# Introduction

The purpose of this safety guide is to provide the information necessary to design, install, verify, and maintain a Safety Instrumented Function (SIF) utilizing the LWT series. This guide provides the necessary requirements for meeting the IEC 61508 functional safety standards.

This chapter defines terms, abbreviations and acronyms used in this document. It also exposes reference documents and how to get product support.

## Terms and abbreviations

<table>
<thead>
<tr>
<th>Term</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic Safety</td>
<td>The equipment must be designed and manufactured such that it protects against risk of damage to persons by electrical shock and other hazards, and against resulting fire and explosion. The protection must be effective under all conditions of the nominal operation and under single fault condition.</td>
</tr>
<tr>
<td>Continuous Mode</td>
<td>Mode where the safety function retains the EUC in a safe state as part of normal operation.</td>
</tr>
<tr>
<td>Fail Annunciation</td>
<td>Failure that does not cause a false trip or prevent safety function but does cause loss of an automatic diagnostic or false diagnostic indication.</td>
</tr>
<tr>
<td>Undetected</td>
<td>Failure that does not cause a false trip or prevent the safety function but does cause loss of an automatic diagnostic and is not detected by another diagnostic.</td>
</tr>
<tr>
<td>Fail Dangerous</td>
<td>Failure that does not respond to a demand from the process (i.e. being unable to go to the defined fail-safe state).</td>
</tr>
<tr>
<td>Detected</td>
<td>Failure that is dangerous but is detected by automatic stroke testing.</td>
</tr>
<tr>
<td>Undetected</td>
<td>Failure that is dangerous and that is not being diagnosed by automatic stroke testing.</td>
</tr>
<tr>
<td>Fail No Effect</td>
<td>Failure of a component that is part of the safety function but that has no effect on the safety function.</td>
</tr>
<tr>
<td>Fail-Safe State</td>
<td>State where the output current is ≤3.6 mA (fail low) or ≥21 mA (fail high)</td>
</tr>
<tr>
<td>Fail Safe</td>
<td>Failure that causes the current output to go to the defined fail-safe state without a demand from the process.</td>
</tr>
<tr>
<td>Functional Safety</td>
<td>The ability of a system to carry out the actions necessary to achieve or to maintain a defined safe state for the equipment under control of the system.</td>

CHAPTER 2

Description

The LWT series is specifically made for industrial applications and harsh environments. It provides continuous level measurement capabilities for process automation and inventory management in industries. It provides precise measurement of any solid or liquid independently from the material properties.

The LWT series of instruments are microprocessor-based level transmitters that use very low power microwave energy to determine the level of the product being measured. A rod or cable “probe” is hung into the vessel to act as a waveguide, i.e. microwave energy stays concentrated around the length of the probe instead of being dispersed, as it would be if there was no probe.

Depending on the type of configuration, it can meet the demands of hazardous area locations, and high pressure and high temperature applications. Ordering specifications are described in the LWT data sheet (AD2). Refer to this datasheet to get exact measuring range, operating temperature and accuracy specifications. The LWT is explosion-proof class 1, division 1.

Additional documentation on LWT series instruments is available for download at https://new.abb.com/products/measurement-products/level/guided-wave-radar-level-transmitters/LWT.
Instrument version

This safety manual applies to guided wave sensor LWT series, with the most up to date revision in this table:

CHAPTER 3

Designing a SIF using the LWT instrument

Figure 1 shows a safety function example with an LWT instrument. The vessel level is monitored by the guided wave level transmitter. The LWT 4–20 mA output loop is proportional to the level, ullage or volume of the vessel. Configuration of the LWT can be performed directly on its HMI or with the HART communication protocol through a computer or handheld terminal. The LWT connects to the user logic device to control one or multiple actuators for process control and SIF.

**Figure 1**  Safety function with LWT monitoring a vessel and user logic controlling it

Safety function

The guided wave level transmitter produces an analog signal, between 4 and 20 mA, proportional to the level, volume or ullage, as defined by the operator. The analog signal is fed to a downstream logics unit such as a PLC or a limit signal generator, and monitored for exceeding a specified maximum or minimum value. All safety functions refer exclusively to this analog output. The total valid range of the output signal shall be configured to a minimum of 3.6 mA and a maximum of 20.5 mA (factory defaults).

The LWT provides the following Type-B safety functions:

- Computes a distance/level measurement.
- Outputs a 4–20 mA signal of the transformed measurement.
- Measurement transformations are user-defined (math functions). These functions can be either on or off. Multiple parameters can be set related to:
  - Damping
  - Linearization function
  - Filtering

The safety related function of the transmitter is the safe monitoring of the level within an accuracy of 2 % of span (2 % of 16 mA). The safe state output current can be configured to be ≤3.6 mA (low alarm) or ≥21.0 mA (high alarm), with the exception of CPU faults, where the current output is in low alarm mode (≤3.6 mA), and 4–20 mA output readback faults, where current output is set to low alarm (≤3.6 mA) for lower than expected current and high alarm (≥21.0 mA) for higher than expected current.

There are other functionalities of the LWT that are not considered as part of the safety function:

- Digital input (optional, external)
- HART communication
- HMI (optional)
- Remote display (optional accessory)

Alarm response and current output

In case of detected critical faults, the configured alarm current will be produced and fed to a subsequent logic unit, e.g., a DCS, and monitored for violation of a defined maximum value.

Selectable alarm current modes

There are two selectable modes for this alarm current:

- HIGH (max alarm current) which is the factory default setting;
  or
- LOW (min alarm current).

DCS configuration

For safe fault monitoring, the following conditions must be fulfilled:

- The LOW ALARM must be configured with a value of ≤3.6 mA;
  or
- The HIGH ALARM must be configured with a value ≥21.0 mA.
- The DCS must be capable of recognizing the selected configured high alarms or low alarms as a malfunction detection.
For safe current output operation, the terminal voltage at the device must be between 15.5 V and 42 V, with a minimum of 21 V for HART functionality.

The DCS loop must provide the required voltage level even if the current output operates on the configured HIGH alarm.

The DCS shall be able to latch a detected high or low alarm, as the LWT alarm state may not be maintained after the alarm-triggering condition is not met anymore.

**Power On behavior**

On startup, the LWT current output will follow the following sequence:

1. Low alarm mode (≤3.6 mA) for approximately 1 s;
2. High alarm mode (≥21.0 mA) for a duration between 20 s and 40 s due to internal power management constraints.
3. Transition to intermediate value for approximately 1 s:
   - For level mode, go to high alarm mode (≥21.0 mA)
   - For distance mode, go to lower range value (4.0 mA)
   - For ullage or level mode, go to lower alarm mode (≤3.6 mA).

If a CPU fault occurs at startup during the instrument self-test, the current output is in low alarm mode (≤3.6 mA).

**Power failure alarm behavior**

As demonstrated through fault insertion testing, some internal hardware failures may cause the LWT to undergo a perpetual reset loop behavior which will be similar to its power on behavior as described above:

1. Low alarm mode (≤3.6 mA) for approximately 1 s;
2. High alarm mode (≥21.0 mA) for approximately between 10 and 20 s.

**Behavior of transition to alarm current**

The 4–20 mA output transition from nominal measurement to alarm current is performed in the following manner:

1. Nominal current output (e.g., 9.8 mA)
2. Transition to intermediate value for one measurement cycle, thus approximately 0.2 s:
   - 4.0 mA if primary value (PV) is set to Ullage or Distance
   - ≥21.0 mA if primary value (PV) is set to Level
3. Alarm current; high or low as described in “Selectable alarm current modes” on page 12.

**Conditions when device is not safety-compliant**

The device is not safety-compliant during the following conditions:

- During configuration
- When HART multidrop mode is activated
- During simulation
- During proof test of the safety function

The fraction of failures without the potential to put the device into a dangerous function status is given by the SFF value shown in “Safety parameters” on page 15.
Overall safety accuracy

The defined value for the safety threshold of the safety function of this device is: 2 % of 4–20 mA span (2 % of 16 mA).

Specific instrument modes and parameters for safety operation

For the proper operation in a Safety Instrumented System, parameters shall have the following values:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Echo Lost Period</td>
<td>[0, 600] s</td>
</tr>
<tr>
<td>Echo Lost Reaction</td>
<td>Failure</td>
</tr>
<tr>
<td>Alarm Delay</td>
<td>[0, 10] s</td>
</tr>
<tr>
<td>Blocking Distance</td>
<td>0</td>
</tr>
</tbody>
</table>

Behavior for undetected faults

If a LWT fault occurs and is not detected through its internal diagnostics, the safety function may output a current between 4 and 20 mA, which exceeds its specified safety accuracy or is not proportional to the level, volume or ullage as defined by the operator.

Environmental limits

The designer of a SIF must check that the product is rated for use within the expected environmental limits. Refer to the user guide (AD1) or datasheet (AD2) for accurate information about environmental limits. Some limits depend on the model and configuration installed on it.

LWT measurements can be affected by vapor in high-temperature and high-pressure applications. The LWT series provides gas phase compensation algorithms for such applications. However, this results in a differing specification for accuracy. Reference distance must be verified during the commissioning phase. More information can be found in AD1 or AD2.

LWT measurements can be affected by high vibration levels which can lead to the instrument not meeting the accuracy specification listed in AD3 or AD4.

The user shall perform verifications to ensure that proper measurements can be made in the target application environment.

Applications limits

LWTs can have flanges made of various types of metal. It is important for the designer to check for material compatibility considering on-site chemical contaminants and air supply conditions. If the LWT is used outside of the application limits or with incompatible materials, the reliability data provided could become invalid.

Design verification

A failure mode, effects and diagnostics analysis (FMEDA) summary report is available from ABB Inc. This report details all the failure rates and failure modes as well as the expected lifetime of the LWT instrument.
The achieved SIL of an entire SIF design must be verified by the designer via a calculation of \( PFD_{\text{AVG}} \) considering architecture, proof test interval, proof test effectiveness, any automatic diagnostics, average repair time and the specific failure rates of all products included in the SIF. Each subsystem must be checked to ensure compliance with minimum hardware fault tolerance requirements.

The safety parameters used for SIL calculation of the SIF are shown in “Safety parameters” below.

### SIL capabilities

#### Systematic integrity

The product meets systematic integrity requirements for SIL 3. A SIF designed with this product must not be used at a SIL level higher than the statement without prior-use justification by the end user or diverse technology redundancy in the design.

#### Random integrity

The LWT is a type B device. Therefore, based on the SFF ≥90 %, when the LWT is used as the only component in a final element subassembly, a design can meet SIL 2 at HFT=0. When the final element assembly consists of many components, the SIL must be verified for the entire assembly using failure rates from all components. This analysis must account for any hardware fault tolerance and architecture constraints.

### Safety parameters

The table below shows the failure rate information obtained from the FMEDA and other useful information.

</tbody>
</table>
Considerations for High demand mode

In high demand mode, the end user shall comply with IEC61508-2 sections 7.4.5.3 and 7.4.5.4 for the failure rates to be applicable.

If compliance to these specified sections is not met, the end user shall contact ABB (see back cover of this document) to calculate appropriate failure rates.

General requirements

The user shall verify that the LWT is suitable for use in safety applications by confirming that the instrument has a metallic tag installed on it and that this tag shows the information illustrated below:

![SIL 2 Safety Integrity Level IEC 61508](image)

The figure below provides an example of this metallic ID tag installed on a LWT instrument.

Personnel performing maintenance and testing on the LWT shall be competent to do so.

Results from proof tests shall be recorded and reviewed periodically.
CHAPTER 4

Installation and commissioning

Only qualified and authorized specialists should be charged with the installation, electrical connection, commissioning, operation, and maintenance of LWT instruments.

Installation

The guided wave level transmitter must be installed with standard practices outlined in the user guide (AD1 or AD2). Environmental parameters such as temperature and pressure, to name a few, must be checked to verify that they do not exceed the LWT ratings. As far as possible, the measuring setup should be free from critical ambient conditions such as vibrations, shocks, and large variations in temperature.

Physical location and placement

The LWT shall be accessible with sufficient room for electrical connection and shall allow manual proof testing, as described in “Proof test” on page 21.

Electrical connection

See the user guide (AD1 or AD2) for electrical connection instructions. Connection details like wire gauges and maximum lengths of cable are described in this guide. Make sure that the LWT is grounded according to national and local electrical codes. Outside installations or installations exposed directly or indirectly to lightning discharges should have a secondary lightning protection module.

Do NOT make electrical connections unless the electrical code designation stamped on the LWT data plate matches the classification of the area in which you want to install the LWT.

Commissioning

The LWT needs to be configured before first use, since it comes with a factory default configuration. This instrument can be configured with the local HMI, with the DTM via the HART interface or with a handheld terminal. Configuring the device with the local HMI is documented in the user guide. During configuration, safe operation of the device shall not be assumed.
Checklist before safety operation

The following items must be checked before safety operation:

- After each startup (power on) of the device, as a part of a safety function, check that the device and its configuration fulfill the safety function of the system.
- Check that the right device is installed on the right measuring point.
- Make sure that the vessel empty (LRV) and vessel full (URV) parameters correspond to real values with appropriate units.
- After every change to the device, as a part of a safety function, such as a change to the installation position of the device, process type change or configuration of safety parameters, the safety function of the device shall be verified (see “Verify safety function” on page 19).
- After the safety function has been checked, device operation must be locked because a change to the measuring system or parameters can compromise the safety function. The write protection shall be enabled before powering up when it is desired to go into safe operation.

Adding password protection

To allow only authorized personnel to modify the LWT configuration, and therefore the safety function behavior, password protection must be added:

1. From the Device Setup menu, select Access Control > Advanced Password.
2. In the password edit screen, edit each password character.
3. Press OK.
4. Repeat steps 1 to 3 for Standard Password instead of Advanced Password.

Enabling/Disabling the write protection

The device shall be write-protected for the safety operation. This could be performed through the following steps:

1. Remove the nameplate by releasing the holding screw lying on the bottom left corner.
2. Use a suitable screwdriver to press the switch down fully.
3. Turn the switch clockwise by 90°.
To deactivate the switch and remove the write protection, push it down slightly and turn 90° counterclockwise.

**Verify safety function**

1. Verify and record the conditions as they are found prior to checking the safety function: write protection is on/off, instrument parameters.
2. Disable write protection before power up.
3. Check the current out precision by simulating current out and measure it with a multimeter. This could be performed by using an EDD/DTM interface or the HMI. The current out test shall test at least 4 mA and 20 mA.
4. Enable write protection and power down. If no alarm is issued after system startup, then the safety function is ensured during run-time.
CHAPTER 5

Operation and maintenance

Proof test

In accordance with IEC 61508, the safety function of the measuring device must be checked at appropriate time intervals. The operator must determine the proof test interval and take this into account when determining the PFD_{avg} value of the guided wave level transmitter. The test must be carried out in such a way that it verifies correct operation of the device.

Testing of fixed output current, HIGH and LOW alarm output current and measuring accuracy are covered in the proof test. Testing of the device can be performed by following the steps described below.

Testing the instrument

To check the safety function of the device, proceed as follows:

1. Verify and record the conditions found prior to checking the safety function: write protection is on/off, instrument parameters, warning messages and error messages.
2. Bridge the safety DCS or take other appropriate measures to prevent inadvertent triggering of alarms.
3. Remove the instrument from its installation flange. Perform a visual inspection and record any visible defects or wear outs.
4. Deactivate write protection (see “Enabling/Disabling the write protection” on page 18).
5. Performing the proof test requires the specified voltage input (see “Alarm response and current output” on page 12) in series with an ammeter (see Figure 2).
6 Set the transmitter output to a HIGH ALARM value by means of the HMI push buttons, HART communication by using a DTM in combination with HART software, or with the Field Information Manager (FIM-Tool) using simulation function (menu: Diagnostics>Simulation Mode>Current Out).

7 Check whether the current output signal reaches the value set for high alarm value.

8 Set the output of the transmitter to a LOW-ALARM value by means of the push buttons of the HMI, HART communication by using the LWT DTM or with the Field Information Manager tool (FIM-Tool) using simulation function (menu: Diagnostics>Simulation Mode>Current Out).

9 Check whether the current output signal reaches this value.

10 Terminate the simulation mode once the output simulation is finished.

11 Activate the write protection (see “Enabling/Disabling the write protection” on page 18) and wait for 10 seconds.

12 Restart the device by powering it off and back on.

13 Check the measured distance or ullage against a secondary standard on an installed device which could be a calibrated reference device, a mobile calibration rig or on a factory calibration rig. The measured values of the secondary standard and the device under test (DUT) must be compared. The amount of deviation between the measured distance, ullage and the set point must not exceed the measured error specified for the safety function (±0.32 mA).

14 Remove the bridging of the safety DCS or restore normal operation in another way.

15 After the test has been performed, the results must be documented and stored in a suitable manner. By using this test method at least 80.9 % (PTC = 0.809) of dangerous, undetected failures are detected. The influence of systematic errors (e.g., medium properties, operating conditions, build-up or corrosion on the safety function) is not fully covered by the test.

If one of the test criteria from the test procedure described above is not fulfilled, the device may no longer be used as part of a safety instrumented system.
Possible error messages

If the LWT is malfunctioning in any way, the LCD displays specific error messages destined to help you identify and solve the problem. The chapter “Maintenance and Troubleshooting” of the user guide explains where the error summary appears and how to access the full details of the error. CPU internal faults will result in the LOW alarm independent from the configured alarm current. Readback faults for the 4–20 mA output will result in the LOW alarm for lower than expected current and HIGH alarm for higher than expected current, independently from the configured alarm current. Other failures will be immediately signaled within the LOW or HIGH alarm range in line with the configured alarm current.

Maintenance

The LWT should have its coupler and probe inspected and cleaned when the proof test is performed (as described in “Proof test” on page 21). No other maintenance is planned.

Repair

To maintain safety operation, repairs must be performed by ABB after the instrument is taken out of service. Replacing modular components by original ABB spare parts is permitted if personnel was trained by ABB for this purpose.

Before sending the unit to ABB, it must be cleaned and decontaminated. ABB must be contacted to obtain the Contamination Data Sheet. After filling out and sending the contamination datasheet to ABB, an RMA number will be issued; after those steps the unit can be sent to ABB for repair.

Refer to the user guide for further details.

Software updates

Software updates, if applicable and recommended by ABB, must be performed by ABB-trained personnel after the instrument is taken out of service.

Useful life

The applied failure rates of the components are valid within the usable service life (8 to 12 years) according to IEC 61508-2 section 7.4.9.5, note 3, and start increasing after this period.

ABB notification

All detected failures that compromise functional safety shall be reported to ABB. Contact ABB customer service as described in “Support” on page 7.
