

ABB DIGITAL ENTERPRISE

Asset Performance Management (APM)

From field data to fleet optimisation.

Utilities rely heavily on their field assets

to serve their primary purpose: delivering power to their customers safely, reliably and economically.

Failure of these critical assets has significant financial, legal and safety implications for utilities and creates economic challenges for the customers they serve.

In today's environment, utilities face many challenges: aging assets, stagnant budgets, new operating risks resulting from distributed energy resources and a workforce in transition. Utilities need to take advantage of advances in predictive and prescriptive analytics in order to meet the expectations of high reliability in spite of these challenges.

ABB APM, part of the Digital Enterprise portfolio, is a solution designed to provide health and performance insights to prevent critical asset failures whilst optimising asset lifecycle costs. The solution enables utilities to leverage their online and offline data to drive more intelligent, risk-based approaches to asset management in alignment with industry standards such as ISO 55000 and PAS 55.

As a proven leader in both electrical systems engineering and asset management process innovation, ABB stands ready to support your transformation to smarter asset performance management. Available on premises or via the cloud, APM combines ABB's unparalleled technical expertise with collaborative asset performance management workflows on a world-class, secure and extendible analytics platform.

APM is an essential solution that enables you to:

- Manage asset health cost-effectively
- Effectively address identified risks
- Prioritise repair and replace decisions
- Know 'when + what if': the next level in prognostics

Manage asset health cost-effectively

Get the bigger picture from the myriad sources of asset data available today and know where to focus your in-depth engineering analysis and scarce field resources. APM collects your data via standard and secure interfaces, and ABB's embedded asset models help interpret the available data to provide new insights.

These models not only consistently identify degrading conditions, asset risks and their relative importance, but also provide expert recommendations and priorities for resolution, analysis and mitigation.

APM supports an engineering evaluation workflow, including notification of key new information, visualisation of core data by asset type, equipment assessment documentation to add context to the data, and initiation and tracking of work in common enterprise asset management (EAM) systems. In addition to the embedded ABB models, APM's Open Model Interface (OMI) enables partners, customers and other providers to add additional asset models and leverage machine learning.

Effectively address identified risks

Early identification of changing and degrading conditions is only the first step in an effective asset performance management program. APM's issue tracking ensures that identified risks are reliably mitigated and resolved. The solution highlights key actions that are at risk and tracks the completion of the important actions in the EAM system. It also provides tools for resolving identified risks before they materialise.

Repair and replace priorities

In addition to resolving issues identified through predictive asset analytics, utilities have much more to accomplish on a daily basis, such as regulatory inspections and maintenance. Most utilities find more work in the backlog than resources to complete it. How do you decide where to start in order to have the most significant impact on overall risk? Though a maintenance prioritisation algorithm, APM provides a suggested order that enables a risk-optimised maintenance schedule.

With limited capital budgets, utilities also must make choices related to long-term spending:

- Considering all pertinent factors, which projects provide the greatest risk reduction?
- Which aging equipment effects can be mitigated more cost-effectively?
- Can additional capital expenditures be justified to the regulator or other stakeholders?

The core building blocks of APM, which include a replacement priority algorithm, lay the foundation to help answer questions like these and support better decision making in the capital planning process

When + what if: the next level in prognostics

Next-level prognostics and scenario simulations give utilities the knowledge of 'when' and 'what if'. By helping utilities to better understand the trade-offs and impacts of different possible scenarios, ABB's APM can improve decision-making and operations planning.

This field-proven technology accurately predicted 99% equipment malfunctions with a time horizon of as much as five years, and the solution's accuracy continues to increase over time through its data-driven machine learning capabilities.

Armed with knowledge of when the risk of asset failure will reach a critical level, users will be able to optimise their corrective action schedule, based on market condition forecasts or leveraging pre-scheduled outage windows for example. Simulation experiments such as, 'How much can the forecast asset failure risk acceleration be postponed by reducing load to 90%?' help users evaluate alternative scenarios for optimal decision making.

From passive to active to predictive

MONITORING

- **Is** our asset still functional?
- **Are** all parameters in the normal range?
- **Are** alert and alarm thresholds set correctly?
- **Do** we observe the right parameters?

DIAGNOSTICS

- **What** condition does our asset have?
- **Why** is this asset condition critical?
- **Where** is the source of the problem?
- **How** could we resolve the problem?

NEXT-LEVEL PROGNOSTICS

- **When** will we reach a critical condition?
- **When** can we expect a malfunction or failure?
- **When** will we get an alert or alarm?
- **What happens if** we take a particular action?

Putting it all together

in a collaborative environment and modular architecture for effective change management.

Leading analysts recommend that the most effective adjustment for achieving financially optimised asset management starts with a focused scope (one asset type, one facility, etc.) and scales to benefit the entire fleet with prioritisation across asset types, locations and other classifications. As an example, APM currently supports over one million assets including transformers, circuit breakers and station batteries in a single instance at a leading United States utility delivering power to customers across 13 states.

Digital Enterprise APM's scalable architecture allows new users to be up and running within hours to support quick returns on effort and low-risk pilots. The application meets core IT requirements such as cyber security, single sign-on and standardised integration to common third-party systems. It is also extendible so that analytics can evolve with the maturity of your asset management program. Extensions may be added by the user and maintained with commonly-available skillsets or with your existing reporting tools, avoiding the need for specialised platform training.

An essential part of your business.

The benefits of asset performance management are well documented:

- Increased reliability by identifying, prioritising and resolving risks before they materialise
- Lower maintenance costs by reducing ineffective time based practices and expensive failures
- Lower capital expenditures by getting longer economical life out of existing assets
- Structured knowledge capture that facilitates job transitions
- More efficient compliance management through lean workflows and embedded reporting

Better still, APM is the most proven and efficient asset performance management solution available on the market. Its speed of implementation and extendibility allows you to start lean, experiment and learn, and accelerate your organisation's digital transition whilst savings are materialised.

Real-world benefits of ABB's APM solution¹

\$14.8M reduction in catastrophic events (avoided asset failure)

\$1.2M reduction in unplanned outages²

\$2.0M reduction in planned outage costs²

Capex & working capital optimisation – **\$1.6M**

Recuperated costs equaling almost **2x initial investment**

15% improvement in asset availability²

20% improvement in labor productivity²

10% reduction in asset running costs²

¹ Value model validation by Deloitte; no endorsement is expressed or implied. Upfront buy-in of ~\$4.5M yields \$7.8M in value in year 1.

² APM Examples of customer-demonstrated and validated first year savings for AEP relative to work prioritisation, prevention of asset failure and improved work.

³ These are first-year savings. For five years, the cumulative savings are roughly \$71M for the first phase of assets (transformers, circuit breakers, batteries)

Experience Digital Enterprise

More than a system. An ecosystem.

APM is part of Digital Enterprise, ABB's portfolio of software, services and hardware that enables asset-intensive industries to be more adaptive, collaborative, insightful and predictive. More than a system, it's an ecosystem that embraces your existing technologies, enabling you to gain the benefits of the latest technological advances without sacrificing the investments you have already made.

The Digital Enterprise portfolio is built on ABB's core technology using the latest software development and delivery paradigms. The modular architecture is designed to support customer needs for agile delivery in a changing market. Customers can deploy precisely what is needed, when it is needed—this 'selective consumption' model liberates customers from the forced 'rip & replace' upgrades of the past. Digital Enterprise is interoperable with our customers' investments in other complementary solutions, and for maximum flexibility and choice, Digital Enterprise is available via the cloud or on premises.
