group (“startup”) in the dialog “Add a New Symbol Set”.
3. Click the button (“Build”) in the toolbar of the dialog in order to display all symbols available in the project. Select the users who should belong to the group. Save the project.
4. Click the button “Configure Symbol Rights”.
   ⇒ The “Symbol Rights” tab of the device editor opens.

5. Click the button (“Synchronization”) to synchronize the display of the symbol sets with
   the device.
   ⇒ If you have not enabled user management on the controller yet, then you will see a
dialog box in the “Users and Groups” tab prompting you to do it.

6. Click “OK” in the dialog box and click the “Users and groups” tab.

7. Click the button (“Synchronization”). Click “Yes” to confirm that user management
   should be enabled.
   ⇒ The “Device User Login” dialog opens.

8. Click “OK” in the dialog box and click the “Users and groups” tab.

9. Click “Synchronization” button.
   ⇒ In “Symbol sets”, you see all sets that have currently been downloaded for the appli-
cation (for this example, at least "startup"). In “Rights”, a table shows the user groups
that are created in the user management of the controller. In the example, we assume
that the default groups “Administrator” and “Service” have been created. When a
symbol set is selected on the left, you see on the right the access rights of the indi-
vidual user groups to this symbol set (access granted; access not granted). The
possible type of access is already defined for each symbol in the symbol configuration
(read, write, execute).

10. On the left, select the “Startup” symbol set and double-click the preset minus sign for
   “Administrator” as well as for “Service”.
   ⇒ The symbol changes into a plus sign. The “Administrator” and “Service” now have
   access to the symbols in the “Startup” symbol set.

1.3.1.10.3 Network variables

The values of network variables can be exchanged between different PLCs in a network. The
variables must be defined in strict, identical lists on both the sender device and receiver device,
and only one device application defines the network variables. The lists can be in one or more
projects.

The network variable list in the sender is a global variable list where specific log and transfer
parameters are defined in their object properties. By adding these properties, you create a "net-
work variable list (sender)" from an ordinary “GVL”. You can also insert a “Network Variable
List (Sender)” object directly into the device tree when this object already has these parameters
set.

The network variable list in the receiver is of type “Network Variable List (Receiver)”. When
creating one, select the respective network variable list of the server. As an alternative, you can
read this variable list from an export file that was generated from the sender list. An export file is
required anyway for defining the sender list in another project.

The network variables are transmitted as broadcasting in one direction only: sender to receiver.
However, it is also possible for a device to contain both sender and receiver lists.
For the NetVarUdp library version 3.5.7.0 and later, a receiver channel is no longer assigned when confirmed transfer is not selected. In this way, network variable exchange is also possible between two controllers on one hardware device.

**NOTICE!**
- If the exchanging devices should be senders and receivers, then the variable list identifiers must be unique in order to prevent abnormal operation. The variable list identifiers are defined in the “Properties” dialog of an object GVL.
- Data exchange via network variables is not possible when:
  - The device (target system) does not support it.
  - A firewall blocks the communication.
  - Another client or application is using the UDP port that is set in the properties of the network variable list.
  - More than one application per sender device and receiver device use network variable lists.
- Only arrays that have limits defined with a literal or constant are transmitted to the receiver application. Constant expressions are not permitted for this purpose.
  - Example: "arrVar : ARRAY[0..g_iArraySize-1] OF INT ;" is not transmitted, but "arrVar : ARRAY[0..10] OF INT ;" is transmitted.
- The maximum size of a network variable is 255 bytes. The possible number of network variables is unlimited.
- If the size of the GVL exceeds the maximum length of the network telegram, then the data is split into multiple telegrams. Depending on the configuration, this can result in data inconsistencies.

Communication by means of network variables is also possible when the PLCs operated with applications from different versions of the development system (V2.3, V3). However, in this case, you cannot use the export/import mechanism for matching the variable lists exactly in the sender and receiver projects. The reason is that an variable export file (*.exp) that is generated from V2.3 does not include the required amount of information necessary for creating a receiving NVL in V3. There is no respective network parameter configuration as a GVL file, which you exported from the sender previously. To get this file, you must recreate the V2.3 NVL in V3 first. Then you can generate an export file and create a receiving NVL in V3 based on this.

An alternate to data exchange between PLCs is the use of data sources. As opposed to the broadcasting method for exchanging network variables, defined point-to-point connections are created between one application and a remote data source.

See also

- § Chapter 1.3.1.25.3.10.10 “Dialog ‘Properties’ - ‘Network Variables’” on page 1052
- § Chapter 1.3.1.25.1.21 “Object ‘GVL’ - Global Variable List” on page 769

Configuring a network variable exchange

The following steps are necessary for exchanging network variables between the sender device and receiver device.
1. **Creating a network variable list in the sender device and generating an export file**

Requirements: An application is inserted in the device tree of the PLC that has been employed as the sender device.

1. Select the application and insert a “Network Variable List (Sender)” object. Make the following settings in the “Add Network Variable List (Sender)” dialog: network type: UDP, example: "NVL_Sender".
2. Double-click the NVL object to open the respective editor and type the declarations of the network variables. Example:
   ```
   VAR_GLOBAL
   iglobvar:INT;
   bglobvar:BOOL;
   strglobvar:STRING;
   END_VAR
   ```
3. Right-click the NVL object in the device tree to open the “Properties”. Open the “Network Variables” tab in the “Properties” dialog. This shows the following settings: Network type: UDP; List identifier: 1; Pack variables; Cyclic transmission: every 50 ms.
4. Note: You can also convert an existing GVL into a network variable list by configuring its network variable properties.
5. Click the “Link To File” tab in the “Properties” dialog of the “NVL_Sender”. Define a file name `<export>.gvl` and a location in the file system for the export file of the GVL. Select the “Export before compile” check box.
6. Click “Build ➔ Build” to compile the application.

The export file for the network variable list is now located in the defined folder.

See also

- Chapter 1.3.1.25.3.10.10 “Dialog ‘Properties’ - ‘Network Variables’” on page 1052

2. **Creating an associated network variable list in the receiver device**

Requirements: A sender device and a receiver device exist in the device tree. An application with a task configuration is inserted below the device. An NVL or a GVL is created below the sender device as network variable list to be sent.

1. Select the application of the receiver in the device tree and click “Add Object ➔ Network Variable List (Receiver)”.
   - The “Add Network Variable List (Receiver)” dialog opens.
2. In the dialog, select the previously created NVL of the sender device and type a name (for example, "NVL_Receiver"). CODESYS populates this recipient list automatically with the variable declarations from the sender list.
   - Note: As an alternative, you can select the “Import from file” option and load the export file that was generated previously from the sender list.

3. **Testing the network variable exchange**

Requirements: A network variable list (sender) exists in the sender device, a network variable list (receiver) exists in the receiver device, and both lists have identical variable declarations.

1. Below the application in the sender device, create a program that increments a network variable. Example: `iglobvar := iglobvar + 1;`.
2. Configure the application task so that this program calls it.
3. Below the application in the receiver device, create a program that writes the value of this network variable to a local variable. Example: ilocalvar:=iglobvar;.

4. Configure the application task so that this program calls it.

5. Download both applications to the controllers and start them. (Set the application as active, login, download, and start.)

6. In the online views of the editors of both programs, check whether the values of iglobvar match in the receiver and the sender.

Configuration of network variable communication between V2.3 and V3 PLCs

Requirements: A global variable list exists in a V2.3 project with network variables that you want to read into your V3 project. In the V3 project in the device tree below the PLC, there is an application with a program that uses the variables.

1. Open the “Properties” dialog of the GVL in the V2.3 project (sender).
2. Insert another PLC into the project as a dummy with an application and a task. Then create the V2.3 GVL below it as follows:
3. Insert a “Network Variable List (Sender)” object named "dummy23" below the dummy application.
4. Right-click “dummy23” to open the “Properties” dialog. Click the “Network Variables” tab. Type the same network properties as the GVL in the V2.3 project.
5. Fill “dummy23” with the same variable declarations as in the V2.3 GVL.
6. Define a location for an export file "dummy23.gvl" in the “Link To File” tab of the “Properties” for “dummy23”.
7. Set the application of the dummy PLC as active and press [F11] to compile. CODESYS creates the export file.
8. Set the application of the physical PLC as active and right-click to open the “Add Object” dialog.
9. Select “Network Variable List (Receiver)” and type a name (for example, "NVL_from_23").
10. Select the “Import from file” check box and select dummy23.gvl, which was generated previously.
11. Check “NVL_from_23”, which has just been created. You must receive the same variable declarations as those in the sender GVL in the V2.3 project.

1.3.1.10.4 Data source manager

In order to have read/write access to remote devices and their running applications, you can add a data source manager to your application with one or more data sources.

The functionality of the data source manager allows for establishing connections and communication to remote devices, and it makes its data available through data source variables. At this time, the partners communicate by means of a point-to-point connection. Depending on the network where the controllers are located, a connection is established via different data source types and different connection types.

During the development phase, you can create a variable list offline by means of local symbol configuration files. In this way, you can develop a local application offline based on the symbol information without a connection to a data source.
The communication between remote and local devices communicate by means of data source types. CODESYS provides the following two types.

**CODESYS Symbolic:**
Data is accessed by means of symbolic monitoring. A symbol file on the remote device is read and the stored variable information is used for the data source variables and the data transfer. The advantage is that the application does not have to be updated in the local device when someone edits modifies the remote application without updating its symbol configuration. If the symbol file is also located on your development system (either a file or a symbol configuration object as part of your project), then the local symbol file can also be read. Then, you can work offline during the development phase.

You will usually use CODESYS Symbolic. Do not use CODESYS Symbolic only if no resources are available for a symbol configuration in the remote PLC.

**CODESYS Application V3:**
Data is accessed by means of address monitoring. This requires that the address information between the remote PLC and the local device match. Disadvantage: For changes to the remote application, the local application (for example the HMI application) is updated. The advantage is that a symbol configuration is not required in the remote application.

Use this communication for embedded or mini PLCs when there are no available resources for the symbol configuration.

See also
- ![Chapter 1.3.1.25.1.9 “Object 'Data Source Manager’” on page 723](#)

**Connection types**
The functionality of the data source manager allows for establishing a point-to-point connection from a local device to one or more remote devices (even through networks). Select the appropriate connection type.

When the communication is based on the data source type **CODESYS Symbolic**, the following connection types are possible:

- **“CODESYS V2”**: The devices are located in the same network. The V2 runtime system on the remote PLC provides a communication interface.
- **“CODESYS V2 (via gateway)”**: The devices are not located in the same network. They are connected via a V2 gateway. Note: For this connection, a “CoDeSys V2.3 Gateway Server” (V2 gateway) must be installed on the development computer where CODESYS V3 is running.
- **“CODESYS V3”**: The devices are located in the same network. The V3 runtime system on the remote PLC provides a communication interface.
- **“CODESYS V3 (via gateway)”**: The devices are not located in the same network. They are connected via a V3 gateway.

When the communication is based on the data source type **CODESYS Application V3**, the runtime system of the local application needs valid communication parameters in order to establish the connection. The network scan function can support you when configuring the data source.
Data transmission

When the local application is in runtime mode, the data source variables that appear in the data source editor of the “Variables” tab are updated in configurable time intervals. The remote application is also executed at this time. Variables that are configured in the visualization, in the trend, as alarms, or for recipes are transferred and stored automatically. When a variable is accessed in IEC code only, the variable is not updated automatically. In this case, you must activate the “Update always” option in the data source editor of the “Variables” tab.

The communication types support the (read or write) data access to variables of the source PLC for the following data types:

- Scalar value at highest level
  Example: PLC_PRG.hugo

- Property to a program or GVL by means of a call when it is marked with `{attribute monitoring := 'call'}`.
  Example: PLC_PRG.PropertyCall

- Variable that is mapped to bit addresses.
  Example in PLC_PRG:
  ```plaintext
  AT %MX0.5 : BOOL;
  ```

- Variable (type `BIT`) in a function block
  Declaration in PLC_PRG:
  ```plaintext
  x, y : BIT, access: PLC_PRG.dutInst.y
  ```

- Structured obtainable variable
  Example in PLC_PRG:
  ```plaintext
  outerInst.innerInst.dwVar
  ```

- Property to POU instance when it is marked with `{attribute monitoring := 'call'}`.
  Example: PLC_PRG.instance.PropertyCall

- Property at highest level and to an instance when it is marked with `{attribute monitoring := 'variable'}`.
  Note: This cannot be written by monitoring or by the data sources.

- Array access with literal index
  Example:
  ```plaintext
  PLC_PRG.arrOfInts[3], PLC_PRG.inst.arrOfBool[1]
  ```

- Nested access (for example, array of structures or structure of arrays)

CAUTION!

Bit access used in visualizations that are transferred via a data source connection function only if they contain literal offset specifications. A visualization cannot process an offset specification by defined constants.

Adding initial data sources

For data exchange between your local device and a remote device, add a “Data Source Manager” object and then a “Data Source” below your application in the device tree. An assistant guides you through the configuration of the data source. Then you can modify the settings in the editor of the object at any time. However, it is not possible to modify the data source type later.
Use the data source type “CODESYS Symbolic”, even if there are not any resources available in the remote PLC for a symbol configuration. As long as the symbol configuration is not affected after an application change in the remote device, you have the advantage that the application does not have to be updated in the local device.

When adding a data source, select a data source type. Then specify the connection settings of the point-to-point connection to the remote device. Ideally, the remote device is being executed in the meantime and CODESYS can establish the connection immediately. Then all available data source variables are displayed from the remote PLC. Select the variables that should be transferred. You can also select all variables. Then the data source is initialized automatically, the data source variables are created below the “DataSources_Objects” folder, and an additional data source is added below the data source manager.

When the data is transferred by means of symbolic monitoring and the symbol file is stored on your development system, then you can read the variable information from the symbol file and work offline. The symbol file is stored as either a file on your development system or a symbol configuration object as part of your project (in CODESYS).

The initial settings can be modified at any time in the editor of the data source.

- Chapter 1.3.1.25.1.9 “Object ‘Data Source Manager’” on page 723

A “CODESYS Control Win V3” is running on the remote device. In addition, an application is running with a symbol configuration.

1. Insert a “Data Source Manager” object below your application in the device tree.
2. Select the “Data Source Manager” object and click “Add Object ➔ Data Source”.
   - The “Add Data Source” dialog opens.
3. Specify the data source name in “Name”.
   - Example: ds_Remote_Device
4. Select the “CODESYS Symbolic” data source type.
   - Data The data is transmitted via symbolic monitoring. The “Initialize Data Source Wizard - Provider Settings” dialog opens.
5. Select the connection type “CODESYS V3”.
6. Select the “Node name” option for “Type of name or address”.
7. In “Name or address of device”, specify the connection parameters for configuring the remote device. Example: “[03A7]”
   - The connection to the remote device is established and the application is read. In addition, the “Initialize Data Source Wizard - Browse Data Items” dialog opens. Below the “Variables” item, the read remote control variables are displayed in a tree view. The top node is the application that is displayed with its remote application name.
8. In the tree view, select the control variables to be transmitted, and click “Exit”.
   - The data source is configured initially. The object ds_Remote_Device is added below the node “Data Source Manager”. The object is open and the data source variables that were created are listed in the tree view on the “Variables” tab. The GVL ds_Remote_Device, where the data source variables are declared, is displayed below the folder “DataSource_Objects”.
Initial connection of devices symbolically with 'CODESYS V3 (via gateway)'

A “CODESYS Control Win V3” is running on the remote device. In addition, an application is running with a symbol configuration. The remote device is located in another network so that the communication must be routed via a gateway.

1. Insert a “Data Source Manager” object below your application in the device tree.
2. Select the “Data Source Manager” object and click “Add Object ➔ Data Source”.
   The “Add Data Source” dialog opens.
3. Specify the data source name in “Name”.
   Example: ds_Remote_Device
4. Select the “CODESYS Symbolic” data source type.
   The data is transmitted via symbolic monitoring. The “Initialize Data Source Wizard - Provider Settings” dialog opens.
5. Select the connection type “CODESYS V3 (via gateway)”. You can also specify the communication parameters for the gateway.
6. Select the “Node name” option for “Type of name or address”.
7. In “Name or address of device”, specify the connection parameters for configuring the remote device. Example: “[03A7]”
   The connection to the remote device is established and the application is read. In addition, the “Initialize Data Source Wizard - Browse Data Items” dialog opens. Below the “Variables” item, the read remote control variables are displayed in the tree view. The top node is the application that is displayed with its remote application name.
8. In the tree view, select the control variables to be transmitted, and click “Exit”.
   The data source is configured initially. The object ds_Remote_Device is added below the node “Data Source Manager”. The object is open and the data source variables that were created are listed in the tree view on the “Variables” tab. The GVL ds_Remote_Device, where the data source variables are declared, is displayed below the folder “DataSource_Objects”.

Initial connection of devices symbolically with 'CODESYS V2'

A “CoDeSys V2.3 SP PLCWinNT V2.4” is running on the remote device. In addition, an application is running with a symbol configuration.

1. Insert a “Data Source Manager” object below your application in the device tree.
2. Select the “Data Source Manager” object and click “Add Object ➔ Data Source”.
   The “Add Data Source” dialog opens.
3. Specify the data source name in “Name”.
   Example: ds_Remote_Device
4. Select the “CODESYS Symbolic” data source type.
   - Data The data is transmitted via symbolic monitoring. The “Initialize Data Source Wizard - Provider Settings” dialog opens.

5. Select the connection type “CODESYS V2”.

6. In “Connection Settings”, specify the connection parameters for configuring the remote device.
   
   Example: Driver type TCP/IP (Level 2 Route), address localhost, port 1200

   - The connection to the remote device is established and the application is read. In addition, the “Initialize Data Source Wizard - Browse Data Items” dialog opens. Below the “Variables” item, the read remote control variables are displayed in a tree view.

7. In the tree view, select the control variables to be transmitted, and click “Exit”.
   
   - The data source is configured initially. The object ds_Remote_Device is added below the node “Data Source Manager”. The object is open and the data source variables that were created are listed in the tree view on the “Variables” tab. The GVL ds_Remote_Device, where the data source variables are declared, is displayed below the folder “DataSource_Objects”.

- Table 40 “Connection settings for CODESYS V2” on page 729

---

A “CoDeSys V2.3 SP PLCWinNT V2.4” is running on the remote device. In addition, an application is running with a symbol configuration. The remote device is located in another network so that the communication must be routed via a gateway.

1. Insert a “Data Source Manager” object below your application in the device tree.

2. Select the “Data Source Manager” object and click “Add Object ➔ Data Source”.
   
   - The “Add Data Source” dialog opens.

3. Specify the data source name in “Name”.
   
   - Example: ds_Remote_Device

4. Select the “CODESYS Symbolic” data source type.
   
   - Data The data is transmitted via symbolic monitoring. The “Initialize Data Source Wizard - Provider Settings” dialog opens.

5. Select the connection type “CODESYS V2 (via gateway)”.
   
   - You can also specify the communication parameters for the gateway.

6. In “Connection Settings”, specify the connection parameters for both the gateway and the device configuring the remote device.
   
   Example: Driver type TCP/IP (Level 2 Route), address localhost, port 1200

   - The connection to the remote device is established and the application is read. The “Initialize Data Source Wizard - Browse Data Items” dialog opens. Below the “Variables” item, the remote control variables are displayed in the tree view.

7. In “Name or address of device”, specify the connection parameters for configuring the remote device. Example: “[03A7]”
   
   - The connection to the remote device is established and the application is read. The “Initialize Data Source Wizard - Browse data items” dialog opens. Below the “Variables” item, the read remote control variables are displayed in a tree view. The top node is the application that is displayed with its remote application name.
8. In the tree view, select the control variables to be transmitted, and click “Exit”.
   - The data source is configured initially. The object `ds_Remote_Device` is added below the node “Data Source Manager”. The object is open and the data source variables that were created are listed in the tree view on the “Variables” tab. The GVL `ds_Remote_Device`, where the data source variables are declared, is displayed below the folder “DataSource_Objects”.

See also

- Table 41 “Connection settings for CODESYS V2 (via gateway)” on page 730

**Initial addition of data source variables from a symbol file**

Ideally, the same symbol file on the remote device is saved on your development system.

1. Insert a “Data Source Manager” object below your application in the device tree.
2. Select the “Data Source Manager” object and click “Add Object ➔ Data Source” in the context menu.
   - The “Add Data Source” dialog opens.
3. Specify the data source name in “Name”.
   - Example: `ds_Symbols`
4. Select the “CODESYS Symbolic” data source type.
   - Data The data is transmitted via symbolic monitoring. The “Initialize Data Source Wizard - Provider Settings” dialog opens.
5. Click the item “From symbol file” in “Variable information”.
6. In “Select symbol file”, specify the storage location and the file name of the symbol file. When code is generated, an XML symbol file is created in the project directory by default.
   - Example: `D:\Projects\V3.5 SP11\Project_A.Device.Application.xml`
   - Tip: When a symbol file is specified, no additional connection settings have to be configured. A connection is not established. You work offline. You have to configure the connection settings only when you need current data from the controller that is transferred online. Activate the option “From connection settings” in the “Variable information” settings.
7. Click “Next”.
   - The “Initialize Data Source Wizard - Search Data Source Variables” dialog opens. Below the “Variables” item, the read symbols are displayed in the tree view.
8. Select the symbols to be transferred in the tree view. Then select “Exit”.
   - The data source is configured initially. The object `ds_Symbols` is added below the node “Data Source Manager”. The object is open and the data source variables that were created based on the symbol file are listed in the tree view on the “Variables” tab. The GVL `ds_Symbols`, where the data source variables are declared, is displayed below the folder “DataSource_Objects”.

- Table 41 “Connection settings for CODESYS V2 (via gateway)” on page 730
Your active project contains the control application for the remove device. The control application includes a symbol configuration with symbols that are added to your local application as data source variables.

1. Insert the “Data Source Manager” object below your local application in the device tree.
2. Select the “Data Source Manager” object and click “Add Object ➔ Data Source”.
   - The “Add Data Source” dialog opens.
3. Specify the data source name in “Name”.
   - Example: ds_Symbols
4. Select the “CODESYS Symbolic” data source type.
   - Data The data is transmitted via symbolic monitoring. The “Initialize Data Source Wizard - Provider Settings” dialog opens.
5. Select the item “<remote device>.<application>.symbol configuration” in “Variable information”.
   - Example: Device.Application.Symbol Configuration
   - Tip: When a symbol file is specified, no additional connection settings have to be configured. A connection is not established. You work offline.
6. Click “Next”.
   - The “Initialize Data Source Wizard - Search Data Source Variables” dialog opens. Below the “Variables” item, the read symbols are displayed in the tree view.
7. Select the symbols to be transferred in the tree view. Click “Finish”.
   - The data source is configured initially. The object ds_Symbols is added below the node “Data Source Manager”. The object is open and the data source variables that were created based on the symbol configuration are listed in the tree view on the “Variables” tab. The GVL ds_Symbols, where the data source variables are declared, is displayed below the folder “DataSource_Objects”.

- Table 41 “Connection settings for CODESYS V2 (via gateway)” on page 730

A “CODESYS Control Win V3” is running on the remote device. The project of the remote device is located on your development computer. The developed application there does not contain a symbol configuration.

Use this communication connection only if no resources are available for a symbol configuration in the remote PLC.

1. Insert a “Data Source Manager” object below your application in the device tree.
2. Select the “Data Source Manager” object and click “Add Object ➔ Data Source”.
   - The “Add Data Source” dialog opens.
3. Specify the data source name in “Name”.
   - Example: ds_Remote_Device
4. Select the “CODESYS ApplicationV3” data source type.
   - Data The data is transmitted via address monitoring. The “Initialize Data Source wizard - Provider settings” dialog opens.
5. Select the “Other project” option for “Select project type”.

Initial addition of data source variables from a symbol configuration

Initial connection of devices with address monitoring
6. For “Choose file”, specify the file and storage location of the project on the remote device. Example: C:\Data\Projects\PLC_A.project.
   - The remote device is displayed in the tree view of the window below, and as a result the connection was established.
7. Select the link “From device”.
   - The connection parameters to the remote device are read and displayed in the dialog. The connection is configured.
8. Click “Next>”.
   - The “Initialize Data Source Wizard - Browse Data Items” dialog opens. Below the “Variables” item, the remote control variables are displayed in the tree view.
9. In the tree view, select the control variables to be transmitted, and click “Exit”.
   - The data source is configured. A connection is established. The settings are stored in the object and can be modified in the editor of the object.

The data source is configured initially. The object ds_Remote_Device is added below the node “Data Source Manager”. The object is open and the data source variables that were created are listed in the tree view on the “Variables” tab. The GVL ds_Remote_Device, where the data source variables are declared, is displayed below the folder “DataSource_Objects”.

- “Tab 'Communication' for CODESYS ApplicationV3” on page 732

### Editing data source variables

In runtime mode, the remote data is saved to the data source variables. The data source variables and their mapping to the remote variables are displayed in the data source editor below of the “Variables” tab. If the local and remote variables have the same names and the same data types, then the data is mapped 1:1. The variables and the data types are created automatically. That is the regular procedure.

You can also map to existing variables. This is necessary, for example, if a visualization includes a data type in an interface. Then the same data must be passed to this visualization. In this case, the declared local variable and the remote variable have the same data type, for example from one library. Moreover, you can map a local variable with a conforming data type to a remote variable. The data type can be created in the “Type Mappings” tab.

The specifically created variables and data types are declared in the “DataSources_Objects” folder. For each data source, a global variable list of the same name as the data source is declared there. Moreover, the data source variables usually have the identical or conforming data type as the remote control variable and they are declared as user-defined data types (DUT objects). Considering all data sources, multiple declaration of the same data types is avoided.

Do not edit the data interface in the “DataSources_Objects” folder manually. It is created initially when adding a data source. Changes can be made later in the editor of the data source.

- Chapter 1.3.1.10.4.4 “Updating data interfaces” on page 291
- Chapter 1.3.1.25.1.10 “Object 'Data Source' - Tab 'Variables'” on page 725

### Selecting variables for data transfer

You can edit the selection of the data source variables.
Requirement: The remote device and its application are running. A data source manager is already inserted below the local application with a data source.

1. Open the editor of the data source.
2. Select the “Variables” tab.
3. Click “Update Variables”.
   ⇒ The “Browse Variables” dialog opens.
4. Activate the variables that should be transferred and click “OK” to close the dialog.
   ⇒ The data source variables are modified according to the selection. The declaration of variables and data types is also modified.
   The “Variables” tab shows the modified selection. Moreover, the mapped remote variable is listed in the “Remote variable” column.

- Chapter 1.3.1.10 “Working with control networks” on page 270
- Chapter 1.3.1.10.4.4 “Updating data interfaces” on page 291
- Chapter 1.3.1.25.1.10 “Object ‘Data Source’ - Tab ‘Variables’” on page 725

Mapping remote variables to a new variables

You need to map a remote variable to a global implicit variable that is created new. That is the regular procedure for transposing data source to 1:1.

Requirement: A project is open. A data source manager and a data source below it are located in the device tree of the local application.

1. Open the editor of the data source.
2. Select the “Variables” tab.
   ⇒ The data source variables are listed.
3. Select a variable and click the symbol in the “Create or map” column.
4. Specify a name in “Local variable”.
   ⇒ A variable is declared automatically and it contains the same value as the mapped remote variable.

Mapping remote variables to an existing variables

You need to map a remote variable to an existing variable.

Requirement: A data source manager and a data source below it are located in the device tree of the local application. The remote data that should be transferred is displayed in the editor of the data source in the “Variable” tab

1. Open the editor of the data source.
2. Select the “Variables” tab.
3. Select a variable and click the symbol in the “Create or map” column.
   ⇒ A variable contains the same value as the mapped remote variable.
First, create a conforming data type and then use it for a variable.

1. Open the editor of the data source.
2. Select the “Type Mappings” tab.
3. Select the data type in the list that you want to edit.
   - The elements of the data type are listed in the window below the data type list
4. Specify a name for the data type. Example: DataType_A. Select the name for the remote data types to which the local type should conform. Example: Library1.DataType_A.
5. Modify it in the window below the data type list and remove the elements that are not necessary for the data transfer.
6. Select the symbol for this data type in the “Create or map” column.
   - The data type DataType_A is declared in the “DataSources_Objects” folder.
7. Select the “Variables” tab.
8. Specify a name in the “Local variable” column. Example: Var_A
9. Select the symbol in the “Create or map” column.
10. Specify the data type DataType_A in the “Mapping type” column.
11. Select the remote variable with the data that should be transferred. Example: appPLC_A.Data_A. Use the input assistance for this.
   - A variable Var_A is declared automatically with the user-defined data type DataType_A. During data transfer, it receives the data of the mapped remote variables.
Example

Library SnakeUtil

The example demonstrates how variables of the data source are created. At this time, new variables are created, data is mapped to existing data types and their variables, and new data types are created with type-conforming mapping.

The remote PLC uses POU instances from the SnakeUtil library and the HMI device visualizes these POU instances. This is why the HMI application requires a variable in the operating interface that has a data type appropriate for a visualization template. As a result, the SnakeUtil library is linked integrated into the HMI application and the HMI variables instantiate the SnakeUtil.SnakeVisu visualization function block.

The following library function blocks from the SnakeUtil library are used in the remote PLC.

- Function block SnakeUtil.Snake: Equipped with much logic and calling from external functions.
- DUT SnakeUtil.PositionInfo: Two values (of the variables x and y)
- DUT: SnakeUtil.DrawingInfo: Image ID
- The SnakeUtil.SnakeVisu visualization function block with transfer parameter SnakeUtil.Snake visualizes the Snake function block.

The following settings are entered in the editor of the “Type Mappings” tab:

In the visualization, a frame is inserted with a reference to SnakeUtil.SnakeVisu. This expects to have the type SnakeUtil.Snake.

The data types SnakeUtil.PositionInfo and SnakeUtil.DrawingInfo are mapped to existing data types (symbol in the “Create or map” column). The data types are small and contain data only.

The SnakeUtil.Snake function block is very complex and calls external functions that are not available in the HMI visualization. The function block with code is not required in the visualization. You need a less extensive but compatible and conforming type in the HMI visualization. Therefore, do not create the original data type directly. Instead, first modify the original data type and remove the unnecessary elements. Then create the new data type Snake by selecting the symbol in the “Create or map” column.

Editing communication

You have added a “Data Source Manager” object and below it a “Data Source” object below your application in the device tree. The connection parameters are displayed in the data source editor of the “Communication” tab. You can modify it there.

The data source type and the current connection type are listed in the status bar. It is not possible to modify the data source type later.

See also

- Chapter 1.3.1.10.4.1 “Adding initial data sources” on page 282
- Chapter 1.3.1.25.1.12 “Object ‘Data Source’ - Tab ‘Communication’” on page 728

Updating data interfaces

The data source variables are updated cyclically in runtime mode. Only the data is updated that either is used in the current visualization or has the property “Update always”.

2020/12/10
You can define the time interval. Moreover, you can define variables whose data is transferred in each update interval, and therefore they are always update. To update variables that are not used in the application code, you can implement an update programmatically with the help of interface functions from the data source manager.

<table>
<thead>
<tr>
<th>NOTICE!</th>
</tr>
</thead>
<tbody>
<tr>
<td>If data traffic between the remote and local device is too high, then the update rate is reduced automatically. This can lead to an incomplete transfer.</td>
</tr>
</tbody>
</table>

See also

- [Chapter 1.3.1.25.1.10 “Object ’Data Source’ - Tab ’Variables’” on page 725](#)

### Setting the update rate

1. Open the editor of the data source.
2. Click the “General and Diagnosis” tab.
3. Specify a value in the “Update rate” field.

   **Example:** 100

   - The data from the remote device to the local device is transferred every 100 ms.

See also

- [Chapter 1.3.1.25.1.13 “Object ’Data Source’ - Tab ’General and Diagnosis’” on page 734](#)

### Selecting the variable for ’Update always’

<table>
<thead>
<tr>
<th>NOTICE!</th>
</tr>
</thead>
<tbody>
<tr>
<td>Avoid updating too many variables always. Each update produces additional data traffic at the connection between the remote and local devices. When data traffic is too high, the update rate is reduced automatically. This can lead to an incomplete transfer.</td>
</tr>
</tbody>
</table>

1. Open the editor of the data source.
2. Activate the option “Update always” for a variable.

   - The data of the variables is transferred at each update cycle, even when the data has not changed.

See also

- [“Tab ’Variables’” on page 725](#)

### Updating data programmatically

The data source manager provides interface functions in the Datasources library. If a data source manager is integrated in the application code, then the global variable g_Datasources is instantiated automatically. This provides access to the interface functions.

Then you can update individual variables that are not called in the active visualization.
The variable `ivar` is activated and deactivated by means of methods from the `Datasources` library so that its value is transferred. Furthermore, you can configure that the variable is updated only over a defined duration in order to save transfer capacity.

```cpp
//Synchronize with DatasourcesTask and block until access is possible
//Regard the feedback in ERR_OK or in ERR_DE_MULTITASKING_LOCKED
if (Datasources.BeginDataConfiguration(TRUE)) {  
    g_DataServer.UseData(ADR('RemoteDevice.Application.PLC_PRG.iVar'));  
    // Deactivate variable
    g_DataServer.ReleaseData(ADR('RemoteDevice.Application.PLC_PRG.iVar'));  
    g_DataServer.EndDataConfiguration();
}
```

The data configuration is started with `BeginDataConfiguration(TRUE)`, thus initializing the synchronization of the task `DatasourceTask` with the application task. The value `TRUE` blocks the processing until the access to the variable is possible; `FALSE` repeats access attempts without blocking. The return values `ERR_OK` and `ERR_DS_MULTITASKING_LOCKED` provide feedback about the access attempts.

When synchronization is successful, the variable is activated by means of the `UseData` method. Then the data configuration is completed with the `EndDataConfiguration` method and the synchronization triggered again with the task `DatasourceTask`.

The `ReleaseData` method is used in the same way for deactivating the variable again at the desired processing time.

### Using remote data

The variables that are listed in the data source editor of the “Variables” tab (and declared in the “DataSources_Objects” folder) can be used in your application like IEC variables. For example, you can visualize the variables. If multiple data sources are available and therefore conflicts occur regarding unique variable names, then you must specify the data source name as the prefix. If no conflicts occur, then this is not necessary and you can map the variables without a data source prefix.

`<data source name>.<function block name>.<variable name>`

### Displaying variable values from the remote device

You need to show the variable value `iTemp` of a remote device in a visualization element of a visualization in the local application (with the data source manager).

Initial situation: A data source `dsRemotePLC` is below the local data source manager where the connection to the remote device is configured. In addition, the variable `iTemp` is selected in the data source editor of the “Variables” tab.

1. Select the visualization element in the editor view. Select the properties “Text variables”-“Text variable” in the “Properties” view.
2. Select the `iTemp` variable.
   - The variable mapping is qualified. Example: `dsRemotePLC.PLC_PRG.iTemp`.
3. Select the “Text” property of the visualization element and type in the following:
   ```text
   Temperature: %s
   ```
   - The value of the `iTemp` variable from the remote device `RemoteDevice` is displayed.
4. Download and start the remote application.
5. Download and start the local application.
   - The visualization starts and displays the actual value of `iTemp`. 
1.3.10.5 Subordinate safety controller

If a safety controller is below the standard controller, then the communication with the development system and the data exchange run via the standard controller. The communication links of the safety controller can interrupt the execution of commands that affect the standard controller. You find a notice about this for each these command.

Possible interruptions

- Temporary interruption: During the execution of the command (for example: download), the connections with the safety controller are interrupted first and then are automatically available again afterwards. If the interruption time is too long, then safety-oriented reactions can occur in the output devices and connected network variable receiver safety controllers. Then in the safety controller, the corresponding communication errors must be acknowledged (if not done automatically) in order to end the safety-oriented reactions. This affects the connection to their field devices and network variable receiver connections to other sender safety controllers. In the case of a connected safety controller with network variable senders, the communication errors must be acknowledged in the other safety controllers.

- Permanent interruption: The execution of commands (for example: delete) leads to an interruption that is ended again by another action (for example: download). As a result of the interruption, safety-oriented reactions can occur in the output devices and connected network variable receiver safety controllers. After ending the interruption, the corresponding communication errors must be acknowledged in the safety controller (if not done automatically) in order to end the safety-oriented reactions.

For a subordinate safety controller, the routing runs via "<Name of SafetyApp>_Mapping". In some cases, it can happen that the user can see this application in the device tree.

CAUTION!

No commands may be executed in the application "<Name of SafetyApp>_Mapping".

- Chapter 1.3.1.10 “Working with control networks” on page 270
1.3.1.11 Transferring an application to the PLC

1.3.1.11.1 Configuring the connection to the PLC .................................................. 295
1.3.1.11.2 Encrypting communication, changing security settings .......................... 296
1.3.1.11.3 Handling of device user management ............................................. 300
1.3.1.11.4 Generating application code ............................................................. 303
1.3.1.11.5 Downloading the application code, logging in, and starting the PLC .... 304
1.3.1.11.6 Generating boot applications ............................................................ 305
1.3.1.11.7 Downloading source code to and from the PLC ............................. 307
1.3.1.11.8 Distributing application code to different memory areas ................. 308

In order to transfer your application to the PLC, the program must be compiled without any errors and the connection settings for the PLC must be set.

If the communication with the controller is encrypted and/or restricted to specific users, then you need the respective certificates and permissions. See here:

- Chapter 1.3.1.11.3 “Handling of device user management” on page 300
- Chapter 1.3.1.9.18 “Encrypting an application” on page 242

You can edit the basic security policy for communication with the device in a dialog on the “Communication Settings” tab of the device editor. See here:

- Chapter 1.3.1.11.2 “Encrypting communication, changing security settings” on page 296

If these requirements are fulfilled, then the application is downloaded to the PLC at login.

1.3.1.11.1 Configuring the connection to the PLC

The connection to the controller is established via a gateway. This gateway can be your development computer or another network computer connected to the controller. The “Communication Settings” dialog is available for configuring the connection path. This dialog opens automatically when you attempt to log in, but the communication settings have not been configured yet.

If the communication with the controller is encrypted and secured by means of user management, then you need a corresponding certificate and credentials to establish the connection to the controller. In this case, see the relevant instructions on the “Encrypting communication and Changing Security Settings” help page.

Requirement: The project can be compiled without any errors. A programmable logic controller (PLC) is inserted in the device tree.

1. In the device tree, select the PLC and click “Project ➔ Edit Object”.
   ☐ The PLC opens in the editor.
2. Select the “Communication Settings” tab.
3. Click “Scan Network” in the menu bar.
   ☐ The “Select Device” dialog opens. All available devices in the network are shown on the left side.
4. Select the required device and click “OK”.
   ☐ The connection path for the PLC is set.
You can reset the communication settings view to the original view in the CODESYS options of the device editor.

1.3.11.2 Encrypting communication, changing security settings

NOTICE!
Recommendations for data security

In order to minimize the risk of data security violations, we recommend the following organizational and technical actions for the system where your applications are running. As far as possible, avoid exposing the PLC and control networks to open networks and the Internet. Use additional data link layers for protection, such as a VPN for teleaccess. Install firewall mechanisms. Restrict access to authorized people. Change any default passwords regularly before and after commissioning.

Use the security features supported by CODESYS and the respective controller, such as encryption of communication with the controller and intentionally restricted user access.

Communication with the device can be protected by means of encryption and user management on the device. You can change the current security preset on the “Communication Settings” tab of the device editor.

Establishing a connection to the controller, logging in, installing a trusted certificate for encrypted communication

- Requirement: Encrypted communication with the controller and user management are enforced on the controller. However, there is no individual password yet, no certificate installed on your computer, and the connection to the controller is not configured yet.

1. In the device tree, double-click the controller.
   - The device editor opens.
2. Click the “Communication Settings” tab.
3. Click “Scan Network”.

- Requirement: Encrypted communication with the controller and user management are enforced on the controller. However, there is no individual password yet, no certificate installed on your computer, and the connection to the controller is not configured yet.
4. Select a controller.
   ⇒ A dialog opens, informing you that the certificate of the device does not have a trusted signature for communication. You are prompted whether or not to install this certificate as trusted in the local "Controller Certificates" store on your computer.

   NOTICE!
   A controller certificate installed in this way is valid for only 30 days.
   This gives you time for the following long-term solutions:
   – Creation of an additional self-signed certificate with a longer term (for example, 365 days). You can do this on the security screen if you have installed the CODESYS Security Agent, even if a certificate already exists. Using the PLC shell of the device editor is not a convenient workaround.
     See below: "Configuring encrypted communication with a controller certificate with a more long-term validity period"
   – Importing a CA-signed certificate. This is currently only possible via the PLC shell commands of the runtime system. Therefore we recommend to use self-signed certificates first.

5. Click “OK” to confirm the dialog prompt.
   ⇒ The certificate is listed as trusted.
   After accepting the self-signed certificate for the first time, you can establish an encrypted connection with the controller again and again without further prompts.

6. If user management is currently enforced, then you are prompted to login. When you login for the first time, enter “Administrator” as your user name and password. Then the “Password expired, please enter a new one!” dialog opens to define an individual password.
   ⇒ You can now login to the controller as usual.

7. All saved controller certificates (from step 5) are kept in the local Windows Certificate Store on your computer. You can access this by means of “Execute”, certmgr.msc command.
   ⇒ All registered certificates for encrypted communication with controllers are listed here in “Controller Certificates”.

Requirement: The CODESYS Security Agent add-on product is installed. You want to replace the temporary certificate (as described above) acquired the first time you connected to the protected controller with a certificate with a longer validity period.

In this case, the “Security Screen” view provides an additional tab: “Devices”. This allows for the simple configuration of certificates for the encrypted communication with controllers. For operation, see the help for CODESYS Security Agent: "Encrypted Communication with Devices via Controller Certificates".

Choose this less convenient method when the CODESYS Security Agent is unavailable to you. In this case, you can set up a certificate with a more long-term validity period for communication encryption on the “PLC Shell” tab of the device editor.
☑ Requirement: You are connected to the controller.

1. At first, you check if a qualified certificate is already on the controller. If no certificate is available, then you create a new certificate.
   
   Open the device editor by double-clicking the controller in the device tree, and select the **PLC Shell** tab.
   
   ⇒ The tab appears with a blank display window. Below that is a command line.

2. Type the following command in the command line: `cert-getapplist`.
   
   ⇒ All used certificates are listed. The list includes information about the runtime component and whether or not the certificate is available.

3. If a certificate still does not exist for the component **CmpSecureChannel**, then type the following command in the input line:

   `cert-genselfsigned <number of the component in the apllist>`

4. Click the **Log** tab and then the refresh button (⇒).
   
   ⇒ The display shows whether or not the certificate was generated successfully.

5. Change back again to the **PLC Shell** tab and type the command `cert-getapplist`.
   
   ⇒ The new certificate for the component **CmpSecureChannel** is displayed.

6. In the next two steps, activate encrypted communication in the security screen of CODESYS.

7. Open the **“Security Screen”** by double-clicking in the status bar.

8. On the **“User”** tab, select the **“Enforce encrypted communication”** option in the **“Security Level”** group.
   
   ⇒ The communication to all controllers is encrypted. If there is not a certificate on a controller, then you cannot login to it.

   The connecting line between the development system, the gateway, and the controller is displayed in yellow on the **“Communication Settings”** tab of the device editor of the controller.

9. As an alternative to the **“Enforce encrypted communication”** option which applies to all controllers, you can also define encrypted communication for specific controllers only. To do this, select the **“Communication Settings”** tab in the editor of the respective controller. Then click **“Encrypted Communication”** in the **“Device”** list box.
   
   ⇒ The communication to this controller is encrypted. If there is not a certificate on the controller, then you cannot login to it.

   The connecting line between the development system, the gateway, and the controller is displayed in yellow on the **“Communication Settings”** tab of the device editor of the controller.

10. When you login to the controller for the first time, a dialog opens with information that the certificate of the controller is not signed by a trustworthy authority. In addition, the dialog displays information about the certificate and prompts for you to install it as a trustworthy certificate in the local store in the **“Controller Certificates”** folder.

    When you confirm the dialog, the certificate is installed in the local store and you are logged in to the controller.

    In the future, communication with the controller will be encrypted automatically with this control certificate.
11. To increase security for key exchange for controllers < V3.5 13.0, you can generate Diffie–
    Hellman parameters on the controller. To do this, type the command cert-gendhparams
    in the input line.

    This is no longer required for controllers >= V3.5.13.0.

    !
    **NOTICE!**
    Caution: Generating the Diffie-Hellman parameters can last for several
    minutes or even several hours. However, this process must be executed
    only one time for each controller. The Diffie-Hellman parameters increase
    security for key exchange and for future attacks against encrypted data
    recording.

Changing the communication policy (encryption, user management)

- Requirement: The connection to the device is established.
- 1. In the device tree, double-click the controller.
   ➜ The device editor opens.
- 2. Click the “Communication Settings” tab.
- 3. Open the “Device” menu in the header of the editor. Click “Change Communication
   Policy”.
   ➜ The “Change Communication Policy” dialog opens.
- 4. In the upper part of the dialog, you can toggle between the “Optional encryption”,
   “Enforced encryption”, and “No encryption” settings.
- 5. In the lower part of the dialog, you can toggle between the “Optional user management”
   and “Enforced user management” settings.

Enabling and disabling enforced encrypted communication

- Requirement: The device supports encrypted communication.
- 1. In the device tree, double-click the controller.
   ➜ The device editor opens.
- 2. Click the “Communication Settings” tab.
- 3. Open the "Device" menu in the header of the editor. Click “Encrypted Communication”.
   The status toggles between enabled and disabled.
   ➜ If the “Encrypted communication” option is selected, then the connection line between
   the development system, the gateway, and the device is highlighted in the editor in
   bold and in color in the graphical representation.

1.3.1.11.3 Handling of device user management

NOTICE!
Recommendations for data security

In order to minimize the risk of data security violations, we recommend the following organizational and technical actions for the system where your applications are running. As far as possible, avoid exposing the PLC and control networks to open networks and the Internet. Use additional data link layers for protection, such as a VPN for teleaccess. Install firewall mechanisms. Restrict access to authorized people. Change any default passwords regularly before and after commissioning.

Use the security features supported by CODESYS and the respective controller, such as encryption of communication with the controller and intentionally restricted user access.

For devices that support a device user management, the device editor includes the “Users and Groups” tab and the “Access Rights”. When offered by the device, you can view and also edit the user management for the device. Here, the defined user groups can be granted or denied specific rights on the controller.

The device user management can already be set up in the device description.

Note the commands in the “Online ➔ Security” menu. You can easily add, edit, or remove a user account on the controller where you are currently logged in.

In order for the “Access Rights” tab to be available in the device editor, the corresponding CODESYS option must be selected in the device editor and unlocked in the device description. If the device editor is not available, then contact the manufacturer of the controller.

In order to grant access rights to user groups, users and user groups first have to be configured on the “Users and Groups” tab of the device editor. User management first has to be set up on the controller before access rights can be configured on it.

General information about device user management

Note that access rights can only be granted to groups, not to individual users. Therefore every user has to be a member of a group.

Access rights can be granted for the following actions which are performed on the individual objects of the controller:

- View
- Modify
- Add/Remove
- Execute

Each object on the controller is usually assigned to just one component. And all of the above access rights can be used by the object. However, in most cases only the following two rights are required for an object:

- “View”
- “Modify”

The objects are organized in a tree structure. There exist two root objects for both of the separate types of objects: “Runtime objects ➔ Device” and “File system objects ➔ /”.

In the file system objects, the rights can be granted to folders of the current execution directory of the controller.
In the runtime objects, all objects are managed that have online access in the controller and therefore have to control the access rights.

In general, the access rights are inherited from the root object (also “Device” or “/”) to the subobjects. This means that if you deny or explicit grant a right to a user group on a parent object, then this first affects all child objects.

For the rights, a distinction also has to be made as to whether a right is explicitly granted, denied, or neutral. Neutral means that it is neither explicitly granted nor denied. In this case, the right of the parent object applies. However, if no right has been explicitly granted or denied in the entire hierarchy of the object, then it is by definition initially denied. This means that all rights are denied at first.

The only exception is the access right for the “View” action. This is explicitly granted initially for every user group both on the “Device” runtime object as well as on the “/” file system object. This allows read access to all objects at first, unless it is explicitly denied in child objects.

The “Everyone” user group has a special position here: This right only applies at the very end of the rights check if no other user group on a level has explicitly granted or denied access.

For an overview table for the objects, see the “Tab ‘Access Rights’” chapter.

See the following instructions for handling the editor for the device user management:

**First-time login on the controller in order to edit or view its user management**

Requirement: the controller has a device user management.

1. Double-click the controller device object in the device tree.
   ➞ The device editor opens.
2. Click the “Users and Groups” tab.
3. Click [Synchronization].
   ➞ A dialog opens prompting whether the device user management should be activated.
4. Click “Yes” to confirm the prompt.
   ➞ The “Device User Logon” dialog opens.
5. Specify “Administrator” as the “User Name” and “Password”.
   ➞ The “Password expired, please enter a new one!” dialog opens.
6. Specify a new “Password”. The password strength is displayed.
   ➞ After you click “OK” to confirm, the device user management is shown in the editor view.

**Setting up a new user in the user management of the controller**

Requirement: the controller has a device user management. You have the corresponding access data.

1. Double-click the controller device object in the device tree.
   ➞ The device editor opens.
2. Click the “Users and Groups” tab.
3. Click [Synchronization] to load the user management configuration from the controller to the editor. If you are not logged in to the device yet, then the “Device User Logon” dialog opens for entering the user name and password.
   ➞ The user management configuration of the device is shown in the editor.
4. In the “Users” view, click “Add”.
   ⇒ The “Add User” dialog opens.

5. Specify the name of the new user and assign the user to a group. This counts as the
   user’s minimum required default group. The user can be assigned to other groups later.
   Define and confirm a “Password” for the user. Define whether the user can change the
   password and whether the user has to change the password at the first login. Click “OK”
   to confirm.
   ⇒ The new user appears in the “Users” view as a new node and in the “Groups” view as
   a new subentry of the selected default group.

Changing of access rights to controller objects in the user management of the controller

Requirement: the controller has a device user management. You have the corresponding
access data.

1. Double-click the controller device object in the device tree.
   ⇒ The device editor opens.

2. Click the “Access Rights” tab.

3. Click (Synchronization) to load the rights management configuration from the controller
to the editor. If you are not logged in to the device yet, then the “Device User Logon”
dialog opens for entering the access data.
   ⇒ The access rights management configuration of the device is shown in the editor.

4. Select the object whose access right you want to change to the left in the object tree.
   ⇒ In the “Rights” view, a table shows the access rights to this object for all configured
   user groups.

5. Double-click the right in the table that you want to change.
   ⇒ If the object has child objects, then a dialog prompts whether you want to modify the
   rights for the child objects.

6. Click “Yes” or “No” to close the prompt.
   ⇒ The rights are switched from “allowed” + to “not allowed” −, or the other way around.
The symbol in the table cell changes accordingly. Explicitly set rights appear in the
  table as green or red symbols. Rights that are inherited from a parent object appear as
  gray symbols.
1. Double-click the controller device object in the device tree.
   ⇒ The device editor opens.
2. Click the “Users and Groups” tab.
3. Click . Select the file (.dum) from the local file system with the saved user management and click “Open” to confirm.
   ⇒ The users and groups described in the file are shown in the editor.
4. Edit the configuration however you like. For example, change the user password or add a new user.
5. Click the “Synchronization” button to transfer the configuration to the device.
   ⇒ A dialog asks you to select the desired operation.
6. Select the “Download the editor content to the device and overwrite the user management there.” option.
   ⇒ The “Device User Logon” dialog opens.
7. Provide valid credentials in order to login to the controller.
   ⇒ After you login successfully, the changes are transferred from the editor to the device. As long as the synchronization is not switched off, CODESYS automatically transfers more changes to the controller that are made in the editor.

### 1.3.1.11.4 Generating application code

The application code is the machine code that a PLC executes when you start an application. CODESYS automatically generates the application code from the source code that was written in the development system. This is done automatically before downloading the application to the PLC. Before the application code is generated, a test is performed for checking the assignments, the data types, and library availability. In addition, the memory addresses are allocated when the application code is generated.

You can execute this command explicitly by clicking “Build ➔ Generate Code”. This is useful for detecting any errors in your source code, even when the PLC is not connected yet. The errors are printed to the message view (“Build” category).

**NOTICE!**

If you have encrypted the application, then consider the following information: If a (new) boot application generated on request after an online change, then the boot application is formed in the RAM with the current code that is NOT encrypted.
Explicit generation of application code

Requirement: The application can be compiled without any errors.

▷ Click “Build ➔ Generate code”.

⇒ The application code is generated. Detailed information about memory allocation is printed in the message view.

See also

● % Chapter 1.3.1.11.6 “Generating boot applications” on page 305
● % Chapter 1.3.1.25.2.5.3 “Command ‘Generate Code’” on page 917

Messages when generating application code

When you generate application code, CODESYS prints information about memory allocation in the message view. Gaps arise in the memory because reallocation is only for new and changed blocks and variables due to the incremental memory compile. Online changes have the same effect. This fragmentation reduces the amount of available memory. However, you can completely reallocate the memory by clicking “Clean” and therefore increase the amount of free memory.

More information about messages at code generation: Syntax errors and errors that CODESYS detects during code generation and memory allocation appear in the message view in the “Build” category. At each code generation, information is also provided about the code size, the data size (in bytes), the contents of the allocated memory, and the highest address used (byte). It depends on the PLC which data and code is stored in which memory areas. For example, code and data is located in the same area on the CODESYS Control Win V3. For the addresses %I, %M, and %Q, memory is always reserved, even when a variable is not assigned to an address. After cleaning the application, the memory is reassigned completely. In this case, small gaps may result from the predefined alignment (normally 8). Larger gaps result from changing a date without cleaning, for example increasing an array range. In this case, only the affected POUs are rebuilt. Online changes have the same effect. Resulting gaps are reused when possible for other changes. As small gaps can no longer be used at all in some cases, the size of the "largest correlating memory gap" of the affected memory area (in bytes) is issued as meaningful information for the current code generation, as well as its percentage of the total memory.

Please note the options for generating applications.

See also

● % Chapter 1.3.1.25.3.10.9 “Dialog ‘Properties’ - ‘Application Build Options’” on page 1051

Encrypting the application code

See also

● % Chapter 1.3.1.9.18 “Encrypting an application” on page 242

1.3.1.11.5 Downloading the application code, logging in, and starting the PLC

In order to download the source code of your application to the PLC, you must log in to the PLC with application. If there are several applications in the project, then you must switch explicitly to the correct application first.

When you download an application to the PLC, CODESYS performs the following checks:

The list of applications on the PLC is compared with the applications available in the project. If they do not match, then you are prompted to download the application that is not on the PLC yet or delete existing applications.
For "externally implemented" blocks in the application to be downloaded, CODESYS checks whether these are available on the PLC. If they are not available, then the message "unresolved reference(s)" is printed to a dialog prompt and to the message view. Then CODESYS compares the parameters (variables) of the blocks in the application to be downloaded and the parameters of the same-named blocks in the application that exists on the PLC (signature check). If there are any discrepancies, then the message "invalid signature(s)" is printed to a dialog prompt and to the message view.

If the "Download Application Info" check box is selected in the application properties, then additional information about the application contents are downloaded to the PLC.

If multiple applications exist for the same device, then notice that the "I/O Mapping" dialog contains the definition for which of the applications is used for the I/O mapping of the device.

See also
● "Chapter 1.3.1.25.1.1 "Object ‘Application’" on page 710"

**Transferring an application and starting the program**

Requirement: The application contains no errors and the communication settings of the PLC are correct. The application does not exist yet on the PLC: The application and the communication with the controller are not encrypted.

1. Select the required application in the device tree. Skip to Step 3 if you have only one application.
2. Click “Set Active Application”.
   ⇒ The application name appears in bold typeface.
3. Click “Online ➔ Login”.
   ⇒ A dialog prompts you whether the application should be created on the PLC.
4. Click “Yes” to confirm.
   ⇒ The application is downloaded to the PLC.
5. Click “Debug ➔ Start” or press the [F5] key.
   ⇒ The application is running on the controller.

### 1.3.11.6 Generating boot applications

A boot application is the application that is started automatically when the controller is switched on or started. For this to happen, the application on the controller must exist as a file `<application name>.app`.

For each application that is running on the controller, a boot application can also be saved there.

By default, CODESYS generates the boot application automatically when an application is downloaded and transfers them to the PLC. The defaults for generating automatically are located in the “Boot application” category of the application “Properties”. When logging in with a changed application, you are still prompted whether or not to generate a new boot application.

In addition, you can create a (new) boot application at any time in online mode by clicking “Online ➔ Create boot application”.

You can create and save a local copy of a boot application in offline mode as well. Then, you can copy this application to the controller with external tools. In this way, you transfer an application to the controller, even when there is no connection to CODESYS.
Generating boot applications on the controller automatically and explicitly

Requirement: Offline mode; the application is compiled without errors. The connection to the controller is configured and the controller is running. The application is active. The following steps demonstrate the options:

1. Click “Online ➔ Login”.
   ⇒ The boot application file `<application name>.app` is created on the controller with the checksum of the boot application `<application name>.crc`.

2. Click “Online ➔ Create Boot Application” explicitly.
   ⇒ The files on the controller are replaced by new files.

3. Log out.

4. Change the application. Log back in to the controller.
   ⇒ You are prompted whether an online change should be performed. You see the “Update boot application” check box in the same dialog box. This is cleared by default, but this can be changed in the “Boot Application” category of the application “Properties”.

5. Keep the check box cleared and continue login.
   ⇒ A new boot application file is not created.

   ⇒ The boot application that was created above is running on the controller.

You can save the encrypted boot application on the controller. These settings are defined in the “Application Build Options” category of the application “Properties”.

See also
- § Chapter 1.3.1.25.3.10.9 “Dialog ‘Properties’ - ‘Application Build Options’” on page 1051
- § Chapter 1.3.1.25.3.10.2 “Dialog ‘Properties’ - ‘Boot Application’” on page 1047
- § Chapter 1.3.1.14.1 “Executing the online change” on page 355
- § Chapter 1.3.1.25.2.6.4 “Command ‘Create Boot Application’” on page 926

Creating boot applications in offline mode

Requirement: Offline mode; the application is compiled without errors. You want to generate a boot application for an application and save it in the file directory for copying it later to the controller by using external tools (without CODESYS).

1. Click “Online ➔ Create Boot Application”.
   ⇒ A dialog box opens for specifying a save location in the local file system.

2. Click a save path and then click “Save”.

3. If the application has changed since the last boot application was generated, then you are prompted to use a new code for the boot application. In this case, click “Yes”.
   ⇒ The “Save as” dialog box opens.

4. Select a directory and click “Save”.
   ⇒ The boot application file `<application name>.app` is created in the given path.

You are prompted whether or not the build information for the boot application is saved.
5. Click “Yes”.
⇒ The build information is saved to the project directory as a file named `<application
name>.compileinfo`. It is a requirement for a possible online change the next time
the application is updated. Please note: Clicking “Build ➔ Clean” deletes this file.

See also
● § Chapter 1.3.1.25.2.6.4 “Command ‘Create Boot Application’” on page 926

When using CODESYS Control Win V3

When using a CODESYS Control Win V3, the application name must also be included in the
configuration file (*.cfg).

[CmpApp]
Application.1=MyApplication

1.3.11.7 Downloading source code to and from the PLC

CODESYS provides the capability of loading project source code to a PLC as a project archive.
You can then transfer this project archive back to the development system from the PLC as
needed.

Requirement: The connection settings are configured for the affected controllers.

**Downloading source code to the PLC**

1. Choose the command “File ➔ Source Download”.
⇒ The dialog box “Select Device” opens.

2. Select the controller to receive the source code. Click “OK”.
⇒ CODESYS writes the archive file `Archiv.prj` to the controller.

![By choosing the command “Online ➔ Source Download to Connected Device”,
you can load the source code directly to the connected device.]

See also
● § Chapter 1.3.1.25.2.1.11 “Command ‘Source Download’” on page 860
● § Chapter 1.3.1.25.2.6.7 “Command ‘Source Download to Connected Device’” on page 929
● § Chapter 1.3.1.25.3.11.5 “Dialog ‘Project Settings’ – ‘Source Download’” on page 1063

**Loading source code from the PLC**

1. Choose the command “File ➔ Source Upload”.
⇒ The dialog box “Select Device” opens.

2. Select the controller to send the source code. Click “OK”.
⇒ The “Extract Project” dialog box opens.
3. Select the destination directory where you want to extract the project archive. Click “Extract”.
   ⇒ CODESYS extracts the project archive to the directory.

4. Then you are prompted to open the project archive. Click “Yes”.
   ⇒ The project opens.

See also
●  Chapter 1.3.1.25.2.1.10 “Command ‘Source Upload’” on page 859

1.3.1.11.8 Distributing application code to different memory areas

CODESYS provides the capability of storing application code in different memory areas on the controller. The requirement is that you are using a controller that supports this functionality. For these specific controllers, your application automatically gets “POU Locations” object for you to assign different memory areas to your individual POUs.

NOTICE!
Also note manufacturer-specific or controller-specific specifications or information about this functionality.

☐ Requirement: The application does not contain any compile errors.

1. Double-click the “POU Locations” object in the “Devices” view.

2. In the open object, click the Generate Code button.
   ⇒ All program blocks of the application are displayed with the respective object type, current location in the memory, and code size.

3. Double-click the entry in the “Configured Location” column for the POUs that you want to store in another memory area.
   ⇒ A list box opens.

4. Select a memory area from the drop-down list.

5. Click “Clean” and then “Generate Code”.
   ⇒ The POUs are stored at the reconfigured memory locations.

See also
●  Chapter 1.3.1.25.1.3 “Object ‘POU Locations’” on page 713
1.3.12 Testing and debugging

CODESYS provides various options for testing your application and detecting errors. You can start your application in simulation mode, even without connecting any hardware. Using breakpoints and stepping commands, you can examine specific parts of a program. By writing values to variables, you can influence the running program.

Commands are provided that reset your application in various different ways, from resetting only non-persistent variables to completely resetting the controller to factory settings.

See also
- Chapter 1.3.1.12.2 “Using breakpoints” on page 310
- Chapter 1.3.1.12.3 “Stepping through a program” on page 313
- Chapter 1.3.1.12.5 “Resetting applications” on page 318

1.3.12.1 Testing in simulation mode

Use simulation mode for testing and debugging your program when you do not have a physical target device. In this mode, the application is started on a simulated device.

The command is available only when you are logged out.

Requirement: You program contains no errors (compiler error messages or compile errors) and you are not logged in.

1. Activate simulation mode as follows:
   - Click “Online ➔ Simulation”, or
   - Right-click the controller in the device tree and click “Simulation”.
     - The name of the controller in the device tree is displayed in italics. In the status line, “Simulation” appears highlighted in red. The “Simulation” command is selected in the main menu.

2. Click “Online ➔ Login”.

3. When logging in with the active application, you will be prompted whether the application “Sim.<device name>.<application name>” should be created and loaded. Click “Yes” to confirm.
   - The application is logged onto the PLC.

4. Now you can check and correct the program flow with the commands provided in the main menu in “Debug”.

5. Log out from the controller and end the simulation mode.

See also
- Chapter 1.3.1.25.2.6.21 “Command ‘Simulation’ on page 937

Limitations
- The focus of the simulation mode is testing and debugging your program of the PLC. That means the functionality of the simulated PLC is limited. Keep in mind that some POUs have no function. They are not creating any compile or download errors, they will simple not work.
- Without an extra available “Virtual Commissioning” license the “Online mode” of the simulated PLC is limited to 2 hours. After 2 hours starting from the “Login”, the “Online mode” is automatically terminated and the PLC is logged out.
- It is not possible to create a “Boot Application” in the simulated PLC. Every “Login” starts with an empty simulated PLC and a download of the application is required.
- When logging in to a simulated PLC the first time a “Windows Security Alert” is displayed. Depending on the application, e.g. if any network communication is implemented, it might be necessary to allow the “Virtual AC500” to communicate on one or multiple network types.
1.3.1.12.2 Using breakpoints

Breakpoints are commonly used for debugging programs. CODESYS supports breakpoints in all IEC editors.

You can set breakpoints at specific positions in the program to force an execution stop and to monitor variable values. You can set special data breakpoints to halt program execution when the value of a specific variable changes.

The halt at a breakpoint or data breakpoint can be linked to additional conditions. You can also redefine breakpoints and data breakpoints as execution points where specific code is executed instead of stopping the program.

The “Breakpoints” view provides an overview of all defined breakpoints. It also includes additional commands for processing batch changes to multiple breakpoints.

In the editor, the following symbols identify the status of a breakpoint or execution point:

- Breakpoint enabled
- Breakpoint disabled
- Breakpoint is set in another instance of the POU open in the editor.
- Halted at breakpoint
- Conditional breakpoint enabled
- Conditional breakpoint disabled
- Execution point enabled
- Execution point disabled
- Conditional execution point enabled
- Conditional execution point disabled
- Data breakpoint enabled
- Data breakpoint disabled
- Halted at data breakpoint
- Data execution point enabled
- Data execution point disabled
- Halted at data execution point
- Conditional data execution point enabled
- Conditional data breakpoint enabled

See also

- Chapter 1.3.1.25.2.3.12 “Command ‘Breakpoints’” on page 885

Whether or not data breakpoints can be set and how many depends on the target system.

Program execution stops at a data breakpoint when the value of a particular variable or memory address changes. As with ordinary breakpoints, the halt can be linked to an additional condition, or specific code can be processed instead of the halt (converted to a data execution point).

You set a data breakpoint either by means of the “New Data Breakpoint” command in the “Debug” menu or by means of the “New” button in the “Breakpoints” view. You specify a qualified variable name or a memory address directly which is to be monitored for changes in its value.
Example

In the following sample code, the memory of the variable `iNumber` is overwritten unintentionally. However, a data breakpoint at the variable `iNumber` will detect when its value changes. The processing then stops with a corresponding message at the array access, which overwrites the variable value: `Idx = 7`. See also below: "Setting a data breakpoint".

```plaintext
PROGRAM PLC_PRG
VAR
  Idx : INT;
  Ary : ARRAY[0..3] OF BYTE;
  iNumber : INT := 55;
END_VAR
FOR idx := 0 TO 6 DO
  Ary[idx] := 0;
END_FOR
```

Breakpoints in applications with multiple tasks

Basically, debugging is not possible for multiple tasks at the same time. While you are working on a task with breakpoints or stepping, breakpoints are ignored in other tasks.

If a block containing a breakpoint is used by multiple tasks, then only the debug task is halted because it arrives at the breakpoint first. All other tasks continue. The “Call Stack” dialog shows which task is currently halted.

If you need a breakpoint to affect only one specific task, then you can define this in the breakpoint properties.

Breakpoints operate separately for each application so that a "HALT ON BP" does not affect any other applications. This applies also to parent/child applications, even if the breakpoint is set in a block that is used by several applications and whose code is located only once on the PLC.

NOTICE!

The I/Os that are called by the debug task are not updated at a halt in the breakpoint, even if you select the “Refresh I/Os in Stop” check box in the PLC settings.

If the application stops at a breakpoint on the PLC, then an online change or download causes all tasks to halt which means the PLC will stop. In this case, CODESYS prompts you whether or not to continue with the login.

See also

- Chapter 1.3.1.25.2.3.15 “Command ‘Call Stack’” on page 888

Setting a single breakpoint (example in ST editor)

Requirement: The application is in online mode and running. The operating mode is “Debug”.

1. In the editor, open a POU programmed in structured text (ST).
2. Place the cursor in the line where a breakpoint will be set.
3. Click “Debug ➔ Toggle Breakpoint” or press [F9].
   - The line is marked in red and identified by the "breakpoint enabled" symbol ( ● ). If the program is halted at the breakpoint, then the line is marked by the "stop at breakpoint" symbol ( ● ). Program processing is stopped and identified in the status line by the red-highlighted HALT ON BP status.
4. Click “Debug ➔ Start” or press [F5].
   - The program continues.
5. Set more breakpoints and check the variable values at the break position.
6. Place the cursor in the line where a breakpoint should be removed.
7. Click “Debug ➔ Toggle Breakpoint” or press [F9].
   ⇒ The marking disappears. The breakpoint is deleted.

See also
● § Chapter 1.3.1.25.2.7.9 “Command ‘Toggle Breakpoint’” on page 940

Defining a breakpoint condition (example in ST editor)

1. In the editor, open a POU programmed in structured text (ST).
2. Place the cursor in the line where a breakpoint will be set.
3. Click “Debug ➔ New Breakpoint”.
   ⇒ The “Breakpoint Properties” dialog opens.
4. Click the “Condition” tab.
5. Click “Break when the hit count is a multiple of” in the “Hit Count” list box.
   Type the value "5" in the field to the right.
6. In addition, you can define a Boolean condition for when the breakpoint should be active.
   Select the “Break, if true” check box. Type a Boolean variable in the text field to the right.
7. Select the “Enable breakpoint immediately” check box.
8. Close the dialog.
   ⇒ The line is marked red and identified by the "conditional breakpoint enabled" symbol (○)

Monitor the running program. As long as the Boolean variable for the condition is FALSE, the breakpoint condition is not fulfilled and the program continues to run. If you set the variable to TRUE, then the condition is fulfilled and the program halts at the breakpoint every 5th pass.

See also
● § Chapter 1.3.1.25.3.5 “Dialog ‘Breakpoint Properties’” on page 1041

Defining an execution point (example in ST editor)

1. In the editor, open a POU programmed in structured text (ST).
2. Place the cursor at the position for an execution point.
3. Click “Debug ➔ New Breakpoint”.
   ⇒ The “Breakpoint Properties” dialog opens.
4. Click the “Execution Point Settings” tab.
5. Select the “Execution point” check box.
   In the “Execute the following code” field, type the following statement: iCounter := iCounter + 1;
   In the “Print a message in the device log” field, type the following text: Execution point reached {iCounter}
6. Close the dialog.

When the program reaches the execution point, it does not halt, but executes the code defined above. In addition, a message is issued to the device log.

See also

● Chapter 1.3.1.25.3.5 “Dialog ‘Breakpoint Properties’” on page 1041

### Setting a data breakpoint

**Requirement:** The application is in online mode and running.

1. Click “View ➔ Breakpoints”.
2. Click “Debug ➔ New Data Breakpoint”.
3. Click the button in the “New breakpoint” dialog (“Data” tab).
4. In the “Input assistant” dialog (“Watch Variables” tab), select the variables for which the program should halt when changed.
   As an alternative, specify the qualified name of the variable on the “Data” tab directly in the input line. Example: PLC_PRG.iNumber. The exact number of bytes to be monitored is specified as the “Size”. A value that corresponds to the data type is set here automatically by default. You can also specify fewer bytes to be monitored.
5. In the “Breakpoints” view, select the line with the data breakpoint and click the button.
   The line is marked and identified by the “Data breakpoint enabled” symbol (●). When the program reaches the data breakpoint (meaning when the value of the selected variables changes), the program processing halts. In the implementation part of the POU, the next line is identified by an arrow (●). This is identified in the status line by the **HALT ON BP** status highlighted in red.
6. Click “Debug ➔ Start” or press [F5].
   The program continues running and halts again when the value of the variables changes again.

See also

● Chapter 1.3.1.25.3.5 “Dialog ‘Breakpoint Properties’” on page 1041

### 1.3.1.12.3 Stepping through a program

You can step through an application and navigate the code. This is useful to check the status of your code at runtime. You can examine the call process, track variable values, or locate errors.

Stepping commands are provided in the “Debug” menu for this purpose. The commands become available when you set breakpoints in online mode and then halt execution at a breakpoint: the application is in “HALT ON BP” state (debug mode). During debug mode, the current break position is highlighted in yellow and marked with the ● symbol in the text editors.
1. Download your application to a controller.
   - The application is highlighted in green. CODESYS and the editors of the POUs are in online mode.

2. In the POUs, set breakpoints at the locations in the code that you want to examine.
   - All breakpoints are listed in the “Breakpoints” view.

3. Start the application.
   - The application starts and the code is processed until the first breakpoint.

   Now the application is in debug mode. In the device tree, the application is labeled with “[halt on breakpoint]”. The status bar provides information about the operating state:

   ![Halt on BP]

   The editor was opened at the current break position. The line of code with an active breakpoint where program execution was halted is highlighted in yellow and marked by the ⚫ symbol. This statement highlighted in yellow has not been executed yet.

   ![Highlighted Code]  

   Now you can select the various stepping commands or display the call tree.

   ![Step Commands]

   Alternatively, you can first start the application and then set a breakpoint.
**Behavior of the stepping command in the 'Debug' menu**

- **Command “Step Over”**
  The statement at the breakpoint position is executed. Program execution halts before the next statement in the POU.
  If the statement contains a call (from a program, function block instance, function, method, or action), then the subordinate POU is processed completely in one step.

- **Command “Step Into”**
  The statement at the breakpoint position is executed. Program execution halts before the next statement.
  If the statement contains a call (from a program, function block instance, function, method, or action), then the program execution jumps to this subordinate POU. The first statement there is executed and the program execution halts before the next statement. The new current breakpoint position is then in the called POU.

- **Command “Step Out”**
  The command executes the POU from the current breakpoint position to the end of the POU and then jumps back to the calling POU. Program execution halts at the calling position (in the line with the call).
  If the current breakpoint position is in the main program, then the POU is run through to the end. Then the program execution jumps back to the beginning (to the program start at the first line of code in the POU) and halts there.

- **Command “Run to Cursor”**
  First set the cursor at any line of code and then execute the command. The program is executed from the current breakpoint position and halts at the current cursor position without executing the code of this line.

- **Command “Set Next Statement”**
  First set the cursor at any line of code (also before the current breakpoint position) and then execute the command. The statement marked with the cursor is executed next. All statements in between are ignored and skipped.

- **Command “Show Next Statement”**
  If you do not see the current breakpoint position, then execute the command. Then the window with the current breakpoint position comes into focus and the breakpoint position is visible.

Click “View ➔ Call Stack” to completely show the previous call tree for the breakpoint position currently reached in the program processing.

![Info](The “Call Stack” view shows the location of the block in the call structure of the program at all times, even before compiling the application.)

### 1.3.1.12.4 Forcing and writing variables

In CODESYS, variable values in the PLC can be changed in online mode. Here we make a distinction between forcing and writing.

When forcing, CODESYS writes the value in each cycle to hold the variable permanently at the forced value.
**NOTICE!**
Please note that forced values must be lifted explicitly by the user. A dialog will appear if forced variables still exist when logging out.

When writing, CODESYS sets the value one time. Therefore, the value can be overwritten by the program at any time.

### Forcing in the declaration part

**Requirement:** Your application includes a POU with declarations. The application is in online mode.

1. Open the POU in the editor by choosing the command “Project ➔ Edit Object”.
2. In the declaration part of the editor, double-click in column (1) “Prepared value” of a variable.
   - The field can be edited and a value can be entered.

3. Perform step 2 for other variables.
4. Click “Debug ➔ Force Values”.
   - The variable values are overwritten with the prepared values. The values are marked with the symbol 🟢.

### Forcing in the implementation part

**Requirement:** The application is in online mode.

1. Open the POU in the editor by choosing the command “Project ➔ Edit Object”.
2. In the implementation part of the editor, double-click an inline monitoring field (1).
   - The dialog “Prepare Value” opens.
3. Enter the new value in the field “Prepare a new value for the next write or force operation”. The prepared value appears in the inline monitoring field.

4. Click “Debug \(\Rightarrow\) Force Values”. The value of the variables is overwritten with the prepared values. The values are marked with the symbol \(\Box\).

---

**View and edit all forced variables**

**1 list**

**Requirement:** The application is in online mode. Several variables are forced.

1. Click “View \(\Rightarrow\) Watch \(\Rightarrow\) Watch All Forces”. The “Watch all forces” view opens. It contains all currently forced variables of the application in the form of a watch list.

2. Select all lines in the list and click “Unforce \(\Rightarrow\) Unforce and Keep All Selected Values” in the drop-down list in the upper left part of the view. The variables are unforced and they get the values that they had before forcing.

---

**Forcing a function block input in CFC**

**Requirement:** An application has a CFC POU that contains a function block, and the application is in offline mode.

---

**NOTICE!**

This kind of forcing uses a data breakpoint internally and is therefore different from forcing with the “Force Values” command or \([F7]\). Values that were forced by the command “Force FB Input” do not respond to the commands “Show All Forces” or “Unforce Values”.

---

1. Open the editor of the CFC POU by double-clicking the object in the tree.
2. Activate the forceability for the desired function block. Select the POU element in CFC and click “CFC \(\Rightarrow\) Prepare POU Element for Forcing”.
3. Login to the application on the target device. In CFC, select the input of the POU and click “Force FB Input” in the context menu. The “Force Value” dialog opens.
4. Set a new value for the input. Example in the case of a TON POU: FALSE for the Boolean input \(\text{IN}\), or \(t\#4s\) for the PT input (TIME). Click “OK” to confirm. The set value is forced immediately. A green circle is displayed at the upper left of the POU element and the name of the input in the element is highlighted in green. For a Boolean value, a small monitoring view with the value also opens at the input. In the monitoring views, the forced value is displayed, for example in the “Value” column, as in the declaration part.
5. To remove the forced value, click “Force FB Input” again. In the “Force Value” dialog, select the “Remove value” option. Forcing is canceled. The input gets the current value from the controller.
1.3.12.5 Resetting applications

Resetting the application stops the program and resets the variables to their initialization values. Depending on the type of reset, retain variables and persistent variables are also reset.

- Reset warm: All variables are reset, except `RETAIN` and `PERSISTENT` variables.
- Reset cold: All variables are reset, except `PERSISTENT` variables.
- Reset origin: All variables are reset.
- Reset origin device: All variables are reset and all applications are deleted.

The following sample program and statements clarify the functionality of the various resets.

See also

- "Lifespan of variables when calling online commands" on page 251

Sample program

Example

Declaraiton

```plaintext
VAR
  iVar: INT := 0;
END_VAR
VAR RETAIN
  iVarRetain: INT := 0;
END_VAR
VAR PERSISTENT
  iVarPersistent : INT := 0;
END_VAR
iVar := 100;
iVarRetain := 200;
iVarPersistent := 300;
```

Implementation

1. Insert the "Persistent Variables" object below the application and open it in the editor.
2. Click "Build ➔ Build".
3. Click "Declare ➔ Add All Instance Paths".
   » The instance path of the persistent variables is inserted.
4. Download the application to the controller.
Requirement: The sample program runs on the controller.

1. Click “Online ➔ Login” to switch to online mode.
2. Monitor the variables iVar, iVarRetain, and iVarPersistent.
3. Click “Online ➔ Reset Warm”.  
   ⇔ You are prompted whether you really want to execute the command.
4. Click “Yes” to confirm the dialog.
   ⇔ The application is reset. The iVar variable is set to the initialization value 0. Both of the other variables retain their values.
5. Click “Online ➔ Reset Cold”.  
   ⇔ You are prompted whether you really want to execute the command.
6. Click “Yes” to confirm the dialog.
   ⇔ The application is reset. The iVar and iVarRetain variables are set to the initialization value 0. The iVarPersistent variable retains its value.
7. Click “Online ➔ Reset Origin”.  
   ⇔ You are prompted whether you really want to execute the command.
8. Click “Yes” to confirm the dialog.  
   ⇔ The application is reset. All variables are reset to their initialization values.

- Chapter 1.3.1.25.2.6.12 “Command ‘Reset Origin Device’” on page 933

1.3.1.12.6 Flow control

With flow control, you can monitor the processing of the application program. Flow control is provided for the ST, FBD, LD, and IL language editors.

With an activated flow control, CODESYS displays the variable values and results from function calls and operations at the respective processing location and time. In this way, the exact lines of code and networks that run through the current cycle are marked in colors. Compare this to standard monitoring, in which CODESYS delivers only the value that a variable has between two processing cycles.

Flow control works in all parts of the editor view that are currently visible. “Flow control enabled” is then displayed in the status line as long as the function is active and flow control positions (processed parts of code) are visible in an editor view.

You can write and force values only in the declaration section.
NOTICE!

When you enable flow control, the cycle time of the application is prolonged.

When “Confirmed Online Mode” is activated in the communication settings, a dialog prompt appears when switching on the flow control to cancel the process.

When flow control is activated, it is not possible to use breakpoints or step through the program.

See also

- § Chapter 1.3.1.25.1.19.2 “Tab ’Communication Settings’” on page 741
- § Chapter 1.3.1.25.2.7.22 “Command ’Flow Control’” on page 947

Display of the flow control in different language editors

By default, CODESYS displays the flow control positions of the processed parts of code as green fields. Unprocessed parts of code are displayed in white.

Please note that the displayed value of an unprocessed code position is an ordinary monitoring value. This is the value between two task cycles.

```
1     i 1619 := i 1619 + 1;
2     b[0] := NOT b[0];
3     IF str "abcdefghj" = str: "" THEN
4     fi2[1.5] := fi1[1.23] &;
5     ELSE
6     fi2[1.5] := -1.5;
8     END_IF:
9     IF D[6.5E+04] <= 0.0 THEN
```

In network editors, CODESYS marks the processed networks with bars on the left edge in the flow control color.

In LD, CODESYS displays the currently processed connecting lines in green and all others in gray. The actual value of the connection is also displayed: TRUE by a bold blue line, FALSE by a bold black line, and unknown or analog values by thin black lines. Combinations of these lines are displayed as dashed lines.
In IL, CODESYS uses two fields for each statement to display the current values: one to the left of the operator with the current accumulator, and one to the right of the operands with the operand value.
1.3.1.12.7 Determining the current processing position with the call stack

You can use the call stack for determining the current position of the program flow. This function is very useful when stepping into programs.

Requirement: The application is in online mode. The program is halted at a breakpoint or you are stepping into it.

▷ Open the call stack by clicking “View ➔ Call Stack”.

▷ The call stack opens. The list shows the current location with the complete call path.

The call stack is also available in offline mode and normal online mode (without using debugging functions). In this case, it receives the last displayed location during a stepped execution, but it is displayed in gray.

See also
- § Chapter 1.3.1.25.2.3.15 “Command ‘Call Stack’” on page 888
- § Chapter 1.3.1.12.3 “Stepping through a program” on page 313

1.3.1.12.8 Checking the task deployment

The Tab “Task deployment” of the device editor indicates in an overview the tasks that process the individual inputs and outputs of the I/O mapping of your application and the priority with which they do so. You can check here whether an unintentional overwriting of values is caused, which can lead to undefined values.

1. Generate code for the application: to do this select, for example, the command “Build ➔ Generate Code”.
2. Open the device editor by double-clicking on the device object in the device tree. Select the “Task deployment” tab.

▷ You obtain a display of the inputs and outputs of your application and the assignment of the tasks and their priorities. See the description of the “Task deployment” tab for details.

See also
- § Chapter 1.3.1.25.1.19.16 “Tab ‘Task deployment’” on page 767

1.3.1.13 Application at runtime

1.3.1.13.1 Monitoring of values................................................................. 323
1.3.1.13.2 Changing values with recipes............................................... 331
1.3.1.13.3 Data recording with trace...................................................... 335
1.3.1.13.4 Data recording with trend..................................................... 344
1.3.1.13.5 Monitoring tasks..................................................................... 349
1.3.1.13.6 Reading the PLC log............................................................... 349
1.3.1.13.7 Analysing errors with core dump........................................... 349
1.3.1.13.8 Using PLC shell for requesting information........................... 351
1.3.1.13.9 PLC operation control via system variables............................. 352
1.3.1.13.10 Backup and restore............................................................... 353
When the application is running on the PLC, in the CODESYS Development System there are some features for monitoring and changing the values of the variables as well as for recording and storing the value charts.

Furthermore, you can poll some information from the PLC, you can have a look into the PLC-log, display a core dump and monitor the time behaviour of the tasks.

Regard also the possibility to restrict the access on the running application in critical states of the machine via online commands provided by CODESYS Development System. For this purpose some system variables are available in a module of the \texttt{ComponentManager} library.

### 1.3.1.13.1 Monitoring of values

In runtime mode, you can monitor the current variable values of a programming object at different places in a project. The following is what we refer to as monitoring:

- Online view of the programming editor of an object: inline monitoring
- Online view of the declaration editor of an object
- Object-independent, configurable watchlists

When you set the \{attribute `monitoring`\...\} pragma, you can monitor the results from function calls and the current variable values in property-type objects.

More options for recording current variable values:

- Read and save recipes
- Record values on a timeline for displaying the history immediately or later: trace and trend features

See also

- Chapter 1.3.1.24.6.2.21 “Attribute ‘monitoring’” on page 619
- Chapter 1.3.1.13.1.2 “Using watch lists” on page 330

- Chapter 1.3.1.13.3 “Data recording with trace” on page 335
- Chapter 1.3.1.13.4 “Data recording with trend” on page 344

### Calling of monitoring in programming objects

When an application is running on the controller, the actual values of variables are displayed in the editors of the POU.s. This is how the values of variables are monitored.

- **Requirement:** The “Enable inline monitoring” option is activated in “Tools \rightarrow Options” in the “Text Editor” category on the “Monitoring” tab.

1. Download an application to the controller and start it.
2. Click “Debug \rightarrow Display Mode \rightarrow Decimal”.
   - The display format of the actual values is set.
3. Click a programming object in the “Devices” view or “POUs” view.
   - The respective editor opens. Actual values of the variables are refreshed continually for both the declaration and implementation.
The actual value of an expression (1) is displayed in the “Value” column (3).
You can write and force a value in the “Prepared Value” (4) column. During the forcing, the actual value is decorated with a red symbol (5).

The expression of an interface reference can be expanded. If the interface points to a global instance, then this global instance is displayed as the first entry below the reference. Afterwards, if the interface reference changes, then the displayed reference is collapsed.

Inline monitoring is the display of the current variable value in the implementation. Depending on the implementation language, the following displays are possible in the implementation part:

- Variables have a window with the current value displayed after their name: `nResult2`. If you have prepared values for variables for forcing or writing, then they are displayed in angle brackets in the inline monitoring view after the current value. After forcing, the respective values are identified by the symbol.
- Network editors and the CFC editor:
  Connecting lines are displayed in color according to their actual Boolean value (blue means TRUE, black means FALSE).
- LD editor:
  The contact and coil elements are also marked.
  For contacts and coils, a prepared value (TRUE or FALSE) is shown in a small view next to the element.
- SFC editor:
  Transitions with the value TRUE are displayed in color according to their actual Boolean value (blue means TRUE, black means FALSE).
  Active steps are displayed in blue.
  Forced transition values are displayed in red in the implementation.
- IL tabular editor:
  Current values are displayed in a separate column.
Monitoring in the LD editor

Monitoring in the SFC editor

You can deactivate the inline monitoring function in “Tools ⇒ Options”, in the “Text Editor” category on the “Monitoring” tab.

Partial monitoring of an array

Limiting the monitoring range

An expanded array shows the actual values for up to 1000 elements. However, this can be confusing. In addition, an array can contain more than 1000 elements. Then it is helpful to limit the range of displayed elements. You can do this in online mode in the following way.

Requirement: An application is running. It contains a multidimensional array variable with more than 1000 elements. Example: `arrBig : ARRAY [0..100, -9..10, -19..20] OF INT;`

1. Click in the field of the “Data Type” column for the `arrBig` variable.
   - The “Monitoring Range” dialog opens.

2. Specify the value `[1, -9, -19]` for “Start”.

3. Specify the value \([1, 10, 20]\) for "End".

\[\Rightarrow\] The actual values of 800 array elements are displayed in the declaration editor. The range is limited to the elements of the index \([1, \langle i \rangle, \langle j \rangle]\) with \(i\) from -9 to 10 and \(j\) from -19 to 20.

Monitoring a function block
When you double-click the editor view of a function block in online mode, a dialog opens where you can choose between viewing the basic implementation or a specific instance.

If you select the basic implementation, then the code is displayed in the editor without current values. Now set a breakpoint in the basic implementation. If the execution halts there, then the current values of the instance that is processed first in the program flow are displayed. Now you can step successively through all instances.

If you select one of the instances, then the editor opens with the code of the function block instance. The current values are displayed in the declaration and, if applicable, in the implementation, and are updated continuously.

See also
- Chapter 1.3.1.25.1.28.2 “Object 'Function Block’” on page 778
- Chapter 1.3.1.12.2 “Using breakpoints” on page 310

Monitoring a property
You can monitor variables in a property object by setting a breakpoint in the function during online mode. When halted there, the current values are displayed.

In addition to your own values, the values of the variables of the superordinate instance are displayed automatically. In the declaration part of the property, the THIS pointer, which points to the superordinate instance, appears in the first line with the current data type information and values.
FUNCTION_BLOCK FB_BaseAlfa
VAR
  iBaseLocal : INT;
  sBaseLocal : STRING;
END_VAR

iBaseLocal := iBaseLocal + 1;
sBaseLocal := 'Testing Text';

FB_BaseAlfa.PorpBeta.Get
iBaseLocal := iBaseLocal + 1;
IF _iBaseLocal > 0 THEN
  PropBeta := TRUE;
END_IF

FB_BaseAlfa.PorpBeta.Set
IF PropBeta = TRUE THEN
  iBaseLocal := 0;
  sBaseLocal := 'Tested IF';
END_IF

PROGRAM PLC_PRG
VAR
  fb_BaseAlfa : FB_BaseAlfa;
END_VAR

fb_BaseAlfa();

IF fb_BaseAlfa.PropBeta = TRUE THEN
  xResult := TRUE;
END_IF
IF xReset THEN
  fb_BaseAlfa.PropBeta := TRUE;
  xReset := FALSE;
END_IF
Monitoring of property access in the superordinate program object

You can monitor the values of subordinate properties in a function block or program in addition to the variable values.

To do this, add either the pragma

\[
\text{attribute 'monitoring' = 'variable'} \quad \text{or} \quad \text{attribute 'monitoring' = 'call'}
\]

To the subordinate property object in the declaration. If you open the superordinate program instance or function block instance at runtime, then the current property values are displayed in the editor in addition to the current variable values.

See also

- § Chapter 1.3.1.25.1.28.8 “Object 'Property’” on page 791
- § Chapter 1.3.1.24.6.2.21 “Attribute 'monitoring’” on page 619

Monitoring a method

You can monitor variables in a method object by setting a breakpoint in the method during online mode. When halted there, the current values are displayed.

In addition to your own values, the values of the variables of the superordinate instance are displayed automatically. In the declaration part of the method, the \textit{THIS} pointer, which points to the superordinate instance, appears in the first line with the current data type information and values.
FUNCTION_BLOCK FB_BaseAlfa
VAR
  iBaseLocal : INT;
  sBaseLocal : STRING;
END_VAR
iBaseLocal := iBaseLocal + 1;
sBaseLocal := 'Testing Text';

METHOD MethBaseAlfa : BOOL // Method of FB_BaseAlfa
VAR_INPUT
END_VAR
VAR
  iMethLocal : INT;
END_VAR
iMethLocal := iMethLocal + 1;

PROGRAM PLC_PRG
VAR
  fb_BaseAlfa : FB_BaseAlfa;
END_VAR
fb_BaseAlfa();
fb_BaseAlfa.MethBaseAlfa();

Monitoring a function
You can monitor variables in a function object by setting a breakpoint in the function during online mode. When halted there, the current values are displayed.

Monitoring the return value of a function call
In the ST editor of a POU, the current return value is displayed as inline monitoring at the position of the POU where a function is called.

The following conditions must be fulfilled:
- The value can be interpreted as a 4-byte numeric value. Example: INT, SINT, or LINT.
- The pragma `{attribute 'monitoring' := 'call'}` is inserted into the function.
Using watch lists

What is a watch list?
A watch list is a user-defined list of project variables that are collected in one view for the purpose of monitoring their values. In online mode, you can write and force variable values in a watch list. Monitoring, writing, and forcing are handled the same way as the declaration editor in online mode. You can customize the format of the representation of floating-point values in the options for monitoring.

There are four, ready-to-use watch lists (Watch <n>) available in a project. Click “View ➔ Watch”.

If the expression is an interface reference, then it can be expanded. If the interface points to a global instance, then this global instance is displayed as the first entry below the reference. If the interface reference changes, then the displayed reference is collapsed.

Creating and editing a watch list (offline or online mode)

Requirement: The project is in either online or offline mode. It includes an application with declared variables that you want added to one of the four possible watch lists.

1. Click “View ➔ Watch ➔ Watch <n>”.
   ⇒ The Watch <n> view opens. It contains a blank table row.
2. Double-click the field in the “Expression” column and type a variable to monitor, either manually or with the input assistant.
   Syntax: <device name>.<application name>.<object name>.<variable name>
   Example: "Dev1.App1.PLC_PRG.ivar"
   If you type the name of a structured variable, then the individual components are displayed automatically in other lines in online mode.
3. Define all successive variables that will be monitored with this list. You can change the order by using drag and drop operations.
   ⇒ The “Execution point”, “Type”, “Address”, “Comment” fields are filled in automatically according to the variables declaration. The symbol before the expression indicates the type of variable: input variable ( ), output variable ( ), or ordinary variable ( ).

   In online mode, you can also create or edit watch lists by right-clicking and choosing the “Add Watch” command.

● ☰ Chapter 1.3.1.25.3.13.14 “Dialog ‘Options’ - ‘Monitoring’” on page 1083

See also
● ☰ Chapter 1.3.1.25.2.3.8 “Command 'Watch' - 'Watch <n>’” on page 883
Adding variables by choosing the 'Add Watch' command (online mode)

Requirement: A project is open and running. It includes an application with declared variables that you want added to a possible watch list.

1. Click “View ➔ Watch <n>” to open the watch list.
2. Place the cursor on a variable in the declaration or implementation part of a POU and right-click to choose the “Add Watch” command.
   ⇒ This adds an entry to the list for the selected variable.
3. You can add other variables in this way or by typing directly into the list in the “Expression” field as described above.
   ⇒ The watch lists are updated immediately.

If a watch list is not open when you click “Add Watch” for a variable, then it is added automatically to the “Watch 1” list.

Writing and forcing variable values is also possible in the watch lists. In online mode, the “Prepared value” column is also available.

See also
- § Chapter 1.3.1.25.2.23.1 “Command ‘Add Watch’” on page 1037

- § Chapter 1.3.1.12.4 “Forcing and writing variables” on page 315

1.3.1.13.2 Changing values with recipes

Use recipes to change or read recipes values for a specific set of variables (recipe definition) on the controller at the same time.

You define the basic settings for recipes, such as location and format, in the object “Recipe Manager”. Insert one or more recipe definitions below this object. A recipe definition comprises one or more recipes for the contained variable. The recipe consists of specific variable values.

You can save a recipe to a file or write directly from files to the PLC.

Recipes can be loaded via the CODESYS development interface, the visualization element, or the application program.

Using recipes on remote devices

The variable values from recipes are transferred automatically to and from another controller when they are data source variables and a data source exchange is configured. Reading and writing occurs synchronously. Therefore, CODESYS updates all variables in a recipe at the same time. After reading or writing, you can use the call `g_RecipeManager.LastError` to check whether or not the transfer was successful (`g_RecipeManager.LastError = 0`).
Using recipes in the CODESYS user interface

The CODESYS development interface provides commands for generating recipes as well as read/write in online mode.

See also
- Chapter 1.3.1.25.2.19 “Menu ‘Recipes’” on page 1015

Using recipes in applications

When the application is in runtime mode, you can use recipes in the user program and visualization elements.

In the user program, you use the methods for the function block RecipeManCommands from the library RecipeManagement. In the visualization, you use recipes via the input configuration (internal command of visualization elements).

During the initialization process, the recipe management reads the values of the variables that are defined in the recipe definition. This operation takes place at the end of the initialization phase of the application. At this point, all initial values of the application variables are set. This is performed to initialize missing values from recipe files correctly.

See also
- RecipeManCommands
- Input configuration Chapter 1.3.5.19.3.6 “Dialog ‘Input Configuration’” on page 1586

Creating recipes

1. Select the “Application” object in the device tree.
2. Click “Project ➔ Add Object ➔ Recipe Manager”.
   ➔ CODESYS adds the Recipe Manager to the device tree.
3. Select the “Recipe Manager” object in the device tree.
4. Click “Project ➔ Add Object ➔ Recipe Definition”.
   ➔ CODESYS adds the recipe definition below the Recipe Manager.
5. Open the editor of the recipe definition by double-clicking the object.
6. Double-click the blank field below “Variable”. Specify the name of a variable that you will define a recipe. The input assistant can be used for this: button.
7. Click “Recipes ➔ Add a New Recipe” and enter a name for the new recipe.
   ➔ A column with the new recipe name appears in the editor.
8. Enter the variable value for this recipe in this field.
9. Insert additional fields as needed.
10. Select a variable value for the recipe and click “Recipes ➔ Save Recipe”. Select a location and file name.
   ➔ CODESYS saves the recipe in the format as defined in the Recipe Manager.
Requirement: A Recipe Manager is available in the application. In a recipe definition, there is a "myRec" recipe with variable values. A myRec.txt recipe file is located on the file system and contains the entries for this recipe.

Example of the recipe file:

```
PLC_PRG.bVar:=0
PLC_PRG.iVar:=2
PLC_PRG.dwVar:=35232
PLC_PRG.stVar:='first'
PLC_PRG.wstVar:='123443245'
```

1. Double-click the "Recipe Definition" object in the device tree to open the tabular editor for the definition of the individual recipes.
   ⇒ You see the myRec column with the current values for this recipe.

2. Edit the myRec.txt file in an external text editor and replace the variable values with other values that you want to load into the recipe definition in CODESYS. Save the file.

3. Click the "myRec" column in the recipe definition and right-click for the "Load Recipe" command.
   ⇒ A dialog prompt notifies you about the possibly needing to perform an online change when logging in again. An online change is necessary when you change the current values of the recipe variables by loading the recipe.

4. Click "Yes" to close the dialog and continue. Select the myRec.txt file from the file explorer for loading.
   ⇒ The recipe values in the recipe definition are updated according to the values read in the file.

If you want to overwrite only individual recipe variables with new values, then remove the values for the other variables before loading to the recipe file. Entries without value definitions are not read, and therefore updating leaves these variables unchanged on the PLC and in the project.

For values of the data type REAL/LREAL, the hexadecimal value is also written to the recipe file in some cases. This is necessary so that the exact identical value is restored when converting back. In this case, change the decimal value and delete the hexadecimal value.

Recipe management on the controller; memory usage

When you clear the "Recipe management in the PLC" option, the Recipe Manager and recipe definitions will not use any memory on the PLC.

If you select this check box, then code is generated for the Recipe Manager and all recipe definitions, and this code is stored on the PLC. The size of the used memory primarily depends on the number of recipes and their variables, as well as the data type of the variables. Whether or not the fields of the recipe definition are filled also has an effect. The memory usage of recipes cannot be calculated. It has to be determined by experimentation at the time it is needed. The following table merely provides some guiding principles.

</tr>
</tbody>
</table>

You can apply recipe values on the controller to recipe definitions in the project, even if these definitions have been modified in the project.

Requirement: The “Recipe management in the PLC” is option is selected in the Recipe Manager.

1. Create a recipe definition RecDef1 in the project, containing the variables PLC_PRG.ivar and PLC_PRG.bvar. Insert a recipe “R1”: value for PLC_PRG.ivar:33; value for PLC_PRG.bvar:TRUE.

2. Login to the controller and download the application.
   ⇒ The recipe file R1.RecDef1.txtrecipe is saved to the default directory of the controller ($PlcLogic$).

3. Logout and add another variable PLC_PRG.dwvar to the recipe definition in the project.

4. Edit the recipe definition file R1.RecDef1.txtrecipe on the device by changing the value for PLC_PRG.ivar from 33 to 34.

   Moreover, add another recipe “R2” on the device. To do this, copy the R1.RecDef1.txtrecipe and rename it to R2.RecDef1.txtrecipe. Then edit this file and change the recipe values: PLC_PRG.ivar:1, PLC_PRG.bvar:FALSE.

   ⇒ Now two recipes “R1” and “R2” are available on the device. In the project, there is only “R1”, and it also contains other values than “R1” on the device.

5. Login again to the controller with online change.

6. Click “Upload Recipes from Device” from the context menu.
   ⇒ A dialog prompt notifies you that executing the command at the next login may trigger an online change, and that the recipes on the runtime system will overwrite the recipes of the current recipe definition.

7. Confirm that you wish to continue.
   ⇒ A dialog prompt notifies you that the recipe for PLC_PRG.dwvar loaded on the device cannot yield a value from the controller.
8. Confirm that you wish to continue.
   ☰ The value of PLC_PRG.ivar in recipe “R1” of the recipe definition in the project changes to 34. The recipe “R2” with the values 1 and FALSE is also listed in the recipe definition now. PLC_PRG.dwvar remains in the recipe definition.

1.3.1.13.3 Data recording with trace

You can use a “Trace” to follow the value history of variables on the controller in a similar way as a digital sampling oscilloscope. When the application is in runtime mode with trace, all statements are executed first within the task cycle. Then, data recording starts with value storage including time stamps. These time stamps are relative and refer to the start time of the data recording. The data yields a discrete time signal and CODESYS displays its course in the trace editor.

A sample (data record) is composed of the value and the time stamp. The runtime system writes the samples to a buffer with a definable size. CODESYS requests the data, saves it in the trace editor buffer, and displays it in the trace diagram as a function of time. You can monitor the value history of the configured variables continually because CODESYS displays the latest data.

You can trigger the data recording. When this happens, the application saves the data from the time of the trigger and CODESYS displays the data at the time of the trigger.

The configuration and the display of a trace are possible in the CODESYS project by means of trace objects in the trace editor. There are the following two object types:

- “Trace”: Inserted below the IEC application in the device tree. This kind of object always contains a purely application-specific trace configuration. You can download this trace configuration to the controller and run it with the application.
- “DeviceTrace”: Inserted below the device object in the device tree. If the PLC supports a trace manager, then you can use one or more “DeviceTrace” objects to access one or more traces that are running on the controller. These can be both application-specific or controller-specific traces. For example, a controller can support traces for recording the processor load. Menu commands allow for access from the CODESYS project to the trace manager in the device.

Access to the trace manager from IEC code is possible by means of the functions from the library CmpTraceMgr.library. For more information, refer to the library documentation.

![NOTICE!]
A running data recording with trace can lead to a significant increase in the cycle time of the IEC task.

![NOTICE!]
Data recording with trace also continues running after logging out of the device.

The device description of a runtime system with trace manager includes the tracemanager entry in the TargetSettings section.

In this case, CODESYS transfers only the trace configuration when downloading the application to the PLC. When you start the trace, the application interprets the configuration on the RTS by means of the trace manager, executes the data recording, and buffers the data sets on the PLC.

The CmpTraceMgr runtime system component provides extended functionality, as compared to data recording with IEC code.
Data recording is therefore possible as follows:

- Parameters on the PLC (for example, the processor load (cpuload, plcload), or the temperature curve of a CPU or a battery). The measurement of the processor load per CPU core (cpuload) is interesting for multicore controllers.
- Device signals (for example, the current path of a drive)
- System variables of another runtime system component

You can configure parameters like IEC variables in the “Trace Configuration” dialog of the “Variable Settings”.

The display of traces that run on the controller is possible in the trace editor of a DeviceTrace object.

Data recording after triggering

To monitor data that depends on an event or a condition, you can free the data recording that depends on a trigger. At runtime, the application checks whether the event has occurred or the condition is fulfilled, and then it buffers the data accordingly.

The trace configuration enables triggering by:

- a trigger variable that maps the event
- a condition as expression
- a combination of trigger variable and condition

Saving samples to a file

You can save samples from the development system to a file. The file can also include the trace configuration.

Table 8: Possible file formats

<table>

### Getting started

**Program**

```plaintext
PROGRAM PLC_PRG
VAR
  iVar : INT;
  rSin : REAL;
  rVar : REAL;
END_VAR

iVar := iVar + 1;
iVar := iVar MOD 33;

rVar := rVar + 0.1;
rSin := 30 * SIN(rVar);
```

**Requirement:** The application is running the PLC_PRG program on the controller.

1. In the device tree, select the application and add a new trace object by clicking “Project ➔ Add Object”.
   - The respective trace editor opens with the commands available in the “Trace” menu.
2. Click “Trace ➔ Configuration”.
   - The “Trace Configuration” dialog box opens.
3. Select a task for running the trace feature. Normally this is the same task that is running in PLC_PRG.
4. Click “Add Variable” to add an entry to the tree view of the trace configuration and assign an IEC variable (for example, PLC_PRG.rSin).

5. Click “Trace ➔ Download Trace”.
   - CODESYS loads the trace configuration to the controller. The application starts recording data and transmits the data to CODESYS, where it is displayed in the trace diagram as a graph. Commands are provided for navigating through the samples and controlling the data recording.

Example

The PLC_PRG program is running on the controller. When you follow the instructions for "Getting Started", CODESYS displays the following trace diagram.

![Trace Diagram]

- (1) : “Configuration”
- (2) : “Add Variable”

Creating trace configuration

For a complete trace configuration, specify at least one task and one variable. In order to trigger the data recording, activate the trigger option and select a trigger variable or specify a recording condition.

See also
- ☀ Chapter 1.3.1.25.3.15.1 “Dialog 'Advanced Trace Settings’” on page 1091

- ☀ Chapter 1.3.1.13.4.2 “Configuring trend recording” on page 346

Assigning a task

In this task, the data recording is executed in runtime mode. Usually the same task is selected where the variables are written.

1. Double-click the trace object.
   - The trace editor opens with the commands available in the “Trace” menu.
2. Click “Trace ➔ Configuration”.
   ⇒ The “Trace Configuration” dialog opens. In the tree view “Trace Record”, the top item is selected and the subdialog “Record Settings” is shown on the right.

3. Click the “arrow down” symbol (▼) in the “Task” drop-down list.
   ⇒ The drop-down list opens with all tasks that are available throughout the application.

4. Select a task for the trace.

See also
● © Chapter 1.3.1.25.3.15.2 “Dialog 'Trace Configuration’” on page 1092

Configuring a trace variable

1. Double-click the trace object.
   ⇒ The trace editor opens. The commands of the “Trace” menu are available.

2. Click “Add Variable”.
   ⇒ The “Trace Configuration” dialog opens. The subdialog “Variable Settings” is displayed on the right.

3. Click ▼ in the input field of the “Variable” setting and select a trace variable in the “Input Assistant” dialog.
   ⇒ The variable is configured for data recording. The trace record tree and the display tree were extended by the variable.

4. Click the “Add Variable” link.
   ⇒ The trace record tree and the display tree receive a new variable. The settings of the variables are available on the right.

5. Select a trace variable.

6. Click “OK” to close the dialog.
   ⇒ The variables are trace variables and are displayed in the trace variable list.

Deleting a trace variable

1. Double-click the trace object.

2. Click a variable in the trace record tree.

3. Click the “Delete Variable” command or press [Del].

4. Click “OK” to close the dialog.
   ⇒ The variable is removed from the trace variable list.

Tracing a parameter

1. Double-click the trace object.

2. Click “Add Variable”.
   ⇒ The “Trace Configuration” dialog opens. The subdialog “Variable Settings” is displayed on the right.

3. Click ▼ (right of the “Variable” setting, left of the input field).

4. Select the “Parameter” option in the drop-down list.

5. Click ▼ and select a parameter from the “Input Assistant” dialog.
6. Configure how the parameter is displayed.
7. Click “OK” to close the dialog.
   ≫ The parameter will be traced and displayed in the trace variable list.

### Configuring a trigger

1. Double-click the trace object.
   ≫ The trace editor opens with the commands available in the “Trace” menu.
2. Click “Trace ➔ Configuration”.
   ≫ The “Trace Configuration” dialog opens. The subdialog “Record Settings” is displayed on the right.
3. Select the “Enable trigger” check box.
4. Select the task in which the trend record is to be executed.
5. Select a variable from the “Trigger Variable” field.
6. Click “OK” to close the dialog.
   ≫ The data recording will be triggered.

The trigger time is displayed as a black line in the diagram in runtime mode.

1. Download the application and start it.
2. Click “Trace ➔ Download Trace”.
   ≫ The trace configuration is loaded. After triggering, the runtime system saves the value graph of the trace variables. The data is displayed in the trace editor. The trigger time is displayed as a black line in the diagram.

### Configuring the display of the time axis

1. Double-click a trace object.
2. Click the “Configuration” link above the configuration tree.
   ≫ The “Trace Configuration” dialog opens.
3. Select “Time axis” in the display tree (below “Presentation (Diagrams)”).
   ≫ The display settings of the time axis are shown on the right.
4. Edit the presets and click the “Preview” link.
   ≫ The changes are seen in the coordinate system preview.
5. Click “Y-axis” in the display tree. The “Y-axis” item is below every configured diagram. Therefore, the display of the value axis is set for each diagram.
   ≫ The subdialog “Display Settings” of the selected axis is displayed on the right.
6. Change the preset value.
   ≫ The changes are applied in the coordinate system preview.
7. Click OK to close the “Trace Configuration” dialog.
   ≫ The display changes are visible in the affected diagrams.
Configuring the display of the trace variable

1. Double-click a trace object.
2. Click the "Configuration" link.
   ⇒ The "Trace Configuration" dialog opens.
3. Select a variable below "Trace Record".
   ⇒ The subdialog "Variable Settings" of the selected variable is displayed on the right.
4. Change a setting, for example the "Line type".
5. Click "OK" to close the dialog.
   ⇒ The display changes are visible in the affected diagrams.

Configuring the buffer for data on the runtime system

1. Double-click a trace object.
2. Click "Trace ➔ Configuration".
   ⇒ The "Trace Configuration" dialog opens. The subdialog "Record Settings" is displayed on the right.
3. Click "Advanced".
   ⇒ The "Advanced Trace Settings" dialog opens.
4. Change the setting "Measure in every n-th cycle" or "Recommended runtime buffer size (samples)".
5. Click "OK" to close the dialog.
   ⇒ The buffer settings are reconfigured. It is applied after the trace configuration is loaded to the RTS the next time.

Editing the trace configuration in runtime mode

Requirement: The application is running on the controller and a trace configuration is loaded.

1. Double-click a variable in the trace record tree.
   ⇒ The "Trace Configuration" dialog opens.
2. Change the color, for example.
   ⇒ The variable is displayed in the new color in the affected diagrams without interrupting the execution of the application.

If you change essential settings, for example a trace variable, then you must download the trace configuration to the controller again.

Operating the data recording

Use menu commands for controlling how data is recorded.

Requirement: The application is loaded on the runtime system and a trace is configured.
Menu commands

- “Trace ➔ Download Trace”
- “Trace ➔ Start Trace”
- “Trace ➔ Stop Trace”
- “Trace ➔ Reset Trigger”

See also

- Chapter 1.3.1.25.2.21.6 “Command ’Download Trace’” on page 1026
- Chapter 1.3.1.25.2.21.16 “Command ’Start Trace’” on page 1033
- Chapter 1.3.1.25.2.21.17 “Command ’Stop Trace’” on page 1033
- Chapter 1.3.1.25.2.21.13 “Command ’Reset Trigger’” on page 1032

Accessing all traces on the controller

If the controller supports the runtime system component CmpTraceMgr (Trace Manager), then you can access all traces from a CODESYS project which are running on the controller. In addition to application-related traces that capture the values of IEC variables, these can also be entirely controller-specific traces (for example, for recording device signal values or the CPU load).

For each trace running on the controller that you want to present in your project, you have to insert an individual “DeviceTrace” object in the device tree.

In order to show a trace from the device in this object, the connection to the PLC has to be configured correctly (“Communication Settings”). Then use one of the following menu commands:

- “Trace ➔ Upload Trace”: Establishes the connection to the PLC and opens the “Online List” dialog for selecting a trace from the controller.
- “Trace ➔ Online List”: Available in online mode only: Also opens the “Online List” dialog.

Now the trace uploaded from the controller can be started and traced in the editor of the DeviceTrace object. The configuration of the presentation (colors, labels, etc.) is the same as with traces for application variables configured in the project.

NOTICE!
Closing the DeviceTrace editor terminates the connection to the controller.

Please note that the connections to the controller is also terminated when the last open “DeviceTrace” editor is closed. In order for device traces to be displayed again in the project, you have to reload them into the “DeviceTrace” objects.

At this time, closing the editor is also the recommended procedure for deliberately terminating the connection to the controller. Logging out is not enough for this.

- Chapter 1.3.1.25.1.40 “Object ’DeviceTrace’” on page 845
- Chapter 1.3.1.25.2.21.19 “Command ’Upload Trace’” on page 1034
- Chapter 1.3.1.25.2.21.12 “Command ’Online List’” on page 1031
Displaying the CPU load with DeviceTrace objects in the CODESYS project (example)

Requirement: The PLC device supports the Trace Manager. For the example described here, this is CODESYS Control Win V3. The device provides traces of the individual CPU loads (CpuLoad), as well as traces of the CPU load caused by the runtime system (PlcLoad). The possible display of the CPU load in the project can be helpful when using multicore functionality.

1. In the project, define the “Communication Settings” for the controller.
2. Select the PLC entry in the device tree and add a “DeviceTrace” object.
4. Set the focus in the trace editor and click “Trace ➔ Upload Trace”.
   - The connection to the controller is established and the “Online List” dialog opens.
5. Select the “PlcLoad” entry in the dialog and click “Upload”. Click OK to close the dialog.
   - Four trace views open in the trace editor to show the CPU load in the runtime system. Three of the traces are for the three CPUs and one trace for the average value. The following text appears for each: "No samples have been recorded."
6. Click “Trace ➔ Start Trace”.
   - The trace recording for the four parameters is displayed.
7. If you also want to display the traces for the CpuLoad per CPU with their average value in the project, then insert another “DeviceTrace” object into the device tree. Name it “Trace_CpuLoad” for example. Load and start the traces for “CpuLoad” in the editor as described above.
   - Now you can monitor all traces in the project:

![Trace views in trace editor](image)

8. If you want to change the appearance of the presentation, then click “Configuration” in the respective trace editor window to access the configuration dialogs. You can use these dialogs (except variable assignments) in the same way as for an IEC variable trace created in a project.
9. To disconnect from the controller, close all open DeviceTrace editor windows. If you are logged in to the device, then logging out is enough to terminate the connection.

Navigating into trace data

Use menu commands to navigate the data in the trace diagram.

Requirement: The application is in online mode.

Menu commands
- “Trace ➔ Cursor”
- “Trace ➔ Mouse Zooming”
- “Trace ➔ Reset View”
- “Trace ➔ AutoFit”
- “Trace ➔ Compress”
- “Trace ➔ Stretch”
Managing trace

Use menu commands to load and save traces in various formats.

Menu commands

- “Trace ➔ Convert to Single-Channel”
- “Trace ➔ Convert to Multi-Channel”

See also

- § Chapter 1.3.1.25.2.21.20 “Command ‘Statistics’” on page 1034

1.3.1.13.4 Data recording with trend

When you want to monitor the development of data over a long period of time for the purpose of reading a trend, you can save the data with “Trend Recording”. You can configure any number of variables or parameters to save their values in a persistent database. This database is located on the PLC and is populated continually at runtime.
Trend recording comprises the following objects:

- (1): “Trend recording task” of type “Task”
- (2): Object of type “Trend Recording Manager”
- (3): Object of type “Trend Recording”

**NOTICE!**

**Timeout for trend recording**

During a trend recording, it can happen that the application task triggers a timeout that is caught with an exception when transitioning from “Running” to “Stop”. Causes can be that file operations with the SQLite database are taking too long or that too many variables are being recorded. This usually happens on a target device with weak performance.

You can avoid the occurrence of an exception:

- Configure the trend recording with less memory demand so that the amount of data that is stored is adapted to the target system.
- Reduce the number of variables.

To display the collected data, you design a visualization with a “Trend” element. This kind of visualization accesses the database for visualizing the data.

See also

- § Chapter 1.3.1.25.1.41 “Object ‘Trend Recording Manager’” on page 845
- § Chapter 1.3.1.25.1.42 “Object ‘Trend Recording’” on page 846
- § Chapter 1.3.1.25.1.43 “Object ‘Trend Recording Task’” on page 849

**Getting started with trend recording**

To execute trend recording on a runtime system, you need an application with a “Trend Recording Manager” object that contains at least one “Trend Recording” object. Then you can configure a database on the runtime system and the data buffering.
1. Add a "Trend Recording Manager" object below your application.
2. Select the "Trend Recording Manager" object and click "Add Object ➔ Trend Recording". Type a name in the "Add Trend Recording" dialog box.
   ⇒ CODESYS creates the object. The editor opens.
3. Type a task in "Record Settings".
4. Click "Add Variable".
   ⇒ CODESYS adds another variables. The blank settings open in the "Variable Settings" to the right of the tree view.
5. Select a valid IEC variable from the "Variable" field.
   ⇒ The IEC variable is configured for trend recording.
6. Build the application.
7. Download the application to the controller and click "Start".
   ⇒ The application records data in runtime mode and saves it to a database.

See also
- Chapter 1.3.1.25.1.42 “Object ‘Trend Recording’” on page 846
- Getting Started with Trend ➔ Chapter 1.3.5.11.1 “Getting started with trend visualization” on page 1165

Configuring trend recording
You can configure a database on the runtime system and the data buffering.

**NOTICE!**
Timeout for trend recording
During a trend recording, it can happen that the application task triggers a timeout that is caught with an exception when transitioning from "Running" to "Stop". Causes can be that file operations with the SQLite database are taking too long or that too many variables are being recorded. This usually happens on a target device with weak performance.

You can avoid the occurrence of an exception:
- Configure the trend recording with less memory demand so that the amount of data that is stored is adapted to the target system.
- Reduce the number of variables.

Assigning tasks In this task, the runtime system records the trend.

1. Double-click a “Trend Recording” object in the device tree.
   ⇒ The respective editor opens. In the tree view of the trend configuration, the top entry is selected, and on the right you see the current configuration in "Record Settings".
2. Click the "arrow down" symbol (▼) in the "Task" drop-down list.
   ⇒ The drop-down list opens with all tasks that are available throughout the application.
3. Select a task for trend recording.

See also
● Chapter 1.3.1.25.1.42 “Object ‘Trend Recording’” on page 846

---

**NOTICE!**
The number of variables is limited for trend recording. You can change this number in the “Trend storage” dialog.

---

**Adding IEC variables**

1. Double-click a “Trend Recording” object in the device tree.
   ➜ The respective editor opens. In the tree view of the trend configuration, the top entry is selected, and on the right you see the current configuration in “Record Settings”.
2. Right-click an entry in the tree view.
3. Click “Add Variable”.
   ➜ CODESYS adds another variables. The blank settings open in the “Variable Settings” to the right of the tree view.
4. Select a valid IEC variable from the “Variable” field.
   ➜ The IEC variable is configured for trend recording.
5. Configure how the variable is displayed in the trend diagram.
6. Configure how the alert color is displayed in the trend diagram.

See also
● Chapter 1.3.1.25.1.42 “Object ‘Trend Recording’” on page 846
● Chapter 1.3.1.25.3.16 “Dialog Box ‘Trend storage’” on page 1097

---

**Removing variables from the configuration**

1. Double-click a “Trend Recording” object in the device tree.
2. Click a variable in the tree view of the configuration.
3. Click “Delete Variable” or press [Del].

---

**Starting conditional trend recording**

You can configure conditional trend recording for execution. Configuration is not possible when depending on triggering. For that you need a “Trace” object.

1. Double-click a “Trend Recording” object in the device tree.
2. Click the top node in the tree view of the trend configuration.
   ➜ The name of the trend configuration is selected and on the right you see the current configuration in “Record Settings”.
3. Assign a Boolean variable, an access to a bit, or a property to the “Record condition” field.
   ➜ When the application is in runtime mode, data is recorded only if the value is TRUE.

See also
● Chapter 1.3.1.13.3 “Data recording with trace” on page 335
Adding parameter

1. Double-click a “Trend Recording” object in the device tree.
   → The respective editor opens. In the tree view of the trend configuration, the top entry is selected, and on the right you see the current configuration in “Record Settings”.
2. Right-click an entry in the tree view.
3. Click “Add Variable”.
   → CODESYS inserts a new variable. The blank settings open in the “Variable Settings” to the right of the tree view.
4. Click the “down” symbol (▼) to the right of the “Variable” label.
5. Select “Parameter” from the drop-down list.
6. Click and select a parameter from the “Input Assistant” dialog.
7. Configure how the parameter is displayed in the trend diagram.
8. Configure how the alert color is displayed in the trend diagram.

See also
● Chapter 1.3.1.25.1.42 “Object ’Trend Recording’” on page 846

Configuring data buffering on the RTS

1. Double-click a “Trend Recording” object in the device tree.
   → The respective editor opens. In the tree view of the trend configuration, the top entry is selected, and on the right you see the current configuration in “Record Settings”.
2. Click “Trend Storage”.
   → The “Trend Storage” dialog opens.
3. Now you can change the settings.

See also
● Chapter 1.3.1.25.3.16 “Dialog Box ’Trend storage’” on page 1097

Configuring additional buffering

1. Double-click a “Trend Recording” object in the device tree.
   → The respective editor opens. In the tree view of the trend configuration, the top entry is selected, and on the right you see the current configuration in “Record Settings”.
2. Click “Advanced”.
   → The “Advanced Trace Settings” dialog opens.
3. Now you can change the settings.

See also
● Chapter 1.3.1.25.3.17 “Dialog Box ’Advanced Trend Settings’” on page 1097
1.3.1.13.5 Monitoring tasks
In online mode, you can display some statistical values of the tasks in the runtime system. This information is very useful for testing clock cycles or solving problems in the runtime performance.
1. Switch to online mode.
2. Select the “Task Configuration” object in the device tree. Click “Project ➔ Edit Object”.
   The task configuration opens in the editor.
3. Click the “Monitor” tab.

See also
● Chapter 1.3.1.13.3.2 “Creating trace configuration” on page 338

1.3.1.13.6 Reading the PLC log
CODESYS provides the capability to display the events and error messages logged in the controller.
See also
● Chapter 1.3.1.25.1.37.3 “Tab 'Monitor’” on page 837

Reading the log Requirement: The controller is running.
1. Select the controller in the device tree.
2. Choose the command “Project ➔ Edit Object”.
   The device editor opens.
3. Choose the tab “Log”.
4. Click on to update the view.
   A connection to the controller is established. The controller in the device tree is highlighted in green.
   All controller log information are displayed.
5. Click on to delete the current list.
6. Filter the view by clicking on the desired category (for example "Information").
7. Save the log entries. Click on and choose a file name.

See also
● Chapter 1.3.1.25.1.19.8 “Tab 'Log’” on page 750

1.3.1.13.7 Analysing errors with core dump
A core dump is a memory snapshot of the application data. In case of an exception error, runtime systems that support this feature automatically store a core dump file (<application name>.core) in the application directory and on the controller.
In online mode, you can also generate a core dump explicitly if the application is currently stopped at breakpoint or if an exception has occurred. In this case, CODESYS stores the core dump file in the project directory and not on the controller.

In offline mode, you can load the core dump from the controller to the project. An online view of the application is then displayed with the data and values at the time of the exception.

In addition, you can call a project view of the controller log file at the time of generating the core dump.

**NOTICE!**

The runtime system must completely support the functionality to assure a correct display of variable values in the core dump view.

In the online view of the application that CODESYS created when loading the core dump into the project, menu commands are displayed as available but do not have any effect in this status. When selecting one of these commands, a message is displayed.

**CAUTION!**

Restriction (CDS-37572): Exception handling in the runtime system may overwrite parts of the variable values in the call stack. Therefore, the original values are lost and important information may no longer be displayed for variables in functions and methods at the time of monitoring.

When creating project archives: If you created a core dump explicitly by clicking “Create Core Dump”, then this option is available automatically in the archive configuration. On the other hand, if you copied the core dump from the PLC, then you can add it to a project archive only by selecting “Additional files”.

Important: A project archive with a core dump must necessarily include the download information. If it does not, then CODESYS cannot use the core dump.

**Loading the core dump and device log into the project for analysis**

Requirement: You have a project open with an application that has produced an exception on the controller. The runtime system is able to create core dumps. The application in the project is in offline mode.

1. Load the required core dump from the controller by clicking “Debug ➔ Load Core Dump”.
   - CODESYS shows an online view of the application. You see the variable values and call stack from the time of error (see below). This includes also the values of the I/O variables in the mapping dialog box of the device configurator and the task configuration. “Core dump loaded” appears in the status line. CODESYS copies the core dump file as <project name>.<device name>.<application name>.<application Guid>.core to the local project directory.

2. Click “Debug ➔ Load Device Log from Core Dump” to load the device log from the time of error into the project.
   - The log view opens (as in online mode of the device editor) with the events at the time of the core dump.

3. After completing the core dump analysis, click “Debug ➔ Close Core Dump”.
   - CODESYS closes the core dump view of the application. The project returns to the normal offline mode with its views.
Creating the core dump of the running application manually

Requirement: A CODESYS application is in online mode. The runtime system supports core dump functionality.

- Click “Debug ➤ Create Core Dump”.
  - CODESYS starts generating a new core dump. A progress bar appears in the status line and a button to cancel the process.
  - CODESYS saves a core dump file to the local project directory as <project name>.<device name>.<application name>.<application Guid>.core.

1.3.1.13.8 Using PLC shell for requesting information

The “PLC shell” in CODESYS is a text-based control monitor (terminal) on a tab of the device editor. There you can enter commands for the request of specific information from the controller, as well as execute actions like starting, stopping or downloading applications. Also a description on the meaning and syntax of the possible commands you can get directly via the PLC shell.

The list of available commands depends on the PLC manufacturer. It can be extended via the so-called SPS Shell Command Handler interface, either in a C-component of the runtime system, or as a function block in an IEC library or project.

The response from the PLC will be shown as a string in an output data window within the tab.

Requesting information about the application on the controller

Requirement: Your project is connected with a controller; Example: CODESYS Control Win V3, on which an application App1 is running.

1. Open the device editor double-clicking on the object CODESYS Control Win V3 in the device tree, and activate tab “PLC Shell”.
   - The tab shows an empty output data window. Below there is an entry field for a command.
2. Click button 
   - The “Insert Standard Command” dialog appears with a list of commands.
3. Choose command “?” and click button “Execute”.
   - The dialog closes and in the output data window you see a list of the supported commands and their possible parameters. Each the syntax for how to enter the command is displayed.
4. Click again [..] and choose command “pid”. In the input assistant supplement the command as follows: pid App1. Press the Enter key.

∴ In the output data window the following gets displayed (the GUIDs are just examples):

   pid App1
   Project Identification
   Application: App1
   Code GUID:0x08a893c0
   Data GUID:0x762d0e90

5. Click button ▼ in the command line.

∴ Command pid App1 is added to the history of already entered commands.

1.3.1.13.9 PLC operation control via system variables

CAUTION!
You are responsible for runtime system services being enabled under safe application conditions and disabled only under critical conditions.

At runtime, the state of an application or facility can become sensitive and disruptive actions can endanger the entire machine or facility. However, in this state you can suppress certain commands and prevent dangerous actions. The “PlcOperationControl” function block and “Component Manager” library are provided for this purpose.

Examples of CODESYS commands that can suppress operations when executed:

● “Online Change”, “Download”
● “Enable Breakpoint”
● “Reset Application”, “Stop Application”
● “Transmit Data”
● “Force Values”, “Write Values”

In order that a backup solution is always in place, you are not permitted to suppress the “Reset origin” and “Delete” commands.

CODESYS will notify you if a currently disabled runtime system service is required when the application is in runtime mode. Then, you can respond with an appropriate countermeasure.

Function block
PlcOperationControl for operation control

This function block is used for enabling and disabling operations.

Table 9: Property (PROPERTY)

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Initial value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xDisableApplicationOnlineChange</td>
<td>BOOL</td>
<td>FALSE</td>
<td>TRUE: Online change is suppressed.</td>
</tr>
<tr>
<td>xDisableApplicationDownload</td>
<td>BOOL</td>
<td>FALSE</td>
<td>TRUE: Download is suppressed.</td>
</tr>
</tbody>
</table>
### Implementing operation control

**Requirement**
- Compiler version $\geq 3.4.3.0$
- In the device description, the PLC operation control is enabled by system variables.

1. Declare an instance of the `PlcOperationControl` function block (for example, `PlcOpCtrl_Inst`).
   ```plaintext```
   <> PlcOpCtrl_Inst : PlcOperationControl;
   ```plaintext```
2. Suppress a command by assigning the respective TRUE property (for example, "Stop Application").
   ```plaintext```
   <> PlcOpCtrl_Inst.xDisableApplicationStop := TRUE;
   ```plaintext```

### 1.3.1.13.10 Backup and restore

CODESYS and the CODESYS standard runtime systems (with version 3.5.8.0 and later) support backing up application-specific files on the PLC. You can execute the required actions in the “Backup and Restore” tab of the generic device editor.

A backup consists of creating and saving a file in zip archive that contains the application-related files and an information file `meta.info`. This backup file has the extension `TBF` (="Target Backup File") and can be saved in the local file system or on the PLC.

The following applies when restoring the software status from the backup file:
- A dialog opens with a list of affected files on the PLC, and you can deactivate optional components.
- If you have to set the application to STOP mode for backup or restore, a dialog prompt will open to warn you about this- Warnings also open when incompatibilities are detected.
- The user interface is blocked when restoring to the PLC.
- Existing files are overwritten without warning.
- Existing boot applications are deactivated as soon as at least one new boot application is part of the restore.

</tr>
</tbody>
</table>
Creating backup files

Requirement: A project is open with an application that is running on the required device. In addition, for this example an external file myExternalFile.txt is inserted as an object below the application. This file is downloaded to the PLC implicitly when downloading the application.

1. Open the device editor by double-clicking the device entry in the device tree. Click the “Backup and Restore” tab.
   ⇒ The tab opens with a menu bar including the “Backup” and “Restore” menus.
2. In the “Backup” menu, select the “Read Backup Information from Device” item.
   ⇒ If the PLC is not connected at the moment, then CODESYS opens a temporary connection to the device and reads the relevant files from the $PlcLogic$ directory of the PLC into a table in the lower part of the tabbed page. In this example, at least the following files will be listed: $PlcLogic$/Application/Application.app, $PlcLogic$/Application/Application.crc, and $PlcLogic$/Application/myExternalFile.txt. In addition, other external, project-dependent files are listed, which have been inserted below the application in the device tree. Furthermore, the source code archive file $PlcLogic$/Archive.prj is listed if you have set the project setting for this (“Implicitly at program download and online change”) as the loading time.
3. In the table, clear the check box for the $PlcLogic$/Application//myExternalFile.txt file in the “Active” column.
4. Select “Save Backup File to Device” in the “Backup” menu.
   ⇒ The “Save as” dialog opens. The file type is predefine as “Backup files (*.tbf)”. 
5. Select a location for the backup file and click “Save”.

Restoring from backup files

Requirement: A project is open with an application that is running on the required device. A backup file is saved to the local file system as described above.

1. Open the device editor by double-clicking the device entry in the device tree. Click the “Backup and Restore” tab.
   ⇒ Click “Restore ➔ Load Backup File from Disc”.
   ⇒ The default prompt opens for selecting a backup file tbf in the local file system.
2. Select the backup file and click “Open”.
   ⇒ The files are read from the backup file and shown in the table of the dialog below. The file $PlcLogic$/Application/myExternalFile.txt that was excluded in the backup is missing.
3. Click “Restore ➔ Restore Backup to Device”.
   ⇒ A dialog prompt opens with information about the actions when restoring.
4. Click “OK” to start restoring the files to the PLC file system.
   ⇒ When restore is complete, you are prompted to restart the PLC in order to activate the loaded application.

1.3.1.14 Updating an application on the PLC

CODESYS offers in principle two possibilities to transfer a modified application to the controller: download and online change.
NOTICE!
If you use a device application, please note the restrictions concerning download and online change.

A download leads to a recompilation of the application. In the process, a syntax check is performed and application code is also created and loaded to the controller. This leads to the running program being stopped. A download is the recommended method of data transfer, since a defined starting state is always created due to the program stop and the re-initialization.

In the case of an online change, only the modified parts are reloaded to the controller. A running program is not stopped for this. You should only carry out an online change in the case of minor changes to the application. In the case of extensive changes the behavior of a program cannot be safely predicted. Please read the notes in the description of the “Online Change” command regarding this.

- ‡ Chapter 1.3.1.14.2 “Execution of a download” on page 356
- ‡ Chapter 1.3.1.25.2.6.5 “Command 'Load’” on page 927
- ‡ Chapter 1.3.1.25.2.6.6 “Command 'Online Change’” on page 928

1.3.1.14.1 Executing the online change
CODESYS automatically offers you an online change if you log in with an application that is already present on the controller, but has been changed since the last download in the programming system. With this procedure only the modified parts are reloaded to the controller. A running program on the controller is not stopped during the online change.

In the view “Memory reserve for online change”, you can configure memory reserves for the online change for function blocks of a project. In this way, instance variables do not have to be moved to the memory after changes are made to a function block for an online change.

NOTICE!
When carrying out the online change, pay attention to the notes in the description of the “Online Change” command.

See also
- ‡ Chapter 1.3.1.25.2.6.6 “Command 'Online Change’” on page 928

- ‡ Chapter 1.3.1.11.4 “Generating application code” on page 303
- ‡ Chapter 1.3.1.9.4 “Configuring the memory reserve for an online change” on page 206

Executing the online change when logging in
Requirement: The connection settings of the controller are correctly set. The applications in the project and on the controller are identical. The project on the controller is running. The application is logged out.

1. Change your application.
2. Click “Online ➔ Login”.
   ➔ A dialog appears with the information that the application has been changed since the last download.
3. Click the “Details…” button
4. Check the details in the “Application information” tab.
   If you have not generated any code since the last change, the command “Application is not up to date. Generate code now?” appears at the bottom edge of the dialog. In this case click this command.
   ⇐ You are shown a comparison view of the objects (objects marked red are different).
5. Close the dialog.
6. Select the option “Login with Online Change” and click “OK”.
   ⇐ The change is loaded to the controller. The running program on the controller is not stopped while doing this. The application is logged in.

See also
● ☞ “View ‘Project Comparison’ - ‘Differences’” on page 906

### Execute online change in the logged-in state (online operation)

Requirement: The connection settings of the controller are correctly set. The applications in the project and on the controller are identical. The project on the controller is running. The application is logged in.

1. Select an object in the device tree. It is best to select a POU or a GVL here.
2. Click “Project ➔ Edit Object (Offline)”.
   ⇐ The object opens in the editor.
3. Change the object. For example, you can declare a new variable or change a value assignment here.
4. Click “Online ➔ Online Change”.
   ⇐ A query will appear, asking whether you really want to execute the online change.
5. Click “Yes” to confirm the dialog.
   ⇐ The change is loaded to the controller.

### 1.3.1.14.2 Execution of a download

A download of the application causes a compilation of the active application. In the process, a syntax check is performed and application code is also created and loaded to the controller. A program running on the controller is stopped during the download.

### Downloading when logging in

Requirement: the connection settings of the controller are correctly set. The applications in the project and on the controller are identical. The project on the controller is running. The application is logged out.
1. Change your application.
2. Select the command “Online ➔ Login”
   ⇒ A dialog box appears with the information that the application has been changed since
   the last download.
3. Select the option “Login with download” and click on “OK”.
   ⇒ The running program on the controller is stopped and the change is loaded to the con-
   troller. The application is logged in.

**Downloading in the logged-in state (online mode)**

Requirement: the connection settings of the controller are correctly set. The applications in the
project and on the controller are identical. The project on the controller is running. The applica-
tion is logged in.

1. Select an object in the device tree. It is best to select a POU or a GVL here.
2. Select the command “Project ➔ Edit Object (Offline)”
   ⇒ The object opens in the editor.
3. Change the object. For example, you can declare a new variable or change a value
   assignment here.
4. Select the command “Online ➔ Download”.
   ⇒ A query will appear, asking whether you really want to execute the download.
5. Confirm the dialog box with “Yes”.
   ⇒ The running program on the controller is stopped and the change is loaded to the con-
   troller.

1.3.1.15 Copying files to/from PLC

In the generic “Files” tab of the device editor, you can copy files to and from the local file system
and the controller.

Requirement: The vendor has unlocked the tab. In the device tree, the connection to the con-
troller is configured. The device is running.

1. Double-click the PLC device object in the device tree to open the device editor.
2. Click the “Files” tab.
3. In “Host” | “Location” on the left part of the view, set the path in the local file system where
   files will be copied to and from. Example: D:\FileTransferWithPLC. If necessary,
   create a new directory by clicking the folder symbol ( ).
   ⇒ The files and directories are shown like in a file manager. Click the refresh symbol ( )
   to update the display.
4. In “Runtime” on the right side of the view, set the required directory for the data transfer in
   the same way.
   ⇒ CODESYS shows the files on the controller.
5. Select the required files from the file system tree for the file transfer (multiple selection is
   possible). You can also select a directory for transferring all files in a folder.
6. Click the left and right arrow symbols ( , ) between the two parts of the view.
   ⇒ CODESYS copies the selected files to the other file system immediately. If a file is not
   already available in the target directory, then it is created. If it is already available and
   not write-protected, then it is overwritten. Otherwise a message is shown.

### 1.3.1.16 Using device applications

Using a device application allows for the separation of globally required data from exclusively control programs:

The global data that is used by all control applications of a device are managed in their own "Device Application" object. They are compiled fully with this object and downloaded to the controller at the time of commissioning. The "Device Application" does not include control programs developed by the user. Because of this, the exclusively control applications of the device are smaller and require less time to download. Reason: The global data does not have to be included at every download or online change. However, loading the global data requires more memory and download time as when using exclusively single applications. Reason: ALL referenced data and the entire code are downloaded to the controller with the device application because it is not clear what is used later or not.

Therefore, using a device application instead of single applications makes sense when

- the device in use has enough memory (for example not an embedded system),
- and if the control tasks should be distributed to multiple applications for improved logical mapping.

**Organization in the device tree:**

- Depending on the device, you can insert the "Device Application" object in the device tree below the "PLC Logic" node of the device. By using different types of child objects, this manages the global data and code segments that are used by all exclusively control applications of the device. Examples: library manager, GVLs, network variable list. The "PLC Logic" node is hidden after the device application is inserted into the device tree.

- The exclusively control program code is contained in one or more ordinary application objects that are displayed in the tree in parallel to the "Device Application". In the hierarchy however, they are ranked below the "Device Application" and can access the global data and variables of the device application. They do not have mutual access to each other and also cannot have any child applications. However, data exchange is possible via the global data of the device application.

**Control and behavior:**

- An online change is not possible for the device application. Therefore, changes to the device application lead to a new download of the device application and the child applications (in the device tree on the same level).

- After a download or reset (warm or cold), the device application is then in status "Stop". You can login, logout, start, stop, and reset all applications of the device application, individually or collectively, via corresponding context menu commands.

- At the first login and download of an application, the device application is also downloaded automatically.

- When commissioning the device, you can use the online configuration mode for testing the I/Os. When commissioning is complete, you must then perform a new download for the applications and the device application.

- If you delete the device application from the device, then its child applications are also deleted from the device.

- When generating a boot application for an application of the device, a boot application is also generated automatically for the device application.

- By default, each application has the property that the device application stops, as well as all other applications, in case of an exception.
● Notes about task configuration:
POUs cannot be called in the task configuration of the device application. This task configuration is used by bus masters in the field in order to reach an approximation of the timing of the bus cycle task when the program is executed. Depending on the device, there are two possibilities:

– You define a task of type “External” in the task configuration of an application. As an external event for triggering the task, you specify the call of the implicitly provided bus master event. This allows for reaching an asynchronous timing compensation with the bus master.

– You define a task of type “Parent task” in the task configuration of an application. For the parent task, you select the cyclic tasks of the bus master from the provided tasks of the device application. This allows for reaching a synchronous timing compensation with the bus master.

Please note the following restriction: Whether or not synchronous calling is executed depends on the state of the device application only. If this is running and the child application is not running, then the code is called anyway.

● Notes about persistent variables:
If the device supports static memory areas for persistent and retain variables, then you can use the “Persistent Variable configuration” object to map the memory also into global and application-specific for remanent data. This makes sense so you do not have to download the device application and all applications to the controller again after a persistent variable list is modified. By default, for devices with static memory management, the entire memory is reserved in the device application for remanent data. However, as soon as you create a persistent variable list in an application, you must also provide a memory area for it there. Even an empty list requires at least a few bytes of memory. For devices without static memory allocation, an individual memory segment is allocated automatically for persistent data for each application.

● Note for symbol configuration:

– A “Symbol Configuration” as a child application of a “Device Application” is not supported.

– You can also apply the references to the symbol configuration libraries of an application in the library manager of the device application. The advantage of this is that the libraries do not have to be downloaded with the application, and therefore the applications are smaller. Refer to the option “Add library placeholder to device application” when adding a “Symbol Configuration” object, or the command with the same name in the “Tools” menu of the symbol configuration.

● ° Chapter 1.3.1.25.1.36 “Object ’Symbol Configuration’” on page 824

1.3.1.16.1 Creating device applications
Requirement: The device you are programming supports a device application.
1. Click “Project ➔ New Project”.
2. Select the “Standard project” template in the “New Project” dialog (“Projects” category). Specify a project name and a storage location, and then click “OK”.
⇒ The “Standard Project” dialog opens for selecting the device and the implementation language for a standard PLC_PRG POU.
3. Select a device (for example, CODESYS Control Win V3) and “Structured Text (ST)”.
4. Delete the “Application” object in the device tree.
5. Select the “PLC Logic” object and click “Add Object”.
6. Add the “Device Application” object.
7. Select the “Device Application” object (1) and click “Add Object”.
   ➢ The drop-down list offers the following objects:
     ● “Application”: The application object is inserted into the tree parallel to the device application, below the device object, but below the device application in the hierarchy. Child application of applications are not possible.
     ● “Global Variable List”
     ● “Network Variable List (Receiver)”
     ● “Network Variable List (Sender)”
     ● “Persistent Variables”
     ● “Recipe Manager”
     ● “Task Configuration”

8. Insert the necessary objects for managing the data and variables that should be available for all applications of the device.

9. Configure the task configuration of your application. As a rule, the task of the bus master is in the task configuration of the device application. In order to harmonize the application processing with the timing of the bus cycle task, you can create a task of type “External” in an application and assign the implicitly provided bus master event to it as the triggering “External event”. As an alternative, synchronous harmonization is possible by specifying the bus cycle task of the device configuration as a "Parent task".

10. To use persistent variables when the device supports static memory, you can perform a specific memory configuration in the project. Aim of this configuration: The memory for persistent variables is no longer 100% for the device application. For this purpose, the “Persistent variable configuration” object is inserted below the device application and the memory segments of the applications are configured in its editor.

In the figure, you can see the example of a device tree with (1) device application and two applications with different task areas. In addition, the tree contains an (4) EtherCAT bus master and a (3) bus task defined in IO_Application. This bus task is triggered by an asynchronous external event triggered by the bus master. Moreover, persistent variable lists and a (2) persistent variable configuration object for the memory configuration of the remanent data are created here.
Inserting into existing project with conventional application organization

To insert the “Device Application” object into an existing project with conventional application organization, proceed as follows:

- Create a new device entry in the tree.
- Delete automatically generated applications below the “PLC Logic” node.
- Insert a “Device Application” object for the selected “PLC Logic” node.
- Move the necessary objects from the old device structure to the new structure and delete the previous device entry.

1.3.1.17 Using redundant PLC devices, CODESYS Redundancy

In the CODESYS Development System, redundancy means that an application can run on two CODESYS PLCs, where only one PLC is active at a given time. If the active PLC fails, then the other PLC takes over without any interruption of the fieldbus control. Even the inactive PLC (standby PLC) always executes the program, reads inputs, and can synchronize with the active PLC over a communication line.

When starting up the redundant system, the PLC that was started first enters standalone mode until the second PLC is started and synchronized. Then the first one switches to active state and the second one switches to passive state (standby). If both PLC devices start at the same time, then the PLC with the higher IP address becomes the active PLC.

The participating PLC devices must have a corresponding runtime system extension. By default, a "Redundancy" object is provided with the accompanying configuration editor in the user interface of the CODESYS Development System.

CODESYS Redundancy supports EtherCAT (3S-Smart Software Solutions GmbH stack) and Profibus over Hilscher CIF50 adapters.

The figure below presents a possible constellation with two redundant PLC devices (active PLC, standby PLC). Programming means the CODESYS Development System.

To operate an application on redundant PLCs, add the "Redundancy Configuration" object to the project. It provides a configuration editor where you define the memory areas of the application to be controlled, the relevant task, and a watchdog. It also provides a display of the current statuses of the both PLC devices at runtime. You can start trigger the switching of roles from passive to active either in the configuration editor or with a library function.

The boot application or the registered memory areas must be updated only on one of the two PLCs. The variable values in the registered memory areas are always synchronous for both PLC devices.

The logger of the runtime system records redundancy events on both devices.

See also

● Chapter 1.3.1.25.1.32 “Object 'Redundancy Configuration' and Redundancy Editor” on page 815
1.3.17.1 Configuring redundant PLC devices

See below for steps how to configure an application for redundant mode on two PLCs.

**NOTICE!**

**User management**

If a user management is used on the PLC, then you must configure the same user name and the same password for access to both PLC devices. Otherwise, online services, such as write variable or online change, are not transmitted to the inactive PLC.

Requirement: The runtime system components for CODESYS Redundancy are installed on both PLC devices. The PLCs are running. They are named PLC1 and PLC2. The project with the respective application is open in CODESYS Development System.

Configure the project

1. Select the application object in the device tree and insert the “Redundancy Configuration” object.
   ⇒ The “Redundancy Configuration” dialog box opens.

2. If you have already configured the communication settings for the top-level PLC, then CODESYS accepts them automatically for PLC1 and displays them in this dialog. To set it as active, open the “Communication” tab by clicking the “Set Active Path PLC 1” button.

3. Click the “Set Active Path PLC 2” button in the “Redundancy Status” tab. Define the communication path for PLC2.

4. In the “Redundancy Configuration” editor, select the “Redundancy Settings” tab and then the “Connection” tab. Specify the IP addresses of both PLC devices in “IP address PLC 1” and “IP address PLC 2”. If possible, select a separate port especially for the connection between PLC devices only. Note: The configuration settings may deviate for OEM-specific redundancy interconnections.

5. Switch to the “General” tab. Define the settings, such as the name of the application task that should control the processing (“Redundancy task”), the watchdog, the services to be executed, and the fieldbuses used.

   EtherCAT settings: The source address for PLC1 must agree with the address used in the EtherCAT master. The source address of PLC2 is the adapter that is used for EtherCAT for PLC2.

6. When both PLCs are running, click the “Write” button in the lower right of the configuration dialog in order to specify the settings in the configuration files of both PLC devices.

7. Optional: For our example, extend the application here by a programmatic query of the redundancy status. Insert a “POU” of type “Program”. An example is shown below this list of steps.

8. If necessary, stop both PLC devices because the changed settings become active only when the runtime system is restarted. Restart in the order described below.

Example of a program for retrieving the redundancy status

```
PROGRAM PLC_PRG
VAR
  state: RedundancyState;
  bResult: BOOL;
END_VAR

bResult := RDCY.GetRedundancyState(ADR(state));
```
You can always follow the status change described in the following instructions by monitoring the variable `state.eRedundancyState` in “PLC_PRG”, as well as in the “Redundancy Status” tab of the “Redundancy Configuration” editor.

### Download the application to PLC1
1. Start PLC1. (The first of the two PLCs that is started enters standalone mode.) Open the online view of “PLC_PRG” and the “Redundancy Status” tab of the “Redundancy Configuration” editor.
   - The variable `state.eRedundancyState` contains the value `RS_CYCLE_STANDALONE`. In the graphical representation, the symbol  appears at PLC1 and the symbol  appears at PLC2.
2. Select the application in the device tree. Click “Online ➔ Login”. Download the application to PLC1 and start the application by clicking “Debug ➔ Start”.
3. If the automatic creation of the boot application is not activated in the application properties, then click “Online ➔ Create Boot Application”.

### Synchronize PLC1 and PLC2
1. Start PLC2.
   - PLC2 reads the boot application from PLC1 and synchronizes the data and the task execution. The redundancy status of PLC1 switches to active. The variable `state.eRedundancyState` receives the value `RS_CYCLE_ACTIVE`. In the graphical representation, the symbol  appears at PLC1. PLC2 switches to the passive state at the same time. Both PLC devices are now running in redundancy mode.
2. To check that both PLC devices execute the same application, you can perform the following steps:
   - Log out of PLC1 by clicking “Online ➔ Logout”.
   - Open the “Communication” tab for PLC1 by double-clicking the device object in the device tree where the application is located. Change the connection settings to PLC2.
   - Click “Online ➔ Login”. There is no message regarding a download. PLC2 applies the boot application from PLC1 automatically.
   - Important: Change the communication settings back to PLC1.
   - Check the redundancy status of PLC2: The variable `state.eRedundancyState` receives the values `RS_CYCLE_STANDBY`. In the graphical representation, the symbol  appears at PLC2.
3. To simulate unexpected failures of PLC1, perform the following steps:
   - Stop PLC1. As a result, PLC1 shows status "Unknown" and PLC2 switches immediately to status "Standalone".
   - Start PLC1. PLC1 has status "Passive" and PLC2 switches to "Active".
4. You can perform the following actions by means of the buttons in the “Redundancy Status” tab:
   - “Switchover”: The active PLC is switched to status "Passive".
   - “Simulation”: The active PLC is switched to status "Simulation" (for testing purposes).
   - “Activate”: The PLC in simulation mode is switched to status "Active".
   - “Synchronize”: The PLC in simulation mode or in error status synchronizes with the other PLC, applies its data, and becomes "Passive".

- § Chapter 1.3.1.25.1.19.2 “Tab ‘Communication Settings’” on page 741
- § Chapter 1.3.1.25.1.32 “Object ‘Redundancy Configuration’ and Redundancy Editor” on page 815
**1.3.1.17.2 Restrictions**

**CODESYS version**
CODESYS Redundancy requires CODESYS V3.5 SP2 or later. The same version of the runtime system must be installed on both PLC devices.

**Real-time tasks and communication**
CODESYS Redundancy synchronizes 1 task. Other tasks and applications are possible, but they run non-synchronized on both PLCs.

CODESYS Redundancy requires real-time task execution and real-time communication. Real-time task execution means that the application task (redundancy task) that is controlled by redundancy has a limited jitter. Real-time communication means that a message that is sent by means of the redundancy interconnection is received by the second PLC within a specific time. The redundancy timeout can be defined in the CODESYS Development System with the "Redundancy Configuration" editor ("Redundancy Settings"). In the runtime system configuration file CODESYSControl.cfg, it is specified by the entry StandbyWaitTime.

The value for the timeout for redundancy must be greater than the sum of the task jitter time and the maximum communication jitter time. These times depend on the system.

Real-time task execution and real-time communication are required for indicating a specific maximum timeout. If this kind of timeout occurs while waiting for a message from the other PLC, then the system assumes that the other PLC is not running anymore. As a result, the waiting PLC and the other PLC switch to standalone mode.

If the task jitter is too high, or the message transmission is delayed, then it is possible for both PLCs to switch to standalone mode. The means that there are synchronization losses and communication problems on the fieldbus.

**IEC timer**
Different execution times on both PLC devices can cause bumps (deviating output values) when switching PLCs. To prevent this, the IEC timer values are frozen during the execution of an IEC task. Calls from IEC timers (example: TON) when executing an IEC task therefore always lead to the same timer values, even if the physical time continues running. This means that it is not possible, for example, to wait actively in a loop, because the IEC timer values do not change in the current task scan.

**POINTER**
POINTER variables must not be declared in data areas that are controlled by redundancy. Reason: Redundancy-controlled values are transmitted to the other PLC during synchronization. However, pointer values are not valid on the other PLC because another memory layout may be located there.

When compiling, the redundancy feature checks that a pointer variable is located in a redundancy-controlled area. A warning is issued for each pointer variable that is detected in such an area. The check can be deactivated in the device description file with the following entry:

```
<Device>
  <Custom>
    <Redundancy DisablePointerChecks="true">
```

**EtherCAT DC**
This redundancy extension is designed more for the process industry than for factory automation. Therefore, EtherCAT drives with distributed clocks are not supported. However, EtherCAT I/Os are supported.

**Map on existing: mapping to existing variables**
The I/O mapping method "map on existing" (mapping I/Os to existing variables) is not recommended for use with CODESYS Redundancy. These variables are not stored in the input or output data areas, but where they are declared. Therefore, they are not synchronized during operation.

**Network variables**
Network variables with write access must not be used because multiple write telegrams are sent at the same time. Network variables with read access are permitted.
File access must not be used because different file data can cause bumps on the different PLCs when they are switched.

If you use files, then you must declare file handles in the data areas that do not subjected to redundancy control. The files must be opened separately on both PLCs, and the file handle of another PLC must not be used for accessing the files on the local PC.

When compiling, CODESYS Redundancy checks that handle variables (RTS_IEC_HANDLE, CAA.HANDLE) are located in a redundantly controlled area. A warning is issued for each handle variable that is detected in such an area.

Online security user management

If an online security user management is used, then you must configure both PLC devices with the same user name and password. Otherwise, online services, such as write variable or online change, are not transmitted to the passive PLC.

1.3.1.18 Using the command-line interface

You can start CODESYS.exe from the command line with the following switches and options.

Syntax:

```
<folder>CODESYS.exe> --<switch or option>
```

Paths or option parameters must be written inside straight quotation marks when they contain spaces, dashes, or slash marks.

Switch --culture (language of the user interface)

In the command line, include this switch after the development system call in order to set the language of the user interface.

Syntax:

```
--culture=<culture>
```

Example

Starting CODESYS with the user interface in English:

```
CODESYS.exe --culture=en
```

See also

- Chapter 1.3.1.25.3.13.12 “Dialog ‘Options’ – ‘International Settings’” on page 1083

Switch --profile (CODESYS profile)

In the command line, include this switch after the development system call in order to start CODESYS with a specific profile. When you start CODESYS without this switch, the “Select Profile” opens.

Syntax:

```
--profile="<profile name>"
```

Example

```
CODESYS.exe --culture=de --profile="CODESYS V3.6"
```

See also

- Chapter 1.3.1.2 “Your first CODESYS program” on page 108
Switch --compare (start project comparison)

In the command line, include this switch after the development system call in order to perform a comparison between two CODESYS projects. Type the path of the project file after the switch and then the path of the reference project. CODESYS starts and opens the “Project Comparison - Differences” view.

Syntax:

```
--compare="<path of project file>" "<path of reference project file>"
```

Example

```
CODESYS.exe --compare "D:\proj\project1.project" "D:\proj\project2.project"
```

See also

- "Chapter 1.3.1.25.2.4.18 “Command 'Compare'” on page 905"

Option --project (CODESYS project)

In the command line, include this option after the development system call in order to open the given project in CODESYS.

Syntax:

```
--project="<path of project file>"
```

Example

```
<path of project file>: File path of project
```

Open the test project:

```
CODESYS.exe --culture=de --project="D:\projects\test.project"
```

See also

- "Chapter 1.3.1.25.2.1.2 “Command ‘Open Project’” on page 853"

Option --projectarchive (CODESYS project archive)

In the command line, include this option after the development system call in order to extract the given project archive and open the project in CODESYS.

Syntax:

```
--projectarchive="<path of project archive file>"
```

Example

```
<path of project archive file>: File path of project archive
```

Extract the test.projectarchive and open the project in the development system:

```
CODESYS.exe --projectarchive="D:\projects\test.projectarchive"
```

See also

- "Chapter 1.3.1.25.2.1.9 “Command ‘Extract Archive’” on page 858"

Option --runscript (execute script)

In the command line, include this option after the development system call in order to execute a given script file from CODESYS.

Table 10: “Command Line Options for --runscript”

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--runscript=&quot;&lt;scriptfile&gt;.py&quot;</td>
<td>CODESYS executes the &lt;scriptfile&gt;.py script file at startup. You must provide the complete path of the script file.</td>
</tr>
<tr>
<td>--scriptargs:'&lt;arg1&gt; &lt;arg2&gt; ... &lt;argn&gt;'</td>
<td>Use this option with the --runscript option. As a result, the parameters &lt;arg1&gt; ... &lt;argn&gt; are passed to the script. The arguments are forwarded to the Python variable sys.argv.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>--noUI</strong></td>
<td>Use this option with the <strong>--runscript</strong> option. The CODESYS user interface is not opened. CODESYS prints all errors, warnings, compiler reports, and command-line messages generated from the script. The script messages (1: Severity Text) can be separated from other messages (2: Severity FatalError, Error, Warning, Information) with the &quot;-&gt;&quot; operator.</td>
</tr>
<tr>
<td><strong>--enableScriptTracing</strong></td>
<td>Use this option with the <strong>--runscript</strong> option. As a result, each command of the script file is shown in the output.</td>
</tr>
<tr>
<td><strong>--textPrompts</strong></td>
<td>Use this option with the <strong>--noUI</strong> option. As a result, message service methods and default dialogs are output in the command line for user input. If you do not specify <strong>--textPrompts</strong>, then all message service prompts are confirmed automatically with default values.</td>
</tr>
<tr>
<td><strong>scriptdebugger {=&quot;&lt;debugger&gt;&quot;}</strong></td>
<td>Use this option with the <strong>--runscript</strong> option. It sets IronPython in debug mode so that external debuggers can be used to debug Python scripts. The following values are defined for &lt;debugger&gt; (uppercase/lowercase is irrelevant).</td>
</tr>
<tr>
<td></td>
<td>* auto: Automatically detects if a debugger is included in every script for the current process. At this time, only .NET-based debuggers can be detected automatically. A detected debugger overwrites the <strong>--enableScriptTracing</strong> flag.</td>
</tr>
<tr>
<td></td>
<td>* .NET: Activates debugging for .NET-based debuggers, such as &quot;Python Tools for Visual Studio&quot; (PTVS) and SharpDevelop. With this option, a debugger can also be included in running scripts, as opposed to &quot;auto&quot;.</td>
</tr>
<tr>
<td></td>
<td>Note: This is currently the default value when <strong>scriptdebugger</strong> is used without providing a value.</td>
</tr>
<tr>
<td></td>
<td>* disabled: Deactivates debugging and automatic detection.</td>
</tr>
<tr>
<td></td>
<td>* script: Switches the IronPython script engine to debug mode for activating the debugging for set-trace debuggers. The script itself must connect to and disconnect from the debugger.</td>
</tr>
<tr>
<td></td>
<td>* tracing: Activates the simple integrated script tracing mode and deactivates the automatic detection (same as the <strong>--scriptTracing</strong> switch).</td>
</tr>
<tr>
<td></td>
<td>* $absolute_path.py$: Absolute path to a Python script that initiates the connection to a Python-based debugger. The IronPython script engine is switched to debug mode for allowing the debugging for set-trace debuggers. This script is executed one time during the initialization and should define the following non-parameterized functions:</td>
</tr>
<tr>
<td></td>
<td>* scriptdebuggersetup is executed immediately before executing the user script to establish the connection to the debugger.</td>
</tr>
<tr>
<td></td>
<td>* scriptdebuggershutdown is called immediately after executing the user script or when the script engine is downloaded and should close the connection to the debugger.</td>
</tr>
</tbody>
</table>
Examples of using transfer parameters in script files with 'sys.argv'  

```python
start /b /wait CODESYS.exe  
--runscript="D:\Script\ArgvAnd__main__Test.py"  
--scriptargs:'username password 3.14 "path="C:\temp\""
```

**Script file:** ArgvAnd__main__Test.py  
```python
from __future__ import print_function
import sys
print("sys.argv: ", len(sys.argv), " elements:")

for arg in sys.argv:
    print(" - ", arg)
print()
print("__name__: ", __name__)
```

**Output result:** std out:  
```
sys.argv: 6 elements:
 - D:\TestScripts\ArgvAnd__main__Test.py  
 - username  
 - password  
 - 3.14  
 - path= "C:temp"
__name__: __main__
```

For more information about the __name__ global variable, see the Python documentation.

**Examples of the message output**  
```
start /b /wait CODESYS.exe --runscript="D:\Script\AmpelTest.py" --noUI 1>ScriptMessages.txt
```

CODESYS forwards all messages that are generated by the script to the ScriptMessages.txt file. Other messages are printed to the command line.

```
start /b /wait CODESYS.exe --runscript="D:\Script\AmpelTest.py" --noUI 2>NUL
```

CODESYS suppresses all messages, except for script messages. The script messages are printed to the command line.
The following `initdebug.py` script was tested successfully with `pydevd`-based debuggers, such as PyDev / LiClipse and PyCharm. To use this script, start CODESYS with the following command line:

```
--profile="Fanta Development Build" --scriptdebugger="D:\test\charmdebug\initdebug.py"
```

**File:** `initdebug.py`

```python
from _future_ import print_function
from _future_ import unicode_literals
import sys
sys.path.append(r"D:\test\Env2\Lib\site-packages\pycharm-debug.egg")
import pydevd
def scriptdebuggersetup():
    pydevd.settrace('localhost', port=51234, stdoutToServer=True, stderrToServer=True)
def scriptdebuggershutdown():
    pydevd.stoptrace()
```

See also

- Chapter 1.3.1.22 “Using scripts” on page 388
- [http://docs.python.org/tutorial/modules.html](http://docs.python.org/tutorial/modules.html)

**Option -- ignorewhitespace**

In the command line, add this option to the development system call after the option `--compare <project1> <project2>` in order to ignore spaces in the project comparison. Note that semantically relevant spaces, for example in STRING literals, are still taken into account.

**Syntax**

```
--compare="<path of project file>" "<path of reference project file>"
--ignorewhitespace="true"|"false"
```

**Example**

```
CODESYS.exe --compare "D:\proj\project1.project" "D:\proj \project2.project" --ignorewhitespace="true"
```

See also

- Chapter 1.3.1.25.2.4.18 “Command ’Compare’” on page 905

**Option -- ignorecomments**

In the command line, add this option to the development system call after the option `--compare <project1> <project2>` in order to ignore comments in the project comparison.

**Syntax**

```
--compare="<path of project file>" "<path of reference project file>"
--ignorecomments="true"|"false"
```

**Example**

```
CODESYS.exe --compare "D:\proj\project1.project" "D:\proj \project2.project" --ignorecomments="true"
```

See also

- Chapter 1.3.1.25.2.4.18 “Command ’Compare’” on page 905

**Option -- ignoreproperties**

In the command line, add this option to the development system call to ignore object attributes (access privileges, compile settings, directories, bitmaps, etc.) in the project comparison.
**Syntax:**
--compare="<path of project file>" "<path of reference project file>"
--ignoreproperties="true"|"false"

**Example**
CODESYS.exe --compare "D:\proj\project1.project" "D:\proj\project2.project" --ignoreproperties="true"

See also
● ⇐ Chapter 1.3.1.25.2.4.18 “Command ‘Compare’” on page 905

**Option --skipunlicensedplugins (component license missing)**

In the command line, add this option to the development system call to skip the prompt whether unlicensed components should still be loaded. If so, then CODESYS does not load these components by implication.

**Example**
CODESYS.exe --skipunlicensedplugins

1.3.1.19 Using libraries

1.3.1.19.1 Information for library developers................................. 372
1.3.1.19.2 Adding a library to the application................................. 373
1.3.1.19.3 Adding a library to the repository................................. 373
1.3.1.19.4 Exporting library files............................................... 374

**Library repository**

The library repository is the storage location on the development system for libraries and associated metadata. You can link any installed the libraries into your project by means of a library manager. Moreover, the libraries are installed with version management for easy library updates.

You can create and edit more repositories in addition to the preinstalled System repository.

See also
● ⇐ Chapter 1.3.1.25.2.8.2 “Command ‘Library Repository’” on page 951

**Library manager**

The library manager manages the libraries that are linked into your project. It displays the libraries by the respective library types and properties. You can link more libraries from the library repository, remove them, or edit their properties.

The library manager can be inserted into the “POUs” view or the “Devices” view. In this way, a project can have one library manager per application and also one cross-application library manager in the “POUs” view. The library modules of the linked libraries in the “POUs” view can be called regardless of the application. The library modules of the linked libraries in the “Devices” view can be called in the respective application code only. Furthermore, placeholder libraries behave differently when downloading depending on their positions.

Libraries that are linked to a specific version in the project also have a placeholder for that version (placeholder library). You can define special placeholder resolutions. You can also use the placeholder resolution that is defined for a device in the device description or that is stored in the library repository for a library. The library manager notifies about the actual placeholder resolution and shows the version that is used when downloading an application (effective version).

If a library manager is linked cross-application in the “POUs” view, then you have global access to its contents. If placeholder libraries are linked, then only the placeholder resolutions in the device description or library repository are checked.
Normally, a library manager is linked in the "Devices" view. Then, only the application code below it calls the library modules. Moreover, the special placeholder resolutions are checked first for placeholder libraries. Only after that are the placeholder resolutions checked that are in the device description or that originate from the library repository.

See also

- Chapter 1.3.1.25.1.25 “Object 'Library Manager’” on page 771

1.3.1.19.1 Information for library developers

In order to avoid consistency problems and to adequately support the user, be sure to adhere to certain rules for the creation, referencing, encryption, protection, and documentation of libraries.

The following description provides only an overview of the library development possibilities. For a more detailed description of these topics, see the "LibDev-Summary" guidelines for library development.

General

- You can define categories for libraries. The libraries are then displayed in the library repository below these categories.
- You can define a namespace for a library in order to enable unambiguous access to the integrated objects. The access becomes unambiguous by adding the namespace in front of the module name:
  `<namespace>.<variable name>`
  Example: AC.Module
- You can open the POUs of unencrypted libraries (`*.library`) by double-clicking the respective entry in the Library Manager.
- You can create the following library types:
  - `*.library`: Implementation library (source code of the library)
  - `*.compiled-library, *.compiled-library-v3`: Protected library; source code no longer accessible.
  - `*.Itfs.library`: Interface library
  - `*.Cnt.library`: Container library
- You can integrate external libraries into the application. External libraries are programmed outside of CODESYS in a different programming language, for example C.

Protection of libraries

- Source code protection:
  When a library is prepared in "compiled-library" format, the source code of the library modules is no longer visible after the library is integrated into a project.
- Signing:
  In CODESYS V3 SP15 and later, a certificate is always used for the signing of library projects (`*.compiled-library-v3`). The signing can be enforced by means of a setting in the security screen. Then for generating a compiled library, you need a certificate suitable for code signing in your user profile.
  For library projects that have to be compatible with CODESYS < V3 SP15 (`*.compiled-library`), only the less safe signing is possible with a private key and a corresponding token. These deprecated methods should only be used for reasons of compatibility. Settings are configured in the “Project Information” on the “Signing” tab.
- Licensing:
  You can protect libraries by means of a license (dongle or soft container). License-protected libraries can be installed in the library repository. However, for use in the project, the valid license has to exist on the computer. Licenses are managed in the License Manager.
Library versions

- You can have several versions of a library installed on the system at the same time.
- You can have several versions of a library integrated into your project at the same time. However, we do not recommend doing this. In this case, each of the libraries must be assigned a unique namespace and access to the symbols must be qualified. Examples: V1.SendBlob, V2.SendBlob

Referenced libraries

- You can integrate a library into other libraries (referenced libraries). The nesting can be of any depth.
- You can define whether referenced libraries should be visible in the Library Manager.
- You can integrate referenced libraries via library placeholders. This way you avoid the problems that could occur due to version dependencies or the necessity to use vendor-specific libraries.

See also

- Chapter 1.3.1.3.6.1 “Retrieving and editing project information” on page 132

1.3.1.19.2 Adding a library to the application

The following instructions describe how to integrate the Util library into your application.

1. Select the library manager and open it in the editor with the command “Project ➔ Edit Object”.
   - The library manager opens in the editor.
2. Execute the command “Library ➔ Add Library”.
   - The “Add Library” dialog box opens.
3. Browse for the library by entering the string 'util' in the input field above.
   - The Util library appears in the library view.
4. Select the Util library and close the dialog box with “OK”.
   - The Util library is added in the library manager.

See also

- Chapter 1.3.1.25.2.14.1 “Command ‘Add Library’” on page 1004
- Chapter 1.3.1.19.3 “Adding a library to the repository” on page 373

1.3.1.19.3 Adding a library to the repository

The following instructions describe how to install a library in the library repository.

1. Select the command “Tools ➔ Library Repository”.
   - The dialog box “Library Repository” opens.
2. Click on the “Install” button.
3. Select the library that you wish to install. You can set a file filter here.
   - The library is added to the repository. The library can now be added in the Library Manager.
1.3.1.19.4 Exporting library files

You can export a library from the library manager of a project or from the library repository and then save it as a file to the hard disk.

**Export from the library manager**

1. Open a library manager of an application in a project.
2. Select a library in the library manager.
3. Click the export command in the context menu.
   - The “Export Library” dialog box opens.
4. If the selected library is linked in the project not only as a compiled library, but also in source format, then both file types are in the drop-down list for “File type”. Otherwise, the filter automatically shows the available type: “*.library” or “*.compiled-library”.
5. Select the file type and storage location and click “Save”.

**Export from the library manager**

1. Open the CODESYS library repository (“Tools” menu).
2. Select a library version in the window of the installed libraries.
3. Click the “Export” button.
   - The “Export Library” dialog box opens.
4. As step 4 and 5 for “Export from the library manager”.

See also

- Chapter 1.3.1.19.2 “Adding a library to the application” on page 373

1.3.1.20 Managing devices

CODESYS manages the installed devices in the device repository. A device repository is a defined location in the file system. In the default CODESYS installation, it is defined with an absolute path as the system repository. You install or uninstall devices in the “Device Repository” dialog. The system installs a device by reading the device description file. The properties of a device are defined in these files regarding configurability, programmability, and possible connections to other devices.

You can use the devices provided in the device repository by adding them to the device tree of your project.

See also

- Chapter 1.3.1.25.2.8.5 “Command ‘Device Repository’” on page 957
- Chapter 1.3.1.20.1 “Installing devices” on page 374

1.3.1.20.1 Installing devices

Install a device in the device repository in order to include it in your project.

1. Click “Tools ➔ Device Repository”.
   - The “Device Repository” dialog box opens.
2. Select the install location. “System Repository” is set by default.
3. Click "Install".
   ⇒ The "Install Device Description" dialog box opens.
4. Select the file path of the device description.
5. Select the file type filter of the required device description.
   ⇒ All device descriptions of the selected file type are listed.
6. Select the required device description and click "Open".
   ⇒ CODESYS adds the device description to the matching category of your device repository.
   
   If errors occur during installation (for example, missing files that are referenced by the device description), then CODESYS displays them in the lower part of the device repository dialog box.

See also

● Chapter 1.3.1.25.2.8.5 “Command 'Device Repository'” on page 957

1.3.1.21 Managing packages and licenses

License manager
In addition to the standard installation of CODESYS, add-ons are available, which are subject to fees and licensing. You receive licenses for these products from 3S-Smart Software Solutions GmbH in the form of ticket numbers, which you can install using the CODESYS License Manager.

The license manager stores the licensing information on an external USB dongle (CODESYS Dongle) that you must connect to your local PC.

In the license repository you can retrieve the current information for each ticket number from the central license server. Other information is also provided, such as whether a license can still be activated or must be returned.

License check when starting CODESYS
When it starts, CODESYS checks the selected profile for plug-ins that are subject to licensing.

● If the profile does not include plug-ins subject to licensing, then CODESYS starts as usual without a message.
● If the profile includes plug-ins subject to licensing and a dongle with the required licenses is connected to the USB port of the computer, then CODESYS starts without any message.
● If the profile includes plug-ins subject to licensing but no dongle is available or a required license cannot be found, then, CODESYS displays the "License Missing" dialog at start-up.
   
   Note: When starting from the command line, this dialog is skipped if you specify the --skipunlicensedplugins option in the command. In this case plug-ins without the required license are automatically not loaded.

License check while program is running
While CODESYS is running, the required licenses are checked every five minutes. If a license is missing, for example because the dongle was removed in the meantime, then the "License missing" dialog opens with the following options:

● Insert the dongle again and press "Retry": If the dongle contains the missing licenses, then you can continue working as usual.
● "Save Current Project and Exit": CODESYS saves the project and closes.
● "Close": CODESYS closes without saving the project.
If you remove the license dongle after the CODESYS plug-in has been loaded, then an error message is displayed.

To solve this problem, insert the dongle again and press the Retry button. If the dongle contains a valid license, the dialog box closes and you can continue working as usual. Clicking “Cancel” will exit CODESYS.

See also

- Chapter 1.3.1.25.2.8.3 “Command ’License Manager’” on page 953
- Chapter 1.3.1.25.2.8.4 “Command ’License Repository’” on page 956

**License manager**

With the license manager in CODESYS you can manage the licenses for add-on products on a CODESYS dongle or in a soft container. A soft container is the software counterpart to a dongle. It allows hardware licenses to be bound to a single PC even without a dongle.

During the licensing a distinction is made as a matter of principle between CODESYS licenses and licenses for individual devices.

- The licensing of CODESYS products is done by the license manager.
- The licensing of end devices is done via the PLC settings. The licensing process takes place in a similar way to the licensing of CODESYS licenses.

See also

- Chapter 1.3.1.25.2.8.3 “Command ’License Manager’” on page 953

**Package manager**

CODESYS provides the Package Manager whose functionality extends the standard installation of CODESYS with additional features and configuration settings. The concept behind the Package Manager is similar to that of a typical Windows installation mechanism.

A package is a ZIP file with the "*.package" file extension.

Possible package components

- Plug-ins
- Libraries
- Device descriptions
- Supplier descriptions
- Profiles
- Information profiles
- Profile changes
- Files
- Extensions for configuration of the menu, toolbar, keyboard shortcuts, and views
- Help modules
- Complete menu configurations for special profiles
- Complete toolbar configurations for special profiles
- Complete keyboard configurations for special profiles
- Options
- Library profiles

You can compare the “Checksum” with the package checksum from the package vendor. CODESYS shows this checksum in the “Details” dialog of the Package Manager and in the “Installation - License Agreement” dialog of the installation assistant. You do this to make sure that you have installed an original package.
In V3.5 SP13 and later, CODESYS checks whether an older version is already installed when installing the development system. If this is the case, then when you start the development system for the first time, you will see the “Import Assistant” dialog for importing the package installations available in the older version.

See also
- Chapter 1.3.1.25.2.8.1 “Command ‘Package Manager’ ” on page 949
- Chapter 1.3.1.21.1 “Installing/Uninstalling a package” on page 377
- Chapter 1.3.1.25.3.1 “Dialog ‘Import Assistant’” on page 1039

### 1.3.1.21.1 Installing/Uninstalling a package

Requirement: You have selected the command “Tools → Package Manager” and the dialog box “Package Manager” is open.

**Installing a package**
1. Click on “Install”
2. In the dialog box “Open”, select a package from the file directory and click on “Open”.
   - The setup wizard opens and guides you through the installation of the package.
   - CODESYS also displays the “checksum” of the package in the dialog box “Installation - License Agreement”.

**Uninstalling a package**
1. Select the package
2. Click on “Uninstall”
   - The wizard opens and guides you through the procedure to uninstall the package.

See also
- Chapter 1.3.1.25.2.8.1 “Command ‘Package Manager’ ” on page 949

### 1.3.1.21.2 Licensing of products

Many CODESYS products are license-protected, so you have to activate a product before you start it. An add-on product that extends the capabilities of the CODESYS Development System is usually activated with a workstation license. Licensing is performed by means of the CODESYS Development System Security Key (dongle), which manages all licenses for your workstation. As an alternative, some products will soon support licensing on a soft container.

In addition, there are the SL products that extend the scope of CODESYS Control SoftPLC systems. These systems are activated with a single device license. An activation code, which is provided as a license activation file, is installed directly on the target. License management on a device is also done by means of a soft container (if supported) in the device, or a dongle connected to the device.

In CODESYS V3.5 SP13 and later, licenses of add-on products on the local computer, as well as single-device licenses, can be managed uniformly in the CODESYS License Manager. For devices with a unique serial number, the License Manager can reactivate the license from an automatically stored license backup file if the license information on the device is lost.

---

If possible, license your products via online activation instead of offline activation.
Online activation

Activation is possible in CODESYS Development System in the “License Manager” dialog. The requirement for this is that your development system has Internet access. The target system itself does not require Internet access.

You can also activate a license on the “License Central” website.

Offline activation

If your workstation computer does not have Internet access, then you can activate products using a license activation file. You get the file from the CODESYS license server. To do this, connect to the server from any computer with Internet access and request the file. Then you transfer the file on any storage medium to your working computer. The product is activated there as usual in CODESYS Development System, both for workstation licenses as well as for single device licenses.

If you have a computer with Internet access where CODESYS Development System is not installed, you can also open the “CodeMeter Control Center” by Wibu Systems to activate the license.

Moreover, for target systems that are based on CODESYS Control Win V3 or CODESYS Control RTE V3, you can activate a single device license directly on a target. This can be useful if you do not have a development system with CODESYS Development System. Then you can do the licensing from the “CodeMeter Control Center”, or you can activate the license from a browser. CodeMeter is installed on Windows-based target systems.

The “CodeMeter Control Center” manages the CodeMeter service and is included with the CODESYS setup.

Online activation of an add-on license on the local computer

The following instructions describe how to perform licensing by means of a dongle. Licensing by means of a soft container is done in the same way.

Requirement: You have Internet access and the CODESYS Development System is installed on the computer where you want to install the license. A dongle is connected to your computer.

1. Click “Tools ➔ License Manager”.
   - The wizard starts with the “License Manager - Select Target” dialog.
2. Select “Workstation” as the target. Click “Next >”. In the “License Manager - Select Container” dialog, select the “Dongle” option. Click “Next >”.
   - The “License Manager” dialog opens and shows the product to be licensed in the “Products” window as not licensed.
3. Select the product and click the “Install Licenses” button on the bottom left.
   - The “Install Licenses on Workstation Dongle <dongle ID> - Select Operation” wizard opens.
4. Select the “Activate License” operation and click “Next >”.
   - The “Install Licenses on Workstation Dongle <dongle ID> - Activate License” dialog opens.
5. Specify the “Ticket ID” that you received from the software manufacturer. The ID consists of 5 blocks, each containing 5 alphanumeric characters.
   - Select the “License server” that provides the license for activating the product. You get the server URL from the software vendor.
6. Click “Next >”.
   - The connection to the license server (http://license.codesys.com) is established.
     - If the specified ticket contains only one license, then a dialog opens to confirm the activation after successful completion of the server action.
     - If the specified ticket contains multiple licenses, then the dialog “Install Licenses - Select Licenses” opens with a list of the licenses managed in the ticket.
7. Select the licenses that should be activated and click “Next >”.
   ⇒ After successful completion of the server action, a dialog opens with the confirmation of the activation.

Alternative

1. Open a browser and select the License Central Internet page.
   ⇒ The “License Manager” dialog opens.
2. Enter your license number.
3. Click “Search”.
4. Click “Next >”
   ⇒ The connection to the license server (http://license.codesys.com) is established.

**Offline activation of an add-on license on the local computer**

Requirement: You want to install the license for an add-on package. The CODESYS Development System is installed on the computer where you want to install the license. The computer does not have Internet access.

For this method, first you create a license request file on the target computer in the CODESYS. Then you copy this file to a computer with Internet access. The “CodeMeter Control Center” must be installed on this computer. You use the CODESYS license server to generate a license activation file for activation on the target computer.

The following instructions describe how to perform licensing by means of a dongle. Licensing by means of a soft container is done in the same way.

1. Click “Tools ➔ License Manager”.
   ⇒ The “License Manager” wizard starts.
2. Select “Workstation” as the target. Click “Next >” and select “Dongle” as the container. Click “Next” again.
   ⇒ The dialog opens for selecting a product and container.
3. Select the dongle where you want to install the license. Example: “Local:CmStick [2-2404696]”.
4. Click “Install Licenses”.
   ⇒ The “Install Licenses on Workstation Dongle <dongle ID> - Select Operation” wizard opens.
5. Select the option “Request License” and click “Next >”.
   ⇒ The “Install Licenses on <computer> - Request License” wizard opens.
6. In the “Software vendor” input field, specify the firmcode from the software vendor that provided the license for activating the product. You can also select the name of the software vendor from the drop-down list.
7. Specify the location and filename of the “Context file”, for example CmStick [2-2404696].WibuCmRaC.
8. Click “Finish”.
   ⇒ The context file (*.WibuCmRaC) is created.
9. Copy this license request file to a computer with Internet access.
10. On this computer, open the CODESYS license server in a browser (http://license.codesys.com).

   ➞ CODESYS License Server:

11. Enter the number of the license ticket and click “Next”.

12. In the subsequent dialog, click “Activate Licenses”.

13. In the next dialog, select the binding for the license. Click the graphic with the CODESYS Runtime Key (dongle).

   ➞ The following dialog opens:
14. In the dialog, select the license container, for example “2-2404696”. Select “Offline license transfer”.
   ⇒ The following dialog opens:

   ![Select license request file (.WibuCmRaC)](image)

15. Select the license request file that you created on the other computer, and click “Upload Request and Continue Now”.
   ⇒ The following dialog opens:

   ![Download License Update File](image)

16. Load the license update file to your computer. Select “Download License Update File Now”.

17. Copy the license update file to the target computer.

18. In the “License Manager” dialog, click the “Install Licenses” button and select the “Install License” option.
   ⇒ The “Install Licenses on Workstation Dongle <dongle ID> - Install License” dialog opens.

19. Enter the path of the license update file in the input field (example: D:\Lic\CmStick [2-2404696].WibuCmRaU).

20. Click “Finish”.
   ⇒ The license update file is installed on the selected dongle.

---

**Offline activation of a windows-based runtime system**

You want to install the license for a runtime system that is based on Windows.

For this method, first you create a license request file on the target computer in the “CodeMeter Control Center”. Then you copy this file to a computer with Internet access. The “CodeMeter Control Center” must be installed on this computer. You use the CODESYS license server to generate a license activation file which you activate on the target computer.
Initial situation: The CODESYS Development System is not installed on the computer where you want to install the license. The computer does not have Internet access.

1. Open the “CodeMeter Control Center”. Double-click in the toolbar.
2. Select the license memory “3S-Smart Software Solutions Softlicenses” in the license overview.
3. Click the “Activate License” button.
   ⇒ The “CmFAS” wizard opens.
4. Click “Next”.
   ⇒ A list of possible actions is displayed.
5. Select “Generate License Request” and click “Next”.
6. Specify a name for the license request file and save it by clicking “Apply”. Close the dialog.
   ⇒ The license request file is generated (example: 32767-4241603201.WibuCmRaC).
7. Copy this license request file to a computer with Internet access.
8. On this computer, open the CODESYS license server in a browser.

   → CODESYS License Server:

![CODESYS License Server](image)

9. Enter the number of the license ticket and click “Next”.
10. In the subsequent dialog, click “Activate Licenses”.
11. In the next dialog, select the binding for the license. Click the graphic with the CODESYS Software Key (soft container).

   → The following dialog opens:

![Select license container](image)
12. In the dialog, select the license container, for example “32767-4241603201 (3S-Smart Software Solutions Soft Licenses). Click “Offline license transfer”.

⇒ The following dialog opens:

```
Select license request file (*.WibuCmRaC)
Durchsuchen... CmStick [2-2404696].WibuCmRaC

Upload request and continue now
```

13. Select the license request file that you created on the other computer, and click “Upload Request and Continue Now”.

⇒ The following dialog opens:

```
Download License Update File

Upload request ✓ Download update Upload receipt

To transfer your licenses offline - Second step "Download Update”:
1. Click "Download license update file now" and save the file on your computer.
2. Import this license update file to the license container with Serial 128-9754372. This file can be imported with the CODESYS. How it works ➔
3. After you have successfully transferred the license update file to the license container, click “Next” to confirm the license transfer.

Download license update file now Next ➔
```

14. Load the license update file to your computer. Click “Download License Update File Now”.

⇒ The dialog opens for saving the file.

15. Save the license update file and copy it to the target computer.

16. Open the “CodeMeter Control Center”.

17. Select the license memory “3S-Smart Software Solutions Softlicenses” in the license overview.

18. Click the “Activate License” button.

⇒ The “CmFAS” wizard opens.

19. Click “Next”.

⇒ A list of possible actions is displayed.

20. Select “Save License Update” and click “Next”.

21. Select the license update file, for example 128-9754375.WibuCmRaU, and click “Apply”.

⇒ The license update file is installed on the selected dongle.
You want to install a single license for a Linux-based runtime system.

☑️ Requirements: Your development system with CODESYS Development System does not have Internet access, but it is connected to the device.

1. Open CODESYS.
2. Create a standard project.
3. Update the device.
4. In CODESYS, click “Tools ➔ License Manager”.
   ⇒ The wizard starts with the “License Manager - Select Target” dialog.
5. Select “Device” as the target. Click “Next >”. In the “License Manager - Select Container” dialog, select the “Softcontainer” option or “Dongle”. Click “Next >”.
   ⇒ The “License Manager” dialog opens. The product to be licensed is displayed in the “Products” view.
6. Click the “Install Licenses” button. In the “Install Licenses on <device> - Select Operation” dialog, select the “Request License” option. Click “Next >”.
   ⇒ The “Install Licenses on <device> - Request License” dialog opens.
7. In the “Software vendor” input field, specify the firmcode from the software vendor that provided the license for activating the product. You can also select the name of the software vendor from the drop-down list.
8. Specify the location and filename of the “Context file”, for example CmStick [2-2404696].WibuCmRaC.
9. Click “Finish”.
   ⇒ The context file (*.WibuCmRaC) is created.
10. Generate the update file (*.WibuCmRaU) in the browser.
11. Copy this license request file to a computer with Internet access. The “CodeMeter Control Center” must be installed on this computer.
12. On this computer, open the CODESYS license server in a browser (http://license.codesys.com).

   CODESYS License Server:

13. Enter the number of the license ticket and click “Next”.
14. In the subsequent dialog, click “Activate Licenses”.
15. In the next dialog, select the binding for the license. Click the graphic with the CODESYS Runtime Key (dongle).

   The following dialog opens:
16. In the next dialog, select the license container, for example “2-2404696”. Click “Offline license transfer”.
   ➤ The following dialog opens:

![Select license request file (.WibuCmRaC)](image)

17. Select the license request file that you created on the other computer, and click “Upload Request and Continue Now”.
   ➤ The following dialog opens:

![Download License Update File](image)

18. Load the license update file to your computer. Click “Download License Update File Now”.
19. Copy the license update file to the target computer.
20. In the “License Manager” dialog, click the “Install Licenses” button.
   ➤ The “Install Licenses on <device> - Select Operation” wizard opens.
21. Select the “Activate License” option, click “Next >”, and specify the ticket number.
22. Click “Next” to transfer the license to the software key (soft container).
   ➤ The license is active.

**Restoring a license**

In CODESYS V3.5 SP13 and later, a license backup file (*.WibuCmRaC) is created automatically when activating workstation licenses for devices with a unique serial number. The file is stored on your computer and on the license server. In case the license files on the device get lost, you can use the License Manager to restore the license from this file.
You have activated a device license.

1. In CODESYS, click “Tools ➔ License Manager”. Follow the wizard with the corresponding entries for the target: Device and container (soft container or dongle), as well as the selection of the corresponding device.

2. In the “License Manager” dialog, click the “Additional Functions” button and select the “Restore License” command.

   The “Restore Licenses” dialog opens.

3. Enter the “Ticket ID” for the device license and click “Restore”.

   CODESYS searches for the saved license backup file, first on the local computer and then on the License Central server. If the file matching the device is found, then the license is restored and activated.

Requirements:

- The CODESYS Development System (V3.5 SP15 or later) is open.
- The gateway and the controller whose information should be read are running.
- No applications exist on the controller.

1. Click “Tools ➔ Device Reader”.

   The “Select Device” dialog opens.

2. Double-click the desired gateway to scan the network.

   If no gateways are displayed, then click “New Gateway” and select the desired gateway in the “Gateway” dialog.

3. Select a controller.

4. Click “OK” to confirm the selection.

   Note: If an application exists on the controller, then a dialog opens to prompt whether or not all applications should be removed from the controller. When you click “No” to this dialog, the license information of the controller cannot be read. The “Device Reader” command is aborted.

   CODESYS creates the list with the license information for the products and device features of the selected controller and displays the information in the “Device Reader” dialog.

1.3.1.22  Using scripts

With the scripting feature in CODESYS, you can automate commands or complex program operations that you would otherwise have to do manually with mouse clicks and text input in the CODESYS user interface. You can start these scripts from the CODESYS user interface (command or configured toolbar) or from the Windows command line.
Examples of use cases

- Integration of CODESYS in automatic build server environments:
  - Continuous Integration (CI)
  - Continuous Delivery (CD)
  - Continuous Testing
- Integration with third-party software, for example:
  - Code generators
  - Creation of projects that are custom tailored to a specific machine configuration
- Creation of documentation
- Updating of libraries:
  - Setting of project information during the release process
- Automatic testing:
  - Mostly in connection with the CODESYS Test Manager
- Outputting variables via monitoring APIs

Scripting language

The CODESYS scripting language is modular and based on IronPython. For this purpose, the CODESYS "ScriptEngine" component combines the IronPython interpreter with the CODESYS development environment. Then you can use the extensive Python framework libraries, which includes file access in networks and much more.

CODESYS does not yet include its own Python editor. Create your scripts with any text editor or the Python editor.

See also
- Chapter 1.3.1.22.2 “Creating a python script” on page 396

Architecture of the ScriptEngine, extension possibilities

The (Iron)Python scripting language used in CODESYS allows for access to the CODESYS scripting APIs for controlling CODESYS operations. Moreover, it lets users effectively apply both the Python standard library and third-party Python modules, as well as third-party .NET framework libraries and .NET assemblies.

Users can execute the scripts from menu commands or configured toolbars in the CODESYS interface or from the Windows command line. Add-ons such as the CODESYS Test Manager also provide ways to execute scripts.
There is not an integrated Python editor in CODESYS. Use your favorite text editor or the Python development environment.

With the Automation Platform APIs, the ScriptEngine APIs can be extended. Examples for this are CODESYS Test Manager and CODESYS SVN. Both provide their own objects and methods as an extension to the scripting APIs. In addition, the CODESYS Test Manager allows for the execution of scripts in a test case. For more information, refer to the respective API documentation of the add-on. Registered Automation Platform users will find more information in the CODESYS Developer Network.

See also
- Chapter 1.3.1.25.2.8.6 “Command ‘Scripting’ - ‘Execute Script File’” on page 958
- Chapter 1.3.1.22 “Using scripts” on page 388
- API Reference Documentation for the ScriptEngine:

1.3.1.22.1 Executing a script

1.3.1.22.1.1 Calling scripts from menu commands ........................................ 390
1.3.1.22.1.2 Starting scripts from the command line ........................................... 391
1.3.1.22.1.3 Calling scripts from toolbar icons...................................................... 392

You can execute Python script files (<filename>.py), which contain a sequence of commands for activating CODESYS functionalities, in the following way:
- From the CODESYS user interface by means of commands in the menu “Tools ➔ Scripting”
- From the CODESYS user interface by means of a customized, configured toolbar
- From the Windows command-line

Calling scripts from menu commands

Requirement: A valid Python script file <filename>.py is located in the file system. The CODESYS user interface is open.
1. (Optional) To monitor the processing of individual commands used in the script, click “Tools "Scripting" "Activate Script Tracing".

2. In CODESYS, click “Tools "Scripting" "Execute Script".
   
   ⇒ The statements in the script are executed and, if script tracing is activated, listed in the message view.

● Chapter 1.3.1.22 “Using scripts” on page 388

---

**Starting scripts from the command line**

In automated environments such as CI (Continuous Integration) servers or if scripts in CODESYS have to be controlled by other programs, menu commands are not appropriate for executing scripts. For these kinds of requirements, you can use the Windows command line to start CODESYS and execute scripts.

**Requirement:** A valid Python script file `<filename>.py` is located in the file system.

1. Create a CMD file that starts with `start CODESYS` and executes the script file with the option `--runscript`. Other options are possible, such as `--noUI` if the CODESYS user interface should not be opened.

2. Open the Windows “Command prompt” and execute the CMD file.

You can pass arguments with additional information to the script. Python scripts can access arguments with the `sys.argv[]` list. The first element (Index 0) is always the name or path of the Python script that is executed, followed by the actual parameters. (This is similar to `argc/ argv` in C.) In addition, scripts can also access environment variables that are set before CODESYS is started with the corresponding Python or .NET APIs.

**Example**

A CMD batch file `argvtestbat.cmd` has the following contents (all in one line):

```
"C:\Program Files (x86)\3S CODESYS V3.5 SP10\CODESYS\Common \CODESYS.exe" --profile="CODESYS V3.5 SP10" -- runscript="D:\Documents\Scripting\ArgvTestScript.py" -- scriptargs: 'username password 3.14 "path="C:\temp\""' --noUI
```

A matching script file `ArgvTestScript.py`: 
from __future__ import print_function

import sys

print("sys.argv: ",
         len(sys.argv),
         " elements:")

for arg in sys.argv:
    print(" - ", arg)

Now when you execute the CMD file, CODESYS starts and executes the script without opening the CODESYS main window. Then CODESYS is exited:

```
C:\Users\user>\G:\Program Files (x86)\CODESYS\CODESYS.exe --runscript=D:\\Misc\trunk\ScriptEngine\ArgTestScript.py --scriptargs:username password 3.14
```

For a complete reference of all possible command line parameters, refer to the help page for the command-line interface in CODESYS in the section for "--runscript".

- Information about .NET API
- Chapter 1.3.1.18 “Using the command-line interface” on page 366

### Calling scripts from toolbar icons

You can provide your own toolbar in the CODESYS user interface with up to 32 icons for calling script files. For this you need an ICO file where the icon is stored, and a PY file where the Python script to be called is stored.

You create the configuration file `config.json` in the installation directory or in the program data directory (CODESYS\Script Commands). Specify the call information outline for each icon in the file. Here you can configure a maximum of 16 icons. You can also store the ICO and PY files in the same directory.

Storage locations
- `<CODESYS installation directory>\CODESYS\Script Commands`
- `%PROGRAMDATA%\CODESYS\Script Commands`

**Example**

**Default installation on Windows 7**

C:\Program Files (x86)\CODESYS 3.5.14.0\CODESYS\Script Commands\  
C:\ProgramData\CODESYS\Script Commands\  

If you store a `config.json` file with different call information at each of the storage locations, then you can configure up to 32 different icons.
Table 11: Call information

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Name    | Required; displayed as icon tooltip  
Example: "Name": "Pause"  |
| Desc    | Optional; comment for icon  
Example: "Desc": "Operation pause"  
Note: Not yet displayed in the user interface |
| Icon    | Required; file path <directory path>\<icon name>.ico of the icon  
Example: "Icon": "pause.ico"  
Hint: If the file is in the same folder as the config.json file, then the file name is enough. |
| Path    | Required; path of the Python script <directory path>\<script name>.ico  
Example: "Path": "stop.py"  
Hint: If the file is in the same folder as the config.json file, then the file name is enough. |
| Params  | Optional; only if the script requires parameters  
Example: "Params": [ "file1", "file2" ] |
Example

File config.json

```json
[
  {
    "Name": "Start",
    "Desc": "Starts processing",
    "Icon": "start.ico",
    "Path": "goon.py",
    "Params": [
      "--continue"
    ]
  },
  {
    "Name": "Pause",
    "Desc": "Pause operation",
    "Icon": "pause.ico",
    "Path": "stop.py",
    "Params": [
      "delay:-1"
    ]
  },
  {
    "Name": "Processing",
    "Desc": "Process again",
    "Icon": "VarStatSmall.ico",
    "Path": "process.py",
    "Params": [
      "exit"
    ]
  }
]
```

The following files are located in the Script Commands:

- config.json
- goon.py
- stop.py
- process.py
- start.ico
- pause.ico
- VarStatSmall.ico

Creating script calls for a toolbar button

1. Create the Script Commands folder in one of the storage locations.
   ➔ C:\ProgramData\CODESYS\Script Commands

2. Create executable Python files there.
   ➔ Example:

   File `copy.py`
   ```python```
   print("The script COPY.PY is executed")
   ```

   File `delete.py`
   ```python```
   print("The script DELETE.PY is executed")
   ```

3. Create the ICO files for the scripts.
   ➔ Example: Copy_before.ico, Copy_below.ico, CopyAll.ico
4. Create a configuration file `config.json` there.
   ⇒ The folder `C:\ProgramData\CODESYS\Script Commands` has the following contents:

   ![Image showing configuration file contents]

5. Open `config.json` and add the outlined call information.
   ⇒
   ```json
   [
   {
     "Name": "Copy Before",
     "Desc": "Copy something",
     "Icon": "Copy_before.ico",
     "Path": "copy.py",
     "Params": [
       "before"
     ]
   },
   {
     "Name": "Copy Below",
     "Desc": "Copy something",
     "Icon": "Copy_below.ico",
     "Path": "copy.py"
   },
   {
     "Name": "Copy All",
     "Desc": "Copy something",
     "Icon": "CopyAll.ico",
     "Path": "copy.py",
     "Params": [
       "all"
     ]
   },
   {
     "Name": "Delete",
     "Desc": "Delete something",
     "Icon": "Delete.ico",
     "Path": "delete.py"
   }
   ]
   ```

6. Start CODESYS.
   ⇒ The script files, configuration file, and symbol files are read and provided in the “Tools ➔ Customize” dialog in the “Command Icons” tab, “ScriptEngine Commands” category.

7. Click “Tools ➔ Customize” and then click the “Toolbars” tab.
8. Select the empty toolbar there and click the “Add toolbar” button.
   ⇒ A line editor opens at the empty toolbar.

9. Type in a name (example: User defined toolbar).
   ⇒ The custom toolbar is displayed in the CODESYS window.

10. Add the recently imported commands and close the dialog.

11. Click one of the icons.
   ⇒ The following output is displayed in the message view.

| 1.3.1.22.2.7 | Comparison of IronPython and cPython.................................. 420 |

Python is a dynamic language. You can start in a simple linear programming style (batch files) and later add the necessary and more powerful means, such as conditions, loops, functions, exceptions, classes, and modules. The focus of the language is on easy and expressive code. Python is more typical in runtime mode and uses an automatic garbage collector to protect the programmer from accidental damage to the entire system.

IronPython is an implementation of Python for .NET and allows for full access to the .NET framework and classes. The implementation of the IronPython interpreter is based on Python Version 2.7.

There are a variety of free manuals and help pages on the internet. See the following links for an introduction and detailed introduction about IronPython.
  – Especially CODESYS-specific questions.
  – Also includes some examples.

### Version incompatibility to python V3.x

The Python programming language will soon be available in the new version V3.x. Some of the older program modules have been removed. 3S-Smart Software Solutions GmbH is planning an update to this new version. Scripting developers should take this into consideration and design their scripts accordingly, for example by using the expression:

```python
from __future__ import print_function
```

You can find more information about this topic at

### Getting started with python for CODESYS

See below for a simple application of a Python script in CODESYS:

1. In any text editor, create a text file `hello.py` with the following contents:
   ```python
   print("Hello, automation!")
   ```
2. Start CODESYS and click "Tools ➔ Scripting ➔ Execute Script File". Select the file `hello.py` in the file system.
   ➔ See the result in the message view:

   ![Message view with output "Hello, automation!"](image)

   For more detailed examples of Python scripts for different use cases with CODESYS, refer to the following help pages:

   See also

   - ![Chapter 1.3.1.22.2.3 “Basic syntax of python (with examples)” on page 398](image)
   - ![Chapter 1.3.1.22.2.4 “Python control structures (with examples)” on page 406](image)
The current prerelease of the script interface documentation has been generated automatically from the underlying .NET and C# sources. Therefore, the documentation includes some expressions that are not familiar to Python programmers. The following overview provides some tips about how these expressions can be understood from the Python perspective.

- An interface is the contract that tells an instance of a class that implements the interface which members (methods, properties) it has to prepare. In IronPython, you can implement one or more .NET interfaces in one class by inheriting from a superclass. If a method is needed for the interface but is not available in the class definition, then an exception is thrown. (The DeviceImportFromSvn.py example shows a class that implements the ImportReporter interface.)

- Each parameter and each method in .NET is typed strictly. The type of parameter is separated by one space character before the parameter name, and the type of return value from a method by one space character before the method name. You can use instances from subclasses when you define a class (or interface). A method without a return value is marked void.

- You can overload methods, as multiple methods of the name can exist in one class. However, the number or the types of parameters must be different. IronPython automatically takes care of the most appropriate method overloading being called.

- The data type `int` corresponds to an integer from -2,147,483,648 to 2,147,483,647. The data type `bool` corresponds to the Python type `True` and `False`. The data type `string` corresponds to the Python types `str` or `unicode`, which are identical in IronPython. The `IDictionary<Object, Object>` data type corresponds to an ordinary Python dictionary. IronPython automatically converts between Python and .NET data types.

- When a `T` type is inherited from `IBaseObject<T>`, it means that this type can be extended by other plug-ins for additional members. The actual use of this extended type as a parameter or return value is marked by `IExtendedObject<T>`. The `IEnumerable<T>` interface to a `T` type means that you can use every Python sequence (generators, lists, tuples, …) that returns `T` type values (or a subclass). Returns the sequence of incompatible objects, and throws an exception at runtime.

- The `IList<T>` interface to a `T` type identifies a typified list that guarantees to include only elements of type `T` (or a subclass). An exception is thrown at runtime when any attempt is made to add an incompatible object.

- The `params T[] name` id for a parameter of type `T` corresponds to the Python mechanism `*name` for variable argument lists.

- In Python, enumerations (enum) do not exist as language constructs. Its purpose is to define an exact number of constant values for a specific purpose, for example the days of the week. Access to .NET enumerations from IronPython works by using "Name.Member", for example via `OnlineChangeOption.Try`. (There are many ways of emulating enums in Python. For examples, see `http://pypi.python.org/pypi/enum` or `http://www.ironpython.info/index.php/Enumerations`.)

- The syntax `T name { get; set; }` defines a property with `name` as the name and `T` as the type. If `set;` is missing, then the property is read-only. In Python, the respective construct is `@property` decorator.

- `Information about .NET API`
- Chapter 1.3.1.22.2.5 “Using scripts to access CODESYS functionalities” on page 411

**Basic syntax of python (with examples)**

Python is similar to the languages of the C family, but there are some significant differences and unique properties.

The most obvious syntactic difference between Python and language such as C and ST is that the Python parser recognizes block structures by their indentation. There is no `BEGIN/END` or braces `{}` to identify the blocks of `IF/ELSE` conditions, `FOR` and `WHILE` loops, or functions.
Comments start with # and extend to the end of the line. In the first and second line of the source code, you can set a special marker to declare the encoding of the file. We recommend that you use UTF-8 as the encoding if ASCII characters are not required.

For debugging purposes, you use print for easy output. With the % operator, you achieve functionality similar to the C function printf(). The output is displayed in the message view of CODESYS.

```
Example:
defining a function with the parameter i
def do_something(i):
    # if branch
    if i>0:
        print("The value is: \%i\" \% i)
        sum += i
        print("The new sum is: \%i\" \% sum)
    # else if (optional, there can be none or several elif branches)
    elif i=0:
        print("The sum did not change: \%i\" \% sum)
    # and the final else branch (also optional).
    else:
        handle_error()
    # an endless while loop
    while True:
        print("I got stuck forever!")
```

Everything that belongs to the same block has to be indented the same distance. The size of the indentation is irrelevant. Elements such as brackets and braces have a higher priority than indentations. Therefore, the following code segment is completely correct, even if it is written in a poor programming style:

```
Example:
# warning: bad style below. Kids, don't try this at home!
if foo >= bar:
    print("foobart")
else:
    print("barfoo")
```

To avoid ambiguity, you should not mix tabs and spaces in a file.

At this time, mixing tabs and spaces girt in Python 3 qualifies as a syntax error.
The official Python Style Guide recommends indentation of four spaces and includes some examples of good and poor style. The Python tutorial provides a summary of coding style.

Python is case-sensitive, similar to and in contrast to ST. Keywords, such as def, if, else, and while, have to be lowercase (in contrast to the ST rule: keywords are uppercase). Two identifiers, such as "i" and "I", also identify two different variables.
the following keywords are reserved in Python and not permitted for use as identifiers for variables, functions, etc.: and | as | assert | break | class | continue | def | del | elif | else | except | exec | finally | for | from | global | if | import | in | is | lambda | not | or | pass | print | raise | return | try | while | with | yield.

Python 3 defined four other keywords: False | None | True | nonlocal. While the first three are really new, the first three were already predefined constants in Python 2 and should not be used for any other purposes.

Variables and data types

Python is a powerful, dynamically typed language -- all type information is evaluated at runtime. Variables hold references to objects, and the object knows its type, not the variable. When a programmer attempts to execute an operation that is not possible (for example, adding an integer and a string), Python throws an exception at runtime.

Consequently, there are no declarations of variables and their types. In Python, variables are created only to assign values to them. This is completely different in C and ST where types are strong and static. Every variable is declared with a type, and at compile time the compiler checks that the type and operators are permitted.

Refer to the following examples for dealing with variables:

Example: Variables

```python
# assign the integer 1 to the variable i (also "creates" the variable")
i = 1

# assign the string "foobar" to the variable s
s = "foobar"

# Add 5 to the integer i - this is equivalent to i = i + 5
i += 5 # i now holds the integer 6.

# Try to add i and s - this will throw an exception when executed
# TypeError: unsupported operand type(s) for +: 'int' and 'str'
result = i + s

# variables can also be "undeclared" by deleting them.
# Further access to the variable i will throw a NameError exception,
# as the variable does not exist any more.
del i

i += 5 # now throws an exception: NameError: name 'i' is not defined
```

All existing variables reference one value only. There is not any unassigned or uninitialized variables in Python. To express the absence of a value, Python provides a special object: None. In C or ST, you would use a null pointer. Its only purpose is to express "no value here", although None is actually an existing instance of the class NoneType.

Numeric types and floating points

In contrast to the dozens of integer types in IEC or C, there is only one integer type in Python. Integer types in Python do not have a fixed size. Instead, they grow as needed and are limited only by available memory.
Example: Integers.py

```python
from __future__ import print_function

i = 1
print(i)

j = 0x1234   # hex number, is 16#1234 in IEC and 4660 in decimal
k = 0o123    # octal number, is 8#123 in IEC and 83 decimal
l = 0b101010 # binary number, is 2#101010 in IEC and 42 in decimal
print(j, k, l)

m = (2 + 3)*10 # k is 50 now
print(m)

n = 10 ** 100 # 10 to the power of 100
print(n)
```

Resulting output:

```
1
1234 123 42
50
10000000000000000000000000000000
```

There is also only one floating-point type in Python which is similar to the IEC data type `LREAL`. It provides 64-bit IEEE floating point arithmetic.

The syntax is like C-based languages for the most part:

Example: Floating-point types

```python
# A simple float...
a = 123.456

# A float containing the integral value 2
b = 2.

# Leading zeros can be left off
c = .3 # same as 0.3

# Exponential / scientific representation
d = -123e-5
```

Two special cases are `True` and `False`, two constants that define the Boolean truth values. They behave similar to the integer values `0` and `1`, except when they are converted into strings and return their names.
Example:
Booleans.py

```python
# booleans behave like integers, except when converted to strings.
# The built-in function "type" can be used to query the type of a value.
print("True: ", True, type(True))
print("False: ", False, type(False))
print("1: ", 1, type(1))
print("False + 0: ", False + 0, type(False + 0))
print("True * 5: ", True * 5, type(True * 5))
```

Resulting output:

<table>
<thead>
<tr>
<th>True:</th>
<th>True &lt;type 'bool'&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>False:</td>
<td>False &lt;type 'bool'&gt;</td>
</tr>
<tr>
<td>1:</td>
<td>1 &lt;type 'int'&gt;</td>
</tr>
<tr>
<td>False + 0:</td>
<td>0 &lt;type 'int'&gt;</td>
</tr>
<tr>
<td>True * 5:</td>
<td>5 &lt;type 'int'&gt;</td>
</tr>
</tbody>
</table>

Strings

In IronPython, strings are always in Unicode and any length. It does not make any difference if they are enclosed in ' or " Strings can also have triple quotation marks """ or ''' which allows for multiline string literals.

Similar to C, special characters can be excluded by means of backslashes (\): As a comparison, the dollar sign ($) is used in IEC for this purpose.

There are also raw strings that have other rules for the backslash. This is practical when the string should have literal backslashes. Example: Windows file paths or regular expressions.
Example:

```
# encoding:utf-8
from __future__ import print_function

a = "a simple string"
b = 'another string'
c = "strings may contain 'quotes' of the other type."
d = "multiple string literals" ' are concatenated ' "by the parser"
e = "Escaping: quotes: " \" backslash: \ newline: \r\n ascii code: \x40"
f = """"triple-quoted strings may contain newlines, "single" 'quotes' and ""multiquotes"" of the other type"
g = "Unicode is also possible: 北京, Москва, Αθήνα, القاهرة"
h = r"c:\raw\strings\retain\backslashes.txt"

# we iterate over a sequence of all the variables defined above:
for i in (a,b,c,d,e,f,g,h):
    print(i) # prints the contents of the variable
```

Resulting output:

```
 ascii code: @
 triple-quoted strings may contain newlines, "single"
 'quotes' and ""multiquotes"" of the other type
 Unicode is also possible: 北京, Москва, Αθήνα, القاهرة
c:\\raw\\strings\\retain\\backslashes.txt
```

Python does not have characters types. Characters are expressed by the use of strings with a length of 1. In this way, iteration via a string, or indexing in a string, returns a single-character string.

- [Python Documentation, Strings](https://docs.python.org/3/library/string.html)

### Lists and tuples (data sets)

Lists and tuples basically correspond to arrays in C and IEC, but there are some noticeable differences:

- Index access is always checked. Accessing a list or a tuple with an invalid index throws an exception.
- Both lists and tuples can contain elements of different types (also other lists and tuples). In contrast in C and IEC, arrays can contain only elements of a single type.
- Lists are dynamic, and elements can be added, removed, or replaced at any time.
- Tuples are not changeable: Once a tuple is created, it cannot be modified anymore.

Lists are created with the `list()` constructor. As an alternative, you can use brackets `[]`. Tuples are created with the `tuple()` constructor or parentheses `()`.
Example:
list_tuples.py

```python
from __future__ import print_function

print("Testing tuples and lists")

# We define a tuple with the numbers from 1 to 10:
t = (1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
print("Tuple:", t)

# We can access the 6th element of the tuple.
# As in C, index counting starts with 0.
print("Element 5:", t[5])

# Subscription is more powerful using the range syntax:
print("Range[2:5]:", t[2:5]) # lower bound is inclusive, upper bound is exclusive.
print("Range[2::2]:", t[2::2]) # start with 3rd element, and print every 2nd element.
print("Range[-3:-1]:", t[-3:-1]) # Start with the 3rd last element, end just before the last element (upper bound is exclusive)
print("Range[::]:", t[::]) # negative step with - print backwards

# lists are similar to tuples...
l = [11, 12, 13, "8", t] # contains mixed types: 3 integers, a string, and the tuple defined above.
print("List:", l)

# ... but elements can be added or removed dynamically.
l.append(9) # Add a 9 to the list.
print("List with 9:", l)

del l[1] # remove the element at index 1, the 12.
print("Removed[1]:", l)
del l[1:3] # Remove the elements at index 1 and 2, the 13 and the '8'.
print("Removed[1:3]:", l)
```

Resulting output:

```
List: [11, 12, 13, '8', (1, 2, 3, 4, 5, 6, 7, 8, 9, 10)]
List with 9: [11, 12, 13, '8', (1, 2, 3, 4, 5, 6, 7, 8, 9, 10), 9]
List Range[3:6:2]: ['8', 9]
Removed[1]: [11, 13, '8', (1, 2, 3, 4, 5, 6, 7, 8, 9, 10), 9]
Removed[1:3]: [11, (1, 2, 3, 4, 5, 6, 7, 8, 9, 10), 9]
```

Dictionary

Python also has a hash table type (also "hashmap"). In contrast to the list, it can be indexed with any elements, for example strings. Its constructor is `dict()` and its literals are declared with braces `{}`.

The sample script `dictionaries.py` creates the output displayed below. In the last line, the script is terminated with a "KeyError" exception:
Example:
dictionaries

```python
from __future__ import print_function
print("Testing dictionaries")

# Declare a dictionary with three entries, the third being a list
d = {1: "a", 2: "b", "my list": [1, 2, 3]}
print(d)

# print the value of the key 1
print(d[1])

# remove the value with the key "my list"
del d["my list"]

# Add a value 4 with the key 3
d[3] = 4
print(d)

# The "get" method returns the second argument if the key cannot be
# found.
print(d.get(1, 42))
print(d.get(23, 42))

# print all keys in the dictionary
for key in d:
    print(key)

# index access for unknown keys will throw a "KeyError" exception!
print(d[23])
```

Resulting output:

And then in the last line, the script terminates:
You can view the stack trace by clicking the "Details" button. Here you find out about line number 27 and the unknown key 23.

Python control structures (with examples)

Loops
As opposed to C and ST, for loops in Python do not count loop variables, but iterate over a sequence. This kind of sequence can be a dictionary, a list, a tuple, the characters in a string, or lines in a file.

The following example shows some for loops:
from __future__ import print_function

print("Enumerating over a simple list:")
for i in (1,2,3,4):
    print(i, end="", "") # end= replaces the newline with ", "
print() # but we still need a newline at the end of this case.

print("Enumerating over the characters in a string:")
for i in "CODESYS": # characters are representet as strings of length 1.
    print(i, end="", "")
print()

print("Enumerating over the integers 1 to 4:")
for i in range(1, 5): # upper bound is exclusive.
    print(i, end="", "")
print()

print("Enumerating using xrange:")
for i in xrange(5): # xrange is similar to range, but needs less memory for large ranges.
    print(i, end="", "")
print()

print("Enumerating including the item number:")
for i, v in enumerate("CODESYS"):
    print(i, v)

Resulting output:

If you require an index or number in addition to the item, then you should use enumerate as shown in the last case of the sample script. The following code is considered as poor style:
**Example: Poor style**

```python
text = "CODESYS"

for i in range(len(text)):  # BAD STYLE!
    v = text[i]             # DON'T TRY THIS AT HOME!
    print(i, v)
```

Besides `for` loops, Python also has `while` loops which are very similar to those in C and ST:

**Example: "while" loops**

```python
i = 0
while i < 3:
    print(i)
    i += 1
```

Note: This example is not very practical. You would more likely use a `for` loop with a range.

**IF / ELSE**

The `if/else` construct is similar to those in other programming languages. Here is a short example:

**Example: "if_else.py"**

```python
from __future__ import print_function
i = int(system.ui.query_string("Please enter an integral number..."))
if i < 0:
    print("Your number was negative.")
elif i > 0:
    print("Your number was positive.")
else:
    print("It seems your number was zero.")
```

The `else` branch is optional and there can be zero, one, or many `elif` branches.

**Functions, classes, and methods**

Python allows for defining functions and classes with methods. A class with methods is basically similar to a function block in ST, or classes in languages such as C++, Java, or C#. However, Python does not support interfaces.

For detailed information, refer to the Python documentation for defining functions and classes.
# defining a function with name sum and two parameters a and b:
def sum(a, b):
    return a + b  # we return the sum of a and b.

# we can now call the function defined above:
print(sum(5, 7))

# Now we define a class Foo:
class Foo:
    # The class gets a method "bar".
    # Note: for methods, the first parameter is always "self" and
    # points to the current instance. This is similar to "this" in
    # ST and other languages.
    def bar(self, a, b):
        print("bar(%s,%s)" % (a, b))

# We create an instance of the class:
f = Foo()

# We call the method bar on the instance.
f.bar("some", "params")

See also
* Python Documentation, Defining Functions
* Python Documentation, Classes

In IEC, you can import libraries for reuse by other written code. As a pendant, there is the possibility in Python of importing modules.

The Python standard library contains many modules for different purposes, such as:
* String processing
* Date and time handling
* Collections
* Threading
* Mathematical functions
* File handling
* Persistence
* Compression and archiving
* Database access
* Encryption services
* Network and Internet access
* Sending of emails

To create your own modules, write a Python file that defines the functions and classes that you want to provide. Save this file to the same directory as our sample script. If you name the file mymodule.py, then you can import it with import mymodule.

Here is an example of importing and using the cosine function and the pi constant from the math module:
from math import cos, pi
print(pi)  # prints 3.14159265359
print(cos(pi))  # prints -1.0

The following contains more examples that access information about the operating system, the Python version, and the interpreter:

import os
print(os.environ["OS"])  

from sys import platform, version, executable
print(platform)
print(version)
print(executable)

There is a special module __future__ for activating new language features. Above all, it is used when Python developers introduce new functionalities that are backward compatible. These kinds of functionalities have to be activated with special "__future__ imports". One example that we use in most of our sample scripts here is the activation of the new power syntax of print as a function instead of a statement.

# make print() a function instead of a statement
from __future__ import print_function

The Python documentation provides a complete list of all __future__ imports.

In addition to the normal Python modules, IronPython code can also access .NET assemblies as if they were Python modules. This opens the access to the .NET framework class library and third-party libraries. Here is an example how to open a dialog box by means of the library Windows Forms:

import clr
clr.AddReference("System.Windows.Forms")
from System.Windows.Forms import MessageBox
MessageBox.Show("Hello")

See also
Using scripts to access CODESYS functionalities

All objects and commands that CODESYS provides for scripting are also in the Python module "scriptengine". Whenever a script is started, an implicit <code>from scriptengine import *</code> results. This allows for easy access to CODESYS. However, if your script imports modules that require access CODESYS APIs, then these modules have to import the module scriptengine themselves.

In the following table, you will find the main objects (categories) that can be used in Python scripts as entry points. For comprehensive documentation about entry points, see the API reference documentation for the CODESYS ScriptEngine.

<table>
<thead>
<tr>
<th>Objects</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>system</td>
<td>Access to general CODESYS functionalities, such as:</td>
</tr>
<tr>
<td></td>
<td>● Exiting CODESYS</td>
</tr>
<tr>
<td></td>
<td>● Handling the general user interface</td>
</tr>
<tr>
<td></td>
<td>● Access to the message memory (including compiler messages)</td>
</tr>
<tr>
<td></td>
<td>● Control of delay and progress bars.</td>
</tr>
<tr>
<td>projects</td>
<td>Access to the CODESYS project as an object tree that combines the three navigator views (devices, POUs, modules) in one project tree. Also allows for the loading, creating, saving, and closing of projects.</td>
</tr>
<tr>
<td></td>
<td>For most objects in a project, there are special methods with detailed functionality, for example compiling, access to ST POUs, export, import, device configuration, etc.</td>
</tr>
<tr>
<td>online</td>
<td>Access to online functionalities, such as:</td>
</tr>
<tr>
<td></td>
<td>● Login to devices and applications</td>
</tr>
<tr>
<td></td>
<td>● Management of access data (user name, password)</td>
</tr>
<tr>
<td></td>
<td>● Performance of network scans</td>
</tr>
<tr>
<td></td>
<td>● Gateway management</td>
</tr>
<tr>
<td>librarymanager</td>
<td>Permits the management of library repositories and viewing, installation, and removal of libraries.</td>
</tr>
<tr>
<td>device_repository</td>
<td>Handling of device repositories; import and export of device descriptions.</td>
</tr>
<tr>
<td>modulerepository</td>
<td>Management of CODESYS Application Composer modules and CODESYS Application Composer repositories.</td>
</tr>
</tbody>
</table>

See the following specific sample scripts for ways to access CODESYS functionalities. For detailed information, see the API reference documentation for the CODESYS ScriptEngine.

✓ Offline help: API Reference Documentation for the ScriptEngine:
✓ Online help: API Reference Documentation for the ScriptEngine:

Example: 
Printing the device tree of the current project

The script PrintDeviceTree.py is an example for navigating in a project. It creates the output of a hierarchical display of all devices in the open project.

Load a project that contains some device objects and execute the script.
Example: PrintDeviceTree.py

```python
# encoding:utf-8
# We enable the new python 3 print syntax
from __future__ import print_function

# Prints out all devices in the currently open project.
print("--- Printing the devices of the project: ---")

# Define the printing function. This function starts with the
# so called "docstring" which is the recommended way to document
# functions in python.
def print_tree(treeobj, depth=0):
    """ Print a device and all its children 
    Arguments:
    treeobj -- the object to print
    depth -- The current depth within the tree (default 0).
    The argument 'depth' is used by recursive call and
    should not be supplied by the user.
    """
    if treeobj.is_device:
        name = treeobj.get_name(False)
        deviceid = treeobj.get_device_identification()
        print("{0}- {1} {2}".format("--"*depth, name, deviceid))
    # we recursively call the print_tree function for the child
    objects.
    for child in treeobj.get_children(False):
        print_tree(child, depth+1)

    # We iterate over all top level objects and call the print_tree
    function for them.
    for obj in projects.primary.get_children():
        print_tree(obj)

print("--- Script finished. ---")
```

The device tree (from the "Devices" view) is displayed in the message view and all non-device
objects are left out:

---

Example: Reading of variables

The script ReadVariable.py logs in to the device and starts the application if necessary.
Then the value of the variable PLC_PRG.iVar1 is read and output. To try the script, you have
to modify the project path and variable names.
Example:

ReadVariable.py

```python
# encoding:utf-8
from __future__ import print_function

# close open project if necessary:
if projects.primary:
    projects.primary.close()

# opens project
proj = projects.open(r"D:\data\projects\Ampel.project")

# set "Ampel.project" to active application
app = proj.active_application
onlineapp = online.create_online_application(app)

# login to device
onlineapp.login(OnlineChangeOption.Try, True)

# set status of application to "run", if not in "run"
if not onlineapp.application_state == ApplicationState.run:
    onlineapp.start()

# wait 1 second
system.delay(1000)

# read value of iVar1
value = onlineapp.read_value("PLC_PRG.iVar1")

# display value in message view or command line
print(value)

# log out from device and close "Ampel.project"
onlineapp.logout()
proj.close()
```

In the extension of the script ReadVariable.py, the script MailVariables.py loads variables and expressions from a recipe file and reads their current values from the controller. Then these values are written back to the same file. In addition, it uses the Python SMTP library to send an email with an attachment containing a list of all variables.

To use the script, you have to modify the paths, email address, and the name of the SMTP server to your environment.
Example:

```
# encoding:utf-8
from __future__ import print_function

# Close current project if necessary and open "ScriptTest.project"
if not projects.primary == None:
    projects.primary.close()
project = projects.open("D:\Data\projects\scriptTest.project")

# retrieve active application
application = project.active_application

# create online application
online_application = online.create_online_application(application)

# login to application.
online_application.login(OnlineChangeOption.Try, True)

# start PLC if necessary
if not online_application.application_state == ApplicationState.run:
online_application.start()

# wait 2 seconds
system.delay(2000)

# open recipe file to read values.
recipe_input_file = open("D:\Data\projects\RecipeInput.txt", "r")
watch_expressions = []
for watch_expression in recipe_input_file:
    watch_expressions.append(watch_expression.strip())
print watch_expressions

# read values from the controllerd
watch_values = online_application.read_values(watch_expressions)
print watch_values

# open output file to write values
recipe_output_file = open("D:\Data\projects\RecipeOutput.txt", "w")
for i in range(len(watch_expressions)):
    recipe_output_file.write(watch_expressions[i])
    recipe_output_file.write(" = ")
    recipe_output_file.write(watch_values[i])
    recipe_output_file.write("\n")

# Close files
recipe_input_file.close()
recipe_output_file.close()

# send Email
# import respective libraries
import smtplib
from email.mime.text import MIMEText

#open output file
recipe_output_file = open("D:\Data\projects\RecipeOutput.txt", "r")
mail = MIMEText(recipe_output_file.read())
```
recipe_output_file.close()

# email address sender and recipient
fromm = "info@example.com"
to = "info@example.com"

# set sender and recipient
mail["Subject"] = "Attention value has changed"
mail["From"] = fromm
mail["To"] = to

# send email
smtp = smtplib.SMTP("name of smtp server")
smtp.sendmail(fromm, [to], mail.as_string())
smtp.quit()

# logout and close application
online_application.logout()
project.close()

Example: Creating and editing of POU's

The script CreateDut.py creates the objects MyStruct, MyAlias, and MyUnion in the CODESYS project. The folder DataTypes already has to be present.
CreateDut.py

```python
# encoding=utf-8
from __future__ import print_function

STRUCT_CONTENT = """
    a : BOOL;
    b : BIT;
    c : BIT;
"""

UNION_WHOLE = """
TYPE MyUnion :
    UNION
        Zahl : INT;
        Prozent : MyAlias;
        Bits : MyStruct;
    END_UNION
END_TYPE
"""

proj = projects.primary
folder = proj.find('DataTypes', recursive = True)[0]

# Create a struct DUT and insert the list of variables just into the right
# place in line two, row 0 (line numbering starts with line 0)
struktur = folder.create_dut('MyStruct') # DutType.Structure is the default
struktur.textual_declaration.insert(2, 0, STRUCT_CONTENT)

# Alias types get their "content" via the base type, which will just end up
# as one line in the declaration part:
# TYPE MyAlias : INT (0..100); END_TYPE
bereich = folder.create_dut('MyAlias', DutType.Alias, "INT (0..100)"

# Instead of injecting the variables into the existing declaration, one can also just replace the complete declaration part, including the
# boilerplate code.
union = folder.create_dut('MyUnion', DutType.Union)
union.textual_declaration.replace(UNION_WHOLE)
```

Example: User interface / Interaction with the user

In some cases, scripts have to interact with the user. We provide some simple APIs for the most common interactions. The sample script System_UI_Test.py shows all of the possible functions in this regard.
from __future__ import print_function

"""Performs some tests on the messagestore and UI."""

print("Some Error, Warning and Information popups:")
system.ui.error("Fatal error: Everything is OK. :-)")
system.ui.warning("Your bank account is surprisingly low")
system.ui.info("Just for your information: 42")

print("Now, we ask the user something.")
res = system.ui.prompt("Do you like this?", PromptChoice.YesNo, PromptResult.Yes);
print("The user selected '%s'" % res)

print("Now, the user can choose between custom options:")
res = system.ui.choose("Please choose:", ("First", 2, 7.5, "Something else"))
print("The user selected option '%s'" % str(res)) # res is a tuple

print("Now, the user can choose several options:")
res = system.ui.select_many("Please select one or more options", PromptChoice.OKCancel, PromptResult.OK, ("La Premiere", "The Second", "Das Dritte")
print("The returned result is: '%s'" % str(res)) # res is a tuple

print("Now, the user can select files and directories")
res = system.ui.open_file_dialog("Choose multiple files:", filter="Text files (*.txt)|*.txt|Image Files (*.BMP;*.JPG;*.GIF)| *.BMP;*.JPG;*.GIF|All files (*.*)|*.*", filter_index = 0, multiselect=True)
print("The user did choose: '%s'" % str(res)) # res is a tuple as multiselect is true.

res = system.ui.save_file_dialog("Choose a file to save:", filter="Text files (*.txt)|*.txt|Image Files (*.BMP;*.JPG;*.GIF)| *.BMP;*.JPG;*.GIF|All files (*.*)|*.*", filter_index = 0)
print("The user did choose: '%s'" % res)

res = system.ui.browse_directory_dialog("Choose a directory", path="C:\")
print("The user did choose: '%s'" % res)

print("Now we query a single line string")
res = system.ui.query_string("What's your name?")
print("Nice to meet you, dear %s." % res)

print("Now we query a multi line string")
res = system.ui.query_string("Please tell me a nice story about your life!", multi_line=True)
if (res):
    print("Huh, that has been a long text, at least %s characters!" % len(res))
else:
    print("Hey, don't be lazy!")

print("Username and password prompts...")
res = system.ui.query_password("Please enter your favourite password!", cancellable=True)
if res:
    print("Huh, it's very careless to tell me your favourite password!")
In the script `ProjectInfoExample.py`, we set some information in the “Project Information” object. The most important information items, such as “Title” and “Version”, have explicit properties. However, you can read and write any other information fields by means of the dictionary syntax. For example, those that are recommended for the properties of a library project.

The example below may seem somewhat unrealistic, but similar code is used in build servers that create, test, and possibly release automatic library projects and other projects. The ScriptEngine is one of the key elements for creating CI (Continuous Integration) and CD (Continuous Delivery) systems.

```python
# encoding: utf-8
from __future__ import print_function
proj = projects.load("D:\Some.library")
info = proj.get_project_info()

# Set some values
info.company = "Test Library Ltd"
info.title = "Script Test Project"
info.version = (0, 8, 15, 4711)
info.default_namespace = "testlibrary"
info.author = "Python von Scriptinger"

# some values recommended in the library toolchain
info.values["DefaultNamespace"] = "testlibrary"
info.values["Placeholder"] = "testlibrary"
info.values["DocFormat"] = "reStructuredText"

# now we set a custom / vendor specific value.
info.values["SpecialDeviceId"] = "PLC0815_4711"

# Enable generation of Accessor functions, so the IEC application can display the version in an info screen.
info.change_accessor_generation(True)

# And set the library to released
info.released = True;
proj.save()
```

See also

- § Chapter 1.3.1.19.1 “Information for library developers” on page 372
The sample script `DeviceImportFromSVN.py` gets a PLCOpenXML file from an external program (in this case a SVN client) and imports it into a new created CODESYS project. To use the script, you have to modify the paths to your environment.

```python
# encoding:utf-8
# Imports a Device in PLCOpenXML from Subversion via command line svn client.
# We enable the new python 3 print syntax
from __future__ import print_function
import sys, os

# some variable definitions:
SVNEXE = r"C:\Program Files\Subversion\bin\svn.exe"
XMLURL = "file:///D:/testrepo/testfolder/TestExport.xml"
PROJECT = r"D:\test.project"

# clean up any open project:
if projects.primary:
    projects.primary.close()

# Fetch the plcopenxml data from Subversion.
# We'll catch the output of the program into the xmldata variable.
# The 'with' construct automatically closes the open pipe for us.
with os.popen('"' + SVNEXE + '" cat ' + XMLURL, 'r') as pipe:
    xmldata = pipe.read()

# create a new project:
proj = projects.create(PROJECT)

# import the data into the project.
proj.import_xml(xmldata, False)

# and finally save. :-)
proj.save()

print("--- Script finished. ---")
```

**Example:**
Calling external commands and importing PLCOpenXML files

The following sample script can perform the calling and installing of a library as part of a CT (Continuous Testing) environment so that they can be tested. In addition to standard-CODESYS, the add-on CODESYS SVN also has to be installed with a valid license.

**Advanced example:**
Calling a library from SVN and installing it in CODESYS
import tempfile

if projects.primary:
    projects.primary.close()

tempdir = tempfile.mkdtemp()
URL = "svn://localhost/testrepo/trunk/SvnTestLibrary/"

proj = svn.checkout(URL, tempdir, "testlibrary", as_library=True)
proj.save()

repo = librarymanager.repositories[0]
librarymanager.install_library(proj.path, repo, True)

proj.close()

---

Transitioning from python 2 to python 3

With Python version 3, Python developers introduced some incompatible changes and removed some obsolete functionalities. At this time, the Python community is still in the transitional phase from version 2 to version 3.

IronPython does not yet support Python 3, but it is being worked on. As the Python community no longer supports Python 2, we intend to upgrade to Python 3 as soon as it is supported by IronPython. Although we strive for a smooth transition, script writers should take care that their scripts are created in a future-proof style. For example, by using the expression `from __future__ import print_function`.

- New in Python 3

Comparison of IronPython and cPython

There are some small differences and Incompatibilities between IronPython and standard Python ("cPython"). Some are direct errors in IronPython and should be removed in future versions. However, others are considered "implementation details" and will remain. Some of them are very challenging topics.

The difference that is most obvious for users is the handling of strings. Original cPython has two different string types for byte strings and Unicode strings. This concept is similar to the data types STRING and WSTRING in IEC. IronPython simply uses .NET strings that are always Unicode-capable and use UTF-16 internally. However, IronPython implements a trick to hide the difference to cPython from the programmer. (Interesting is that the developers completely reengineered string handling for the new Python version 3. A module was developed that is much closer to that of IronPython. Afterwards, only Unicode strings are used and there is an individual data type for handling raw bytes.)

Python modules that are written in C cannot be imported into IronPython because cPython uses internal data structures that are completely different from IronPython. Most of the standard library modules were reimplemented in IronPython. However, some modules (such as the TK interface) are not available as long as they are not ported to IronPython explicitly. On the other hand, IronPython provides access to .NET assemblies including the .NET framework (as shown above), which more than compensates for this feature.
While cPython uses reference counting and a deterministic garbage collector for cleaning up cyclic garbage, IronPython relies on the non-deterministic .NET garbage collector. In most cases, this difference does not matter. But when you open files or other resources from the Python standard library or the .NET framework, you should make sure to close them later. It is best to use the `with` statement with the Python context manager or .NET `IDisposable` instances.

Due to the increased networking of controllers and plants, potential threats are also quickly rising. Therefore, you should carefully consider all possible security measures.

Security measures are absolutely necessary to protect data and communication channels from unauthorized access.

On the following help pages, you can learn more about the safety functions of CODESYS and the controller.

### 1.3.1.23.1 General information

Below is some general information about security measures. This information applies regardless of the use in CODESYS or on in a controller connected to CODESYS.

**Access protection with user management**

As a means of protecting against unauthorized access to data, it is necessary to configure user accounts with specific access rights. Only a user with the credentials has access to the data or functions.

The following types of user management are roughly distinguished:

- **Simple user management:**
  To access data, only a password or the valid combination of user name and password has to be entered. This means that access can be only granted or denied. Graduated rights cannot be configured.

- **Group-based user management:**
  The access rights are assigned to user groups. Users who belong to a group can access the data or functions after entering the credentials with precisely these assigned and different rights.

**Encryption, signature**

Encryption:

Encryption of data means the following: Data is converted into an unreadable form and can only be made readable again with a matching key. In the simplest case, the key is a password or a key pair.

There are two types of encryption methods:
• Symmetrical method: (the only type of encryption until the mid-1970s)
  Characteristic: Use of a secret key
  Advantages: Fast, easy encoding
  Disadvantages: The key must be shared secretly.

• Asymmetric method:
  Characteristic: Use of a key pair (private/secret key and public key)
  Advantages: The public key can be made accessible to anyone, and authentication possible with it.
  Disadvantages: Slow (approx. 1,000 to 10,000 times slower than symmetric methods); complex encoding; long key lengths

Key exchange is usually performed by asymmetric methods; encryption and decryption by symmetric methods.

Signature:
In order for the irrefutable ownership and integrity of a message to be verifiable, it should be provided with a signature. The following steps are common:

• Sender: Determines a unique hash value over the data (H)
• Sender: Encrypts the hash value with private key (He)
• Recipient: Also calculates the hash value and decrypts the He with the public key and compares the two values. This allows the sender to be identified uniquely and verifies that the sender owns the private key.

In the case of asymmetric encryption, a public key contained in a certificate is first exchanged between the sender and the recipient. In addition, each participant needs a private key with which they can decrypt the data if they have the certificate. So if you want to access a certificate, you need a certificate AND a private key.

Hash methods are necessary for this:

• Hash method:
  Characteristic: Unique fingerprint of the data (for example, checksum of the data)
  As low a collision as possible (it is very difficult to find / construct two different data for a single hash value)

Certificates
In order to assign the public key to an identity, it is usually embedded in a certificate.

In certificate-based systems, each user receives a digital certificate. The certificate is used for digital identification. It contains information about the identity and the public key of the user. Each certificate is authenticated by an issuing authority, which in turn may be authenticated by higher authorities. The trust system of this PKI (Public Key Infrastructure) is strictly hierarchical. The common trust anchor is a root certificate.

Contents of a certificate:

• Version
• Serial number
• Algorithm ID
• Issuer (authority or company)
• Validity from (not before) to (not after)
• Certificate owner (subject)
• Certificate owner key information (subject public key)
  – Public key algorithm
  – Public key of the certificate owner
• Unique ID of the issuer (optional)
• Unique ID of the owner (optional). The owner owns the private key that matches the public key.
• Extensions
  – Purpose (extended key usage)
  – ...

The certificate consists of 2 parts / files:
● Public X.509 certificate (can be issued to anyone)
● Private key that matches the certificate or its public key only (must be kept secret).

For information on how to manage the certificates in your local "Windows Certificate Store" you can also see in the current Help:

● Chapter 1.3.1.6 “Protecting and saving a project” on page 139

1.3.1.23.2 Security for the development system

In CODESYS, you can apply access protection to projects, libraries, as well as individual applications. In addition to a simple write protection for a project, a user management (credentials, access rights) and encryption using certificates should be used.

See current help:

● Chapter 1.3.1.6 “Protecting and saving a project” on page 139

1.3.1.23.3 Security for the runtime system / PLC

Communication with the controller connected in the CODESYS project should be protected against unauthorized access in the following ways:

● Enabling user management: simple or group-based
● Certificate-based encryption of communication with the controller

NOTICE!

With CODESYS V3.5 SP14, encrypted communication and user management are not enforced yet by default for SL runtime systems. However, you can explicitly set the communication to safe mode.

Enabling security features

First switch the communication to encryption so that you do not reveal any credentials to other users in the network when transferring the user management.

Enforcing encrypted communication

● On the controller:
  − Runtime version >= 3.5 SP14: Encryption can be enabled for “Communication Policy” and enforced for all clients.
  − Runtime version < 3.5 SP14: The controller can communicate with or without encryption. Encryption is not enforced.

See the current help regarding this:

● Chapter 1.3.1.11.2 “Encrypting communication, changing security settings” on page 296

● In CODESYS:
  − Encrypted communication can be selected as an option in the device editor on the “Communication Settings” tab (command or “Change Communication Policy” dialog) or in the “Security Screen” view.

See the current help regarding this:

● Chapter 1.3.1.11.2 “Encrypting communication, changing security settings” on page 296

If the CODESYS Security Agent is installed, then see the help for CODESYS Security Agent.
Enforcing a user management

- On the controller:
  - Runtime version >= 3.5 SP14: User management can be enabled for “Communication Policy” and enforced.
  - Runtime version < 3.5 SP14: Simple user management or one for users/groups with respective rights can be enabled.

- In CODESYS:
  - See the current help regarding this:
    - Chapter 1.3.1.11.2 “Encrypting communication, changing security settings” on page 296
    - Chapter 1.3.1.11.3 “Handling of device user management” on page 300

**OPC UA server**  
See current help:
- Chapter 1.3.3.1 “OPC UA server” on page 1100

### 1.3.1.23.4 FAQ

</tr>
</tbody>
</table>

#### Certificate expired

If the certificate from the controller for encrypted communication has expired (valid from “not before” until “not after”), you get a prompt with a corresponding message in CODESYS when you attempt to access the controller. For example, to renew the expired certificate, you can accept the expired certificate and connect to the controller.

You will see this message again every time you try to login until a valid certificate is installed on the controller.

If you have created or imported a new certificate on the controller, then this new certificate will be available for you to accept the next time you login.

See also
- Chapter 1.3.1.11.2 “Encrypting communication, changing security settings” on page 296

#### New certificate (while the current one is still valid)

A new certificate can be issued before the existing certificate expires. This makes it possible for the encrypted communication to continue seamlessly. As soon as a new certificate is available on the controller parallel to the one currently used, the new certificate will be offered by the controller at the next login attempt. All you have to do is accept it.
See also
● “Installing a controller certificate for encrypted communication via the PLC shell of the device editor” on page 297

### Client does not support security feature

#### User management

The following CODESYS clients do not support user management yet:

- WebServer < V3.5.14.0

In order for these clients to be able to establish a connection to the controller, the user management must not be enabled.

#### Encrypted communication

The following CODESYS clients do not support encrypted communication yet:

- Data servers with compiler version <= V3.5.9.0
- WebVisu < V3.5.14.0 or in the case of enabled file transfer
- WebServer < V3.5.14.0
- Remote TargetVisu
- Data source ApplicationV3
- OPC Server V3
- PLCHandler < V3.5.14.0

In order for these clients to be able to establish a connection to the controller, the encrypted communication can be set as optional. Therefore clients can establish either an encrypted or an unencrypted connection.

> Do not use the same user or password for encrypted and unencrypted communication.

See also
● “Chapter 1.3.1.11.2 “Encrypting communication, changing security settings” on page 296

### CA-signed certificates preferred (PLC shell)

Using CA-signed certificates is not conveniently supported yet in CODESYS. However, you can still request and use these types of certificates. In the device editor, on the “PLC Shell” tab, you export the required CSR files to the file system and import from there the CER files sent from the certification authority.

#### Requesting and providing a CA-signed certificate

- You are connected to the controller.

1. First you generate certificate signing requests (CSR) of all server certificates.
   For this purpose, click the “PLC Shell” tab of the controller and type the command `cert-createcsr` in the input line.

2. Click the “Log” tab and then the refresh button (⟳).
   In the log entries, you can see that the CSR files were generated.
3. Click the "Files" tab and open the file path `cert/export` in the right side of the "Runtime" dialog.
   ⇒ The `export` folder contains the generated CSR files, for example `0_CmpsecureChannel.csr, 1_CmpApp.csr, 2_CmpWebServer.csr`.
4. Select a file path where you wish to insert the CSR files in the left side of the "Host" dialog, mark the CSR files in the right side of the dialog, and click `<<`.
   ⇒ The CSR files are copied to the required folder.
5. These requests can be signed for certification signing by a certificate authority (CA), and then you receive a signed certificate from the certification authority.
6. In the steps that follow, you import these signed server certificates to your controller.

| NOTICE! |
| Caution: Self-signed certificates of the server must be deleted before importing the CA-signed certificates. |

7. Select the "Path" `cert/import` in the right side of the "Runtime" dialog.
8. In the left side of the "Host" dialog, select the path in the file system where you saved the signed certificates and selected the certificates.
9. Click `>>`.
   ⇒ The certificates are copied to the `cert/import` folder.
10. Click the "PLC Shell" tab.
11. Type the command `cert-import own <file name of the certificate.cer>` in the input line of the tab and press the `[Enter]` key.
   ⇒ The signed certificates are available to the runtime system servers.

See also
- `Chapter 1.3.1.25.1.19.10 “Tab 'PLC Shell'” on page 753`
- `Chapter 1.3.1.25.1.19.8 “Tab 'Log'” on page 750`
- `Chapter 1.3.1.25.1.19.7 “Tab 'Files'” on page 750`

Problems at login

If you have entered an incorrect password when logging in to the user management of the controller, then the login dialog reappears immediately afterwards. After three incorrect attempts, the controller is locked for a defined period of time. However, stricter policies on the controller can lead to the user being locked out and only authorized again by an administrator.

See also
- `Chapter 1.3.1.25.2.6.2 “Command 'Login'” on page 923`

Disabling user management

| NOTICE! |
| After disabling the user management, your controller is accessible again for everyone in the network of the controller. Therefore, you should only do this in justified exceptional cases or if the clients used do not support any user management. |
To delete the user management of the controller after any unintentional activation, proceed as follows:

1. If the security policy for device user management is set to "Enforced", first set it back to "Optional".
2. Execute the "Reset Origin Device" command. This deletes the user management and you can then reconnect to the controller without having to enter user credentials.

See also

- § Chapter 1.3.1.11.2 “Encrypting communication, changing security settings” on page 296
- § Chapter 1.3.1.25.2.6.12 “Command ‘Reset Origin Device’” on page 933
- § Chapter 1.3.1.11.3 “Handling of device user management” on page 300
- § Chapter 1.3.1.6 “Protecting and saving a project” on page 139

Permitting encrypted communication again

| Remember that not every controller supports the deactivation of encrypted communication. |
| NOTICE! |
| We strongly advise against disabling encrypted communication. Especially in connection with an enabled user management, encrypted communication should be enabled so that credentials do not fall into the wrong hands. |

To disable encrypted communication with the controller again, proceed as follows:

1. If the communication policy for encrypted communication is set to "Enforced", first set it back to "Optional".
2. In the device editor, on the "Communication Settings" tab in the "Device" menu, disable "Encrypted communication". If you have installed the CODESYS Security Agent, then you can also change the setting in the "Security Screen".
   - CODESYS establishes unencrypted communication again with the controller. Other clients can also communicate again without encryption.

- § Chapter 1.3.1.11.2 “Encrypting communication, changing security settings” on page 296
- § Chapter 1.3.1.25.2.3.18 “Command ‘Security Screen’” on page 891
1.3.1.24 Reference, Programming

1.3.1.24.1 Programming languages and editors

1.3.1.24.1.1 Declaration editor.................................................. 428
1.3.1.24.1.2 Common functions in graphical editors.................... 429
1.3.1.24.1.3 Structured text and extended structured text (ExST).... 430
1.3.1.24.1.4 Sequential function chart (SFC)............................ 442
1.3.1.24.1.5 Function block diagram / Ladder diagram / Instruction list (FBD/LD/IL).................................................. 461
1.3.1.24.1.6 Continuous function chart (CFC) and page-oriented CFC 476

You program a POU in each case in the editor for the implementation language that you selected when creating the POU. CODESYS offers a text editor for ST and graphic editors for SFC, FBD/LD/IL and CFC.

The editor opens with a double-click on the POU in the device tree or in the “POUs” view.

Each of the programming language editors consists of two sub-windows:

- In the upper part you make declarations in the “declaration editor”, in text or tabular form depending on the setting.
- In the lower part you insert the implementation code in the respective language.

You can configure the display and the behavior of each editor project-wide on the associated tab of the CODESYS options.

Declaration editor

The declaration editor is used for declaring variables in the variable lists and POUs.

If the declaration editor is used with an implementation language editor, then is opens in a view above the implementation language editor.

The declaration editor offers two possible views: textual and tabular. In the dialog in “Tools \ Options \ Declaration Editor”, you define whether only the textual view or only the tabular view is available, or whether you can switch between both views by means of the buttons on the right side of the editor view.

A rectangle selection is possible in the textual view of the declaration editor. You can find the key combination for the rectangle selection in the help page for the ST editor.

### Declaration editor in online mode

In online mode, you see the tabular view of the editor. The header always contains the current object path: `<device name>.<application name>.<object name>`. In contrast to offline mode, the table also contains the columns “Value” and “Prepared Value”.

The “Value” column shows the actual value on the PLC, offering monitoring functionality. If the expression is an array, then you can define the range of the array indices to monitor. You do this, double-click the “Data Type” column to open the “Monitoring Area” dialog and type in the “Start Index” and the “End Index” of the required range. You can use a scrollbar to define a series of 1000 elements easily.

The “Prepared value” column contains the value that you prepared for forcing or writing.

If you double-click a “Prepared Value” field, then you can specify a value explicitly for writing or forcing. In the case of enumerations, a combo box opens from which you can select a value. In the case of a Boolean variable you can toggle the prepared value with the help of the [Enter] key or the [Space] bar. If an expression (variable) is of a structured data type, for example the instance of a function block or an array variable, then a plus or a minus sign is placed in front.

You can customize the format of the representation of floating-point values in the options for monitoring.

### Common functions in graphical editors

The implementation part of the graphical editors for FBD, LD, CFC, and SFC contains a toolbar in the lower right corner.

| ![Keyboard] | Return to normal editing mode: The mouse pointer changes back to the shape of the default arrow. You can select and edit elements in the editor view. |
| ![Panning] | Panning tool: The mouse pointer changes to the shape of two crossed arrows. You can click and drag anywhere in the editor view to move the visible area of the FBD/LD/IL editor or also pivot a CFC chart. |
| ![Magnification] | Magnification tool: A magnified window opens in the lower right corner of the editor view and the mouse pointer changes to the shape of a cross. As you move the mouse pointer over your diagram, the magnification tool shows the area of the diagram under the cross at 100% magnification. Note: If you click in the view, then the magnification tool closes and the part of the diagram that the tool contained is displayed at 100% magnification. If you want to retain the set zoom factor, then you should use the default arrow ( ![Keyboard]) for returning to the default editing mode. |
| ![Zooming] | Zooming tool: This opens a drop-down list with a selection of zoom factors. Clicking more selections ( . . . ) will open the “Zoom” dialog for typing other values. The current zoom factor is always shown to the left of the symbol. |

Zooming with the scroll wheel: By holding down the [Ctrl] key and moving the scroll wheel, you can change the zoom factor in steps of 10%.

Every graphical editor has its own “ToolBox” view that is located on the right of the editor view by default. The toolbox contains elements that you can drag to insertion points in the editor view. CODESYS highlights the insertion points with gray position flags in the shape of diamonds, triangles, or arrows. These flags are green when you move the mouse pointer over them. When you release the mouse button, CODESYS inserts the element at the selected position.

It is also possible to use the mouse for moving elements in the editor.
You can drag function block declarations in the FBD, LD, and CFC graphical editors to the editor view. To do this, select the full declaration (variable name and data type) and drag it to a suitable position in the editor view. In the ladder diagram, you can also drag Boolean declarations to the editor and insert them as contacts.

### ST editor

The ST editor is a textual editor used for the implementation of code in Structured Text (ST) and Extended Structured Text (ExST).

The line numbering is displayed on the left side of the editor. When inputing programming elements, the "List components" functionality (activated in the CODESYS options, "SmartCoding" category) and the input assistant [F2] are also helpful. When the cursor is placed over a variable, CODESYS shows a tooltip with information for declaring variables.

The box selection can be made with the following key combinations:
- [Shift] + [Alt] + [Arrow right]: The selected area is extended one position to the right.
- [Shift] + [Alt] + [Arrow left]: The selected area is extended one position to the left.
- [Shift] + [Alt] + [Arrow up]: The selected area is extended one position up.
- [Shift] + [Alt] + [Arrow down]: The selected area is extended one position down.

The behavior (for example parentheses, mouse actions, tabs) and appearance of the editor are configured in the "Text Editor" category of the CODESYS options.

For an incremental search for strings in the editor, open an input field at the bottom edge of the editor by means of the key combination [Ctrl] + [Shift] + [i]. As soon as you start typing in characters, the corresponding search locations are highlighted in color in the editor. The number of found matches is shown to the right of the input field. You can set the cursor at the search location by using the arrow keys or the key combinations [Alt] + [Page up] or [Alt] + [Page down].

When you place the cursor on a symbol name, all occurrence locations of the symbol within the editor are highlighted in color. The search locations correspond to the hits in the cross-reference list. For very large projects, this can cause input delays. In this case, you can disable the function in the options of the text editor.

CODESYS identifies syntax errors already when inputing in the editor and shows the corresponding messages in the message view ("Precompile" category). If the corresponding option is selected in the CODESYS options ("SmartCoding" category), then the error locations in the text are also underlined with a wavy red line.

ST editor in online mode

In online mode CODESYS displays the variables and expressions in the ST editor. The writing and forcing of the variables and expressions as well as debugging functions (breakpoints, single step execution) are also possible.

If you use assignments as expressions in ST programming, no further breakpoint positions are created within a line.

ST expressions

An expression is a construct that returns a value following its evaluation.

Expressions are composed of operators and operands. In Extended Structured Text (ExST) you can also use assignments as expressions. An operand can be a constant, a variable, a function call or a further expression.

<table>
<thead>
<tr>
<th>Examples</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2014</td>
<td>(* Constant *)</td>
</tr>

- “ExST - Extended structured text” on page 201

Evaluation of expressions

The evaluation of an expression takes place by processing the operators according to certain rules of binding. CODESYS processes the operator with the strongest binding first. Operators with the same binding strength are processed from left to right.

<table>

## Assignments

1.3.1.24.1.3.4.1 ST assignment operator......................................................... 432
1.3.1.24.1.3.4.2 ST assignment operator for outputs......................................... 432
1.3.1.24.1.3.4.3 ExST assignment ‘S=’.............................................................. 433
1.3.1.24.1.3.4.4 ExST assignment ‘R=’............................................................ 434
1.3.1.24.1.3.4.5 ExST – Assignment as expression........................................... 435
1.3.1.24.1.3.4.6 Assignment operator ‘REF’................................................... 435

### ST assignment operator

**Syntax:**

<operand> := <expression>

This assignment operator executes the same function as the `MOVE` operator.

See also
- % Chapter 1.3.1.24.3.6 “Operator ‘MOVE’” on page 512

### ST assignment operator for outputs

The assignment operator => assigns the output of a function, a function block, or a method to a variable. The position on the right side of the operator can also be blank.

**Syntax**

<output> => <variable>
FBcomp_Output1 and FB_Output2 are outputs of a function block. The value of FBcom_Output1 is assigned to the variable bVar1.

**ExST assignment 'S='**

When the operand of the Set assignment switches to TRUE, then TRUE is assigned to the variable to the left of the operator. The variable is set.

<variable name> S= <operand name> ;

The variables and the operand have the data type BOOL.

**Example**

```plaintext
PROGRAM PLC_PRG
VAR
  xOperand: BOOL := FALSE;
  xSetVariable: BOOL := FALSE;
END_VAR

xSetVariable S= xOperand;
```

When the operand xOperand switches from FALSE to TRUE, then TRUE is also assigned to the variable xSetVariable. But then the variable keeps this state, even if the operand continues to change its state.

---

**Multiple assignments**

In the case of multiple assignments within a code line, the individual assignments are not processed from right to left, but all assignments refer to the operands at the end of the code line.

**Example**

```plaintext
FUNCTION funCompute : BOOL
VAR_INPUT
  xIn : BOOL;
END_VAR
IF xIn = TRUE THEN
  funCompute := TRUE;
RETURN;
END_IF

PROGRAM PLC_PRG
VAR
  xSetVariable: BOOL;
  xResetVariable: BOOL := TRUE;
  xVar: BOOL;
END_VAR

xSetVariable S= xResetVariable R= funCompute(xIn := xVar);
```

xResetVariable gets the R= assignment of the return value of funCompute. xSetVariable gets the S= assignment of its return value of funCompute, but not from xResetVariable.
ExST assignment 'R='

When the operand of the Reset assignment switches to \texttt{TRUE}, then \texttt{FALSE} is assigned to the variable to the left of the operator. The variable is reset.

\begin{verbatim}
<variable name> R= <operand name> ;
\end{verbatim}

The variables and the operand have the data type \texttt{BOOL}.

**Example**

\begin{verbatim}
VAR
  xOperand: BOOL := FALSE;
  xResetVariable: BOOL := TRUE;
END_VAR

xResetVariable R= xOperand;
\end{verbatim}

When the operand \texttt{xOperand} switches from \texttt{FALSE} to \texttt{TRUE}, then \texttt{FALSE} is also assigned to the variable \texttt{xResetVariable}. But then the variable keeps its state, even if the operand continues to change its state.

**NOTICE!**

In the case of multiple assignments within a code line, the individual assignments are not processed from right to left, but all assignments refer to the operands at the end of the code line.

**Example**

\begin{verbatim}
FUNCTION funCompute : BOOL
  VAR_INPUT
    xIn : BOOL;
  END_VAR
  IF xIn = TRUE THEN
    funCompute := TRUE;
    RETURN;
  END_IF
END_FUNCTION

PROGRAM PLC_PRG
  VAR
    xSetVariable: BOOL;
    xResetVariable: BOOL := TRUE;
    xVar: BOOL;
  END_VAR
  xSetVariable S= xResetVariable R= funCompute(xIn := xVar);
  xResetVariable gets the \texttt{R=} assignment of the return value of \texttt{funCompute}.
  xSetVariable gets the \texttt{S=} assignment of its return value of \texttt{funCompute}, but not from \texttt{xResetVariable}.
\end{verbatim}
ExST – Assignment as expression

In ExST, as an extension to the IEC 61131-3 standard, CODESYS permits the use of assignments as expressions.

### Examples

<table>
<thead>
<tr>
<th>Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>int_var1 := int_var2 := int_var3 + 9;</code></td>
<td>(* <code>int_var1</code> and <code>int_var2</code> receive the value of <code>int_var3 + 9</code> *)</td>
</tr>
<tr>
<td><code>real_var1 := real_var2 := int_var;</code></td>
<td>(* <code>real_var1</code> and <code>real_var2</code> receive the value of <code>int_var</code> *)</td>
</tr>
<tr>
<td><code>int_var := real_var1 := int_var;</code></td>
<td>(* Incorrect assignment, the data types do not correspond! *)</td>
</tr>
<tr>
<td><code>IF b := (i = 1) THEN</code>&lt;br&gt;<code>i := i + 1; END_IF</code></td>
<td></td>
</tr>
</tbody>
</table>

Assignment operator 'REF'

This operator generates a reference (pointer) to a value.

**Syntax:**

```
REF= <variable>
```

**Example**

```
A : REFERENCE TO DUT;
B : DUT;
C : DUT;

A REF= B; // corresponds to A := ADR(B);
A := C; // corresponds to A^ := C;
```

1.3.1.24.1.3.5.11 ST comments........................................................................ 442

ST statement 'IF'

The IF statement is used for checking a condition and, depending on this condition, for executing the subsequent statements.

A condition is coded as an expression that returns a Boolean value. If the expression returns TRUE, then the condition is fulfilled and the corresponding statements after THEN are executed. If the expression returns FALSE, then the following conditions, which are identified with ELSIF, are evaluated. If an ELSIF condition returns TRUE, then the statements are executed after the corresponding THEN. If all conditions return FALSE, then the statements after ELSE are executed.

Therefore, at most one branch of the IF statement is executed. ELSIF branches and the ELSE branch are optional.

Syntax

IF <condition> THEN  
<statements>   
( ELSIF <condition> THEN  
<statements> )*  
( ELSE  
<statements> )?  
END_IF;  
// { ... }* None, once or several times  
// { ... }? Optional
Example

PROGRAM PLC_PRG
VAR
  iTemp: INT;
  xHeatingOn: BOOL;
  xOpenWindow: BOOL;
END_VAR

IF iTemp < 17 THEN
  xHeatingOn := TRUE;
ELSIF iTemp > 25 THEN
  xOpenWindow := TRUE;
ELSE
  xHeatingOn := FALSE;
END_IF;

The program is run as follows at runtime:
For the evaluation of the expression \( iTemp < 17 = \text{TRUE} \), the subsequent statement is executed and the heating is switched on. For the evaluation of the expression \( iTemp < 17 = \text{FALSE} \), the subsequent ELSIF condition \( iTemp > 25 \) is evaluated. If this is true, then the statements in ELSIF are executed and the view is opened. If all conditions are \text{FALSE}, then the statement in ELSE is executed and the heating is switched off.

See also

- Chapter 1.3.1.24.1.3.3 “ST expressions” on page 431

ST instruction ‘FOR’

The FOR loop is used to execute instructions with a certain number of repetitions.

Syntax:

FOR <counter> := <start value> TO <end value> {BY <increment> } DO
  <instructions>
END_FOR;

The section inside the curly parentheses {} is optional.
CODESYS executes the <instructions> as long as the <counter> is not greater, or - in case of negative increment - is not smaller than the <end value>. This is checked before the execution of the <instructions>.

Every time the instructions <instructions> have been executed, the counter <counter> is automatically increased by the increment <increment>. The increment <increment> can have any integral value. If you do not specify an increment, the standard increment is 1.

Example

FOR iCounter := 1 TO 5 BY 1 DO
  iVar1 := iVar1*2;
END_FOR;

If you have pre-configured iVar1 with 1, iVar1 has the value 32 after the FOR loop.
CAUTION!
The end value <end value> may not attain the same value as the upper limit of the data type of the counter.

If the end value of the counter is equal to the upper limit of the data type of the counter, an endless loop results. For example, an endless loop results in the above example if iCounter is of the data type SINT and the <end value> equals 127, since the data type SINT has the upper limit 127.

As an extension to the IEC 61131-3 standard you can use the CONTINUE instruction within the FOR loop.

See also
- § Chapter 1.3.1.24.5.2 “Integer data types” on page 570
- § Chapter 1.3.1.24.1.3.5.9 “EXST instruction ‘CONTINUE’” on page 441

ST instruction ‘CASE’

Use this dialog box for pooling several conditional instructions containing the same condition variable into a construct.

Syntax:
CASE <Var1> OF
  <value1>:<instruction1>
  <value2>:<instruction2>
  <value3, value4, value5>:<instruction3>
  <value6 ... value10>:<instruction4>
  ...
  <value n>:<instruction n>
{ELSE <ELSE-instruction>}
END_CASE;

The section within the curly brackets {} is optional.

Processing scheme of a CASE instruction.
- If the value of the variable <Var1> is <value i>, then the instruction <instruction i> is executed.
- If the variable <Var1> has non of the given values, then the <ELSE-instruction> is executed.
- If the same instruction is executed for several values of the variable, then you can write the values in sequence, seperated by commas.

Example

CASE iVar OF
  1, 5: bVar1 := TRUE;
      bVar3 := FALSE;
  2: bVar2 := FALSE;
      bVar3 := TRUE;
  10..20: bVar1 := TRUE;
          bVar3 := TRUE;
ELSE
  bVar1 := NOT bVar1;
  bVar2 := bVar1 OR bVar2;
END_CASE;
**ST instruction 'WHILE'**

The **WHILE** loop is used like the **FOR** loop in order to execute instructions several times until the abort condition occurs. The abort condition of a **WHILE** loop is a boolean expression.

**Syntax:**

```st
WHILE <boolean expression> DO
  <instructions>
END_WHILE;
```

CODESYS repeatedly executes the `<instructions>` for as long as the `<boolean expression>` returns **TRUE**. If the boolean expression is already **FALSE** at the first evaluation, then CODESYS never executes the instructions. If the boolean expression never adopts the value **FALSE**, then the instructions are repeated endlessly, as a result of which a runtime error results.

**Example**

```st
WHILE iCounter <> 0 DO
  Var1 := Var1*2
  iCounter := iCounter-1;
END_WHILE;
```

**NOTICE!**

You must ensure by programming means that no endless loops are caused.

In a certain sense the **WHILE** and **REPEAT** loops are more powerful than the **FOR** loop, since you don't need to already know the number of executions of the loop before its execution. In some cases it is thus only possible to work with these two kinds of loop. If the number of executions of the loop is clear, however, then a **FOR** loop is preferable in order to avoid endless loops.

As an extension to the IEC 61131-3 standard you can use the **CONTINUE** instruction within the **WHILE** loop.

See also

- § Chapter 1.3.1.24.1.3.5.2 “ST instruction ‘FOR’” on page 437
- § Chapter 1.3.1.24.1.3.5.9 “EXST instruction ‘CONTINUE’” on page 441

**ST instruction 'REPEAT'**

The **REPEAT** loop is used like the **WHILE** loop, but with the difference that CODESYS only checks the abort condition after the execution of the loop. The consequence of this behavior is that the **REPEAT** loop is executed at least once, regardless of the abort condition.

**Syntax:**

```st
REPEAT
  <instructions>
UNTIL <boolean expression>
END_REPEAT;
```

CODESYS executes the `<instructions>` until the `<boolean expression>` returns **TRUE**. If the boolean expression already returns **TRUE** at the first evaluation, CODESYS executes the instructions precisely once. If the boolean expression never adopts the value **TRUE**, then the instructions are repeated endlessly, as a result of which a runtime error results.
Example

```plaintext
REPEAT
  Var1 := Var1*2;
iCounter := iCounter-1;
UNTIL
iCounter = 0
END_REPEAT;
```

In a certain sense the **WHILE** and **REPEAT** loops are more powerful than the **FOR** loop, since the number of executions of the loop doesn't already need to be known before its execution. In some cases you can only work with these two kinds of loop. If the number of executions of the loop is clear, however, then a **FOR** loop is preferable in order to avoid endless loops.

As an extension to the IEC 61131-3 standard you can use the **CONTINUE** instruction within the **WHILE** loop.

See also

- [Chapter 1.3.1.24.1.3.5.4 “ST instruction 'WHILE'” on page 439](#)
- [Chapter 1.3.1.24.1.3.5.2 “ST instruction 'FOR'” on page 437](#)
- [Chapter 1.3.1.24.1.3.5.9 “EXST instruction 'CONTINUE'” on page 441](#)

**ST statement 'RETURN'**

Use the **RETURN** statement in order to exit from a function block. You can make this dependent on a condition, for example.

Example

```plaintext
IF xIsDone = TRUE THEN
  RETURN;
END_IF;

iCounter := iCounter + 1;
```

If the value of `xIsDone` is equal to **TRUE**, then the function block is exited immediately and the statement `iCounter := iCounter + 1;` is not executed.

See also

- [Chapter 1.3.1.24.1.3.5.1 “ST statement 'IF'” on page 436](#)

**ST instruction 'JMP'**

The **JMP** instruction is used to execute an unconditional jump to a program line that is marked by a jump label.

**Syntax:**

```plaintext
<label>: <instructions>
JMP <label>;
```

The jump label `<label>` is any unique identifier that you place at the beginning of a program line. On reaching the **JMP** instruction, a return to the program line with the `<label>` takes place.
Example

iVar1 := 0;
_label1: iVar1 := iVar1+1;
(*instructions*)

IF (iVar1 < 10) THEN
  JMP _label1;
END_IF;

NOTICE!

You must ensure by programming means that no endless loops are caused. For example, you can make the jump conditional.

ST instruction 'EXIT'

The EXIT instruction is used in a FOR, WHILE or REPEAT loop in order to end the loop regardless of other abort conditions.

See also

- § Chapter 1.3.1.24.1.3.5.2 “ST instruction 'FOR'” on page 437
- § Chapter 1.3.1.24.1.3.5.4 “ST instruction 'WHILE'” on page 439
- § Chapter 1.3.1.24.1.3.5.5 “ST instruction 'REPEAT'” on page 439

EXST instruction 'CONTINUE'

CONTINUE is an instruction of the Extended Structured Text (ExST).

The instruction is used inside FOR, WHILE and REPEAT loops in order to jump to the beginning of the next execution of the loop.

Example

FOR Counter:=1 TO 5 BY 1 DO
  INT1:=INT1/2;
  IF INT1=0 THEN
    CONTINUE; (* to provide a division by zero *)
    END_IF
  Var1:=Var1/INT1; (* executed, if INT1 is not 0 *)
END_FOR;

Erg:=Var1;

ST function block call

Syntax

<FB-instance>(<FB input variable>:=<value or address>, <other FB input variables>);
The timer function block **TON** is instanced in **TMR:TON** and called with assignments for the parameters **IN** and **PT**. The output **Q** is addressed with **TMR.Q** and assigned to the variable **varA**.

- Qualifiers for actions in SFC
- Implicit variables
- SFC flags
- Elements

**SFC editor**

The SFC editor is graphical editor. A new SFC POU includes an Init step and a subsequent transition.

In the SFC editor, you can insert individual elements into the diagram by means of commands in the “SFC” menu, the context menu, or the “ToolBox” view.

When inserting by means of a menu command, the elements that can be inserted at the currently selected position are available.

Before inserting branches parallel to multiple actions and transitions, you must highlight these actions and transitions in a multiple selection.

You can also drag SFC elements from the “ToolBox” view to the diagram. When you drag an element over the editor, CODESYS marks all possible insertion points with gray boxes. If you move the mouse over a gray box, then the color of the box changes to green. When you release the mouse button, the object is inserted at that location.
If you drag a branch into the diagram, then you must set the beginning and the end of the branch using the mouse pointer. You set the beginning of the branch by releasing the mouse button at an insertion point. The color of the box then changes to red. You set the end of the branch by clicking the second insertion point. Then CODESYS inserts a branch around the objects between the beginning and end markers.

For copying step and transition elements that call action objects or transition objects, two different duplication modes can be set. Either the references are copied at the same time, or the referenced objects are embedded and duplicated when copying.

You define the look and feel of the editor in the CODESYS options ("SFC Editor").

- "Common functions in graphical editors" on page 429
- "Sequential function chart (SFC)" on page 442
- "Programming the sequential function chart (SFC)" on page 202
- "Dialog 'Options' - 'SFC Editor'" on page 1074

**SFC editor in online mode**

In the SFC editor, you can display the variables and expressions in use on the controller in online mode. You can also write and force variables and expressions. Debugging functions, such as breakpoints and step-by-step execution, are not yet available.

You can set the online display of the SFC elements and attributes in the CODESYS options ("SFC Editor").

If you have declared SFC flags explicitly, then they are displayed in the declaration section in online mode. They are not displayed in offline mode.

*Please note the processing order of elements in an SFC diagram.*

In online mode, CODESYS displays active steps in blue.

Processing order in SFC

Basic element behavior

- Active step: An active step includes actions currently being executed. In online mode, CODESYS displays active steps in blue.
- Initial step: In the first cycle after calling a POU in SFC, the initial step is activated automatically and the step action is executed.
- CODESYS executes IEC actions at least two times: the first time is when the step is activated, and the second time when the step is deactivated (but not until the next cycle).
- Alternative branches: If the step before the branch is active, then CODESYS passes the first transition of each alternative branch line from left to right. CODESYS activates the subsequent step in the first branch line with a transition yielding TRUE.
- Parallel branches: If the step before the branch (horizontal double line) is active and the transition before the branch yields TRUE, then CODESYS activates the first steps in every branch line. The branch lines are then processed at the same time. The step after the end of the branch is activated when every last step in each branch line is active and the transition after the double line yields TRUE.

1. Reset IEC actions
CODESYS resets the internal action control flags of the action qualifiers (N, R, S, L, D, P, SD, DS, SL). These flags control IEC actions. However, flags are not reset when they are called within actions.

2. Execute exit actions
CODESYS verifies whether all steps fulfill the condition for executing the exit action for each step. The order of verification follows the layout in the SFC diagram, from top to bottom and from left to right.
CODESYS executes an exit action when the step is deactivated (after any entry and step actions have been executed in the preceding cycle and the condition for the subsequent step yields TRUE).

3. Execute entry actions
CODESYS verifies whether all steps fulfill the condition for executing the entry action for each step. The order of verification follows the layout in the SFC diagram, from top to bottom and from left to right. If the conditions are fulfilled, then CODESYS executes the entry actions.
CODESYS executes an entry action as soon as the transition of the preceding step has been processed and yields TRUE, thus indicating that the step has been activated.

4. Time check / Execute step actions
CODESYS performs the following check for each step in the order of the SFC layout:
- CODESYS copies the elapsed time of the active step to the respective implicit step variable <step name>.t. (not yet implemented)
- If a timeout occurs, then CODESYS sets the respective error flags. (not yet implemented)
- For non-IEC steps: CODESYS executes the step action.

5. Execute IEC actions
CODESYS executes the IEC actions in alphabetical order, passing through the list of actions two times. In the first pass, CODESYS executes the IEC actions for each step that was deactivated in the preceding cycle. In the second pass, the IEC actions are executed for each active step.
6. Transition check / Activate next steps

The transitions are passed as follows: If a step is active in the current cycle and the subsequent transition yields `TRUE` and any defined minimum time of the step has elapsed, then the subsequent step is activated.

**NOTICE!**

Please note when executing actions:

An action can be executed multiple times within the same cycle if you use it in multiple SFC diagrams. For example, if a sequential function chart includes two IEC actions A and B, both of which are programmed in SFC and call an IEC action C, then the IEC action C is called two times.

If you use the same IEC action at the same time in different levels of an SFC diagram, then this can lead to unpredictable results when processing. For this reason, CODESYS issues a corresponding error message. This error message can appear for projects that have been created in an earlier version of the development system.

Please note: It is possible to use implicit variables to monitor the processing status of steps and actions and to control processing.

See also

- Chapter 1.3.1.24.1.4.5 “Implicit variables” on page 446
- Chapter 1.3.1.24.1.4.4 “Qualifiers for actions in SFC” on page 445

Qualifiers for actions in SFC

You assign qualifiers to IEC steps. Qualifiers describe how a step action is processed.

Qualifiers are processed by the `SFCActionControl` function block in the library `IecSfc.library`. The library is automatically integrated into the project by the SFC plug-in.

<table>
<thead>
<tr>
<th>Qualifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Non-stored</td>
</tr>
<tr>
<td>R0</td>
<td>overriding Reset</td>
</tr>
<tr>
<td>S0</td>
<td>Set (Stored)</td>
</tr>
<tr>
<td>L</td>
<td>time Limited</td>
</tr>
<tr>
<td>D</td>
<td>time Delayed</td>
</tr>
<tr>
<td>P</td>
<td>Pulse</td>
</tr>
<tr>
<td>SD</td>
<td>Stored and time Delayed</td>
</tr>
<tr>
<td>DS</td>
<td>Delayed and Stored</td>
</tr>
<tr>
<td>-----</td>
<td>-------------------</td>
</tr>
<tr>
<td>CODESYS begins executing the action only after the given delay time has elapsed following step activation and the step is still active. The action is executed until it receives a reset.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>SL</th>
<th>Stored and time Limited</th>
</tr>
</thead>
<tbody>
<tr>
<td>CODESYS executes this action as soon as the step is active. The action is executed until the given time has elapsed or it receives a reset.</td>
<td></td>
</tr>
</tbody>
</table>

You must enter the times for the L, D, SD, DS, and SL qualifiers in the format of a TIME constant.

When an IEC action is deactivated, it is executed one more time. This means that CODESYS executes this kind of action at least two times. This also applies to actions with the P qualifier.

See also

- ☞ Chapter 1.3.1.9.3.4.1 “Programming the sequential function chart (SFC)” on page 202

Implicit variables

Every SFC object supplies implicit variables for you to monitor the status of steps and IEC actions at runtime. These implicit variables are declared automatically by CODESYS for each step and each IEC action.

The implicit variables are structure instances of the type `SFCStepType` for steps and type `SFCActionType` for actions. The variables have the same names as their elements, for example "step1" variable name for "step1" step name. The structure members describe the status of a step or action or the currently elapsed time in an active step.

In the element properties, you can define whether CODESYS should export a symbol definition for this flag to the symbol configuration.

See also

- ☞ Chapter 1.3.1.24.1.4.7.6 “SFC element properties” on page 459

**Step and action status**

Syntax for the implicit variable declaration:

```
<step name>:SFCStepType;
_<action name>:SFCActionType;
```

**Table 13: The following implicit variables are available for step or IEC action status:**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;step name&gt;.x</code></td>
<td>Shows the activation status in the current cycle. When <code>&lt;step name&gt;.x</code> = TRUE, CODESYS processes the step in the current cycle.</td>
</tr>
<tr>
<td><code>&lt;step name&gt;._x</code></td>
<td>Shows the activation status for the next cycle. When <code>&lt;step name&gt;._x</code> = TRUE and <code>&lt;step name&gt;.x</code> = FALSE, CODESYS processes the step in the next cycle. This means that <code>&lt;step name&gt;._x</code> is copied to <code>&lt;step name&gt;.x</code> at the beginning of a cycle.</td>
</tr>
</tbody>
</table>
The flag `t` yields the current elapsed time since the step was activated. This applies only to steps, regardless of whether a minimum time has been defined or not in the step properties. Also see SFC flag SFCError.

For internal use only

| IEC action | 
| --- | --- |
| `<action name>._x` | TRUE when the action is being executed. |
| `<action name>._x` | TRUE when the action is active. |

**NOTICE!**

You can use the above variables to force a specific status value to a step (activate a step). However, note that this can cause an unstable status in the SFC.

See also
- Chapter 1.3.1.24.1.4.6 “SFC flags” on page 447

**Access to implicit variables**

Syntax for access:

Assign the implicit variable directly in the POU: `<variable name>:=<step name>..<implicit variable> or <variable name>:=<action name>..<implicit variable>`

**Example**

```plaintext
status:=step1._x;
```

From another POU, with the POU name: `<variable name>:=<POU name>..<step name>..<implicit variable> or <variable name>:=<POU name>..<action name>..<implicit variable>`

**Example**

```plaintext
status:=SFC_prog.step1._x;
```

**Symbol generation**

In the element properties of a step or action, you define whether CODESYS should add a symbol definition for the step or action flag. In the “Properties” view, you have to select the necessary access rights in the “Symbol” column.

See also
- Chapter 1.3.1.24.1.4.7.6 “SFC element properties” on page 459

**SFC flags**

SFC flags are implicitly generated variables with predefined names used for controlling the processing of an SFC diagram. You can use these flags, for example, to display timeouts or reset step chains. In addition, you can activate tip mode specifically to activate transitions. You have to declare and activate these variables in order to have access to them.

**Implicit generation of SFC flags**

CODESYS declares SFC flags automatically when you activate the respective options. You can set this option in the “SFC Settings” tab of the properties dialog box for each POU, or in the “SFC” project settings dialog box for each SFC POU in the project.
The SFC settings for the SFC flags of individual POUs are effective only if you have not selected the "Use defaults" check box. If you select this option, then the settings apply that were defined in the project settings.

SFC flags that you declare in the SFC settings dialog box are visible only in the online view of the SFC block.

See also

- Chapter 1.3.1.25.3.10.13 “Dialog 'Properties' - 'SFC Settings’” on page 1055

Explicit generation of SFC flags

Manual declaration, which was necessary in CoDeSys V2.3, is now only required to enable write access from another block. In this case, you should note that when you declare the flag in a global variable list, you must deactivate its "Declare" setting in the SFC settings dialog box. If you do not do this, then a local SFC flag is implicitly declared that CODESYS uses instead of the global variable.
You have created an SFC block named sfc1, which contains the s1 step. You have defined timeouts in the step properties. (See "Online view of SFC block sfc1" below.)

If for any reason the s1 step remains active longer than its time properties have permitted (timeout), then CODESYS sets the SFCError flag to permit access by the application.

To permit access, you have to declare and activate the SFC flag in the SFC settings. If you have only declared it, then the SFC flag is only displayed in the online view of sfc1 in the declaration section, but it has no function.

Now the SFC flag can be referenced within the POU, for example in an action (2) or outside of the block (1).

Online view of the SFC block sfc1
SFCError is TRUE as long as a timeout occurs within *sfc2*.

### Access to the flags

**Syntax for access**

Within the POU, you assign the flag directly: `<variable name>:=<SFC flag>`

**Example**

```plaintext
checkerror:=SFCerror;
```

**From another block with POU name:** `<variable name>:=<POU-Name>.<SFC flag>`

**Example**

```plaintext
checkerror:=SFC_prog.SFCerror;
```

If you need write access from another block, then you also have to declare the SFC flag explicitly as a VAR_INPUT variable in the SFC block or globally in a GVL.
### Example

Local declaration:

```plaintext
PROGRAM SFC_prog
VAR_INPUT
  SFCinit:BOOL;
END_VAR

Global declaration in a global variable list:

```plaintext
VAR_GLOBAL
  SFCinit:BOOL;
END_VAR

PROGRAM PLC_PRG
VAR
  setinit: BOOL;
END_VAR
```

```plaintext
SFC_prog.SFCinit:=setinit;  // write access to SFCinit in SFC_prog
```

### SFC flags

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SFCInit</td>
<td>BOOL</td>
<td>TRUE: CODESYS resets the sequence to the initial step. The other SFC flags are also reset (initialization). While the variable is TRUE, the initial step remains set (active), but its actions are not executed. Only when you reset SFCInit to FALSE does the block processing continue.</td>
</tr>
<tr>
<td>SFCReset</td>
<td>BOOL</td>
<td>This functions similar to SFCInit. However, CODESYS continues processing after the initialization of the initial step. For example, in the initial step, you could immediately reset the SFCReset flag to FALSE.</td>
</tr>
<tr>
<td>SFCError</td>
<td>BOOL</td>
<td>TRUE if a timeout occurs in an SFC diagram. If second timeout occurs in the program, it is not registered unless you previously reset the variable SFCError. The declaration of SFCError is a requirement for other flag variables to function for controlling the chronological sequence (“SFCErrorStep”, SFCErrorPOU, SFCQuitError).</td>
</tr>
<tr>
<td>SFCEnableLimit</td>
<td>BOOL</td>
<td>Used specifically for activating (TRUE) and deactivating (FALSE) the timeout control in steps using SFCError. If you declare and activate this variable (SFC settings), then you must set it to TRUE for SFCError to work. If you do not, then the timeouts are ignored. This is useful, for example, at start-up or in manual operation. If you do not declare the variable, then SFCError will work automatically. The requirement is the declaration of SFCError.</td>
</tr>
<tr>
<td>SFCErrorStep</td>
<td>String</td>
<td>Stores the name of the step that caused a timeout, which was registered by SFCError. The requirement is the declaration of SFCError.</td>
</tr>
<tr>
<td>SFCErrorPOU</td>
<td>String</td>
<td>Stores the name of the block in which a timeout occurred and was registered by SFCError. The requirement is the declaration of SFCError.</td>
</tr>
<tr>
<td>SFCQuitError</td>
<td>BOOL</td>
<td>As long as this boolean variable is TRUE, CODESYS pauses the processing of the SFC diagram and any timeout in the variable SFCError is reset. If you reset the variable to FALSE, then all previous times in the active steps are reset. The requirement is the declaration of SFCError.</td>
</tr>
<tr>
<td>SFCPause</td>
<td>BOOL</td>
<td>As long as this variable is TRUE, CODESYS pauses the processing of the SFC diagram.</td>
</tr>
<tr>
<td>SFCTrans</td>
<td>BOOL</td>
<td>TRUE if a transition is active.</td>
</tr>
</tbody>
</table>
### Name | Data Type | Description
--- | --- | ---
SFCCurrentStep | String | Shows the name of the active step, regardless of the time monitoring. In parallel branches, the name of the step of the rightmost branch line is always stored.  
SFCTip, SFCTipMode | BOOL | Controls the tip mode of the SFC block. If you enable this flag with SFCTipMode=TRUE, then you can activate the next step only by setting SFCTip to TRUE. While SFCTipMode is set to FALSE, transitions can also be used to continue activation.

**Elements**

1.3.1.24.1.4.7.1 SFC elements 'Step' and 'Transition' .................................................. 452  
1.3.1.24.1.4.7.2 SFC element 'Action' .............................................................................. 454  
1.3.1.24.1.4.7.3 SFC element 'Branch' ............................................................................... 457

1.3.1.24.1.4.7.5 SFC element 'Macro' ................................................................................ 458  
1.3.1.24.1.4.7.6 SFC element properties .......................................................................... 459

**SFC elements 'Step' and 'Transition'**

As a rule, CODESYS inserts steps and transitions as combinations. Inserting a step without a transition or a transition without a step causes an error when compiling. You can modify this by double-clicking the name.

![Step symbol; Transition symbol](image)

**NOTICE!**

Step names must be unique within the scope of the parent block. Consider this especially when using actions that were also programmed in SFC.

Please note that you can convert a step into an initial step by clicking "Init step" or by setting the respective property in the SFC properties.

All steps are defined by the step properties, which you can display and edit in the "Properties" view, depending on the set options.

You have to add those actions to the step which are to be executed when the step is active. A distinction is made between IEC actions and step actions. Details for this are found in the chapter about the SFC element "Action".

A transition must include the condition for the subsequent step to be active as soon as the value of the condition yields TRUE. Therefore, a transition condition must yield TRUE or FALSE. It can be defined in one of two ways:

- **(1) Inline condition (direct):** You replace the default transition name with either the name of a Boolean variable, a Boolean address, a Boolean constant, or a statement with a Boolean result, for example (i<100) AND b. You cannot specify programs, function blocks, or assignments here.

- **(2) Multi-use condition (separate transition or property object):** You replace the default transition name with the name of a transition or property object (condition). You create these objects by clicking "Project ➔ Add Object". This allows multiple use of transitions, for example "condition_xy" in the figures below. Like an inline condition, the object can contain a Boolean variable, Boolean address, Boolean constant, or an statement with a Boolean result. In addition, it can also contain multiple statements with any code.
**NOTICE!**

The user is responsible for assigning the required expression to a transition variable if the transition includes multiple instructions.

Transitions that reference a transition or property object are marked with a small triangle in the upper right corner of the transition box.

As opposed to CoDeSys V2.3, now CODESYS treats a transition condition like a method call. The entry has the following syntax:

```
<transition name>::=<transition condition>
```
You will find an example (condition_xy) in the figure above.

**SFC element ‘Action’**

Symbol: 

An action includes one or more statements in one of the valid implementation languages. You can assign an action to a step.

Actions that you use in SFC steps must be created as POUs in the project.

Exception: In the case of IEC actions, which you add to a step as action association, you can also specify a Boolean variable instead of an action object. The value of these variables is switched between FALSE and TRUE each time the "action" is executed.

**NOTICE!**

You must define unique step names within the scope of the parent block. An action written in SFC cannot contain a step with a name identical to the step to which the action is assigned.

A distinction is made between IEC actions and step actions:

1. **IEC actions**

IEC actions comply with the IEC1131-3 standard. They are executed according to their qualifiers.

IEC actions are executed two times: first when the step is activated and second when the step is deactivated. If you assign multiple actions to one step, then the action list is processed from top to bottom.

Each action box includes the qualifier in the first column and the action name in the second column, both of which can be edited directly.
NOTICE!
If the same global Boolean variable is associated as an IEC action in different SFC blocks, then this can result in undesired overwriting effects.

In contrast to step actions, you can use different qualifiers for IEC actions. Moreover, each IEC action is provided with a control flag. This directs CODESYS to execute an action only one time at any moment, even if the action is called by another step at the same time. This cannot be guaranteed for step actions.

You assign IEC actions to steps by clicking “SFC ➔ Insert Action Association”.

See also
- ⇐ Chapter 1.3.1.25.2.11.14 “Command ’Insert Action Association’” on page 972
- ⇐ Chapter 1.3.1.24.1.4.4 “Qualifiers for actions in SFC” on page 445

2. Step actions
You can use these step actions to extend the IEC standard.

- **Entry action:**
  CODESYS executes this action after the step is activated and before the main action is executed.
  You reference a new action, or an action created below the SFC object, from a step by means of the “Entry action” element property (2). You can also add a new action to the step by means of the “Add Entry Action” command. The entry action is marked with an ⧫ in the lower left corner of the step box.

- **Main action:**
  CODESYS executes this action when the step is active and any entry actions have already been processed. However, in contrast to IEC actions (see above), these step actions are not executed a second time when the step is deactivated. Moreover, you cannot use qualifiers here.
  You add an existing action to a step by means of the “Main action” element property (1). You can create and add a new action by clicking the step element. A main action is marked with a filled triangle in the upper right corner of the step box.

- **Exit action:**
  CODESYS executes this action one time when the step is deactivated. Please note, however, that an exit action is not executed in the same cycle, but at the beginning of the next cycle.
  You reference a new action, or an action created below the SFC object, from a step by means of the “Exit action” element property (3). You can also add a new action to the step by means of the “Add Exit Action” command. The exit action is marked with an ✗ in the lower right corner of the step box.
The main difference between step actions and IEC actions with a qualifier N is that an IEC action is always executed two times: when the step is activated and when the step is deactivated. See the following example:

You have attached the Action_AS1 action to the AS1 step as a step action (left) and as an IEC action with qualifier N (right). Because two transitions are activated in each case, the time to reach the initial step again is two PLC cycles. This is true as long as the iCounter counter variable was initialized at 0 and then incremented in the Action_AS1 action. After the Init step is reactivated, iCounter returns a value of 1 in the example on the left. In the example on the right, a value of 2 is returned because the IEC action is executed a second time due to the deactivation of AS1.

Another difference is that step actions can be pseudo-embedded. In this case, they can be called only from the related step. If you copy this step, CODESYS creates new action objects automatically and copies the respective implementation code. You define whether or not a step action is embedded, either when the first action is inserted into the step, or later in the "Duplicate when copying" element property. In general, this behavior can also be preset in the SFC options.

Finally, for IEC actions a Boolean variable can be specified instead of an action object. This is not possible for step actions.
SFC element 'Branch'

Symbol

Use branches to program parallel or alternative sequences in the sequential function chart.

For alternative branches, CODESYS processes just one of the branch lines at a time, depending on the preceding transition condition. Parallel branches are processed at the same time.

See also
●  Chapter 1.3.1.24.1.4.3 “Processing order in SFC” on page 444
●  Chapter 1.3.1.9.3.4.1 “Programming the sequential function chart (SFC)” on page 202
●  Chapter 1.3.1.25.2.11.13 “Command ‘Insert Branch Right’” on page 971

Parallel branch

For parallel branches, the branch lines must begin and end with steps. Parallel branch lines can contain additional branches.

The horizontal lines before and after the branch are double lines.

Processing in online mode: If the preceding transition (t2 in the example) yields TRUE, then the first steps in all parallel branch lines are active (Step11 and Step21). CODESYS processes the individual branch lines at the same time and the subsequent transition is passed afterwards (t3).

The "Branch<n>" jump marker is added automatically to the horizontal line that indicates the beginning of a branch. You can define this marker as the jump destination.

Please note that you can convert a parallel branch into an alternative branch by clicking "Alternative".

See also
●  Chapter 1.3.1.25.2.11.11 “Command ‘Alternative’” on page 971

Alternative branch

The horizontal line before and after the branch is a single line.

In an alternative branch, the branch lines must begin and end with transitions. The branch lines can contain additional branches.
If the step before the branch is active, then CODESYS passes the first transition of each alternative branch line from left to right. For the first transition that yields **TRUE**, the associated branch line opens, thus activating the step following the transition.

Please note that you can convert an alternative branch into a parallel branch by clicking "Parallel".

See also

- § Chapter 1.3.1.25.2.11.10 “Command 'Parallel'” on page 970

**SFC element 'Jump'**

Symbol $
$  

Use a jump to define which actions in a step should be executed next as soon as the transition preceding the jump is **TRUE**. Jumps may become necessary, as execution paths cannot cross or lead upwards.

Excluding the required jump at the end of a diagram, you can generally insert jumps only at the end of a branch.

The destination of a jump is defined by the added text string, which you can edit directly. The jump destination can be a step name or the marker for a parallel branch.

**SFC element 'Macro'**

Symbol $
$
A macro includes part of the SFC diagram, but it is not displayed in detail in the main view of the editor.

Using macros does not influence the processing flow. Macros are used for hiding specific parts of the diagram, for example to increase overall clarity.

You open the macro editor by double-clicking the macro box or by clicking “SFC ➔ Zoom Into Macro”. You can program here just like in the main view of the SFC editor. To close the macro editor, click “SFC ➔ Zoom Out of Macro”.

Macros can also include other macros. The caption of the macro editor always shows the path of the open macro within the diagram, for example:

```
Macro1 ➔ Macro2
```

- % Chapter 1.3.1.25.2.11.21 “Command ’Zoom Out of Macro’” on page 974

**SFC element properties**

You edit the properties of an SFC element in the “Properties” view. Click “View ➔ Element Properties” to open this view. The properties to be displayed depend on the currently selected element.
The properties that are displayed in the SFC diagram next to the element depend on the settings in the “View” tab of the SFC editor options.

### General

<table>
<thead>
<tr>
<th>Property</th>
<th>Value description</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Name”</td>
<td>Element name, by default &quot;&lt;element&gt;&lt;consecutive number&gt;&quot;, for example step name &quot;Step0&quot;, &quot;Step1&quot;, branch name &quot;Branch0&quot;, etc.</td>
</tr>
<tr>
<td>“Comment”</td>
<td>Element comment in text, for example “counter reset”. You can insert line breaks by pressing [Ctrl]+[Enter].</td>
</tr>
</tbody>
</table>
| “Symbol” | For each SFC element, CODESYS declares an implicit variable with the same name as the element. The configuration determines whether this flag variable should be exported to the symbol configuration and which access rights for the symbol should be applied in the PLC.  
  - “No access”: The symbol is exported to the symbol configuration but cannot be accessed from the PLC.  
  - “Read”: The symbol is exported to the symbol configuration and can be read from the PLC.  
  - “Write”: The symbol is exported to the symbol configuration and can be written from the PLC.  
  - “Read/Write”: Combination of read and write.  
  - Empty: A symbol is not exported to the symbol configuration. |

### Specific

<table>
<thead>
<tr>
<th>Property</th>
<th>Value description</th>
</tr>
</thead>
</table>
| “Init step”            | [✔]: This option is activated only for the defined initial step. By default, this is the first step in an SFC diagram.  
  Note: If you activate this property for another step, then it must be deactivated in the previous step to prevent compilation errors. |
| “Duplicate when copying”| [✔]: When copying the step or transition, a new object is created for each called action or transition. It contains a copy of the implementation code of the copied object.  
  [☐]: When copying a step or transition, the link to the called object is retained for the respective action or transition. No new objects are generated. The source and the copies of the step or transition call the same action or transition. |
**Property** | **Value description**
---|---
"Times" | Minimum time that the step is active, even when the subsequent transition is TRUE.
  ● "Minimum active" | Maximum time that the step can be active. If this time is exceeded, then CODESYS sets the \texttt{SFCError} implicit variable to TRUE.
  ● "Maximum active" | Times according to IEC syntax (for example t#8s) or the \texttt{TIME} variable; default: t#0s.

"Actions" | \textbf{● "Entry action"}: CODESYS executes these actions after activating the step.
  ● "Step action" | \textbf{● "Step action"}: CODESYS executes this action when the step is active and any entry actions have already been processed.
  ● "Exit action" | \textbf{● "Exit action"}: CODESYS executes this action in the subsequent cycle when the step is deactivated.

**When using the respective implicit SFC variables and flags, you receive information about the status of a step or an action or about timeouts.**

1.3.1.24.1.5.4 Elements........................................................................ 470

**FBD/LD/IL editor**

The FBD/LD/IL editor is a combined editor of the programming languages FBD, LD and IL.

*If necessary, IL can be activated in the CODESYS options.*

There is a common set of commands and elements and CODESYS automatically converts the 3 programming languages into one another internally.

The code in the implementation part is structured in all three languages with the aid of networks.

The "FBD/LD/IL" menu provides the commands for working in the editor.

In offline and online modes, you can switch editors at any time by using the menu command in "View".

The behavior of the FBD/LD/IL editor is defined by the settings in "Tools ‣ Options" (category "FBD, LD and IL").
NOTICE!
There are some special elements that CODESYS cannot convert and thus it displays only in the applicable language. There are also constructs that are not clearly convertible between IL and FBD and are therefore ‘normalized’, i.e. nullified, when converted back to FBD. This concerns: negation of expressions and explicit/implicit assignment of function block inputs and outputs.

An error-free conversion between the languages requires syntactically correct code. Otherwise parts of the implementation can be lost.

### FBD and LD editor

**Inserting and arranging elements**

You can drag elements with the mouse from the view “Tools” (toolbox) into the implementation part of the editor. Alternatively you can use the commands of the context menu or the “FBD/LD/IL” menu.

Settings for the display and interface are defined in the CODESYS options, category “FBD/LD/IL”.

If you drag an element with the mouse over a network in the editor, all possible insertion positions are displayed with gray diamond-shaped, triangular or arrow-shaped position marks. As soon as the mouse pointer is located over one of these marks, the mark turns green. If the mouse button is now released, CODESYS inserts the element at this position.

![Example](image)

If you drag a function block or an operator from the toolbox or a network at the left-hand side of the network onto one of the two arrows, then CODESYS automatically creates a new network and inserts the element there.

In order to replace an element, drag a suitable other element onto its position with the mouse. Elements that you can replace by the new element are marked by CODESYS in the editor with text fields, for example “Replace”, “Attach input”.

You can use the usual commands in the menu “Edit” for cutting, copying, pasting and deleting elements. Copying also works with drag-and-drop by holding down the [Ctrl] key.

**NOTICE!**
The operators with EN/ENO functionality can only be inserted in the FBD and IL editors.

### Selecting elements

A box or a connecting line in the editor is selected by clicking on it with the mouse so that it has the focus. Multiple selection is possible by keeping the [Ctrl] key pressed. A selected element is shaded red.

**Tooltip**
If the cursor points to certain elements, for example to a variable or to an input, a tooltip appears showing information about this element.

In the case of elements underlined with a wavy red line, the tooltip shows the pre-compile error message of the error that occurs with this element.

**Navigating in the editor**

<table>
<thead>
<tr>
<th>Table 14: Navigating in the editor</th>
</tr>
</thead>
<tbody>
<tr>
<td>With the help of the keys and commands described below, you can place the focus within the editor on a different cursor position. The change between the positions is also network-spanning in function.</td>
</tr>
<tr>
<td>[←]</td>
</tr>
<tr>
<td>[→]</td>
</tr>
<tr>
<td>[↑][↓]</td>
</tr>
<tr>
<td>[Ctrl] + [Home]</td>
</tr>
<tr>
<td>[Ctrl] + [End]</td>
</tr>
<tr>
<td>[Page Up]</td>
</tr>
<tr>
<td>[Page Down]</td>
</tr>
<tr>
<td>Command “Go to…”</td>
</tr>
</tbody>
</table>

**Opening function blocks**

If a function block is inserted in the editor, then you can open its implementation by a double-click or with the context menu command “Browse for symbol ➔ Go to definition”.

**IL editor**

**Inserting and arranging elements:**

You can insert elements with the help of the commands of the menu “FBD/LD/IL” in the context menu. You can also drag a new network from the tool box into the implementation part of the editor by drag-and-drop.

You can use the usual commands in the menu “Edit” for cutting, copying, pasting and deleting elements. Copying also works with drag-and-drop by holding down the [Ctrl] key.

**NOTICE!**

Please note that operators with EN/ENO functionality can only be inserted in the FBD and IL editors.
Each program line is entered in a table row.

**Table 15: Structure of networks in the IL editor**

<table>
<thead>
<tr>
<th>Column</th>

### FBD/LD/IL editor in online mode

In online mode the current value of each variable is displayed behind the variable in the editor. Writing/forcing and the setting of breakpoints is possible.

If the variable is presently forced, this is indicated directly in front of the forced value by $\mathbf{\text{F}}$. If a value has been prepared for writing or forcing, this value is displayed directly behind the current value in square brackets $\langle \text{value}\rangle$.

#### Example

**Forced variable:**

$B\text{Var1} \mathbf{\text{F}} \langle \text{TRUE} \rangle$

**Prepared value**

$i\text{Var1} \langle 0<12> \rangle$

In the online view of a ladder diagram (LD) the connecting lines are marked in color: connections with the value $\text{TRUE}$ are displayed as a thick blue line, connections with the value $\text{FALSE}$ as a thick black line. Conversely, connections with an unknown or analog value are displayed normally (thin black line).

![NOTICE!](image)

Note that values of the connections are calculated from the monitored variables. This is not a genuine flow control.

### Breakpoints
Possible positions for breakpoints are in principle the positions at which values of variables can change (instructions), at which the program branches or at which another box is called.

Possible breakpoint positions:
- On the entire network: causes the breakpoint to be set at the first possible position in the network.
- On a box, if the box contains an assignment. Not possible with operator boxes, for example ADD, DIV.
- On assignments.
- At the end of the box at the position of the return to the calling box. In online mode an empty network automatically appears here; it is marked by 'RET' in place of a network number.

**NOTICE!**
At present you cannot directly set a breakpoint on the first box in the network. However, if you set a breakpoint on the entire network, this breakpoint marking is transferred automatically to the first box in online mode.

**NOTICE!**
Breakpoints in methods: CODESYS automatically sets a breakpoint in all methods that can be called. Therefore, if a method managed by an interface is called, breakpoints are set in all methods that occur in function blocks that implement this interface as well as in all derived function blocks that use the method. If a method is called by a pointer to a function block, CODESYS sets the breakpoints in the method of the function block and in all derived function blocks that use the method.

<thead>
<tr>
<th>Several operands for 1 operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Options</td>
</tr>
<tr>
<td>- You enter the operands into consecutive rows, separated by commas in the 2nd column.</td>
</tr>
<tr>
<td>- You repeat the operator in consecutive rows.</td>
</tr>
</tbody>
</table>

### Description

- **Variant 1:**
  - LD 2
  - ADD 3, 4, 6
  - ST 1VAR

- **Variant 2:**
  - LD 2
  - ADD 3
  - ADD 4
  - ADD 6
  - ST 1VAR

### Examples

<table>
<thead>
<tr>
<th>Complex operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>For a complex operand, you enter the opening parenthesis ( in the first column. You enter the closing parenthesis in the first column in a separate row following the operand entries of the following rows.</td>
</tr>
<tr>
<td>A string is rotated by a character each cycle:</td>
</tr>
<tr>
<td>LD stRotate</td>
</tr>
<tr>
<td>RIGHT (stRotate</td>
</tr>
<tr>
<td>LEN 1</td>
</tr>
<tr>
<td>)</td>
</tr>
<tr>
<td>CONCAT (stRotate</td>
</tr>
<tr>
<td>LEFT 1</td>
</tr>
<tr>
<td>)</td>
</tr>
<tr>
<td>ST stRotate</td>
</tr>
<tr>
<td>Application</td>
</tr>
<tr>
<td>-----------------------------</td>
</tr>
</tbody>
</table>
| Function block call, program call | Column 1: Operator `CAL` or `CALC`  
Column 2: Name of the function block instance or the program and opening parenthesis ( . If no parameters follow, the closing parenthesis ) is entered here.  
Rows following that:  
Column 1: parameter name followed by `:=` for input parameter or `=>` for output parameter  
Column 2: parameter value followed by a comma , if further parameters follow. The closing parenthesis ) is input after the last parameter.  
As a limitation according to the IEC standard, complex expressions cannot be used here. You must assign such constructs to the function block or the program before the call. | ![Example](image) |
| Function Call               | Row 1: Column 1: `LD`  
Column 2: input variable  
Row 2: Column 1: Function name Column 2: further input parameters separated by commas.  
CODESYS writes the return value into the accumulator.  
Row 3: Column 1: `ST` Column 2: variable into which the return value is written | ![Example](image) |
| Action call                 | Like function block call or program call.  
The action name is appended to the name of the FB instance or the program.                                                                                                                                     | ![Example](image) |
### Jump

## FBD/LD/IL element 'Network'

**Symbol: **

A network is the base unit of an FBD or LD program. In the FBD/LD/IL editor, the networks are arranged in a list. Each network is provided with a sequential network number on the left side and can include: logical and arithmetic expressions, program/function/function block calls, jumps, or return statements.

An IL program consists of at least one network. This network can include all IL statements of the program.

You can provide each network with a title, comment, or label. In the CODESYS options (category "FBD, LD, and IL", you can define whether network title, comment, and separator between individual networks are displayed in the editor.

Click the first line of the network to enter a network title. Click the second line of the network to enter a network comment.
FBD/LD/IL element 'Box'

Symbol: ☐

A box and its call can represent additional functions, for example IEC function blocks, IEC functions, library function blocks, operators.

A box can have any number of inputs and outputs.

If the box also provides an image file, the box icon is displayed inside the box. The requirement is that the option “Show box symbol” is activated in the CODESYS options, category "FBD, LD and IL".

If you have changed the box interfaces, you can update the box parameters with the command “FBD/LD/IL Update Parameters” without having to re-insert the box.

See also

- Chapter 1.3.1.25.2.13.38 “Command ‘Update Parameters’” on page 1002

FBD/LD/IL element 'Assignment'

Symbol: ☐

The FBD editor shows a newly inserted assignment as a line with 3 question marks after it. The LD editor shows a newly inserted assignment as a coil with 3 question marks located above it.

After insertion you can replace the placeholder ??? by the name of the variable to which the signal coming from the left is to be assigned. The input assistant is available to you for this.

In IL an assignment is programmed via the operators LD and ST.

FBD/LD/IL element 'Box with EN/ENO'

Symbol: ☐

The element is available only in the FBD and LD editors.

The box generally corresponds to the FBD/LD/IL element “Box”; however, this box additionally contains an EN input and an ENO output. EN and ENO have the data type BOOL.

Function of the EN input and ENO output: if the input EN has the value FALSE at the time of the calling the box, the operations defined in the box are not executed. Otherwise, i.e. if EN has the value TRUE, these operations are executed. The ENO output has the same value as the EN input.

See also

- Chapter 1.3.1.25.2.13.6 “Command ‘Insert Box with EN/ENO’” on page 994
- Chapter 1.3.1.24.1.5.4.2 “FBD/LD/IL element ‘Box’” on page 471
FBD/LD/IL element 'Input'

Symbol: "44"

The maximum number of inputs depends on the type of box.

A newly added input is first marked with "??". You can replace the string "??" by a variable or a constant.

See also
- Chapter 1.3.1.25.2.13.13 “Command 'Insert Input’' on page 995
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

FBD/LD/IL element 'Label'

The label is an optional identifier for a network in FBD and LD, which you can specify as a destination for a jump.

If you insert a jump label in a network, it will be added as an editable field “Label:” in the network.

See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.25.2.13.11 “Command 'Insert Label’' on page 995

FBD/LD/IL element 'Jump'

Symbol →

In FBD or LD a jump is inserted either directly before an input, directly after an output or at the end of the network, depending on the current cursor position.

You enter a jump label as the jump destination directly behind the jump element.

In IL you program a jump with the instruction JMP.

See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.25.2.13.10 “Command 'Insert Jump’' on page 995
- Chapter 1.3.1.24.1.5.4.6 “FBD/LD/IL element 'Label’' on page 472

FBD/LD/IL element 'Return'

This element immediately interrupts the execution of the box if the input of the RETURN element goes TRUE.

In an FBD or LD network you can place the Return instruction parallel to or after the preceding elements.

In IL the RET instruction is available to you for this purpose.

See also
- Chapter 1.3.1.25.2.13.12 “Command 'Insert Return’' on page 995
- Chapter 1.3.1.24.1.5.3 “Modifiers and operators in IL” on page 466

FBD/LD/IL element 'Branch'

Symbol: 〒
The element is available in the LD and FBD editor and represents an open line branch. A line branch splits the processing line from the current cursor position onwards into 2 subnetworks, which are executed in succession from top to bottom. You can branch each subnetwork further, as a result of which multiple branches are created within a network.

Each subnetwork is given a marker symbol (rectangle) at the branch point, which you can select in order to execute further commands.

- The commands “Copy”, “Cut” and “Paste” are not available for subnetworks.

In order to delete a subnetwork, you must first delete all elements of the network and then the marker symbol of the subnetwork.

See also
- Chapter 1.3.1.25.2.13.33 “Command 'Insert Branch’” on page 1001
- Chapter 1.3.1.25.2.13.34 “Command 'Insert Branch Above’” on page 1001
- Chapter 1.3.1.25.2.13.35 “Command 'Insert Branch Below’” on page 1001

**FBD/LD/IL element 'Execute'**

Symbol: 

The element is a box that enables you to directly enter ST code in the FBD and LD editors. You can drag the “Execute” element with the mouse from the “Tools” view into the implementation part of your POU. If you click on “Enter ST code here...”, an input field opens where you can input multiple-line ST code.

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

**LD element 'Contact'**

Symbol: 

The element is available only in the LD editor.
A contact passes on the signal TRUE (ON) or FALSE (OFF) from left to right until the signal finally reaches a coil in the right-hand part of the network. For this purpose a boolean variable containing the signal is assigned to the contact. To do this, replace the placeholder ??? above the contact with the name of a boolean variable.

You can arrange several contacts both in series and in parallel. In the case of two parallel contacts, only one needs to obtain the value TRUE in order for ON to be passed on to the right. If contacts are connected in series, all of them must obtain the value TRUE in order for ON to be passed on to the right by the last contact in the series. Hence, you can program electrical parallel and series connections with LD.

A negated contact forwards the signal TRUE if the variable value is FALSE. You can negate an inserted contact with the help of the command “FBD/LD/IL → Negation” or insert a negated contact from the “Tools” view.

If you place the mouse pointer on a contact with the left mouse button pressed and with a network selected, the button “Convert to coil” appears in the network. If you now move the mouse pointer onto this button, still with the mouse button pressed, and then release the mouse button over this button, CODESYS converts the contact into a coil.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

LD element ‘Coil’

Symbol: in the editor

The element is available only in the LD editor.

A coil adopts the value supplied from the left and saves it in the boolean variable assigned to the coil. Its input can have the value TRUE (ON) or FALSE (OFF).

Several coils in a network can only be arranged in parallel.

In a negated coil the negated value of the incoming signal is stored in the boolean variable that is assigned to the coil.

Set coil, Reset coil

Symbol: , in the editor

Set coil: If the value TRUE arrives at a set coil, the coil retains the value TRUE. As long as the application is running, the value can no longer be overwritten here.

Reset coil: If the value TRUE arrives at a reset coil, the coil retains the value FALSE. As long as the application is running, the value can no longer be overwritten here.

You can define an inserted coil as a set or reset coil with the help of the command “FBD/LD/IL → Set/Reset” or insert it as an element “Set Coil” and “Reset Coil” from the “Tools” view.

See also

- Chapter 1.3.1.25.2.13.14 “Command ‘Insert Coil’” on page 996
- Chapter 1.3.1.25.2.13.16 “Command ‘Insert Reset Coil’” on page 996

- Chapter 1.3.1.25.2.13.31 “Command ‘Set/Reset’” on page 1000

LD element ‘Branch Start/End’

Symbol: →
The element serves the closed line branch.

See also

- Chapter 1.3.1.24.1.5.4.14 “Closed branch” on page 475
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.25.2.13.36 “Command 'Set Branch Start Point'” on page 1001
- Chapter 1.3.1.25.2.13.37 “Command 'Set Branch End Point'” on page 1002

Closed branch

A closed branch is available in LD only, and it contains a starting point and an end point. It is used for implementing parallel analyses of logical elements.

Inserting a closed branch

- Command “FBD/LD/IL ➔ Insert Contact Parallel (Below) ”
- Command “FBD/LD/IL ➔ Insert Contact Parallel (Above) ”
- Command “FBD/LD/IL ➔ Set Branch Start/End Point”

Closed branch at a contact

When you select one or more contacts and then execute the command “Insert Contact in Parallel”, a parallel branch is added with a single vertical line. For this kind of branching, the signal flow passes through both branches. This is an OR construct of both branches.

Closed branch at a block, OR evaluation, or short-circuit evaluation

New: When you select a box and execute the command “Insert Contact in Parallel”, a parallel branch is inserted with a double vertical line. This indicates that a short-circuit evaluation (SCE) is implemented. SCE allows for the execution of a function block with a Boolean output to be bypassed if a specific condition is TRUE. The condition can be displayed in the LD editor as a branch connected parallel to the function block branch. The short circuit condition is defined by one or more contacts in this branch that are interconnected parallel or sequentially.

Functional principle:

The branches that do not include the function block are processed first. If CODESYS detects the value TRUE for one of these branches, then the function block is not called in the parallel branch. In this case, the value at the input of the function block is sent directly to the output. If CODESYS determines FALSE for the SCE condition, then the box will be called and the Boolean result of its processing is passed on. If all branches contain function blocks, they are analyzed from top to bottom and their outputs are logically ORed. If there are no branches with function blocks, normal OR operations are performed.
The function block instance \( x_1 \) (TON) has a Boolean input and a Boolean output. The execution of \( x_1 \) is skipped if TRUE is determined for the condition in the parallel line branch. The condition value results from the OR and AND operations that connect contacts \( \text{cond1}, \text{cond2} \) and \( \text{cond3} \).

\( x_1 \) is executed if the condition value from the connection of the contacts \( \text{cond1}, \text{cond2} \) and \( \text{cond3} \) is FALSE.

\[ \begin{align*}
\text{P_IN} & := b_1 \text{ AND } b_2; \\
\text{IF} \ ((\text{P_IN AND cond1}) \text{ AND } (\text{cond2 OR cond3})) \text{ THEN} & \quad \text{P_OUT} := \text{P_IN}; \\
\text{ELSE} & \quad \text{x1(IN := P_IN, PT := {p 10}t\#2s);} \\
& \quad \text{tElapsed := x1.ET;} \\
& \quad \text{P_OUT := x1.Q;} \\
\text{END_IF} & \\
\text{bRes} & := \text{P_OUT AND b3;}
\end{align*} \]

From an external point of view, a function block diagram consists of inputs and outputs, with data being processed between them. From an internal point of view, a function block diagram consists of POUs and their connections which represent data (signals) and act as assignment operators in ST. The overall behavior is composed of the behavior of the inserted POUs which call other POUs or library POUs.

Code in the "Continuous Function Chart (CFC)" implementation language mainly illustrates the data flow through the system. Therefore, a continuous function chart is also referred to as a "signal flow chart".

In the page-oriented CFC editor, you can wire POUs to each other and create well-structured function block diagrams distributed over multiple pages. The page-oriented editor behaves like the CFC editor, but provides the following functionality:

The page-oriented editor behaves like the CFC editor, but provides additional functionality. The editor supports you with the following functions:

- Creating pages
- Setting the page size
- Copying and inserting pages in the page navigator
- Copying the implementation of a POU in the CFC implementation language and inserting into a page
- Well-structured and space-saving arranging of inputs, outputs, and connection marks in the border areas
- Connection over pages with connection marks

CFC editor

Configuring the editor

You can configure the appearance, behavior, and printing for the entire project in the CODESYS options in the “CFC Editor” category. For example, on the “View” tab, you can configure the color of the connecting lines depending on the data type.

Editing

| Cursor symbol: ✈️  | Requirement: "Pointer" is selected in the “ToolBox” view. The symbol indicates that you can edit in the editor. Select elements or connections to move them or to execute commands. |
| Cursor symbol: ➔  | Requirement: An element is selected in the “ToolBox” view. Clicking in the editor inserts the selected element. You can also drag an element to the editor. |
| Dragging a function block instance from the declaration in the editor | Requirement: A line is selected in the declaration of the CFC. The instance is inserted as a POU with name, type, and all pins. |
| Dragging a variable from the declaration to a POU pin in the editor | The variable is inserted as an input or output with a connection to the POU pin in focus. Hint: The cursor indicates when your focused location is valid for a variable: |
**[Ctrl] + click in the programming area**

Requirement: An element is selected in the “ToolBox” view.
As long as you hold down the [Ctrl] key, a selected element is created each time you click in the programming area.

**[Ctrl]+[Right Arrow]**

Requirement: In the CFC program, **exactly** one output pin is selected for an element.
The selection is moved so that the input pin at the end of the connecting line is selected. In the case of multiple pins, all are selected.

![Diagram](image1.png)

**[Ctrl]+[Left Arrow]**

Requirement: In the CFC program, **exactly** one input pin is selected for an element.
The selection is moved so that the output pin at the beginning of the connecting line is selected. In the case of multiple pins, all are selected.

Example:

![Diagram](image2.png)

## Connecting

You can insert connecting lines between element connections. Connecting lines are inserted by means of auto-routing so that connecting lines are automatically optimal and as short as possible. The connecting lines are checked for collisions.

<table>
<thead>
<tr>
<th>Dragging a pin to another</th>
<th>A connecting line is inserted between the two element pins.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command “Connect Selected Pins”</td>
<td>Requirement: Multiple pins are selected. The pins are marked in red.</td>
</tr>
</tbody>
</table>
Move an inserted element so that it touches the pin of another element.

Requirement: The “Enable AutoConnect” option is selected. The touching pins are connected automatically.

The connection icon is located in the upper right corner of the editor. A green icon indicates collision-free connections. A red icon indicates collisions. Clicking the icon opens a menu with commands for collision processing, for example the “Show Next Collision” command.

Requirement: A connection is selected and the “Connection Mark” command is executed. Instead of a long connecting line, a connection is represented by connection marks.

- "Chapter 1.3.1.25.2.12.22 “Command ‘Show Next Collision’” on page 986"

Commands when editing
See also
- "Chapter 1.3.1.25.2.12 “Menu ‘CFC’” on page 977"

See also
- "Chapter 1.3.1.24.1.2 “Common functions in graphical editors” on page 429"
- "Chapter 1.3.1.9.3.2.2 “Programming in the CFC editor” on page 193"
- "Chapter 1.3.1.9.3.2.1 “Automatic execution order by data flow” on page 189"
- "Chapter 1.3.1.25.2.12 “Menu ‘CFC’” on page 977"
- "Chapter 1.3.1.25.3.10.12 “Dialog ‘Properties’ - ‘CFC Execution Order’” on page 1054"

CFC editor, page-oriented

POUs generated in the “Continuous Function Chart (CFC) - page-oriented” cannot be converted into “Continuous Function Chart (CFC)” POUs or back.
Editing

You can drag a “Page” element from the “ToolBox” view to the page navigation. Then an additional page is inserted.

You can select existing pages in the page navigation and duplicated them by clicking “Edit ➔ Copy” and “Edit ➔ Paste”.

The size of the page is changed by means of the “Edit Page Size” command.

Connections over multiple pages are established by means of the “Connection Mark - Source” and “Connection Mark - Sink” elements. When you drag a connecting line from an input pin or an output pin to the border area, a new connection mark is created automatically. The advantage is that the "List components" input assistance provides all previously defined connection mark sources.

If you have selected an element in the editor, then you can use the arrow keys to move the selection from one element to the next to navigate through the circuit. If you then select a connection mark and press another arrow key, even the corresponding connection mark of the next/previous page will be selected.

You can transfer networks from a CFC POU to the program area of a page-oriented CFC by clicking “Edit ➔ Copy” and “Edit ➔ Paste” (from the clipboard). You can also use drag&drop.

Execution order

The execution order is determined automatically according to the order of the pages as they are sorted in the page navigator of the editor. Within a page, a page-oriented CFC object behaves like a CFC object. Therefore, you can switch between “Auto Data Flow Mode” and “Explicit Execution Order Mode”.

Additional commands in “CFC page-oriented”

CFC editor in online mode

In online mode, you can monitor and change variable values of the controller. In addition, debugging features are provided such as breakpoints and stepping.

Monitoring

As usual, you can monitor values in the declaration part as well as in the implementation part (with inline monitoring).

Inline monitoring of a function block is possible only when an instance of the function block is open. No values are displayed in the basic implementation view.
The connections between Boolean variables are displayed in color according to their actual value: **TRUE** in blue and **FALSE** in black. The element pins are decorated with the actual value.

**Example**

An application contains a CFC POU. An internal Boolean variable is switched there. With each cycle, the variable `iToggle` switches its state from **TRUE** to **FALSE**.

In the case of scalar variables, the element pins are decorated with the actual values.
Example

In online mode in the declaration editor, you can prepare a value for forcing or writing a monitored variable.

When you select the “Prepare values in implementation part” check box in the “CFC Editor” category of the CODESYS options, you can also prepare values in the implementation part.

To do this, open the “Prepare Value” dialog by double-clicking an element or the monitoring box next to an element. No dialog appears for Boolean variables. However, with each mouse click on the value displayed next to the variable, the values TRUE and FALSE are toggled.

Prepared values are displayed in angle brackets. After executing a write or a force, a red "F" is shown in the monitoring box.

You can write input parameters of function block instances of type VAR_INPUT CONSTANT in online mode and modify the parameters in this way. After logging out, you save these parameters by clicking “Save Prepared Parameters to Project”.

Forcing and writing of variables

Changing of constant input parameters of function block instances
Requirement: A CFC editor is active. An instantiated function block has VAR_INPUT CONSTANT variables in its declaration.

1. In the editor, open the POU by calling the function block instance.
   ⇢ The declaration of FB_DoIt has been supplemented by the constant MAXIMUM.

   ```
   FUNCTION_BLOCK FB_DoIt
   VAR_INPUT
     iAlfa : INT;
     iBravo: INT;
     sCharlie : STRING := 'Charlie';
     xItem : BOOL;
     iDelta : INT;
   END_VAR
   VAR_INPUT CONSTANT
     MAXIMUM : INT := 12;
   END_VAR
   VAR_OUTPUT
     iResult : INT;
     sResult : STRING;
     xResult : BOOL;
   ```

2. Login to the controller.
3. Click the "Parameters" button of the function block instance.
   ⇢ The "Edit Parameters" dialog opens.
4. Click the "Value" column in an inline monitoring field of a parameter.
   ⇢ The "Prepare Value" dialog opens.
5. Type 20 in the "Prepare a new value for the next write or force operation" field.
6. Click "OK" to confirm the entry.
   ⇢ The prepared value is shown in angle brackets next to the current value (for example, <20>).
7. Click “Debug ➔ Write Values”.
   ⇒ The prepared value is written. The parameter is changed and displayed in the project in brackets after the value.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Value</th>
<th>Initial value</th>
<th>Min</th>
<th>Max</th>
<th>Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>⋯</td>
<td>MAXIMUM</td>
<td>INT 20</td>
<td>20</td>
<td>12</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The difference between both values is shown by a red cross next to the parameter field of the function block instance.

8. Click “Edit Parameters” to close the dialog. Logout.
9. Click “CFC ➔ Save Prepared Parameters to Project”.
   ⇒ The change parameter values are saved to the project. The asterisk next to the parameter field disappears.

**Breakpoint locations**

Possible position of a breakpoint
- Element “Output”
  Variables are described.
- Element “Box”
  POU is called.
- Element “RETURN”
  The program flow is branched.
- Element “Selector”
  Structure elements are described.

Click “Debug ➔ Toggle Breakpoint” to set a new breakpoint or delete an existing breakpoint. A red circle in the block diagram represents an active breakpoint.
NOTICE!

A breakpoint is set automatically in all methods that can be called. Therefore, if a method is called that is defined over an interface, then breakpoints are set in all methods of function blocks that implement this interface. This also applies to all inherited function blocks that define methods.

You can process a POU in steps in debug mode. A called POU is supplemented internally by a `RETURN` at the beginning before the element with the number 0 and at the end after the last element. When stepping, these are started automatically.

CFC element 'Input'

Symbol: ➞

CODESYS inserts an input element by default with the text “???” . You can directly edit this field by clicking on it and entering a constant value or a variable name. Alternatively you can open the input assistant in order to select a variable by clicking on ▼▼.

CFC element 'Output'

Symbol: ⇥

CODESYS inserts an output element by default with the text “???” . You can directly edit this field by clicking on it and entering a constant value or a variable name. Alternatively you can open the input assistant in order to select a variable by clicking on ▼▼.
CFC element 'Box'

Symbol: 📦

You use the element in order to insert an operator, a function, a function block or a program. By default CODESYS inserts the element with the name "???". You can directly edit this field by clicking on it and entering a function block name. Alternatively you can open the input assistant and select a function block by clicking on it.

In the case of a function block, CODESYS additionally displays an input field ("???") above the function block symbol. You must replace this name by the name of the function block instance. If you instance a function block with constant input parameters, the function block element displays the 'Parameter...' field in the bottom left corner. You edit the parameters by clicking on this field.

In order to replace an existing box, you replace only the currently inserted identifier with the desired new name. When doing this, please note that CODESYS adapts the number of input and output pins in accordance with the definition of the POU and that existing assignments may therefore be deleted.

See also
● ✔ Chapter 1.3.1.25.2.12.18 “Command ‘Edit Parameters’” on page 984

CFC element 'Jump'

Symbol: ⇔

You use the element in order to define a position at which program execution is to continue. You must define this target position by a label. To do this, enter the name of the mark in the input field "???". If you have already inserted the corresponding label, you can also select it via the input assistant (⋯).

See also
● ✔ Chapter 1.3.1.24.1.6.4.7 “CFC element 'Label'” on page 487

CFC element 'Label'

Symbol: ⬤

A label defines a position to which program execution jumps with the help of a jump element.

In online mode CODESYS automatically inserts a RETURN flag at the end of a CFC function block.

See also
● ✔ Chapter 1.3.1.24.1.6.4.6 “CFC element 'Jump'” on page 487

CFC element 'Return'

Symbol: ⇩

Use the element in order to exit the function block.

Please note that in online mode in the CFC editor a return element is automatically inserted before the first line and after the last element. In single-step execution CODESYS automatically jumps to the return element at the end before exiting the function block.

CFC element 'Composer'
The composer element is for handling structural components. The individual components of a structure are made available to you as an input. For this purpose you must name the composer element like the structure concerned (replace the “???”).

The composer element is the counterpart to the selector element.

See also

- § Chapter 1.3.1.24.1.6.4.10 “CFC element 'Selector'” on page 488

CFC element 'Selector'

Symbol: 

The selector element is for handling structural components. The individual components of a structure are made available to you as an output. For this purpose you must name the selector element like the structure concerned (replace the “???”).

The selector element is the counterpart to the composer element.

See also

- § Chapter 1.3.1.24.1.6.4.9 “CFC element 'Composer'” on page 487

CFC element 'Comment'

Symbol: 

With this element you input a comment in the CFC editor. Replace the placeholder text in the element by the comment text. A line break can be inserted with the aid of the shortcut \[Ctrl\] + [Enter].

CFC element 'Connection Mark - Source/Sink'

Symbol: ↔, ↔

You can use connection marks instead of a connecting line between elements. That helps you to display complex diagrams more clearly.

For a valid connection you must connect an element “Connection Mark - Source” with the output of an element and an element “Connection Mark - Sink” with the input of another element. Both marks must bear the same name. The names are not case-sensitive.

Notes on naming

- The standard name for connection marks is C-<nr>. <nr> is a sequential number starting with 1.
- You can rename the standard name. In doing so, you must make sure that the connection mark - source and connection mark - sink have the same name.
- If you change the name of the connection mark - source, the destination name is automatically renamed.
- If you change the name of the connection mark - sink, the source name is retained.

Observe the command “Connection Mark” for the automatic transformation of an existing connection.

See also

- § Chapter 1.3.1.25.2.12.31 “Command 'Connection Mark'” on page 988
- §
CFC element 'Input Pin'

Symbol: 

Depending on the type of function block you can add further inputs to an inserted function block element. To do this you must select the function block element and drag the function block input element onto the body of the function block.

Please note: You can drag an input or output connection to another position on the function block with the [Ctrl] key pressed.

See also

- Chapter 1.3.1.24.1.6.4.14 “CFC element 'Output Pin’” on page 489

CFC element 'Output Pin'

Symbol: 

Depending on the type of function block you can add further outputs to an inserted function block element. To do this you must select the function block element and drag the function block output element onto the body of the function block.

Please note: You can drag an input or output connection to another position on the function block with the [Ctrl] key pressed.

The scope of a variable defines how and where you can use a variable. You define the scope in the variable declaration.

**Local variables - VAR**

Local variables are declared between the keywords VAR and END_VAR in the declaration part of programming objects.

You have read-only access to local variables by using the instance path.

You can extend local variables with an attribute keyword.
Example

```c
VAR
 iVar1 : INT;
END_VAR
```

See also

- § Chapter 1.3.1.9.20 “Data persistence” on page 249

Input variables - VAR_INPUT

Input variables are used at the inputs of function blocks.

**VAR_INPUT** variables are declared between the keywords **VAR_INPUT** and **END_VAR** in the declaration part of programming objects.

You can extend input variables with an attribute keyword.

Example

```c
VAR_INPUT
 iIn1 : INT; (* 1st input variable *)
END_VAR
```

See also

- § Chapter 1.3.1.9.20 “Data persistence” on page 249

Output variables - VAR_OUTPUT

Output variables are used at the outputs of function blocks.

**VAR_OUTPUT** variables are declared between the keywords **VAR_OUTPUT** and **END_VAR** in the declaration part of programming objects. CODESYS returns the values of this variable to the calling POU. There you can retrieve the values and continue using them.

You can extend output variables with an attribute keyword.

Example

```c
VAR_OUTPUT
 iOut1 : INT; (* 1st output variable *)
END_VAR
```

See also

- § Chapter 1.3.1.9.20 “Data persistence” on page 249

Output variables in functions and methods

According to the IEC 61131-3 standard, functions and methods have additional outputs. You have to assign these additional outputs when calling the function, as shown below.

Example

```c
fun(iIn1 := 1, iIn2 := 2, iOut1 => iLoc1, iOut2 => iLoc2);
```
Input/Output variable (VAR_IN_OUT)

A VAR_IN_OUT variable is an input/output variable, which is part of a POU interface and serves as a formal pass-by-reference parameter.

Syntax declaration

```plaintext
<keyword> <POU name>
VAR_IN_OUT
   <variable name> : <data type> ( := <initialization value> )? ;
END_VAR
<keyword> : FUNCTION | FUNCTION_BLOCK | METHOD | PRG
```

You can declare an input/output variable in the VAR_IN_OUT declaration section in the POUs PRG, FUNCTION_BLOCK, METHOD, or FUNCTION. As an option, a constant of the declared data type can be assigned as an initialization value. The VAR_IN_OUT variable can be read and written.

Usage

- **Call**: When a POU is called, the formal VAR_IN_OUT variable receives the actual variable (pass-by-reference variable) as the argument. In runtime mode, no copies are generated when parameters are passed. Instead, the formal variable receives a reference to the actual variable passed remotely. The referential variables contain a memory address internally as a value to the actual value (pass as pointer, call-by reference). It is not possible to specify a constant (literal) or a bit variable directly as an argument.
- **Read/write access within the POU**: If the variable is written to within the POU, then this affects the passed variable. When the POU is exited, the performed changes are retained. This means that a POU uses its VAR_IN_OUT variables just like the calling POU uses its variables. Read access is always permitted.
- **Read/write access remotely**: VAR_IN_OUT variables cannot be directly read or written remotely via `<function block instance name>`.`<variable name>`. This works only for VAR_INPUT and VAR_OUTPUT variables.
- **Passing string variables**: If a string variable is passed as an argument, then it is recommended when the actual variable and the formal variable have the same length. Otherwise, the passed string can be manipulated accidentally. This problem does not occur in the case of VAR_OUTPUT CONSTANT parameters.
- **Passing bit variables**: A bit variable cannot be passed directly to a VAR_IN_OUT variable because it needs an intermediate variable.

> When a string is passed as a variable or a constant to a formal VAR_IN_OUT CONSTANT variable, the string is automatically passed completely. You do not have to check the string length.

See also

- Chapter “Transfer variable VAR_IN_OUT CONSTANT” on page 493
Example

Passing arrays

```plaintext
TYPE DUT_A :
STRUCT
  xA: BOOL;
  iB: INT;
END_STRUCT
END_TYPE

FUNCTION_BLOCK FB_SetArray
VAR_IN_OUT
  aData_A : ARRAY[0..1] OF DUT_A; // Formal variable
END_VAR
aData_A[0].xA := TRUE;
aData_A[0].iB := 100;

PROGRAM PLC_PRG
VAR
  fbSetA : FB_SetArray;
aSpecialData : ARRAY[0..1] OF DUT_A; // Actual variable
END_VAR
fbSetA(aData_A := aSpecialData);
```

Passing strings

```plaintext
{attribute 'qualified_only'}
VAR_GLOBAL
  g_sDEV_STATUS : STRING(25) := 'Device_A';
END_VAR

FUNCTION_BLOCK FB_SetStatus
VAR_IN_OUT
  sDeviceStatus : STRING(25); // Formal parameter
END_VAR
sDeviceStatus := CONCAT(sDeviceStatus, ' Activ');

PROGRAM PLC_PRG
VAR
  fbDoB : FB_SetStatus;
END_VAR
fbDoB(sDeviceStatus := GVL.g_sDEV_STATUS); //Call with actual parameter
```

The variable `sDeviceStatus` is part of the POU interface of `FB_B`. When calling `fbDoB`, first a device name is assigned to the string and then the string is manipulated.

Passing bit variables

```plaintext
VAR_GLOBAL
  xBit0 AT %MX0.1 : BOOL;
  xTemp : BOOL;
END_VAR
```
FUNCTION_BLOCK FB_DoSomething
VAR_INPUT
  xIn : BOOL;
END_VAR
VAR_IN_OUT
  xInOut : BOOL;
END_VAR
IF xIn THEN
  xInOut := TRUE;
END_IF

PROGRAM PLC_PRG
VAR
  xIn : BOOL;
  DoSomething_1  : FB_DoSomething;
  DoSomething_2  : FB_DoSomething;
END_VAR

// The following line of code causes a compiler error:
// C0201: Typ 'BIT' is not equal to type 'BOOL' of VAR_IN_OUT 'xInOut'
DoSomething_1(xIn := xIn, xInOut := xBit0);

// Workaround
xTemp := xBit0;
DoSomething_2(xIn := xIn, xInOut := xTemp);
xBit0 := xTemp;

The program calls the function block instances DoSomething_1 and DoSomething_2. As a result of the direct assignment of the bit variable xBit0 to the VAR_IN_OUT input, a compiler error is generated when the DoSomething_1 instance is called. In contrast, calling the DoSomething_2 instance with the assignment of an intermediate variable is correct code.

Transfer variable
VAR_IN_OUT CONSTANT

Syntax declaration
<keyword> <POU name>
VAR_IN_OUT CONSTANT
  <variable name> : <data type>; // formal parameter
END_VAR
<keyword> : FUNCTION | FUNCTION_BLOCK | METHOD | PRG

VAR_IN_OUT CONSTANT variables are declared without assigning an initialization value.

Usage:
- When calling the POU, a constant variable or a literal is passed. All data types are permitted for this. Consequently, write access is not permitted.
- Passing parameters of a string constant: The string length of the constants can be any size, and the string length does not depend on the string length of the VAR_IN_OUT CONSTANT variables.

If the “Replace constants” option is selected in “Project ➔ Project Settings” (category “Compile Options”), then the passing of the parameter of a constant or constant variable with a base data type causes a compiler error to be generated.
This variable is supported in compiler version >= 3.5.2.0.

Example
Passing parameters of string constants and string variables

FUNCTION funManipulate : BOOL
VAR_IN_OUT
sReadWrite : STRING(16); (* Can be read or written here in POU *)
dwVarReadWrite : DWORD; (* Can be read or written here in POU *)
END_VAR
VAR_IN_OUT CONSTANT
c_sReadOnly : STRING(16); (* Constant string variable can only be read here in POU *)
END_VAR

sReadWrite := 'String_from_POU';
dwVarReadWrite := STRING_TO_DWORD(c_sReadOnly);

PROGRAM PRG_A
VAR
sVarFits : STRING(16);
sValFits : STRING(16) := '1234567890123456';
dwVar : DWORD;
END_VAR

// The following line of code causes the compiler error C0417:
// C0417: VAR_IN_OUT parameter 'sReadWrite' needs a variable with write access as input.
funManipulate(sReadWrite := '1234567890123456',
c_sReadOnly := '1234567890123456',
dwVarReadWrite := dwVar);

// Correct code
funManipulate(sReadWrite := sValFits, c_sReadOnly := '23',
dwVarReadWrite := dwVar);
funManipulate(sReadWrite := sVarFits, c_sReadOnly := sValFits,
dwVarReadWrite := dwVar);

In the code, strings are passed to the funManipulate function via different VAR_IN_OUT variables. When passing a literal, a compiler error is output to a VAR_IN_OUT variable. When passing a constant variable to a VAR_IN_OUT CONSTANT variable, correct code is generated even for passing string variables.

- Chapter 1.3.1.24.2.11 “Constant variables - VAR CONSTANT” on page 497
Global variables - VAR_GLOBAL

Global variables are ordinary variables, constants, external or remanent variables that are recognized within the entire project.

You declare global variables in global variable lists or in the declaration section of programming objects between the keywords VAR_GLOBAL and END_VAR.

The system recognizes a global variable when you prepend the variable name with a dot (for example, .iGlobVar1).

**NOTICE!**
If a local variable that is declared in a block has the same name as a global variable, then it has precedence within the block.

**NOTICE!**
For compiler version 3.2.0.0 and later, CODESYS always initializes global variables before the local POU variables.

**Example**

```
VAR_GLOBAL
  iVarGlob1 : INT;
END_VAR
```

See also
- § Chapter 1.3.1.25.1.21 “Object 'GVL' - Global Variable List” on page 769
- § Chapter 1.3.1.24.3.67 “Operator - Global namespace” on page 555

Temporary variable - VAR_TEMP

This function is an extension of the IEC 61131-3 standard.

You declare temporary variables locally between the keywords VAR_TEMP and END_VAR.

VAR_TEMP declarations are possible only in program blocks and function blocks.

CODESYS initializes temporary variables each time the block is called.

The application can access the temporary variables only in the implementation section of a program block or a function block.

**Example**

```
VAR_TEMP
  iVarTmp1 : INT; (*1st temporary variable *)
END_VAR
```

Static variables - VAR_STAT

This function is an extension of the IEC 61131-3 standard.

You declare static variables locally between the keywords VAR_STAT and END_VAR. CODESYS initializes static variables the first time each block is called.

You can access static variables only from within the namespace where the variables are declared (like static variables in C). But static variables retain their values when the application leaves the block. For example, you can use static variables as counters for function calls.
You can extend static variables with an attribute keyword.

**Example**

```
VAR_STAT
  iVarStat1 : INT;
END_VAR
```

See also
-  `$ Chapter 1.3.1.9.20 “Data persistence” on page 249`

**External variables - VAR_EXTERNAL**

External variables are global variables that are imported into a block.

You declare these variables between the keywords `VAR_EXTERNAL` and `END_VAR`. If the global variable does not exist, then an error message is printed.

**NOTICE!**

CODESYS does not require you to declare a global variable as external in order to use it in a POU. The keyword exists only for maintaining compliance with IEC 61131-3.

**Syntax**

```
<POU keyword> <POU name>
VAR_EXTERNAL
  <variable name> : <data type>;
END_VAR
```

Initialization is not permitted.

**Example**

```
FUNCTION_BLOCK FB_DoSomething
  VAR_EXTERNAL
  iVarExt1 : INT; (* 1st external variable *)
END_VAR
```

See also
-  `$ Chapter 1.3.1.25.1.21 “Object 'GVL' - Global Variable List” on page 769`

**Instance variables - VAR_INST**

CODESYS does not save a `VAR_INST` method variable in a method stack, but in the stack of the function block instance. This means that the `VAR_INST` variable functions like other Variables of the function block instance, and it is not reinitialized each time the method is called.

`VAR_INST` variables are permitted in methods only and you can access these variables only within the method. The variable values of instance variables are monitored in the declaration section of the method.

You can extend instance variable with an attribute keyword.
Example

```plaintext
METHOD meth_last : INT
VAR_INPUT
  iVar : INT;
END_VAR
VAR_INST
  iLast : INT := 0;
END_VAR
meth_last := iLast;
iLast := iVar;
```

Configuration variables - VAR_CONFIG

Use configuration variables for assigning complete addresses to variables that are declared in function blocks with incomplete addresses and will be mapped on device I/Os.

Declare the variables in a global variables list between VAR_CONFIG and END_VAR. The global variables list is termed "variables configuration", where you type the configuration variables with a complete instance path and the correct address.

Example

Declaration of the variable xLocIn with incomplete address %I* in a function block:

```plaintext
FUNCTION_BLOCK locio

VAR
  xLocIn AT %I* : BOOL := TRUE;
END_VAR

The locio function block is used in the PLC_PRG program:

```plaintext
PROGRAM PLC_PRG

VAR
  locioVar1 : locio;
END_VAR
```

The correct variables configuration in the global variable list is as follows:

```
VAR_CONFIG
  PLC_PRG.locioVar1.xLocIn AT %IX1.0 : BOOL;
END_VAR
```

See also

- Chapter 1.3.1.9.12.1 “Variables configuration - VAR_CONFIG” on page 227

Constant variables - VAR CONSTANT

Constant variables are declared in global variable lists or in the declaration part of programming objects. In implementations, constant variables can be accessed as read-only via the instance path.

Syntax

```plaintext
<scope>  CONSTANT
    <identifier> : <data type> := <initialization> ;
END_VAR
```

```plaintext
<scope> : VAR | VAR_INPUT | VAR_STAT | VAR_GLOBAL
```

2020/12/10
Always assign an initialization value when declaring a constant variable. Then the constant cannot be written any more.

**Example**

**Declaration**

```plaintext
VAR CONSTANT
  c_rTAXFACTOR : REAL := 1.19;
END_VAR
```

**Call**

```plaintext
rPrice := rValue * c_rTAXFACTOR;
```

In implementations, you can access constant variables exclusively as read-only. Constant variables are located to the right of the assignment operator.

See also

- Chapter 1.3.1.24.2.4 “Input/Output variable (VAR_IN_OUT)” on page 491

### Persistent variable - PERSISTENT

Persistent variables are declared in the declaration section `VAR_GLOBAL RETAIN PERSISTENT` in the persistent global variable list. For variables that are marked with the `PERSISTENT` keyword outside of the persistence editor, instance paths are added there.

As of CODESYS version 3.3.0.1, a variable declaration with `PERSISTENT RETAIN` has the same effect as with `RETAIN PERSISTENT` or `PERSISTENT`.

#### Syntax of the declaration in the global persistent variable list

```plaintext
VAR_GLOBAL PERSISTENT RETAIN
  <identifier>: <data type> (:= <initialization>)?;
  <instance path to POU variable>
END_VAR
```

#### Syntax of the declaration in POU's

```plaintext
<scope> PERSISTENT RETAIN
  <identifier>: <data type> ( := <initialization> )?; // ( ... )? :
Optional
END_VAR
<scope> : VAR | VAR_INPUT | VAR_OUTPUT | VAR_IN_OUT | VAR_STAT | VAR_GLOBAL
```

An assignment of inputs, outputs, or memory addresses with the `AT` keyword is not permitted.

**Never use the POINTER TO data type in persistent variable lists. If the application is downloaded again, their addresses could change. The corresponding compiler warnings are shown in the message window.**

**If you frequently change the names or data types of remanent variables, then it is better to declare them as retain variables with the RETAIN keyword only.**
NOTICE!
Declare variables directly in the list of persistent variables and avoid inserting instance paths. As a result, this takes up twice as much memory and also increases the cycle time.

Example

Declaration in the persistent variable list

```plaintext
{attribute 'qualified_only'}
VAR_GLOBAL PERSISTENT RETAIN
g_iCounter : INT;
// Generated instance path of persistent variable
PLC_PRG.fb_A.iPersistentCounter_A: INT;
END_VAR
```

Declaration in the function block FB_A:

```plaintext
FUNCTION_BLOCK FB_A
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR PERSISTENT
   iPersistentCounter_A : INT;
END_VAR
```

Declaration in the program PLC_PRG:

```plaintext
VAR
   fb_A1 : FB_A;
END_VAR
```

Possible declaration locations

<table>
<thead>
<tr>
<th>Locality</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Directly in the persistent global variable list</td>
<td>The variable is persistent and lies in the protected memory area.</td>
</tr>
<tr>
<td>Locally in a program with an instance path in the persistent variable list</td>
<td>The variable is persistent and lies in the protected memory area and in the memory (double allocation).</td>
</tr>
<tr>
<td>Locally in a function block with an instance path in the persistent variable list</td>
<td>This variable is not persistent. A warning is shown in the message window. Hint: Click “Declarations ➔ Add All Instance Paths” to import the variables into the persistent variable list.</td>
</tr>
<tr>
<td>Only locally in a program</td>
<td>This variable is not persistent. A warning is shown in the message window. Hint: Click “Declarations ➔ Add All Instance Paths” to import the variables into the persistent variable list.</td>
</tr>
<tr>
<td>Only locally in a function block</td>
<td>This declaration does not have any effect. This variable is not persistent.</td>
</tr>
<tr>
<td>Locally in a function</td>
<td></td>
</tr>
</tbody>
</table>

In the persistence editor, click “Add All Instance Paths” if local variables are marked with PERSISTENT.
Whenever possible, avoid marking variables, which are declared in a function block, with `PERSISTENT`. This is because the function block instance is stored entirely in remanent memory and not just the marked variable.

- Chapter 1.3.1.9.20.1 “Preserving data with persistent variables” on page 252

**Retain variable - `RETAIN`**

Retain variables are declared by the keyword `RETAIN` is added in programming objects in the scope `VAR`, `VAR_INPUT`, `VAR_OUTPUT`, `VAR_IN_OUT`, `VAR_STAT`, or `VAR_GLOBAL`.

**Syntax in the declaration**

```plaintext
<scope> RETAIN
   <identifier>: <data type> { := <initialization> }? // ( ... )? : Optional
END_VAR
<scope> : VAR | VAR_INPUT | VAR_OUTPUT | VAR_IN_OUT | VAR_STAT | VAR_GLOBAL
```

An assignment of inputs, outputs, or memory addresses with the `AT` keyword is not permitted.

**Example**

In a POU:

```plaintext
VAR RETAIN
   iVarRetain: INT;
END_VAR
```

In a GVL:

```plaintext
VAR_GLOBAL RETAIN
   g_iVarRetain: INT;
END_VAR
```

**Possible declaration locations**

<table>
<thead>
<tr>
<th>Locality</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Locally in a program</td>
<td>Only the variable lies within the retain memory area.</td>
</tr>
<tr>
<td>Globally in a global variable list</td>
<td>Only the variable lies within the retain memory area.</td>
</tr>
<tr>
<td>Locally in a function block</td>
<td>The entire instance of the function block with all of its data lies within the retain memory area. Only the declared retain variable is protected.</td>
</tr>
<tr>
<td>Locally in a function</td>
<td>Even the variable does not lie within the retain memory area. This declaration does not have any effect.</td>
</tr>
<tr>
<td>Locally and persistently in a function</td>
<td>Even the variable does not lie within the retain memory area. This declaration does not have any effect.</td>
</tr>
</tbody>
</table>
Whenever possible, avoid marking variables of a function block with RETAIN.

- Chapter 1.3.1.9.20.2 “Preserving data with retain variables” on page 254

SUPER

SUPER is a special variable and is used for object-oriented programming.

SUPER is the pointer of a function block to the basic function block instance from which the function block was generated. The SUPER pointer thus also permits access to the implementation of the methods of the basic function block (basic class). A SUPER pointer is automatically available for each function block.

You can use SUPER only in methods and in the associated function block implementations.

Dereferencing of the pointer: SUPER^.

Use of the SUPER pointer: with the help of the keyword SUPER you call a method that is valid in the instance of the basic class or parent class.

Examples

ST:

SUPER^.METH_DoIt();

FBD/CFC/LD

---

THIS is not yet implemented for the instruction list (IL).
Use of **SUPER** and **THIS** pointers

```plaintext
FUNCTION_BLOCK FB_Base
  VAR_OUTPUT
    iCnt : INT;
  END_VAR

  METHOD METH_DoIt : BOOL
    iCnt := -1;
  END_METHOD

  METHOD METH_DoAlso : BOOL
    METH_DoAlso := TRUE;
  END_METHOD

FUNCTION_BLOCK FB_1 EXTENDS FB_Base
  VAR_OUTPUT
    iBase : INT;
  END_VAR

  THIS^.METH_DoIt();  //Call of the methods of FB_1
  THIS^.METH_DoAlso();

  SUPER^.METH_DoIt();   //Call of the methods of FB_Base
  SUPER^.METH_DoAlso();
  iBase := SUPER^.iCnt;

  METHOD METH_DoIt : BOOL
    iCnt := 1111;
    METH_DoIt := TRUE;
  END_METHOD

PROGRAM PLC_PRG
  VAR
    myBase : FB_Base;
    myFB_1 : FB_1;
    iTHIS : INT;
    iBase : INT;
  END_VAR

  myBase();
  iBase := myBase.iCnt;
  myFB_1();
  iTHIS := myFB_1.iCnt;
```

See also

- % Chapter 1.3.1.24.5 “Data types” on page 569
- % Chapter 1.3.1.24.2.15 “THIS” on page 502

**THIS**

**THIS** is a special variable and is used for object-oriented programming.

**THIS** is the pointer of a function block to its own function block instance. A **THIS** pointer is automatically available for each function block.

You can use **THIS** only in methods and in function blocks. **THIS** is available for the implementation in the input assistant in the category “Keywords”.

Dereferencing of the pointer: **THIS**^
Use of the `THIS` pointer

- If a local variable obscures a function block variable in a method, you can set the function block variable with the `THIS` pointer. See example below (1)
- If the pointer to the function block’s own function block instance is referenced for use in a function. (See example below (2))

```
ST:
THIS^.METH_DoIt();

FBD/CFC/LD:
```

```
THIS^  
  METH_DoAlso  
  METH_DoAlso  
```

*`THIS` is not yet implemented for the instruction list (IL).*
Examples

(1) The local variable iVarB obscures the function block variable iVarB.

```plc
FUNCTION_BLOCK fbA
VAR_INPUT
  iVarA: INT;
END_VAR
iVarA := 1;

FUNCTION_BLOCK fbB EXTENDS fbA
VAR_INPUT
  iVarB: INT := 0;
END_VAR
iVarA := 11;
iVarB := 2;

METHOD DoIt : BOOL
VAR_INPUT
END_VAR
VAR
  iVarB: INT;
END_VAR
iVarB := 22;    // The local variable iVarB is set.
THIS^.iVarB := 222;    // The function block variable iVarB is set even though iVarB is obscured.
```

```plc
PROGRAM PLC_PRG
VAR
  MyfbB: fbB;
END_VAR
MyfbB(iVarA:=0, iVarB:= 0);
MyfbB.DoIt();
```

(2) A function call requires the reference to its own instance.

```plc
FUNCTION funA
VAR_INPUT
  pFB: fbA;
END_VAR
...

FUNCTION_BLOCK fbA
VAR_INPUT
  iVarA: INT;
END_VAR
...

FUNCTION_BLOCK fbB EXTENDS fbA
VAR_INPUT
  iVarB: INT := 0;
END_VAR
iVarA := 11;
iVarB := 2;

METHOD DoIt : BOOL
VAR_INPUT
END_VAR
VAR
  iVarB: INT;
END_VAR
iVarB := 22;    // The local variable iVarB is set.
funA(pFB := THIS^);    // funA is called via THIS^.
```

PROGRAM PLC_PRG
VAR
  MyfbB: fB;
END_VAR
MyfbB(iVarA:=0 , iVarB:= 0);
MyfbB.DoIt();

1.3.1.24.3 Operators

CODESYS V3 supports all IEC-61131-3 operators. These operators are recognized implicitly throughout the project. In addition to these IEC operators, CODESYS also supports some non-IEC 61131-3 operators.

Operators are used in blocks, such as functions.

For information about the processing order (binding strength) of the ST operators, please refer to the section on ST expressions.

CAUTION!
For operations with floating-point data types, the computational result depends on the applied target system hardware.

CAUTION!
For operations with overflow or underflow in the data type, the computational result depends on the applied target system hardware.

Overflow/underflow in the data type

The CODESYS compiler generates code for the target device and computes temporary results always with the native size that is defined by the target device. For example, computation is performed at least with 32-bit temporary values on x86 and ARM systems and always with 64-bit temporary values on x64 systems. This provides considerable advantages in the computation speed and often also produces the desired result. But this also means that an overflow or underflow in the data type is not truncated in some cases.
Examples

Example 1

The result of this addition is not truncated and the result in \texttt{dwVar} is 65536.

\begin{verbatim}
VAR
wVar : WORD;
dwVar : DWORD;
END_VAR

wVar := 65535;
dwVar := wVar + 1;
\end{verbatim}

Example 2

The overflow and underflow in the data type is not truncated and the results \((bVar1, bVar2)\) of both comparisons are \texttt{FALSE} on 32-bit and 64-bit hardware.

\begin{verbatim}
VAR
wVar1 : WORD;
wVar2 : WORD;
bVar1 : BOOL;
bVar2 : BOOL;
END_VAR

wVar1 := 65535;
wVar2 := 0;
bVar1 := (wVar1 + 1) = wVar2;
bVar2 := (wVar2 - 1) = wVar1;
\end{verbatim}

Example 3

By the assignment to \texttt{wVar3}, the value is truncated to the target data type \texttt{WORD} and the result \texttt{bVar1} is \texttt{TRUE}.

\begin{verbatim}
VAR
wVar1 : WORD;
wVar2 : WORD;
wVar3 : WORD;
bVar1 : BOOL;
END_VAR

wVar1 := 65535;
wVar2 := 0;
wVar3 := (wVar1 + 1);
bVar1 := wVar3 = wVar2;
\end{verbatim}

Example 4

In order to force the compiler to truncate the temporary results, a conversion can be inserted. The type conversion makes sure that both comparisons are 16-bit only and the results \((bVar1, bVar2)\) of both comparisons are each \texttt{TRUE}.

\begin{verbatim}
VAR
wVar1 : WORD;
wVar2 : WORD;
bVar1 : BOOL;
bVar2 : BOOL;
END_VAR

wVar1 := 65535;
wVar2 := 0;
bVar1 := \texttt{TO\_WORD}(wVar1 + 1) = wVar2;
bVar2 := \texttt{TO\_WORD}(wVar2 - 1) = wVar1;
\end{verbatim}

Call operators
- Chapter 1.3.1.24.3.33 “Operator ‘CAL’” on page 525
Implicit conversion from a larger type to a smaller type is not possible (for example, from INT to BYTE or from DINT to WORD). You must use a special type conversion to convert from a larger type to a smaller type. As a rule, you can convert any elementary type into any other elementary type.

**Typed conversion**:
<elementary type1>_TO_<elementary type2>

**Overflow conversion**:
TO_<elementary type2>

---

**NOTICE!**

In the case of ...TO_STRING conversions, CODESYS generates the string left-aligned. If the string length is defined too short, then it will be truncated on the right.

---

**NOTICE!**

If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from LREAL to DINT is negative.

### Namespace operators

Namespace operators are extended from IEC 61131-3 operators and make it possible for you to provide unique access to variables and modules, even when you use the same name multiple times for variables or modules in a project.

- Chapter 1.3.1.24.3.67 “Operator - Global namespace” on page 555
- Chapter 1.3.1.24.3.68 “Operator - Namespace for global variables lists” on page 555
Working with different tasks requires the synchronization of these tasks. This is especially true when working on multicore platforms. Some special operators are provided in CODESYS to support this synchronization.

These operators are extensions of IEC-61131-3. The operators `TEST_AND_SET` and `__COMPARE_AND_SWAP` are used for similar tasks.

See also
- Chapter 1.3.1.24.3.66 “Operator ‘TEST_AND_SET’” on page 554
- Chapter 1.3.1.24.3.64 “Operator ‘__COMPARE_AND_SWAP’” on page 552
- Chapter 1.3.1.24.3.65 “Operator ‘__XADD’” on page 553

Other operators
- Chapter 1.3.1.24.3.56 “Operator ‘__DELETE’” on page 538
- Chapter 1.3.1.24.3.57 “Operator ‘__ISVALIDREF’” on page 541
- Chapter 1.3.1.24.3.58 “Operator ‘__NEW’” on page 541

- Chapter 1.3.1.24.3.60 “Operator ‘__QUERY_POINTER’” on page 545
- Chapter 1.3.1.24.3.71 “Operator ‘INI’” on page 556
- Chapter 1.3.1.24.3.61 “Operators ‘__TRY’, ‘__CATCH’, ‘__FINALLY’, ‘__ENDTRY’” on page 546

Operator ‘ADD’

This IEC operator is used for adding variables.

Permitted data types: BYTE, WORD, DWORD, LWORD, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, LREAL, TIME, TIME_OF_DAY (TOD), DATE, DATE_AND_TIME (DT)

Possible combinations for TIME data types: TIME+TIME = TIME, TOD+TIME = TOD, DT+TIME = DT

Feature in the FBD/LD editor: You can extend the ADD operator to function block inputs. The number of additional function block inputs is limited.
Examples

**ST:**

```
var1 := 7+2+4+7;
```

**FBD:**

---

### Operator 'MUL'

This IEC operator is used for multiplying variables.

**Permitted data types:** BYTE, WORD, DWORD, LWORD, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, LREAL, TIME

Feature in the FBD/LD editor: You can extend the MUL operator to additional function block inputs. The number of additional function block inputs is limited.

---

**Examples**

**ST:**

```
var1 := 7*2*4*7;
```

**FBD:**

---

### Operator 'SUB'

This IEC operator is used for subtracting variables.
Permitted data types: BYTE, WORD, DWORD, LWORD, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, LREAL, TIME, TIME_OF_DAY (TOD), DATE, DATE_AND_TIME (DT)

Possible combinations for TIME data types: TIME-TIME = TIME, DATE-DATE = TIME, TOD-TOD = TOD, TOD-TOD = TIME, DT-TIME = DT, DT-DT = TIME

Negative TIME values are undefined.

Examples

<table>
<thead>
<tr>
<th>ST:</th>
<th>FBD:</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>var1 := 7-2;</code></td>
<td><img src="image" alt="SUB" /></td>
</tr>
</tbody>
</table>

Operator 'DIV'

This IEC operator is used for dividing variables.

Permitted data types: BYTE, WORD, DWORD, LWORD, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, LREAL, TIME

NOTICE!
Division by zero may have different results depending on the target system.

Examples

<table>
<thead>
<tr>
<th>ST:</th>
<th>FBD:</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>var1 := 8/2;</code></td>
<td><img src="image" alt="FBD" /></td>
</tr>
</tbody>
</table>

1. Series of DIV blocks, 2. Single DIV block, 3. DIV blocks with EN/ENO parameters
Please note that it is possible to monitor division by zero at runtime by using the implicit monitoring functions **CheckDivInt**, **CheckDivLint**, **CheckDivReal**, and **CheckDivLReal**.

See also

- % Chapter 1.3.1.25.1.29.2 “POU 'CheckDivInt'” on page 801
- % Chapter 1.3.1.25.1.29.3 “POU 'CheckDivLint'” on page 801
- % Chapter 1.3.1.25.1.29.4 “POU 'CheckDivReal'” on page 802
- % Chapter 1.3.1.25.1.29.5 “POU 'CheckDivLReal'” on page 803

**Operator 'MOD'**

This IEC operator is used for modulo division.
The result of the function is the integer remainder of division.

**Permitted data types:** BYTE, WORD, DWORD, LWORD, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT

**NOTICE!**
Division by zero may have different results depending on the target system.

**Examples**

Result in Var1: 1

**ST:**

```
var1 := 9 MOD 2;
```

**FBD:**

![MOD diagram]

**Operator 'MOVE'**

This IEC operator is used for assigning a variable to another variable of a corresponding type.

Because the **MOVE** block is available in the CFC, FBD, and LD editors, you can also use the **EN/ENO** functionality for variable assignment.

**CFC with EN/ENO function:**

CODESYS assigns the value of **var1** to **var2** only if "en_i" yields **TRUE**.

**ST:**

```
ivar2 := MOVE(ivar1);
```

This corresponds to:

```
ivar2 := ivar1;
```
Operator 'INDEXOF'

This operator is an extension of the IEC 61131-3 standard.

Instead of the INDEXOF operator, the ADR operator is provided in CODESYS V3 for obtaining a pointer at the index of a block.

See also
● § Chapter 1.3.1.24.3.30 “Operator ‘ADR’” on page 524

Operator 'SIZEOF'

This operator is an extension of the IEC 61131-3 standard.

This operator is used for defining the number of bytes that are required by the variable \( x \). The SIZEOF operator always yields an unsigned value. The type of return variable adapts to the detected size of the variable \( x \).

<table>
<thead>
<tr>
<th>Return Value of ( \text{SIZEOF}(x) )</th>
<th>Data type of the constant (CODESYS uses this implicitly for detected size)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 &lt;= size of ( x ) &lt; 256</td>
<td>USINT</td>
</tr>
<tr>
<td>256 &lt;= size of ( x ) &lt; 65536</td>
<td>UINT</td>
</tr>
<tr>
<td>65536 &lt;= size of ( x ) &lt; 4294967296</td>
<td>UDINT</td>
</tr>
<tr>
<td>4294967296 &lt;= size of ( x )</td>
<td>ULINT</td>
</tr>
</tbody>
</table>

Examples

Result in \( \text{Var1}:10 \)

ST:

\[
\text{arr1 : ARRAY}[0..4] \text{ OF INT;}
\]
\[
\text{Var1 : INT;}
\]
\[
\text{var1 := SIZEOF(arr1);} \quad (* \text{var1 := USINT#10}; *\)
\]

Operator 'NOT'

This IEC operator is used for the bitwise \text{NOT} of a bit operand.

When the respective input bit yields 0, the output bit also yields 1, and vice-versa.

Permitted data types: BOOL, BYTE, WORD, DWORD, LWORD

Examples

Result in \( \text{var1:2#0110_1100} \)

ST:

\[
\text{var1 := NOT 2#1001_0011;}
\]

FBD:

![Diagram of NOT operator]

Operator 'AND'

This IEC operator is used for the bitwise \text{AND} of bit operands.
When the input bits all yield 1, the output bit also yields 1; otherwise 0.

Permitted data types: BOOL, BYTE, WORD, DWORD, LWORD

### Examples

<table>
<thead>
<tr>
<th>Result in</th>
<th>ST:</th>
<th>FBD:</th>
</tr>
</thead>
<tbody>
<tr>
<td>var1</td>
<td>var1 := 2#1001_0011 AND 2#1000_1010;</td>
<td>var1 := 2#1001_0011 AND 2#1000_1010;</td>
</tr>
</tbody>
</table>

#### Operator 'OR'

This IEC operator is used for the bitwise OR of bit operands.

When at least one of the input bits yields 1, the output bit also yields 1; otherwise 0.

Permitted data types: BOOL, BYTE, WORD, DWORD, LWORD

<table>
<thead>
<tr>
<th>Result in</th>
<th>ST:</th>
<th>FBD:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Var1</td>
<td>Var1 := 2#1001_0011 OR 2#1000_1010;</td>
<td>Var1 := 2#1001_0011 OR 2#1000_1010;</td>
</tr>
</tbody>
</table>

#### Operator 'XOR'

This IEC operator is used for the bitwise XOR of bit operands.

When only one of the two input bits yields 1, the output bit also yields 1. When both inputs yield 1 or 0, then the output yields 0.

Permitted data types: BOOL, BYTE, WORD, DWORD, LWORD

---

**NOTICE!**

Please note the following behavior of the XOR block in extended form (more than two inputs): CODESYS compares the inputs in pairs and then the corresponding results (according to the standard, but not necessarily according to expectations).
Examples

Result in var1: 2#0001_1001

ST:
var1 := 2#1001_0011 XOR 2#1000_1010;

FBD:

Operator 'AND_THEN'

This operator is an extension of the IEC 61131-3 standard.

The AND_THEN operator is permitted only for programming in structured text with the AND operation of BOOL and BIT operands with short-circuit evaluation. This means that:

When all operands yield TRUE, the result of the operands also yield TRUE; otherwise FALSE.

However, CODESYS also executes the expressions on other operands only if the first operand of the AND_THEN operator is TRUE. This can prevent problems with null pointers, for example in conditions such as IF (ptr <> 0 AND_THEN ptr^ = 99) THEN....

In contrast, CODESYS always evaluates all operands when using the AND IEC operator.

See also
● “Chapter 1.3.1.24.3.10 “Operator ‘AND’ on page 513

Operator 'OR_ELSE'

This operator is an extension of the IEC 61131-3 standard.

The OR_ELSE operator is permitted only for programming in structured text: OR operation of BOOL and BIT operands; with short-circuit evaluation. This means:

When at least one of the operands yields TRUE, the result of the operation also yields TRUE; otherwise FALSE.

In contrast to using the OR IEC operator, for OR_ELSE the expressions on all other operators are not evaluated as soon as one of the operands is evaluated as TRUE.

Example

VAR
    bEver: BOOL;
    bX: BOOL;
    dw: DWORD := 16#000000FF;
END_VAR
bEver := FALSE;
bX := dw.8 OR_ELSE dw.1 OR_ELSE dw.1 OR_ELSE (bEver := TRUE);

See also
● “Chapter 1.3.1.24.3.11 “Operator ‘OR’ ” on page 514
Operator 'SHL'

This IEC operator is used for bitwise shift of an operand to the left.

\[
\text{erg} := \text{SHL} \left( \text{in}, n \right)
\]

\text{in}: \text{Operand that is shifted to the left}

\text{n}: \text{Number of bits to shift \text{in} to the left}

\begin{center}
\textbf{NOTICE!}

If \(n\) overwrites the data type width, then it depends on the target system how the \text{BYTE}, \text{WORD}, \text{DWORD}, \text{and LWORD} operands are padded. The target systems cause padding with zeros or \(n \mod \text{\text{<tab width>}}\).
\end{center}

\begin{center}
\textbf{NOTICE!}

Please note the number of bits that CODESYS uses for this operation as defined by the data type of the input variable \text{in}.
\end{center}

\textbf{Examples}

The results for \text{erg} \_ \text{byte} and \text{erg} \_ \text{word} are different, although the values of the \text{in} \_ \text{byte} and \text{in} \_ \text{word} input variables are the same and the data types of the input variables are different.

\textbf{ST}:

\begin{verbatim}
PROGRAM shl_st
VAR
  in_byte : BYTE := 16#45; (* 2#01000101 )
  in_word : WORD := 16#0045; (* 2#0000000001000101 )
  erg_byte : BYTE;
  erg_word : WORD;
  n: BYTE := 2;
END_VAR

  erg_byte := SHL(in_byte,n); (* Result is 16#14, 2#00010100 *)
  erg_word := SHL(in_word,n); (* Result is 16#0114, 2#0000000100010100 *)
\end{verbatim}

\textbf{FBD}:

\begin{center}
\begin{tikzpicture}
  \node [pin={[pin distance=1cm]below:2}, text width=0.25cm, text centered] at (0,0) {in};
  \node [text width=0.25cm, text centered] at (0.5,0) {2};
  \node [text width=0.25cm, text centered] at (1,0) {erg_byte};
  \node [text width=0.25cm, text centered] at (0.5,0.5) {\textbf{SHL}};
\end{tikzpicture}
\end{center}

Operator 'SHR'

This IEC operator is used for bitwise shift of an operand to the right.

\[
\text{erg} := \text{SHR} \left( \text{in}, n \right)
\]

\text{in}: \text{Operand that is shifted to the right}

\text{n}: \text{Number of bits for shifting \text{in} to the right}
NOTICE!
If \( n \) overwrites the data type width, then it depends on the target system how the BYTE, WORD, DWORD, and LWORD operands are padded. The target systems cause padding with zeros or \( n \) MOD <tab width>.

**Examples**

```st
PROGRAM shr_st
VAR
  in_byte : BYTE:=16#45; (* 2#01000101 *)
  in_word : WORD:=16#0045; (* 2#0000000001000101 *)
  erg_byte : BYTE;
  erg_word : WORD;
  n: BYTE :=2;
END_VAR

  erg_byte := SHR(in_byte,n); (* Result is 16#11, 2#00010001 *)
  erg_word := SHR(in_word,n); (* Result is 16#0011,
  2#0000000000010001 *)
```

**FBD:**

```
in_byte --- Shr --- erg_byte

2
```

**Operator 'ROL'**

This IEC operator is used for bitwise rotation of an operand to the left.

**Permitted data types:** BYTE, WORD, DWORD, LWORD

```st
erg := ROL (in, n)
```

CODESYS moves \( in \) n-times one bit to the left and adds the bit to the leftmost position from the right.

NOTICE!
Please note the number of bits that CODESYS uses for this operation as defined by the data type of the input variable \( in \). If this is a constant, then CODESYS uses the smallest possible data type. The data type of the output variables still does not influence this operation.
The results for `erg_byte` and `erg_word` are different depending on the data type of the input variables, although the values of the `in_byte` and `in_word` input variables are the same.

**ST:**

```plaintext
PROGRAM rol_st

VAR
  in_byte : BYTE := 16#45;
  in_word : WORD := 16#45;
  erg_byte : BYTE;
  erg_word : WORD;
  n : BYTE := 2;
END_VAR

erg_byte := ROL(in_byte, n); (* Result: 16#15 *)
erg_word := ROL(in_word, n); (* Result: 16#0114 *)
```

**FBD:**

![FBD diagram](image)

**IL:**

```
LD  in_byte
ROL n
ST  erg_byte
```

**Operator 'ROR'**

This IEC operator is used for bitwise rotation of an operand to the right.

Permitted data types: BYTE, WORD, DWORD, LWORD

```plaintext
erg := ROR(in, n)
```

CODESYS moves `in` n-times one bit to the right and adds the bit to the rightmost position from the left.

Please note the number of bits that CODESYS uses for this operation as defined by the data type of the input variable `in`. If this is a constant, then CODESYS uses the smallest possible data type. The data type of the output variables still does not influence this operation.
The results for `erg_byte` and `erg_word` are different depending on the data type of the input variables, although the values of the `in_byte` and `in_word` input variables are the same.

**ST:**

```plaintext
PROGRAM ror_st

VAR
  in_byte : BYTE := 16#45;
  in_word : WORD := 16#45;
  erg_byte : BYTE;
  erg_word : WORD;
  n: BYTE := 2;
END_VAR

erg_byte := ROR(in_byte,n); (* Result: 16#51 *)
erg_word := ROR(in_word,n); (* Result: 16#4011 *)
```

**FBD:**

![FBD diagram](image)

---

**Operator 'SEL'**

The IEC operator is used for bitwise selection.

```plaintext
OUT := SEL(G, IN0, IN1) means:
OUT := IN0; if G = FALSE
OUT := IN1; if G = TRUE
```

Permitted data types:

IN0, ..., INn and OUT: Any identical data type. Make sure that variables of the identical type are used at all three positions, especially when using user-defined data types. The compiler checks for type identity and returns any compile errors. The assignment of function block instances to interface variables is specifically not supported.

G: BOOL

---

**NOTICE!**

When G is TRUE, CODESYS does not compute an expression that precedes IN0. When G is FALSE, CODESYS does not compute an expression that precedes IN1.

Caution: In the case of graphical programming languages, the expressions at IN0 and IN1 are computed independently of the G input when a “Box”, “Jump”, “Return”, “Line Branch”, or “Edge Detection” precedes.
Examples

ST:
Var1 := SEL(TRUE, 3, 4); (* Result: 4 *)

FBD:

---

Operator 'MAX'

This IEC operator is used for the maximum function. It yields the largest value of two values.

\[
\text{OUT} := \text{MAX(IN0, IN1)}
\]

Permitted data types: all

Examples

ST:
Result: 90
Var1 := MAX(30, 40);
Var1 := MAX(40, MAX(90, 30));

FBD:
Result: 90

---

Operator 'MIN'

This IEC operator is used for the minimum function. It yields the smallest value of two values.

\[
\text{OUT} := \text{MIN(IN0, IN1)}
\]

Permitted data types: all
Examples | Result: 30
---|---
ST: | 
Var1:=MIN(90,30); 
Var1 := MIN(MIN(90,30),40); 
FBD: 

![FBD Diagram](image)

**Operator 'LIMIT'**

This IEC selection operator is used for limiting.

\[
\text{OUT} := \text{LIMIT}(\text{Min}, \text{IN}, \text{Max})
\]

**Means:** \(\text{OUT} := \text{MIN} (\text{MAX} (\text{IN}, \text{Min}), \text{Max})\)

Max is the upper limit and Min is the lower limit for the result. If the IN value is above the Max upper limit, then LIMIT yields Max. If the value of IN is below the Min lower limit, then the result is Min.

Permitted data types for IN and OUT: all

Examples | Result in Var1 is 80
---|---
ST: | 
Var1 := LIMIT(30,90,80); 

**Operator 'MUX'**

This IEC operator is used as a multiplexer.

\[
\text{OUT} := \text{MUX}(\text{K}, \text{IN0}, \ldots, \text{INn})
\]

**Means:** \(\text{OUT} = \text{IN}_K\)

Permitted data type for K: BYTE, WORD, DWORD, LWORD, SINT, USINT, INT, UINT, DINT, LINT, ULINT, OUDINT.

IN0, ..., INn, and OUT: Any identical data type. Make sure that variables of the identical type are used at all three positions, especially when using user-defined data types. The compiler checks for type identity and returns any compile errors. The assignment of function block instances to interface variables is specifically not supported.

MUX selects the K-th value from a set of values. The first value is K=0. If K is greater than the number of other inputs (n), then CODESYS passes on the last value (INn).

**NOTICE!**

For runtime optimization, CODESYS computes only the expression that precedes \(\text{IN}_K\). However, CODESYS computes all branches in simulation mode.
### Examples

Result in \( \text{Var1} \) is 30.

**ST:**

\[ \text{Var1} := \text{MUX}(0, 30, 40, 50, 60, 70, 80); \]

### Operator 'GT'

This IEC operator is used for the "greater than" function.

Permitted data types of the operands: any basic data type.

If the first operand is greater than the second operand, then the operator yields the result **TRUE**; otherwise **FALSE**.

**Examples**

Result: **FALSE**

**ST:**

\[ \text{VAR1} := 20 > 30; \]

**FBD:**

![FBD diagram for GT](image)

### Operator 'LT'

This IEC operator is used for the "less than" function.

Permitted data types of the operands: any basic data type.

If the first operand is less than the second operand, then the operator yields the result **TRUE**; otherwise **FALSE**.

**Examples**

Result: **TRUE**

**ST:**

\[ \text{Var1} := 20 < 30; \]

**FBD:**

![FBD diagram for LT](image)

### Operator 'LE'

This IEC operator is used for the "less than or equal to" function.

Permitted data types of the operands: any basic data type.

If the first operand is less than or equal to the second operand, then the operator yields the result **TRUE**; otherwise **FALSE**.
Examples

Result in Var1: TRUE

ST:
Var1 := 20 <= 30;

Operator 'GE'

This IEC operator is used for the "greater than or equal to" function.
Permitted data types of the operands: any basic data type.
If the first operand is greater than or equal to the second operand, then the operator yields the result TRUE; otherwise FALSE.

Examples

Result: TRUE

ST:
VAR1 := 60 >= 40;

Operator 'EQ'

This IEC operator is used for the "equals" function.
Permitted data types of the operands: any basic data type, depending on target system and compiler version: structure data type.
If the operands are equal, then then the operator yields the result TRUE, otherwise FALSE.

Examples

Result: TRUE

ST:
VAR1 := 40 = 40;

Operator 'NE'

This IEC operator is used for the "does not equal" function.
Permitted data types of the operands: any basic data type, depending on target system and compiler version: structure data type.
If the operands are not equal, then the operator yields the result **TRUE**; otherwise **FALSE**.

If the target system supports the data type, then as from compiler version >= 3.5.7.0 also operands of type **STRUCT** (structure) can be compared. Example: IF (stStruct1 := stStruct2) THEN....

### Examples

**Result in Var1 is FALSE**

**ST:**

Var1 := 40 <> 40;

**FBD:**

![Diagram of Var1]

---

### Operator ‘ADR’

This operator is an extension of the IEC 61131-3 standard.

ADR yields the address of its argument in a **DWORD**. You can pass this address to the manufacturer functions or assign them to a pointer in the project.

---

**NOTICE!**

As opposed to CoDeSys V2.3, you can use the ADR operator with function names, program names, function block names, and method names. Therefore, **ADR** replaces the **INDEXOF** operator. When using function pointers, please note that you can pass a function pointer to external libraries, but it is not possible to call a function pointer from within CODESYS. To enable a system call (runtime system), you must set the respective object property (**Build** tab) for the function object.

---

**CAUTION!**

When you apply an online change, address contents can shift, causing **POINTER** variables to reference invalid memory ranges. To avoid problems, make sure that CODESYS updates pointer values in every cycle.

---

**CAUTION!**

Do not return **Pointer-TO** variables of functions and methods to the caller or assign them to global variables.

### Examples

**ST:**

`dwVar := ADR(bVAR);`

---

### Operator ‘Content Operator’

This operator is an extension of the IEC 61131-3 standard.

You can use this operator to dereference pointers by appending the operator as `^` to the pointer identifier.
CAUTION!
When using pointers to addresses, please note that applying an online change can shift address contents.

Example

ST:

```
pt : POINTER TO INT;
var_int1 : INT;
var_int2 : INT;
pt := ADR(var_int1);
var_int2 := pt^;
```

Operator 'BITADR'

This operator is an extension of the IEC 61131-3 standard.

```
BITADR yields the bit offset within a segment in a DWORD.
```

NOTICE!
The offset depends on whether the byte addressing check box is selected or cleared in the target system settings.

The highest value nibble (4 bits) in this DWORD defines the memory range:

- **Flag:** 16x40000000
- **Input:** 16x80000000
- **Output:** 16xC0000000

CAUTION!
When using pointers to addresses, please note that applying an online change can shift address contents.

Examples

ST:

```
VAR
  Var1 AT %IX2.3 : BOOL;
  bitoffset: DWORD;
END_VAR

bitoffset := BITADR(var1); (* Result if byte addressing = TRUE: 16x80000013, if byte addressing = FALSE: 16x80000023 *)
```

Operator 'CAL'

This IEC operator is used for calling function blocks.

In IL, **CAL** calls the instance of a function block.

```
CAL <function block> (<input variable1> := <value>, <input variableN> := <value>)
```
Example

Call of the \texttt{Inst} instance of a function block with assignment of the input variables \texttt{Par1} and \texttt{Par2} with 0 or \textsc{true}.

\texttt{CAL Inst(Par1 := 0, Par2 := \textsc{true});}

---

**Operator ‘BOOL\_TO’**

The IEC operator is used for converting the \texttt{BOOL} data type to another data type.

\texttt{BOOL\_TO\_<data\ type>}

For number types the result is 1, when the operand is \textsc{true}, and 0, when the operand is \textsc{false}.

For the \texttt{STRING} data type, the result is \textsc{true} or \textsc{false}.

\begin{itemize}
  \item \textbf{NOTICE!} If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from \texttt{LREAL} to \texttt{DINT} is \textsc{negative}.
\end{itemize}

---

**Examples**

<table>
<thead>
<tr>
<th>ST code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{i := BOOL_TO_INT(TRUE);}</td>
<td>1</td>
</tr>
<tr>
<td>\texttt{str := BOOL_TO_STRING(TRUE);}</td>
<td>\textsc{true}</td>
</tr>
<tr>
<td>\texttt{t := BOOL_TO_TIME(TRUE);}</td>
<td>T#1ms</td>
</tr>
<tr>
<td>\texttt{tof := BOOL_TO_TOD(TRUE);}</td>
<td>TOD#00:00:00.001</td>
</tr>
<tr>
<td>\texttt{dat := BOOL_TO_DATE(FALSE);}</td>
<td>D#1970</td>
</tr>
<tr>
<td>\texttt{dandt := BOOL_TO_DT(TRUE);}</td>
<td>DT#1970-01-01-00:00:01</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>FBD code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRUE – \texttt{BOOL_TO_INT} – i</td>
<td>1</td>
</tr>
<tr>
<td>TRUE – \texttt{BOOL_TO_STRING} – str</td>
<td>\textsc{true}</td>
</tr>
<tr>
<td>TRUE – \texttt{BOOL_TO_TIME} – t</td>
<td>T#1ms</td>
</tr>
<tr>
<td>TRUE – \texttt{BOOL_TO_TOD} – tof</td>
<td>TOD#00:00:00.001</td>
</tr>
<tr>
<td>FALSE – \texttt{BOOL_TO_DATE} – t</td>
<td>D#1970-01-01</td>
</tr>
<tr>
<td>TRUE – \texttt{BOOL_TO_DT} – dandt</td>
<td>DT#1970-01-01-00:00:01</td>
</tr>
</tbody>
</table>
Operator 'TO_BOOL'

The IEC operator is used for converting from another variable type into a BOOL variable.

_<data type>_TO_BOOL

The result yields TRUE when the operand does not equal 0. The result yields FALSE when the operand equals 0.

For the STRING type, the result is true if the operand is TRUE; otherwise it is FALSE.

**NOTICE!**
If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from LREAL to DINT is negative.

### Examples

<table>
<thead>
<tr>
<th>ST code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>b := BYTE_TO_BOOL(2#11010101);</td>
<td>TRUE</td>
</tr>
<tr>
<td>b := INT_TO_BOOL(0);</td>
<td>FALSE</td>
</tr>
<tr>
<td>b := TIME_TO_BOOL(T#5ms);</td>
<td>TRUE</td>
</tr>
<tr>
<td>b := STRING_TO_BOOL('TRUE');</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>FBD code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE_TO_BOOL</td>
<td>TRUE</td>
</tr>
<tr>
<td>INT_TO_BOOL</td>
<td>FALSE</td>
</tr>
<tr>
<td>TIME_TO_BOOL</td>
<td>TRUE</td>
</tr>
<tr>
<td>STRING_TO_BOOL</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

See also

- **“Type conversion operators” on page 508**

Operator 'TO_<xxx>,'

The IEC operator is used for converting variables of one data type into another data type, where the input type is not explicitly given (overflow conversion).

<data type>_TO_<data type>

The function depends on what is described for each typed conversion.
NOTICE!
If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from LREAL to DINT is negative.

Examples

ST implementation language:

```st
VAR
  iVar : INT;
  bVar : BOOL;
  sVar : STRING;
  rVar : REAL;
END_VAR
iVar := TO_INT(4.22);            (* Result:  4 *)
bVar := TO_BOOL(1);            (* Result: TRUE *)
sVar := TO_STRING(342);        (* Result: '342' *)
rVar := TO_WORD('123');        (* Result: 123 *)
```

See also
● “Type conversion operators” on page 508

Operator `<INT Type>_TO_<INT Type>`

Conversion of one integer data type into another integer data type.
`<INT data type>_TO_<INT data type>`

NOTICE!
Information can be lost when converting from larger data types to smaller data types. If the number to be converted exceeds the range limit, then CODESYS ignores the first bytes of the number.

NOTICE!
If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from LREAL to DINT is negative.

Examples

Result in si:127

ST:
  si := INT_TO_SINT(4223);
If you save the integer 4223 (16#107f in hexadecimal notation) as a SINT variable, then this variable is assigned the value 127 (16#7f in hexadecimal notation).

FBD:
Operator 'REAL_TO_/ LREAL_TO'  

The IEC operator is used for converting the REAL and LREAL data types into another data type.

```plaintext
REAL_TO_<data type>  
LREAL_TO_<data type>
```

CODESYS rounds the real value of the operand up or down to an integer value and then converts it into the respective type. Exceptions are the STRING, BOOL, REAL, and LREAL data types.

**NOTICE!**  
The rounding logic for borderline cases depends on the target system or the FPU (Floating Point Unit) of the target system. For example, a value of −1.5 can be converted differently on different controllers.

**NOTICE!**  
When converting data types from REAL or LREAL into SINT, USINT, INT, UINT, DINT, UDINT, LINT, or ULINT, if the value of the REAL/LREAL number is outside the value range of the integer, then you will receive an undefined result depending on the target system. Then an exception is also possible. To get code that is independent of the target system, you must use the application to catch value range overflows. If the REAL/LREAL number is within the range, then the conversion operates the same way on all systems.

When converting the STRING type, note that the total length of the decimal number is limited to 16 characters. If the (L)REAL number has more decimal places, then the sixteenth place is rounded and represented as a string. If the STRING is defined too short for the number, then CODESYS truncates it from the right.

**NOTICE!**  
Information can be lost when converting from larger data types to smaller data types.

**NOTICE!**  
If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from LREAL to DINT is negative.
Examples

<table>
<thead>
<tr>
<th>ST code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>i := REAL_TO_INT(1.5);</td>
<td>2</td>
</tr>
<tr>
<td>j := REAL_TO_INT(1.4);</td>
<td>1</td>
</tr>
<tr>
<td>i := REAL_TO_INT(-1.5);</td>
<td>-2</td>
</tr>
<tr>
<td>j := REAL_TO_INT(-1.4);</td>
<td>-1</td>
</tr>
</tbody>
</table>

FBD code

- “Type conversion operators” on page 508

Operator 'TIME_TO/TIME_OF_DAY_TO'

The IEC operator is used for converting the TIME and TIME_OF_DAY data types into another data type.

<TIME data type>_TO_<data type>

Internally, CODESYS saves the time (in milliseconds) to a DWORD (for TIME_OF_DAY since 00:00). CODESYS converts this value.

For the STRING data type, the result is the time constant.

NOTICE!

Information can be lost when converting from larger data types to smaller data types.

NOTICE!

If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from LREAL to DINT is negative.
### Examples

<table>
<thead>
<tr>
<th>ST code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>str := TIME_TO_STRING(T#12ms);</code></td>
<td>T#12ms</td>
</tr>
<tr>
<td><code>dw := TIME_TO_DWORD(T#5m);</code></td>
<td>300000</td>
</tr>
<tr>
<td><code>si := TOD_TO_SINT(TOD#00:00:00.012);</code></td>
<td>12</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

### Operator ‘DATE_TO/DT_TO’

The IEC operator is used for converting the `DATE` and `DATE_AND_TIME` data types into another data type.

`<DATE data type>_TO_<data type>`

Internally, CODESYS saves the date in a `DWORD` (in seconds since 01 January 1970). CODESYS converts this value.

For the `STRING` data type, the result is the date constant.

**NOTICE!**

Information can be lost when converting from larger data types to smaller data types.

**NOTICE!**

If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from `LREAL` to `DINT` is negative.
Examples

<table>
<thead>
<tr>
<th>ST code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>b := DATE_TO_BOOL(D#1970-01-01);</td>
<td>FALSE</td>
</tr>
<tr>
<td>i := DATE_TO_INT(D#1970-01-15);</td>
<td>29952</td>
</tr>
<tr>
<td>i := DT_TO_BYTE(DT#1970-01-15-05:05:05);</td>
<td>129</td>
</tr>
<tr>
<td>str := DT_TO_STRING(DT#1998-02-13-14:20);</td>
<td>DT#1998-02-13-14:20</td>
</tr>
</tbody>
</table>

FBD code

<table>
<thead>
<tr>
<th>FBD code</th>
<th>Result</th>

<td>DT#1998-02-13-14:20</td>
</tr>
</tbody>
</table>

See also
- ☑ “Type conversion operators” on page 508

Operator ‘STRING_TO’

The IEC operator is used for converting the STRING data type into another data type.

**STRING_TO_.<data type>**

You must define the STRING operand according to the IEC 61131-3 standard. The value has to be a valid constant (literal) of the target type. This affects any given exponential values, infinite values, prefixes, grouping characters (.), and commas. Additional characters after the digits of a number are permitted (for example, 23xy). Additional characters before a number are not permitted.

The operand must be a valid value of the target data type.

**NOTICE!**

If the data type of the operand does not match the target data type or if the value is outside the range of the target data type, then the result output depends on the processor type and is therefore undefined. Information can be lost when converting from larger data types to smaller data types.
NOTICE!
If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from LREAL to DINT is negative.

| Examples |
|-----------------|----------------|
| **ST code**     | **Result**     |
| b := STRING_TO_BOOL('TRUE'); | TRUE         |
| w := STRING_TO_WORD('abc34'); | 0            |
| w := STRING_TO_WORD('34abc'); | 34           |
| t := STRING_TO_TIME('T#127ms'); | T#127ms     |
| r := STRING_TO_REAL('1.234'); | 1,234        |
| bv := STRING_TO_BYTE('500'); | 244          |

<table>
<thead>
<tr>
<th>FBD code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="STRING_TO_BOOL" /></td>
<td>TRUE</td>
</tr>
</tbody>
</table>

See also
- ☞ “Type conversion operators” on page 508

Operator 'TRUNC'
The IEC operator is used for converting the REAL data type into the DINT data type. CODESYS takes only the integer part of the number.

In CoDeSys V2.3, the TRUNC operator converts REAL into INT. If you import a V2.3 project, then CODESYS automatically replaces TRUNC with TRUNC_INT.

If CODESYS cannot represent the input value by a DINT or INT, then the result of this function is undefined. The behavior of such input values is platform-dependent.

NOTICE!
If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from LREAL to DINT is negative.

- “Type conversion operators” on page 508

Operator 'TRUNC_INT'

The IEC operator is used for converting the REAL data type into the INT data type. CODESYS takes only the integer part of the number.

TRUNC_INT corresponds to the TRUNC operator in CoDeSys V2.3, and it is used automatically at this point when importing V2.3 projects. Note the change function of TRUNC.

If CODESYS cannot represent the input value by a DINT or INT, then the result of this function is undefined. The behavior of such input values is platform-dependent.

NOTICE!

If the input value of a type conversion operator is outside the value range of the output data type, then the result of the operation is undefined and dependent on the platform. This is the case, for example, if the input value for the conversion from LREAL to DINT is negative.

Examples

Result in iVar: 1

ST:

iVar := TRUNC_INT(1.9); (* Result: 1 *)
iVar := TRUNC_INT(-1.4); (* Result: -1 *)

- “Type conversion operators” on page 508

Operator 'ABS'

This IEC operator yields the absolute value of a number.

Permitted data types for input and output variables and numeric constants: any numeric basic data type

Examples

Result in i: 2

ST:

i := ABS(-2);

FBD:

Operator 'SQRT'

This IEC of course yields the square root of a number.

Permitted data types for input variables: any numeric basic data type
Permitted data types for output variables: REAL or LREAL

Examples

Result in q: 4

ST:

```
q := SQRT(16);
```

FBD:

Operator 'LN'

This IEC operator yields the natural logarithm of a number.
Permitted data types for input variables: any numeric basic data type
Permitted data types for output variables: REAL and LREAL

Examples

Result: 3.80666

ST:

```
q := LN(45);
```

FBD:

Operator 'LOG'

This IEC operator yields the base-10 logarithm of a number.
The input variable can be any numeric basic data type, but the output variable must be the data type REAL or LREAL.

Examples

Result in q: 2.49762

ST:

```
q := LOG(314.5);
```

FBD:

Operator 'EXP'

This IEC operator yields the exponential function.
Permitted data types for input variables: any numeric basic data type
Permitted data types for output variables: REAL and LREAL
### Example

**Power function with literals**

Var1 := EXPT(7,2);

FBD:

```
  EXPT

```

Return value: Var1 = 49

---

### Example

**Power function with variables**

PROGRAM PLC_PRG
VAR
  lrPow : LREAL;
  iBase : INT := 2;
  iExponent : INT := 7;
END_VAR

lrPow := EXPT(iBase, iExponent);

Return value: lrPow = 128

---

### Operator 'EXPT'

This IEC operator raises a number to a higher power and returns the power of the base raised to the exponent: \( \text{power} = \text{base}^{\text{exponent}} \). The input values (parameters) are the base and the exponent. The power function is undefined if the base is zero and the exponent is negative. However, the behavior depends on the platform in this case.

Syntax:

\[
\text{EXPT}(<\text{base}>,<\text{exponent}>)
\]

Permitted data types for the input values: Numeric base data types (SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, LREAL, BYTE, WORD, DWORD, and LWORD)

Permitted data types for the return value: Floating-point number types (REAL and LREAL)

---

### Operator 'SIN'

This IEC operator yields the sine value of a number.

Permitted data types for input variables that measure the angle in radians: any numeric basic data type

Permitted data types for output variables: REAL and LREAL

---

Result in q: 7.389056099

ST:

\[ q := \text{EXP}(2); \]

FBD:

```
  EXP

```

2 \rightarrow q

Examples
### Operator 'COS'

This IEC operator yields the cosine value of a number.

Permitted data types for input variables that measure the angle in radians: any numeric basic data type

Permitted data types for output variables: \texttt{REAL} and \texttt{LREAL}

**Examples**

Result in \( q \): 0.479426

ST:

\[
q := \text{SIN}(0.5);
\]

FBD:

![SIN block](image)

**Examples**

Result in \( q \): 0.877583

ST:

\[
q := \text{COS}(0.5);
\]

FBD:

![COS block](image)

### Operator 'TAN'

This IEC operator yields the tangent value of a number.

Permitted data types for input variables that measure the angle in radians: any numeric basic data type

Permitted data types for output variables: \texttt{REAL} and \texttt{LREAL}

**Examples**

Result in \( q \): 0.546302

ST:

\[
q := \text{TAN}(0.5);
\]

FBD:

![TAN block](image)

### Operator 'ASIN'

This IEC operator yields the arcsine value of a number.

Permitted data types for input variables: any numeric basic data type

Permitted data types for output variables: \texttt{REAL} and \texttt{LREAL}
Examples

Result in q: 0.523599

ST:
q := ASIN(0.5);

FBD:

Operator 'ACOS'

This IEC operator yields the arccosine value of a number. The value is computed in radians.
Permitted data types for input variables that measure the angle in radians: any numeric basic data type
Permitted data types for output variables: REAL and LREAL

Examples

Result in q: 1.0472

ST:
q := ACOS(0.5);

FBD:

Operator 'ATAN'

This IEC operator yields the arctangent value of a number. The value is computed in radians.
Permitted data types for input variables that measure the angle in radians: any numeric basic data type
Permitted data types for output variables: REAL and LREAL

Examples

Result in q: 0.463648

ST:
q := ATAN(0.5);

FBD:

Operator '__DELETE'

This operator is an extension of the IEC 61131-3 standard.
NOTICE!
For compatibility, the compiler version must be >= 3.3.2.0.

The operator releases the memory of instances that the "__NEW" operator generated dynamically. The __DELETE operator does not have a return value and the operand is set to zero after this operation.

Requirement: In the properties dialog of the application, the “Use dynamic memory allocation” check box is selected in the “Application Build Options” tab.

__DELETE (<pointer>)

NOTICE!
Two tasks should not call __DELETE simultaneously. Either you use a semaphore (SysSemEnter) or comparable method to prevent any concurrent calling of __DELETE, or you use __DELETE in one tasks only (recommended).

You can use a semaphore (SysSemEnter) to prevent two tasks from allocating memory at the same time. As a consequence, the extensive use of __DELETE causes higher jitter.

If Pointer references a function block, then CODESYS calls the associated FB_EXIT method before the pointer is set to zero.
FUNCTION_BLOCK FBDynamic

VAR_INPUT
  in1, in2 : INT;
END_VAR

VAR_OUTPUT
  out : INT;
END_VAR

VAR
  test1 : INT := 1234;
  _inc : INT := 0;
  _dut : POINTER TO DUT;
  neu : BOOL;
END_VAR

out := in1 + in2;

METHOD FB_Exit : BOOL

VAR_INPUT
  bInCopyCode : BOOL;
END_VAR

__Delete(_dut);

METHOD FB_Init : BOOL

VAR_INPUT
  bInitRetains : BOOL;
  bInCopyCode : BOOL;
END_VAR

_dut := __NEW(DUT);

METHOD INC : INT

VAR_INPUT
END_VAR

_inc := _inc + 1;
INC := _inc;

PLC_PRG(PRG)

VAR
  pFB : POINTER TO FBDynamic;
  bInit: BOOL := TRUE;
  bDelete: BOOL;
  loc : INT;
END_VAR

IF (bInit) THEN
  pFB := __NEW(FBDynamic);
  bInit := FALSE;
END_IF
IF (pFB <> 0) THEN
    pFB^.(in1 := 1, in2 := loc, out => loc);
    pFB^.INC();
END_IF

IF (bDelete) THEN
    __DELETE(pFB);
END_IF

Operator ‘__ISVALIDREF’

This operator is an extension of the IEC 61131-3 standard.

The operator is used for checking whether a reference refers to a valid value. For a description of use and an example, refer to the description for the REFERENCE data type.

See also
- § Chapter 1.3.1.24.5.13 “Reference” on page 579

Operator ‘__NEW’

The operator is an extension of the IEC 61131-3 standard.

The __NEW operator reserves dynamic memory to instantiate function blocks, user-defined data types, or arrays of standard types. The operator returns a matching typed pointer.

Requirement: In the properties dialog of the parent application, on the “Application Build Options” tab, the “Use dynamic memory allocation” option is selected.

Syntax

<pointer name> := __NEW( <type> ( , <size> )? );
__DELETE( <pointer name> );

<type> : <function block> | <data unit type> | <standard data type>

The operator generates an instance of the type <type> and returns a pointer to this instance. Then the initialization of the instance is called. If <type> is a scalar standard data type, then the optional operand <size> is also evaluated. Then the operator generates an array of type <standard data type> and size <size>. If the attempt to allocate memory fails, then __NEW returns the value 0.

Use the operator within the assignment ":=". Otherwise an error message is displayed.

A function block or a user-defined data type whose instance is created dynamically with __NEW uses a fixed memory area. Here it is required that you mark the objects with the pragma (attribute 'enable_dynamic_creation'). It is not required for function blocks that are part of a library.

If you change the data layout of the function block in online mode, then you cannot execute a login with an online change afterwards. This is because the memory area of the function block instance has been invalidated. You change the data layout when you add new variables to the function block, delete existing variables, or change the data types of variables.
Example

Array (DWORD):

```plaintext
PROGRAM PLC_PRG
VAR
  pdwScalar : POINTER TO DWORD; // Typed pointer
  xInit : BOOL := TRUE;
  xDelete : BOOL;
END_VAR

IF (xInit) THEN
  pdwScalar := __NEW(DWORD, 16); // Allocates memory (16 dwords) and assigns them to pointer pdwScalar
END_IF
IF (xDelete) THEN
  __DELETE(pdwScalar); // Frees memory of pointer
END_IF
```

Function block:

```plaintext
{attribute 'enable_dynamic_creation'}
FUNCTION_BLOCK FBComputeGamma
VAR_INPUT
  iAlpha : INT;
  iBeta : INT;
END_VAR
VAR_OUTPUT
  iGamma : INT;
END_VAR
VAR
END_VAR

iGamma := iAlpha + iBeta;
```

User-defined data type (DUT):

```plaintext
{attribute 'enable_dynamic_creation'}
TYPE ABCDATA :
  STRUCT
    iA, iB, iC, iD : INT;
  END_STRUCT
END_TYPE

PROGRAM PLC_PRG
VAR
  pABCDData : POINTER TO ABCDATA; // Typed pointer
  xInit : BOOL := TRUE;
END_VAR
```
PROGRAM PLC_PRG
VAR
pbDataAlpha : POINTER TO BYTE;
pDataBeta : POINTER TO BYTE;
xInit : BOOL := TRUE;
xDelete : BOOL;
usiCnt : USINT;
bTestC: BYTE;
END_VAR

IF (xInit) THEN
    pbDataAlpha := __NEW(BYTE, 16); // Allocates 16 bytes for pbDataAlpha
    pDataBeta := __NEW(BYTE); // Allocates memory for pDataBeta
    xInit := FALSE;
    FOR usiCnt := 0 TO 15 DO
        pbDataAlpha[usiCnt] := usiCnt; // Writes to new array
    END_FOR
    pDataBeta^:= 16#FF; // Writes to new data
END_IF

bTestC := pbDataAlpha[12]; // Reads new array by index access

IF (xDelete) THEN // Frees memory
    ___DELETE(pbDataAlpha);
    ___DELETE(pDataBeta);
END_IF

Array (BYTE):

NOTICE!

We do not recommend the simultaneous execution of two tasks that both call the __NEW operator. You use either a semaphore (SysSemEnter) or a comparable technique to prevent a concurrent call of __NEW. However, this results in a higher jitter when __NEW is applied extensively.

We recommend that you call __NEW operators in one task only.

Operator '__QUERYINTERFACE'

This operator is an extension of the IEC 61131-3 standard.

At runtime, the operator executes a type conversion of an interface reference into another type. The operator returns a BOOL result. TRUE means that CODESYS has performed the conversion successfully.

__QUERYINTERFACE(<ITF_Source>,<ITF_Dest>);

1. Operand: Interface reference or FB interface
2. Operand: Interface reference with required target type

The requirement for the explicit conversion is that both the ITF_Source and ITF_Dest are derived from Interface __System.IQueryInterface. This interface is implicitly available does not require a library.
Example

INTERFACE ItfBase EXTENDS __System.IQueryInterface
METHOD mbase : BOOL
END_METHOD

INTERFACE ItfDerived1 EXTENDS ItfBase
METHOD mderived1 : BOOL
END_METHOD

INTERFACE ItfDerived2 EXTENDS ItfBase
METHOD mderived2 : BOOL
END_METHOD

FUNCTION_BLOCK FB1 IMPLEMENTS ItfDerived1
METHOD mbase : BOOL
mbase := TRUE;
END_METHOD
METHOD mderived1 : BOOL
mderived1 := TRUE;
END_METHOD
END_FUNCTION_BLOCK

FUNCTION_BLOCK FB2 IMPLEMENTS ItfDerived2
METHOD mbase : BOOL
mbase := FALSE;
END_METHOD
METHOD mderived2 : BOOL
mderived2 := TRUE;
END_METHOD
END_FUNCTION_BLOCK

PROGRAMM POU
VAR
inst1 : FB1;
inst2 : FB2;
itfbase1 : ItfBase := inst1;
itfbase2 : ItfBase := inst2;
itfderived1 : ItfDerived1 := 0;
itfderived2 : ItfDerived2 := 0;
xResult1, xResult2, xResult3, xResult4: BOOL;
END_VAR

xResult1 := __QUERYINTERFACE(itfbase1, itfderived1); // xResult = TRUE, itfderived1 <>0
                  // references
the instance inst1
xResult2 := __QUERYINTERFACE(itfbase1, itfderived2); // xResult = FALSE, itfderived2 = 0
xResult3 := __QUERYINTERFACE(itfbase2, itfderived1); // xResult = FALSE, itfderived1 = 0
xResult4 := __QUERYINTERFACE(itfbase2, itfderived2); // xResult = TRUE, itfderived2 <> 0
                  // references
the instance inst2

Operator '___QUERYPOINTER'
This operator is an extension of the IEC 61131-3 standard.
At runtime, the operator makes it possible to convert the type of an interface reference of a function block to a pointer. The operator returns a BOOL result. TRUE means that CODESYS has performed the conversion successfully.

**NOTICE!**

For compatibility, the definition of the pointer to be converted must be an extension of the base interface "__SYSTEM.IQueryInterface".

`__QUERYPOINTER (<ITF_Source>, <Pointer_Dest>)`

The operator receives an interface reference or a FB instance with the required target types as the first operand and a pointer as the second operand. After processing `__QUERYPOINTER`, Pointer_Dest receives the pointer to the reference or instance of a function block that the ITF_Source interface reference currently refers to. Pointer_Dest is not typed and can be cast to any type. You have to make sure of the type. For example, the interface could offer a method that returns a type code.

**Operators '__TRY', '__CATCH', '__FINALLY', '__ENDTRY'**

These operators are extended from the IEC 61131-3 standard and they are used for specific exception handling in IEC code.

**Syntax**

```
__TRY
  <statements_try>
__CATCH(exec)
  <statements_catch>
__FINALLY
  <statements_finally>
__ENDTRY
  <statements_next>
```

When a statement in the __Try operator throws an exception, the application does not stop. Instead, the application executes the statements in __Catch, starts the exception handling, and then executes the statements in __FINALLY. The exception handling ends with __ENDTRY, and the application executes the subsequent statements.

An IEC variable for an exception has the data type `__System.ExceptionCode`. 

---

PLC Automation with V3 CPUs
Programming with IEC 61131-3 editor > CODESYS Development System

2020/12/10

3ADR010583, 1, en_US

546
If the statement in \_TRY throws an exception, then program execution is not stopped. Instead, the statement in \_CATCH is executed. Therefore, in this example, the application executes the exc function, then the statement in \_FINALLY, and finally the statement in \_ENDTRY.

FUNCTION Tester : UDINT
VAR_INPUT
  count : UDINT;
END_VAR
VAR_OUTPUT
  strExceptionText : STRING;
END_VAR
VAR
  exc : __SYSTEM.ExceptionCode;
END_VAR
\_TRY
  Tester := tryFun(count := count, testcase := g_testcase);  // This statement is tested. If it throws an exception, then the statement in \_CATCH is executed first, and then the statement in \_FINALLY.
  \_CATCH(exc)
    HandleException(exc, strExceptionText => strExceptionText);
  \_FINALLY
    GVL.g_count := GVL.g_count + 2;
\_ENDTRY

) UDINT ;
END_TYPE

Operator ‘__VARINFO’

This operator is an extension of the IEC 61131-3 standard.
The operator yields information about a variable. You can save the information as data structure in a variable of data type __SYSTEM.VAR_INFO.

Syntax in the declaration:

<name of the info variable> : __SYSTEM.VAR_INFO; // Data structure for info variable

Syntax for the call:

<name of the info variable> := __VARINFO( <variable name> ); // Call of the operator
FUNCTION_BLOCK FB_Velocity
VAR_INPUT
  rVelocity: REAL := 1.2;
END_VAR
VAR_OUTPUT
END_VAR
VAR
  infoVelocity: __SYSTEM.VAR_INFO; //Info of Velocity
END_VAR

infoVelocity := __VARINFO(rVelocity); // Gets the info of Velocity locally

PROGRAM PLC_PRG
VAR
  iCounter : INT := 0; // Counts the calls
  infoCounter : __SYSTEM.VAR_INFO; //Info of Counter
  arrA : ARRAY [1..2, 1..2, 1..2] OF INT := [0, 1, 2, 3, 4, 5, 6, 7]; // Stores the A data
  infoA : __SYSTEM.VAR_INFO; //Info of A
  fbVel : FB_Velocity;
END_VAR

iCounter := iCounter + 1;
infoCounter := __VARINFO(iCounter);
infoA := __VARINFO(arrA);
fbVel();

The iCounter and arrA variables are recognized in the application code. The variable information is saved in the infoCounter and infoA variables. Moreover, the FB_Velocity function block is instantiated.

---

**Operator '__CURRENTTASK'**

This operator is an extension of the IEC 61131-3 standard.

In runtime mode, the operator provides information about the IEC task that is currently running.

The operator is supported only on target systems in which the target system setting memory-layout\max-stack-size is set to a value > 0.

The operator allows for access to a structure with two variables:

- **TaskIndex**: Zero-based index that identifies the task
- **pTaskInfo**: Detailed information about the currently running task. It can be assigned to a POINTER TO Task_Info2 from the library CmpIecTask.

The operator cannot be used in the declaration of a POU. This would result in an error message. If the current task cannot be determined, then the TaskIndex -1 and the pTaskInfo are zero.
Example

//Declaration
VAR
   idx : INT;
   pInfo : POINTER TO Task_Info2;
END_VAR

//Program code
idx := __CURRENTTASK.TaskIndex;
pInfo := __CURRENTTASK.pTaskInfo;

Operator '__COMPARE_AND_SWAP

The multicore operator is an extension of the IEC 61131-3 standard.
The operator can be used for implementing a semaphore, for example to guarantee exclusive access to a variable written to by different tasks.

__COMPARE_AND_SWAP gets a pointer to a data type __XWORD variable, an old value, and a new value as its input (example: bMutex := __COMPARE_AND_SWAP(ADR(dwSynch), dwOld, dwNew)); The old and new values can also be data type __XWORD variables. The referenced __XWORD variable is compared with the old value and if both are equal, then the new value is written. The result of the function is TRUE when the new value could be written.

The compiler automatically replaces the data type __XWORD with DWORD on 32-bit systems and LWORD on 64-bit systems.

This operation is atomic, so it cannot be interrupted by another task, even on multicore platforms.
Example

The following example shows a typical usage. Exclusive access to a type STRING variable, which is addressed via the pstrOutput pointer, should be implemented.

The access to a string is not atomic. If multiple tasks write to the same string at the same time, then the contents may be inconsistent.

With this function, it is now possible to write the same STRING variable in different tasks.

```plaintext
FUNCTION ExclusiveStringWrite : BOOL
VAR_INPUT
    strToWrite : STRING;
    pstrOutput : POINTER TO STRING;
END_VAR
VAR_STAT
    dwSynch : __XWORD;
END_VAR
VAR
    bMutex: BOOL;
END_VAR

bMutex:= __COMPARE_AND_SWAP(ADR(dwSynch), 0, 1); (* compare with 0 and write 1 as atomic operation *)
IF bMutex THEN                         // bMutex is TRUE if write could be done
    pstrOutput^ := strToWrite;         // Now you can write safely on the string
    dwSynch := 0;                      // The __XWORD variable must be reset.
    ExclusiveStringWrite := TRUE;      // Writing was successful
ELSE
    ExclusiveStringWrite := FALSE;     // Writing was not successful
END_IF
```

See also

- ¶ Chapter 1.3.1.24.3.66 “Operator 'TEST_AND_SET’” on page 554

Operator ‘__XADD’

The multicore operator is an extension of the IEC 61131-3 standard.

The operator can be used for implementing an atomic counter. If an integer variable is incremented by means of ordinary addition, for example `iTest := iTest + 1;`, then this operation is not executed atomically. Another access to the variable could take place between reading and writing the variable.

If the counter is incremented in multiple tasks, then the counter result can be less than the number of counting cycles. So if two tasks execute the above code one time and the variable previously had the value 0, then the variable can then have the value 1. This is especially problematic if arrays are being processed in multiple tasks and a unique index is required for the array in each processing cycle.

When the __XADD operator is called, it gets a pointer to a type DINT variable as the first summand and a type DINT value as the second summand. __XADD returns the old value of the first summand and in the same step adds the second summand to the first summand.

For example, the function call can look like this: `diOld := __XADD(ADR(diVar), deAdd);`
The following example shows a typical usage. An array should be populated from two tasks. In the process, all positions in the array should be used and no position should be overwritten. With this function, multiple tasks can populate a Boolean array.

```plaintext
FUNCTION WriteToNextArrayPosition : BOOL
VAR_EXTERNAL
  g_diIndex : DINT;  // Index and array are globally defined and used by multiple tasks
  g_boolArray : ARRAY [0..1000] OF BOOL;
END_VAR
VAR_INPUT
  bToWrite : BOOL;
END_VAR
VAR
  diIndex : DWORD;
END_VAR

diIndex := __XADD(ADR(g_diIndex), 1);        // Returns a unique index
WriteToNextArrayPosition := FALSE;
IF (diIndex >= 0 AND diIndex <= 1000) THEN
  g_boolArray[diIndex] := bToWrite;         //Writes to unique index
  WriteToNextArrayPosition := TRUE;         // TRUE: Array was not full yet
END_IF
```

**Operator 'TEST_AND_SET'**

The multicore operator is an extension of the IEC 61131-3 standard.

The operator can be used for implementing a semaphore, for example to guarantee exclusive access to a variable written to by different tasks.

`TEST_AND_SET` gets a type DWORD variable as its input. Write access to this variable must be possible. The variable is set to 1 and the previous value is returned as the result.

The operation is atomic, which means that it cannot be interrupted by another task. This also applies to multicore platforms.

For example, the call in the program is `dwOldValue := TEST_AND_SET(dw);`, in which the variables `dwOldValue` and `dw` must be of data type DWORD.
The following example shows a typical usage. Exclusive access to a type STRING variable, which is addressed via the pstrOutput pointer, should be implemented. The access to a string is not atomic. If multiple tasks write to the same string at the same time, then the contents may be inconsistent. With the TEST_AND_SET function, it is now possible to write the same STRING variable in different tasks.

```plaintext
FUNCTION ExclusiveStringWrite : BOOL
VAR_INPUT
    strToWrite : STRING;
    pstrOutput : POINTER TO STRING;
END_VAR
VAR_STAT
    dwSynch : DWORD;
END_VAR
VAR
    dwOldValue : DWORD;
END_VAR

    dwOldValue := TEST_AND_SET(dwSynch);  // Write the 1 and read the old value at the same time
    IF dwOldValue = 0 THEN  // 0 means: no other task is currently writing
        pstrOutput^ := strToWrite;  // Now you can write safely on the string
        dwSynch := 0;  // The DWORD must be reset
        ExclusiveStringWrite := TRUE;  // Writing was successful
    ELSE
        ExclusiveStringWrite := FALSE;  // Writing was not successful
```

**Operator - Global namespace**

This operator is an extension of the IEC 61131-3 standard.

An instance path that begins with a dot (.) always opens a global namespace. If there is a local variable that has the same name <varname> as a global variable, then you refer to the global variable as .<varname>.

**Operator - Namespace for global variables lists**

This operator is an extension of the IEC 61131-3 standard.

You can use the name of a global variables list (GVL) as a namespace identifier for the variables that are defined in the list. This makes it possible to use variables with the same name in different global variables lists and still access specific variables uniquely. You use a dot (.) to prepend the name of the global variables list to the variable name.

<global variable list name>..<variable>

**Example**

```plaintext
globlist1.varx := globlist2.varx;
```

The globlist1 and globlist2 global variables lists each contain a varx variable. CODESYS copies the varx global variable from the globlist2 list to varx in the globlist1 list.
If you reference a variable that is declared in several global variables lists without referencing the prepended list name, then an error message is printed.

Operator - Library namespace

This operator is an extension of the IEC 61131-3 standard.

Syntax: `<library namespace>.<library identifier>

Example: `LIB_A.FB_A`

A library module identifier is appended with the library namespace (as a prefix separated by a dot) for unique and qualified access to the library module. The namespace usually coincides with the library name.

Example

A library is included in a project and contains the module `FB_A`. However, the function block with the same name is already available locally in the project. Identify the library module as `LIB_A.FB_A` in order to access the library module, not the local function block.

```plaintext
var1 := FB_A(in := 12); // Call of the project function FB_A  
var2 := LIB_A.FB_A(in := 22); // Call of the library function FB_A
```

You can define another identifier for the namespace. To do this, specify a namespace in the project information (library developers: when creating a library project). As an alternative, you can specify a specific namespace for a library in the library manager in the "Properties" dialog box (application developers: when creating an application).

- `Chapter 1.3.1.19 “Using libraries” on page 371`
- `Chapter 1.3.1.25.2.14.4 “Command ‘Placeholders’” on page 1008`
- `Chapter 1.3.1.25.1.25 “Object ‘Library Manager’” on page 771`

Operator - Enumeration namespace

This operator is an extension of the IEC 61131-3 standard.

You can use the TYPE name of an enumeration for unique access to an enumeration constant. In this way, you can use the same constant names in different enumerations.

The enumeration name is prepended to the constant name with a dot (\`).

```plaintext
<enumeration name>.<constant name>
```

Example

The constant `Blue` is a component of both the enumeration `Colors` and the enumeration `Feelings`.

```plaintext
color := Colors.Blue; // Access to component blue in enumeration Colors

feeling := Feelings.Blue; // Access to component blue in enumeration Feelings
```

Operator 'INI'

The INI operator is a CoDeSys V2.3 operator. In CODESYS V3, the `FB_init` method replaces the INI operator. You can still use this operator in projects that are imported from CoDeSys V2.3.
The **INI** operator is used for initializing retain variables of a function block instance used in a POU.

Assign the operator to a Boolean variable.

**Syntax:**

```
<Boolean variable name> := INI <FB instance name>, <Boolean value>;
<Boolean value> : TRUE | FALSE
```

If the second parameter of the operator yields **TRUE**, then CODESYS initializes all retain variables that are defined in the function block `<FB instance name>`.

**Examples**

`fbinst` is the instance of the function block `fb1`, where the retain variable `retvar` is defined.

**ST:**

Declaration in the block:

```
VAR
  fbinst : fb1;
  b : BOOL;
END_VAR
```

Program part:

```
b := INI(fbinst, TRUE);
ivar := fbinst.retvar; (* => retvar is initialized *)
```

**FBD**

![FBD Diagram]

**1.3.1.24.4 Operands**

You declare constants with the keyword **CONSTANT**. Constants can be either local or global.

**Syntax:**

```
VAR CONSTANT <identifier>:<Type> := <initialization>; END_VAR
```

- Chapter 1.3.1.24.4.13 “Functions” on page 568

bool constants

BOOL constants are the truth values TRUE (1) and FALSE (0).

See also

- Chapter 1.3.1.24.5.1 “Data type ‘BOOL’” on page 570

Time/LTIME constant

You can use TIME constants to operate the standard timer modules. The constant has a size of 32 bits and therefore a resolution in milliseconds.

In addition, the time constant LTIME is available as a time basis for high-resolution timers. The LTIME constant has a dimension of 64 bits and therefore a resolution in nanoseconds.

Date constant

Syntax

<time keyword> # <length of time>

<time keyword> : TIME | time | T | t

<length of time> : ( <number of days>d )? ( <number of hours>h )? ( <number of minutes>m )? ( <number of seconds>s )? ( <number of milliseconds>ms )? // ( ... )? Optional

The order of time units must not be changed. However, it is not required to specify all units. It is permitted to write the units in uppercase.

Time units

- D | d: Days
- H | h: Hours
- M | m: Minutes
- s | s: Seconds
- MS | ms: Milliseconds
Examples

Correct time constants of an ST assignment

```plaintext
VAR
    timLength : TIME := T#14ms;
    timLength1 : TIME := T#100s12ms; // Overflow in the highest unit is allowed.
    timLength2 : TIME := T#12h34m15s;
    timCompare : TIME;
    xIsOK: BOOL;

    timLongest := T#49D17H2M47S295MS; // 4294967295
END_VAR

IF timLength < T#15MS THEN
    IF timCompare < timLength1 THEN
        xIsOK := TRUE;
    END_IF;
END_IF
```

Table 19: Incorrect usage:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timIncorrect := t#5m68s;</td>
<td>Overflow at a lower position</td>
</tr>
<tr>
<td>timIncorrect1 := 15ms;</td>
<td>Time marker T# missing</td>
</tr>
<tr>
<td>timIncorrect2 := t#4ms13d;</td>
<td>Incorrect order of time units</td>
</tr>
</tbody>
</table>

LTIME constant

Syntax

```plaintext
<long time keyword> # <length of high resolution time>

<long time keyword> : LTIME | ltime
<length of high resolution time> : <length of time> ( <number of microseconds>us )? ( <number of nanoseconds>ns )? // ( ...)? Optional
```

You can use the same units for LTIME constants as for TIME constants. Moreover, you can specify microseconds and nanoseconds because the specified time is calculated in higher time resolution. LTIME literals are treated internally as data type LWORD and therefore the value resolved in nanoseconds.

Additional time units

- US | us: Microseconds
- NS | ns: Nanoseconds

Examples of correct usage of an ST assignment:

```plaintext
PROGRAM PLC_PRG
VAR
    ltimLength := LTIME#1000d15h23m12s34ms2us44ns;
    ltimLength1 := LTIME#3445343m3424732874823ns;
END_VAR
```
DATE constant

Use DATE constants for specifying dates.

Syntax

```
$date keyword#$<year>-<month>-<day>
```

```
$date keyword$ : DATE | date | D | d
$year$ : 1970-2106
$month$ : 1-12
$day$ : 1-31
```

DATE literals are treated internally as data type DWORD, which corresponds to an upper limit of DATE#2106-2-7.

Example

```
PROGRAM PLC_PRG
VAR
    dateStart : DATE := D#2018-8-8;
    dateEnd : DATE := d#2018-8-31;
    dateCompare : DATE := DATE#1996-05-06;
    xIsDuringTheTime : BOOL;
    dateEarliest : DATE : D#1970-1-1; // = 0
    dateLatest : DATE : DATE#2106-2-7; // = 4294967295
END_VAR

IF dateStart < dateCompare THEN
    IF dateCompare < dateEnd THEN
        xIsDuringTheTime := TRUE;
    END_IF;
END_IF
```

See also

- % Chapter 1.3.1.24.5.5 “Time data types” on page 572
- % Chapter 1.3.1.24.4.4 “DATE_AND_TIME constant” on page 560
- % Chapter 1.3.1.24.4.5 “TIME_OF_DAY constant” on page 561

DATE_AND_TIME constant

DATE_AND_TIME constants are a combination of date and time.

Syntax

```
$date and time keyword#$<date and time value>
```

```
$date and time keyword$ : DATE_AND_TIME | date_and_time | DT | dt
$date and time value$ : <year>-<month>-<day>-<hour>:<minute>:<second>
$year$ : 1970-2106
```
DATE_AND_TIME literals are treated internally as data type DWORD. The time is therefore processed in seconds and can take values from January 1, 1970 00:00 and until February 7, 2106 06:28:15.

**Example**

```plaintext
PROGRAM PLC_PRG
VAR
   dtDate : DATE_AND_TIME := DATE_AND_TIME#1996-05-06-15:36:30;
   dtDate1: DATE_AND_TIME := DT#1972-03-29-00:00:00;
   dtDate2: DATE_AND_TIME := DT#2018-08-08-13:33:20.5;
   dtEarliest : DATE_AND_TIME := DATE_AND_TIME#1979-1-1-00:00:00; // 0
   dtLatest : DATE_AND_TIME := DATE_AND_TIME#2106-2-7-6:28:15; // 4294967295
END_VAR
```

See also

- § Chapter 1.3.1.24.5.5 “Time data types” on page 572
- § Chapter 1.3.1.24.4.3 “DATE constant” on page 560
- § Chapter 1.3.1.24.4.5 “TIME_OF_DAY constant” on page 561

**TIME_OF_DAY constant**

You can use this constant to define the time of day.

**Syntax**

```plaintext
<time keyword>#<time value>
```

<time keyword> : TIME_OF_DAY | time_of_day | TOD | tod
<time value> : <hour>:<minute>:<second>
<hour> : 0-23
<minute> : 0-59
<second> : 0.000-59.999

You can also specify fractions of a second. TIME_OF_DAY literals are nevertheless treated internally as DWORD and the value is resolved in milliseconds.

**Examples**

```plaintext
PROGRAM POU
VAR
   todClockTime : TIME_OF_DAY := TIME_OF_DAY#15:36:30.123;
   todEarliest : TIME_OF_DAY := TIME_OF_DAY#0:0:0.000;
   todLatest : TOD := TOD#23:59:59.999;
END_VAR
```
See also

- % Chapter 1.3.1.24.5.5 “Time data types” on page 572
- % Chapter 1.3.1.24.4.3 “DATE constant” on page 560
- % Chapter 1.3.1.24.4.4 “DATE_AND_TIME constant” on page 560

Numeric constants

Numeric values can be binary, octal, decimal, and hexadecimal numbers. If an integer value is not a decimal number, then you must write its base followed by the number sign (#) before the integer constant. You enter the hexadecimal digit values for the numbers 10 to 15 as usual with the letters A-F.

You can use an underscore within a numeric value.

<table>
<thead>
<tr>
<th>Examples:</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
</tr>
<tr>
<td>2#1001_0011</td>
</tr>
<tr>
<td>8#67</td>
</tr>
<tr>
<td>16#A</td>
</tr>
<tr>
<td>DINT#16#A1</td>
</tr>
</tbody>
</table>

This type of numeric value can be BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL, or LREAL.

Implicit conversions from "larger" to "smaller" types are not permitted. You cannot simply use a DINT variable as an INT variable. For this, you have to use a type conversion function.

See also

- % Chapter 1.3.1.24.3 “Operators” on page 505
- % Chapter 1.3.1.24.4.9 “Typed literals” on page 564

As number constants basically are treated as integers, in divisions you must enter a constant in the format of a floating-point number in order not to loose the remainder. For example: Division 1/10 results in 0, division 1.0/10 results in 0.1.

REAL/LREAL constants

You can specify floating-point numbers as REAL and LREAL constants either in decimal notation or exponential notation with mantissa and exponent. The decimal point serves as the decimal separator according to the International System of Units (English).

Syntax of exponential notation

<significand> e | E <exponent>

exponent: -44..38 // REAL
exponent: -324..308 // LREAL
Table 20: REAL literal

<table>
<thead>
<tr>

String constants

A string constant is a character string enclosed in single straight quotation marks. The characters are coded according to the character set specified in ISO/IEC 8859-1. Therefore, a string constant can include spaces and accented characters, as these belong to this character set. This is also referred to as a string literal, or simply a string.

Example: 'Hello world!'

When a dollar sign ($) is in a string constant, the following two characters are interpreted as a hexadecimal code according to the coding in ISO/IEC 8859-1. The code also corresponds to ASCII code. In addition, please note the special cases.

Table 22: Hexadecimal code

<table>
<thead>
<tr>
<th>String with $ code</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>'$&lt;8-bit code&gt;'</td>
<td>8-bit code: Two-digit hexadecimal number that is interpreted according to ISO/IEC 8859-1.</td>
</tr>
<tr>
<td>'$41'</td>
<td>A</td>
</tr>
<tr>
<td>'$9A'</td>
<td>©</td>
</tr>
<tr>
<td>'$40'</td>
<td>@</td>
</tr>
<tr>
<td>'$0D'</td>
<td>Control character: Line break (corresponds to '$R')</td>
</tr>
<tr>
<td>'$0A'</td>
<td>Control character: New line (corresponds to '$L' and '$N')</td>
</tr>
</tbody>
</table>
Table 23: Special cases

<table>
<thead>
<tr>
<th>String with $ code</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>'$L',  '$l'</td>
<td>Control character: Line feed (corresponds to '$0A')</td>
</tr>
<tr>
<td>'$N',  '$n'</td>
<td>Control character: New line (corresponds to '$0A')</td>
</tr>
<tr>
<td>'$P',  '$p'</td>
<td>Control character: Form feed</td>
</tr>
<tr>
<td>'$R',  '$r'</td>
<td>Control character: Line break (corresponds to '$0D')</td>
</tr>
<tr>
<td>'$T',  '$t'</td>
<td>Control character: Tab</td>
</tr>
<tr>
<td>'$&quot;'</td>
<td>Dollar sign: $</td>
</tr>
<tr>
<td>'$'</td>
<td>Single straight quotation mark: '</td>
</tr>
</tbody>
</table>

Example

Constant declaration

```python
VAR CONSTANT
  constA : STRING := 'Hello world';
  constB : STRING := 'Hello world $21'; // Hello world!
END_VAR
```

Typed literals

With the exception of REAL/LREAL constants (LREAL is always used here), CODESYS uses the smallest possible data type when calculating with IEC constants. If you want to use another data type, then you can use typed literals without having to declare the constants explicitly. When doing this, provide the constants with a prefix that indicates the type.

**Syntax:**

```plaintext```
<type>#<literal>
```

- `<type>` defines the desired data type; possible values: BOOL, SINT, USINT, BYTE, INT, UINT, WORD, DINT, UDINT, DWORD, REAL, LREAL. You must capitalize the entire type name.

- `<literal>` defines the constants. The entry must match the data type defined in `<Type>`.

**Example:**

```plaintext```
var1 := DINT#34;
```

If CODESYS cannot convert the constant into the target type without data loss, then an error message is issued.

You can use typed constants wherever you can use normal constants.

Access to variables in arrays, structures, and blocks

**Syntax for access to**

- **Two-dimensional array components:** `<array name>[index1, index2]`
- **Structural variables:** `<structure name>.<variable name>`
- **Function block and program variables:** `<function block name>.<variable name>`

**See also**

- % Chapter 1.3.1.24.5.14 “Data type ’ARRAY’” on page 581
- % Chapter 1.3.1.24.5.16 “Structure” on page 594
- % Chapter 1.3.1.25.1.28.2 “Object ’Function Block’” on page 778
- % Chapter 1.3.1.25.1.28.1 “Object ’Program’” on page 777
Bit access to variables

**NOTICE!**
Implement concurrent bit access by two tasks only if the processor can execute bit access directly on the memory. All x86 and x64 systems have commands for bit access in memory. Systems such as ARM and PPC cannot access bits directly in the memory.

If two tasks execute bit access simultaneously, even though the processor cannot perform bit access directly in the memory, then proceed as follows. Use a semaphore (SysSemEnter) or a similar technique to prevent competing bit access. However, it is best to execute the bit access within a task.

**Syntax for declarations:**
```plaintext
<variable name> : <data type> ( := <initialization> )? ;
```
```
<data type> = BYTE | WORD | DWORD | LWORD | SINT | USINT | INT | DINT | UDINT | LINT | ULINT
```

**Syntax for calls:**
With a bit access, a single bit is accessed with read or write permissions within an integer variable. To do this, add a period and an index to the variable identifier that addresses the bit within the variable. Indexing is 0-based. The index is a positive integer starting at 0. You can also specify the index as a constant variable.

**Example**
```
PROGRAM PLC_PRG
VAR
  wA : WORD := 16#FF;
  xB : BOOL := 0;
END_VAR
wA.2 := xB;
```

In the program, the third bit of the variable `wA` is set to the value of variable `xB`.

```
wA = 2#1111_1111_1111_1011 = 16#FFFB
```

**Example: Bit access to a variable with a global constant variable**
You can use a global constant as an index to access a bit within an integer variable.

**Declaration in a global variable list:**
```
VAR_GLOBAL CONSTANT
c_usiENABLE : USINT := 2;
END_VAR
```

The constant `c_usiENABLE` addresses the bit in the integer variable.

**Declaration of a POU:**
```
VAR
  iX : INT;
END_VAR
```

**Call with bit access:**
```
iX.c_usiENABLE := TRUE; // The third bit in the variable iX is set TRUE
```
Bit access with BIT data types

With the BIT data type, you can combine single bits into a structure and then access them individually. The bit is then addressed with the component name.

Example:

Access to BIT data types

Declaration of the structure:

```plaintext
TYPE ControllerData :
  STRUCT
    Status_OperationEnabled : BIT;
    Status_SwitchOnActive : BIT;
    Status_EnableOperation : BIT;
    Status_Error : BIT;
    Status_VoltageEnabled : BIT;
    Status_QuickStop : BIT;
    Status_SwitchOnLocked : BIT;
    Status_Warning : BIT;
  END_STRUCT
END_TYPE
```

Declaration of the POU:

```plaintext
VAR
  ControllerDrive_1 : ControllerData;
END_VAR
```

Bit access:

```plaintext
ControllerDrive1.OperationEnabled := TRUE;
```

- § Chapter 1.3.1.24.5.10 “Data type ‘BIT’” on page 577

Addresses

CAUTION!
If you use pointers to addresses, then the contents of addresses can be moved during an online change. If you use absolute addresses, then the contents of addresses does not change during an online change.

Syntax:

```plaintext
%<memory area prefix> ( <size prefix> )? <memory position>
```

- **<memory area prefix>** : I | Q | M
- **<size prefix>** : X | B | W | D
- **<memory position>** : <number> ( .<number> )* // Depends on the target system

When defining an address, you use specific character strings to express memory position and size. An address is marked with the percent sign (%), followed by the memory range prefix, the optional size prefix, and the memory range position. The numbering that you use for addressing the memory position depends on the target system.
### Memory Range Prefix

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Input memory range for &quot;Inputs&quot;&lt;br&gt;For physical inputs via input drivers, &quot;Sensors&quot;</td>
</tr>
<tr>
<td>Q</td>
<td>Output memory range for &quot;Outputs&quot;&lt;br&gt;For physical outputs via output drivers, &quot;Actuators&quot;</td>
</tr>
<tr>
<td>M</td>
<td>Flag memory range</td>
</tr>
</tbody>
</table>

### Size Prefix

<table>
<thead>
<tr>
<th>Size Prefix</th>
<th>Data Type</th>
<th>Data Width</th>
</tr>
</thead>
<tbody>
<tr>
<td>No size prefix</td>
<td>Single bit</td>
<td></td>
</tr>
<tr>
<td>X</td>
<td>Single bit</td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>BYTE</td>
<td>8 bits</td>
</tr>
<tr>
<td>W</td>
<td>WORD</td>
<td>16 bits</td>
</tr>
<tr>
<td>D</td>
<td>DWORD</td>
<td>32 bits</td>
</tr>
</tbody>
</table>

### Examples

- `%QX7.5`<br>Single bit address of the output bit 7.5
- `%Q7.5`<br>Word address of the input word 215
- `%IW215`<br>Byte address of the output byte 7
- `%MD48`<br>Address of a double word at memory position 48 in flag memory
- `%IW2.5.7.1`<br>Word address of an input word; interpretation dependent on the current controller configuration
- `VAR wVar AT %IW0 : WORD; END_VAR`<br>Variable declaration with address information of an input word
- `VAR xActuator AT %QW0 : BOOL; END_VAR`<br>Boolean variable declaration<br>Note: For Boolean variables, one byte is allocated internally if a single bit address is not specified. A change in the value of `xActuator` affects the range from QX0.0 to QX0.7.
- `VAR xSensor AT IX7.5 : BOOL; END_VAR`<br>Boolean variable declaration with explicit specification of a single bit address. On access, only the input bit 7.5 is read.

### Memory position

Make sure that the address is valid as follows:

To map a valid address in an application, you must know the required position (applicable memory range) in the process image: input memory range (I), output memory range (Q), and flag memory range (M) — see above. Furthermore, you have to specify the required size prefix: bit, BYTE, WORD, DWord (see above: X, B, W, D)
The current device configuration and device settings (hardware structure, device description, I/O settings) play a decisive part. Note specifically the differences in the interpretation of bit addresses for devices with "byte addressing mode" and devices with "word-oriented IEC addressing mode". For example, in a byte addressing device, the number before the point of bit address %IX5.5 addresses byte 5. On the other hand, in a word-addressed device, it addresses word 5. In contrast, addressing with a word or byte address is independent of the device type: with %IW5 always word 5 is addressed and with byte address %IB5 always byte 5. Regardless of size and addressing mode, you can address different memory cells therefore with the same address information.

The following table shows the comparison of byte addressing and word-oriented IEC addressing for bits, bytes, words, and double words. It also shows the overlapping memory ranges that are present in the case of byte addressing (see also the example below the table).

Regardless of size and addressing mode, you can address different memory cells therefore with the same address information.

<table>
<thead>
<tr>
<th>DWords / Words</th>
<th>Bytes</th>
<th>X (bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>byte addressing</td>
<td>word oriented IEC addressing</td>
<td>byte addressing</td>
</tr>
<tr>
<td>D0</td>
<td>W0</td>
<td>W0</td>
</tr>
<tr>
<td>D1</td>
<td>W1</td>
<td>W1</td>
</tr>
<tr>
<td>...</td>
<td>W2</td>
<td>W2</td>
</tr>
<tr>
<td>...</td>
<td>W3</td>
<td>W3</td>
</tr>
<tr>
<td>...</td>
<td>D1</td>
<td>W2</td>
</tr>
<tr>
<td>...</td>
<td>W3</td>
<td>W3</td>
</tr>
<tr>
<td>...</td>
<td>D2</td>
<td>W4</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>...</td>
<td>D(n-3)</td>
<td>D(n/4)</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>...</td>
<td>D(n)</td>
<td>D(n/4)</td>
</tr>
</tbody>
</table>

n = byte number

Example of memory range overlapping in the case of the byte addressing mode

D0 contains B0 - B3, W0 contains B0 and B1, W1 contains B1 and B2, and W2 contains B2 and B3. Consequently, in order to avoid overlap, you must not use W1 (also D1, D2, and D3) for addressing.

Functions

In ST, you can use a function call as an operand.

Example:

```
Result := Fct(7) + 3;
```

TIME() function

This function yields the time (in milliseconds) that has elapsed since system boot.
The data type is TIME.

Example in ST:

```plaintext
systime := TIME();
```

1.3.1.24.5 Data types

When programming in CODESYS, you can use different data types or instances of function blocks. Moreover, you assign a data type to every identifier. The data type defines how much memory CODESYS reserves and how these values are interpreted.

The following group of data types are provided:

**Standard data types**

CODESYS supports all IEC 61131-3 data types.

- Chapter 1.3.1.24.5.1 “Data type ‘BOOL’” on page 570
- Chapter 1.3.1.24.5.2 “Integer data types” on page 570
- Chapter 1.3.1.24.5.3 “Data type ‘REAL’ / ‘LREAL’” on page 570
- Chapter 1.3.1.24.5.4 “Data type ‘STRING’” on page 571
- Chapter 1.3.1.24.5.9 “Data type ‘WSTRING’” on page 577
- Chapter 1.3.1.24.5.5 “Time data types” on page 572
- Chapter 1.3.1.24.5.8 “Data type ‘LTIME’” on page 576

**Extensions to the IEC 61131-3 standard**

- Chapter 1.3.1.24.5.6 “Data type ‘UNION’” on page 572
- Chapter 1.3.1.24.5.10 “Data type ‘BIT’” on page 577
- Chapter 1.3.1.24.5.11 “Special data types ‘__UXINT’ and ‘__XWORD’” on page 577
- Chapter 1.3.1.24.5.13 “Reference” on page 579
- Chapter 1.3.1.24.5.12 “Pointers” on page 577

**User-defined data types**

You can create user-defined data types in two ways:

- DUT object in the POU window
- data type in a block in the declaration

**NOTICE!**

Please note the recommendations for naming and object.

- Chapter 1.3.1.24.5.14 “Data type ‘ARRAY’” on page 581
- Chapter 1.3.1.24.5.16 “Structure” on page 594
- Chapter 1.3.1.24.5.17 “Enumerations” on page 595

- Chapter 1.3.1.24.5.12 “Pointers” on page 577
- Chapter 1.3.1.24.5.18 “Subrange types” on page 599
Data type 'BOOL'

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Values</th>
<th>Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL</td>
<td>TRUE (1), FALSE (0)</td>
<td>8 bit</td>
</tr>
</tbody>
</table>

See also
- Chapter 1.3.1.24.4.1 “BOOL constants” on page 558

Integer data types

CODESYS provides the following integer data types.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Lower Limit</th>
<th>Upper Limit</th>
<th>Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>0</td>
<td>255</td>
<td>8 bit</td>
</tr>
<tr>
<td>WORD</td>
<td>0</td>
<td>65535</td>
<td>16 bit</td>
</tr>
<tr>
<td>DWORD</td>
<td>0</td>
<td>4294967295</td>
<td>32 bit</td>
</tr>
<tr>
<td>LWORD</td>
<td>0</td>
<td>264-1</td>
<td>64 bit</td>
</tr>
<tr>
<td>SINT</td>
<td>-128</td>
<td>127</td>
<td>8 bit</td>
</tr>
<tr>
<td>USINT</td>
<td>0</td>
<td>255</td>
<td>8 bit</td>
</tr>
<tr>
<td>INT</td>
<td>-32768</td>
<td>32767</td>
<td>16 bit</td>
</tr>
<tr>
<td>UINT</td>
<td>0</td>
<td>65535</td>
<td>16 bit</td>
</tr>
<tr>
<td>DINT</td>
<td>-2147483648</td>
<td>2147483647</td>
<td>32 bit</td>
</tr>
<tr>
<td>UDINT</td>
<td>0</td>
<td>4294967295</td>
<td>32 bit</td>
</tr>
<tr>
<td>LINT</td>
<td>-263</td>
<td>263-1</td>
<td>64 bit</td>
</tr>
<tr>
<td>UUINT</td>
<td>0</td>
<td>264-1</td>
<td>64 bit</td>
</tr>
</tbody>
</table>

NOTICE!
Information can be lost when converting from larger to smaller types.

See also
- Chapter 1.3.1.24.4.6 “Numeric constants” on page 562

Data type 'REAL' / 'LREAL'

The data types REAL and LREAL are floating-point types according to IEEE 754. They are necessary when using decimal numbers and floating-point numbers in decimal notation or exponential notation.
## Table 24: Target system: CODESYS Control Win V3

<table>
<thead>
<tr>
<th>Data type</th>
<th>Smallest value number</th>
<th>Largest value number</th>
<th>Storage space</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL</td>
<td>1.0E-44</td>
<td>3.402823E+38</td>
<td>32 bit</td>
</tr>
<tr>
<td>LREAL</td>
<td>4.94065645841247E-32</td>
<td>1.7976931348623157E+308</td>
<td>64 bit</td>
</tr>
</tbody>
</table>

### Example

```plaintext
PROGRAM PLC_PRG
    VAR
        rMax: REAL := 3.402823E+38; // Largest number
        rPosMin : REAL := 1.0E-44; // Smallest positive number
        rNegMax: REAL := -1.0E-44; // Largest negative number
        rMin: REAL := -3.402823E+38; // Smallest number
        lrMax: LREAL := 1.7976931348623157E+308; // Largest number
        lrPosMin : LREAL := 4.94065645841247E-32; // Smallest positive number
        lNegMax: LREAL := -4.94065645841247E-32; // Largest negative number
        lrMin: LREAL := -1.7976931348623157E+308; // Smallest number
    END_VAR
```

### NOTICE!

Support for the LREAL data type depends on the target device in use. Refer to the respective documentation as to whether or not the 64-bit type LREAL is converted to REAL or remains as LREAL when compiling the application. Conversion may result in the loss of information.

### NOTICE!

If the value of the REAL/LREAL number is outside of the value range of the integer, then an undefined result is yielded from a data type conversion from REAL or LREAL to SINT, USINT, INT, UINT, DINT, UDINT, LINT, or ULINT. The result depends on the target system. An exception error is also possible. To get code that is independent of the target system, the application must catch value range violations.

If the REAL/LREAL number is within the value range of the integer data type, then the conversion operates the same way on all systems.

See also
- “REAL/LREAL constants” on page 562

### Data type ‘STRING’

A variable of the STRING data type can include any character string. The amount of memory that is allocated during a declaration refers to characters and is shown in parentheses or brackets. If a size is not defined, then CODESYS allocates 80 characters by default.

As a rule, CODESYS does not limit the string length; however, the string function processes lengths from 1 to 255 only. If a variable is initialized with a string that is too long for the data type, then CODESYS truncates the string accordingly from the right.
NOTICE!
The memory required for a STRING variable is always one byte per character plus one additional byte (for example, 81 bytes for a STRING[80] declaration).

Example of a string declaration with 35 characters:

```
str : STRING(35):= 'This is a String';
```

See also

- § Chapter 1.3.1.24.4.8 “String constants” on page 563
- § Chapter 1.3.1.24.5.9 “Data type 'WSTRING'” on page 577

Time data types

Time data types are treated internally as DWORD. TIME and TIME_OF_DAY are resolved in milliseconds, and DATE_AND_TIME is resolved in seconds.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Lower limit</th>
<th>Upper limit</th>
<th>Storage space</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME</td>
<td>T#0d0h0m0s0ms</td>
<td>T#49d17h2m47s295ms</td>
<td>32 bit</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>TIME_OF_DAY</td>
<td>TOD#0:0:0.000 00:00:00.000</td>
<td>TOD#23:59:59.99 23:59:59.999</td>
<td>32 bit</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>DATE</td>
<td>D#1970-1-1 01/01/70</td>
<td>DATE#2106-2-7 06:28:15</td>
<td>32 bit</td>
<td>Day</td>
</tr>
<tr>
<td>DATE_AND_TIME</td>
<td>DT#1979-1-1-00:00 01/01/1970</td>
<td>DT#2106-2-7-6:28:15</td>
<td>32 bit</td>
<td>Seconds</td>
</tr>
</tbody>
</table>

See also

- § Chapter 1.3.1.24.4.5 “Data type 'LTIME'' on page 576
- § Chapter 1.3.1.24.4.2 “TIME/LTIME constant” on page 558
- § Chapter 1.3.1.24.4.3 “DATE constant” on page 560
- § Chapter 1.3.1.24.4.4 “DATE_AND_TIME constant” on page 560
- § Chapter 1.3.1.24.4.5 “TIME_OF_DAY constant” on page 561

Data type 'UNION'

A UNION is a data structure that usually contains different data types.

In a union, all components have the same offset and therefore the same amount of memory. In the following declaration example of a union, an assignment to `name.a` will also affect `name.b`.
Example

```plaintext
TYPE name:
UNION
    a : LREAL;
    b : LINT;
END_UNION
END_TYPE
```

Data type ‘ANY’ and ‘ANY_<type>’

When implementing a function or a method, you can declare inputs (VAR_INPUT) as variables with a generic IEC data type (ANY or ANY_<type>). As a result, you can implement calls that have different call parameters for the data type.

At runtime, you can retrieve the transferred value and its type by means of a predefined structure within the programming block for the input variable.

With compiler versions > 3.5.1.0, the generic IEC data types listed below are supported. The table shows the generic data type that permits elementary data types.

<table>
<thead>
<tr>
<th>Hierarchy of Generic Data Types</th>
<th>Elementary Data Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANY</td>
<td>ANY_BIT</td>
</tr>
<tr>
<td>ANY_DATE</td>
<td>ANY_REAL</td>
</tr>
<tr>
<td>ANY_NUM</td>
<td>ANY_REAL</td>
</tr>
<tr>
<td>ANY_INT</td>
<td>ANY_INT</td>
</tr>
<tr>
<td>ANY_STRING</td>
<td></td>
</tr>
<tr>
<td>STRING</td>
<td></td>
</tr>
</tbody>
</table>
The transfer parameters of the function calls have different data types.

```plaintext
FUNCTION AnyBitFunc : BOOL
  VAR_INPUT
    value : ANY_BIT;
  END_VAR
FUNCTION AnyDateFunc : BOOL
  VAR_INPUT
    value : ANY_DATE;
  END_VAR
FUNCTION AnyFunc : BOOL
  VAR_INPUT
    value : ANY;
  END_VAR
FUNCTION AnyIntFunc : BOOL
  VAR_INPUT
    value : ANY_INT;
  END_VAR
FUNCTION AnyNumFunc : BOOL
  VAR_INPUT
    value : ANY_NUM;
  END_VAR
FUNCTION AnyRealFunc : BOOL
  VAR_INPUT
    value : ANY_REAL;
  END_VAR
FUNCTION AnyStringFunc : BOOL
  VAR_INPUT
    value : ANY_STRING;
  END_VAR

PROGRAM PLC_PRG
  VAR
    xValue : BOOL := TRUE;
    byValue : BYTE := 16#AB;
    wValue : WORD := 16#1234;
    dwValue : DWORD := 16#6789ABCD;
    lwValue : LWORD := 16#0123456789ABCDEF;
    sValue : STRING := 'xyz';
    wsValue : WSTRING := "abc";
    dtValue : DATE_AND_TIME := DT#2017-02-20-11:07:00;
    dValue : DATE := D#2017-02-20;
    todValue : TIME_OF_DAY := TOD#11:07:00;
    rValue : REAL := 42.24;
    lrValue : LREAL := 24.42;
    usiValue: USINT := 12;
    uiValue : UINT := 1234;
    udiValue : UDINT := 12345;
    uliValue : ULINT := 123456;
    siValue: SINT := -12;
    iValue : INT := -1234;
    diValue : DINT := -12345;
    liValue : LINT := -123456;
  END_VAR

  AnyFunc(xValue);
  AnyFunc(byValue);
  AnyFunc(wValue);
  AnyFunc(dwValue);
  AnyFunc(lwValue);
  AnyFunc(sValue);
  AnyFunc(wsValue);
  AnyFunc(dtValue);
  AnyFunc(todValue);
```
When compiling the code, an ANY data type is replaced internally with the following structure:

```plaintext
TYPE AnyType :
  STRUCT
    // the type of the actual parameter
typeclass : __SYSTEM.TYPE_CLASS ;
    // the pointer to the actual parameter
pvalue : POINTER TO BYTE;
    // the size of the data, to which the pointer points
diSize : DINT;
  END_STRUCT
  END_TYPE
```

The actual call parameter will assign the structure elements at runtime.
Example

This compares whether or not the two passed variables have the same type and the same value.

```
FUNCTION Generic_Compare : BOOL
VAR_INPUT
  any1 : ANY;
  any2 : ANY;
END_VAR
VAR
  pTest : POINTER TO ARRAY [0..100] OF POINTER TO DWORD;
  icount: DINT;
END_VAR

pTest := ADR(any1);
Generic_Compare := FALSE;
IF any1.typeclass <> any2.typeclass THEN
  RETURN;
END_IF
IF any1.diSize <> any2.diSize THEN
  RETURN;
END_IF
// Byte comparison
FOR icount := 0 TO any1.diSize-1 DO
  IF any1.pvalue[iCount] <> any2.pvalue[iCount] THEN
    RETURN;
  END_IF
END_FOR
Generic_Compare := TRUE;
RETURN;
// END_FUNCTION
```

Data type 'LTIME'

You can use the data type LTIME as a time base for high-resolution timer. A high-resolution timer has a resolution in nanoseconds.

<table>
<thead>
<tr>
<th>Data type</th>

<tr>
<td>LTIME</td>
<td>0</td>
<td>213503d23h34m33s709ms551us615ns</td>
<td>64 bit</td>
</tr>
</tbody>
</table>

Syntax:

```
LTIME#<time declaration>
```

The time declaration can include units of time that apply for the TIME constant as well as:

- "us": microseconds
- "ns": nanoseconds

Example:

```
LTIME1 := LTIME#1000d15h23ms2us44ns
```

See also

- Chapter 1.3.1.24.5.5 “Time data types” on page 572
Data type 'WSTRING'

The data type WSTRING is interpreted in Unicode format as opposed to the data type STRING (ASCII). As a result of this coding, the number of displayed characters for WSTRING depends on the characters. A length of 10 for WSTRING means that the length of the WSTRING can take a maximum of 10 WORDs. However, for some characters in Unicode, multiple WORDs are required for coding a character so that the number of characters do not have to correspond to the length of the WSTRING (10 in this case). The data type requires 1 WORD of memory per character plus 1 WORD of extra memory. Each STRING requires only 1 byte. The data type WSTRING is terminated with a 0.

Example:  

```plaintext
wstr : WSTRING := "This is a WString";
```

See also

- § Chapter 1.3.1.24.5.4 “Data type 'STRING'” on page 571
- § Chapter 1.3.1.24.4.8 “String constants” on page 563

Data type 'BIT'

You can use the BIT data type only for single variables in structures or in a function block. The possible values are TRUE (1) and FALSE (0).

A BIT element requires 1 bit of memory. Therefore, you can reference single bits of a structure by name. BIT elements that are declared in succession are bundled in bytes. In this way, you can optimize memory use as opposed to BOOL types, which reserve 8 bits each. On the other hand, bit access is significantly more time-consuming. Therefore, you should use the BIT data type only when you need to define data in a predefined format.

See also

- § Chapter 1.3.1.24.5.16 “Structure” on page 594

Special data types '__UXINT' and '__XWORD'

CODESYS supports systems with address registers of 32-bit and 64-bit widths. For making the IEC code as independent from the target system as possible, you use the pseudo data types __UXINT and __XWORD. The compiler checks which target system types are current and then converts these data types into the appropriate standard data types.

- __UXINT is converted into ULINT on 64-bit platforms and UDINT on 32-bit platforms.
- __XWORD is converted into LWORD on 64-bit platforms and DWORD on 32-bit platforms.

Pointers

Pointers store the addresses of variables, programs, function blocks, methods, and functions while an application program is running. A pointer points to one of the objects mentioned or to a variable with any data type.

**Syntax of a pointer declaration:**

```plaintext
<identifier>: POINTER TO <data type | function block | program | method | function>;
```

When dereferencing a pointer, the value of the address to which the pointer points is determined. In order to dereference a pointer, append the content operator to the pointer identifier (see `pt^` in the example below).

Using the address operator ADR, you can assign the address of a variable to a pointer.
**Example**

```plaintext
VAR
    pt:POINTER TO INT;  (* declaration of pointer pt *)
    var_int1:INT := 5;  (* declaration of variables var_int1 and var_int2 *)
    var_int2:INT;
END_VAR

pt := ADR(var_int1); (* pointer pt is assigned to address of var_int1 *)
var_int2:= pt^;      (* value 5 of var_int1 is assigned to variable var_int2 by dereferencing of pointer pt *)
```

**NOTICE!**

If a pointer to a device input is used, then the access (for example `pTest := ADR(input);`) is considered to be a write access. This leads to a compiler warning when code is generated: "...invalid assignment target".

If you require a construct of this kind, you must first copy the input value (`input`) to a variable with write access.

In online mode, you can jump from a pointer to the declaration location of the referenced variable by clicking the "Go To Reference" command.

- § Chapter 1.3.1.24.3.31 “Operator ‘Content Operator’” on page 524
- § Chapter 1.3.1.24.3.30 “Operator ‘ADR’” on page 524
- § Chapter 1.3.1.25.2.2.37 “Command ‘Go To Reference’” on page 876

**Function pointers to external functions**

CODESYS supports function pointers that replace the `INDEXOF` operator. You can pass these pointers to external libraries. However, CODESYS does not provide any means for calling a function pointer from within an application in the development system. The function of the runtime system for the registration of callback functions (system library function) expects the function pointer. Depending on which callback was registered, the runtime system implicitly calls the function concerned (in the case of STOP for example). So that such a system call is possible (runtime system), you must set the corresponding object property in the “Build” tab.

You can use the `ADR` operator for functions, programs, function blocks, and methods. CODESYS outputs the address of a pointer to the function, not the address of the function, because the values of functions can change after an online change. This address is valid as long as the function exists on the target system.

See also

- § Chapter 1.3.1.25.3.10.4 “Dialog ‘Properties’ - ‘Build’” on page 1048
- § Chapter 1.3.1.24.3.30 “Operator ‘ADR’” on page 524

**Index access to pointers**

In CODESYS, index access `"[]"` to type `POINTER`, `STRING`, and `WSTRING` variables is permitted.

- `pint[i]` returns the basic data type
- Index access to pointers is done arithmetically: If you use index access for a `POINTER TO` variable, then CODESYS computes the offset by `pint[i] = (pint + i * SIZEOF(base type))^`. The index access also causes an implicit dereferencing of the pointer. The resulting data type is the basic data type of the pointer. Note that `pint[7] != (pint + 7)^`. 
● When you use the index access with a variable of the type STRING, you get the character at the offset of the index expression. The result is a BYTE type. str[i] returns the i-th character of the string as SINT (ASCII).

● When you use the index access with a variable of the type WSTRING, you get the character at the offset of the index expression. The result is a WORD type. wstr[i] returns the i-th character of the string as INT (Unicode).

The result of the difference between two pointers is of type DWORD, even on 64-bit platforms, when the pointers are 64-bit pointers.

Note that it is possible to use references which control a value directly, in contrast to pointers.

Note that it is possible to monitor the memory access of pointers at runtime by the implicit monitoring function CheckPointer

---

Reference

A REFERENCE is also a pointer, but it has some advantages over a POINTER:

● Ease of use: The reference does not have to be dereferenced explicitly (with ^) in order to access the contents of the referenced object.

● Nicer syntax for passing of values: If an input is a REFERENCE TO, then you do not have to write ADR(value) explicitly for a(refInput := value).

● Type safety: Unlike the pointer, for references the compiler checks that the base type is the same when assigning two references

You declare a reference in accordance with the following syntax:

Syntax

<identifier> : REFERENCE TO <data type>

Example

A : REFERENCE TO DUT;
B : DUT;
C : DUT;

A REF= B; // corresponds to A := ADR(B);
A := C; // corresponds to A^ := C;
You cannot declare references in the following ways:

- REFERENCE TO REFERENCE
- or ARRAY OF REFERENCE
- or POINTER TO REFERENCE.

Furthermore, you cannot declare a reference to a bit variable.

NOTICE!
CODESYS initializes references (at 0) with compiler version >= V3.3.0.0.

NOTICE!
When a reference is used for a device entry, write access is enabled (for example, ref REF= input;). This leads to a compiler warning when code is generated: "...invalid assignment target".

If you require this kind of construct, then first you must copy the input value (input) to a variable with write access.

Checking for valid references

You can use the operator __ISVALIDREF in order to check whether a reference points to a valid value, i.e. to a value not equal to 0.

Syntax:

<Boolean variable> := __ISVALIDREF(<with REFERENCE TO <data type> declared identifier>);

<Boolean variable> is TRUE when the reference points to a valid value; otherwise FALSE.

Example

Declaration:

ivar : INT;
ref_int : REFERENCE TO INT;
ref_int0 : REFERENCE TO INT;
testref : BOOL := FALSE;

Implementation:

ivar := ivar + 1;
ref_int REF= ivar;
ref_int0 REF= 0;
testref := __ISVALIDREF(ref_int); (* becomes TRUE, because ref_int points to ivar, which is non-zero *)
testref := __ISVALIDREF(ref_int0); (* becomes FALSE, because ref_int0 is set to 0 *)

In compiler version 3.5.7.40 and later, the implicit monitoring function "CheckPointer" also affects REFERENCE variables the same as pointer variables.

See also

- § Chapter 1.3.1.24.1.3.4.6 “Assignment operator ‘REF’” on page 435
- § Chapter 1.3.1.25.1.29.10 “POU ‘CheckPointer’” on page 809
Data type 'ARRAY'

An array is a collection of data elements of the same data type. CODESYS supports one- and multi-dimensional arrays of fixed or variable length.

Array of fixed length

You can define arrays in the declaration part of a POU or in global variable lists.

Syntax of the declaration of a one-dimensional array

```plaintext
<variable name> : ARRAY[<dimension>] OF <data type> ( := <initialization> )? ;
```

- `<variable name>`: Name of the variable.
- `<dimension>`: Lower index bound..<upper index bound>.
- `<data type>`: Elementary data types | User defined data types | Function block types.
- `( := <initialization> )?`: Optional.

Syntax of the declaration of a multi-dimensional array

```plaintext
<variable name> : ARRAY[<1st dimension>, <next dimension>+ ] OF <data type> ( := <initialization> )? ;
```

- `<variable name>`: Name of the variable.
- `<1st dimension>`: <1st lower index bound>..<1st upper index bound>.
- `<next dimension>`: <next lower index bound>..<next upper index bound>.
- `<data type>`: Elementary data types | User defined data types | Function block types.
- `( := <initialization> )?`: Optional.

The index limits are integers; maximum of the data type DINT.

Syntax for data access

```plaintext
<variable name>[<index of 1st dimension>, <index of next dimension>]*
```

- `( <index of 1st dimension>, <index of next dimension> )*`: 0, one or more further dimensions.

Note the capability of using the implicit monitoring function `CheckBounds()` to monitor the index limits at runtime.

Example

One-dimensional array of 10 integer elements

```plaintext
VAR
  aiCounter : ARRAY[0..9] OF INT;
END_VAR
```

Lower index limit: 0

Upper index limit: 9

Initialization

```plaintext
aiCounter : ARRAY[0..9] OF INT := [0, 10, 20, 30, 40, 50, 60, 70, 80, 90];
```

Data access

```plaintext
iLocalVariable := aiCounter[2];
```

The value 20 is assigned to the local variable.
Example

2-dimensional array

VAR
    aiCardGame : ARRAY[1..2, 3..4] OF INT;
END_VAR

1st dimension: 1 to 2
2nd dimension: 3 to 4

Initialization

Data access

iLocal_1 := aiCardGame[1, 3]; // Assignment of 10
iLocal_2 := aiCardGame[2, 4]; // Assignment of 20

Example

3-dimensional array

VAR
    aiCardGame : ARRAY[1..2, 3..4, 5..6] OF INT;
END_VAR

1st dimension: 1 to 2
2nd dimension: 3 to 4
3rd dimension: 5 to 6

Initialization

aiCardGame : ARRAY[1..2, 3..4, 5..6] OF INT := [10, 20, 30, 40, 50, 60, 70, 80];

Data access

iLocal_1 := aiCardGame[1, 3, 5]; // Assignment of 10
iLocal_2 := aiCardGame[2, 3, 5]; // Assignment of 20
iLocal_3 := aiCardGame[1, 4, 5]; // Assignment of 30
iLocal_4 := aiCardGame[2, 4, 5]; // Assignment of 40
iLocal_5 := aiCardGame[1, 3, 6]; // Assignment of 50
iLocal_6 := aiCardGame[2, 3, 6]; // Assignment of 60
iLocal_7 := aiCardGame[1, 4, 6]; // Assignment of 70
iLocal_8 := aiCardGame[2, 4, 6]; // Assignment of 80

Initialization

aiCardGame : ARRAY[1..2, 3..4, 5..6] OF INT := [2(10), 2(20), 2(30), 2(40)]; // Short notation for [10, 10, 20, 20, 30, 30, 40, 40]

Data access

iLocal_1 := aiCardGame[1, 3, 5]; // Assignment of 10
iLocal_2 := aiCardGame[2, 3, 5]; // Assignment of 10
iLocal_3 := aiCardGame[1, 4, 5]; // Assignment of 20
iLocal_4 := aiCardGame[2, 4, 5]; // Assignment of 20
iLocal_5 := aiCardGame[1, 3, 6]; // Assignment of 30
iLocal_6 := aiCardGame[2, 3, 6]; // Assignment of 30
iLocal_7 := aiCardGame[1, 4, 6]; // Assignment of 40
iLocal_8 := aiCardGame[2, 4, 6]; // Assignment of 40
Example

3-dimensional arrays of a user-defined structure

```plaintext
TYPE DATA_A
STRUCT
  iA_1 : INT;
  iA_2 : INT;
  dwA_3 : DWORD;
END_STRUCT
END_TYPE

PROGRAM PLC_PRG
VAR
  aData_A : ARRAY[1..3, 1..3, 1..10] OF DATA_A;
END_VAR

The array aData_A consists of a total of 3 * 3 * 10 = 90 array elements of data type DATA_A.

Initialize partially

```
aData_A : ARRAY[1..3, 1..3, 1..10] OF DATA_A := [(iA_1 := 1, iA_2 := 10, dwA_3 := 16#00FF), (iA_1 := 2, iA_2 := 20, dwA_3 := 16#FF00), (iA_1 := 3, iA_2 := 30, dwA_3 := 16#FFFF)];
```

In the example, only the first 3 elements are initialized explicitly. Elements to which no initialization value is assigned explicitly are initialized internally with the default value of the basic data type. This initializes the structure components at 0 starting with the element aData_A[2,1,1].

Data access

```
iLocal_1 := aData_A[1,1,1].iA_1; // Assignment of 1
dwLocal_2 := aData_A[3,1,1].dwA_3; // Assignment of 16#FFFF
```

Example

Array of a function block

```plaintext
FUNCTION BLOCK FBObject_A
VAR
  iCounter : INT;
END_VAR
...

PROGRAM PLC_PRG
VAR
  aObject_A : ARRAY[1..4] OF FBObject_A;
END_VAR

The array aObject_A consists of 4 elements. Each element instantiates a FBObject_A function block.

Function Call

```
aObject_A[2]();
```
### Example

**Implementation of FB_Something with method FB_Init**

```plaintext
FUNCTION_BLOCK FB_Something
  VAR
    _nId : INT;
    _lrIn : LREAL;
  END_VAR
  ...
  METHOD FB_Init : BOOL
    VAR_INPUT
      bInitRetains : BOOL;
      bInCopyCode : BOOL;
      nId : INT;
      lrIn : LREAL;
    END_VAR

    _nId := nId;
    _lrIn := lrIn;
  END_VAR

The function block FB_Something has a method FB_Init that requires 2 parameters.
```

**Instantiation of the array with initialization**

```plaintext
PROGRAM PLC_PRG
  VAR
    fb_Something_1 : FB_Something(nId := 11, lrIn := 33.44);
    a_Something : ARRAY[0..1, 0..1] OF FB_Something[(nId := 12, lrIn := 11.22), (nId := 13, lrIn := 22.33), (nId := 14, lrIn := 33.55), (nId := 15, lrIn := 11.22)];
  END_VAR
```

### Array of arrays

The declaration of an "array of arrays" is an alternative syntax for multidimensional arrays. A collection of elements is nested instead of dimensioning the elements. The nesting depth is unlimited.

**Syntax for declaration**

```plaintext
<variable name> : ARRAY[<first>] ( OF ARRAY[<next>] )+ OF <data type> ( := <initialization> )? ;

<first> : <first lower index bound>..<first upper index bound>

<next> : <lower index bound>..<upper index bound> // one or more arrays

<data type> : elementary data types | user defined data types | function block types

// (...)+ : One or more further arrays
// (...)? : Optional

**Syntax for data access**

```plaintext
<variable name>[<index of first array>] ( [<index of next array>] )+ ;
// (...)* : 0, one or more further arrays
```
Example

PROGRAM PLC_PRG
VAR
   aiPoints : ARRAY[1..2,1..3] OF INT := [1,2,3,4,5,6];
   ai2Boxes : ARRAY[1..2] OF ARRAY[1..3] OF INT := [ [1, 2, 3],
   [4, 5, 6]]; 
   [ [ [1, 2, 3, 4], [5, 6, 7, 8], [9, 10, 11, 12] ], [ [13, 14, 15,
   16], [17, 18, 19, 20], [21, 22, 23, 24] ] ];
   ARRAY[1..5] OF INT;
END_VAR

aiPoints[1, 2] := 1200;
ai2Boxes[1][2] := 1200;

The variables `aiPoints` and `ai2Boxes` collect the same data elements, however the syntax
for the declaration differs from that of the data access.

Array of variable length

In function blocks, functions, or methods, you can declare arrays of variable length in the
VAR_IN_OUT declaration section. The LOWER_BOUND and UPPER_BOUND operators are pro-
vided for determining the index limits of the actual used array at runtime.

Syntax of the declaration of a one-dimen-
sional array of variable length

<variable name> : ARRAY[*] OF <data type> ( := <initialization> )? ;

<data type> : elementary data types | user defined data types | function block types
// (...)? : Optional
**Syntax of the declaration of a multi-dimensional array of variable length**

<variable name> : ARRAY[* (, *)+] OF <data type> ( := <initialization> )?;

<data type> : elementary data types | user defined data types | function block types

// (...)+ : One or more further dimensions
// (...)? : Optional

**Syntax of the operators for calculating the limit index**

LOWER_BOUND( <variable name> , <dimension number> )
UPPER_BOUND( <variable name> , <dimension number> )

**Example**

The `SUM` function adds the integer values of the array elements and returns the calculated sum as a result. The sum is calculated across all array elements available at runtime. As the actual number of array elements will only be known at runtime, the local variable is declared as a one-dimensional array of variable length.

```plaintext
FUNCTION SUM: INT;
VAR_IN_OUT
    aiData : ARRAY[*] OF INT;
END_VAR

VAR
    diCounter, diResult : DINT;
END_VAR

diResult := 0;
FOR diCounter := LOWER_BOUND(aiData, 1) TO UPPER_BOUND(aiData, 1)
    diResult := diResult + A[i];
END_FOR;
SUM := diResult;
```

**Data Type ‘__VECTOR’**

Vector operations are supported natively only on 64-bit processors and offer a performance advantage only on these processors. The data sheet of the controller provides information about the processor used on the controller.

Currently, vector operations on the x86/64-bit platforms with SSE2 and ARM64 with NEON are supported natively. On all other platforms, vector operations are translated into individual statements. For example, vector addition is then executed with multiple single addition operations.

The command set extensions of the processors are SIMD extensions. SIMD (Single Instruction, Multiple Data) describes a computer architecture in which multiple data sets of the same type are processed simultaneously in parallel and therefore faster with one command call. In vector operations, for example, 4 pairs of numbers can then be added at the same time.
A vector data type is an array of floating-point numbers with a maximum of 8 elements. The operators \_vc<operator name> are available for this data type. You can use these to implement vector operations without additional function calls.

When indexing a vector variable, you can access a single element of the vector. The index starts at 0 and goes until <vector size> - 1.

### Example

```plaintext
PROGRAM PLC_PRG
VAR
  vcA : __VECTOR[3] OF REAL;
END_VAR

vcA[0] := 1.1;
vcA[1] := 2.2;
vcA[2] := 3.3;
```

### Syntax

<variable name> : __VECTOR[ <vector size> ] OF <element type> ( := <initialization> )?

<vector size> : 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8
<element type> : REAL | LREAL

A vector data type is an array of floating-point numbers with a maximum of 8 elements. The operators __vc<operator name> are available for this data type. You can use these to implement vector operations without additional function calls.

### Syntax for index access

<variable name>[ <index> ]

<index> : 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7

When indexing a vector variable, you can access a single element of the vector. The index starts at 0 and goes until <vector size> - 1.

### Determining the optimal vector size

Use the optimal vector size depending on your target system as the vector size in order to program the most efficient code possible.

For target systems whose computer architecture is generally suitable for vector processing, we do not recommend using vectors of arbitrary size. There is an optimal vector size depending on the type of data processing of the processor. Vectors that are declared with this array size are processed as quickly as possible. Vectors that are declared as a larger array do not have an advantage in speed. Vectors that are declared as smaller arrays do not take full advantage of the processor's capabilities.

You can query the optimal size at runtime. You can find the information in the constants Constants.vcOptimalREAL (for vectors with REAL elements) and Constants.vcOptimalLREAL (for vectors with LREAL elements). The constants have the LREAL data type. If a constant returns the value 1 as the optimal value, then this means that accelerated vector processing is not available for the target system.
An application that is loaded on the CODESYS Control Win V3 x64 target system returns the following values at runtime:

![Device Application PLC_PRG screenshot](image1)

**Example**

```plc
PROGRAM PLC_PRG
VAR
  iOVS_REAL : INT; // Optimal vector size for REAL elements
  iOVS_LREAL : INT; // Optimal vector size for LREAL elements
END_VAR

iOVS_REAL := Constants.vcOptimalREAL;
iOVS_LREAL := Constants.vcOptimalLREAL;
```

The operator calculates the sum of two vectors.

**Operator **__VCADD**

**Syntax**

```plc
<vector variable> := <1st vector operand> __VCADD <2nd vector operand>;
```

**Example of addition**

```plc
FUNCTION_BLOCK FB_ADD
VAR
  vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
  vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 3);
  vcResult : __VECTOR[3] OF REAL;
END_VAR

vcResult := vcA __VCADD vcB;
```

The operator calculates the difference between two vectors.

**Operator **__VCSUB**

**Syntax**

```plc
<vector variable> := <vector minuend> __VCSUB <vector subtrahend>;
```
### Example of subtraction

```plaintext
FUNCTION_BLOCK FB_SUB
VAR
  vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
  vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 3);
  vcResult0 : __VECTOR[3] OF REAL;
  vcResult1 : __VECTOR[3] OF REAL;
END_VAR

vcResult0 := vcA __VCSUB vcB;
vcResult1 := vcB __VCSUB vcA;
```

### Example of multiplication

```plaintext
FUNCTION_BLOCK FB_MUL
VAR
  rScalar : REAL := 1.1;
  vcA : __VECTOR[3] OF REAL;
  vcB : __VECTOR[3] OF REAL;
  vcResult0 : __VECTOR[3] OF REAL;
  vcResult1 : __VECTOR[3] OF REAL;
END_VAR

vcResult0 := vcA __VCMUL vcB;
vcResult1 := rScalar __VCMUL vcB;
vcResult2 := vcA __VCMUL 3.3;
```

### Operator __VCMUL

The operator calculates the product of two vectors or a scalar (floating-point number) and a vector.

**Syntax**

```plaintext
<vector variable> := <1st vector operand> __VCMUL <2nd vector operand> | <scalar operand> __VCMUL <vector operand> | <vector operand> __VCMUL <scalar operand> ;
```

### Operator __VCDIV

The operator calculates the quotient of two vectors or a vector and a scalar.

**Syntax**

```plaintext
<vector variable> := <vector dividend> __VCDIV <vector divisor> | <vector dividend> __VCMUL <scalar divisor> ;
```
**Example of division**

```plaintext
FUNCTION_BLOCK FB_DIV
VAR
  iScalar : INT := 3;
  rScalar : REAL := 1.5;
  vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
  vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 3);
END_VAR

vcResult0 := vcA __VCDIV vcB;
// ERROR CODE vcResult1 := rScalar __VCDIV vcB;
// ERROR CODE vcResult1 := iScalar __VCDIV vcB;
// ERROR CODE vcResult1 := 3.3 __VCDIV vcB;
vcResult2 := vcA __VCDIV 1.5;
vcResult2 := vcA __VCDIV iScalar;
vcResult2 := vcA __VCDIV rScalar;
```

**Operator _VCDOT**

The operator calculates the dot product (scalar product) of two vectors.

**Syntax**

```plaintext
<scalar variable> := <1st vector operand> __VCDOT <2nd vector operand> ;
```

**Example of a dot product**

```plaintext
FUNCTION_BLOCK FB_DOT
VAR
  rResult : REAL;
  vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
  vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 3);
END_VAR

rResult := vcA __VCDOT vcB; // = 18
```

**Operator _VCSQRT**

The operator calculates the square root of each element in the vector.

**Syntax**

```plaintext
<vector variable> := __VCSQRT( <vector operand> ) ;
```

**Example of a square root**

```plaintext
FUNCTION_BLOCK FB_SQRT
VAR
  vcA : __VECTOR[3] OF REAL := __VCSET_REAL(4, 9, 16);
END_VAR

vcResult0 := __VCSQRT(vcA);
```
The operator calculates the maximum vector of two vectors. The maximum is determined element by element.

<vector variable> := __VCMAX( <1st vector operand>, <2nd vector operand>);

**Example of a maximum vector**

```plaintext
FUNCTION_BLOCK FB_MAX
VAR
  vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
  vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 6);
  vcResult0 : __VECTOR[3] OF REAL;
END_VAR
vcResult0 := __VCMAX(vcA, vcB);
```

The operator calculates the minimum vector of two vectors. The minimum is determined element by element.

<vector variable> := __VCMIN( <1st vector operand>, <2nd vector operand>);

**Example of a minimum vector**

```plaintext
FUNCTION_BLOCK FB_MIN
VAR
  vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
  vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 6);
  vcResult0 : __VECTOR[3] OF REAL;
END_VAR
vcResult0 := __VCMIN(vcA, vcB);
```

The operator sets all elements of a vector in a statement. The elements have the REAL data type.

<vector variable> := __VCSET_REAL( <first literal>, ( < next literal> )+ ) ;
( ... )+ // number of elements have to match

**Example**

```plaintext
FUNCTION_BLOCK FB_SET
VAR
  vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
  vcB : __VECTOR[3] OF REAL := __VCSET_REAL(1, 2, 3);
END_VAR
vcA := __VCSET_REAL(4, 4, 4);
vcB := __VCSET_REAL(1.1, 2.2, 3.3);
```
The operator sets all elements of a vector at once in a statement. The elements have the LREAL data type. They can be used wherever variables are valid, such as in assignments in implementations or as parameters in function calls.

Syntax

```
<vector variable> := __VCSET_LREAL( <first literal>, ( <next literal> )+ )
```

Example

```
FUNCTION_BLOCK FB_SET
VAR
    vc1A : __VECTOR[3] OF LREAL := __VCSET_LREAL(3, 3, 3);
    vc1B : __VECTOR[3] OF LREAL := __VCSET_LREAL(1, 2, 3);
END_VAR

vc1A := __VCSET_LREAL(-1.7976931348623158E+308, 0.0, 1.7976931348623158E+308);
vc1B := __VCSET_LREAL(-1.7976931348623158E+308, 0.0, 1.7976931348623158E+308);
```

Operator __VCLOAD_REAL

The operator interprets any arbitrary memory area as a vector. This is helpful for connecting vector variables to existing code. The operator requires 2 parameters. The first parameter indicates the number of vector elements. The second parameter is a pointer to the REAL data.

Syntax

```
<vector variable> := __VCLOAD_REAL( <vector size>, <pointer to data of type REAL> )
```

Example of vectorization

```
FUNCTION_BLOCK FB_LOAD
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    rData0 : REAL := 1.234;
    rData1 : REAL := 5.678;
    rData2 : REAL := 9.123;
    pData : POINTER TO REAL := ADR(rData0);

    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
END_VAR

vcA := __VCLOAD_REAL(3, pData);
```

Operator __VCLOAD_LREAL

The operator interprets any arbitrary memory area as a vector. This is helpful for connecting vector variables to existing code. The operator requires 2 parameters. The first parameter indicates the number of vector elements. The second parameter is a pointer to the LREAL data.

Syntax

```
<vector variable> := __VCLOAD_LREAL( <vector size>, <pointer to data of type LREAL> )
```

Example of vectorization

```
FUNCTION_BLOCK FB_LOAD
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    rData0 : REAL := 1.234;
    rData1 : REAL := 5.678;
    rData2 : REAL := 9.123;
    pData : POINTER TO REAL := ADR(rData0);

    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(3, 3, 3);
END_VAR

vcA := __VCLOAD_REAL(3, pData);
```
Example of vectorization

```plaintext
FUNCTION_BLOCK FB_LOAD
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    lrData0 : LREAL := -1.7976931348623158E+308;
    lrData1: LREAL := 1.6E+308;
    lrData2 : LREAL := 1.7E+308;
    lrData3 : LREAL := -1.6E+308;
    plData: POINTER TO LREAL := ADR(lrData0);

    vclA : __VECTOR[4] OF LREAL := __VCSET_LREAL(4, 4, 4, 4);
END_VAR
vclA := __VCLOAD_LREAL(4, plData);
```

Example of storage

```plaintext
FUNCTION_BLOCK FB_STORE
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
    rData0 : REAL := 3;
    rData1: REAL := 3;
    rData2 : REAL := 3;
    pData: POINTER TO REAL := ADR(rData0);

    lrData0 : LREAL := 4;
    lrData1: LREAL := 4;
    lrData2 : LREAL := 4;
    lrData3 : LREAL := 4;
    plData: POINTER TO LREAL := ADR(lrData0);

    vcA : __VECTOR[3] OF REAL := __VCSET_REAL(1.234, 5.678, 9.123);
    vclA : __VECTOR[4] OF LREAL := __VCSET_LREAL(-1.7976931348623158E+308, 1.6E+308, 1.7E+308, -1.6E+308);
END_VAR
__VCSTORE(pData, vcA);
__VCSTORE(plData, vclA);
```

- § Chapter 1.3.1.25.1.29.1 “POU ‘CheckBounds’” on page 797
Structure

You create a structure in a project with a “DUT” object by clicking “Add Object”.

The structure declaration begins with the keywords TYPE and STRUCT, and ends with the keywords END_STRUCT and END_TYPE.

Syntax for the structure declaration:

```
TYPE <structure name>:
STRUCT
  <variable declaration 1>
  ...
  <variable declaration n>
END_STRUCT
END_TYPE
```

<structure name> is a type that CODESYS recognizes through the entire project and you can use as a standard data type.

You can also use nested structures. The only restriction is that you are not permitted to assign addresses to variables (because the AT declaration is not permitted).

**Example of a structure definition named Polygonline**

```
TYPE polygonline:
STRUCT
  start:ARRAY [1..2] OF INT;
  point1:ARRAY [1..2] OF INT;
  point2:ARRAY [1..2] OF INT;
  point3:ARRAY [1..2] OF INT;
  point4:ARRAY [1..2] OF INT;
  end:ARRAY [1..2] OF INT;
END_STRUCT
END_TYPE
```

See also

- ≡ Chapter 1.3.1.25.1.14 “Object 'DUT’” on page 735
- ≡ Chapter 1.3.1.24.3.28 “Operator 'EQ’” on page 523

**Initializing structures**

**Example:**

```
pPoly_1 : polygonline := ( start:=[3,3], point1:=[5,2], point2 := [7,3], point3 := [8,5], point4 := [5,7], end := [3,5]);
```

You are not permitted to use initializations with variables. For an example of initializing an array of a structure, please see the help page for the ARRAY data type.

See also

- ≡ Chapter 1.3.1.24.5.14 “Data type 'ARRAY’” on page 581

**Accessing structure members**

You access structure members with the following syntax:

```
<structure name>.<component name>
```

Therefore, you can use `poly_1.start` to access the `start` component of the `polygonline` structure in the above example.
See also

- § Chapter 1.3.1.24.5.14 “Data type 'ARRAY’” on page 581

**Bit access in structures**

Bit is a special data type that you define in structures only. It reserves one bit of memory and permits single bits of a structure to be addressed by a name.

```
TYPE <structure name>:
  STRUCT
    <bit name bit1> : BIT;
    <bit name bit2> : BIT;
    <bit name bit3> : BIT;
    ...
    <bit name bitn> : BIT;
  END_STRUCT
END_TYPE
```

You can access the BIT structure member with the following syntax:

```
<structure name>.<bit name>
```

You cannot use any references or pointers to BIT variables. Furthermore, you are not permitted to use BIT variables in arrays.

See also

- § Chapter 1.3.1.24.5.10 “Data type 'BIT’” on page 577

**Enumerations**

An enumeration is a user-defined data type composed of a series of comma-separated components (enumeration values) for declaring user-defined variables. Moreover, you can use the enumeration components like constants whose identifier `<enumeration name>.<component name>` is recognized globally in the project.

You declare an enumeration in a DUT object, which you have already created in the project by clicking “Add Object”.

**Declaration**

**Syntax**

```
( {attribute 'strict'} )? // Pragma optional but recommended
TYPE <enumeration name> :
  ( <first component declaration>,
    ( <component declaration> ,)+
    <last component declaration>
  ) ( <basic data type> )? ( := <default variable initialization> )? ;
END_TYPE
```

```
( ... )? : Optional
<component declaration> : <component name> ( := <component initialization> )?
<basic data type> : INT | UINT | SINT | USINT | DINT | UDINT | LINT | ULINT | BYTE | WORD | DWORD | LWORD
<variable initialization> : <one of the component names>
```
In an enumeration declaration, at least 2 components are usually declared. However, you can declare as many as you want. Every single component can be assigned its own initialization. Enumerations automatically have the basic data type INT, but you can specify another basic data type. Moreover, you can specify a component in the declaration with which an enumeration variable is then initialized.

The pragma {attribute 'strict'} causes a strict type test to be performed as described below.

```
{attribute 'qualified_only'}
{attribute 'strict'}
TYPE COLOR_BASIC :
{
  yellow,
  green,
  blue,
  black
}
; // Basic data type is INT, default initialization for all COLOR_BASIC variables is yellow
END_TYPE
```

**Enumeration with explicit basic data type**

Extensions to the IEC 61131-3 standard

The basic data type for an enumeration declaration is INT by default. However, you can also declare enumerations that are based explicitly on another integer data type.

```
<basic data type> : INT | UINT | SINT | USINT | DINT | UDINT | LINT | ULINT | BYTE | WORD | DWORD | LWORD
```

```
TYPE COLOR :
{
  white := 16#FFFFFF00,
  yellow := 16#FFFFFF00,
  green := 16#FF00FF00,
  blue := 16#FF0000FF,
  black := 16#88000000
} DWORD := black; // Basic data type is DWORD, default initialization for all COLOR variables is black
END_TYPE
```

**Strict programming rules**

**NOTICE!**

In CODESYS V3.5 SP7 and later, the pragma {attribute 'strict'} is added automatically in the first line when declaring an enumeration.

The strict programming rules are activated when adding the pragma {attribute 'strict'}. 

The following code is considered a compiler error:

- Arithmetic operations with enumeration components
  - For example, an enumeration variable cannot be used as a counter variable in a `FOR` loop.
- Assignment of a constant value, which does not correspond to an enumeration value, to an enumeration component
- Assignment of a non-constant variable, which has another data type as the enumeration, to an enumeration component

Arithmetic operations can lead to undeclared values being assigned to enumeration components. A better programming style is to use `SWITCH/CASE` statements for processing component values.

### Declaration and initialization of enumeration variables

#### Syntax

```
<variable name> : <enumeration name> ( := <initialization> )? ;
```

For a declaration of an enumeration variable with user-defined data type `<enumeration name>`, this can be initialized with an enumeration component.

#### Example

```plc
PROGRAM PLC_PRG
VAR
  colorCar: COLOR;
  colorTaxi : COLOR := COLOR.yellow;
END_VAR
```

The variable `colorCar` is initialized with `COLOR.black`. That is the default initialization for all enumeration variables of type `COLOR` and defined this way in the type declaration. The variable `colorTaxi` has its own initialization.

If no initializations are specified, then the initialization value is 0.

#### Example

```plc
PROGRAM PLC_PRG
VAR
  cbFlower : COLOR_BASIC;
  cbTree: COLOR_BASIC := COLOR_BASIC.green;
END_VAR
```

The variable `cbFlower` is initialized with `COLOR_BASIC.yellow`. That is the default initialization for all enumeration variables of type `COLOR_BASIC`. Because the enumeration declaration does not specify a component for initialization, the system automatically initializes with the component that has the value 0. This is usually the first of the enumeration components. However, it can also be another component that is not in the first position but explicitly initialized with 0.

The variable `cbTree` has an explicit initialization.

If no value is specified for both the type and the variable, then the following rule applies: If an enumeration contains a value for 0, then this value is the default initialization, and if not, then the first component in the list.
Example

**Initialization with the 0 component**

```plaintext
TYPE ENUM :
(
    e1 := 2,
    e2 := 0,
    e3
)
;
END_TYPE

PROGRAM PLC_PRG
VAR
    e : ENUM;
END_VAR

The variable `e` is initialized with `ENUM.e2`.
```

**Initialization with the first component**

```plaintext
TYPE ENUM2 :
(
    e1 := 3,
    e2 := 1,
    e3
)
;
END_TYPE

PROGRAM PLC_PRG
VAR
    e2 : ENUM2;
END_VAR

The variable `e2` is initialized with `ENUM.e1`.
```

**Unique access to enumeration components**

Extensions to the IEC 61131-3 standard

The enumeration components can also be used as constant variables with the identifier `<enumeration name>.<component name>`. Enumeration components are recognized globally in the project and access to them is unique. Therefore, a component name can be used in different enumerations.

Example

**Component blue**

```plaintext
PROGRAM PLC_PRG
VAR
    cbFlower : COLOR_BASIC;
    colorCar : COLOR;
END_VAR

(* unambiguous identifiers although the component names are identical *)
    cbFlower := COLOR_BASIC.blue;
    colorCar := COLOR.blue;

(* invalid code *)
    cbFlower := blue;
    colorCar := blue;
```
Subrange types

A subrange type is a data type whose value range is a subset of a base type.

Syntax for the declaration:

```
<name> : <int type> (<lower limit>..<upper limit>);
```

<table>
<thead>
<tr>
<th>&lt;name&gt;</th>
<th>valid IEC identifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;int type&gt;</td>
<td>data type of the subrange</td>
</tr>
<tr>
<td></td>
<td>(SINT, USINT, INT, UINT, DINT, UDINT, BYTE, WORD, DWORD, LINT, ULINT, LWORD).</td>
</tr>
<tr>
<td>&lt;lower limit&gt;</td>
<td>Lower limit of the range: constants that have to be compatible with the basic data type. The lower limit is also included in this range.</td>
</tr>
<tr>
<td>&lt;upper limit&gt;</td>
<td>Upper limit of the range: constants that have to be compatible with the base data type. The upper limit is also included in this range.</td>
</tr>
</tbody>
</table>

Examples:

```
VAR
  i : INT (-4095..4095);
  ui : UINT (0..10000);
END_VAR
```

If you assign a value to a subrange type in the declaration or implementation section that is not within this range (example: i:=5000), then CODESYS issues an error message.

Please note: In runtime mode, it is possible to monitor the range limits of a subrange type by using the implicit monitoring functions CheckRangeSigned and CheckRangeUnsigned.

1.3.1.24.6 Pragmas

1.3.1.24.6.1 Message pragmas................................................................. 600
1.3.1.24.6.2 Attribute pragmas............................................................. 601
1.3.1.24.6.3 Conditional pragmas......................................................... 637
1.3.1.24.6.4 Region pragma............................................................... 644

Pragma instructions affect the properties of one or more variables with regard to the compilation or pre-compilation process. Various categories of pragmas are available to you for this.
Message pragmas

Message pragmas serve to force the display of messages in the Message window during the compilation process.

Insertion position: separate or already existing line in the text editor of a POU.

Table 25: 4 types of message pragmas

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Message type</th>
</tr>
</thead>
<tbody>
<tr>
<td>{text (&lt;'textstring'&gt;)}</td>
<td>“Text”: display of &lt;textstring&gt;.</td>
</tr>
<tr>
<td>{info (&lt;'textstring'&gt;)}</td>
<td>“Information”: display of &lt;textstring&gt;.</td>
</tr>
<tr>
<td>{warning (&lt;'textstring'&gt;)}</td>
<td>“Warning”: display of &lt;textstring&gt;.</td>
</tr>
<tr>
<td>{error (&lt;'textstring'&gt;)}</td>
<td>“Error”: display of &lt;textstring&gt;.</td>
</tr>
</tbody>
</table>

Unlike the attribute pragma 'obsolete', you define the warning locally for the current position.

In the CODESYS Message window you can jump with the help of the commands “Next Message” and “Previous Message” from a message of the category “Information”, “Warning” and “Error” to the source position of the message. This means you jump to the position where the pragma is added in the source code.

Example

```plaintext
VAR
  var : INT; {info 'TODO: should get another name'}
  bvar : BOOL;
  arrTest : ARRAY [0..10] OF INT;
  i:INT;
END_VAR
  arrTest[i] := arrTest[i]+1;
  ivar:=ivar+1;
{warning 'This is a warning'}
{text 'Part xy has been compiled completely'}
```

Display in the Message window:

<table>
<thead>
<tr>
<th>Messages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Build</td>
</tr>
<tr>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
</tr>
<tr>
<td>build started: Application: Res.App2</td>
</tr>
<tr>
<td>typify code</td>
</tr>
<tr>
<td>Compile time before typification: 6 ms</td>
</tr>
<tr>
<td>Compile time after typification: 15 ms</td>
</tr>
<tr>
<td>TODO: should get another name!</td>
</tr>
<tr>
<td>This is a warning</td>
</tr>
<tr>
<td>Part xy has been compiled completely</td>
</tr>
<tr>
<td>Compile complete -- 1 errors, 2 warnings</td>
</tr>
</tbody>
</table>
Attribute pragmas affect the compilation and the pre-compilation.

CODESYS supports a series of pre-defined attribute pragmas. In addition you can use user-defined pragmas, which you can query with the help of conditional pragmas before the compilation of the project.
Attributes are defined within the declaration part. Exception: For the objects Action and Transition, which have no own declaration part, you can define the attributes at the beginning of the implementation part.

When you define own attributes, please make them unambiguous. Uniqueness can be reached for example by adding a prefix to the attribute name. OEMs can use the vendor prefix for this purpose.

User-defined attributes

User-defined attributes are any application-defined or user-defined attributes that you can apply to POUs, actions, data type definitions and variables. You can query a user-defined attribute with the help of conditional pragmas before the compilation of the application.

You can query user-defined attributes with conditional pragmas with the operator hasattribute.

More detailed information and examples can be found in the chapter 'Conditional pragmas'.

Syntax:

{attribute 'attribute'}

Example for POUs and actions

Attribute 'vision' for function “fun1”

\[
\begin{align*}
\text{FUNCTION fun1 : INT} \\
\text{VAR_INPUT i : INT;} \\
\text{END_VAR}
\end{align*}
\]

Example for variables

Attribute 'DoCount' for variable ivar:

\[
\begin{align*}
\text{PROGRAM PLC_PRG} \\
\text{VAR} \\
\text{(attribute 'DoCount');} \\
\text{ivar:INT;} \\
\text{bvar:BOOL;} \\
\text{END_VAR}
\end{align*}
\]
Example for data types

Attribute 'aType' for data type DUT_1:

```plaintext
{attribute 'aType'}
TYPE DUT_1 :
  STRUCT
    a:INT;
    b:BOOL;
  END_STRUCT
END_TYPE
```

See also
-  Chapter 1.3.1.24.6.3 “Conditional pragmas” on page 637

Attribute 'call_after_global_init_slot'

```plaintext
NOTICE!
VAR_INPUT declarations in functions or methods that use the attribute lead to compile errors. Reason: Input variables are unknown in this case at the time of the call, which occurs implicitly during the online change.
```

The effect of this pragma is that all functions and programs containing this attribute are called after the global initialization. You define the order of calling by means of the attribute value.

**Syntax:**

```plaintext
{attribute 'call_after_global_init_slot' := '<slot>'}
```

*<slot>*: Integer value that defines the ranking in the order of the calls; the lower the value, the earlier the call takes place. If several function blocks have the same ranking for the attribute, then the order of their calls remains indefinite.

Insert location: First line above the declaration part of functions and programs

If a method possesses the attribute, CODESYS determines all instances of the corresponding function block and calls all instances in the specified slot. In this case you have no influence on the order of the instances among themselves.

See also
-  Chapter 1.3.1.24.10 “Methods 'FB_Init', 'FB_Reinit', and 'FB_Exit'” on page 653

Attribute 'call_after_init'

```plaintext
NOTICE!
VAR_INPUT declarations in functions or methods that use the attribute lead to compile errors. Reason: Input variables are unknown in this case at the time of the call, which occurs implicitly during the online change.
```

The effect of this pragma is that a method is called implicitly after the initialization of a function block instance. For reasons of performance you must add the attribute both to the function block and to the method in its own first line above the declaration part.
Syntax:

{attribute 'call_after_init'}

Call: First line above the declaration part of the method and the function block.
CODESYS calls the method after the method FB_init and after the variable values of an initialization expression in the instance declaration have become valid.

This functionality is supported from compiler version 3.4.1.0.

Example

Definition:

{attribute 'call_after_init'}
FUNCTION_BLOCK FB
... <function block definition>

{attribute 'call_after_init'}
METHOD FB_AfterInit
... <method definition>

The definition implements, for example, the following declaration in the subsequent code processing:

inst : FB := (in1 := 99);

Code processing:

inst.FB_Init();
inst.in1 := 99;
inst.FB_AfterInit();

This allows a reaction to the user-defined initialization in FB_AfterInit.

See also

- Chapter 1.3.1.24.10 “Methods ‘FB_Init’, ‘FB_Reinit’, and ‘FB_Exit’” on page 653

Attribute 'call_after_online_change_slot'

NOTICE!

VAR_INPUT declarations in functions or methods that use the attribute lead to compile errors. Reason: Input variables are unknown in this case at the time of the call, which occurs implicitly during the online change.

The effect of this pragma is that all functions and programs containing this attribute are called after an online change. You define the order of calling by means of the attribute <slot>.

Syntax:

{attribute 'call_after_online_change_slot' := '<slot>'}

<slot>: Integer value that defines the ranking in the order of the calls; the lower the value, the earlier the call takes place. If several function blocks have the same ranking for the attribute, then the order of their calls remains indefinite.

Call: First line above the declaration part of functions and programs.

If a method possesses the attribute, then CODESYS determines all instances of the function block concerned. CODESYS calls all instances in the specified slot. In this case you have no influence on the order of the instances among themselves.
NOTICE!
Since the application cannot run during the online change, each code executed in this situation can lead to a jitter. Therefore, keep the extent of the executive code as small as possible.

See also
- § Chapter 1.3.1.25.2.6.6 “Command ‘Online Change’” on page 928

Attribute 'call_before_global_exit_slot'

NOTICE!

VAR_INPUT declarations in functions or methods that use the attribute lead to compile errors. Reason: Input variables are unknown in this case at the time of the call, which occurs implicitly during the online change.

The effect of this pragma is that all functions and programs containing this attribute in a dedicated first line of their declaration are called before the GlobalExit. The GlobalExit takes place before a new download or a reset. Function blocks provided with an FB_Exit method are affected. The order of calling is defined by means of the attribute value.

Syntax:

{attribute 'call_before_global_exit_slot' := '<slot>'}

Insert location: First line above the declaration part of functions and programs.

<slot>: Integer value that defines the ranking in the order of the calls; the lower the value, the earlier the call takes place. If several function blocks have the same ranking for the attribute, then the order of their calls remains indefinite.

If a method possesses the attribute, then the method is called for all instances of the function block concerned. CODESYS calls all instances in the specified slot. In this case you have no influence on the order of the instances among themselves.

See also
- § Chapter 1.3.1.24.10 “Methods ‘FB_Init’, ‘FB_Reinit’, and ‘FB_Exit’” on page 653

Attribute 'call_on_type_change'

With this pragma, you can mark a method of a function block A that should be called when the data type changes for one or more function blocks B, C, etc. that are referenced by A. The referencing can be defined by a pointer variable or a REFERENCE variable.

Syntax:

{attribute 'call_on_type_change' := '<name of the first referenced function block>|<name of the second referenced function block>|<name of the ... referenced function block>'}

Insert location: Line above the first line in the method declaration.
Example

Function blocks with references

FUNCTION_BLOCK FB_A
  ...
  VAR
    var_pt: POINTER TO FB_B;
    var_ref: REFERENCE TO FB_C;
  END_VAR
  ...

{attribute 'call_on_type_change' := 'FB_B, FB_C'}

METHOD METH_react_on_type_change : INT
  VAR_INPUT
  ...

Method for reaction to a type change in the references FB_B and FB_C

Attribute 'const_replaced', attribute 'const_no_replaced'

The effect of the pragma \{attribute 'const_replaced'} is that the compiler option "Replace constants" is explicitly activated for all global constants containing this attribute in the constant declaration.

Accordingly, you insert the pragma \{attribute 'const_non_replaced'} in order to explicitly deactivate the compiler option "Replace constants". This can be desirable, for example, so that a constant is available in the symbol configuration.

The option "Replace constants" in the dialog box "Project Settings", category "Compile Options" is preset for the entire project.

Syntax:

\{attribute 'const_replaced'}

\{attribute 'const_non_replaced'}

Insertion position: line above the declaration line of the global variables.

Example

The constants iTestCon and bTestCon are available in the symbol configuration, because the option "Replace constants" is deactivated.

VAR_GLOBAL CONSTANT
  \{attribute 'const_non_replaced'}
  iTestCon    :   INT  := 12;
  (attribute 'const_non_replaced')
  bTestCon    :   BOOL := TRUE;
  rTestCon    :   REAL := 1.5;
END_VAR

VAR_GLOBAL
  iTestVar    :   INT  := 12;
  bTestVar    :   BOOL := TRUE;
END_VAR

See also

- Chapter 1.3.1.25.3.11.3 “Dialog Box ‘Project Settings’ - ‘Compileoptions’” on page 1062
- Chapter 1.3.1.10.2 “Symbol configuration” on page 275
Attribute 'dataflow'

With this pragma you control the data flow in the processing of function blocks in the FBD/LD/IL editor. The attribute defines the input or output of a function block to which the continuing connection to the next or previous function block is connected.

You may provide only 1 input and 1 output with the attribute in the declaration of a function block.

**Syntax:**

```
{attribute 'dataflow'}
```

Insertion position: line above the line with the declaration of the corresponding variables.

In the case of function blocks without the attribute 'dataflow', CODESYS determines the data flow as follows: first of all the connection is placed between an output and an input of same data type. The highest input or output variable of the function blocks is always taken. If there are no variables of a corresponding data type, CODESYS connects the highest output with the highest input of the neighboring function blocks.

**Example**

The connection between FB and the preceding function block is established via the input variable i1. The connection between FB and the following function block is established via the output variable outRes1.

```plaintext
FUNCTION_BLOCK FB
VAR_INPUT
  r1 : REAL;
  {attribute 'dataflow'}
  i1 : INT;
  i2 : INT;
  r2 : REAL;
END_VAR

VAR_OUTPUT
  {attribute 'dataflow'}
  outRes1 : REAL;
  out1 : INT;
  g1 : INT;
  g2 : REAL;
END_VAR
```

**See also**

- Chapter 1.3.1.9.3.1.1 “Programming function block diagrams (FBD)” on page 184

Attribute 'displaymode'

With this pragma you define the display mode of an individual variable. This definition overwrites the global setting for the display of the monitoring variable, which takes place via the commands in the menu “Debug ➔ Display Mode”.

**Syntax:**

```
{attribute 'displaymode':=<displaymode>}
```

The following definitions are possible
- Binary format
  - {attribute 'displaymode':='bin'}
  - {attribute 'displaymode':='binary'}
- Decimal format
  - attribute 'displaymode':='dec'}
  - {attribute 'displaymode':='decimal'}
- Hexadecimal format
  - {attribute 'displaymode':='hex'}
  - attribute 'displaymode':='hexadecimal'}

Insertion position: line above the line with the declaration of the corresponding variables.

Example

```plaintext
VAR
  {attribute 'displaymode':='hex'}
  dwVar1: DWORD;
END_VAR
```

See also
- % Chapter 1.3.1.25.2.7.24 “Command 'Display Mode' - 'Binary', 'Decimal', 'Hexadecimal’” on page 948

Attribute 'estimated-stack-usage'

The pragma provides an estimated value for the stack size requirement. Methods with recursive calls cannot pass a stack check because stack usage cannot be determined. As a result, a warning is issued. To prevent this warning, you can give the method an estimated value (in bytes) for the stack size requirement. Then the method passes the stack check successfully.

Syntax

```plaintext
{attribute 'estimated-stack-usage' := '<estimated stack size in bytes>'}
```

Example

```plaintext
{attribute 'estimated-stack-usage' := '127'} // 127 bytes
METHOD PUBLIC DoIt : BOOL
  VAR_INPUT
END_VAR
```

Insert location: First line above the declaration part of the method.
The section "Method call" includes an example that uses this pragma.

Recursive method call

Within its implementation, a method can call itself, either directly by means of the THIS pointer, or by means of a local variable for the assigned function block.

Use recursions mainly for processing recursive data types such as linked lists. In general, we recommend to be careful when using recursion, as unexpectedly deep recursions can cause stack overflow and machine downtime.
The following program PLC PRG calculates the factorial of a number in the FB_Factorial function block in a different way, each in its own method.

- Method m_Iterative: Iterative
- Method m_Pragmahed: Recursive with warning suppression
- Method m_Recursive: Recursive
- Method m_Temp: Temporary with warning suppression

A warning is issued for the m_Recursive method only.

// Contains the data of the factorial calculation of uiNumber
TYPE FACTORIAL_RESULT:
  STRUCT
    uiNumber : UINT;
    udiIterative : UDINT;
    udiRecursive : UDINT;
    udiPragmaed : UDINT;
    udiTemp : UDINT;
  END_STRUCT
END_TYPE

PROGRAM PLC_PRG
VAR
  fb_Factorial_A : FB_Factorial;
  factorial_A : FACTORIAL_RESULT := (uiNumber := 9,
    udiIterative := 0, udiRecursive := 0, udiPragmaed := 0);
END_VAR

fb_Factorial_A.p_Number := factorial_A.uiNumber;
factorial_A.udiIterative := fb_Factorial_A.m_Iterative();
factorial_A.udiRecursive := fb_Factorial_A.m_Recursive(uiN := factorial_A.uiNumber);
factorial_A.udiPragmaed := fb_Factorial_A.m_Pragmaed(uiN := factorial_A.uiNumber);
factorial_A.udiTemp := fb_Factorial_A.m_Temp(uiN := factorial_A.uiNumber);
// Factorial calculation in different ways
FUNCTION_BLOCK FB_Factorial
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
uiN : UINT;
udiIterative : UDINT;
udiPragmaed : UDINT;
udiRecursive : UDINT;
END_VAR

// Iterative calculation
METHOD PUBLIC m_Iterative : UDINT
VAR
uiCnt : UINT;
END_VAR
m_Iterative := 1;
IF    uiN > 1 THEN
    FOR uiCnt := 1 TO uiN DO
        m_Iterative := m_Iterative * uiCnt;
    END_FOR;
RETURN;
ELSE
    RETURN;
END_IF;

// Recursive calculation with suppressed warning
METHOD PUBLIC mPragmaed : UDINT
VAR_INPUT
uiN : UINT;
END_VAR
VAR
mPragmaed := 1;
IF    uiN > 1 THEN
    mPragmaed := uiN * THIS^.mPragmaed(uiN := (uiN - 1));
RETURN;
ELSE
    RETURN;
END_IF;

// Recursive calculation
METHOD PUBLIC m_Recursive : UDINT
VAR_INPUT
uiN : UINT;
END_VAR
VAR
m_Recursive := 1;
IF    uiN > 1 THEN
    m_Recursive := uiN * THIS^.m_Recursive(uiN := (uiN - 1));
RETURN;
ELSE
    RETURN;
END_IF;

// Called by temporary FB instance
METHOD PUBLIC m_Temp : UDINT
VAR_INPUT
uiN : UINT;
END_VAR
VAR
    fb_Temp : FB_Factorial;
END_VAR
m_Temp := 1;
IF    uiN > 1 THEN
    m_Temp := uiN * fb_Temp.m_Temp{uiN := (uiN - 1)};
    RETURN;
ELSE
    RETURN;
END_IF;

PROPERTY p_Number : UINT
    uiN := p_Number; //Setter method

Only the m_Recursive issues a warning when the program is executed.

Attribute 'ExpandFully'
The effect of this pragma is that the components of an array used as an input variable for referenced visualizations are made visible in the Properties dialog box of the visualization.

Syntax:
(attribute 'ExpandFully')

Insertion position: the line above the line with the declaration of the array.
The visualization "visu" is to be inserted into a frame inside the visualization "visu_main". arr is defined as an input variable in the interface editor of "visu" and will thus be available later for assignments in the Properties dialog box of the frames in "visu_main". In order to also make the individual components of arr available in this Properties dialog box, you must insert the attribute 'ExpandFully' directly before arr in the interface editor of visu. Declaration in the interface editor of "visu":

```
VAR_INPUT  
{attribute 'ExpandFully')
arr : ARRAY[0..5] OF INT;
END_VAR
```

Example

```
Example
```

Attribute 'global_init_slot'

This pragma defines the initialization order of function blocks or global variable lists. Variables in a list (GVL or POU) are initialized from top to bottom.

If there are several global variable lists, then the initialization order is not defined.

The initialization does not apply for the initialization of literal values, for example 1, 'hello', 3.6, or constants of base data types. However, you must define the initialization order yourself if there are dependencies between the lists. You can assign a defined initialization slot to a GVL or POU with the 'global_init_slot' attribute.

Syntax:
```
{attribute 'global_init_slot' := '<slot>'}
```

(slot): Integer value that defines the position in the call order. The default value for a POU (program, function block) is 50000. The default value for a GVL is 49990. A lower value means an earlier initialization. Caution: If several blocks or GVLs receive the same value for the 'global_init_slot' attribute, then the initialization order remains undefined.

Insert location: The pragma always affects the entire GVL or POU and therefore it must be located above the VAR_GLOBAL or POU declaration.
The program includes two global variable lists “GVL_1” and “GVL_2”, as well as a “PLC_PRG” program that uses variables from both lists. “GVL_1” uses the variable B for initializing a variable A, which is initialized in “GVL_2” with a value of 1000.

```
VAR_GLOBAL   //49990
A : INT := GVL_2.B*100;
END_VAR

VAR_GLOBAL   //49990
B : INT := 1000;
C : INT := 10;
END_VAR

PROGRAM PLC_PRG  //50000
VAR
ivar: INT := GVL_1.A;
ivar2: INT;
END_VAR
ivar:=ivar+1;
ivar2:=GVL_2.C;
```

In this case, the compiler prints an error because GVL_2.B is used for initializing GVL_1.A before “GVL_2” has been initialized. You can prevent this by using the global_init_slot attribute to position “GVL_2” before “GVL_1” in the initialization sequence.

In this example, “GVL_1” must have at least a slot value of 49989 in order to achieve the earliest initialization within the program. Every lower value has the same effect:

```
{attribute 'global_init_slot' := '100'}
VAR_GLOBAL
B : INT := 1000;
END_VAR
```

Note: Using GVL_2.C in the implementation part of “PLC_PRG” is also not critical even without using a pragma because both GVLs are initialized before the program in either case.

## Attribute 'hide'

The pragma prevents variables or POUs from being shown in the CODESYS user interface. In this way, you can intentionally hide variables or POUs from the user. As a result, the variables or POUs are neither visible in the Library Manager nor are they suggested in the input assistant or in the "List components" function. In online mode, they are not visible in the declaration part and debug functionalities cannot be applied to them.

If the instance path to a variable is known, then it can be addressed in the code even when it has the hide attribute.

**Syntax:**

```
{attribute 'hide'}
```

*Insert location:* For variables, above the line with the declaration of the variables. For POUs, in the first line.
The function block “myPOU” uses the attribute {attribute 'hide'}:

FUNCTION_BLOCK myPOU

VAR_INPUT
  a:INT;
  {attribute 'hide'}
  a_invisible: BOOL;
  a_visible: BOOL;
END_VAR

VAR_OUTPUT
  b:INT;
END_VAR

Two instances of the function block “myPOU” are defined in the main program.

PROGRAM PLC_PRG

VAR
  POU1, POU2: myPOU;
END_VAR

When the input value for POU1 is implemented, the "List components" function, which opens when you type POU1. (in the implementation part of “PLC_PRG”), displays the variables a, a_visible, and b, but not the hidden variable a_invisible.

Example

With the pragma hide_all_locals you can hide all local variables of a declaration.

See also

- § Chapter 1.3.1.24.6.2.14 “Attribute 'hide_all_locals'” on page 614

Attribute 'hide_all_locals'

This pragma prevents all local variables of a signature from being visible in the display of the 'List components' function, in the input assistant or in the declaration part in online mode.

Syntax:

{attribute 'hide_all_locals'}

Insertion position: first line above the declaration part of the POU.
Example  The function block “myPOU” uses the attribute:

```plaintext
{attribute 'hide_all_locals'}
FUNCTION_BLOCK myPOU
VAR_INPUT
  a: INT;
END_VAR

VAR_OUTPUT
  b: BOOL;
END_VAR

VAR
  c,d: INT;
END_VAR
```

Two instances of the function block “myPOU” are defined in the main program.

```plaintext
PROGRAM PLC_PRG
VAR
  POU1, POU2: myPOU;
END_VAR
```

While an input value for “POU1” is now implemented, the ‘List components’ function, which opens when typing POU1, in the implementation part of PLC_PRG, displays the variables a and b, but not the hidden local variables c or d.

See also

- § Chapter 1.3.1.24.6.2.13 “Attribute 'hide'” on page 613

**Attribute 'initialize_on_call'**

This pragma can be applied to input variables. It causes the input variables of a function block to be initialized on each call of the function block. If an input expects a pointer and this pointer has been removed in the course of an online change, this input will be set to zero.

**Syntax:**

```plaintext`
{attribute 'initialize_on_call'}
```

Insertion position: line above the line with the declaration of the corresponding input variables.

**Attribute 'init_namespace'**

The effect of this pragma is that a variable of the type `STRING` or `WSTRING`, which is declared in a library function block with this pragma, is initialized when used in the project with the current namespace of the library.

**Syntax**

```plaintext`
{attribute 'init_namespace'}
```

Insertion position: the line above the line with the declaration of the variables in a library function block.
The function block “POU” is provided with the necessary attributes:

```
FUNCTION_BLOCK POU
VAR_OUTPUT
  {attribute 'init_namespace'}
  myStr: STRING;
END_VAR
```

An instance fb of the function block POU is defined within the main program PLC_PRG:

```
PROGRAM PLC_PRG
VAR
  fb:POU;
  newString: STRING;
END_VAR
newString := fb.myStr;
```

The variable myStr is initialized with the current namespace, for example MyLib. This value is assigned to newString in the main program.

See also

- Chapter 1.3.1.25.1.25 “Object ‘Library Manager” on page 771

### Attribute 'init_on_onlchange'

The effect of this pragma is that the variable to which the pragma is applied is initialized with each online change.

**NOTICE!**

For compiler version 3.5.0.0 and later, a fast online change is performed for minor changes. In this case, only the modified blocks are compiled and downloaded. In particular, no initialization code is generated. This means that also no code is generated when variables with the `init_on_onlchange` attribute are initialized. As a rule, this has no effect because the attribute is used primarily for initializing variables with addresses. However, it cannot happen that a variable changes its address during an online change.

To secure the effect of the `init_on_onlchange` attribute in the entire application code, you must deactivate the fast online change in general for the application by using the compiler definition `no_fast_online_change`. To do this, insert the definition in the application “Properties” (“Build” tab).

**Syntax:**

```
{attribute 'init_on_onlchange'}
```

**Insert location:** The line above the line with the declaration of the variables.

See also

- Chapter 1.3.1.25.3.10.4 “Dialog ‘Properties’ - ‘Build’” on page 1048

### Attribute 'instance-path'

This pragma can be applied to a local STRING variable and causes this local STRING variable to be initialized in sequence with the device tree path of the POU to which it belongs. This can be useful for error messages. The application of the pragma requires the application of the attribute 'reflection' to the associated POU, as well as the application of the additional attribute 'noinit' to the STRING variable.

**Syntax:**

```
{attribute 'instance-path'}
```

The following function block contains the attributes 'reflection', 'instance-path' and 'noinit'.

```plaintext
{attribute 'reflection'}
FUNCTION_BLOCK POU
{attribute 'instance-path'}
{attribute 'noinit'}
  str: STRING;
END_VAR
```

An instance "myPOU" of the function block “POU” is defined within the main program "PLC_PRG":

```plaintext
PROGRAM PLC_PRG
VAR
  myPOU:POU;
  myString: STRING;
END_VAR
myPOU();
myString:=myPOU.str;
```

Following the initialization of the instance myPOU, the path of the instance myPOU is assigned to the string variable str, in the example PLCWinNT.Application.PLL_PB.myPOU. This path is assigned in the main program to the variable myString.

### Example

#### NOTICE!

You can define the length of a string to be whatever you like (even >255), but you must consider that the string will be truncated at the end if it is assigned to a variable whose data type is too small for it.

See also

- ¶ Chapter 1.3.1.24.6.2.34 “Attribute 'reflection'” on page 634
- ¶ Chapter 1.3.1.24.6.2.26 “Attribute 'noinit'” on page 623

### Attribute 'io_function_block', 'io_function_block_mapping'

With the 'io_function_block' attribute, you mark a function block in order to prepare it for the assignment to a channel in the I/O mapping of the device configuration. Then it is shown in the “Select function block” dialog.

With the 'io_function_block_mapping' attribute, you mark a parameter that should be used when mapping the FB to a device channel in this kind of function block. You can provide the attribute to multiple parameters of the function block. For I/O mapping, the first one is used automatically whose type matches the channel (input, output, data type).

**Syntax:**

```plaintext
{attribute 'io_function_block'}
{attribute 'io_function_block_mapping'}
```

**Insert location:** The line above the first line in the declaration of the function block, or the line above the parameter declaration.
Example

FUNCTION_BLOCK Scale_Output_Int
VAR_INPUT
  iInput : INT;
  iNumerator : INT;
  iDenominator : INT := 1;
  iOffset : INT := 0;
END_VAR
VAR_OUTPUT
  iOutput : INT;
END_VAR

See also

- Chapter 1.3.1.25.3.3 “Dialog ‘Select Function Block’” on page 1040
- “Linking a device with a function block instance” on page 167

Attribute 'linkalways'

The effect of this pragma is that the associated object is marked with the compiler and is thus always contained in the compiler information. This means that the object is always compiled and loaded to the PLC. The pragma works for POUs and GVLs that are located below an application or in libraries below an application or are contained in the “POUs” view. The “Always link” option in the “Compile” category of the object properties has the same effect.

Syntax:

{attribute 'linkalways'}

Insertion position: the line above the line with the keyword VAR_GLOBAL in the declaration part of POUs and GVLs.

If you use the symbol configuration editor, CODESYS uses the marked POU as the basis for the selectable variables of the symbol configuration used.

Example

The implementation of the global variable list “GVLMoreSymbols” uses the attribute 'linkalways':

{attribute 'linkalways'}
VAR_GLOBALS
  g_iVar1: INT;
  g_iVar2: INT;
END_VAR

Through this code the variables of “GVLMoreSymbols” are made available as selectable symbols.
Attribute 'monitoring'

The effect of this pragma is that you can monitor values of properties or function calls in the online view of the IEC editor or in a watch list. There are two possible attribute values for this: 'variable' and 'call'.

Syntax

```
{attribute 'monitoring' := 'variable'}
{attribute 'monitoring' := 'call'}
```

Monitoring of programming objects and their properties

In the online view of a function block or program, you can monitor the subordinate properties in addition to the local variables. This allows you to monitor the values of the Get and Set methods.

Insert either the pragma `{attribute 'monitoring' := 'variable'}` or `{attribute 'monitoring' := 'variable'}` in the declaration of the property block. The current values of the property are then displayed automatically in the IEC editor or in a watch list.
In online mode, the PLC_PRG object shows the value of the Minutes property at the call location inline in the ST editor. This is because the pragma `{attribute 'monitoring':='variable'}` is located in the declaration of the Minutes property.

Example

Check carefully for each application which attribute pragma is suitable for displaying the desired value. This depends on whether further operations with the variables are implemented within the property.

1. **Pragma `{attribute 'monitoring':='variable'}`:**

An implicit variable is created for the property, which is then always given the current property value when the application calls the `Set` or `Get` method. The value stored last in this variable is displayed in the monitoring.

2. **Pragma `{attribute 'monitoring':='call'}`:**

You can use this attribute only for properties that return simple data types or pointers, but not for structured types. The value to be monitored is read or written by calling the property directly. This means that the monitoring service of the runtime executes the `Get` or `Set` method of the property.

**NOTICE!**

When you insert the pragma `{attribute 'monitoring':='call'}` for monitoring, you have to pay attention to possible side effects. These kinds of side effects can occur if additional operations are implemented in the property.

**NOTICE!**

The pragma `{attribute 'monitoring'}` is also evaluated for the symbol configuration. Only read access is possible for the value `'variable'`.

With the context menu command “Add Watch”, a variable on which the cursor is currently positioned is applied directly into the monitoring list in online mode.
The forcing or writing of functions is not supported. However, you can implicitly implement forcing by adding an additional input parameter for the respective function, which serves as an internal force flag.

Function monitoring is not possible in the compact runtime system.

See also

- Chapter 1.3.1.25.1.28.8 “Object ‘Property’” on page 791

**Attribute 'no_assign', Attribute 'no_assign_warning'**

The pragma 'no_assign' results in compiler errors being displayed if an instance of the function block is assigned to another instance of the same function block. Such assignments are often to be avoided if the function block contains pointers and pointers lead to problems, because they are copied as well during the value assignment.

The pragma 'no_assign_warning' results in the same as for the pragma 'no_assign' with compiler warnings instead of compiler errors.

**Syntax:**

```plaintext
{attribute 'no_assign'}
```

Insert location: First line in the declaration part of a function block.
Assignment of function block instances containing pointers.

In this example the value assignment of the function block instances will lead to problems during the execution of `fb_exit`:

```plaintext
VAR_GLOBAL
  inst1 : TestFB;
  awsBufferLogFile : ARRAY [0..9] OF WSTRING(66);(* Area: 0,
  Offset: 0x1304 (4868)*)
  LogFile : SEDL.LogRecord := (sFileName := 'LogFile.log',
    pBuffer := ADR(awsBufferLogFile), udiMaxEntriesFile := UDINT#10000,
    udiMaxBuffered := UDINT#10, uiLineSize := UINT#64, wsSep := " ",
    xCircular := TRUE, siDateFormat := SINT#0, siTimeFormat := SINT#0);
END_VAR

PROGRAM PLC_PRG
VAR
  inst2 : TestFB := inst1;
  LogFileNew
END_VAR

In this case LogRecord manages a list of pointers, for which various actions are executed in the case of `fb_exit`. Problems result due to the assignment, because `fb_exit` will be executed twice. You should prevent this by adding the attribute 'no_assign' in the declaration of the function block "TestFB":

```plaintext
{attribute 'no_assign'}
FUNCTION_BLOCK TestFB
VAR_INPUT
...
```

The following compiler errors are then displayed:

```plaintext
C0328: Assignment not allowed for type TestFB
C0328: Assignment not allowed for type LogRecord
```

If the pragma `no_assign_warning` is used instead of the pragma `no_assign` for the function block "TestFB", then the C0328 message is issued as compiler warning, not as a compiler error.

Attribut 'no_check'

This pragma prevents the check function being called for the POU (POUs for implicit checks). Since the check functions can affect the processing speed of the program, it can be useful to apply the attribute to function blocks that have already been checked or are frequently called.

You add the pragma to the declaration of a POU.

Syntax:

```plaintext
{attribute 'no_check'}
```

Insertion position: first line in the declaration part of the POU.

**NOTICE!**

The attribute also automatically affects the child objects of a POU!

Example: If the attribute is entered in a program, check functions will also not be carried out for actions that are assigned to this program.
Attribute 'no_copy'

In general an online change requires a re-allocation of instances, for example of a POU. In the process, the value of the variable contained in the instance is copied.

The pragma prevents the value of the variable contained in the instance from being copied in the course of an online change; instead, the variable is re-initialized in the course of an online change. This can be useful for a local pointer variable that points to a variable that has just been shifted by the online change and thus has a changed address.

You insert the attribute in the declaration part above the line of the declaration of the variables concerned.

Syntax:

{attribute 'no_copy'}

Attribute 'no-exit'

This attribute suppresses the call of the FB_exit method of a function block for a certain one of its instances. To do this you insert the attribute in the line before the declaration of the function block instance.

Syntax:

{attribute 'no-exit'}

Example

The method "FB_exit" is added to the function block "POU_ex". Two instances of the function block "POU_ex" are created in the main program "PLC_PRG":

PROGRAM PLC_PRG
VAR
  POU1 : POU_ex;
  {attribute 'no-exit'}
  POU2 : POU_ex;
END_VAR

POU1 is called, POU2 is not called.

See also

● "Chapter 1.3.1.24.10 ‘Methods ‘FB_Init’, ‘FB_Reinit’, and ‘FB_Exit’’ on page 653"

Attribute 'noinit'

This pragma is applied to variables that should not be implicitly initialized.

Syntax:

{attribute 'no_init'}

{attribute 'no-init'}

{attribute 'noinit'}

Insertion position: line above the declaration line of the variables concerned in the declaration part.
Example

PROGRAM PLC_PRG
VAR
  A : INT;
  [attribute 'no_init']
  B : INT;
END_VAR

When the associated application is reset, the integer variable A is implicitly re-initialized with 0, whereas the variable B retains its current value.

Attribute 'no_instance_in_retain'

With this attribute you can prevent the instance of a certain function block from being stored in the retain area.

Syntax:

{attribute 'no_instance_in_retain'}

Insertion position:

Line above the FUNCTION_BLOCK declaration in the declaration part of the function block. An error message is then displayed if an instance of the function block is declared as a RETAIN variable.

See also

● Chapter 1.3.1.9.20 “Data persistence” on page 249

Attribute 'no_virtual_actions'

This pragma is used for function blocks that are derived from a function block implemented in SFC and use the fundamental SFC sequence of this base class. The actions called from it exhibit the same virtual behavior as methods. This means that the implementations of the actions in the base class can be replaced by the derived class with its own specific implementations.

If you apply the pragma to the base class, then its actions are protected against overloading.

Syntax:

{attribute 'no_virtual_actions'}

Insertion position: top line in the declaration part of the function block
The function block “POU_SFC” is the base class for the derived function block “POU_child”. The derived class “POU_child” calls the sequence of the base class written in SFC with the special variable SUPER.

The exemplary implementation of this sequence is limited to the initial step, followed by a single step with a linked step action ActiveAction. This step with a linked step action takes care of the configuration of the output variables.

```plaintext
an_int:=an_int+1;    // Counting the action calls
test_act:='father_action';
METH();              // Call of the method METH in order to set the string variable test_meth
```

In the case of the derived class POU_child the step action is replaced by a special implementation of ActiveAction. Active Action differs from the original only by the assignment of the string 'child_action' in place of 'father_action' at the variable test_act.

Likewise, the method “METH”, which assigns the string 'father_method' in the base class of the variable test_meth, is overwritten so that “test_meth” is now given the value 'child_method'. The main program “PLC_PRG” calls an instance of the function block POU_child named ‘Child’. As expected the value of the string reflects the call of action and method of the derived class:
Now, however, you place the pragma `{attribute 'no_virtual_actions'}` in front of the base class:

```plaintext
{attribute 'no_virtual_actions'}
FUNCTION_BLOCK POU_SFC...
```

As a result the behavior changes: while the implementation of the derived class is still used for method METH, the call of the step action now results in a call of the action `ActiveAction` of the base class. Therefore `test_act` is now given the value `'father_action'`:

```plaintext
<table>
<thead>
<tr>
<th>Expression</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Child</td>
<td>POU_child</td>
<td></td>
</tr>
<tr>
<td>test_meth</td>
<td>STRING</td>
<td>'child_method'</td>
</tr>
<tr>
<td>test_act</td>
<td>STRING</td>
<td>'child_action'</td>

<tr>
<td>an_int</td>
<td>INT</td>
<td>33</td>
</tr>
</tbody>
</table>
```

### Attribute 'pingroup'

The effect of this pragma is that the input pins or output pins (parameters) are grouped in the declaration of a function block. In the FBD/LD editor a pin group defined in this way can be displayed as an enlarged or reduced unit on the inserted function block. Several groups are possible and are distinguished by their names. CODESYS saves the respective state (reduced) per function block box with the project options.

**Syntax:**

```plaintext
{attribute 'pingroup' := '<group name>'}
```

**Insertion position:** line above the declaration of the input or output variables concerned in the declaration part of a function block.
Two groups are defined: general \((i_1, \text{out}_1)\) and group1 \((i_2, g_1)\). \(r_1, r_2, \text{outRes}_1\) and \(g_2\) are always displayed.

```plaintext
FUNCTION_BLOCK FB
VAR_INPUT
  r1 : REAL;
  \{attribute 'pingroup' := 'general'\}
  i1 : INT;
  \{attribute 'pingroup' := 'group1'\}
  i2 : INT;
  r2 : REAL;
END_VAR

VAR_OUTPUT
  \text{outRes}_1 : REAL;
  \{attribute 'pingroup' := 'general'\}
  \text{out}_1 : INT;
  \{attribute 'pingroup' := 'group1'\}
  g1 : INT;
  g2 : REAL;
END_VAR
```

**Example**

Attribute 'pin_presentation_order_inputs/outputs'

The pragmas are evaluated in the CFC, FBD, and LD graphical editors, causing the order of inputs/outputs of the affected function block to be displayed as specified. You program the order by assigning the names of the inputs/outputs to the attribute in the desired order.

**Syntax**

```plaintext
{attribute 'pin_presentation_order_inputs' := '<First_Input_Name>,
(<Next_Input_Name>,)* ( *, )? (<Next_Input_Name>,)*
<Last_Input_Name>'}
{attribute 'pin_presentation_order_outputs' := '<First_Output_Name>,
(<Next_Output_Name>,)* ( *, )? (<Next_Output_Name>,)*
<Last_Output_Name>'}
```

- **●** The terminal character serves as a wildcard for all inputs/outputs that are not specified in the display order. If the terminal character is missing, then the missing inputs/outputs are appended at the end.
- **●** The contents of the parentheses are optional.
- **●** The contents of the parentheses are optional again and can therefore occur not at all, one time, or several times.
- **●** Insert location: First line in the declaration part of a function block.

**NOTICE!**

This pragma is not evaluated when pragma \{attribute 'pingroup' := '<Group_Name>'\} is used.
Example

{attribute 'pin_presentation_order_inputs' := 'input_2,*,input_1'}
{attribute 'pin_presentation_order_outputs' := 'output_2, output_1'}
FUNCTION_BLOCK POU_BASE
VAR_INPUT
  input_1 : BOOL;
  input_2 : INT;
  input_3 : INT;
  input_4 : INT;
END_VAR

VAR_OUTPUT
  output_1 : BOOL;
  output_2 : INT;
  output_3 : INT;
  output_4 : BOOL;
END_VAR

FUNCTION_BLOCK PLC_PRG
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
  pouBase_A: POU_BASE;
END_VAR

In the representation of function module instance pouBase_A, the pragmas result in the following arrangement of input and output pins:

![Pin arrangement example]

- ¶ Chapter 1.3.1.24.6.2.29 “Attribute 'pingroup'” on page 626

Attribute 'obsolete'

The effect of this pragma is that a defined warning is displayed for a data type definition during compilation if the data type (structure, function block, etc.) is used in the project. This enables you, for example, to draw attention to the fact that a data type is no longer valid because, for example, an interface has changed and this should also be implemented in the project.

In contrast to a message pragma this warning is defined centrally for all instances of a data type.

Syntax:

{attribute 'obsolete' := 'user defined text'}

Insertion position: line of the data type definition or in a line above it.
**Example**

The pragma is inserted in the definition function block `fb1`:

```plaintext
{attribute 'obsolete' := 'datatype fb1 not valid!'}
FUNCTION_BLOCK fb1
VAR_INPUT
i:INT;
END_VAR
```

If you use `fb1` as a data type, for example in `fbinst:fb1`, the following warning will be displayed when compiling the project: "datatype fb1 not valid".

See also
- Chapter 1.3.1.24.6.1 “Message pragmas” on page 600

**Attribute 'pack_mode'**

This pragma defines how a data structure is packed during the allocation. The attribute must be inserted above the data structure and affects the packing of the entire structure.

**Syntax:**

```plaintext
{attribute 'pack_mode' := '<Value>'}
```

Insert location: above the declaration of the data structure

**Table 26: Possible values for <Value>:**

<table>
<thead>
<tr>
<th>pack_mode</th>
<th>Associated packing method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>aligned,</td>
<td>All variables are allocated to byte addresses. There are no memory gaps.</td>
</tr>
</tbody>
</table>
| 1         | 1-byte-aligned            | There are
- 1-byte variables at byte addresses
- 2 byte variables at addresses divisible by 2. A maximum gap of 1 byte results.
- 4 byte variables at addresses divisible by 2. A maximum gap of 1 byte results.
- 8 byte variables at addresses divisible by 2. A maximum gap of 1 byte results.
- Strings are always at byte addresses. No gaps result. |
| 2         | 2-byte-aligned            | |

PLC Automation with V3 CPUs

<table>
<thead>
<tr>
<th>pack_mode</th>
<th>Associated packing method</th>
<th>Description</th>
</tr>
</thead>
</table>
| 4         | 4-byte-aligned            | There are  
  - 1-byte variables at byte addresses  
  - 2 byte variables at even addresses. A maximum gap of 1 byte results.  
  - 4 byte variables at addresses divisible by 4. A maximum gap of 3 byte results.  
  - 8 byte variables at addresses divisible by 4. A maximum gap of 3 byte results.  
  - Strings are always at byte addresses. No gaps result. |
| 8         | 8-byte-aligned            | There are  
  - 1-byte variables at byte addresses  
  - 2 byte variables at addresses divisible by 2. A maximum gap of 1 byte results.  
  - 4 byte variables at addresses divisible by 4. A maximum gap of 3 byte results.  
  - 8 byte variables at addresses divisible by 8. A maximum gap of 7 byte results.  
  - Strings are always at byte addresses. No gaps result. |

Depending on the structure, there may be no difference in the memory mapping of the individual modes. Therefore, the memory allocation of a structure with pack_mode = 4 can correspond to that of pack_mode = 8.

Arrays of structures: If the structures are combined in arrays, then bytes are added at the end of the structure so that the next structure is aligned.

Example 1

```plaintext
Example

{attribute 'pack_mode' := '1'}

TYPE myStruct:
  STRUCT
    Enable: BOOL;
    Counter: INT;
    MaxSize: BOOL;
    MaxSizeReached: BOOL;
  END_STRUCT
END_TYPE
```

The memory range for a variable of the data type myStruct is allocated 'aligned': If the storage address of its component Enable is 0x0100, for example, then the component Counter follows at the address 0x0101, MaxSize at address 0x0103 and MaxSizeReached at address 0x0104. In the case of 'pack_mode' := 2, Counter would be at 0x0102, MaxSize at 0x0104 and MaxSizeReached at 0x0106.
Example 2

```plaintext
STRUCT
  Var1 : BOOL := 16#01;
  Var2 : BYTE  := 16#11;
  Var3 : WORD  := 16#22;
  Var4 : BYTE  := 16#44;
  Var5 : DWORD := 16#88776655;
  Var6 : BYTE  := 16#99;
  Var7 : BYTE  := 16#AA;
  Var8 : DWORD := 16#AA;
END_TYPE
```

</tr>
</tbody>
</table>
```
Attribute 'qualified_only'

The effect of this pragma is that variables of a global variable list are only addressed by specifying the global variable name, for example `gvl.g_var`. This also applies to variables of the type Enumeration and can be helpful in avoiding being mistaken for local variables.

**Syntax:**

```
{attribute 'qualified_only'}
```

Insertion position: line above `VAR_GLOBAL` in a GVL

**Example**

Global Variable List "GVL":

```
{attribute 'qualified_only'}
VAR_GLOBAL
 iVar: INT;
END_VAR
```

Within a POU, for example "PLC_PRG", the global variable `iVar` can only be addressed using the prefix `GVL`:

```
GVL.iVar:=5;
```

Conversely, the following incomplete call of the variable will create an error:

```
iVar:=5;
```

Attribute 'reflection'

This purpose of this pragma is to identify function blocks in which CODESYS is to search for local STRING variables to which the attribute 'instance-path' is applied.

**Syntax:**

```
{attribute 'reflection'}
```

An example can be found in the description of the attribute 'instance-path'

See also

- § Chapter 1.3.1.24.6.2.18 “Attribute ‘instance-path’” on page 616

Attribute 'to_string'

The pragma affects how the result of converting an enumeration component with the `TO_STRING` operator is output. If the enumeration declaration has the pragma, then the name of the enumeration component appears as a string instead of the numeric value.

**Syntax:**
(attribute 'to_string')

Insert location: First line above the declaration part of the enumeration.

Example

Declaration of the enumeration color:

```
{attribute 'to_string'}
TYPE color :
(
    red := 0,
    blue := 1,
    green := 2
);
END_TYPE
```

Conversion with TO_STRING:

```
PROGRAM PLC_PRG
VAR
    i_color: Color;
    s_show_color: STRING;
END_VAR
i_color := 1;
s_show_color := TO_STRING(i_color);
```

In this case, \texttt{s\textunderscore show\textunderscore color} gets the value 'blue' instead of '1' as the conversion result.

See also

- \(\Phi\) Chapter 1.3.1.24.5.17 “Enumerations” on page 595

Attribute 'subsequent'

This pragma is used to allocate variables to a memory space directly behind one another. If the list changes, the entire variable list is allocated to a new memory space. This pragma is used in programs and global variable lists.

Syntax:

```
{attribute 'subsequent'}
```

\textbf{NOTICE!}

\begin{itemize}
  \item VAR\_TEMP in a program with the attribute 'subsequent' leads to a compiler error.
\end{itemize}

If a variable appears in the list 'RETAIN', the total list is saved as 'RETAIN'.

Attribute 'symbol'

The pragma \{attribute 'symbol'} defines which variables of a program or a global variable list are to be adopted into the symbol configuration. This means that the variables are exported as symbols to a symbol list. This symbol list is then available for external access both as an XML file in the project directory and as a file that is invisible to the user on the target system. For example, the symbol list is then available for access by an OPC server. The variables thus equipped with a symbol are loaded by CODESYS to the controller, even if they are not explicitly configured or visible in the editor of the symbol configuration.
In any case, however, an object “Symbol configuration” must be created below the application concerned in the device tree.

**Syntax:**
```
{attribute 'symbol' := '<access possibilities>'}
```

<access possibilities>: none, read, write, readwrite. The default value readwrite applies if no parameter is specified.

**Insertion position:**
- in order to affect only an individual variable, you must place the pragma in the line before the variable declaration.
- In order to be effective for all variables in the declaration part of a program, you must place the pragma in the first line of the declaration editor. In this case, too, you can still set instructions for individual variables explicitly in the respective line.

### Example
With the following configuration the variables A and B are exported with read and write permission. Variable D is exported with read permission.
```
{attribute 'symbol' := 'readwrite'}
PROGRAM PLC_PRG
VAR
  A : INT;
  B : INT;
{attribute 'symbol' := 'none'}
  C : INT;
{attribute 'symbol' := 'read'}
  D : INT;
END_VAR
```

### See also
- Chapter 1.3.1.9.7 “Using pragmas” on page 211
- Chapter 1.3.1.10.2 “Symbol configuration” on page 275

**Attribute 'warning disable', attribute 'warning restore'**

This pragma causes certain warnings to be suppressed. The `warning restore` pragma causes a suppressed message to be reactivated.

**Syntax:**
```
{warning disable <compiler ID>}
{warning restore <compiler ID>}
```

<compiler ID>: ID located at the beginning of an error or a warning message.

### Example
**Compiler message:**
```
typify code ...
C0196: Implicit conversion from unsigned Type 'UINT' to signed Type 'INT': possible change of sign
Compile complete -- 0 errors
```

Applying the pragma to a variable declaration:
```
VAR
  {warning disable C0195}
  test1 : UINT := -1;
{warning restore C0195}
  test2 : UINT := -1;
END_VAR
```

test1 does not generate an error message, test2 generates an error message.
Attribute 'enable_dynamic_creation'

The pragma `enable_dynamic_creation` is needed for using the `__NEW` operator for function blocks.

**Syntax:**

```
{attribute 'enable_dynamic_creation'}
```

Insert location: First line in the declaration of the function block.

See also

- ¶ Chapter 1.3.1.24.3.58 “Operator '__NEW'” on page 541

Attribute 'ProcessValue'

With the 'ProcessValue' attribute, you mark a component of a structure. In the CFC editor, you can then use the command “Use attributed member as input” in order to connect this structure to an input of scalar type.

**Syntax:**

```
{attribute 'ProcessValue'}
```

Insert location: Line above the affected structure variable.

**Example**

```plaintext
TYPE QINT :
  STRUCT
    Status : STRING;
    {attribute 'ProcessValue'}
    Value1 : INT;
    Value2 : INT;
  END_STRUCT
END_TYPE
```

See also

- ¶ Chapter 1.3.1.25.2.12.36 “Command 'Use Attributed Member as Input'” on page 990

Conditional pragmas

The purpose of conditional pragmas is to influence the generation of code in the pre-compilation process or the compilation process. The ST implementation language supports these pragmas.

**NOTICE!**

They use conditional pragmas in the implementations of POUs. CODESYS does not evaluate these conditional pragmas if you use them in the declaration part.

With conditional pragmas you affect whether implementation code is taken into account for the compilation. For example, you can make this dependent on whether a certain variable is declared, whether a certain function block exists, etc.
<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>{define &lt;identifier&gt;}</td>
<td>The value can be queried and compared later with hasvalue.</td>
</tr>
<tr>
<td>{undefine &lt;identifier&gt;}</td>
<td>The {define} statement of the identifier &lt;identifier&gt; is canceled, and the identifier is 'undefined' again from now on. The pragma is ignored if the specified identifier is not defined at all.</td>
</tr>
<tr>
<td>{IF &lt;expr&gt;}... {ELSIF &lt;expr&gt;}... {ELSE}... {END_IF}</td>
<td>These are pragmas for the conditional compilation. The specified expressions &lt;expr&gt; must be constant at the time of compilation; they are evaluated in the order in which they appear here until one of the expressions indicates a non-zero value. The text linked to the instruction is compiled; the other lines are ignored. The order of the sections is fixed. The ELSIF and ELSE sections are optional. The ELSIF-segments may occur any number of times. You can use several conditional compilation operators within the constants &lt;expr&gt;.</td>
</tr>
<tr>
<td>&lt;expr&gt;</td>
<td>You can use one or more operators within the constant expression &lt;expr&gt; within the conditional compilation pragma {IF} or {ELSIF}.</td>
</tr>
</tbody>
</table>

- § Chapter 1.3.1.9.3.3 “Structured text (ST), extended structured ext (ExST)” on page 200

### Operator defined (<identifier>)

This operator causes the expression to be given the value TRUE. The requirement is that the identifier <identifier> was defined with the help of a {define} instruction and not undefined again afterwards with an {undefine} instruction; otherwise FALSE is returned.

#### Example

Requirement: The applications App1 and App2 exist. The variable pdef1 is defined by a {define} statement in App1, but not in App2.

```plaintext
{IF defined (pdef1)}
(* This code is processed in App1 *)
{info 'pdef1 defined'}
  hugo := hugo + SINT#1;
{ELSE}
(* the following code is only processed in App2 *)
{info 'pdef1 not defined'}
  hugo := hugo - SINT#1;
{END_IF}
```

This also contains an example of a message pragma: Only the message pdef1 defined is displayed in the message view when the application is compiled, because pdef1 is actually defined. The message pdef1 not defined is displayed if pdef1 is not defined.

### Operator defined (variable: <variable>)

This operator causes the expression to be given the value TRUE if the variable <variable> is declared within the current scope; otherwise FALSE is returned.
<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
</table>
| The two applications App1 and App2 exist. The variable `g_bTest` is declared in App1, but not in App2. | `{IF defined (variable: g_bTest))
(* the following code is only processed in App2*)
g_bTest := x > 300;
(END_IF)` |
| The operator causes the expression to be given the value TRUE if a data type is declared with the identifier `<identifier>`; otherwise FALSE is returned. | |
| The two applications App1 and App2 exist. The data type `DUT` is declared in App1, but not in App2. | `{IF defined (type: DUT))
(* the following code is only processed in App1*)
bDutDefined := TRUE;
(END_IF)` |
| The operator causes the expression to be given the value TRUE if a function block or an action with name `<pou-name>` exists; otherwise FALSE is returned. | |
| The two applications App1 and App2 exist. The function block `CheckBounds` exists in App1, but not in App2. | `{IF defined (pou: CheckBounds))
(* the following code is only processed in App1 *)
arrTest[CheckBounds(0,i,10)] := arrTest[CheckBounds(0,i,10)] + 1;
ELSE
(* the following code is only processed in App2 *)
arrTest[i] := arrTest[i]+1;
(END_IF)` |
| Not yet implemented! | The operator causes the expression to be given the value TRUE if a task is defined with the name `<identifier>`; otherwise FALSE is returned. |
| The two applications App1 and App2 exist. The task `PLC_PRG_Task` is defined in App1, but not in App2. | `{IF defined (task: PLC_PRG_Task))
(* the following code is only processed in App1 *)
   erg := plc_prg.x;
ELSE
(* the following code is only processed in App2 *)
   erg := prog.x;
(END_IF)` |
Not yet implemented!

The operator causes the expression to be given the value **TRUE** if a resource object with the name `<identifier>` exists for the application; otherwise **FALSE** is returned.

**Example**

Requirement: The two applications App1 and App2 exist. A resource object `glob_var1` of the global variable list exists for App1, but not for App2.

```plaintext
{IF defined (resource:glob_var1)}
(* the following code is only processed in App1 *)
gvar_x := gvar_x + ivar;
{ELSE}
(* the following code is only processed in App2 *)
x := x + ivar;
{END_IF}
```

The operator causes the expression to be given the value **TRUE** if the application runs on a simulated device, i.e. in simulation mode.

The operator causes the expression to be given the value **FALSE**, if the CPU memory is organized in Big Endian (Motorola byte order).

If the expression returns the value **TRUE**, then the code generator produces an FPU code (for the floating-point unit processor) when calculating with **REAL** values. Otherwise CODESYS emulates FPU operations, which is much slower.

**<register size>: Size of a CPU register in bits**

This operator causes the expression to return the value **TRUE** if the size of a CPU register is equal to `<register size>`.

Possible values for `<register size>`

- **16** for 186 and C16x,
- **64** for X86-64 bit
- **32** for X86-32 Bit

The checked pack mode depends on the device description, not on the pragma that can be specified for individual DUTs.

**This operator causes the expression to be given the value **TRUE** if the attribute `<attribute>` is specified in the first line of the declaration part of the function block `<pou name>`; otherwise **FALSE** is returned.**
Requirement: The two applications App1 and App2 exist. The function fun1 is declared in App1 and App2. However, in App1 it is also provided with the pragma {attribute 'vision'}.

**In App1:**

{attribute 'vision'}
FUNCTION fun1 : INT
VAR_INPUT
    i : INT;
END_VAR
VAR
END_VAR

**Function fun1 in App2:**

FUNCTION fun1 : INT
VAR_INPUT
    i : INT;
END_VAR
VAR
END_VAR

**Pragma instruction:**

{IF hasattribute (pou: fun1, 'vision')}
(* the following code is only processed in App1 *)
gervar := fun1(ivar);
{END_IF}

See also

- Chapter 1.3.1.24.6.2.1 “User-defined attributes” on page 602

**Operator: hasattribute**

The operator hasattribute(variable: <variable>, '<attribute>') causes the expression to be given the value TRUE if the pragma {attribute '<attribute>'} is assigned to the variable in the line before the variable declaration; otherwise FALSE is returned.

**Example**

Requirement: The two applications App1 and App2 exist. The variable g_globalInt is used in App1 and App2, but in App1 the attribute 'DoCount' is assigned to it in addition.

**Declaration of g_globalInt in App1**

VAR_GLOBAL
    {attribute 'DoCount'}
    g_globalInt : INT;
    g_multiType : STRING;
END_VAR

**Declaration of g_globalInt in App2**

VAR_GLOBAL
    g_globalInt : INT;
    g_multiType : STRING;
END_VAR

**Pragma instruction:**

{IF hasattribute (variable: g_globalInt, 'DoCount')}
(* the following code is only processed in App1 *)
g_globalInt := g_globalInt + 1;
{END_IF}
This operator causes the expression to be given the value TRUE if the variable <variable> is of the data type <type-spec>; otherwise FALSE is returned.

Possible data types for <type-spec>:

- LREAL
- REAL
- LINT
- DINT
- INT
- SINT
- ULINT
- UDINT
- UINT
- USINT
- TIME
- LWORD
- DWORD
- WORD
- BYTE
- BOOL
- STRING
- WSTRING
- DATE_AND_TIME
- DATE
- TIME_OF_DAY

Example

Requirement: The two applications App1 and App2 exist. The variable g_multitype is declared in App1 with data type LREAL, in App2 with data type STRING.

```plaintext
{IF (hastype (variable: g_multitype, LREAL))
 (* the following code is only processed in App1 *)
  g_multitype := (0.9 + g_multitype) * 1.1;
{ELSiF (hastype (variable: g_multitype, STRING))
 (* the following code is only processed in App2 *)
  g_multitype := 'this is a multitalent';
{END_IF}
```

Operator hasvalue

This operator causes the expression to be given the value TRUE if a variable is defined with the identifier <define-ident> and has the value <char-string>; otherwise FALSE is returned.

```plaintext
Operator hasvalue (define-ident, '<char-string>')
```
### Example

Requirement: The two applications App1 and App2 exist. The variable test is used in the applications App1 and App2; in App1 it is given the value 1, in App2 the value 2.

```plaintext
{IF hasvalue(test,'1')}
(* the following code is only processed in App1 *)
x := x + 1;
{ELSIF hasvalue(test,'2')}
(* the following code is only processed in App2 *)
x := x + 2;
{END_IF}
```

### Operator `hasconstantvalue(<variable>, <literal expression>)`

You can use this operator to query the declared value of a constant.

```plaintext
{IF hasconstantvalue(test,'1')}
(* the following code is only processed in App1 *)
x := x + 1;
{ELSIF hasconstantvalue(test,'2')}
(* the following code is only processed in App2 *)
x := x + 2;
{END_IF}
```

### Example

**Requirement:**

```plaintext
{IF hasconstantvalue(test,'1')}
(* the following code is only processed in App1 *)
x := x + 1;
{ELSIF hasconstantvalue(test,'2')}
(* the following code is only processed in App2 *)
x := x + 2;
{END_IF}
```

### Operator `NOT <operator>`

The expression is given the value TRUE if the reverse value of `<operator>` returns the value TRUE. `<operator>` can be one of the operators described in this chapter.

```plaintext
{IF defined (pou: PLC_PRG1) AND NOT (defined (pou: CheckBounds))}
(* the following code is only processed in App2 *)
bANDNotTest := TRUE;
{END_IF}
```

### Example

**Requirement:**

```plaintext
{IF defined (pou: PLC_PRG1) AND NOT (defined (pou: CheckBounds))}
(* the following code is only processed in App2 *)
bANDNotTest := TRUE;
{END_IF}
```

### Operator `<operator> AND <operator>`

The expression is given the value TRUE if the two specified operators return TRUE. `<operator>` can be one of the operators described in this chapter.

```plaintext
{IF defined (pou: PLC_PRG1) AND (defined (pou: CheckBounds))}
(* the following code is only processed in App1 *)
bANDTest := TRUE;
{END_IF}
```

### Example

**Requirement:**

```plaintext
{IF defined (pou: PLC_PRG1) AND (defined (pou: CheckBounds))}
(* the following code is only processed in App1 *)
bANDTest := TRUE;
{END_IF}
```
The expression returns TRUE if one of the two specified operators returns TRUE. `<operator>` can be one of the operators described in this chapter.

Example

Requirement: The two applications App1 and App2 exist. The POU PLC_PRG1 exists in App1 and App2, and the POU CheckBounds exists only in App1.

```plaintext
{IF defined (pou: PLC_PRG1) OR (defined (pou: CheckBounds))} (* the following code is only processed in App1 and in App2 *)
bORTest := TRUE;
{END_IF}
```

Operator

() parenthesizes the operators.

Region pragma

This pragma is used for grouping several lines into one block in a text editor. The block can be named. Region pragmas can also be nested.

Code with region pragma: Expanded and collapsed views

1.3.1.24.7 Identifiers

Rules for identifier designation

- An identifier must not contain spaces or special characters.
- Capitalization is ignored. For example, VAR1 and var1 refer to the same variable.
- The underscore is recognized. For example, A_BCD and AB_CD are treated as two different identifiers. Multiple consecutive underscores are not permitted.
- The length of an identifier is unlimited.

Rules for multiple use of identifiers (namespaces)

- An identifier must not be declared two times locally.
- An identifier can be used more than one time globally. If a local variable has the same name as a global variable, then the local variable has priority within the POU.
- An identifier must not be identical to a keyword, such as the VAR_global scope.
● A variable that is declared in a global variable list can have the same name as a variable defined in another GVL. CODESYS provides features that extend the standard for the namespace or scope of variables:
  – Global namespace operator:
    An instance path that begins with a dot always opens a global namespace. If there is a local variable (for example, `ivar`) that has the same name as a global variable, then you refer to the global variable as `.ivar`.
  – The name of a global variable list can define the namespace uniquely for the include variables. Therefore, you can declare variables with the same name in different global variables list and still uniquely reference by prepending the list name.
    For example, `globlist1.ivar := globlist2.ivar; (* ivar from GVL globlist2 is copied to ivar in GVL globlist1 *)`.
  – Variables that are defined in the global variable list of a library included in the project can be addressed uniquely according to the following syntax:
    `<name scope library>.< GVL name>.<variable name>`
    For example, `globlist1.ivar := lib1.globlist1.ivar (* ivar from GVL globlist1 in library lib1 is copied to ivar in GVL globlist1 *)`.

● When inserting a library, you also use the library manager to define a namespace. In this way, you can make unique references to library blocks and library via `<namespace library>.<block name|variable name>`. Please note that when libraries are nested, you must reference the namespaces of all libraries are in succession
    Example: If `Lib1` is referenced by `Lib0`, then the block `func` in `Lib1` is addressed via `Lib0.Lib1.fun:ivar := Lib0.Lib1.fun(4, 5); (* return value from func is copied to variable ivar in the project *)`

We recommend that you apply the following rules in addition to the items that you have to consider specifically for variables declaration. By doing this, you will achieve the best possible harmonization when assigning names.

**Recommendations for variable names**
Whenever possible, you should name variables in Hungarian notation in applications and libraries. Find a meaningful, short, English name for each variable as a base name, which can consist of several words. Write the first letter of each word in uppercase, the remaining letters in lowercase. In front of the base name, append a prefix in lowercase to indicate the data type of the variable.

**Example:** `iFileSize : INT;`

<table>

</tbody>
</table>

### Recommendations for identifiers for visualizations

**NOTICE!**

Please note that a visualization is not named the same as another block in the project because this may cause problems when changing visualizations.

- *Chapter 1.3.1.24.2 “Variables” on page 489*

### 1.3.1.24.8 Shadowing rules

In CODESYS, you are generally allowed to use the same identifier for different elements. For example, a POU and a variable can be named the same. However, you should avoid this practice in order to prevent confusion.

Negative example: In the following code snippet, a local function block instance has the same name as a function:

**Example**

```plaintext
FUNCTION YYY : INT
;
END_FUNCTION

FUNCTION_BLOCK XXX
;
END_FUNCTION_BLOCK

PROGRAM PLC_PRG
VAR
    YYY : XXX;
END_VAR
YYY();
END_PROGRAM
```

In such a case as this, it is unclear whether the instance or the function is called in the program.

To make sure that names are always unique, you should follow naming conventions, such as certain prefixes for variables. Rules for assigning identifiers can be found in the "Identifiers" section of the help.
Naming conventions can be checked automatically using the static code analysis of CODESYS. Static code analysis could also detect the duplicate use of the name `YYY` and report it as an error.

The consistent use of the attribute `qualified_only` for enumerations and global variable lists and the use of qualified libraries can also prevent ambiguous situations.

**Shadowing:** The compiler does not report any errors or warnings if the same identifier is used for different elements. Instead, the compiler searches the code in a specific order for the declaration of the identifier. If a declaration is found, then the compiler does not search for any other declarations elsewhere. If other declarations do exist, then they are "shadowed" for the compiler. The following section describes the shadowing rules (that is, the search order that the compiler uses when searching for the declaration for identifiers). The section "Ambiguous access and qualified access" provides ways to prevent ambiguous access and bypass shadowing rules.

### Search order in the application

When the compiler encounters a single identifier in the code of an application, it searches for the corresponding declaration in the following order:

1. Local variables of a method
2. Local variables in the function block, program, or function, and in any base function blocks
3. Local methods of the POU
4. Global variables in the application, if the `qualified_only` attribute is not set in the variable list where the global variables are declared
5. Global variables in a parent application, if the `qualified_only` attribute is not set in the variable list where the global variables are declared
6. Global variables in referred libraries when neither the library nor the variable list requires qualified access
7. POU or type names from the application (that is, names of global variable lists, function blocks, and so on)
8. POU or type names from a parent application
9. POU or type names from a library
10. Namespaces of locally referred libraries and libraries that are published by libraries
11. Global variables in the “POUs” view, unless the `qualified_only` attribute is set in the variable list where they are declared
12. POU or type names from the “POUs” view (that is, names of global variable lists, function blocks, and so on)

Libraries that are inserted in the Library Manager of the “POUs” view are mirrored in the Library Manager in all applications in the project with the appropriate placeholder resolution. These libraries then form a common namespace with the libraries in the application. Therefore, there is no shadowing of libraries in the pool by libraries in the application.

### Search order in the library

When the compiler encounters a single identifier in the code of a library, it searches for the corresponding declaration in the following order:

1. Local variables of a method
2. Local variables in the function block, program, or function, and in any base function blocks
3. Local methods of the POU
4. Global variables in the local library, if the `qualified_only` attribute is not set in the variable list where the global variables are declared
5. Global variables in referred libraries when neither the library nor the variable list requires qualified access
6. POU or type names from the local library (that is, names of global variable lists, function blocks, and so on)
7. POU or type names from a referred library
8. Namespaces of locally referred libraries and libraries that are published by locally refereed libraries

**Ambiguous access and qualified access**

Despite these search orders, ambiguous access can still occur. For example, this is the case when a variable with the same name exists in two global variable lists that do not require qualified access. Such a case is reported by the compiler as an error (for example: ambiguous use of the name XXX).

This kind of ambiguous use can be made unique by means of qualified access, for example by accessing via the name of the global variable list (example: GVL.XXX).

Qualified access can also always be used to avoid shadowing rules.
- The name of the global variable list can be used to uniquely access a variable in the list.
- The name of a library can be used to uniquely access elements in the library.
- The THIS pointer be used to uniquely access variables in a function block, even if a local variable with the same name exists in a method of the function block.

To find the declaration location of an identifier at any time, use the command "Edit ➔ Browse ➔ Go to Definition". This can be especially helpful if the compiler produces an apparently obscure error message.

**Searching in instance paths**

The search orders described above do not apply to identifiers that exist as components in an instance path or to identifiers that are used as inputs in calls.

For access of the following type yy.component, it depends on the entity described by yy where the declaration of component is searched for.

If yy denotes a variable with a structured data type (that is, type STRUCT or UNION), then component is searched for in the following order:
- Local variables of the function block
- Local variables of the basic function block
- Methods of the function block
- Methods of the basic function block

If yy denotes a global variable list or a program, then component is searched for in this list only.

If yy denotes a namespace of a library, then component is searched for in this library exactly as described in the section above "Search order in the library".

Only in the second instance does the compiler decide whether access to the found element is granted (that is, whether the variable is only locally accessible, or whether a method is private). If access is not allowed, an error is issued.

**1.3.1.24.9 Keywords**

In all editors, you must capitalize keywords that for example denote scopes, data types, or operators.

Keywords cannot be used as variable names.
When CODESYS creates implicit code, variables and functions are generally given a name that is prepended with two underscores (__). The use of double underscores in the implementation code is prevented automatically. This eliminates conflicts between internal system identifiers and identifiers assigned by the programmer.

The following keywords are used in the CODESYS export format. Therefore, you may not use them as identifiers:

- ACTION
- END_ACTION
- END_FUNCTION
- END_FUNCTION_BLOCK
- END_PROGRAM

Other valid keywords:

- VAR_ACCESS
- READ_ONLY
- READ_WRITE
- PARAMS

**1.3.1.24.10 Methods 'FB_Init', 'FB_Reinit', and 'FB.Exit'**

You can declare the methods explicitly in order to influence the initialization of function block variables, as well as the behavior when exiting function blocks.

The type of the return value for the implicit methods is **BOOL**. The value is not evaluated by the system, but the type should not be changed.

**FB_Init** is always available implicitly and it is used primarily for initialization. For a specific influence, you can also declare the methods explicitly and provide additional code there with the standard initialization code.

**FB_Reinit** must be implemented explicitly. If this method exists, then it is called after the instance of the affected function block is copied. That happens during an online change after changes to the function block declaration (signature change) in order to reinitialize the new instance module. To reinitialize the basic implementation of the function block, you must call **FB_Reinit** explicitly.
FB Exit must be implemented explicitly. If there is an implementation, then the method is called before the controller removes the code of the function block instance (implicit call).

The following shows some use cases of these methods for different operating conditions.

Operating condition "First download"

When downloading an application to a PLC with factory settings, the memory of all variables must be offset to the required initial state. In this way, the data areas of function block instances are assigned the required values. By the explicit implementation of FB_Init for function blocks, you can react specifically to this situation in the application code. By evaluating the method parameters bInCopyCode (FALSE) and bInitRetains (TRUE), you can detect this operating condition clearly. (See "Operating condition "Online Change"" and "Operating condition "Re-download"".)

Within the scope of the online change, you can influence the initialization of function block instances by means of the methods FB Exit, FB_Init, and FB_Reinit. During the online change, the changes to the application that were made in offline mode are applied in the running PLC. This is the reason that the old instances of the function blocks are replaced by new instances as much as possible without incident. If no changes were made to the declaration part of a function block in the application before login, but in the implementation only, then the data areas are not replaced. Only code blocks are replaced. Then the methods FB Exit, FB_Init, and FB_Reinit are not called.

In the code of the FB_Init method, the parameter bInCopyCode (TRUE) can be evaluated to detect whether or not an online change is being executed.

The following calls occur in succession during an online change:

1. FB Exit

   old_inst.FB Exit(bInCopyCode := TRUE);

   You can call FB Exit when exiting the old instance in order to trigger specific cleanup tasks before the copy operation. In this way, you can prepare the data for the following copy operation and influence the state of the new instance. You can notify other parts of the application about the pending change in location in the memory. Pay special attention to the variables of type POINTER and REFERENCE. These may no longer refer to the required memory locations after the online change. Interface variables (INTERFACE) are handled separately by the compiler and they are adapted accordingly during the online change. External resources such as sockets, files, or other handles can be applied by the new instance, in some case unchanged. Often they do not have to be treated specially during an online change. (See "Operating condition "Re-download""

2. FB_Init

   new_inst.FB_Init(bInitRetains := FALSE, bInCopyCode := TRUE);

   FB Init is called before the copy operation and can be used in order to execute specific operations for the online change. For example, you can initialize variables accordingly at the new location in the memory, or notify other parts of the application about the new location of specific variables in the memory.

3. Copy operation: copy

   copy(&old_inst, &new_inst);

   Existing values remain unchanged. For this purpose, they are copied from the old instance into the new instance.
4. `FB_Reinit`
   `new_inst.FB_Reinit();`

   This method is called after the copy operation and should set defined values for the variables of the instance. For example, you can initialize variables accordingly at the new location in the memory, or notify other parts of the application about the new location of specific variables in the memory. Design the implementation independent of the online change. The method can also be called from the application at any time in order to reset a function block instance to its original state.

   **With the `{attribute 'no_copy'}` attribute, you can prevent that this is copied during the online change for a single variable of the function block. It always retains the initial value.**

See also

- § Chapter 1.3.1.25.2.3.19 “Command ‘Settings of Memory Reserve for Online Change’ ” on page 894

### Operating condition "New download"

When downloading an application, an existing application may be replaced on the PLC. Therefore, the provision of memory for the present function blocks must be regulated. You can use the `FB_Exit` method for implementing the required steps for this. For example, you can offset external resources (with socket and file handles) in a defined state.

You can detect this operating condition by checking whether or not the parameter `bInCopyCode = FALSE` for the `FB_Exit` method.

### Operating condition "Start of application"

The initial assignments are processed before the first cycle of the application tasks.

**Example**

```
T1 : TON := (PT:=t#500ms);
```

These kinds of assignments are executed only after calling `FB_Init`. In order to control the effects of these assignments, you can provide a function block or a method of a function block with the `{attribute 'call_after_init'}` attribute. You must add the attribute above the declaration part of the function block body and above the declaration part of the corresponding method. A POU that extends another POU which uses the `{attribute 'call_after_init'}` attribute must also have the attribute. For the benefit of clarity, we recommend that the corresponding methods are overwritten with the same name, the same signature, and the same attribute. This requires calling `SUPER^.MyInit`. The name of the method can be chosen without restriction. (Exceptions: `FB_Init`, `FB_Reinit`, and `FB_Exit`). The method is called after processing the initial assignments and before starting the application tasks. Therefore, the method can react to user input.

When using `FB_Init` or `{attribute 'call_after_init'}`, remember that detecting errors in the `FB_Init` method or in methods decorated with the `{attribute 'call_after_init'}` attribute is tedious, because the setting of breakpoints may not have the expected effect.

**NOTICE!**

If the explicitly defined initialization code is reached during execution, then the function block instance is already completely initialized via the implicit initialization code. Therefore, there must not be a `SUPER^.FB_Init` call.
**NOTICE!**

FB_Init replaces the INI operator used in CoDeSys V2.3. The methods cannot be compared to the design of a constructor, such as in C#, C++, or Java. This has consequences for function blocks that extend other function blocks. (See below: "Derived function blocks")

### Interface of method FB_Init

METHOD FB_Init : BOOL
VAR_INPUT
  bInitRetains : BOOL; // TRUE: the retain variables are initialized (reset warm / reset cold)
  bInCopyCode : BOOL; // TRUE: the instance will be copied to the copy code afterward (online change)
END_VAR

You can declare additional function block inputs in an FB_init method. Then you have to set these inputs in the declaration of the function block instance.

### Example Method FB_Init for the serialdevice function block

METHOD PUBLIC FB_Init : BOOL
VAR_INPUT
  bInitRetains : BOOL; // initializing of retain variable
  bInCopyCode : BOOL; // instance is copied to copy code
  iCOMnum : INT; // additional input: number of the COM interface, that is to be observed
END_VAR

Instantiation of the serialdevice function block:

```plaintext
com1: serialdevice(iCOMnum:=1);
com0: serialdevice(iCOMnum:=0);
```

### Interface of method FB_Reinit

METHOD FB_Reinit : BOOL

There is the mandatory parameter bInCopyCode.

### Interface of method FB_Exit

METHOD FB_Exit : BOOL
VAR_INPUT
  bInCopyCode : BOOL; // TRUE: the exit method is called in order to leave the instance which will be copied afterwards (online change).
END_VAR
If a function block is derived from another function block, then the `FB_Init` method of the derived function block must define the same parameters as the `FB_Init` method of the basic function block. However, you can add further parameters in order to set up a special initialization for the instance.

The function blocks `MainFB`, `SubFB`, and `SubSubFB` are derived from each other. Therefore, `SubFB EXTENDS MainFB` and `SubSubFB EXTENDS SubFB` apply.

### Example

Compiler error C0001

**Message:** Constant '<constant value>' too large for type '<data type>'

**Possible error cause:** A typed constant is too large for the given data type or a constant is too large for each possible data type.

**Error correction:** Use smaller constants or an appropriate data type for a typed constant.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
  test1: INT;
  test2: INT;
  test3: LREAL;
END_VAR

test1 := 12345678912345566991923939292939911;
test2 := INT#123456;
test3 := 10E500;
```

---

**Message:** Constant '<constant value>' too large for type '<data type>'

**Possible error cause:** A typed constant is too large for the given data type or a constant is too large for each possible data type.

**Error correction:** Use smaller constants or an appropriate data type for a typed constant.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
  test1: INT;
  test2: INT;
  test3: LREAL;
END_VAR

test1 := 12345678912345566991923939292939911;
test2 := INT#123456;
test3 := 10E500;
```
Compiler error C0002

Message: '<operator 1>' or '<operator 2>' expected instead of '<tag>'
Possible error cause: Syntax error
Error correction: Use the correct syntax.

Example of the error:

```
PROGRAM PLC_PRG
  Fun(1;

  --> C0002: ',' or ')' expected instead of ';'
```
END_VAR

test2 := test1.z;

--> C0032: Type 'Unknown type: 'test1.z'' cannot be converted to type 'INT'
--> C0004: 'z' is to a component of 'DUT'

Compiler error C0005

Message: Constant overflow in address '<address>'
Possible error cause: At least one component in the address does not fit into a 32-bit integer value.
Error correction: Use a valid address expression.

Example of the error:

PROGRAM PLC_PRG
VAR
  X: BYTE;
END_VAR

X := %QB5555555555;

--> C0005: Constant overflow in address '%??'

Compiler error C0006

Message: '<operator>' expected instead of '<token>'
Possible error cause: Syntax error
Error correction: Use the correct syntax.

Example of the error:

PROGRAM PLC_PRG
VAR
  x: INT;
  bTest : BOOL;
END_VAR

IF bTest
  x := 9;
END_IF

--> C0006: 'THEN' expected instead of 'x'

Compiler error C0007

Message: Expression expected instead of '<token>'
Possible error cause: Syntax error
Error correction: Use the correct syntax.
Example of the error:

PROGRAM PLC_PRG
VAR
  x: INT;
  bTest : BOOL;
END_VAR

IF THEN
  x := 9;
END_IF

--> C0007: Expression expected instead of 'THEN'

Compiler error C0008

Message: Unexpected end-of-file found: '<operator 1>', '<operator 2>', or '<operator 3>' expected
Possible error cause: Syntax error
Error correction: Use the correct syntax.

Example of the error:

PROGRAM PLC_PRG
VAR
  x: INT;
  bTest : BOOL;
END_VAR

IF bTest THEN
  x := 9;

--> C0008: Unexpected end-of-file found: 'ELSIF', 'ELSE' or 'END_IF' expected

Compiler error C0009

Message: Unexpected token '<token>' found
Possible error cause: Syntax error
Error correction: Use the correct syntax.

Example of the error:

PROGRAM PLC_PRG
VAR
END_VAR

END_FOR;

--> C0009: Unexpected token 'END_FOR' found

Compiler error C0010

Message: Unexpected end-of-file found: '<token>' expected
Possible error cause: Syntax error
Error correction: Use the correct syntax.
Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i: INT;
END_VAR

FOR i := 0 TO 2 DO
  ;
--> C0010: Unexpected end-of-file 'END_FOR' found
```

**Compiler error C0011**

Message: No 'CASE' label found

Possible error cause: Syntax error in a CASE statement. A statement in a CASE statement is not assigned to a CASE label.

Error correction: Add a CASE label.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i: INT;
  x: INT;
END_VAR

CASE i OF
  x := 9;
END_CASE
--> C0011: No 'CASE' label found

Error correction:

CASE i OF
  0:
    x := 9;
END_CASE
```

**Compiler error C0013**

Message: At least one statement is expected.

Possible error cause: At least one statement is expected at some positions in the code. For example, in the THEN and ELSE part of an IF statement, or in the body of a FOR loop.

Error correction: Add at least one statement at the selected position. It is enough to write a blank statement ";".

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  bTest: BOOL;
END_VAR

IF bTest THEN
  END_IF
--> C0013: At least one statement is expected
```

**Compiler error C0016**

Message: Counter initialization expected
Possible error cause: Syntax error in a FOR loop. The counter variable is not initialized correctly.

Error correction: Pay attention to the correct syntax of the FOR loop.

```
FOR i := 0 TO 10 DO
  ;
END_FOR
```

Example of the error:

```
PROGRAM PLC_PRG
VAR
  i: INT;
END_VAR

FOR i TO 10 DO
  ;
END_FOR

--> C0015: Counter initialization expected
```

Error correction:

```
PROGRAM PLC_PRG
VAR
  i: INT;
END_VAR

FOR i := 0 TO 10 DO
  ;
END_FOR
```

Compiler error C0018

Message: <expression> is not a valid assignment target

Possible error cause: An expression with no write permission is on the left side of an assignment. Example: a constant.

Error correction: Assign only to variables that have write access.

Example of the error:

```
PROGRAM PLC_PRG
VAR
  i: INT;
END_VAR

VAR CONSTANT
  j: INT := 0;
END_VAR

j := i;

--> C0018: 'j' is not a valid assignment target
```

Compiler error C0020

Message: '<statement>' is no valid statement

Possible error cause: Syntax error (for example, too few or too many characters)

Error correction: Make sure that the syntax is correct.

Example of the error:

```
PROGRAM PLC_PRG
VAR
  x : INT;
END_VAR

x = 2;

--> C0020: '(x = 2); ' is no valid statement
```
Example:
```
x := 2;
```

**Compiler error C0022**

**Message:** '<operator>' needs exactly '<number of operands>' operands  
**Possible error cause:** Too many or too few operands are assigned to an operator.  
**Error correction:** Assign the required number of operands to the operator.

**Example of the error:**
```
PROGRAM PLC_PRG
VAR
  i : INT;
  pt: POINTER TO INT;
END_VAR

pt := ADR(i,1);
```

**Error correction:**
```
Example:
pt := ADR(i);
```

**Compiler error C0023**

**Message:** '<operator>' needs at least '<number of operands>' operands  
**Possible error cause:** Too few operands are assigned to an operator.  
**Error correction:** Assign the required number of operands to the operator.

**Example of the error:**
```
PROGRAM PLC_PRG
VAR
  i : INT;
END_VAR

i := MUX(30,40);
```

**Error correction:**
```
Example:
i := MUX(30,40,50);
```

**Compiler error C0026**

**Message:** Identifier expected instead of '<invalid identifier>'  
**Possible error cause:** An invalid identifier is passed to a method.  
**Error correction:** Use valid identifiers.
Example of the error:

METHOD 123
VAR_INPUT
END_VAR

--> C0243: The name used in the signature is not identical to the object name
--> C0026: Identifier expected instead of '123'

Error correction:

Example:
METHOD METH123

Compiler error C0027

Message: size of string expected after '
Possible error cause: The length of the string is not specified.
Error correction: Specify a string length between the parentheses.

Example of the error:

PROGRAM PLC_PRG
VAR
str : STRING();
END_VAR

--> C0027: size of string expected after '('
--> C0006: ';, :=, REF=, ( or ' expected instead of ')''

Error correction:

Example:
str : STRING(100);

Compiler error C0030

Message: Direct Address expected after 'AT' instead of '<identifier>'
Possible error cause: Either an invalid address or no address is assigned after 'AT'.
Error correction: Specify a valid address.

Example of the error:

PROGRAM PLC_PRG
VAR
i AT ABC : INT;
END_VAR

--> C0030: Direct Address expected after 'AT' instead of 'ABC'

Error correction:

Example:
i AT %IW0 : INT;

Compiler error C0031

Message: Type definition expected instead of '<no data type>'
Possible error cause: An invalid type definition is assigned to the identifier.
Error correction: Specify a valid type definition.
Example of the error:

```plaintext
PROGRAM PLC_PRG
  VAR
    i : 0;
  END_VAR

--> C0031: Type definition expected instead of '0'
```

Error correction:

```plaintext
Example:
  i : INT;
```

Compiler error C0032

**Message:** Type ‘<type 1>’ can not be converted to type ‘<type 2>’

**Possible error cause:** A variable is assigned to another variable with an incompatible type.

**Error correction:** Use a type conversion.

Example of the error:

```plaintext
PROGRAM PLC_PRG
  VAR
    test1: INT;
    test2: STRING;
  END_VAR

  test1 := test2;

-->C0032: Type 'STRING' cannot be converted to type 'INT'
```

Error correction:

```plaintext
Example:
  test1 := TO_INT(test2);
```

Compiler error C0035

**Message:** Program name, function or function block instance expected instead of '<invalid function>'

**Possible error cause:** A function is called that does not exist.

**Error correction:** Make sure that only program names, functions, and function Block Instances that exist are called.

Example of the error:

```plaintext
PROGRAM PLC_PRG
  VAR
  END_VAR

  PLC_PRG.METH1();

  METHOD METH
    VAR_INPUT
    END_VAR

--> C0004: 'METH1' is no component of 'PLC_PRG'
--> C0035: Program name, function or function block instance expected instead of 'PLC_PRG.METH1'
```

Error correction:

```plaintext
Example:
  PLC_PRG.METH();
```
Compiler error C0037
Message: '<invalid input>' is no input of '<function name>'
Possible error cause: A local variable is defined in a function call.
Error correction: Declare the variable as an input parameter.

Example of the error:
PROGRAM PLC_PRG
VAR
  i : INT;
END_VAR
i := TEST(iVar := 1);

FUNCTION TEST : INT
VAR
  iVar : INT;
END_VAR

--> C0037: 'iVar' is no input of 'TEST'

Error correction:
Example:
VAR_INPUT
  iVar : INT;
END_VAR

Compiler error C0038
Message: '<invalid output>' is no output of '<function name>'
Possible error cause: A local variable is handled as an output in a function call.
Error correction: Declare the variable as an output parameter.

Example of the error:
PROGRAM PLC_PRG
VAR
  i : INT;
  x : INT;
END_VAR
i := TEST(iVar => x);

FUNCTION TEST : INT
VAR
  iVar : INT;
END_VAR

--> C0038: 'iVar' is no output of 'TEST'

Error correction:
Example:
VAR_OUTPUT
  iVar : INT;
END_VAR

Compiler error C0039
Message: VAR_IN_OUT '<invalid variable>' must be assigned in call of '<function block name>'
Possible error cause: An IN_OUT variable is not passed to a function block that requires an IN_OUT variable.
Error correction: Assign the IN_OUT variable.
Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
   inst : FB;
END_VAR

FUNCTION_BLOCK FB
VAR_IN_OUT
   inout : INT;
END_VAR

--> C0039: VAR_IN_OUT 'inout' must be assigned in call of 'FB'

Error correction:

Example:
inst(inout := i);
```

Compiler error C0040

Message: Function '<function name>' requires exactly '<number of inputs>' input

Possible error cause: Too many or too few parameters are passed to the called function.

Error correction: Pass exactly as many parameters to the function as are expected.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
   i : INT;
END_VAR

i := TEST(1,2);

FUNCTION TEST : INT
VAR_INPUT
   IN: INT;
END_VAR

--> C0040: Function 'TEST' requires exactly '1' inputs

Error correction:

Example:
i := Test(1);
```

Compiler error C0041

Message: VAR_IN_OUT parameter '<parameter name>' of '<function name>' needs variable with write access as input

Possible error cause: The passed parameter is not a variable with write access (but a constant for example).

Error correction: Pass a VAR_IN_OUT parameter with write access to the function.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
   i : INT;
   x : INT;
END_VAR

i := Test(31415);

FUNCTION TEST : INT
```
VAR_IN_OUT
  in_out: INT;
END_VAR

--> C0041: VAR_IN_OUT' parameter 'in_out' of 'TEST' needs variable with write access as input

Error correction:
Example:
i := Test(x);

Compiler error C0043

Message: Wrong formal parameter: '<parameter name>' expected in this place
Possible error cause: The parameters are assigned to the function explicitly in the wrong order.
Error correction: Specify the parameters in the correct order.

Example of the error:
PROGRAM PLC_PRG
VAR
  i : INT;
END_VAR
i := Test(iPar2 := 2, 5);

FUNCTION Test : INT
VAR_INPUT
  iPar1 : INT;
  iPar2 : INT;
END_VAR

--> C0043: Wrong formal parameter: 'iPar1' expected in this place
--> C0412: Multiple input assignments for parameter ''

Error correction:
i := Test(5, iPar2 := 2);

Compiler error C0044

Message: Assignment to input missing for parameter '<input variable name>' in call of '<function block name>'
Possible error cause: A parameter is passed although an input variable is not declared.
Error correction: Declare an input variable.

Example of the error:
PROGRAM PLC_PRG
VAR
  inst : FB;
END_VAR
inst(1);

FUNCTION_BLOCK FB
VAR_INPUT
--- C0044: Assignment to input missing for parameter '1' in call of 'FB'

Error correction:
Example:
VAR_INPUT
  _in : INT;
END_VAR

Compiler error C0045

Message: Use of 'THIS' is not allowed in this context
Possible error cause: In order to be assigned to the current instance, THIS can be used only in a method, action, transition, or in the body of a function block. This error message appears for all other positions.
Error correction: Use THIS in an allowed context only.

Example of the error:
PROGRAM PLC_PRG
VAR
  test1: INT;
END_VAR

THIS^.test1 := 19;

--- C0018: 'THIS^.test1' is not a valid assignment target
--- C0062: 'THIS^' is not a structure variable
--- C0045: Use of 'THIS' is not allowed in this context

Compiler error C0046

Message: Identifier '<identifier name>' not defined
Possible error cause: An identifier is used that is not declared.
Error correction: Declare the variables that you want to use.

Example of the error:
PROGRAM PLC_PRG
VAR
  END_VAR
  i := 1;

--- C0018: 'i' is no valid assignment target
--- C0046: Identifier 'i' not defined

Error correction:
Example:
VAR
  i : INT;
END_VAR

Compiler error C0047

Message: Cannot apply indexing with '[' to an expression of type '<data type>'
Possible error cause: A data type that is not an array is indexed with '[]'.

Error correction: Index data types with '[]' only if they are declared as arrays.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
END_VAR
i[1];
```

--> C0047: Cannot apply indexing with '[]' to an expression of type 'INT'

Compiler error C0048

Message: Array requires exactly '<number>' indexes

Possible error cause: Too many or too few indexes are specified when using an array.

Error correction: Specify as many indexes as there are dimensions assigned to the array.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  arr1 : ARRAY[1..2,1..3] OF INT;
END_VAR
arr1[1] := 5;
```

--> C0048: Array requires exactly 2 indexes

Error correction:
Example:
```
arr1[1,2] := 5;
```

Compiler error C0049

Message: The constant index '<index value>' is not within the range from '<start index>' to '<end index>'

Possible error cause: An index is specified that is outside the size of the array.

Error correction: Use only indexes that are within the size of the array.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  arr1 : ARRAY[1..2] OF INT;
END_VAR
arr1[3] := 1;
```

--> C0049: The constant index '3' is not within the range from '1' to '2'

Error correction:
Example:
```
arr1[2] := 1;
```

Compiler error C0050

Message: Bitaccess requires literal or symbolic integer constant
Possible error cause: No literal or an integer constant is specified in a bit access.

Error correction: Use a literal or an integer constant.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
  x : INT;
END_VAR

i.x := FALSE;
```

--> C0018: 'i.x' is no valid assignment target
--> C0050: Bitaccess requires literal or symbolic integer constant

Error correction:

```plaintext
Example:
i := Test(x);
```

Compiler error C0061

Message: Bitaccess on function call is not allowed

Possible error cause: Bit access is performed on a function.

Error correction: Use bit access only for supported data types.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
END_VAR

Test().2;

FUNCTION Test : INT
VAR_INPUT
END_VAR

--> C0061: Bitaccess on function call is not allowed
```

Compiler error C0062

Message: '<variable name>' is no structured variable

Possible error cause: A variable that is not a structure variable is treated like a structure variable.

Error correction: Make sure that the variable is a structure variable.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  pt : PUNKT;
  i : INT;
END_VAR

i.x := 1024;

TYPE Punkt :
```
STRUCT
  x : REAL;
  y : REAL;
END_STRUCT
END_TYPE

--> C0018: 'i.x' is no valid assignment target
--> C0062: 'Variable' is no structured variable

Example:
pt.x := 1024;

Compiler error C0064
Message: Dereferencing requires a pointer
Possible error cause: A variable that is not a pointer variable is dereferenced.
Error correction: Dereference only variables that are pointer variables.

Example of the error:
PROGRAM PLC_PRG
VAR
  i : INT;
  pi : POINTER TO INT;
END_VAR
i^:=1;

--> C0018: 'i^' not a valid assignment target
--> C0064: Dereferencing requires a pointer

Error correction: Example:
pi := ADR(i);
pi^ := 1;

Compiler error C0066
Message: Cannot compare type '<data type>' with type '<data type>'
Possible error cause: Two data types are compared which cannot be compared with each other.
Error correction: Compare only data types that can be compared with each other.

Example of the error:
PROGRAM PLC_PRG
VAR
  i : INT;
  re : REAL;
  str: STRING;
  b : BOOL;
END_VAR
b := i > str;

--> C0066: Cannot compare type 'INT' with type 'STRING'

Error correction: Example:
b := i > re;
Compiler error C0068

Message: Compare not possible on objects of type ‘<data type>’

Possible error cause: Objects are being compared in which a comparison is not possible.

Error correction: Compare only data types in which a comparison is possible (INT, REAL, etc.).

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  b : BOOL;
  arr1 : ARRAY [1..2] OF INT;
  arr2 : ARRAY [1..2] OF INT;
END_VAR

b := arr1 > arr2;

--> C0068: Compare not possible on objects of type 'ARRAY [1..2]'
```

Compiler error C0069

Message: Compare not possible on objects of type ‘<data type>’ or ‘<data type>’

Possible error cause: Two different objects are being compared in which a comparison is not possible.

Error correction: Compare only data types in which a comparison is possible (INT, REAL, etc.).

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  b : BOOL;
  arr1 : ARRAY [1..2] OF INT;
  arr2 : ARRAY [1..3] OF INT;
END_VAR

b := arr1 > arr2;

--> C0069: Compare not possible on objects of type 'ARRAY [1..2]' or 'ARRAY [1..3]'
```

Compiler error C0070

Message: 'INI' operator needs function block instance or data unit type instance

Possible error cause: Neither a function block instance nor a DUT instance is applied to the INI operator.

Error correction: Pass only function block instances or DUT instances to the INI operator.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  b : BOOL;
  inst : FB;
END_VAR

b := INI(b, TRUE);

FUNCTION_BLOCK FB
VAR

```
INI operator needs function block instance or data unit type instance

Example:
\[ b := \text{INI}(\text{inst}, \text{TRUE}); \]

Compiler error C0072

Message: Operator <operator name>' is not possible on type '<data type>'

Possible error cause: An operator is applied to an incompatible type.

Error correction: Apply operators only on compatible types.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
  str : STRING;
END_VAR

str := \text{ABS}(str);
```

Error correction:

Example:
\[ i := \text{ABS}(i); \]

Compiler error C0074

Message: Unexpected array initialisation

Possible error cause: Syntax error in the array initialization

Error correction: Correct the syntax

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  arr1 : INT := [1,2,3,4,5,6];
END_VAR
```

Error correction:

Example:
\[ \text{arr1} : \text{ARRAY }[1..6] \text{ OF INT := } [1,2,3,4,5,6]; \]

Compiler error C0075

Message: Too many initializers for array

Possible error cause: Too many values are specified for the size of the array.

Error correction: The number of assigned values must correspond to the size of the array.
Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  arr1 : ARRAY [1..5] OF INT := [1,2,3,4,5,6];
END_VAR
```

--> C0075: Unexpected array initialisation

Error correction:
```
Example:
arr1 : ARRAY [1..6] OF INT := [1,2,3,4,5,6];
```

Compiler error C0076

Message: Unexpected structure initialisation
Possible error cause: Syntax error in the structure initialization
Error correction: Make sure that the syntax is correct.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  st1 : INT := (p1 := 1);
END_VAR
```

--> C0076: Unexpected structure initialisation
--> C0032: Cannot convert type 'STRUCT(p1:=1)' to type 'INT'
--> C0046: Identifier 'p1' not defined
--> C0018: 'p1' is no valid assignment target

Error correction:
```
Example:
st1 : STRUCT1 := (p1:=1,p2:=10);
```

Compiler error C0077

Message: Unknown type: '<data type>'
Possible error cause: Invalid data type in the declaration (maybe a syntax error)
Error correction: Specify valid data types only.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i : INTEGER;
END_VAR
```

--> C0077: Unknown type: 'INTEGER'

Error correction:
```
Example:
arr1 : ARRAY[1..2] OF STRUCT1 := (p1:=1,p2:=10);
```

Compiler error C0080

Message: Functionblock '<function block name>' must be instantiated to be accessed
Possible error cause: Missing function Block Instantiation
Error correction: Instantiate the function block.
Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
END_VAR

FB();

FUNCTION_BLOCK FB
VAR
END_VAR

--> C0080: Functionblock 'FB' must be instantiated to be accessed

Error correction:

Example:
VAR
  inst : FB;
END_VAR
  inst();
```

Compiler error C0081

Message: Unexpected Pragma: '<pragma name>' found without matching 'if'
Possible error cause: The IF condition is missing when using the pragma.
Error correction: Complete the IF condition of the pragma.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
END_VAR
  i := 5;
  {END_IF}

--> C0081: Unexpected Pragma: 'END_IF' found without matching 'if'

Error correction:

Example:
  {IF <expression>}
  i := 5;
  {END_IF}
```

Compiler error C0082

Message: '<invalid pragma>' is no valid condition for pragma
Possible error cause: When using a pragma, an invalid expression is used in the IF condition.
Error correction: Use valid pragma conditions.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
END_VAR
```
{IF abc}
i := 5;
{END_IF}

--> C0082: '!!!ERROR!!!' is no valid condition for pragma

Error correction:
Example:
{IF defined (abc)}

Compiler error C0084

**Message:** '<pragma operand>' is no valid operand for pragma

**Possible error cause:** Syntax error

**Error correction:** Use valid pragma operands.

Example of the error:
PROGRAM PLC_PRG
VAR
END_VAR

{IF defined(0)}
{END_IF}

--> C0084: 'defined(null)' is no valid operand for pragma

Error correction:
Example:
{IF defined (abc)}

Compiler error C0086

**Message:** No definition found for interface '<interface name>'

**Possible error cause:** An undefined interface is used.

**Error correction:** Define the interface.

Example of the error:
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR

FUNCTION_BLOCK FB IMPLEMENTS XY
VAR
END_VAR

--> C0086: No definition found for interface 'XY'

Error correction:
Example:
INTERFACE XY

Compiler error C0087

**Message:** There is no implementation for method '<method name>' defined in interface '<interface name>'.

**Possible error cause:** One of the methods specified by the interface has not be provided by the implemented function block.
**Error correction:** Implement all methods that are specified by the interface.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR

INTERFACE XY
METHOD METH1
VAR_INPUT
END_VAR

FUNCTION_BLOCK FB IMPLEMENTS XY
VAR
END_VAR
METHOD METH2
VAR_INPUT
END_VAR

--> C0087: There is no implementation for method 'METH1' defined in interface 'XY'
```

**Compiler error C0089**

**Message:** Interface of overridden method '{0}' of interface '{1}' does not match declaration

**Possible error cause:** The signature of the implemented method does not match the signature of the method in the interface.

**Error correction:** Make sure that the same return types and parameters are declared.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR

INTERFACE XY
METHOD METH1
VAR_INPUT
    iPar : INT;
END_VAR

FUNCTION_BLOCK FB IMPLEMENTS XY
VAR
END_VAR
METHOD METH1
VAR_INPUT
END_VAR

--> C0089: Interface of overridden method 'METH1' of interface 'XY' does not match declaration
```
Compiler error C0090

**Message:** No definition found for base class '<function name>'

**Possible error cause:** The function block specified as the base does not exist or is not a function block.

**Error correction:** Use a function block as the base.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
  inst : FB;
END_VAR

FUNCTION_BLOCK FB EXTENDS POU
VAR
END_VAR

FUNCTION POU
VAR
END_VAR

--> C00090: No definition found for base class 'POU'
```

Compiler error C0091

**Message:** Recursion in base function block list: <function name>

**Possible error cause:** A base function block is extended by itself.

**Error correction:** Recursion in base function block lists is not possible.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
  inst : FB;
END_VAR

FUNCTION_BLOCK FB EXTENDS FB
VAR
END_VAR

--> C00091: Recursion in base function block list: FB -> FB
```

Compiler error C0094

**Message:** Interface of overridden method '<method name>' of interface '<function block name>' doesn't match declaration

**Possible error cause:** The signature of the method of the first interface does not match the signature of the method in the second interface, which is extended by the first.

**Error correction:** Align the signatures.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
  xyz : XY2;
END_VAR
```
FUNCTION_BLOCK XY
METHOD METH1
VAR_INPUT
END_VAR

FUNCTION_BLOCK XY2 EXTENDS XY
METHOD METH1
VAR_INPUT
  iPar : BOOL;
END_VAR

--> C00094: Interface of the overridden method METH1 of interface XY doesn't match declaration

Compiler error C0096

Message: Only one base function block may be defined in EXTENDS-list.
Possible error cause: Two or more base function blocks are defined in the EXTENDS list.
Error correction: Define only one base function block in the EXTENDS list.

Example of the error:
PROGRAM PLC_PRG
VAR
  fb : FB;
END_VAR

FUNCTION_BLOCK FB EXTENDS FB2, FB3
VAR
END_VAR

FUNCTION_BLOCK FB2
VAR
END_VAR

FUNCTION_BLOCK FB3
VAR
END_VAR

--> C00096: Only one base function block may be defined in EXTENDS-list

Compiler error C0097

Message: Duplicate definition of variable '<variable name>' in function block '<function block name>' and in base '<base function block name>'
Possible error cause: A variable is declared with the same name in a function block and its base.
Error correction: Use different variable names.

Example of the error:
PROGRAM PLC_PRG
VAR
  fb : FB;
END_VAR

FUNCTION_BLOCK FB EXTENDS FB2
VAR
  i : INT;
END_VAR

FUNCTION_BLOCK FB2
VAR
  i : INT;
END_VAR

--> C00097: Duplicate definition of variable 'i' in function block 'FB' and in base 'FB2'

Compiler error C0098

Message: The keyword "FUNCTIONBLOCK" is no longer supported. Use "FUNCTION_BLOCK" instead.
Possible cause of error: Syntax error
Error correction: Use the keyword "FUNCTION_BLOCK".

Example of the error:

PROGRAM PLC_PRG
VAR
  inst : FB;
END_VAR

FUNCTIONBLOCK FB
VAR
END_VAR

--> C0098: The keyword "FUNCTIONBLOCK" is no longer supported. Use "FUNCTION_BLOCK" instead. Use "FUNCTION_BLOCK" instead.

Compiler error C0101

Message: Data Recursion: '<recursion>'
Possible error cause: Recursive data initialization over two function blocks
Error correction: Avoid recursions for data initialization.

Example of the error:

PROGRAM PLC_PRG
VAR
  inst0 : FB1;
END_VAR

FUNCTION_BLOCK FB1
VAR
  inst1 : FB2;
END_VAR

FUNCTION_BLOCK FB2
VAR
  inst2 : FB1;
END_VAR

--> C0101: Data Recursion: FB1->FB2->FB1
Compiler error C0102

**Message:** Out of retain memory: Variable '<variable name>', <byte size> bytes.

**Possible error cause:** More retain memory is used than is available on the PLC. It is also possible that the retain memory is too fragmented due to incremental builds.

**Error correction:** Use the "Clean" for fragmenting the memory. This will force the reallocation of all data at the next build.

Compiler error C0104

**Message:** 'Out of global data memory: Variable '<variable name>', <byte size> bytes.

**Possible error cause:** More memory for data is used than is available on the PLC. It is also possible that the memory is too fragmented due to incremental builds.

**Error correction:** Use the "Clean" for fragmenting the memory. This will force the reallocation of all data at the next build.

Compiler error C0114

**Message:** Invalid destination <jump label> for 'JMP'

**Possible error cause:** Syntax error or typographical error in the JMP destination

**Error correction:** Correct the typographical or syntax error.

**Example of the error:**

```
PROGRAM PLC_PRG
VAR
END_VAR
JMP 0;
```

--> C0114: Invalid destination 0 for 'JMP'

Compiler error C0116

**Message:** The label '<jump label>' is a duplicate

**Possible error cause:** A label is defined multiple times.

**Error correction:** Define each label one time only.

**Example of the error:**

```
PROGRAM PLC_PRG
VAR
END_VAR
JMP label;
label:
label:
```

--> C0116: The label 'LABEL' is a duplicate

Compiler error C0117

**Message:** No such label '<jump label>' within the scope of the 'JMP' statement

**Possible error cause:** A jump is made to a label that does not exist.
**Error correction:** Define the label that you specify as the destination.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
END_VAR
JMP A;
```

--> C0117: No such label 'A' within the scope of the 'JMP' statement

**Compiler error C0118**

**Message:** The label '<jump label>' has not been referenced.

**Possible error cause:** A jump label is defined that is not referenced.

**Error correction:** Remove the unused jump labels.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
END_VAR
LABEL:
```

--> C0118: The label ' LABEL' has not been referenced

**Compiler error C0119**

**Message:** An 'FB_init'-Method of a functionblock or struct needs two inputs 'bInitRetains' and 'bInCopyCode' of type BOOL.

**Possible error cause:** One or both of the inputs 'bInitRetains' and 'bInCopyCode' of type BOOL is missing.

**Error correction:** Define the missing inputs.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
  inst : FB;
END_VAR

FUNCTION_BLOCK FB
METHOD FB_init
  VAR_INPUT
END_VAR
```

--> C0119: An 'FB_init'-Method of a functionblock or struct needs two inputs 'bInitRetains' and 'bInCopyCode' of type BOOL

**Error correction:**

```plaintext
Example:
METHOD FB_init
  VAR_INPUT
    bInitRetains : BOOL;
    bInCopyCode : BOOL;
END_VAR
```
Compiler error C0120

Message: An 'FB Exit'-Method of a functionblock or struct needs an input 'bInCopyCode' of type BOOL.

Possible error cause: The input 'bInCopyCode' of type BOOL is missing.

Error correction: Define the input.

Example of the error:

```plaintext
PROGRAM PLC_PRG
  VAR
    inst : FB;
  END_VAR

  FUNCTION_BLOCK FB
    METHOD FB_exit
      VAR_INPUT
      _bInCopyCode : BOOL;
    END_VAR
  END_FUNCTION_BLOCK

--> C0120: An 'FB Exit'-Method of a functionblock or struct needs an input 'bInCopyCode' of type BOOL.

Error correction:

Example:

METHOD FB_exit
  VAR_INPUT
    _bInCopyCode : BOOL;
  END_VAR
```

Compiler error C0122

Message: Expression 'SUPER' is not allowed in this context

Possible error cause: "SUPER^" is used outside of derived function blocks.

Error correction: Use "SUPER^" in function blocks only.

Example of the error:

```plaintext
PROGRAM PLC_PRG
  VAR
  END_VAR

  SUPER^.METH(TRUE, TRUE);

--> C0122: Expression 'SUPER' is not allowed in this context
```

Compiler error C0124

Message: 'Initialization' is no valid initialization for an enumeration

Possible error cause: A data type that is not ANY_INT is used for the enum initialization.

Error correction: Use only ANY_INT for enum initializations.

Example of the error:

```plaintext
PROGRAM PLC_PRG
  VAR
    inst : DUT;
  END_VAR

  TYPE DUT :
```

2020/12/10
(  
    enum_member := 1.5  
) DWORD;  
END_TYPE

--> C0032: Cannot convert type 'LREAL' to type 'DUT'  
--> C0124: 'Initialization' is no valid initialization for an  
enumeration

Compiler error C0125

Message: The constant <constant value> is assigned to more than one enumeration.
Possible error cause: The same value is assigned to two or more enumerations.
Error correction: Assign different values to the enumerations.

Example of the error:

PROGRAM PLC_PRG  
VAR  
  inst : DUT;  
END_VAR

TYPE DUT :  
{  
    enum_member := 0,  
    enum_member2 := 0  
};  
END_TYPE

--> C0125: The constant 0 is assigned to more than one enumeration

Compiler error C0126

Message: Variable of type '<data type>' requires exactly 1 Index
Possible error cause: Multiple indexes are assigned to a variable with one index.
Error correction: Assign only one index.

Example of the error:

PROGRAM PLC_PRG  
VAR  
  pi : POINTER TO INT;  
END_VAR  
pi[0,1] := 0;

--> C0126: Variable of type 'POINTER TO INT' requires exactly 1 Index

Error correction:

Example:

pi[0] := 0;

Compiler error C0130

Message: <object> '<object name>' referenced without parentheses '(())'
Possible error cause: A method is referenced without parentheses.
Error correction: Always reference methods by means of parentheses.
Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  inst : FB;
END_VAR
inst.METH1

--> C0130: METHOD 'METH1' referenced without parentheses '()'
```

Error correction:

```plaintext
Example:
inst.METH1();
```

Compiler error C0131

**Message:** '<value>' is not allowed as operand for 'ADR'

**Possible error cause:** A constant is passed as an operand to the operator ADR.

**Error correction:** Use only valid operands for ADR.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
  pt : POINTER TO INT;
END_VAR
pt := ADR(1);

--> C0131: '1' is not allowed as operand for 'ADR'
```

Error correction:

```plaintext
Example:
pt := ADR(i);
```

Compiler error C0132

**Message:** No enclosing loop of which to EXIT

**Possible error cause:** EXIT is used outside of a loop.

**Error correction:** Use EXIT inside of a loop only.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
END_VAR
EXIT;

--> C0132: No enclosing loop of which to EXIT
```

Compiler error C0136

**Message:** ambiguous use of name '<variable name>'

**Possible error cause:** A variable is declared in multiple GVLs.

**Error correction:** Qualify the variable with the desired GVL.
Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  j : INT := g_i;
END_VAR

GVL1:
VAR_GLOBAL
  g_i : INT;
END_VAR

GVL2:
VAR_GLOBAL
  g_i : INT;
END_VAR

--> C0136: ambiguous use of name 'g_i'
```

Error correction:

Example:

```plaintext
j : INT := GVL1.g_i;
```

Compiler error C0139

**Message:** The code `<code>` has no effect. Is this the intent?

**Possible error cause:** The written code is syntactically correct but does not do anything.

**Error correction:** Write code that has a purpose.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
END_VAR

i;

--> C0139: The code 'i;' has no effect. Is this the intent?
```

Compiler error C0140

**Message:** Reference assign is only allowed to variables of Reference type

**Possible error cause:** An attempt is made to assign a reference value to a variable not defined as a reference type.

**Error correction:** Define the variable as a reference type.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
  I_r : INT;
END_VAR

I_r REF= i;

--> C0140: Reference assign is only allowed to variables of Reference type
```

Error correction:

Example:

```plaintext
I_r : REFERENCE TO INT;
```
Compiler error C0141

**Message:** Reference assign needs variable with write access

**Possible error cause:** A constant is assigned to the reference assignment.

**Error correction:** Assign a writable variable.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
  I_r : REFERENCE TO INT;
END_VAR

I_r REF= 314;

--> C0141: Reference assign needs variable with write access
```

**Error correction:**

```
Example:
I_r REF= i;
```

Compiler error C0142

**Message:** A local variable named '<variable name>' is already defined in '<pou name>'

**Possible error cause:** The same variable name is used two times.

**Error correction:** Use different variable names.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
  i : INT;
END_VAR

--> C0142: A local variable named 'i' is already defined in 'PLC_PRG'
```

Compiler error C0143

**Message:** The property '<property name>' cannot be used in this context because it lacks the get accessor

**Possible error cause:** The property does not have Get access.

**Error correction:** Make sure that the property has a Get access definition.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
  i : INT;
  inst: FB;
END_VAR

i := inst.Prop;

FUNCTION_BLOCK FB
VAR
END_VAR
```
PROPERTY Prop : INT
Set;

--> C0143: The property 'Prop' cannot be used in this context because it lacks the get accessor

Compiler error C0144

Message: Inheritance only allowed in Functionblocks, Interfaces and Structures
Possible error cause: An attempt is made to use inheritance in an object that does not permit inheritance.
Error correction: Use EXTENDS in function blocks, interfaces, and structures only.

Example of the error:
PROGRAM PLC_PRG
VAR
    inst : DUT_1;
END_VAR

TYPE DUT:
    (enum_member := 0);
END_TYPE

TYPE DUT_1 EXTENDS DUT:
    (enum_memberX := 0);
END_TYPE

--> C0144: Inheritance only allowed in Functionblocks, Interfaces and Structures

Compiler error C0145

Message: Interfaces can only be implemented by Functionblocks
Possible error cause: An attempt is made to implement an interface outside of a function block.
Error correction: Implement interfaces only in function blocks.

Example of the error:
PROGRAM PLC_PRG
VAR
END_VAR

POU();

FUNCTION POU IMPLEMENTS ITF
VAR
END_VAR

--> C0145: Interfaces can only be implemented by Functionblocks

Compiler error C0149

Message: Variable declarations are not allowed in interfaces
Possible error cause: An attempt is made to define a variable in an interface.

Error correction: Do not define variables in interfaces.

Example of the error:

```
PROGRAM PLC_PRG
VAR
  inst : ITF;
END_VAR

INTERFACE ITF
VAR_INPUT
  i : INT;
END_VAR

--> C0149: Variable declarations are not allowed in interfaces
```

Compiler error C0161

Message: Border <array bound> of array is no constant value

Possible error cause: A variable is specified as an array bound.

Error correction: Use constants for the array bounds.

Example of the error:

```
PROGRAM PLC_PRG
VAR
  i : INT := 3;
  arr1 : ARRAY[1..i] OF INT;
END_VAR

--> C0161: Border 'i' of array is no constant value
```

Error correction:

```
Example:
arr1 : ARRAY[1..3] OF INT;
```

Compiler error C0162

Message: Number <number of array values> of array initialisations is no constant value

Possible error cause: The initialization \([\text{Wert1}, \text{AnzahlWert2} (\text{Wert2})]\) works only with a constant for \(\text{AnzahlWert2}\).

Error correction: Use constants only.

Example of the error:

```
PROGRAM PLC_PRG
VAR
  i : INT := 3;
  arr1 : ARRAY[1..4] OF INT := [1,i(7)];
END_VAR

--> C0162: Number 'i' of array initialisations is no constant value
```

Error correction:

```
Example:
arr1 : ARRAY[1..4] OF INT := [1,3(7)];
```

Compiler error C0168

Message: ‘VAR_CONFIG’ declaration only allowed in VAR_CONFIG - list
Possible error cause: 'VAR_CONFIG' is used outside of a VAR_CONFIG list.
Error correction: Use 'VAR_CONFIG' only in VAR_CONFIG lists.

Example of the error:

PROGRAM PLC_PRG
VAR_CONFIG
  i : INT;
END_VAR

--> C0168: 'VAR_CONFIG' declaration only allowed in VAR_CONFIG - list

Compiler error C0169

Message: 'VAR_GLOBAL' declaration only allowed in Global variable list
Possible error cause: 'VAR_GLOBAL' is used outside of global variable lists.
Error correction: Use 'VAR_GLOBAL' in global variable lists only.

Example of the error:

PROGRAM PLC_PRG
VAR_GLOBAL
  i : INT;
END_VAR

--> C0169: 'VAR_GLOBAL' declaration only allowed in Global variable list

Compiler error C0174

Message: 'VAR_TEMP' declaration not allowed in this place
Possible error cause: 'VAR_TEMP' is used outside of a program or function block.
Error correction: Use 'VAR_TEMP' inside of programs and function blocks only.

Example of the error:

PROGRAM PLC_PRG
VAR
END_VAR

FUN();

FUNCTION FUN
VAR_TEMP
END_VAR

--> C0174: 'VAR_TEMP' declaration not allowed in this place

Compiler error C0175

Message: 'RETAIN' or 'PERSISTENT' not allowed in this place
Possible error cause: 'RETAIN' or 'PERSISTENT' is used in a function.
Error correction: Use 'RETAIN' or 'PERSISTENT' at the intended locations.
Example of the error:

PROGRAM PLC_PRG
VAR
  inst : POU;
END_VAR

FUNCTION POU
VAR
END_VAR

--> C0175: 'RETAIN' or 'PERSISTENT' not allowed in this place

- Chapter 1.3.1.24.2.13 “Retain variable - RETAIN” on page 500
- Chapter 1.3.1.24.2.13 “Retain variable - RETAIN” on page 500

Compiler error C0177

Message: `<object>` is of type 'type' and cannot be instantiated
Possible error cause: An attempt is made to instantiate a function.
Error correction: Instantiate only objects that can be instantiated.

Example of the error:

PROGRAM PLC_PRG
VAR
  inst : POU;
END_VAR

FUNCTION POU
VAR
END_VAR

--> C0177: 'POU' is of type 'FUNCTION' and cannot be instantiated

Compiler error C0178

Message: No external access to 'VAR_IN_OUT' parameter '<parameter name>' of '<object name>'
Possible error cause: An attempt is made to remotely access a 'VAR_IN_OUT' parameter.
Error correction: Do not remotely access 'VAR_IN_OUT' parameters.

Example of the error:

PROGRAM PLC_PRG
VAR
  inst : FB;
  i : INT;
END_VAR
  i := inst.in_out;

FUNCTION_BLOCK FB
VAR_IN_OUT
  _in_out : INT;
END_VAR

--> C0178: No external access to 'VAR_IN_OUT' parameter 'in_out' of 'FB'
Compiler error C0182

**Message:** Return type is only possible for POUs of Type FUNCTION and METHOD

**Possible error cause:** An attempt is made to define a return value in a program.

**Error correction:** Define a return value only in methods and functions.

**Example of the error:**

```plc
PROGRAM PLC_PRG : BOOL
VAR
END_VAR

--> C0182: Return type is only possible for POUs of Type FUNCTION and METHOD
```

Compiler error C0185

**Message:** It is not possible to perform component access '.', index access '[' or call '(' on result of function call. Assign result to help variable first.

**Possible error cause:** Component or index access to the result of a function call is performed.

**Error correction:** Assign the result to a variable in order to access.

**Example of the error:**

```plc
PROGRAM PLC_PRG
VAR
    it : ITF;
END_VAR

POU_1()[0].METH1();

FUNCTION POU_1 : ARRAY[0..0] OF ITF

INTERFACE ITF

METHOD METH1

--> C0185: It is not possible to perform component access '.', index access '[' or call '(' on result of function call. Assign result to help variable first.
```

Compiler error C0189

**Message:** ';' expected instead of '<token>'

**Possible error cause:** Syntax error

**Error correction:** Make sure that the syntax is correct.

**Example of the error:**

```plc
PROGRAM PLC_PRG
VAR
    INT
END_VAR

--> C0009: Unexpected Token '<Token>' found
--> C0189: ';' expected instead of 'INT'
```
Compiler error C0190

Message: ';' expected instead of end of POU
Possible error cause: Syntax error in the POU
Error correction: Make sure that the syntax is correct.

Example of the error:
```
PROGRAM PLC_PRG
VAR
  i : INT;
END_VAR
i := 5
```

Compiler error C0191

Message: The operator 'INDEXOF' is no longer supported. Use ADR instead. ADR on a POU-Name returns a Pointer to a Pointer to the function code.
Possible error cause: The outdated operator 'INDEXOF' is used.
Error correction: Use the operator 'ADR'.

Compiler error C0195

Message: Implicit conversion from signed Type '<data type 1>' to unsigned Type '<data type 2>' : possible change of sign
Possible error cause: A sign conflict may have been missed in the implicit conversion.
Error correction: Convert only data types with the same sign implicitly.

Example of the error:
```
PROGRAM PLC_PRG
VAR
  i : INT;
  b : UINT;
END_VAR
b := i;
```

Compiler error C0196

Message: Implicit conversion from unsigned Type '<data type 1>' to signed type '<data type 2>' : possible change of sign
Possible error cause: A sign conflict may have been missed in the implicit conversion.
Error correction: Use explicit conversions.

Example of the error:
```
PROGRAM PLC_PRG
VAR
  i : INT;
  b : UINT;
END_VAR
```
i := b;

--> C0196: Implicit conversion from unsigned Type 'UINT' to signed type 'INT': possible change of sign

Compiler error C0197

**Message:** Implicit conversion from '<data type 1>' to '<data type 2>': possible loss of information

**Possible error cause:** An attempt is made to convert a variable from data type DINT or LINT to data type REAL.

**Error correction:** For DINT, use the data type LREAL, and when converting from LINT to LREAL make sure that the value of LINT does not exceed the capacity of LREAL.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
    i : DINT;
    b : REAL;
END_VAR
b := i;

--> C0197: Implicit conversion from 'DINT' to 'REAL': possible loss of information
```

Compiler error C0198

**Message:** String constant '<string value>' too long for destination type '<data type>'

**Possible error cause:** The string constant has too many characters.

**Error correction:** Use shorter string constants or declare larger strings.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
    str : STRING(4) := '12345';
END_VAR

--> C0198: String constant '12345' too long for destination type 'STRING(4)'
```

Compiler error C0199

**Message:** Interface '<interface name>' must be instantiated to be accessed

**Possible error cause:** An attempt is made to access an interface method without the interface being instantiated.

**Error correction:** Instantiate the interface.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
    ITF.METH();
```
INTERFACE ITF
METHOD METH
VAR_INPUT
END_VAR

--> C0199: Interface 'ITF' must be instantiated to be accessed

Example correction:
itest: ITF;

Compiler error C0201

Message: Type '<data type 1>' is not equal to type '<data type 2>' of VAR_IN_OUT 'Variable'

Possible error cause: The data type that is passed to the function as a VAR_IN_OUT parameter does not match the data type defined in it.

Error correction: Pass a variable with the correct data type.

Example of the error:
PROGRAM PLC_PRG
VAR
  Inst: POU;
  b : BOOL;
END_VAR

inst(in_out := b);

FUNCTION_BLOCK POU
VAR_IN_OUT
  _in_out : INT;
END_VAR

--> C0201: Type 'BOOL' is not equal to type 'INT' of VAR_IN_OUT 'Variable'

Compiler error C0203

Message: Only Structures and Function Blocks can contain variables of type BIT.

Possible error cause: An attempt is made to declare a variable of type BIT outside of structures and function blocks.

Error correction: Declare variables of type BIT only in structures and function blocks.

Example of the error:
PROGRAM PLC_PRG
VAR
  b : BIT;
END_VAR

--> C0203: Only Structures and Function Blocks can contain variables of type BIT.

Compiler error C0204

Message: Variables of type BIT must be declared within a VAR_INPUT-, VAR_OUTPUT or VAR-block.

Possible error cause: An attempt is made to define a variable of type BIT or as a VAR_IN_OUT parameter.
**Error correction:** Define variables of type BIT only within a VAR_INPUT, VAR_OUTPUT or VAR block.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
    inst : FB;
END_VAR

FUNCTION_BLOCK FB
VAR_IN_OUT
    b : BIT;
END_VAR

--> C0204: Variables of type BIT must be declared within a VAR_INPUT-, VAR_OUTPUT or VAR-block
```

**Compiler error C0205**

**Message:** POINTER TO BIT is not allowed

**Possible error cause:** An attempt is made to declare a POINTER TO BIT.

**Error correction:** Do not declare POINTER TO BIT.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
    pt : POINTER TO BIT;
END_VAR

--> C0205: POINTER TO BIT is not allowed
```

**Compiler error C0206**

**Message:** BIT is not allowed as base type of an array

**Possible error cause:** An attempt is made to declare a BIT array.

**Error correction:** Do not declare BIT arrays.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
    arr : ARRAY[1..2] OF BIT;
END_VAR

--> C0206: BIT is not allowed as base type of an array
```

**Compiler error C0208**

**Message:** 'MOD' is not defined for 'REAL'

**Possible error cause:** An attempt is made to perform a modulo operation with a variable of type REAL.

**Error correction:** Modulo operations are only possible with variables of type ANY_INT.
Example of the error:

```
PROGRAM PLC_PRG
VAR
    r1 : REAL;
END_VAR
r1 := r1 MOD 2;
```

--> C0208: 'MOD' is not defined for 'REAL'

Compiler error C0211

**Message:** Variable declaration expected instead of <expression>

**Possible error cause:** Syntax error

**Error correction:** Make sure that the syntax is correct.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    VAR
    END_VAR
END_VAR
```

--> C0211: Variable declaration expected instead of VAR END_VAR

Compiler error C0212

**Message:** VAR, VAR_INPUT, VAR_OUTPUT or VAR_INOUT expected instead of <expression>

**Possible error cause:** Syntax error

**Error correction:** Make sure that the syntax is correct.

Example of the error:

```
PROGRAM PLC_PRG
i : INT;
```

--> C0212: VAR, VAR_INPUT, VAR_OUTPUT or VAR_INOUT expected instead of i : INT;

Compiler error C0216

**Message:** Case label duplicate

**Possible error cause:** A CASE label is used multiple times.

**Error correction:** Use each CASE label only one time.

Example of the error:

```
PROGRAM PLC_PRG
VAR
    i : INT;
END_VAR

CASE i OF
    1: i := i+1;
    1: i := i+2;
```
ELSE
  i := i+10;
END_CASE;

--> C0216: Case label duplicate

Compiler error C0217

Message: Case label <case label> also contained in range <case range begin> .. <case range end>

Possible error cause: A CASE label is part of the range of another CASE label.

Error correction: Make sure that there is no intersecting.

Example of the error:

PROGRAM PLC_PRG
VAR
  i : INT;
END_VAR
CASE i OF
  3..5: i := i+2;
  4: i := i+2;
ELSE
  i := i+10;
END_CASE;

--> C0217: Case label 4 also contained in range 3 .. 5

Compiler error C0218

Message: Case label requires literal or symbolic integer constant

Possible error cause: An attempt is made to use a variable as a CASE label.

Error correction: Use only literals and symbolic integer constants.

Example of the error:

PROGRAM PLC_PRG
VAR
  i : INT;
  a : INT := 2;
END_VAR
CASE i OF
  1: i := i+1;
  a: i := i+2;
ELSE
  i := i+10;
END_CASE;

--> C0218: Case label requires literal or symbolic integer constant

Compiler error C0219

Message: Case contains overlapping range <case range 1 begin> .. <case range 1 end> and <case range 2 begin> .. <case range 2 end>

Possible error cause: Two branches of CASE markers have the same elements or subsets.

Error correction: Make sure that there is no intersecting.
Example of the error:
```
PROGRAM PLC_PRG
VAR
  i : INT;
END_VAR
CASE i OF
  3..5: i := i+2;
  1..4: i := i+2;
ELSE
  i := i+10;
END_CASE;

--> C0219: Case contains overlapping range 1 .. 4 and 3 .. 5
```

Compiler error C0221

**Message:** Direct Address '<address>' malformed

**Possible error cause:** An address is not displayed completely.

**Error correction:** Make sure that the address is displayed correctly.

Example of the error:
```
PROGRAM PLC_PRG
VAR
  xVar : BOOL;
END_VAR;
xVar := %IX0;

--> C0221: Direct Address '%IX0' malformed
```

Error correction:
```
Example:
xVar := %IX0.2;
```

Compiler error C0222

**Message:** Outputs can't be of type 'REFERENCE TO'

**Possible error cause:** An attempt is made to define `REFERENCE TO` as an output parameter.

**Error correction:** Do not use `REFERENCE TO` as an output parameter.

Example of the error:
```
PROGRAM PLC_PRG
VAR
  inst : FB;
END_VAR
FUNCTION_BLOCK FB
VAR_OUTPUT
  re : REFERENCE TO INT;
END_VAR

--> C0222: Outputs can't be of type 'REFERENCE TO'
```

Compiler error C0224

**Message:** Call Recursion: <recursion>

**Possible error cause:** A function calls itself.

**Error correction:** Make sure that functions are not recursive.
Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR

POU();

FUNCTION POU
VAR
END_VAR

POU();

--> C0224: Call Recursion: POU -> POU
```

Compiler error C0227

**Message:** Initialisation of constant variable `<constant name>` not constant

**Possible error cause:** A constant is initialized with a variable.

**Error correction:** Initialize constants only with constant values.

Example of the error:

```
PROGRAM PLC_PRG
VAR
 i : INT;
END_VAR
VAR CONSTANT
 k : INT := i;
END_VAR

--> C0227: Initialisation of constant variable 'k' not constant
```

Compiler error C0228

**Message:** No initial value for constant variable '<constant name>'

**Possible error cause:** A constant is not initialized.

**Error correction:** Initialize the constants.

Example of the error:

```
PROGRAM PLC_PRG
VAR
END_VAR
VAR CONSTANT
 k : INT;
END_VAR

--> C0228: No initial value for constant variable 'k'
```

Error correction:

Example:

```
k : INT := i;
```

Compiler error C0234

**Message:** First Operand of `__QueryInterface` must be an interface reference or the instance of a function block

**Possible error cause:** Incorrect operands are passed to the operator `__QueryInterface`.

**Error correction:** Pass an interface reference or the instance of a function block.
Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
    a : INT;
    ITFref, ITFref2 : ITF;
    ITFref2 : ITF2;
END_VAR

__QueryInterface(a , ITFref);

INTERFACE ITF EXTENDS __SYSTEM.IQueryInterface
INTERFACE ITF2 EXTENDS ITF

--> C0234: First Operand of __QueryInterface must be an interface reference or the instance of a function block
```

Error correction:

```plaintext
Example:
__QueryInterface(ITFref2, ITFref);
```

Compiler error C0235

**Message:** Second Operand of __QueryInterface must be an interface reference

**Possible error cause:** Incorrect operands are passed to the operator __QueryInterface.

**Error correction:** Pass an interface reference.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
    a : INT;
    ITFref, ITFref2 : ITF;
    ITFref2 : ITF2;
END_VAR

__QueryInterface(ITFref2, a);

INTERFACE ITF EXTENDS __SYSTEM.IQueryInterface
INTERFACE ITF2 EXTENDS ITF

--> C0235: Second Operand of __QueryInterface must be an interface reference
```

Error correction:

```plaintext
Example:
__QueryInterface(ITFref2, ITFref);
```

Compiler error C0236

**Message:** Wrong type definition for VAR_EXTERNAL <variable name>

**Possible error cause:** The variable is declared in VAR_GLOBAL / VAR_EXTERNAL as different types.

**Error correction:** Use the same type definition in VAR_GLOBAL and VAR_EXTERNAL.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR_EXTERNAL
    ig : STRING;
END_VAR
```
Compiler error C0236

Message: Wrong type definition for VAR_EXTERNAL ig
Possible error cause: An attempt is made to declare a variable in VAR_EXTERNAL which does not exist in VAR_GLOBAL.
Error correction: Make sure that the identifiers match.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR_EXTERNAL
    ig : INT;
END_VAR

--> C0236: Wrong type definition for VAR_EXTERNAL ig
```

Compiler error C0237

Message: No global definition found for VAR_EXTERNAL '<variable name>'
Possible error cause: An attempt is made to declare a variable in VAR_EXTERNAL which does not exist in VAR_GLOBAL.
Error correction: Make sure that the identifiers match.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR_EXTERNAL
    i : INT;
END_VAR

VAR_GLOBAL
    ig : INT;
END_VAR

--> C0237: No global definition found for VAR_EXTERNAL 'i'
```

Compiler error C0238

Message: No initial value allowed for VAR_EXTERNAL <variable name>
Possible error cause: An attempt is made to initialize a variable in VAR_EXTERNAL.
Error correction: Do not initialize variables in VAR_EXTERNAL.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR_EXTERNAL
    ig : INT := 2;
END_VAR

VAR_GLOBAL
    ig : INT;
END_VAR

--> C0238: No initial value allowed for VAR_EXTERNAL ig
```

Compiler error C0239

Message: Interface <interface name 1> does not extend <interface name 2>
Possible error cause: The used interface does not extend another interface.
Error correction: Extend the interface.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
    ITFref : ITF;
    ITFref2 : ITF2;
END_VAR
```

Example of the error:
__QueryInterface(ITRef2,ITRef);

INTERFACE ITF
INTERFACE ITF2 EXTENDS ITF

--> C0239: Interface ITF__Union does not extend __System.IQueryInterface

**Error correction:**

Example:
INTERFACE ITF EXTENDS __System.IQueryInterface

---

**Compiler error C0240**

**Message:** First Operand of __QueryPointer must be an interface reference or the instance of a function block

**Possible error cause:** Incorrect operands are passed to the operator __QueryPointer.

**Error correction:** Pass an interface reference or the instance of a function block.

**Example of the error:**

PROGRAM PLC_PRG
VAR
  a : INT;
  ITRef : ITF;
  pt : POINTER TO FB;
END_VAR

__QueryPointer(a,pt);

--> C0240: First Operand of __QueryPointer must be an interface reference or the instance of a function block

**Error correction:** __QueryPointer (ITRef, pt);

---

**Compiler error C0241**

**Message:** Second Operand of __QueryPointer must be pointer

**Possible error cause:** Incorrect operands are passed to the operator __QueryPointer.

**Error correction:** Pass a pointer.

**Example of the error:**

PROGRAM PLC_PRG
VAR
  b : INT;
  ITRef : ITF;
  pt : POINTER TO FB;
END_VAR

__QueryPointer(ITRef,b);

INTERFACE ITF EXTENDS __System.IQueryInterface

--> C0241: Second Operand of __QueryPointer must be pointer

**Error correction:** __QueryPointer (ITRef, pt);
Compiler error C0242

Message: Operand of __DELETE must be pointer
Possible error cause: An incorrect operand is passed to the operator __DELETE.
Error correction: Pass a pointer.

Example of the error:

```plaintext
PROGRAM PLC_PRG
VAR
  a : INT;
  pt : POINTER TO INT;
END_VAR
__DELETE(a);

--> C0242: Operand of __DELETE must be pointer
```

Compiler error C0243

Message: The name used in the signature is not identical to the object name
Possible error cause: The object name differs from the name used in the code.
Error correction: make sure that the names are the same.

Example of the error:

```plaintext
FUNCTION_BLOCK POU
VAR_IN_OUT
  arrin : ARRAY [*] OF INT;
END_VAR
VAR
  arretest : ARRAY [0..5] OF INT;
```

Compiler error C0380

Message: The Operators LOWER_BOUND and UPPER_BOUND are only supported for arrays of variable length.
Possible error cause: One of the two operators LOWER_BOUND or UPPER_BOUND is not used for an array of variable length.
Error correction: Use the operators LOWER_BOUND and UPPER_BOUND only for an array of variable length.
test1: DINT;
test2: DINT;
END_VAR

test1 := UPPER_BOUND(arrin, 0);
test2 := UPPER_BOUND(arrtest, 0);

--> C0380: The operators LOWER_BOUND and UPPER_BOUND are supported only for arrays with variable length.

Compiler error C0509

Message: Multiple assignments for operator '__New' not allowed

Possible error cause: In one line of code, the assignment operator "=" is called a multiple number of times with the __New operator.

Error correction: Program the memory allocation with the __New operator in a separate line of code for each pointer that points to dynamically allocated memory.

Example of the error:

PROGRAM PLC_PRG
VAR
   pbAlpha : POINTER TO BYTE; // Typed pointer to Alpha
   pbBeta: POINTER TO BYTE; // Typed pointer to Beta
   xInit : BOOL := TRUE;
   xDelete : BOOL;
END_VAR

IF (xInit) THEN
   pbBeta := pbAlpha := __NEW(BYTE); // Incorrect code for memory allocation
END_IF

pbBeta := pbAlpha := 16#01;

IF (xDelete) THEN
   __DELETE(pbAlpha); // Frees memory of pointer
END_IF

--> C0509: Multiple assignments for operator '__New' not allowed

Error correction:

PROGRAM PLC_PRG
VAR
   pbAlpha : POINTER TO BYTE; // Pointer to Alpha
   pbBeta: POINTER TO BYTE; // Pointer to Beta
   xInit : BOOL := TRUE;
   xDelete : BOOL;
END_VAR

IF (xInit) THEN
   pbAlpha := __NEW(BYTE); // Allocates memory for Alpha
   pbBeta := __NEW(BYTE); // Allocates memory for Beta
END_IF

pbBeta := pbAlpha := 16#01; // Multiple assignment

IF (xDelete) THEN
   __DELETE(pbAlpha); // Frees memory of pointer
END_IF
 Compiler error C0511

**Message:** The function block '<function block name>' is ABSTRACT and cannot be used as a target for an assignment.

**Possible error cause:** A value was assigned to an abstract function block. The concrete function blocks may have different types and therefore cannot be copied.

**Error correction:** In order to copy the data of the function block, concrete function blocks have to be used.

**Example of the error:**

```plaintext
PROGRAM PLC_PRG
VAR
refAbstract1 : REFERENCE TO AbstractPOU;
refAbstract2 : REFERENCE TO AbstractPOU;
END_VAR

refAbstract1 := refAbstract2;
--> C0511: The function block 'refAbstract1' is ABSTRACT and cannot be used as a target for an assignment.

**Error correction:**
Use the reference assignment REF= to assign the reference refAbstract1 to the same function block as refAbstract2.
```

1.3.1.25 Reference, User Interface

1.3.1.25.1 Objects

Objects in CODESYS provide special functionalities to create applications. Examples: Application, program, function, Library Manager, devices, image pool. Objects are managed in tree structures in the views "Devices", "POUs" and "Modules".

You can add an object to the belonging "tree" by use of the command “Project ➤ Add Object”. The possible insert positions depends on the position within the tree.

Each object provides properties, which can be viewed and accessed with the command from the context menu of the object.

See also

- Chapter 1.3.1.24.3.58 “Operator __NEW__” on page 541
- Chapter 1.3.1.24.6.2.39 “Attribute enable_dynamic_creation” on page 637

Object 'Application'

**Symbol:** 🐤

The object "Application" is presented as a node in the device tree. It comprises objects required for an executable control program.
You can insert an application object below a “PLC Logic” node, that is below a programmable device, or as a child application below an already existing application object (parent application).

Below each application there must be a “Task Configuration”, where you define which program of the application will be called by which task, using which settings.

Additionally, below an application you insert the modules of your control program, for example POU s, global variables lists, library manager. These modules will be only available for this application and its child applications.

Additionally the application may use instances of project-global modules. Project-global modules are managed in the “POUs” view. Using instances of such modules follows the thinking of object-oriented programming.

Below a “PLC Logic” device object you can insert multiple applications. They must have unique names.

![Application Structure Diagram]

**NOTICE!**
An Online Change after a modification of the parent application will remove the child application from the PLC.

If there are multiple applications directly below a device object, you must define which application shall be responsible for the I/O-handling of the device. CODESYS will use the variables of this application for the communication with the target system. Set the application in tab “PLC Settings” of the device editor.

The application to be currently used for online mode operations, must be set "active"; see “App2” in the figure shown above.

You can set special properties for an application in the “Application Build Options” tab of the “Properties” dialog. For example: Activation of dynamic memory allocation.

When downloading the application to the PLC, you can add information on the application content. Again this is to be activated in the “Application Build Options” tab. Then you will be able later to compare the application on the PLC with the application currently active in CODESYS.

If you want to add application-specific information on author, version and an application-specific short description, then modify the common Project Information entries, using the “Information” tab of the application “Properties” dialog.
When you are going to log in to the target system (PLC or simulation) with an application, CODESYS first will check, which applications are currently on the PLC and whether the application parameters on the target match those of the project configuration. Appropriate messages will tell you about mismatches and possible proceedings. During this step you also may remove applications from the PLC.

In the “Applications” tab of the device editor you can see, which applications are currently available on the device. In this tab you can remove applications from the target system. Possibly the list also shows applications, which are not represented by a separate object in the device tree, like for example <Application>_symbols.app. This application contains a symbol list created for the application (see on "Symbol Configuration").

Object 'Device Application'

Symbol: 📁

The “Device Application” object centrally manages all device-global data that can be used by all applications of the device. The applications can be restricted therefore to exclusively control programs.

It depends on the device whether or not the device application is supported.

If the “Device Application” object is selected, then you can insert the following other objects:

- “Application” (on or more applications for the logical mapping of your control program)
- and the following objects for global data and variables that are available for all applications of the device:
  - “Library Manager” (inserted automatically)
  - “Global Variable List”
  - “Network Variable List”
  - “Persistent Variable Configuration” (if supported by the device)
  - “Persistent Variables”
  - “Recipe Manager”
  - “Task Configuration”: In practice, the task configuration of the device application often contains the bus cycle task of the bus master. In order to harmonize the timing of the processing of the POUs with the bus cycle task, you can configure a task of type “External” or “Parent task” in the task configuration of an application. Refer to the help page for “Create device applications”.

Inserting into existing project with conventional application organization

To insert the “Device Application” object into an existing project with conventional application organization, proceed as follows:

- Create a new device entry in the tree.
- Delete automatically generated applications below the “PLC Logic” node.
- Insert a “Device Application” object for the selected “PLC Logic” node.
- Move the necessary objects from the old device structure to the new structure and delete the previous device entry.
In online mode, there are commands in the context menu of the “Device Application” object for simultaneously starting, stopping, and resetting of applications of the device.

Object ‘POU Locations’

This object is available only for specific controllers. It is displayed automatically in the device tree. The object cannot be added or removed manually. The object can be used for mapping the executable code of an application in different code areas on the controller. Specifically small controllers often have limited internal code areas (flash memory). If one or more additional code areas (for example, external flash memory) are available on the controller, then the location of the code POUs of an application can be changed specifically.

If there are no specific requirements, then the code POUs are stored sequentially in the code areas (“default”). This means that the next code POUs are stored in the next areas only when the first code area is filled. In the “POU Locations” editor, you will see the current location of the POUs in the memory areas and you can change them specifically.

Editor ‘POU Locations’

Double-clicking the “POU Locations” object in the device tree of the controller opens the editor. Then it receives the entry “<application>“. After a code generation, all program blocks of the application are displayed with the respective object type, current location in the memory, and code size.

In the “Configured Location” column, you can set one of the memory areas other than the “Current Location” for each POU or library.

In order to move the POUs to the recently configured memory locations, you first have to “Clean” and then “Generate Code” again.

Make sure to pay attention to the messages in the category “POU Locations”. This also shows when a code POU cannot be moved as expected.

<table>
<thead>
<tr>
<th>“Clean”</th>
<th>Deletion of the compile information for the application. Corresponds to the menu command “Build ➔ Clean”. Requirement for moving the POUs to the configured memory locations.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Generate code”</td>
<td>Starting of the code generation for the application. Corresponds to the menu command “Build ➔ Generate Code”. Requirement for moving the POUs to the configured memory locations.</td>
</tr>
<tr>
<td>“Objects”</td>
<td>Objects of the application, including the objects from the referenced libraries</td>
</tr>
<tr>
<td>“Type”</td>
<td>Object type; examples: “Function block”, “Method”, “Library”</td>
</tr>
<tr>
<td>“Current location”</td>
<td>Current memory location of the POU: area_&lt;n&gt;.</td>
</tr>
</tbody>
</table>
### Object 'Persistent Variable Configuration'

Symbol: ![Persistent Variable Configuration](image)

The object can be inserted below a "Device Application" if the device supports static memory areas (static memory) for persistent and retain variables. It is used for segmenting this static memory. This allows for memory mapping for persistent and retain variables in a global memory in the device application and in memory areas for each application.

For devices that support static memory areas, the memory area for the persistent and retain variables is 100% for the device application by default.

**NOTICE!**
Changes to this configuration, as all changes to the device application, require a complete download of all applications.

### Table 27: Editor 'Persistent Variable Configuration'

<table>
<thead>
<tr>
<th>Static Memory Segmentation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Application</strong></td>
</tr>
<tr>
<td><strong>Offset</strong></td>
</tr>
<tr>
<td><strong>Size</strong></td>
</tr>
</tbody>
</table>

**Graphical representation of memory mapping**

Memory mapping for applications is represented graphically. A horizontal bar represents the memory, beginning with offset 0 on the left. Each application appears as a block on the bar according to their values for offset and size. By clicking an application block, the associated values are displayed in the fields above.

**Example:**

![Persistent Variable Configuration](image)
Object 'Alarm Configuration'

The object “Alarm Configuration” is for the management of alarms. It consists of alarm classes, alarm groups and optionally an alarm storage. The alarm configuration does not have a configuration.

If you insert the object, CODESYS also automatically inserts the following predefined objects:

- Alarm class “Error”
- Alarm class “Info”
- Alarm class “Warning”
- Alarm storage “AlarmStorage”

You can use these objects, but you don't have to. You can delete them and replace them by objects that you add yourself.

See also

- Chapter 1.3.1.25.1.6 “Object 'Alarm Class’” on page 715
- Chapter 1.3.1.25.1.7 “Object 'Alarm Group’” on page 718
- Chapter 1.3.1.25.1.8 “Object 'Alarm Storage’” on page 721

Object 'Alarm Class'

An alarm class describes the general properties of an alarm. These include the type of acknowledgement of the alarm and the actions that are to take place automatically if a certain alarm status is attained. In the definition of the alarm class you can also define the font of the message in the visualization elements.

<table>
<thead>
<tr>
<th>“Priority”</th>
<th>Specification of the priority of the alarms in this class (0-255). The priority describes the priority of the alarm condition. 0 represents the highest priority, 255 the lowest.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Archiving”</td>
<td>CODESYS records the alarms in this class. To do this you must create an object “Alarm Storage”.</td>
</tr>
</tbody>
</table>

Table 28: “Acknowledgment”

<table>
<thead>
<tr>
<th>“Acknowledgement method”: Definition of how an alarm is acknowledged.</th>
<th>“REP”: Alarm inactive after rectification of the cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activating 3.</td>
<td>Deactivating 5.</td>
</tr>
</tbody>
</table>

| | “ACK”: Alarm inactive after acknowledgement; acknowledgement method for events |
| | Activating 5. | Confirming 7. |
"REP_ACK": Alarm inactive after rectification of the cause and acknowledgement

"ACK_REP": Alarm inactive after acknowledgement and rectification of the cause

"ACK_REP_ACK": Inactive after optional acknowledgement that the alarm was received, rectification of the cause and acknowledgement that the alarm situation was ended

Alarm status:
- ① Normal: No alarm situation
- ② Active: Alarm situation has occurred
- ③ Wait for confirmation: there is no longer an alarm; acknowledgement has not taken place yet
- ④ Active, Acknowledged: Alarm still exists; acknowledgement already completed

Status transitions:
- ⑤ Activate: Alarm situation occurs ("alarm coming")
- ⑥ Deactivate: Alarm situation ended ("alarm going")
- ⑦ Confirm: Acknowledgement of an alarm that is already ended
- ⑧ ACK: Acknowledgement of an alarm that still exists

Note: CODESYS displays this diagram in a tooltip if you position the mouse pointer over the selection box in the configuration editor.

You frequently have to ensure that the user notices the alarm during operation. Various actions are available in the alarm class for this. The user must confirm (acknowledge) the alarm in order for the alarm to be removed from the alarm list.

"Acknowledge separately"  ✔ During operation the user cannot acknowledge the alarm together with other alarms, but must acknowledge it separately. This prevents the user from inadvertently acknowledging an alarm together with other alarms.

Table 29: “Notification Actions”

You can assign a list of actions to each alarm class that are to be executed as soon as the alarm is subject to a status transition.

<table>
<thead>
<tr>
<th>“Action”</th>
<th>Select one of the following actions by double-clicking the action column:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>“Variable”: Value assignment of a variable</td>
</tr>
<tr>
<td></td>
<td>“Execute”: Execution of a program</td>
</tr>
<tr>
<td></td>
<td>“Call”: Call a function block instance</td>
</tr>
</tbody>
</table>
“Activate”  
“Deactivate”  
“Confirm”  
“ACK”  

The available status transitions depend on the selected “acknowledgement method”.

☑️: The action is executed with the status transition.

“Details”  
Displays a summary of the action. You define the action below the table or edit the action directly in this row.

“Deactivation”:  
Variable via which an application can deactivate the action.

<table>
<thead>
<tr>
<th>Table 30: “Variable/Execute/Call”</th>
</tr>
</thead>
<tbody>
<tr>
<td>You define the parameters of the action in the field below the table. The parameters depend on the selected action:</td>
</tr>
</tbody>
</table>

- **Variable:**
  - “Variable”: Variable to which you assign a value or an expression. In the field on the right: Assigned variable or expression. You can select the variables via the input assistant (....).
  - In the case of boolean variables you can use the placeholder ALARM, in the case of integer variables the placeholder STATE. In the case of string variables you can enter any IEC literal (e.g. "too high").
    - ALARM: Status (TRUE or FALSE) of the alarm of this alarm class that was last activated/deactivated
    - STATE: Status of the alarm of this alarm class that last changed its status. (0: Normal, 2: Active, 3: WaitingForConfirmation, 4: ActiveAcknowledged)

- **Execute:**
  - “Executable file”: Path and file name of the executable file on the controller.
  - “Parameter”: One or more parameters that you add to the call. You separate several parameters by a space.

- **Call:**
  - “Function block instance”: Function block that is called. The function block must implement the interface IAlarmNotifiable (AlarmManager.library). The desired action on a change of state is implemented in the method Execute.
  - “Additional parameter structure”: If the function block requires an additional parameter structure, the structure members are listed in this table and can be filled here. An additional parameter structure is defined in the function block with the attribute AlarmManagerAdditionalData.

  **Example:** The function block has the attribute {attribute 'AlarmManagerAdditionalData' := 'StructEmailParams'}.

  The structure employed must consist of scalar components or components of the type POINTER TO. CODESYS does not support the ARRAY data type or user-defined data types.

  **Note:** Using the attribute {attribute 'AlarmManagerMandatoryParameter'} you can identify structure members as mandatory parameters.
Table 31: “Presentation Options for Alarm Table/Alarm Banner”

<table>
<thead>
<tr>
<th>“Status”</th>
<th>Alarm status. The available statuses depend on the selected “acknowledgement method”.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Font”</td>
<td>The standard dialog for the selection of a font or color is opened with the button.</td>
</tr>
<tr>
<td>“Background color”</td>
<td>Background color for the alarm message</td>
</tr>
<tr>
<td>“Bitmap”</td>
<td>You can add a bitmap by entering the bitmap ID. If no image file is assigned to this ID yet, the standard file search dialog opens. After having selected a file, the bitmap definition of the image pool “GlobalImagePool” is added.</td>
</tr>
<tr>
<td>“Transparent”</td>
<td>Activate this option if the bitmap has a transparent color.</td>
</tr>
<tr>
<td>“Transparent color”</td>
<td>Color that is to be displayed transparently. Relevant only if the “Transparent” option has been activated.</td>
</tr>
</tbody>
</table>

- % Chapter 1.3.1.9.21.2 “Configuring the alarm management” on page 258
- % Chapter 1.3.1.25.1.7 “Object ‘Alarm Group’” on page 718
- % Chapter 1.3.1.25.1.8 “Object ‘Alarm Storage’” on page 721

Object ‘Alarm Group’

Use alarm groups for organizing individual alarms in the alarm management of an application. Each alarm is assigned to one alarm group only. To configure an alarm group, insert an “Alarm Group” object below an “Alarm Configuration” object in the device tree.

A common deactivation variable can be assigned to all alarms that are assigned to a group. You can create a hierarchical structure of alarm groups in the device tree with the help of folder elements.

The dialog of the alarm group editor includes a table listing all alarms of the group. The dialog displays the basic settings for the entire group, such as deactivation,archiving, and associated text list, as well as the properties of the individual alarms. You can edit the values in the list. Note the option of exporting and importing alarms to and from a CSV file (see below).

Dialog ‘Alarm Group’

<table>
<thead>
<tr>
<th>“Text list”</th>
<th>Name of the text list where the alarm message text is saved (see below: “Message”). CODESYS generates the list automatically when you create an alarm group. You can also select an existing text list here.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Archiving”</td>
<td>Selection of the alarm storage object for the alarm group. When you specify an alarm storage object, CODESYS activates the alarm storage.</td>
</tr>
<tr>
<td>“Deactivation”</td>
<td>Boolean variable that deactivates all alarms in this group. CODESYS does not trigger these alarms any longer, even if the alarm condition is fulfilled. Alarms that are already active are not affected by this.</td>
</tr>
</tbody>
</table>
Table 32: Table of alarms

You enter the properties of the individual alarms in the corresponding table columns. Depending on the selected observation type, CODESYS sets additional parameters in input fields below the table.

<table>
<thead>
<tr>
<th>“ID”</th>
<th>This unique ID corresponds to the ID of the associated text list. You can change the ID in the “ID” field of the table. The ID must always be unique within the alarm group. A change of the ID in the alarm table also directly causes a change in the text list, and the other way around.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Observation type”</td>
<td>Drop-down list of observation types. Depending on the type, different editing fields are available below the table that define the condition for the alarm. The fields define an expression that triggers the alarm. See the following table.</td>
</tr>
<tr>
<td>“Details”</td>
<td>This field shows the configuration settings (defined in the fields below the table) for the selected alarm type. You can also enter the condition directly into the field. If you input an expression that does not match the currently selected observation type, the type is automatically adapted.</td>
</tr>
<tr>
<td>“Deactivation”</td>
<td>Variable for deactivating the alarm (optional).</td>
</tr>
<tr>
<td>“Class”</td>
<td>Assigned alarm class.</td>
</tr>
<tr>
<td>“Message”</td>
<td>Required entry of a message text (message) that CODESYS will display in the “Alarm Table” visualization element when the alarm occurs. The text entered here is transferred automatically by CODESYS to the text list for the alarm group. You can insert line breaks by pressing [Ctrl]+[Enter]. CODESYS supports the following placeholders, which are replaced by the actual value at runtime:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Placeholder</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;DATE&gt;</td>
<td>Date of the change to the present status.</td>
</tr>
<tr>
<td>&lt;TIME&gt;</td>
<td>Time of the last status change.</td>
</tr>
<tr>
<td>&lt;EXPRESSION&gt;</td>
<td>Expression (defined within the alarm) that triggered the alarm.</td>
</tr>
<tr>
<td>&lt;PRIORITY&gt;</td>
<td>Priority of the alarm (defined in the alarm class).</td>
</tr>
<tr>
<td>&lt;TRIGGERVALUE&gt; *</td>
<td>Value that caused the alarm condition to become true.</td>
</tr>
<tr>
<td>&lt;ALARMID&gt;</td>
<td>Alarm ID as displayed in the first column of the alarm table.</td>
</tr>
<tr>
<td>&lt;CLASS&gt;</td>
<td>Name of the alarm class (defined in the alarm).</td>
</tr>
<tr>
<td>&lt;ALLDEFAULT&gt;</td>
<td>Complete information about the alarm is output.</td>
</tr>
<tr>
<td>&lt;CURRENTVALUE&gt; *</td>
<td>Actual value of the monitored variable.</td>
</tr>
<tr>
<td>&lt;LATCH1&gt; *</td>
<td>Value of the first latch variable at the time when the alarm was triggered.</td>
</tr>
<tr>
<td>&lt;LATCH2&gt; *</td>
<td>Value of the second latch variable at the time when the alarm was triggered.</td>
</tr>
<tr>
<td>&lt;ALARM&gt;</td>
<td>TRUE in the case of the alarm status ‘Active’, FALSE with every other alarm status.</td>
</tr>
<tr>
<td>&lt;STATE&gt;</td>
<td>Alarm status: 0 = ‘normal’, 1 = ‘active’, 2 = ‘waiting for ACK’, 3 = ‘active, acknowledged’ (still active and already acknowledged).</td>
</tr>
</tbody>
</table>
* For `<TRIGGERVALUE>`, `<CURRENTVALUE>`, and `<LATCHn>`, you can also use formatting specifications, such as those that are valid for the C function "printf" (example: "The value is `<CURRENTVALUE> %d`").

By default, only one column is available for message text. You can add more columns from the context menu which will be available in the "Data type" property for column configuration of the "Alarm table" and "Alarm banner" visualization elements.

"Min. pending time": Defines the minimum duration for fulfilling the alarm condition so that CODESYS triggers the alarm. In this way, CODESYS can inhibit alarm conditions that occur only for a short time.

IEC 61131 compliant format (example: `t=#2ms`).

"Latch var 1", "Latch var 2" The latch variables are used to record additional values when the alarm becomes active. A latch variable has to be a scalar type (8-byte) or a STRING or WSTRING type. CODESYS records a latch variable or a latch expression when the alarm becomes active. In this way, it allows additional information about the alarm to be provided.

Note: With the respective configuration of the "Alarm table" element or "Alarm banner" element, you can filter the occurring alarms in the visualization by the contents of the latch variable.

Example: When monitoring a motor speed, the temperature and the current are additionally recorded.

By default, columns are available for two latch variables. You can add more columns from the context menu which will be available in the "Data type" property for column configuration of the "Alarm table" and "Alarm banner" visualization elements.

"Higher prio. alarm" When the alarm is triggered, it can be acknowledged by triggering another alarm.

Example: A temperature monitor should issue a warning at > 60 °C and an error at > 90 °C. If the temperature rises, then the warning is displayed starting at 60 °C. At 90 °C and higher, the alarm for the error is triggered (this automatically acknowledges the 60 °C warning).

Table 33: Monitoring types

<table>
<thead>
<tr>
<th>Monitoring type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Digital&quot;:</td>
<td>&quot;Expression&quot;: Expression to be monitored. On the right side of the expression for the comparison. In the center, you select the desired comparison operator (&quot;=&quot; or &quot;&gt;&quot;).</td>
</tr>
<tr>
<td>&quot;Upper limit&quot;:</td>
<td>&quot;Expression&quot;: As described for &quot;Digital&quot;, but with the compare options &quot;&gt;&quot; or &quot;&gt;=&quot;, and optionally a &quot;Hysteresis in %&quot;.</td>
</tr>
<tr>
<td>&quot;Lower limit&quot;:</td>
<td>&quot;Expression&quot;: As described for &quot;Digital&quot;, but with the compare options &quot;&lt;&quot; or &quot;&lt;=&quot; and optionally a &quot;Hysteresis in %&quot;.</td>
</tr>
<tr>
<td>&quot;Inside range&quot;:</td>
<td>&quot;Expression&quot;: Expression to be monitored. &quot;Range&quot;: CODESYS triggers the alarm when the monitored expression is within the range defined here. The left field defines an expression for the lower limit of this range. The right field defines an expression for the upper limit. The expression to be monitored is displayed in the field in-between. You have to set the comparison operators accordingly. You can define a &quot;Hysteresis in %&quot; optionally.</td>
</tr>
</tbody>
</table>
### “Outside range”:

“Expression”: Expression to be monitored.

“Range”: CODESYS triggers the alarm when the monitored expression is outside the range defined here. The left field defines an expression for the lower limit of this range. The right field defines an expression for the upper limit. The expression to be monitored is displayed in the field in-between. You have to set the comparison operators accordingly. You can define a “Hysteresis in %” optionally.

### “Change”:

“Expression”: Expression to be monitored. CODESYS triggers the alarm when its value changes.

### “Event”:

In this case, the application triggers the alarm (event alarm) by using functions from the library `AlarmManager.library`.

1) For this observation type, you can monitor the specified expression as absolute or relative. Absolute means that the limit value is defined by a fixed value or a variable that returns a fixed value. Relative means that the limit value depends on an expression; for example: upper limit: “Variable x >= 0.9 * y”.

“Hysteresis in %”: When you specify a hysteresis, the alarm condition is fulfilled until a certain deviation from the specified limit value is reached. The size of the deviation is specified as a percentage [%] of the limit value. Example: Upper limit: `i_temp >= 30` Hysteresis: 10%. The alarm is active when the variable `i_temp` reaches or exceeds the value 30. The alarm is no longer active if the value falls below 27.

The context menu includes the following commands for adding and removing additional columns for messages and latch variables:

- “Add message column”
- “Remove message column”
- “Add latch var column”
- “Remove latch var column”

### Exporting and importing of alarms

In the context menu of the alarm table you will find commands for the export and import of alarms to and from a CSV file:

- **“Export Alarms”**: The command opens the default dialog for saving a file in the file system. The default file type is `Alarm Group Export File (*.csv)`. This way you can export the current alarm list to a CSV file.
- **“Import Alarms”**: The command opens the default dialog for searching for a file in the file system. The default file type is `Alarm Group Export File (*.csv)` for describing alarm definitions.

### Object ‘Alarm Storage’

**NOTICE!**

In case of a reset (origin), CODESYS clears the alarm storage file.

In “Alarm Storage”, you define the settings for the database file where CODESYS saves the alarms that occur. You can insert the object only once below an alarm configuration.
There is exactly one memory file located in a database. As an option, CODESYS saves this file in a file directory on the controller. You cannot change the name it is derived from the application name according to the following convention: `<application name>.alarmstorage.sqlite`. The alarm classes and alarm groups define whether or not the memory file should be used.

<table>
<thead>
<tr>
<th>“Subdirectory:”</th>
<th>Name of a subdirectory on the PLC where CODESYS saves the memory file (optional).</th>
</tr>
</thead>
<tbody>
<tr>
<td>“No limit”</td>
<td>No limit for the file size for the alarm storage.</td>
</tr>
<tr>
<td>“Maximum number of records”</td>
<td>Number of recorded entries that CODESYS saves. When this number is reached and a new entry is queued in the ring buffer, CODESYS deletes the oldest entry.</td>
</tr>
<tr>
<td>“Maximum storage size”</td>
<td>Maximum size of the memory file with specification of the unit. CODESYS converts this size implicitly into an approximate maximum number of entries that can be saved in the file (ring buffer).</td>
</tr>
<tr>
<td>“Circular buffer”</td>
<td>For display purposes only (not editable).</td>
</tr>
</tbody>
</table>

- : Memory in a circular buffer
- : Memory in an unlimited buffer

The records that CODESYS saves in the database can be displayed in the “Alarm Table” visualization element.

Command 'CSV Export of Alarm Storage'

**Function:** This command opens the “Alarm Storage Export Configuration” dialog box.

**Call:** Context menu of the “Alarm Storage” object.

**Requirements:** The application is in online mode with an alarm configuration. An alarm storage is configured.

This command opens the “Alarm Storage Export Configuration” dialog box.

**Dialog box 'Alarm Storage Export Configuration' - 'Basic Settings'**

**“Export file”:** Path to the generated CSV file in the file system

**Table 34: “Alarms to Export”**

| “Export all” | All listed alarms are exported. |
| “Export alarms in timestamp range (timestamp activated)” | Defined time range for the export of the listed alarms. This refers to the timestamp when the alarm was activated. The min./max. time stamps that are available in the alarm storage or were the last ones to be used in an export are shown by means of “From” and “Until”. When selecting the time range, the smallest unit is one second. |
Table 35: “Language”

| “Language” | The drop-down list includes all languages that are available in text lists for alarm texts, as well as the default language (<Standard>). |

Dialog box
'Alarm Storage Export Configuration' - 'Advanced Settings'

Table 36: “Sort by Time Stamp Activated”

| “Ascending” | Sort order by the time stamp when the alarm was activated |
| “Descending” | |

Table 37: “File Format”

| “Formatted values and timestamps” | The time stamps are formatted with the date and time format as defined below. REAL and LREAL values are formatted in number format. |
| “Raw data from alarm storage file” | The time stamps and values are written unformatted to the CSV file, as they appear in the alarm storage. Alarms, alarm groups, and alarm classes are written in non-readable form to the CSV file as internal IDs. |

Table 38: “Formatting Options”

| Defines the formatting of the entries in the CSV file. Possible only if the “Formatted values and timestamps” data format is selected. |
| “REAL format (printf syntax)” | Setting: “%.1f” |
| “Date format” | The settings are applied from the system control. |
| “Time format” | The settings are applied from the system control. |

Table 39: “Separator”

| “Semicolon” | The entries in the CSV file are separated by a semicolon. |
| “Comma” | The entries in the CSV file are separated by a comma. |
| “Tab” | The entries in the CSV file are separated by a tab. |

| “Local time” | Available only if the “Formatted values and timestamps” data format is selected. |
| ☑: The time stamps are written to the CSV file in local time. |
| ☐: The time stamps are written to the CSV file in universal time coordinated (UTC). |

Object ‘Data Source Manager’

Symbol: 

This object is used as a node for managing the data sources below it. At least one data source must be available. An application with the data source manager communicates with remote devices.

---

**NOTICE!**

The remote controller should be running and the remote controller application loaded and started.

---

See also
- § Chapter 1.3.1.25.1.9 “Object ‘Data Source Manager’” on page 723
- § Chapter 1.3.1.25.1.10 “Object ‘Data Source’ - Tab ‘Variables’” on page 725

---

`Dialog 'Initialize data source wizard - Provider settings' (for 'CODESYS Symbolic')`

The settings of this dialog are described in the following section: Object ‘Data source’ - Tab ‘Communication’.

This dialog is used for the initial configuration of the connection when you select “CODESYS Symbolic” as the data source type. The communication takes place by means of symbolic monitoring. The configuration can be modified later in the editor of the data source in the “Communication” tab.
See also
- "Tab 'Communication' for CODESYS Symbolic" on page 728

The settings of this dialog are described in the following section: Object 'Data source' - Tab 'Communication'.

This dialog is used for the initial configuration of the connection when you select "CODESYS ApplicationV3" as the data source type. The communication takes place by means of address monitoring.

See also
- "Tab 'Communication' for CODESYS ApplicationV3" on page 732

The settings of this dialog are described in the section "Object 'Data source'", heading "Dialog 'Choose variables'".

Function: You can select the variables for the data transfer from the variables of the remote PLC. By clicking "Exit", the data source is initialized and the data types and variables (data interface) are declared below the folder "DataSources_Objects". You can modify the settings in the editor of the data source object.

Call: Automatic

See also
- "Dialog 'Choose Variables" on page 726

Object 'Data Source' - Tab 'Variables'

Symbol:

The object (type "Data source") manages the access to the data of a remote device in the tabs "Variables", "Type mappings", "Communication", and "General and diagnosis". The status bar which is always visible notifies you about the data source type and the most important communication settings.

See also
- Chapter 1.3.1.10 "Working with control networks" on page 270

- Chapter 1.3.1.25.1.13 "Object 'Data Source' - Tab 'General and Diagnosis'" on page 734

Tab 'Variables'

The variables for the data originating from the remote source are declared in the global variable list <name of data source>. The GVL acts as a data interface for remote control and it is located below the application and folder "DataSources_Objects".

In this way, you can develop a local application offline based on the symbol information without a connection to a data source.

"Update variables" Establishes a connection to the remote device and opens the dialog "Choose variables".

2020/12/10 3ADR010583, 1, en_US 725
<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>“Remote variable”</strong></td>
<td>Variable in the remote PLC</td>
</tr>
</tbody>
</table>

**Dialog 'Choose Variables'**

**Symbol:** 🔄

**Function:** This dialog lists the remote variables that are accessed by means of the configured connection.

**Call:** Click “Update variables” in the “Variables” tab.

**Requirement:** The remote PLC is running. The control application is downloaded.
### Variables

The remote variables are listed in the tree view. The top node is identified by the remote application name. Its variables are listed below that. Structured data is listed with all of its subordinate elements.

**Example:** `appControl_A`

- The variable is selected for transferring to the local device. When the variable is structured, it is accepted with all subelements. If the variables themselves are subelements, then only this subelement is accepted without accepting the structure completely.

- Red font: When a variable is displayed in a red font, the variable is not available (anymore) in the remote PLC.

- Note: You can remove the variable from the list by clicking “Uncheck unavailable variables”.

  - The variable is not selected for the transfer.

  - The variable has expandable elements. By clicking the symbol, the variable is extended by their elements.

  **“Insert elements structured”**

  - The selected variables are transferred with this structure if they are structured.

  - The variable is transferred unstructured with a scalar data type.

  **“Uncheck unavailable variables”**

  Requirement: The link is visible when previously are no longer available in the variable available on the remote PLC. These variables are marked in red in the window above. The symbol configuration or the application presumably changed in the remote PLC.

  By clicking the command, the red variables are removed from the drop-down list.

### Status bar

Information about the data source type and the most important communication settings

If the communication is established by means of the data source type CODESYS Symbolic, then the name of the data source type, the connection type, and the network name of the remote device are displayed.

If the communication is established by means of data source type CODESYS ApplicationV3, then the name of the data source type, the storage location of the remote project, and the instance name of the remote application.

**Example:** `CODESYS ApplicationV3 (D:\Projects\Project_A): Project_A.App_A`

### Object 'Data Source' - Tab 'Type Mappings'

The tab lists the non-scalar data types as they are currently available in the “DataSources_Objects” folder. You can edit or delete the data type declaration by selecting a data type and then the declared elements in the lower window. Moreover, you can modify the name, reset access rights, map another type, or select another remote variable.

See also

- Chapter 1.3.1.10.4.2 “Editing data source variables” on page 288

### Tab ‘Type Mappings’
"Local type" | Data type in the local application.
---|---
"Create or map" | ● Mapping to a new created data type. Declared in the "DataSources_Objects" folder.
| ● Mapping to an existing data type
| ● Mapping to a type-conforming data type. Declared in the "DataSources_Objects" folder.
"Mapping name" | Name of the data type
"Remote type" | Data type of the remote PLC

List with the subordinate elements of the selected data type.

| "Local variable" | Local variable name of the element of the selected data type |
| "Access rights" | Access rights to the element |
| "Type mapping" | Data type of the element |
| "Remote variable" | Remote variable name of the element of the selected data type |

[Del] Removes the selected element.

Object 'Data Source' - Tab 'Communication'

The tab includes the communication settings for the remote data source. When adding a data source, a data source type was selected, and the communication settings to the data source were configured depending on it. Then communication settings are managed and edited on this tab. The contents of the tab vary according to the data source type and connection.

See also
- Chapter 1.3.1.10.4.1 “Adding initial data sources” on page 282
- Chapter 1.3.1.25.1.9 “Object 'Data Source Manager'” on page 723

Tab 'Communication' for CODESYS Symbolic

This is the tab when CODESYS Symbolic has been selected as the data source type in the initial configuration. For an active connection, communication takes place by means of symbolic monitoring. Instead of establishing a connection, a reference can be made to a symbol file where the required variable information is stored. In this way, you can develop a local application offline based on the symbol information without a connection to a data source.

| "Variable information" | Source of the variable information |
| "From connection settings" | A connection is established actively according to the communication settings specified below ("Connection type" and "Connection settings"). The variable information is read from the remote control application. |
| "<device name>.<application name>.symbol configuration" | The variable information is read from the symbol configuration, which is part of the active project and located in the device tree at the object of the remote controller below the application. At this time, no active connection is established. |
“From symbol file” The variable information is read from a symbol configuration file that is stored on the development system. Specify this data in the input field “Choose symbol file”. At this time, no active connection is established to a controller.

“Choose symbol file” Path of the symbol file
Requirement: “From symbol file” is set in “Variable information”.
The symbol file is stored on the development system and contains the required variable information. By default, a symbol file path is created in the project directory in the following structure: <project folder>\<project name>.<device name>.<application name>.xml.
Example: D:\Projects\Project_A\VisualizeWithHMI.Device.Application.xml
Note: If the “Alarm table” element or “Trend” element is used in the visualization, then the symbol file required for symbolic access and the respective project must both be saved in the same folder. The project contains the configuration for the alarm table element or the trend recording for the trend element. This is the default case for automatically generated symbol files.
Example: D:\Projects\Project_A\VisualizeWithHMI.project

“Connection type” Connection type between the remote PLC and the local device. Depending on the selected connection type, the following settings below change.
Note: If possible, avoid a direct connection without a gateway.

“CODESYS V2” The devices are located in the same network. The V2 runtime system on the remote PLC provides a communication interface.

“CODESYS V2 (via Gateway)” The devices are not located in the same network. They are connected via a V2 gateway.

“CODESYS V3” The devices are located in the same network. The V3 runtime system on the remote PLC provides a communication interface. Default

“CODESYS V3 (via Gateway)” The devices are not located in the same network. They are connected via a V3 gateway.

</tr>
</thead>
</table>
| Requirement: The setting “Type” is “Login using the following credentials”.

Tab ‘Communication’ for CODESYS ApplicationV3

This is the tab when CODESYS ApplicationV3 has been selected as the data source type in the initial configuration. The communication takes place by means of address monitoring.
**“Select the project type”**
- “Current project”: The control application is part of the current project.
- “Other project”: The control application is stored as a separate project and not part of the current project.

**“Choose file”**
Name and path of the project that the application contains for the remote PLC.
Example: D:\plcs\plc_A.project
Requirement: The “Select the project type” is “Other Project”.

Window that lists the detected control variables in a tree view. When the control data is displayed here, a connection can be established.

---

**Table 46: “Target Device”**

| **“Automatic configuration”** | CODESYS attempts to read the configuration automatically from the source project. At this time, the communication settings of the device are accepted in the active network path. They are configured in the editor of the device in the “Communication” tab. |
| “[undetermined]”: No configuration can be read. |

**“Manual configuration”**

**“Dynamic from variable”**
The communication parameters are configured at runtime by means of an IEC variable of the application of data type `DatasourceAppV3.ConnectionSetup`.  
 Opens the input for selecting the IEC variables for dynamic configuration.  
 The data type `DatasourceAppV3.ConnectionSetup` (struct) is defined in the `Datasource ApplicationV3 Access` library. For the configuration, the structure member `xDataValid` first has to be set to `FALSE`. If the address data has been specified, then `xDataValid` has to be set back to `TRUE`.  
 Use case: The communication parameters are not available yet when a project is being created.

**“Use device address”**
The communication takes place through the address specified here.

**“From device”**
By clicking “From device”, CODESYS automatically enters the data of the connected data source device as it is configured in its “Communication Settings”.

**“Derive device address automatically”**:  
The communication takes place through the address that is defined in the “Communication Settings” of the target device.  
Note: Recommended setting

**“Use device address”**
The address of the connected data source device is entered as configured in its communication settings.  
Example: [057B]

The following cases lead to an incorrect address:
- The gateway for communication with the device is running on a computer with multiple addresses.
- The device where the application is running with the data source manager has multiple IP addresses or other interfaces (USB, serial, etc.) for communication with CODESYS.
- The CODESYS runtime system and the gateway are not located in the same Ethernet subnet.  
  Hint: Use the “Automatic configuration” setting.

**“Search for the target device using the network scan”**
Possible search criteria for the device:

**“Node name”**
Example: WST06

**“Target type”**
Example: 4096
"Target ID"  Example: 0000 0001

"Target version"  Example: 1.0.0.0

"Network location":
- "Direct child of the data sources plc": The scanned remote PLC has an address that is running with the address of the local controller (of the data source manager).
  Example: Data sources PLC: 0000.0001; remote source PLC: 0000.0001.0001
- "Direct child of node with address": Specify the address of the parent node
- "Direct child of the data source plc or of the node with address": Combination of both options above.

"Search type":
- "First found device": The first controller in the device tree is selected that fulfills the specified criteria.
- "Exactly found device": The controller is selected that fulfills the specified criteria.
  Note: The data source manager waits until the network scan is complete. This usually takes about 10 seconds.

Table 47: “Login Configuration”

If a user management is configured on the remote PLC, then valid access data is required at login.

"Type"

- “Login using the following credentials”: The access data is hard-coded in the “User name” and “Password” settings. They are used at each connection attempt.
- “Login using the credentials determined at runtime”: At runtime, a dialog prompts for the name and password.

"User name"  Example: max.smith
  Requirement: The setting “Type” is “Login using the following credentials”.

"Password"  Example: ...
  Requirement: The setting “Type” is “Login using the following credentials”.

"Advanced"  
  ☑: The following settings are visible.
  Requirement: “Automatic configuration” is activated.

"Default communication buffer"  Example: 50000

Object ‘Data Source’ - Tab ‘General and Diagnosis’
The “General and Diagnosis” tab provides information about the status of the data source communication.

Tab ‘General and Diagnosis’
Table 48: “Update Configuration”

"Update rate (ms)"  Example: 200
Object 'DUT'

Symbol: ⚫ for DUT without text list support; ⬇️ for DUT (type: enumeration) with text list support

A DUT (data unit type) describes a user-specific data type. You can add a “DUT” object below the application or in the “POUs” view.

When adding the object, you can specify definition (see below: Dialog “Add DUT”).

Syntax

```
TYPE <identifier> : <DUT component declaration>
END_TYPE
```

The component declaration depends on the selected type, structure, or enumeration.

Example:

```
The following two DUTs define the structures struct1 and struct2, in which struct2 extends struct1. This mean that struct2.a can be used to access the a variable.

    TYPE struct1 :
        STRUCT
            a:INT;
            b:BOOL;
        END_STRUCT
    END_TYPE

    TYPE struct2 EXTENDS struct1 :
        STRUCT
            c:DWORD;
            d:STRING;
        END_STRUCT
    END_TYPE
```

Dialog 'Add DUT'

Function: You use this dialog log for configuring a new DUT. The DUT (Data Unit Type) describes a user-specific data type.

Call: Menu bar “Project ➔ Add Object ➔ DUT”; context menu of the application object.

| “Name” | DUT name |
Table 50: “Type”

<table>
<thead>
<tr>
<th>“Structure”</th>
<th>The DUT consists of a structure of various data types. “Extends”: The structure extends an existing structure. In this way, the definitions of the extended DUT are automatically valid in the new DUT.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Enumeration”</td>
<td>The DUT consists of a series of integer constants. For declaration syntax, please refer to the help page for &quot;Enumerations&quot;. “Add text list support”: The text list support allows the localization of enumeration components. In addition, both the symbolic and numeric enumeration values are shown in the text display of a visualization element. When an enumeration variable with text list support is specified in the “Text variable” property of a visualization element, the enumeration variable obtains the additional &lt;enumeration name&gt;. By clicking the buttons on the right edge of the editor, you can switch between “Textual view” and “Localized view” (text list). The DUT object is found as the symbol in the device tree and in the “POUs” view. Example: You use the PLC_PRG.enVar variable (type myEnum). myEnum is a DUT with text list support. Then the entry in the property editor looks like PLC_PRG.enVar &lt;myEnum&gt;. If the enumeration type is modified in the application, then you are prompted to allow CODESYS to update the affected visualizations accordingly. Note: Text list support can be added or removed at any time for an existing enumeration object. For this purpose, the commands “Add Text List Support” and “Remove Text List Support” are provided in the context menu of the object.</td>
</tr>
<tr>
<td>“Alias”</td>
<td>Definition of an alias for a “Base type”. You can type in the base type directly or select it using the input assistant or array assistant.</td>
</tr>
<tr>
<td>“Union”</td>
<td>All components reserve the same storage space for this data type. The memory requirement of a union is determined by the memory requirement of its &quot;largest&quot; component.</td>
</tr>
</tbody>

Object ‘External File’

An “External File” is any file that you add to the project in the “POUs” view or “Devices” view. Click “Project ➔ Add Object” to open the “Add External File” dialog and define how the file belongs to the project.

An external file which was inserted in the “POUs” view is never downloaded to the controller.

An external file which was added in the “Devices” view is always downloaded to the controller when an online change or a download is performed due to an IEC code change.

When an external file is downloaded to the controller, it is not updated in the project.

Dialog ‘Add External File’
“File path” | The button opens a dialog for selecting a file in the local file system.
---|---
“Name” | Object name for the file in CODESYS. If you do not type anything, the file will have its previous name.

Table 51: “File Handling”
| “Remember the link” | The file is available in the project only as long as it exists in the defined file path. |
| “Remember the link and embed into project” | CODESYS saves an internal copy of the file in the project, as well as the link to the defined file path. The update option selected below applies as long as the external file exists there. Otherwise CODESYS uses the version saved in the project. |
| “Embed into project” | CODESYS saves only one copy of the file in the project. There is no longer a link to the external file. |

Table 52: “Change Tracking”
| “Reload the file automatically” | If the external file changes, then CODESYS updates the file in the project. |
| “Prompt whether to reload the file” | If the external file changes, then a dialog prompt opens whether CODESYS should also update the file in the project. |
| “Do nothing” | The file remains unchanged in the project, even if the external file changes. |

| “Display File Properties” | Clicking this button opens the default “Properties of <file name>” dialog, which you can also open in the Windows file system by right-clicking the file. |
| “Open” | The file object is inserted into the device tree (“Devices” or “POUs” view) and opened in the editor for the matching file format. |

Object ‘C Code Module’

Symbol: 

This object is for integrating C-code modules into a CODESYS project. You define the necessary configuration parameters on the tabs of the object.

The object “C Code Module” is added to the application in the device tree. Together with the object, CODESYS automatically appends the folders “Extensions”, “IEC Interface” and “Source Files”.

(1) “C Code Module”
(2) “Extensions”
(3) “IEC Interface”

(4) “Source Files”

You can add the following objects to a “C Code Module”:

- “C Code File”
- “DUT”
- “POU”

**Tab 'Includes & Defines'**

</tr>
</tbody>
</table>
Object ‘C Code File’

Symbol: 🗄

This object contains the C-code for the C-integration in its editor.

The C-code files can be created in the following ways:

- You add an object “C Code Module” to the application and, in the dialog box “Add C Code Module”, you specify a source directory containing C-code files; you import this directory into CODESYS.
- You add an object “C Code File” to a “C Code Module” and in doing so you specify a C-file in the dialog box “Add C Code File” that you import into CODESYS.
- You add an object “C Code File” to a “C Code Module” and in doing so you specify the name for a new C-file in the dialog box “Add C Code File”. As opposed to the two other methods you create an empty file by doing this.

Possible file formats of a C-code file:

- *.c
- *.ccp
- *.h
- *.hpp

You can make simple changes to the C-code in the text editor.

Objects for C-stubs:
'iec_external.c' and 'iec_external.h'

If you create C-stubs with the command “Create Stub Implementation in C”, these are stored in the objects “iec_external.c” and “iec_external.h” of the “Extensions” folder. The object “iec_external.c” contains the C-stubs, “iec_external.h” contains the associated declarations.

NOTICE!

The object “iec_external.c” contains a marked range for header includes (range between /** INCLUDE SECTION BEGIN **/ and /** INCLUDE SECTION END **/). You may not change this range!

Object ‘Device’ and generic device editor

Symbol: 

A device object represents a type of hardware; examples: control device, fieldbus node, bus node, drive, I/O module, monitor. The arrangement of the device objects in the device tree, that is the view “Devices” in CODESYS, maps the hardware structure. In the device object configuration editors inter alia you connect the controller I/Os with project variables.

Use command “Add Device” or “Insert Device” to insert a device object in the device tree. Depending on the insert position CODESYS always offers the currently matching devices.

A double-click on a device object in the device tree opens the associated device editor. The editor provides generic and device-specific tabs for the device configuration.

See also
Generic device editor

The generic device editor contains tabs for the configuration of a PLC device in CODESYS. Additionally there are device-specific tabs, so that the configuration editor consists of many different dialogs, depending on the device.

The editor opens after a double-click the device object in the device tree ("Devices" view).

You can make general settings for a device editor in the CODESYS “Options” in the “Device Editor” category. For example, you can show and hide the tabs of the generic device editor.

A device editor is given the name of the device. The following tabs of the generic device editor can be included:

- “Communication”: Configuration of the connection between the development system and a programmable device (PLC). Not available in the case of pure I/O devices.
- “Applications”: List of the applications on the controller.
- “<device> Parameters”: Display and configuration of device parameters.
- “Files”: Configuration of the file transfers between a host file system and the device.
- “Log”: Display of the PLC log file.
- “PLC Settings”: Configuration of the handling of the I/Os: which application, behavior in the stop state, updating, bus cycle options, etc.
- “PLC Shell”: Text-based control monitor for interrogating certain information from the controller.
- “Users and Groups”: User management with regard to the device at runtime.
- “Access Rights”: Rights for access to objects and files on the device.
- “Symbol Rights”: Access rights of individual user groups to symbols (symbol sets) on the device.
- “Task List”: Overview of all inputs and outputs, which are assigned to tasks – useful for troubleshooting.
- “Status”: Device-specific status and diagnostic messages.
- “Information”: General information about the device (name, vendor, version etc.)

- % Chapter 1.3.1.8 “Configuring I/O links” on page 155

Tab 'Communication Settings'

In this tab of the generic device editor, you define the connection between CODESYS and the device where your application should run.

If you prefer the classic mode of display for the dialog, then select it in the CODESYS “Options” (“Device Editor” category).

You select a gateway and a target device from the list boxes. The possible selections depend on the entries in the “Manage gateways” and “Manage favorite devices” dialogs (see the “Gateway” menu).

You can also type in select the target device directly with the IP address (example: “192.168.101.109”), device address (example: “[056D]”), or device name (example: “MyDevice”). After the device is entered successfully, CODESYS searches for the device in the network of the gateway.
The option of searching by device name requires unique device names in the network.

The filled circle on the lower right corner of the gateway symbol provides information about the connection status:

- Red: CODESYS cannot establish the connection.
- Green: The connection is established.
- Black: The connection status is unknown.

Some communication protocols allow regular checking of the gateway so that the status cannot be displayed.

Clicking the filled circle of the target device starts a network scan for the device. This works only if the network is not already being scanned.
“Scan network” This button opens the “Select Device” dialog. It lists all configured gateways with the associated devices. You can select one target device from this list. Refer to the description of the classic view below for details about this dialog.

“Gateway” This menu includes the following commands:
- “Add New Gateway”: Opens the “Gateway” dialog for defining a new gateway channel.
- “Manage Gateways”: Opens the “Manage Gateways” dialog with an overview of all gateways. You can add or delete entries here or change their order.
- “Configure the Local Gateway”: Opens the “Gateway Configuration” dialog. You can configure the block drivers for the local gateway.

“Device” This menu includes the following commands:
- “Add Current Device to Favorites”: Adds the currently set device to the list of favorite devices.
- “Manage Favorite Devices”: Opens the favorites dialog with a list of all preferred devices. In this dialog, you can add or delete entries or change their order. The top device is the default.
- “Rename Active Device”: Opens the “Change Device Name” dialog.
- “Wink Current Device”: Devices that support this function illuminate a flashing signal.
- “Send Echo Service”: CODESYS sends five echo services to the PLC. These are used to test the network connection, similar to the ping function. The services are sent first without data packets and then with data packets. The scope of the data packets depends on the communication buffer of the PLC. A message box opens with information about the average echo service delay and the scope of the sent data packets.
- “Store Communication Settings in Project”: CODESYS saves the communication settings in the project for reuse on the same computer.
  Note: If you use the project on another computer, then you have to reset the active path.
- “Confirmed Online Mode”: CODESYS requires you to confirm the following when calling the following online commands (for safety purposes): Force values, Write values, Multiple loading, Remove force list, Single cycle, Start, Stop.
- “Filter Network Scans by Target ID”: The display is limited on the devices that have the same target ID as the current device configured in the project.
- “Encrypted Communication”: The communication to this controller is encrypted. A certificate of the controller is required in order to log in to the controller. If the certificate is not available, then an error message opens prompting whether or not the certificate should be displayed and installed.
  If the “Enforce Encrypted Communication” option is selected as “Security level” in the “Security Screen” view, then the “Encrypted Communication” command is disabled here.
- “Change Communication Policy” Opens the “Change Communication Policy” dialog for changing the device setting for the encryption of communication.

Table 55: Dialog “Change Communication Policy”

| If a new communication policy is selected in this dialog, then the configuration on the controller is changed. | “Communication” |

**Communication Settings - Classic Mode**
In the CODESYS options, you can activate the classic mode of the dialog ("Tools ➔ Options", category "Device editor").

<table>
<thead>
<tr>
<th>“Select the network path to the controller”</th>
<th>Gateway channel for the connection.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Select the channel from the lower part of the view.</td>
</tr>
</tbody>
</table>
Table 56: “View displaying configured gateway channels and network devices”

<table>
<thead>
<tr>
<th>Left side of view</th>
<th>Tree structure of the configured gateway channels with the connected devices in the local network:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><img src="image" alt="Gateway-1" /> + <img src="image" alt="User1[0146]" /> <img src="image" alt="User2[0124]" /></td>
</tr>
</tbody>
</table>

Note: CODESYS saves these entries on the local system, not in the project.

The device entries are preceded by a device symbol (●). Entries with a target ID that are different from those currently configured in the project are displayed in gray.

Clicking “Scan Network” refreshes the list.

Note: If you created the first project on the local system, then the local gateway is listed as an entry in the tree by default. CODESYS starts this gateway automatically on system boot.

The filled circle on the lower right corner of the gateway symbol provides information about the connection status:
- Red: CODESYS Development System cannot establish the connection.
- Green: The connection is established.
- Black: The connection status is unknown.

Note: Some communication protocols allow regular checking of the gateway so that the status cannot be displayed.

Each of the device entries in the tree consist of a symbol followed by the “Device Name” > [“Device Address”]. On the right side of the view, you also see the “Target ID”, “Target Name”, “Target Type”, “Target Vendor”, and “Target Version”.

Right side of view | Information about the gateway channel of device selected on the left side of the view.

When a gateway channel is selected in the left view, the following information is displayed: “Device Name”, “IP-Address”, “Port”, “Driver”

When a device is selected in the left view, the following information is displayed (depending of the device): “Device name”, “Device address”, “Number of channels”, “Block driver”, “Serial number”, “Encrypted communication”, “Target vendor”, “Target ID”, “Target name”, “Target type”, “Target version”.

Table 57: “Filter and sorting functions on the right side of the dialog”

<table>
<thead>
<tr>
<th>Filter</th>
<th>You can reduce the displayed list of devices that have the same “Target ID” as the current device configured in the project.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sorting order</td>
<td>You can sort the list by “Name” or “Device Address” in alphabetical or ascending order.</td>
</tr>
</tbody>
</table>

Table 58: Command buttons on the right side of the dialog

<table>
<thead>
<tr>
<th>Set Active Path</th>
<th>The command sets the selected communications channel as active. Double-clicking the entry in the channel tree achieves the same result.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Gateway</td>
<td>This command opens the “Gateway” dialog where you can define a gateway that CODESYS should add to the current configuration.</td>
</tr>
<tr>
<td>Add Device</td>
<td>This command opens the “Add Device” dialog. Here you can manually define a device that is to be inserted under the gateway entry currently selected in the tree. Please note the functionality of “Scan Network” as well.</td>
</tr>
<tr>
<td>Scan Network</td>
<td>The command starts a search for available devices in the local network. The configuration tree of the gateway is refreshed accordingly.</td>
</tr>
</tbody>
</table>
Table 59: “Commands in the context menu of the gateway tree and device tree in the dialog”

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Scan for Device by Address”</td>
<td>The command searches the network for devices with a unique address as given in the configuration tree. CODESYS displays the detected devices with the given address below the gateway. The search always applies to the devices below the selected gateway or below the selected entry.</td>
</tr>
<tr>
<td>“Scan for Device by Name”</td>
<td>The command searches the network for devices with the same name as given in the configuration tree. Capitalization is ignored here. CODESYS displays the detected devices below the gateway with the given name together with its unique device address. The search always applies to the devices below the selected gateway or below the selected entry.</td>
</tr>
<tr>
<td>“Scan for Device by IP Address”</td>
<td>The command searches the network for devices with a unique IP address as given in the configuration tree. CODESYS displays the detected devices with the given address below the gateway together with its name. The search always applies to the devices below the selected gateway or below the selected entry.</td>
</tr>
<tr>
<td>“Send Echo Service”</td>
<td>CODESYS sends five echo services to the PLC. These are used to test the network connection, similar to the ping function. The services are sent first without data packets and then with data packets. The scope of the data packets depends on the communication buffer of the PLC. A message box opens with information about the average echo service delay and the scope of the sent data packets.</td>
</tr>
<tr>
<td>“Delete Selected Device”</td>
<td>This command deletes the selected device from the channel tree.</td>
</tr>
<tr>
<td>“Edit Gateway”</td>
<td>This command opens the “Gateway” dialog for editing the settings for the selected gateway.</td>
</tr>
<tr>
<td>“Configure the Local Gateway”</td>
<td>This command opens a dialog for configuring a local gateway. This provides an alternative to manually editing the Gateway.cfg file.</td>
</tr>
</tbody>
</table>

Table 60: Options in the lower part of the dialog

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| “Don’t store communication settings in project” | ☑️: The current connection settings are saved to the local CODESYS options on your computer, not in the project. This means that you have to reset them if you use the project on another system.  
☐: The settings are saved in the project and CODESYS Development System restores them automatically when you open the project on another computer. |
| “Confirmed online mode”                       | ☑️: CODESYS requires you to confirm the following when calling the following online commands (for safety purposes): “Force Values”, “Write Values”, “Multiple Loading”, “Release Forcelist”, “Single Cycle”, “Start”, “Stop”. |

Tab 'Parameters'

This dialog is intended for test purposes. Its values should be changed only by experts.

The device-specific parameters are displayed in a table on this tab of the generic device editor. The device description defines which parameters you can edit in this dialog.
You can sort the entries in alphabetically ascending or descending order or in the default order by clicking the column header.

<table>
<thead>
<tr>
<th>“Parameter”</th>
<th>Parameter name, not editable</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Type”</td>
<td>Data type of the parameter, not editable</td>
</tr>
<tr>
<td>“Value”</td>
<td>Initially displays the default value of the parameter, directly or the corresponding symbol name. Non-editable parameters are displayed in light-gray. If the parameter is editable you can open an input field, a drop-down list or a file selection dialog with a double-click the table field and use it to change the value.</td>
</tr>
<tr>
<td>“Default value”</td>
<td>Default value of the parameter defined by the device description, not editable</td>
</tr>
<tr>
<td>“Unit”</td>
<td>Unit of measure for the value (example: &quot;ms&quot; for milliseconds; not editable)</td>
</tr>
<tr>
<td>“Description”</td>
<td>Short description of the parameter specified by the device description, not editable</td>
</tr>
</tbody>
</table>

**Tab ‘Applications’**

On this tab of the generic device editor you can see which applications exist on the device. Depending on the system you can delete the applications from the device or retrieve detailed information about the application.

<table>
<thead>
<tr>
<th>“Applications on the PLC”</th>
<th>List of the applications found via “Refresh list” during the last scan of the control device.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Delete”</td>
<td>Deletes the application selected in the list or all listed applications on the controller</td>
</tr>
<tr>
<td>“Delete All”</td>
<td>Note: If a safety controller is inserted below a PLC, then this command can permanently interrupt the communication links of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system. The safe field devices and the other safety controller can enter the safe state as a reaction. The connection to the development system is affected only in the case of a safety controller that is connected to the main controller via a fieldbus. For more information, refer to the section “Subordinate Safety Controller”.</td>
</tr>
<tr>
<td>“Details”</td>
<td>Opens the dialog box “Details”. It displays information defined for the application on the “Information” tab of the dialog box “Properties”.</td>
</tr>
<tr>
<td>“Contents”</td>
<td>Requirement: The “Download the application info” option is activated in the “Properties” of the application object on the “Application generation options” tab. This causes information about the contents of the application to be additionally loaded to the PLC. The “Contents” button opens a dialog box with additional information about the differences between the latest generated code and the application code that exists on the controller. The different modules are displayed in a comparison view.</td>
</tr>
<tr>
<td>“Refresh List”</td>
<td>The controller is scanned for applications and the list is refreshed accordingly</td>
</tr>
</tbody>
</table>

You can configure the commands “Remove Application from Device” and “Remove Applications from Device” by means of the dialog box form “Tools ➔ Customize”. These commands correspond to the “Delete” and “Delete All” buttons.
Tab 'Backup and Restore'

In this tabbed page of the generic device editor, you can backup and restore the application-specific file on the PLC by saving and reading a zip archive.

Requirement: The communication settings are correct for connection to the device. The application for backup is available on the PLC.

<table>
<thead>
<tr>
<th>Table 61: Menu Bar</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>“Backup”</strong></td>
</tr>
<tr>
<td>This button opens a menu with the following commands:</td>
</tr>
<tr>
<td>- ✋ “Read Backup Information from Device”: This command searches for application-specific files from the $PlcLogic$ directory of the PLC and lists them in a table in the lower part of the tabbed page.</td>
</tr>
<tr>
<td>- 📁 “Create Backup File and Save to Disk”:</td>
</tr>
<tr>
<td>Requirement: The “Read Backup Information from Device” command was used for determining the backup-related files. These files are located in the table in the lower part of the tabbed page.</td>
</tr>
<tr>
<td>This command compresses the files in the table set as “Active” and the meta.info information file into a backup zip file. The file extension is tbf (=&quot;Target Backup File&quot;).</td>
</tr>
<tr>
<td>- ✋ “Save Backup File to Device”:</td>
</tr>
<tr>
<td>Requirement: The backup file has been saved to the disk. This command saves the backup file to the TBF directory of the PLC.</td>
</tr>
</tbody>
</table>

| **“Restore”**       |
| This button opens a menu with the following commands: |
|   - 📁 “Load Backup File from Disk”: This command opens the “Open” dialog box for navigating the file system for a saved backup file. The included files are listed in a table in the lower part of the tabbed page. |
|   - ✋ “Load Backup File from Device”: This command generates a list of all backup files found on the PLC. Select one of these files to view its contents in a table on the tabbed page. For the restore operation, you can deactivate optional components and edit the comments. |
|   - ✋ “Restore on Device”: This command is available if at least one component of the backup file that is currently loaded in the tabbed page is set to active. It prompts for restoring the application status on the device. The user interface is blocked during restore. You can cancel the operation. |

<table>
<thead>
<tr>
<th>Table 62: “Target Information”</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>“ID”</strong></td>
</tr>
<tr>
<td><strong>“Type”</strong></td>
</tr>
<tr>
<td><strong>“Version”</strong></td>
</tr>
</tbody>
</table>
**Table 63: “Backup Information”**

| “File name” | Storage path of the backup file. Clicking the symbol ( ) opens the file system dialog box. Example: PlcLogic$/Application/Application.crc |
| “Size of active files” | (in kilobytes) Total size of the files set as active in the table (example: 206 KB (210965 bytes)). |
| “Mode” | Defines the scope of the backup: “Application”. The application-related files are added to the archive. |
| “Comment” | Optional entry for comments to be saved in the meta.info file of the backup and reading when the files are restored. |

**Table 64: Table of files for backup**

| “Active” | ☑: Optional files can be deactivated here for exclusion in the backup file. Required components are shown here with a green check mark (no check box). |
| “Component” | Affected components (example: file system) |
| “File” | Name of the component file to back up (example: $PlcLogic$/ Application/Application.app) |
| “Size” | File size in bytes (example: 43280) |
| “Requires STOP” | ☑: For components, the application must be stopped before backup and restore. A dialog prompt will open to warn you of any backup or restore conflicts. |

See also

-  Chapter 1.3.1.13.10 “Backup and restore” on page 353

**Tab 'Synchronized Files’**

This tab of the generic device editor lists the files that are downloaded to the PLC when the application is downloaded. For example, these are external files that were added to an application.

Implicit files, such as the source code archive file, are displayed here only if their time of download is configured for this and the “Show implicit files for application download on the editor of a PLC” option is activated in the CODESYS options (category “Device Editor”).

| “File name” | Name of the file below the application, or direct name of the implicitly transferred file (example: archive.prj). Double-click the file name to open the file. |
| “Host path” | Storage location or original location of the file (example: D:\Proej\Files). Double-click the path to open the directory in the file explorer. |
| “Time interval” | Time interval of the file update on the PLC (example: After download / online change of the application). |
| “Information” | Object-dependent additional information (example: Object: external file). |
| “Origin” | General origin type of the file (example: External file object, Source code download provider). |

-  Chapter 1.3.1.25.1.15 “Object ‘External File’” on page 736
Tab 'Files'

In this tab of the generic device editor, you can transfer files between CODESYS (host) and the PLC. If the communication settings are correct and the PLC is online, then CODESYS establishes the connection automatically to the PLC for the duration of the file transfer.

Table 65: "Left Side View, Host"

<table>
<thead>
<tr>
<th>“Location”</th>
<th>Path in the file system of the host; set like in the default file manager. Subdirectories and files are shown in the lower part of the view with name, size, and change date.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Opens the dialog box for creating a new directory in the set path</td>
</tr>
<tr>
<td></td>
<td>Deletes the selected files or directories</td>
</tr>
<tr>
<td></td>
<td>Updates the list of files and directories for the set path (location)</td>
</tr>
<tr>
<td>![&lt;&lt;] ![&gt;&gt;]</td>
<td>Copies the selected files and directories to the other file system immediately. If a file is not already available in the target directory, then it is created. If it is already available and not write-protected, then it is overwritten. Otherwise a message is shown.</td>
</tr>
<tr>
<td></td>
<td>corresponds to the “Write File to Controller” command</td>
</tr>
<tr>
<td></td>
<td>corresponds to the “Write File from Controller” command</td>
</tr>
</tbody>
</table>

By default, the commands “Write File to Controller” and “Write File from Controller” are not included in any menu. You can add it to a menu by using the dialog box from “Tools ➤ Customize” (command category “Online”).

- Chapter 1.3.1.25.1.19.1 “Generic device editor” on page 741
- Chapter 1.3.1.15 “Copying files to/from PLC” on page 357

Tab 'Log'

You can view the PLC log in this tab of the generic device editor. It lists the events that were recorded on the target system. This concerns:
- Events during the startup and shutdown of the system (components loaded, with version)
- Application download and loading of the boot application
- Custom entries
- Log entries from I/O drivers
- Log entries from data sources

The “Log” tab also opens when you click “Open Log Page”. You can configure this as a menu command in the “Customize” dialog.

“Offline recording”
- Default settings
- The PLC also records actions that are not related to the connection with the controller.

“UTC time”
- Standard setting; the time stamp is converted to the local time on the computer as indicated by the time zone of the operating system.
- The time stamp of the runtime system is displayed.
### "Severity"

There are four categories for the severity of the event:

- 🟠: Message
- 🟡: Warning
- 🟥: Error
- 🟢: Debugging

You can show or hide each category with the help of the corresponding button in the bar above the list. Each button shows the number of log entries of the category concerned.

### "Time stamp"

Date and time (example: 12-01-2007 09:48)

### "Description"

Description of the event, for example Import function failed of

### "Component"

Name of the runtime system component concerned, e.g. CmpApp

<table>
<thead>
<tr>
<th>Drop-down list with component names</th>
<th>The log list displays only events that concern the selected component</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logger</td>
<td>Drop-down list with all available recordings. The standard setting is the &lt;Default Logger&gt; specified by the target system, at present identical to 'PlcLog' for the CODESYS runtime system</td>
</tr>
<tr>
<td>Refreshes the log list</td>
<td>Refreshes the log list</td>
</tr>
<tr>
<td>Exports the list contents to an xml file. You can select the file name and storage directory.</td>
<td>Exports the list contents to an xml file. You can select the file name and storage directory.</td>
</tr>
<tr>
<td>Imports a log list from an xml file. The list is then displayed in a separate window.</td>
<td>Imports a log list from an xml file. The list is then displayed in a separate window.</td>
</tr>
<tr>
<td></td>
<td>The displayed log list is emptied, i.e. all entries are deleted.</td>
</tr>
</tbody>
</table>

**Note for error checking:** For exceptions with the description *SOURCEPOSITION*, the affected function opens in the editor by double-clicking it or from the “Display Source Code in Editor” command in the context menu. The cursor jumps to the line that is causing the error. You can also perform this diagnosis when you have the CODESYS project archive, including the download information files and the exported log file. If the affected function is protected, then the following message appears: "The source code is not available for <function name>".

### Tab 'PLC Settings'

On this tab of the generic device editor you make the basic settings for the configuration of the PLC, for example the handling of inputs and outputs and the bus cycle task.

| "Application for I/O handling" | Application that is responsible for the I/O handling. |
Table 66: “PLC Settings”

<table>
<thead>
<tr>
<th>“Refresh I/Os in stop”</th>
<th>CODESYS refreshes the values of the input and output channels even if the PLC is in the stop state. If the watchdog detects a malfunction, the outputs are set to the predefined default values.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CODESYS does not refresh the values of the input and output channels when the PLC is in the stop state.</td>
</tr>
</tbody>
</table>

“Behavior of the outputs at stop”

Handling of the output channels when the controller enters the stop state:

- “Retain values”: The current values are retained.
- “All outputs to default value”: The default values resulting from the I/O mapping are assigned.
- “Execute program”: You can control the handling of the output values via a program contained in the project, which CODESYS executes at “STOP”. Enter the name of the program in the field on the right.

“Always update variables”

Global setting that defines whether or not CODESYS updates the I/O variables in the bus cycle task. This setting is effective for I/O variables of the slaves and modules only if ’deactivated’ is defined in their update settings.

- “Deactivated (update only if used in a task)”: CODESYS updates the I/O variables only if they are used in a task.
- “Activates 1 (use bus cycle task if not used in another task)”: CODESYS updates the I/O variables in the bus cycle task if they are not used in any other task.
- “Activate 2 (always in bus cycle task)”: CODESYS updates all variables in each cycle of the bus cycle task, regardless of whether they are used and whether they are mapped to an input or output channel.

Table 67: “Bus Cycle Options”

| “Bus cycle task” | Task that controls the bus cycle. By default the task defined by the device description is entered.  
By default the bus cycle setting of the superordinate bus device (use cycle settings of the superordinate bus) applies, i.e. the device tree is scanned upwards for the next valid bus cycle task definition.  
Pay strict attention to the following notes! |

NOTICE!
Before you select the “<unspecified>” setting for the bus cycle task, you should be aware that “<unspecified>” means that the default setting given in the device description goes into effects. You should therefore check this description. Use of the task with the shortest cycle time may be defined as the default there, but use of the task with the longest cycle time could equally well be defined!

NOTICE!
For fieldbuses, a fixed cycle matrix is necessary to assure a determined behavior. Therefore, do not use the type ‘free-running’ for a bus cycle task.
### Table 68: “Additional Settings”

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Force variables for the I/O mapping”</td>
<td>This setting is available only if it is supported by the device. When compiling the application CODESYS creates two global variables for each I/O channel that is mapped to a variable in the dialog “I/O Mapping”. You can use these variables for the forcing of the input or output value on this channel, for example via an HMI visualization.</td>
</tr>
<tr>
<td>“Activate diagnostics for devices”</td>
<td>CODESYS automatically integrates the library CAA Device Diagnosis in the project and creates an implicit function block for each device. If there is already a function block for the device, then either an extended FB is used (for example with EtherCAT) or a further FB instance is added. This then contains a general implementation of the device diagnostics. By means of the FB instances you can determine the status of all devices in the application and evaluate errors. In addition, the library contains functions for the programmatic editing of the device tree. Example: Scanning of all children of a bus system, jumping to the parent element.</td>
</tr>
<tr>
<td>“Display I/O warnings as errors”</td>
<td>Warnings concerning the I/O configuration are displayed as errors.</td>
</tr>
</tbody>
</table>

### Tab ‘PLC Shell’

This tab of the generic device editor includes a text-based control monitor for querying specific information from the controller. You can specify device-dependent commands for this and receive the response from the controller in a result window.

### Table 69: 3S-Smart Software Solutions GmbH standard commands

<table>

### Tab `<device name> I/O Mapping`

**Devices with I/O channels**

This tab is displayed in device editors for devices with I/O channels. It shows the available channels and allows for the mapping of input, output, and memory addresses of the controller to variables or entire function blocks of the application. In this way you create the so-called 'I/O mapping'.

The application that is to take care of the I/O handling is defined on the “PLC Settings” tab.

> You can use the ‘online configuration mode’ if the device supports it. In this mode you can access the I/Os of the hardware without having to load a real application to the device beforehand.

> You can also create the I/O mapping in the dialog “Edit IO Mapping”. Here you get a mapping list with search and filter functions for an entire device tree.

**NOTICE!**

**Mapping ‘too large’ data types**

- If a variable of a data type that is larger than a byte is mapped to a byte address, the value of the variable will be truncated to byte size there! For monitoring the variable value in the ‘I/O Mapping’ dialog, this means the following: In the root element of the address, the value is displayed that the variable currently has in the project. The current individual bit values of the byte are displayed in succession in the bit elements below that, but this may not be sufficient for the entire variable value.

Example of the tab “<device name> I/O Mapping” for a CAN bus slave:
The tab contains a table for the editing of the I/O mapping. The information displayed for the inputs and outputs originates from the device description.

| “Find” (1)   | Input field for a search string for the mapping table. The search results are marked in yellow. |
| “Filter” (2) | Drop-down list for filtering I/O mapping displayed listed in the mapping table: |
|             | ● “Show all” |
|             | ● “Show only outputs” |
|             | ● “Show only inputs” |
|             | ● “Show only unmapped variables” |
|             | ● “Show only mapped variables” |
|             | ● “Show only mapping to existing variables” |
|             | ● “Show only mapping to new variables” |
| “Add FB for I/O channel” (11) | Depending on the device, available if the channel entry is selected in the mapping table. Opens the “Select Function Block” dialog for selecting the function block that should be linked directly to the channel. |
| “Go to instance” (12) | Available if the entry is selected in the mapping table. Jumps to the corresponding entry in the “<device name> IEC Objects” tab. |
Depending on the device, the inputs and outputs of the device are displayed as nodes and below them, indented, the associated channels or, depending on the device, only the implicitly created device instance.

The symbol indicates the type of channel:

- ✴️: Input
- ✩: Output

Double-clicking the cell opens an input field.

- Option 1: The variable already exists; specify complete path: <application name>,<module name>,<variable name>; example: appl.plc_prg.ivar; input assistance via [xxx].
- Option 2: The variable does not exist yet; enter a simple name; automatically created internally as a global variable.

Depending on the device, inputs or outputs can be linked directly to a function block. In this case, the button ✴️ "Add FB for I/O Channel" is activated. See above.

<table>
<thead>
<tr>
<th>“Mapping” (3)</th>
<th>Type of mapping:</th>
</tr>
</thead>
<tbody>
<tr>
<td>✴️</td>
<td>Variable already exists</td>
</tr>
<tr>
<td>✩</td>
<td>New variable</td>
</tr>
<tr>
<td>✭</td>
<td>Mapping to function block instance</td>
</tr>
</tbody>
</table>

| “Channel” (4) | Symbolic name of the channel. |

| “Address” (5) | Address of the channel, for example %IW0. |

Address strikethrough: indicates that you should not assign any further variables to this address. Reason: Although the variable specified here – as an already existing variable – is managed at a different memory location, ambiguities could result during the writing of the values, particularly with outputs.

- ✱: Indicates that this address has been edited and fixed. If the arrangement of the device objects in the device tree changes, CODESYS does not adapt this address automatically.

| “Type” (6) | Data type of the channel, for example BOOL. |

Structures or bit fields defined in the device description are displayed only if they are part of the IEC standard and are identified as IEC data types in the device description. Otherwise the table cell remains empty.

When mapping structured variables, the editor prevents you from entering both the structure variable (example: %QB0) and individual structure elements (example: %QB0.1 and QB0.2). Therefore, if there is a main entry with a subtree of bit channel entries in the mapping table, then the following applies: You can input a variable either into the line of the main entry, or into the lines of the sub-elements (bit channels), but not into both.

| “Default value” | Default value of the parameter that applies to the channel: Appears only if the option “Set all outputs to default” is activated in the “PLC Settings” for the behavior of the outputs at stop. |

Note: For compiler version V3.5 SP11 and later, the initialization value of the variables is used automatically as the default value when mapping to an existing variable. You can edit the “Default value” field only if you map to a new created variable or if no mapping is specified. In older versions, users had to specify explicitly that the default value and initialization value were identical.

| “Unit” (7) | Unit for the parameter value, for example ms for milliseconds. |

| “Description” (8) | Brief description of the parameter. |

| “Current value” | Actual value of the parameter applied to the channel; displayed in online mode only. |
"Reset mapping" (9) CODESYS resets the mapping settings to the default values defined by the device description file.

"Update variables" (10) Definition for the device object about updating I/O variables. The default value is defined in the device description:
- "Use parent device setting": Update according to the setting of the superordinate device.
- "Enabled 1 (use bus cycle task if not used in any task)": CODESYS updates the I/O variables in the bus cycle task if they are not used in any other task.
- "Enabled 2 (always in bus cycle task)": CODESYS updates all variables in each cycle of the bus cycle task, regardless of whether they are used and whether they are mapped to an input or output channel.

If a UNION is represented by I/O channels in the mapping dialog, it depends on the device whether mapping to the root element is also possible.

Devices with I/O drivers For devices with I/O drivers, you can set the bus cycle task here in the "I/O Mapping" tab if the general settings should not be used ("PLC Settings" tab).

Table 70: Bus cycle options

| "Bus cycle task" | The drop-down list provides all tasks that are defined in the task configuration of the active application (example: "MainTask"). In case of "Use parent bus cycle setting", the settings of the parent node will be used. |

General information about the bus cycle task As a rule, for each IEC task the used input data is read at the start of each task (1) and the written output data is transferred to the I/O driver at the end of the task (3). The implementation in the I/O driver is decisive for further transfer of the I/O data. It is responsible for the time frame and time point that the actual transfer to the corresponding bus system occurs.

The bus cycle task of the PLC can be defined globally for all fieldbuses in the PLC settings. For some fieldbuses, however, you can change this independent of the global setting. The task with the shortest cycle time is used as the bus cycle task (setting: "unspecified" in the PLC settings). The messages are normally sent on the bus in this task.

Other tasks copy only the I/O data from an internal buffer that is exchanged only with the physical hardware in the bus cycle task.

![Diagram of bus cycle task and data flow](image-url)
(1) Read inputs from input buffer          (2) IEC task
(3) Write outputs to output buffer      (4) Bus cycle
(5) Input buffer                                    (6) Output buffer
(7) Copy data to/from bus                         (8) Bus cycle task, priority 1, 1 ms
(9) Bus cycle task, priority 5                      (10) Bus cycle task, priority 5
(11) Bus cycle task, priority 10, interrupted by task 5

**Task usage**

The "Task Deployment" provides an overview of used I/O channels, the set bus cycle task, and the usage of channels.

```
WARNING!

If an output is written in various tasks, the status is undefined, as this can be overwritten in each case.

If the same inputs are used in various tasks, it is possible for the input to change during the processing of a task. This happens if the task is interrupted by a task with a higher priority and causes the process image to be read again.

Solution: At the beginning of the IEC task, copy the input variables to variables and then work only with the local variables in the rest of the code.

Conclusion: Using the same inputs and outputs in several tasks does not make any sense and can lead to unexpected reactions in some cases.
```

**Tab <device name> IEC Objects'**

```
NOTICE!

Please note that manually creating another instance of the device object can lead to malfunctions.
```

In this tab of the generic device editor, "objects" are listed that allow for access to the device from the IEC application. In online mode, this is used as the monitoring view.

For devices for which a function block instance is created implicitly, at least this instance is listed as an object here in the table. This instance can be used, for example, in order to restart a bus or to query information from the application. The device type determines whether this kind of device instance is available and which access options it has. Please refer to the help for the special device configuration.

Instances of function blocks that are linked with inputs or outputs of the device are also displayed here. The mapping of a function block to a channel is defined in the “<device name> I/O Mapping” tab. The "Go to Instance" command takes you directly to the affected object from there.

In addition, you can create more objects in the table here that are not yet linked with a device channel.
In online mode, you can use the table of IEC objects as a monitoring view. It also shows the current value, the address, and the comment for the function block variable at the channel. Finally, it provides the capability of writing and forcing values.

| **“Add”** | Opens the “Select Function Block” dialog for creating a new instance or for editing the instance selected in the table. |
| **“Edit”** | Deletes the selected entry. |
| **“Delete”** | Jumps from the selected entry directly to the corresponding mapping in the “<device name> I/O Mapping” tab. |
| **“Variable”** | The object name comprises the device name and the function block name. Example: EL2004 Relay. Changing the device name has an immediate effect. The part of the name after the device name is editable here. |
| **“Mapping”** | Mapping type, as in the “<device name> I/O Mapping” tab |
| **“Type”** | Data type: Here it is the name of the function block. |
| **“Value”** | In online mode only: Display of the current value, the address, and the comment for the variable at the channel. Moreover, the option of specifying a value for writing or forcing the variable. |
| **“Prepared value”** |
| **“Address”** |
| **“Comment”** |

**Tab 'Users and Groups’**

**NOTICE!**

**Recommendations for Data Security**

In order to minimize the risk of data security violations, we recommend the following organizational and technical actions for the system where your applications are running. As far as possible, avoid exposing the PLC and control networks to open networks and the internet. Use additional data link layers for protection, such as a VPN for teleaccess and install firewall mechanisms. Limit access to authorized persons, change any existing standard passwords during the initial commissioning and continue to change them regularly.

On this tab of the generic device editor you edit the device user management of the controller. Depending on how it is supported by the device, you can define user accounts and user groups. In combination with the configuration on the “Access Rights” tab, you thus control access to control objects and files at runtime.

Requirements: The controller has a user management and allows it to be edited. You have login data in order to be able to log in to the controller.

**It is possible to apply user account definitions from the project user management into the device user management (see below: “Import” button).**
Table 71: Toolbar of the tab

<table>
<thead>
<tr>
<th>Button</th>
<th>Description</th>
</tr>
</thead>
</table>
| Synchronization | Switches on and off the synchronization between the editor and the user management on the device. If the button is not pressed, then the editor is blank or it contains a configuration that you loaded from the hard disk. If the button is pressed, then CODESYS synchronizes the display in the editor continuously with the current user management on the connected device. If you activate the synchronization while the editor contains a user configuration that is not synchronized with the device yet, then you are prompted what should happen to the editor contents. Options:  
  - “Upload from the device and overwrite the editor content”: The configuration on the device is loaded into the editor, overwriting the current contents.  
  - “Download the editor content to the device and overwrite the user management there”: The configuration in the editor is transferred to the device and applied there. |
| Import from disk | Opens the default dialog for selecting and importing a user management configuration from the hard disk. When you click the button in the “Users and Groups” tab, the file type is “Device user management files (*.dum)”. When you click the button in the “Access Rights” tab, the file type is “Device rights management files (*.dum)”. |
| Export to disk | Opens the default dialog for saving a file to the hard disk. This saves the user management configuration as an XML file. The data type is “Device rights management files (*.drm)”. |

“Device user” User name of the user currently logged in on the device

**Tab ‘Access Rights’**

**NOTICE!**

**Recommendations for data security**

In order to minimize the risk of data security violations, we recommend the following organizational and technical actions for the system where your applications are running. Whenever possible, avoid exposing the PLC and control networks to open networks and the Internet. Use additional data link layers for protection, such as a VPN for teleaccess, and install firewall mechanisms. Restrict access for authorized persons only, and change any existing standard passwords during the initial commissioning. In addition, change them regularly.

**NOTICE!**

Detailed information on the concept and use of device user management is provided in "Handling of Device User Management".

There you will also find the following instructions on how to use the editor:
- Initial login to the controller for editing and viewing its user management
- Setting up a new user in the user management of the controller
- Changing access rights to controller objects in the user management of the controller
- Loading user management from a *.dum file, modifying it, and downloading it to the controller in offline mode
On this tab of the device editor, you define the device access rights of device users to objects on the controller. As in the project user management, users must be members of at least one user group and only user groups can be granted certain access rights.

Requirements for the “Access Rights” tab to be displayed:
- In the CODESYS options, in the “Device editor” category, the “Show access rights page” option must be selected.
  Note that this CODESYS option can be overwritten by the device description.

Requirements for the access rights to be granted to user groups
- A component for the user management has to be available on the controller. That is the primary requirement.
- Users and user groups have to be configured on the “Users and Groups” tab.

Table 75: Toolbar of the tab

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
</table>
| ![Synchronization](image) | Switches on and off the synchronization between the editor and the user management on the device. If the button is not pressed, then the editor is blank or it contains a configuration that you loaded from the hard disk. If the button is pressed, then CODESYS synchronizes the display in the editor continuously with the current user management on the connected device. If you activate the synchronization while the editor contains a user configuration that is not synchronized with the device yet, then you are prompted what should happen to the editor contents. Options:  
  - “Upload from the device and overwrite the editor content”: The configuration on the device is loaded into the editor, overwriting the current contents.  
  - “Download the editor content to the device and overwrite the user management there”: The configuration in the editor is transferred to the device and applied there. |
| ![Import from disk](image) | Opens the default dialog for selecting and importing a user management configuration from the hard disk. When you click the button in the “Users and Groups” tab, the file type is “Device user management files (*.dum)”. When you click the button in the “Access Rights” tab, the file type is “Device rights management files (*.drm)”. |

Table 76: “Objects”

In the tree structure, the objects are listed to which actions can be executed at runtime. The objects are each assigned by their object source and partially sorted in object groups. In the “Rights” view, you can configure the access options for a user group to a selected object.

Object source (root node)
- “File system objects ➔ Device”: In these objects, the rights can be granted to folders of the current execution directory of the controller.  
- “Runtime objects ➔ /”: In these objects, all objects are managed that have online access in the controller and therefore have to control the access rights.

A description of the objects is located in the table. ➔ “Overview of the objects” on page 765

Object groups and objects (indented)

---

2020/12/10

3ADR010583, 1, en_US

763
Table 77: “Rights”

In general, the access rights are inherited from the root object (also “Device” or “/”) to the subobjects. This means that if a permission of a user group is denied or explicitly granted to a parent object, then this first affects all child objects.

The table applies for the object that is currently selected in the tree. For every user group, it shows the rights currently configured for the possible actions on this object.

<table>
<thead>
<tr>
<th>Possible actions on the object:</th>
</tr>
</thead>
<tbody>
<tr>
<td>● “Add/Remove”</td>
</tr>
<tr>
<td>● “Modify”</td>
</tr>
<tr>
<td>● “View”</td>
</tr>
<tr>
<td>● “Execute”</td>
</tr>
</tbody>
</table>

When an object is clicked, a table on the right side shows the access rights of the available user groups for the selected object.

This allows you to quickly see:

● Which access rights are evaluated by an object
● Which user group has which effective rights to which object

Meanings of the symbols

● +: Access right granted explicitly
● -: Access right denied explicitly
● 🔴: Access right granted through inheritance
● 🔴: Access right denied through inheritance
● 🕰️: The access right was not granted or denied explicitly and also not inherited by the parent object. Access is not possible.
● No symbol: Multiple objects are selected that have different access rights.

Change the permission by clicking the symbol.
The “Logger” object on the “Access Rights” tab was created by the "Logger" component and controls its access rights. It is located directly below the "Device" runtime object.

The possible access rights for this object can be granted only for the “View” action.

Initially, each object has a read access. This means that every user can read the "Logger" of a controller. If this access right should be denied for a single user group ("Service" in the example), then the read access to the logger object has to be denied explicitly.

Overview of the objects

| “Runtime objects” ➔ “Device” |  |
| "Logger" | Online access to the logger is read only. Therefore, only the “View” access right can be granted or denied here. |
| "PlcLogic" | All IEC applications are inserted here automatically as child objects during download. When an application is deleted, it is removed automatically. This allows specific control of online access to the application. Access rights can be assigned centrally over all applications in the "PlcLogic". The "Administrator" and "Developer" user groups have full access to the IEC applications. The "Service" and "Watch" user groups only have read access (for example for read-only monitoring of values). |

The following table shows which action is affected in particular when a specific access right is granted for an IEC application.

- The right has to be set explicitly.
-: The right is not relevant.

<table>

</tr>
</tbody>
</table>

**“PlcShell”**

Only the “Modify” permission is evaluated at this time. This means that only when the “Modify” permission has been granted to a user group can PLC shell commands also be evaluated.

**“RemoteConnections”**

Additional external connections to the controller can be configured below this node. Currently, access to the CODESYS OPC UA server can be configured here.

**“Settings”**

This is the online access to the configuration settings of a controller. By default, access to “Modify” is granted only to the administrator.

**“UserManagement”**

This is the online access to the user management of a controller. By default, read/write access is granted only to the administrator.

**“X509”**

This controls the online access to the X.509 certificates. Two types of access are distinguished here:

- Read (“View”)
- Write (“Modify”)

Every operation is assigned to one of these two access rights. Each operation is inserted as a child object below X509. Therefore, access per operation can now be fine-tuned even more.

**“File system objects ➔ /”**

All folders from the execution path of the controller are inserted below the “/” file system object. This allows you to grant specific rights to each folder of the file system.

-  § Chapter 1.3.1.25.1.19.13 “Tab ‘Users and Groups’” on page 760

**Tab ’Symbol Rights’**

In this tab of the generic device editor, you define the access rights of different user groups (clients) to the individual symbol sets available on the controller.
Requirement: User management must be set up on the PLC. An application was downloaded to the controller for which symbol sets were defined in the CODESYS project. They have access data for logging in to the controller.

In the “Symbol Sets” view, all symbol sets are listed below the “Application” node whose definition was downloaded with the application to the controller.

In the “Rights” view, the user groups defined in the user management of the controller are listed in a table. When a symbol set is selected, you see the access rights of the corresponding user group to the symbols of this set. Access granted; Access not granted. You can change the access rights by double-clicking the symbol.

Click the button to save the current access configuration to an XML file. The file type is “Device symbol management files (*.dsm)”. Click the button to read a file like this from the hard drive.

Tab 'Task deployment’

This sub-dialog box of the device editor displays a table of inputs and outputs as well as their assignment to the defined tasks.

The information only becomes visible after code has been generated for the application. It is used for troubleshooting, because it shows where inputs or outputs are used in several tasks with different priorities. Multiple use can lead to undefined values through overwriting.
Table 78: “I/O deployment for tasks” (1)

<table>
<thead>
<tr>
<th>“I/O Channels” (2)</th>
<th>All inputs and outputs of the linked devices. The display corresponds to that in the dialog box “I/O Mapping” of the device editor. By double-clicking on an input or output you can open the associated I/O mapping editor.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“&lt;task name&gt;” (3)</td>
<td>A column appears for every task defined in the task configuration. The title contains the task name and priority. The priority of the tasks decreases from first to the last column. A red cross appears in the box for inputs and outputs that are written or read by a task: 🔴. In addition, the task defined as a “Bus cycle task” in the “PLC Settings” of the device editor is marked at these points with a blue double arrow symbol 🔄. Following a mouse-click on the title cell, only the I/Os assigned to this task are displayed. Following a mouse-click on the “I/O channels” cell, all channels are shown again.</td>
</tr>
</tbody>
</table>

Object 'GlobalTextList'

Symbol: 📜

This object is for the management and translation of texts that are written as static text in visualizations in the project. It contains a table with these texts. If you write a text in a visualization in an element under the property “Texts”, CODESYS automatically adds a line in the table. You cannot write any new text here, you can only edit an existing text.

In addition CODESYS makes the following commands available, in order to consolidate the “GlobalTextList”:
- “Check Visualization Text IDs”
- “Update Visualization Text IDs”
- “Remove Unused Text List Entries”

The object is located in the POUs view and exists once at the most
Object 'GVL' - Global Variable List

Symbol: ☰

A global variable list is used for the declaration, editing and display of global variables.

A GVL is added to the application or the project with the command "Project ➔ Add Object ➔ Global Variable List".

If you insert a GVL under an application in the Device tree, the variables are valid within this application. If you add a GVL in the POU's view, the variables are valid for the entire project.

You can apply settings for the editor of the object in the dialog "Tools ➔ Options" in the categories "Declaration Editor" and "Text Editor".

If the target system supports network functionality, you can convert the variables of a GVL into network variables and thus use them for data exchange with other devices in the network. To do this you must define corresponding properties for the GVL in the "Network Variables" tab of the "Properties" dialog.

Object 'GVL' - Global Variable List (task-local)

Symbol: ☰

A global variable list (task-local) is used for the declaration, editing and display of global variables. For this special global variable list, the declared variables in the list can be written by one task only. All other tasks have only read-only access. This makes sure that the values of these variables are always consistent, even for multicore projects.
The object is available for compiler version 3.5.13.0 with the corresponding device description.

| Task with write access | Task that has exclusive write access to the variables. |

See also
- % Chapter 1.3.1.9.2.5 “Using task-local global variable lists” on page 177

- % Chapter 1.3.1.25.1.21 “Object ‘GVL’ - Global Variable List” on page 769
- % Chapter 1.3.1.25.1.37.5 “Tab ‘Task Groups’” on page 838

Object 'Persistent variable list'

Symbol: ¶

The object contains the declaration of global persistent variables in the declaration section
VAR_GLOBAL PERSISTENT RETAIN .. END_VAR. The variables are stored in special non-volatile memory.

The persistence editor shows the variables as a list in the usual way. The displayed list does not influence the persistence behavior of the variables, but only the list stored internally in the process image. The list there contains all variables ever declared in chronological order. Variables that you have removed are marked with a placeholder and continue to exist as a gap.

The declaration section can also contain instance paths, which refer to locally declared persistent variables and were created with the command “Declarations ➤ Add All Instance Paths”.

NOTICE!
Before you decide how to set up persistence for an application, it would be helpful for you to be familiar with the use cases described in the “Data Persistence” section. Moreover, it is helpful if you can differentiate between the mechanisms of persistent variables, retain variables, variables of the Persistence Manager, and recipe variables.

Commands

The following commands are provided in the persistence editor:
- Command “Declarations ➤ Add All Instance Paths”
- Command “Declarations ➤ Reorder List and Clear Gaps”

- % Chapter 1.3.1.9.20.2 “Preserving data with retain variables” on page 254
- % Chapter 1.3.1.25.2.17.4 “Command ‘Add all instance paths’” on page 1012

Object 'Image Pool'

The “Image Pool” object contains a table with image ID assignments.
“ID” | ID of the image; you reference this ID, for example in the visualization of the image.
---|---
“File name” | File path of the image; if you click for more settings ( ), the “Select Image” dialog box opens.
“Image” | Show a thumbnail of the image.
“Link type” | Opens the “Select Image” dialog box, where you define the link type.

**Dialog box 'Select Image'**

| “Image file” | Name and directory of the image file (example: "C:\Programme\images \logo.bmp") CODESYS supports the following image formats: BMP, EMF, GIF, ICO, JPG, PNG, SVG, and TIFF. Please note that a controller may not support all formats. Whether or not you can use images formatted as scalable vector graphics (*.svg) depends on the operating system. Any necessary information is located in the device description of the hardware vendor. |

**Table 79: “File Handling”**

| “Remember the link” | CODESYS saves only the link. CODESYS automatically updates any changes to an image file in the image pool. You must ensure that the path of the image file does not change. When saving the project as an archive, CODESYS embeds the image file in the project archive. |
| “Remember the link and embed into project” | CODESYS copies the image to the image pool and the link information is retained. In this way, CODESYS recognizes any changes to the image file and then update the image pool as needed. This behavior is controlled with the options in the next table. Embedded image files increase the memory requirement of the project. |
| “Embed into project” | CODESYS copies the image to the image pool. If the image file is changed again afterwards, then it is not updated in the project. For libraries, you must embed the image in the project. Embedded image files increase the memory requirement of the project. |

**Table 80: “Change Tracking”**

These options are available only if you have selected the “Remember the link and embed into project” check box as described above.

| “Reload the file automatically” | CODESYS automatically updates the image file in the project without prompting. |
| “Prompt whether to reload the file” | If the image file has changed, you may be prompted whether or not the image file should be updated. |
| “Do nothing” | CODESYS does not update the image file in the image pool. |

**Object 'Library Manager’**

Symbol: 🎨

The Library Manager lists all libraries that were integrated in the project for creating applications. It provides information about the type of library, its properties, and its contents.
You can expand or collapse the list of integrated libraries, as well as edit library properties for non-dependent libraries.

The Library Manager consists of three views:

● Upper view: List of integrated libraries
● Lower left view: Tree structure with all modules of the library selected in the upper view
● Lower right view: Documentation for the module selected in the tree

<td>A placeholder library that is integrated below an application is resolved by assigning a special resolution to the placeholder library in the “Placeholders” dialog. Then the selected library is loaded. Other resolutions are ignored. If no special resolution is given, then a check is performed as to whether or not a resolution is specified in the device description and library profile of the application. The first search hit is applied.</td>
</tr>
</tbody>
</table>
Symbol with tooltip to notify about the current device-dependent resolution of the selected library.

Example when the Library Manager is in the “Devices” view: “This placeholder is explicitly redirected to this version (see the Placeholders dialog)”

Example when the Library Manager is in the “POUs” view: “In the 'Device_1' device, the placeholder is resolved to 'VisuElemAlarms, 1.0.0.0 (System)’”

A placeholder library that is integrated in the “POUs” view is resolved by checking depending on the application whether or not a resolution is specified in the device description. Afterwards, the library profile is checked. The first detected resolution is used. If you have assigned a special resolution to the placeholder library in the “Placeholders” dialog, then this will **always be ignored**. The result is shown in the tooltip of the symbol.

Library that is signed with a trusted certificate (compatible with CODESYS >= V3 SP15)

Library that is signed with a trusted certificate, but references at least one unsigned library

Library that is signed with a private key and token (compatible with CODESYS < V3 SP15)

Library that is not signed, or signed with an untrusted or expired certificate. In the case of an untrusted certificate, the “Trust Certificate” command is provided in the context menu.

Library that is defined as optional and not currently available

Library whose status is being determined

Licensed library for which no valid license is currently available

Library symbol for a library that cannot be loaded because its signature (encryption) could not be verified

Object ‘Network Variable List (Sender)’

Symbol: 🌐

A network variable list (sender) is used for declaring and listing global variables that should be sent to network variable lists (receiver) of other devices or network projects.

You add the object to the device tree by clicking “Add Object ➤ Network Variable List (Sender)” of an application.

You can configure the protocol and transfer parameters in the “Add Network Variable List (Sender)” dialog box or “Properties” dialog box of the object in the “Network Variables” tab.
**Dialog Box 'Add Network Variable List (Sender)'**

**Function:** This dialog box defines the network properties for the sender NVL. When you close the dialog box, CODESYS adds the sender NVL of the application to the device tree.

**Call:** Main menu “Project ➔ Add Object ➔ Network Variable List (Sender)” while the application is selected in the device tree.

This dialog box corresponds to the “Network Variables” tab in the “Properties” of the network variable list object.

See also
- Chapter 1.3.1.25.3.10.10 “Dialog 'Properties' - ‘Network Variables’” on page 1052
- Chapter 1.3.1.25.1.27 “Object 'Network Variable List (Receiver)’” on page 775
- Chapter 1.3.1.10.3.1 “Configuring a network variable exchange” on page 278

**Object 'Network Variable List (Receiver)'**

**Symbol:** 📚

The object is used for listing the received network variables and displaying the information: network and transmit information and sender.

You add the object to an application by clicking “Add Object ➔ Network Variable List (Receiver)’”.

The network variable list (receiver) shows the received network variables, which were declared in network variable list (sender) of another device or project. You cannot change the network variables in the object editor.

The object editor consists of two parts:
- Information about the sender and transfer log of the list
- List of declarations of network variables

**Dialog Box 'Add Network Variable List (Receiver)’**

**Function:** This dialog box defines the receiver NVL to a sender NVL and adds the receiver NVL to the application object in the device tree.

**Call:** Main menu “Project ➔ Add Object ➔ Network Variable List (Receiver)” (when the application object is selected).

| “Task” | Task of the current application that controls the variables to be received. |
| “Sender” | Drop-down list |
| | • Available sender NVLs of another device in the project |
| | • “Import from file”: Required if the necessary sender NVL is defined in another project. For this, the necessary sender NVL must have been generated in another project as “GVL export file *.gvl” in the properties dialog of the NVL in the ”Link To File” tab. |
| “Import from file” | File name in “GVL export file *.gvl” format if you have selected “Import from file” for “Sender”. |

See also
- Chapter 1.3.1.10.3.1 “Configuring a network variable exchange” on page 278
- Chapter 1.3.1.25.1.26 “Object 'Network Variable List (Sender)’” on page 774

**Object 'POU’**

**Symbol:** 📚
An object of the type “POU” is a Program Organization Unit in a CODESYS project. You write source code for your controller program in POUs.

There are the following types of POUs:
- Program
- Function
- Function block

A “POU” object is inserted by using the command “Project ➔ Add Object” in the Device tree or in the “POUs” view. When adding a POU you define the POU type and the implementation language.

You can also add other programming objects (method, action, etc.) to these objects.

**Calling POUs**

Certain POUs can call other POUs. Recursions are not permitted.

When calling POUs via the namespace, CODESYS browses the project for the POU to be called in accordance with the following order:

1. Current application
2. “Library Manager” of the current application
3. “POUs” view
4. “Library Manager” in the “POUs” view

The term “POU” is also used in CODESYS for the “POUs” view in which CODESYS manages the global objects in the project.

See also
- Chapter 1.3.1.25.1.28 “Object ‘POU’” on page 775
- Chapter 1.3.1.25.3.10 “Dialog ‘Properties’” on page 1046

**Dialog 'Add POU’**

**Function:** The dialog is used to configure a new POU according to the IEC 61131-3 standard. This means that a POU can be a program, a function, or a function block.

**Call:** Menu bar: “Project ➔ Add Object”; context menu in the “Devices” view when an application is selected; context menu in the “POUs” view

| “Name” | Name of POU |

- ☝ Chapter 1.3.1.9.23.2 “Implementing interfaces” on page 265

Object ‘Program’

A program is a POU that supplies one or more values during execution. After execution of the program, all values are retained until the next execution. The order of calling the programs within an application is defined in task objects.

A program is added to the application or the project using the command “Project ➔ Add Object ➔ POU”. In the Device tree and in the “POUs” view the program POUs have the suffix “(PRG)”.

The editor of a program consists of the declaration part and the implementation part.

The uppermost line of the declaration part contains the following declaration:

PROGRAM <program> 

Calling a program

Programs and function blocks can call a program. A program call is not permitted in a function. There are no instances of programs.
If a POU calls a program and values of the program change as a result, these changes are retained until the next program call. The values of the program are also retained even if the repeat call takes place by another POU. This differs from the call of a function block. When calling a function block only the values of the respective instance of the function block change. The changes only need to be observed if a POU calls the same instance again.

You can also set the input or output parameters for a program directly when calling.

**Syntax:** `<program>({<input variable> := <value>, <output value> => <value>})`:

If you insert a program call via the input assistant and the "Insert with arguments" option in the input assistant is activated at the same time, CODESYS adds input and/or output parameters to the program call in accordance with the syntax.

### Examples

**Calls:**

**IL:**

```
CAL PLC_PRG()

in1:= 2

LD PLC_PRG.out2

ST erg
```

With assignment of the parameters:

```
CAL PLC_PRG()

in1:= 2,

out2=> erg)
```

**ST:**

```
PLC_PRG()

erg := PLC_PRG.out2;
```

With assignment of the parameters:

```
PLC_PRG(in1:=2, out1=>erg);
```

### See also

- [Chapter 1.3.1.25.1.28 “Object 'POU'” on page 775](#)
- [Chapter 1.3.1.9.17 “Task configuration” on page 239](#)

### Object 'Function Block'

A function block is a POU that supplies one or more values during execution.

The object is added to the application or the project using the command "Project ➔ Add Object ➔ POU". In the Device tree or in the "POUs" view the function block POU's have the suffix "(FB)".

You always call a function block via an instance that is a copy of the function block.

The editor of a function block consists of the declaration part and the implementation part.
After execution the values of the output variables and the internal variables are retained until the next execution. This means that the function block does not necessarily supply the same output values with the same input variables when called repeatedly.

In addition to the functionality described in IEC 61131-3, you can also use function blocks in CODESYS for the following functionalities of object-oriented programming:

- Extension of a function block
- Implementation of interfaces
- Methods
- Properties

The uppermost line of the declaration part contains the following declaration:

```plaintext
FUNCTION_BLOCK <access specifier> <function block> | EXTENDS <function block> | IMPLEMENT <comma-separated list of interfaces>
```

**Calling a function block**

The call always takes place via an instance of the function block. When calling a function block only the values of the respective instance change.

Declaration of the instance:

```plaintext
<instance> : <function block>;
```

You access a variable of the function block in the implementation part as follows:

```plaintext
<instance>.<variable>
```

**NOTICE!**

Please note the following:

- From outside of the function block instance you can access only the input and output variables of a function block, not the internal variables.
- Access to a function block instance is limited to the POU in which the instance is declared, unless you have declared the instance as global.
- You can assign the desired values to the function block variables when calling the instance.
Access to function block variables:
The function block “FB1” has the input variable iVar1 of the type INT and the output variable out1. In the following the variable iVar1 is called from the program “Prog”.

```plaintext
PROGRAM Prog
VAR
  inst1:FB1;
END_VAR

  inst1.iVar1 := 33;  (* FB1 is called and the value 33 is assigned to the variable iVar1 *)
  inst1();            (* FB1 is called, that's necessary for the following access to the output variable *)
  ires := inst1.out1  (* the output variable out1 of the FB1 is read *)
```

In FBD:

```
inst1

FB1

33 - iVar1  out1 - ires
```

Assigning variable values during the call:
In the text languages IL and ST you can directly assign values to the input and/or output variables when calling the function block.

The assignment of a value to an input variable takes place with `:=`
The assignment of a value to an output variable takes place with `=>`

Example
The instance CMD_TMR of the timer function block is called with assignments for the input variables IN and PT. Subsequently, the output variable Q of the timer is assigned to the variable A.

```
CMD_TMR (IN := %IX5, PT := 100=);
A := CMD_TMR.Q;
```

If you insert a function block instance via the “input assistant” and the option “Insert with arguments” is activated in the “Input Assistant” dialog box, CODESYS inserts the call with all input and output variables. You then only need to insert the desired value assignment. In the above example CODESYS inserts the call as follows: CMD_TMR (IN:= ,PT:= , Q=> ).

See also
- § Chapter 1.3.1.25.1.28 “Object ‘POU’” on page 775
- § Chapter 1.3.1.9.23.1 “Extension of function blocks” on page 263
- § Chapter 1.3.1.9.23.2 “Implementing interfaces” on page 265

- § Chapter 1.3.1.25.1.28.8 “Object ‘Property’” on page 791
Object 'Function'

A function is a POU that supplies precisely one data element when executed and whose call in textual languages can occur as an operator in expressions. The data element can also be an array or a structure.

The object is added to the application or the project by clicking “Project ➤ Add Object ➤ POU”. In the device tree or in the “POUs” view, function POUs have the “(FUN)” suffix.

**NOTICE!**

Functions have no internal status information, which means that functions do not save the values of their variables until the next call. Calls of a function with the same input variable values always supply the same output value. Therefore, functions must not use global variables and addresses!

The editor of a function consists of the declaration part and the implementation part.

The top line of the declaration part contains the following declaration:

FUNCTION <function> : <data type>

Below that, you declare the input and function variables.

The output variable of a function is the function name.

**NOTICE!**

If you declare a local variable in a function as RETAIN, this has no effect. In this case, CODESYS issues a compiler error.

**NOTICE!**

You cannot mix explicit and implicit parameter assignments in function calls in CODESYS V3. This means that you have to use either only explicit or only implicit parameter assignments in function calls. The order of the parameter assignments when calling a function is arbitrary.

Calling a function

In ST, you can use the call of a function as an operand in expressions.

In SFC, you can use a function call only within step actions or transitions.
Examples

Function with declaration part and a line implementation code

According to the IEC 61131-3 standard, functions can have additional outputs. You declare the additional outputs in the function between the keywords `VAR_OUTPUT` and `END_VAR`. The function is called according to the following syntax:

```
<function> (<function output variable1> => <output variable 1>,
<function output variable n> => <output variable n>)
```

Function calls:

**ST:**

```
result := POU_Funct(5,3,22);
```

**AWL:**

```
LD
POU_Funct
3
ST
```

**FBD:**

```
POU_Funct := ivar1 + ivar2 * ivar3;
```

Example

The `fun` function is defined with two input variables `in1` and `in2`. The output variable of the `fun` function is written to the locally declared output variables `loc1` and `loc2`.

```
fun(in1 := 1, in2 := 2, out1 => loc1, out2 => loc2);
```
Object 'Interface'

Symbol: ☠

Keyword: INTERFACE

An interface is a means of object-oriented programming. The object ITF describes a set of method and property prototypes. In this context, prototype means that the methods and properties contain only declarations and no implementation.

This allows different function blocks having common properties to be used in the same way. An object "ITF" is added to the application or the project with the command "Project ➤ Add Object ➤ Interface".

Table 83: “Adding an interface”

<table>
<thead>
<tr>
<th>&quot;Inheritance&quot;</th>
<th>Interface name</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Name&quot;</td>
<td></td>
</tr>
<tr>
<td>&quot;Extends&quot;</td>
<td>☑️: Extends the interface that you enter in the input field or via the input assistant ☑️. This means that all methods of the interface that extend the new interface are also available in the new interface.</td>
</tr>
</tbody>
</table>

You can add the objects “Interface property” and “Interface Method” to the object "ITF". Interface methods may contain only the declarations of input, output and input/output variables, but no implementation.

So that you can also use an interface in the program, there must be a function block that implements this interface.

This means:

- the function block contains the interface in its IMPLEMENTS list in its declaration part
- the function block contains an implementation for all methods and property prototypes of the interface

A function block can implement one or more interfaces. You can use the same method with identical parameters, but different implementation code in different function blocks.

Please note the following:

- You may not define variables within an interface. An interface has no implementation part and no actions. Only a collection of methods is defined, in which you may define only input, output and input/output variables.
- CODESYS always treats variables declared with the type of an interface as references.
- A function block that implements an interface must contain implementation code for the methods of the interface. You have named the methods exactly as in the interface and the methods contain the same input, output and input/output variables as in the interface.
NOTICE!

Interface references and online change

The following can happen with a compiler version < 3.4.1.0: if a function block changes its data because variables are added or deleted, or because the type of variables changes, then CODESYS copies all instances of the function block to a new memory location. In this case, however, an interface reference refers not to the new memory location, but still to the old one.

In case of compiler versions >= 3.4.1.0, CODESYS automatically re-addresses the interface references so that CODESYS also references the correct interface in case of an online change. CODESYS requires additional code and more time for this, so that jitter problems can occur depending on the number of objects concerned. Therefore, CODESYS displays the number of variables and interface references concerned before the execution of the online change and you can then decide whether the online change should be executed or aborted.

Example

Definition of an interface and its use in a function block

You have inserted the interface "ITF" below the application. The interface contains the methods "Method1" and "Method2". "ITF", "Method1" and "Method2" contain no implementation code. You insert the required variable declarations only in the declaration part of the methods.

If you subsequently insert a function block in the device tree that implements the interface "ITF", CODESYS automatically also inserts the methods "Method1" and "Method2" under the function block. Here you can implement function-block-specific code in the methods.

Object 'Method'

Symbol: METHOD

Keywords: METHOD
Methods are an extension of the IEC 61131-3 standard and a tool for object-oriented programming which is used for data encapsulation. A method contains a declaration and an implementation. However, unlike a function, a method is not an independent POU, and it is subordinated to a function block or program. A method can access all valid variables of the superordinate POU.

You can use interfaces for the organization of methods.

You can add a method below a program or a function block. Click “Project ➤ Add Object ➤ Method” to open the “Add Method” dialog.

### Declaration
- The variables of a method contain temporary data that are valid only during the execution of the method (stack variables). All variables that are declared and implemented in a method are reinitialized each time the method is called.
- Like functions, methods can have additional outputs. You must assign these additional outputs in the method call.
- Depending on the declared access specifier, a method can be called only within its own namespace (INTERNAL), only within its own POU and its derivatives (PROTECTED), or only within its own POU (PRIVATE). For PUBLIC, the method can be called from anywhere.

Interface methods can have declared input, output, and VAR_IN_OUT variables, but do not contain an implementation.

See also
- Chapter 1.3.1.25.1.28.6 “Object 'Interface Method’” on page 788

### Implementation
- Access to function block instances or program variables is permitted in the implementation of the method.
- The THIS pointer allows for access to its own function block instance. Therefore, the pointer is permitted only in methods that are assigned to a function block.
- A method cannot access VAR_TEMP variables of the function block.
- A method can call itself recursively.

#### NOTICE!
When you copy a method below a POU and add it below an interface, or move the method there, the contained implementation is removed automatically.

### Calling a method

#### Syntax for calls:
```
<return value variable> := <POU name> . <method name> ( <method input name> := <variable name> , <further method input name> := <variable name> )* ;
```

For the method call, you assign transfer parameters to the input variables of the method. Respect the declaration when doing this. It is enough to specify the names of the input variables without paying attention to their order in the declaration.
METHOD PUBLIC DoIt : BOOL
  VAR_INPUT
    iInput_1 : DWORD;
    iInput_2 : DWORD;
    sInput_3 : STRING(12);
  END_VAR
  bFinishedMethod := fbInstance.DoIt(sInput_3 := 'Hello World ',
    iInput_2 := 16#FFFF, iInput_1 := 16);

When the method is called, the return value of the method is assigned, for example, to variables declared locally. When you omit the names of the input variables, you have to pay attention to the declaration order.

Example
Declaration
METHOD PUBLIC DoIt : BOOL
  VAR_INPUT
    iInput_1 : DWORD;
    iInput_2 : DWORD;
    sInput_3 : STRING(12);
  END_VAR
Call
  bFinishedMethod := fbInstance.DoIt(16, 16#FFFF,'Hello World ');

Recursive method call
Within the implementation, a method can call itself, either directly by means of the THIS pointer, or by means of a local variable for the assigned function block.

- THIS^. <method name> ( <parameter transfer of all input and output variables> )
  Direct call of the relevant function block instance with the THIS pointer
- VAR fb_Temp : <function block name>; END_VAR
  Call by means of a local variable of the method that temporarily instantiates the relevant function block

A compiler warning is issued for a recursive call. If the method is provided with the pragma {attribute 'estimated-stack-usage' := 'estimated_stack_size_in_bytes'}), then the compiler warning is suppressed. For an implementation example, see the "Attribute 'estimated-stack-usage'" chapter.

To call methods recursively, it is not enough to specify only the method name. If only the method name is specified, then a compiler error is issued: "Program name, function or function block instance expected instead of"

- § Chapter 1.3.1.24.6.2.10 “Attribute ‘estimated-stack-usage’” on page 608
- § Chapter 1.3.1.24.2.15 “THIS” on page 502

Special methods of a function block
| **FB_Init** | Declarations automatically implicit, but explicit declaration also possible.  
Contains initialization code for the function block, as is defined in the declaration part of the function block. |
| **FB_Reinit** | Explicit declaration is necessary.  
Call after the instance of the function block was copied (as during an online change). It reinitializes the new instance module. |
| **FB_Exit** | Explicit declaration is necessary.  
Call for each instance of the function block before a new download or a reset or during an online change for all shifted or deleted instances. |

### Properties
Provides **Set** and/or **Get** accessor methods.

**See also**
- Chapter 1.3.1.24.10 “Methods ‘FB_Init’, ‘FB_Reinit’, and ‘FB_Exit’” on page 653
- Chapter 1.3.1.25.1.28.8 “Object ‘Property’” on page 791
- Chapter 1.3.1.25.1.28.7 “Object ‘Interface Property’” on page 788

### Dialog 'Add Method'
**Function:** Defines a method below the selected POU when the dialog is closed.

**Call:** Menu bar: “Project ➔ Add Object ➔ Method”; context menu

**Requirement:** A program (PRG) or a function block (FUNCTION_BLOCK) is selected in the “POUs” view or the “Devices” view.

The interface of a method inserted below a basic function block is copied when a method with the same name is inserted below a derived function block.

| **“Name”** | Example: `meth_DoIt`.  
The standard methods `FB_Init` and `FB_Exit` are offered in a list box if they are not already inserted below the POU. If it is a derived function block, then the list box also offers all of the methods of the basic function block. |
| **“Return type”** | Default data type or structured data type of return value  
Example: `BOOL` |
| **“Implementation language”** | Example: “Structured Text (ST)” |
| **“Access specifier”** | Controls access to data.  
- “PUBLIC” or not specified: Access is not restricted.  
- “PRIVATE”: Access is restricted to the program, function block, or GVL. The object is marked as (private) in the POU or device view. The declaration contains the keyword PRIVATE.  
- “PROTECTED”: Access is restricted to the program, function block, or GVL with its derivations. The declaration contains the keyword PROTECTED. The object is marked as (protected) in the POU or device view.  
- “INTERNAL”: Access to the method is restricted to the namespace (library). The object is marked as (internal) in the POU or device view. The declaration contains the keyword INTERNAL. |
| **“Abstract”** | ☑: Identifies that the method does not have an implementation and the implementation is provided by the derived FB |
| **“Add”** | Adds a new method below the selected object. |
When you do object-oriented programming and want to use inheritance for blocks, you have the
following support: When you insert a method, action, etc. below an inherited block, the “Add
Object” dialog box includes a combo box with a list of methods, actions, etc. used in the base
block. In this way, you can easily accept a method definition of the base and adapt it accordingly
for the inherited method of the block. Methods and attributes with the PRIVATE access modifier
are not available in this selection because they should not be inherited. When accepted into the
inherited block, methods and attributes with the PUBLIC access modifier automatically have a
blank access modifier field. (Functionally, this means the same thing.)

- Chapter 1.3.1.9.23 “Object-oriented programming” on page 263

Object 'Interface Method'

Symbol: 🟢

This object is used for object-oriented programming.

The object “Interface Method” is added to an interface via the command “Project ➔ Add Object”.

If a method is inserted underneath an interface, you can add and instance only variable declara-
tions (input, output and input/output variables) in this method.

You can only add program code to the method if a function block 'implements' the interface to
which the method belongs. CODESYS then inserts the method underneath the function block.

See also
- Chapter 1.3.1.25.1.28.4 “Object 'Interface'” on page 783
- Chapter 1.3.1.25.1.28.5 “Object 'Method'” on page 784
- Chapter 1.3.1.9.23.2 “Implementing interfaces” on page 265

Object 'Interface Property'

Symbol: 🛠

Interface properties are an extension of the IEC 61131-3 standard and a tool for object-oriented
programming. An interface property declares the accessor methods Get and Set (no imple-
mentation code). Therefore, a function block that implements an interface also inherits their
interface properties.

You can add an interface property to the device tree for an interface. Then an interface is
extended with the accessor methods Get and Set. The Get accessor is for read access. The
Set accessor is for write access. You can delete an unneeded accessor. Click “Project ➔ Add Object ➔ Interface Property” to add an accessor. The “Add Interface Property” dialog
opens.

See also
- Chapter 1.3.1.25.1.28.4 “Object 'Interface'” on page 783
- Chapter 1.3.1.25.1.28.8 “Object 'Property'” on page 791
This interface `itf_A` has the property `Literal_A` with the accessor methods `Get` and `Set`. The function blocks `fb_A1` and `fb_A2` implement the interface `itf_A` and therefore inherit its interface property. Each FB has its own implementation.

**Interface itf_A**

```plaintext
INTERFACE itf_A
VAR
END_VAR
PROPERTY Literal_A : STRING
```

**FB fb_A1**

```plaintext
FUNCTION_BLOCK fb_A1 IMPLEMENTS itf_A
VAR
  str_1 : STRING;
  str_2 : STRING;
  iCnt : INT;
END_VAR
iCnt := iCnt + 1;
str_1 := 'Function block A1';
```
VAR

Literal_A := CONCAT (str_1, ' and property.');

VAR

str_2 := Literal_A;

FUNCTION_BLOCK fb_A2 IMPLEMENTS itf_A
VAR
str_1 : STRING;
str_2 : STRING;
iCnt : INT;
END_VAR

iCnt := iCnt + 1;
str_1 := 'Function block A2';

PROGRAM PLC_PRG
VAR
iCnt : INT;
my_1 : fb_A1;
my_2 : fb_A2;
strName_1 : STRING;
strName_2: STRING;
END_VAR

iCnt := iCnt + 1;
my_1();
my_2();
strName_1:= my_1.Literal_A;
strName_2:= my_2.Literal_A;
my_1.Literal_A := 'Hello 1';
my_2.Literal_A := 'World 2';

This leads to the following monitoring of PLC_PRG when the application is in runtime mode:
Properties are an extension of the IEC 61131-3 standard and a tool for object-oriented programming. Properties are used for data encapsulation because they allow for external access to data and act as filters at the same time. For this purpose, a property provides the accessor methods Get and Set which allows for read and write access to the data of the instance below the property.

You can add a property with accessor methods below a program, a function block, or a global variable list. Click “Project ➔ Add Object ➔ Property” to open the “Add Property” dialog.

You can add an interface property below an interface.

When you copy a property that is inserted below a POU and add it below an interface, or if you move the property there, the included implementations are removed automatically.

<td></td>
</tr>
</tbody>
</table>

**Editor 'Property'**

You can program the data access in the editor. The code can contain additional local variables. However, it must not contain any additional input variables or (as opposed to a function or method) output variables.

| **Abstract** | ✔: Identifies that the property does not have an implementation and the implementation is provided by the derived FB |
| **Add** | Adds a new property below the selected object and below that the accessor methods Get and Set. Note: When you select a property, you can also add a previously removed accessor explicitly by clicking “Add Object”. |
Function block

```plaintext
FUNCTION_BLOCK fb_A
VAR_INPUT
END_VAR
VAR_OUTPUT
END_VAR
VAR
  iA : INT;
  iB : INT;
END_VAR
  iA := iA + 1;
```

Property Value_A

```plaintext
PROPERTY PUBLIC Value_A : INT
```

Accessor method fb_A.Value_A.Get

```plaintext
VAR
  Value_A := iA;
END_VAR
```

Accessor method fb_A.Value_A.Set

```plaintext
VAR
  iB := Value_A;
```

Get and Set accessor

When the `Set` accessor is called, the property is written. It is then used in the same way as an input parameter. When the `Get` accessor is called, the property is read. It is then used in the same way as an output parameter. Access is restricted by means of access specifiers, and the objects are marked accordingly.

When a property is accessed as read only or write only, you can delete the unneeded accessor.

You can add accessors explicitly by selecting a property and clicking “Add Object”. A dialog opens, either “Add Get Accessor” or “Add Set Accessor”. There you can set the implementation language and the access.

<table>
<thead>
<tr>
<th>&quot;Implementation language&quot;</th>
<th>Example: “Structured Text (ST)”</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>&quot;Access specifier&quot;</th>
<th>Access is not restricted.</th>
</tr>
</thead>
<tbody>
<tr>
<td>PUBLIC or unspecified</td>

</tr>
<tr>
<td>PRIVATE</td>
<td>Access to the property is restricted to the program, function block, or GVL and its derivations. The declaration contains the keyword. The object is marked as (protected) in the POU or device view.</td>
</tr>
</tbody>
</table>
Access to the method is restricted to the namespace (the library). The object is marked as (internal) in the POU or device view. The declaration contains the keyword.

“Add” Adds the accessor methods Get or Set below the selected property.

Monitoring of properties in online mode

The following pragmas are provided for the monitoring of properties in online mode. You insert them at the top position of the property definition:

- `{attribute 'monitoring' := 'variable'}`
  Each time the property is accessed, CODESYS saves the actual value to a variable and displays the value of this variable. This value can become outdated if no more access to the property takes place in the code.

- `{attribute 'monitoring' := 'call'}`
  Each time the value is displayed, CODESYS calls the code of the Get accessor. If this code contains a side effect, then the monitoring executes the side effect.

You can monitor a property with the help of the following functions.

- Inline monitoring
  Requirement: The “Enable inline monitoring” option is selected in the “Text Editor” category of the “Options” dialog.

- Watch list

Input assistance when creating inheriting blocks

When you do object-oriented programming and want to use inheritance for blocks, you have the following support: When you insert a method, action, etc. below an inherited block, the “Add Object” dialog box includes a combo box with a list of methods, actions, etc. used in the base block. In this way, you can easily accept a method definition of the base and adapt it accordingly for the inherited method of the block. Methods and attributes with the PRIVATE access modifier are not available in this selection because they should not be inherited. When accepted into the inherited block, methods and attributes with the PUBLIC access modifier automatically have a blank access modifier field. (Functionally, this means the same thing.)

See also:

- § Chapter 1.3.1.9.23.1 “Extension of function blocks” on page 263
- § Chapter 1.3.1.9.23 “Object-oriented programming” on page 263

Object ‘Action’

Symbol: 🌈

In an action, you implement additional program code, which you can further implement as in another language as the base implementation. This base implementation is a function block or a program where you inserted the action.

An action does not have its own declaration and it works with the data from the base implementation. This means that the action uses the input and output variables and the local variables from its base implementation.

Add an “Action” to a function block or program by clicking “Project ➔ Add Object ➔ Action”.

Object 'Action'
Table 85: “Add Action”

<table>
<thead>
<tr>
<th>“Name”</th>
<th>Name of the action</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Implementation language”</td>
<td>Drop-down list of implementation language</td>
</tr>
</tbody>
</table>

Input assistance when creating inheriting blocks

When you do object-oriented programming and want to use inheritance for blocks, you have the following support: When you insert a method, action, etc. below an inherited block, the “Add Object” dialog box includes a combo box with a list of methods, actions, etc. used in the base block. In this way, you can easily accept a method definition of the base and adapt it accordingly for the inherited method of the block. Methods and attributes with the *PRIVATE* access modifier are not available in this selection because they should not be inherited. When accepted into the inherited block, methods and attributes with the *PUBLIC* access modifier automatically have a blank access modifier field. (Functionally, this means the same thing.)

Calling an action

Syntax:

<program>.<action> or <FB instance>.<action>

To call an action from only within the base implementation, you only have to provide the action name.

Examples

Calling a “Reset” action from another POU

The call is not executed from the base implementation.

Declaration:

```plaintext
PROGRAM PLC_PRG
VAR
  Inst : Counter;
END_VAR
```

Calling a “Reset” action from an IL POU

```plaintext
CAL Inst.Reset(In := FALSE)
LD Inst.Out
ST ERG
```

Calling a “Reset” action from an ST POU

```plaintext
Inst.Reset(In := FALSE);
Erg := Inst.out;
```

Calling a “Reset” action from an FBD POU

![Diagram](image_url)

*Actions are used frequently in the SFC implementation language.*

Object 'POUs for Implicit Checks'

You can add these special POUs to an application to equip them with implicit monitoring functions. At runtime, these functions check the limits of arrays or subrange types, the validity of pointer addresses, and division by zero. Please note: This option can be disabled for devices that are already equipped with these kinds of monitoring blocks by a special implicit library.

The command “Add Object ➔ POU for Implicit Checks” is used for adding to the application. The command opens the “Add POU for Implicit Checks” dialog where you can select a monitoring function type (see table below). Depending on the monitoring function, you have to adapt the implementation code or create it yourself from scratch.

To prevent multiple inclusions, monitoring functions that have already been inserted are disabled in the “Add POU for Implicit Checks” dialog.

**NOTICE!**

To get the feature for monitoring functions, do not edit their declaration part. However, you are permitted to add local variables.

After removing an implicit monitoring function (example: Check Bounds) from the project, only a download is possible, not an online change. A corresponding message is issued.

By default, CODESYS does not run implicit checks for function blocks from libraries used in the application. However, you can extend the check to the libraries by opening the “Properties” dialog of the application and specifying the compiler definition checks_in_libs in the “Compiler-Defines” field in the “Build” tab. This definition affects implementation libraries (*.library) only, not protected libraries (*.compiled-library).

You can use the "no_check" attribute to deactivate the check for special POUs in the project.

**POU 'CheckBounds'**

**Functions for Bound Checks:**

- **CheckBounds**

The task of this monitoring function is to handle bound violations appropriately. Examples of reactions to violations include setting error flags and changing the value of the array index. The check is performed only for one variable array index. An incorrect constant array index causes a compiler error. CODESYS calls the function implicitly when values are assigned to an ARRAY variable.

After inserting the function, you receive automatically generated code in the declaration and implementation parts. See below.
Declaration part

```plaintext
// Automatically generated code: DO NOT EDIT
FUNCTION CheckBounds : DINT
VAR_INPUT
    index, lower, upper: DINT;
END_VAR
```

Implementation

```plaintext
// This automatically generated code is a suggested implementation.
IF  index < lower THEN
    CheckBounds := lower;
ELSIF  index > upper THEN
    CheckBounds := upper;
ELSE
    CheckBounds := index;
END_IF

(* It is also possible to set a breakpoint, log messages or e.g. to
halt on an exception:
Add CmpApp.library, SysExcept.library and SysTypes2_Itf as newest.
Declaration:
VAR
    _pApp : POINTER TO CmpApp.APPLICATION;
    _result   : SysTypes.RTS_IEC_RESULT;
END_VAR

Implementation:
    _pApp := AppGetCurrent(pResult:=_result);
    IF  index < lower THEN
        CheckBounds := lower;
        IF _pApp <> 0 THEN
            AppGenerateException(pApp:=_pApp,
                ulException:=RtsExceptions.RTSEXCPT_ARRAYBOUNDS);
        END_IF
    ELSIF  index > upper THEN
        CheckBounds := upper;
        IF _pApp <> 0 THEN
            AppGenerateException(pApp:=_pApp,
                ulException:=RtsExceptions.RTSEXCPT_ARRAYBOUNDS);
        END_IF
    ELSE
        CheckBounds := index;
    END_IF
*)
```

When the “CheckBounds” function is called, it receives the following input parameters:
- **index**: Index of the array element
- **lower**: Lower limit of the array range
- **upper**: Upper limit of the array range

The return value is the index of the array element, as long as it is within a valid range. If not, then the CODESYS returns either the upper or lower limit, depending on which threshold was violated.
In the sample program below, the index falls short of the defined lower limit of the `a` array.

```
PROGRAM PLC_PRG
VAR
  a: ARRAY[0..7] OF BOOL;
  b: INT:=10;
END_VAR
  a[b]:=TRUE;
```

In this example, the `CheckBounds` function causes `a` to change the upper limit of the array range index to 10. The value `TRUE` is assigned then to the element `a[7]`. In this way, the function corrects array access outside of the valid array range.
Add the following libraries in the library manager of the application:

- CmpApp.library and SysExcept.library as placeholder libraries
- SysTypes2_Itfs.library with “Newest version always”

Add a “CheckBounds” object below the application and modify the specified code as shown below.

**FUNCTION CheckBounds : DINT**

**VAR_INPUT**

index, lower, upper: DINT;

**END_VAR**

**VAR**

_pApp : POINTER TO CmpApp.APPLICATION;
_Result : ISystypes2.RTS_IEC_RESULT;

**END_VAR**

// This automatically generated code is a suggested implementation.
_pApp := AppGetCurrent(pResult := _Result);
IF  index < lower THEN CheckBounds := lower;
IF _pApp <> 0 THEN
    AppGenerateException(pApp := _pApp, ulException := RtsExceptions.RTSEXCPT_ARRAYBOUNDS);
END_IF
ELSIF index > upper THEN CheckBounds := upper;
IF _pApp <> 0 THEN
    AppGenerateException(pApp:=_pApp, ulException:=RtsExceptions.RTSEXCPT_ARRAYBOUNDS);
END_IF
ELSE
    CheckBounds := index;
END_IF

Program a “MAIN_PRG” object below the application with the contents shown below.

**PROGRAM MAIN_PRG**

**VAR**

xInit    : BOOL;
arData   : ARRAY[0..7] OF BYTE;
i        : INT;
dwAdr       : DWORD;

**END_VAR**

IF NOT xInit THEN // Required for CheckBounds
    xInit := TRUE;
END_IF

// Set i to a value > 7 or < 0
// Generates an exception in CheckBounds, user-defined
arData[i] := 11;

When you load and start this application, an exception will be thrown when array bounds are violated. Processing stops in “CheckBounds” so that the type of error can be detected.

- § Chapter 1.3.1.25.1.19.8 “Tab ‘Log’” on page 750
POU 'CheckDivInt'

To prevent division by zero, you can use the functions CheckDivInt, CheckDivLint, CheckDivReal, and CheckDivLReal. If you include these functions in the application, then they are called before each division operation in the code.

CAUTION!

To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

The default implementation of CheckDivReal:

```
// This is automatically generated code: DO NOT EDIT
FUNCTION CheckDivReal : REAL
VAR_INPUT
  divisor:REAL;
END_VAR

IF divisor = 0 THEN
  CheckDivReal:=1;
ELSE
  CheckDivReal:=divisor;
END_IF;
```

The DIV operator uses the output of the CheckDivReal function as a divisor. In the sample program below, CheckDivReal prevents division by 0 by changing the implicit value of the divisor d from "0" to 1 before the division operation is executed. Therefore, the division result is 799.

```
PROGRAM PLC_PRG
VAR
  erg:REAL;
  v1:REAL:=799;
  d:REAL:=0;
END_VAR
  erg:= v1 / d;
```

- Chapter 1.3.1.9.22 “Using POUs for implicit checks” on page 262

POU 'CheckDivLInt'

To prevent division by zero, you can use the functions CheckDivInt, CheckDivLint, CheckDivReal, and CheckDivLReal. If you include these functions in the application, then they are called before each division operation in the code.
CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

The default implementation of CheckDivReal:

Declaration section:

// This is automatically generated code: DO NOT EDIT
FUNCTION CheckDivReal : REAL
VAR_INPUT
    divisor:REAL;
END_VAR

Implementation section:

// This automatically generated code is a suggested implementation.
IF divisor = 0 THEN
    CheckDivReal:=1;
ELSE
    CheckDivReal:=divisor;
END_IF;

The DIV operator uses the output of the CheckDivReal function as a divisor. In the sample program below, CheckDivReal prevents division by 0 by changing the implicit value of the divisor d from "0" to 1 before the division operation is executed. Therefore, the division result is 799.

PROGRAM PLC_PRG
VAR
    erg:REAL;
    v1:REAL:=799;
    d:REAL:=0;
END_VAR
    erg:= v1 / d;

POU 'CheckRangeSigned'

Function for monitoring the range limits of a subrange type of type DINT.

This monitoring function is responsible for the appropriate handling violations to range limits. Examples of reactions to violations include setting error flags and changing values. The functions are called implicitly when a value is assigned to a subrange type variable.

CAUTION!

To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

When the function is called, it receives the following input parameters:
- value: Value that should be assigned to the subrange type variables
- lower: Lower range limit
- upper: Upper range limit

The return value is the assignment value as long as it is within the valid range. If not, then either the upper or lower limit is returned, depending on which threshold was violated.

For example, the assignment i := 10*y is replaced implicitly by i := CheckRangeSigned(10*y, -4095, 4095);
If \( y \) is "1000", then "10*1000=10000" is not assigned to \( i \) like in the original code. Instead, the upper range limit of "4095" is assigned.

The same is true for \text{CheckRangeUnsigned} function.

\begin{center}
\begin{tabular}{|c|}
\hline
\textbf{NOTICE!} \\
If functions are not available, then the subrange is not checked for the respective variables at runtime. In this case, you can assign any value between \(-2147483648\) and \(+2147483648\) (or between 0 and \(4294967295\)) to a variable of subrange type \text{DINT/UDINT}. You can assign any value between 
\(-9223372036854775808\) and \(+9223372036854775807\) (or between 0 and 
\(18446744073709551615\)) to a variable of a subrange type \text{LINT/ULINT}. \\
\hline
\end{tabular}
\end{center}

\begin{center}
\begin{tabular}{|c|}
\hline
\textbf{CAUTION!} \\
Linking area monitoring functions can lead to endless loops. For example, an endless loop can occur if the counter variable of a \text{FOR} loop is a subrange type and the counting range for the loop exits the defined subrange. \\
\hline
\end{tabular}
\end{center}

\begin{center}
\begin{tabular}{|l|}
\hline
\textbf{Example of an endless loop:} \\
\text{VAR} \\
\hspace{1cm} ui : UINT (0..10000); \\
\hspace{1cm} ... \\
\hspace{1cm} END_VAR \\
\hspace{1cm} FOR ui:=0 TO 10000 DO \\
\hspace{2cm} ... \\
\hspace{1cm} END_FOR \\
The program never exits the \text{FOR} loop because the \text{CheckRangeSigned} monitoring function prevents \text{ui} from being set to a value greater than 10000. \\
\hline
\end{tabular}
\end{center}

\begin{center}
\begin{tabular}{|l|}
\hline
\textbf{Example for \text{CheckRangeSigned}} \\
The assignment of a value to a \text{DINT} variable of a signed subrange type is a condition for automatically calling the \text{CheckRangeSigned}. This function restricts the assignment value to the subrange as defined in the variables declaration. The default implementation of the function in \text{ST} is as follows: \\
\hspace{1cm} Declaration section: \\
\hspace{2cm} // This is automatically generated code: DO NOT EDIT \\
\hspace{2cm} FUNCTION CheckRangeSigned : DINT \\
\hspace{2cm} VAR_INPUT \\
\hspace{3cm} value, lower, upper: DINT; \\
\hspace{2cm} END_VAR \\
\hspace{1cm} Implementation: \\
\hspace{2cm} // This automatically generated code is a suggested implementation. \\
\hspace{2cm} IF (value < lower) THEN \\
\hspace{3cm} CheckRangeSigned := lower; \\
\hspace{2cm} ELSEIF (value > upper) THEN \\
\hspace{3cm} CheckRangeSigned := upper; \\
\hspace{2cm} ELSE \\
\hspace{3cm} CheckRangeSigned := value; \\
\hspace{2cm} END_VAR \\
\hline
\end{tabular}
\end{center}
POU 'CheckLRangeSigned'

Function for monitoring the range limits of a subrange type of type LINT.

For an implementation example of range monitoring, refer to the help page for the CheckRangeSigned function.

This monitoring function is responsible for the appropriate handling violations to range limits. Examples of reactions to violations include setting error flags and changing values. The functions are called implicitly when a value is assigned to a subrange type variable.

**CAUTION!**
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

When the function is called, it receives the following input parameters:

- **value**: Value that should be assigned to the subrange type variables
- **lower**: Lower range limit
- **upper**: Upper range limit

The return value is the assignment value as long as it is within the valid range. If not, then either the upper or lower limit is returned, depending on which threshold was violated.

For example, the assignment `i := 10*y` is replaced implicitly by `i := CheckRangeSigned(10*y, -4095, 4095);`

If `y` is "1000", then "10*1000=10000" is not assigned to `i` like in the original code. Instead, the upper range limit of "4095" is assigned.

The same is true for CheckRangeUnsigned function.

**NOTICE!**
If functions are not available, then the subrange is not checked for the respective variables at runtime. In this case, you can assign any value between -2147483648 and +2147483648 (or between 0 and 4294967295) to a variable of subrange type DINT/UDINT. You can assign any value between -9223372036854775808 and +9223372036854775807 (or between 0 and 18446744073709551615) to a variable of a subrange type LINT/ULINT.

**CAUTION!**
Linking area monitoring functions can lead to endless loops. For example, an endless loop can occur if the counter variable of a FOR loop is a subrange type and the counting range for the loop exits the defined subrange.
The program never exits the FOR loop because the `CheckRangeSigned` monitoring function prevents `ui` from being set to a value greater than 10000.

POU 'CheckPointer'

Monitoring function for pointers (Checkpoint)

Use this function to monitor the memory access of pointers in runtime mode. As opposed to other monitoring functions, a standard suggestion does not exist for the implementation of CheckPointer. You must define an implementation according to your own requirements.

The CheckPointer function should check whether the returned pointer references a valid memory address; monitors whether the orientation of the referenced memory range matches the variable type that the pointer refers to. If both conditions are fulfilled, then the pointer is returned. If not, then the function should complete an appropriate error handling.

CAUTION!
To obtain the feature for monitoring functions, do not edit the declaration section. However, you are permitted to add local variables.

NOTICE!
An implicit monitoring function call does not occur for THIS pointer and SUPER pointer.
NOTICE!

For compiler version 3.5.7.40 and later, the implicit check function "Checkpointer" also acts on REFERENCE variables in the same way as on pointer variables.

// Automatically generated code: DO NOT EDIT
FUNCTION CheckPointer : POINTER TO BYTE
VAR_INPUT
  ptToTest : POINTER TO BYTE;
  iSize : DINT;
  iGran : DINT;
  bWrite: BOOL;
END_VAR

// Not a standard implementation. Please add your own code here.
CheckPointer := ptToTest;

When the function is called, CODESYS provides the following input parameters:

- ptToTest: Target address of the pointer
- iSize: Size of the referenced variable; the data type of iSize must be compatible with INT and cover the dimensional scope of the variables.
- iGran: Granularity of the referenced size; this is the largest non-structured data type contained in the referenced variables; the data type of iGran must be compatible with INT
- bWrite: Access type (TRUE = write access, FALSE = read access); the data type of bWrite must be BOOL

When the result of the check is positive, the unchanged pointer is returned (ptToTest).

Object 'Project Settings'

Symbol: 📖

Function: This object contains the configuration of the project.

Call:

- “Project ➔ Project Settings”
- Double-click on the object in the device tree

CODESYS saves the project settings directly in the project. If, for example, you transfer a project to another system, the "Project Settings" object is also transferred with it without a project archive being required.

The project settings are valid project-wide and offer setting possibilities for various categories such as “AS” or “Users and Groups”. The available categories vary, depending on which software packages you have installed via the package manager.

See also

- "Chapter 1.3.1.3.6.2 “Making project settings” on page 134"
- "Chapter 1.3.1.25.2.8.1 “Command ‘Package Manager’” on page 949"
- "Chapter 1.3.1.25.3.11.1 ‘Dialog ‘Project Settings’ - ‘SFC’” on page 1059"
- "Chapter 1.3.1.25.3.11.2 ‘Dialog Box ‘Project Settings’ - ‘Users and Groups’” on page 1060"
Object 'Project Information'

Symbol: 🔄

Function: The object contains the properties, meta-information, and project information. With this, you can check the authorship and integrity of the project.

Call
- Double-click the object in the device tree
- Menu bar: “Project ➔ Project Information”

Requirement: CODESYS creates the object when you click “Project ➔ Project Information”, and the dialog opens.

CODESYS saves the project information directly in the project. For example, if you transfer a project to another system, then the “Project Information” object is also transferred. You do not need a project archive.

Tab ‘File’
The tab displays the properties of the project file and their attributes. You cannot edit these attributes. They correspond to the file properties of Windows Explorer.

Tab ‘Summary’
The tab contains general information and meta-information of the project file. CODESYS uses this information to create keys on the “Properties” tab. For example, if the name Company_A is specified in “Company”, then the Company key with the value Company_A is provided on the “Properties” tab.

NOTICE!
If you save your project as a library project, then you should pay attention to the guidelines for library developers (Library Development Summary).

For a library project, a “Company”, a “Title”, and a “Version” must be specified to install the library.

<table>
<thead>
<tr>
<th>“Company”</th>
<th>Name of the company (example: Company_A).</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Title”</td>
<td>Title of the project (example Automation_A).</td>
</tr>
<tr>
<td>“Version”</td>
<td>Version of the project (example: 0.0.0.1).</td>
</tr>
<tr>
<td>“Released”</td>
<td>✅: Activates protection from modification. Result: If you edit the project now, then a dialog prompt opens to confirm whether you really want to change the project. If you reply to this prompt one time by clicking “Yes”, then no additional prompts appear for more editing actions.</td>
</tr>
</tbody>
</table>
“Library Categories”
Categories of the library project, according to which you can sort in the “Library Repository” dialog. If no category is specified, then the category “Other” is assigned to the library.

The categories originate from one or more external description files in XML format. However, they can also originate from a library project that has already been created.

Requirement: The project is a library project.

The “Library Categories” dialog opens where you can add library categories.

“Default namespace”
If you do not define a standard namespace here, then the name of the library file is applied automatically as the namespace.

“Author”
Author of the project (example: Arnold Best).

“Description”
Example: For internal use only

“Library compatibility”
List box for setting the CODESYS version for which the currently open library project is compatible, including all later versions). The setting is relevant with regard to the certificate-based signing of compiled libraries which is possible only as of V3 SP15.

● § Chapter 1.3.4.1 “Guidelines for creating libraries” on page 1105
● § Chapter 1.3.1.25.2.8.2 “Command ‘Library Repository’” on page 951

Tab ‘Properties’
On this tab, you can define keys that you can control externally from user-specific programs.

NOTICE!
If you have opened a library project, then note the description of the relevant keys in the guidelines for library developers (Library Development Summary).

If you have opened a symbol library as a project, then the key VisuSymbolLibrary = TRUE must be defined. It identifies the library as a symbol library.
### Key
Name of the key. Specify any string of text for the new key, or select an existing key from the "Properties" table.

### Type
Data type of the key. Possible types: "Text", "Date", "Number", "Boolean", "Version".

### Value
Value of the key in permitted format
- "Text": Any character string
- "Date": Example: Friday, January 1, 2016 00:00:00. Minimum entry for the date: 1.1
- "Number": Integer in Integer32 format with or without a sign (example: -32500).
- "Boolean": True or False, capitalization irrelevant.
- "Version": Examples: 1.1, 1.0.1.0, maximum four figures.

### Add
Adds the new defined key to the "Properties" table.

### Modify
Saves the change made for the key selected in the "Properties" table.

### Remove
Removes the key selected in the "Properties" table.

### Properties
List of the properties that are defined as keys. CODESYS creates keys automatically for the information in the "Summary" tab.
Click a key to edit it in the input fields above the list.

- Using the Symbol Library in the Visualization
- Chapter 1.3.1.25.3.10.16 “Dialog 'Properties' - 'Image Pool'” on page 1057

### Tab 'Statistics'
The dialog provides statistical information about the number of objects of the individual type or use in the project.

### Tab 'Licensing'
The dialog is for the license protection of libraries.

CAUTION!
You can protect only compiled libraries in this way.

### Table 88: "Variables"

| "Activate dongle licensing" | ☑: The library requires a dongle with a license to use it. |
| "Firm code" | License information that must be supplied from the dongle for using the library later. |
| "Product code" | |
| "Activation URL" | |
| "Activation mail" | |

See also
- Chapter 1.3.4.1 “Guidelines for creating libraries” on page 1105
- Chapter 1.3.1.21 “Managing packages and licenses” on page 375
Tab 'Signing'  
When a certificate-signed library is created (possible as of CODESYS V3 SP15) and library compatibility with CODESYS < V3 SP15 is not set, the settings on this tab are disabled. In this case, the signing is done by means of a certificate that has to be assigned to the user profile in the security screen.

One method, which is not recommended but may be necessary in some case for compatibility with versions < V3 SP15, is the less secure signing of a library by means of a vendor-specific, one-time key in this dialog. Requirement: This key is available as a private key file (*.libpk) with an associated token. The user of the library also has to obtain this key in order to be able to check whether the last signing was actually performed by the library vendor.

<table>
<thead>
<tr>
<th>“Activate signing”</th>
<th>CODESYS signs the library project with a single-use, manufacturer-specific key.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Private key file”</td>
<td>Location of the private key file *.libpk (example: D:\for lib developers only\mycomp_libkey.libpk).</td>
</tr>
</tbody>
</table>
| “Public key token” | Example: 427A5701DA3CF3CF  
Requirement: A private key file is specified, and CODESYS has read and entered the token. |
| “Create Private Key File” | CODESYS creates a new private key file. |

- “Deprecated: Signing a library project (only for version compatibility with CODESYS < SP15)” on page 133

Options for creating blocks for accessing project information
### Automatically generate 'Project Information' POUs

Note: The functions that are created with this option can be used only if the runtime system supports the **WSTRING** data type. If this is not the case, then you can use the functions that were created automatically for the with the individual items of the project information, at least in the application for accessing properties. These functions are not registered in the runtime system.

- CODESYS creates POUs of the **FUNCTION** type in the “POUs” view, allowing programmatic access to the project properties in the application. The function blocks GetCompany, GetTitle and GetVersion are created for the properties “Company”, “Title” and “Version”.

The following function blocks are available for user-defined properties:

- GetBooleanProperty: BOOL (TRUE/FALSE)
- GetNumberProperty: DINT (numeric value)
- GetTextProperty: WSTRING (character string)
- GetTextProperty2: POINTER TO WSTRING (unlimited length)
- GetVersionProperty: VERSION (version number as character string)

Note: Do not activate this option for standard libraries, because this can cause problems on smaller systems due to the additional memory requirements.

<table>
<thead>
<tr>
<th>Automatically generate 'Library Information' POUs</th>
</tr>
</thead>
</table>

- CODESYS creates POUs of the **FUNCTION** type in the “POUs” view, allowing programmatic access to the project properties in the application.

For the “Version” and “Released” properties, the following functions are created:
- GetLibVersion (version number as character string),
- GetLibVersionNumber (version number as numeric value), and
- IsLibReleased (TRUE/FALSE).

Note: These functions are not registered in the runtime system. The option is available as an alternative solution is the runtime system does not support the **WSTRING** data type, therefore not permitting you to use the functions created with the “Automatically generate 'Project Information' POUs” option.

<td>Tab 'Redundancy Settings' - 'Redundancy Link' ................. 817</td>
</tr>
<tr>
<td>1.3.1.25.1.32.7</td>
<td>Tab 'Redundancy Settings' - 'General' ............................. 818</td>
</tr>
<tr>
<td>1.3.1.25.1.32.8</td>
<td>Tab 'Registered Areas' ...................................................... 819</td>
</tr>
</tbody>
</table>

The “Redundancy Configuration” object contains the editor for the CODESYS Redundancy feature. Here you configure two configured and redundant PLC devices that execute the same application. At any one time, just one of the PLCs controls the execution, while the other is in standby mode. If the active PLC fails, then the other PLC takes control without any interruption in the processing.

You add the object below the application in the device tree by clicking “Add Object”.

Depending on the device description, the editor includes one or all of the following tabs:
● "Redundancy Status": Configuration of the communication between both PLCs. Status change and status bar. Synchronization:
● “Applications”: Information about the application on PLC2. Corresponds to the tab with the same name in the device editor of the primary controller.
● “Files”: File transfer with PLC2. Corresponds to the tab with the same name in the device editor of the primary controller.
● “Log”: Display of the log messages from PLC2. Corresponds to the tab with the same name in the device editor of the primary controller.
● “PLC Shell”: Transmission of PLC shell commands to PLC2. Corresponds to the tab with the same name in the device editor of the primary controller.
● “Redundancy Settings”:
  – “Connection”: IP addresses and ports of both PLC devices.
  – “General”: Timeout, task, available services, and fieldbus settings.
● “Registered Areas”: Definition of the data areas to be controlled by CODESYS Redundancy (programming objects, address ranges).

● § Chapter 1.3.1.25.2.4.1 “Command ‘Add Object’” on page 897

Tab 'Redundancy Status'

In this tab of the “Redundancy Configuration” dialog, you define the network path to the other PLC. PLC1 and PLC2 are displayed in a graphic with information about the current status of the PLC, about the gateway used, and about the device itself (name, type, version, address, and vendor).

At runtime, you can use the following buttons to change the status of the PLC devices or start synchronization, each depending on the situation.

| “Activate” | Requirement: Simulation mode.  
| Switches the PLC to “Active” status. |
| “Switch” | Switches the PLC from “Active” status to “Passive” status. |
| “Synchronize” | Synchronizes the passive PLC with the active PLC (values, data, addresses in the areas registered for redundancy). |
| “Simulation” | Switches the PLC from “Passive” status to “Simulation” status. |

The mode of each PLC is indicated by one of the following circle symbols in the lower right corner of the device graphic. They are also indicated as text in “Redundancy state” and in the value of eRedundancyState of a variable type RedundancyState (if used in the application):
### Status

<table>
<thead>
<tr>
<th>Status</th>
<th>Value of eRedundancyState</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unknown</td>
<td>No assignment; Displayed when there is no online connection to the controller.</td>
</tr>
</tbody>
</table>

- Chapter 1.3.1.17 “Using redundant PLC devices, CODESYS Redundancy” on page 362

### Tab 'Applications'

This tab in the “Redundancy Configuration” dialog corresponds to the tab with the same name in the device editor of the PLC. It contains information about the applications located on the other PLC.

See also
- Chapter 1.3.1.25.1.19.4 “Tab 'Applications’” on page 747
- Chapter 1.3.1.17 “Using redundant PLC devices, CODESYS Redundancy” on page 362

### Tab 'Files'

This tab in the “Redundancy Configuration” dialog corresponds to the tab with the same name in the device editor of the PLC. It is used for exchanging files with the second PLC.

See also
- Chapter 1.3.1.17 “Using redundant PLC devices, CODESYS Redundancy” on page 362
- Chapter 1.3.1.25.1.19.7 “Tab 'Files’” on page 750

### Tab 'Log'

This tab in the “Redundancy Configuration” dialog corresponds to the tab with the same name in the device editor of the PLC. It is used for displaying log book messages from the second PLC.

See also
- Chapter 1.3.1.17 “Using redundant PLC devices, CODESYS Redundancy” on page 362
- Chapter 1.3.1.25.1.19.8 “Tab 'Log’” on page 750

### Tab 'PLC Shell'

This tab in the “Redundancy Configuration” dialog corresponds to the tab with the same name in the device editor of the PLC. It is used for retrieving information from the second PLC.

See also
- Chapter 1.3.1.17 “Using redundant PLC devices, CODESYS Redundancy” on page 362
- Chapter 1.3.1.25.1.19.10 “Tab 'PLC Shell’” on page 753

### Tab 'Redundancy Settings' - 'Redundancy Link'

This tab in the “Redundancy Configuration” dialog is used for configuring the connection between both redundant PLC devices. It is used for synchronizing and triggering status changes. If possible, use a separate port especially for this communication only.
Table 89: “Redundancy Link” / “1st Redundancy Link”

<table>
<thead>
<tr>
<th>“IP address PLC 1”</th>
<th>Example: 192.168.101.176</th>
</tr>
</thead>
<tbody>
<tr>
<td>“IP address PLC 2”</td>
<td>Example: 192.168.101.87</td>
</tr>
<tr>
<td>“Port”</td>
<td>Defines the IP port for the connection between both redundant PLC devices. Example: 1205</td>
</tr>
</tbody>
</table>

“Use two redundant links”  
☑️ An additional network connection for redundant control is available. If one network connection fails, then the second connection can be used.

Table 90: “2nd Redundancy Link”

<table>
<thead>
<tr>
<th>“IP address PLC 1”</th>
<th>Example: 192.168.101.178</th>
</tr>
</thead>
<tbody>
<tr>
<td>“IP address PLC 2”</td>
<td>Example: 192.168.101.21</td>
</tr>
<tr>
<td>“Port”</td>
<td>Defines the IP port for the second connection between both redundant PLC devices. Example: 1205</td>
</tr>
</tbody>
</table>

“Read”  
Clicking this button reads the current redundancy link settings for PLC1 into the dialog.

“Write”  
Clicking this button transmits the available redundancy link settings to both PLC devices.

See also
- Chapter 1.3.1.17 “Using redundant PLC devices, CODESYS Redundancy” on page 362

Tab 'Redundancy Settings' - 'General'
This tab in the “Redundancy Configuration” dialog is used for configuring watchdogs, specifying the used task, and desired services and settings of the fieldbus for redundant operation.

Table 91: “Application”

<table>
<thead>
<tr>
<th>“Timeout (ms)”</th>
<th>Time, when exceeded that the PLC switches to stand-alone mode, if it has not received a message from the second PLC. In this case, the task execution is delayed by this time interval. The setting is stored in the RTS configuration file. Recommendation: Set this timeout value higher than the maximum task jitter time plus the maximum transmission time for redundancy messages.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Redundancy task name”</td>
<td>Task that is synchronized between both PLC devices. Only one task can be synchronized. The setting must be stored in the RTS configuration file (button or manually).</td>
</tr>
</tbody>
</table>

Table 92: “Services”

The CODESYS online services selected here are executed on both PLC devices simultaneously in the same cycle.

| “Force variable” | ☑️ The services for forcing variable values are executed on both PLCs. |
| "Write variable" | ☑️ The services for writing variable values are executed on both PLCs. |
Table 93: “Fieldbus Settings”

| “EtherCAT” | EtherCAT is used as the fieldbus.  
  ● “Source address (MAC) PLC1”: This corresponds to the EtherCAT master address.  
  ● “Source address (MAC) PLC2”: This must be different from the address above. It must correspond to the PLC2 adapter that is used for EtherCAT.  
The NIC settings for the adapter must be set on both PLCs. Automatically searching for the respective PLC is possible by means of the “Scan” button. |
| “Profibus” | Profibus is used as the fieldbus. |

| “Read” | Clicking this button reads the current redundancy link settings for PLC1 into the dialog. |
| “Write” | Clicking this button transmits the available redundancy link settings to both PLC devices. |

See also

- § Chapter 1.3.1.17 “Using redundant PLC devices, CODESYS Redundancy” on page 362

Tab 'Registered Areas'

This tab in the “Redundancy Configuration” dialog is used for defining the data area that should be controlled by the redundant configuration.

By default, all data areas are controlled by CODESYS Redundancy. They are transmitted from the active PLC to the passive PLC during the synchronization phase. However, if you exclude areas from the control as "private" or "local", then select them in the available dialog. Examples of private and local data: diagnostic data of a fieldbus, file handles, and other operating system handles that are valid for the local PC only.

Defining the data area is separated on two tabs:

- Tab “Variables”: All global variable lists and program POUs of the application are provided automatically. Deactivate the check boxes of those that should not be controlled redundantly. Also note the “Select all / Clear all” check box under the selection view.
- Tab “Addresses”: Here you can specify an area of direct addresses that should be controlled by CODESYS Redundancy. The “Add” button opens a dialog for defining the start and size of a “Register address range”. With the “Edit” and “Delete” buttons, you can change or remove existing entries.

NOTICE!

On a redundant system, be careful when using file handles and operating system handles, as they can lead to different data on each of the PLCs.
NOTICE!

The method of mapping a device input to an existing project variable is not recommended. If you do use it, then keep in mind that variables mapped in this way are not stored in the input or output data areas. This means that they are not included in the synchronization of the redundant PLCs.

See also
- Chapter 1.3.1.17 “Using redundant PLC devices, CODESYS Redundancy” on page 362
- “Linking a device input with an existing project variable (“mapping”)” on page 164

Object 'Recipe Manager'
Tab 'Storage'
The recipe manager provides functions for maintaining user-defined variable lists, known as recipe definitions. The recipe definitions can be stored in recipe files on the PLC.

<table>
<thead>
<tr>
<th>“Storage Type”</th>
<th>“Textual”: CODESYS saves the recipe in a readable Format with the configured columns and delimiters.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Binary”: CODESYS saves the recipe in a non-readable binary format. This format requires less storage space.</td>
<td></td>
</tr>
<tr>
<td>Note: You can read binary recipes again only if you have not changed the variable lists.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>“File path”</th>
<th>&lt;directory name&gt;\</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example: AllRecipes\</td>
<td></td>
</tr>
<tr>
<td>Relative path on the runtime system The path must end with a slash (&quot;`).</td>
<td></td>
</tr>
<tr>
<td>The directory is created on the target system in the directory for the runtime files (PlcLogic).</td>
<td></td>
</tr>
<tr>
<td>Example of the file path in the runtime system: PlcLogic/AllRecipes</td>
<td></td>
</tr>
<tr>
<td>CODESYS saves a file in this directory for each recipe when downloading to the PLC. The requirement is that you select the option “Recipe management in the PLC”.</td>
<td></td>
</tr>
<tr>
<td>The files are loaded to the recipe manager each time the application is restarted.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>“File extension”</th>
<th>File extension for the recipe file in the format .&lt;file extension&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>The resulting default name for recipe files is in the form &lt;recipe&gt;.&lt;recipe definition&gt;.&lt;file extension&gt;.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>“Separator”</th>
<th>Delimiters between the individual values in the saved file</th>
</tr>
</thead>
</table>

| “Available Columns” | Defines which information is saved in which order in the recipe file |
| “Selected Columns” | |
| “Save as Default” | CODESYS uses the settings on the tab throughout the entire project for all other recipe managers. |

Tab 'Common'

| “Recipe management in the PLC” | Must be selected for the user program or visualization elements to load recipes in runtime mode. If you transfer recipes to the PLC exclusively via the CODESYS program interface, then you can clear this option. |
Table 94: “Save Recipe”

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| “Save recipe changes to recipe files automatically” | When “Recipe management in the PLC” is selected, there is the following option for saving the recipe:  
☑️ We recommend this option because it helps the recipe manager operate “normally”. The recipe files on the PLC are updated automatically in runtime mode whenever a recipe is changed. |

Table 95: “Load Recipe”

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Download only for exact match of the variable list”</td>
<td>☒️: The recipe is only downloaded if the file on the PLC contains all variables from the variable list of the recipe definition of the application and these are sorted in the same order. Additional entries at the end are ignored. If the required match does not exist, then the error status ERR_RECIPE_MISMATCH is set (RecipeManCommands GetLastError).</td>
</tr>
<tr>
<td>“Download variables with matching names”</td>
<td>☒️: The recipe values are downloaded only for those variables that have the same name in the recipe definition of the application as in the recipe file on the PLC. If the variable lists differ in composition and sorting, then no error status is set. In this way, recipe files can also be downloaded if variables in the file or in the recipe definition have been deleted.</td>
</tr>
</tbody>
</table>

Table 96: “Write Recipe”

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Limit the variable to min/max when recipe value is out of the range”</td>
<td>☐️: If the recipe contains a value that is outside of the value range specified in the definition, then the defined minimum or maximum value is written to the PLC variable instead of this value.</td>
</tr>
<tr>
<td>“Do not write to a variable when the recipe value is out of the min/max range”</td>
<td>☑️: If the recipe contains a value that is outside of the value range specified in the definition, then no value is written to the PLC variable. It retains its current value.</td>
</tr>
</tbody>
</table>

Table 97: “Read Recipe”

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| “Check recipe for changes” | Always use the function block RecipeManCommands from RecipeManagement.library to read recipes. Never call the method cyclically. This is because each call can be written to the file system, which is time-intensive and burdens the controller. For example, the number of write cycles is limited for a Raspberry Pi.  
☑️: With each method call, the current PLC variable values are first read into the recipe. Then the system checks whether the values have changed. Only if the values have changed is the recipe saved. This means that the recipe file is overwritten with the current recipes. This option can be used in order to update the recipe file in the local file system only if recipe values have changed on the PLC. However, it affects performance because it generates additional code for checking.  
☐️: With each method call, the current PLC variable values are first read into the recipe. Then the recipe is written to the recipe file in the local file system. Note: As the file system is written to each call, the controller can be very burdened. |
Table 98: Option “Save recipe changes to recipe files automatically” is activated.

<table>
<thead>
<tr>
<th>Menu Commands</th>
<th>Behavior of the recipes defined in the project</th>
<th>Behavior of the defined recipes at runtime</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Online ➔ Reset Warm”</td>
<td>The recipes of all recipe definitions are downloaded with the values from the current projects.</td>
<td>Dynamically generated recipes remain unchanged.</td>

- Chapter 1.3.1.25.2.19.9 “Command ‘Read and Save Recipe’” on page 1018
- Chapter 1.3.1.25.1.34 “Object ‘Recipe Definition’” on page 823
- Method Calls of the 'Recipe Management' Library
Object 'Recipe Definition'

In the recipe definition (1), you define different data sets for the variables, which are termed recipes (2).

You can toggle the display of the recipe definition between the flat list view (3) and the structured view (4). In the structured view, CODESYS groups variables according to structure.

<table>
<thead>
<tr>
<th>“Type”</th>
<th>Entered automatically</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Name”</td>
<td>Optional</td>
</tr>
<tr>
<td>“Minimal Value”</td>
<td>If the variable value is less than the “Minimal Value” or greater than the “Maximal Value”, then CODESYS sets the value to the “Minimal Value” or “Maximal Value”.</td>
</tr>
<tr>
<td>“Maximal Value”</td>
<td></td>
</tr>
<tr>
<td>“Comment”</td>
<td>Additional information, for example the unit of the value.</td>
</tr>
<tr>
<td>“Current Value”</td>
<td>Current variable value; not shown in online mode</td>
</tr>
</tbody>
</table>

Table 100: “Additional commands in the context menu in the structured view”

| “Add Sibling” | Adds a sibling variable to the recipe definition. |
| “Add Child”   | Adds a child variable to the recipe definition. |

See also

- Chapter 1.3.1.13.2 “Changing values with recipes” on page 331

Object 'TextList'

This object is for the creation, management and translation of texts. It contains a table with texts, to which you can add new texts. A text that you have written here can be selected in a visualization in an element in the property “Dynamic texts”. During operation the visualization displays this text dynamically in the selected language.

If the object is assigned to an alarm group and is located under the object “Alarm Configuration”, CODESYS adds the texts of the alarm group to the table. You can also add texts.

<table>
<thead>
<tr>
<th>“ID”</th>
<th>Unambiguous identifier of the text</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Standard”</td>
<td>Source text as character string, for example Information A: %i possibilities . Add a line break by pressing the keyboard shortcut [Ctrl] + [Enter]. Double-click in the field in order to edit the text.</td>
</tr>
</tbody>
</table>

The table contains as many language columns as you have added. A language column is named with a language code that you entered when creating the column with the command “Insert Language”.

2020/12/10
**Object 'Symbol Configuration'**

You can use the symbol configuration for creating symbol descriptions for project variables. Click **"Project ➔ Add Object"** to add a symbol configuration object to the device tree. Then define specific presets. See dialog below: **"Add Symbol Configuration"**.

If you use a **"DeviceApplication"**, the following applies: The device application itself cannot have a symbol configuration. However, symbols from the device application are offered for selection in the symbol configurations of their child applications.

Double-click the **"Symbol Configuration"** object to open the symbol configuration editor.

**Dialog 'Add Symbol Configuration'**

**Function:** This dialog is used to define the defaults for a **"Symbol Configuration"** object.

**Call:** **"Project ➔ Add Object ➔ Symbol Configuration"** menu; context menu of the application object.

<table>
<thead>
<tr>
<th><strong>Include comments in XML</strong></th>
<th>Exports the symbol file with the comments assigned to the variables.</th>
</tr>
</thead>
<tbody>

<th>Description</th>
</tr>
</thead>
</table>
| ![Folder View](folder_icon) “View” | You can use this button for activating and deactivating the following categories of variables used in the configuration editor:
  - ![Folder Unconfigured from Project](unconfigured_icon) “Unconfigured from Project”: Variables that have not been added to the symbol configuration, but are provided in the project.
  - ![Folder Unconfigured from Libraries](unconfigured_icon) “Unconfigured from Libraries”: Variables that have not been added to the symbol configuration, but are provided in the project.
  - ![Folder Symbols Exported via Attribute](unconfigured_icon) “Symbols Exported via Attribute”: This filter also lists the variables that have already been marked for export in the symbol file by means of the `{attribute 'symbol' := 'read'}` pragma. These symbols are marked in gray. The “Attribute” column shows which access rights are set by the pragma. |
| ![Folder Build](build_icon) “Build” | Compiles the project. Requirement for current preparation of variables in the configuration editor. |
## "Settings"

- "Support OPC UA Features":
  Note: Availability and editability of this option depend on the device.
  - When downloading the symbol configuration, additional information is also downloaded to the controller. The information below is necessary for operating the OPC UA server. This currently includes the following information:
    - Base types of inherited function blocks
    - Contents of attributes that were assigned via compiler pragmas
    - Scopes (example: VAR_INPUT, VAR_OUTPUT, VAR_IN_OUT)
- "Include Comments in XML"
  - Exports the symbol file with the comments assigned to the variables.
- "Include Node Flags in XML"
  - The namespace node flags provide additional information about the origin of a node in the namespace. The node flags always get included in the symbol table when OPC UA is activated. However, its inclusion in the XML file can be deactivated as some defective parsers have problems with it.
- "Configure Comments and Attributes"
  - Opens the "Comments and Attributes" dialog. Here you configure the details of what should be included in the symbol configuration and XML file with respect to comments and attributes.
- "Configure Synchronisation with IEC Tasks":
  - Opens the dialog "Properties - <device name>", "Options" tab.
  - This setting allows for the symbolic clients (e.g. visualizations or database links based on the PLCHandler) to have consistent read/write access synchronized with the IEC tasks. For a detailed description of this setting, see the "Setting: Configuring Synchronisation with IEC Tasks" section below.
  - Note: Variable access which is synchronous with the IEC tasks can increase the jitter for all IEC applications on this device. Synchronized consistent access can interrupt the real-time capability.
- Drop-down list for defining the data layout type for the client of the symbol configuration:
  - "Optimized Layout": Recommend for new projects. Calculates the output layout in optimized form detached from the internal compiler layout. Does not generate any gaps for unpublished elements and strictly fulfills the requirements for memory alignment of the data types. Requires compiler version 3.5.7.0 or later.
  - "Compatibility Layout": This setting is used for the compatibility of old projects. The data layout created for the client is matched as much as possible to the layout created internally by the compiler. Due to the configuration possibilities of the symbol configuration which have grown over time, problematic offsets can still result.
  - Causes of offsets:
    - Memory gaps due to internal pointers or references in function blocks and structure components that are not released for symbol configuration.
    - Memory gaps that occur differently in 32-bit and 64-bit systems depending on the data type, such as __XINT / __XWORD.
    - Fields that are at uneven addresses. Some clients are not set up for this.
    - Unintentional memory misalignment, which occurs when using the attributes 'pack_mode' or 'relative_offset'.
- "Use Empty Namespaces by Default (V2 Compatibility)": Required when using a CODESYS V2-compatible OPC server configuration.
  - Behavior same as in CODESYS V2.3.
    - Program variables are exported without an application name
      (Application.PLC_FRG.MyVar → PLC_FRG.MyVar)
    - Global variables are exported additionally without the GVL name
      (Application.GVL.MyGlobVar → .MyGlobVar)
**“Enable Direct I/O Access”:** This feature is potentially dangerous and **not intended for operation in production**. Activate only for error checking and tests, or when commissioning the machinery (for example, for checking cables connections).

- [ ] In the symbol configuration, you can also use access to direct I/O addresses that correspond to IEC syntax (for example, "%IX0.0"). Access to input addresses (I) is read-only*. Access to output addresses (Q) and memory addresses (M) can be read-write.

*Information: In simulation mode, write access to symbols is also possible for input addresses.

Because external clients for protocols such as OPC or OPC UA do not always support IEC syntax for direct addresses, access is also provided using an array syntax in the namespace __MIO of the implicit code. For example, you can also access __MIO.MIO_IX[2].x3 instead of %IX2.3.

However, the symbols for array access are hidden in browsers because some clients cannot handle the large number of nodes (several thousand depending on the size of the I/O ranges).

**“Support Calls of Functions, FBs, Methods and Programs”:**

- Note: Availability and editability of this option depend on the device.

- [ ] The access rights “execute” can be set in the symbol table for symbols of POUs of type function, function block, method, or program. The “Support OPC UA Features” option also has to be selected in the “Settings”.

**“Include Call Information in XML”:**

- [ ] The information about called functions, function blocks, methods, or programs is also listed in the XML file of the symbol configuration. The option is enabled only if the option “Support Calls of Functions, FBs, Methods and Programs” is supported by the device.

**“Enable Symbol Sets”:**

- [ ] A toolbar with buttons and a drop-down list is displayed above the symbol table. You can use this to configure symbol sets for client-specific assignment of access rights to the controller. See "Toolbar for symbol set configuration" below.

**Download**

If you use a device that supports its own application file for the symbol configuration, then this button is also available in the toolbar. If you change the symbol configuration in online mode, then you can load the new <application name>._symbols file immediately to the PLC.

**Tools**

**“Save the XSD Scheme File”:** This command opens the standard dialog for saving a file in the file system. With this command, you can prepare the XSD format of the symbol file, for example for use in external programs.

**“Add Library Placeholder to Device Application (Recommended, but May Trigger a Download)”**: This option is relevant when a “Device Application” is used. The library references for the symbol configuration libraries, which are available in the Library Manager below the application, are also inserted into the Library Manager of the device application. For more information, see the description of the same-named option in the “Add Symbol Configuration” dialog.
Table 103: Symbol table

Setting: Configure synchronization with IEC tasks

For synchronously consistent access, the symbolic client waits in the runtime system when processing a read or write request until a time is found when no IEC task is executed. When this gap is detected, restarting the IEC tasks is prevented until all values of the variable list have been copied. Then the IEC tasks are planned again as usual. Synchronized access can cause a delayed starting of IEC tasks, which is shown as increased jitter. As all applications in the runtime system are managed by a common scheduler, this potential impairment of the real-time behavior affects all applications on the device. All applications of the device are affected, regardless of whether or not they include a symbol configuration or they have been downloaded to the controller from one or more CODESYS projects. Therefore, the runtime system permits synchronized consistent access only if this it allows all applications that are downloaded to the controller at the time of access.

The setting is located in the editor of the symbol configuration of the “Settings” menu. In addition, the setting is also located in the context menu of the controller when you click the “Properties” command and then select the “Options” tab in the opened dialog.

For applications without symbol configuration, the setting can only be found in the properties dialog.

NOTICE!

After changing the setting, all applications downloaded to the device by means of a download or online change must be reloaded and all boot applications updated.

In which cases is synchronized consistent access necessary?

As a rule, there is no need for consistent values for visualized values because it is mostly irrelevant from which IEC task cycle the changed values originate. It is completely irrelevant for seldom changed values. Even when writing there are almost no hard consistency demands because typically the machine must be in a kind of standby mode (for example when writing recipes) in which there is no direct access to the values written as recipes.

In contrast, consistent values are particularly necessary for database links to save production data. For clocked machines, however, these values must be synchronous with the production timing (one value set per produced product) and not consistent with reference to one or more IEC tasks. With reference to the machine clocking, the consistency must be already ensured by the IEC application. For this purpose, the values that arise during a production cycle are typically collected in a global variable list. At the end of the cycle, the symbolic client is notified by means of an additional variable (BOOL or counter) that the machine cycle has ended and the values are valid. Now the client has the chance to archive the values from the production cycle. Depending on necessity, the successful reading can also be displayed in the opposite direction by means of a released variable, so that the production can also be halted in case the production data cannot be archived. Synchronized consistent access is not necessary and helpful for this use case because the synchronization takes place at the application level.
In contrast, synchronized consistent access by symbolic clients is typically applied in the process industry with continuously running systems without production clocking when, for example when process values are written consistently and cyclically in a fixed time frame of 60s. This can take place either by synchronization on the application level similar to clocked machines (see above) or by synchronization of the synchronized consistent symbolic access. The advantage of the latter is that no logic has to be implemented in the IEC program and access is controlled entirely by the client.

**CAUTION!**

Due to the increased jitter, the synchronized consistent monitoring is not suitable for motion or real-time critical applications. For these reasons, synchronized consistent access should be released and used only if it is absolutely necessary.

If a client uses synchronous consistent access released by this setting, then it has and effect on the client. Depending on the scheduler of the runtime system, the response time can jitter more here for read/write access because the system might still have to wait for an execution gap of the IEC tasks. Read and/or write access can still fail when IEC tasks run for a long time (in the range of several 100 ms) or the CPU load is close to 100% for an extended period of time with one or more IEC tasks (in the range of several 100 ms). Therefore, the availability of the values also depends on the load of the controller by the IEC application.

Moreover, the client can minimize the effects on itself and on the runtime system if it observes the following in the definition of the variable lists to be read or written:

- Synchronized consistent access only to those variables that are absolutely and consistently required.
- Separate variable lists for variables that have to be consistent and for variables that could be inconsistent.
- Divide variable lists with several consistent variables into several smaller lists.
- Select read intervals for cyclic reading of values as large as possible.

Entries marked in red in the symbol table show variables that they are configured for export to the symbol file but are currently invalid in the application. The cause for this can be that the declaration has been removed from the block.

In version 3.5.8.0 and later, a warning appears in the editor if variables that have configured symbols are not used in the IEC code or are not mapped in the case of I/O variables. In addition, the compiler indicates variables that are referenced from outdated library versions in the symbol configuration.

**NOTICE!**

Object variables that are not used in the program code remain uncompiled by default and are therefore not available in the symbol configuration. However, CODESYS provides variables from uncompiled objects in the symbol configuration when one of the following conditions is met:

- The “Link always” POU property is selected.
- The `attribute 'linkalways'` pragma is used.

- Chapter 1.3.1.24.6.2.20 “Attribute ‘linkalways’” on page 618
Example of data layout types

The following examples from an IEC application will show how gaps can result in the client-side memory layout caused by unpublished symbols, internal "invisible" pointers, or a "pack mode" definition in the device description. With the "Optimized Layout" setting, the gaps are avoided. The symbol file contains different information about the size and offset of memory locations, depending on the selected layout setting.

Example: Large structure

// Example of a big structure, where not all members get published :

```plaintext
STRUCT
    {attribute 'symbol':='readwrite'}
    PublicNumber : INT;

    {attribute 'symbol':='none'}
    InternalData : ARRAY[0..100] OF BYTE;

    {attribute 'symbol':='readwrite'}
    SecondNumber : INT;

    {attribute 'symbol':='none'}
    MoreData : ARRAY[0..100] OF BYTE;
END_STRUCT
END_TYPE
```

Resulting entries in the symbol file; pay attention to size and byteoffset:

```xml
<TypeUserDef name="T_LargeStructure" size="208" nativesize="208" typeclass="Userdef" pouclass="STRUCTURE" iecname="LargeStructure">
    <UserDefElement iecname="PublicNumber" type="T_INT" byteoffset="0" vartype="VAR" />
    <UserDefElement iecname="SecondNumber" type="T_INT" byteoffset="104" vartype="VAR" />
</TypeUserDef>
```

```
<TypeUserDef name="T_LargeStructure" size="4" nativesize="208" typeclass="Userdef" pouclass="STRUCTURE" iecname="LargeStructure">
    <UserDefElement iecname="PublicNumber" type="T_INT" byteoffset="0" vartype="VAR" />
    <UserDefElement iecname="SecondNumber" type="T_INT" byteoffset="2" vartype="VAR" />
</TypeUserDef>
```

Symbol file, large structure, compatibility layout option

Symbol file, large structure, optimized layout option

Example: Structure with uneven addresses

// The following mechanisms can cause memory misalignment:
// - {attribute 'relative_offset':='...'} at a member
// - {attribute 'pack_mode':='...'} at a structure declaration
// - target setting 'memory-layout\pack-mode' in the device description

```plaintext
{attribute 'pack_mode':='1'}
TYPE UnevenAddresses:
    STRUCT
        {attribute 'relative_offset':='3'}
        {attribute 'symbol':='readwrite'}
        PublicNumber : INT;
```
Resulting entries in the symbol file; pay attention to size and byteoffset:

```xml
<TypeUserDef name="T_UnevenAddresses" size="13" nativesize="13" typeclass="Userdef" pouclass="STRUCTURE" iecname="UnevenAddresses">
  <UserDefElement iecname="PublicNumber" type="T_INT" byteoffset="3" vartype="VAR" />
  <UserDefElement iecname="PublicValue" type="T_LREAL" byteoffset="5" vartype="VAR" />
</TypeUserDef>

<TypeUserDef name="T_UnevenAddresses" size="16" nativesize="13" typeclass="Userdef" pouclass="STRUCTURE" iecname="UnevenAddresses">
  <UserDefElement iecname="PublicNumber" type="T_INT" byteoffset="0" vartype="VAR" />
  <UserDefElement iecname="PublicValue" type="T_LREAL" byteoffset="8" vartype="VAR" />
</TypeUserDef>
```

// Each POU contains some implicit variables, which do not get published. Depending on the data type these might cause memory gaps of different sizes.

```xml
<TypeUserDef name="T_POU" size="24" nativesize="24" typeclass="Userdef" pouclass="FUNCTION_BLOCK" iecname="POU">
  <UserDefElement iecname="in" type="T_INT" byteoffset="16" vartype="VAR_INPUT" />
  <UserDefElement iecname="out" type="T_INT" byteoffset="18" vartype="VAR_OUTPUT" />
</TypeUserDef>

<TypeUserDef name="T_POU" size="4" nativesize="24" typeclass="Userdef" pouclass="FUNCTION_BLOCK" iecname="POU">
  <UserDefElement iecname="in" type="T_INT" byteoffset="0" vartype="VAR_INPUT" />
</TypeUserDef>
```

Example:

**Function block**

Each POU contains some implicit variables, which do not get published. If it is a data type such as `__XWORD`, then different sizes of memory gaps result in the client-side data layout, depending on whether the system is 64-bit or 32-bit.

Resulting entries in the symbol file for 64-bit and 32-bit; pay attention to size and byteoffset:
Object 'Task Configuration'

Symbol: 📖

The object is used to define and display the basic settings for the task configuration.

The "Task Configuration" object must be included exactly one time in each application.

"Task Configuration" tabs and functions

- "Properties": Display of the basic settings
- "System Events": Linking of POU calls with system events
- "Monitor": Display of the status and current statistics for the cycles times in online mode
- "Variable Usage": Overview of the tasks that access the variables and how they do it
- "Task Groups": Definitions of the tasks groups and their assignment to CPUs
- "CPU Load": Graphical representation of the CPU load in online mode

Tab 'Properties'

Object: “Task Configuration”
In this tab, you define the basic settings of the task configuration as predefined by the target system, such as the maximum values for tasks and watchdog parameters.

Tab 'System Events'

Object: “Task Configuration”
In the “System Events” tab, you define which events call which functions and whether or not the configuration is currently activated. You use this tab when a system event (instead of a task) should call a project function.

<table>
<thead>
<tr>
<th>“Add Event Handler”</th>
<th>Opens the “Add Event Handler” dialog box</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Remove Event Handler”</td>
<td>Deletes the selected list assignment</td>
</tr>
<tr>
<td>“Event Info”</td>
<td>Shows information from the corresponding event library</td>
</tr>
<tr>
<td>“Open Event Function”</td>
<td>Opens the editor of the new function for the selected assignment You have selected the implementation language of the new function in the “Add Event Handler” dialog box.</td>
</tr>
</tbody>
</table>

Assignment of functions to call for events with: “Name”, “Description”, “Function to call”, and “Active” (activate/deactivate configuration).

Table 109: “Add Event Handler”

Adds a new assignment "Event – Function to call" to the list

| “Event” | The list of choices depends on the target device. CODESYS marks unavailable events with a red symbol in front of the name.  
A list of all possible system events is located at the end of this section. |
| “Function to call” | Function name (“POU”, type “FUNCTION”)  
You must enter the name of the new function. CODESYS inserts the function to the device tree after you confirm the dialog box. |
| “Scope” | ● “Application”: Function is available for the application  
● “POUs”: Function is available for the entire project |
| “Implementation language” | Implementation language for the new function |
| “Description” | Short description of the selected event |

Features in “Online Mode”
The list of assignments from called functions to events also includes the following information: “Event Status”, “Call Count”, and the “Online Reset” button.

| “Event Status” | 0: No error has occurred.  
Does not equal 0: error. You must consult the respective runtime system documentation. |
<p>| “Call Count” | Displays how often the event has occurred or the associated function has been called. |
| “Online Reset” | CODESYS reinitializes the event lists and resets the counter for the events/function calls. Incorrectly initialized events are displayed with a red status cell. |</p>

</tbody>
</table>

**Tab 'Monitor'**

Object: “Task Configuration”

This tab shows the following information in online mode: status for tasks in the task configuration and some current measurements of the cycles and cycle times. CODESYS updates the values in the same time interval as for the monitoring of values from the PLC.

Reset the displayed values by right-clicking the task and then clicking the “Reset” command in the context menu.

<table>
<thead>
<tr>
<th>“Task”</th>
<th>Task name (as defined in the task configuration)</th>
</tr>
</thead>
</table>
| “Status”                      | • “Not created”: The task has not been started since the last update (especially for event tasks).  
                              | • “Generated”: The task is recognized in the runtime system, but not yet in operation.  
                              | • “Valid”: The task is operating normally.  
                              | • “Exception”: The task has produced an exception status. |
| “IEC Cycle Count”             | Number of cycles executed since starting the application where the IEC code was executed (0 if the target system does not support the counter function) |
| “Cycle Count”                 | Number of executed cycles since logging in to the PLC. It depends on the target system whether cycles are also counted where the application is not running. In these cases, the “Cycle Count” may be greater than the “IEC Cycle Count”. |
| “Last Cycle Time (µs)”        | Last measured cycle time [µs] |
| “Average Cycle Time (µs)”     | Average cycle time over all cycles [µs] |
| “Max. Cycle Time (µs)”        | Maximum measured cycle time over all cycles [µs] |
| “Min. Cycle Time (µs)”        | Minimum measured cycle time over all cycles [µs] |
“Jitter (µs)”

Last measured jitter [µs]

Jitter is the difference between the time when the task should be started and the time when the task is actually started. For example, if the task should be started every 1000 µs and it actually starts after 1100 µs, then the jitter is 100 µs.

“Min. Jitter (µs)”

Minimum measured jitter [µs]

“Max. Jitter (µs)”

Maximum measured jitter [µs]

“Core”

Number of processor cores on which the task is currently running.

Example: 2

Note: The controller has a multi-core CPU.

Tab 'Variable Usage'

Object: “Task Configuration”

The "Variable Usage" tab provides an overview of all variables and their usage. There you can see the tasks where variables are accessed.

When using multicore, write access (w) to a variable should take place only in a task because otherwise it can cause inconsistencies.

In the context menu, you can hide individual tasks and show the cross-reference list to variables.

<table>
<thead>
<tr>
<th>“Variables”</th>
<th>Name of the variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Type”</td>
<td>Data type</td>
</tr>
<tr>
<td>“Number”</td>
<td>Number of tasks that access these variables.</td>
</tr>
<tr>
<td>“&lt;task name&gt;”</td>
<td>Access to the variable (r: read, w: write, rw: read/write)</td>
</tr>
</tbody>
</table>

Tab 'Task Groups'

Object: “Task configuration”

You define task groups in the “Task Groups” tab. Task groups can be distributed over the individual processor cores in multicore systems. Tasks in a task group always run on the same processor core.

<table>
<thead>
<tr>
<th>“Add Group”</th>
<th>The button adds a new task group named NewGroup_&lt;no&gt;.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Remove Group”</td>
<td>Deletes the selected task group.</td>
</tr>
<tr>
<td>“Group Name”</td>
<td>The name can be changed by double-clicking in the field.</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------------------------------</td>
</tr>
<tr>
<td>“Core”</td>
<td>Determines the processor core for process the tasks of this group.</td>
</tr>
<tr>
<td></td>
<td>● “Free floating”: All tasks are bound dynamically to different processor cores. The user does not have any influence over this. The operating system is responsible for the distribution.</td>
</tr>
<tr>
<td></td>
<td>● “Sequentially pinned”: All tasks are bound and fixed to different processor cores. The user does not have any influence over this.</td>
</tr>
<tr>
<td></td>
<td>● “Fixed pinned”: All tasks are bound to one processor core. By default, the runtime system determines the processor core.</td>
</tr>
<tr>
<td></td>
<td>● “&lt;core number&gt;”: Fixed defined processor core. If the processor core is not available, then an error message is issued.</td>
</tr>
</tbody>
</table>

Object 'Task'

Symbol: 🎉

In this object, you define the conditions for starting and calling the task.

You insert the object below “Task Configuration” in the device tree.

Tab 'Configuration'

Object: “Task”

<table>
<thead>
<tr>
<th>“Priority”</th>
<th>Possible values: 0..16, where 0 is the highest priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Task group”</td>
<td>Assigned task group. This assignment is shown in parentheses in the device tree. Task groups can be assigned to specific processor cores in multicore. The task group is shown in parentheses after the task in the device tree.</td>
</tr>
</tbody>
</table>

Table 110: “Type”

<table>
<thead>
<tr>
<th>“Cyclic”</th>
<th>CODESYS processes the task in cycles. The cycle time of the task is defined in the input field “Interval”.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Event”</td>
<td>CODESYS starts processing the task as soon as the global variable defined in the input field “Event” contains a rising edge.</td>
</tr>
<tr>
<td>“Freewheeling”</td>
<td>CODESYS starts processing the task again automatically in a continuous loop at program start and at the end of a complete pass. Cycle time is not defined.</td>
</tr>
<tr>
<td>------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>“Status”</td>
<td>CODESYS starts task processing as soon as the variable defined in the “Event” input field yields the Boolean value TRUE.</td>
</tr>
<tr>
<td>“External”</td>
<td>CODESYS starts processing the task as soon as the event defined in the “Event” input field occurs. The target system determines which events are supported and offered in the dropdown list. (Not to be confused with system events).</td>
</tr>
<tr>
<td>“Interval”</td>
<td>Task-cycle time Required for the types “Cyclic” or “External Event” when the event requires a given time. Time interval after which the task should be restarted. If you enter a number here, then you can select the desired unit in the dropdown list after the input field. If you select “ms”, then an entry is automatically displayed in TIME format, for example t#200ms, as soon as the window is in focus again. You can also enter the task cycle time directly in TIME format. Entries in [µs] format are always displayed as a pure number.</td>
</tr>
<tr>
<td>“Parent task”</td>
<td>Only for projects with a “Device Application” You can use this task type in order to couple the processing of an application with a task of a “Device application”. In practice, the bus master task is managed primarily in the task configuration of the device application and a coupling with this allows for a harmonization with the timing of the bus master.</td>
</tr>
</tbody>
</table>

**NOTICE!**

For fieldbuses, a fixed cycle matrix is necessary to assure a determined behavior. Therefore, you should not use “Type” “Freewheeling” for a bus cycle task.

**NOTICE!**

Please note the following difference between the processing types “Status” and “Event”. If the given event yields TRUE, then the start condition of a task of type “Status” is fulfilled. In contrast, the start of a task of type “Event” requires a switch of the event from FALSE to TRUE. If the scanning rate of the task scheduler is too low, then the rising edge of the event can remain unnoticed.

**NOTICE!**

Please note: When setting the task cycle time, identify which bus system is currently being used. For example, the task cycle time in a CAN bus system must match the currently set transmission rate and the number of frames used in the bus. In addition, the times set for heartbeat, node guarding, and sync should always be a multiple of the task cycle time. If not, then CAN frames can be lost.
Table 11: "Watchdog"

Defines the time monitoring for a task. If the target system supports an advanced watchdog configuration, then the following settings may be predefined in the device description.

- Upper and lower limit
- Default watchdog time
- Time percentage

The default watchdog settings depend on the device.

"Enable"

The watchdog is active.

If the task exceeds the currently set “Time” of the watchdog, then the task is halted with an error status (exception). The application in whose task the error occurred and its child applications are also halted. In this way, all tasks of the affected applications are also halted. Then the currently defined “Sensitivity” is also taken into account. If you activate the option "Update I/Os" in the “PLC Settings” of the PLC, then CODESYS resets the outputs to the defined default values.

Possible cases:

- Several consecutive timeouts:
  - Sensitivity: 0, 1 - exception in cycle 1
  - Sensitivity: 2 - exception in cycle 2
  - Sensitivity: n - exception in cycle n
- Single timeout: Exception if the cycle time of the current cycle is longer than (time * sensitivity). Example: Time=t#10ms, Sensitivity=5 (i.e., exception as soon as the one-time task runs longer than 50 ms)

"Time (e.g. t#200ms)"

Watchdog time

Defines the watchdog for a task (with “Sensitivity”); description as for “Enable”.

Depending on the target system, the monitoring interval is given as a percentage of the task interval if possible. In this case, the drop-down list for the unit is disabled and displays “%”.

"Sensitivity"

Number

Defines the watchdog for a task (with the watchdog time); description as for “Enable”.

Using the functions from the library CmpIecTask.library, you can deactivate a watchdog for specific PLC cycles. This is useful for cycles that demand more time due to initialization.

Example

Deactivating/reactivating the watchdog:

```plaintext
hIecTask := RTS_IEC_HANDLE //Declaration of the variable hIecTask
hIecTask := IecTaskGetCurrent(0);
IecTaskDisableWatchdog(hIecTask); // Watchdog disabled
...
IecTaskEnableWatchdog(hIecTask); Watchdog enabled
```

List of POUs that control the task:

The calling order corresponds to the POU order in the list (from top to bottom).

"Add Call"

Defines a new program call
Object 'Trace'

Symbol: 

An object of type "Trace" is used for configuring and displaying application-specific trace data in one or more charts. At application runtime, value curves of trace variables, which you can monitor in the trace editor in CODESYS, are recorded on the controller. The requirement is that setting of a trace configuration, the transfer of the trace configuration to the controller, and the starting of the trace recording. The recorded data is transferred to the development system and displayed in diagrams according to the configuration. You can navigate through the data when tracing.

If the controller supports a trace manager, then you can use the 'DeviceTrace' object type in the trace manager to access all traces that are running on the controller.

Double clicking the trace object opens the trace editor. The corresponding toolbar contains the most important trace commands. The trace variable list shows the variable whose value curve is recorded.

- (1): Toolbar of the trace editor
- (2): Trace editor
At application runtime, the runtime system buffer of the trace component is filled with the recorded samples. The data is transferred to the development system and stored in its trace editor buffer. The trace editor accesses this data and visualizes it in diagrams as a graph over time. If you close the trace editor, the trace editor buffer will be freed up.

Use menu commands for controlling the trace. In addition, you can use menu commands, keyboard shortcuts, and mouse input for navigating through the data.

- Chapter 1.3.1.13.3.5 “Navigating into trace data” on page 343

**Trace variable list**

The trace variable list provides an overview of the current trace configuration. When you double-click a trace variable, the dialog “Trace configuration” also opens with its variable settings.

<table>
<thead>
<tr>
<th><strong>Context menu in the trace variable list</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>“Add Variable”</strong></td>
</tr>
<tr>
<td><strong>“Visible”</strong></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
"Display Settings" Opens the “Trace Configuration” dialog. Select a configuration item in the tree view “Trace record” or “Presentation (Diagrams)”.

“Configuration” Opens the “Trace Configuration” dialog. The “Variable Settings” are displayed on the right.

- Chapter 1.3.1.13 “Application at runtime” on page 322

Object 'DeviceTrace'

Symbol: 📊

A “DeviceTrace” object shows trace data in one or more diagrams, as does a “Trace” object. The difference is that a “DeviceTrace” directly accesses traces that are running on the controller. The object is inserted below the device in the device tree. Therefore there is no immediate dependency on the applications in the CODESYS project.

You can use the DeviceTrace for visualizing the processor load of a multicore controller.

For more information about the editor and its operation, refer to the help page for the “Trace” object.

- Chapter 1.3.1.9.17.2 “Multicore” on page 241

Object 'Trend Recording Manager'

Symbol 📈

A “Trend Recording Manager” object makes it possible to save data at runtime in a database for a long period of time. This data is recorded with the “CmpTraceMgr” runtime system component. In the device tree, this object is used as a node for trend recordings that are created below an application. It is available below an application only one time.
Object 'Trend Recording'

Symbol: 📊

A "TrendRecording" object is always located below a "Trend Recording Manager" and enables editing of the trace configuration. At runtime, CODESYS loads the configuration that is available to the CmpTraceMgr runtime system component. You can configure an application with any number of trend recordings.

**NOTICE!**

**Timeout for trend recording**

During a trend recording, it can happen that the application task triggers a timeout that is caught with an exception when transitioning from “Running” to “Stop”. Causes can be that file operations with the SQLite database are taking too long or that too many variables are being recorded. This usually happens on a target device with weak performance.

You can avoid the occurrence of an exception:
- Configure the trend recording with less memory demand so that the amount of data that is stored is adapted to the target system.
- Reduce the number of variables.

The editor includes the configuration for trend recording. The tree view shows the trend configuration and enables navigation there.

The top entry contains the trend name. When this entry is selected, the “Record Settings” appear next to it. An entry is located here for each variable that data was recorded continuously. When a variable is selected, the “Variable Settings” appear next to it.

### Table: Trend Recording Actions

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Add Variable&quot;</td>
<td>When you click the link, a new entry appears in the trend configuration with its blank configuration below the “Variable Settings” group.</td>
</tr>
<tr>
<td>&quot;Delete Variable&quot;</td>
<td>The selected variable is removed. Requirement: A variable is selected.</td>
</tr>
</tbody>
</table>

See also
- Command ‘Edit trend recording’ § Chapter 1.3.5.19.2.17 “Command ‘Edit Trend Recording’” on page 1577

**'Recording settings'**

The data is recorded in the runtime system component using the function that is also used for trace. The settings that appear here are the same. The options that are not required here are deactivated.

The settings that affect the trigger are deactivated. Only a trace configuration for a trace editor can configure triggering.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Task&quot;</td>
<td>Task where data was recorded. Click the &quot;down&quot; symbol (▼) to open a drop-down list with all tasks available in the project. In general the trend recording runs in the same task as the main program. For example: MainTask</td>
</tr>
</tbody>
</table>

- § Chapter 1.3.1.25.2.4.1 “Command ‘Add Object’” on page 897
- § Chapter 1.3.1.25.1.42 “Object ‘Trend Recording’” on page 846
| "Record condition" | Recording condition for which the application records data:  
| | - IEC variable of type INT The condition is fulfilled for TRUE.  
| | - Bit access to an integer variable. The condition is fulfilled for 1.  
| | As read access to a property.  
| The contents of a pointer are not permitted. |
| "Comment" | Comment (example: Data recording of sensor A) |
| "Resolution" | Resolution that the application saves the time stamp  
| | Note: If the task where the trend object is executed has a cycle time of 1 ms or less, then you should set the resolution of the time stamp to “1 μs”. |
| "Trend storage" | The “Trend storage” dialog opens. |
| "Advanced" | The “Advanced Trend Settings” dialog opens. |

See also  
- § Chapter 1.3.1.25.3.16 “Dialog Box ‘Trend storage’” on page 1097  
- § Chapter 1.3.1.25.3.17 “Dialog Box ‘Advanced Trend Settings’” on page 1097

| "Variable settings" |
| "Variable" | Variable for recorded value. |
| | - IEC variable with valid type.  
| | - Property  
| | - Reference  
| | - Contents of the pointer  
| | - Array element of a valid data type  
| | - Enumeration of a valid data type  
| | Valid data types are all standard types, except STRING, WSTRING, and ARRAY. |
| "Parameter" | Parameter for recorded value. |
| | The “Input Assistant” dialog lists all valid system parameters in the “Parameters” category of the “Categories” tab. |
| | Click the symbol to toggle between “Variable” and “Parameter”. |
| "Attached y axis" | Y-axis of the trend diagram that displays the “Variable”. The drop-down list provides the standard y-axis and the configured y-axes.  
| | Requirement: This option is visible only when the “Trend” visualization element has configured additional y-axes in the “Edit Display Settings” dialog. |
| "Display variable name" | ☑: The visualization shows the name of the IEC variable in the trend diagram in runtime mode. Either alone or in parentheses after the “Description”  
| | ☐: The name of the IEC variable is shown and does not appear in parentheses after the “Description”.  
| | Requirement: If any text is typed in “Description”, then you can disable the option. |
**Description**

Text for the tooltip (example: Sensor A): When a visualization user focuses on the variable in the trend diagram, the visualization shows the text as a tooltip. The text is typed into the “GlobalTextList” object and can be localized there.

When the “Display Variable Name” property is activated, then the text is supplemented with the variable name in parentheses. Example: Sensor A (PLC_PRG.iSensor_A)

If “Description” does not contain any text, then “Display Variable Name” is enabled. The name is then alone without parentheses (for example, PLC_PRG.iSensor_A).

If a legend is assigned to the trend, then the trend variable is labeled in the legend and shown as the trend is configured here.

<table>

</table>
Object 'Trend Recording Task'

Symbol 

If you design a visualization with a “Trend” element, then CODESYS automatically extends the “Task Configuration” with a “Trend Recording Task”. The task is below an application one time at most and calls the VisuTrendStorageAccess.GlobalInstances.g_TrendRecordingManager.CyclicCall program to run the trend recording manager.

- Chapter 1.3.1.13.4 “Data recording with trend” on page 344

Object 'Unit Conversion'

Symbol 

A “Unit Conversion” object is used to define a conversion rule. The following table lists all defined conversion rules. You can edit a conversion rule in the input fields listed below the table.

Table of conversion rules

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>&lt;name&gt; : &lt;name&gt;_Impl is the name of the conversion rule. CODESYS automatically implements the entry as a function block &lt;name&gt;_Impl and instances it as &lt;name&gt;.</td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Type of conversion rule</td>
<td></td>
</tr>
<tr>
<td></td>
<td>“Single scaling (offset)”: adds an offset to the input variable. Result := Input + Offset</td>
<td></td>
</tr>
<tr>
<td></td>
<td>“Single scaling (factor)”: multiplies the input variable by a factor. Result := Input * Factor</td>
<td></td>
</tr>
<tr>
<td></td>
<td>“Linear scaling 1 (factor and offset)”: converts the input variable with a factor and offset. Result := Input * Factor + Offset</td>
<td></td>
</tr>
<tr>
<td></td>
<td>“Linear scaling 2 (Base and target range)”: converts the input variable for the output value to be within a target range. CODESYS calculates the functional linear equation internally.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>“User defined conversion”: configures a user-defined conversion rule with IEC operators. The input variable is rValue.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>“Switchable conversion”: defines a conversion rule that CODESYS executes independent of any specified language or variable.</td>
<td></td>
</tr>
<tr>
<td><strong>Setting</strong></td>
<td>Displays the configured conversion rule.</td>
<td></td>
</tr>
</tbody>
</table>

If you design a visualization with a “Trend” element, then CODESYS automatically extends the “Task Configuration” with a “Trend Recording Task”. The task is below an application one time at most and calls the VisuTrendStorageAccess.GlobalInstances.g_TrendRecordingManager.CyclicCall program to run the trend recording manager.

<td></td>
</tr>
<tr>
<td><strong>Setting</strong></td>
<td>Displays the configured conversion rule.</td>
<td></td>
</tr>
</tbody>
</table>
**“Condition”**
- "TRUE": CODESYS always executes the conversion.
- "Language": If the language in the visualization is the language defined here, then CODESYS executes the conversion. The current visualization language is located in the `VisuElems.CurrentLanguage` variable.
- "Variable": If the comparison is TRUE, then CODESYS executes the conversion rule. CODESYS can pass the comparison for a constant, variable, or IEC expression.
  
You can edit the comparison below the table in the “Condition Setting”.

**“Condition Setting”**
If you select "TRUE" as the "Condition", then the field is hidden.
If you configure "Language" as the "Condition", then the field shows the current configuration, for example en, de.
If you select "Variable" as the "Condition", then the field shows the current configuration, for example `PLC_PRG.bActual=PLC_PRG.bSet`.
You can edit the current condition setting below the table in the input fields for “Condition Setting”.

**Input field 'Single scaling (offset)'**
The input variable is added with an offset.

**"Offset"**
- as a number, including REAL
- as an IEC variable

**Input field 'Single scaling (factor)'**
The input variable is multiplied by the factor.

**"Factor"**
- as a number, including REAL
- as an IEC variable

**Input field 'Linear scaling 1 (factor and offset)'**
The input variable is converted with the linear equation defined below.

**"Factor"**
- as a number, including REAL
- as an IEC variable

**"Offset"**
- as a number, including REAL
- as an IEC variable

**Input field 'Linear scaling 2 (Base and target range)'**
The input variable is converted to be within a target range. CODESYS internally creates a linear equation from the following input values.

**"Base start value"**
Lowest possible value for the input variable.
- as a number, including REAL
- as an IEC variable

**"Base end value"**
Highest possible value for the input variable.
- as a number, including REAL
- as an IEC variable
"Target start value" | Lowest possible value for the output variable.  
| as a number, including REAL  
| as an IEC variable

"Target end value" | Highest possible value for the output variable.  
| as a number, including REAL  
| as an IEC variable

Example | Conversion of electric current from a 10-bit input signal to an amperage range of 4-20 mA

| "Base start value" | 0 |
| "Base end value" | 1024 |
| "Target start value" | 4.0 |
| "Target end value" | 20.0 |

Example | Conversion rule as mathematical function of rValue The input variable is rValue.

Example | Reverse function of the function defined in \"Convert\"

Example | Use this conversion rule when you want to apply a conversion that is language-specific or variable-dependent.

Example | The Conv_A_LanguageDependent conversion rule that defines which conversion rule is executed for the English or German language.

### 1.3.1.25.2 Menu Commands

By default the most important commands are already provided in the CODESYS user interface. If you want to customize the menu configuration individually, choose command “Tools ➔ Customize ➔ Menu”.

When you have installed any packages or add-ons, additional menus and commands might be available.

---

#### Menu 'File'

**Command ‘New Project’**

Symbol: ☰, Shortcut: [Ctrl] + [N]

**Function:** This command opens the “New Project” dialog box for the creation of a new project file.

**Call:** “File” menu

---

**'New Project' dialog box**

**Function:** Selection of a project category and a project template.

**Call:** “File ➔ New Project”

Depending on the template, you obtain a project that is automatically equipped with a certain range of objects.

---

**Table 115: “Categories”**

<table>
<thead>
<tr>
<th>Libraries</th>
<th>Projects</th>

<th>“Projects” category:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>“Empty project”</td>
<td>Contains only the “Project Settings” object.</td>
</tr>
<tr>
<td>“Standard project”</td>
<td>Contains a basic range of objects and libraries. A wizard assists with the creation — see below.</td>
</tr>
<tr>
<td>“Standard project with Application Composer”</td>
<td>Contains a basic range of objects and libraries for working with the Application Composer. A wizard assists with the creation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>“Libraries” category:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>“CODESYS container library”</td>
<td>Library that contains only further libraries, but no function blocks of its own.</td>
</tr>
<tr>
<td>“CODESYS interface library”</td>
<td>Library only for the definition of the interface of a software component. Thus contains only objects that do not generate any code (constants, structures, interfaces, etc.).</td>
</tr>
<tr>
<td>“Empty library”</td>
<td>Contains only the “Project Settings” object.</td>
</tr>
<tr>
<td>“External CODESYS library”</td>
<td>Target-system-specific library which is implemented as part of the runtime system (in ANSI C or C++).</td>
</tr>
<tr>
<td>“Name”</td>
<td>Name of the project to be created. Depending on the template, a standard name appears. The numerical suffix ensures the uniqueness of the name in the file system. You can change the file name, taking into consideration the file path conventions of the operating system. Periods are not permitted in names. CODESYS automatically adds the appropriate file extension to the selected template.</td>
</tr>
</tbody>
</table>
| “Location” | Location for the new project file. 

opens a dialog box for browsing the file system. 

Displays the history of previously entered paths. |
| “OK” | CODESYS opens a new project. An error symbol next to the input field draws attention to missing specifications. If you place the mouse pointer on it, a tooltip appears, informing you what to do. |

“Standard Project” dialog box

**Function:** Wizard for the creation of a standard project.

**Call:** Command “File ➤ New Project”; in the “New Project” dialog box, select the “Projects” category and the “Standard project” template and click on “OK”.

| “Device” | Selection list with PLC devices. The selected device is inserted as an object in the Devices view below the root node. |
| “PLC_PRG in” | Selection list with the programming languages. The automatically inserted program PLC_PRG is created in the selected language. |

See also

● Chapter 1.3.1.3.1 “Creating standard projects” on page 124

Command ‘Open Project’

**Symbol:** ⌘ **Shortcut:** [Ctrl] + [O]

**Function:** This command opens the standard dialog box for opening a file. Here you can browse the file system for a CODESYS project file and open it in the development system.

**Call:** “File” menu
Depending on the selected file format

### 'Open Project' dialog box

<table>
<thead>
<tr>
<th>&quot;File type&quot;</th>
<th>Selection list for filtering the type of file</th>
</tr>
</thead>
<tbody>
<tr>
<td>● &quot;All supported files&quot;</td>
<td>files in all supported formats.</td>
</tr>
<tr>
<td>● Project files: CODESYS project files from V3, file extension &quot;project&quot;</td>
<td></td>
</tr>
<tr>
<td>● Project archive files: CODESYS project archives from V3, file extension &quot;projectarchive&quot;</td>
<td></td>
</tr>
<tr>
<td>● Library files: Library projects from V3, file extension &quot;library&quot;</td>
<td></td>
</tr>
</tbody>
</table>

| "Open" | CODESYS opens the selected project file. If necessary, it is converted first. |

### Command 'Close Project'

**Function:** This command closes the currently opened project. CODESYS remains opened.

**Call:** "File" menu. In addition implicitly when opening a new/other project, while another project is still open.

If the project contains unsaved changes, a query appears, asking whether the project should be saved.

If you have not yet explicitly saved the project, a query appears asking whether you wish to delete the project files.

### Command 'Save project'

**Symbol:** 📖, shortcut [Ctrl] + [S]

**Function:** this command saves the project file.

**Call:** "File" menu

This command saves the project file with the current project name, which appears in the title bar of the main window. If the project has been changed since it was last saved, the project name is given an asterisk.

The command is not available if the project is read-only.

Write protection exists if

- the project is identified in the project information (summary) as 'Released'
- the option "Open read-only" was selected in the dialog box "Open Project" when opening the project

Write protection is indicated by a line in the top right corner of the main window. A mouse-click on this line brings up a menu with commands for the possible actions:

- "Save project under a different file name on the disk": a mouse-click on this option leads to 'Save file as...' and
- "Exit read-only mode": appears only if the option "Open read-only" was selected when opening the project.
- "Remove read-only attribute from the project on the disk": appears only if the project file had been provided with the property 'Read-only' on the disk at the time of opening.
- "Remove identification 'Released' in the project information": appears only if this attribute is currently set.

**Backup copy**
Optionally a backup copy of the project file can be created. If the option "Create backup copy" is activated in the option dialog box 'Load and Save', the project is additionally copied to a file <projectname.backup> each time the project is saved.

See also
- § Chapter 1.3.1.25.2.1.5 “Command 'Save Project as'” on page 855
- § Chapter 1.3.1.6.8 “Save project” on page 150
- § Chapter 1.3.1.25.3.13.13 “Dialog ‘Options’ – ‘Load and Save’” on page 1083

Command 'Save Project as'

This command opens the standard Windows dialog box for saving a file. The project can be stored with the desired location and file type.

<table>
<thead>
<tr>
<th>“File type”</th>
<th>For both normal projects and library projects, this drop-down list contains the respective versions of the development system for which the project can be saved. If the current project contains add-ons that are not available in the selected memory format (profile), then the “Extend Profile” dialog box opens.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- “Project files (CODESYS v&lt;version&gt;) (*.project)”: The project is saved as a CODESYS project file &quot;&lt;project name&gt;.project &quot; for the currently used or selected version of the development system.</td>
</tr>
<tr>
<td></td>
<td>- “Library files (CODESYS v&lt;version&gt;) (*.library)”: The project is saved as a CODESYS library file &quot;&lt;project name&gt;.library&quot; for the currently used or selected version of the development system.</td>
</tr>
<tr>
<td></td>
<td>If the project should be opened later in an older version, then it makes sense to save for precisely this version, as you will then be informed immediately about possible data loss.</td>
</tr>
</tbody>
</table>

Before saving a project as a library:
- Make sure that the rules for creating libraries have been followed. |
- If it is to be possible to configure global constants provided by the library at a later time in an application, then you must define them in a parameter list. A parameter list is a special type of global variable list. |
- When saving the project, no automatic check for errors is performed. |
- Unlike CoDeSys V2.3, there is no distinction between 'external' and 'internal' libraries. Now you can define in the properties of each individual project object whether or not it should be treated as 'external'. |
- Consider whether the library created is to be installed in the system library repository immediately. If so, then use the command ‘Save project and install in the library repository’. |
- If you want to protect the library project from later changes, then set the “Released” attribute in the “Project Information” dialog box. At the next attempt to save the project, a corresponding message will be displayed and the user must respond to the write protection with deliberate actions. |
- If you save the project as a version of the development system other than the one currently in use, then you will be informed first about possible data loss. |

Dialog box 'Extend Profile'

In this dialog box, the selected profile (memory format) can be extended by the add-ons that are contained in the current project. The profile is saved temporarily and then deleted after being saved or exported.

<table>
<thead>
<tr>
<th>“Add to profile”</th>
<th>☑: The current profile is extended by the add-on so that the add-on data of the current project is also saved.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Add-on”</td>
<td>The add-on of the current project that is not contained in the selected memory format.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>“Version”</th>
<th>Version of the “Add-on” included in the current profile. If several versions are installed, then the version can be selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Save profile”</td>
<td>Opens the “Enter Profile Name” dialog box. In this dialog box, specify the name for the new profile. The new profile is saved permanently at $ProgramData$/PRODUCT$/CustomInformationalProfiles.</td>
</tr>
<tr>
<td>“Use saved profile”</td>
<td>The profile which was permanently saved in “Save profile” is used for saving or exporting the current project.</td>
</tr>
</tbody>
</table>

- § Chapter 1.3.1.25.2.1.6 “Command ‘Save Project and Install into Library Repository’” on page 856

Command 'Save Project and Install into Library Repository’

**Function:** this command saves the project as a library in the 'system' library repository.

**Call:** Main menu “File”.

With this command CODESYS saves the project as a library in the 'system' library repository. This is an extension to the saving of a project as a library file using the “Save Project as” command. The library is installed on the local system and is immediately available for insertion into a project.

See also

- § Chapter 1.3.1.25.2.1.5 “Command 'Save Project as’” on page 855

Command 'Save Project as Compiled Library’

**Function:** This command saves a library project in encrypted form.

**Call:** Menu bar: “File”

The command opens the standard dialog for saving a file in the file system. The “Compiled CODESYS Libraries” file type is already preset. The file extension is .compiled-library-v3 or .compiled-library (CODESYS < SP15). In this format, then source code of the library POU is not visible when the library is used in a project.

If the “Enforce signing of compiled libraries” option is selected in the “Security Screen” view, then a library project has to be provided with a digital certificate-based signature when being saved. In the “Project Information”, on the “Summary” tab, a “Library compatibility” with a CODESYS version >= V3 SP15 is set by default. In this case, the project file is stored with the file extension .compiled-library-v3 when being saved as a compiled and signed library. If you still have not specified a suitable valid certificate for your user profile in the “Security Screen”, then a dialog prompt opens next for you to do this. Afterwards, you can execute the save command again.

In all other respects, compiled library files behave just like *.library files, and therefore they can be installed and referenced with the same steps.

We recommend the use of compiled libraries signed with certificates. Besides the protection of the source code and the unauthorized use of a library, less memory is also used which results in shorter loading times.
If you have the corresponding help files with translations, then as of CODESYS V3 SP15 you can extend the library documentation with the translation into other languages. This is done as follows:

Place the files created for the new languages _lmd_<language>.aux in a directory <library name>.lmd parallel to the library project <library name>.compiled-library-v3. If the files are correct, then they are included in the compiled library file when saving the library project by means of the "Save Project as Compiled Library" command.

Example: The directory standard.lmd is exists parallel to the library file standard.compiled-library-v3 and contains the file _lmd_fr.aux with the French translation of the library documentation. After the compiled library is saved, the French version of the documentation is also available in the Library Manager.

**Command 'Save/Send Archive'**

**Function:** This command opens the dialog “Project Archive” for the configuration of project archives.

**Call:** Menu bar: “File ➪ Project Archive”

An archive file (*.projectarchive) contains all files contained and referenced in the currently opened project. It can either be saved or dispatched as an e-mail attachment. The dispatch by email is very helpful for providing an employee with all project-relevant files. The file can be simply unpacked again with the command “Extract Archive”.

**NOTICE!**

The archiving function is not intended for the storage of a project, but rather for the simple summarizing of all project-relevant files.

See also

- Chapter 1.3.1.6.9 “Saving/Sending the project archive” on page 152
- Chapter 1.3.1.25.2.1.9 “Command ‘Extract Archive’” on page 858

**Dialog 'Project Archive'**

The dialog displays all the categories that can be added to the project archive. In this dialog, complete categories or individual objects from the categories can be added to the project archive by setting a check mark (√).

Entries that are display as red in the list require your attention. Move the mouse pointer over this library for more information.
"Additional files"  Opens the dialog "Additional Files". Here, further files can be added to the archive with the "Add" button.

"Comment"  Opens the "Comment" dialog. Here, comments can be added to the archive.

"Save"  Creates the archive file and saves it. The storage location and the archive name are specified in the subsequent dialog.

"Send"  Creates a temporary archive file that is attached to an empty e-mail. A correct installation of the MAPI (Messaging Application Programming Interface) is required for the successful execution of this operation. Failure is documented by the display of a corresponding error message. The temporary archive is automatically deleted after sending the e-mail.

### Command 'Extract Archive'

**Function:** The command extracts a project archive, that was created with the command "Save/ Send Archive". You have to configure which objects of the archive CODESYS shall extract and in which directory of the file system they will be copied.

**Call:** Main menu "File ➔ Project Archive"

The file extension of an archive is .projectarchive.

After the archive is selected, the dialog "Extract Project Archive" opens to configure the extract parameters.

#### Dialog Box 'Extract Project Archive'

This dialog box shows the contents of the project archive. You can exclude complete categories or single objects from categories by clearing the check boxes (✓) from the extraction.

**Table 118: "Locations"**

<table>
<thead>
<tr>
<th>Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Extract into the same folder where the archive is located&quot;</td>
<td>The archive is extracted to the same directory.</td>
</tr>
<tr>
<td>&quot;Extract into the following folder&quot;</td>
<td>The contents of the archive are extracted to the given path.</td>
</tr>
<tr>
<td>&quot;Advanced&quot;</td>
<td>Opens the &quot;Advanced&quot; dialog box for you to define where special and additional files from the archive are extracted.</td>
</tr>
</tbody>
</table>

**Table 119: "Contents"**

<table>
<thead>
<tr>
<th>Content</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Items&quot;</td>
<td>Shows the contents of the archive structured in object categories.</td>
</tr>
<tr>
<td>✓</td>
<td>The object is extracted.</td>
</tr>
<tr>
<td>□</td>
<td>The object is not extracted.</td>
</tr>
<tr>
<td>&quot;Comment&quot;</td>
<td>Comment that was entered when creating the project archive</td>
</tr>
<tr>
<td>&quot;Extract&quot;</td>
<td>If an extracted file has the same name as an existing file in the target directory, then a dialog box opens, prompting whether the local file should be replaced. The decision can be applied automatically to any additional conflicting names. In this case, you have to select the ✓ &quot;Apply to all objects and files&quot; check box.</td>
</tr>
</tbody>
</table>
Table 120: "Repositories"

| "Install devices into" | Drop-down list with currently available repositories. Select the repositories, in which CODESYS shall install the devices and the libraries of the archive. |
| "Install libraries into" |

Table 121: "Additional Files"

By default the "additional files" are set to "Do not extract". Select the entries in the table and chose one of the following options:

| "Extract into project folder" | Folder of the project file |
| "Extract into folder" | User defined folder |
| "Do not extract" | Default |

See also
- Chapter 1.3.1.25.2.1.8 "Command 'Save/Send Archive'" on page 857

Command 'Source Upload'

**Function:** This command loads the project source code (as project archive) from the controller.

**Call:** Main menu "File".

**Requirement:** The network path for the controller must be configured.

After you execute the command, an overview opens with all devices in the network. Select a controller from this overview. The dialog box "Extract Project Archive" then opens with export settings.

- Chapter 1.3.1.11.7 "Downloading source code to and from the PLC" on page 307
- Chapter 1.3.1.25.2.1.11 "Command 'Source Download'" on page 860

Dialog Box 'Extract Project Archive'

This dialog box shows the contents of the project archive. You can exclude complete categories or single objects from categories by clearing the check boxes (☐) from the extraction.

Table 122: “Locations”

| "Extract into the same folder where the archive is located" | The archive is extracted to the same directory. |
| "Extract into the following folder" | The contents of the archive are extracted to the given path. |
| "Advanced" | Opens the "Advanced" dialog box for you to define where special and additional files from the archive are extracted. |

Table 123: “Contents”

| "Items" | Shows the contents of the archive structured in object categories. |
| "Comment" | Comment that was entered when creating the project archive. |
| ☑ | The object is extracted. |
| ☐ | The object is not extracted. |
If an extracted file has the same name as an existing file in the target directory, then a dialog box opens, prompting whether the local file should be replaced. The decision can be applied automatically to any additional conflicting names. In this case, you have to select the **Apply to all objects and files** check box.

**Command 'Source Download'**

**Function:** This command loads the project source code (as project archive) to the controller.

**Call:** Main menu “File”.

**Requirement:** The network path for the controller must be configured.

After you execute the command, an overview opens with all devices in the network. Select a controller from this overview. Then the Archiv.prj project archive is downloaded to this controller. You can click “Source Upload” to upload the complete source code to the CODESYS development system at a later time.

If you are already connected to a controller (in online mode), then the “Source Download to Connected Device” command is also available for this process.

**Command 'Print'**

**Symbol:**  

**Function:** This command opens the default Windows dialog box for printing documents.

**Call:** Main menu “File”

See also
- Chapter 1.3.1.25.3.11.6 “Dialog ‘Project Settings’ - ‘Page Setup’” on page 1064

**Command 'Print Preview'**

**Function:** This command opens a print preview for the currently open element.

**Call:** Main menu “File”

**Requirement:** An object is open in the editor.

**Command 'Page Setup'**

**Symbol:**  

**Function:** This command opens the “Page Setup” dialog box for configuring the layout of the printed version of the project contents.

**Call:** Main menu “File ➤ Page Setup”
Command ‘Recent Projects’

Function: Opens the list of the projects used recently, from which you can select a project to open.

Call: “File” menu

Command ‘Exit’

Shortcut: [Alt]+[F4]

Function: this command exits from the programming system. If a project is currently opened that has been changed since it was last saved, a dialog box opens asking whether the project should be saved.

Call: “File” menu
Menu 'Edit'

| 1.3.1.25.2.2.43 | Command 'Refactoring' - 'Reorder Variables'.......................... 880 |

**Standard Commands**

CODESYS provides the following standard commands:

- **Undo**: ⬤, shortcut: \[Ctrl\] + \[Z\]
- **Redo**: ⬤, shortcut: \[Ctrl\] + \[Y\]
• Cut: \(\text{⌘}X\), shortcut: [Ctrl] + [X]
• Copy: \(\text{⌘}C\), shortcut: [Ctrl] + [C]
• Paste: \(\text{⌘}V\), shortcut: [Ctrl] + [V]
• Delete: \(\text{⌘}X\), shortcut: [Ctrl]
• Select all: shortcut: [Ctrl] + [A]

Not all editors support the “Insert” command. In some editors it can be used with limitations. Graphical editors only support the command if the pasted elements will create a valid construct.

In object trees like POU's or device view the command refers to the currently selected object. Multi selection is possible.

Command 'Find', 'Find in Project'
Symbol \(\text{⌘}F\), keyboard shortcut: [Ctrl]+[F]
Symbol \(\text{⌘}F\), keyboard shortcut [Ctrl]+[Shift]+[F]

Function: These commands scan the project or parts of it for a specified character string.

Call: Menu bar: “Edit \(\rightarrow\) Find Replace”

This command opens the “Find” dialog where the searched character string is specified and the search options are defined.

Dialog 'Find'

| “Search for” | Character string to be searched. |
| “Match case” | ✓: The search considers uppercase and lowercase. |
| “Match whole word” | ✓: Only character strings are found that exact matches. |
| “Search up” | ✓: The specified search range runs upwards. |
| “Use regular expressions” | Use the \(\text{⌘}\) button to receive support when specifying regular expressions. |
| “Search in” | ☑: Drop-down list with the areas of the project to be searched: |
| | • “Active editor” |
| | • “All open editors” |
| | • “Selected objects & Subobjects” |
| | • “Entire project” |
| | • “Entire project & Uncompiled libraries” |
| | • “Selection only” |
| “Find next” | Start the search |
| “Find all” | All search results are listed in the message view with their object path, project name, object name, and object position. Possible additional information for position: “(Decl)” = Declaration part of the object; “(Impl)” = Implementation part of the object |
| “Replace” | Switches to the “Replace” dialog |

The color of the search result markings can be customized in the options of the text editor. This is done by means of the parameter “Selection color” - “Inactive” in the “Text Area” tab.
Dialog for setting the objects to be searched

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Entire project&quot;</td>
<td>All editable positions in all objects of the project are searched.</td>
</tr>
<tr>
<td>&quot;Entire project and all uncompiled libraries&quot;</td>
<td>All editable positions in all objects of the project, including integrated uncompiled libraries, are searched.</td>
</tr>
<tr>
<td>&quot;Within the following objects&quot;</td>
<td>Only the editable positions within the objects defined here are searched:</td>
</tr>
<tr>
<td>- &quot;Scheme&quot;</td>
<td>The &quot;Save&quot; command saves the current search configuration by the specified name. All saved schemes are available in the drop-down list.</td>
</tr>
<tr>
<td>- &quot;Object types&quot;</td>
<td>The object is searched.</td>
</tr>
<tr>
<td>- &quot;Name filter&quot;</td>
<td>Name filter for the searched objects. The placeholder &quot;*&quot; can be used.</td>
</tr>
<tr>
<td>Example: Filter &quot;<em>CAN</em>&quot;: All objects are searched that have &quot;CAN&quot; in the name.</td>
<td></td>
</tr>
<tr>
<td>&quot;All open editors&quot;</td>
<td>All editors are searched that are currently open in a window.</td>
</tr>
<tr>
<td>&quot;Active editor&quot;</td>
<td>Only the editor is searched where the cursor currently is.</td>
</tr>
<tr>
<td>&quot;Selection only&quot;</td>
<td>Only the text is searched that is currently selected in an object.</td>
</tr>
</tbody>
</table>

Command 'Replace', 'Replace in Project'

Symbol  
keyboard shortcut: [Ctrl]+[H]  
keyboard shortcut: [Ctrl]+[Shift]+[H]  
Function: These commands scan the project or parts of it for a specified character string and replaces it.  
Call: Menu bar: “Edit ➔ Find Replace”  
Requirement: The application is in online mode.  
This command opens the "Replace" dialog where the search and replace character strings are specified and the search options are defined.

Table 124: In addition to the options of the “Search” dialog, the following settings are still possible:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Replace with&quot;</td>
<td>Input field for the new character string.</td>
</tr>
<tr>
<td>&quot;Replace&quot;</td>
<td>Each next found string is highlighted in the editor and replaced (step-by-step replace).</td>
</tr>
<tr>
<td>&quot;Replace all&quot;</td>
<td>All found strings are replaced at one time without them being displayed in the editors.</td>
</tr>
<tr>
<td>&quot;Leave changed objects open after &quot;Replace all&quot;&quot;</td>
<td>The editors of the found objects remain open.</td>
</tr>
</tbody>
</table>
Replacement in referenced libraries is not possible.

Command 'Find Next'

Symbol ⌘, keyboard shortcut [F3]

**Function:** During the search for a certain string within the project, this command selects the next match at its position in the respective editor.

**Call:** Menu “Edit ➔ Search Replace”

**Requirement:** You have already started searching the project for a certain string by using the commands “Find” or “Replace”.

See also
- % Chapter 1.3.1.25.2.2.2 “Command 'Find', 'Find in Project’” on page 863

- % Chapter 1.3.1.9.15 “Searching and replacing in the entire project” on page 236

Command 'Find Next (Selection)'

Keyboard shortcut [Ctrl] + [F3]

**Function:** The command searches the project for the next string matching the string which is currently selected or in which you have currently placed the cursor.

**Call:** Menu “Edit ➔ Find Replace”

**Requirement:** You have the cursor placed in an editable string in your project, or you have selected an editable string.

See also
- % Chapter 1.3.1.25.2.2.2 “Command 'Find', 'Find in Project’” on page 863

- % Chapter 1.3.1.9.15 “Searching and replacing in the entire project” on page 236

Command 'Find Previous'

Symbol ⌘, keyboard shortcut [Shift] + [F3]

**Function:** During the search for a certain string within the project, this command selects the next match at its position in the respective editor.

**Call:** Menu “Edit ➔ Search Replace”

**Requirement:** You have already started searching the project for a certain string by using the commands “Find” or “Replace”.

See also
- % Chapter 1.3.1.25.2.2.2 “Command 'Find', 'Find in Project’” on page 863

- % Chapter 1.3.1.9.15 “Searching and replacing in the entire project” on page 236
Command 'Find Previous (Selection)'

Keyboard shortcut: [Ctrl] + [Shift] + [F3]

**Function:** The command searches the project for the previous string matching the string which is currently selected or in which you have currently placed the cursor.

**Call:** Menu “Edit ➔ Find Replace”

**Requirement:** You have the cursor placed in an editable string in your project, or you have selected an editable string.

See also
- ° Chapter 1.3.1.25.2.2.2 “Command ‘Find’, ‘Find in Project’” on page 863

Command 'Insert File as Text'

**Function:** This command copies the contents of a text file to the active editor as the current cursor position.

**Call:** The command is not in any menu by default. You can add it to a menu by using the dialog box from “Tools ➔ Customize” (command category “Text Editor”).

**Requirement:** The file must have the extension .txt. The command is available in a text editor only.

Many development environments and text processing applications provide the option of exporting code and text as a plain text file. This command can copy the contents of this file to the editor.

See also
- ° Chapter 1.3.1.25.3.13.20 “Dialog ‘Options’ - ‘Text Editor’” on page 1086

Command 'Overwrite Mode'

**Shortcut:** [Insert]

**Function:** This command activates the overwrite mode.

**Call:** Menu “Edit ➔ Advanced”

**Requirement:** A text editor is opened.

If the overwrite mode is activated, characters in front of the cursor are overwritten when entering new characters. If the overwrite mode is deactivated, characters are inserted and existing characters in front of the cursor are retained.

See also
- ° Chapter 1.3.1.25.3.13.20 “Dialog ‘Options’ - ‘Text Editor’” on page 1086

Command 'View Whitespace'

**Symbol:** \( \_a \_b \)

**Function:** This command causes control characters for spaces and tabs to be shown.

**Call:** Menu “Edit ➔ Advanced”

**Requirement:** A text editor is opened.

CODESYS visualizes spaces by a period and tabs by an arrow.
See also

- Chapter 1.3.1.25.3.13.20 “Dialog ‘Options’ - ‘Text Editor’” on page 1086

Command 'View Indentation Guides'

Function: This command activates the indentation help lines.
Call: Menu “Edit ➔ Extended”
Requirement: A text editor is opened.
If the indentation help lines are activated, a broken line is inserted for each manual indentation in the code. This facilitates the overview of the different levels in the code. You can insert manual indentations with the [Tab] key.
See also

- Chapter 1.3.1.25.3.13.20 “Dialog ‘Options’ - ‘Text Editor’” on page 1086

Command 'Go to Line'

Function: With this command the cursor jumps to a defined line in the code.
Call: Menu “Edit ➔ Extended”
Requirement: A text editor is opened.
This command opens a dialog box with an input field “Line number”.
See also

- Chapter 1.3.1.25.3.13.20 “Dialog ‘Options’ - ‘Text Editor’” on page 1086

Command 'Make Uppercase'

Shortcut: [Ctrl]+[Shift]+[U]
Function: This command converts all lowercase letters in the selected code into uppercase letters.
Call: Menu “Edit ➔ Advanced”
Requirement: A text editor is opened and code is selected, or the declaration editor is opened and variable declarations are selected.
See also

- Chapter 1.3.1.25.3.13.20 “Dialog ‘Options’ - ‘Text Editor’” on page 1086

Command 'Make Lowercase'

Shortcut: [Ctrl]+[U]
Function: This command converts all uppercase letters in the selected code into lowercase letters.
Call: Menu “Edit ➔ Advanced”
Requirement: a text editor is opened and code is selected, or the declaration editor is opened and variable declarations are selected.

- Chapter 1.3.1.25.3.13.20 “Dialog ‘Options’ - ‘Text Editor’” on page 1086
Command 'Go to Matching Bracket'

**Function:** This command makes the cursor jump to the other part of the selected code parenthesis.

**Call:** Menu “Edit ➔ Advanced”

**Requirement:** A text editor is opened and the cursor is positioned at an opening or closing code parenthesis. If you position the cursor at a code parenthesis, CODESYS displays the corresponding parenthesis in color, provided you have activated the option “Associated parentheses” in the CODESYS options in the “Text Editor” category, “Text Area” tab.

See also
- “Tab ‘Text Area’” on page 1087

Command 'Select to Matching Bracket'

**Function:** This command selects the entire code section within the currently selected code parentheses.

**Call:** Menu “Edit ➔ Extended”

**Requirement:** A text editor is opened and the cursor is positioned at an opening or closing code parenthesis. If you position the cursor at a code parenthesis, CODESYS displays the corresponding parenthesis in color, provided you have activated the option “Associated parentheses” in the project options in the “Text Editor” category, “Text Area” tab.

See also
- Chapter 1.3.1.25.3.13.20 “Dialog ‘Options’ - ‘Text Editor’” on page 1086

Command 'Expand All Folds'

**Function:** This command expands all collapsed code segments in the textual editor or result locations in the cross-reference list so that the code and all search locations are displayed in full again.

**Requirement:** A textual editor is active and indentation is activated in the “Options” (“Text Editor” category); or the cross-reference list is active.

**Call:** Textual editors: main menu “Edit ➔ Advanced”, or right-click. In the cross-reference list: right-click.

See also
- Chapter 1.3.1.25.3.13.20 “Dialog ‘Options’ - ‘Text Editor’” on page 1086
- Chapter 1.3.1.25.2.2.18 “Command ‘Collapse All Folds’” on page 868
- “Right-click commands in the cross-reference list” on page 888

Command 'Collapse All Folds'

**Function:** This command collapses all expanded code segments in the textual editor or result locations in the cross-reference list. In this way, only the uppermost level of code and only the root node of the result locations displayed.

**Requirement:** A textual editor is active and indentation is activated in the “Options” (“Text Editor” category); or the cross-reference list is active.

**Call:** In textual editors: main menu “Edit ➔ Advanced”, or right-click. In the cross-reference list: right-click.

Command 'Comment Out Selected Lines’

Symbol //; keyboard shortcut: [Ctrl]+[O]

Function: The command inserts comment marks ('//') at the beginning of the selected lines.

Call: Menu bar: “Edit ➔ Advanced”, context menu

Requirement: In the ST editor, either the cursor is located in a line of the implementation or multiple lines are selected.

See also
- § Chapter 1.3.1.25.2.2.20 “Command ‘Uncomment Selected Lines’” on page 869

Command 'Uncomment Selected Lines'

Symbol //; keyboard shortcut: [Ctrl]+[I]

Function: The command removes any comment marks ('//') at the beginning of the selected lines.

Call: Menu bar: “Edit ➔ Advanced”, context menu

Requirement: In the ST editor, either the cursor is located in a line of the implementation or multiple lines are selected.

See also
- § Chapter 1.3.1.25.2.2.19 “Command 'Comment Out Selected Lines’” on page 869

Command 'Enable Inline Monitoring'

Function: This command enables or disables the inline monitoring function. This works the same way as the check box with the same name in the CODESYS options (“Text Editor” category).

Requirement: A text editor is active.

Call: Context menu of the text editor in the “Advanced” submenu.

See also
- § “Tab 'Monitoring’” on page 1088
- § Chapter 1.3.1.13.1 “Monitoring of values” on page 323

Command 'Toggle Bookmark'

Symbol , keyboard shortcut [Ctrl]+[F12]

Function: The command sets or removes a bookmark at the current position.

Call: Menu bar: “Edit ➔ Bookmarks”

Requirement: A POU is open in the editor and the cursor is at a program line.

See also
- § Chapter 1.3.1.9.14.3 “Setting and using bookmarks” on page 234
Command 'Next Bookmark (Active Editor)'
Symbol: ✌; keyboard shortcut: [F12]
Function: The command jumps to the next bookmark in the active editor.
Call: Menu bar: “Edit ➔ Bookmarks”
Requirement: A POU is open in the editor and the cursor is positioned in the POU.
See also
- Chapter 1.3.1.25.2.2.24 “Command 'Next Bookmark’” on page 870
- Chapter 1.3.1.9.14.3 “Setting and using bookmarks” on page 234

Command 'Next Bookmark'
Symbol: ✌
Function: The command jumps to the next bookmark in the “Bookmarks” view and in the project, and opens the respective POU. The order of jumping to bookmarks corresponds to the order of bookmarks in the table of the “Bookmarks” view.
Call:
- “Next Bookmark” button in the “Bookmarks” view
- The command is not in any menu by default. You can add it to a menu by using the dialog from “Tools ➔ Customize” (command category “Bookmarks”).
Requirement:
- A project is open.
- The “Bookmarks” view is open.
See also
- Chapter 1.3.1.25.2.2.23 “Command 'Next Bookmark (Active Editor)’” on page 870

Command 'Previous Bookmark (Active Editor)'
Symbol: ⬄; keyboard shortcut: [Shift]+[F12]
Function: The command jumps to the previous bookmark in the active editor.
Call: Menu bar: “Edit ➔ Bookmarks”
A POU is open in the editor and the cursor is positioned in the POU.
See also
- Chapter 1.3.1.25.2.2.26 “Command 'Previous Bookmark’” on page 870
- Chapter 1.3.1.9.14.3 “Setting and using bookmarks” on page 234

Command 'Previous Bookmark'
Symbol: ⬄
Function: The command jumps to the previous bookmark in the “Bookmarks” view and in the project, and opens the respective POU. The order of jumping to bookmarks corresponds to the order of bookmarks in the table of the “Bookmarks” view.
Call:
- “Previous Bookmark” button in the “Bookmarks” view
- The command is not in any menu by default. You can add it to a menu by using the dialog from “Tools ➔ Customize” (command category “Bookmarks”).
Requirement:
● A project is open.
● The “Bookmarks” view is open.

See also
● § Chapter 1.3.1.25.2.2.25 “Command ‘Previous Bookmark (Active Editor)’” on page 870
● § Chapter 1.3.1.9.14.3 “Setting and using bookmarks” on page 234

Command 'Clear All Bookmarks (Active Editor)'
Symbol:  
Function: The command deletes all bookmarks in the active editor.
Call: Menu bar: “Bookmarks”
Requirement: A POU is open in the editor and the cursor is positioned in the POU.
See also
● § Chapter 1.3.1.25.2.2.28 “Command ‘Clear All Bookmarks’” on page 871
● § Chapter 1.3.1.9.14.3 “Setting and using bookmarks” on page 234

Command 'Clear All Bookmarks'
Symbol:  
Function: The command deletes all bookmarks in the open project.
Call: The command is not in any menu by default. You can add it to a menu by using the dialog from “Tools ➔ Customize” (command category “Bookmarks”).
Requirement: A POU is open in the editor and the cursor is positioned in the POU.
See also
● § Chapter 1.3.1.25.2.2.27 “Command ‘Clear All Bookmarks (Active Editor)’” on page 871
● § Chapter 1.3.1.9.14.3 “Setting and using bookmarks” on page 234

Command 'Browse Cross-References'
Symbol:  
Function: This command shows all occurrences of a variable in the view “Cross-Reference List”.
Call: Main menu “Edit ➔ Browse”; cross-reference list: toolbar.
Requirement: A POU is open in the editor and the cursor is at a variable, or the view “Cross-Reference List” is open and a variable is in the “Name” input field.
See also
● § Chapter 1.3.1.9.14.1 “Using the cross-reference list to find occurrences” on page 232

Command 'Browse Call Tree'
Symbol:  
Function: The command opens the view “Call Tree”, which displays the calls of a module and also its callers.
Call:
● Menu “Edit ➔ Browse”
● Context menu, see below: Requirement
**Requirement:** A module is opened in the editor and the cursor is placed in a variable, or a module is selected in the “Devices” view or in the “POUs” view.

See also

- Chapter 1.3.1.25.2.3.16 “Command ‘Call tree’” on page 889

**Command ‘Auto Declare’**

Keyboard shortcut: [Shift]+[F2]

**Function:** The command opens the “Auto Declare” dialog, which supports the declaration of a variable.

**Call:** Menu bar: “Edit”

**Requirement:** An object or a device of the project is opened in the editor.

Due to the auto-declaration function, the “Auto Declare” dialog also appears when the cursor is located in the implementation part of a POU in a line containing the name of an undeclared variable. The requirement for this is that you must have selected the command “Tools ➔ Options” and activated the option “Declare unknown variables automatically (AutoDeclare)” in the category “SmartCoding”.

Thanks to the smart tag function, the “Declare variable” command also appears when you place the cursor over an undeclared variable in the implementation part of the ST editor and then click ⏩

**Dialog ‘Auto Declare’**

<table>
<thead>
<tr>
<th>“Scope”</th>
<th>Scope of the variable that is not declared yet.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Example: VAR (default setting for local variables)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>“Name”</th>
<th>Variable name that is not declared yet</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Example: bIsValid</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>“Type”</th>
<th>Example: BOOL</th>
</tr>
</thead>
</table>

- ▼: Lists the standard data types.
- ➔
  - “Input Assistant”: Opens the “Input Assistant” dialog
  - “Array Assistant”: Opens the “Array” dialog

<table>
<thead>
<tr>
<th>“Object”</th>
<th>Object where the new variable is declared. By default, the object that you are editing now.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Example: fbA</td>
</tr>
</tbody>
</table>

- ▼: Lists that objects where the variable can be declared.

If no objects are available for the selected “Scope”, the entry “<create object>” appears. If you select the entry “<create object>”, the dialog “Add Object” appears for the generation of a suitable object.

<table>
<thead>
<tr>
<th>“Initialization”</th>
<th>Example: FALSE</th>
</tr>
</thead>
</table>

If you do not specify an initialization value, then the variable is initialized automatically.

قدرة: Opens the “Initialization Value” dialog. This procedure is helpful for the initialization of structured variables.
"Address" Memory address of the application for the variable that is not declared yet.
Example: %IX1.0
Note:
Possible only for the following scopes:
● Local variable (VAR)
● Global variable (VAR_GLOBAL)
● Or for a persistent variable (PERSISTENT).

"Flags" Attribute keywords
● CONSTANT: Keyword for a constant.
● RETAIN: Keyword for a remanent variable.
● PERSISTENT: Keyword for a persistent variable ( stricter than RETAIN).
The selected attribute keyword is added to the variable declaration.

"Comment" Example: New input In1
In the tabular declaration editor the comment entered is displayed in the column "Comment", while in the textual declaration editor it is displayed above the variable declaration.

"Apply changes using refactoring" If you exit the dialog, then the variable is not declared yet, but then it opens the “Refactoring” dialog. You can continue editing your changes here.
The option appears for the following scopes:
● Input variable (VAR_INPUT)
● Output variable (VAR_OUTPUT)
● VAR_IN_OUT variables (input variable and output variable)

"OK" The variable is declared and appears in the declaration.
Example:

VAR RETAIN
  // New input In1
  xIn1 AT %IX1.0: BOOL := FALSE;
END_VAR

Dialog 'Array'

"Ranks and base type specification" Definition of the field sizes (“Dimension”) by entering the lower and upper limits and the "Base type" of the array. You can enter the basic type directly or with the help of the dialogs "Input Assistant" or “Array” if you click the button.

"Result" Display of the defined array.

NOTICE!
CODESYS only re-initializes variables if you have modified the initialization values of the variables.

Dialog 'Initialization Value'

List of the variables with name (“Expression”), “Initialization Value” and “Data Type”.
Modified initialization values are displayed in bold lettering.

Input field below the list Input of an initialization value for the selected variable(s).
"Apply value to selected lines" | Change of the initialization value of the selected line(s) according to the value of the input field.

"Reset selected lines to default values" | Establishment of the standard initialization values.

"OK" | CODESYS applies the initialization values in the "Auto Declare" dialog.

- % Chapter 1.3.1.24.1.3.1 “ST editor” on page 430

Command 'Input Assistant'
Symbol: 📚; keyboard shortcut: [F2]
Function: This command opens the “Input Assistant” dialog which helps you to select one of the possible programming elements at the current cursor position.
Call: Menu bar: “Edit”; context menu.
Requirement: A POU is open in the editor and the cursor is at a program line.

Dialog 'Input Assistant' - Tab 'Categories'
The input assistant provides all program elements that you can insert at the current cursor position in the editor.
The elements are sorted by “Categories”. In the category “Variables”, you can also set a “Filter” for the scope, for example “Local variables”, “Global variables”, or “Constants”.

"Structured view" | : The elements are displayed in a structure tree. You can show/hide the columns “Type”, “Address”, and “Origin” by right-clicking the column title and selecting/clearing the column name in the dropdown list.
| : The elements are displayed in a flat structure.

"Show documentation" | : The dialog is extended with the “Documentation” field.

"Insert with arguments" | : Elements that include arguments (for example, functions) also insert with these arguments at the cursor position.
Example: If you insert the function block fb1, which contains an input variable fb1_in and an output variable fb1_out, “with arguments”, then this appears in the editor as follows: fb1(fb1_in:= , fb1_out=> ).

"Insert with namespace prefix" | : Inserts the selected element with the appended namespace. In the case of library modules, the check box remains disabled if the requirement for a namespace has been defined in the library properties.

If you create objects with the same name in the same category, whether globally (“POUs” view) or assigned to an application (“Devices” view), then only one entry appears in the input assistant. The usage conforms to the usual call priority (application assigned before global).
Dialog 'Input Assistant' - Tab 'Text Search'

This tab allows you to search for specific objects. When you begin typing a search string into the search field, the names of all objects are listed whose names include the search string. Double-click an object to insert it at the current cursor position in the editor.

<table>
<thead>
<tr>
<th>“Filters”</th>
<th>Limits the search to a specific variable category</th>
</tr>
</thead>
</table>

Command 'Go to Source Position'

Function: The command sets the cursor to the position in the source code that causes the message.

Call: Main menu “Edit”, context menu of the message in the message view.

Requirements: A message is selected in the message view.

Use the command “Next Message” or “Previous Message” to display the source code position of the next or previous message.

See also
- Chapter 1.3.1.25.2.2.34 “Command 'Next Message’’ on page 875
- Chapter 1.3.1.25.2.2.35 “Command 'Previous Message’’ on page 875
- Chapter 1.3.1.25.2.3.5 “Command 'Messages’’ on page 882

Command 'Next Message'

Keyboard shortcut: [F4]

Function: This command selects the next message in the messages view.

Call: Main menu “Edit”.

If the last message in the list has been reached, then the marking jumps to the beginning.

See also
- Chapter 1.3.1.25.2.2.35 “Command 'Previous Message’’ on page 875

Command 'Previous Message'

Keyboard shortcut: [Shift]+[F4]

Function: This command selects the previous message in the messages view.

Call: Main menu “Edit”

If the first message in the list has been reached, then the marking jumps to the end.

See also
- Chapter 1.3.1.25.2.2.34 “Command 'Next Message’’ on page 875

Command 'Go to Definition'

Symbol: 🔍
Function: This command shows the definition locations of a variable or function.

Call: Main menu “Edit ➔ Browse”

Requirement: A POU is open in the editor and the cursor is at a variable or function.

See also
● Chapter 1.3.1.9.14.2 “Finding declarations” on page 234

Command 'Go To Reference'

Symbol: 

Function: The command opens the declaration location of the variable that is referenced by the pointer currently in focus in online mode.

Call:
● Context menu in the declaration part or implementation code
● Menu bar: “Edit ➔ Browse”

Requirement: Online mode. A POU is open in the editor and the cursor is at a pointer. The referenced variable is stored in static memory.

See also
● Chapter 1.3.1.24.5.12 “Pointers” on page 577

Command 'Go to Instance'

Symbol: 

Function: This command opens the instance of a function block in a new window.

Call: Menu bar: “Edit ➔ Browse for Symbol”

Requirement: The application is in online mode. A POU is open in the editor and the cursor is at an instance of a function block.

The command is not available for temporary instances or instances from compiled libraries.

See also
● Chapter 1.3.1.9.14.2 “Finding declarations” on page 234

Command 'Refactoring' - 'Rename <...>,'

Function: This command opens a dialog box for renaming an object or variable across the project.

Call: Main menu “Edit ➔ Refactoring” or right-click.

Requirement: An object is selected in the device tree or in the “POUs” view, or the cursor is placed before or on a variable identifier in the declaration section of a programming object.

You can rename the following:
● Variables
● POUs
● GVLs
Dialog box 'Rename'

<table>
<thead>
<tr>
<th>“Current name”</th>
<th>Name of the object or variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>“New name”</td>
<td>Input field for a new name.</td>
</tr>
<tr>
<td></td>
<td>If the name already exists, then CODESYS reports this directly below this input field.</td>
</tr>
<tr>
<td>“OK”</td>
<td>Can be activated if you have typed a valid name in “New name”.</td>
</tr>
<tr>
<td></td>
<td>Opens the “Refactoring” dialog box.</td>
</tr>
<tr>
<td></td>
<td>The affected objects and occurrences are highlighted in both views.</td>
</tr>
<tr>
<td></td>
<td>You can determine how to handle the occurrences in each view by right-clicking the occurrences and clicking the available commands.</td>
</tr>
</tbody>
</table>

Dialog box 'Refactoring'

This dialog box displays all occurrences in the project. The affected objects and occurrences are highlighted in both views.

| Right view | Displays the occurrence within an object where “Current name” occurs. |
| Left view  | Device tree of the project with the object. |

You can determine how to handle the occurrences in each view by right-clicking the occurrences and clicking the available commands.

| “Reject this change” | Reject the single change in view on the right. |
| “Accept this object” | Accept all changes in the affected object. |
| “Reject this object” | Reject all changes in the affected object. |
| “Accept whole project” | Accept all changes in the project. |
| “Reject whole project” | Reject all changes in the project. |

CODESYS highlights the accepted changes in yellow and the rejected changes in gray.

Command 'Refactoring' - 'Update Referenced Pins'

NOTICE!

Currently, this command applies only to the CFC, FBD, LD, and IL editors. It is a combination of the “Reset Pins” and “Update Parameters” commands.

Function: This command modifies the pins according to the latest block declaration in all affected occurrences of the block.

Call: Main menu “Edit ➔ Refactoring” or right-click.
**Requirement:** The cursor is placed in the name of the block in the first line of the block declaration or in the device tree.

See also

- Chapter 1.3.1.9.16 “Refactoring” on page 236
- Chapter 1.3.1.25.2.12.24 “Command 'Reset Pins'” on page 986
- Chapter 1.3.1.25.2.13.38 “Command 'Update Parameters'” on page 1002

**Command 'Refactoring' - 'Add Variable'**

**Symbol:**

**Function:** This command enables the declaration of variables in a POU, as well as the automatic update to the occurrence of the POU.

**Call:** Main menu “Edit ➤ Refactoring”, or right-click.

**Requirements:** The declaration part is in focus.

The command opens the default dialog box for declaring variables.

See also

- “Dialog 'Auto Declare'” on page 872

**Dialog box 'Refactoring'**

After clicking “OK” to close the declaration dialog, the “Refactoring” dialog box opens with two frames.
Before you decide which changes to accept at which locations, select the required option from the drop-down list (3) at the upper right part of the window:

### Examples

1. By refactoring, the `fun` block receives a new input variable `input3` with the initialization value 1. The change has the following effect:
   
   **Before:**
   
   ```
   fun(a + b, 3, TRUE);
   fun(input1:= a + b , input2 :=3 , inputx := TRUE);
   ```
   
   **After:**
   
   ```
   fun(a + b, 3, 1, TRUE);
   fun(input1:= a + b , input2 :=3 , inputx := TRUE);
   ```

2. By refactoring, the "fun" block receives a new input variable `input3` with the placeholder text "_REFACTOR_":
   
   **Before:**
   
   ```
   inst(input1 := a + b, input2 := 3, inputx := TRUE);
   fun(a + b, 3, TRUE);
   ```
   
   **After:**
   
   ```
   inst(input1 := a + b, input2 := 3, input3 := _REFACTOR_, inputx := TRUE);
   fun(a + b, 3, _REFACTOR_, TRUE);
   ```

See also

- % Chapter 1.3.1.9.16 "Refactoring" on page 236
- % Chapter 1.3.1.25.2.2.39 "Command 'Refactoring' - 'Rename <...>’" on page 876

### Command 'Refactoring' - 'Remove <variable>,'

**Symbol:** æ
t

**Function:** This command removes an input or output variable from the POU and all occurrences of the POU.

**Call:** Main menu “Edit ➔ Refactoring”, or right-click.
Requirements: In the declaration part of the POU, the cursor is located in the identifier of the variable to be removed.

Then, the command opens a dialog box with information about the removal. After you confirm this, the “Refactoring” dialog box opens. For a description of the “Refactoring” dialog box, refer to the “Edit ➔ Refactoring ➔ Rename” help page.

When you accept the changes in the “Refactoring” dialog box, the respective input and output parameters are deleted at the occurrence locations of the affected POU.

In CFC, only the connection is removed between the removed input or output to the block. The input or output itself remains in the chart.

Example in ST
In a POU, refactoring removes the input4 input variable. The occurrences are updated automatically:

Before removal:
```plaintext
inst(input1 := a + b, input2 := 3, input4 := 1, input5 := TRUE);
fun(a + b, 3, 1, TRUE);
```

After removal:
```plaintext
inst(input1 := a + b, input2 := 3, input5 := TRUE);
fun(a + b, 3, TRUE);
```

Command 'Refactoring' - 'Reorder Variables'

Symbol: [Reorder]

Function: This command allows changing the order of variables in the declaration editor for the selected scope: VAR_INPUT, VAR_OUTPUT, or VAR_IN_OUT.

Call: “Edit ➔ Refactoring”; context menu of the focused scope in the declaration editor.

Requirement: One of the above scopes is selected in the declaration, and more than one variable is declared in it.

The command opens the “Reorder” dialog box with a list of all declarations of the selected scope. You can drag a selected declaration up or down to another position.

Standard Menu in View 'Devices', 'POUs', 'Modules'

The views "Devices", "POUs" and "Modules" provide the button in the top right corner to open a menu with the following commands:

- Open in editor: Opens the selected object in the corresponding editor.
- Find object: Opens the dialog "Find Object" for the object tree. Starting to enter a search string all matching objects will be displayed with their path. Use the button "Open" to open the selected search result in the editor.
- Sort by type: Sorts the objects in the view alphabetic by type.
- Sort by name: Sorts the objects in the view alphabetic by name.
- Sort ascending: Displays the chosen sorting in ascending order.
- Sort descending: Displays the chosen sorting in descending order.
- Track active editor: CODESYS selects the object, that is opened in the active editor, in the device tree of the view.

Command 'Devices'

Symbol: view: [Alt] + [D]

Function: The command opens the view "Devices" in the CODESYS main window. The view contains the project's "device tree", where you configure your applications

Button opens the standard menu for navigating in the tree view.

Call: Menu “View”
Command ‘POUs’

Symbol: 🟢, Shortcut: [Alt] + [1]

**Function:** This command opens the “POUs” view in the CODESYS main window. POUs located here are available in the entire project.

**Call:** Menu “View”

See also

- § Chapter 1.3.1.8.1 “Device tree and device editor” on page 155

</tr>
</tbody>
</table>

---

**Command 'Element properties'**

**Symbol:** 🗒️

**Function:** This command opens the “Element Properties” view.

**Call:** Main menu “View”

This command opens the properties view for the open object. This view is available only for a few objects, for example visualization and POU (SFC).

The properties are displayed in a structured table. You change the property values by clicking into the value fields. You can filter or sort the properties view.

---

**Command 'ToolBox'**

**Symbol:** 🎨

**Function:** This command opens the “ToolBox” view.

**Call:** Main menu “View”

This command opens the toolbox view for the open object. By default, this view is available for graphical editors and visualizations. It includes the graphical programming elements that you can drag into the editor.

---

**Command 'Watch' - 'Watch <n>'**

**Symbol:** 📈

**Function:** This command opens the "Watch <n>" view. You can populate a watchlist with variables from your project in order to monitor, force, or write these variable values in an individual view in online mode. The value "n" can be 1, 2, 3, or 4 for a total of up to four watchlists.

**Call:** Main menu “View”

See also

- [Chapter 1.3.1.13.1.2 “Using watch lists” on page 330](#)

---

**Command 'Watch' - 'Watch All Forces'**

**Symbol:** 📈

**Function:** The command opens the view “Watch All Forces”, which is a special form of a watch list.

**Call:** Menu “View ➔ Watch ➔ Watch all Forces”

**Requirement:** A project is in offline mode or in online mode.

The view contains all variables currently prepared for forcing, and all forced variables of the application in 1 list. The list allows the same actions as other watch lists. Additionally in the selection menu “Unforce...” the following commands are available:
● “Unforce and Keep All Selected Values”: For all selected list entries the variables will be set to the forced value and the forcing will be released.
● “Unforce and Restore All Selected Values”: For all selected list entries the variables will be reset to the values they had before they got forced, and the forcing will be released.

See also
● Chapter 1.3.1.12.4 “Forcing and writing variables” on page 315
● Chapter 1.3.1.13.1.2 “Using watch lists” on page 330

Command 'Add All Forces to Watchlist'

Function: The command adds all variables of the active application, which are currently prepared for forcing, or which are already forced, to the watchlist. Please regard, that this works only for docked watch list views.

Call: Context menu of view “Watch”

Requirement: Online mode, a watch list view is active.

There is a special watch list: “Watch All Forces”. This view shows automatically all variables currently prepared for forcing or already being forced. It provides additional commands for releasing any forces.

See also
● Chapter 1.3.1.13.1.2 “Using watch lists” on page 330
● Chapter 1.3.1.25.2.3.8 “Command ‘Watch’ - ‘Watch <n>’” on page 883
● Chapter 1.3.1.25.2.3.9 “Command ‘Watch’ - ‘Watch All Forces’” on page 883
● Chapter 1.3.1.12.4 “Forcing and writing variables” on page 315

Command 'Bookmarks'

Symbol: 📚

Function: This command opens the “Bookmarks” view.

Call: Menu bar: “View”.

| “Previous Bookmark” | Jumps to the bookmark that above the selected bookmark in the table and opens the respective POU in the editor. |
| “Next Bookmark” | Jumps to the bookmark that below the selected bookmark in the table and opens the respective POU in the editor. |
| X | Deletes the selected bookmark from the table and in the respective POU. |

List of bookmarks in the project with the following information: “Bookmark”, “Object”, and “Position”.

You can edit the bookmark order per drag&drop.

When you double-click a row, CODESYS opens the respective “Object” in the editor and jumps to this bookmark.

| “Bookmark” | Name of the bookmark as assigned by CODESYS in ascending numerical order: “Bookmark_0”, “Bookmark_2” etc. |
| “Bookmark” | If the bookmark is selected and you click in the field, then it is editable and you can modify the bookmark name. |
"Object" Name and project path of the POU where the bookmark is set
Example: POU_Add [PLC_1: SPS-Logic: Application]

"Position" Position of the bookmark in the POU
Example: Row 3, Column 1 (Impl)

(Impl): in the implementation part of the POU
(Decl): in the declaration part of the POU

See also
- Chapter 1.3.1.9.14.3 “Setting and using bookmarks” on page 234
- Chapter 1.3.1.25.2.2.24 “Command 'Next Bookmark’” on page 870
- Chapter 1.3.1.25.2.2.26 “Command ‘Previous Bookmark’” on page 870

Command 'Breakpoints'
Symbol: 🛡
Function: This command opens the “Breakpoints” view.
Call: Menu bar: “View”.
This view shows an overview of all defined breakpoints for an application. You have access to all breakpoint commands within this view.

Table 126: Table of current breakpoints

| "Application" | Select the required application from the list. |
| "POU" | Name of the function block that will receive the breakpoint |
| "Location" | Location of the breakpoint in the POU |
| ● Text editor: Line number and column number |
| ● Graphical editor: Network number or element number |
| For function blocks, "(Impl)" indicates that the breakpoint is located in the implementation of the function block, not in an instance. |
| "Instance Path" | Complete object path of the breakpoint location. |
| "Tasks" | Names of tasks that will be effective when the breakpoint is executed. If there are no restrictions, then "(all)" is displayed here. |
| "Condition" | ● "Break always": No additional enable condition defined; the breakpoint is always enabled. |
| ● Boolean expression. The expression must yield TRUE for the breakpoint to be enabled. |
| "Hit Count Condition" | When the breakpoint should be in effect (depending on the hit count) |
| "Current Hit Count" | How often the breakpoint has already been reached up to now during the execution |

Table 127: Toolbar

| "New Breakpoint" | This command opens the “Breakpoint Properties” dialog. |
| "New Breakpoint" | This command opens the “New Breakpoint” dialog. |
| "Clear Breakpoint" | Removes the breakpoint (not the same as disable) |

Command 'Breakpoints'
Symbol: 🛡
Function: This command opens the "Breakpoints" view.
Call: Menu bar: “View”.
This view shows an overview of all defined breakpoints for an application. You have access to all breakpoint commands within this view.

Table 126: Table of current breakpoints

| "Application" | Select the required application from the list. |
| "POU" | Name of the function block that will receive the breakpoint |
| "Location" | Location of the breakpoint in the POU |
| ● Text editor: Line number and column number |
| ● Graphical editor: Network number or element number |
| For function blocks, "(Impl)" indicates that the breakpoint is located in the implementation of the function block, not in an instance. |
| "Instance Path" | Complete object path of the breakpoint location. |
| "Tasks" | Names of tasks that will be effective when the breakpoint is executed. If there are no restrictions, then "(all)" is displayed here. |
| "Condition" | ● "Break always": No additional enable condition defined; the breakpoint is always enabled. |
| ● Boolean expression. The expression must yield TRUE for the breakpoint to be enabled. |
| "Hit Count Condition" | When the breakpoint should be in effect (depending on the hit count) |
| "Current Hit Count" | How often the breakpoint has already been reached up to now during the execution |

Table 127: Toolbar

| "New Breakpoint" | This command opens the “Breakpoint Properties” dialog. |
| "New Breakpoint" | This command opens the “New Breakpoint” dialog. |
| "Clear Breakpoint" | Removes the breakpoint (not the same as disable) |
| **“Enable/Disable Breakpoint”** | Toggles the status of the breakpoint or execution point between "enabled" and "disabled"
- ● Breakpoint enabled
- ○ Breakpoint disabled
- ● Execution point enabled
- ○ Execution point disabled
- ● Data breakpoint enabled
- ○ Data breakpoint disabled
- ● Data execution point enabled
- ○ Data execution point disabled

As opposed to "Clear breakpoint", a disabled breakpoint remains in the list and can be enabled again.

| “Properties” | The “Breakpoint Properties” dialog opens for editing the breakpoint parameters. This dialog is the same as “New Breakpoint”. In online mode, you can change the breakpoint into an execution point.

| “Go to Source Position” | Opens the online view of the affected block. The cursor is set at the breakpoint location.

| “Clear All Breakpoints” | Deletes all breakpoints and execution points in the application. The list is cleared. Not to be confused with "deactivate".

| “Enable All Breakpoints” | Enables all currently disabled breakpoints and execution points.

| “Disable All Breakpoints” | Disables all currently enabled breakpoints and execution points. The points remain in the list and can be enabled again.

Command 'Cross Reference List'

**Symbol:** ☑

**Function:** This command opens the “Cross Reference List” view.

**Call:** Menu bar: “View”, or “Edit ➔ Browse ➔ Browse Cross References”.

This view shows a list of cross-references for a symbol in the project. The symbol can be a variable, a POU (program, function block, function), or a user-specific data type (DUT). The cross-reference list offers two basic types of searches:

- **Text search:** By specifying a symbol name, the cross-references of all symbols in the project are displayed with their names. If multiple symbols with the same name are found, then the display can be limited to individual declarations by means of the context menu.
- **Declaration search:** The symbol can be selected by means of the input assistant or by specifying a qualified path (for example, Device.Application.PLC_PRG.i or __POOL.POU.a). Then only the occurrence locations of this symbol are displayed, even if there exist other symbols with the same name.
### Input Field
Symbol name (variable name, POU name, DUT name). Input options:
- Selection of a declared symbol by means of the input assistant (🔍 button).
- Manual input of the symbol name. Triggering of the search by pressing the ✉️ button or the [Enter] key.

For the text search, you can use the placeholders "*" (any number of characters) or "?" (exactly any one character) in combination with a partial string of a variable identifier.

Use the percent sign "%" to search for IEC addresses. Examples: "%MW8", "%M".

More options outside of cross-reference list view:
- Use the command “Browse for Symbol ➔ Browse Cross References” if the name of a declared symbol is selected in an editor, or if the cursor is in the name field. A search is also possible if the object is selected in the device tree or POU pool.
- Automatic if the name of a declared symbol is selected in an editor, or if the cursor is in the name field. A automatic search is also possible if the object is selected in the device tree or POU pool.

Requirement: CODESYS option “Automatically list selection in cross reference view” is activated (category “SmartCoding”).

The following input is valid:
- Variable name, simple or qualified. Examples: "iVar", "PLC_PRG.iVar".
- POU name: Examples: "PLC_PRG", "myFB".
- DUT name: Example: "mySTRUCT".
- Strings combined with placeholders: asterisk (*) for any character or question mark (?) for exactly one characters).

Example: "iVar*" applies to iVar1, iVar_g1b2, iVar45, etc. "iVar?" refers to iVar1, iVar2, iVarX, and so on, but not iVar_g1b2, iVar45 and so on...
- "%<IEC address>": CODESYS searches for variables that are assigned to this address and direct memory access. Example: "%QB0", "%Q0 := 2."
"POU" | Block name; also a task name if a block call in the task configuration.
---|---
"Variable" | Only the variable name (for example, iVar)
---|---
"Access" | Type of access to the variable at the occurrence location: "Declaration"/ "Read"/ "Write"/ "Call".
Special case for pointers: An assignment type p := ADR(var1) is displayed as write | address when searching for var1. The reason for this: Any write access to p is not displayed when searching for var1. Write access is also possible by means of pointer variables.
---|---
"Type" | Data type of the variable
---|---
"Address" | IEC address if variables are assigned Example: "AT %QB0".
---|---
"Position" | Location of the occurrence in the POU editor, for example line number, network number, declaration part, or implementation part. Example: "line 1, column 1 (Impl)".
---|---
"Object" | POU name plus complete path of the occurrence location in brackets (if this is found in the "Devices" view). Example: "PLC_PRG [Device:Plc Logic:Application]"
---|---
"Comment" | Comments if available in the declaration of the variable

The search yields all result locations in the project and in included, uncompiled libraries.

### Right-click commands in the cross-reference list

- **Show source position**: Opens the respective POU and marks the occurrence: for root entries, the declaration, and for subordinate entries, the respective occurrence location. As an alternative, you can double-click a line.

- **Limit Results to Selected Declaration**: Limits the display of results to the selected symbol declaration if multiple declarations are found.

- **Expand All**: In the list, only the root nodes of the result locations are shown.

- **Collapse All**: In the list, every single result location is shown.

### Command 'Browse Cross References in Classic View'

**Symbol:** 🔄

**Function:** This command opens the “Classic Cross Reference List” view.

**Call:** The command is not in any menu by default. You can add it to a menu by using the dialog box from “Tools ➔ Customize” (command category “Browse Project”).

The view corresponds to the “Cross Reference List” view before CODESYS V3.5 SP6.

### Command 'Call Stack'

**Symbol:** 🔄

**Function:** This command opens the “Call Stack” view.

**Call:** Main menu “Debug”.

---

888 3ADR010583, 1, en_US 2020/12/10
This view is very useful when you want to step into programs. It shows the current location with the complete call path.

<table>
<thead>
<tr>
<th>“Application”</th>
<th>Name of the active application that controls the current POU</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Task”</td>
<td>Name of the task that controls the current POU</td>
</tr>
<tr>
<td>“POU”</td>
<td>Name of the POU where program execution has halted</td>
</tr>
<tr>
<td></td>
<td>The first line in the list describes the current execution location (marked with a yellow arrow). If this location is in a block that is called by another block, then the call location is described in the second line. In turn, if the caller is called by yet another block, then that call location is described in the third line, and so on.</td>
</tr>
<tr>
<td>“Location”</td>
<td>Position within the POU where program execution has halted</td>
</tr>
<tr>
<td></td>
<td>● Line and column numbers for textual editors</td>
</tr>
<tr>
<td></td>
<td>● Network or element numbers for graphical editors</td>
</tr>
<tr>
<td>“Instance path”</td>
<td>Instance where program execution has halted</td>
</tr>
</tbody>
</table>

The call stack is also available in offline mode and normal online mode when you are not currently using any debugging functions. In this case, it receives the last displayed location during a stepped execution, but it is displayed in gray.

The “Call Tree” view, in contrast to the “Call Stack”, at any time provides information on the calls of a POU.

● § Chapter 1.3.1.25.2.3.16 “Command ‘Call tree’” on page 889

Command 'Call tree'

Symbol: 

Function: This command opens the “Call Tree” view.

Call:
● “View” menu
● Context menu of a callable block in the “Devices” or “POUs” view.

View ‘Call tree’
The call tree is available at all times, even before compiling the application. It is a static representation of the caller and the calls of the block that you specify explicitly. Therefore, the tree always contains two root nodes above the respective call order is displayed as successive indented entries. Recursive calls are detected quickly in this tree representation.

Example of a call tree (1) for the (2) PLC_PRG block:
- (3) Node “<block name> is called by:”
- (4) Node “<block name> calls:”

<table>
<thead>
<tr>
<th>“Block name”</th>
<th>Name of the program block; specified manually, by dragging from another view, or by means of the button ( \text{\textcolor{red}{\textbullet}} ). The drop-down list includes the last specified block names.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Toolbar and keyboard usage</td>
<td></td>
</tr>
<tr>
<td>: Find block</td>
<td>CODESYS searches for the block specified in “Block name” and displays its caller and calls.</td>
</tr>
<tr>
<td>Use block from the input assistant</td>
<td>The “Input Assistant” dialog box opens for selecting a block call or instance call. The call tree is refreshed automatically after the selection.</td>
</tr>
<tr>
<td>Show source code position of the selected block</td>
<td>CODESYS jumps to the occurrence location of the block in the source code of the program.</td>
</tr>
<tr>
<td>[F4]: Show source code position of the next block</td>
<td>The selection in the call tree jumps to the next or previous block in the call structure. At the same time, the associated source code position is opened in the respective editor. Note: Double-clicking an entry in the call tree also opens the associated source code position.</td>
</tr>
<tr>
<td>[Shift]+[F4]: Show source code position of the previous block</td>
<td></td>
</tr>
</tbody>
</table>

- Display of the call tree:

| “Symbol” | “<block name> is called by”: The call order is displayed for below this node. The bottom entry in this tree structure shows the start of the calls. “<block name> calls”: The calls from this block are displayed below this node. The bottom entry in this tree structure shows the end of the call chain. |
| “Position” | For the root node in the call tree: Line numbers of the declaration (“Decl”) of the block. For the caller or calls below the root node: Line number, column number, and network number of the position, depending on the implementation language. |

- Context menu for the entry selected in the tree:

| “Collapse All” | The expanded entries in the call tree are collapsed, except for the two root nodes. |
| “Show Source Position” | CODESYS jumps to the occurrence location of the block in the source code of the program. |
| “Set as New Root Node” | The entry selected in the call tree is displayed in “Block name”. The tree is refreshed automatically for the new root nodes. |
The “Call list” view is provided for immediate information when stepping through a program, as opposed to the static call tree that provides call information about a block. The call list always shows the full call path of the current position that is reached.

Command 'Memory'

Symbol:

Function: In CODESYS V3.5 version earlier than SP11, the command opens the “Memory” view.

Call: Menu bar: “View → Memory”.

As of SP11, the command provides the notice that you must install the CODESYS Memory Tools package (available in the CODESYS Store) in order to use the memory view. After installation, you can open the “Memory” view by clicking “View → Show Memory View”.

Command 'Security Screen'

Symbol:

Function: The command opens the “Security Screen” view.

Call:
- “View” menu
- ☰ icon or ☰ in the status bar
  The icon is displayed in blue when a valid certificate is specified for the digital signature. When only one client certificate is specified for the encrypted communication, the icon remains gray, resulting in the client certificate providing no increased security for the user.

The following security features of CODESYS are configured and displayed in the view:
- Personal user certificate
- Encrypted communication
- Encryption and signatures of IEC projects
- Encryption and signature of download, online change, and boot application
- Security level

If the CODESYS Security Agent add-on product is installed, then the “Security Screen” view provides an additional “Devices” tab. This allows for the configuration of certificates for the encrypted communication with controllers.

Tab 'User'

On this tab, certificates are configured that are required for the encrypted communication and the digital signature of the user. Only certificates with private keys can be specified here. The user profile is saved as an XML file in the user options.
“User Profile and Certificate Selection”  
By default, the login name for Windows is specified as the user profile.

| List box with existing user profiles |  O: Opens the “User Profiles” dialog. Here you specify the name for a new user profile.  
|                                       | ✗: Deletes the selected user profile. This user profile is no longer displayed in the list box. |

“Digital Signature”  
O: Opens the “Certificate Selection” dialog for selecting the certificate for the digital signature.  
One certificate can be selected. The certificate must have a private key.  
✗: Deletes the displayed certificate.  
One certificate can be selected. The certificate must have a private key.

“Project File Decryption”  
O: Opens the “Certificate Selection” dialog for selecting the certificate for decrypting project files.  
One certificate can be selected. The certificate must have a private key.  
✗: Deletes the displayed certificate.

See also  
●  § Chapter 1.3.1.25.3.18 “Dialog ‘Certificate Selection’” on page 1098

Table 128: “Security Level”

<table>
<thead>
<tr>
<th>“Activate the Use of Certificates for Enhanced Security”</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Enforce encrypted communication”</td>
</tr>
</tbody>
</table>
| “Enforce encryption of project files” | ☑: All project files of the user are encrypted with a certificate. When the project is saved, it is encrypted with the certificate specified in the project settings (“Project Settings ➔ Security” dialog). The selected certificate is displayed on the “Project” tab in the “Project file encryption” group.  
To open this project, the certificate to be encrypted must be specified in “Project file decryption” with a private key. |
| “Enforce signing of project files” | ☑: All project files of the user are signed with a certificate. In “Digital Signature”, a certificate must be specified with a private key.  
When a project is saved, a signature file <project name>.project.p7s is generated in the project directory containing the signature. |
| “Enforce encryption of downloads, online changes and boot applications” | ☑: The data that is downloaded to the controller must be encrypted with a controller certificate.  
This certificate is defined directly either in the properties dialog of the application on the “Encryption” tab, or in the security screen, on the “Project” tab, in the “Encryption of Boot Application, Download and Online Change” group.  
Controller certificates are located in the local Windows Certificate Store in the “PLC Certificates” directory. If the certificates of your controller are not available in the directory, then they first have to be loaded from the controller and installed to the directory. For instructions, see the “Controller Certificates” chapter. |
**“Enforce signing of downloads, online changes and boot applications”**

![Image](image1.png)

The online code (downloads, online changes, and boot applications) must be signed with a certificate with a personal key. The certificate is selected from the "Digital signature" area.

**Requirement:** The “Encryption of boot application, download and online change” option is selected.

**“Enforce signing of compiled libraries”**

![Image](image2.png)

The "File ➔ Save Project as Compiled Library" command generates a signed library `<library name>.compiled-library-v3`.

**Requirements**
- A certificate with a private key that supports code signing is available.
- A library compatibility >= CODESYS V3 SP15 is set in the project information.

**See also**
- "Chapter 1.3.1.25.2.1.7 “Command ‘Save Project as Compiled Library’” on page 856"
- "Chapter 1.3.1.19.1 “Information for library developers” on page 372"

**Tab ‘Project’**

All project-specific settings are configured on this tab. These elements are active only when a primary project is loaded.

**“Project file encryption”**

**“Technology”**

![Image](image3.png)

Opens the “Project Settings ➔ Security” dialog

When you select the “Encryption” project setting and then “Certificates” in the dialog, you can choose a corresponding certificate by clicking ![Image](image4.png). For more information, see the description of the “Project Settings: Security” dialog.

**“Certificates of Users Sharing this Project”**

Area for listing the certificates that encrypt the project file.

**“Encryption of Boot Application, Download and Online Change”**

List of the applications of the controller

Double-clicking an application in the list opens the “Properties ➔ Encryption” dialog. Depending on the settings of the "Security Level" on the "User" tab of the security screen, the following fields are available in the open properties dialog:
- "Encryption" tab with active "Certificates" area
- "Encryption" tab with "Encryption Technology" list box.

In the "Properties ➔ Encryption" dialog, click the ![Image](image5.png) button to select the controller certificate for "Encryption of Boot Application, Download and Online Change". For more information, see the description of the "Properties: Encryption" dialog.

Controller certificates are located in the local Windows Certificate Store in the "PLC Certificates" directory. If the certificates of your controller are not available in the directory, then they first have to be loaded from the controller and installed to the directory. For instructions, see the "Protecting and Saving a Project" - "Encryption with Certificates" chapter.

**See also**
- "Chapter 1.3.1.25.3.11.7 “Dialog ‘Project Settings’ - ‘Security’” on page 1064"

- "Chapter 1.3.1.6.7 “Encrypting projects with certificates” on page 149"
Tab 'Devices'

This tab is available only after you have installed the CODESYS Security Agent add-on. For a description of this tab, see the help for the CODESYS Security Agent.

Command 'Settings of Memory Reserve for Online Change'

**Function:** This command opens the “Online Change Memory Reserve” view.

**Call:** Menu bar: “View”.

In the view, memory reserves are configured for the function blocks during the online change.

| “Scan Application” | - Searches the selected application for function blocks and displays them in the “Function blocks” area  
| - Updates the “Function blocks” area after the application is built again.  
| - Updates the “Function blocks” area after an online change. |

Drop-down list with the applications of the open project: Selection of the application whose function blocks should be displayed and/or edited in this view.

<table>
<thead>
<tr>
<th>Table 129: “Function Blocks”</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>“All”</strong></td>
</tr>
<tr>
<td><strong>“Pool”</strong></td>
</tr>
<tr>
<td><strong>“No memory-reserve”</strong></td>
</tr>
<tr>
<td><strong>“&lt;memory reserve&gt; bytes”</strong></td>
</tr>
</tbody>
</table>

Information about the function blocks:

Multiple selection is also possible when selecting a POU for the configuration of the memory reserve.

| **“Function block”** | Name of the function block |
|---|
| **“Size”** | Size of the function block  
Size of an instance of a function block  
Specified in bytes |
| **“Number of instances”** | Number of instances of a function block in the project |
| **“Memory reserve”** | Display of the memory reserve for each instance of the function block |
| **“Additional memory for all instances”** | Product of “Number of instances” and “Memory reserve” |
| **“Remaining memory reserve”** | Number of bytes that are available as reserve. |
Table 130: “Settings”

| **Memory reserve (in bytes)** | Input field for the memory reserve for the selected function block. Specified in bytes
| Requirement: the application is not located on the controller yet or you have allowed the memory reserve to be changed by clicking the “Edit” button in the “Allow editing” area. |
| **Apply for Selection** | The “Memory reserve (in bytes)” is assigned to the function block and the table column “Memory Reserve” is updated. In multiple selection, the specified value is assigned to each function block. In order to update the columns “Size”, “Number of Instances”, “Additional Memory for All Instances”, and “Remaining Size of the Memory Reserve”, click “Build ➔ Build”, and then click the “Scan Application” button. |

Table 131: “Enable Editing”

| **Enable** | The input field “Memory reserve (in bytes)” is editable. This button is modified in “Editable”. |

Table 132: “Information”

| **Number of FBs** | Total number of function blocks in the application |
| **Additional memory for all instances** | Sum of the memory reserves of all function block instances of the application. Specified in bytes |

Command ‘Start Page’

Symbol: 🗯

Function: This command opens the “Start Page” view.

Call: Main menu “View”

The view includes some basic commands and a list of recently opened projects. In addition, the CODESYS homepage is displayed.

If you access the Internet through a proxy, then you can save the authentication data in the project options (“Proxy Settings”) so you do not have to provide this data every time you use this command.

By moving the mouse pointer over the list of recently opened projects, you can remove or pin individual projects in the list. Pinned projects remain in this list until you remove the pin.

In the project options (“Load and Save”), you can configure whether this start page should open automatically when you start CODESYS.

Command ‘Add Object’

Symbol: 

**Function:** This command opens a submenu with objects that contain all objects that can be inserted, depending on the current position in the “Devices” or “POUs” view.

**Call:** “Project” menu, context menu in the “Devices” or “POUs” view.

**Requirement:** If CODESYS is to insert the object in the device tree, select an already existing object under which the new one is can be inserted indented. If CODESYS is to insert the object in the POUs tree, set the focus in any free place in the CODESYS window.

Command ‘Add Folder’

Symbol: 

2020/12/10  3ADR010583, 1, en_US  897
Function: This command opens a dialog box for defining a new folder in the Devices or POUs view.

Call: “Project” menu, context menu in the Devices or POUs view

You cannot structure the arrangement of device nodes and device objects through folders that you have created yourself.

This command inserts the folder below the object that has just been selected in the tree. If no object is selected, CODESYS inserts the folder right at the top in the tree directly under the root node.

Command ‘Insert Device’

Function: this command opens the dialog box “Add Device” for the selection of a device object that is to be inserted in the device tree below the currently selected object.

Call: Context menu of a device object in the device tree.

Requirement: An object is selected in the device tree below which a device object can be inserted.

See also
- § Chapter 1.3.1.8 “Configuring I/O links” on page 155
- § Chapter 1.3.1.8.1 “Device tree and device editor” on page 155

Dialog box ‘Add device’

Function: Depending on the currently selected position in the device tree, the dialog box offers a selection of the devices that can be inserted at this point. In addition, it contains the commands also available in the context menu: “Insert Device”, “Add Device”, “Plug Device”, “Update Device”.

Requirement: The devices are installed in the device repository on the local system.

“Name” Name with which the device is to appear in the device tree. Must be a valid IEC identifier.

Table 133: “action”

| “Add device”      | CODESYS inserts the selected device indented below the selected object in the device tree. |
| “Insert device”   | CODESYS inserts the selected device at the same level as the selected object below it in the device tree. |
| “Plug device”     | CODESYS inserts the selected device in the selected slot. If the slot is already occupied, the existing module is replaced by the new one. |
| “Update device”   | CODESYS replaces the device selected in the device tree by the one selected. Please note: Depending on the device, this may cause the configuration already done in the device editor to be overwritten with the default values! |
### String for full text search
This field is editable after clicking in it. For any character string entered, only those devices that include the character string are displayed in the lower view. The matched string is highlighted in yellow for these devices.

### Vendor:
Drop-down list with manufacturers whose available devices are displayed.

### Group by category
- **☑**: The available devices (newest version) are sorted by category. The category is defined in the device description file.
- **☐**: The available devices appear flat and alphabetically sorted.

### Display all versions (for experts only)
- **☑**: In addition, all other available versions of the devices can also be selected.
- **☐**: Only the newest version of each device is available for selection

### Display outdated versions
- **☑**: In addition, outdated versions of the devices can also be selected. Outdated versions result, for example, from the update of plug-ins.
- **☐**: Outdated device versions are not displayed.

The information provided by the device description file is displayed:
- device name, vendor, categories, version, order number and a short description, device-specific bitmap.

- ☐ Chapter 1.3.1.25.2.4.4 “Command ‘Plug Device’” on page 899
- ☐ Chapter 1.3.1.25.2.4.6 “Command ‘Update Device’” on page 901

### Command ‘Plug Device’

**Function**: Like the command “Add Device”, this command opens the dialog box “Add Device” for the selection of a device object that is to be inserted in the device tree in the currently selected slot.

**Call**: Context menu of the slot of a device object in the device tree.

**Requirement**: The slot of a device object is selected in the device tree.

An empty slot is identified by the symbol and the entry "<empty> (empty)". An occupied slot is given the symbol and the name of the device.

In the case of an occupied slot, this command replaces the existing module with the new one.

### Command ‘Scan for Devices’

**Function**: This command establishes a brief connection to the hardware and determines the devices in the network. You can then adopt the devices found into the device tree of your project.

**Call**: Main menu “Project”, context menu of a device object in the device tree.

**Requirement**: The settings for communication with the control device are correct. The gateway and the PLC are running. The device supports the scan function.
To use the scan functionality, you must log in once in order to load the library to the controller.

The command refers to the master controller selected in the device tree. For example, an already inserted PROFINET IO controller can be selected and the command used to determine the I/O devices and I/O modules assigned to it.

After scanning, the dialog box “Scan for Devices” appears with the results.

Table 134: “Scanned Devices”

| “Device name, Device type, Address, Station name, etc.” | Data about the scanned device depending on network type. When you change a value in the list of scanned devices, the value is shown in italics. This indicates that the new value has been changed in the editor in CODESYS, but not in the device. When you download the value to the device, it is shown normally. Value that indicate differences between the project and the scanned device are shown in orange. If several device descriptions are available for the scanned device, then the name is displayed in bold. The selection of the matching device description is resolved differently for different fieldbuses. Details can be found in the corresponding fieldbus sections. If a device description cannot be found, then the following message is shown: "Attention! The device was not found in the repository." Depending on the bus system, additional information is displayed, such as manufacturer number and product number. The device cannot be inserted into the project without the installed device description. |

| “Show differences to project” | □: The table in the dialog also shows additional configured devices (in the device tree of the project). □: The table shows all scanned devices. The configured devices are not shown. |

| “Scan Devices” | Starts a new search. |

| “Copy all devices to project” | The device that is selected in the table is inserted into the device tree in the project. If nothing is selected, then all scanned devices are shown. |

NOTICE!

If you insert devices, which are available in the device tree, to the device tree with “Copy All Devices to Project”, then the following should be noted. The data of the “Process Data” and “<...> I/O Mapping” tabs of the existing devices can be overwritten with the data of the recently inserted devices.

Table 135: “Configured Devices”

This part of the dialog is visible only when you select the “Show differences to project” option. Differences between the scanned and configured devices are color-coded. Devices in green are identical on both sides. Device in red are available only in the view of the scanned or configured devices.

If you have selected a device in both views, then the scanned devices are inserted above the selected configured device.
If you have selected a device in both views, then the scanned devices are inserted below the selected configured device.

If you have selected a device in both views, then the configured devices are replaced by the selected scanned device.

All scanned devices are copied to the project.

Deletes the selected configure device.

The dialogs for the scan differ depending on the type of device. Please refer to the help pages for the respective device editor.

See also

- "Scanning the current hardware and applying devices into the project" on page 160

Command 'Update Device'

Function: Like the command “Add Device”, this command opens the dialog box “Add Device” for the selection of a device object. This object is inserted in the device tree in place of the currently selected object.

Call: Context menu of a device object in the device tree.

Requirement: An object is selected in the device tree below which a device object can be inserted.

With this command you can insert either a different version of a device or a different type of device in place of the previous one.

The symbolic device name used in the device tree is retained, but the device type specified in parentheses behind it changes if a different type has been selected. Thus if only the device version is changed, the object entry appears unchanged.

If the device type does not change, the configuration tree indented below the device entry concerned is retained. In this case the configuration settings also remain the same. Inconsistencies in the configuration resulting from the device update are reported by CODESYS at the next compilation of the application. This also concerns implicitly inserted libraries, which CODESYS does not remove accordingly during a device update.

Command 'Edit Object'

Function: This command opens the object in its editor.

Call: Main menu “Project”, context menu.

Requirement: An object is selected in the device tree or in the “POUs” view.
Command 'Edit Object with'

**Function:** When multiple objects are available for an object, this command opens a dialog box for selecting an editor.

If only one editor is available for an object, then this command opens the object in that editor.

**Call:** Main menu “Project” or shortcut menu (right-click)

**Requirement:** An object is selected in the device tree or in the “POUs” view.

In the standard installation of CODESYS, there is no object that has multiple available editors.

Command 'Edit Object (Offline)'

**Function:** The command opens the object offline in the editor.

**Call:** Main menu “Project”, Context menu

**Requirement:** The application is in online mode. An object is selected in the device tree or in the “POUs” view.

The command allows you to edit objects in online mode. After editing you transfer the changes to the controller by use of the command “Online ➔ Online Change” or “Online ➔ Load”.

See also

- § Chapter 1.3.1.25.2.6.6 “Command ‘Online Change’” on page 928

Command 'Set Active Application'

**Function:** This command sets the selected application as the active application.

**Call:** Main menu “Project”, or right-click the “Application” object.

**Requirement:** The project has at least two applications. The selected application is not active.

Online actions apply only to the active application. The name of an active application is displayed in bold typeface in the device tree.

Command 'Project information'

**Symbol:**  

**Function:** This command opens the dialog box “Project Information”.

**Call:** Main menu “Project”

When you execute the command in the project for the first time, CODESYS creates the “Project Information” object.

Command 'Project Settings'

**Symbol:**  

**Function:** This command opens the “Project Settings” dialog box.

**Call:** “Project” menu or double-click on the object “Project Settings” in the “POUs” view
Requirement: A project is open.

See also
- Chapter 1.3.1.3.6.2 “Making project settings” on page 134

Command 'Project Environment'

Function: This command opens the “Project Environment” dialog box.

Call: “Project” menu

Requirement: A project is open.

this command is for checking the currentness of software and files integrated in the project and enables them to be updated.

Command 'Project Localization' - 'Create Localization Template'

Function: This command opens the “Create Localization Template” dialog. Define here which information should be exported from the project to a translation template (*.pot file).

Call: Menu bar: “Project ➤ Project Localization”.

Requirement: A project is open.

Dialog 'Create Localization Template'

This dialog is used for selecting the textual information that should be used in the localization template.

Table 136: “Include the Following Information”

<table>
<thead>
<tr>
<th>“Names”</th>
<th>Texts, such as dialog captions and object names in the device tree</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Identifier”</td>
<td>Variable identifier (example: Counter)</td>
</tr>
<tr>
<td>“Strings”</td>
<td>Example: 'count' in the following declaration: strVar: STRING :=</td>
</tr>
<tr>
<td></td>
<td>'count';</td>
</tr>
<tr>
<td>“Comments”</td>
<td>Comment texts in the POU</td>
</tr>
</tbody>
</table>
**"Position information"**

Selection of which positions of the selected text categories in the project should be included in the translation file. The position information is located in the first line(s) of a segment for a translation. Example:

```
#: D:\Proj1.project\Project_Settings:1
msgid "Project settings"
msgstr ""
```

- **“All”**: All detected positions of the text are listed.
- **“First appearance”**: In the translation file, the position is included in the project where the text to be translated appears for the first time.
- **“None”**

**“Generate”**

This button opens the dialog for saving a file. The translation template is created in a text file of type *.pot (portable object template). Each further generation creates a completely new template file.

---

**Command ‘Project Localization’ - ’Manage Localizations’**

**Function**: This command opens the “Manage localizations” dialog. Select the desired localization language in the dialog or the original version of the project. You can still accept the localization files *.<language>.po into the project or remove them.

**Call**: Menu bar: “Project ➔ Project localization”.

**Requirement**: A project is open.

---

**Dialog 'Manage localizations'**

**“Available Localizations”**

List of the localization files available in the project. Example:

```
proj1-de.po
proj1-en.po
<original version>
```

The original version is always available. The project can be edited only in the original version.

**“Add”**

This button opens the dialog for selecting an additional po file from the file system.

**“Remove”**

This button removes the po file, which is selected on the left side, from the project.

**“Default localization”**

☑: The selected localization is for the default localization. The entry is display in bold.

**“Switch Localization”**

Use this button to switch to the selected localization.

**“OK”**

The project is displayed in the language that is provided by the file selected below the files. If you select “<original version>”, then the project appears in the editable non-localized version.

Command 'Compare'

Symbol: 

Table 137: “Document Project” dialog box
**Function:** This command opens the “Project Comparison” dialog. In this dialog, you define the reference project to compare with the current project. You configure the comparison process by means of options. When the dialog is exited, the comparison starts and the result is shown in the view “Project Compare - Differences”.

**Call:** Menu bar: “Project ➔ Compare”.

**Requirement:** A project is open.

### Dialog 'Project Comparison'

**Table 138: “Compare the currently open project with:”**

<table>
<thead>
<tr>
<th>“Project on disk”</th>
<th>Path of the reference project on the file system.</th>
</tr>
</thead>
</table>
| “Project in a source control database” | “Host”: Name of the host where the source code management is located.  
“Port”: Number of the port for connecting to the source code management.  
“Location”: Path of the reference project.  
Requirement: The project is linked to source code management (for example, CODESYS SVN). |

**Table 139: “Compare Options”**

| “Ignore whitespace” | ☑: Whitespace differences between the current project and the reference project are ignored. |
| “Ignore comments” | ☑: Comments in the programming code are excluded from the comparison. |
| “Ignore properties” | ☑: Object properties are excluded from the comparison. |

| “OK” | Starts the project compare and displays the result in the view “Project compare - Differences”.

### View 'Project Comparison' - 'Differences'

The project compare view opens when you click “OK” to close the “Project Compare” dialog.
(1) Object tree of the current project
(2) Object tree of the reference project
(3) Command 'Accept Block', command 'Accept Single'
(4) Compare options, configured in 'Project Compare' dialog
   Compare statistics: added, deleted, and changed objects

Table 140: Toolbar

</tbody>
</table>
Table 141: Display of differences with colors, and symbols

<table>
<thead>
<tr>
<th>Font Style</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Black font</td>
<td>Objects are identical.</td>
</tr>
</tbody>
</table>

Object name with 🔄: Child objects of the object are different

<table>
<thead>
<tr>
<th>Font Style</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gray highlight</td>
<td>Objects are different.</td>
</tr>
<tr>
<td>Gray highlight + bold blue font</td>
<td>Object is only in the reference project.</td>
</tr>
<tr>
<td>Gray highlight + bold green font</td>
<td>Object is only in the open project (not in reference project).</td>
</tr>
<tr>
<td>Gray highlight + red font + 🔄</td>
<td>Object has different properties.</td>
</tr>
<tr>
<td>Gray highlight + red font + 🔄</td>
<td>Access rights of object and reference object are different.</td>
</tr>
<tr>
<td>Gray highlight + bold red font + 🔄</td>
<td>Implementation of objects is different. Double-click the line to display the object-specific compare view.</td>
</tr>
</tbody>
</table>

Yellow highlight | Object is activated for acceptance. |

Yellow highlight + 🔄: Adding the reference object to the open project is activated.

Yellow highlight + ✗: Deleting the object (in the open project) is activated.

Yellow highlight + 🔄: Acceptance of the properties of the reference project is activated.

Yellow highlight + red font + 🔄: Acceptance of the access rights of the reference project is activated.

Gray highlight + bold red font + 🔄: Acceptance of the implementation of the reference project is activated.

"Compare options" | Defined comparison options in the "Project Comparison" dialog.

"Compare statistics" | Number of additions, deletions, and changes in the current project, as compared to the reference project. "Change" means differences of an object available in both projects.

The dialog prompt opens: "Do you want to commit the changes which you made in the diff view?"

"Yes": The contents, properties, or access rights of the objects highlighted in yellow are modified in the project. Now they correspond to the reference project. Then the project compare view is closed completely.

View 'Project Comparison' - '<object name> Differences'

Function: Detail compare view

Call in the project compare view:
- Select an object that is identified as having different contents which you need to view in detail. Click 🔄.
- Double-click the object.

Table 142: Toolbar

<table>
<thead>
<tr>
<th>Toolbar</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>🔄</td>
<td>Switch back to the project compare view.</td>
</tr>
<tr>
<td>✗</td>
<td>Selects the next line below in the code where differences were detected.</td>
</tr>
</tbody>
</table>
Selects the next line above in the code where differences were detected.

"Accept Block" The block (with all subordinate lines) is selected for acceptance of the reference blocks into the current project.

A block in the detailed compare view consists of the unit where the cursor is located and all corresponding units that have the same difference markers. A unit is a line, network, or element. Subsequent lines of a line are examples of corresponding units.

Repeated clicking of "Accept Block" undoes the effects of its last change.

"Accept Single" The line is selected in the current object for acceptance of the reference line.

Switches between the default display where different units (lines, networks, elements) are displayed in red and another display: The units are displayed as recently added in the open project. In the reference project, they are displayed as deleted.

Available within the detailed compare view only.

Note: Depending on the display, detected differences in the statistics are counted as changed, inserted, or deleted.

Table 143: Display of differences with colors, and symbols

<table>
<thead>
<tr>
<th>Style</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Black font</td>
<td>Objects are identical.</td>
</tr>
<tr>
<td>Gray highlight + bold blue font</td>
<td>Code is only in the reference project.</td>
</tr>
<tr>
<td>Gray highlight + bold green font</td>
<td>Code is only in the current project (not in reference project).</td>
</tr>
<tr>
<td>Yellow highlight</td>
<td>The object is activated for acceptance.</td>
</tr>
</tbody>
</table>

The dialog prompt opens: “Do you want to commit the changes which you made in the diff view?”

“Yes”: The code highlighted in yellow is accepted into the project. The code corresponds to the reference project. Then the detailed view is closed and the project view is displayed. You can continue working with project compare.

Dialog 'Accept'

Table 144: “Which meta data should be accepted?”

<table>
<thead>
<tr>
<th>Meta data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Access rights&quot;</td>
<td>[✓]: Access rights that are selected for acceptance.</td>
</tr>
<tr>
<td>&quot;Accepted groups&quot;</td>
<td>Grouping with access rights accepted by the reference project. A group is accepted if it is present in both projects with different access rights. Example: Group A</td>
</tr>
<tr>
<td>&quot;Unaccepted groups (missing in a project)&quot;</td>
<td>The group is not accepted if it is not present in one of the two projects.</td>
</tr>
<tr>
<td>&quot;Properties&quot;</td>
<td>[✓]: Properties activated for accept</td>
</tr>
<tr>
<td></td>
<td>Requirement: The properties of the reference object and object are different.</td>
</tr>
</tbody>
</table>
“OK” Settings are accepted.

Command 'Commit Accepted Changes'

Symbol: ✚

Function: This command commits the accepted differences from the project comparison to the current project.

Call: “Project ➔ Commit Accepted Changes”.

Requirement: Changes from the project comparison have been accepted.

The changes are only copied to the project. This command does not save them to the hard disk.

See also
• ☹ Chapter 1.3.1.5.2 “Opening the Detailed Compare View” on page 138

Command 'Export'

Function: This command opens a dialog box for exporting objects from a project to an XML file.

Call: Menu bar: “Project”.

Dialog 'Export'

This dialog box lists all objects from the device tree, POU tree, and module tree that CODESYS can export.

<table>
<thead>
<tr>
<th>One file per subtree</th>
<th>✓: CODESYS generates a separate export file for each subtree that is located directly under the root node and includes selected files.</th>
<th>◻: CODESYS generates one export file for all selected objects.</th>
</tr>
</thead>
</table>

“Saved version”

This version should correspond to the target version where the export file will later be imported.
If the current project contains plug-ins or add-ons that are not available in the selected memory format (profile), then the “Extend Profile” dialog box opens. In this dialog box, the selected profile can be extended with the add-ons.

• ☹ Chapter 1.3.1.4.1 “Exporting and importing projects” on page 135

Command 'Import'

Function: This command opens a dialog box for importing objects from an XML file.

Call: Menu “Project”

Requirement: A project is open.
Dialog box 'Import PLCopenXML'

The dialog box lists all objects from the export file that CODESYS can import at this point.

<table>
<thead>
<tr>
<th>“Currently selected target objects”</th>
<th>Object that is selected in the Device tree</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Insertable items”</td>
<td>Displays all objects of the export file that CODESYS can insert below the selected object.</td>
</tr>
<tr>
<td>“Show contents”</td>
<td>Displays the contents of the export file in a tree structure</td>
</tr>
</tbody>
</table>

Command 'Export PLCopenXML'

**Function:** This command opens a dialog box for exporting objects from a project into an XML file in the PLCopen format.

**Call:** Menu “Project”

Dialog box 'Export PLCopenXML'

The dialog box lists all objects from the Device tree that CODESYS can export into an XML file in accordance with the PLCopen format.

*The PLCopenXML scheme does not permit VAR_GLOBAL and VAR_GLOBAL CONSTANT POUs to be in the same variable list. Therefore, if you wish to export both, you must first divide the variables into two separate variable lists.*

See also

- § Chapter 1.3.1.25.2.4.23 “Command 'Import PLCopenXML’” on page 911

Command 'Import PLCopenXML'

**Function:** This command opens a dialog box for importing objects from an XML file in PLCopen format.

**Call:** Menu “Project”

**Requirement:** A project is open.

Dialog box 'Import PLCopenXML'

The dialog box lists all objects from the PLCopen export file that CODESYS can import at this point.

<table>
<thead>
<tr>
<th>“Currently selected target object”</th>
<th>Object that is selected in the Device tree</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Insertable items”</td>
<td>Displays all objects of the export file that CODESYS can insert below the selected object.</td>
</tr>
</tbody>
</table>

*The PLCopenXML scheme does not permit VAR_GLOBAL and VAR_GLOBAL CONSTANT POUs to be in the same variable list. Therefore, if you wish to export both, the variables must first be divided into two separate variable lists.*
This command opens the dialog box “Login”. Here you specify the project that you wish to edit and enter the login data for a user account with the corresponding rights. In addition, you can open the password manager from this dialog box.

The command is available in the menu “Project ➔ User Management”.

See also

● § Chapter 1.3.1.6.6 “Logging in via user account and password manager” on page 147

Command 'User management' – 'Log out User'

Symbol: 

The user currently logged in to the project is logged out again with this command. This takes place without a dialog box or message, unless no user is currently logged in.

The command is available in the menu “Project ➔ User Management”.

If the user is currently logged in to several projects or to libraries integrated in them (it does not have to be the same user account), then the dialog box “Logout” opens, in which the specific project or library project can be selected from which the current user is to be logged out.

The status bar always displays the user who is currently logged into the project.

A double-click on the field “Current user” in the status bar enables quick access to the “Login” or “Logout” dialog box.

● § Chapter 1.3.1.25.2.4.24 “Command 'User management' – 'Log in User'” on page 911

Command 'User management' – 'Rights...'

This command opens the dialog box “Rights”, in which you define the actions that may be carried out, the user groups that may carry them out and the project objects on which they may be carried out.

The command is available in the menu “Project ➔ User Management”.

See also

● § Chapter 1.3.1.6.5 “Protecting objects in the project by access rights” on page 146

Command 'Insert Device'

Function: Like the command “Add Device”, this command opens a dialog box “Insert Device” for the selection of a device object. This object is inserted in the device tree at the same level as the currently selected object.

Call: Context menu of a device object in the device tree.

Requirement: An object is selected in the device tree below which a device object can be inserted at the same level.
Command 'Generate EtherCAT XML'

The command is not integrated in the standard main menu. You can add it via the dialog box "Tools ➔ Customize" from the category "Devices".

**Function:** This command opens the standard dialog box for saving a file in the local file system. You can define a name and a storage location for an xml file, in which CODESYS is to store the EtherCAT configuration of the EtherCAT master currently selected in the device tree. This may be necessary in order to operate an external EtherCAT stack.

**Call:** Context menu of an EtherCAT master device object in the device tree.

See also
- Chapter 1.3.1.8 "Configuring I/O links" on page 155

Command 'Generate Sercos SCI XML'

The command is not integrated in the standard menu. You can add it via the dialog box "Tools ➔ Customize" from the category "Devices".

**Function:** This command opens the standard dialog box for saving a file in the local file system. You can define a name and a location for an xml file in which CODESYS then stores the configuration data of the sercos master currently selected in the device tree. This may be necessary in order to operate an external sercos stack.

**Call:** Context menu of a sercos master device object in the device tree.

See also
- Chapter 1.3.1.8 "Configuring I/O links" on page 155
- Chapter 1.3.1.1.2.1 "Customizing menus" on page 103

Command 'Disable Device' – 'Enable Device'

**Function:** This command switches back and forth between the enabled (activated) and disabled (deactivated) states of a device in the bus system.

**Call:** Context menu of a device object in the device tree.

**Requirement:** The project is in offline mode. The bus driver must support the function.

A disabled device is not taken into account and is not addressed. Note that with some bus systems the deactivation of a node can lead to the master stopping.

The entry of a disabled device in the tree appears in light-gray lettering. When logging in, disabled devices are additionally marked with a red triangle ▲.

See also
- Chapter 1.3.1.8 "Configuring I/O links" on page 155
Command 'Edit I/O Mapping'

**Function:** This command opens the "Edit I/O Mapping" dialog box. This displays all I/O mappings of the currently selected device object, including I/O mappings of all additional device objects that are inserted in the device tree below this object.

**Call:** Context menu of a device object in the device tree.

### Dialog box 'Edit I/O mapping'

You can edit the I/O mapping in this dialog box in exactly the same way as in the dialog box "I/O mapping" of the individual device editors. The respective other dialog boxes are directly updated accordingly.

| "Search" | Input field for a search string for the mapping table. The search results are marked in yellow. |
| "Filter" | Drop-down list for filtering I/O assignments displayed listed in the mapping table: |
|          | ● “Show all” |
|          | ● “Show outputs only” |
|          | ● “Show inputs only” |
|          | ● “Show unmapped variables only” |
|          | ● “Show mapped variables only” |
|          | ● “Show mappings to existing variables only” |
|          | ● “Show mappings to new variables only” |

In the context menu you will find among other things the following commands:

"Export Mappings to CSV": Stores the mappings of a device and its sub-devices in an external file. To do this you select the device in the device tree or in the mapping list.

"Import Mappings from CSV": Inserts mappings from a file created beforehand by export.

- ☞ Chapter 1.3.1.25.2.4.32 “Command ‘Import Mappings from CSV’” on page 914

Command 'Import Mappings from CSV'

**Function:** The command opens the standard dialog for searching for a file in the local file system. The filter is set to file format .csv, for the selection of a file to which the I/O mapping configuration of a device was previously exported. CODESYS reads the configuration back into the current project.

**Call:** Context menu of a device object in the “Devices” view.

**Requirement:** A project with a device with I/O mapping configuration is opened. The device matches the exported .csv file.

**NOTICE!**

You can edit the .csv file externally before import. Please note: The entries of the file to the I/O mapping of the device are assigned by the device name and the parameter name. Parameter names that are not unique are numbered sequentially in this file (@<n>).

Fields without contents in the .csv file are ignored at import. To remove an existing entry in the I/O mapping by importing, you have to add a space in the respective field in the .csv file.
Command 'Export Mapping to CSV'

**Function:** This command opens the standard dialog for saving a file in the local file system. The filter is set to file format **csv**. After specifying a name and a location, CODESYS stores the I/O mapping configuration in a CSV file.

**Call:** Context menu of a device object in the “Devices” view.

**Requirement:** A device object with an I/O mapping configuration is selected in the device tree.

Parameter names that are not unique are numbered sequentially in this file (@<n>).

Command 'Import Mappings from CSV'

See also
- Chapter 1.3.1.25.2.4.31 “Command ‘Export Mapping to CSV’” on page 914
- Chapter 1.3.1.8.3 “Configuring devices and I/O mapping” on page 162

Command 'Read PLC Parameter File to Configuration'

**Function:** This command reads the configuration file **IoConfig.par** of the PLC and stores the values in the project. Such a file is created if the parameters of the PLC have been changed by another device, for example via a visualization. Then these parameters are changed only in the memory of the PLC, but not in the configuration of the project.

**Call:** Context menu of the PLC device object

**Requirement:** You have made the command available using the dialog in “Tools ➔ Customize”.

See also
- “Read PLC parameter file to configuration” on page 163

Command 'Online Config Mode'

**Function:** This command is for switching the online configuration mode on and off. At switch-on it establishes a connection to the PLC and loads an implicitly created application “**HiddenOnlineConfigModeApp**” to the PLC. Depending on the device, CODESYS goes into simple online configuration mode or a dialog box appears for selecting between simple and advanced online configuration mode.

**Call:** Context menu of the PLC object in the device tree

**Requirement:** The communication settings for the PLC device are correctly set.

Simple online configuration mode:

This command creates the implicit application **HiddenOnlineConfigModeApp** and loads it to the controller. The application automatically initializes all inputs and outputs of the controller once. After that you can access the I/Os as follows:

- Read I/Os
- Write outputs
- Diagnosis (in the device tree and on the “Status” tab of the device editor)
- Scan (of the current hardware)
- Interactive online functions, if supported (for example, writing asynchronous messages)

Advanced online configuration mode (parameter mode):

If there are already applications on the PLC and the controller supports it, the command first opens the dialog box “Devices”, which displays the applications existing on the controller. From this dialog you can connect via the button “Parameter mode” to the PLC and then access the values of the device parameters without having to log in with a real application.

**Writing and forcing in the I/O mapping**

In online configuration mode the writing and forcing of values on the “I/O Mapping” tab works differently to the way it works in real online mode. The outputs are written immediately after insertion into the table. There is no “Prepared Value” column; instead, the initial values can be changed directly after a double-click on the column “Current Value”.

---

**Dialog box 'Config application mode'**

This dialog box appears after the command “Online Config Mode” if the device supports the advanced online configuration mode and there are already real applications on the controller.

<table>
<thead>
<tr>
<th>“Parameter mode”</th>
<th>The controller configuration in the project is compared with that on the device. If they correspond, CODESYS establishes a connection to the PLC. Unlike the simple online configuration mode it permits the reading and – if supported by the driver – the writing of parameters in the generic device editor. The applications already loaded to the device remain unchanged in this case!</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Config application mode”</td>
<td>CODESYS switches to the ‘simple online configuration mode’.</td>
</tr>
</tbody>
</table>

---

**Command 'Build'**

Symbol: ⌘, keyboard shortcut: [F11].

---
**Function:** This command starts the build process for the active application.

**Call:** Main menu “Build”.

During the compile process, CODESYS performs a syntactic validation of all objects in the application. However, code is not generated like at login to the target system or download of the application. The compile process is always performed automatically when you login with a changed program.

When the check is complete, CODESYS displays any error messages or warnings in the messages view (“Build” category).

If the program has not been changed since it was compiled without errors the last time, then it is not recompiled. The message “The application is current” appears. If the syntactic validation is repeated, then you must execute the “Rebuild” command.

See also

- Chapter 1.3.1.25.2.5.2 “Command ‘Rebuild’” on page 917

**Command ‘Rebuild’**

**Function:** This command starts the build process for the active application, even if the last build contained errors.

**Call:** Main menu “Debug”.

See also

- Chapter 1.3.1.25.2.5.1 “Command ‘Build’” on page 916

**Command ‘Generate Code’**

**Function:** This command starts the code generation for the active application.

**Call:** Menu bar: “Build”

When generating code with this command, code is generated as when downloading the application to the PLC, but the code is not transferred to the PLC. Other source code tests are performed as well for checking the code for bugs that were not detected by the compiler and for fixing any bugs before the code is used in online mode.

See also

- Chapter 1.3.1.11.4 “Generating application code” on page 303

**Command ‘Generate Runtime System Files’**

**Function:** This command generates a C stub file and an M4 interface file from the current library project. These files are used as the basis for creating an external library file.

**Call:** Main menu “Build”.

This command opens the “Generate Files for Runtime System” dialog box.

| "Output directory" | Directory where CODESYS creates the runtime system files. Click the “more” button to open the default dialog box for browsing the file system. |
Table 145: “Which files do you want to create?”

**M4 interface file**

- Interface file `<project name>Itf.m4` with definitions. Example of m4 file:

```
/*
 * $interface$ SysFile</interface>
 */

- `extern C`{
  
  typedef enum
  {
    FS_OK = 0,
    FS_NO_FILE = 1,
    FS_ILLEGAL_POS = 2,
    FS_FULL = 3,
    FS_EMPTY = 4,
    FS_BUFFER_FULL = 5
  } filestatus;

  /*
   * ANSI C file access modes
   */
  #define AM_READ   0
  #define AM_WRITE  1
  #define AM_APPEND 2

  /*
   * ANSI C file access modes
   */
  #define AM_READ_Plus  0
  #define AM_WRITE_Plus 1
  #define AM_APPEND_Plus 2

  typedef enum
  {
    AM_READ = 0,
    AM_READ_Plus = 1,
    AM_APPEND = 2,
    AM_READ_Plus = 3
  } filestatus;
```

**C stub file**

- Stub file for reprogramming the library in C. Example of stub file:

```
#include "Cmpstd.h"
#include "Cmerrors.h"
#include "CmpItf.h"
#include "SysFileDep.h"

void CDCC CDCCEXT sysfilegetpath(sysfilegetpath_struct *p)
{
}

void CDCC CDCCEXT sysfilerename(sysfilerename_struct *p)
{
}

void CDCC CDCCEXT sysfilewriter(syfilewriter_struct *p)
```

**Command ‘Clean’**

**Function:** This command deletes the build information for the active application.

**Call:** Main menu “Build”.

During the last download, the build information was created and saved to a file (*.compileinfo). After a cleaning process, an online change is no longer possible for the affected application. The application must be fully downloaded to the controller again.

See also
- Chapter 1.3.1.25.2.5.6 “Command ‘Clean All’” on page 919

Command ‘Clean All’

**Function:** This command deletes the build information for all applications in the project.

**Call:** Main menu “Build”.

During the last download, the build information was created in the local file system and saved to a file (*.compileinfo).

This command requires a download before another login. An online change is no longer possible. As compared to the “Clean” command (only the active application), CODESYS regenerates the language model for all objects, which is very time-consuming.

**NOTICE!**
Reconsider carefully whether or not executing this command is really necessary. If you only want to rebuild and download the active application, then execute the “Clean” command.

See also
- Chapter 1.3.1.25.2.5.5 “Command ‘Clean’” on page 918

Command ‘Check All Pool Objects’

**Function:** The command causes a build run, that is a syntax check, for all pool objects, which are managed in the POU s view and thus are available in the entire project. Especially this is useful when creating libraries.

**Call:** By default the command is not available in any menu. You can add it to a menu using the dialog “Tools ➔ Customize”, command category “Build”.

**NOTICE!**
The command does not trigger code generation. Also no compile information file will be stored in the project directory.

See also
- Chapter 1.3.1.25.3.14.1 “Dialog ‘Customize’ - ‘Menu’” on page 1089
- Chapter 1.3.1.19.1 “Information for library developers” on page 372

Command ‘Check All Application Objects’

**Function:** This command starts a build operation for all objects of the active application, even for the POU s that are not used by the application. After the build operation, the errors that were found in the unused objects are also displayed in the message window.

**Call:** The command is not in any menu by default. You can add it to a menu by using the dialog from “Tools ➔ Customize” (command category “Build”).

**Requirement:** An application of the open project is active.
NOTICE!
The command does not result in code generation. In addition, no file is created in the project directory with information about the build operation.

See also
- Chapter 1.3.1.25.3.14.1 “Dialog ‘Customize’ - ‘Menu’” on page 1089

Command 'Check Library Compatibility'

Function: The command triggers a check whether the currently opened library project is compatible with the last installed version of this library (next lower version number).

Call: By default the command is not available in any menu. You can add it to a menu by using the “Tools ➔ Customize” dialog, command category “Build”.

Requirement: A library project is opened.

The check regards differences in the implemented interfaces of a method. So, after the check you will get displayed error messages in the messages window in the following cases:
- Adding or removing inputs or outputs of function blocks, functions or methods
- Changing the data type of inputs or outputs
- Modifying the implemented interfaces of a method

See also
- Chapter 1.3.1.25.3.14.1 “Dialog ‘Customize’ - ‘Menu’” on page 1089
- Chapter 1.3.1.19.1 “Information for library developers” on page 372

Command 'C Integration' - 'Update C Sources'

Function: this command opens the dialog “Update C Sources” for updating the objects in the project that have changed in the source directory on the disk.

Call: Menu bar: “Build”; context menu.

Requirement: An object “C Code Module” or “C Implemented Library” is selected. When adding the C-code module in the dialog “Add C Code Module”, you have activated the option “Check folder for source code changes”.

<table>
<thead>
<tr>
<th>“File”</th>
<th>File that has changed on the disk.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Action”</td>
<td>Action that is executed in CODESYS if you click “Update”.</td>
</tr>
<tr>
<td>“Update options”</td>
<td>“Remove IEC interfaces due to changed header files”</td>
</tr>
<tr>
<td></td>
<td>“Export source files to the monitored project folder”</td>
</tr>
<tr>
<td>“Refresh”</td>
<td>CODESYS updates the listed files.</td>
</tr>
</tbody>
</table>

See also
- Chapter 1.3.1.25.1.16 “Object ‘C Code Module’” on page 737
- Chapter 1.3.1.25.2.5.11 “Command ‘C Integration – Open in IDE’” on page 920
- Chapter 1.3.1.9.11 “Integrating C Modules” on page 222

Command 'C Integration – Open in IDE'

**Call**: Main menu “Create”, context menu

**Requirement**: You have opened an object “C Code Module” and the associated IDE is not opened.

If the IDE is closed, CODESYS checks whether the files have been changed and, in such a case, a dialog box appears for confirming the update of the C-code module in CODESYS.

See also

- Chapter 1.3.1.25.3.10.5 “Dialog ‘Properties’ – ‘Build’ (C-integration)” on page 1049
- Chapter 1.3.1.25.2.5.10 “Command ‘C Integration’ - ‘Update C Sources’” on page 920
- Chapter 1.3.1.9.11 “Integrating C Modules” on page 222

**Command ‘C Integration’ - 'Export C Sources'**

**Function**: The command exports all C-code files of a C-code module and saves them in the folder that you select in the dialog “Find Folder”.

**Call**: Menu bar: “Build”; context menu.

**Requirement**: A C code module is selected in the device tree.

See also

- Chapter 1.3.1.9.11 “Integrating C Modules” on page 222

**Command ‘C Integration – Create Stub Implementation in C’**

**Function**: This command creates C-stubs for the selected POU and stores them in the “Extensions” folder in the objects "iec_external.c" and "iec_external.h".

**Call**: Main menu “Build”, context menu

**Requirement**: A POU that is inserted under the object of the type “C Code Module” is selected in the device tree. The application has been compiled without errors.

See also

- Chapter 1.3.1.25.1.17 “Object ‘C Code File’” on page 739
- Chapter 1.3.1.9.11 “Integrating C Modules” on page 222

**Command ‘Create IEC Interface’**

**Function**: The command creates corresponding IEC objects from the selected file with the format *.h or *.hpp and stores these IEC objects in the folder “IEC interface”.

**Call**: Main menu “Build”, context menu

**Requirement**: You have selected an imported C-code file of the format *.h or *.hpp in the device tree below the object “C Code Module”.

If you select the command and the header file is free of errors, the dialog box “C Functions” opens with a list of the functions of the file that is to be exported.

**Dialog box ‘Create IEC interface’**

| “Function” | List of the functions  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>You select the functions for which a corresponding IEC object is to be created.</td>
</tr>
</tbody>
</table>

| “Import” | CODESYS generates corresponding IEC objects for the selected C-functions and stores them in the folder “IEC interface” below the object “C Code Module”. |
Command 'Generate Disassembly File'

**Function:** This command generates a disassembly file `<project name>.asm` from the current project and saves it in the file directory in the project folder.

**Call:** The command is not in any menu by default. You can add it to a menu by using the dialog box from "Tools ➔ Customize" (command category "Build").

Command 'Choose active application'

**Symbol:** App [Device PLC Logic]

The command is implemented as a list box from which you can set an application active. By default, the list box is located on the toolbar.

**Function:** The list box displays the currently active application with its device path.

**Call:** The list box contains all applications that are organized in the "Devices" view. By clicking an entry in the list box, you activate the selected application.

**Requirement:** The project has multiple applications.
When you call commands in the “Build” oder “Online” menus, these commands are applied to the active application. This is displayed in the list box, and also displayed in bold in the device tree. In particular, this applies to the “Build ➔ Build” and “Online ➔ Login” commands.

You can also access these commands using the command icons on the toolbar where the list box is located. When the command icons are called, they are also applied to the active application.

However, if you call a command from the context menu of a device object in the device tree, then the command is applied to the corresponding object. For example, by calling 📲, you can establish a connection to an application on the device which is not active.

See also

- ☰ Chapter 1.3.1.25.2.4.10 “Command ‘Set Active Application’” on page 902
- ☰ Chapter 1.3.1.25.2.5.1 “Command ‘Build’” on page 916
- ☰ Chapter 1.3.1.25.2.6.2 “Command ‘Login’” on page 923

Command ‘Login’

Symbol: 📲, shortcut: [Alt]+[F8]

**Function:** The command connects the application to the target system (PLC to simulated device) and starts the online mode.
Call: Menu bar: “Online”; context menu of an “Application” object

Requirement: The application contains no errors and the communication settings are configured.

A dialog prompt opens if the communication settings are incorrect. You can then switch directly to the “Communication Settings” of the PLC.

If you click “Login” from the online menu, then the currently active application is connected to the target system. If you choose this command from the context menu (right-click) while an application is selected in the device tree, then that application is logged in, even if it is not set as the active application.

If an online user management is configured on the target device, then you are prompted for user data when you login. The “Device User Login” dialog opens for this.

CAUTION!
Check controller accessibility
For security reasons, controllers should not be accessible from the Internet or untrusted Networks under any circumstances! In particular, the TCP/IP programming ports (usually UDP-Ports 1740..1743 and TCP-Ports 1217 + 11740 or the controller specific ports) should not be accessible from the internet without protection. In case Internet access to the controller is needed, using a safe mechanism is absolutely mandatory, such as VPN and password protection of the controller.

see also: § Chapter 1.3.1.11.3 “Handling of device user management” on page 300

NOTICE!
If a safety controller is inserted below a controller, then this command can interrupt the communication connections temporarily.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the "Subordinate Safety Controllers" chapter.

Possible situations when logging in:

- A later version of the device description (than in the project) is on the PLC. A warning prompt is displayed with the option to cancel the process.
- The application does not exist on the PLC: You are prompted to confirm the download.
- The application is already on the PLC and has not been changed since the last download. The login continues without any more prompts.
- The application exists on the PLC, but it has been changed since the last download. You are prompted to select one of the following options:
  - Login with online change (Note the information about online changes in the help page "Command ‘Online Change’").
  - Login with download
  - Login without any change

The position also provides the option of updating the boot application on the PLC.

- An unknown version of the application exists on the PLC. CODESYS prompts you to replace it.
A version of the application exists on the PLC and is running. CODESYS prompts you to login anyway and overwrite the currently running application.

The application on the PLC is currently halted at a breakpoint. You are logged out and the program has been changed: CODESYS prompts you with a warning that the PLC will be stopped completely if an online change or download occurs. This happens also if several tasks exist and the breakpoint affects only one of them.

Click “Details” in the dialogs above to open the “Application Information” dialog.

See also

- Chapter 1.3.1.25.2.6.6 “Command ‘Online Change’” on page 928
- Chapter 1.3.1.10.5 “Subordinate safety controller” on page 294

The dialog provides two tabs with comparative information about the application changed in the development system and its previous version currently located on the PLC. There are two tabs:

- “Application information”: The application properties of the “Application in the IDE” (Integrated Development Environment) are compared with those of the “Application in the PLC”. Project name, Last modification, IDE version, Author, Description. In addition, CODESYS shows the objects that have changed since the last download.
- “Application contents”: When the “Download application info” is selected, the contents of the applications on both the (1) development system and (2) PLC can be compared. The “Download application info” option is located on the “Application Build Options” tab of the application properties.

If the code in the development system is not current, then (3) “Application not up to date. Generate code now?” appears at the bottom left of the dialog. Execute this command to update the application source code.

This detailed information can help you to better assess the effects of login in the current situation and to make a decision about downloading the new application.

The comparison can also be displayed in the device editor (“Applications” tab) by clicking “Content”.

See also

- Chapter 1.3.1.25.1.19.4 “Tab ‘Applications’” on page 747
- Chapter 1.3.1.5 “Comparing projects” on page 137
Unknown applications on the PLC

If one or more applications are already on the PLC, but are not in the project, then CODESYS opens a dialog with a list of these applications. You can then define whether an application should be deleted before loading the current application from the PLC. This also applies to child applications that are on the PLC, but have been deleted from the project in the meantime.

Compiling the project before login

If an application program has not been compiled since the last change, then CODESYS compiles the project before login. This operation is the same as the “Build” command when logged out.

If compile errors occur, then a dialog prompt opens. The errors are printed to the message view (“Build” category). You can then decide whether or not you login without downloading the program to the PLC.

See also

- Chapter 1.3.1.25.2.5.1 “Command ‘Build’” on page 916

Error at login

If an error occurs when logging in to the PLC, then CODESYS cancels the loading operation with an error message. The error dialog gives you the options of showing the error details. If an exception was thrown and the text *SOURCEPOSITION* is included in the log, then you can display the affected function in the editor by clicking “Show in Editor”. The cursor jumps to the line containing the error.

Messages during the download operation

If CODESYS downloads the project to the PLC at login, then the following information is printed to the message view:

- Generated code size
- Size of the global data
- Resulting memory requirement on the PLC
- List of the affected blocks (for online change)

In online mode, you cannot change the settings of the devices or modules. You have to logout of the application for changing device parameters. Depending on the bus system, there may be some special parameters that you can also change in online mode.

CODESYS saves the view configuration separately in online and offline mode. In addition, views are closed that cannot be used in any operating mode. For this reason, the view can change automatically at login.

Command 'Logout'

Symbol: ☐, keyboard shortcut: [Ctrl]+[F8].

Function: This command disconnects the application from the target system (controller or simulated device) and returns to offline mode.

Call: Main menu “Online”, or context menu of the “Application” object.

Command 'Create Boot Application'

Function: This command generates a boot application.

Call: Main menu “Online”.

926 3ADR010583, 1, en_US 2020/12/10
A boot application is the application that is started automatically when the controller is switched on or started.

In offline mode, you can save the boot application in any directory. In online mode, CODESYS save the boot application to the target device. The file name is <application name>.app.

See also
- [Chapter 1.3.1.11.6 “Generating boot applications” on page 305](#)
- [Chapter 1.3.1.25.1.1 “Object ‘Application’” on page 710](#)

## Command 'Load'

**Function:** This command causes a compilation of the active application with subsequent download to the controller.

**Call:** Menu bar: “Online”.

**Requirement:** The application is in online mode.

When you execute this command, CODESYS performs a syntax check and generates the application code. This code is downloaded to the PLC. Furthermore, CODESYS generates the build log <project name>.<device name>.<application ID>.compile info in the project directory.

**NOTICE!**
During loading all variables are re-initialized with the exception of persistent variables.

**NOTICE!**
If a safety controller is inserted below a controller, then this command can interrupt the communication connections temporarily.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the “Subordinate Safety Controllers” chapter.

The description of the “Login” command describes the possible situations when logging in and loading.

If you attempt to download an application when the same version of the application is already on the PLC, then you get the message: "Program is unchanged. Application was not downloaded". CODESYS downloads the application to the PLC.

During loading a record of the actions being executed (generation of code, execution of initialization, etc.) appears in the Message window in the message category “Compile”. Furthermore, information is displayed regarding the memory ranges, the size of the code, the global data and the allocated memory. For the purpose of clarity, as opposed to the online change, the modified function blocks are no longer listed.

See also
- [Chapter 1.3.1.25.2.6.2 “Command 'Login’” on page 923](#)
- [Chapter 1.3.1.10.5 “Subordinate safety controller” on page 294](#)
Command 'Online Change'

**Function:** This command is used for initiating an online change on the current application. When this is done, CODESYS re-downloads only the changed parts of an application that is already running on the PLC.

**Call:** Menu bar: “Online”; context menu of object: “Application”

**Requirement:** The application is in online mode.

The command is available in the context menu if an application is selected in the device tree. In this way, you can perform an online change just for one application, even if that application is not currently active.

An online change is not possible after the “Clean All” and “Clean” commands. The cleaning process deletes the compile information (build log) that was generated automatically at code generation. This log is the basis for an online change.

---

**CAUTION!**

An online change changes the running application program and requires a restart.

Make sure that the new application code still has the required effect on the controlled system.

Depending on the controlled plant, the plant and workpieces may be damaged or the health and life of persons could be endangered.

---

**NOTICE!**

If an online change is performed, then the application-specific initializations (example: homing) are not executed because the machine retains its status. For this reason, the new program code may not have the intended effect.

1. Pointer variables retain their value from the last cycle. If a pointer refers to a variable whose value was changed in an online change, then the variable no longer yields the correct value. Make sure that pointer variables are re-assigned in each cycle.

2. After the parent application has been changed, a child application is removed from the PLC when an online change is performed.

---

**NOTICE!**

For compiler version 3.5.0.0 and later, a fast online change is performed for minor changes. In this case, only the modified blocks are compiled and downloaded. In particular, no initialization code is generated. This means that also no code is generated when variables with the `init_on_onlchange` attribute are initialized. As a rule, this has no effect because the attribute is used primarily for initializing variables with addresses. However, it cannot happen that a variable changes its address during an online change.

To secure the effect of the `init_on_onlchange` attribute in the entire application code, you must deactivate the fast online change in general for the application by using the compiler definition `no fast online change`. To do this, insert the definition in the application “Properties” (“Build” tab).

At the time of download, CODESYS also lists the changed interfaces, affected variables, and all blocks with new generated code in the “Build” category of the message view. If memory locations change, a dialog will inform you of possible problems in conjunction with pointers.
In the view “Memory Reserve for Online Change”, memory reserves can be configured for the online change so that instance variables do not have to be moved in the memory when changing a function block in an online change.

See also

Command 'Source Download to Connected Device'

**Function:** This command loads the project source code (as project archive) to the controller currently connected.

**Call:** Main menu “Online”.

**Requirement:** The application is in online mode.

See also

- Chapter 1.3.1.25.2.1.10 “Command ‘Source Upload” on page 859
- Chapter 1.3.1.25.2.1.11 “Command ‘Source Download” on page 860

Command 'Multiple Download'

**Function:** The command causes the code generation of the applications contained in the project as well as the loading of the applications to the corresponding controllers.

**Call:** Menu bar: “Online”

The command opens a dialog with a list of the applications. In this dialog, select the applications that are to be loaded. Then, CODESYS performs the syntax check of these applications and generates the respective code. The code is then downloaded to the respective PLC. For each selected application, CODESYS generates a build log with the name <project name>.<device name>.<application ID>.compileinfo in the project directory.

**NOTICE!**

If a safety controller is inserted below a controller, then this command can interrupt the communication connections temporarily.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the “Subordinate Safety Controllers” chapter.

Dialog 'Multiple Download'
“Please select the items to be downloaded”:
Selection of the applications. The applications are thereby also loaded to different controllers.

“Move Up”, “Move Down”:
Change of the order of download of the applications.
The applications are downloaded to the PLCs in the order of this list. By default, this list is alphabetically sorted. Parent-child relationships of applications are thereby taken into account.

“OK”:
Checks the syntax of all selected applications. Afterwards, the communication with the associated controller is verified for each application before the download takes place.

Table 146: “Online Change Options”

If an earlier version already exists on the PLC and is different from the current version, then the following options are provided:

“Try to perform an online change. If this is not possible, perform a full download.”
Activated by default. If an online change cannot be executed for one of the applications, then a download is performed.

“Force an online change. If this is not possible, cancel the operation.”
If an online change cannot be performed for (at least) one of the applications, then no download is performed and the online change is terminated (for example, if you have executed the command “Clean All” beforehand).

“Always perform a full download.”
Downloads all parts of the applications to the PLC, regardless of any existing versions.

For selected applications that do not exist on the PLC yet, CODESYS performs a download automatically to the PLC.

Table 147: “Other Options”

“Delete all applications on the PLC which are not part of the project.”
Corresponding applications are deleted

“Start all applications after download or online change”
The applications are started after the download or online change.

“Do not release forced variables”
If an application with forced variables exists on the controller, and if the implementation of this application has been changed, then no download is performed for this application.
The message “Error: Skipped because one or more variables have been forced” appears for this application in the window “Multiple Download - Result”.

Note that variables with the key attribute PERSISTENT RETAIN are not generally initialized. If you change the data layout, however, the persistent variables are automatically re-initialized.

After completion of the download a listing of all selected applications appears in the download order that you configured. In addition, you are shown information on the success of the download for each application.

Command 'Reset Cold'

Function: The command results in a cold start of the active application on the controller.

Call: Menu bar: "Online"

Requirement: The application is in online mode.

NOTICE!

If a safety controller is inserted below a controller, then this command can interrupt the communication connections temporarily.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus. For more information, see the "Subordinate Safety Controllers" chapter.

After restarting with "Reset Cold", the following happens:

- Application code is retained on the controller.
- Variables are initialized (with the initialization value or the default initialization value 0), and the previous values are lost.
- Retain variables are initialized, and the previous values are lost.
- Persistent variables are retained with values.
- Breakpoints that were set in the code are retained with their status (for example, activated or deactivated).
- The application goes into the "STOP" state.

You can also select the command while debugging the application when it halts at a breakpoint in the "HALT ON BP" state. Then either the warm start is executed immediately, or the remaining statements of the current cycle are processed. Therefore, a message window opens for you to select the next action. However, the message window opens only if the runtime system is capable of restarting the cycle without terminating it first.

After the reset, you can run the application as usual and, for example, start the execution by clicking "Debug → Start".

- Chapter 1.3.1.25.2.6.10 “Command ‘Reset Warm’” on page 931
- Chapter 1.3.1.25.2.6.11 “Command ‘Reset Origin’” on page 932

Command 'Reset Warm'

Function: The command results in a warm start of the active application on the controller.

Call: Menu bar: “Online”

Requirement: The application is in online mode.
NOTICE!

If a safety controller is inserted below a controller, then this command can interrupt the communication connections **temporarily**. Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the "Subordinate Safety Controllers" chapter.

After restarting with "Reset Warm", the following happens:

- Application code remains loaded on the controller.
- Variables are initialized (with the initialization value or the default initialization value 0).
- Retain variables are retained with values.
- Persistent variables are retained with values.
- Breakpoints that were set in the code are retained with their status (for example, activated or deactivated).
- The application goes into the “STOP” state.

You can also select the command while debugging the application when it halts at a breakpoint in the “HALT ON BP” state. Then either the warm start is executed immediately, or the remaining statements of the current cycle are processed. Therefore, a message window opens for you to select the next action. However, the message window opens only if the runtime system is capable of restarting the cycle without terminating it first.

After the reset, you can run the application as usual and, for example, start the execution by clicking “Debug ➔ Start”.

- Chapter 1.3.1.25.2.6.11 “Command 'Reset Origin'” on page 932

**Command 'Reset Origin'**

**Function:** The command results in a reset origin of the active application on the controller.

**Call:** Menu bar: “Online”

**Requirement:** The application is in online mode.
NOTICE!

If a safety controller is inserted below a controller, then this command can interrupt the communication connections permanently.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the "Subordinate Safety Controllers" chapter.

After restarting with "Reset Origin", the following happens:

- The application code is deleted, and as a result the application has no state.
- Variables are deleted, and the values are lost.
- Retain variables are deleted, and the values are lost.
- Persistent variables are deleted, and the values are lost.
- Breakpoints that were set in the code are lost.

Command 'Reset Origin Device'

**Function:** The command resets the device to its factory settings. All applications, boot applications, and remanent variables will be deleted from the device.

**Call:** Right-click a programmable device in the device tree.

**Requirement:** The application is in online mode.

NOTICE!

If a safety controller is inserted below a controller, then this command can interrupt the communication connections permanently.

Connections of the safety controller to other safety controllers (via safety network variables), to field devices, and to the development system are affected. The safe field devices or other safety controller can enter the safe state as a reaction. The connection to the development system is affected only when a safety controller that is connected to the main controller via a fieldbus.

For more information, see the "Subordinate Safety Controllers" chapter.

Command 'Logoff Current Device User'

Symbol: 

Function: This command logs out the user currently logged in to the controller (device). If CODESYS still has a connection to the controller, then it will be disconnected.

Call: Main menu “Online”.

Requirement: The application is in online mode.

You can manage the device user management in the “Users and Groups” tab and “Access control” of the device editor. The commands in the “Online ➔ Security” menu provide another simple option for protecting access to the target device.

See also
- § Chapter 1.3.1.25.1.19.13 “Tab 'Users and Groups'” on page 760
- § Chapter 1.3.1.11.3 “Handling of device user management” on page 300

Command 'Add Device User'

Symbol: 

Function: This command configures a new device user and adds this user to the administrator group.

Call: Menu bar: “Online ➔ Security”

Requirement: The device supports a device user management. You are logged in to the device as a user.

You can manage the device user management in the “Users and Groups” tab and “Access control” of the device editor. The commands in the “Online ➔ Security” menu provide another simple option for protecting access to the target device.

See also
- § Chapter 1.3.1.25.1.19.13 “Tab 'Users and Groups'” on page 760
- § Chapter 1.3.1.11.3 “Handling of device user management” on page 300

This command opens the “Add Device User” dialog. Here you define the access data of the new user.

The dialog corresponds to the dialog in the “Users and Groups” tab of the device editor for adding a new user.

Please use a strong password as follows:
- Password length >= 8 characters (best >= 12)
- Use uppercase and lowercase
- Include numbers
- Use special characters
- Do not use existing names or sequence of characters that are easy to guess (for example, “123”, “abc”, “qwerty”)
CAUTION!

After performing this action, you can no longer use a blank user name and password to log in. You must remember your password.

See also
- Chapter 1.3.1.25.2.6.15 “Command ‘Remove Device User’” on page 935
- Chapter 1.3.1.25.2.6.16 “Command ‘Change Password Device User’” on page 935

Command 'Remove Device User'

Symbol: 🗝

Function: This command removes a user from the user management on the target system (device).

Call: Menu bar: “Online ➔ Security”

 Requirement: You are logged in to the device as a user.

You can manage the device user management in the “Users and Groups” tab and “Access control” of the device editor. The commands in the “Online ➔ Security” menu provide another simple option for protecting access to the target device.

See also
- Chapter 1.3.1.25.1.19.13 “Tab ‘Users and Groups’” on page 760
- Chapter 1.3.1.11.3 “Handling of device user management” on page 300

This command opens the “Remove Device User” dialog. Specify the user name and password of the user to be removed and click “OK” to confirm.

CAUTION!

After performing this action, you can no longer use this removed user account to log in. If this user is the only one on the target system, then a dialog prompt notifies you that this user cannot be removed.

See also
- Chapter 1.3.1.25.2.6.14 “Command ‘Add Device User’” on page 934
- Chapter 1.3.1.25.2.6.16 “Command ‘Change Password Device User’” on page 935

Command 'Change Password Device User'

Symbol: 🗝

Function: This command changes the password for the user who is currently logged on the PLC.

Call: Menu bar: “Online ➔ Security”

Requirement: You are logged in to the device as a user.

The command opens the “Change Password for Device User” dialog for defining a new password.
NOTICE!
After performing this action, you can no longer use the previous password to log in.

Please use a strong password as follows:

- Password length \(\geq 8\) characters (best \(\geq 12\))
- Use uppercase and lowercase
- Include numbers
- Use special characters
- Do not use existing names or sequence of characters that are easy to guess (for example, "123", "abc", "qwerty")

See also

- Chapter 1.3.1.25.2.6.14 “Command ‘Add Device User’” on page 934

- Chapter 1.3.1.11.3 “Handling of device user management” on page 300

Command 'Stop Execution on Handled Exceptions'

**Function:** This command halts the application where the error is located despite a programmed exception handling.

**Call:** This command is not available by default, but it can be configured from the “Tools ➔ Customize”, “Add Command” dialog box (“Online” category).

**Requirement:** The application is in online mode and contains a programmed exception handling with the `__TRY` and `__CATCH` operators.

If you have configured this command from the “Online” menu and you call it from there, then the currently active application is affected. Furthermore, this command can help you to detect errors.

See also

- Chapter 1.3.1.24.3.61 “Operators ‘__TRY’, ‘__CATCH’, ‘__FINALLY’, ‘__ENDTRY’” on page 546
- “Adding commands” on page 103
- Chapter 1.3.1.25.2.8.9 “Command ‘Customize’” on page 959

Command 'Connect to Device'

**Function:** The command establishes a connection to the device currently selected in the device tree.

**Call:** Context menu of the device.

**Requirements:** A device is selected in the device tree. The communication settings are configured correctly.

See also

- Chapter 1.3.1.25.2.6.19 “Command ‘Disconnect from Device’” on page 936

Command 'Disconnect from Device'

**Function:** The command disconnects the connection from a device.

**Call:** Context menu of the device.

**Requirements:** A device is selected in the device tree.
See also

● § Chapter 1.3.1.25.2.6.18 “Command 'Connect to Device’” on page 936

**Command 'Wink'**

**Symbol:**

**Function:** The command causes a short blinking of an LED of the connected controller. Thus the hardware can be identified clearly.

**Call:** By default the command is not available in any menu. You can add it to a menu by using the “Tools → Customize” dialog, command category “Build”.

**Requirements:** The controller supports this function and the communication settings are configured correctly.

**Command 'Simulation'**

**Function:** This command switches the development system to simulation mode.

**Call:** Menu bar: “Online”

In simulation mode, you can start and debug the active application on a simulated target device. A physical target device is not necessary for testing the online behavior of an application. When logging in for the first time, you are prompted whether the application should be created or loaded. For a simulated device, you do not have to configure the communication settings. In CODESYS simulation mode, the controller entry in the device tree is shown in italics.

**NOTICE!**

No C code for simulation mode

- In simulation mode, C code is not generated and loaded to the runtime system. To simulate the code contained in the C modules anyway, you can implement it for this purpose in the respective IEC objects of the C code module.

To switch off simulation mode, log out of the controller and execute the “Simulation” command again.

This command affects the active application only. Via context menu the simulation mode can be activated for the selected application.

**Command 'Operating Mode'**

**Function:** These commands set the controller in a state that prevents accidental change to the project.

**Call:** Menu bar: “Online → Operating Mode”

You can use these commands, for example, to lock the state of a controller in order to prevent the controller from switching to another state while you program another controller.

When programming is complete, the controller should then be switched to a defined and externally visible state that is set exactly the same way after reboot.
If it supports the controller, then you can switch the controller to the following operating modes:

- **Debug**: No restrictions
- **Locked**: The current state of debugging is locked on the application. No more breakpoints can be set and no variables can be forced. Writing variables is still possible. Only the "RUN" state of an application is preserved in the "Locked" operating mode even if the controller is restarted. Otherwise the application remains in "STOP" state.
- **Operational**: Nothing can be changed. Breakpoints cannot be set. Writing variables is still possible.

The symbols ◼, ◽, and ◼ in the status bar indicate the current operating mode. Double-clicking one of these symbols opens a help window.

Conditions for activating the "Operational" mode

- A boot application for each application must be present on the controller.
- There must not be any active breakpoints set.
- All applications must be running.
- There must not be any forced values present.
- Moreover, the device can define more of its own restrictions.

You cannot switch the operating mode between "Locked" and "Operational".

---

</table>
Command 'Start'

Symbol: \[;\] keyboard shortcut: [F5]

**Function:** This command starts the application (status: “RUN”).

**Call:** Menu bar: “Debug”; context menu of object: “Application”

**Requirement:** The application is in online mode and its status is “STOP”.

Executing this command from the “Debug” menu will affect the application that is currently in focus.

See also

- § Chapter 1.3.1.11.5 “Downloading the application code, logging in, and starting the PLC” on page 304

Command 'Stop'

Symbol: \[\]; keyboard shortcut: [Shift]+[F8]

**Function:** This command stops the application (status: “STOP”).

**Call:** Menu bar: “Debug”; context menu of object: “Application”

**Requirement:** The application is in offline mode and its status is “RUN”.

Executing this command from the “Debug” menu will affect the application that is currently in focus.

Command 'Single Cycle'

Keyboard shortcut [Ctrl]+[F5]

**Function:** This command executes the active application for one cycle.

**Call:** Main menu “Debug”.

**Requirement:** The application is in online mode and the program is halted at a program step.

Command 'New Breakpoint'

Symbol: \[\], keyboard shortcut [Alt]+[F7].

**Function:** This command opens the “Breakpoint Properties” dialog box.

**Call:** Main menu “Debug”.

**Requirement:** The application must be in online mode.

See also

- § Chapter 1.3.1.12.2 “Using breakpoints” on page 310

Command 'New Data Breakpoint'

Symbol: \[\\]

**Function:** This command opens the “New Breakpoint” dialog.
Call: Menu bar: “Debug”.

Requirement:

- The application is in online mode.
- The device description file of the target device contains the entries for the "data breakpoints" functionality.

See also

- Appendix A.3.1.25.3.8 “Dialog ‘New Breakpoint’” on page 1044
- Appendix A.3.1.12.2 “Using breakpoints” on page 310

Command 'Edit Breakpoint'

Symbol: 

Function: This command opens the “Breakpoint Properties” dialog box.

Call: Main menu “Debug”.

Requirement: The application is in online mode and the cursor is halted at a breakpoint.

See also

- Appendix A.3.1.12.2 “Using breakpoints” on page 310

Command 'Enable Breakpoint'

Function: This command enables a disabled breakpoint.

Call: Main menu “Debug”.

Requirement: The application is in online mode and the cursor is halted at a disabled breakpoint.

See also

- Appendix A.3.1.12.2 “Using breakpoints” on page 310

Command 'Disable Breakpoint'

Function: This command disables an enabled breakpoint.

Call: Main menu “Debug”.

Requirement: The application is in online mode and the cursor is halted at an enabled breakpoint.

See also

- Appendix A.3.1.12.2 “Using breakpoints” on page 310

Command 'Toggle Breakpoint'

Keyboard shortcut [F9]

Function: This command sets a breakpoint or clears an existing breakpoint.

Call: Main menu “Debug”.

Requirement: The application is in online mode. The cursor is positioned at a breakpoint.

See also

- Appendix A.3.1.12.2 “Using breakpoints” on page 310
Command 'Step Over'

Symbol ☑, shortcut [F10]

**Function:** The command executes the statement where the program is currently located and halts before the next statement in the POU.

**Call:** Menu bar: “Debug”

**Requirement:** The application is in online mode and the program is halted at the current break position (debug mode).

If the executed statement contains a call (from a program, function block instance, function, method, or action), then the subordinate POU is processed completely in one step and returned to the call. Then it halts before the next statement (in the next line of code).

> Click “Step Into” to jump to a subordinate POU and process it in single steps.

See also

- ⇨ Chapter 1.3.1.12.3 “Stepping through a program” on page 313
- ⇨ Chapter 1.3.1.25.2.7.11 “Command ‘Step Over’” on page 941

Command 'Step Into'

Symbol ☑, shortcut [F11]

**Function:** The command executes the statement where the program is currently located and halts before the next statement.

**Call:** Menu bar: “Debug”

**Requirement:** The application is in online mode and the program is halted at the current break position (debug mode).

If the executed statement contains a call (from a program, function block instance, function, method, or action), then the program execution jumps to this subordinate POU. Its code opens in a separate editor. The first statement there is executed and the program execution halts before the next statement. The new current breakpoint position is then in the called POU.

> Click “Step Over” to remain in the currently active POU and execute the call in one step.

See also

- ⇨ Chapter 1.3.1.12.3 “Stepping through a program” on page 313
- ⇨ Chapter 1.3.1.25.2.7.10 “Command ‘Step Over’” on page 941

Command 'Step Out'

Symbol ☑, shortcut [Ctrl]+[F11]

**Function:** The command executes the program until the next return and halts afterwards.

**Call:** Menu bar: “Debug”
**Requirement:** The application is in online mode and the program is halted at the current breakpoint position (debug mode).

If the current breakpoint position is in a subordinate POU, then this is run through to the end. Then the program execution jumps back to the calling point in the calling POU and halts there (in the line with the call).

If the current breakpoint position is in the main program, then the POU is run through to the end. Then the program execution jumps back to the beginning (to the program start at the first line of code in the POU) and halts there.

See also

- Chapter 1.3.1.12.3 “Stepping through a program” on page 313

**Command ‘Run to Cursor’**

Symbol: ⏯️

**Function:** The command executes a program until a specified position as marked by the cursor.

**Call:** Menu bar: “Debug”

**Requirement:** The application is in online mode and the program is halted at the current breakpoint position (debug mode). Moreover, you have marked any line of code in any POU with the cursor.

The statements between the current breakpoint position and the cursor position are executed in one step. Then the execution halts at the cursor position, which then becomes the next breakpoint position. Remember that the line of code where you placed the cursor is reached but not executed.

See also

- Chapter 1.3.1.12.3 “Stepping through a program” on page 313

**Command ‘Set Next Statement’**

Symbol: 🎉

**Function:** The command determines which statement is executed next.

**Call:** Menu bar: “Debug”

**Requirement:** The application is in online mode and the program is halted at the current breakpoint position (debug mode). Moreover, you have marked any line of code in any POU with the cursor.

The line of code marked with the cursor becomes the current breakpoint position without executing the statements in between or the statement that jumped to it.

See also

- Chapter 1.3.1.12.3 “Stepping through a program” on page 313

**Command ‘Show Next Statement’**

Symbol: ➤

**Function:** The command displays the program statement that is processed in the next step.

**Call:** Menu bar: “Debug”
**Requirement:** The application is in online mode and the program is halted at the current break position (debug mode). The break position is in a line of code that you cannot see.

The command makes the window with the current breakpoint position active (in the code highlighted in yellow and marked with the symbol) and makes the breakpoint position to become visible. This is useful if you have multiple editors open and the breakpoint position is hidden in an inactive editor.

- © Chapter 1.3.1.12.3 “Stepping through a program” on page 313

---

**Command 'Force Values’**

Keyboard shortcut \[F7\]

**Function:** This command sets a permanent predefined value to a variable on the controller.

**Call:** Main menu “Debug”.

**Requirement:** The application is in online mode.

---

**CAUTION!**

Unusual changes to variable values in an application currently running on the controller can lead to undesired behavior of the controlled machinery.

Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled machinery, the result may lead to damage to machinery and equipment or injury to health and life of personnel.

With this command, CODESYS permanently sets one or more variables of the active application to defined values on the controller. This is done at the beginning and end of a processing cycle. Processing sequence: 1) read inputs, 2) force values, 3) process code, 4) force values, 5) write outputs.

You can prepare values as follows:
- Click in the “Prepared value” field in the declaration section and type in the value. For Boolean variables, you change the value by clicking the field.
- Click in the inline monitoring field in the implementation section of the FBD/LD/IL editor
- Click in the “Prepared value” field in the monitoring view and type in the value.

A forced value is marked with the forced symbol ( ).

CODESYS forces the value until you explicitly lift it by
- Clicking “Unforce Values”
- Lifting the force in the “Prepare Value” dialog box
- Logging out of the application

---

The command “Force Values [All Applications]” affects all application in the project and is not included in a menu by default.

See also
- © Chapter 1.3.1.25.3.7 “Dialog Box ‘Prepare Value” on page 1043

- © Chapter 1.3.1.12.4 “Forcing and writing variables” on page 315
Command 'Write Values'

Keyboard shortcut [Ctrl]-[F7]

**Function:** This command sets a predefined value to a variable on the controller one time.

**Call:** Main menu “Debug”.

**Requirement:** The application is in online mode.

---

**CAUTION!**

Unusual changes to variable values in an application currently running on the controller can lead to undesired behavior of the controlled machinery. Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled machinery, the result may lead to damage to machinery and equipment or injury to health and life of personnel.

---

With this command, one or more variables of the active application are set to defined values on the controller one time. Writing is done one time at the beginning of the next cycle.

Values are prepared by

- Clicking in the field “Prepared value” in the declaration section
- Clicking in the inline monitoring field in the implementation section
- Clicking in the field “Prepared value” in the watch window

---

The command “Write Values [All Applications]” affects all application in the project and is not included in a menu by default.

---

See also

- ☞ Chapter 1.3.1.25.2.7.16 “Command ‘Force Values’” on page 943
- ☞ Chapter 1.3.1.12.4 “Forcing and writing variables” on page 315

---

Command 'Unforce Values'

Keyboard shortcut [Alt]+[F7]

**Function:** This command resets the forcing of all variables. The variables receive their current values from the PLC.

**Call:** “Debug”.

**Requirement:** The application is in online mode.

The “Remove Force List” command has the same functionality as this command with one difference. If the “Remove Force List” command cannot be executed for all forced values, then no message is displayed.

---

**CAUTION!**

Unusual changes to variable values in an application currently running on the PLC can lead to undesired behavior of the controlled machinery. Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled system, the result may lead to damage to machinery and equipment or injury to health and life of personnel.
The command “Force Values [All Applications]” affects all application in the project and is not included in a menu by default.

See also
- Chapter 1.3.1.25.2.7.16 “Command ‘Force Values’” on page 943
- Chapter 1.3.1.12.4 “Forcing and writing variables” on page 315

Command ‘Force All Values from <Device.Application>’

Function: This command resets all values of variables from the selection <Device.Application> to predefined values permanently.

Call:
- Context menu of the application in the device tree
- Context menu in the editor of a POU from the selected application

Requirement: The application is in online mode.

CAUTION!
Unusual changes to variable values in an application currently running on the controller can lead to undesired behavior of the controlled machinery.
Evaluate possible dangers before forcing variable values. Take the respective safety precautions. Depending on the controlled machinery, the result may lead to damage to machinery and equipment or injury to health and life of personnel.

With this command, CODESYS permanently sets one or more variables of the active application to defined values on the PLC. This is done at the beginning and end of a processing cycle. Order of processing: 1) read inputs, 2) force values, 3) process code, 4) force values, 5) write outputs.

You can prepare values as follows:
- Click in the “Prepared value” field in the declaration part and type in the value. For Boolean variables, you change the value by clicking the field.
- Click in the inline monitoring field in the implementation part of the FBD/LD/IL editor
- Click in the “Prepared value” field in the monitoring view and type in the value.

A forced value is marked with the forced symbol (F).
CODESYS forces the value until you explicitly lift it by
- Clicking “Unforce Values”
- Clicking “Unforce All Values from <Device.Application>”
- Lifting the force in the “Prepare Value” dialog
- Logging out of the application

The command “Force Values [All Applications]” affects all application in the project and is not included in a menu by default.

Command 'Flow Control'

**Function:** This command activates and deactivates the flow control.

**Call:** Menu "Debug"

**Requirement:** The application is in online mode.

---

### NOTICE!

An active flow control extends application runtime.

When "Confirmed Online Mode" is activated in the communication settings, a dialog prompt appears when switching on the flow control to cancel the process.

When flow control is activated, it is not possible to use breakpoints or step through the program.

---

### Menu 'Core Dump'

1.3.1.25.2.7.23.1 Command 'Load Core Dump' .................... 947
1.3.1.25.2.7.23.2 Command 'Create Core Dump' .................... 947
1.3.1.25.2.7.23.3 Command 'Close Core Dump' .................... 948
1.3.1.25.2.7.23.4 Command 'Load Device Log from Core Dump' .... 948

---

### Command 'Load Core Dump'

**Function:** CODESYS scans the project directory for core dump files. When a new core dump is forced with the "Create Core Dump" command, the dump file is automatically loaded from the controller to the project directory. If multiple core dump files are available, then CODESYS prompts you to choose whether the latest file should be opened in the project. You can also select one of the other files.

When a file is loaded into the project, an online view of the application appears with state of the application at the time when the core dump was generated. You can then view the variable values afterwards. Finally, the call tree is also available.

**Call:** Main menu "Debug ➔ Core Dump".

**Requirement:** The application is in offline mode.

---

### NOTICE!

You can close the core dump view only by clicking "Close Core Dump". The "Logout" command has no effect in this view.

---

See also

- ↕ Chapter 1.3.1.13.7 “Analysing errors with core dump” on page 349
- ↕ Chapter 1.3.1.25.2.7.23.2 “Command ‘Create Core Dump’” on page 947
- ↕ Chapter 1.3.1.25.2.7.23.3 “Command ‘Close Core Dump’” on page 948

---

### Command 'Create Core Dump'

**Function:** This command causes CODESYS to check whether a core dump file is already available on the controller.

If a core dump file is available, then CODESYS prompts you to load this file to the project directory.
With the following requirements, CODESYS generates a new dump file with the current application data:
- A core dump file is still not available or CODESYS has rejected a core dump file from being loaded.
- The application is currently stopped at breakpoint or an exception has occurred.

The generated core dump file is saved directly to the project directory: `<project name>_<device name>_<application name>_<application Guid>.core`. You can cancel the file generation by clicking the button in the status bar.

The amount of detail in the dump depends on the support from the runtime system. Runtime systems that are appropriate for this purpose generate just one dump in the case of an exception error. The core dump output from clicking “Load Core Dump” can therefore be used for error analysis.

**Call:** Main menu “Debug ➔ Core Dump”.

**Requirement:** The application is in online mode.

**See also**
- Chapter 1.3.1.13.7 “Analysing errors with core dump” on page 349
- Chapter 1.3.1.25.2.7.23.1 “Command ‘Load Core Dump’” on page 947

**Command 'Close Core Dump’**

**Function:** This command closes the core dump view of the application that is open in the project.

**Call:** Main menu “Debug ➔ Core Dump”.

**Requirement:** The application is in offline mode and you have loaded a core dump file to the project from the controller.

**See also**
- Chapter 1.3.1.13.7 “Analysing errors with core dump” on page 349

**Command 'Load Device Log from Core Dump’**

**Function:** This command imports the controller log list that was saved with the last generated core dump. The log list is displayed in the same view as in online mode in the “Log” tab of the device editor.

**Call:** Main menu “Debug ➔ Core Dump”.

**Requirement:** The application is in offline mode and a core dump is open in the project.

**See also**
- Chapter 1.3.1.13.7 “Analysing errors with core dump” on page 349
- Chapter 1.3.1.25.1.19.8 “Tab ‘Log’” on page 750

**Command 'Display Mode’ - 'Binary', 'Decimal', 'Hexadecimal’**

**Function:** These commands in the “Display Mode” submenu are used for setting the format of values in the display mode when monitoring in online mode.

**Call:** Main menu “Debug”.

**Requirement:** The project is in either online or offline mode.
The "Binary" and "Hexadecimal" display modes are unsigned, and "Decimal" is signed.

### Install

Opens the standard dialog box for browsing for a package in the file system. The standard file type is ".package.

You can also install two versions of a package.

Following the selection of the package the setup wizard appears with the dialog box:

- **"Installation - License Agreement"**
  
  CODESYS also displays the "Checksum" of the package in this dialog box. Appears only if the package contains a license agreement.

- **"Choose Setup Type"**
  
  The options are package-dependent.
  
  - **"Complete setup":** CODESYS installs all components.
  
  - **"Typical setup":** CODESYS installs a standard set from components defined in the package.

- **"Installation - target system versions"**: You select which of the already existing target system versions are to be updated by the package installation. You must select at least one version profile.

### Uninstall

Uninstalls the selected package

- If "Display Versions" is not activated, CODESYS uninstalls all versions of the selected package.

- If "Display Versions" is activated and you have selected a package node at the highest level, CODESYS uninstalls all versions of the selected package.

- If "Display Versions" is activated and you have selected a single package version, CODESYS uninstalls precisely this version.

### Details

Opens the dialog box "Details" for the selected package with the following tabs:

- **"Package Details"**
  
  - **"Name":** package name
  
  - **"Version":**
  
  - **"Checksum":** SHA-1 CRC of the package
  
  - **"Vendor":**
  
  - **"Copyright":**
  
  - **"Description":**
  
  - **"Installation date":**

- **"License agreement":**

- **"Installation log":**

### Search for updates in background

☑️: CODESYS automatically searches for updates after each start of the programming system and after that once per hour.

### Display versions

☑️: Displays all versions of the installed packages.

---

You can compare the "CRC" that CODESYS displays in the dialog box "Details" and in the dialog box "Installation - License Agreement" of the setup wizard with the package CRC of the package vendor. This way you can ensure that you have installed an original package.

If you install a newer version of the programming system in the same installation directory as the previous version, the license information for the packages already installed is retained and CODESYS displays the information in the dialog box "Package Manager".
**Table 149: “Updates”**

<table>
<thead>

</tbody>
</table>

Table 154: “Library Profiles”

A library profile defines the library version with which CODESYS resolves a library placeholder if a certain compiler version is set in the project.

| “Import”  | Imports a *.libraryprofile file. |
|           | If the import already contains existing placeholder entries, a query appears asking whether CODESYS should overwrite it. |
| “Export”  |Exports an xml file with the extension *.libraryprofile with the assignments of the selected placeholder entries; you can only select a single entry of a “Compiler version”. |

Placeholder resolutions can also be defined in the target device currently in use and even by a specific local specification in the Placeholders dialog in the Library Manager.

Command 'License Manager'

Symbol: ⚑

Function: This command opens the wizard for configuring licenses for CODESYS add-on products. The wizard starts with the “License Manager - Select target” dialog.

Call: Menu bar: “Tools”.

The License Manager can handle licenses for CODESYS add-on products on the local computer, as well as licenses for RTS add-on products on devices. It supports both the installation in a soft container and on a dongle.

Dialog 'License Manager - Select Target'

This is the start dialog of the License Manager wizard. Here you decide where the license will be installed.

| “Workstation” | Local computer |
| "Device"      | Controller. The connection to this device must be configured correctly in order to license (“Communication Settings” tab of the device editor). |

After clicking “Next”, you decide the container where you want to manage the licenses.

Dialog 'License Manager - Select container'

| “Dongle” | A corresponding dongle must be connected to the computer or device. Not all devices support dongles. |
| “Softcontainer” | CODESYS Security Key. A corresponding soft container must be registered in the CodeMeter Control Center. The CODESYS installation provides an existing soft container. |

If you are installing a product on your local computer (“Workstation”), then the “License Manager” opens immediately for the specific selection of the dongle or soft container, and the next actions. This happens after you choose the container type and click “Next >”.

If you are licensing the add-on product for a controller, then first the dialog opens for selecting the device in the network after you click “Next >”. This dialog corresponds to the classic view of the “Communication Settings” tab of the device editor.
| “Container” | Depending on whether “Dongle” or “Softcontainer” was selected: Drop-down list of all CODESYS dongles or soft containers that were found on the computer or device. |
| “Products” | List of all installed products that are subject to licensing. A prepended symbol indicates the existence and validity of the license. On the right side of the window, the following information is displayed for the selected product and corresponding licenses: |
| | “Name” |
| | “Company” |
| | “Unit counter” |
| | “License quantity” |
| | “Usage period” |
| | “Feature map” |
| | “Activation time” |
| | “Expiration time” |
| | “Firmcode” |
| | “Product code” |
| | “Description” |

**“Install Licenses”**

Opens the dialog “Install licenses on <computer> - Select Operation”:

- “Activate license”: Opens the dialog “Install licenses on <computer> - Activate License” (see more below)
- “Request license”: Opens the dialog “Install licenses on <computer> - Request License” (see more below)
- “Install license”: Opens the dialog “Install licenses on <computer> - Install License” (see more below)

**“Additional Functions”**

Opens the menu with the following actions:

- “Return license”: Opens the “Return Licenses” (see more below)
- “Restore license”: This function is available in the case of device licensing only. Opens the “Restore Licenses” dialog (see more below)

**Table 155: “Install Licenses on <computer> - Activate License”**

This is the recommended way to activate a license available via the License Server when you have an Internet connection. Requirement: The computer has an Internet connection.

**“Ticket ID”**

Input field for the ticket ID that you received from the software vendor. The ticket ID consists of five sets of five alphanumerical characters (for example: LYSQ3-ZU93K-24LWC-XGWJ8-5AY7H).

**“License server”**

Drop-down list of the license server that provides the license for activating the product. You receive the server URL from the software vendor.

**“Select Ticket from Repository”**

Opens the “License Repository” dialog.

**“Next”**

CODESYS connects to the license server.

- If the specified ticket contains only one license, then a dialog opens to confirm the successful activation after completion of the server action.
- If the specified ticket contains multiple licenses, then the dialog “Install licenses - Select Licenses” opens with a list of these licenses (see description below).
Table 156: “Install Licenses - Select Licenses”

<table>
<thead>
<tr>
<th>Selection of the licenses to be activated for the ticket which you specified in the dialog “Install Licenses - Activate License”.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>“Name”</strong></td>

<tr>
<td><strong>“Available”</strong></td>
</tr>
<tr>
<td><strong>“Used”</strong></td>
</tr>
<tr>
<td><strong>Total</strong></td>
</tr>
<tr>
<td><strong>Next</strong></td>
</tr>
</tbody>
</table>

Table 157: “Install Licenses on <computer> - Request License”

If the computer does not have an Internet connection, then you can generate a context file from this dialog. The file “WibuCmRaC” is then transmitted to the license server via an Internet-enabled computer. When activation is complete, a license update file “WibuCmRaU” is provided for download.

| **“Software vendor”** | Input field for firmcodes from the software vendor that provided the license for activating the product. As an alternative, you can select the software vendor from the drop-down list. |
| **“Context file”** | Location and name |

Table 158: “Install Licenses on <computer> - Install License”

If you downloaded a license update file from the Internet during software activation, then you can use this dialog to install the license on your dongle. To do this, specify the path of the license update file in the input field.

Table 159: “Return License”

If the license permits, you can return it in order to reactivate it later on another computer.

| **“Ticket ID”** | Field for specifying the ticket ID that was used for licensing. |
| **“License server”** | Drop-down list for selecting the license server that provides the license for activating the product. You receive the server URL from the software vendor. |
| **“Load License(s)”** | Button for showing all current licenses installed for the given ticket ID on the server in the “Licenses” window. |
| **“Licenses”** | List of licenses available on the server for the given ticket ID. The following information for the selected license is displayed next to the window on the right: |
| | ● “Name” |
| | ● “Number of activations” |
| | ● “Return allowed” |
| | ● “Activation type” |
| | ● “Activation date” |
| | ● “Firmcode” |
| | ● “Comment” |
| **“Return License(s)”** | Button for returning the selected license(s). These can be reactivated later on another system. |
Table 160: "Install Licenses - Restore Licenses"

<table>

- Chapter 1.3.1.25.1.19.2 “Tab ‘Communication Settings’” on page 741
- Chapter 1.3.1.25.2.8.4 “Command ‘License Repository’” on page 956

Command ‘License Repository’

Symbol: 

**Function:** This command opens the dialog box “License Repository” for viewing information about the individual licenses.

**Call:** Main menu “Tools”

**Requirements:** CODESYS is in offline or online mode.

In the license repository, after entering the ticket number, you can obtain information about the licenses concerned from the central license server.

To do this you can paste the ticket number(s) from the clipboard or import it/them from a text file.

Table 161: “Tickets”

<table>
<thead>
<tr>
<th>&lt;List of the ticket IDs imported into the repository for components requiring licenses&gt;</th>
<th>If you select an entry in the list of tickets, the name and the status of the licensed component are displayed here.</th>
</tr>
</thead>
</table>
| “Licenses” | ✔️: License available and valid  

  🎎: License found, but invalid  

  🐘: License not found  

  In the right-hand part of the dialog box you will then receive the following information about this license: |
| “Name”: name of the product to be licensed  

  “Item number”: item number in the license server.  

  “Return allowed”: It is possible to have this license deactivated so that it can be re-activated on another system.  

  “Can be activated”: you can have the license activated via the license manager.  

  “Activation quantity”: number of activations that have taken place so far.  

  “Activation date”: date of the current activation  

  “Container serial”  

  “Firm codes”  

  “Comment” |
**"Import Tickets"**

The standard dialog box for browsing the local file system appears. If you open a text file containing one or more "tickets", i.e. license numbers, these are imported into the repository. Alternatively you can also insert the numbers from the clipboard into the list.

**Command 'Device Repository'**

Symbol: ![Command](image)

**Function:** This command opens the “Device Repository” dialog. This dialog is used for managing the devices that are installed on the local system and can be integrated into CODESYS projects.

**Call:** Menu bar: “Tools”.

**Dialog 'Device Repository'**

<table>
<thead>
<tr>
<th>CAUTION!</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not change the internal device repository manually. Do not copy any files to or from the repository. Always use the device repository dialog to install or uninstall devices.</td>
</tr>
</tbody>
</table>

**"Location"**

Shows the device repository directory on the local system. The list box shows the currently set save locations. By default, CODESYS creates the system repository during installation. The devices of the selected location are listed in the “Installed device descriptions” field.

**"Edit Locations"**

Opens the “Edit Repository Locations” dialog.

**Table 162: Dialog 'Edit Repository Locations'**

<table>
<thead>
<tr>
<th>List of the repositories with “Location” and “Name”.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>&quot;Add&quot;</strong></td>
</tr>
<tr>
<td><strong>&quot;Edit&quot;</strong></td>
</tr>
<tr>
<td><strong>&quot;Remove&quot;</strong></td>
</tr>
</tbody>
</table>

**Table 163: “Installed device descriptions”**

<table>
<thead>
<tr>
<th>List of device descriptions in multilevel tree structure. Shows all device descriptions with “Name”, “Vendor”, and “Version”. The top nodes represent device categories, for example PLCs, fieldbuses, and logical devices.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>&quot;String for full-text search in all devices&quot;</strong></td>
</tr>
<tr>
<td><strong>&quot;Vendor&quot;</strong></td>
</tr>
</tbody>
</table>
“Install” Opens the “Install Device Description” dialog.
For the default devices with file type “*.devdesc.xml”. You can also select manufacturer-specific description files, such as “*.gsd” files for PROFIBUS DP modules, “*.eds” and “*.dcf” files for CAN devices.
When you click “OK” to confirm the selection, CODESYS inserts the new device into the device repository. If an error occurs during installation (for example, missing files that are referenced by the device description), then CODESYS reports the error to the lower part of the device repository dialog.

“Uninstall” Removes the selected device. If you delete the device from the device repository, then it is no longer available for use in the programming system.

“Renew Device Repository” Updates all devices in the device repository.
When new versions of import plug-ins are available, some device descriptions may be outdated. The affected devices are marked with a warning symbol (⚠️). This command opens a dialog to confirm the update.

“Download Missing Device Descriptions” Opens when you use devices in your project that are not available in the device repository. When you execute this command, a list of missing devices is displayed. There you can select the corresponding devices for download.

“Details” Opens the “Details” dialog for the selected device description. This dialog provides additional information from the device description file.

NOTICE!
During installation, CODESYS copies the device description files and all additional reference files to an internal location. Therefore, any changes to the original files no longer influence the installed devices. You must reinstall the devices to make any changes effective. We recommended that you change the internal version number of a device description after a modification.

Command 'Scripting' - 'Execute Script File'
Symbol: 🌐
Function: This command opens a dialog for selecting and then executing the script file (*.py).
Call: Menu bar: “Tools ➔ Scripting”.
See also
- Chapter 1.3.1.22 “Using scripts” on page 388

Command 'Scripting' - 'Enable Script Tracing'
Symbol: 🌐
Function: This command makes CODESYS print all commands from the script file to the message view. Use this command for monitoring and debugging scripts. A blue frame around the symbol indicates that the option is active.
Call: Main menu “Tools ➔ Scripting”.
Command 'Scripting' - 'Scripts'

**Function:** This command executes a script that is stored in the ScriptDir folder.

**Call:** Menu bar: “Tools ➔ Scripting ➔ Scripts”.

**Requirement:** The ScriptDir folder exists in the CODESYS installation directory. Python scripts are stored in this folder with the file extension .py.

All scripts that are contained in the ScriptDir folder are executable as menu commands and are sorted alphabetically by file name.

Command 'Customize'

**Function:** This command opens the “Customize” dialog box, where you can customize the menus, toolbars, and keyboard shortcuts according to your individual requirements.

**Call:** Main menu “Tools”

Command 'Options'

**Function:** The command opens the dialog box “Options” for the configuration of the CODESYS options. These options define the behavior and appearance of the CODESYS user interface. CODESYS saves the settings in your current user profile on your local system. The current profile specifies the standard settings.

**Call:** “Tools” menu

Command 'Import and Export Options'

**Function:** This command opens the “Import and Export Options” dialog. Here you can configure the export and import of selected settings of the CODESYS options. The settings are saved to an XML file with the default extension (options.xml).

**Call:** Menu bar: “Tools”.

Dialog 'Import and Export Options'
In the table, you can select the categories of options, either user-specific or machine-specific (computer), whose current settings are to be exported to the XML file.

**“File”**: Path of the export file in the local file system. Example: D:\system1.options.xml.

Button Opened the default dialog to search for an existing file in the local file system, or to create one. The “File type” option export (*.options.xml) is preset.

**“Import selected options”**

**“File”**: Path of the options export file whose contents are to be imported.

Button Opens the default dialog to search for an existing file of type option export (*.options.xml) in the local file system.

After you click “OK” to close the dialog, the settings described in the file are applied to the project.

---

**Command 'Device Reader’**

**Function**: The command opens the standard “Select Device” dialog and reads the license and product information of the selected controller. This license and product information is displayed in the “Device Reader” dialog.

**Call**: Menu bar: “Tools”

**Requirement**: No applications exist on the controller.

---

Command 'Next Editor'

Keyboard shortcut: [Ctrl]+[F6]

Function: This command switches focus from the currently active view to the next view. The next view is identified by the tab to the right of the currently active tab.

Call: Main menu “Window”

Requirement: At least one object is open.

See also
● Chapter 1.3.1.25.2.9.2 “Command ‘Previous Editor’” on page 961

Command 'Previous Editor'

Keyboard shortcut: [Shift]+[Ctrl]+[F6]

Function: This command switches focus from the currently active view to the previous view. The previous view is identified by the tab to the left of the currently active tab.

Call: Main menu “Window”

Requirement: At least one object is open.

See also
● Chapter 1.3.1.25.2.9.1 “Command ‘Next Editor’” on page 961

Command 'Close All Editors'

Symbol: 🗑

Function: This command closes all currently open editor views.

Call: Main menu “Window”

Requirement: At least one editor is open.
Command 'Close All Editors of Inactive Applications'

**Function:** This command closes all editor views for objects that are located directly below a currently inactive application. Object editors in the POU view remain open.

**Call:** Main menu “Window”

**Requirement:** At least one object of an inactive application is open.

See also
- Chapter 1.3.1.25.2.9.3 “Command ‘Close All Editors’” on page 961
- Chapter 1.3.1.25.2.9.16 “Command ‘Close All Editors But This’” on page 965

Command 'Reset Window Layout'

**Function:** This command resets all currently open windows and views to their default positions. You are prompted for a confirmation before the command is executed.

**Call:** Main menu “Tools”

Command 'New Horizontal Tab Group'

**Symbol:** ⏴

**Function:** This command moves the currently active view to a new, separate tab group below the existing one.

**Call:** Main menu “Window” or context menu of the tab

**Requirement:** Several editor views are open as tabs next to each other. If you open another object in the editor, then this is automatically included in the tab group that is currently in focus.

See also
- Chapter 1.3.1.25.2.9.7 “Command ‘New Vertical Tab Group’” on page 962

Command 'New Vertical Tab Group'

**Symbol:** ▼

**Function:** This command moves the currently active view to a new, separate tab group to the right of the existing one.

**Call:** Main menu “Window” or context menu of the tab

**Requirement:** Several editor views are open as tabs next to each other. If you open another object in the editor, then this is automatically included in the tab group that is currently in focus.

See also
- Chapter 1.3.1.25.2.9.6 “Command ‘New Horizontal Tab Group’” on page 962
Command 'Float'

**Function:** This command releases a docked view from its frame in the user interface and reposi-
sitions it on the screen as a floating window.

**Call:** Main menu “Window”

**Requirement:** The application is in online mode.

This window can then be positioned outside of the user interface. Use the “Dock” command to
return a floating window to the frame of the user interface.

See also
- \* Chapter 1.3.1.25.2.9.9 “Command ‘Dock’” on page 963

Command 'Dock'

**Function:** This command returns a floating window, which was released by the “Float” com-
mand, to the frame of the user interface.

**Call:** Main menu “Window”

See also
- \* Chapter 1.3.1.25.2.9.8 “Command ‘Float’” on page 963

Command 'Auto Hide'

Keyboard shortcut: [F7]

**Function:** This command shows or hides a view.

**Call:** Main menu “Window”

Hide simply means that CODESYS minimizes the view to a tab at the bottom of the user inter-
face which is visible only when you move the mouse over the tab. The command functions like
a check box. When a window is hidden, the check box is selected in the menu. When you click
the command again, the checkbox is cleared and the window is shown.

Command 'Next Pane'

Keyboard shortcut: [F6]

**Function:** This command sets the focus on the next pane.

**Call:** Main menu “Window”

**Requirement:** An object is open that contains two or more panes.

Example: If an object is open in the ST editor and the cursor is currently in the declaration sec-
tion, then command sets the focus to implementation section.

See also
- \* Chapter 1.3.1.25.2.9.12 “Command ‘Previous Pane’” on page 963

Command 'Previous Pane'

Keyboard shortcut: [Shift]+[F6]

**Function:** This command sets the focus on the previous pane.

**Call:** Main menu “Window”

**Requirement:** An object is open that contains two or more panes.
Example: If an object is open in the ST editor and the cursor is currently in the declaration section, then command sets the focus to implementation section.

See also

- % Chapter 1.3.1.25.2.9.11 “Command ‘Next Pane’” on page 963

Command ‘Toggle First Pane’

Keyboard shortcut [Alt]+[F6]

Function: This command shows and hides the declaration view.

Call: “Window”.

Requirement: The cursor is positioned in the editor of one of the following objects:

- POU
- Transition
- Method
- Get accessor method of a property
- Set accessor method of a property
- Visualization

You can also toggle the subviews by means of the buttons.

See also

- % Chapter 1.3.1.25.2.9.14 “Command ‘Toggle Second Pane’” on page 964

Command ‘Toggle Second Pane’

Function: This command shows and hides the implementation view.

Call: “Window”.

Requirement: The cursor is positioned in the editor of one of the following objects:

- POU
- Transition
- Method
- Get accessor method of a property
- Set accessor method of a property
- Visualization

You can also toggle the subviews by means of the buttons.

See also

- % Chapter 1.3.1.25.2.9.13 “Command ‘Toggle First Pane’” on page 964

Command ‘Windows’

Function: This command opens the “Windows” dialog box, which lists all open objects. You can then activate or close any of the listed views.
Call: Main menu “Window”

Command 'Close All Editors But This'
Function: This command closes all editor views except the currently open one.
Call: Right-click the tab
Requirement: At least two objects are open.
See also
● § Chapter 1.3.1.25.2.9.3 “Command ’Close All Editors’” on page 961
● § Chapter 1.3.1.25.2.9.4 “Command ’Close All Editors of Inactive Applications’” on page 962

Command 'Select Object in Navigator'
Function: This command selects the object of the active editor in the device tree.
Call: Right-click the tab
Requirement: At least one object is open.
This command is executed automatically when you select the “Track active editor” option for the device tree.
See also
● § Chapter 1.3.1.25.2.9.18 “Command ’Select Parent Object in Navigator’” on page 965

Command 'Select Parent Object in Navigator'
Function: This command selects the parent object in the device tree.
Call: Right-click the tab
Requirement: At least one object is open.
See also
● § Chapter 1.3.1.25.2.9.17 “Command ’Select Object in Navigator’” on page 965

Commands of the Submenu 'Window'
Function: The command activates the selected window.
Call: Main menu “Window”
For each opened editor window the menu “Window” contains a command “<n><object name>”.
Choosing this command activates the corresponding window. In offline mode CODESYS adds the extension “(Offline)”. To differentiate between the implementation or the instances of a function block the extension “(Impl)” or “<instance path>” is added.
Menu 'Help'

1.3.1.25.2.10.1  Command 'Contents'............................................................... 966
1.3.1.25.2.10.2  Command 'Index'............................................................... 966
1.3.1.25.2.10.3  Command 'Find'............................................................... 966
1.3.1.25.2.10.4  Command 'About'............................................................... 967

Command 'Contents'

Symbol: ; keyboard shortcut: [Ctrl]+[Shift]+[F1]

Function: This command opens the CODESYS help.

Call: Menu bar: “Help”.

Command 'Index'

Symbol: ; keyboard shortcut: [Ctrl]+[Shift]+[F2]

Function: This command opens the CODESYS help.

Call: Menu bar: “Help”.

An index search is not possible in the online help. The “Index” tab opens in the offline help.

All index entries of the help are listed alphabetically in the index view.

<table>
<thead>
<tr>
<th>“Look for”</th>
<th>As you type letters into the input field, CODESYS searches automatically for matches in the index list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Display”</td>
<td>Opens the help page for the highlighted index entry in the list and displays the title of the help page and location of the help file (*.chm) in the “Index results for &lt;index entry&gt;” view. When several pages are found and then displayed in this view, then you view a specific help page by clicking its entry in the list. Clicking an entry in the index list achieves the same result.</td>
</tr>
</tbody>
</table>

Command 'Find'

Symbol: 💡

Function: This command opens the CODESYS help.

Call: Menu bar: “Help”.

In the online help, you can run a full-text search from the input field on the top right of the help page. The “Find” tab opens in the offline help.

Table 165: Tab ‘Search’

<table>
<thead>
<tr>
<th>“Search for”</th>

Command 'Init Step'

**Symbol:** ![Symbol](image)

**Function:** This command converts the selected step into an initial step.

**Call:** Main menu “SFC”
After you choose this command, the borders of the step element change to a double line. The previous initial step is automatically displayed as a normal step with a single-line border.

You can also activate and deactivate the property “Init step” in the properties dialog of a step. However, CODESYS does not automatically adjust the settings of other steps.

This command is useful if you want to convert a diagram. When you create a new SFC object, it automatically includes an initial step followed by a transition (TRUE) and a jump back to the initial step.

Please note: In online mode, it is possible to reset the diagram to the initial step using the SFCInit and SFCReset flags.

- § Chapter 1.3.1.24.1.4.7.1 “SFC elements 'Step' and 'Transition’” on page 452

**Command 'Insert Step After'**

Symbol: 

**Function:** This command inserts a step after the selected point.

**Call:** Menu bar “SFC”; context menu in SFC editor

The new step is named Step<n> by default, where n is an incremental number starting at 0 for the first step that is inserted in addition to the initial step. The name can be edited by clicking on it.

See also

- § Chapter 1.3.1.25.2.11.7 “Command 'Insert Step-Transition After’” on page 969
- § Chapter 1.3.1.25.2.11.1 “Command 'Init Step’” on page 967
- § Chapter 1.3.1.24.1.4.7.1 “SFC elements 'Step' and 'Transition’” on page 452

**Command 'Insert Transition After'**

Symbol: 

**Function:** This command inserts a transition after the selected point.

**Call:** Menu bar “SFC”; context menu in SFC editor
The new transition is named Trans<n> by default, where n is an incremental number beginning at 0 for the first transition. The name can be edited by clicking on it.

See also
- § Chapter 1.3.1.25.2.11.7 “Command 'Insert Step-Transition After’” on page 969
- § Chapter 1.3.1.24.1.4.7.1 “SFC elements 'Step' and 'Transition’” on page 452

Command 'Insert Transition'

Symbol: \( \uparrow \uparrow \)

Function: This command inserts a transition before the selected point.

Call: Menu bar “SFC”; context menu in SFC editor

The new transition is named Trans<n> by default, where n is an incremental number beginning at 0 for the first transition. The name can be edited by clicking on it.

See also
- § Chapter 1.3.1.25.2.11.7 “Command 'Insert Step-Transition After’” on page 969
- § Chapter 1.3.1.24.1.4.7.1 “SFC elements 'Step' and 'Transition’” on page 452

Command 'Insert Step-Transition'

Symbol: \( \uparrow \nabla \)

Function: This command inserts a step and a transition before the selected point.

Call: Main menu “SFC”

If you have selected a step, then CODESYS inserts a new step-transition combination. If you have selected a transition, then a new transition-step combination is inserted.

The new step is named Step<n> by default, where n is an incremental number beginning at 0 for the first step that was inserted in addition to the initial step. The new transition is named Trans<n> by default. You can edit the default names directly by clicking the names.

See also
- § Chapter 1.3.1.25.2.11.7 “Command 'Insert Step-Transition After’” on page 969
- § Chapter 1.3.1.25.2.11.1 “Command 'Init Step’” on page 967
- § Chapter 1.3.1.24.1.4.7.1 “SFC elements 'Step' and 'Transition’” on page 452

Command 'Insert Step-Transition After'

Symbol: \( \nabla \uparrow \)

Function: This command inserts a step and a transition after the selected point.

Call: Main menu “SFC”

If you have selected a step, then CODESYS inserts a new transition-step combination. If you have selected a transition, then a new step-transition combination is inserted.

The new step is named Step<n> by default, where n is an incremental number beginning at 0 for the first step that was inserted in addition to the initial step. The new transition is named Trans<n> by default. You can edit the default names directly by clicking the names.

See also
- § Chapter 1.3.1.25.2.11.6 “Command 'Insert Step-Transition’” on page 969
Command 'Add Entry Action'

Symbol: 

**Function:** This command opens the “Add Entry Action” dialog box where you define a new entry action. Depending on the SFC options, a dialog prompt may open for selecting the duplication mode for the new step action.

**Call:** Menu bar: “SFC”; context menu of the selected step element.

**Requirement:** A step element in SFC is selected.

The entry action is opened automatically in the ST editor. The step element contains an \( \equiv \) in the lower left corner.

**Options:**

- **“Copy reference: A new step will call the same actions”:** If the step is copied in SFC, the link to the step action(s) is also copied. The steps copied by each other will therefore call the same actions.
- **“Copy implementation: New action objects are created for a new step.”:** This means that the step actions for a copied step are embedded. By default, the generated action objects appear below an SFC box in the device tree or “POUs” view. These objects contain a copy of the original implementation code of the respective action.

The display of the embedded objects can be activated and deactivated in the tree by means of the “Show Embedded Objects” and “Hide Embedded Objects” commands in the context menu of an SFC object.

See also

- § Chapter 1.3.1.25.2.11.25 “Command ‘Do Not Display Embedded Objects’” on page 976

Command 'Parallel'

Symbol: 

**Function:** This command converts the selected alternative branch into a parallel branch.

**Call:** Main menu “SFC”

**Requirement:** The horizontal connecting line of a branch is selected.
Please note that after you convert a branch, you must check and modify the layout of the steps and transitions before and after the branch.

See also
● % Chapter 1.3.1.25.2.11.11 “Command ‘Alternative’” on page 971

Command ‘Alternative’

Symbol: ☑

Function: This command converts the selected parallel branch into an alternative branch.

Call: Main menu “SFC”

Requirement: The horizontal connecting line of a branch is selected.

Please note that after you convert a branch, you must check and modify the layout of the steps and transitions before and after the branch.

See also
● % Chapter 1.3.1.25.2.11.10 “Command ‘Parallel’” on page 970

Command ‘Insert Branch’

Symbol: ☑

Function: This command inserts a branch to the left of the selected point.

Call: Main menu “SFC”

This command functions similar to the “Insert Branch Right” command.

See also
● % Chapter 1.3.1.24.1.4.7.3 “SFC element ‘Branch’” on page 457
● % Chapter 1.3.1.25.2.11.13 “Command ‘Insert Branch Right’” on page 971

Command ‘Insert Branch Right’

Symbol: ☑

Function: This command inserts a branch to the right of the selected point.

Call: Main menu “SFC”

The type of inserted branch depends on the selected element.

● If the uppermost element of the selected elements is a transition or an alternative branch, then CODESYS inserts an alternative branch.

● If the uppermost element of the selected elements is a step, a macro, a jump, or a parallel branch, then CODESYS inserts a parallel branch with the Branch<x> jump marker, where x is an incremental number. You can edit the default name of the jump marker or define the jump marker as a jump destination.

● If a common element of an existing branch (horizontal line) is selected, then CODESYS inserts the new branch line as a branch line on the far right. If an entire branch line of an existing branch is selected, then CODESYS inserts the new branch line directly to the right as a new branch line.

Please note: You can convert a branch into another type with the “Alternative” and “Parallel” commands.
The following image shows a new inserted parallel branch generated by the “Insert Branch Right” command while the Step11 step was selected. CODESYS automatically inserts a step (Step2 in the example).

Processing in online mode: If \( t_2 \) yields TRUE, then CODESYS executes Step2 immediately after step11 and before \( t_3 \) is passed.

Thus, CODESYS processes both branch lines as opposed to alternative branches.

Example of alternative branch

The following image shows a new inserted alternative branch generated by the “Insert Branch Right” command while the \( t_4 \) transition was selected. CODESYS automatically inserts a step (Step32 in the example), a preceding transition, and a subsequent transition (\( t_{41}, t_{42} \)).

Processing in online mode: If Step3 is active, then CODESYS passes the subsequent transitions (\( t_4, t_{41} \)) from left to right. The first branch line of the main branch with the first transition yielding TRUE is passed. Therefore, only one branch line is processed as opposed to with a parallel branch.

See also

- § Chapter 1.3.1.24.1.4.7.3 “SFC element ‘Branch’” on page 457
- § Chapter 1.3.1.25.2.11.12 “Command ‘Insert Branch’” on page 971
- § Chapter 1.3.1.25.2.11.10 “Command ‘Parallel’” on page 970
- § Chapter 1.3.1.25.2.11.11 “Command ‘Alternative’” on page 971

Command 'Insert Action Association'

Symbol: \( \text{inded} \)

Function: This command assigns an IEC action to a step.

Call: Main menu “SFC”
**Requirement:** A step is selected.

CODESYS inserts the action element to the right of the selected step element.

If you have already assigned one or more actions to the step, they are displayed in an action list. The new action is then inserted as follows:

- If you selected the step element, the action is inserted as the first action of the step at first position of the action list.
- If you selected one of the available actions in the action list, then the action is inserted directly above the selected action.

The left section of the action element includes the qualifier (N by default). You enter the action name in the right section. To set this value, click in the box to obtain an editing frame. You must have already created this action as a POU in the project.

You can also edit the qualifier. Valid qualifiers are described in the chapter “Qualifiers for Actions in SFC”.

See also

- Chapter 1.3.1.25.2.11.15 “Command ’Insert Action Association After’” on page 973
- Chapter 1.3.1.24.1.4.4 “Qualifiers for actions in SFC” on page 445

**Command 'Insert Action Association After’**

**Symbol:** :eq:

**Function:** This command assigns an IEC action to a step.

**Call:** Main menu “SFC”

**Requirement:** A step is selected.

This command functions similar to the “Insert Action Association” command. The difference between the two commands is that CODESYS inserts the new action in the last position of the action list, not the first position. If you select an action in the action list, then CODESYS inserts the new action at the bottom of the list, not at the top.

See also

- Chapter 1.3.1.25.2.11.14 “Command ’Insert Action Association’” on page 972
- Chapter 1.3.1.24.1.4.4 “Qualifiers for actions in SFC” on page 445

**Command 'Insert Jump'**

**Symbol:** :eq:

**Function:** This command inserts a jump element before the selected element.

**Call:** Main menu “SFC”

**Requirement:** A step is selected.

CODESYS automatically inserts the jump with the Step destination. Then, you still have to replace this jump destination with an actual destination by using the input assistant.

See also

- Chapter 1.3.1.24.1.4.7.4 “SFC element ‘Jump’” on page 458
- Chapter 1.3.1.25.2.11.17 “Command ’Insert Jump After’” on page 973

**Command 'Insert Jump After’**

**Symbol:** :eq:

**Function:** This command inserts a jump element after the selected element.
Call: Main menu “SFC”
CODESYS automatically inserts the jump with the Step destination. Then, you still have to replace this jump destination with an actual destination by using the input assistant.

See also
- Chapter 1.3.1.24.1.4.7.4 “SFC element ‘Jump’” on page 458
- Chapter 1.3.1.25.2.11.16 “Command ‘Insert Jump’” on page 973

Command 'Insert Macro'

Symbol: 
Function: This command inserts a macro element before the selected element.
Call: Main menu “SFC”
The new macro is named Macro<x> by default, where x is an incremental number beginning at 0 for the first macro. You can edit the default name directly by clicking the name.
To edit the macro, click “Zoom Into Macro” in the macro editor.

See also
- Chapter 1.3.1.25.2.11.20 “Command ‘Zoom Into Macro’” on page 974
- Chapter 1.3.1.25.2.11.19 “Command ‘Insert Macro After’” on page 974

Command 'Insert Macro After'

Symbol: 
Function: This command inserts a macro element after the selected element.
Call: Main menu “SFC”
This command functions similar to the “Insert Macro” command.

See also
- Chapter 1.3.1.25.2.11.20 “Command ‘Zoom Into Macro’” on page 974
- Chapter 1.3.1.25.2.11.18 “Command ‘Insert Macro’” on page 974

Command ‘Zoom Into Macro’

Symbol: ⬆
Function: This command opens a macro for editing in the macro editor.
Call: Main menu “SFC”
Requirement: A macro is selected.
By choosing this command, CODESYS closes the main view of the SFC editor and opens the macro editor. This is also an SFC editor for editing the section of the SFC diagram that is displayed as a macro box in the main view.
Click “Zoom Out of Macro” to return to the main view.

See also
- Chapter 1.3.1.25.2.11.21 “Command ‘Zoom Out of Macro’” on page 974

Command 'Zoom Out of Macro'

Symbol: ⬇
**Function:** This command closes the macro editor and returns to the main view of the SFC editor.

**Call:** Main menu “SFC”

**Requirement:** A macro is open in the macro editor.

See also

- § Chapter 1.3.1.25.2.11.20 “Command 'Zoom Into Macro’” on page 974

---

**Command 'Paste After'**

Symbol: 📋

**Function:** This command pastes the elements from the clipboard after the selected position.

**Call:** Main menu “SFC”.

---

**Command 'Change Duplication' - 'Set'**

**Function:** This command embeds every step action or transition, which is called by a step or transition in the SFC box, with the caller. In this way, the action or transition object can be called only from exactly this caller (pseudo-embedding). The result is that copying step and transition elements that call actions or transitions automatically creates new action or transition objects. The implementation code is also copied.

**Call:** Menu bar: “SFC”.

For more details about duplication mode, refer to the help page for the SFC element properties and the instructions for adding step actions.

> Pseudo-embedded objects can be hidden in the “Devices” or “POUs” view by means of a command.

See also

- § Chapter 1.3.1.24.1.4.7.6 “SFC element properties” on page 459
- § Chapter 1.3.1.9.3.4.1 “Programming the sequential function chart (SFC)” on page 202

---

**Command 'Change Duplication' - 'Remove'**

**Function:** This command removes the embedding of action, transition, and property objects by a step or transition that calls it for the entire SFC box. In this way, the pseudo-embedding of the action, transition, or property objects is removed. If step or transition elements are copied, which call actions, transitions, or properties, then the copying calls the same actions and transitions as the source.

**Call:** Menu bar: “SFC”.

For more details about duplication mode, refer to the help page for the SFC element properties and the instructions for adding step actions.

> Pseudo-embedded objects can be hidden in the “Devices” or “POUs” view by means of a command.

- Chapter 1.3.1.25.2.11.25 “Command 'Do Not Display Embedded Objects'” on page 976

Command 'Do Not Display Embedded Objects'

**Function:** This command causes action and transition objects, which are embedded in an SFC box by a step or transition, do not appear in the tree.

**Call:** Context menu of an SFC box in the “Devices” or “POUs” view.

Command 'Edit Worksheet'

Function: This command opens the “Edit Worksheet” dialog box in which you set the size of the worksheet.

Call: Main menu “CFC”

Requirements: A CFC editor is active.

Dialog box 'Edit worksheet'
| “Use following dimensions” | Here is where you set the size of the worksheet. Your change is only accepted if the size is sufficient for the existing program. |
| “Adapt the dimensions automatically” | Automatically adapts the size of the worksheet to the size of your program. |
| “Move the working sheet origin relatively” | Shifts the worksheet along the x or y axis. The input of negative numbers is permitted. |

**Command 'Edit Page Size’**

**Function:** This command opens the “Edit Page Size” dialog box, in which you change the size of the page-oriented CFC editor.

**Call:** Main menu “CFC”

**Requirements:** A page-oriented CFC editor is active.

**Dialog box 'Edit page size' dialog box**

| “Width” | Width of the page (minimum 24, maximum 1024). Elements outside of the working area are marked red. |
| “Height” | Height of the page (minimum 24, maximum 1024). Elements outside of the working area are marked red. |
| “Margin width” | Width of the margin (minimum 6, maximum 25% or page width). |
| “Set as standard for new CFC objects” | The current settings are selected as standard for new CFC objects. |

See also

- [Chapter 1.3.1.24.1.6.4.1 “CFC element 'Page’” on page 486](#)

**Command 'Negate’**

**Symbol:** -\( \triangleright \)

**Function:** This command negates the selected function block input or function block output.

**Call:** Main menu “CFC”, context menu

**Requirements:** A CFC editor is active. A function block input or function block output is selected.

**Command 'EN/ENO’**

**Symbol:** \( \triangleright EN \)

**Function:** This command adds a boolean input “\( \triangleright EN \)” (Enable) and a boolean output “\( \triangleright ENO \)” (Enable Out) to the selected function block.

**Call:** Main menu “CFC”, context menu

**Requirements:** A CFC editor is active. A function block is selected.

The added input “\( \triangleright EN \)” activates the function block. The function block is executed only if the input is \( \text{TRUE} \). The value of this signal is output at the “\( \triangleright ENO \)” output.
Command 'None'

Symbol: \[ \text{None} \]

**Function:** This command removes a Reset (R) or a Set (S) from the input of the “Output” element.

**Call:** Main menu “CFC \( \Rightarrow \) Set/Reset”, context menu “Set/Reset”

**Requirements:** A CFC editor is active. The input of an “Output” element is selected.

Command 'R-Reset'

Symbol: \[ \text{R-Reset} \]

**Function:** This command adds a reset to the input of a boolean element “Output”.

**Call:** Main menu “CFC \( \Rightarrow \) Set/Reset”, context menu “Set/Reset”

**Requirements:** A CFC editor is active. The input of an “Output” element is selected.

If an element “Output” has a reset input, the boolean output value is set to “FALSE” as soon as the value of the input is “TRUE”. The value “FALSE” remains at the output, even if the input value changes again.

See also

- Chapter 1.3.1.25.2.12.7 “Command ‘S-SET’” on page 979

Command 'S-SET'

Symbol: \[ \text{S-SET} \]

**Function:** This command adds a set (S) to the input of a boolean element “Output”.

**Call:** Main menu “CFC \( \Rightarrow \) Set/Reset”, context menu “Set/Reset”

**Requirements:** A CFC editor is active. The input of an “Output” element is selected.

If an element “Output” has a set input, the boolean output value is set to “TRUE” as soon as the value of the input is “TRUE”. The value “TRUE” remains at the output, even if the input value changes again.

See also

- Chapter 1.3.1.25.2.12.6 “Command ‘R-Reset’” on page 979

Command 'REF= (Reference Assignment)'

Symbol: \[ \text{REF=} \]

**Function:** This command assigns a reference to an element “Output”.

**Call:** Main menu “CFC \( \Rightarrow \) Set/Reset”, context menu “Set/Reset”

**Requirements:** A CFC editor is active. The input of an “Output” element is selected.
Example:

Declaration:

```plaintext
ref_int : REFERENCE TO INT;
a : INT;
```

CFC:

![Diagram of CFC example]

This corresponds to the ST-code `ref_int REF= a;`

Further information can be found in the description of the data type `REFERENCE TO`.

- Chapter 1.3.1.9.3.2.2 “Programming in the CFC editor” on page 193
- Chapter 1.3.1.24.5.13 “Reference” on page 579

Command 'Display Execution Order'

**Function:** The command temporarily shows a numbered tag for all CFC elements of the programming object.

**Call**:
- Menu bar: “CFC ➔ Execution Order”
- Context menu in the CFC editor

**Requirement:** A CFC editor is active and the “Auto Data Flow Mode” property is selected.

The numbers represent the automatically determined execution order. The execution order is determined by data flow. In the case of multiple networks, it is determined by their topological position in the editor.

The tags are hidden as soon as you click in the CFC editor.

See also:
- Chapter 1.3.1.9.3.2.1 “Automatic execution order by data flow” on page 189
- Chapter 1.3.1.25.2.12.10 “Command 'Set Start of Feedback’” on page 980
- Chapter 1.3.1.25.3.10.12 “Dialog ‘Properties’ - ‘CFC Execution Order’” on page 1054

Command 'Set Start of Feedback'

**Symbol:** ➔

**Function:** The command defines the selected element as the starting point within a feedback.

**Call**:
- Menu bar: “CFC ➔ Execution Order”
- Context menu: “Execution Order”

**Requirement:** A CFC editor is active and the “Auto Data Flow Mode” property is selected. Moreover, a network of the CFC POU contains a feedback, and an element within the feedback is selected.

In the CFC editor, the starting point within the feedbacks is decorated with the ➔ symbol. Then the element has the lowest number in the execution order within the feedbacks. At runtime, the processing of the feedback begins with this element.
Command 'Send to Front'

Symbol: 🎚

**Function:** The command numbers the elements so that the selected elements are located at the front of the execution order.

**Call:** Menu bar: “CFC ➔ Execution Order”, context menu: “Execution Order”

**Requirements:** A CFC editor is active and the “Explicit Execution Order Mode” property is selected. At least one element is selected.

The selected elements get the lowest numbers beginning at 0 while keeping the previous order. The remaining elements are numbered so that their execution order remains the same. The topological positions of the elements are retained anyway.

- Chapter 1.3.1.25.2.12.17 “Command 'Order by Topology'” on page 983

Command 'Send to Back'

Symbol: 🎚

**Function:** The command numbers the elements so that the selected elements are located at the end of the execution order.

**Call:** Menu bar: “CFC ➔ Execution Order”, context menu: “Execution Order”

**Requirements:** A CFC editor is active and the “Explicit Execution Order Mode” property is selected. At least one element is selected.

The selected elements get the highest numbers while keeping the previous order. The remaining elements are numbered so that their execution order remains the same. The topological positions of the elements are retained anyway.

- Chapter 1.3.1.25.2.12.17 “Command 'Order by Topology'” on page 983
Command 'Move Up'

Symbol: 

**Function:** The command numbers the elements so that the selected elements are located one position forward.

**Call:** Menu bar: “CFC ➔ Execution Order”; context menu: “Execution Order”

**Requirements:** A CFC editor is active and at least one element is selected. The “Explicit Execution Order Mode” property is selected.

The selected elements get a numbering decreased by one while keeping the previous order. The selected elements are processed one position earlier. The remaining elements are numbered so that their execution order remains the same. The topological positions of the elements are retained anyway.

- Chapter 1.3.1.25.2.12.17 “Command ‘Order by Topology’” on page 983

Command 'Move Down'

Symbol: 

**Function:** The command numbers the elements so that the selected elements are located one position backward.

**Call:** Menu bar: “CFC ➔ Execution Order”; context menu: “Execution Order”

**Requirements:** A CFC editor is active and at least one element is selected. The “Explicit Execution Order Mode” property is selected.

The selected elements get a numbering increased by one while keeping the previous order. The elements are processed one position later. The remaining elements are numbered so that their execution order remains the same. The topological positions of the elements are retained anyway.

- Chapter 1.3.1.25.2.12.17 “Command ‘Order by Topology’” on page 983

Command 'Set Execution Order'

**Function:** The command opens a dialog for setting the number of the selected element to any value.
Call: Menu bar: “CFC ➔ Execution Order”; context menu: “Execution Order”

Requirements: A CFC editor is active and the “Explicit Execution Order Mode” property is selected. Exactly one element is selected.

The selected element gets the number specified in the dialog. The remaining elements are numbered so that their execution order remains the same. The topological positions of the elements are retained anyway.

See also

- § Chapter 1.3.1.25.2.12.17 “Command 'Order by Topology'” on page 983

Command 'Order by Data Flow'

Function: The command numbers the elements in the program by data flow, or in the case of multiple networks by their topological position in the editor.

Call: Menu bar: “CFC ➔ Execution Order”; context menu: “Execution Order”

Requirements: A CFC editor is active and the “Explicit Execution Order Mode” property is selected.

The command is also available when no element is selected.

The execution order is determined by data flow. In the case of multiple networks, it is determined by their topological position of the networks. All numbered elements of the POU are set accordingly. Afterwards, the execution order is identical to that in auto data flow mode. The topological positions of the elements are retained anyway.

See also
- § Chapter 1.3.1.9.3.2.1 “Automatic execution order by data flow” on page 189
- § Chapter 1.3.1.25.3.10.12 “Dialog 'Properties' - 'CFC Execution Order'” on page 1054

- § Chapter 1.3.1.25.2.12.14 “Command 'Move Down'” on page 982
- § Chapter 1.3.1.25.2.12.17 “Command 'Order by Topology'” on page 983

Command 'Order by Topology'

Function: The command orders the execution order of the elements by their topological position from right to left and from top to bottom.

Call: Menu bar: “CFC ➔ Execution Order”; context menu: “Execution Order”

Requirements: A CFC editor is active and the “Explicit Execution Order Mode” property is selected. At least one element is selected.
The command applies to all elements in the program, even if not all elements are selected when the command is executed. The topological positions of the elements are retained anyway.

Command 'Edit Parameters'

Function: This command opens the “Edit Parameters” dialog box, where you change the constant input parameters of a function block.

Call: Main menu “CFC ➔ Edit Parameters”, or “Right-Click ➔ Edit Parameters”, click the “Parameter” function block.

Requirements: A CFC editor is active. An instantiated function block has VAR_INPUT CONSTANT variables in its declaration.

This functionality applies only to blocks that are inserted in a CFC with CODESYS >= V3.5 SP4.

CODESYS displays blocks with VAR_INPUT CONSTANT variables by the word “Parameter” in the lower left corner of the block.

Dialog Box 'Edit Parameters'

<table>
<thead>
<tr>
<th>“Parameters”</th>
<th>Name of the variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Type”</td>
<td>Data type of the variables</td>
</tr>
<tr>
<td>“Value”</td>
<td>Click into the field to type a value.</td>
</tr>
<tr>
<td>“Initial Value”</td>
<td>Initialization Value</td>
</tr>
<tr>
<td>“Category”</td>
<td>Additional information about the parameters; these values are defined by attributes and cannot be changed in this dialog box.</td>
</tr>
<tr>
<td>“Unit”</td>
<td>● parameterCategory</td>
</tr>
<tr>
<td>“Min”</td>
<td>● parameterUnit</td>
</tr>
<tr>
<td>“Max”</td>
<td>● parameterMinValue</td>
</tr>
<tr>
<td></td>
<td>● parameterMaxValue</td>
</tr>
</tbody>
</table>

“Delete Prepared Parameters” This command is active when you write a prepared value (“Debug ➔ Write Value”).

When you exit the field and the dialog box by clicking “OK”, the value changes are applied to the project.
FUNCTION_BLOCK FB1
VAR_INPUT CONSTANT
  {attribute 'parameterCategory':='General'}
  {attribute 'parameterUnit':= 'm/s'}
  {attribute 'parameterMinValue':= '0'}
  {attribute 'parameterMaxValue':= '100'}
  fbin1:INT;
  fbin2:DWORD:=24354333;
  fbin3:STRING:='abc';
END_VAR

This functionality and the declaration of variables with keyword VAR_INPUT CONSTANT applies only to the CFC editor. In the FBD editor, CODESYS always shows all input parameters on the block, regardless of whether or not they are declared as VAR_INPUT or VAR_INPUT CONSTANT. CODESYS also does not make a distinction about this in text editors.

See also
- § Chapter 1.3.1.24.1.6.3 "CFC editor in online mode" on page 480
- § Chapter 1.3.1.25.2.12.19 "Command 'Save Prepared Parameters to Project'" on page 985

Command 'Save Prepared Parameters to Project'

**Function:** This command saves the prepared parameter values to the project.

**Call:** Main menu “CFC”.

**Requirements:** A CFC editor is active. Parameter values of function block instances are changed in online mode. You are in offline mode.

If the values of constants on the controller are different from the values in the application, then this is indicated by a red asterisk next to the parameter field. Clicking "Incur Prepared Parameters" saves the controller values to the application.

See also
- § "Changing of constant input parameters of function block instances" on page 482
- § Chapter 1.3.1.25.2.12.18 "Command 'Edit Parameters'" on page 984

Command 'Connect Selected Pins'

**Symbol:** 🔄

**Function:** The command establishes a connection between the selected pins.

**Call:** Main menu “CFC”, context menu

**Requirements:** A CFC editor is active. Precisely one output and several inputs are selected.

In order to select the pins you must keep the [CTRL] key pressed while clicking on the pins. Then you execute the command.

See also
- § Chapter 1.3.1.25.2.12.23 "Command 'Select Connected Pins'" on page 986
Command 'Unlock Connection'

Symbol: [Image]

**Function:** This command unlocks a disabled connection.

**Call:** Main menu “CFC ➔ Routing”, context menu “Routing”

**Requirements:** A CFC editor is active. A connection or a connection mark is selected.

You obtain a disabled connection if you change the connections of the automatic routing. If you wish to carry out automatic routing again, you must first unlock a disabled connection.

With a mouse-click on the [Image] icon of a disabled connection you can similarly unlock this connection.

See also
- Chapter 1.3.1.9.3.2.2 “Programming in the CFC editor” on page 193
- Chapter 1.3.1.24.1.6.4.12 “CFC element ‘Connection Mark - Source/Sink’” on page 488

Command 'Show Next Collision'

**Function:** This command displays the next collision in the editor and marks the place concerned.

**Call:** Menu menu “CFC ➔ Routing”, context menu “Routing”

**Requirements:** A CFC editor is active and at least one connection with a collision is present.

This function is very useful if you operate with large networks and see only one sub-area. A collision is additionally indicated to you by the red bordered symbol in the top right corner of the editor.

Command 'Select Connected Pins'

Symbol: [Image]; shortcut: [Ctrl]+[Left Arrow], or [Ctrl]+[Right Arrow]

**Function:** The command selects all pins that are connected to the currently selected line, or connected to the currently selected connection mark in page-oriented CFC.

**Call:** “CFC” menu; context menu

**Requirements:** A CFC editor or a page-oriented CFC editor is active. One line and therefore exactly one connection or exactly one connection mark is selected.

See also
- Chapter 1.3.1.24.1.6.1 “CFC editor” on page 477
- Chapter 1.3.1.24.1.6.2 “CFC editor, page-oriented” on page 479
- Chapter 1.3.1.24.1.6.4.12 “CFC element ‘Connection Mark - Source/Sink’” on page 488

Command 'Reset Pins'

Symbol: [Image]

**Function:** The command restores deleted pins of a function block.

**Call:** Main menu “CFC ➔ Pins”, context menu “Pins”

**Requirements:** A CFC editor is active and a function block is selected.
The command restores all inputs and outputs of the function block just as they are defined in its implementation.

See also
- Chapter 1.3.1.25.2.12.25 “Command ’Remove Unused Pins’” on page 987

**Command ’Remove Unused Pins’**

**Symbol:** 

**Function:** The command removes all unused pins of the selected element.

**Call:** Menu “CFC ➔ Pins”, context menu “Pins”

**Requirements:** A CFC editor is active. An element is selected.

See also
- Chapter 1.3.1.25.2.12.24 “Command ’Reset Pins’” on page 986

**Command ’Add Input Pin’**

**Symbol:** 

**Function:** The command adds a further input to the selected function block.

**Call:** Main menu “CFC ➔ Pins”, context menu “Pins”

**Requirements:** A CFC editor is active. A function block is selected.

See also
- Chapter 1.3.1.25.2.12.27 “Command ’Add Output Pin’” on page 987

**Command ’Add Output Pin’**

**Symbol:** 

**Function:** The command adds a further output to the selected function block.

**Call:** Main menu “CFC ➔ Pins”, context menu “Pins”

**Requirements:** A CFC editor is active. A suitable function block is selected.

See also
- Chapter 1.3.1.25.2.12.26 “Command ’Add Input Pin’” on page 987

**Command ’Route All Connections’**

**Symbol:** 

**Function:** This command cancels all manual changes to the connections in the program and re-establishes the original state.

**Call:** Main menu “CFC ➔ Routing”, context menu “Routing”

**Requirements:** A CFC editor is active.

CODESYS cannot automatically route connections that are fixed by control points. You must remove the control points before executing the command. Use the “Remove Control Point” command to do this. Furthermore you must disconnect connections that have been changed manually and are marked by the icon. Use the “Disconnect Connection” command to do this.
See also

- Chapter 1.3.1.25.2.12.29 “Command 'Remove Control Point'' on page 988
- Chapter 1.3.1.25.2.12.21 “Command 'Unlock Connection'' on page 986

Command 'Remove Control Point'

**Function:** This command removes a control point.

**Call:** Context menu “Routing”

**Requirements:** A CFC editor is active. You have selected a connecting line.

If you move the mouse pointer over a selected connecting line, the existing control points are displayed with yellow circle symbols. Set the cursor on the control point to be deleted and execute the command from the context menu.

See also

- Chapter 1.3.1.24.1.6.4.2 “CFC element 'Control Point'” on page 486
- Chapter 1.3.1.25.2.12.30 “Command 'Create Control Point'” on page 988

Command 'Create Control Point'

**Symbol:** 🔽

**Function:** The command creates a control point on a connecting line.

**Call:** Context menu “Routing”

**Requirements:** A CFC editor is active. The cursor is over a connection.

The control point is created in the position on the connection at which the cursor is located when calling the command. The command corresponds to the “Control Point” element in the “Tools” window.

- Chapter 1.3.1.25.2.12.29 “Command 'Remove Control Point'” on page 988

Command 'Connection Mark'

**Symbol:** ☻

**Function:** This command switches the display of the connection between two elements back and forth between a connecting line and the use of connection marks.

**Call:** Main menu “CFC”, context menu

**Requirements:** A CFC editor is active. A connection or a connection mark is selected.

If you have selected a connecting line, the command removes this line and adds a “Connection Mark - Source” at the output of one element and a “Connection Mark - Sink” at the input of the other. Both are given the same name by default, “C-><n>”, where n is a sequential number.

If you select a pair of connection marks, the command converts these marks into a connecting line.

See also

- Chapter 1.3.1.24.1.6.4.12 “CFC element 'Connection Mark - Source/Sink'” on page 488
Command 'Create group'

Symbol: ☑️

**Function:** This command groups the selected elements.

**Call:** Main menu “CFC ➔ Group”, context menu “Group”

**Requirements:** A CFC editor is active. Several elements are selected.

Grouped elements can only be moved together. The position of the elements is not affected by the grouping.

See also

- Chapter 1.3.1.25.2.12.33 “Command 'Ungroup’” on page 989

Command 'Ungroup'

Symbol: ✗

**Function:** The command undoes a previous grouping.

**Call:** Main menu “CFC ➔ Group”, context menu “Group”

**Requirements:** A CFC editor is active. A grouping is selected.

See also

- Chapter 1.3.1.25.2.12.32 “Command 'Create group’” on page 989

Command 'Prepare Function Block Element for Forcing'

**Function:** This command activates and deactivates the forceability of the inputs for a function block element.

**Call:**

- CFC
- Context menu

**Requirements:** The CFC editor is in offline mode and a function block element is selected.

After executing the command, the command “Force FB Input” is available in online mode to open a dialog for forcing the POU input values.

See also

- Chapter 1.3.1.25.2.12.35 “Command 'Force FB Input’” on page 989
- Chapter 1.3.1.24.1.6.1 “CFC editor” on page 477
- Chapter 1.3.1.12.4 “Forcing and writing variables” on page 315

Command 'Force FB Input'

**NOTICE!**

This kind of forcing uses a data breakpoint internally and is therefore different from forcing with the “Force Values” command or [F7].

Values that were forced by the command “Force FB Input” do not respond to the commands “Show All Forces” or “Unforce Values”.

**Function:** This command opens the “Force Value” dialog to force the selected input of a function block. Forcing can be canceled with the same command and dialog.
Call:

- CFC
- Context menu

Requirements: The "forcability" of the function block is activated (by the command "Prepare Box for Forcing"). The CFC editor is in online mode and the input of the function block is selected in the CFC editor.

In the "Force Value" dialog, you can either specify a value that the input of the function block should be forced, or remove the currently forced value.

After forcing, the input is highlighted in green again. Boolean inputs get a small monitoring view with the forced value. The forced value is displayed in the "Value" column of monitoring views (in the declaration part of the POU or in a watch list).

Dialog 'Force Value'

| "Expression" | Name of the function block input. Example: TON_1.IN. |
| "Type"       | Data type of the input                               |

Table 166: "What do you want to do?"

| "Set a new value to force" | ⚠️ You can specify a new value in the input field. The format must correspond to the data type. |
| "Remove value"            | ⚠️ Forcing at the input is canceled.                                                             |

- Chapter 1.3.1.25.2.12.34 “Command 'Prepare Function Block Element for Forcing'” on page 989

Command 'Use Attributed Member as Input'

Symbol: →

Function: This command allows for connecting a structure member to a scalar type input.

Call: Menu bar: "CFC ➔ Pins"; context menu: "Pins"

Requirements: A CFC editor is active and a function block input is selected.

The member of the structure that is connected to the input of the subsequent function block must be provided with the pragma \{attribute 'ProcessValue\}. The data type of the structure member has to be compatible with the data type of the subsequent input. Inputs connected in this way are flagged with the "V" symbol.
Example

```plaintext
TYPE QINT :
STRUCT
    Status : STRING;
    {attribute 'ProcessValue'}
    Value1 : INT;
    Value2 : INT;
END_STRUCT
END_TYPE

PROGRAM PLC_PRG
VAR
    input1: QINT;
    output1: QINT;
    intValue: INT;
END_VAR

If you do not execute the command “Use attributed member as input” for this link, then a compiler error is issued.

### Command 'Insert Network'

**Symbol:** ![Insert Network](image)

**Shortcut:** `[Ctrl] + [I]`

**Function:** This command inserts a further network in the FBD/LD/IL editor.

**Call:** Main menu "FBD, LD, IL", context menu
**Requirements**: The FBD, LD or IL editor is active. No box is selected.

See also

- % Chapter 1.3.1.24.1.5.4.1 “FBD/LD/IL element 'Network'” on page 470
- % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- % Chapter 1.3.1.25.2.13.2 “Command 'Insert Network (Below)’” on page 993

---

**Command 'Insert Network (Below)'**

Symbol: [ ], shortcut: [Ctrl]+ [T]

**Function**: This command inserts a further network in the FBD/LD/IL editor below the selected network.

**Call**: Main menu “FBD, LD, IL”, context menu

**Requirements**: The FBD, LD or IL editor is active. A network is selected. No box is selected.

See also

- % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

---

**Command 'Toggle Network Comment State'**

Symbol: [··· ], shortcut: [Ctrl]+ [O]

**Function**: The command comments the selected network in or out.

**Call**: Main menu “FBD, LD, IL”, context menu

**Requirements**: The FBD, LD or IL editor is active. A network is selected, but no box is selected.

See also

- % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

---

**Command 'Insert Assignment'**

Symbol: [··· ], shortcut: [Ctrl]+ [A]

**Function**: This command inserts an assignment in the FBD or LD editor.

**Call**: Main menu “FBD/LD/IL”, context menu

**Requirements**: The FBD, LD or IL editor is active. A network is selected, but no box is selected.

**In IL an assignment is programmed via the operators LD and ST.**

See also

- % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

---

**Command 'Insert Box'**

Symbol: [··· ], shortcut: [Ctrl]+ [B]

**Function**: This command inserts a box that is available in the project at the end of the selected network.

**Call**: Main menu “FBD, LD, IL”, context menu
**Requirements:** The FBD, LD or IL editor is active. A network is selected, but no box is selected.

If you select this command the input assistant opens, where you can select the desired box.

See also:
- % Chapter 1.3.1.24.1.5.4.2 “FBD/LD/IL element 'Box'” on page 471
- % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- % Chapter 1.3.1.9.6 “Using input assistance” on page 208

**Command 'Insert Box with EN/ENO'**

Symbol: ☉; shortcut: [Ctrl] + [Shift] + [E]

**Function:** This command inserts a box with a boolean input “Enable” and a boolean output “Enable Out” at the end of the selected network.

**Call:** Main menu “FBD, LD, IL”, context menu

**Requirements:** The FBD, LD or IL editor is active. A network is selected, but no box is selected.

See also:
- % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- % Chapter 1.3.1.9.6 “Using input assistance” on page 208

**Command 'Insert Empty Box'**

Symbol: ☐; shortcut: [Ctrl] + [Shift] + [B]

**Function:** This command inserts an empty function block at the end of the currently selected network.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The FBD, LD or IL editor is active. A network is selected, but no box is selected.

See also:
- % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

**Command 'Insert Empty Box with EN/ENO'**

Symbol: ☒

**Function:** The command inserts an empty box with a Boolean input “Enable” and a Boolean output “Enable Out” at the end of the selected network.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The FBD editor, the IL editor or the LD editor is active. A network must be selected. No other box may be selected.

If “Enable” has the value FALSE at the time of the function block call, then the operations defined in the fb are not executed. Otherwise, if “Enable” has the value TRUE, these operations are executed. The ENO output acts as a repeater of the EN input.

See also:
- % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

**Command 'Insert Box Parallel (Below)'**

**Function:** This command inserts an empty box parallel below the selected function block.

**Call:** Menu bar: “FBD/LD/IL”; context menu.
**Requirements:** A box is selected in the LD editor.
See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

### Command ‘Insert Jump’

**Symbol:** ➔
**Shortcut:** [Ctrl]+[L]

**Function:** This command inserts a jump element before the selected element.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The FBD, LD or IL editor is active. A connecting line is selected.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.24.1.5.4.7 “FBD/LD/IL element ’Jump’” on page 472

### Command ‘Insert Label’

**Symbol:** ⇌

**Function:** This command inserts a jump label into the currently selected network.

**Call:** Main menu “FBD, LD, IL”, context menu

**Requirements:** The FBD, LD or IL editor is active. A network is selected. No jump label is selected.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.24.1.5.4.6 “FBD/LD/IL element ’Label’” on page 472

### Command ‘Insert Return’

**Symbol:** ↓

**Function:** This command inserts an element “Return” in the selected place.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The FBD, LD or IL editor is active. A box output is selected.

If a box is selected, the command “Append Input” is available in the context menu. The input is inserted at the lower end of the box.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.24.1.5.4.8 “FBD/LD/IL element ’Return’” on page 472

### Command ‘Insert Input’

**Symbol:** +, shortcut: [Ctrl]+[Q]

**Function:** This command adds a further input to an extendable box (ADD, OR, ADD, MUL, SEL) above the selected input.

**Call:** “FBD/LD/IL” menu

**Requirements:** The FBD or LD editor is active. An input of a box is selected.

If a box is selected, the command “Append Input” is available in the context menu. The input is inserted at the lower end of the box.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
Command 'Insert Coil'

Symbol: ![coil] shortcut: [Ctrl] + [A]

**Function:** This command inserts a coil into the network.

**Call:** Main menu “FBD, LD, IL”, context menu

**Requirements:** The LD editor is active. A network, a coil or a connecting line is selected, but no box is selected.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Insert Set Coil'

Symbol: ![set coil]

**Function:** This command inserts a set coil into the network.

**Call:** Main menu “FBD, LD, IL”, context menu

**Requirements:** The LD editor is active. A network, a coil or a line is selected, but no box is selected.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Insert Reset Coil'

Symbol: ![reset coil]

**Function:** This command inserts a reset coil into the network.

**Call:** Main menu “FBD, LD, IL”, context menu

**Requirements:** The LD editor is active. A network, a coil or a line is selected, but no box is selected.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

- “Ladder diagram (LD)” on page 183

Command 'Insert Contact'

Symbol: ![contact], shortcut: [Ctrl] + [K]

**Function:** This command inserts a contact to the left of the selected element.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The LD editor is active. A line or a contact is selected.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.24.1.5.4.11 “LD element ‘Contact’” on page 473
Command 'Insert Contact (Right)"

Symbol: 🗓️, shortcut: [Ctrl] + [D]

Function: This command inserts a contact to the right of the selected element.

Call: Main menu “FBD/LD/IL”, context menu

Requirements: The LD editor is active. A line, a contact or a box is selected.

See also
● Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
● Chapter 1.3.1.24.1.5.4.11 “LD element ‘Contact’” on page 473

Command 'Insert Contact in Parallel (Below)"

Symbol: 🕯️; keyboard shortcut: [Ctrl]+[R]

Function: This command inserts a contact with lines in parallel with and below the selected element.

Call: Menu bar: “FBD/LD/IL”; context menu.

Requirements: The LD editor is active. A line or a contact or a box is selected.

You can program closed parallel branches in a LD network as short circuit evaluation (SCE) or OR constructs. SCE branches are displayed with double vertical lines, and OR branches with single lines. Refer to the help page for "Closed branches".

See also

● Chapter 1.3.1.24.1.5.4.14 “Closed branch” on page 475

Command 'Insert Contact in Parallel (Above)"

Symbol: 🕯️; keyboard shortcut: [Ctrl]+[P]

Function: This command inserts a contact with lines in parallel with and above the selected element.

Call: Menu bar: “FBD/LD/IL”; context menu.

Requirements: The LD editor is active. A line, a contact or a box is selected.

You can program closed parallel branches in a LD network as short circuit evaluation (SCE) or OR constructs. SCE branches are displayed with double vertical lines, and OR branches with single lines. Refer to the help page for "Closed branches".
Command 'Toggle Parallel Mode'

**Function:** This command toggles a parallel branch between an OR construct and the Short Circuit Evaluation (SCE).

**Call:** Menu bar: “FBD/LD/IL”; context menu.

**Requirements:** The LD editor is active. A vertical line of a parallel branch is selected.

You can program closed parallel branches in a LD network as short circuit evaluation (SCE) or OR constructs. SCE branches are displayed with double vertical lines, and OR branches with single lines. Refer to the help page for “Closed branches”.

Command 'Insert Negated Contact'

**Symbol:** ⼴, shortcut: \[Ctrl\] + \[K\]

**Function:** This command inserts a negated contact to the left of the selected element.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The LD editor is active. A line or a contact is selected.

See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.24.1.5.4.11 “LD element 'Contact’” on page 473

Command 'Insert Negated Contact Parallel (Below)'

**Symbol:** ⼴

**Function:** The command inserts a negated contact with lines in parallel with and below the selected element.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The LD editor is active. A line, a contact or a box is selected.

See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.9.3.1.2 “Programming ladder diagrams (LD)” on page 186
Command 'Paste Contacts: Paste Below'

Shortcut: [Ctrl] + [F]

Function: This command inserts a previously copied contact with lines below the selected element.

Call: Main menu “FBD/LD/IL ➔ Paste”, context menu

Requirements: the LD editor is active.

See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.24.1.5.4.11 “LD element ‘Contact’” on page 473

Command 'Paste Contacts: Paste Above'

Shortcut: [Ctrl] + [F]

Function: This command inserts a previously copied contact with lines above the selected element.

Call: Main menu “FBD/LD/IL ➔ Paste Contacts”, context menu

Requirements: the LD editor is active. A line or a contact is selected.

See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.24.1.5.4.11 “LD element ‘Contact’” on page 473

Command 'Paste Contacts: Paste Right (After)'

Shortcut: [Ctrl] + [G]

Function: this command inserts a previously copied contact to the right of the selected element.

Call: Main menu “FBD/LD/IL ➔ Paste Contacts”, context menu

Requirements: The LD editor is active. A line or a contact is selected.

See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.24.1.5.4.11 “LD element ‘Contact’” on page 473

Command 'Insert IL Line Below'

Symbol: 

Function: The command inserts an instruction line below the selected line.

Call: Main menu “FBD/LD/IL”, context menu

Requirements: The IL editor is active. A line is selected.

See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Delete IL Line'

Symbol: , shortcut: [Ctrl]+[Del]

Function: This command deletes the selected instruction line.
Call: Main menu “FBD/LD/IL”, context menu

Requirements: The IL editor is active. A line is selected.

See also
● % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Negation'

Symbol: \[\text{_negation}\], shortcut: [Ctrl] + [N]

Function: This command negates the following elements:

● Input/output of a box
● Jump
● Return
● Coil

Call: Main menu “FBD/LD/IL”, context menu

Requirements: The FBD or LD editor is active. The corresponding element is selected.

See also
● % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Edge Detection'

Symbol FBD: \[\text{edge}\], symbol LD: \[\text{edge}\], shortcut: [Ctrl] + [N]

Function: This command inserts an edge detector before the selected box input or box output.

Call: Main menu “FBD/LD/IL”, context menu

Requirements: The FBD or LD editor is active. A box input or box output is selected.

See also
● % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Set/Reset'

Symbol: \[\text{set/reset}\], shortcut [Ctrl] + [M]

Function: In the case of an element with a boolean output, this command switches between reset, set and no mark.

Call: Main menu “FBD/LD/IL”, context menu

Requirements: The FBD or LD editor is active. An element with a boolean output is selected.

See also
● % Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Set Output Connection'

Symbol: \[\text{set output}\], shortcut [Ctrl]+ [W]

Function: This command turns the selected box output into the forwarding box output.

Call: Main menu “FBD/LD/IL”, context menu

Requirements: The FBD or LD editor is active. One of several box outputs is selected.
See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Insert Branch'
Symbol: $\text{\texttrademark}\text{\textregistered}$, shortcut [Ctrl] + [Shift] + [V]

Function: This command creates an open line branch on the selected line.

Call: Main menu “FBD/LD/IL”, context menu

Requirements: The FBD or LD editor is active. An input or an output of a box is selected.

Command 'Insert Branch Above'
Symbol: $\text{\texttrademark}\text{\textregistered}$

Function: This command inserts a line branch above the selected open line branch.

Call: Main menu “FBD/LD/IL”, context menu

Requirements: The FBD or LD editor is active. An open line branch is selected.

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461
- Chapter 1.3.1.24.1.5.4.9 “FBD/LD/IL element 'Branch'” on page 472

Command 'Insert Branch Below'
Symbol: $\text{\texttrademark}\text{\textregistered}$

Function: This command inserts a line branch below the selected open line branch.

Call: Main menu “FBD/LD/IL”, context menu

Requirements: The FBD or LD editor is active. An open line branch is selected.

- Chapter 1.3.1.24.1.5.4.9 “FBD/LD/IL element 'Branch'” on page 472

Command 'Set Branch Start Point'
Symbol: $\text{\texttrademark}\text{\textregistered}$

Function: This command sets the starting point of a line branch on the selected line.

Call: Main menu “FBD/LD/IL”, context menu

Requirements: The LD editor is active. A line is selected.

Command 'Set Branch End Point'

Symbol:  

**Function:** This command sets the end point of a line branch on the selected line.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The LD editor is active. A line is selected. A starting point of the line branch has been set.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Update Parameters'

**Function:** This command enters changes to the declaration of the selected element in the diagram.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The FBD, LD or CFC editor is active. A box is selected. An extending change has been made to the declaration.

The command checks whether a box and its declaration in the declaration editor correspond. The change is accepted for the box only if the declaration was extended. Deletions and overwrites are not updated.

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Remove Unused FB Call Parameters'

Symbol:  

**Function:** This command deletes inputs and outputs of the selected box to which no variable and no value were assigned. However, the default inputs and outputs are always retained.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The FBD or LD editor is active. A box is selected. The box has interfaces to which no value is assigned.

See also

- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'Repair POU'

Symbol:  

**Function:** This command repairs internal inconsistencies in the selected box.

**Call:** Main menu “FBD/LD/IL”, context menu

**Requirements:** The FBD or LD editor is active. The defective box is selected. The editor has found internal inconsistencies in the programming module that can possibly be resolved automatically. CODESYS reports the inconsistencies in the Message window.

This situation is conceivable when editing a project that was created with an older programming system version that did not yet handle the inconsistency concerned as an error.

Command 'View as Function Block Diagram'

**CAUTION!**

*Loss of data!* An error-free conversion requires syntactically correct code. Otherwise parts of the implementation can be lost.

Shortcut: `[Ctrl] + [1]`

**Function:** This command converts the active instruction list or the active ladder diagram into the function block diagram.

**Call:** Menu “FBD/LD/IL → View”

**Requirements:** The LD or IL editor is active.

See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'View as Ladder Logic'

**CAUTION!**

*Loss of data!* An error-free conversion requires syntactically correct code. Otherwise parts of the implementation can be lost.

Shortcut: `[Ctrl] + [2]`

**Function:** This command converts the current function block code or the active instruction list into a ladder diagram.

**Call:** Menu “FBD/LD/IL → View”

**Requirements:** The FBD or IL editor is active.

See also
- Chapter 1.3.1.24.1.5.1 “FBD/LD/IL editor” on page 461

Command 'View as Instruction List'

*If necessary, IL can be activated in the CODESYS options.*

**CAUTION!**

*Loss of data!* An error-free conversion requires syntactically correct code. Otherwise parts of the implementation can be lost.

Shortcut: `[Ctrl] + [3]`

**Function:** This command converts the active function block code or the active ladder diagram into an instruction list.

**Call:** Menu “FBD/LD/IL → View”

**Requirements:** The LD or FBD editor is active.
Command 'Go to'

Symbol:

**Function:** This command allows you to jump to any network.

**Call:** Main menu “FBD/LD/IL”

**Requirements:** The LD, FBD or IL editor is active. A network is selected.

This command opens a dialog box with an input field. Enter the number of the desired network in the input field.

Menu 'Library'

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.3.1.25.2.14.1</td>
<td>Command 'Add Library'................................. 1004</td>
</tr>
<tr>
<td>1.3.1.25.2.14.2</td>
<td>Command 'Try to Reload Library'............................ 1005</td>
</tr>
<tr>
<td>1.3.1.25.2.14.3</td>
<td>Command 'Properties'........................................ 1006</td>
</tr>
<tr>
<td>1.3.1.25.2.14.4</td>
<td>Command 'Placeholders'..................................... 1008</td>
</tr>
<tr>
<td>1.3.1.25.2.14.5</td>
<td>Command 'Export Library'.................................... 1008</td>
</tr>
</tbody>
</table>

Command 'Add Library'

**Function:** The command opens the “Add Library” dialog. In this dialog, you can add libraries to the Library Manager and then integrate them in your application.

**Call:** Menu bar: “Libraries”

**Requirement:** The Library Manager is open in the editor.

Dialog 'Add Library'

<table>
<thead>
<tr>
<th>“Library”</th>
<th>Suitable libraries that are installed in the library repository. For example, the selection of libraries is defined in the device description or by the OEM. By default, the displayed libraries are grouped into categories.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Company”</td>
<td>Creator of the library</td>
</tr>
<tr>
<td>“Advanced”</td>
<td>Opens the advanced “Add Library” dialog</td>
</tr>
</tbody>
</table>

Specific libraries can be blacklisted in a device description. These libraries cannot be added below this device in the Library Manager.

Dialog ‘Add Library’ – ‘Advanced’

You should use this dialog only if you have expert knowledge of library referencing. Using this dialog, you can link special versions or change placeholder definitions.

We recommend seriously that you follow the guidelines for the creation of libraries when developing and referencing libraries.

Table 167: Tab ‘Library’

<table>
<thead>
<tr>
<th>“Company”</th>
<th>Filtering the list according to vendor</th>
</tr>
</thead>
</table>
| “Group by category” | ☑: Display of the libraries in a tree structure grouped in categories.  
☐: Display of the libraries in alphabetical order in a flat structure. |
| “Display all versions” | ☑: Display of all versions of the libraries. Version specification ‘*’ means the latest version available in the repository.  
☐: Display of the latest versions of the libraries only. A multiple selection of libraries is possible in this display. To do this, hold down the [Shift] key and select the entries. |
| “Details” | Opens a detailed view with the library modules. |
| “Library Repository” | Opens the “Library Repository” dialog. There you can install more libraries to your local system. |

Table 168: Tab ‘Placeholder’

| “Placeholder name” | The input field provides a combo box for entering the valid placeholder names that are read from the currently accessible device descriptions. You can also enter a new placeholder name in order to define a free placeholder, which is not resolved by the device or by the library profile. |
| “Default library” | CODESYS uses this library when for any reason no device is available that the resolution defines. In this way it is possible to compile the current project without errors. |

Note about placeholder resolution

For compiler version V3.5.8.0 and later, the following statement applies in the case of library placeholders with a resolution in the device description that are located in the Library Manager of the POU pool. This placeholder is always resolved automatically according to the description of the device that compiles the application.

Command ‘Try to Reload Library’

**Function:** This command tries to reload the selected library.

**Call:** Main menu “Library”.

**Requirement:** A library is selected that failed to load.
If for any reason a library is not available in the defined repository location when a project is opened, CODESYS displays a corresponding error message. Once you have rectified the error, i.e. when the library is properly available again, you can reload the library with this command without having to leave the project.

- Chapter 1.3.1.25.2.8.2 “Command 'Library Repository'” on page 951

Command 'Properties'

**Function:** This command opens the “Properties” dialog box for the library selected in the library manager.

**Call**

- “Library” menu
- Context menu of the selected library
- symbol in the toolbar of the library manager

**Requirement:** A library is selected.

![](notice)

This dialog is intended for library developers. Please use this only if you have profound knowledge of library referencing. In addition, please follow the guidelines for library developers.

- Guidelines for Developing Libraries

Dialog box 'Properties'

**Table 169: “General”**

<table>
<thead>
<tr>
<th>“Namespace”</th>
<th>Namespace of the selected library. By default, this is identical to the library name, unless it was defined explicitly in the project information when the library was created. You can change the namespace for the open project.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong> LA</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>“Standard”</th>
<th>Library that triggers the placeholder when no other trigger is defined or is possible.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Requirement:</strong> The selected library is a library placeholder, and therefore the setting is available.</td>
<td></td>
</tr>
<tr>
<td><strong>Note:</strong> Regarding compiler version 3.5.8.0 and later: In the case of library placeholders that have a trigger in the device description and that located in the library manager of the “POUs” view, the placeholder is always triggered automatically according to the description of the device for which the application is compiled.</td>
<td></td>
</tr>
</tbody>
</table>

If the selected library is developed in compliance with the "Guidelines for Developing Libraries", then we do not recommend that you change the following settings.
Table 170: “Version”

<table>
<thead>
<tr>
<th>Selection of version constraint</th>
