Safety

For your safety!

- Strictly follow this manual.
- Only install switchgear in indoor conditions suitable for electrical equipment.
- Ensure that installation, operation and maintenance is only carried out by professional electricians.
- Comply fully with the standards in force (IEC or local), the connection conditions of the local power utility and the applicable safety at work regulations.
- Ensure that installation, operation and maintenance is only carried out by professional electricians.
- Observe the relevant information in the manual for all actions involving the switchgear.
- For use of the circuit-breaker, refer to the relative manual.

Skilled personnel

All the installation, commissioning, running and maintenance operations must be carried out by skilled personnel with in-depth knowledge of the apparatus.

When carrying out maintenance work, the regulations in the country of installation must be strictly complied with.

Maintenance work must only be performed in a professional way by trained personnel familiar with the characteristics of the switchgear, in accordance with all the relevant IEC safety regulations and those of other technical authorities, also complying with any further instructions of primary importance. It is recommended that ABB service personnel be called in to perform the servicing and repair work.

Critical messages

Pay special attention to the information shown in the manual by the following symbol:

- DANGER - identifies the most serious and immediate hazards which cause serious personal injury or death
- WARNING - identifies hazards or unsafe practices which can result in serious personal injury or death
- CAUTION - identifies hazards or unsafe practices which can result in minor personal injury or product or property damage
- NOTE - identifies important procedures or requirements that, if not followed, can result in product or property damage

WARNING

Make sure that the specified electrical ratings are not exceeded under switchgear operating conditions. Keep the manuals accessible to all personnel involved in installation, operation and maintenance. The user's personnel must act responsibly in all matters affecting safety at work and correct handling of the switchgear

WARNING

Always follow the instructions in the manual and respect the rules of good engineering practice! Hazardous voltages can cause serious injury or death! Before proceeding with any work on this equipment, disconnect the power supply and earth live parts. Follow the safety regulations in force on the installation site

Contact us!

If you have any further questions about this manual, our field service team will be pleased to help. See the backside of this manual for contact information.
General aspects

UniSec is indoor air insulated switchgear for medium voltage secondary distribution. It is the result of ABB’s quest for continuous innovation, following a vision to meet ever-changing market needs.

This new series of switchgear offers a wide range of technical and long-term solutions. Safety and reliability, user-friendliness, simple installation, as well as environmental sustainability were the driving forces in its development.

UniSec is constructed by placing standardized units side by side in a coordinated way. Construction and testing are carried out in the factory.

Operation and maintenance manual

This manual provides information on operation and maintenance of UniSec units. It includes details about the units and service conditions. Operation of the switchgear is illustrated in this manual and the instructions for replacing and mounting new apparatus are also given.

To help you use UniSec, there is a troubleshooting chapter, with typical problems you might face when using the switchgear.

The final chapter gives an example of product recycling. There is a separate instruction manual for installation of the switchgear.

</table>

Table 1. IEC Standards
Service conditions

Normal service conditions
The switchgear is designed for use in normal indoor service conditions as defined in the relevant IEC standards (see Table 1.). If the conditions deviate from the normal service conditions defined in the IEC standards (IEC 62271-1), this has to be agreed separately with the manufacturer.

</tbody>
</table>

Pollution
The ambient air must not be significantly polluted by dust, smoke, corrosive and/or flammable gases, vapours or salt.

(1) Contact ABB for -25 °C operating temperatures and -40 °C storage temperatures

Table 2. Service conditions

Special service conditions
At site altitudes above 1000 m, the effects of the reduction in dielectric strength of the insulating air must be taken into account (please refer to IEC standard 61271-1). Increased ambient temperatures must be compensated in the design of the busbars and branch conductors, as well as for the components, otherwise the current carrying capacity will be limited.

DANGER
When the switchgear operate in areas with high humidity and/or major temperature fluctuations, there is a risk of dew deposits, which must remain an exception in normal service conditions for indoor switchgear. Preventive action (e.g. fitting electric heaters) must be taken into consideration with the manufacturer to avoid this condensation phenomenon and any resulting corrosion or other adverse effects. Control of the heaters depends on the relative project and details must be taken from the order documents.

</tr>
</tbody>
</table>

(1) Only for panels with withdrawable circuit-breaker only for panels up to 17.5 kV
(2) Only LSCZA 750mm H2000

Table 4. Internal arc classification

NOTE
UniSec switchgear must be installed in closed rooms suitable for electrical equipment. This means that access must be restricted to authorized personnel only
2. Design and construction

2.1 Construction of the switchgear and main components

**General aspects**
In designing the UniSec unit, special attention was paid to increased reliability of use and improved personnel safety in the case of an arc fault. In order to improve personnel safety and maintenance work, the units are divided into separate compartments. The compartments are designed to withstand the very rapid rises in temperature and pressure caused by a possible arc fault condition.

2.2 Conception of the units and apparatus

**2.2.1 Compartments**
UniSec is class LSC2A and LSC2B switchgear (for units with withdrawable circuit-breaker) according to the IEC62271-200 Standard.

**Compartments**
The unit is divided into the following compartments:

1. **Busbar compartment**
The air-insulated busbar compartment is situated on the top of the unit and usually runs through the whole switchgear. A measuring or isolating unit placed in the middle of the switchgear divides the main busbar compartment.

Tools are required to open the busbar compartment. It is designated a “tool-based accessible compartment”.

**WARNING**
When opening the busbar compartment, the user should take measures to ensure safety (i.e. busbars must be de-energized and earthed)

2. **Switch-disconnector compartment**
The three-position switch-disconnector is located between the main busbar and cable compartments. Its housing consists of a top half made of epoxy resin and a bottom half of stainless steel and is filled with SF6 gas, with the electrical parts of the switch-disconnector inside it. The bottom stainless steel part forms a metallic partition between the busbar and cable compartments. This partition makes the product safer by improving protection against contacts.

**WARNING**
This compartment is designated a “non-accessible compartment”. It must not be opened
3. Cable compartment
The cable compartment is reserved for the incoming/outgoing feeder cable connections, fuses, earthing switches or instrument transformers.
In the units classified LSC2A/PM, the removable circuit-breaker (vacuum or gas) is housed on the left side of the cable compartment.
If the units are equipped with switch-disconnectors, there are interlocks to ensure that live parts inside are de-energized and earthed before opening. This compartment is then designated an “interlock-controlled accessible compartment”.
If the units are not equipped with switch-disconnectors, the compartments are provided with padlocking facilities. This compartment is therefore designated as an “interlock-controlled accessible compartment”.

4. Apparatus compartment (only for units with withdrawable circuit-breaker)
The three-pole monoblocs are positioned in the apparatus compartment and house the fixed connection contacts of the circuit-breaker with the busbar and cable compartments.
The shutters are of the metal type (PM) or insulation type (PI) and are worked automatically during movement of the apparatus from the racked-out to the racked-in position and vice versa.
The metal shutters allow metal partitioning between the busbar compartment and the cable compartment. For units up to 17.5 kV, instead the insulation shutters allow insulated segregation between the busbar compartment and cable compartment.

5. Control compartment
This compartment houses the switch-disconnector and earthing switch operating mechanisms, mechanical interlocks with position indicators, trip coils, voltage indicators and auxiliary contacts.

6. Auxiliary circuit compartment
Questa cella può essere in versione base o grande a seconda del tipo di applicazione. Qui sono alloggiati il cablaggio secondario, i blocchi terminali e i relè.

7. Pressure relief flaps
The pressure relief flaps on the back of the units direct the pressure waves and gases to optional arc ducts and filters behind the switchgear. This way, the risk of harm to the operator due to an internal arc is minimized. The rear plate of each unit has two arc pressure relief openings:
• The upper gas relief flap is for the busbar and switching compartment
• The lower gas relief flap is for the circuit-breaker and cable compartment

**WARNING**
If the units are not equipped with earthing switch on the load side of the DIN current transformers, use an external earthing system to earth the components on the load side of the earthing switch

2.2.2 Service continuity

**LSC Category**
For switchgear, the Loss of Service Continuity Category (LSC) describes the extent to which other compartments and/or functional units can remain energized when a main circuit compartment is opened. According to IEC 62271-200, the Loss of Service Continuity (LSC) of UniSec switchgear is LSC2A-PM and LSC2B-PM or LSC2B-PI for the withdrawable circuit-breaker units. Letter code PM or PI means that the segregation partitions between live parts and open compartments are the metallic or insulating type.

</tr>
</tbody>
</table>

Table 5.2. Access to the LSC2B unit compartments (according to IEC 62271-200 Standard)
2. Design and construction

2.3 Enclosure and partitioning

Material
The enclosure and internal partitions of the units are made of 2 mm thick galvanised steel sheet. Doors and end plates are thoroughly cleaned and treated against corrosion before receiving a high quality coating of paint. The finishing coat is RAL 7035 colour (special colours by agreement). The doors of the cable compartments are pressure-resistant and are fitted with inspection windows. The auxiliary circuit compartment for secondary equipment is completely protected from the high voltage area thanks to the steel sheet partition.

Cable and circuit-breaker compartments
The high voltage compartment (circuit-breaker or cable compartment) is fitted with inspection windows. Neighbouring units are partitioned from one another by the side walls of each unit. The front of the unit is closed by a pressure-resistant removable door. On the sides of the end units, cover plates ensure a good appearance and are mechanically and thermally arc proof.

Ventilation openings
Openings in the outer enclosure are needed for ventilating the extra heat, which may be generated in the busbars and branch connections. The pressure relief flaps form the ventilation openings for the units.

2.4 General information on interlocking

The function of the interlocks is to prevent incorrect operations, guaranteeing the highest level of safety for both personnel and the plant. The interlocking function is also operational even if the doors of the cable compartment, operating mechanism compartment and apparatus compartment are open.

Purpose
The purpose of the interlocking devices is to prevent incorrect operation of the switch-disconnector and earthing switch and thereby to ensure personnel safety. Interlocking is in operation even if the doors to the cable and control compartments are open.

Interlocking
Interlocking includes:
- Normal interlocking, which is fitted as standard on all the units
- Additional interlocking devices, which are optional and to be chosen by the customer

Interlocking units for the LSC2A-PM units
Positions
Switch-disconnector, switch-fuse combination units, and circuit-breaker units have two operating holes for the switch-disconnectors:
- upper hole for the “open” and “closed” position
- lower hole for the “earthed” position.

Interlock between the operating lever of the switch-disconnector and the motor
This is an electrical lock that prevents the motor from functioning when the operating lever is in the seat of the line and earth switch-disconnector. If a motor operator is installed, the spring is charged by a motor operated by pushbuttons on the panel front. Insertion of the operating lever, which can only be performed in the open-closed positions, acts on a microswitch which cuts off the power supply to the motor, thereby preventing it from operating.

Locking devices
The padlock prevents use of the operating handle in any position (“closed”, “open” and “earthed”).

Earthing switches
Interlocking also applies to the earthing switches used to earth the bottom of the fuses and current transformers. These switches are mechanically connected to the operating device of the GSec switch-disconnector and work simultaneously with the GSec when it is operated between the “open” and “earthed” position.

Door open
The GSec switch-disconnector is locked in the “earthed” position until the door is closed.

Additional interlocking
Interlocks
- For separate units, interlocking between the circuit-breaker and the GSec can be arranged with key interlocks.
- Interlocking can be checked with a microswitch when the motor is activated.
- Double key lock on the GSec switch-disconnector. Additional locks, such as Ronis and Profalux, are also possible.

Table 6. shows different interlocks
Type I1: MV/LV/Transformers
Prevents earthing switch closing on a transformer protection unit unless the LV circuit-breaker is locked in the "open" or "isolated" position. Prevents access to the transformer if the earthing switch for transformer protection has not been closed.

Type I2: Prevents earthing switch closing of a load-side unit unless the line-side switch is locked in the "open" position.

Type I3: Prevents simultaneous closing of two switches.

Type I4: Cross interlocking
Prevents an earthing switch closing if the switch of the other unit has not been locked in the "open" position.

Type I5: Prevents the earthing switch of the incoming unit from closing unless the switch-disconnector is locked in the "open" position.

Table 9.

Table 10.

Accessory devices

Fail-safe on the shutters
The device locks the shutters when the apparatus is removed from the compartment. The operator cannot open the shutters manually. The shutters can only be activated by the apparatus truck or by the service trucks.

Apparatus compatibility matrix - switchgear unit
The apparatus multi-contact plug and relative socket of the switchgear unit are fitted with a mechanical die, which makes apparatus racking-in into a switchgear unit with inappropriate rated current impossible.

Circuit-breaker mechanical operating mechanism
The apparatus compartment is fitted with a mechanical devices which makes it possible to operate closing and/or opening of the circuit-breakers directly by means of the front control pushbuttons, keeping the door closed.
The commands can be given with the circuit-breakers in the service and withdrawn position.

Table 11.
3. Operation of the switchgear

3.1 General warnings and precautions

⚠️ DANGER
Do not walk on the roof of the units

⚠️ Danger
Switchgear operations must be carried out with the doors closed

⚠️ WARNING
Operations and any type of work must be carried out by trained and specialized personnel who are familiar with the plant and follow all the safety regulations in accordance with the IEC Standards and other regulations in force, as well as any local work regulations and instructions

3.2 Putting into service

3.2.1 Preparatory work
Before connection to the medium voltage network
The following work must be carried out in preparation for putting into service:
- Check the general condition of the switchgear for any damage or defects.
- Visually inspect the switching devices, isolating contacts, insulating parts, etc.
- Check the connection of the main earthing busbar to the installation earthing conductor (following the appropriate safety regulations).
- Check the paintwork for any damage and, where necessary, touch up as described in section 5.3.
- Remove all residues of materials, foreign objects and tools from the switchgear.
- Clean the switchgear, rubbing down insulating parts with a clean, dry, soft, non-fraying cloth. Remove any traces of greasy or sticky dirt as described in section 5.4.
- Correctly remount all covers etc. removed during assembly and testing procedures.
- Preparatory work for circuit-breakers:
  - Clean the insulating parts with a clean dry cloth
  - Check that the upper and lower terminals are clean and free from any deformation caused by shocks received during transport and storage
  - If the HD4 circuit-breaker is equipped with a pressure measuring device, it is advisable to check the SF\textsubscript{6} gas pressure
  - Switch the auxiliary and control voltage on
- Carry out testing operations on switching devices either manually or using electrical control, simultaneously observing the relative position indicators
- Check the mechanical and electrical interlocks for effectiveness, without using force
- Check the SF\textsubscript{6} gas pressure of the GSec switch-disconnector and HD4 circuit-breaker (if available)
- Set the protective devices in the switchgear to the required values and check their operation with testing equipment
- Instruct local operators regarding the basic features for correct use of the switchgear
- Check apparatus readiness for operation and the operating status of the electrical systems on the supply side and load side of the switchgear

Other checkpoints
Depending on the allocation of responsibilities, it may also be necessary to check the following equipment in the vicinity of the switchgear:
- Power cables
- Auxiliary cables
- Auxiliary power source
- Remote control system
- Complete earthing system
- Switchgear installation room equipment
- Switchgear installation room characteristics:
  - Pressure resistance in the case of an arc fault
  - Ventilation
  - Temperature
  - Humidity.

3.2.2 Start-up
Instructions
- Comply with all relevant safety regulations
- Ensure that the switch-disconnectors and circuit-breakers in the system are in the OPEN position (4.3 Operating the switchgear)
- Remove any existing earthing and short-circuiting connections in the critical operating area
- Energize the power supply feeders
- Connect the switchgear step by step, observing the signals and indicators
- Where necessary, check that the conductors are in phase when there are several incoming feeder cables and switchgear sections
- Carry out all measurements and check that all functions that depend on the high voltage power supply are connected
- Check there are no irregularities of any kind
3. Operation of the switchgear

3.3 Operating the switchgear

The operating mechanism of the earthing switch contacts is only manual, whereas the switch-disconnector can have either a manual or motor operating mechanism.

**WARNING**

During switching operations, the lever of disconnectors equipped with a motor must be removed from its operating seat before proceeding with opening/closing operations using the pushbuttons.

**NOTE**

For SBM units, the operating mechanisms of the line side earthing switch and switch disconnecter contacts and manual and not motor operated.

**WARNING**

When the two line side isolators are operated (unit SBM), they will set to the opening or closing positions at the same time.

**NOTE**

When using the operating handle, turn it by about 85-90 degrees for the line and 170-180 for earthing.

3.3.1 Unit with single-spring operating mechanism

1. Closing the switch-disconnector from the “open” position

   a) Fit the operating lever into the upper hole.
   b) Turn the lever clockwise to the “closed” position.

2. Opening the switch-disconnector from the “closed” position

   a) Fit the operating lever into the upper hole.
   b) Turn the lever counter-clockwise to the “open” position.
3. Operation from the "open" position to the "earthed" position
   a) Fit the operating lever into the lower hole.
   b) Turn the lever clockwise to the "earthed" position.

NOTE
   It is only possible to open the cable compartment door when only when the switch-disconnector is in the "earthed" position

4. Opening the switch-disconnector from the "earthed" position
   a) Close the cable compartment door.
3. Operation of the switchgear

b) Fit the operating lever into the lower hole.
c) Turn the lever counter-clockwise to the “open” position.

Figure 11. “Earthed” position with the operating lever in the lower hole

Figure 12. “Open” position

NOTE
In the SBR functional unit, the circuit above the circuit-breaker is earthed by operating the earth switch

Figure 13. “Open” position for SBR functional unit with 3 earthing switches

Figure 14. “Open” position for SBR functional unit with 2 earthing switches

Figure 15. Front view of SDM unit

NOTE
Line side isolator GSec can be installed on either the right or left in the SDM unit

Figure 16. HBC cover

NOTE
In the HBC unit, open the circuit-breaker before the closing operation using the push-button in the upper part of the operating mechanism and, move stud A to allow the handle to be inserted. This is only allowed if the operation can be done
3.3.2 Unit with double-spring operating mechanism

⚠️ NOTE
When the motor-operated unit has a double-spring operating mechanism, it is advisable to push the button up so as to uncover the control shaft hole. This facilitates the operation by slowing down the motor.

1. Closing the switch-disconnector from the “open” position
a) Push the button up to release the operating shaft hole (arrow).
b) Put the operating handle into the upper hole.
c) Turn it clockwise.
d) Take the operating lever out.
e) Press the pushbutton down to release the pushbuttons (arrow).

f) Push the right-hand closing pushbutton (green “I”) to take the unit to the “closed” position.

The spring is now charged.
3. Operation of the switchgear

2. Opening the switch-disconnector from the “closed” position
   a) Press the left-hand pushbutton (green “O”) to take the unit to the “open” position.

3. Switching from “open” position to “earthed” position
   a) Fit the operating lever into the lower hole.
   b) Turn the lever clockwise to the “earthed” position.

4. Opening the switch-disconnector from the “earthed” position
   a) Close the cable compartment door.
   b) “Earthed” position.
   c) Fit the operating lever into the lower hole.
   d) Turn the lever counter-clockwise to the “open” position.

NOTE
It is only possible to open the cable compartment door when the switch-disconnector is in the “earthed” position.
5. DRC unit operation from the “open” position to the “earthed” position

**NOTE**
Turn the key on the supply side to release the earthing lock in order to enable the operation

a) Put the operating lever into the hole.
b) Turn the lever clockwise to the “earthed” position.

**NOTE**
It is only possible to open the cable compartment door when the switch-disconnector is in the “earthed” position.
3. Operation of the switchgear

6. DRC unit switching from the earthed to the open position
   a) Close the cable compartment door.
   b) Put the operating lever into the hole.
   c) Turn the lever counter-clockwise to the “open” position.

7. Switching SDD unit

   A: Push button for electrical charging motor
   I: Discharging springs seat (emergency or maintenance)
   B: Opening push-button
   L: Indicator of springs status
   C: Closing push-button
   D: Locking key
   E: Push button cover for manual operation
   F: Selector for manual and automatic transfer
   G: Spring loading
   H: Closing/opening of earthed switch disconnector

   **WARNING**

   Turn key to Manual position before performing any operation in the local mode

7.1 Switching from earth position to service position with ATS, SDD unit
   a) Remove the earths (window H) and bring the units into open position.
   b) Close window E.
   c) Turn selector F to upper central position (window E is locked).
d) Remove locking key D to lock sector F in the upper central position.
e) Insert the ringed key with the locking key removed from D selector S01.

f) Through S01, select the main unit 1 or 2.

GIVE THE KEY TO THE ADMINISTRATOR

\[ \text{NOTE} \]

The system is automatically operational (if voltage is present in the chosen unit this will automatically close)

7.2 Switching from the earth position to service position with manual switching, SDD unit
a) Remove the earths (window H) and bring the units into open position.

b) Select, through the selector position left or right the unit to be operate.

c) Charge the springs by means of push button A (electrical charging) or by means of lever in window G (manual charging).
d) Window L shows the status of the charged springs.
e) Close the disconnector using push button C.

8.1 Switching from the closed position to the earth position (taking out of service) with ATS, SDD unit
a) Turn S01 to position 0.

b) Turn key to Manual position before performing any operation in the local mode.

c) Remove the key from selector switch S01 and put it back in D to release selector switch F.
d) Set selector switch F to the lower central position to free window E.
e) Discharge the springs of the second disconnector (see procedure 9.2).
f) Earth the two disconnecters.

8.2 Switching from the closed position to the earth position (taking out of service), manual switching
a) Open the disconnector pressing push button B.
b) Discharge the springs of the second disconnector (see procedure 9.2).
c) Earth the two disconnecters.
9. Switching to discharge the springs of the disconnecters

9.1 Spring unloading for supplementary maintenance
Press push-button B. Comply with the instructions below if the springs fail to unload:
   a) Fit tool K or similar (fig. 43) into window I (fig. 39). Lever up the stud (fig. 40) to release the seat where the operating lever is inserted (fig. 41).
   b) Fit the lever into window G (fig. 42) and use it to lever up the plastic protection N.
   c) Slightly turn the lever clockwise to release the motor.
   d) Remove the lever.
   e) Unload the springs by pressing push-button B with a pointed tool.

9.2 Spring unloading for out-of-service procedures
Press push-button B. Comply with the instructions below if the springs fail to unload:
   a) Select the unit to be unloaded by positioning selector switch F.
   b) Fit tool K or similar (fig. 43) into window I (fig. 39). Lever up the stud (fig. 40) to release the seat where the operating lever is inserted (fig. 41).
   c) Fit the lever into window G (fig. 42) and use it to lever up the plastic protection N.
   d) Slightly turn the lever clockwise to release the motor.
   e) Remove the lever.
   f) Unload the springs by means of push-button B.

10. Earthing a feeder with the opposite line in service

10.1 Automatic (with ATS)
Example for earthing upright 1 with upright 2 closed in service.
   a) Set selector switch S01 to the Manual position.
   b) Follow procedure 9.1 to discharge the springs of line 1.
   c) Insert the switch-operating lever in H.
   d) Earth line 1.

10.2 Manual (without ATS)
Example for earthing upright 1 with upright 2 closed in service.
   a) Open line 2 with push button B.
   b) Move selector F for line 1 switching.
   c) Unload the springs of riser 1 in accordance with procedure 9.2.
   d) Insert the switch-operating lever in H.
   e) Earth line 1.
   f) Return the selector to the initial position.
   g) Insert the lever in G.
   h) Charge the springs.
   i) Close line 2 with push button C.

NOTE
Extraordinary maintenance procedure

NOTE
The spring releasing operation is guaranteed for a limited number of times < 10

WARNING
With the earthing with manual switching there will be no voltage in the system; it is both possible and recommended to leave the springs of the line which is not in service discharged in order to avoid this problem

NOTE
In the case of a motor-operated unit with double-spring operating mechanism, all remote controlled operations must be inhibited before the mechanical operations are performed
3.3.3 No-load spring release

<table>
<thead>
<tr>
<th>NOTE</th>
</tr>
</thead>
<tbody>
<tr>
<td>No-load spring releasing operation is guaranteed for a limited number of times &lt; 25</td>
</tr>
</tbody>
</table>

If the springs are loaded and the disconnector is open, the operator can release the springs without changing the condition of the disconnector.

Operating sequence:

1. Remove the protective cover from the operating mechanism.
2. Insert the tool (screwdriver) as indicated in the figure and inhibit the interlock.
3. Fit the operating lever into the seat.
4. Turn the operating lever clockwise to release the motor.
5. Remove the operating lever from the seat.
6. Unload the springs by means of the opening button.

In the case of a non-motor operated double-spring operating mechanism:

1. Unload the springs by means of the opening button.

In the case of a motor operated double-spring operating mechanism with GSec cad (printed circuit board):

1. remove the protective enclosure from the operating mechanism
2. insert a screwdriver as shown in the photo, and move the lever downwards
3. release the springs
4. fit the protective enclosure back in place.

3.3.4 Operating units fitted with key interlocks

The units can be fitted with key interlocks. The key interlocks are available separately for both the line switch and the earthing switch. The key locks can only be used in the following cases:

- The line circuit-breaker can set to the following 3 positions when the operating mechanism is the single-spring type:
  - “open-free” (1 key that locks the switch in the “open” position).
  - “closed-free” (1 key that locks the switch in the “closed” position).
  - combination of “open-free” and “closed-free” (2 keys).

- The line circuit-breaker can only set to the following position when the operating mechanism is the double-spring type:
  - “open-free” (1 key that only turns when the switch is in the “open” position, with springs discharged)

- The earthing switch can set to the following 3 positions with both single- and double-spring operating mechanisms:
  - “open-free” (1 key that locks the switch in the “open” position).
  - “earthed-free” (1 key that locks the switch in the “earthed” position).
  - combination of “open-free” and “earthed-free” (2 keys).
3. Operation of the switchgear

Figure 47 shows an example of key interlocks. The single-spring operating unit has 2 key interlocks for the line circuit-breaker plus 2 key interlocks for the earthing switch.

3.3.4.1 Earthing in safe conditions from switchgear front
Key locks "A" with key "2" and "B" with key "1" are mandatory for these operations. The switch-disconnector operating mechanism can only be type 1S (single-spring).

Operating sequences: earthing the unit
a) Set the switch-disconnector’s two-position “local” and “remote” selector to the “local” position.
b) Close the earthing switch either electrically or mechanically.
c) Remove key "2" from lock "A" and key "1" from lock "B". This prevents the switch-disconnector from being operated either mechanically or electrically.
d) Open the door of the unit by pulling the handle up.
e) Only access the compartment after having checked that all conductive power components are earthed.

NOTE
Only for units equipped with motor-operated switching to earth

3.3.5 Operations in switch-disconnector units
General aspects
3-position line side isolators with earthing switch are installed between the busbar and circuit breaker to ensure that the contacts open in accordance with the specifications. Both earthing switches are mechanically connected to the operating mechanism and are operated at the same time between the “open” position and “earthed” position. A mechanical interlock between the circuit-breaker and disconnectors is required since the disconnecter is unable to interrupt rated currents.

Operation sequences: earthing the unit
a) Open the circuit-breaker electrically or mechanically using the button (this releases the circuit-breaker key fastened to that of the disconnectors).
b) Insert the key to release the disconnectors and open them (simultaneous operation).
c) Close the earthing switches on both sides of the circuit-breaker, as indicated in the previous pages.
d) Open the door of the unit by pulling the handle up.
e) Access the cubicle after having checked to make sure that all the conductive power components are earthed.
**Operating sequence: connection of the network unit**

a) Shut the door of the unit by pushing the handle down.
b) Open the earthing switches
c) Close the disconnectors (simultaneous operation) and remove the key.
d) Close the circuit-breaker with the button.

**CAUTION**

The following interventions can only be carried out by skilled personnel

**WARNING**

Carry out the following interventions paying special attention to safety!

**NOTE**

Per tutte le altre unità

3.3.6 Operations in the circuit-breaker unit

**General aspects**

To achieve contact opening in accordance with the specified requirements, a 3-position switch-disconnector with an earthing switch is mounted between the busbar and the circuit-breaker. An additional earthing switch is connected to the lower side of the circuit-breaker (current transformers and MV cables). Both earthing switches are mechanically connected to the operating mechanism and are operated simultaneously between the “open” and the “earthed” positions. Because the switch-disconnector is capable of breaking nominal currents, there is no need for any mechanical interlocks between the circuit-breaker and the switch-disconnector.

**Operation sequences: earthing the unit**

a) Open the circuit-breaker either electrically or mechanically using the pushbutton.
b) Open the GSec switch-disconnector.
c) Close the earthing switches on both sides of the circuit-breaker as instructed on the previous pages.

**Operation sequences: connecting the unit to the network**

a) Open the earthing switches.
b) Close the switch-disconnector.
c) Close the circuit-breaker using the pushbutton.

d) Remove the operating mechanism compartment cover (see chapter 4.4.2).
e) Push the locking plate into the upper position.

**3.3.7 Cable testing**

**CAUTION**

The following interventions can only be carried out by skilled personnel

**WARNING**

Carry out the following interventions paying special attention to safety!

**NOTE**

During the cable test, the earthing switch will be open when the cable compartment door is open

**3.3.7.1 Cable testing position**

a) Put the operating handle in the earth seat.
b) Turn the handle clockwise to the “earthed” position.
3. Operation of the switchgear

f) Put the operating handle into the earth seat.
g) Turn the handle counter-clockwise to the “open” position.
Cable testing can now be carried out.
After completing cable testing, carry out the above stages in reverse order.

3.3.7.2 Cable testing procedure for SBR functional unit
a) Open the circuit breaker.
b) Open the switch-disconnector.
c) Close the earth switch.
d) Open the cable compartment door.
e) Open the busbar compartment door.
f) Bypass the busbar compartment door interlock; pull down with a tool the metal interlock, in the busbar compartment over the mechanism.
g) Open the earth switch.
h) Open the downside earth switch of the cable compartment.

Figure 51. Busbar compartment door interlock for SBR

3.3.7.3 Cable test panel - UniSec BE
a) Fit lever into earthing switch seat.
b) Turn lever clockwise to “earthed” position.

c) Open cable compartment door.
d) Push locking plate upwards.

Figure 52. Earthed position

3.3.7.4 Motor-operated cable test panel - UniSec BE
a) Turn selector switch to “O” and lock it with the padlock.
b) Fit lever into earthing switch seat.
d) Turn lever counter-clockwise to “earthing switch open” position.
The cable test can now be performed.
After test has terminated, work through previous operations in reverse order.

Figure 53.

Figure 54.
d) Open cable compartment door.
e) Push locking plate upwards.

f) Fit lever into earthing switch seat.
g) Turn lever counter-clockwise to “earthing switch open” position.
The cable test can now be performed.
After test has terminated, work through previous operations in reverse order.
3. Operation of the switchgear

3.3.8. WBC and WBS type units
The WCB and WSB units can be fitted with Vmax up to 17.5 kV and VD4/sec at 24 kV series vacuum circuit-breaker or with a VSC/P series vacuum contactor.

The apparatus, always in the withdrawable version, is mounted on a truck which allows the following positions in relation to the compartment:

- **RACKED-IN**: main and auxiliary circuits connected;
- **ISOLATED**: partially isolated with main circuits disconnected and auxiliary circuits connected (plug connector inserted); fully isolated with main and auxiliary circuits disconnected (plug connector removed);
- **RACKED-OUT**: main and auxiliary circuits disconnected and apparatus racked out of the switchgear.

In the racked-in and isolated positions, the apparatus remains in the compartment with the door closed and its position can be seen through the switchgear inspection window. The front hooking-up crosspiece allows the racking-in/isolation operation, with the door closed, by means of the special operating lever.

The apparatus is fitted with special locks, placed on the front crosspiece, which allow it to be hooked up into the corresponding joints of the compartment.

A lock prevents the truck from advancing into the switchgear when the earthing switch is closed, whereas with the truck in the intermediate position between isolated and racked-in, a lock prevents circuit-breaker closing (both mechanical and electrical).

On request, a locking magnet can be mounted on the truck which, if de-energized, prevents truck operation.

The cord with the connector (plug) for connecting the auxiliary circuits to the instrument compartment, comes out of the upper part of the control box.

The auxiliary circuit-breaker contacts and the truck racked-in and isolated contacts are available on-board the circuit-breaker. Some metal slides are fixed onto the sides of the apparatus for operating the partition shutter of the upper medium voltage contacts.
3.3.8.1. Operations for racking the apparatus into and out of the switchgear

NOTE
When operations are carried out with the circuit-breaker racked out of the switchgear, pay great attention to the moving parts. The circuit-breaker must only be racked into the unit in the open position. Racking in and out must be gradual to avoid any shocks which might deform the mechanical interlocks.

1. Passing from circuit-breaker racked-out to the “isolated” position
   a) Move the truck close to the switchgear, insert the hooking up brackets and lock the wheels.
   b) Release the circuit-breaker from the truck, moving the two handles at the same time towards the median axis of the circuit-breaker, at the same time progressively pushing the circuit-breaker by means of the handles towards the back of the switchgear until the circuit-breaker is locked with the two handles which snap sideways into the lateral guide slots.
   c) Unlock the truck wheels, lift the hooking-up brackets and move the truck away from the switchgear.

NOTE
Make sure that the handles have snapped laterally (horizontal truck locks inserted in their seats)

2. Passing from the “isolated” to the “isolated for test” position (connection of the auxiliaries)
   a) Insert and hook up the mobile connector in the fixed socket of the enclosure.

3. Passing from the “isolated for test” to the “connected” position (with earthing switch open)
   a) Close the circuit-breaker compartment door by pushing the handle downwards.
   b) Tighten the knurled screws fully.
   c) Check that:
      – the earthing switch locking magnet is energized (if provided);
      – the key locks are deactivated, if present.
   d) Insert the operating lever in the earthing switch seat, making the ridge coincide with one of the two slots.
   e) Open the earthing switch by turning the operating lever clockwise.
   f) Remove the operating lever from the earthing switch seat.

NOTE
Check that the compartment door is locked

   g) Close the shutter of the earthing switch operating seat by turning the small handle clockwise. This operation unlocks the circuit-breaker and a prevention lock on insertion of the operating lever into the earthing switch seat is activated.
   h) Check that the locking magnet on the circuit-breaker truck is energized (if provided) and verify that the key lock on connection (if provided) is deactivated.
   i) Insert the unlocking key, close the door and fully tighten the knurled screws.
   j) Fully insert the circuit-breaker truck racking-in lever in its seat in the centre of the door and turn it clockwise until the circuit-breaker is fully connected.
   k) Check that the circuit-breaker is connected through inspection window.
3. Operation of the switchgear

3.3.8.2. Racking-out operation (only with circuit-breaker open)

1. Passing from the “connected” to the “isolated for test” position (with circuit-breaker open)
   a) Through the inspection window, check that the circuit-breaker is open (indicator in position “O”).
   b) Fully insert the circuit-breaker truck racking-in/out lever in its seat in the centre of the door and turn it (about 20 turns) anticlockwise until the circuit-breaker stops.
   c) Open the shutter of the earthing switch operating seat by turning the small operating mechanism lever anticlockwise.
   d) Insert the operating lever in the earthing switch seat, making the ridge coincide with one of the two slots.
   e) Close the earthing switch by turning the operating lever clockwise.
   f) Remove the operating lever from the earthing switch seat.
   g) Open the door by pulling the handle upwards.

2. Passing from the “isolated for test” to the “isolated” position (disconnection of the auxiliaries)
   a) Release the mobile connector and remove it from the fixed socket of the enclosure.

3. Passing from the “isolated” to “racked-out” position
   a) Move the truck close to the switchgear.
   b) Insert the hooking up brackets and lock the truck wheels.
   c) Move the two handles at the same time towards the median axis of the circuit-breaker and at the same time pull the circuit-breaker, by means of the handles, towards the outside on the truck.
   d) Leave the handle free and continue racking-out until the circuit-breaker locks with the handles, which snap sideways locking the circuit-breaker on the truck.
   e) Release the wheels, lift the hooking-up brackets and move the truck away from the switchgear.

3.3.8.3. Earthing switch operation

Check that the earthing switch key locks (if present) are deactivated. Check that the earthing switch electromechanical lock (if present) is energized. The earthing switch can only be operated with the circuit-breaker in the isolated or racked-out position and with the compartment door closed. Once started, the operations must always be completed.

1. Closing
   a) Check that the circuit-breaker is in the isolated or racked-out position.
   b) Check that the door is closed, the knurled screws fully tightened and the handle completely closed.
   c) Open the earthing switch operating seat shutter by turning the small lever of the operating mechanism anticlockwise, freeing the earthing switch operating seat.
d) Insert the operating lever in the earthing switch seat, making the ridge coincide with one of the two slots.
e) Close the earthing switch by turning the operating lever clockwise.
f) Remove the operating lever.

2. Opening
   a) Insert the operating lever in the earthing switch seat, making the ridge coincide with one of the two slots.
   b) Open the earthing switch by turning the operating lever anticlockwise.
   c) Remove the operating lever from the earthing switch seat.
   d) Close the earthing switch operating seat shutter by turning the operating mechanism clockwise. This operation releases the circuit-breaker and a prevention lock is activated against insertion of the operating lever in the earthing switch.

3.3.8.4. Operation sequence of the WBC and WBS units

⚠️ NOTE
Once started, all the operations must be completed. The lever must be removed on completion of the operation. In the case of coupling with other units, which require interlocks, it is up to the customer to join the keys with a welded ring in order to ensure safety of the operation sequence.
Before opening the door, check that the voltage indicators on the load side of the circuit-breaker are off and check the position of the apparatus through the inspection windows

1. Circuit-breaker compartment
   a) Through the inspection window, check that the circuit-breaker position indicator shows it is open "O".
   b) Take the circuit-breaker to the isolated position.
   c) Loosen and fully unscrew the knurled screws.
   d) Open the circuit-breaker door.
   This procedure can be carried out with service continuity (busbar compartment and cable energized).

2. Cable compartment
   a) Through the inspection window, check that the circuit-breaker position indicator shows it is open "O".
   b) Take the circuit-breaker to the isolated position.
   c) Check that the voltage indicators are off.
   d) Close the earthing switch (if present).
   e) Loosen and fully unscrew the knurled screws.
   f) Open the cable compartment door by pulling the handle upwards.

3. Putting into service
   a) Close the cable compartment door.
   b) Close the circuit-breaker compartment door and push the handle downwards.
   c) Fully screw in the knurled screws.
   d) Close the circuit-breaker compartment door and push the handle downwards. In the case of WCB and WSB, close the cable compartment door.
   e) Open the earthing switch (if present).
   f) Take the circuit-breaker to the connected position.
   g) Close the circuit-breaker electrically or use the mechanical pushbuttons on the panel (where requested).
   h) Through the inspection window, check that the circuit-breaker is closed (indicator on "I").
3. Operation of the switchgear

3.4 Opening the doors and covers

3.4.1 Cable compartment door
a) Lift the door handle.
b) Pull the door open.

3.4.2 Control compartment cover
a) Unscrew the screws in the corners of the compartment.
b) Remove the cover.

3.4.3 Basic auxiliary circuits compartment door
a) Turn the handle or knurled screw on the rh side of the compartment.
b) Pull the door open.

3.4.4 Large auxiliary circuits compartment door
a) Turn the handle or knurled screw on the rh side of the compartment.
b) Pull the door open.
3.4.5 Door of the BIG auxiliary circuit compartment
a) Turn the handle or knurled screw on the rh side of the compartment.
b) Open the door.

Figure 69. BIG auxiliary circuit compartment door closed

3.4.6 Incoming cable earthing procedure, according to CEI 0-16 standard
Earthing the incoming cables can be carried out in two ways:
1. by applying mobile devices (insulating rod)
2. by means of an earthing switch.

Cable earthing procedure using mobile devices (insulating rod)
1. Request an intervention by the electricity supply company to de-energize the connection cable and make it safe.
2. Check that the voltage indicator, on the power distribution side, does not indicate any presence of voltage in the incoming cables.
3. Isolate your plant, earth and short-circuit it to prevent any possibility of power supply to the circuit.
4. Make sure there is no voltage in the cable by using voltage indicator lamps.
5. Remove the fixing screws on the cover with the wording “Panel which can only be removed after intervention by the electricity supply company”.
6. Connect the mobile earthing cable located inside the cabinet.
7. Put a terminal of the mobile earthing device shown in the figure in the insulating rod seat.
8. Using the insulating rod, connect the terminal of the earthing device to the earthing point on the power distribution side. Make this connection starting from phase L3 (phase furthest inside).

9. Repeat operations 7 and 8 for phases L2 and L1 as well. At this point the switchgear is safe and the maintenance work can be carried out.
10. On completion of the work, remove the mobile earthing device, following the above sequence in reverse order.

Procedure for earthing using an earthing switch
1. Request an intervention by the electricity supply company to de-energize the connection cable and make it safe.
2. Take delivery of the key from the people in charge from the electricity supply company, as a guarantee that the earthing switch of the power distribution delivery compartment has been closed.
3. Check that there is no voltage in the cable, by means of the voltage indicator lamps.
4. Insert the key, ringed with the electricity supply company key, in the special seat on the cable compartment cover, with the wording “Switch can only be operated after intervention by the electricity supply company” and free the operating seat of the earthing switch on the cable side.
5. Close the earthing switch on the cable side by acting on the operating shaft. At this point, the switchgear is made safe and the maintenance work can be carried out.
6. Unscrew the cable compartment door screw and lift the door to access the cable compartment.
7. To put the switchgear back into service, use the above sequence in reverse order.
3. Operation of the switchgear

3.4.7 Cable compartment door for the SBR unit

a) Ask the electricity supply company to isolate the connection cable and guarantee that it is in a safe condition.

b) Ensure that the (VPIS) voltage indicator in the lower part of the electricity supply company side does not indicate the presence of power in the incoming cable.

c) Open the circuit-breaker.

d) Open the switch-disconnector.

e) Open the interlock of the lower line isolator with the key.

f) Pull the shutter lever of the lower earthing switch of the cable compartment to the right.

g) Close the lower earthing switch of the cable compartment.

h) Open the second key interlock (accessory) in the top right corner of the cable compartment cover.

i) Break the sealing wire on the screw and then unscrew the screw of the cable compartment door.
3. Isolate your plant, earth and short-circuit it to prevent any possibility of power supply to the circuit.
4. Make sure there is no voltage in the cable by using voltage indicator lamps.
5. Remove the fixing screws on the cover with the wording “Panel which can only be removed after intervention by the electricity supply company”.
6. Connect the mobile earthing cable located inside the cabinet.
7. Put a terminal of the mobile earthing device shown in the figure in the insulating rod seat.

8. Using the insulating rod, connect the terminal of the earthing device to the earthing point on the power distribution side. Make this connection starting from phase L3 (phase furthest inside).

9. Repeat operations 7 and 8 for phases L2 and L1 as well. At this point the switchgear is safe and the maintenance work can be carried out.
10. On completion of the work, remove the mobile earthing device, following the above sequence in reverse order.

3.4.8 Busbar compartment door for the SBR unit
a) Open the circuit-breaker.
b) Open the switch-disconnector.
c) Close the earthing switch.
d) Lift and open the busbar compartment door.

3.4.9 Incoming cable earthing procedure, in accordance with standard IEC 0-16 with HBC panel
The incoming cables can be earthed by applying movable devices (insulating rods).

Cable earthing procedure using mobile devices (insulating rod)
1. Request an intervention by the electricity supply company to de-energize the connection cable and make it safe.
2. Check that the voltage indicator, on the power distribution side, does not indicate any presence of voltage in the incoming cables.
3. Operation of the switchgear

3.4.10 Cable compartment door for the HBC unit
a) Open the circuit-breaker.
b) Open the switch-disconnector.
c) Close the earthing switch.
d) Lift and open the cable compartment door.

3.4.11 Opening the cable compartment of the DRC and DRS unit
Make sure that the unit is not powered and earth the earthing switch. The door can be opened in the same way as the doors of the other units but only after the screw of the locking mechanism has been removed (fig. 82).

3.4.12 Opening the cable compartment of SDM and SDC units (750 mm)
Make sure that the unit is not powered and earth the earthing switch. These units are closed with two 375 mm doors, one of which closes the compartment with the switch-disconnector while the one alongside closes the cable compartment. The door of the cable compartment can be opened in the same way as the doors of the other units but only after the screw of the locking mechanism has been removed (fig. 82).

3.5 Voltage indicators
UniSec units can be equipped with a voltage presence indicating system in accordance with IEC 61958 (VPIS) or IEC 61243-5 (VDS).

3.5.1 Voltage indicators VPIS
VPIS indicators are used to indicate the presence of service medium voltage.

**NOTE**
The indication of VPIS alone is not sufficient to prove that the system is de-energized: if the operating procedures require them, relevant voltage indicators according to IEC 61243-5 must be used.

The energized state of the unit is indicated by a flashing light with frequency of repetition of at least 1 Hz.

**NOTE**
Under very bright lighting it may be necessary to improve visibility by additional means.

**Operating temperature**
The VPIS will operate reliably over a temperature range of –25° to +50°C.

**Phase comparison and testing of VPIS**
Each phase of the integrated voltage presence indicating system has a connection point on the front panel, which can be used to perform phase comparison and to test the voltage presence indicator. Fujian Nanping Anda Electrical Manufacture Co. Ltd. product type DXN-HXQ-01 is recommended for phase comparison.

**Threshold values for voltage presence indication**
The indication corresponding to “voltage present” appears when the actual line-to-earth voltage is between 45% of the nominal voltage and the rated voltage. The indication corresponding to “voltage present” does not appear when the actual line-to-earth voltage is less than 10% of the nominal voltage.
3.6 Pressure monitoring devices
A device for monitoring the gas in the switch-disconnector can be installed on the front of the panel.
The devices described below can be installed.

Temperature compensated pressure switch (Pressure regulator)
The device is self-powered and maintenance-free.
The operator communicates with the device by means of two pushbuttons on the front.
- Pushbutton 1: Check: shows whether the display is functioning correctly;
- Pushbutton 2: Interrogates the monitoring device: the following information can be displayed:
  - OK: correct operating pressure;
  - Low: low pressure (minimum level for operation);
  - Very low: insufficient pressure (operation cannot be performed).
These indications can be displayed remotely by means of 2 contacts built into the device.

Operating temperature
The VDS works reliably with a temperature range from –25 °C to +50 °C.

Phase comparator
The phase comparator detects the balance or unbalance of the phases between the interface and/or the test points. Detection is by means of an luminous indicator.
The recommended phase comparator of the VDS is the PCM-HR type, made by Maxeta. It consists of a 1.4 m long test cable.

Threshold values for voltage indication
When the line-earth voltage is between 45% and 120% of rated voltage, indication of "voltage present" must appear. The "voltage present" indication must not appear when the line-earth voltage is less than 10% of the rated voltage.

3.5.2 Voltage indicators VDS
VDS is used to detect the presence or absence of medium voltage according to IEC 61243-5.
The VDS are based on the HR system, the system consists of a fixed device, installed in the switchgear, coupled with a mobile device to visually detect the presence or absence of service voltage and phase balance and on which the indicator lights are installed.
The state of voltage present is visually indicated with at least 1 Hz repetition frequency. Flashing light indication whose impulse frequency must be between 1 Hz and 3 Hz with an impulse/pause ratio of 4 to 1.
The "voltage indicators" which are recommended are the VM1 type used as a mobile device and VM3 type, used as a fixed and mobile device, made by Maxeta.
The "voltage indicators" have a maximum operating voltage threshold of 90 V and a maximum current threshold of 2.5 µA at 50 Hz.

Pressure gauge
The device detects the measurement in temperature compensated zones and monitors the operating pressure of the gas in the switch-disconnector.
The pressure gauge has 2 reference zones:
- green: correct operating pressure;
- red: insufficient pressure (operation cannot be performed).
There is also a version with remote indications.
3. Operation of the switchgear

3.7 GSec operating mechanism

The “motor operating device” (MOD) charges springs and coils (only for operating mechanism type 2 of the GSec (SD) switch-disconnector). MOD is based on electronic circuits and includes protection and diagnostic functions that improve the reliability, resources and safety of the system. The MOD includes a local operator panel interface (HMI) and binary inputs and outputs. The MOD also includes the logic and safety functions required for the disconnector operations.

The protection functions include overcurrent for the coils and motor, over-temperature for the power driver and monitoring of the auxiliary power supply voltage.

The diagnostic functions include supervision of the control circuits (for both the binary inputs), motor and coil continuity control and, finally, congruence of the position and state of the disconnector.

The information regarding the state of the diagnostics and of the protections is made available locally by means of the HMI and remotely by the binary inputs and outputs.

The following figure shows the GSec MOD functional block diagram. In this figure, the diagnostic and protection functional locks are highlighted in white.

1. Disconnector operation

The GSec MOD carries out the disconnector opening and closing operations. The internal logic locks these operations when the disconnector is in the earthed position or when safety conditions are not fulfilled. The safety conditions include: key locks, SF6 gas pressure and the state of the fuse.

The position of the disconnector and the state of the safety conditions are acquired by microswitches connected to the MOD.

The switch-disconnector operations are performed by means of a DC motor piloted by the MOD, which allows the spring to be charged (or the springs, in the case of operating mechanism type 2). In the case of operating mechanisms type 2, the MOD pilots the coils so as to release the springs.

2. Local operator panel (HMI)

The following figure shows the local HMI which has 3 pushbuttons and 5 LEDs.

The opening and closing pushbuttons allow local motor operation of the disconnector. The L/R pushbutton allows selection of the local or remote operating mode.

The mode selected is indicated by two LEDs incorporated in the same pushbutton. When local mode is selected, the binary control inputs are disabled, whereas when the remote mode is selected the HMI opening and closing pushbuttons are disabled. The Ready and Alarm LEDs display the state of the protection and diagnostic functions. The Comm LED is reserved for future applications.

3. Binary inputs

The binary inputs include the opening and closing commands. The trip threshold is set to 85% of the rated voltage (in the case of operating mechanism type 2, the trip threshold of the opening command is set to 70% of the rated voltage). The minimum impulse time needed for the command to be carried out is 300 ms. Please contact a sales representative for information about other settings available on request (the minimum time which can be set is 100 ms).

Both the opening and closing inputs provide feedback on the state of the diagnostic and protection functions.

When the disconnector is ready and is able to operate, the inputs allow circulation of a small current.
On the other hand, in the case of a fault, their impedance becomes high, blocking current circulation. A “Trip Circuit Supervision” (TCS) type relay connected to one of these binary inputs produces an alarm in the case of a fault. Each binary input also includes a TCS and a self-diagnosis circuit. These functions allow any faults in the binary input circuits to be detected, among which: wire cut off, short-circuit and fault in the binary input circuitry. These functions are optional and require the use of two external resistances to be added to the control circuit. Please contact a sales representative to enable this function.

4. Binary outputs
Three binary outputs are available: SD READY, FUSE, LOCAL. The SD READY contact is normally closed when no faults have been detected by the diagnostic and protection functions and the disconnector is ready to operate. Contact closed indicates that the whole disconnector is functioning correctly and can be operated. Every fault found by the diagnostic or protection functions makes this contact open. FUSE indicates the state of the disconnector fuse, for the applications where it is provided. LOCAL indicates that the MOD is in local operating mode. The state of this output changes following pressing of the HMI R/L key.

5. Diagnostics
The diagnostics continually verifies the conditions of the disconnector mechanical operating mechanism, the safety conditions, the motor, the coils, the binary inputs and the quality of the auxiliary power supply. In particular, diagnostics is able to detect a faulty position of the disconnector. The fault conditions are displayed by the local HMI by means of two LEDs. Coding of the LED indications is given to help the operator identify the fault. In the case of remote control, the SD READY binary output and the binary inputs are used to signal a fault, as already described previously. In the case of a fault, no disconnector operations are allowed.

6. Protection functions
The motor and coil control circuits are protected against overcurrents, short-circuits and over-temperatures. Any one of these events causes interruption of the operation by the MOD. These events are signalled by the HMI, by the SD READY binary output and by the binary inputs as already described above.

Electrical characteristics
The electrical characteristics of the GSec MOD are listed in the following tables.

### Characteristics of the power supply

<table>
<thead>
<tr>
<th>Rated Voltage</th>

\(^{2}\) These conditions can only occur when the internal TCSs are enabled and the MOD is in REMOTE mode. The disconnector can be operated using the HMI by setting the MOD to LOCAL mode.

Table 16.
3. Operation of the switchgear

Remote control of the GSec

The following diagrams show examples of remote control of the GSec. Both circuits allow any fault in the system to be identified.

Remote control with 6 wires

The following figure shows GSec connection for remote control using just 6 wires. Other cables can be used to acquire further information (for example, the position of the disconnector directly from the auxiliary contacts, the LOCAL and FUSE binary outputs, etc.).

This circuit uses the internal TCS function of the binary inputs. In particular, this function requires the use of two external resistors connected in parallel with the remote control pushbuttons. This circuit allows any fault in the system to be found.

In particular, the SD READY lamp turns off when one of the following conditions occurs:
- One of the 6 wires in interrupted
- Any fault in the MOD
- Any fault in the motor or in the coils
- Any infringement of the disconnector safety conditions
- Disconnector out of position (not ready for operation)
- Any fault regarding the binary inputs including short-circuit at the input connector.

Figure 88.
Remote control with 4 wires
The following figure shows the connection for remote control of the Gsec using just 4 wires. Other cables can be used to acquire further information (for example, the position of the disconnector, directly from the auxiliary contacts, the LOCAL and FUSE binary outputs, etc.). The internal TCS of the binary inputs are optional, but if enabled allow verification of operation of the binary inputs. In this case, the external resistances are not needed because they are replaced by the external TCS. This diagram works with the same performances even with just one external TCS, by replacing the other TCS with a simple resistance.

This circuit allows any fault in the system to be found.
In particular, the SD READY lamp turns off when one of the following conditions occurs:
- One of the 4 wires is interrupted
- Any fault in the MOD
- Any fault in the motor or in the coils
- Any infringement of the disconnector safety conditions
- Disconnector out of position (not ready for operation)
- Any fault regarding the binary inputs including short-circuit at the input connector (when the internal TCS are enabled).
4. Service and maintenance

4.1 General warnings and cautions

**WARNING**
Pay attention to the following safety warnings:
Preparation of switchgear for safe assembly
1. For each case, set safe working conditions with the utility safety officer.
2. Make sure that national safety regulations are followed.
3. Make sure there is no voltage in the busbars and cable terminals and that the risk of reconnection is eliminated in all units. Any remote control must also be prevented.
4. Operate the switch (or the combination switch-fuse unit) into the "open" and then into the "earthed" position.
5. Make sure that auxiliary circuits are also disconnected from all possible power supply sources (including instrument transformers).

Tools required
- Screwdriver
- Hand tools for 10 mm screws
- M10 (M8) torque wrench
- Hexagonal-head spanners 5, 6 and 8
- Vacuum cleaner
- Cleaning cloths
- Mild alkaline cleaning agent - Do not use trichloroethane, carbon tetrachloride or any kind of alcohol, etc. for cleaning
- Clean water
- Silicone liquid - In special cases, insulating surfaces can be covered with a thin layer of silicone liquid such as DC200/100CS or similar
- Instruction manuals
- Test equipment.

Checkpoints
- Check that there are no visible signs of, or damage from, partial discharges
- There should not be any visible signs of overheated connections
- All components should perform perfectly and any faulty components must be replaced.

Maintenance instructions
Maintenance serves for preserving trouble-free operation and achieving the longest possible working life of the switchgear.

It comprises the following closely related activities:
- **Inspection**: Determination of the actual conditions
- **Servicing**: Measures to preserve the specified conditions
- **Repairs**: Measures to restore the specified conditions.

The inspection and servicing intervals for some of the apparatus/components (e.g. parts subject to wear) are determined by fixed criteria, such as switching frequency, length of service and number of short-circuit breaking operations. On the other hand, for other parts, the length of the intervals may depend, for example, on the different modes of operation in individual cases, the degree of loading and environmental factors (including pollution and aggressive air). The time intervals for maintenance work to be carried out always depend on the operating conditions of the switchgear and, above all on the mode of operation, the number of rated and short-circuit current switching operations, ambient temperature, pollution, etc.

The maintenance intervals and measures to be taken given in Table 18 are recommended for UniSec switchgear under normal service conditions. Three year intervals are recommended for all maintenance measures in more demanding conditions (such as areas with high pollution levels). The switch-disconnector 1- and 2-spring operating mechanisms are maintenance-free and do not need any lubrication.

Other important instruction manuals
The operation of all protection relays should be checked in accordance with the manufacturer’s instructions.
For circuit-breakers, refer to the following installation and service instructions:

<table>
<thead>
<tr>
<th>Circuit-breaker:</th>
<th>Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vacuum circuit-breaker:</td>
<td>1VCD600189 (Vmax – 12...17.5 kV – 630...1250 A – 16...31.5 kA Installation and maintenance manual)</td>
</tr>
<tr>
<td>Vacuum circuit-breaker:</td>
<td>647654 (VD4 – 12...24 kV – 630...3150 A – 16...50 kA Installation and maintenance manual)</td>
</tr>
<tr>
<td>SF₆ circuit-breaker:</td>
<td>647021 (HD4 – 12-40.5 kV – 630-3600 A – 16-50 kA Installation and maintenance manual)</td>
</tr>
</tbody>
</table>

Table 17. Circuit-breaker installation and maintenance instructions
4.2 Maintenance intervals

We recommend carrying out the maintenance work at the following intervals:

<table>
<thead>
<tr>
<th>Activity performed</th>
<th>According to section</th>
<th>Time interval in years</th>
<th>According to number of switching operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inspection</td>
<td>5.3</td>
<td>5(2)</td>
<td></td>
</tr>
<tr>
<td>Maintenance</td>
<td>5.4</td>
<td>5(2)</td>
<td></td>
</tr>
<tr>
<td>Repairs</td>
<td>5.4</td>
<td>As required</td>
<td>As required</td>
</tr>
</tbody>
</table>

(2) Under more demanding service conditions, we recommend shortening this interval appropriately
(3) According to the results of the inspection
(4) G5ec
- Electrical endurance: 100 breaking operations at 630A
- 5 short-circuit making operations
- Mechanical endurance: 5000 no-load operations
- Circuit-breakers: See the manuals
- Earthing switch: 5 making operations – 1000 no-load operations

Table 18. Maintenance Intervals

4.3 Inspection

General aspects
Where necessary, the working area must be isolated and secured against accidental re-connection before inspection, in accordance with the “Safety Regulations” specified by IEC standards and corresponding national standards. The switchgear condition must be monitored by regular inspections. Under normal operating conditions, inspections should be carried out once every four years by suitably trained professional electricians.

Instructions
Carry out the following inspections:
- Visually check for dirt, corrosion and moisture.
- Check for effects of high temperature on the main circuits.
- Check for traces of partial discharges on insulating material parts.
- Check for traces of current leakage on insulating parts.
- Visually check the surfaces of the contact systems.
  - The contact points must be cleaned if signs of overheating (discoloured surface) are visible.
- Check the general condition and lubricate (Klüber NCA 52) the earthing switch contacts.
- Check the operating pressure of the gas-insulated switching devices where possible.

The inspection must also include checking correct mechanical/electrical operation of the following switching devices:
- Actuators
- Interlocking devices
- Protection devices
- Signalling devices
- Switchgear accessories and auxiliary devices (e.g. storage batteries).

⚠️ NOTE
With regard to the various switching devices, their own instruction manual should be followed

No partial discharge must occur on the surfaces of equipment at the operating voltage. This can, for example, be detected by characteristic noises, a clearly perceptible smell of ozone, or visible glowing in the dark.

⚠️ NOTE
Under abnormal operating conditions (including adverse climatic conditions) and/or particular environmental conditions (among which, heavy pollution and aggressive atmosphere), inspection at shorter intervals may be necessary

Repair measures
If any irregular conditions are detected, appropriate servicing or repair measures must be taken.

4.4 Servicing

Instructions
If the need for servicing measures is established during the course of an inspection, proceed as follows:
1. Tighten all electrical connections (main busbars, switches, measuring devices, cables, etc.) to the correct torque, as specified in the installation and tightening torque instructions.
2. Clean all parts (disconnectors, circuit-breakers, tripping mechanisms, motors, etc.) with a vacuum cleaner and visually inspect them. Clean the surfaces in general:
   - Lightly settled dry dust deposits: clean with a soft dry cloth.
   - Wipe down after cleaning, using clean water and then dry carefully.
3. Perform a closing/opening operation on all disconnectors and circuit-breakers, including the earthing switches.
4. Service and maintenance

4. Connect the auxiliary control voltage, but ensure that no remote signals can activate the components. Perform one electrical operation sequence on all motor-operated devices and tripping mechanisms.

5. Clean the busbar and cable compartments. Remove the switchgear unit roof and clean the GSec switch-disconnector insulation materials and busbars with a clean dry soft cloth. Remove all ingrained dirt, such as sticky or greasy stains using a cloth and a mild alkaline detergent. Wipe with a damp cloth using clean water and carefully dry the surface. Do the cleaning in the same way in the cable compartment (bottom of GSec switch-disconnector, instrument transformers, busbars and circuit-breaker).

6. If needed, clean and grease (Klüber NCA 52) the earthing switch contactor, blade and operating mechanism.

NOTE
Should partial discharges occur as a result of condensation, application of a thin silicone film over the surface concerned is often effective as a temporary remedy. It is advisable to ask the ABB after-sales service department for advice regarding permanent solutions to this uncommon type of problem.

4.5 Repairs

4.5.1 Switchgear in general
Instructions
Carry out repair work immediately after a defect has been discovered.

- Completely remove all rust from damaged paintwork areas on steel sheet and other steel parts by mechanical means, e.g. with a wire brush
- Lightly roughen the surrounding paint and carefully degrease the entire surface. Then immediately apply an anti-rust primer and, after an appropriate hardening time, apply the top coat. Only use suitable and compatible paint products
- Apply the top coat in the standard RAL 7035 colour, or the relevant special colour.

- Carefully remove any oxidation from galvanized surfaces:
  - For zinc surfaces use a wire brush or special cleaning pad, e.g. Scotch-Brite, and remove any lightly settled particles with a dry, non-fraying cloth. Then treat the cleaned parts with zinc spray or zinc powder paint and, finally, with aluminium spray for colour matching
  - Passivate the surfaces of operating parts and any rust formation on phosphatised parts with a wire brush or metal-free cleaning pad, e.g. Scotch-Brite, and then clean with a dry cloth. Grease evenly (with Klüber NCA 52)

CAUTION
Follow the maintenance instructions in the manuals for the relative components

- Check that the bolt connections at the contact points in the busbar system and the earth connections are tight, and that the contact system functions correctly
- Where necessary, grease the slide plates and bearings in the unit again, or thoroughly clean them. Then grease them again with Klüber NCA 52 lubricant

NOTE
Tighten to the correct torque! The tightening torques can be found at the end of the manual!

4.6 Replacing and mounting new apparatus

4.6.1 Replacing melted fuses
Investigating and clearing a fault
The fuses cannot be regenerated. According to IEC Publication 60282-1, all three fuses must be replaced, even if only one or two of the them have blown. Exceptions are allowed when it is verified that the fuses have not been subjected to any overcurrent.

If the fused switch-disconnector units (SFC, SFS or SFV) are equipped with a fuse tripping mechanism, the switch-disconnector opens automatically by means of the striker pin(s) of the fuse(s) and the tripping mechanism.
Instructions
- Check that the colour of the fuse indicator is red and the position indicator is in the "open" position.
- Operate the switch to "earthed" position (see chapter 4.3 Operating the switchgear).
- Open the door.
- The upper and lower fuse holders are earthed and the fuses can be removed and installed manually.

Removing the fuses
a) Start from phase L1 (near the door).
b) Pull the fuse from its upper part until it is released.

c) Lift the fuse upwards so that the lower part is also released.

d) Carry out the same steps for the L2 and L3 phases.

Installing the fuses
a) Start installation from phase L3 (the one furthest away from the door).
b) The fuse striker pin must be facing upwards. First of all, insert the lower part of the fuse in the bottom fuse holder.

c) Push the upper part into the top fuse holder.
4. Service and maintenance

4.6.2.1 Mounting the circuit-breaker

Dismantling of the circuit-breaker

1. Before dismantling.

CAUTION
Operate the circuit-breaker and switch to the open position. Check that the cable is de-energized and close the earthing switches. Prevent any power supply from the cable.

NOTE
The same screws are used for re-installation.

2. Remove the front cover of the circuit-breaker.

---

d) Rotate the fuse until the arrow and technical data texts are pointing towards the door.

e) Close the door.

f) Operate the switch-disconnector to the "open" and then to "closed" position (4.3 Operating the switchgear).
3. Remove the internal cover plate.  
   a) Unscrew the three screws.

4. Unscrew the two screws from the lower part of  
   the circuit-breaker.

5. Remove the door.  
   a) Open the door.  
   b) Lift the door.

6. Remove the middle part in order to get more  
   working space.  
   a) Unscrew the four screws on the front of the unit.  
   b) Unscrew the two screws inside the unit.

7. Disconnect the busbars from the lower switch- 
   disconnector poles.  
   a) Unscrew the screws.

8. Remove the circuit-breaker caps (only HD4/sec  
   circuit-breaker).  
   a) Unscrew the screws.  
   b) Remove the caps.
4. Service and maintenance

9. Disconnect the busbars from the upper circuit-breaker poles.
   a) Three upper poles of the circuit-breaker.
   b) Unscrew the upper circuit-breaker screws and remove the part involved (only HD4/sec circuit-breaker).

10. Disconnect the busbars from the lower circuit-breaker poles.
    a) Remove all the insulator caps, then unscrew the screws (only in the 24 kV unit).
    b) Unscrew the screws.

11. Take the circuit-breaker out of the unit.

Figure 104. Removing the upper poles of the circuit-breaker
Figure 105. Connections
Figure 106. Disconnecting the busbars
Figure 107. Taking the circuit-breaker out of the unit
Installing a new circuit-breaker

3. Screw the two screws into the lower part of the circuit-breaker.

11. Install the front cover of the circuit-breaker.
4. Service and maintenance

12. Installation completed.

4.6.2.2 Mounting the circuit-breaker for the SBR functional unit

Dismantling of the circuit-breaker

a) Open the circuit-breaker
b) Open the line switch-disconnector
c) Close the earthing switch
d) Open the busbar compartment door
e) On the left side of the busbar compartment, unscrew and extract the L part

f) Lift and remove the circuit-breaker cover
g) Remove the 5 screws and the two metal sheet parts on the lower left side of the circuit-breaker.

h) Remove the 2 screws and the metal braking part at the bottom of the circuit-breaker.

i) Remove the circuit-breaker busbar screws.

For circuit-breaker with K7 sensor:

j) Remove the screws at the top of the circuit-breaker poles.
k) Remove the 3 busbars at the top of the circuit-breaker poles

m) Extract the circuit-breaker.

l) Disconnect the cable connectors and terminal blocks at the top of the circuit-breaker

Installing a new circuit-breaker
Remove the circuit-breaker:

a) Insert the new circuit-breaker; for this operation there is a rail and a centring pin.

b) Fix the circuit breaker-braking part with 2 screws.

c) Mount the 2 metal sheet parts on the lower and left side of the circuit-breaker, and screw them into the fixing point.
4. Service and maintenance

d) Mount the circuit-breaker cover.

Figure 139. Circuit-breaker cover

e) Insert and screw in the circuit-breaker cover locking part.

Figure 140. Circuit-breaker screw lock for the SBR unit

f) Screw in the busbars on the right side of the circuit-breaker.

Figure 141. Circuit-breaker terminals and K7 current sensors

g) Tighten the screws on the circuit-breaker upper busbars.

Figure 142. Circuit-breaker busbar connections

h) Screw in the screws at the top of the circuit-breaker poles.

Figure 143. Upper circuit-breaker terminals

i) Close the busbar compartment door.
4.6.2.3 Remove the circuit breaker from SBC-W and SBS-W units

1. Before removing the circuit breaker.

CAUTION
Operate the circuit-breaker and switch to the open position. Check that the cable is de-energized and close the earthing switches. Prevent any power supply from the cable.

2. Remove the front cover of the unit.

3. Extract the operating handle from the unit pushing and moving up the lever.

4. Unplug the secondary circuit breaker wiring.

5. Insert the operating lever in the dedicated operating seat.

NOTE
If it is not possible insert the lever due to interferences between operating lever and other applications, rotate counterclockwise the mechanism’s shaft helping with the visible screw on it and then insert the operating handle.
4. Service and maintenance

6. Operate on the lever until the circuit breaker leave the switchgear’s contacts.

4.6.2.4 Insert the circuit breaker on SBC-W and SBS-W units

1. Slide the circuit breaker inside the unit until the circuit breaker’s contact reach the switchgear’s contacts inside the unit.

7. Remove the operating handle.
8. Take the circuit breaker out of the unit.

Figure 149.

Figure 151.

2. Insert the operating handle in the dedicated opening in the left side of the unit.

3. Push the operating lever to allow the insertion of the circuit breaker.

Figure 150.

Figure 152.
4. Inserire la leva di manovra nella sede di dedicata.

CAUTION
Check if all six circuit-breaker’s contacts are inside switchgear’s contacts. After the insertion of the CB with the lever, please check the correct position of the contacts inside the plug as indicate in the picture; to have the right positioning the front of the CB have to touch the plane L of the CB support

5. Plug the secondary circuit breaker wiring.

6. Install the front cover of the unit.
4. Service and maintenance

4.6.3.1 Mounting the voltage indicator

Installing the voltage indicator

1. Cover
   a) Unscrew.
   b) Remove the cover of the control compartment.

2. Voltage indicator.
   a) Unscrew the screws.
   b) Unscrew the screws (the earthing wire is under the screw).
   c) Disconnect the cables.
   d) Installing a new voltage indicator: carry out the previous operations in reverse order.

   **NOTE**
   The positions of the cables in the voltage indicator are named L1, L2 and L3 from left to right. The cables have a mark to indicate their correct position.

4.6.3.2 Mounting the lower voltage indicator for the SBR functional unit

   a) Unscrew and remove the cover from the mechanism.
   b) Unscrew and extract the voltage indicator module.
   c) Open the cable compartment door.
   d) Disconnect the voltage indicator cables from the lower isolators.
4.6.4  WBS-WBC units - Circuit-breaker door emergency release instructions

![Figure 163. Isolator terminals for voltage indicator cable connections](image1)

**NOTE**

All of these operations will be done by authorized personnel.

1. On the front of the circuit breaker door you have to unscrew the following screws (please see the picture below):
   - a) Unscrew and remove the mechanism cover.
   - b) On the circuit breaker is withdrawn (on test position) you have to unscrew only the two screws on the top.
   - c) If the circuit breaker cannot be withdrawn, is mandatory to unscrew all the screws highlighted in RED (on the top and on the bottom).
   - d) Disconnect the voltage indicator cables from the lower isolators.
   - e) Insert the new voltage indicator.
   - f) Connect the voltage indicator cables.
   - g) Mount the mechanism cover.

2. If the circuit breaker is withdrawn (on test position) you have to unscrew only the two screws on the top.

3. If the circuit breaker cannot be withdrawn, is mandatory to unscrew all the screws highlighted in RED (on the top and on the bottom).

4. On the back of the door, after unscrew the top screws, the piece highlighted in RED in the picture below, will be released (must to be mounted after the maintenance of the cubicle, before to put in service again the switchboard):

![Figure 164. Isolator terminals for voltage indicator cable connections](image2)

![Figure 165.](image3)

![Figure 166.](image4)
4. Service and maintenance

5. After unscrew the screw on the bottom, the door cannot be opened yet:

6. Must to be used a steel pin with the diameter 2 mm that must to be inserted in the hole and push in order to move the plastic piece highlighted in RED in the picture below; in the same time is necessary to lift the door:

4.7 Spare parts, auxiliary materials and lubricants

4.7.1 Spare parts
Available on request
A spare parts list for procurement of spare parts is available on request. This basically includes moving parts and parts subject to wear. When parts are required, the serial number of the relative switchgear or switching device should always be indicated.

4.7.2 Auxiliary materials and lubricants

<table>
<thead>
<tr>
<th>Lubricant</th>
<th>Klüber NCA 52</th>
</tr>
</thead>
<tbody>
<tr>
<td>Touching up paint</td>
<td>Standard colour RAL 7035</td>
</tr>
</tbody>
</table>

Table 19. Lubricants and auxiliary materials

After all of this sequences of operations the door can be opened.
Please pay attention at the warning inside of this document.

⚠️ NOTE
All of these instructions will be put inside to Manual of Installation, new release

Table 20. Troubleshooting
6. Recycling

6.1 General aspects
The instructions for recycling the UniSec product are given below. This includes materials used for the packing and for the product. It also includes handling instructions for when the product is taken out of service.

The environmental regulations vary from country to country and frequently change. For this reason, it is recommended that local professionals be contacted about how to proceed when the product is taken out of service.

Together with this document, information should also be given about returning the product after it has been taken out of service.

Dealing with waste requires permission in most countries and you must get permission for your own company.

ABB can give you more information, especially about SF6 gas. Please contact us if you have any questions.

Information about local landfills can be obtained from the environmental agency. A product that is no longer in service can be dealt with in two alternatively ways. The product can be manually demolished or crushed mechanically.

Information about suitable facilities can be obtained from the local environmental agency.

⚠️ NOTE

All parts containing hazardous waste must be removed and sent to a facility set up for this purpose

⚠️ NOTE

It is always necessary to act in accordance with the local legal requirements in force for disposal of the product

Table 21. Product materials

SF₆

SF₆ is a fluorinated greenhouse gas covered by the Kyoto Protocol and care must be taken not to cause emissions of SF₆. At the end of its life, the greenhouse gas must be recovered.

All operations must be carried out by skilled personnel with in-depth knowledge of SF₆ gas.

⚠️ NOTE

Consult the Service page of website www.abb.com/mediumvoltage for information about SF₆ gas and the relative management procedures
