LOGISTICS

Reaching new heights

Working with industry and academic partners, ABB has been able to move beyond theoretical research results to introduce the first limited-version ACS880 drive control program with an anti-pendulum function for stacker crane customers. This new function minimizes mast oscillations and enhances stability, helping customers to reduce material cycling time.

The materials handling industry typically uses stacker cranes to store and retrieve loads. This industry is under increasing pressure to fulfill economic and sustainability targets. Decreased material handling cycle times, demands for reduced costs and energy consumption require the use of ever taller and more lightweight cranes (less metal). These structurally less stiff cranes should position loads rapidly and precisely while maintaining workload stability and safety. Yet, such crane frame structures are flexible by nature; crane motion can result in harmful mast oscillations. The inertial force of acceleration or braking movement can reduce stability and derail positioning accuracy; compromising safety and possibly damaging the material being moved. Moreover, the dynamics of these machines
develop an anti-pendulum function. Enter ABB to provide these customers with an anti-pendulum solution to minimize mast oscillations, accurately and rapidly.

How it all began and establishing a path
Understanding the important connection between collaboration and innovation to achieve the full potential of their drive control solutions, ABB works closely with their business and academic partners. In early 2017, ABB began a collaborative investigation to determine the feasibility of including an anti-pendulum function and functional safety (and additional base control features) in their ACS880 Position control program for stacker cranes. Having relied on an ACSM1 motion control drive for stacker crane control for over a decade, one of ABB’s customers sought a solution to an expanding challenge: achieve higher throughput economically and sustainably in ever taller warehouses, yet avoid mast oscillations in a 68-ton 32 m tall stacker crane that must lift and shift 6-ton loads.

ABB joined forces with the University of Linz, Austria (JKU) to investigate such an

A dependable partner
With sustainability and performance paramount, stacker crane manufacturers know they can depend on ABB to provide control strategies to fit their logistical needs and meet environmental and economic goals. ABB introduced ACSM1 motion control drives in 2007. These flexible and versatile drives provide general speed and torque as well as versatile motion control features. Used to control induction, synchronous and asynchronous servo- and high torque motors with various feedback devices, these drives are used by stacker crane customers. Building on innovation, ABB introduced the ACS880 Position control program as a successor to the classic ACSM1 motion control drives for stacker crane customers in 2018 – with absolute and relative positioning, profiled positioning, position synchronizing and fast position latching. Nonetheless, small scale crane manufacturers have yet to develop an anti-pendulum function. Enter ABB to provide these customers with an anti-pendulum solution to minimize mast oscillations, accurately and rapidly.

Stacker crane manufacturers know that ABB will provide control strategies to fit their logistical needs.
In 2017, ABB began exploring an anti-pendulum function for ACS880 Position control program. The theoretical-, testing- and design phases critical, an intense partnership evolved with each partner doing what they do best. And, because there is usually a gap between what is theoretically possible and what is practically viable, ABB expanded the preliminary results through tests and design iterations, turning them into tangible benefits that are manifested in a new ACS880 Program control anti-pendulum function.

The research projects: an introduction

Having established a collaborative synergy between ABB and JKU, the parallel research projects focused on:

• Developing mathematical models to capture the dynamics of single mast stacker cranes: the JKU test bench (TB), small-scale demonstrator model, and ABB’s stacker crane (ABB SC).
• Calibrating the generic model by identifying the parameters of the specific cranes in question.
• Creating a control scheme to generate the position and reference speed for the crane so that it does not oscillate during motion.
• Determining a feedback system so that residual oscillations due to model imperfections or external disturbances are cancelled.

Theoretical basis: mathematical models

To determine the feasibility of creating an anti-pendulum control function, flatness-based trajectory generation approaches were applied to ABB stacker cranes [1,2,3]. Test crane dynamics of both the ABB SC and JKU TB were modeled as a mixed-dimensional system that included partial differential equations (PDEs), ordinary differential equations (ODEs) and consideration of boundary conditions.

In each case, the PDEs are discretized by employing the Rayleigh-Ritz Method so that a pure ODE system is achieved to facilitate ease of system analysis and controller design at a later stage.

Nevertheless, the Rayleigh-Ritz discretization requires the choice of an ansatz function; the
of equations, ABB and JKU could obtain a sound model of the ABB SC→01.

Model calibration: identifying parameters
The sound theoretical model serves as a blueprint for describing the dynamics of stacker cranes. Nonetheless, for the practical application of the model to a specific stacker crane model, parameters must be identified. These unknown parameters were calibrated: flexural rigidity, $E I$, density of the mast, $p A$ and mast damping coefficient, $d_m$.

Using measurement data from a real-world stacker crane fitted with a ACSM1 motion control drive, ABB could derive system parameters. Accelerating the drive unit so that the crane travels at constant speed without oscillating;
then abruptly stopping the system, results in mast oscillations. The lifting unit is moved to two different positions (heights). Once the main oscillation frequency and its exponential decay was determined, a system of nonlinear equations relating the oscillation frequencies and damping ratios to the parameters \(E_I, \rho A \) and \(d_m\), were solved. Parameters were then applied to a third height as a control.

Having identified mast and drive parameters of the ABB SC, the resultant calibrated dynamic models were then directly used for drive control development.

**Trajectory tracking and robustness studies**

To ensure that oscillation is minimized during crane motion, ABB developed control schemes to generate position and reference speed for the cranes.

Using polynomials to parameterize all system variables by means of flat outputs and derivatives, ABB’s resulting equations similar to [3], depend on the flat outputs and their time derivatives; these were implemented in the trajectory generator → 02a.

Here, a well-tuned P-PI cascade tracking the references generated by the flatness-based trajectory planner works well if no external

ABB’s control system superbly and robustly positions the stacker crane with minimal residual oscillation.
an anti-pendulum control function that is easy to engineer yet delivers excellent performance and reliability.

ABB's new control method for point-to-point positioning of the stacker crane includes an input shaper →04a, trajectory planning, with the existing control chain of the ACS880 Position control program (motion profile generator, position controller and speed controller) [7,8].

Input shapers are designed so that a created command signal tends to cancel its own vibration, reducing the residual swaying of the disturbances are present →02b. To mitigate mast oscillations, in case of such disturbances, the cascade was extended with integrated feedback in the driving unit by means of a damping-injection control law [5,6].

By considering lifting-unit mass and beam parameters as uncertain quantities (although they were known) robustness was determined. The result is an amazingly robust system in both the JKTU TB and the ABB SC cases →03. Critically, only major system parameter deviations impacted beam oscillations in the JKTU TB; slight differences in lifting mass (+/- 10 percent) had almost no impact on the ABB SC; these are excellent results.

Translating theory into design
ABB strives for the best performing and economical control systems for their customers; this means using the most promising results. Therefore, ABB used the verified modeling →01 and the motion control results →03, as a basis, to develop an anti-pendulum control function that is easy to engineer yet delivers excellent performance and reliability.

ABB's new control method for point-to-point positioning of the stacker crane includes an input shaper →04a, trajectory planning, with the existing control chain of the ACS880 Position control program (motion profile generator, position controller and speed controller) [7,8].

Customers can now accurately move loads, rapidly and affordably in the tallest of warehouses.

Translating theory into design
ABB strives for the best performing and economical control systems for their customers; this means using the most promising results. Therefore, ABB used the verified modeling →01 and the motion control results →03, as a basis, to develop an anti-pendulum control function that is easy to engineer yet delivers excellent performance and reliability.

ABB's new control method for point-to-point positioning of the stacker crane includes an input shaper →04a, trajectory planning, with the existing control chain of the ACS880 Position control program (motion profile generator, position controller and speed controller) [7,8].

Customers can now accurately move loads, rapidly and affordably in the tallest of warehouses.
Control schemes are illustrated.

ACS880 anti-sway crane control program (for EOT cranes) + H5050 scheme is illustrated in which the reference input changes are divided into two segments where the second is delayed in relation to oscillation cycle time.

ACS880 anti-pendulum position control scheme for stacker cranes is similar to the crane control scheme except that the division is into three segments instead of two. This is more robust against oscillation time error.

Motion profiles generated that illustrate the impact of enabling the anti-pendulum functionality. The black line: 01.10 Motor torque, grey: 86.03 Actual speed, and red: 88.07 is estimated acceleration.

6 Motion profiles generated that illustrate the impact of enabling the anti-pendulum functionality. The black line: 01.10 Motor torque, grey: 86.03 Actual speed, and red: 88.07 is estimated acceleration.

Once the motion profile generator was selected and modified, ABB could design, and successfully implement the system identification procedures once the crane has reached its target position.

Because input shaping and damping injection (which dampens the existing residual swaying once the crane has reached its target position) yielded good results, demonstrating excellent performance even when only one function was enabled [7], ABB’s experts included only input shaping (with a three-step input shaper) in the final anti-pendulum control function, which is currently available → 04 – 05 [8].

Oscillation swing time curves of empty and full loads based on crane target height. Below oscillation break height, mass of the load is not considered to impact the oscillation swing time; above the oscillation break height, the mass of the load will have a proportional effect on the oscillation swing time.
For storing and obtaining the needed system parameters, i.e., damping ratio and swing time.

In this way, ABB’s designed control system superbly and robustly positions the stacker crane with the desired dynamics and minimal residual oscillation.

**ACS880 Position Control Anti-pendulum Function**

Achieving a practical, yet economical, anti-pendulum function with excellent performance was ABB’s goal from the onset. By designing a control function with a precise dynamic model of a stacker crane, an accurate calculation of motion is now possible →05b; ABB’s resultant ACS880 ACS880 Position control program firmware (+N5700) in a special version with the anti-pendulum function is the culmination of these goals [8]. System stabilization is now possible in as little as 0.25 s.

Here, the standard position reference profile is modified so that it suppresses oscillations initiated by the motion profile itself to a load, acting as an oscillating mass →06. Pendulum suppression performance relies on the calculated system oscillation swing time, the time between two successive peaks of the decaying vibration, calculated for every operating point by the system based on curves (for every mass and height of the load) →07, additional parameters that the user must set, and the damping ratio, a constant given by the user. With the damping ratio \( \zeta \) calculated using logarithmic decrement:

\[
\zeta = \frac{\ln \frac{A_1}{A_2}}{2\pi}
\]

where \( A_1 \) and \( A_2 \) are the vibration amplitudes at two successive peaks of the decaying vibration; and the other parameters easily obtained or applied, ABB’s stacker crane customers will now be able to minimize unwanted oscillations for every storage floor and load encountered.

**Delivering Viable Products**

Following the commissioning of the first ACS880 Position control program for stacker cranes in spring of 2019, ABB implemented the anti-pendulum function prototype. Successfully field-tested at an end-customer site in summer 2020, the first product-level limited-version ACS880 drive control program with an anti-pendulum function was commissioned and released with customized software for a stacker crane customer in early 2021. A new version that targets ABB’s general stacker crane customers is currently being developed and is scheduled for release in 2022.

Thanks to the close collaboration with industry and academia, ABB has been able to provide stacker crane customers with an ACS880 Position control program with an anti-pendulum function that fits their needs. Stacker crane systems can now accurately move loads more rapidly and therefore more affordably without fear of oscillations, even in the tallest of warehouses →08. By reducing the time required to stabilize the structure from approximately 3.0 s to 0.25 s, material cycling times can be significantly reduced.

Moving beyond theoretical results to include tests and design iterations, ABB turns ideas into tangible innovative products. This is one way that ABB helps customers handle demanding logistic activity to better meet challenging economic and sustainability targets so important in today’s competitive business environment. •

**Acknowledgements**

This work would not have been possible without the dedication and previous research efforts of many individuals. We would like to extend our gratitude to Tobias Malzer, Markus Schöberl, Martin Staudecker, Matias Niemelä and Stefan Baum.
With pressure to decrease material handling cycle times in ever taller warehouses, Stacker crane customers now depend on ABB to provide innovative solutions, such as the anti-pendulum function, to meet their demanding logistics needs.
