The requests to process other read or write Modbus jobs is transferred via the DRIVE_DATA variable at the IN_OUT variable DRIVE_DATA which can be connected to several other read/write function blocks e.g. ACS_MOD_READ_N_PRM *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212* or ACS_MOD_WRITE_N_PRM *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215* of this drive.

Communication with several ACS Drives

If several drives are used, for each drive a communication function block such as ACS_COM_MOD_TCPx_ENHANCED or ACS_COM_MOD_TCPx function block must be programmed.

The function block provides the basic start/stop signals, basic diagnosis signals and the scaling of the SPEED_REF input and ACT_SPEED to the ACS fieldbus scaling range -20000 .. +20000.

The AC500 CPU types provide different numbers of usable TCP/IP sockets. For each ACS Modbus TCP communication block (ACS_COM_MOD_TCPx and ACS_COM_MOD_TCPx_ENHANCED) one socket will be needed.

The user has to check that the programmed number of ACS_COM_MOD_TCPx or ACS_COM_MOD_TCPx_ENHANCED communication blocks is not higher than the number of available free sockets for the used CPU.

Diagnosis

The output ERNO, which reflects an actual error number is only valid for one cycle if DONE and ERR output are set to TRUE.

To catch this error number an external function must be programmed.

However there are internal diagnosis variables available, which are not shown at any output, but can be accessed from the function block instance. This can be done in three ways:

- Opening the "+" sign of function block instance in the declaration part being online.
- Create an assignment in the code with <instance>.<diagnosis variable>.
- Create a visualization element of the function block see ACS_COM_MOD_TCPx_ENHANCED_VISU_PH *Chapter 1.5.6.5.4.2 “ACS_COM_MOD_TCPx_ENHANCED_VISU_PH faceplate for the function block ACS_COM_MOD_TCPx_ENHANCED” on page 2405*.

The additional diagnosis variables are:

iWriteErrCnt:	number of errors in write jobs since EN = TRUE
wLastWriteErno:	holds the error number of the last executed write job

iReadErrCnt:	number of errors in read jobs since EN = TRUE
wLastReadErno:	holds the error number of the last executed read job

Preconditions

The function block is working with all ACS drives via Modbus TCP communication with field bus adapter FENA-X1.

The data transfer to other function blocks for this drive communication to the ACS drive is realized via the IN_OUTPUT variable DRIVE_DATA, which must be connected to ACS_COM_MOD_TCPx_ENHANCED even if no other function block is connected.

The following ACS drive parameters have to be set according to the configuration of the Modbus line and the inputs of the function block.

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

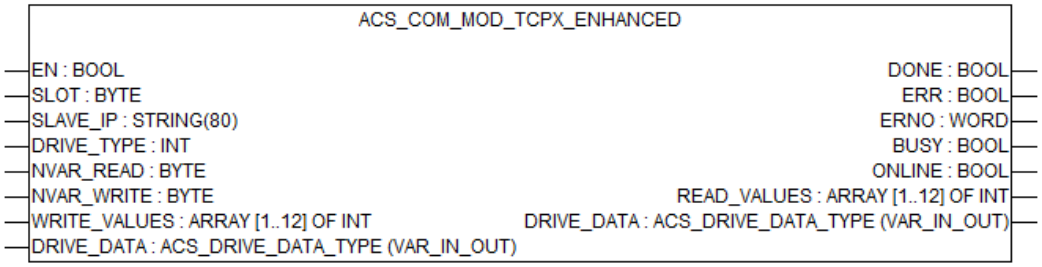
Setting according to AC500 configuration or function block input	**ACS355**	**ACS850, ACQ810, ACSM1,**	**ACS880, ACS580**	**ACX550, ACS800, DCS550, DCS800**
Communication module:	FENA-01	FENA-11	FENA-11	ENHANCED not possible with RETA-0X
Fieldbus activation = EXT FBA	98.02	50.01	50.01	
COMM RATE = Auto (0)	51.03	51.03	51.03	
IP CONFIGURATION = Static IP (0) ! not default ! Set 51.27 (Refresh) after first change to "Static IP".	51.04	51.04	51.04	
IP ADDRESS1 .. IP ADDRESS4	51.05 .. 51.08	51.05 .. 51.08	51.05 .. 51.08	
SUBNET CIDR = e.g. 255.255.255.0 = 24	51.09	51.09	51.09	
PROTOCOL / PROFILE = MB/TCP ABB E (ABB Drives Profile Enhanced) (1)	51.02	51.02	51.02	
Word order for 32-bit parameter access	No 32-bit access	51.22	51.22	
Timeout mode = None(0) or Any message(1), but not Ctrl write(2) as these values are only written after changes	51.21	51.21	Timeout mode	

Setting according to AC500 configuration or function block input	ACS355	ACS850, ACQ810, ACSM1,	ACS880, ACS580	ACX550, ACS800, DCS550, DCS800
Modbus Timeout. Depending on Timeout mode. Value in 100ms.	51.20	51.20	Modbus timeout	
Refresh settings in drive	51.27	51.27	51.27	

For further settings, e.g. reaction of drive at communication error, please see related drive and fieldbus manual.

Please refer FENA-X1 Ethernet adapter manual for more information.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable) Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the block is active, the current values are available at the outputs.

After a rising edge (FALSE -> TRUE) of input EN output ONLINE is set to FALSE and parameters are read from the ACS drive.

After successfully reading and writing of the ACS parameters, output ONLINE is set to TRUE.

The processing of continuously read of status information from the drive (SW, ACT_VALUE1 and ACT_VALUE2) and writing of Control Word and Reference Values (CW, SPEED_REF, REF_VALUE2) after changes to the drive is started.

If EN is reset to FALSE while a Modbus job is performed (BUSY = TRUE), the function block will be processed until the Modbus job is terminated (DONE = TRUE for 1 cycle).

If EN = FALSE the outputs ONLINE are reset to zero, as well as the data SW, actValue1 and actValue2 on the DRIVE_DATA variable are reset to zero. The elements of the READ_VALUES array are also reset to zero.

SLOT (slot) Data type: BYTE

At input SLOT, the Modbus interface number is specified:

SLOT = 1 : internal Ethernet communication module ETH1

SLOT = 2 : internal Ethernet communication module ETH2

SLOT = 11 : SLOT1 (CM597-ETH)

SLOT = 21 : SLOT2 (CM597-ETH)

SLOT = 31 : SLOT3 (CM597-ETH)

SLOT = 41 : SLOT4 (CM597-ETH)

Default value = 1. Valid values = 1, 2, 11, 21, 31, 41

SLAVE_IP (slave IP-Address)

Data type: STRING

IP Address of the drive (slave) to which the connecton shall be established must be specified here as string. Used with 4 times 3 digits.

Default value: ‘192.168.005.003’

DRIVE_TYPE (drive type)

Data type: INT, Default value: ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM. The input can be set either by the value directly or by using the enum.

ENUM	Value
ACS_DRIVE_ACS800	1
ACS_DRIVE_ACSM1	2
ACS_DRIVE_ACS350	3
ACS_DRIVE_ACS355	4
ACS_DRIVE_ACS310	5
ACS_DRIVE_ACS550	6
ACS_DRIVE_ACH550	7
ACS_DRIVE_ACQ810	8
ACS_DRIVE_ACS850	9
ACS_DRIVE_ACS880	10
ACS_DRIVE_ACS580	11
ACS_DRIVE_DCS800	12
ACS_DRIVE_DCS550	13
ACS_DRIVE_ACH580	14
ACS_DRIVE_ACS380	15
ACS_DRIVE_ACS480	16
ACS_DRIVE_ACQ580	17

NVAR_READ (number of variables for reading)

Data type: BYTE

With the input NVAR_READ the function block can be configured to read between 1 and 12 signals from the drive. All read data is written to the array at the READ_VALUE output. Configuration in ACS drive is depending of configured parameters in group FBD DATA IN in drive

Default value = 0. Minimum 0, Maximum 12.

To read/write "one" 32-bit data, the NVAR should be equal to 2. Accordingly this has to be followed if we want to read/write more than one data. The user has to check that the programmed number of ACS_COM_MOD_TCPx or ACS_COM_MOD_TCPx_ENHANCED communication blocks is not higher than the number of available free sockets for the used CPU.

NVAR_WRITE (number of variables for writing)

Data type: BYTE

The internal Modbus write job writes 3 + NVAR_WRITE words starting from Modbus register address 400001 to the drive, every time a change in those variables is detected.

With the input NVAR_WRITE the function block can be configured to write between 0 and 12 variables more to the drive in addition to the 3 controls (CW, ref1 and ref2). These are always written to Modbus registers addresses 400001 .. 400003 if changed.

If NVAR_WRITE input is set to e.g. 5 the internal write job addresses the Modbus registers from 400001 .. 400008.

The first 3 signals are always the Control Word (CW), Reference value1 and Reference value2 and will be taken from the DRIVE_DATA variable.

The additional NVAR_WRITE data will be taken from the array at the WRITE_VALUES input.

Default value = 0. Minimum 0, Maximum 12.

WRITE_VALUES (write values to mapped parameters in drive group DATA_OUT)

Data type: ARRAY[1..12] OF INT

The values from the array at input WRITE_VALUE will be written to Modbus registers 400004 400015 in the drive. The number of data written to the drive is specified at the input NVAR_WRITE.

See table in chapter Writing Control Word and Reference Values to the drive for information about how to configure the drive.

DRIVE_DATA (drive data)

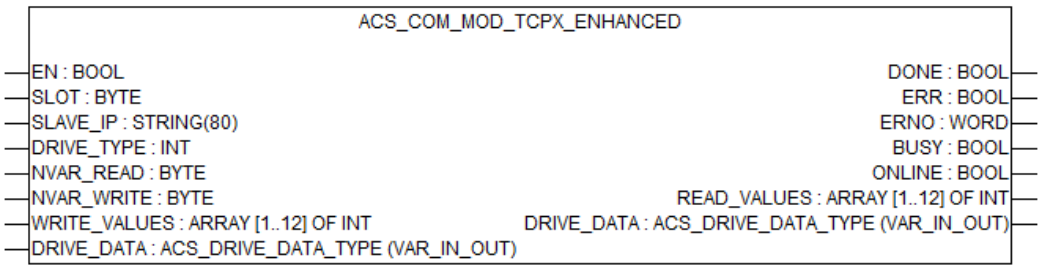
Data type: ACS_DRIVE_DATA_TYPE ↬ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_TCPx_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus TCP jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy)

Data type: BOOL

Output BUSY indicates whenever there is a communication action performed.

ONLINE (online)

Data type: BOOL

After the first time input EN is set to TRUE and at least one read job and one write job is performed successfully, output ONLINE is set to TRUE.

Output ONLINE is reset to FALSE after a rising edge of EN or if an error occurs while reading the status information or writing the Control Word and Reference Values.

READ_VALUES (array of read values)

Data type: ARRAY[1..12] OF INT

At output READ_VALUES the values of the array are updated after the read status information job was terminated successfully (DONE = TRUE, ERR = FALSE, BUSY = FALSE).

The read status information job is requested cyclically. It reads data from the ACS drive starting at Modbus register 400051 up to the number specified at input 3 + NVAR_READ

READ_VALUES contains the data as follows:

READ_VALUES[1] = <Modbus register 400054>

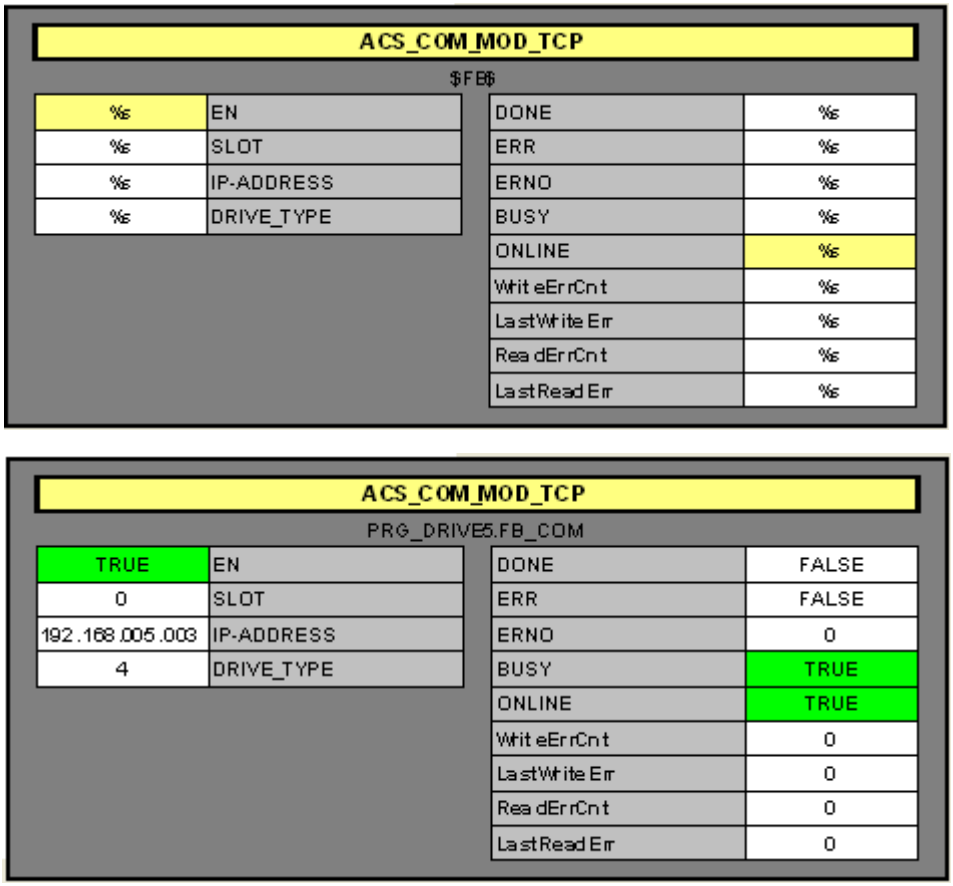
READ_VALUES[2] = <Modbus register 400055>

...

READ_VALUES[12] = <Modbus register 400065>.

1.5.6.5.4 Visualization

ACS_COM_MOD_TCPx_VISU_PH faceplate for the function block ACS_COM_MOD_TCPx



Visualization element ACS_COM_MOD_TCPx_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_TCPx *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385* function block which instance was used to replace the placeholder FB.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

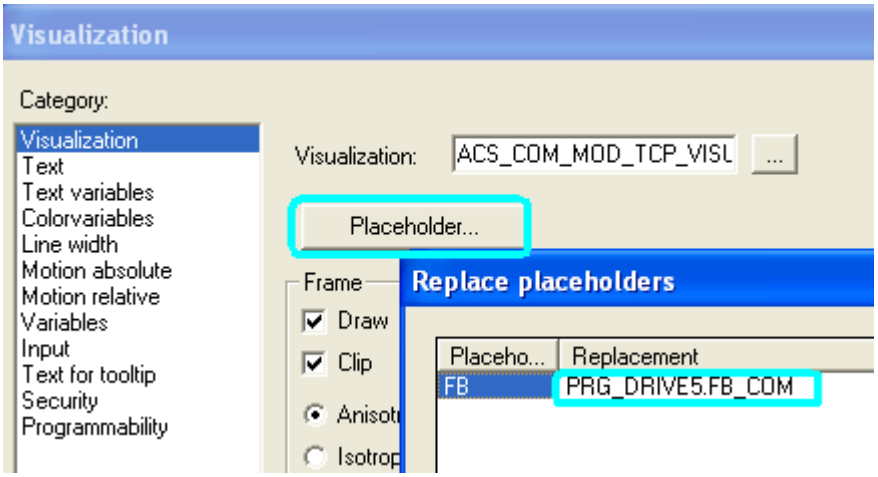
Visualization information

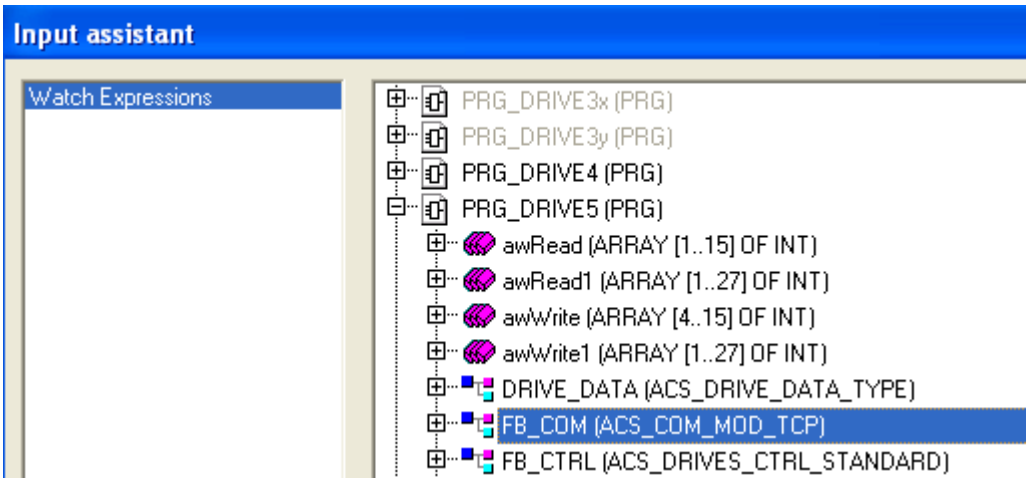
Available in runtime system:	V2.4
Included in library:	ACSDrivesComModTCP_Ext_AC500_V24.lib

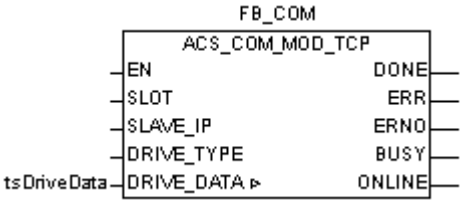
Visualization description

Visualization element ACS_COM_MOD_TCPx_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_TCPx *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385*function block which instance was used to replace the placeholder FB.

All inputs of that ACS_COM_MOD_TCPx ↳ *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385* function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.







Parameters

Access R/W

EN Access via: Toggle
Description: EN input

SLOT Access via: Numpad 1, 2, 11, 21, 31, 41
Description: SLOT (module number) of the communication module

IP_ADDRESS Access via: Text
Description: Slave address

DRIVE_TYPE Access via: Numpad 1 ..17

Description: DRIVE_TYPE input

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Drivel.FB_COM

Access R

MCW Description: Control Word to the drive

RefValue1 Description: Reference value 1 to the drive

RefValue2 Description: Reference value 2 to the drive

DONE Description: DONE output.

ERR Description: ERR output.

ERNO Description: ERNO output.

BUSY Description: BUSY output.

ONLINE Description: ONLINE output

WriteErrCnt Description: Numbers of write errors since EN = TRUE, is reset to 0 with rising edge of EN.

LastWriteErno Description: Error number of the last write job. See error messages of ETH_MOD_MAST function block.

ReadErrCnt Description: Numbers of read errors since EN = TRUE, is reset to 0 with rising edge of EN.

LastReadErno Description: Error number of the last read job. See error messages of ETH_MOD_MAST function block.

Colors

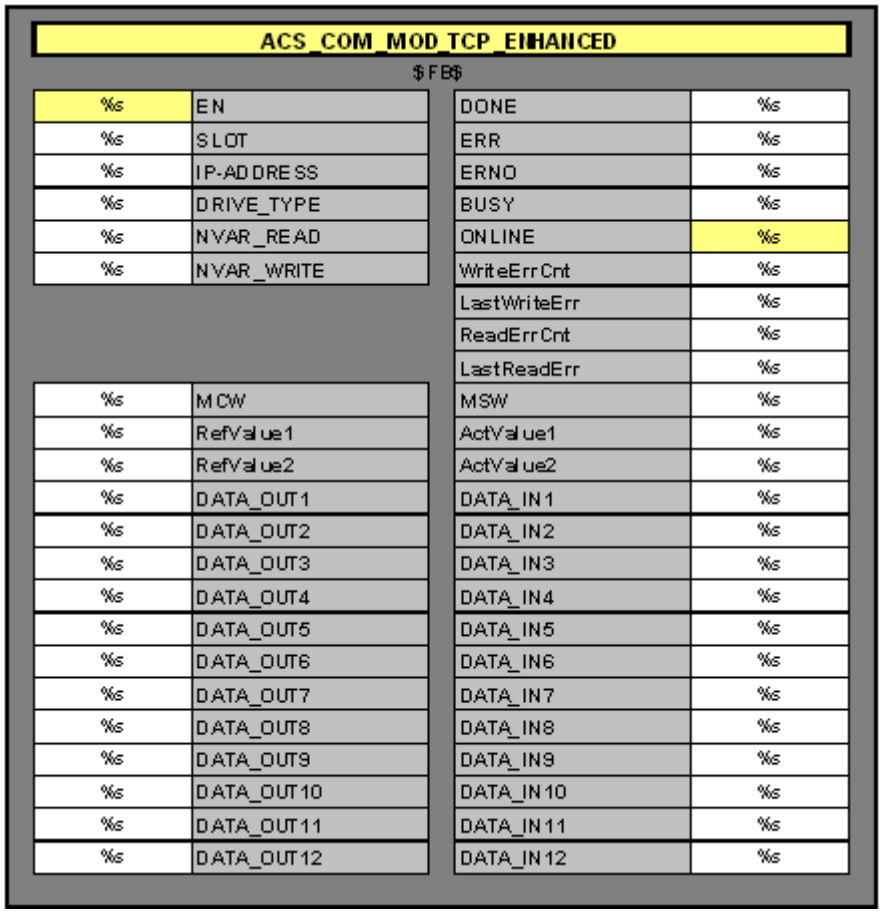
The color of the variables have the following meaning:

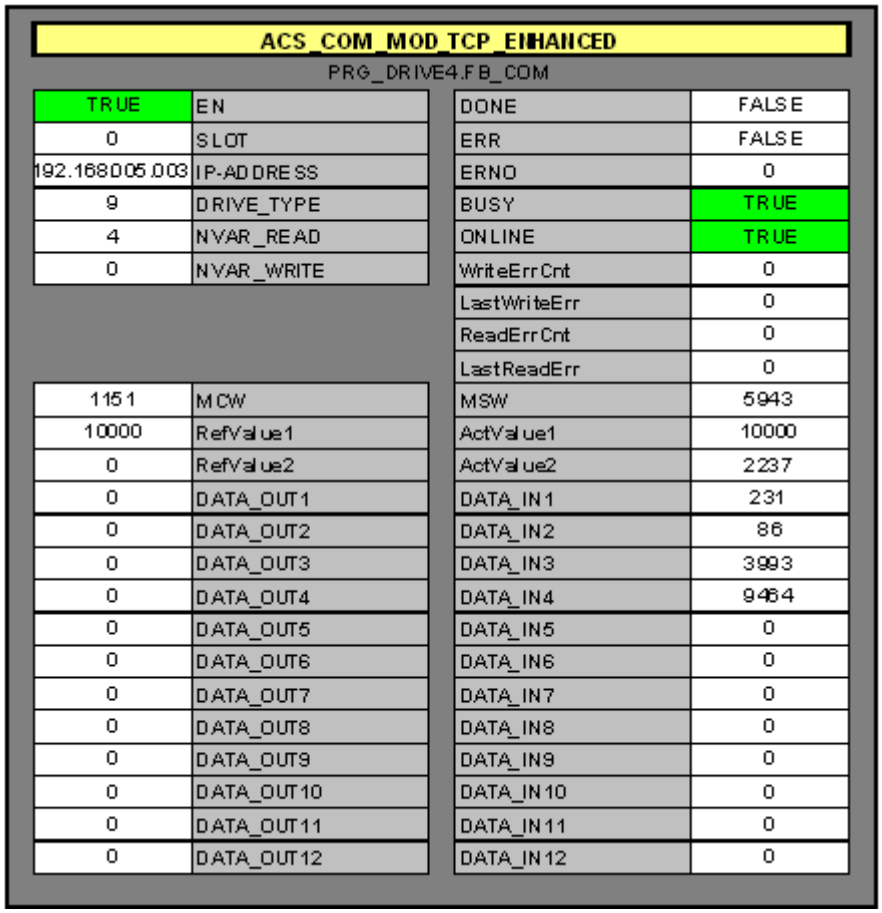
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_COM_MOD_TCPx_ENHANCED_VISU_PH faceplate for the function block ACS_COM_MOD_TCPx_ENHANCED





Visualization element ACS_COM_MOD_TCPx_ENHANCED_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_TCPx_ENHANCED ↳ *Chapter 1.5.6.5.3.2 “ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2392* function block which instance was used to replace the placeholder FB.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

Visualization information

Available in runtime system:	V2.4.x
Included in library:	ACSDrivesCom-ModTCP_Ext_AC500_V24_App.lib

Visualization description

Visualization element ACS_COM_MOD_TCPx_ENHANCED_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_TCPx_ENHANCED ↳ *Chapter 1.5.6.5.3.2 “ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2392* function block which instance was used to replace the placeholder FB.

All inputs of that ACS_COM_MOD_TCPx_ENHANCED function block, which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.

green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

1.5.6.6 ACS / DCS Drives communication via PROFIBUS

1.5.6.6.1 Preconditions for the use of the ACS / DCS drives communication via PROFIBUS library

The function blocks contained in the library can only be executed in RUN mode of the PLC, but not in simulation mode.

The blocks can only be used in combination with the ACSDrives-Base_AC500_V20 Library.

The library is released for the following products:

- CPUs: AC500
- Fieldbus: PROFIBUS
- Drives: ACS800, ACSM1, ACS355, ACS550, ACH550, ACQ810, ACS850, ACS880, ACS580, DCS550, DCS800
- PROFIBUS configuration:
  Prior to the use of the function blocks PROFIBUS Communication Module has to be configured accordingly using Automation Builder, at "Interfaces".

If the ACS_PB_READ_N_PRM_DPV1 function blocks are used at the same time the DriveManager is connecting, refreshing or writing variables, it might come to an error on either the ACS_PB_READ_N_PRM_DPV1 block or the DriveManager.

The DriveManager might be disconnected!

1.5.6.6.2 Components of the ACS / DCS drives communication via PROFIBUS library

Function blocks

ACS_COM_PB ↳ *Chapter 1.5.6.6.3.1 “ACS_COM_PB communication block via PROFIBUS” on page 2412*	Basic communication block for ABB / DCS drives via PROFIBUS DP using FBPA-01 or RPBA-01 communication modules including direct access for PZD1..3
ACS_COM_PB_PZD ↳ *Chapter 1.5.6.6.3.2 “ACS_COM_PB_PZD communication block for direct access to PZD4..12” on page 2415*	Communication block, which gives direct access for PZD4..12
ACS_PB_READ_PRM_DPV0 ↳ *Chapter 1.5.6.6.3.3 “ACS_PB_READ_PRM_DPV0 read parameters from ABB drives via PROFIBUS DPV0” on page 2420*	Read a parameter from drive via PROFIBUS DPV0 (using PKWs) - only for PPO-Types PPO 1, 2, 5 or 7
ACS_PB_WRITE_PRM_DPV0 ↳ *Chapter 1.5.6.6.3.4 “ACS_PB_WRITE_PRM_DPV0” on page 2423*	Write a parameter to drive via PROFIBUS DPV0 (using PKWs) - only for PPO-Types PPO 1, 2, 5 or 7
ACS_PB_READ_N_PRM_DPV1 ↳ *Chapter 1.5.6.6.3.5 “ACS_PB_N_READ_PRM_DPV1 read parameters from ABB drives via PROFIBUS DPV1” on page 2425*	This function block reads up to 37 parameters from an ACS / DCS drive via PROFIBUS DPV1 in a single query.
ACS_PB_WRITE_N_PRM_DPV1 ↳ *Chapter 1.5.6.6.3.6 “ACS_PB_N_WRITE_PRM_DPV1 write parameters from ABB drives via PROFIBUS DPV1” on page 2431*	This function block writes up to 37 parameters to an ACS / DCS drive via PROFIBUS DPV1 in a single query.

Visualizations

ACS_COM_PB_VISU_PH ↳ *Chapter 1.5.6.6.4.1 “ACS_COM_PB_VISU_PH visualization to run the ACS_COM_PB function block.” on page 2438*	Visualization to run the ACS_COM_PB function block.

ACS_PB_WRITE_PRM_DPV0_VISU_PH ↳ *Chapter 1.5.6.6.4.4 “ACS_PB_WRITE_PRM_DPV0_VISU_PH visualization to run the ACS_PB_WRITE_PRM_DPV0 function block.” on page 2445*	Visualization to run the ACS_PB_WRITE_PRM_DPV0 function block.

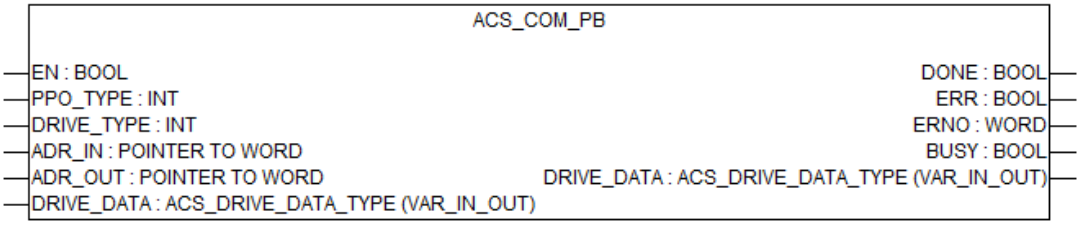
ACS_PB_READ_N_PRM_DPV1_VISU_PH *Chapter 1.5.6.6.4.5 "ACS_PB_READ_N_PRM_DPV1_VISU_PH visualization to run the ACS_PB_READ_N_PRM_DPV1 function block." on page 2447*	Visualization to run the ACS_PB_READ_N_PRM_DPV1 function block.
ACS_PB_WRITE_N_PRM_DPV1_VISU_PH *Chapter 1.5.6.6.4.6 "ACS_PB_WRITE_N_PRM_DPV1_VISU_PH visualization to run the ACS_PB_WRITE_N_PRM_DPV1 function block." on page 2449*	Visualization to run the ACS_PB_WRITE_N_PRM_DPV1 function block.

Global variables

ACS_VERSION_INFOR-MATION	Stores all the version information of the file along with the change log. No variable is declared inside this section.

1.5.6.6.3 Function blocks

ACS_COM_PB communication block via PROFIBUS



Function block ACS_COM_PB provides a PROFIBUS interface to the cyclic exchanged process data (PZD) of the PROFIBUS. It includes the handshake to READ/WRITE single parameters via PKWs variables for PPO-Types, that include PKWs (only in DPV0).

Function block information

Available in runtime system:	V2.4
Included in library:	ACSDrivesComPB_AC500_V24.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_COM_PB provides a PROFIBUS interface to the cyclic exchanged process data (PZD) of the PROFIBUS. It includes the handshake to read / write single parameters via PKWs variables for PPO-Types that include PKWs (only in DPV0).

ACS and DCS drives offer different telegram types in their GSD file for cyclic data transmission. These different telegrams are so called Parameter Process Data Object (PPO). Each PPO contains a Process Data channel (PZD) and sometimes (only for DPV0) also a Parameter channel (PKW). (For more details refer to FPBA-01 or RPBA-01 PROFIBUS DP user manual.)

To READ / WRITE single parameters via PKWs, the separate blocks ACS_PB_READ_PRM_DPV0 and ACS_PB_WRITE_PRM_DPV0 can be used and therefore must be connected to the same DRIVE_DATA variable as the ACS_COM_PB.

For PROFIBUS the following function blocks can only be used together with this ACS_COM_PB block:

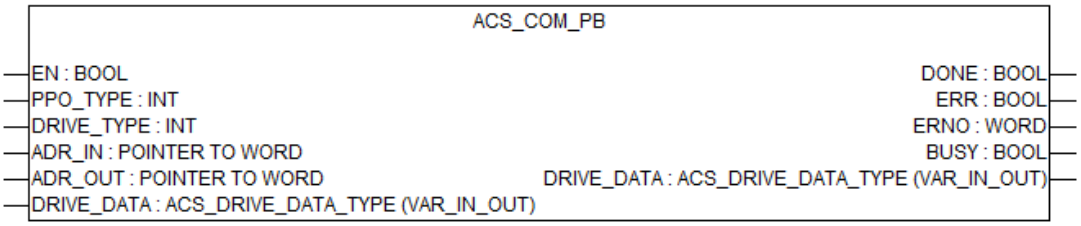
- ACS_COM_PB_PZD
- ACS_PB_READ_PRM_DPV0
- ACS_PB_WRITE_PRM_DPV0

- ACS_DRIVES_CTRL_STANDARD
- ACS_DRIVES_CTRL_ENG
- ACS3XX_DRIVES_CTRL_BASIC
- DCS_DRIVES_CTRL

In the Automation Builder configuration one of the PPO types 1..8 with predefined number of PKW and PZDs has to be selected. ADR_IN and ADR_OUT inputs of the function block need to be connected to the address of the first input process variable, and to the address of the first output variable respectively.

> *For parameter setting inside drive, please refer the respective drives / fieldbus module manual for parameter setting.*

Input description



> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN (enable)

Data type: BOOL

It enables function block processing.

The function block is not processed, if input EN = FALSE.

While input is set to TRUE, the inputs are continuously checked for validity and plausibility.

If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

PPO_TYPE (parameter process data object type)

Data type: INT

At the input PPO_TYPE the configured PPO-Type must be set.

E.g., if PPO-Type 5 is configured the input PPO_TYPE must be set to 5.

DRIVE_TYPE (drive type)

Data type: ENUM, Default value: ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM or INT. (Please refer ACS_DRIVE_ENUM for details.) The input can be set either by the value directly or by using the enum.

ADR_IN (ADR_IN)

Data type: POINTER TO WORD

Address of the first process input variable (PZD).

(PKW0 or PZD0 if no PKW is available in the PPO-Type).

With this address and the correct input PPO_TYPE, all other variables can be accessed directly via the function block ACS_COM_PB_PZD and a drives control block (e.g. ACS_DRIVES_CTRL_STANDARD, DCS_DRIVES_CTRL, ACS_DRIVES_CTRL_ENG, ACS3XX_DRIVES_CTRL_BASIC). So the configuration of input and output variables can be reduced to the first variable only.

ADR_OUT (ADR_OUT)

Data type: POINTER TO WORD

Address of the first process output variable (PZD).

(PKW0 or PZD0 if no PKW is available in the PPO-Type).

With this address and the correct input PPO_TYPE, all other variables can be accessed directly via the function block ACS_COM_PB_PZD and a drives control block (e.g. ACS_DRIVES_CTRL_STANDARD, DCS_DRIVES_CTRL, ACS_DRIVES_CTRL_ENG, ACS3XX_DRIVES_CTRL_BASIC). So the configuration of input and output variables can be reduced to the first variable only.

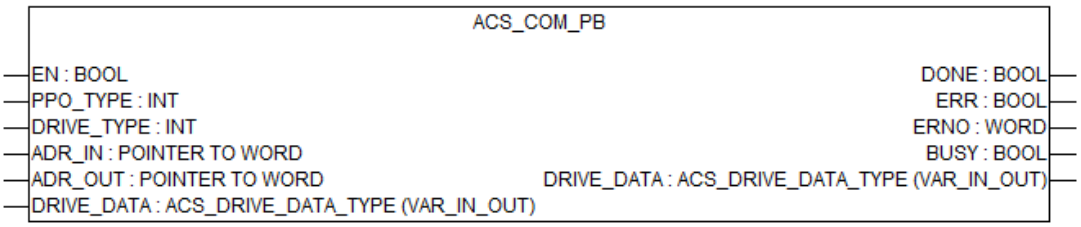
DRIVE_DATA (drive data)

Data type: ACS_DRIVE_DATA_TYPE ↳ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the processing state of the block.

If DONE = FALSE, the function block is not processed due to EN = FALSE and all outputs are set to 0.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in a separate table of Error Messages (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BUSY (busy) Data type: BOOL

Output BUSY = TRUE is indicating that the function block is enabled.

In case of an error of this block, the BUSY output will be set to FALSE while ERR = TRUE. In case of a read / write error of a function block that is attached to the DRIVE_DATA variable, the BUSY will stay TRUE and ERR = TRUE.

Calling of ACS_COM_PB in ST

```
AcsComPb (EN                                    := xAcsComPb_EN,

PPO_TYPE              := iAcsComPb_Ppo_Type,

DRIVE_TYPE         := iAcsComPb_Drive_Type,

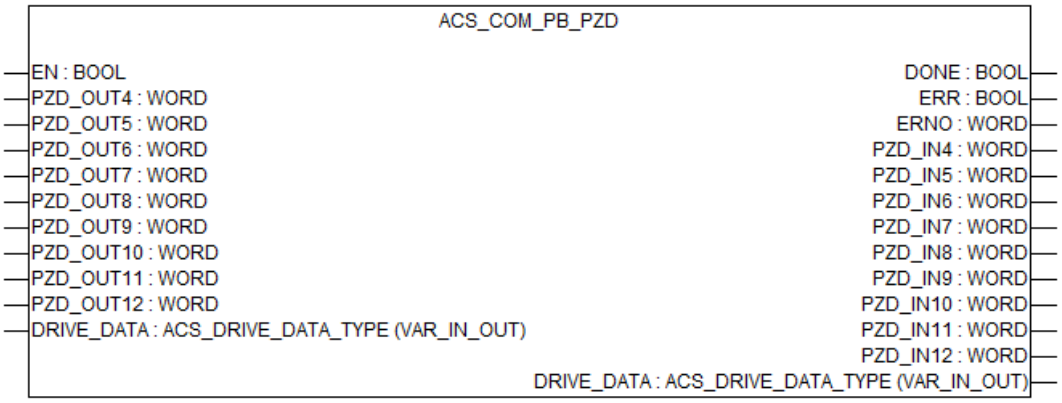
ADR_IN                          := ADR(pAcsComPb_AdrIn),

ADR_OUT                   := ADR(pAcsComPb_AdrOut),

                                                DRIVE_DATA      :=
AcsComPb_DriveData);

xAcsComPb_Done     := AcsComPb.DONE;
xAcsComPb_Err         := AcsComPb.ERR;
wAcsComPb_Erno     := AcsComPb.ERNO;
xAcsComPb_Busy  := AcsComPb.Busy
```

ACS_COM_PB_PZD communication block for direct access to PZD4..12



Function block ACS_COM_PB_PZD gives direct access to the PZD 4 .. 12. It must be used together with ACS_COM_PB function block.

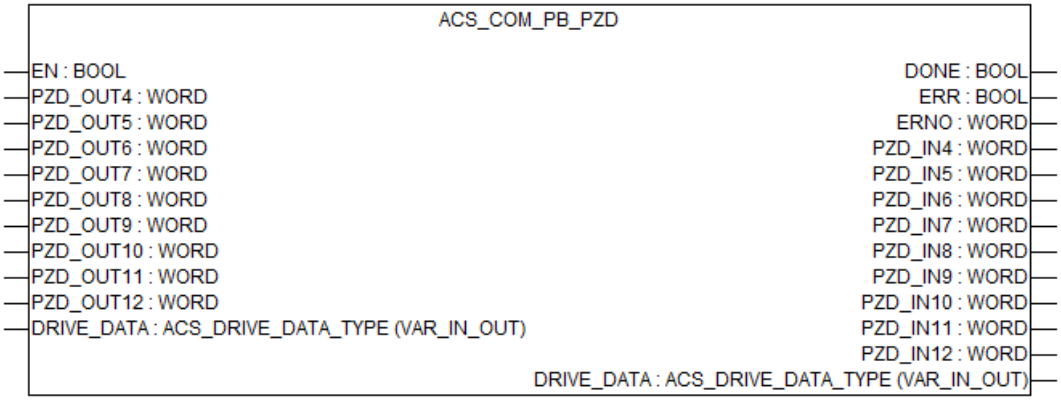
Function block information

Available in runtime system:	V2.4 and above
Included in library:	ACSDrivesComPB_AC500_V24.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_COM_PB_PZD gives direct access to the PZD 4 .. 12. User can use PZD 4 to 12 IN and OUT to read and write PZD parameters with ease. Therefore the DRIVE_DATA variable must be connected to the related ACS_COM_PB function block.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the function block is active, the current values are available at the outputs.

If the function block is deactivated (EN = FALSE), then all outputs are reset to zero.

PZD_OUT4 (PZD output 4)

Data type: WORD

Process Data word to drive

Available with PPO_Type: 2,4,5,6,7,8

PZD_OUT5 (PZD output 5)

Data type: WORD

Process Data word to drive

Available with PPO_Type: 2,4,5,6,7,8

PZD_OUT6 (PZD output 6)
Data type: WORD
Process Data word to drive
Available with PPO_Type: 2,4,5,6,7,8

PZD_OUT7 (PZD output 7)
Data type: WORD
Process Data word to drive
Available with PPO_Type: 5,6,7,8

PZD_OUT8 (PZD output 8)
Data type: WORD
Process Data word to drive
Available with PPO_Type: 5,6,7,8

PZD_OUT9 (PZD output 9)
Data type: WORD
Process Data word to drive
Available with PPO_Type: 5,6,7,8

PZD_OUT10 (PZD output 10)
Data type: WORD
Process Data word to drive
Available with PPO_Type: 5,6,7,8

PZD_OUT11 (PZD output 11)
Data type: WORD
Process Data word to drive
Available with PPO_Type: 7,8

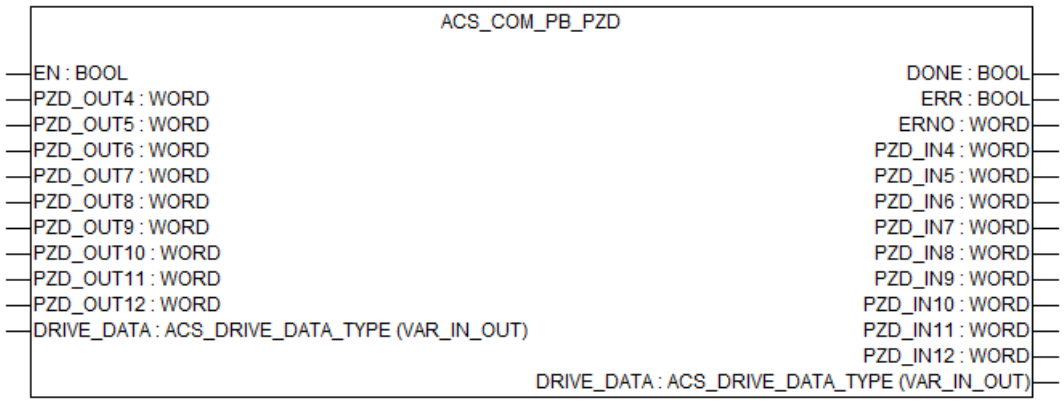
PZD_OUT12 (PZD output 12)
Data type: WORD
Process Data word to drive
Available with PPO_Type: 7,8

DRIVE_DATA (drive data)
Data type: ACS_DRIVE_DATA_TYPE ↯ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the processing state of the function block.

The DONE remains TRUE as long as the EN is TRUE.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in a separate table of Error Messages (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

PZD_IN4 (PZD input 4)

Data type: WORD

Process Data word to drive

Available with PPO_Type: 2,4,5,6,7,8

PZD_IN5 (PZD input 5)

Data type: WORD

Process Data word to drive

Available with PPO_Type: 2,4,5,6,7,8

PZD_IN6 (PZD input 6)

Data type: WORD

Process Data word to drive

Available with PPO_Type: 2,4,5,6,7,8

PZD_IN7 (PZD input 7)
Data type: WORD

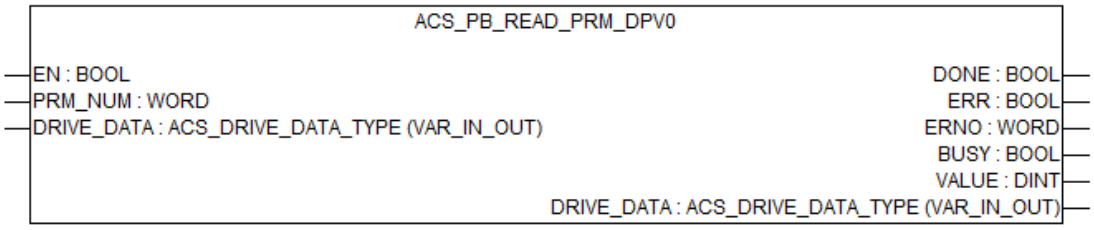
ACS_PB_READ_PRM_DPV0 read parameters from ABB drives via PROFIBUS DPV0



Function block ACS_PB_READ_PRM_DPV0 is used to read parameters from ACS / DCS drive using PROFIBUS communication via PKW. It must be used together with ACS_COM_PB function block.

Function block information

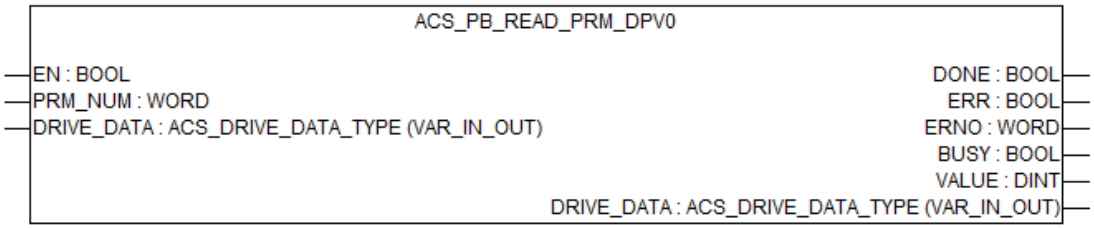
Available in runtime system:	V2.4 and above
Included in library:	ACSDrivesComPB_AC500_V24.lib
Function block type:	Function block with historical values.

If the ACS_PB_READ_N_PRM_DPV1 function block is used at the same time the DriveManager is connecting, refreshing or writing variables it might come to an error on either the ACS_PB_READ_N_PRM_DPV1 block or the DriveManager.

Block description

Function block ACS_PB_READ_PRM_DPV0 reads one drive parameter using PROFIBUS DPV0 communication via PKW especially for ABB Drives. This function block works only with PPO types that contains the PKW part (e.g. PPO 1, 2, 5 or 7.)

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type: BOOL

It enables function block processing.

The function block is not processed if input EN = FALSE.

While input is set to TRUE, the inputs are continuously checked for validity and plausibility.

If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

PRM_NUM (parameter number)

Data type: WORD

Input PRM_NUM is the parameter number in the drive which will be read. The parameter number is calculated from group number and index.

Parameter: 2 digits = group, 2 digit = index, e.g. Par 20.06 = 2006

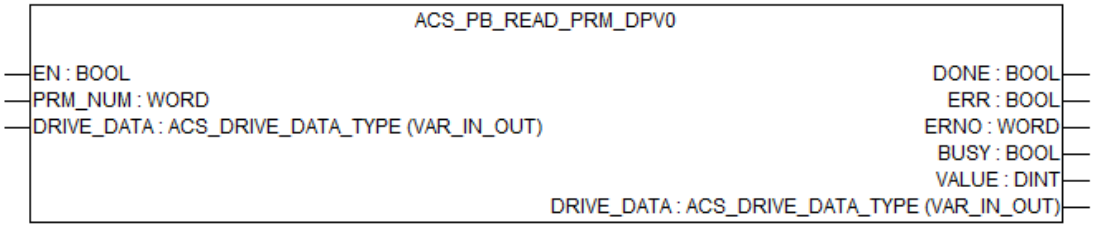
DRIVE_DATA (drive data)

Data type: ACS_DRIVE_DATA_TYPE ↬ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

Output description



DONE (done) Data type: BOOL

Output DONE indicates the processing of the function block. If DONE = FALSE, the function block is not processed due to EN = FALSE and all outputs are set to 0.

For that reason, the other outputs always have to be considered together with output DONE. All other outputs are only valid, if DONE = TRUE.

DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in a separate table of Error Messages (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BUSY (busy) Data type: BOOL

Output BUSY = TRUE indicates, that the read job requested by the function block is being processed.

VALUE (value) Data type: DINT

Parameter value of the READ parameter

Calling of ACS_PB_READ_PRM_DPV0 in ST

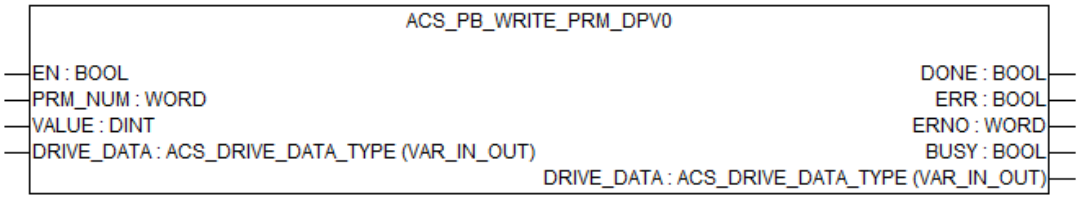
```
AcsPBReadPrmDpv0     (EN                                  :=
xAcsPBReadPrmDpv0_En,

            PRM_NUM             := wAcsPBReadPrmDpv0_PrmNum,

            DRIVE_DATA := AcsPBReadPrmDpv0_DriveData);

xAcsPBReadPrmDpv0_Done            := AcsPBReadPrmDpv0.DONE;
xAcsPBReadPrmDpv0_Err                := AcsPBReadPrmDpv0.ERR;
xAcsPBReadPrmDpv0_Busy            := AcsPBReadPrmDpv0.BUSY;
diAcsPBReadPrmDpv0_Value    := AcsPBReadPrmDpv0.VALUE;
```

ACS_PB_WRITE_PRM_DPV0



Function block ACS_PB_WRITE_PRM_DPV0 is used to write parameters to ACS / DCS drive using PROFIBUS communication. It must be used together with ACS_COM_PB function block

Function block information

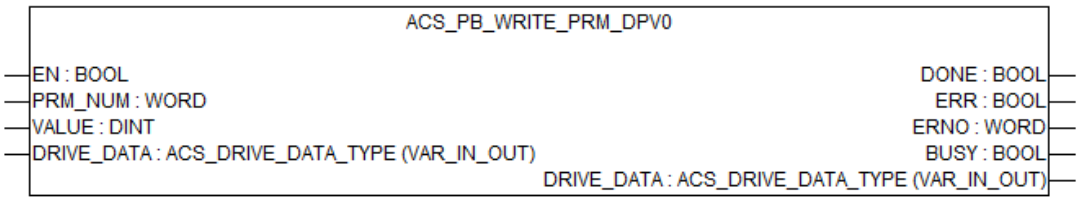
Available in runtime system:	V2.4 and above
Included in library:	ACSDrivesComPB_AC500_V24.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_PB_WRITES_PRM_DPV0 writes one drive parameter using PROFIBUS DPV0 communication via PKW especially for ABB Drives.

This function block works only with PPO types that contain the PKW part (e.g. PPO 1, 2, 5 or 7.)

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type: BOOL

It enables function block processing (edge sensitive).

The function block is not processed if input EN = FALSE.

While input is set to TRUE, the inputs are continuously checked for validity and plausibility.

If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

PRM_NUM (parameter number)

Data type: WORD

Input PRM_NUM is the parameter number in the drive which will be read. The parameter number is calculated from group number and index.

Parameter: 2 digits = group, 2 digit = index, e.g. Par 20.06 = 2006

VALUE (value)

Data type: DINT

Parameter value of the READ parameter

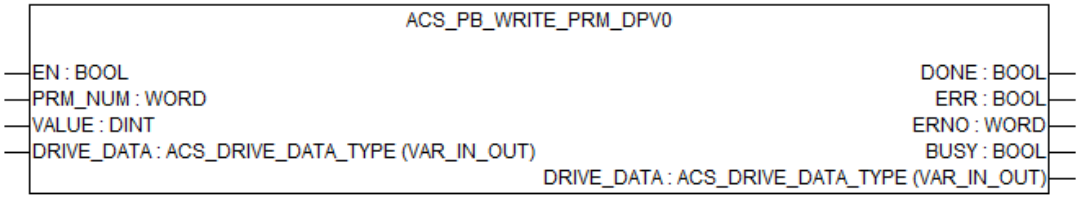
DRIVE_DATA (drive data)

Data type: ACS_DRIVE_DATA_TYPE ↬ *Chapter 1.5.6.2.6.2 "ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive" on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the processing of the function block. If DONE = FALSE, the function block is not processed due to EN = FALSE and all outputs are set to 0.

For that reason, the other outputs always have to be considered together with output DONE. All other outputs are only valid, if DONE = TRUE.

DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in a separate table of Error Messages (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BUSY (busy)

Data type: BOOL

Output BUSY is not used at the moment.

Calling of ACS_PB_WRITE_PRM_DPV0 in ST

```
AcsPBWritePrmDpv0 (EN                                    :=
xAcsPBWritePrmDpv0_En,

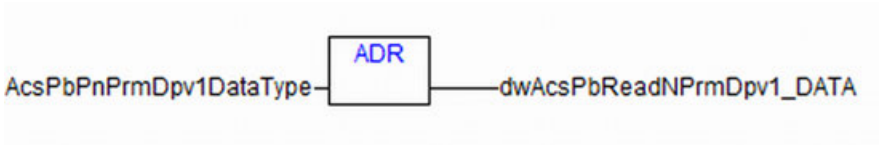
            PRM_NUM              := wAcsPBWritePrmDpv0_PrmNum,

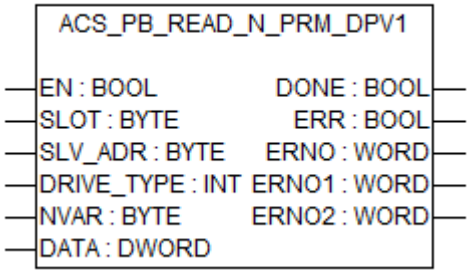
            VALUE                      := diAcsPBWritePrmDpv0_Value,

            DRIVE_DATA := AcsPBWritePrmDpv0_DriveData);

xAcsPBWritePrmDpv0_Done        := AcsPBWritePrmDpv0.DONE;
xAcsPBWritePrmDpv0_Err            := AcsPBWritePrmDpv0.ERR;
wAcsPBWritePrmDpv0_Erno     := AcsPBWritePrmDpv0.ERNO;
xAcsPBWritePrmDpv0_Busy        := AcsPBWritePrmDpv0.BUSY;
```

ACS_PB_N_READ_PRM_DPV1 read parameters from ABB drives via PROFIBUS DPV1





Function block ACS_PB_READ_N_PRM_DPV1 is used for reading maximum 37 parameters from a drive via PROFIBUS DPV1 in a single query.

Function block information

Available in runtime system:	V2.4 and above
Included in library:	ACSDrivesComPB_AC500_V24.lib
Function block type:	Function block with historical values.

> *If the ACS_PB_READ_N_PRM_DPV1 function block is used at the same time the DriveManager is connecting, refreshing or writing variables, it might come to an error on either the ACS_PB_READ_N_PRM_DPV1 block or the DriveManager.*

Block description

Function block ACS_PB_READ_N_PRM_DPV1 reads maximum 37 parameters from the drive in a single query. The number of parameters to be read is specified at the input NVAR. Parameters to read to the drive is specified at the DATA input.

ACS_PB_PN_PRM_DPV1_DATA_TYPE structure must be declared to a variable and connected to DATA input using ADR, which is to be entered with Group, Index .

Read parameter type and values are stored in the same variable.

ACS_PB_PN_PRM_DPV1_DATA_TYPE structure has the following array elements:

- abyPrmGroup : Array of 37 BYTE for specifying parameter Group.
- abyPrmIndex : Array of 37 BYTE for specifying parameter Index
- abyPrmType : Array of 37 BYTE
  READ parameter data type will be available here. For details refer to ACS_PB_PN_PRM_TYPE_ENUM *Chapter 1.5.6.2.5.2 “ACS_PB_PN_PRM_TYPE_ENUM” on page 2251*
- adwPrmValue: Array of 37 DWORD
  READ parameter value will be available here.

> *Currently user cannot use enumeration from ACS_PB_PN_PRM_TYPE_ENUM.*
>
> *Instead user need to use numerical values from ACS_PB_PN_PRM_TYPE_ENUM only.*

The values in the structure area are updated, when the READ job was performed without error. This is indicated by DONE=TRUE and ERR=FALSE.

Example

If the user need to read Parameter 10.01 and 11.05, then user need to enter the group and index number separately in input DATA as below:

DataStructure : ACS_PB_PN_PRM_DPV1_DATA_TYPE

Parameter Group : DataStruct.abyPrmGroup[1]:= 10; DataStruct.abyPrmGroup[2]:= 11;

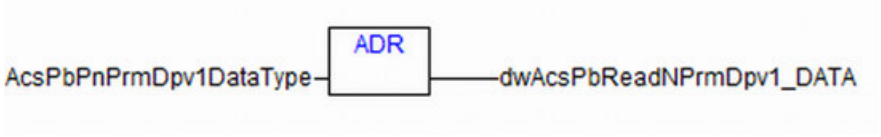
Parameter Index : DataStruct .abyPrmIndex [1]:= 01; DataStruct .abyPrmIndex [2]:= 05;

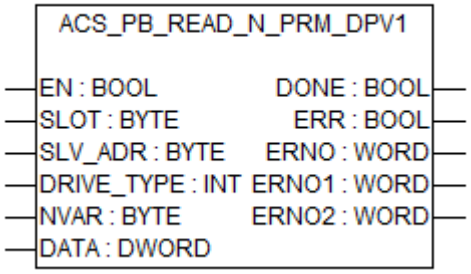
Parameter Type : Once read operation is complete parameter type will be stored inside DataStruct. abyPrmType [1]:= xx; DataStruct. abyPrmType [2]:= xx;

Parameter Value : Value will be stored inside DataStruct. adwPrmValue [1]:= xx; DataStruct. adwPrmValue [2]:= xx;

The values in the structure area are updated once the read job is performed without error. This is indicated by DONE=TRUE and ERR=FALSE.

Input description





EN (enable)

Data type: BOOL

In order to enable the function block processing, input EN has to be set from FALSE to TRUE.

While input is set to TRUE, the inputs are continuously checked for validity and plausibility.

If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

Default value = FALSE.

> *If multiple ACS_PB_READ_N_PRM_DPV1 and / or multiple ACS_PB_WRITE_N_PRM_DPV1 functions blocks enabled at the same time it may cause for error Read / Write error.*

SLOT (slot)

Data type: BYTE, Default value: 1, Range: 1 to 6

At input SLOT the communication module SLOT (module number) is selected, which should be used by the function block. All external Communication Modules are serially numbered from right to left, starting with module number 1.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

If the SLOT number is given incorrect or invalid, then the function block will displays an error. In such case ERR=TRUE and ERNO=16#4020.

SLV_ADR (slave address)

Data type: BYTE, Default value: 1, Range: 1 to 126

At input SLV_ADR, the address of the drive (slave), from which the parameter value is to be read, must be specified.

The function block is designed to be used with a fix SLAVE device. The SLAVE input should not be changed, while the program is running. If changed, nevertheless the new value will become effective, only after the function block is enabled again.

If the SLV_ADR is given incorrect or invalid, then the function block will display an error. In such case ERR=TRUE and ERNO=16#4030.

DRIVE_TYPE (drive type)

Data type: INT, Default value = ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM (enumeration). The input can be set either by the value directly or by using the enum ↳ *Chapter 1.5.6.2.5.1 “ACS_DRIVE_ENUM enumerations to select the type of drive used” on page 2251*.

If the DRIVE_TYPE is given invalid, then the function block will display an error. In such case ERR=TRUE and ERNO=16#4040.

NVAR (number of variables)

Data type: BYTE, Default value: 0, Range: 0 to 37

With input NVAR the function block can be configured to read between 0 to 37 drive parameter values.

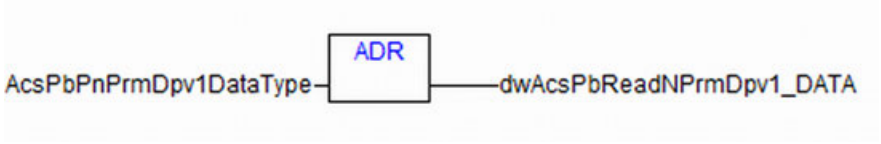
If the NVAR is given incorrect or invalid, then the function block will display an error. In such case ERR=TRUE and ERNO=16#4040.

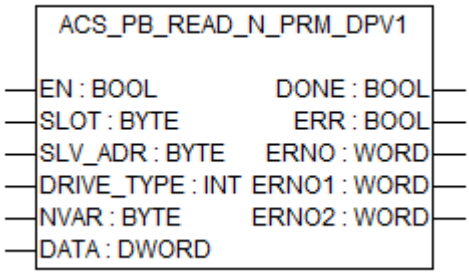
DATA (data)

Data type: DWORD

Input Data must be connected to the variable of type ACS_PB_PN_PRM_DPV1_DATA_TYPE for specifying READ parameter group and index. Each drive must have its own DATA variable.

Output description





DONE (done)

Data type: BOOL

Output DONE indicates the processing of the function block. If DONE = FALSE, the function block is not processed due to EN = FALSE and all outputs are set to 0.

For that reason, the other outputs always have to be considered together with output DONE. All other outputs are only valid, if DONE = TRUE.

DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in a separate table of Error Messages (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ERNO1 (error number 1)

Data type: WORD, Default value: 0, Range: ≥0

Output ERNO1 provides additional error information in case an error occurred during processing. ERNO1 always has to be considered together with the outputs DONE, ERR and ERNO. The value applied at ERNO1 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC).

The encoding of the error messages output at ERNO is explained in a separate table "Error Messages" (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Encoding of ERNO1 Parameter error messages

ERNO1 of the DPV1 function blocks is encoded as follows. The upper nibble (the higher significant 4 bits) describes the error class, the lower nibble represents the error cause.

Error class				Error code			
Bit: 7	6	5	4	3	2	1	0
ERNO1							
DEC	HEX			Error class / Error code			
0	0			Reserved			
...	...						
159	9F			Reserved			
160	A0			10 Application / 0 Read error			
161	A1			10 Application / 1 Write error

ERNO2 (error number 2)

Data type: WORD, Default value: 0, Range: ≥0

Output ERNO2 provides an additional DPV1-specific error information, if an error occurred during processing. ERNO2 always has to be considered together with the outputs DONE, ERR and ERNO. The value applied at ERNO2 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC). The encoding of ERNO2 is completely manufacturer-specific.

Calling of ACS_PB_READ_N_PRM_DPV1 in ST

```
dwAcsPbReadNPrmDpv1_DATA:= ADR (AcsPbPnPrmDpv1DataType)
ACS_PB_READ_N_PRM_DPV1
(EN                              := xAcsPbReadNPrmDpv1_EN,

SLOT                           := byAcsPbReadNPrmDpv1_SLOT,

                                          SLV_ADR              :=
byAcsPbReadNPrmDpv1_SLV_ADR,

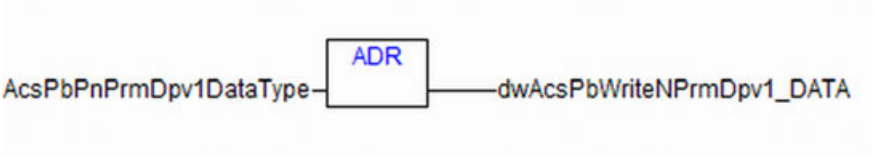
                                          DRIVE_TYPE :=
iAcsPbReadNPrmDpv1_DRIVE_TYPE,

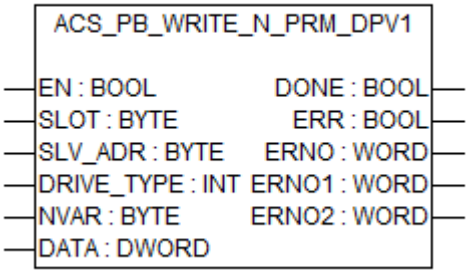
NVAR                           := byAcsPbReadNPrmDpv1_NVAR,

DATA                           := dwAcsPbReadNPrmDpv1_DATA);

xAcsPbReadNPrmDpv1_DONE          := ACS_PB_READ_N_PRM_DPV1.DONE;
xAcsPbReadNPrmDpv1_ERR              := ACS_PB_READ_N_PRM_DPV1.ERR;
wAcsPbReadNPrmDpv1_ERNO          := ACS_PB_READ_N_PRM_DPV1.ERNO;
wAcsPbReadNPrmDpv1_ERNO1      := ACS_PB_READ_N_PRM_DPV1.ERNO1;
wAcsPbReadNPrmDpv1_ERNO2      := ACS_PB_READ_N_PRM_DPV1.ERNO2;
```

ACS_PB_N_WRITE_PRM_DPV1 write parameters from ABB drives via PROFIBUS DPV1





Function block ACS_PB_WRITE_N_PRM_DPV1 is used for writing maximum 37 parameters to a drive via PROFIBUS in a single query.

Function block information

Available in runtime system:	V2.4 and above
Included in library:	ACSDrivesComPB_AC500_V24.lib
Function block type:	Function block with historical values.

If the ACS_PB_WRITE_N_PRM_DPV1 function block is used at the same time the DriveManager is connecting, refreshing or writing variables, it might come to an error on either the ACS_PB_WRITE_N_PRM_DPV1 block or the DriveManager.

Block description

Function block ACS_PB_WRITE_N_PRM_DPV1 writes maximum 37 parameters to drive in a single query. The number of parameters to be write is specified at the input NVAR.

Another limit while using the WRITE function block is, it can process only up to 240 byte data in one request or 37 drive parameters whichever is lower. If the WRITE data length is more than 240 byte, the function block generates error code 16#7012.

Parameters to write to the drive is specified at the DATA input.
ACS_PB_PN_PRM_DPV1_DATA_TYPE structure must be declared to a variable and connected to DATA input using ADR, which is to be entered with Group, Index, types and values.

ACS_PB_PN_PRM_DPV1_DATA_TYPE structure has the following array elements:

- abyPrmGroup : Array of 37 BYTE for specifying parameter Group.
- abyPrmIndex : Array of 37 BYTE for specifying parameter Index
- abyPrmType : Array of 37 BYTE for specifying parameter type, please refer the respective drives manual for parameter data type and enter the respective ENUM / VALUE . For details about ENUM / VALUE please refer ACS_PB_PN_PRM_TYPE_ENUM *Chapter 1.5.6.2.5.2 “ACS_PB_PN_PRM_TYPE_ENUM” on page 2251*
- adwPrmValue: Array of 37 BYTE for specifying parameter value

Currently user cannot use enumeration from ACS_PB_PN_PRM_TYPE_ENUM.

Instead user need to use numerical values from ACS_PB_PN_PRM_TYPE_ENUM only.

The values in the structure area are updated, when the WRITE job was performed without error. This is indicated by DONE=TRUE and ERR=FALSE.

Example

If the user need to read Parameter 10.01 and 11.05, then user need to enter the group and index number separately in input DATA as below:

DataStructure : ACS_PB_PN_PRM_DPV1_DATA_TYPE

Parameter Group : DataStruct.abyPrmGroup[1]:= 10; DataStruct.abyPrmGroup[2]:= 11;

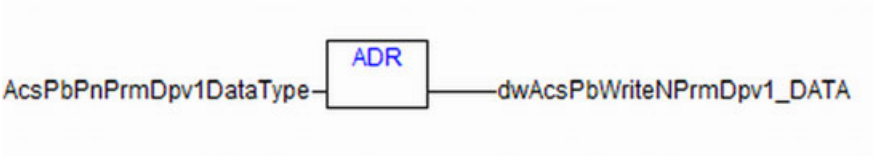
Parameter Index : DataStruct .abyPrmIndex [1]:= 01; DataStruct .abyPrmIndex [2]:= 05;

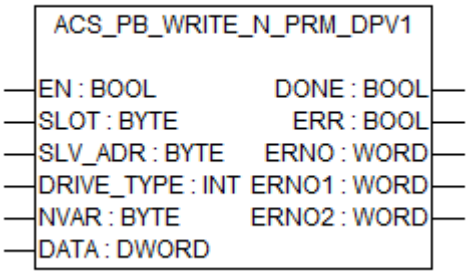
Parameter Type : DataStruct. abyPrmType [1]:= xx; DataStruct. abyPrmType [2]:= xx; . . DataStruct. abyPrmType [37]:= xx;

Parameter Value : And the value will be stored inside DataStruct. adwPrmValue [1]:= xx; DataStruct. adwPrmValue [2]:= xx;

The values in the structure area are written to drive when the write job is performed without error. This is indicated by DONE=TRUE and ERR=FALSE.

Input description





EN (enable)

Data type: BOOL

In order to enable the function block processing, input EN has to be set from FALSE to TRUE.

While input is set to TRUE, the inputs are continuously checked for validity and plausibility.

If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

Default value = FALSE.

If multiple ACS_PB_READ_N_PRM_DPV1 and / or multiple ACS_PB_WRITE_N_PRM_DPV1 functions blocks enabled at the same time it may cause for error Read / Write error.

SLOT (slot)

Data type: BYTE, Default value: 1, Range: 1 to 6

At input SLOT the communication module SLOT (module number) is selected, which should be used by the function block. All external Communication Modules are serially numbered from right to left, starting with module number 1.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

If the SLOT number is given incorrect or invalid, then the function block will displays an error. In such case ERR=TRUE and ERNO=16#4020.

SLV_ADR (slave address)

Data type: BYTE, Default value: 1, Range: 1 to 126

At input SLV_ADR, the address of the drive (slave), from which the parameter value is to be read, must be specified.

The function block is designed to be used with a fix SLAVE device. The SLAVE input should not be changed, while the program is running. If changed, nevertheless the new value will become effective, only after the function block is enabled again.

If the SLV_ADR is given incorrect or invalid, then the function block will display an error. In such case ERR=TRUE and ERNO=16#4030.

DRIVE_TYPE (drive type)

Data type: INT, Default value = ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM (enumeration). The input can be set either by the value directly or by using the enum ↳ *Chapter 1.5.6.2.5.1 “ACS_DRIVE_ENUM enumerations to select the type of drive used” on page 2251*.

If the DRIVE_TYPE is given invalid, then the function block will display an error. In such case ERR=TRUE and ERNO=16#4040.

NVAR (number of variables)

Data type: BYTE, Default value: 0, Range: 0 to 37

With input NVAR the function block can be configured to read between 0 to 37 drive parameter values.

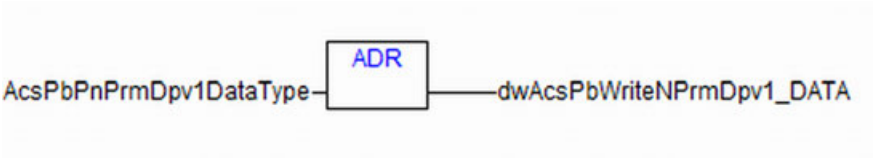
If the NVAR is given incorrect or invalid, then the function block will display an error. In such case ERR=TRUE and ERNO=16#4040.

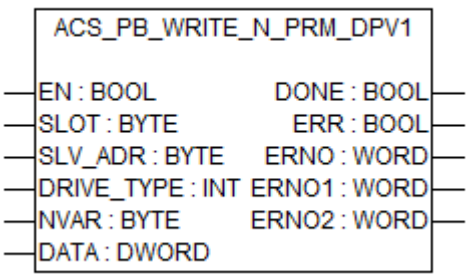
DATA (data)

Data type: DWORD

Input Data must be connected to the variable of type ACS_PB_PN_PRM_DPV1_DATA_TYPE for specifying READ parameter group and index. Each drive must have its own DATA variable.

Output description





DONE (done)

Data type: BOOL

Output DONE indicates the processing of the function block. If DONE = FALSE, the function block is not processed due to EN = FALSE and all outputs are set to 0.

For that reason, the other outputs always have to be considered together with output DONE. All other outputs are only valid, if DONE = TRUE.

DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in a separate table of Error Messages (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ERNO1 (error number 1)

Data type: WORD, Default value: 0, Range: ≥0

Output ERNO1 provides additional error information in case an error occurred during processing. ERNO1 always has to be considered together with the outputs DONE, ERR and ERNO. The value applied at ERNO1 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC).

The encoding of the error messages output at ERNO is explained in a separate table "Error Messages" (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Encoding of ERNO1 Parameter error messages

ERNO1 of the DPV1 function blocks is encoded as follows. The upper nibble (the higher significant 4 bits) describes the error class, the lower nibble represents the error cause.

Error class				Error code			
Bit: 7	6	5	4	3	2	1	0
ERNO1							
DEC	HEX			Error class / Error code			
0	0			Reserved			
...	...						
159	9F			Reserved			
160	A0			10 Application / 0 Read error

183	B7			11 Access / 7 Invalid value range
184	B8			11 Access / 8 Invalid parameter
185	B9			11 Access / 9 Invalid type
186	BA			11 Access / 10 Manufacturer-specific
...	...			...
191	BF			11 Access / 15 Manufacturer-specific
192	C0			12 Resources / 0 Read conflict
193	C1			12 Resources / 1 Write conflict
194	C2			12 Resources / 2 Resource used
195	C3			12 Resources / 3 Resource not available
196	C4			Reserved
...	...			...
199	C7			Reserved
200	C8			12 Resources / 10 Manufacturer-specific
...	...			...
207	CF			12 Resources / 15 Manufacturer-specific
208	D0			Reserved
...	...			...
255	FF			Reserved

ERNO2 (error number 2)

Data type: WORD, Default value: 0, Range: ≥0

Output ERNO2 provides an additional DPV1-specific error information, if an error occurred during processing. ERNO2 always has to be considered together with the outputs DONE, ERR and ERNO. The value applied at ERNO2 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC). The encoding of ERNO2 is completely manufacturer-specific.

Calling of ACS_PB_WRITE_N_PRM_DPV1 in ST

```
dwAcsPbWriteNPrmDpv1_DATA:= ADR (AcsPbPnPrmDpv1DataType)
ACS_PB_WRITE_N_PRM_DPV1                 (EN         :=
xAcsPbWriteNPrmDpv1_EN,

SLOT                          := byAcsPbWriteNPrmDpv1_SLOT,

                                          SLV_ADR             :=
byAcsPbWriteNPrmDpv1_SLV_ADR,

                                          DRIVE_TYPE :=
iAcsPbWriteNPrmDpv1_DRIVE_TYPE,

NVAR                          := byAcsPbWriteNPrmDpv1_NVAR,

DATA                          := dwAcsPbWriteNPrmDpv1_DATA);

xAcsPbWriteNPrmDpv1_DONE      := ACS_PB_WRITE_N_PRM_DPV1.DONE;
xAcsPbWriteNPrmDpv1_ERR          := ACS_PB_WRITE_N_PRM_DPV1.ERR;
wAcsPbWriteNPrmDpv1_ERNO      := ACS_PB_WRITE_N_PRM_DPV1.ERNO;
wAcsPbWriteNPrmDpv1_ERNO1  := ACS_PB_WRITE_N_PRM_DPV1.ERNO1;
wAcsPbWriteNPrmDpv1_ERNO2  := ACS_PB_WRITE_N_PRM_DPV1.ERNO2;
```

1.5.6.6.4 Visualization

In the application program, the user can add the visualization object in the project. In this object, the user needs to add faceplate of the desired function block, as shown in the figure.

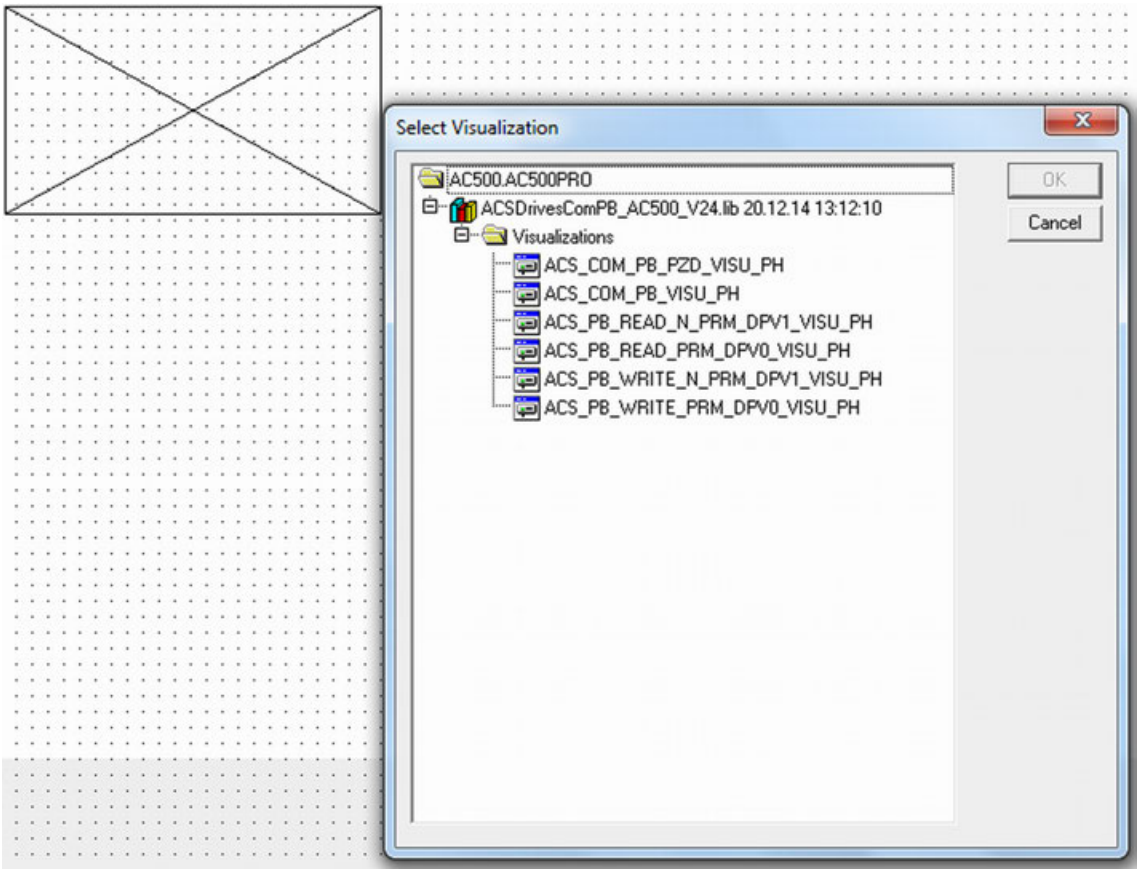

Fig. 166: Visualization

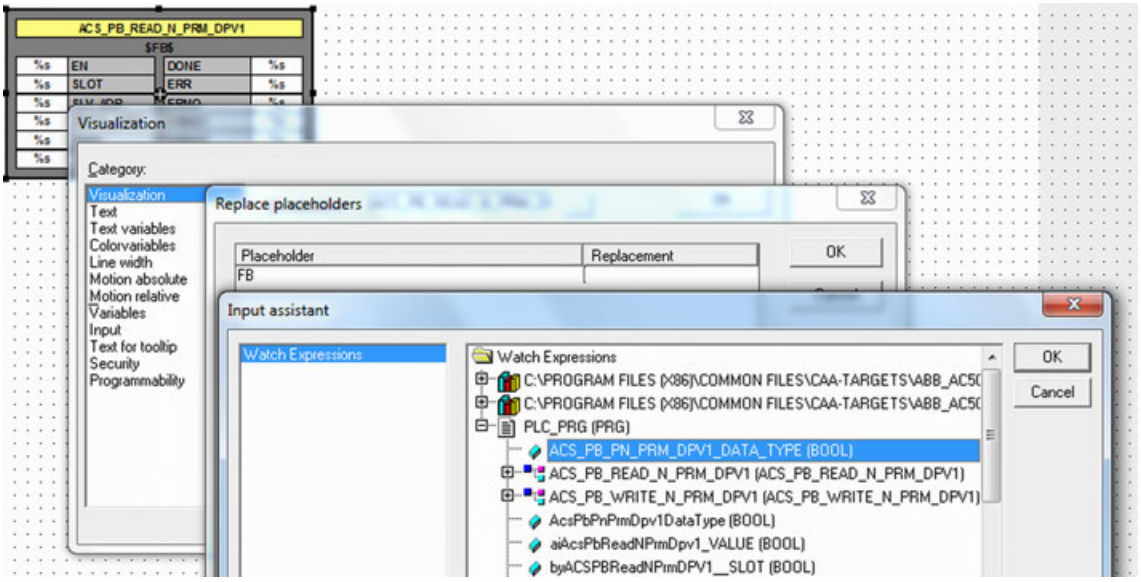

Fig. 167: Visualization: file selection

In the following chapter, overall visualization and visualization for each individual function block are discussed in detail.

ACS_COM_PB_VISU_PH visualization to run the ACS_COM_PB function block.

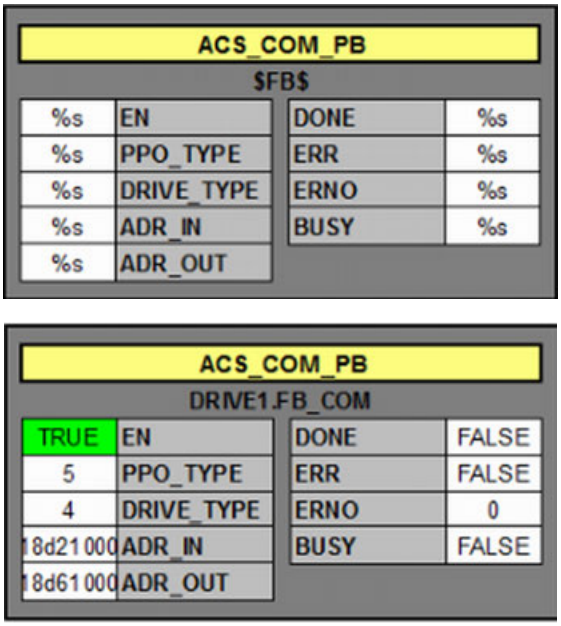

Fig. 168: Visualization in offline / online mode

Visualization information

Available in runtime system:	V2.4
Included in library:	ACSDrivesBase_AC500_V20.lib

Visualization description

Visualization element ACS_COM_PB_VISU_PH is used to show the actual values of all inputs and outputs of the instance of ACS_COM_PB_VISU_PH function block.

The visualization is also used to control the function block by those inputs, which are not connected inside the program.

Parameters

Access R/W

EN

Access via: Toggle

Description: EN input

Enables the function block by TRUE value of input EN.

PRO_TYPE

Access via: Numpad

Description: PRO_TYPE input 1, 2, 3, 4, 5, 6, 7 or 8

DRIVE_TYPE

Access via: Text

Description: DRIVE_TYPE input

ADR_IN

Access via: Text

Description: Address of first process input variable

ADR_OUT

Access via: Text

Description: Address of first process output variable

All inputs of ACS_COM_PB_VISU_PH function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

Access R

DONE Description: DONE output.

To indicate, the Function Block processing is completed.

ERR Description: ERR output.

Function Block processed with error.

ERNO Description: ERNO output.

BUSY Description: BUSY output.

Colors

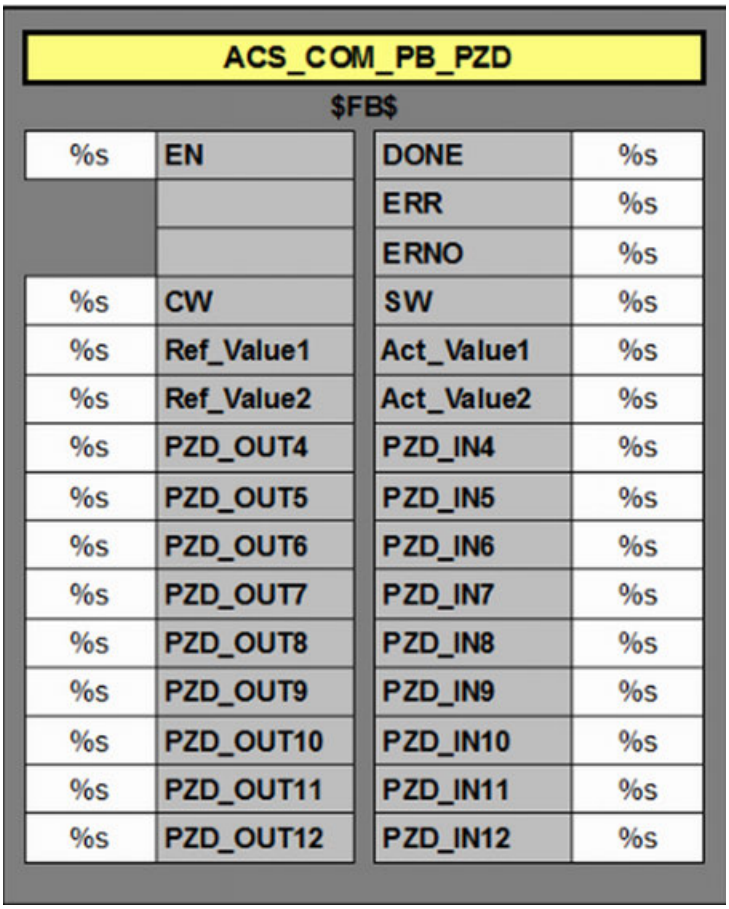
The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_COM_PB_PZD_VISU_PH visualization to run the ACS_COM_PB_PZD function block.



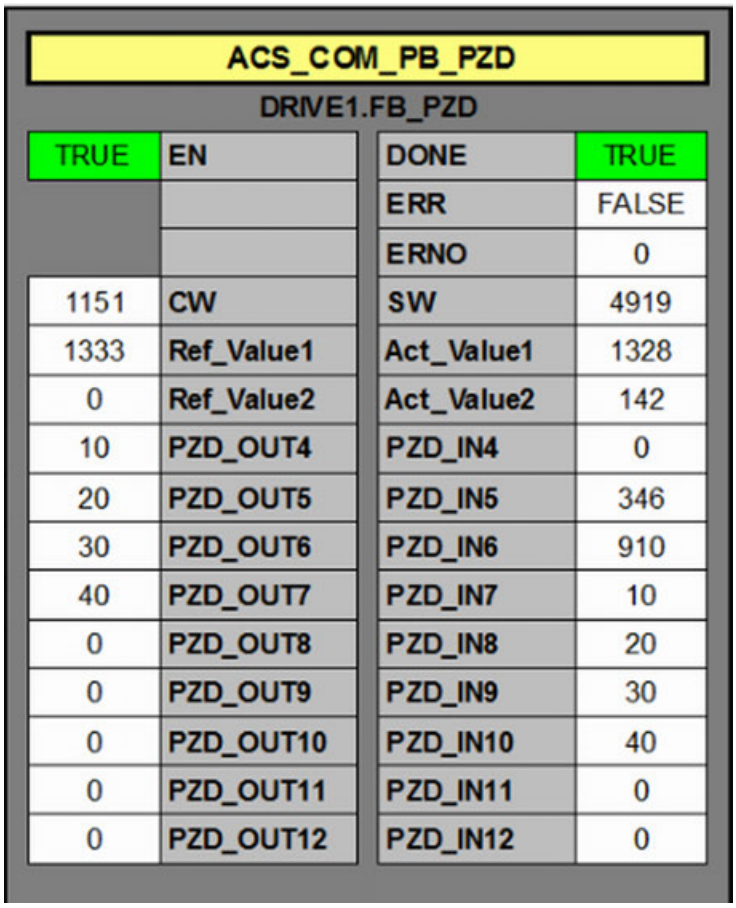


Fig. 169: Visualization in offline / online mode

Visualization information

Available in runtime system:	V2.4
Included in library:	ACSDrivesBase_AC500_V20.lib

Visualization description

Visualization element ACS_COM_PB_PZD_VISU_PH is used to show the actual values of all inputs and outputs of the instance of ACS_COM_PB_PZD_VISU_PH function block.

The visualization is also used to control the function block by those inputs, which are not connected inside the program.

Parameters

Access R/W

EN

Access via: Toggle

Description: EN input

Enables the function block by TRUE value of input EN.

PZD_OUT4

Access via: Text

Description: Process data word 4 to drive

PZD_OUT5

The Value applied at ERNO1 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC).

ERNO2 Description: Additional error information.

The Value applied at ERNO2 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC).

Colors

The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_PB_WRITE_N_PRM_DPV1_VISU_PH visualization to run the ACS_PB_WRITE_N_PRM_DPV1 function block.

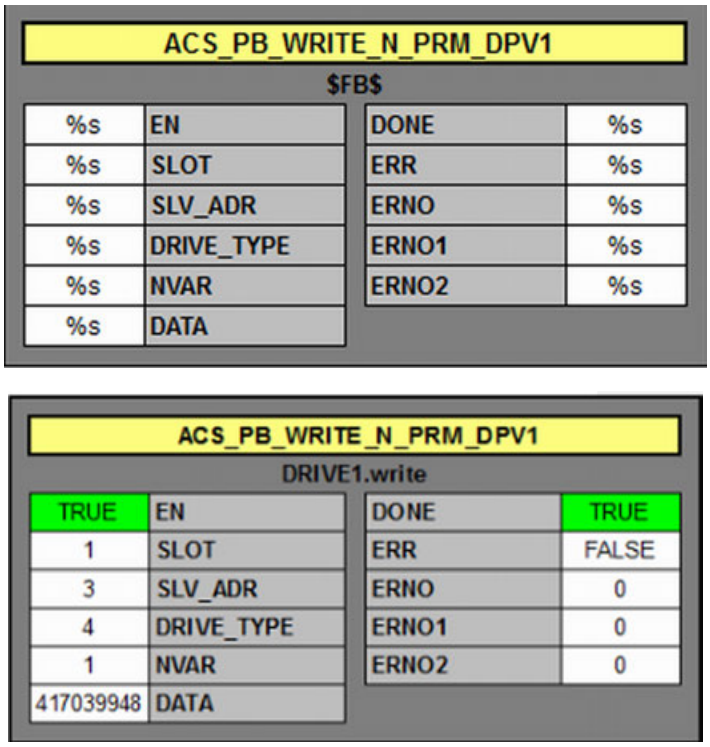

Fig. 173: Visualization in offline / online mode

Visualization information

Available in runtime system:	V2.4
Included in library:	ACSDrivesBase_AC500_V20.lib

Visualization description

Visualization element ACS_PB_WRITE_N_PRM_DPV1_VISU_PH is used to show the actual values of all inputs and outputs of the instance of ACS_PB_WRITE_N_PRM_DPV1_VISU_PH function block.

The visualization is also used to control the function block by those inputs, which are not connected inside the program.

Parameters

Access R/W

EN Access via: Toggle

Description: EN input

Enables the function block by TRUE value of input EN.

SLOT Access via: Text

Description: SLOT, in which the PROFIBUS master communication module is mounted.

SLV_ADR Access via: Text

Description: PROFIBUS station address.

DRIVE_TYPE Access via: Text

Description: DRIVE_TYPE input

NVAR Access via: Text

Description: Number of drive parameters to be read from drive using PROFIBUS.

All inputs of ACS_PB_WRITE_N_PRM_DPV1_VISU_PH function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

Access R

DONE Description: DONE output.

To indicate, the Function Block processing is completed.

ERR Description: ERR output.

Function Block processed with error.

ERNO Description: ERNO output.

DATA Description: Data input to connect structure ACS_PB_PN_PRM_DPV1_DATA_TYPE for specifying READ parameter group and index.

ERNO1 Description: Additional error information.

The Value applied at ERNO1 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC).

ERNO2 Description: Additional error information.

The Value applied at ERNO2 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC).

Colors

The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

1.5.6.7 ACS / DCS Drives read / write parameter via PROFINET library

1.5.6.7.1 Preconditions for the use of the ACS / DCS drives read / write parameter via PROFINET library

The function blocks contained in the library can only be executed in RUN mode of the PLC, but not in simulation mode.

The blocks can only be used in combination with the ACSDrives-Base_AC500_V20 Library.

The library is released for the following products:

- CPUs: AC500
- Fieldbus: PROFINET
- Drives: ACS800, ACSM1, ACS355, ACS550, ACH550, ACQ810, ACS850, ACS880, ACS580, DCS550, DCS800
- PROFINET configuration:
  Prior to the use of the function blocks, PROFINET Communication Module has to be configured accordingly using Automation Builder, at "Interfaces".

If multiple ACS_PN_READ_N_PRM_DPV1 and / or multiple ACS_PN_WRITE_N_PRM_DPV1 function blocks are enabled at the same time, it may cause an READ / WRITE error.

1.5.6.7.2 Components of PROFINET read / write library

ACSDrivesComPN_AC500_V24 Library contains PROFINET DPV1 READ / WRITE function blocks and visualizations.

Function blocks

ACS_PN_READ_N_PRM_DPV1 ↳ *Chapter 1.5.6.7.4.1 “ACS_PN_READ_N_PRM_DPV1 read parameters from ABB drives via PROFINET DPV1” on page 2453*	This function block reads maximum 37 parameters from an ACS Drive via PROFINET.
ACS_PN_WRITE_N_PRM_DPV1 ↳ *Chapter 1.5.6.7.4.2 “ACS_PN_WRITE_N_PRM_DPV1 write parameters from ABB drives via PROFINET DPV1” on page 2457*	This function block writes maximum 37 parameters to an ACS Drive via PROFINET.

Visualizations

ACS_PN_READ_N_PRM_DPV1_VISU_PH ↳ *Chapter 1.5.6.7.5.1 “ACS_PN_READ_N_PRM_DPV1_VISU_PH faceplate of ACS_PN_READ_N_PRM_DPV1 function block.” on page 2463*	Visualization to run the ACS_PN_READ_N_PRM_DPV1 function block.
ACS_PN_WRITE_N_PRM_DPV1_VISU_PH ↳ *Chapter 1.5.6.7.5.2 “ACS_PN_WRITE_N_PRM_DPV1_VISU_PH visualization to run the ACS_PN_WRITE_N_PRM_DPV1 function block.” on page 2465*	Visualization to run the ACS_PN_WRITE_N_PRM_DPV1 function block.

Global variables

ACS_PN_VERSION_INFORMATION	Stores all the version information of the file along with the change log. No variable is declared inside this section.

1.5.6.7.3 Overview of the ACS / DCS drives read / write parameter via PROFINET function blocks

Used abbreviations:

FBhv	Function block with historical values
FBnohv	Function block without historical values
F	Function
Enum	Enumeration
Struct	Structure
Visu	Visualization

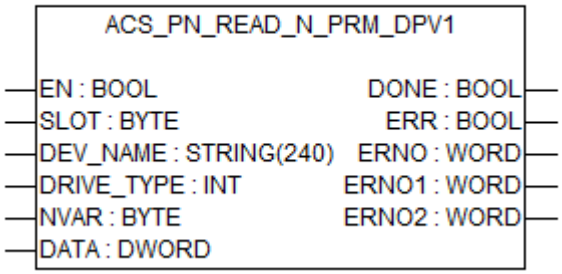
1.5.6.7.4 Function blocks

ACS_PN_READ_N_PRM_DPV1 read parameters from ABB drives via PROFINET DPV1



Function block ACS_PN_READ_N_PRM_DPV1 reads maximum 37 parameters from the drive in a single query. The number of parameters to be read is specified at the input NVAR.

Function block information

Available in runtime system:	V2.4 and above
Included in library:	ACSDrivesComPN_AC500_V24.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_PN_READ_N_PRM_DPV1 reads maximum 37 parameters from the drive in a single query. The number of parameters to be read is specified at the input NVAR.

Parameters to read to the drive is specified at the DATA input.
ACS_PB_PN_PRM_DPV1_DATA_TYPE structure must be declared to a variable and connected to DATA input using ADR, which is to be entered with Group, Index.

Read parameter type and values are stored in the same variable.

ACS_PB_PN_PRM_DPV1_DATA_TYPE structure has the following array elements:

- abyPrmGroup : Array of 37 BYTE for specifying parameter Group.
- abyPrmIndex : Array of 37 BYTE for specifying parameter Index

- abyPrmType : Array of 37 BYTE
  READ parameter data type will be available here. For details refer to ACS_PB_PN_PRM_TYPE_ENUM *Chapter 1.5.6.2.5.2 “ACS_PB_PN_PRM_TYPE_ENUM” on page 2251*
- adwPrmValue: Array of 37 DWORD
  READ parameter value will be available here.

> *Currently user cannot use enumeration from ACS_PB_PN_PRM_TYPE_ENUM.*
>
> *Instead user need to use numerical values from ACS_PB_PN_PRM_TYPE_ENUM only.*

The values in the structure area are updated, when the READ job was performed without error. This is indicated by DONE=TRUE and ERR=FALSE.

Example

If the user need to read Parameter 10.01 and 11.05, then user need to enter the group and index number separately in input DATA as below:

DataStructure : ACS_PB_PN_PRM_DPV1_DATA_TYPE

Parameter Group : DataStruct.abyPrmGroup[1]:= 10; DataStruct.abyPrmGroup[2]:= 11;

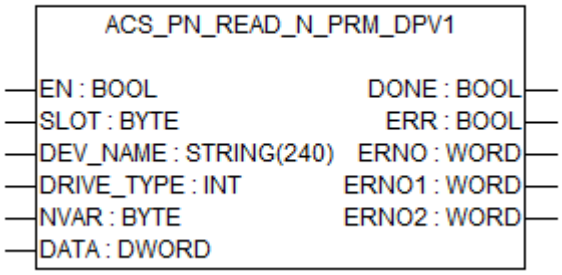
Parameter Index : DataStruct .abyPrmIndex [1]:= 01; DataStruct .abyPrmIndex [2]:= 05;

Parameter Type : Once read operation is complete parameter type will be stored inside DataStruct. abyPrmType [1]:= xx; DataStruct. abyPrmType [2]:= xx;

Parameter Value : And the value will be stored inside DataStruct. adwPrmValue [1]:= xx; DataStruct. adwPrmValue [2]:= xx;

The values in the structure area are updated once the read job is performed without error. This is indicated by DONE=TRUE and ERR=FALSE.

Input description



EN (enable)

Data type: BOOL

In order to enable the function block processing, input EN has to be set from FALSE to TRUE.

While input is set to TRUE, the inputs are continuously checked for validity and plausibility.

If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

Default value = FALSE.

If multiple ACS_PN_READ_N_PRM_DPV1 and / or multiple ACS_PN_WRITE_N_PRM_DPV1 functions blocks enabled at the same time it may cause for error Read / Write error.

SLOT (slot)

Data type: BYTE, Default value: 1, Range: 1 to 6

At input SLOT the communication module SLOT (module number) is selected, which should be used by the Function Block. All external communication modules are serially numbered from right to left, starting with module number 1.

If the SLOT number is given incorrect or invalid, then the function block will displays an error. In such case ERR=TRUE and ERNO=16#4020.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_NAME (device name)

Data type: STRING, Default value: "Not Available", Range: 1 to 240

At input DEV_NAME, the name of the drive (slave) from which the parameter value to be read must be specified.

The function block is designed to be used with a fix SLAVE device.

If the DEV_NAME is given incorrect or invalid, then the function block will displays an error. In such case ERR=TRUE and ERNO=16#4030.

The DEV_NAME input should not be changed, while the program is running. If changed, nevertheless the new value will become effective only after the function block is enabled again.

DRIVE_TYPE (drive type)

Data type: ENUM, Default value: ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM or INT. (Please refer ACS_DRIVE_ENUM for details.) The input can be set either by the value directly or by using the enum.

NVAR (number of variables)

Data type: BYTE, Default value: 0, Range: 0 to 37

With input NVAR the function block can be configured to read between 0 to 37 drive parameter values.

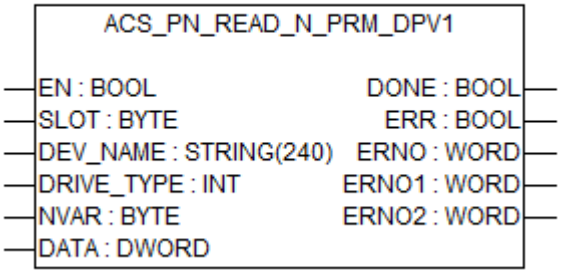
If the NVAR is given incorrect or invalid, then the function block will display an error. In such case ERR=TRUE and ERNO=16#4040.

DATA (data)

Data type: DWORD

Input Data must be connected to the variable of type ACS_PB_PN_PRM_DPV1_DATA_TYPE for specifying READ parameter group and index. Each drive must have its own DATA variable.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the processing of the function block. If DONE = FALSE, the function block is not processed due to EN = FALSE and all outputs are set to 0.

For that reason, the other outputs always have to be considered together with output DONE. All other outputs are only valid, if DONE = TRUE.

DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in a separate table Error Messages of the ACS Drives function block libraries(see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ERNO1 (error number 1)

Data type: WORD, Default value: 0, Range: ≥0

Reserved output.

ERNO2 (error number 2)

Data type: WORD, Default value: 0, Range: ≥0

Reserved output.

Calling of ACS_PN_READ_N_PRM_DPV1 in ST

```
dwAcsPnReadNPrmDpv1_DATA:= ADR (AcsPbPnPrmDpv1DataType)
ACS_PN_READ_N_PRM_DPV1 (EN                                    :=
xAcsPnReadNPrmDpv1_EN,

                                SLOT                          :=
```

```
byAcsPnReadNPrmDpv1_SLOT,

                          DEV_NAME          :=
byAcsPnReadNPrmDpv1_DEV_NAME,

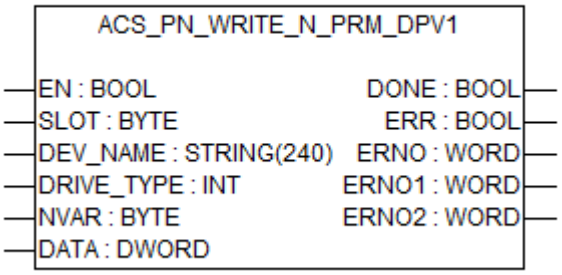
                          DRIVE_TYPE :=
iAcsPnReadNPrmDpv1_DRIVE_TYPE,

                          NVAR                          :=
byAcsPnReadNPrmDpv1_NVAR,

                          DATA                          :=
dwAcsPnReadNPrmDpv1_DATA);

xAcsPnReadNPrmDpv1_DONE     := ACS_PN_READ_N_PRM_DPV1.DONE;
xAcsPnReadNPrmDpv1_ERR         := ACS_PN_READ_N_PRM_DPV1.ERR;
wAcsPnReadNPrmDpv1_ERNO     := ACS_PN_READ_N_PRM_DPV1.ERNO;
wAcsPnReadNPrmDpv1_ERNO1 := ACS_PN_READ_N_PRM_DPV1.ERNO1;
wAcsPnReadNPrmDpv1_ERNO2 := ACS_PN_READ_N_PRM_DPV1.ERNO2;
```

ACS_PN_WRITE_N_PRM_DPV1 write parameters from ABB drives via PROFINET DPV1



Function block ACS_PN_WRITE_N_PRM_DPV1 writes maximum 37 parameters to the drive in a single query. The number of parameters to be write is specified at the input NVAR.

Function block information

Available in runtime system:	V2.4 and above
Included in library:	ACSDrivesComPN_AC500_V24.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_PN_WRITE_N_PRM_DPV1 writes maximum 37 parameters to the drive in a single query. The number of parameters to be write is specified at the input NVAR.

Another limit while using the write function block is, it can process only up to 240 byte data in one request or 37 drive parameters whichever is lower. If the write data length is more than 240 byte, the function block generates an error code 16#7012.

Parameters to write to the drive are specified at the DATA input.
ACS_PB_PN_PRM_DPV1_DATA_TYPE structure must be declared to a variable and connected to DATA input using ADR, which is to be entered with Group, Index.

ACS_PB_PN_PRM_DPV1_DATA_TYPE structure has the following array elements:

- abyPrmGroup : Array of 37 BYTE for specifying parameter Group.
- abyPrmIndex : Array of 37 BYTE for specifying parameter Index

- abyPrmType : Array of 37 BYTE for specifying parameter type , Please refer the respective Drives manual for parameter data type and enter the respective ENUM / VALUE . For details about ENUM / VALUE please refer ACS_PB_PN_PRM_TYPE_ENUM *Chapter 1.5.6.2.5.2 “ACS_PB_PN_PRM_TYPE_ENUM” on page 2251*
- adwPrmValue: Array of 37 BYTE for specifying parameter value
  The values in the structure area are updated, when the WRITE job was performed without error. This is indicated by DONE=TRUE and ERR=FALSE.

> *Currently user cannot use enumeration from ACS_PB_PN_PRM_TYPE_ENUM.*
>
> *Instead user need to use numerical values from ACS_PB_PN_PRM_TYPE_ENUM only.*

The values in the structure area are updated, when the WRITE job was performed without error. This is indicated by DONE=TRUE and ERR=FALSE.

Example

If the user need to read Parameter 10.01 and 11.05, then he need to enter the group and index number separately in input DATA as below:

DataStructure : ACS_PB_PN_PRM_DPV1_DATA_TYPE

Parameter Group : DataStruct.abyPrmGroup[1]:= 10; DataStruct.abyPrmGroup[2]:= 11;

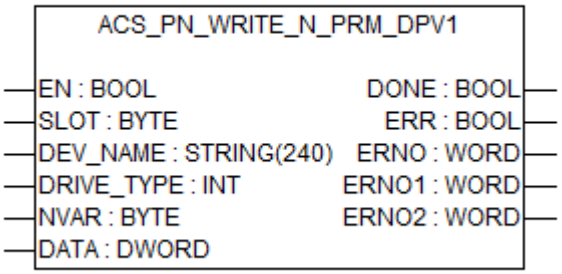
Parameter Index : DataStruct .abyPrmIndex [1]:= 01; DataStruct .abyPrmIndex [2]:= 05;

Parameter Type : DataStruct. abyPrmType [1]:= xx; DataStruct. abyPrmType [2]:= xx;

Parameter Value : DataStruct. adwPrmValue [1]:= xx; DataStruct. adwPrmValue [2]:= xx;

The values in the structure area are written to drive when the write job is performed without error. This is indicated by DONE=TRUE and ERR=FALSE.

Input description



EN (enable)

Data type: BOOL

In order to enable the function block processing, input EN has to be set from FALSE to TRUE.

While input is set to TRUE, the inputs are continuously checked for validity and plausibility.

If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

Default value = FALSE.

If multiple ACS_PN_READ_N_PRM_DPV1 and / or multiple ACS_PN_WRITE_N_PRM_DPV1 functions blocks enabled at the same time it may cause for error Read / Write error.

SLOT (slot)

Data type: BYTE, Default value: 1, Range: 1 to 6

At input SLOT the communication module SLOT (module number) is selected, which should be used by the Function Block. All external communication modules are serially numbered from right to left, starting with module number 1.

If the SLOT number is given incorrect or invalid, then the function block will displays an error. In such case ERR=TRUE and ERNO=16#4020.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_NAME (device name)

Data type: STRING, Default value: "Not Available", Range: 1 to 240

At input DEV_NAME, the name of the drive (slave) from which the parameter value to be read must be specified.

The function block is designed to be used with a fix SLAVE device.

If the DEV_NAME is given incorrect or invalid, then the function block will displays an error. In such case ERR=TRUE and ERNO=16#4030.

The DEV_NAME input should not be changed, while the program is running. If changed, nevertheless the new value will become effective only after the function block is enabled again.

DRIVE_TYPE (drive type)

Data type: ENUM, Default value: ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM or INT. (Please refer ACS_DRIVE_ENUM for details.) The input can be set either by the value directly or by using the enum.

NVAR (number of variables)

Data type: BYTE, Default value: 0, Range: 0 to 37

With input NVAR the function block can be configured to read between 0 to 37 drive parameter values.

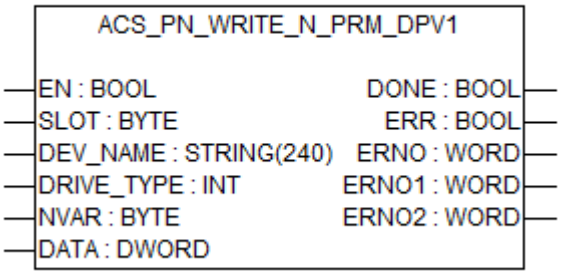
If the NVAR is given incorrect or invalid, then the function block will display an error. In such case ERR=TRUE and ERNO=16#4040.

DATA (data)

Data type: DWORD

Input Data must be connected to the variable of type ACS_PB_PN_PRM_DPV1_DATA_TYPE for specifying READ parameter group and index. Each drive must have its own DATA variable.

Output description



DONE (done) Data type: BOOL

Output DONE indicates the processing of the function block. If DONE = FALSE, the function block is not processed due to EN = FALSE and all outputs are set to 0.

For that reason, the other outputs always have to be considered together with output DONE. All other outputs are only valid, if DONE = TRUE.

DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in a separate table Error Messages of the ACS Drives function block libraries(see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ERNO1 (error number 1) Data type: WORD, Default value: 0, Range: ≥0

Reserved output.

ERNO2 (error number 2) Data type: WORD, Default value: 0, Range: ≥0

Reserved output.

Calling of ACS_PN_WRITE_N_PRM_DPV1 in ST

```
dwAcsPnWriteNPrmDpv1_DATA:= ADR (AcsPbPnPrmDpv1DataType)
ACS_PN_WRITE_N_PRM_DPV1 (EN                                  :=
xAcsPnWriteNPrmDpv1_EN,

                                SLOT                         :=

                                NVAR                         :=
byAcsPnWriteNPrmDpv1_NVAR,

                                DATA                         :=
dwAcsPnWriteNPrmDpv1_DATA);

xAcsPnWriteNPrmDpv1_DONE     := ACS_PN_WRITE_N_PRM_DPV1.DONE;
xAcsPnWriteNPrmDpv1_ERR         := ACS_PN_WRITE_N_PRM_DPV1.ERR;
wAcsPnWriteNPrmDpv1_ERNO     := ACS_PN_WRITE_N_PRM_DPV1.ERNO;
wAcsPnWriteNPrmDpv1_ERNO1 := ACS_PN_WRITE_N_PRM_DPV1.ERNO1;
wAcsPnWriteNPrmDpv1_ERNO2 := ACS_PN_WRITE_N_PRM_DPV1.ERNO2;
```

1.5.6.7.5 Visualization

In the application program, the user can add the visualization object in the project. In this object, the user needs to add faceplate of the desired function block, as shown in the figure.

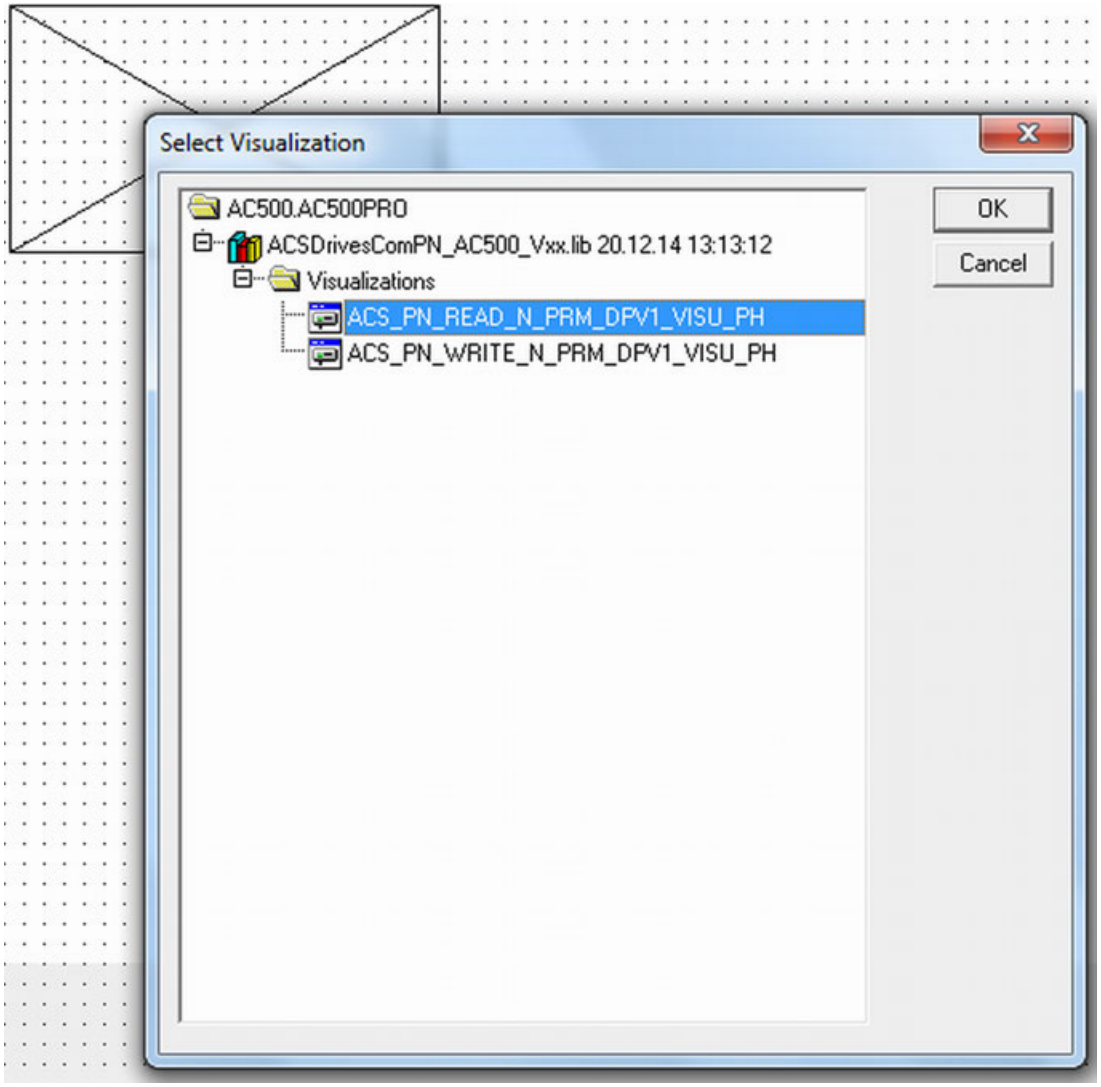

Fig. 174: Visualization

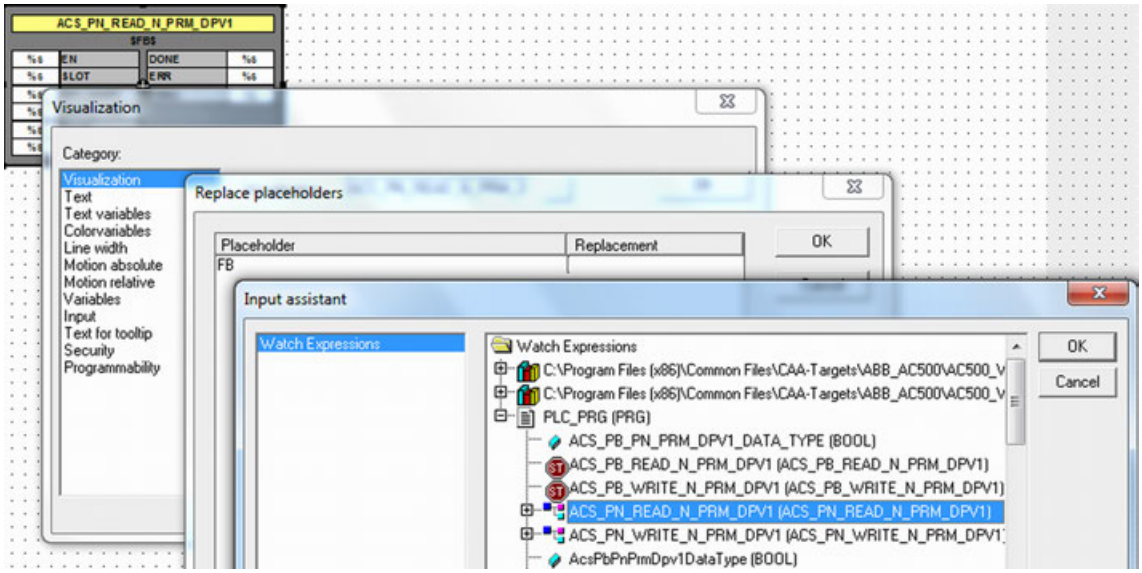

Fig. 175: Visualization: file selection

In the following chapter, overall visualization and visualization for each individual function block are discussed in detail.

ACS_PN_READ_N_PRM_DPV1_VISU_PH faceplate of ACS_PN_READ_N_PRM_DPV1 function block.

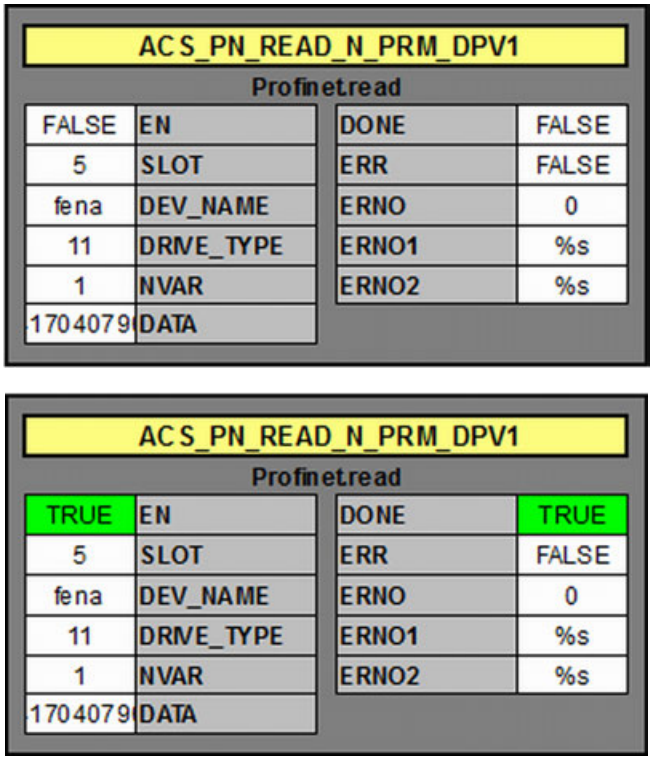

Fig. 176: Visualization in offline / online mode

Visualization information

Available in runtime system:	V2.4
Included in library:	ACSDrivesBase_AC500_V20.lib

Visualization description

Visualization element ACS_PN_READ_N_PRM_DPV1_VISU_PH is used to show the actual values of all inputs and outputs of the instance of ACS_PN_READ_N_PRM_DPV1_VISU_PH function block.

The visualization is also used to control the function block by those inputs, which are not connected inside the program.

Parameters

Access R/W

EN

Access via: Toggle

Description: EN input

Enables the function block by TRUE value of input EN.

SLOT

Access via: Text

Description: SLOT, in which the PROFIBUS master communication module is mounted.

DEV_NAME (device name)

Data type: STRING, Default value: "Not Available", Range: 1 to 240

At input DEV_NAME, the name of the drive (slave) from which the parameter value to be read must be specified.

The function block is designed to be used with a fix SLAVE device.

If the DEV_NAME is given incorrect or invalid, then the function block will displays an error. In such case ERR=TRUE and ERNO=16#4030.

The DEV_NAME input should not be changed, while the program is running. If changed, nevertheless the new value will become effective only after the function block is enabled again.

DRIVE_TYPE Access via: Text

Description: DRIVE_TYPE input

NVAR Access via: Text

Description: Number of drive parameters to be read from drive using PROFIBUS.

Access R

DONE Description: DONE output.

To indicate, the Function Block processing is completed.

ERR Description: ERR output.

Function Block processed with error.

ERNO Description: ERNO output.

DATA Description: Data input to connect structure ACS_PB_PN_PRM_DPV1_DATA_TYPE for specifying READ parameter group and index.

All inputs of ACS_PN_READ_N_PRM_DPV1_VISU_PH function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

Colors

The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_PN_WRITE_N_PRM_DPV1_VISU_PH visualization to run the ACS_PN_WRITE_N_PRM_DPV1 function block.

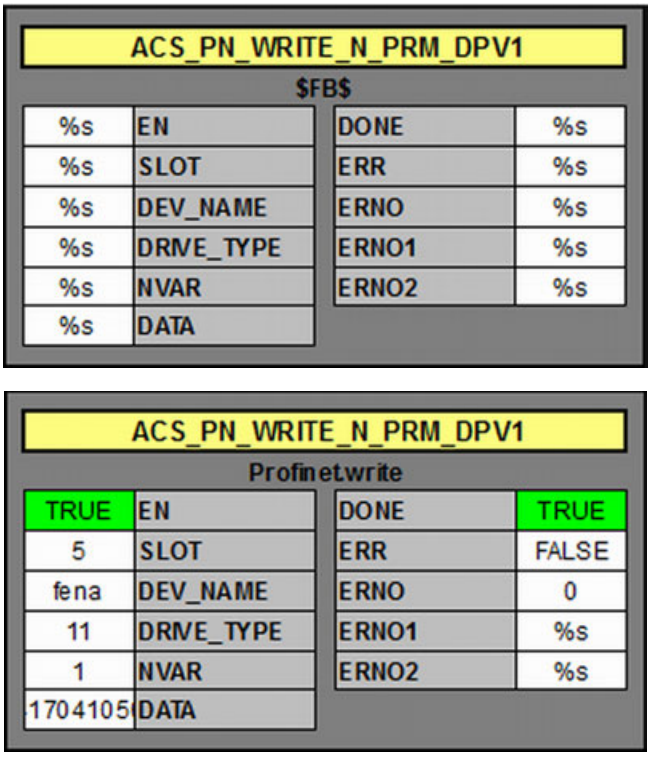

Fig. 177: Visualization in offline / online mode

Visualization information

Available in runtime system:	V2.4
Included in library:	ACSDrivesBase_AC500_V20.lib

Visualization description

Visualization element ACS_PN_WRITE_N_PRM_DPV1_VISU_PH is used to show the actual values of all inputs and outputs of the instance of ACS_PN_WRITE_N_PRM_DPV1_VISU_PH function block.

The visualization is also used to control the function block by those inputs, which are not connected inside the program.

Parameters

Access R/W

EN

Access via: Toggle

Description: EN input

Enables the function block by TRUE value of input EN.

SLOT

Access via: Text

Description: SLOT, in which the PROFIBUS master communication module is mounted.

DEV_NAME (device name)

Data type: STRING, Default value: "Not Available", Range: 1 to 240

At input DEV_NAME, the name of the drive (slave) from which the parameter value to be read must be specified.

The function block is designed to be used with a fix SLAVE device.

If the DEV_NAME is given incorrect or invalid, then the function block will displays an error. In such case ERR=TRUE and ERNO=16#4030.

The DEV_NAME input should not be changed, while the program is running. If changed, nevertheless the new value will become effective only after the function block is enabled again.

DRIVE_TYPE

Access via: Text

Description: DRIVE_TYPE input

NVAR

Access via: Text

Description: Number of drive parameters to be read from drive using PROFIBUS.

All inputs of ACS_PN_WRITE_N_PRM_DPV1_VISU_PH function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

Access R

DONE

Description: DONE output.

To indicate, the Function Block processing is completed.

ERR

Description: ERR output.

Function Block processed with error.

ERNO

Description: ERNO output.

DATA (data)

Data type: DWORD

Input Data must be connected to the variable of type ACS_PB_PN_PRM_DPV1_DATA_TYPE for specifying READ parameter group and index. Each drive must have its own DATA variable.

Colors

The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

1.5.6.8 DCS drives library

1.5.6.8.1 Preconditions for the use of the DCS drives library

The function blocks contained in the library can only be executed in RUN mode of the PLC, but not in simulation mode.

Some of the blocks can only be used in combination with one of the ACSDrivesComXXX_AC500_Vyy libraries, e.g. the ACSDrivesComModRTU_AC500_V20.lib.

The library is released for the following products:

- CPUs: AC500 and AC500-eCo
  Connection of more drives depends on performance of used CPU, communication type and settings.
- Fieldbus: PROFIBUS DP, Modbus RTU, Modbus TCP, PROFINET, CANopen

Compatibility

To check the compatiblity of drives and their communication modules, please refer to the following table that shows the tested combinations:

Communication	PLC communication modules		PLC Fieldbus Adapter of drive			Drive		
	PLC communication module	Firmware Version	Fieldbus Adapter (FBA)	FBA comm sw ver	FBA appl sw ver	Drive	Firmware Version	Drive Rating ID
PROFIBUS	CM572-DP	V1.0.97	RPBA	132h	307h	DCS550	-1.3	
		V1.0.97	RPBA	132h	307h	DCS800	-3.6

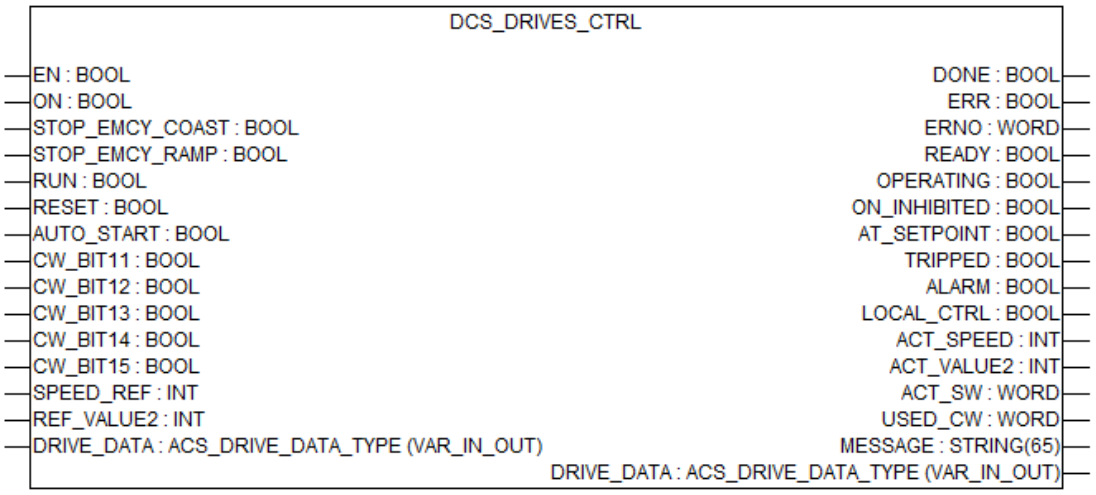
1.5.6.8.4 Function blocks

DCS_DRIVES_CTRL Control of DCS Drives with ABB-Drives profile using a communication block

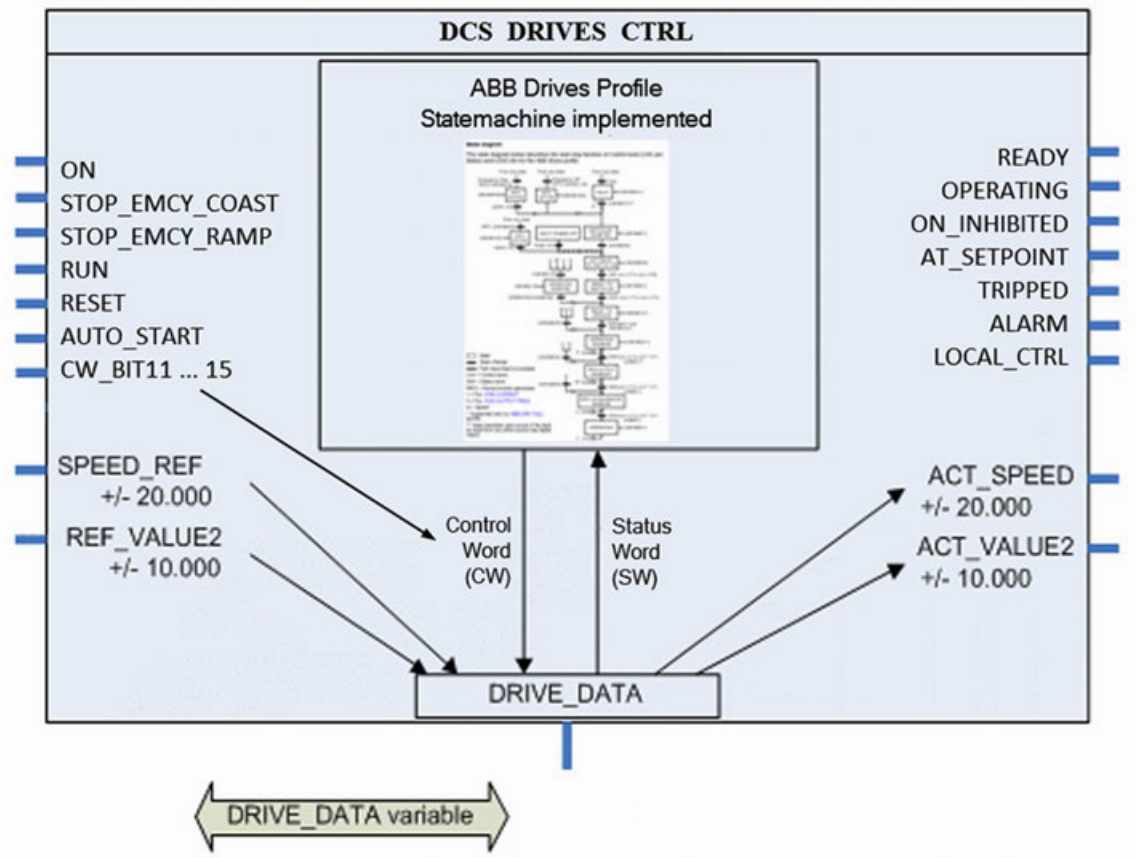


Function block DCS_DRIVES_CTRL is used for controlling DCS Drives with ABB Drives Profile connected to a communication block via a DRIVE_DATA variable.

Block data

Available as of runtime system:	V2.3.3
Included in library:	DCSDrives_AC500_V24.lib
Function block	with historical values

Description



The function block DCS_DRIVES_CTRL is used for controlling DCS Drives with ABB Drives profile.

The function block provides standard start/stop signals to control the drive and standard diagnosis signals read from the drive.

According to the input signals and the actual Status Word (SW), read from the DRIVE_DATA variable, the ABB drives profile state machine is executed. The Control Word (CW) is build and written to the DRIVE_DATA variable. For diagnosis purpose the CW is also written to the output USED_CW.

SPEED_REF input has to be given in the fieldbus range of -20000 .. +20000, according to the scaling parameter in the drive (e.g. Par. 11.05 of ACS355).ACT_SPEED provides the actual speed in the fieldbus range of -20000 .. +20000, according to the scaling parameter in the drive (e.g. Par. 11.05 of ACS355). ACS_REF_SCALING function block could be used to scale the fieldbus range to a physical value.

If the connected communication block (via DRIVE_DATA variable) is disabled or not parameterized correctly, all outputs except DONE, ERR and ERNO are reset to zero. This can be checked by the ERNO output.

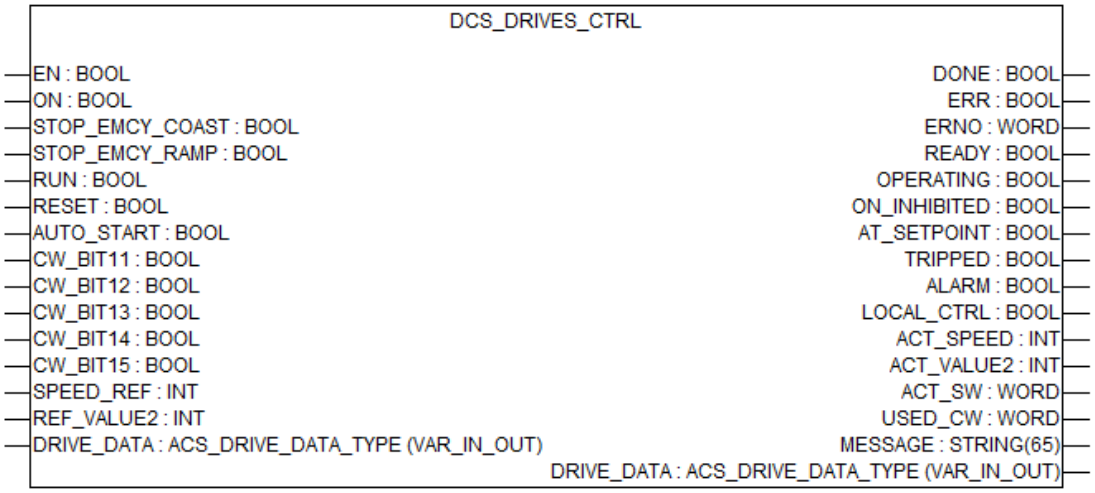
Preconditions

The function block is only working for DCS drives using ABB Drive profile. The data transfer to the drive is realized via the IN_OUT variable DRIVE_DATA, which must be connected to an ACS_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.2 “ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU” on page 2301* or an ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360* function block.

For the necessary configuration of parameters in the drive see table below.

Drive Parameter	DCS800	DCS550	Comment
EXT1 COM-MANDS	10.01 = ManCtrlWord	10.01 = ManCtrlWord	Fieldbus interface as source for start and stop
EXT1/EXT2 SEL	10.07 (HandAuto) MCW: Bit11 11.02 (Ref1Mux) MCW: Bitt11 11.12 (Ref2Mux) Invert 11.02	10.07 (HandAuto) MCW: Bit11 11.02 (Ref1Mux) MCW: Bitt11 11.12 (Ref2Mux) Invert 11.02	Fieldbus interface as source to switch to EXT2 control place. Tbd / tbc
REF1 SELECT	11.03 = SpeedRef2301	11.03 = Spee-dRef2301	Fieldbus interface as source for speed refer-ence
FAULT RESET SEL	NA	NA	Fieldbus interface as source for fault reset
PROFILE	NA	NA	Control Profile to ABB Drives Profile classic or enhanced.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable) Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the function block is active, the current values are available at the outputs.

If the function block has been deactivated, all outputs are set to 0, with the exception of the USED_CW output to 1024 (hex 0400 - only remote bit).

ON (switch on)

Data type: BOOL

With a rising edge of the input ON (FALSE->TRUE) the DCS Drive Contactors are closed, field exciter and fans are started. (depending on the drive configuration, it might directly starts, if RUN = TRUE). (bit 0 of the Control Word On / OFF1N)

If ON = FALSE, the drive is stopped via Off1Mode (21.02). After reaching zero speed, the main Contactors will be switched off.

According to the ABB Drives Profile a new rising edge of input ON will be ignored, until zero speed was reached.

With the AUTO_START function an automatically internally rising edge of this input can be generated to avoid waiting for and detecting zero speed.

STOP_EMCY_COAST (stop emergency coast)

Data type: BOOL, Default value: TRUE

STOP_EMCY_COAST=TRUE enables normal operation of the drive.

Input STOP_EMCY_COAST=FALSE will coast the drive (bit 1 of the Control Word OFF2). A new rising edge of the START input is needed to start the drive again.

STOP_EMCY_RAMP (stop emergency ramp)

Data type: BOOL, Default value: TRUE

STOP_EMCY_RAMP = TRUE enables normal operation of the drive.

Input STOP_EMCY_RAMP = FALSE will stop the drive along the emergency ramp, defined in the drive (bit 2 of the Control Word OFF3). A new rising edge of the START input is needed to start the drive again.

STOP_EMCY_RAMP (stop emergency ramp)

Data type: BOOL, Default value: TRUE

STOP_EMCY_RAMP = TRUE enables normal operation of the drive.

Input STOP_EMCY_RAMP = FALSE will stop the drive along the emergency ramp, defined in the drive (bit 2 of the Control Word OFF3). A new rising edge of the START input is needed to start the drive again.

RUN (run)

Data type: BOOL

Input RUN = TRUE will start the drive (bit 3 of the Control Word RUN / INHIBIT_OP).

RUN = FALSE will stop the drive depending on the StopMode configuration (Par. 21.03)

Depending on the drive configuration a new rising edge of the input ON might be needed to restart the drive. With the AUTO_START function an automatically internally rising edge of this input can be generated each 1 sec.

RESET (reset)

Data type: BOOL

Input RESET is used to reset the drive (bit 7 in the Control Word RESET).

RESET = TRUE resets faults and warnings in the drive. It does not reset the function block itself.

For DCS drives to reset the drive the input ON and the input RUN must be reset to FALSE.

CW_BIT11 (Control Word bit 11)

Data type: BOOL

Input CW_BIT11 = TRUE sets the Control Word Bit11. The meaning is according to the user specific drive configuration.

CW_BIT12 (Control Word bit 12)

Data type: BOOL

Input CW_BIT12 = TRUE sets the Control Word Bit12. The meaning is according to the user specific drive configuration.

CW_BIT13 (Control Word bit 13)

Data type: BOOL

Input CW_BIT13 = TRUE sets the Control Word Bit13. The meaning is according to the user specific drive configuration.

CW_BIT14 (Control Word bit 14)

Data type: BOOL

Input CW_BIT14 = TRUE sets the Control Word Bit14. The meaning is according to the user specific drive configuration.

CW_BIT15 (Control Word bit 15)

Data type: BOOL

Input CW_BIT15 = TRUE sets the Control Word Bit15. The meaning is according to the user specific drive configuration.

AUTO_START (auto start)

Data type: BOOL

Input AUTO_START enables the auto start function of the function block.

The AUTO_START function internally creates cyclically switch on / start commands on the Control Word. So that the ON and RUN input of the function block can be used as level sensitive inputs.

They don´t need to be reset to FALSE and back to TRUE to restart the drive after a normal stop.

The AUTO_START function is not working, if the stop was caused by an emergency stop, e.g. STOP_EMCY_COAST or STOP_EMCY_RAMP input or STO. The time of cyclically retries is 1second.

WARNING!

Automatically start!

Be aware, that the drive starts automatically, if the AUTO_START function is enabled and additionally ON, RUN, STOP_EMCY_COAST and STOP_EMCY_RAMP inputs are set to TRUE.

Details of implementation:

The function will internally reset the ON or RUN bit of the Control Word to create a rising edge on one of these bits to the drive.

The ON bit (bit 0 of Control Word OFF1) is reset to FALSE in case that the ON input is set, but the RDY_ON (bit 0 of Status Word) feedback from drive was still missing after 1sec. Then the ON bit (bit 0 of Control Word OFF1) is set to the value of the ON input again. The RUN bit (bit 3 of Control Word INHIBIT_OP) is reset to FALSE in case that the ON and RUN inputs are set, but the RDY_REF (bit 2 of Status Word) feedback from drive is still missing. Then after 1 sec the RUN bit (bit 3 of Control Word INHIBIT_OP) is set to the value of the RUN input again.

Use Case:

This function is especially useful in e.g. the following situation:

- The drive is running and local control is enabled by the panel on the drive. There the drive is stopped and after a time the control is switched back to the PLC.
  Then the auto start function restarts the drive automatically without the need to give an external rising edge to the input ON and RUN.

SPEED_REF (speed reference)

Data type: INT

Input SPEED_REF must be given in fieldbus equivalent value between -20000 .. +20000.

20000 = the value, defined in the drive as Ref1 Max (e.g. Par.11.05 Ref1 Max for ACS3XX).

Tbc for DCS and RMBA: For drive types ACS3XX, ACS550 and ACH550 using a Modbus RTU connection the speed reference value send to the drive is limited to 20000 or +20000. If the input exceeds this limits, the ERR output is set to TRUE, output ERNO is set to the message that indicates that the input of SPEED_REF is out of range.

Nevertheless the function block is processed normally.

REF_VALUE2 (reference value 2)

Data type: INT

Input REF_VALUE2 must be given in fieldbus equivalent value between -10000 .. +10000.

10000 = the value defined in the drive as Ref2 Max (e.g. Par.11.08 Ref2 Max for ACS3XX).

Tbc for DCS and RMBA: For the drive types ACS3XX, ACS550 and ACH550 using a Modbus RTU connection the Reference Value2, send to the drive is limited to 10000 or + 10000. If the input exceeds this limits, the ERR output is set to TRUE, output ERNO is set to the message that indicates that the input of REF_VALUE2 is out of range.

Nevertheless the function block is processed normally.

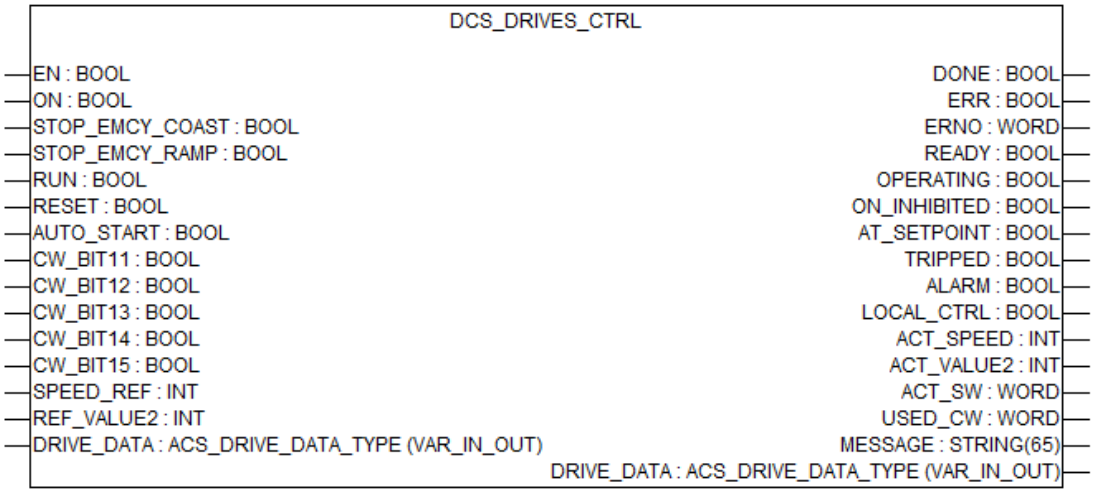
DRIVE_DATA (drive data)

Data type: ACS_DRIVE_DATA_TYPE ↳ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

READY (ready)

Data type: BOOL

Output READY=TRUE indicates that the drive is ready to switch on (Bit 0 in the status word from the drive).

OPERATING (operating)

Data type: BOOL

Output OPERATING=TRUE indicates, that the drive is modulating. The drive is enabled and running (Status Word of drive bit: RDY_REF = TRUE).

This indication works, even if the drive is controlled from another control place, e.g. local panel.

This is different to the ACS_DRIVES_CTRL_STANDARD or ACS_DRIVES_CTRL_STANDARD_GEN.

ON_INHIBIT (on is inhibited)

Data type: BOOL

Output ON_INHIBITED=TRUE indicates, that the OnInhibited state is active (Bit 6 in the Status Word from the drive).

This is the case after a fault or an Emergency Off / Coast Stopp (Off2) or an E-stop (Off3) or via digital input “Off2” (10.08) or E Stop (10.09).

AT_SETPOINT (actual value is at setpoint)

Data type: BOOL

Output AT_SETPOINT=TRUE indicates, that the actual value (MotSpeed (1.04)) and the set-point (SpeedRef4 (2.18)) are in the tolerance zone.

TRIPPED (tripped)

Data type: BOOL

Output TRIPPED=TRUE indicates, that the drive is tripped (Bit 3 in the Status Word from the drive).

ALARM (alarm)

Data type: BOOL

Output ALARM=TRUE indicates, that the drive has an alarm (Bit 7 in the Status Word from the drive).

LOCAL_CTRL (local control)

Data type: BOOL

Output LOCAL_CTRL = TRUE indicates, that the drive is not controlled from remote control e.g. PLC (LOCAL_CTRL = inverted bit 9 in the Status Word from the drive - REMOTE). LOCAL_CTRL might be set to TRUE due to no connection to the drive or the drive was set to local control via the drive panel or a drive configuration tool from PC.

ACT_SPEED (actual speed)

Data type: INT

Output ACT_SPEED returns the actual speed value from the drive. The scaling depends on the drive settings.

ACT_VALUE2 (actual value 2)

Data type: INT

Output ACT_VALUE2 returns the value from the drive parameterized in the drive for Actual Value2 on the fieldbus.

ACT_SW (actual status word)

Data type: WORD

Output ACT_SW returns the actual Status Word read from the drive.

USED_CW (used control word)

Data type: WORD

Output USED_CW returns the Control Word, that was build in the function block due to the inputs and Status Word according the ABB Drives Profile state machine.

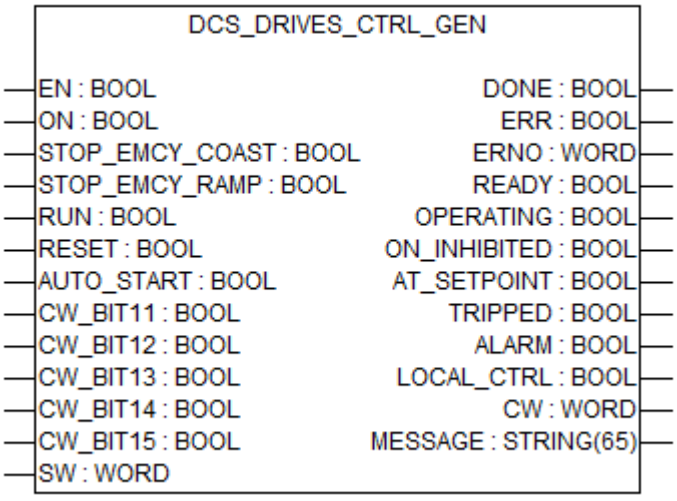
The USED_CW is sent to the drive as Control Word.

MESSAGE (message)

Data type: STRING

Output MESSAGE gives information about the actual state of the function block. This string also indicates what would be the next steps to continue to start the drive, or which signal from the drive is missing.

DCS_DRIVES_CTRL_GEN control of DCS drives with ABB-Drives profile via generic fieldbus

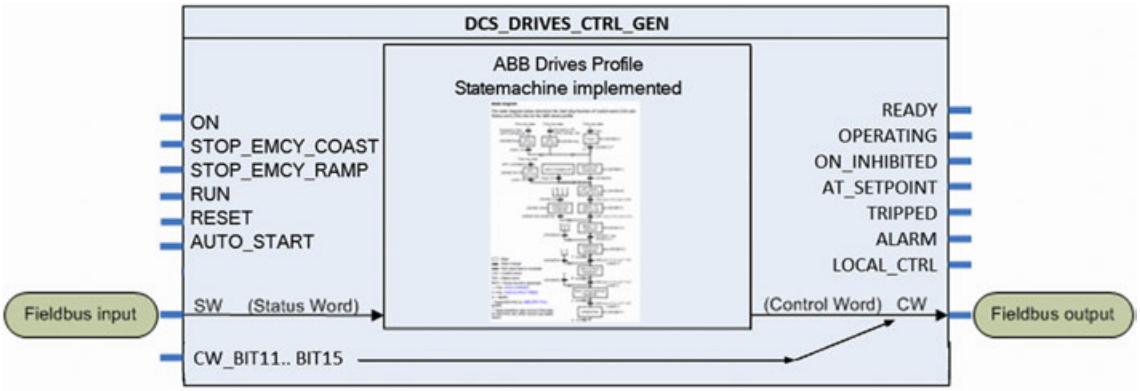


Function block DCS_DRIVES_CTRL is used for controlling DCS Drives with ABB Drives profile connected to a communication block via a DRIVE_DATA variable.

Block data

Available as of runtime system:	V2.3.3
Included in library:	DCSDrives_AC500_V24.lib
Function block	with historical values

Description



The function block DCS_DRIVES_CTRL is used for controlling DCS Drives with ABB Drives profile.

The function block provides standard start/stop signals to control the drive and standard diagnosis signals read from the drive.

According to the input signals and the actual Status Word (SW), read from the DRIVE_DATA variable, the ABB Drives profile state machine is executed. The Control Word (CW) is build and written to the DRIVE_DATA variable. For diagnosis purpose the CW is also written to the output USED_CW.

SPEED_REF input has to be given in the fieldbus range of -20000 .. +20000, according to the scaling parameter in the drive (e.g. Par. 11.05 of ACS355).ACT_SPEED provides the actual speed in the fieldbus range of -20000 .. +20000, according to the scaling parameter in the drive (e.g. Par. 11.05 of ACS355). ACS_REF_SCALING function block could be used to scale the fieldbus range to a physical value.

If the connected communication block (via DRIVE_DATA variable) is disabled or not parameterized correctly, all outputs except DONE, ERR and ERNO are reset to zero. This can be checked by the ERNO output.

Preconditions

The function block is only working for DCS drives using ABB Drive profile. The data transfer to the drive is realized via the IN_OUT variable DRIVE_DATA, which must be connected to an ACS_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.2 “ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU” on page 2301* or an ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360* function block.

Table 138: Necessary configuration of parameters in the drive

Drive Parameter	DCS800	DCS550	Comment

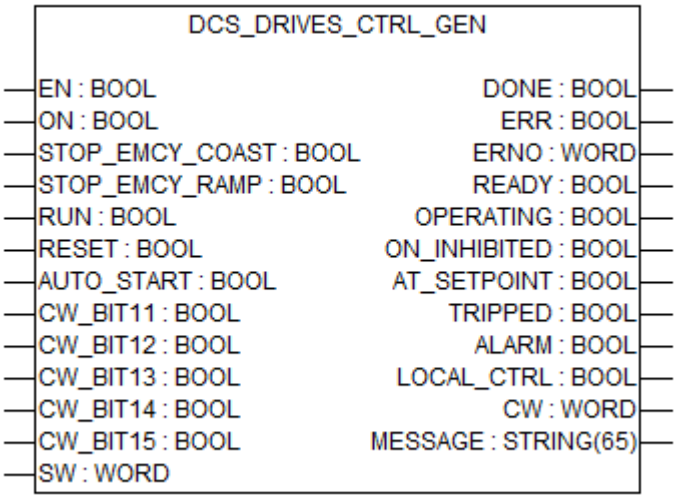
FAULT RESET SEL	NA	NA	Fieldbus interface as source for fault reset
PROFILE	NA	NA	Control Profile to ABB Drives Profile classic or enhanced.

Input description



EN (enable) Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the function block is active, the current values are available at the outputs.

If the function block has been deactivated, all outputs are set to 0, with the exception of the CW output to 1024 (hex 0400 - only remote bit).

ON (switch on) Data type: BOOL

With a rising edge of the input ON (FALSE->TRUE) the DCS Drive Contactors are closed, field exciter and fans are started. (depending on the drive configuration, it might directly starts, if RUN = TRUE). (bit 0 of the Control Word On / OFF1N)

If ON = FALSE, the drive is stopped via Off1Mode (21.02). After reaching zero speed, the main Contactors will be switched off.

According to the ABB Drives Profile a new rising edge of input ON will be ignored, until zero speed was reached.

With the AUTO_START function an automatically internally rising edge of this input can be generated to avoid waiting for and detecting zero speed.

STOP_EMCY_COAST (stop emergency coast)

Data type: BOOL, Default value: TRUE

STOP_EMCY_COAST=TRUE enables normal operation of the drive.

Input STOP_EMCY_COAST=FALSE will coast the drive (bit 1 of the Control Word OFF2). A new rising edge of the START input is needed to start the drive again.

STOP_EMCY_RAMP (stop emergency ramp)

Data type: BOOL, Default value: TRUE

STOP_EMCY_RAMP = TRUE enables normal operation of the drive.

Input STOP_EMCY_RAMP = FALSE will stop the drive along the emergency ramp, defined in the drive (bit 2 of the Control Word OFF3). A new rising edge of the START input is needed to start the drive again.

RUN (run)

Data type: BOOL

Input RUN = TRUE will start the drive (bit 3 of the Control Word RUN / INHIBIT_OP).

RUN = FALSE will stop the drive depending on the StopMode configuration (Par. 21.03)

Depending on the drive configuration a new rising edge of the input ON might be needed to restart the drive. With the AUTO_START function an automatically internally rising edge of this input can be generated each 1 sec.

RESET (reset)

Data type: BOOL

Input RESET is used to reset the drive (bit 7 in the Control Word RESET).

RESET = TRUE resets faults and warnings in the drive. It does not reset the function block itself.

For DCS drives to reset the drive the input ON and the input RUN must be reset to FALSE.

CW_BIT11 (Control Word bit 11)

Data type: BOOL

Input CW_BIT11 = TRUE sets the Control Word Bit11. The meaning is according to the user specific drive configuration.

CW_BIT12 (Control Word bit 12)

Data type: BOOL

Input CW_BIT12 = TRUE sets the Control Word Bit12. The meaning is according to the user specific drive configuration.

CW_BIT13 (Control Word bit 13)

Data type: BOOL

Input CW_BIT13 = TRUE sets the Control Word Bit13. The meaning is according to the user specific drive configuration.

CW_BIT14 (Control Word bit 14)

Data type: BOOL

Input CW_BIT14 = TRUE sets the Control Word Bit14. The meaning is according to the user specific drive configuration.

CW_BIT15 (Control Word bit 15)

Data type: BOOL

Input CW_BIT15 = TRUE sets the Control Word Bit15. The meaning is according to the user specific drive configuration.

AUTO_START (auto start)

Data type: BOOL

Input AUTO_START enables the auto start function of the function block.

The AUTO_START function internally creates cyclically switch on / start commands on the Control Word. So that the ON and RUN input of the function block can be used as level sensitive inputs.

They don´t need to be reset to FALSE and back to TRUE to restart the drive after a normal stop.

The AUTO_START function is not working, if the stop was caused by an emergency stop, e.g. STOP_EMCY_COAST or STOP_EMCY_RAMP input or STO. The time of cyclically retries is 1second.

WARNING!

Automatically start!

Be aware, that the drive starts automatically, if the AUTO_START function is enabled and additionally ON, RUN, STOP_EMCY_COAST and STOP_EMCY_RAMP inputs are set to TRUE.

Details of implementation:

The function will internally reset the ON or RUN bit of the Control Word to create a rising edge on one of these bits to the drive.

The ON bit (bit 0 of Control Word OFF1) is reset to FALSE in case that the ON input is set, but the RDY_ON (bit 0 of Status Word) feedback from drive was still missing after 1sec. Then the ON bit (bit 0 of Control Word OFF1) is set to the value of the ON input again. The RUN bit (bit 3 of Control Word INHIBIT_OP) is reset to FALSE in case that the ON and RUN inputs are set, but the RDY_REF (bit 2 of Status Word) feedback from drive is still missing. Then after 1 sec the RUN bit (bit 3 of Control Word INHIBIT_OP) is set to the value of the RUN input again.

Use Case:

This function is especially useful in e.g. the following situation:

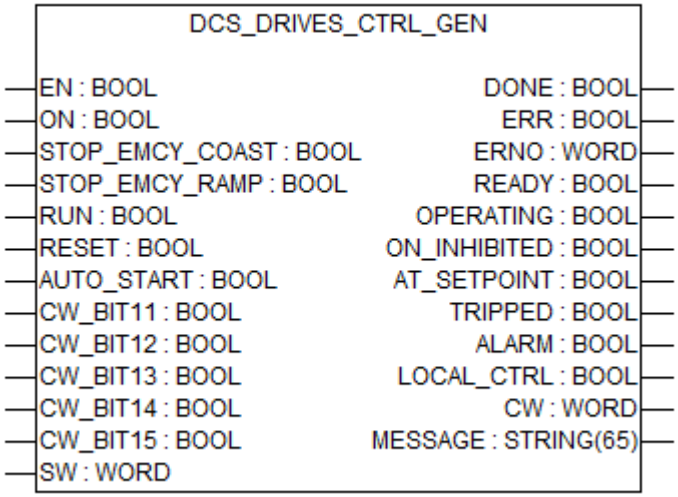
- The drive is running and local control is enabled by the panel on the drive. There the drive is stopped and after a time the control is switched back to the PLC.
  Then the auto start function restarts the drive automatically without the need to give an external rising edge to the input ON and RUN.

SW (Status Word)

Data type: WORD

Input Status Word from drive. Connect Status Word from fieldbus to this input.

Output description



DONE (done) Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter ↬ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

READY (ready) Data type: BOOL

Output READY=TRUE indicates that the drive is ready to switch on (Bit 0 in the status word from the drive).

OPERATING (operating) Data type: BOOL

Output OPERATING=TRUE indicates, that the drive is modulating. The drive is enabled and running (Status Word of drive bit: RDY_REF = TRUE).

This indication works, even if the drive is controlled from another control place, e.g. local panel.

This is different to the ACS_DRIVES_CTRL_STANDARD or ACS_DRIVES_CTRL_STANDARD_GEN.

ON_INHIBIT (on is inhibited)

Data type: BOOL

Output ON_INHIBITED=TRUE indicates, that the OnInhibited state is active (Bit 6 in the Status Word from the drive).

This is the case after a fault or an Emergency Off / Coast Stopp (Off2) or an E-stop (Off3) or via digital input “Off2” (10.08) or E Stop (10.09).

AT_SETPOINT (actual value is at setpoint)

Data type: BOOL

Output AT_SETPOINT=TRUE indicates, that the actual value (MotSpeed (1.04)) and the set-point (SpeedRef4 (2.18)) are in the tolerance zone.

TRIPPED (tripped)

Data type: BOOL

Output TRIPPED=TRUE indicates, that the drive is tripped (Bit 3 in the Status Word from the drive).

ALARM (alarm)

Data type: BOOL

Output ALARM=TRUE indicates, that the drive has an alarm (Bit 7 in the Status Word from the drive).

LOCAL_CTRL (local control)

Data type: BOOL

Output LOCAL_CTRL = TRUE indicates, that the drive is not controlled from remote control e.g. PLC (LOCAL_CTRL = inverted bit 9 in the Status Word from the drive - REMOTE). LOCAL_CTRL might be set to TRUE due to no connection to the drive or the drive was set to local control via the drive panel or a drive configuration tool from PC.

CW (Control Word)

Data type: WORD

Output CW returns the Control Word that was build in the function block using the inputs and Status Word according to the ABB Drives Profile state machine.

Connect CW directly to the fieldbus. The CW output will keep it´s value, even if the drive is not controlled from this block anymore. E.g., if local control or EXT2 is enabled.

This is different to the ACS_DRIVES_CTRL_STANDARD or ACS_DRIVES_CTRL_STANDARD_GEN.

MESSAGE (message)

Data type: STRING

Output MESSAGE gives information about the actual state of the function block. This string also indicates what would be the next steps to continue to start the drive, or which signal from the drive is missing.

1.5.6.8.5 Enumerations

DCS_DRIVE_ENUM enumerations to be used at the input DRIVE_TYPE of ACS_COM_xxx function blocks

Enumerations DCS_DRIVE_ENUM can be used at the input of any communication block ACS_COM_xxx e.g. ACS_COM_MOD_RTU, ACS_COM_MOD_TCP or ACS_COM_PB.

Table 139: Enumeration data

Available as of runtime system:	V1.3.2
Included in library:	DCSDrives_AC500_V24.lib

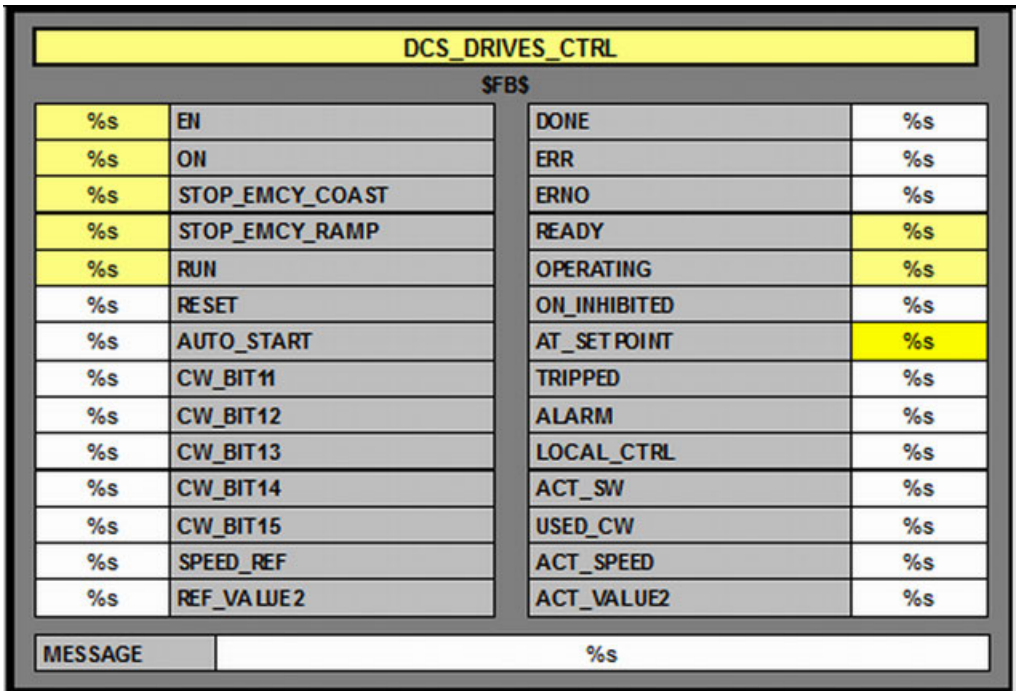
Table 140: ENUMs

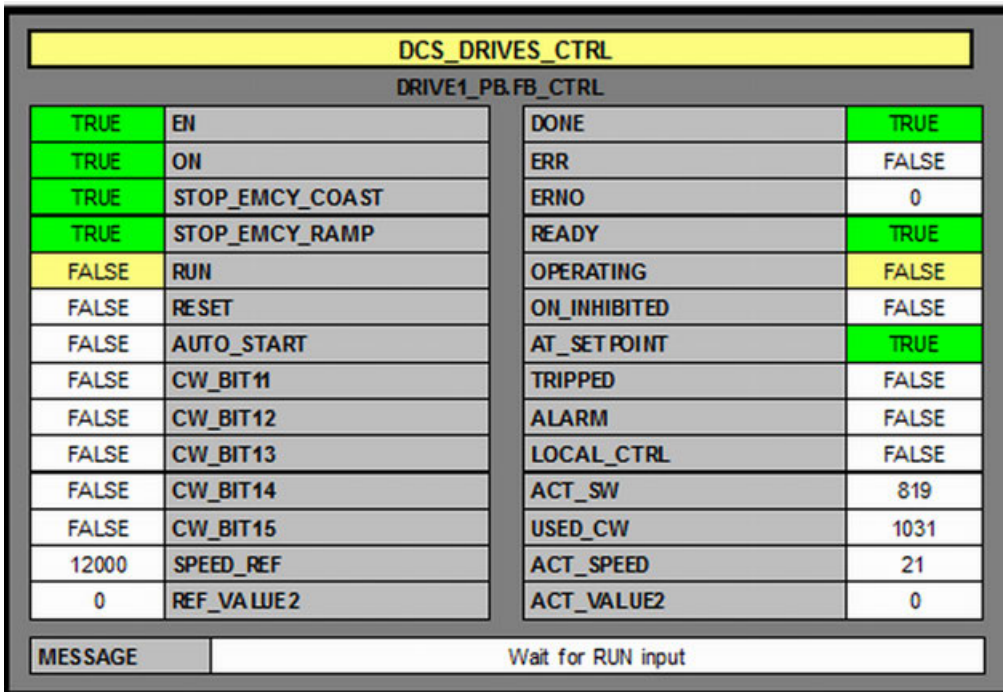
Enumeration	Type	Value	Description
DCS_DRIVE_DCS800	INT	12	
DCS_DRIVE_DCS550	INT	13	

These Enumerations can be used at the input DRIVE_TYPE of any communication block ACS_COM_xxx e.g. ACS_COM_MOD_RTU, ACS_COM_MOD_TCP or ACS_COM_PB, for a better reading.

1.5.6.8.6 Visualization

DCS_DRIVES_CTRL_VISU_PH faceplate of function block DCS_DRIVES_CTRL





Visualization element DCS_DRIVES_CTRL_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an DCS_DRIVES_CTRL function block, which instance was used to replace the placeholder FB.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

Visualization information

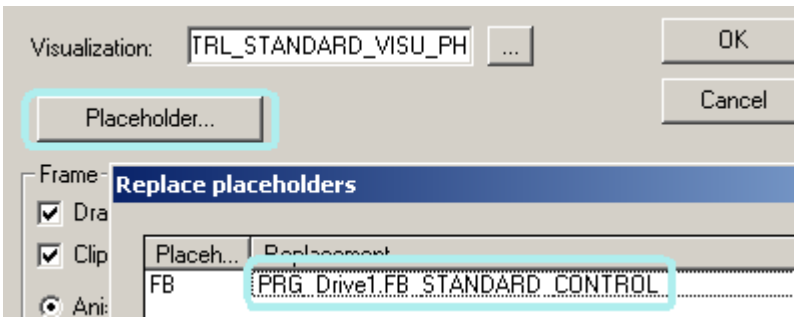
Available in runtime system:	V1.3.2
Included in library:	DCSDrivesBase_AC500_V24.lib

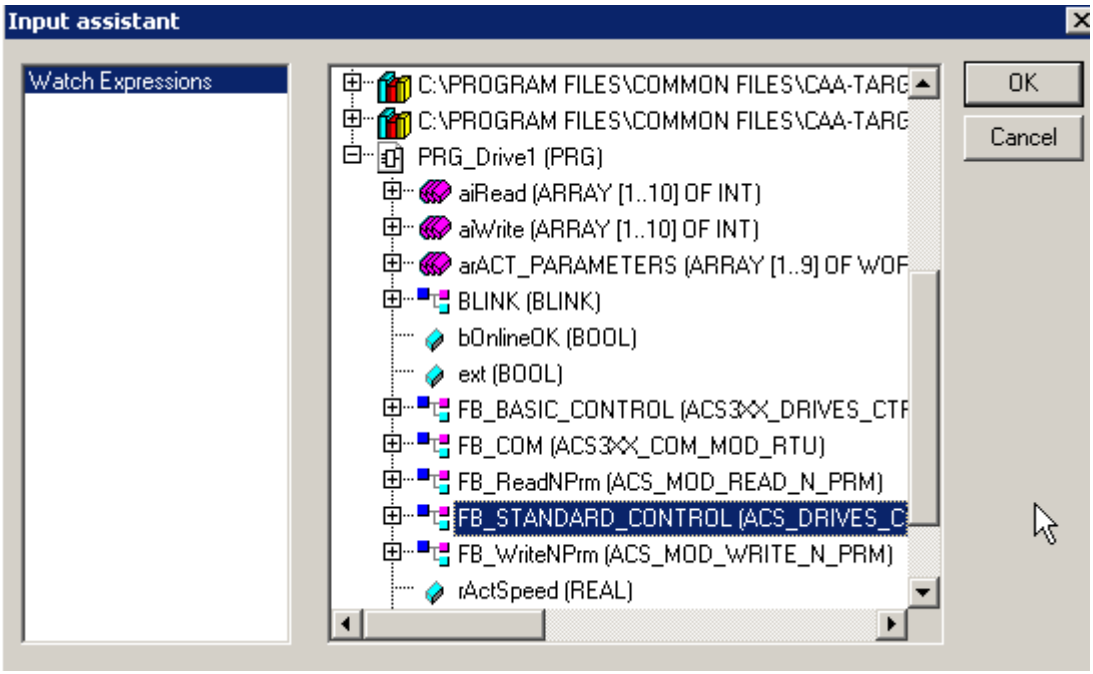
Visualization description

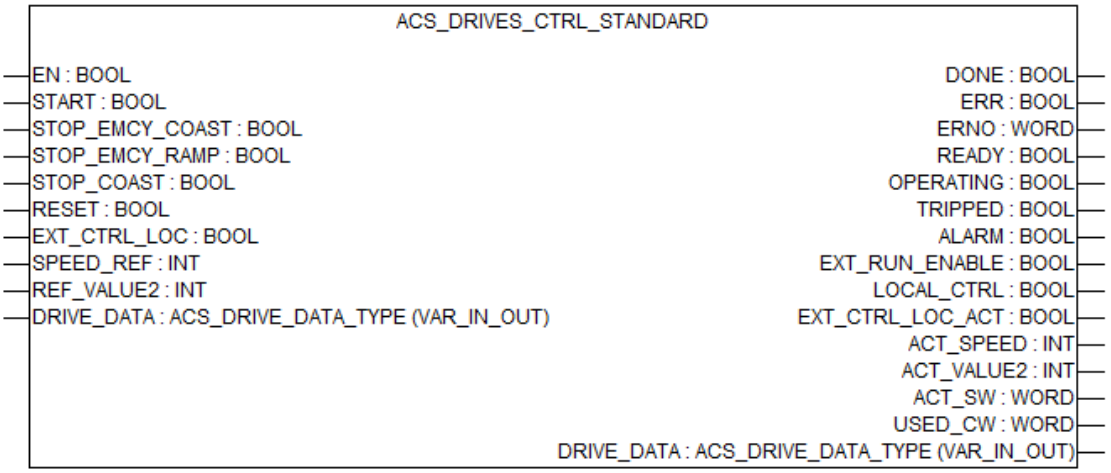
Visualization element DCS_DRIVES_CTRL_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an DCS_DRIVES_CTRL function block which instance was used to replace the placeholder FB.

All inputs of that DCS_DRIVES_CTRL function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.

Additionally, a text message of the actual state, e.g. missing input or missing feedback from drive, is given by the variable MESSAGE, shown next to label MESSAGE.







Parameters

Access R/W

EN Access via: Toggle
Description: EN input

ON Access via: Toggle
Description: ON input

EMCY_COST Access via: Toggle
Description: EMCY_COAST input

EMCY_RAMP Access via: Toggle
Description: EMCY_RAMP input

RUN Access via: Toggle
Description: RUN input

RESET Access via: Toggle
Description: RESET input

CW_BIT 11 Access via: Toggle
Description: CW_BIT 11 input

CW_BIT 12 Access via: Toggle
Description: CW_BIT 12 input

CW_BIT 13 Access via: Toggle
Description: CW_BIT 13 input

CW_BIT 14 Access via: Toggle
Description: CW_BIT 14 input

CW_BIT 15 Access via: Toggle
Description: CW_BIT 15 input

AUTO_START Access via: Toggle
Description: AUTO_START input

SPEED_REF Access via: Text, -32768...+32768
Description: SPEED_REF input

REF_VALUE2 Access via: Text, -32768...+32768
Description: REF_VALUE 2 input

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Drive1.FB_BASIC_CTRL

Access R

DONE Description: DONE output

ERR Description: ERR output

ERNO Description: ERNO output

READY Description: READY output

OPERATING Description: OPERATING output

ON_INHIBITED Description: ON_INHIBITED output

AT_SETPOINT Description: AT_SETPOINT output

TRIPPED Description: TRIPPED output

ALARM Description: ALARM output

LOC_CTRL Description: LOC_CTRL output

ACT_SPEED Description: ACT_SPEED output

ACT_VALUE2 Description: ACT_VALUE 2 output

MESSAGE Description: MESSAGE output

Colors

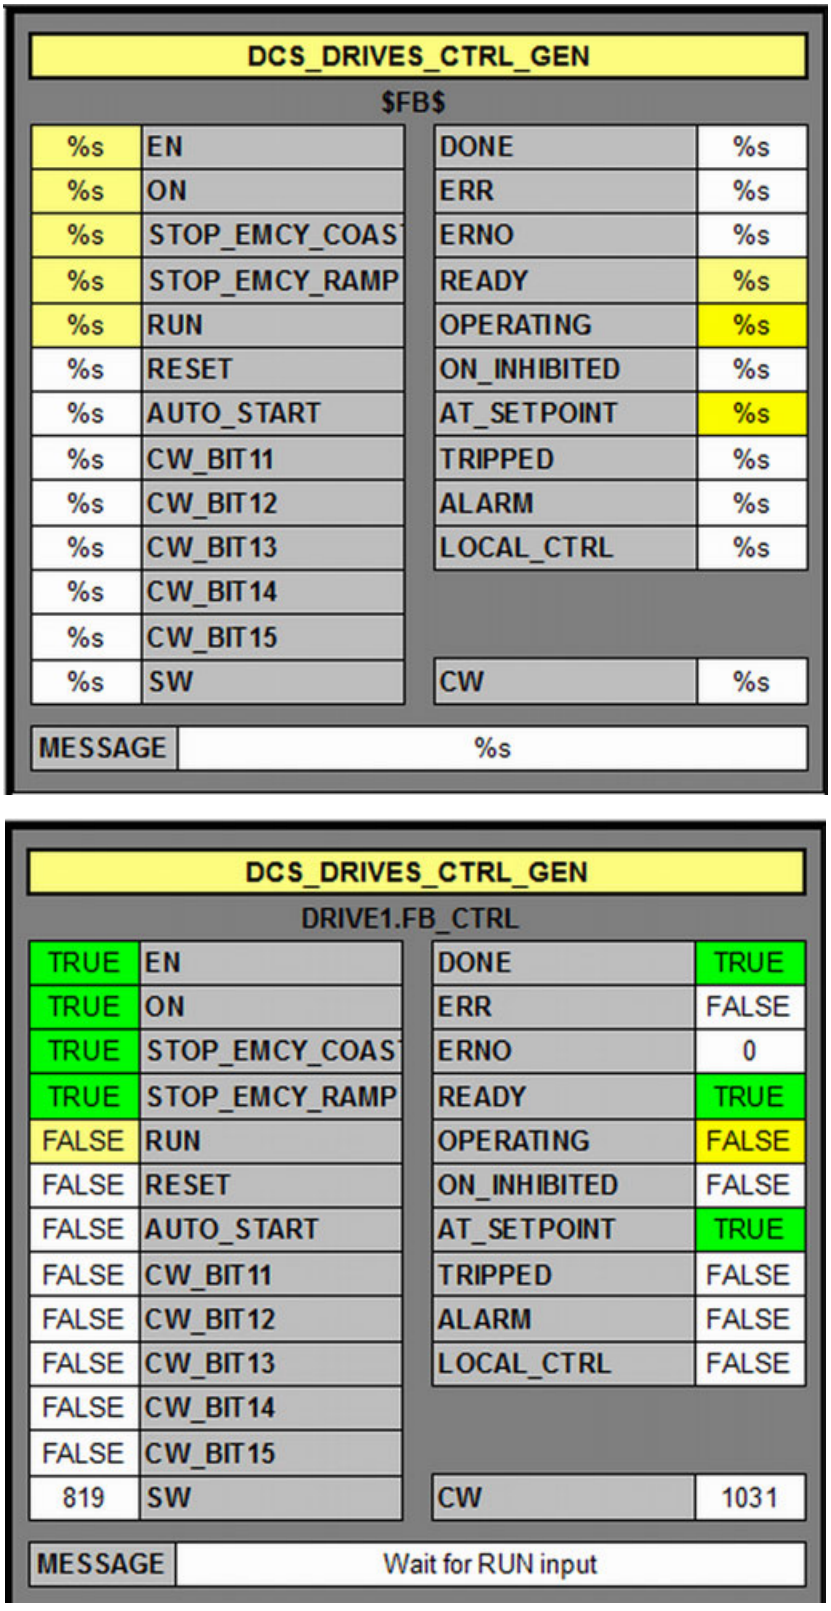
The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

DCS_DRIVES_CTRL_GEN_VISU_PH faceplate of function block DCS_DRIVES_CTRL_GEN



Visualization element DCS_DRIVES_CTRL_GEN_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an DCS_DRIVES_CTRL_GEN function block, which instance was used to replace the placeholder FB.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

Visualization information

Available in runtime system:	V1.3.2
Included in library:	DCSDrivesBase_AC500_V24.lib

Visualization description

Visualization element DCS_DRIVES_CTRL_GEN_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an DCS_DRIVES_CTRL_GEN function block which instance was used to replace the placeholder FB.

All inputs of that DCS_DRIVES_CTRL_GEN function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.

Additionally, a text message of the actual state, e.g. missing input or missing feedback from drive, is given by the variable MESSAGE, shown next to label MESSAGE.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

1.5.6.9 Examples

Example projects for the libraries can be found in the folder: \Users\Public\Documents\AutomationBuilder\Examples

1.5.7 BACnet B-ASC library

1.5.7.1 System technology

BACnet B-ASC library allows to integrate an AC500 processor module into a BACnet network and to exchange data between the processor module and other devices connected to BACnet network. The library provides the BACnet B-ASC profile which enables the processor module to act as a server. The processor module receives client requests, performs them and reports back the results.

You can use BACnet IP or MS/TP as communication protocol. For BACnet IP communication use a device with onboard Ethernet. For MS/TP communication use a device with onboard serial interface.

A proprietary BACnet protocol stack is embedded into some interface implementation which connects the protocol stack to system resources like operating system and communication interfaces.

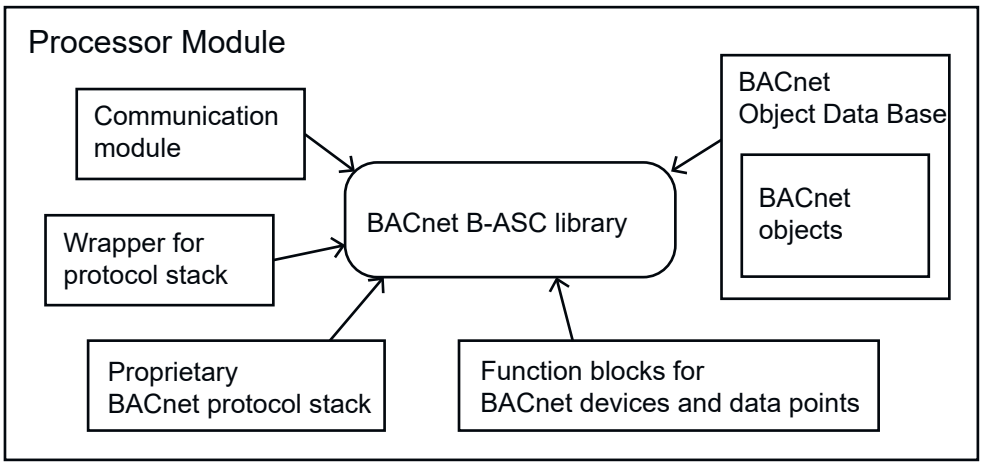

Fig. 178: BACnet B-ASC model

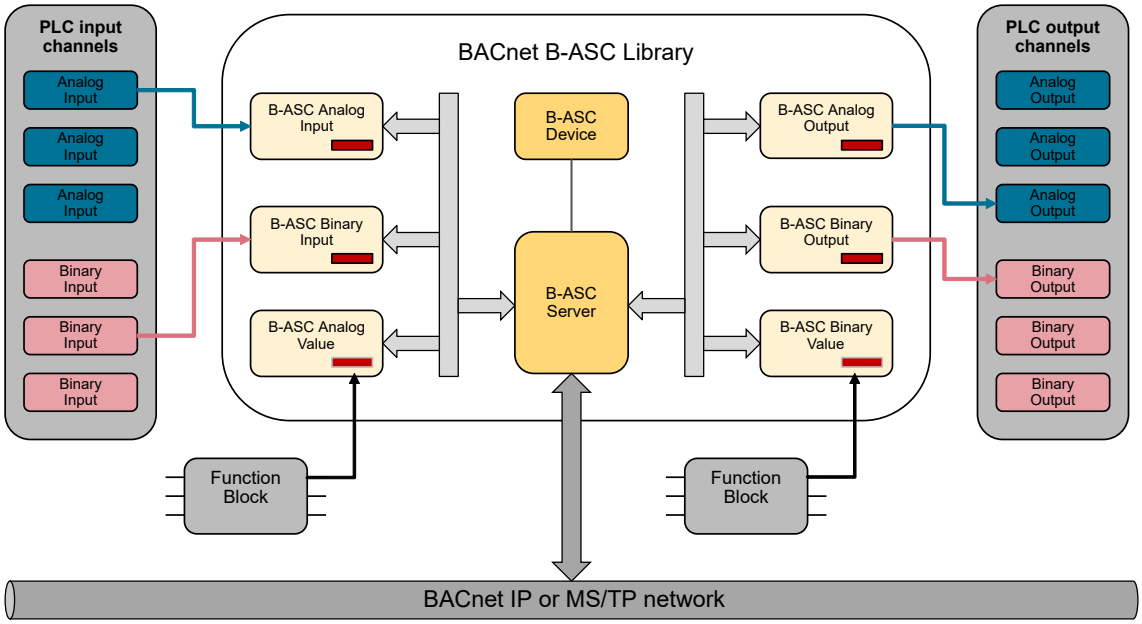
BACnet B-ASC library acts as follows.

- BACnet server protocol stack runs in AC500 system task context.
- BACnet request messages are received and responded via IP or serial interface.
- Execution of BACnet protocol state machine by protocol stack.
- Servicing received requests in detail by BACnet B-ASC library object implementation.

The BACnet B-ASC library provides a set of function blocks representing the server, device and data points. The function blocks are the programming interface to the user application.



Function blocks BASC_SERVER and BASC_DEVICE are mandatory. The other function blocks are optional *Chapter 1.5.7.2 “Function blocks” on page 2495*.

When initializing the function blocks via downloading to the processor module, the function blocks evaluate their inputs OBJ_ID and OBJ_NAME and register at the object database. Later changes at these inputs are not evaluated. With each further call by the application the function blocks synchronize the inputs and outputs with the associated BACnet property `Present_Value`. Received BACnet requests will be serviced by the protocol stack. If an object is addressed that is registered at the object database the request is routed to this object to be handled in detail.

The communication module provides a network layer which acts as interface between proprietary BACnet protocol stack and communication drivers.

Configuration in Automation Builder

For BACnet IP no special configuration is needed. The onboard Ethernet interface will be selected via function block input.

For BACnet MS/TP

1. Configure serial interface to use with protocol "COM1 - SysLibCom".
2. Adjust the settings as it is required for RS-485 communications. For further details see *Chapter 1.6.5.2.11 “Serial interfaces COM1 and COM2” on page 6098*.

Task configuration in CODESYS

All function blocks have to be called in tasks with cyclically processing.

You can use the function blocks with:

- PLC_PRG with automatic task configuration or manual task configuration.
- One single program or different programs.
- One single task or different tasks.

With different programs assigned to different tasks you can define different cycle times and priorities.

Executing BACnet protocol stack is decoupled from IEC task execution. BACnet protocol stack runs in a system task. IEC task cycle times and priorities do not influence receiving of requests and sending of responses. Function block BASC_SERVER does the initialization work only. Function block BASC_DEVICE provides static settings of the BACnet device only. Therefore it does not matter in which IEC task these function blocks are placed.

For the other function blocks the IEC task cycle time and priority are important. These function blocks update their present values while be called by the IEC task.

Limitations

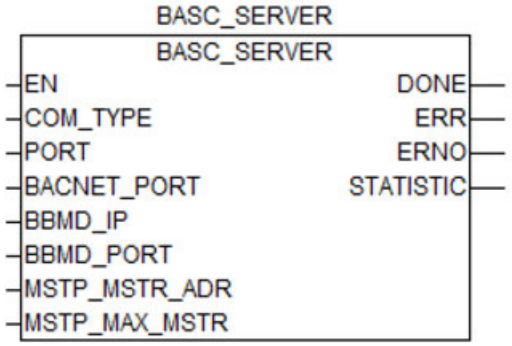
- No support of COV (change of value), alarms and events reporting.
- Supported string lengths: up to 40 characters for object names.
- Supports UTF-8 character set.
- Maximum number of object instances depends on available user memory of the processor module.
- The response of a `readProperty` service on the device object property `Object_List` can transfer maximum 93 object instances even if more objects are used. Due to limitations of used BACnet protocol stack.
- No support of message segmentation due to used BACnet protocol stack.
- The supported baud rates are 9600 Baud, 19200 Baud and 38400 Baud.

1.5.7.2 Function blocks

The function blocks in this library can only be executed in RUN mode of the processor module, not in simulation mode.

BACnet B-ASC library is based on BACnet data communication protocol according to ISO 16484-5.

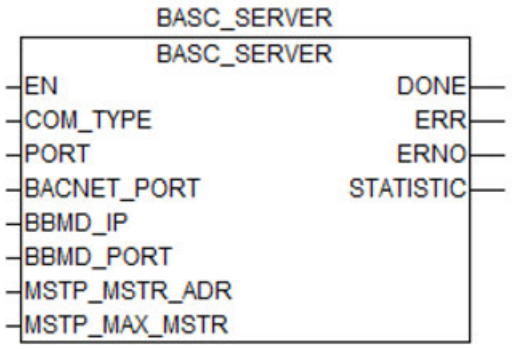
1.5.7.2.1 BASC_SERVER



Parameter	Value
Included in library	BACnet_B-ASC_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	C interface

Function block BASC_SERVER encapsulates the BACnet protocol stack. This function block can be instantiated only once. The input parameters of the function block are used to configure the BACnet protocol and the desired network type.

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. If input EN = TRUE BACnet protocol stack is initialized and system background task is started. As long as EN remains TRUE BACnet protocol stack execution is active. BACnet messages will be received and responded. The function block is not processed if input EN = FALSE.

COM_TYPE (communication type)

Data type	Default value	Range	Unit
BASC_COM_TYPE_ ENUM	BASC_IP_COM	BASC_IP_COM, BASC_MSTP_COM	-

Set communication type ↳ *"BASC_COM_TYPE_ENUM" on page 2517*.

PORT

Data type	Default value	Range	Unit
BYTE	1	Depends on the used processor module	-

Set port number.

If COM_TYPE = IP, 1 = ETH1, 2 = ETH2...

If COM_TYPE = MS/TP, 1 = COM1, 2 = COM2...

BACNET_PORT

Data type	Default value	Range	Unit
WORD	47808(16#BAC0)	0 ... 65535	-

Set BACnet port number to act at the BACnet network.

If COM_TYPE = IP, set the BACnet port number to be used.

If COM_TYPE = MS/TP, input will be ignored.

BBMD_IP (broadcast management device IP)

Data type	Default value	Range	Unit
STRING(15)	0.0.0.0	-	-

Set IP address of BACnet Brodcast Management Device to register as foreign device.

If COM_TYPE = IP, set the IP address to be used.

If COM_TYPE = MS/TP, input will be ignored.

BBMD_PORT (broadcast management device port)

Data type	Default value	Range	Unit
WORD	47808(16#BAC0)	0 ... 65535	-

Set BACnet port number of BACnet Brodcast Management Device to register as foreign device.

If COM_TYPE = IP, set the port number to be used.

If COM_TYPE = MS/TP, input will be ignored.

MSTP_MSTR_ADR (MS/TP master address)

Data type	Default value	Range	Unit
BYTE	1	1-127	-

Set BACnet master address for MS/TP protocol to act as master at the MS/TP network.

If COM_TYPE = IP, input will be ignored.

If COM_TYPE = MS/TP, set the master address to be used.

MSTP_MAX_MSTR (MS/TP maximum master address)

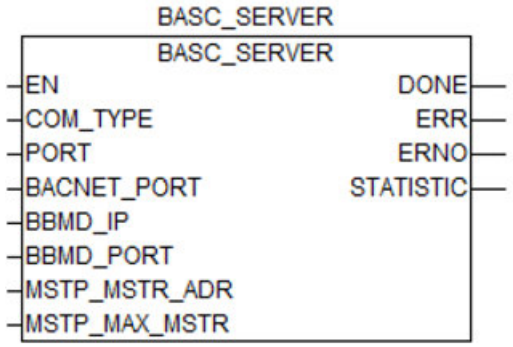
Data type	Default value	Range	Unit
BYTE	127	1-127	-

Set BACnet maximum master address for MS/TP protocol. Used when scanning the MS/TP network for other master devices.

If COM_TYPE = IP, input will be ignored.

If COM_TYPE = MS/TP, set the maximum master address to be used.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

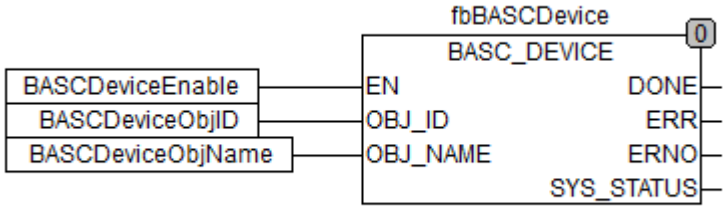
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATISTIC

Data type	Default value	Range	Unit
BASC_STA-TISTIC_COUNTER_TYPE	-	-	-

Statistic data *“BASC_STATISTIC_COUNTER_TYPE” on page 2518*.

1.5.7.2.2 BASC_DEVICE



Parameter	Value
Included in library	BACnet_B-ASC_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	C interface

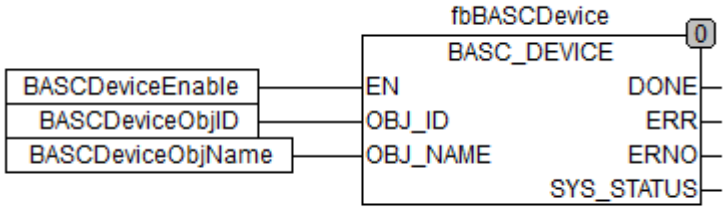
BASC_DEVICE represents the BACnet server device provided by BACnet B-ASC library. The inputs are used to configure corresponding BACnet device object properties. The outputs provide the BACnet device status.

Table 141: Device object properties provided at the BACnet network by BASC_DEVICE

Property	Characteristics	Value	BACnet conformance code
Object_Identifier	Set via input OBJ_ID	-	R - read
Object_Name	Set via input OBJ_NAME	-	R - read
System_Status	Updates output SYS_STATUS	-	R - read
Object_Type	Constant	DEVICE (8)	R - read
Vendor_Name	Constant	ABB	R - read
Vendor_Identifier	Constant	808	R - read
Model_Name	Constant	AC500-PM5xx	R - read
Firmware_Revision	Constant	B-ASC library V1.0.0	R - read
Application_Software_Version	Constant	0.0.0	R - read
Protocol_Version	Constant	1	R - read
Protocol_Revision	Constant	12	R - read
Protocol_Services_Supported	Constant	Who-Is / I-Am Who-Has / I-Have Read property Write property Device communication control	R - read

Property	Characteristics	Value	BACnet conformance code
Protocol_Object_Types_Supported	Constant	Analog input Analog output Analog value Binary input Binary output Binary value Device	R - read
Object_List	Depends on used objects	-	R - read
Max_APDU_Length_Accepted	Constant	480	R - read
Segmentation_Supported	Constant	No segmentation (3)	R - read
APDU_Timeout	Constant	10000	R - read
Number_Of_APDU_Retries	Constant	0	R - read
Device_Address_Binding	Constant	Empty list	R - read
Database_Revision	Constant	1	R - read
Max_Master	Depends on setting in BASC_SERVER	127	R - read
Max_Info_Frames	Constant	1	R - read

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

OBJ_ID (object ident number)

Data type	Default value	Range	Unit
WORD	0	0...4194302	-

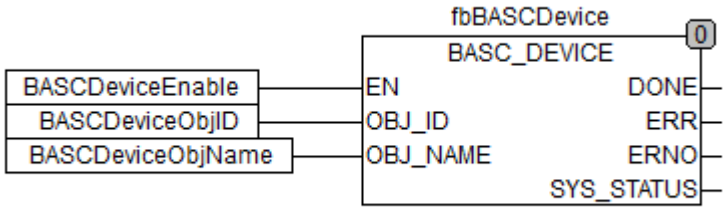
Defines the BACnet object ident number. The object ident number has to be unique within the BACnet network.

OBJ_NAME (object name)

Data type	Default value	Range	Unit
STRING(40)	Empty string	-	-

Defines the BACnet object name. The object name has to be unique within BACnet network.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

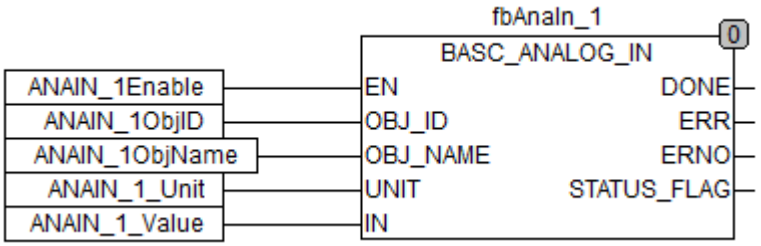
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

SYS_STATUS (system status)

Data type	Default value	Range	Unit
BASC_DEV_STATUS_ENUM	BASC_NON_OPERATIONAL	BASC_NON_OPERATIONAL, BASC_OPERATIONAL	-

Indicates the current state of the BACnet device ↳ *“BASC_DEV_STATUS_ENUM” on page 2518*.

1.5.7.2.3 BASC_ANALOG_IN



Parameter	Value
Included in library	BACnet_B-ASC_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	C interface

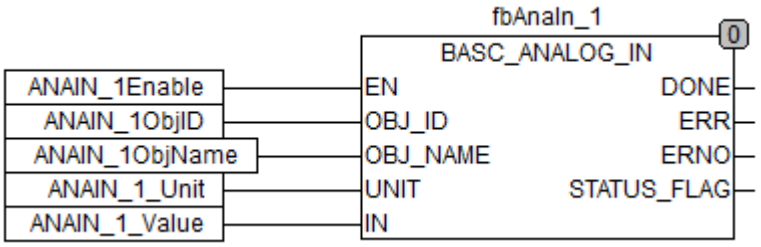
BASC_ANALOG_IN allows to connect an IEC variable with a BACnet object type "analog input". This object represents a physical analog input of the device. Connect the variables mapped to the physical analog inputs to this function block only.

Table 142: Analog input object properties provided at the BACnet network by BASC_ANALOG_IN

Property name	Characteristics	Value	BACnet conformance code
Object_Identifier	Set via input OBJ_ID	-	R - read
Object_Name	Set via input OBJ_NAME	-	R - read
Units	Set via input UNIT	-	R - read
Present_Value	Set via input IN	-	R - read
Status_Flags	Updates output STATUS_FLAG	-	R - read
Object_Type	Constant	ANALOG_INPUT (0)	R - read
Event_State	Constant	NORMAL (0)	R - read
Out_Of_Service	Set via BACnet write services	-	W - read/write

If property `Out_Of_service` = TRUE the property `Present_Value` becomes writable.

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input EN is set to TRUE input IN is evaluated and used to update BACnet object property `Present_Value`.

OBJ_ID (object ident number)

Data type	Default value	Range	Unit
WORD	0	0...4194302	-

Defines the BACnet object ident number. The object ident number has to be unique within the BACnet network.

OBJ_NAME (object name)

Data type	Default value	Range	Unit
STRING(40)	Empty string	-	-

Defines the BACnet object name. The object name has to be unique within BACnet network.

UNIT

Data type	Default value	Range	Unit
BASC_ENG_UNITS_ENUM	BASC_NO_UNITS	All units defined in BACnet standard.	-

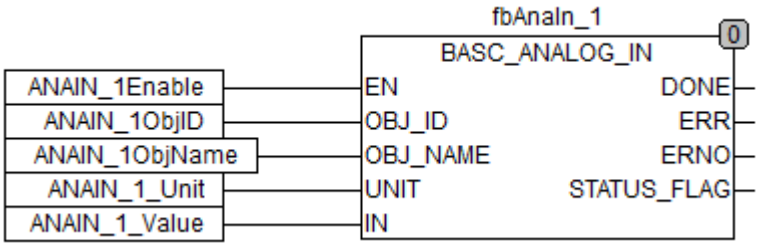
Indicates the engineering unit of the `Present_Value` property of the object. In BACnet network the value connected to the function block input IN will be interpreted as value of this engineering unit.

IN

Data type	Default value	Range	Unit
REAL	0.0	-3.40282347E38...3.40282347E38	-

To be connected to an IEC variable representing a physical input of the processor module. The value will be used to update BACnet property `Present_Value`.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

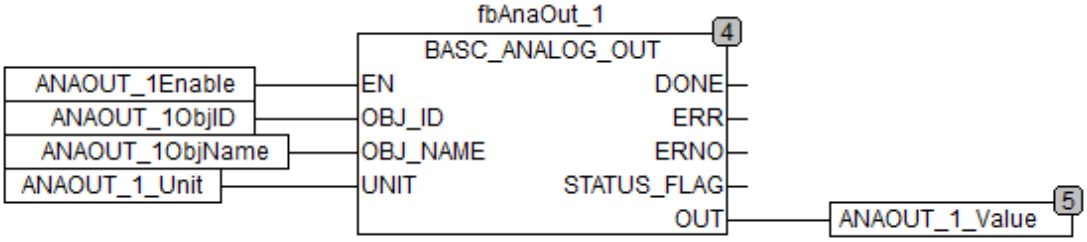
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATUS_FLAG

Data type	Default value	Range	Unit
WORD	-	-	-

BACnet B-ASC library supports property `Status_Flags`. The current value of this property will be provided at output STATUS_FLAG.

1.5.7.2.4 BASC_ANALOG_OUT



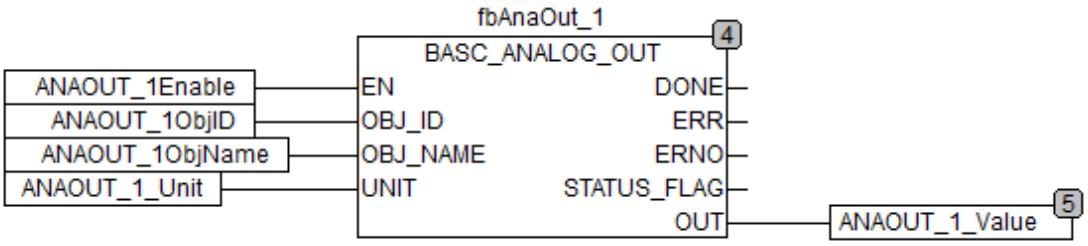
Parameter	Value
Included in library	BACnet_B-ASC_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	C interface

BASC_ANALOG_OUT allows to connect an IEC variable with a BACnet object type "analog output". This object represents a physical analog output of the device. Connect the variables mapped to the physical analog outputs to this function block only.

Table 143: Analog output object properties provided at the BACnet network by BASC_ANALOG_OUT

Property	Characteristics	Value	BACNet conformance code
Object_Identifier	Set via input OBJ_ID	-	R - read
Object_Name	Set via input OBJ_NAME	-	R - read
Units	Set via input UNIT	-	R - read
Present_Value	Updates output OUT	-	W - read/write
Status_Flags	Updates output STATUS_FLAG	-	R - read
Object_Type	Constant	ANALOG_OUTPUT (1)	R - read
Event_State	Constant	NORMAL (0)	R - read
Out_Of_Service	Set via BACnet write services	-	W - read/write
Priority_Array	Set via BACnet write services	-	R - read
Relinquish_Default	Constant	0.0	R - read

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input EN is set to TRUE output OUT is updated with current value of BACnet object property `Present_Value`.

OBJ_ID (object ident number)

Data type	Default value	Range	Unit
WORD	0	0...4194302	-

Defines the BACnet object ident number. The object ident number has to be unique within the BACnet network.

OBJ_NAME (object name)

Data type	Default value	Range	Unit
STRING(40)	Empty string	-	-

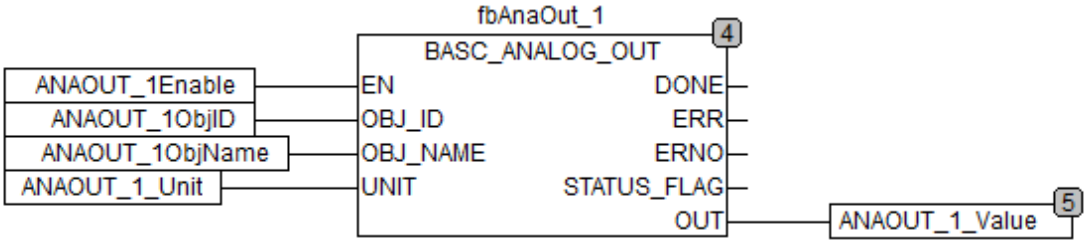
Defines the BACnet object name. The object name has to be unique within BACnet network.

UNIT

Data type	Default value	Range	Unit
BASC_ENG_UNITS_ ENUM	BASC_NO_UNITS	All units defined in BACnet standard.	-

Indicates the engineering unit of the `Present_Value` property of the object. In BACnet network the value connected to the function block input IN will be interpreted as value of this engineering unit.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATUS_FLAG

Data type	Default value	Range	Unit
WORD	-	-	-

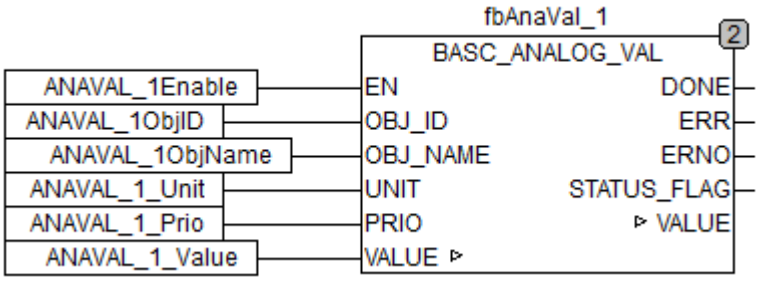
BACnet B-ASC library supports property `Status_Flags`. The current value of this property will be provided at output STATUS_FLAG.

OUT

Data type	Default value	Range	Unit
REAL	0.0	-3.40282347E38...3.40282347E38	-

To be connected to an IEC variable representing a physical output of the processor module. This output will be updated with the BACnet object property `Present_Value`.

1.5.7.2.5 BASC_ANALOG_VAL



Parameter	Value
Included in library	BACnet_B-ASC_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	C interface

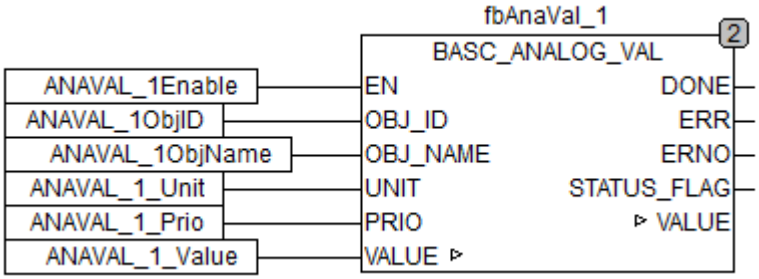
BASC_ANALOG_VAL allows to connect an IEC variable with a BACnet object type "analog value". This object represents an analog value that is neither physical input nor physical output of the device. Connect the internal IEC variables to this function block only.

Table 144: Analog value object properties provided at the BACnet network by BASC_ANALOG_VAL

Property	Characteristics	Value	BACNet conformance code
Object_Identifier	Set via input OBJ_ID	-	R - read
Object_Name	Set via input OBJ_NAME	-	R - read
Units	Set via input UNIT	-	R - read

Property	Characteristics	Value	BACNet conformance code
Present_Value	Set via input VALUE, Updates output VALUE	-	W – read/write
Status_Flags	Updates output STATUS_FLAG	-	R - read
Object_Type	Constant	ANALOG_VALUE (2)	R - read
Event_State	Constant	NORMAL (0)	R - read
Out_Of_Service	Set via BACnet write services	-	W - read/write
Priority_Array	Set via BACnet write services	-	R - read
Relinquish_Default	Constant	0.0	R - read

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input EN is set to TRUE input VALUE is evaluated and used to update BACnet object property `Present_Value`.

OBJ_ID (object ident number)

Data type	Default value	Range	Unit
WORD	0	0...4194302	-

Defines the BACnet object ident number. The object ident number has to be unique within the BACnet network.

OBJ_NAME (object name)

Data type	Default value	Range	Unit
STRING(40)	Empty string	-	-

Defines the BACnet object name. The object name has to be unique within BACnet network.

UNIT

Data type	Default value	Range	Unit
BASC_ENG_UNITS_ENUM	BASC_NO_UNITS	All units defined in BACnet standard.	-

Indicates the engineering unit of the `Present_Value` property of the object. In BACnet network the value connected to the function block input IN will be interpreted as value of this engineering unit.

PRIO

Data type	Default value	Range	Unit
BYTE	1	1...16	-

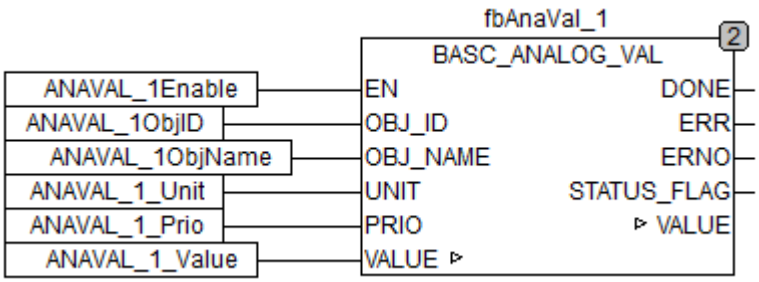
Defines the BACnet priority that will be used on updating the property `Present_Value` of the analog value object.

VALUE

Data type	Default value	Range	Unit
REAL	0.0	-3.40282347E38….3.40282347E38	-

To be connected to an IEC variable representing this object type. The value will be used to update BACnet property `Present_Value`.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

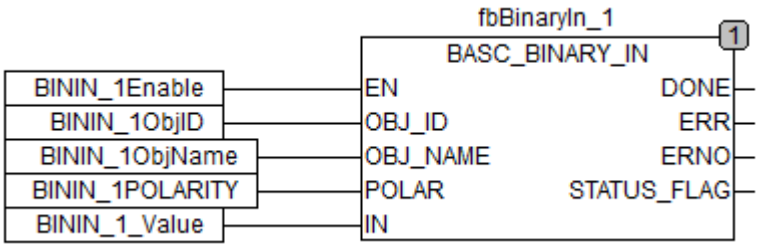
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATUS_FLAG

Data type	Default value	Range	Unit
WORD	-	-	-

BACnet B-ASC library supports property `Status_Flags`. The current value of this property will be provided at output STATUS_FLAG.

1.5.7.2.6 BASC_BINARY_IN



Parameter	Value
Included in library	BACnet_B-ASC_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	C interface

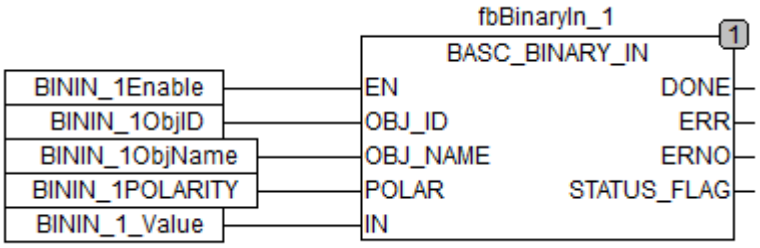
BASC_BINARY_IN allows to connect an IEC variable with a BACnet object type "binary input". This object represents a physical binary input of the device. Connect the variables mapped to physical binary inputs to this function block only.

Table 145: Binary input properties provided at the BACnet network by BASC_BINARY_IN

Property	Characteristics	Value	BACNet conformance code
Object_Identifier	Set via input OBJ_ID	-	R - read
Object_Name	Set via input OBJ_NAME	-	R - read
Polarity	Set via input POLAR	-	R - read
Present_Value	Set via input IN	-	R - read
Status_Flags	Updates output STATUS_FLAG	-	R - read
Object_Type	Constant	BINARY_INPUT (3)	R - read
Event_State	Constant	NORMAL (0)	R - read
Out_Of_Service	Set via BACnet write services	-	W - read/write

> *If property* `Out_Of_service` *= TRUE the property* `Present_Value` *becomes writable.*

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input EN is set to TRUE input IN is evaluated and used to update BACnet object property `Present_Value`.

OBJ_ID (object ident number)

Data type	Default value	Range	Unit
WORD	0	0...4194302	-

Defines the BACnet object ident number. The object ident number has to be unique within the BACnet network.

OBJ_NAME (object name)

Data type	Default value	Range	Unit
STRING(40)	Empty string	-	-

Defines the BACnet object name. The object name has to be unique within BACnet network.

POLAR

Data type	Default value	Range	Unit
BASC_POLAR_ENUM	BASC_NORMAL	BASC_NORMAL, BASC_REVERSE	-

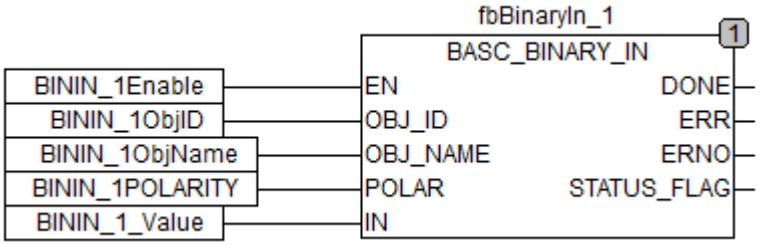
Defines the polarity of the value that is connected to the input IN. Polarity is defined according to BACnet standard ↳ *"BASC_POLAR_ENUM" on page 2518*.

IN

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

To be connected to an IEC variable representing a physical input of the processor module. The value will be used to update BACnet property `Present_Value`.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

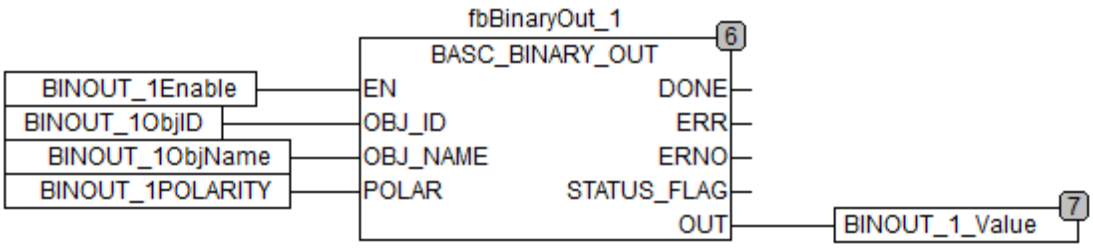
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATUS_FLAG

Data type	Default value	Range	Unit
WORD	-	-	-

BACnet B-ASC library supports property `Status_Flags`. The current value of this property will be provided at output STATUS_FLAG.

1.5.7.2.7 BASC_BINARY_OUT



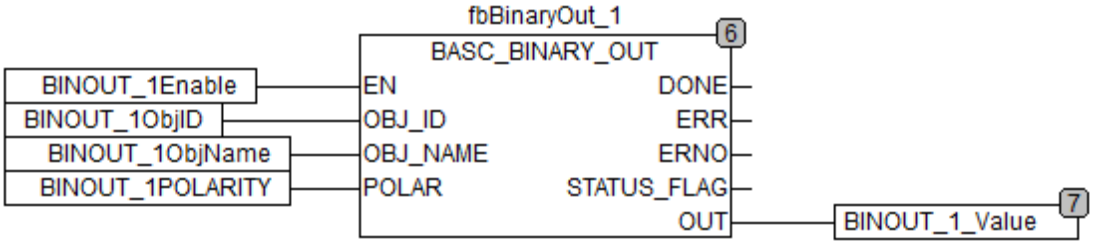
Parameter	Value
Included in library	BACnet_B-ASC_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	C interface

BASC_BINARY_OUT allows to connect an IEC variable with a BACnet object type "binary output". This object represents a physical binary output of the device. Connect the variables mapped to physical binary outputs to this function block only.

Table 146: Binary output properties provided at the BACnet network by BASC_BINARY_OUT

Property name	Characteristics	Value	BACNet conformance code
Object_Identifier	Set via input OBJ_ID	-	R - read
Object_Name	Set via input OBJ_NAME	-	R - read
Polarity	Set via input POLAR	-	R - read
Present_Value	Updates output OUT	-	W - read/write
Status_Flags	Updates output STATUS_FLAG	-	R - read
Object_Type	Constant	BINARY_OUTPUT (4)	R - read
Event_State	Constant	NORMAL (0)	R - read
Out_Of_Service	Set via BACnet write services	-	W - read/write
Priority_Array	Set via BACnet write services	-	R - read
Relinquish_Default	Constant	INACTIVE	R - read

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input EN is set to TRUE output OUT is updated with current value of BACnet object property `Present_Value`.

OBJ_ID (object ident number)

Data type	Default value	Range	Unit
WORD	0	0...4194302	-

Defines the BACnet object ident number. The object ident number has to be unique within the BACnet network.

OBJ_NAME (object name)

Data type	Default value	Range	Unit
STRING(40)	Empty string	-	-

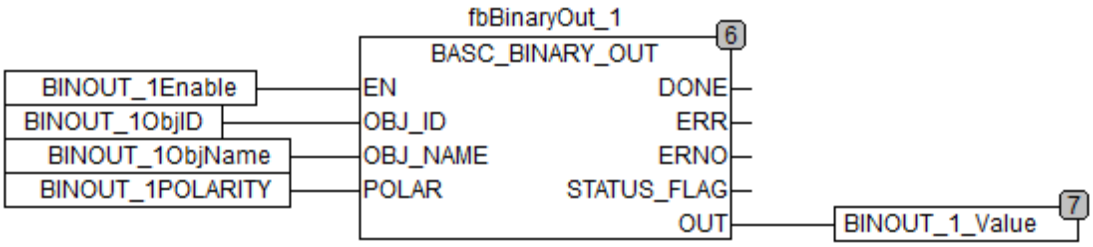
Defines the BACnet object name. The object name has to be unique within BACnet network.

POLAR

Data type	Default value	Range	Unit
BASC_POLAR_ENUM	BASC_NORMAL	BASC_NORMAL, BASC_REVERSE	-

Defines the polarity of the value that is connected to the input IN. Polarity is defined according to BACnet standard *"BASC_POLAR_ENUM" on page 2518*.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 "Error messages of the AC500 V2 function block libraries" on page 735*).

STATUS_FLAG

Data type	Default value	Range	Unit
WORD	-	-	-

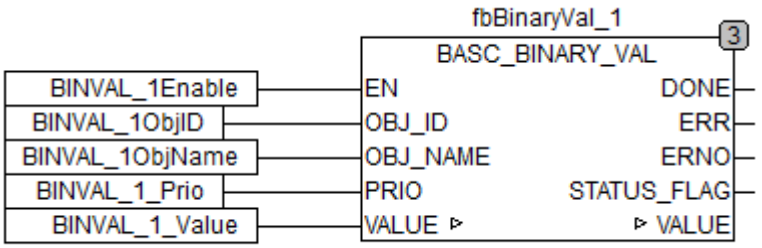
BACnet B-ASC library supports property `Status_Flags`. The current value of this property will be provided at output STATUS_FLAG.

OUT

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

To be connected to an IEC variable representing a physical output of the processor module. This output will be updated with the BACnet object property `Present_Value`.

1.5.7.2.8 BASC_BINARY_VAL



Parameter	Value
Included in library	BACnet_B-ASC_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	C interface

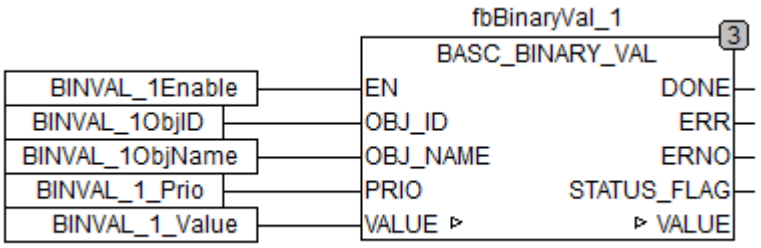
BASC_BINARY_VAL allows to connect an IEC variable with a BACnet object type "binary value". This object represents a binary value that is neither physical input nor physical output of the device. Connect the internal IEC variables to this function block only.

Table 147: Binary value object properties provided at the BACnet network by BASC_BINARY_VAL

Property name	Characteristics	Value	BACNet conformance code
Object_Identifier	Set via input OBJ_ID	-	R - read
Object_Name	Set via input OBJ_NAME	-	R - read
Present_Value	Set via input VALUE Updates output VALUE	-	W – read/write
Status_Flags	Updates output STATUS_FLAG	-	R - read
Object_Type	Constant	BINARY_VALUE (5)	R - read
Event_State	Constant	NORMAL (0)	R - read

Property name	Characteristics	Value	BACNet conformance code
Out_Of_Service	Set via BACnet write services	-	W - read/write
Priority_Array	Set via BACnet write services	-	R - read
Relinquish_Default	Constant	INACTIVE	R - read

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input EN is set to TRUE input VALUE is evaluated and used to update BACnet object property `Present_Value`.

OBJ_ID (object ident number)

Data type	Default value	Range	Unit
WORD	0	0...4194302	-

Defines the BACnet object ident number. The object ident number has to be unique within the BACnet network.

OBJ_NAME (object name)

Data type	Default value	Range	Unit
STRING(40)	Empty string	-	-

Defines the BACnet object name. The object name has to be unique within BACnet network.

PRIO

Data type	Default value	Range	Unit
BYTE	16	1...16	-

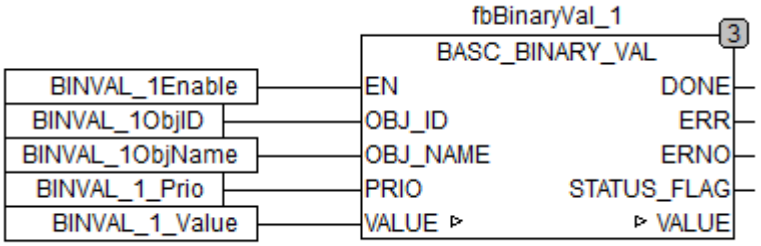
Defines the BACnet priority that will be used on updating the property `Present_Value` of the analog value object.

VALUE

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

To be connected to an IEC variable representing this object type. The value will be stored in BACnet property `Present_Value`.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATUS_FLAG

Data type	Default value	Range	Unit
WORD	-	-	-

BACnet B-ASC library supports property `Status_Flags`. The current value of this property will be provided at output STATUS_FLAG.

1.5.7.3 Structures and enumerations

BASC_COM_TYPE_ENUM Enumeration for BACnet communication layers ↳ *“COM_TYPE (communication type)” on page 2496*.

Parameter	Value	Description
BASC_IP_COM	0	Use BACnet IP communication.
BASC_MSTP_COM	1	Use BACnet MS/TP communication.

BASC_DEV_STATUS_ENUM Enumeration for BACnet device status values *“SYS_STATUS (system status)” on page 2501*.

Parameter	Value	Description
BASC_OPERATIONAL	0	The device is initialized successfully and in operation.
BASC_NON_OPERATIONAL	4	The device is not in operation.

BASC_ENG_UNITS_ENUM Enumeration for BACnet units *“UNIT” on page 2509*. This enumeration lists all units defined in BACnet standard *Further information on page 2495*.

BASC_POLAR_ENUM Enumeration of BACnet values for polarity of `Present_Value` property *“POLAR” on page 2514*.

Parameter	Value	Description
BASC_NORMAL	0	Physical state relation. ACTIVE = physical on.
BASC_REVERSE	1	Physical state relation. ACTIVE = physical off.

BASC_STATISTIC_COUNTER_TYPE Structure of statistic data *“STATISTIC” on page 2498*.

Parameter	Type	Value	Description
dwNumReceivedRequests	DWORD	0	Number of received request.
dwNumRepliesSuccess	DWORD	0	Number of replies with success.
dwNumRepliesFailure	DWORD	0	Number of replies with failure.

1.5.7.4 Hardware

An AC500 processor module equipped with an integrated Ethernet or serial interface is required. Only one communication protocol at a time is supported.

1.5.7.5 Examples

Example projects for the libraries can be found in the folder: \Users\Public\Documents\AutomationBuilder\Examples

1.5.8 FM502-CMS library

1.5.8.1 System technology

The WAV File and CMS-IO libraries are libraries to enable the work with the *Chapter 1.6.4.4.3 “FM502-CMS function module” on page 5723*. A measurement can be started using the CMS-IO library. The results are stored by the Function Module FM502-CMS on the processor module flash disk as WAV files. Data handling of the WAV files is possible with the WAV-File Library.

For immediate local analysis an application library for signal processing is available. SP_Library on *www.abb.com/PLC*. The application program then may use signal processing blocks to read and analyze the data, to calculate status and trends of the monitored equipment already locally on the PLC. Typically the measurement need to be labeled with the operation point details from a control program section and the signal processing needs further information, values or parameters also used in the control section (e.g. rated values of the equipment, speed if not measured with the FM502 counter functions).

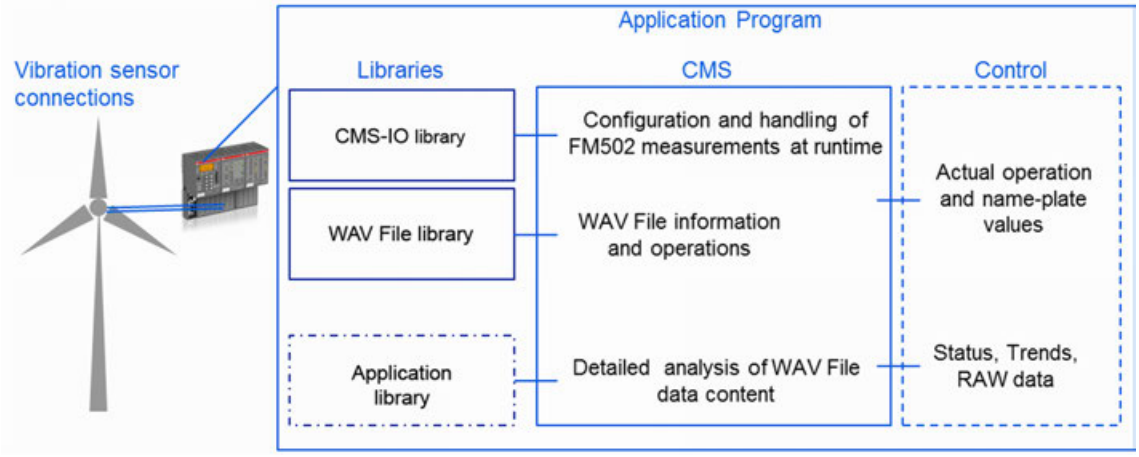


Fig. 179: CMS application and programming

1.5.8.1.1 CMS-IO library

The CMS-IO library contains all function blocks necessary for using the Function Module FM502-CMS.

In addition, it is possible to change the configuration of the analog channels during run time via function blocks.

Once a FM502-CMS has been added to the configuration, the CMS-IO library is automatically included with the next compilation of the project.

1.5.8.1.2 WAV File library

The WAV File library is used for reading, writing and handling the the stored WAV files.

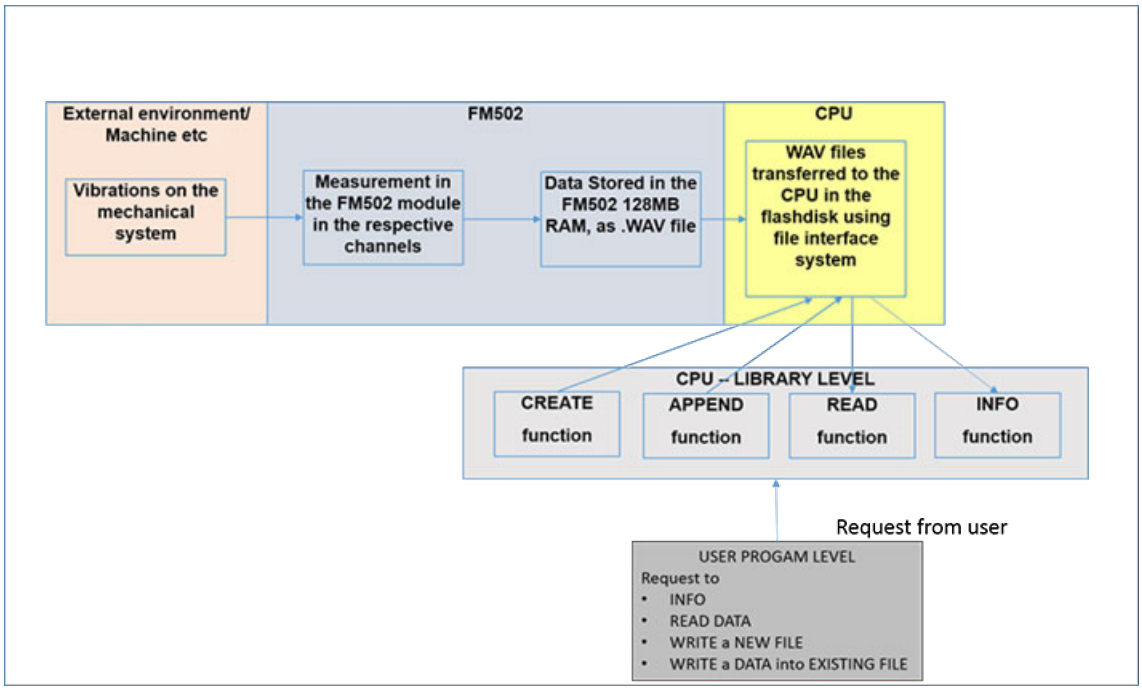

Fig. 180: Process map

To unzip the generated WAV files, the archive function blocks of the ↳ *Chapter 1.5.4.4 “CAA_File library” on page 789* are needed in addition. Example: Function block ↳ *Chapter 1.5.4.4.2.6 “FILE_ArchiveUnpack” on page 801*. The CAA_File libraries (CAA_...lib) are automatically included when configuring the FM502-CMS.

Architecture

Internally the WAV File library uses the four chunk structure model of the WAV files to handle the data in the read and write operations.

To perform the correct data handling the WAV File library uses a structure internally. This structure is a group of data stored in the following order:

- RIFF Chunk ID,
- File Size,
- RIFF Type,
- Format Chunk ID,
- Channel Information,
- Sampling Frequency,
- Block Align,
- Bits per Sample,
- Data Chunk ID,
- Data,
- Label Information.

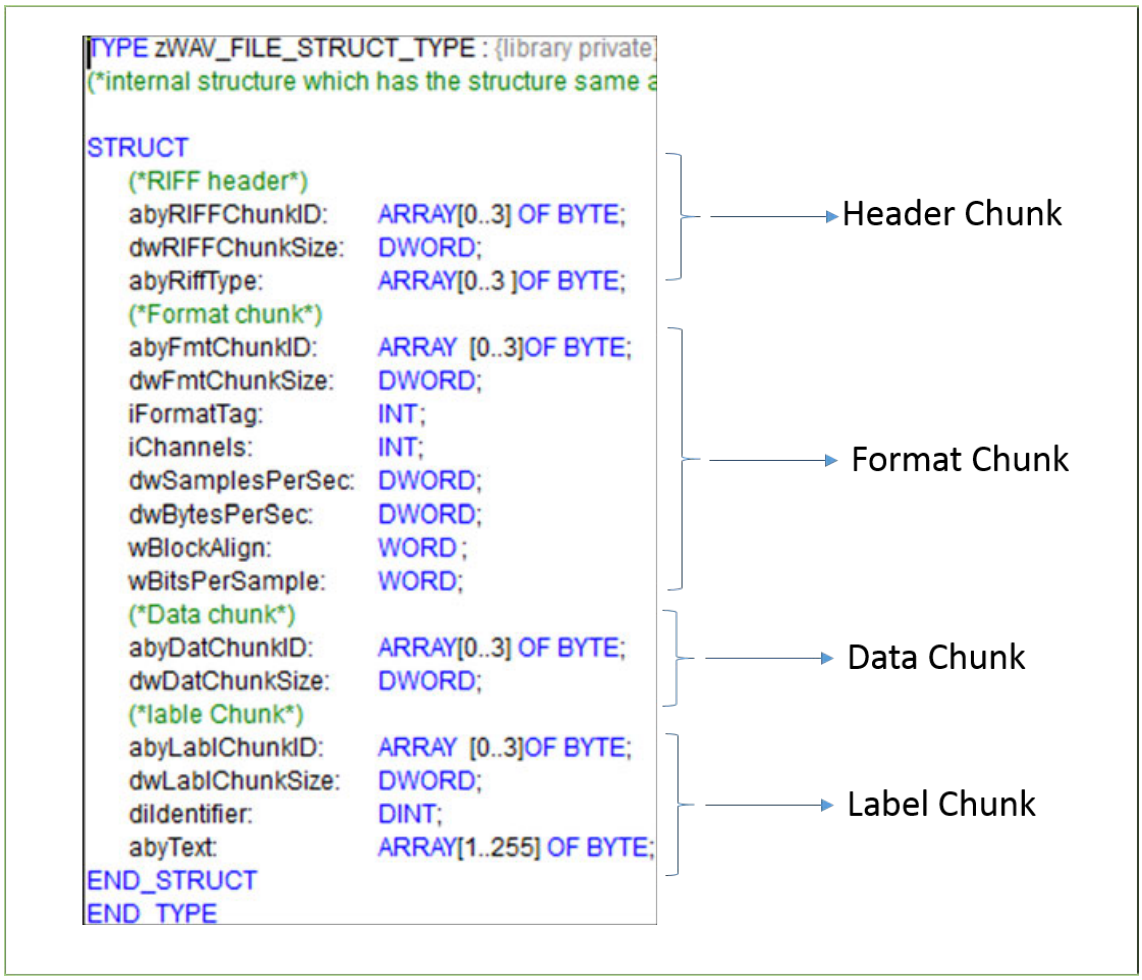

Fig. 181: Internal data type of the library

Read and write WAV files

A single READ or WRITE functionality in this library is executed in the following steps:

1. Open the file to create the handle.
   ⇨ Validates the file, if already present (except in function block CREATE).
2. Set the pointer to the file position from where the desired READ or WRITE operation is to be executed.
3. Assign the inputs of the function block to the internal structure.
   ⇨ Stores the data in the proper structure before writing (in function blocks CREATE and APPEND).
4. Perform the READ/WRITE operation.
   ⇨ Stores the data in the proper structure after reading (in function blocks INFO and READ)
5. Assign the outputs to the function block.
6. Close the file.

With the development of the WAV-File library the user can get the following benefits:

- Specific function blocks to perform the specific task.
- Either a function block or the visualization can be used.

- The function blocks internally take care of four important tasks
  - Opening the file and validating it.
  - Preparing the proper data structure at the time of reading or writing, according to the WAV file standards.
  - Performing the READ or WRITE operation.
  - Closing the file.
- Simple to understand and execute.

1.5.8.1.3 WAV file format

The wave audio file format or commonly known as the WAV files are the type of audio files which was developed by Microsoft and IBM. It stores the data in the structured format in the dedicated memory area called as chunks.

The measurement data will be stored in the WAV file format. One WAV file will be created for each active channel.

Table 148: RIFF header

Data type	Endian	Length	File offset	Identifier	Value
BYTE[4]	Big	4	0 (0x00)	bfChunkID	"RIFX"
DWORD	Little	4	4 (0x04)	dwChunkSize	Data length - 8
BYTE[4]	Big	4	8 (0x08)	bfRiffType	"WAVE"

Table 149: Format chunk

Data type	Endian	Length	File offset	Identifier	Value
BYTE[4]	Big	4	12 (0x0C)	bfChunkID	"fmt"
DWORD	Little	4	16 (0x10)	dwChunkSize	Data length - 8
INT	Little	2	18 (0x12)	wFormatTag	0x0001 (PCM)
INT	Little	2	20 (0x14)	wChannels	0x0001 (1 ch.)
DWORD	Little	4	24 (0x18)	dwSamples-PerSec	100 Hz - 50.000 kHz
DWORD	Little	4	28 (0x1C)	dwBytes-PerSec	Sample rate * block align
WORD	Little	2	32 (0x1E)	wBlockAlign	4 byte
WORD	Little	2	34 (0x20)	wBitsPer-Sample	32 bit

Table 150: Data chunk

Data type	Endian	Length	File offset	Identifier	Value
BYTE[4]	Big	4	36 (0x24)	bfChunkID	"data"
DWORD	Little	4	40 (0x28)	dwChunkSize	Data length - 8
BYTE[]	Big	Undefined	44 (0x2C)	bfData	Measurement data

Table 151: Label chunk

Data type	Endian	Length	File offset	Identifier	Value
BYTE[4]	Big	4	44+sz(bfData)	bfChunkID	“labl”
DWORD	Little	4	48+sz(bfData)	dwChunkSize	Data length -8
DINT	Little	4	52+sz(bfData)	dwIdentifier	Identifier
BYTE[256]	Little	255	56+sz(bfData)	bfText	„Label Text“

Use of the WAV file

The unique and structured architecture is of a great help in the condition monitoring systems (CMS). The CMS monitors the stability of the mechanical system. The vibration data of the machine/system can be recorded using the sensors. These sensors will convert the physical data into the analog inputs to the CPU and its modules. These data is stored in the WAV file structure and can be re-read for the analysis purpose using the mathematical tools.

Main purpose of the WAV file

The main purpose of the WAV files is to do the analysis in the CMS. For this purpose the WAV File Library is developed. This would help the user to perform the READ/WRITE operations on the WAV file using the AC500 PLC and its programming tool.

1.5.8.1.4 Limitations

Memory

Although the file size can be 128 MB, however the amount of data which the user wants to read or write is limited due to the user data capacity of the processor module.

The maximum user data capacity of the processor module is up to 4 MB which also includes the application program. In any case the WAV file will be able to handle less than 4 MB data.

WAV files (Single/Multi Channel)

The WAV File library can only READ/APPEND a single channel WAV file. In case the user tries to READ/APPEND the multi-channel WAV file, the function block will throw an error message.

Measured data

All measured data is read and stored in the buffer as bytes and not as real values. In the same way while writing, the library accepts the data in the buffer as bytes.

Data loss when using function block WAV_FILE_CREATE

No error occurs, when the user creates a new file with the same name of an already existing file. This is due to the limitation of the CAA_File library WRITE functionality. The user needs to take care, otherwise the existing file might get overwritten with the new data.

Usage of function blocks

The CAA_File library restricts the usage of more than 20 CAA functions at a time. Since the WAV File library function blocks consists of CAA functions internally, the user might get an error (error code 5803) from the library. Also simultaneous enabling of the WAV File function blocks on the same file may generate the error from the CAA_File library.

1.5.8.2 CMS-IO library for modul handling

Preconditions

The function blocks of the CMS-IO library are only working in the RUN mode of the processor module. Using the library in the SIMULATION mode will not provide any valid or usable diagnosis information.

The encoder/counter interface inside the FM502-CMS can be used in different configurable operation modes. The operation mode is activated during the initialization phase (power-on, cold start, warm start).

The data exchange from and to the user program is performed using input and output operands. These necessary operands are created and reserved automatically, when the Function Module is added into the configuration.

Operation modes

Inputs and outputs which are not used by the counters are available for other tasks.

Table legend: A = input channel A, B = input channel B, Z = output channel Z.

Operation Mode	Function	Used inputs	Description	Function block
0-1	No counter	None	This operating mode is selected, if the integrated high-speed counter is not needed.	-
1-1	Up/down counter (A)	A = Counting input	1 bidirectional 32-bit counter on input A (dynamic changes) with set and reset input operation, end value reached indicator, touch/ catch value and overflow flag.	CMS_IO_32BIT_CNT
2-1	Up/down with release input (B)	A = Counting input B = Enable input	1 bidirectional 32-bit counter with enable input. Counting is valid when input B is TRUE. Dynamic up/down count possibility, with set and reset input operation, end value reached indicator, touch/ catch value and overflow flag.	CMS_IO_32BIT_CNT
3-2	Up/down counters (A,B)	A = Counting input 0 B = Counting input 1	2 bidirectional 16-bit counter (on rising edge count) functions, with separate up/down, reset operation and overflow flag.	CMS_IO_16BIT_2CNT
4-2	Up/down (A, B on falling edges)	A = Counting input 0 B = Counting input 1	2 bidirectional 16-bit counter functions (with A on rising edge count and B on falling edge count), With separate up/down, reset operation and overflow flag.	CMS_IO_16BIT_2CNT
5-1	Up/down dynamic set (B) / rising edge	A = Counting input B = Dynamic set input	1 bidirectional 32-bit counter with set and reset input, end value reached indicator, touch/ catch value and overflow flag. Additional function to mode 1 is the dynamic set input (B) on rising edge sets START_VALUE.	CMS_IO_32BIT_CNT

Opera-tion Mode	Function	Used inputs	Description	Function block
6-1	Up/down dynamic set (B) / falling edge	A = Counting input B = Dynamic set input	1 bidirectional 32-bit counter with set and reset input, end value reached indicator, touch/ catch value and overflow flag. Additional function to mode 1 is the dynamic set input (B) on falling edge sets START_VALUE.	CMS_IO_32BIT_CNT
7-1	Reserved	None	-	-
8-1	Up/down with release (B), 0 cross detection	A = Counting input B = Enable input	1 bidirectional 16-bit counter (in range of -32768 to 32767) with enable input and zero crossover detection (CF). Counting is valid when input B is TRUE. With set and reset input operation and touch/catch value.	CMS_IO_16BIT_CNT

Identifying a FM502-CMS at the function block

The function blocks have to identify every FM502-CMS connected to the processor module. Therefore the Automation Builder automatically creates an instance description of the module. This instance description is available as a global variable in CODESYS. Use the input INST to connect the address of the instance *“INST (instance)” on page 2527*.

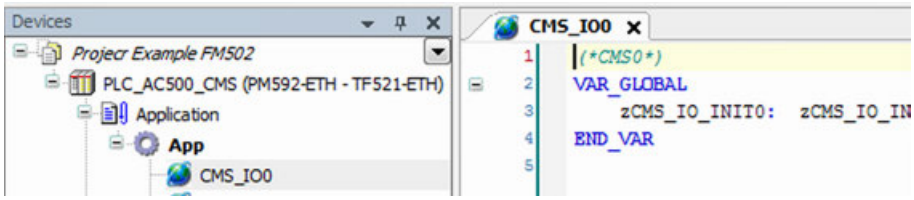

Fig. 182: Global variable in Automation Builder

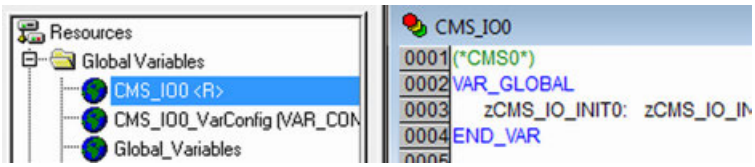

Fig. 183: Global variable in CODESYS

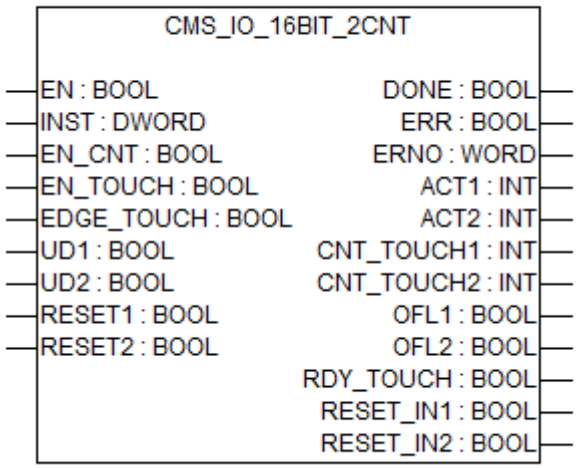
1.5.8.2.1 Function blocks

CMS_IO_16BIT_2CNT

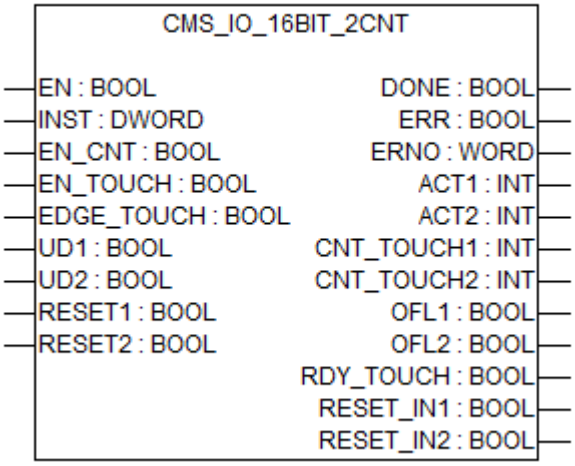


Parameter	Value
Included in library	CMS_IO_AC500_V24.lib
Available as of firmware	V2.4.0, FM502-CMS firmware: V1.0
Type	Function block with historical values
Group	Counters

The module FM502-CMS provides *Chapter 1.6.4.4.3.4.3 “Two 16 bit up/down counters” on page 5738* functions.

Possible operation modes: 3-2, 4-2 *“Operation modes” on page 2524*

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

INST (instance)

Instance description of the Function Module that should be controlled via this function block. The variable is automatically generated during the configuration with the Automation Builder. Use the operator ADR to get the address of the variable.

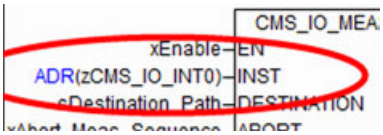


Fig. 184: Example

EN_CNT (enable counter)

Data type: BOOL

If EN_CNT=TRUE , pulse counting of counter is enabled. If EN_CNT=FALSE, no pulse counting is performed and the pulses are lost. If counting has already started and EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

EN_TOUCH (enable touch)

Data type: BOOL

A rising edge at input EN_TOUCH enables a catch/touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at digital inputs DI0, DI1, DC2, DC3 (for counters A and B) causes the function block to store the actual counter value ACT1 and ACT2 and to display this value at output CNT_TOUCH1 and CNT_TOUCH2.

If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

EDGE_TOUCH

Data type: BOOL

If EDGE_TOUCH = FALSE, a catch/touch value will be operate on falling edge of the configured digital input (for counters A and B).

If EDGE_TOUCH = TRUE, a catch/touch value will be operate on rising edge of the configured digital input (for counters A and B).

UD1 (up/down mode for counter 1)

Data type: BOOL

At input UD1, the counting selection is set for up/down counting mode for counter A:

UD1=FALSE: count up

UD1=TRUE: count down

UD2 (up/down mode for counter 2)

Data type: BOOL

At input UD2, the counting selection is set for up/down counting mode for counter B:

UD2=FALSE: count up

UD2=TRUE: count down

RESET1 (reset counter 1)

Data type: BOOL

If input RESET1 = TRUE, the counter value (ACT1) is reset to 0. As long as input RESET1 = TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at input DI0, DI1, DC2, DC3 (for counter A) causes the function block to reset the value at output ACT1.

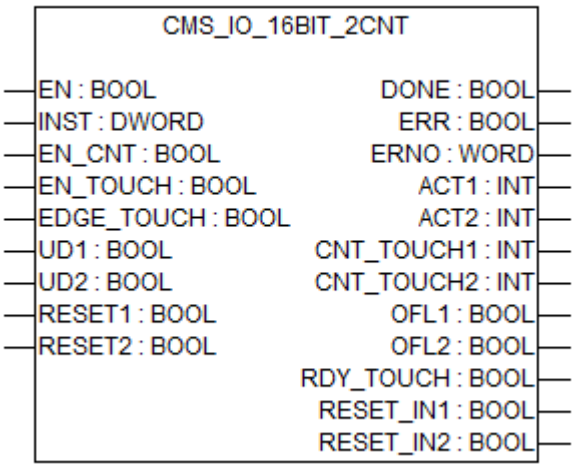
RESET2 (reset counter 2)

Data type: BOOL

If input RESET2 = TRUE, the counter value (ACT2) is set to 0.As long as input RESET2 = TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at input DI0, DI1, DC2, DC3 (for counter B) causes the function block to reset the value at output ACT2.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ACT1 (actual value 1)

Data type: INT

The current counter value (actual value) from counter A can be retrieved at any time using the output ACT1 of the function block.

ACT2 (actual value 2)

Data type: INT

The current counter value (actual value) from counter B can be retrieved at any time using the output ACT2 of the function block.

CNT_TOUCH1

Data type: INT

The output CNT_TOUCH1 (counter touch value 1) displays the result of the catch/touch trigger measurement for counter A.

CNT_TOUCH2 (counter touch value 2)

Data type: INT

The output CNT_TOUCH2 displays the result of the catch/touch trigger measurement for counter B.

OFL1 (overflow counter 1)

Data type: BOOL

The overflow from counter A is specified at the output OFL1.

The counter operates as infinite counter. It is set to TRUE, when an overflow occurs, i. e. the counter value ACT1 rises to value 16#FFFF= -1. Any exceeding or falling below this value (depending on use up and use down) will set OFL1=TRUE. The output OFL1 is reset when the configuration is changed, and if counter value ACT1 is set or reset.

OFL2 (overflow counter 2)

Data type: BOOL

The overflow from counter B is specified at the output OFL2.

The counter operates as infinite counter. It is set to TRUE when an overflow occurs, i. e. the counter value ACT2 rises to value 16#FFFF= -1. Any exceeding or falling below this value (depending to use up and use down) will set OFL2=TRUE. The output OFL2 is reset when the configuration is changed, and if counter value ACT2 is set or reset.

RDY_TOUCH (ready catch/ touch value)

Data type: BOOL

The output RDY_TOUCH is set to TRUE, when a new catch/touch value is available. If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

RESET_IN1 (reset input counter 1)

Data type: BOOL

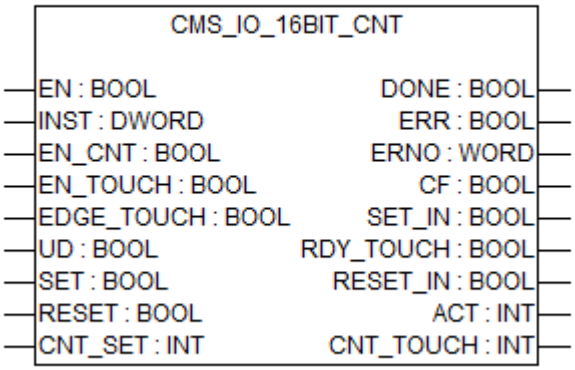
The output RESET_IN1 is set to TRUE, if one of the digital inputs DI0, DI1, DC2, DC3 is configured as RESET input for counter A and has a TRUE signal or the input RESET of CMS_IO_16BIT_2CNT is set to TRUE.

RESET_IN2 (reset input counter 2)

Data type: BOOL

The output RESET_IN2 is set to TRUE, if one of the digital inputs DI0, DI1, DC2, DC3 is configured as RESET input for counter B and has a TRUE signal or the input RESET of CMS_IO_16BIT_2CNT is set to TRUE.

CMS_IO_16BIT_CNT

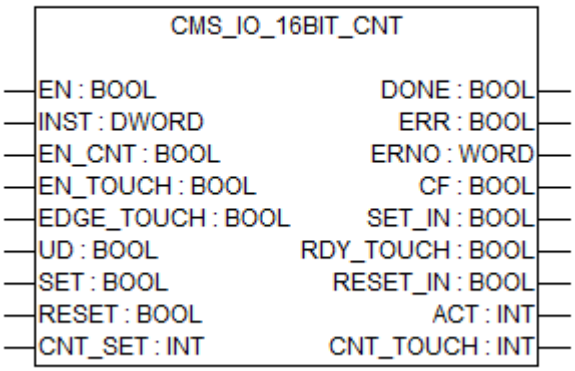


Parameter	Value
Included in library	CMS_IO_AC500_V24.lib
Available as of firmware	V2.4.0, FM502-CMS firmware: V1.0
Type	Function block with historical values
Group	Counter & Encoder

The FM502-CMS provides one *Chapter 1.6.4.4.3.4.2 “16-bit bidirectional counter” on page 5737* function.

Possible operation modes: 8-1 *“Operation modes” on page 2524*

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

INST (instance)

Instance description of the Function Module that should be controlled via this function block. The variable is automatically generated during the configuration with the Automation Builder. Use the operator ADR to get the address of the variable.

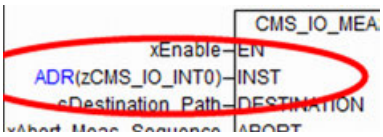


Fig. 185: Example

EN_CNT (enable counter)

Data type: BOOL

If EN_CNT=TRUE , pulse counting of counter is enabled. If EN_CNT=FALSE, no pulse counting is performed and the pulses are lost. If counting has already started and EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

EN_TOUCH (enable touch)

Data type: BOOL

A rising edge at input EN_TOUCH enables a catch/touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at digital inputs DI0, DI1, DC2, DC3 (for counters A and B) causes the function block to store the actual counter value ACT1 and ACT2 and to display this value at output CNT_TOUCH1 and CNT_TOUCH2.

If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

EDGE_TOUCH

Data type: BOOL

If EDGE_TOUCH = FALSE, a catch/touch value will be operate on falling edge of the configured digital input (for counters A and B).

If EDGE_TOUCH = TRUE, a catch/touch value will be operate on rising edge of the configured digital input (for counters A and B).

UD (up/down mode)

Data type: BOOL

At input UD, the counting selection is set for up/down counting mode:

UD=FALSE: count up

UD=TRUE: count down

SET (set counter)

Data type: BOOL

If set input SET=TRUE, the counter takes the values from input START_VALUE to transfer it to output ACT. As long as input SET=TRUE, no pulses are counted because the counter is always overwritten by the input START_VALUE.

A rising edge at input causes the function block to store the START_VALUE value and to display this value at output ACT.

RESET (reset counter)

Data type: BOOL

If input RESET = TRUE, the counter value (ACT) is reset to 0. As long as input RESET = TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at digital input DI0, DI1, DC2, DC3 causes the function block to reset the value at output ACT.

CNT_SET

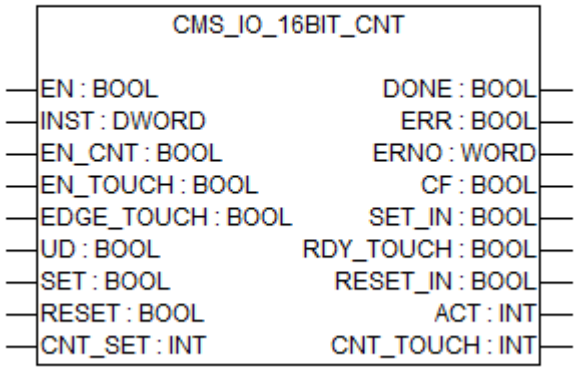
Data type	Default value	Range	Unit
INT	-	-	-

The counter can be set to a start value. This value must be applied to the input CNT_SET.

If input SET=TRUE, counter takes this value.

Input START_VALUE corresponds to output low word in "counter settings".

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

CF (carry flag)

Data type: BOOL

If the zero crossover indicator CF=TRUE, this output indicates the sign of the actual counter value ACT. It is set to FALSE, when counter value ACT is less than or equal to zero. It is set to TRUE otherwise.

SET_IN (set input counter)

Data type: BOOL

The output SET_IN is set to TRUE, if one of the inputs is configured as SET input.

RDY_TOUCH (ready catch/ touch value)

Data type: BOOL

The output RDY_TOUCH is set to TRUE, when a new catch/touch value is available. If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

RESET (reset counter)

Data type: BOOL

If input RESET = TRUE, the counter value (ACT) is reset to 0. As long as input RESET = TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at digital input DI0, DI1, DC2, DC3 causes the function block to reset the value at output ACT.

ACT (actual value)

Data type: INT

The current counter value (actual value) can be retrieved at any time using the output ACT of the function block.

CNT_TOUCH (counter touch value)

Data type: INT

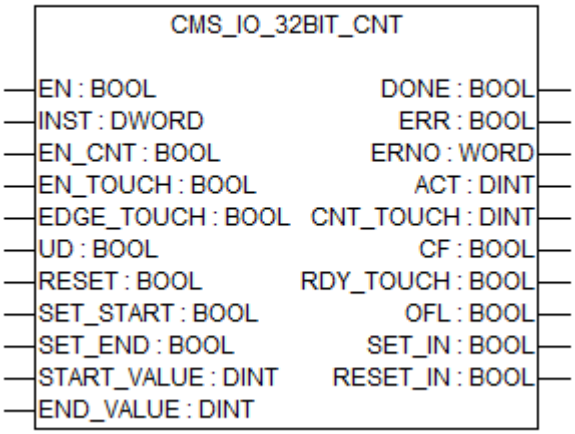
The output CNT_TOUCH displays the result of the catch/touch trigger action.

CNT_TOUCH (counter touch value)

Data type: DINT

The output CNT_TOUCH displays the result of the catch/touch trigger action.

CMS_IO_32BIT_CNT 32-bit counter

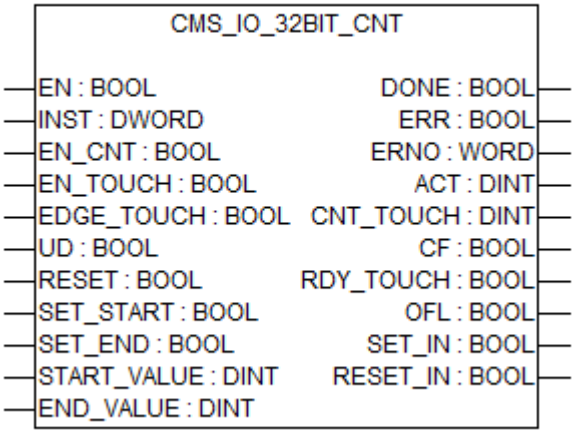


Parameter	Value
Included in library	CMS_IO_AC500_V24.lib
Available as of firmware	V2.4.0, FM502-CMS firmware: V1.0
Type	Function block with historical values
Group	Counter & Encoder

The FM502-CMS provides one *Chapter 1.6.4.4.3.4.1 “32-bit bidirectional counter” on page 5736* functions.

Possible operation modes: 1-1, 2-1, 5-1, 6-1 *“Operation modes” on page 2524*

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

INST (instance)

Instance description of the Function Module that should be controlled via this function block. The variable is automatically generated during the configuration with the Automation Builder. Use the operator ADR to get the address of the variable.

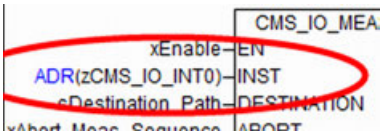


Fig. 186: Example

EN_CNT (enable counter)

Data type: BOOL

If EN_CNT=TRUE , pulse counting of counter is enabled. If EN_CNT=FALSE, no pulse counting is performed and the pulses are lost. If counting has already started and EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

EN_TOUCH (enable touch)

Data type: BOOL

A rising edge at input EN_TOUCH enables a catch/touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at digital inputs DI0, DI1, DC2, DC3 (for counters A and B) causes the function block to store the actual counter value ACT1 and ACT2 and to display this value at output CNT_TOUCH1 and CNT_TOUCH2.

If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

EDGE_TOUCH

Data type: BOOL

If EDGE_TOUCH = FALSE, a catch/touch value will be operate on falling edge of the configured digital input (for counters A and B).

If EDGE_TOUCH = TRUE, a catch/touch value will be operate on rising edge of the configured digital input (for counters A and B).

UD (up/down mode)

Data type: BOOL

At input UD, the counting selection is set for up/down counting mode:

UD=FALSE: count up

UD=TRUE: count down

RESET (reset counter)

Data type: BOOL

If input RESET = TRUE, the counter value (ACT) is reset to 0. As long as input RESET = TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at digital input DI0, DI1, DC2, DC3 causes the function block to reset the value at output ACT.

SET_START (set start value)

Data type: BOOL

If set input SET=TRUE, the counter takes the values from input START_VALUE to transfer it to output ACT. As long as input SET=TRUE, no pulses are counted because the counter is always overwritten by the input START_VALUE.

A rising edge at input causes the function block to store the START_VALUE value and to display this value at output ACT.

SET_END (set end value)

Data type: BOOL

If input SET_END=TRUE, the counter is set to the value specified at input END_VALUE.

START_VALUE

Data type: DINT

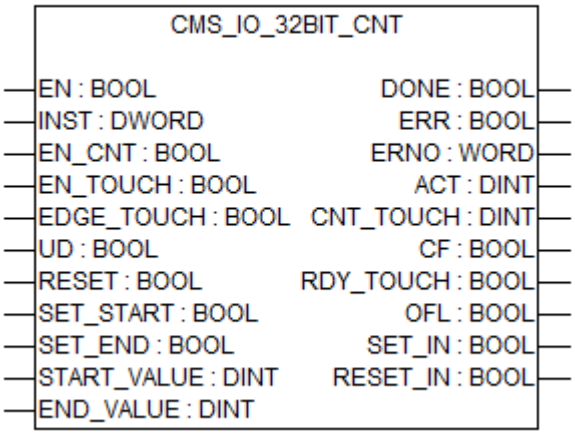
The counter can be set to a start value. This value must be applied to the input START_VALUE.

END_VALUE

Data type: DINT

If the counter reaches the planned input END_VALUE, the binary output CF is set to TRUE and the value is stored.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ACT (actual value)

Data type: DINT

The current counter value (actual value) can be retrieved at any time using the output ACT of the function block.

CNT_TOUCH (counter touch value)

Data type: DINT

The output CNT_TOUCH displays the result of the catch/touch trigger action.

CF (carry flag)

Data type: BOOL

If the zero crossover indicator CF=TRUE, this output indicates the sign of the actual counter value ACT. It is set to FALSE, when counter value ACT is less than or equal to zero. It is set to TRUE otherwise.

RDY_TOUCH (ready catch/ touch value)

Data type: BOOL

The output RDY_TOUCH is set to TRUE, when a new catch/touch value is available. If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

OFL (overflow)

Data type: BOOL

The overflow is specified at the output OFL.

The counter operates as infinite counter. An overflow occurs corresponding to the 32-bit value at 16#80000000 = 2147483648. Any exceeding or falling below of this value (depending to up and down use) will set OFL to TRUE.

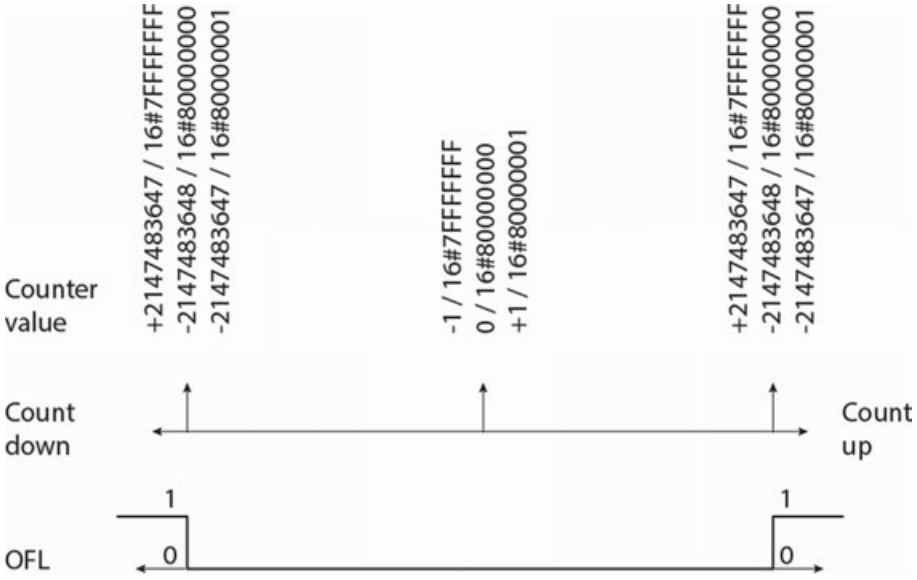


Fig. 187: Detection for output OFL

SET_IN (set input counter)

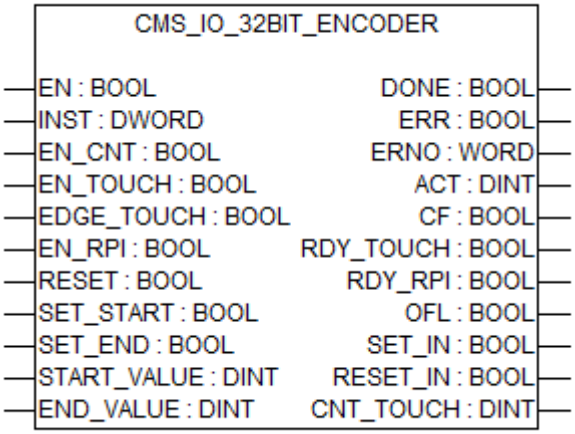
Data type: BOOL

The output SET_IN is set to TRUE, if one of the inputs is configured as SET input.

RESET_IN (reset input counter) Data type: BOOL

The output RESET_IN is set to TRUE, if one of the inputs is configured as RESET input.

CMS_IO_32BIT_ENCODER

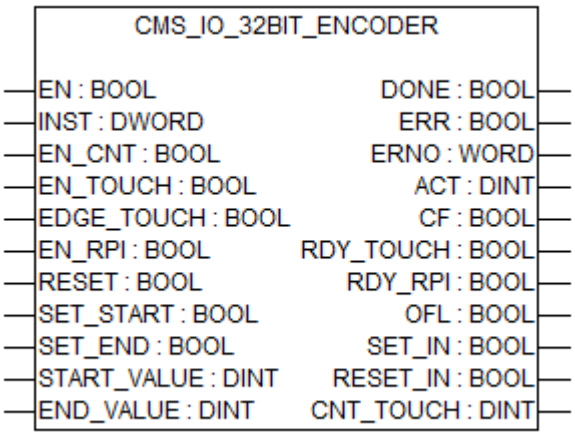


Parameter	Value
Included in library	CMS_IO_AC500_V24.lib
Available as of firmware	V2.4.0, FM502-CMS firmware: V1.0
Type	Function block with historical values
Group	Counter & Encoder

The FM502-CMS provides one ↳ *Chapter 1.6.4.4.3.5.1 “Incremental encoder” on page 5740* function for relative positioning with 3 signals.

Possible operation modes: 11-1, 12-1, 13-1 ↳ *“Operation modes” on page 2524*

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

INST (instance)

Instance description of the Function Module that should be controlled via this function block. The variable is automatically generated during the configuration with the Automation Builder. Use the operator ADR to get the address of the variable.

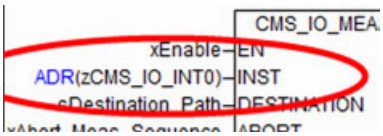


Fig. 188: Example

EN_CNT (enable counter)

Data type: BOOL

If EN_CNT=TRUE , pulse counting of counter is enabled. If EN_CNT=FALSE, no pulse counting is performed and the pulses are lost. If counting has already started and EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

EN_TOUCH (enable touch)

Data type: BOOL

A rising edge at input EN_TOUCH enables a catch/touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at digital inputs DI0, DI1, DC2, DC3 (for counters A and B) causes the function block to store the actual counter value ACT1 and ACT2 and to display this value at output CNT_TOUCH1 and CNT_TOUCH2.

If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

EDGE_TOUCH

Data type: BOOL

If EDGE_TOUCH = FALSE, a catch/touch value will be operate on falling edge of the configured digital input (for counters A and B).

If EDGE_TOUCH = TRUE, a catch/touch value will be operate on rising edge of the configured digital input (for counters A and B).

EN_RPI (enable reference point initiator)

Data type: BOOL

A rising edge at input EN_RPI enables a reference point initiator measurement. If input EN_RPI = TRUE, a rising edge at digital inputs DI0, DI1, DC2, DC3 (for counter 0) validates the counter value capture and the counter reset during the capture.

Only one function may be enabled at a time, either the RPI (reference point indicator) or TOUCH (touch trigger measurement). If both functions are enabled simultaneously or if the execution of one function is not yet completed when enabling the other function, a RPI function will have a higher priority than TOUCH.

RESET (reset counter)

Data type: BOOL

If input RESET = TRUE, the counter value (ACT) is reset to 0. As long as input RESET = TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at digital input DI0, DI1, DC2, DC3 causes the function block to reset the value at output ACT.

SET_START (set start value)

Data type: BOOL

If set input SET=TRUE, the counter takes the values from input START_VALUE to transfer it to output ACT. As long as input SET=TRUE, no pulses are counted because the counter is always overwritten by the input START_VALUE.

A rising edge at input causes the function block to store the START_VALUE value and to display this value at output ACT.

SET_END (set end value)

Data type: BOOL

If input SET_END=TRUE, the counter is set to the value specified at input END_VALUE.

START_VALUE

Data type: DINT

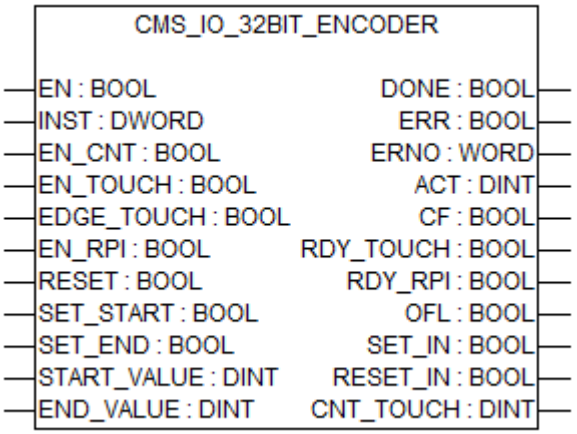
The counter can be set to a start value. This value must be applied to the input START_VALUE.

END_VALUE

Data type: DINT

If the counter reaches the planned input END_VALUE, the binary output CF is set to TRUE and the value is stored.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ACT (actual value)

Data type: DINT

The current counter value (actual value) can be retrieved at any time using the output ACT of the function block.

CF (carry flag)

Data type: BOOL

If the zero crossover indicator CF=TRUE, this output indicates the sign of the actual counter value ACT. It is set to FALSE, when counter value ACT is less than or equal to zero. It is set to TRUE otherwise.

RDY_TOUCH (ready catch/ touch value)

Data type: BOOL

The output RDY_TOUCH is set to TRUE, when a new catch/touch value is available. If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

RDY_RPI (ready reference point initiator)

Data type: BOOL

The output RDY_RPI is set to TRUE, when the RPI operation is done. If input EN_RPI is set to FALSE, the output RDY_RPI is set to FALSE.

OFL (overflow)

Data type: BOOL

The overflow is specified at the output OFL.

The output OFL is set to TRUE, when the counter value ACT passes from -1 to 0 or from 0 to -1.

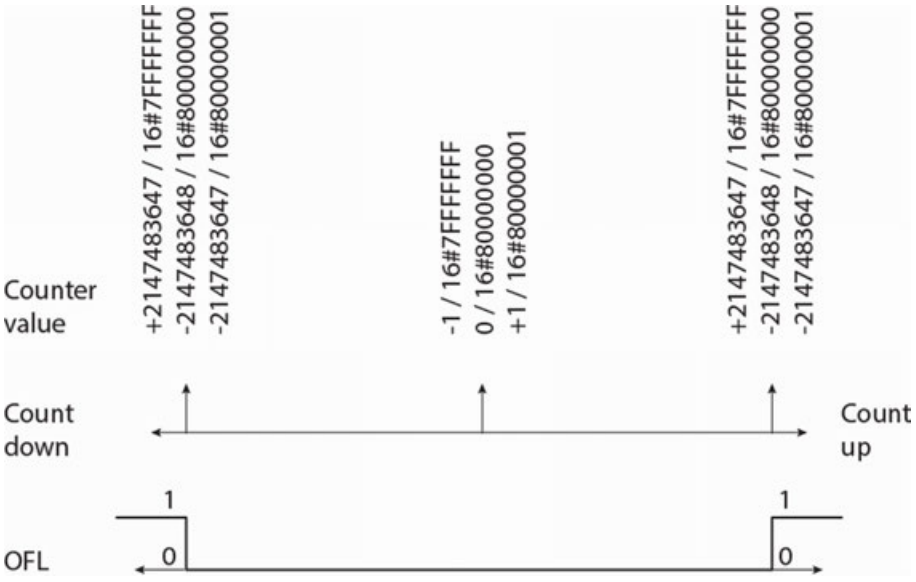


Fig. 189: Detection for output OFL (overflow)

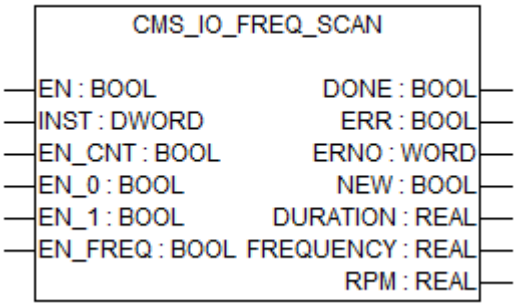
SET_IN (set input counter)
Data type: BOOL
The output SET_IN is set to TRUE, if one of the inputs is configured as SET input.

RESET_IN (reset input counter)
Data type: BOOL
The output RESET_IN is set to TRUE, if one of the inputs is configured as RESET input.

CNT_TOUCH (counter touch value)
Data type: DINT
The output CNT_TOUCH displays the result of the catch/touch trigger action.

CMS_IO_FREQ_SCAN

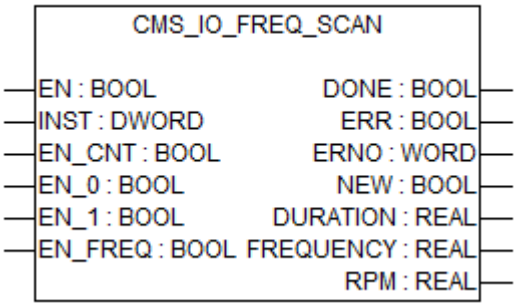


Parameter	Value
Included in library	CMS_IO_AC500_V24.lib
Available as of firmware	V2.4.0, FM502-CMS firmware: V1.0
Type	Function block with historical values
Group	Counter & Encoder

The FM502-CMS provides one channel Z which can be used to measure times, frequencies and rotational speeds with a resolution of 1 µs. The function block should be used to control with input EN_CNT, configure the capture on falling edge with input EN_0 or rising edge with input EN_1 of signal, and the specification of the mode of the measurement (*Chapter 1.6.4.4.3.6 "FM502-CMS used as time frequency meter" on page 5747*) with input EN_FREQ.

Possible operation modes: 15-1 *"Operation modes" on page 2524*

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

INST (instance)

Instance description of the Function Module that should be controlled via this function block. The variable is automatically generated during the configuration with the Automation Builder. Use the operator ADR to get the address of the variable.

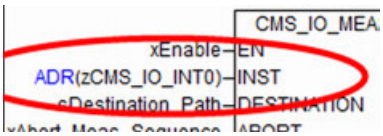


Fig. 190: Example

EN_CNT (enable counter)

Data type: BOOL

If EN_CNT=TRUE , pulse counting of counter is enabled. If EN_CNT=FALSE, no pulse counting is performed and the pulses are lost. If counting has already started and EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

EN_0 (enable 0)

Data type: BOOL

If EN_0=TRUE, the time frequency measurement will be captured on the falling edge of signal.

EN_1 (enable 1)

Data type: BOOL

If EN_1=TRUE, the time frequency measurement will be capture on rising edge of signal.

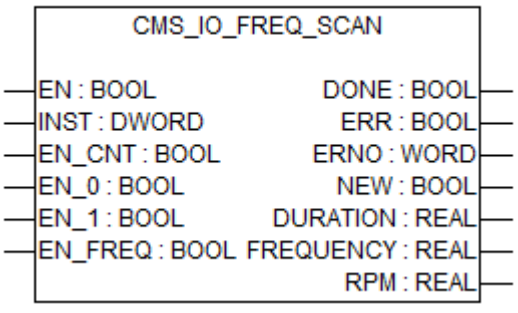
EN_FREQ

Data type: BOOL

If EN_FREQ=FALSE, the time frequency measurement will be specified in time mode and displayed on output DUR (in µs).

If EN_FREQ= TRUE, the time frequency measurement will be specified in frequency and rpm modes and displayed on output FREQ (in Hz) and RPM (in rotation per minute).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NEW

Data type: BOOL

If output NEW=TRUE, a new timing value is available.

DUR

Data type: REAL

The output DUR (duration) is used for display the result of timing measurement. If the input EN_FREQ=FALSE, measured time is in µs.

FREQ (frequency)

Data type: REAL, unit: Hz

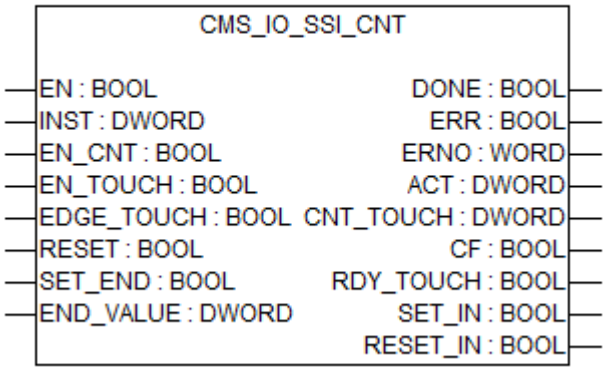
The output FREQ is used to display the result of time measurement. If the input EN_FREQ = TRUE, measured frequency is shown.

RPM (rotations per minute)

Data type: REAL, unit: rpm

The output RPM is used to display the result of timing measurement. If the input EN_FREQ = TRUE, measured speed of rotation is shown.

CMS_IO_SSI_ENC

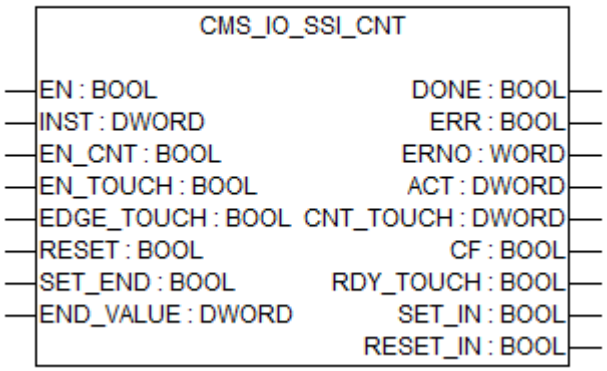


Parameter	Value
Included in library	CMS_IO_AC500_V24.lib
Available as of firmware	V2.4.0, FM502-CMS firmware: V1.0
Type	Function block with historical values
Group	Counter & Encoder

The FM502-CMS *Chapter 1.6.4.4.3.5.2 “Absolute SSI encoder” on page 5744*function.

Possible operation modes: 14-1 *“Operation modes” on page 2524*

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

INST (instance) Instance description of the Function Module that should be controlled via this function block. The variable is automatically generated during the configuration with the Automation Builder. Use the operator ADR to get the address of the variable.

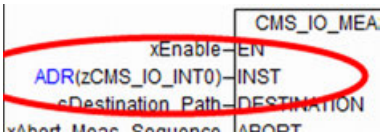


Fig. 191: Example

EN_COUNT (enable frequency output) Data type: BOOL

If EN_CNT = TRUE, pulse counting of counter is enabled. If EN_CNT = FALSE, no pulse counting is performed and the pulses are lost.

If counting has already started and if EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

EN_TOUCH (enable touch) Data type: BOOL

A rising edge at input EN_TOUCH enables a catch/touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at digital inputs DI0, DI1, DC2, DC3 (for counters A and B) causes the function block to store the actual counter value ACT1 and ACT2 and to display this value at output CNT_TOUCH1 and CNT_TOUCH2.

If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

EDGE_TOUCH Data type: BOOL

If EDGE_TOUCH = FALSE, a catch/touch value will be operate on falling edge of the configured digital input (for counters A and B).

If EDGE_TOUCH = TRUE, a catch/touch value will be operate on rising edge of the configured digital input (for counters A and B).

RESET (reset counter) Data type: BOOL

If input RESET = TRUE, the counter value (ACT) is reset to 0. As long as input RESET = TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at digital input DI0, DI1, DC2, DC3 causes the function block to reset the value at output ACT.

SET_END (set end value) Data type: BOOL

If input SET_END=TRUE, the counter is set to the value specified at input END_VALUE.

END_VALUE Data type: DWORD

If the counter reaches the planned input END_VALUE, the binary output CF is set to TRUE and the value is stored.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ACT (actual value)

Data type: DWORD

The current counter value (actual value) can be retrieved at any time using the output ACT of the function block.

CNT_TOUCH

Data type: DWORD

The output CNT_TOUCH (counter touch value) displays the result of the catch/touch trigger action.

CF (carry flag)

Data type: BOOL

If the zero crossover indicator CF=TRUE, this output indicates the sign of the actual counter value ACT. It is set to FALSE, when counter value ACT is less than or equal to zero. It is set to TRUE otherwise.

RDY_TOUCH (ready catch/ touch value)

Data type: BOOL

The output RDY_TOUCH is set to TRUE, when a new catch/touch value is available. If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

SET_IN (set input counter)

Data type: BOOL

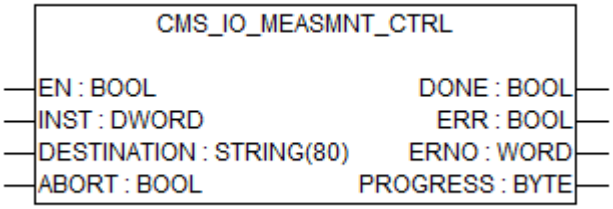
The output SET_IN is set to TRUE, if one of the inputs is configured as SET input.

RESET_IN (reset input counter)

Data type: BOOL

The output RESET_IN is set to TRUE, if one of the inputs is configured as RESET input.

CMS_IO_MEASMNT_CTRL



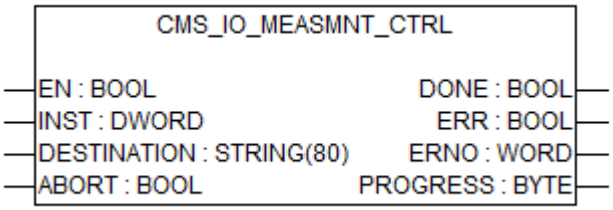
Parameter	Value
Included in library	CMS_IO_AC500_V24.lib
Available as of firmware	V2.4.0, FM502-CMS firmware: V1.0
Type	Function block with historical values
Group	Measurement

Possible operation modes: 1-1, 2-1 *“Operation modes” on page 2524*

Control for *Chapter 1.6.4.4.3.3 “FM502-CMS analog measurement” on page 5730*.

CMS_IO_MEASMNT_CTRL needs the destination path where to store the measurement files. When EN = TRUE the configured measurement starts and the files are stored at destination path as ZIP file. The ZIP file includes the WAV files. Each WAV file per activated channel and encoder. When there are activated channels with different sample rate, there will be another encoderWAV file for every channel with different sample rate. The time for measurement and transmitting depends on the number of active channels, the sample rate, the record length value.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

INST (instance) Instance description of the Function Module that should be controlled via this function block. The variable is automatically generated during the configuration with the Automation Builder. Use the operator ADR to get the address of the variable.

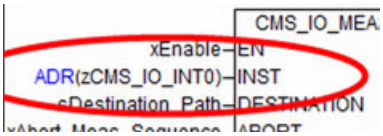


Fig. 192: Example

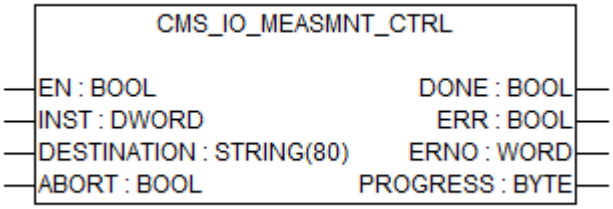
DESTINATION Data type: STRING

To store the measurement files after the measurement progress. Example: flashdisk/Meas.zip. Filename in 8.3 characters.

ABORT Data Type: BOOL

A rising edge at input stops the measurement or transmitting. When ABORT = TRUE, measurement data will be deleted.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

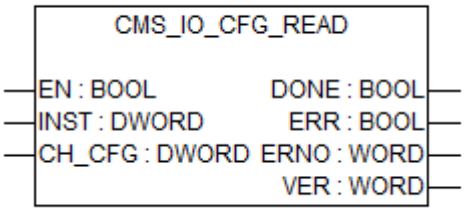
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

PROGRESS Data type: BYTE

Percentage of transmitting the measurement files from Function Module to processor module.

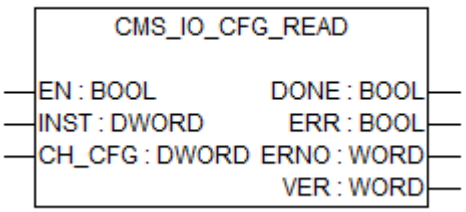
CMS_IO_CFG_READ



Parameter	Value
Included in library	CMS_IO_AC500_V24.lib
Available as of firmware	V2.4.0
Available as of device firmware	V1.0
Type	Function block with historical values
Group	Configuration

Read configuration of analog channels from FM502-CMS.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

INST (instance) Instance description of the Function Module that should be controlled via this function block. The variable is automatically generated during the configuration with the Automation Builder. Use the operator ADR to get the address of the variable.

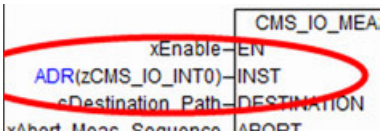


Fig. 193: Example

CH_CFG (channel configuration)

Data type: DWORD (address of CMS_IO_CFG_FM502_TYPE)

Address where channel configuration data will be read from and written into the function module.

↳ *Chapter 1.6.4.4.3.2.2.1 “Parameter set” on page 5726*

Output description

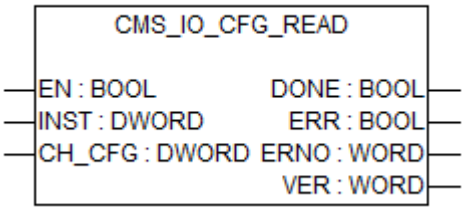

Fig. 194: Function block CMS_IO_CONFIG_READ

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

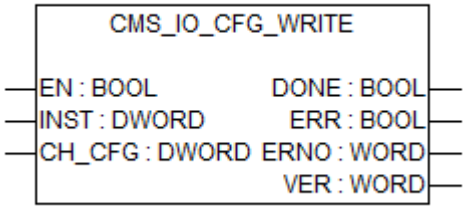
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

VER (version index)

Data type: WORD

Version index of configuration data.

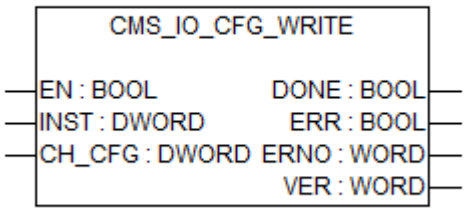
CMS_IO_CFG_WRITE



Parameter	Value
Included in library	CMS_IO_AC500_V24.lib
Available as of firmware	V2.4.0
Available as of device firmware	V1.0
Type	Function block with historical values
Group	Configuration

With this function block you can change the configuration of the function module also during the run time of the CODESYS. Configuration cannot be written while function block CMS_IO_MEASMNT_CTRL is active. When configuration data has an error (plausibility will be checked in function module) or will be sent while CMS_IO_MEASMNT_CTRL is active, configuration data will be deleted and the old one will be used. If the function module gets an error while configuration data is written to the function module, the function block CMS_IO_CFG_READ output DONE will be TRUE, but errors can be seen in diagnosis system of processor module. Encoder/counter function blocks will be reset, when the configuration is written.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

INST (instance)

Instance description of the Function Module that should be controlled via this function block. The variable is automatically generated during the configuration with the Automation Builder. Use the operator ADR to get the address of the variable.

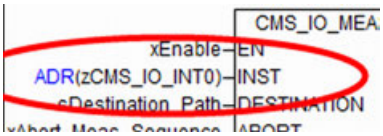


Fig. 195: Example

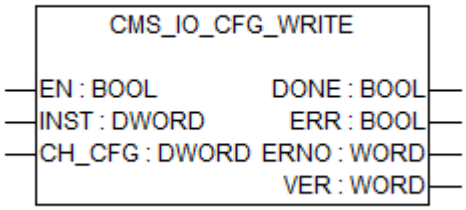
CH_CFG (channel configuration)

Data type: DWORD (address of CMS_IO_CFG_FM502_TYPE)

Address where channel configuration data will be read from and written into the function module.

↳ *Chapter 1.6.4.4.3.2.2.1 “Parameter set” on page 5726*

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

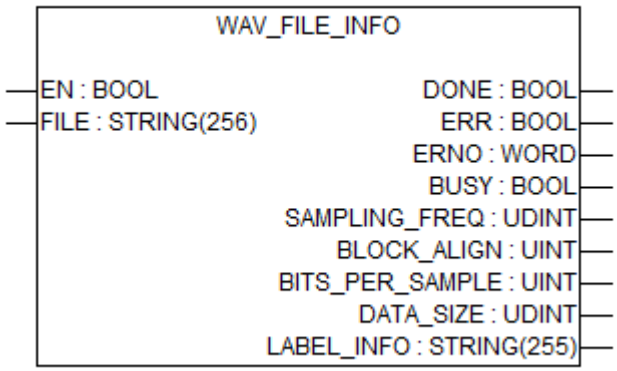
VER (version index) Data type: WORD

Version index of configuration data.

1.5.8.3 WAV file library for data handling

1.5.8.3.1 Function blocks

WAV_FILE_INFO

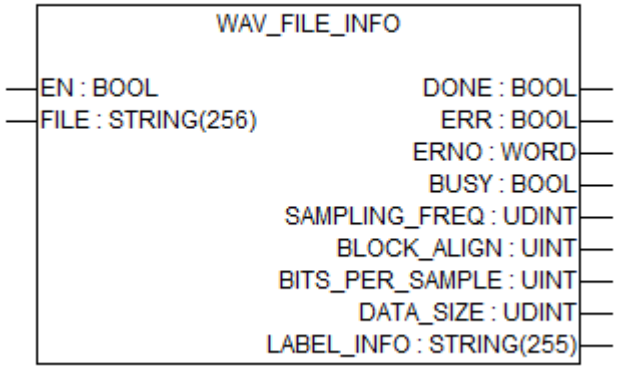


Parameter	Value
Included in library	WAV_FILE_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Group	-

Function block WAV_FILE_INFO is used to retrieve the WAV file properties. This function block does not read the measured data values present in the file. The user can get the file information on the WAV file which may be needed before performing the read and write operations.

Function block WAV_FILE_INFO works with the file in the READ mode.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

FILE (file path and name)

Data type: STRING

Input is used to enter the absolute path and name of the file whose information is required.

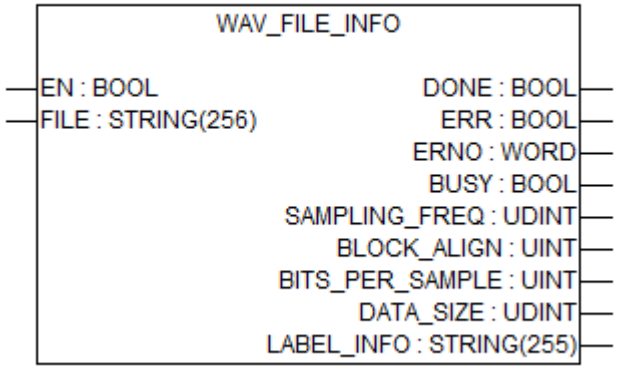
If the path or the file name given is incorrect or invalid, an error occurs at output ERNO and output ERR = TRUE.

Example of the value of FILE

File is present on the flash: flashdisk\Sample.wav

File is present on the memory card: SDCard\Sample.wav

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BUSY

Data type: BOOL

Output BUSY stays TRUE, till the processing of the function block is in progress. Once the processing is done, output BUSY becomes FALSE and output DONE becomes TRUE. In the course of output ERR=TRUE, or the input EN=FALSE, output BUSY becomes FALSE.

SAMPLING_FREQ (sampling frequency)

Data type: UDINT

Output SAMLING_FREQ captures the sampling frequency of the WAV file. The sampling frequency is the number of samples of data, stored in one second.

BLOCK_ALIGN

Data type: UDINT

Output BLOCK_ALIGN captures the respective value of the WAV file. The value gives the number of bytes present in one sample of data recorded in the WAV file.

The BLOCK_ALIGN value is a function of bits per sample, number of channels and sampling frequency *Chapter 1.5.8.1 “System technology” on page 2519*.

BITS_PER_SAMPLE

Data type: UINT

Output BITS_PER_SAMPLE stores the number of bits present in one sample of the data.

DATA_SIZE

Data type: UDINT

Output DATA_SIZE stores the value of number of bytes from the measured data which is present in the WAV file.

LABEL_INFO

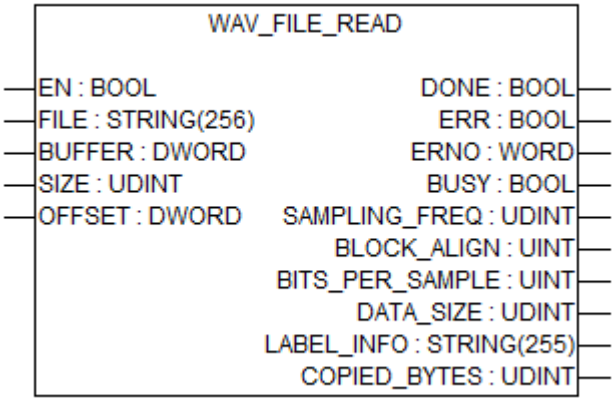
Data type: STRING[255]

Output LABEL_INFO captures the label information, which stores the channel and encoder information.

Function call in ST

```
Inst_File_Info(
        EN:=TRUE,
        FILE:=:= 'flashdisk\Sample.WAV',
        xInfoDone:= Inst_File_Info.DONE,
        xInfoError:= Inst_File_Info.ERR,
        wInfoErNo:= Inst_File_Info.ERNO
        dwInfoSamplingFreqInst_File_Info.SAMPLING_FREQ
        wInfoBlockAlign:= Inst_File_Info.BLOCK_ALIGN
        wInfoResolution:= Inst_File_Info.BITS_PER_SAMPLE
        dwInfoDataSize:= Inst_File_Info.DATA_SIZE
        sInfoLable:= Inst_File_Info.LABLE_INFO);
```

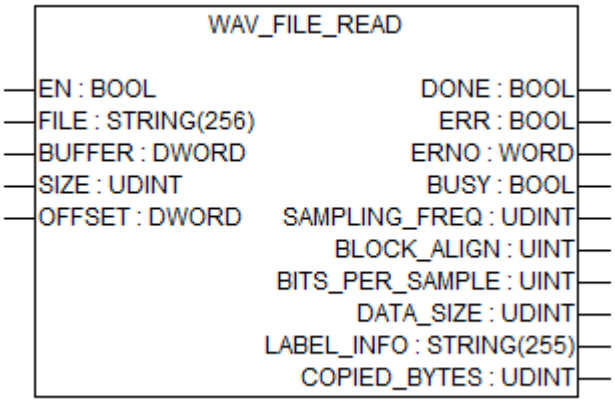
WAV_FILE_READ



Parameter	Value
Included in library	WAV_FILE_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Group	-

Function block WAV_FILE_READ is used to retrieve the WAV file properties and to read the measured data stored in the file.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

FILE (file path and name)

Data type: STRING

Input is used to enter the absolute path and name of the file whose information is required.

If the path or the file name given is incorrect or invalid, an error occurs at output ERNO and output ERR = TRUE.

Example of the value of FILE

File is present on the flash: flashdisk\Sample.wav

File is present on the memory card: SDCard\Sample.wav

BUFFER (memory buffer)

Data type: DWORD, Default value = 0

Input BUFFER contains the memory address of the array where all the measured data is stored after reading.

Example

If the measured data is stored in the array 'abyReadData[1..100]', then BUFFER=ADR(abyReadData).

SIZE (size of data to be read)

Data type: UDINT, Default value = 1, Range ≥ 1 (block align) and ≤ data size of the file.

Input SIZE gives the number of bytes of the measured data to be read and stored in the buffer. The function block would throw an error, if value of SIZE given as 0. For a given file, the input SIZE value must always be the integral multiple of its block align value.

Example

With data size = 1000 and block align = 4, the valid value of SIZE is in the range from 4 to 1000.

SIZE must not exceed the data size of the WAV file.

OFFSET (memory offset)

Data type: UDINT, Default value = 0, Range ≥ 0 and ≤ data size of the file.

Input OFFSET is an offset in terms of number of bytes. It points to the byte from where the reading should start.

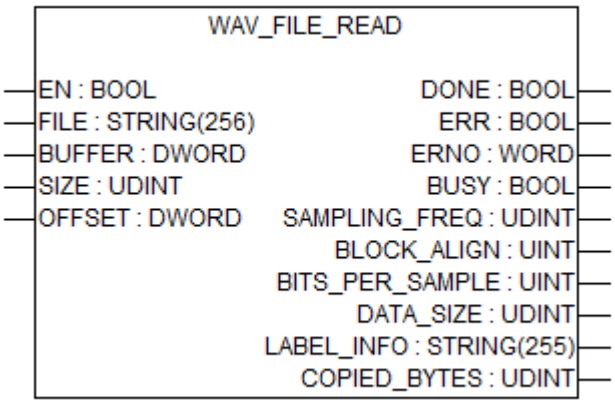
Example

If the value of OFFSET = 10, the function block will read from the 11th measured data present inside the file.

OFFSET is an integral multiple of the block align

OFFSET must not exceed the data size of the WAV file.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BUSY

Data type: BOOL

Output BUSY stays TRUE, till the processing of the function block is in progress. Once the processing is done, output BUSY becomes FALSE and output DONE becomes TRUE. In the course of output ERR=TRUE, or the input EN=FALSE, output BUSY becomes FALSE.

SAMPLING_FREQ (sampling frequency)

Data type: UDINT

Output SAMLING_FREQ captures the sampling frequency of the WAV file. The sampling frequency is the number of samples of data, stored in one second.

BLOCK_ALIGN

Data type: UDINT

Output BLOCK_ALIGN captures the respective value of the WAV file. The value gives the number of bytes present in one sample of data recorded in the WAV file.

The BLOCK_ALIGN value is a function of bits per sample, number of channels and sampling frequency *Chapter 1.5.8.1 “System technology” on page 2519*.

BITS_PER_SAMPLE

Data type: UINT

Output BITS_PER_SAMPLE stores the number of bits present in one sample of the data.

DATA_SIZE

Data type: UDINT

Output DATA_SIZE stores the value of number of bytes from the measured data which is present in the WAV file.

LABEL_INFO

Data type: STRING[255]

Output LABEL_INFO captures the label information, which stores the channel and encoder information.

COPIED_BYTES

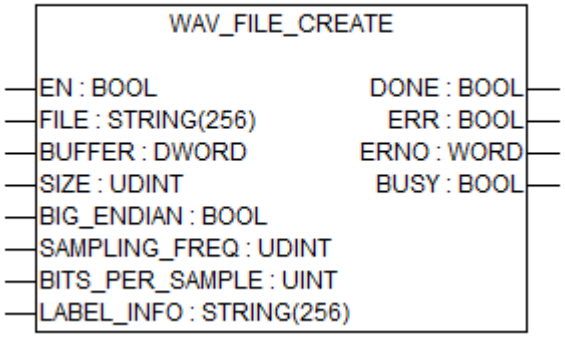
Data type: UDINT

Output COPIED_BYTES stores the number of bytes, the function block read and stored in the buffer area.

Function call in ST

```
Inst_File_READ(
        EN:=TRUE,
        FILE:=:= 'flashdisk\Sample.WAV',
        BUFFER:= ADR(abyReadData),
        SIZE:= 100,
        OFFSET:= 0,
        xReadDone:= Inst_File_Read.DONE,
        xReadError:= Inst_File_Read.ERR,
        wReadErNo:= Inst_File_Read.ERNO,
        dwReadSamplingFreq:= Inst_File_Read.SAMPLING_FREQ,
        wReadBlockAlign:= Inst_File_Read.BLOCK_ALIGN,
        wReadResolution:= Inst_File_Read.BITS_PER_SAMPLE,
        dwReadDataSize:= Inst_File_Read.DATA_SIZE,
        ReadLabel:= Inst_File_Read.LABEL_INFO,
        udiReadBytes:= Inst_File_Read.COPIED_BYTES);
```

WAV_FILE_CREATE

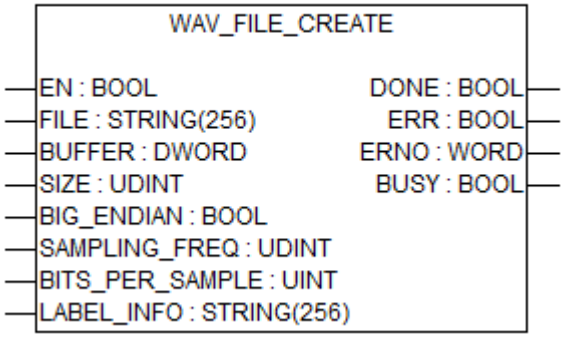


Parameter	Value
Included in library	WAV_FILE_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Group	-

Function block WAV_FILE_CREATE is used to create a new file by giving the required properties of the file.

This function block creates a new WAV file by handling the file in the WRITE mode. It is possible to write the data in the big or the little endian format.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

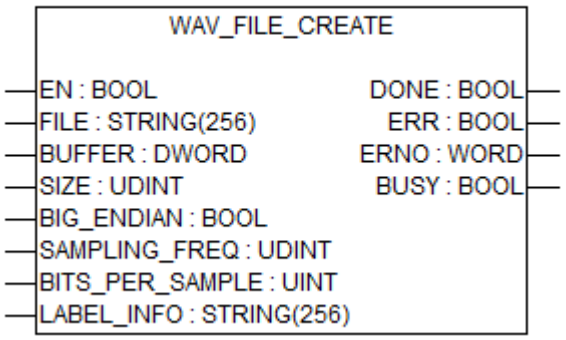
The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

FILE (file path and name)	Data type: STRING Input is used to enter the absolute path and name of the file whose information is required. If the path or the file name given is incorrect or invalid, an error occurs at output ERNO and output ERR = TRUE.
Example of the value of FILE	File is present on the flash: flashdisk\Sample.wav File is present on the memory card: SDCard\Sample.wav
BUFFER (memory buffer)	Data type: DWORD, Default value = 0 Input BUFFER contains the memory address of the array where all the measured data is stored after reading.
Example	If the measured data is stored in the array 'abyReadData[1..100]', then BUFFER=ADR(abyReadData).
SIZE (size of data to be read)	Data type: UDINT, Default value = 1, Range ≥ 1 (block align) and ≤ data size of the file. Input SIZE gives the number of bytes of the measured data to be read and stored in the buffer. The function block would throw an error, if value of SIZE given as 0. For a given file, the input SIZE value must always be the integral multiple of its block align value.
Example	With data size = 1000 and block align = 4, the valid value of SIZE is in the range from 4 to 1000.
	SIZE must not exceed the data size of the WAV file.
BIG_ENDIAN	Data type: BOOL, default value: FALSE = little endian Input BIG_ENDIAN decides if the file to be created will be a big endian or a little endian. BIG_ENDIAN = TRUE = big endian data file.
SAMPLING_FREQ (sampling frequency)	Data type: UDINT, default value: 1, range: > 0. Input SAMPLING_FREQ enters the sampling frequency of the WAV file to be created. The sampling frequency is the number of samples of data stored in one second.
BITS_PER_SAMPLE	Data type: UINT Input BITS_PER_SAMPLE enters the number of bits present in one sample of the data. ● 16, 24, 32 or 64 are the valid values for this input.
LABEL_INFO	Data type: STRING[255] Input LABEL_INFO enters the label information. The label information normally stores the channel and encoder information.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BUSY

Data type: BOOL

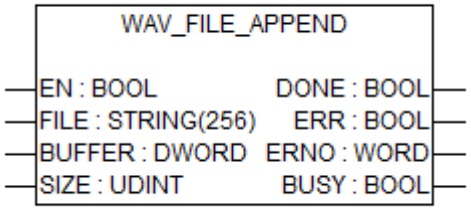
Output BUSY stays TRUE, till the processing of the function block is in progress. Once the processing is done, output BUSY becomes FALSE and output DONE becomes TRUE. In the course of output ERR=TRUE, or the input EN=FALSE, output BUSY becomes FALSE.

Function call in ST

```
Inst_File_CREATE(
         EN:=TRUE,
         FILE:=:= 'flashdisk\Sample.WAV',
         BUFFER:= ADR(abyCreateData),
         SIZE:= 100,
         BIG_ENDIAN:= FALSE,
         SAMPLING_FREQ:= 50000,
```

```
BITS_PER_SAMPLE:= 16,
xCreateDone:= Inst_File_Info.DONE
xCreateError:= Inst_File_Info.ERR
wCreateErNo:= Inst_File_Info.ERNO
dwCreateBusy:= Inst_File_Create.BUSY);
```

WAV_FILE_APPEND

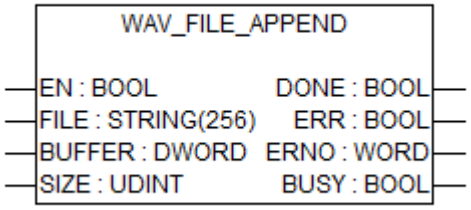


Parameter	Value
Included in library	WAV_FILE_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Group	-

Function block WAV_FILE_APPEND is used if you want to add more data samples to an existing WAV file.

This function block appends the WAV file by handling the file in the WRITE mode.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

FILE (file path and name)

Data type: STRING

Input is used to enter the absolute path and name of the file whose information is required.

If the path or the file name given is incorrect or invalid, an error occurs at output ERNO and output ERR = TRUE.

Example of the value of FILE	File is present on the flash: flashdisk\Sample.wav File is present on the memory card: SDCard\Sample.wav

BUFFER (memory buffer)

Data type: DWORD, Default value = 0

Input BUFFER contains the memory address of the array where all the measured data is stored after reading.

Example	If the measured data is stored in the array 'abyReadData[1..100]', then BUFFER=ADR(abyReadData).

SIZE (size of data to be read)

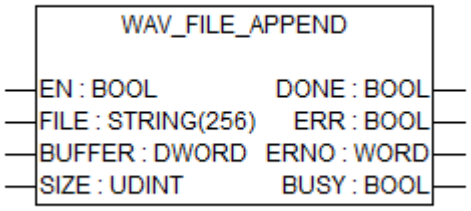
Data type: UDINT, Default value = 1, Range ≥ 1 (block align) and ≤ data size of the file.

Input SIZE gives the number of bytes of the measured data to be read and stored in the buffer. The function block would throw an error, if value of SIZE given as 0. For a given file, the input SIZE value must always be the integral multiple of its block align value.

Example	With data size = 1000 and block align = 4, the valid value of SIZE is in the range from 4 to 1000.

SIZE must not exceed the data size of the WAV file.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BUSY

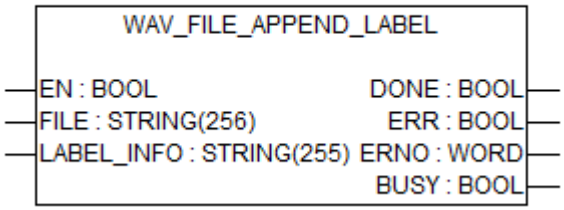
Data type: BOOL

Output BUSY stays TRUE, till the processing of the function block is in progress. Once the processing is done, output BUSY becomes FALSE and output DONE becomes TRUE. In the course of output ERR=TRUE, or the input EN=FALSE, output BUSY becomes FALSE.

Function call in ST

```
Inst_File_APPEND(
         EN:=TRUE,
         FILE:=:= 'flashdisk\Sample.WAV',
         BUFFER:= ADR(abyAppendData),
         SIZE:= 100,
         xAppendDone:= Inst_File_Append.DONE
         xAppendError:= Inst_File_Append.ERR
         wAppendErNo:= Inst_File_Append.ERNO
         dwAppendBusy:= Inst_File_Append.BUSY);
```

WAV_FILE_APPEND_LABEL

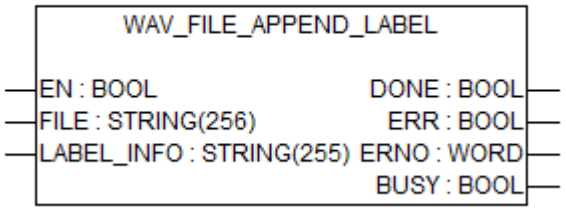


Parameter	Value
Included in library	WAV_FILE_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Group	-

Function block WAV_FILE_APPEND_LABEL is used if you want to add a label to an existing WAV file.

This function block appends the WAV file by handling the file in the WRITE mode.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The function block is activated by a TRUE at the input EN.

A FALSE keeps the function block deactivated.

Is the function block activated, the values being present at the inputs are processed and the output values are delivered.

FILE (file path and name)

Data type: STRING

Input is used to enter the absolute path and name of the file whose information is required.

If the path or the file name given is incorrect or invalid, an error occurs at output ERNO and output ERR = TRUE.

Example of the value of FILE

File is present on the flash: flashdisk\Sample.wav

File is present on the memory card: SDCard\Sample.wav

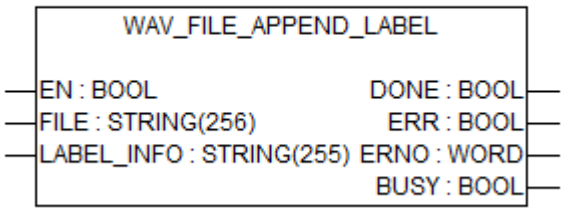
LABEL_INFO

Data type: STRING

Input is used to append the information as a label to the WAV file.

If the total length of the label information is bigger than 256 signs, an error occurs at output ERNO and output ERR = TRUE.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Output DONE indicates the processing state of the function block.

After completion or abortion of processing (due to an error), DONE is set to TRUE, for one cycle, as long as input EN = TRUE.

This output always has to be considered together with output ERR. If ERR is TRUE, then the corresponding error code is displayed by output ERNO.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Output ERR indicates, whether an error occurred during control processing.

In case of error, the error number can be read at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

Output ERNO provides an error identifier, if an invalid value was applied to an input, or if an error occurred during request processing. Then the error number is displayed at the output (see, error messages).

Output ERNO always has to be considered together with output ERR. The value output at ERNO is only valid, if output ERR is TRUE.

BUSY

Data type: BOOL

Output BUSY stays TRUE, till the processing of the function block is in progress. Once the processing is done, output BUSY becomes FALSE and output DONE becomes TRUE. In the course of output ERR=TRUE, or the input EN=FALSE, output BUSY becomes FALSE.

Function call in ST

```
Inst_File_APPEND_LABEL(
         EN:=TRUE,
         FILE:= 'flashdisk\Sample.WAV',
         LABEL INFO:= 'Label information',
         xAppendDone:= Inst_File_Append_Label.DONE
         xAppendError:= Inst_File_Append_Label.ERR
         wAppendErNo:= Inst_File_Append_Label.ERNO
         dwAppendBusy:= Inst_File_Append_Label.BUSY);
```

zWAV_FILE_BYTES_TO_STRING

Internal function block to retrieve the string of label section of the WAV-File. The data stored in terms of bytes is converted into the string equivalent.

1.5.8.3.2 Structures

Structure	Function
zWAV_FILE_LOOKUP_TYPE	Internal structure not for the user access. To create a look up table of ASCII format and characters.
zWAV_FILE_STRING_TO_ASCII_TYPE	Internal structure not for the user access. Has the elements for ASCII format and character of a string.
zWAV_FILE_STRUCT_TYPE	Internal structure not for the user access. Has the structure same as the WAV-File standards

1.5.8.3.3 Variables

Table 152: Global variables

Variable	Function
WAV_FILE_VERSION_INFORMATION	Stores all the version information of the file along with the change log. It has no variable declared inside this section.
dwWAV_FILE_VisuBackgroundColor Group: WAV_FILE_VISU_COLOR_INFO	Visualization elements: background color 16#00<B><G><R>
dwWAV_FILE_VisuTitleColor Group: WAV_FILE_VISU_COLOR_INFO	Visualization elements: title background color 16#00<B><G><R>

1.5.8.3.4 Visualization

A visualization object can be used to show the actual values of all inputs and outputs of the instance of the function block. The visualization can also be used to control the function block by those inputs which are not connected inside the program.

In CODESYS, you can add a visualization object in the project and select the required function block visualization.

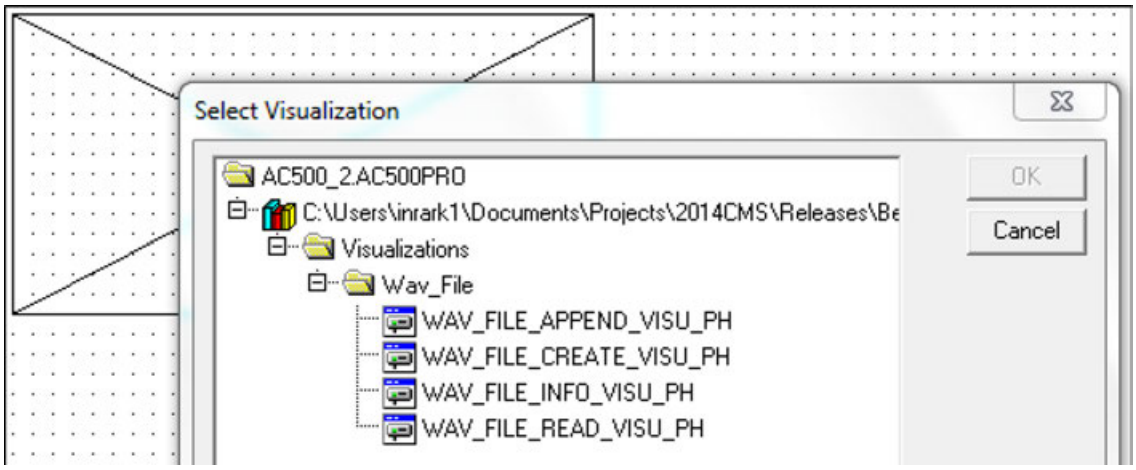


Fig. 196: Visualization: Selection of function blocks

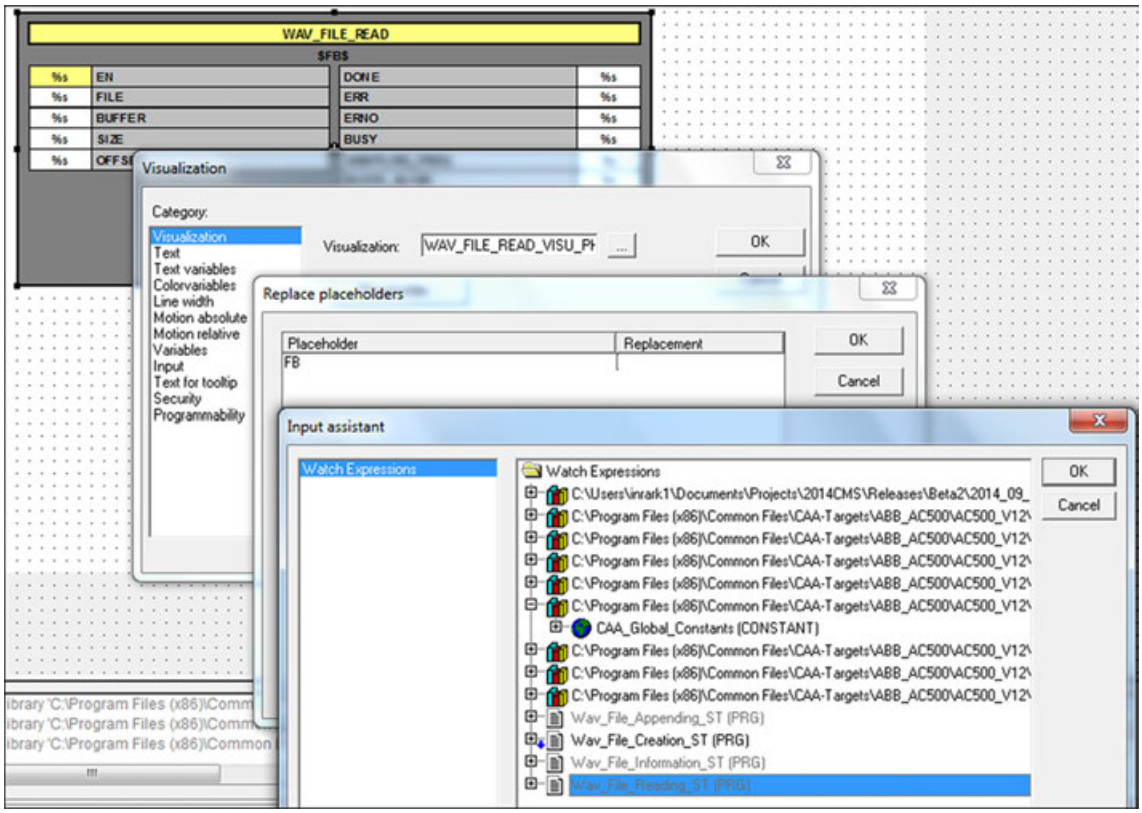

Fig. 197: Example: WAV_FILE_READ_VISU_PH

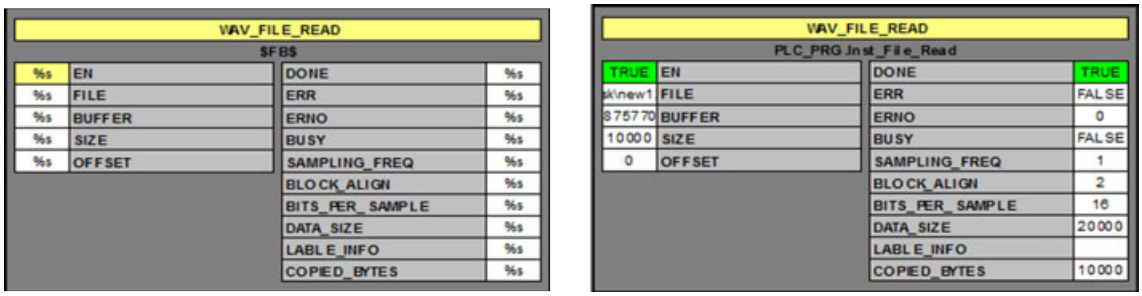

Fig. 198: Example: WAV_FILE_READ_VISU_PH in offline and online mode

Colors

- WHITE: Current FALSE and should be FALSE in normal operation.
- GREEN: Current TRUE and should be TRUE in normal operation.
- YELLOW: Current FALSE but should be TRUE in normal operation.
- RED: Current TRUE but should be FALSE in normal operation.

Color of the background can be changed by writing a value to the global variable dwWAV_FILE_VisuBackgroundColor.

Color of the title can be changed by writing a value to the global variable dw WAV_FILE_VisuTitleColor.

1.5.8.4 Examples

Example projects for the libraries can be found in the folder: \Users\Public\Documents\AutomationBuilder\Examples

1.5.9 Motion control library

Safety instructions

- All pertinent state, regional, and local safety regulations must be observed when installing and using this product. When functions or devices are used for applications with technical safety requirements, the relevant instructions must be followed.
- Read the complete safety instructions of the user's manuals for the drives you are using, before installation and commissioning.
- Read all safety instructions of the AC500 PLC. See System description AC500 or chapter *Chapter 1.6.1.4 “Regulations” on page 3709* in the online help.
- Read the Important user Information. See chapter *Chapter 1.6.1.1 “Safety instructions” on page 3697* in the online help.

1.5.9.1 Preconditions for the use of the libraries

The user has to read the following instructions and documents before using the libraries:

The library package has been released for the software and firmware versions listed in the readme file of Automation Builder only (see “Help ➔ Automation Builder Release Notes”) . In no event will ABB or its representatives be liable for loss of data, profits, revenue or consequential, incidental or other damage that may result from the use of other versions of product, software or firmware versions. The error-free operation of the HA library with other devices, software or firmware versions should be possible but cannot be guaranteed and may need adaptations e. g. of example programs.

The first version of Motion Control Library Package PS5611-Motion has been released with Automation Builder 2.4.0.There after the package is updated with several changes. For details on all changes please refer PS5611-Motion release note area from Automation Builder release notes.

The Motion control package contains follows libraries:

Library	Automation Builder	PLC firmware
ABB_MotionControl_AC500	AB 2.4.0 or higher	AC500 V3 firmware version 3.3.1 or higher AC500-eCo V3 firmware version 3.4.0 or higher
ABB_Ecat_CiA402_AC500		
ABB_MathFunctions_AC500		
ABB_MotionContro-lEco_AC500 (kernel blocks for Eco V3 PLCs)		
ABB_MotionControl-Load_AC500	AB 2.5.0 or higher	AC500 V3 firmware version 3.5.0 or higher

The version 3.0.0 of the Motion Control Library Package PS552-MC-E has been released for:

- AC500 and AC500-eCo, AC500 Firmware version 2.3
- Control Builder Plus V2.3
- CODESYS V2.3.9.x

The PS552-MC libraries V3.0.0 have been tested with the following product / firmware / software versions:

- CM579-ETH EtherCAT Communication Module firmware 2.6.7
- Bosch Indra Drive Cs FW MPB-16V20-D5-1-NNN-NN
- ACSM1 FW 1510 + FECA-01 FW 109
- ACS355 FW 5040 + FECA-01 FW 109
- ACS355 FW 4050 + FPBA-01 FW 201B

- ACSM1 Motion FW 1510 + FPBA-01 FW 201B
- ACSM1 FW v1.8.2

In no event will ABB or its representatives be liable for loss of data, profits, revenue or consequential, incidental or other damage that may result from the use of other versions of product / software / firmware versions. The error-free operation of the PS552-MC-E V3.0.0 with other devices / software / firmware versions should be possible but can not be guaranteed and may need adaptations e.g. of example programs.

CAUTION!
Generally, the user in all applications is fully and alone responsible for checking all functions carefully, especially for safe and reliable operation.

The function blocks contained in the library can only be executed in RUN mode of the PLC, but not in simulation mode.

Limits on number of synchronized axis

There are limits on the minimum EtherCAT cycle time, user can configure in each PLC type.

Table 153: Details on the limits on the minimum EtherCAT cycle time

PLC type	PM5630	PM5650	PM5670
Min. EtherCAT master cycle time	2 ms	1 ms	0,5 ms

Other than the above limits, there is also limits on configuring the number of synchronized axis in each PLC type. This limits is based on the EtherCAT master cycle time configured under EtherCAT master.

Table 154: Details on the limits for each PLC type

PLC type	PM5630	PM5650	PM5670
Number of synchronized axis in 1 ms	-	8	16
Number of synchronized axis in 2 ms	4	16	32
Number of synchronized axis in 4 ms	8	32	64

“Number of axis” is counted in Automation Builder is based on the number of Kernel function block instance declared in the IEC application. In this way, it is made sure all real and virtual axis are counted.

User can increase the EtherCAT cycle time to accommodate more “Number of axis” in the same PLC type.

User can use the *[Statistics]* tab from Automation Builder to see how many axis are supported for the particular PLC type and for the EtherCAT master cycle time configured. Once the axis is configured user need to update the *[Statistics]* tab by *“Generate Code”* to get the updated information.

Automation Builder allows an additional axis than what is mentioned in the above table to support one virtual axis additionally.

> *Please remove any Kernel function block instance which is declared but not used in the application to get the correct number of axis calculated by Automation Builder under the [Statistics] tab.*

1.5.9.2 Overview

The PS552-MC is a Motion Control software to create Motion Control applications based on function blocks according to the standard of PLCopen Motion Control ↳ *Chapter 1.5.9.3 “PLCopen” on page 2587*.These function blocks can be used for Central Motion Control as well as for drive-based Motion Control axis implementations.

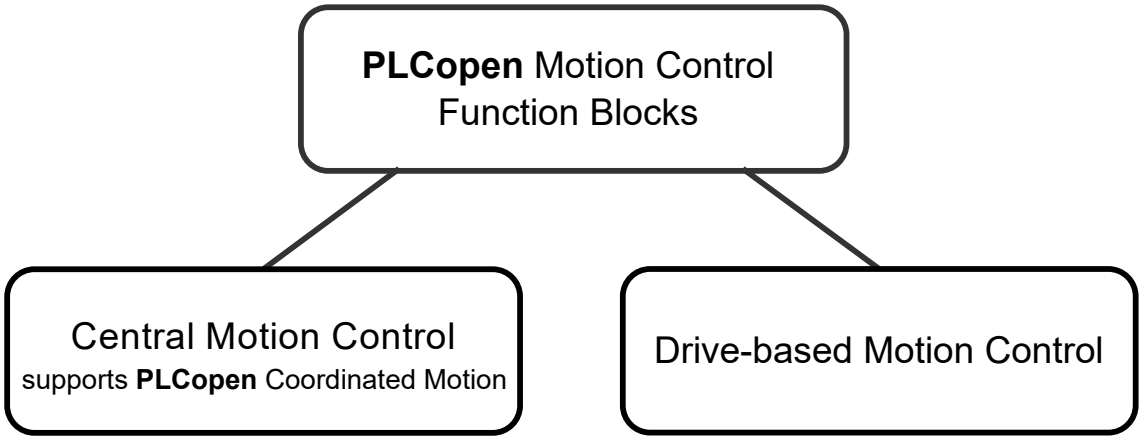

Fig. 199: Use of PLCopen function blocks for different axis implementations provided by PS552-MC

The Central Motion Control axis implementation covers a wide range of possible Motion Control functionalities starting from single axis movements to master-follower axes to perform electronic gearing and CAM functions up to coordinated Motion Control in cartesian coordinates with optional kinematic transformations to realize even a portal or robotic application.

There are different drive-based Motion Control implementations for specific ABB drives. PLCopen function blocks can be used to control the motion capabilities of the drives from AC500 PLC.

This documentation contains the following chapters:

- Overview
  In the subsequent chapters general information are provided for a better understanding of Motion Control with AC500 PLC and PS552-MC. There is also an overview of the available PLCopen function blocks and their compatibility with Central Motion Control and the provided drive-based Motion Control axis implementations.
- PLCopen
  The principle of the PLCopen Motion Control standard is explained as well as how PLCopen function blocks can be used to create PLC Motion Control application programs.
- Central Motion Control (PLC-Based)
  This chapter explains how PLC-based Motion Control with AC500 can be realized and how it can be used in combination with the available PLCopen function blocks.
- PLC-based Motion Control Fluid Power Extension or Load Control
  This chapter explains how the PLCopen part 6 Fluid Power - extension also called “Load Control” can be used to practically realize also a form of Torque control (or -profiling) and how it can be used in combination with the available PLCopen function blocks and switch between Torque/Load control and position control.

- Drive-Based Motion
  Control Different realizations for specific drives and modules are introduced and explained. Drive or module dependent restictions as well as device dependent commissioning instruction are given.
- PLCopen function blocks
  This chapter covers the documentation of all included PLCopen Motion Control function blocks of this product.
- Glossary
  All abbreviations used in this documentation are listed here.

1.5.9.2.1 Motion Control with PS552-MC

With PS552-MC different Motion Control system structures are possible. Independently of the system structure a typical Motion Control application consists of the following system elements:

- An application program which contains PLCopen function blocks that defines the general application behavior and logics.
- A profile generator which generates a position profile based on the dynamic specifications of the application program to guide the axis to the desired positions.
- A position control loop which outputs a speed reference signal to minimize the following error.

To achieve the best system structure for an application these components can be separated into different devices. Each type of structure has its own kind of interface and type of signals which need to be transferred between the interacting devices.

All shown Motion Control system structures (drive based or central Motion Control with or without position control loop) can be combined together in the same application program for a Motion Control project.

1.5.9.2.2 PLC-based motion control

With central Motion Control based on an AC500 PLC and PS552-MC the application program is done in the PLC but also the profile generator. The implementation of the profile generator is based on a set of function blocks which are named Compact Motion (CMC).

The profile generator of many possible axes is centrally placed inside the AC500 PLC. Therefore multiaxis motion functionalities become easily available and can be accessed by PLCopen function blocks. As a result, Motion Control functionalities are almost drive independent.

Available motion control functionalities:

- Simple axis Movements
- Electronic Gearin
- Electronic CAMs
- Position Profiles
- Velocity Profiles
- Acceleration Profiles
- Load control (Torque profilling)
- Simple Movements in 3D
- Path Movements in 3D
- Kinematic Transformations for Roboitc Applications

Then the output is a position reference signal which the drive will follow. A new position reference value will be calculated with every cycle of the PLC and has to be transferred to the drive, which demands real time capabilities to the PLC and to the communication channel. A real time fieldbus like EtherCAT is needed. The feedback of the actual position can be used for supervision purposes during operation and is needed to adjust the value of the position reference before the drive will be enabled.

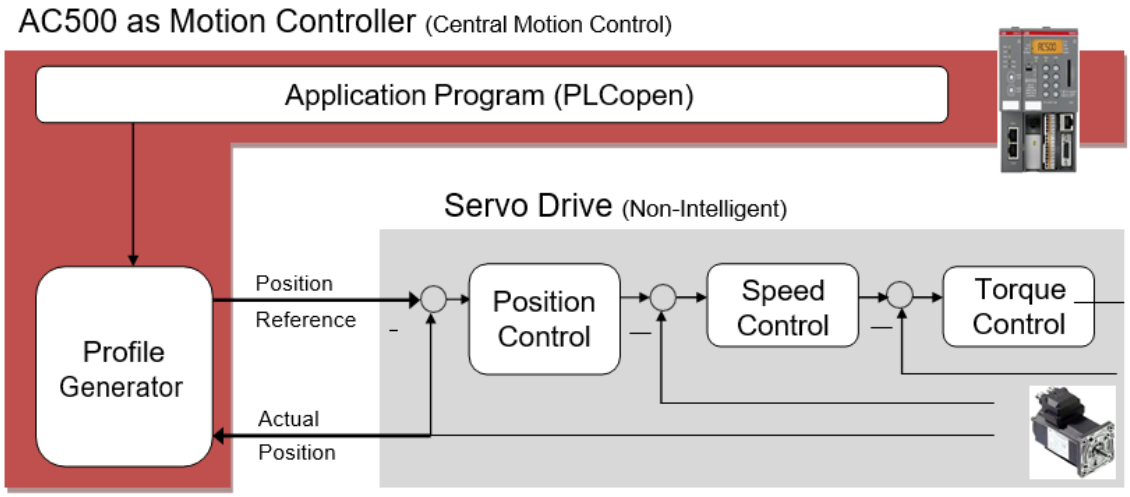

Fig. 200: System structure of Central Motion Control with AC500 PLC and PS552-MC

With central Motion Control it is also possible to include the position control loop to the AC500 PLC. In this case a speed reference signal will be transferred to the drive which makes it possible to perform the full range of motion functionalities with standard drives. To close the position control loop a feedback of the actual position is mandatory.

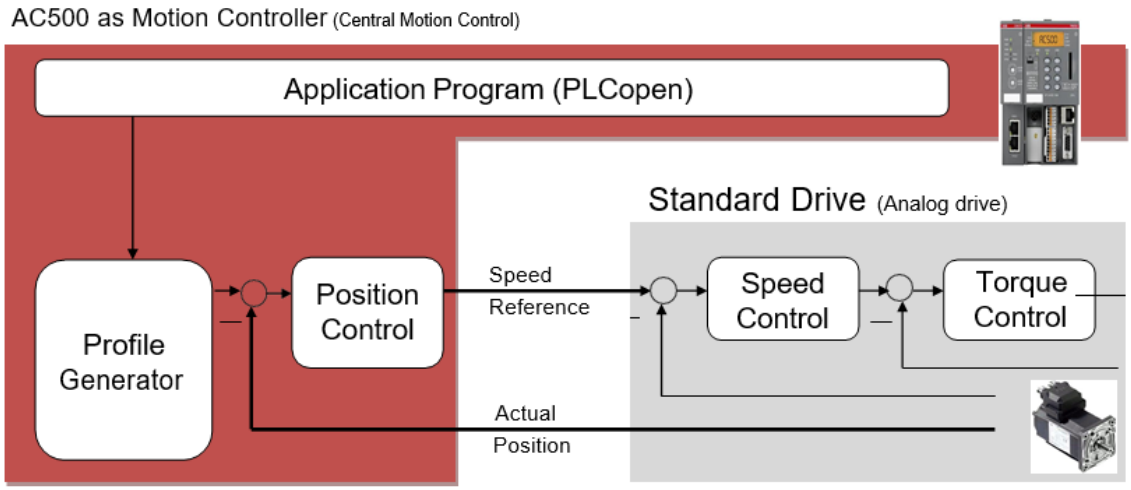

Fig. 201: Central Motion Control with AC500 PLC and PS552-MC, closed position control loop

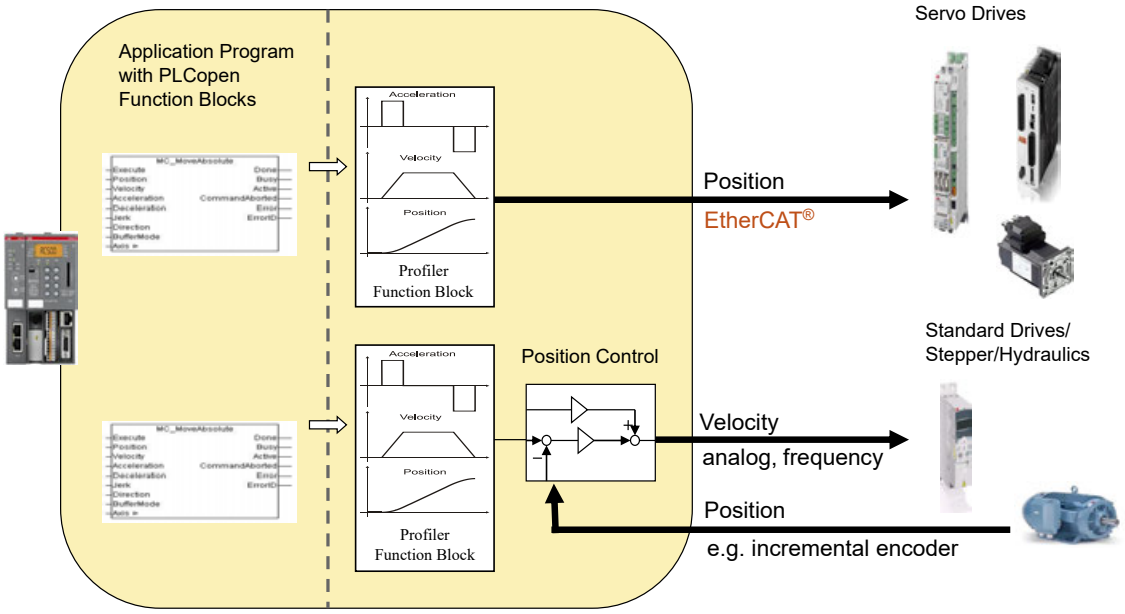

Fig. 202: PLC-based Motion Control with AC500 PLC and PS552-Motion, different axis implementations at the same time

1.5.9.2.3 Drive-Based Motion Control

For drive-based Motion Control the application program is done in the AC500 PLC with PLCopen function blocks included in PS552-MC. Based on this program commands and parameters will be transferred to the drive. Then the drive will act on its own during operation. Actual values and parameters can be read by the PLC. The commanded movement will be performed by the drive itself using its own profile generator for positioning drives or speed ramps in case of standard drives.

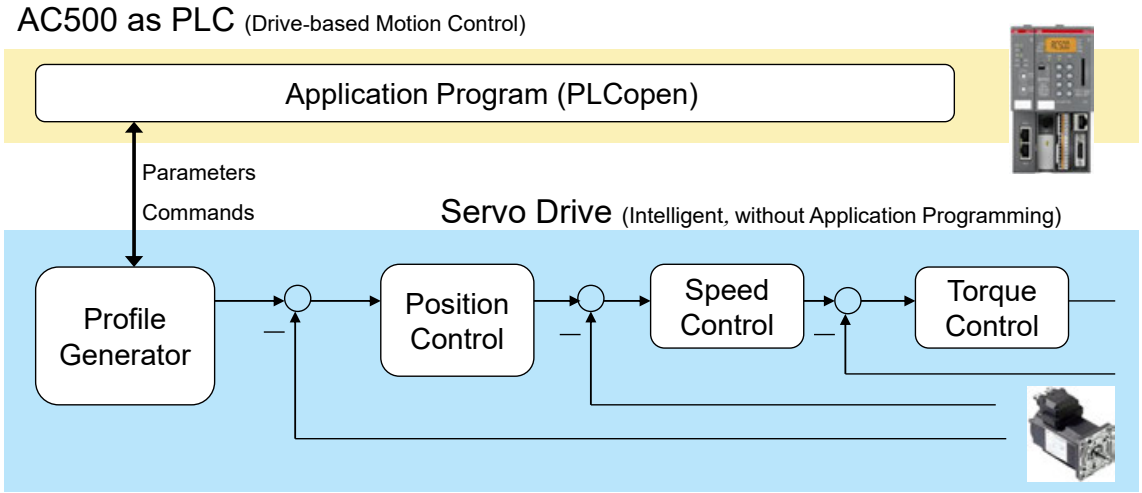

Fig. 203: System structure of drive-based Motion Control with AC500 PLC and PS552-MC

The available Motion Control functionalities depend on the used drive system.

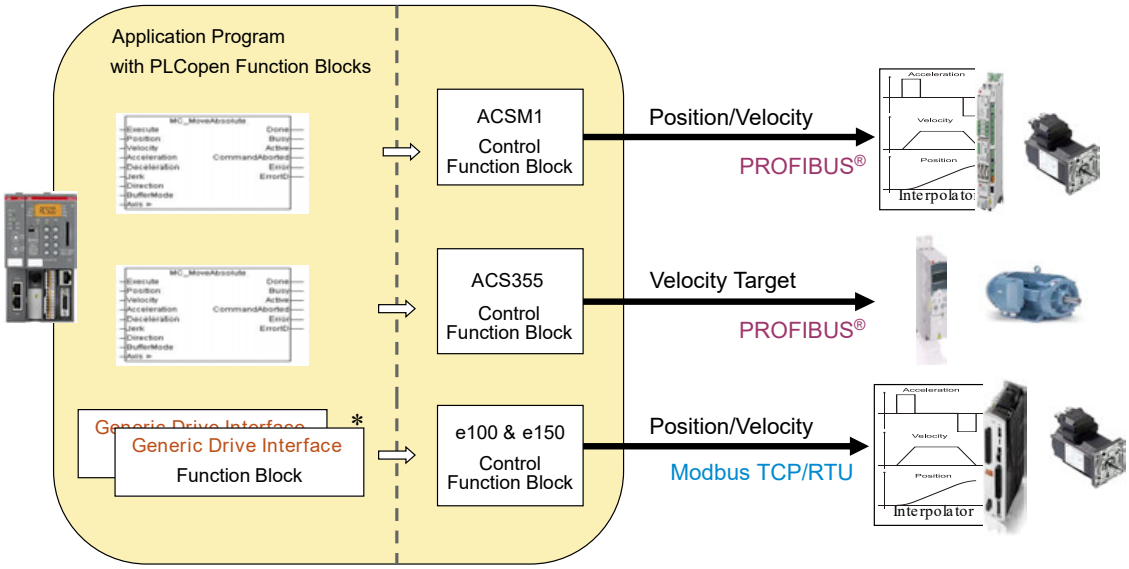

Fig. 204: Drive-based Motion Control with AC500 PLC and PS552-MC, different axis implementations at the same time

The generic drive interface is an implementation which is not part of PS552-MC, but is available as application note for MicroFlexTM e100 and MicroFlex e150 drives.

1.5.9.2.4 Overview of PLCopen function blocks

The following tables give an overview of the defined function blocks, divided into administrative (not driving motion) and motion related sets. They give an overview which function block could be used for the different possible configurations.

The function blocks are part of the library MC_Block_AC500_V11.

> *Function blocks for PLCopen Coordinated Motion are compabible with PLC-based central Motion Control only.* *Chapter 1.5.9.4.9 “PLCopen coordinated motion” on page 2679*

If there are restrictions concerning a certain drive ("XXX") which lead to a different or limited behavior compared to the standard the respective chapter is supplemented with an additional paragraph "Notes for XXX".

1.5.9.2.5 Overview of libraries

▷ Add the following libraries for the listed applications.

⇨ In some cases by adding a library, there will be other libraries added automatically.

Application	Library to be added manually	Libraries added automatically
Central Motion Control	MC_Blocks_AC500_V11. lib	-
	CompactMotionControl_AC500_V12.lib	MC_Base_AC500_V11.lib
Central Motion Control, optional for EtherCAT	ECAT_AC500_APPL_V21.lib	-
Central Motion Control, optional auxiliary	MathFunctions_AC500_V23.lib	-
Central Motion Control - Coordinated Motion Control	MC_Blocks_AC500_V11.lib	-
	MC_CoBlocks_AC500_V11.lib	CompactMotionControl_AC500_V12.lib MC_Base_AC500_V11.lib CoordinatedMotion_AC500_V23.lib MathFunctions_AC500_V23.lib CMC_Ext_AC500_V23.lib
Central Motion Control - Coordinated Motion Control, optional for EtherCAT	ECAT_AC500_APPL_V21.lib	-
Central Motion Control - Coordinated Motion Control, optional auxiliary	CMC_Transformationen_AC500_V23.lib	-
Drive-based Motion Control, ACSM1 via PROFIBUS	MC_Blocks_AC500_V11.lib	-
	ACSM1_MC_support_AC500_V11.lib	ACSM1_AC500_V11.lib MC_Base_AC500_V11.lib
Drive-based Motion Control, ACS355 via PROFIBUS	MC_Blocks_AC500_V11.lib	-

Application	Library to be added manually	Libraries added automatically
	ACS350_MC_support_AC500_V11.lib	ACS350_AC500_V11.lib MC_Base_AC500_V11.lib
Drive-based Motion Control, FM562 via AC500 I/O bus	MC_Blocks_AC500_V11.lib	-
	MC_Base_AC500_V11.lib	-
	PTO_FM562_MC_support_V22.lib	-

The features of the function blocks provided with PS552-MC can be used from the PLC program according to PLCopen standard. Different drives and different Motion Control realizations could be used and can be combined with each other as well as different fieldbusses.

1.5.9.2.6 Overview of data types

The following data types are used for the PS552-MC Motion Control library. The data types are defined in the library file MC_BASE_AC500_V11. The corresponding elements can be used for the function blocks inputs.

Table 161: Structures

Data type	Elements	Element data type
CMC_AXIS_IO	limitSwitchPos	BOOL
	limitSwitchNeg	BOOL
	absRefSwitch	BOOL
MC_PPROFILE *Chapter 1.5.9.4.6.1 "PositionPositionProfile" on page 2653*	master_position	LREAL
	interpolation_point	LREAL
	velocity_ratio	LREAL
	acceleration_ratio	LREAL
MC_TPROFILE *Chapter 1.5.9.4.6.2 "PositionTimeProfile" on page 2654*	interpolation_point	LREAL
	first_derivative	LREAL
	second_derivative	LREAL
	delta_time	TIME

Data types of PLCopen Coordinated Motion Control: *Chapter 1.5.9.4.9.2.10 “ABB specific data structures” on page 2701*

1.5.9.2.7 Naming of function blocks and data structures

PLCopen

All function blocks and data types named MC_xxx are implemented according to PLCopen definition and follow the PLCopen documentation. They may have additional inputs but according to PLCopen rules.

All function blocks and data types named MCA_xxx are implemented corresponding to PLCopen rules with adaptations specific to AC500. They are AC500 specific extensions to the PLCopen library.

Central Motion Control

All function blocks named CMC_xxx belong to the implementation of Central Motion Control.

All data types named CMC_xxx belong to the implementation of Central Motion Control.

All data types named MC_xxx are implemented according PLCopen definition and follow the PLCopen documentation.

All data types named AXIS_xxx exist according to PLCopen definition. The content is ABB specific and not documented.

All function blocks named zCMC_xxx belong to the implementation of Central Motion Control. These are not documented and not intended for customer use.

Drive-based Motion Control

All function blocks starting with a name of a specific product (e.g. PTO_FM562_xxx, ACSM1_xxx, ACS800_xxx or ACS350_xxx) are intendend to be used with this product.

1.5.9.3 PLCopen

Based on application requirements and project specifications engineers are required to use or select a wide range of Motion Control hardware. In the past this required unique software to be created for each application even though the functions are the same. PLCopen motion standard provide a way to have standard application libraries that are reusable for multiple hardware platforms. This lowers development, maintenance and support costs while eliminating confusion. In addition, engineering becomes easier, training costs decrease, and the software is reusable across platforms. Effectively, this standardization is done by defining libraries of reusable components. In this way the programming is less hardware dependent, the reusability of the application software increased, the cost involved in training and support reduced, and the application becomes scalable across different control solutions. Due to the data hiding and encapsulation, it is usable on different architectures, for instance ranging from centralized to distributed or integrated to networked control. It is not specifically designed for one application, but will serve as a basic layer for ongoing definitions in different areas. As such it is open to existing and future technologies.

ABB is a member of the PLCopen organization. More Information about PLCopen can be read on the *PLCopen website*.

Fig. 205: PLCopen Motion Control logo

Function blocks according to PLCopen are designed for controlling axes via the language elements consistent with those defined in the IEC 61131-3 standard. It was decided by the task force that it would not be practical to encapsulate all the aspects of one axis into only one function block. The retained solution is to provide a set of command-oriented function blocks that have a reference to the axis, e.g. the abstract data type Axis, which offers flexibility, ease of use and reusability.

Implementations based on IEC 61131-3 (for instance via function blocks and SFC) will be focused towards the interface (look-and-feel/proxy) of the function blocks. This specification does not define the internal operation of the function blocks.

PLCopen Motion Control function blocks can be used in any IEC 61131-3 programming language. The following picture shows an example of a function block used in Function Block Diagram (FBD) language.

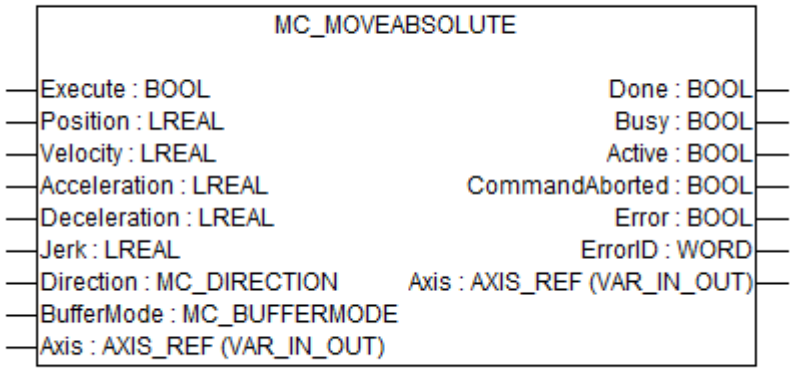

Fig. 206: Command for absolute positioning according to PLCopen standard

Application programs which use the manufacturer independent function blocks according to PLCopen will lead to the following advantages:

- Reusable software structure for different platforms.
- Programming based on function blocks.
- Function blocks can be used in any IEC 61131-3 language.

All function blocks which are defined by PLCopen will have the following qualities independently to the manufacturer of the motion control system:

- Same inputs/outputs
- Same functional behavior
- Same name

The following parts of the PLCopen motion control definition are completely or partly included in this product:

- Part 1: Function blocks for motion control
- Part 2: Extensions
- Part 3: User Guidelines
- Part 4: Coordinated Motion
- Part 5: Homing Procedures

1.5.9.3.1 Programming guidelines

This chapter explains some rules on the usage of the libraries and the structure Axis_Ref.

- In general, the kernel function block and the transfer of axis IO data should be processed in a cyclic task. This task should be as short and real-time as possible to achieve the best motion control performance. Always make sure Kernel function block is called at the highest priority task and other applications must be at a lower priority task.
- If Axis_Ref is used as input on a user defined function block or program or function, always use it as VAR_IN_OUT and never use it as VAR_INPUT or VAR_OUTPUT. The reason is that this would
  - Break the consistency and destroy data.
  - Consume a lot of computing power by copying data.
- Any instance of a function block should be called only once per cycle and in only one specific task.

  If the instance is used in several tasks, it has to be checked that is not called several times.

  Because this could corrupt the handshake from function block to Axis_Ref to CMC_MOTION_KERNEL_REAL and vice versa.

- Some PLCopen function blocks are only allowed to be called within the same task as the CMC_MOTION_KERNEL_REAL function block. This is mentioned in the function block descriptions.
- If PLCopen function blocks are called from a different task, they cycle time should be at least 2 times the cycle time for CMC_MOTION_KERNEL_REAL function block is.

Axis data type Axis_Ref

The Axis_Ref is a structure that contains information on the corresponding axis. It is used as a VAR_IN_OUT in all Motion Control function blocks defined in this document. The content of this structure is implementation dependent and can ultimately be empty. If there are elements in this structure, the supplier shall support the access to them, but this is outside of the scope of this document. The refresh rate of this structure is also implementation dependent. According to IEC 61131-3 it is allowed to switch the Axis_Ref for an active function block, for instance from Axis1 to Axis2. However, the behavior of this can vary across different platforms, and is not encouraged to do.

Axis_Ref data type declaration:

TYPE Axis_Ref : STRUCT

(Content is implementation dependent)

END_STRUCT

Example:

TYPE Axis_Ref : STRUCT

AxisNo: UINT; AxisName: STRING (255);

…….

END_STRUCT

1.5.9.3.2 The single axis state diagram

The following diagram normatively defines the behavior of the axis at a high level when multiple motion control function blocks are simultaneously activated. This combination of motion profiles is useful in building a more complicated profile or to handle exceptions within a program. (In real implementations there may be additional states at a lower level defined). The basic rule is that motion commands are always taken sequentially, even if the PLC had the capability of real parallel processing. These commands act on the axis' state diagram.

The axis is always in one of the defined states (see diagram below). Any motion command that causes a transition changes the state of the axis and, as a consequence, modifies the way the current motion is computed. The single axis state diagram is an abstraction layer of what the real state of the axis is, comparable to the image of the I/O points within a cyclic (PLC) program. A change of state is reflected immediately when issuing the corresponding motion command.

The response time of immediately is system dependent, coupled to the state of the axis, or an abstraction layer in the software.

The diagram is focused on a single axis. The multiple axis function blocks, MC_CamIn, MC_GearIn and MC_Phasing, can be looked at, from a single axis state diagram point of view, as multiple single-axes all in specific states. For instance, the CAM-master can be in the state Continuous Motion. The corresponding slave is in the state Synchronized Motion. Connecting a slave axis to a master axis has no influence on the master axis.

The state Disabled describes the initial state of the axis. In this state the movement of the axis is not influenced by the function blocks. The axis feedback is operational. If the MC_Power function block is called with Enable=TRUE while being in state Disabled, this either leads to Standstill if there is no error inside the axis, or to ErrorStop if an error exists.

Calling MC_Power with Enable=FALSE in any state, the axis goes to the state Disabled, either directly or via any other state. If a motion generating function block controls an axis, while the MC_Power function block with Enable=FALSE is called, the motion generating function block is aborted (CommandAborted).

The intention of the state ErrorStop is that the axis goes to a stop, if possible. There are no further inputs from function blocks accepted until a reset has been done from the ErrorStop state.

The transition Error refers to errors from the axis and axis control, and not from the function block instances. These axis errors may also be reflected in the output of the function blocks instances errors.

Issuing MC_Home in any other state than StandStill will go to ErrorStop, even if MC_Home is issued from the state Homing itself.

Function blocks which are not listed in the single axis state diagram do not affect the state of the axis, meaning that whenever they are called the state does not change. They are:

MC_ReadStatus; MC_ReadAxisError; MC_ReadParameter; MC_ReadBoolParameter; MC_WriteParameter; MC_WriteBoolParameter; MC_ReadActualPosition and MC_CamTable-Select.

Calling the function block MC_Stop in state StandStill changes the state to Stopping and back to Standstill when Execute = FALSE. The state Stopping is kept as long as the input Execute is TRUE. The output Done is set when the stop ramp is finished.

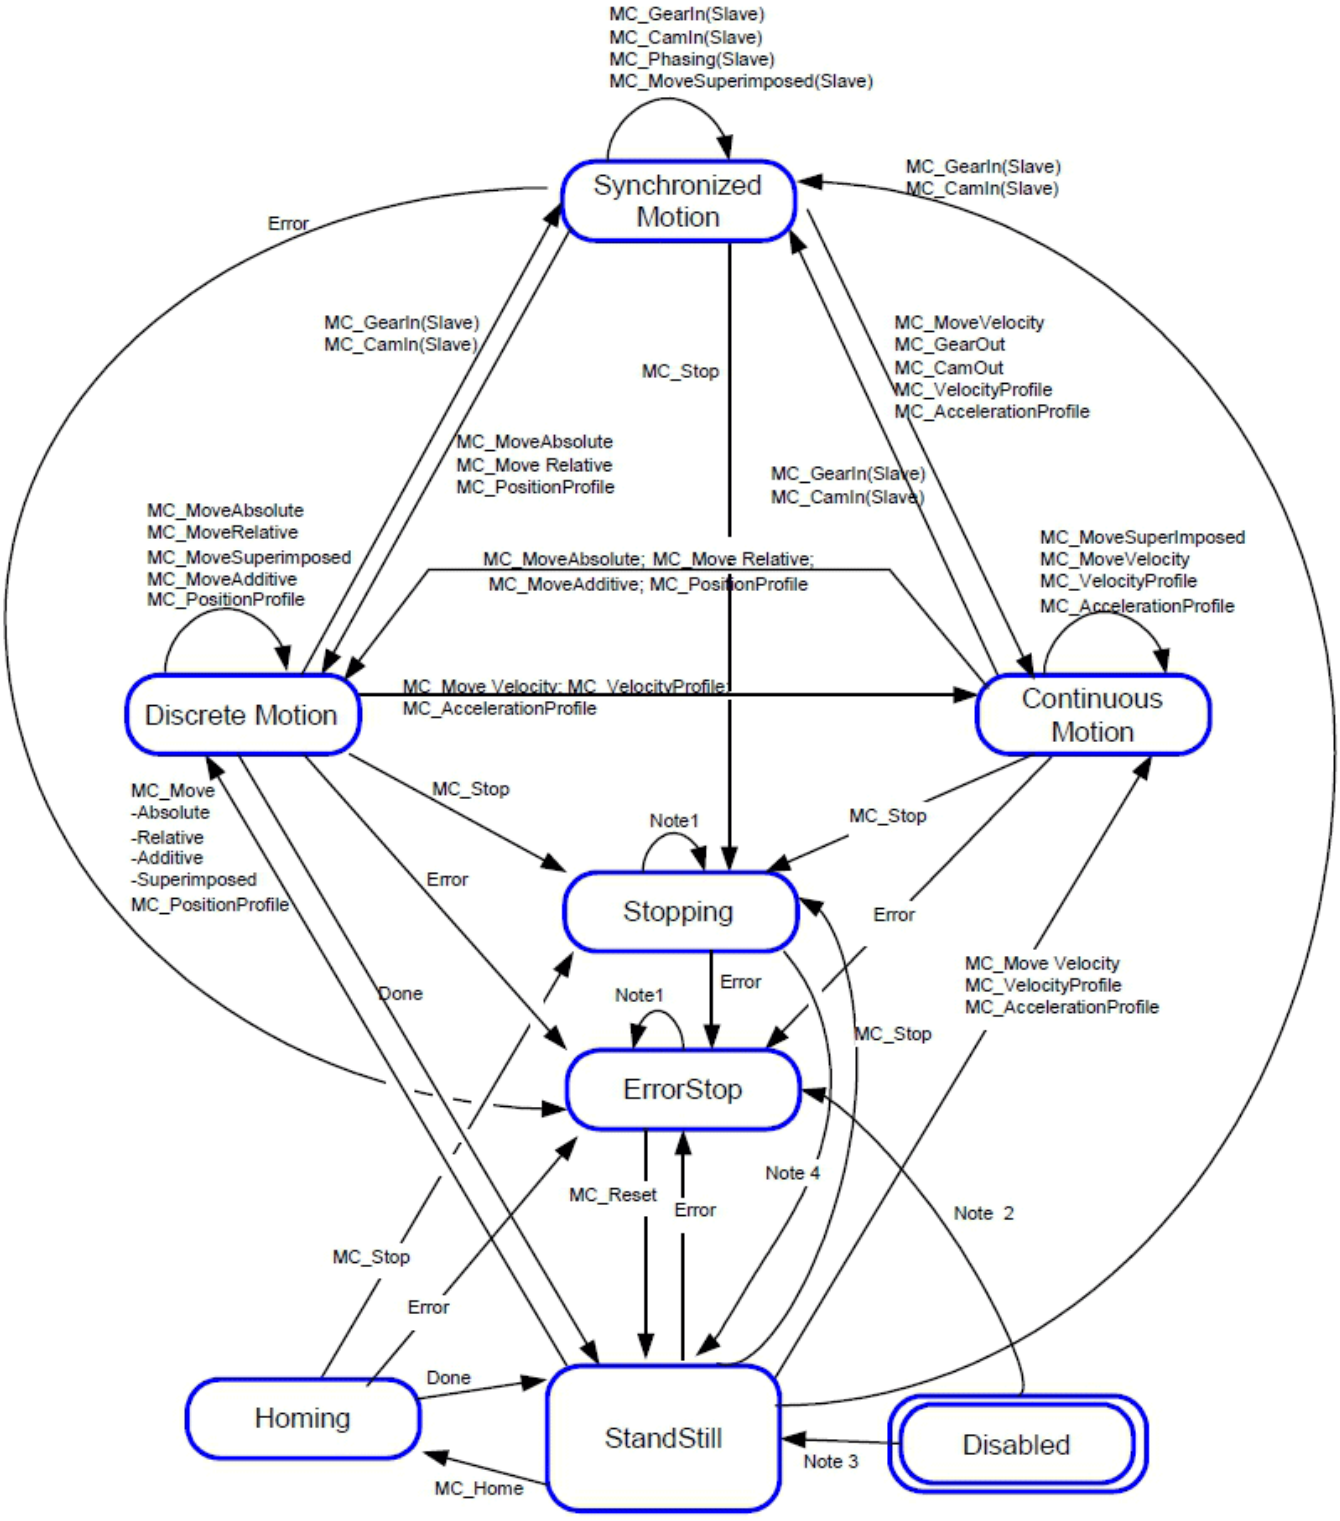

Fig. 207: Function block state behavior

1. In this state ErrorStop or Stopping, all function blocks can be called, although they will not be executed, except MC_Reset and Error – they will generate the transition to StandStill or ErrorStop respectively.

2. Power.Enable=TRUE and there is an error in the Axis.

3. Power.Enable=TRUE and there is no error in the Axis.

4. MC_Stop.Done AND NOT MC_Stop.Execute.

1.5.9.3.3 Visualizations

For usage with the PLCopen Library, a set of visualization objects is defined. These visualizations use the placeholder concept, which means that they could be used in an actual visualization several times and be instantiated by replacing the “placeholder” with an effective data-structure.

Two types of visualizations exist:

- As placeholder, an instance of Axis_Ref should be used. These are named: MC_VISU_Axis_name.
- As placeholder, an instance of the respective PLCopen function block should be used. These visualizations are named MC_VISU_FB_name where "name" could be MoveAbsolute or MoveVelocity, so the complete element is named MC_VISU_FB_MoveAbsolute or MC_VISU_FB_MoveVelocity.

The background colour and the colour for the title of each element could be changed. The colours are defined in some global predefined variables in MC_VISU_COLOR_INFORMATION. By changing these values, different colours will be used.

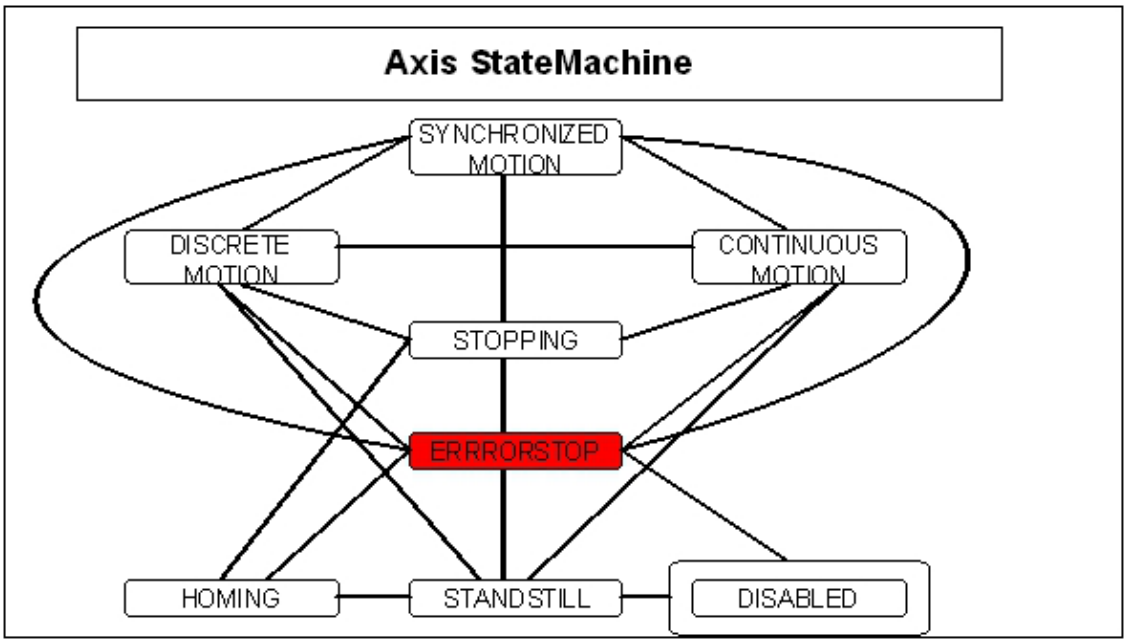
```
VAR_GLOBAL
    MC_VISU_BACKGROUND_COLOR:DWORD:=16#8080;
    MC_VISU_TITLE_COLOR:DWORD:=16#80FFFF;
END_VAR
```

Below, some existing visualizations are shown.

MC_VISU_Axis_StateMachine

This shows the state machine of the axis according to PLCopen definition. The active state is shown green except the ErrorStop which is shown red. Usually, it starts with Disabled. When no remote connection to the drive is available, it will switch to ErrorStop immediately.

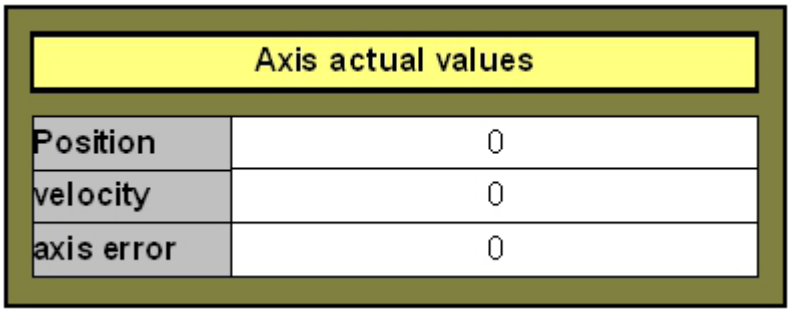
The placeholder of this visualization has to be connected to an instance of the data type Axis_Ref.



MC_VISU_Axis_actual

This object shows some actual values.

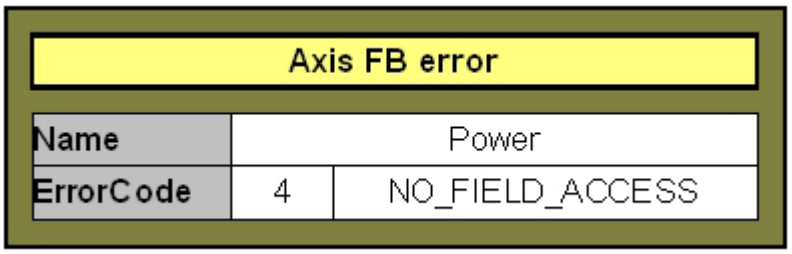
The Placeholder of this visualization has to be connected to an instance of the data type Axis_Ref.



MC_VISU_Axis_FB_error

This object shows the error information connected to the PLCopen function blocks. This is NOT a drive error. If no error occurs in the execution of a function block, just the name is shown. If an error occurred, it shows the name of the function block as well as the error number and a short description. In the example below, the MC_Power function block recognized that no fieldbus connection to the drive was available.

The Placeholder of this visualization has to be connected to an instance of the data type Axis_Ref.



1.5.9.3.4 Error codes

Besides the diagnosis information of the drive which is described in the respective drive documentation, there are a number of error codes directly related to the function blocks. These error codes are displayed at the output “ErrorID” of the function block.

Error Code	Mnemonic	Explanation
0	MC_Ok	No Error
1	WRONG_STATE	A function block was activated not according to the state machine, e.g. tried to start a movement while in state Disabled.
2	DRIVE_PROBLEM	The drive indicates an error, e.g. tripped.
3	PARAM-ETER_EXCEEDS_LIMIT	A parameter at the function block is outside the possible range. This does not refer to the parameter range which is allowed for the drive but just to the 32-Bit Integer which is used for internal calculation.
4	NO_FIELD_ACCESS	No fieldbus connection to the drive.
5	BUS_PROBLEM	Not used
6	ABS_SWITCH_ERROR	During Homing, (when done by function blocks) limit switch not according to moving direction e.g. the positive switch occurred when moving in negative direction.
7	TIMEOUT	Timeout in block execution.

Error Code	Mnemonic	Explanation
8	NAK	Parameter access not applicable
9	MC_TimeLimitExceeded	Used by function blocks with TimeLimit.
10	MC_DistanceLimitExceeded	Used by function blocks with DistanceLimit.
11	MC_TorqueLimitExceeded	Used by function blocks with TorqueLimit.
12	NOT_IMPLEMENTED	Functionality not implemented for certain axis type.

1.5.9.3.5 Error handling

All access to the drive/motion control is via function blocks. Internally these function blocks provide basic error checking on the input data. Exactly, how this is done is implementation dependent. For instance, if MaxVelocity is set to 6000, and the Velocity input to a function block is set to 10,000, a basic error report is generated. In the case where an intelligent drive is coupled via a network to the system, the MaxVelocity parameter is probably stored on the drive. The function block must take care of the errors generated by the drive internally. With another implementation, the MaxVelocity value could be stored locally. In this case the function block will generate the error locally.

Both centralized and decentralized error handling methods are possible when using the motion control function blocks.

Centralized error handling is used to simplify programming of the function block. Error reaction is the same independent of the instance in which the error has occurred.

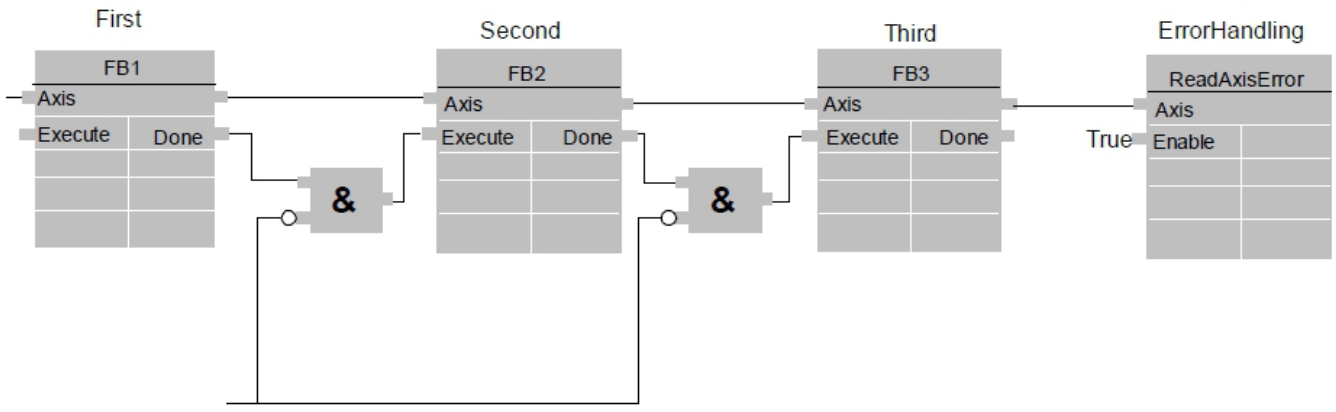


Fig. 208: Function blocks with centralized error handling

Decentralized error handling gives the possibility of different reactions depending on the function block in which an error occurred.

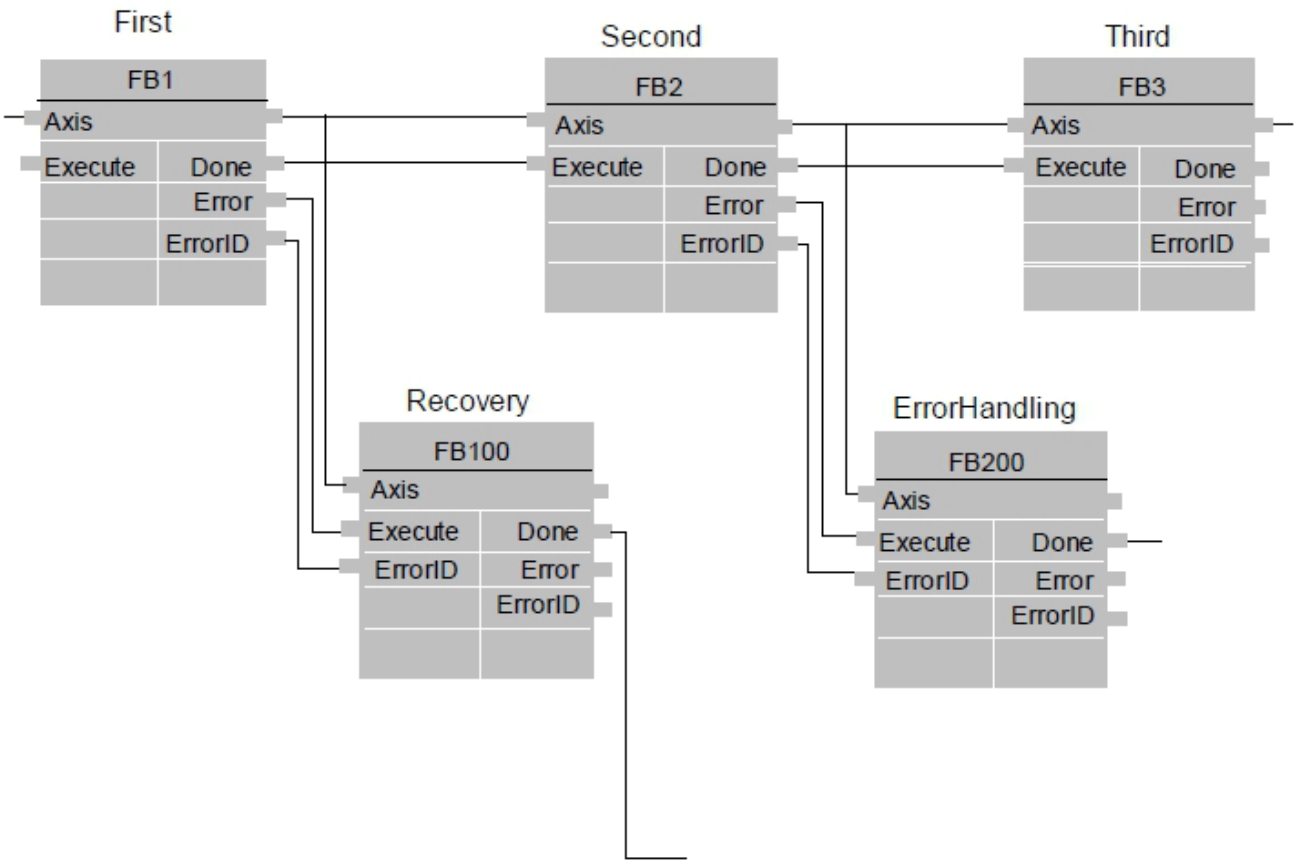

Fig. 209: function blocks with decentralized error handling

1.5.9.3.6 PLCopen parameter

Additional parameters are available by ReadParameter and WriteParameter function blocks.

Please see the following function blocks to read and write parameters:

- *MC_ReadParameter*
  Chapter 1.5.9.6.3.6 “MC_ReadParameter” on page 2844
- *MC_WriteParameter*
  Chapter 1.5.9.6.3.8 “MC_WriteParameter” on page 2848
- *MC_ReadBoolParameter*
  Chapter 1.5.9.6.3.7 “MC_ReadBoolParameter” on page 2846
- *MC_WriteBoolParameter*
  Chapter 1.5.9.6.3.9 “MC_WriteBoolParameter” on page 2850

Parameter number (PN)	Name	Datatype	Min.	Max.	Default	R/W	Comments
1	CommandedPosition	DINT				R	Commanded position.
2	SWLimitPos	DINT	-2147483647	2147483647	2147483647	R/W	Positive Software limit switch position.

INC_PER_R * U_PER__REV_DENOMINATOR /U_PER_REV_NOMINATOR	xxx	3276	The resolution could not be higher than 3276 INC/u.

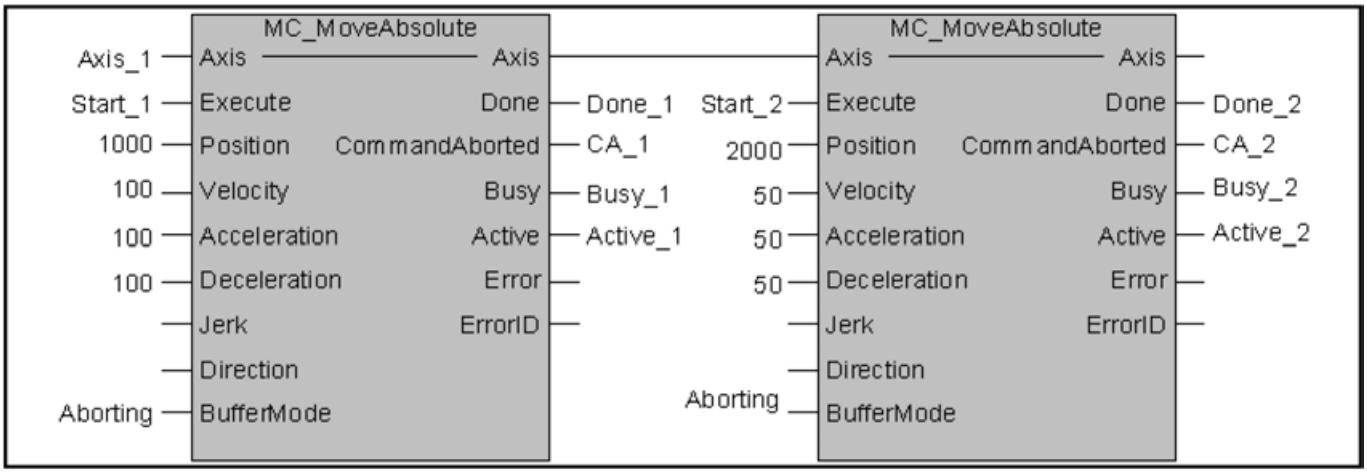
Table 164: Limitations for the inputs of PLCopen function blocks when used with CMC_MOTION_KERNEL_REAL

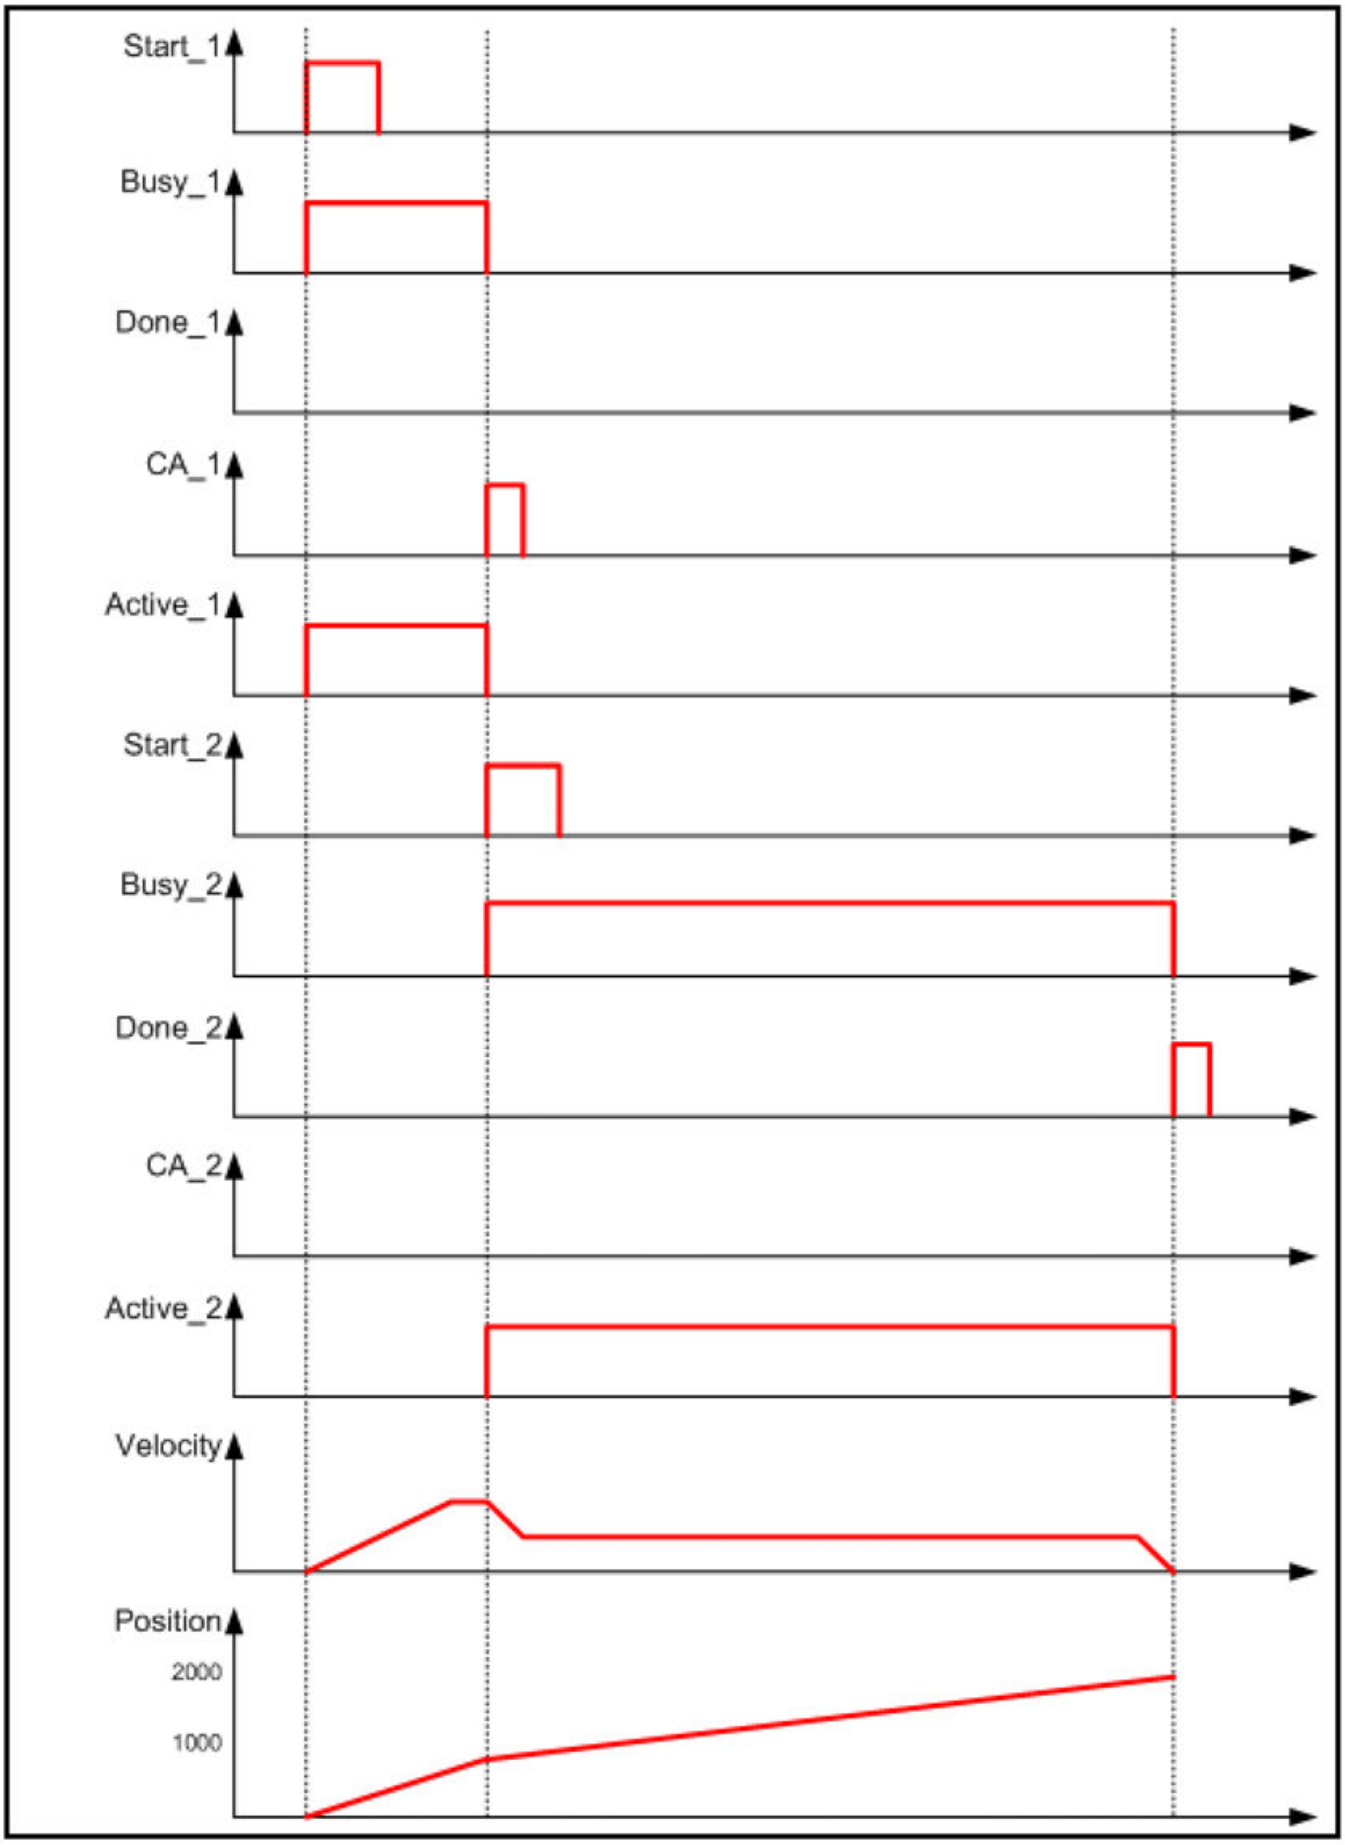
Parameter	Min.	Max.
Velocity	x	x
Acceleration, Deceleration	1	x
Position	-2147483647	2147483647

1.5.9.3.8 General restrictions

Restrictions for the available function blocks

- As buffered mode, MC_Aborting is realized as a default. This does NOT mean that the axis stops when another movement is started while an ongoing movement is still active. It means instead that the new movement will take control immediately and change the velocity to its own velocity by using its own acceleration or deceleration.
- The buffered mode MC_Buffered could be reached with using the axis state StandStill as enable signal for the Execute of the next block.
- From the Extended Inputs and Outputs at the function blocks, the following are not realized:
  - BufferedMode: The realization just supports the MC_Aborting mode.
  - The following Outputs at ReadStatus are not supported: ConstantVelocity, Accelerating and Decelerating.
  - TorqueLimit for Homing function blocks.





Start_1
Busy_1
Done_1
CA_1
Active_1
Start_2
Busy_2
Done_2
CA_2
Active_2
Velocity
Position
2000
1000

MC_Aborting Mode The diagram shows the behavior with BufferMode MC_Aborting, which is the only available BufferMode. When the second Block is activated, it will take control and will continue on its own velocity. The velocity is changed by using the acceleration value from the second function block. The movement will not be stopped in between. The first function block shows CommandAborted when the second function block is activated.

MC_Buffered A behavior according to BufferMode MC_Buffered could be reached by using the Done output from the first function block to enable the Execute of the second function block.

1.5.9.3.9 Behavior of the function block inputs and outputs

General rules

Table 165: General rules

Output exclusivity	The outputs Busy, Done, Error, and CommandAborted are mutually exclusive: Only one of them can be TRUE on one function block. If Execute is TRUE, one of these outputs has to be TRUE. Only one of the outputs Active, Error, Done and CommandAborted is set at the same time.
Output status	The outputs Done, InGear, InSync, InVelocity, Error, ErrorID and CommandAborted are reset with the falling edge of Execute. However, the falling edge of Execute does not stop or even influence the execution of the actual function block. It must be guaranteed that the corresponding outputs are set for at least one cycle if the situation occurs, even if execute was reset before the function block completed. If an instance of a function block receives a new execute before it has finished (as a series of commands on the same instance), the function block will not return any feedback, like Done or CommandAborted, for the previous action.
Input parameters	The parameters are used with the rising edge of the execute input. To modify any parameter, it is necessary to change the input parameter(s) and to trigger the motion again.
Missing input parameters	According to IEC 61131-3, if any parameter of a function block input is missing (open) then the value from the previous invocation of this instance will be used. In the first invocation the initial value is applied.
Position versus distance	Position is a value defined within a coordinate system. Distance is a relative measure related to technical units. Distance is the difference between two positions.
Sign rules	Velocity, Acceleration, Deceleration and Jerk are always positive values. Position and Distance can be both positive and negative.
Error Handling Behavior	All function blocks have two outputs, which deal with errors that can occur while executing that function block. These outputs are defined as follow:
	Error Rising edge of Error informs that an error occurred during the execution of the function block. ErrorID: Error number

	The outputs Done, InVelocity, InGear, and InSync mean successful completion so these signals are logically exclusive to Error. Types of errors: ● Function blocks (e.g. parameters out of range, state machine violation attempted), ● Communication, ● Drive Instance errors do not always result in an axis error (bringing the axis to StandStill). The error outputs of the relevant function block are reset with falling edge of Execute.
Function block naming	In case of multiple libraries within one system (to support multiple drive/ motion control systems), the function block naming may be changed to MC_FunctionBlockName_SupplierID.
Behavior of Done output	The outputs Done, InGear, InSync... are set when the commanded action has been completed successfully. With multiple function blocks working on the same axis in a sequence, the following applies: When one movement on an axis is interrupted with another movement on the same axis without having reached the final goal, Done of the first function block will not be set.
Behavior of CommandAborted output	CommandAborted is set, when a commanded motion is interrupted by another motion command. The reset-behavior of CommandAborted is like that of Done. When CommandAborted occurs, the other output-signals such as **InVelocity** are reset.
Inputs exceeding application limits	If a function block is commanded with parameters which result in a violation of application limits, the instance of the function block generates an error. The consequences of this error for the axis are application specific and thus should be handled by the application program.
Behavior of Busy output	Every function block can have an output Busy, reflecting that the function block is not finished. Busy is SET at the rising edge of Execute and RESET when one of the outputs Done, Aborted, or Error is set. It is recommended that this function block should be kept in the active loop of the application program for at least as long as Busy is true, because the outputs may still change. For one axis, several function blocks might be busy, but only one can be active at a time. Exceptions are MC_SuperImposed and MC_Phasing, where more than one function block related to one axis can be active.
Output **Active**	The output Active is required on buffered function blocks. This output is set at the moment the function block takes control of the motion of the according axis. For un-buffered mode the outputs Active and Busy can have the same value.
Enable and Valid/Status	The input Enable is coupled to output Valid. Enable is level sensitive, and Valid shows that a valid set of outputs is available at the function block. The output Valid is TRUE as long as an output value of Valid is available and the input Enable is TRUE. The relevant output value can be refreshed as long as the input Enable is TRUE. If there is a function block error, the output is not Valid (Valid set to FALSE). When the error condition disappears, the values will reappear and output Valid will be set again.

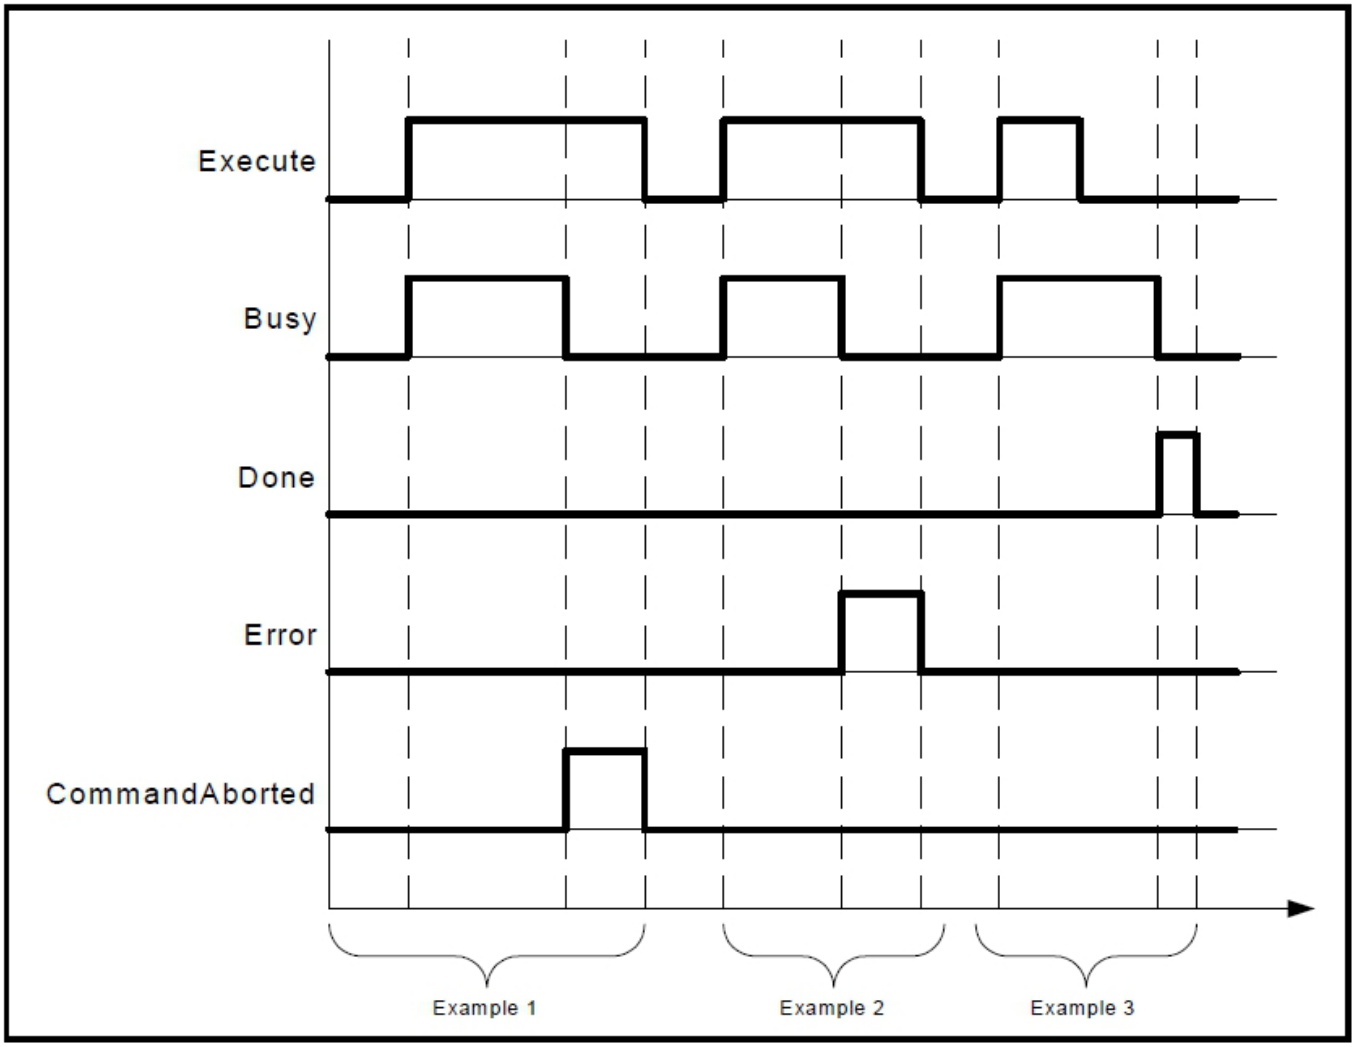


Fig. 210: Behavior of the Execute/Done style function blocks.

Why is the command input edge sensitive?

The input Execute for the different function blocks described in this document always triggers the function with its rising edge. The reason for this is that with edge triggered Execute new input values may be commanded during execution of a previous command. The advantage of this method is a precise management of the instant a motion command is performed. Combining different function blocks is then easier in both centralized and decentralized models of axis management. The output Done can be used to trigger the next part of the movement. The example given below is intended to explain the behavior of the function block execution.

The following figure illustrates the sequence of three function blocks First, Second and Third controlling the same axis. These three function blocks could be for instance various absolute or relative move commands. When First is completed the motion its rising output First.Done triggers Second.Execute. The output Second.Done AND In13 triggers the Third.Execute.

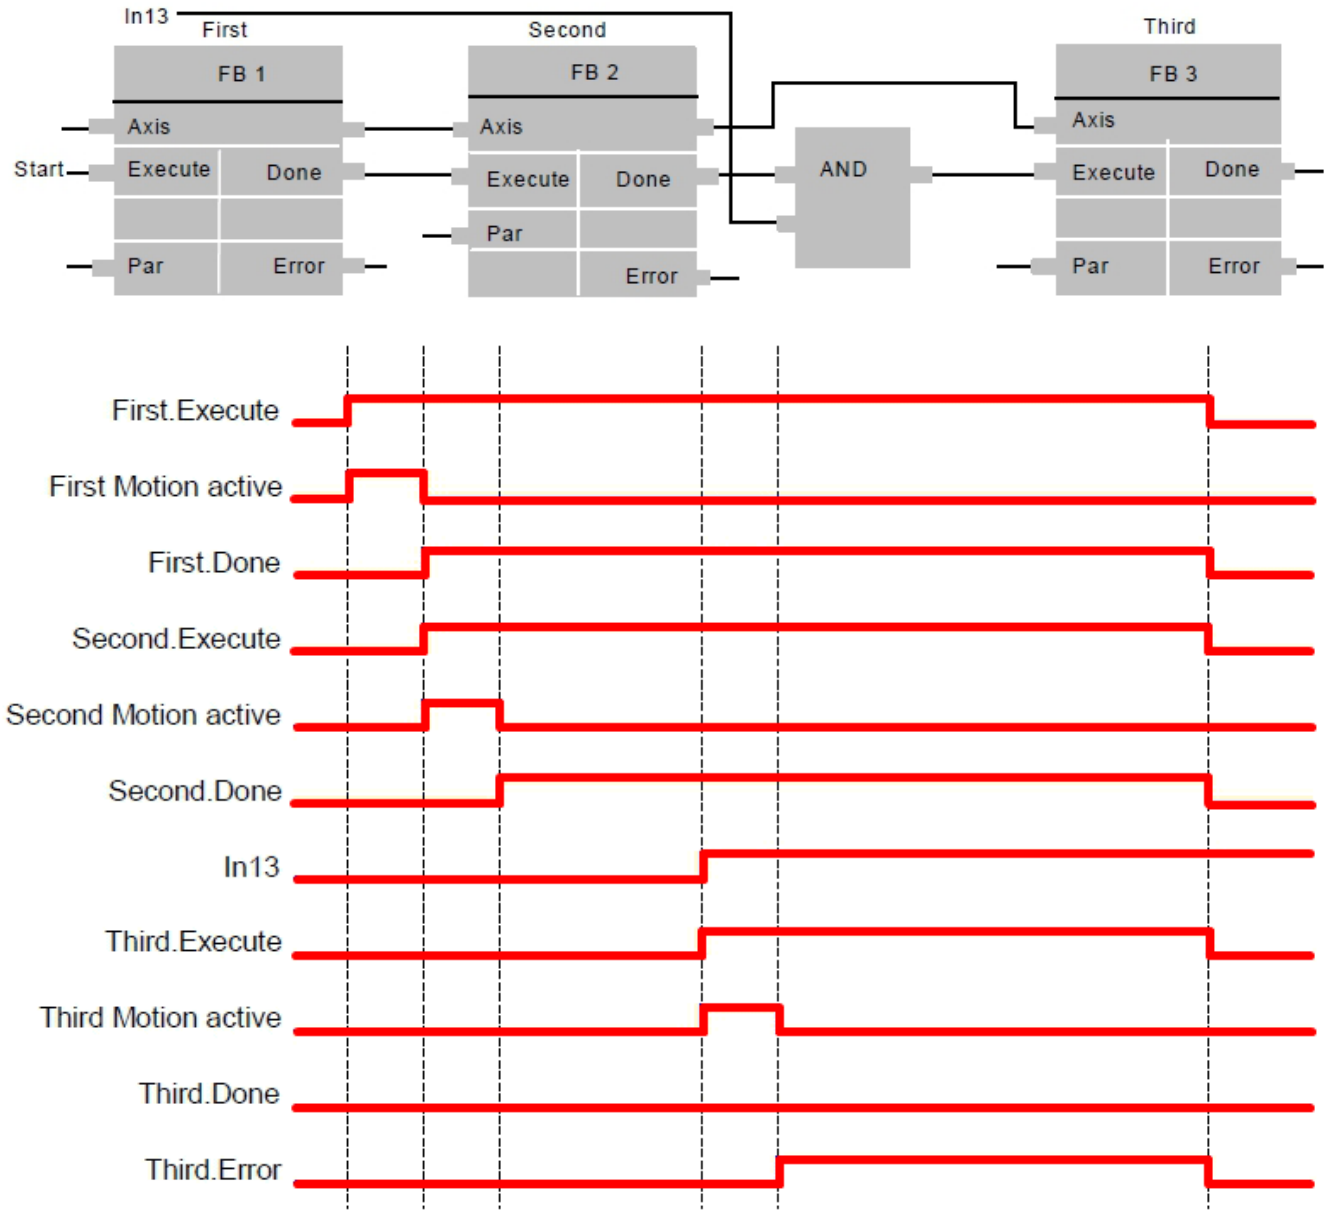

Fig. 211: Function blocks to perform a complex movement

The input ContinuousUpdate

Like described in the previous chapter, the input Execute triggers a new movement. With a rising edge of this input the values of the other function block inputs are defining the movement. Until version 1.1 of PLCopen there was the general rule that a later change in these input parameters does not affect the ongoing motion.

Nevertheless, there are numerous application examples, where a continuous change of the parameters is needed. The user could retrigger the input Execute of the function block, but this complicated the application.

Therefore, the input ContinuousUpdate has been introduced. It is an extended input to all applicable function blocks. If it is TRUE, when the function block is triggered (rising Execute), it will - as long as it stays TRUE – make the function block use the current values of the input variables and apply it to the ongoing movement. This does not influence the general behavior of the function block nor does it impact the single axis state diagram. In other words it only influences the ongoing movement and its impact ends as soon as the function block is no longer Busy or the input ContinuousUpdate is set to FALSE.

It can be that certain inputs like BufferMode are not really intended to change every cycle. However, this has to be dealt with in the application, and is not forbidden in the specification

If ContinuousUpdate is FALSE with the rising edge of the input Execute, a change in the input parameters is ignored during the whole movement and the original behavior of previous versions is applicable. The ContinuousUpdate is not a retriggering of the input Execute of the function block. A retriggering of a function block which was previously aborted, stopped, or completed, would regain control on the axis and modify its single axis state diagram. Opposite to this, the ContinuousUpdate only effects an ongoing movement. Also, a ContinuousUpdate of relative inputs (e.g. Distance in MC_MoveRelative) always refers to the initial condition (at rising edge of Execute).

Example

- MC_MoveContinuousRelative is started at Position 0 with Distance 100, Velocity 10 and ContinuousUpdate set TRUE. Execute is Set and so the movement is started to position 100.
- While the movement is executed (let the drive be at position 50), the input Distance is changed to 130, Velocity 20.
- The axis will accelerate (to the new Velocity 20) and stop at Position 130 and set the output Done and does not accept any new values.

1.5.9.3.10 Unit of length

The only specification for physical quantities is made on the unit of length (noted as [u]) that is to be coherent with its derivatives i.e. (velocity [u/s]; acceleration [u/s^2]; jerk [u/s^3]). Nevertheless, the unit [u] is not specified (manufacturer dependent). Only its relations with others are specified.

1.5.9.3.11 Aborting versus buffered modes

Some of the function blocks have an input called BufferMode. With this input, the function block can either work in a Non-buffered mode (default behavior) or in a Buffered mode. The difference between those modes is when they should start their action:

- A command in a non-buffered mode acts immediately, even if this interrupts another motion,
- A command in a buffered mode waits till the current function block sets its output Done (or InPosition, InVelocity...).
- The library just supports the mode "aborting" (MCAborting)

The following examples describe the different behavior of these modes:

Example 1: Standard behavior of two following absolute movements

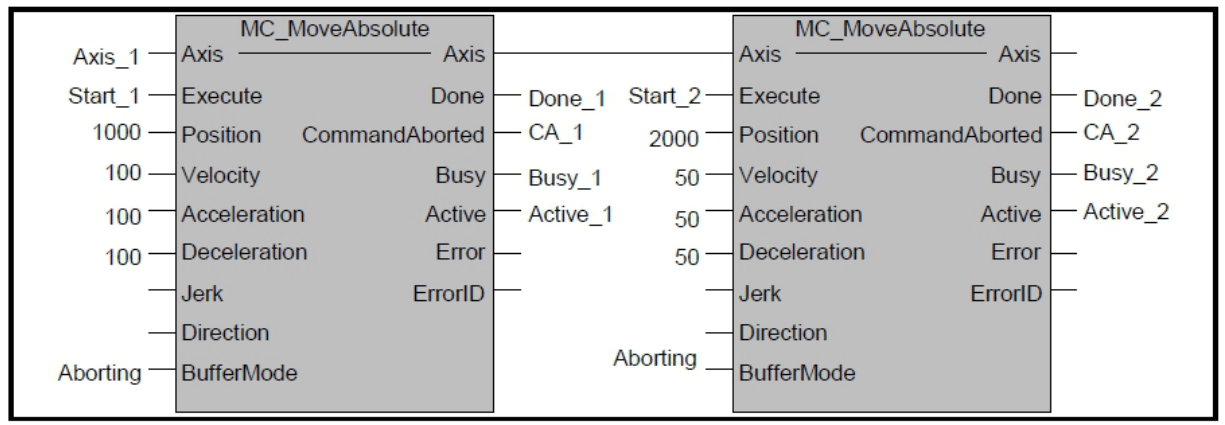

Fig. 212: Basic example with two MC_MoveAbsolute on same axis

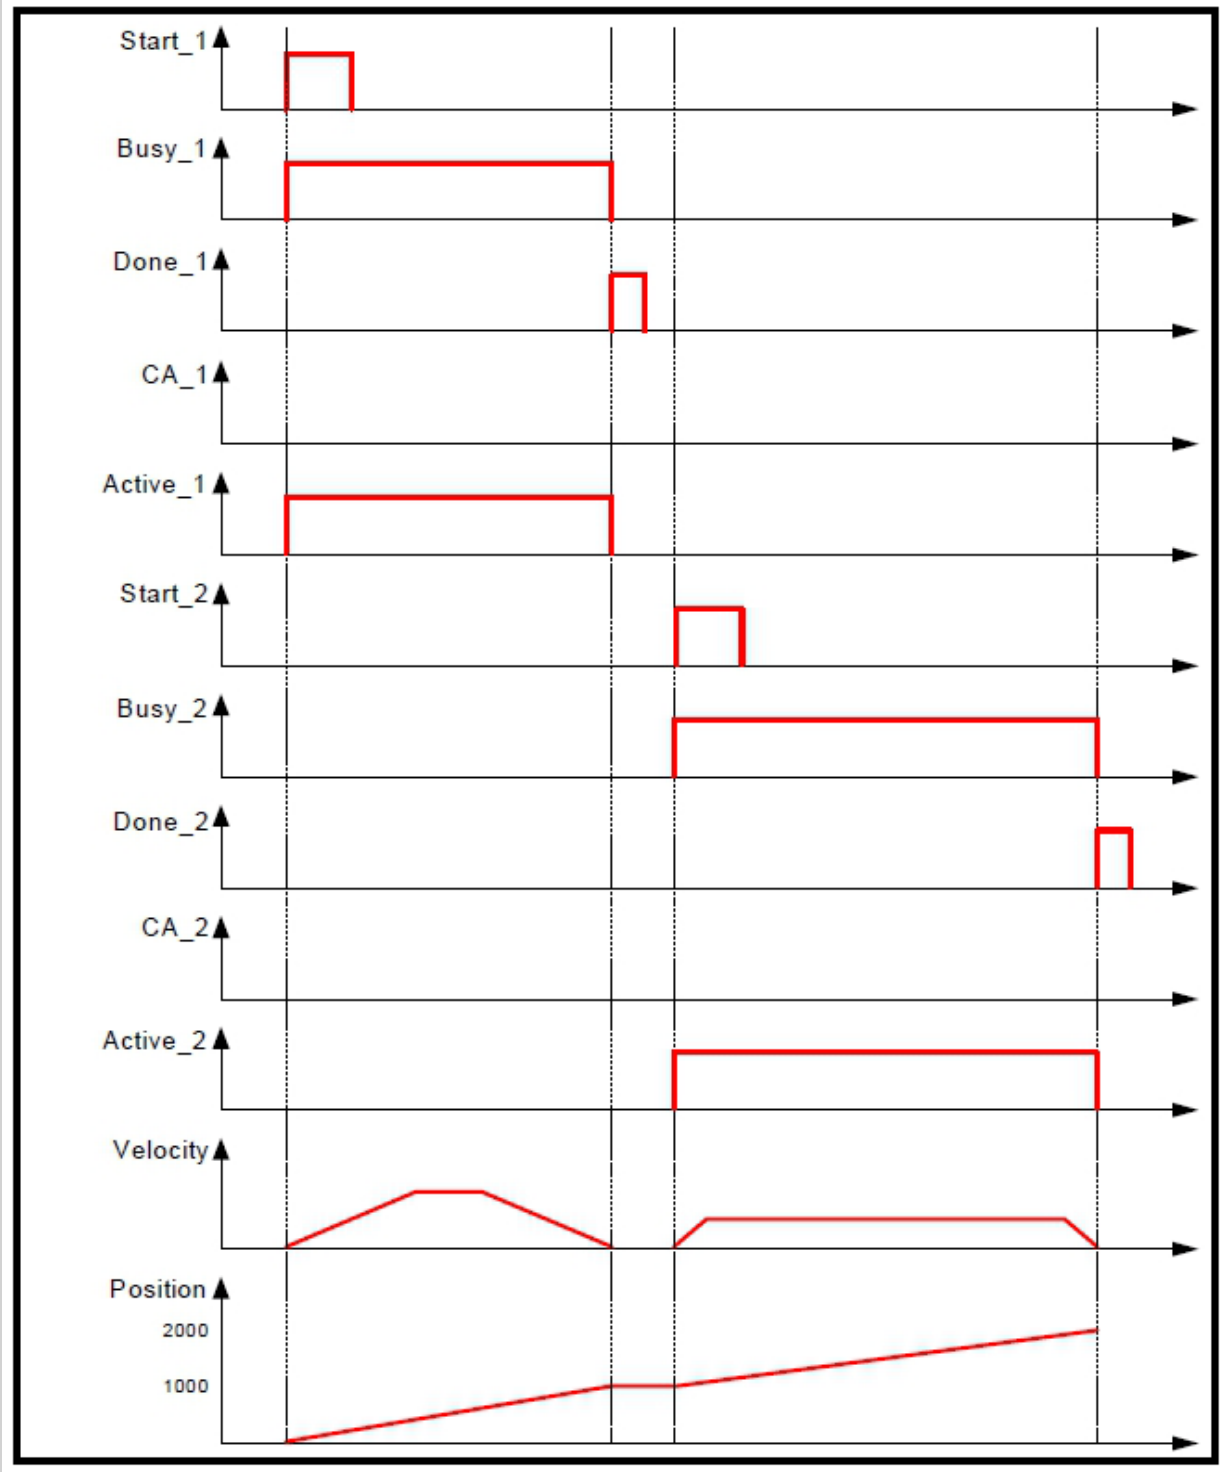

Fig. 213: Timing diagram for example above without interference between function block 1 and function block 2

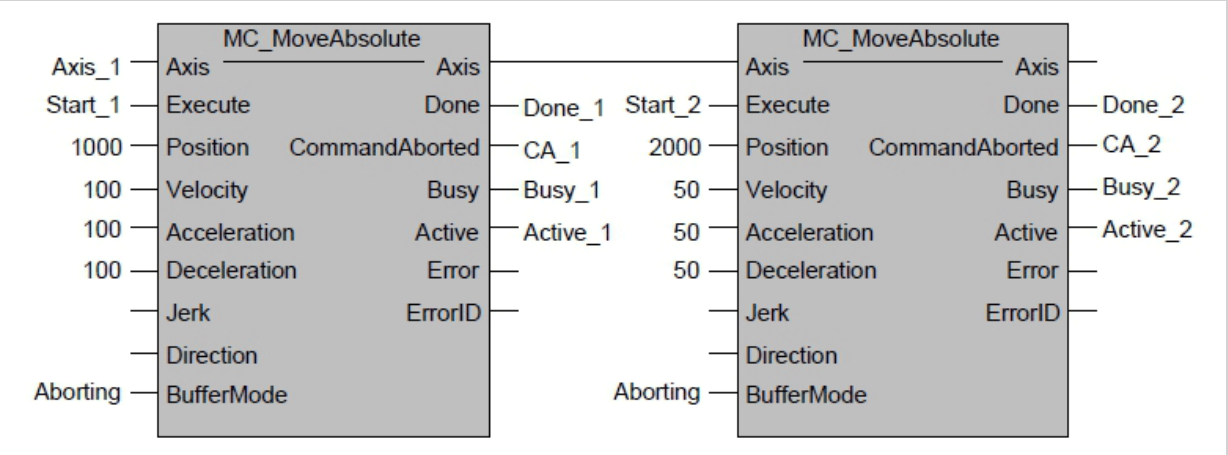
Example 2: Aborting motion



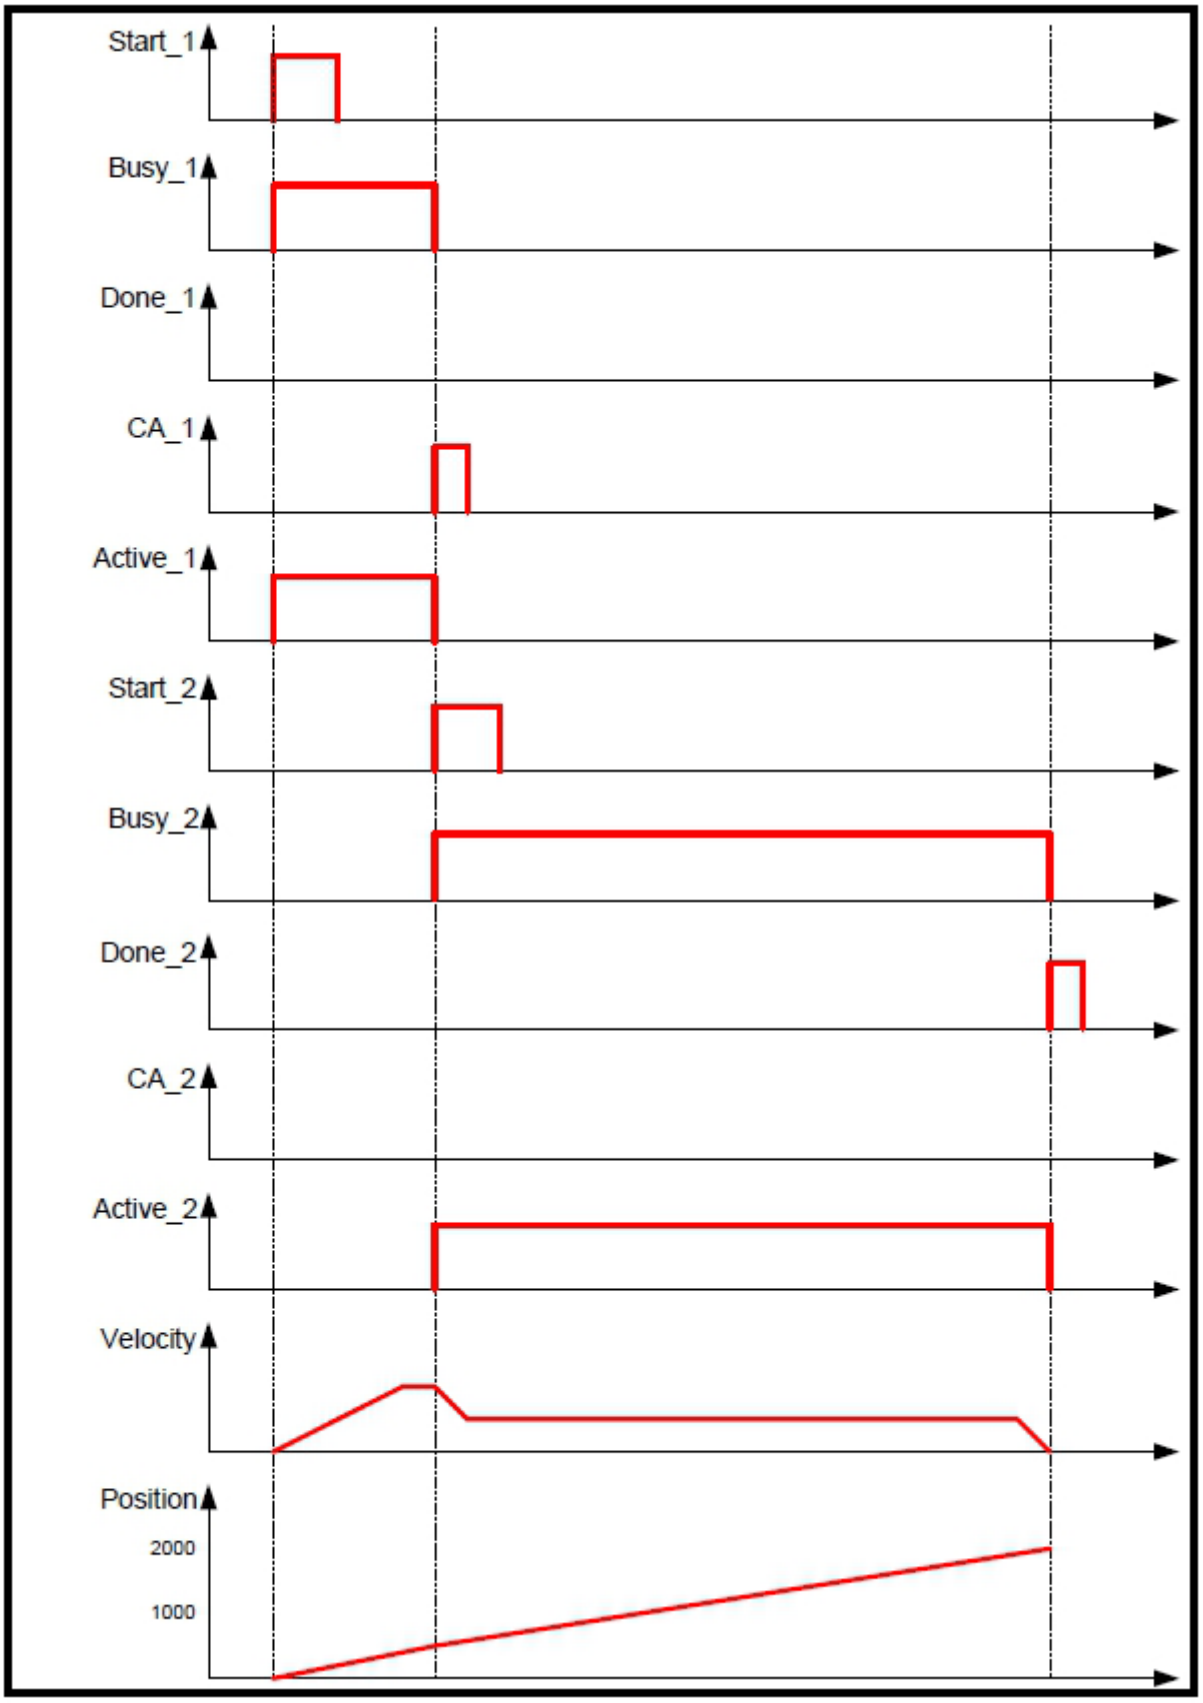


Fig. 214: Timing diagram for example above with function block 2 interrupting function block 1 (McAborting Mode)

If an on-going motion is aborted by another movement, it can occur that the braking distance is not sufficient due to deceleration limits.

In rotary axis, a modulo can be added. A modulo axis could go to the earliest repetition of the absolute position specified, in cases where the axis should not change direction and reverse to attain the target position.

In linear systems, the resulting overshoot can be resolved by reversing, as each position is unique and therefore there is no need to add a modulo to reach the correct position..

1.5.9.3.12 PLCopen examples

Example: A function block instance controls different motions of an axis

The following figure shows an example where the function block (MC_MoveVelocity) is used to control AxisX with three different values of Velocity. In a Sequential Function Chart (SFC) the velocity 10, 20, and 0 is assigned to V. To trigger the input Execute with a rising edge the variable E is stepwise set and reset.

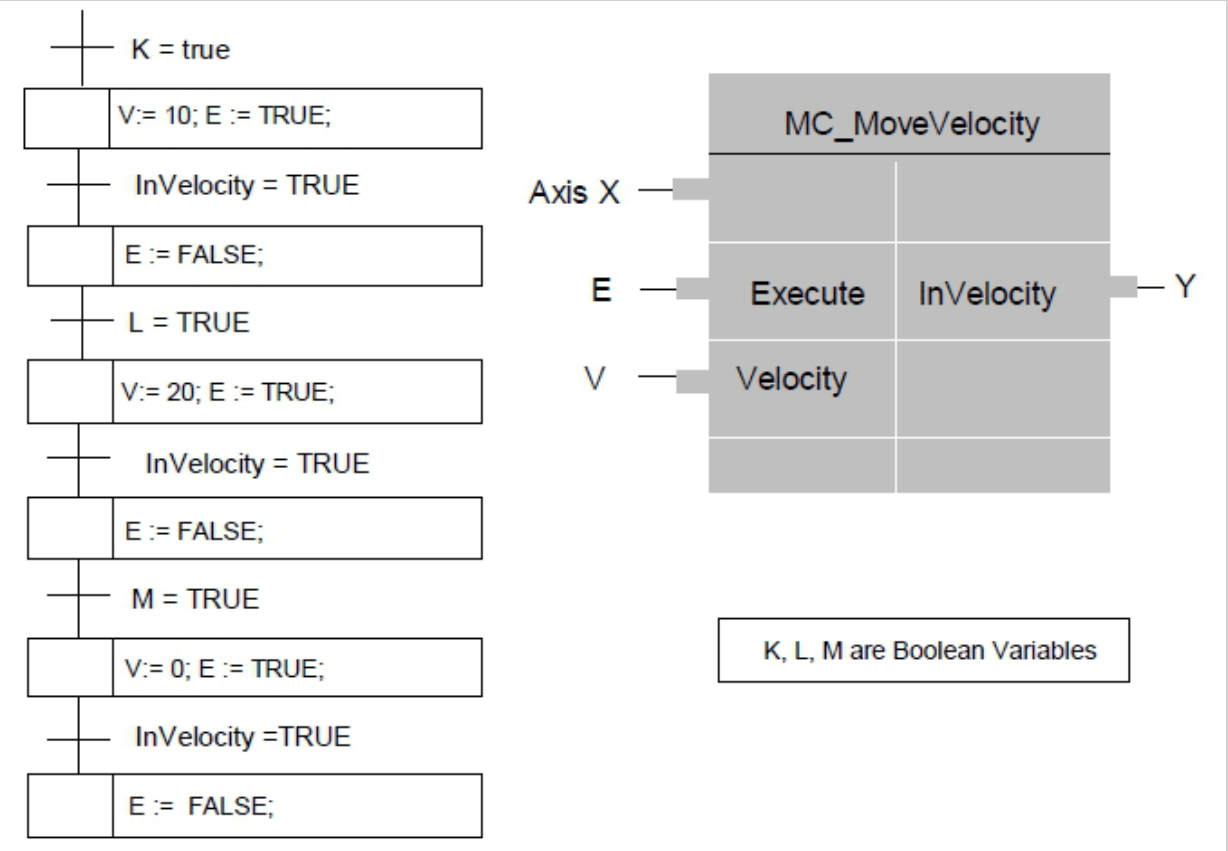

Fig. 215: Single function block with SFC

The following timing diagram explains how it works:

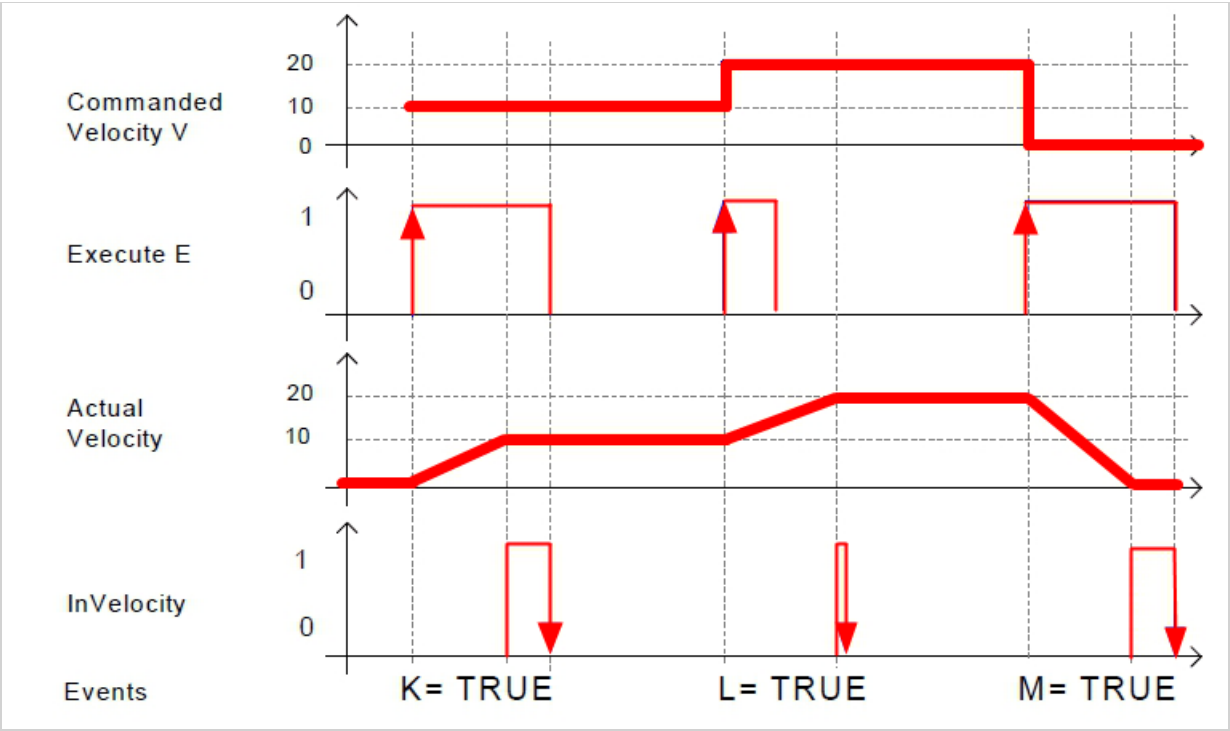

Fig. 216: Timing diagram for a usage of single function block

The second InVelocity is set for only one cycle because the Execute has gone low before the ActualVelocity equals CommandedVelocity.

Example: Different function blocks instances control the motions of an axis

Different instances related to the same axis can control the motions on an axis. Each instance will then be responsible for one part of the global profile.

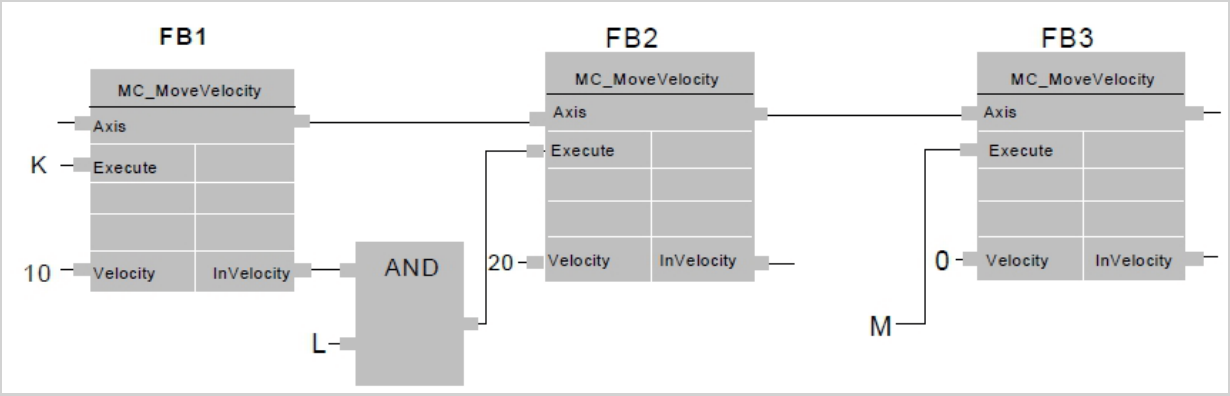

Fig. 217: Cascaded function blocks

The timing diagram:

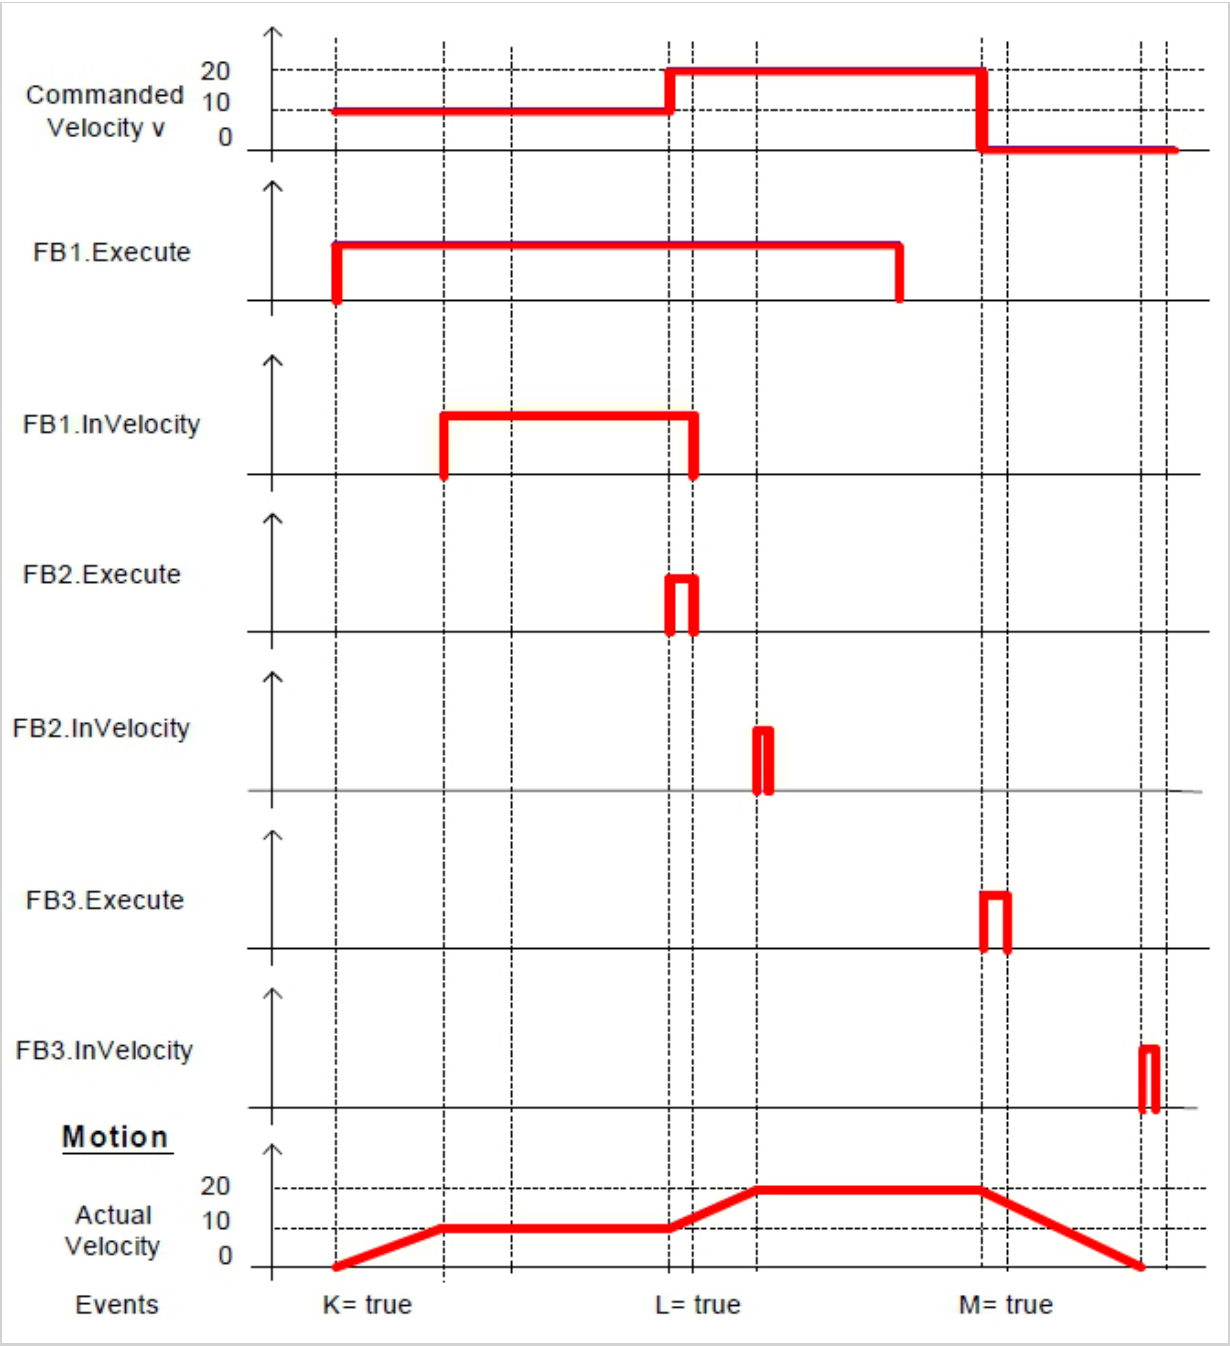

Fig. 218: Cascaded function blocks timing diagram

A corresponding solution written in LD looks like:

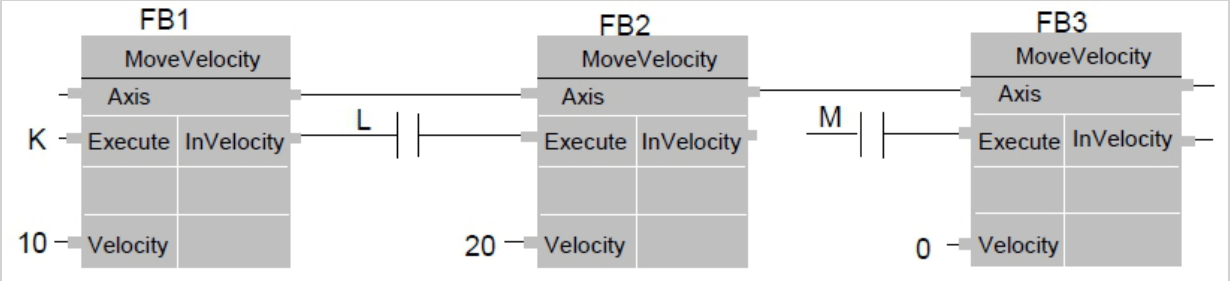

Fig. 219: Cascaded function blocks with LD

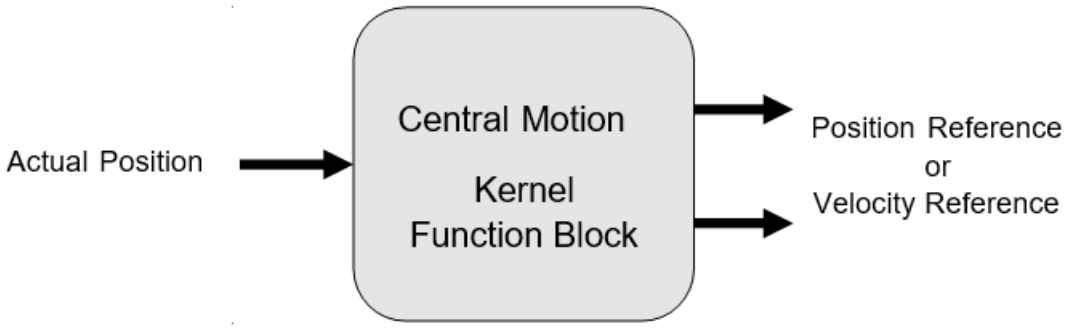
1.5.9.4 PLC-based motion control

1.5.9.4.1 Central Motion Control Architecture

The implementation of an axis for central Motion Control in the AC500 PLC is done by the use of the function blocks from the Compact Motion library file (CompactMotionControl_AC500_V12.lib).

With the function blocks of Compact Motion Control a Motion Control profiler can be used inside the PLC. As shown in the following figure it is needed to provide the actual position of the drive. The output can be either a position or a velocity reference signal. The used output signal will then be used to move the axis in the desired way.



There are 2 possibilities to send a reference value to the drive:

- When the position control loop is closed by the PLC by a CMC_MOTION_KERNEL_x function block, the output Speed_Reference should be connected to the drive. The value of Speed_Reference can be scaled with the axis parameters Max_Rpm and MAX_REFERENCE.
- When the position control loop is closed by the drive, the output Position_Reference should be connected to the drive. The unit for the output Position_Reference is incremented as well as the input Drive_ActualPosition.

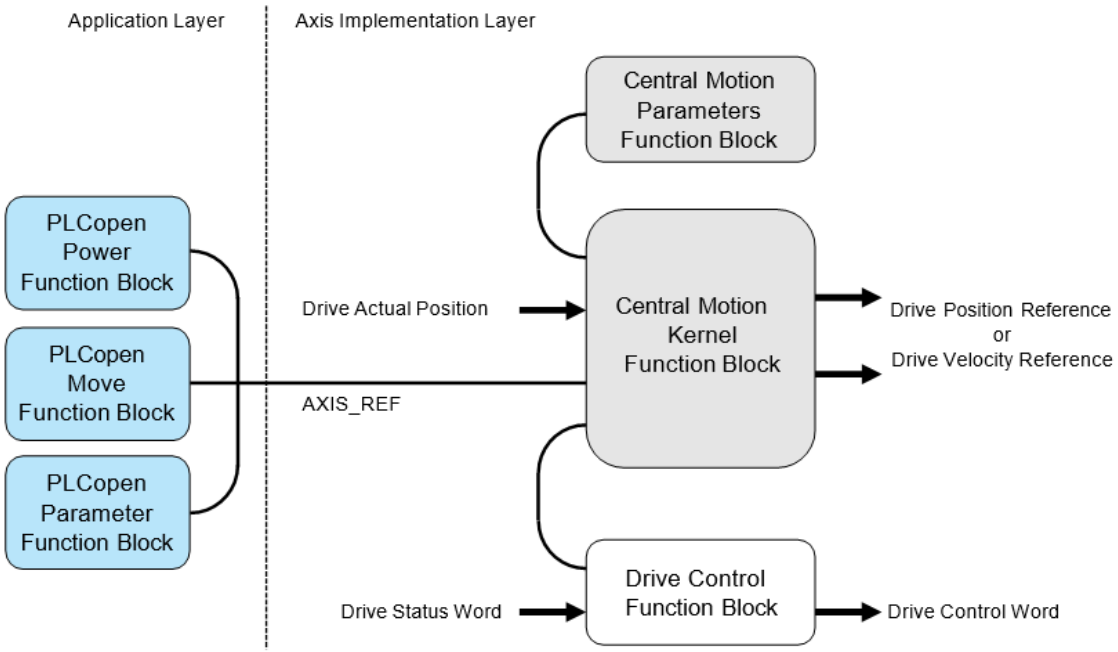


Fig. 220: Architecture for centralized motion control

In general the programming of a machine consists of two layers as shown in the figure above.

In the application layer function blocks according to PLCopen Motion Control are used to program the application sequences with all necessary types of movements and administrational commands. Due to the standard PLCopen Motion Control this can be reused in any other machine programs that used PLCopen function blocks.

The axis implementation layer is responsible for the execution of the commands from the application layer and can be programmed for each axis in a different way depending on the used hardware components.

Table 166: Needed function blocks for an application with central Motion Control

Library	Content
CompactMotionControl_AC500_V12.lib	Kernel function block, Parameters function block, Axis Simulation function block
MC_Base_AC500_V11.lib	Data types for AC500 Motion Control
MC_Blocks_AC500_V11.lib	Motion Control function blocks according to PLCopen

For a central motion axis implementation the use of the function blocks CMC_Motion_Kernel_Real and CMC_Axis_Control_Parameter_Real or CMC_Motion_Kernel_Int and CMC_Axis_Control_Parameter_Int is mandatory.

The Compact Motion function block design is independent from any bus architecture or any specific drive features.

Example for a possible system architecture

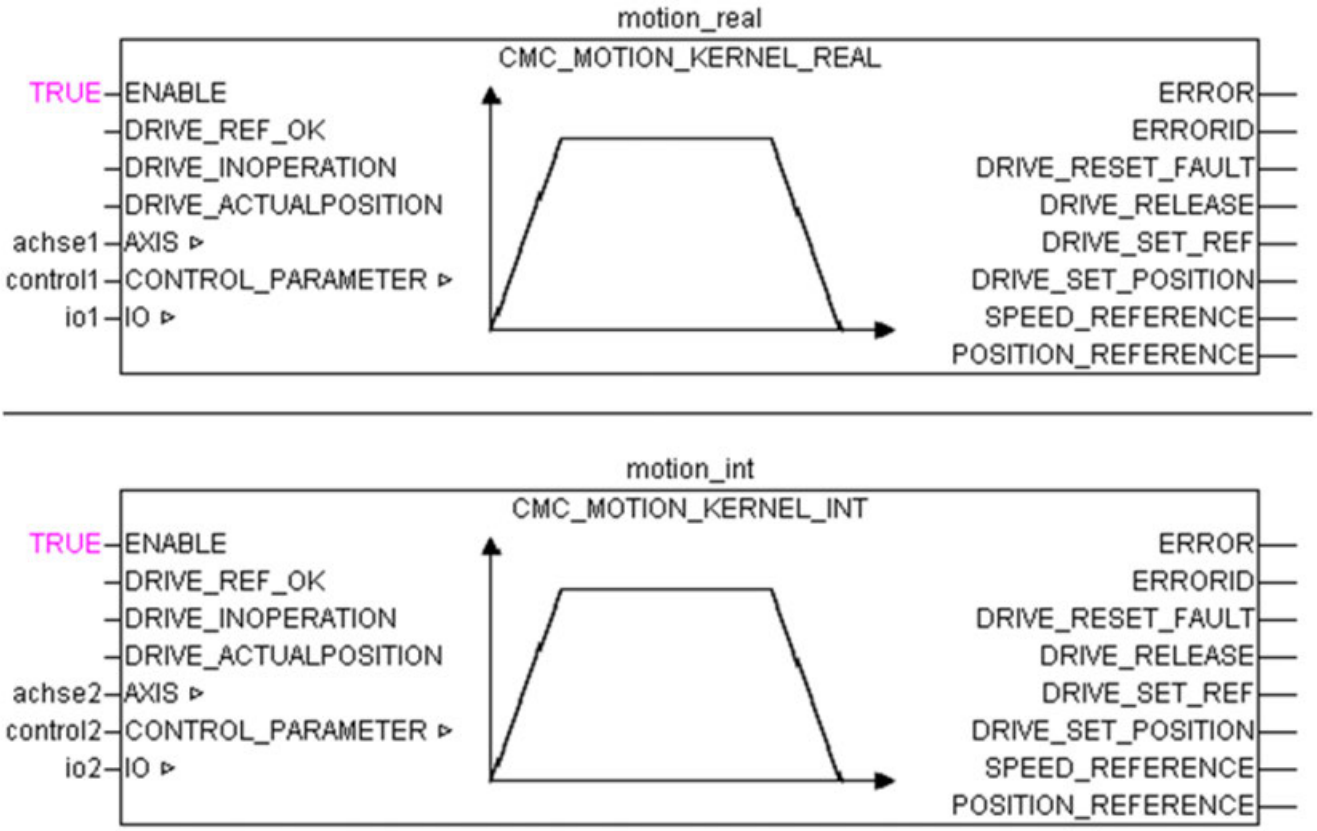
System	Velocity reference	Position feedback
System A	Output via analog output channel as voltage or current	From incremental encoder connected to CD522 I/O module
System B	Output via EtherCAT network	Input via EtherCAT network
System C	Output as frequency signal of CD522 I/O module	From incremental encoder connected to CD522 I/O module
System D	Output via PROFINET IO network	Input via PROFINET IO network

In case the velocity reference value is used from the kernel function block the position control loop is closed inside the drive. In this case, it is necessary to adjust the related parameters from the parameters function block. When the position reference will be used the position control loop is closed inside the drive. In this case, the internal control loop is just used to monitor the position and velocity.

When the position reference is used for the drive the following aspects have to be taken care of:

- *It is necessary to use a real time fieldbus, like EtherCAT.*
- *The PLC cycle has to be synchronized to the fieldbus cycle.*
- *The task calculation times may not exceed the used cycle time.*

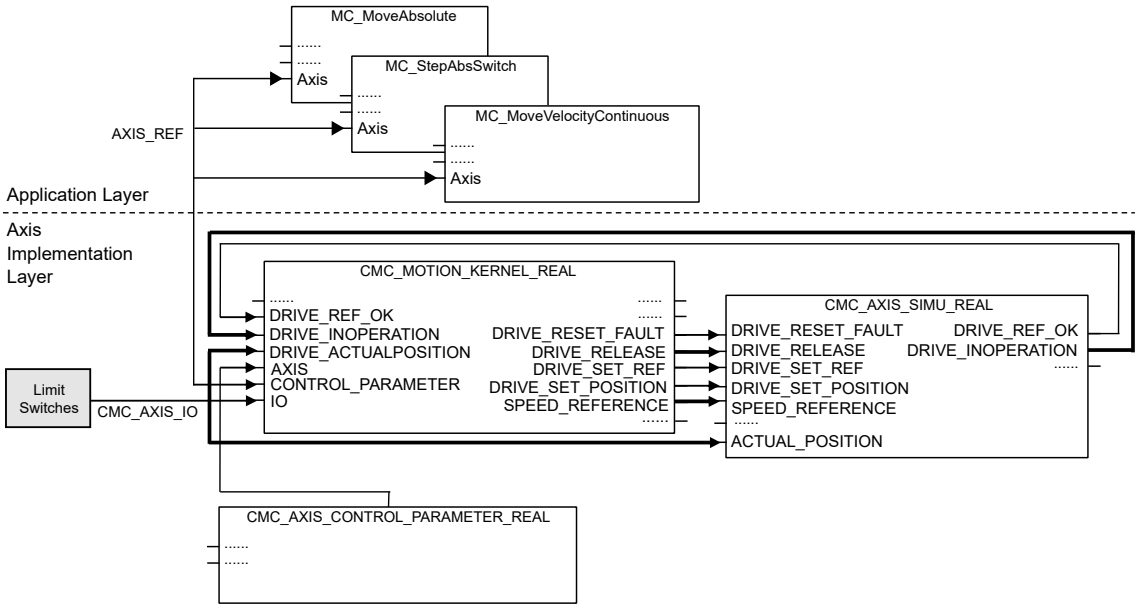
The drive's status should be managed by a specialized function block that supports the used type of drive as shown in the figure above. The kernel function block is the main function block which is needed to operate an axis with central Motion Control. It must be used with the parameter function block which is the interface to input parameters which are used to setup the axis.



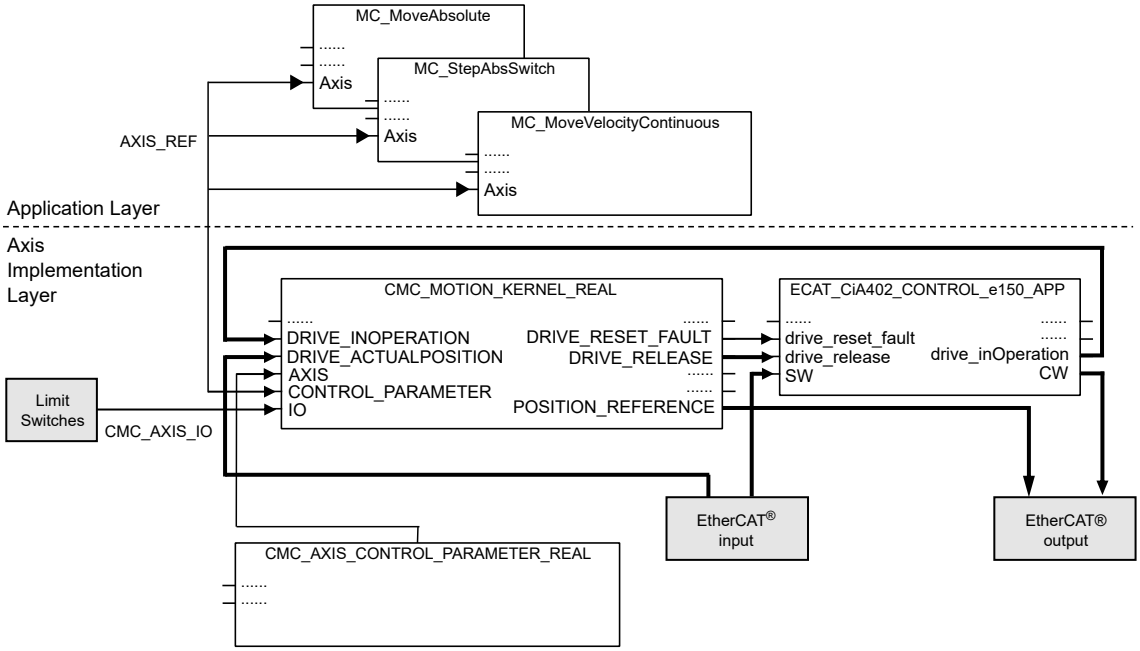
The corresponding function blocks for drive-based motion control are the function blocks <DriveName>_ACCESS.

The drive has to be accessed outside the CMC_MOTION_KERNEL function block. Actual values and reference values might be transferred by a synchronized fieldbus or by I/Os. The function block CMC_Motion_Kernel has to run inside the same task as the function blocks MC… and to be called every cycle and at least once before any function block MC… is activated.

The following figure shows an example with an axis simulation. The main data signals are drawn in bold lines. Here, the drive will receive a speed reference signal which means that the position control loop is closed inside the PLC by the Compact Motion function blocks. The time behavior of the simulated drive can be set by the parameter T1 at the axis simulation function block. If the time constant is to slow and the axis parameter Control_Time is too short the simulationed axis will run into instability – like a real drive. Sample values: *Chapter 1.5.9.4.2.3 “How to use the axis simulation” on page 2625*



The following figure shows an example with a MicroFlex e150 on an EtherCAT network. The main data signals are drawn in bold lines. Here, the drive will receive a position reference signal which means that the position control loop is closed inside the drive.



In the example the main signals are to be transferred via EtherCAT network. The drive control function block for the MicroFlex e150 can be found in the ECAT_AC500_APPL_V21 library.

Kernel function block

Kernel Arithmetic

The Compact Motion Control function blocks are available in two variants. Function blocks with the ending REAL use floating point arithmetic which results in a higher precision. These function blocks are intended to be used with PM59x PLCs.

Function blocks with the ending INT use integer arithmetic which uses less calculation time on PLCs without floating point CPUs. There are some restrictions connected with the use of these function blocks as shown in the following table. Also the use of some PLCopen function blocks will not be supported. ↯ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

Function blocks with the prefix CMC always have to be used with others of the same kind.
Function blocks with the ending REAL should not be compined with those with the ending INT.

Topic	CMC_Motion_Kernel_Int	CMC_Motion_Kernel_Real
Arithmetic	Integer arithmetic for interpolation and control loop.	Real arithmetic for interpolation and control loop.
Recommended PLC		Recommended to use in PLC with floating-point unit, e.g. PM59x.
Jerk	Acceleration and deceleration will be changed in a single step to the required value.	The jerk input of MC_xxx will be used in positioning, ● Jerk=0 "Acceleration and deceleration will be changed in a single step to the required value. ● Jerk >0 "Acceleration and deceleration will be changed regarding the maximum jerk. ● Every ramp will need a certain time longer in case jerk>0. This time is: (acceleration / jerk). ● The given acceleration at MC_xxx equates the maximum acceleration which is reached during the ramp.

How does the parameter for jerk influence the axis movements

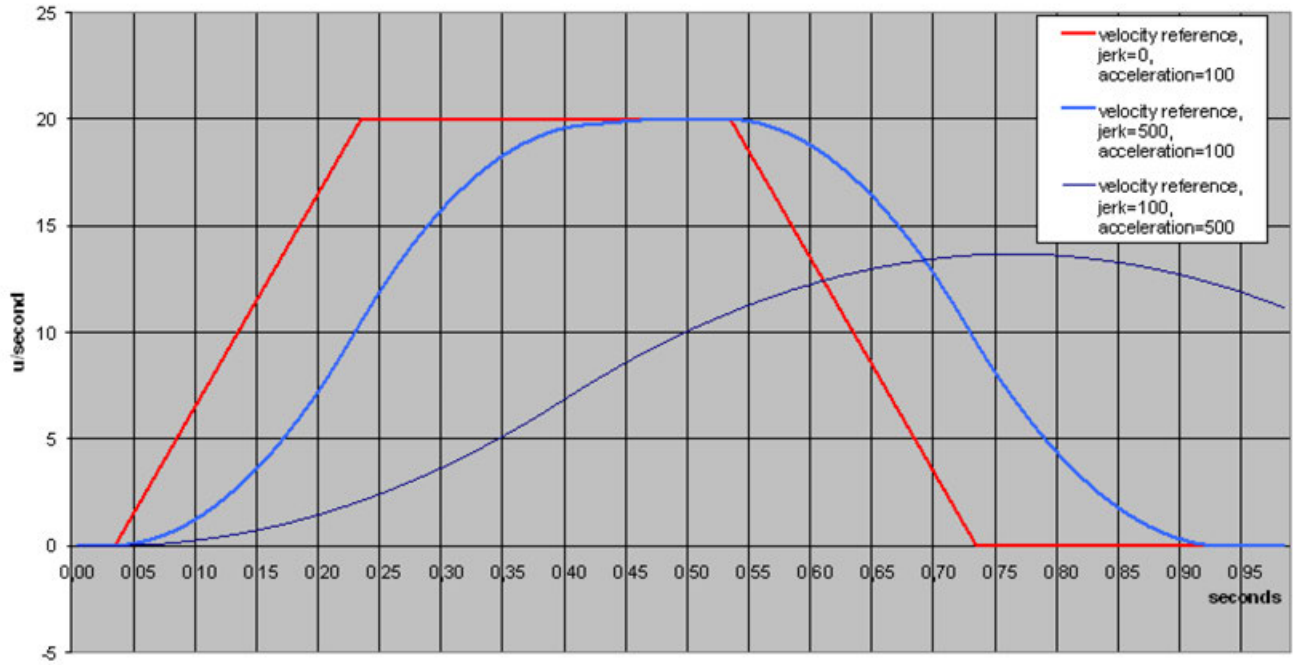


Fig. 221: Velocity reference with different jerk values

The diagram shows the result with different jerk values and the same velocity and acceleration.
The time needed for acceleration with jerk=0 is:

Time1=velocity/acceleration=(20/100)s=0.2s

The additional time with jerk=500 will be:

Time2=acceleration/jerk=(100/500)s = 0.2s

So the total time is:

Time=Time1 + Time2=0.2s + 0.2s=0.4s

In the last example with jerk=100, the velocity and acceleration values are not reached.

1.5.9.4.2 Basic functionalities

How to connect a drive

The connection to a drive must be done with the inputs and outputs of the function block CMC_Motion_Kernel_Real or CMC_Motion_Kernel_Int. All inputs and outputs of the kernel function block with the prefix “Drive_” are intended to be used with a drive, but in some cases not all of them are needed. In all cases the input Drive_ActualPosition has to be connected with the actual position of the axis. This value can be received by an I/O module of the PLC or via a fieldbus.

Depending on which device closes the position control loop either the output Speed_Reference or Position_Reference output has to be used. The value of Speed_Reference can be connected to an analog output module or be transferred via a fieldbus. The value of Position_Reference should be exclusively sent via a real-time fieldbus like EtherCAT.

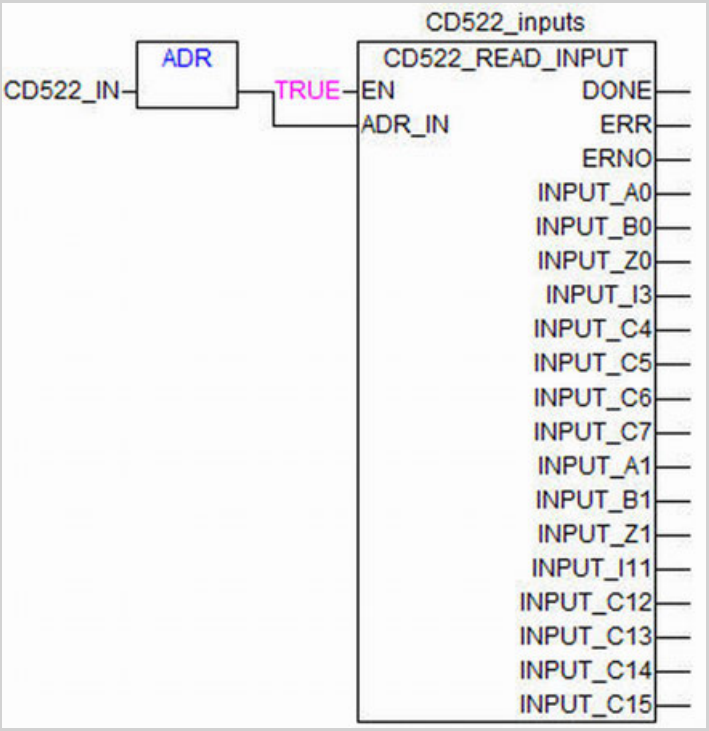
Example 1: Analog drive - Motor with incremental encoder

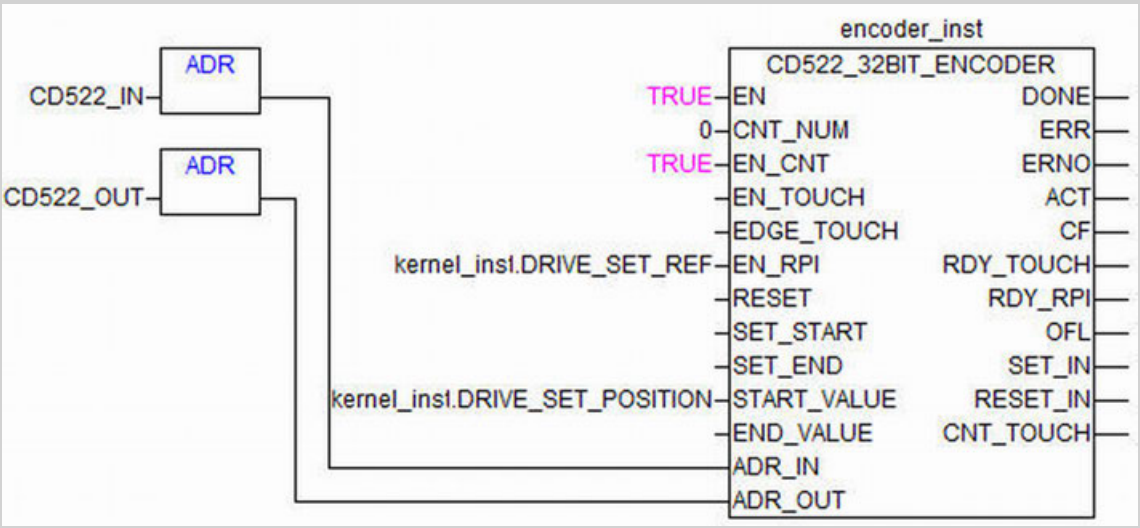
In the example the position control loop will be closed by the PLC, therefore the input Drive_ActualPosition and the output Speed_Reference are to be used.

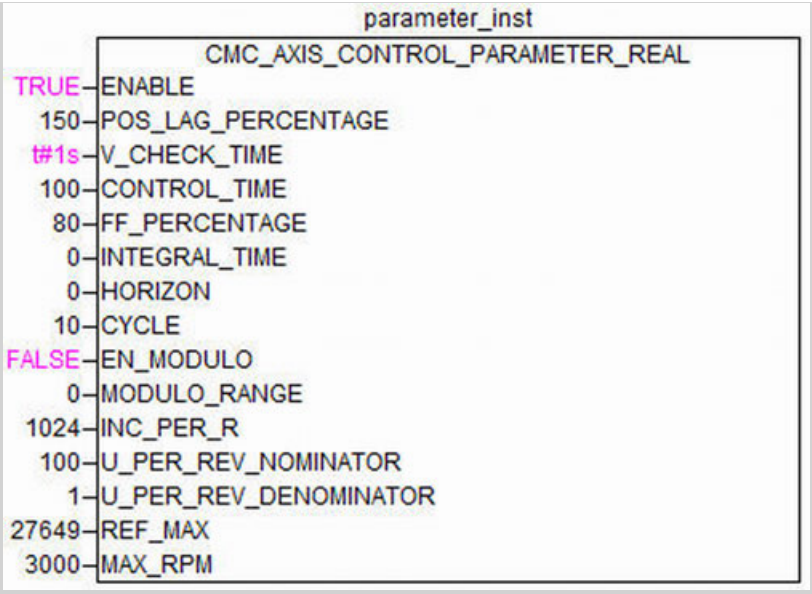
In combination with the I/O module CD522 and the corresponding function block CD522Encoder32Bit the position of the encoder can be used. For the effective resolution of the encoder parameter Inc_Per_R of the parameter function block has to be used.

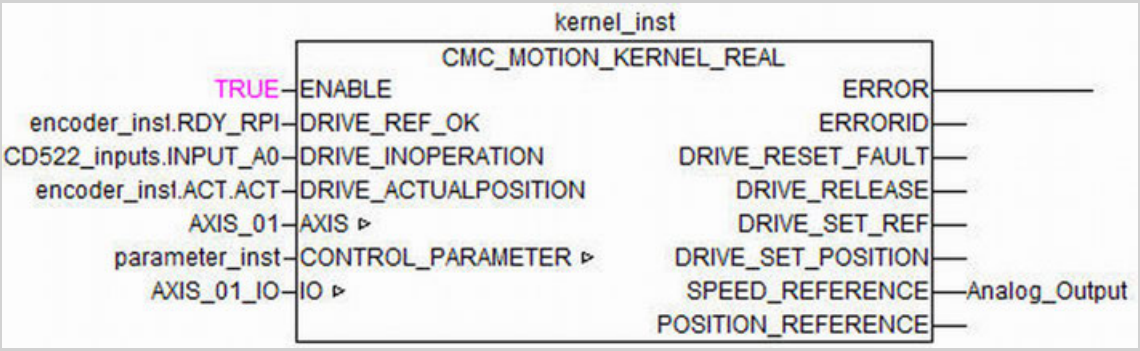
The output Speed_Reference can be written directly to the global variable of an output channel of an analog module but can also be transferred via a fieldbus. The scaling of this output value can be done with the parameters Ref_Max and Max_Rpm of the function block CMC_Axis_Control_Parameter_Real or CMC_Axis_Control_Parameter_Int.

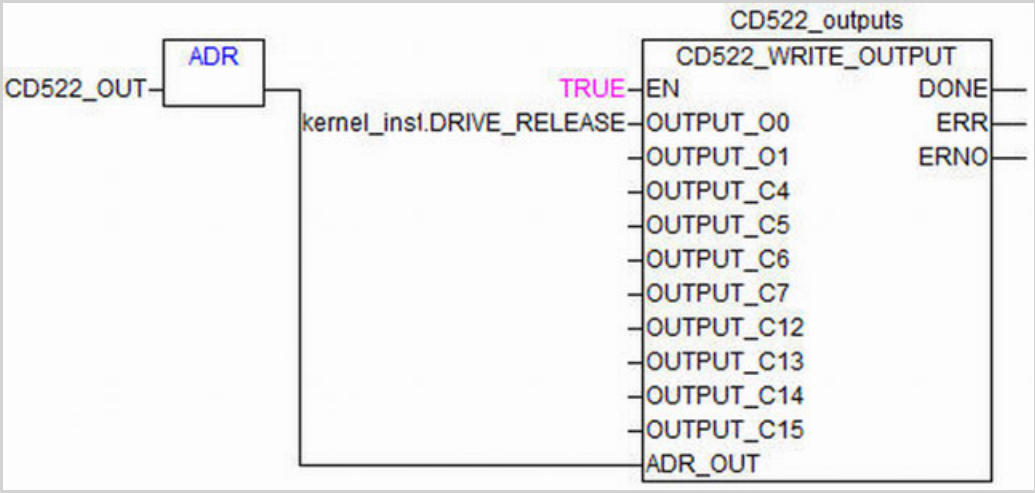
The scaling of the Speed_Reference value can be set with the inputs Ref_Max and Max_Rpm of the parameter function block.









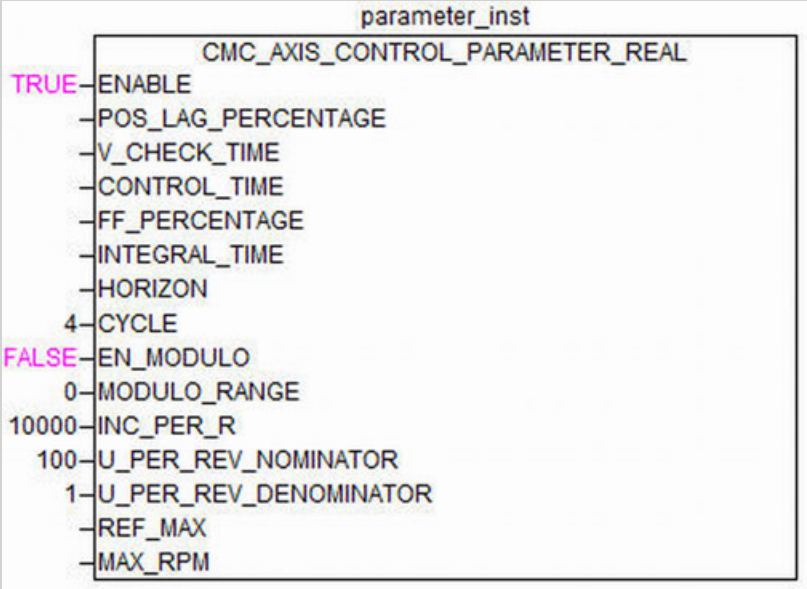


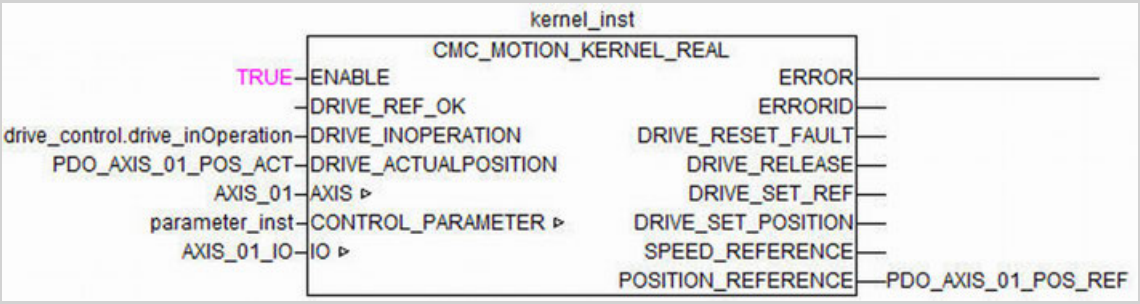
In order to finish a homing sequence which is done by the function block MC_StepRefPulse the outputs Drive_Set_Ref and Drive_Set_Position from the kernel function block have to be connected with the inputs EN_RPI and START_VALUE of the CD552 I/O module function block. Also the output RdyRpi of the CD552 I/O module function block has to be connected with Drive_Ref_Ok from the kernel function block.

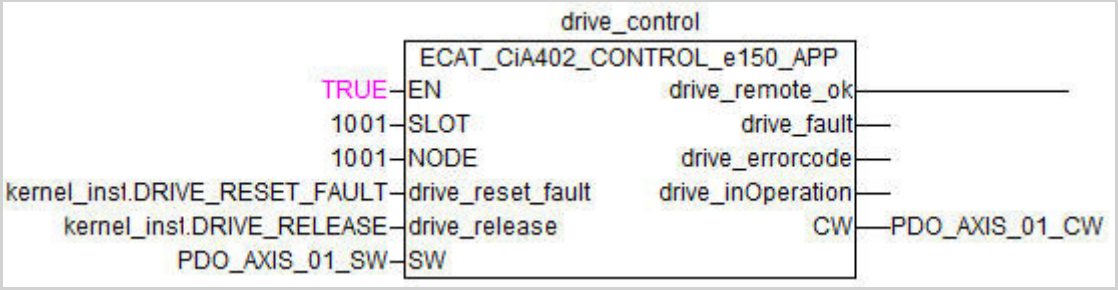
To enable and disable the drive Drive_Release could be connected to a binary output to activate the drive. Drive_InOperation could be connected to a binary input to get the information that Drive_Release was successful.

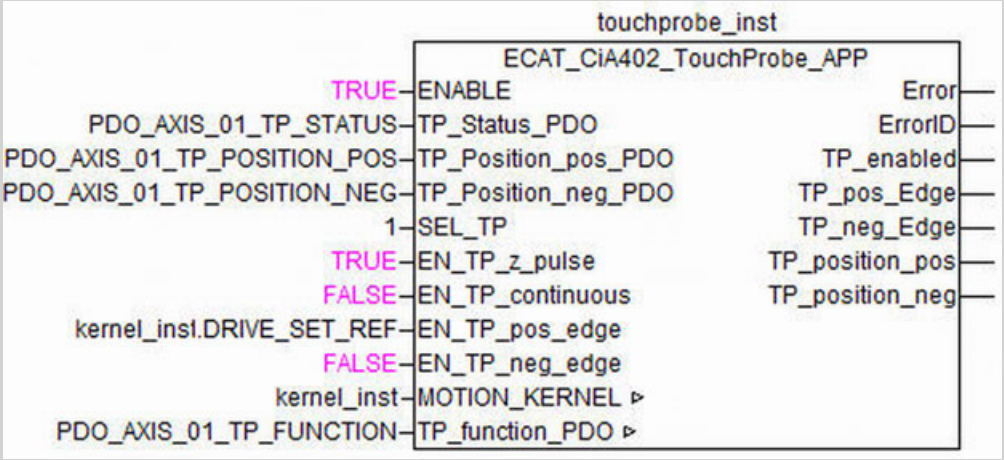
Example 2: Servo Drive - Microflex e150 via EtherCAT in contiuous positioning mode (csp)

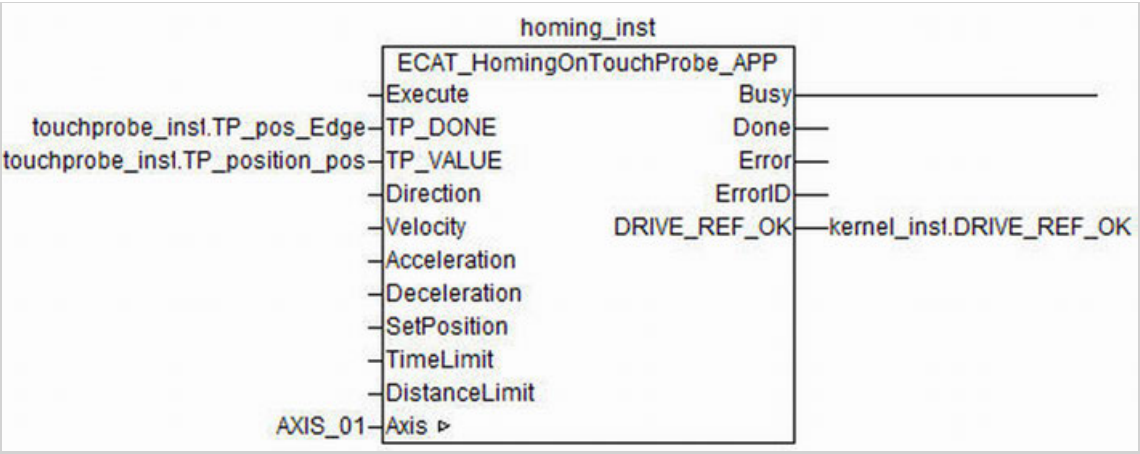
In the example the position control loop will be closed by the drive, therefore the input Drive_ActualPosition and the output Position_Reference are to be used. The inputs refering to the position control loop of the parameter function block do not have to be set.











To enable and disable the drive Drive_Release and Drive_Inoperation have to be connected to the control function block ECAT_CiA402_Control_App of the library ABB_Ecat_CiA402_AC500.library, which controls the status and control word of the drive.

All function blocks from this library are not password protected and free to be changed in order to be adapted for different drives. The library and the function blocks are marked with the ending _APP.

For a precise homing finish, a position can be latched from the MicroFlex e150 drive, by the use of the Touch Probe objects, which are available in the MicroFlex e150 EtherCAT configuration. To use these Touch Probe objects the function block ECAT_CiA402_TouchProbe_APP can be used.

In addition to the Touch Probe function block the homing can be executed with the function block ECAT_HomingOnTouchProbe_APP, which uses the latched position from the Touch Probe objects.

How to enable and disable a drive

In order to enable a drive the function block MC_Power has to be used within the applicational layer. The kernel function block will then, if possible, output a rising edge on the output Drive_Release which can be connected to the drive-control function block which performs the needed actions on the drives control word to enable the drive. As soon the drive states enabled, this signal can be connected to the input Drive_In_Operation of the kernel function block. The axis state according to the single axis state diagram of PLCopen will then switch from Disabled to Standstill.

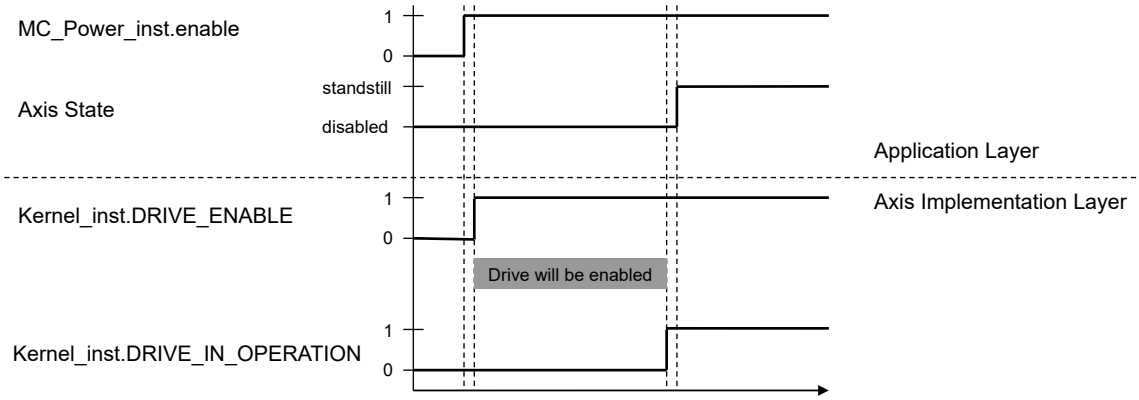


Fig. 222: Enabling sequence of a drive

As long as the drive is in state Disabled or ErrorStop the input Drive_Actual_Position will be copied to the output Position_Reference of the kernel function block. The output Speed_Reference will be zero.

When the axis is in operation, which means it is not in state Disabled or ErrorStop, then the output Position_Reference will be calculated by the kernel function block and the position control loop will be closed, which outputs non zero value for the output Speed_Reference in case of a following error. The input Actual_Position should then follow the position reference. The difference of both values is the following error and will be supervised by the kernel function block.

In case of drive problem, Drive_InOperation should be reset. The function block will open the position control loop and Speed_Reference will be set to zero.

For the most drives the status is control by the drives control word whereas the drives status word represents its actual status. In order to enable the drive it might be necessary to pass through several drives states according a defined scheme which depends on the used drive. Therefore the library ECAT_AC500_APPL_V21.lib is added to PS552-MC which contains function blocks to operate with different drives on an EtherCAT network. There is also the PS553-DRIVES software which can be used to control the state of a drive.

How to use the axis simulation

It is possible to use a simulated axis instead of a real drive.

The axis simulation can be used in the following use cases:

- When the real drive is not available the simulation can be used to test all available motion functionalities to verify the application program.
- The simulation can be used to create a virtual master axis and synchronize other axes to it.

The simulation is realized by the function block CMC_Axis_Simu_Real or CMC_Axis_Simu_Int. Depending on the used version of the kernel function block the corresponding version of the simulation function block has to be used.

Homing will be possible if the limit-switches (data type CMC_Axis_IO) are simulated also. This is not done by CMC_Axis_Simu but could be realized in the PLC program.

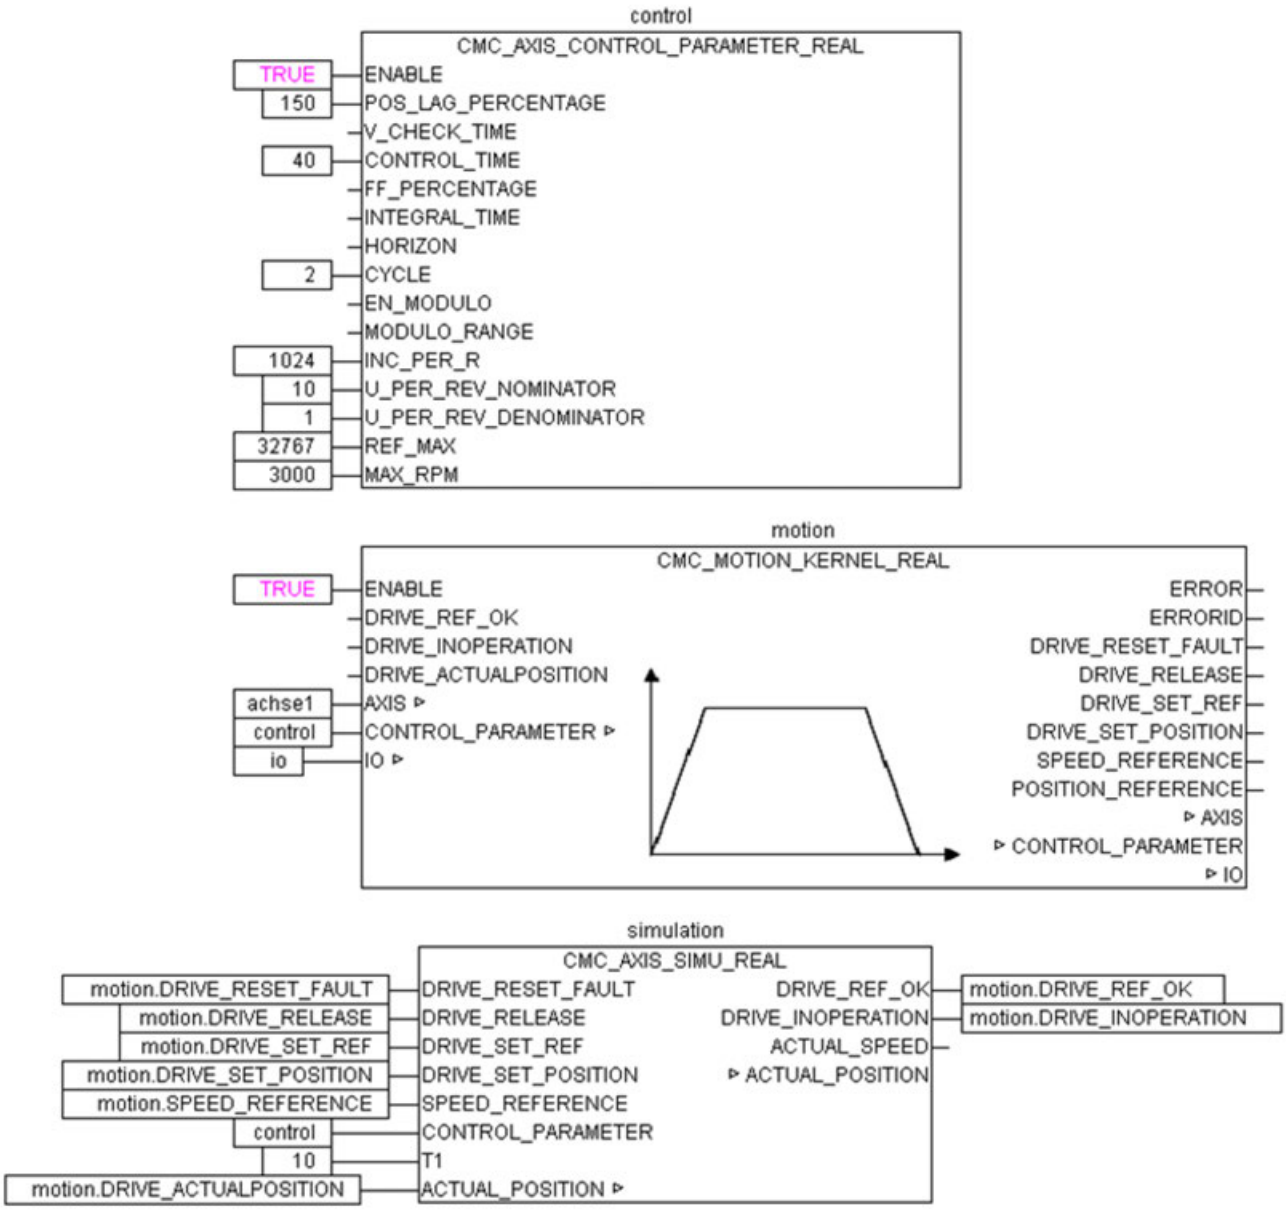

Fig. 223: Example for Simulation

The drive velocity is simulated by PT1-Characteristic. The input T1 gives the time constant for this PT1 as multiple of the cycle time. All other properties are simulated according to the CMC_Axis_Control_Parameter.

> *The value of the time behavior from the axis simulation function block set by the input T1 has to be at least four times smaller than the value of the axis parameter Control_Time from the parameter function block.*

How to perform a homing

The homing of an axis is a procedure which consists of up to two phases. For each phase there are different function blocks available. The available function blocks are according to PLCopen and belong to the application layer.

Table 167: Overview of the available homing function blocks

	Phase 1	Phase 2/Finish Homing
MC_StepAbsSwitch	X	
MC_StepDirect		X
MC_StepLimitSwitch	X	
MC_StepRefPulse		X

In order to create a complete homing sequence one function block of each phase can be used.

First phase

The used function blocks will change the axis state to Homing and will move the axis to approach installed limit switches or a dedicated absolute switch in the desired directions. No manipulation of a position value will be done in this phase. The use of function blocks of this phase is optional for a homing.

The signals of the installed limit switches have to be written to a variable of the data type CMC_Axis_IO.

Second phase

Function blocks from this phase will also change the axis state to Homing if this has not already happen and will finish the homing. Therefore a new position will be set to the axis. The axis state will then switch back to Standstill.

The use of a function block of the second phase is mandatory for a homing.

In general with AC500 Central Motion Control there are two position values: One position value will represent the encoder counts of a drive or the CD522 module which is connected to the input Drive_ActualPosition of the kernel function block. The other position is a user defined scaled unit which is used for PLCopen function blocks.

There are different ways to finish the homing by manipulate and adjust a position value. Which value should be manipulated depends on the used drive or module and its capabilities. See the following types A, B and C.

Type A

The user defined position unit will be changed only. The function block MC_StepDirect must be used here. This type of homing is less complex than the other types but also less precise.

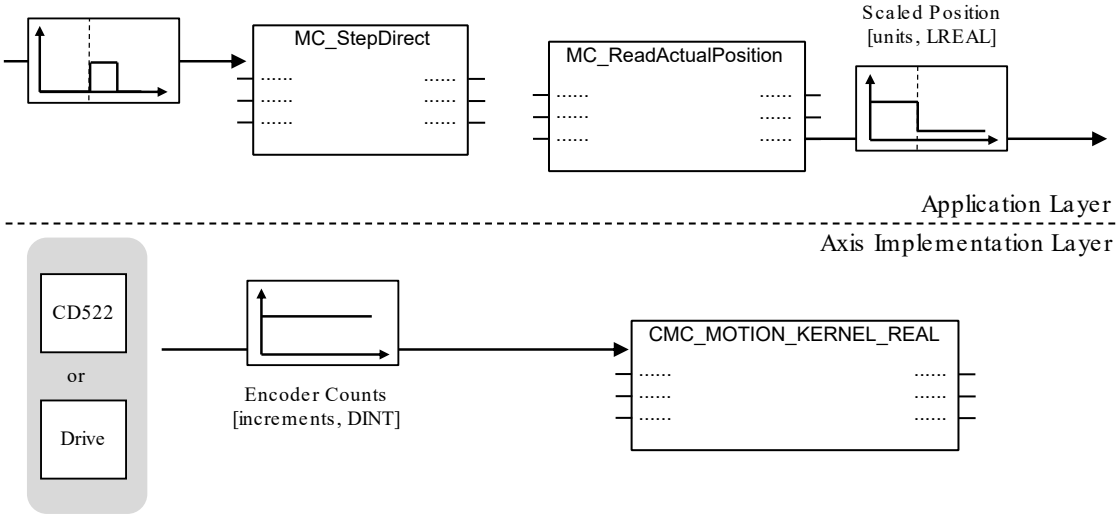

Fig. 224: Homing Type A

Type B

The Drive or the CD522 module will change its own position value, the encoder counts.

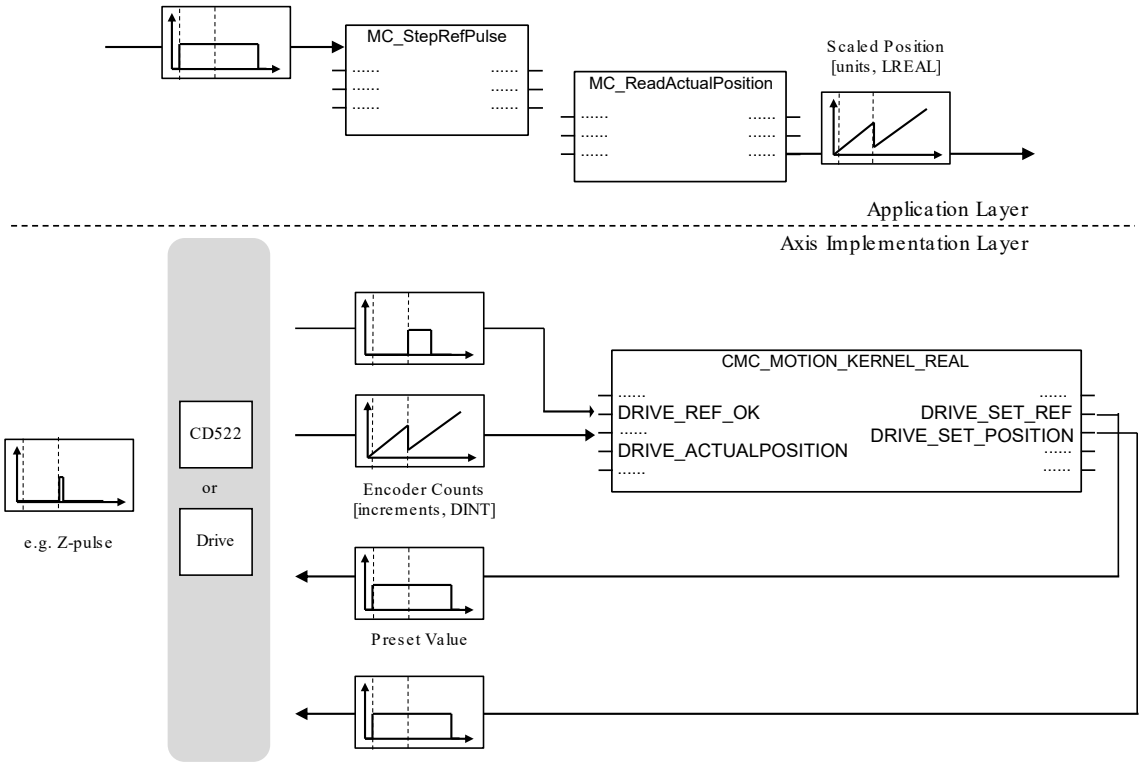

Fig. 225: Homing Type B

The process will be started by the execution of the function block MC_StepRefPulse.

The axis will start to move.

The output Drive_Set_Ref of the kernel function block will then set the drive to sense for a digital signal. At the same time the kernel function block outputs a preset value which will replace the actual encoder count value at the moment the digital signal occurs.

This signal can be a Z-pulse of an incremental encoder but also any other signal from a sensor. This functionality may require a configuration of the drive or the CD522 module in order to be used.

In the same cycle when the new position value is set there also has to be a boolean signal stating a new position value at the input Drive_Ref_Ok of the kernel function block. The user defined position value will then be shifted accordingly.

Example of type B for phase 2: *Chapter 1.5.9.4.2.1 “How to connect a drive” on page 2620*

Type C

The encoder count position value will not be changed but involves registration capabilities of a drive or the CD522 module.

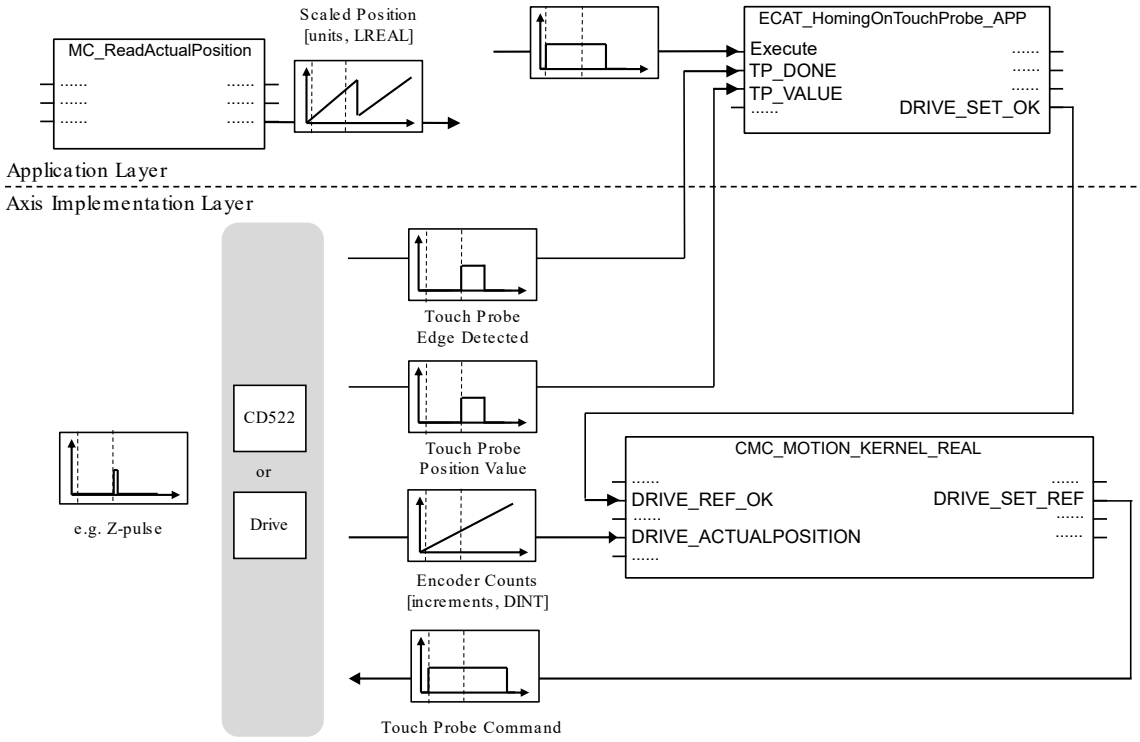

Fig. 226: Homing Type C

The process will be started by the execution of the function block ECAT_HomingOnTouchProbe_APP (ABB_Ecat_CiA402_AC500.library).

The axis will start to move.

The output Drive_Set_Ref of the kernel function block will then command the drive or the CD522 module to activate the Touch Probe functionality. This will configure the drive to latch a position at the moment a digital signal occurs. The digital signal can be a Z-pulse of an incremental encoder but also any other signal from a sensor. This functionality may require a configuration of the drive or the CD522 module in order to be used.

In combination with the latched position value there is a boolean signal which states that a new latch value has been received. In case of the module CD522 this encoder count position value has to be converted from encoder counts to equivalent user scaled units by the use of the function “CMC_Get_Units_From_Inc” (CompactMotionContral_AC500_V12.lib) before it can be connected to the function block ECAT_HomingOnTouchProbe_APP.

To manage the Touch Probe objects of a drive within the CiA402 profile (e.g. MicroFlex e150) the function block ECAT_HomingOnTouchProbe_APP (ECAT_AC500_V12.lib) can be used. This will also cover the conversion from encoder counts to user scaled units.

At the end of the process the function block ECAT_HomingOnTouchProbe_APP will manipulate the user scaled position value according to the latched position from the drive and the users settings.

Example of type C for phase 2: ↳ *Chapter 1.5.9.4.2.1 “How to connect a drive” on page 2620*

For further information see: *AN00220-001 - AC500 and MicroFlex e150 - EtherCAT Homing Methods*

How to Use a CAM curve

The CAM functionality is only available in combination with the kernel function block CMC_Motion_Kernel_Real ↳ *Chapter 1.5.9.4.8.1 “CMC_MOTION_KERNEL_REAL” on page 2659*.

General usage

The usage of a CAM function is based on the following elements:

- CAM table defined with the data type MC_PProfile.
- An instance of the function block MC_CamTableSelect
  ↳ *Chapter 1.5.9.6.3.1 “MC_CamTableSelect” on page 2832*.
- An instance of the function block MCA_Cam_Extra (optional)
  ↳ *Chapter 1.5.9.6.5.1 “MCA_CAM_EXTRA” on page 2878*.
- An instance of function block MC_CamIn
  ↳ *Chapter 1.5.9.6.2.1 “MC_CamIn” on page 2799*.
- An instance of function block MC_CamOut
  ↳ *Chapter 1.5.9.6.2.2 “MC_CamOut” on page 2803*.

The following steps are necessary to use a CAM table

1. Declare a CAM table as an array of the data type MC_PProfile in the program.
2. Write data to this array.
3. Use the address of the CAM table at the input CamTable of the function block MC_CamTableSelect.
4. Execute the function block MC_CamTableSelect to process the data of the CAM table with the function block’s input parameters
5. Additionally you can execute the function block MCA_Cam_Extra for optional parameters after the processing of the function block MC_CamTableSelect.
6. Execute the function block MC_CamIn to start the slave axis movement according to the CAM table data and parameters.
   ⇨ The axis will operate in the axis state Synchronized Motion.
7. To leave the axis state you can execute the function block MC_CamOut.
   ⇨ The axis state will switch to state Continuous Motion and maintains its last velocity as long as there is no other command.
8. You can also use any other motion command interrupt the Synchronized Motion.

CAM table

CAM data is done with one table (two dimensional – describing master and slave positions together).

The data of the elements (array of data type MC_PProfile) can either be assigned within the declaration or can be assigned during run time before the execution of the function block MC_CamTableSelect.

It can be filled with data in the following ways:

- To use a predefined variable list.
- To calculate the values within the program (before using the MC_CamTableSelect).
- To send values by any communication access to the PLC.

In order to use the new data it is necessary to execute the function block MC_CamTableSelect again. In case the CAM table is executed the function block MC_CamTableSelect may not be executed.

Elements of the data type MC_PProfile: ↳ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

The inputs MasterSyncPosition and MasterSyncDistance of the function block MC_CamIn can be used to define a distance to synchronize the slave axis onto the CAM table during the start. In case master axis moves with negative velocity the parameter MasterSyncDistance can be negative. The MasterSyncPosition should always be within the range of the CAM table master position.

MasterSyncDistance = 0 will deactivate the synchronization. In this case the slave axis should be moved on the CAM curve before MC_CamIn is executed, otherwise a following error can occure.

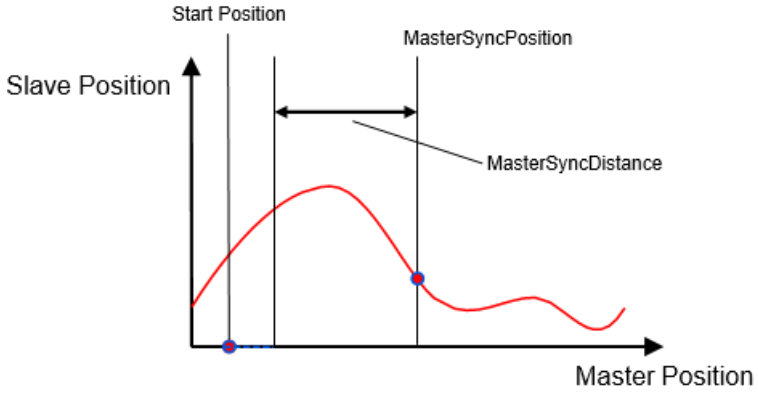

Fig. 227: CAM profile figure

The master position in the CAM table must be strictly monotonic rising.

The length of a CAM table is just restricted by the memory size of the PLC. When long tables are used, it is recommended to call CamTableSelect in a task with lower priority as it will need a considerable computing time.

It is possible to hold several CamTables as a pool and to switch from one to another. This has to be done at matching positions as no means for synchronization are available.

The offset and scaling values (except the time-scale) are transferred continuously. This will allow to follow a "Moving Target" by adjusting these values.

The parameters at MC_CamTableSelect, MC_CamIn and function and MCA_Cam_Extra also modify the behavior:

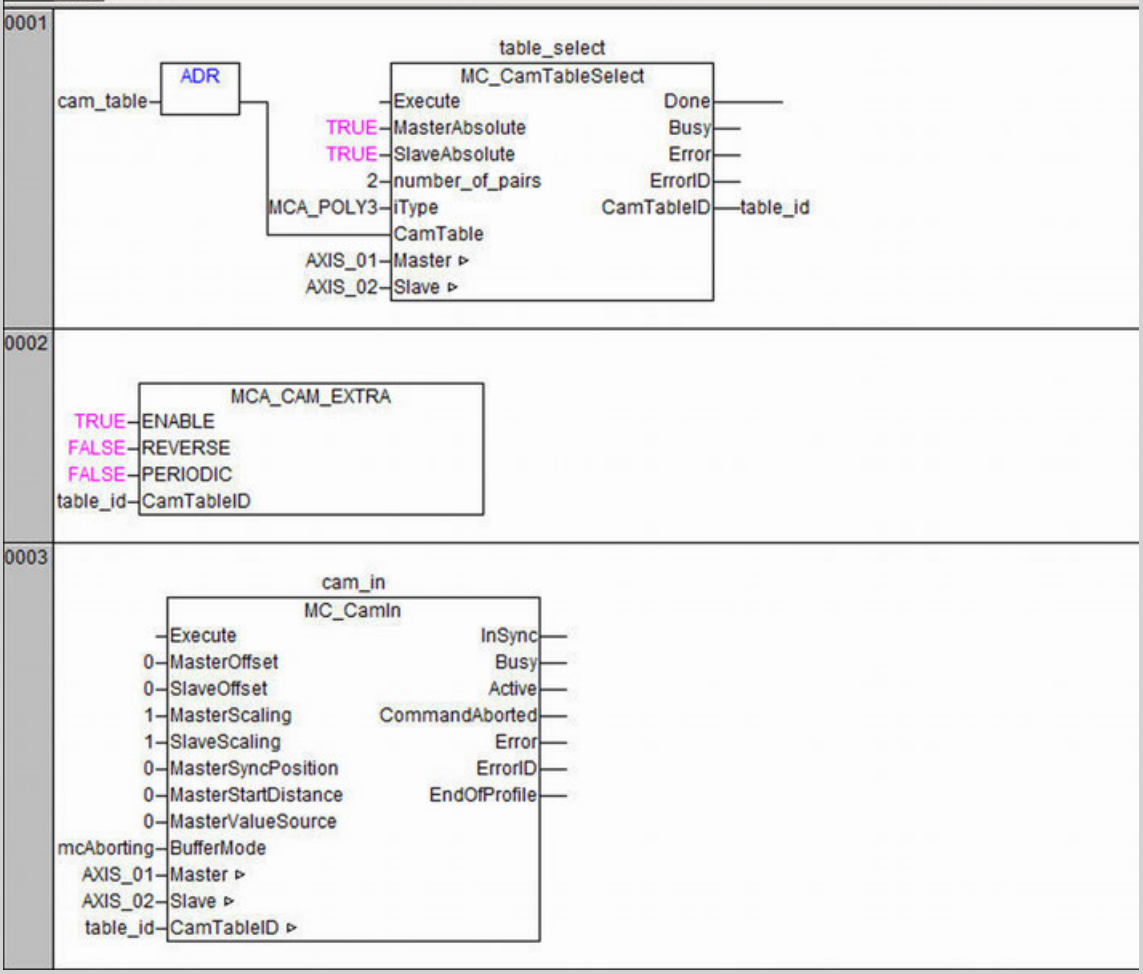
Parameter MC_CamTableSelect	Type	Default value	Comment
MasterAbsolute	BOOL	FALSE	TRUE=Master_position from MC_PProfile equals the master axis absolute position. FALSE=CAM is executed relative to the master axis actual position at start.
SlaveAbsolute	BOOL	FALSE	TRUE=interpolation_point from MC_PProfile equals the slave axis absolute position. FALSE=CAM is started from actual slave position. The values "interpolation_point" are relative to the slave axis position at start.
iType	MC_ABB_iTypes_ENUM		Interpolationtype.
Number_of_pairs	INT		Number of points used in TimePosition Array.

Parameter MC_CamIn	Type	Default value	Comment
MasterOffset	LREAL	0	Just used with MasterAbsolute=TRUE, ignored otherwise. Used position for cam-table is: Master axis position-Masteroffset.
SlaveOffset	LREAL	0	Just used with SlaveAbsolute=TRUE, ignored otherwise. Used position is slave axis position=interpolation_point+Slaveoffset.

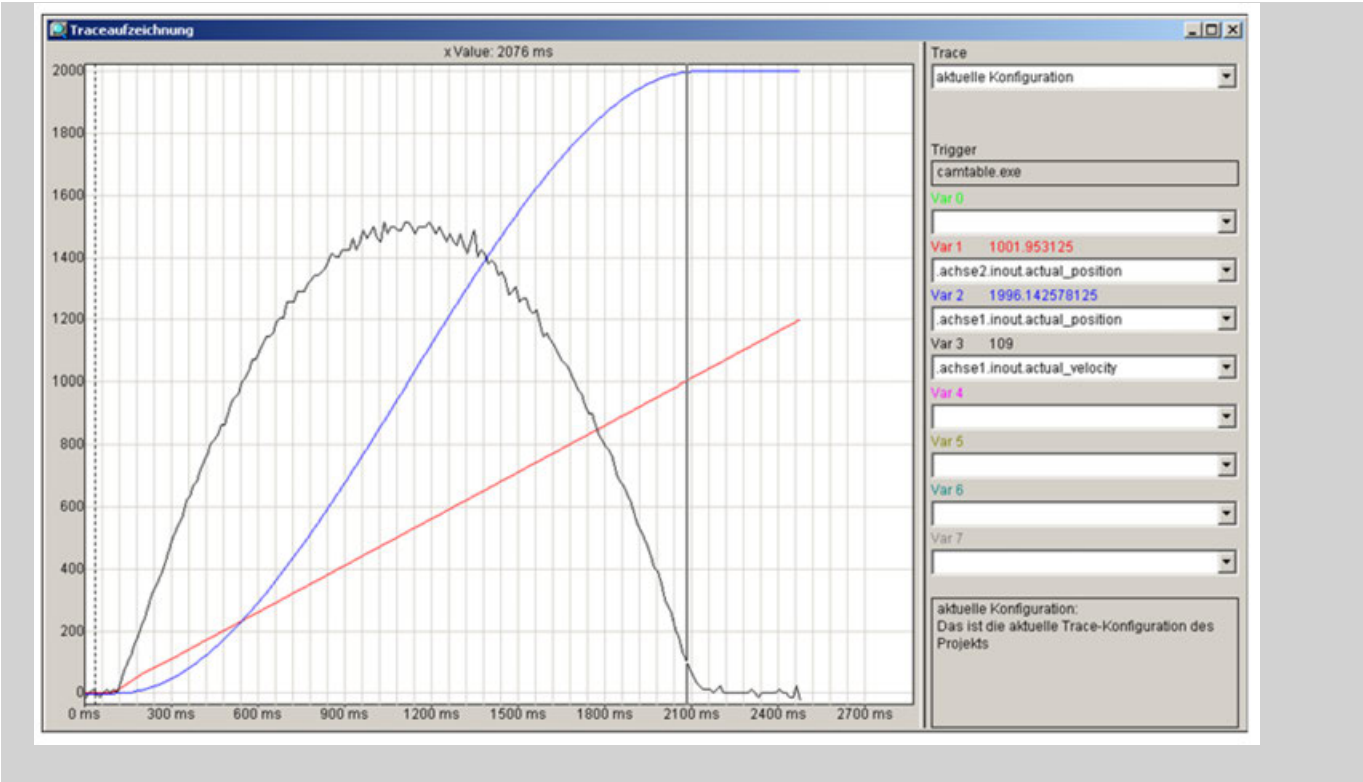
Parameter MC_CamIn	Type	Default value	Comment
MasterScaling	LREAL	1	The position used for interpolation is multiplied by MasterScaling, e.g MasterScaling=2, the scaled master will pass the position range with double velocity and within the half distance compared to its real velocity and position.
SlaveScaling	LREAL	1	Interpolation result is multiplied by Slave-Scaling, e.g SlaveScaling=2: Slave axis will run twice the distance.
MasterSyncPosition	LREAL	0	Start synchronization at master axis position=MasterSyncPosition-Master-StartDistance+MasterOffset, meet the CamTable at master axis position=MasterSyncPosition. In case of MasterAbsolute=FALSE: start at "actualPosition+MasterSyncPosition-MasterStartDistance", meet the CamTable at "actualPosition+MasterSyncPosition"!!! It is just possible to use the "sync" mechanism when the axis is in StandStill on start.
MasterStartDistance	LREAL	0	A negative value will create a reverse synchronization mode, which means the master should move in negative direction to synchronize. It is independent from the Reverse-Bit which indicates how to end the movement.
These 2 parameters are "extras" to be written with the MCA_Cam_Extra function. When the parameters are used, the MCA_Cam_Extra has to be called after the MC_CamTableSelect.			
Periodic	BOOL	TRUE for master “Modulo”, FALSE for master linear axis	CamTable will not reach "EndOfProfile" but will be repeated periodically. When the master is a linear axis, it has to move forward and backward within the CamTable position range, but even when it leaves this position range, the CamTable will stay active.
Reverse	BOOL	FALSE	Just necessary when a CamTable is NOT "periodic" and will run in reverse direction (master with negative velocity) Reverse=FALSE, the CamTable is ready when the master leaves the position range in positive direction, e.g. when it moves from 359° to 0° on a rollover axes Reverse=TRUE, the CamTable is ready when the master leaves the position range in negative direction.

Example for CAM curve

```
0002 VAR
0003     cam_table     : ARRAY [0..1] OF MC_PProfile :=
0004                   (Master_position  := 0     ,interpolation_point:= 0     ,Velocity_ratio:=  0  ,Acceleration_ratio:= 0 ),
0005                   (Master_position  := 1000  ,interpolation_point:= 2000  ,Velocity_ratio:=  0  ,Acceleration_ratio:= 0 );
0006     cam_in        : MC_CamIn;
0007     table_id      : MC_CAM_ID;
0008     table_select  : MC_CamTableSelect;
0009     AXIS_01       : AXIS_REF;
0010     AXIS_02       : AXIS_REF;
0011 END_VAR
0012
```



In the example, the slave will run from 0 to 2000 while the master runs from 0 to 1000. The slave will start and end with velocity=0, no matter which velocity the master has during start. The slave will reach the maximum velocity when it is at position 1000 and the master is at position 500.



How to use an external axis

To use multiaxis PLCopen function blocks with an externally sensed axis as master axis the following structure can be used for the axis implementation:

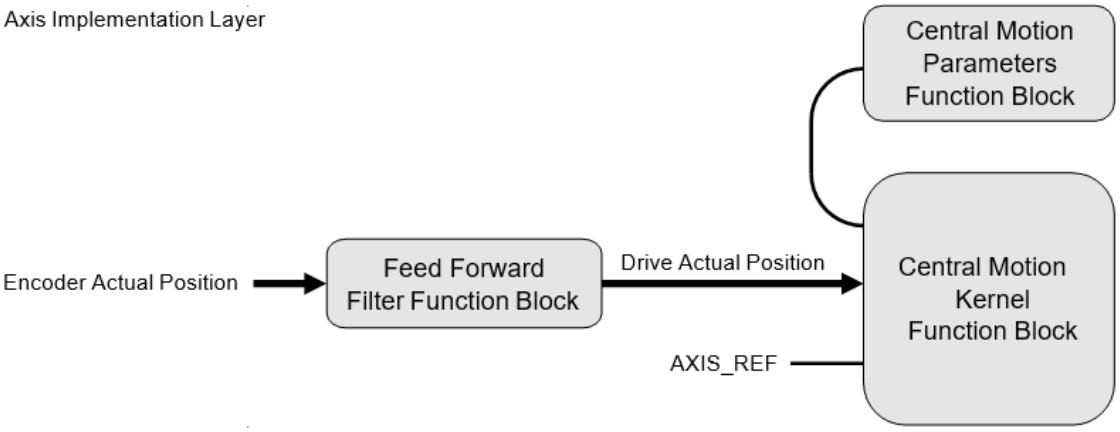


Fig. 228: Structure synchronization to an external axis

The use of a feed forward filter function block is needed if the slave axis has to follow the position of the external axis. In this case there will be a time delay between sensing the position of the external axis and moving the follower axis along the sensed position. The filter function block will then add a certain distance to the external axis' position depending of its speed.

The filter function block MATH_LINEAR_REGRESSION from the library MathFunctions_AC500_V23 can be used here.

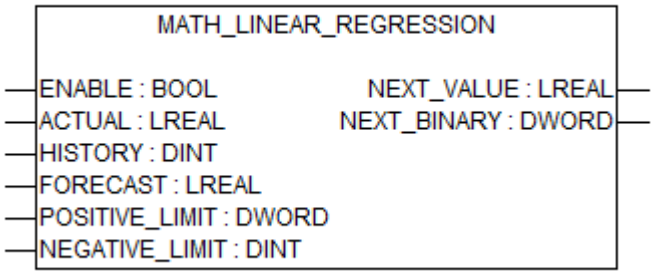

Fig. 229: Filter function block to feed forward an externally sensed position

For an axis which is following the external axis, the value “mcActualValue” (from MC_Source enumeration) for the input “MasterValueSource” for multi-axis PLCopen function blocks has to be used.

When the filter function block MATH_LINEAR_REGRESSION is used to process an actual position, 2 different purposes are fulfilled:

- A jitter or noise can be compensated
- It is possible to calculate a forecast-position to compensate for a delay in position measurement

> *Process the actual position or any other master axis always before the slave axis.*
>
> *Otherwise, an additional one cycle-delay is introduced.*

The MATH_LINEAR_REGRESSION function block calculates the progress for a variable which is captured in equidistant periods of time and is assumed to follow a linear curve. It uses the Gauss “least squares” -algorithm to do so. The line is calculated in a way that the sum of squares for the distances from the measured points to the assumed straight line is minimized.

A noise or jitter influence of the value is compensated and a predictive value for the variable with an adjustable forecast horizon can be calculated.

Linear equation:

$$\mathrm{Line[i]} = \mathrm{gradient} * \mathrm{i} + \mathrm{offset}$$

Sum of squares:

$$sum = \sum_{i=1}^{\infty history} (\mathrm{x[i]} - \mathrm{line[i]})^2$$

The gradient and offset for the line are calculated in a way that “sum” is minimized. Then these 2 values are used to calculate the forecast value:

$$\mathrm{NEXT\_VALUE} := \mathrm{gradient} * \mathrm{FORECAST} + \mathrm{offset}$$

FORECAST=0 would mean: value right now, no future or past considered.

When the ACTUAL value is a modulo value, for example a single turn encoder or a rollover axis, this has to be considered in the calculation. The 2 input values POSITIVE_LIMIT and NEGATIVE_LIMIT can be used to configure this. They define the upper and lower limit for ACTUAL. Also, the NEXT_BINARY will as a result be limited to these borders.

Example

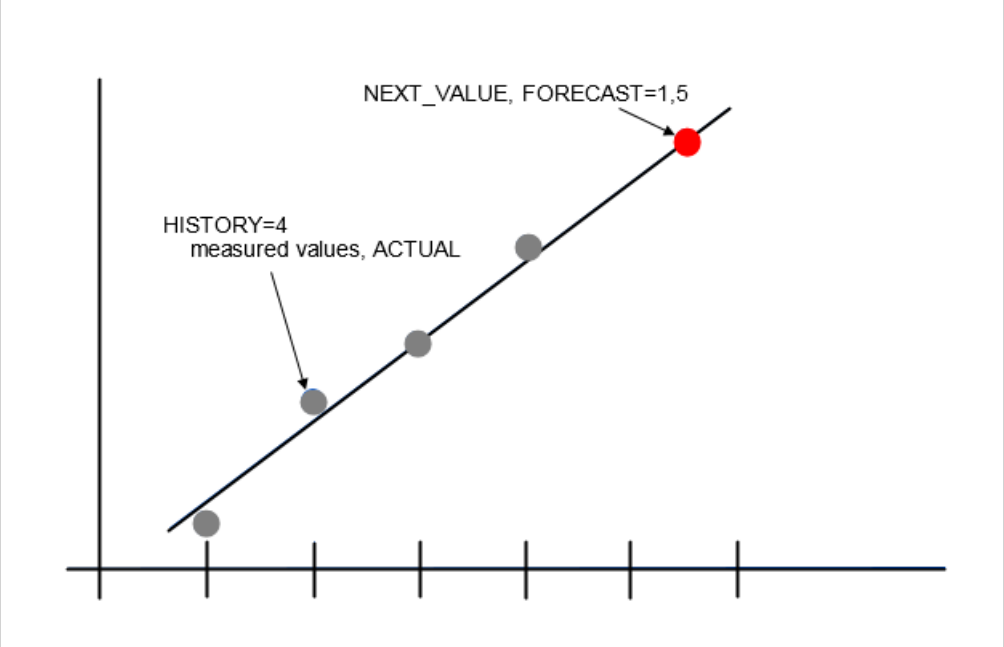

Fig. 230: Next Value_Forecast

How to use an encoder/drive with <> 32-bit position overrun

The incremental position as actual position at the function block CMC_Motion_Kernel_Real is usually assumed as position with a 32-bit position overrun. As well as it is the reference position which is sent to the drive.

Any modulo-axis configuration should be done inside the PLC.

Some drives are requested to correct their positions themselves for a non-linear axis which should constantly run into the same direction.

In this case, the drive has to be configured as a modulo-axis and the function block CMC_Motion_Kernel_Real needs some additional function blocks to create the 32-bit value ↳ *Chapter 1.5.9.4.3.4 “Roll-Over axis” on page 2646*.

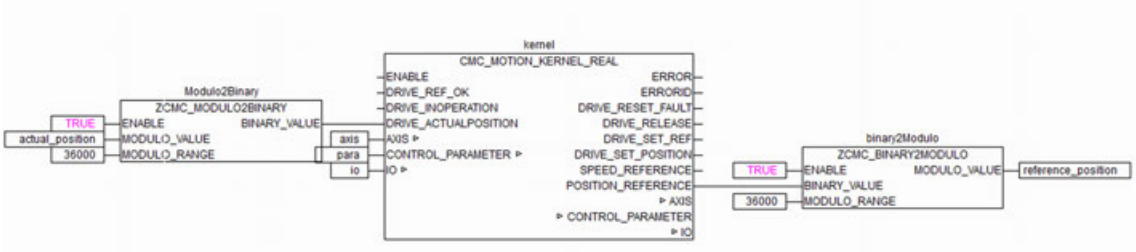

Fig. 231: Kernel

The function block CMC_Modulo2Binary will convert any position with any Modulo_Range to a 32-bit binary position.

The actual_position is assumed to run between 0 to Modulo_Range.

The actual_position should not change > 1/4 Modulo_Range between two scan cycles.

The function block ZCMC_Modulo2Binary will convert the 32-bit binary position reference from CMC_Motion_Kernel_Real to a position reference which runs from 0 to Modulo_Range.

How to do position correction “on the fly”

Sometimes it is required to have a position correction "on the fly". For example, it can happen that a position is wrong due to mechanical slip and that a switch which is passed by during the movement is used to capture a position value.

In other cases, it is required to synchronize the position to a print mark, so an actual_position has to be corrected, but not the movement of the printed material.

For both applications, the function block MCA_SetPositionContinuous can be used. It will use ramps and a limited velocity for the correction, so it will be tolerable to execute it during an ongoing movement and while the axis is activated in a multi-axis movement.

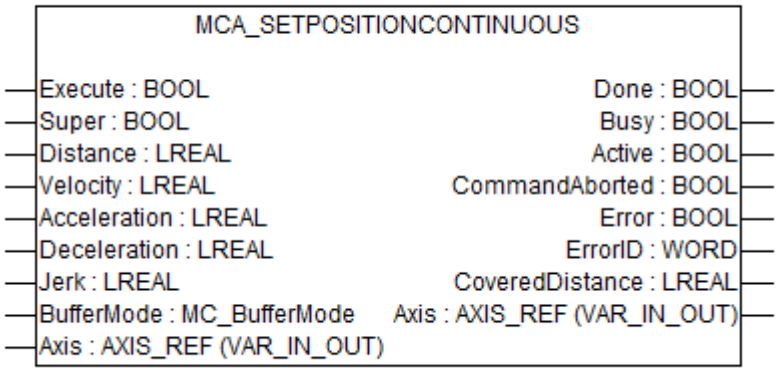

Fig. 232: MCA_Set PositionsContinuous

The block can be used in any axis state except ERRORSTOP and HOMING.

Two different operation modes are possible:

1. SuperImp=FALSE
   - The actual_position will be modified.
   - The block will not cause any movement.
   - If a PLCopen block in DISCRETE_MOTION (positioning) is active during the execution, this block will not reach Done as the actual_position is modified.
   - If a slave axis is coupled to an axis while MCA_SetPositionContinuous is executed (with SuperImp=FALSE) it will follow.
   - This mode is possible while the axis is in state DISABLED.
2. SuperImp=TRUE
   - The actual_position will stay constant.
   - A mechanical movement is executed (without changing the axis state machine).
   - A slave axis will not follow.
   - This behavior is similar to a superimposed movement.
   - It is not possible when the axis is in state DISABLED.

The block can just be aborted by another MCA_SetPositionContinuous.

How to limit the movement

It is possible to limit the movement by position (software limit switches) and by velocity. By default, no software limit switches are activated in PS552. It is possible to activate them by accessing some PLCopen parameter.

The functionality described below is just available with linear axes.

	Parameter	Data type	Minimum	Maximum	Default	R/W	Description
2	SWLimitPos	DINT	-2147483647	2147483647	2147483647	R/W	Positive software limit switch position.
3	SWLimitNeg	DINT	-2147483647	2147483647	2147483647	R/W	Negative software limit switch position.
4	EnableLimitPos	BOOL	FALSE	TRUE	FALSE	R/W	Enable positive software limit switch.
5	EnableLimitNeg	BOOL	FALSE	TRUE	FALSE	R/W	Enable negative software limit switch.
2003	EnableLimit2Decelerate	BOOL	FALSE	TRUE	FALSE	R/W	Enable software limit switches to decelerate
2004	EnableLimitAbort	BOOL	FALSE	TRUE	FALSE	R/W	Enable that software limit switches will abort ongoing movement FALSE = Limits position and velocity, decelerates and shows a warning until the position limit is reached, then ERROR STOP TRUE = Switches off any ongoing motion and decelerates to the position limit, then ERROR STOP
2005	EnableLimtVelocity	BOOL	FALSE	TRUE	FALSE	R/W	If the velocity is limited the unmoved position will be covered whenever possible
2006	SWLimit2DecPos	LREAL	-2147483647	2147483647	2147483647	R/W	Used as end position for EnableLimit2Decelerate
2007	SWLimit2DecNeg	LREAL	-2147483647	2147483647	2147483647	R/W	Used as end position for EnableLimit2Decelerate
2008	MaxPositionGap	LREAL	0	21474836 4700	0	R/W	Used to stop the ongoing movement if position is behind

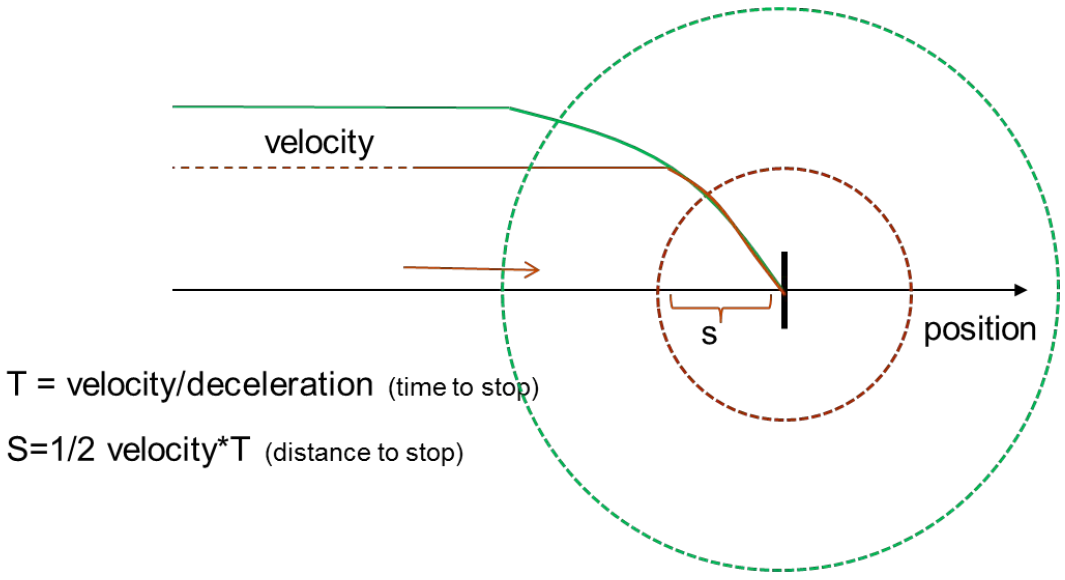
The following different behavior is possible:

- No limitation at all (default)
- Limit position with ERRORSTOP:
  - Limit position between SWLimitNeg to SWLimitPos, axis to state ERRORSTOP in case the position range is left.
- Limit velocity and acceleration:
  - Limit velocity to paraMaxVelocityAppl and acceleration/deceleration to paraMaxDecelerationAppl, create WARNING_VELOCITY, not state changes for axis, abort movement is optional when MaxPositionGap is reached due to limitation.
- Limit Position with ramp-down:
  - In addition, it is possible to limit the position between SWLimit2DecNeg and SWLimit2DecPos. paraMaxDecelerationAppl is used to ramp down.

When activated with EnableLimitPos or EnableLimitNeg, the reaction will be as follows:

- When the control position reaches the respective limit switch, the axis will go to state ERRORSTOP, and Drive_Release will be switched off. The actual_position might be behind, depending on the following error. It is assumed that a drive or application specific braking is performed. The axis will be stopped behind the limit.
- The axis could be switched on again by MC_Power. A movement in the opposite direction will be possible.
- The functionality of EnableLimitPos and EnableLimitNegis unchanged.

You can use the limitation of movement to achieve a soft or adjustable braking in advance before reaching the software limit switch. The limitation is activated by three Boolean parameter and will calculate a position distance to the limit switch, which depends on the actual velocity and given deceleration ramp. “paraMaxDecelerationAppl” is used for deceleration. It will decelerate the axis by the given deceleration ramp when the calculated position is reached and stop at the software limit switch. The original behavior is not modified, so if also these software limit-switches are activated, the axis might be set to state ERRORSTOP.



There are 2 different modes:

- EnableLimitAbort = TRUE
  Any ongoing motion will be aborted immediately (when the distance to stop is reached, as shown in the above diagram), a warning is shown
  The axis will be decelerated to reach the software limit switch.
- EnableLimitAbort =FALSE, EnableLimitDecelerate=TRUE
  A warning is shown and the velocity is reduced, with respect to the given deceleration and position limit.
  The ongoing motion is not aborted. If it was just a “tight fit”, e.g. in a master slave movement and the direction is turned soon enough, it might be possible to continue the movement.
  As the ongoing movement is not interrupted, an activated movement might not be completed, for example a MC_MoveAbsolute will never reach its target position. A warning is shown at function block CMC_Motion_Kernel_Real.

When EnableLimitPos = TRUE or EnableLimitNeg = TRUE, and the values for SWLimitPos or SWLimitNeg are set, the axis will be set to state ERRORSTOP when these position limits are reached.

In addition, the function block will allow to limit the velocity. With EnableLimitVelocity = TRUE, it will monitor the velocity demand from the position reference and limit the position reference, so the given velocity limit will not be exceeded. A warning will be shown. The velocity used for limitation is MaxVelocityAppl.

The velocity limitation can be used to prevent short-term velocity peeks. The limited position will be caught up later, whenever possible. This can result in not-expected behavior. The WARNING issued by CMC_Motion_Kernel_Real can be checked and used to stop a movement. The movement will be aborted automatically when the position is by MaxPositionGap behind.

- *For a single axis movement, the commanded velocity is limited at the beginning. No position gap will occur.*
- *In a multi-axis movement, the slave axis follows a master. This can result in a position gap. A velocity peek from the master axis can be reduced by using the limitation. If the master is too fast because of the value for MaxPositionGap, the movement will be aborted.*

When EnableLimit2Decelerate or EnableLimitAbort are used, the velocity is limited to MaxVelocitySystem with EnableLimitVelocity = FALSE. The function modifies the position reference. This modified position reference is used to control the drive. Whenever the limitation interferes the kernel will show a warning or an error. The warning or error message will disappear when the situation is cleared.

Parameter Number	Parameter Name	Value	Comments
4	EnableLimitPos	TRUE	ERRORSTOP when positions exceed, no previous warning or deceleration.
5	EnableLimitNeg	TRUE	
2003	EnableLimit2Decelerate	FALSE	
2004	EnableLimitAbort	FALSE	
2005	EnableLimtVelocity	FALSE	

Parameter Number	Parameter Name	Value	Comments
4	EnableLimitPos	FALSE/TRUE	Reduce the velocity when reaching a position limit within the deceleration distance calculated by using MaxDecelerationAppl. Display a warning at CMC_Motion_Kernel_Real. The underlying movement stays active. With EnableLimitPos = TRUE or EnableLimitNeg = TRUE: When the Position limit is reached, the axis is set to mode ERRORSTOP also if EnableLimitPos or EnableLimitNeg are used. Otherwise, just the movement is limited, without affecting the state machine. An activated positioning movement will not reach its target. Velocity is limited to MaxVelocitySystem.
5	EnableLimitNeg	FALSE/TRUE	
2003	EnableLimit2Decelerate	TRUE	
2004	EnableLimitAbort	FALSE	
2005	EnableLimtVelocity	FALSE	

Parameter Number	Parameter Name	Value	Comments
4	EnableLimitPos	FALSE/TRUE	Reduce the velocity when reaching a position limit within the deceleration distance calculated by using MaxDecelerationAppl. Display a warning at CMC_Motion_Kernel_Real. The underlying movement stays active. With EnableLimitPos = TRUE or EnableLimitNeg = TRUE: When the Position limit is reached, the axis is set to mode ERRORSTOP also if EnableLimitPos or EnableLimitNeg are used. Otherwise, just the movement is limited, without affecting the state machine. An activated positioning movement will not reach its target. Velocity is limited to MaxVelocitySystem. The active PLCopen function block is aborted as soon as the warning is issued. With EnableLimitPos = TRUE or EnableLimitNeg = TRUE: When the Position limit is reached, the axis is set to mode ERRORSTOP.
5	EnableLimitNeg	FALSE/TRUE	
2003	EnableLimit2Decelerate	---	
2004	EnableLimitAbort	TRUE	
2005	EnableLimtVelocity	FALSE	

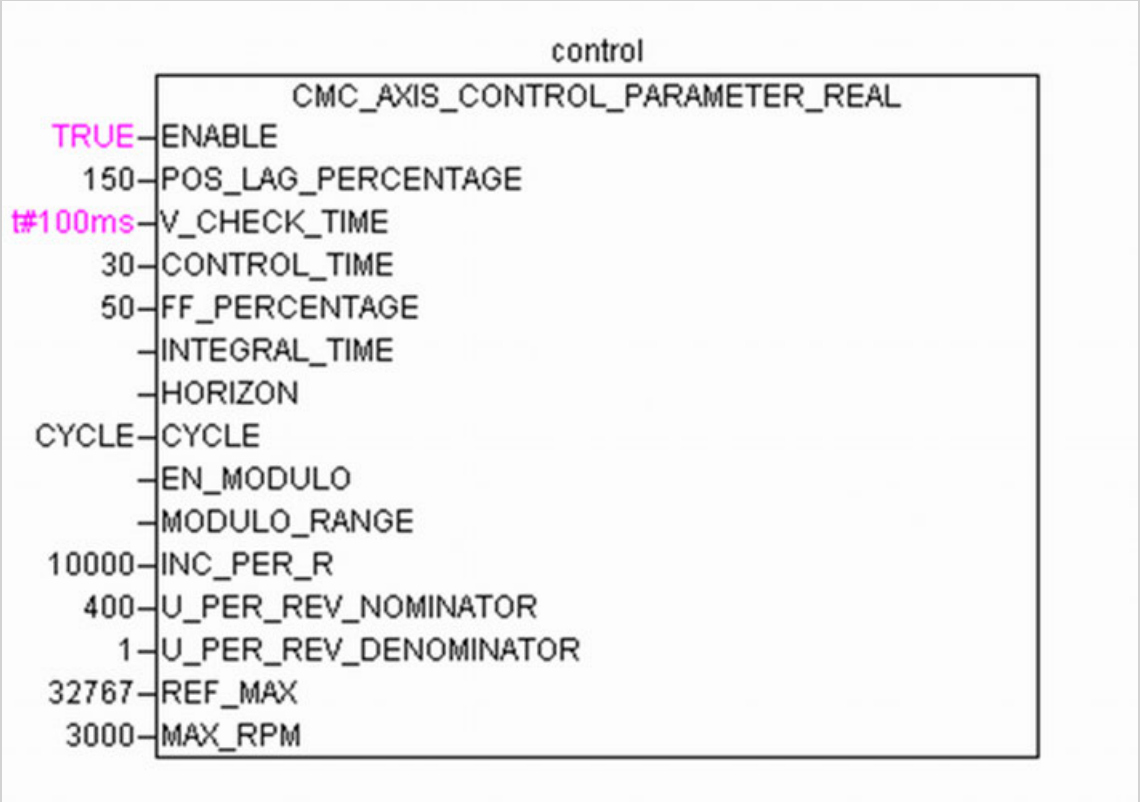
Parameter Number	Parameter Name	Value	Comments
4	EnableLimitPos	---	The velocity is checked and also limited to the value MaxVelocityAppl. A warning is shown. The active movement is not aborted. This functionality works independent from software limit switches.
5	EnableLimitNeg	---	
2003	EnableLimitDecelerate	---	
2004	EnableLimitAbort	---	
2005	EnableLimtVelocity	TRUE	

1.5.9.4.3 Axis parameters

The parameters for axis configuration and adjustment are set by the function blocks CMC_AXIS_CONTROL_PARAMETRS_REAL ↳ *Chapter 1.5.9.4.8.3 “CMC_AXIS_CONTROL_PARAMETER_REAL” on page 2666* or CMC_AXIS_CONTROL_PARAMETRS_INT ↳ *Chapter 1.5.9.4.8.4 “CMC_AXIS_CONTROL_PARAMETER_INT” on page 2669*.

Depending on the version of the kernel function block the corresponding version of the parameters function block has to be used. The instance will then be connected to the kernel function block by its instance name.

Example



- FF_PERCENTAGE=0
- INTEGRAL_PART=0
- HORIZON=0

In the example the control structure is a simple position control loop with just proportional gain. When the application does not require minimized position following error it should be used this way as it is simple to adjust, robust and requires minimal performance. The proportional gain is then adjusted by Control_Time. Just change values at CMC_Axis_Control_Parameter when the position control loop is open (Drive_Release=FALSE, the axis state is Disabled). The values are sending to the control loop whit a positive edge at "Enable". The CMC_Motion_Kernel block needs to be already enabled.

Supervision

Pos_Lag_Percentage

This parameter configures the position window for the supervision of the following error.

The default value is 150[%]. A value of 0[%] will deactivate the supervision function.

The size of the position window depends on the setting of the parameters Control_Time and Max_Rpm *“Control_Time” on page 2643*.

Position Window [Increments] = (Inc_Per_R) * (Max_Rpm/60) * (Control_Time/1000)

Position Window [Units] = (U_Per_Rev_Nominator/ U_Per_Rev_Denominator) * (Max_Rpm/60) * (Control_Time/1000)

Example

Position Window [Increments] = (10000) * (6000/60) * (50/1000) = 50000 [Increments]

Position Window [Units] = (1/1) * (6000/60) * (50/1000) = 5 [Units]

A value of 100% will result in a position window which corresponds to the expected following error with the giving Control_Time at Max_Rpm. Therefore it is recommended to use values higher than 100[%]. In case the parameter FF_Percentage is used smaller values can be used.

If the supervised position window is exceeded the axis state will change to ERRORSTOP.

V_Check_Time

After the configured time the drive’s actual velocity has to be at least 50 % of the commanded velocity. This function can also be used in case the Position Reference is transferred to the drive.

A value of 0 will deactivate this supervision function.

If the supervised velocity window is exceeded the axis state will change to ERRORSTOP.

Position control loop

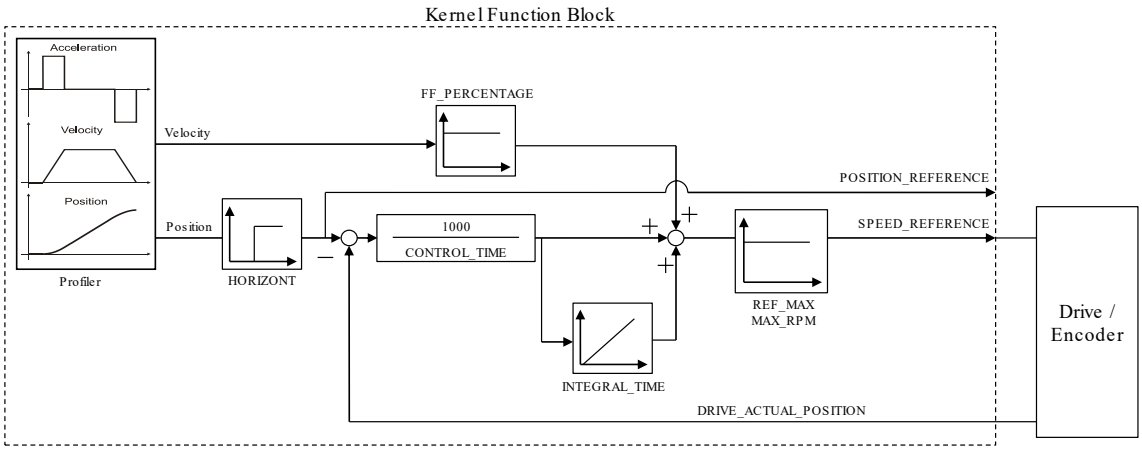


Fig. 233: Basic structure of position control loop

Control_Time

The default value is 100 which leads to a proportional gain of 10.

> *In case the value of Control Time is too short the position control loop will run into instability.*

In case the position control loop is not used this parameter must not be set to 0.

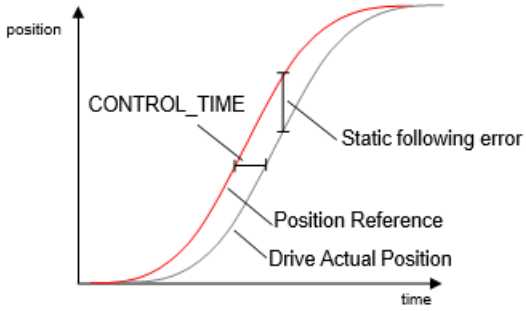

Fig. 234: Control Time and static following error in case the feed forward of velocity and the integrational part of the position control loop is not used.

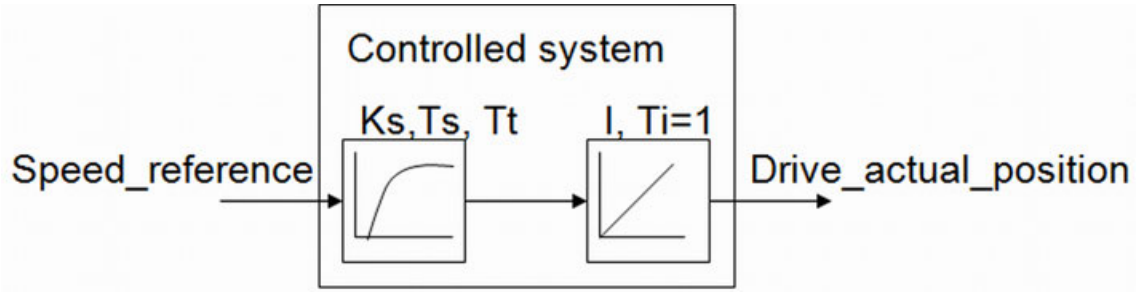
The static following error depends on the axis velocity and can be calculated easily: Control Time multiplied by the axis velocity (p_error = v * CT).

In general it should be aimed to reach a high position control loop gain with a short Control Time to achieve a small following error. As the reaction times take account in the possible Control Time of the complete system (parameters of the drive control loop, PLC cycle time as well as the communication fieldbus) should be considered.

As a basic rule the Control Time should be at least four times longer than the reaction time between the output of the Speed Reference and the input of actual position.

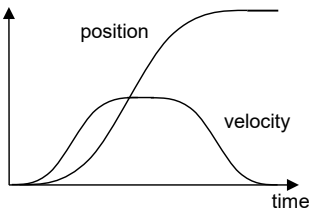


When the time Ts and Tt is measured, a control_time of 4 * (Ts + Tt) will result in an aperiodic damping of the position control loop. It is important to measure the values from inside the PLC (e.g. Trace) to have the complete reaction times included. Practical values for Control_Time might be from 50 - 500ms. The PLC cycle time as well as bus cycle times and mechanical reaction will influence the value.

FF_Percentage The default value is 0.

In case a velocity feedforward has to be configured a value of up to 80 is recommended. For larger values than 80 the parameter Horizon needs to be used as the resulted position will overshoot otherwise.

A value of 100 adds a velocity to the Speed Reference output which corresponds exactly to the ongoing Position Reference value.



Integral_Part

The integral part of the position control loop can be used to eliminate a permanent positioning error, e.g. in case of hanging loads.

The time value can be regarded as the time the integrator needs to sum up the input value to reach the same value for its output.

> *In case the Integral Part Time is too short the position control loop will run into instability.*

Horizon

A communication delay of the Speed Reference value to the drive system can cause an overshoot during positioning caused by the velocity feedforward gain.

This function will compensate this communication delay to prevent an overshoot by time shifting the signals Velocity Feed Forward and Position Reference relatively to each other.

The value of Horizon can be approximately assumed to be the time delay of the communication delay.

The delay time might be caused by the cycle time of the control loop and by any delay in sending the speed reference, delay in the drive to build up the torque and delay to receive the actual position. To overcome this delay, a Horizon > 0 might be used. The feed forward reference will be created in advance, while the proportional gain is applied to the original motion profile. The delay is then compensated.

This function should not be used if the feed forward parameter FF_Percentage is 0.

A value of 0 will deactivate this function, which is the default value.

While this function is used, it will increase the needed PLC calculation time for this axis.

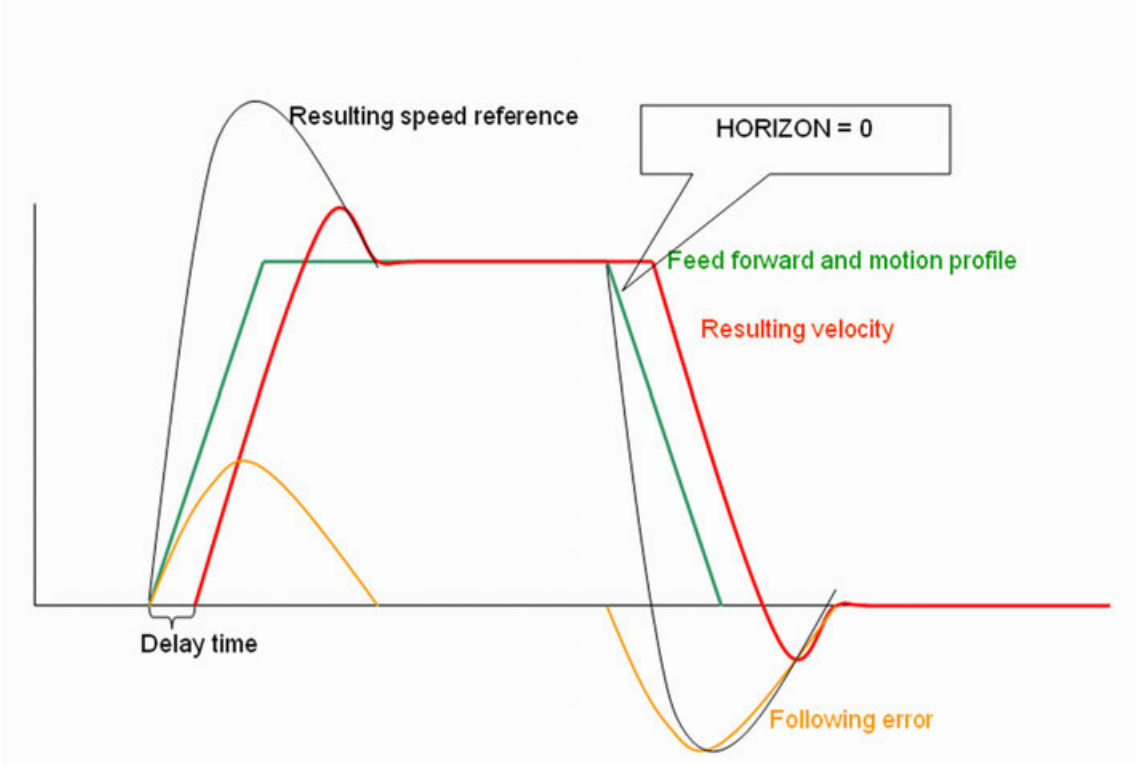


Fig. 235: Result with Horizon=0

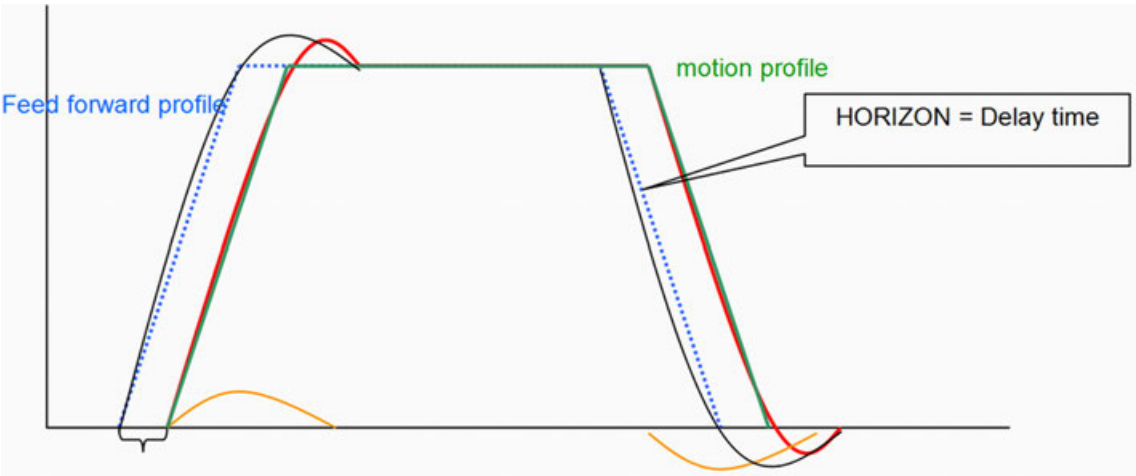

Fig. 236: Result with Horizon>0

PLC cycle time

Cycle

This parameter represents the cycle time in which the kernel function block of the axis is called. If the configured cycle time is not correct the resulting acceleration and speed of an axis will be not correct also.

In case the task execution of the axis is synchronized to a fieldbus (e.g. EtherCAT) the cycle time of the fieldbus has to be used.

Roll-Over axis

If the Position Reference value is used, the drive must able to perform a position over-run after 32 bit. If the drive's position over-run is different, it can be adapted with the function blocks CMC_Binary2Modulo and CMC_Modulo2Binary from the library ABB_MotionControl_AC500.library. Incompatibility can cause an axis to trip after hours of operation.

The possible position following error has to be smaller the ½ Modulo_Range. Make sure that the modulo range is large enough.

Position following error = (100 - FF_Percentage) * Max_Rpm * Inc_Per_R * Control_Time/6000000. This is the maximum value at constant velocity.

En_Modulo

With this parameter the axis can be configured as a roll-over axis.

Modulo_Range

The modulo range will be defined in drive position counts (DINT). It will result that the scaled unit position which is used by the PLCopen function blocks will stay within the defined range.

Example

```
En_Modulo             = TRUE
Modulo_Range          = 20000
Inc_Per_Rev             = 10000
U_Per_Rev_Nominator     = 360      (e.g. degree)
U_Per_Rev_Denominator     = 1
```

The scaled unit's position will cover the range from 0 to 720 (degrees).

In some cases it is not suitable to set the modulo range of an application with the DINT value of the parameter Modulo_Range only. In such cases the parameters 2001 Modulo_Nominator and 2002 Modulo_Denominator can be used to scale the parameter Modulo_Range to a more precise value.

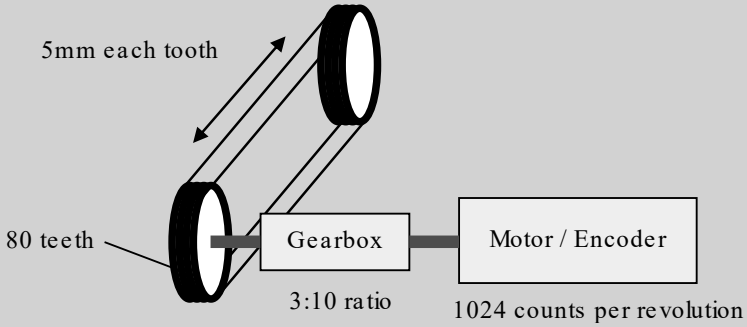
Parameter Modulo_Nominator and Modulo_Denominator (supported with CMC_Motion_Kernel_Real)

These parameters can be used to modify the Modulo_Range in a way that fractions of an increment could be used for 1 modulo (=rollover) distance

- Default: Modulo_Nominator=1 and Modulo_Denominator=1: the actual position for an axis is limited between 0 and Modulo_Range increments.
- Limitations: Modulo_Range*Modulo_Nominator < 2147483647. Otherwise: default values will be used.
- When modifying these parameters, the position control loop should be opened.

Example

```
En_Modulo             = TRUE
Modulo_Range          = 1024
Modulo_Nominator        = 10
Modulo_Denominator        = 3
Inc_Per_R             = 1024
U_Per_Rev_Nominator     = 80*5*3
U_Per_Rev_Denominator     = 10
```



Result of parameters Modulo_Range, Modulo_Nominator and Modulo_Denominator: The modulo range will cover one revolution of the toothed-belt wheel.

Result of parameters U_Per_Rev_Nominator and U_Per_Rev_Denominator: One scaled unit corresponds to one mm of the tooth belt.

Example: Gearbox 10.1

	Option1	Option2
En_Modulo	TRUE	TRUE
Modulo_Range	10240	10240
Modulo_Nominator	1	1
Modulo_Denominator	1	1
Inc_Per_R	1024	10240
U_Per_Rev_Nominator	36	360
U_Per_Rev_Denominator	1	1
Max_Rpm	3000	300

The two options above describe exactly the same configuration. The Modulo_Range is equivalent to 10 motor revolutions and is 10240 increments. For the position, 1u means 1° and the resolution is 360°/10240inc = 0,035°/Inc = 1°/28,44 Inc.

Example: Gearbox 10.3

	Option1	Option2
En_Modulo	TRUE	TRUE
Modulo_Range	1024	10240
Modulo_Nominator	10	1
Modulo_Denominator	3	3
Inc_Per_R	1024	10240
U_Per_Rev_Nominator	108	1080
U_Per_Rev_Denominator	1	1
Max_Rpm	3000	300

The two options above describe exactly the same configuration. The gearbox is 10:3, so the Modulo_Range is equivalent to 1024*10/3 = 3413 + 1/3 increments. For the first option, the resulting modulo range is calculated 1024*10/3, for option2, it is 10240*1/3. For the position, 1u means 1° and the resolution is 108°/1024inc = 0,105°/Inc = 1°/9.481 Inc.

Scaling of the unit of length

Inc_Per_R With this parameter the number of the drive position counts each revolution of the motor (DINT) have to be entered.

U_Per_Rev_Denominator & U_Per_Rev_Nominator With these two parameters the number of units which correspond to one revolution of the motor have to be entered.

The units of length can be scaled to values like: mm, inch, degree, …

All dynamic parameters of the PLCopen function blocks like velocity, acceleration and jerk are based on seconds. Velocity [units/s], acceleration [units/s²], jerk [units/s³]

Example 1

```
Inc_Per_Rev            = 10000
U_Per_Rev_Nominator     = 360
U_Per_Rev_Denominator     = 1
```

This will scale one unit to one degrees of the motor shaft. Correspondingly a velocity [units/s] of 360 will turn the motor shaft one revolution per second.

Example 2 In the example one unit will be scaled to one millimeter of the conveyor.

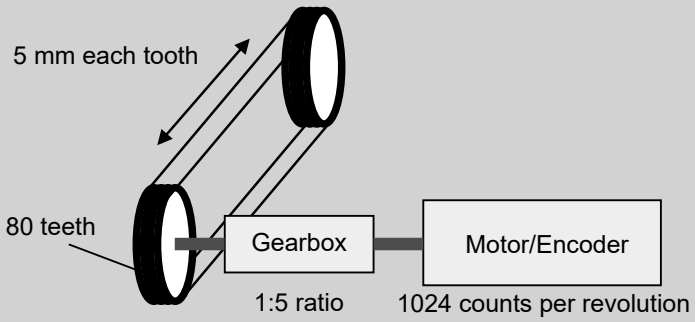


Fig. 237: Scaling units

How many units will pass after one revolution of the motor? (80*5mm) / 5 = 80

```
Inc_Per_Rev            = 1024
U_Per_Rev_Nominator     = 80
U_Per_Rev_Denominator     = 1
```

Example 3 In the example one unit will be scaled to one millimeter of the conveyor.

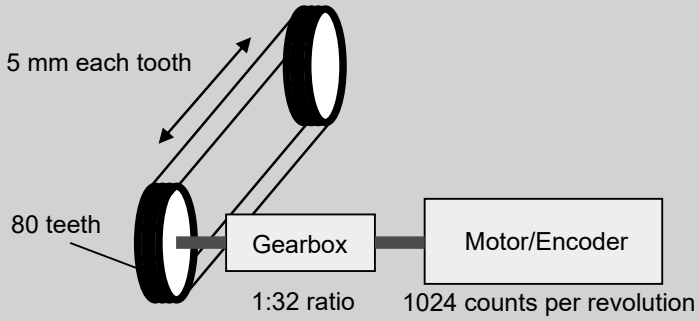

Fig. 238: Scaling units

How many units will pass after one revolution of the motor? (80*5mm) / 32 = 12,5 = 125 / 10

```
Inc_Per_Rev             = 1024
U_Per_Rev_Nominator      = 125
U_Per_Rev_Denominator      = 10
```

Scaling of the speed reference output

These two parameters are used to scale Speed Reference output of the kernel FB in order to reach the intended velocity by the output value and to limit the highest possible output value.

Ref_Max Highest possible output value of the Speed Reference output. The Speed Reference value that corresponds to the parameter Max_Rpm should be used.

Max_Rpm Maximum speed of the motor in revolutions per minute.

Example

- Analog Drive: 1000 rpm at 2 Volts, 3200 rpm at 6,4 Volts (max.)
- Analog output module: 10 Volts output at digital value 27648
- Ref_Max = 17695 (= 27648 / 10 * 6,4)
- Max_Rpm = 3200

Access and modify parameters

All modifications will be effective immediately. There is no extra plausibility check and values are not checked for limitations.

Use this functionality with care.

Some parameters are collected inside a structure in Axis_Ref, and can be accessed and modified immediately. They are the same parameters as used with function blocks MC_Write-Parameter and MC_ReadParameter *Chapter 1.5.9.3.6 “PLCopen parameter” on page 2595*.

The differences are:

- Only available with CMC_Motion_Kernel_Real
- The parameter values are LREAL instead of DINT and can be used with decimals.
- The parameters will be effective immediately.
- There is no check for consistency or limits.
- The parameters for position control can be checked and modified by accessing the structure Axis_Parameter.CMC_Pos_Control in addition.

Parameter for position control	Description
KP	Proportional gain in positive direction. Used directly to multiply the following error and create the Reference_Prop.
KF	Feed forward in positive direction. Used directly to multiply the speed reference and create the Reference_FF.
KP_BACK	Proportional gain in negative direction. Used directly to multiply the following error and create the Reference_Prop.
KF_BACK	Feed forward in negative direction. Used directly to multiply the speed reference and create the Reference_FF.
TI	Integration time. When parameter is used the position control loop has an additional integral part. In TI cycle, the Reference_ITG will reach the value of Reference_Prop, when KI=100*KP.
KI	Proportional gain, used for integral part of position control loop.
KF_100	Value for feed forward gain, if 100% would be used.
Max_Time	Delay time used for supervision of velocity. With Max_Time=0, no supervision is executed.
D_XS_Max	Maximum possible velocity in [u/cycle]. The maximum allowed following error is part of the parameter structure, PLCopen parameter paraMaxPositionLag.
Ref_Max	Limit for Speed_Reference.

Element actual of Axis_Ref

The element `actual` represents actual values from inside the position control loop.

Value	Description
Position	Actual position in [u] to control the axis.
Control_Position	Reference position in [u] which is actually used for control loop.
D_XS	Distance in [u] to be moved per cycle.
D_XSS	Following error in [u].
Reference_Prop	Proportional part for Speed_Reference.
Reference_FF	Feed forward part for Speed_Reference.
Reference_ITG	Integral part for Speed_Reference.

Possible to use different gain for forward/ backward movement , possible improvement for hydraulic axis or vertical movement

See parameter KP/KP_BACK and KF/KF_BACK.

Limitation for velocity and acceleration and deceleration

From library version 3.1 on, these values are not limited to the 16-bit range of values (32767). The limit for velocity is calculated by the values given at CMC_Axis_Control_Parameter_Real and the acceleration is limited such that this velocity can not be reached faster than 1 cycle.

1.5.9.4.4 Programming guidelines

To achieve the best results for Motion Control the actual position has to be transferred in best possible quality (with minimal jitter) to the PLC. The position feedback is expected to be in increments as the data type is a DINT.

The kernel function block (CMC_Motion_Kernel_Real or CMC_Motion_Kernel_Int) has to be called every cycle and its task requires a fixed cycle time.

A variable of type Axis_Ref is used to connect to the PLCopen function blocks and their kernel function block.

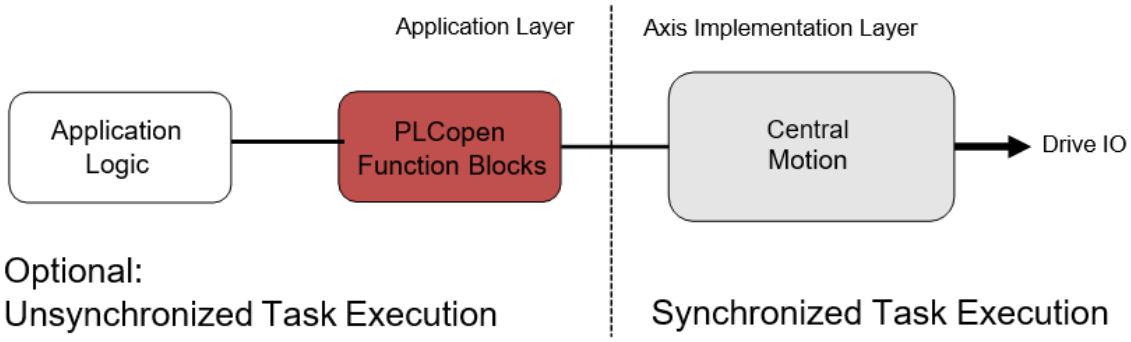
The function block CMC_Axis_Control_Parameter_Real or CMC_Axis_Control_Parameter_Int has be used for the axis configuration. *Chapter 1.5.9.4.3 “Axis parameters” on page 2642*

The signal of the limits switches and the absolute switch should be connected to the elements of the data type CMC_Axis_IO. The signal of the absolute switch must be TRUE in case the axis hits the sensor. The signal of a corresponding limit switch has to be true when the axis leaves the area surrounded by the limit switches. If needed the signal has to be inverted before it is connected to the elements of the data type.

Task configuration

The kernel function block and the transfer of axis IO data should be processed in a cyclic task. This task should be as short and real-time as possible to achieve the best motion control performance. Always make sure Kernel function block is called at the highest priority task and other applications must be at a lower priority task.

In order to save PLC processing time the most PLCopen function blocks as well as the application logic can also be processed in a task which runs on a lower priority than the real-time task with the axis implementation as shown in the figure below.



All PLCopen function blocks which must be called in the same task than the kernel function block:

- MC_CombineAxes
- MCA_MoveByExternalReference
- MCA_SetCoordinateTransformation
- MCA_SetDynamicFollower
- MCA_SyncInfeedToPath
- MCA_SyncCamToPath
- MC_SetCoordinateTransform
- MC_SetCartesianTransform (only if the transformation will be changed during run time)
- MC_SyncAxisToGroup

In case the position reference is transferred to the drive the task of the axis implementation should be synchronized to the fieldbus cycle. The following figures show an example for EtherCAT:

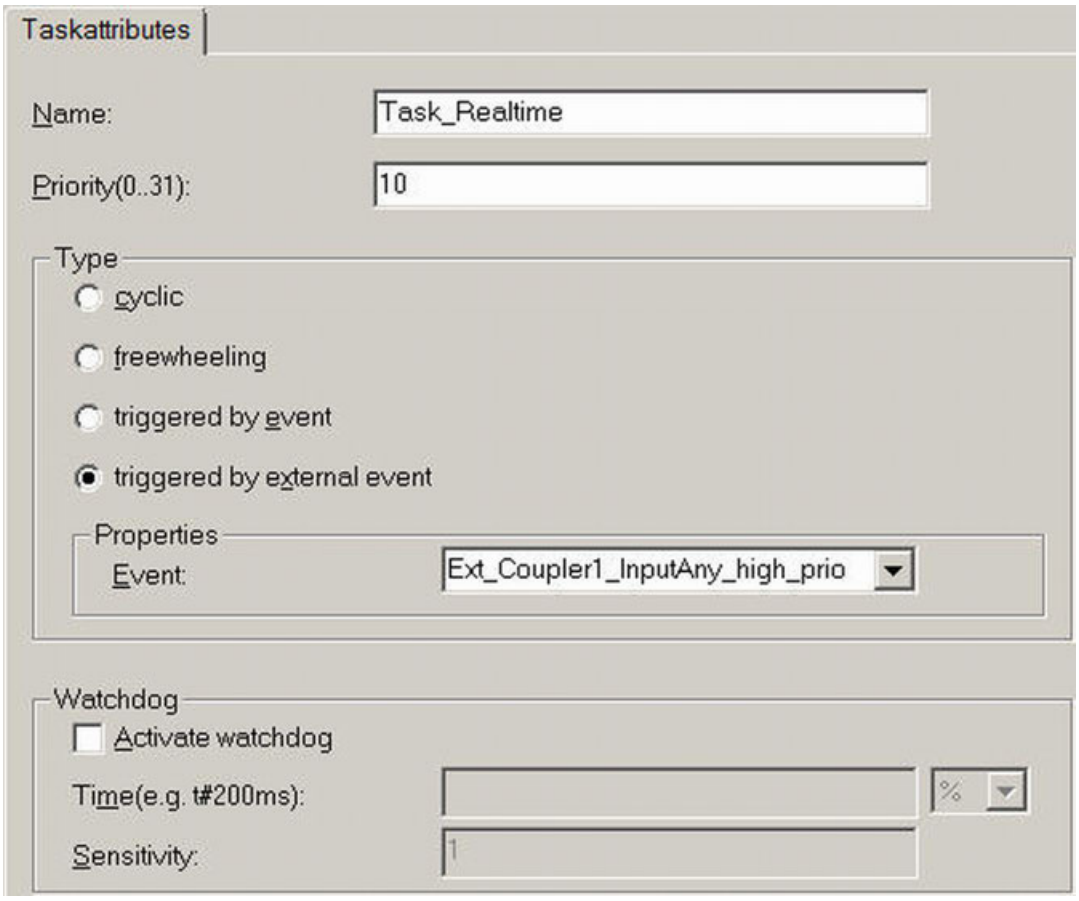


Fig. 239: Task of axis layer

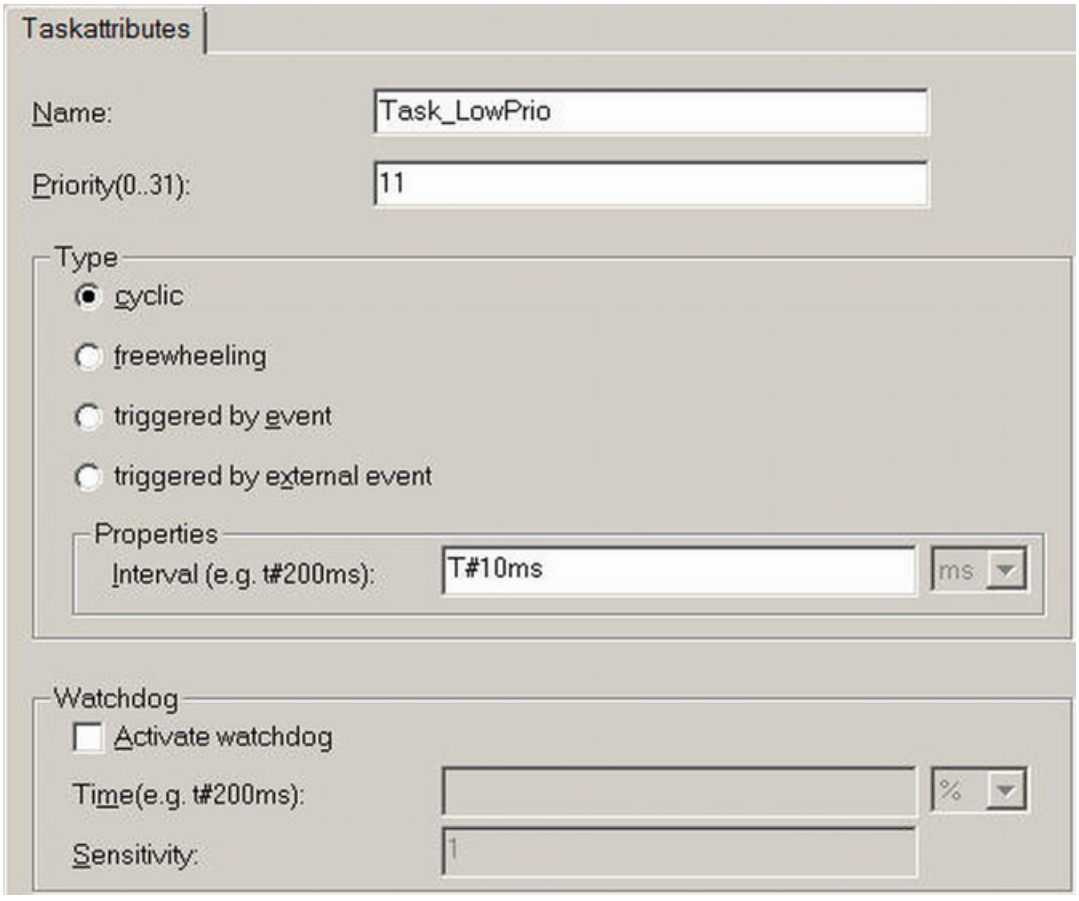

Fig. 240: Task of application implementation

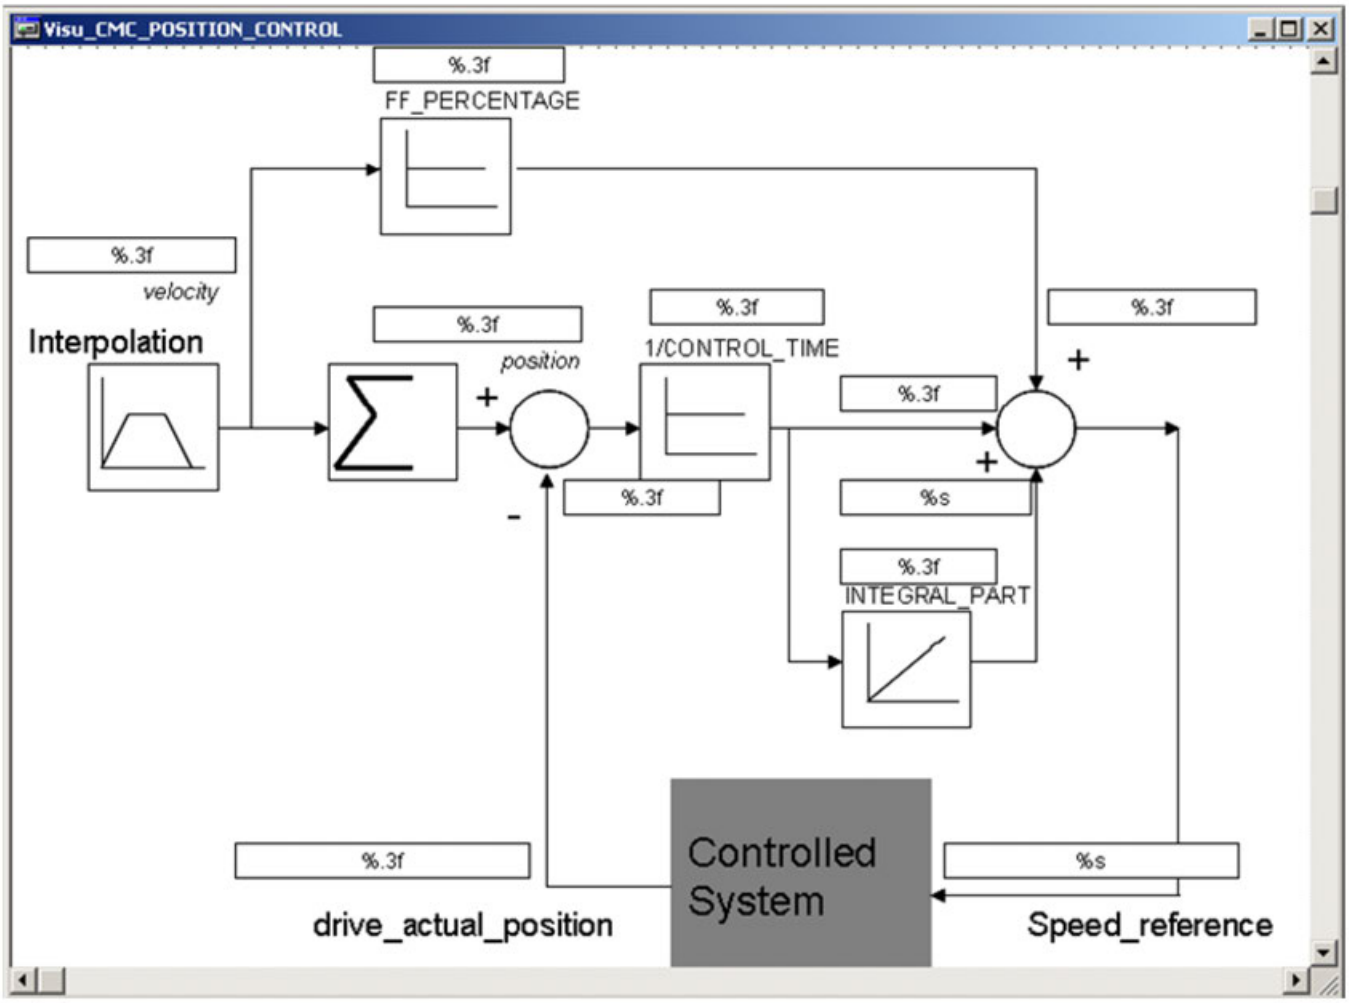
1.5.9.4.5 Visualization

The structure of the position control loop is also as visualization element Visu_CMC_POSITION_CONTROL. included in CompactMotionControl_AC500_V21.lib. As placeholder, an instance of CMC_Motion_Kernel_Real or CMC_Motion_Kernel_Int has to be used. The visualization shows all numbers as they are really used inside the block, the adjustment for different resolution or cycle times is already included.



1.5.9.4.6 ABB specific data structures

Not all data structures are defined by PLCopen. Some specific structures are described in the following chapter. In addition to the data in these arrays, the movement is modified by offset and scaling values at the respective function block. These offset and scaling values (except the time-scale) are transferred continuously. This will allow to follow a "Moving Target" by adjusting these values.

PositionPositionProfile

The data type MC_PProfile is used for CamTable. An array has to be defined and provided at MC_CamTableSelect. Several CamTables could be defined and the axis could change between them on the fly. There is no routine of smooth movement from one table to the next so the user has to take care just to switch on appropriate positions. Details are described in the documentation included with the library.

Declaration example CAM_table

```
ARRAY[1..3] OF MC_PProfile:=
    (Master_position:=    0    ,interpolation_point :=
0    ,Velocity_ratio:= 0    ,Acceleration_ratio:= 0 ),
(Master_position:=    50    ,interpolation_point :=
25    ,Velocity_ratio:= 0    ,Acceleration_ratio:= 0 ),
(Master_position:=    100    ,interpolation_point :=
0    ,Velocity_ratio:= 0    ,Acceleration_ratio:= 0 );
```

PositionTimeProfile

This structure is used for time based profiles, e.g. MC_PositionProfile:

Interpolation types for profiles

The curves defined by an array of MC_PProfile hold master position points and according slave positions. When the master position is between 2 points, the according position for the slave is interpolated. Different types of interpolation are possible. The type is defined in MC_ABB_iTypes_Enum . The master could be a real axis or some virtual axis which could be created by just writing values for position and velocity to the Axis_Master variable as shown in the example. The same interpolation types could be used on MC_TProfile.

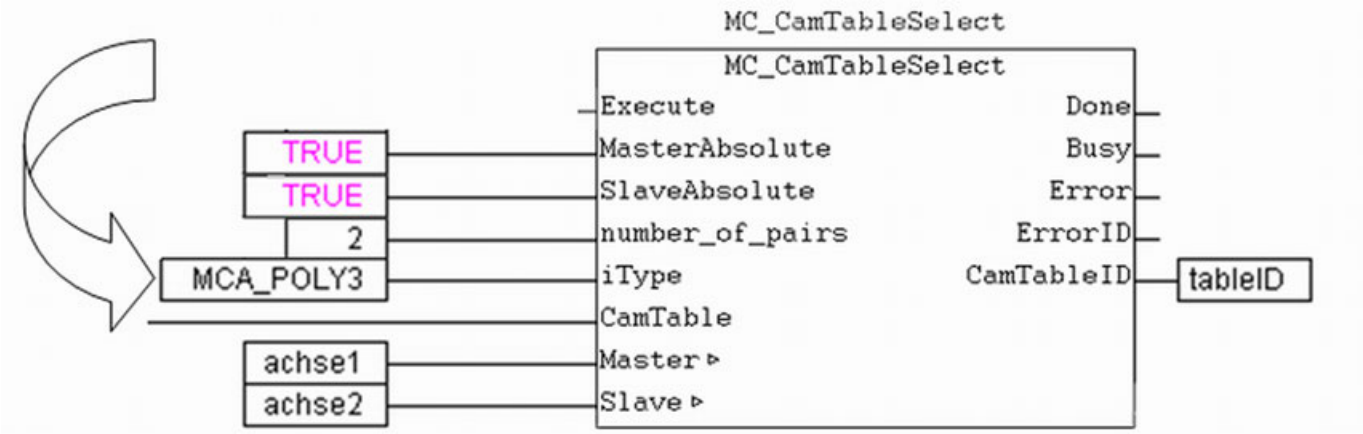


Table 168: Overview of different interpolations

Interpolation Types	Results in	Requires
MCA_LINEAR	Linear interpolation with constant velocity between interpolation points.	profile.MC_PProfile_Array[x].master_position, profile.MC_PProfile_Array[x].interpolation_point
MCA_SPLINE_NATURAL	Cubic spline interpolation without jerk.	profile.MC_PProfile_Array[x].master_position, profile.MC_PProfile_Array[x].interpolation_point
MCA_SPLINE_COMPLETE	Cubic spline interpolation without jerk, start and end of profile with velocity=0.	profile.MC_PProfile_Array[x].master_position, profile.MC_PProfile_Array[x].interpolation_point

Interpolation Types	Results in	Requires
MCA_POLY3	Polynomial interpolation with linear velocity between interpolation points.	profile.MC_PProfile_Array[x].master_position, profile.MC_PProfile_Array[x].interpolation_point, profile.MC_PProfile_Array[x].velocity_ratio
MCA_POLY5	Polynomial interpolation with linear acceleration between interpolation points.	profile.MC_PProfile_Array[x].master_position, profile.MC_PProfile_Array[x].interpolation_point, profile.MC_PProfile_Array[x].velocity_ratio, profile.MC_PProfile_Array[x].acceleration_ratio

The interpolations allow to run on smooth curves without the need to define a large number of points. The following chapter shows the results with different interpolation modes for a sinus-curve with 10 interpolation points. The following table gives the mean deviation.

Interpolation Type	Mean deviation [ppm]
MCA_LINEAR	19686 =1.9%
MCA_SPLINE_NATURAL	151=0.0151%
MCA_SPLINE_COMPLETE	25510=2.5%
MCA_POLY3	131=0.0131%
MCA_POLY5	0.37

The original curve is represented by y_sinus for position and v_sinus for velocity. The diagrams show the result which is achieved by different interpolation types.

MCA_LINEAR

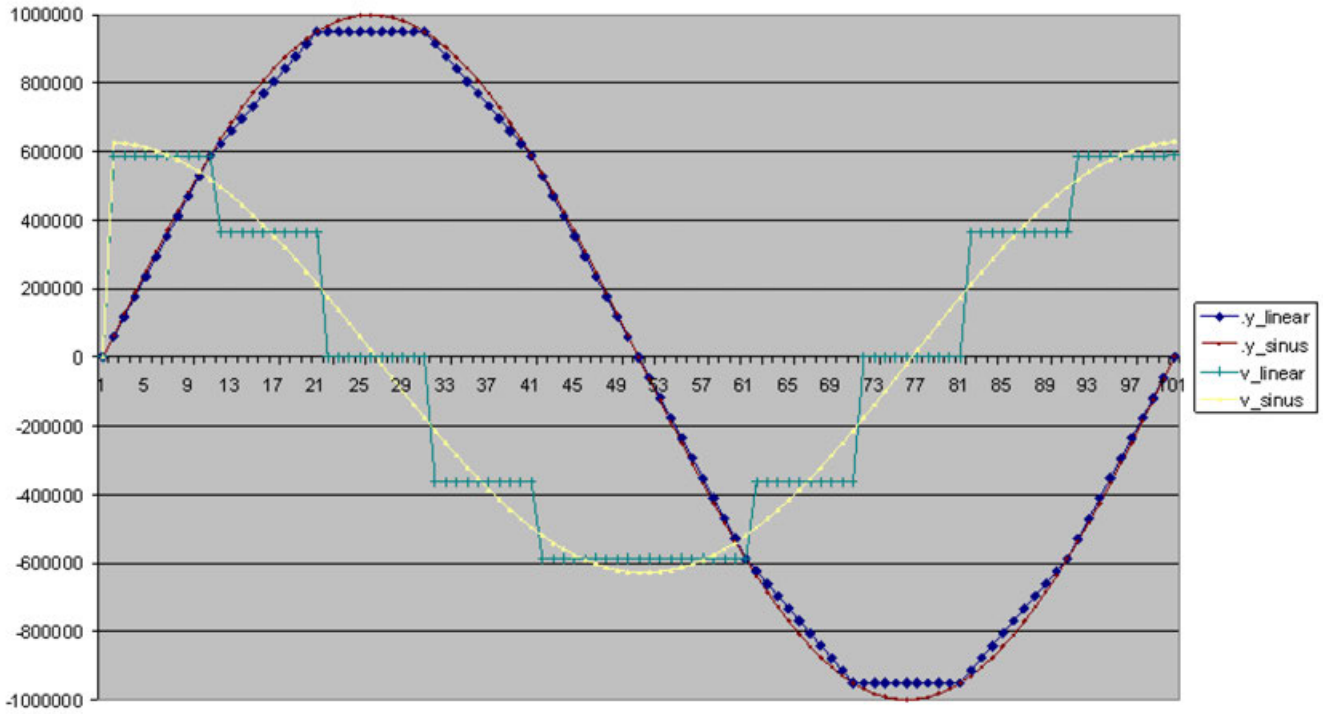

Fig. 241: Results from linear interpolation

The velocity is constant between the interpolation points.

MCA_POLY3

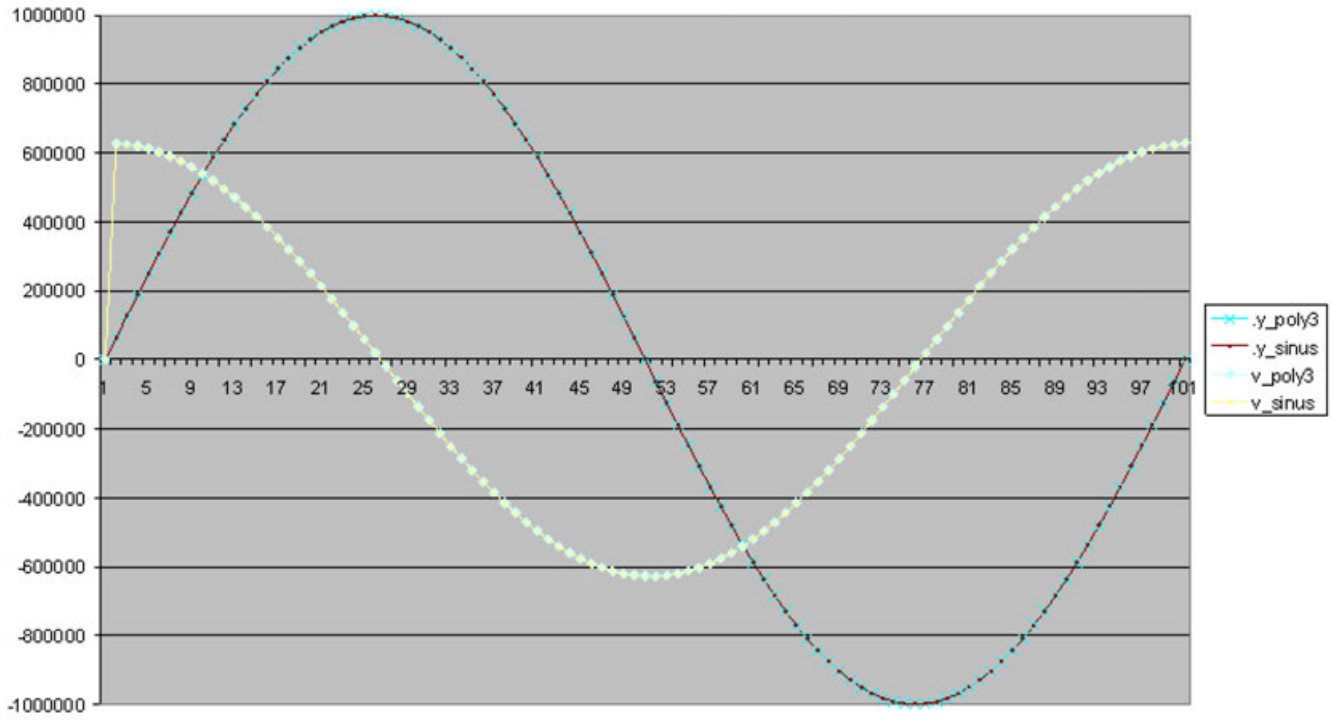

Fig. 242: Results from polynomial interpolation

The result looks almost identical to the original curve. The mean deviation shows that MCA_POLY3, MCA_POLY5 and MCA_SPLINE_NATURAL produce results which follow the original curve really good and are almost identical. The spline interpolation produces a jerk-free curve without the need of providing velocity values and acceleration values in advance.

MCA_COMPLETE

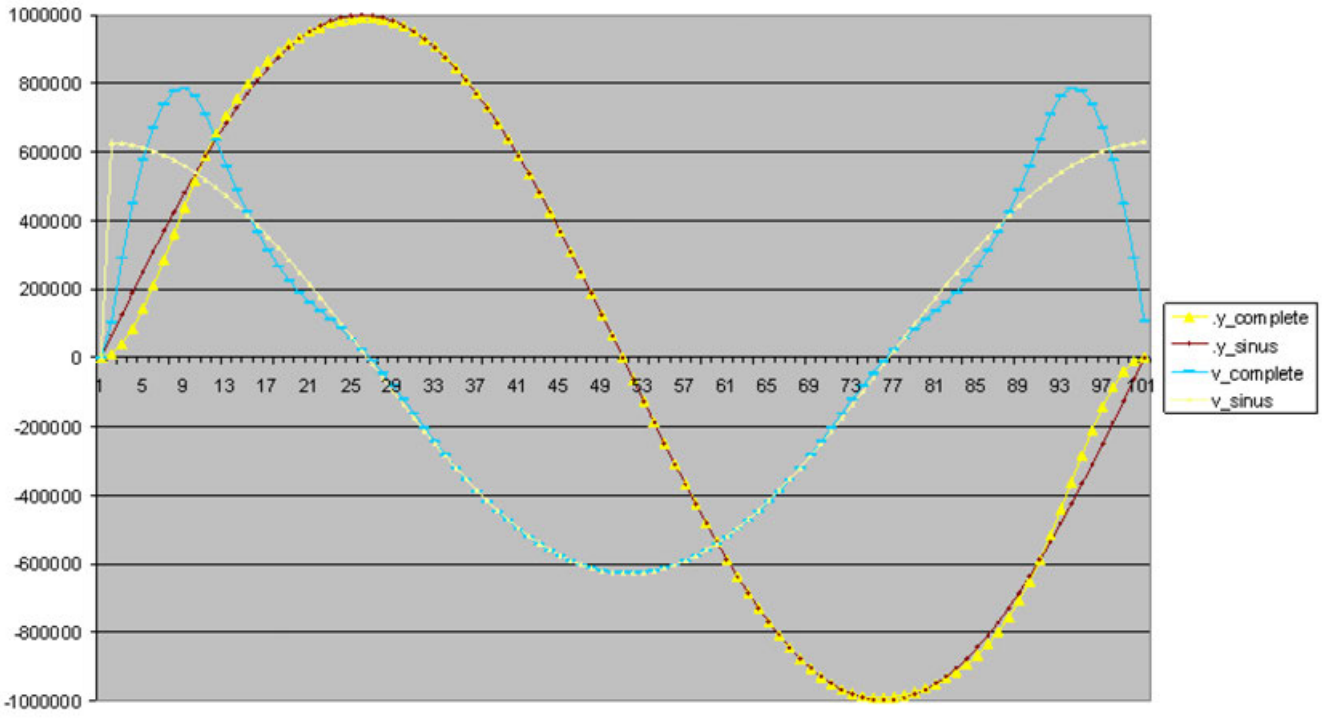

Fig. 243: Results from complete spline interpolation

In the beginning and the end, the curve does not follow the original curve. The reason is that it starts with velocity=0 and produces a jerk free result.

So the favoured result has to be considered in advance to choose the right interpolation method. With these different methods it is not necessary to provide a large number of interpolation points to get good results and smooth acceleration and deceleration ramps.

1.5.9.4.7 Appendix

List of all PLCopen and ABB specific function blocks in PS552-MC (for V2 PLC) and PS5611-Motion (for V3)

SNo	Funktion block type	Funktion block name	Motion Library V2 (PS552-MC)	Motion Library V3 (PS5611-Motion)

PLCopen Part 4 –Coordinated Motion is only available for V2 PLC and not yet available for V3 PLC.

1.5.9.4.8 Function blocks for central motion control implementation

CMC_MOTION_KERNEL_REAL

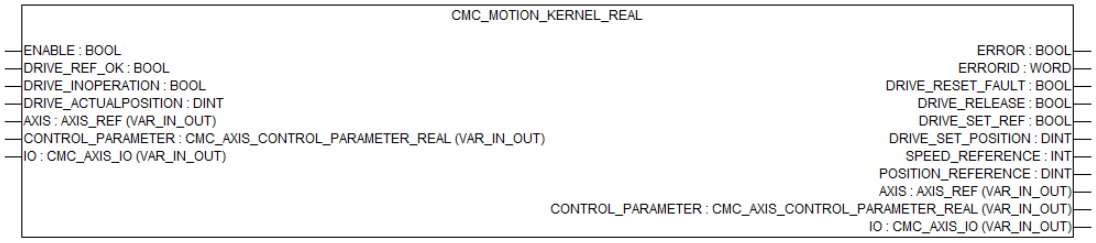

Fig. 244: Function block CMC_MOTION_KERNEL_REAL

Table 169: General information

Available as of runtime system	V1.2
Included in library	CompactMotionControl_AC500_V21.LIB
Type	Function block with historical values

The kernel function block is the fundamental part of the Central Motion Control axis implementation named Compact Motion. It performs floating point artithmetic for all calculations. More detailed information about this function block and the use of it: *Chapter 1.5.9.4 “PLC-based motion control” on page 2615*

Input description

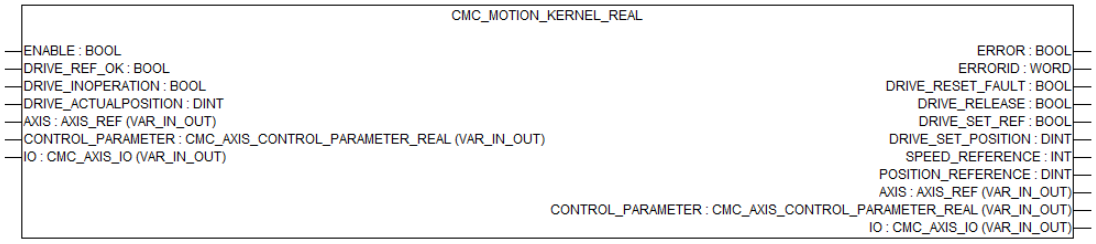

Fig. 245: Function block CMC_MOTION_KERNEL_REAL

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

If the function block is stored in a RETAIN memory area, the connected AXIS has to be RETAIN.

ENABLE Data type: BOOL

Release of function block. Enable has to be set before new control parameters are released by CMC_AXIS_CONTROL_PARAMETER.

DRIVE_REF_OK Data type: BOOL

Indication for homing.

DRIVE_INOPERATION Data type: BOOL

Indication that drive is running.

DRIVE_ACTUALPOSITION Data type: DINT

Actual position in increments.

Axis Data type: AXIS_REF

Reference to the axis.

CONTROL_PARAMETER Data type: CMC_AXIS_CONTROL_PARAMETER

Parameters for configuration and adjustment of the control loop.Fig. 233

IO Data type: CMC_AXIS_IO

By the structure IO (CMC_AXIS_IO), some binary inputs are provided. The PLC program has to define a variable of type CMC_AXIS_IO and to assign the inputs.

Output description

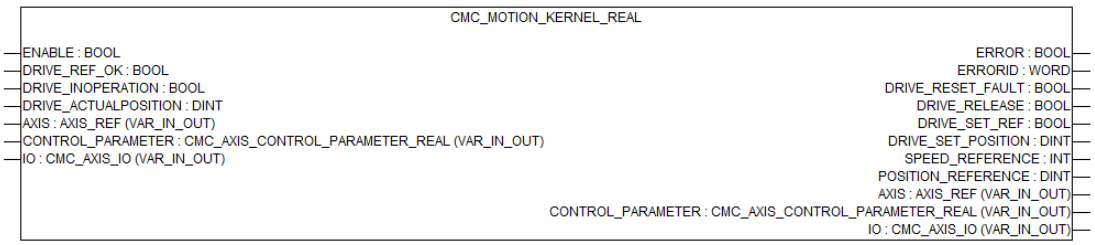

Fig. 246: Function block CMC_MOTION_KERNEL_REAL

Error Data type: BOOL

Signals that an error has occurred within the function block.

ERRORID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

The error codes ERRORID also sets the output-bit ERROR=TRUE and sets the axis in state ERROR_STOP. To allow a new movement the error codes ERRORID require that either the axis is disabled/enabled by MC_Power or the error reset is disabled/enabled by MC_Reset.

The error codes ErrorID_WARNING will not set ERROR=TRUE, and will not set the axis to ERROR_STOP. The error codes ErrorID_WARNING do not require the MC_Reset or MC_Power. It is possible the axis is stopped and ongoing motion is aborted by a WARNING.

The value will be shown until:

- An other error or warning occurs
- MC_Reset or MC_Power is used

ErrorCode	Value	Description
ErrorID_POSITION_FOLLOW	1	The position lag was to large (parameter POS_LAG_PERCENTAGE) or the velocity had a wrong value by 50% for a certain time (parameter V_CHECK_TIME).
ErrorID_POSSW	2	The actual position did exceed the positive Software limit switch position.This supervision has to be activated with MC_WriteParameter.
ErrorID_NEGSW	3	The actual position did exceed the negative Software limit switch position. This supervision has to be activated with MC_WriteParameter.
ErrorID_VELOCITY_FAULT	4	The measured velocity and commanded velocity are > 50% (related to maximum velocity) apart.
ErrorID_INTERPOLATION_FAULT	5	Position following error occurred, but reason most likely a interpolation problem, not drive problem (e.g. CAM Table, position step).
ErrorID_WARNING_POSITIONOVERRUN	13	A linear axis has a 32bit position overrun (configure modulo instead).
ErrorID_WARNING_VELOCITYLIMIT	10	Velocity or acceleration/deceleration are in limitation, set by parameter EnableLimitVelocity.
ErrorID_WARNING_POSITIONLIMITPOS	11	Velocity or acceleration/deceleration are in limitation, set by parameter EnableLimitVelocity (MaxVelocityAppl, MaxDecelerationAppl) Position is in limitation towards position limit (SWLimit2DecPos) .
ErrorID_WARNING_POSITIONLIMITNEG	12	Position is in limitation towards position limit (SWLimit2DecNeg).
ErrorID_WARNING_ABORT	14	Axis has been aborted due to too large position gap in velocity limit.

DRIVE_RESET_FAULT Data type: BOOL

Binary signal to be used for resetting the drive error, if applicable.

DRIVE_RELEASE Data type: BOOL
Activate the drive.

DRIVE_SET_REF Data type: BOOL
Activate homing.

DRIVE_SET_POSITION Data type: DINT
Position to be used at homing.

SPEED_REFERENCE Data type: DINT
Reference value for the drive.

POSITION_REFERENCE Data type: DINT
Position reference value for the drive in increments.

CMC_MOTION_KERNEL_INT

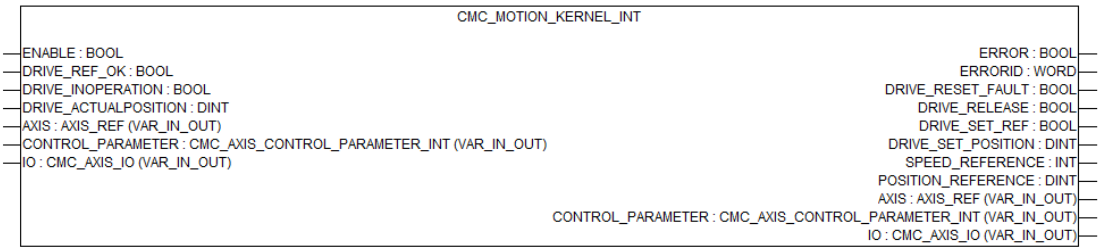

Fig. 247: Function block CMC_MOTION_KERNEL_INT

Table 170: General information

Available as of runtime system	V1.2
Included in library	CompactMotionControl_AC500_V21.LIB
Type	Function block with historical values

The kernel function block is the fundamental part of the Central Motion Control axis implementation named Compact Motion. It performs integer based calculations which use less CPU processing time on the following PLCs: eCo, PM57x, PM58x. As a result of the integer based calculations the available motion control functions are limited. More detailed information about this function block and the use of it: *Chapter 1.5.9.4 “PLC-based motion control” on page 2615*

Input description

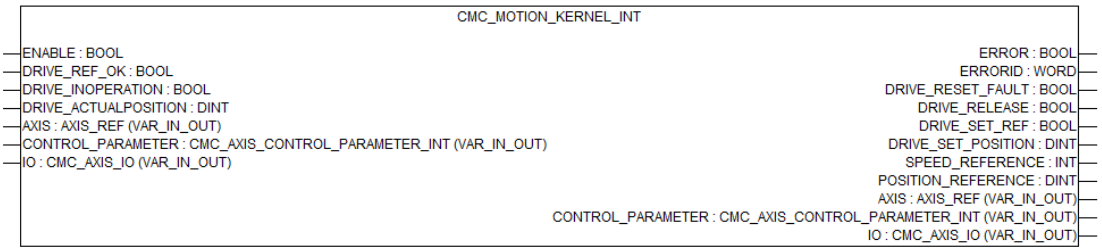

Fig. 248: Function block CMC_MOTION_KERNEL_INT

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

ENABLE

Data type: BOOL

Release of function block. Enable has to be set before new control parameters are released by CMC_AXIS_CONTROL_PARAMETER.

DRIVE_REF_OK

Data type: BOOL

Indication for homing.

DRIVE_INOPERATION

Data type: BOOL

Indication that drive is running.

DRIVE_ACTUAL POSITION

Data type: DINT

Actual position in increments.

Axis

Data type: AXIS_REF

Reference to the axis.

CONTROL_PARAMETER

Data type: CMC_AXIS_CONTROL_PARAMETER

Parameters for configuration and adjustment of the control loop.Fig. 233

IO

Data type: CMC_AXIS_IO

By the structure IO (CMC_AXIS_IO), some binary inputs are provided. The PLC program has to define a variable of type CMC_AXIS_IO and to assign the inputs.

Output description

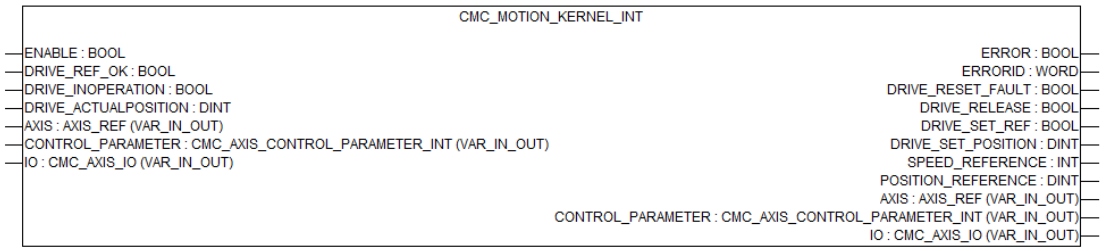

Fig. 249: Function block CMC_MOTION_KERNEL_INT

Error Data type: BOOL

Signals that an error has occurred within the function block.

ERRORID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

The error codes ERRORID also sets the output-bit ERROR=TRUE and sets the axis in state ERROR_STOP. To allow a new movement the error codes ERRORID require that either the axis is disabled/enabled by MC_Power or the error reset is disabled/enabled by MC_Reset.

The error codes ErrorID_WARNING will not set ERROR=TRUE, and will not set the axis to ERROR_STOP. The error codes ErrorID_WARNING do not require the MC_Reset or MC_Power. It is possible the axis is stopped and ongoing motion is aborted by a WARNING.

The value will be shown until:

- An other error or warning occurs
- MC_Reset or MC_Power is used

ErrorCode	Value	Description
ErrorID_POSITION_FOLLOW	1	The position lag was to large (parameter POS_LAG_PERCENTAGE) or the velocity had a wrong value by 50% for a certain time (parameter V_CHECK_TIME).
ErrorID_POSSW	2	The actual position did exceed the positive Software limit switch position.This supervision has to be activated with MC_WriteParameter.
ErrorID_NEGSW	3	The actual position did exceed the negative Software limit switch position. This supervision has to be activated with MC_WriteParameter.
ErrorID_VELOCITY_FAULT	4	The measured velocity and commanded velocity are > 50% (related to maximum velocity) apart.
ErrorID_INTERPOLATION_FAULT	5	Position following error occurred, but reason most likely a interpolation problem, not drive problem (e.g. CAM Table, position step).
ErrorID_WARNING_POSITIONOVERRUN	13	A linear axis has a 32bit position overrun (configure modulo instead).
ErrorID_WARNING_VELOCITYLIMIT	10	Velocity or acceleration/deceleration are in limitation, set by parameter EnableLimitVelocity.
ErrorID_WARNING_POSITIONLIMITPOS	11	Velocity or acceleration/deceleration are in limitation, set by parameter EnableLimitVelocity (MaxVelocityAppl, MaxDecelerationAppl) Position is in limitation towards position limit (SWLimit2DecPos) .
ErrorID_WARNING_POSITIONLIMITNEG	12	Position is in limitation towards position limit (SWLimit2DecNeg).
ErrorID_WARNING_ABORT	14	Axis has been aborted due to too large position gap in velocity limit.

DRIVE_RESET_FAULT Data type: BOOL

Binary signal to be used for resetting the drive error, if applicable.

DRIVE_RELEASE Data type: BOOL

Activate the drive.

DRIVE_SET_REF Data type: BOOL
Activate homing.

DRIVE_SET_POSITION Data type: DINT
Position to be used at homing.

SPEED_REFERENCE Data type: DINT
Reference value for the drive.

POSITION_REFERENCE Data type: DINT
Position reference value for the drive in increments.

CMC_AXIS_CONTROL_PARAMETER_REAL

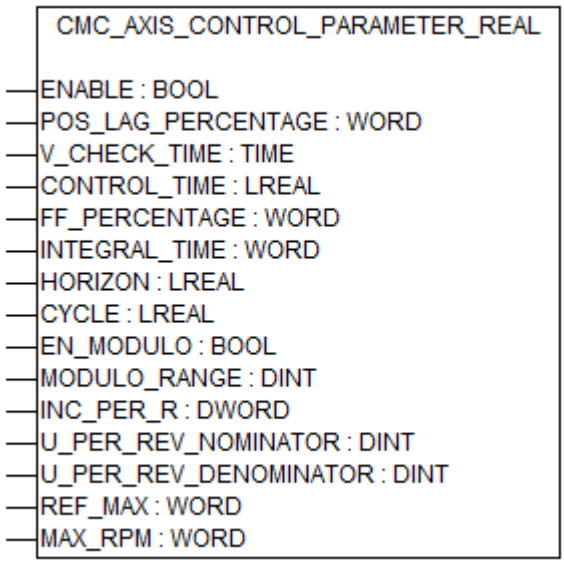

Fig. 250: Function block CMC_AXIS_CONTROL_PARAMETER_REAL

Interface function block for axis configuration and adjustment of the control loop.

> *Enable the function block before any PLCopen-block is used.*

To change parameters follow these steps:

1. MC_Power.ENABLE=FALSE, this will disable the axis.
2. CMC_AXIS_CONTROL_PARAMETER_REAL.ENABLE=FALSE.
3. Modify the parameter.
4. CMC_AXIS_CONTROL_PARAMETER_REAL.ENABLE=TRUE.

> *Some of these parameters result in position control loop parameters. These can also be modified directly (while CMC_AXIS_CONTROL_PARAMETER_REAL.ENABLE = TRUE) by using the axis parameter structure.*

This function block must be used in combination with the function block CMC_MOTION_KERNEL_REAL ↳ *Chapter 1.5.9.4.8.1 “CMC_MOTION_KERNEL_REAL” on page 2659*.

Functional group	Parameter
Axis supervision	POS_LAG_PERCENTAGE
	V_CHECK_TIME
Position Control Loop	CONTROL_TIME
	FF_PERCENTAGE
	INTEGRAL_TIME
	HORIZON
PLC system	CYCLE
Rollover axis	EN_MODULO
	MODULO_RANGE
Scaling units of length	INC_PER_R
	U_PER_REV_NOMINATOR
	U_PER_REV_DENOMINATOR
Scaling the Speed Reference output	REF_MAX
	MAX_RPM

Input description

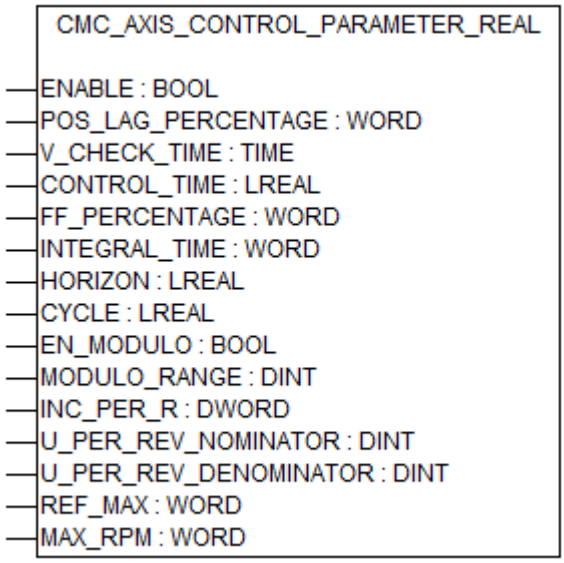

Fig. 251: Function block CMC_AXIS_CONTROL_PARAMETER_REAL

ENABLE Data type: BOOL

Enable new parameters with a positive edge.

POS_LAG_PER-CENTAGE Data type: WORD, default: 150, unit: %

Value for supervision of position difference. 100 is at least necessary to reach the maximum velocity with FF_PERCENTAGE = 0.

V_CHECK_TIME Data type: TIME, default: 100, unit: ms

Delay time for the supervision of actual velocity. With V_CHECK_TIME = 0, this supervision will be disabled.

CONTROL_TIME Data type: LREAL, default: 100, unit: ms

Determines the gain for position control loop. A lower time means a larger proportional gain for position control loop. The value means: In case FF_PERCENTAGE = 0, the drive will run CONTROL_TIME ms behind its position reference.

FF_PER-CENTAGE Data type: WORD, default: 0, unit: %

Feed-forward gain, usually should be <80%. For larger values, the parameter HORIZON needs to be used as the position will overshoot otherwise.

INTE-GRAL_TIME Data type: WORD, default: 0, unit: ms

Integration time for position control loop, 0 means no integral part is used.

HORIZON Data type: LREAL, default: 0, unit: ms

Gives a time in advance for the feed-forward. This could compensate reaction times. HORIZON > 0 requires more computing power.

CYCLE Data type: LREAL, default: 10, unit: ms

Cycle time of the PLC program.

EN_MODULO Data type: BOOL, default: FALSE

Enable rollover axis.

MODULO_RAN GE Data type: DINT, unit: increment

Distance for rollover, maximum value is 0x3FFFFFFF.

INC_PER_R Data type: DWORD, default: 1024

Increments per revolution for actual position.

U_PER_REV_N OMINATOR Data type: DINT, default: 1024

Units per revolution.

U_PER_REV_DENOMINATOR Data type: DINT, default: 1

Units per revolution.

REF_MAX Data type: WORD, default: 32767

Maximum value for SPEED_REFERENCE.

MAX_RPM Data type: WORD, default: 1500, unit: 1/m

Maximum value for rotations per minute, has to be the value which is reached at SPEED_REFERENCE = REF_MAX.

CMC_AXIS_CONTROL_PARAMETER_INT

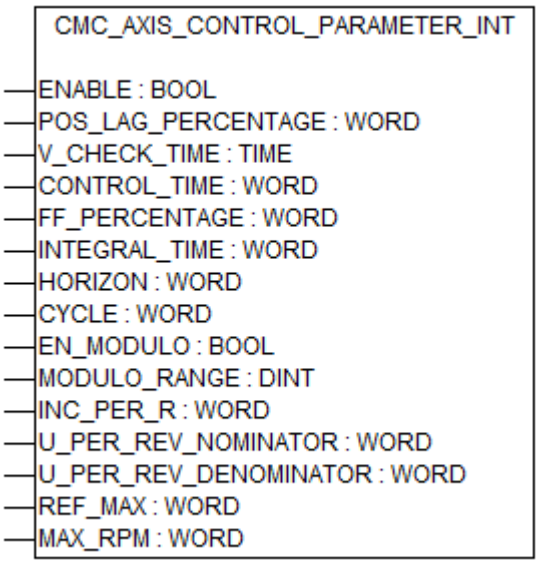

Fig. 252: Function block CMC_AXIS_CONTROL_PARAMETER_INT

Interface function block for axis configuration and adjustment of the control loop.

This function block must be used in combination with the function block CMC_MOTION_KERNEL_INT ↳ *Chapter 1.5.9.4.8.2 “CMC_MOTION_KERNEL_INT” on page 2662*.

Functional group	Parameter
Axis supervision	POS_LAG_PERCENTAGE
	V_CHECK_TIME
Position Control Loop	CONTROL_TIME
	FF_PERCENTAGE
	INTEGRAL_TIME
	HORIZON
PLC system	CYCLE
Rollover axis	EN_MODULO
	MODULO_RANGE

Functional group	Parameter
Scaling units of length	INC_PER_R
	U_PER_REV_NOMINATOR
	U_PER_REV_DENOMINATOR
Scaling the Speed Reference output	REF_MAX
	MAX_RPM

Input description

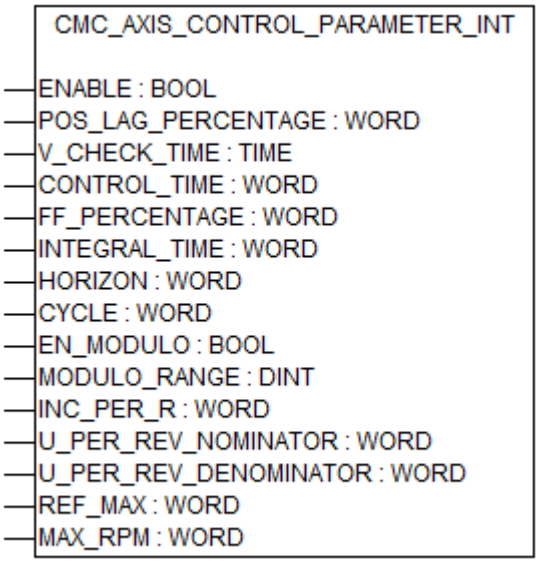

Fig. 253: Function block CMC_AXIS_CONTROL_PARAMETER_INT

ENABLE Data type: BOOL

Enable new parameters with a positive edge.

POS_LAG_PERCENTAGE Data type: WORD, default: 150, unit: %

Value for supervision of position difference. 100 is at least necessary to reach the maximum velocity with FF_PERCENTAGE = 0.

V_CHECK_TIME Data type: TIME, default: 100, unit: ms

Delay time for the supervision of actual velocity. With V_CHECK_TIME = 0, this supervision will be disabled.

CONTROL_TIME Data type: LREAL, default: 100, unit: ms

Determines the gain for position control loop. A lower time means a larger proportional gain for position control loop. The value means: In case FF_PERCENTAGE = 0, the drive will run CONTROL_TIME ms behind its position reference.

FF_PERCENTAGE Data type: WORD, default: 0, unit: %

Feed-forward gain, usually should be <80%. For larger values, the parameter HORIZON needs to be used as the position will overshoot otherwise.

INTEGRAL_TIME Data type: WORD, default: 0, unit: ms

Integration time for position control loop, 0 means no integral part is used.

HORIZON Data type: LREAL, default: 0, unit: ms

Gives a time in advance for the feed-forward. This could compensate reaction times. HORIZON > 0 requires more computing power.

CYCLE Data type: LREAL, default: 10, unit: ms

Cycle time of the PLC program.

EN_MODULO Data type: BOOL, default: FALSE

Enable rollover axis.

MODULO_RANGE Data type: DINT, unit: increment

Distance for rollover, maximum value is 0x3FFFFFFF.

INC_PER_R Data type: DWORD, default: 1024

Increments per revolution for actual position.

U_PER_REV_NOMINATOR Data type: WORD, default: 1024

Units per revolution.

U_PER_REV_DENOMINATOR Data type: WORD, default: 1

Units per revolution.

REF_MAX Data type: WORD, default: 32767

Maximum value for SPEED_REFERENCE.

MAX_RPM Data type: WORD, default: 1500, unit: 1/m

Maximum value for rotations per minute, has to be the value which is reached at SPEED_REFERENCE = REF_MAX.

CMC_AXIS_SIMU_REAL

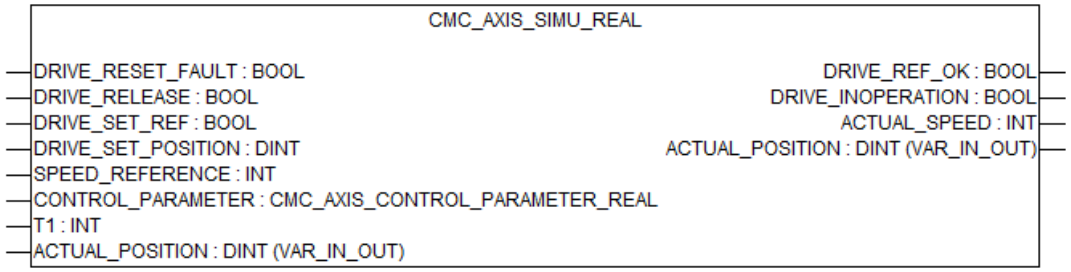

Fig. 254: Function block CMC_AXIS_SIMU_REAL

Function block to simulate a drive. This function block can be used in combination with the function block CMC_MOTION_KERNEL_REAL ↳ *Chapter 1.5.9.4.8.1 “CMC_MOTION_KERNEL_REAL” on page 2659*. Detailed information: ↳ *Chapter 1.5.9.4.2.3 “How to use the axis simulation” on page 2625*

CMC_AXIS_SIMU_INT

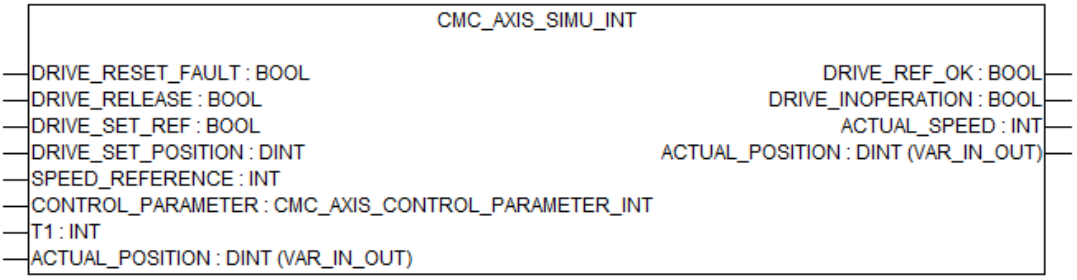

Fig. 255: Function block CMC_AXIS_SIMU_INT

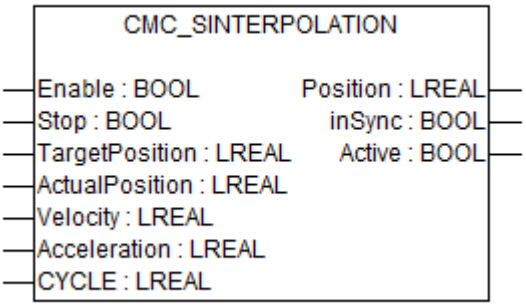
Function block to simulate a drive. This function block can be used in combination with the function block CMC_MOTION_KERNEL_INT ↳ *Chapter 1.5.9.4.8.2 “CMC_MOTION_KERNEL_INT” on page 2662*. Detailed information: ↳ *Chapter 1.5.9.4.2.3 “How to use the axis simulation” on page 2625*

CMC_SInterpolation



The function block can be used for a simple interpolation. Alternatively, the function block CMC_SIPosi_Loop can be used ↳ *Chapter 1.5.9.4.8.8 “CMC_SIPosiLoop” on page 2676*.

The function block allows to create a very simple, basic axis for linear movement. The function block can be either used independent to create a basic axis with/without position control loop or it can be used in combination with PLCopen function blocks.

The function block creates a positioning interpolation towards TargetPosition and uses the given velocity and acceleration values. The funciton block has to be used within the real-time cycle, same as CMC_MOTION_KERNEL_REAL. The result is given to output Position. The TargetPosition and also Velocity and Acceleration can be changed anytime and will be used at once. With Enable = FALSE, the funciton block sets the output Position to ActualPosition, this is similar to an open loop.

Table 171: Behavior of inputs

Enable	Stop	Behavior
FALSE	-	Output Position = ActualPosition
TRUE	FALSE	Interpolates output Position to reach Target-Position with the given velocity and accelera-tion.
TRUE	TRUE	Ramps down to velocity = 0.

Table 172: Behavior of outputs

InSync	Active	Behavior
FALSE	TRUE	Function block is activated, position and velocity is not yet reached.
TRUE	FALSE	Funciton block is activated, position is reached, output Position = TargetPosition.
FALSE	FALSE	Funciton block is either disabled or stopped, velocity = 0.

Use in combination with MC_MoveByExternalReference

This way, a positioning axis can be created with modifying the parameters for positioning “on the fly”, without the need of a certain state machine to follow.

Use in combination with MCA_SetDynamicFollower

The function block will smooth the movement when a group has to follow a conveyor. It will create defined ramps to accelerate to the conveyors position and also can be used to prevent a position jump when switching between 2 conveyors or before switching of the follower.

Use to create a simple, basic positioning axis

A very basic, simple positioning axis can be created this way. Be aware that there is not additional check if the axis really follows, also no scaling for the position is included. If function block CMC_SIPosiLoop is used, it will check for position or velocity following error.

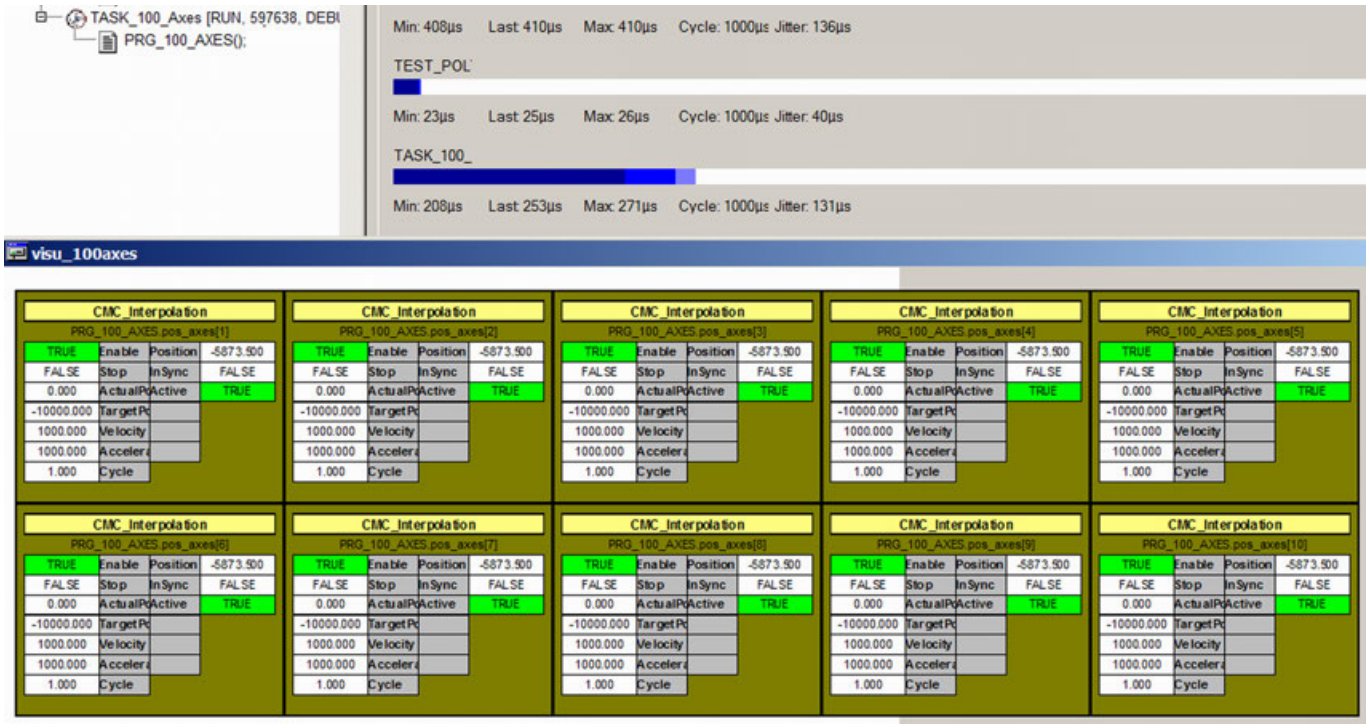


Fig. 256: Cycle time which was used for a PM590 when calculating 100 simple axes in a PLC task and priority 10.

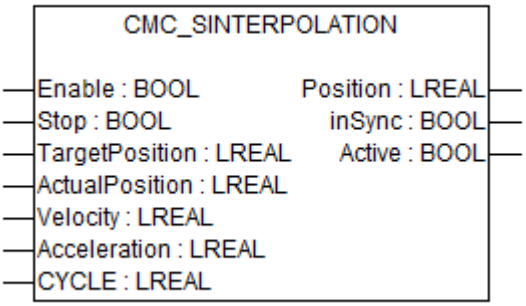
Input description



Enable Data type: BOOL

Enables the interpolation.

Stop Data type: BOOL

TargetPosition Data type: LREAL

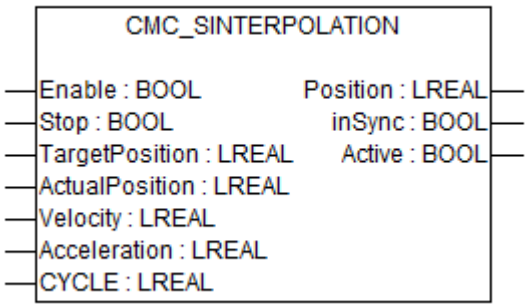
ActualPosition Data type: LREAL

Velocity Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

CYCLE Data type: LREAL, default: 10, unit: ms
Cycle time of the PLC program.

Output description

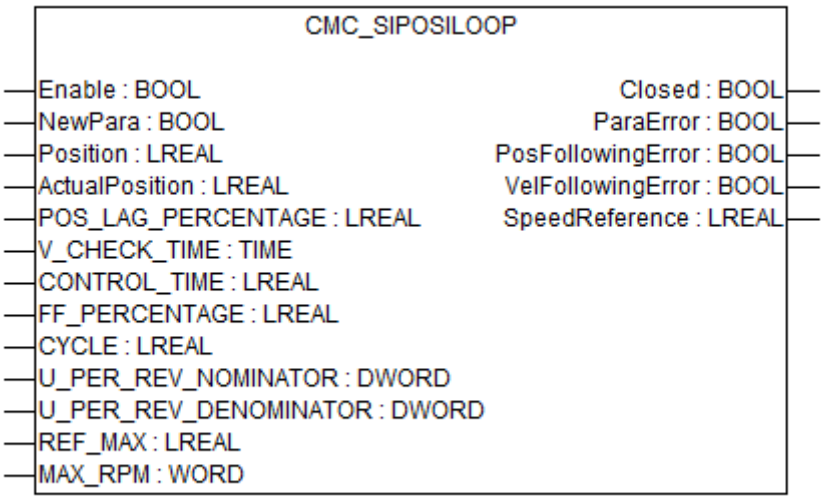


Position Data type: LREAL, unit: u
New absolute position.

InSync Data type: BOOL
Iindicates that Position reached TargetPosition.

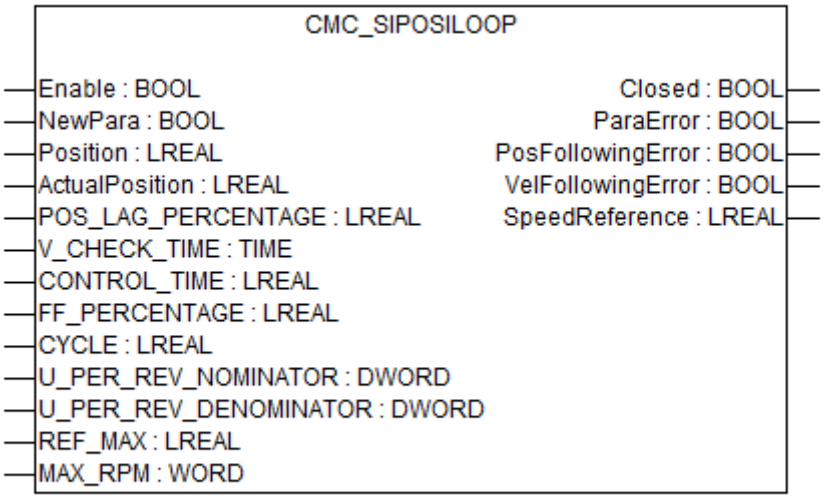
Active Data type: BOOL
Interpolation is activated.

CMC_SIPosiLoop



The function block can be used as a position control loop and can create a simple positioning axis if combined with CMC_SInterpolation. The CMC_SIPosiLoop uses same parameter setup as the parameter block CMC_AXIS_CONTROLPARAMETER_REAL.

Input description



Enable Data type: BOOL

Enable the block while TRUE, will close the position control loop.

NewPara Data type: BOOL

The block will use new input parameter with a positive edge.

Position Data type: LREAL

Reference position

ActualPosition Data type: LREAL

Actual position

POS_LAG_PER-CENTAGE Data type: WORD, default: 150, unit: %

Value for supervision of position difference. 100 is at least necessary to reach the maximum velocity with FF_PERCENTAGE = 0.

V_CHECK_TIME Data type: TIME, default: 100, unit: ms

Delay time for the supervision of actual velocity. With V_CHECK_TIME = 0, this supervision will be disabled.

CONTROL_TIME Data type: LREAL, default: 100, unit: ms

Determines the gain for position control loop. A lower time means a larger proportional gain for position con- trol loop. The value means: In case FF_PERCENTAGE = 0, the drive will run CONTROL_TIME ms behind its position reference.

FF_PER-CENTAGE Data type: WORD, default: 0, unit: %

Feed forward gain, usuallz shoul be <80%. For larger values, the paramter HORIZON needs to be used as the position will overshoot otherwise.

CYCLE Data type: LREAL, default: 10, unit: ms

Cycle time of the PLC program.

U_PER_REV_NOMINATOR Data type: DINT, default: 1024

Units per revolution.

U_PER_REV_DENOMINATOR Data type: DINT, default: 1

Units per revolution.

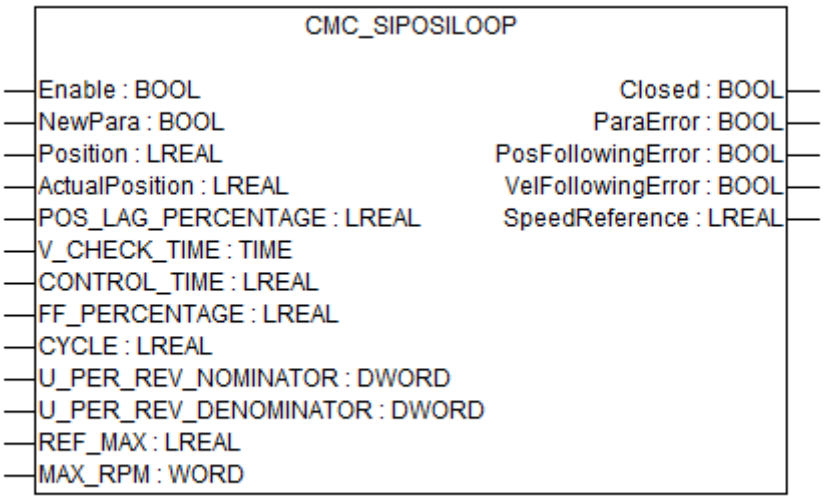
REF_MAX Data type: WORD, default: 32767

Maximum value for SPEED_REFERENCE.

MAX_RPM Data type: WORD, default: 1500, unit: 1/m

Maximum value for rotations per minute, has to be the value which is reached at SPEED_REFERENCE = REF_MAX.

Output description



Closed Data type: BOOL

Position control loop is closed, no active error.

ParaError Data type: BOOL

Indicates wrong input parameter.

PosFollowingError Data type: BOOL

Indicates position following error.

VelFollowingError Data type: BOOL

Indicates velocity following error.

SpeedReference Data type: LREAL

Speed Reference value which should be send to the drive. This value is scaled with MAX_RPM and REF_MAX: SpeedReference=REF_MAX => the axis should move with MAX_RPM.

CMC_GET_UNITS_FROM_INC

This function converts the drive's position value (DINT) which is exchanged between drive and PLC to the corresponding scaled position unit (LREAL) which is used by the PLCopen function blocks.

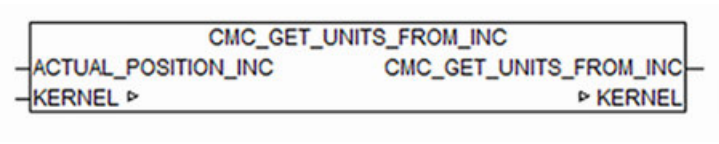


Fig. 257: CMC_GET_UNITS_FROM

Use case:

- The drive or an I/O module is used to capture an axis encoder position in relation to a binary signal (touch trigger). This position is delivered in [increments].
  If then the position is to be used in the PLCopen context, a unit position is required. It can be difficult to calculate this unit-position. Not just the scaling position units has to be considered but also the position might have experienced several correction measures. Measures like “SetPositionContinuous” or corrections due to modulo position overrun. To create the unit-value which matches a certain increment-value, the function CMC_GET_UNITS_FROM_INC has to be used.

Input:

ACTUAL_POSITION_INC Data type: DINT
A position [increments], for example captured by the drive as result for a touch trigger

KERNEL Data type: CMC_MOTION_KERNEL_REAL
Kernel block instance which belongs to the specific axis.

Result: The position [u], which describes exactly the same position as ACTUAL_POSIITON_INC, just transferred in to the axis coordinate system and delivered in [u].

1.5.9.4.9 PLCopen coordinated motion

Principles of coordinated motion

Coordinate system and kinematic transformation

The essence of a trajectory is the coordinated motion of two or more axes from a starting point to a target point via a defined path with a specified path velocity. As path one can think of a straight line, a circular movement, or via a spline function. The definition of a path -or any position information - in space requires a coordinate system. Within this specification three coordinate systems are defined:

ACS - Axis related

MCS - Machine related

PCS - Product or workpiece related

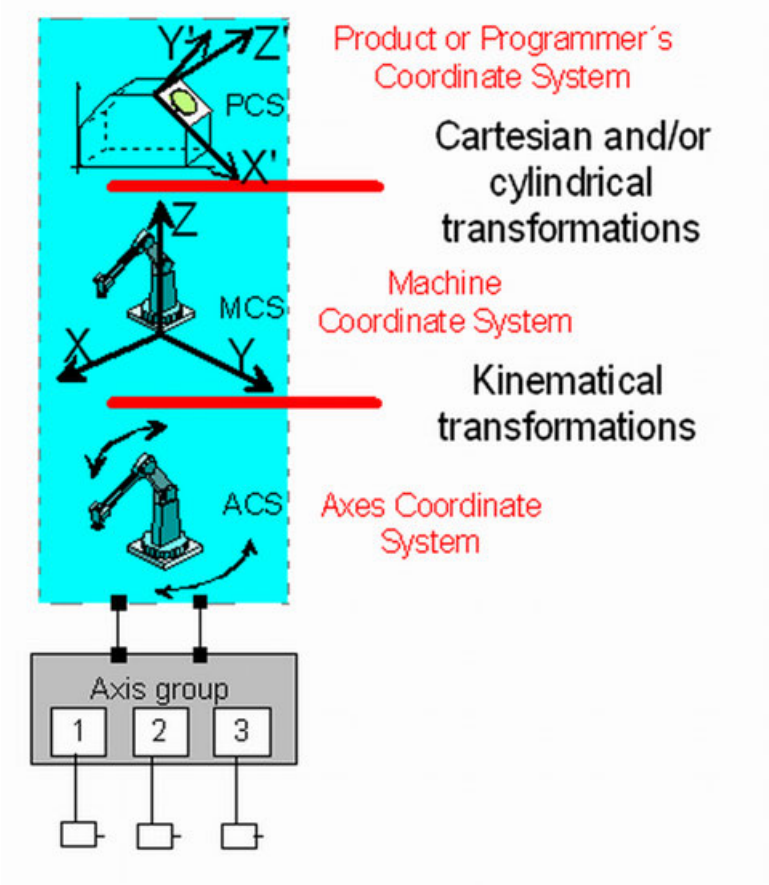

Fig. 258: Overview of the coordinate systems and transformations

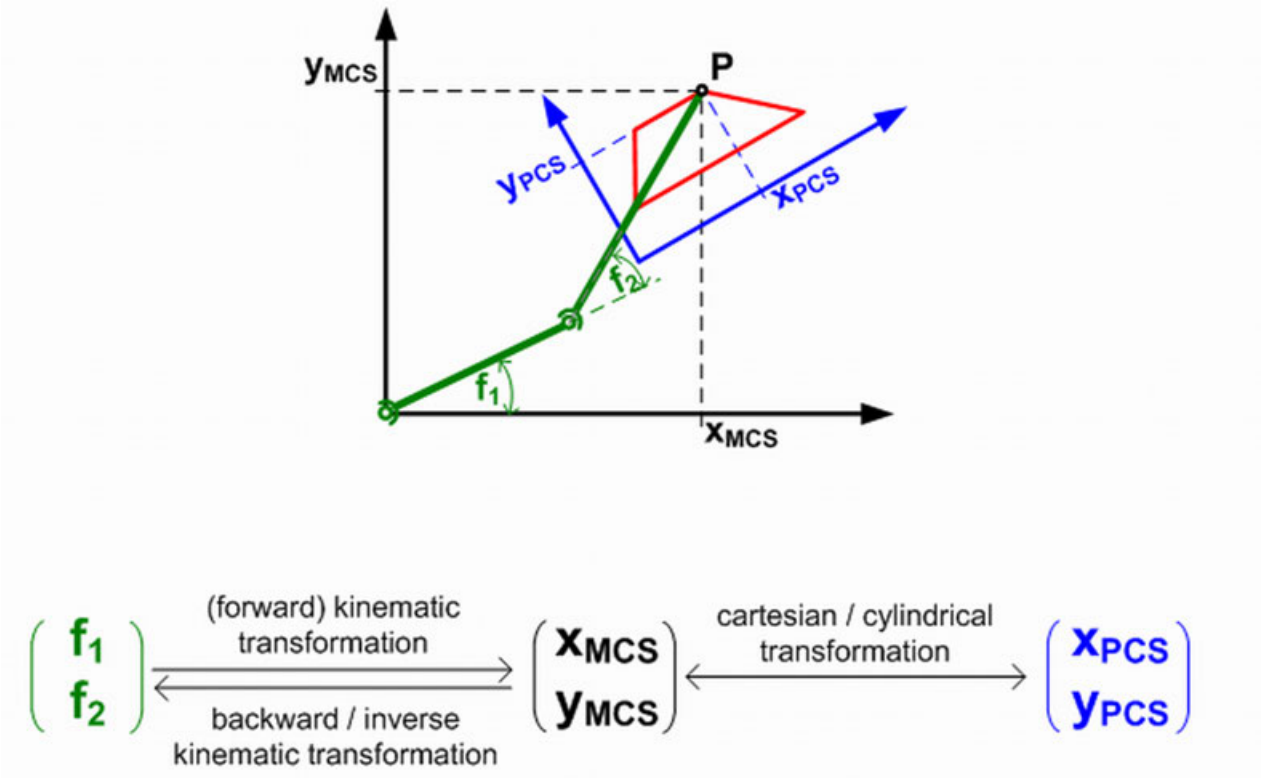

Fig. 259: Example for specifying point P in PCS, MCS or ACS assuming a SCARA robot with two rotary axes

ACS: Axes Coordinate System

Actual position of the physical axis (after homing).

MCS: Machine Coordinate System

Cartesian coordinate system with the origin is a fixed position relative to the machine. (Sometimes called “World Coordinate System” or “Base Coordinate System”). (Note: with Cartesian build machines, MCS may be identical to ACS, or mapped via a trivial transformation). The coordinate system from the physical multiple axes ACS is linked to the MCS via a kinematic transformation (forward and backward conversion).

PCS: Product Coordinate System

The real work piece can have a rotation or shift to the MCS or even might be moving relative to the MCS, and often one wants to describe the trajectory independent from the machine situation. To map these two worlds (MCS to PCS and vice versa), a cartesian or cylindrical transformation is normally done. The coordinate system of the product can be called PCS: "Product Coordinate System", or "Program Coordinate System" in CNC world. There can be more than one PCS transformation applicable at the same time. In this case the ENUM to specify the coordinate system (CS) has to be extended. A PCS can be a static or a dynamic transformation.

In order to specify a point or orientation in space a position always has to be related to a coordinate system. By means of transformations this position can be transformed to other coordinate systems. Within this specification, function blocks are defined for these transformations, hiding the complexity of these transformations to the programmer in its day to day use. All multi axes motion commands are related to only one of the coordinate systems at the same time.

Example for specifying point P in PCS, MCS or ACS assuming a SCARA robot with two rotary axes

Point P is situated on a 2D workpiece. It can be described equivalent in PCS, MCS and ACS. Point P could be specified by referring to PCS resulting in the position PPCS = (x_{PCS}, y_{PCS}). Given the shift and orientation of PCS relative to MCS, point P equivalently could be speci-fied by PMCS = (x_{MCS}, y_{MCS}). Assuming a SCARA robot with two rotary axes point P also could be described by the angles of the axes P_{ACS} = (ϕ1, ϕ2).

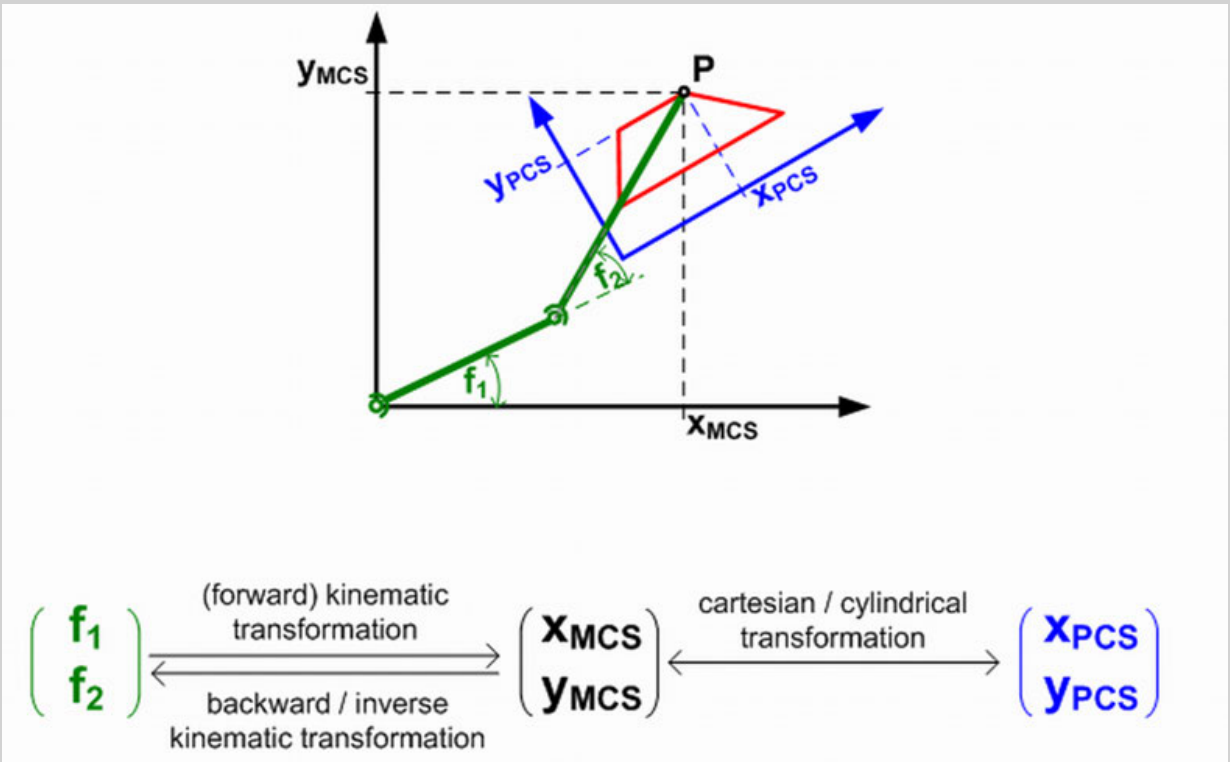

Fig. 260: Specifying point P in PCS, MCS or ACS assuming a SCARA robot with two rotary axes

Red trapezoid	Point P, situated on a 2 D workpiece
Blue	PCS
Black	MCS
Green	ACS

Kinematic transformation

Axes are connected via mechanical links providing movements of the ‘Tool Center Point’, TCP in space. TCP is a dis-tinguished point of the machine, sometimes also called ‘Point of Interest’, POI, or ‘effector’. The physical assembly of the axes and therefore the position of the TCP in MCS is described by a so called kinematic transformation. The kinematic transformation connects ACS to MCS (forward conversion). By applying the kinematic transformation on a position related to ACS, this position can be transformed into a position in MCS. The other way round, applying the inverse kinematic transformation, a position related to MCS can be transformed into a position in ACS (backward conversion).

With simple cartesian machine constructions, in which axes are directly oriented in X-, Y-, and Z-directions of MCS, the kinematic transformation can easily be specified. One just has to define which axis is in the X-direction, which in Y, and which in the Z-direction. In the simplest case ACS is identically to MCS and one needn’t distinguish between both. But in praxis there are many non-cartesian structures, like SCARA robots or Tripods, where the kinematic transformation is more complex.

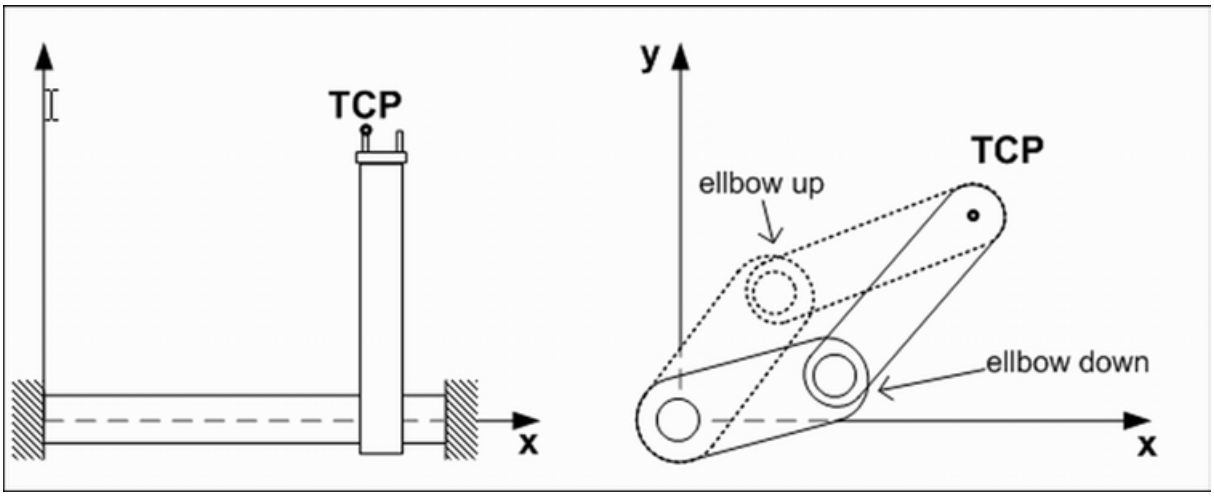

Fig. 261: Example for reaching the same position in space with a) a cartesian handling (2 linear axes) and b) a SCARA (2 rotary axes) with two possible configurations (elbow down and elbow up). (Note: the orientation is fixed in both examples)

Above example demonstrates how a position in space could be reached by a cartesian handling or a SCARA. Whereas the positions of the linear axes are more or less identical to the coordinates of the position in MCS, the positions of the axes of the SCARA are not that easy to calculate. Additionally there are two possible solutions of the backward kinematic transformation, different configurations of the machine: elbow down and elbow up.

How do commands behave in dynamic coordinate systems?

If the TCP should follow a moving target, this can be achieved by a dynamic coordinate transformation, leading to a PCS which is moving in relation to the MCS.

The activation of a dynamic transformation is done by activating MCA_SetDynamicFollower (ABB specific function block).

If there is a dynamic transformation active, the axis may follow the dynamic transformation or stay in the static ACS or MCS. The following example is showing the behavior. The example describes a robot fetching a screw from a fixed position and mounting it on a product that is moving on a belt.

Step	Move command	Axes (group) behavior	Application example
1	Activating Transformation ACS to MCS	Group is staying still (not moving)	Initialization, MCS is static
2	MC_MoveAbsolute in MCS	Group moves to the commanded position in MCS and stays in static MCS (not moving)	Moving to standby position and waiting for products
3	Motion command in static MCS	Group moves to the commanded position in MCS and stays in static MCS (not moving)	Moving to a fixed box of screws
4	Motion command in static MCS	Picking command	Picking up a screw
5	Activating a dynamic PCS	PCS is active and moves synchronized with the belt	PCS is ready for use
6	Motion command in dynamic PCS	Group moves to commanded position in PCS and is moving together with the dynamic PCS	Placing the screw and following the product on the belt

Step	Move command	Axes (group) behavior	Application example
7	Screwing command	Group is still following the product on the belt	Screw is being screwed into the product
8	Motion command in static MCS	Group moves to commanded position in MCS at the fixed screw box	Moving to the fixed box of screws and waiting for the next product on the belt
9	Motion command in dynamic PCS	Group moves to commanded position in PCS and is moving together with the dynamic PCS	Placing the screw to the new product and following the product on the belt

Rule: An axis group stays in the coordinate system which is specified with the last motion command. If this is a PCS with dynamic transformation, it will follow the PCS (keeping the same position in this PCS).

Movements

Applying a movement on a machine via a function block causes the TCP to move towards the new commanded position. The kind of function block applied specifies the path via which the new target position is reached. (Note: the coordinate system in which the new commanded position is specified does not have an influence on the path.)

Basically there are two types of movements which have to be distinguished:

- Point - to - Point movements, PTP (also referred to as Joint Interpolated Movements)
  With this type the essence is to reach the commanded position as fast as possible. This can be achieved by moving each axis on the shortest way from its starting position to its target position. Usually this kind of movement is the fastest way to reach a new commanded position, because at any time at least one axis moving at it’s dynamic limit. The path and the path velocity of the TCP are not important. They are determined by the process of the positions of the axes and the kinematic transformation of the machine. Therefore this kind of movement is applicable for handlings and whenever the path of the TCP is not crucial. It is recommended that all axes will arrive at the commanded position at the same point in time (synchronized).
  The applicable function blocks as specified herein are:
  – MC_MoveDirectAbsolute
  – MC_MoveDirectRelative
- Cartesian Path movements, CP (also referred to as Continuous Path movements):
  CP movements cause the TCP to move along a defined path in Cartesian space. A path can be (a set of) a straight line, a circular movement, or a spline function. The path via which the new commanded position is reached is important. For example, this is essential if a workpiece is being processed. Further, the path velocity of the TCP can be controlled directly. Contrary to point-to-point movements the process of the position of each axis is determined by the desired path and the inverse kinematic transformation.
  The applicable function blocks as specified herein are:
  – MC_MoveLinearAbsolute
  – MC_MoveLinearRelative
  – MC_MoveCircularAbsolute
  – MC_MoveCircularRelative
  – MC_MovePath

The figure below illustrates the differences between different types of movement by means of a theoretical machine.

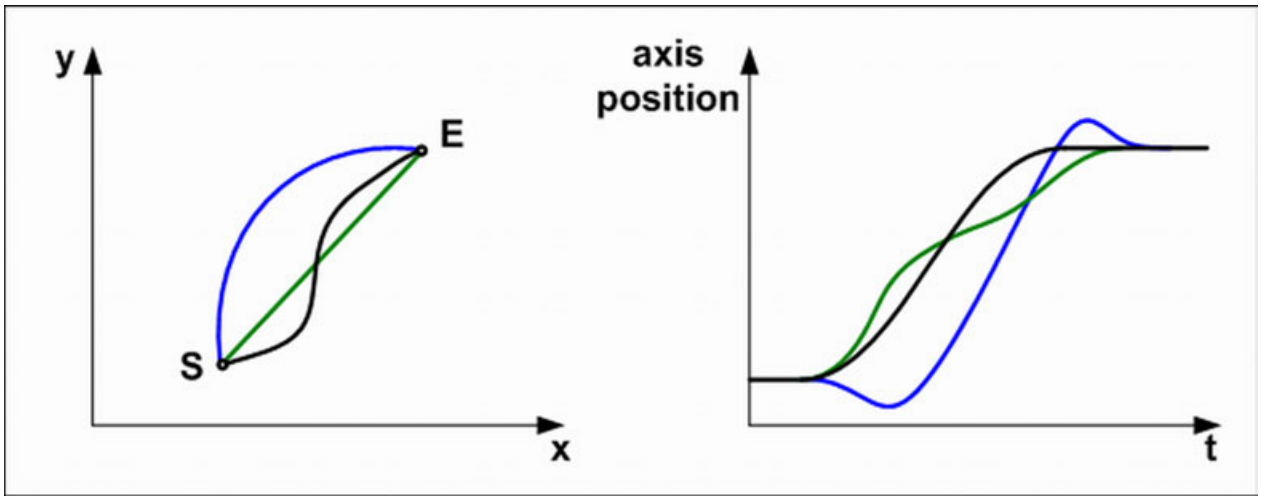

Fig. 262: Different types of movements MC_MoveDirect (black), MC_MoveLinear (green) and MC_MoveCircular (blue) and typical positions of one of the axis of the machine participating in the movement

Blending and buffering of movements

General information

A fundamental part of interpolated motion control is blending of (buffered) consecutive motion commands on an axes group. Without blending the TCP of an axes group moves towards the commanded position, decelerates and comes to standstill exactly at the commanded position. The following buffered motion command doesn’t become active until now. Obviously the axes group has to accelerate again. In many applications a different behavior of the TCP is desired and one wants to concatenate movements without stopping.

Reasons for this are:

- Reduction of the process cycle time (e.g. pick and place)
- Generate a smoother movement in order to reduce the mechanical stress
- Some applications demand a constant Velocity of the TCP (e.g. applying glue, painting, welding, etc.)

All this can be achieved by different types of blending. Common to all types of blending is a modification of the origi-nal path, resulting in a smooth trajectory without corners.

Blending of motion commands in interpolated motion control differs from blending of motion commands on single axes. With single axes the commanded position is always reached. Just the velocity at the time when the commanded position is reached (or passed) can be changed according to the input parameter BufferMode.

With interpolated motion control several types of blending can be thought of, depending on the application and proc-ess. Therefore new types of blending have to be introduced for interpo-lated motion control.

The input parameter for blending might vary due to the kind of interpolation method applied. So this input is ABB specific.

The type of inserted curve that modifies the original path (the ‘contour curve’) is not part of this specification and can be defined by the ABB specific input parameter for blending.

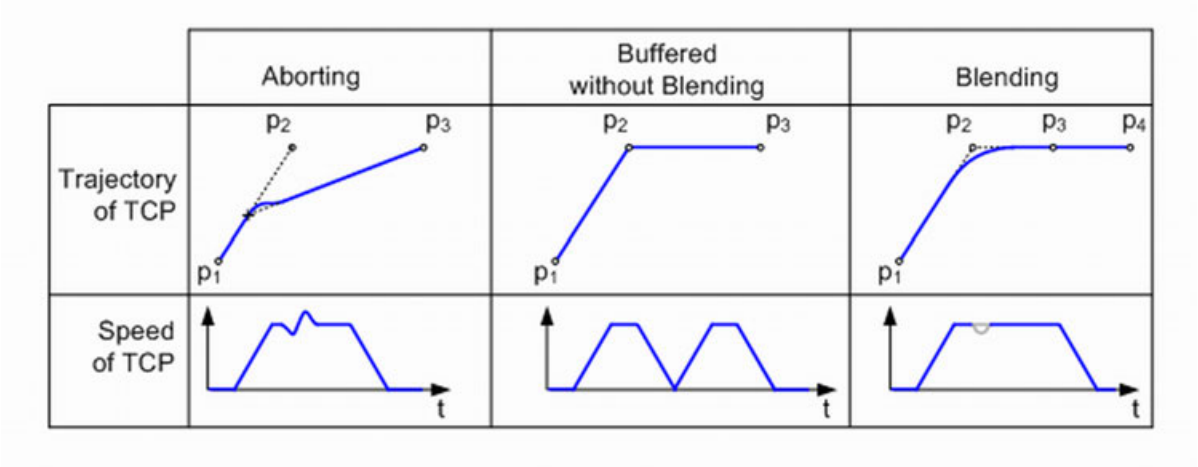

Fig. 263: Trajectories and process of Velocity in principle of two consecutive motion commands in three modes

AC500 realization

No buffered modes are realized. As no buffered mode is realized, the Transition modes are unavailable as well.

- The default mode which is used is “Aborting”. The TCP will move directly towards the next commanded position and use the next commanded velocity/acceleration/deceleration.
- Behavior according to “Buffered without Blending” can be reached by using the output DONE of the previous block to activate the next movement.
- A behavior as shown above in “Blending” could be achieved by using MC_MovePath and a dedicated corner distance.

Realization in AC500

Overview

This chapter describes the usage of PLCopen function blocks for motion control with ABB-PLC AC500. These function blocks are based on **Part4_CoordinatenMotion_V10.pdf, V. 1.1**.

The features could be used from the PLC program according to PLCopen standard. Different drives could be used and could be combined with each other as well as different fieldbusses. The following table gives an overview about the available features.

PLCopen Coordinated Motion and Principles of Coordinated Motion

Some information in this chapter require knowledge from the following chapters:

- *Chapter 1.5.9.4.9.1 “Principles of coordinated motion” on page 2679*

The library is not restricted to the use with a specific fieldbus, but it is recommended to use a synchronized bus.

Library	Version	Drive	Fieldbus	Description
MC_Base_AC500	1.1	Any	Any	Data types
MC_Blocks_AC500	1.1	Any	Any	PLCopen function blocks for single and multi axis
MC_CoBlocks_AC500	2.1	Any	Any	PLCopen function blocks for coordinated motion

Library	Version	Drive	Fieldbus	Description
CompactMotion_AC500	1.2	Any	Any	Motion control for single and multi axis
CoordinatedMotion_AC500	2.1	Any	Any	Motion control for coordinated motion
CMC_Ext_AC500	2.1	Any	Any	External libray, just used by other libraries
CMC_Transforma-tionen_AC500_APPL	2.1	Any	Any	Exemplary implementation for transformations
MathFunctions_AC500	2.1	Any	Any	Vector and matrix mathematic used by other libraries

The CMC_Transformation_AC500_APPL_V21.lib holds some kinematical transformations which are used to connect the MCS and ACS axes. This library is open, the integrated transformations might be copied and modified to match the specific requirements.

General rules

The following chapter explains some rules on the usage of the libraries.

- A general rule is that ALL PLCOpen function blocks which are used for a specific drive are to be used in the same PLC-task. When multitasking is used for the PLC, it is allowed to have different drives in different tasks, but all Funciton Blocks belonging to a specific drive need to be in the same task. There is no multithreading protection for the AXIS_REF instance.
- The CMC_MotionKernel… and the COMC_Group… function blocks might be in a different task then the PLCopen Blocks (MC…). All function blocks belonging to the same fieldbus Communication Module have to be called from the same task.
- When AXIS_REF or AXES_GROUP_REF is used as input on a user defined FUNCTION_BLOCK or PROGRAM or FUNCTION, then ALLWAYS use it as VAR_IN_OUT and NEVER use it as VAR_INPUT or VAR_OUTPUT. The reason is that this would
  - Break the consistency and destroy data
  - Consume a lot of computing power by copying data.
- The "Min update time" update time for the fieldbus, defined under *“PLC Configuration ➔ Communication Modules[FIX] ➔ <fieldbus master type>”* must not exceed the half of the scantime of the PLC-task. E.g. scantime of PLC-task is 5ms, then "Min update time" should not be greater than 2ms.
- The functionality of CompactMotion_AC500 library may be combined with the CoordinatedMotion_AC500 library. All single axis functions could still be used for an axis, even when it is combined with others to a group .

Create a group

The basic functionality in coordinated motion is to combine several axes in a movement in 3D-cartesian space. The combination of axes is named “group” and the movement is executed by the group.

Several axes could be combined to realize a group which performs coordinated motions in a specific coordinate sys-tem. The single axis block from CompactMotion_AC500 Library will be available too, and have to be combined with the group-block to realize the complete functionality. The Group-Block does not realize a position control or direct access to an axis, therefore the CompactMotion_AC500 library is used for this.

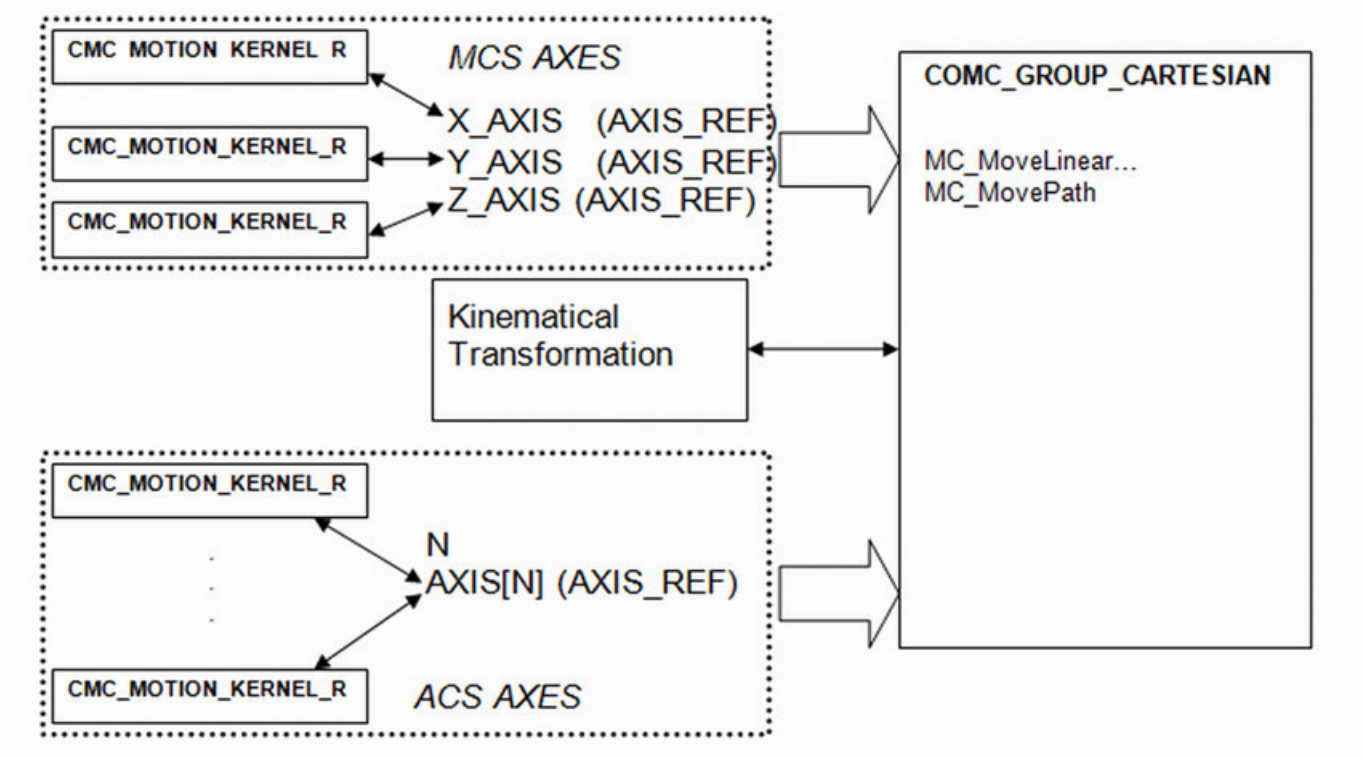

Fig. 264: architecture

The COMC_GROUP_CARTESIAN supports interpolation in a 3-dimensional Cartesian space. The MCS AXES repre-sent the 3 axes for this system. Depending on the mechanical construction, 3 or more real axes are necessary to realize the 3 dimensional movement. These are named ACS AXES and linked by a kinematical transformation to the MCS AXES.

State transitions

As the single axis and the group are related, the state machines for both are connected. The following description gives an overview:

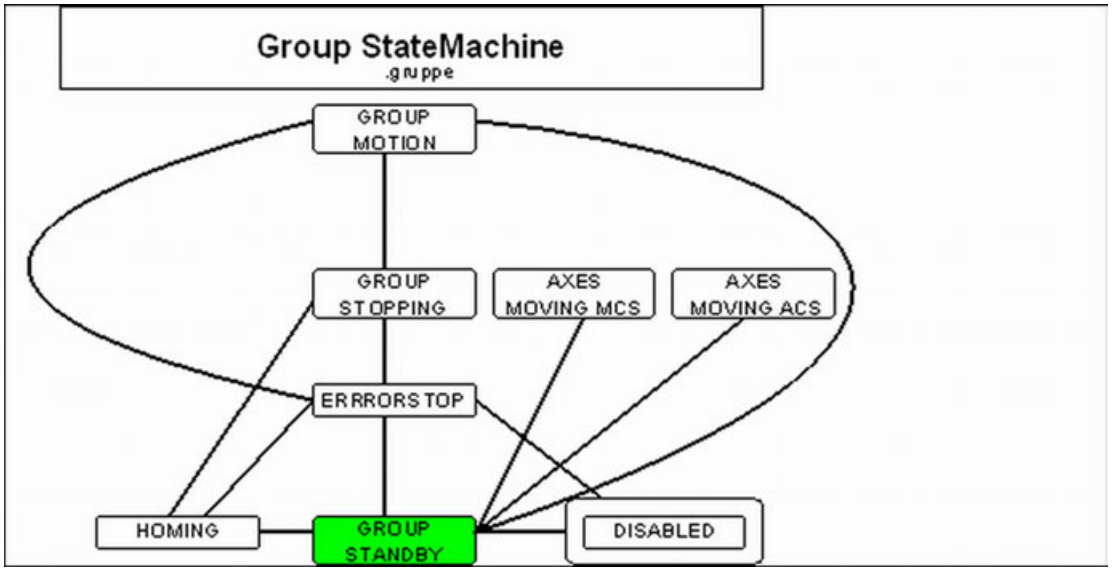

Fig. 265: state machine for group

MC_GroupEnable

- Precondition: The ACS axes are in state StandStill
- Postcondition:
  - The group changes to state GroupStandby.
  - The ACS axes and MCS axes changed to Synchronized Motion. All axes could be moved by the group.

MC_GroupDisable

- Precondition: None
- Postcondition:
  - The group changes to state GroupDisabled.
  - The ACS axes change from Synchronized Motion to StandStill or keep their state if not in Synchronized Motion.
  - The MCS axes change to state Disabled.

MC_Move… applied to GROUP

- Precondition: The group is in state Standby or GroupMotion.
- The group changes to state GroupMotion.
- When a MCS or ACS movement was executed, the group state has to be checked before a group block can be started.

Any axis changes its state (other then Disabled or ErrorStop)

- Precondition: The group was in a state other then Disabled or ErrorStop.
- Postcondition: The group is changed to AXES_MOVING_MCS or AXES_MOVING_ACS, as soon as ALL axes are in StandStill again, they will automatically be changed to Synchronized Motion and the group will change to GroupStandby.

Any ACS axis changes its state to ErrorStop

- Precondition: None
- Postcondition: The group state is set to Disabled. The MCS axes are set to Disabled.

Any MCS axis changes its state to ErrorStop

- Precondition: None
- Postcondition: The group state is set to ErrorStop.

Any axis changes its state to Disabled

- Precondition: None
- Postcondition: The group state is set to Disabled. The MCS axes are set to Disabled.

General restrictions

Table 173: Function blocks realized in CoordinatedMotion_AC500

Administrative	**Motion**	
Coordinated	**Coordinated**	**Synchronized**
MC_GroupEnable	MC_GroupStop	MC_SyncAxisToGroup
MC_GroupDisable	MC_GroupHalt	MC_SyncGroupToAxis
MC_SetCartesianTransform	MC_GroupInterrupt	
MC_SetCoordinateTransform	MC_GroupContinue

Table 174: Additional ABB specific function blocks

Function block	Comment
MCA_SetCoordinateTransformation *Chapter 1.5.9.7.3.3 “MCA_SetCoordinateTransformation” on page 3016*	Replaces MC_SetCartesianTransform
MCA_SetDynamicFollower *Chapter 1.5.9.7.3.4 “MCA_SetDynamicFollower” on page 3018*	Replaces MC_TrackRotaryTable, MC_TrackConveyorBelt and MC_SetDynCoordTransform
MCA_PathEvent *Chapter 1.5.9.7.3.2 “MCA_PathEvent” on page 3015*	Set a binary signal output related to path positions
MCA_MoveHelixRelative *Chapter 1.5.9.7.3.1 “MCA_MoveHelixRelative” on page 3008*	Allows a circular movement > 2Pi and a coordinated vertical movement
MCA_MovePathPos *Chapter 1.5.9.7.3.5 “MCA_MovePathPos” on page 3022*	A path movement with an included previous positioning to start position

Restrictions to be considered

The following extended inputs and outputs at the function blocks are not realized:

- BufferedMode: The realization just supports by default the “Aborting” mode.
- TransitionMode: The realization just supports by default a transition starting with the actual velocity.
- TransitionParameter: Not supported.
- CoordSystem: Set by default when using the specific group or function block.

When CoordSystem is available as an input, the type is MC_COORD_SYSTEM with values:

- MC_DEFAULT_COORD = the last activated coordinate system, MCS or PCS
- MC_MCS_COORD
- MC_PSC_COORD

A movement which is executed in a specific coordinate system also switches the group to the specified system.

To access the axes in ACS system, specific function blocks are used or the information has to be retrieved from the ACS axes directly.

Usage of function blocks

The basic function block is COMC_GROUP_CARTESIAN. *Chapter 1.5.9.7.1.20 “COMC_GROUP_CARTESIAN” on page 2994* It has to be called every cycle and at least once before any MC… function block is activated.

Coordinate transformations

Different transformations may be used to transfer the data from MCS to ACS (axes coordinate system) and back. Just the actual positions and reference positions are transferred, as shown in the diagram below.

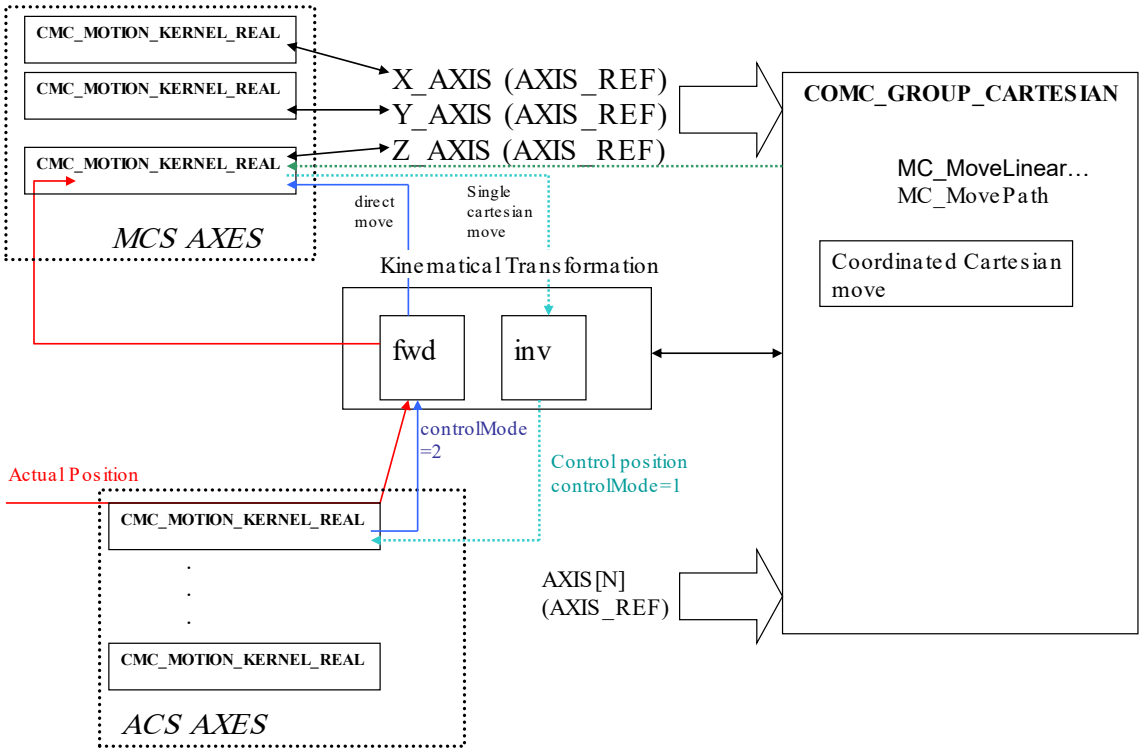

Fig. 266: Data flow for actual and reference position

The controlMode is switched internally and creates a different flow for control position, depending on the required movement, e.g if a direct movement on joints or a cartesian movement is required.

The actual position is always received from the ACS axes and transferred to the MCS axes by the forward transformation.

In a coordinated group movement or in a movement of cartesian axes, the reference position is transferred from the MCS axes to the ACS axes by the inverse transformation.

In case of a direct movement or a movement of ACS axes, the reference position is transferred by the forward transformation from ACS axes to MCS axes.

The calculation of actual positions is executed as follows:

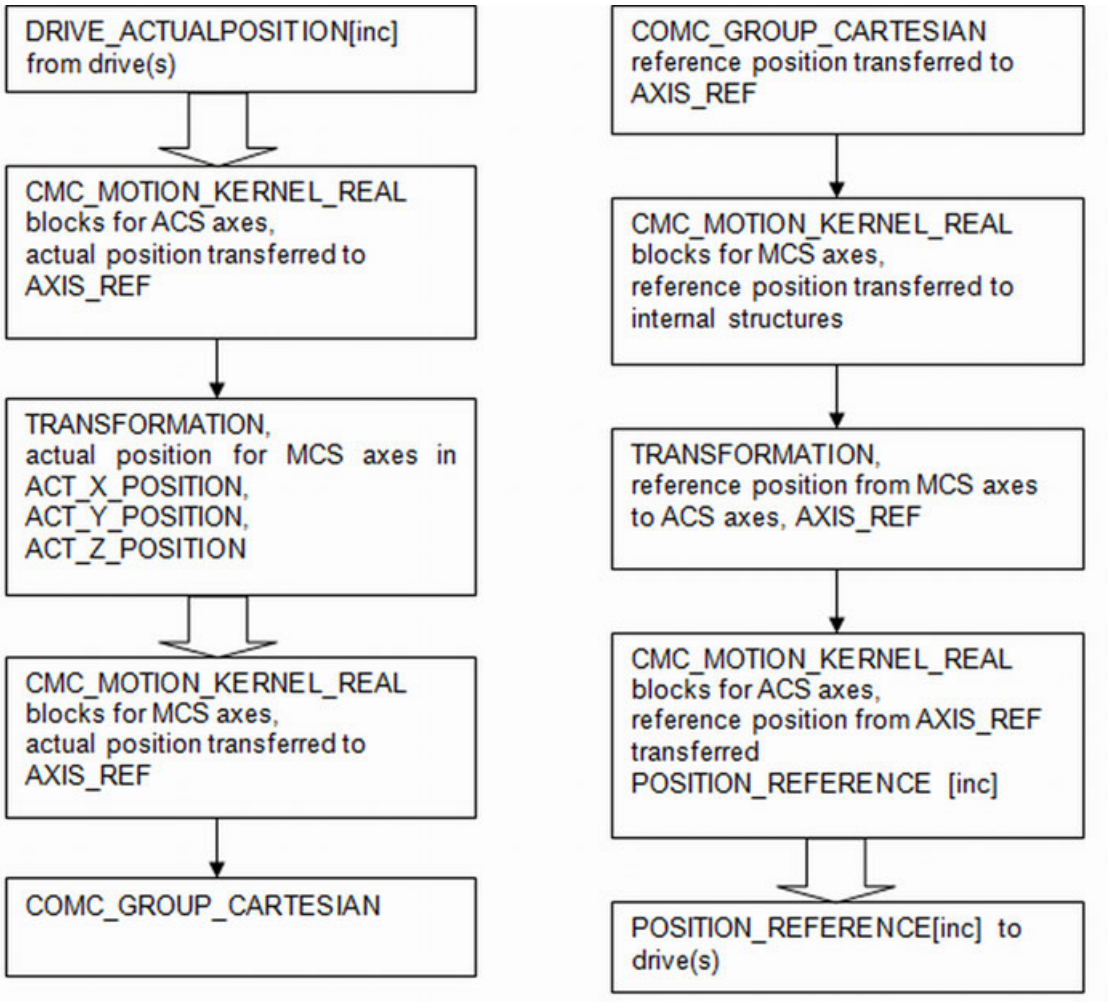

Fig. 267: Calculation of actual positions and reference positions for coordinated axes

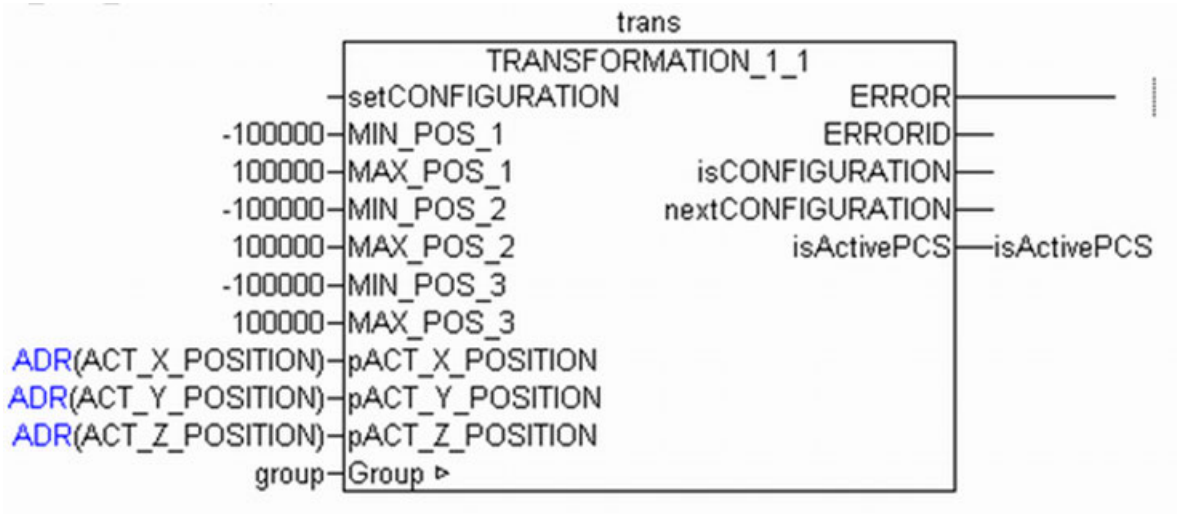
The user is free to define an own algorithm for transformation of coordinates.

The basic structure is given by the function block TRANSFORMATION_1_1. It does a 1:1 transformation. Any other transformation has to be created following the same structure.

For 1_1 Transformation, no different configurations are possible, nextCONFIGURATION = 0.

Structure of TRANSFORMATION_1_1

As an example, the TRANSFORMATION_1_1 is shown. To create an own transformation, this function block could be used and modified. The modified function block may have additional inputs and outputs. The functionality is realized by using different actions. Actions named ACTION_GENERIC_xxx are not allowed to change. Actions named ACTION_APP_xxx have to be changed according to the required transformation.



Input description

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

setConfiguration
Data type: WORD
Required configuration, if more than 1 solution for forward transformation is possible.

MIN_POS_1
Data type: LREAL
Minimal position for Cartesian axis 1.

MAX_POS_1
Data type: LREAL
Maximal position for Cartesian axis 1.

MIN_POS_2
Data type: LREAL
Minimal position for Cartesian axis 2.

MAX_POS_2
Data type: LREAL
Maximal position for Cartesian axis 2.

MIN_POS_3
Data type: LREAL
Minimal position for Cartesian axis 3.

MAX_POS_3
Data type: LREAL
Maximal position for Cartesian axis 3.

pACT_X_POSITION Data type: POINTER TO LREAL

Actual position, to be used at the corresponding CMC_MOTION_KERNEL… function block.

pACT_Y_POSITION Data type: POINTER TO LREAL

Actual position, to be used at the corresponding CMC_MOTION_KERNEL… function block.

pACT_Z_POSITION Data type: POINTER TO LREAL

Actual position, to be used at the corresponding CMC_MOTION_KERNEL… function block.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

isCONFIGURATION Data type: WORD

Active configuration.

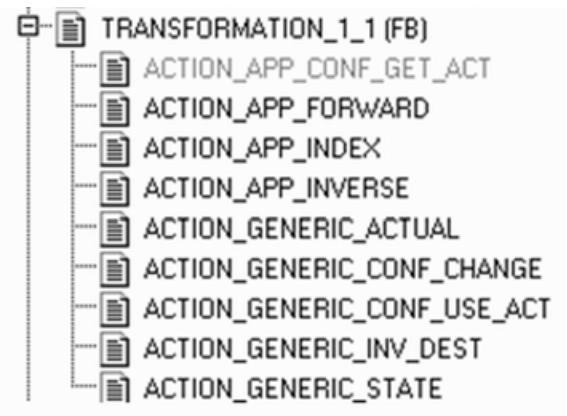
nextCONFIGURATION Data type: WORD

Configuration which will be reached by the next direct movement, if more than one solution for forward transformation is possible and isConfiguration differs from setConfiguration.

isActivePCS Data type: BOOL

PCS (Product Coordinate System) is activated, group movements are executed related to PCS instead MCS and tracking (e.g. Conveyor tracking) is possible.

Structure of actions within a transformation



The functionality is realized in different actions. All actions named “ACTION_GENEREC_xxx” don´t need to be changed for different transformations. The actions “ACTION_APP_xxx” need to be changed according to the transformation needed. A constant is needed to define the number of ACS axes. This has to be modified according to the transformation.

```
VAR CONSTANT
  (**NUMBER*)
     N_ACS_AXES:WORD:=3;
END
```

The minimal and maximal positions are not mandatory. It depends on the transformation if these are necessary or if additional limits have to be considered.

Responsibilities of different actions

- ACTION_APP_INDEX calculates the index and address for the used TRANSFORMATION-Block. The name of the actual block has to be used
  - TransformationIndex:=INDEXOF(Transformation_1_1).
  - Use the name of your own transformation block here.
- ACTION_APP_CONF_GET_ACT: Take the actual positions of ACS axes and determine the mechanical configuration actually used, write the result to isCONFIGURATION.
- ACTION_APP_FORWARD: Hold the forward transformation and calculates the actual position by using the actual positions from ACS axes and creating X_FORWARD, Y_FORWARD and Z_FORWARD.
- ACTION_APP_INVERSE: Holds the inverse transformation and calculates the positions POS1, POS2 and POS3 from the input in X_FORWARD, Y_FORWARD and Z_FORWARD. POS1, POS2 and POS3 are used as reference positions to the ACS axes or as destination positions to the ACS axes in case of a direct movement.
- ACTION_GENERIC_ACTUAL: Not to be modified. Uses X_FORWARD, Y_FORWARD and Z_FORWARD and calculates the actual positions ACT_X_POSITION, ACT_Y_POSITION and ACT_Z_POSITION by involving the dynamic transformation, if activated. These position values are calculated in [u]. They have to be used at position input for the MCS axes, instead of an actual position directly received from the drive.
- ACTION_GENERIC_CONF_CHANGE: Not to be modified.
- ACTION_GENERIC_CONF_USE_ACT: Not to be modified
- ACTION_GENERIC_FWD_DEST: Not to be modified.
- ACTION_GENERIC_STATE: Not to be modified.

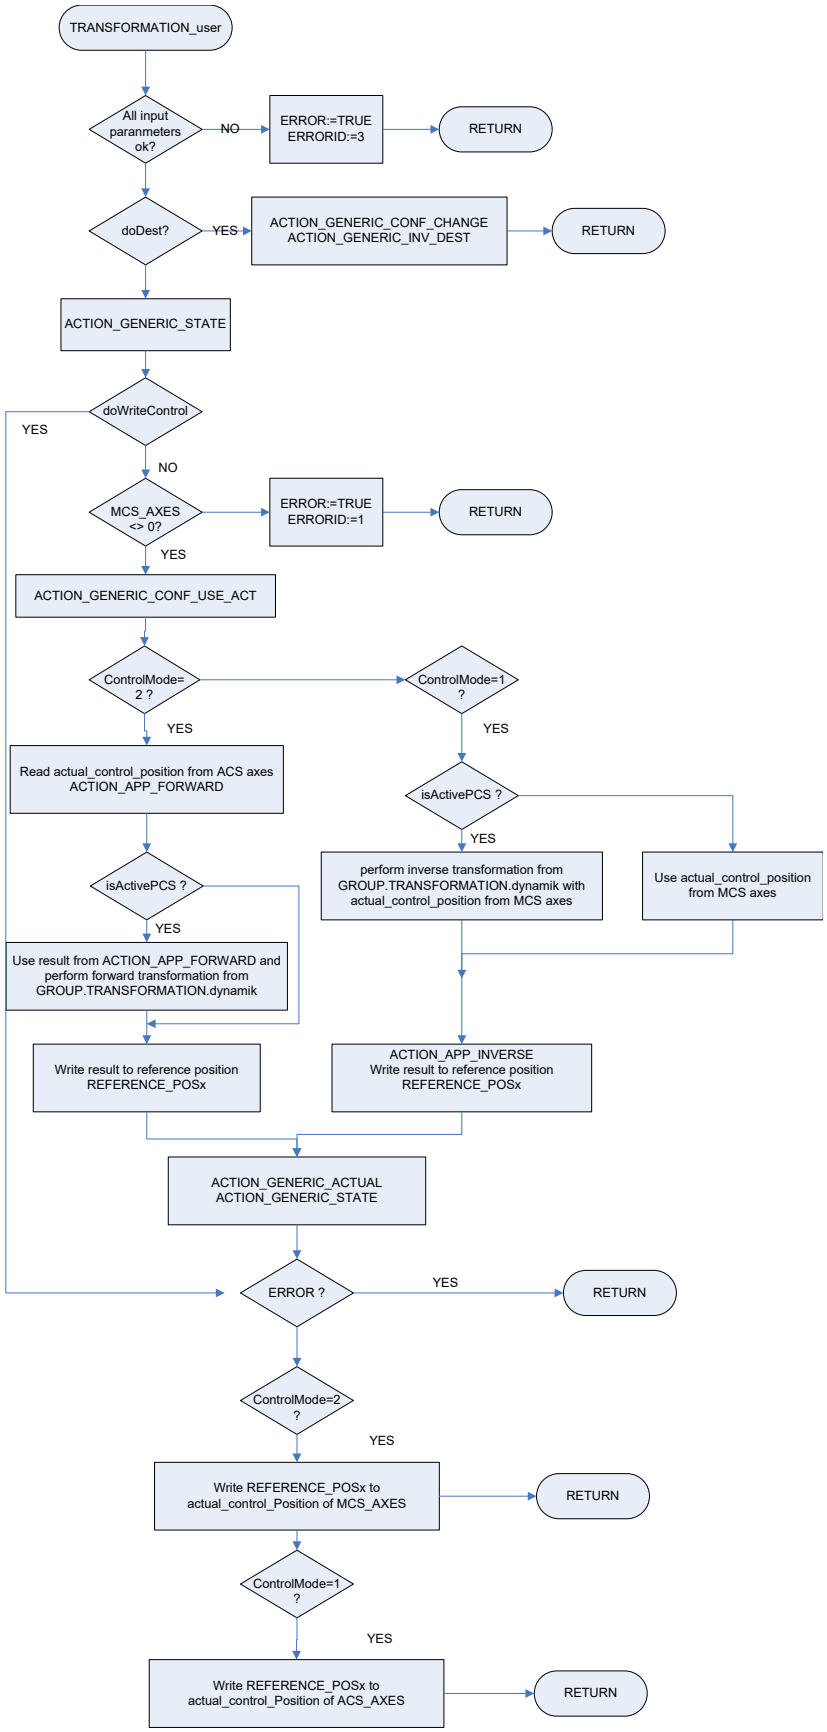


Fig. 268: Flowchart for the transformations implementation

Change of configurations

It might be possible to reach the same target position by using different mechanical configurations, e.g. elbow_up and elbow_down in a SCARA robot.

Sequence in changing the configuration

For changing the configuration, a direct movement has to be executed.

When different configurations are possible, the following situations have to be considered:

- No change in configuration is required: setConfiguration=nextConfiguration=isConfiguration
- The configuration should be changed: setConfiguration<>nextConfigurtion=isConfiguration
  start a direct movement: setConfiguration=nextConfiguration<> isConfiguration
  movement to required position is ready: setConfiguration=nextConfiguration=isConfiguration

Different actions have to consider the configuration:

- ACTION_APP_CONF_GET_ACT: generate a value for the actual active configuration form the ACS axes actual positions. Write the result to isCONFIGURATION.
- A new desired configuration could be written to the input setCONFIGURATION. This will be used when a di-rect movement is performed and will be written to nextCONFIGURATION.
- When no change in configuration is performed, the values setCONFIGURATION, nextCONFIGURATION and isCONFIGURATION will be identical.
- The action ACTION_APP_FORWARD should use the value from nextCONFIGURATION to calculate its result.

PCS (Product Coordinate System)

Basically, the MCS axes represent a 3 dimensional Cartesian space.

It is linked with the used “TRANSFORMATION” function block to the ACS axes which are the real movement axes.

The MCS has a fixed origin and the 3 axes X,Y,Z follow the right hand rule.

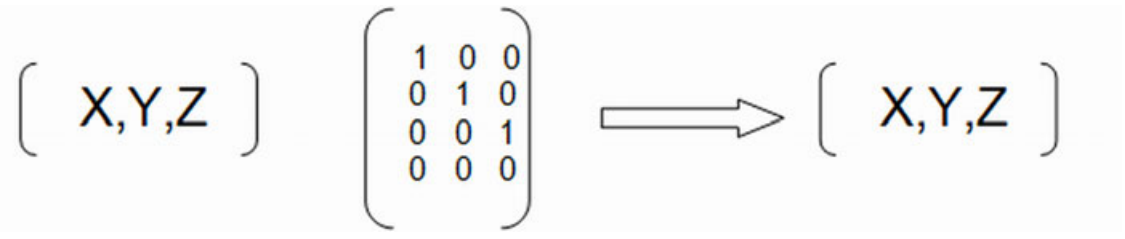
It is possible to use a PCS for all movements of the cartesian axes.

The PCS is activated with MCA_SetCoordinateTransformation.

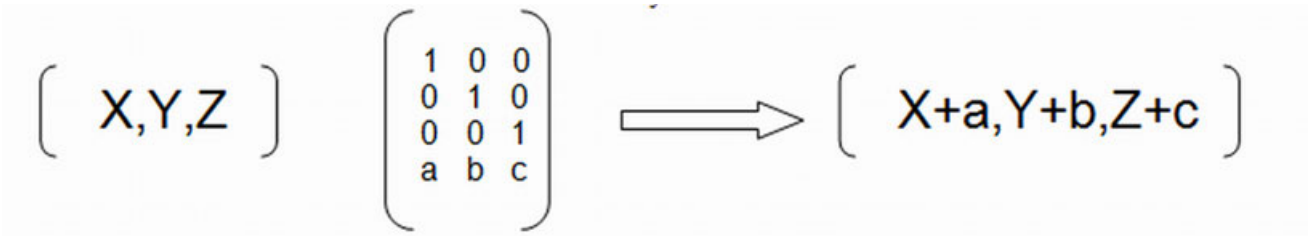
The calculation is implemented by a homogeneous transformation using a FORWARD matrix to transform MCS to PCS and an INVERSE matrix to transform PCS to MCS coordinates.

The PCS is a Cartesian system as well and might be turned and shifted and use different scaling compared to the MCS system.

A matrix without modification would have the following values:



A matrix which does a shift of the coordinate system will look as follows:



For transformation from MCS to PCS, the forward matrix means:

- The first line points the direction of PCS X-Axis, with respect to MCS
- The second line points the direction of PCS Y-Axis, with respect to MCS
- The third line points direction of PCS Z-axis, with respect to MCS

So the lines represent the vector for the new coordination systems axes. If the length for a line is different from "1", it means the new system has also a different scaling.

The matrix might be created by using the function “COMC_TeachCartesianTransformation”. This block allows teaching the relation between MCS and PCS.

How to switch the coordinate system

The PCS coordinate system allows to move the group in relation to a certain product workspace and not just in relation to the machines coordinates. It is also possible to follow a moving product by utilizing the PCS coordinate system. And move it continuously.

Table 175: Available function blocks for doing so

Function block	Step	Activation time	Used data format	Dynamic	From → To
MCA_Set-Coordinate-Transforma-tion	Step 1	Enable	Matrix	Yes	MCS → PCS
MC_SetCoor-dinateTrans-form	Step 1	Execute	Matrix	While Exe-cute=true	MCS → PCS
MCA_SetDy-namicFol-lower	Step 2	Enable	Translation/ Rotation	Yes	PCS → PCS'
MC_SetCarte-sianTransform	Step 2	Execute	Translation/ Rotation	While Exe-cute=true	PCS → PCS'

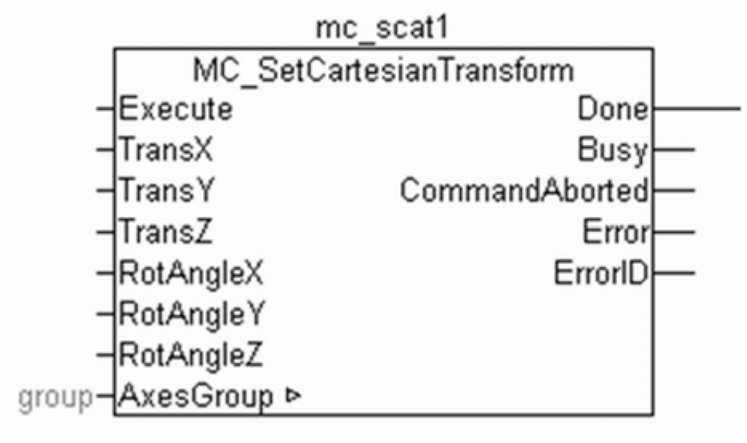
Activation time The function blocks with input Enable will be activated immediately with Enable=TRUE. The function blocks with “Execute” will be enabled with the next movement after Execute=TRUE. The function blocks with “Enable” will be deactivated with Enable=FALSE. The function blocks with “Execute” will be deactivated when an other transformation is activated.

Step Any step 2 transformation can just be active while a step 1 transformation is in place. The step 1 transformation function blocks will allow dynamic transformation while Execute=TRUE. “Frozen” values will be used with Execute=FALSE after once activated.

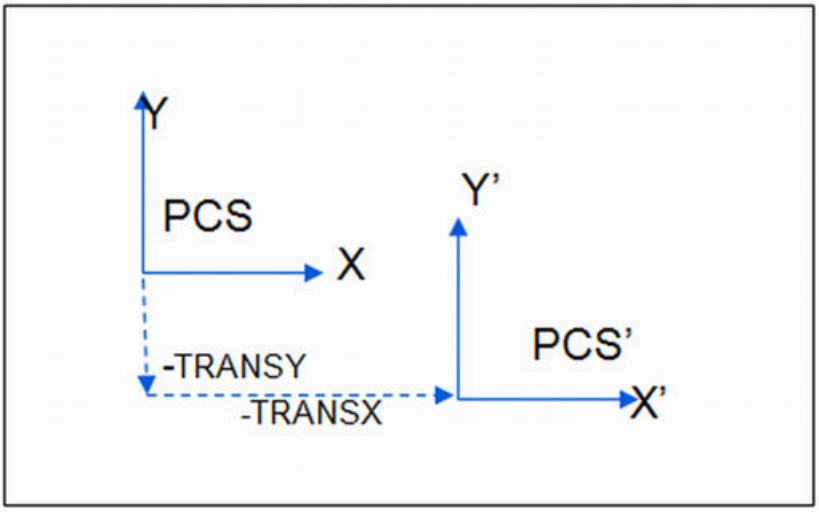
It is possible to do the transformation in 2 steps.

Step 1 is a precondition for any of the step 2 Funciton Blocks. The matrix used in step 1 is a more complete way to setup a PCS coordinate system, as it would also allow modifying the scaling for any axis in addition to translation and rotation. The forward and inverse matrix can be gained by using the COMC_TeachCartesianTransformation function block.

It is also possible to use the matrix in a dynamic way, e.g. modifying the values on the fly, but as usually the dynamic requirement is restricted to a specific translation or rotation, a step 2 function block can be used for this, once the PCS system has been set up.



The step 2 function blocks allow to use translation vectors in X, Y, Z direction and rotation angles for a rotation around X, Y, Z coordinate axis.



TransX	-18
TransY	10
RotangleZ	0

This transformation would modify the actual position as follows, when it is applied to the group in StandStill with the given parameter.

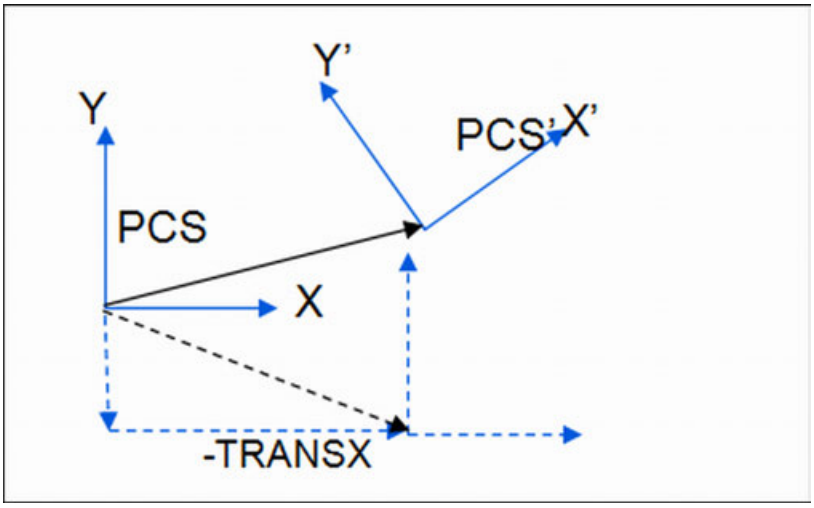
	PCS, PCS'	**PCS, PCS'**
X	0, 0	0, -18
Y	0, 0	0, 10
Z	0, 0	0, 0

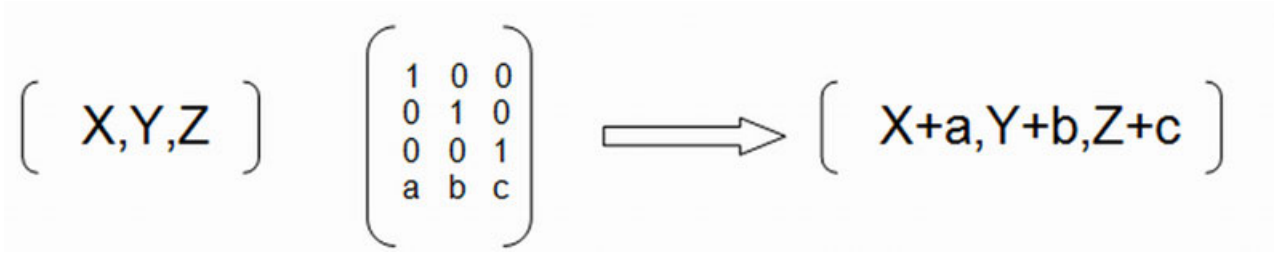
A group-movement to position 0,0,0 will move the group to the origin of the new PCS coordinate system.

When the function block MCA_SetDynamicFollower is enabled with TransX=0 and TransY=0 and the values are applied to the activated function block, the group will keep its PCS position constant and follow the translation. This will result in a real movement and modify the ACS and MCS positions.

	PCS, PCS'	PCS, PCS'
X	0, 0	18, 0
Y	0, 0	-10, 0
Z	0, 0	0, 0

When an additional rotation is applied (in this case RotAngleZ), this rotation is done with respect to the original PCS coordinate system. When a rotation should be done related to the “new” PCS’ system, the translation vector has to be applied to the matrix which builds the PCS system.





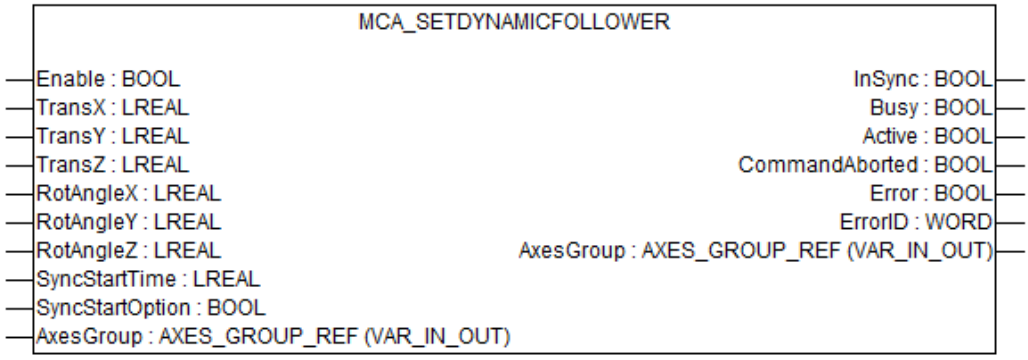
In the forward matrix, the values a,b,c match –TransX, -TransY and –TransZ. In the inverse matrix, the values a,b,c match TransX,TransY and TransZ.

How to teach the conversion matrix

When the group is activated in the MCS coordinate system, it is possible to teach the matrix (inverse and forward) which is necessary to reach the PCS coordinate system. 4 points are needed to do so. They should not be in a line or on the same level, they need to be 3-dimensional independent. ↳ *Chapter 1.5.9.7.1.21 “COMC_TeachCartesianTransformation” on page 2996*

Dynamic coordinate transformation

When a PCS is active, it is also possible to activate a dynamic coordinate transformation in addition which would allow move the axes in relation to a moving product. To do this, the function block “MCA_SetDynamicFollower” has to be used (also MC_SetCartesianTransform would be possible). With this function block, a movement in X and Y direction (related to PCS coordinates) and a rotation around the z-axis is possible.



Related to the FORWARD_MATRIX, this would mean:

$$\begin{pmatrix} c & -s & 0 \\ s & c & 0 \\ 0 & 0 & 1 \\ t_x & t_y & 0 \end{pmatrix}$$

With c = cos(alpha) and s = sin(alpha). Alpha is the angle used to turn around the z-axis. When transformations beyond the “MCA_SetDynamicFollower” options are needed, the matrix could be directly modified.

1. To move the product in the PCS X/Y plane, use MCA_SetDynamicFollower.
2. To turn the product around the Z-axis of PCS (e.g. rotary table), use MCA_SetDynamic-Follower.
3. To do both above movements, use MCA_SetDynamicFollower.

☑ The product is moved in 3 dimensions.

▷ Use MC_SetCartesianTransform or manipulate FORWARD_MATRIX and INVERSE_MATRIX accordingly.

ABB specific data structures

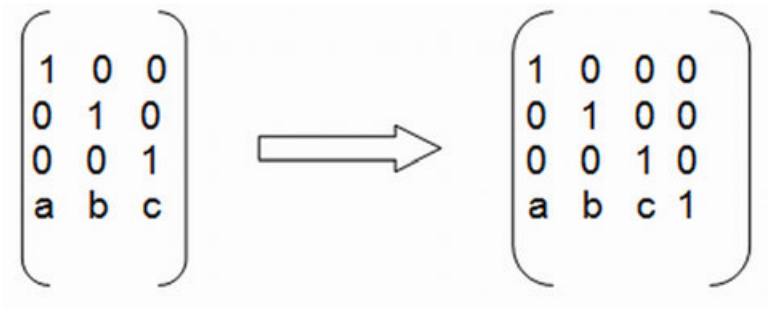
Not all data structures are defined by PLCopen. Some specific structures are described in the following chapter.

Data structures to be used for MCS-PCS transformation

The data type MC_COORD_REF is foreseen for the MCS->PCS transformation in forward (MCS to PCS) and inverse (PCS to MCS) direction. The data type is defined as follows:

```
TYPE MC_COORD_REF :
STRUCT
    INVERSE_MATRIX:     MATRIX_4_3;
    FORWARD_MATRIX:     MATRIX_4_3;
END_STRUCT
END_TYPE
```

The INVERSE_MATRIX should be the inverted matrix to FORWARD_MATRIX. It is not checked if this is really true, but when this rule is not followed it will not be possible to control the MCS axes as actual positions and reference positions would differ. According to the formal rules of matrices math, a square matrix would be necessary to allow inversion. The homogeneous transformation which is used for coordinate transformations expands the matrices to 4x4, so the rules are fulfilled.



Declaration example

```
CoordTransform_neutral:MC_COORD_REF:=
(INVERSE_MATRIX    :=(m:=1,0,0,0,1,0,0,0,1,0,0,0),
 FORWARD_MATRIX    :=(m:=1,0,0,0,1,0,0,0,1,0,0,0));
```

Data structures to be used for moving the group on a path

MC_PATH_REF

This structure is used for moving a Cartesian group on a path. It is evaluated by MC_PathSelect, which creates the structure MC_PATH_DATA_REF to be used for the path movement.

A path movement can be done with the following function blocks:

- MC_MovePath: Move on a path with a defined velocity/in a defined time.
- MC_MovePathPos: Move on a path with a defined velocity/in a defined time including the movement to the path start position.
- MC_SyncGroupToAxis: Move on a path following a master axis.

```
TYPE MC_PATH_REF :
(*This structure is used for moving a Cartesian group on a path*)
STRUCT
    CORNER_DISTANCE:LREAL;    (*u *)
    ACCELERATION_TIME:LREAL;  (*s*)
    pPATHPOINTS:POINTER TO MC_PATH_POINT;
    NUMBER_OF_POINTS:DINT;(*number of points*)
    CORNER_MODE:DWORD;        (*0 = "DISTANCE", 1 = "TANGENTE"*)
    TRANSITION_MODE:MC_TRANSITION_MODE;(*TmConstantVelocity possible with CORNER_MODE=0*)
END_STRUCT
END_TYPE
```

For PathMovement and BufferedMovement, the TMConstantVelocity can be used as TransitionMode and will influence the path-movement in a way that the velocity is kept constant, no matter the angle, as described with buffered movement. It is applied in combination with mode CORNER_MODE=0 (use CORNER_DISTANCE). This special TransitionMode is added to MC_PATH_REF. Any other value at TRANSITION_MODE will result in default behavior, which means a deceleration during a corner, depending on the angle *Chapter 1.5.9.7.3.9 “MCA_MoveBuffered” on page 3030*.

CORNER_DISTANCE Data type: LREAL, unit: u

Distance at which the velocity vector start to leave the actual direction and turning towards the next point. The value has to be >=0.

ACCELERATION_TIME Data type: LREAL, unit: ms

Time which is used to reach the path-velocity.

pPATHPOINTS Data type: POINTER TO MC_PATH _POINT

Pointer to an array which hold the points on the path.

NUMBER_OF_POINTS Data type: DINT

Number of points.

CORNER_MODE Data type: DWORD

=0 => use CORNER_DISTANCE.

=1 => use CORNER Interpolation.

=0x100 => use CORNER_DISTANCE, but related to MASTER_POSITION (ignore V_PATH).

=0x101 => use CORNER Interpolation, but related to MASTER_POSITION (ignore V_PATH).

Table 176: Available options

CORNER_MODE	MC_MovePath/MCA_MovePathPos	MC_SyncGroupToAxis
0,1	The movement is executed by time, calculated based on V_PATH.	The movement is executed by synchronizing to a master axis. The master positions are calculated based on V_PATH which means V_PATH gives the relation from slave/master velocity [u(slave)/u(master)] instead of [u/s].
0x100, 0x101	The movement is executed by time, calculated based on MASTER_POSITION. The given values are interpreted as [s].	The movement is executed by synchronizing to a master axis. MASTER_POSITION is used. The group will reach the given X/Y/Z point when the master axis reaches MASTER_POSITION. The points are not reached exactly but modified by CORNER_DISTANCE or the CORNER algorithm.

MC_PATH_POINT

V_PATH Data type: LREAL, unit: u/s

Path velocity which should be reached from this point to the following point.

The velocity V_PATH is used when the movement is executed by MC_MovePath or MCA_MovePathPos. The interpolation aims to reach V_PATH as path velocity, so V_PATH determines the interpolation progress. When using a path movement controlled by a master axis (MC_SyncGroupToAxis), the MASTER_POSITION is used instead, according to a CAM Table movement. V_PATH is then ignored.

X Data type: LREAL, unit: u

Position for the X-Axis.

Y Data type: LREAL, unit: u

Position for the Y-Axis.

Z Data type: LREAL, unit: u

Position for the Z-Axis.

MASTER_POSITION Data type: LREAL

Position for master axis used by MC_SyncGroupToAxis, unit: u.

Time when used with MC_MovePath or MCA_MovePathPos, unit: ms.

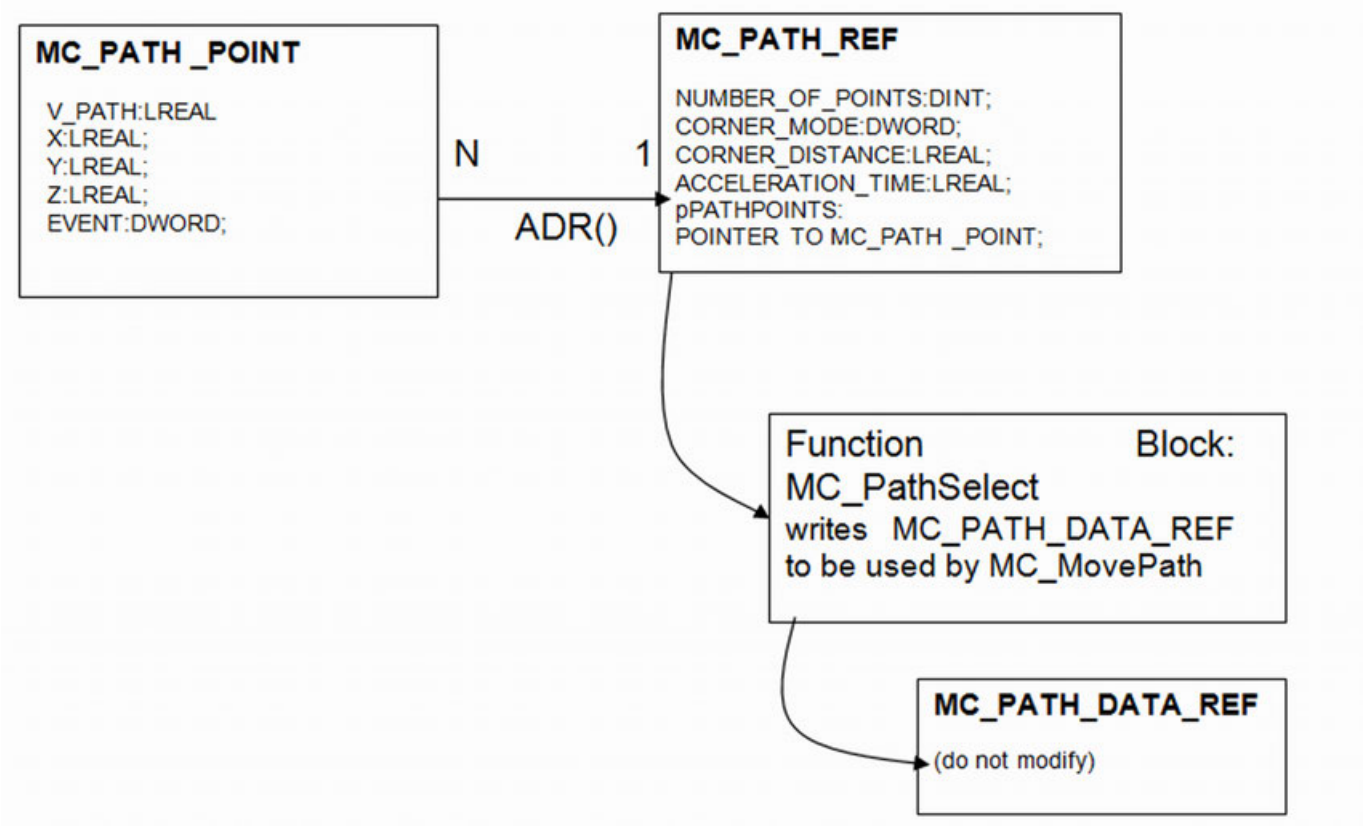
EVENT Data type: DWORD

Binary pattern which would be displayed by function block MCA_PathEvent.

MC_PATH_DATA_REF

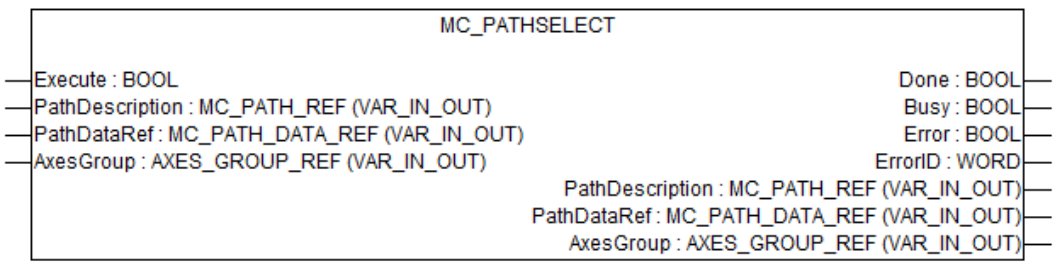
Filled by MC_PATH_SELECT, not to be modified.

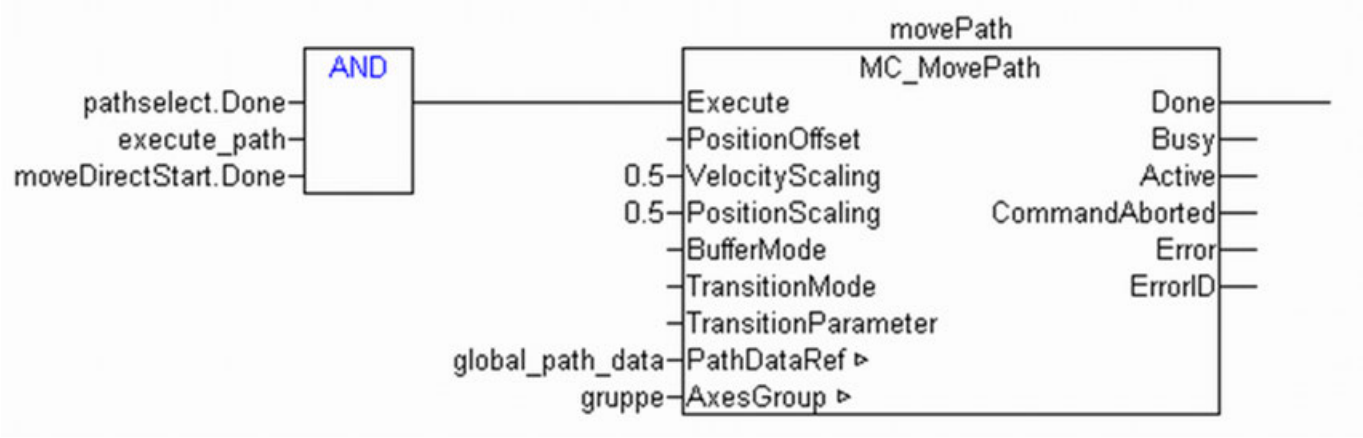
The structure MC_PATH_DATA_REF is completely filled out by the function block MC_PATH_SELECT. The basic data which has to be provided in an array of MC_PATH_POINT is prepared to be used by the function block MC_MOVE_PATH.

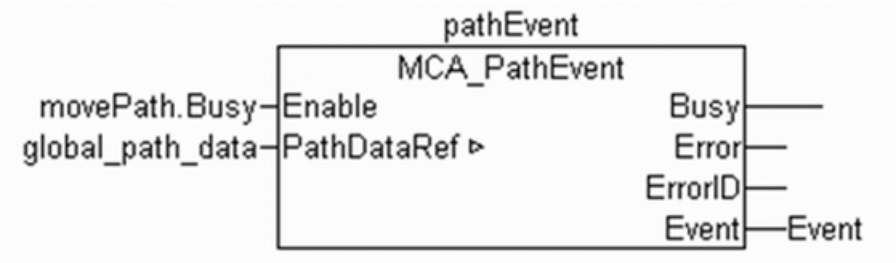


Example for using the path data

1. Create an element of type MC_PATH_REF.
   path_description: MC_PATH_REF;
2. Create an array of type MC_PATH _POINT.
   path_array: ARRAY[1..7] OF MC_PATH _POINT;
3. Fill the MC_PATH_REF with data.
   path_description.ACCELERATION_TIME:=100;(*ms*)
   path_description.corner_mode:=0;
   path_description.CORNER_DISTANCE:=50;(*mm*)
   path_description.N:=7;
   path_description.Path:=ADR(path_array);
4. Initialize the path_array itself.







The PathDescription has to be evaluated by MC_PathSelect. The resulting information is transferred by PathDataRef to the function block MC_MovePath which starts the movement. The MC_PathSelect just needs to be called once when the PathDescription has been changed. When the same data is used several times, it is enough to just call the MC_MovePath.

The MCA_PathEvent is an additional ABB specific function block which allows writing an “Event” value (32Bit) according to the position which is actually reached by the path interpolation. “Event” matches the respective value of EVENT as element of MC_PATH_POINT, when the group reaches this point.

Interpolation modes available for MC_MovePath

Two different interpolation modes are available:

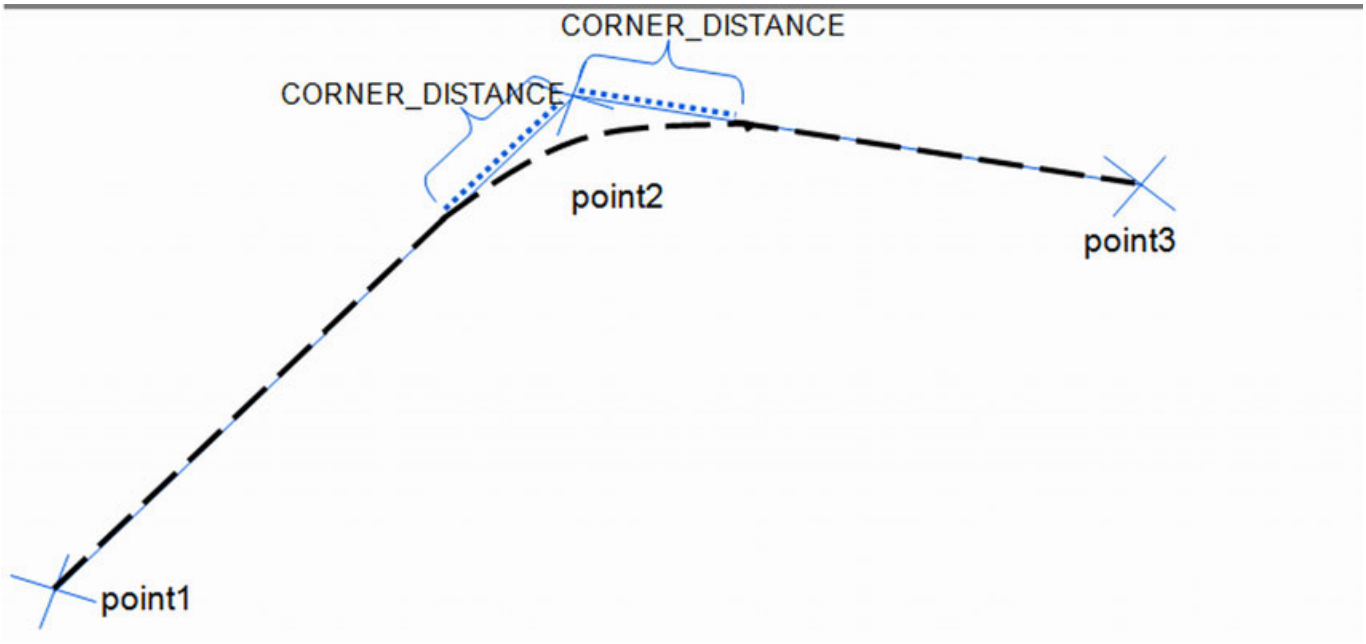


Fig. 269: Behavior with CORNER_MODE=0

When CORNER_MODE in MC_PATH_REF is =0, the movement will be executed on the given path between 2 points until the given CORNER_DISTANCE is reached. Then the direction will be changed and the TCP will again reach the path from point 2 to point 3 at CORNER_DISTANCE behind point 2.

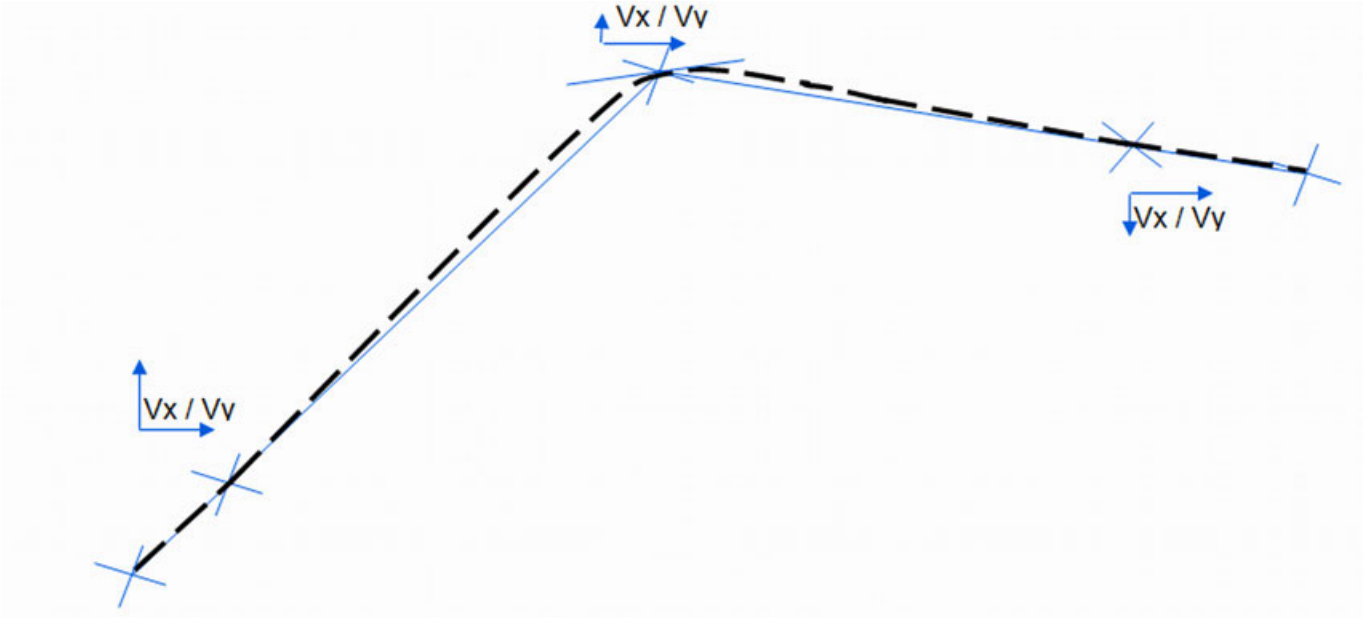

Fig. 270: Behavior with CORNER_MODE=1

When CORNER_MODE=1 in MC_PATH_REF, the interpolation will meet every given point but will modify the velocity before the corner to direct the movement towards the next point and to reach a continuous ve-locity profile while doing so. A cubic interpolation is used from point-to-point in a way that a smooth velocity curve is achieved in every single direction (X/Y/Z). The acceleration is not taken in to account and just 3 consecutive points influence every specific movement.

The following diagram shows the 2 different interpolations for a very simple path.

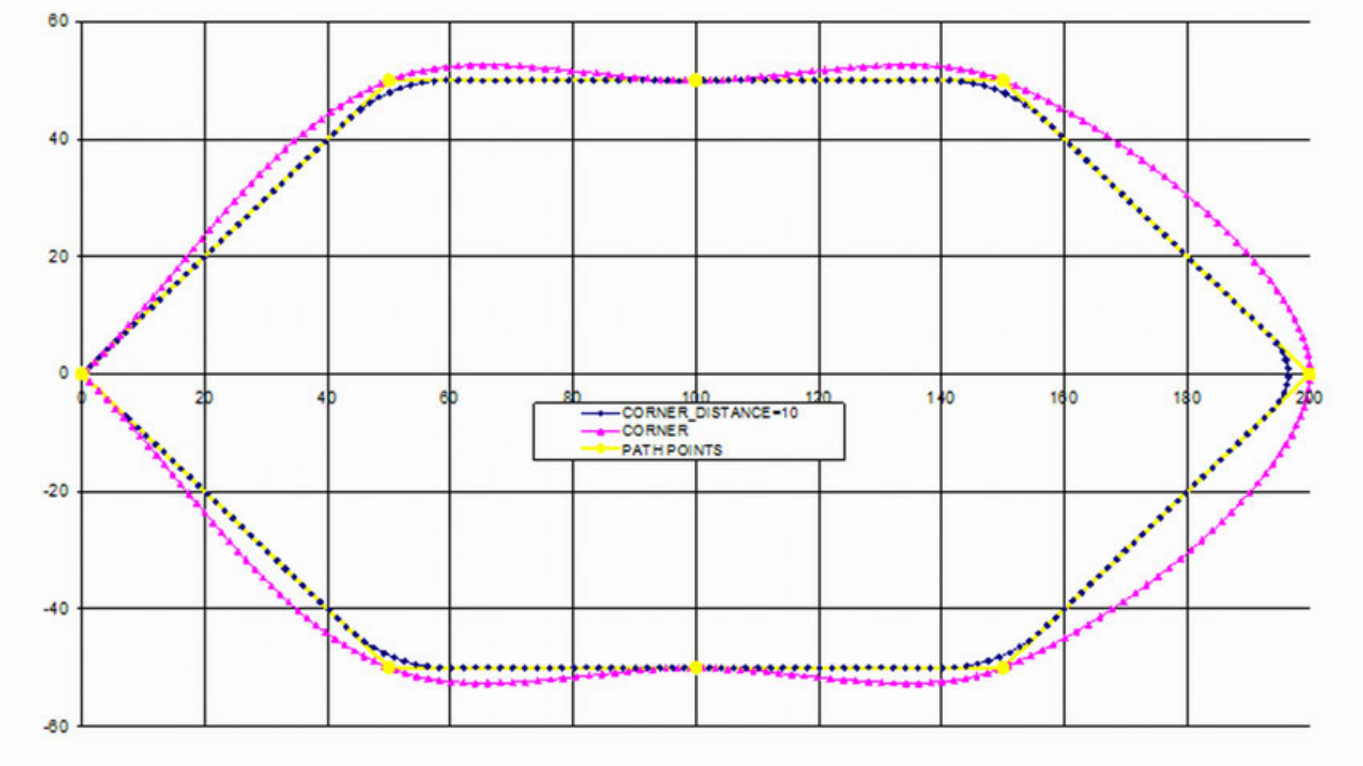

Fig. 271: POSITION comparison

Table 177: The points are:

X	Y
0	0
50	50
100	50
150	50
200	0
150	-50
100	-50
50	-50
0	0

The yellow curve shows the original points, the pink curve the interpolation result for CORNER_MODE=1 and the blue curve the result for CORNER_MODE=0 with CORNER_DISTANCE=10.

-CORNER_MODE=0: the given path, as a linear movement from point-to-point, is followed, just at the given distance from the corner (predefined X/Y-point) this path is left and the movement turned into the direction of the next point.

-CORNER_MODE=1: the interpolation meets the given points, but the linear path is left as a cubic interpolation is performed to achieve a smooth movement.

A second example is shown with far more points to define the curve. In this case, it seems almost as if there was no difference between the 2 modes:

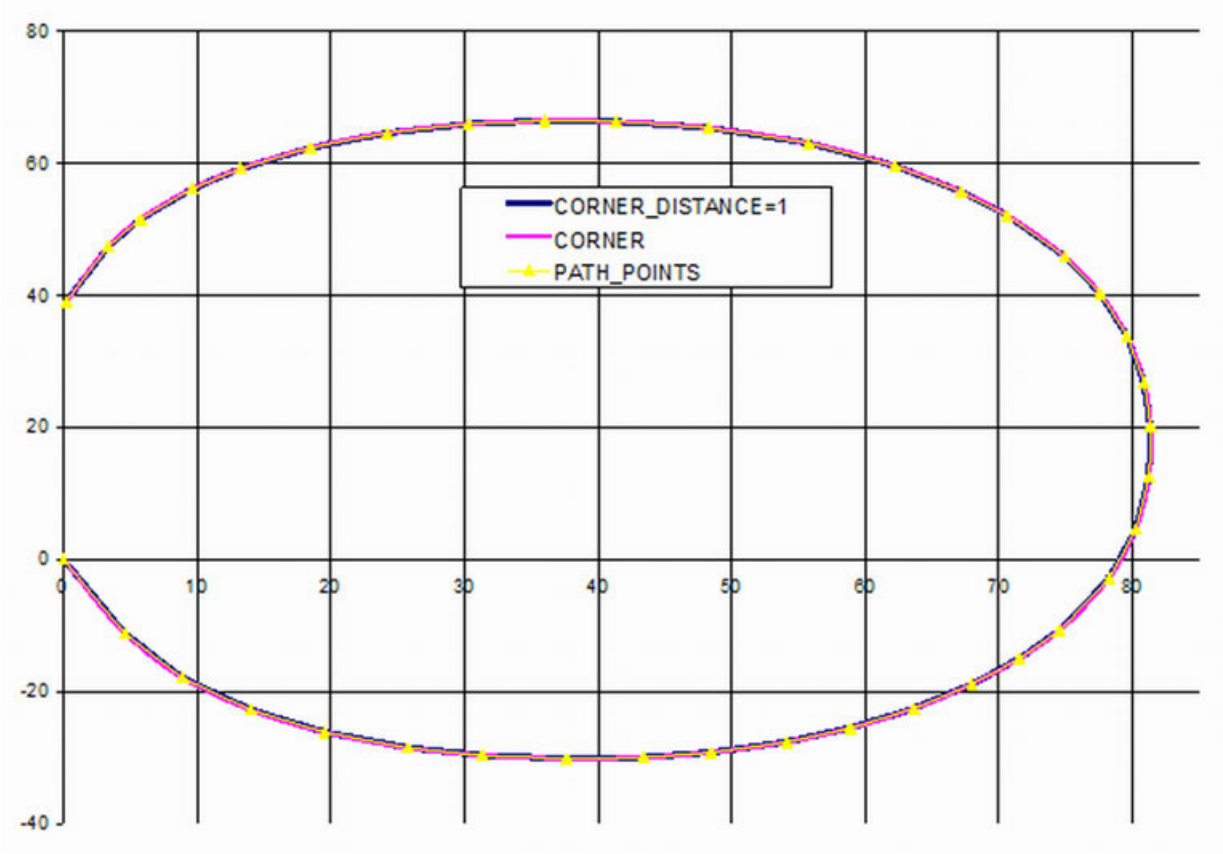

Fig. 272: POSITION comparison

The difference is to be seen when exploring the curve in more detail. In this case, a CORNER_DISTANCE=1 is used, so the interpolation follows the path somehow “edgy”, while CORNER_MODE=1 creates a rounded curve.

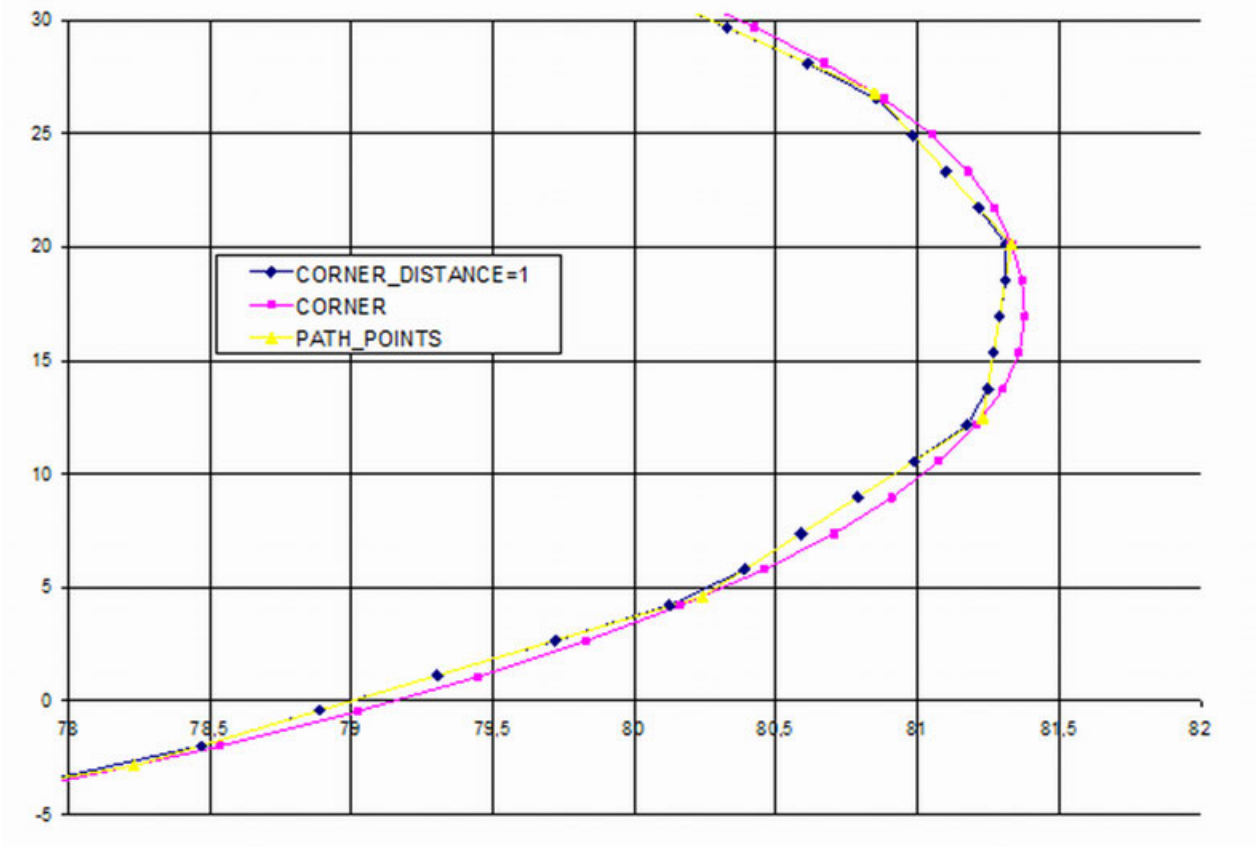

Fig. 273: POSITION comparison in detail

An even clearer difference is to be seen in the velocity curve:

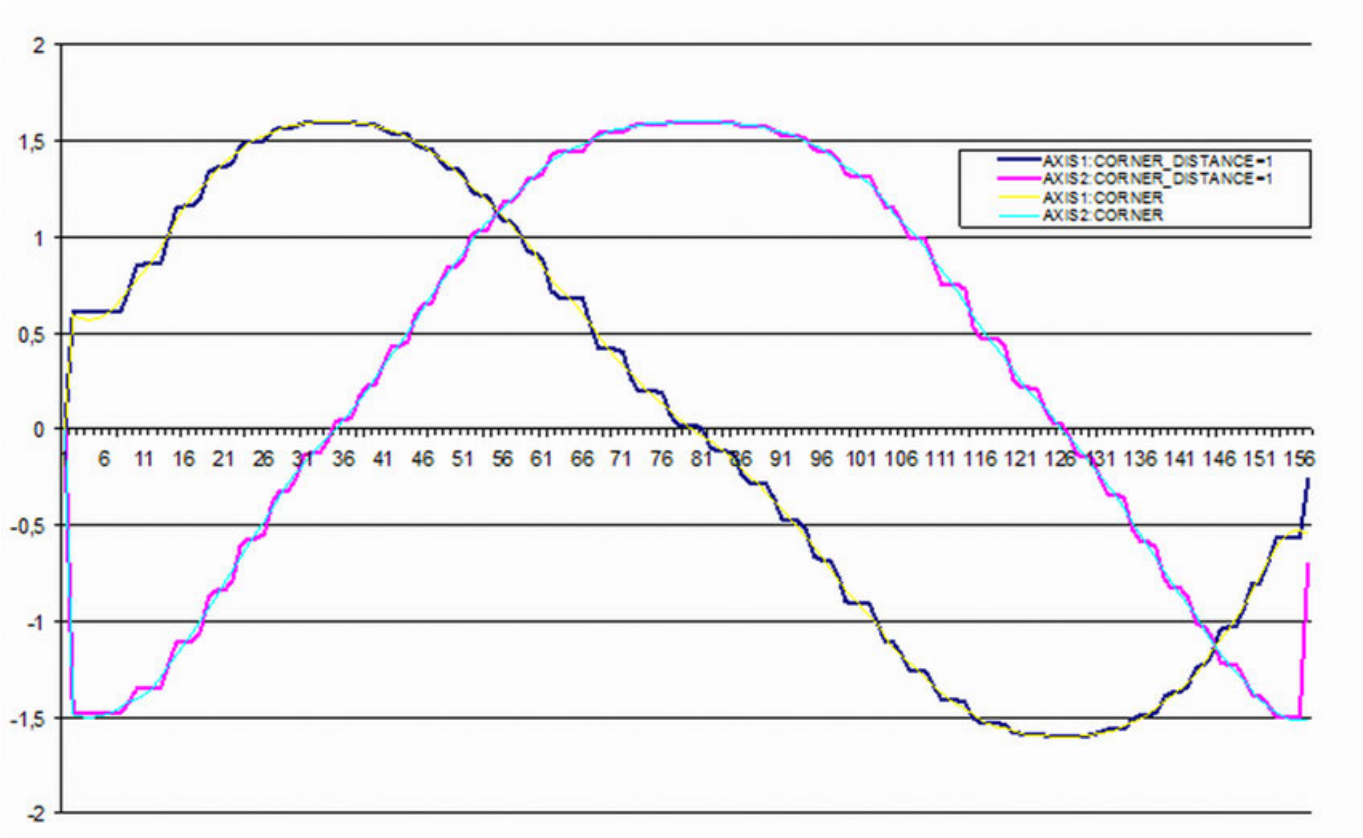

Fig. 274: VELOCITY comparison

-with CORNER_MODE=0, a constant velocity is maintained during the linear parts of the path. Just the section de-scribed by CORNER_DISTANCE (in this case, CORNER_DISTANCE=1) is used to change direction and velocity.

-with CORNER_MODE=1, a continuous velocity transition is achieved.

Model

Group state diagram

The group state diagram describes the commanded state of the group of axes. It is on top of the single axis state diagram *Chapter 1.5.9.3.2 “The single axis state diagram” on page 2589*. While axes are in a group state, the single axis state diagram is also active per axis. Therefore interdependencies between the two types of state diagrams exist.

GroupDisabled is the initial state at power up where a group can be created. Issuing MC_GroupEnable leaves this state.

The next state is GroupStandby. In this state the group is enabled and no function block has control on one of the axes in the group. In this state the group can additionally be altered and homed if needed (State GroupHoming).

In the state GroupHoming a homing sequence can be defined for a group of axis. This can be applicable due to the mechanical constraints of multiple motors. For example in an mechanical construct looking like the letter “I“ with two motor mechanically coupled via one band or belt moving over the form of the letter I, need to be homed differently.

If a function block has control on (one of the axis of) the group, the state changes to Group-Moving.

GroupStopping is a special state that deals with the MC_GroupStop command, which automat-ically tranfers to the state GroupStandby as soon as Done = SET and Execute = FALSE in MC_GroupStop.

In case an error arises (in one of the axis) the state changes to GroupErrorStop, which can only be left via issuing MC_ResetGroup.

Explanations

Group motion commands will always lead to a Synchronized Motion state in the single axis state diagram. In case of a GroupStandby all axes of the group are also in single axis state StandStill.

A GroupErrorStop will not lead to ErrorStops of the grouped axes as the error may only affect the group. In case of a single axis ErrorStop the Group will also change to GroupErrorStop as the single error effects the group.

The group state diagram reflects the state of the group and the issued function blocks.

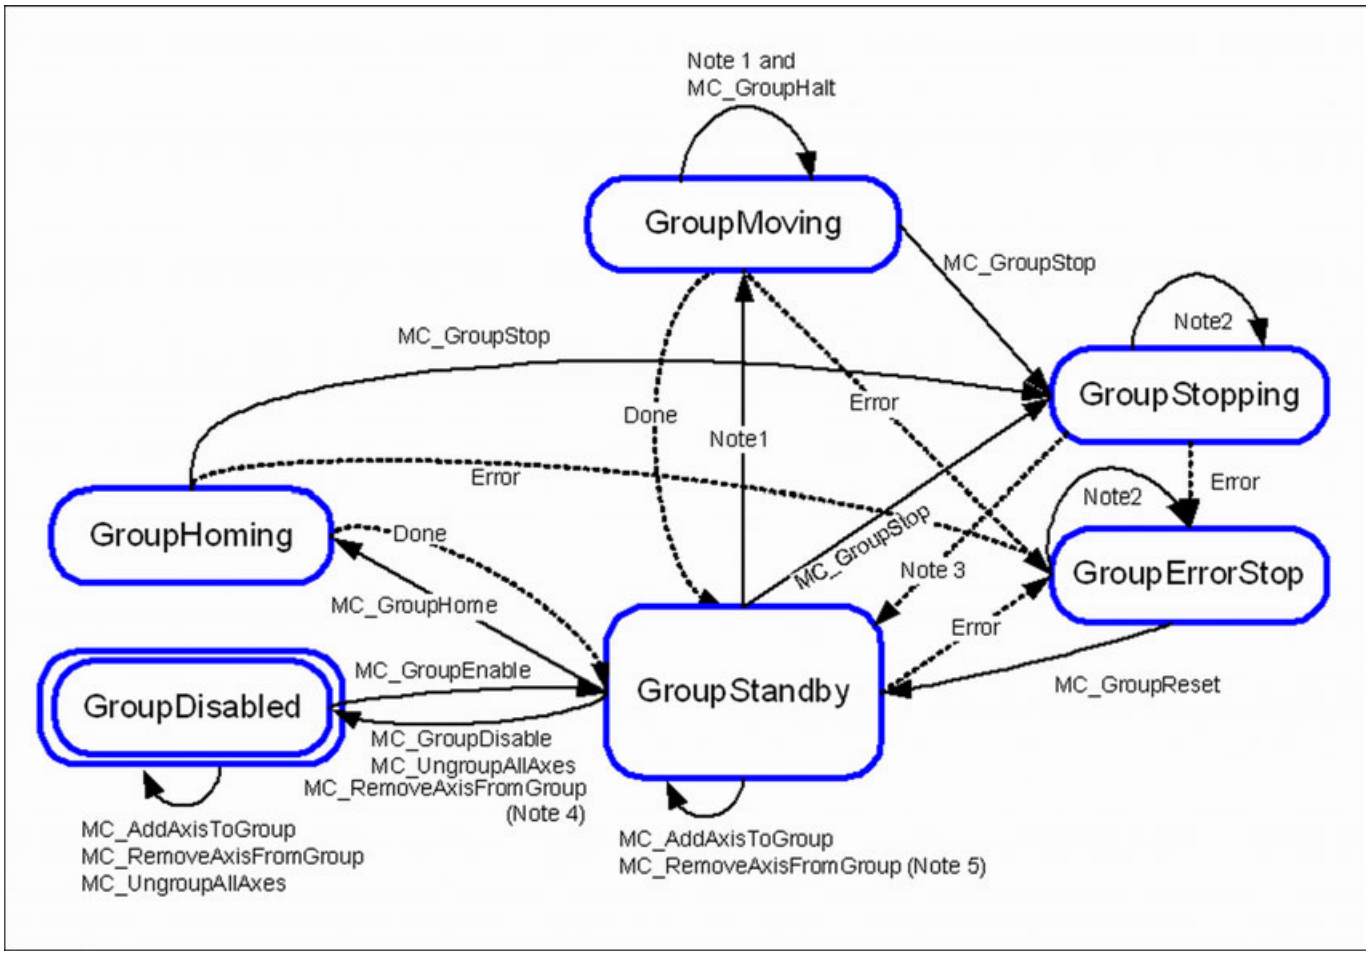

Fig. 275: The group state diagram

Relationship single axis and group state diagrams

Example of the relationship between three single axes combined in an axes group.

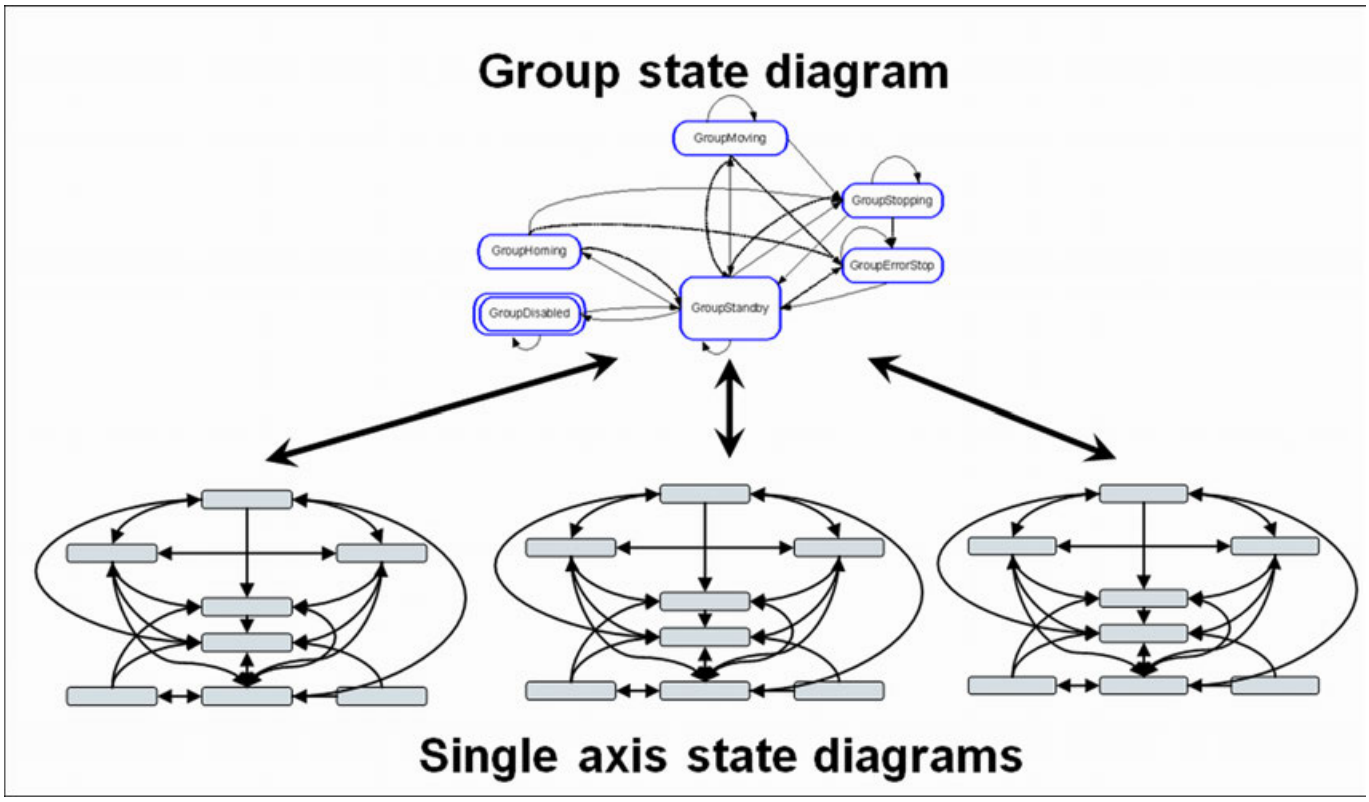

Fig. 276: Relationship single axis and group state diagrams

When a number of axes are grouped, and a single axis command, like MC_MoveAbsolute, is issued to an axis in this group, there are basically three options:

- Not allowed. Issuing a single axis command is not accepted and not performed: it signals this by setting the er-ror output of the applicable (issued) single axis function block. There is no change to the group, and as such continues their movements.
- Aborting the current group command(s), as well as following group commands, and continue with the single axis command only. The remaining axes of the group move to the state StandStill (via an implicit MC_Halt per axis). The original trajectory will not be finalized.
- Superimpose the single axis commands to the group commands.

This specification does not restrict to any of these options. This means that different implementations of this behavior will exists, and the supplier of the system has to specify what their system does support.

General rules for the interaction between a single axis towards its groups (for all 3 options above):

- If at least one axis in the group is moved by a command then the group is in the state GroupMoving.
- If all axes are in StandStill, the group can be in the state GroupStandby, GroupDisabled or GroupErrorStop.
- If one axis in a group is in ErrorStop, the whole group is in GroupErrorStop.
- If a single axis MC_Home is issued the group is in state GroupMoving.
- If a single axis MC_Stop is issued the group is in state GroupMoving.
- If supported by the system, it is allowed to disable a single axis of the axis group without influencing the axes group state. This can be useful to save energy or to apply a mechanical brake for a single axis not involved in the on-going motion.

General rules for the interaction between a group and the single axis in it (for all 3 options above):

- If the group is commanded by a group moving command, all the single axes in the group are in the state Synchronized Motion.
- If the group is in the state GroupStandby, the states of the single axes do not have to be all in StandStill.
- If the group is in the state GroupErrorStop the state of the single axis is not affected.

Table 178: Overview of the influence of group motion commands on a single axis state

Command	Group State	Axis State
MC_MoveLinearXxx MC_MoveCircularXxx MC_MoveDirectXxx MC_MovePath MC_GroupHalt MC_TrackConveyorBelt MC_TrackRotaryTable	GroupMoving	Synchronized Motion
MC_GroupStop	GroupStopping / Group-Standby	Synchronized Motion / Stand-Still
MC_GroupReset	GroupErrorStop / Group-Standby	Not relevant for Axis
MC_GroupHome	GroupHoming	Synchronized Motion

Explanation: A stopping group leaves the single axis in Synchronized Motion as none of the single axis performs a single axis stop.

Input execution mode

The input MC_EXECUTION_MODE is an ENUM providing information on the behavior of administrative function blocks.

The modes are:

- Immediately - the functionality is immediately valid and may influence the on-going motion but not the state.
- Delayed - The functionality is valid when the ongoing motion command sets one of the following output parame-ters: Done, Aborted or Error. This also implies that the output parameter Busy is set to FALSE.
- Queued - The new functionality becomes valid when all previous motion commands sets one of the following output parameters: Done, Aborted or Error. This also implies that the output parameter Busy is set to FALSE.

General rules

The following chapter explains some rules on the usage of the libraries.

- A general rule is that ALL PLCOpen function blocks which are used for a specific drive are to be used in the same PLC-task. When multitasking is used for the PLC, it is allowed to have different drives in different tasks, but all Funciton Blocks belonging to a specific drive need to be in the same task. There is no multithreading protection for the AXIS_REF instance.
- The CMC_MotionKernel… and the COMC_Group… function blocks might be in a different task then the PLCopen Blocks (MC…). All function blocks belonging to the same fieldbus Communication Module have to be called from the same task.

- When AXIS_REF or AXES_GROUP_REF is used as input on a user defined FUNCTION_BLOCK or PROGRAM or FUNCTION, then ALLWAYS use it as VAR_IN_OUT and NEVER use it as VAR_INPUT or VAR_OUTPUT. The reason is that this would
  - Break the consistency and destroy data
  - Consume a lot of computing power by copying data.
- The "Min update time" update time for the fieldbus, defined under *“PLC Configuration ➔ Communication Modules[FIX] ➔ <fieldbus master type>”* must not exceed the half of the scantime of the PLC-task. E.g. scantime of PLC-task is 5ms, then "Min update time" should not be greater than 2ms.
- The functionality of CompactMotion_AC500 library may be combined with the CoordinatedMotion_AC500 library. All single axis functions could still be used for an axis, even when it is combined with others to a group .

Axes grouping

Within this specification for interpolation, the related axes are grouped in an “AxesGroup”, and can be accessed via the type AXES_GROUP_REF. The relationship between the different axis levels and groups is shown hereunder.

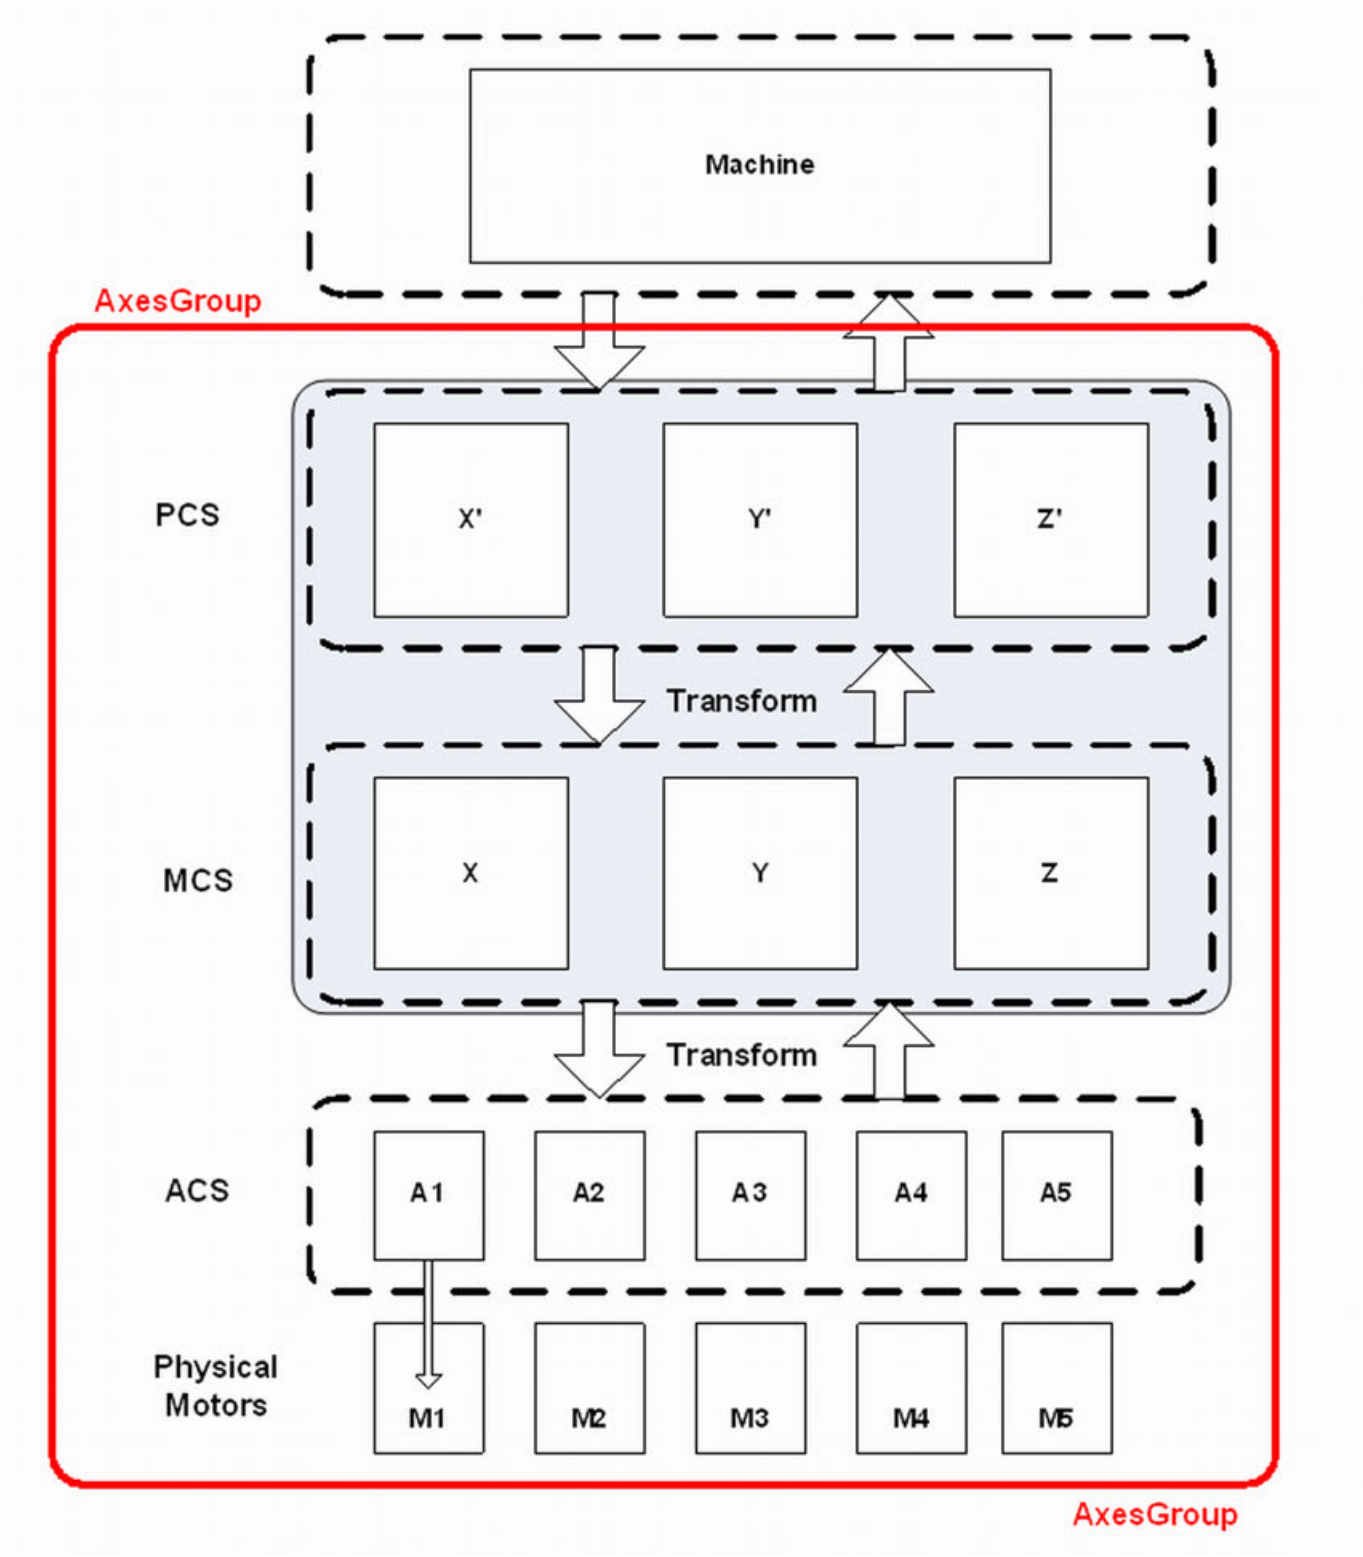

Fig. 277: Overview AxesGroup

The AxesGroup shown in red above provides the interface to the user of the group of axes.

AC500: All group movement is applied to the MCS or PCS axes. The output "isActivePCS" from the transfor-mation block shows if a PCS system is active.

- *isActivePCS=true => all group movement is done in the PCS (product coor-dinate system).*
- *isActivePCS=false => all group movement is done in the MCS (machine coordinate system).*

A movement in ACS coordinates could be done by using single axis blocks and the respective ACS axis as AXIS_REF.

Parameters in the AxesGroupRef can include remaining time and remaining distance before target position (or velocity or equal) is reached.

↳ *Chapter 1.5.9.7.1.20 "COMC_GROUP_CARTESIAN" on page 2994*

Axes group synchronized motion

The function blocks MC_SyncGroupToAxis ↳ *Chapter 1.5.9.7.1.18 "MC_SyncGroupToAxis" on page 2988* and MC_SyncAxisToGroup ↳ *Chapter 1.5.9.7.1.19 "MC_SyncAxisToGroup " on page 2991* deal with a master/slave relationship between a single or group of axes and a single or group of axes for coordination purposes.

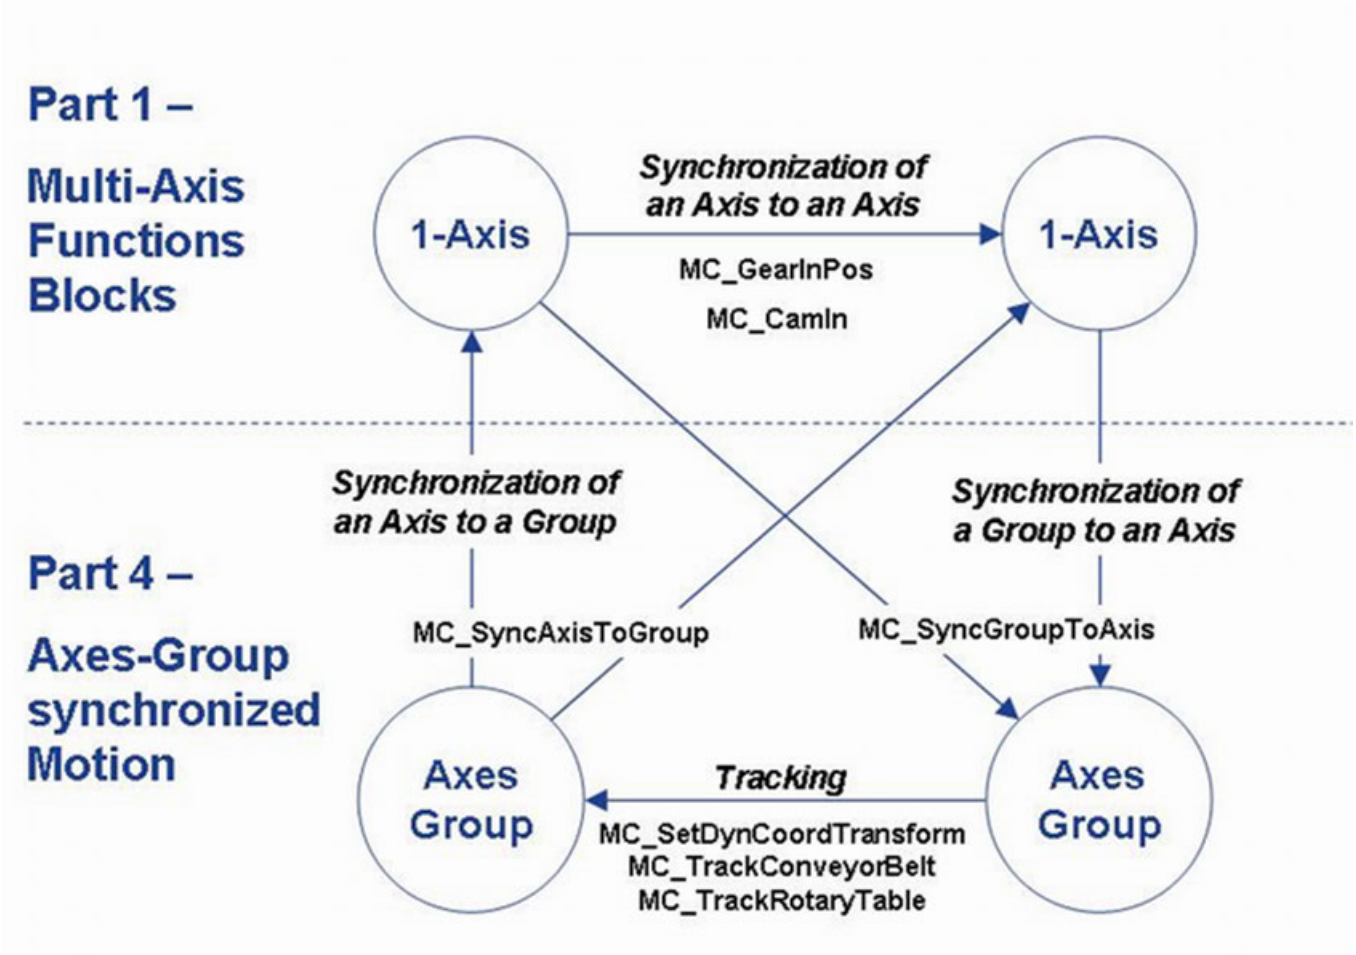

Fig. 278: Graphical explanation of coordination

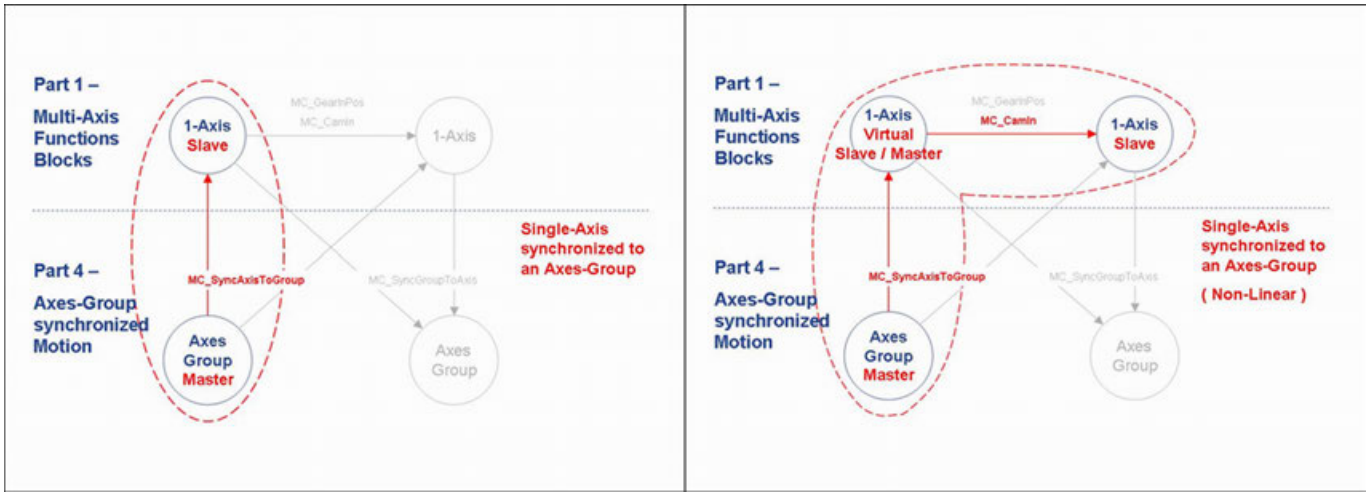
There are two kinds of coordinated motion that have to be distinguished from a programming point of view and in the realization of the motion control itself. These two modes are identified here through their names:

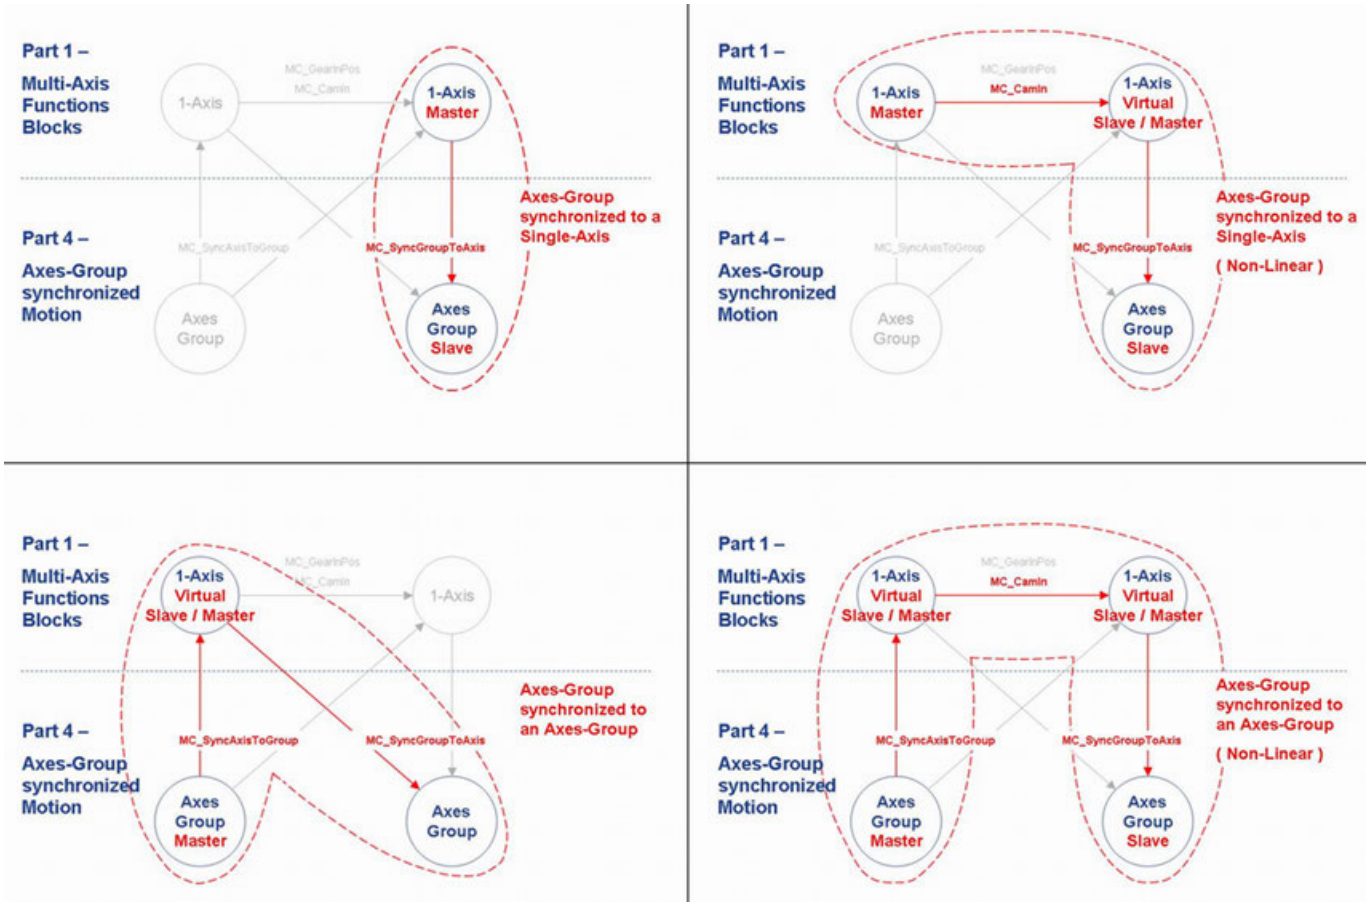
- Synchronization
- Tracking

Synchronization

The relationship between single axis commands and synchronized motion is shown here. There are 6 possibilities of associations:

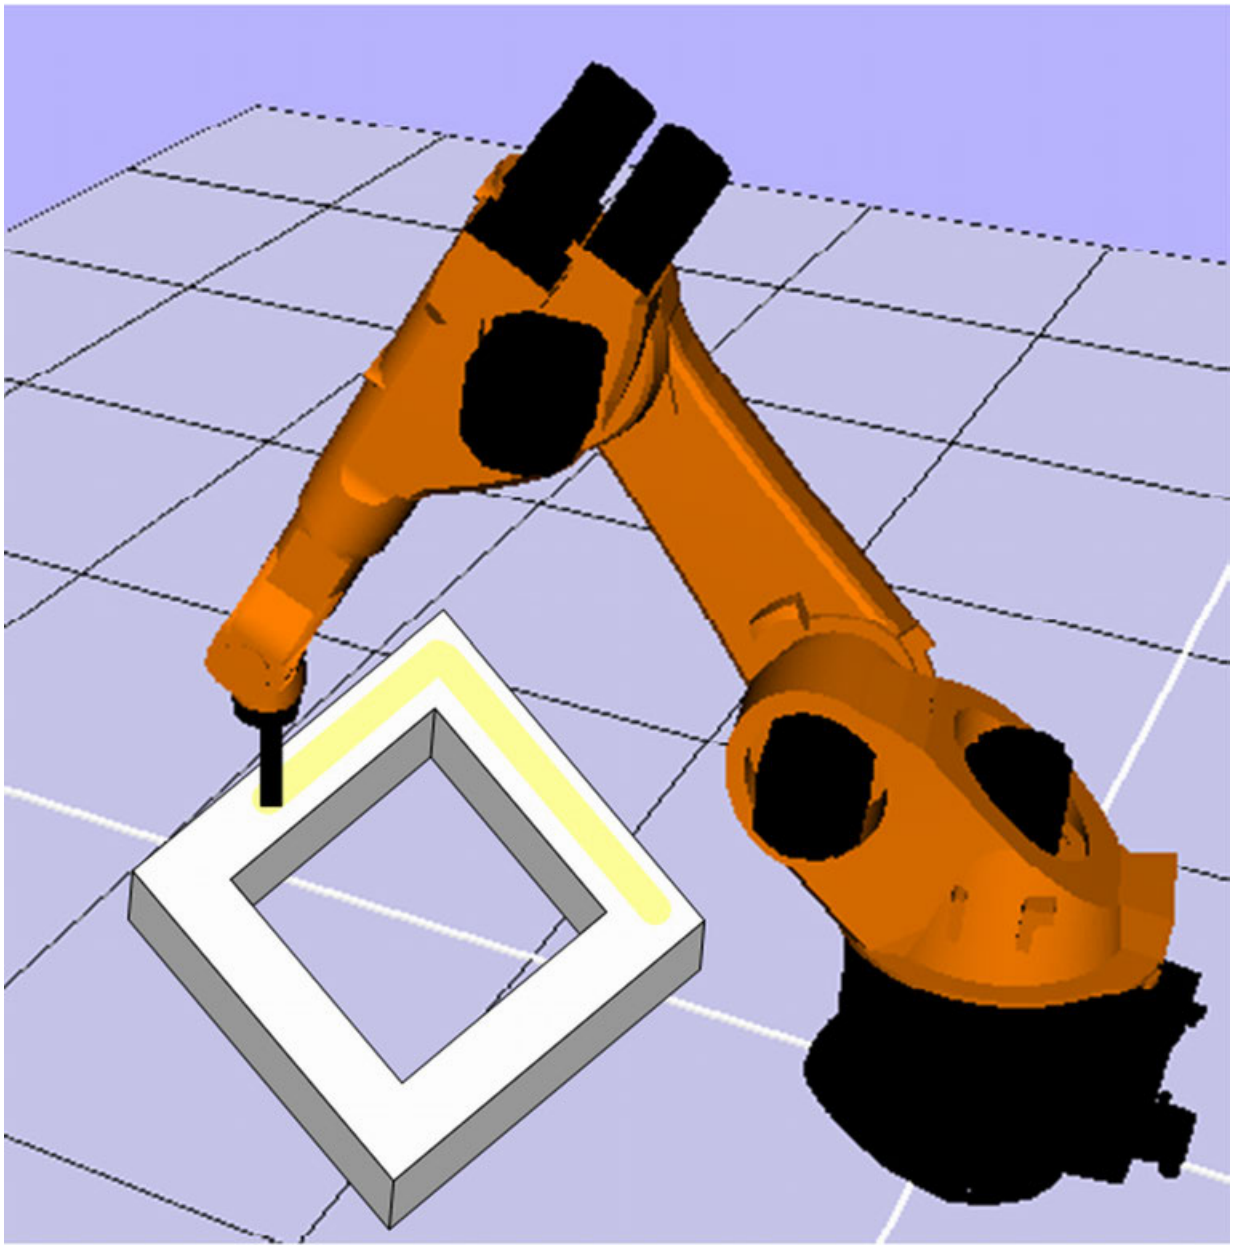
1. Single-axis synchronized to an Axes-Group, Linear synchronization,
2. Single-axis synchronized to an Axes-Group, Non-Linear synchronization (using MC_CamIn),
3. Axes-Group axis synchronized to a Single-axis, Linear synchronization,
4. Axes-Group axis synchronized to a Single-axis, Non-Linear synchronization (using MC_CamIn)
5. Axes-Group axis synchronized to an Axes-Group, Linear synchronization,
6. Axes-Group axis synchronized to an Axes-Group, Non-Linear synchronization (using MC_CamIn).





Synchronization of single axis to an axes group

This is an example of a single axis (as slave) synchronized to an axes group (master). The master follows its path and the slave is linked to the position, velocity, acceleration, or any other magnitude of the master. An example is glue dispensing, where the amount of glue to be dispensed is coupled to the velocity of the TCP of the robot. The single axis slave motor movement of the glue dispenser is coupled to the trajectory of the TCP of the group over the surface of the object via MC_AxisFollowGroup. Alternatively, if the position information is not critical, one can use MC_GroupReadActualVelocity, perhaps combined with a gearing factor, and thus providing the input to the motor of the glue dispenser.



Synchronization of an axes group to a single axis

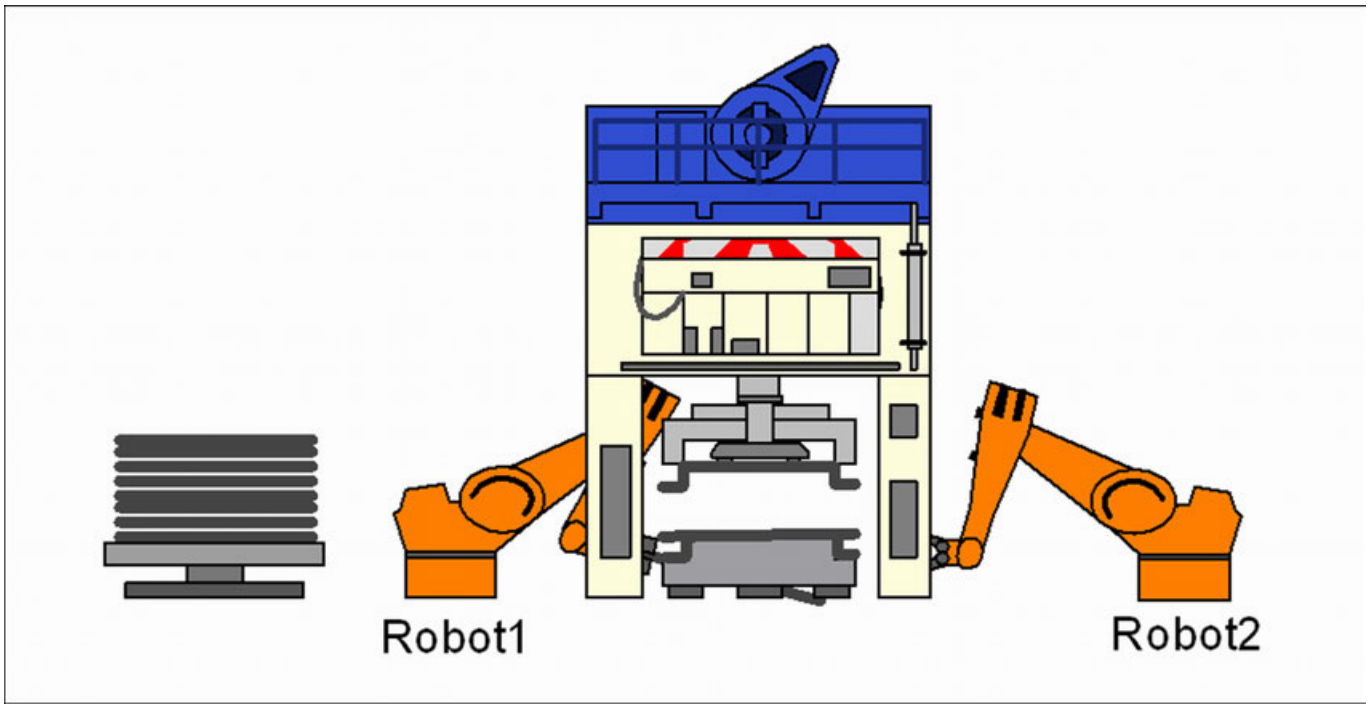
This mode combines an axes group (as slave) with an axis as master in order that the slave executes its path with synchronization to the progress of the master, meaning linked to a 1-dimensional source for synchronization.

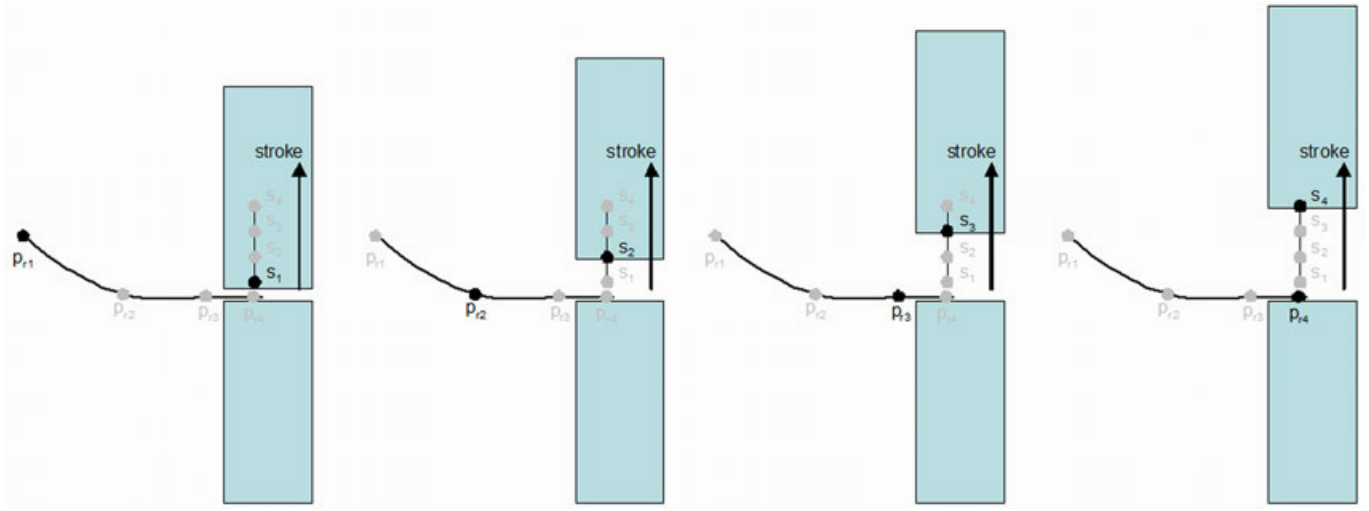
Examples here include press synchronization. As an example of synchronization between a master single axis and a group can be the robot which places material in a press machine:

The robot has to synchronize to the opening phase of the press. A second robot also synchronizes to take the material out. The master is the (single or virtual) axis controlling the press. The axes group for both robot 1 and robot 2 has to follow the press in a certain area of the master movement:

Opening for robot 2 to take the product out and closing for robot 1 to add the new product. For this synchronization the function block MC_SyncGroupToAxis is defined.

In case the slave is an axes group, a transformation to a virtual axis can be applicable to generate the 1-dimensional synchronization data. In case both the master and the slave are axes groups, a virtual master axis on the slave side is applicable (linked via cam profiles to the different axes) to use the 1-dimensional synchronization data of the master side.



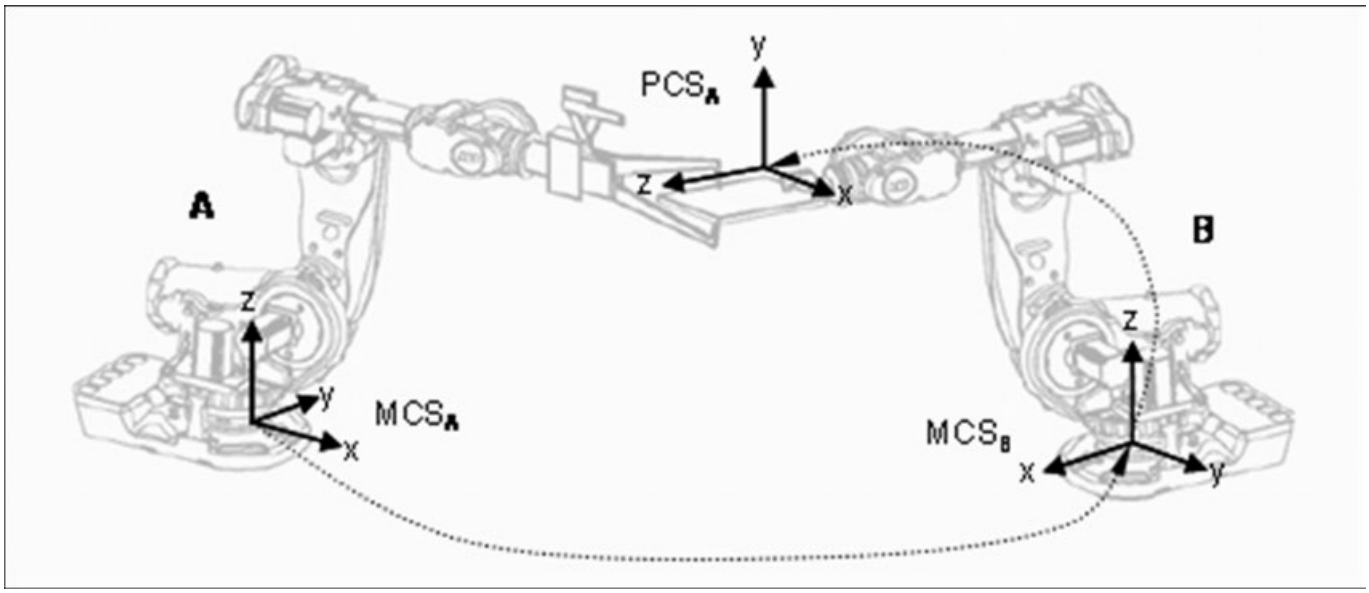


Tracking

Tracking is characterized by an axis group (A) that follows with its movement the movement of a single axis or another axis group (B). During the coordinated following A is performing a movement/task relative to the movement of B. The tracking data is a multidimensional source incl. position and orientation. Solutions can include a moving coordinate system or a multidimensional gear functionality. Tracking can be seen as a superposition of two movements, although these movements are independent. One, which is the movement of the product (moving PCS) and the second one, which describes the path of the TCP that would be executed if the product is standing still (Positions have to be defined in PCS). The Position of the PCS and therefore also the movement of the PCS relative to MCS is described by the coordinate transformation MCS to PCS. For tracking the following function blocks are defined here: MC_SetDynCoordTransform as a general one, and MC_TrackConveyorBelt plus MC_TrackRotaryTable for specific applications.

> *The considerations on the limitations of the dynamics or mechanics are implementation specific.*

Basic example: The basic example for the tracking of an axis group and a single axis is conveyor tracking, where the robot picks or places parts on the moving conveyor or is putting some crème on a cake moving on the belt. An example for the tracking of another axes group is having two robots, where robot B is holding a work piece, and robot A is performing some welding on the part at the same time B is moving the work piece (see figure.



Generally there is no difference if A is tracking a single axis or an axis group, when thinking of a single axis as an axis group having only one axis but also a kinematic (even if it is very simple). Then concepts of the motion planning as well as of programming are the same.

Example: A second tracking example deals with synchronization of a group and a transportation belt. The group synchronizes to the belt, which is the master. We have a (simple) Cartesian robot, consisting of 3 motors moving 3 axis. Application examples are to pick something from the belt (with a correction in the Z-position), or to put some cream on a cookie that is lying on the belt.

1.5.9.5 Drive-Based motion control

1.5.9.5.1 Drive-based motion architecture

To connect a real axis to the PLCopen function blocks, a certain driver function block has to be used for every axis type. These function blocks are named XXX_ACCESS and are realized for a variety of drives. By creating new driver function blocks, additional drives or additional types of motion control software might be included.

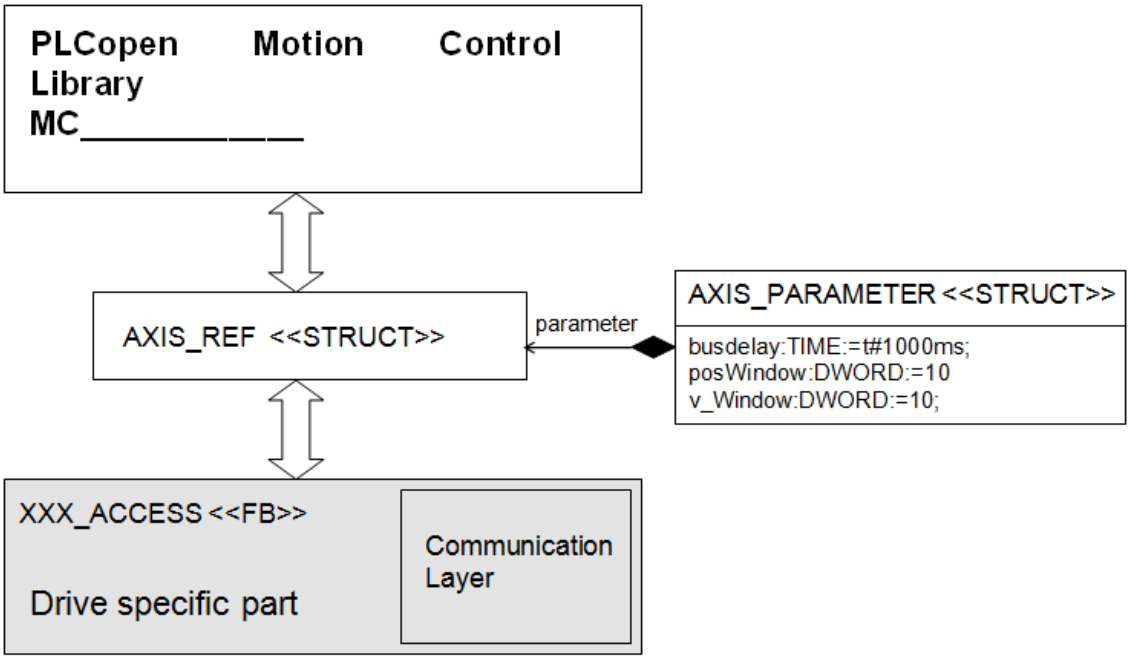

Fig. 279: Architecture

The usage of the “XXX_ACCESS” is dependent on the different drive types. For all drives, the structure AXIS_REF holds an element parameter from type AXIS_PARAMETER. This is initialized with some default values but might be adjusted to the specific application. ↳ *Chapter 1.5.9.5.2.3 “ACSM1_ACCESS_dc driver unit in decentralized motion control” on page 2725*
↳ *Chapter 1.5.9.5.3.3 “ACS350_ACCESS_dc” on page 2736*

1.5.9.5.2 Realization with ACSM1 on PROFIBUS DP network

General restrictions

Restrictions for the available function blocks

- As buffered mode, MCAborting is realized as a default.
- The “Jerk” is not available at the function block. When it is used, it is possible to send the respective parameter separately to the drive or to adjust it with the drives configuration software.
- From the Extended inputs and outputs at the function blocks, the following are not realized:
  - BufferedMode: The realization for ACSM1 just supports by default the MCAborting mode.
  - Jerk: A maximum jerk could be adjusted by parameters of the drive.
- For the parameter number (WriteParameter, ReadParameter), the following options are available:
  - The PROFIDRIVE parameter number.
  - The ACSM1 parameter number + 40000
    This manipulation of the parameter number is necessary to distinguish between the different types of parameter number.

Preconditions

- An instance of the AXIS_REF structure has to be created.
- A connection to the drives fieldbus interface has to be established.
- The drives parameter need to be adjusted to match the requirements.

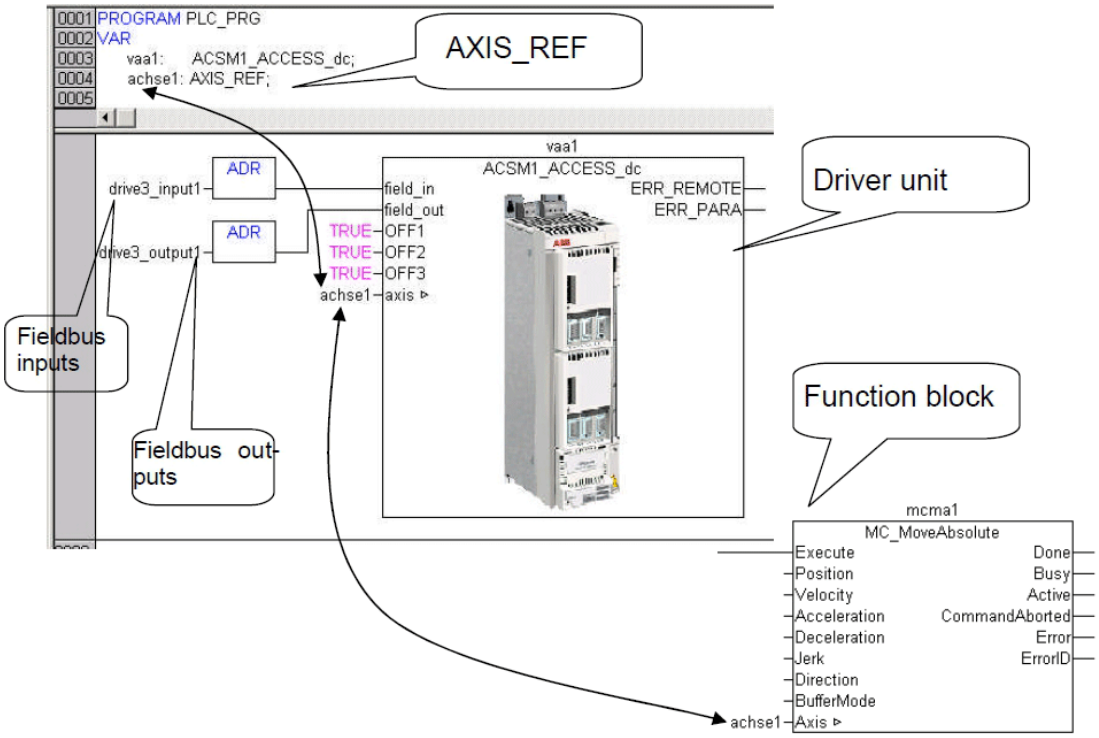

Fig. 280: Usage of function blocks

ACSM1_ACCESS_dc driver unit in decentralized motion control

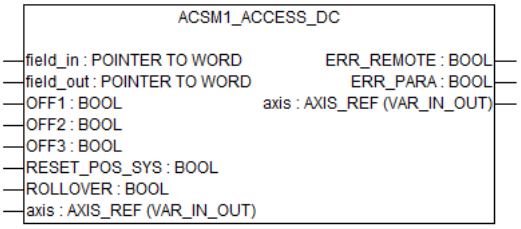

Fig. 281: Function block ACSM1_ACCESS_dc

To make this function block work, the following additional information should be considered:

↳ *Chapter 1.5.9.5.3.5 “Adjustment of parameters for drive” on page 2739*

↳ *Chapter 1.5.9.5.3.6 “MC_VISU_ACS350_mcw, MC_VISU_ACS350_msw” on page 2740*

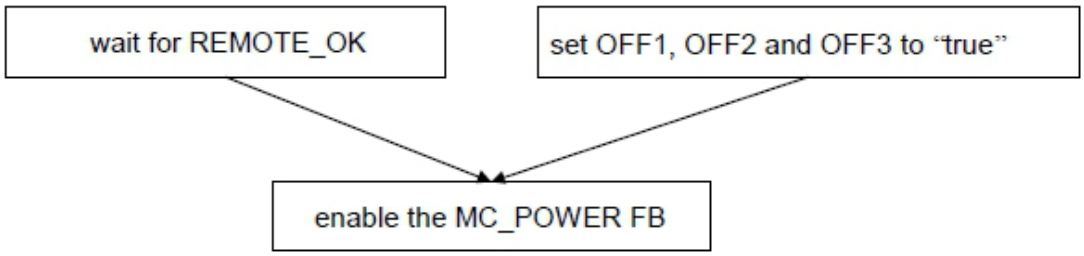
This function block is used as driver unit for PLCopen function blocks with ACSM1 in decentralized Motion Control.

During normal operation, the drive will be completely controlled by the fieldbus interface. For safety reasons, this could be combined with additional measures through binary inputs on the drive. So the drive would be in defined state when the fieldbus is not yet initialized or in case of communication problems. For coordination, the inputs OFF1, OFF2 and OFF3 are available at the driver unit function block ACSM1_ACCESS_dc. Adjust parameters in Group 10 of the drive when this additional control should be used. Then connect the binary values OFF1, OFF2 and OFF3 to the respective inputs.

When the fieldbus interface is ok (shown by REMOTE_OK) OFF1, OFF2 and OFF3 should be switched to TRUE before the MC_Power function block is enabled. When an emergency stop should be executed, the sequence depends on the required Stopping mode. (Details can be found in the drive manual.)

The priority of the signals is as follows: OFF2 > OFF3 > OFF1

CAUTION!
When switching off the drive ACSM1 via the MC_Power and ACSM1_ACCSESS_dc blocks, the drive is completely switched off. This results in limited use of the “brake holding function” of the drive, as for example the drive parameter 35.04 BRAKE CLOSE DELAY is no longer effective. This can result in increased wear of the holding brake depending on the application, in particular with suspended loads.



1. Use this sequence to power on the drive.
2. Use the following sequence to power on the drive:

   Set OFF1 or OFF2 or OFF3 or a combination to FALSE, depending on required stop mode. This will already reset the internal power-on state machine to the respective state and change the signals in the fieldbus CW (control word). In addition, disable the MC_Power function block. A sequence for these two actions is not required, but the MC_Power will show an error message when it is not disabled while the drive is already stopped.

If the Enable input at MC_Power is set to FALSE, bit 3 (ENABLE) in the control word is set to zero.

- *If the input OFF1 at the block ACSM1_ACCSESS_dc is set to FALSE: Bit 3 (ENABLE) and Bit 0 (OFF1) in the control word are set to zero.*
- *If the input OFF2 at the block ACSM1_ACCSESS_dc is set to FALSE: Bit 3 (ENABLE) Bit 0 (OFF1) and Bit 1 (OFF2) in the control word are set to zero.*
- *If the input OFF3 at the block ACSM1_ACCSESS_dc is set to FALSE: Bit 3 (ENABLE), Bit 0 (OFF1), Bit 1 (OFF2) and Bit 2 (OFF3) in the control word are set to zero.*

Input description

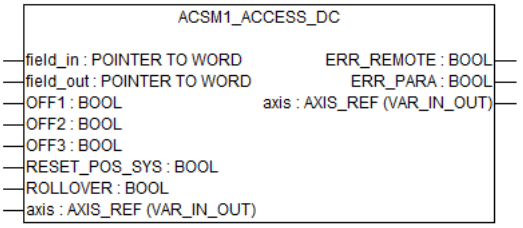


Fig. 282: Function block ACSM1_ACCESS_dc

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

field_in Data type: POINTER TO WORD

At this input, the address of the input data from drive to PLC should be connected.

field_out Data type: POINTER TO WORD

At this input, the address of the output data from PLC to drive should be connected.

OFF1 Data type: BOOL

Stop along the currently active deceleration ramp.

OFF2 Data type: BOOL

Power off the motor.

RESET_POS_SYS Data type: BOOL

Matches Bit3 in parameter POS_STYLE1 (62.09), refer to ACSM1 documentation. Just use it combined with absolute positioning.

ROLLOVER Data type: BOOL

Matches Bit5 in parameter POS_STYLE1 (62.09), refer to ACSM1 documentation. Just use it combined with absolute positioning.

> *In case of a linear positioning axis, use input-parameter Direction=SHORTEST for absolute positioning.*

Axis Data type: AXIS_REF

This data structure is needed to connect this driver unit to the PLCopen function blocks.

Output description

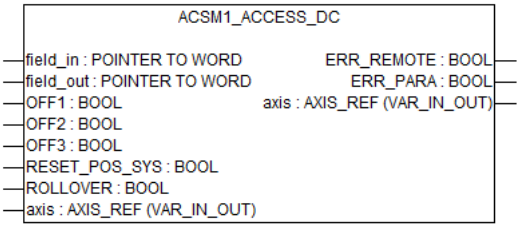

Fig. 283: Function block ACSM1_ACCESS_dc

ERR_REMOTE Data type: BOOL

This output indicates that no fieldbus connection to the drive is available. When this is shown, the PLC is not able to control the drive via fieldbus. This has to be considered in the PLC application to switch off the drive by other measures.

ERR_PARA Data type: BOOL

This output indicates that a parameter access was not successful. The reason could be a wrong parameter number at function block or the drive configuration.

Adjustment of parameters for drive

The drive has to be adjusted to use the PROFIDRIVE profile. To do this and to establish the PROFIBUS connection to the PLC follow the according documentation. In addition, some parameters have to be adjusted. These are listed in the following tables. For further commissioning, follow the chapter “Start-Up” in the drives manual (Link setzen auf?).

Parameter	Name	Value	Mnemonic	Comment
START/STOP				
10.1	EXT1 START FUNC	3	FBA	FBA, 2.12 FBA MAIN CW.
10.4	EXT2 START FUNC	3	FBA	FBA, 2.12 FBA MAIN CW.

REFERENCE CTRL				
34.01	Ext1/Ext2 Sel	0	False	Select External 1.
34.02	Ext1 Mode 1 or 2 Sel	0	False	Model

PROFILE REFERENCE				
65.01	PROF REF SOURCE	2	Fieldbus	Means Fieldbus for 65.02.. 65.05, the others are configured.
65.22	PROF VEL REF SEL	4	FBA REF2	Take fieldbus reference for velocity in PROF VEL MODE.

PROFILE GENERATOR				
66.05	POS ENABLE	0	False	Logical OR or with CW.

POS REF LIMIT				
77.03	POS REF ENA	0	False	Logical OR with reject traversing task bit.
77.06	POS DECEL LIM			Value for deceleration on reject trav-ersing task.

FIELDBUS				
51.01	FBA TYPE	1	Enable	
50.02	COMM LOSS FUNC	1	Fault	Trips the drive.
50.03	COMM LOSS TIMEOUT	X		Any timeout.
50.04	FBA REF1 MODESEL	3	Position	Ref1 and Act1 as Position.
50.05	FBA REF2 MODESEL	4	Velocity	Ref2 and Act2 as Velocity.
50.06, 50.07		x		anyway?
50.8,50.9,50.10 ,50.11				to be defined

FBA Settings				
51.01	FBA TYPE	1		=PROFIBUS DP Displays the type of the fieldbus adapter module.
51.02	NODE ADDRESS			According to PLC configuration.
51.03	BAUDRATE			According to PLC configuration.
51.04	TELEGRAM TYPE	5		(= PPO5) Displays telegram type selected by PLC configuration tool.
51.05	PROFILE	4		(= PROFIdrive Positioning)Con-trol word according to the PRO-FIdrive Positioning mode.
51.27	FPBA PARAM-ETER REFRESH	1		Refreshes the fieldbus parame-ters. Will be set to 0 (done) by drive.

FBA Data In				
52.01	FBA DATA IN1	4		Status word.
52.02	FBA DATA IN2	15		Actual value 1 Position(HW).
				(LW)
52.04	FBA DATA IN4	16		Actual value 2 Velocity(HW)
				(LW)
52.06	FBA DATA IN6	413		POS REF PROF GEN
52.08	FBA DATA IN8	801		ACTIVE FAULT
52.09				

FBA Data Out				
53.01	FBA DATA OUT2	1		Control word.
53.02	FBA DATA OUT2	12		Reference 1 Position (HW).
				(LW)
53.04	FBA DATA OUT4	13		Reference 2 Velocity (HW)
				(LW)
53.06	FBA DATA OUT6	65.06		Acceleration (HW)
53.07	FBA DATA OUT7			Acceleration (LW)
53.08	FBA DATA OUT8	65.07		Deceleration (HW)
53.09	FBA DATA OUT9			Deceleration (LW)
53.10	FBA DATA OUT10	65.09		POS STYLE

POS CORRECTION				
62.02	HOMING STARTFUNC	0	Normal	

Start and stop the drive

The following table shows the additional control bits which could be linked to OFF1 and OFF3 at the function block ACSM1_ACCESS_dc. These additional control bits could be set to "TRUE" to have full control through Fieldbus interface or could be mapped to binary inputs.

Parameter	Name	Value	Mnemonic	Function
START/STOP				
10.10	EM STOP OFF3	1	True Bit pointer	Default, controlled by Fieldbus. The drive is stopped along the emergency stop ramp time, 25.11 EM STOP TIME.
10.11	EM STOP OFF1	1	True Bit pointer	Default, controlled by Fieldbus. Stop along the currently active deceleration ramp.

For example: The drive will execute an OR-Connection from 10.10 and the OFF3-Bit at the ACSM1_ACCESS_dc Block to stop along the emergency ramp. With 10.10 = Bit pointer, the drive might be forced to stop along an emergency ramp without using the PLC to initialize this. This measure allows managing emergency situations without the PLC.

Units for position, velocity, acceleration and deceleration

The PLCopen definition uses as unit for position an abstract unit u, for velocity u/s (u per second) and for acceleration u/s^2 (u per squared second). So it does not matter which unit is selected, but they need to be in certain relations. To get more information, Technical Units (Link setzen). The ACSM1 supports this strategy. Adjustments have to be made in group 60. As a constraint, it has to be considered that although the values are in LREAL-Format at the function block, they will be transferred as 32-Bit Integer so the 32-Bit Integer defines the limits.

Table 179: Parameters for unit adjustment

Parameter	Name	Value	Mnemonic	Comment
POS FEEDBACK				
60.01	POS ACT SEL	0, 1		Depends on the drive configuration.
60.02	POS AXIS MODE	0, 1		Depends on the drive configuration.
60.03	LOAD GEAR MUL			*Chapter 1.5.9.5.2.7 “Gear functions” on page 2732*
60.04	LOAD GEAR DIV			*Chapter 1.5.9.5.2.7 “Gear functions” on page 2732*
60.05	POS UNIT	0, 1, 2, 3	REVOLUTION, DEGREE, METER, INCH	Determines the abstract unit **u**.
60.06	FEED CONST NUM			Scaling for speed.
60.07	FEED CONST DEN			
60.08	POS2INT SCALE		Power of ten	Scaling for position (u/s)
60.09	POS RESOLUTION			Determines the number of bits used for one revolution. Should be at least 16. The Bits remaining of the 32-bit integer is used for the count of whole revolutions.
60.10	POS SPEED UNIT	0	u/s	Speed in units per second or minute or hour.
60.11	POS SPEED2INT		Power of ten	Scaling for speed (rev/s)
60.12	POS SPEED SCALE	1		Scaling for speed, acceleration and deceleration.
60.13	MAXIMUM POS			Depends on the drive configuration.
60.14	MINIMUM POS			Depends on the drive configuration.
60.15	POS THRESHOLD			Depends on the drive configuration.

Some examples:

- The encoder has 1024 Bits per evolution, that are 10 bits (not relevant for PLCopen),
- The load moves 40 mm per revolution,
- The abstract unit **u** should be mm.

The following table shows the adjustment which are relevant for this configuration:

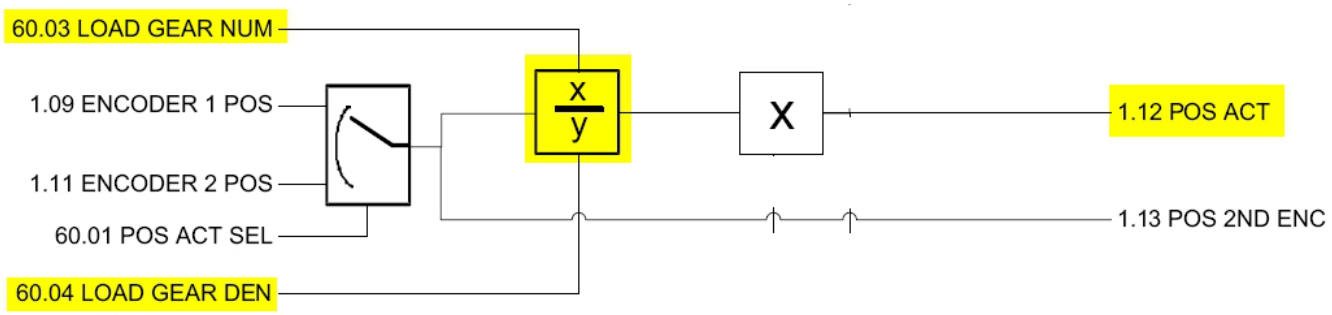
Table 180: Example for unit adjustment

Parameter	Name	Value	Mnemonic	Comment
60.05	POS UNIT	2	METER	Determines the abstract unit **u**.
60.06	FEED CONST NUM	40		Scaling for speed.
60.07	FEED CONST DEN	1000		
60.08	POS2INT SCALE	1000	1000	(Power of Ten). Scaling for position.
60.09	POS RESO-LUTION	16	18	Determines the number of Bits used per revolution. (Should be at least 16). Bits used for number of whole revolutions is (32 -18 =14) No influence on PLCopen.
60.10	POS SPEED UNIT	0	u/s	Units per Seconde (per minute, per hour).
60.11	POS SPEED2INT	1000	1000	(Power of Ten) Scaling for speed.

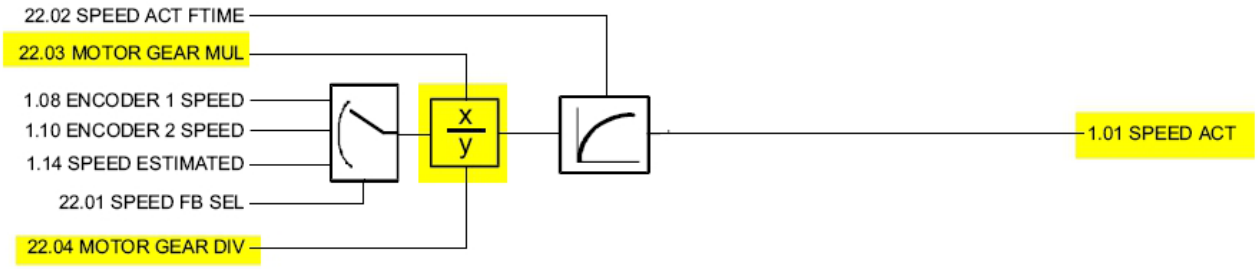
Gear functions

In use with a load gear and encoder signals directly from the motor some adjustment of drive parameters have to be done. The actual position POS ACT (Par 1.12) is calculated as shown, depending on the load gear parameters 60.03 and 60.04.

Example of gear 1:7 , 7 rev on motor side leads to 1 rev. on load side: Par.60.03 = 1, Par. 60.04 = 7.



In use with a load gear and encoder signals from the load side the actual speed is calculated as the load speed. This should be compensated with the motor gear function, Par. 22.03 and 22.04 for the speed control.



Example of gear 1:7 , 7 rev on motor side leads to 1 rev. on load side: Par.22.03 = 1, Par. 22.04 = 7.

As POS ACT, Par 1.12 (set in Par 71.01) is used as position input for speed reference the gear ratio function has to be used to adapt the position for internal speed reference. Par 71.07 = 60.04 x 22.03 and Par. 71.08 = 60.03. x 22.04.

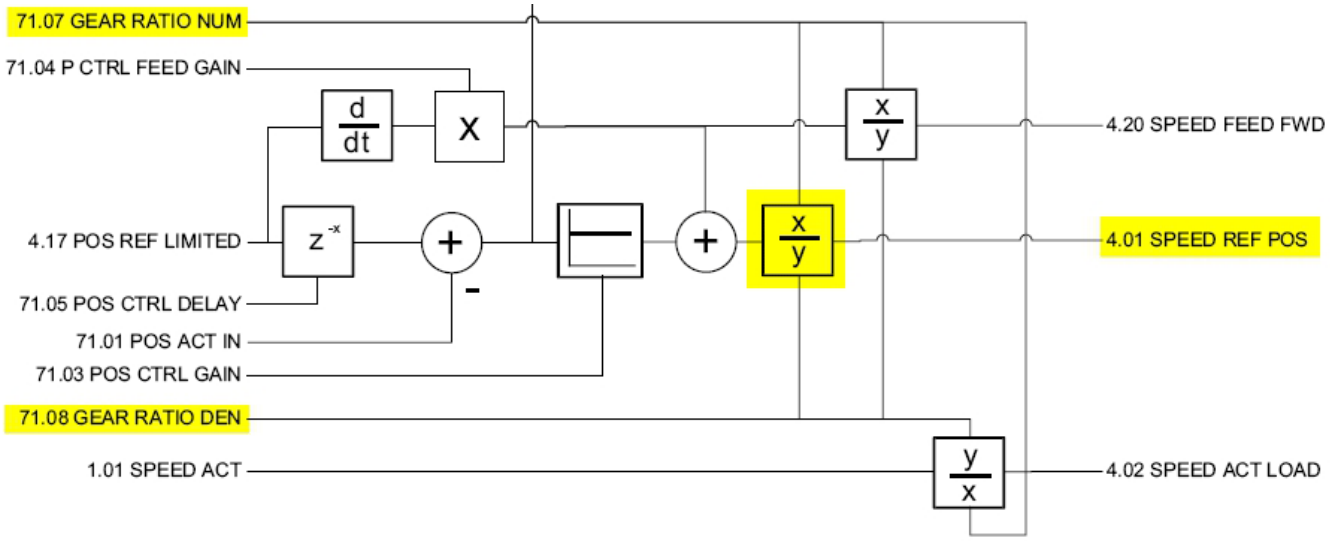


Table 181: Parameters for gear functions

Parameter	Name	Value	Mnemonic	Comment
SPEED FEEDBACK				
22.03	MOTOR GEAR MUL			Numerator for load gear if load encoder is used for speed feedback.
22.04	MOTOR GEAR DIV			Denominator for load gear function if load encoder is used for speed feedback.
POS FEEDBACK				
60.03				Numerator for load gear function if mo-tor encoder is used for pos. feedback.
60.04				Denominator for load gear function if motor encoder is used for pos. feedback.
POSITION CTRL				
71.07	GEAR RATIO MUL	=60.04 x 22.03		Gear ration function to compensate gear calculation for speed and/or position 71.07 =! (60.04 * 22.03).
71.08	GEAR RATIO DIV	=60.03 x 22.04		Scaling ratio for load gear 71.08 =! (60.03*22.04)

Some examples:

- The load gear has 1:7 (7rev of motor =1 rev. of load),
- Encoder on motor side is used for position and speed control.

Just the adjustments which are relevant for this configuration are shown below:

Table 182: Example for gear functions

Param-eter	Name	Value	Mnemonic	Comment
22.03	MOTOR GEAR MUL	1		Motor gear function if encoder on load side is used.
22.04	MOTOR GEAR NOM	1		
60.03	LOAD GEAR NOM	1		Scaling for mech. gear for position 1:7 (7 rev. motor=1 rev. load).
60.04	LOAD GEAR DIV	7		
71.07	GEAR RATIO MUL	7		Scaling for mech. Gear 1:7 (7 rev. motor=1 rev. load).
71.08	GEAR RATIO DIV	1		

MC_VISU_ACSM1_msw, MC_VISU_ACSM1_mcw

These objects show the main status word and main control word of the drive as it is defined for Profidrive Profile.

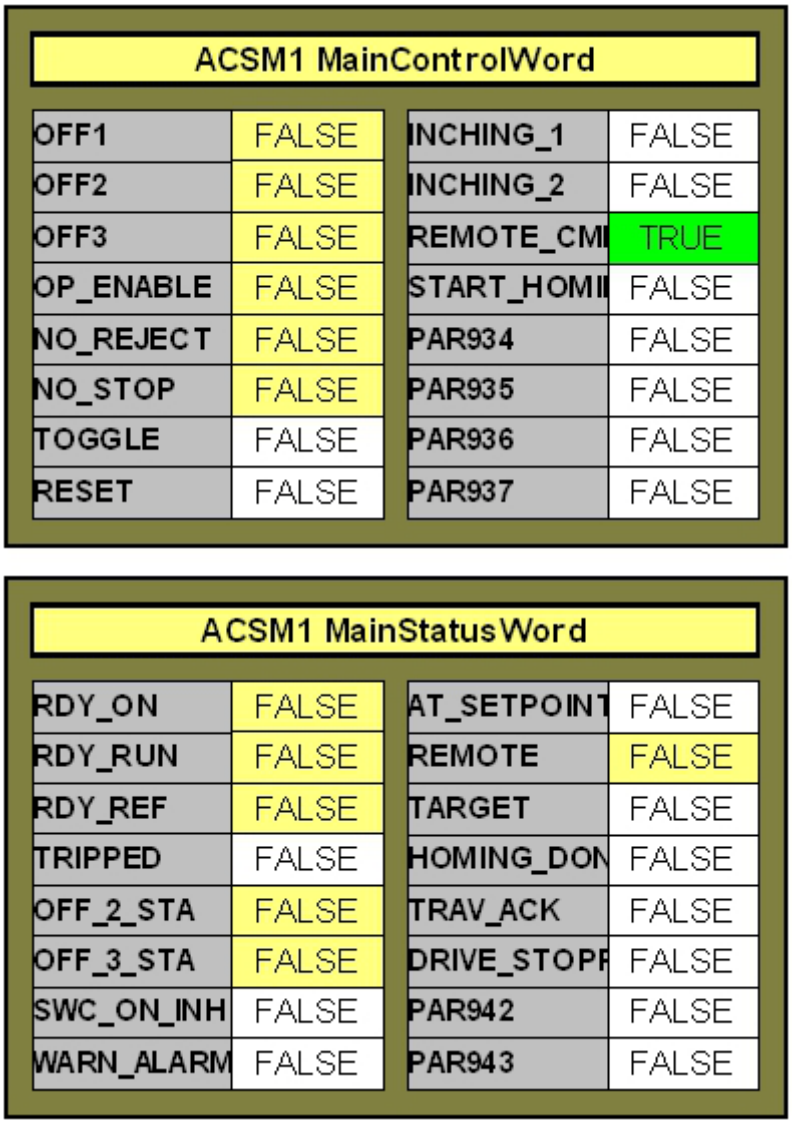

Fig. 284: MC_VISU_ACSM1_mcw, MC_VISU_ACSM1_msw

The colour coding is as follows:

- When the state differs from the expected state (for an active drive) it is shown yellow.
- When the state is equivalent to the expected state (for an active drive) it is shown green.
- An error is shown red.

1.5.9.5.3 Realization with ACS35x on PROFIBUS-DP network

General restrictions

Restrictions for the available function blocks

- As buffered mode, MC_Aborting is realized as a default.
- From the Extended Inputs and Outputs at the function blocks, the following are not realized:
- BufferMode: The realization for ACS35x just supports by default the MC_Aborting mode.
- For all supported PLCopen function blocks the input parameter Jerk will not be used.

- Active
- For the parameter number (WriteParameter, ReadParameter), the following options are available:
  – The PLCopen parameter number
  – The ACS35x parameter number: + 40000
    This manipulation of the parameter number is necessary to distinguish between the different types of parameter number.

Preconditions

The usage of function blocks is like the usage for ACSM1 ↳ *Chapter 1.5.9.5.2.2 “Preconditions” on page 2725*. The corresponding function block ACS350_ACCESS_DC is used to connect AXIS to the drive.

ACS350_ACCESS_dc

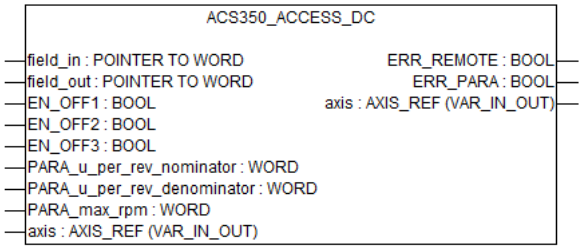

Fig. 285: Function block ACS350_ACCESS_dc

Table 183: General information

Available as of runtime system	V1.2
Included in library	ACS350_MC_support_AC500_V11.lib
Type	Function block without historical values

To make this function block work, the following additional information should be considered:

↳ *Chapter 1.5.9.5.3.5 “Adjustment of parameters for drive” on page 2739*

↳ *Chapter 1.5.9.5.3.6 “MC_VISU_ACS350_mcw, MC_VISU_ACS350_msw” on page 2740*

The function block ACS350_ACCESS_dc is used as driver unit for PLCopen function blocks with ACS35x in decentralized motion control.

During normal operation, the drive will be completely controlled by the fieldbus interface. For safety reasons, this could be combined with additional measures through binary inputs on the drive. So the drive would be in defined state when the fieldbus is not yet initialized or in case of communication problems. For coordination, the inputs EN_OFF1, EN_OFF2 and EN_OFF3 are available at the driver unit function block ACS350_ACCESS_dc. When the fieldbus interface is ok (shown by ERR_REMOTE=FALSE) EN_OFF1, EN_OFF2 and EN_OFF3 should be switched to "true" before the MC_Power function block is enabled. When an emergency stop should be executed, the sequence depends on the required Stopping mode. (Details could be found in the drive manual.) The priority of the signals is as follows:

EN_OFF2 >EN_OFF3> EN_OFF1

Do the following to power off:

Set EN_OFF1 or EN_OFF2 or EN_OFF3 or a combination to "false", depending on required stop mode. This will already reset the internal power-on state machine to the respective state and change the signals in the fieldbus CW. In addition, disable the MC_POWER function block. A sequence for these 2 actions is not required, but the MC_POWER will show an error message when it is not disabled while the drive is already stopped.

Input description

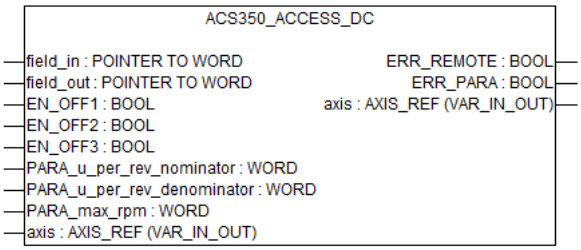

Fig. 286: Function block ACS350_ACCESS_dc

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

field_in Data type: POINTER TO WORD

At this input, the address of the input data from drive to PLC should be connected.

field_out Data type: POINTER TO WORD

At this input, the address of the output data from PLC to drive should be connected.

EN_OFF1 Data type: BOOL

Stop along the currently active deceleration ramp.

EN_OFF2 Data type: BOOL

Power off the motor.

EN_OFF3 Data type: BOOL

The drive is stopped along the emergency stop ramp time.

PARA_u_per_rev_nominator Data type: WORD

Units per revolution.

PARA_u_per_rev_denominator Data type: WORD

Units per revolution.

PARA_max_rpm Data type:WORD

Maximum value for rotations per minute.

Axis Data type: AXIS_REF

This data structure is needed to connect this driver unit to the PLCopen function blocks.

Output description

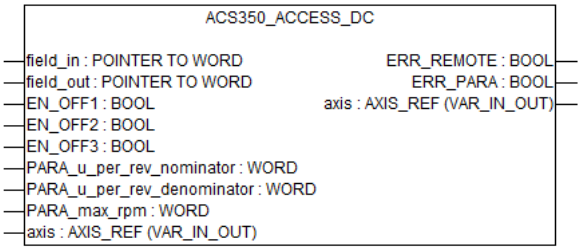

Fig. 287: Function block ACS350_ACCESS_dc

ERR_REMOTE Data type: BOOL

This output indicates that no fieldbus connection to the drive is available. When this is shown, the PLC is not able to control the drive via fieldbus. This has to be considered in the PLC application to switch off the drive by other measures.

ERR_PARA Data type: BOOL

This output indicates that a parameter access was not successful. The reason could be a wrong parameter number at function block or the drive configuration.

Units for position, velocity, acceleration and deceleration

The PLCopen definition uses as unit for position an abstract unit [u], for velocity [u/s](u per second) and for acceleration [u/s^2](u per squared second). So it does not matter which unit is selected, but they need to be in certain relations. The ACS35x follows a different this strategy. To establish the conversion of different units, the parameters:

- PARA_MAX_RPM
- PARA_U_PER_REV_NOMINATOROR
- PARA_U_PER_REV_DENOMINATOR
  Have to be adjusted at the function block ACS350_ACCESS_DC.

Some example:
- The motor moves at maximum with 1500 rpm.
- It is planned to use revolutions as unit, so the velocity will be in revolutions/second and the acceleration and deceleration will be in revolutions/s^2
  - PARA_MAX_RPM=1500
  - PARA_U_PER_REV_NOMINATOR=1
  - PARA_U_PER_REV_DENOMINATOR=1
- It is planned to use degrees as unit, so the velocity will be in degrees/second and the acceleration and deceleration will be in degrees/s^2
  - PARA_MAX_RPM=1500
  - PARA_U_PER_REV_NOMINATOR=360
  - PARA_U_PER_REV_DENOMINATOR=1

Adjustment of parameters for drive

The drive has to be adjusted to use the ABBdrive profile. To do this, and to establish the PROFIBUS connection to the PLC you have to follow the according documentation. In addition, some parameters have to be adjusted. These are listed in the following tables. For further commissioning, follow the chapter "Start-Up" in the drives manual.

Table 184: Parameter adjustment for ACS35x

MC_VISU_ACS350_mcw, MC_VISU_ACS350_msw

These objects show the main status word and main control word of the drive as it is defined for Profidrive Profile.

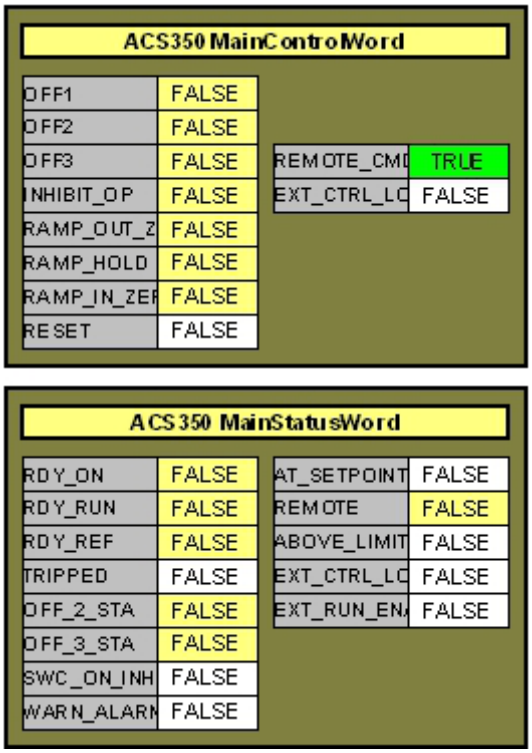

Fig. 288: MC_VISU_ACS350_mcw, MC_VISU_ACS350_msw

The colour coding is as follows:

- When the state differs from the expected state (for an active drive) it is shown yellow.
- When the state is equivalent to the expected state (for an active drive) it is shown green.
- An error is shown red.

1.5.9.5.4 Realization with FM562

Special function blocks are available to manage and control the function of the FM562 module. These function blocks are contained in PTO Library PTO_FM562_MC_support_V22.lib and PLCopen Libraries MC_Base_AC500_V11.lib and MC_Blocks_AC500_V11.lib.

PLCopen Library contains modular function blocks based on PLCopen motion control standard and can be used for various motion devices e.g: ACSM1, ACS35x, ACS800, E100, E150 and FM562.

PTO Library provides function blocks that adapts specific PLCopen function blocks to FM562 PTO module and also adds other specialized function for FM562.

General restrictions

Restrictions for the available function blocks

- Buffered mode is not implemented
- The Jerk is defined as a fixed value. When it is to be used, set “0” as “Jerk off” and “1” as Jerk on.
- State cannot be changed between Discrete Motion and Continuous Motion directly, state error will be generated.
- By executing function block MC_Reset, the state will transfer from ErrorStop to StandStill as well as resetting the current axis position to 0.

PTO_FM562_ACCESS adapts specific PLCopen blocks to FM562

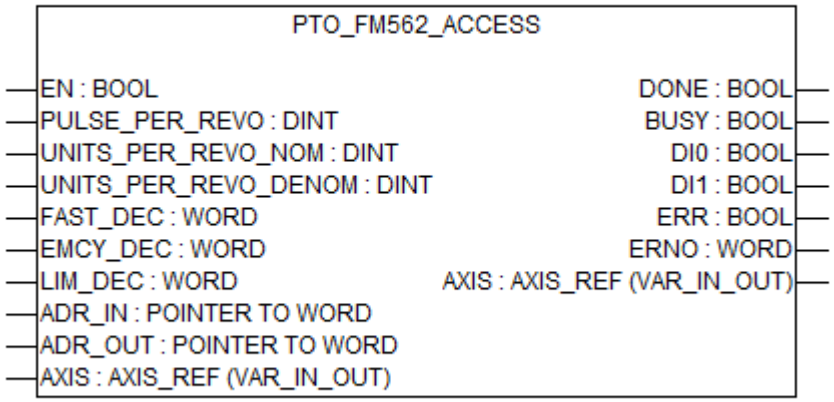

Table 185: General information

Available as of runtime system	V2.2
Included in library	PTO_FM562_MC_support_V22.lib
Type	Function block without historical values

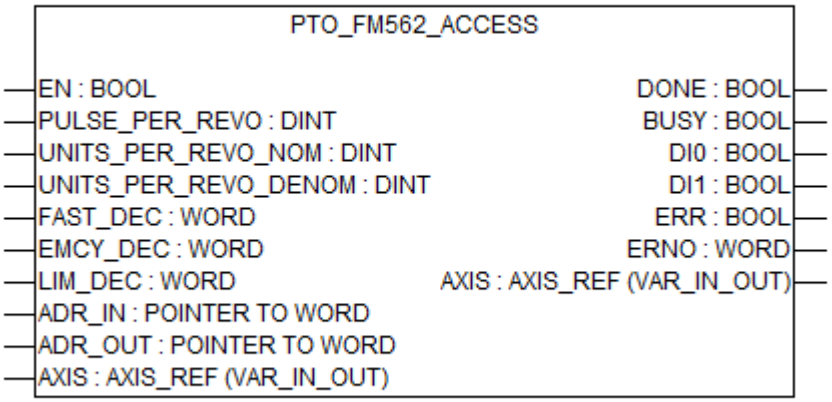
Description

The function block PTO_FM562_ACCESS is used to adapt specific PLCopen blocks to FM562 module and also adds other specialized function for FM562.

PLCopen function blocks must be used with function block PTO_FM562_ACCESS for realizing positioning and speed control with FM562. PTO_FM562_ACCESS supported PLCopen function blocks are:

- MC_MoveAbsolute *Chapter 1.5.9.6.1.1 “MC_MoveAbsolute” on page 2747*
- MC_MoveRelative *Chapter 1.5.9.6.1.2 “MC_MoveRelative” on page 2751*
- MC_MoveVelocity *Chapter 1.5.9.6.1.6 “MC_MoveVelocity” on page 2767*
- MC_Power *Chapter 1.5.9.6.3.2 “MC_Power” on page 2835*
- MC_Reset *Chapter 1.5.9.6.3.5 “MC_Reset” on page 2842*
- MC_Stop *Chapter 1.5.9.6.1.9 “MC_Stop” on page 2781*
- MC_SetPosition *Chapter 1.5.9.6.3.13 “MC_SetPosition” on page 2858*
- MC_ReadStatus *Chapter 1.5.9.6.3.3 “MC_ReadStatus” on page 2837*
- MC_ReadActualPosition *Chapter 1.5.9.6.3.10 “MC_ReadActualPosition” on page 2852*
- MCA_MoveVelocityContinuous *Chapter 1.5.9.6.5.4 “MCA_MoveVelocityContinuous” on page 2882*

Input description



EN (enable)

Data type: BOOL

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input is set to TRUE, the inputs are continuously checked for validity and plausibility.

PULSE_PER_REVO (pulse per revolution), UNITS_PER_REVO_NOM DINT (units per revolution nominator), UNITS_PER_REVO_DENOM DINT (units per revolution denominator)

Data type: DINT, range: 0001 to FFFF hex (1 to 2147483647)

These three parameters shall be used together for scaling, which are only be changed when PLCopen state machine is in “Disable” or when MC_Power is OFF.

Pulses per revolution depend on specific stepper drive/motor, how many pulses need to be created to turn 1 revolution.

When 1 revolution move e.g 40 mm, 1 mm is used as unit: UNITS_PER_REV_NOM=40 and UNITS_PER_REV_DENOM=1

When using additional gearbox 1:3: UNITS_PER_REV_NOM=40 and UNITS_PER_REV_DENOM=3

When using angle as unit: U_PER_REV_NOMINATOR=360, UNITS_PER_REV_DENOM=1

When working with revolutions 1 u = 1: UNITS_PER_REV_NOM=1, UNITS_PER_REV_DENOM= 1

FAST_DEC (fast deceleration)

Data type: WORD, range: 0001 to FFFF hex (1 to 65,535 u/s^2)

Fast deceleration for stopping CPU, set before the operation starts. The fast deceleration ramp is "FAST_DEC" multiples "increments per unit" (scaling).

EMCY_DEC (emergency deceleration)

Data type: WORD, range: 0001 to FFFF hex (1 to 65,535 u/s^2)

Emergency deceleration: for configurable digital input 1 "DI1" is configured as "Stop". When "emergency stop" DI1 is triggered (DI1=TRUE), PTO will decelerate with "EMCY_DEC" deceleration. The emergency deceleration ramp is "EMCY_DEC" multiples "increments per unit" (scaling).

LIM_DEC (limit deceleration)

Data type: WORD, range: 0001 to FFFF hex (1 to 65,535 u/s^2)

Limit deceleration: for configurable digital input 0 "DI0" is configured as "Enable (external hardware enable)". During operation digital input DI0=TRUE which shows external 24 V digital input. When "right/left limit stop" is triggered which means the external 24 V digital input is disabled (DI0=FALSE), PTO will decelerate with "LIM_DEC" deceleration rate. The limit deceleration ramp is "LIM_DEC" multiples "increments per unit" (scaling).

ADR_IN (address of process image input)

Data type: POINTER TO WORD

Pointer to structure of FM562 inputs. At this input, the address of the first input data from the structure of FM562 input should be connected. The use of an ADR operator is needed.

ADR_OUT (address of process image output)

Data type: POINTER TO WORD

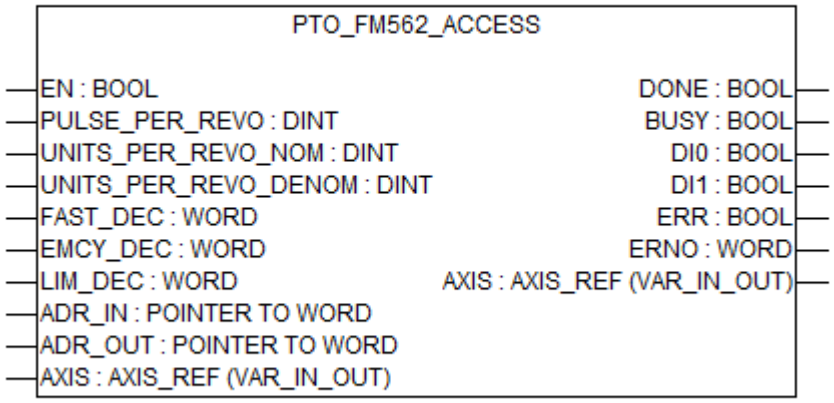
Pointer to structure of FM562 outputs. At this input, the address of the first output data from the structure of FM562 output should be connected. The use of an ADR operator is needed. The operand address of the first input and output data of each axis of FM562 must be mapped to input ADR_IN and ADR_OUT. Define and create configuration data will be emerged automatically as global variable after creating configuration data.

Axis

Data type: AXIS_REF

Reference to the axis.

Output description



DONE (done)

Data type: BOOL

The output DONE signals the completion of the process triggered with the EN input. After finishing of the process (pulse output finished or pulse output stopped), DONE is TRUE.

BUSY (busy)

Data type: BOOL

Output BUSY shows pulse output status, after pulse output start and before it finished/stopped/error occurred, the BUSY output will continuously be TRUE.

DI0 (digital input 0 or digital input 2)

Data type: BOOL

Output DI0 indicates the status of digital input0 or input2. The digital input0 or input2 can be configured by FM562 configuration in CBP. If input0 or input2 is configured as "Axis enable/ Limit switch" (external hardware enable), then DI0=TRUE or DI2=TRUE indicates that input0 or input2 is connected with 24 V input; DI0=FALSE or DI2=FALSE indicates input0 or input2 is not connected with 24 V, so PTO will stop output. If input0 or input2 is configured as "No function", PTO will be in operation without reading status of input0 or input2.

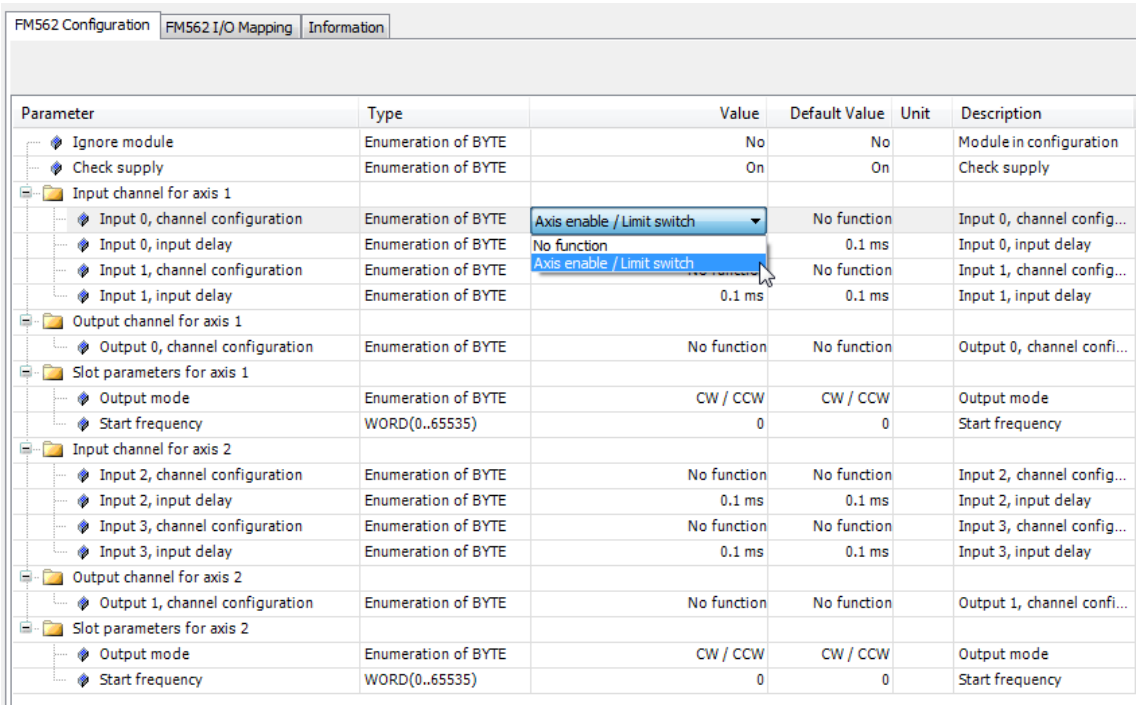


Fig. 289: Output DI0

DI1 (digital input 1 or digital input 3)

Data type: BOOL

Output DI1 indicates the status of digital input1 or digital input3. The digital input1 or input3 can be configured by FM562 configuration in CBP. If DI1 is configured as “Stop”, then if DI1=TRUE, PTO output is emergently stopped. If DI1 is configured as “No function”, PTO will be in operation without reading states of DI1. If DI1 is configured as “Registration”, current pulse number is recorded and can be checked on FM562 IO mapping when DI1=TRUE.

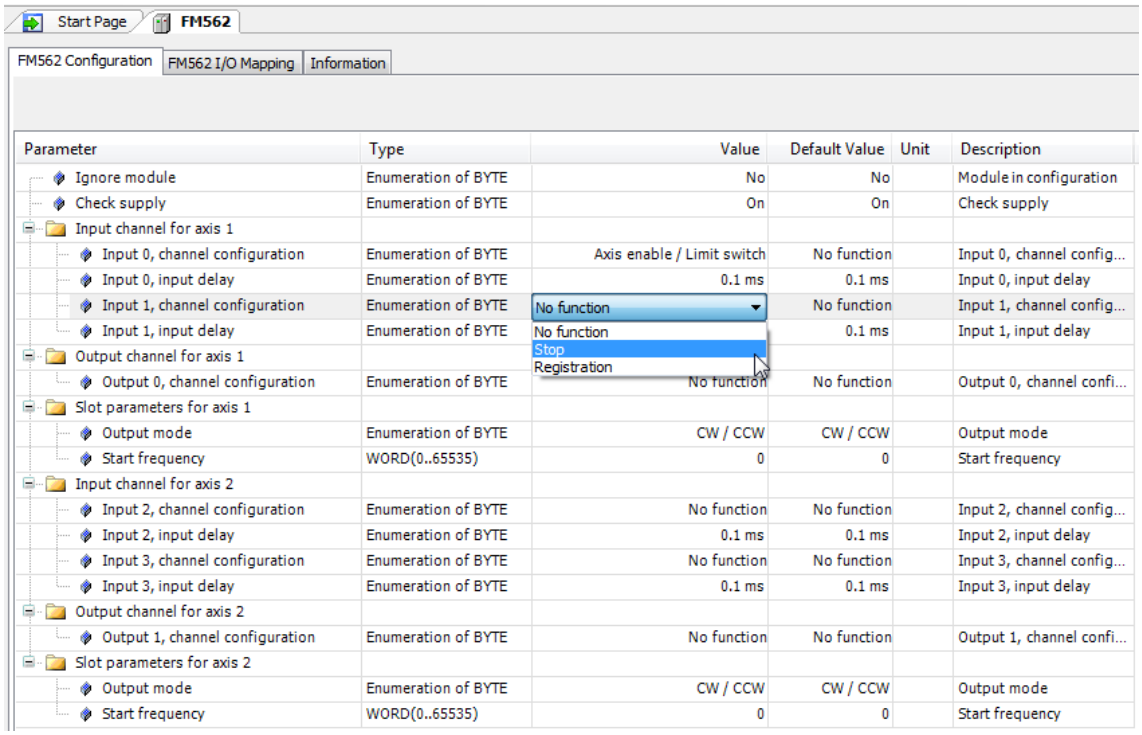

Fig. 290: Output DI1

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during data reception. If ERR is TRUE, an error occurred, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

ERNO always has to be considered together with the output ERR. The value output at ERNO is only valid if ERR is TRUE.

Quick start documentation for FM562

A quick start documentation for FM562 can be found in the folder C:\Users\Public\Documents\AutomationBuilder\Examples.

1.5.9.6 PLCopen function blocks (Single and multi axis)

1.5.9.6.1 Single-Axis function blocks

MC_MoveAbsolute

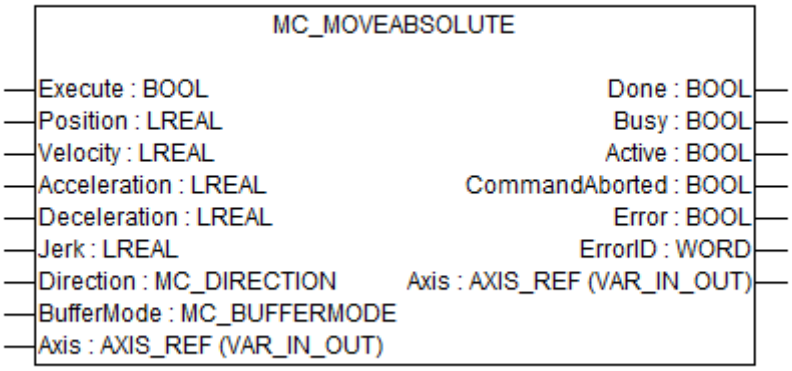

Fig. 291: Function block MC_MoveAbsolute

Table 186: General information

Available as of runtime system	V2.2
Included in library	MC_Block_AC500_V11.lib
Type	Function block with historical values

See the following chapter to check if this function block is supported by the used axis implementation: ↬ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↬ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

This function block commands a controlled motion to a specified absolute position.

- *This action completes with velocity zero if no further action are pending,*
- *If there is only one mathematical solution to reach the commanded position (like in linear systems), the value of the input direction is ignored,*
- *For modulo axis - valid absolute position values are in the range of [0, [360, (360 is excluded), or corresponding range. The application, however, may shift the commanded position of MC_MoveAbsolute into the corresponding modulo range. For relative positions, modulo 360 is applicable.*
- *The Enum type "shortest_way" is focused to a trajectory which will go through the shortest route. The decision which direction to go is based on the current position where the command is issued.*

Example

The following figure shows two examples of the combination of two function blocks MC_MoveAbsolute.

The left part of timing diagram illustrates the case if the second function block is called after the first one. If first reaches the commanded position of 6000 (and the velocity is 0) then the output Done causes the second Functino Block to move to the position 10000.

The right part of the timing diagram illustrates the case if the second move function block starts the execution while the first function block is still executing. In this case the first motion is interrupted and aborted by the test signal during the constant velocity of the first function block. The second function block moves directly to the position 10000 although the position of 6000 is not yet reached.

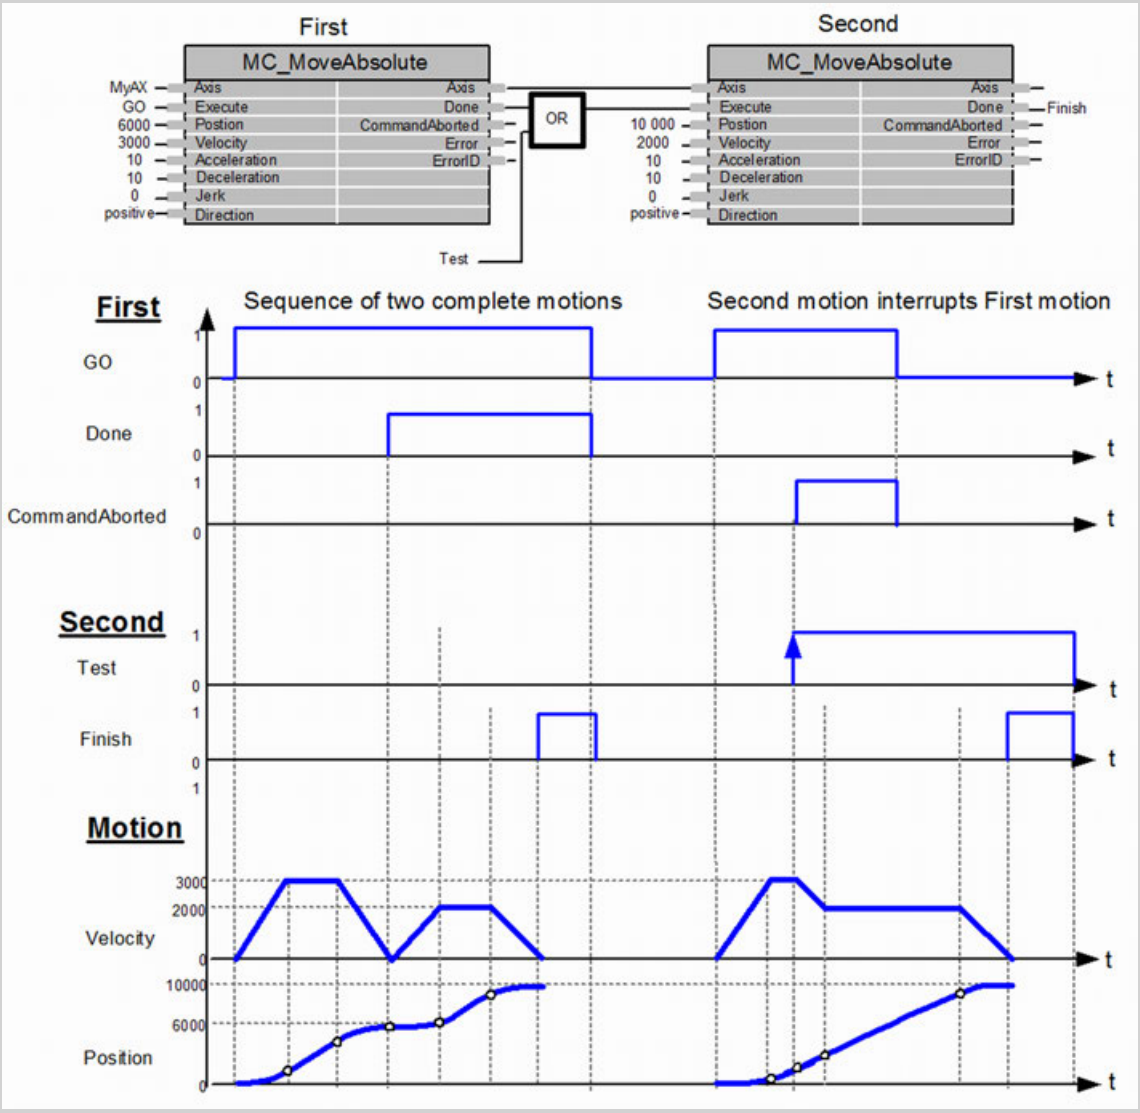

Fig. 292: These examples are based on two instances of the function block: Instance ”First“ and ”Second“.

Using this function block with FM562

Input Jerk: 1 = jerk on, 2 = jerk off

Input Direction: 0 = DEFAULT, 1 = POSITIVE, 3 = NEGATIVE

Input BufferMode: Not implemented

Input description

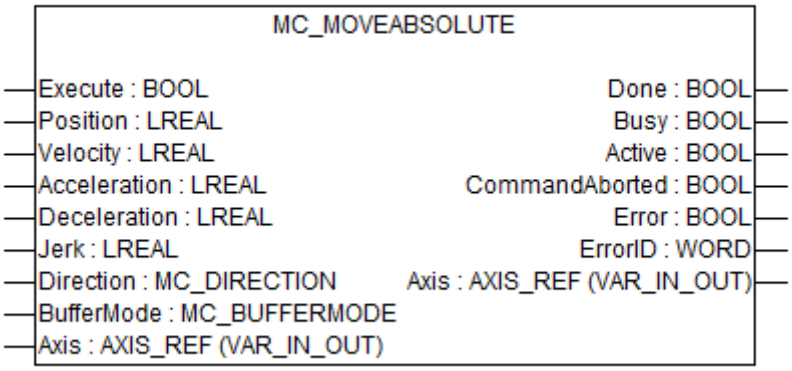

Fig. 293: Function block MC_MoveAbsolute

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

Position Data type: LREAL, unit: u
Reference position.

Velocity Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

Direction Data type: MC_Direction, range: DEFAULT, POSITIVE, SHORTEST, NEGATIVE, CURRENT
Enum type.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

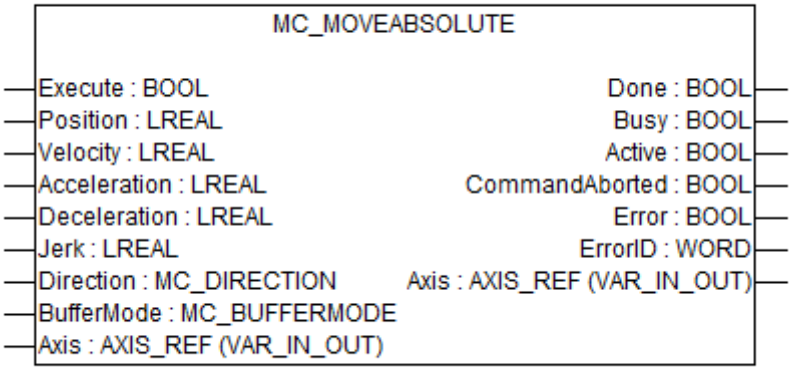

Fig. 294: Function block MC_MoveAbsolute

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveRelative

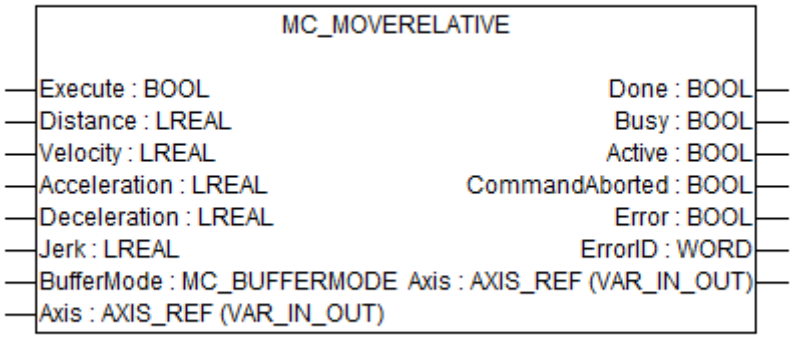

Fig. 295: Function block MC_MoveRelative

Table 187: General information

Available as of runtime system	V2.2
Included in library	MC_Block_AC500_V11.lib
Type	Function block with historical values

See the following chapter to check if this function block is supported by the used axis implementation: ↳ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↳ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

This function block commands a controlled motion of a specified distance relative to the actual position at the time of the execution.

This action completes with velocity zero if no further action are pending.

The following figure shows the example of the combination of two MC_MoveRelative function blocks:	1.) The left part of timing diagram illustrates the case if the second function block is called **after** the first one. If the first one reaches the commanded distance 6000 (and the velocity is 0) then the output Done causes the second function block to move to the distance 10000. 2.) The right part of the timing diagram illustrates the case if the second move function blocks starts the execution **while** the first function block is still executing. In this case the first motion is interrupted and aborted by the test signal during the constant velocity of the first function block. The second function block **adds on the actual position** of 3250 the distance 4000 and moves the axis to the resulting position of 7250.

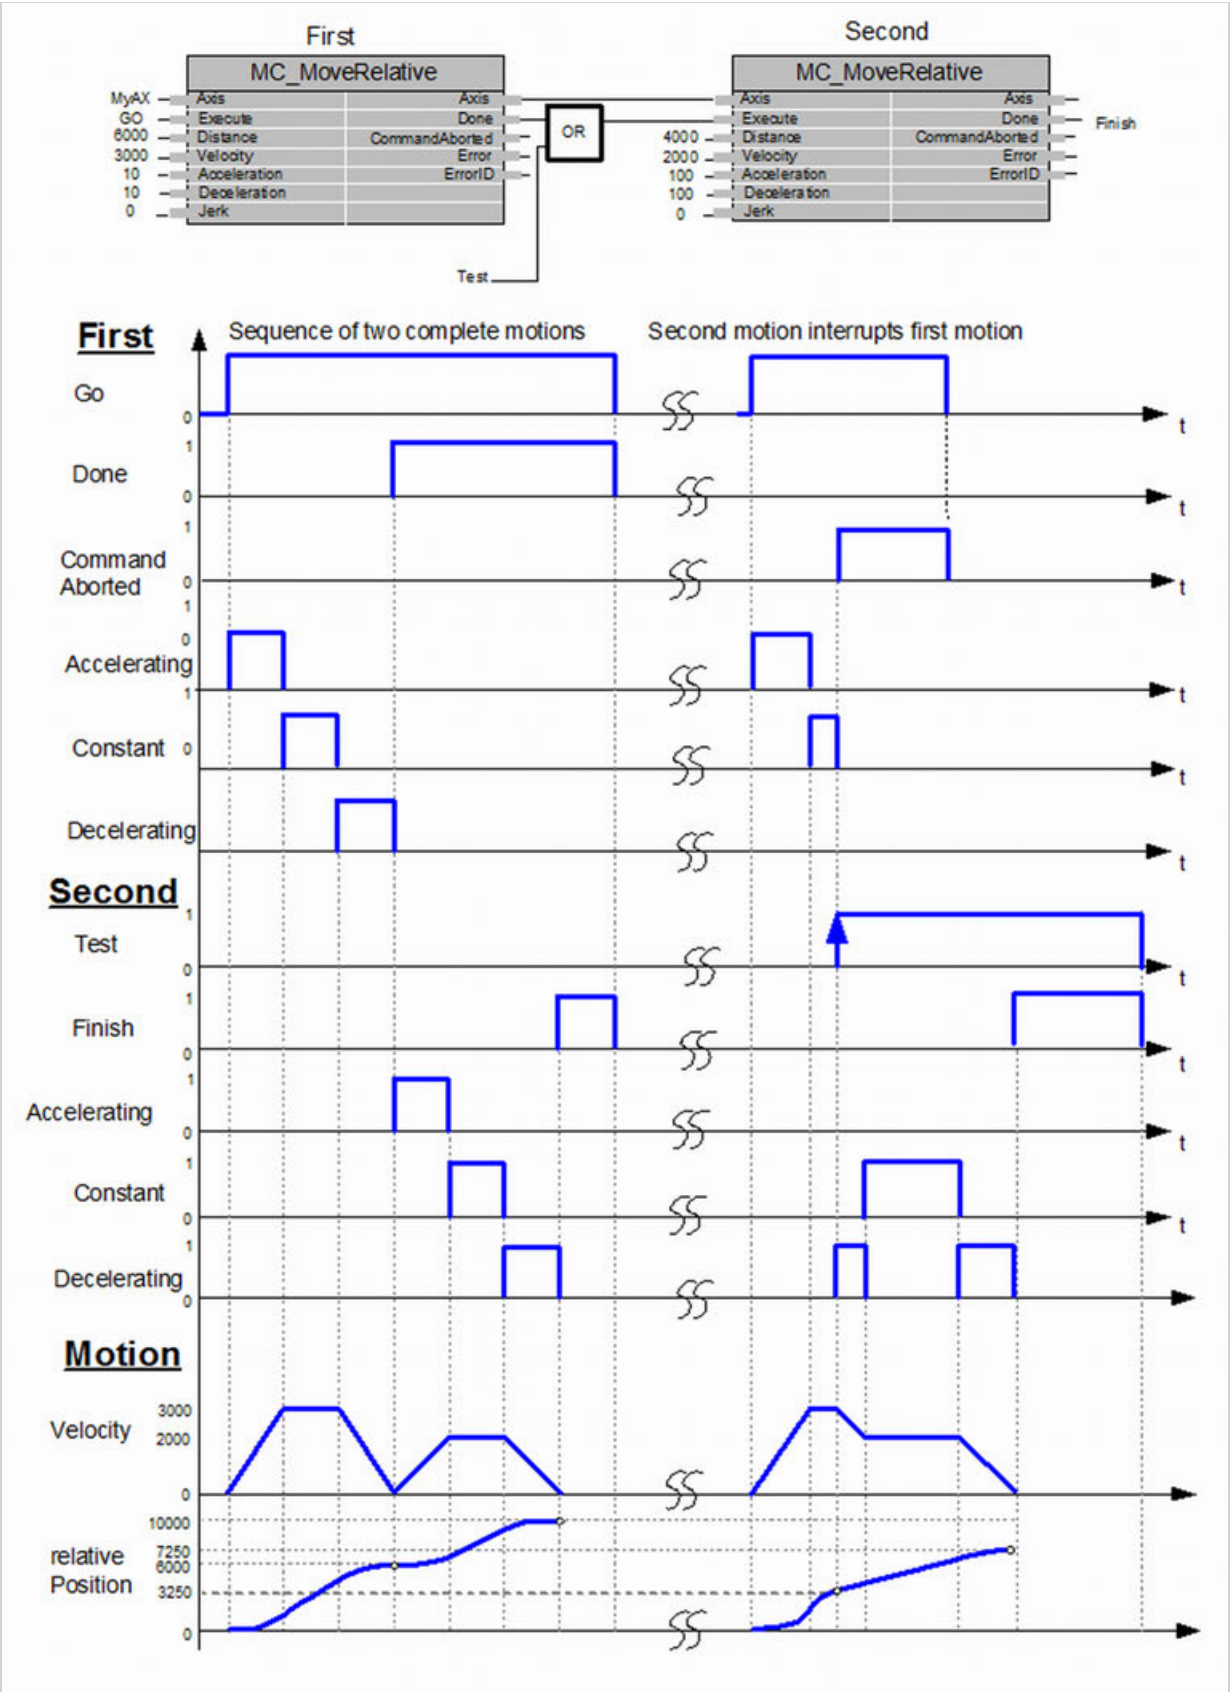

Fig. 296: Timing diagram for MC_MoveRelative

Using this function block with FM562

Input Jerk: 1 = jerk on, 2 = jerk off

Input BufferMode: Not implemented

Input description

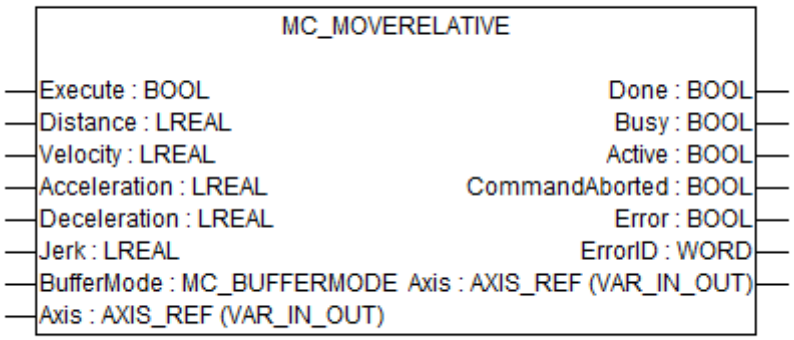

Fig. 297: Function block MC_MoveRelative

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute

Data type: BOOL

Starts the function block at rising edge.

Distance

Data type: LREAL, unit: u

Relative distance for the motion.

Velocity

Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

Acceleration

Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Deceleration

Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

Jerk

Data type: LREAL, range: > 0, unit: u/s^3

Value of the Jerk.

BufferMode

Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

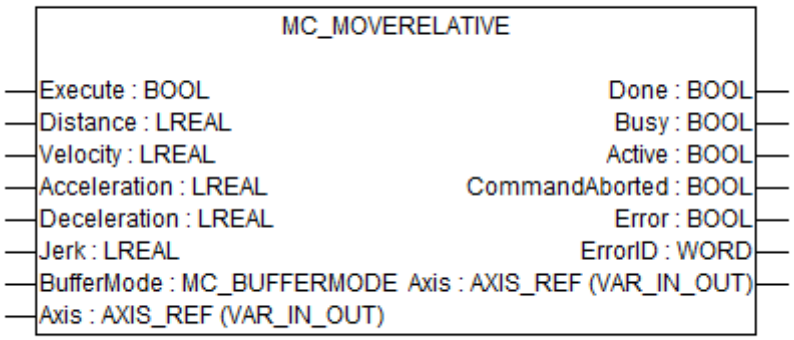

Fig. 298: Function block MC_MoveRelative

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandA-borted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveAdditive

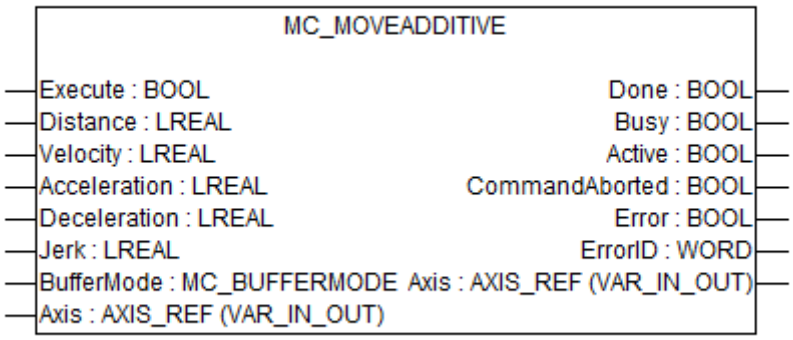

Fig. 299: Function block MC_MoveAdditive

This function block commands a controlled motion of a specified relative distance additional to the most recent commanded position in the state Discrete Motion. The most recent commanded position may be the result of a previous MC_MoveAdditive motion which was aborted. If the function block is activated in the Continuous Mode the specified relative distance is added to the actual position at the time of the execution.

See the following chapter to check if this function block is supported by the used axis implementation: ↳ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↳ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Examples of the combination of two function blocks while the axis is in state discrete motion

1.) The left part of timing diagram illustrates the case if the second function block is called **after** the first one. If the first one reaches the commanded distance 6000 (and the velocity is 0) then the output "Done" causes the second function block to move to the distance 10000.

2.) The right part of the timing diagram illustrates the case if the second move function blocks starts the execution **while** the first function block is still executing. In this case the first motion is interrupted and aborted by the test signal during the constant velocity of the first function block. The second function block **adds on the previous commanded position** of 6000 the distance 4000 and moves the axis to the resulting position of 10000.

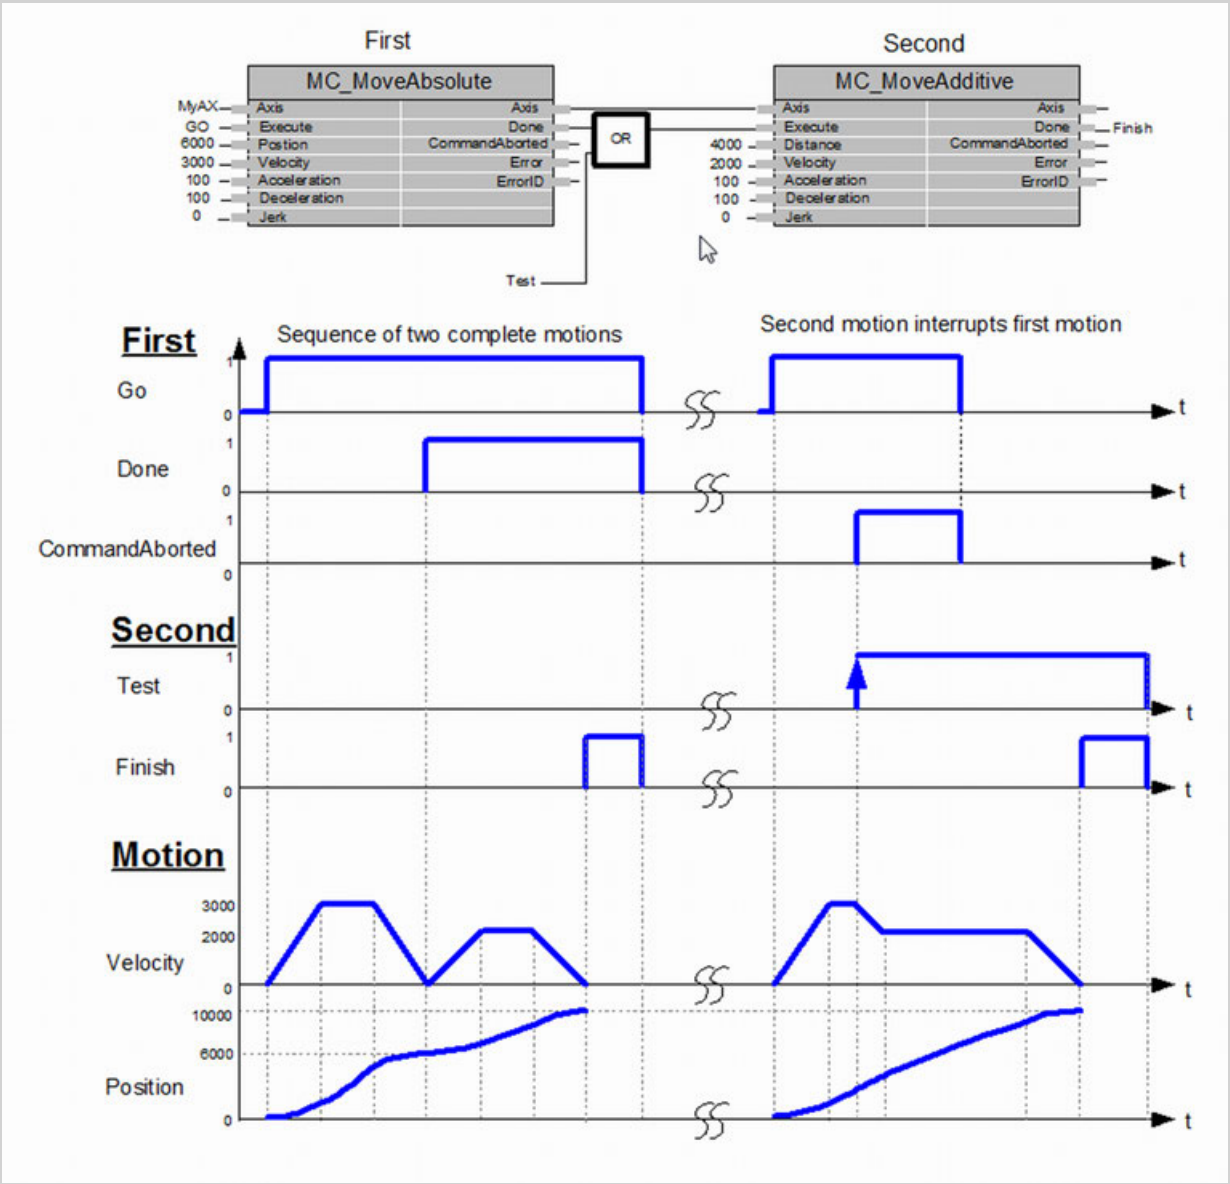

Fig. 300: Timing diagram for MC_MoveAdditive

Input description

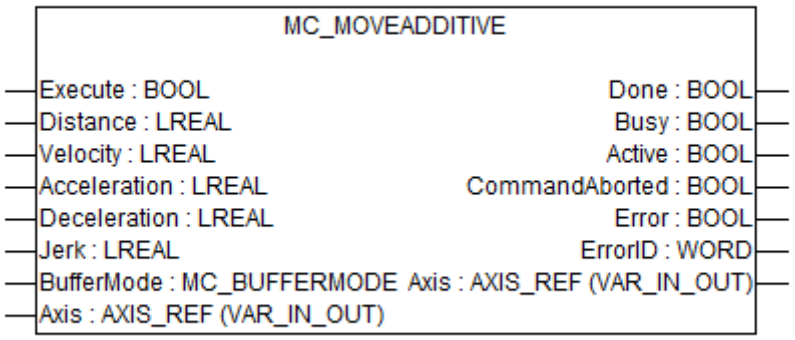

Fig. 301: Function block MC_MoveAdditive

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

Distance Data type: LREAL, unit: u
Relative distance for the motion.

Velocity Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

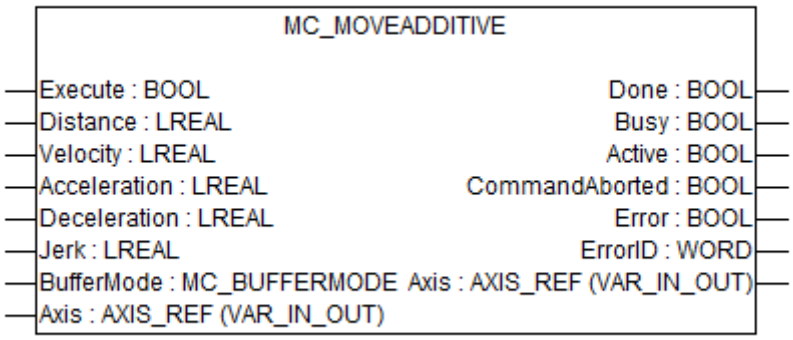

Fig. 302: Function block MC_MoveAdditive

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveSuperImposed

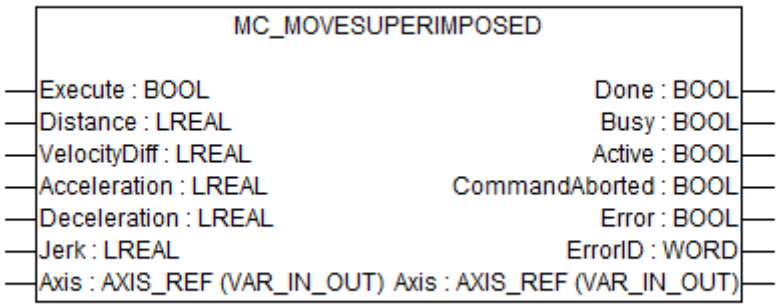

Fig. 303: Function block MC_MoveSuperimposed

This function block commands a controlled motion of a specified relative distance additional to an existing motion. The existing motion is not interrupted, but is superimposed by the additional motion.

- *If MC_MoveSuperImposed is active, then any other command in aborting mode except MC_MoveSuperImposed will abort both motion commands: Both the MC_MoveSuperImposed and the underlying motion command. In any other mode, the underlying motion command is not aborted*
- *If MC_MoveSuperImposed is active and another MC_MoveSuperImposed is commanded, only the on-going MC_MoveSuperImposed command is aborted, and replaced by the new MC_MoveSuperImposed, but not the underlying motion command*
- *The function block MC_MoveSuperimposed causes a change of the velocity and, if applicable, the commanded position of an on-going motion in all relevant states*
- *In the state StandStill the function block MC_MoveSuperimposed acts like MC_MoveRelative*
- *The values of Acceleration, Deceleration, and Jerk are additional values to the on-going motion, and not absolute ones. With this, the underlying function block always finishes its job in the same period of time regardless of whether a MC_MoveSuperimposed function block takes place concurrently*
- *MC_MoveSuperimposed acts on the slave axis, while MC_Phasing acts on the master side, as seen from the slave*
- *•The output "Active" has a different behavior as in buffered function blocks*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

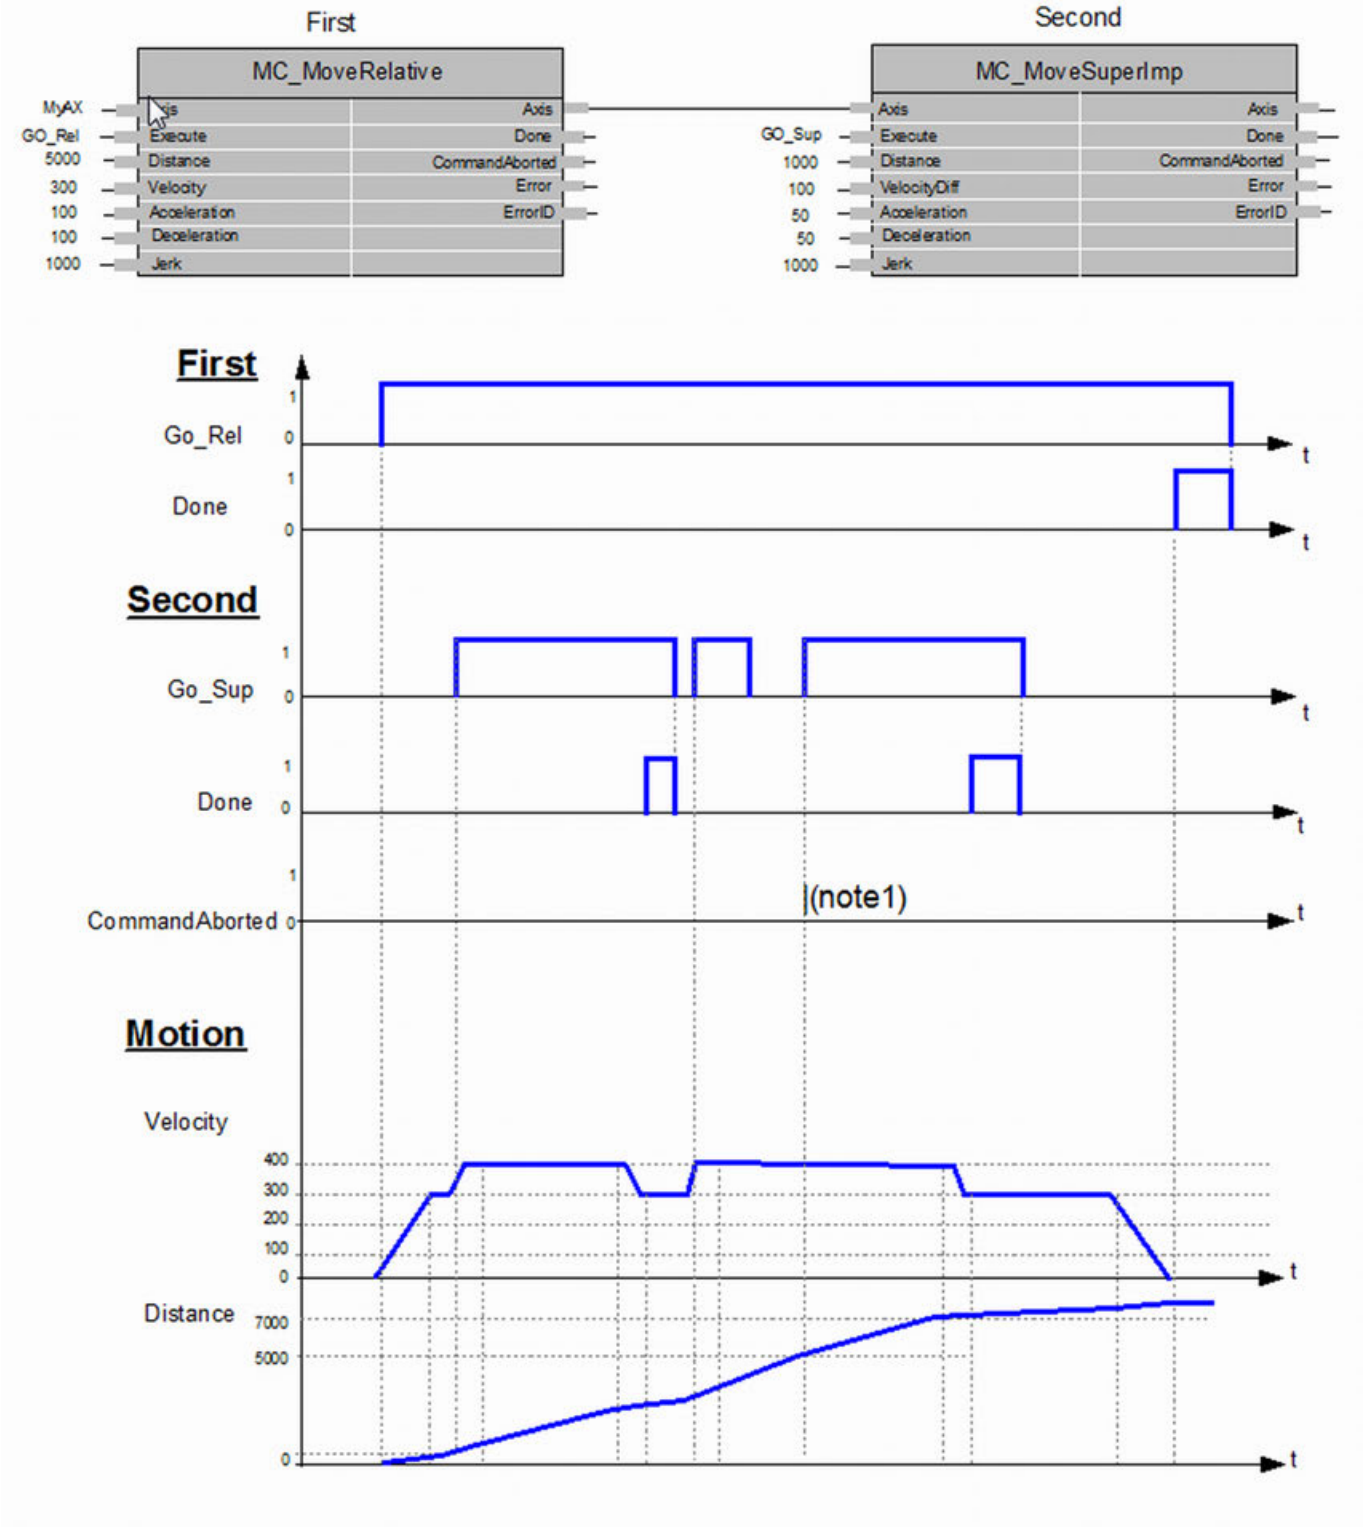

Fig. 304: Timing diagram for MC_MoveSuperimposed

- *The CommandAborted is not visible here, because the new command works on the same instance. ↬ Chapter 1.5.9.3.9.1 “General rules” on page 2601*
- *The end position is between 7000 and 8000, depending on the timing of the aborting of the second command set for the MC_MoveSuperimposed.*

Example of MC_MoveSuperImposed during camming:

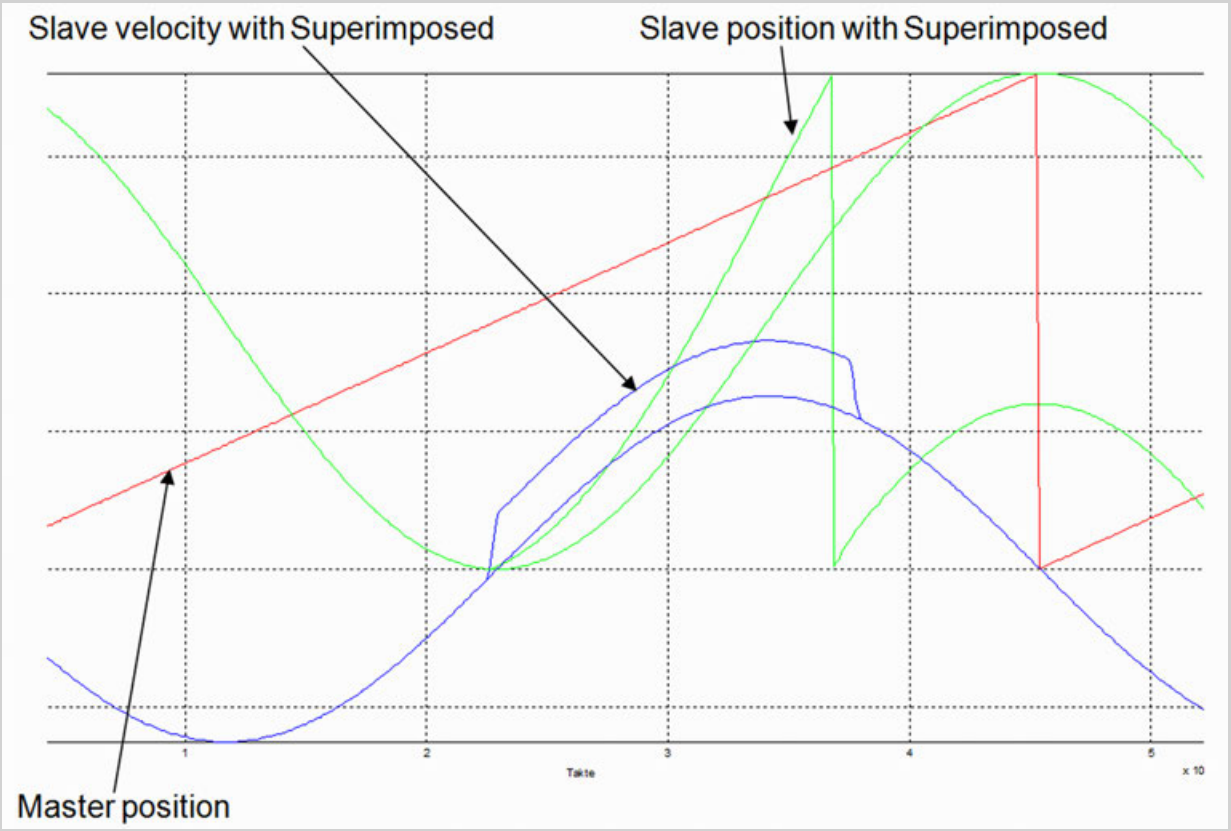

Fig. 305: Timing diagram of effect of MC_MoveSuperImposed on same axis

At Slave velocity, the double line shows the effect of MoveSuperimposed while in Synchronized Motion during Camming. The same is valid for the related slave position.

Input description

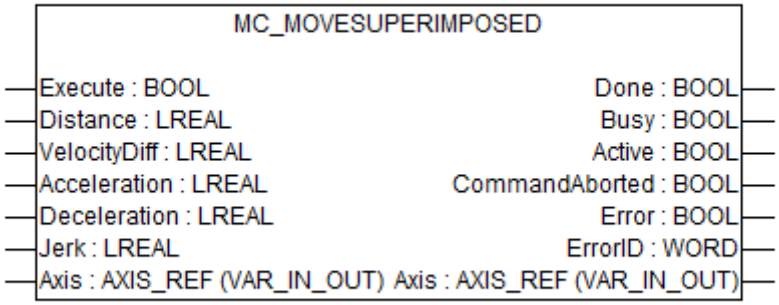

Fig. 306: Function block MC_MoveSuperimposed

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

Distance Data type: LREAL, unit: u
Relative distance for the motion.

VelocityDiff Data type: LREAL, unit: u/s
Value of the maximum velocity difference to the ongoing motion (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

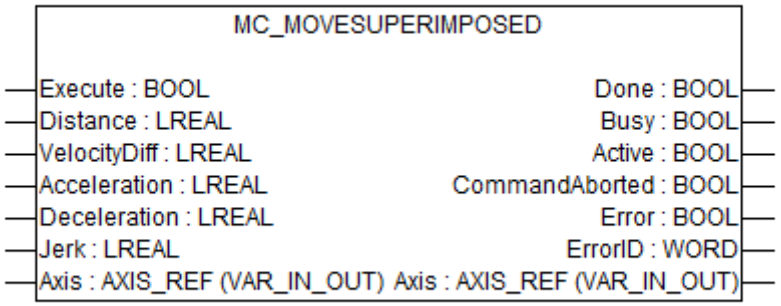

Fig. 307: Function block MC_MoveSuperimposed

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_HaltSuperimposed

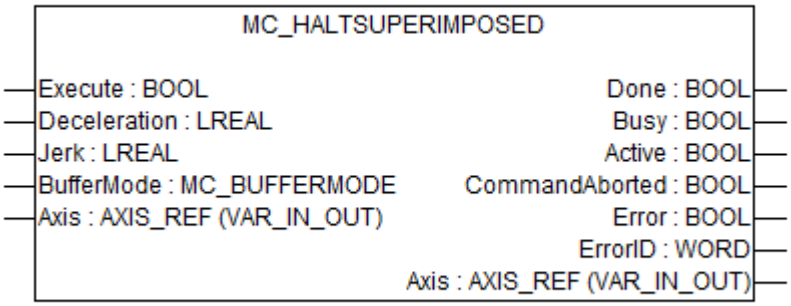

Fig. 308: Function block MC_HaltSuperimposed

This function block commands a halt to all superimposed motions of the axis. The underlying motion is not interrupted.

Input description

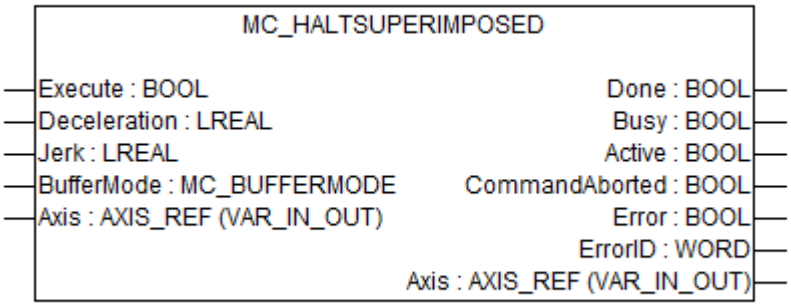

Fig. 309: Function block MC_HaltSuperimposed

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute
Data type: BOOL
Starts the function block at rising edge.

Deceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk
Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode
Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis
Data type: AXIS_REF
Reference to the axis.

Output description

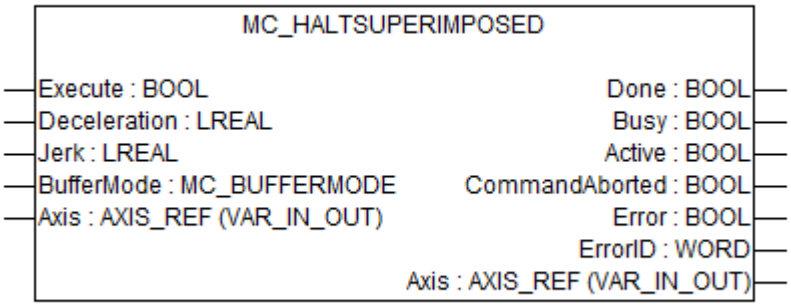

Fig. 310: Function block MC_HaltSuperimposed

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished and new output values are to be expected.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveVelocity

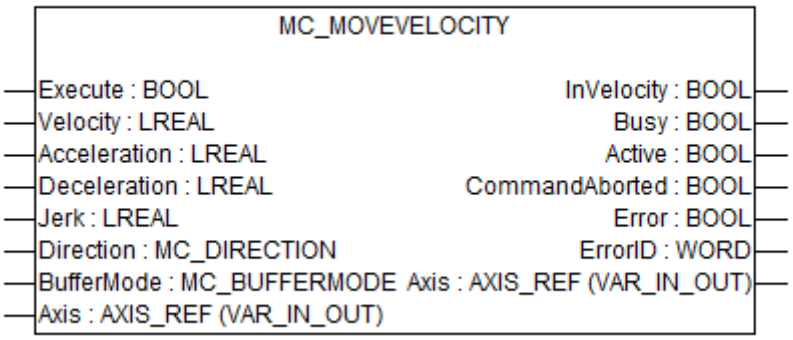

Fig. 311: Function block MC_MoveVelocity

Table 188: General information

Available as of runtime system	V2.2
Included in library	MC_Block_AC500_V11.lib
Type	Function block with historical values

This function block commands a never ending controlled motion at a specified velocity.

- *To stop the motion, the function block has to be interrupted by another function block issuing a new command.*
- *The signal "InVelocity" has to be reset when the block is aborted by another block or at the falling edge of "Execute".*
- *In combination with MC_MoveSuperimposed, the output “"nVelocity" stays TRUE once the velocity setpoint of the axis has reached the commanded velocity.*

See the following chapter to check if this function block is supported by the used axis implementation: ↬ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↬ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Examples of the combination of two function blocks MC_MoveVelocity

The left part of timing diagram illustrates the case if the second function block is called after the first one is completed. If first reaches the commanded velocity 3000 then the output First.InVelocity AND the signal Next causes the second function block to move to the velocity 2000.

The right part of the timing diagram illustrates the case if the second function block starts the execution while the first function block is not yet InVelocity. The following sequence is shown: The first motion is started again by Go at the input First.Execute. While the first function block is still accelerating to reach the velocity 3000 the first function block will be interrupted and aborted because the test signal starts the Run of the second function block. Now the second function block runs and decelerates the velocity to 2000.

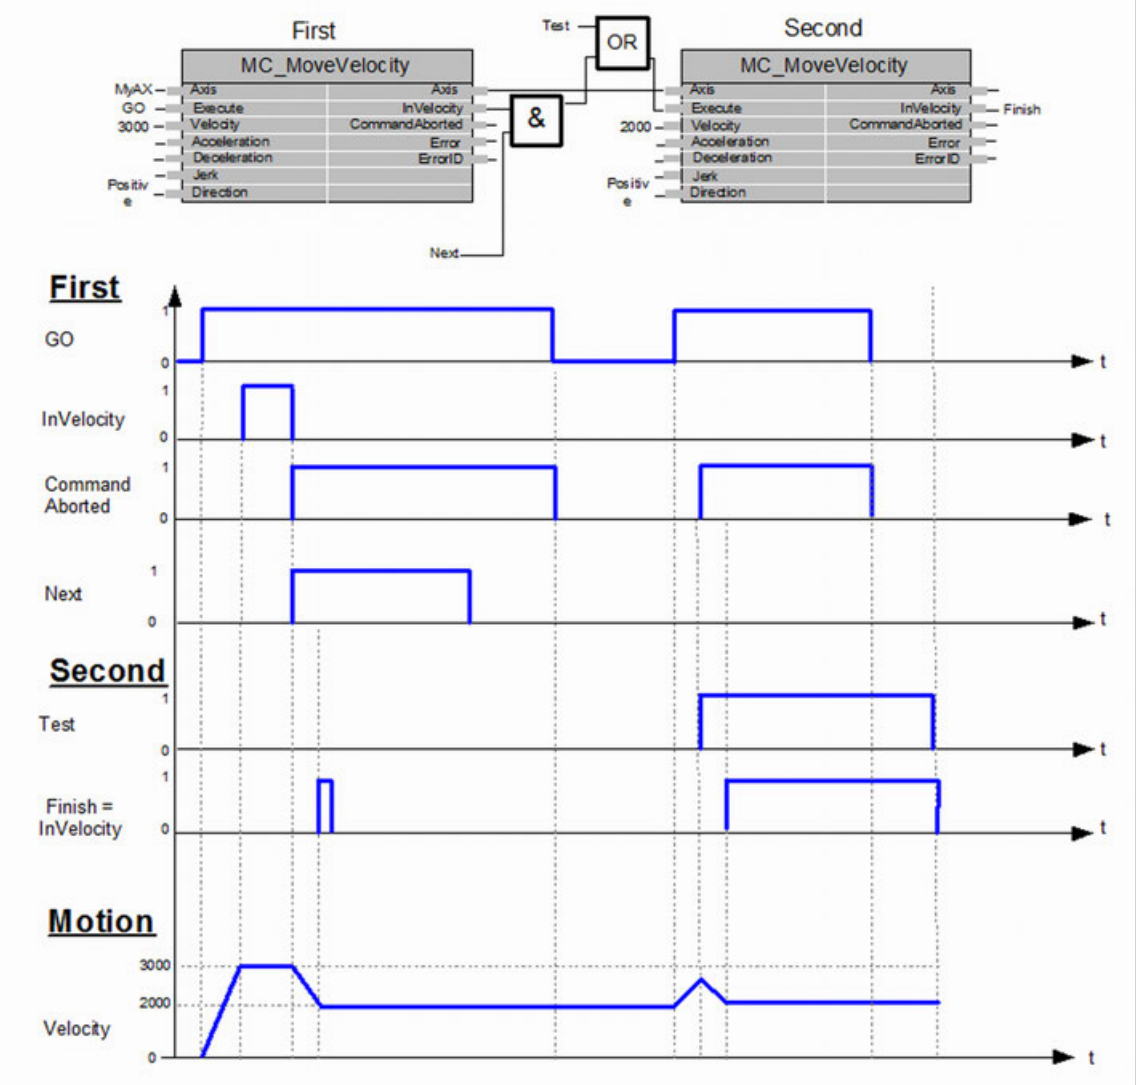

Fig. 312: MC_MoveVelocity timing diagram

Using this function block with FM562

Input Jerk: 1 = jerk on, 2 = jerk off

Input Direction: Enum type: 0 = DEFAULT, 1 = POSITIVE, 3 = NEGATIVE

Input BufferMode: Not implemented

Input description

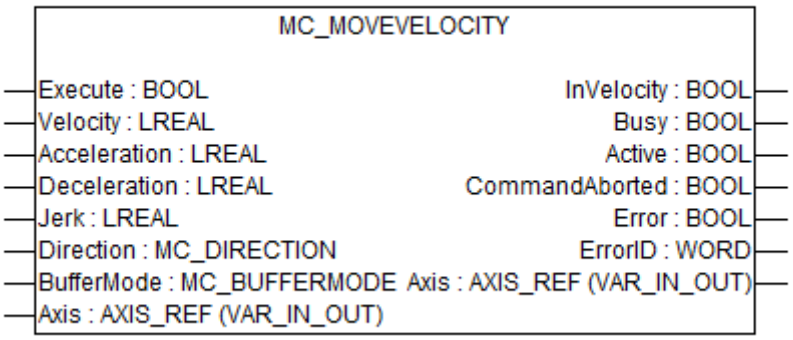

Fig. 313: Function block MC_MoveVelocity

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute

Data type: BOOL

Starts the function block at rising edge.

Velocity

Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

Acceleration

Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Deceleration

Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

Jerk

Data type: LREAL, range: > 0, unit: u/s^3

Value of the Jerk.

Direction

Data type: MC_Direction, range: DEFAULT, POSITIVE, SHORTEST, NEGATIVE, CURRENT

Enum type.

> *Shortest way not applicable, DEFAULT is equivalent with CURRENT*

BufferMode

Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

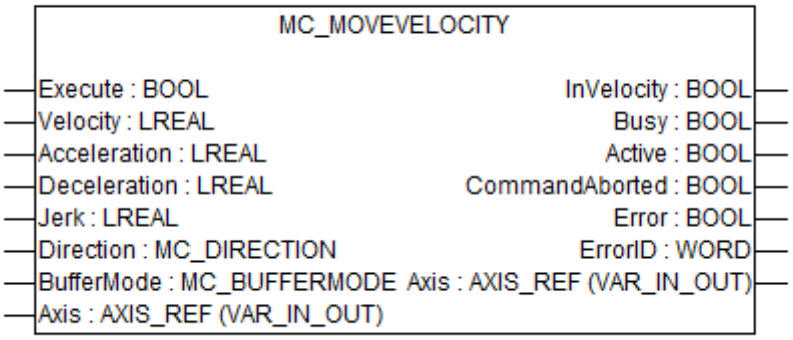

Fig. 314: Function block MC_MoveVelocity

InVelocity Data type: BOOL
Commanded velocity reached (first time reached).

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveContinuousAbsolute

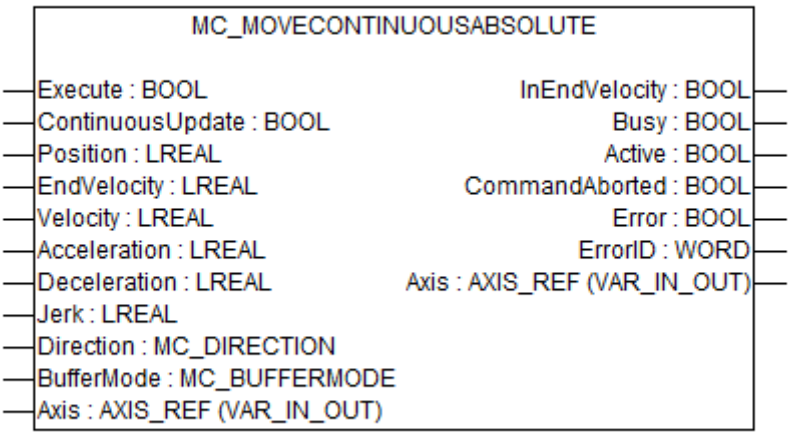

Fig. 315: Function block MC_MoveContinuousAbsolute

This function block commands a controlled motion to a specified absolute position ending with the specified velocity.

- *If the commanded position is reached and no new motion command is put into the buffer, the axis continues to run with the specified "EndVelocity".*
- *The function block will start the axis with state DiscreteMotion, while positioning.*
- *It will change to state Continuous Motion (meaning: it will not stop by itself) with EndVelocity <> 0.*
- *It will change to standstill with EndVelocity=0.*

See the following chapter to check if this function block is supported by the used axis implementation: ↬ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↬ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

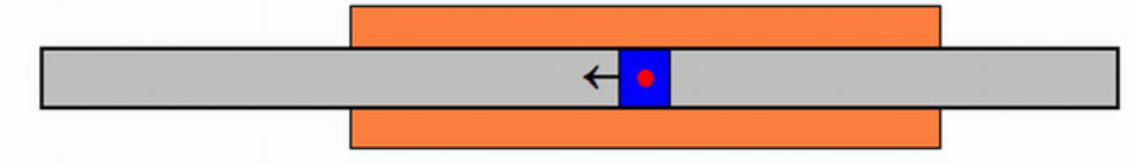
One use case for MC_MoveContinuousAbsolute is a linear cutter. One linear axis that is carrying a laser device that is used to cut a workpiece.

☑ Start from lrIdlePos.

1. Move the laser with fast velocity over the position lrStartCutPos. The laser is off during this movement.

2. Turn back and make sure to have the speed lrCutVelocity when at lrStartCutPos. At this position, switch the laser on.

3. Travel over the work piece with this constant speed while the laser is on.



4. When reaching lrEndCutPos switch off the laser and move back to idle position with fast velocity.

During the cutting process the laser must be moved with a fix velocity, no acceleration or deceleration phase can be tolerated. The laser must be moved to its waiting position after the cutting was done.

Example MC_MoveContinuousAbsolute

The explained movement can be achieved with the function block MC_MoveContinuousAbsolute in the following way:

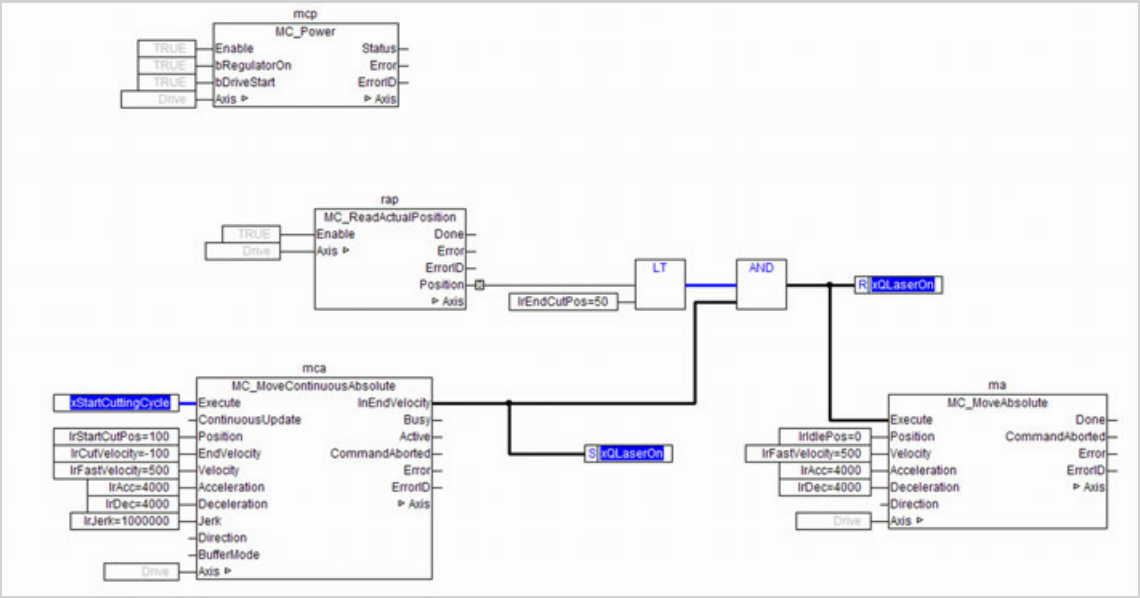


Fig. 316: Example MC_MoveContinuousAbsolute

Started with a rising edge of xStartCuttingCycle, the instance `mca` of MC_MoveContinuousAbsolute will move the axis with lrFastVelocity over lrStartCutPos, turn back and have the speed lrCutVelocity when reaching lrStartCutPos again in negative direction. In this point in time, `InEndVelocity` is set, and the laser is switched on. As no other motion function block interrupts this movement, MC_MoveContinuousAbsolute will keep travelling in negative direction with the current speed. After the axis has overstepped the position lrEndPos, where the laser is switched off, the MC_MoveAbsolute instance `ma` moves the axis with high speed to its idle position.

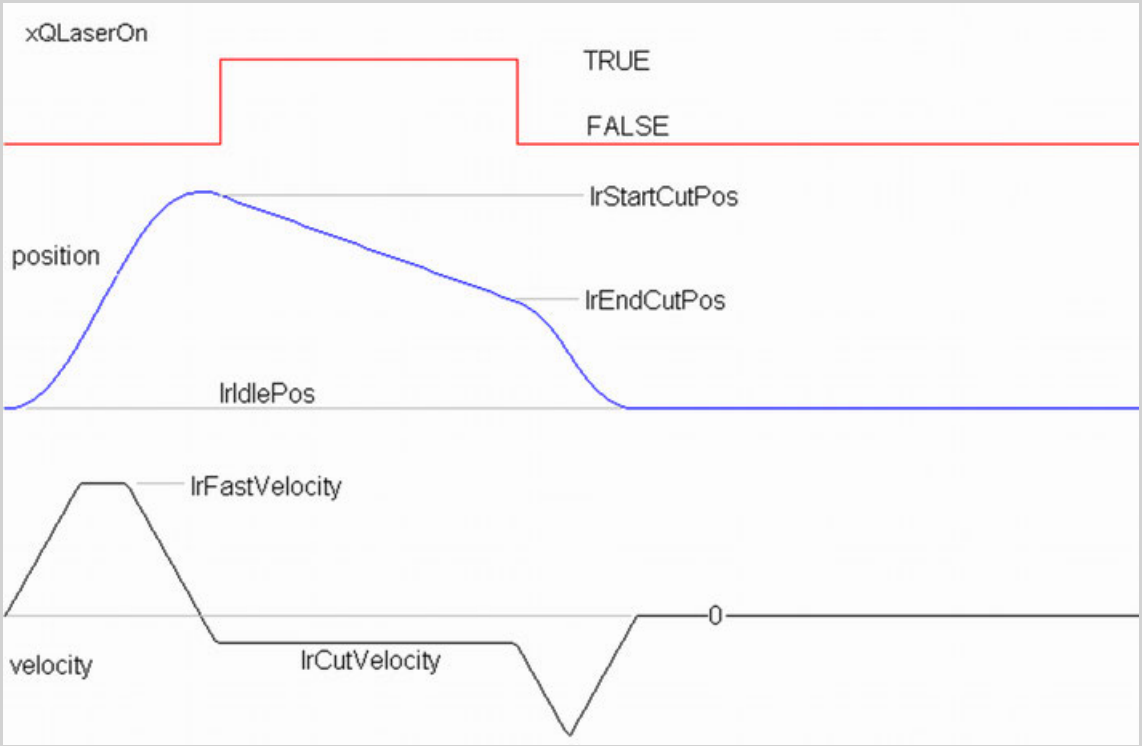

Fig. 317: Example MC_MoveContinuousAbsolute timing diagram

Input description

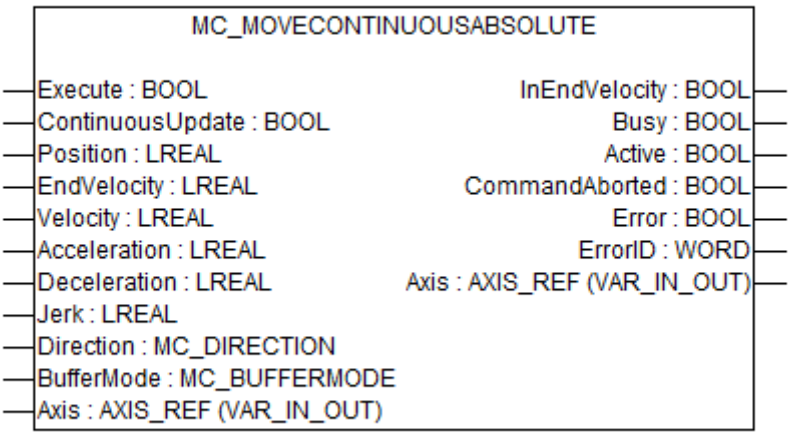

Fig. 318: Function block MC_MoveContinuousAbsolute

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute
Data type: BOOL
Starts the function block at rising edge.

ContinousUpdate
Data type: BOOL
Chapter 1.5.9.3.9.3 “The input ContinuousUpdate” on page 2604

Position
Data type: LREAL, unit: u
Reference position.

EndVelocity
Data type: LREAL
Value of the end velocity [u/s]. Signed value.

Velocity
Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk

Jerk is not supported with this function block.

Direction Data type: MC_Direction, range: DEFAULT, POSITIVE, SHORTEST, NEGATIVE, CURRENT
Enum type.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

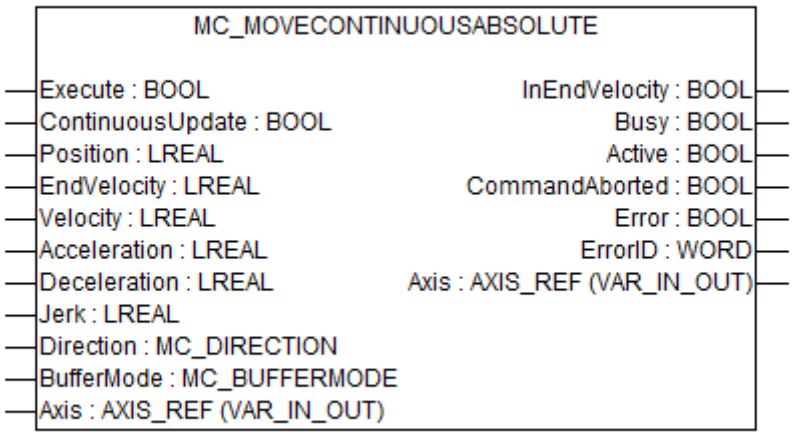

Fig. 319: Function block MC_MoveContinuousAbsolute

InEndVelocity Data type: BOOL
Commanded distance reached and running at requested end velocity .

Busy Data type: BOOL
The function block is not finished and new output values are to be expected.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveContinuousRelative

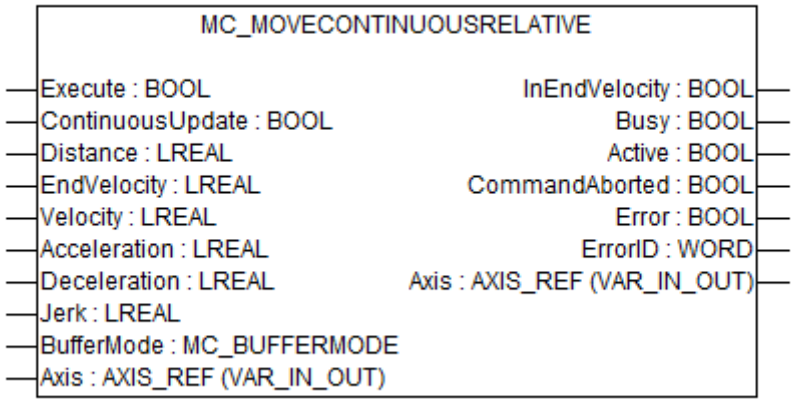

Fig. 320: MC_MoveContinuousRelative

This function block commands a controlled motion of a specified relative distance ending with the specified velocity.

- *If the commanded position is reached and no new motion command is put into the buffer, the axis continues to run with the specified "EndVelocity".*
- *The function block will start the axis with state DiscreteMotion, while positioning.*
- *It will change to state Continuous Motion (meaning: it will not stop by itself) with EndVelocity <> 0.*
- *It will change to standstill with EndVelocity=0.*
- *This function block is specified here for systems without the support for the "BufferMode".*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Execute
Data type: BOOL
Starts the function block at rising edge.

ContinousUpdate
Data type: BOOL
Chapter 1.5.9.3.9.3 “The input ContinuousUpdate” on page 2604

Distance
Data type: LREAL, unit: u
Relative distance for the motion.

EndVelocity
Data type: LREAL
Value of the end velocity [u/s]. Signed value.

Velocity
Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk

Jerk is not supported with this function block.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

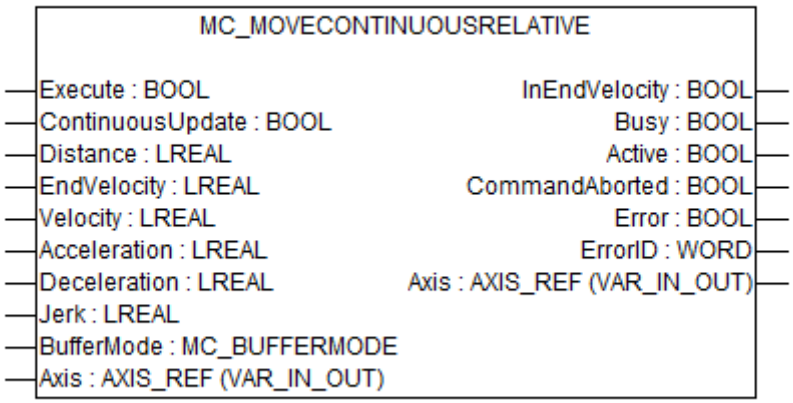

Fig. 324: MC_MoveContinuousRelative

InEndVelocity Data type: BOOL
Commanded distance reached and running at requested end velocity .

Busy Data type: BOOL
The function block is not finished and new output values are to be expected.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_Stop

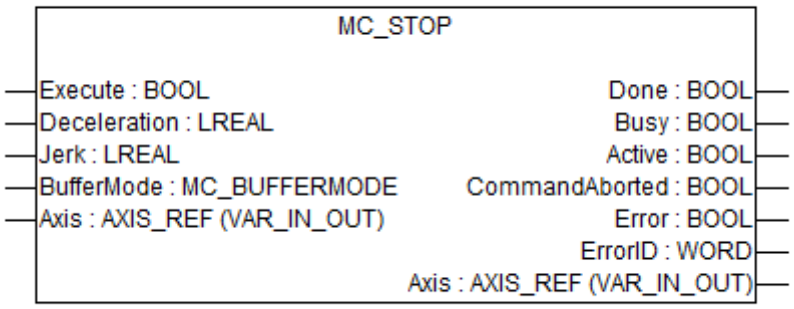

Fig. 325: Function block MC_Stop

Table 189: General information

Available as of runtime system	V2.2
Included in library	MC_Block_AC500_V11.lib
Type	Function block with historical values

This function block commands a controlled motion stop and transfers the axis to the state Stopping. It aborts any ongoing function block execution. While the axis is in state Stopping, no other function block can perform any motion on the same axis. After the axis has reached velocity zero, the Done output is set to TRUE immediately. The axis remains in the state Stopping as long as Execute is still TRUE or velocity zero is not yet reached. As soon as Done is SET and Execute is FALSE the axis goes to state StandStill.

As long as Execute is high, the axis remains in the state Stopping and may not be executing any other command.

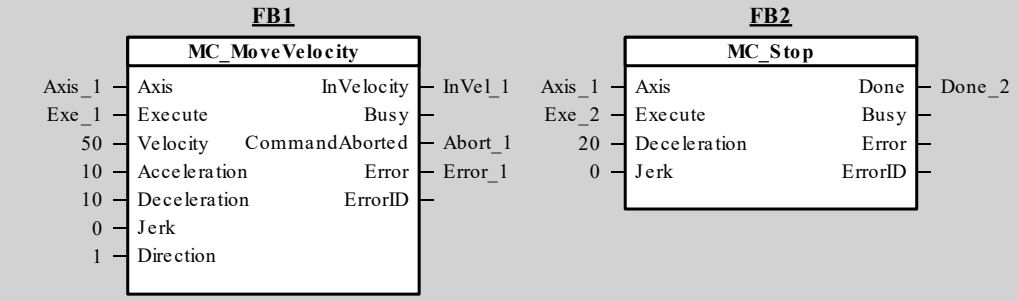
See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

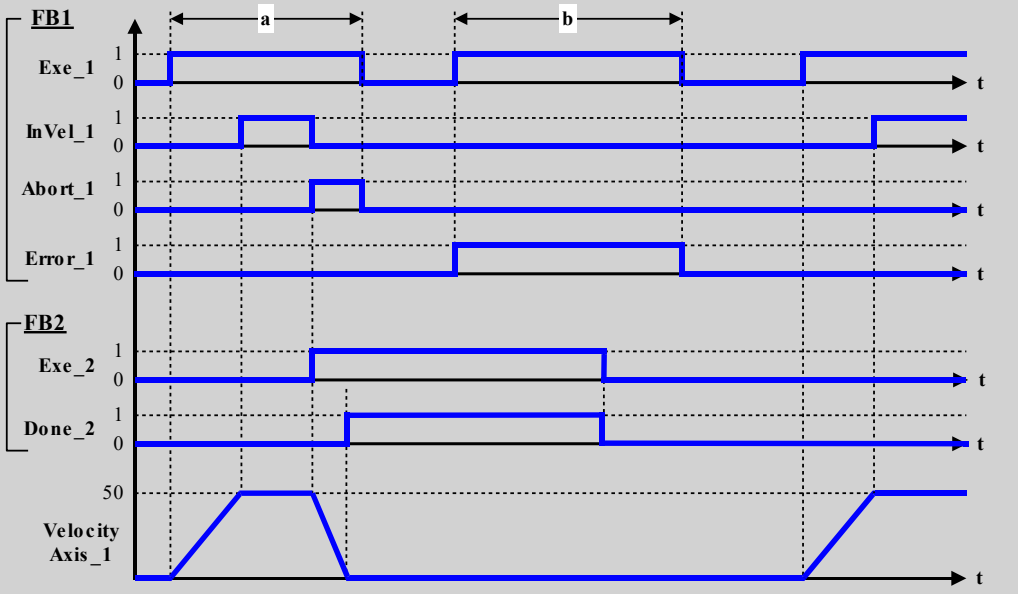
For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Example: Behavior of MC_Stop in combination with MC_MoveVelocity

- A rotating axis is ramped down with function block MC_Stop.
- The axis rejects motion commands as long as MC_Stop parameter Execute = TRUE. Function block MC_MoveVelocity reports an error indicating the busy MC_Stop command.





Using this function block with FM562

Input Jerk: Not implemented

Input BufferMode: Not implemented

Input description

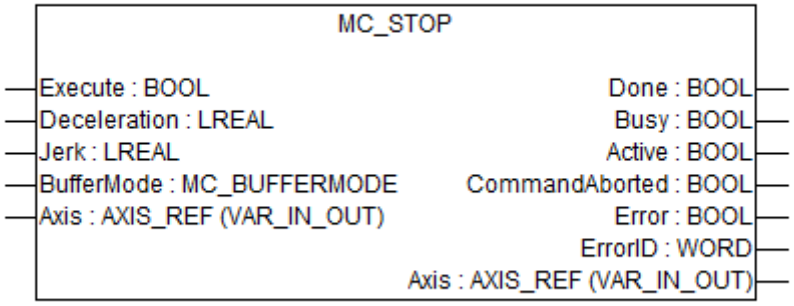


Fig. 326: Function block MC_Stop

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute Data type: BOOL
Starts the function block at rising edge.

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

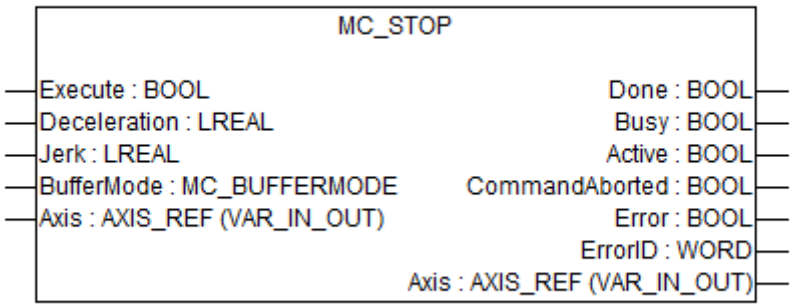

Fig. 327: Function block MC_Stop

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_Halt

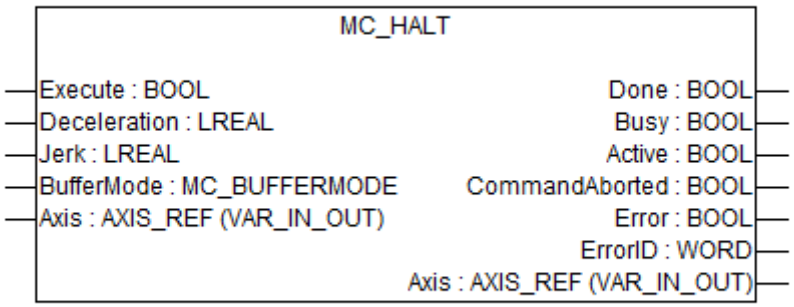

Fig. 328: Function block MC_Halt

This function block commands a controlled motion stop. The axis is moved to the state Discrete Motion, until the velocity is zero. With the Done output set, the state is transferred to StandStill.

- *MC_Halt is used to stop the axis under normal operation conditions. In non-buffered mode it is possible to set another motion command during deceleration of the axis, which will abort the MC_Halt and will be executed immediately.*
- *If this command is active the next command can be issued. E.g. a driverless vehicle detects an obstacle and needs to stop. MC_Halt is issued. Before the standstill is reached the obstacle is removed and the motion can be continued by setting another motion command, so the vehicle does not stop.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Example: Behavior of MC_Halt in combination with MC_Move-Velocity

- A rotating axis is ramped down with function block MC_Halt.
- Another motion command overrides the MC_Halt command. MC_Halt allows this, in contrast to MC_Stop. The axis can accelerate again without reaching standstill.

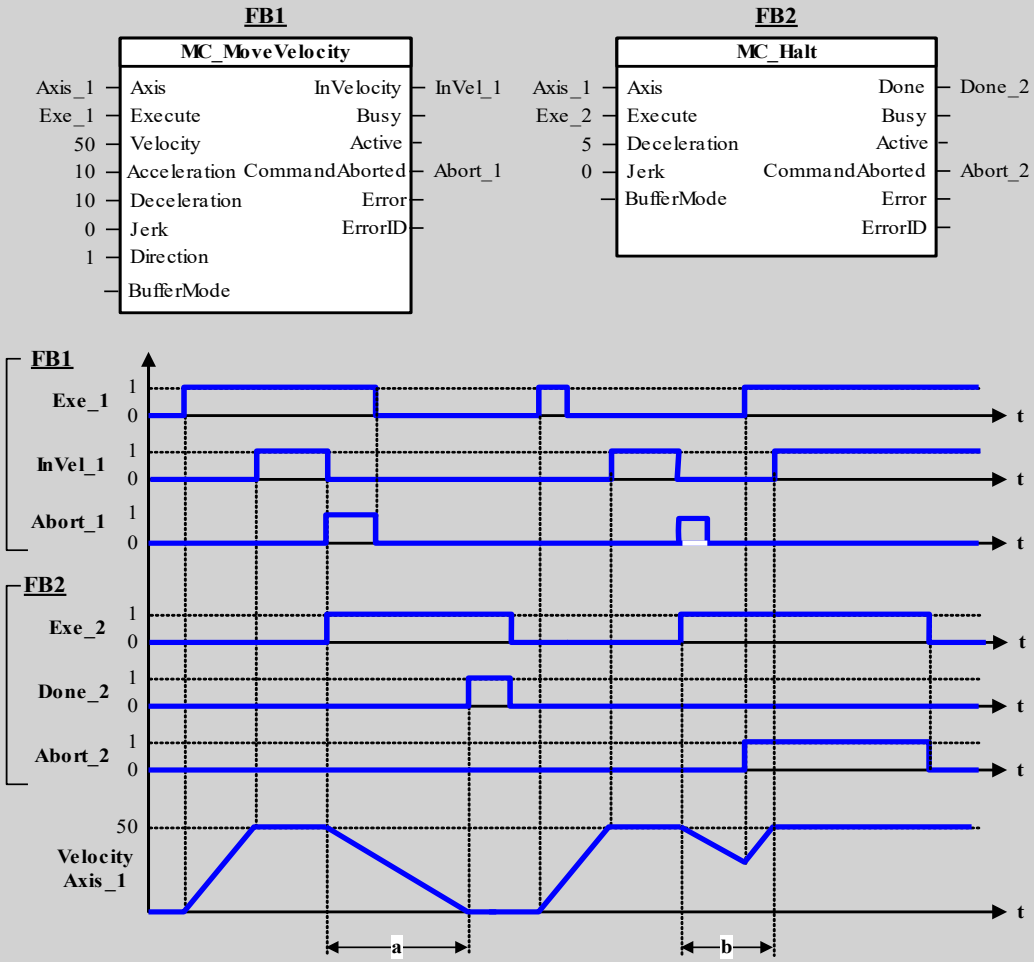

Fig. 329: Example MC_Halt

Input description

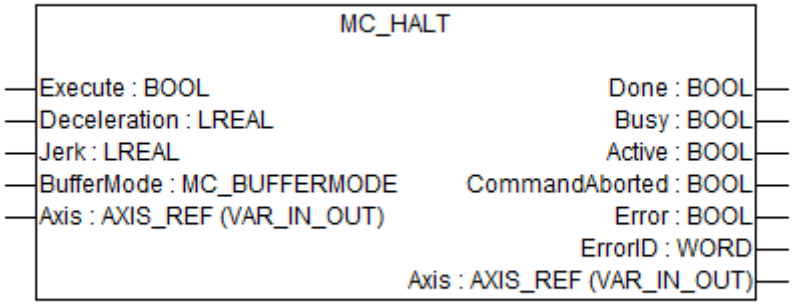

Fig. 330: Function block MC_Halt

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

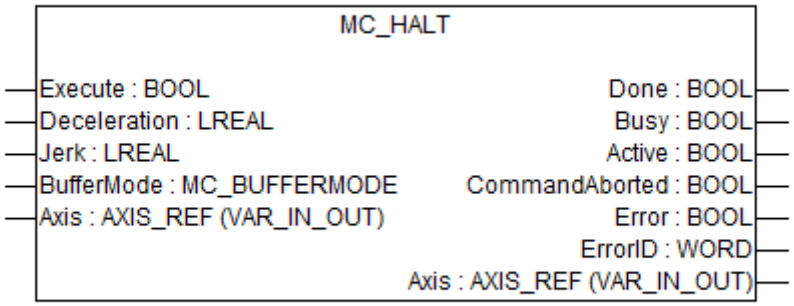

Fig. 331: Function block MC_Halt

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_PositionProfile

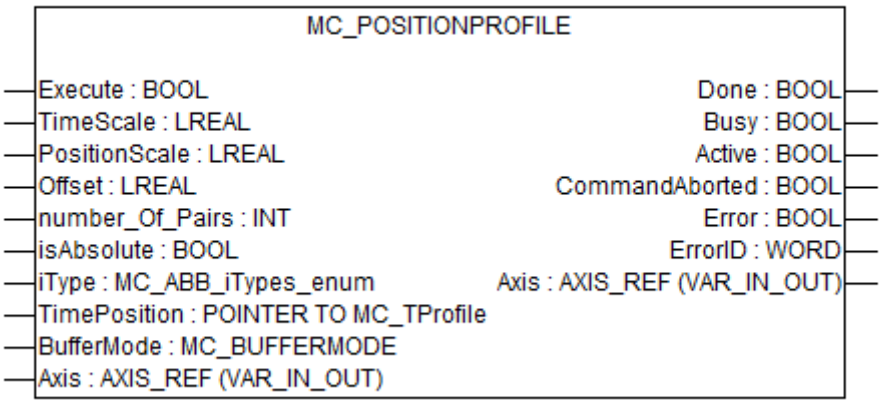

Fig. 332: Function block MC_PositionProfile

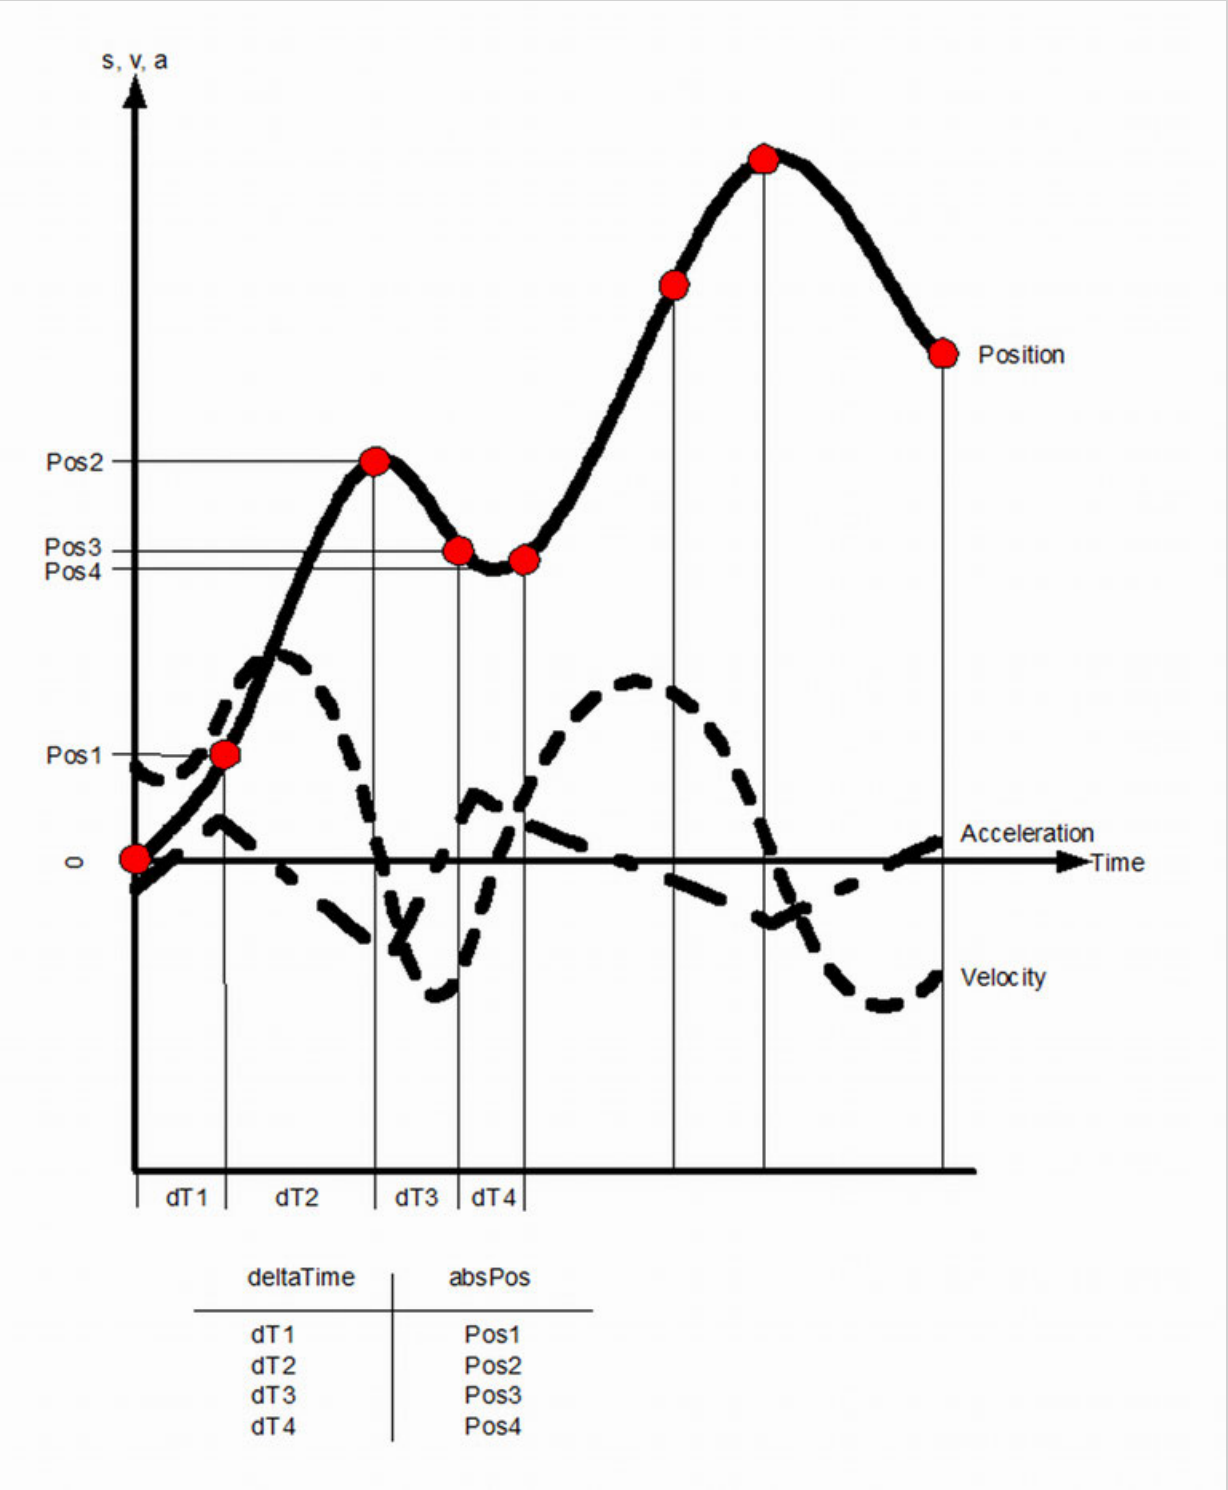
This function block commands a time-position locked motion profile .

- *MC_TPROFILE is an ABB specific data type.*
- *This functionality does not mean it runs one profile over and over again: It can shift between different profiles.*
- *Alternatively to this function block, the CAM function block coupled to a virtual master can be used.*

Example of time/position profile



deltaTime	absPos
dT1	Pos1
dT2	Pos2
dT3	Pos3
dT4	Pos4

The Time / Velocity and Time / Acceleration Profiles are similar to the Position Profile, with sampling points on the Velocity or Acceleration lines.

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

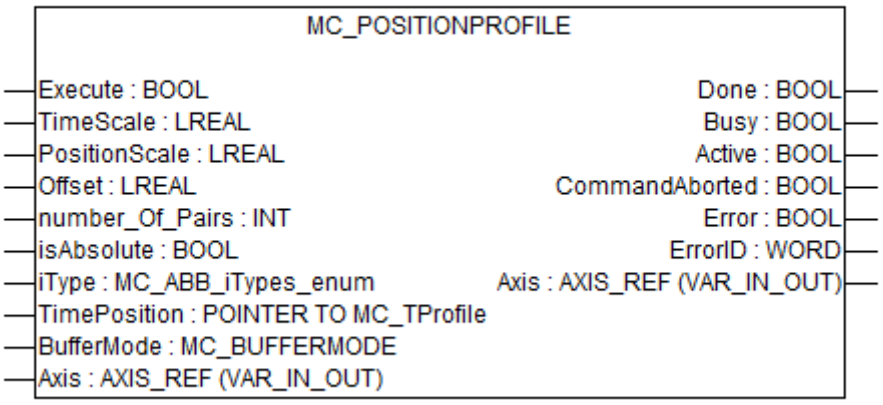


Fig. 333: Function block MC_PositionProfile

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

TimePosition
Data type: MC_TP_REF
Reference to Time/Position. Description: *Further information on page 2787*

Execute
Data type: BOOL
Starts the function block at rising edge.

TimeScale
Data type: LREAL, unit: t.u.
Overall time scaling factor of the profile.

PositionScale
Data type: LREAL, unit: t.u.
Overall Position scaling factor.

Offset
Data type: LREAL, unit: u/s
Overall offset for profile.

Number_of_pairs
Data type: INT
Number of points used in TimePosition Array.

isAbsolute Data type: BOOL

TRUE → Profile holds absolute position values.

iTYPE Data type: MC_ABB_iTypes_ENUM

Interpolationtype, possible values are:

- MCA_SPLINE_COMPLETE
- MCA_SPLINE_NATURAL
- MCA_POLY5
- MCA_POLY3
- MCA_LINEAR

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

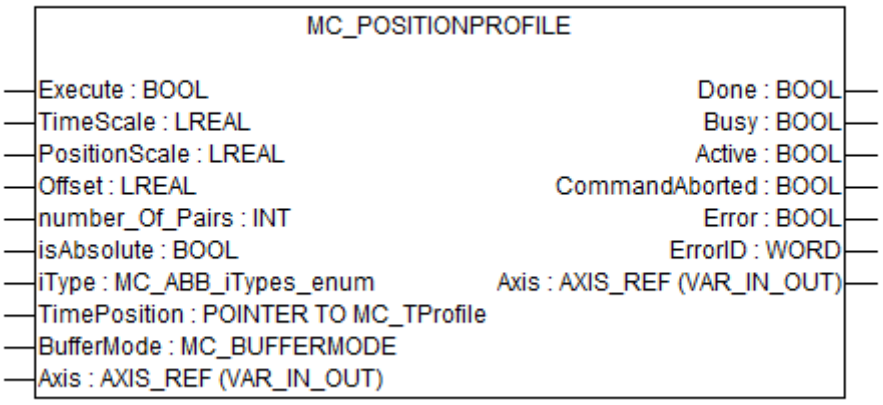

Fig. 334: Function block MC_PositionProfile

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted
Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error
Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID
Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_VelocityProfile

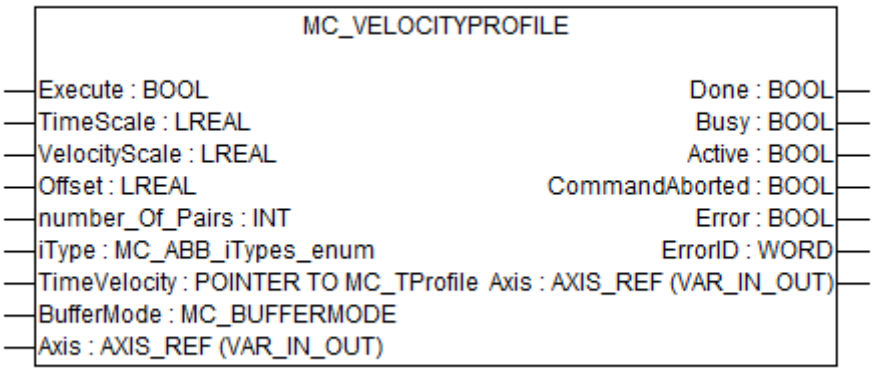

Fig. 335: MC_VelocityProfile

This function block commands a time-velocity locked motion profile.

- *MC_TPROFILE is an ABB specific data type.*
- *This functionality does not mean it runs one profile over and over again: It can shift between different profiles.*
- *Alternatively to this function block, the CAM function block coupled to a virtual master can be used.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

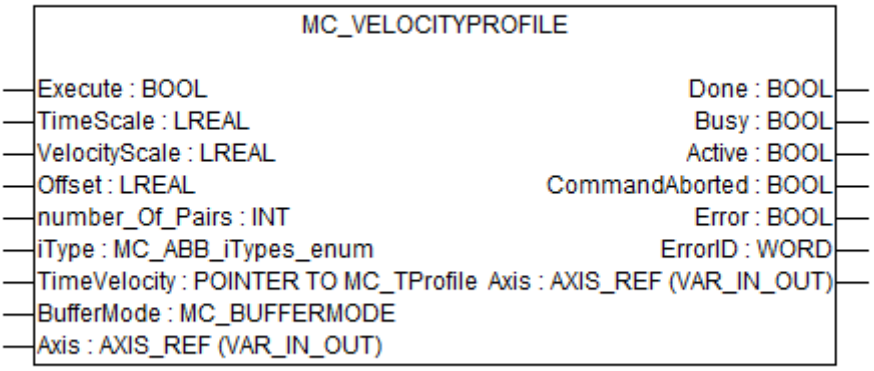

Fig. 336: Function block MC_VelocityProfile

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

TimeScale Data type: LREAL, unit: t.u.

Overall time scaling factor of the profile.

VelocityScale Data type: LREAL

Overall velocity scaling factor of the profile.

Offset Data type: LREAL, unit: u/s

Overall offset for profile.

Number_of_pairs Data type: INT

Number of points used in TimeVelocity Array.

iTYPE Data type: MC_ABB_iTypes_ENUM

Interpolationtype, possible values are:

- MCA_SPLINE_COMPLETE
- MCA_SPLINE_NATURAL
- MCA_POLY5
- MCA_POLY3
- MCA_LINEAR

TimeVelocity Data type: POINTER TO MC_TPROFILE
Reference to time/velocity. MC_TPROFILE is an ABB specific data type.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

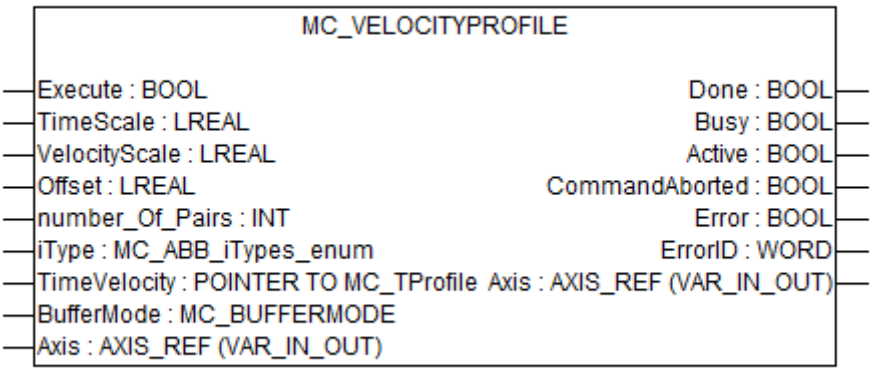

Fig. 337: Function block MC_VelocityProfile

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_AccelerationProfile

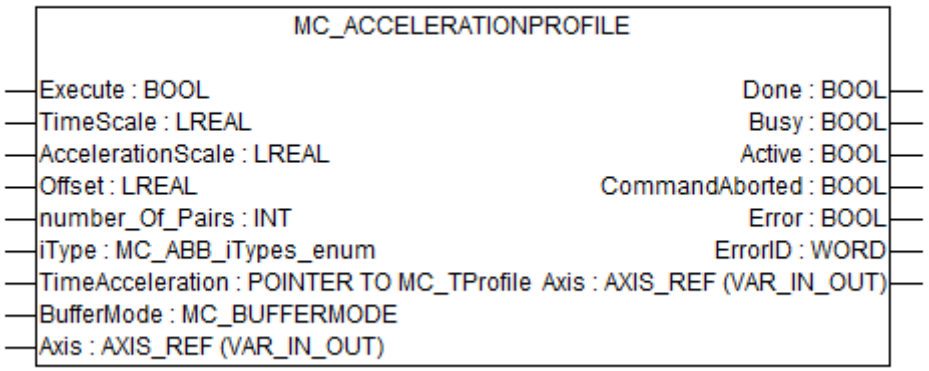

Fig. 338: Function block MC_AccelerationProfile

This function block commands a time-acceleration locked motion profile

- *MC_TPROFILE is an ABB specific datatype.*
- *Alternatively to this function block, the CAM function block coupled to a virtual master can be used.*

Example of an acceleration profile

A profile is made from a number of sequential "A to B" positioning points. It is simple to visualize, but requires a lot of sequences for a smooth profile. These requirements are often beyond the capability of low-end servos. Alternatively, by using a modest amount of constant acceleration segments it is possible to define a well-matching motion profile. With this method the capability range of low-end servos can be extended. It is possible to make matching to either:

1.) Position versus time profile

2.) Master versus slave axis

Advantages:

- Compact description of a profile.
- Smooth profile properties by nature.
- Low processor power requirements.

Disadvantages:

- Higher programming abstraction level with existing tools.

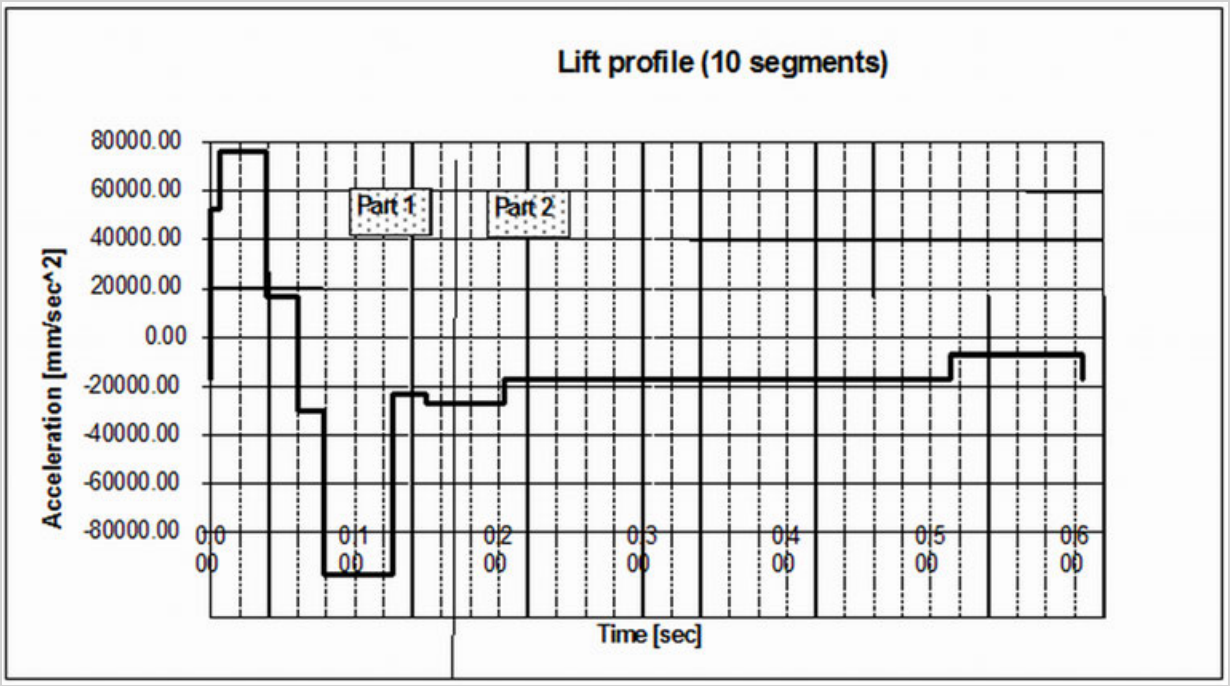

Fig. 339: Acceleration Profile, 10 segments only

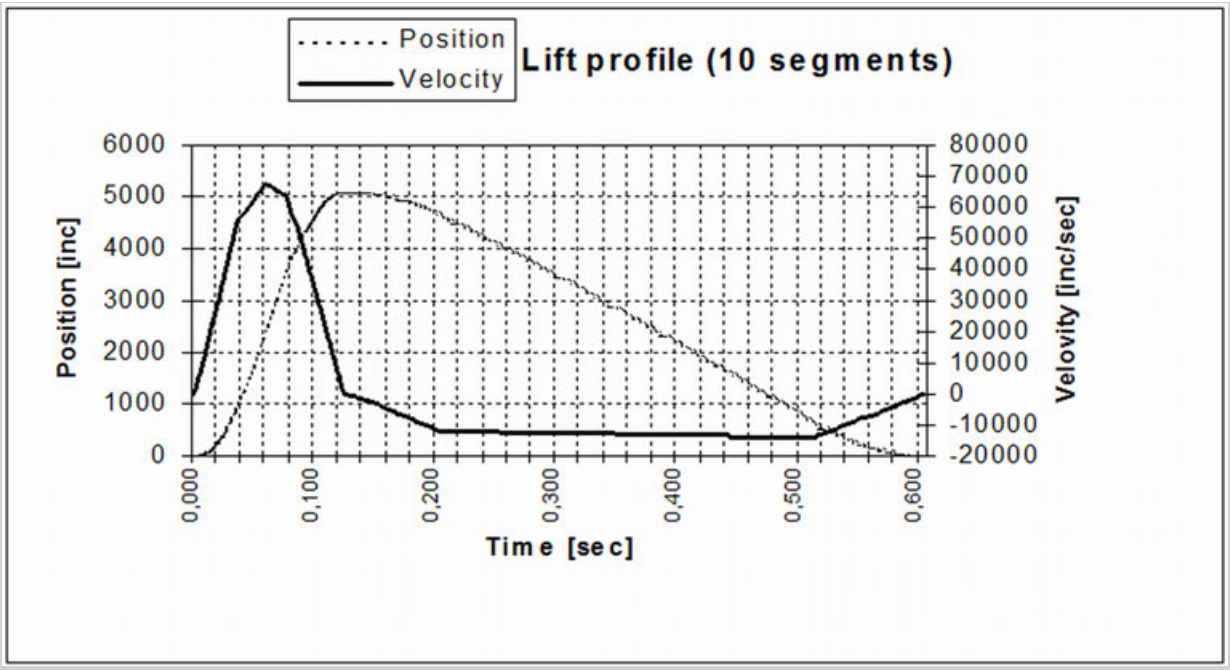

Fig. 340: Resulting Position Profile

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 "Overview of PLCopen function blocks" on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 "Overview of data types" on page 2585*

Input description

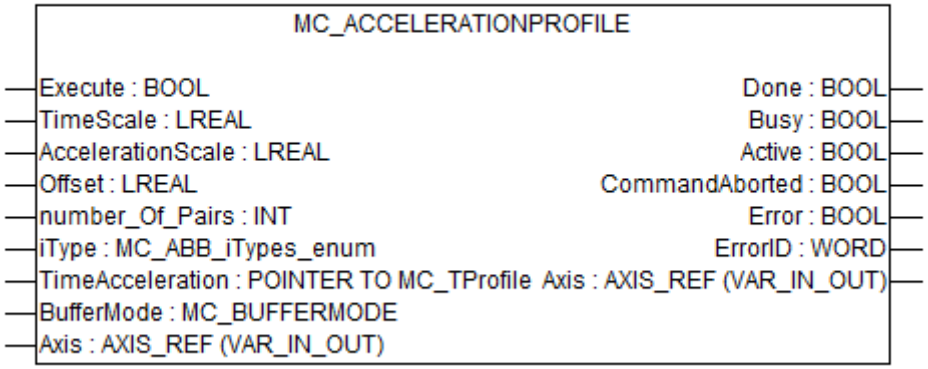

Fig. 341: Function block MC_AccelerationProfile

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute
Data type: BOOL
Starts the function block at rising edge.

TimeScale
Data type: LREAL, unit: t.u.
Overall time scaling factor of the profile.

Acceleration-Scale
Data type: LREAL
Scale factor for acceleration amplitude.

Offset
Data type: LREAL, unit: u/s
Overall offset for profile.

Number_of_pairs
Data type: INT
Number of points used in TimeAcceleration Array.

iTYPE
Data type: MC_ABB_iTypes_ENUM
Interpolationtype, possible values are:

- MCA_SPLINE_COMPLETE
- MCA_SPLINE_NATURAL
- MCA_POLY5
- MCA_POLY3
- MCA_LINEAR

TimeAcceleration
Data type: MC_TA_REF
Reference to Time / Acceleration. Description: *“Example of an acceleration profile” on page 2795*

BufferMode
Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis
Data type: AXIS_REF
Reference to the axis.

Output description

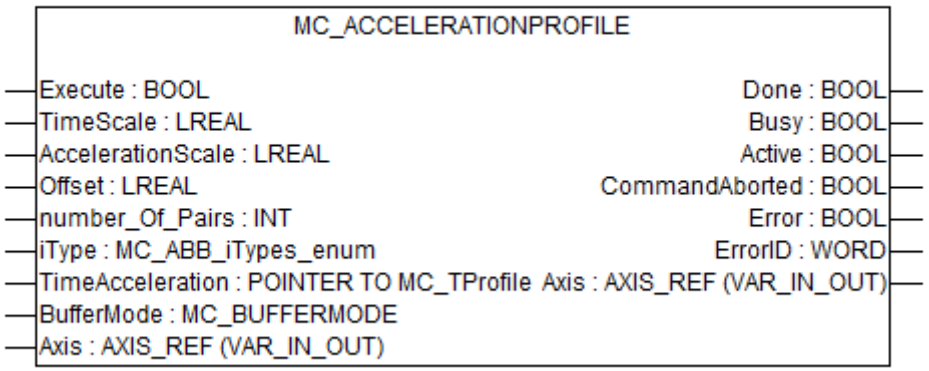

Fig. 342: Function block MC_AccelerationProfile

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

1.5.9.6.2 Multi-Axis function blocks

With Multi-Axis function blocks a synchronized relationship exists between two or more axes. The synchronization can be related to time or position. Often this relationship is between a master axis and one or more slave axes. A master axis can be a virtual axis. From the single axis state diagram point of view, the multi-axis function blocks related to camming and gearing can be looked at as a master axis in one state (for instance: MC_MoveContinuous) and the slave axis in a specific synchronized state, called SychronizedMotion. *Chapter 1.5.9.3.2 “The single axis state diagram” on page 2589*

MC_CamIn

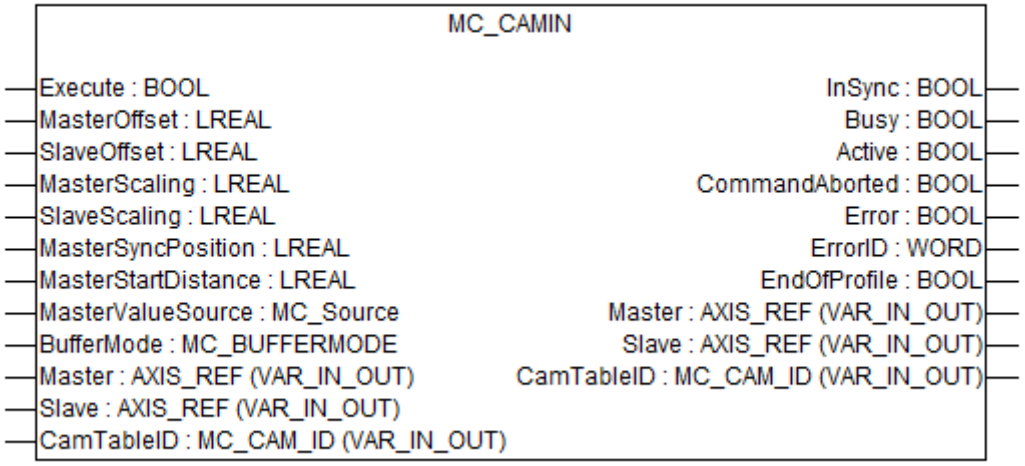

Fig. 343: Function block MC_CamIn

This function block engages the CAM.

- *It is not required that the master is stationary.*
- *If the actual master and slave positions do not correspond to the offset values when MC_CamIn is executed, either an error occurs or the system deals with the difference automatically.*
- *The Cam is placed either absolute or relative to the current master and slave positions.*
  Absolute: The profile between master and slave is seen as an absolute relationship.
  Relative: The relationship between master and slave is in a relative mode.
- *If a cam-table is to be used "relative", the first position has to be =0.*
- *This function block is not merged with the MC_CamTableSelect function block because this separation enables changes on the fly.*
- *A mechanical analogy to a slave offset is a cam welded with additional constant layer thickness. Because of this the slave positions have a constant offset and the offset could be interpreted as axis offset of the master shaft, if linear guided slave tappets are assumed.*

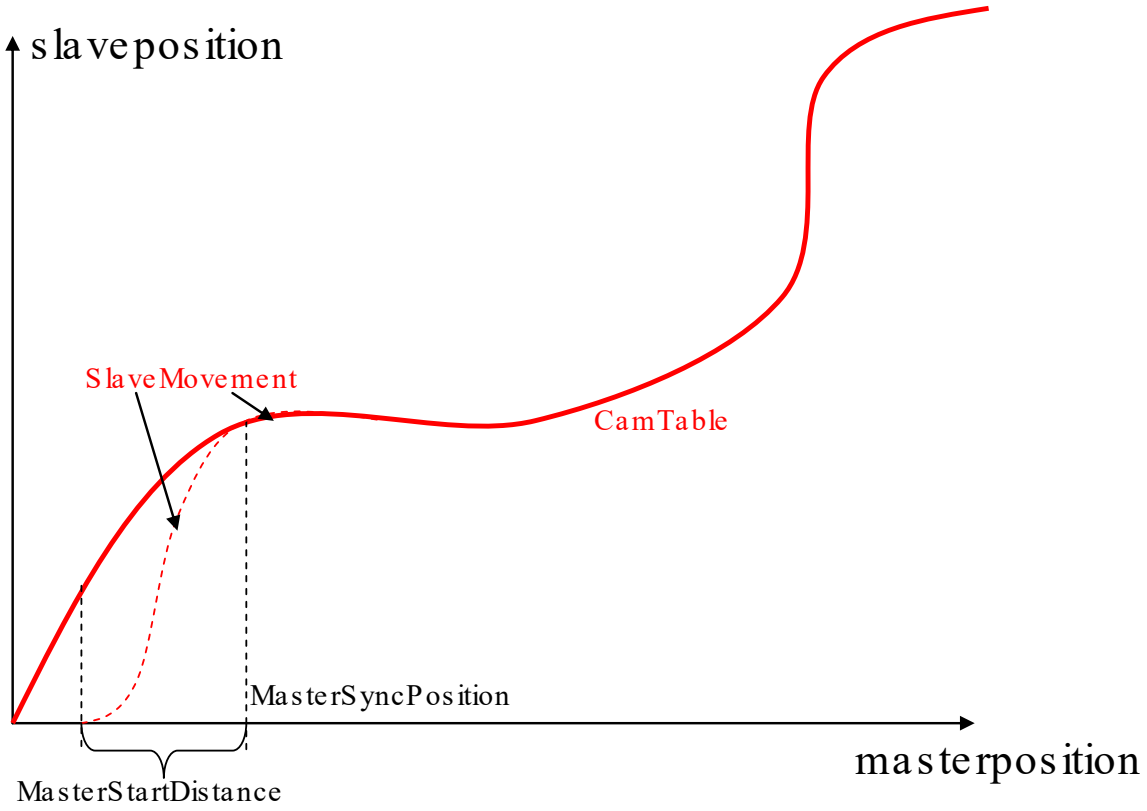
See the following chapter to check if this function block is supported by the used axis implementation: ↬ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↬ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

In case MasterSyncPosition and MasterStartDistance are = 0 (default value), the Cam-Function is started with the rising edge of “Execute”. When the master did not yet reach a position in the cam area, the slave axis is stopped.

With MasterStartDistance <> 0 the slave axis needs to be in state StandStill when activating MC_CamIn. The function block will wait until the master axis reaches the position MasterSyncPosition-MasterStartDistance. The slave will then be started and be synchronized to the CAM table, to the position and velocity which is indicated by the master position MasterSyncPosition.



The MC_CamIn has parameters to scale the cam-table values (MasterScaling, SlaveScaling). It has to be considered that MasterOffset and SlaveOffset are scaled exactly like the corresponding cam-table values. The MasterSyncPosition and MasterStartDistance are not scaled at all, these positions are related to the actual master position whereas the MasterOffset and SlaveOffset are related to the cam-table.

Input description

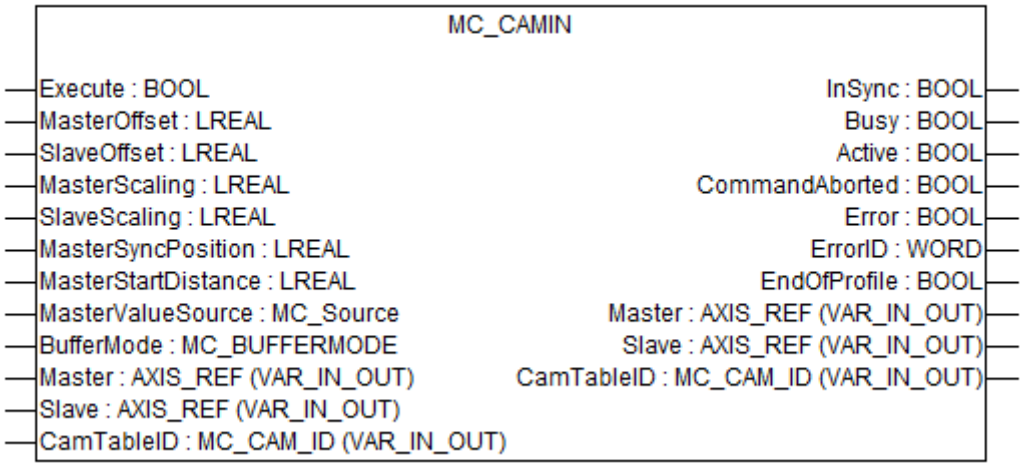


Fig. 344: Function block MC_CamIn

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute

Data type: BOOL

Starts the function block at rising edge.

MasterOffset

Data type: LREAL

Offset of master table. Angular offset of the master shaft to cam.

SlaveOffset

Data type: LREAL, default: 0

Offset of slave table. Sharpened cam (i.e higher elevation and deeper depression).

MasterScaling

Data type: LREAL, default: 1.0

Factor for the master profile. From the slave point of view the master overall profile is multiplied by this factor.

SlaveScaling

Data type: LREAL, default: 1.0

Factor for the slave profile. The overall slave profile is multiplied by this factor.

MasterSyncPosition

Data type: LREAL

The position of the master in the path where the group is insync with the master. (If the ‘MasterSyncPosition’ does not exist, at the first point of the path the master and slave are synchronized).

The inputs acceleration, deceleration and jerk are not added here.

MasterStartDistance

Data type: LREAL

The master distance for the slave to start to synchronize to the master.

MasterValueSource

Data type: MC_SOURCE

Defines the source for synchronization:

mcSetValue - Synchronization on master set value.

mcActualValue - Synchronization on master actual value.

BufferMode

Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Master

Data type: AXIS_REF

Reference to the master axis.

Slave Data type: AXIS_REF
Reference to the slave axis.

CamTableID Data type: MC_CAM_ID
Identifier of CAM Table to be used in the MC_CamIn function block.

Output description

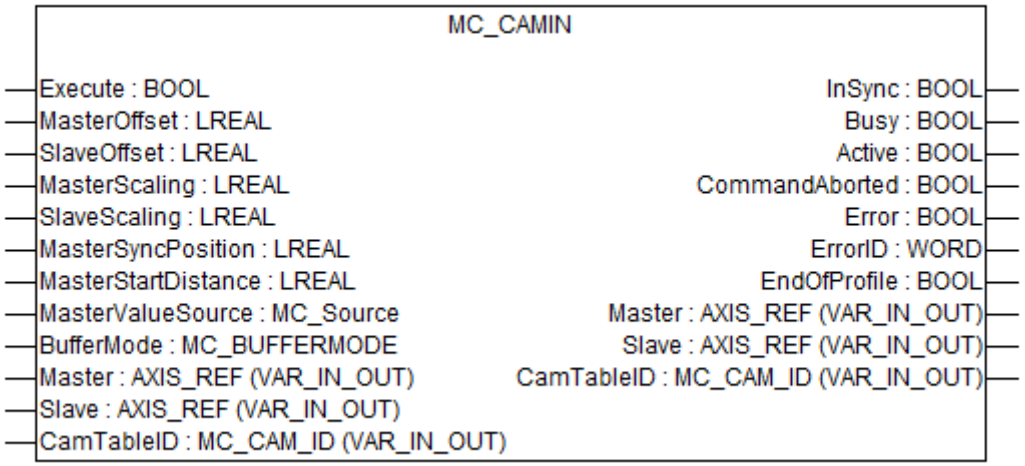

Fig. 345: Function block MC_CamIn

InSync Data type: BOOL
Cam is engaged for the first time.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

EndOfProfile Data type: BOOL

Pulsed output signaling the cyclic end of the CAM Profile.

MC_CamOut

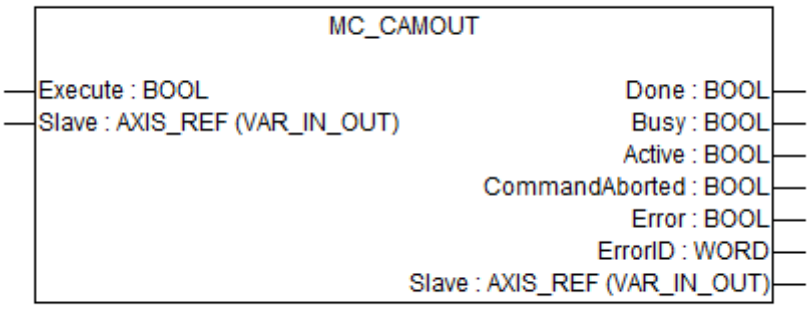

Fig. 346: Function block MC_CamOut

This function block disengages the Slave axis from the Master axis immediately.

> *It is assumed that this command is followed by another command, for instance MC_Stop, MC_GearIn, or any other command. If there is no new command, the default condition should be: Maintain last velocity. If there is no new command the axis will maintain its last velocity.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

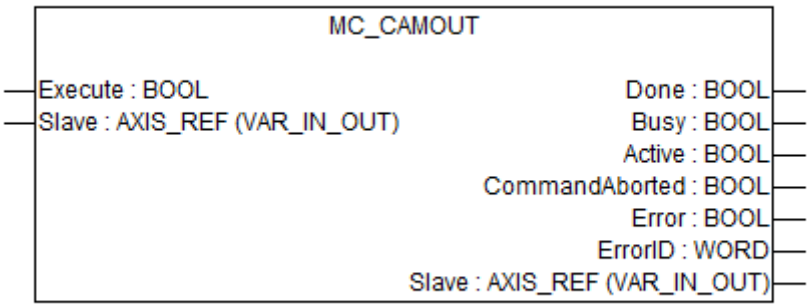

Fig. 347: Function block MC_CamOut

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

Slave Data type: AXIS_REF

Reference to the slave axis.

Output description

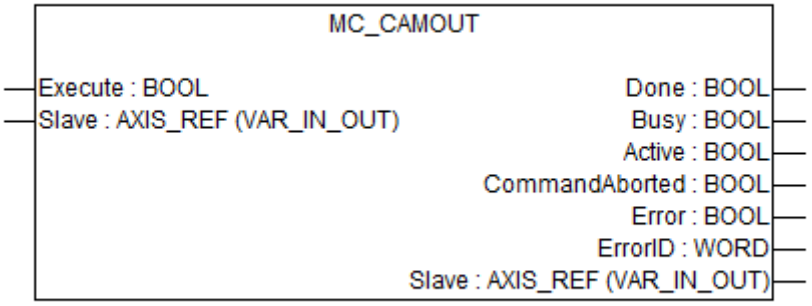

Fig. 348: Function block MC_CamOut

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block with Busy = TRUE has control on the axis.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_GearIn

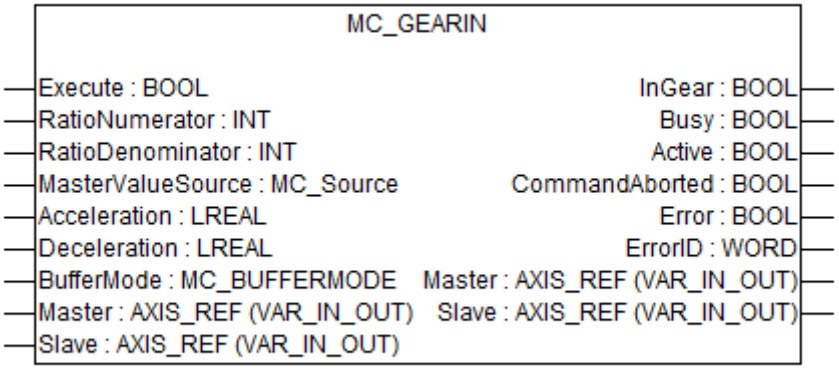

Fig. 349: Function block MC_GearIn

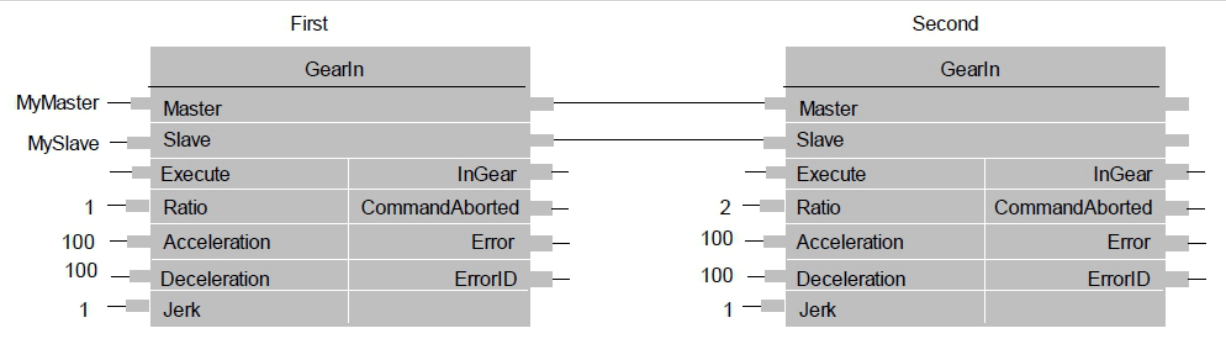
This function block commands a ratio between the VELOCITY of the slave and master axis.

- *The slave ramps up to the ratio of the master velocity and locks in when this is reached. Any lost distance during synchronization is not caught up.*
- *The gearing ratio can be changed while MC_GearIn is running, using a consecutive MC_GearIn command without the necessity to MC_GearOut first*
- *InGear is set the first time the ratio is reached.*
- *After being InGear, a position locking is performed.*

Example



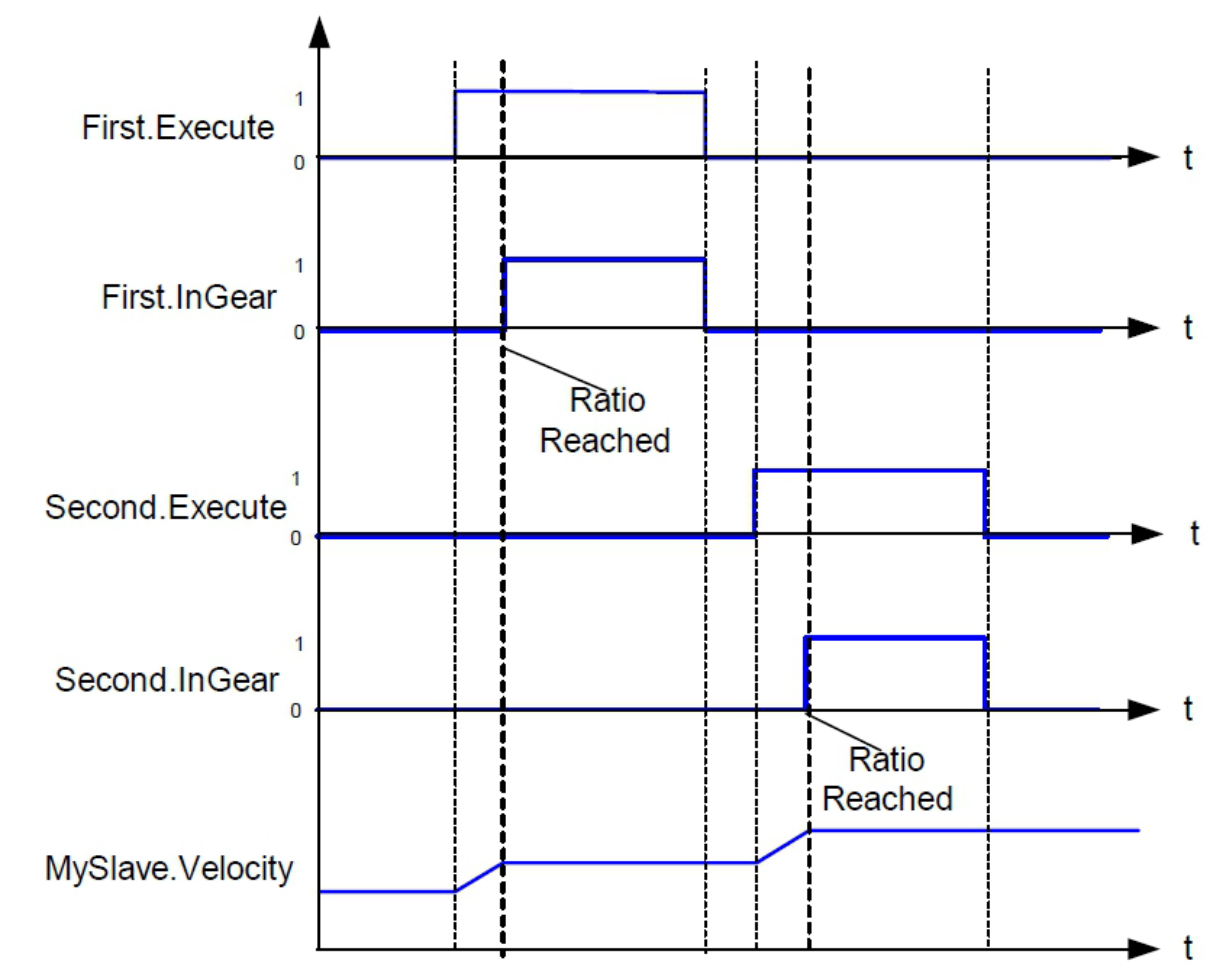


Fig. 350: Gear timing diagram

See the following chapter to check if this function block is supported by the used axis implementation: ↳ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↳ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

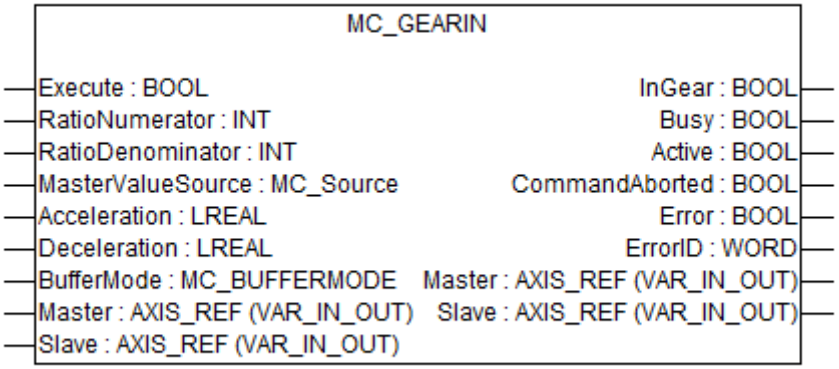

Fig. 351: Function block MC_GearIn

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute
Data type: BOOL
Starts the function block at rising edge.

RatioNumerator
Data type: INT
Gear Ratio Numerator.

RatioDenominator
Data type: INT
Gear Ratio Denominator.

MasterValueSource
Data type: MC_SOURCE
Defines the source for synchronization:
mcSetValue - Synchronization on master set value.
mcActualValue - Synchronization on master actual value.

Acceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk
Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Master Data type: AXIS_REF
Reference to the master axis.

Slave Data type: AXIS_REF
Reference to the slave axis.

Output description

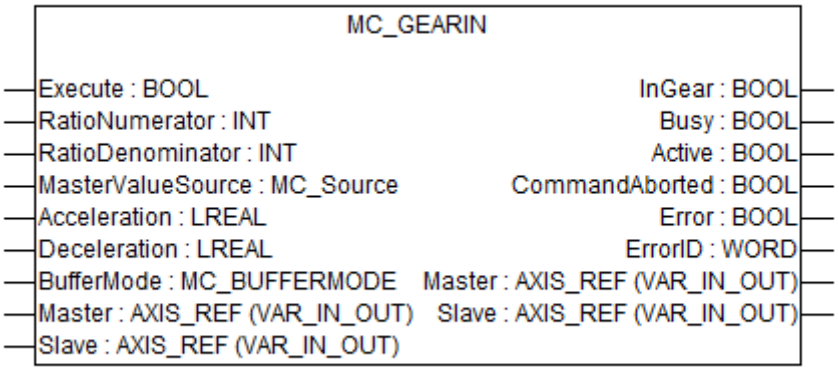

Fig. 352: Function block MC_GearIn

InGear Data type: BOOL
Commanded gearing completed.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_GearInPos

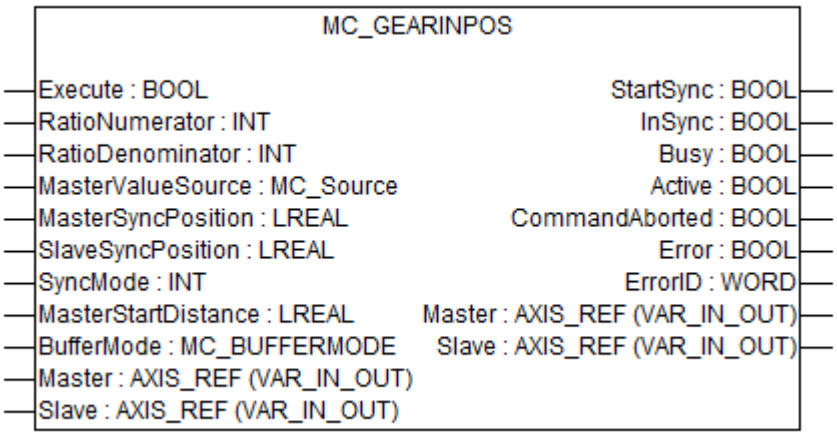

Fig. 353: Function block MC_GearInPos

This function block commands a gear ratio between the position of the slave and master axes from the synchronization point onwards.

- *If MasterStartDistance is implemented, any previous motion is continued until master crosses "MasterSyncPosition – MasterStartDistance" in the correct direction (according to the sign of MasterStartDistance). At that point in time the output StartSync is set. When a "Stop" command is executed on the "Slave" axis before the synchronization has happened, it inhibits the synchronization and the Function Bock issues "CommandAborted".*
- *If the MasterStartDistance is not specified, the system itself could calculate the set point for StartSync based on the other relevant inputs.*

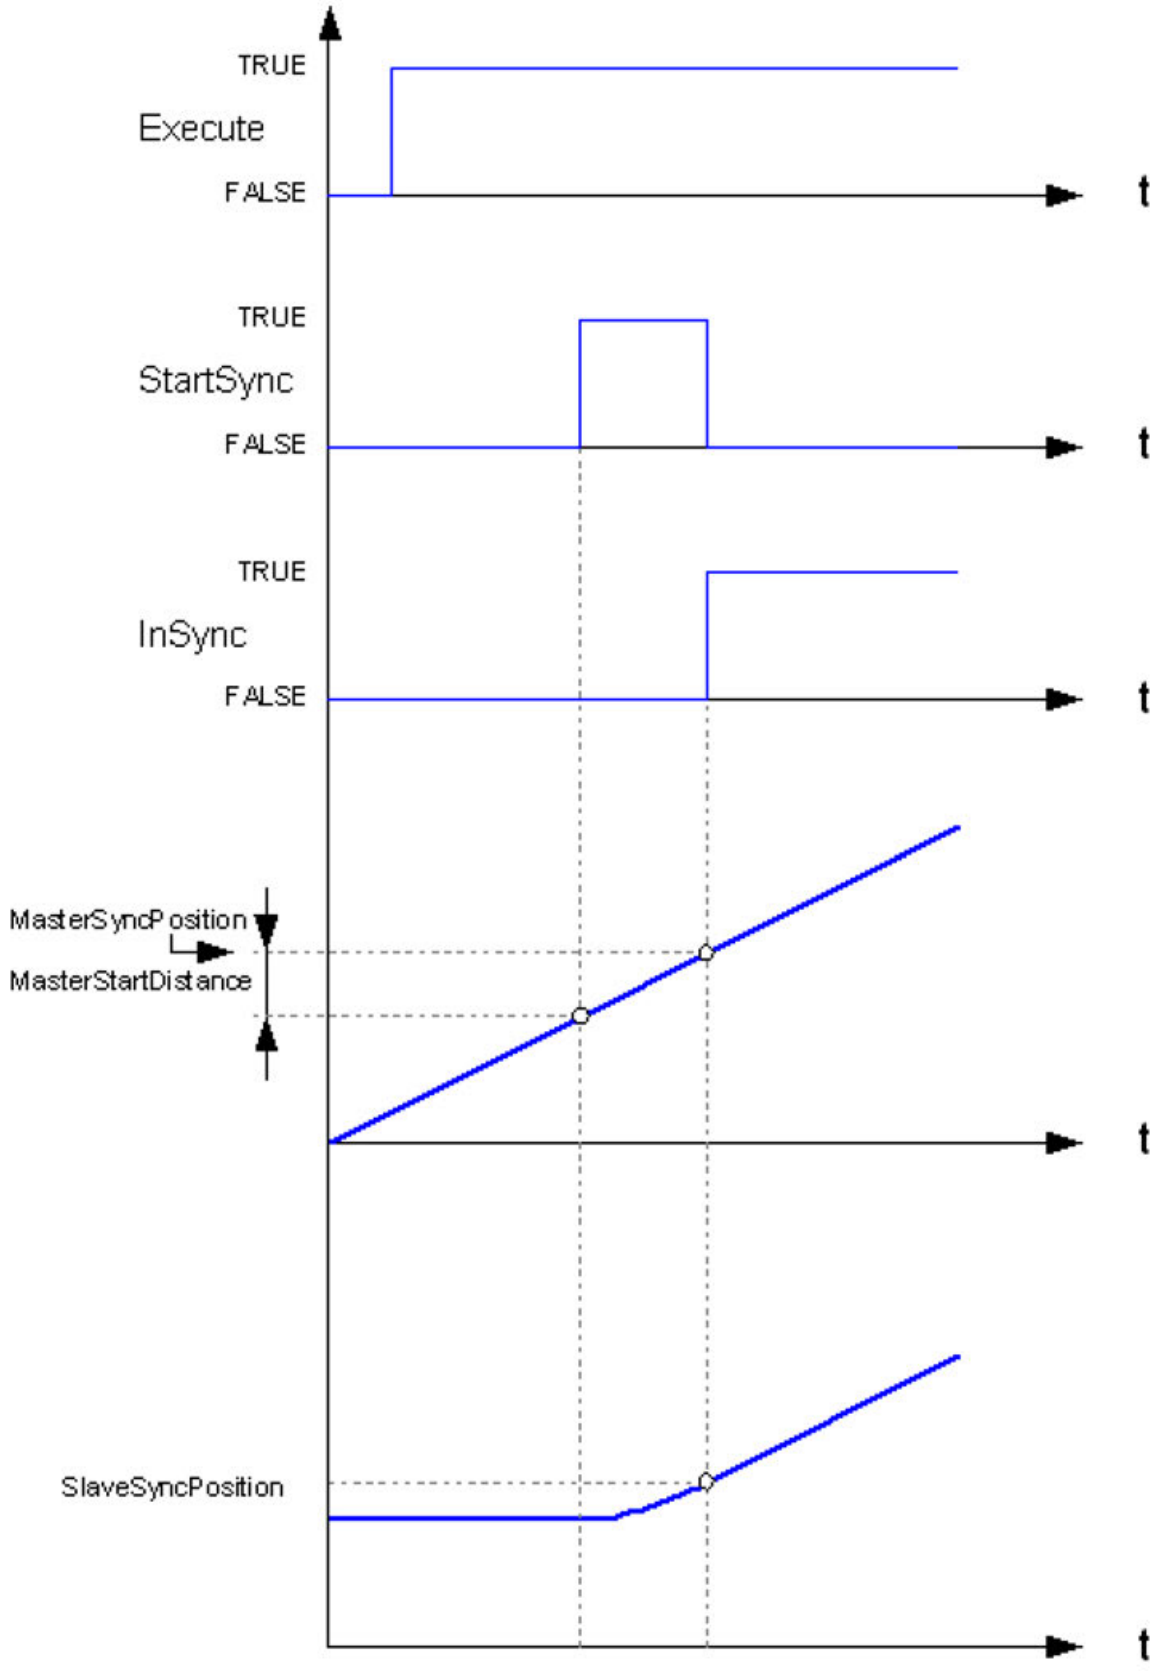

Fig. 354: Timing Diagram of MC_GearInPos

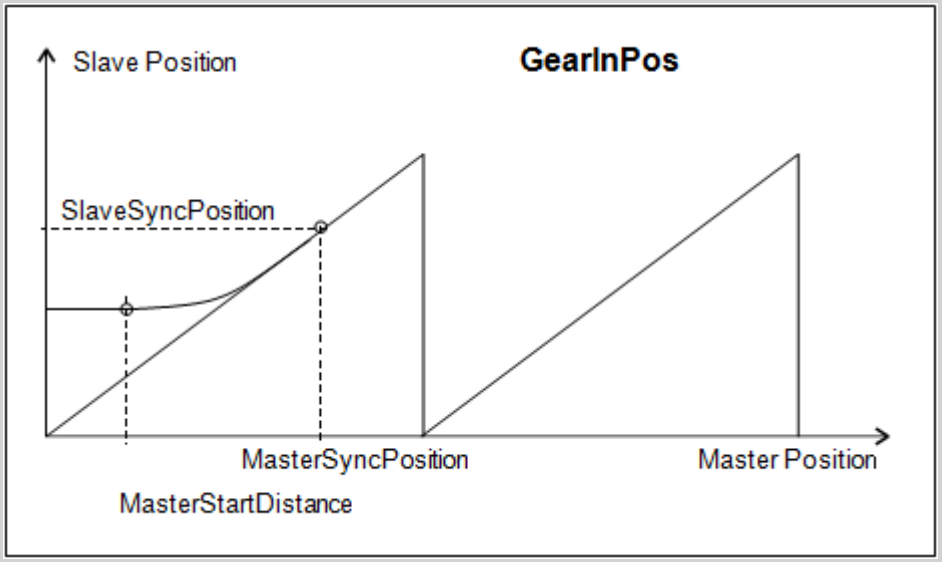
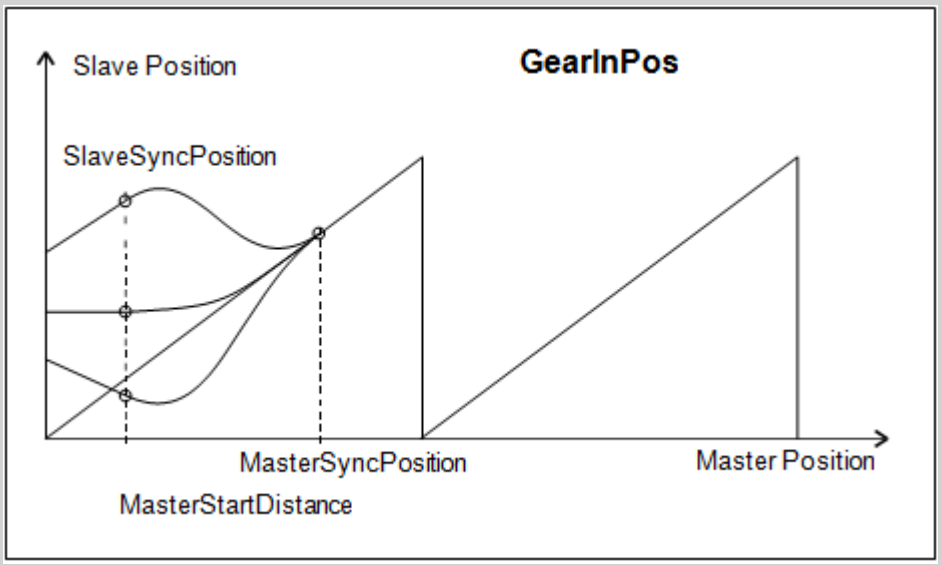
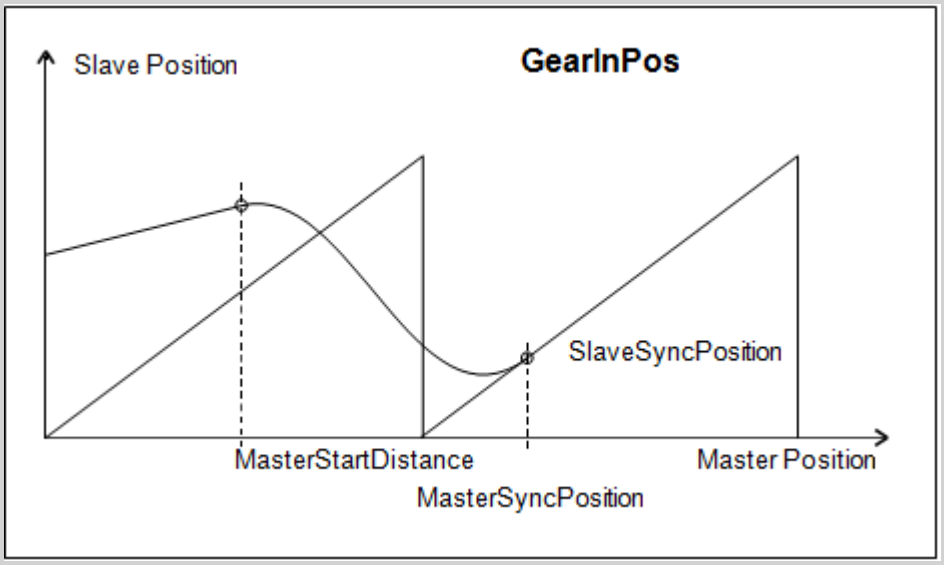
Different examples of MC_GearInPos







Input description

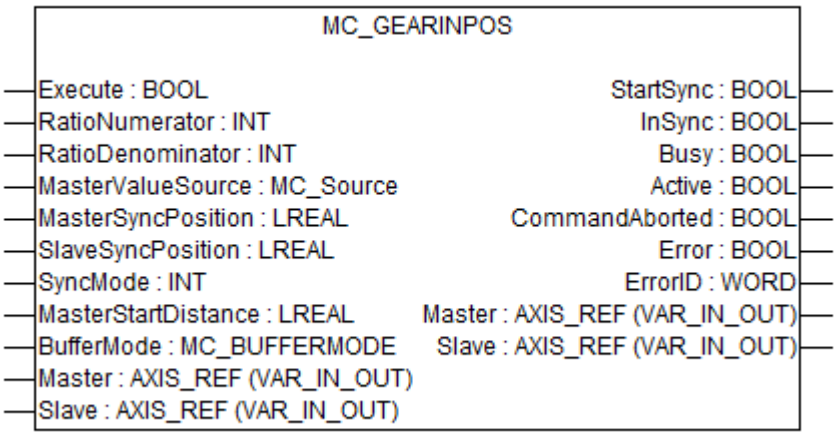


Fig. 355: Function block MC_GearInPos

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute

Data type: BOOL

Starts the function block at rising edge.

RatioNumerator

Data type: INT

Gear Ratio Numerator.

RatioDenominator

Data type: INT

Gear Ratio Denominator.

MasterValueSource

Data type: MC_SOURCE

Defines the source for synchronization:

mcSetValue - Synchronization on master set value.

mcActualValue - Synchronization on master actual value.

MasterSyncPosition

Data type: LREAL

The position of the master in the path where the group is insync with the master. (If the ‘MasterSyncPosition’ does not exist, at the first point of the path the master and slave are synchronized).

> *The inputs acceleration, deceleration and jerk are not added here.*

SlaveSyncPosition Data type: LREAL

Slave Position at which the axes are running in sync.

SyncMode Data type: INT

This function block does not support different modes. Synchronization direction is determined by the sign of MasterStartDistance.

MasterStartDistance Data type: LREAL

The master distance for the slave to start to synchronize to the master.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Master Data type: AXIS_REF

Reference to the master axis.

Slave Data type: AXIS_REF

Reference to the slave axis.

Output description

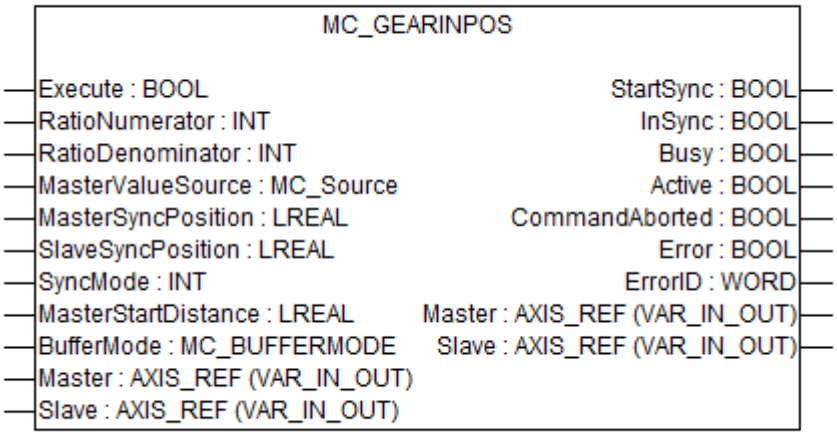

Fig. 356: Function block MC_GearInPos

StartSync Data type: BOOL

Commanded gearing starts.

InSync Data type: BOOL

Commanded gearing completed.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_GearOut

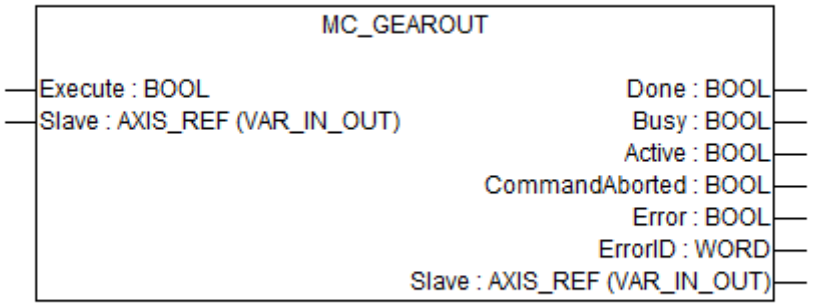

Fig. 357: Function block MC_GearOut

This function block disengages the Slave axis from the Master axis.

- *It is assumed that this command is followed by another command, for instance MC_Stop, MC_GearIn, or any other command. If there is no new command, the default condition should be: maintain last velocity.*
- *After issuing the function block there is no function block active on the slave axis till the next function block is issued (what can result in problems because no motion command is controlling the axis). Alternatively, one can read the actual velocity via MC_ReadActualVelocity and issue MC_MoveVelocity on the slave axis with the actual velocity as input. The function block is here because of compatibility reasons.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

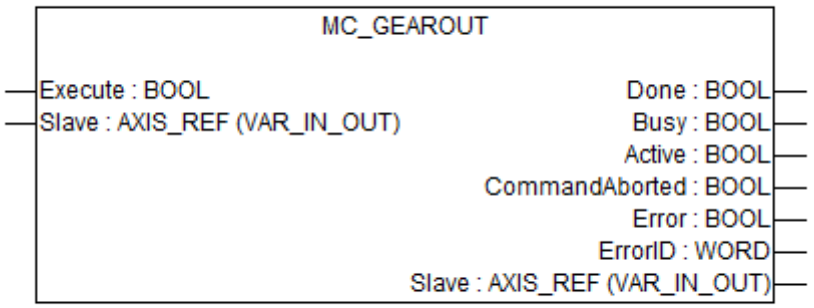

Fig. 358: Function block MC_GearOut

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

Slave Data type: AXIS_REF

Reference to the slave axis.

Output description

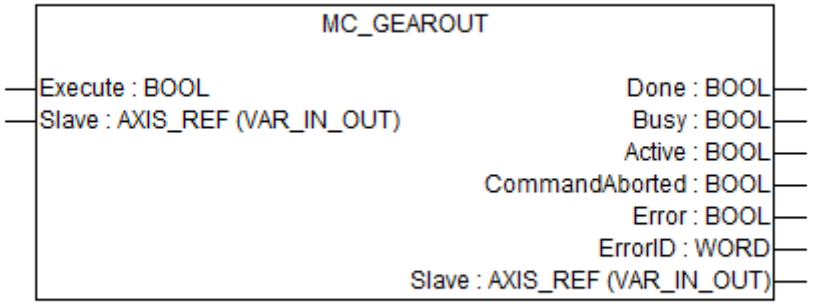

Fig. 359: Function block MC_GearOut

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_PhasingAbsolute

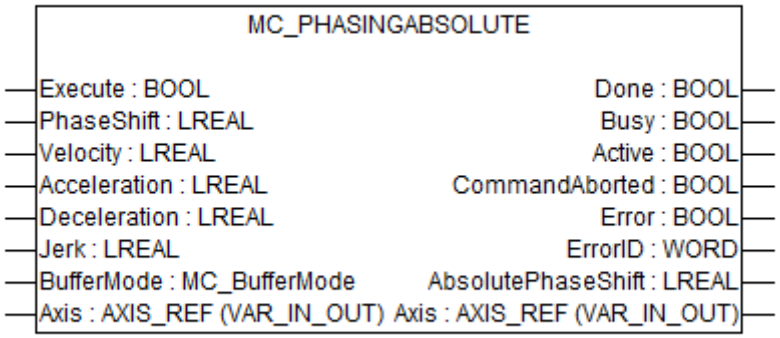

Fig. 360: Function block MC_PhasingAbsolute

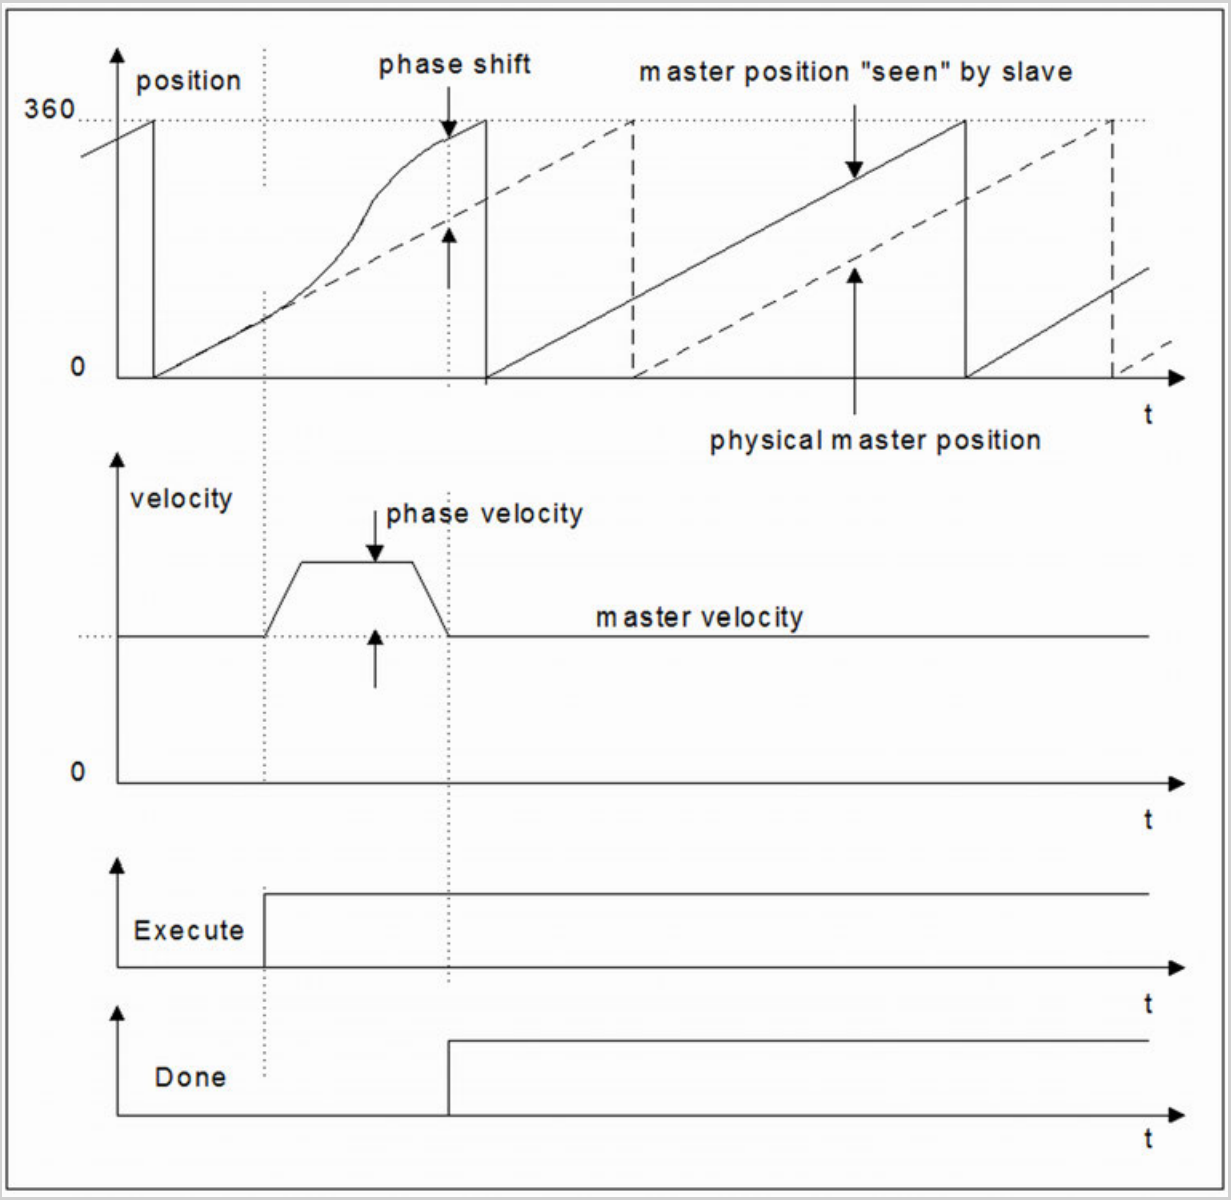
This function block creates an absolute phase shift in the master position of a slave axis. The master position is shifted in relation to the real physical position. This is analogous to opening a coupling on the master shaft for a moment, and is used to delay or advance an axis to its master. The phase shift is seen from the slave. The master does not know that there is a phase shift experienced by the slave. The phase shift remains until another "Phasing" command changes it again.

Phase, Velocity, Acceleration, Deceleration and Jerk of a phase shift are controlled by the function block.

Timing example of MC_Phasing



The following graph shows the effect of "Phasing".

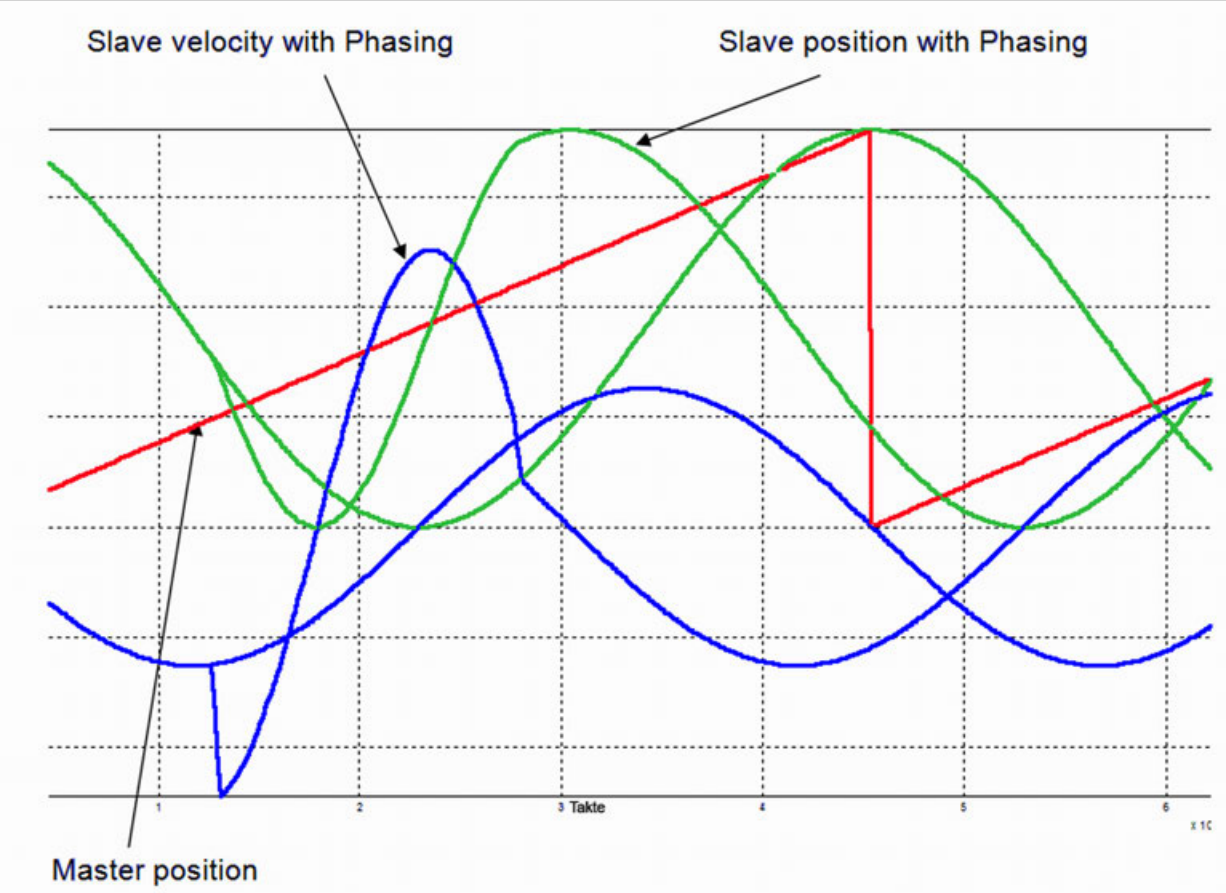


Fig. 361: Example of MC_Phasing

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 "Overview of PLCopen function blocks" on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 "Overview of data types" on page 2585*

Input description

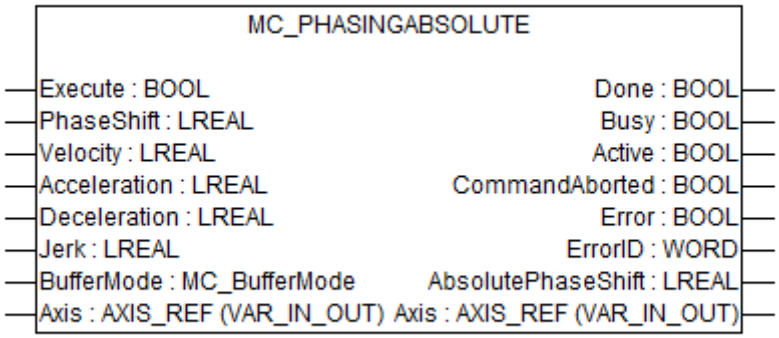

Fig. 362: Function block MC_PhasingAbsolute

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute Data type: BOOL
Starts the function block at rising edge.

PhaseShift Data type: LREAL, unit: u
Absolut phase difference in master.

Velocity Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

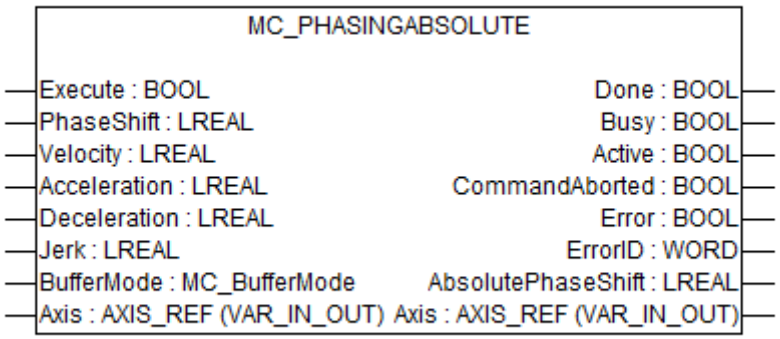

Fig. 363: Function block MC_PhasingAbsolute

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

AbsolutePhaseShift Data type: LREAL
Displays the covered distance since it was started continuously.

MC_PhasingRelative

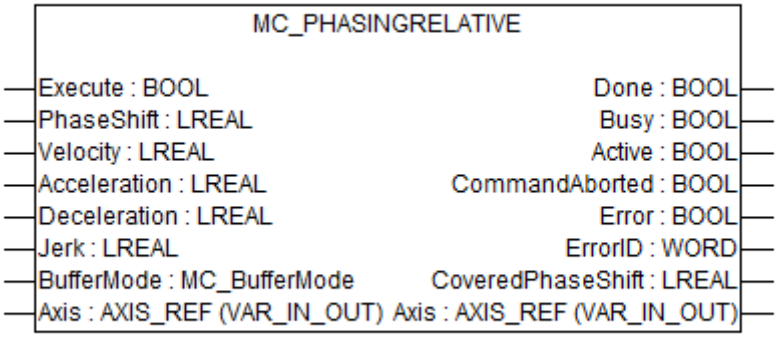

Fig. 364: Function block MC_PhasingRelative

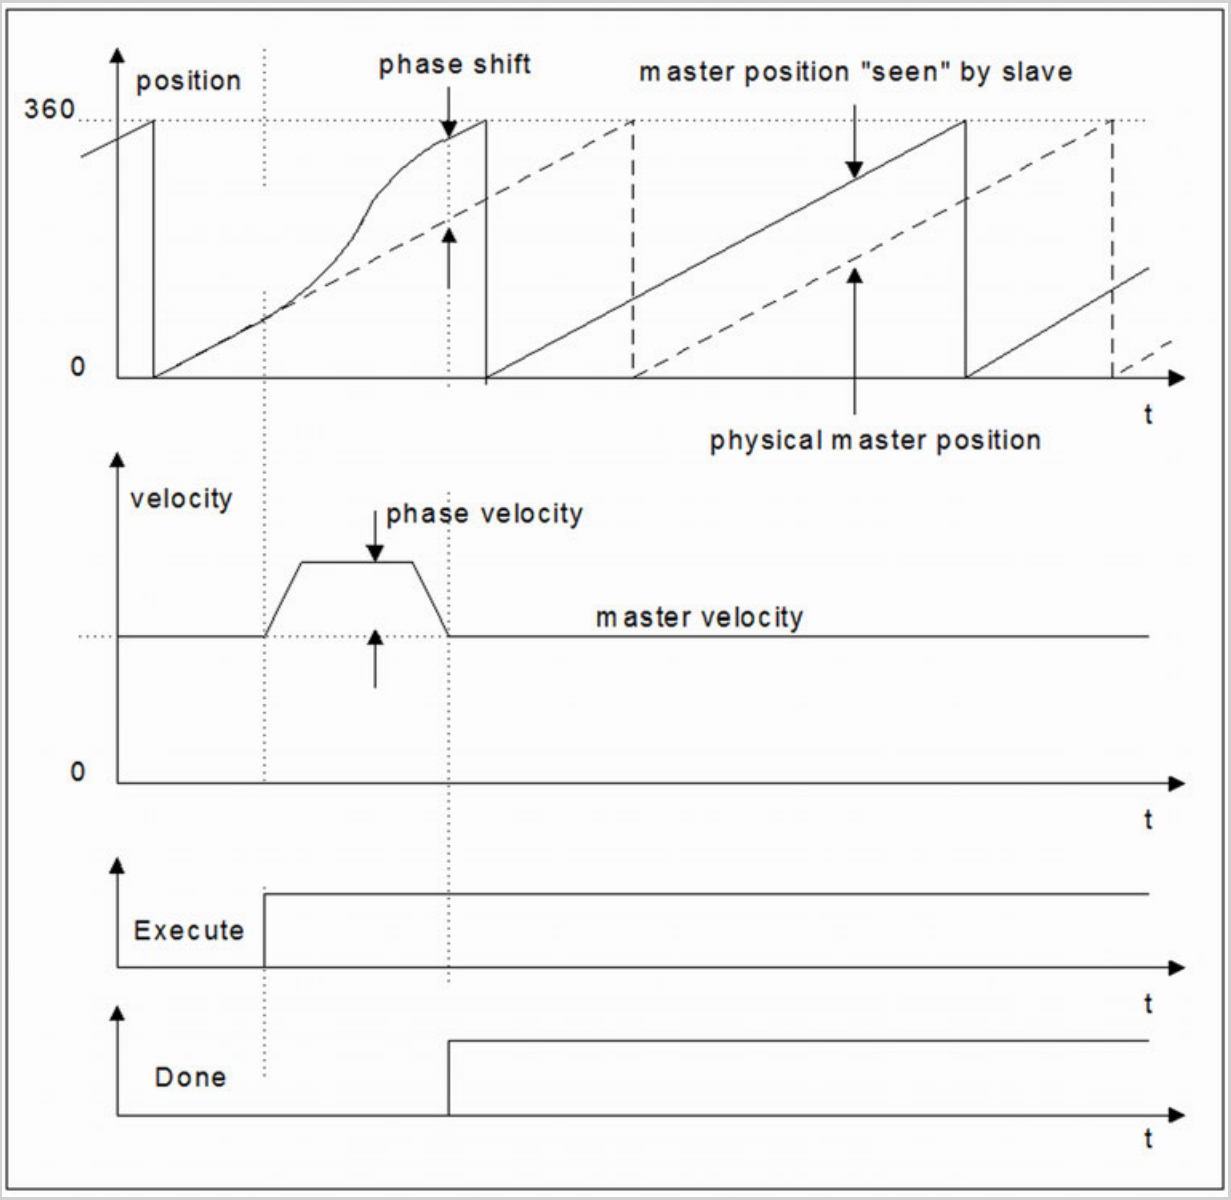
This function block creates a relative phase shift in the master position of a slave axis. The master position is shifted in relation to the real physical position. This is analogous to opening a coupling on the master shaft for a moment, and is used to delay or advance an axis to its master. The phase shift is seen from the slave. The master does not know that there is a phase shift experienced by the slave. The phase shift remains until another "Phasing" command changes it again.

> *Phase, Velocity, Acceleration, Deceleration and Jerk of a phase shift are controlled by the function block.*

Timing example of MC_Phasing



The following graph shows the effect of "Phasing".

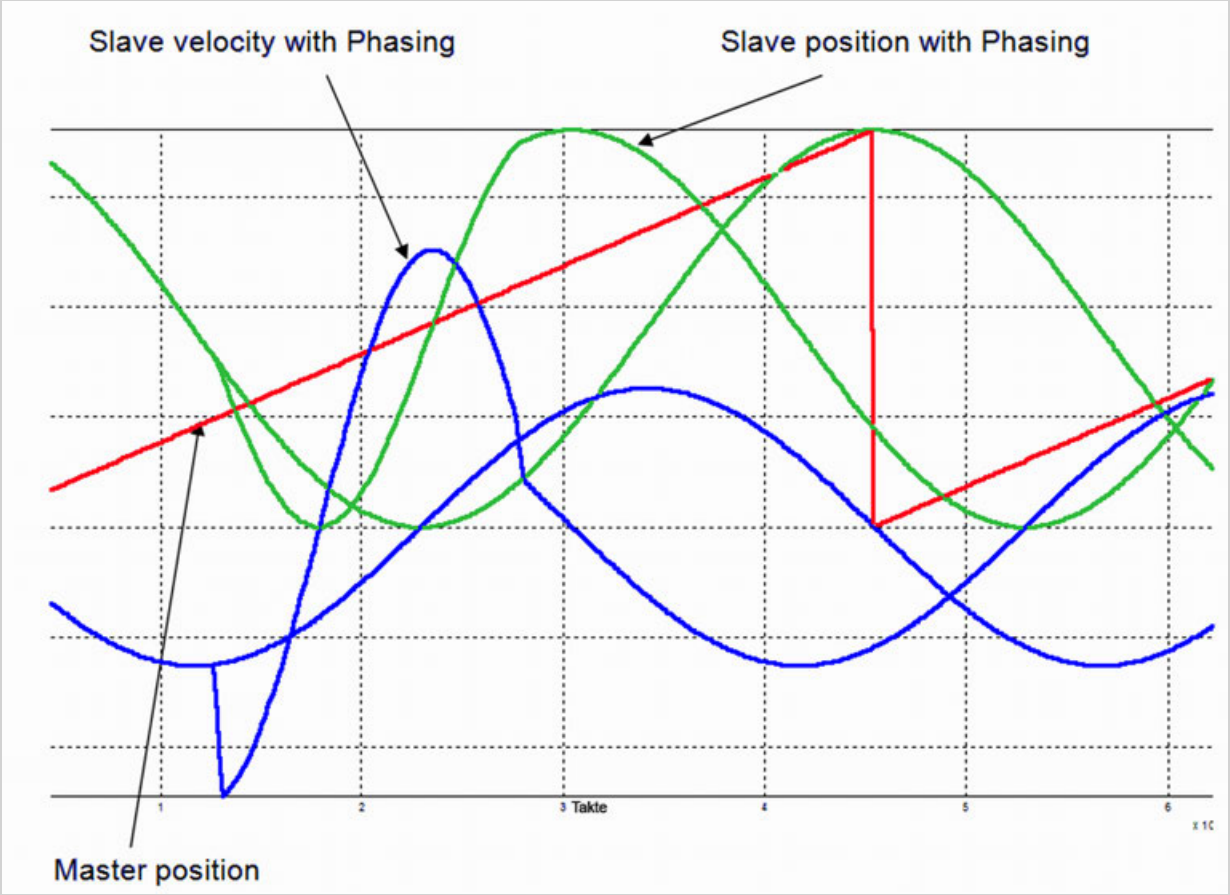


Fig. 365: Example of MC_Phasing

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 "Overview of PLCopen function blocks" on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 "Overview of data types" on page 2585*

Input description

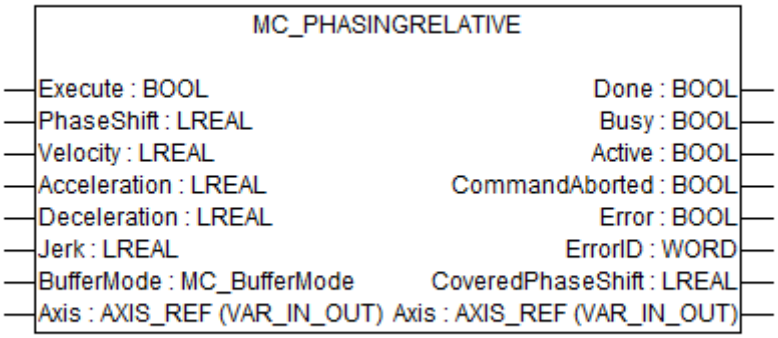

Fig. 366: Function block MC_PhasingRelative

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute Data type: BOOL
Starts the function block at rising edge.

PhaseShift Data type: LREAL, unit: u
Absolut phase difference in master.

Velocity Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

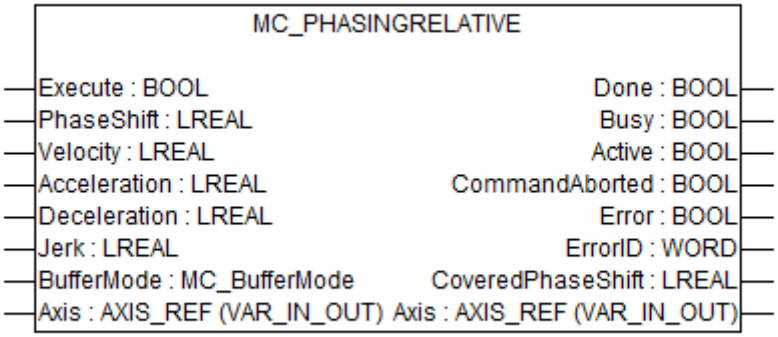

Fig. 367: Function block MC_PhasingRelative

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

CoveredPhaseShift Data type: LREAL
Displays the covered distance since it was started continuously.

MC_CombineAxes

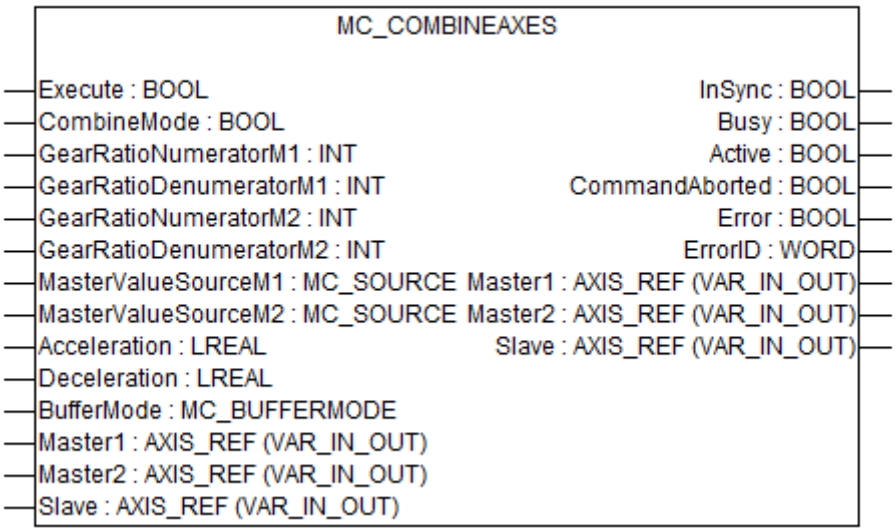

Fig. 368: Function block MC_CombineAxes

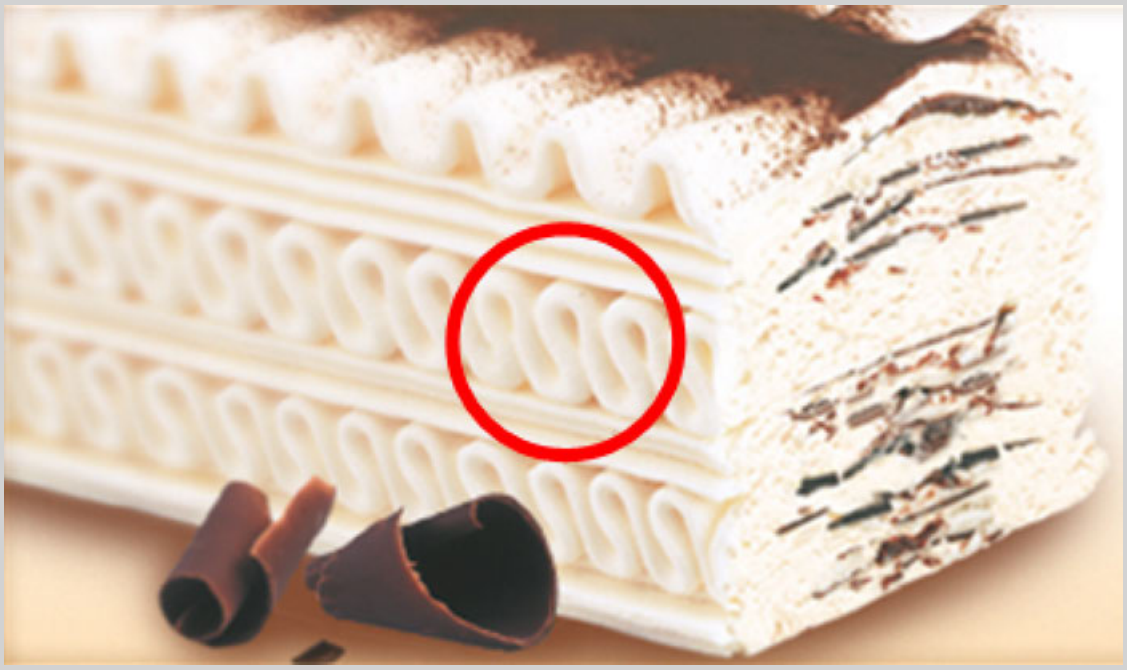
This function block combines the motion of 2 axes into a third axis with selectable combination method. Basically, it is a calculation of a new position setpoint based on the 2 position setpoints of the input axes. This function block is reflected in the single axis state diagram like a Synchronized Motion type. As application example one can work with a separate profile synchronized to an object on a moving belt, or a rotating knife with flexible covered distance to be cut.

To stop the motion, the function block has to be interrupted by another function block issuing a new command.

This block has to be called from the same task as CMC_MOTION_KERNEL_REAL.

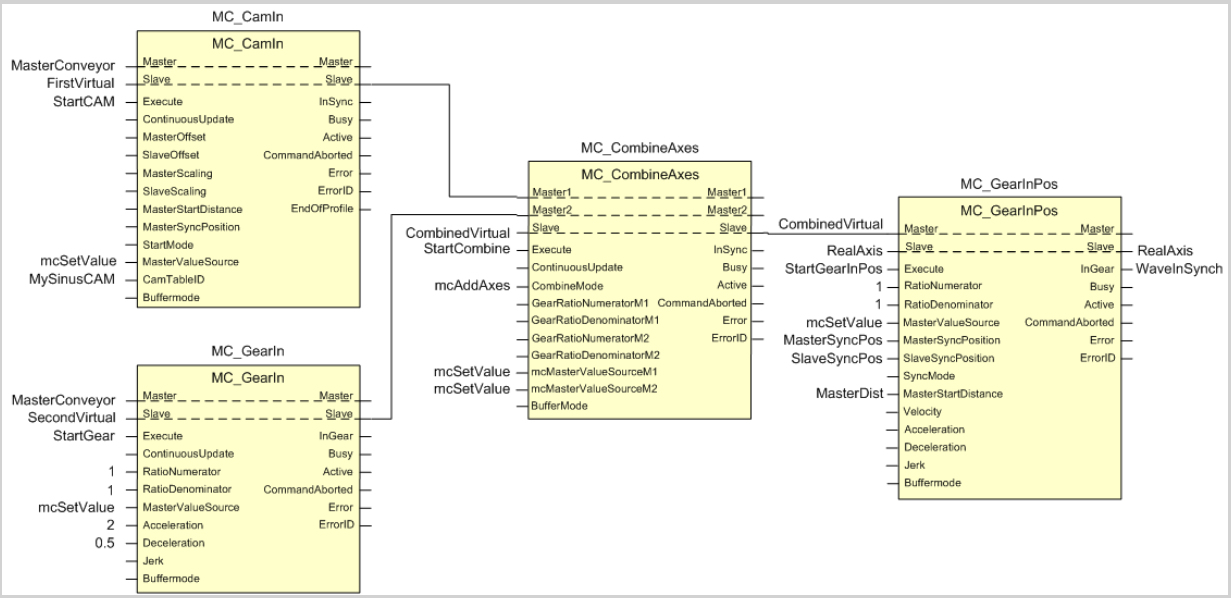
Example ice cream



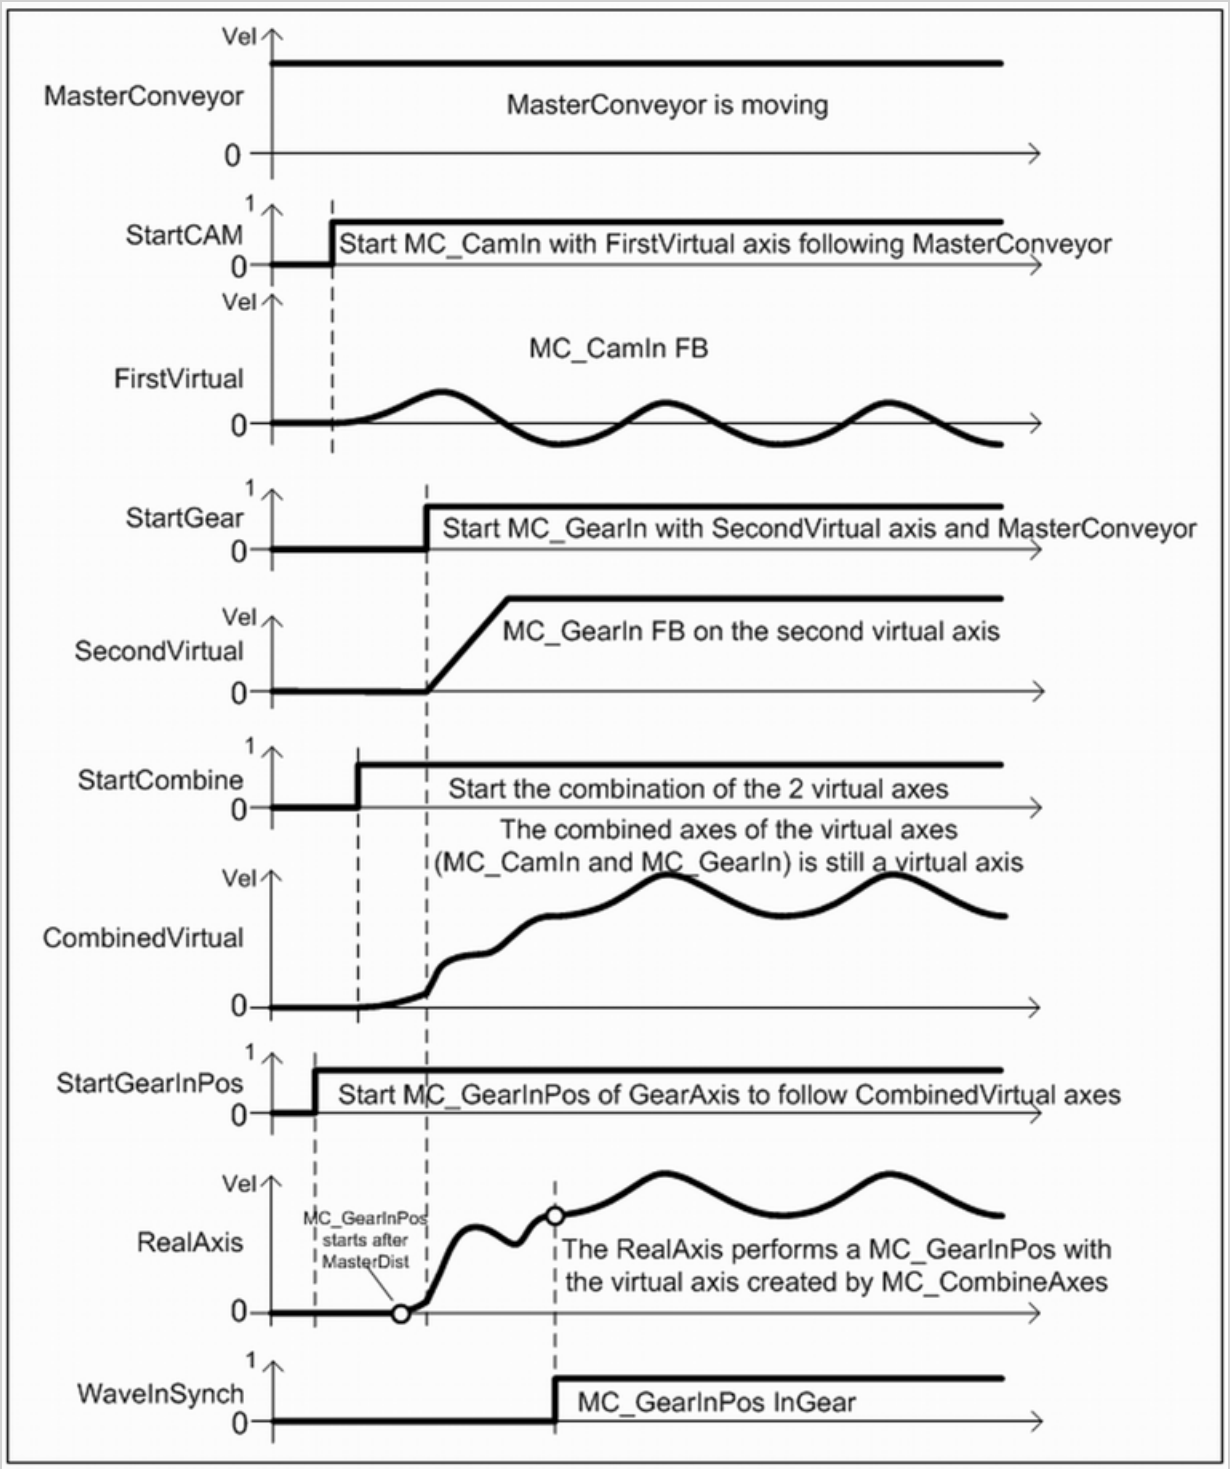
MC_CombineAxes can generate special synchronized movements that are not possible or complex to generate in other ways. In the following example, a CAM function block and the result of a Gear function block are both synchronized to a conveyor master, are added to generate a virtual master for a MC_GearInPos function of the final axis that will execute the movement. The particular application of this example could be a machine to deposit the icecream waving layers on top of the icecream base travelling through the freezer line in icecream factory. The dosing axis has to synchronize with a waving manner to the conveyor carrying the icecream base block. And it has to do this in a particular starting position and wave phase to achieve the expected result (therefore the GearInPos). With the CAM function block one can define different wave patterns easily (like the one longer in the top of icecream).

Another case application can be chocolate bars with decoration (individual bars in mouldings). The dosificator makes the wave synchronized with conveyor and returns for the next.

Application example of MC_CombineAxes



The corresponding timing diagram for MC_CombineAxes example



See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

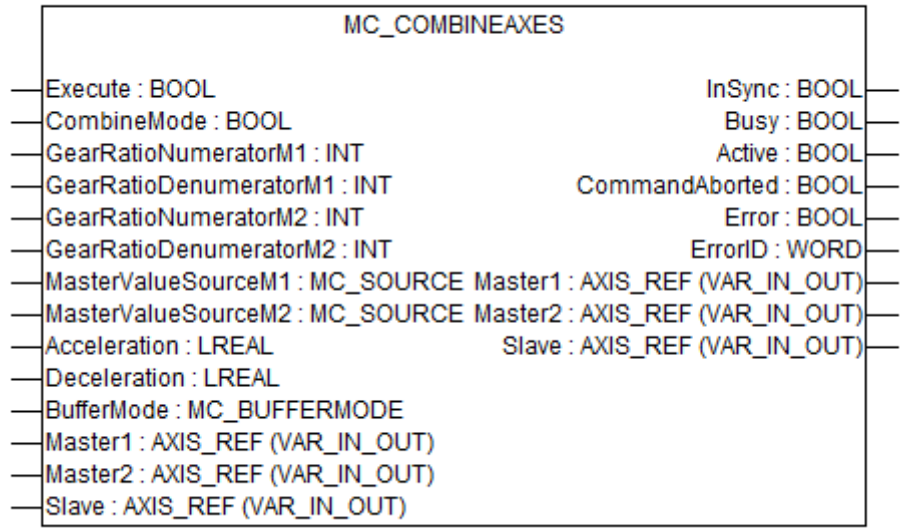


Fig. 369: Function block MC_CombineAxes

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute
Data type: BOOL
Starts the function block at rising edge.

CombineMode
Data type: BOOL
Defines the type of combination applied to AxisOut:
FALSE: Addition of the 2 input axes positions
TRUE: Substraction of the 2 input axes positions.

GearRatioNumeratorM1
Data type: INT
Numerator for the gear factor for master axis 1 towards the slave.

GearRatioDenominatorM1
Data type: INT
Corresponding denominator for master axis 1.

GearRatioNumeratorM2
Data type: INT
Numerator for the gear factor for master axis 2 towards the slave.

GearRatioDenominatorM2
Data type: INT
Corresponding denominator for master axis 2.

MasterValueSourceM1
Data type: MC_SOURCE
Defines the source for synchronization for master axis 1:
mcSetValue: Synchronization on master set value.
mcActualValue. Synchronization on master actual value .

MasterValueSourceM2
Data type: MC_SOURCE
Defines the source for synchronization for master axis 2:
mcSetValue: Synchronization on master set value.
mcActualValue: Synchronization on master actual value .

BufferMode
Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Master1
Data type: AXIS_REF
Reference to the first master axis.

Master2
Data type: AXIS_REF
Reference to the second master axis.

Slave
Data type: AXIS_REF
Reference to the resulting combined axis. Can be a virtual axis or linked directly to a real axis.

Output description

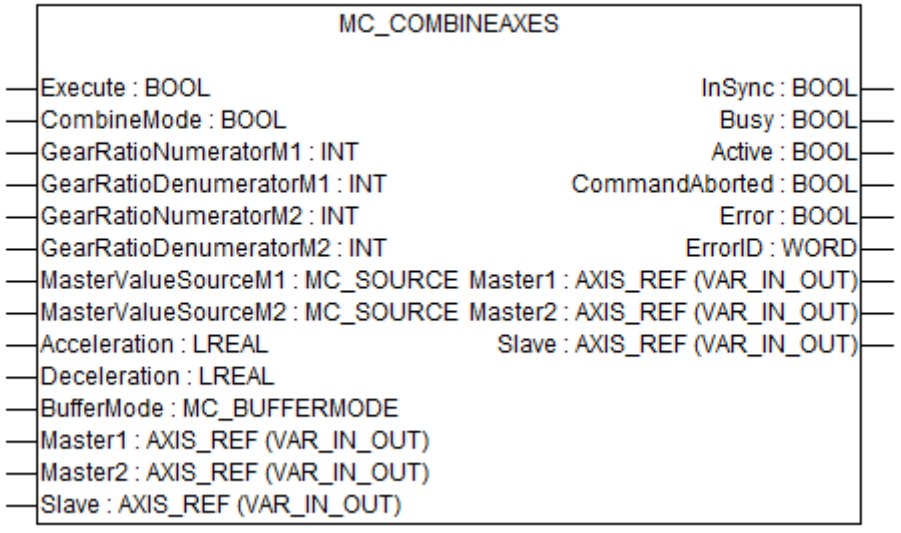

Fig. 370: Function block MC_CombineAxes

InSync Data type: BOOL
Is TRUE if the set value = the commanded value.

Busy Data type: BOOL
The function block is not finished and new output values are to be expected.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

1.5.9.6.3 Administrative function blocks

MC_CamTableSelect

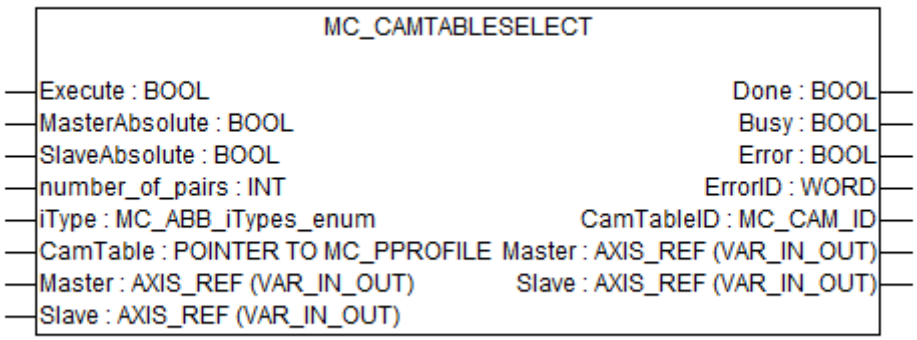

Fig. 371: Function block MC_CamTableSelect

This function block selects the CAM tables by setting the connections to the relevant tables.

- *A virtual axis can be used as master axis.*
- *MC_PPROFILE is an ABB specific data type.*
- ***CamTableSelect makes data available. This can include:***
  - *Starting point of a download of a profile.*
  - *Start to generate a CAM profile.*
  - *PC – based : No function. It is referenced by a pointer.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

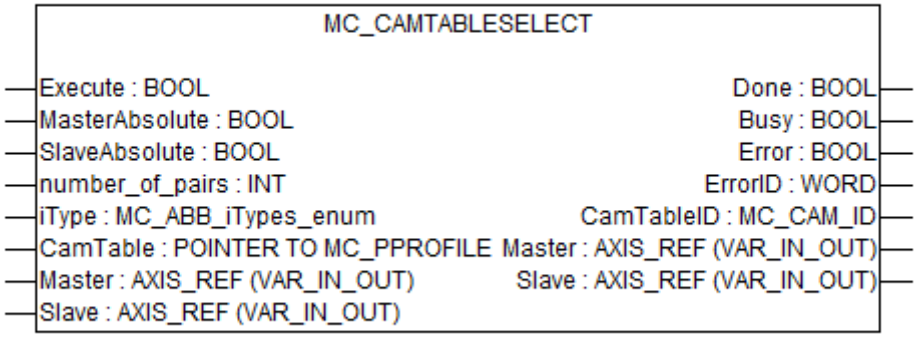

Fig. 372: Function block MC_CamTableSelect

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

MasterAbsolute Data type: BOOL

1=absolute

0 = relative coordinates

SlaveAbsolute Data type: BOOL

1=absolute

0 = relative coordinates

Number_of_pairs Data type: INT

Number of points used in CamTableTimeAcceleration array.

iTYPE Data type: MC_ABB_iTypes_ENUM

Interpolationtype, possible values are:

- MCA_SPLINE_COMPLETE
- MCA_SPLINE_NATURAL
- MCA_POLY5
- MCA_POLY3
- MCA_LINEAR

CamTable Data type: POINTER TO MC_PPROFILE

Reference to CAM description.

Master Data type: AXIS_REF

Reference to the master axis.

Slave Data type: AXIS_REF

Reference to the slave axis.

Output description

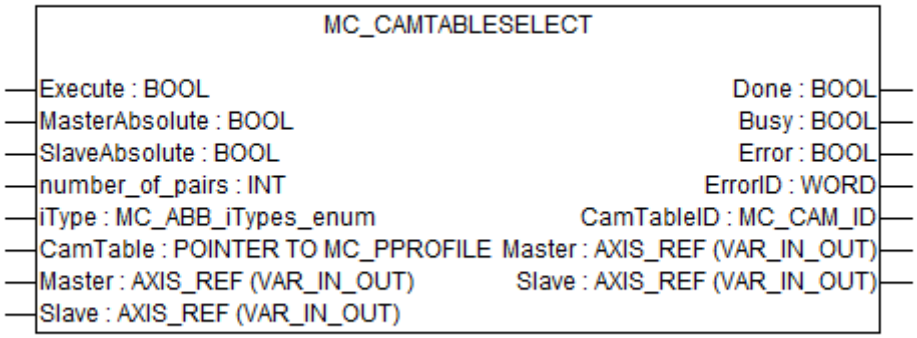

Fig. 373: Function block MC_CamTableSelect

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block with Busy = TRUE has control on the axis.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

CamTableID Data type: MC_CAM_ID

Identifier of CAM Table to be used in the MC_CamIn function block.

MC_Power

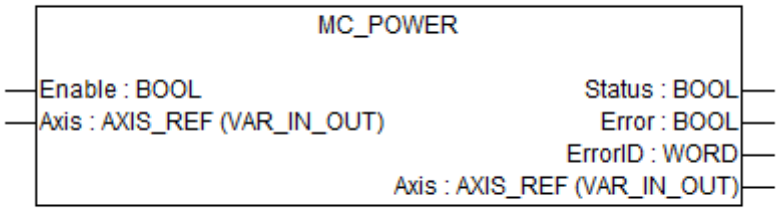

Fig. 374: Function block MC_Power

Table 190: General information

Available as of runtime system	V2.2
Included in library	MC_Block_AC500_V11.lib
Type	Function block with historical values

This function block controls the power stage (on or off). If this function block is called with Enable=TRUE while being in Disabled, this either leads to StandStill if there is no error inside the axis or to ErrorStop if an error exists.

- *If the function block MC_Power is called with the Enable true while being in Disabled, this either leads to Standstill if there is no error in the axis, or to ErrorStop if an Error exists.*
- *It is possible to set an error variable when the Command is TRUE for a while and the Status remains FALSE with a Timer function block and an AND Function (with inverted Status input). It indicates that there is a hardware problem with the power stage.*
- *If power fails (also during operation) it will generate a transition to the state ErrorStop.*
- *When MC_Power is called with Enable FALSE the axis goes to state Disabled for every state including ErrorStop.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Using this function block with FM562 Input variable AXIS of MC_Power must be the same with input variable AXIS of PTO_FM562_ACCESS. Therefore, the specific axis information contained in AXIS_REF structure can be transferred from PLCopen Library to PTO Library and then to FM562 IO mapping.

Input description

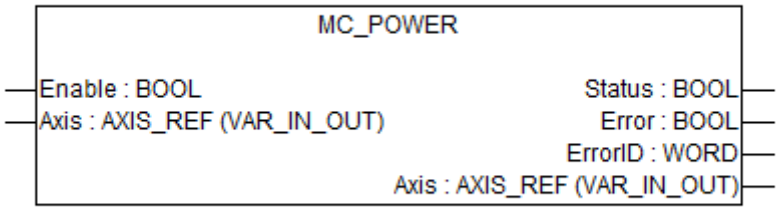

Fig. 375: Function block MC_Power

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

As long as Enable = TRUE, power is on.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

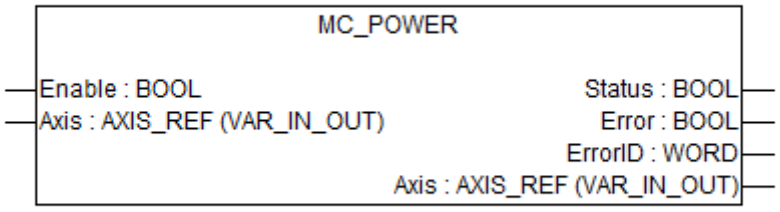

Fig. 376: Function block MC_Power

Status Data type: BOOL

Effective state of the power stage.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_ReadStatus

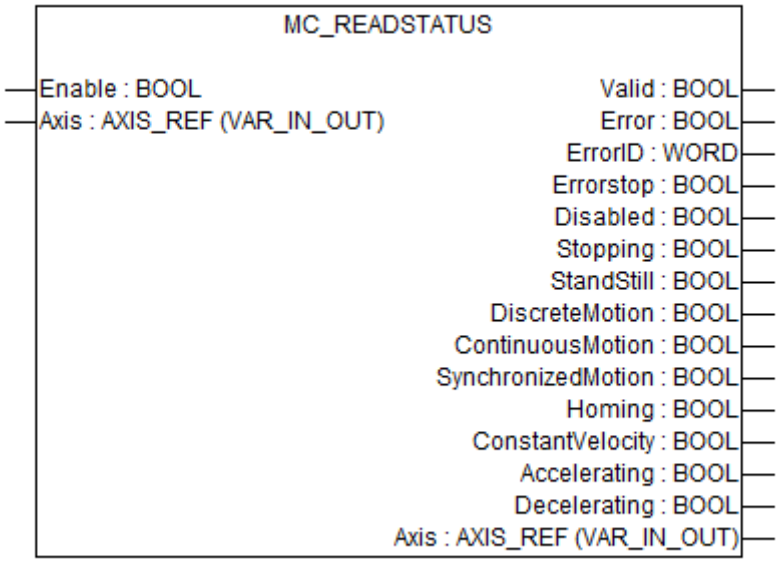

Fig. 377: MC_ReadStatus

This function block returns in detail the status of the axis with respect to the motion currently in progress.

See the following chapter to check if this function block is supported by the used axis implementation: ↳ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↳ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Using this function block with FM562

Output SynchronizedMotion: Not implemented

Output Homing: Not implemented

Output ConstantVelocity: Not implemented

Output Accelerating: Not implemented

Output Decelerating: Not implemented

Input description

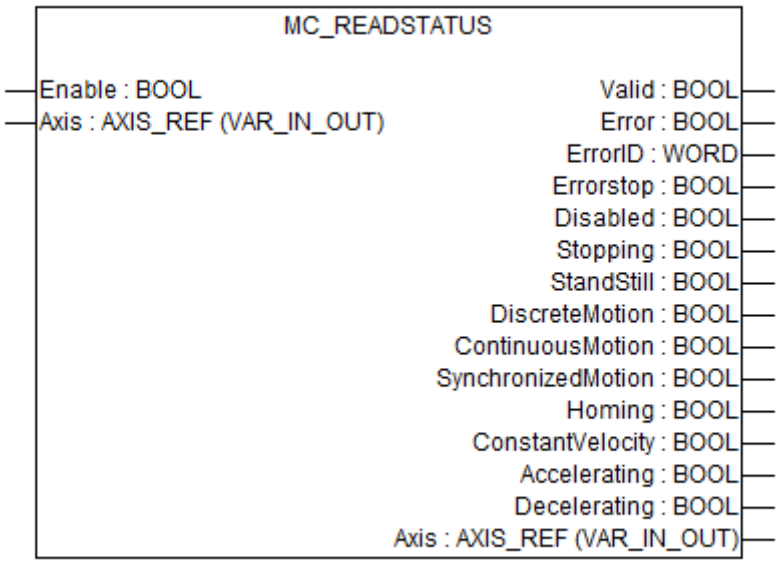

Fig. 378: Function block MC_ReadStatus

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Get the value of the parameter continuously while enabled.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

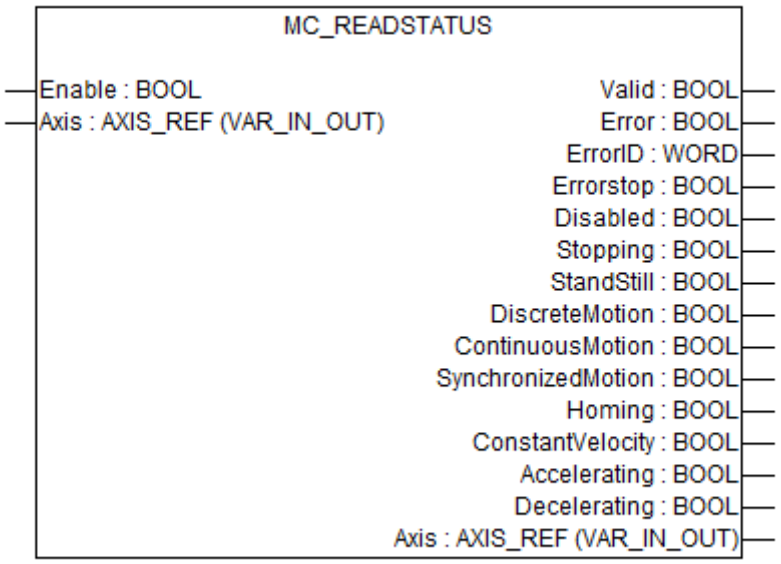

Fig. 379: Function block MC_ReadStatus

Valid Data type: BOOL

Parameter available.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

ErrorStop Data type: BOOL

See single axis state diagram. *Chapter 1.5.9.3.2 “The single axis state diagram” on page 2589*

Disabled Data type: BOOL

Is SET if the axis is in the Disabled state.

Stopping Data type: BOOL

See single axis state diagram. *Chapter 1.5.9.3.2 “The single axis state diagram” on page 2589*

StandStill Data type: BOOL

See single axis state diagram. *Chapter 1.5.9.3.2 “The single axis state diagram” on page 2589*

DiscreteMotion Data type: BOOL

See single axis state diagram. *Chapter 1.5.9.3.2 “The single axis state diagram” on page 2589*

ContinuousMotion Data type: BOOL

See single axis state diagram. *Chapter 1.5.9.3.2 “The single axis state diagram” on page 2589*

SynchronizedMotion Data type: BOOL

See single axis state diagram. *Chapter 1.5.9.3.2 “The single axis state diagram” on page 2589*

Homing Data type: BOOL

See single axis state diagram. *Chapter 1.5.9.3.2 “The single axis state diagram” on page 2589*

ConstantVelocity Data type: BOOL

Motor moves with constant velocity.

Accelerating Data type: BOOL

Increasing energy of the motor.

Decelerating Data type: BOOL

Decreasing energy of the motor.

MC_ReadAxisError

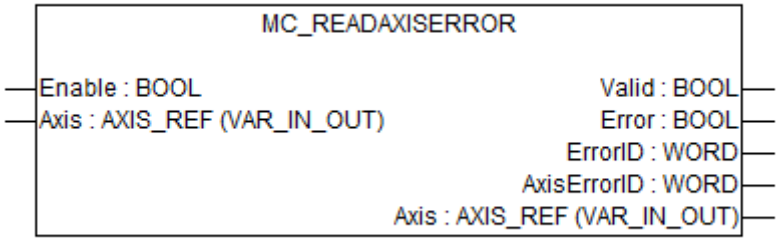

Fig. 380: Function block MC_ReadAxisError

This function block describes general axis errors not relating to the function blocks.

> *This function block is the equivalent to read the AxisErrorID parameter using MC_ReadParameter.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 "Overview of data types" on page 2585*

Input description

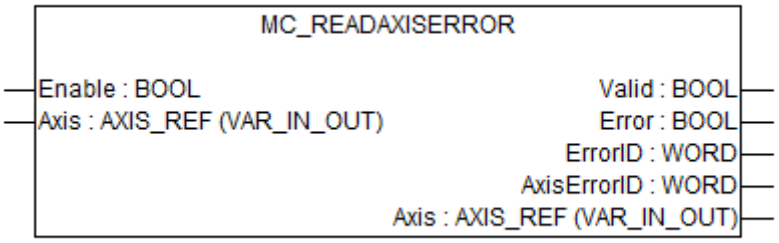

Fig. 381: Function block MC_ReadAxisError

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

As long as Enable = TRUE, power is on.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

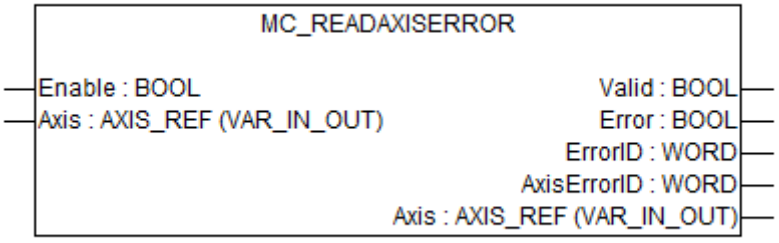

Fig. 382: Function block MC_ReadAxisError

Valid Data type: BOOL

Parameter available.

Error Data type: BOOL

Error flag.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

AxisErrorID Data type: WORD

The value of the axis error. These values are drive specific and only valid when it is possible to read an error from the drive (e.g. by fieldbus).

In Drive-based motion, the AxisErrorID shows the value which is configured for the process image.

In PLC-based motion, the AxisErrorID shows the CMC_MOTION_KERNEL… ErrorID.

MC_Reset

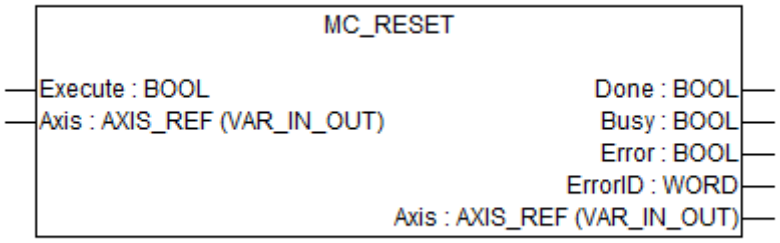

Fig. 383: Function block MC_Reset

Table 191: General information

Available as of runtime system	V2.2
Included in library	MC_Block_AC500_V11.lib
Type	Function block with historical values

This function block makes the transition from the state ErrorStop to StandStill by resetting all internal axis-related errors. It does not affect the output of the function block instances.

In addition, a reset message is sent to the drive (e.g. output DRIVE_RESET_FAULT at CMC_MOTION_KERNEL... or by ACCESS function block).

If used with FM562, MC_Reset also gives a command to reset position data on FM562 IO mapping and offset position set by MC_SetPosition.

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

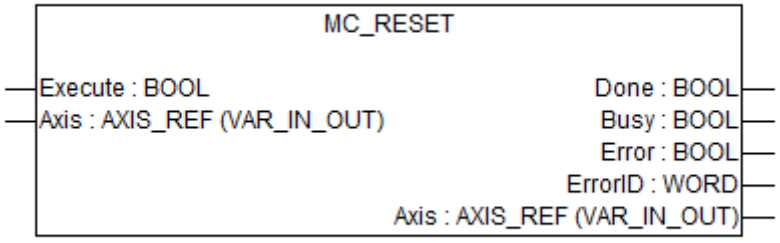

Fig. 384: Function block MC_Reset

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

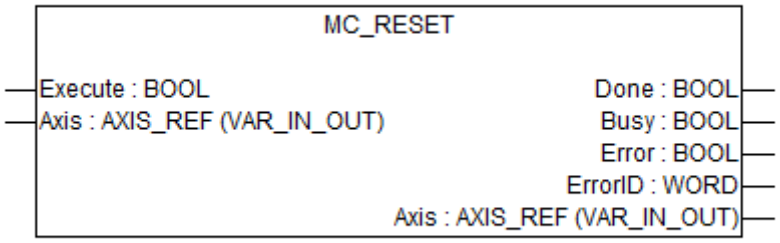

Fig. 385: Function block MC_Reset

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block with Busy = TRUE has control on the axis.

Error Data type: BOOL

Error flag.

ErrorID Data type: WORD

Error identification ↳ *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_ReadParameter

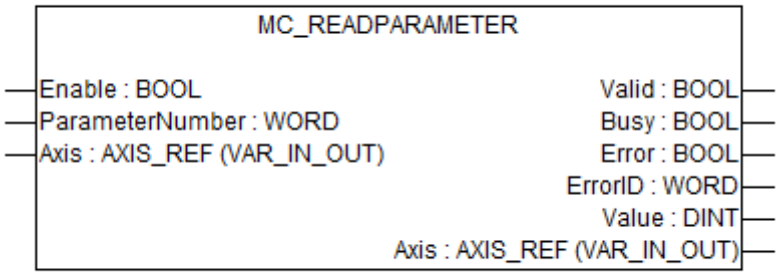

Fig. 386: Function block MC_ReadParameter

When a drive based axis implementation is used, the function block returns the value of a drive specific parameter or a PLCopen parameter. When the Central Motion Control axis implementation is used, a parameter according to the list PLCopen parameter is returned. ↳ *Chapter 1.5.9.3.6 “PLCopen parameter” on page 2595*

> *All available parameters are listed in this table: ↳ Chapter 1.5.9.3.6 “PLCopen parameter” on page 2595*

See the following chapter to check if this function block is supported by the used axis implementation: ↳ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↳ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

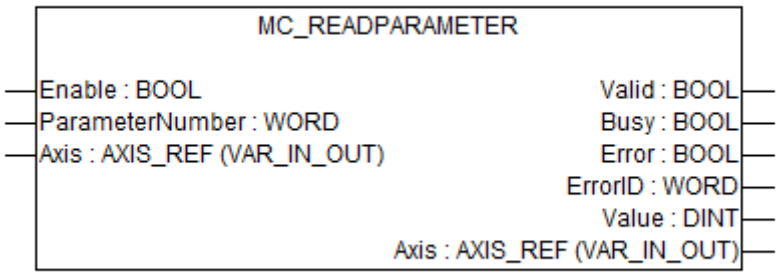

Fig. 387: Function block MC_ReadParameter

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable

Data type: BOOL

Get the value of the parameter continuously while enabled.

Parameter-Number

Data type: INT

Number of the parameter. One can also use as symbolic parameter names which are declared as VAR CONST.

Axis

Data type: AXIS_REF

Reference to the axis.

Output description

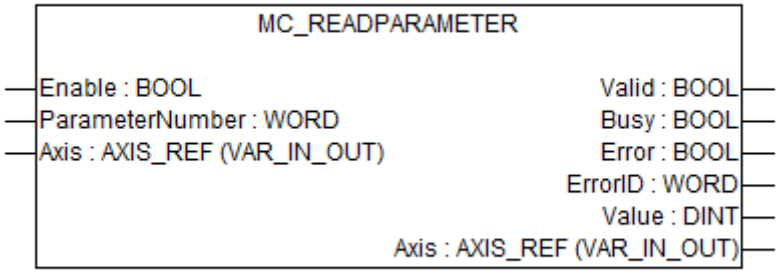

Fig. 388: Function block MC_ReadParameter

Valid

Data type: BOOL

Parameter available.

Busy Data type: BOOL

The function block with Busy = TRUE has control on the axis.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification ↳ *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

Value Data type: DINT

Value of the specified parameter in the datatype.

MC_ReadBoolParameter

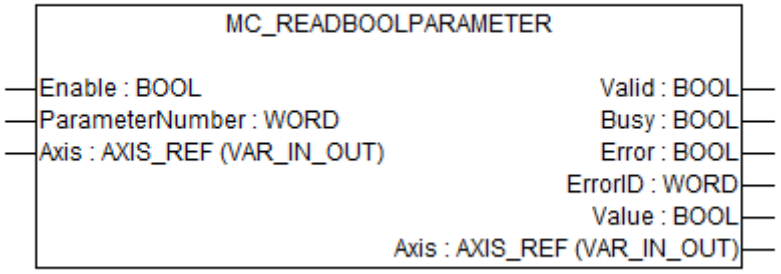

Fig. 389: Function block MC_ReadBoolParameter

When a drive based axis implementation is used, the function block returns the value of a drive specific BOOL parameter or a PLCopen BOOL parameter. When the Central Motion Control axis implementation is used, a BOOL parameter according to the list PLCopen parameter is returned. ↳ *Chapter 1.5.9.3.6 “PLCopen parameter” on page 2595*

All available parameters are listed in this table: ↳ Chapter 1.5.9.3.6 “PLCopen parameter” on page 2595

See also:

Execute

Data type: BOOL

Starts the function block at rising edge.

Parameter-Number

Data type: INT

Number of the parameter (correspondence between number and parameter is to be specified later).

Value

Data type: LREAL

New value of the specified parameter.

Axis

Data type: AXIS_REF

Reference to the axis.

Output description

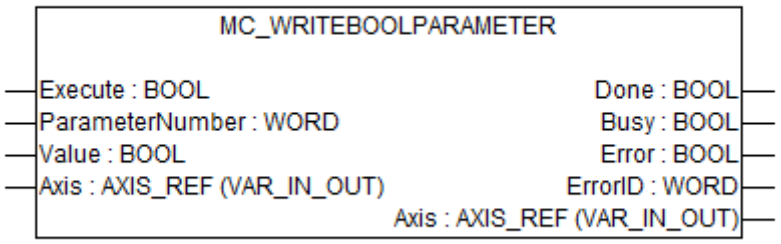

Fig. 397: Function block MC_WriteBoolParameter

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block with Busy = TRUE has control on the axis.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_ReadActualPosition

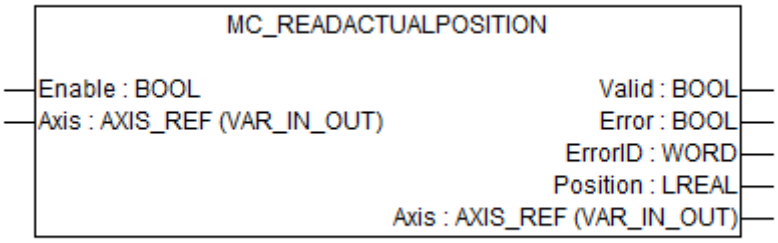

Fig. 398: MC_ReadActualPosition

Table 192: General information

Available as of runtime system	V2.2
Included in library	MC_Block_AC500_V11.lib
Type	Function block with historical values

This function block returns the actual position.

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

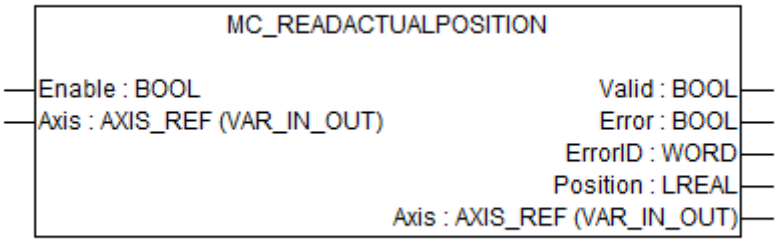

Fig. 399: MC_ReadActualPosition

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Get the value of the parameter continuously while enabled.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

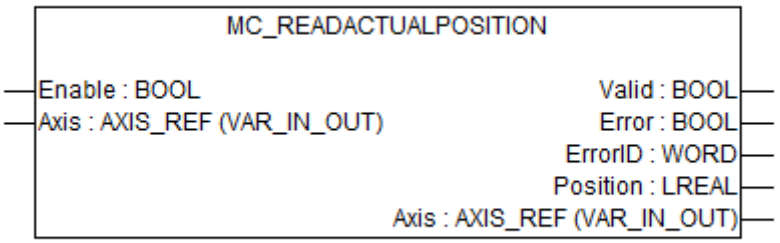

Fig. 400: MC_ReadActualPosition

Valid Data type: BOOL

Parameter available.

Busy Data type: BOOL

The function block with Busy = TRUE has control on the axis.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

Position Data type: LREAL, unit: u

New absolute position.

MC_ReadActualVelocity

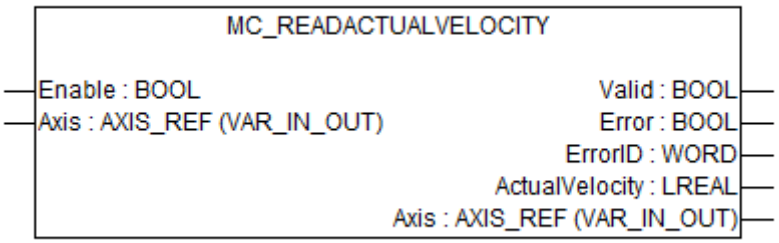

Fig. 401: MC_ReadActualVelocity

This function block returns the value of the actual velocity as long as Enable is set. Valid is true when the data-output “Velocity” is valid. If Enable is reset, the data loses its validity, and all outputs are reset, no matter if new data is available.

The output ActualVelocity can be a signed value.

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

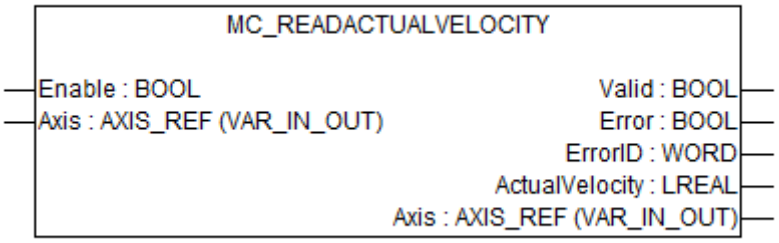

Fig. 402: MC_ReadActualVelocity

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Get the value of the parameter continuously while enabled.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

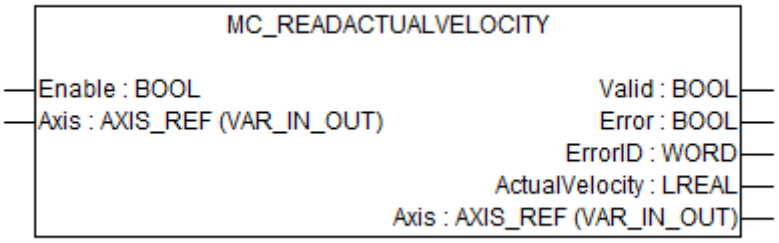

Fig. 403: MC_ReadActualVelocity

Valid Data type: BOOL

Parameter available.

Busy Data type: BOOL

The function block is not finished and new output values are to be expected.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

ActualVelocity Data type: LREAL, unit: u/s

The value of the actual velocity.

MC_SetOverride

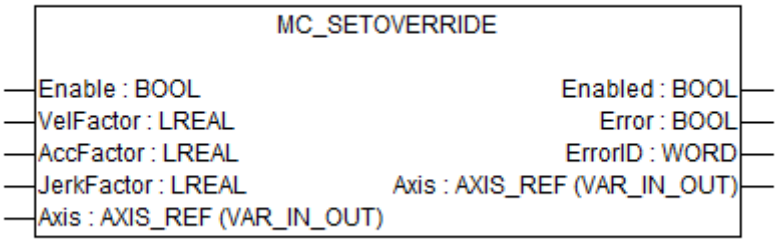

Fig. 404: Function block MC_SetOverride

This function block sets the values of override for the whole axis. The override parameters are applied as a factor that is multiplied to the set velocity, acceleration, deceleration and jerk during the executing of a motion function block. Ongoing motion commands are not affected when override factors are changed.

- The Input AccFactor acts on positive and negative acceleration (deceleration).
- This function block sets the factor. The override factor is valid until a new override is set.
- The default values of the override factors are 1.0.
- The value of the overrides can be between 0.0 and 1.0. Values > 1.0 and values < 0.0 are not allowed. The value 0.0 is not allowed for AccFactor and JerkFactor.

- *Override does not act on slave axes. (Axes in the state Synchronized Motion).*
- *The function block does not influence the single axis state diagram.*
- *The override factors are just effective to modify the velocity, acceleration, deceleration and jerk which are provided as explicit values by PLCopen function blocks. They do not modify a movement which is commanded by other means as camming, gearing, profiling, where no explicit velocity, acceleration,deceleration and jerk is in place.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

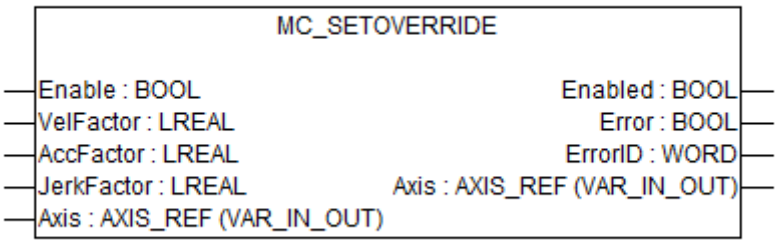

Fig. 405: Function block MC_SetOverride

Enable Data type: BOOL

If SET, it writes the value of the override factor continuously. If RESET it should keep the last value.

VelFactor Data type: LREAL

New override factor for the velocity.

AccFactor Data type: LREAL

New override factor for the acceleration or deceleration.

JerkFactor Data type: LREAL

New override factor for the velocity.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

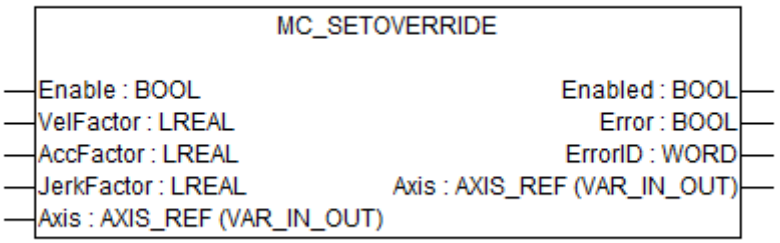

Fig. 406: Function block MC_SetOverride

Enabled Data type: BOOL

Signals that the override factor(s) is (are) set successfully.

Busy Data type: BOOL

The function block is not finished and new output values are to be expected.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_SetPosition

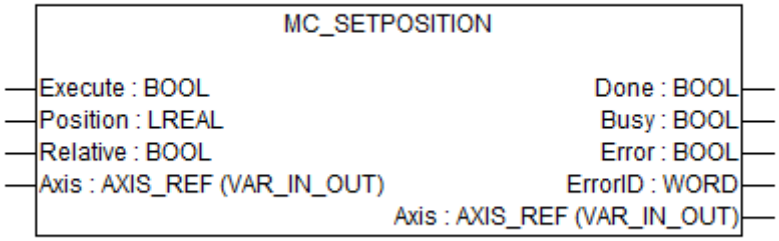

Fig. 407: Function block MC_SetPosition

This function block shifts the coordinate system of an axis by manipulating both the set-point position as well as the actual position of an axis with the same value without any movement caused. (Re-calibration with same following error). This can be used for instance for a reference situation. This function block can also be used during motion without changing the commanded position, which is now positioned in the shifted coordinate system.

The function block may just be called in: StandStill, Continuous Motion, ErrorStop or Disabled.

- *RELATIVE means that position is added to the actual position value of the axis at the time of execution. This results in a recalibration by a specified distance.*
- *ABSOLUTE means that the actual position value of the axis is set to the value specified in the position parameter.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

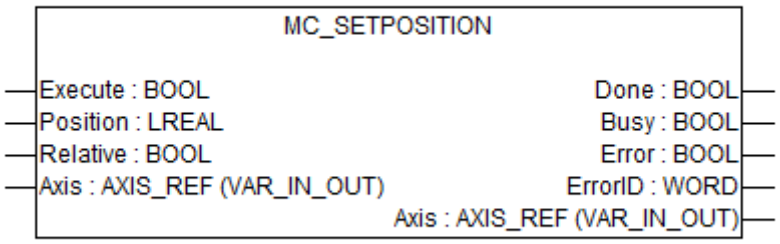

Fig. 408: Function block MC_SetPosition

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

Position Data type: LREAL, unit: u

Position unit (Means ‘Distance’ if Relative= TRUE).

Relative Data type: BOOL, default: FALSE

Relative distance if TRUE. Absolute position if FALSE.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

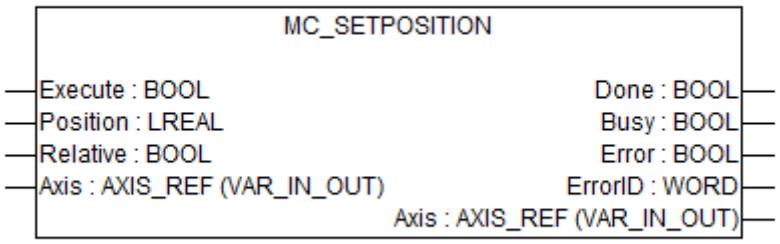

Fig. 409: Function block MC_SetPosition

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

1.5.9.6.4 Homing function blocks

For further information see: *AN00220-001 - AC500 and MicroFlex e150 - EtherCAT Homing Methods*

MC_StepAbsSwitch

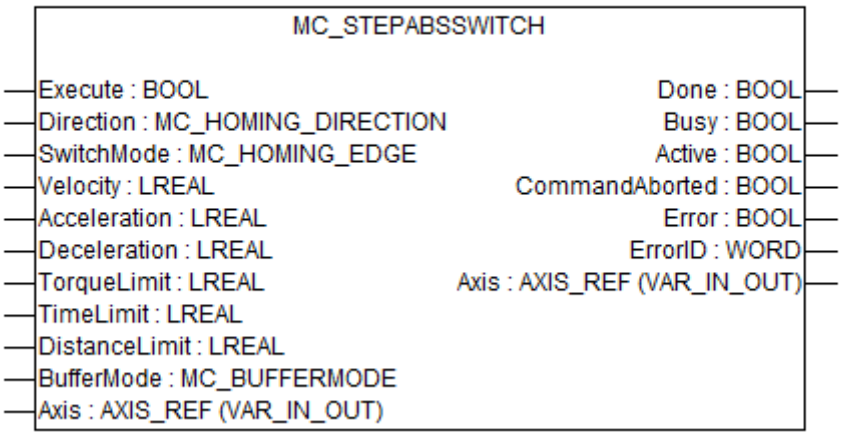

Fig. 410: Function block MC_StepAbsSwitch

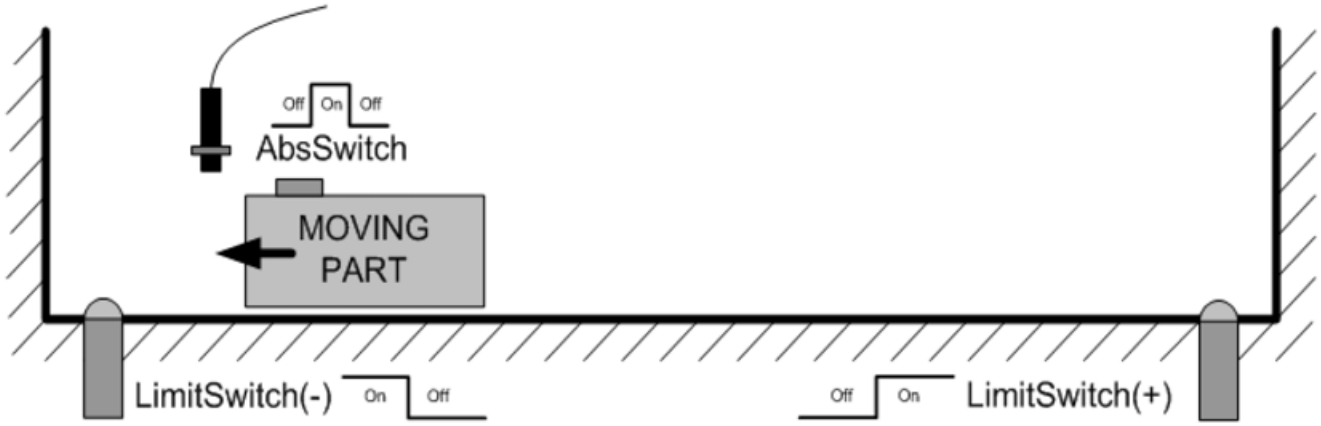
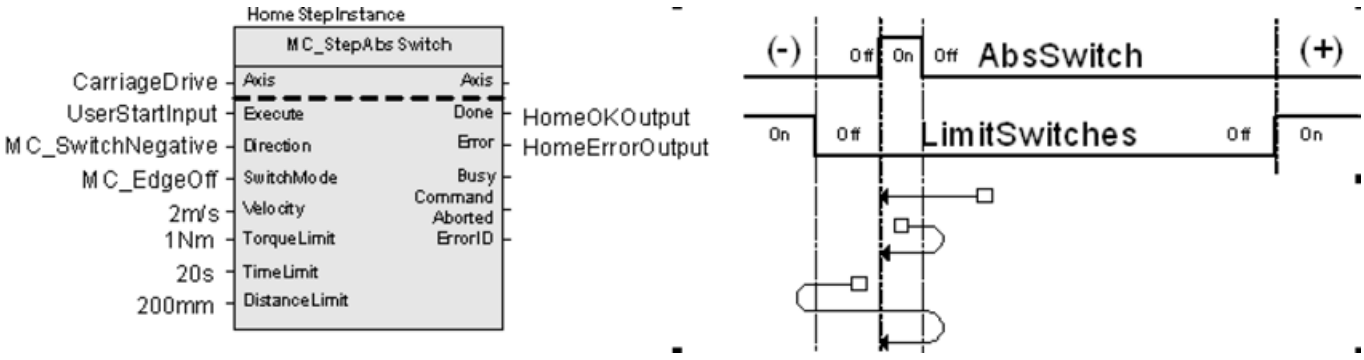
This function block performs a homing function by searching for an absolute positioned external physical switch. (An Absolute Switch has two “Off” (or “On”) areas – see example). For central Motion Control implementation: The signal of the Absolute Switch has to be written to the variable “absRefSwitch” of the data type CMC_AXIS_IO.

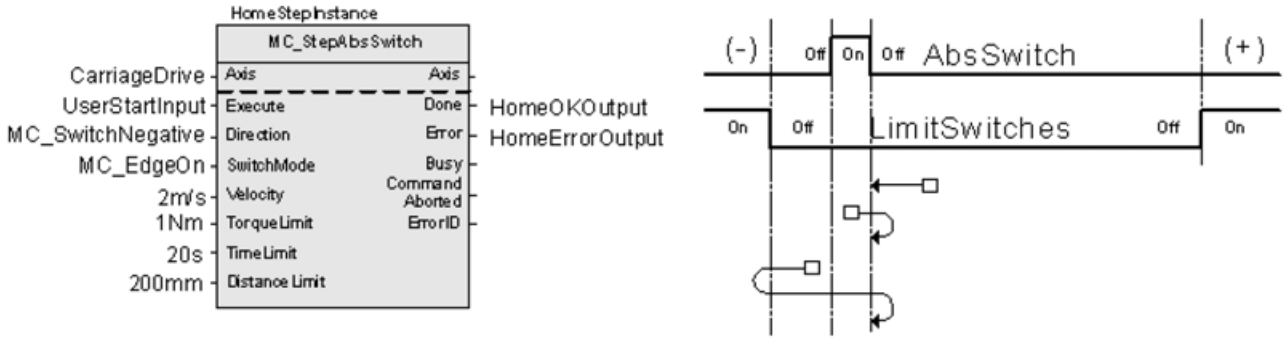
> *Inside the operation area the limit switches have to be logically FALSE and outside the borders the signal of the corresponding limit switch has to be logically TRUE.*
>
> *If needed the signal from the sensor must be inverted before it is connected to an element the AXIS_IO data type.*



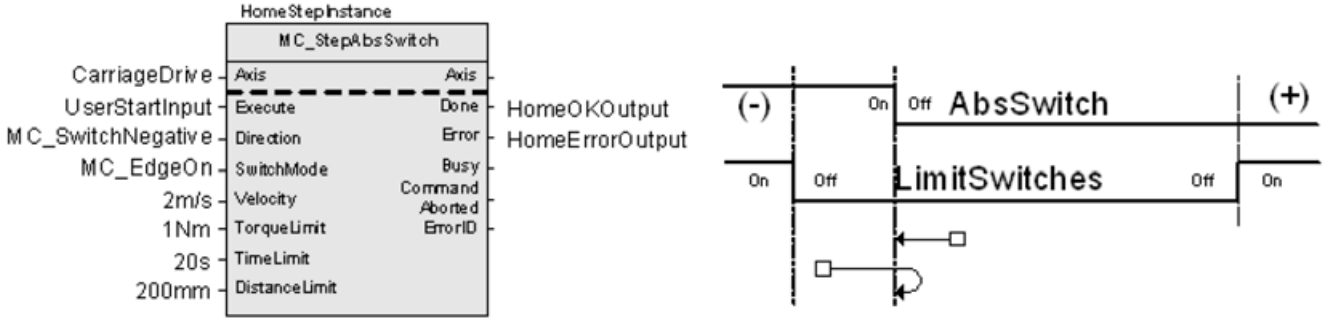
This physical layout has the risk that homing is started in the wrong direction (escaping the switch). To support such case, it implements a special behavior when Limit Switches are found (or the AbsSwitch itself is "On" at Execute):

- Axis State is set to Homing,
- The homing is commanded in the most likely direction were the sensor can be found. In the example (-),
- The velocity is defined by the input,
- Both time and distance limits can cause an error if exceeded,
- If any LimitSwitch is found during Homing (any of them), then a special process is started in the opposite direction, the AbsSwitch is searched to switch off (or "On" depending on SwitchMode setting). The Edge (passed by), and homing process is restarted in the original direction and with the same conditions. This ensures that the end conditions are always same,
- If the SwitchMode is either MC_SwitchNegative or MC_SwitchPositive, then the special process is also started in opposite direction depending from the switch state at "Execute",
- The direction changes only when the specified Velocity is reached (InVelocity),
- This function block does not modify the actual position,
- This function block does not leave the Homing State when done.
- This function block can only be used once for a homing sequence.

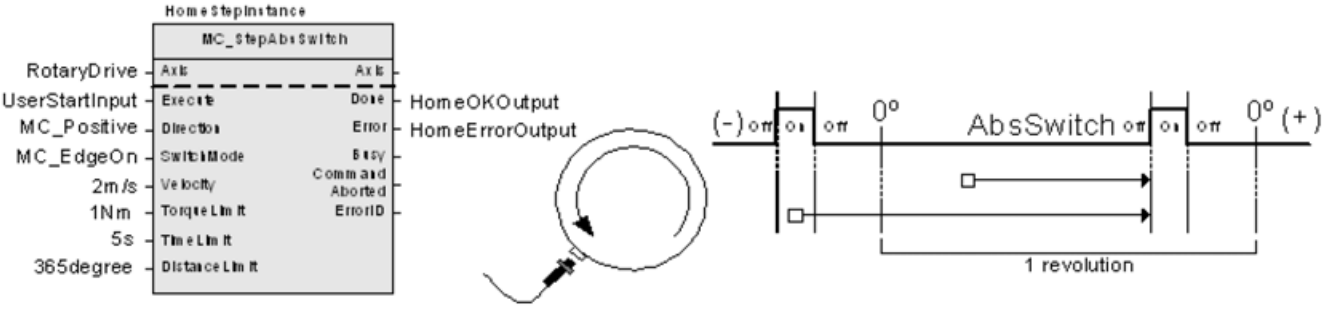




An overlapping switch configuration is also possible. This has same the behavior as working on the limit switches:



If the input direction is set to a fixed direction (MC_Positive or MC_Negative), then the initial switch state is ignored (used for example in rotary axis where only one sense of rotation is allowed):



With an overlapping switch configuration either MC_EdgeOn or MC_EdgeOff can be used for the input SwitchMode. This depends on the switching behavior of the absolute switch and the used option for the input Direction.

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

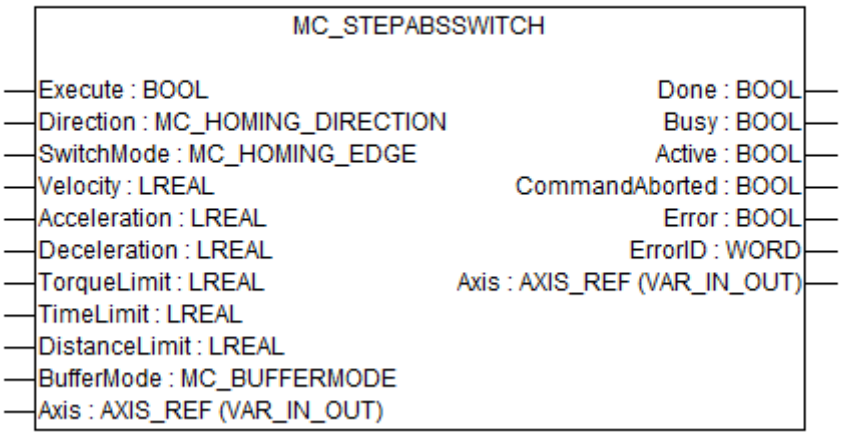


Fig. 411: Function block MC_StepAbsSwitch

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

Direction Data type: MC_HOMING_DIRECTION

Specifies the direction of the motion if any:

- MC_Positive = Starts in positive direction always.
- MC_Negative = Starts in negative direction always.
- MC_SwitchPositive = Depends on Switch status at Execute edge. If Switch is "Off", direction is positive, if "On" it is negative.
- MC_SwitchNegative = Like previous, but opposite.

SwitchMode Data type: MC_HOMING_SWITCH

Sensor condition to finalize this function block in any switch mode:

- MC_On = When sensor is ON.
- MC_Off = When sensor is OFF.
- MC_EdgeOn = When Off to On transition in sensor.
- MC_EdgeOff = When On to Off transition in sensor.

Velocity Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

TorqueLimit Data type: LREAL, unit: t.u.

Maximum torque or force. 0 = No torque limit.

Central Motion Control implementation (Compact Motion Control): TorqueLimit value will not be used.

TimeLimit Data type: LREAL, unit: s
If the function block condition is not met in the TimeLimit, an error is issued.
0 = No time limit.

DistanceLimit Data type: LREAL
If the Funciton Block condition is not met within a DistanceLimit travel, an error is issued.
0 = No distance limit.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

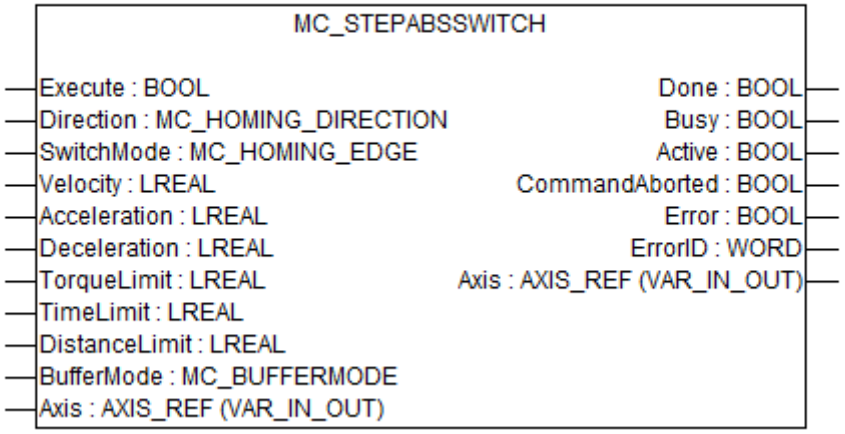

Fig. 412: Function block MC_StepAbsSwitch

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

Specific error numbers:

- MC_TimeLimitExceeded
- MC_DistanceLimitExceeded
- MC_TorqueLimitExceeded

MC_StepDirect

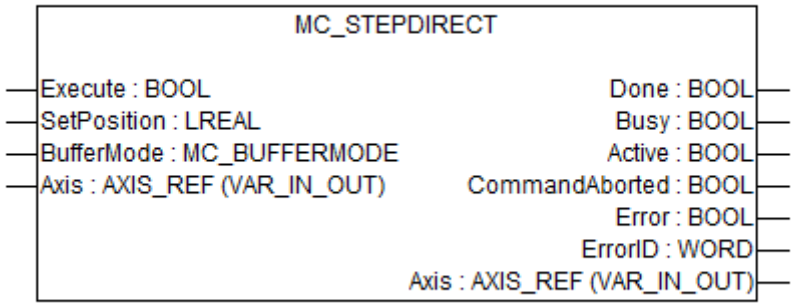

Fig. 413: Function block MC_StepDirect

This function block performs a static homing by directly forcing an actual position. No physical motion is performed in this mode. This is equivalent to a MC_SetPosition action, but clears the Homing State.

- *This function block modifies actual position and sets to the "SetPosition" input value at the end.*
- *This function block clears the Homing State when Done.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

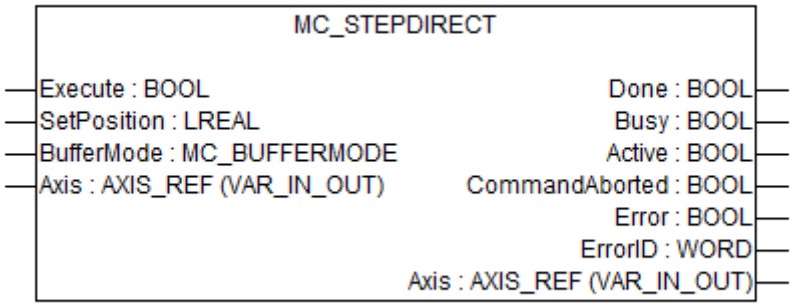

Fig. 414: Function block MC_StepDirect

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

SetPosition Data type: LREAL, unit: u

Value of the absolute position to be set when homing is done.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

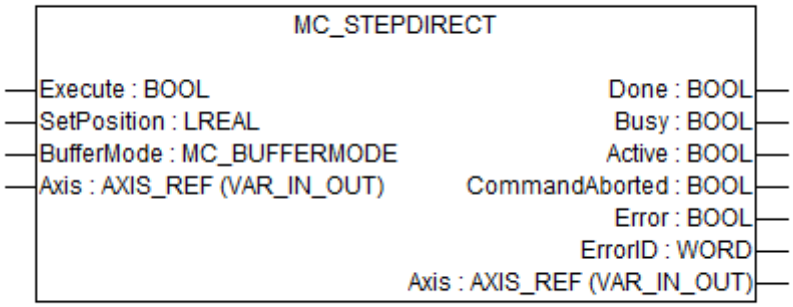

Fig. 415: Function block MC_StepDirect

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_StepLimitSwitch

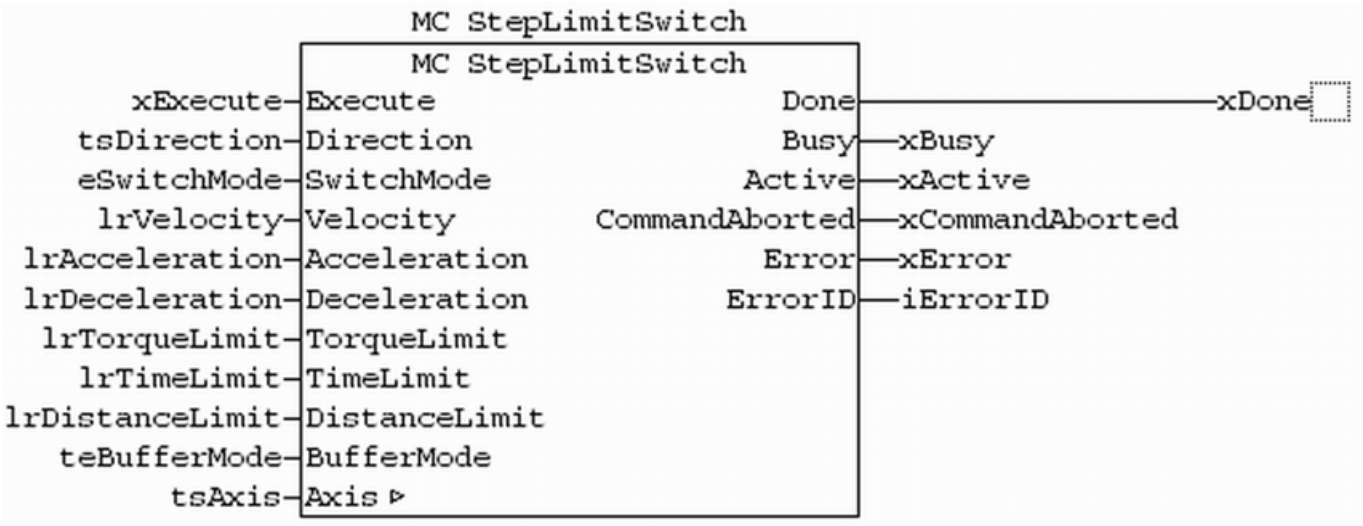

Fig. 416: Function block MC_StepLimitSwitch

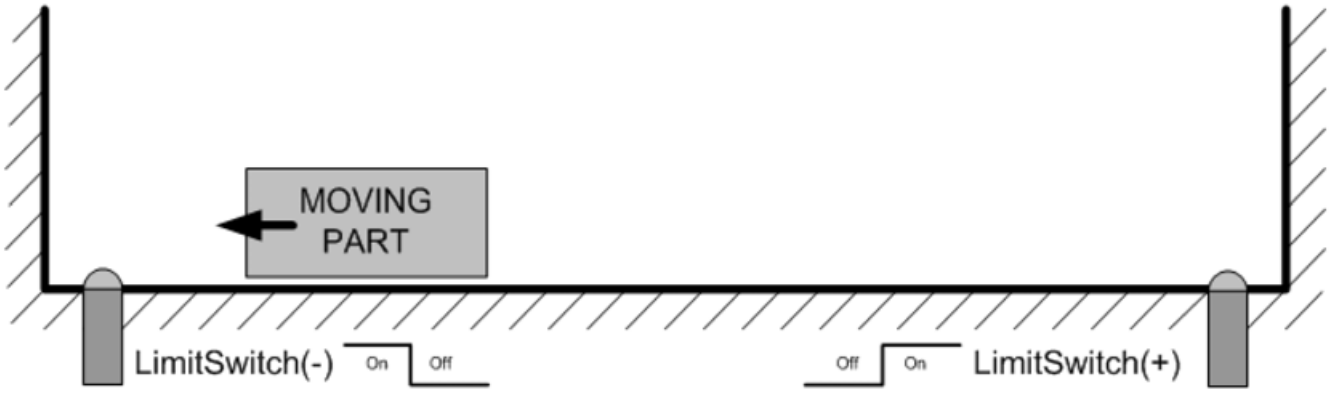
This function block performs a homing function by searching for sensor using only limit switches. (A limit switch has 1 "Off" (or "On") area). The signal of the Limit Switches have to be written to the variables “limitSwitchPos” and “limitSwitchNeg” of the data type CMC_AXIS_IO.

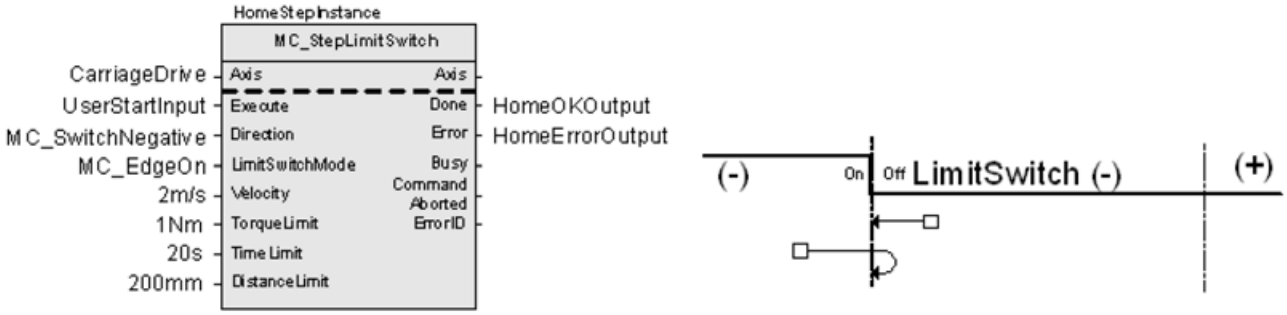
Inside the operation area the limit switches have to be logically FALSE and outside the borders the signal of the corresponding limit switch has to be logically TRUE.

If needed the signal from the sensor must be inverted before it is connected to an element the AXIS_IO data type



In this case the limit switches (always active once moving part working area has been surpassed) are used for homing procedure.

- The axis State is changed to Homing.
- Home is commanded by user in the desired homing direction at the selected Velocity.
- If LimitSwitch is found "On" on rising "Execute", then the process is started in the opposite direction as specified, LimitSwitch is search for "Off" (or On depending in LimitSwitchMode setting) Edge (released), and process is restarted again in original direction. This ensures that the end conditions are always the same.
- The time and distance limits can cause error if exceeded.
- The direction changes only when the specified velocity is reached, this ensures acceleration and deceleration spaces are fixed.
- This function block does not modify actual position.
- This function block does not leave the Homing State when done.
- This function block can only be used once for a homing sequence.



See the following chapter to check if this function block is supported by the used axis implementation: ↳ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↳ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

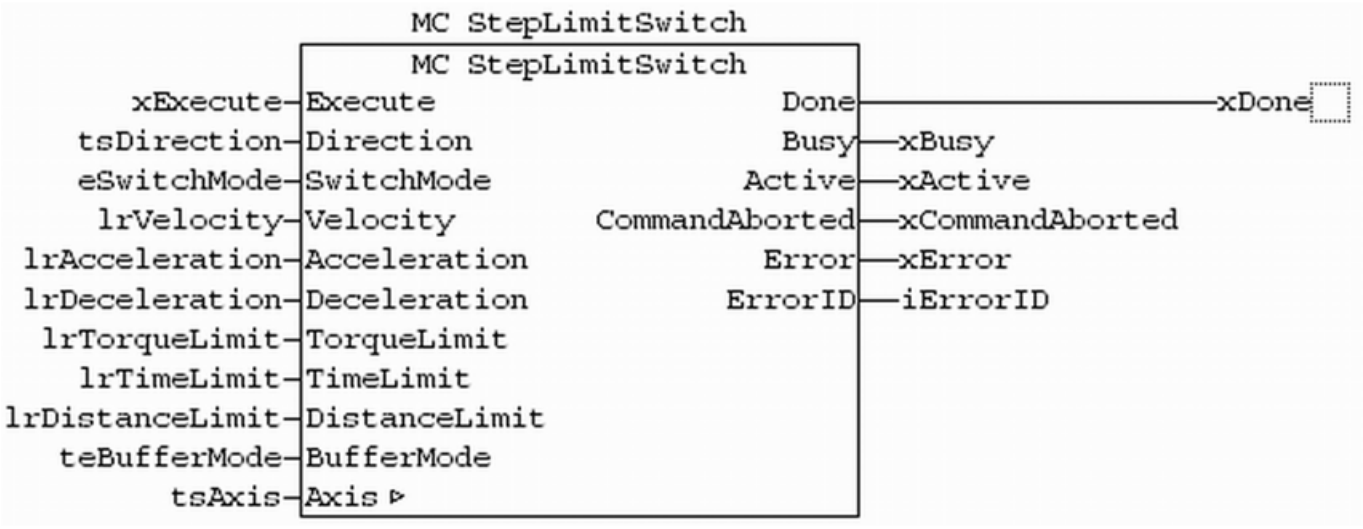


Fig. 417: Function block MC_StepLimitSwitch

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute

Data type: BOOL

Starts the function block at rising edge.

Direction

Data type: MC_HOMING_DIRECTION

Specifies the direction of the motion and corresponding LimitSwitch to search for, just MC_Positive and MC_Negative are possible:

- MC_Positive = Positive direction searching positive LimitSwitch.
- MC_Negative = Negative direction searching negative LimitSwitch.

SwitchMode

Data type: MC_HOMING_EDGE

Sensor condition to finalize this function block:

- MC_On = When sensor is ON.
- MC_EdgeOn = When Off to On transition in sensor.

Velocity

Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

Acceleration

Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Deceleration

Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

TorqueLimit Data type: LREAL, unit: t.u.

Maximum torque or force. 0 = No torque limit.

Central Motion Control implementation (Compact Motion Control): TorqueLimit value will not be used.

TimeLimit Data type: LREAL, unit: s

If the function block condition is not met in the TimeLimit, an error is issued.

0 = No time limit.

DistanceLimit Data type: LREAL

If the Funciton Block condition is not met within a DistanceLimit travel, an error is issued.

0 = No distance limit.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

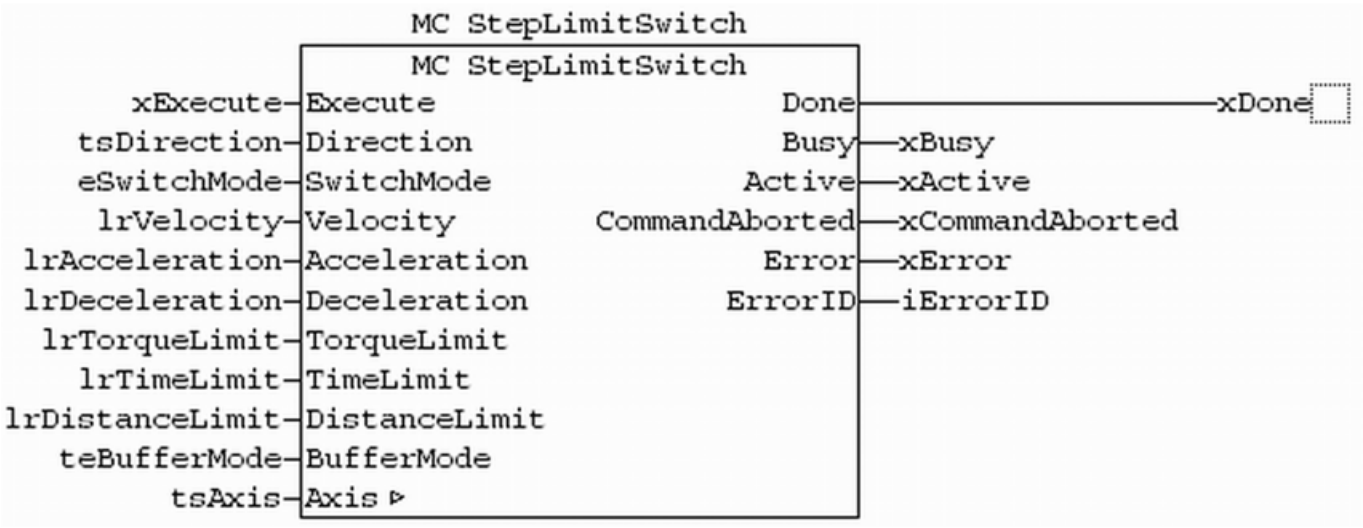

Fig. 418: Function block MC_StepLimitSwitch

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

Specific error numbers:

- MC_TimeLimitExceeded
- MC_DistanceLimitExceeded
- MC_TorqueLimitExceeded

MC_StepRefPulse

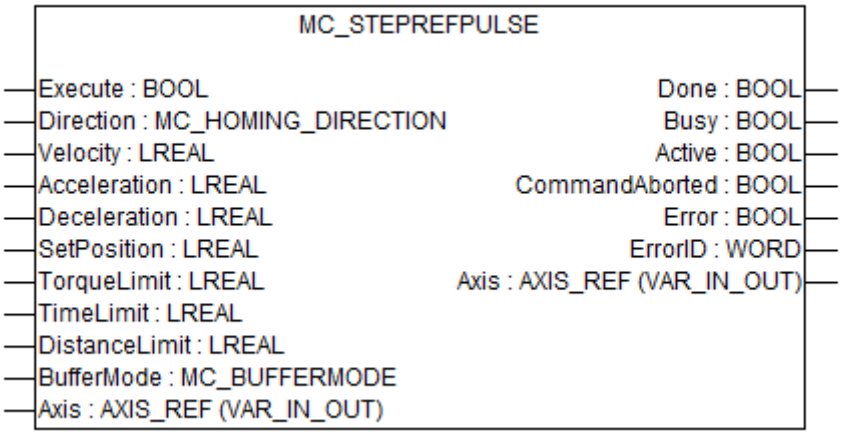

Fig. 419: Function block MC_StepRefPulse

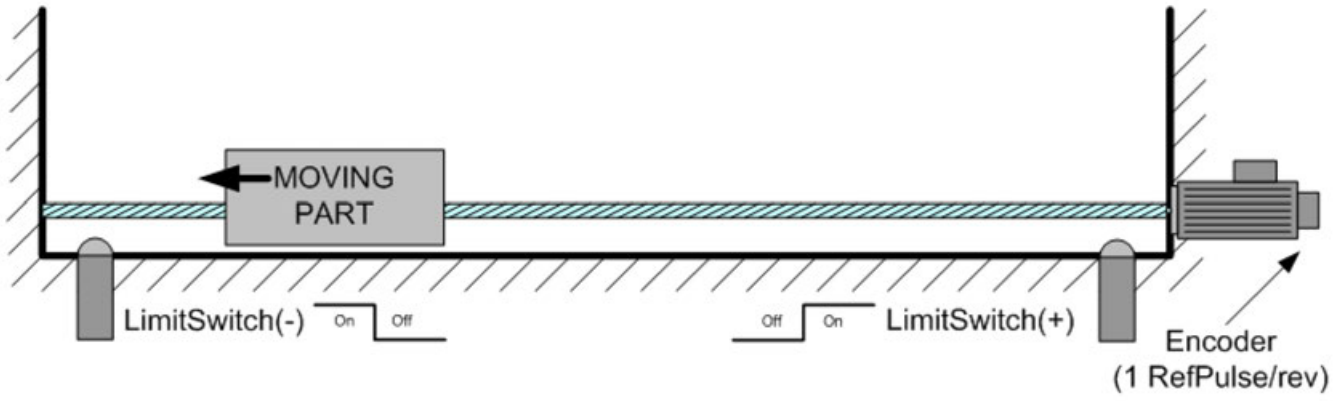
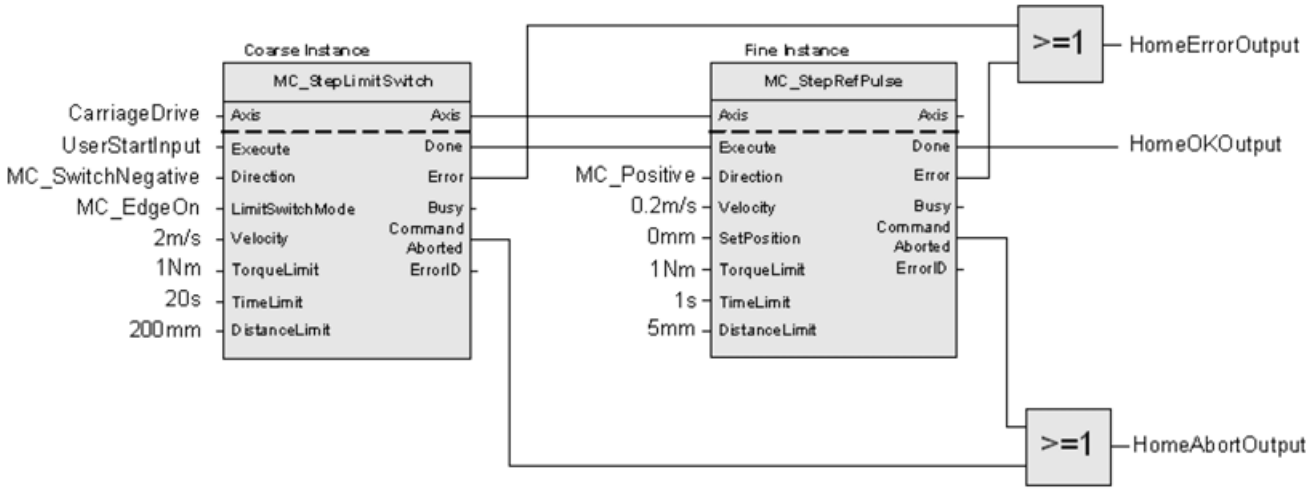
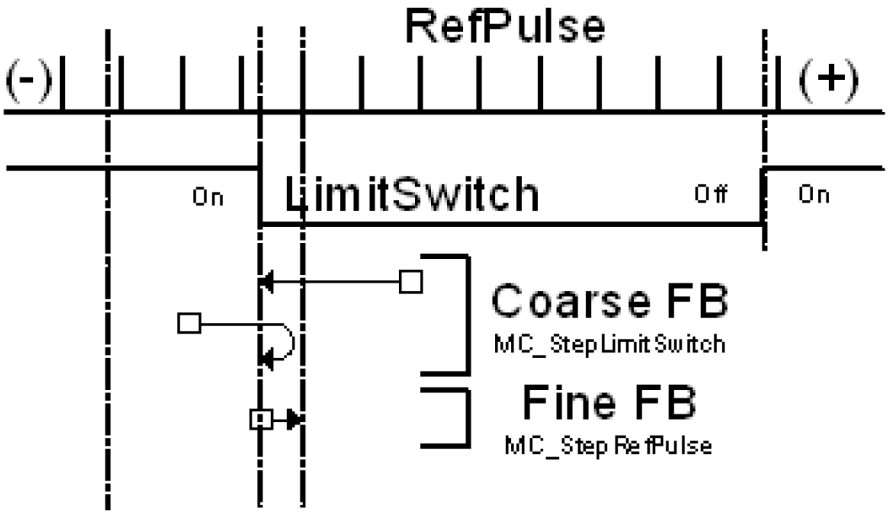
This function block performs homing by searching for zero pulse (also called Marker or reference pulse) in encoder. The reference pulse appears once per encoder revolution. The advantage in using Reference Pulse for homing is the higher accuracy and precision that can be achieved compared to traditional optical, mechanical or magnetic sensors.



- The axis state is changed to Homing if not already in.
- Home is commanded by user in the desired homing direction at the programmed velocity.
- First occurrence of the Reference Pulse, Homing is finished.
- Torque is limited. Time and Distance Limits can cause error if exceeded.
- This Function modifies actual position and sets to the "SetPosition" input value at the end
- This function block clears the Homing State when Done.

It is common that a first approach is performed against a mechanical sensor at higher velocity, and after a Reference Pulse, at a lower velocity. This is a traditional 2-Step homing (Coarse by external Switch in reverse and Fine by Reference Pulse in forward). For ease of use both functions could be grouped together in single function block. Advantage having the function blocks separate is that any combination is possible (MC_Block and after MC_RefPulse, etc.), stating different velocity and conditions for each Step (higly flexible), without increasing homing function block complexity too much.





See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 "Overview of PLCopen function blocks" on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 "Overview of data types" on page 2585*

Input description

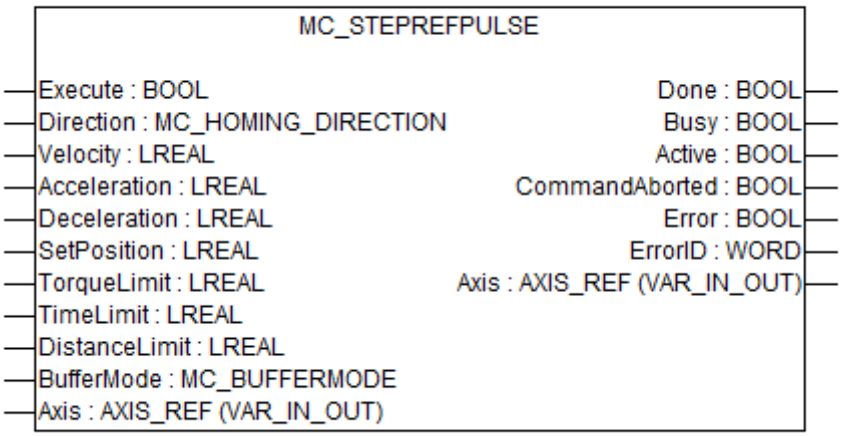


Fig. 420: Function block MC_StepRefPulse

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

Direction Data type: MC_HOMING_DIRECTION

Specifies the direction to start the motion, just MC_Positive and MC_Negative are possible to use:

- MC_Positive = Starts in positive direction always
- MC_Negative = Starts in negative direction always

Velocity Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

SetPosition Data type: LREAL, unit: u

Value of the absolute position to be set when homing is done.

TorqueLimit Data type: LREAL, unit: t.u.

Maximum torque or force. 0 = No torque limit.

Central Motion Control implementation (Compact Motion Control): TorqueLimit value will not be used.

TimeLimit Data type: LREAL, unit: s

If the function block condition is not met in the TimeLimit, an error is issued.

0 = No time limit.

DistanceLimit Data type: LREAL

If the Funciton Block condition is not met within a DistanceLimit travel, an error is issued.

0 = No distance limit.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Axis Data type: AXIS_REF

Reference to the axis.

Output description

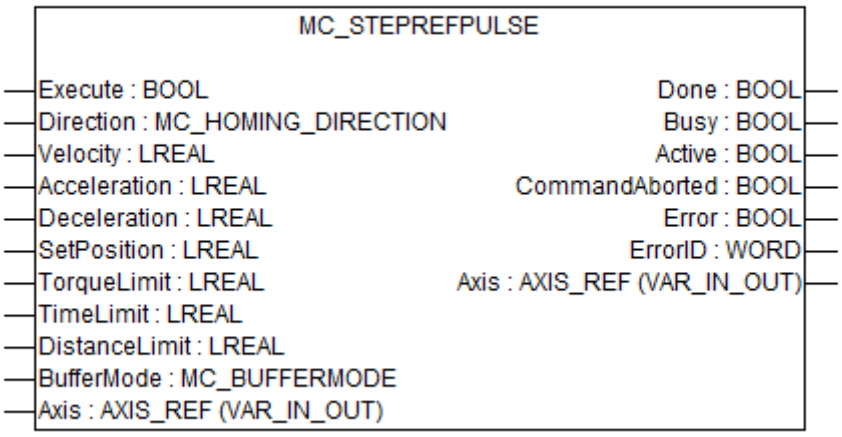

Fig. 421: Function block MC_StepRefPulse

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

Specific error numbers:

- MC_TimeLimitExceeded
- MC_DistanceLimitExceeded
- MC_TorqueLimitExceeded

MC_Home

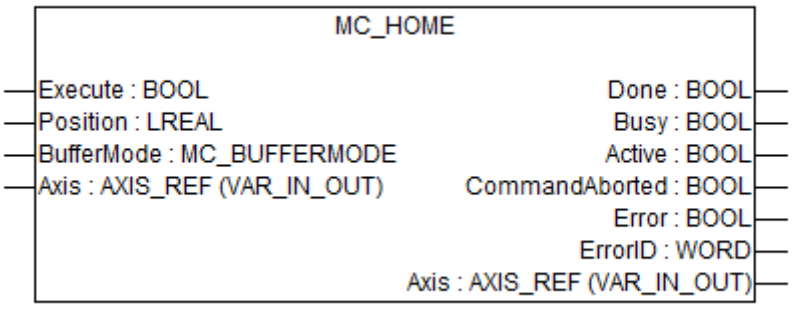

Fig. 422: Function block MC_Home

This function block commands the axis to perform the search home sequence. The details of this sequence are manufacturer dependent and can be set by the axis' parameters. The input Position is used to set the absolute position when reference signal is detected. This Function Bock completes at StandStill.

See the following chapter to check if this function block is supported by the used axis implementation: ↳ *Chapter 1.5.9.2.4 "Overview of PLCopen function blocks" on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↳ *Chapter 1.5.9.2.6 "Overview of data types" on page 2585*

Input description

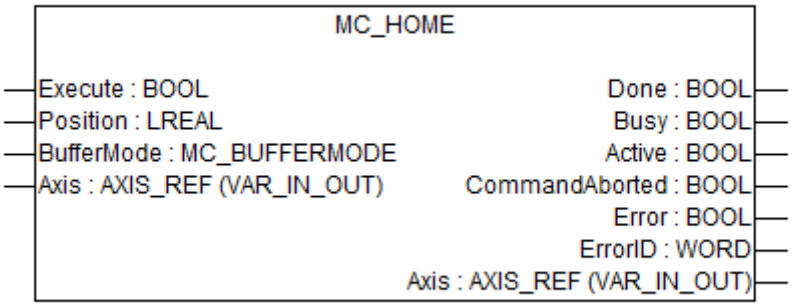

Fig. 423: Function block MC_Home

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

Position Data type: LREAL, unit: u
New absolute position.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output description

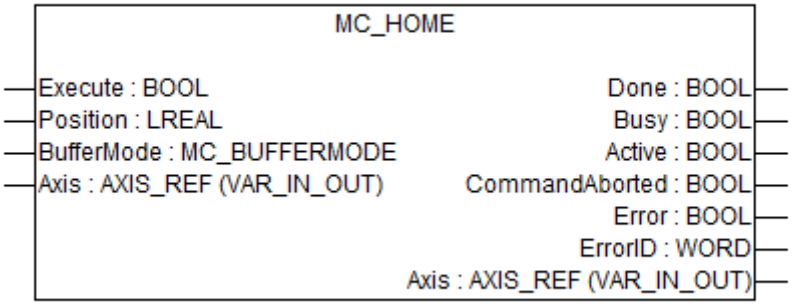

Fig. 424: Function block MC_Home

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

1.5.9.6.5 ABB specific function blocks

The ABB specific function blocks follow the general rules defined by PLCopen and implement some additional features.

MCA_CAM_EXTRA

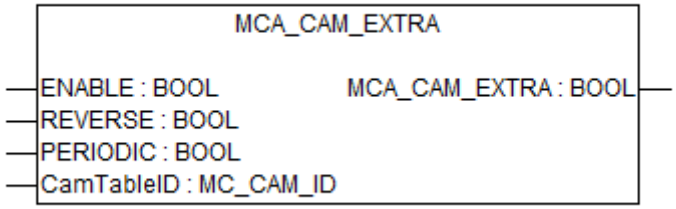

Fig. 425: Function MCA_CAM_EXTRA

This function is just usable together with MC_CamTableSelect and should be called right after MC_CamTableSelect to modify 2 mode-bits which define the behavior for the MC_CamIn more precise. Without this function, the default values will be used instead.

This Function modifies the CAM Table behavior.

- *With ENABLE = TRUE, the 2 bits will be written all the time and will be effective. So a cam table could be used in PERIODIC=TRUE mode and will come to a stop when the master leaves its position range when PERIODIC = FALSE is used.*
- *With MODULO-AXIS:*
  Uusage with PERIODIC = FALSE and position range for master equals MODULORANGE: When the master reaches 360°, the movement will be ready, even when it was started just at 359°.

See the following chapter to check if this function block is supported by the used axis implementation: ↬ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↬ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input Description

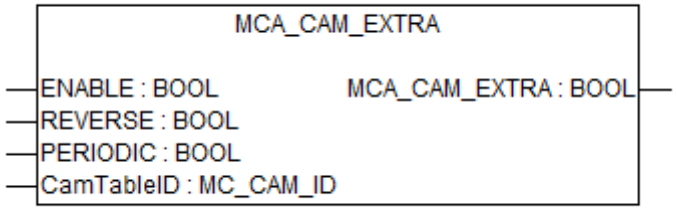

Fig. 426: Function MCA_CAM_EXTRA

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

ENABLE Data type: BOOL

Writes the values while ENABLE = TRUE.

REVERSE Data type: BOOL

Default value=FALSE, just relevant with PERIODIC = FALSE, the cam-table will reach "EndOf-Profile" when the master axis leaves the position range in the given direction

REVERSE = FALSE: positive direction

REVERSE= TRUE: negative direction.

PERIODIC Data type: BOOL

Default value = TRUE for master axis= MODULO, FALSE otherwise PERIODIC= TRUE, the CAM table will not reach EndOfProfile.

CamTableID Data type: MC_CAM_ID

Identifier of CAM Table to be used in the MC_CamIn function block.

MCA_Parameter

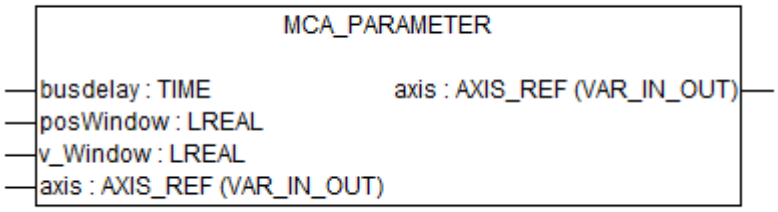

Fig. 427: Function MCA_Parameter

This function can be used to change the default values of the following parameters:

- Target position window. The default value is 10 units.
- Target velocity window. The default vaule is 10 units.
- Maximum fieldbus delay. If this value will be exceeded then it will be assumed that there is a communication error.

The block MCA_Parameter has to be used to adjust the velocity limit when velocities < 10 u/s should be used (10 u/s: default value).

The parameter v_Window defines the limit for the axis to reach its target velocity or standstill.

CAUTION!
This detection will not work properly when smaller velocities are used, especially the block MC_StepLimitSwitch will not stop the axis when reaching the switch!

See the following chapter to check if this function block is supported by the used axis implementation: ↳ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↳ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input Description

busdelay Data type: TIME

A delay time to wait for fieldbus data. When the delay time is to long, the reaction time of function blocks might be increased, while when it is to short an error might be indicated although everything is ok.

posWindow Data type: DWORD

A position window to indicate that the movement is ready. It is a supervision additional to the drives control. When this value is too small, e.g. 1 increment, it might happen that a movement never indicates to be ready.

v_Window Data type: DWORD

A velocity window to indicate that the axis reached the commanded velocity.

MCA_Power

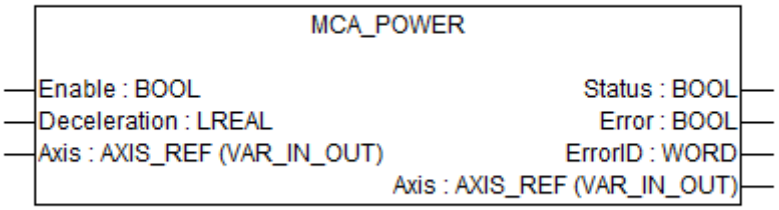

Fig. 428: Function block MCA_Power

This function block controls the power stage (on or off).

- *The basic behavior is the same as MC_Power.*
- *The additional input "Deceleration" is used to ramp the axis down to velocity = 0 in case it was moving when the MCA_Power was activated by a positive edge on "Enable"*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input Description

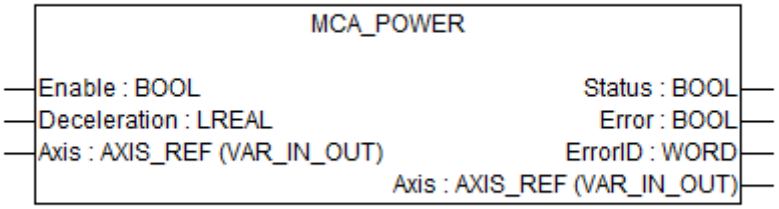

Fig. 429: Function block MCA_Power

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

As long as Enable = TRUE, power is on.

Deceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

Axis Data type: AXIS_REF

Reference to the axis.

Output Description

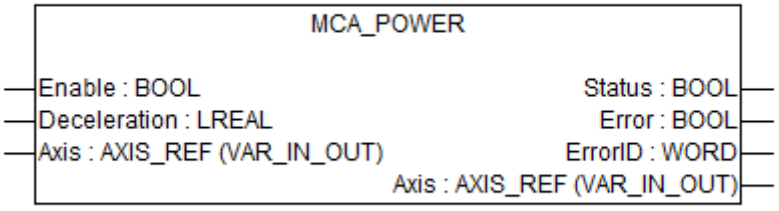

Fig. 430: Function block MCA_Power

Status Data type: BOOL

Effective state of the power stage.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_MoveVelocityContinuous

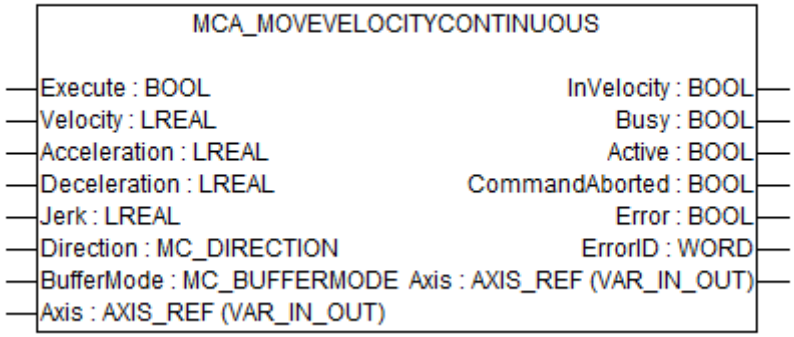

Fig. 431: Function block MCA_MoveVelocityContinuous

Table 193: General Information

Available as of runtime system	V2.2
Included in library	MC_Block_AC500_V11.lib
Type	Function block with historical values

This function block commands a never ending controlled motion at a specified velocity.
The difference to function block MC_MoveVelocity *Chapter 1.5.9.6.1.6 “MC_MoveVelocity” on page 2767* is that the values for Velocity, Acceleration and Deceleration can be modified continuously. If there is a change of the velocity, the reaction on the signal InVelocity will be delayed for 1 cycle.

- *To stop the motion, the function block has to be interrupted by another function block issuing a new command.*
- *The signal "InVelocity" has to be reset when the block is aborted by another block or at the falling edge of "Execute".*
- *In combination with MC_MoveSuperimposed, the output “"nVelocity" stays TRUE once the velocity setpoint of the axis has reached the commanded velocity.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Using this function block with FM562

Input Jerk: 1 = jerk on, 2 = jerk off

Input Direction: 0 = DEFAULT, 1 = POSITIVE, 3 = NEGATIVE

Input BufferMode: Not implemented

Input Description

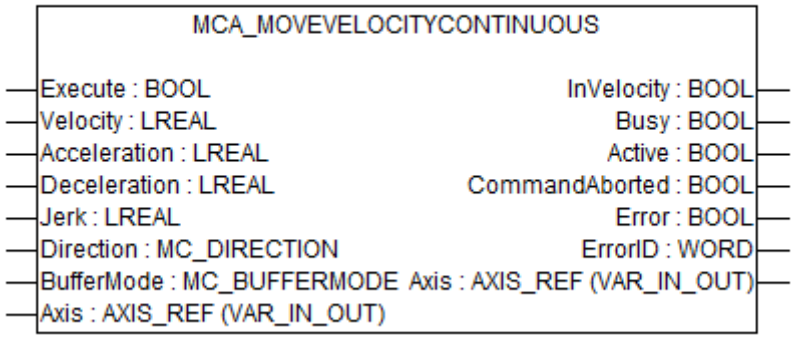

Fig. 432: Function block MCA_MoveVelocityContinuous

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute

Data type: BOOL

Starts the function block at rising edge.

Velocity

Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

Acceleration

Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Deceleration

Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

Jerk

Data type: LREAL, range: > 0, unit: u/s^3

Value of the Jerk.

Direction Data type: MC_Direction, range: DEFAULT, POSITIVE, SHORTEST, NEGATIVE, CURRENT
Enum type.

> *Shortest way not applicable, DEFAULT is equivalent with CURRENT*

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output Description

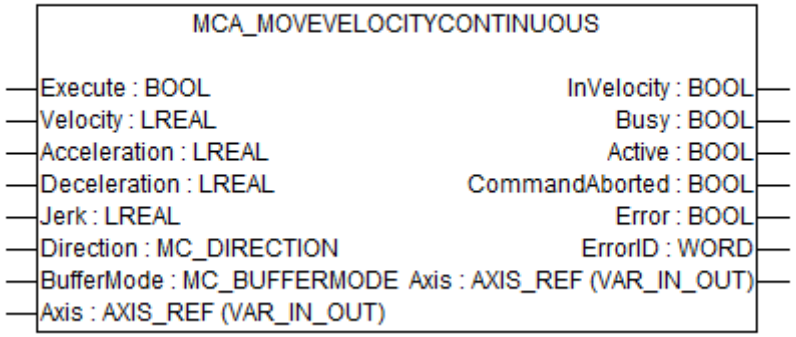

Fig. 433: Function block MCA_MoveVelocityContinuous

InVelocity Data type: BOOL
Commanded velocity reached (first time reached).

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_MoveByExternalReference

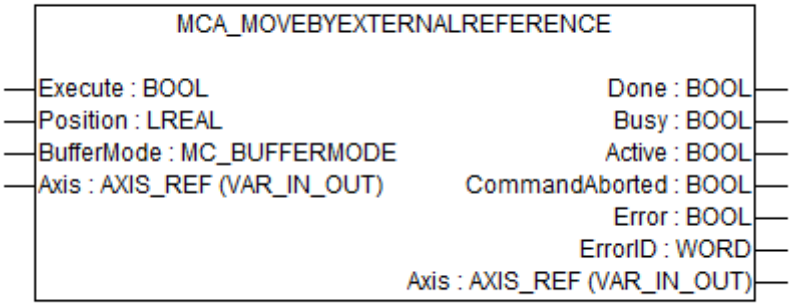

Fig. 434: Function block MCA_MoveByExternalReference

This function block gives a reference position to the axis which is directly passed to the position control loop. The axis will follow the given position without a ramp but immediately. The reference position is evaluated continuously.

> *To stop the motion, the function block has to be interrupted by another function block issuing a new command.*
>
> *This block has to be called from the same task as CMC_MOTION_KERNEL_REAL.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input Description

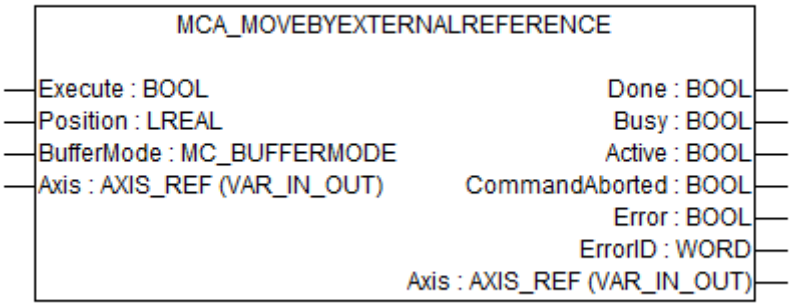

Fig. 435: Function block MCA_MoveByExternalReference

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute Data type: BOOL
Starts the function block at rising edge.

Position Data type: LREAL, unit: u
Reference position.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF
Reference to the axis.

Output Description

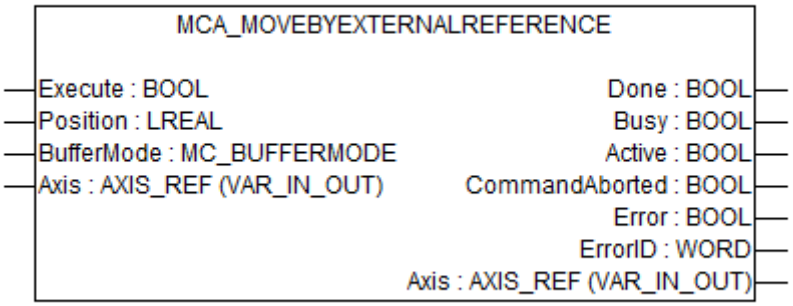

Fig. 436: Function block MCA_MoveByExternalReference

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_Home

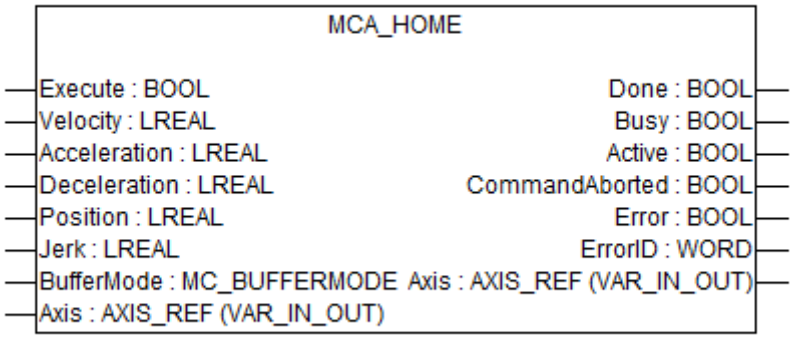

Fig. 437: Function block MCA_Home

The difference to the MC_Home is that the values for velocity, acceleration and deceleration can be set as inputs. The velocity is normally set by a parameter in the drive, so the input Velocity often does not influence the homing procedure. Acceleration and Deceleration are at start of the system zero as no other movement was done before. To performe a homing with defined Acceleration and Deceleration the inputs Acceleration and Decelerationcan be used.

This function block commands the axis to perform the «search home» sequence. The details of this sequence are manufacturer dependent and can be set by the axis’ parameters. The input Position is used to set the absolute position when reference signal is detected. The inputs Velocity, Acceleration, Deceleration are to define the homing motion start parameters. This Function Bock completes at StandStill.

The Homing procedure is executed according the definition in the drive.

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input Description

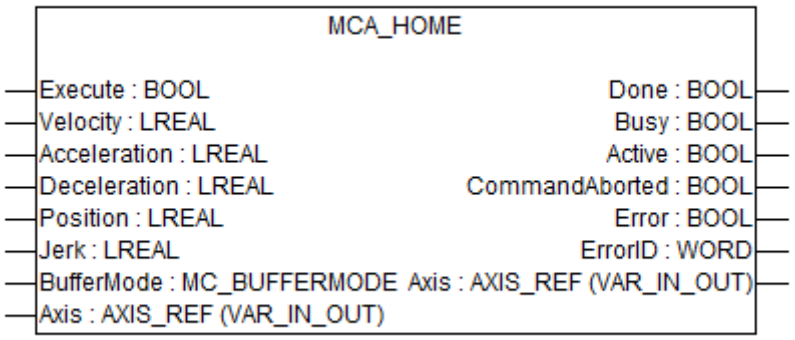

Fig. 438: Function block MCA_Home

Execute Data type: BOOL

Starts the function block at rising edge.

Velocity Data type: LREAL, unit: u/s

Value of the maximum velocity (not necessarily reached). The homing sequence in some drives uses Velocity from an internal parameter, so this input than has no influence .

Acceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

Position Data type: LREAL, unit: u

Absolute position when the reference signal is detected.

Jerk Data type: LREAL, range: > 0, unit: u/s^3

Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Axis Data type: AXIS_REF

Reference to the axis.

Output Description

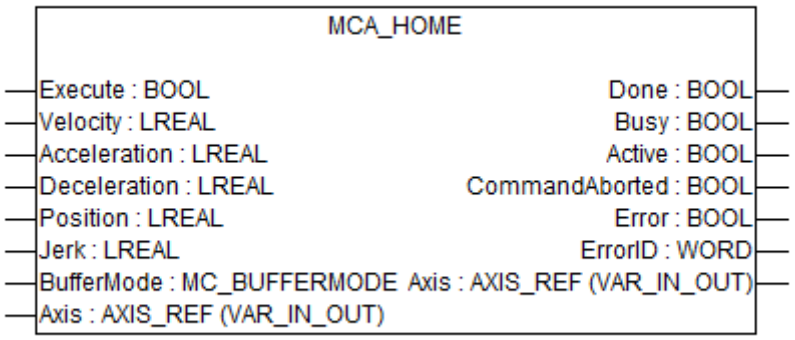

Fig. 439: Function block MCA_Home

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandA-borted Data type: BOOL
Command is aborted by another command.

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_DriveBasedHome

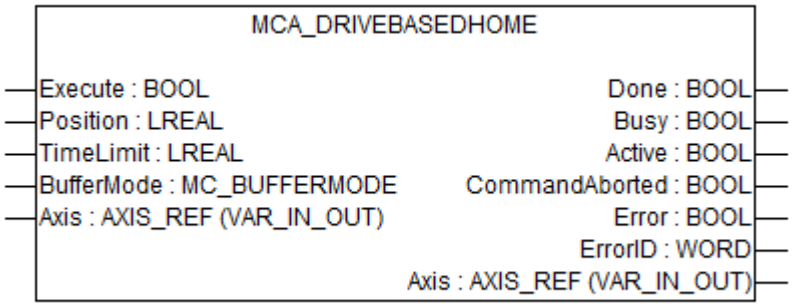

Fig. 440: Function block MCA_DriveBasedHome

This function block can be used to execute a homing procedure directly in the drive. It requires the drive supports 402-profile specific homing sequences.

The function block can be used in combination with:

- *ECAT_402ParameterHoming_APP* to send parameters
- *ECAT_CiA402_CONTROL_APP* to control the drive state machine and to set it to the appropriate operating mode

Input Description

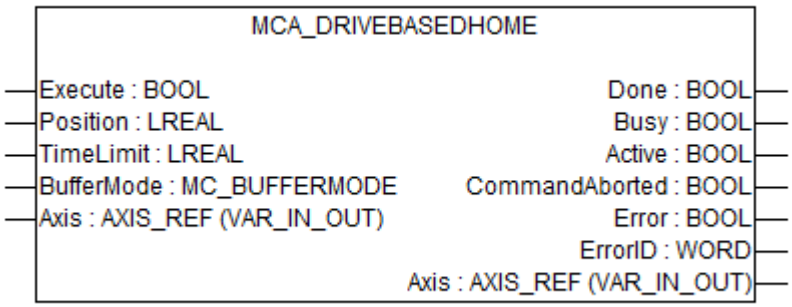

Fig. 441: Function block MCA_DriveBasedHome

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

Position Data type: LREAL, default: 0

Position value in units, which will be used as home offset for the drive.

TimeLimit Data type: LREAL, default: 0
A time in seconds, which will be used as an upper limit for the time available to do the homing.
If the time is exceeded, the function block will show an Error.
With *TimeLimit = 0*, the limit is ignored.

Axis Data type: AXIS_REF
Reference to the axis.

Output Description

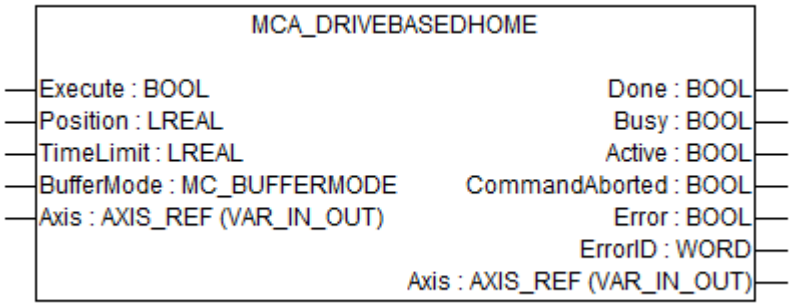

Fig. 442: Function block MCA_DriveBasedHome

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command.

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_Indexing

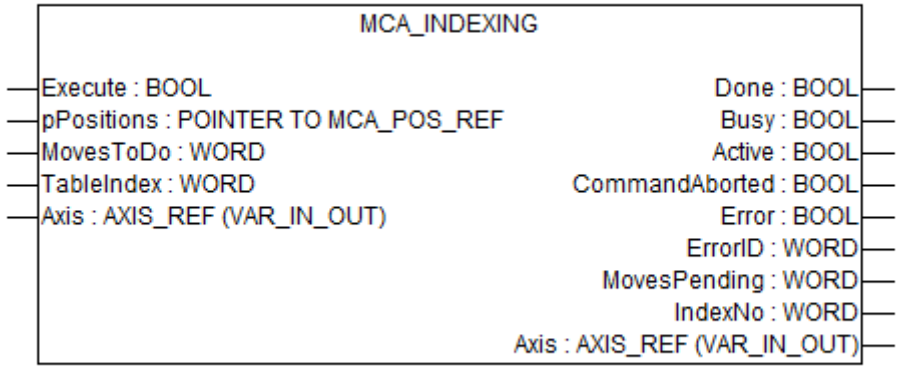

Fig. 443: MCA_Indexing

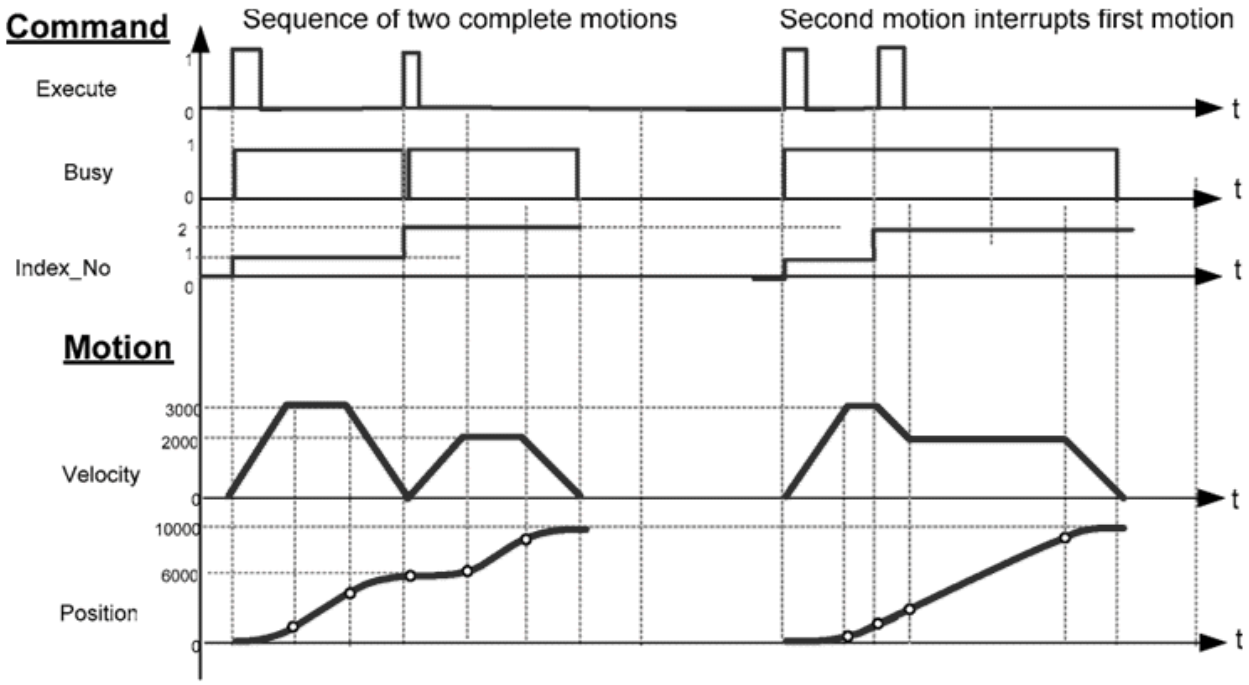
This function block will – upon R_Trig on Execute – do a number of relative or absolute moves, listed in a table (Array of MCA_POS_REF). The function block will position the axis to a complete stop at target position and continue with the next move from the table upon next R_Trig signal or automatically.



See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input Description

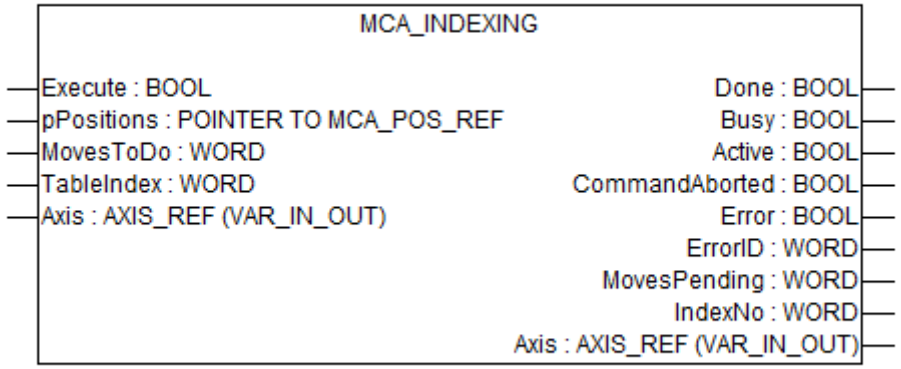


Fig. 444: MCA_Indexing

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

pPositions Data type: POINTER

Pointer to an array of MCA_POS_REF. The array needs to have at least (TableIndex + MovesToDo-1) elements.

MovesToDo Data type: WORD

Number of moves to be performed one after another.

TableIndex Data type: WORD

Index to an array of MCA_POS_REF, points to the movement to be performed on rising edge of **Execute**, start with **1** for the first entry.

Axis Data type: AXIS_REF

Reference to the axis.

Output Description

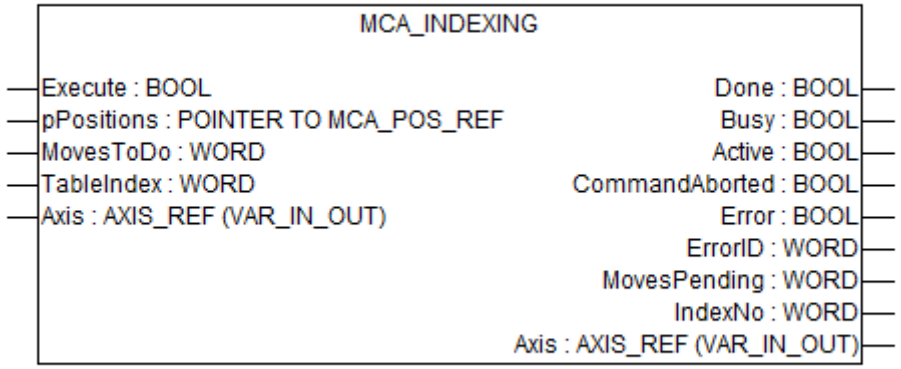

Fig. 445: MCA_Indexing

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block with Busy = TRUE has control on the axis.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command.

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MovesPending Data type: WORD
Indicates the number of moves still to execute.

IndexNo Data type: WORD
Index executing or last index completed, starts with **1**.

MCA_POS_REF

This structure is used to define the movement performed by MCA_Indexing. An array of this structure has to be created. Every single element holds the data for a complete movement. The address of this array has to be connected to input **pPositions** of MCA_Indexing.

MCA_POS_REF	Type	Comment
Position	LREAL	
Velocity	LREAL	
Acceleration	LREAL	
Deceleration	LREAL	
Mode	BOOL	TRUE = Use absolute positoning. FALSE = Use relative positoning.

MCA_JogAxis

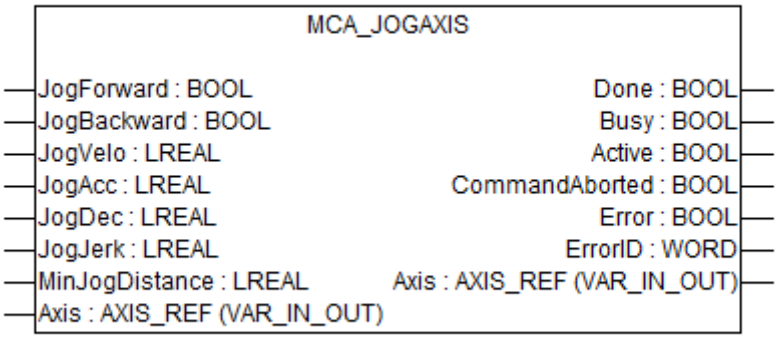

Fig. 446: Function block MCA_JogAxis

This function block jogs an axis for at least a given distance forward or backward with the selected jog velocity and acceleration.

This function block will, after rising edge on JogForward or JogBackward, start a continuous move (at least for the minimum distance) and continue upon high-level on these inputs with a continuous motion, until they are FALSE, then on their falling edge, the axis is regularly decelerated to stop. The movement is carried out on Jog velocity for the minimum distance or longer.

- *In case of both Enable signals are high, the function block will assume the result to be low as in an EXOR conjunction.*
- *In case of MinJogDistance= 0, no specified distance is moved and the movement will stop as soon as the JogForward and JogBackward= FALSE.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input Description

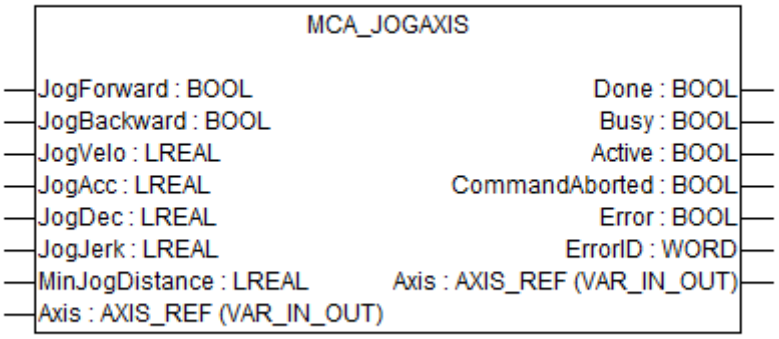

Fig. 447: Function block MCA_JogAxis

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

JogForward Data type: BOOL
Moves forward while “JogForward” =TRUE.

JogBackward Data type: BOOL
Moves backward while “JogBackward” =TRUE.

JogVelo Data type: LREAL
Velocity to jog .

JogAcc Data type: LREAL
Acceleration.

JogDec Data type: LREAL
Deceleration.

JogJerk Data type: LREAL
Jerk.

MinJogDistance Data type: LREAL
Minimum distance to jog (in t.u. [u]).

Axis Data type: AXIS_REF
Reference to the axis.

Output Description

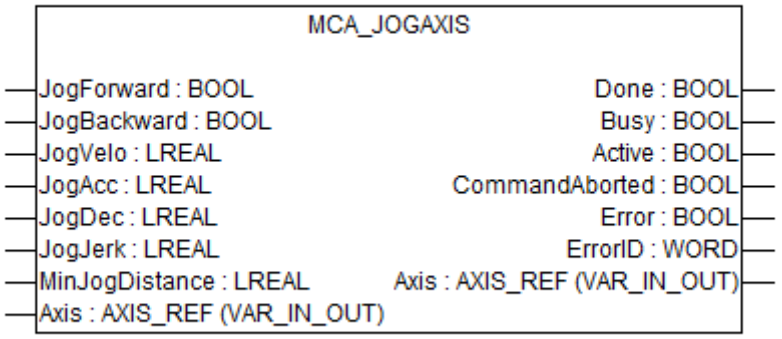

Fig. 448: Function block MCA_JogAxis

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_WriteParameterList

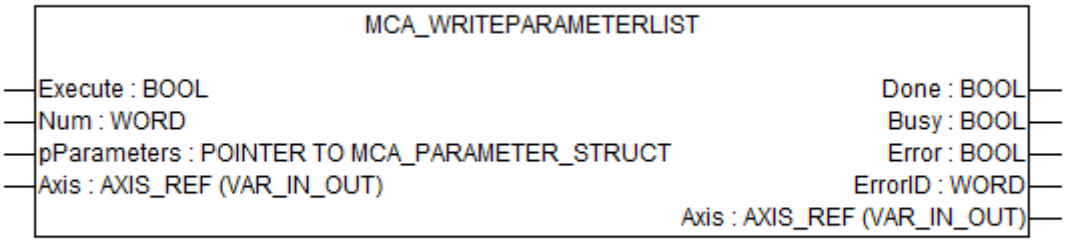

Fig. 449: Function block MCA_WriteParameterList

The function block writes a list of parameters by using the MC_WriteParameter. The rules for utilizing the function block correspond to MC_WriteParameter as well as the ErrorIds. All parameters and parameter numbers have to be stored in an array of type MCA_PARAMETER_STRUCT. The address of the first element is to be given to the function block's input “parameters”. The number of elements to be written is declared at input Num.

See the following chapter to check if this function block is supported by the used axis implementation: ↬ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↬ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input Description

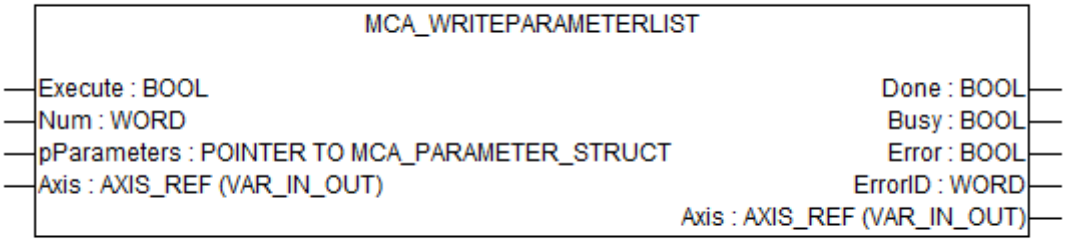

Fig. 450: Function block MCA_WriteParameterList

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

Num Data type: WORD

Number of the parameters to be written.

pParameters Data type: POINTER

Points to an array of type MCA_Parameter_STRUCT which holds the parameter numbers and values.

Axis Data type: AXIS_REF

Reference to the axis.

Output Description

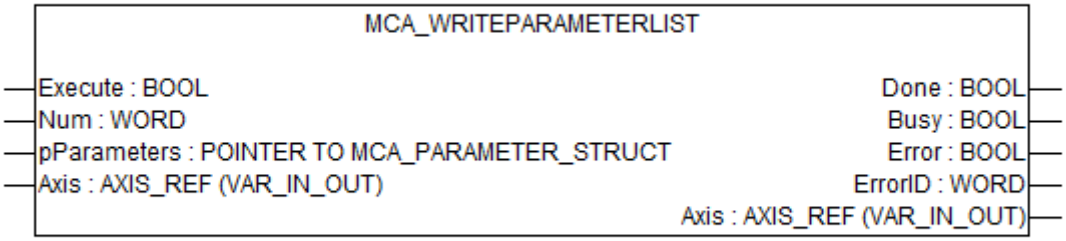

Fig. 451: Function block MCA_WriteParameterList

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_ReadParameterList

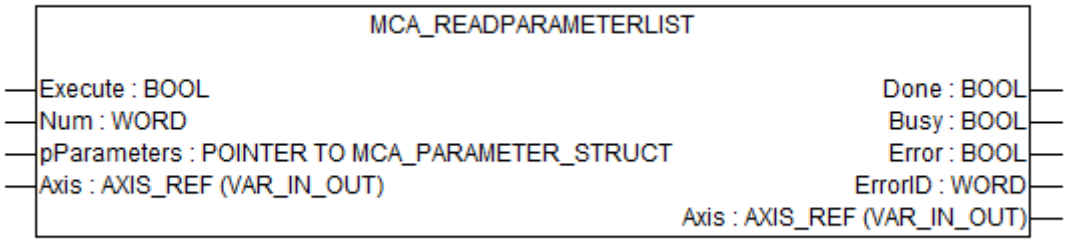

Fig. 452: Function block MCA_ReadParameterList

The function block reads a list of parameters by using the MC_ReadParameter. The rules for utilizing the function block correspond to MC_ReadParameter as well as the ErrorIds. All parameters and parameter numbers have to be stored in an array of type MCA_PARAMETER_STRUCT. The address of the first element is to be given to the function block's input parameters. The number of elements to be read is declared at input Num.

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 "Overview of PLCopen function blocks" on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 "Overview of data types" on page 2585*

Input Description

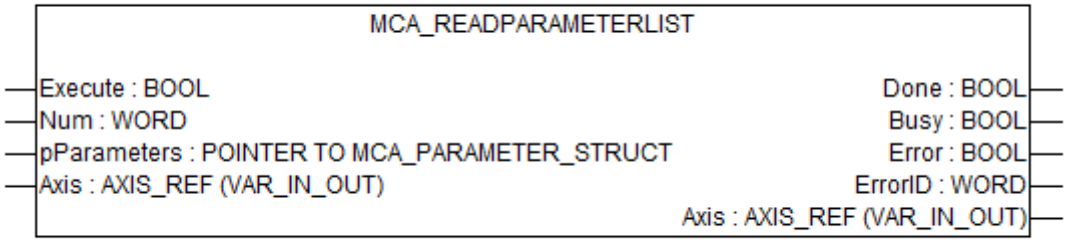

Fig. 453: Function block MCA_ReadParameterList

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

Num Data type: WORD

Number of the parameters to be written.

pParameters Data type: POINTER

Points to an array of type MCA_Parameter_STRUCT which holds the parameter numbers and values.

Axis Data type: AXIS_REF

Reference to the axis.

Output Description

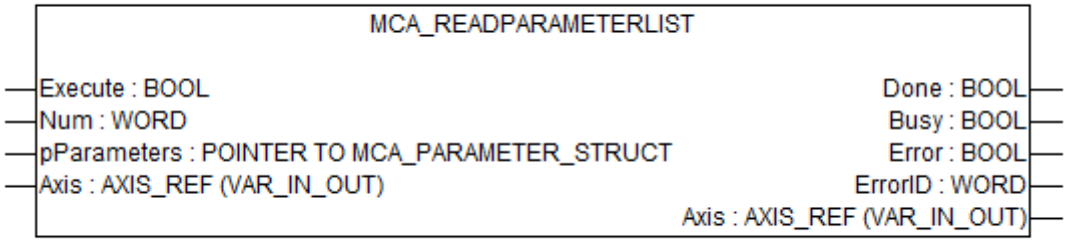

Fig. 454: Function block MCA_ReadParameterList

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block with Busy = TRUE has control on the axis.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

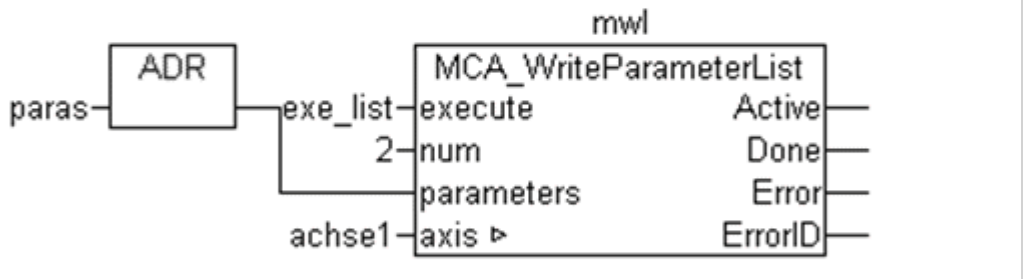
MCA_PARAMETER_STRUCT

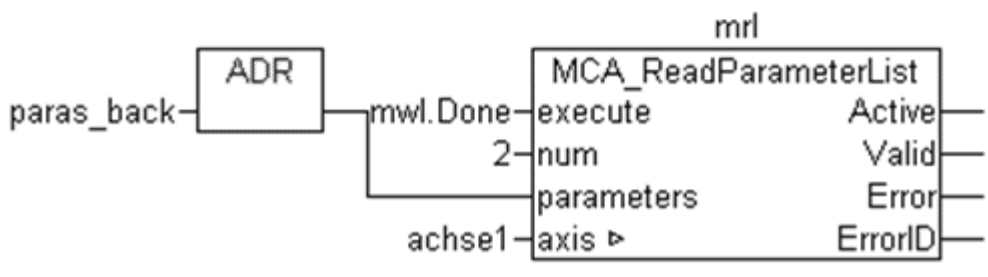
This structure is used to define the parameter list used by MCA_ReadParameterList or MCA_WriteParameterList. An array of this structure has to be created. The address of this array has to be connected to input **Parameters** of MCA_ReadParameterList or MCA_WriteParameterList

MCA_PARAM-ETER_STRUCT	Type	Comment
ParameterNumber	WORD	
Value	DINT	In case of WriteParameterList, **Value** will be written to the Parameter indicated by ParameterNumber. In case of ReadParameterList, the function block will read the Parameter indicated by ParameterNumber and write it to **Value**.

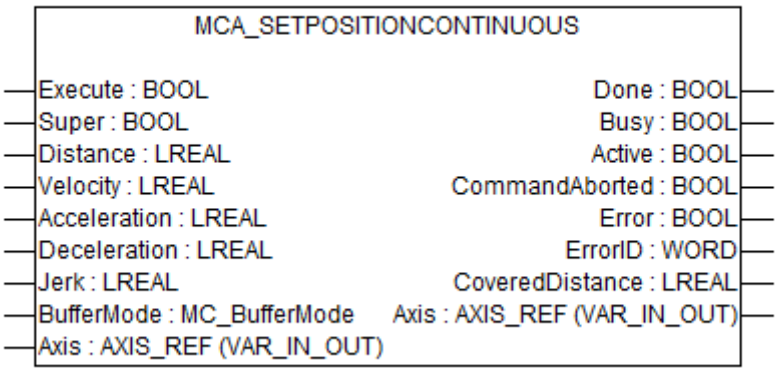
This example write 2 parameters to “achse1” and reads them back afterwards:

```
PROGRAM ParameterReadWrite
VAR
    paras_back:ARRAY[0..1]OF MCA_Parameter_STRUCT:=
        (ParameterNumber:=41001,value:=0),
        (ParameterNumber:=43401,value:=0);
    paras:ARRAY[0..1]OF MCA_Parameter_STRUCT:=
        (ParameterNumber:=41001,value:=3),
        (ParameterNumber:=43401,value:=0);
    mrl: MCA_ReadParameterList;
    mrw:MCA_WriteParameterList;
END_VAR
```





MCA_SetPositionContinuous



This function block shifts the coordinate system of an axis by manipulating either the set-point position or the actual position of an axis. This can be used for instance for a reference situation “on the fly” where no abrupt position change is allowed, eg when a slave axis is linked to the modified axis. This function block can also be used during motion without changing the commanded position, which is now positioned in the shifted coordinate system. A continuous position correction will be achieved, with a defined profile.

- *The function block is allowed in any state except ErrorStop or Homing. In Discrete Motion, just mode SUPER = TRUE is possible.*
- *The block will not change the axis state even when it results in a movement.*
- *With Super = TRUE, the axis will hold the setpoint position while an offset is applied to the actual position. This will result in a movement as the position control loop will keep the distance between setpoint- and actual position constant. A slave axis will not see this movement and will not follow. When the block is ready, the axis will have moved physically by -Distance but the positions in AXIS_REF will not have been changed.*
- *With Super = FALSE, the behavior equals MC_SetPosition, but executed continuously. The axis will physically stay where it is but the actual position and setpoint-position are modified. A slave axis will follow.*
- *With Super = FALSE: When it is acceptable and required to correct the position with a jump, use Acceleration = -1.*

See the following chapter to check if this function block is supported by the used axis implementation: ↳ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↳ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input Description

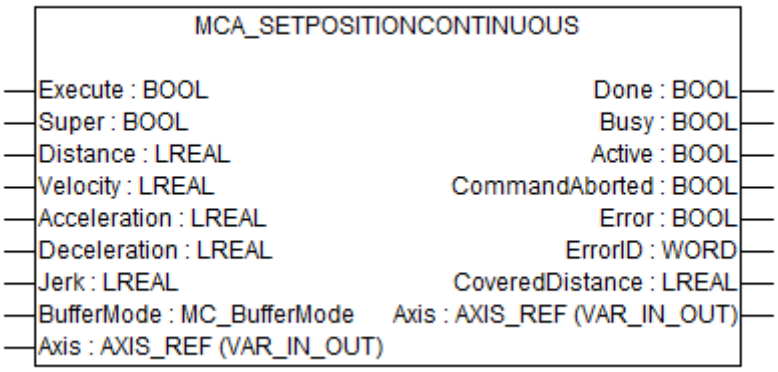


Fig. 455: Function block MCA_SetPositionContinuous

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

Super Data type: BOOL
Defines 2 different modes.

Distance Data type: LREAL, unit: u
Relative distance for the motion.

Velocity Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis Data type: AXIS_REF

Reference to the axis.

Output Description

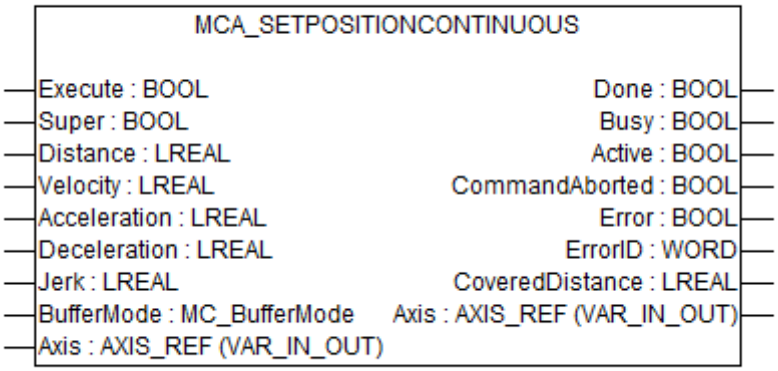

Fig. 456: Function block MCA_SetPositionContinuous

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

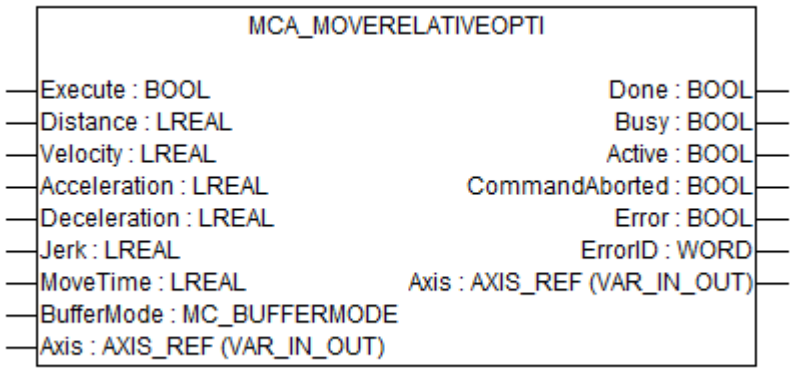
ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

CoveredDistance Data type: LREAL

Shows the progress, starts with 0 and ends with Covered-Distance= Distance. The value is just valid while the function block is active.

MCA_MoveRelativeOpti



This function block is designed to allow an easier setup for positioning movement. The input MoveTime which receives the allowed time to move the given distance. The other inputs, as Velocity, Acceleration, Deceleration and Jerk can be left "0", then the movement will use the system limits and perform an as “soft” as possible positioning.

- It will always use a Jerk (when possible).
- To switch off the usage of Jerk, use Jerk = -1 as input parameter.
- Use the smallest possible acceleration/deceleration.
- Use the smallest possible velocity.

If it is not required to create a movement with limited Jerk, the input Jerk = -1 should be used. The acceleration and deceleration is applied with a "jump" but a smaller maximum value is reached.

If parameters as Velocity, Acceleration and Deceleration are set, these will be considered to be the upper limits during the movement. If it is not possible to execute the movement in the given time, an error will be shown. The function block gives also a suggestion which values could be used to execute the movement within the time limitations.

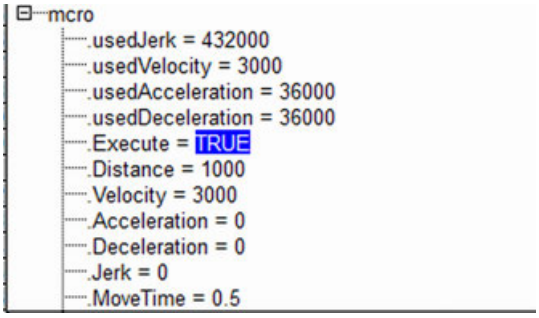
If the velocity was too small, the internal variable usedVelocity will hold the smallest possible value to execute the movement in the given time. This would mean execute it without any ramps. usedAcceleration and usedDeceleration will be "0" in this case.

If the velocity was ok, but acceleration and deceleration too small, usedVelocity will show the value from input Velocity and variables usedAcceleration and usedDeceleration will hold the necessary values to execute the movement in the given time.

With move_Time = 0, the behavior for the function block is identical with MC_MoveRelative ↬ Chapter 1.5.9.6.1.2 “MC_MoveRelative” on page 2751.

It is possible to use just Distance and MoveTime as input parameters. In this case, the function block will take the axis configuration parameters as limitations for the movement and always create the smoothest possible interpolation.

If parameters are given which are not possible to use, e.g. velocity is too small to reach the target in the given time, the function block´s internal variables usedJerk, usedVelocity, usedAcceleration and usedDeceleration will show a possible solution.

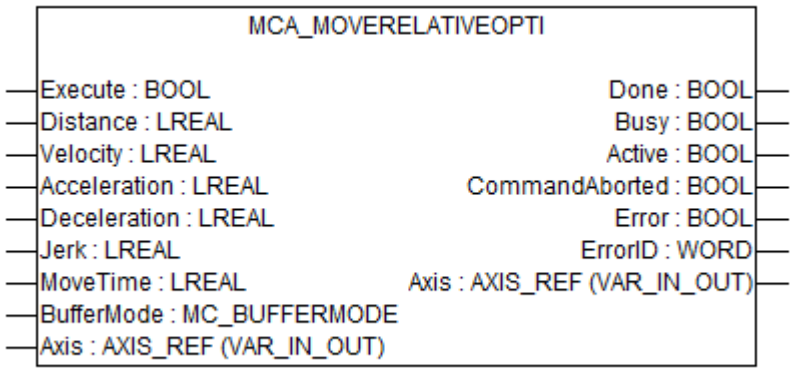


See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 "Overview of PLCopen function blocks" on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 "Overview of data types" on page 2585*

Input Description



Execute Data type: BOOL

Starts the function block at rising edge.

Distance Data type: LREAL, unit: u

Relative distance for the motion.

Velocity Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

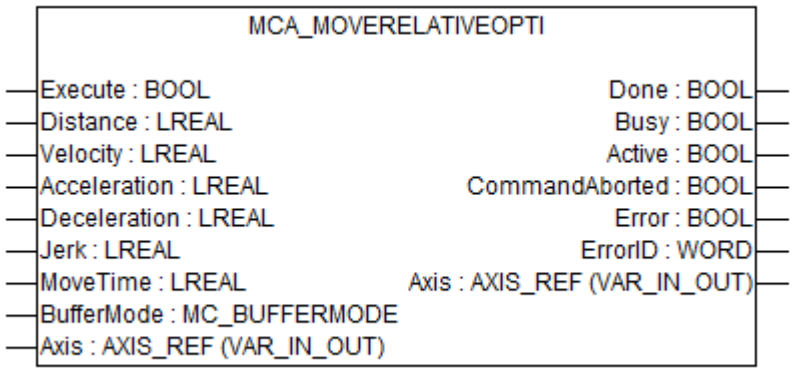
Jerk
Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

MoveTime
Data type: LREAL, range: > 0, unit: s
Time to be used for the movement.

BufferMode
Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

Axis
Data type: AXIS_REF
Reference to the axis.

Output Description



Done
Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy
Data type: BOOL
The function block is not finished.

Active
Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted
Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error
Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_GearInDirect

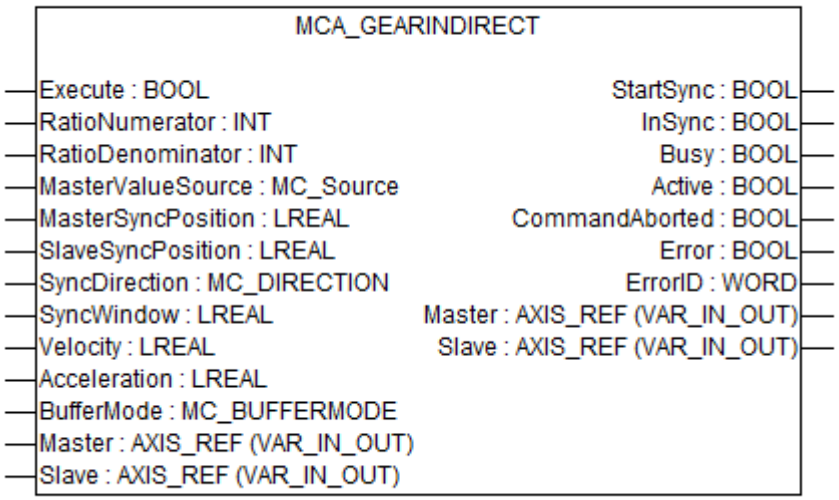


Fig. 457: MCA_GearInDirect

This function block commands a gear ratio between the position of the slave and master axes from the synchronization point onwards.

The function block behaves as follows:

- Synchronization starts right away, no matter if the master moves or is in standstill.
- The synchronization is limited by the given velocity and acceleration, and achieved as fast as possible, so it can happen that:
  - The 2 axes are synchronized earlier then the 2 given positions
  - The 2 axes are synchronized later then the 2 given positions
- Following formula is used:
  - slavePosition = (masterPosition-MasterSyncPosition)*RatioNumerator/RatioDenumerator+SlaveSyncPosition
- In a modulo-axis, it is possible to reach the synchronization point in different directions.
  The input parameter SyncDirection with its possible values: POSITIVE, NEGATIVE or SHORTEST can be used to set this direction.
  Inside the SyncWindow, automatically the direction SHORTEST will be used. It is important to set a SyncWindow>0 for a modulo axis, because otherwise, slightest deviations could result in moving a complete modulo distance.
  - Inside SyncWindow, the slave axis will move SHORTEST to reach the SlaveSyncPosition
  - Outside SyncWIndow, it will move the given SyncDirection, which can be POSITIVE or NEGATIVE
- If a direction POSITIVE or NEGATIVE is used in a linear axis, the slave will wait until the master reaches a position which allows the slave to move the required direction.

Input Description

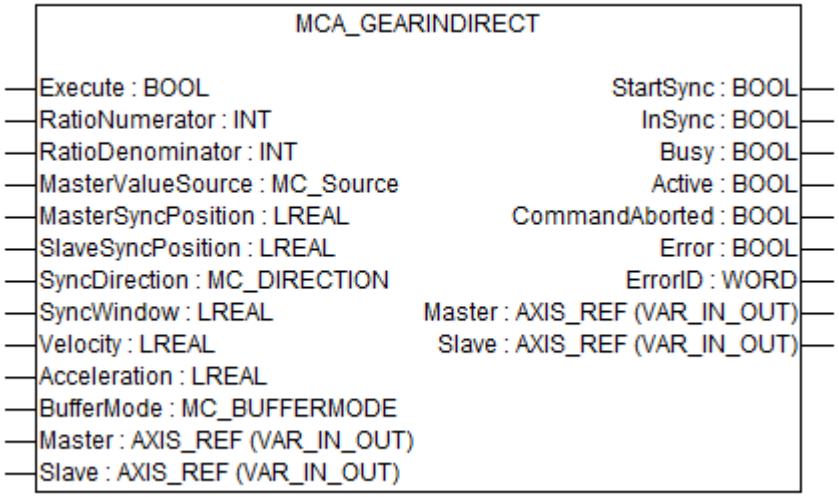

Fig. 458: MCA_GearInDirect

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute
Data type: BOOL
Starts the function block at rising edge.

RatioNumerator
Data type: INT
Gear Ratio Numerator.

RatioDenominator
Data type: INT
Gear Ratio Denominator.

MasterValueSource
Data type: MC_SOURCE
Defines the source for synchronization:
mcSetValue - Synchronization on master set value.
mcActualValue - Synchronization on master actual value.

MasterSyncPosition
Data type: LREAL
The position of the master where the slave is insync with the master.

SlaveSyncPosition
Data type: LREAL
Slave Position at which the axes are running in sync.

SyncDirection
Data type: MC_DIRECTION

Moving direction for the slave to start the movement.

POSITIVE, NEGATIVE or SHORTEST are applicable.

SyncWindow Data type: LREAL

- when the slave is outside the SyncWindow, it will move the direction which is given in SyncDirection
- when the slave is inside the SyncWindow, it will move SHORTEST to meet the SlaveSync-Position.

Velocity Data type: LREAL

Velocity which limits the synchronization movement.

The slave has to be able to move faster than the master axis, otherwise it is possible the SlaveSyncPosition is never reached when the master starts to move.

Acceleration Data type: LREAL

Acceleration which limits the synchronization movement.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Master Data type: AXIS_REF

Reference to the master axis.

Slave Data type: AXIS_REF

Reference to the slave axis.

Output Description

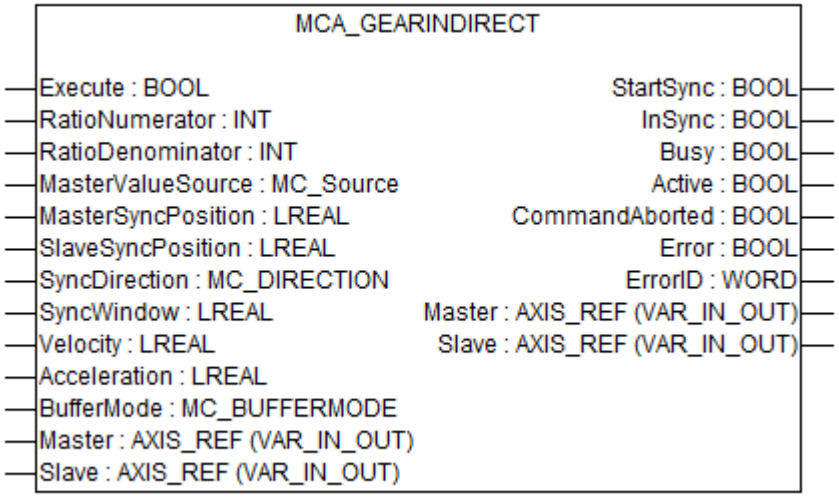

Fig. 459: MCA_GearInDirect

StartSync Data type: BOOL
Commanded gearing starts.

InSync Data type: BOOL
Commanded gearing completed.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_CamInDirect

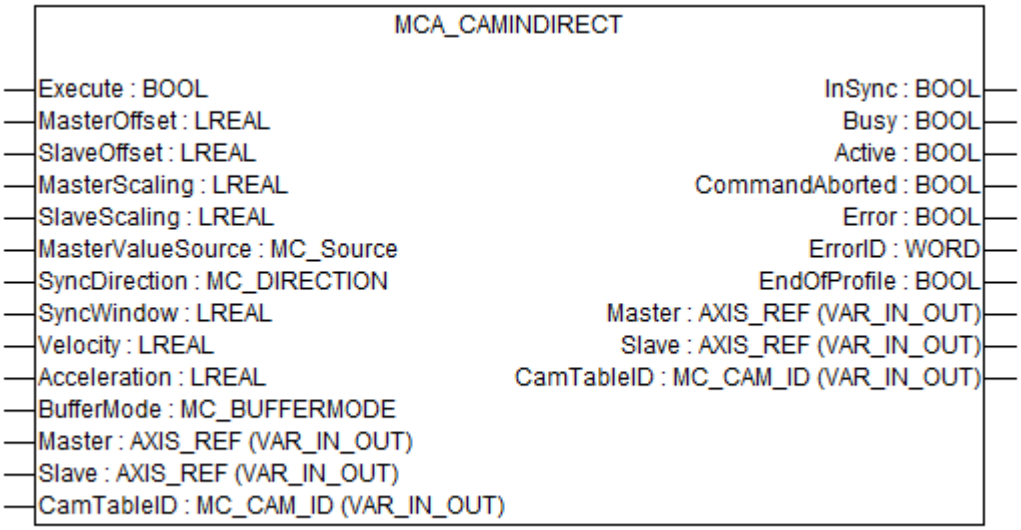

Fig. 460: MCA_CamInDirect

This function block engages the Cam.

- *It is not required that the master is stationary.*
- *If the actual master and slave positions do not correspond to the offset values when MC_CamIn is executed, either an error occurs or the system deals with the difference automatically.*
- *The Cam is placed either absolute or relative to the current master and slave positions.*

  Absolute: The profile between master and slave is seen as an absolute relationship.

  Relative: The relationship between master and slave is in a relative mode.
- *This function block is not merged with the MC_CamTableSelect function block because this separation enables changes on the fly.*
- *A mechanical analogy to a slave offset is a cam welded with additional constant layer thickness. Because of this the slave positions have a constant offset and the offset could be interpreted as axis offset of the master shaft, if linear guided slave tappets are assumed.*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

The function block behaves as follows:

- If the master is inside the position range which is described in the cam-table data, synchronization starts right away, no matter if the master moves or is in standstill.
- If the master is outside the position range which is described in the cam-table data, the slave position is not modifed.

- The synchronization is limited by the given Velocity and Acceleration, and achieved as fast as possible.
  The function block will show InSync when synchronization process is completed and the slave axes reference position matches the cam-table data for the current master position.
- In a modulo-axis, it is possible to reach the synchronization point in different directions.
  The input parameter SyncDirection with its possible values: POSITIVE, NEGATIVE or SHORTEST can be used to set this direction.
  Inside the SyncWindow, automatically the direction SHORTEST will be used.
  It is important to set a SyncWindow>0 for a modulo axis, because otherwise, slightest deviations could result in moving a complete modulo distance.
  – Inside SyncWindow, the slave axis will move SHORTEST to reach the SlaveSyncPosition
  – Outside SyncWIndow, it will move the given SyncDirection, which can be POSITIVE or NEGATIVE
- If a direction POSITIVE or NEGATIVE is used in a linear axis, the slave will wait until the master reaches a position which allows the slave to move the required direction.

> *The MC_CamIn has parameters to scale the cam-table values (MasterScaling, SlaveScaling).*
>
> *It has to be considered that MasterOffset and SlaveOffset are scaled exactly like the corresponding cam-table values.*

Input Description

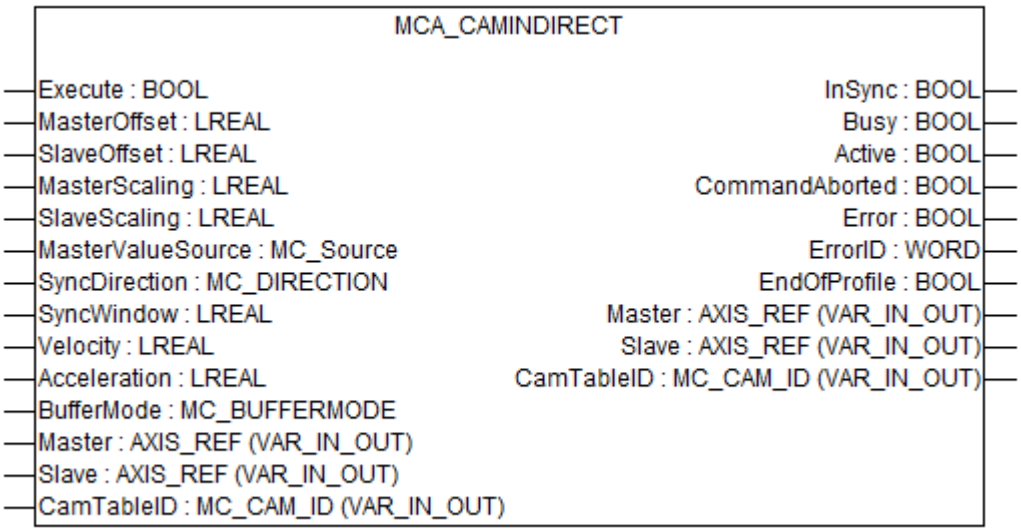

Fig. 461: MCA_CamInDirect

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

MasterOffset Data type: LREAL

Offset of master table. Angular offset of the master shaft to cam.

SlaveOffset Data type: LREAL, default: 0

Offset of slave table. Sharpened cam (i.e higher elevation and deeper depression).

MasterScaling Data type: LREAL, default: 1.0

Factor for the master profile. From the slave point of view the master overall profile is multiplied by this factor.

SlaveScaling Data type: LREAL, default: 1.0

Factor for the slave profile. The overall slave profile is multiplied by this factor.

MasterValue-Source Data type: MC_SOURCE

Defines the source for synchronization:

mcSetValue - Synchronization on master set value.

mcActualValue - Synchronization on master actual value.

SyncDirection Data type: MC_DIRECTION

Moving direction for the slave to start the movement.

POSITIVE, NEGATIVE or SHORTEST are applicable.

SyncWindow Data type: LREAL

- when the slave is outside the SyncWindow, it will move the direction which is given in SyncDirection
- when the slave is inside the SyncWindow, it will move SHORTEST to meet the SlaveSync-Position.

Velocity Data type: LREAL

Velocity which limits the synchronization movement.

The slave has to be able to move faster than the master axis, otherwise it is possible the SlaveSyncPosition is never reached when the master starts to move.

Acceleration Data type: LREAL

Acceleration which limits the synchronization movement.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Master Data type: AXIS_REF

Reference to the master axis.

Slave Data type: AXIS_REF
Reference to the slave axis.

CamTableID Data type: MC_CAM_ID
Identifier of CAM Table to be used in the MC_CamIn function block.

Output Description

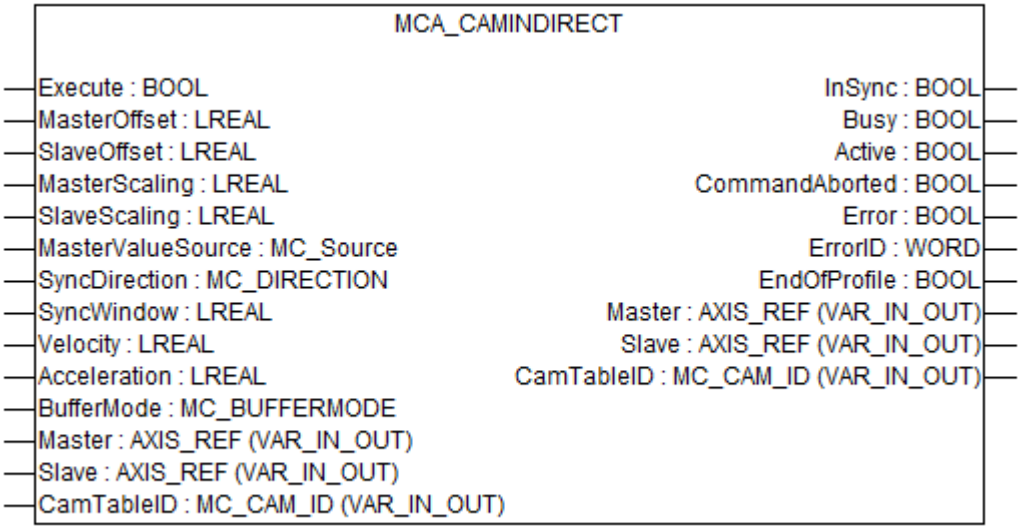

Fig. 462: MCA_CamInDirect

InSync Data type: BOOL
Cam is engaged for the first time.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandA-borted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

EndOfProfile Data type: BOOL

Pulsed output signaling the cyclic end of the CAM Profile.

MCA_SetOperatingMode

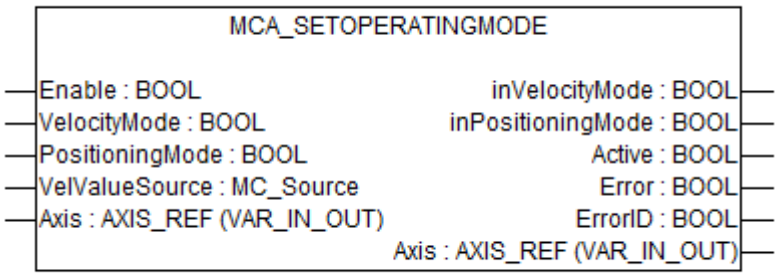

Fig. 463: Function block MCA_SetOperatingMode

This function block changes the axis mode from positioning to velocity mode and vice versa.

By default, an axis is always a positioning axis which has to follow either the drives or the PLCs position control loop. In some applications, the movement is limited (e.g. by torque restrictions) so the position can´t be reached.

A position controlled axis would first speed up, and then create a following error, both caused by the increasing position lag.

The function block MCA_SetOperatingMode can be used to prevent this behavior and will switch between velocity- and position controlled behavior “on the fly”.

> *To use the function block MCA_SetOperatingMode, the drive has to be used in CSV (ContinuousSyncronuousVelocity), or an analog drive has to be used, which means it has to move controlled by SPEED_REFERENCE (Kernel).*

If the function block is called in StandStill, ErrorStop or Disabled, it will be effective immediately.

In any other mode, it will be effective with the next “Execute” rising edge on a function block which activates a movement. It can be called while the axis is moving and will create a bump-less transition between the velocity- and position controlled mode.

In velocity mode:

- The SPEED_REFERENCE is created by feed-forward, in an open loop. (It is not required to set FF_PERCENTAGE parameter) REFERENCE_POSITION will follow the DRIVE_ACTUAL_POSITION Position following error is not supervised.
- REFERENCE_POSITION will follow the DRIVE_ACTUAL_POSITION.
- Position following error is not supervised.

See the following chapter to check if this function block is supported by the used axis implementation: ↬ *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

For this function block there is a visualization in the Library MC_Blocks_AC500_V11.

See the following chapter for a list of available data types: ↬ *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input Description

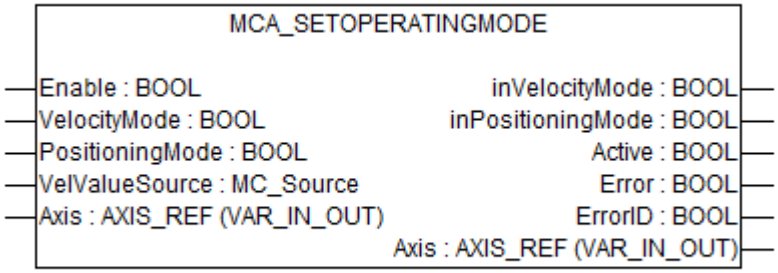

Fig. 464: Function block MCA_SetOperatingMode

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable

Data type: BOOL

Enables the function block to switch the operating mode. A rising edge is not required, the block will be operate if Enable=TRUE and will react to the VelocitiyMode/PositioningMode inputs.

VelocityMode=TRUE/PositioningMode=FALSE=> switch axis to velocity mode.

VelocityMode=FALSE/PositioningMode=TRUE=> switch axis to positioning mode.

VelocityMode=PositioningMode => no change.

VelocityMode

Data type: BOOL, default: FALSE

Demands the axis to be set in VelocityMode.

Positioning-Mode

Data type: BOOL, default: FALSE

Demands the axis to be set in PositioningMode.

Axis

Data type: AXIS_REF

Reference to the axis.

Output Description

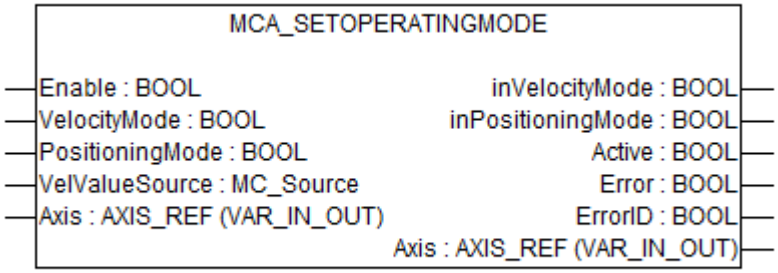

Fig. 465: Function block MCA_SetOperatingMode

InVelocityMode Data type: BOOL

Shows the axis state.

InPositioning-Mode Data type: BOOL

Shows the axis state.

Active Data type: BOOL

Indicates that the function block has control on the axis.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_PhasingByMaster

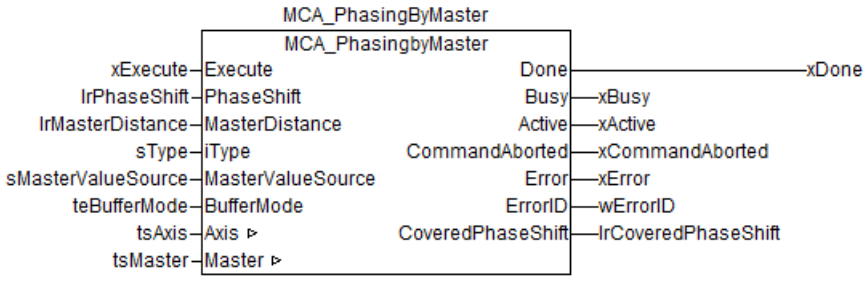

Fig. 466: Function block MCA_PhasingByMaster

This function block performs a movement for the relation to the master axis of the specified axis. A real movement is just performed in case the axis is in synchronized motion.

This function block creates a relative phase shift in the master position of a slave axis. The master position is shifted in relation to the real physical position. This is analogous to opening a coupling on the master shaft for a moment and is used to delay or advance an axis to its master. The phase shift is seen from the slave. The master does not know that there is a phase shift experienced by the slave. The phase shift remains, until another “Phasing” command changes it again.

> *The phasing is executed with respect to a master movement and will use a polynomial interpolation*

See the following chapter to check if this function block is supported by the used axis implementation: *Chapter 1.5.9.2.4 “Overview of PLCopen function blocks” on page 2577*

See the following chapter for a list of available data types: *Chapter 1.5.9.2.6 “Overview of data types” on page 2585*

Input description

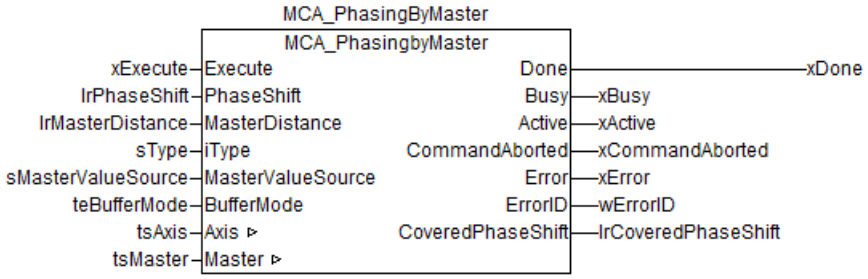

Fig. 467: Function block MCA_PhasingByMaster

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge

Phaseshift Data type: LREAL

[u] = Technical unit, phase difference in master

MasterDistance Data type: LREAL

[u] Distance master has to move

iType Data type: MC_ABB_iTypes_Enum

Interpolationtype, possible values are:

- MCA_SPLINE_COMPLETE
- MCA_SPLINE_NATURAL
- MCA_POLY5

- MCA_POLY3
- MCA_LINEAR

MasterValue-Source
Data type: MC_Source
Decide to use the actual position or reference position of master axis

BufferMode
Data type: MC_BufferMode
Not supported, default mcABORTING used

Axis
Data type: Axis_Ref
Reference to axis

Master
Data type: Axis_Ref
Reference to master axis

Output description

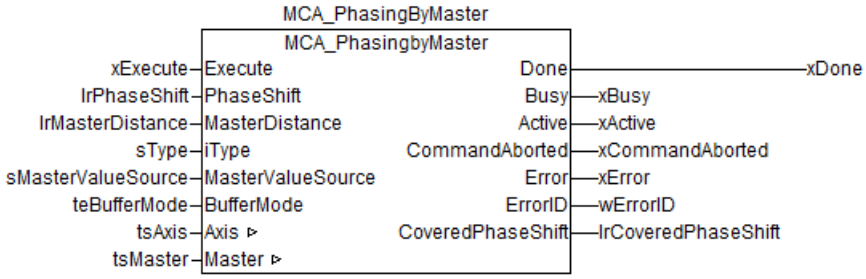

Fig. 468: Function block MCA_PhasingByMaster

Done
Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished

Busy
Data type: BOOL
The function block is not finished

Active
Data type: BOOL
Indicates that the function block has control on the axis

CommandA-borted
Data type: BOOL
Command is aborted by another command from other PLCopen function block

Error
Data type: BOOL
Signals that error has occurred within function block

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*

CoveredPhase-Shift Data type: LREAL

Actual phase shift of master axis to slave axis, valid while function block is busy

1.5.9.7 PLCopen function blocks (Coordinated motion control)

1.5.9.7.1 Standard function blocks

MC_GroupEnable

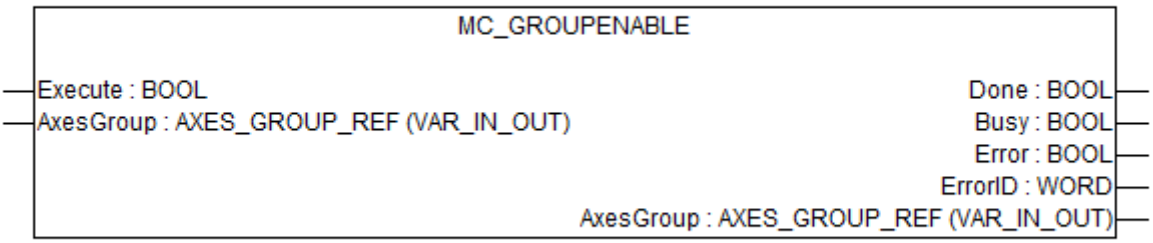

Fig. 469: MC_GroupEnable

This function block changes the state for a group from GroupDisabled to GroupStandby. This is an administrative function block, since no movement is generated.

> *The command does not influence the power state of any of the single axes in the group.*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

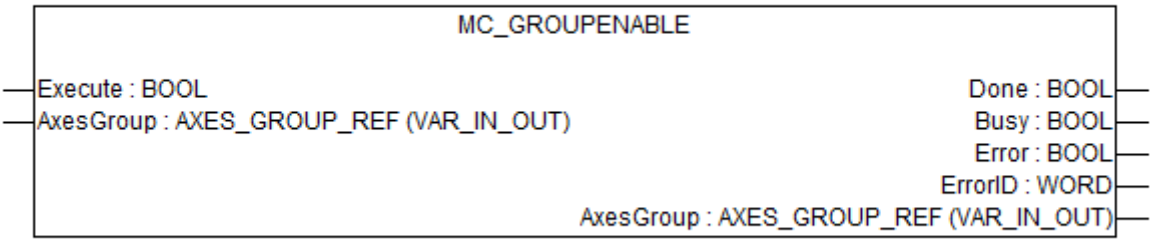

Fig. 470: MC_GroupEnable

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

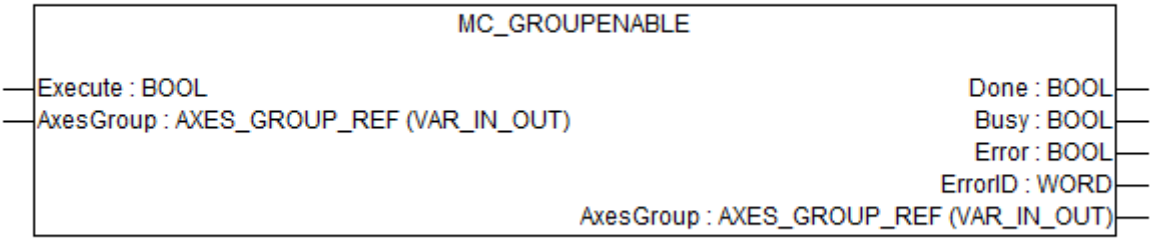

Fig. 471: MC_GroupEnable

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_GroupDisable

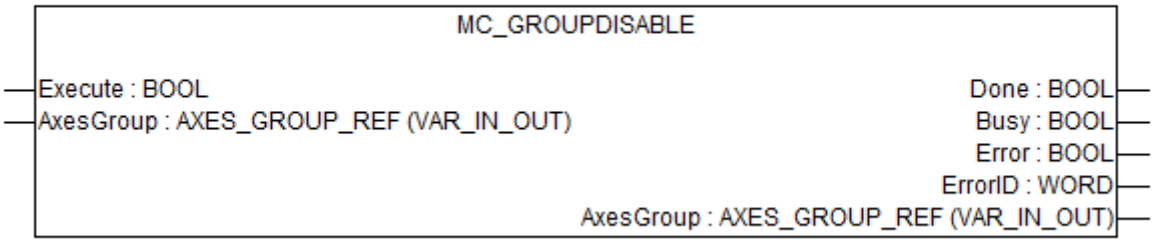

Fig. 472: MC_GroupDisable

This function block changes the state for a group to GroupDisabled, although it is an administrative FB, since no movement is generated. If the axes are not standing still while issuing this command, it is up to the application to take the necessary precautions.

> *The command does not influence the power state of any of the single axes in the group.*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

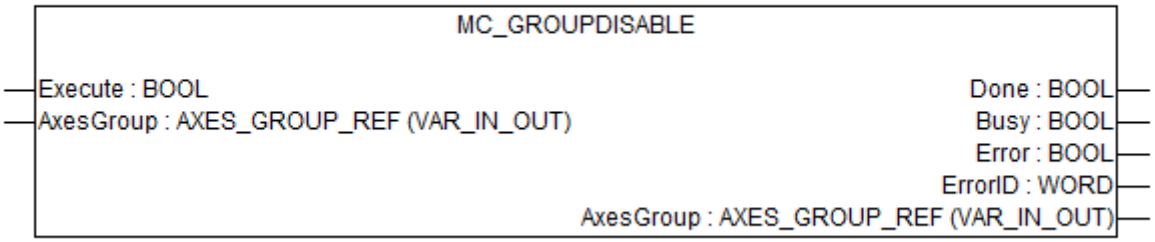

Fig. 473: MC_GroupDisable

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

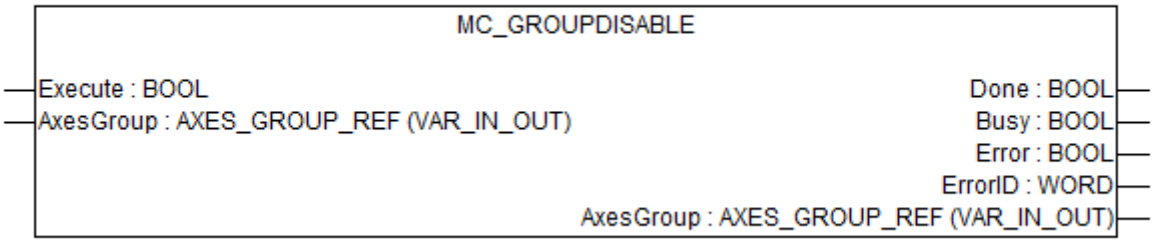

Fig. 474: MC_GroupDisable

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_GroupReadActualPosition

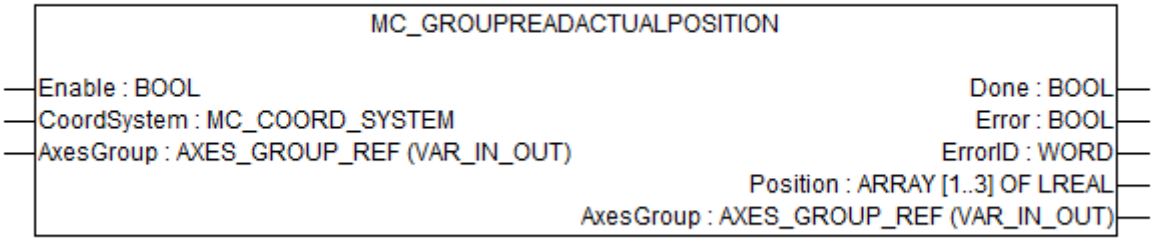

Fig. 475: Function block MC_GroupReadActualPosition

This function block returns the actual position in the selected coordinate system of an axes group. This is an administrative function block, since no movement is generated.

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

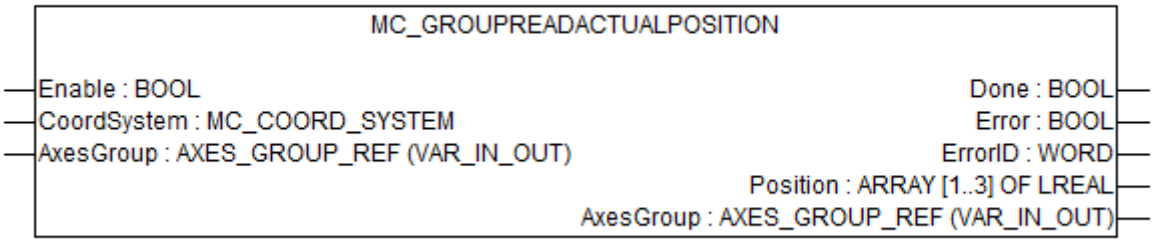

Fig. 476: Function block MC_GroupReadActualPosition

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Get the actual position in the selected coordinate system of the axes group continuously while enabled.

CoordSystem Data type: MC_COORD_SYSTEM; range: MC_DEFAULT_COORD, MC_MCS_COORD, MC_PCS_COORD

Reference to the coordinate system (MCS, PCS).

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

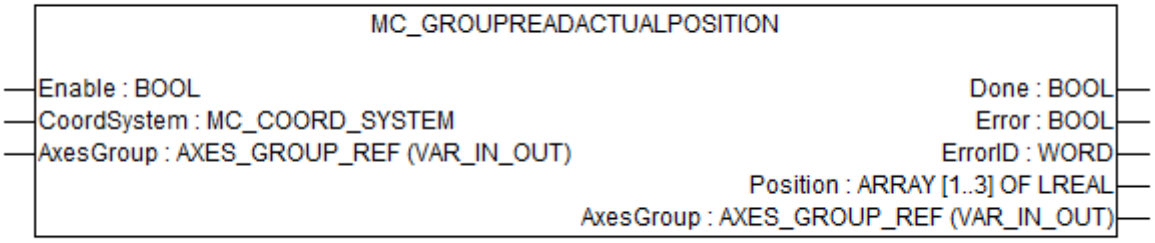

Fig. 477: Function block MC_GroupReadActualPosition

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

Position Data type: ARRAY [1..3] OF REAL

Current position of the group.

MC_GroupReadActualVelocity

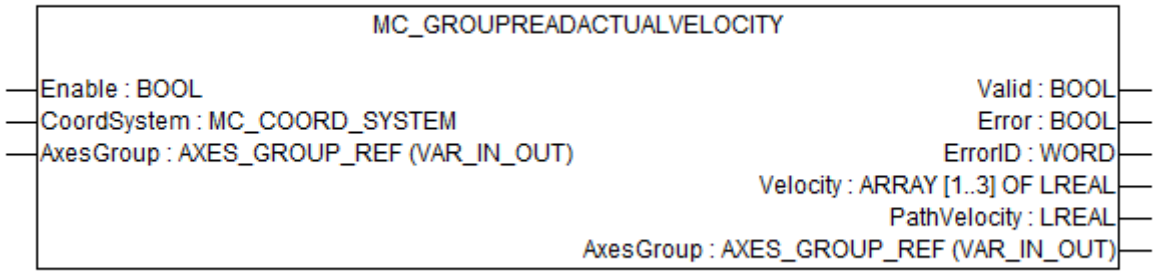

Fig. 478: MC_GroupReadActualVelocity

This function block returns the actual velocity in the selected coordinate system of an axes group. This is an ad-ministrative function block, since no movement is generated.

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

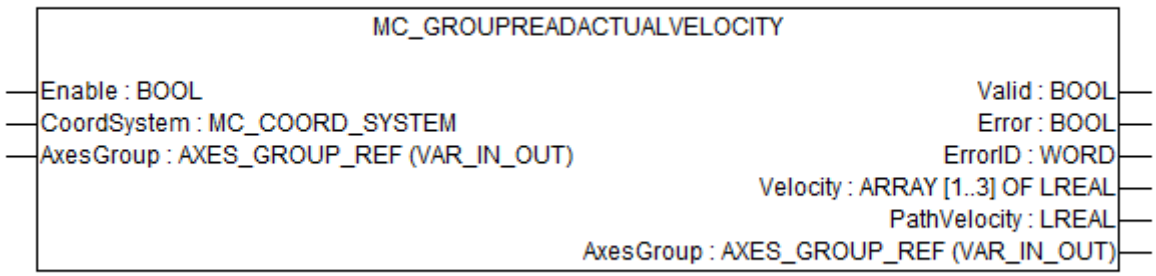

Fig. 479: MC_GroupReadActualVelocity

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Get the actual position in the selected coordinate system of the axes group continuously while enabled.

CoordSystem Data type: MC_COORD_SYSTEM; range: MC_DEFAULT_COORD, MC_MCS_COORD, MC_PCS_COORD

Reference to the coordinate system (MCS, PCS).

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

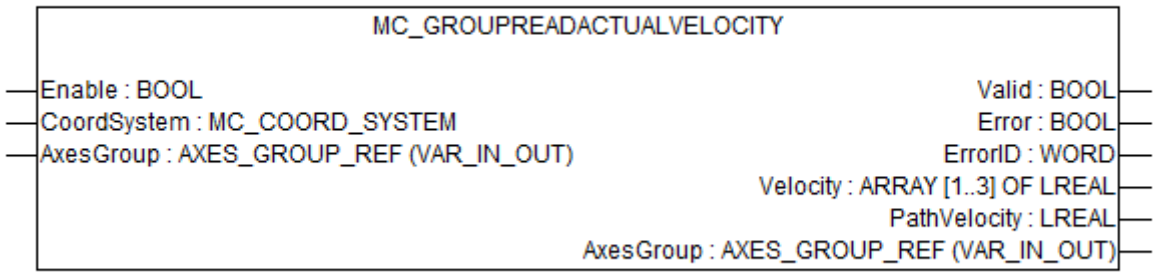

Fig. 480: MC_GroupReadActualVelocity

Valid Data type: BOOL

True if valid outputs are available.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

Velocity Data type: ARRAY [1..3] OF REAL

Current velocity of the group:

- in ACS the velocities of the different axes,
- in MCS and PCS it provides the velocity of the TCP .

PathVelocity Data type: REAL

Current path velocity (speed, combined result) of the TCP.

MC_GroupStop

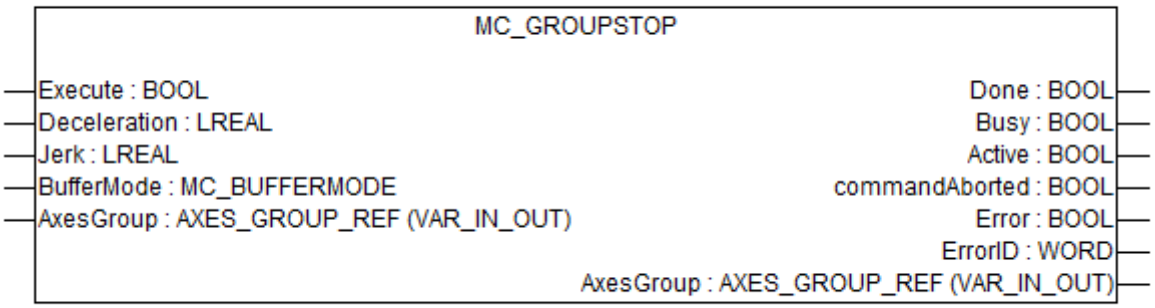

Fig. 481: MC_GroupStop

This function block commands a controlled motion stop and transfers the axes group to the state GroupStopping. It aborts any ongoing function block execution. While the axes group is in state GroupStopping, no other function block can perform any motion on the same axes group. After the axes group has reached velocity zero, the Done output is set to TRUE immediately. The axes group remains in the state GroupStopping as long as Execute is still TRUE or velocity zero is not yet reached. As soon as Done is SET and Execute is FALSE the axes group goes to state GroupStandby. The command can only be aborted by MC_GroupDisable.

- *The relevant axes stay on the path.*
- *If Deceleration is set to zero, the minimum value = 1 is used instead.*
- *If issued during a MoveDirectXxx command, the velocity/acc-/deceleration/jerk values as properties of the AxisRef of each axis are used, and not specified within this function block, and not to be exceeded during the movement.*
- *Any synchronization of the group to a master is cancelled by issuing MC_GroupStop*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Timing diagram

A typical timing diagram for MC_GroupStop is shown below, including the relevant states and state-transitions:

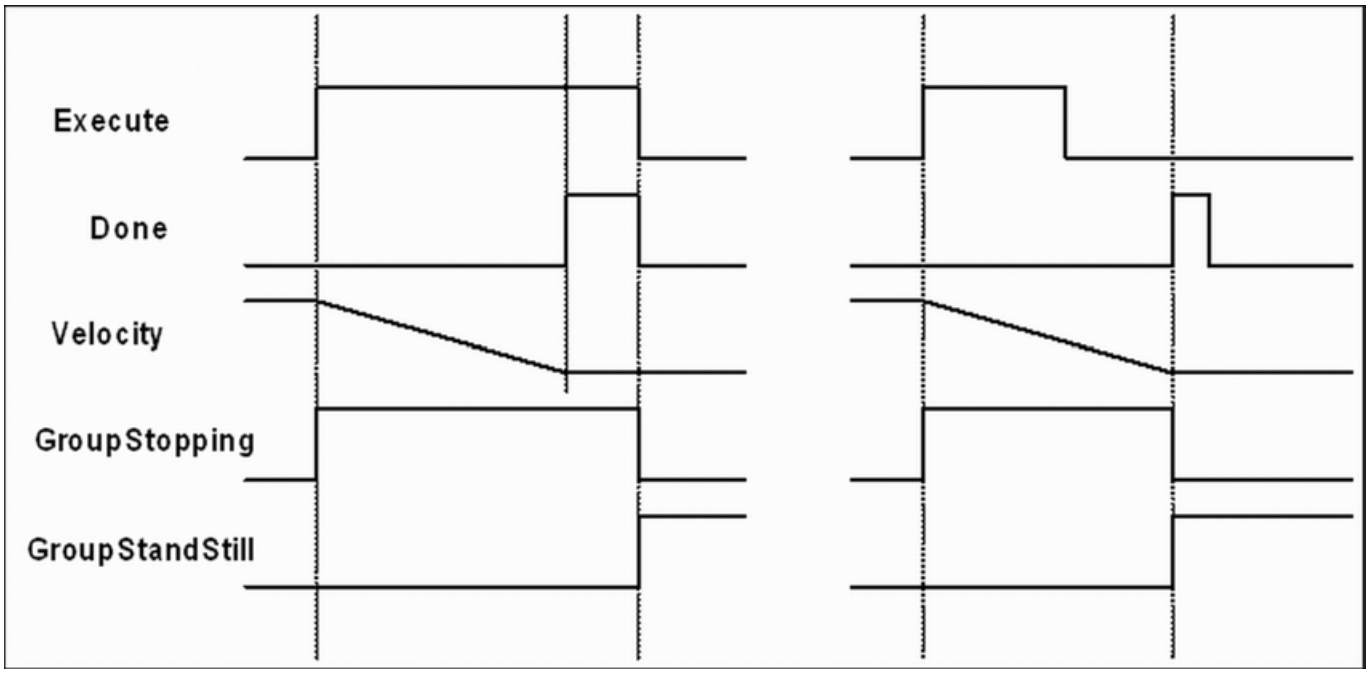

Fig. 482: MC_GroupStop timing diagram

The example below shows the behavior in combination with a MC_MoveLinearRelative:

- An axes group in linear movement is ramped down with function blocks MC_GroupStop. The group stops on the original path,
- The axes group rejects motion commands as long as MC_GroupStop parameter “Execute” = TRUE. Function block MC_MoveLinearRelative reports an error indicating the busy MC_GroupStop command. This error is an function block error, so the group is not moving to the state GroupErrorStop,
- At the 3rd “Exe1” rising edge, the group starts the next movement.

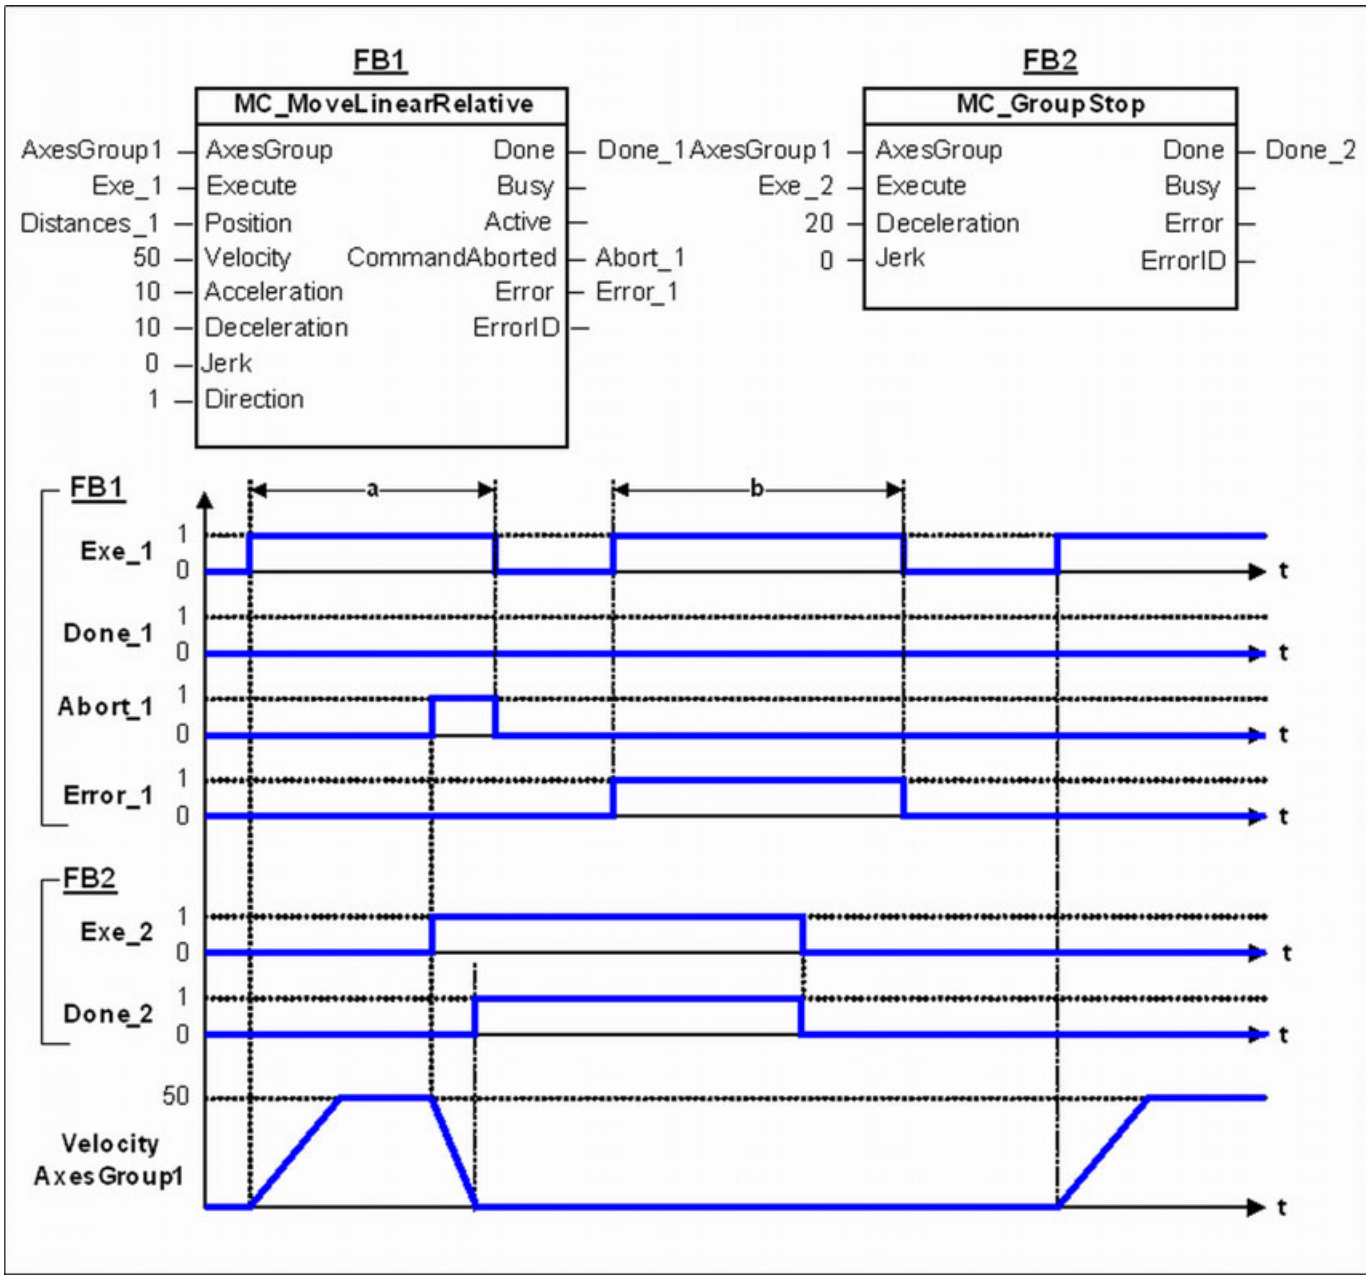

Fig. 483: Behavior of MC_GroupStop in combination with MC_MoveLinearRelative

The following example demonstrates the behavior of MC_GroupStop in combination with two MC_MoveLinearAbsolute which are blended with defined constant path velocity:

Time	Description
t_0	Two function blocks MC_MoveLinearAbsolute are commanded on axes group MyAxesGroup. The first function block becomes active immediately and MyAxesGroup starts to move from its actual position (20.0; 20.0) towards the first target position.
t_1	Shortly after the TCP has started to move on the blending contour blending Lin1 into Lin2, a FB MC_GroupStop is issued in buffermode Aborting. The state of the axes group changes from GroupMoving to GroupStopping. MyAxesGroup decelerates, following the path which would have been executed without having issued MC_GroupStop. Though the path velocity of MyAxesGroup decreases strictly monotonic while stopping, single axes of the group might accelerate in between due to the given path and kinematic transformation of MyAxesGroup.
t_2	MyAxesGroup comes to standstill. The Done output of the function block MC_GroupStop is set. Since the input Execute of the function block Stop is still set the group stays in state GroupStopping.
t_3	The input Execute of the function block Stop is reset. All outputs of the function block Stop are reset. The group state changes to GroupStandby.

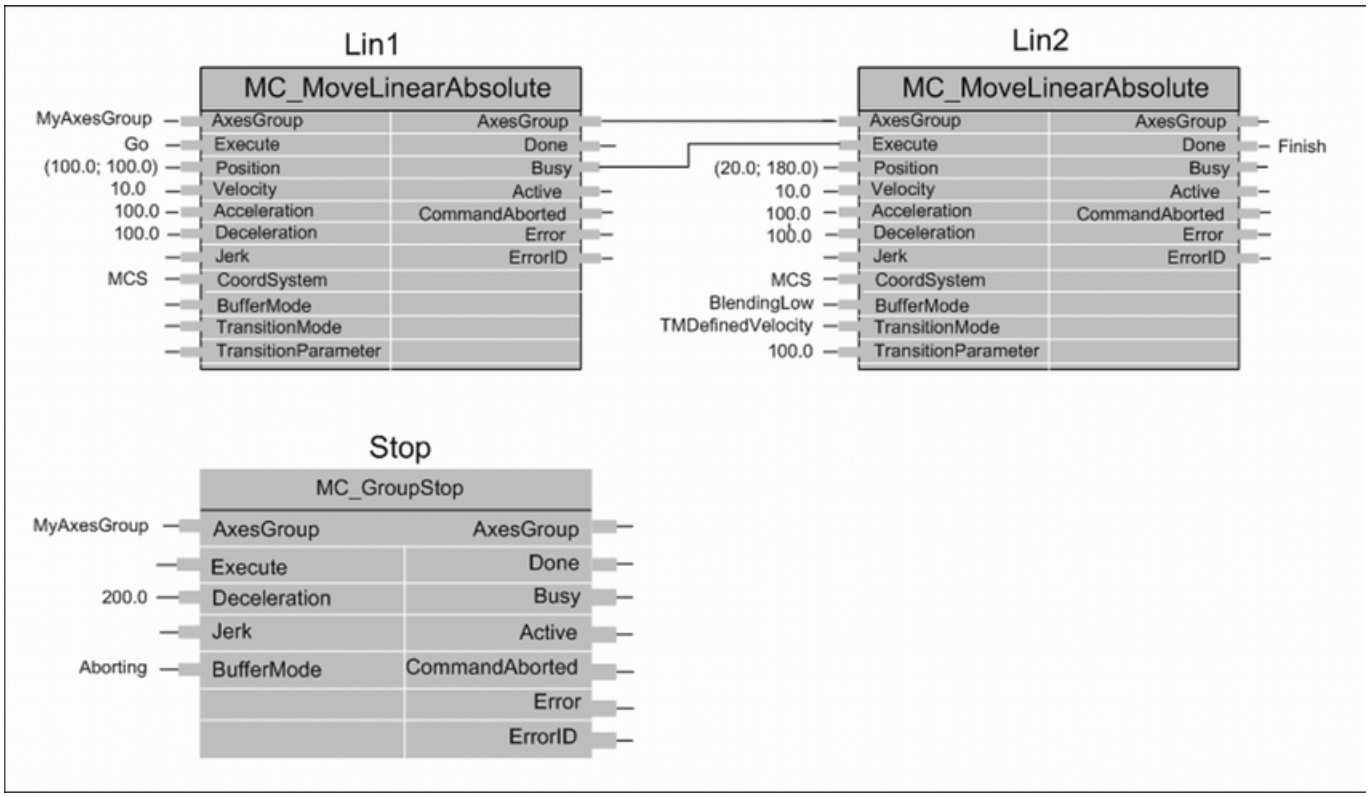

Fig. 484: Example of MC_GroupStop in combination with two MC_MoveLinearAbsolute

Input description

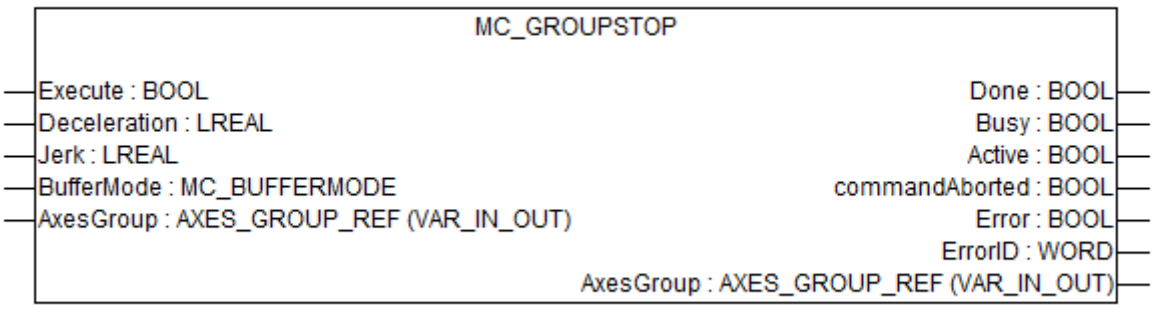

Fig. 485: MC_GroupStop

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

AxesGroup Data type: AXES_GROUP_REF
Reference to a group of axes.

Output description

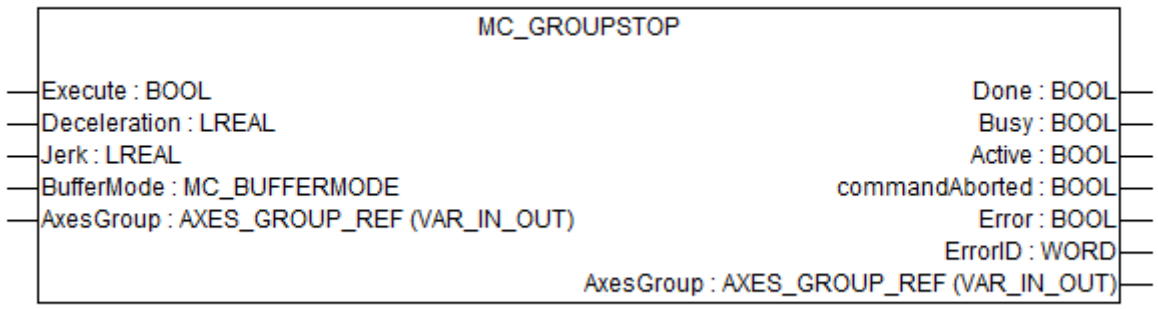

Fig. 486: MC_GroupStop

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by disabling MC_Power of one or more of the axes in the group. The state changes to GroupDisabled.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_GroupHalt

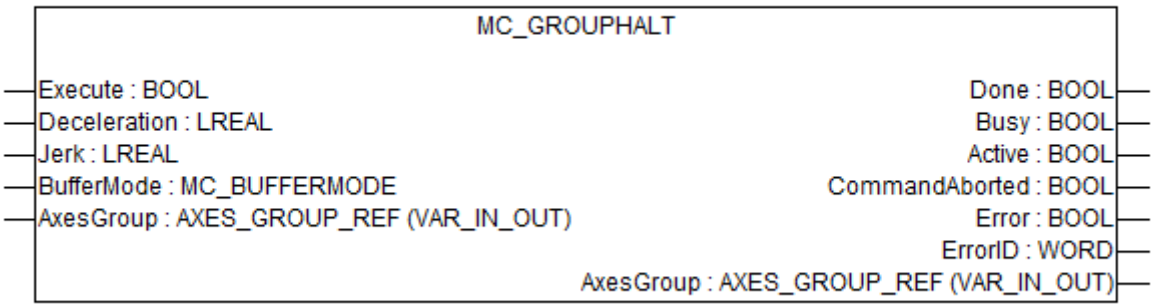

Fig. 487: MC_GroupHalt

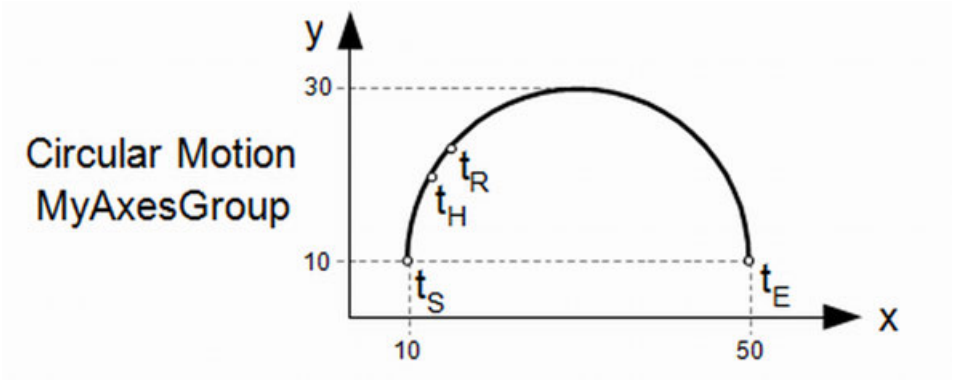
This function block commands a controlled motion stop. It aborts any ongoing function block execution. Ax-esGroup is moved to the state GroupMoving, until the velocity is zero. With the DONE output set, the state is transferred to GroupStandby.

- *MC_GroupHalt is used to stop the axes group under normal operation conditions. In non-buffered mode: during deceleration of the axes group it is possible to set another motion command, which will abort the MC_GroupHalt and will be executed immediately,*
- *If this command is active the next command can be issued. For example a driverless vehicle detects an obstacle and needs to stop. MC_GroupHalt is issued. Before the StandStill is reached the obstacle is removed and the motion can be continued by setting another motion command, so the vehicle does not stop,*
- *The relevant axes stay on the same path which would have been executed without having issued MC_GroupHalt.*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

The following example shows the behavior of MC_GroupHalt in combination with a MC_MoveCircularAbsolute:	MyAxesGroup starts at Position (10.0; 10.0; 0.0). A FB MC_MoveCircularAbsolute is commanded with aux-iliary position (30.0; 30.0; 0.0) and end position (50.0; 10.0; 0.0). This results in a 180° circular motion within the xy-plane of any coordinate system.

Point of Time	Description
t_h	The circular motion is aborted by FB MC_GroupHalt. MyAxesGroup stays on the path during halt.
t_r	R) MC_MoveCircularAbsolute is executed again and aborts MC_GroupHalt. MC_GroupHalt allows this, in con-trast to MC_GroupStop. AxesGroup can accelerate again without reaching StandStill. (MC_MoveCircularAbsolute can be retriggered in order to continue the original circular motion as long as MyAxesGroup didn't pass the auxiliary position.)
t_e	E) MyAxesGroup reaches end position (50.0; 10.0; 0.0)



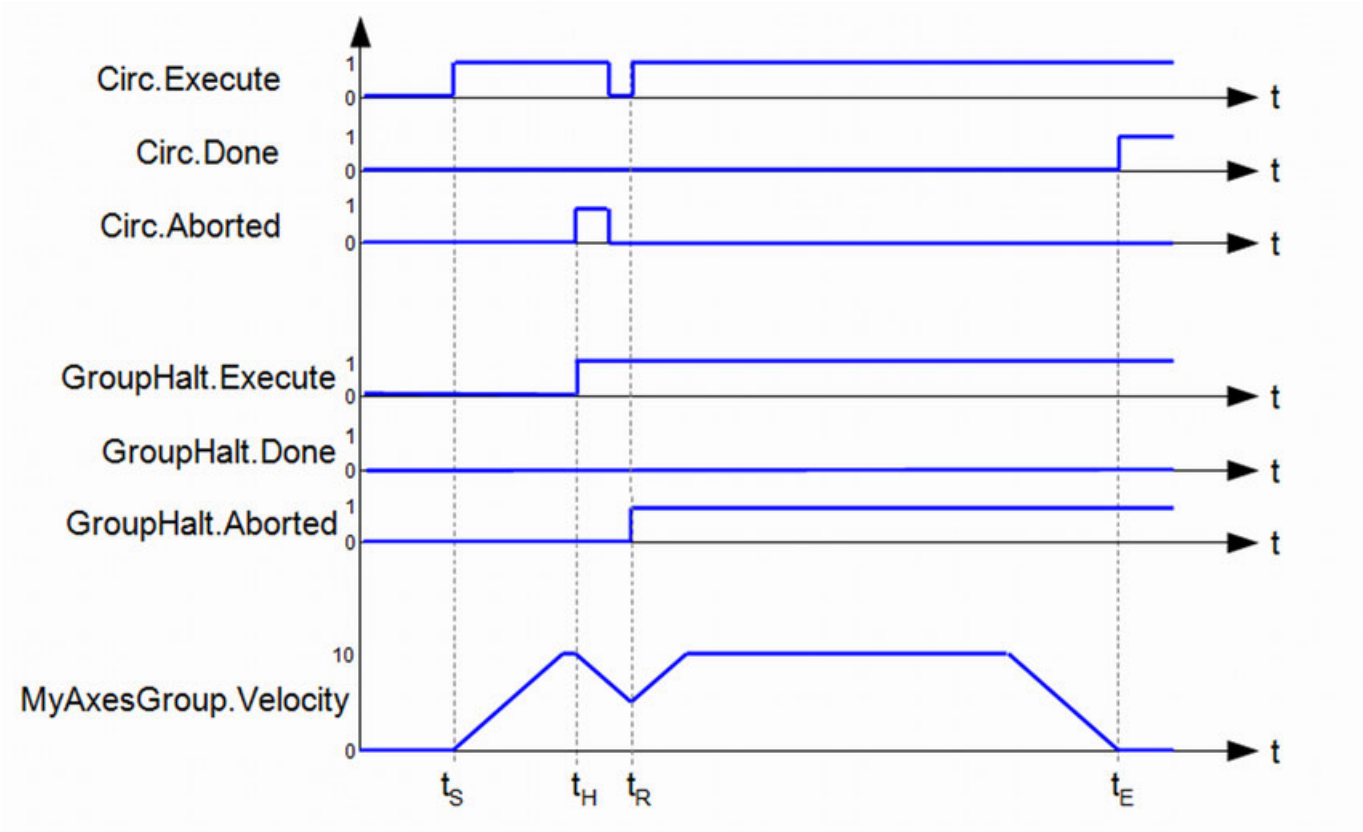


Fig. 488: Behavior of MC_GroupHalt in combination with MC_MoveCircularAbsolute

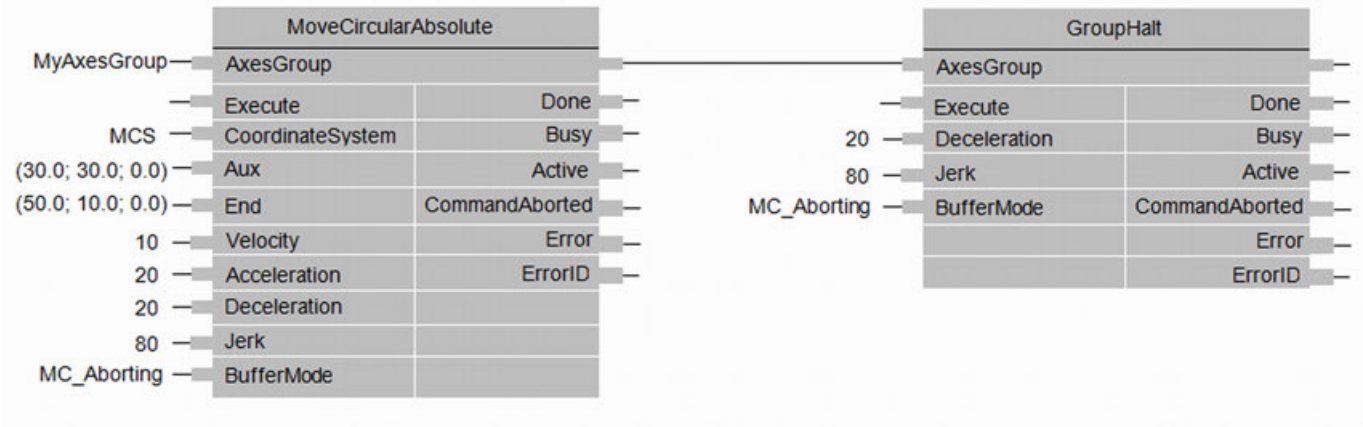

Input description

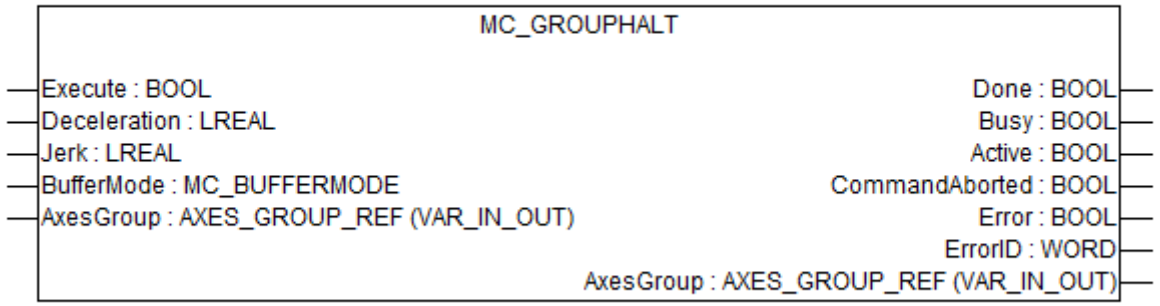

Fig. 489: MC_GroupHalt

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

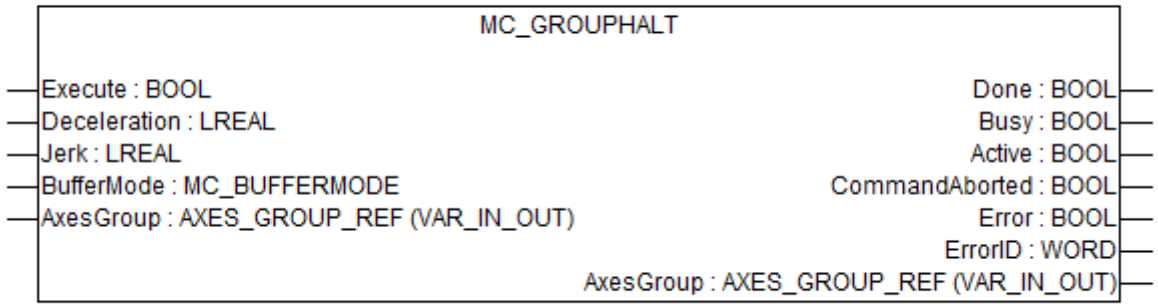

Fig. 490: MC_GroupHalt

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by disabling MC_Power of one or more of the axes in the group. The state changes to GroupDisabled.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification ↳ *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_GroupInterrupt

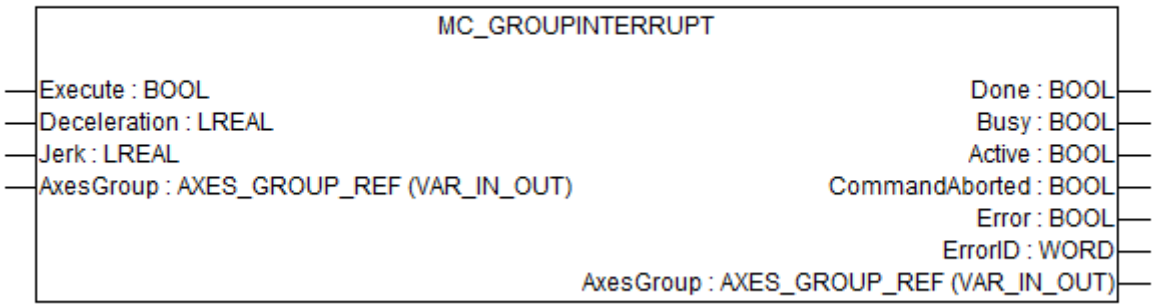

Fig. 491: MC_GroupInterrupt

This function block interrupts the on-going motion and stops the group from moving, however does not abort the interrupted motion (meaning that at the interrupted function block the output CommandAborted will not be Set, Busy is still high and Active is reset). It stores all relevant track or path information internally at the moment it becomes active. The AxesGroup stays in the original state even if the velocity zero is reached and the DONE output set.

- *This function block is coupled to MC_GroupContinue. Issuing MC_GroupContinue transfers the program back to the situation at issuing MC_GroupInterrupt.*
- *Further motion commands may be accepted by the group.*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

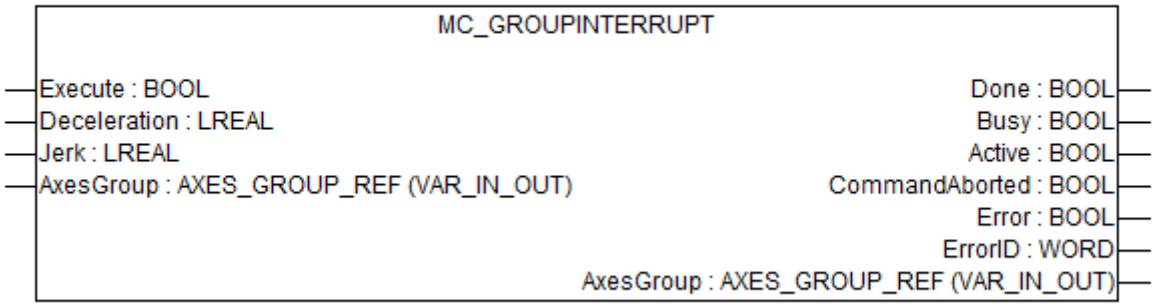

Fig. 492: MC_GroupInterrupt

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute Data type: BOOL
Starts the function block at rising edge.

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

AxesGroup Data type: AXES_GROUP_REF
Reference to a group of axes.

Output description

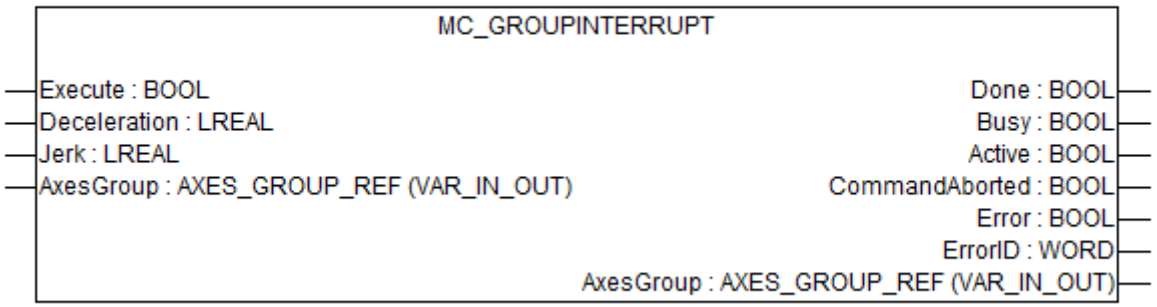

Fig. 493: MC_GroupInterrupt

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by disabling MC_Power of one or more of the axes in the group. The state changes to GroupDisabled.

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_GroupContinue

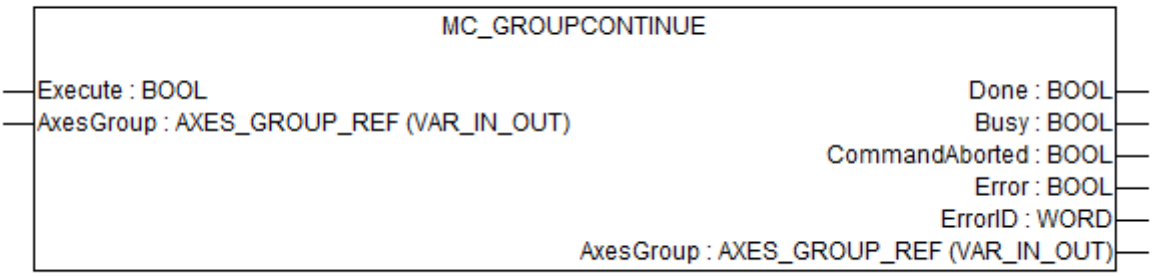

Fig. 494: MC_GroupContinue

This function block transfers the program back to the situation at issuing MC_GroupInterrupt. It uses internally the data set as stored at issuing MC_GroupInterrupt, and at the end (output DONE set) transfer the control on the group back to the original function block doing the movement on the axes group, meaning also that at the originally inter-rupted function block the output Busy is still high and Active is set again.

- *The dynamics of the function block that is continued can be used for the Velocity, Acceleration, Deceleration and Jerk,*
- *This function block can also be used to continue after an error in case the necessary set of data is stored at the occurrence of the error.*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

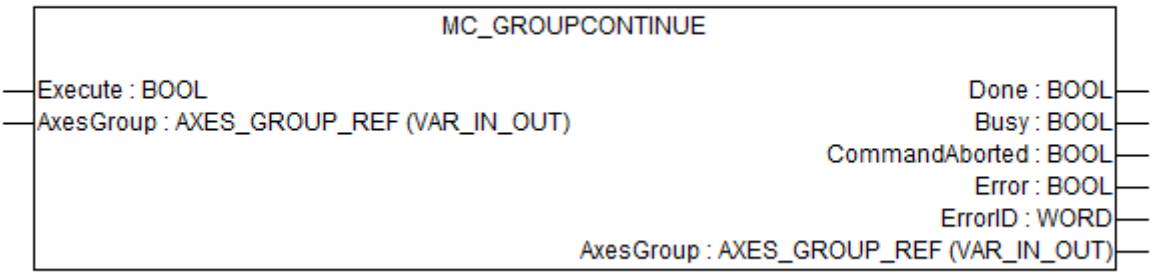

Fig. 495: MC_GroupContinue

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

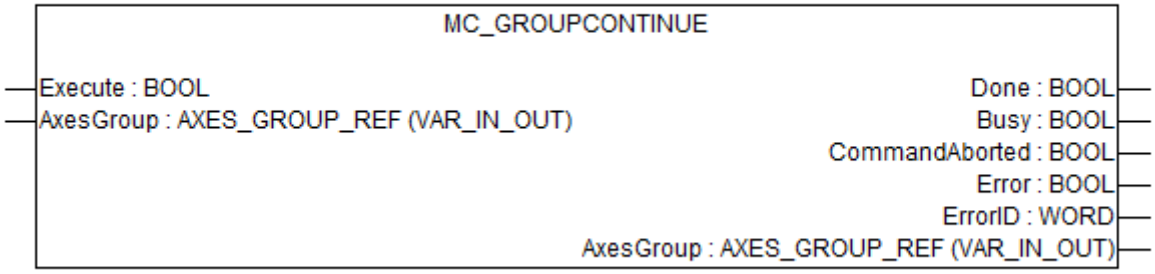

Fig. 496: MC_GroupContinue

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

CommandAborted Data type: BOOL

Command is aborted by disabling MC_Power of one or more of the axes in the group. The state changes to GroupDisabled.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_GroupReadStatus

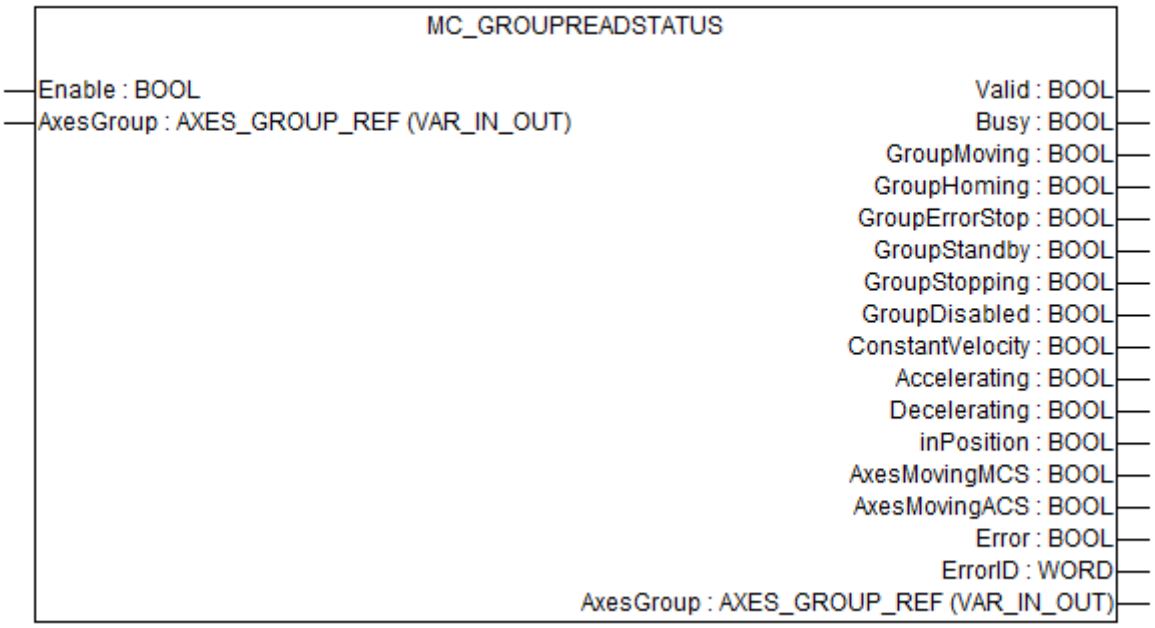

Fig. 497: MC_GroupReadStatus

This function block returns the status of an axes group according to the active Group-Functiom Block. This is an administrative Funcion Block, since no movement is generated.

> *The outputs reflect the commanded state of the group.*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

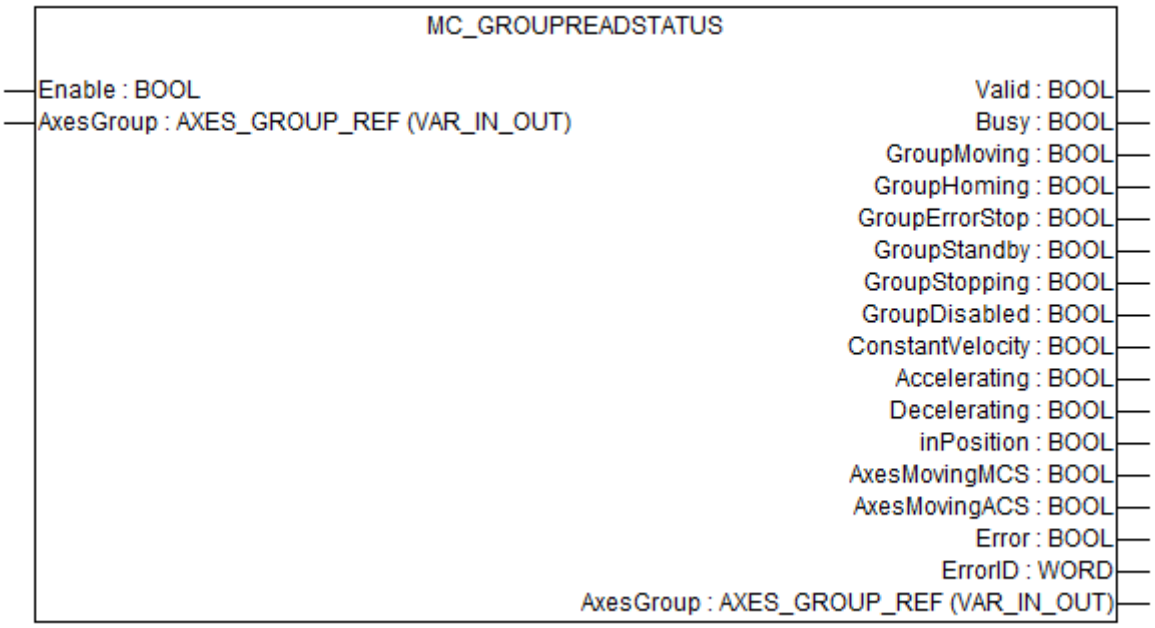

Fig. 498: MC_GroupReadStatus

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Get the actual position in the selected coordinate system of the axes group continuously while enabled.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

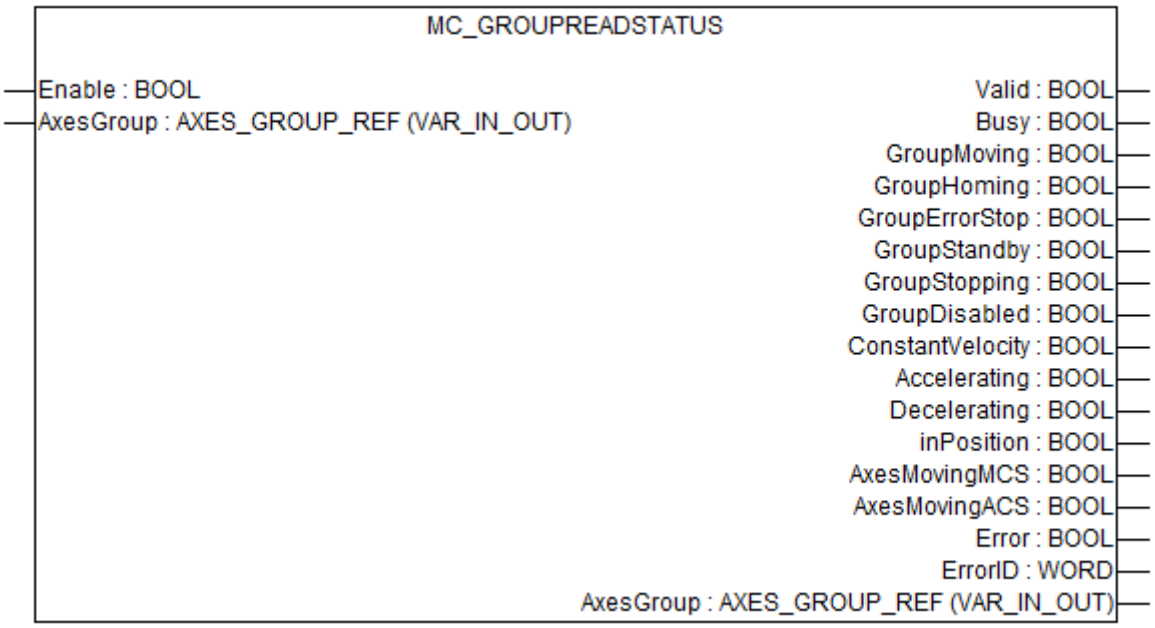

Fig. 499: MC_GroupReadStatus

Valid Data type: BOOL
True if valid outputs are available.

Busy Data type: BOOL
The function block is not finished.

GroupMoving Data type: BOOL
See group state diagram. *Chapter 1.5.9.4.9.3.1 “Group state diagram” on page 2711*

GroupHoming Data type: BOOL
See group state diagram. *Chapter 1.5.9.4.9.3.1 “Group state diagram” on page 2711*

GroupErrorStop Data type: BOOL
See group state diagram. *Chapter 1.5.9.4.9.3.1 “Group state diagram” on page 2711*

GroupStandby Data type: BOOL
See group state diagram. *Chapter 1.5.9.4.9.3.1 “Group state diagram” on page 2711*

GroupStopping Data type: BOOL
See group state diagram. *Chapter 1.5.9.4.9.3.1 “Group state diagram” on page 2711*

GroupDisabled Data type: BOOL
See group state diagram. *Chapter 1.5.9.4.9.3.1 “Group state diagram” on page 2711*

ConstantVelocity Data type: BOOL
Moving with constant velocity on commanded path.

Accelerating Data type: BOOL
Increasing Velocity on commanded path.

Decelerating Data type: BOOL
Decreasing Velocity on commanded path.

InPosition Data type: BOOL
Movement has reached target position .

MovingMCS Data type: BOOL
At least 1 MCS axis is in single axis movement.

MovingACS Data type: BOOL
At least 1 ACS axis is in single axis movement.

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveLinearAbsolute

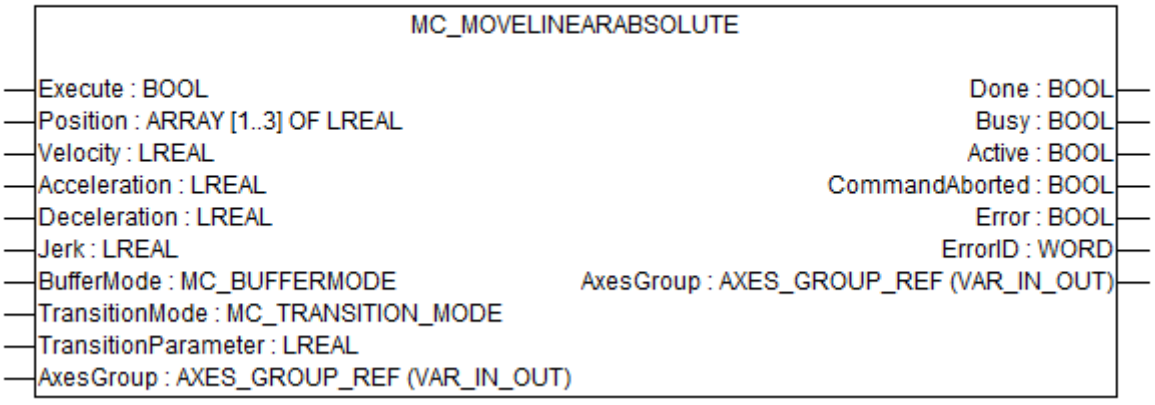

Fig. 500: MC_MoveLinearAbsolute

This function block commands an interpolated linear movement on an axes group from the actual position of the TCP to an absolute position in the specified coordinate system.

- *This function block applies to the MCS or PCS System, depending which is activated and also follows the dynamic transformation when activated,*
- *The behavior on interrupting an ongoing motion corresponds BufferMode=MC_Aborting, TransitionMode = TMDefinedVelocity, TransitionParameter = 100%.*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

MC_MoveLinearAbsolute - Example

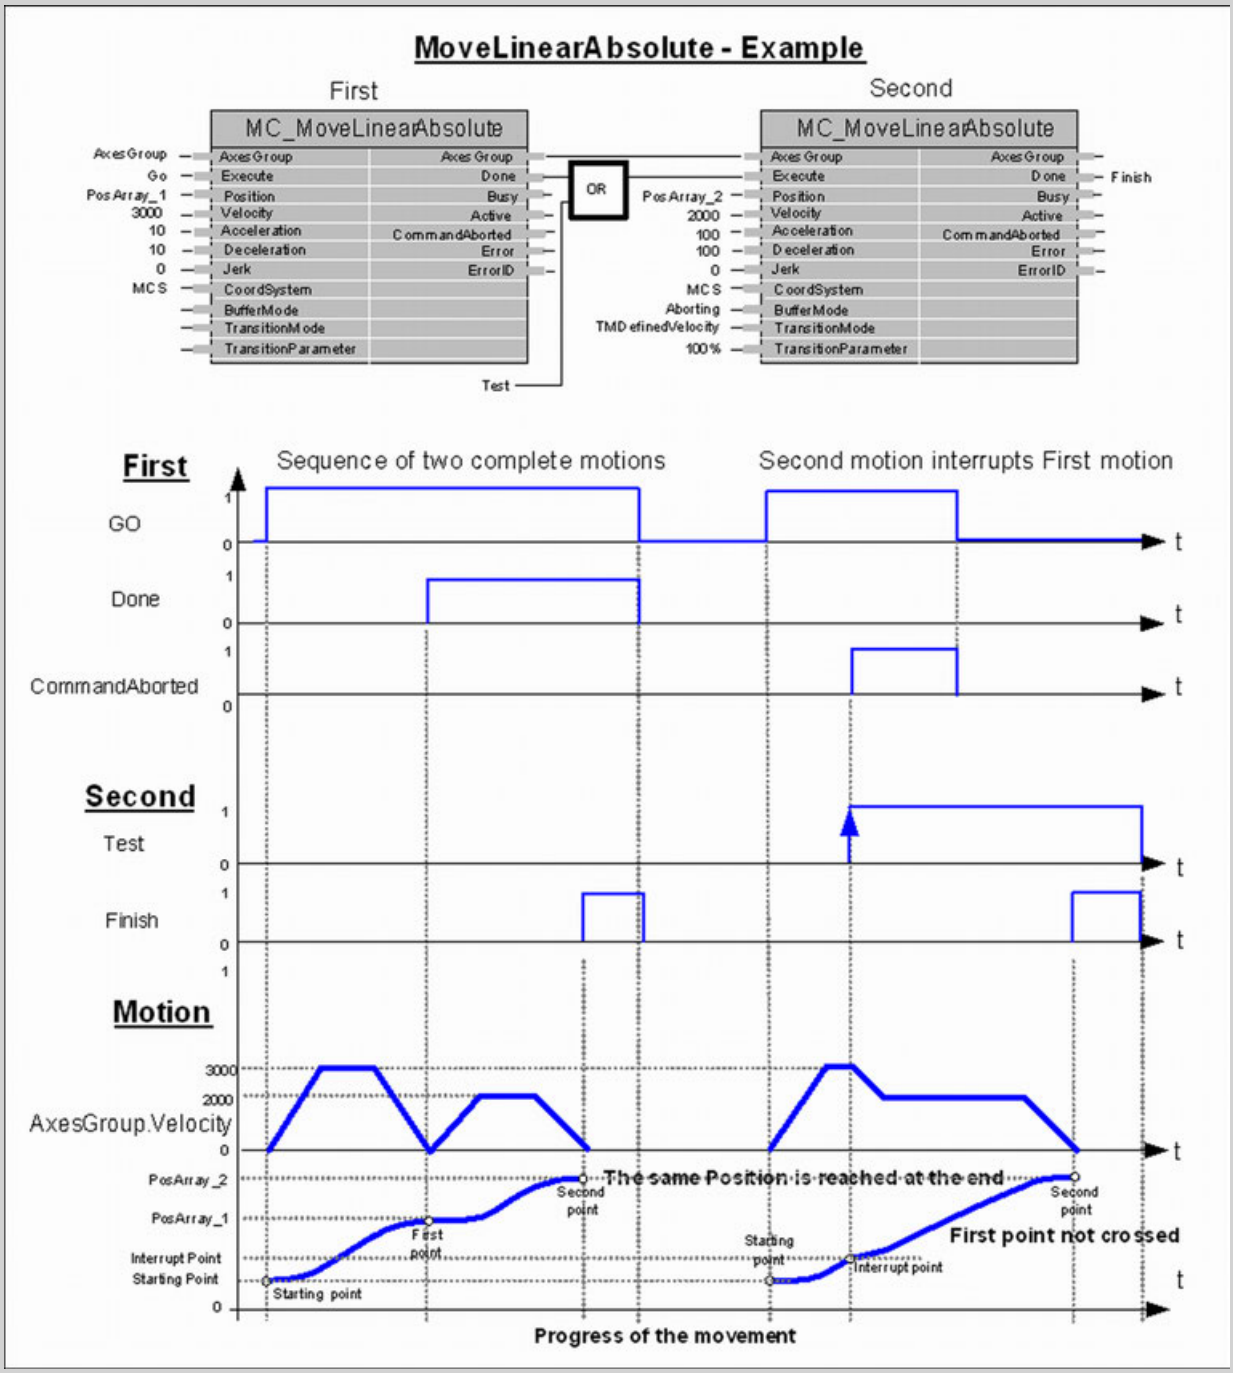

Fig. 501: MC_MoveLinearAbsolute Example

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute
Data type: BOOL
Starts the function block at rising edge.

Position
Data type: ARRAY [1..3] OF REAL
Array of absolute end positions for each dimension in the specified coordinate system. ↬ *"Position" on page 3038*

Velocity
Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk
Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode
Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

TransitionMode Data type: MC_TRANSITION_MODE

The realization just supports by default a transition starting with the actual velocity.

TransitionParameter Data type: LREAL

Additional parameter for the transition mode.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

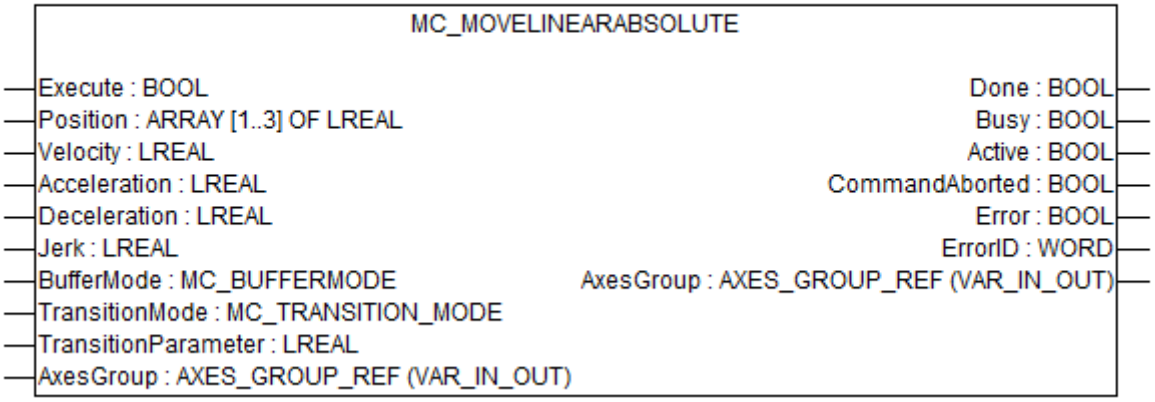

Fig. 503: MC_MoveLinearAbsolute

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by disabling MC_Power of one or more of the axes in the group. The state changes to GroupDisabled.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveLinearRelative

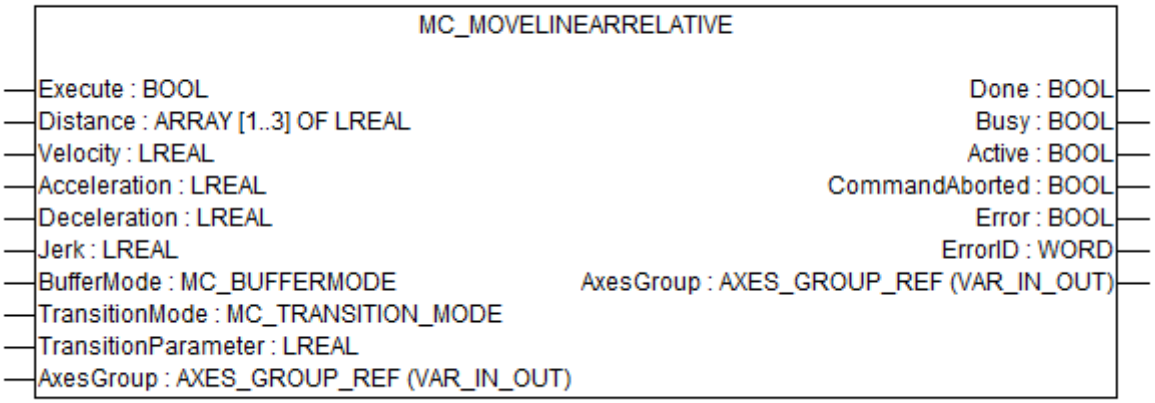

Fig. 504: MC_MoveLinearRelative

This function block commands an interpolated linear movement on an axes group from the actual position of the TCP to a relative position in the specified coordinate system.

> *This function block applies to the MCS or PCS System, depending which is activated and also follows the dynamic trans-formation when activated*

MC_MoveLinearRelative - Example 1

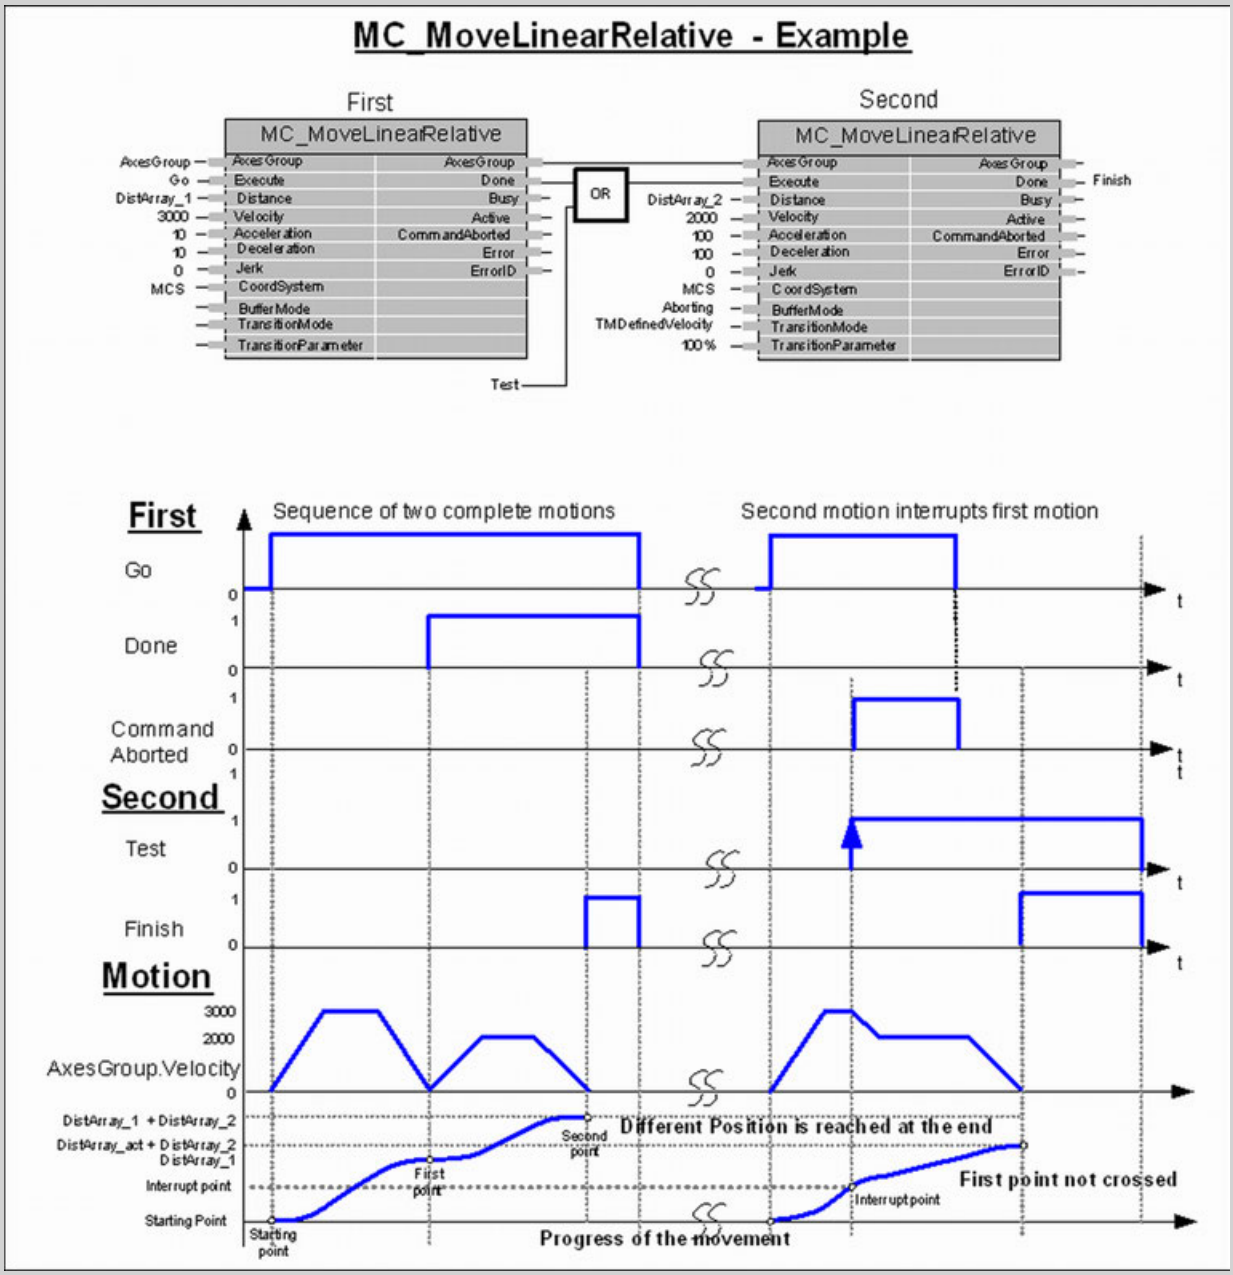

Fig. 505: Example MC_MoveLinearRelative

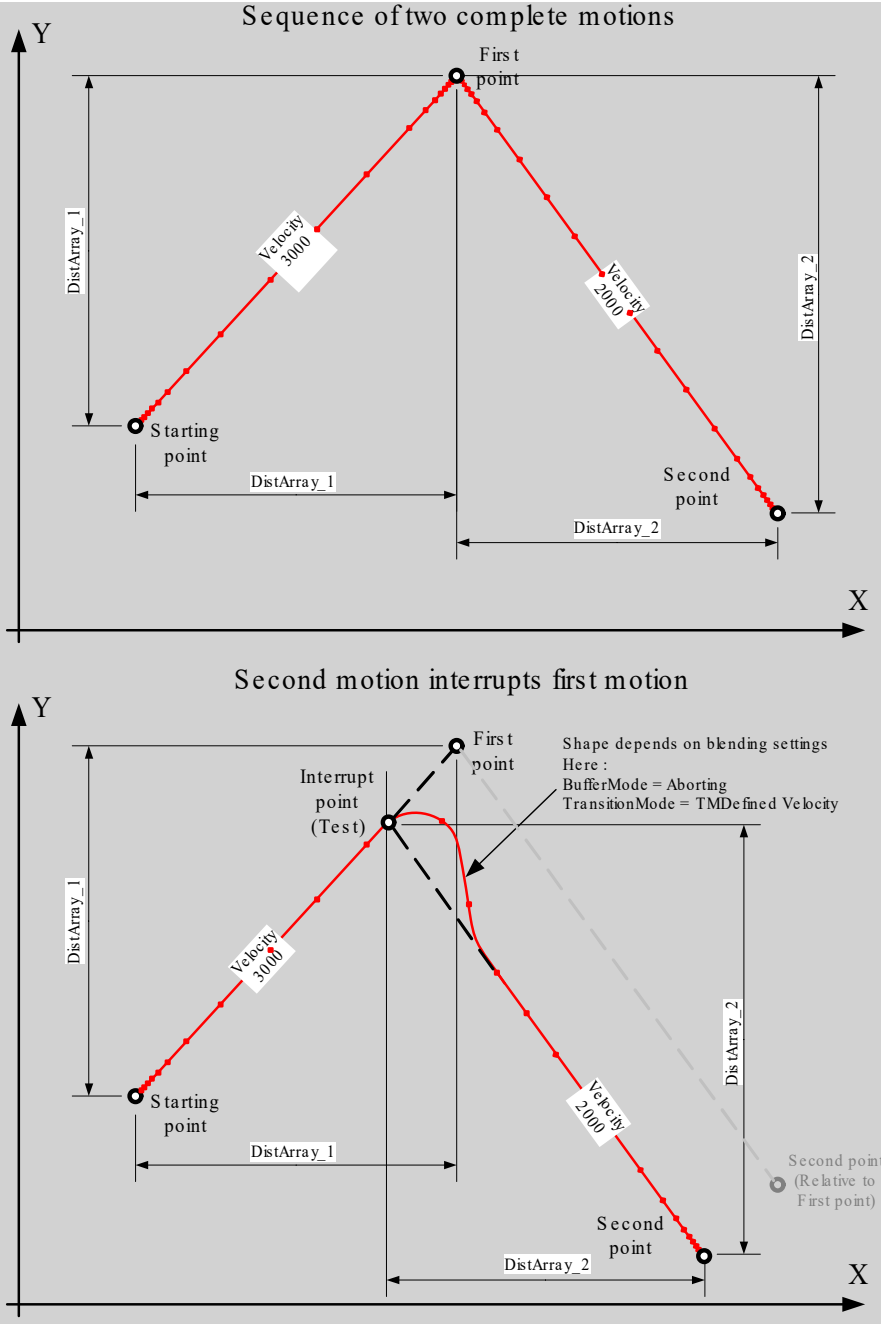

Fig. 506: Timing diagram for example above. The dots on the red line are based on the same timing difference and represent the velocity.

MC_MoveLinearRelative - Example 2

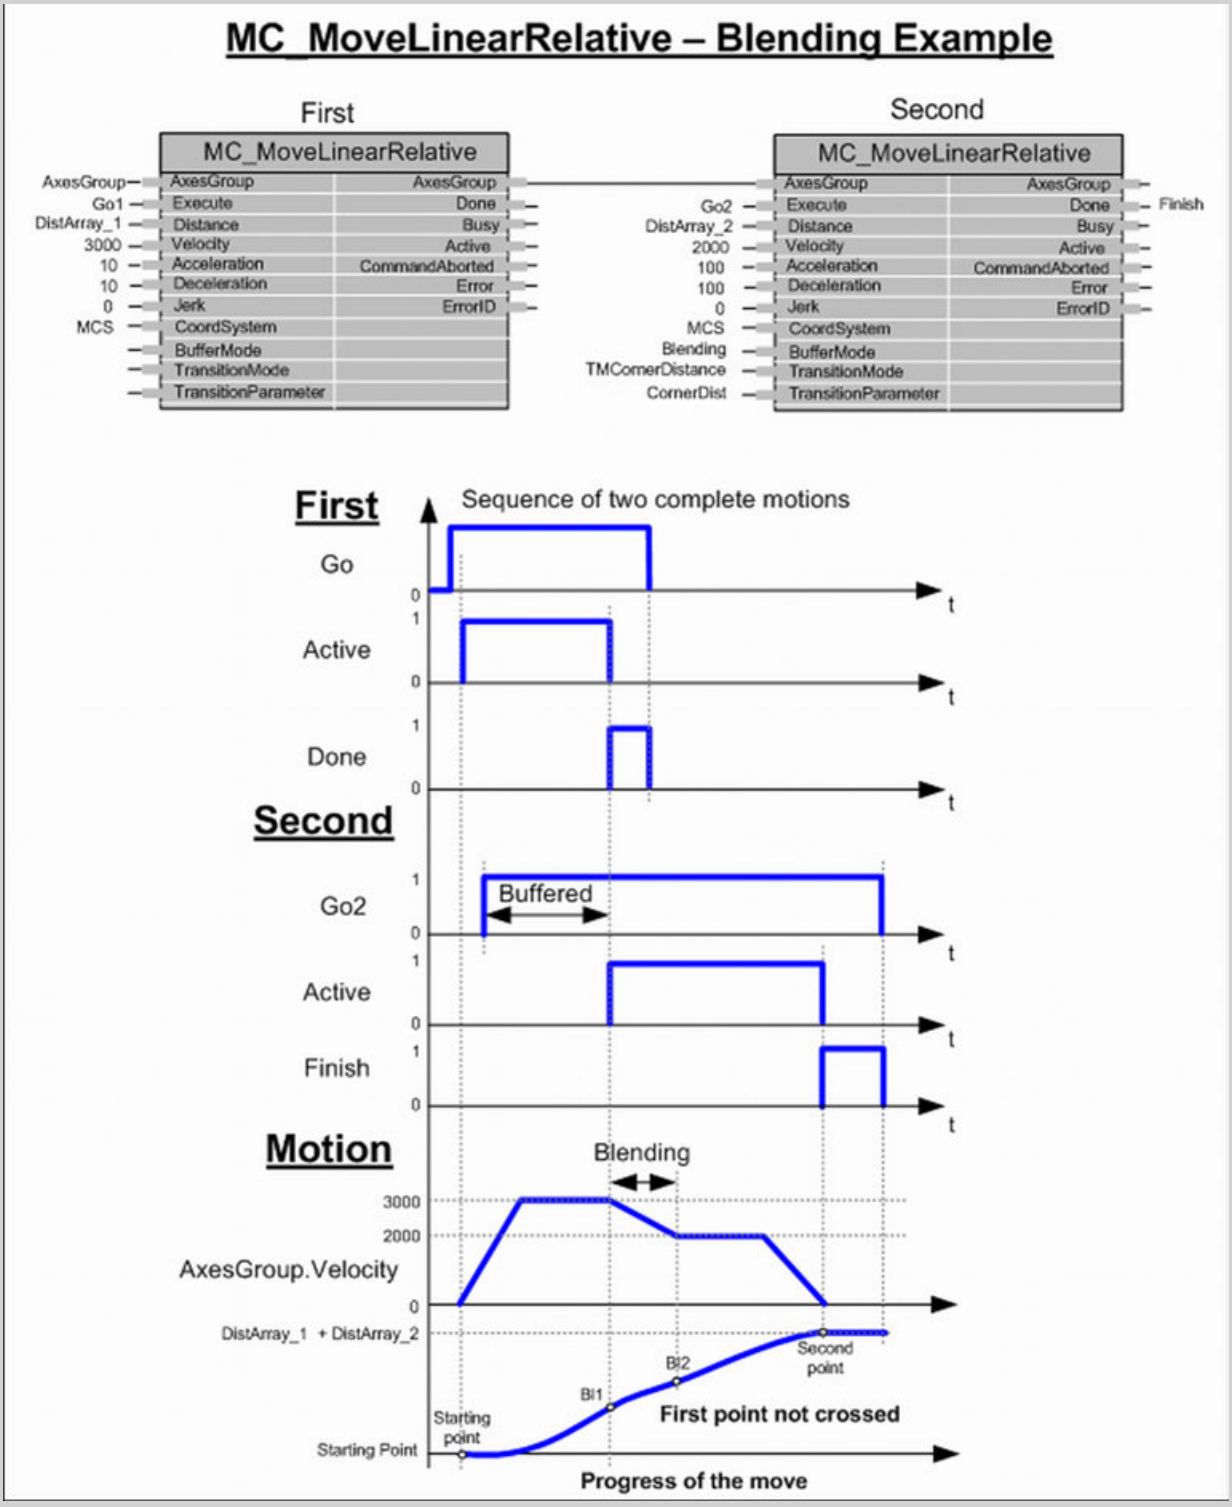

Fig. 507: Second example with MC_MoveLinearRelative and Blending

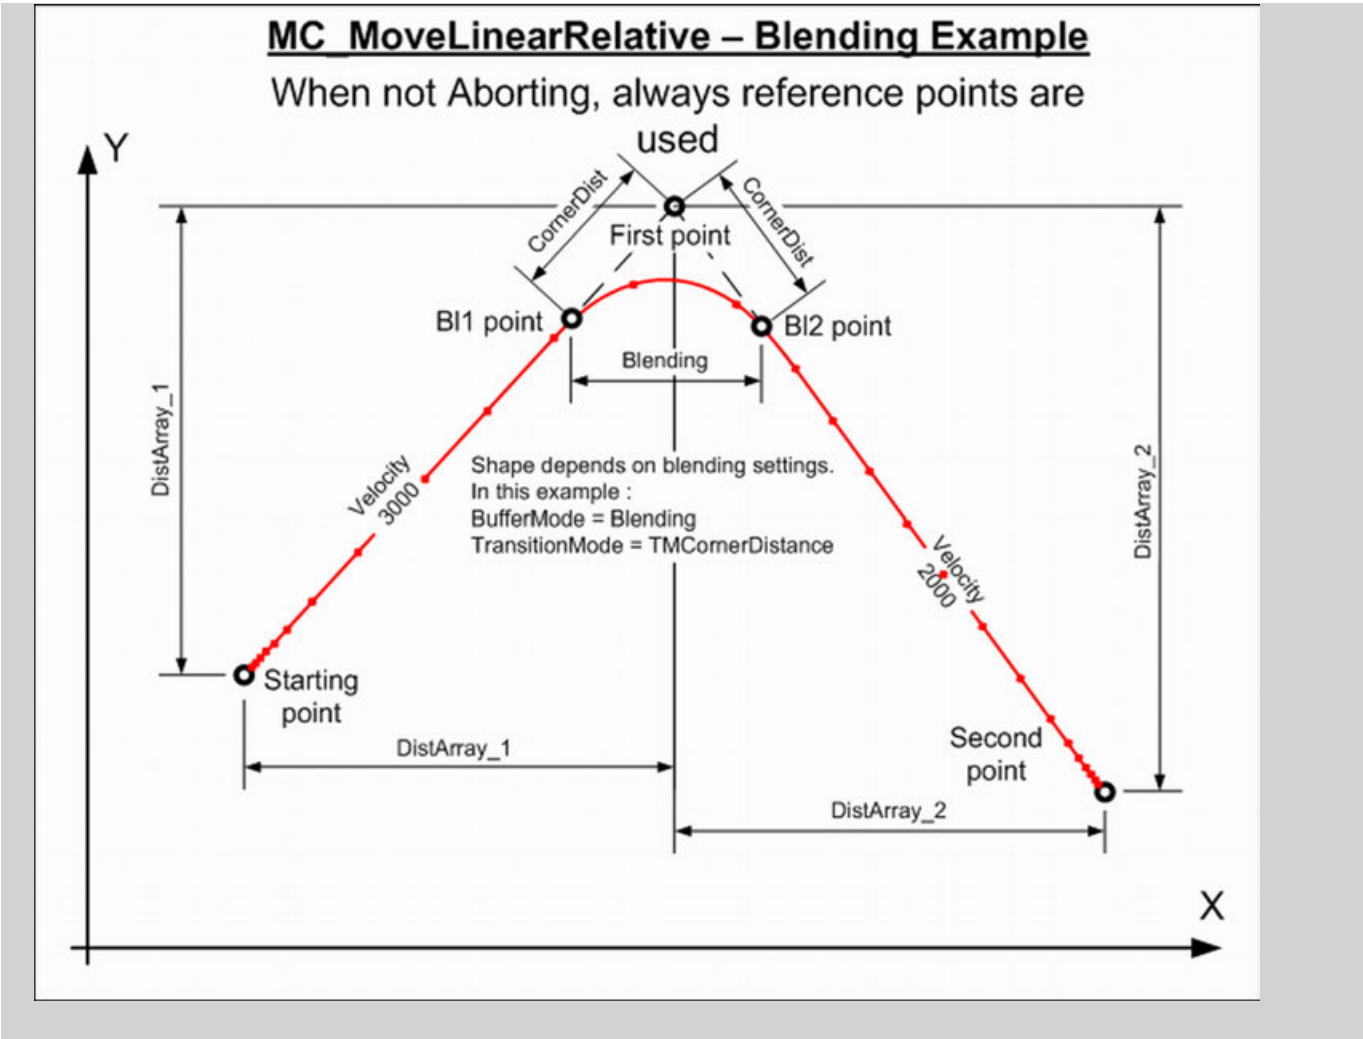
Timing diagram for example below (the dots on the red line are based on the same timing difference and representing the velocity):



Input description

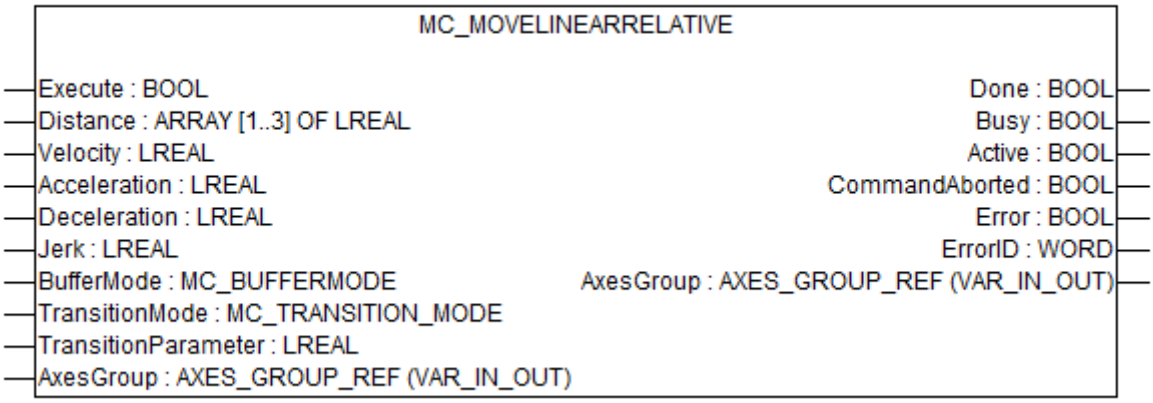


Fig. 508: MC_MoveLinearRelative

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute
Data type: BOOL
Starts the function block at rising edge.

Distance
Data type: ARRAY [1..3] OF LREAL
Array of relative distances for each dimension in the specified coordinate system.

Velocity
Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk
Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode
Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

TransitionMode
Data type: MC_TRANSITION_MODE
The realization just supports by default a transition starting with the actual velocity.

TransitionParameter
Data type: LREAL
Additional parameter for the transition mode.

AxesGroup
Data type: AXES_GROUP_REF
Reference to a group of axes.

Output description

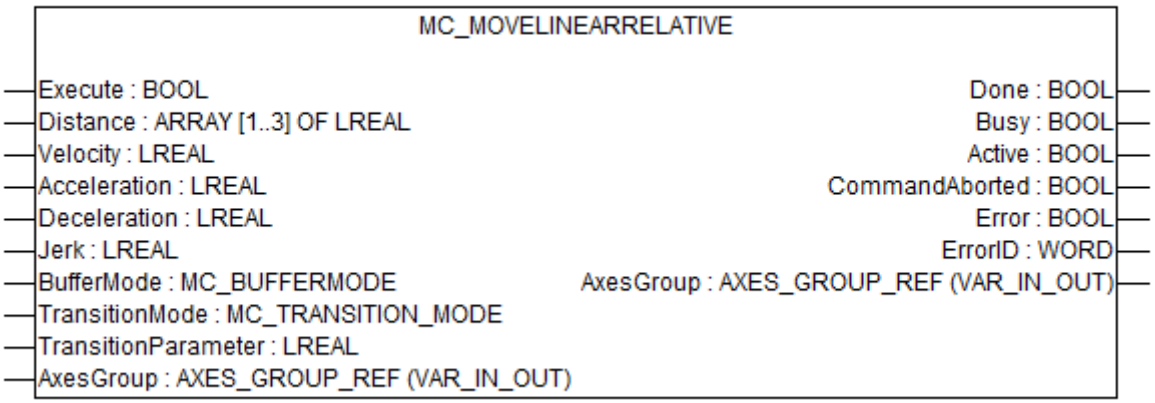

Fig. 509: MC_MoveLinearRelative

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveCircularAbsolute

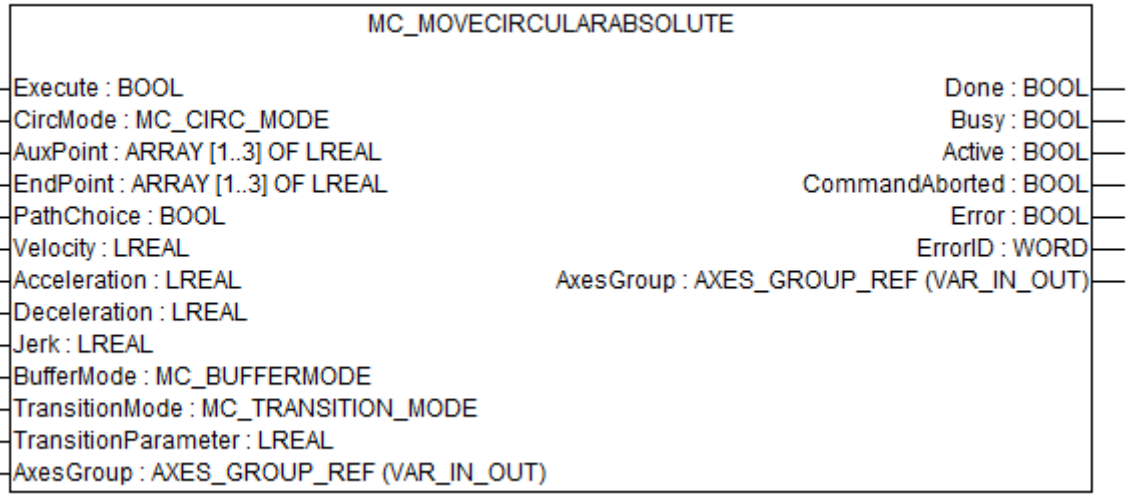

Fig. 510: MC_MoveCircularAbsolute

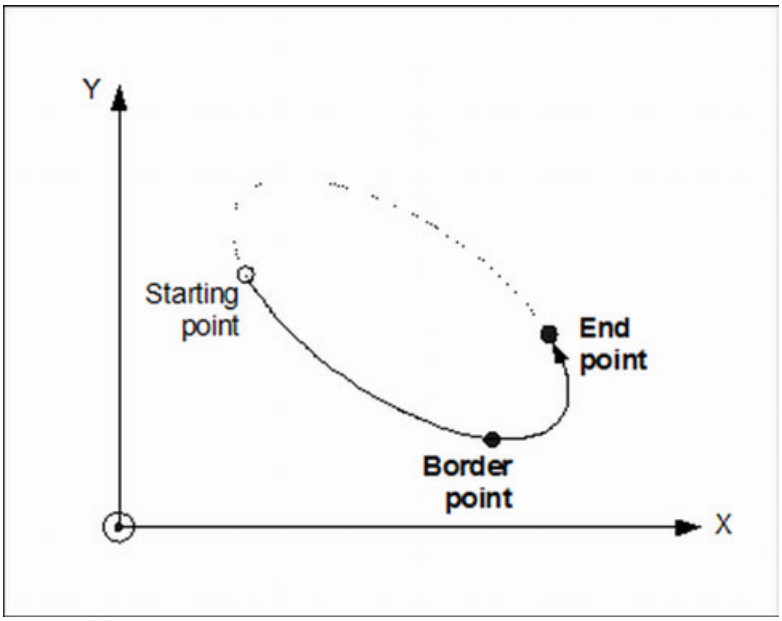
This function block commands an interpolated circular movement on an axes group from the actual position of the TCP. The end point as well as the auxiliary point (meaning depending on applied mode, see below) are defined absolutely in the specified coordinate system.

> *This function block applies to the MCS or PCS System, depending which is activated and also follows the dynamic transformation when activated*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

CircMode = BORDER



The user defines the end point and a border point (= input 'AuxPoint') on the sector of the circle, which shall be cruised by the machine.

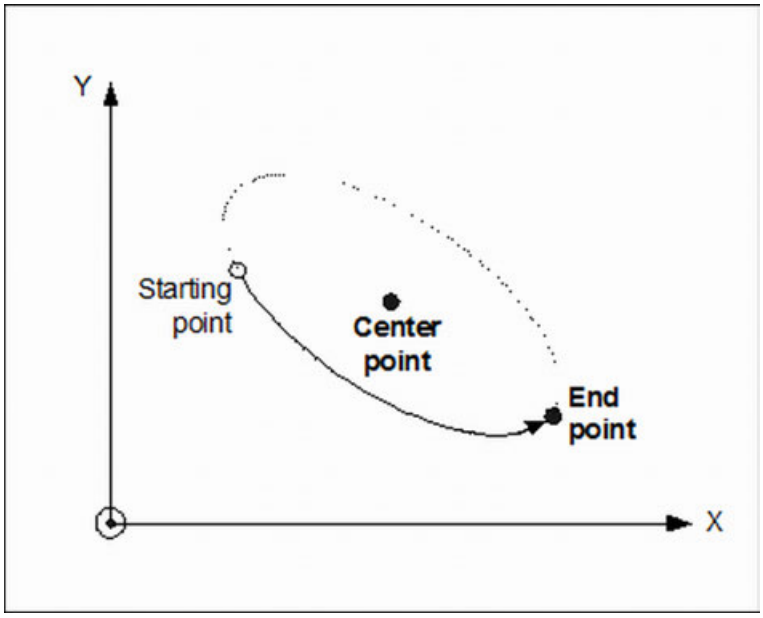
Advantages of this mode:

- The border point usually can be reached by the machine, i.e. it can be teached.

Inconvenience of this mode:

- Restriction to angles$<2\pi$ in one single command.

CircMode = CENTER

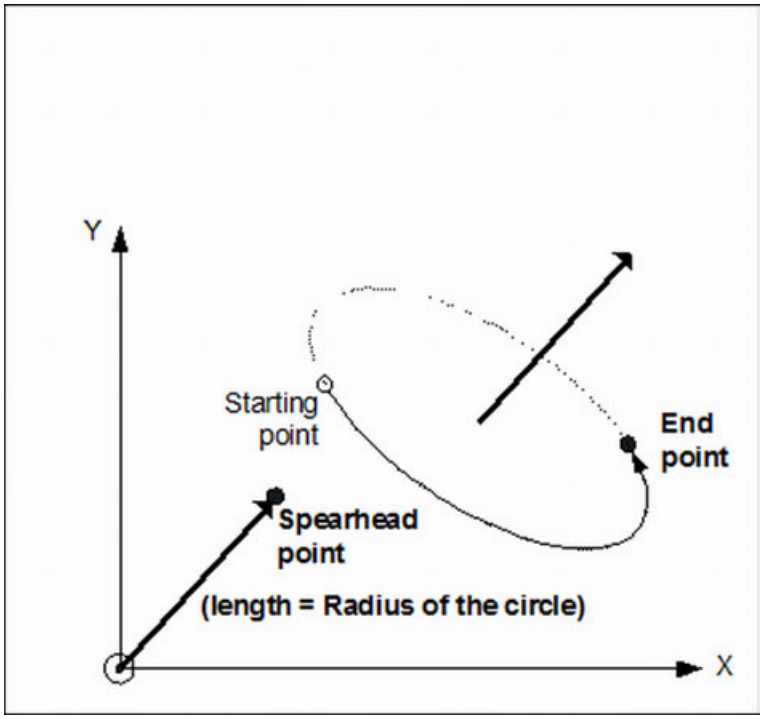


The user defines the end point and the center point (= input 'AuxPoint') of the circle. When using this mode, the input 'PathChoice' defines, if the short or the long sector has to be cruised by the machine.

Inconveniencies of this mode:

- Restriction to angles $< 2\pi$ and $\neq \pi$ in one single command,
- Overdetermination of circle equation,
- The center point usually cannot be teached in due to collisions with obstacles.

CircMode = RADIUS



The user defines the end point and the perpendicular vector of the circle plane according to the rule of right thumb (see figure below). The length of the vector corresponds to the radius of the circle. The spearhead point of the vector is the input signal 'AuxPoint' in absolute coordinates, i.e. referring to the origine of the coordinate system specified in 'CoordSystem'. If the diameter is larger than the distance between starting and end point, two different circles have to be considered. When using this mode, the input 'PathChoice' defines, if the circle with the short sector or the circle with the long sector to reach the end point has to be cruised by the machine. With positive radius value the shortest possible circle is determined, and with negative radius value the largest possible circle.

Inconvenience of this mode:

- Restriction to angles $< 2\pi$ in one single command,
- Overdetermination of circle equation.

Example:	AuxPoint = (50,0,0) →Circle in plane parallel to y-z plane with radius 50 and rotation around axis parallel to x-axis according to the rule of right thumb (CoordSystem = MCS).

MC_MoveCircularAbsolute - Sequenced example

Sequenced example of 2 MC_MoveCircularAbsolute function blocks:

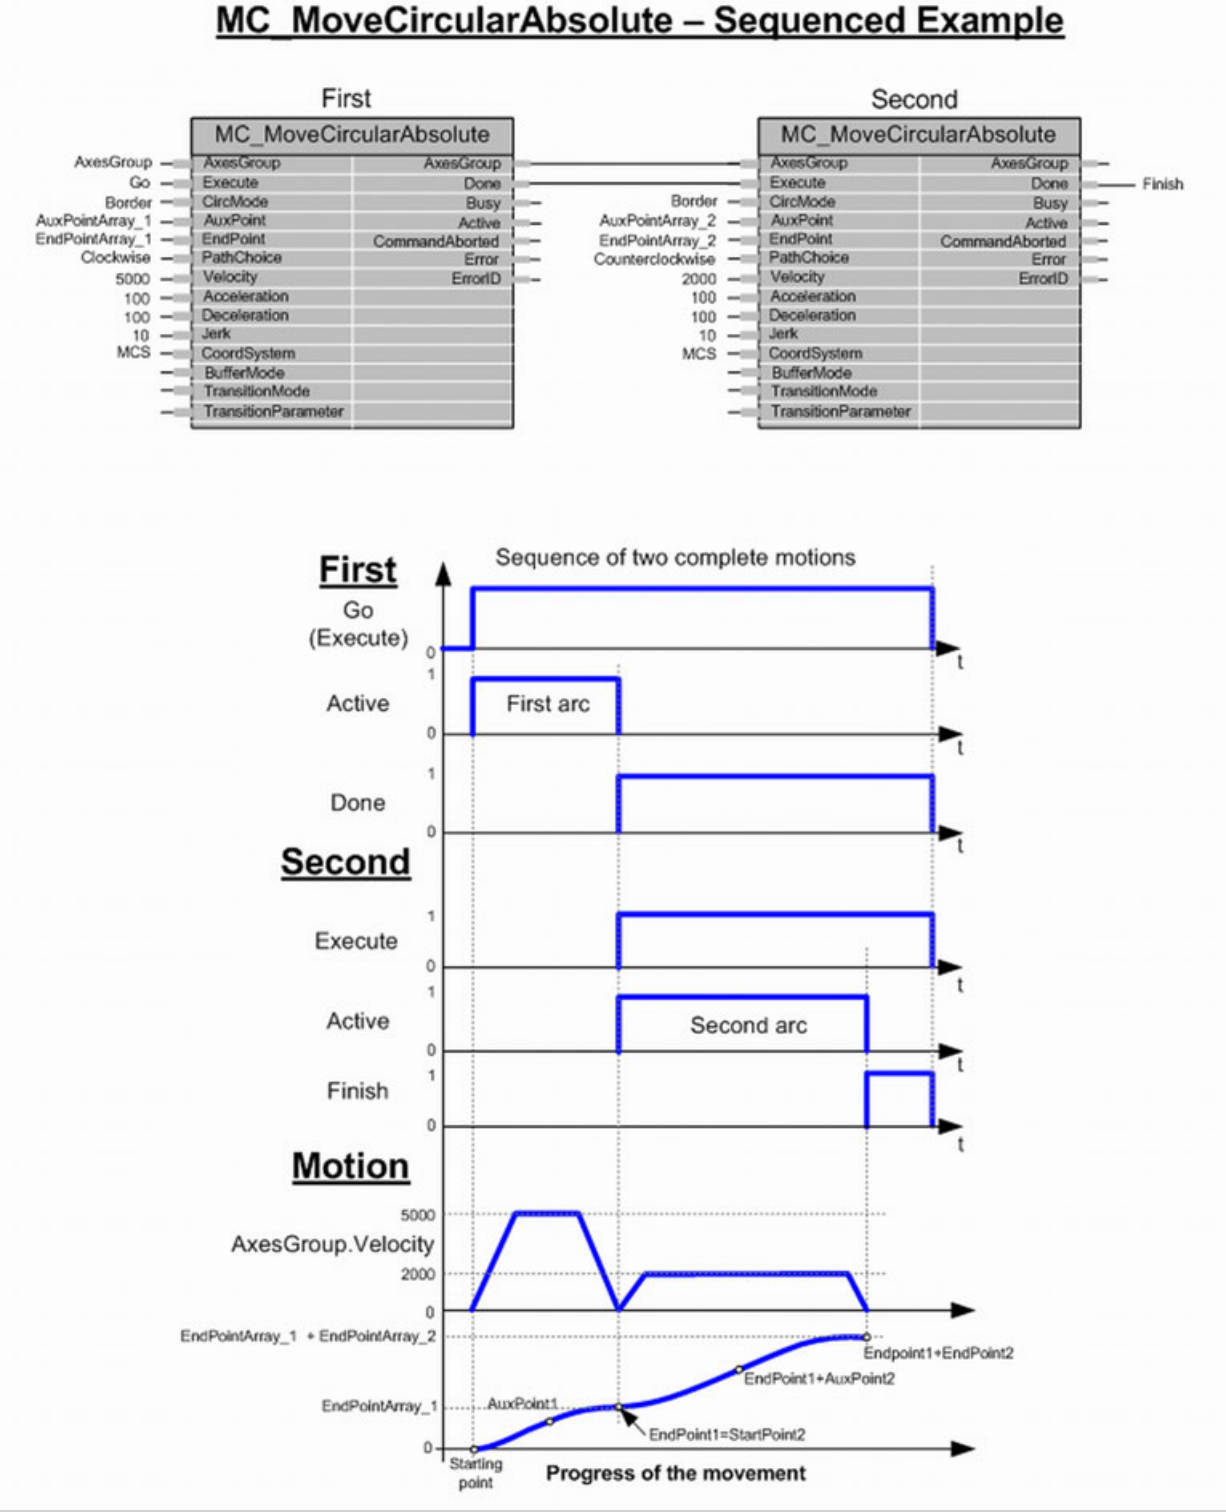


Fig. 511: Example MC_MoveCircularAbsolute

Timing diagram of example above. The dots on the red line are based on the same timing difference and representing thevelocity:

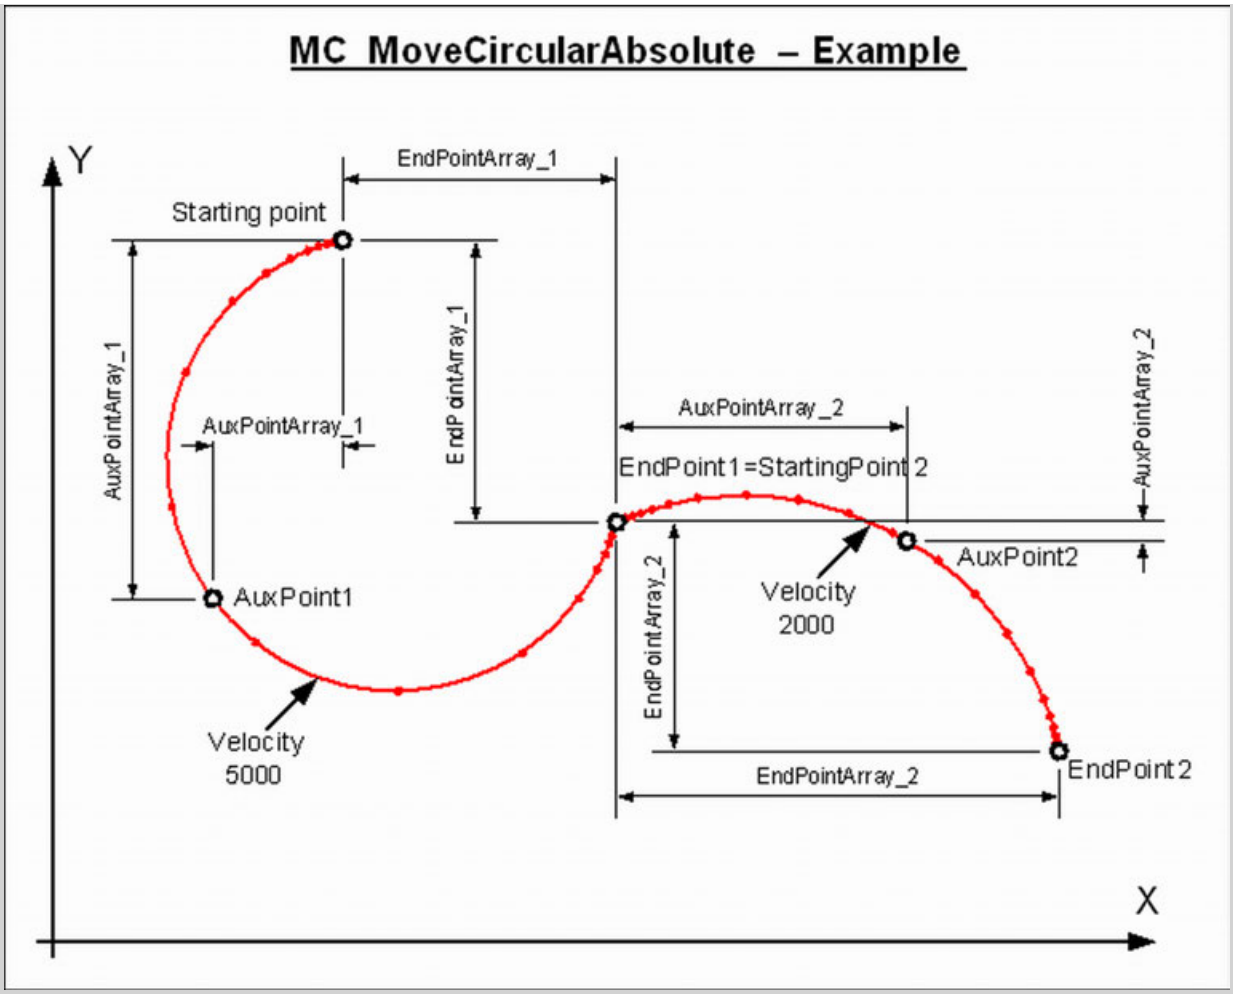

Fig. 512: Example MC_MoveCircularAbsolute

Input description

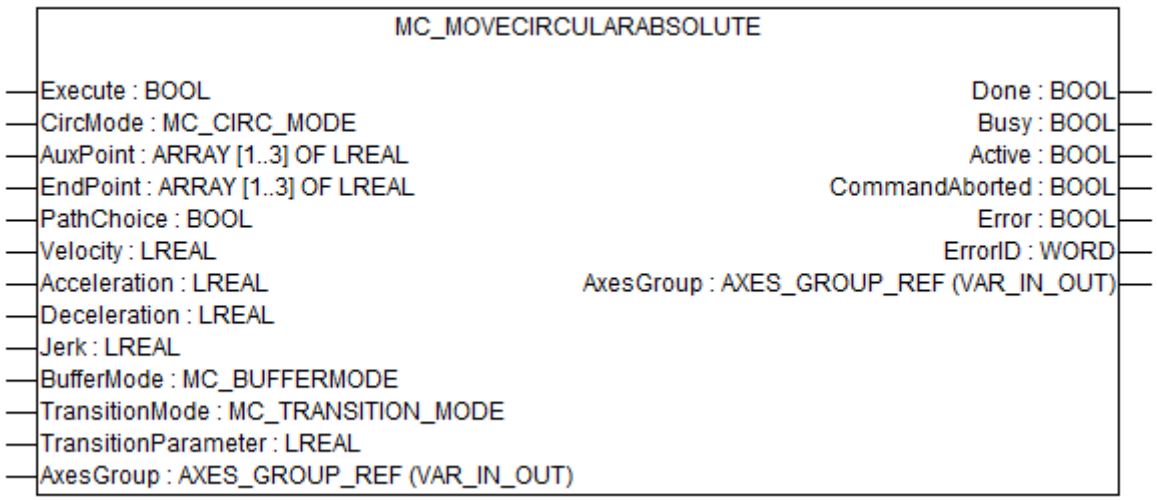

Fig. 513: MC_MoveCircularAbsolute

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute

Data type: BOOL

Starts the function block at rising edge.

CircMode

Data type: MC_CIRC_MODE

Specifies the meaning of the input signals 'AuxPoint' and 'CircDirection'.

- MC_BORDER:
  'AuxPoint' defines a point on the circle which is crossed on the path from the starting to the end point.
- MC_CENTER:
  'AuxPoint' defines the center point of the circle.
- MC_RADIUS:
  'AuxPoint' defines the spearhead point of the perpendicular of the circle plane according to the rule of right thumb. The radius of the circle is the length of the vector.

In the function block MC_MoveCircularAbsolute, the points are specified absolutely, i.e. the perpendicular vector begins in the origine and ends in the spearhead point specified at the input signal 'AuxPoint'.

AuxPoint

Data type: ARRAY [1..3] OF REAL

Array of positions for each dimension in the coordinate system specified by the input signal CoordSystem. These positions are defined relatively to the according positions of the starting point.

EndPoint

Data type: ARRAY [1..3] OF REAL

Array of absolute positions for each dimension in the coordinate system specified by the input signal CoordSystem. These positions are defined relatively to the according positions of the starting point.

PathChoice

Data type: BOOL

Choice of path: False = clockwise, true = counterclockwise.

Velocity

Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

Acceleration

Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Deceleration

Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

TransitionMode Data type: MC_TRANSITION_MODE
The realization just supports by default a transition starting with the actual velocity.

TransitionParameter Data type: LREAL
Additional parameter for the transition mode.

AxesGroup Data type: AXES_GROUP_REF
Reference to a group of axes.

Output description

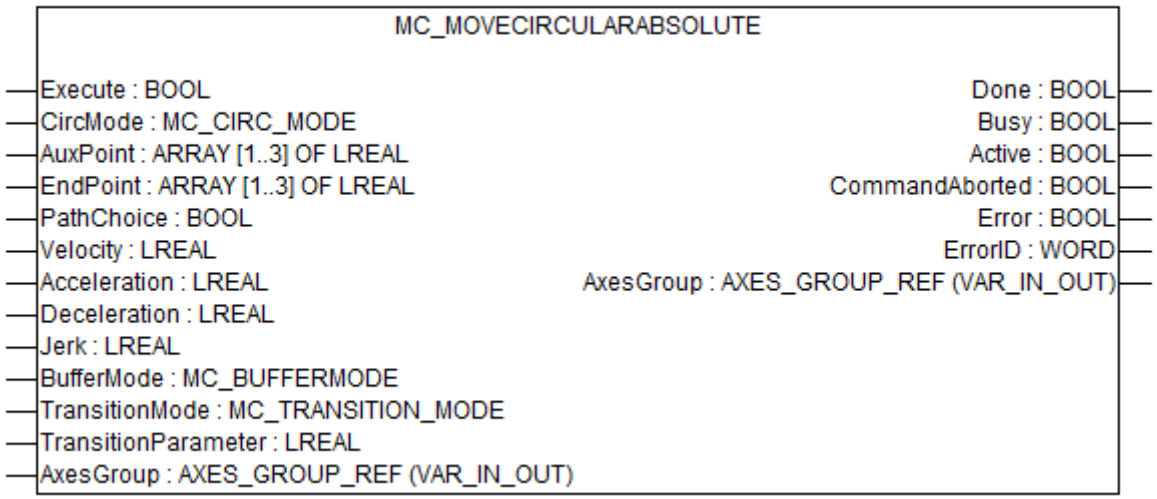

Fig. 514: MC_MoveCircularAbsolute

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveCircularRelative

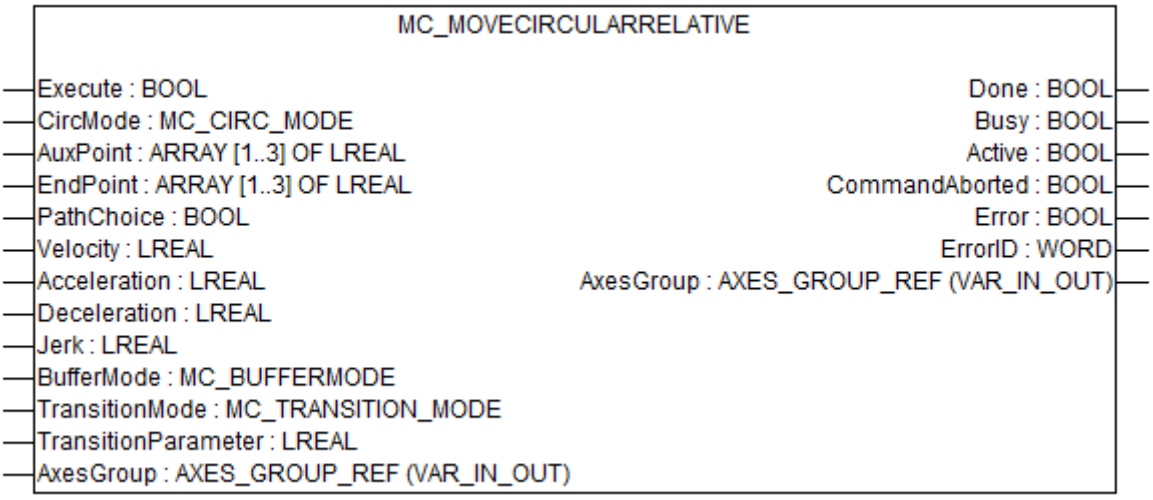

Fig. 515: MC_MoveCircularRelative

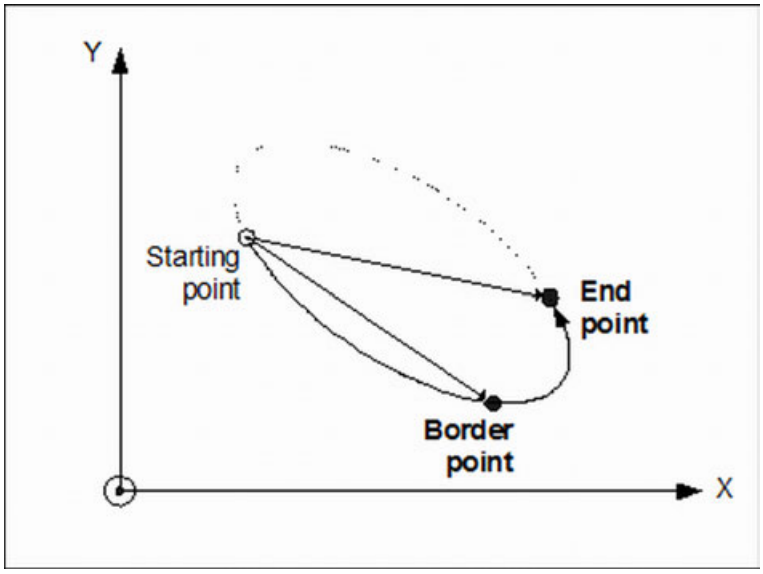
This function block commands an interpolated circular movement on an axes group from the actual position of the TCP. The end point as well as the auxiliary point (meaning depending on applied mode, see below) are defined in the specified coordinate system relatively to the starting point.

> *This function block applies to the MCS or PCS System, depending which is activated and also follows the dynamic transformation when activated.*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

CircMode = BORDER



The user defines the end point and a border point (= input 'AuxPoint') on the sector of the circle, which shall be cruised by the machine. Both points are defined relatively to the starting point.

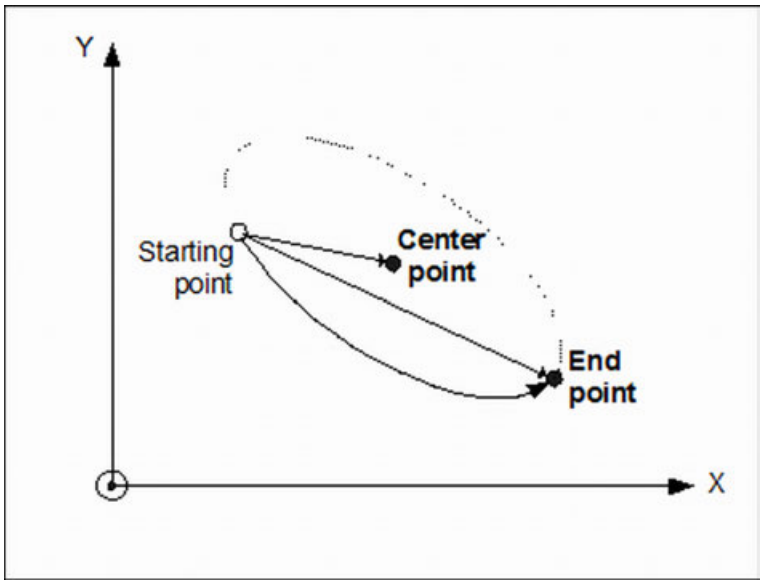
Advantages of this mode:

- The border point usually can be reached by the machine, i.e. it can be teached.

Inconvenience of this mode:

- Restriction to angles $<2\pi$ in one single command.

CircMode = CENTER

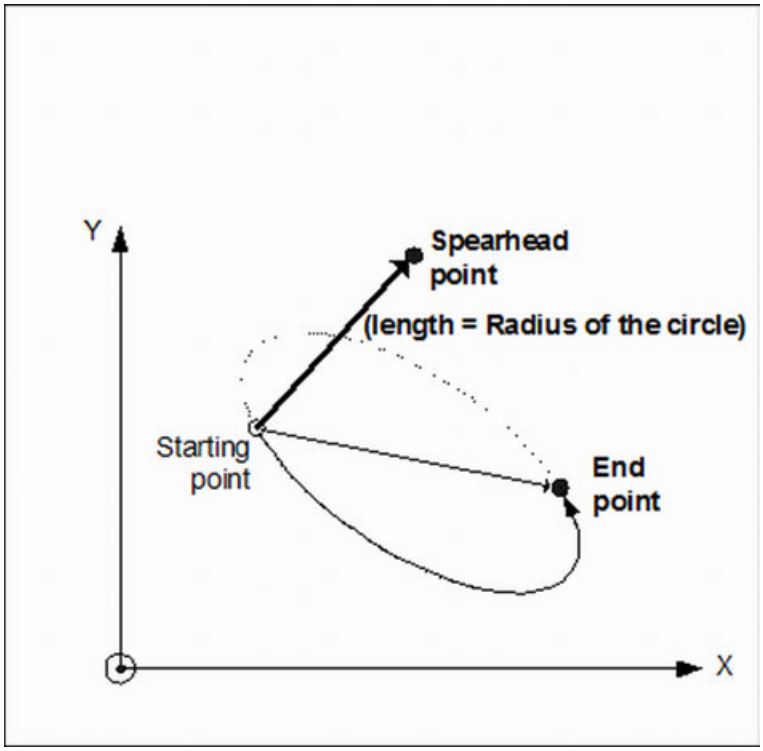


The user defines the end point and the center point (= input 'AuxPoint') of the circle. Both points are defined relatively to the starting point When using this mode, the input 'PathChoice' defines, if the short or the long sector has to be cruised by the machine.

Inconveniencies of this mode:

- Restriction to angles $< 2\pi$ and $\neq \pi$ in one single command,
- Overdetermination of circle equation,
- The center point usually cannot be teached-in due to collisions with obstacles.

CircMode = RADIUS



The user defines the end point and the perpendicular vector of the circle plane according to the rule of right thumb (see figure below). The length of the vector corresponds to the radius of the circle. The spearhead point of the vector is defined relatively to the starting point at the input signal 'AuxPoint'. If the diameter is larger than the distance between starting and end point, two different circles have to be considered. When using this mode, the input 'PathChoice' defines, if the circle with the short sector or the circle with the long sector to reach the end point has to be cruised by the machine. With positive radius value the shortest possible circle is determined, and with negative radius value the largest possible circle

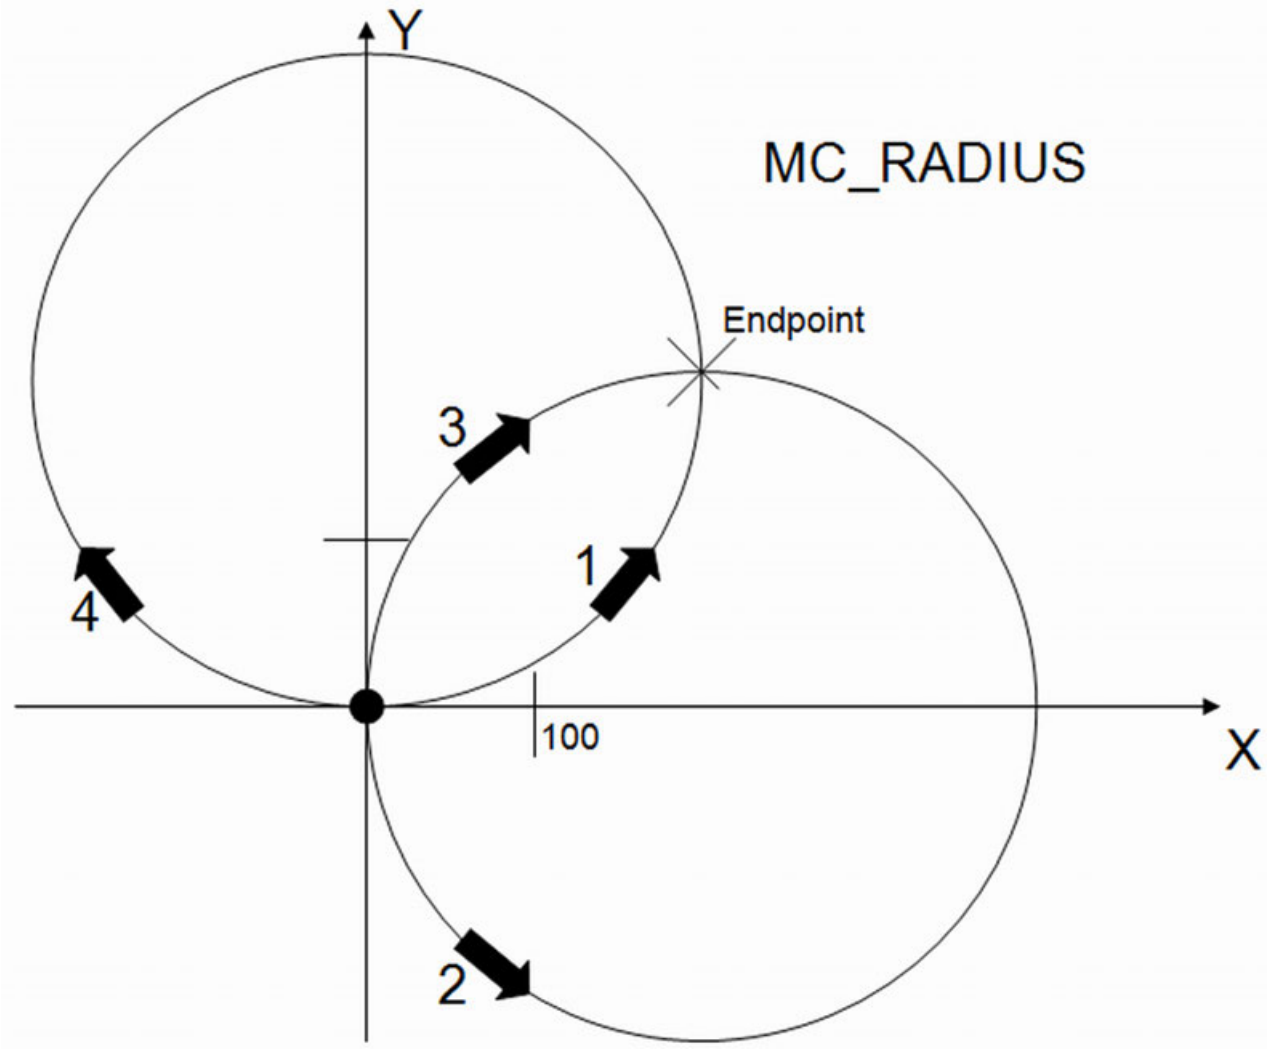
Inconvenience of this mode:

- Restriction to angles $<2\pi$ in one single command,
- The perpendicular vector has to be computed,
- Overdetermination of circle equation.

Example:	AuxPoint = (starting_point[0], starting_point[1] - 30, starting_point[2]) → Circle in plane parallel to x-z plane with radius 30 and rotation around axis parallel to y-axis contrariwise the rule of right thumb (CoordSystem = MCS).

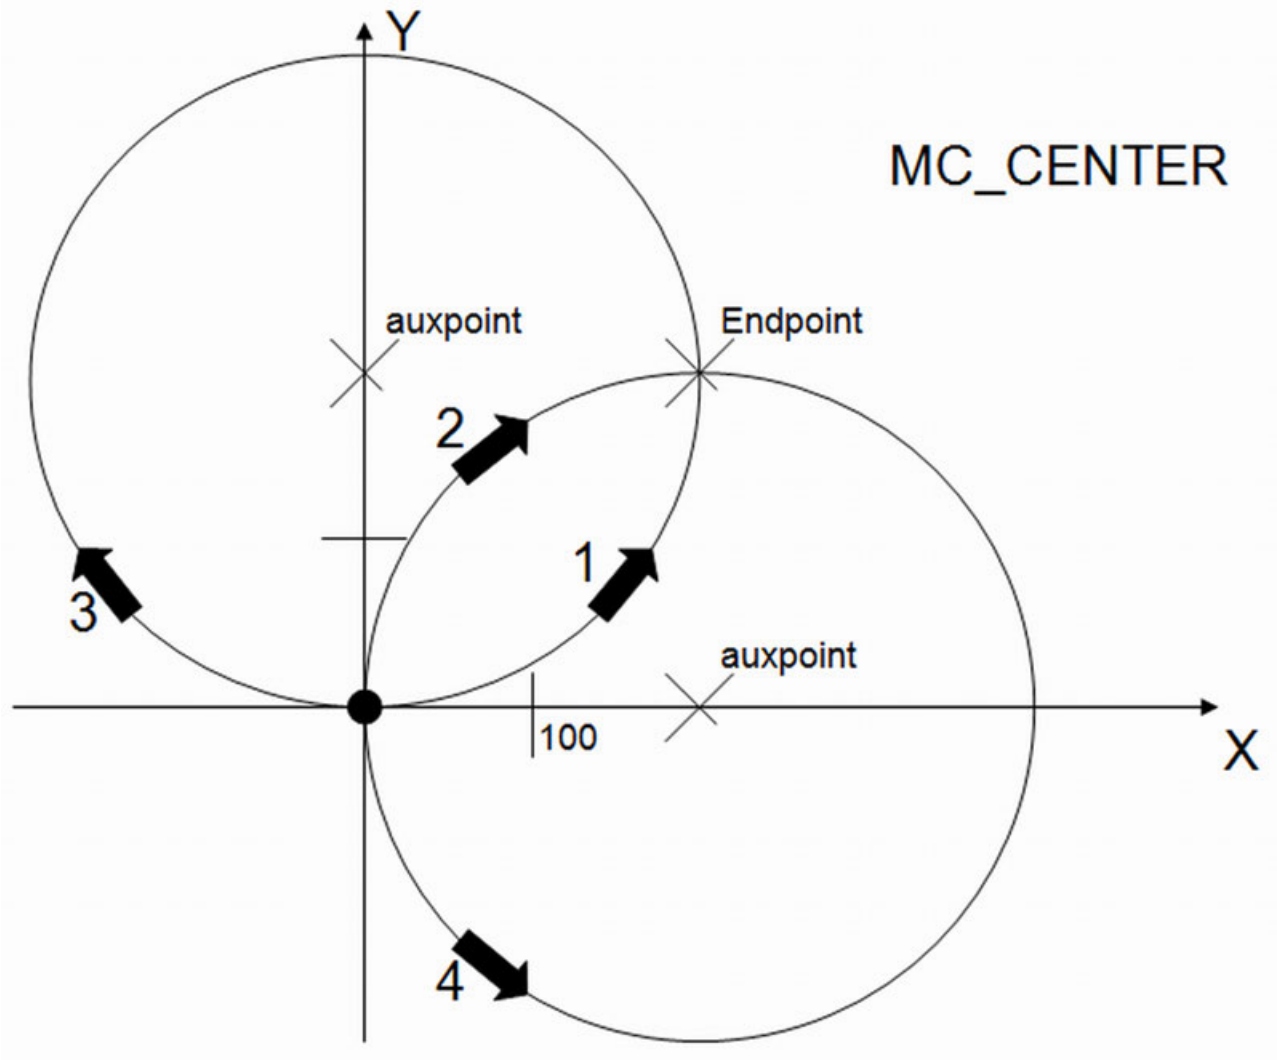
With CircMode=MC_RADIUS, Endpoint is a point at the circle and Auxpoint a vector which is perpendicular of the circle plane according to the rule of right thumb. The radius of the circle is the length of Auxpoint. The moving direction is always positive (counterclockwise), PathChoice determines if the long or short distance is moved.

MC_RADIUS



MC_RADIUS	PathChoice	Auxpoint	Endpoint
1	FALSE (short)	0,0,200	200,200,0
2	TRUE (long)	0,0,200	200,200,0
3	FALSE (short)	0,0,-200	200,200,0
4	TRUE (long)	0,0,-200	200,200,0

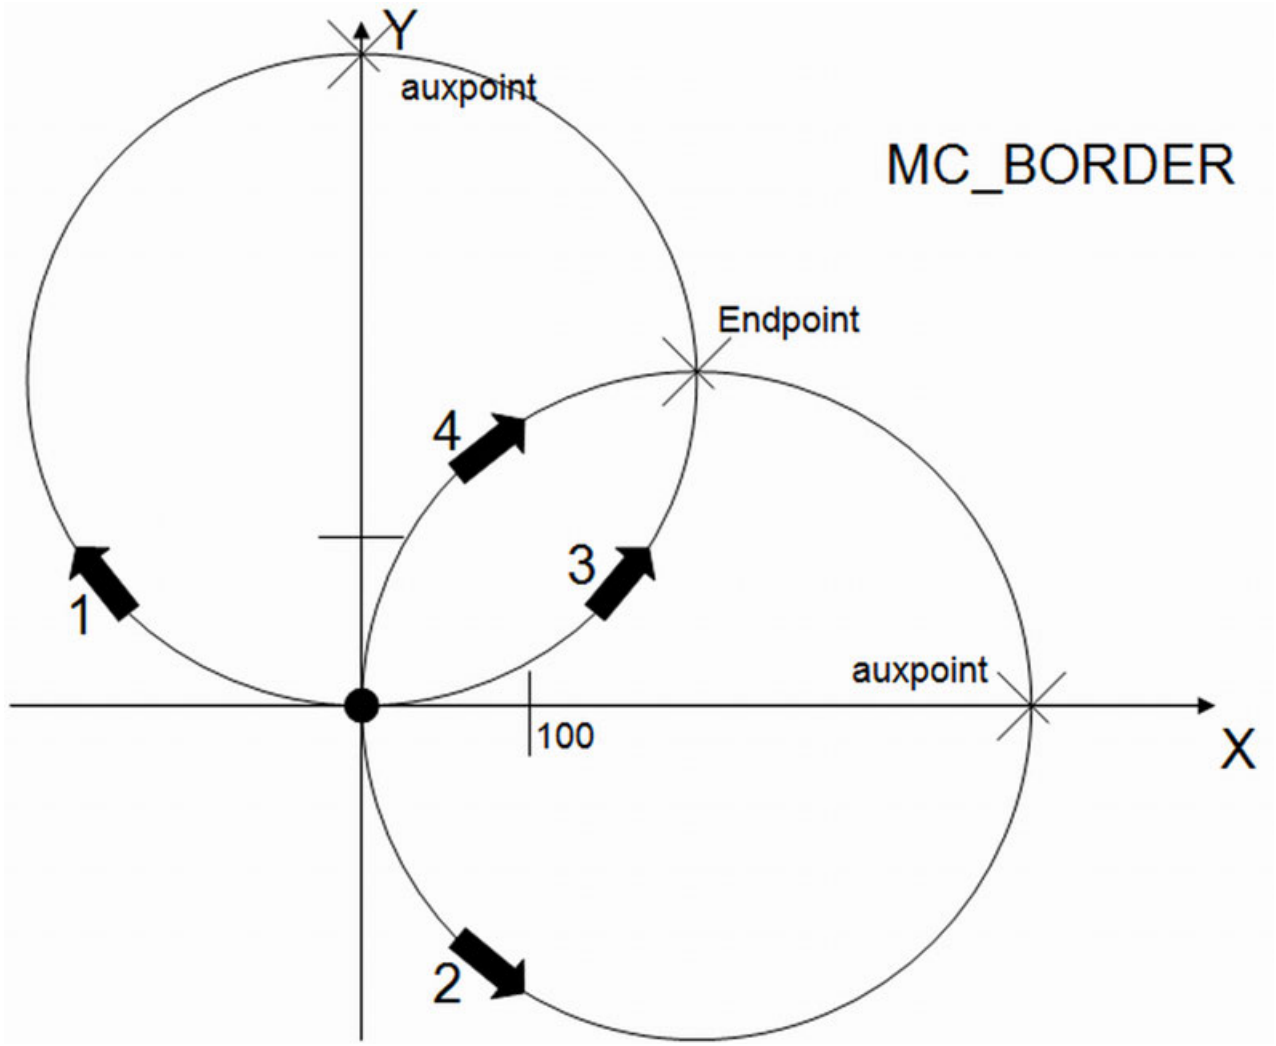
MC_CENTER



With CircMode=MC_CENTER, Endpoint is a point at the circle where the movement stops and Auxpoint is the center point. Both are relative to the start point. The circle plane is defined by Auxpoint x Endpoint. Restriction to angles $<2\pi$ and $\neq \pi$as the definition is not unique otherwise.

MC_CENTER	PathChoice	Auxpoint	Endpoint
1	FALSE (short)	0,200,0	200,200,0
2	FALSE (short)	200,0,0	200,200,0
3	TRUE (long)	0,200,0	200,200,0
4	TRUE (long)	200,0,0	200,200,0

MC_BORDER



With CircMode=MC_BORDER, Endpoint is a point at the circle where the movement stops and Auxpoint is a point on the circle. Both are relative to the start point.

MC_RADIUS	PathChoice	Auxpoint	Endpoint
1	-	0,400,0	200,200,0
2	-	400,0,0	200,200,0
3	-	141,59,0	200,200,0
4	-	59,141,0	200,200,0

Input description

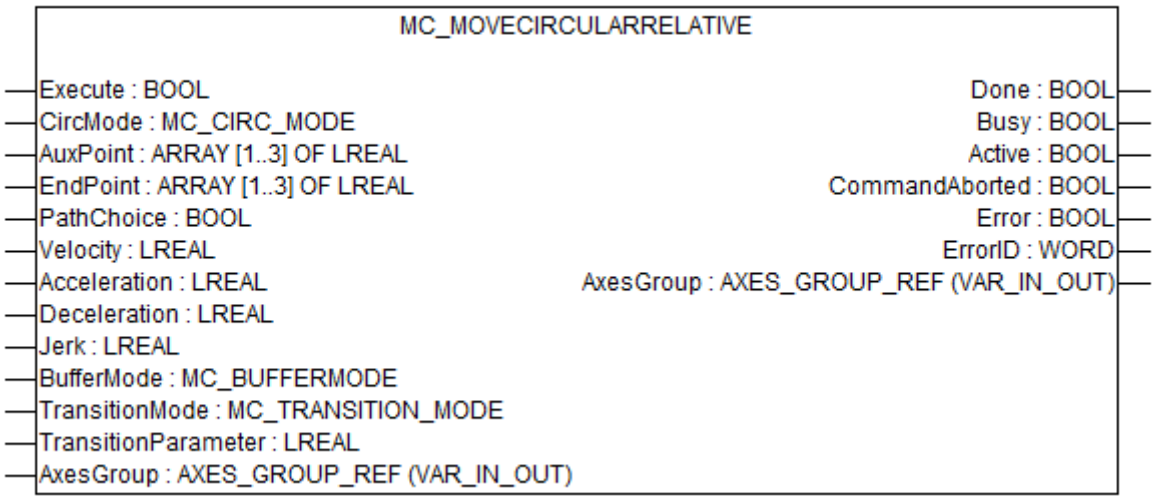


Fig. 516: MC_MoveCircularRelative

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute

Data type: BOOL

Starts the function block at rising edge.

CircMode

Data type: MC_CIRC_MODE

Specifies the meaning of the input signals 'AuxPoint' and 'CircDirection'.

- MC_BORDER:
  'AuxPoint' defines a point on the circle which is crossed on the path from the starting to the end point.
- MC_CENTER:
  'AuxPoint' defines the center point of the circle.
- MC_RADIUS:
  'AuxPoint' defines the spearhead point of the perpendicular of the circle plane according to the rule of right thumb. The radius of the circle is the length of the vector.

In the function block MC_MoveCircularAbsolute, the points are specified absolutely, i.e. the perpendicular vector begins in the origine and ends in the spearhead point specified at the input signal 'AuxPoint'.

AuxPoint

Data type: ARRAY [1..3] OF REAL

Array of positions for each dimension in the coordinate system specified by the input signal CoordSystem. These positions are defined relatively to the according positions of the starting point.

EndPoint Data type: ARRAY [1..3] OF REAL

Array of absolute positions for each dimension in the coordinate system specified by the input signal CoordSystem. These positions are defined relatively to the according positions of the starting point.

PathChoice Data type: BOOL

Choice of path: False = clockwise, true = counterclockwise.

Velocity Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3

Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

TransitionMode Data type: MC_TRANSITION_MODE

The realization just supports by default a transition starting with the actual velocity.

TransitionParameter Data type: LREAL

Additional parameter for the transition mode.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

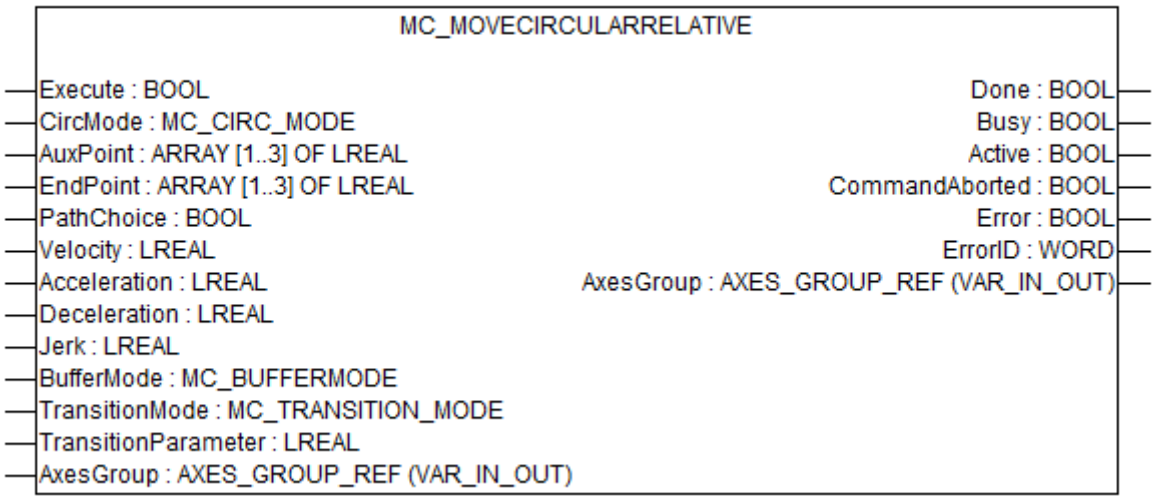

Fig. 517: MC_MoveCircularRelative

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveDirectAbsolute

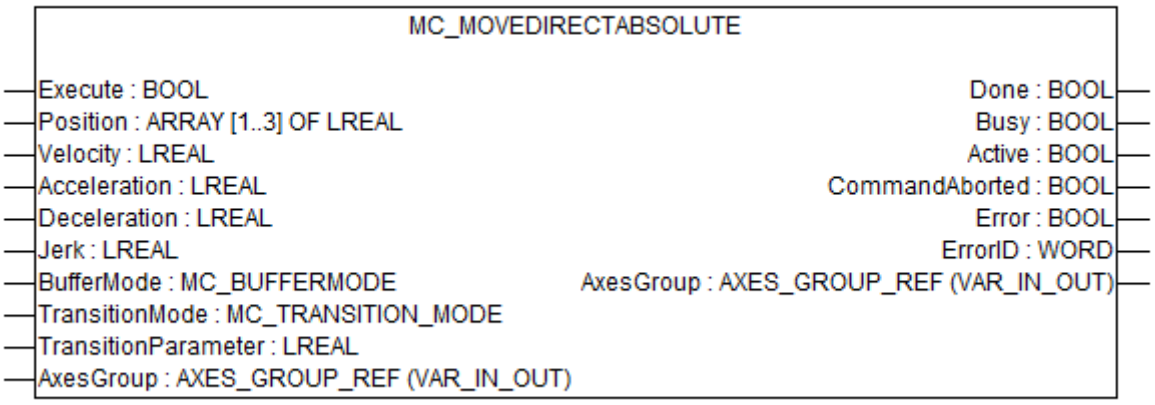

Fig. 518: MC_MoveDirectAbsolute

This function block commands a movement of an axes group to the specified absolute position in the specified coordinate system without taking care of how (on which path) the target position is reached.

- *The velocity/acceleration/deceleration/jerk of every axis are properties of each axis and not specified within this function block, but not to be exceeded during the move.*
- *This function block applies to the MCS or PCS System, depending which is activated and does not follow the dynamic transformation when activated.*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

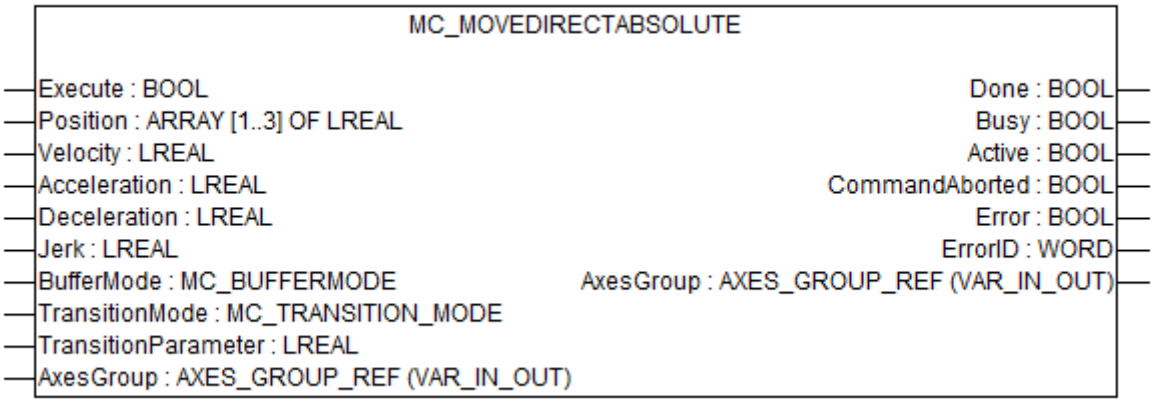

Fig. 519: MC_MoveDirectAbsolute

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute
Data type: BOOL
Starts the function block at rising edge.

Position
Data type: ARRAY [1..3] OF REAL
Array of absolute end positions for each dimension in the specified coordinate system. *"Position" on page 3038*

Velocity
Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk
Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode
Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

TransitionMode
Data type: MC_TRANSITION_MODE
The realization just supports by default a transition starting with the actual velocity.

TransitionParameter
Data type: LREAL
Additional parameter for the transition mode.

AxesGroup
Data type: AXES_GROUP_REF
Reference to a group of axes.

Output description

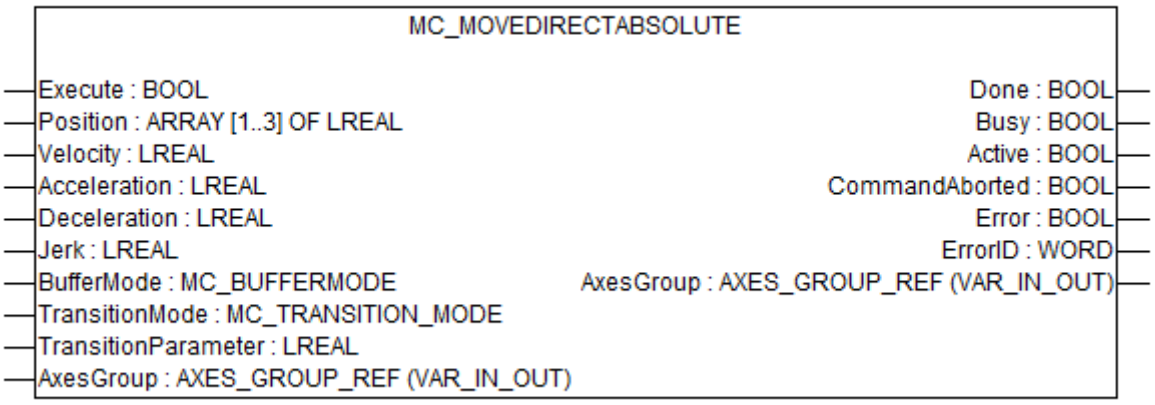

Fig. 520: MC_MoveDirectAbsolute

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MoveDirectRelative

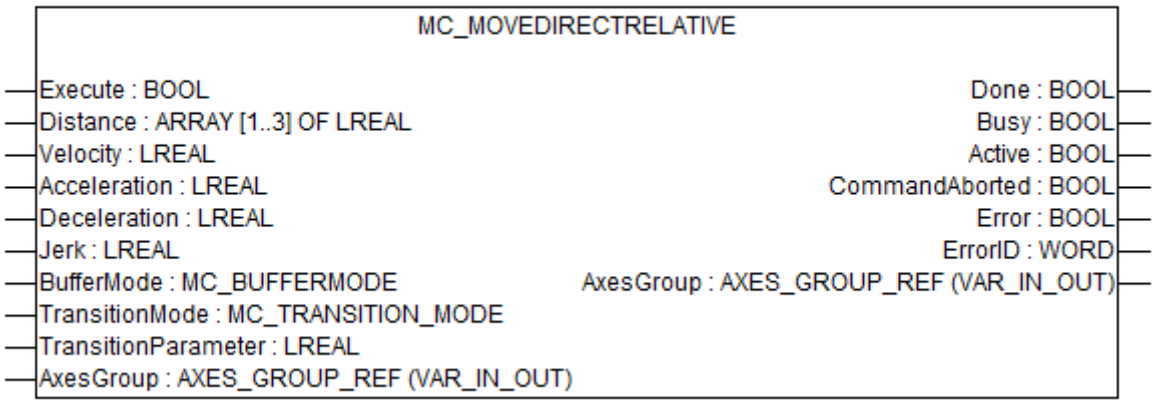

Fig. 521: MC_MoveDirectRelative

This function block commands a movement of an axes group to a relative position without taking care of how (on which path) the target position is reached. Start position is the actual position of the TCP.

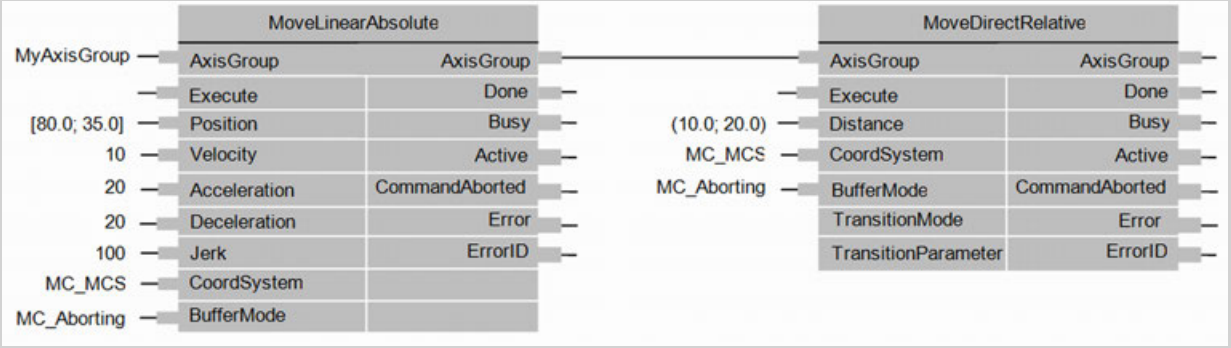
- *The velocity/acceleration/deceleration/jerk of every axis are properties of each axis and not specified within this function block, but not to be exceeded during the move.*
- *This function block applies to the MCS or PCS System, depending which is activated and does not follow the dynamic transformation when activated.*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Behavior of MC_MovePositionDirectRelative

Following example shows the behavior of MC_MovePositionDirectRelative. All positions are related to MCS:

- Starting at position p0 (10; 10) a MC_MoveLinearAbsolute to position p1 (80; 35) is commanded,
- While the TCP is moving towards p1, the MC_MoveLinearAbsolute command is aborted by a MC_MovePositionDirectRelative command. The actual position of the TCP, when MC_MovePositionDirectRelative becomes active, is (44.5; 21.63),
- The TCP leaves the line p0p1 and moves to the new target position p2 (54.5; 41.63). The resulting trajectory depends on the kinematic transformation of the axes group.



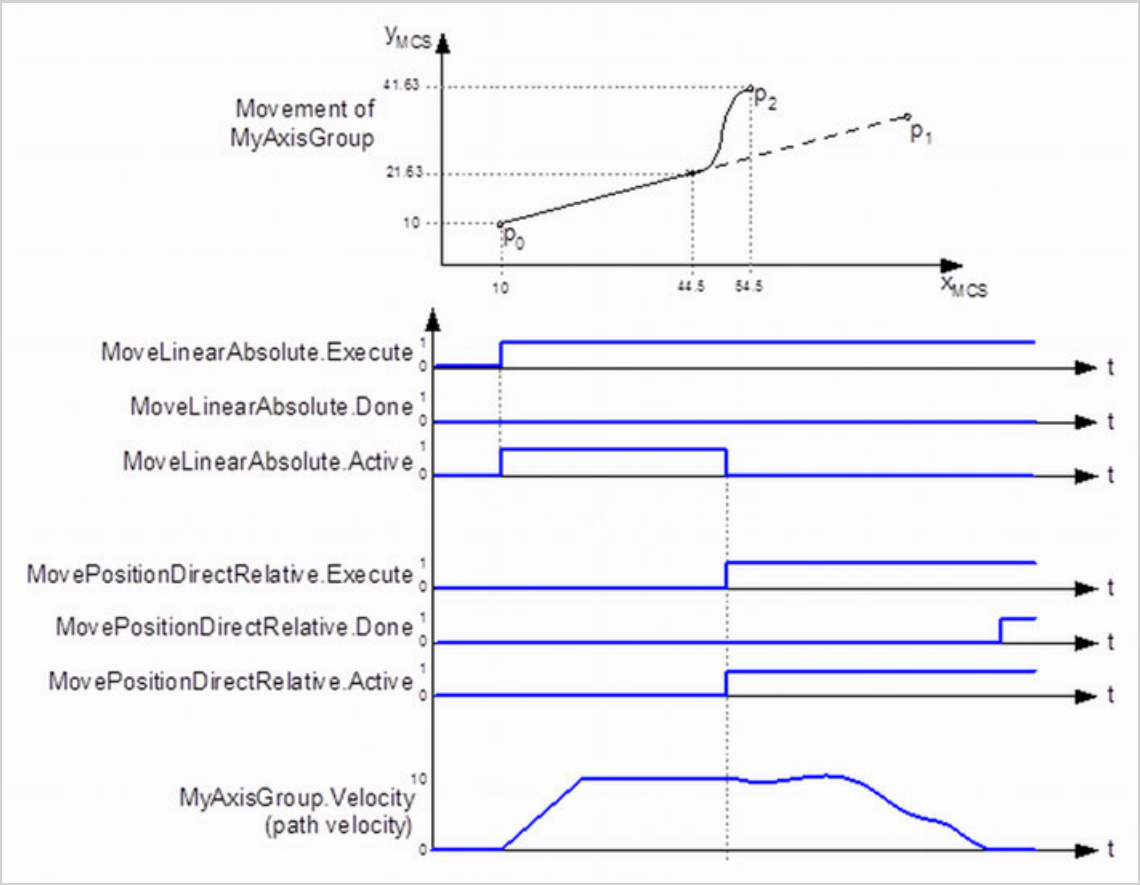


Fig. 522: Example MC_MoveDirectRelative

Input description

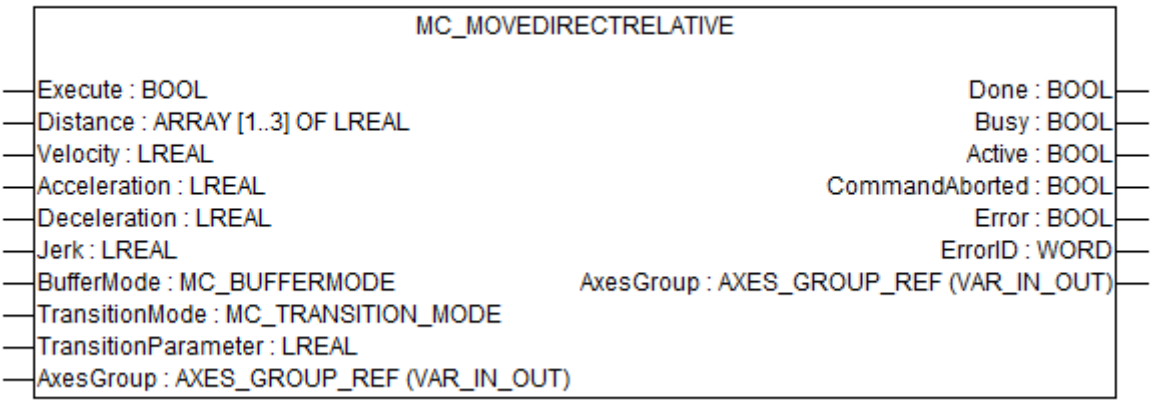

Fig. 523: MC_MoveDirectRelative

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

Distance Data type: ARRAY [1..3] OF LREAL
Array of relative distances for each dimension in the specified coordinate system.

Velocity Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

TransitionMode Data type: MC_TRANSITION_MODE
The realization just supports by default a transition starting with the actual velocity.

TransitionParameter Data type: LREAL
Additional parameter for the transition mode.

AxesGroup Data type: AXES_GROUP_REF
Reference to a group of axes.

Output description

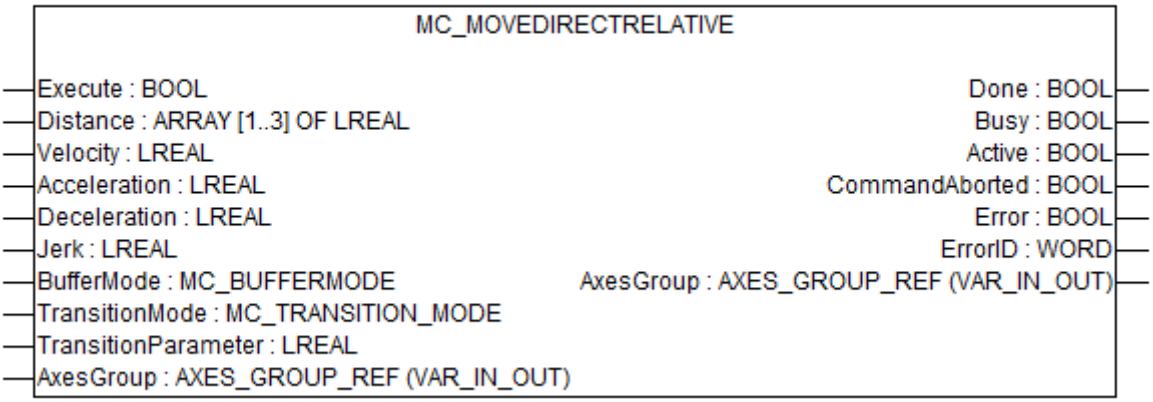

Fig. 524: MC_MoveDirectRelative

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_PathSelect

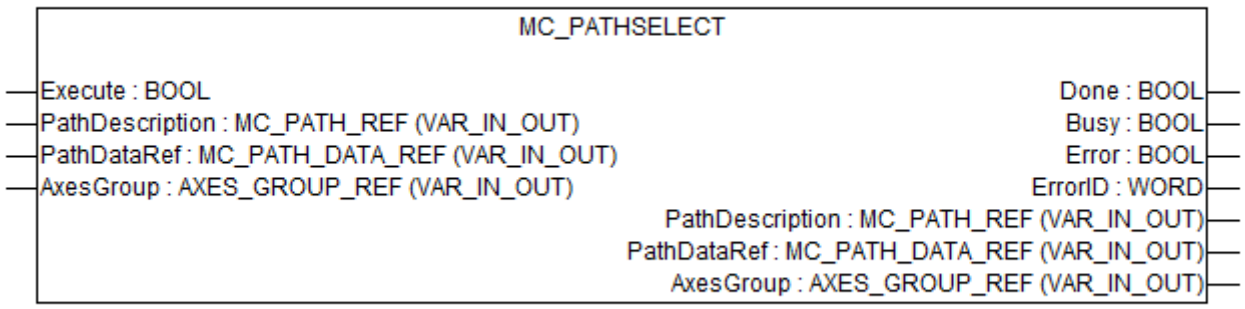

Fig. 525: MC_PathSelect

This function block prepares the relevant path data and makes these available to the system as an output (PathData). Administrative function block.

MC_PATH_DATA_REF and MC_PATH_REF are ABB specific data types.

PathSelect makes data available.This can include:

1.) Starting point of a download of a path profile, as represented in PathData and referenced by PathDescription,

2.) Start to generate a path profile.

This function block applies to the MCS or PCS System, depending which is activated.

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

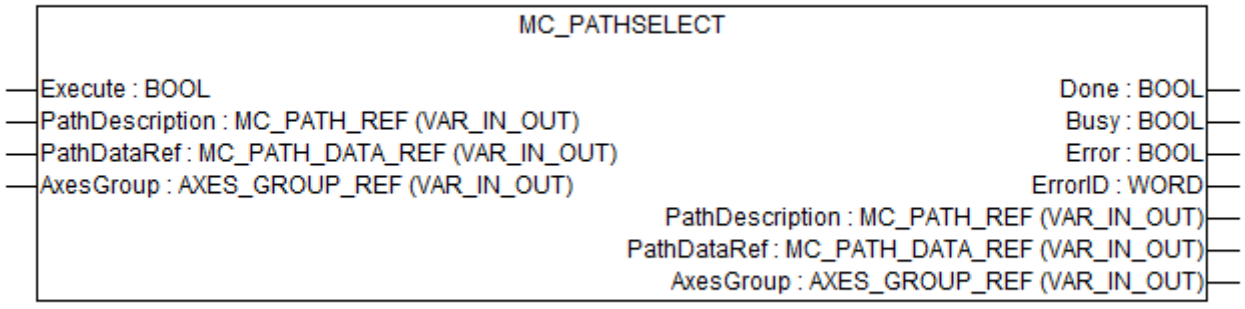

Fig. 526: MC_PathSelect

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

PathDescription Data type: MC_PATH_REF
Reference to the path description.

PathDataRef Data type: MC_PATH_DATA_REF
Reference to the path data which can be prepared by MC_PathSelect.

AxesGroup Data type: AXES_GROUP_REF
Reference to a group of axes.

Output description

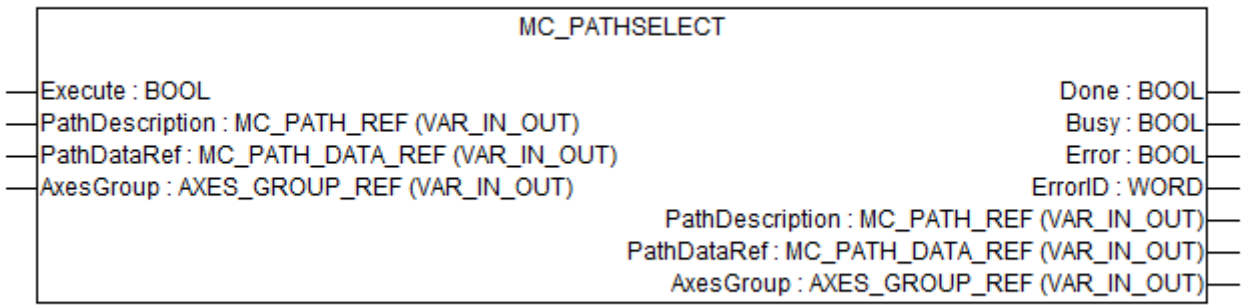

Fig. 527: MC_PathSelect

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_MovePath

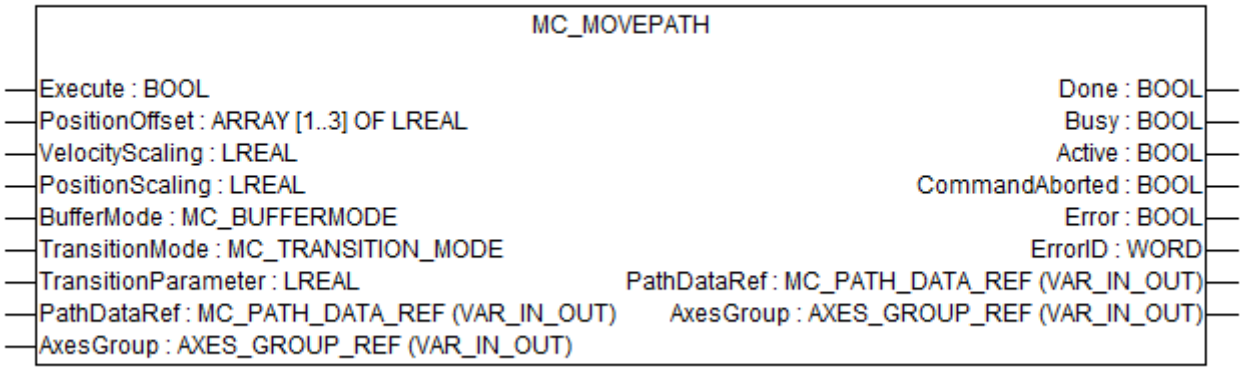

Fig. 528: MC_MovePath

This function block commands an AxesGroup to move according to the path specified in the PathData.

> *This function block applies to the MCS or PCS System, depending which is activated and also follows the dynamic transformation when activated*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Explanation: The complete path could be moved with PositionOffset and could be stretched with Position-Scaling. The path velocity could be modified with the value VelocityScaling. The used velocity will be the pathvelocity (V_PATH) multiplied by VelocityScaling. When the path movement is started, the actual position for each axis should be equal to: PathPosition * PositionScaling + PositionOffset

Position-Offset	Position-Scaling	1.Path posi-tion	Actual axis position	Behavior
0	1	0	0	Ok, movement starts at position 0.
0	1	1000	1000	Ok, movement starts at position 1000.
0	2	500	1000	Ok, movement starts at position 1000.
1000	1	0	1000	Ok, movement starts at position 1000.
-1000	1	1000	0	Ok, movement starts at position 0.
-1000	2	500	0	Ok, movement starts at position 0.

Input description

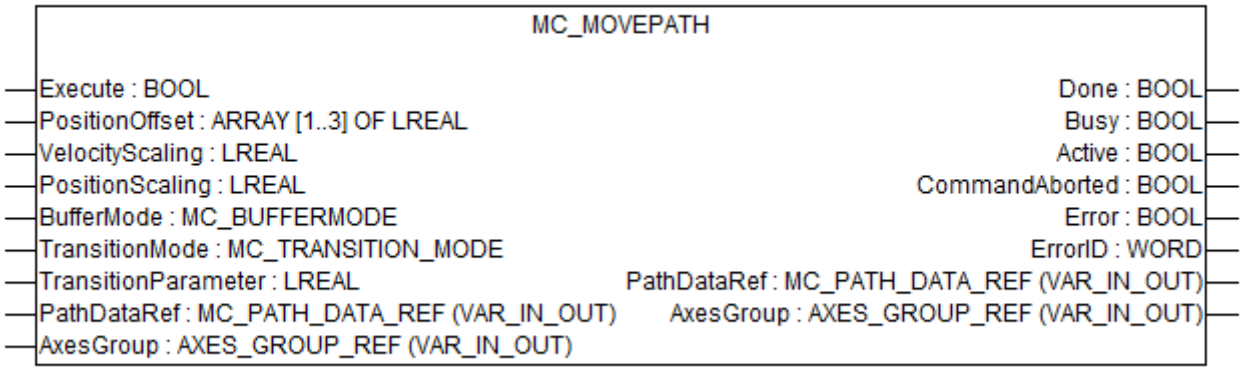

Fig. 529: MC_MovePath

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

PositionOffset Data type: ARRAY [1..3] OF LREAL

Allows to define an offset to the position in PathData. The movement starts at actual position and positionOffset. This position should be the same as the first Path Position.

VelocityScaling Data type: LREAL, default: 1

Allows to increase or decrease the path velocity.

PositionScaling Data type: LREAL, default: 1

Allows to scale the position values defined in PathData.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

TransitionMode Data type: MC_TRANSITION_MODE

The realization just supports by default a transition starting with the actual velocity.

TransitionParameter Data type: LREAL

Additional parameter for the transition mode.

PathDataRef Data type: MC_PATH_DATA_REF
Reference to the path data which can be prepared by MC_PathSelect.

AxesGroup Data type: AXES_GROUP_REF
Reference to a group of axes.

Output description

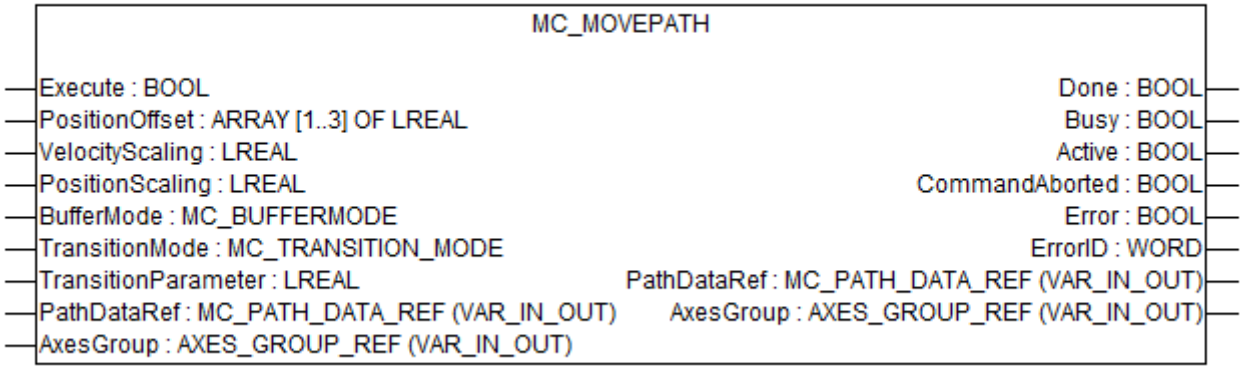

Fig. 530: MC_MovePath

Done Data type: BOOL
Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandA-borted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_SyncGroupToAxis

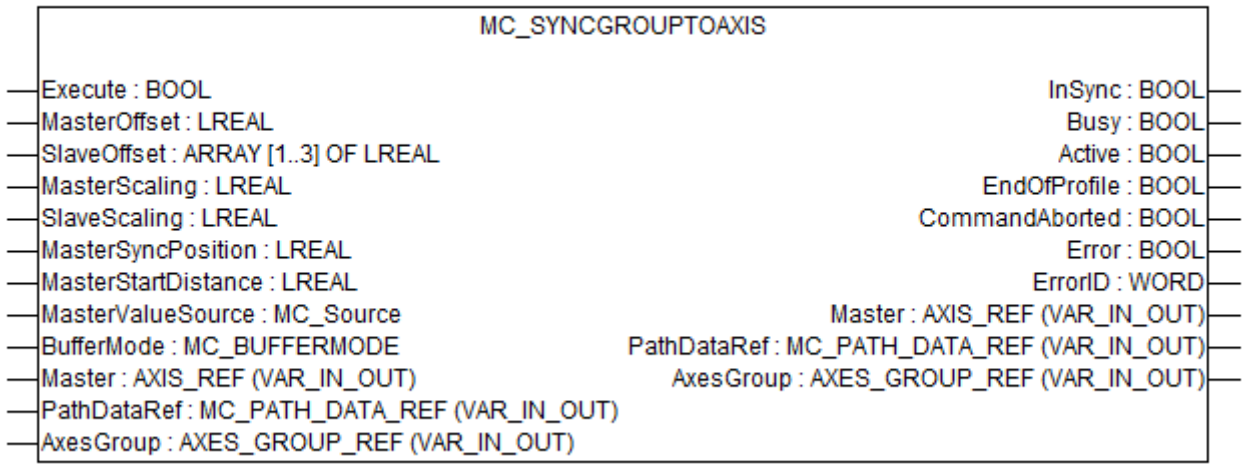

Fig. 531: Function block MC_SyncGroupToAxis

This function block commands an interpolated path movement on an axes group in the applicable coordinate system. The multi axes motion is synchronized with the Master motion like in a cam function.

- *This synchronization of the axes group can be stopped via MC_GroupStop or any other motion command,*
- *The interpolation executed corresponds to MC_MovePath, just that MC_MovePath processes the path data in relation to time while MC_SyncGroupToAxis processes the path data in relation to the master position,*
- *It is possible to start the movement in advance and ramp-in to reach the path at position MasterSyncPosition. This functionality is executed with MasterStartDistance < > 0.*

Input description

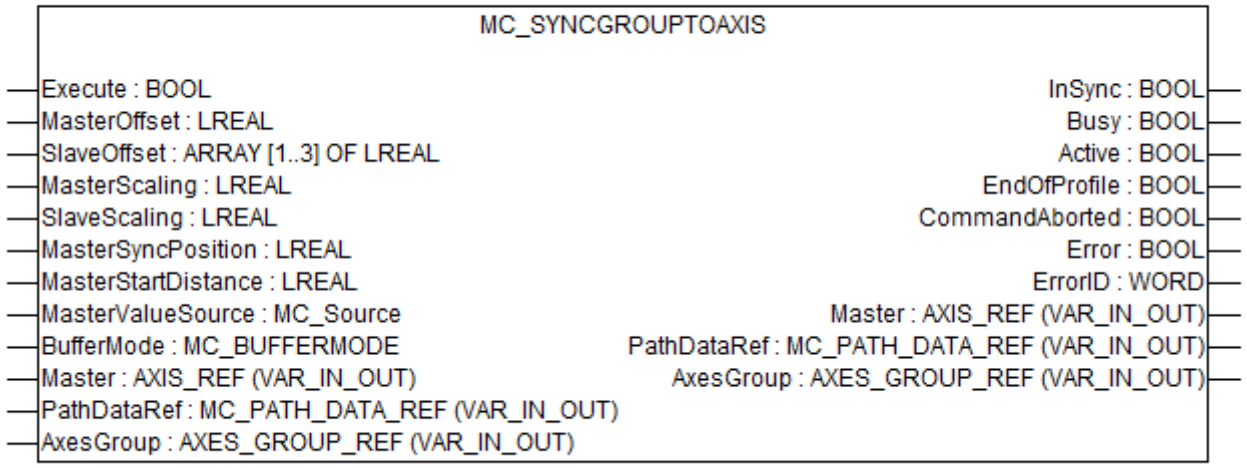

Fig. 532: Function block MC_SyncGroupToAxis

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute

Data type: BOOL

Starts the function block at rising edge.

MasterOffset

Data type: LREAL

Offset of master table. Angular offset of the master shaft to cam.

SlaveOffset

Data type: ARRAY [1..3] OF LREAL

Offset of slave table. The slave will start at the 1. path position + SlaveOffset.

MasterScaling

Data type: LREAL, default: 1.0

Factor for the master profile. From the slave point of view the master overall profile is multiplied by this factor.

SlaveScaling

Data type: LREAL, default: 1.0

Factor for the slave profile. The overall slave profile is multiplied by this factor.

MasterSyncPosition

Data type: LREAL

The position of the master in the path where the group is insync with the master. (If the ‘MasterSyncPosition’ does not exist, at the first point of the path the master and slave are synchronized).

The inputs acceleration, deceleration and jerk are not added here.

MasterStartDistance

Data type: LREAL

The master distance for the slave to start to synchronize to the master.

MasterValueSource

Data type: MC_SOURCE

Defines the source for synchronization:

mcSetValue - Synchronization on master set value.

mcActualValue - Synchronization on master actual value.

BufferMode

Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

Master

Data type: AXIS_REF

Reference to the master axis.

PathDataRef Data type: MC_PATH_DATA_REF
Reference to the path data which can be prepared by MC_PathSelect.

AxesGroup Data type: AXES_GROUP_REF
Reference to a group of axes.

Output description

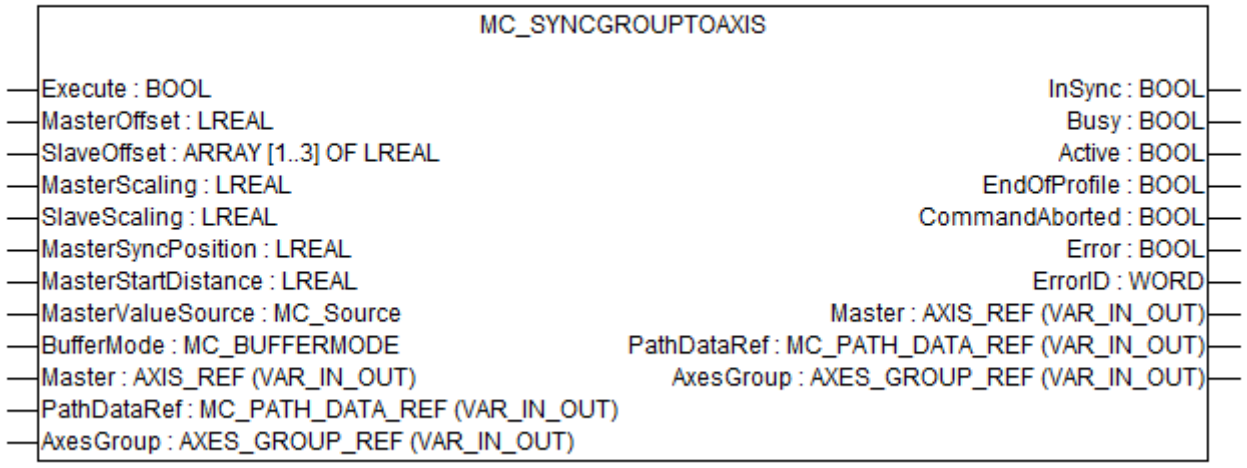

Fig. 533: Function block MC_SyncGroupToAxis

InSync Data type: BOOL
The axes group follows the master axis.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification ↳ *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_SyncAxisToGroup

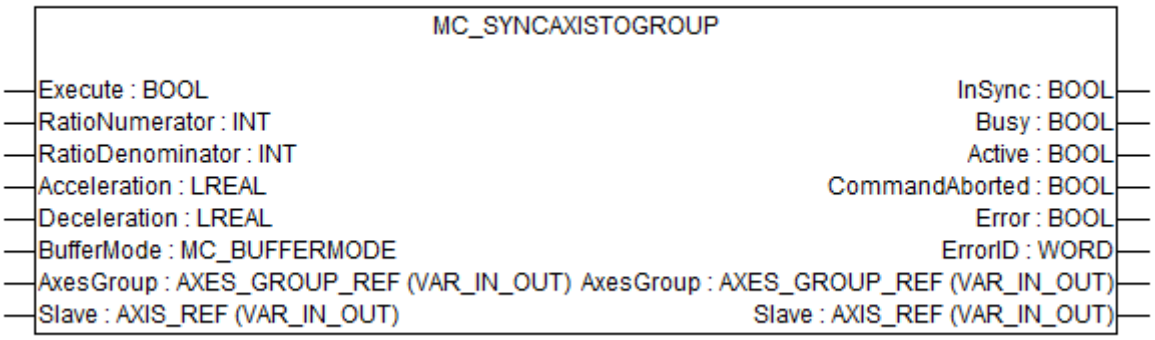

Fig. 534: MC_SyncAxisToGroup

This function block maps a single axis to a group. The single axis output represents the path length progression of the axes group. There is the ability to set a ratio between group and single axis.

- *This function block equals the mileage counter (odometer) in a car of the group and shows this via the Slave axis,*
- *The slave ramps up to the ratio of the path speed and locks in position when this is reached,*
- *The gearing ratio can be changed while function block is running, using a consecutive call of the function block,*
- *InSync is set the first time the ratio is reached,*
- *After being InSync, a position locking or just a speed locking is system specific. The function block is stopped by issuing a single axis function block.*

This function block applies to the MCS or PCS System, depending which is activated and also follows the dynamic transformation when activated.

This function block has to be called within the real-time task.

Input description

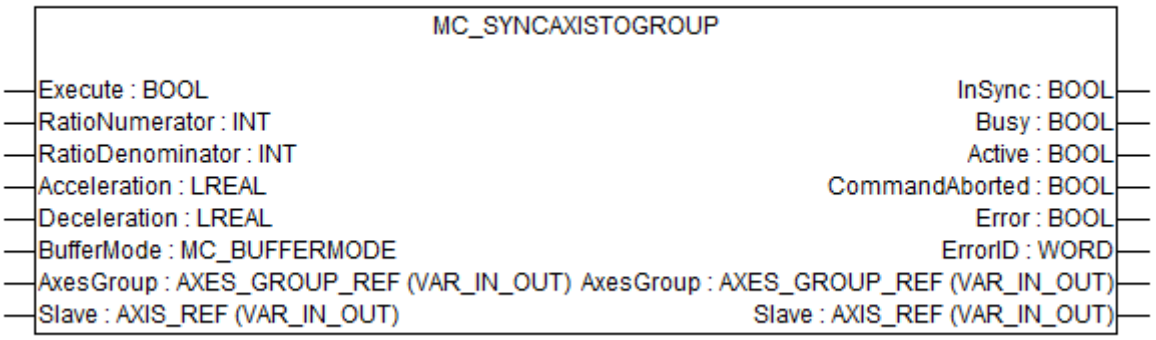

Fig. 535: MC_SyncAxisToGroup

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

RatioNumerator Data type: INT
Gear Ratio Numerator.

RatioDenominator Data type: INT
Gear Ratio Denominator.

Acceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

AxesGroup Data type: AXES_GROUP_REF
Reference to a group of axes.

Slave Data type: AXIS_REF
Reference to the axis (real or virtual).

Output description

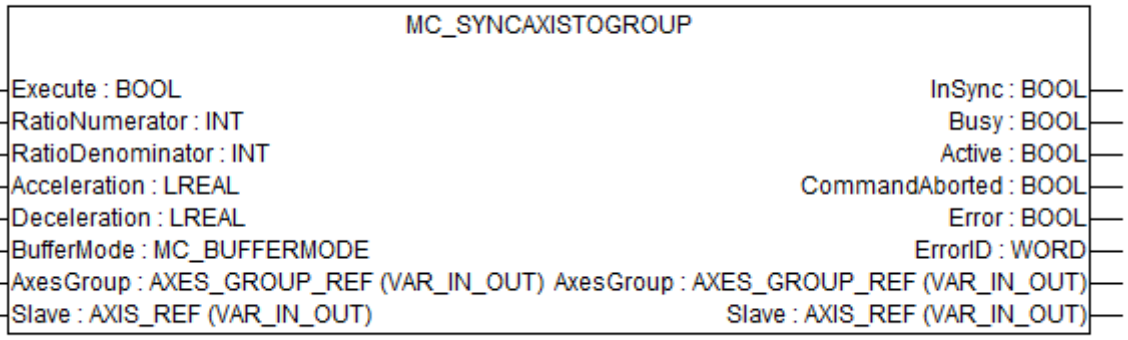

Fig. 536: MC_SyncAxisToGroup

InSync Data type: BOOL
The (virtual) slave generates valid values.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

COMC_GROUP_CARTESIAN

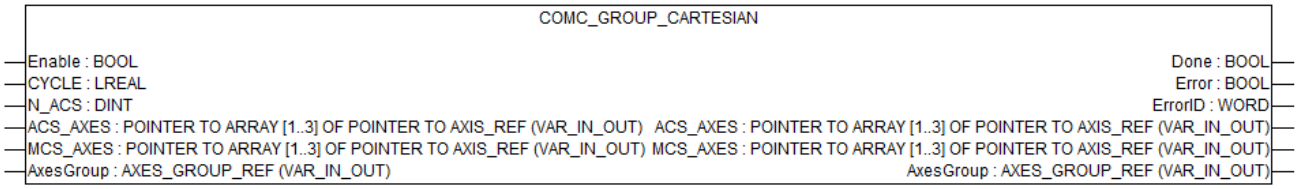

Fig. 537: Function block COMC_GROUP_CARTESIAN

Table 194: General information

Available as of runtime system	V1.2 and above
Included in library	CoordinatedMotion_AC500_V21.LIB
Type	Function block with historical values

This function block has to be called every cycle and at least once before any MC… function block is activated.

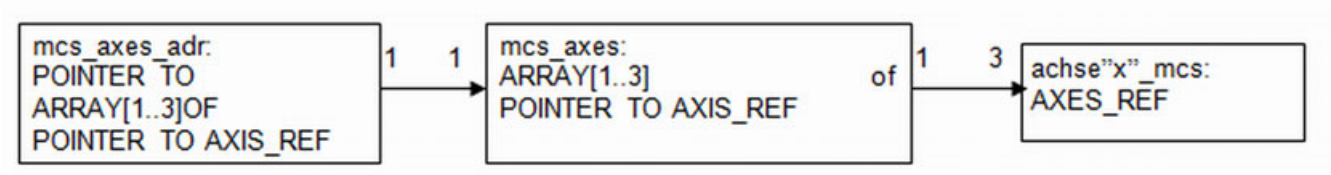
The MCS axes form a cartesian system according to the “right hand rule”. These axes are fix, so it is not possible to add or remove an axis. When just 2 dimensions are needed, a dummy-axis which runs on simulation should be created.

The addresses should be calculated as follows:

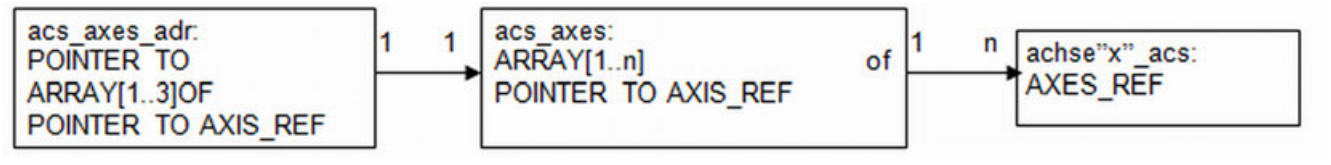
```
acs_axes[1]:=ADR(achse1_acs);
acs_axes[2]:=ADR(achse2_acs);
acs_axes[3]:=ADR(achse3_acs);
acs_axes_adr:=ADR(acs_axes);
mcs_axes[1]:=ADR(achse1_mcs);
mcs_axes[2]:=ADR(achse2_mcs);
mcs_axes[3]:=ADR(achse3_mcs);
mcs_axes_adr:=ADR(mcs_axes);
```

This should be done every cycle as on an online change, addresses of variables might be changed. The actual address has to be provided to the block in every cycle.

The different elements are linked by ADR operator.



The number of ACS axes is flexible, although an array with 3 elements is used as type. A larger array could be used instead and the number of elements be provided at N_ACS.



Input description

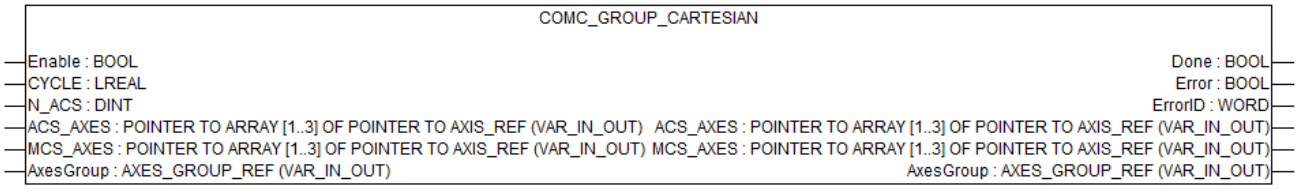


Fig. 538: Function block COMC_GROUP_CARTESIAN

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Release of function block.

CYCLE Data type: INT

Cycle time of the PLC task in ms.

N_ACS Data type: INT

Number of ACS Axes

ACS_AXES Data type: POINTER TO ARRAY[1..3] OF POINTER TO AXIS_REF

Access to the machine axes, the number is variable and the array might have a different number of elements. It depends on the used coordinate transformation

MCS_AXES Data type: POINTER TO ARRAY[1..3] OF POINTER TO AXIS_REF

Access to the Cartesian axes. These have to be 3 axes, for X, Y, Z coordinate in a right handed coordinate system

GROUP Data type: AXES_GROUP_REF

Group reference

Output description

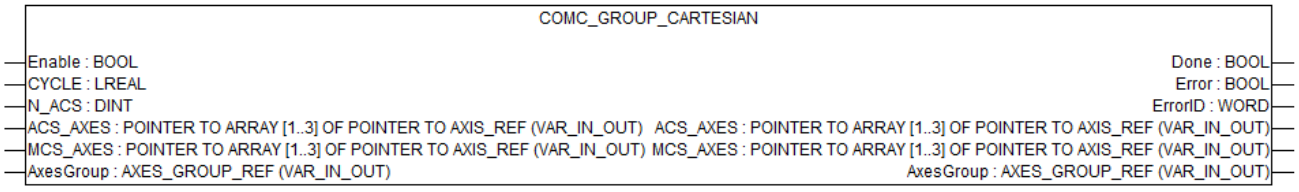

Fig. 539: Function block COMC_GROUP_CARTESIAN

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

COMC_TeachCartesianTransformation

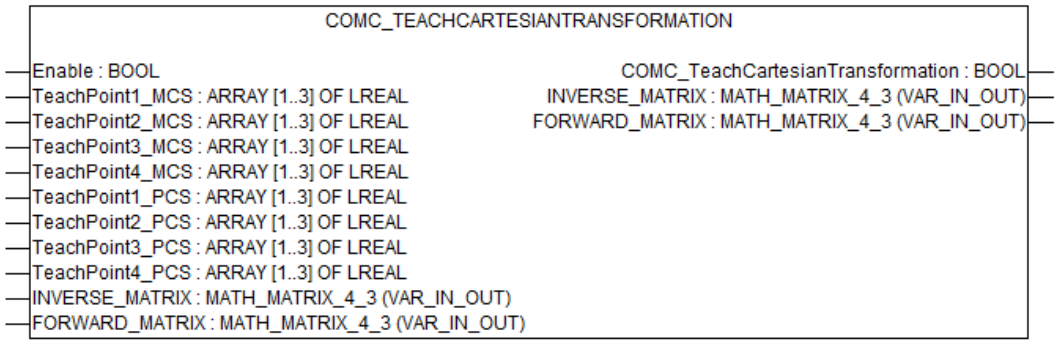

Fig. 540: Function COMC_TeachCartesianTransformation

The function calculates matrices to be used for Cartesian coordinate transformation.

> *Four teach points from both coordinate systems are necessary to do so. The points need to be linearly independent, which means it is not possible to have 3 points on a line or all 4 points on a plane. As result, the Function will calculate FORWARD_MATRIX and INVERSE_MATRIX which could be used with Funciton Block “MCA_SetCoordinateTransformation” to switch over from MCS to PCS. The Function has a BOOL value as return value which is TRUE in case of success. When FALSE is returned, the condition of linear independent points needs to be checked.*

Input description

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Activates the Funcion.

TeachPoint1_MCS
Data type: ARRAY[1..3] OF LREAL
Teach point for x, y, z values in MCS. Refers to the same point as TeachPoint1_PCS in PCS coordinates.

TeachPoint2_MCS
Data type: ARRAY[1..3] OF LREAL
Teach point for x, y, z values in MCS. Refers to the same point as TeachPoint2_PCS in PCS coordinates.

TeachPoint3_MCS
Data type: ARRAY[1..3] OF LREAL
Teach point for x, y, z values in MCS. Refers to the same point as TeachPoint3_PCS in PCS coordinates.

TeachPoint4_MCS
Data type: ARRAY[1..3] OF LREAL
Teach point for x, y, z values in MCS. Refers to the same point as TeachPoint4_PCS in PCS coordinates.

TeachPoint1_PCS
Data type: ARRAY[1..3] OF LREAL
Teach point for x, y, z values in PCS.

TeachPoint2_PCS
Data type: ARRAY[1..3] OF LREAL
Teach point for x, y, z values in PCS.

TeachPoint3_PCS
Data type: ARRAY[1..3] OF LREAL
Teach point for x, y, z values in PCS.

TeachPoint4_PCS
Data type: ARRAY[1..3] OF LREAL
Teach point for x, y, z values in PCS.

INVERSE_MATRIX
Data type: MATRIX_4_3
Result of the Function, a matrix with 4 lines and 3 columns, to be used for transform PCS to MCS coordinates.

FORWARD_MATRIX
Data type: MATRIX_4_3
Result of the Function, a matrix with 4 lines and 3 columns, to be used for transform MCS to PCS coordinates.

1.5.9.7.2 Transformation function blocks

Although the transformation function blocks are administrative function blocks, they can be buffered. Additional transformation function blocks are available as ABB specific function blocks MCA_.... ↪ *Chapter 1.5.9.7.3 “ABB specific function blocks” on page 3008*

MC_SetCartesianTransform MCS to PCS

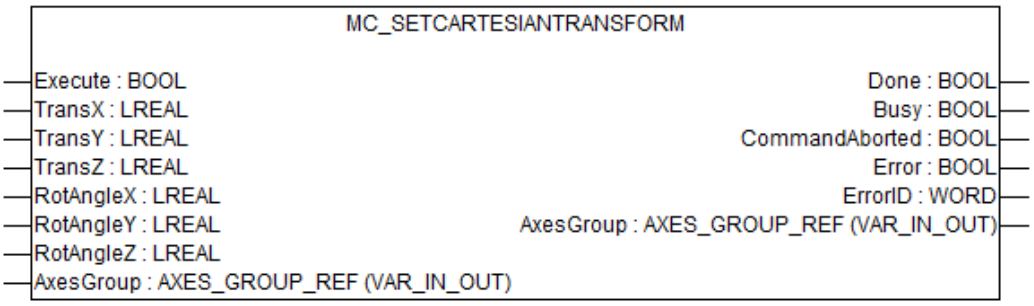

Fig. 541: Function block MC_SetCartesianTransform

This function block sets a Cartesian transformation between the MCS and PCS.

The transformation will be activated on the next group movement, e.g. MC_MoveLinearAbsolute. When the block is activated, it first will be “Busy”. The Group will activate the transformation on the next movement, the block changes to “Done”. The transformation will be used until an other transformation is activated.

- First, the rotation is applied in Z/Y/X direction and then the translation, with respect to the already rotated coordinate system. When it is more reasonable to apply first the translation, this could be done with feeding the translation values to MC_SetCoordinateTransform. This function block (or MCA_SetCoordinateTransformation) is a precondition for the use of MC_SetCartesianTransform.
- De-selection of PCS can be done by a execution of this function block with {TransX, TransY, TransZ, RotAngleX, RotAngleY, RotAngleZ }={0, 0, 0, 0, 0, 0} as translation and rotation input values.
- The values could as well be modified dynamically.
- A precondition for the use of MC_SetCartesianTransform is to activate a PCS first by MC_SetCoordianteTransform or MCA_SetCoordinateTransformation. A neutral transformation could be used for this which is available from the library as CoordTransform_neutral.
- The transformation is combined with a block using “CoordTransform” but it is not possible to combine it with a different block using translation vectors and rotation angles. In combination with CoordTransform, the CoordTransform is executed first.

The transformation will be activated on the next group movement, e.g. MC_MoveLinearAbsolute. When the function block is activated, it first will be “Busy”. The Group will activate the transformation on the next movement, the function block changes to “Done”. The transformation will be used until an other transformation is activated.

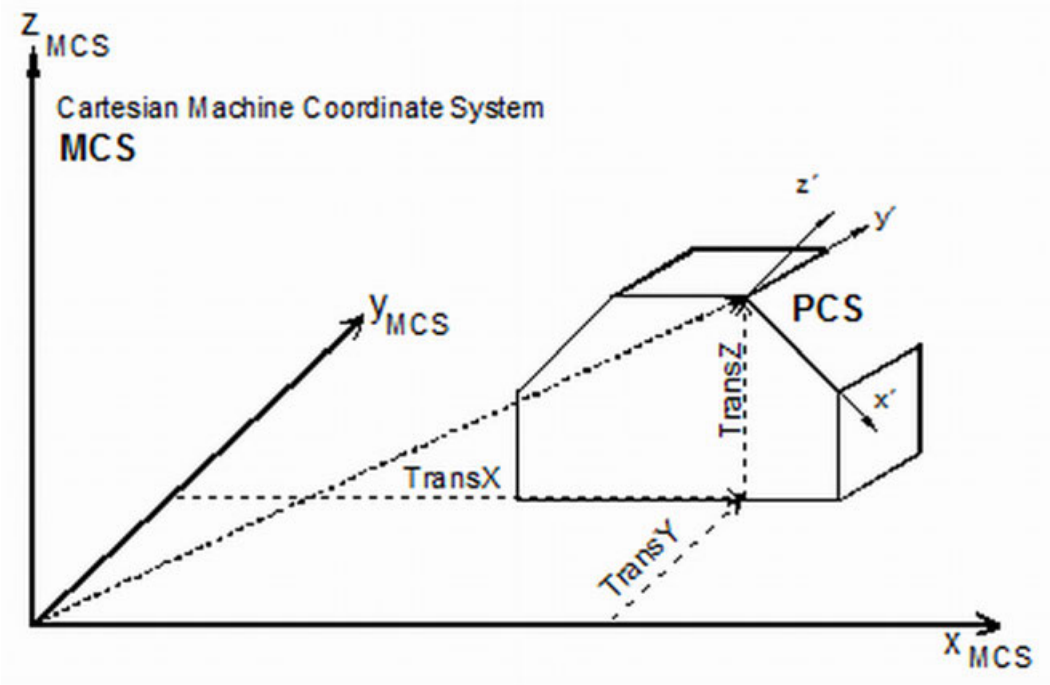

Fig. 542: Definition of the translation

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Example of the definition fo the rotation

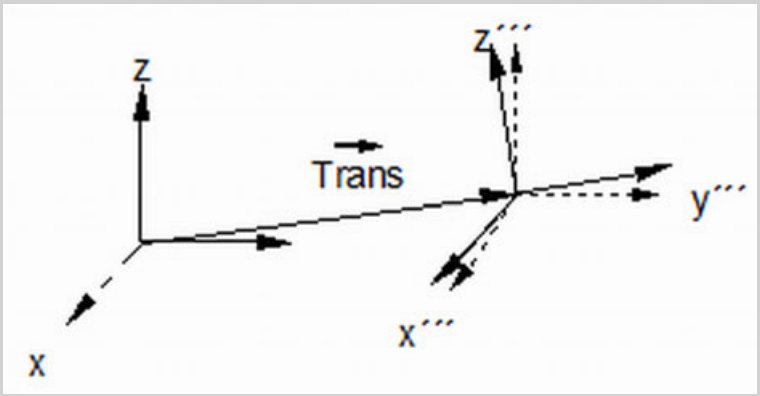

Fig. 543: The rotation is defined by a subsequent rotation around every coordinate direction beginning with the Z-direction.

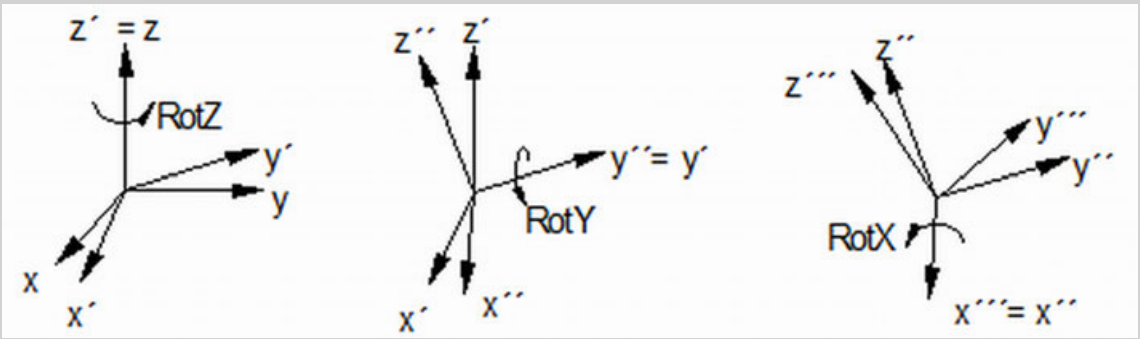

Fig. 544: Definition of the rotation

Input description

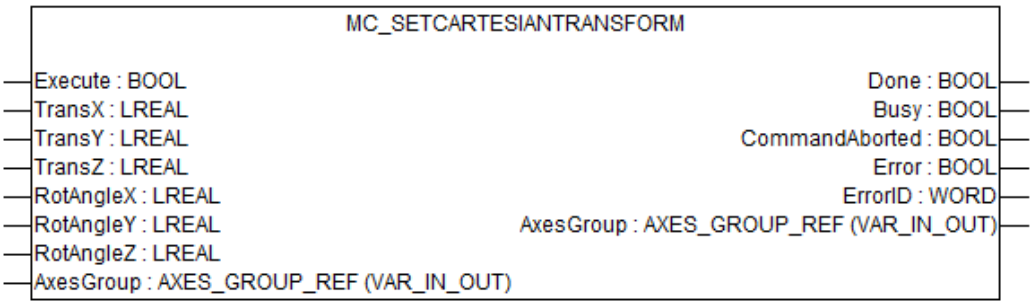

Fig. 545: Function block MC_SetCartesianTransform

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL
Starts the function block at rising edge.

TransX Data type: LREAL
X-component of Translation Vector.

TransY Data type: LREAL
Y-component of Translation Vector.

TransZ Data type: LREAL
Z-component of Translation Vector.

RotAngleX Data type: LREAL, unit: rad
Rotation angle in X-direction.

RotAngleY Data type: LREAL, unit: rad
Rotation angle in Y-direction.

RotAngleZ Data type: LREAL, unit: rad
Rotation angle in Z-direction.

AxesGroup Data type: AXES_GROUP_REF
Reference to a group of axes.

Output description

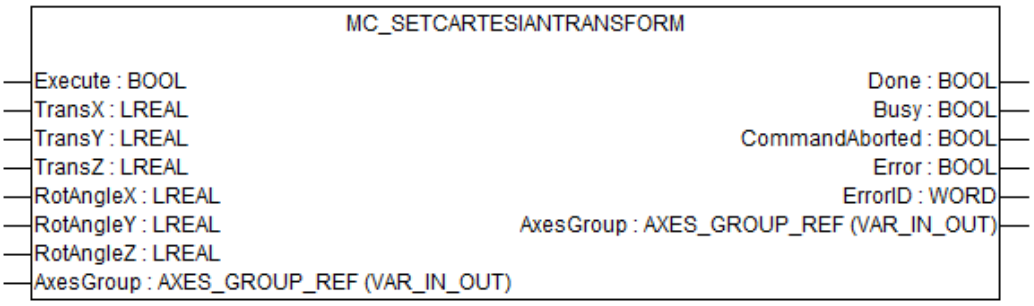

Fig. 546: Function block MC_SetCartesianTransform

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_SetCoordinateTransform MCS to PCS

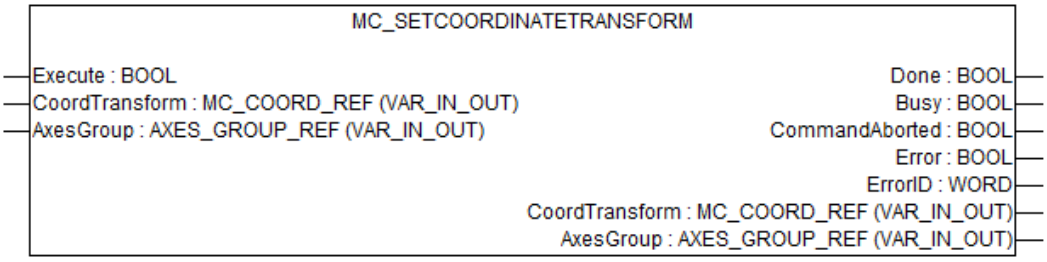

Fig. 547: MC_SetCoordinateTransform

This function block sets a coordinate transformation between the MCS and PCS.

- CoordTransform refers to a coordinate transformation including the parameters. The details of the transformation and of the parameters are outside the scope of PLCopen.
- The system may supports a neutral transformation. With activating the neutral transformation the axes are referenced in the MCS system again.
- The Transformation could as well be dynamic.
- This function block does not start a movement (administrative function block). The movement is initiated by a command in PCS.

The transformation will be activated on the next group movement, e.g. MC_MoveLinearAbsolute. When the block is activated, it first will be “Busy”. The Group will activate the transformation on the next movement, the block changes to “Done”. The transformation will be used until an other transformation is activated.

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

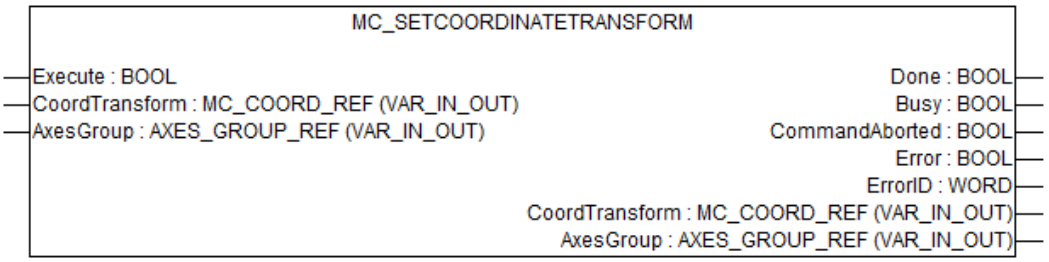

Fig. 548: MC_SetCoordinateTransform

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute Data type: BOOL

Starts the function block at rising edge.

CoordTransform Data type: MC_COORD_REF

Reference to a Coordinate Transformation. ABB specific datatype.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

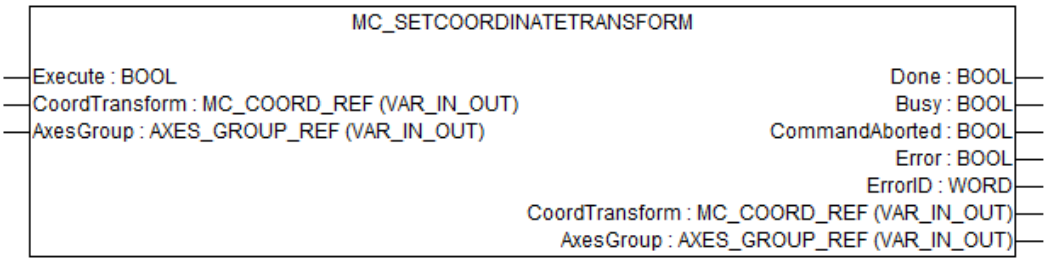

Fig. 549: MC_SetCoordinateTransform

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MC_ReadCartesianTransform MCS to PCS

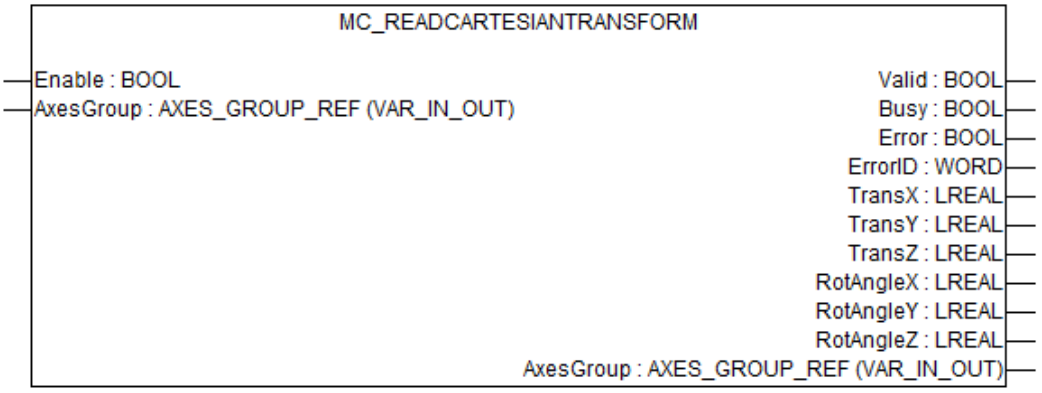

Fig. 550: Function block MC_ReadCartesianTransform

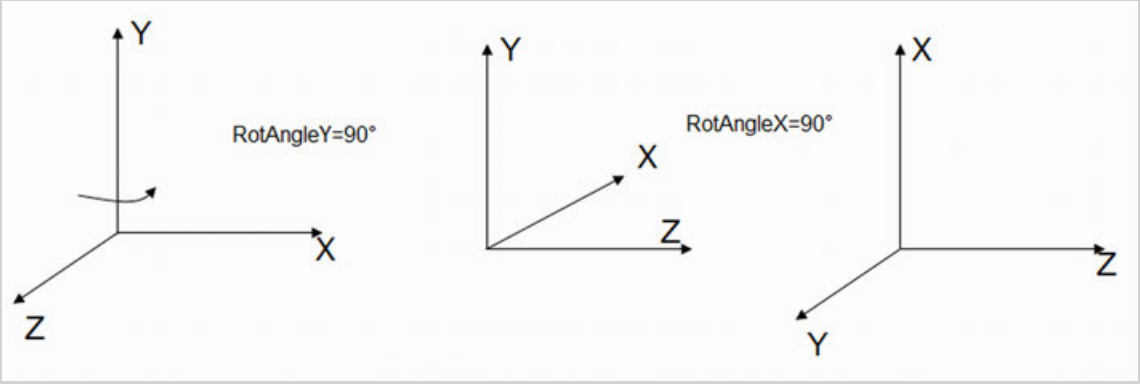
This function block reads the parameter of the cartesian transformation that is active between the MCS and PCS. .It combines the used matrix (MC_SetCoordinateTransform or MCA_SetCoordinateTransformation) and rotation angles (MCA_SetDynamicFollower or MC_SetCartesianTransform) to a rotation angles and translation vector result.

> *This result is just valid when an orthogonal matrix has been used. Any matrix with non-orthogonal vectors included could not be represented this way.*

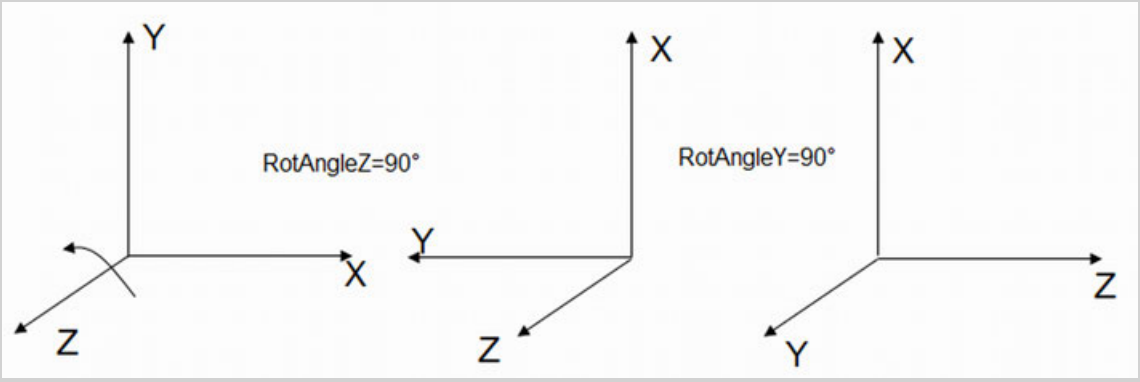
- When a dynamic transformation is activated, the function block will as well display the actual dynamic values.
- When different transformations are active, the function block will give the combined result.
- The function block will give the FORWARD (from MCS to PCS) transformation.
- Several rotations are possible to achieve the same result, so it might happen that the angles which are displayed do not match the given angel values at function block MCA_SetDynamicFollower. The possible rotation angles to achieve the same result are not unique.

Example: The following rotations achieve the same result:

	1.	2.
RotAngleX	0	90°
RotAngleY	90°	90°
RotAngleZ	90°	0



or



This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

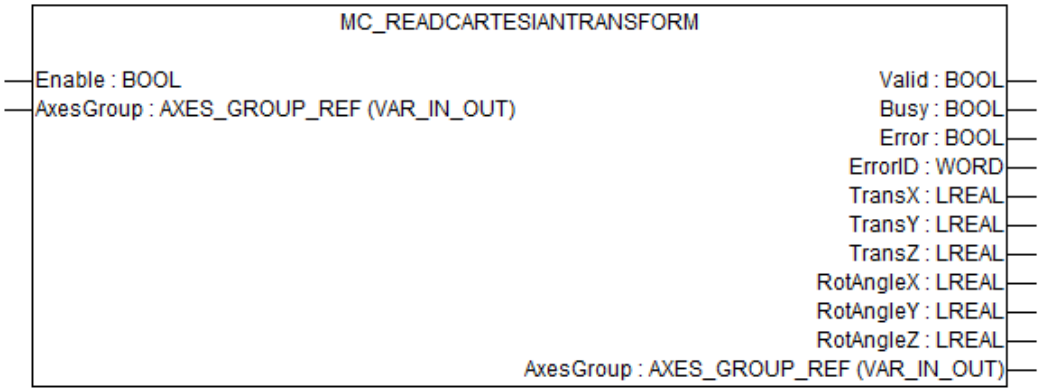


Fig. 551: Function block MC_ReadCartesianTransform

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Get the cartesian transformation parameter of the axes group continuously while enabled.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

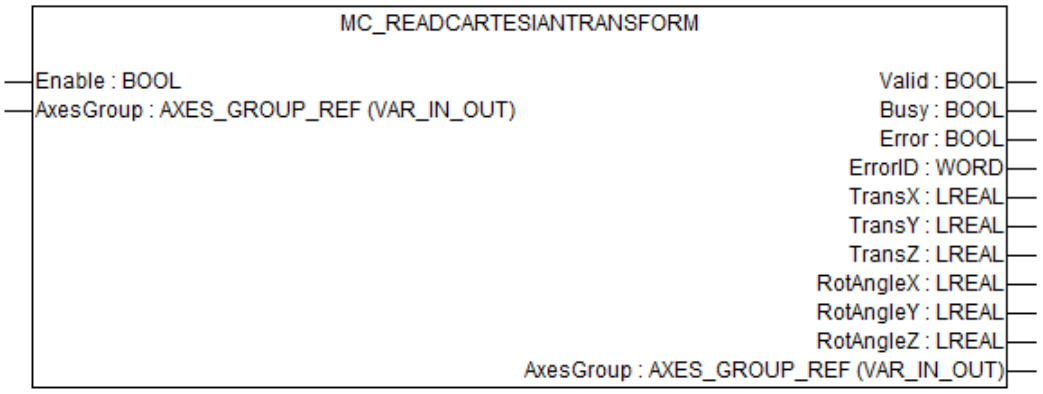

Fig. 552: Function block MC_ReadCartesianTransform

Valid Data type: BOOL

True if valid outputs are available.

Busy Data type: BOOL
The function block is not finished.

Error Data type: BOOL
Signals that an error has occurred within the function block.

ErrorID Data type: WORD
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

TransX Data type: LREAL
X-component of Translation Vector.

TransY Data type: LREAL
Y-component of Translation Vector.

TransZ Data type: LREAL
Z-component of Translation Vector.

RotAngleX Data type: LREAL, unit: rad
Rotation angle in X-direction.

RotAngleY Data type: LREAL, unit: rad
Rotation angle in Y-direction.

RotAngleZ Data type: LREAL, unit: rad
Rotation angle in Z-direction.

MC_ReadCoordinateTransform MCS to PCS

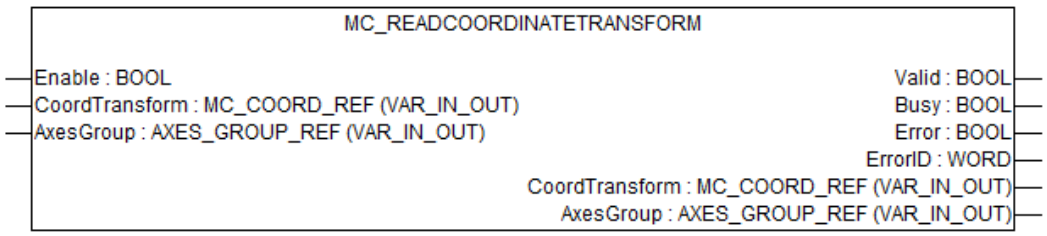

Fig. 553: Function block MC_ReadCoordinateTransform

This function block reads the coordinate transformation that is active between the MCS and PCS.

- When a dynamic transformation is activated, the function block will as well display the actual dynamic values.
- When different transformations are active, the function block will give the combined result.
- The function block will give the FORWARD (from MCS to PCS) and INVERSE (from PCS to MCS) transformation.

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

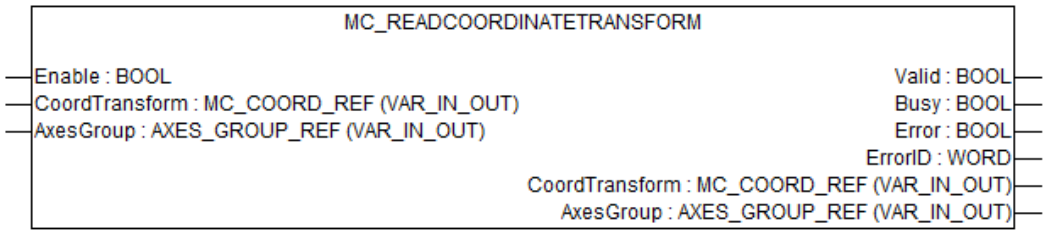

Fig. 554: Function block MC_ReadCoordinateTransform

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Get the actual coordinate transformation reference of the axes group continuously while enabled.

CoordTransform Data type: MC_COORD_REF

Reference to a Coordinate Transformation. ABB specific datatype.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

Valid Data type: BOOL

True if valid outputs are available.

Busy Data type: BOOL

The function block is not finished.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

1.5.9.7.3 ABB specific function blocks

The ABB specific function blocks follow the general rules defined by PLCopen and implement some additional features.

MCA_MoveHelixRelative

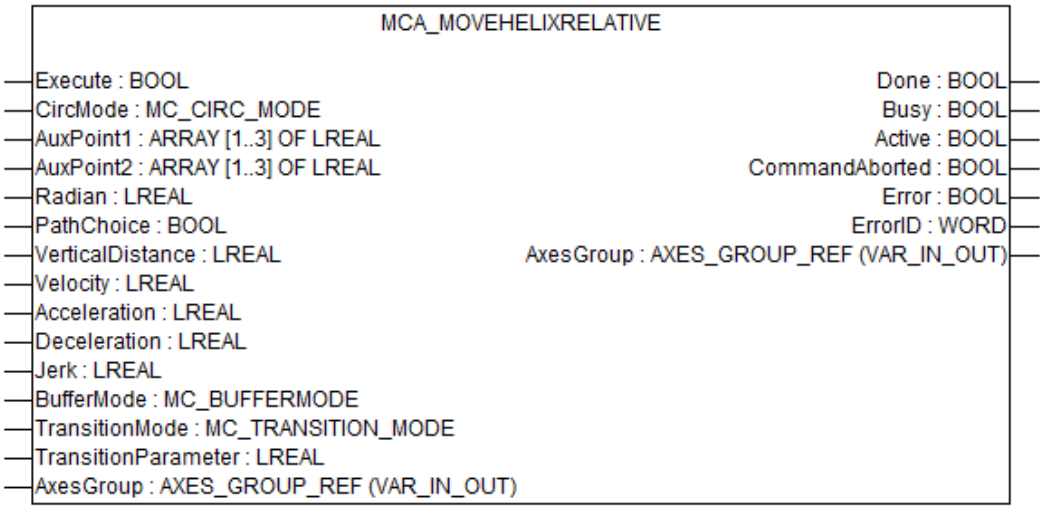

Fig. 555: Function block MCA_MoveHelixRelative

This function block commands an interpolated circular movement on an axes group from the actual position of the TCP. Two auxiliary points (meaning depending on applied mode, see below) are defined in the specified coordinate system relatively to the starting point. The 1. auxiliary point has a meaning accordingly to the CircMode input while the 2. auxiliary point just represents any point on the circle to define the plane, it does not define the end point.

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

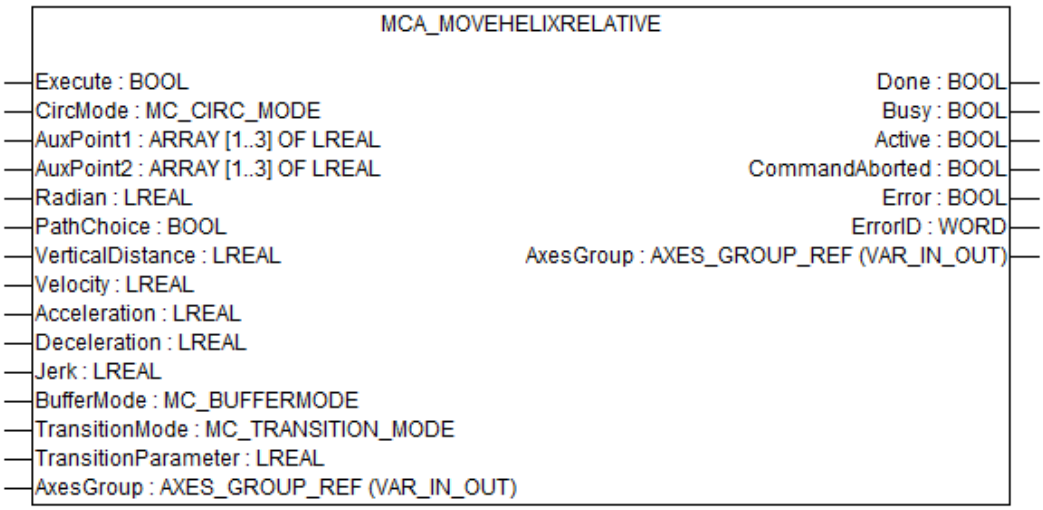

Fig. 556: Function block MCA_MoveHelixRelative

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Execute

Data type: BOOL

Starts the function block at rising edge.

CircMode

Data type: MC_CIRC_MODE

Specifies the meaning of the input signals 'AuxPoint' and 'CircDirection'.

- MC_BORDER:
  'AuxPoint' defines a point on the circle which is crossed on the path from the starting to the end point.
- MC_CENTER:
  'AuxPoint' defines the center point of the circle.
- MC_RADIUS:
  'AuxPoint' defines the spearhead point of the perpendicular of the circle plane according to the rule of right thumb. The radius of the circle is the length of the vector.

In the function block MC_MoveCircularAbsolute, the points are specified absolutely, i.e. the perpendicular vector begins in the origine and ends in the spearhead point specified at the input signal 'AuxPoint'.

AuxPoint1

Data type: ARRAY [1..3] OF LREAL

Array of positions for each dimension in the coordinate system specified by the input signal CoordSystem. These positions are defined relatively to the according positions of the starting point.

AuxPoint2 Data type: ARRAY [1..3] OF LREAL

Array of positions for each dimension in the coordinate system specified by the input signal CoordSystem. These positions are defined relatively to the according positions of the starting point.

Radian Data type: LREAL

The radian measure to be moved. This allows to move > 360° with a single block.

PathChoice Data type: BOOL

On mode MC_RADIUS, PathChoice=TRUE defines that Auxpoint2 is to be reached on the longer sector of the circle. In other modes, the input is ignored.

VerticalDistance Data type: LREAL

Distance to be move for the 3. direction. A basic circle is moved on a plane and with VerticalDistance <>0, an additional movement vertical to the plane is performed which combines to a helix.

Velocity Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Deceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the deceleration (decreasing energy of the motor).

Jerk Data type: LREAL, range: > 0, unit: u/s^3

Value of the Jerk.

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported

Defines the behavior of the axis.

TransitionMode Data type: MC_TRANSITION_MODE

The realization just supports by default a transition starting with the actual velocity.

TransitionParameter Data type: LREAL

Additional parameter for the transition mode.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

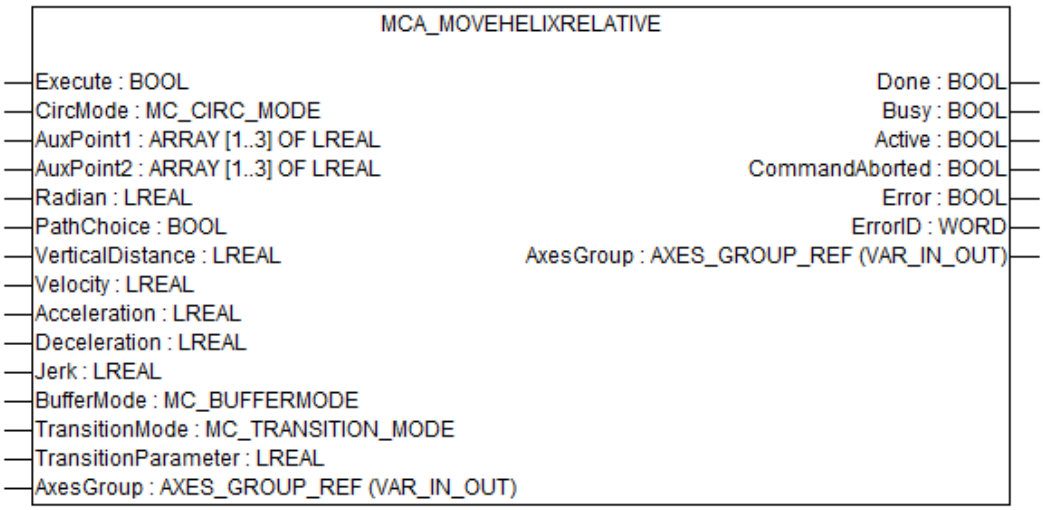

Fig. 557: Function block MCA_MoveHelixRelative

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

Auxpoint1 and Auxpoint2

The Auxpoint1 and Auxpoint2 define a plane at which the circle is to be moved. The positive direction is determined by the “right hand rule”. When the thumb points in direction of the perpendicular vector, the fingers show the positive direction.

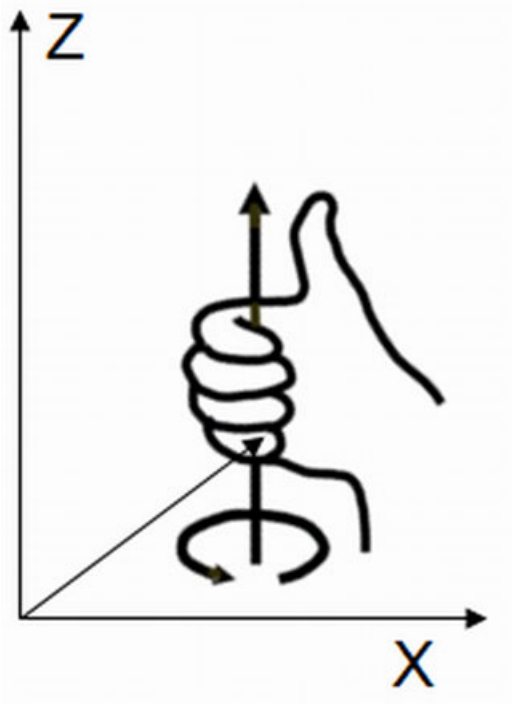

Fig. 558: Right hand rule

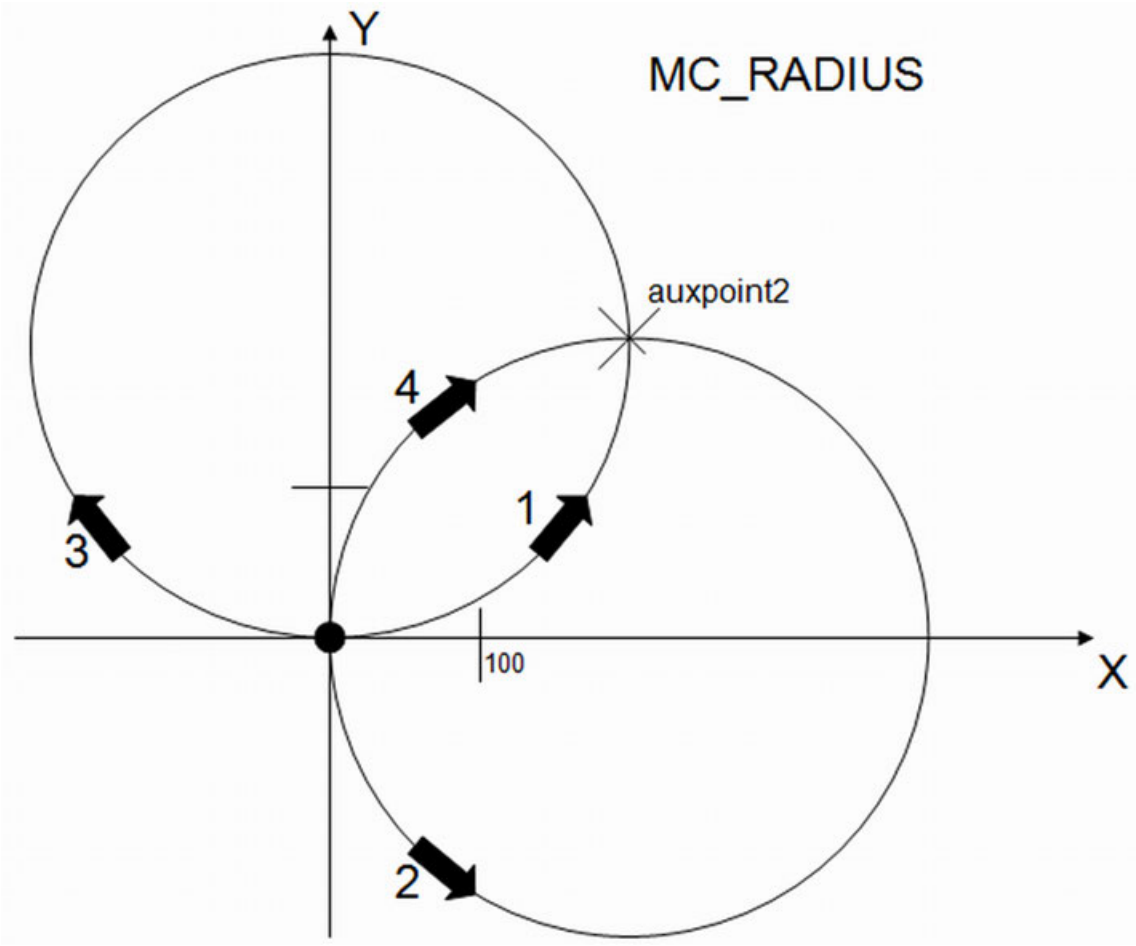
Examples for different input parameters with start at position 0/0/0

Circ-Mode=MC_RADIUS



With CircMode=MC_RADIUS, Auxpoint2 is a point at the circle and Auxpoint1 a vector which is perpendicular of the circle plane according to the rule of right thumb. The radius of the circle is the length of Auxpoint1. Two different cricles are possible.

- PathChoice = FALSE:: when moving in positive direction, the Auxpoint2 is reached on the short sector.
- PathChoice = TRUE: when moving in positive direction, Auxpoint2 is reached on the longer sector.

The direction is determined by the right thumb rule according to the perpendicular vector (Auxpoint1)

MC_RADIUS	PathChoice	Radian	Auxpoint1	Auxpoint2
1	FALSE	2 PI	0,0,200	200,200,0
2	TRUE	2 PI	0,0,200	200,200,0
3	FALSE	- 2 PI	0,0,200	200,200,0
4	TRUE	- 2 PI	0,0,200	200,200,0

Circ-Mode=MC_CENTER

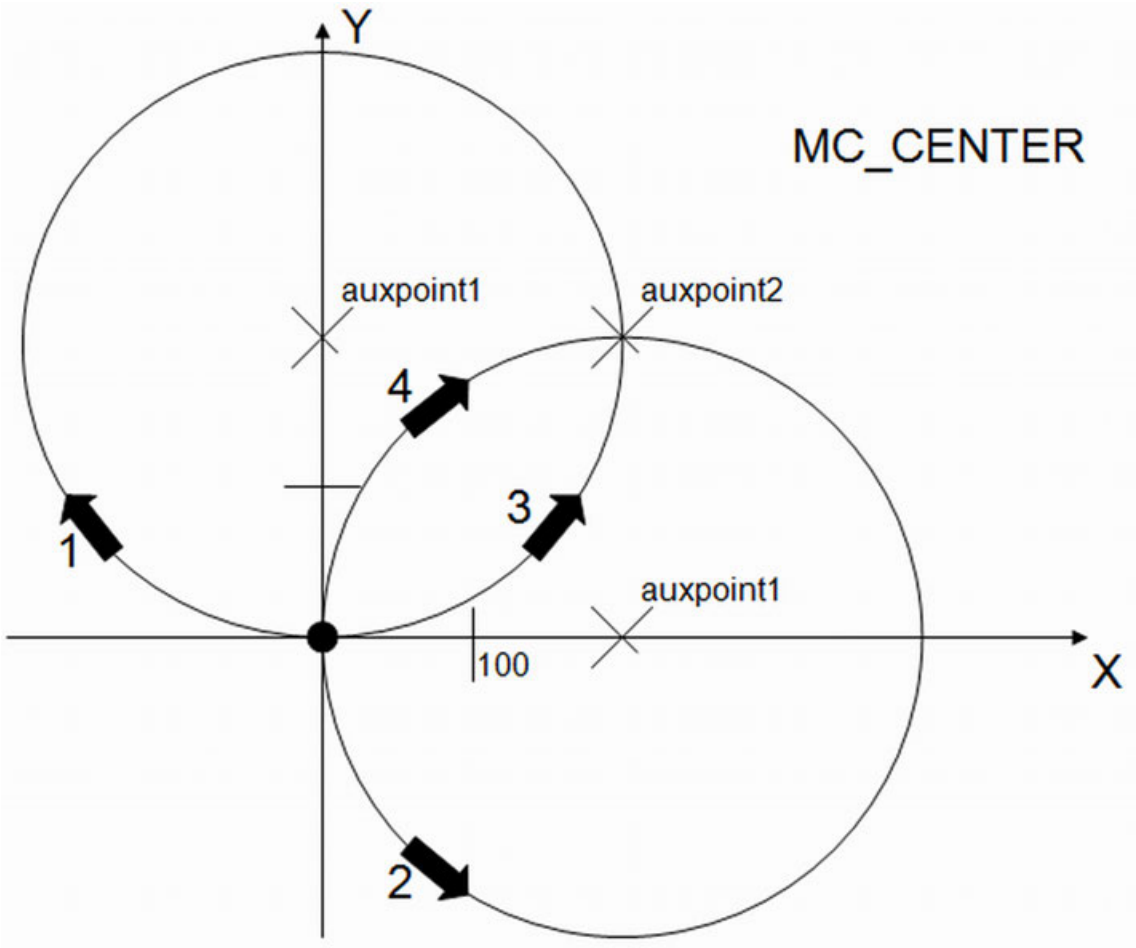


Fig. 559: CircMode=MC_CENTER

With CircMode=MC_CENTER, Auxpoint2 is a point at the circle and Auxpoint1 is the center point. Both are relative to the start point. The circle plane is defined by Auxpoint1 x Auxpoint2

MC_CENTER	PathChoice	Radian	Auxpoint1	Auxpoint2
1	-	2 PI	0,200,0	200,200,0
2	-	2 PI	200,0,0	200,200,0
3	-	- 2 PI	0,200,0	200,200,0
4	-	- 2 PI	200,0,0	200,200,0

Circ-Mode=MC_BORDER

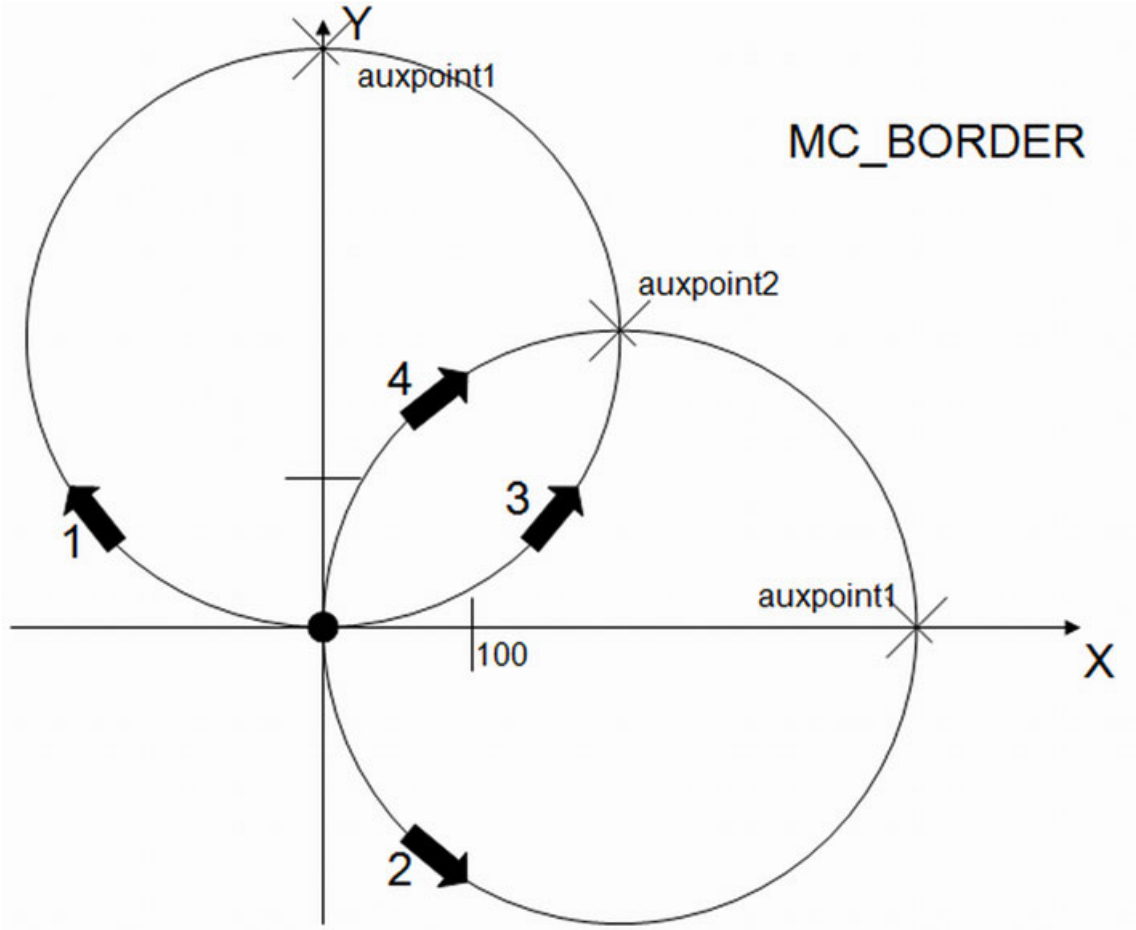

Fig. 560: CircMode=MC_BORDER

With CircMode=MC_BORDER, Auxpoint1 and Auxpoint2 are points at the circle. The circle plane is defined by Auxpoint1 x (Auxpoint1-Auxpoint2).

MC_BORDER	PathChoice	Radian	Auxpoint1	Auxpoint2
1	-	2 PI	0,400,0	200,200,0
2	-	2 PI	400,0,0	200,200,0
3	-	- 2 PI	0,400,0	200,200,0
4	-	- 2 PI	400,0,0	200,200,0

MCA_PathEvent

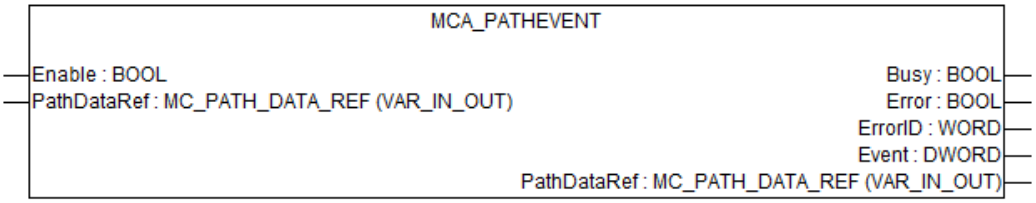

Fig. 561: Function block MCA_PathEvent

When moving the axes group on a path, it might be necessary to activate some digital event while certain positions are passed. To do so, the event is filled as a bit pattern the element EVENT in MC_PATH_POINT. *Chapter 1.5.9.4.9.2.10.2.2 “MC_PATH_POINT” on page 2704*

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

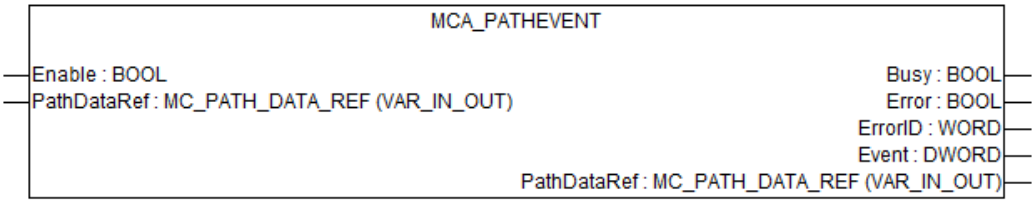

Fig. 562: Function block MCA_PathEvent

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

As long as Enable = TRUE, power is on.

PathDataRef Data type: MC_PATH_DATA_REF

Reference to the path data which can be prepared by MC_PathSelect.

Output description

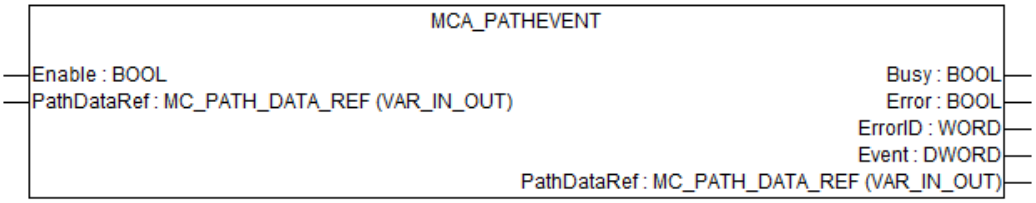

Fig. 563: Function block MCA_PathEvent

Busy Data type: BOOL

The function block is not finished.

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification ↳ *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

Event Data type: DWORD

Bit pattern which is specified at the actually crossed path section.

MCA_SetCoordinateTransformation

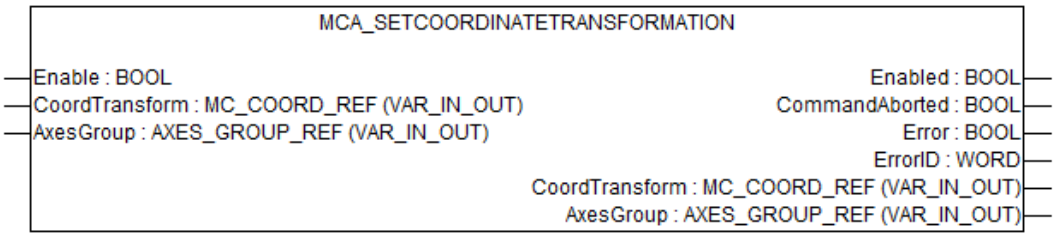

Fig. 564: Function block MCA_SetCoordinateTransformation

This function block is used to fulfill the functionality of MC_SetCoordinateTransformation by a different implementation. It will activate a PCS. The PCS system is active while Enabled=TRUE. All blocks related to the group movement or to a movement of an axis linked to the cartesian coordinate system (MCS axes of group) will then be executed using the PCS.

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

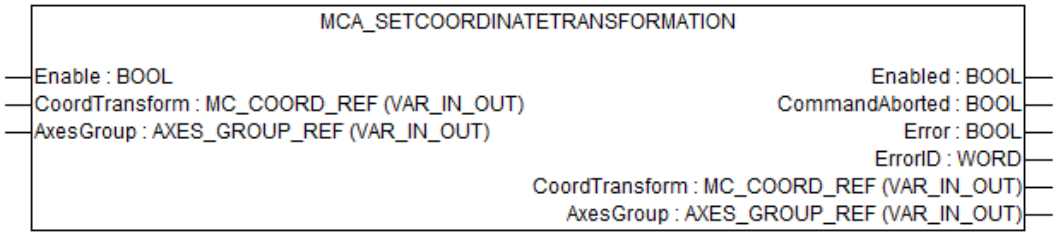

Fig. 565: Function block MCA_SetCoordinateTransformation

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

Enable Data type: BOOL

Activate the PCS.

CoordTransform Data type: MC_COORD_REF

Reference to a Coordinate Transformation. ABB specific datatype.

CoordTransform Data type: MC_COORD_REF

Holds a matrix which is used to perform a homogenous coordinate transform from PCS to MCS and a matrix to transform MCS to PCS.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

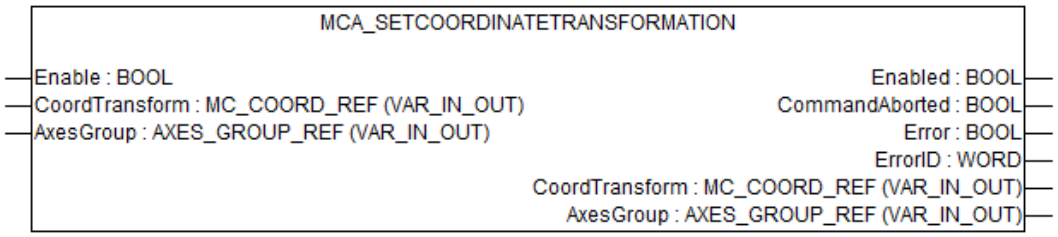

Fig. 566: Function block MCA_SetCoordinateTransformation

Enabled Data type: BOOL

The PCS is used.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_SetDynamicFollower

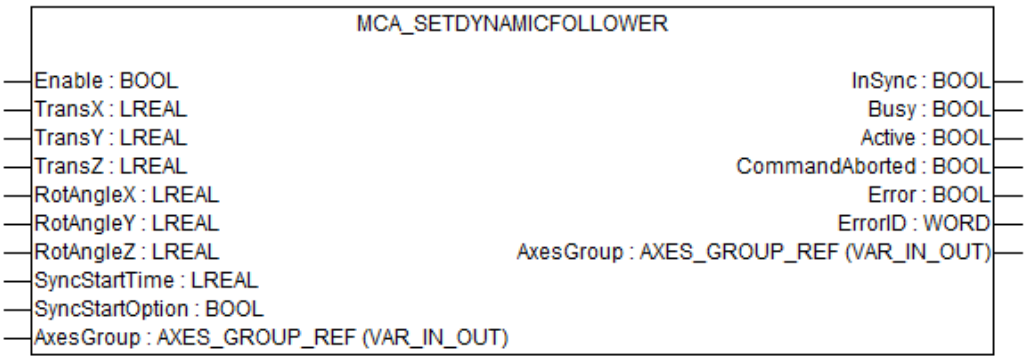

Fig. 567: Function block MCA_SetDynamicFollower

This function block activates a dynamic coordinate transformation and allows to follow a moving product. It replaces the functionality of MC_TrackConveyorBelt and MC_TrackRotaryTable.

▷ Activate a PCS first by MC_SetCoordianteTransform or MCA_SetCoordinateTransformation.

- The group is not allowed to be in any moving state when the block is activated.
- As soon as “Busy” is shown, it is allowed to start a movement.

When a synchronization to a moving coordinate system is performed, the function block allows to synchronize the group to this movement with a ramp. The two inputs SyncStartTime and SyncStartOption are available to configure the synchronization process.

A synchronization is performed with SyncStartTime > 0. The group will need SyncStartTime ms to do this. A polynomial movement is used and the result is superimposed to any other movement. The PCS position will stay constant during this process, just the ACS is moving. The process is ready when the function block shows INSYNC. A group movement can be started as soon as Busy = TRUE.

With Enable = FALSE, the function block is deactivated. This is always done without any ramp. When a ramp is needed, this has to be achieved by activating an other instance of this function block.

SyncStartTime	SyncStartOption	Behavior
0	-	The group will follow the PCS coordinate system without synchronization process.
> 0	FALSE	After the synchronization, the ACS and MCS positions will have the same values as if SyncStartTime = 0 would have been used.
> 0	TRUE	After the synchronization, the ACS and MCS positions will be shifted by the position distance which was needed to synchronize.

The function block performs first a rotation with the X/Y/Z-axis as axis of rotation and then a translation in X/Y/Z-direction. The result is a modified PCS coordinate system.

The transformation moves the coordinate system in parallel to the X/Y plane when no rotation using the X- or Y-axis is performed.

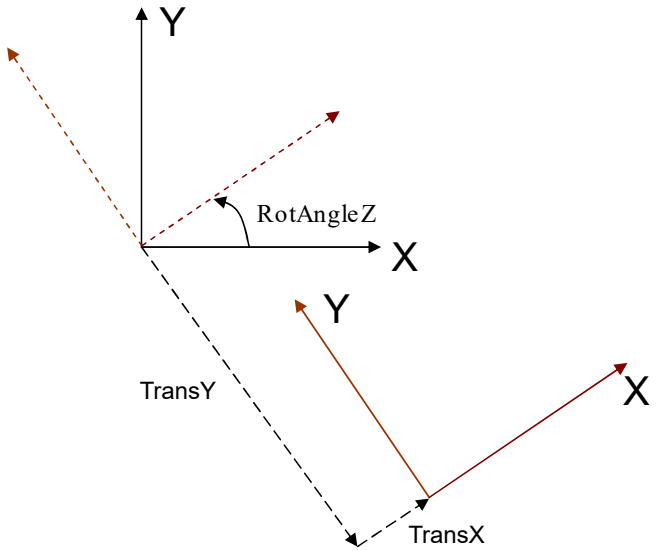

Fig. 568: MCA_SetDynamicFollower Rotation angle

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

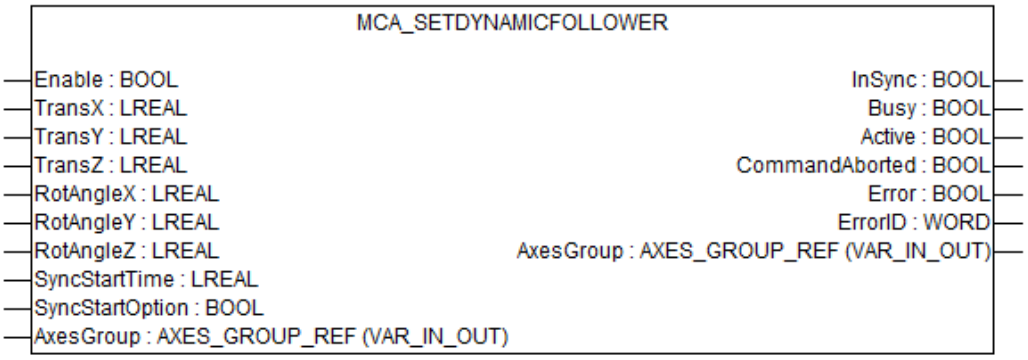

Fig. 569: Function block MCA_SetDynamicFollower

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

This block has to be called from the same task as CMC_MOTION_KERNEL_REAL.

Enable Data type: BOOL
Activate/deactivate the dynamic coordinate transformation.

TransX Data type: LREAL
Distance in X-direction.

TransY Data type: LREAL
Distance in Y-direction.

TransZ Data type: LREAL
Distance in Z-direction.

RotAngleX Data type: LREAL, unit: rad
Rotation angle in X-direction.

RotAngleY Data type: LREAL, unit: rad
Rotation angle in Y-direction.

RotAngleZ Data type: LREAL, unit: rad
Rotation angle in Z-direction.

SyncStartTime Data type: LREAL, unit: ms

A time used to synchronize to a moving transformation.

SyncStartOption Data type: BOOL

This option will result in a different synchronization profile. FALSE: Synchronize to the position where the function block was enabled, move opposite direction if necessary, this is a "CATCH UP" mode. TRUE: Allow a distance to synchronize. A later movement will nevertheless reach the same positions, just the synchronization process differs.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

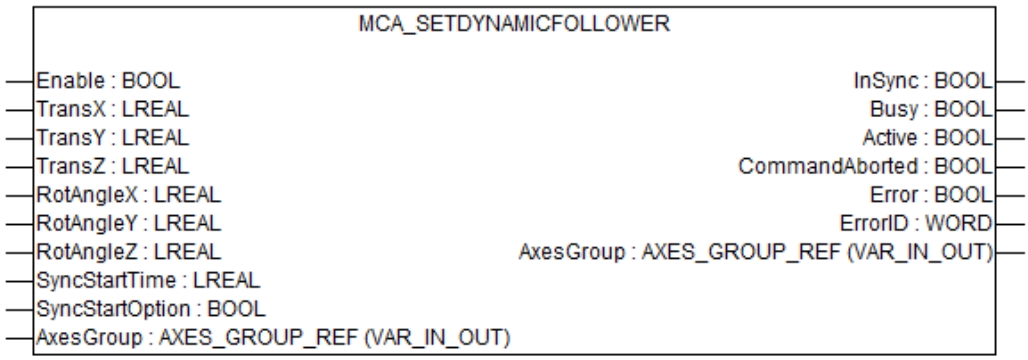

Fig. 570: Function block MCA_SetDynamicFollower

InSync Data type: BOOL

Dynamic coordinate transformation is active and synchronization ready.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandA-borted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_MovePathPos

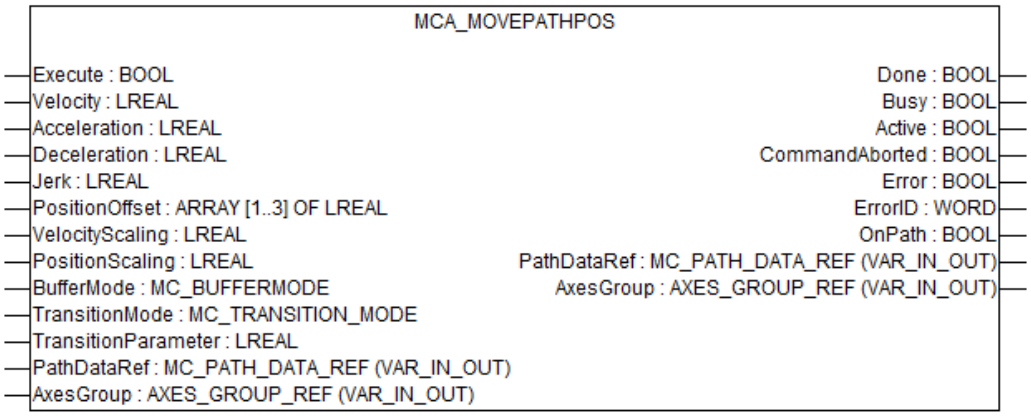

Fig. 571: Function block MCA_MovePathPos

This function block commands an AxesGroup to move according to the path specified in the PathData. The functionality is identical to MC_MovePath with the additional feature to move the group to the path start position first, using the given velocity, acceleration and deceleration.

This function block applies to the MCS or PCS System, depending which is activated and also follows the dynamic transformation when activated.

This function block is only supported for PLC-based central Motion Control with Coordinated Motion structures.

Input description

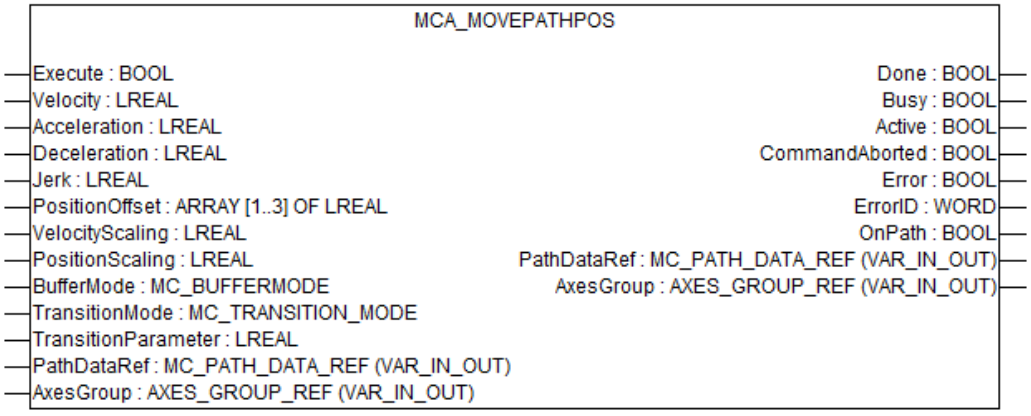

Fig. 572: Function block MCA_MovePathPos

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

Execute
Data type: BOOL
Starts the function block at rising edge.

Velocity
Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

Acceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

Deceleration
Data type: LREAL, range: > 0, unit: u/s^2
Value of the deceleration (decreasing energy of the motor).

Jerk
Data type: LREAL, range: > 0, unit: u/s^3
Value of the Jerk.

PositionOffset
Data type: ARRAY [1..3] OF LREAL
Allows to define an offset to the position in PathData. The movement starts at actual position and positionOffset. This position should be the same as the first Path Position.

VelocityScaling
Data type: LREAL, default: 1
Allows to increase or decrease the path velocity.

PositionScaling
Data type: LREAL, default: 1
Allows to scale the position values defined in PathData.

BufferMode
Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

TransitionMode
Data type: MC_TRANSITION_MODE
The realization just supports by default a transition starting with the actual velocity.

TransitionParameter
Data type: LREAL
Additional parameter for the transition mode.

PathDataRef
Data type: MC_PATH_DATA_REF
Reference to the path data which can be prepared by MC_PathSelect.

AxesGroup Data type: AXES_GROUP_REF

Reference to a group of axes.

Output description

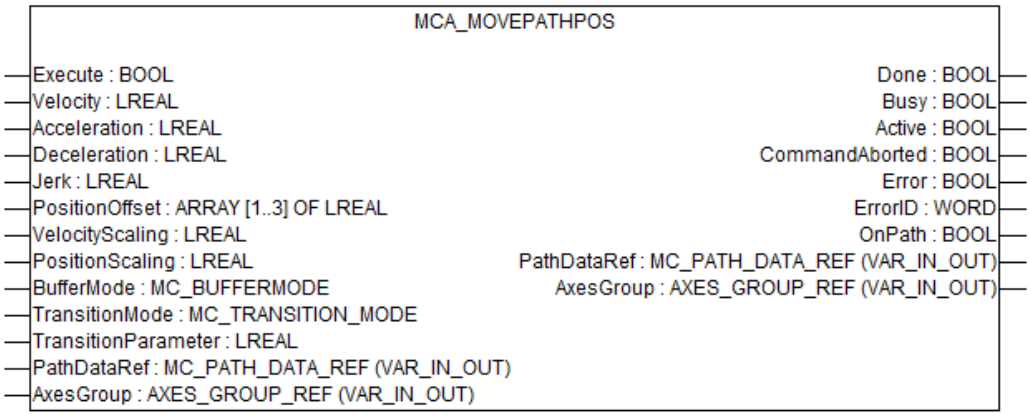

Fig. 573: Function block MCA_MovePathPos

Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

Error Data type: BOOL

Signals that an error has occurred within the function block.

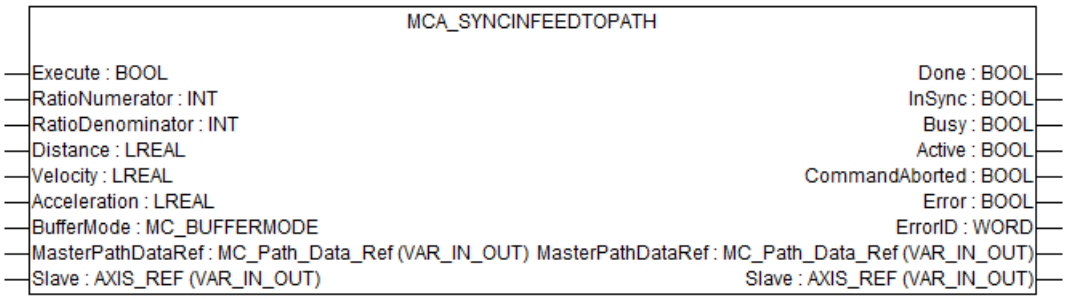
ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

OnPath Data type: BOOL

This output = TRUE when the function block starts to interpolate on the given path, so the prior positioning to the first path position is completed.

MCA_SyncInfeedToPath

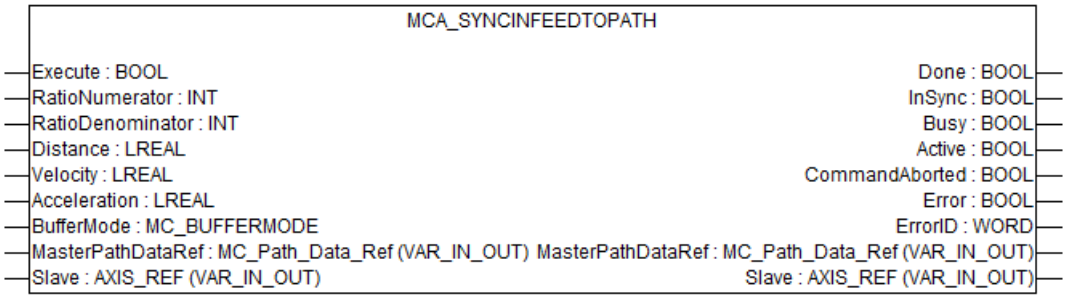


This function block maps a single axis to a group. The axis will follow a group in a path-movement.

It will either use the value given as Distance and move this distance while the groups moves the given path. When RatioNumerator and RatioDenumerator are both different from 0, the groups moving distance will be used instead and the axis be couple like GearIn to the group movement. The axis will then move the groups total distance, modified by the given ratio. The slave axis will always follow the master-group in a MCA_LINEAR mode, as a continuous master movement is expected. The slave movement is limited by the given velocity and acceleration.

> *This function block has to be called within the real-time task.*

Input description



Execute
Data type: BOOL
Starts the function block at rising edge.

RatioNumerator
Data type: INT
Gear Ratio Numerator.

RatioDenominator
Data type: INT
Gear Ratio Denominator.

Distance Data type: LREAL, unit: u
Relative distance for the motion.

Velocity Data type: LREAL, range: > 0, unit: u/s
Value of the maximum velocity (not necessarily reached).

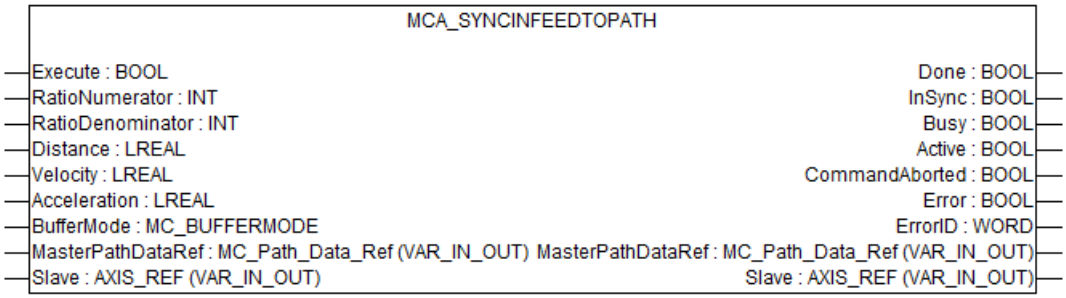
Acceleration Data type: LREAL, range: > 0, unit: u/s^2
Value of the acceleration (increasing energy of the motor).

BufferMode Data type: MC_BUFFERMODE, default: MC_Aborting, no other modes supported
Defines the behavior of the axis.

MasterPathDataRef Data type: MC_Path_Data_Ref
Reference to the path data which can be prepared by MC_PathSelect.

Slave Data type: AXIS_REF
Reference to the slave axis.

Output description



InSync Data type: BOOL
Dynamic coordinate transformation is active and synchronization ready.

Busy Data type: BOOL
The function block is not finished.

Active Data type: BOOL
Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL
Command is aborted by another command (PLCopen function block).

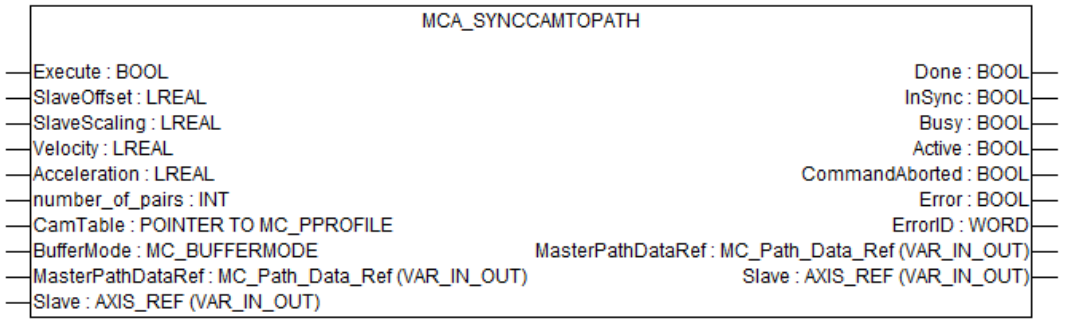
Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

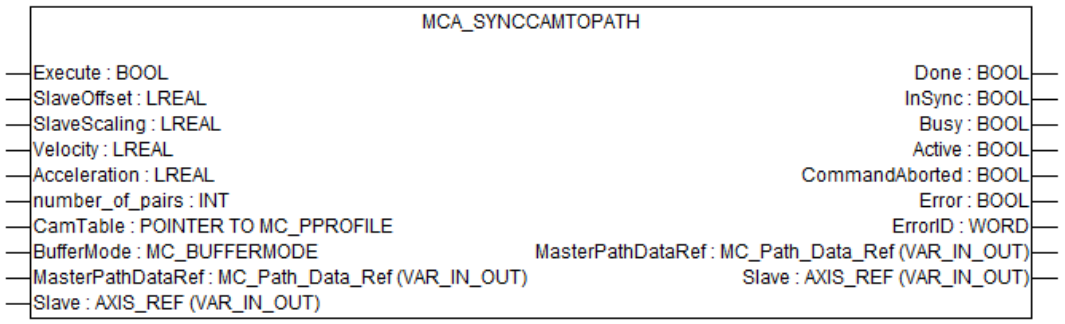
MCA_SyncCamToPath



This function block maps a single axis to a group. The axis is coupled with an own path to the group path. It will follow the group movement from point-to-point with respect to it´s own paths definition. The slave axis will always follow the master in a MCA_LINEAR mode, as a continuous movement is expected. The slave movement is limited by the given velocity and acceleration.

This function block has to be called within the real-time task.

Input description



Execute Data type: BOOL

Starts the function block at rising edge.

SlaveOffset Data type: LREAL, default: 0

Offset of slave table. Sharpened cam (i.e higher elevation and deeper depression).

SlaveScaling Data type: LREAL, default: 1.0

Factor for the slave profile. The overall slave profile is multiplied by this factor.

Velocity Data type: LREAL, range: > 0, unit: u/s

Value of the maximum velocity (not necessarily reached).

Acceleration Data type: LREAL, range: > 0, unit: u/s^2

Value of the acceleration (increasing energy of the motor).

Number_of_pairs Data type: INT

Number of points used in CamTableTimeAcceleration array.

CamTable Data type: POINTER TO MC_PPROFILE

Reference to CAM description.

BufferMode Data type: MC_BUFFERMODE, range: MC_Aborting, MC_Buffered, MC_Blending, default: MC_Aborting

Defines the behavior of the axis.

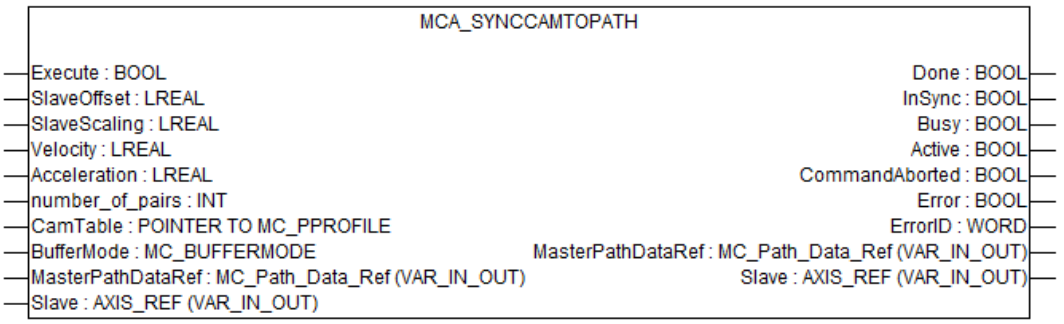
MasterPathDataRef Data type: MC_Path_Data_Ref

Reference to the path data which can be prepared by MC_PathSelect.

Slave Data type: AXIS_REF

Reference to the slave axis.

Output description



InSync Data type: BOOL

Dynamic coordinate transformation is active and synchronization ready.

Busy Data type: BOOL

The function block is not finished.

Active Data type: BOOL

Indicates that the function block has control on the axis.

CommandAborted Data type: BOOL

Command is aborted by another command (PLCopen function block).

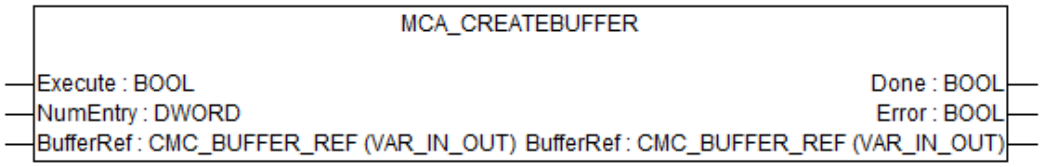
Error Data type: BOOL

Signals that an error has occurred within the function block.

ErrorID Data type: WORD

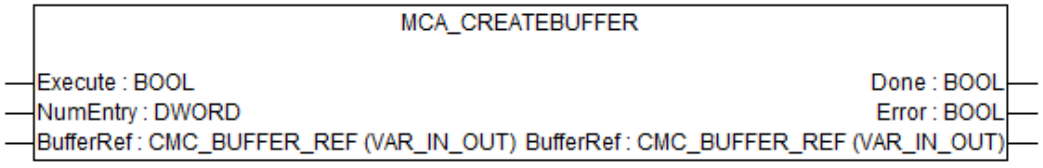
Error identification *Chapter 1.5.9.3.4 “Error codes” on page 2593*.

MCA_CreateBuffer



A movement with move buffers which can be modified on the fly, and which are executed in a FIFO mode, is possible for coordinated motion with the two function blocks: MCA_CreateBuffer and MCA_MoveBuffered *Chapter 1.5.9.7.3.9 “MCA_MoveBuffered” on page 3030*. The function block MCA_CreateBuffer is used to create a buffer with NumEntry placeholders to store the different movements. The function block will fill the variable BufferRef. This variable can be used with function block MCA_MoveBuffered. The buffers will be used as a ring, in a FIFO way, so any number of movements can be executed, just NumEntry to be stored in advance. The number of entries can be changed on a rising edge. This should not be done while the buffer is in use, as the function block will delete the contents and create a new, empty buffer.

Input description



Execute Data type: BOOL

Starts the function block at rising edge.

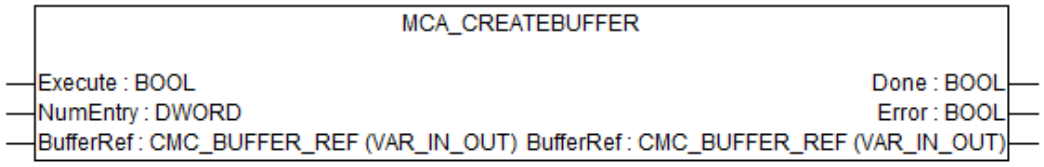
NumEntry Data type: DWORD

BufferRef

BufferRef Data type: CMC_BUFFER_REF

Container for move buffers

Output description



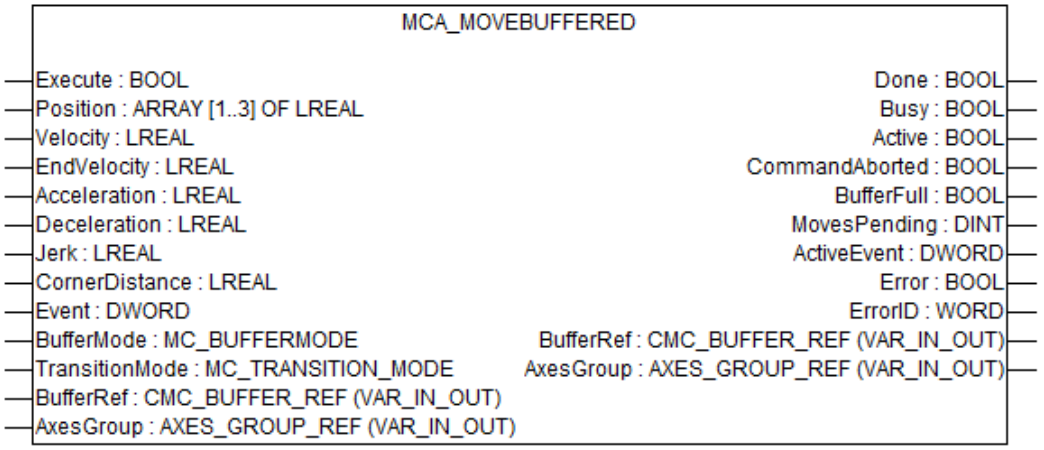
Done Data type: BOOL

Shows the status of the function block. Done = TRUE if the execution is finished.

Error Data type: BOOL

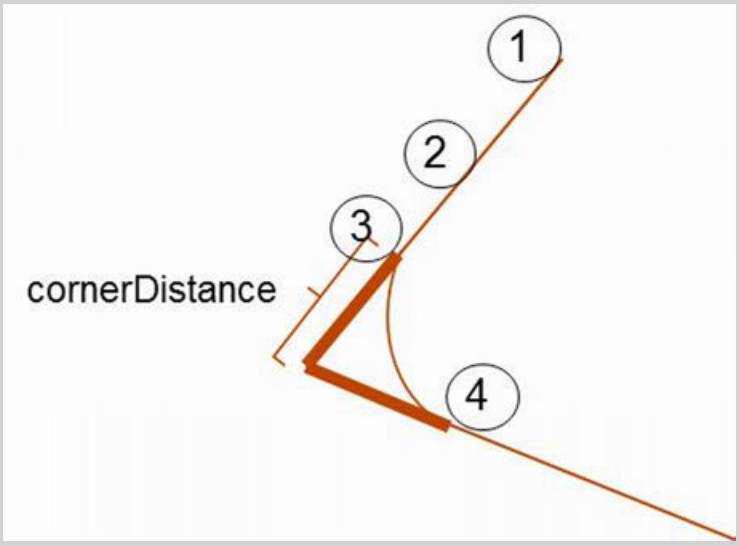
Signals that an error has occurred within the function block.

MCA_MoveBuffered



The function block triggers an absolute, linear movement at a rising edge of input Execute. The first movement will be started directly. Any following rising edge on input Execute will store the given movement to input BufferRef. The output MovesPending will indicate how many entries in BufferRef are occupied and wait for execution. They will be executed automatically and movements will be blended. The behavior of blending can be modified by the inputs EndVelocity, CornerDistance, BufferMode, TransitionMode.

Example



The movement will start at position (1) with velocity = 0. Different behavior will be reached depending on the value for EndVelocity. The velocity which is reached at position (4) depends on the chosen BufferMode. The velocity curve is also modified by the TransitionMode.

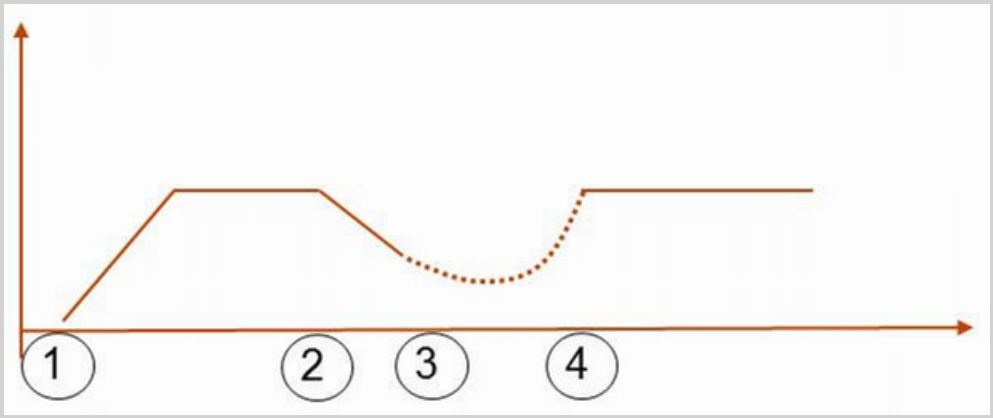
Legend for all examples: s = distance to move, v = velocity, a = deceleration

Behavior of blending modified by EndVelocity

With input EndVelocity = 0, the movement will be planned in a way that it could stop at the corner (position). So the blending might be executed in a lower velocity.

With input EndVelocity > 0, the movement will be executed in a way that at the corner EndVelocity would be reached. An EndVelocity > 0 should not be used for the last intended movement as this will mean that no deceleration ramp is planned.

Example



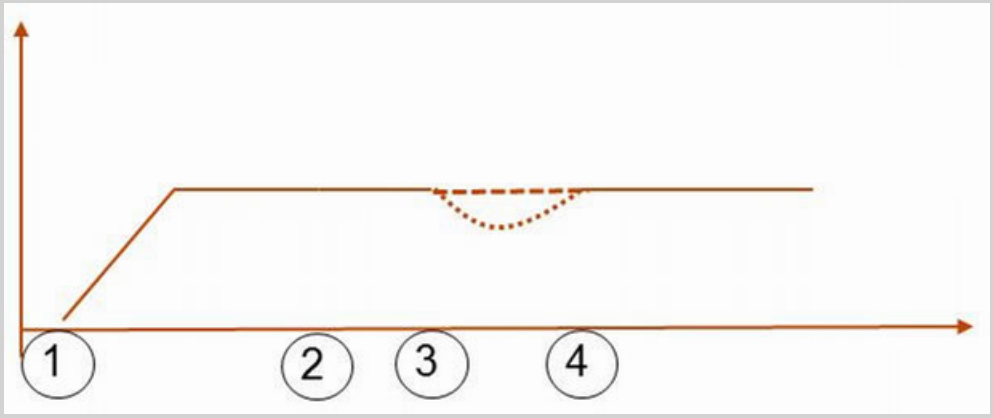
With EndVelocity = 0, depending on the value for Deceleration, it might be necessary to start a brake ramp at a certain position (2). The ramp is calculated in a way that a stop would be reached at the corner:

s = 0.5*v*v/a

s < input CornerDistance: No deceleration ramp.

s > input CornerDistance: Decelerate from a distance s from the corner, a smaller velocity is reached at position 3.

At CornerDistance, position (3), the blending to the next movement is executed.



With EndVelocity = Velocity, the movement will continue at constant speed. When CornerDistance is reached, the blending to the next movement is executed.

Behavior of blending modified by CornerDistance

With CornerDistance D = 0, the movement will stop at the given position and then continue with the next movement. This requires EndVelocity = 0.

With CornerDistance D > 0: If the distance between two positions is < 2*CornerDistance, half position distance is used instead as CornerDistance. At a distance CornerDistance from the target position of a given movement, the direction is changed towards the next position. It is assumed that the velocity for the next movement can be reached within the CornerDistance D.

Behavior of blending modified by BufferMode

The input BufferMode will determine which velocity will be reached at the end of the corner, when the next movement is running. It can be either the actual velocity at position (3) or the commanded velocity for the next movement.

Option	Description
mcBlendingLow	Default. The smaller velocity is used.
mcBlendingHigh	The higher velocity is used.

Option	Description
mcBlendingPrevious	The current velocity at positioin (3) is used.
mcBlendingNext	The commanded velocity for the next movement is used.

Behavior of blending modified by TransitionMode

At input TransitionMode you can choose TMConstantVelocity or other values.

With TransitionMode = TMConstantVelocity, the velocity will be kept constant if for position (3) and (4) an identical value is commanded. In case of two different values, a linear transition is performed. The position movement will be circular.

With TransitionMode = NOT TMConstantVelocity: Depending on the angle between the two movements, the velocity will decelerate. A smaller angle will mean a slower movement at the corner.

Angle	Velocity corner
0°	0
60°	0.5*v
90°	0.67*v
135°	0.87*v
180°	1*v = a straight line

Example 1

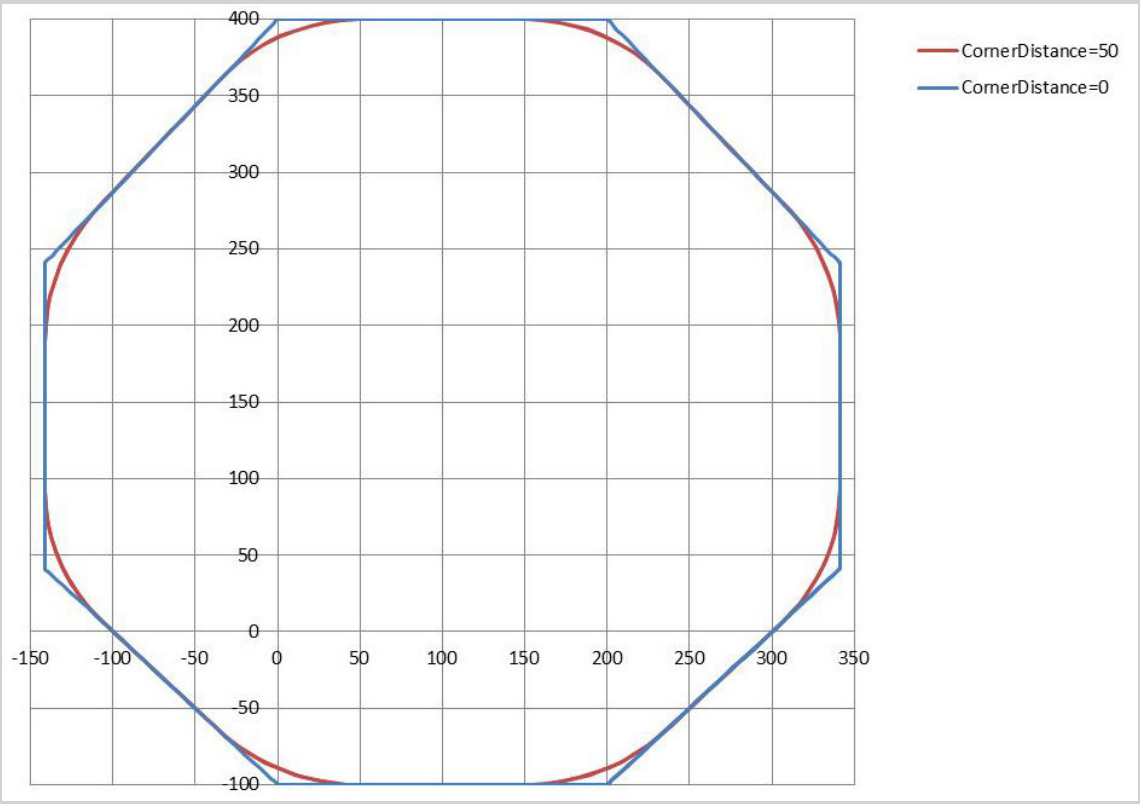


Fig. 574: Movement in X/Y coordinates modified with CornerDistance.

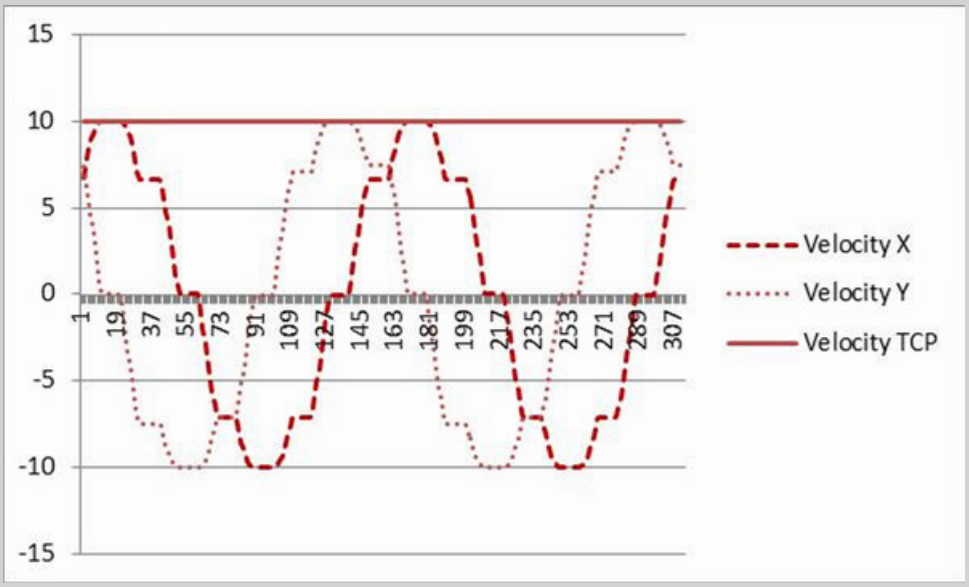

Fig. 575: Resulting velocity curves when CornerDistance = 50, TransitionMode = TMConstantVelocity and EndVelocity = Velocity. In this case, BufferMode does not make a difference as the velocity values are identical.

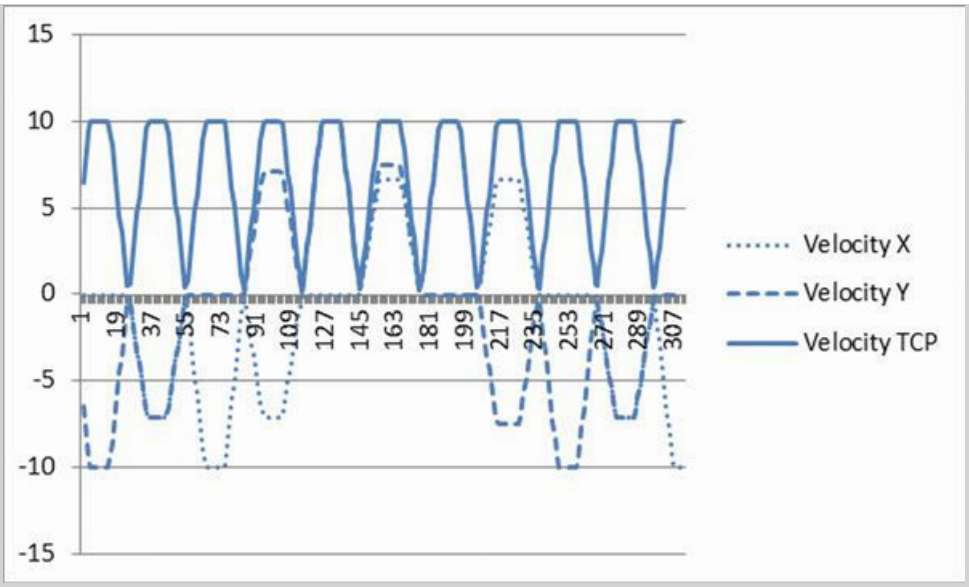

Fig. 576: Resulting velocity curves when CornerDistance = 0 and EndVelocity = 0. In this case, BufferMode and TransitionMode do not make a difference.

Example 2

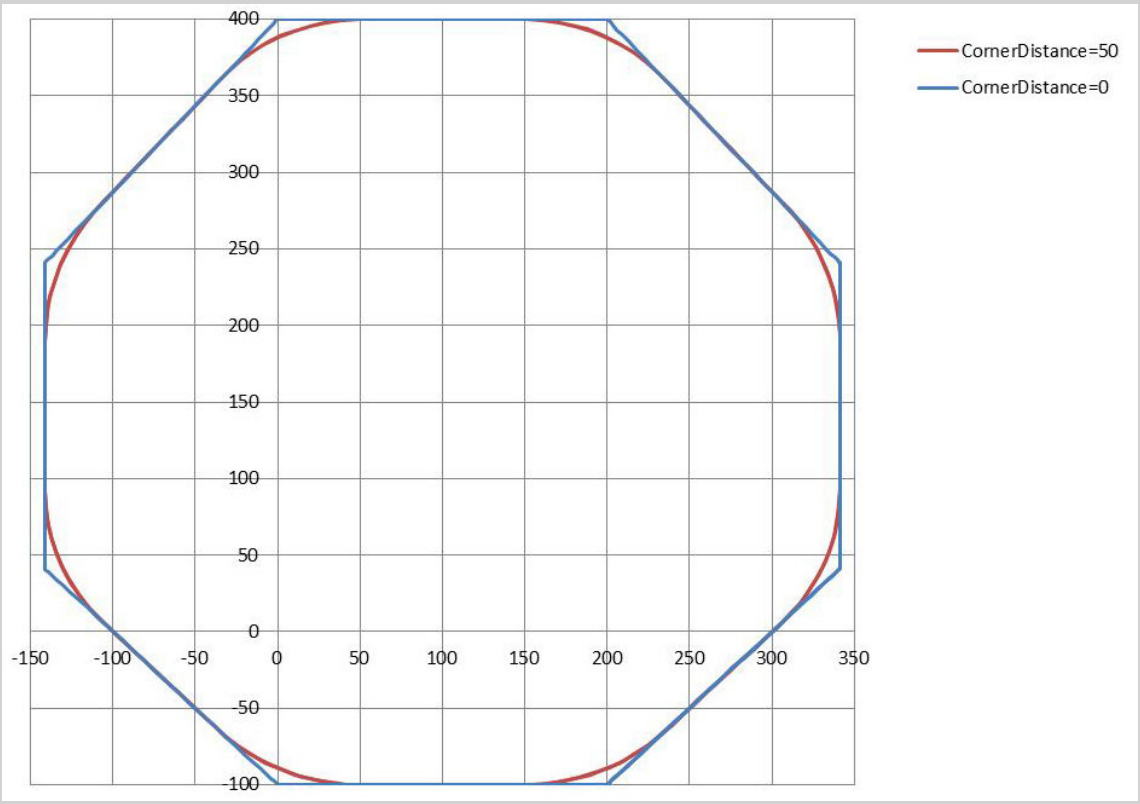

Fig. 577: Movement in X/Y coordinates modified with CornerDistance.

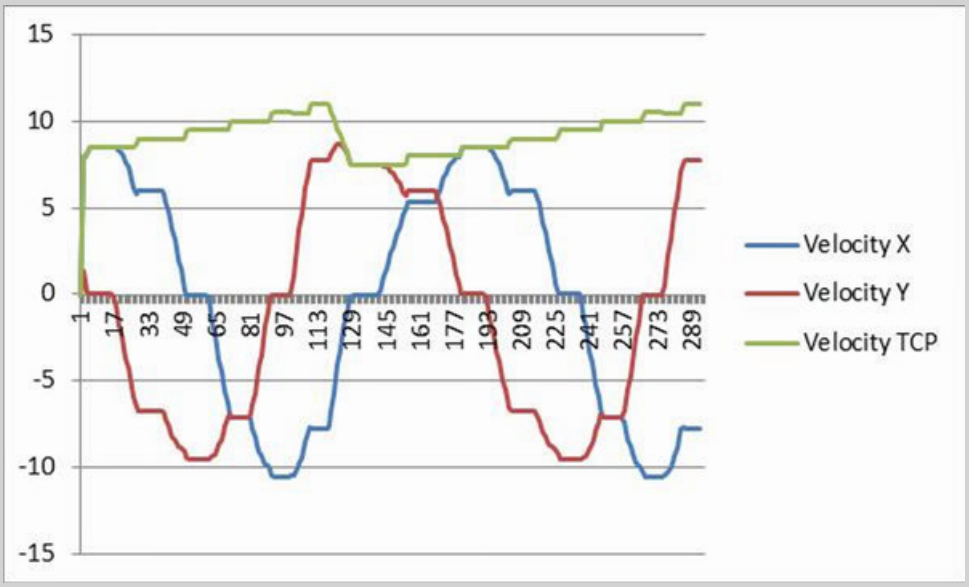

Fig. 578: Resulting velocity curves with different velocity values for each segment. BufferMode = MCBlendingLow and TransitionMode = TMConstantVelocity.

BufferMode	Transition-Mode	EndVelocity	CornerDis-tance	Behavior
x	x	0	0	Stop at the corner, use deceleration.
x	x	> 0	0	Reach EndVelocity at the corner, switch direction without ramp.

BufferMode	Transition-Mode	EndVelocity	CornerDis-tance	Behavior
!	TMConstant-Velocity	=Velocity	> 0	Move at commanded velocity until CornerDistance is reached, decide next velocity depending on BufferMode, perform any velocity transition during the corner (if different velocity are commanded).
!	NOT TMCon-stantVelocity	= Velocity	> 0	As above, but movement during the corner will be slower.
!	!	> 0	> 0	Plan the movement to reach EndVelocity at the corner, use the BufferMode and Tran-sitionMode parameter when CornerDistance is.

1.5.9.8 Glossary

ACS Axes Coordinate System: The system of coordinates related to the physical motors and the single movements caused by the single drives.

Blending A way that consecutive function blocks cooperate in the transition from the first to the next.

Contour curve Inserted curve that modifies the original path. It is the resulting curve after blending.

Coordinate system The reference system in which a coordinate or path is described.

Corner deviation The shortest distance between the programmed corner point and the contour curve.

Corner distance Distance of the start point of the contour curve to the programmed target point.

Direction The orientational components of a vector in space. (Note: this is different from the MC_Direction input as used in part 1).

Drive A unit controlling a motor via the current and timing in its coils.

Group-FB The set of function blocks that can work on a group of axes.

MCS Machine Coordinate System: The system of coordinates that is related to the machine. A Cartesian coordinate system with the origin in a fixed position relative to the machine (the origin is defined during the machine setup).

Sometimes called "World Coordinate System" or "Base Coordinate System".

(Note: with Cartesian build machines, MCS is a Cartesian Coordinate system and may be identical to ACS, or mapped via a trivial transformation). The coordinate system from the physical multiple axes ACS is linked to the MCS via a kinematic transformation (forward and backward conversion). The MCS represents an imaginable space with up to 6 dimensions.

Motor	An actuator focused to a movement, converting electrical energy in a force or torque.
Orientation	The rotational components of a vector in space.
Path	Set of continuous positions and orientation information in multi-dimensional space. Geometrical description of a space curve that the TCP of an axesgroup moves along.
PathData	Description of a path which can include additional information like velocity and acceleration.
PCS	The coordinate system of the product can be called PCS: Product Coordinate System (or "Program Coordinate System" in CNC world, or Programmers Coordinate System). The PCS is based on the MCS typically by shifting and maybe rotating the MCS. The Zero point of the PCS is related to the product and can be changed during run time by the program. The real work piece can have a rotation or shift to the MCS (machine coordinate system) or even might be moving relative to the MCS (machine coordinate system). By specifying a trajectory in PCS one is able to describe the trajectory independent from the machine situation. To map these two worlds (MCS to PCS and vice versa), a cartesian or cylindrical transformation is normally done.
Position	Apoint in space which is described by different coordinates. Depending on the used system and transformation it can consist of up to 6 dimensions (coordinates) meaning 3 Cartesian coordinates in space and 3 coordinates for the orientation. In ACS there can be even more than 6 coordinates. If the same position is described in different coordinate systems the values of the coordinates are different.
Pose (not used)	Position and orientation (DIN EN ISO 8373). Position is used instead in this document.
Scara	A special kinematic for robot or handling applications.
Speed	The absolute value of the velocity without direction.
Synchronization	Combines an axis or axes group (as slave) with an axis as master in order that the slave executes its path with synchronization to the progress of the master, meaning linked to a one-dimension source for synchronization.
TCP	Tool Centre point, the point in the machine that is commanded to move, typically the center or the head of the tool. It can be described in different coordinate systems.
Tracking	Is characterized by an axis group that follows with its movement the movement of another axis group.
Trajectory	Time dependent description of the path the TCP of an axes group moves along. Additionally to the geometrical description of the space curve, time dependent state variables like velocity, acceleration, jerk, forces etc. are specified.
Velocity	In ACS: For a group of axes this means the velocities of the different axes.

Iin MCS and PCS: It provides the velocity of the TCP.

1.5.9.9 Examples

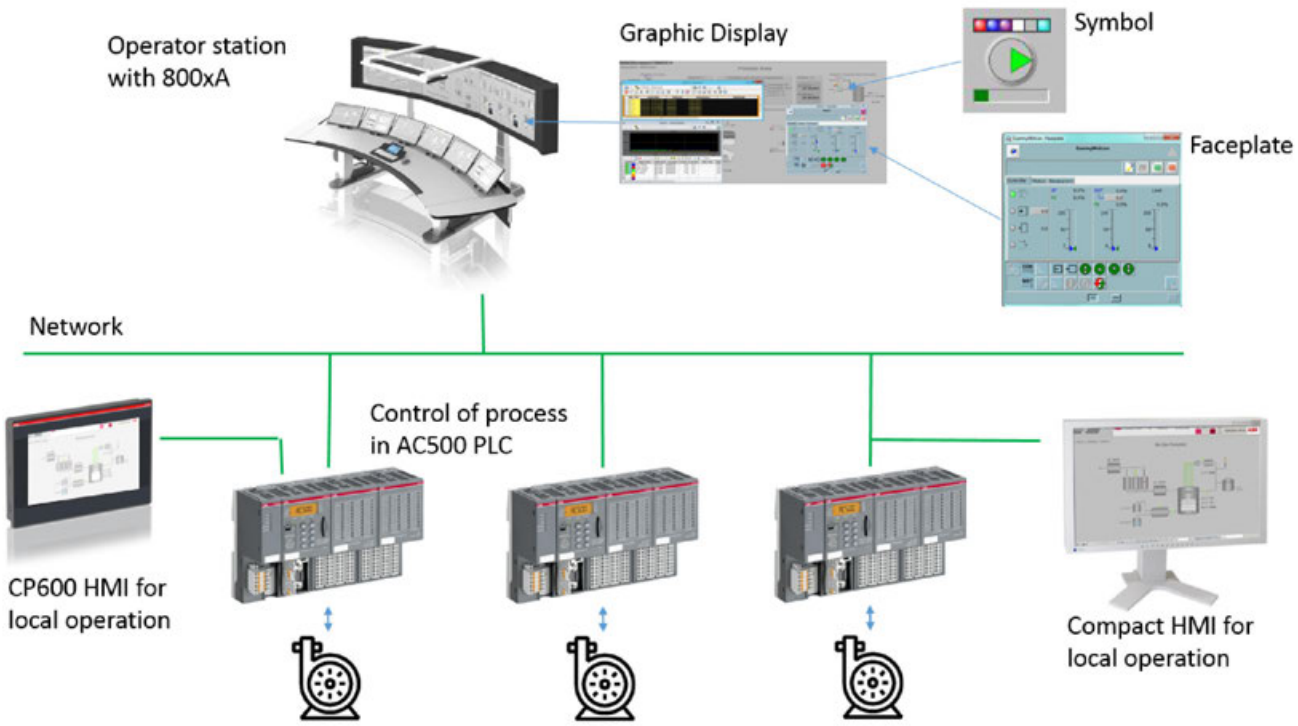
Example projects for the libraries can be found in the folder: \Users\Public\Documents\AutomationBuilder\Examples

1.5.10 Process control object (PCO) library

1.5.10.1 PCO library - System technology

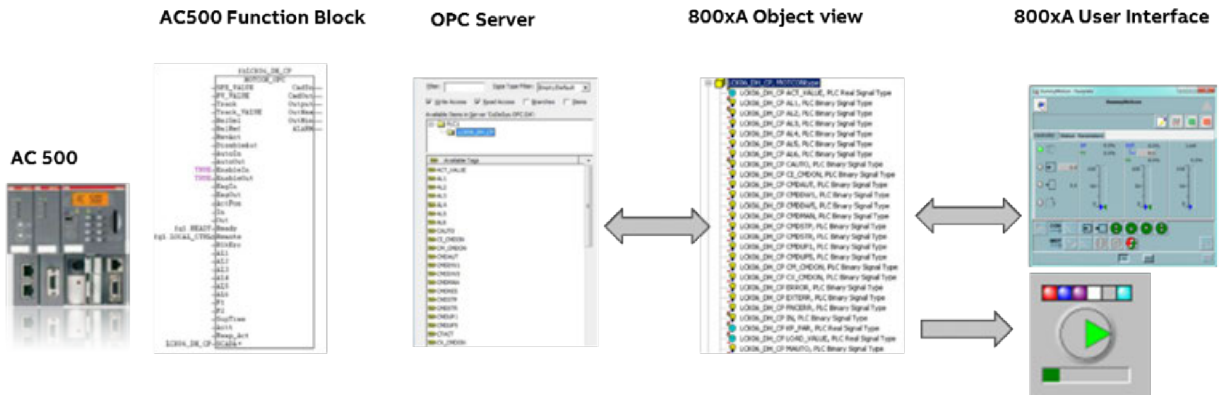
1.5.10.1.1 Introduction

800xA Connect in combination with AC500 Process Control Object (PCO) library allows to easily integrate AC500 into 800xA for process control:



The AC500 PCO Library contains function blocks for Process Control Objects like motors, valves, PID controllers, alarms, etc. Those function blocks are integrated into 800xA via OPC.

A corresponding 800xA aspect object allows control and monitoring of the Process Control Objects with 800xA User Interface like faceplates and graphic elements:

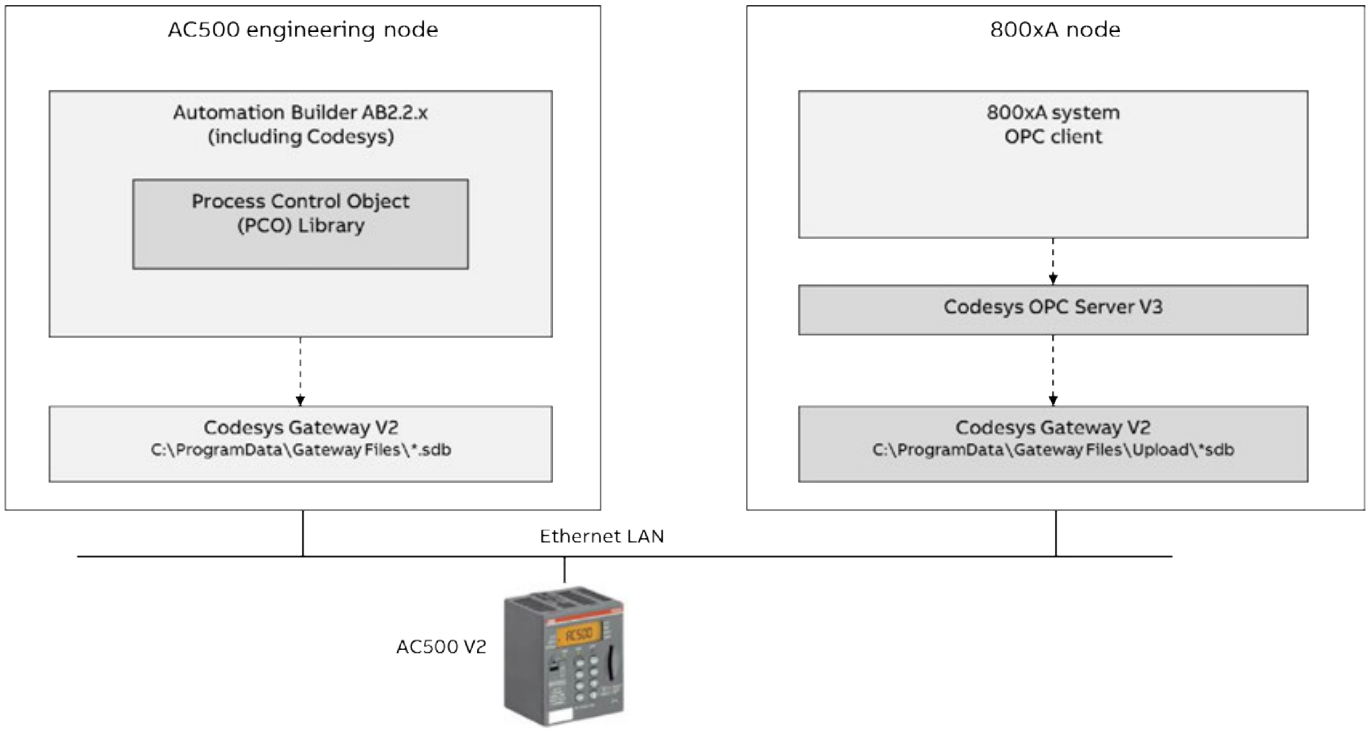


AC500 Function Block
OPC Server
800xA Object view
800xA User Interface
AC 500

1.5.10.1.2 Installation

For integration of AC500 into 800xA it is recommended to have at least two nodes:

- AC500 engineering node with Automation Builder and PCO library
- 800xA engineering node for engineering and operation of 800xA. The OPC server for AC500 (*"Codesys OPC Server V3.5"*) must be installed on this node for connectivity with AC500.



> *It is also possible to install the AC500 Automation Builder on the 800xA engineering node,*
>
> *but this document describes the general case with two nodes.*

Install Automation Builder on AC500 engineering node

Latest Automation Builder installation files and instructions can be found *here*.

During installation the PCO library can be chosen as an option.

Install AC500 PCO Library on AC500 engineering node

If the PCO library is not yet installed from the beginning it can be installed using the Automation Builder Installation Manager:

Install AC500 connect on 800xA node

> *The information can be found in the corresponding chapter in the ABB Ability™ System 800xA User Manual 2PAA119792.*

Install AC500 OPC server on 800xA node

The AC500 OPC Server (*"Codesys OPC Server 3.5"*) must be installed on the 800xA engineering node. The AC500 OPC server is part of the Automation Builder installation, but it is not required to install the full Automation Builder on the 800xA engineering node.

Latest Automation Builder installation files can be found *here*.

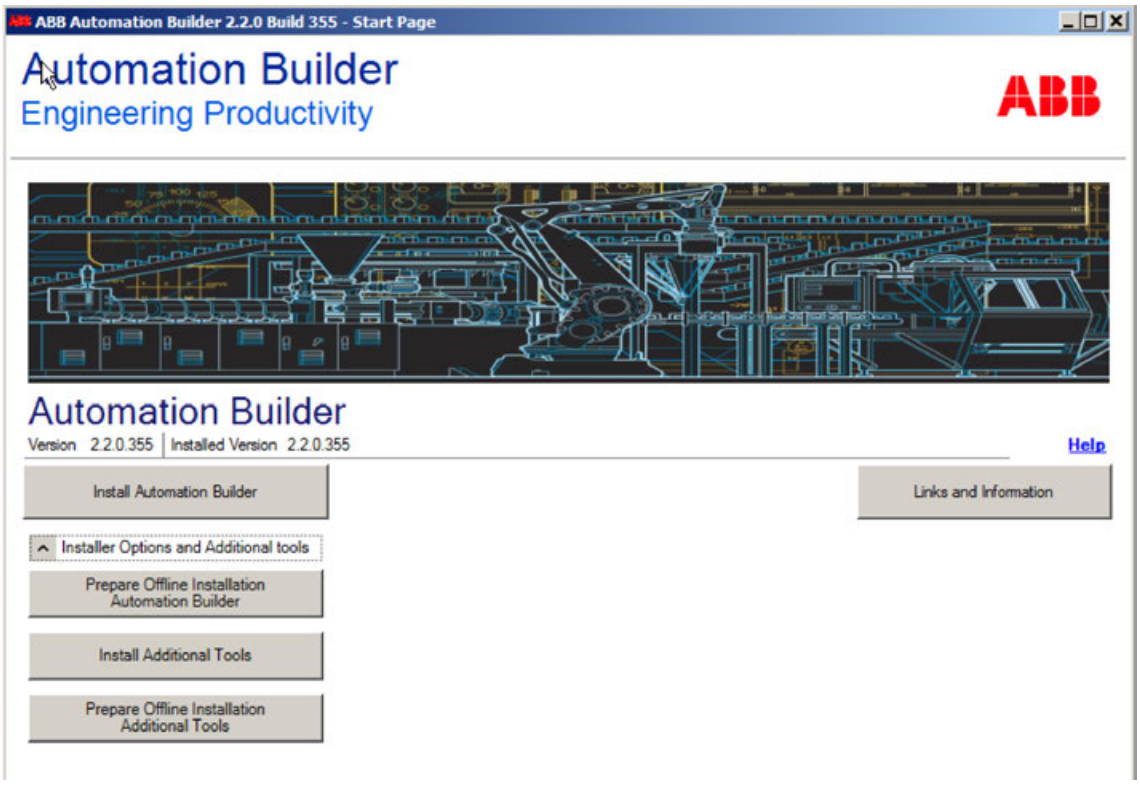
Checkpoint 1

1. Before starting the installation ensure that all OPC clients from previous versions are closed:
   - *"ABB OPC Tunnel"*
   - Gateway (CODESYS gateway server)

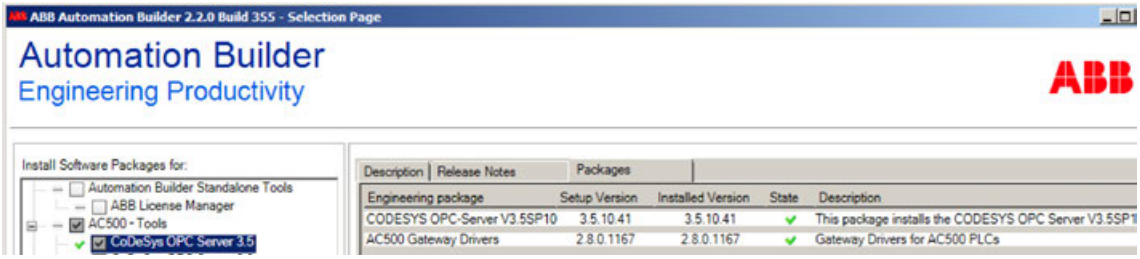
   > *This can be checked in the Windows Task Manager.*

   The following processes must have disappeared:
   - *"Gateway.exe"*,
   - *"CoDeSysOPC.exe"*,
   - *"WinCoDeSysOPC.exe"* and
   - *"OCTsvc.exe"*

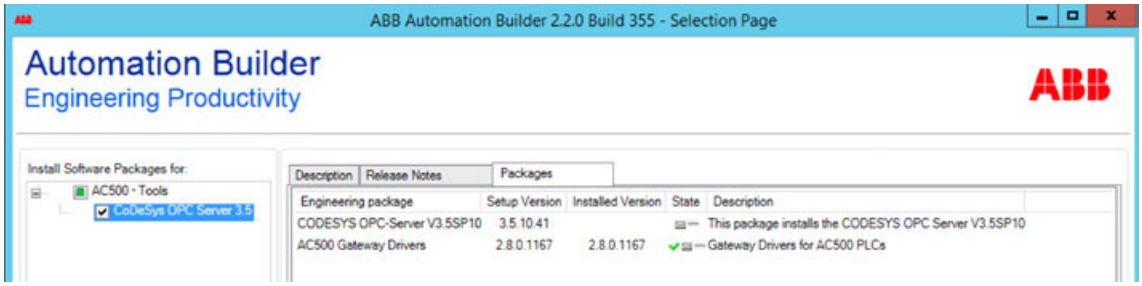
   ⇨ If not:
   - End the processes with the Windows Task Manager.
   - Stop *"ABB OPC Tunnel Windows Component Service"* in Services (local).
2. Start the Automation Builder installation.



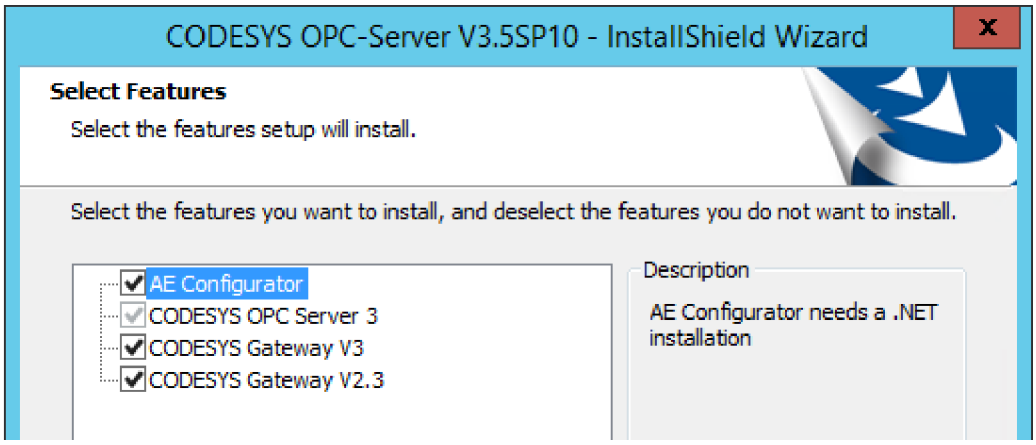
3. Select *[Install Additional Tools]* and install the *"CODESYS OPC Server 3.5"* which includes the *"AC500 Gateway Drivers"*:



4. Alternatively, you can select *[Prepare Offline Installation Additional Tools]* to create an USB-stick containing the *"CODESYS OPC Server 3.5"* and use this for installation on the 800xA engineering node.



5. During installation on the 800xA engineering node select all features.



1.5.10.1.3 Prerequesites

800xA license

The information can be found in the corresponding chapter in the ABB Ability™ System 800xA User Manual 2PAA119792.

AC500 license

A separate license is not required for the PCO library.

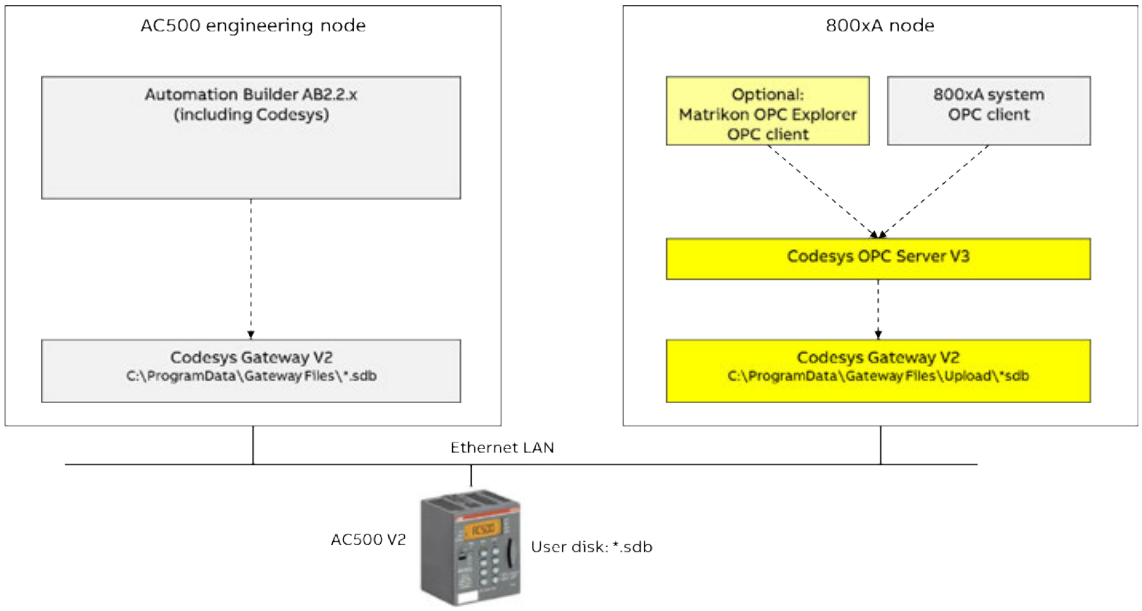
1.5.10.1.4 Configuration

This chapter descibes the configuration of AC500 engineering node and 800xA engineering node.

Configure AC500 OPC server

Communication of AC500 to 800xA is done through OPC. Therefore it is required to install the AC500 OPC server (see *Chapter 1.5.10.1.2.4 “Install AC500 OPC server on 800xA node” on page 3042*) and to configure it accordingly.

Basic configuration workflow for AC500 OPC Server: The definition of the items (symbols) to be exchanged over OPC DA are stored in the symbol file *“*.sdb”*. The symbol file is generated by the AC500 engineering tool Automation Builder which is running on the AC500 engineering node. When downloading the application to the AC500 PLC the *“*.sdb”* file is stored on the user disk of the PLC. Finally, the OPC Server running on the 800xA engineering node uploads the *“*.sdb”* file in order to configure the tags accordingly.



This chapter describes how to setup the OPC connection on the AC500 engineering node as well as on the 800xA engineering node.

AC500 engineering node

It is assumed that a simple AC500 project was configured with an AC500 engineering node running the Automation Builder. For more information please check chapter ↳ *Chapter 1.5.10.1.5.1 “Create function blocks in AC500 V2” on page 3057*.

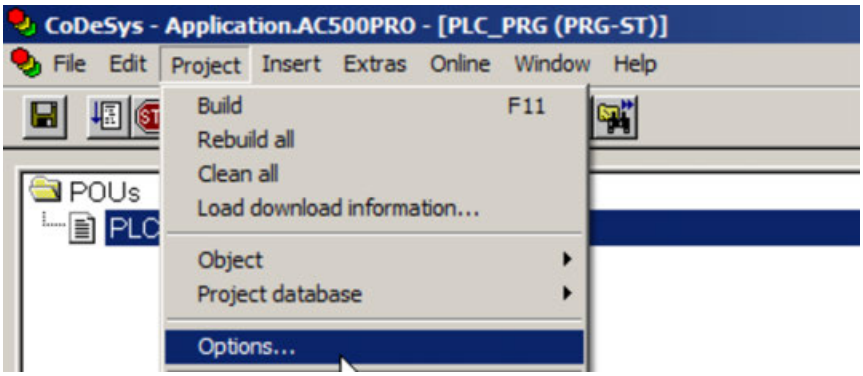
As a quick start the simple motor example “PCO_Motor_Demo_AB223.project” can be used which comes with the PCO library package, see folder

C:\Users\Public\Documents\AutomationBuilder\Examples\PS573-PCO.

The following chapter describes the configuration steps to prepare the AC500 for OPC communication to the 800xA engineering node.

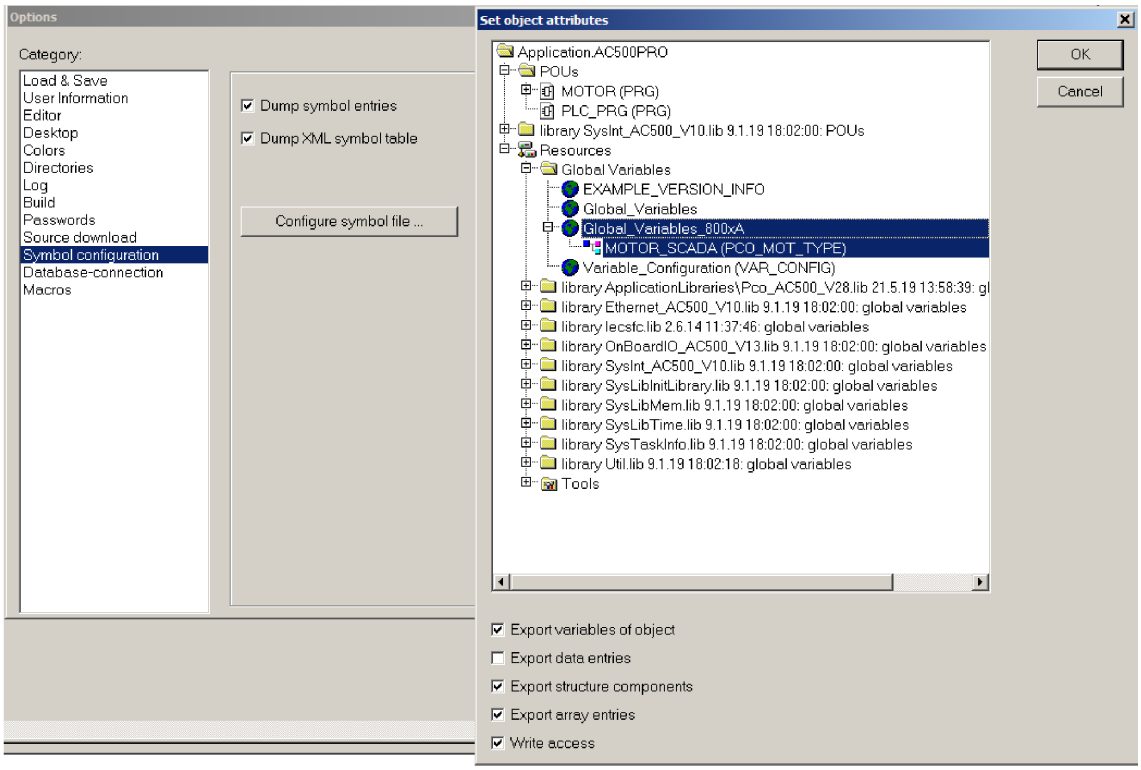
Configure symbol file in Automation Builder

1. Open Automation Builder and start the application of the project which will open CODESYS.
2. Select *“Options”* in menu *“Project”*.



3. Configure symbol file according to the instructions in the Automation Builder help: ↳ *Chapter 1.6.5.5.1.2.5.1.1 “Configure a symbol file” on page 6285*

For the example “PCO_Motor_Demo_AB223.project” it should look like this:

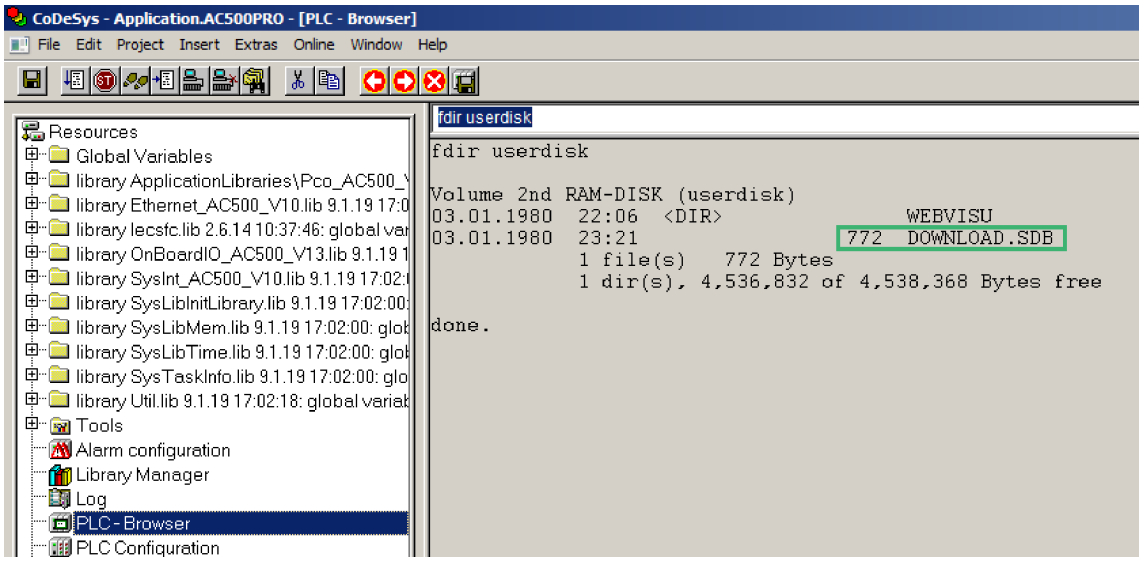


Create and download symbol file

1. Follow the instruction in the Automation Builder help: ↳ *Chapter 1.6.5.5.1.2.5.1.2 “Create and download a symbol file” on page 6287*

Checkpoint 2

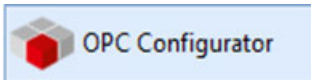
2. Verify that the symbol file is downloaded to the PLC by opening the *“PLC-Browser”* in *“CODESYS”* (online mode) and entering *“fdir userdisk”*:



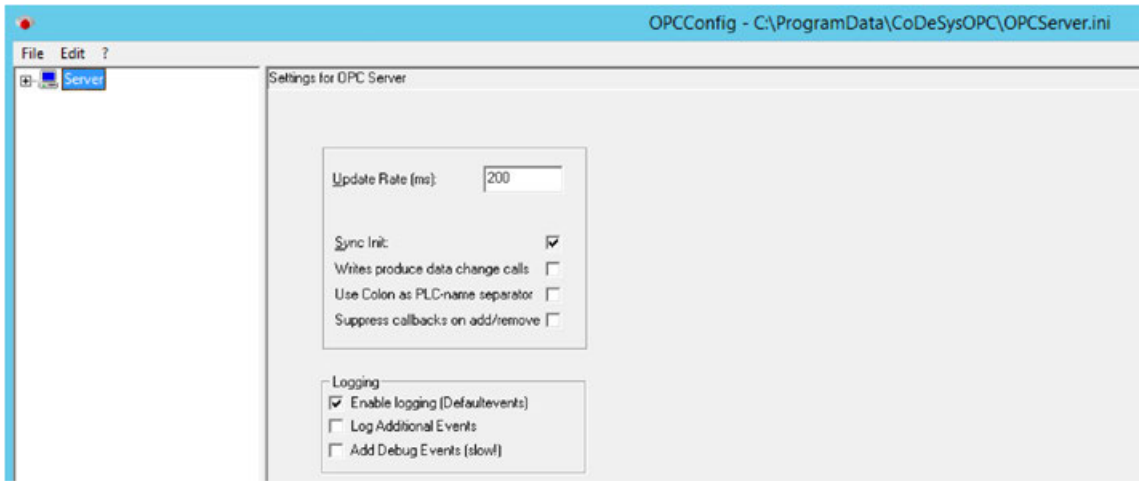
800xA engineering node

Configure OPC server

1. Start *“OPC Configurator”*.



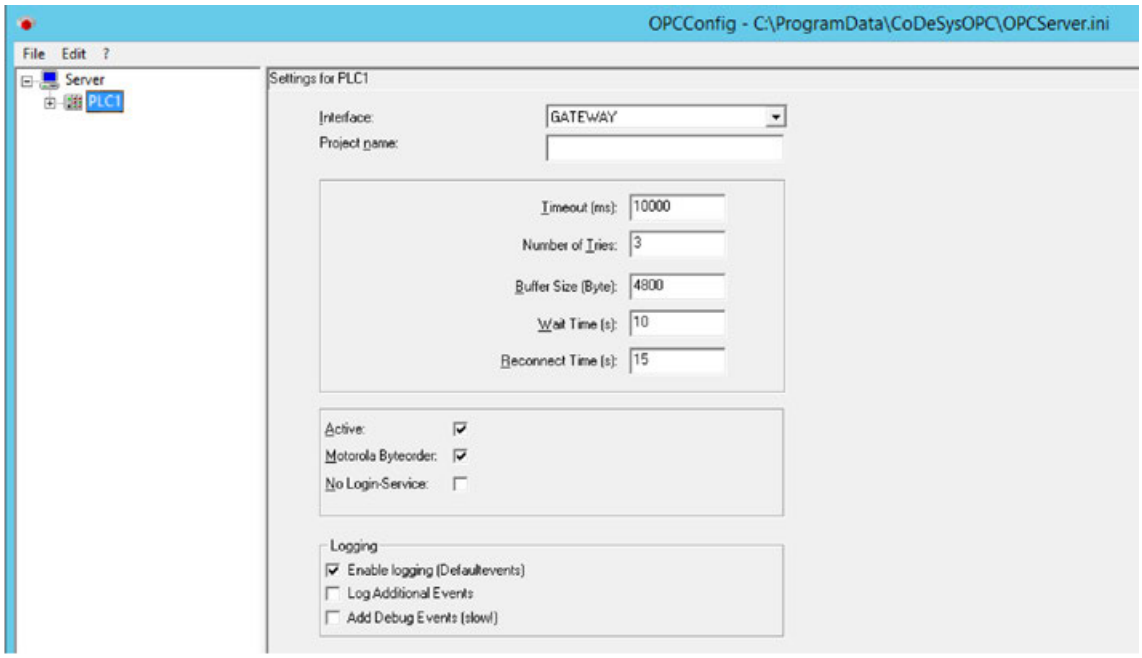
2. Default values of the server need not to be changed.



⇨

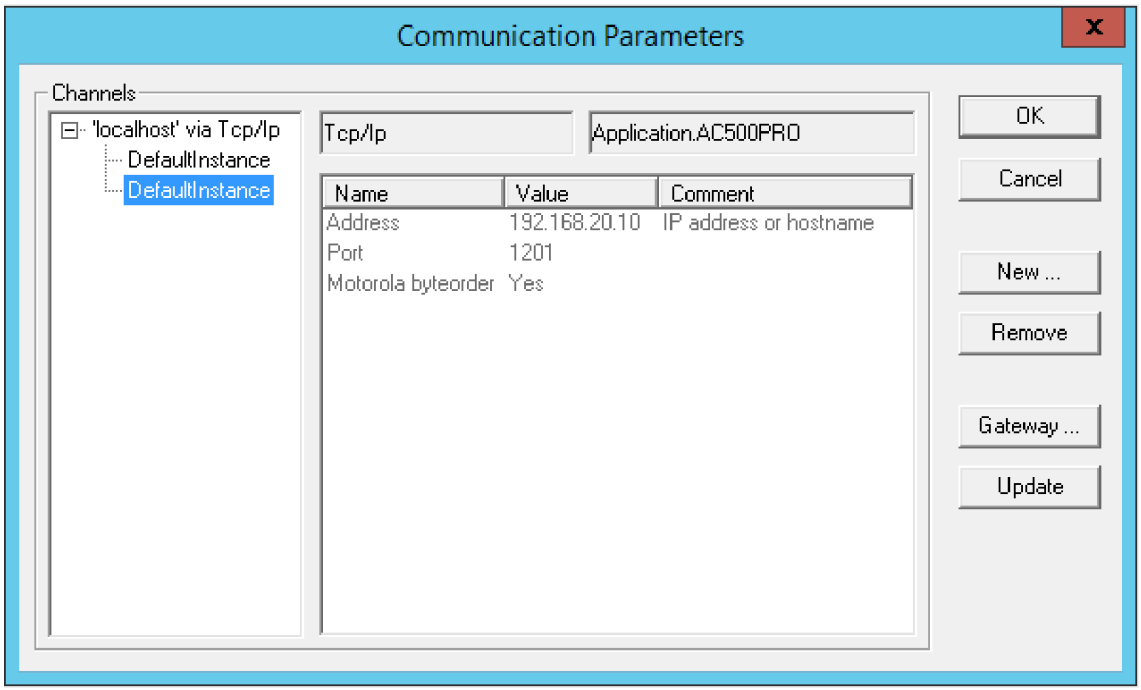
> *“Update Rate” may should not be “0 ms”! The default value of “200 ms” is suitable value of many applications. The adjustment for the update rate depends on the number of symbols (variables). For a big number of symbols it would be better to increase the update rate.*

3. Configure the PLC1.



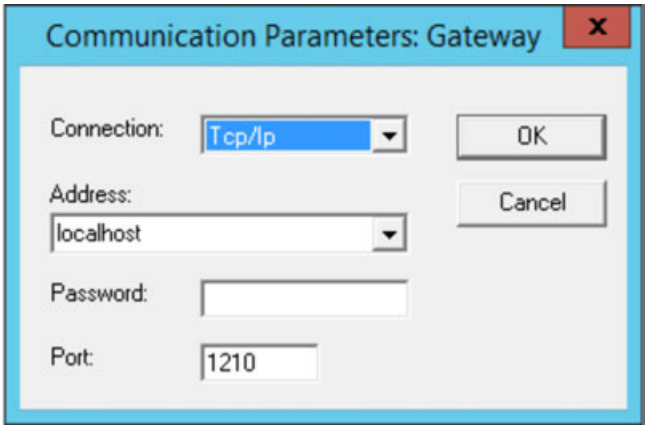
4.
   - Choose *“Interface” “GATEWAY”*.
     This is the V2 Gateway which communicates with the AC500 V2.
   - *“Project name”* can be empty.
   - Increase *“Buffer Size [Byte]”* to *“4800”*
   - The checkboxes *“Active”*, *“Motorola Byteorder”* must be checked.
   - The checkbox *“Enable logging [Defaultevents]”* allows a later diagnosis.

5. Configure connection. Click *[Edit]* and *[New]* to configure a new *"Tcp/Ip"* connection.

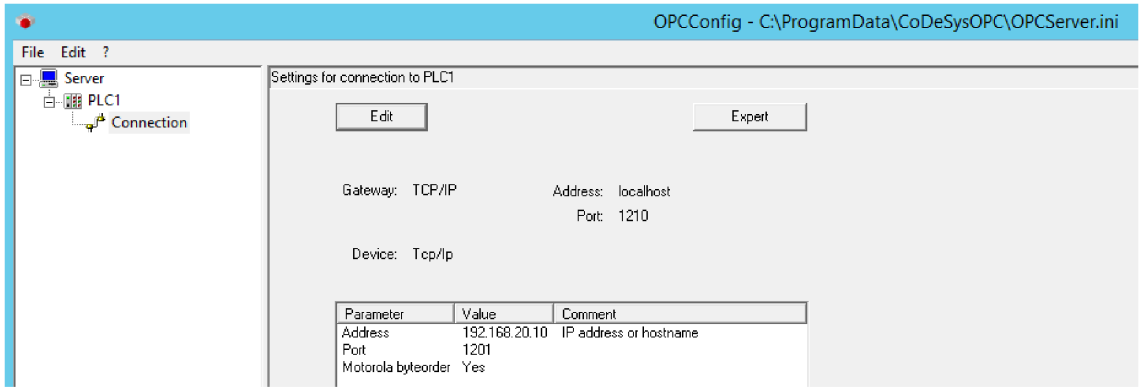


⇨ Address must be the IP address of the connected Ethernet port of AC500.

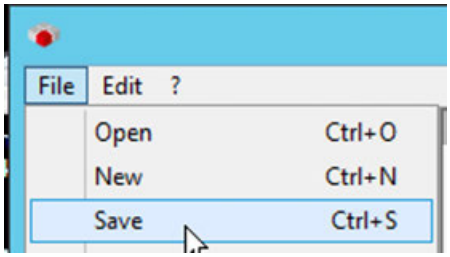
6. Click *[Gateway]* and configure *"Tcp/Ip"*.



7. Final configuration looks like this:



8. Save the configuration.



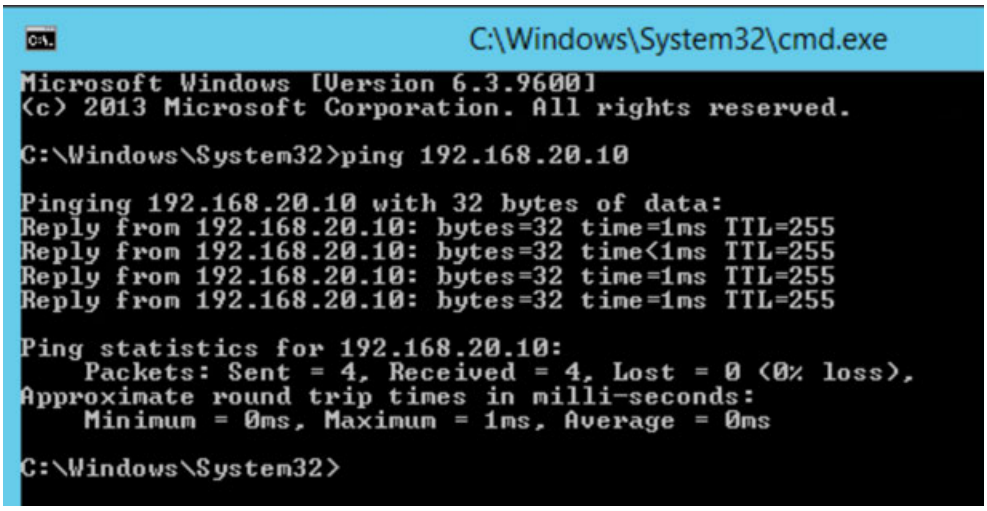
Read OPC data with matrikon test client (optional)

This chapter describes how to install and configure the Matrikon OPC test client. This is an optional step but it is recommended to test the basic OPC communication before doing any 800xA specific configuration.

The AC500 must be connected to the 800xA engineering node and its IP address must be in the same LAN.

Checkpoint 3

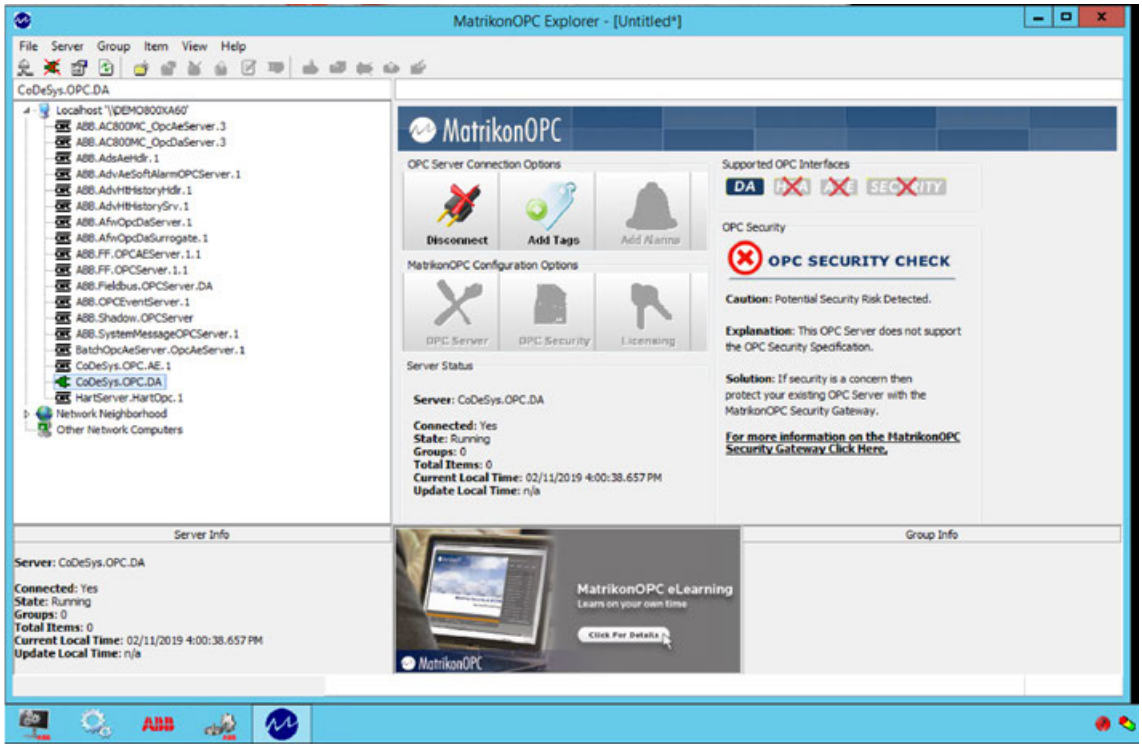
1. Test if you can ping the PLC from 800xA engineering node:



2. Install an OPC test client, for example from Matrikon.

> *More information on test clients can be found in the the Automation Builder help: ↳ Chapter 1.6.5.5.1.2.3.3 “OPC clients for tests” on page 6284*

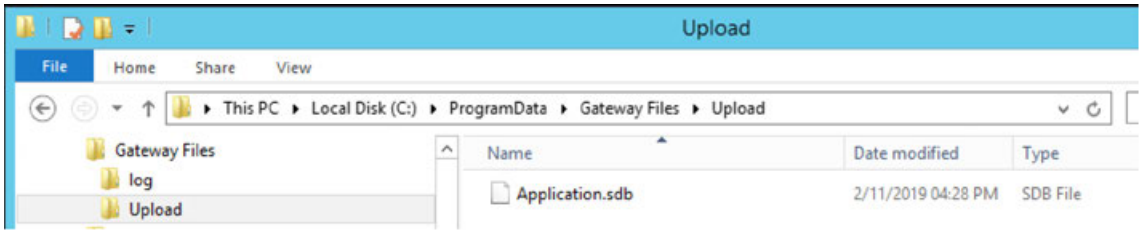
3. Start the OPC test client (here: *“Matrikon OPC Explorer”*) and connect the *“CoDeSys.OPC.DA”*:



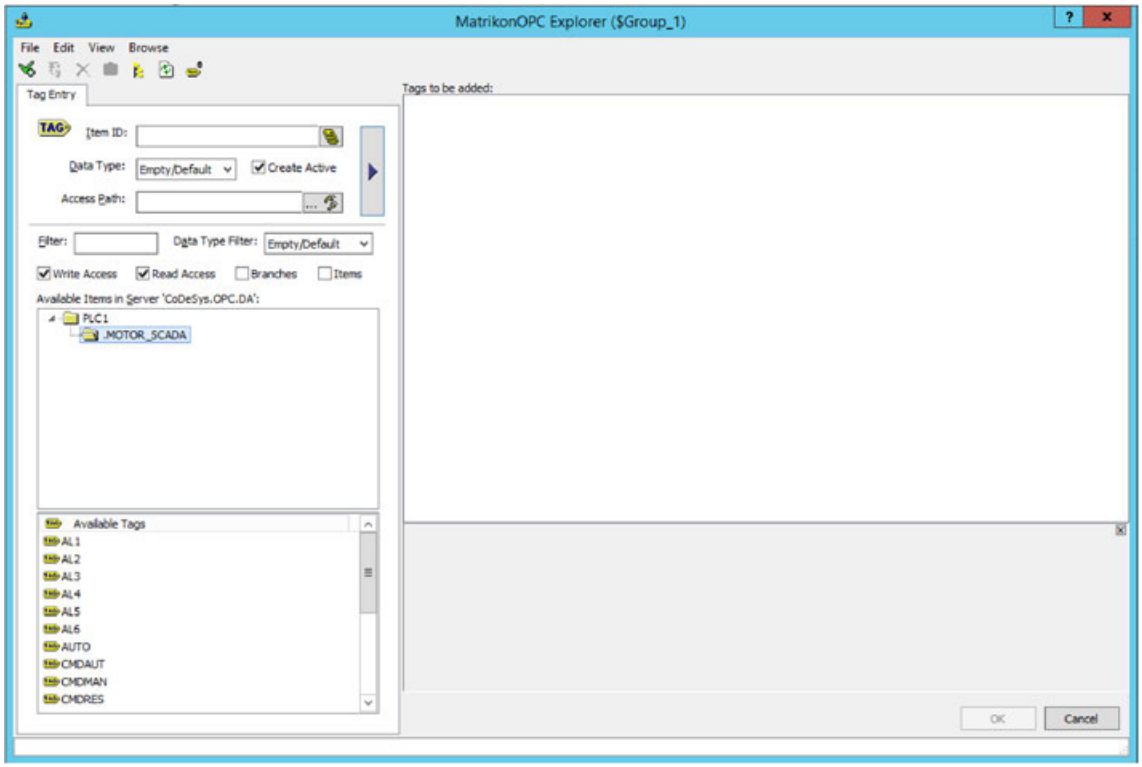
Checkpoint 4

4. After clicking *[eConnect]* the *“Tray Icon”* of the CODESYS gateway turns from idle to active .

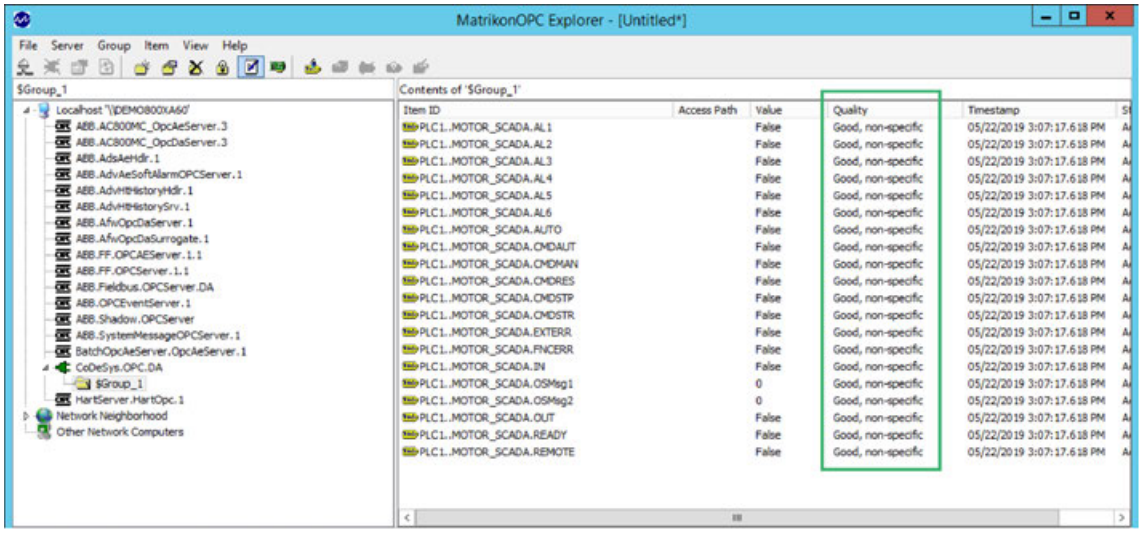
   Furthermore, the sdb file is uploaded from the PLC to the following Gateway folder: C:\ProgramData\Gateway Files\Upload



5. Add tags.



6. Watch the values of the added tags.



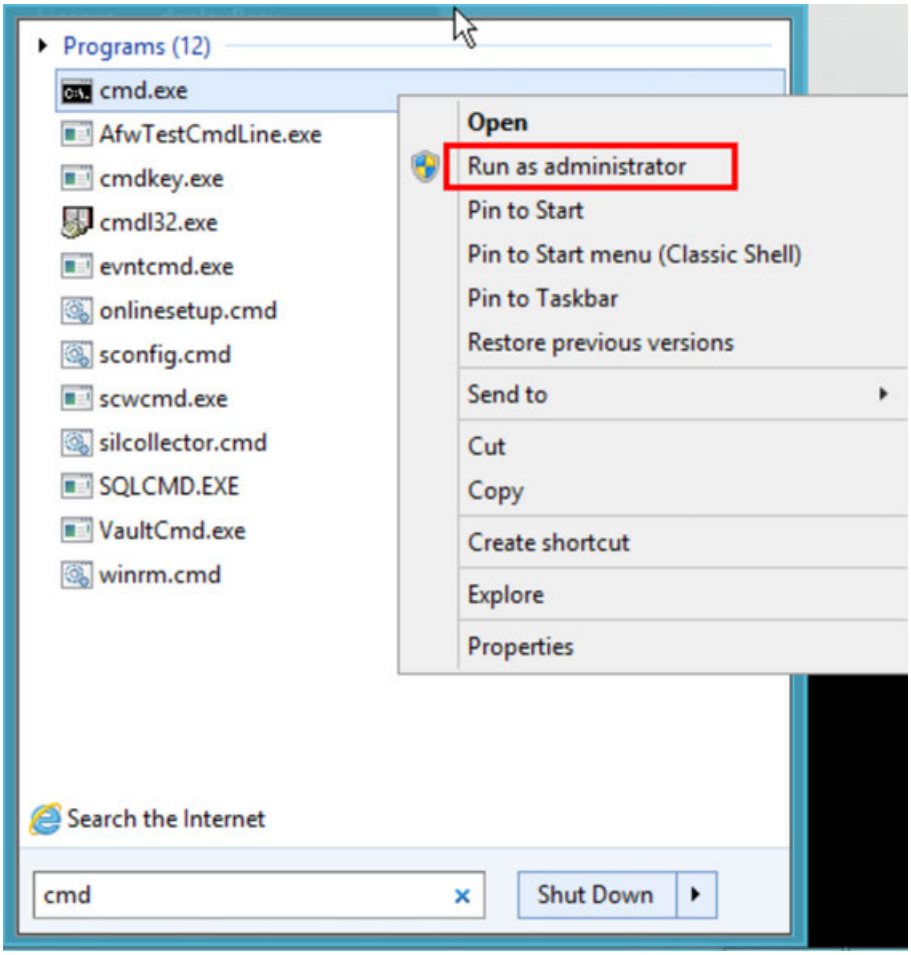
Checkpoint 5 7. Quality of the tag must be *“Good”*

Register OPC server as system service

For use with 800xA it is important that the OPC server runs with Session ID 0 (like all other 800xA services).

Therefore OPC server must be registered as service.

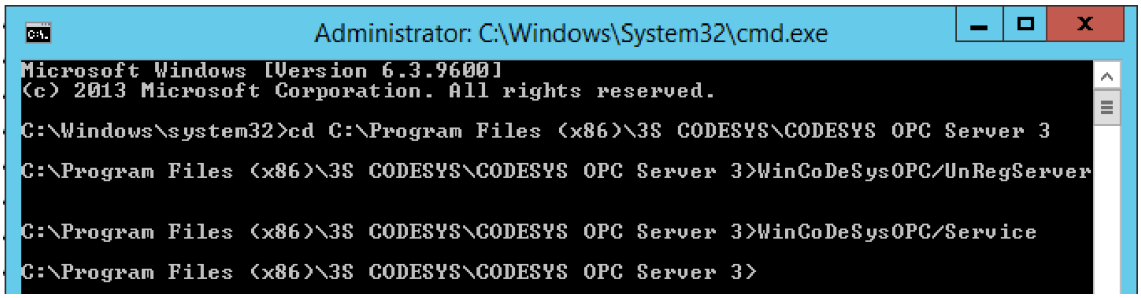
1. Start a command prompt as administrator.



2. Go to the CoDeSysOPC V3 installation folder.
3. Unregister the OPC server with *“WinCoDeSysOPC/UnRegServer”*.
4. Register the OPC server as system service with *“WinCoDeSysOPC/Service”*

Checkpoint 6

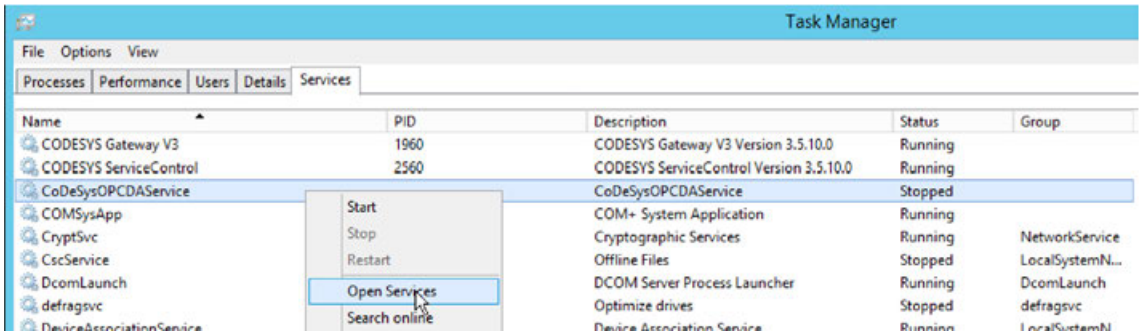
5. During this procedure there should be no errors, terminal should look like this:



⇨

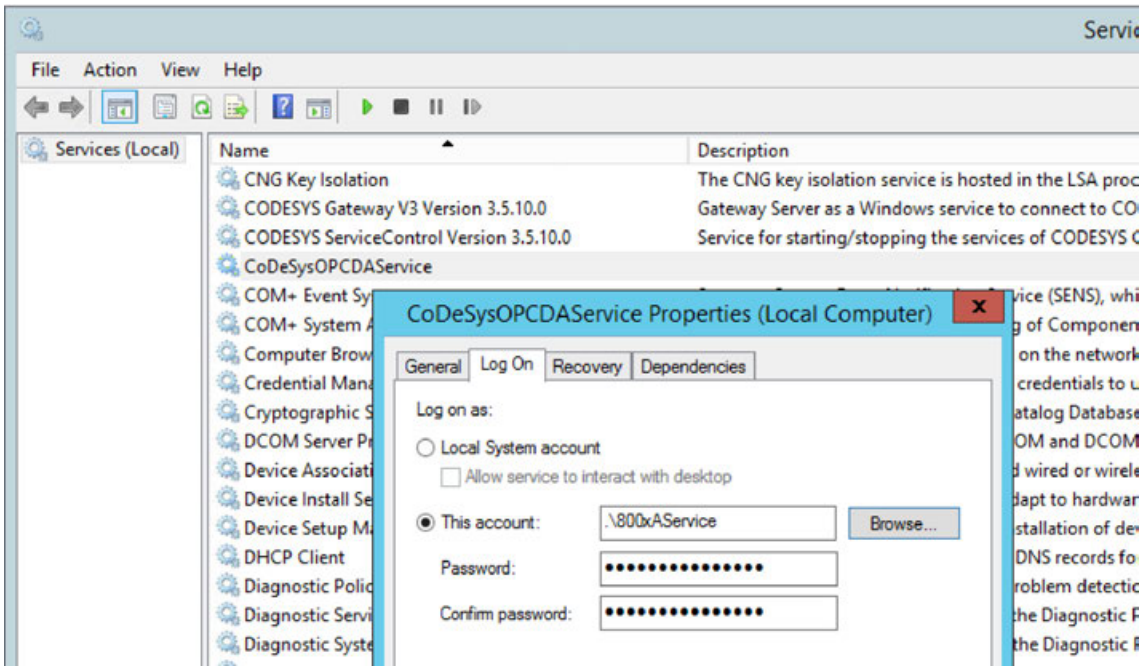
Same information in Automation Builder online help: ↳ Chapter 1.6.5.5.1.2.3.2.1 “Register OPC server V3 as a system service” on page 6284

6. Open Task Manager and select *"CoDeSysOPCDAService"* from the *"Service"* menu.
   Right-click the *"CoDeSysOPCDAService"* and select *"Open Services"*:



7. Double-click *"CoDeSysOPCDAService"* and configure properties, logon with 800xAService account.

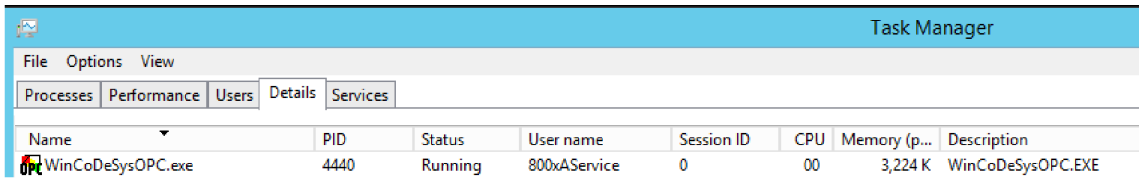
> *"800xAService" in the example, maybe different!*



8. Restart the service (right-click).

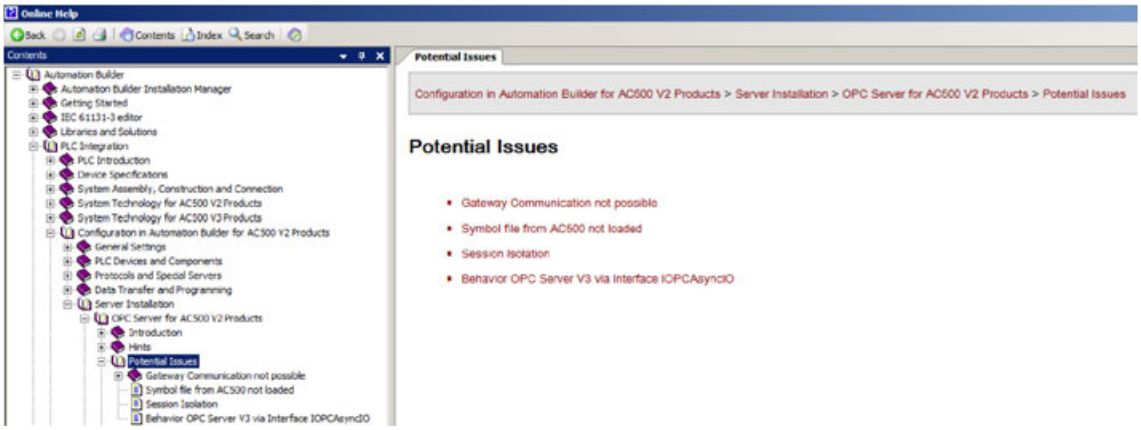
Checkpoint 7

9. Now the process runs with *User name "800xAService"* and *Session ID " 0"*.



Troubleshooting

In case of any problems please check the potential issues in the Automation Builder help:
↳ *Chapter 1.6.5.5.1.3 “Potential issues” on page 6303*



Create PLC generic control network object

This configuration is done on the 800xA node.

The information can be found in the corresponding chapter in the ABB Ability™ System 800xA User Manual 2PAA119792.

Configure PLC connect services

This configuration is done on the 800xA node.

The information can be found in the corresponding chapter in the ABB Ability™ System 800xA User Manual 2PAA119792.

Create AC500 controller and GCN configuration

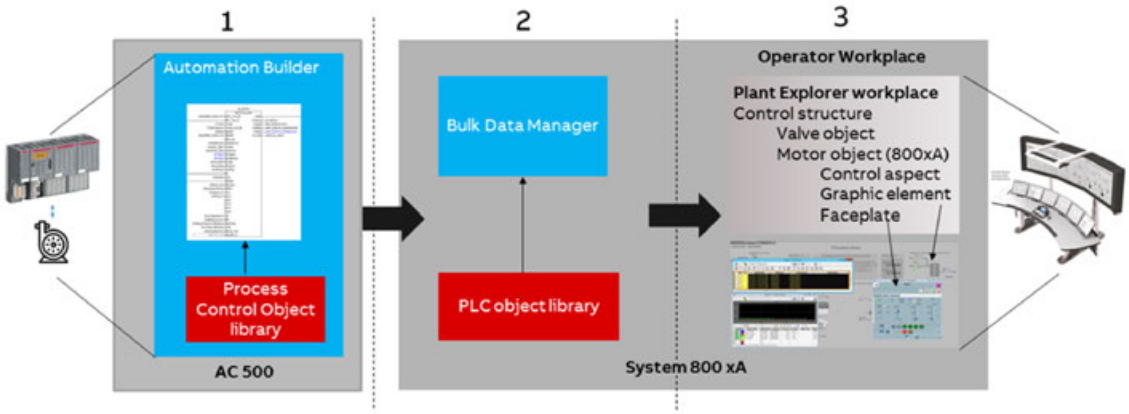
This configuration is done on the 800xA node.

The information can be found in the corresponding chapter in the ABB Ability™ System 800xA User Manual 2PAA119792.

1.5.10.1.5 Engineering workflow

Engineering is done in the following steps:

1. Create application in AC500 using the AC500 PCO library.
2. Create equivalent structure in *“Bulk Data Manager”*.
3. Populate PLC objects to control structure using the 800xA PLC object library.



Create function blocks in AC500 V2

1. For general introduction to AC500 configuration please refer to the chapter *Chapter 1.2 “Getting started” on page 12*.
2. Create a new project: *Chapter 1.6.5.1.1 “Project handling” on page 5757*
3. Transfer data to CODESYS: *Chapter 1.6.5.4.1 “Data transfer and CODESYS programming” on page 6196*
4. Program your application in *Chapter 1.4.1 “Development system” on page 145*

Function blocks of PCO library

The PCO library contains the AC500 function blocks (motors, valves, …) which can be integrated into 800xA.

The function blocks can be controlled and monitored by 800xA during operation.

Installation of the PCO library is described in *Chapter 1.5.10.1.2.2 “Install AC500 PCO Library on AC500 engineering node” on page 3041*.

All function blocks are described in *Chapter 1.5.10.2 “PCO library - function block description (V2)” on page 3062*.

Create instances using bulk data manager

> *The information can be found in the corresponding chapter in the ABB Ability™ System 800xA User Manual 2PAA119792.*

1.5.10.1.6 Capacity and Performance

AC500 function block performance

The PCO (Process Control Object) Library is usable on the whole range of AC500 platform including AC500-eCo PLC's.

The maximum number of function blocks per CPU is limited:

- By the available program memory for each CPU type.
- By the available speed for each CPU type.
- By the PLC cycle time which needs to be set to achieve desired CPU load.

The table below portrays the performance overview of various CPU's. It shows two typical configurations as examples.

These examples can be used by user to understand the performance of PLC's and choose the PLC based on application.

Small configuration

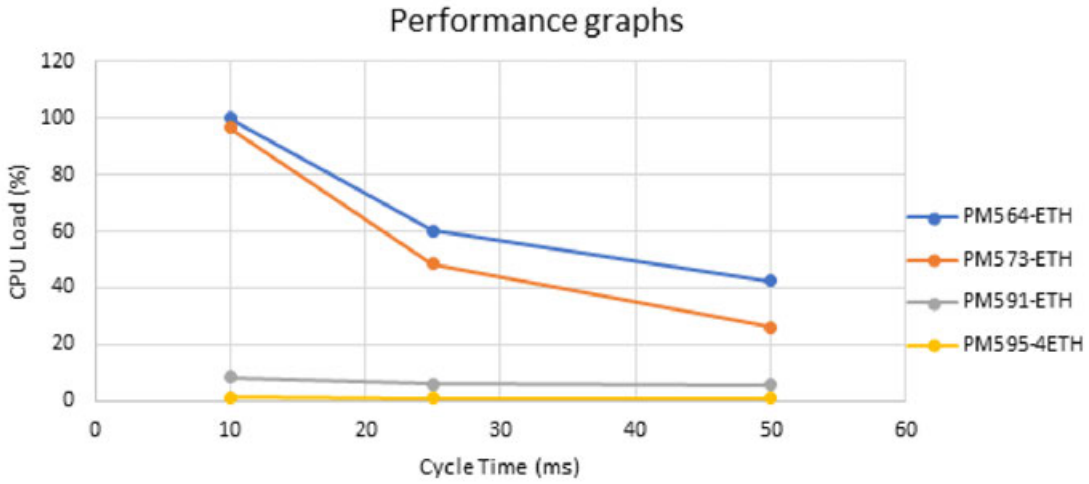
It uses 39 instances of function blocks. The various blocks used are:

Function block	Number of Instances
PCO_BINSET	1
PCO_BIN	12
PCO_ALARM	6
PCO_ANASET	1
PCO_ANA	1
PCO_ANAALM	9
PCO_ANALIM	1
PCO_MOT	3
PCO_VALV	2
PCO_MOTCON	1
PCO_PIDCON	1
PCO_VALVCON	1
Total	**39**

When these instances of function blocks were downloaded the memory coverage in various PLC's is shown in the following table:

PLC	Required User Data Memory (% used from total available)
PM564-ETH	7730 → 75 %
PM573-ETH	7730 → 3 %
PM591-ETH	7730 → 0.18 %
PM595-4ETH	7730 → 0.05 %

The cycle time versus the CPU load for various PLC's are shown in table below. The user needs to select the cycle time based on desired CPU load. Cycle time and CPU load are inversely proportional and are depicted in the following figure. It is not desirable for the CPU load to be 100 % and hence the cycle time needs to be chosen likewise.



Medium configuration

It uses 49 instances of function blocks. The various blocks used are:

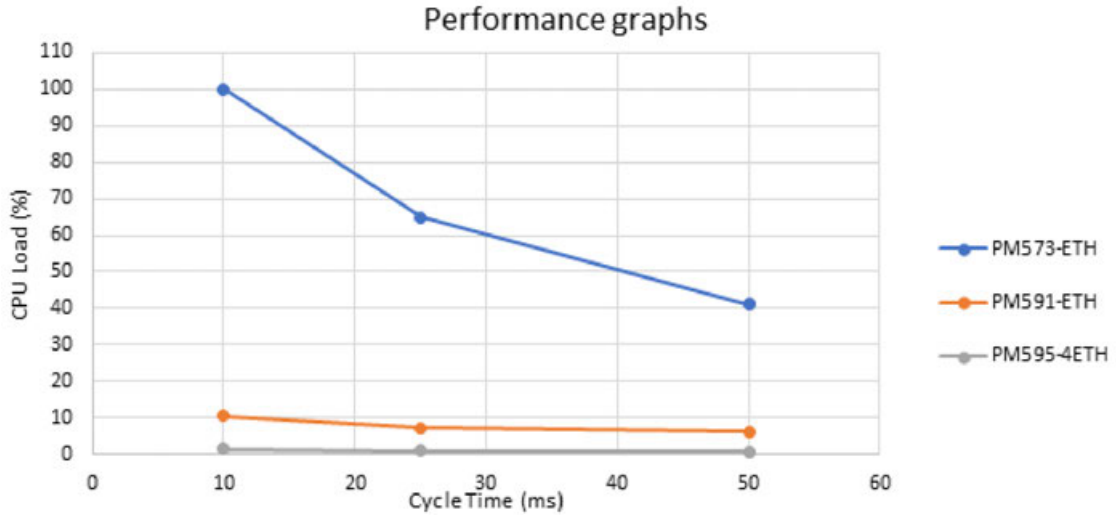
Function block	Number of Instances
PCO_BINSET	3
PCO_BIN	6
PCO_ALARM	2
PCO_ANASET	2
PCO_ANA	1
PCO_ANAALM	9
PCO_ANALIM	1
PCO_MOT	2
PCO_VALV	1
PCO_MOTCON	7
PCO_PIDCON	1
PCO_VALVCON	14
Total	**49**

When these instances of function blocks were downloaded the memory coverage in various PLC's is shown in the following table:

PLC	**Required User Data Memory (% used from total available)**
PM573-ETH	18258 → 7 %
PM591-ETH	18258 → 0.44 %
PM595-4ETH	18258 → 0.11 %

Here the program could not be downloaded to PM564-ETH because of the less memory available (Program Code Memory Max - 131072 Bytes) and here it is 18258 Bytes and hence PM573-ETH, PM591-ETH and PM595-4ETH were used for testing.

The cycle time versus the CPU load for various PLC's are shown in table below. The user needs to select the cycle time based on desired CPU load. Cycle time and CPU load are inversely proportional and are depicted in the following figure. It is not desirable for the CPU load to be 100 % and hence the cycle time needs to be chosen likewise.



Memory usage per function block

The table below shows the memory size of each function block of the PCO library.

This information can be used by the user to select the CPU type based on its application.

Component	Required User Program Memory (Bytes) (Max - 524288)	Required User Data Memory (Bytes) (Max - 65536)		Size of individual FB (Bytes)
		Number of 1 Function Block Instance	Number of 5 Function Block Instances	
Project no program	4338 (0 %)	1958 (2 %)		
Project with Library	4354 (0 %)	1962 (2 %)		
PCO_BINSET	5070 (0 %)	1976 (3 %)	2008 (3 %)	14
PCO_BIN	5174 (0 %)	1991 (3 %)	2087 (3 %)	29
PCO_ALARM	5206 (0 %)	1991 (3 %)	2087 (3 %)	29
PCO_ANASET	5018 (0 %)	1978 (3 %)	2010 (3 %)	16
PCO_ANA	5174 (0 %)	1974 (3 %)	1998 (3 %)	12
PCO_ANAALM	19522 (3 %)	2166 (3 %)	2870 (4 %)	204
PCO_ANALIM	12498 (2 %)	2078 (3 %)	2510 (3 %)	116
PCO_MOT	10922 (2 %)	2288 (3 %)	3488 (5 %)	326
PCO_VALV	11402 (2 %)	2326 (3 %)	3670 (5 %)	364
PCO_MOTCON	30814 (5 %)	2772 (4 %)	5748 (8 %)	810
PCO_PIDCON	25310 (4 %)	2468 (3 %)	4324 (6 %)	506
PCO_VALVCON	26686 (5 %)	2550 (3 %)	4678 (7 %)	588

The percentages in the bracket denote the memory consumed out of the total available. Tested using PM566-ETH.

800xA performance

The information can be found in the corresponding chapter in the ABB Ability™ System 800xA User Manual 2PAA119792.

1.5.10.2 PCO library - function block description (V2)

1.5.10.2.1 Scope and structure of this document

The purpose of this library description is to explain different components of the Process Control Object (PCO) library.

1.5.10.2.2 Process control object (PCO) library

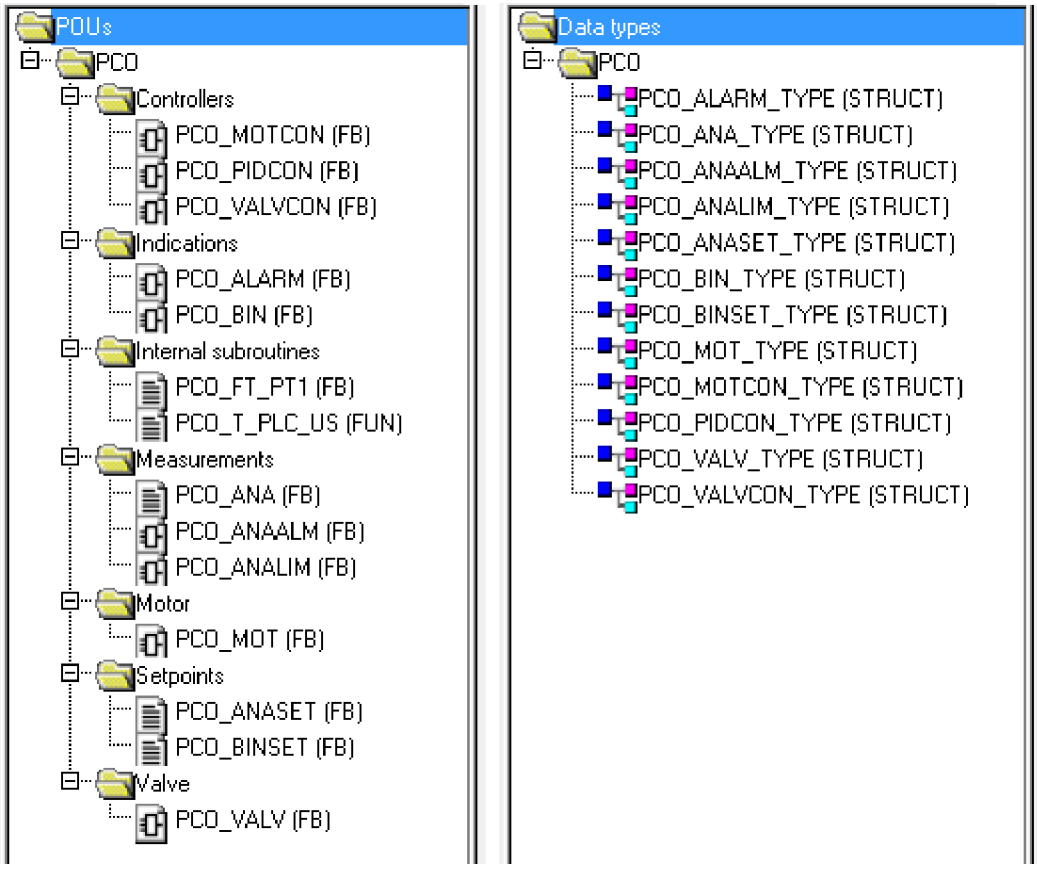
Process Control Object (PCO) Library is developed for use in any process application.

It includes function blocks for controlling motors, valves and measurements.

There are no prerequisites.

Components of the PCO library

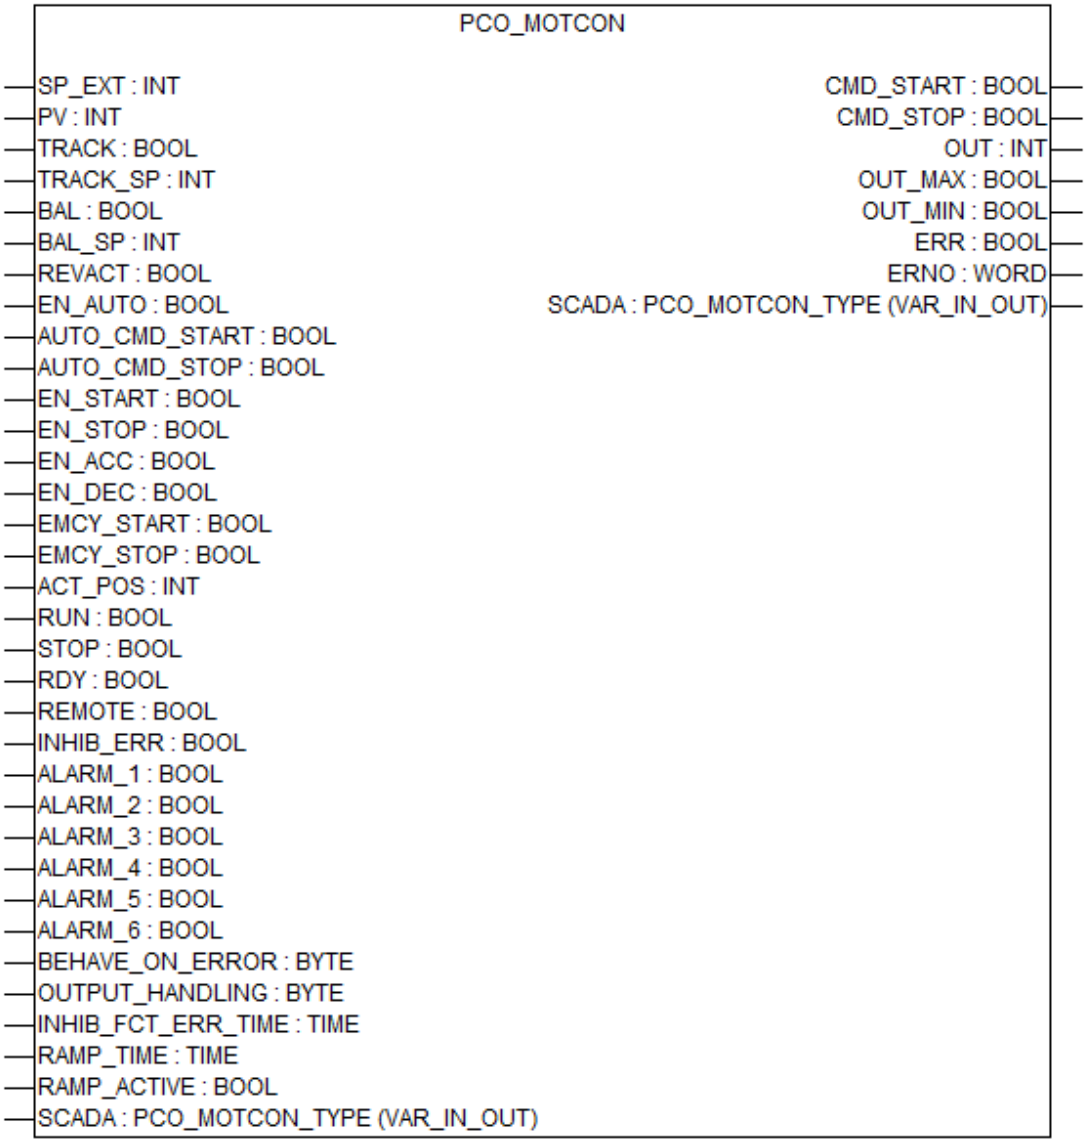
The PCO library contains the following function blocks and structures:



Function blocks

Controllers

PCO_MOTCON



This function block is designed for controlling a variable speed drive motor.

The function block is similar to PCO_MOT (Fixed speed motor controller), but in addition to PCO_MOT the function block has a built in PID controller used for speed control of the motor.

The PID controller can be switched between three different setpoints:

- **Internal Setpoint**
  Set from SCADA faceplate, variable in SCADA side is SPI_PAR.
- **External Setpoint**
  Function block input SP_EXT, calculated setpoint or output from another PID controller (e.g. PIDCON) in a cascade control system.
- **Tracking Setpoint**
  The output of the PID controller follows the function block input tracking setpoint, TRACK_SP and if TRACK input is active.

To make the controller follows various setpoints, the following variables need to be set:

The values set below are default values, the user can change based on the application.

Settings in SCADA side	Data type	When the controller must follow		
		Internal Setpoint	External Setpoint	Tracking Setpoint
SCADA.KP_PAR	INT	1	1	1
SCADA.TD_PAR	INT	0	0	0
SCADA.TI_PAR	INT	1	1	1
SCADA.OH_PAR	INT	10000	10000	10000
SCADA.OL_PAR	INT	0	0	0
SCADA.CI_CMDON	BOOL	TRUE	-	-
SCADA.SPI_PAR	INT	Needs to be set	-	-
SCADA.CX_CMDON	BOOL	-	TRUE	-

Settings in FB side	Data type	When the controller must follow		
		Internal Setpoint	External Setpoint	Tracking Setpoint
EN_AUTO	BOOL	TRUE	TRUE	TRUE
SP_EXT	INT	-	Needs to be set	-
TRACK	BOOL	-	-	TRUE
TRACK_SP	INT	-	-	Needs to be set
EN_ACC	BOOL	TRUE	TRUE	TRUE
EN_DEC	BOOL	TRUE	TRUE	TRUE

By switching to one of these setpoints, when command from SCADA, i.e. SCADA.SPIACT or SCADA.SPXACT or SCADA.CTACT is active, the PID controller will be put into automatic mode.

It is possible to set the PID controller into manual mode from the SCADA system to allow manual positioning.

The following variable needs to be configured to set the controller to manual mode.

Settings in FB side	Data type	Controller Manual Mode
No settings need to be done.		

Setting in SCADA side	Data type	Controller Manual Mode
SCADA.CM_CMDON	BOOL	Variable Rising edge needs to be given to reset auto mode.

The manual positioning can be done in two ways, both controlled form the SCADA faceplate.

1. Stepwise 1 % up / down or 5 % up / down.

   This is manually set by the following variables on the SCADA faceplate:

   - SCADA.CMDUP1
   - SCADA.CMDUP5
   - SCADA.CMDDW1
   - SCADA.CMDDW5

   The controller output varies based on the command given.

2. Download a new position. Manual position is set through OUT_PAR variable on the SCADA faceplate. The controller output varies accordingly.

If BAL (Input) of the function block is TRUE, then controller output varies according to BAL_SP entered at the input of the function block. This has higher priority over manual commands or external or internal setpoints.

But if TRACK input is selected then the controller follows the TRACK_SP.

When the controller is set to TRACK mode, the controller gets set to auto mode, whereas when the controller is set to BAL mode, the controller is not in auto mode. In both cases the controller output is not dependent on the actual process value.

The function block has built in a ramp to slow down the manual positioning. The ramp can be switched ON by the input RAMP_ACTIVE by setting the RAMP_ACTIVE high. The ramp time can be entered at RAMP_TIME input of the function block.

Cycle time for the program must be faster than RAMP_TIME / 100 to calculate the actuator time correctly!

Utilizing the inputs of the function block BEHAVE_ON_ERROR and OUTPUT_HANDLING different modes of CMD_START and CMD_STOP can be configured. E.g. if CMD_START and CMD_STOP should be pulsed or persistent signals. In addition, 6 different alarms can be connected to the function block (ALARM_1 to ALARM_6, thermal switch etc.)

Set motor to auto mode

The motor can be switched to automatic mode or manual mode, if EN_AUTO input is TRUE in the function block.

Settings in FB side	Data type	Set Motor to Auto Mode
EN_AUTO	BOOL	ACTIVE
REMOTE	BOOL	ACTIVE
RDY	BOOL	ACTIVE

Settings in SCADA side	Data type	Set Motor to Auto Mode
SCADA.CMDAUT	BOOL	Rising edge needs to be given.

Start / stop motor in auto mode

Settings in FB side	Data type	Start / Stop Motor in Auto Mode
INHIB_FCT_ERR_TIME	TIME	The value of INHIB_FCT_ERR_TIME has to be greater than 0 s to avoid functional error.
EN_START	BOOL	ACTIVE
EN_STOP	BOOL	ACTIVE
AUTO_CMD_START	BOOL	Rising edge needs to be given to AUTO_CMD_START input of FB to start the motor.
AUTO_CMD_STOP	BOOL	Rising edge needs to be given to AUTO_CMD_STOP input of FB to stop the motor.

Settings in SCADA side	Data type	Start / Stop Motor in Auto Mode
No settings need to be done.		

Set motor to manual mode

The motor is forced to manual mode. EN_AUTO = FALSE.

The motor can be operated in manual mode if EN_AUTO is either TRUE or FALSE.

The difference is that if EN_AUTO is TRUE, the switching between Auto and Manual is possible, else the motor and controller are both to Manual.

Settings in FB side	Data type	Set Motor to Manual Mode
REMOTE	BOOL	ACTIVE
RDY	BOOL	ACTIVE

Settings in SCADA side	Data type	Set Motor to Manual Mode
SCADA.CMDMAN	BOOL	Rising edge of SCADA.CMDMAN input to reset auto mode if it was set before

Start / stop motor in manual mode

Settings in FB side	Data type	Start / Stop Motor in Manual Mode
INHIB_FCT_ERR_TIME	TIME	The value of INHIB_FCT_ERR_TIME has to be greater than 0 s to avoid functional error.
EN_START	BOOL	ACTIVE
EN_STOP	BOOL	ACTIVE

Settings in SCADA side	Data type	Start / Stop Motor in Manual Mode
CMDSTR	BOOL	Rising edge of CMDSTR needs to be given.
CMDSTP	BOOL	Rising edge of CMDSTP needs to be given.

In automatic mode the motor can be started/stopped using the function block inputs (AUTO_CMD_START/AUTO_CMD_STOP).

In manual mode the motor can be started and stopped from the SCADA faceplate.

The function block includes supervision of the feedback signals RUN and STOP from the motor.

If the motor fails to run or stop within the supervision time INHIB_FCT_ERR_TIME, it will generate a functional error.

If the function block input RDY is FALSE, then an external error is generated. This function block can be used in combination with the object type MOTCON_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Examples

The function block is used for controlling a variable speed drive motor, which in turn can be used for controlling the level of fluid in a tank.

These components are included in the following example:

- Tank
- Level measurement
- Pump
- Main power supply, circuit breaker (or similar)

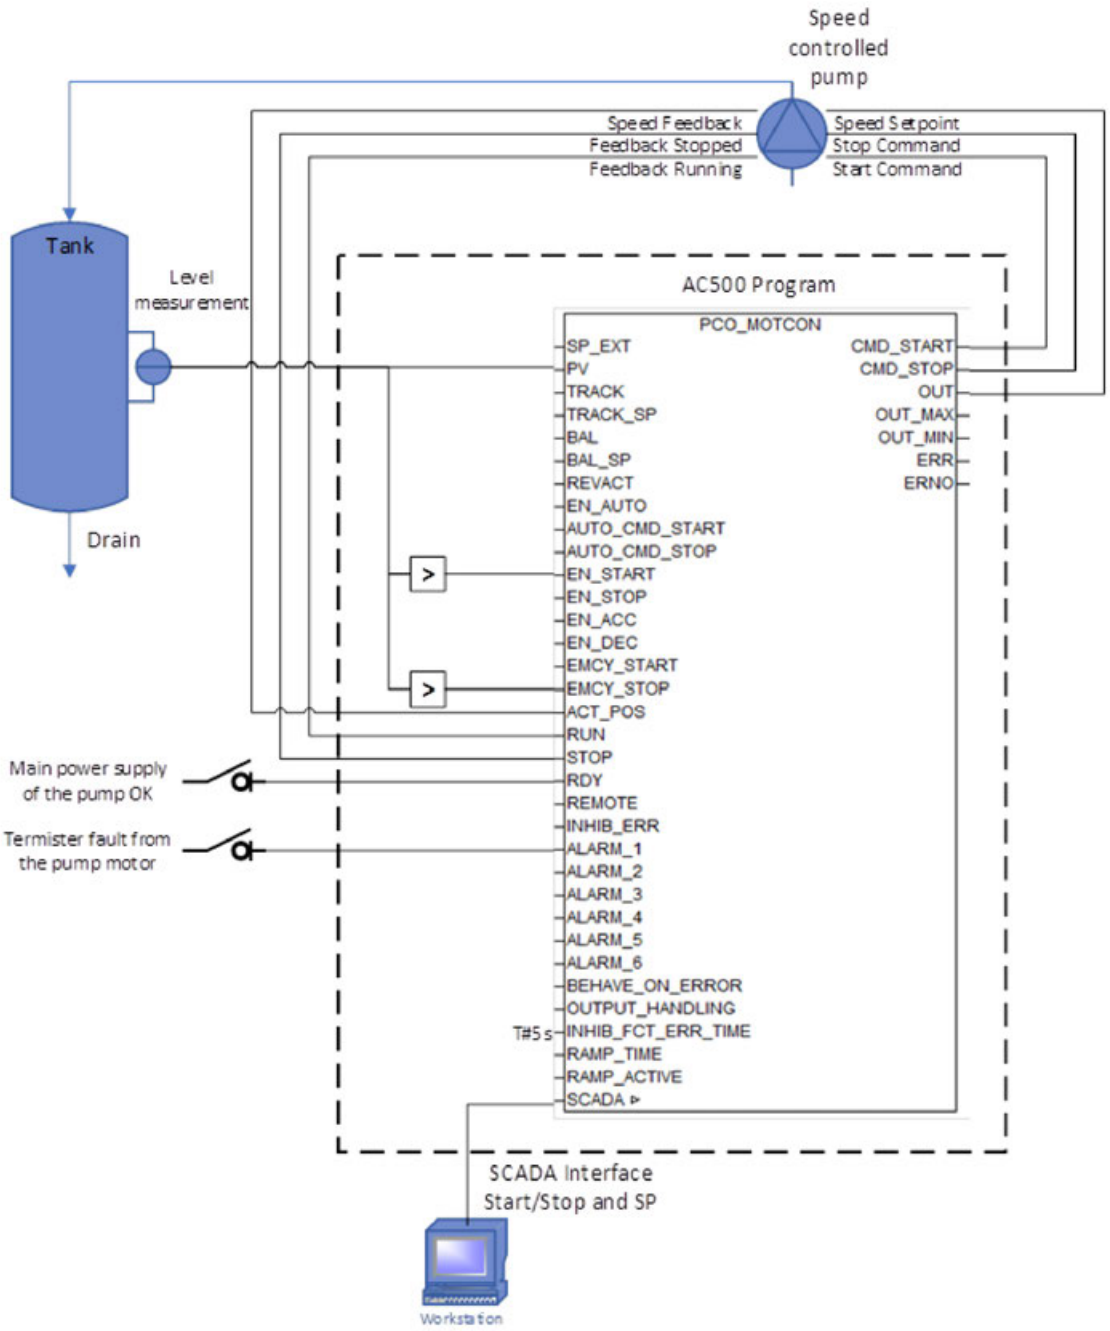
Manual mode:

- Pump controlled by the operator.

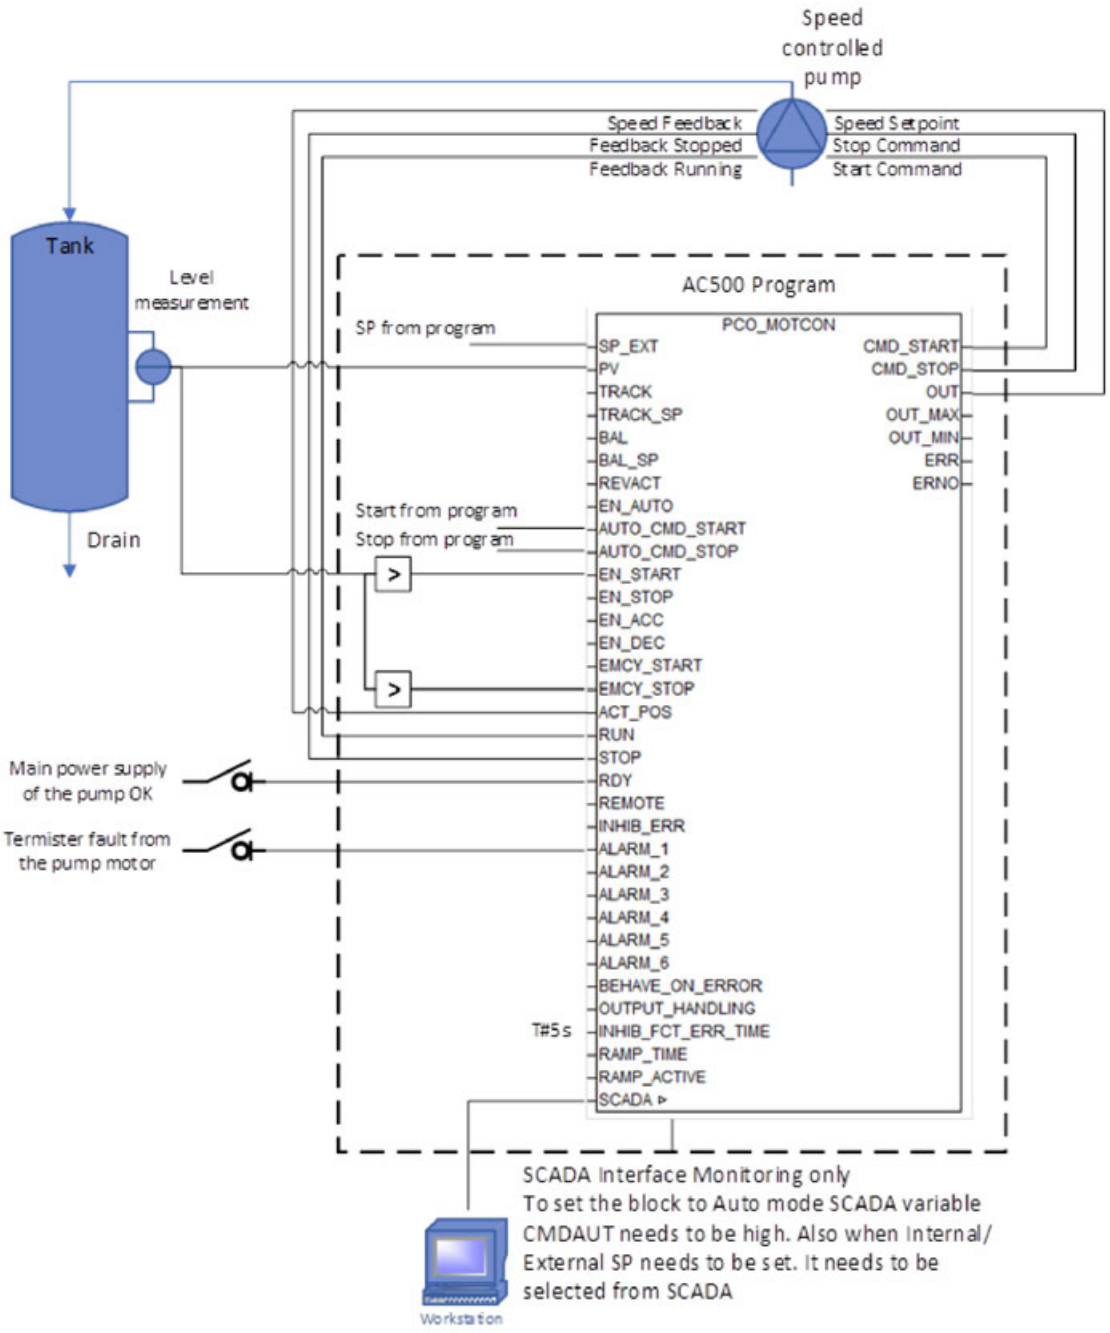
Automatic mode:

- Pump controlled by the AC500 controller.

PCO_MOTCON manual mode example



PCO_MOTCON automatic mode example



Scaling

Scaling of the SCADA Parameters

In the 800xA system the values coming from the PLC are shown by default 1:1 in the operator screens and faceplates.

The default scaling is 0 ... 100 from PLC is shown as 0 % … 100 % or 0 % ... 100.00 % for the operator (SCADA). Therefore a scaling must be done for most signals either in the *“Bulk Data Manager”* or directly in the *Engineering Workplace* > *Control Structure* > *…* > *Signal Configuration* > *Range*.

Assuming that all signals on the operator workplace should be shown in 0 % … 100 % the following table gives an overview of the scaling of the PLC values in the 800xA system.

PVmin and PVmax are here the minimum and maximum of the PV input, reflecting the process value in the PLC program. The PV typically comes from the output of the function block PCO_ANAALM. This scales its IN, coming directly from the analog input, to the OUT according to the inputs SCALE_MIN and SCALE_MAX.

The process value, e.g. 0 bar ... 16 bar can so be rescaled to the value 0 ... 16000 (SCALE_MIN … SCALE_MAX).

OPC	**FB**	**AC500**		**800xA**		**Remark**
Signal name SCADA.x	**In/Output-name**	**Range default**	**Range actual program**	**PLC Range def.: 0…100**	**SCADA Range def: 0…100% or 0…100.00%**	
PV_VALUE	PV	0…27648	PVmin…PVmax PVmin … PVmax	PVmin…PVmax	0…100	
SPX_VALUE	SP_EXT	0…27648	PVmin…PVmax	PVmin…PVmax	0…100	
	TRACK_SP	0…10000	0…10000 fix			
	BAL_SP	0…10000	0…10000 fix			
ACT_VALUE	ACT_POS	0…10000	ACTmin… ACTmax	ACTmin…ACTmax	0…100	
OUT_PAR	-	0…10000	0…10000 fix	0…10000	0…100	
OL_PAR	-	0…10000	0…10000 fix	0…10000	0…100	Set from 800xA
OH_PAR	-	0…10000	0…10000 fix	0…10000	0…100	Set from 800xA
	OUT	0…27648		-	-	
OUT_VALUE	-	0…10000		0…10000	0…100	Scaled from OUT. Seen in 800xA
SPI_PAR	-	0…27648	-	PVmin…PVmax	0…100.00	Set from 800xA
KP_PAR	-	0…100	0…(27648 / (PVmax- PVmin))	PVmin…PVmax or PVmin/100…PVmax/100	0…100.00 (%) or 0..1.00 (as factor)	
TD_PAR	-			0...1000	0...1000.00	
TI_PAR	-			0...1000	0...1000.00	

Scaling of the SCADA.PV_VALUE

The output from the controller is based on 0 % ... 100 % → 0 ... 27648 for connection direct to an analog output of the AC500 I/Os.

To show the PV in % in 800xA, it must be scaled accordingly in the 800xA signal configuration:

SCADA.Signal_Configuration.Range.Low limit = 0

SCADA.Signal_Configuration.Range.High limit = 100

SCADA.Signal_Configuration.Range.Low limit in PLC = 0

SCADA.Signal_Configuration.Range.High limit in PLC = 27648

Scaling of the Setpoints, SCADA.SPI_PAR and SCADA.SPX_VALUE

SCADA.SPI_PAR and SCADA.SPX_VALUE must have the same scaling as the process value PV.

Scaling of the Parameter SCADA.KP_PAR

If the setpoint and the process value (PV) do not have equal scaling (0 ... 27648), there is a need for scaling the SCADA.KP_PAR parameter in 800xA to achieve the right proportional gain.

The scaling of the coefficient of proportionality (SCADA.KP_PAR) is dependent on the scaling of the process value (PV).

The PV typically comes from the output of the function block PCO_ANAALM. This scales the IN, coming directly from the analog input, to the OUT according to the inputs SCALE_MIN and SCALE_MAX.

The process value, e.g. 0 bar ... 16 bar can so be rescaled to the value 0 ... 16000 (SCALE_MIN ... SCALE_MAX).

The scaling of the KP [%] is then calculated by the formula:

$$KP[\%] = \frac{Out_{\max} - Out_{\min}}{PV_{\max} - PV_{\min}} \times 100 = \frac{27648 - 0}{SCALE_{\max} - SCALE_{\min}} \times 100$$

In the mentioned example, 100 % of KP.

$$100\ \%\ of\ KP = \frac{[27648 - 0]}{[16000 - 0]} \times 100 = 172.8$$

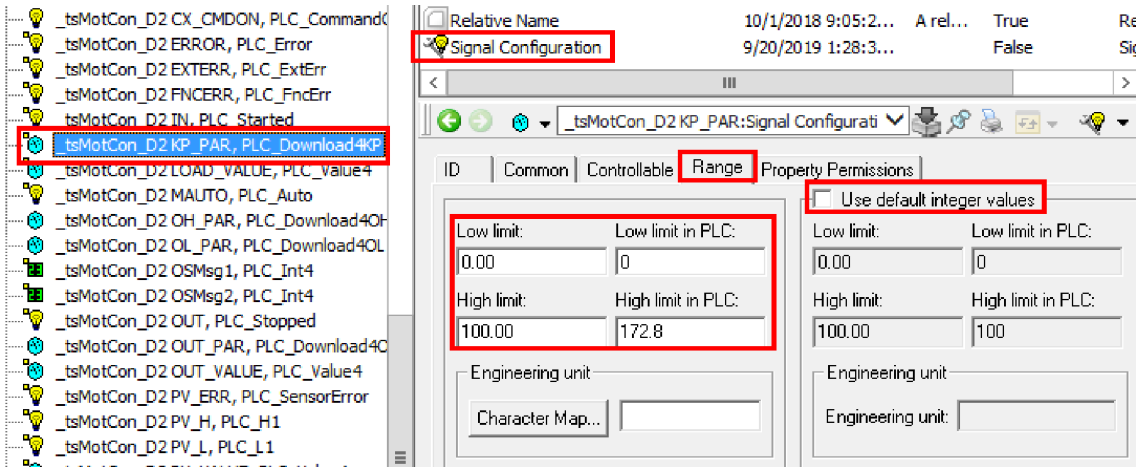
If the wanted range of SCADA.KP_PAR in SCADA is chosen to be 100 %, then the range in SCADA control structure should be adapted to

SCADA.Signal Configuration.Range.Low limit = 0

SCADA.Signal Configuration.Range.High limit =100

SCADA.Signal Configuration.Range.Low limit in PLC = 0

SCADA.Signal Configuration.Range.High limit in PLC = [27648 - 0] / [16000 - 0] × 100 = 172.8



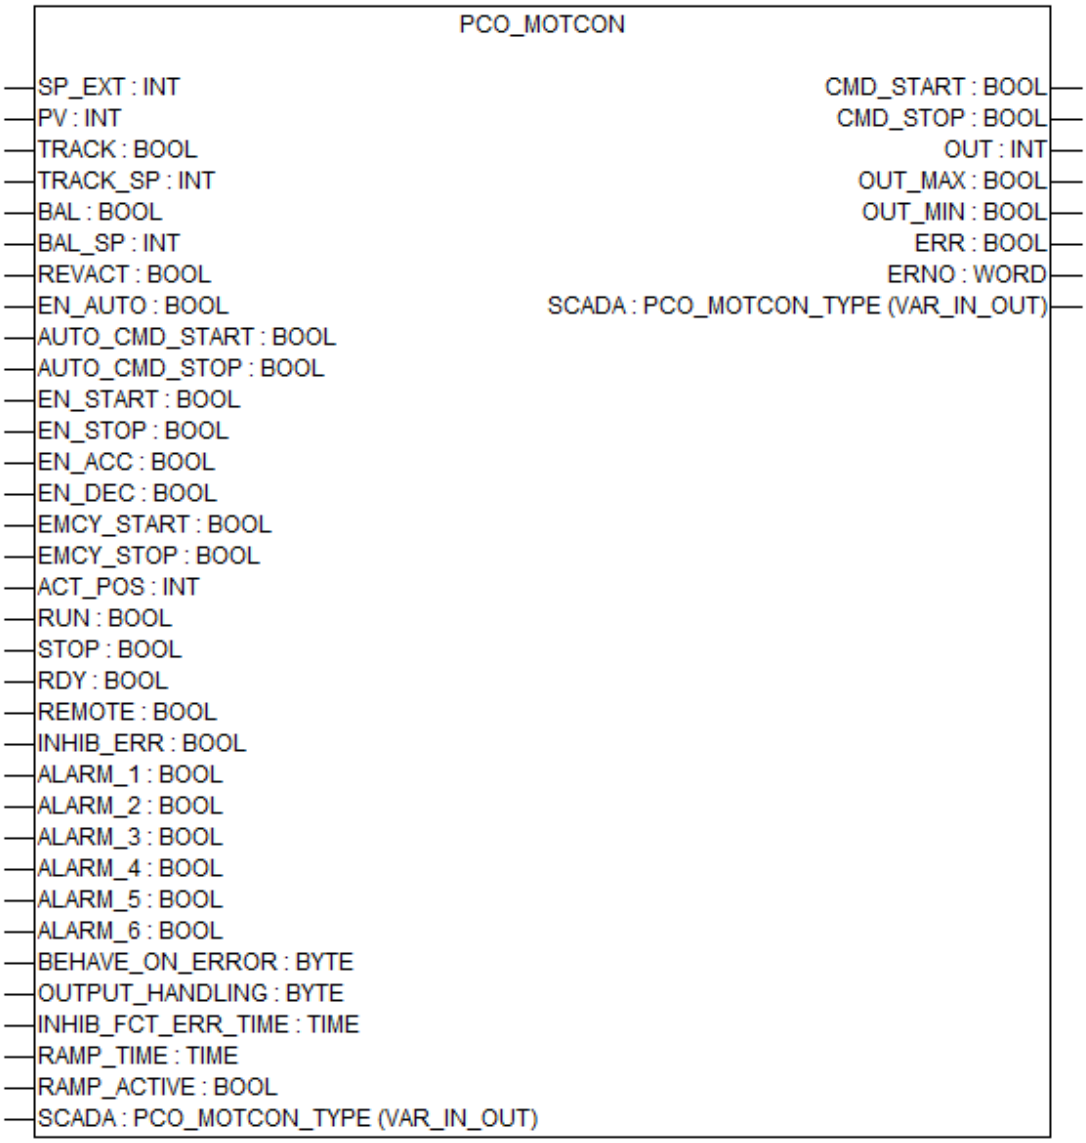
Scaling of the TRACK_SP AND BAL_SP

Input range of TRACK_SP or BAL_SP is 0 ... 10000 and the controller OUT range is 0 ... 27648.

So if the TRACK/BAL_SP is x then the controller output is defined as:

$$OUT = \frac{x}{10000} \times 27648$$

Input description



SP_EXT

Data type	Default value	Range	Unit
INT	0	0 ... 27648	-

External setpoint.

Calculated setpoint or output from another PID controller (e.g. PCO_PIDCON) in a cascade control system.

PV

Data type	Default value	Range	Unit
INT	0	0 ... 27648	-

Process value (PV) to be controlled.

TRACK

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Tracking mode.

PCO_MOTCON can be set in Tracking mode if the value of TRACK is TRUE.

Output of the controller will be set to TRACK_SP.

Tracking mode has higher priority compared to balancing mode.

TRACK is independent of operation mode of PCO_MOTCON.

TRACK_SP

Data type	Default value	Range	Unit
INT	0	0 ... 10000	-

Tracking setpoint.

Output of the controller will be set to TRACK_SP if value of TRACK is TRUE.

BAL

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Balancing mode.

PCO_MOTCON can be set in Balancing mode if value of BAL is TRUE and value of TRACK is FALSE.

Output of the controller will be set to BAL_SP.

BAL is independent of operation mode of PCO_MOTCON.

BAL_SP

Data type	Default value	Range	Unit
INT	0	0 ... 10000	-

Balancing setpoint.

Output of the controller will be set to BAL_SP if value of BAL is TRUE.

REVACT

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Reverse Action

Value of REVACT is FALSE, Controller will increase output if Setpoint is less than Process value.

Value of REVACT is TRUE, Controller will decrease output if Setpoint is greater than Process value.

EN_AUTO

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable automatic mode of the PCO_MOTCON.

PCO_MOTCON can be set in automatic mode if value of EN_AUTO is TRUE.

PCO_MOTCON is forced in manual mode if value of EN_AUTO is FALSE.

AUTO_CMD_START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Force the motor to start if it is in automatic mode.

E.g.AUTO_CMD_START could be activated from a sequence in the PLC program. The function block reacts on "0" to "1" transition of this input.

If AUTO_CMD_START and AUTO_CMD_STOP are active at the same time, then the commands CMD_START and CMD_STOP get reset.

AUTO_CMD_STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Force the motor to stop if the actuator is in automatic.

AUTO_CMD_STOP could be activated from a sequence in the PLC program. The function block reacts on "0" to "1" transition of this input.

If AUTO_CMD_START and AUTO_CMD_STOP are active at the same time, then the commands CMD_START and CMD_STOP get reset.

EN_START

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable start of the motor.

Motor can be started if value of EN_START is TRUE.

Motor cannot be started if value of EN_START is FALSE.

EN_START is independent of operation mode of PCO_MOTCON.

EN_START has no effect in case of emergency start of motor EMCY_START.

EN_START has no effect on a motor already running.

EN_STOP

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable stop of the motor.

Motor can be stopped if value of EN_STOP is TRUE.

Motor cannot be stopped if value of EN_STOP is FALSE.

EN_STOP is independent of operation mode of PCO_MOTCON.

EN_STOP has no effect in case of emergency stop of motor EMCY_STOP.

EN_STOP has no effect on an already stopped motor.

EN_ACC

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable increase of controller output.

Controller can increase output if value of EN_ACC is TRUE.

Independent of operation mode of PCO_MOTCON.

EN_DEC

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable decrease of controller output.

Controller can decrease output if value of EN_DEC is TRUE.

Independent of operation mode of PCO_MOTCON.

EMCY_START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Emergency start of motor.

Motor will start if value of EMCY_START is TRUE and value of EMCY_STOP is FALSE.

If value of EMCY_START is TRUE and value of EMCY_STOP is TRUE, the motor will stop.

Independent of operation mode of PCO_MOTCON.

EMCY_STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Emergency stop of motor.

Motor will stop if value of EMCY_STOP is TRUE.

If value of EMCY_START is TRUE and value of EMCY_STOP is TRUE, the motor will stop.

Independent of operation mode of PCO_MOTCON.

ACT_POS

Data type	Default value	Range	Unit
INT	0	0 ... 10000	-

Feedback speed of motor.

RUN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Feedback signal from the motor.

Motor is running if the value of RUN is TRUE.

Independent of operation mode of PCO_MOTCON.

STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Feedback signal from the motor.

Motor is stopped if the value of STOP is TRUE.

Independent of operation mode of PCO_MOTCON.

RDY

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Motor is ready for operation.

Motor is ready for operation if value of RDY is TRUE.

Value of RDY is FALSE results in an external error.

Independent of operation mode of PCO_MOTCON.

REMOTE

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Allow motor to be controlled from SCADA.

Value of REMOTE is TRUE, control from SCADA and function block is enabled.

Value of REMOTE is FALSE, motor is controlled only from function block.

PCO_MOTCON will align the block according to feedback signals.

Independent of operation mode of PCO_MOTCON.

INHIB_ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Suppression of alarms.

If value of INHIB_ERR is TRUE, all alarms from PCO_MOTCON are suppressed.

Independent of operation mode of PCO_MOTCON.

EXT_ACK

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

External acknowledge of alarms.

If value of EXT_ACK is TRUE, all alarms from PCO_MOTCON are acknowledged.

Independent of operation mode of PCO_MOTCON.

Alarm_1

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 1.

If value of ALARM_1 is TRUE Alarm_1 is active.

Independent of operation mode of PCO_MOTCON.

Alarm_2

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 2.

If value of ALARM_2 is TRUE Alarm_2 is active.

Independent of operation mode of PCO_MOTCON.

Alarm_3

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 3.

If value of ALARM_3 is TRUE Alarm_3 is active.

Independent of operation mode of PCO_MOTCON.

Alarm_4

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 4.

If value of ALARM_4 is TRUE Alarm_4 is active.

Independent of operation mode of PCO_MOTCON.

Alarm_5

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 5.

If value of ALARM_5 is TRUE Alarm_5 is active.

Independent of operation mode of PCO_MOTCON.

Alarm_6

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 6.

If value of ALARM_6 is TRUE Alarm_6 is active.

Independent of operation mode of PCO_MOTCON.

BEHAVE_ON_ERROR

Data type	Default value	Range	Unit
BYTE	0	0 ... 3	-

Actions that need to be executed by the FB at the event of error as set by the user.

The user can set a range of values from 0 ... 3.

BEHAVE_ON_ERROR = 0 causes the output to remain unaffected in case of a functional error or an external error (Not ready).

BEHAVE_ON_ERROR = 1 causes a stop command in case of a functional error.

BEHAVE_ON_ERROR = 2 causes a stop command in case of an external error.

BEHAVE_ON_ERROR = 3 causes a stop command in case of a functional error or an external error.

This parameter is independent of operation mode (whether Auto/ Manual) of PCO_MOTCON.

OUTPUT_HANDLING

Data type	Default value	Range	Unit
BYTE	0	0 ... 2	-

Behavior of command outputs, CMD_START / CMD_STOP.

The user can set a range of values from 0 ... 2

OUTPUT_HANDLING = 0 causes the output (CMD_START / CMD_STOP) to be reset at RUN or STOP feedback.

OUTPUT_HANDLING = 1 causes the output (CMD_START / CMD_STOP)) to remain active at RUN or STOP feedback.

With OUTPUT_HANDLING = 2 the output (CMD_START / CMD_STOP) is performed as 1 s pulse. This parameter is independent of operation mode (whether Auto / Manual) of PCO_MOTCON.

INHIB_FCT_ERR_TIME

Data type	Default value	Range	Unit
TIME	TIME#5s	-	-

Maximum delay time from command to response from process.

If response is not received within this time limit, a function error will be generated.

RAMP_TIME

Data type	Default value	Range	Unit
TIME	TIME#30s	-	-

Actuator ramp time from 0 % ... 100 %

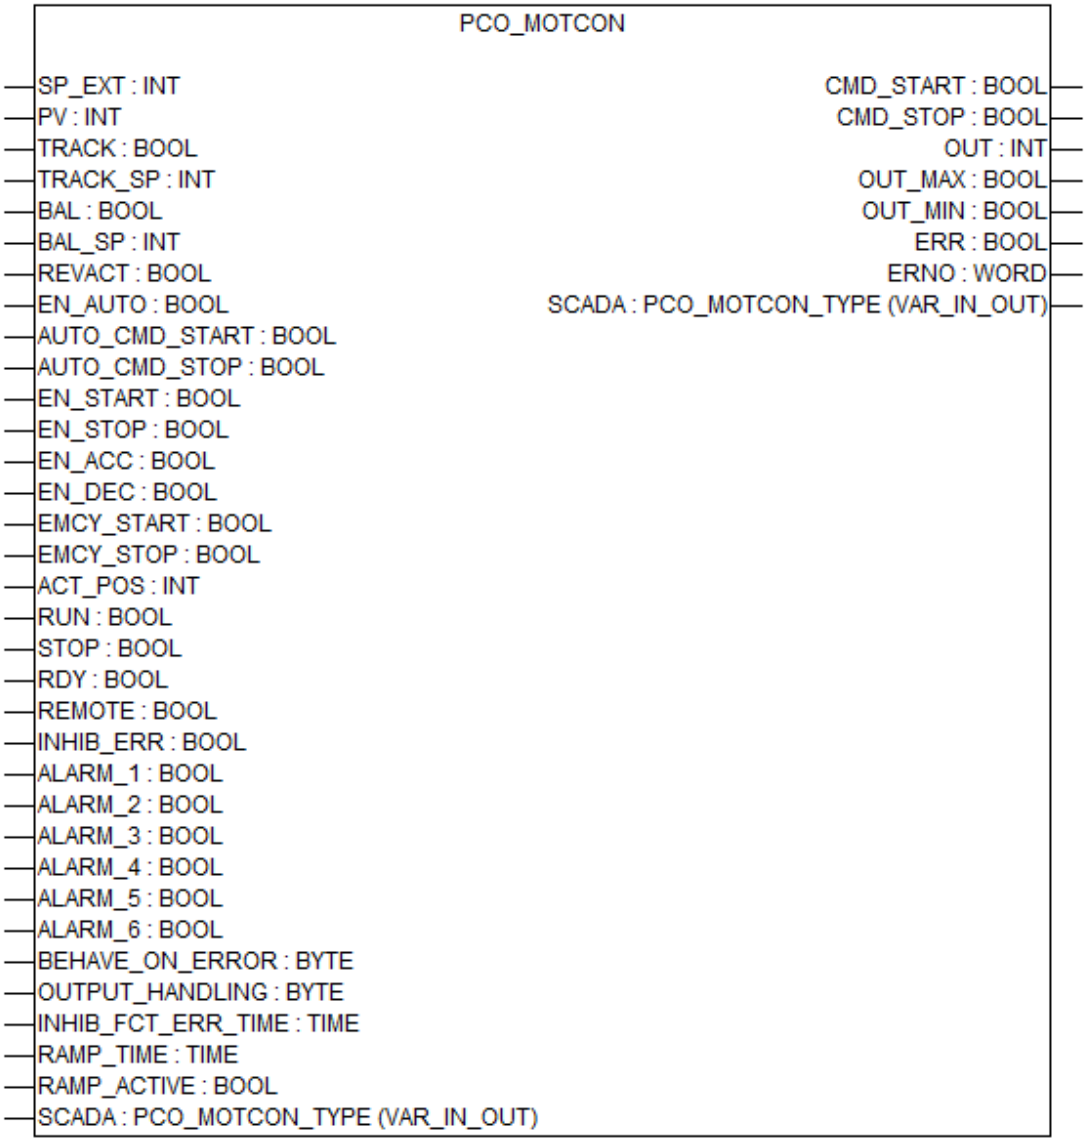
RAMP_ACTIVE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The value RAMP_ACTIVE is TRUE activates ramp under manual positioning.

The value RAMP_ACTIVE is FALSE activates no ramp.

Output description



CMD_START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Command output start, to be connected to hardware output.

CMD_STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Command output stop, to be connected to hardware output.

OUT

Data type	Default value	Range	Unit
INT	0	0 ... 27648	-

Controller output to the motor to attain the desired speed of the motor.

OUT_MAX

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Output max limit reached, controller at max limit.

OUT_MIN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Output min limit reached, controller at min limit.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Common alarm, including:

- Functional error
- External error (input RDY)
- Input Parameter error
- ALARM_1
- ALARM_2
- ALARM_3
- ALARM_4
- ALARM_5
- ALARM_6
- EMCY_START
- EMCY_STOP

ERNO

Data type	Default value	Range	Unit
WORD	0	-	-

Error number

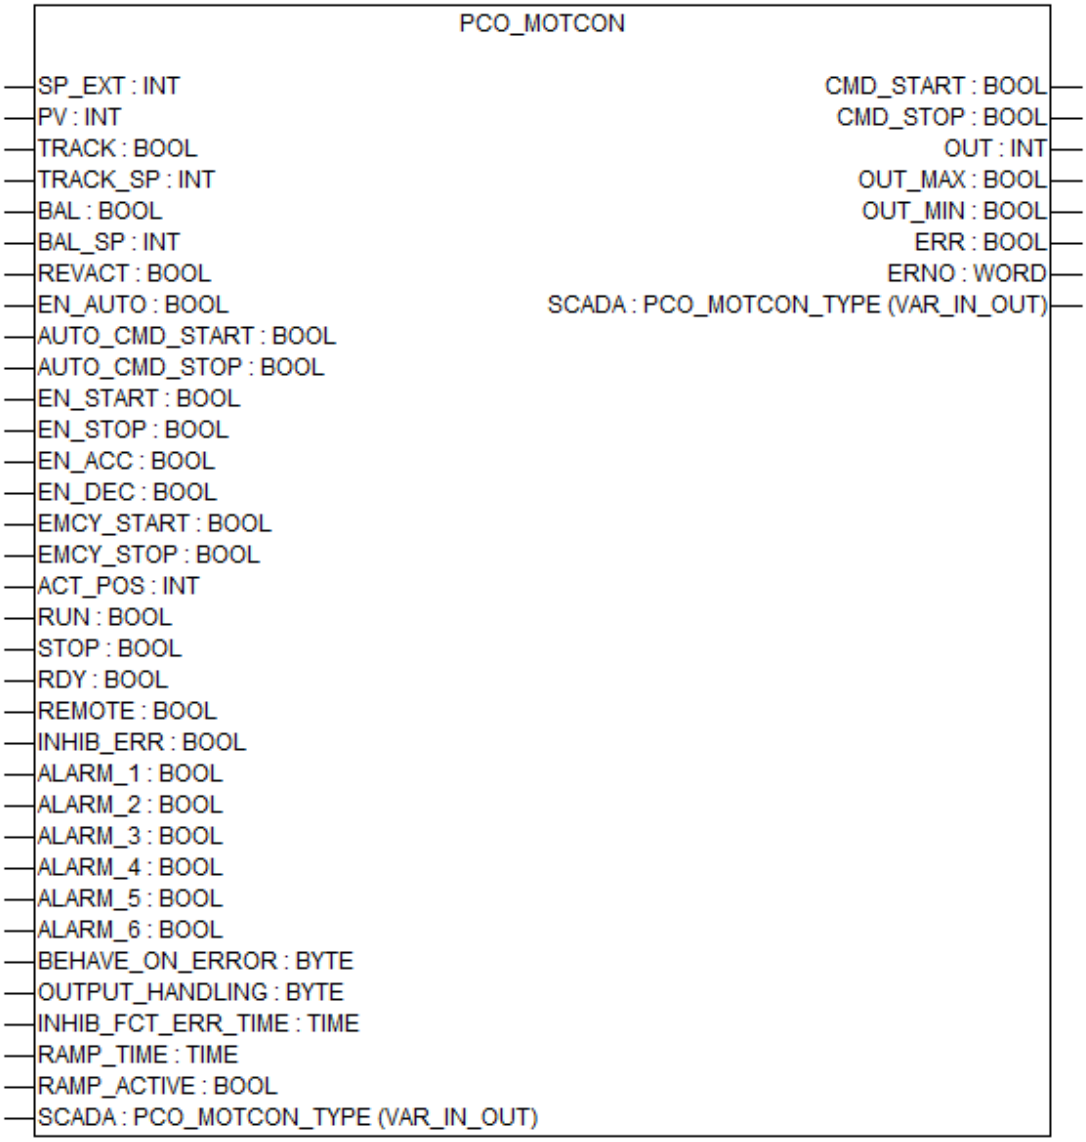
Output provides an error identifier if an invalid value was applied to an input.

ERNO always must be considered together with the output ERR.

The value output at ERNO is only valid if value of ERR is TRUE.

The error messages encoding is explained in *“Standard Function Block Libraries AC500”* in *“Error Messages of the Function Block Libraries”*.

Input/output description



SCADA

Data type	Default value	Range	Unit
PCO_MOTCON_ TYPE	-	-	-

Structure variable for communication between AC500 and SCADA system.

To retain the variable value in case of power ON/OFF or download, the variable connected to the SCADA In/Output should be declared as (global) retain persistant (or use %R area) variable in the program.

Detailed information on the scaling see *“Scaling” on page 3089*.

Parameter	Data type	Description	In-/Output
SCADA.CMDSTR	BOOL	Start command in Manual mode	Input
SCADA.CMDSTP	BOOL	Stop command in Manual mode	Input

Parameter	Data type	Description	In-/Output
SCADA.CMDAUT	BOOL	Auto command	Input
SCADA.CMDMAN	BOOL	Manual command	Input
SCADA.CMDRES	BOOL	Acknowledge active alarms	Input
SCADA.MAUTO	BOOL	Motor in automatic mode	Output
SCADA.IN	BOOL	Motor is running	Output
SCADA.OUT	BOOL	Motor is stopped	Output
SCADA.REMOTE	BOOL	Motor can be controlled from OS REMOTE = FALSE → Local operation	Output
SCADA.READY	BOOL	Motor is ready for operation	Output
SCADA.FNCERR	BOOL	Functional error	Output
SCADA.EXTERR	BOOL	External error (is generated when the motor is not ready)	Output
SCADA.AL1	BOOL	Auxiliary alarm no. 1	Output
SCADA.AL2	BOOL	Auxiliary alarm no. 2	Output
SCADA.AL3	BOOL	Auxiliary alarm no. 3	Output
SCADA.AL4	BOOL	Auxiliary alarm no. 4	Output
SCADA.AL5	BOOL	Auxiliary alarm no. 5	Output

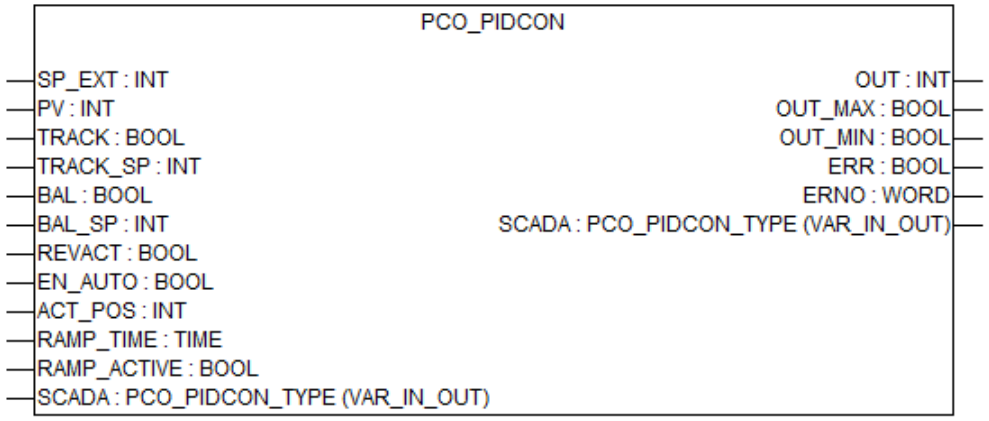
PCO PIDCON



This is a standard PID controller that can be used to control any component that has an analog positioning option.

The PID controller can be switched between three different setpoints:

- **Internal Setpoint**
  Set from SCADA faceplate, variable in SCADA side is SPI_PAR.
- **External Setpoint**
  Function block input SP_EXT, calculated setpoint or output from another PID controller (e.g. PIDCON) in a cascade control system.
- **Tracking Setpoint**
  The output of the PID controller follows the function block input tracking setpoint, TRACK_SP and if TRACK input is active.

To make the controller follows various setpoints, the following variables need to be set:

The values set below are default values, the user can change based on the application.

Settings in SCADA side	Data type	When the controller must follow		
		Internal Setpoint	External Setpoint	Tracking Setpoint
SCADA.KP_PAR	INT	1	1	1
SCADA.TD_PAR	INT	0	0	0
SCADA.TI_PAR	INT	1	1	1
SCADA.OH_PAR	INT	10000	10000	10000
SCADA.OL_PAR	INT	0	0	0
SCADA.CI_CMDON	BOOL	TRUE	-	-
SCADA.SPI_PAR	INT	Needs to be set	-	-
SCADA.CX_CMDON	BOOL	-	TRUE	-

Settings in FB side	Data type	When the controller must follow		
		Internal Set-point	External Set-point	Tracking Set-point
EN_AUTO	BOOL	TRUE	TRUE	TRUE
SP_EXT	INT	-	Needs to be set	-
TRACK	BOOL	-	-	TRUE
TRACK_SP	INT	-	-	Needs to be set

By switching to one of these setpoints, when command from SCADA, i.e. SCADA.SPIACT or SCADA.SPXACT or SCADA.CTACT is active, the PID controller will be put into automatic mode.

It is possible to set the PID controller into manual mode from the SCADA system to allow manual positioning.

The manual positioning can be done in two ways, both controlled form the SCADA faceplate.

1. Stepwise 1 % up / down or 5 % up / down.

   This is manually set by the following variables on the SCADA faceplate:

   - SCADA.CMDUP1
   - SCADA.CMDUP5
   - SCADA.CMDDW1
   - SCADA.CMDDW5

   The controller output varies based on the command given.

2. Download a new position. Manual position is set through OUT_PAR variable on the SCADA faceplate. The controller output varies accordingly.

If BAL (Input) of the function block is TRUE, then controller output varies according to BAL_SP entered at the input of the function block. This has higher priority over manual commands or external or internal setpoints.

But if TRACK input is selected then the controller follows the TRACK_SP.

When the controller is set to TRACK mode, the controller gets set to auto mode, whereas when the controller is set to BAL mode, the controller is not in auto mode. In both cases the controller output is not dependent on the actual process value.

The function block has built in a ramp to slow down the manual positioning. The ramp can be switched ON by the input RAMP_ACTIVE by setting the RAMP_ACTIVE high. The ramp time can be entered at RAMP_TIME input of the function block.

Cycle time for the program must be faster than RAMP_TIME / 100 to calculate the actuator time correctly!

6 different alarms can be connected to the function block
(ALARM_1 → ALARM_6, Torque switch etc.).

The valve can be switched to automatic or manual mode from the SCADA faceplate, if the input EN_AUTO = TRUE.

This function block can be used in combination with the object type PIDCON_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Examples

The function block is used for controlling a PID controller which in turn controls the level of fluid in a tank.

These components are included in the following example:

- Tank
- Level measurement
- Pump

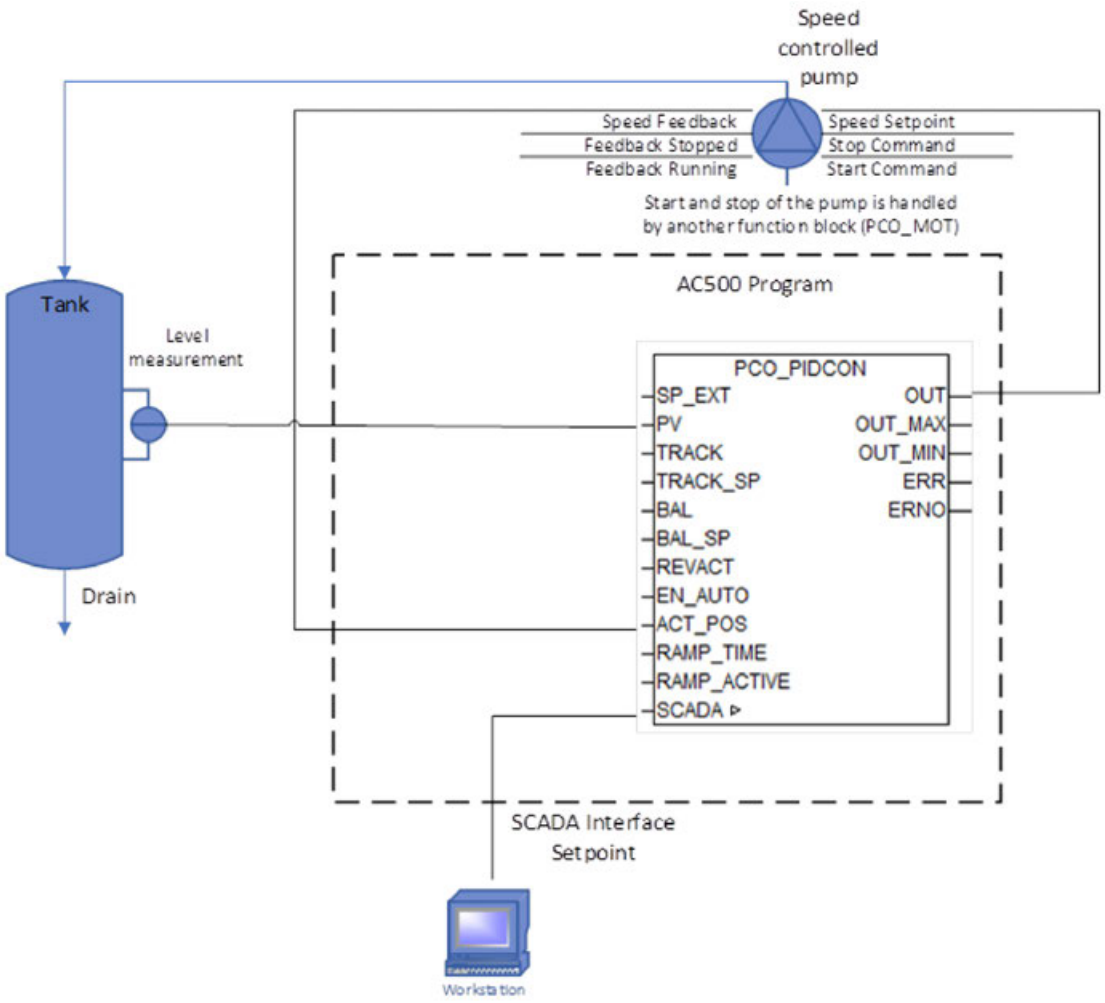
Manual mode:

- Pump controlled by the operator.

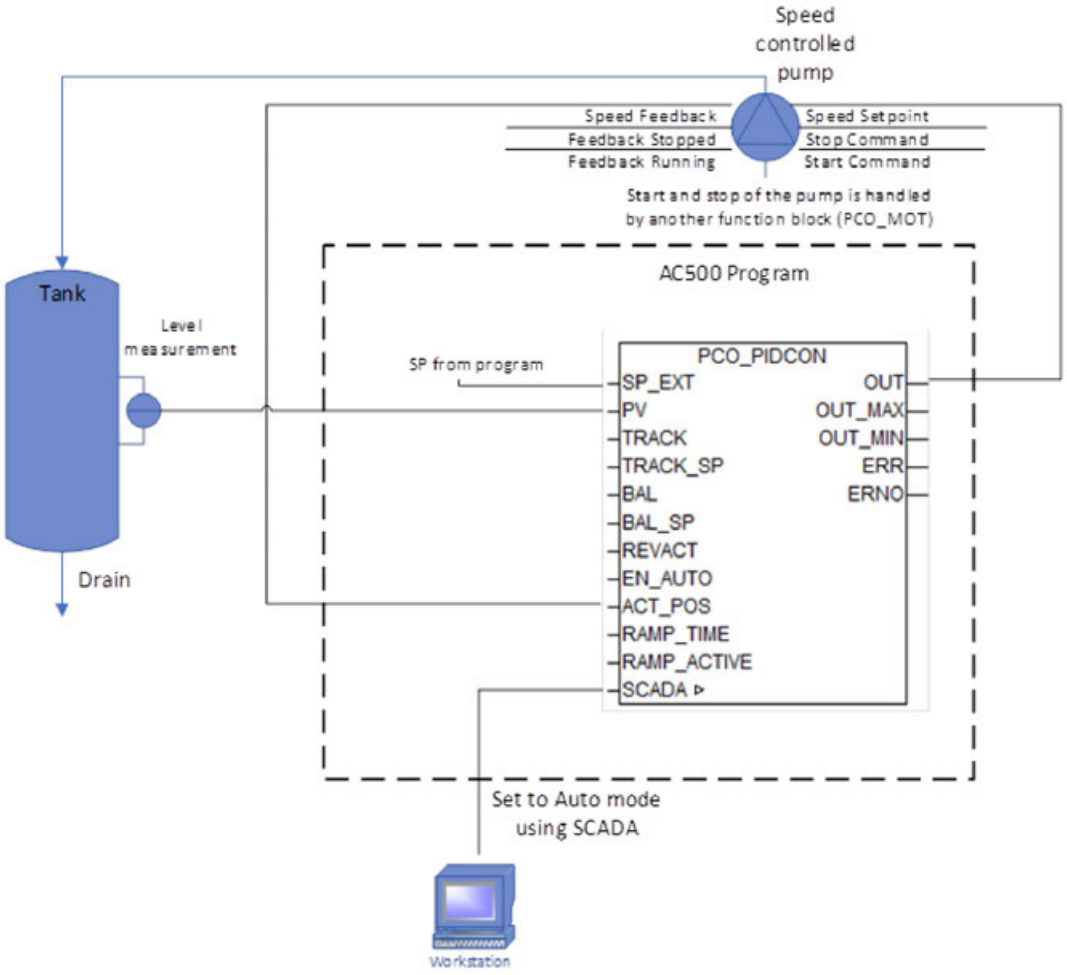
Automatic mode:

- Pump controlled by theAC500 controller.

PCO_PIDCON manual mode example



PCO_PIDCON automatic mode example



Scaling

Scaling of the SCADA Parameters

In the 800xA system the values coming from the PLC are shown by default 1:1 in the operator screens and faceplates.

The default scaling is 0 ... 100 from PLC is shown as 0 % … 100 % or 0 % ... 100.00 % for the operator (SCADA). Therefore a scaling must be done for most signals either in the *"Bulk Data Manager"* or directly in the *Engineering Workplace* > *Control Structure* > … > *Signal Configuration* > *Range*.

Assuming that all signals on the operator workplace should be shown in 0 % … 100 % the following table gives an overview of the scaling of the PLC values in the 800xA system.

PVmin and PVmax are here the minimum and maximum of the PV input, reflecting the process value in the PLC program. The PV typically comes from the output of the function block PCO_ANAALM. This scales its IN, coming directly from the analog input, to the OUT according to the inputs SCALE_MIN and SCALE_MAX.

The process value, e.g. 0 bar ... 16 bar can so be rescaled to the value 0 ... 16000 (SCALE_MIN … SCALE_MAX).

OPC	FB	AC500		800xA		Remark
Signal name SCADA.x	**In/Output-name**	**Range default**	**Range actual program**	**PLC Range def.: 0…100**	**SCADA Range def: 0…100% or 0…100.00%**	
PV_VALUE	PV	0…27648	PVmin…PVmax PVmin … PVmax	PVmin…PVmax	0…100	
SPX_VALUE	SP_EXT	0…27648	PVmin…PVmax	PVmin…PVmax	0…100	
	TRACK_SP	0…10000	0…10000 fix			
	BAL_SP	0…10000	0…10000 fix			
ACT_VALUE	ACT_POS	0…10000	ACTmin… ACTmax	ACTmin…ACTmax	0…100	
OUT_PAR	-	0…10000	0…10000 fix	0…10000	0…100	
OL_PAR	-	0…10000	0…10000 fix	0…10000	0…100	Set from 800xA
OH_PAR	-	0…10000	0…10000 fix	0…10000	0…100	Set from 800xA
	OUT	0…27648		-	-	
OUT_VALUE	-	0…10000		0…10000	0…100	Scaled from OUT. Seen in 800xA
SPI_PAR	-	0…27648	-	PVmin…PVmax	0…100.00	Set from 800xA
KP_PAR	-	0…100	0…(27648 / (PVmax- PVmin))	PVmin…PVmax or PVmin/100…PVmax/100	0…100.00 (%) or 0..1.00 (as factor)	
TD_PAR	-			0...1000	0...1000.00	
TI_PAR	-			0...1000	0...1000.00	

Scaling of the SCADA.PV_VALUE

The output from the controller is based on 0 % ... 100 % → 0 ... 27648 for connection direct to an analog output of the AC500 I/Os.

To show the PV in % in 800xA, it must be scaled accordingly in the 800xA signal configuration:

SCADA.Signal_Configuration.Range.Low limit = 0

SCADA.Signal_Configuration.Range.High limit = 100

SCADA.Signal_Configuration.Range.Low limit in PLC = 0

SCADA.Signal_Configuration.Range.High limit in PLC = 27648

Scaling of the Setpoints, SCADA.SPI_PAR and SCADA.SPX_VALUE

SCADA.SPI_PAR and SCADA.SPX_VALUE must have the same scaling as the process value PV.

Scaling of the Parameter SCADA.KP_PAR

If the setpoint and the process value (PV) do not have equal scaling (0 ... 27648), there is a need for scaling the SCADA.KP_PAR parameter in 800xA to achieve the right proportional gain.

The scaling of the coefficient of proportionality (SCADA.KP_PAR) is dependent on the scaling of the process value (PV).

The PV typically comes from the output of the function block PCO_ANAALM. This scales the IN, coming directly from the analog input, to the OUT according to the inputs SCALE_MIN and SCALE_MAX.

The process value, e.g. 0 bar ... 16 bar can so be rescaled to the value 0 ... 16000 (SCALE_MIN ... SCALE_MAX).

The scaling of the KP [%] is then calculated by the formula:

$$KP[\%] = \frac{Out_{\max} - Out_{\min}}{PV_{\max} - PV_{\min}} \times 100 = \frac{27648 - 0}{SCALE_{\max} - SCALE_{\min}} \times 100$$

In the mentioned example, 100 % of KP.

$$100\ \%\ of\ KP = \frac{[27648 - 0]}{[16000 - 0]} \times 100 = 172.8$$

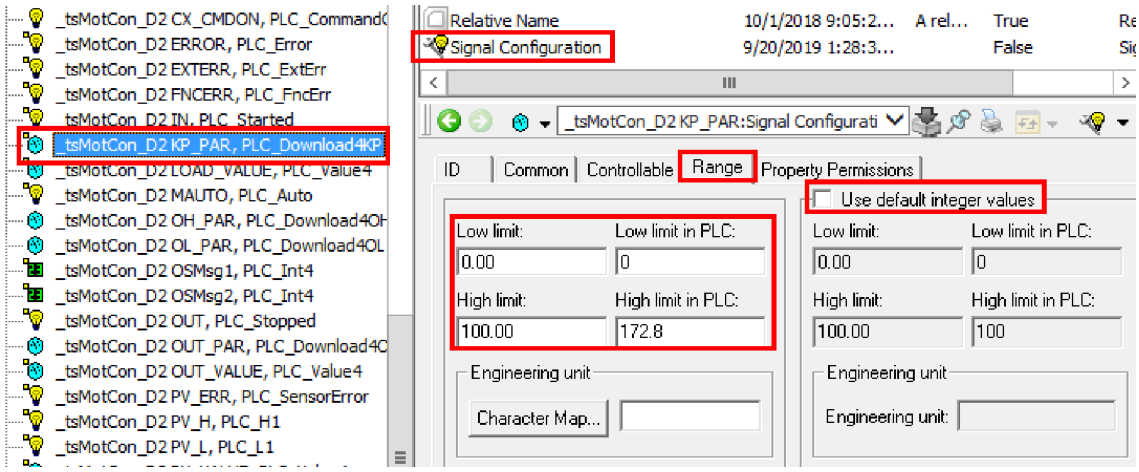
If the wanted range of SCADA.KP_PAR in SCADA is chosen to be 100 %, then the range in SCADA control structure should be adapted to

SCADA.Signal Configuration.Range.Low limit = 0

SCADA.Signal Configuration.Range.High limit =100

SCADA.Signal Configuration.Range.Low limit in PLC = 0

SCADA.Signal Configuration.Range.High limit in PLC = [27648 - 0] / [16000 - 0] × 100 = 172.8



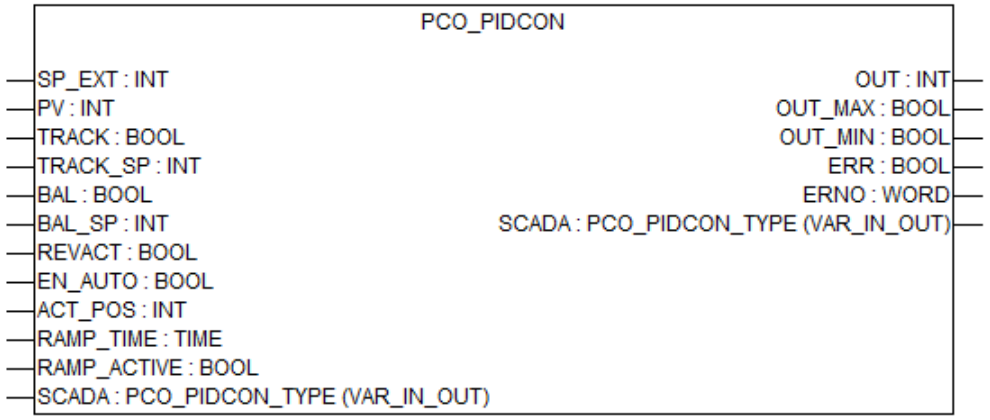
Scaling of the TRACK_SP AND BAL_SP

Input range of TRACK_SP or BAL_SP is 0 ... 10000 and the controller OUT range is 0 ... 27648.

So if the TRACK/BAL_SP is x then the controller output is defined as:

$$OUT = \frac{x}{10000} \times 27648$$

Input description



SP_EXT

Data type	Default value	Range	Unit
INT	0	0 ... 27648	-

External setpoint.

Calculated setpoint or output from another PID controller (e.g. PCO_PIDCON) in a cascade control system.

PV

Data type	Default value	Range	Unit
INT	0	0 ... 27648	-

Process value (PV) to be controlled.

TRACK

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Tracking mode.

PCO_PIDCON can be set in Tracking mode if the value of TRACK is TRUE.

Output of the controller will be set to TRACK_SP.

Tracking mode has higher priority compared to balancing mode.

TRACK is independent of operation mode of PCO_PIDCON.

TRACK_SP

Data type	Default value	Range	Unit
INT	0	0 ... 10000	-

Tracking setpoint.

Output of the controller will be set to TRACK_SP if value of TRACK is TRUE.

BAL

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Balancing mode.

PCO_PIDCON can be set in Balancing mode if value of BAL is TRUE and value of TRACK is FALSE.

Output of the controller will be set to BAL_SP.

BAL is independent of operation mode of PCO_PIDCON.

BAL_SP

Data type	Default value	Range	Unit
INT	0	0 ... 10000	-

Balancing setpoint.

Output of the controller will be set to BAL_SP if value of BAL is TRUE.

REVACT

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Reverse Action

Value of REVACT is FALSE, Controller will increase output if Setpoint is less than Process value.

Value of REVACT is TRUE, Controller will decrease output if Setpoint is greater than Process value.

EN_AUTO

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable automatic mode of the PCO_PIDCON.

PCO_PIDCON can be set in automatic mode if value of EN_AUTO is TRUE.

PCO_PIDCON is forced in manual mode if value of EN_AUTO is FALSE.

ACT_POS

Data type	Default value	Range	Unit
INT	0	0 ... 10000	-

Feedback speed of motor.

RAMP_TIME

Data type	Default value	Range	Unit
TIME	TIME#30s	-	-

Actuator ramp time from 0 % ... 100 %

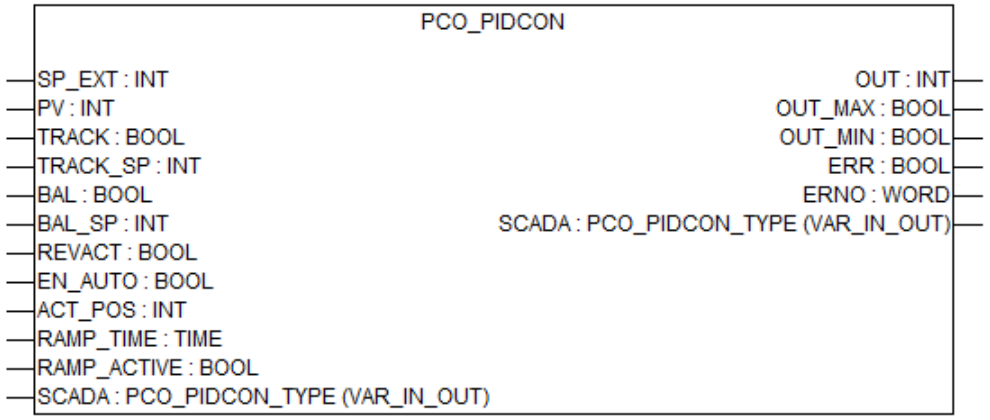
RAMP_ACTIVE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The value RAMP_ACTIVE is TRUE activates ramp under manual positioning.

The value RAMP_ACTIVE is FALSE activates no ramp.

Output description



OUT

Data type	Default value	Range	Unit
INT	0	0 ... 27648	-

Controller output to the motor to attain the desired speed of the motor.

OUT_MAX

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Output max limit reached, controller at max limit.

OUT_MIN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Output min limit reached, controller at min limit.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Common alarm, Input Parameter error.

ERNO

Data type	Default value	Range	Unit
WORD	0	-	-

Error number

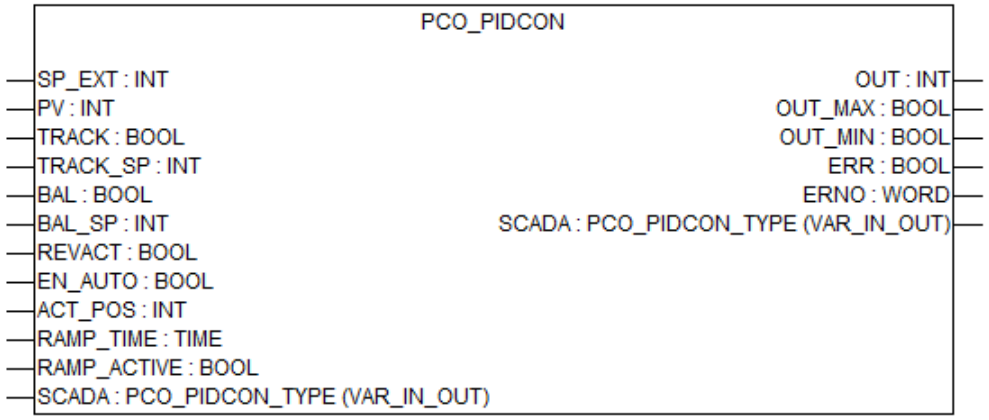
Output provides an error identifier if an invalid value was applied to an input.

ERNO always must be considered together with the output ERR.

The value output at ERNO is only valid if value of ERR is TRUE.

The error messages encoding is explained in *“Standard Function Block Libraries AC500”* in *“Error Messages of the Function Block Libraries”*.

Input/output description



SCADA

Data type	Default value	Range	Unit
STRUCTURE	-	-	-

Structure variable for communication between AC500 and SCADA system.

To retain the variable value in case of power ON/OFF or download, the variable connected to the SCADA In/Output should be declared as (global) retain persistant (or use %R area) variable in the program.

Detailed information on the scaling see *"Scaling" on page 3102*.

Parameter	Data type	Description	In-/Output

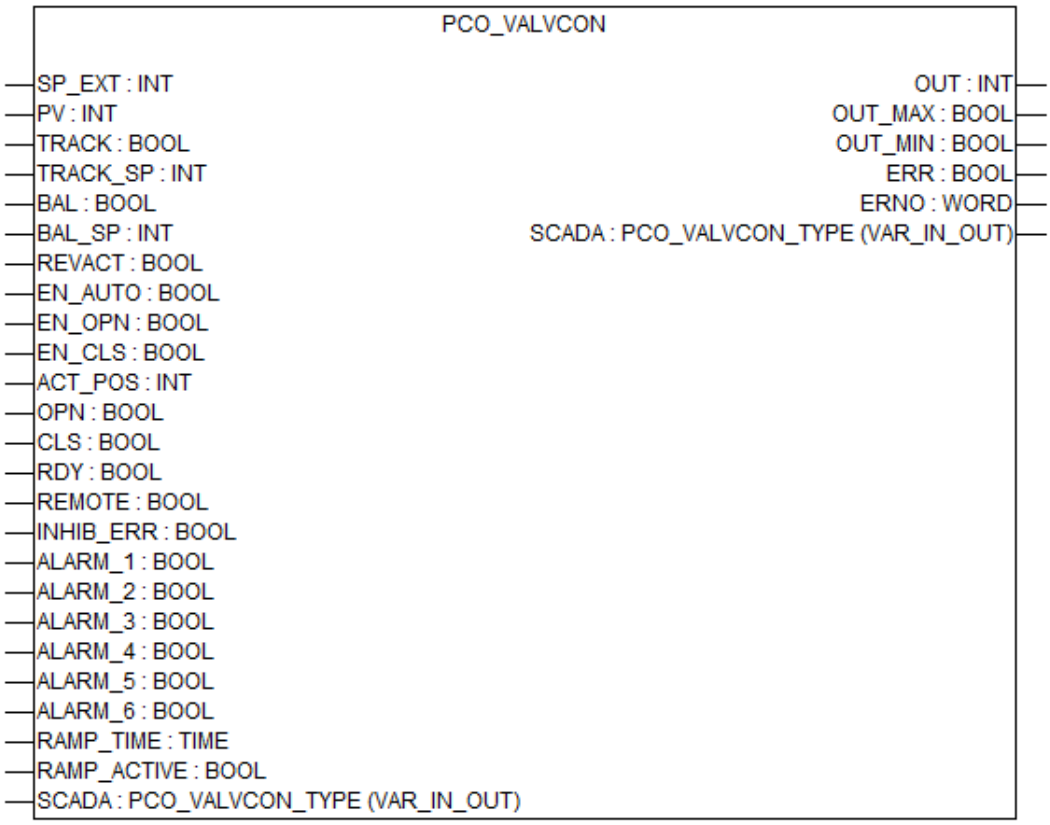
PCO_VALVCON



This function block is designed for controlling a variable position valve.

The function block is similar to PCO_VALV (open/close valve), but in addition to PCO_VALV the function block has a built in PID controller, used for position control of the valve.

The PID controller can be switched between three different setpoints:

- **Internal Setpoint**
  Set from SCADA faceplate, variable in SCADA side is SPI_PAR.
- **External Setpoint**
  Function block input SP_EXT, calculated setpoint or output from another PID controller (e.g. PIDCON) in a cascade control system.
- **Tracking Setpoint**
  The output of the PID controller follows the function block input tracking setpoint, TRACK_SP and if TRACK input is active.

To make the controller follows various setpoints, the following variables need to be set:

> *The values set below are default values, the user can change based on the application.*

Settings in SCADA side	Data type	When the controller must follow		
		Internal Setpoint	External Setpoint	Tracking Setpoint
SCADA.KP_PAR	INT	1	1	1
SCADA.TD_PAR	INT	0	0	0
SCADA.TI_PAR	INT	1	1	1
SCADA.OH_PAR	INT	10000	10000	10000
SCADA.OL_PAR	INT	0	0	0
SCADA.CI_CMDON	BOOL	TRUE	-	-
SCADA.SPI_PAR	INT	Needs to be set	-	-
SCADA.CX_CMDON	BOOL	-	TRUE	-

Settings in FB side	Data type	When the controller must follow		
		Internal Set-point	External Set-point	Tracking Set-point
EN_AUTO	BOOL	TRUE	TRUE	TRUE
SP_EXT	INT	-	Needs to be set	-
TRACK	BOOL	-	-	TRUE
TRACK_SP	INT	-	-	Needs to be set

By switching to one of these setpoints, when command from SCADA, i.e. SCADA.SPIACT or SCADA.SPXACT or SCADA.CTACT is active, the PID controller will be put into automatic mode.

It is possible to set the PID controller into manual mode from the SCADA system to allow manual positioning.

The manual positioning can be done in two ways, both controlled form the SCADA faceplate.

1. Stepwise 1 % up / down or 5 % up / down.

   This is manually set by the following variables on the SCADA faceplate:

   - SCADA.CMDUP1
   - SCADA.CMDUP5
   - SCADA.CMDDW1
   - SCADA.CMDDW5

   The controller output varies based on the command given.

2. Download a new position. Manual position is set through OUT_PAR variable on the SCADA faceplate. The controller output varies accordingly.

If BAL (Input) of the function block is TRUE, then controller output varies according to BAL_SP entered at the input of the function block. This has higher priority over manual commands or external or internal setpoints.

But if TRACK input is selected then the controller follows the TRACK_SP.

When the controller is set to TRACK mode, the controller gets set to auto mode, whereas when the controller is set to BAL mode, the controller is not in auto mode. In both cases the controller output is not dependent on the actual process value.

The function block has built in a ramp to slow down the manual positioning. The ramp can be switched ON by the input RAMP_ACTIVE by setting the RAMP_ACTIVE high. The ramp time can be entered at RAMP_TIME input of the function block.

Cycle time for the program must be faster than RAMP_TIME / 100 to calculate the actuator time correctly!

6 different alarms can be connected to the function block
(ALARM_1 → ALARM_6, Torque switch etc.).

The valve can be switched to automatic or manual mode from the SCADA faceplate, if the input EN_AUTO = TRUE.

The position of the valve is controlled by the PID controller based on the process values.

If EN_Auto = FALSE, then the function block is forced to manual mode.

The position of the valve is controlled by the OUT_PAR value or by the commands CMDDW1, CMDDW5, CMDUP5, CMDUP1.

In automatic mode the valve is position controlled using the SP_EXT input as the position reference.

In manual mode the valve is position controlled using a setpoint from the SCADA interface, OUT_PAR.

Using the function block inputs EN_OPN and EN_CLS it is possible to prevent the valve from opening or closing by setting the respective input = FALSE. The inputs OPN and CLS are feedback indicators of the valve open and valve closed position. This is only used as display information for the SCADA faceplate.

When the controller is in automatic mode (following its internal, external or track setpoint) and then either the EN_AUTO input or the READY input are reset to FALSE, the controller is forced to manual mode. In this case a functional error is generated for three seconds. The three seconds are long enough to ensure that the functional error is logged in the 800xA system.

This function block can be used in combination with the object type VALVCON_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Examples

The function block is used for controlling variable position valve which in turn controls the level of fluid in a tank.

These components are included in the following example:

- Tank
- Level measurement
- Valve
- Main power supply, circuit breaker (or similar)

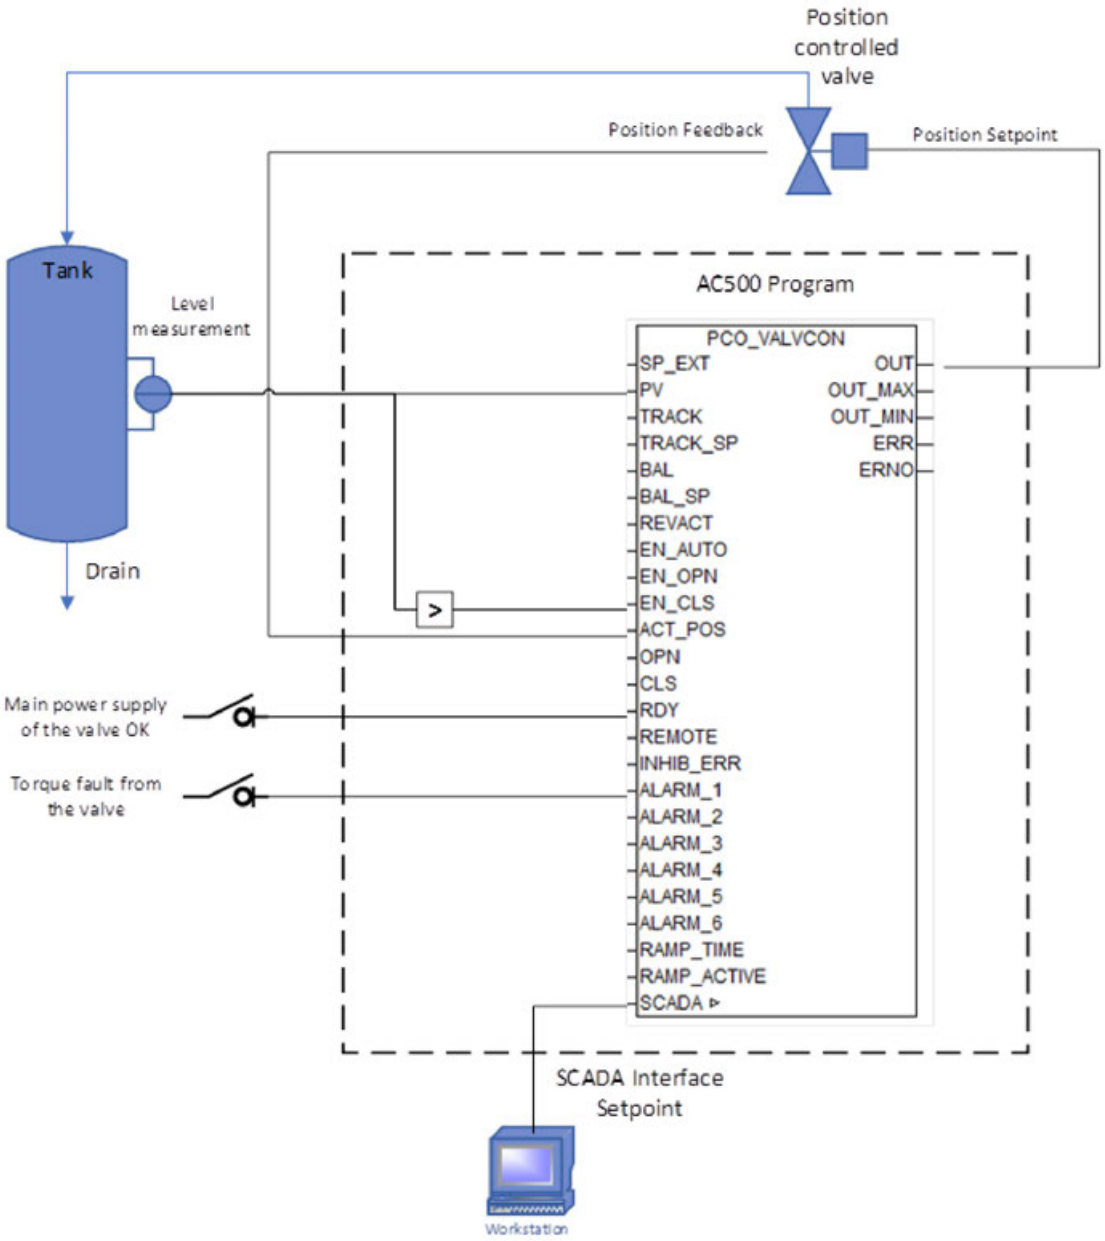
Manual mode:

- Valve controlled by the operator.

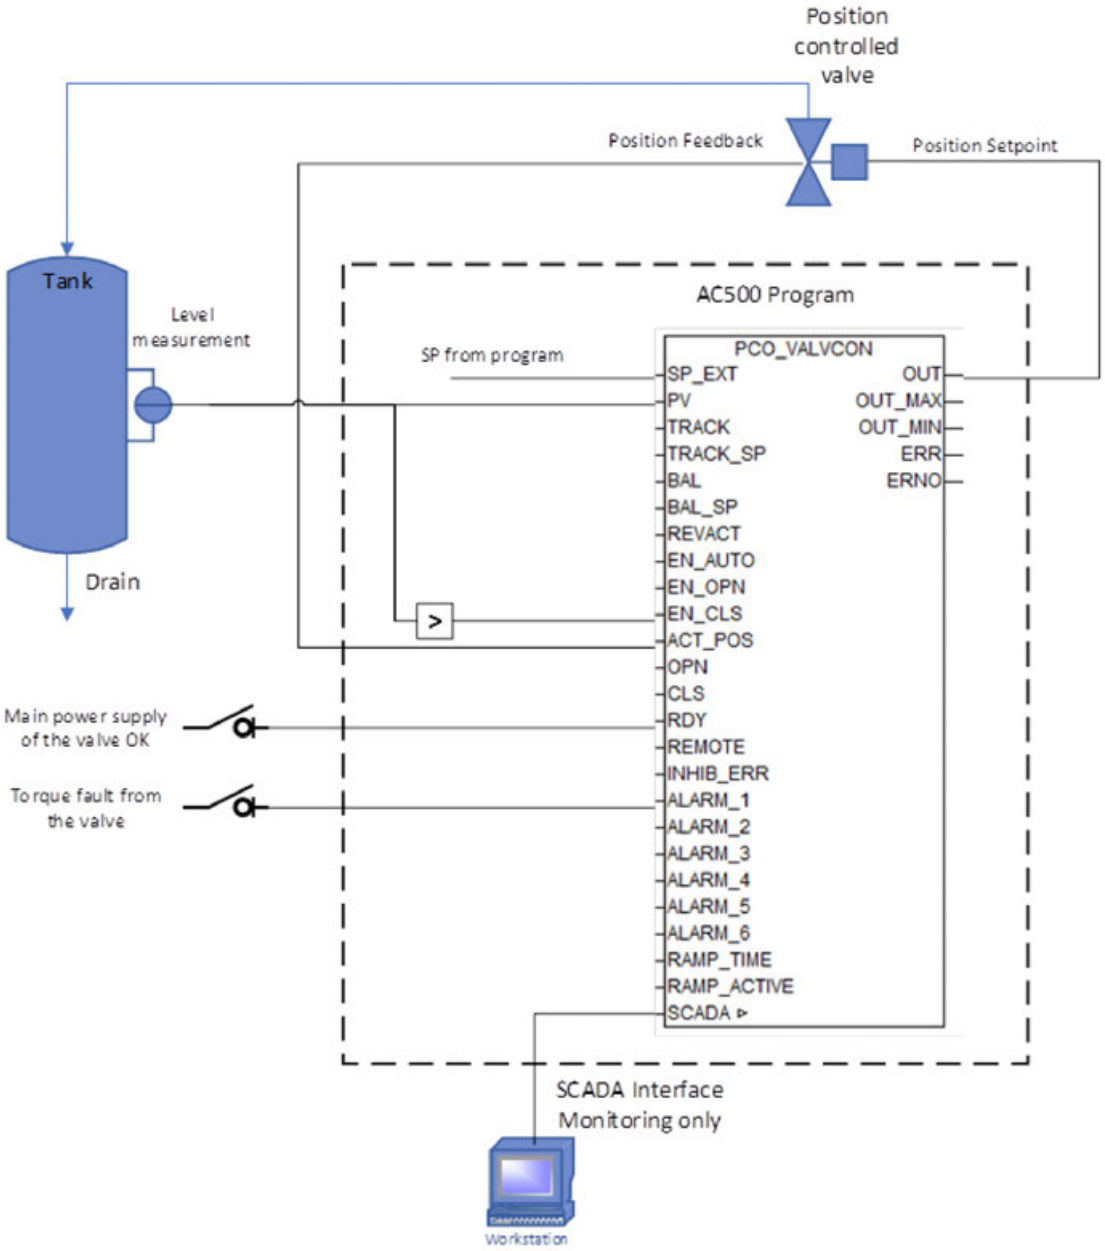
Automatic mode:

- Valve controlled by the AC500 controller.

PCO_VALVCON manual mode example



PCO_VALVCON automatic mode example



Scaling

Scaling of the SCADA Parameters

In the 800xA system the values coming from the PLC are shown by default 1:1 in the operator screens and faceplates.

The default scaling is 0 ... 100 from PLC is shown as 0 % … 100 % or 0 % ... 100.00 % for the operator (SCADA). Therefore a scaling must be done for most signals either in the *"Bulk Data Manager"* or directly in the *Engineering Workplace* > *Control Structure* > … > *Signal Configuration* > *Range*.

Assuming that all signals on the operator workplace should be shown in 0 % … 100 % the following table gives an overview of the scaling of the PLC values in the 800xA system.

PVmin and PVmax are here the minimum and maximum of the PV input, reflecting the process value in the PLC program. The PV typically comes from the output of the function block PCO_ANAALM. This scales its IN, coming directly from the analog input, to the OUT according to the inputs SCALE_MIN and SCALE_MAX.

The process value, e.g. 0 bar ... 16 bar can so be rescaled to the value 0 ... 16000 (SCALE_MIN … SCALE_MAX).

OUT_VALUE	-	0…10000		0…10000	0…100	Scaled from OUT. Seen in 800xA
SPI_PAR	-	0…27648	-	PVmin…PVmax	0…100.00	Set from 800xA
KP_PAR	-	0…100	0…(27648 / (PVmax- PVmin))	PVmin…PVmax or PVmin/100…PVmax/100	0…100.00 (%) or 0..1.00 (as factor)	
TD_PAR	-			0...1000	0...1000.00	
TI_PAR	-			0...1000	0...1000.00	

Scaling of the SCADA.PV_VALUE

The output from the controller is based on 0 % ... 100 % → 0 ... 27648 for connection direct to an analog output of the AC500 I/Os.

To show the PV in % in 800xA, it must be scaled accordingly in the 800xA signal configuration:

SCADA.Signal_Configuration.Range.Low limit = 0

SCADA.Signal_Configuration.Range.High limit = 100

SCADA.Signal_Configuration.Range.Low limit in PLC = 0

SCADA.Signal_Configuration.Range.High limit in PLC = 27648

Scaling of the Setpoints, SCADA.SPI_PAR and SCADA.SPX_VALUE

SCADA.SPI_PAR and SCADA.SPX_VALUE must have the same scaling as the process value PV.

Scaling of the Parameter SCADA.KP_PAR

If the setpoint and the process value (PV) do not have equal scaling (0 ... 27648), there is a need for scaling the SCADA.KP_PAR parameter in 800xA to achieve the right proportional gain.

The scaling of the coefficient of proportionality (SCADA.KP_PAR) is dependent on the scaling of the process value (PV).

The PV typically comes from the output of the function block PCO_ANAALM. This scales the IN, coming directly from the analog input, to the OUT according to the inputs SCALE_MIN and SCALE_MAX.

The process value, e.g. 0 bar ... 16 bar can so be rescaled to the value 0 ... 16000 (SCALE_MIN ... SCALE_MAX).

The scaling of the KP [%] is then calculated by the formula:

$$KP[\%] = \frac{Out_{\max} - Out_{\min}}{PV_{\max} - PV_{\min}} \times 100 = \frac{27648 - 0}{SCALE_{\max} - SCALE_{\min}} \times 100$$

In the mentioned example, 100 % of KP.

$$100\ \%\ of\ KP = \frac{[27648 - 0]}{[16000 - 0]} \times 100 = 172.8$$

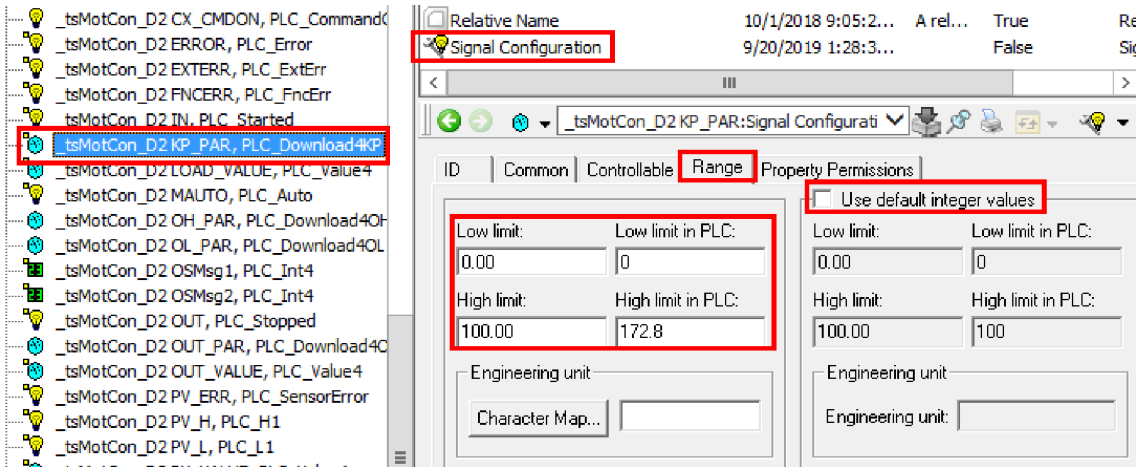
If the wanted range of SCADA.KP_PAR in SCADA is chosen to be 100 %, then the range in SCADA control structure should be adapted to

SCADA.Signal Configuration.Range.Low limit = 0

SCADA.Signal Configuration.Range.High limit =100

SCADA.Signal Configuration.Range.Low limit in PLC = 0

SCADA.Signal Configuration.Range.High limit in PLC = [27648 - 0] / [16000 - 0] × 100 = 172.8



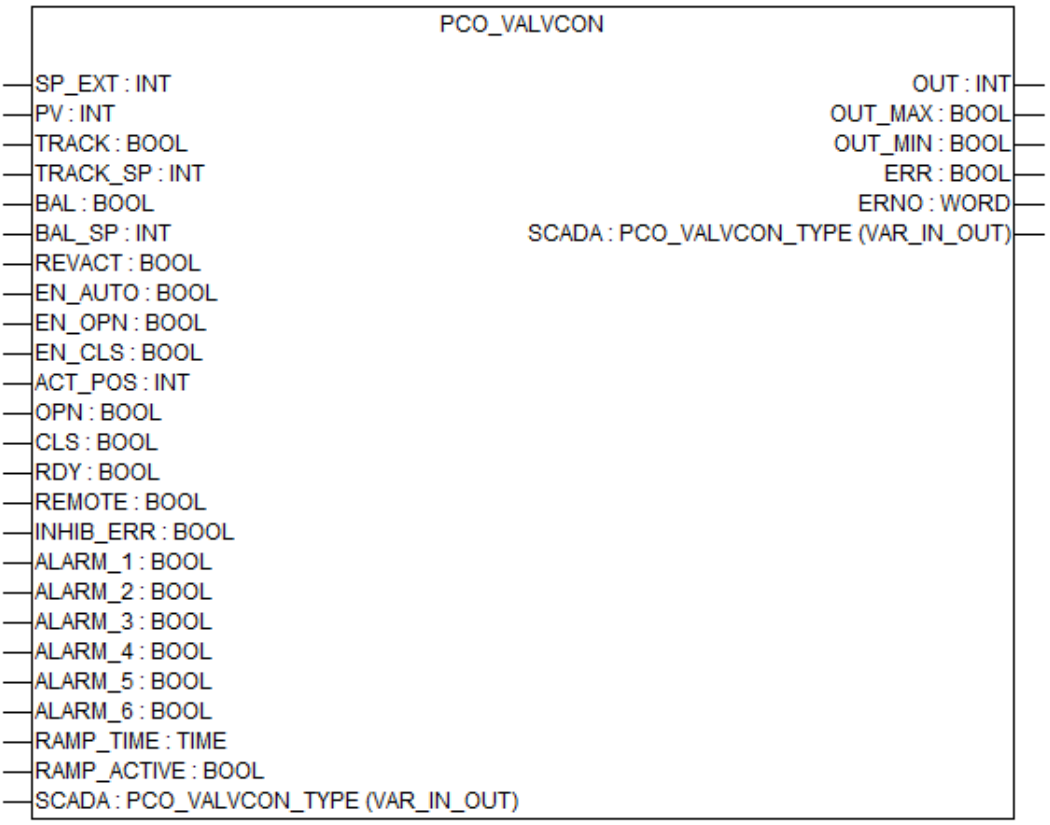
Scaling of the TRACK_SP AND BAL_SP

Input range of TRACK_SP or BAL_SP is 0 ... 10000 and the controller OUT range is 0 ... 27648.

So if the TRACK/BAL_SP is x then the controller output is defined as:

$$OUT = \frac{x}{10000} \times 27648$$

Input description



SP_EXT

Data type	Default value	Range	Unit
INT	0	0 ... 27648	-

External setpoint.

Calculated setpoint or output from another PID controller (e.g. PCO_VALVCON) in a cascade control system.

PV

Data type	Default value	Range	Unit
INT	0	0 ... 27648	-

Process value (PV) to be controlled.

TRACK

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Tracking mode.

PCO_VALVCON can be set in Tracking mode if the value of TRACK is TRUE.

Output of the controller will be set to TRACK_SP.

Tracking mode has higher priority compared to balancing mode.

TRACK is independent of operation mode of PCO_VALVCON.

TRACK_SP

Data type	Default value	Range	Unit
INT	0	0 ... 10000	-

Tracking setpoint.

Output of the controller will be set to TRACK_SP if value of TRACK is TRUE.

BAL

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Balancing mode.

PCO_VALVCON can be set in Balancing mode if value of BAL is TRUE and value of TRACK is FALSE.

Output of the controller will be set to BAL_SP.

BAL is independent of operation mode of PCO_VALVCON.

BAL_SP

Data type	Default value	Range	Unit
INT	0	0 ... 10000	-

Balancing setpoint.

Output of the controller will be set to BAL_SP if value of BAL is TRUE.

REVACT

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Reverse Action

Value of REVACT is FALSE, Controller will increase output if Setpoint is less than Process value.

Value of REVACT is TRUE, Controller will decrease output if Setpoint is greater than Process value.

EN_AUTO

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable automatic mode of the PCO_VALVCON.

PCO_VALVCON can be set in automatic mode if value of EN_AUTO is TRUE.

PCO_VALVCON is forced in manual mode if value of EN_AUTO is FALSE.

EN_OPN

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable valve to open.

Valve can be opened if value of EN_OPN is TRUE.

Valve cannot be opened if value of EN_OPN is FALSE.

EN_CLS

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable valve to close.

Valve can be closed if value of EN_CLS is TRUE.

Valve cannot be closed if value of EN_CLS is FALSE.

ACT_POS

Data type	Default value	Range	Unit
INT	0	0 ... 10000	-

Position feedback of valve.

OPN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Feedback signal from the valve.

If the value of OPN is TRUE, the valve is open.

CLS

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Feedback signal from the valve.

If the value of CLS is TRUE, the valve is closed.

RDY

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Valve is ready for operation.

Valve is ready for operation if value of RDY is TRUE.

Value of RDY is FALSE results in an external error.

REMOTE

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Allow valve to be controlled from SCADA.

Value of REMOTE is TRUE control from SCADA and function block is enabled.

Value of REMOTE is FALSE valve is controlled only from function block.

INHIB_ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Suppression of alarms.

If value of INHIB_ERR is TRUE, all alarms from PCO_VALVCON are suppressed.

Alarm_1

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 1.

If value of ALARM_1 is TRUE Alarm_1 is active.

Independent of operation mode of PCO_VALVCON.

Alarm_2

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 2.

If value of ALARM_2 is TRUE Alarm_2 is active.

Independent of operation mode of PCO_VALVCON.

Alarm_3

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 3.

If value of ALARM_3 is TRUE Alarm_3 is active.

Independent of operation mode of PCO_VALVCON.

Alarm_4

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 4.

If value of ALARM_4 is TRUE Alarm_4 is active.

Independent of operation mode of PCO_VALVCON.

Alarm_5

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 5.

If value of ALARM_5 is TRUE Alarm_5 is active.

Independent of operation mode of PCO_VALVCON.

Alarm_6

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 6.

If value of ALARM_6 is TRUE Alarm_6 is active.

Independent of operation mode of PCO_VALVCON.

RAMP_TIME

Data type	Default value	Range	Unit
TIME	TIME#30s	-	-

Actuator ramp time from 0 % ... 100 %

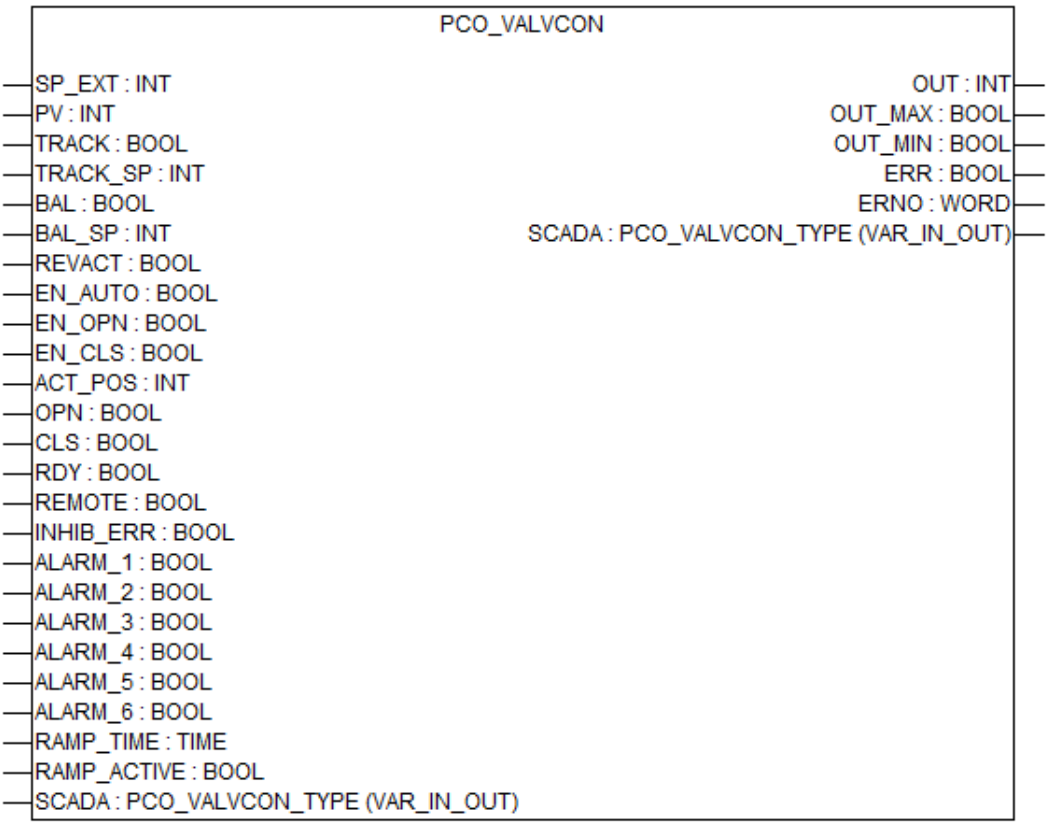
RAMP_ACTIVE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The value RAMP_ACTIVE is TRUE activates ramp under manual positioning.

The value RAMP_ACTIVE is FALSE activates no ramp.

Output description



OUT

Data type	Default value	Range	Unit
INT	0	0 ... 27648	-

Controller output to the valve to attain the desired position of the valve.

OUT_MAX

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Output max limit reached, controller at max limit.

OUT_MIN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Output min limit reached, controller at min limit.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Common alarm, including:

- Functional error
- External error (input RDY)
- Input Parameter error
- ALARM_1
- ALARM_2
- ALARM_3
- ALARM_4
- ALARM_5
- ALARM_6

ERNO

Data type	Default value	Range	Unit
WORD	0	-	-

Error number

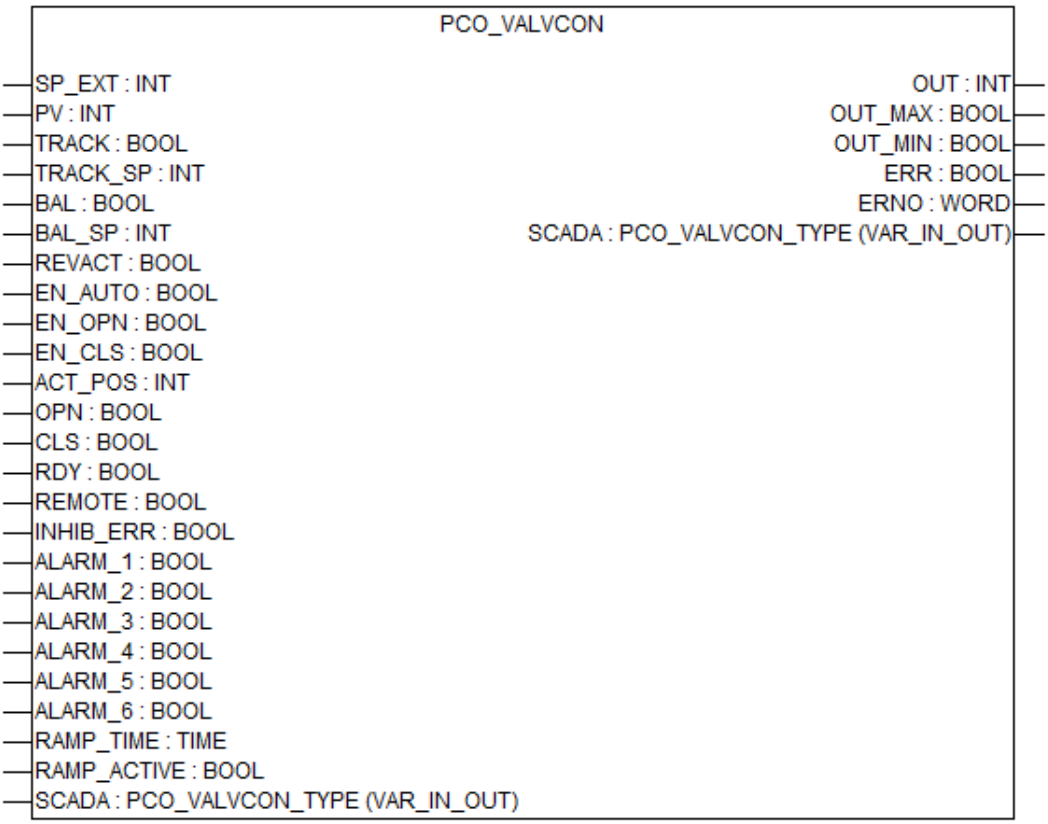
Output provides an error identifier if an invalid value was applied to an input.

ERNO always must be considered together with the output ERR.

The value output at ERNO is only valid if value of ERR is TRUE.

The error messages encoding is explained in *“Standard Function Block Libraries AC500”* in *“Error Messages of the Function Block Libraries”*.

Input/output description



SCADA

Data type	Default value	Range	Unit
PCO_VALVCON_TYPE	-	-	-

Structure variable for communication between AC500 and SCADA system.

To retain the variable value in case of power ON/OFF or download, the variable connected to the SCADA In/Output should be declared as (global) retain persistant (or use %R area) variable in the program.

Detailed information on the scaling see *"Scaling" on page 3102*.

Parameter	Data type	Description	In-/Output
SCADA.OPEN	BOOL	Valve is open	Output
SCADA.CLOSED	BOOL	Valve is closed	Output
SCADA.REMOTE	BOOL	Valve can be controlled from OS REMOTE = FALSE → Local operation	Output
SCADA.READY	BOOL	Valve is ready for operation	Output
SCADA.FNCERR	BOOL	Functional error	Output
SCADA.EXTERR	BOOL	External error (is generated when the valve is not ready)	Output
SCADA.AL1	BOOL	Auxiliary alarm no. 1	Output

Parameter	Data type	Description	In-/Output
SCADA.AL2	BOOL	Auxiliary alarm no. 2	Output
SCADA.AL3	BOOL	Auxiliary alarm no. 3	Output
SCADA.AL4	BOOL	Auxiliary alarm no. 4	Output
SCADA.AL5	BOOL	Auxiliary alarm no. 5	Output
SCADA.AL6	BOOL	Auxiliary alarm no. 6	Output
SCADA.ACT_VALUE	INT	Actual position of the valve, scaling as input ACT_POS (0 ... 10000)	Output
SCADA.CM_CMDON	BOOL	Manual command for the controller	Input
SCADA.CI_CMDON	BOOL	Auto command to set the internal setpoint for the controller	Input
SCADA.CX_CMDON	BOOL	Auto command to set the external setpoint for the controller	Input
SCADA.CMDUP5	BOOL	Manual command to increase output by 5 %	Input
SCADA.CMDUP1	BOOL	Manual command to increase output by 1 %	Input
SCADA.CMDDW1	BOOL	Manual command to decrease output by 1 %	Input
SCADA.CMDDW5	BOOL	Manual command to decrease output by 5 %	Input
SCADA.CAUTO	BOOL	Controller is in automatic mode	Output
SCADA.SPIACT	BOOL	Internal setpoint is active	Output
SCADA.SPXACT	BOOL	External setpoint is active	Output
SCADA.CTACT	BOOL	Tracking setpoint is active	Output
SCADA.PV_H	BOOL	Process value at high limit	Output
SCADA.PV_L	BOOL	Process value at low limit	Output
SCADA.PV_ERR	BOOL	Process value error	Output
SCADA.OUT_PAR	INT	Manual position setpoint Scale 0 ... 10000	Input
SCADA.SPI_PAR	INT	Internal setpoint value	Input
SCADA.KP_PAR	INT	Coefficient of proportionality (gain) % of the controller	Input
SCADA.TD_PAR	INT	Time constant for D-part of the controller	Input
SCADA.TI_PAR	INT	Time constant for integration of the controller	Input
SCADA.OH_PAR	INT	Output high limit (0 ... 10000) of the controller	Input
SCADA.OL_PAR	INT	Output low limit (0 ... 10000) of the controller	Input
SCADA.OUT_VALUE	INT	Output from the controller Scale 0 ... 10000	Output
SCADA.PV_VALUE	INT	Process value to be controlled	Output
SCADA.SPX_VALUE	INT	External setpoint value	Output
SCADA.OSMsg1 *)	WORD	Word representing the status of the PCO_VALVCON	Output

Parameter	Data type	Description	In-/Output
SCADA.OSMsg2 *)	WORD	Word representing the status of the PCO_VALVCON	Output
AspectObjectType _Valvcon_PLC	BOOL	(* Name of the 800xA Aspect Object type (AOT) to be used by the 800xA uploader, the live value is not used, only the name is relevant *)	Output

*) structure described separately

SCADA.OSMsg1

Data type	Default value	Range	Unit
WORD	-	-	-

Word representing the status of the PCO_VALVCON.

Bit	Description
Bit 0	Valve is open
Bit 1	Valve is closed
Bit 2	Not used
Bit 3	Not used
Bit 4	External error (Not ready)
Bit 5	Functional error
Bit 6	Valve released for opening
Bit 7	Valve released for closing
Bit 8	Local operation (Not remote)
Bit 9	Common alarm (External alarm + Functional alarm + ALARM_1 ... ALARM_6)
Bit 10	Not used
Bit 11	Motor in automatic mode
Bit 12	Not used
Bit 13	Motor not released for automatic mode
Bit 14	Motor released for increase speed
Bit 15	Motor released for decrease speed

SCADA.OSMsg2

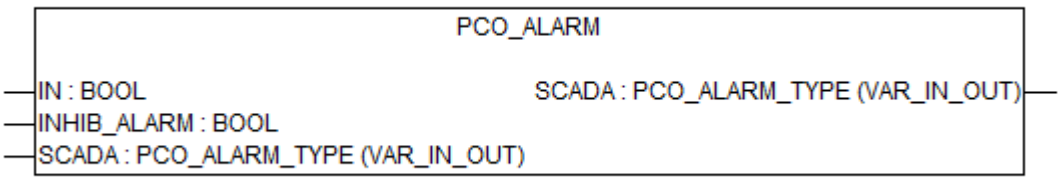
Data type	Default value	Range	Unit
WORD	-	-	-

Word representing the status of the PCO_VALVCON.

Bit	Description
Bit 0	Not used
Bit 1	Not used
Bit 2	Internal setpoint (PID controller)
Bit 3	External setpoint (PID controller)
Bit 4	Track setpoint (PID controller)
Bit 5	Auxiliary alarm 1
Bit 6	Auxiliary alarm 2
Bit 7	Auxiliary alarm 3
Bit 8	Auxiliary alarm 4
Bit 9	Auxiliary alarm 5
Bit 10	PID controller in automatic mode
Bit 11	PID controller in manual mode
Bit 12	Auxiliary alarm 6
Bit 13	Not used
Bit 14	Not used
Bit 15	Not used

Indications

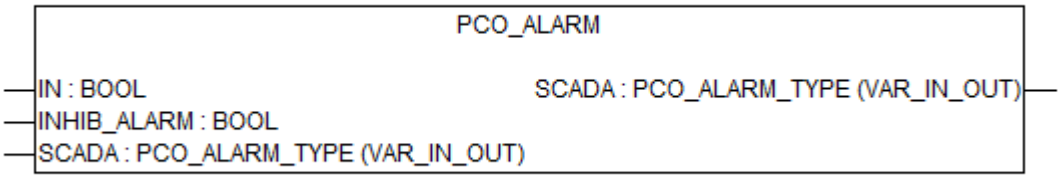
PCO_ALARM



The function block is used to send an alarm to the SCADA system.

The alarm sent to SCADA is extended minimum 3 seconds to ensure alarm detection in the SCADA system, even if the alarm at the input goes off before 3 seconds. The variable that represents the alarm in the SCADA side is "Status". This function block can be used in combination with the object type ALARM_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Input description



IN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Alarm input.

If value of IN is TRUE, then an alarm is sent to SCADA.

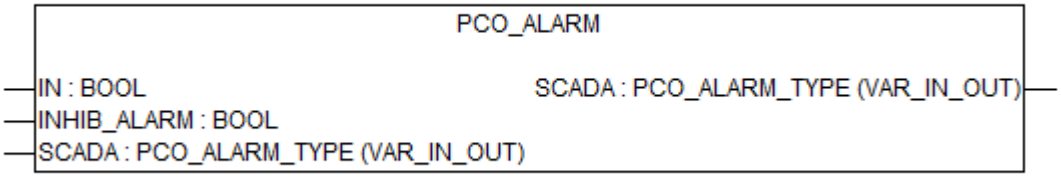
INHIB_ALARM

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Alarm inhibit.

If value of INHIB_ALARM is TRUE, then no alarm is sent to SCADA regardless of the value on IN.

Input/output description



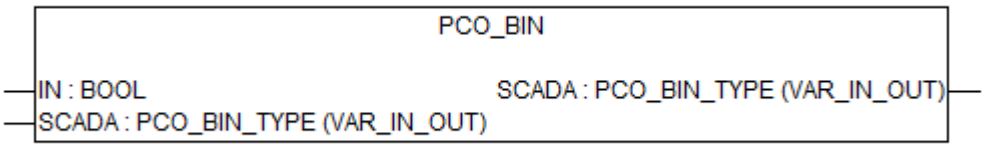
SCADA

Data type	Default value	Range	Unit
PCO_ALARM_TYPE	-	-	-

Structure variable for communication between AC500 and SCADA system.

Parameter	Data type	Description	In-/Output
SCADA.STATUS	BOOL	Alarm status, TRUE = Alarm	Output
AspectObjectType _Alarm_PLC	BOOL	(* Name of the 800xA Aspect Object type (AOT) to be used by the 800xA uploader, the live value is not used, only the name is relevant *)	Output

PCO_BIN



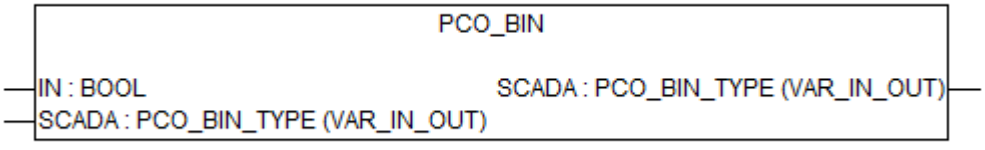
The function block is used to send an event or an indication to the SCADA system.

The event is entered at IN input of the function block and its presence is depicted as "Status" variable in SCADA.

The event sent to SCADA is extended minimum 3 seconds to ensure detection in the SCADA system.

This function block can be used in combination with the object type BIN_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Input description



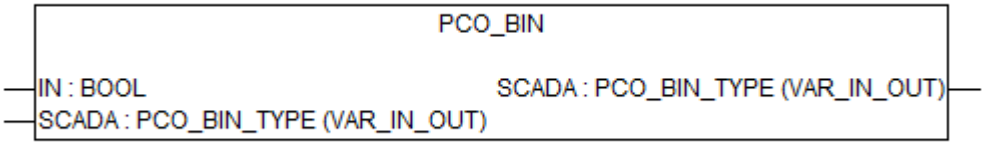
IN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Event input.

If value of IN is TRUE, then an event is sent to SCADA.

Input/output description



SCADA

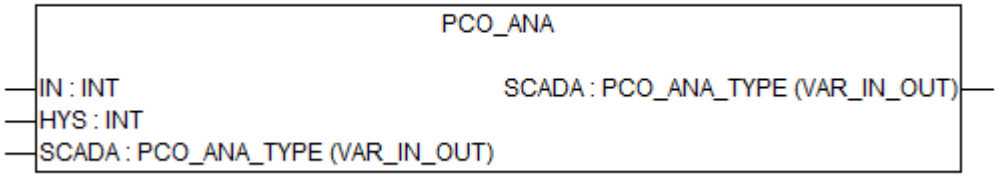
Data type	Default value	Range	Unit
PCO_BIN_TYPE	-	-	-

Structure variable for communication between AC500 and SCADA system.

Parameter	Data type	Description	In-/Output
SCADA.STATUS	BOOL	Event status. If value is TRUE then event is depicted, else no event. The event is maintained for a minimum of 3 seconds, even if the event becomes FALSE before that.	Output
AspectObjectType_Bin_PLC	BOOL	(* Name of the 800xA Aspect Object type (AOT) to be used by the 800xA uploader, the live value is not used, only the name is relevant *)	Output

Measurements

PCO_ANA



The function block is used to send an analog value to the SCADA system with hysteresis limits.

The hysteresis limit can be entered from the FB. The value of the analog signal is depicted in SCADA through a variable named value. SCADA.VALUE is only updated, if IN input (analog input) has changed more than the HYS input limits defined.

For example:

Let the analog input be defined as 2, the SCADA.VALUE gets assigned as 2. Suppose the hysteresis is 3 then the range of up to which the input can vary is (2-3) and (2+3) which is -1 ... 5.

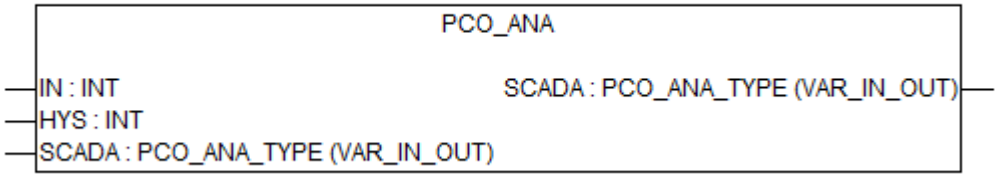
If an input -1 is given, then the SCADA.VALUE does not change (as it is in the range of -1 ... 5).

If -2 is given at the input, then the SCADA.VALUE gets set to -2 and then the input range becomes -5 ... 1.

There is no scaling in the function block.

This function block can be used in combination with the object type ANA_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Input description



IN

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

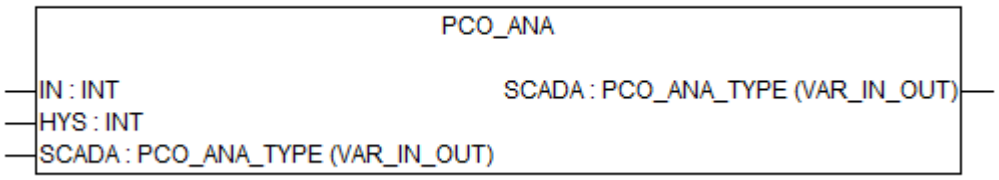
Analog input that must be sent to the SCADA system.

HYS

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

Dead band limit for input.

Input/output description



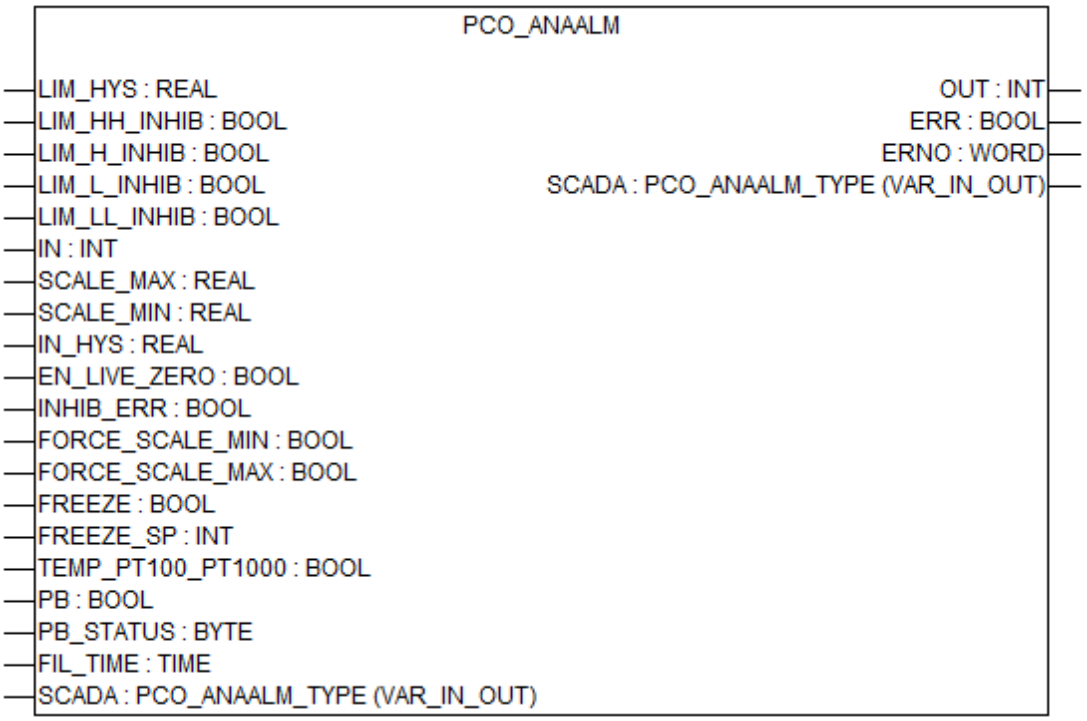
SCADA

Data type	Default value	Range	Unit
PCO_ANA_TYPE	-	-	-

Structure variable for communication to and from SCADA system.

Parameter	Data type	Description	In-/Output
SCADA.VALUE	INT	Analog input within the hysteresis limits.	Output
AspectObjectType _Ana_PLC	BOOL	(* Name of the 800xA Aspect Object type (AOT) to be used by the 800xA uploader, the live value is not used, only the name is relevant *)	Output

PCO_ANAALM



The function block is designed for controlling an analog input with limit supervision.

The function block can be configured to handle the different ranges of the analog input, due to different electrical signals. E.g.

- 4 mA ... 20 mA
- 0 V ... 10 V or
- PT100 /PT1000

> *Please refer to AC500 hardware manual for detailed information regarding analog input modules and different parameters.*

This function block checks whether the analog output of the FB are within HH, H or LL , L limits.

The limits need to be entered from the SCADA side.

- SCADA.LIMH2
- SCADA.LIMH1
- SCADA.LIML1
- SCADA.LIML2

The function block rescales the analog input (IN) from the actual value at IN to SCALE_MIN → SCALE_MAX.

The IN range is from 0 ... 27648.The OUT is defined by:

$$OUT = \frac{IN}{27648} \times (SCALE_{\max} - SCALE_{\min}) + SCALE_{\min}$$

If TEMP_PT100_PT1000 or PB are to be set = TRUE, no rescaling of IN is made.

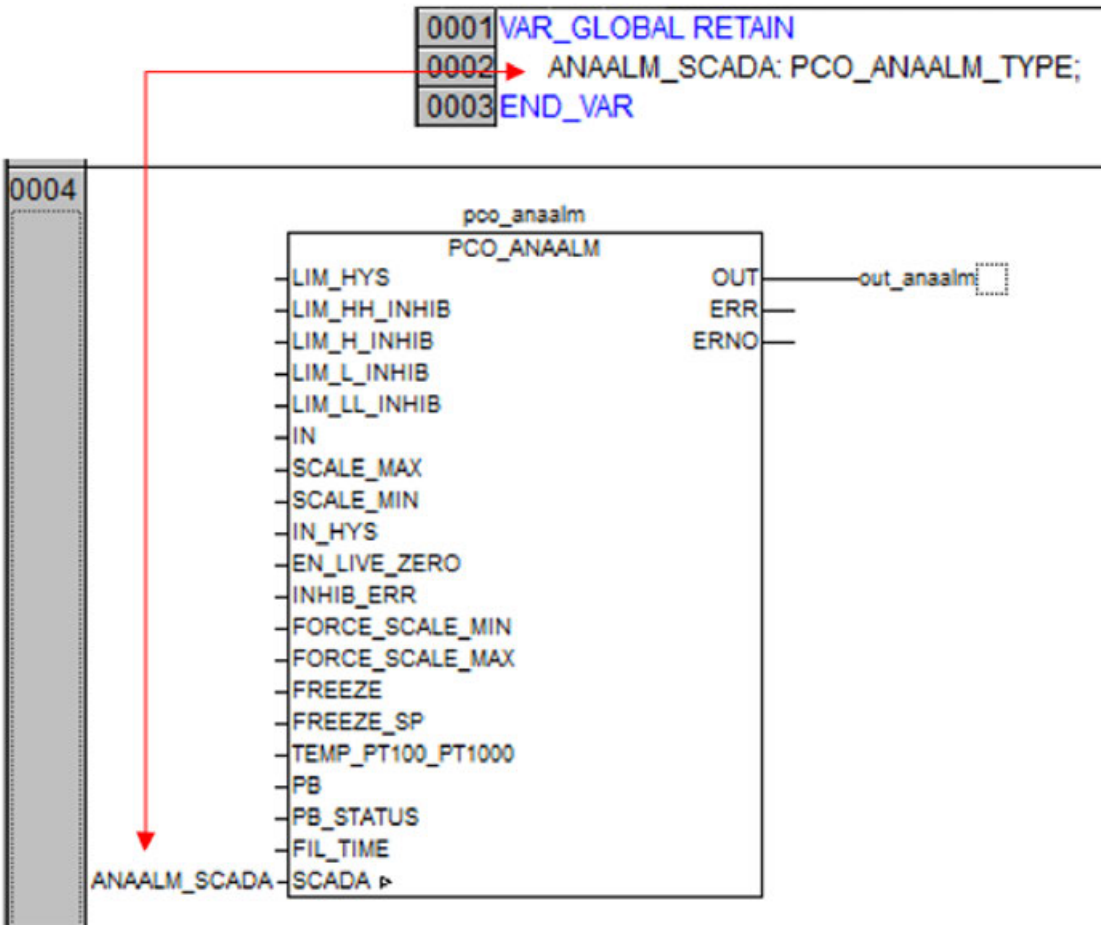
If an analog input is connected to an I/O module and the module cannot detect live zero (2 V ... 10 V), live zero can be set if value of EN_LIVE_ZERO is TRUE.

Zero point suppression. The function block will force the input to zero when the input is between 0 and 0 - IN_HYS

The value can be preset to SCALE_MIN (FORCE_SCALE_MIN = TRUE) or SCALE_MAX (FORCE_SCALE_MAX = TRUE).

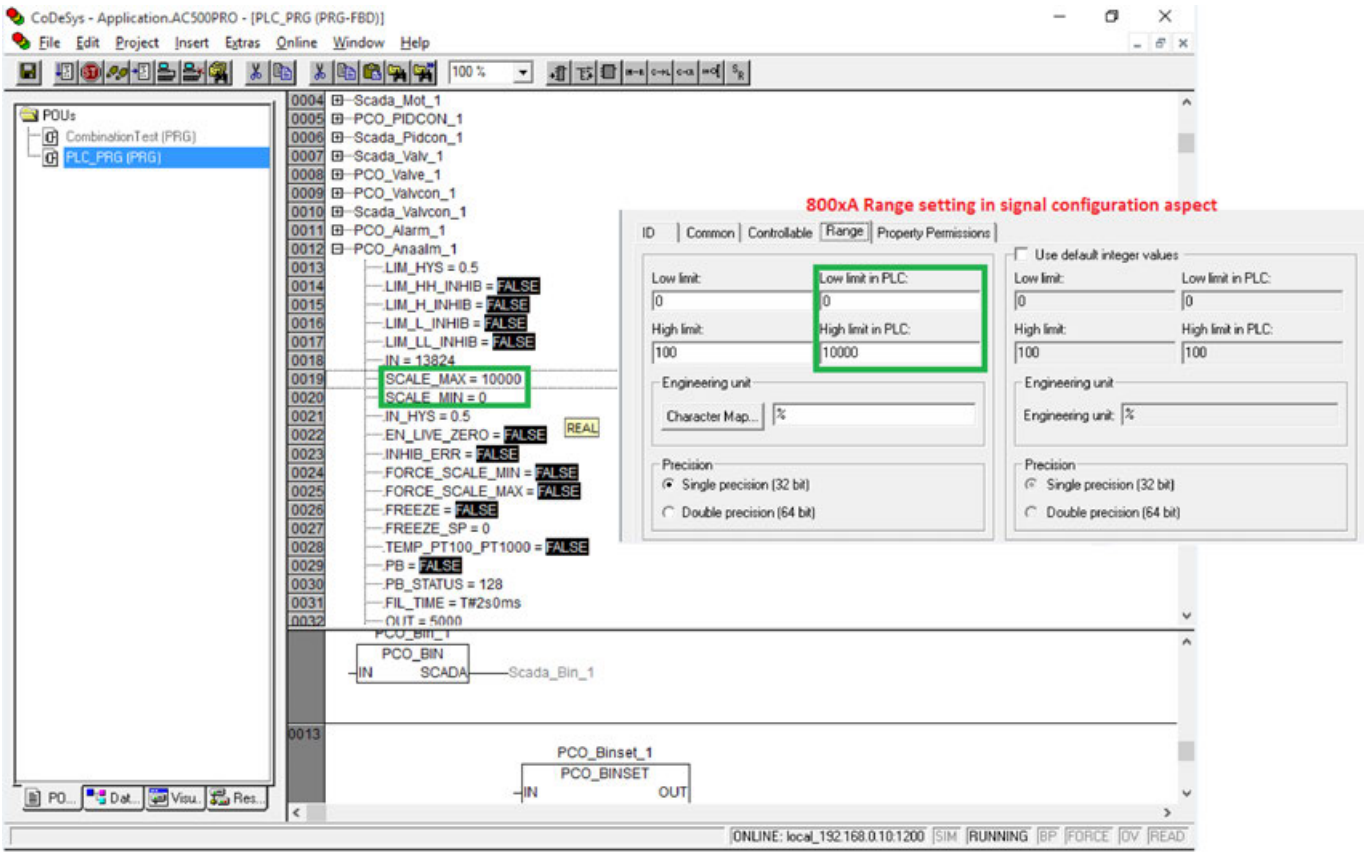
The output value from the function block can be frozen to a specific value (FREEZE = TRUE and the specific value on FREEZE_SP).

To retain the variable value in case of power ON/OFF or download, the variable connected to the SCADA In/Output should be declared as global retain persistant (or use %R area) variable in the program.

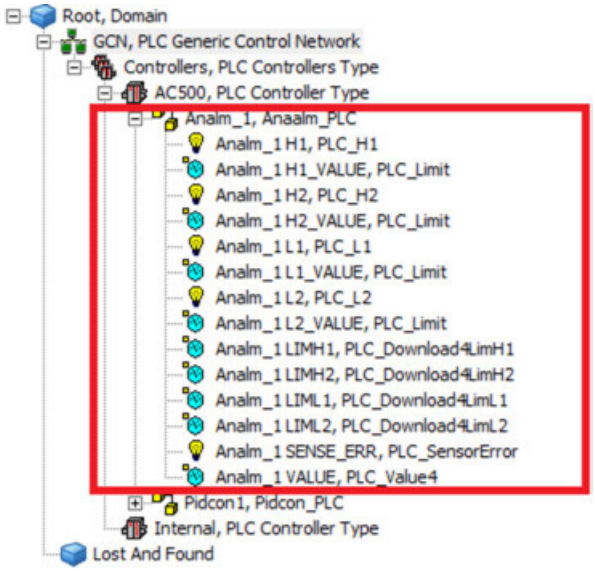


For PCO_ANAALM function block, the scaling needs to be taken care in the 800xA side. Whatever value for SCALE_MAX and SCALE_MIN is entered in the function block the similar setting needs to be done in the 800xA side scaling settings.

It is as shown in the figures below:



The same setting needs to be done for the other variables present in the ANAALM object tree.



The limit supervision consists of up to two high and two low alarms.

A SENSOR ERROR is generated in the SCADA side in the following conditions:

1. When the analog input is not within the tolerance of 1000, hence the input can vary over a range of -1000 ... 28648, after which it generates an error.

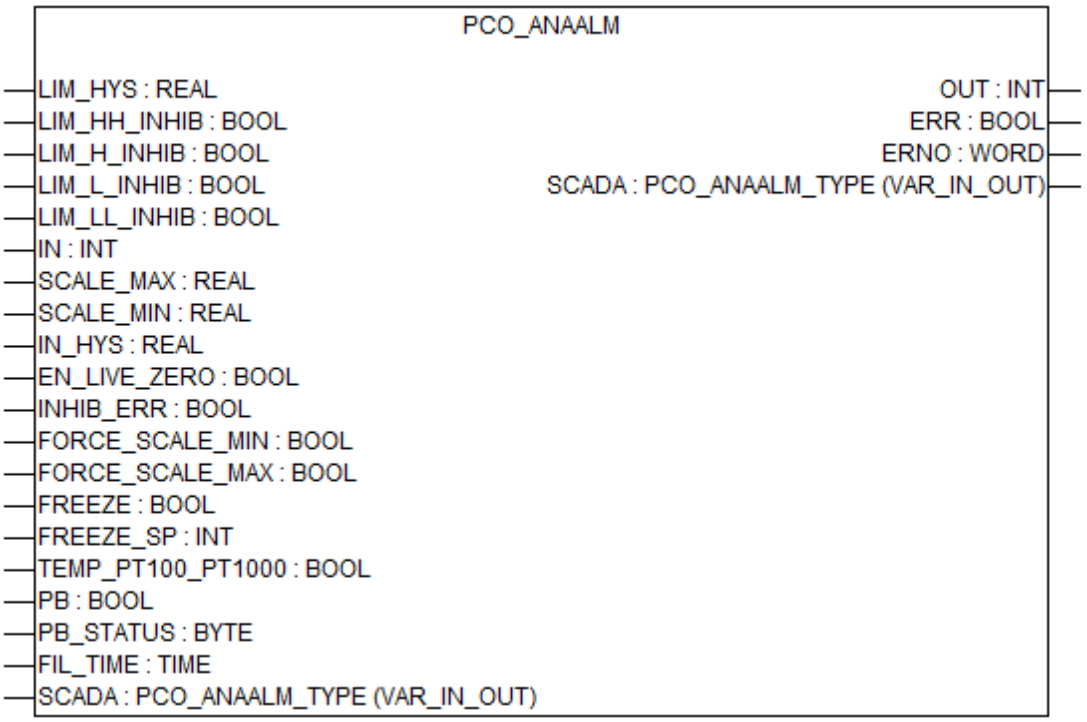
2. The output obtained at the end is not within the limits of SCALE_MIN and SCALE_MAX.

3. When the PB input is activated and the PB_STATUS is not equal to 128.

> *Inputs and outputs can stay unconnected, if their functions are not needed.*

This function block can be used in combination with the object type ANAALM_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Input description



LIM_HYS

Data type	Default value	Range	Unit
REAL	0.5	0 ... 100	%

Dead band for Alarm Limit. % of scale (SCALE_MAX – SCALE_MIN).

LIM_HH_INHIB

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Suppression of highhigh alarm.

If value of LIM_HH_INHIB is TRUE, then suppress highhigh alarm.

LIM_H_INHIB

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Suppression of high alarm.

If value of LIM_H_INHIB is TRUE, then suppress high alarm.

LIM_L_INHIB

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Suppression of low alarm.

If value of LIM_L_INHIB is TRUE, then suppress low alarm.

LIM_LL_INHIB

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Suppression of lowlow alarm.

If value of LIM_LL_INHIB is TRUE, then suppress lowlow alarm.

IN

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

Analog input. The input must be in the range of 0 ... 27648.

Value to SCADA is scaled according to SCALE_MIN and SCALE_MAX.

SCALE_MAX

Data type	Default value	Range	Unit
INT	27648	-32768 ... 32767	-

Scaling parameter. Maximum value for output to SCADA and output of the function block.

IN will be rescaled to the range defined between SCALE_MIN and SCALE_MAX by the user.

SCALE_MIN

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

Scaling parameter. Minimum value for output to SCADA and output of the function block.

IN will be rescaled to the range defined between SCALE_MIN and SCALE_MAX by the user.

IN_HYS

Data type	Default value	Range	Unit
REAL	0.5	0 ... 100	%

Dead band for analog input.

If IN + IN_HYS > SCADA or IN - IN_HYS < SCADA, then SCADA value is updated.

EN_LIVE_ZERO

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Enable live zero for analog input.

An analog input is connected to an I/O module or CPU and the module cannot detect live zero (2 V ... 10 V), live zero can be set if value of EN_LIVE_ZERO is TRUE.

INHIB_ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Suppression of all alarms.

If value of INHIB_ERR is TRUE, all alarms are suppressed.

FORCE_SCALE_MIN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Force output from function block.

If value of FORCE_SCALE_MIN is TRUE, output for SCADA and OUT are forced to SCALE_MIN.

When FORCE_SCALE_MAX and FORCE_SCALE_MIN inputs are made high at the same time, FORCE_SCALE_MAX has higher priority.

FORCE_SCALE_MAX

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Force output from function block.

If value of FORCE_SCALE_MAX is TRUE, output for SCADA and OUT are forced to SCALE_MAX.

When FORCE_SCALE_MAX and FORCE_SCALE_MIN inputs are made high at the same time, FORCE_SCALE_MAX has higher priority.

FREEZE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Force output from function block.

If value of FREEZE is TRUE, output for SCADA and OUT are forced to FREEZE_SP.

FREEZE_SP

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

Freeze setpoint.

If value of FREEZE is TRUE, the SCADA and OUT will be forced to FREEZE_SP.

PB

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Select PROFIBUS type of input.

If value of PB is TRUE, the analog input is not from an I/O module but from a PROFIBUS communication line.

No scaling of the SCADA and OUT value.

PB_STATUS

Data type	Default value	Range	Unit
BYTE	128	0 ... 255	-

Status of PROFIBUS communication.

If value of PB_STATUS is not equal to 128, a sensor error is generated.

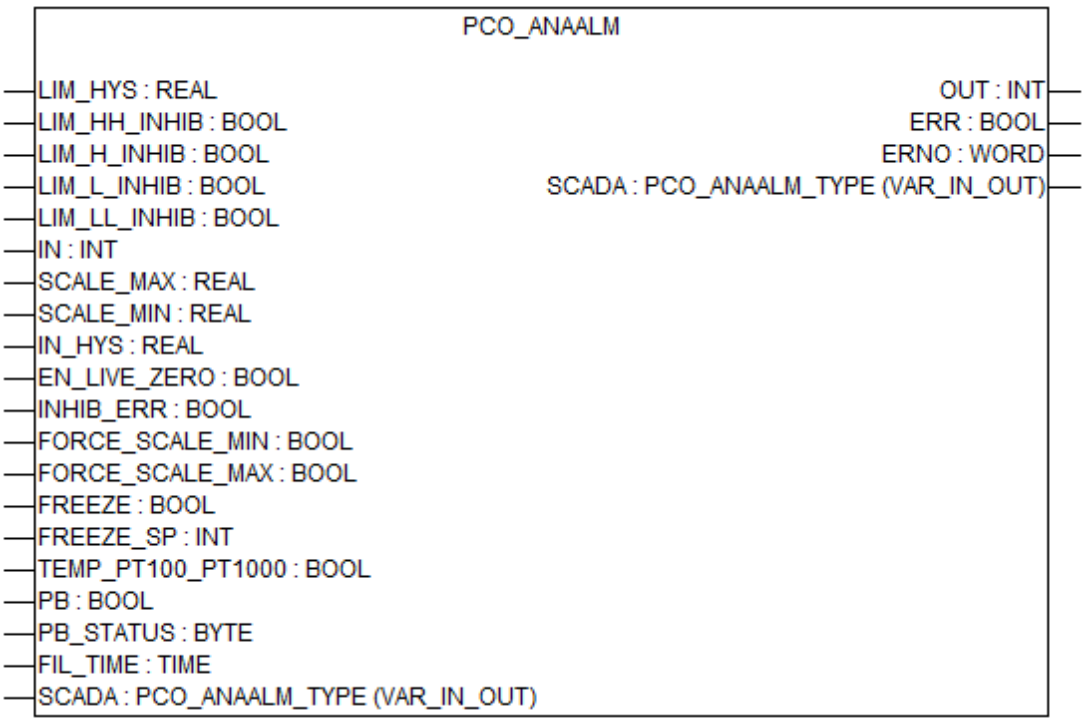
If value of PB_STATUS is 128, measurement is ok.

FIL_TIME

Data type	Default value	Range	Unit
TIME	TIME#2s	-	-

Filter time. 1st order filter for the input damps the variation of input.

Output description



OUT

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

Scaled output, output scaled according to SCALE_MIN and SCALE_MAX.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Common alarm, Input Parameter error.

ERNO

Data type	Default value	Range	Unit
WORD	0	-	-

Error number

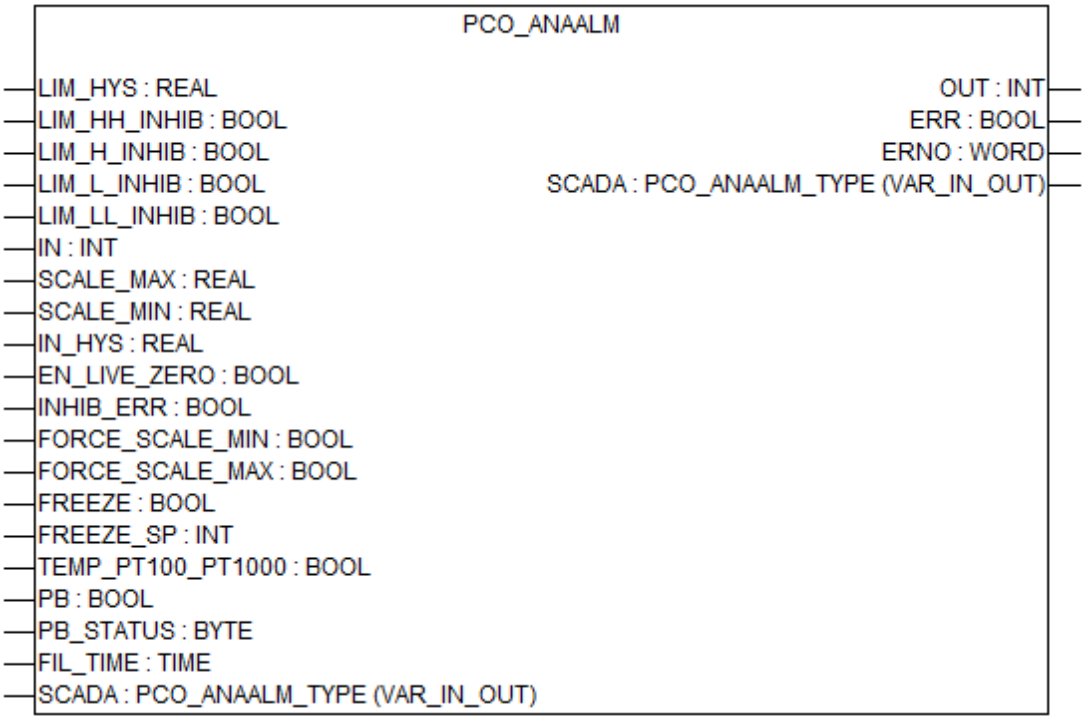
Output provides an error identifier if an invalid value was applied to an input.

ERNO always must be considered together with the output ERR.

The value output at ERNO is only valid if value of ERR is TRUE.

The error messages encoding is explained in *"Standard Function Block Libraries AC500"* in *"Error Messages of the Function Block Libraries"*.

Input/output description



SCADA

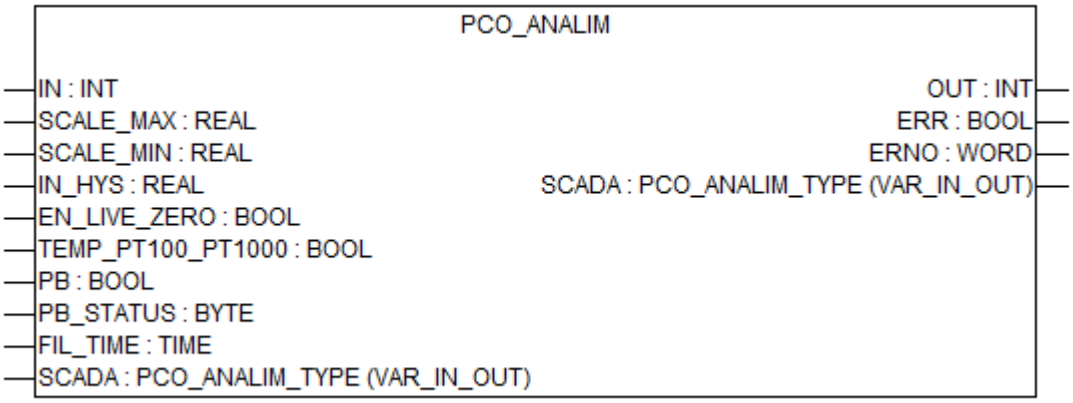
Data type	Default value	Range	Unit
PCO_ANAALM_ TYPE	-	-	-

Structure variable for communication between AC500 and SCADA system.

Parameter	Data type	Description	In-/Output
SCADA.VALUE	INT	Rescaled input value.	Output
SCADA.SENSE_ERR	BOOL	Sensor error. Open circuit or short circuit.	Output
SCADA.H2	BOOL	High-high alarm (H2).	Output
SCADA.H1	BOOL	High alarm (H1).	Output

Parameter	Data type	Description	In-/Output
SCADA.L1	BOOL	Low alarm (L1).	Output
SCADA.L2	BOOL	Low-low alarm (L2).	Output
SCADA.LIMH2	INT	Parameter from OS: Limit for H2 alarm.	Input
SCADA.LIMH1	INT	Parameter from OS: Limit for H1 alarm.	Input
SCADA.LIML1	INT	Parameter from OS: Limit for L1 alarm.	Input
SCADA.LIML2	INT	Parameter from OS: Limit for L2 alarm.	Input
SCADA.H2_VALUE	INT	Parameter to SCADA: Limit for H2 alarm	Output
SCADA.H1_VALUE	INT	Parameter to SCADA: Limit for H1 alarm	Output
SCADA.L1_VALUE	INT	Parameter to SCADA: Limit for L1 alarm	Output
SCADA.L2_VALUE	INT	Parameter to SCADA: Limit for L2 alarm	Output
AspectObjectType _Anaalm_PLC	BOOL	(* Name of the 800xA Aspect Object type (AOT) to be used by the 800xA uploader, the live value is not used, only the name is relevant *)	Output

PCO_ANALIM



The function block is designed for controlling an analog input without limit supervision.

The function block can be configured to handle the different ranges of the analog input, due to different electrical signals. E.g.

- 4 mA ... 20 mA
- 0 V ... 10 V or
- PT100 /PT1000

> *Please refer to AC500 hardware manual for detailed information regarding analog input modules and different parameters.*

The function block rescales the analog input (IN) from the actual value to SCALE_MIN → SCALE_MAX.

The IN range is from 0 ... 27648.The OUT is defined by:

$$OUT = \frac{IN}{27648} \times (SCALE_{\max} - SCALE_{\min}) + SCALE_{\min}$$

If TEMP_PT100_PT1000 or PB are to be set = TRUE, no rescaling of IN is made.

If an analog input is connected to an I/O module and the module cannot detect live zero (2 V ... 10 V), live zero can be set if value of EN_LIVE_ZERO is TRUE.

Zero point suppression. The function block will force the input to zero when the input is between 0 and 0 - IN_HYS

A SENSOR ERROR is generated in the SCADA side in the following conditions:

1. When the analog input is not within the tolerance of 1000, hence the input can vary over a range of -1000 ... 28648, after which it generates an error.

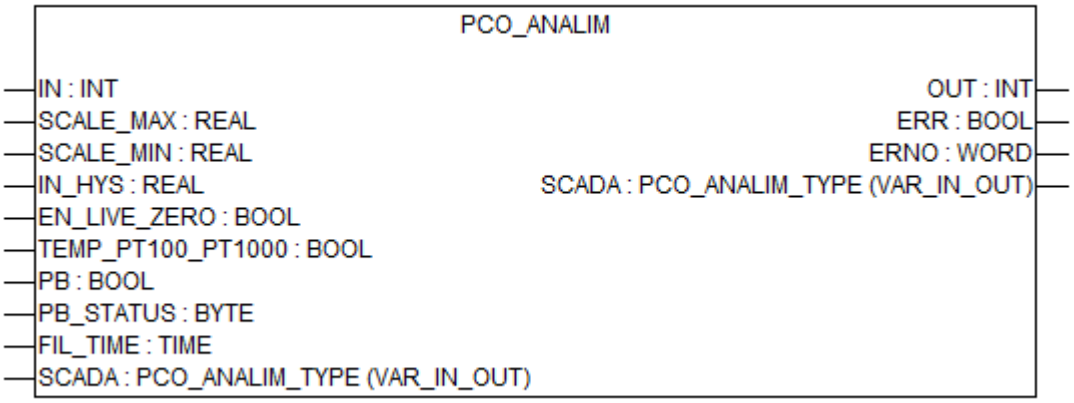
2. The output obtained at the end is not within the limits of SCALE_MIN and SCALE_MAX.

3. When the PB input is activated and the PB_STATUS is not equal to 128.

> *Inputs and outputs can stay unconnected, if their functions are not needed.*

This function block can be used in combination with the object type ANALIM_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Input description



IN

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

Analog input. The input must be in the range of 0 ... 27648.

Value to SCADA is scaled according to SCALE_MIN and SCALE_MAX.

SCALE_MAX

Data type	Default value	Range	Unit
INT	27648	-32768 ... 32767	-

Scaling parameter. Maximum value for output to SCADA and output of the function block.

IN will be rescaled to the range defined between SCALE_MIN and SCALE_MAX by the user.

SCALE_MIN

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

Scaling parameter. Minimum value for output to SCADA and output of the function block.

IN will be rescaled to the range defined between SCALE_MIN and SCALE_MAX by the user.

IN_HYS

Data type	Default value	Range	Unit
REAL	0.5	0 ... 100	%

Dead band for analog input.

If IN + IN_HYS > SCADA or IN - IN_HYS < SCADA, then SCADA value is updated.

EN_LIVE_ZERO

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Enable live zero for analog input.

An analog input is connected to an I/O module or CPU and the module cannot detect live zero (2 V ... 10 V), live zero can be set if value of EN_LIVE_ZERO is TRUE.

TEMP_PT100_PT1000

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Select temperature sensor type of input.

If value of TEMP_PT100_PT1000 is TRUE, a temperature sensor is connected direct on an I/O module.

No scaling of the SCADA and OUT value.

PB

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Select PROFIBUS type of input.

If value of PB is TRUE, the analog input is not from an I/O module but from a PROFIBUS communication line.

No scaling of the SCADA and OUT value.

PB_STATUS

Data type	Default value	Range	Unit
BYTE	128	0 ... 255	-

Status of PROFIBUS communication.

If value of PB_STATUS is not equal to 128, a sensor error is generated.

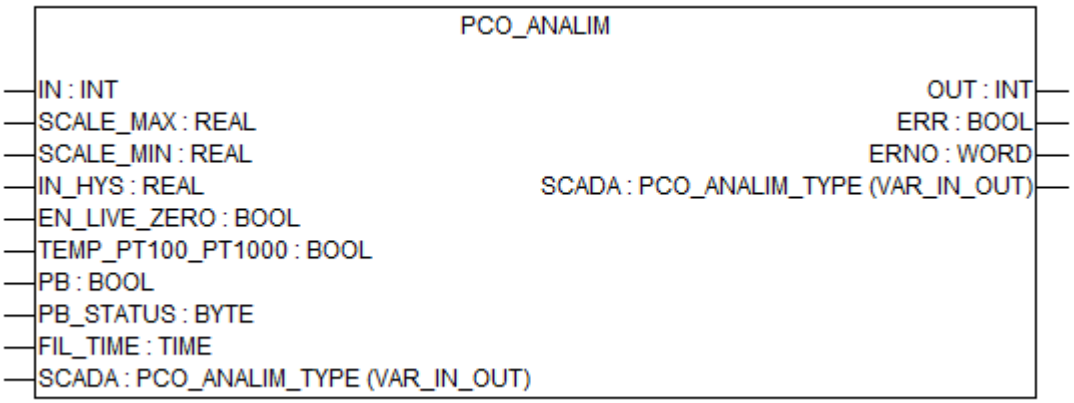
If value of PB_STATUS is 128, measurement is ok.

FIL_TIME

Data type	Default value	Range	Unit
TIME	TIME#2s	-	-

Filter time. 1st order filter for the input damps the variation of input.

Output description



OUT

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

Scaled output, output scaled according to SCALE_MIN and SCALE_MAX.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Common alarm, Input Parameter error.

ERNO

Data type	Default value	Range	Unit
WORD	0	-	-

Error number

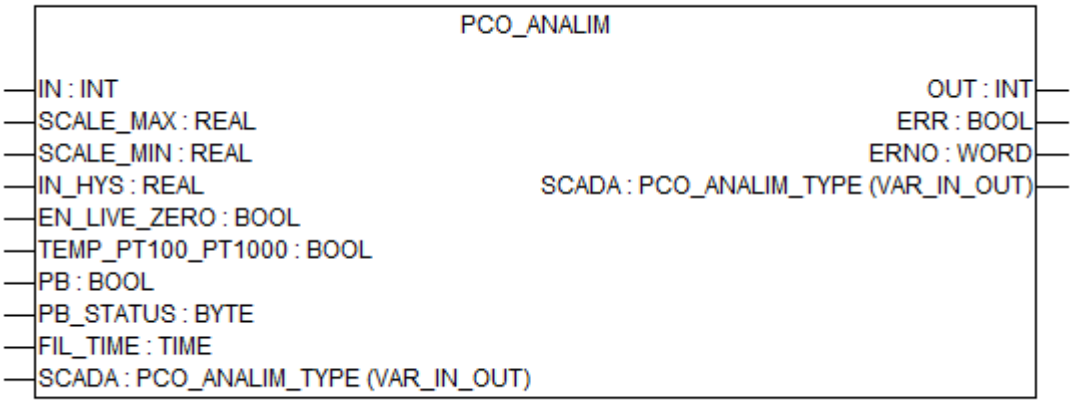
Output provides an error identifier if an invalid value was applied to an input.

ERNO always must be considered together with the output ERR.

The value output at ERNO is only valid if value of ERR is TRUE.

The error messages encoding is explained in *"Standard Function Block Libraries AC500"* in *"Error Messages of the Function Block Libraries"*.

Input/output description



SCADA

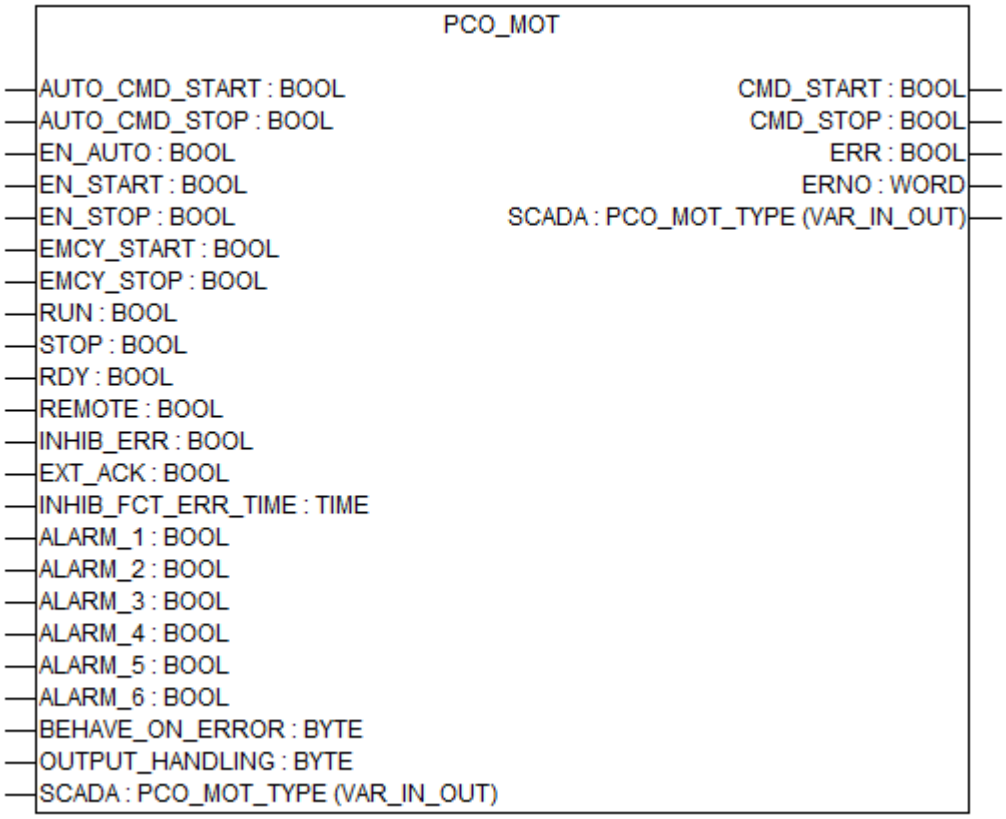
Data type	Default value	Range	Unit
PCO_ANALIM_TYPE	-	-	-

Structure variable for communication to and from SCADA system.

Parameter	Data type	Description	In-/Output
SCADA.VALUE	INT	Rescaled input value.	Output
SCADA.SENSE_ERR	BOOL	Sensor error. Open circuit or short circuit.	Output
AspectObjectType _Analim_PLC	BOOL	(* Name of the 800xA Aspect Object type (AOT) to be used by the 800xA uploader, the live value is not used, only the name is relevant *)	Output

Motor

PCO_MOT



This function block is designed for controlling a fixed speed motor.

Utilizing the inputs of the function block BEHAVE_ON_ERROR and OUTPUT_HANDLING different modes of CMD_START and CMD_STOP can be configured. E.g. if CMD_START and CMD_STOP should be pulsed or persistent signals. In addition, 6 different alarms can be connected to the function block (ALARM_1 to ALARM_6, thermal switch etc.).

Set motor to auto mode

The motor can be switched to automatic mode from the SCADA faceplate if the input EN_AUTO is TRUE.

Settings in FB side	Data type	Set Motor to Auto Mode
EN_AUTO	BOOL	TRUE
REMOTE	BOOL	ACTIVE
RDY	BOOL	ACTIVE

Settings in SCADA side	Data type	Set Motor to Auto Mode
SCADA.CMDAUT	BOOL	Rising edge needs to be given.

Start / stop motor in auto mode

Settings in FB side	Data type	Start / Stop Motor in Auto Mode
INHIB_FCT_ERR_TIME	TIME	The value of INHIB_FCT_ERR_TIME has to be greater than 0 s to avoid functional error.
EN_START	BOOL	ACTIVE
EN_STOP	BOOL	ACTIVE
AUTO_CMD_START	BOOL	Rising edge needs to be given to AUTO_CMD_START input of FB
AUTO_CMD_STOP	BOOL	Rising edge needs to be given to AUTO_CMD_STOP input of FB

Settings in SCADA side	Data type	Start / Stop Motor in Auto Mode
No settings need to be done.		

Set motor to manual mode

The motor can be switched to manual mode.

If the input EN_AUTO is FALSE, then the function block is forced to manual mode.

The motor can be operated in manual mode if EN_AUTO is either TRUE or FALSE.

The difference is that if EN_AUTO is TRUE, the switching between Auto and Manual is possible, else the motor and controller are both to Manual.

Settings in FB side	Data type	Set Motor to Manual Mode
REMOTE	BOOL	ACTIVE
RDY	BOOL	ACTIVE

Settings in SCADA side	Data type	Set Motor to Manual Mode
SCADA.CMDMAN	BOOL	Rising edge of SCADA.CMDMAN input to reset auto mode if it was set before

Start / stop motor in manual mode

Settings in FB side	Data type	Start / Stop Motor in Manual Mode
INHIB_FCT_ERR_TIME	TIME	The value of INHIB_FCT_ERR_TIME has to be greater than 0 s to avoid functional error.
EN_START	BOOL	ACTIVE
EN_STOP	BOOL	ACTIVE

Settings in SCADA side	Data type	Start / Stop Motor in Manual Mode
CMDSTR	BOOL	Rising edge of CMDSTR needs to be given.
CMDSTP	BOOL	Rising edge of CMDSTP needs to be given.

In automatic mode the motor can be started/stopped using the function block inputs (AUTO_CMD_START/AUTO_CMD_STOP).

In manual mode the motor can be started and stopped from the SCADA faceplate.

The function block includes supervision of the feedback signals RUN and STOP from the motor.

If the motor fails to run or stop within the supervision time INHIB_FCT_ERR_TIME, it will generate a functional error.

An external error is generated when READY input is false.

This function block can be used in combination with the object type MOT_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Examples

The function block is used for controlling a fixed speed motor, which can be used for controlling the level of fluid in a tank.

These components are included in the following example:

- Tank
- Level switch (high and low)
- Pump
- Main power supply, circuit breaker (or similar)

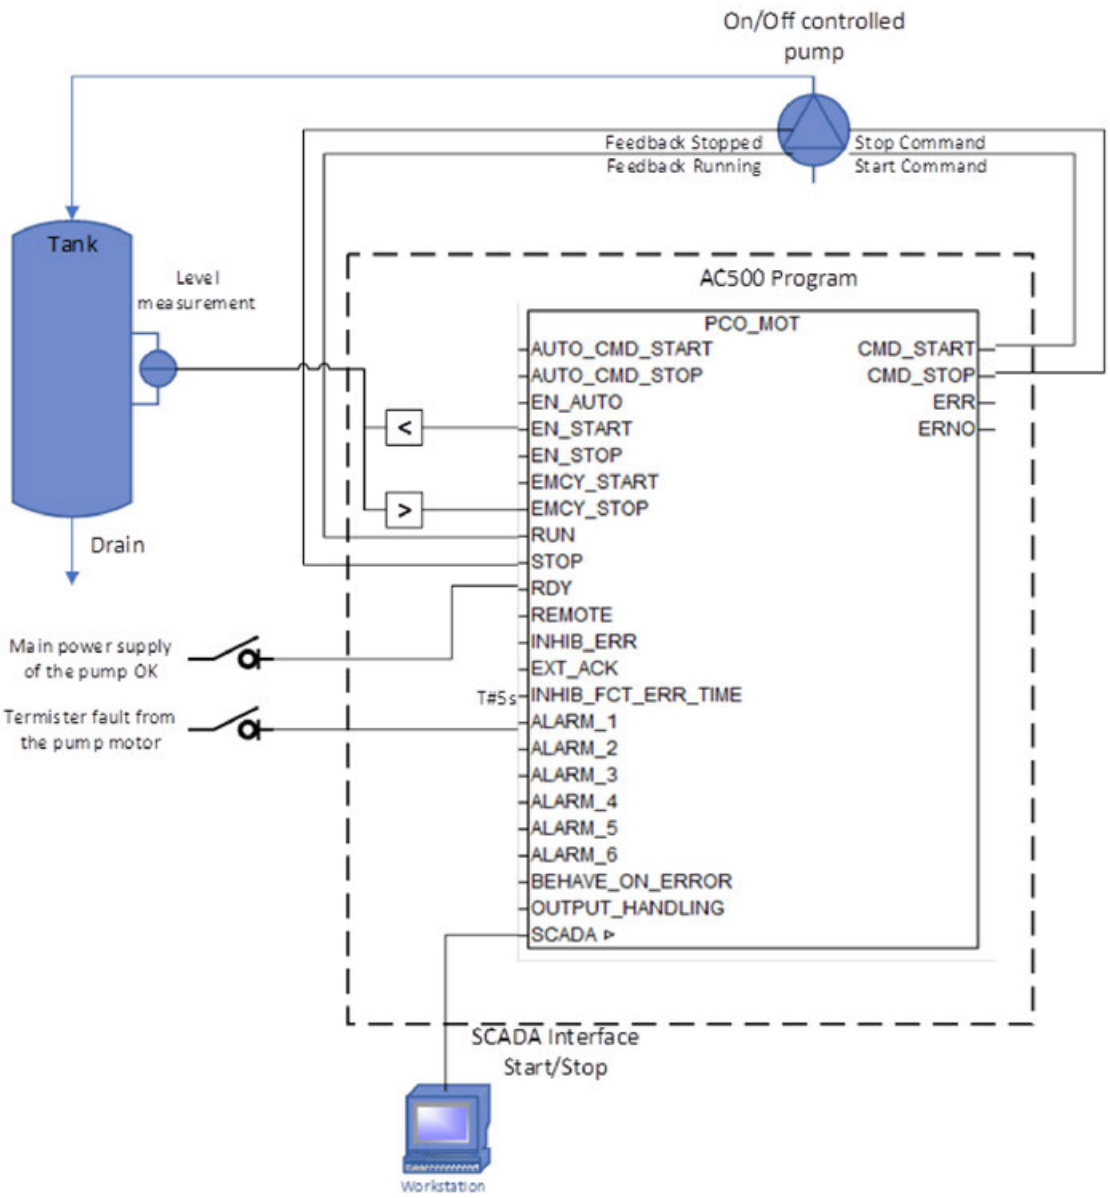
Manual mode:

- Pump controlled by the operator.

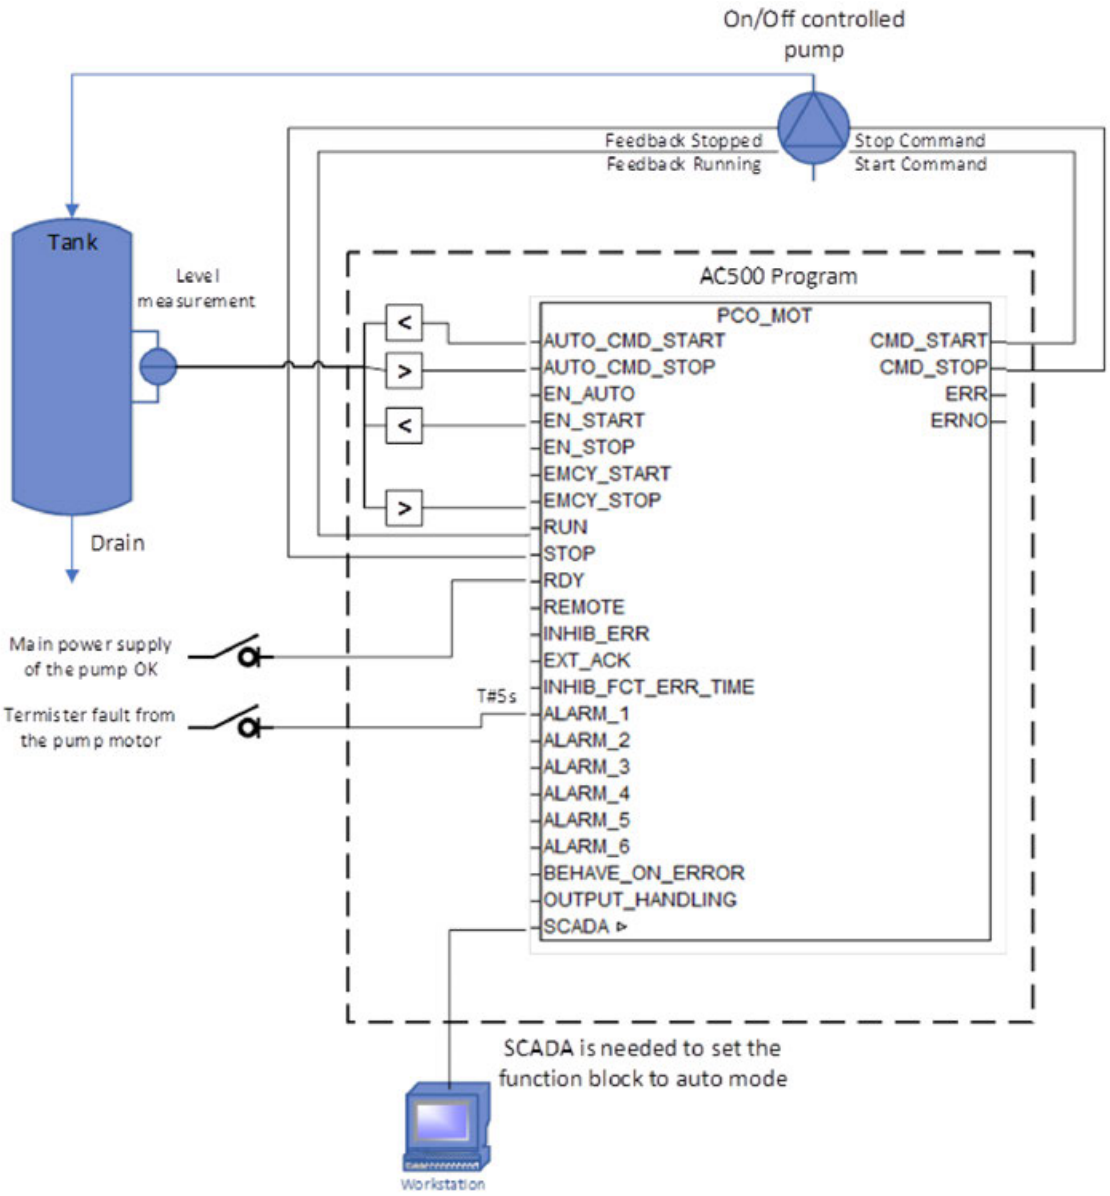
Automatic mode:

- Pump controlled by the AC500 controller.

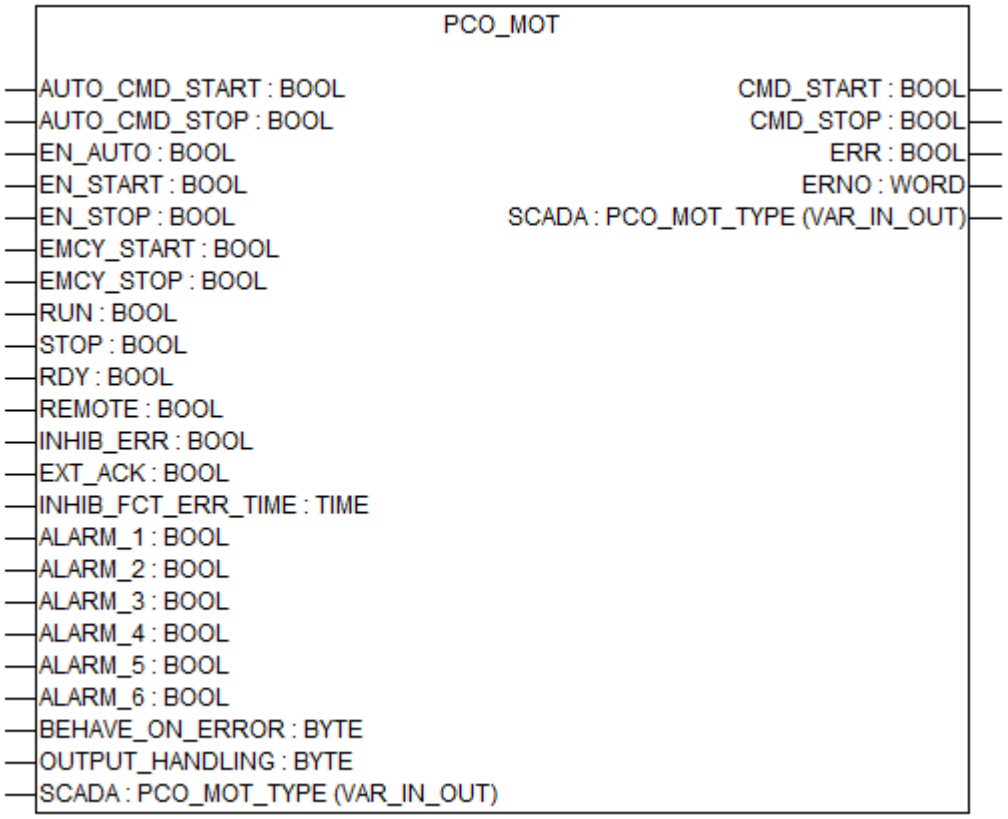
PCO_MOT manual mode example



PCO_MOT automatic mode example



Input description



AUTO_CMD_START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Force the motor to start if it is in automatic mode.

E.g.AUTO_CMD_START could be activated from a sequence in the PLC program. The function block reacts on "0" to "1" transition of this input.

If AUTO_CMD_START and AUTO_CMD_STOP are active at the same time, then the commands CMD_START and CMD_STOP get reset.

AUTO_CMD_STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Force the motor to stop if the actuator is in automatic.

AUTO_CMD_STOP could be activated from a sequence in the PLC program. The function block reacts on "0" to "1" transition of this input.

If AUTO_CMD_START and AUTO_CMD_STOP are active at the same time, then the commands CMD_START and CMD_STOP get reset.

EN_AUTO

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable automatic mode of the PCO_MOT.

PCO_MOT can be set in automatic mode if value of EN_AUTO is TRUE.

PCO_MOT is forced in manual mode if value of EN_AUTO is FALSE.

But the motor can also be operated in manual mode if EN_AUTO is TRUE provided that manual start and stop selection is made on the SCADA side.

EN_START

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable start of the motor.

Motor can be started if value of EN_START is TRUE.

Motor cannot be started if value of EN_START is FALSE.

EN_START is independent of operation mode of PCO_MOT.

EN_START has no effect in case of emergency start of function block motor EMCY_START.

EN_START has no effect on a motor already running.

EN_STOP

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable stop of the motor.

Motor can be stopped if value of EN_STOP is TRUE.

Motor cannot be stopped if value of EN_STOP is FALSE.

EN_STOP is independent of operation mode of PCO_MOT.

EN_STOP has no effect in case of emergency stop of function block motor EMCY_STOP.

EN_STOP has no effect on an already stopped motor.

EMCY_START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Emergency start of motor.

If value of EMCY_START is TRUE and value of EMCY_STOP is FALSE, the motor will start.

If value of EMCY_START is TRUE and value of EMCY_STOP is TRUE, the motor will stop.

Independent of operation mode of PCO_MOT.

EMCY_STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Emergency stop of the motor.

If value of EMCY_STOP is TRUE, the motor will stop.

If value of EMCY_START is TRUE and value of EMCY_STOP is TRUE, the motor will stop.

Independent of operation mode of PCO_MOT.

RUN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Feedback signal from the motor.

Motor is running if the value of RUN is TRUE.

Independent of operation mode of PCO_MOT.

STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Feedback signal from the motor.

Motor is stopped if the value of STOP is TRUE.

Independent of operation mode of PCO_MOT.

RDY

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Motor is ready for operation.

Motor is ready for operation if value of RDY is TRUE.

Value of RDY is FALSE results in an external error.

Independent of operation mode of PCO_MOT.

REMOTE

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Allow motor to be controlled from SCADA.

Value of REMOTE is TRUE control from SCADA and function block is enabled.

Value of REMOTE is FALSE motor is controlled only from function block.

PCO_MOT will align the block according to feedback signals.

Independent of operation mode of PCO_MOT.

INHIB_ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Suppression of alarms.

If value of INHIB_ERR is TRUE, all alarms from PCO_MOT are suppressed.

Independent of operation mode of PCO_MOT.

EXT_ACK

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

External acknowledge of alarms.

If value of EXT_ACK is TRUE, all alarms from PCO_MOTCON are acknowledged.

Independent of operation mode of PCO_MOT.

INHIB_FCT_ERR_TIME

Data type	Default value	Range	Unit
TIME	TIME#5s	-	-

Maximum delay time from command to response from process.

If response is not received within this time limit, a function error will be generated.

Alarm_1

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 1.

If value of ALARM_1 is TRUE Alarm_1 is active.

Independent of operation mode of PCO_MOT.

Alarm_2

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 2.

If value of ALARM_2 is TRUE Alarm_2 is active.

Independent of operation mode of PCO_MOT.

Alarm_3

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 3.

If value of ALARM_3 is TRUE Alarm_3 is active.

Independent of operation mode of PCO_MOT.

Alarm_4

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 4.

If value of ALARM_4 is TRUE Alarm_4 is active.

Independent of operation mode of PCO_MOT.

Alarm_5

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 5.

If value of ALARM_5 is TRUE Alarm_5 is active.

Independent of operation mode of PCO_MOT.

Alarm_6

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 6.

If value of ALARM_6 is TRUE Alarm_6 is active.

Independent of operation mode of PCO_MOT.

BEHAVE_ON_ERROR

Data type	Default value	Range	Unit
BYTE	0	0 ... 3	-

Actions that need to be executed by the FB at the event of error as set by the user.

The user can set a range of values from 0 ... 3.

BEHAVE_ON_ERROR = 0 causes the output to remain unaffected in case of a functional error or an external error (Not ready).

BEHAVE_ON_ERROR = 1 causes a stop command in case of a functional error.

BEHAVE_ON_ERROR = 2 causes a stop command in case of an external error.

BEHAVE_ON_ERROR = 3 causes a stop command in case of a functional error or an external error.

This parameter is independent of operation mode (whether Auto/ Manual) of PCO_MOT.

OUTPUT_HANDLING

Data type	Default value	Range	Unit
BYTE	1	0 ... 2	-

Behavior of command outputs, CMD_START / CMD_STOP.

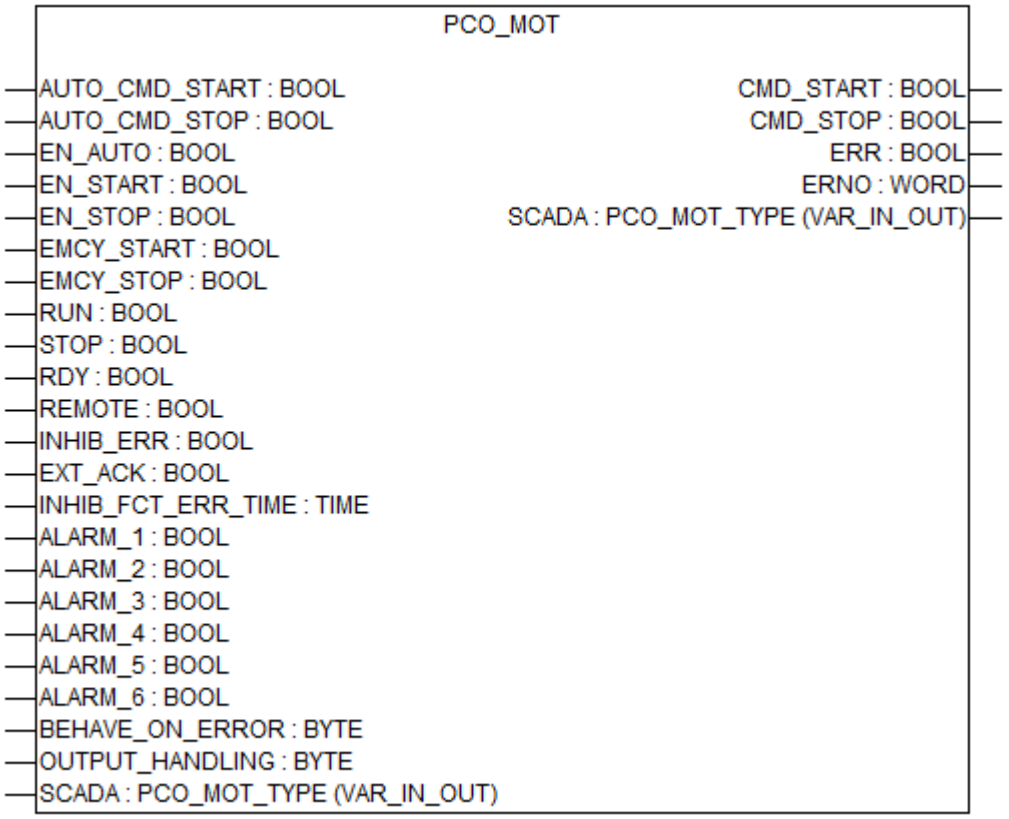
The user can set a range of values from 0 ... 2

OUTPUT_HANDLING = 0 causes the output (CMD_START / CMD_STOP) to be reset at RUN or STOP feedback.

OUTPUT_HANDLING = 1 causes the output (CMD_START / CMD_STOP)) to remain active at RUN or STOP feedback.

With OUTPUT_HANDLING = 2 the output (CMD_START / CMD_STOP) is performed as 1 s pulse. This parameter is independent of operation mode (whether Auto / Manual) of PCO_MOT.

Output description



CMD_START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Command output start, to be connected to hardware output.

CMD_STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Command output stop, to be connected to hardware output.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Common alarm, including:

- Functional error
- External error (input RDY)
- Input Parameter error
- ALARM_1
- ALARM_2
- ALARM_3
- ALARM_4
- ALARM_5
- ALARM_6
- EMCY_START
- EMCY_STOP

ERNO

Data type	Default value	Range	Unit
WORD	0	-	-

Error number

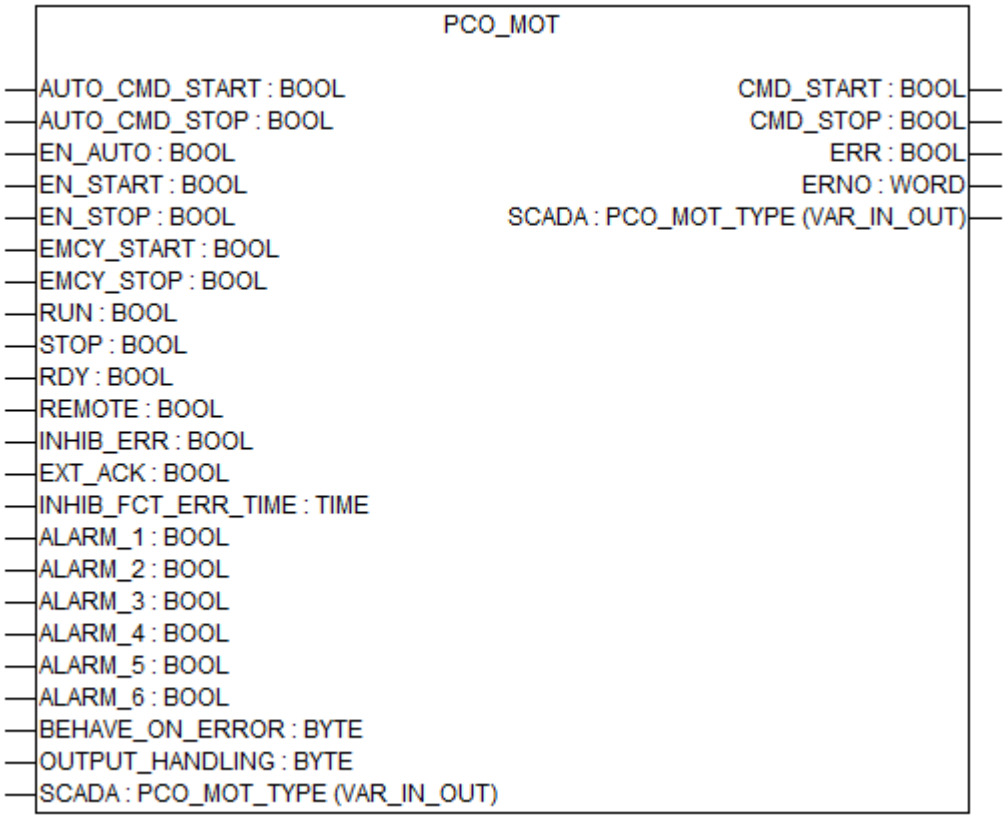
Output provides an error identifier if an invalid value was applied to an input.

ERNO always must be considered together with the output ERR.

The value output at ERNO is only valid if value of ERR is TRUE.

The error messages encoding is explained in *“Standard Function Block Libraries AC500”* in *“Error Messages of the Function Block Libraries”*.

Input/output description



SCADA

Data type	Default value	Range	Unit
PCO_MOT_TYPE	-	-	-

Structure variable for communication between AC500 and SCADA system.

Parameter	Data type	Description	In-/Output

Bit 15	Not used

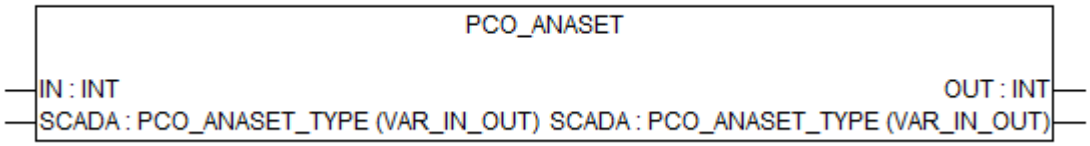
Setpoints

PCO_ANASET



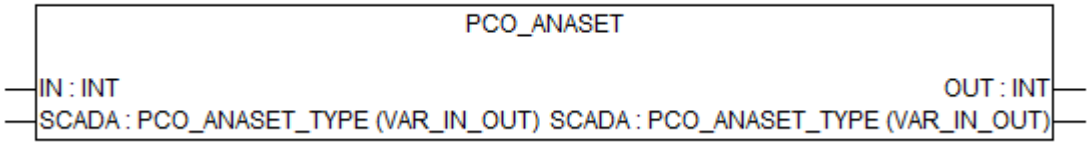
This function block is designed for receiving an analog setpoint from the SCADA system.

This value is entered at .PAR variable of the SCADA side. The actual analog setpoint is entered at IN input of the function block and it is represented by .VALUE variable in the SCADA side.

To retain the variable value in case of power ON/OFF or download, the variable connected to the SCADA In/Output should be declared as global retain persistant (or use %R area) variable in the program.

This function block can be used in combination with the object type ANASET_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Input description



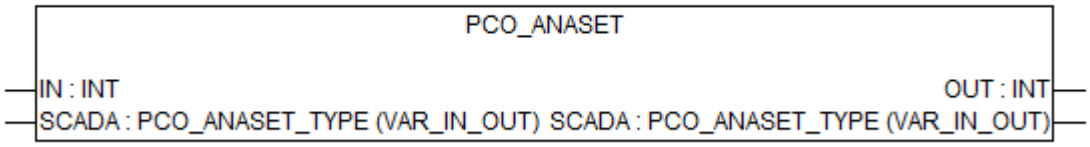
IN

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

Actual setpoint.

Parameter is sent to SCADA.

Output description



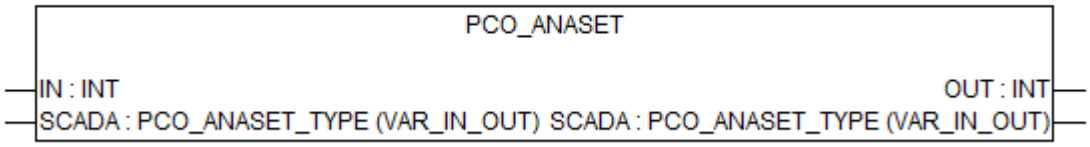
OUT

Data type	Default value	Range	Unit
INT	0	-32768 ... 32767	-

Setpoint received from SCADA.

Parameter received from SCADA.

Input/output description



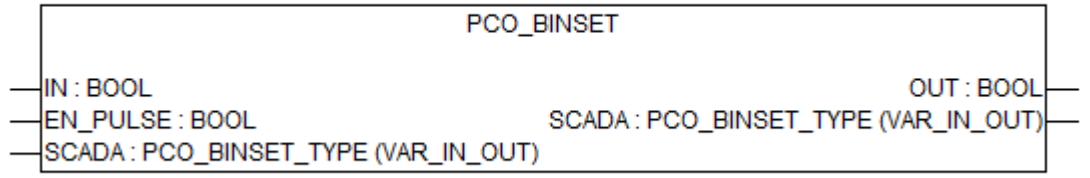
SCADA

Data type	Default value	Range	Unit
PCO_ANASET_TYPE	-	-	-

Structure variable for communication between AC500 and SCADA system.

Parameter	Data type	Description	In-/Output
SCADA.VALUE	INT	Actual setpoint	Output
SCADA.PAR	INT	Setpoint from SCADA	Input
AspectObjectType _Anaset_PLC	BOOL	(* Name of the 800xA Aspect Object type (AOT) to be used by the 800xA uploader, the live value is not used, only the name is relevant *)	Output

PCO_BINSET



This function block is designed for receiving single command from the SCADA system.

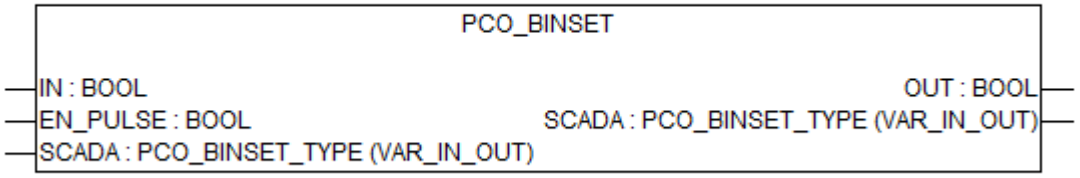
EN_PULSE input is used to reset command from SCADA. CMD variable from SCADA side is used to give command.

If value of EN_PULSE is TRUE, the command will only be active for one program cycle.

The CMD variable is connected to OUT (output) of function block.

This function block can be used in combination with the object type BINSET_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

Input description



IN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Actual status, that is the result of a command from SCADA side.

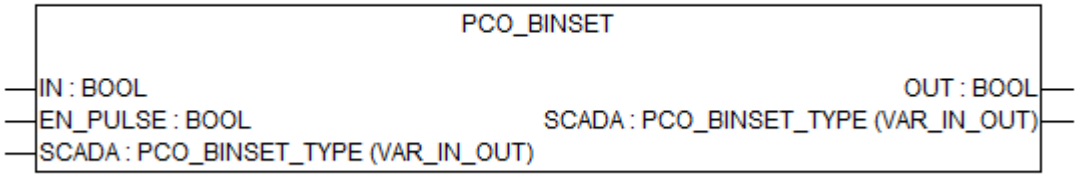
EN_PULSE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Pulse output.

If value of EN_PULSE is TRUE, CMD variable would be reset and OUT will only be active for one program cycle.

Output description



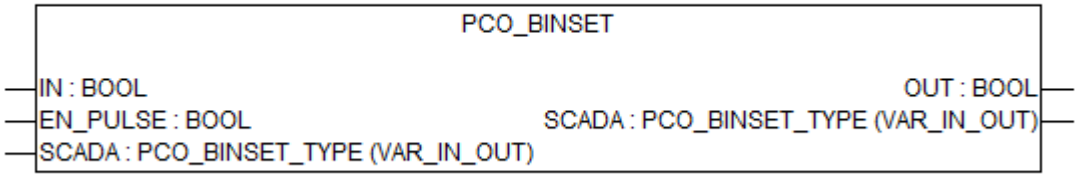
OUT

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Single command from SCADA.

If value of EN_PULSE is TRUE the single command will only be active for one program cycle.

Input/output description



SCADA

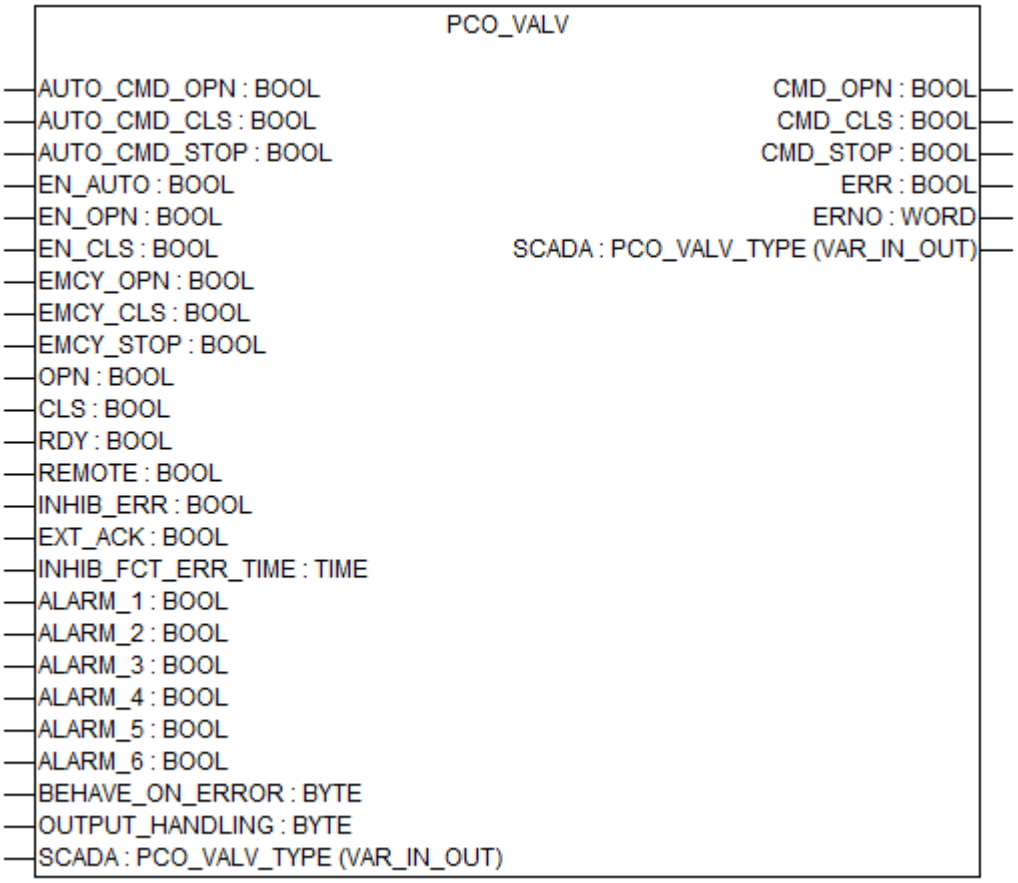
Data type	Default value	Range	Unit
PCO_BINSET_TYPE	-	-	-

Structure variable for communication between AC500 and SCADA system.

Parameter	Data type	Description	In-/Output
SCADA.STATUS	BOOL	Actual status, feedback	Output
SCADA.CMD	BOOL	Single command from SCADA	Input
AspectObjectType _Binset_PLC	BOOL	(* Name of the 800xA Aspect Object type (AOT) to be used by the 800xA uploader, the live value is not used, only the name is relevant *)	Output

Valve

PCO_VALV



This function block is designed for controlling a motor controlled ON/OFF valve.

Utilizing the inputs of the function block BEHAVE_ON_ERROR and OUTPUT_HANDLING different modes of CMD_OPN, CMD_STOP and CMD_CLS can be configured. E.g. if CMD_OPN should be pulsed or persistent signals. In addition, 6 different alarms can be connected to the function block (ALARM_1 to ALARM_6, thermal switch etc.)

There are two modes in which the valve can be operated, Auto mode or Manual mode.

In automatic mode the valve can be opened/stopped/closed using the function block inputs (AUTO_CMD_OPN/AUTO_CMD_STOP/AUTO_CMD_CLS).

Set valve to auto mode

The valve is set to auto mode when the following conditions are satisfied:

Settings in FB side	Data type	Set Valve to Auto Mode
EN_AUTO	BOOL	TRUE
REMOTE	BOOL	ACTIVE
RDY	BOOL	ACTIVE

Settings in SCADA side	Data type	Set Valve to Auto Mode
SCADA.CMDAUT	BOOL	Rising edge needs to be given.

Open / stop / close valve in auto mode

Settings in FB side	Data type	Open / Stop / Close Valve in Auto Mode
INHIB_FCT_ERR_TIME	TIME	The value of INHIB_FCT_ERR_TIME has to be greater than 0 s to avoid functional error.
EN_OPN	BOOL	ACTIVE
EN_CLS	BOOL	ACTIVE
AUTO_CMD_OPN	BOOL	Rising edge needs to be given to AUTO_CMD_OPN input of FB
AUTO_CMD_STP	BOOL	Rising edge needs to be given to AUTO_CMD_STP input of FB
AUTO_CMD_CLS	BOOL	Rising edge needs to be given to AUTO_CMD_CLS input of FB

Settings in SCADA side	Data type	Open / Stop / Close Valve in Auto Mode
SCADA.CMDAUT	BOOL	Rising edge needs to be given.

Set valve to manual mode

In manual mode the valve can be opened and closed from the SCADA faceplate.

The valve is set to manual mode when the following conditions are satisfied:

Settings in FB side	Data type	Set Valve to Manual Mode
REMOTE	BOOL	ACTIVE
RDY	BOOL	ACTIVE

Settings in SCADA side	Data type	Set Valve to Manual Mode
SCADA.CMDMAN	BOOL	Rising edge of SCADA.CMDMAN input to reset auto mode if it was set before

Open / close valve in manual mode

Settings in FB side	Data type	Open / Close Valve in Manual Mode
INHIB_FCT_ERR_TIME	TIME	The value of INHIB_FCT_ERR_TIME has to be greater than 0 s to avoid functional error.
EN_OPN	BOOL	ACTIVE
EN_CLS	BOOL	ACTIVE

Settings in SCADA side	Data type	Open / Close Valve in Manual Mode
CMDOPN	BOOL	Rising edge of CMDOPN needs to be given.
CMDCLS	BOOL	Rising edge of CMDCLS needs to be given.

This function block can be used in combination with the object type VALVCON_PLC included in PLC Object Library (an object library for 800xA based PLC Connect).

The function block includes supervision of the feedback signals OPN and CLS from the valve.

If the valve fails to open or close within the supervision time INHIB_FCT_ERR_TIME, it will raise a functional error.

Actions in case of a functional error are controlled by the parameter BEHAVE_ON_ERROR.

Examples

The function block is used for controlling a valve which in turn controls the level of fluid in a tank.

These components are included in the following example:

- Tank
- Level switch (high and low)
- Valve
- Main power supply, circuit breaker (or similar)

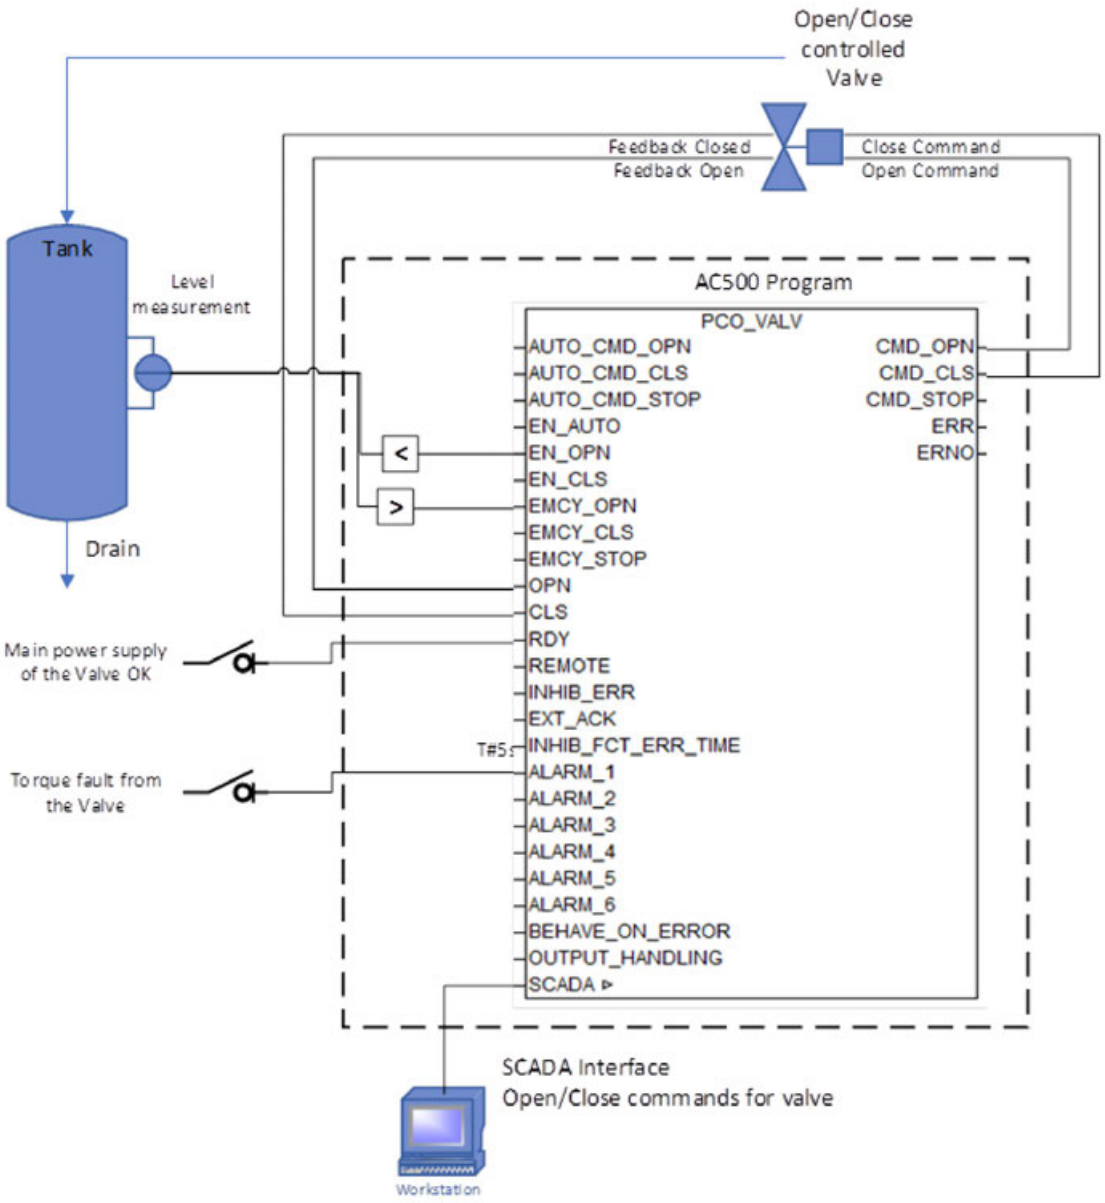
Manual mode:

- Valve controlled by the operator.

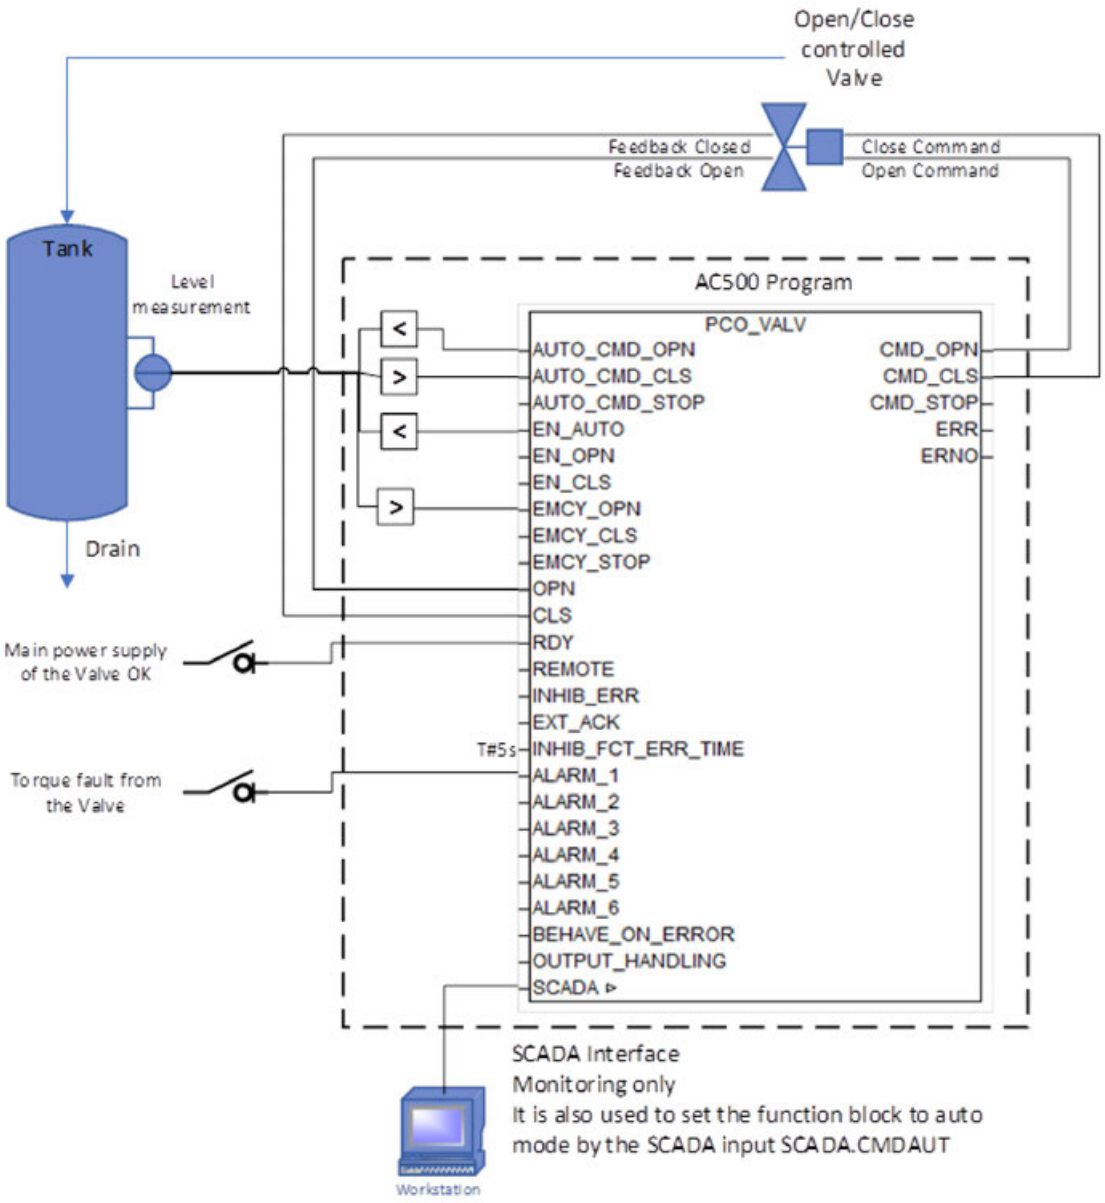
Automatic mode:

- Valve controlled by the AC500 controller.

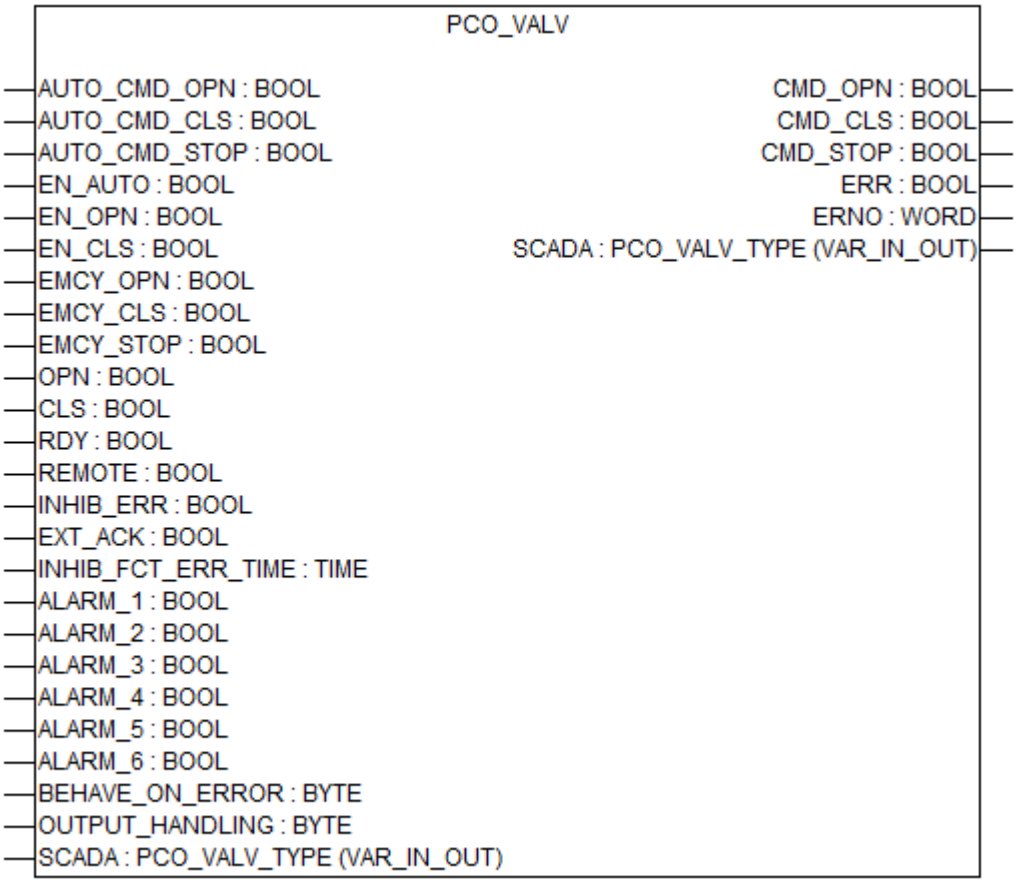
PCO_VALV manual mode example



PCO_VALV automatic mode example



Input description



AUTO_CMD_OPN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Force the valve to open, if the valve is in automatic mode.

AUTO_CMD_OPN could be activated from a sequence in the PLC program. The function block reacts on "0" to "1" transition of this input.

If AUTO_CMD_OPN and AUTO_CMD_CLS are active at the same time, then the commands CMD_OPN and CMD_CLS get reset.

AUTO_CMD_CLS

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Force the valve to close, if the valve is in automatic mode.

AUTO_CMD_CLS could be activated from a sequence in the PLC program. The function block reacts on "0" to "1" transition of this input.

If AUTO_CMD_OPN and AUTO_CMD_CLS are active at the same time, then the commands CMD_OPN and CMD_CLS get reset.

AUTO_CMD_STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Force the valve to stop, if the valve is in automatic mode.

Valve will stop in intermediate position.

AUTO_CMD_STOP could be activated from a sequence in the PLC program. The function block reacts on "0" to "1" transition of this input.

EN_AUTO

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable automatic mode of the PCO_VALV.

PCO_VALV can be set in automatic mode if value of EN_AUTO is TRUE.

PCO_VALV is forced in manual mode if value of EN_AUTO is FALSE.

EN_OPN

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable opening of the valve.

Valve can be opened if value of EN_OPN is TRUE.

Valve cannot be opened if value of EN_OPN is FALSE.

EN_OPN has no effect in case of emergency open of the valve, e.g. EMCY_OPN.

EN_OPN has no effect on an already opened valve.

EN_CLS

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Enable closing of the valve.

Valve can be closed if value of EN_CLS is TRUE.

Valve cannot be closed if value of EN_CLS is FALSE.

EN_CLSN has no effect in case of emergency close of the valve, e.g. EMCY_CLS.

EN_CLS has no effect on an already closed valve.

EMCY_OPN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Emergency open of the valve.

If value of EMCY_OPN is TRUE and value of EMCY_CLS is FALSE, the valve will open.

If value of EMCY_OPN is TRUE and the value of EMCY_CLS is TRUE, the valve will close.

If value of EMCY_STOP is TRUE, the valve will stop.

Independent of operation mode of PCO_VALV.

EMCY_CLS

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Emergency close of the valve.

If value of EMCY_CLS is TRUE, the valve will close.

If value of EMCY_OPN is TRUE and value of EMCY_CLS is TRUE, the valve will close.

If value of EMCY_STOP is TRUE, the valve will stop.

Independent of operation mode of PCO_VALV.

EMCY_STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Emergency stop of the valve.

If value of EMCY_STOP is TRUE, the valve will stop. Highest priority.

Independent of operation mode of PCO_VALV.

OPN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Feedback signal from the valve.

If the value of OPN is TRUE, the valve is open.

Independent of operation mode of PCO_VALV.

CLS

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Feedback signal from the valve.

If the value of CLS is TRUE, the valve is closed.

Independent of operation mode of PCO_VALV.

RDY

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Valve is ready for operation.

Valve is ready for operation if value of RDY is TRUE.

Value of RDY is FALSE results in an external error.

Independent of operation mode of PCO_VALV.

REMOTE

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

Allow valve to be controlled from SCADA.

Value of REMOTE is TRUE control from SCADA and function block is enabled.

Value of REMOTE is FALSE valve is controlled only from function block.

PCO_VALV will align the block according to feedback signals.

Independent of operation mode of PCO_VALV.

INHIB_ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Suppression of alarms.

If value of INHIB_ERR is TRUE, all alarms from PCO_VALV are suppressed.

Independent of operation mode of PCO_VALV.

EXT_ACK

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

External acknowledge of alarms.

If value of EXT_ACK is TRUE all alarms from PCO_VALV are acknowledged.

Independent of operation mode of PCO_VALV.

INHIB_FCT_ ERR_TIME

Data type	Default value	Range	Unit
TIME	TIME#5s	-	-

Maximum delay time from command to response from process.

If response is not received within this time limit, a function error will be generated.

Alarm_1

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 1.

If value of ALARM_1 is TRUE Alarm_1 is active.

Independent of operation mode of PCO_VALV.

Alarm_2

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 2.

If value of ALARM_2 is TRUE Alarm_2 is active.

Independent of operation mode of PCO_VALV.

Alarm_3

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 3.

If value of ALARM_3 is TRUE Alarm_3 is active.

Independent of operation mode of PCO_VALV.

Alarm_4

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 4.

If value of ALARM_4 is TRUE Alarm_4 is active.

Independent of operation mode of PCO_VALV.

Alarm_5

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 5.

If value of ALARM_5 is TRUE Alarm_5 is active.

Independent of operation mode of PCO_VALV.

Alarm_6

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Auxiliary alarm no. 6.

If value of ALARM_6 is TRUE Alarm_6 is active.

Independent of operation mode of PCO_VALV.

BEHAVE_ON_ERROR

Data type	Default value	Range	Unit
BYTE	0	0 ... 3	-

Actions that need to be executed by the FB at the event of error as set by the user.

The user can set a range of values from 0 ... 3.

BEHAVE_ON_ERROR = 0 causes the output to remain unaffected in case of a functional error or an external error (Not ready).

BEHAVE_ON_ERROR = 1 causes a stop command in case of a functional error.

BEHAVE_ON_ERROR = 2 causes a stop command in case of an external error.

BEHAVE_ON_ERROR = 3 causes a stop command in case of a functional error or an external error.

This parameter is independent of operation mode (whether Auto/ Manual) of PCO_VALV.

OUTPUT_HANDLING

Data type	Default value	Range	Unit
BYTE	1	0 ... 2	-

Behavior of command outputs, CMD_START / CMD_STOP.

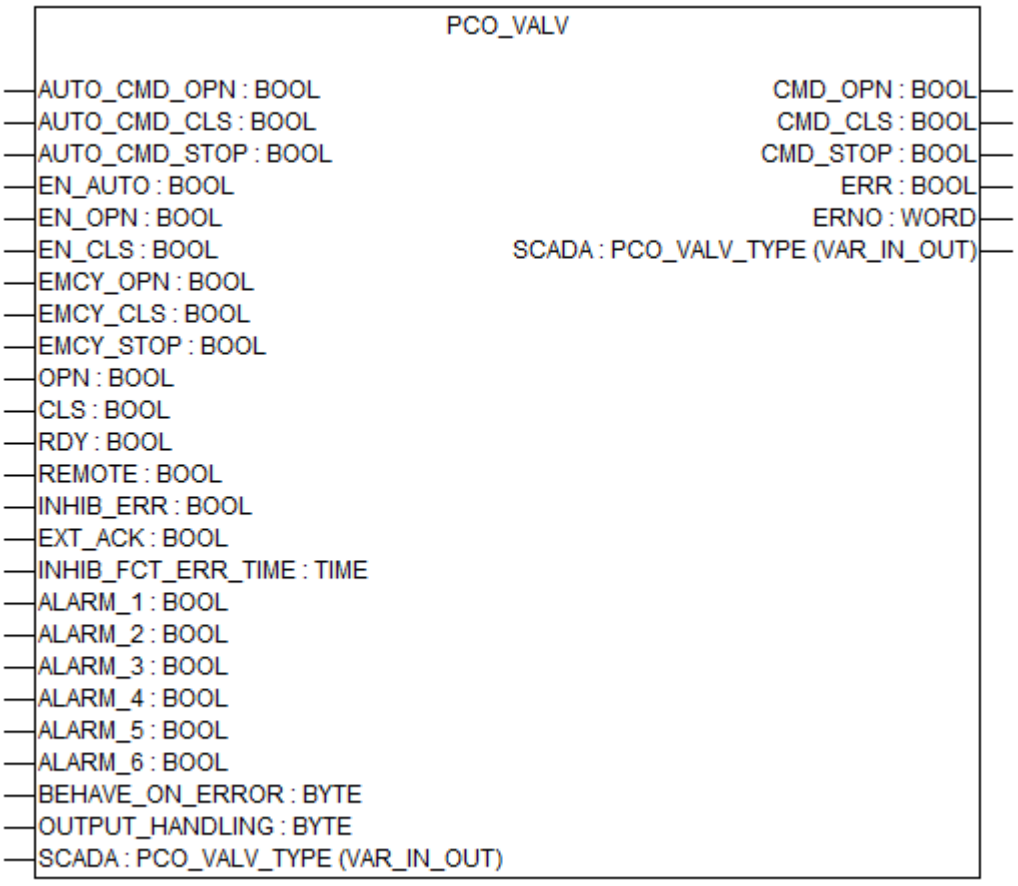
The user can set a range of values from 0 ... 2

OUTPUT_HANDLING = 0 causes the output (CMD_START / CMD_STOP) to be reset at RUN or STOP feedback.

OUTPUT_HANDLING = 1 causes the output (CMD_START / CMD_STOP)) to remain active at RUN or STOP feedback.

With OUTPUT_HANDLING = 2 the output (CMD_START / CMD_STOP) is performed as 1 s pulse. This parameter is independent of operation mode (whether Auto / Manual) of PCO_VALV.

Output description



CMD_OPN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Command output open to be connected to hardware output.

CMD_CLS

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Command output close to be connected to hardware output.

CMD_STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Command output stop, to be connected to hardware output.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Common alarm, including:

- Functional error
- External error (input RDY)
- Input Parameter error
- ALARM_1
- ALARM_2
- ALARM_3
- ALARM_4
- ALARM_5
- ALARM_6
- EMCY_OPN
- EMCY_CLS
- EMCY_STOP

ERNO

Data type	Default value	Range	Unit
WORD	0	-	-

Error number

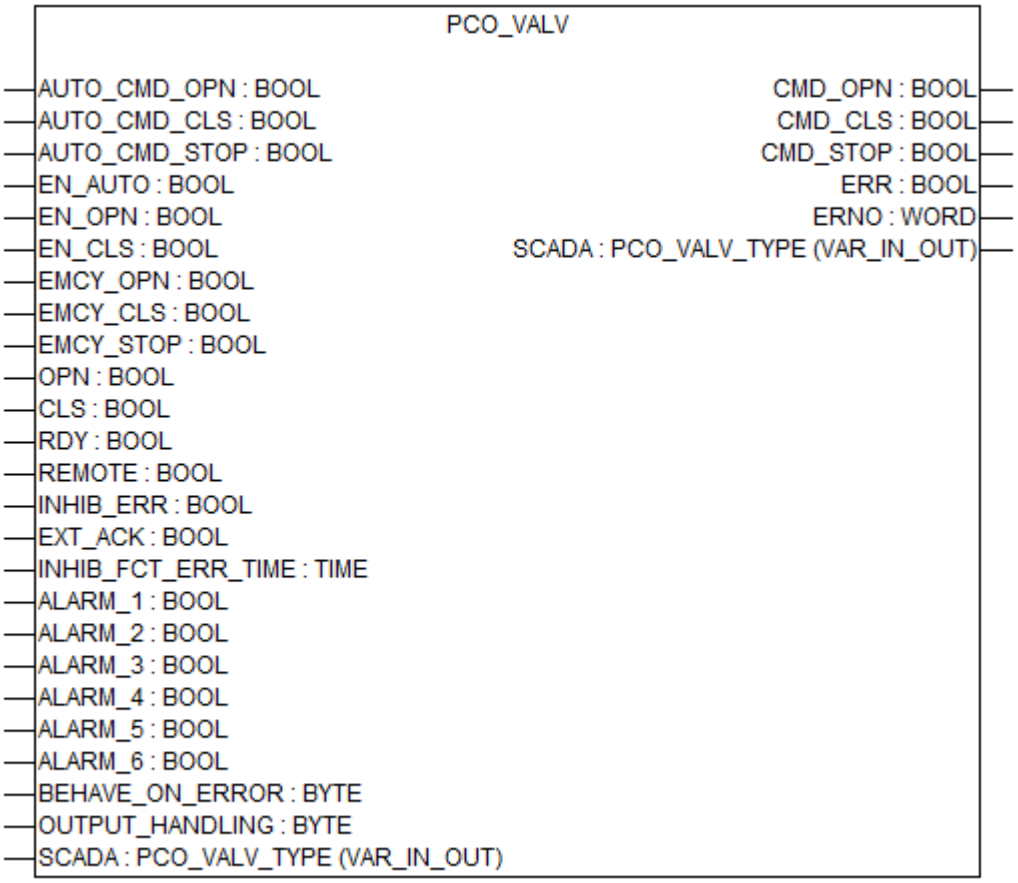
Output provides an error identifier if an invalid value was applied to an input.

ERNO always must be considered together with the output ERR.

The value output at ERNO is only valid if value of ERR is TRUE.

The error messages encoding is explained in *“Standard Function Block Libraries AC500”* in *“Error Messages of the Function Block Libraries”*.

Input/output description



SCADA

Data type	Default value	Range	Unit
PCO_VALV_TYPE	-	-	-

Structure variable for communication to and from SCADA system.

Parameter	Data type	Description	In-/Output
SCADA.CMDOPN	BOOL	Open command	Input
SCADA.CMDCLS	BOOL	Close command	Input
SCADA.CMDSTP	BOOL	Stop command	Input
SCADA.CMDAUT	BOOL	Auto command	Input
SCADA.CMDMAN	BOOL	Manual command	Input
SCADA.CMDRES	BOOL	Acknowledge active alarms	Input
SCADA.AUTO	BOOL	Valve in automatic mode	Output

SCADA.OSMsg1 *)	WORD	Word representing the status of the PCO_VALV	Output
SCADA.OSMsg2 *)	WORD	Word representing the status of the PCO_VALV This includes the status of emergency status and alarm status.	Output
AspectObjectType _Valv_PLC	BOOL	(* Name of the 800xA Aspect Object type (AOT) to be used by the 800xA uploader, the live value is not used, only the name is relevant *)	Output

*) structure described separately

SCADA.OSMsg1

Data type	Default value	Range	Unit
WORD	-	-	-

Word representing the status of the PCO_VALV.

Bit	Description
Bit 0	Valve is open
Bit 1	Valve is closed
Bit 2	Valve opening
Bit 3	Valve closing
Bit 4	External error (Not ready)
Bit 5	Functional error
Bit 6	Valve released for opening
Bit 7	Valve released for closing
Bit 8	Local operation (Not remote)
Bit 9	Common alarm (External alarm + Functional alarm + EMCY_OPN/EMCY_CLS/EMCY_STOP + ALARM_1 ... ALARM_6)
Bit 10	Unacknowledged alarm
Bit 11	Valve in automatic mode
Bit 12	Not used
Bit 13	Valve not released for automatic mode
Bit 14	Not used
Bit 15	Not used

SCADA.OSMsg2

Data type	Default value	Range	Unit
WORD	-	-	-

Word representing the status of the PCO_VALV.

This includes the status of emergency status and alarm status.

Bit	Description
Bit 0	Emergency open
Bit 1	Emergency close
Bit 2	Auxiliary alarm 1
Bit 3	Auxiliary alarm 2
Bit 4	Auxiliary alarm 3
Bit 5	Auxiliary alarm 4
Bit 6	Auxiliary alarm 5

Bit 14	Not used
Bit 15	Not used

1.5.11 Solar library

1.5.11.1 Preconditions for the use of the Solar_AC500 library

PS562-SOLAR libraries are working on AC500 and AC500-eCo, but depending on the application, number of axes and its total program, memory restrictions on the AC500-eco can occur.

For the highly accurate NREL algorithm, meant for focusing systems with high concentration factor, PM573 or larger should be chosen.

The included example programs "Example_Solar_2Axis_ACS3XX.project" (uses NREL) and "ExamplePM564_NOAA_Solar_2Axis_ACS3XX.project" show complete examples for different accuracies and CPU families, see example program description pdf.

The function blocks of PS562-SOLAR libraries are usable and have been tested for AC500 control systems with a runtime system of version V1.3 and above.

The libraries have been tested with PM564, PM573, PM583, PM592.

The function blocks of the solar library are only working in RUN mode of the PLC. Usage of these libraries in the simulation mode will not provide always valid or usable behavior/values.

User needs to add DC541_AC500_V11 library along with Solar_AC500_V22 Library.

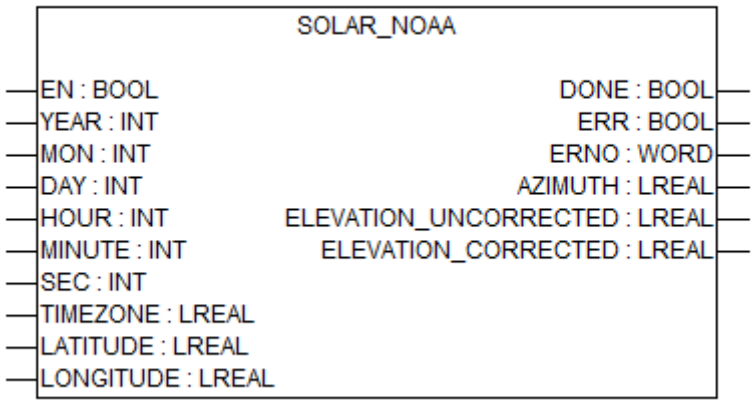
The above named examples need additionally the ACS Drives Libraries from the PS553-DRIVES package, which can be downloaded from www.abb.com/PLC:

- On right side menu under heading "Your preferences": Select "English" as language ... (country doesn´t matter).
- On right side menu under "More Info Links" : Click on "PS501 Updates".
- Select "PS501-UPDA: PS553-DRIVES…" to download *.zip file.

1.5.11.2 SOLAR_AC500 library

1.5.11.2.1 TRACK folder

SOLAR_NOAA



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function blocks without historical values.
Group	Package of functions to get the position of the sun

This function block calculates the position of the sun, elevation and azimuth, according to: date, time and location, with an azimuth error = ± 0.01° and elevation error = ±0.03°. This function embeds the SOLAR_NOAAs algorithm.

Output parameters are solar elevation and solar azimuth. These outputs are the topocentric coordinates of the sun which use the observer's location as a centre of the coordinate system.

The end-user may use the RTC of the AC500 system by using the CLOCK function block of the library named SysExt_AC500_V10.lib or may use any other source to calculate the position of the sun.

Table 195: Size of used data for SOLAR_NOAA function block and execution time for each CPU type

	PM583	PM591	PM564
Data Size	4299 bytes	4299 bytes	4299 bytes
Program Size	20622 bytes	10742 bytes	20834 bytes
Execution Time	3 ms	1 ms	5 ms

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

YEAR INT (year) Range of values: from 2000 to 6000.

MON INT (month) Range of values: from 1 to 12.

DAY INT (day) Range of values: from 1 to 31.

HOUR INT (hour) Range of values: from 0 to 23.

MINUTE INT (minute) Range of values: from 0 to 59.

SEC INT (second) Range of values: from 0 to 59.

TIMEZONE LREAL (time zone) Observer time zone (negative west of Greenwich).

Time zone = Standard Time - Universal Time

Format: hours.

Range of values: -12...12.

Resolution: 0.1 hour.

LATITUDE LREAL (latitude) Observer latitude (negative south of equator).

Format: degrees.

Range of values: from -90.00 to 90.00.

LONGITUDE LREAL (longitude) Observer longitude (negative west of Greenwich).

Format: degrees.

Range of values: from -180.00 to 180.00.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

AZIMUTH LREAL (azimuth)

Topocentric azimuth. Eastward from north (0°=360°=north, 90°=east, 180°=south, 270°=west).

Format: degrees.

Range of values: from 0 to 359.9999.

Error values:

- Northern hemisphere: area between latitudes from 70° to 24°. In this area the accuracy of function SOLAR_NOAA is ±0,02° azimuth.
- Southern hemisphere: area between latitudes from -70° to -24°. In this area the accuracy of function SOLAR_NOAA is ±0,08° azimuth.
- Equator: area between 24° and -24°. In this area the accuracy of function SOLAR_NOAA is 0,08° azimuth. Note that in this area, around 12:00 h (solar time) maximum error values may be greater because of the high speed of the azimuth axis at 12.00 h (solar time). It must move from 90° to 270° in a few seconds.

ELEVATION_UNCORRECTED LREAL (elevation_uncorrected)

Topocentric elevation angle (0°=sunrise, 90°=zenith).

Format: degrees.

Range of values: -90.00...90.00. Negative values=darkness.

Elevation error: ±0.015°.

If elevation goes through zero at special locations at sunset / sunrise, also slightly larger errors can occur (mind that energy production is close to zero anyway).

For latitudes greater than 72° north or less than 72° south, accuracy may be lower due in part to the effects of atmospheric refraction.

ELEVATION_CORRECTED LREAL (elevation_corrected)

Topocentric elevation angle (0°=sunrise, 90°=zenith). This value includes atmospheric refraction effects.

Format: degrees.

Range of values: -90.00...90.00. Negative values=darkness.

Elevation Error: ±0.015°.

If elevation goes through zero at special locations at sunset / sunrise, also slightly larger errors can occur (mind that energy production is close to zero anyway).

P = 1010 mBar.

Temp = 10°C.

Refraction = 0,5667.

Atmospheric refraction is the angular displacement of astronomical objects from their true or geometrical position, because of the bending of rays in the earth's atmosphere.

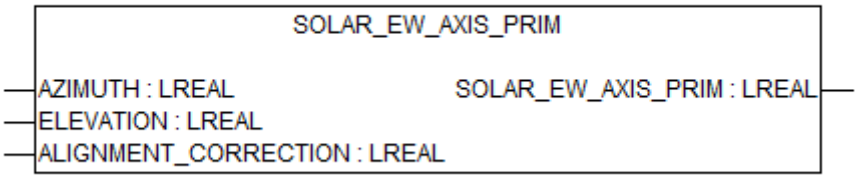
1.5.11.2.2 AXIS folder

SOLAR_EW_AXIS_PRIM



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Functions
Group	Package of functions to get the axis angle of the tracker to follow the sun

This function block calculates the angle of east to west axis according to: azimuth, elevation and correction alignment factor.

Input description

AZIMUTH LREAL (azimuth)

Topocentric azimuth angle. Eastward from north (0°=360°=north, 90°=east, 180°=south, 270°=west).

Format: degrees.

Range of values: from 0 to 359.9999.

ELEVATION LREAL (elevation)

Topocentric elevation angle (0°=sunrise, 90°=zenith).

Format: degrees.

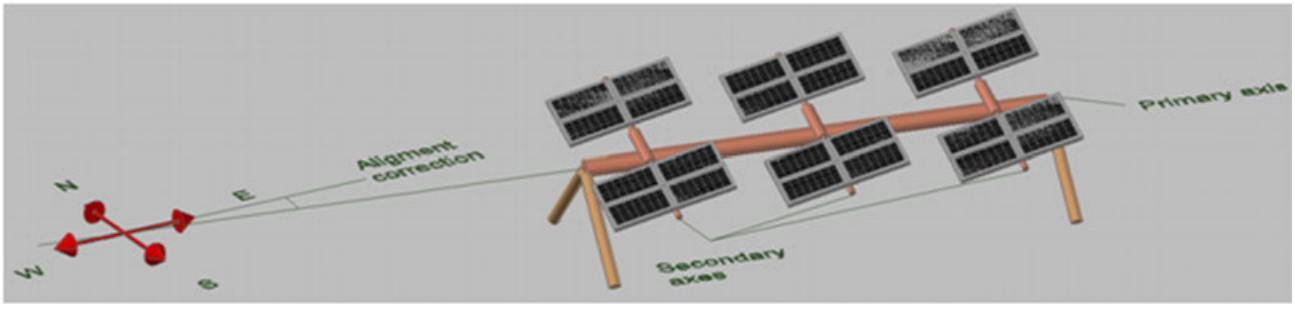
Range of values: -90.00...90.00. Negative values=darkness.

ALIGNMENT_CORRECTION LREAL (alignment correction)

Angle between system axis and east (clockwise).

Format: degrees.

Range of values: -180.00...180.00.



Output description

(Output) LREAL

Angle of east to west axis (0°=zenith, -90°=north, 90°=south).

Format: degrees.

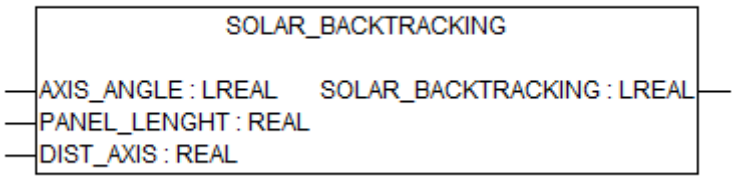
1.5.11.2.3 BACKTRACK folder

SOLAR_BACKTRACKING



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function
Group	Package of functions to get the optimum tracker position to avoid shadows

This function calculates the optimum tracker position to reduce shadowing by optimizing solar panel position, when position of the sun gets low (early morning + late evening). Axis angle is calculated according to: axis angle for solar tracking in one axis, calculated regardless shadows, distance between rows of Solar Trackers and height of them.

Output parameter is the optimum axis angle which avoids shadowing between rows of Solar Trackers.

Input description

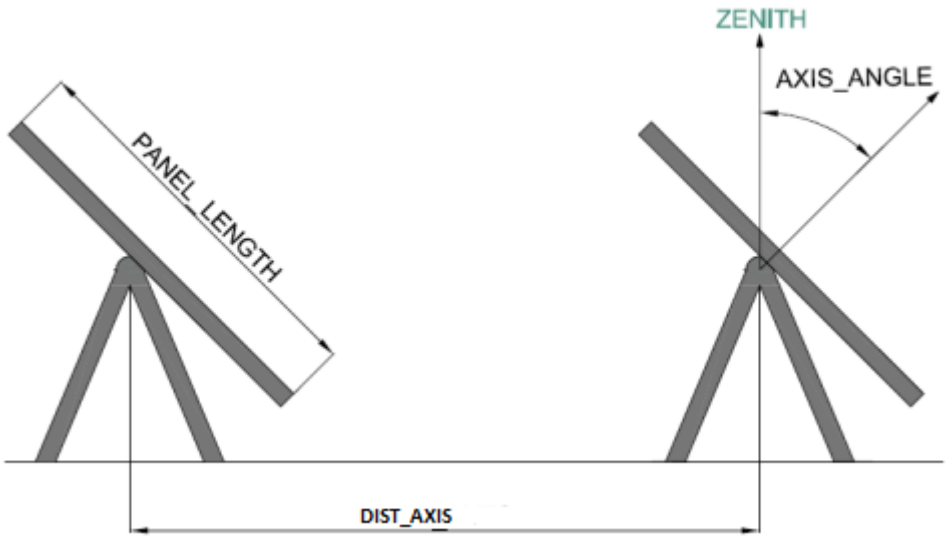
AXIS_ANGLE LREAL (axis angle)
Angle of main axis (0°=zenith, anticlockwise).
Format: degrees.

PANEL_LENGTH REAL (panel length)
Value that indicates the total length of panels.
Format: meters.

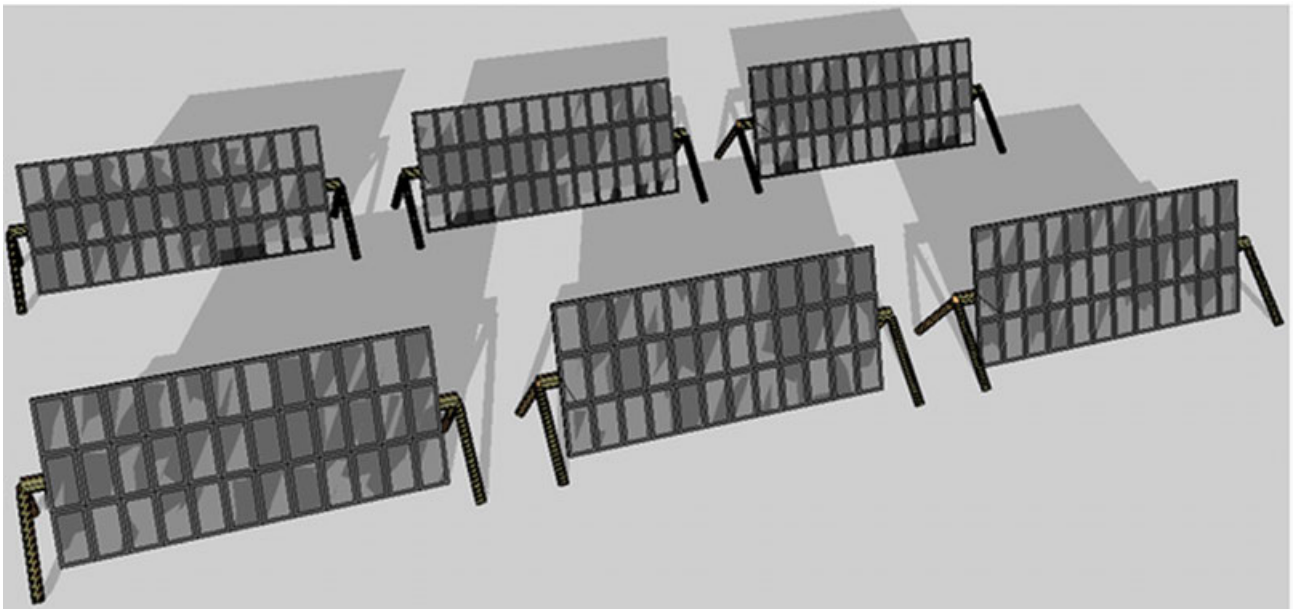
DIST_AXIS REAL (distance axis)
Distance between rows of Solar Trackers.
Format: meters.

Output description

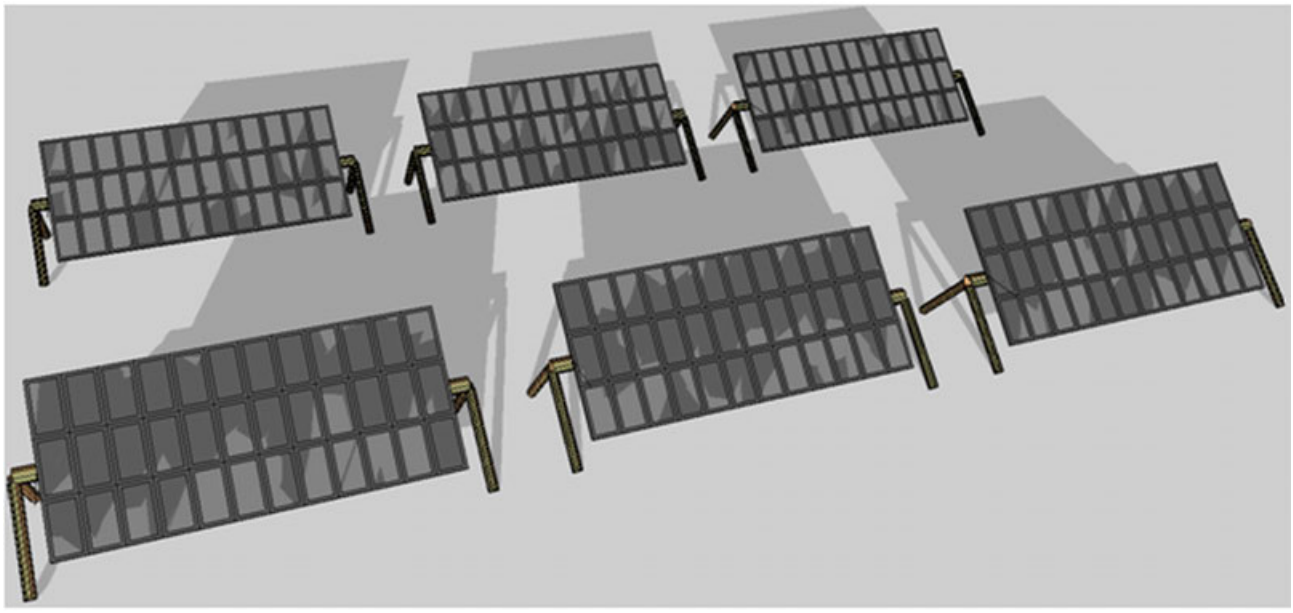
(Output) REAL
The block output is the optimum axis angle which avoids shadowing between rows of Solar Trackers.
Format: degrees.
Dimensional features:



Example:



Shadow effects, early morning, on north to south single axis trackers positioned with the angle calculated regardless shadows, using SOLAR_NS_AXIS_PRIM.



Position of the same tracker at the same date, time and location avoiding shadows between rows of trackers by correcting the axis angle with the function block SOLAR_BACKTRACKING.

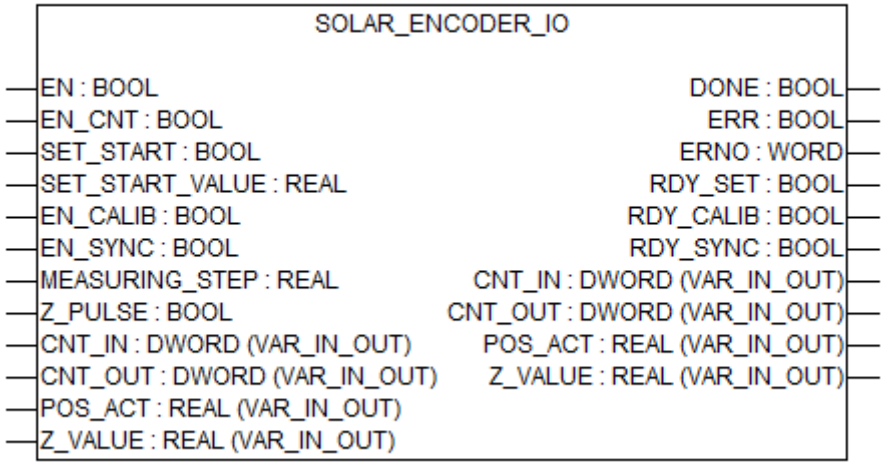
SOLAR_BACKTRACKING_DIST_AXIS);
```

1.5.11.2.4 POSITION folder

SOLAR_ENCODER_IO



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function block with historical values.
Group	Package of functions to get the position of the sun

The SOLAR_ENCODER_IO is used to easily integrate, with any S500 I/O card, Incremental encoders (A, B) plus inductive proximity sensor (Z) as positioning sensors for Solar Trackers.

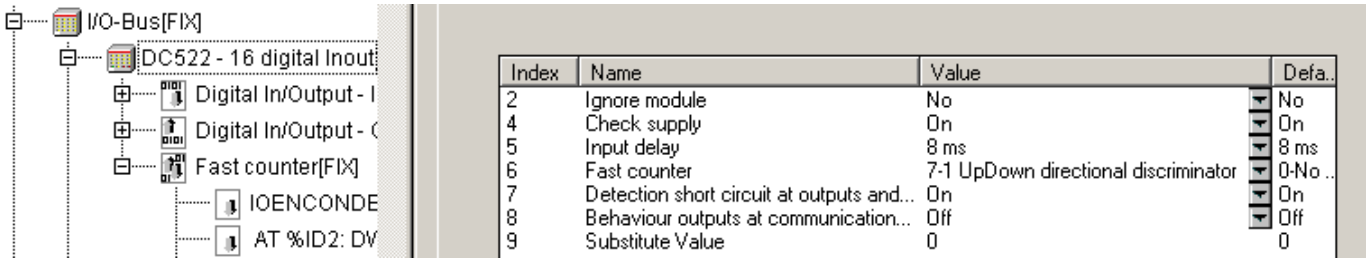
This function uses the fast counters which have several I/O modules to integrate Incremental encoders. The counting modules with fast counters, and its features, are described in ↳ *Chapter 1.6.2.6.1.2.10 “Fast counter” on page 4351*.

> *The functionality 'Fast Counter' only works with communication interface modules which are mounted at the I/O bus of an AC500 CPU. An exception is the CS31 communication interface module DC551-CS31, which contains a fast counter that is made operationally by the address setting on the module.*

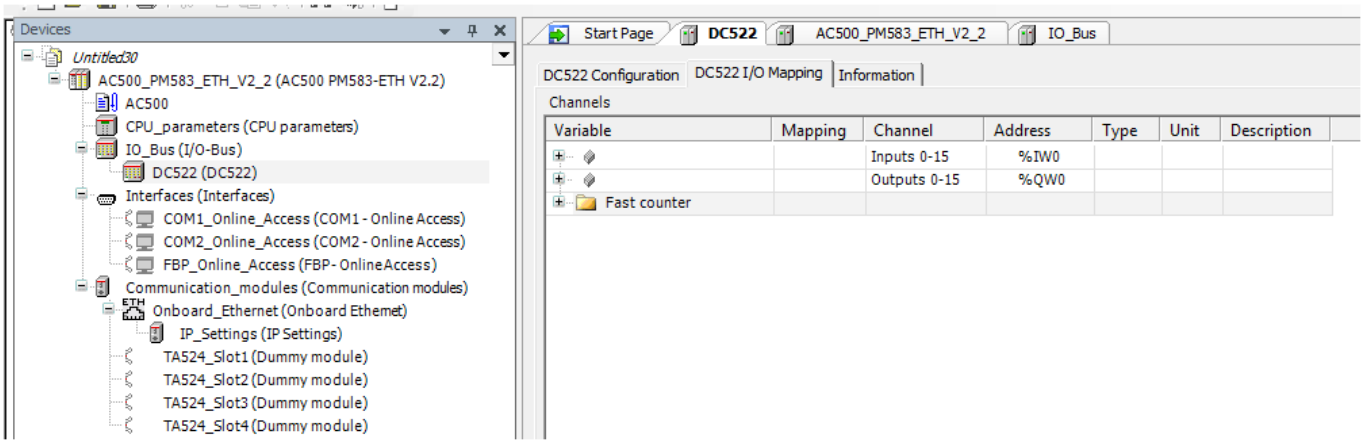
The I/O modules on the I/O bus have two inputs of fast counters per module, which are activated via software in the PLC configuration. Each module counter can be configured up to 10 possible modes. After that, it is activated during the initialization phase (power-on, cold start, warm start).

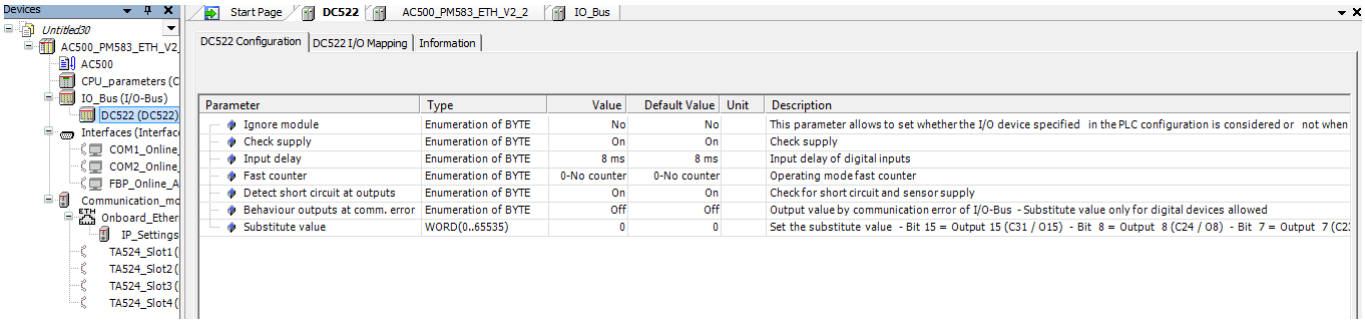
The function block SOLAR_ENCODER_IO should be used configuring the module parameter "Fast counter" with the operating modes 7, 9 or 10, to determine the counting procedure in x1, x2 or x4 count respectively. The different meanings of each fast counter mode are explained down below:

Example: Configuration of module DC522 to use the fast counter to integrate an Incremental encoder in x1 mode:



In Contol Builder Plus V2.0 and above:





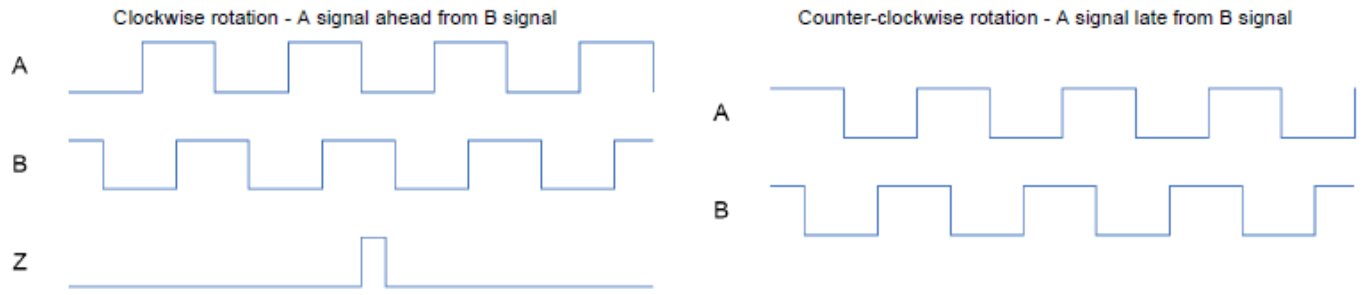
Fast counter: "7-1 UpDown directional discriminator"

The x1 counting mode is used. The encoder module discriminates the rotating way and count one pulse for each rising edge of the A signal.

In this mode the maximum counting frequency is 35 kHz.

The rotation is identified with a shift angle (90°) between A and B signal. In the I/O module, the clockwise rotation is identified with A signal in advance to B (see figure below).

Example: Direction identification using A and B signals:



Fast counter: "9-1 UpDown directional discriminator X2"

The x2 counting mode is used. The module counts both the positive edges and the negative edges of trace A.

The result is the double number of counting pulses, so the precision increases correspondingly.

In this operating mode, the maximum counting frequency is 30 kHz.

Fast counter: "10-1 UpDown directional discriminator X4"

The x4 counting mode is used. The counter counts the positive and negative edges of the traces A and B. In this operating mode, the maximum counting frequency is 15 kHz.

The I/O modules provide 2 fast counter inputs to use for relative positioning with 2 signals (A, B).

> *To acquire the Z signal, a conventional input channel should be used.*

Due to that, the Z signal will be set at least:

CPU	Minimum time to warranty the Z signal will be acquire
<583	T>10 ms
>590	T>1 ms

This table represents the time necessary to read the Z signal, using a task configured at the maximum frequency for each CPU.

The following table shows the S500 modules that contain a fast counter and which of the digital inputs are reserved for the counter.

MODULE	ASIGNED INPUTS	
	CHANNEL A	CHANNEL B
DC522	C8	C9
DC523	C16	C17
DC532	C24	C25
DC524	I24	I25
DX522	I0	I1
DC531-CS31	C16	C17

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

EN_CNT BOOL (enable counter)

If EN_CNT = TRUE, pulse counting of counter is enabled. If EN_CNT = FALSE, no pulse counting is performed and pulses are not stored even the encoder device changes its position.

If counting has already started and if EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

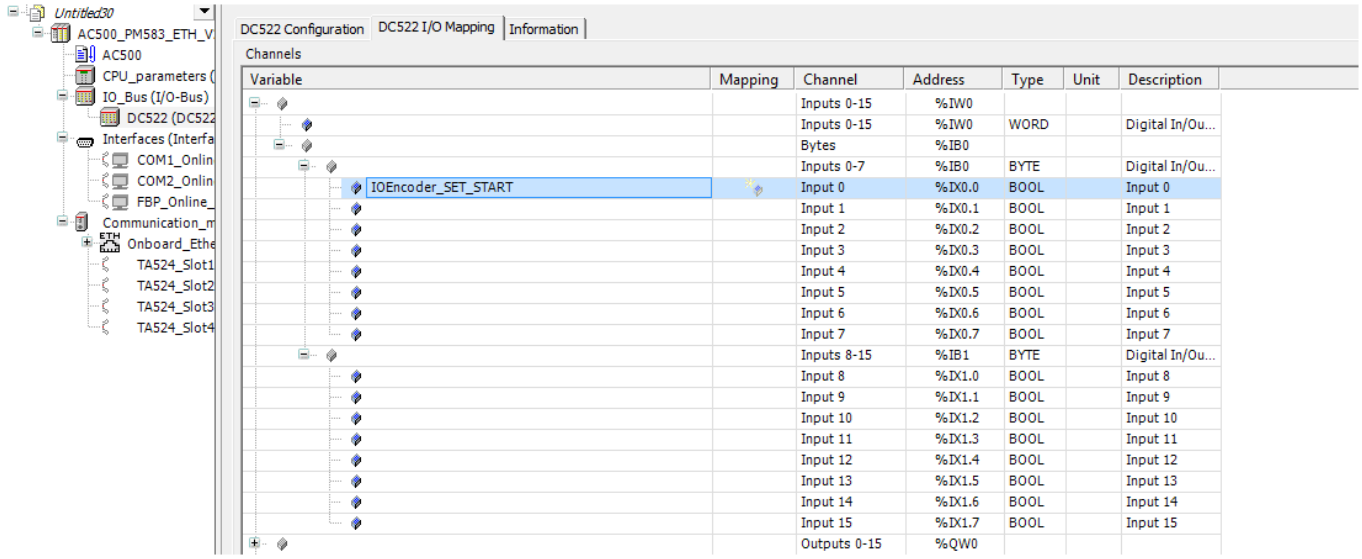
SET_START BOOL (set start)

If set input SET_START = TRUE, the counter takes the values from input SET_START_VALUE to transfer it to ACT. As long as input SET_START = TRUE, no pulses are counted because the counter is always overwritten by the input SET_START_VALUE.

To synchronize the counter value with the mechanical zero reference based on signal Z, a conventional input channel should be used to read the Z signal as follows:

Example: Use of conventional input channel to acquire the reference signal:

In Control Builder Plus V2.0 and above:



When the input channel which represents the Z channel is activated, the SET_START goes to true, and ACT goes to the value which is indicated by SET_START_VALUE.

SET_START_VALUE REAL (set start value)

The counter can be set to a Start value. This value must be applied to the input SET_START_VLAUE.

If input SET_START=TRUE, the counter takes this value.

EN_CALIB BOOL (enabling calibrate)

If EN_CALIB = TRUE, when a rising edge is detected at the encoder´s reference point (Z) signal, output Z_VALUE will take the stored value in POS_ACT and output RDY_CALIB is set to TRUE. If this input is continuously set to TRUE, only one calibrating process will be done even system reaches encoder´s reference point (Z) once again. In order to enable another calibrating process, input EN_CALIB has to be set to FALSE and set to TRUE again.

Calibrating process is executed out of CPU cycle, and it is able to detect the multiple rising edges that appear when a simple limit switch is used. Due to that, it is recommended to use devices assembled especially for this purpose (high accuracy limit switch).

Inputs used as reference point Z in the calibrating process are:

Counter0 -> I3

Counter1 -> I11

EN_SYNC BOOL (enabling synchronize)

If input EN_SYNC = TRUE, when a rising edge is detected at the encoder´s reference point (Z) signal, output POS_ACT will take the value stored at Z_VALUE, output RDY_SYNC is set to TRUE only during a program cycle. While EN_SYNC is set to TRUE, POS_ACT output will take the value stored at Z_VALUE every time that a rising edge is detected at the encoder´s reference point (Z) signal.

Inputs used as reference point Z in the synchronisation process are:

Counter0 -> Z0

Counter1 -> Z1

MEASURING_STEP REAL (measuring step)

Indicates the resolution of the encoder device (see technical data from manufacturer). For example, using an incremental encoder with a resolution of 10000 pulses each 360° and x4 counting mode (software configuration), measuring step will use the following value:

360 / (4 x 10000) = 0,009

Format: Degrees.

Z_PULSE BOOL (input signal Z)

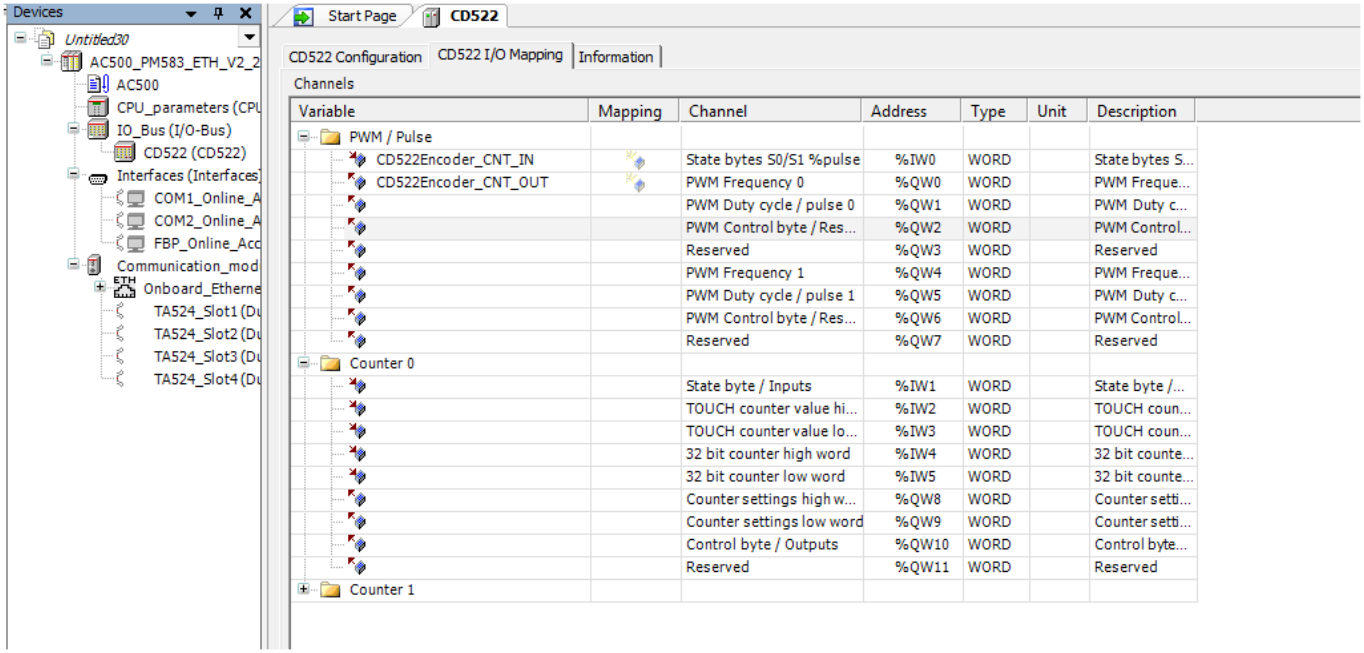
The output Z_PULSE indicates that encoder's reference point Z has been reached. This signal is only visible if programs execution time is slower than the signal of encoder's reference point (Z).

CNT_IN WORD (counter input)

First input data of counter input. The use of an ADR operator is not needed.

Example (for counter 0):

In Control Builder Plus V2.0 and above:

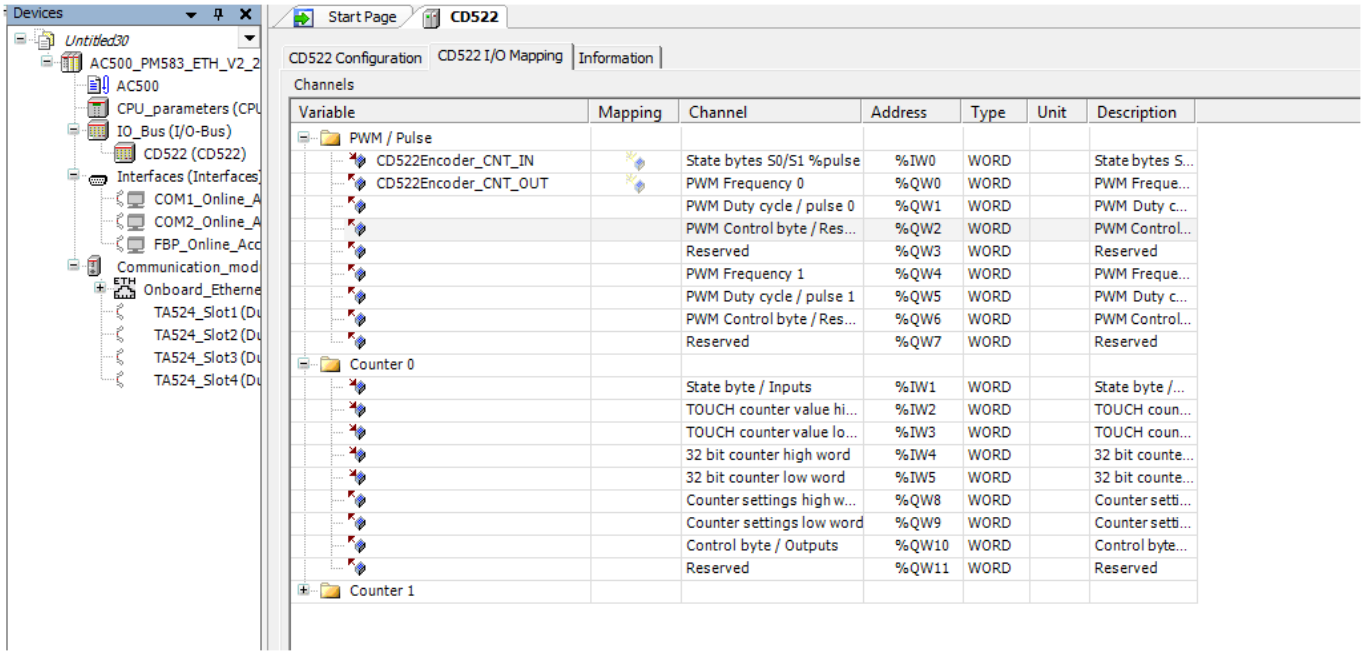


CNT_OUT WORD (counter output)

First output data of counter output. The use of an ADR operator is not needed.

Example (for counter 0):

In Control Builder Plus V2.0 and above:



POS_ACT REAL (position_actual)

The current position (actual position) can be retrieved at any time using the output POS_ACT of the function block. If a shutdown occurs, value of actual position will be lost. Due to that, that parameter must be declared as a retain variable.

If communications problem occurs between CPU and module CD522, position value stored in POS_ACT will be lost.

Format: Degrees.

Z_VALUE REAL (z value)

Indicates the position of the encoders reference point (Z). The user is able to configure where the Z position is.

Format: Degrees.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

RDY_SET BOOL (ready set start)

When the action of SET_START finishes, RDY_SET is set to TRUE for only one cycle.

RDY_CALIB BOOL (ready calibration)

The output RDY_CALIB displays the ready message of the calibrating process. While input EN_CALIB is set to TRUE, RDY_CALIB = TRUE.

If EN_CALIB = TRUE and rising edge is detected at Z_PULSE signal, RDY_CALIB will be set to TRUE until EN_CALIB = FALSE.

RDY_SYNC BOOL (ready synchronisation)

The output RDY_SYNC displays the ready message of the synchronisation process. It is set to TRUE only for one cycle.

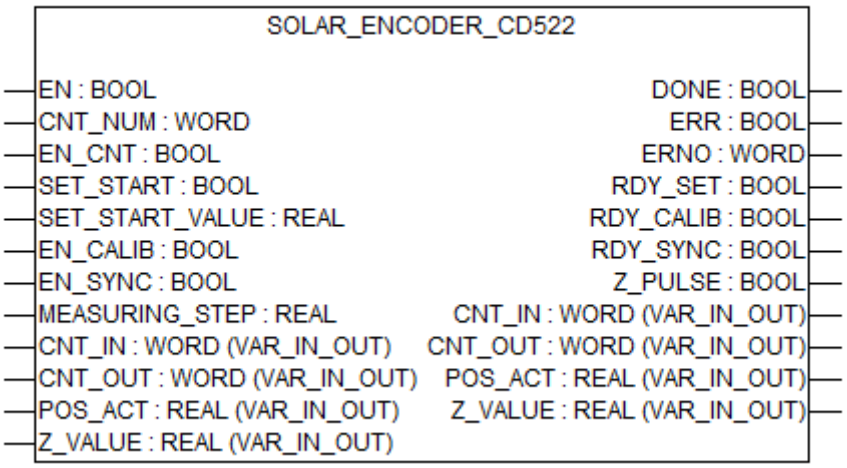
SOLAR_ENCODER_CD522



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function block with historical values
Group	Package of functions to get the position of the sun

Function block to easily integrate, with the CD522 card, incremental encoders (A, B, Z) as positioning sensors for Solar Trackers.

The SOLAR_ENCODER_CD522 is used to easily integrate, with the CD522 card, incremental encoders (A, B, Z) as positioning sensors for Solar Trackers.

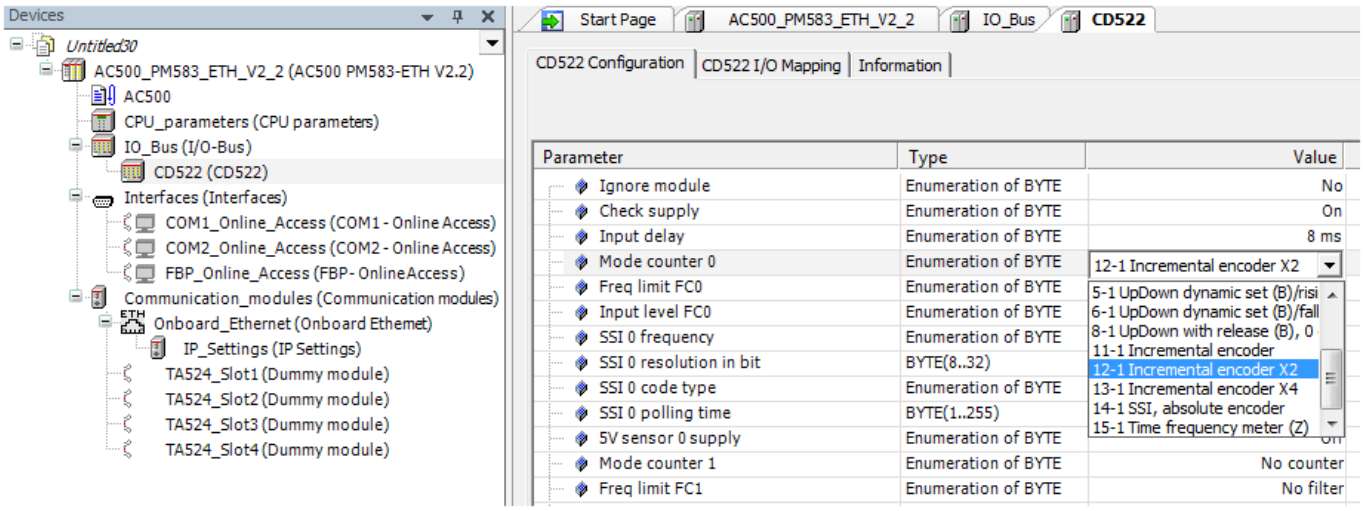
The module CD522 can be used in 12 different configurable operating modes. The operating mode is configured in PLC Configuration using module parameters. After that, it is activated during the initialization phase (power-on, cold start, warm start).

In order to configure and use the function encoder of module CD522, different operating modes are available. The function block SOLAR_ENCODER_CD522 should be used by configuring the parameter 6 or 14 ("Mode counter 0" or "Mode counter 1") in modes 11, 12 or 13 to use the incremental encoder as: Incremental encoder, Incremental encoder X2 or Incremental encoder X4 respectively.

See user manual ↬ *Chapter 1.6.2.7.2.1 “CD522 - Encoder, counter and PWM module” on page 4635*

Example: Configuration of module CD522 to control an incremental encoder:

In Control Builder Plus V2.0 and above:



The meaning of the different operating modes available to control an incremental encoder is:

Operating Mode 11 "Incremental encoder"

Should be specified in PLC Configuration; parameter "Mode counter" in order to use one up/down counter for position sensor x1 count.

Operating Mode 12 "Incremental encoder X2"

Should be specified in PLC Configuration; parameter "Mode counter" in order to use one bidirectional counter for position sensor x2 count.

Operating Mode 13 "Incremental encoder X4"

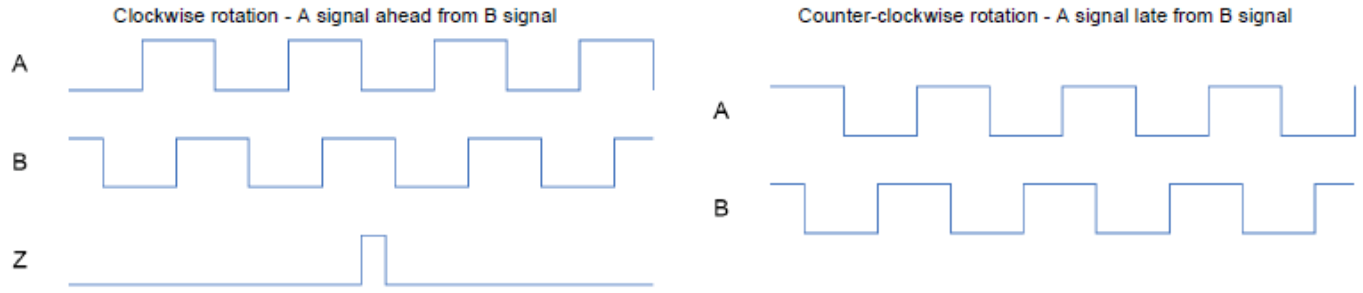
Should be specified in PLC Configuration; parameter "Mode counter" in order to use one bidirectional counter for position sensor x4 count.

The module CD522 provides 2 encoder functions for relative positioning with 3 signals. 2 signals are used for rotation discrimination and pulse count, identified by A0 and B0 for counter0 and A1 and B1 for counter1. The third one is used in multi-turn encoder to count the number of rotation (mechanical zero), identified by Z0 for counter0 and Z1 for counter1. Signals Z0 and Z1 are used in synchronization process. Inputs I3 and I11 needs to be defined as touch input.

> *If the setup needs both Calibration & Synchronization then the Z pulse from the encoder to be connected to both Z0 & I3 inputs for counter0 and Z1 & I11 inputs for counter1.*

The rotation is identified with a shift angle (90°) between A and B signal. In the module CD522, the clockwise rotation is identified with A signal in advance to B (see figure below).

Example: Direction identification using A and B signals:



Depending on which kind of operating mode is specified, the counting procedure will be x1, x2 or x4 count. Basically the x1 counting mode is used (mode 11). The encoder module discriminates the rotating way and count one pulse for each rising edge of the A signal.

In order to increase resolution, the x2 counting mode can be specified (mode 12). The encoder module counts both the positive edges and the negative edges of trace A. This results in the double number of counting pulses. The precision increases correspondingly.

The resolution could be multiplied by 4, using the x4 counting mode (mode 13). The encoder module counts a pulse on both rising and falling edge of A signal and B signal.

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CNT_NUM WORD (counter number)

Indicates which counter is going to be used.

If CNT_NUM = 0, the counter 0 will be used.

If CNT_NUM = 1, the counter 1 will be used.

EN_CNT BOOL (enable counter)

If EN_CNT = TRUE, pulse counting of counter is enabled. If EN_CNT = FALSE, no pulse counting is performed and the pulses are lost.

If counting has already started and if EN_CNT = FALSE, the pulse counting stops and counter value POS_ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value POS_ACT will continue since previous value.

While EN_CNT is set to FALSE, it is possible to modify the stored value in POS_ACT variable. When EN_CNT is set to TRUE again, counter value POS_ACT will continue since previous value.

SET_START BOOL (set start)

If set input SET_ START = TRUE, the counter takes the values from input SET_START_VALUE to transfer it to POS_ACT. After that, RDY_SET = TRUE. As long as input SET_ START = TRUE, no pulses are counted because the counter is always overwritten by the input SET_START_VALUE.

SET_START_VALUE REAL (set start value)

The counter can be set to a Start value. This value must be applied to the input SET_START_VLAUE.

If input SET_START=TRUE, the counter takes this value.

EN_CALIB BOOL (enabling calibrate)

If EN_CALIB = TRUE, when a rising edge is detected at the encoder´s reference point (Z) signal, output Z_VALUE will take the stored value in POS_ACT and output RDY_CALIB is set to TRUE. If this input is continuously set to TRUE, only one calibrating process will be done even system reaches encoder´s reference point (Z) once again. In order to enable another calibrating process, input EN_CALIB has to be set to FALSE and set to TRUE again.

Calibrating process is executed out of CPU cycle, and it is able to detect the multiple rising edges that appear when a simple limit switch is used. Due to that, it is recommended to use devices assembled especially for this purpose (high accuracy limit switch).

Inputs used as reference point Z in the calibrating process are:

Counter0 -> I3

Counter1 -> I11

EN_SYNC BOOL (enabling synchronize)

If input EN_SYNC = TRUE, when a rising edge is detected at the encoder´s reference point (Z) signal, output POS_ACT will take the value stored at Z_VALUE, output RDY_SYNC is set to TRUE only during a program cycle. While EN_SYNC is set to TRUE, POS_ACT output will take the value stored at Z_VALUE every time that a rising edge is detected at the encoder´s reference point (Z) signal.

Inputs used as reference point Z in the synchronisation process are:

Counter0 -> Z0

Counter1 -> Z1

MEASURING_STEP REAL (measuring step)

Indicates the resolution of the encoder device (see technical data from manufacturer). For example, using an incremental encoder with a resolution of 10000 pulses each 360° and x4 counting mode (software configuration), measuring step will use the following value:

360 / (4 x 10000) = 0,009

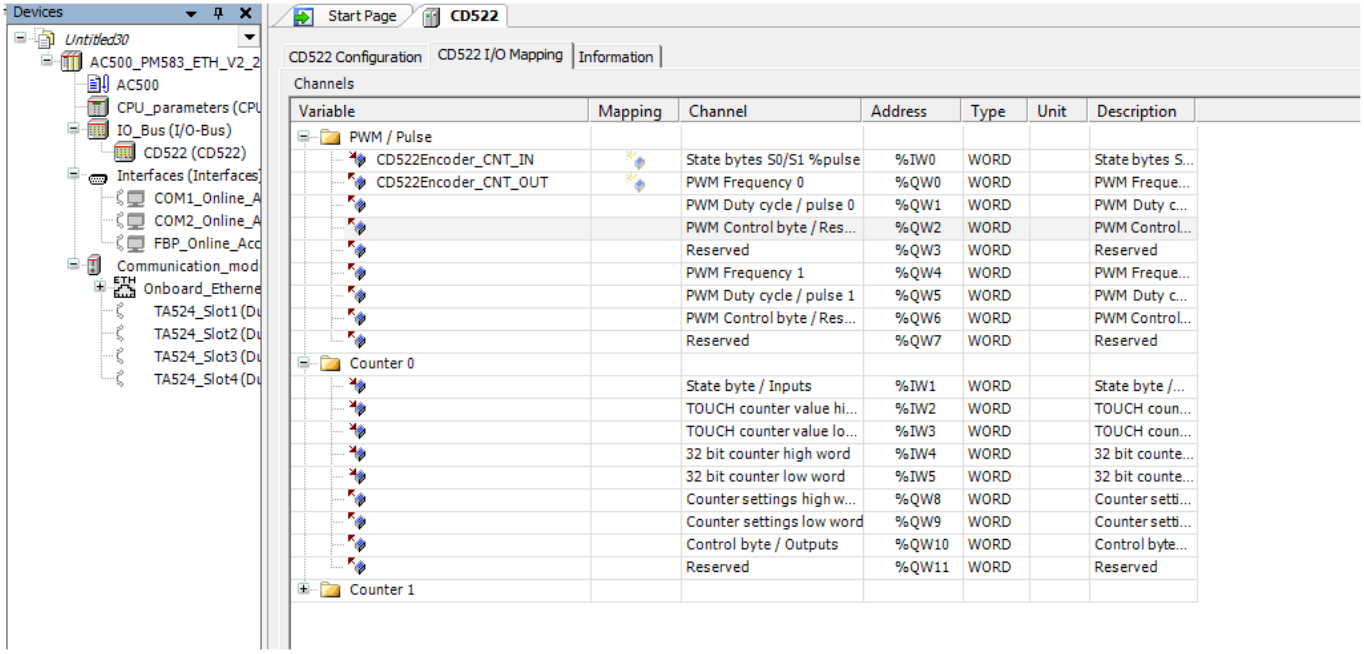
Format: Degrees.

CNT_IN WORD (counter input)

First input data of counter input. The use of an ADR operator is not needed.

Example (for counter 0):

In Control Builder Plus V2.0 and above:

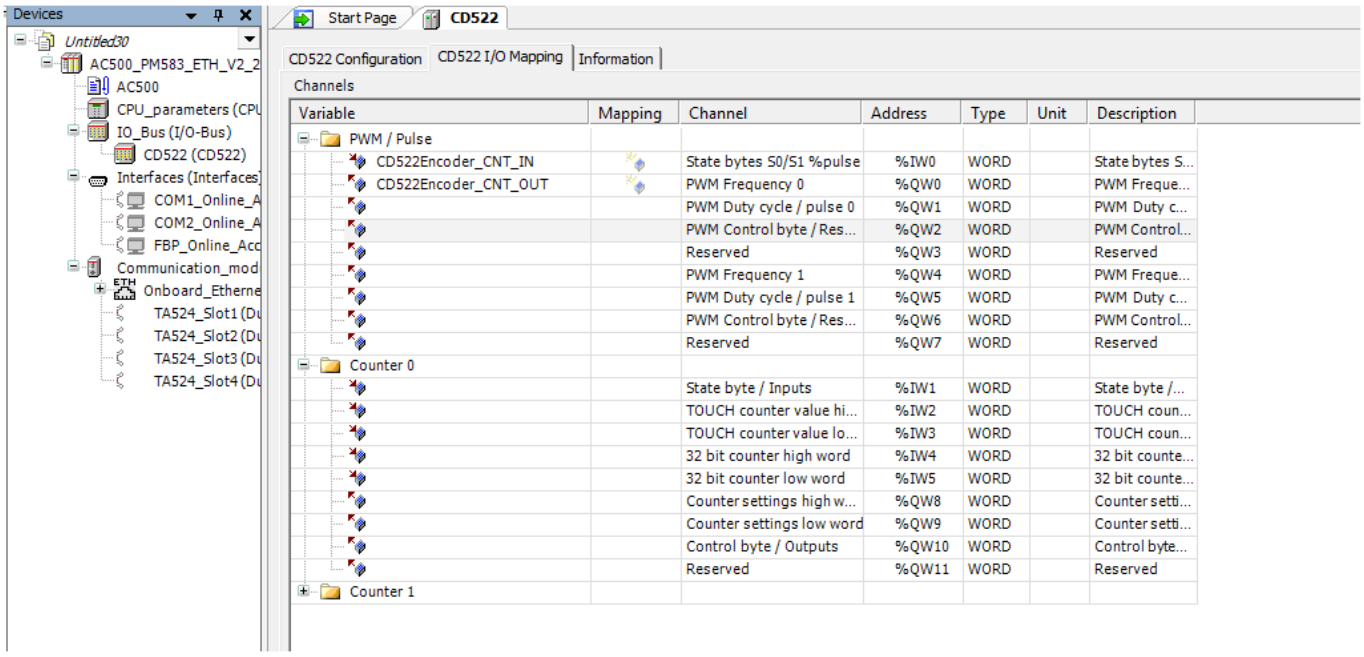


CNT_OUT WORD (counter output)

First output data of counter output. The use of an ADR operator is not needed.

Example (for counter 0):

In Control Builder Plus V2.0 and above:



POS_ACT REAL (position_actual)

The current position (actual position) can be retrieved at any time using the output POS_ACT of the function block. If a shutdown occurs, value of actual position will be lost. Due to that, that parameter must be declared as a retain variable.

If communications problem occurs between CPU and module CD522, position value stored in POS_ACT will be lost.

Format: Degrees.

Z_VALUE REAL (z value)

Indicates the position of the encoders reference point (Z). The user is able to configure where the Z position is.

Format: Degrees.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

RDY_SET BOOL (ready set start) When the action of SET_START finishes, RDY_SET is set to TRUE for only one cycle.

RDY_CALIB BOOL (ready calibration) The output RDY_CALIB displays the ready message of the calibrating process. While input EN_CALIB is set to TRUE, RDY_CALIB = TRUE.

If EN_CALIB = TRUE and rising edge is detected at Z_PULSE signal, RDY_CALIB will be set to TRUE until EN_CALIB = FALSE.

RDY_SYNC BOOL (ready synchronisation) The output RDY_SYNC displays the ready message of the synchronisation process. It is set to TRUE only for one cycle.

Z_PULSE BOOL (input signal Z) The output Z_PULSE indicates that encoder's reference point Z has been reached. This signal is only visible if programs execution time is slower than the signal of encoder's reference point (Z).

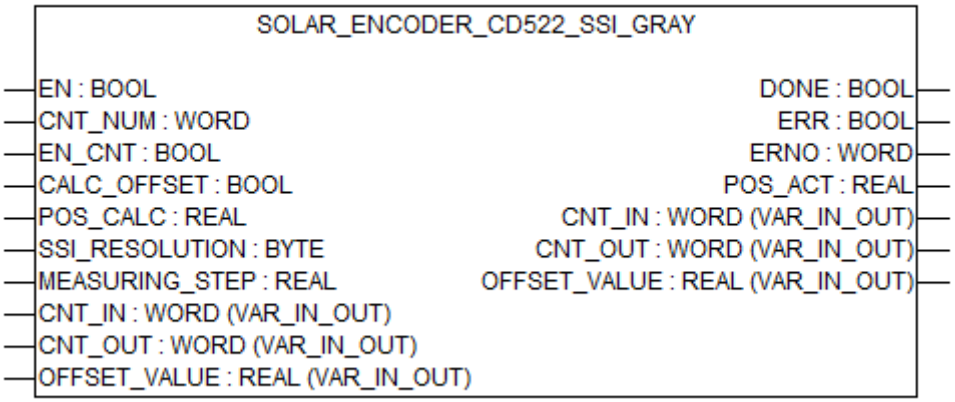
SOLAR_ENCODER_CD522_SSI_GRAY



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function block without historical values .
Group	Package of functions to get the position of the sun

Function block to easily integrate, with the CD522 card, absolute encoders SSI GRAY as positioning sensors for Solar Trackers.

The module CD522 can be used in 12 different configurable operating modes. The operating mode is configured in PLC Configuration using module parameters. After that, it is activated during the initialization phase (power-on, cold start, warm start).

In order to configure and use the function counter of module CD522, different operating modes are available. The function block CD522_SSI should be used configuring the parameter 6 or 14 ("Mode counter 0" or "Mode counter 1") with the operating mode:

Operating Mode 14 "SSI, absolute encoder"

Should be specified in PLC Configuration; parameter "Mode counter" in order to use absolute encoder with SSI interface.

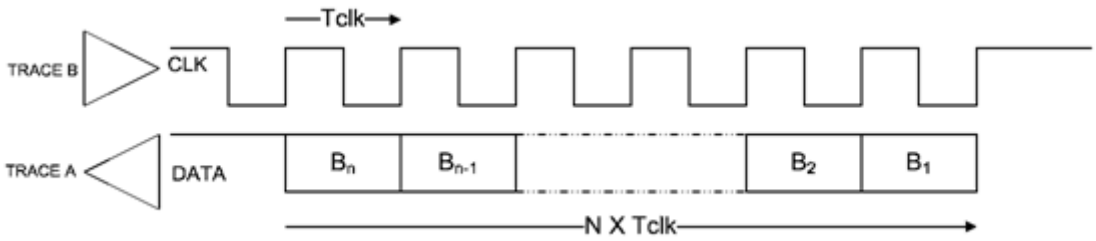
The module CD522 provides 2 SSI absolute encoder functions. There is an interface for absolute angle and linear encoders (displacement measurement systems).

It allows the transmission of absolute position information through a serial data transfer.

The transmission is based on synchronous serial communication. The device sends a clock signal to the encoder and synchronously, the encoder returns the positioning data from the most significant to the less significant bit.

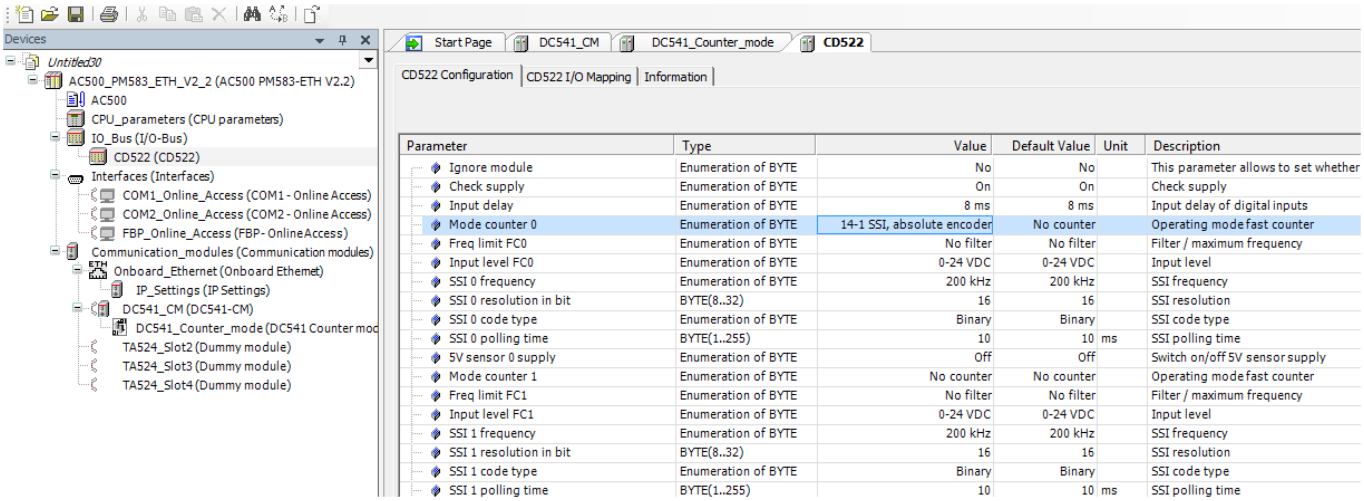
The synchronization for a new data stream is based on time without clock pulse. This quiet time depends on the encoder.

Chronogram with data organization with the clock pulse:



The resolution of the encoder device (see technical data from manufacturer) can be set (with configuration, number of bits, etc.) in PLC Configuration, parameter "SSI resolution in bit" (see figure below).

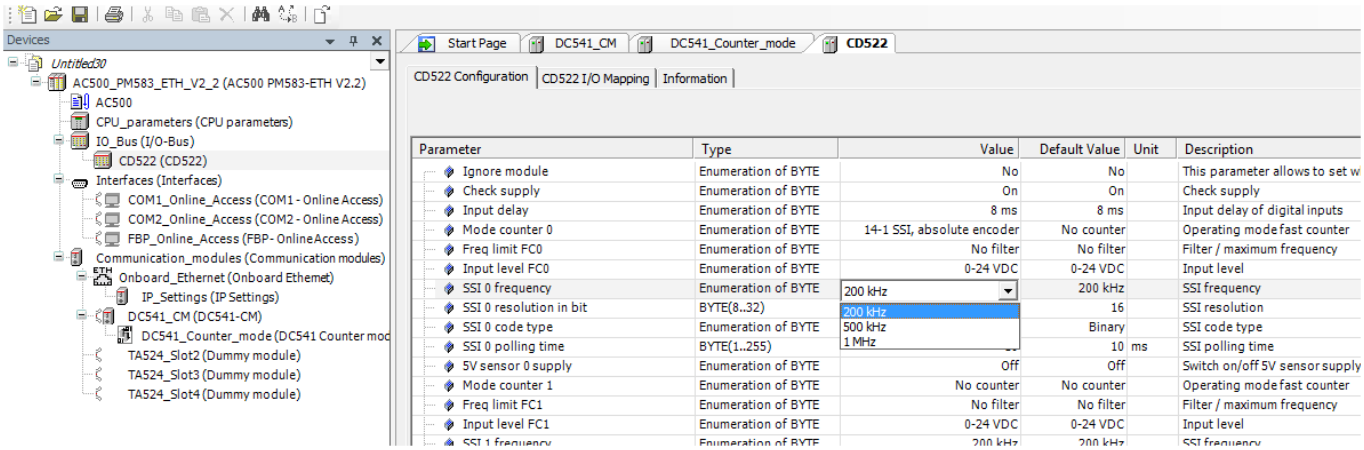
In Control Builder Plus V2.0 and above :



The trace B of module CD522 is switched as output signal (differential). On the rising edge of the signal, the sensor shifts a new value, starting from the most significant bit.

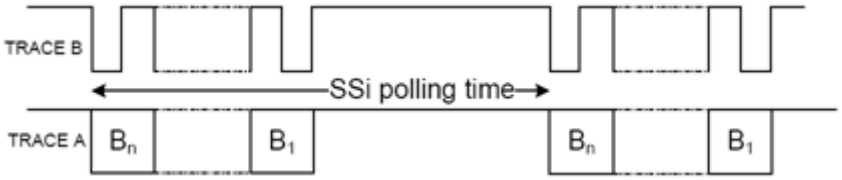
The clock frequency can be set to 200 kHz, 500 kHz, and 1 MHz and should be specified in PLC Configuration, parameter "SSI frequency" (see figure below).

In Control Builder Plus V2.0 and above:



SSI Polling time definition

The complete read sequence is launched regularly by the module CD522. The interval between each sequence can be set from 1 ms to 255 ms in PLC Configuration, parameter "SSI polling time" (see figure below).



Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CNT_NUM WORD (counter number)

Indicates which counter is going to be used:

If CNT_NUM = 0, the counter 0 will be used.

If CNT_NUM = 1, the counter 1 will be used.

EN_CNT BOOL (enable counter)

IF EN_CNT = TRUE, communications process with SSI encoder is enabled. If EN_CNT = FALSE, communications process with SSI encoder is not enabled.

CALC_OFFSET BOOL (calculated offset)

This input is used to calibrate the positioning sensor. When rising edge is detected at CALC_OFFSET, function block proceeds as follow:

OFFSET_VALUE = POS_CALC ACT_CNT,

where ACT_CNT is the read value directly from encoder (internal variable).

Once the system is calibrated, this value remains constant during the normal working of the system. This value should be check to do a correct calibration after maintenance operations.

POS_CALC REAL (position_calculted)

It is the right position of our tracker and it is used to calibrate the system. This value must be obtained by using high accuracy tools (not assembled in the tracker) or by using a solar radiation sensor to determine if tracker is right focused.

Format: Degrees.

SSI_RESOLUTION BYTE (SSI RESOLUTION)

The resolution of the encoder device setting by number of bits. Min. 8 bits, max. 32 bits.

MEASURING_STEP REAL (measuring step)

Indicates the resolution of the encoder device (see technical data from manufacturer). For example, using an incremental encoder with a resolution of 10000 pulses each 360° and x4 counting mode (software configuration), measuring step will use the following value:

360 / (4 x 10000) = 0,009

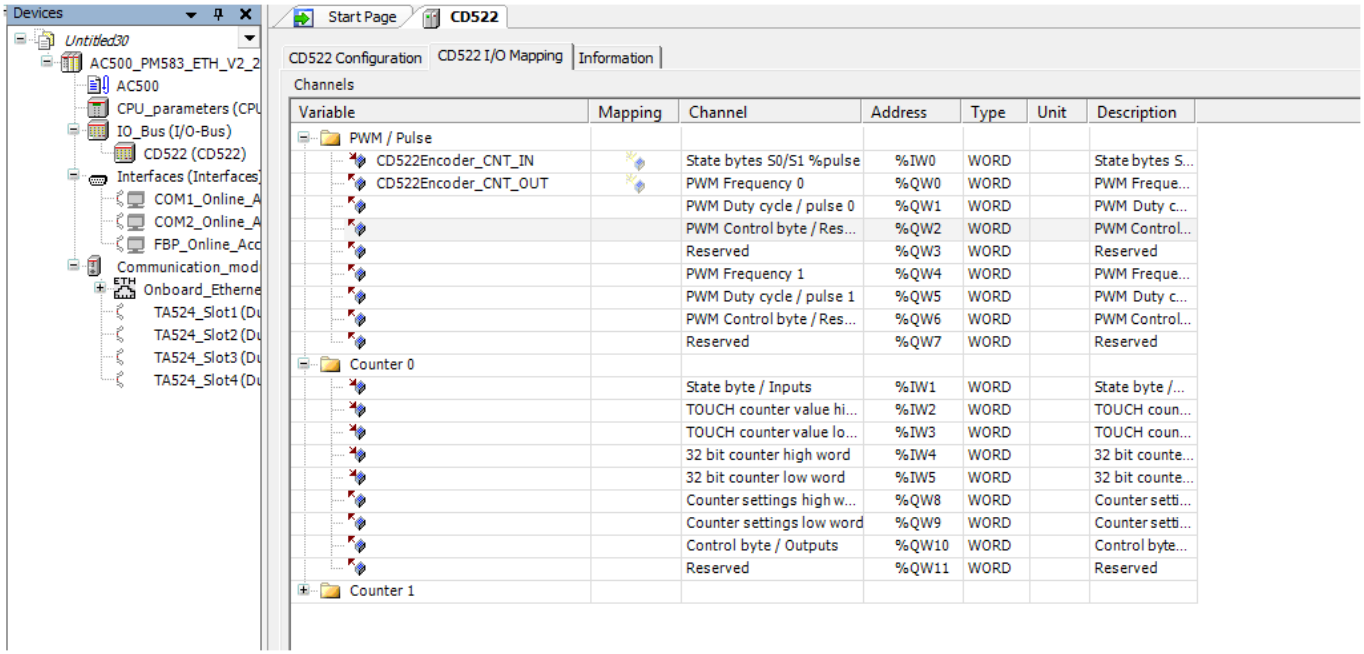
Format: Degrees.

CNT_IN WORD (counter input)

First input data of counter input. The use of an ADR operator is not needed.

Example (for counter 0):

In Control Builder Plus V2.0 and above:

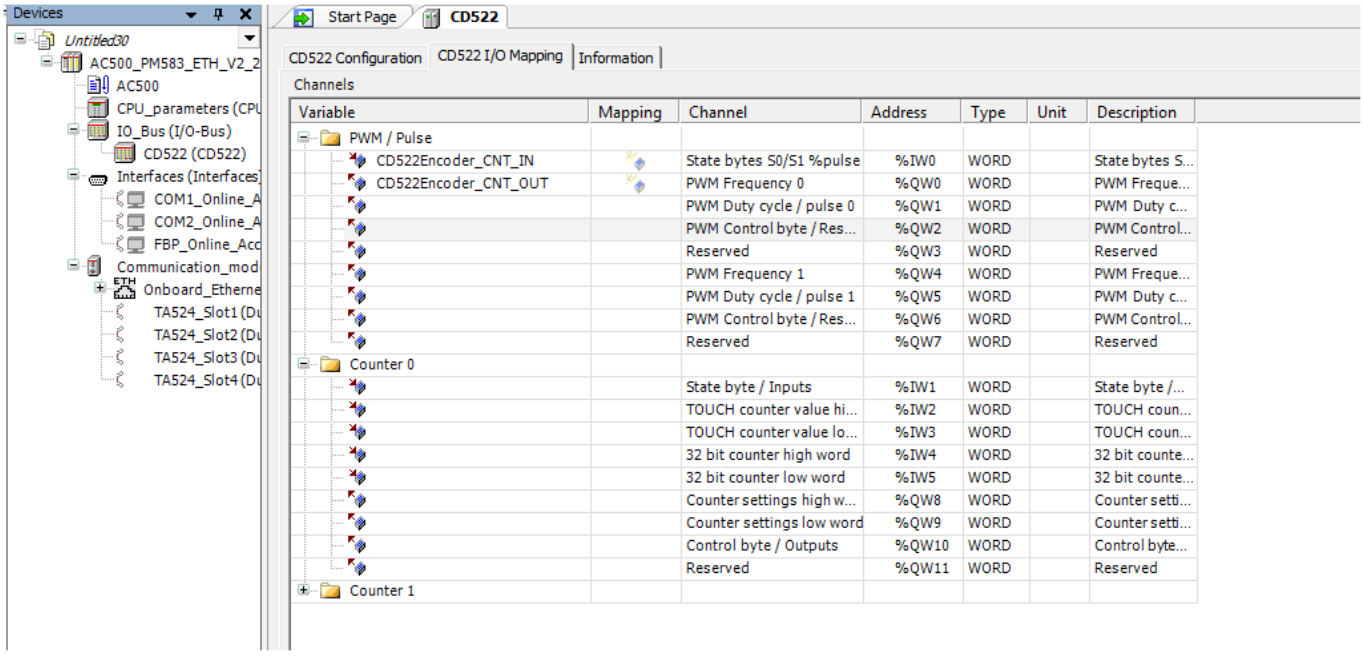


CNT_OUT WORD (counter output)

First output data of counter output. The use of an ADR operator is not needed.

Example (for counter 0):

In Control Builder Plus V2.0 and above:



OFFSET_VALUE REAL (offset value)

Value added to ACT_CNT (internal variable) to obtain a calibrating process.

POS_ACT = ACT_CNT + OFFSET_VALUE,

where ACT_CNT is the directly read value from encoder (internal variable).

Format: Degrees.

POS_ACT REAL (position_actual)

The current position (actual position) can be retrieved at any time using the output POS_ACT of the function block. If a shutdown occurs, value of actual position will be lost. Due to that, that parameter must be declared as a retain variable.

If communications problem occurs between CPU and module CD522, position value stored in POS_ACT will be lost.

Format: Degrees.

Output description

DONE

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

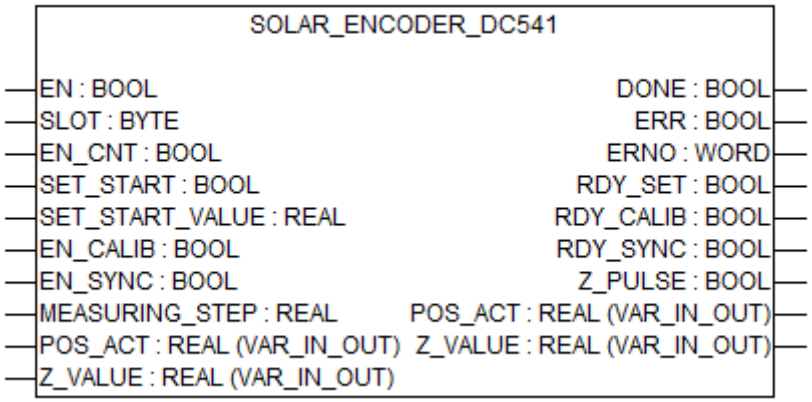
SOLAR_ENCODER_DC541



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function block with historical values
Group	Package of functions to get the position of the sun

The SOLAR_ENCODER_DC541 is used to easily integrate, with the DC541 module, incremental encoders (A, B, Z) as positioning sensors for Solar Trackers.

The module DC541 can be done a count of signals up to 60 kHz. Pulse multiplication (x2 or x4) is not used.

The counter always uses the channels C0...C3 of the DC541:

C0: Track A of the incremental encoder

C1: Track B of the incremental encoder

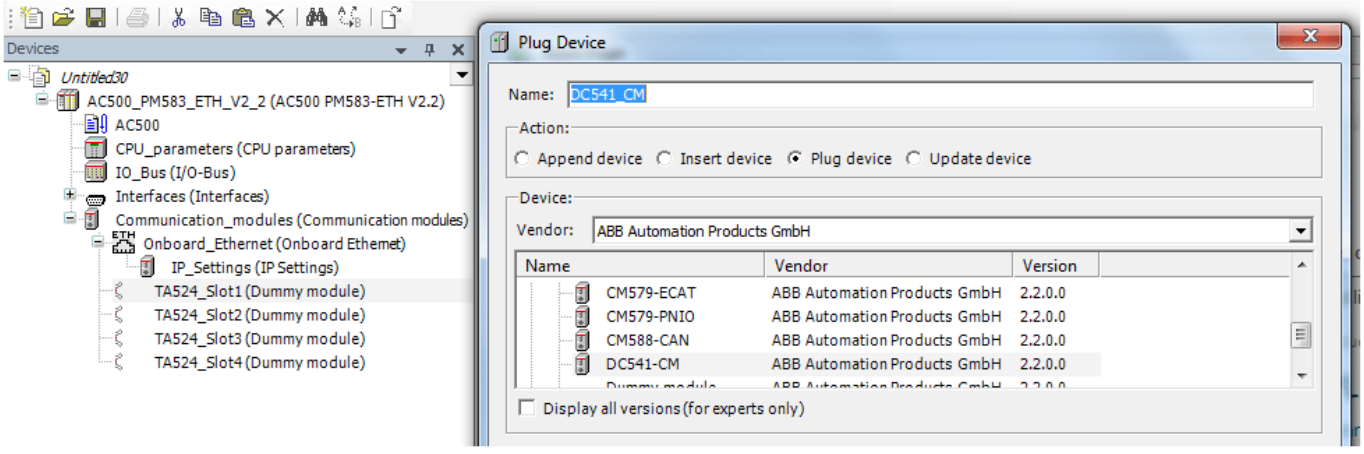
C2: Track Z of the incremental encoder

In order to configure and use the function counter of module DC541, the module should be configured as follow:

Configuration of module DC541 to control an incremental encoder.

Step 1:

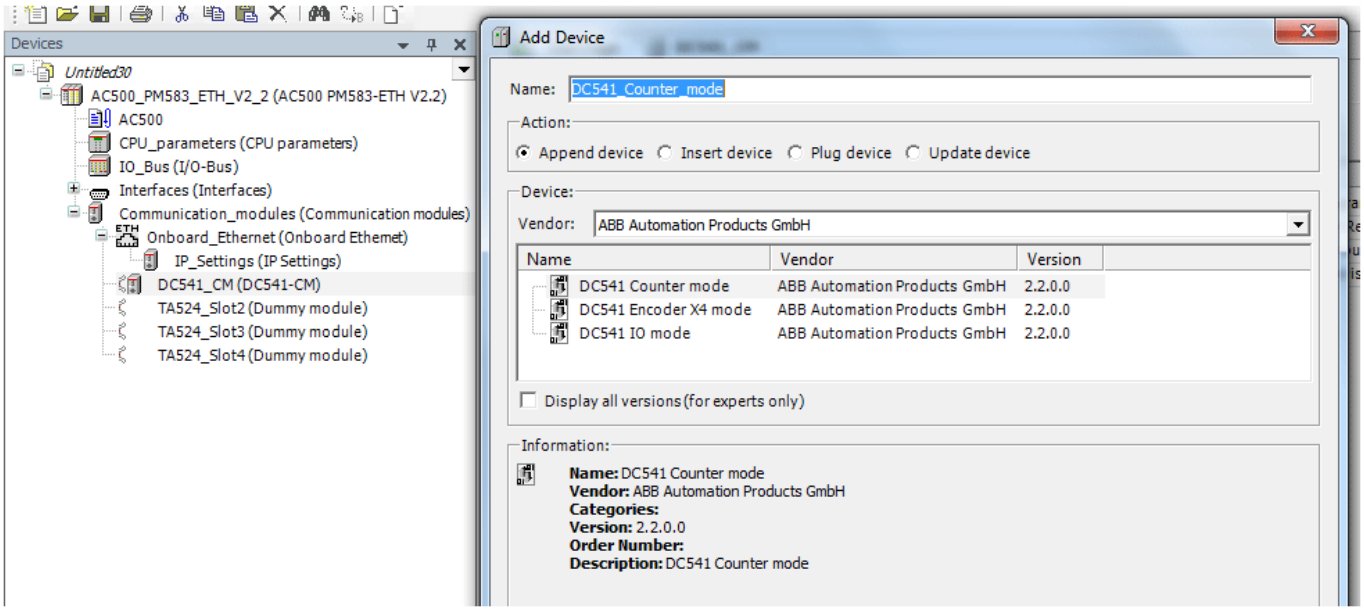
In Control Builder Plus V2.0 and above:



The function block SOLAR_ENCODER_DC541 should be used configuring the module as a "Counter mode".

In Control Builder Plus V2.0 and above:

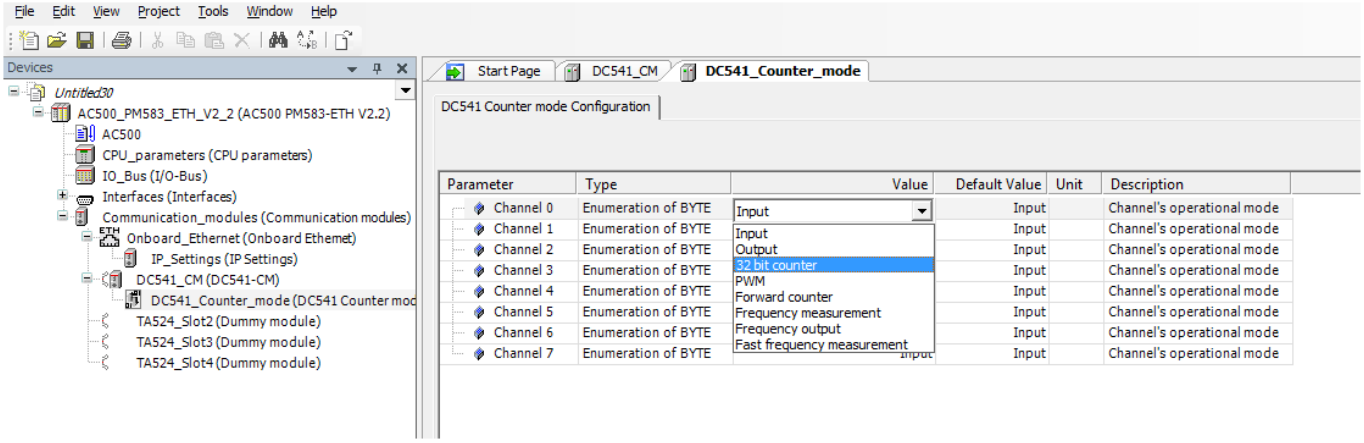
Last step is to configure the "Channel 0" as "32-bit counter".



Configuration of module DC541 to control an incremental encoder.

Step 3:

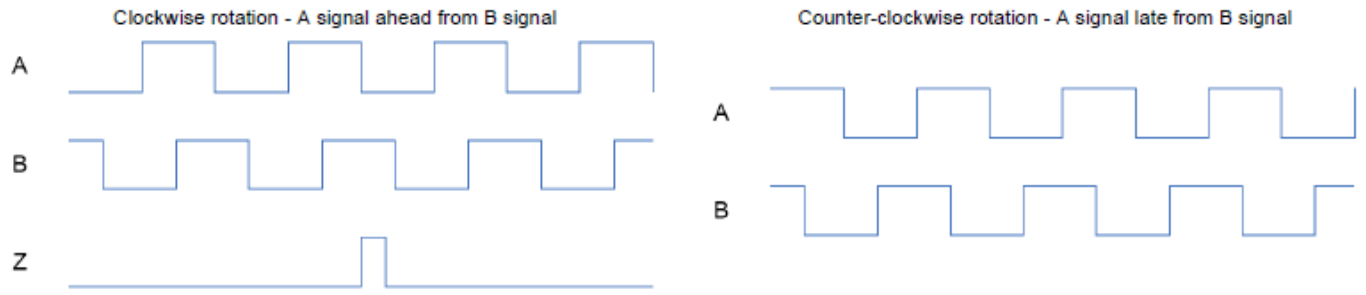
In Control Builder Plus V2.0 and above:



The module DC541 provides an encoder function for relative positioning with 3 signals. 2 signals are used for rotation discrimination and pulse. The third one is used in multi-turn encoder to count the number of rotation (mechanical zero).

The rotation is identified with a shift angle (90°) between A and B signal. In the module DC541, the clockwise rotation is identified with A signal in advance to B (see figure below).

Example: Direction identification using A and B signals:



Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

EN_CNT BOOL (enable counter)

If EN_CNT = TRUE, pulse counting of counter is enabled. If EN_CNT = FALSE, no pulse counting is performed and pulses are not stored even the encoder device changes its position.

If counting has already started and if EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

SET_START BOOL (set start)

If set input SET_ START = TRUE, the counter takes the values from input SET_START_VALUE to transfer it to POS_ACT. After that, RDY_SET = TRUE. As long as input SET_ START = TRUE, no pulses are counted because the counter is always overwritten by the input SET_START_VALUE.

SET_START_VALUE REAL (set start value)

The counter can be set to a Start value. This value must be applied to the input SET_START_VLAUE.

If input SET_START=TRUE, the counter takes this value.

EN_CALIB BOOL (enabling calibrate)

If EN_CALIB = TRUE, when a rising edge is detected at the encoder´s reference point (Z) signal, output Z_VALUE will take the stored value in POS_ACT and output RDY_CALIB is set to TRUE. If this input is continuously set to TRUE, only one calibrating process will be done even system reaches encoder´s reference point (Z) once again. In order to enable another calibrating process, input EN_CALIB has to be set to FALSE and set to TRUE again.

Calibrating process is executed out of CPU cycle, and it is able to detect the multiple rising edges that appear when a simple limit switch is used. Due to that, it is recommended to use devices assembled especially for this purpose (high accuracy limit switch).

Inputs used as reference point Z in the calibrating process are:

Counter0 -> I3

Counter1 -> I11

EN_SYNC BOOL (enabling synchronize)

If input EN_SYNC = TRUE, when a rising edge is detected at the encoder´s reference point (Z) signal, output POS_ACT will take the value stored at Z_VALUE, output RDY_SYNC is set to TRUE only during a program cycle. While EN_SYNC is set to TRUE, POS_ACT output will take the value stored at Z_VALUE every time that a rising edge is detected at the encoder´s reference point (Z) signal.

Inputs used as reference point Z in the synchronisation process are:

Counter0 -> Z0

Counter1 -> Z1

MEASURING_STEP REAL (measuring step)

Indicates the resolution of the encoder device (see technical data from manufacturer). For example, using an incremental encoder with a resolution of 10000 pulses each 360° and x4 counting mode (software configuration), measuring step will use the following value:

360 / (4 x 10000) = 0,009

Format: Degrees.

POS_ACT REAL (position_actual)

The current position (actual position) can be retrieved at any time using the output POS_ACT of the function block. If a shutdown occurs, value of actual position will be lost. Due to that, that parameter must be declared as a retain variable.

If communications problem occurs between CPU and module CD522, position value stored in POS_ACT will be lost.

Format: Degrees.

Z_VALUE REAL (z value)

Indicates the position of the encoders reference point (Z). The user is able to configure where the Z position is.

Format: Degrees.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

RDY_SET BOOL (ready set start)

When the action of SET_START finishes, RDY_SET is set to TRUE for only one cycle.

RDY_CALIB BOOL (ready calibration)

The output RDY_CALIB displays the ready message of the calibrating process. While input EN_CALIB is set to TRUE, RDY_CALIB = TRUE.

If EN_CALIB = TRUE and rising edge is detected at Z_PULSE signal, RDY_CALIB will be set to TRUE until EN_CALIB = FALSE.

RDY_SYNC BOOL (ready synchronisation)

The output RDY_SYNC displays the ready message of the synchronisation process. It is set to TRUE only for one cycle.

Z_PULSE BOOL (input signal Z)

The output Z_PULSE indicates that encoder's reference point Z has been reached. This signal is only visible if programs execution time is slower than the signal of encoder's reference point (Z).

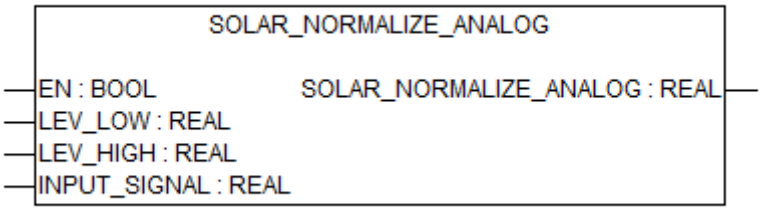
SOLAR_NORMALIZE_ANALOG



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function
Group	Package of functions to get the position of the sun

The SOLAR_NORMALIZE_ANALOG function is used to easily integrate, with any S500 AI/AO card, standard sensor type 4 "“ 20 mA or 0 "“ 10V as positioning sensors for Solar Trackers. This function can be used to integrate analog sensors such as inclinometers.

According to the signal sensor provided and the movement range of the system, SOLAR_NORMALIZE_ANALOG gets the current system position. Internally function SOLAR_NORMALIZE_ANALOG uses the corresponding decimal values given by the AI/AO card when an analog input is detected.

Table 196: Input values (analog signals) with their corresponding decimal values for AX/521 and AX/522 modules

Range	0...10 V	-10...+10 V	0...20 mA	4...20 mA	Digital Input	Decimal Value
NORMAL RANGE	10.0000 : 0.0004	10.0000 : 0.0004	20.0000 : 0.0007	20.0000 : 4.0006	ON	27648 : 1
	0.0000	0.0000	0	4	OFF	0

1.5.11.2.5 ACTUATOR folder

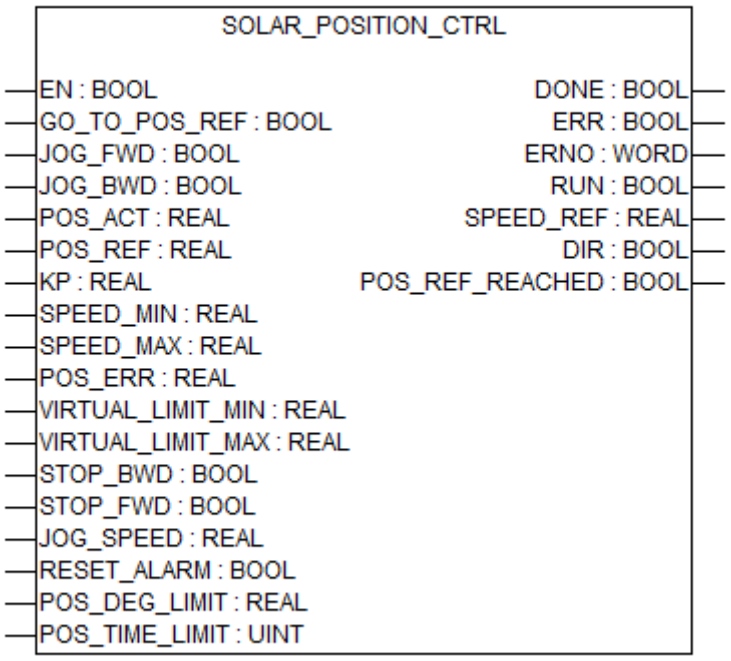
Preconditions for the use of the ACTUATOR folder

To communicate with ACS355 drive, use Chapter 1.5.6 “ACS / DCS drives libraries” on page 2192.

Refer example application for more details of configuration and programming.

Alternatively use Chapter 1.5.4.22 “Modbus library” on page 1697 also for communication with the drive.

SOLAR_POSITION_CTRL



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function
Group	Package of functions to get the position of the sun

Function block to manage the positioning control.

According to the positioning reference, it gets the speed parameters to set the system in the desired position. Output parameters are Run-Stop, Direction and Speed to reach the calculated position of the system.

Output parameters are Run, Direction and Speed to reach the desired position of the system.

Depends on the input parameters, the manipulated variable (SPEED) to control the actuators will be:

- GO_TO_POS_REF = TRUE

Select pulse start for positioning: Start by rising edge of a pulse. The signal has to stay TRUE during the positioning task.

According to the reference of positioning gets the SPEED parameter to set the system in this position, by calculating the control action by using a proportional controller.

SPEED_REF = (POS_REF-POS_ACT) * KP * (limit of [SPEED_MIN and SPEED_MAX]).

- JOG_FWD = TRUE

SPEED_REF = JOG_SPEED. To move the system forward manually.

- JOG_BWD = TRUE

SPEED_REF = (-1) * JOG_SPEED. To move the system backward manually.

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

GO_TO_POS_REF BOOL (go to position reference)

In order to use the proportional control system to reach the SETPOINT, input GO_TO_POS_REF has to be set to TRUE.

JOG_FWD BOOL (jog forward)

In order to manually move the system forward, input JOG_FWD has to be set to TRUE. As long as JOG_FWD is set to TRUE, and STOP_FWD is deactivated, SPEED = JOG_SPEED.

VIRTUAL_LIMIT_MAX is not considered when JOG_FWD is activated.

JOG_BWD BOOL (jog backward)

In order to manually move the system backward, input JOG_ BWD has to be set to TRUE. As long as JOG_BWD is set to TRUE, and STOP_BWD is deactivated, SPEED = (-1) * JOG_SPEED.

VIRTUAL_LIMIT_MAX is not considered when JOG_BWD is activated.

POS_ACT REAL (position actual)

ACT indicates the current position of the system.

Format: Degrees.

POS_REF REAL (position reference)

SETPOINT indicates the desired position to locate the system.

Format: Degrees.

KP REAL (kp)

KP indicates the proportional gain of the proportional control system.

SPEED_MIN REAL (speed min)

Minimum speed of the drive, expressed as a percent of the maximum speed of the drive. This value is used during positioning control (GO_TO_POS_REF = TRUE).

This function block is having a speed range of 0 "“ 100 %. SPEED_MIN must be set between 0 "“ 100 %.

SPEED_MAX REAL (speed max)

Maximum speed of the drive, expressed as a percent of the maximum speed of the drive. This value is used during positioning control (GO_TO_POS_REF = TRUE).

This function block is having a speed range of 0 "“ 100 %. SPEED_MAX must be set between 0 "“ 100 %.

POS_ERR REAL (position error / position window)

Indicates the area where the system is considered correctly enough positioned (the control loop considers the POS_REF reached). The system is inside this window movement when the position error is smaller than POS_REF. The position error indicates the difference between the POS_REF and the POS_ACT.

POS_ERR value must be larger than resolution of the positioning devices (encoders or inclinometers).

VIRTUAL_LIMIT_MIN REAL (virtual limit minimum)

The lower limit of the movement range of the system. This value is only considered during positioning control (GO_TO_POS_REF = TRUE). JOG movements are not influenced by this limit value.

Format: Degrees.

VIRTUAL_LIMIT_MAX REAL (virtual limit maximum)

The upper limit of the movement range of the system. This value is only considered during positioning control (GO_TO_POS_REF = TRUE). JOG movements are not influenced by this limit value.

Format: Degrees.

STOP_BWD BOOL (stop backward)

This input should be used in order to integrate the lower limit switch signal which indicates the mechanical lower limit of the movement of the system.

If STOP_BWD = TRUE the mechanical lower limit of the movement range has been reached and the output RUN will be set to 0. Forward movement is allowed.

STOP_FWD BOOL (stop forward)

This input should be used in order to integrate the upper limit switch signal which indicates the mechanical upper limit of the movement of the system.

If STOP_FWD = TRUE the mechanical upper limit of the movement range has been reached and the output RUN will be set to 0. Backward movement is allowed.

JOG_SPEED REAL (jog speed)

JOG_SPEED indicates the JOG speed of the drive. This value is expressed as a percent of the maximum speed of the drive.

During a JOG movement this value will set to the SPEED output.

This function block is having a speed range of 0 "“ 100 %. JOG_SPEED must be set between 0 "“ 100 %.

RESET_ALARM BOOL (reset alarm / error)

Boolean signal that resets the ERR and ERNO outputs.

POS_DEG_LIMIT REAL (position degrees limit)

When the primary axis of the actuator (gear or hydraulic piston) changes its direction of rotation, this axis covers an angular distance, POS_DEG_LIMIT, whereas the tracker will not change its position. Only when POS_DEG_LIMIT is reached, the tracker starts its movement. This concept is similar to "backlash" in gear trains.

Format: Degrees.

This value depends on each tracker and its actuator (motors, gears or hydraulic systems).

POS_ACT (t) - POS_ACT (t + POS_TIME_LIMIT) | > POS_DEG_LIMIT,

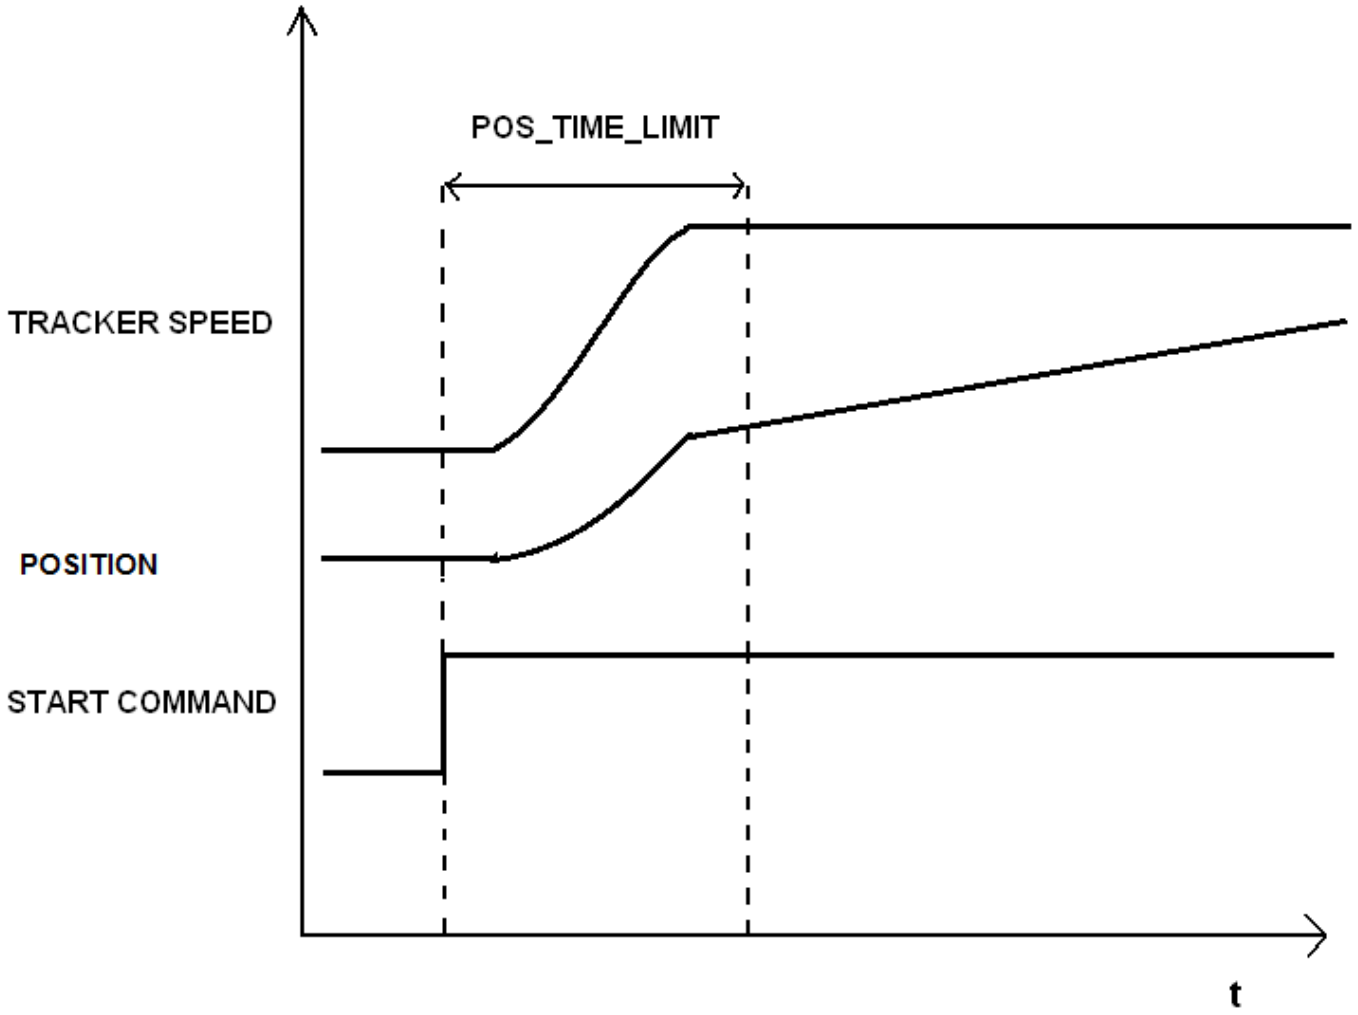
where:

t = time.

POS_TIME_LIMIT UNIT (position time limit)

Indicates the needed time to cover POS_DEG_LIMIT distance without any fault. The expected distance must be covered in a time smaller than POS_TIME_LIMIT milliseconds. Otherwise, it generates error and corresponding error is displayed.

Format: Milliseconds.



Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

RUN BOOL (run)

RUN output should be used as start command for the drive. It is set to TRUE, if no limit is reached no error occurred and either a jog command is set or normal operation sets the SPEED_REF not to zero.

SPEED_REF REAL (speed reference)

To output parameter SPEED_REF indicates the input to the drive, the manipulated variable to control the system positioning. Depending on the working mode SPEED_REF will be:

Input Parameters (Working mode)	Additional Input Parameters Considered	Output SPEED_REF
GO_TO_POS_REF = TRUE	POS_ERR < (POS_REF "“ POS_ACT) VIRTUAL_LIMIT_MIN < POS_ACT < VIR-TUAL_LIMIT_MAX STOP_BWD = FALSE STOP_FWD = FALSE	SPEED_REF = KP*(POS_REF - POS_ACT)
JOG_FWD = TRUE	STOP_FWD = FALSE	SPEED_REF = JOG_SPEED
JOG_BWD = TRUE	STOP_BWD = FALSE	SPEED = (-1) * JOG_SPEED

SPEED_REF is in terms of 0-100 %. User needs to convert this output to 0-50 Hz before giving to the drive.

DIR BOOL (direction)

If SPEED >= 0 -> DIR = TRUE

If SPEED < 0 -> DIR = FALSE

POS_REF_REACHED BOOL (position reference reached)

POS_REF_REACHED is set to TRUE as long as the system has reached the POS_REF or it is inside the area between POS_ERR > (POS_REF - POS_ACT).

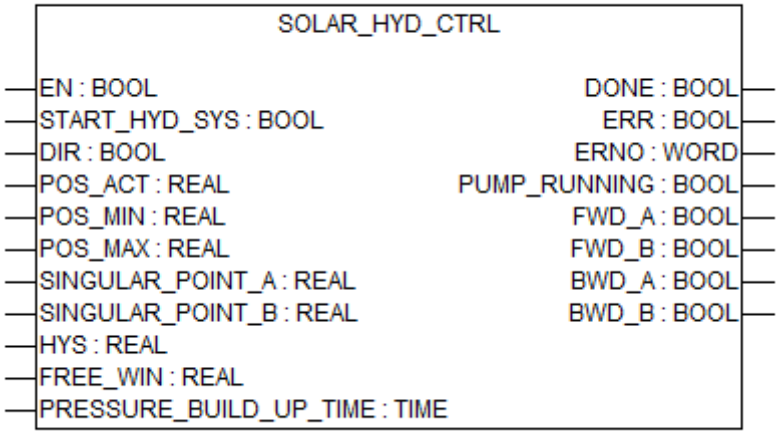
SOLAR_HYD_CTRL



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function
Group	Package of functions to get the position of the sun

Function block to manage two pistons as actuator device.

- Hydraulic system to move the tracker.

Hydraulic system is based in the action of two hydraulic pistons (Piston A and Piston B) that are controlled by four solenoid valves. Each hydraulic piston has two solenoid valves to control its movement. These solenoid valves are two position valves.

A1: Backward piston A (piston A reduces its length).

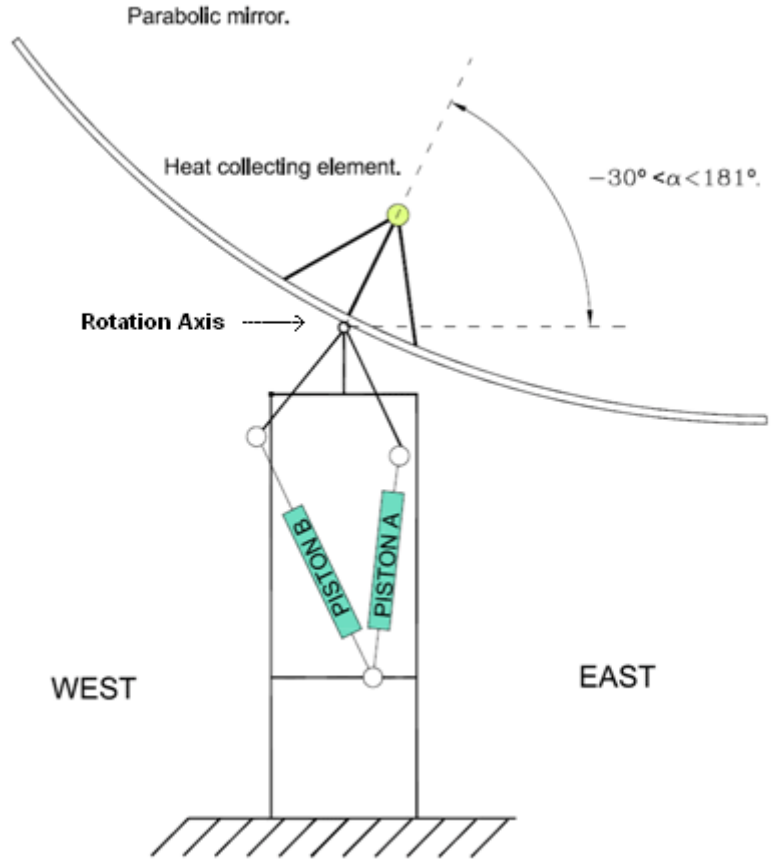
A2: Forward piston A (piston A increases its length).

B1: Backward piston B (piston B reduces its length).

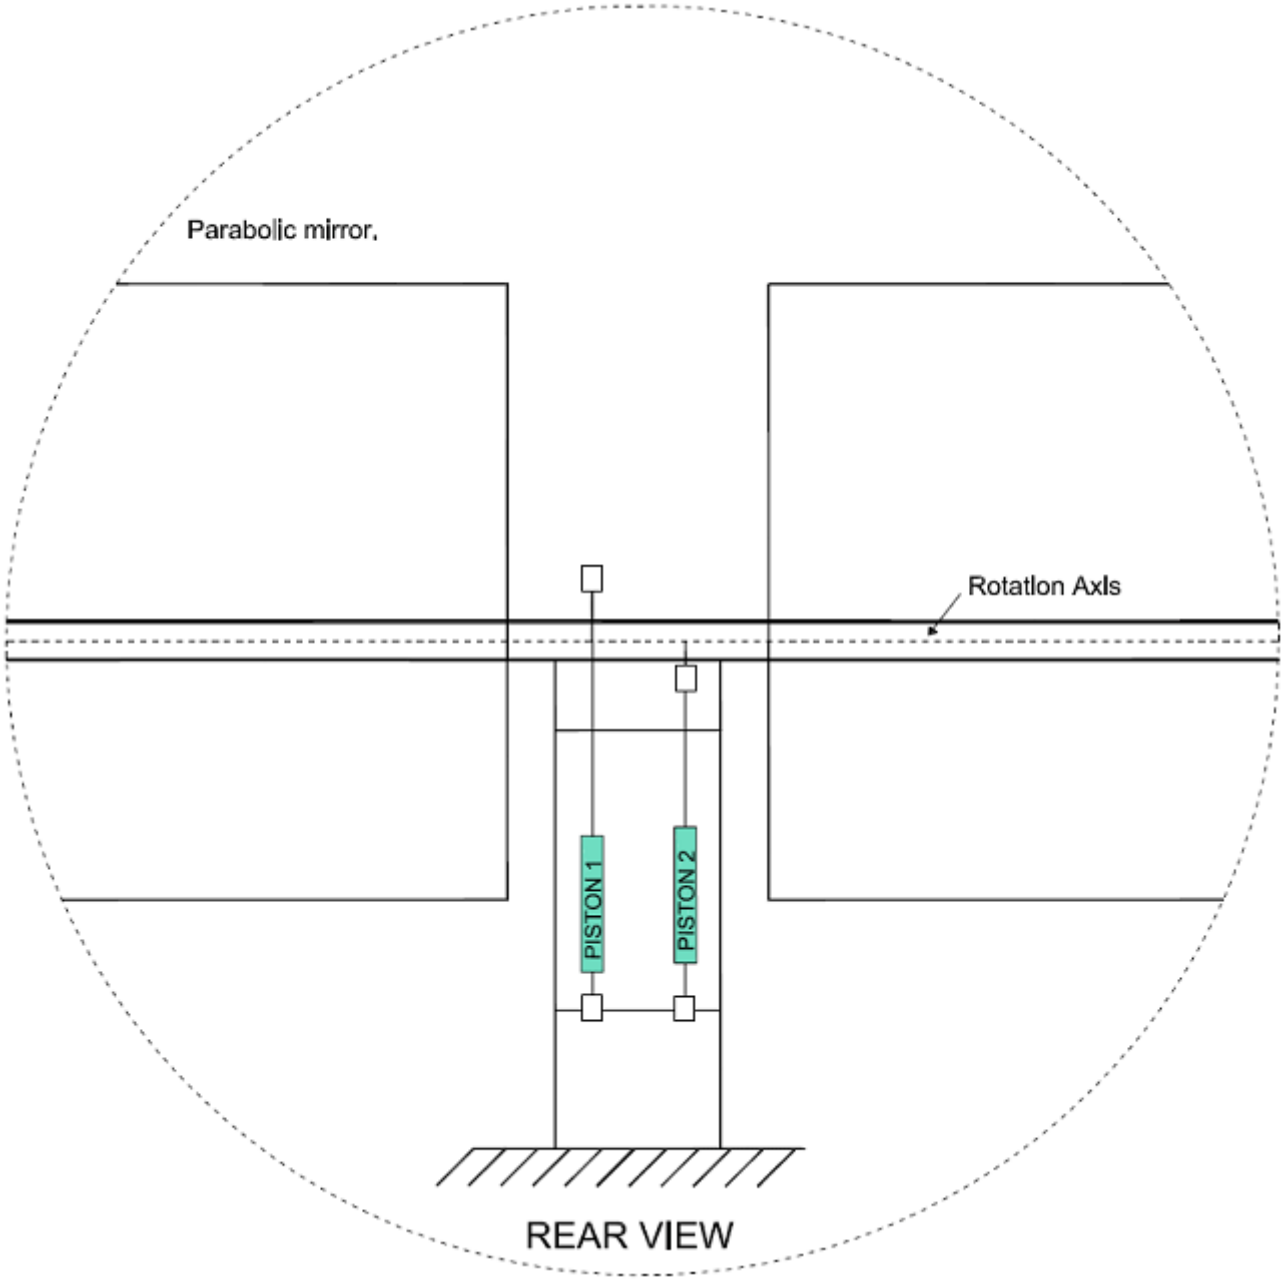
B2: Forward piston B (piston B increases its length).

Hydraulic system also has an oil pump to get pressure into the hydraulic circuit. This pumps works for a few periods of time, it doesnt work continuously.

Movement range of tracker [-30° - 181°]:



Movement cycle of the hydraulic pistons:



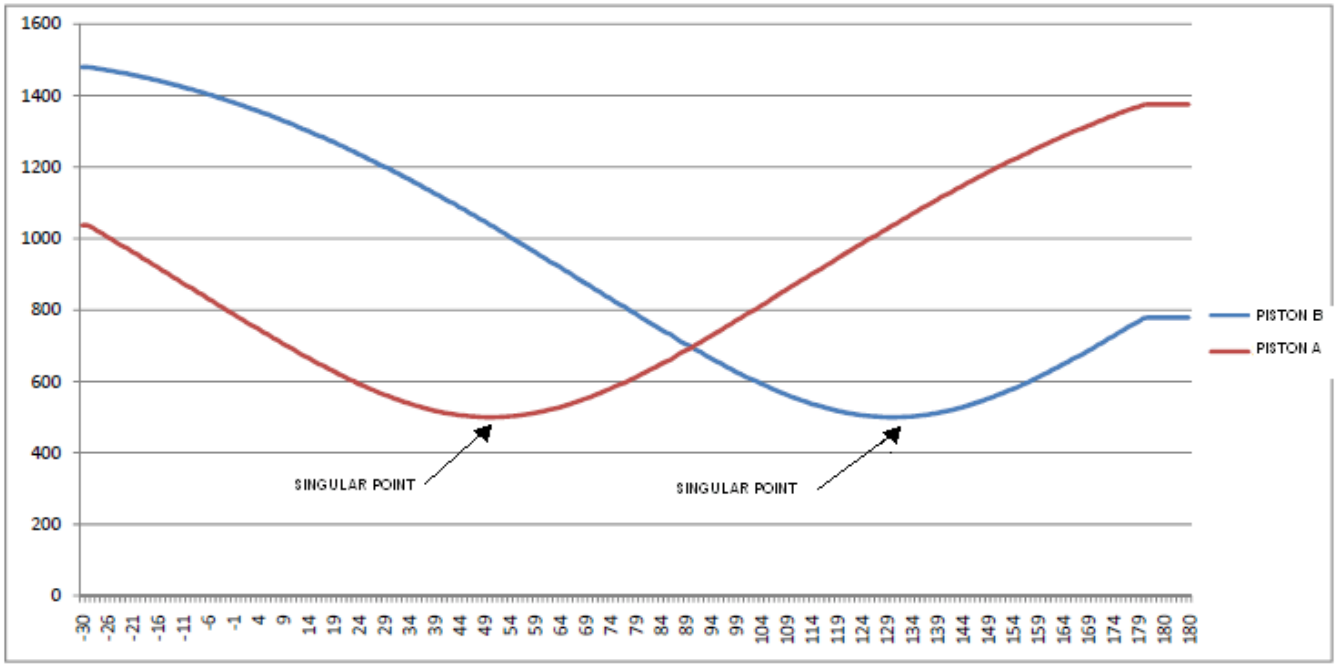
Movement cycle of the hydraulic piston is the following:

During a part of the movement cycle, both pistons are running in the same direction (both are pulling or pushing at the same time).

During a part of the movement cycle, one piston has reached its singular point. In this position, the piston does not generate any torque in the system.

During a part of the movement cycle, both pistons are running in opposite directions (one of them is pulling and the other one is pushing at the same time).

Figure below shows the movement cycle of the hydraulic pistons:



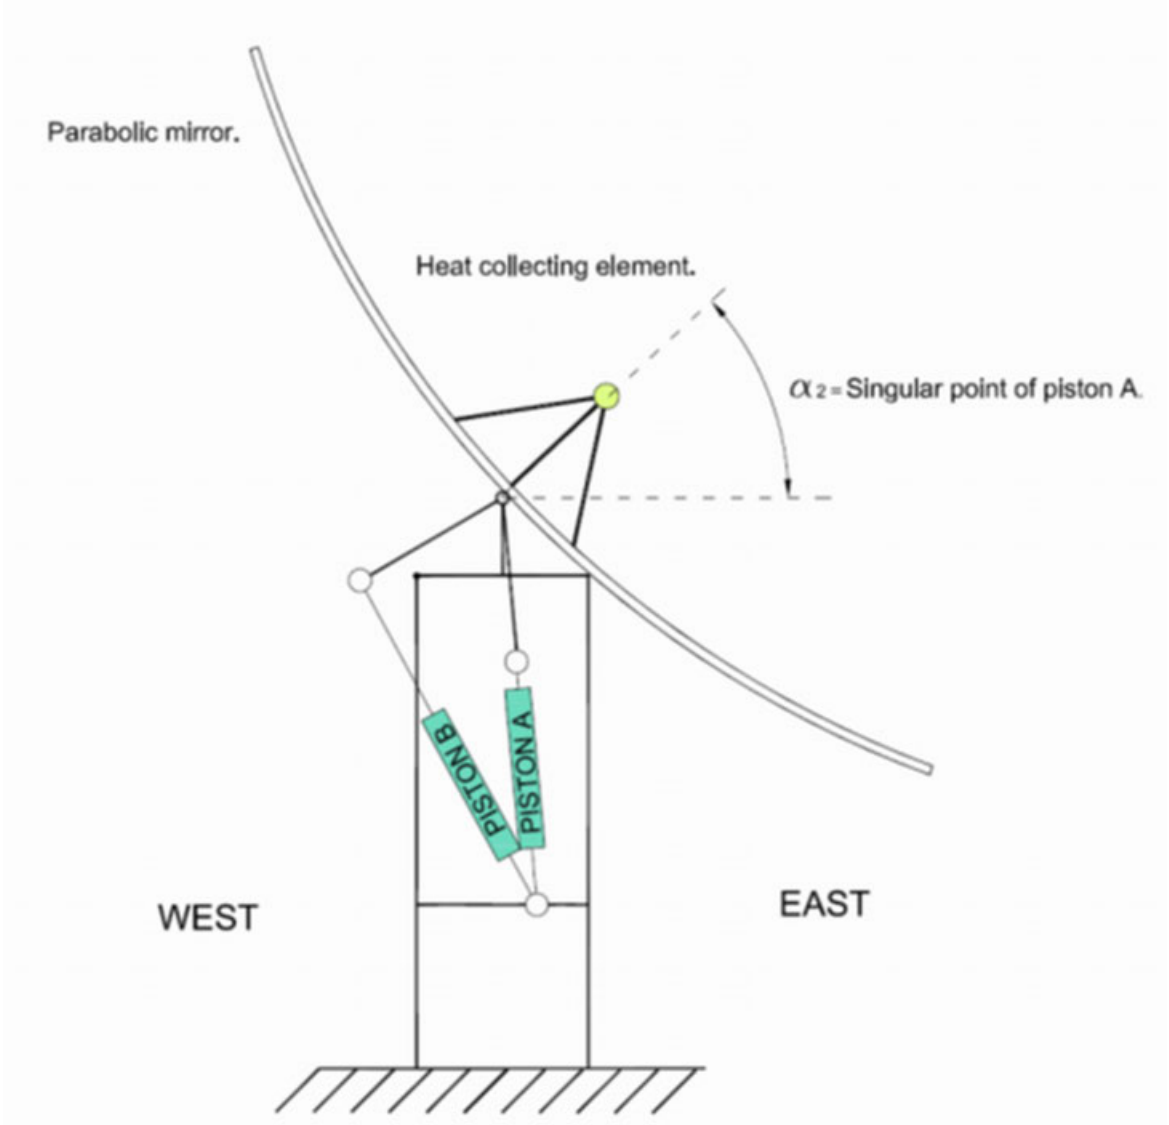
X-axis represents the allowed position range of Solar Tracker (these values are configurable by the user).

Y-axis represents the length of the hydraulic pistons.

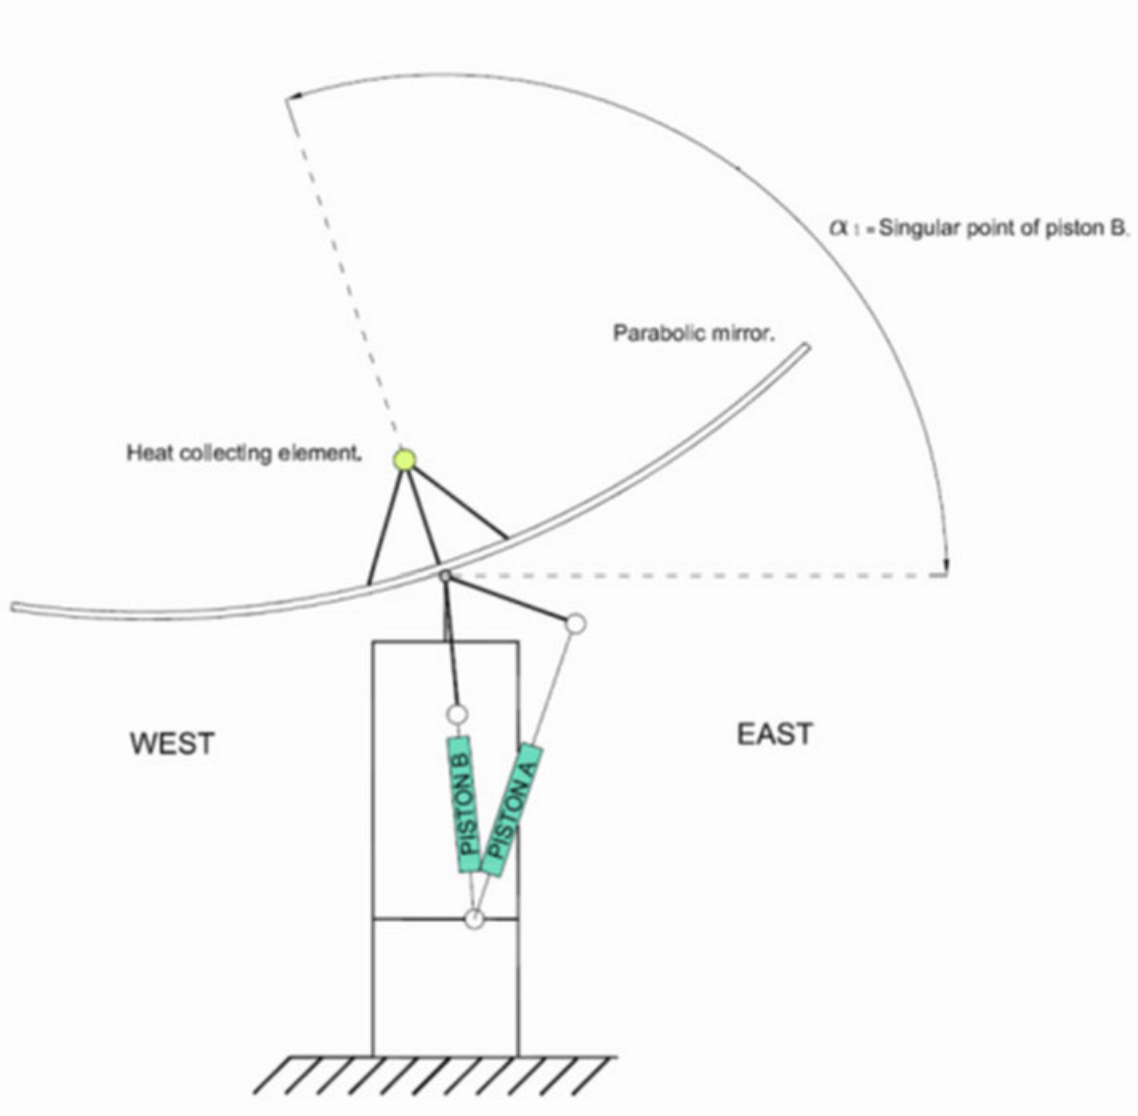
In this case, singular points are:

- Piston A: 49°.
- Piston B: 130°.

The singular point for piston A. Its value is ±2:



The singular point for piston B. Its value is ±1:



Movement control: To control the movement of the hydraulic pistons, it is necessary to operate on the solenoid valves. Depending on tracker position and direction of rotation, from east to west or from west to east, it is necessary to operate on determined solenoid valves.

Table below shows sequence of solenoid valves.

	SOLENOID VALVES			
Tracker Position Range	**A1**	**A2**	**B1**	**B2**
-30º < α < 49º-σ	1	0	1	0
49º-σ < α < 49º+σ	0 (FREE-WINDOW)	0 (FREE-WINDOW)	1	0
49º+σ < α < 130º - σ	0	1	1	0
130º- σ< α < 130º + σ	0	1	0 (FREE-WINDOW)	0 (FREE-WINDOW)
130º+σ < α < 181	0	1	0	1

Where:

A1: backward piston A A2: forward piston A.

B1: backward piston B B2: forward piston B.

1: solenoid valve is ON 0: solenoid valve is OFF.

Ïf: free-window (degrees) ±: angular position of the Solar Tracker (degrees).

> *All range position values that appear in the table above are configurable and depend on each tracker. A previous geometrical analysis is needed due to there are many kind of trackers. You can use this table as an example.*

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START_HYD_SYS BOOL (start hydraulic system) Boolean input that enables SOLAR_HYD_CTRL block.

DIR BOOL (direction) Boolean input that indicates the direction movement of Solar Tracker.

TRUE: = forward, FALSE: = backward.

POS_MIN REAL (position minimum) Lower limit of the movement range.

Format: Degrees.

POS_MAX REAL (maximum position) Upper limit of the movement range.

Format: Degrees.

SINGULAR_POINT_A REAL (singular_point_A) Indicates a position of the Solar Tracker (angular position). In that position, the mechanical structure of Solar Tracker shows a singular point concerning to piston A. In that situation, piston A does not generate any torque value. This value is given by tracker manufacturer.

Format: Degrees.

SINGULAR_POINT_B REAL (singular_point_B) Indicates a position of the Solar Tracker (angular position). In that position, the mechanical structure of Solar Tracker shows a singular point concerning to piston B. In that situation, piston B does not generate any torque value. This value is given by tracker manufacturer.

Format: Degrees.

HYS REAL (hysteresis) Hysteresis value to avoid unnecessary piston movement. This value is obtained by testing the behavior of the Solar Tracker.

Format: Degrees.

FREE_WIN REAL (free window) Value of semi angle in which hydraulic piston does not generate any torque value. Movement of hydraulic piston is free when is placed inside this window. This value is obtained by testing the behavior of the Solar Tracker.

Format: Degrees.

PRESSURE_BUILD_UP_TIME TIME (pressure build up time)

Time to achieve the correct hydraulic pressure in the circuit.

Format: Seconds.

Standard: 500ms.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

PUMP_RUNNING BOOL (pump running)

Indicates that pump is working.

FWD_A BOOL (forward a)

Indicates that hydraulic piston A is running forward.

FWD_B BOOL (forward b)

Indicates that hydraulic piston B is running forward.

BWD_A BOOL (backward a)

Indicates that hydraulic piston A is running backward.

BWD_B BOOL (backward b)

Indicates that hydraulic piston B is running backward.

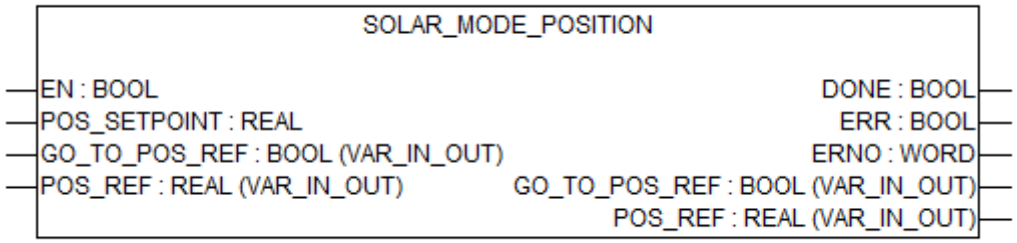
1.5.11.2.6 MODE folder

SOLAR_MODE_POSITION



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function block without historical values
Group	Package of function blocks for different control modes

This function block represents an operation mode that allows to move the Solar Tracker to a position defined by the user. It shall keep the Solar Tracker in this position awaiting for new commands or new position value.

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

POS_SETPOINT REAL (position setpoint) Position value defined by the user.

GO_TO_POS_REF BOOL (go to position reference) Boolean expression that indicates the process is able to move Solar Tracker.

POS_REF REAL (position_reference) Desired position to locate the tracker.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

Function call in IL

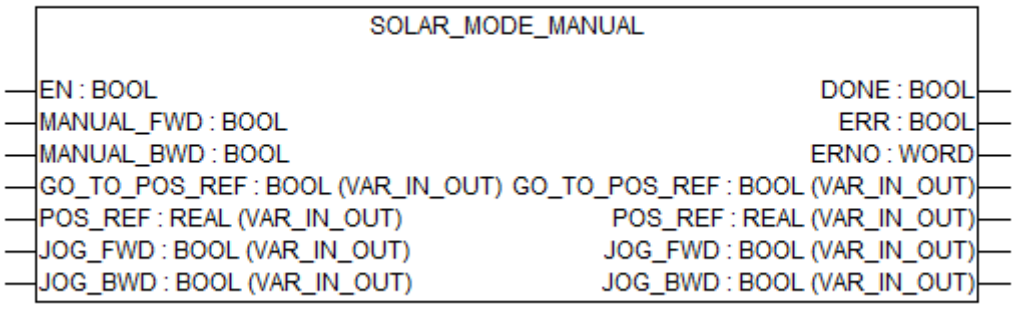
SOLAR_MODE_MANUAL



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function block without historical values
Group	Package of function blocks for different control modes

This function block represents an operation mode that allows to set the system in manual mode. User is able to move the system by using drives directly. While this mode is active, system will not respond to any commands from the solar control field.

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

MANUAL_FWD BOOL (manual forward) In order to move manually the system forward, input JOG_FWD has to be set to TRUE.

MANUAL_BWD BOOL (manual backward) In order to move manually the system backward, input JOG_BWD has to be set to TRUE.

GO_TO_POS_REF BOOL (go to position reference) Boolean expression that enables position control block.

POS_REF REAL (position_reference) Desired position to locate the tracker.

JOG_FWD BOOL (jog forward) Boolean expression that indicates that drive is running forward.

JOG_BWD BOOL (jog backward) Boolean expression that indicates that drive is running backward.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

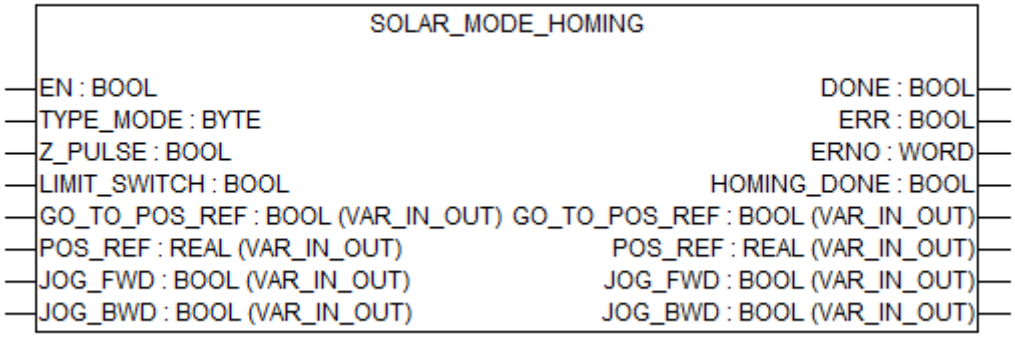
SOLAR_MODE_HOMING



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function block without historical values
Group	Package of function blocks for different control modes

Set the system to look for the reference point initialization (Z).

This function block represents an operation mode that allows to search the reference point initialization. Systems moves until reference point is reached. This mode assumes that system has a high accuracy mechanical limit switch to indicate that home position has been reached.

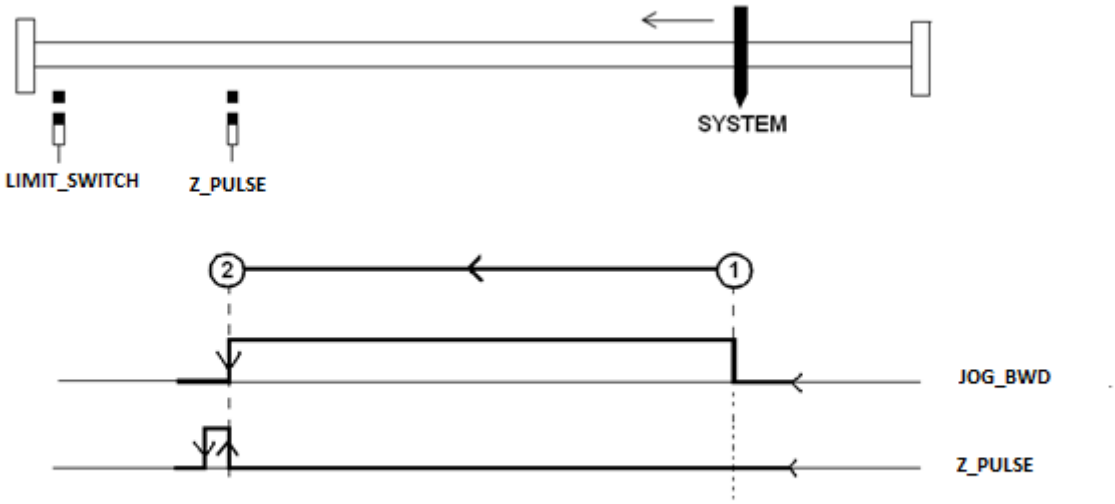
Figure below indicates how this operation mode works. In this document there are explained four basics systems according to:

- Type of device to indicate reference point initialization.
- Direction of movement. (Negative direction left and positive direction to the right).

Modules DC541 and DC522 use rising edge to synchronization and initialization process, so this four types use rising edge to calculate home position.

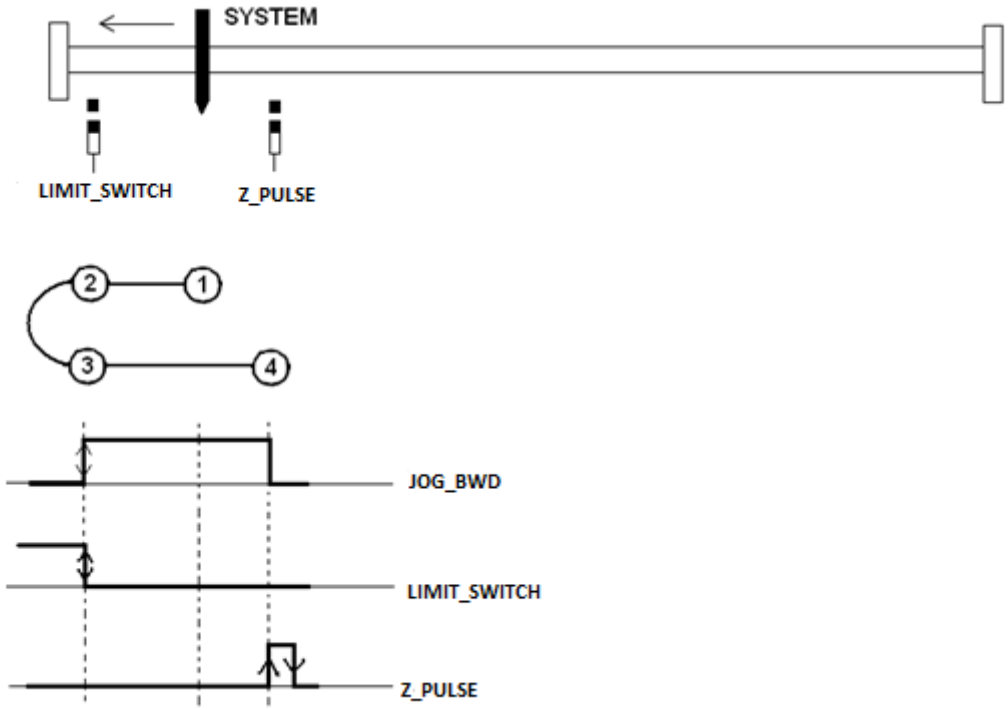
Type 1: Using encoder reference point Z_PULSE and limit switch to determinate home position.

First movement: Negative direction (left):



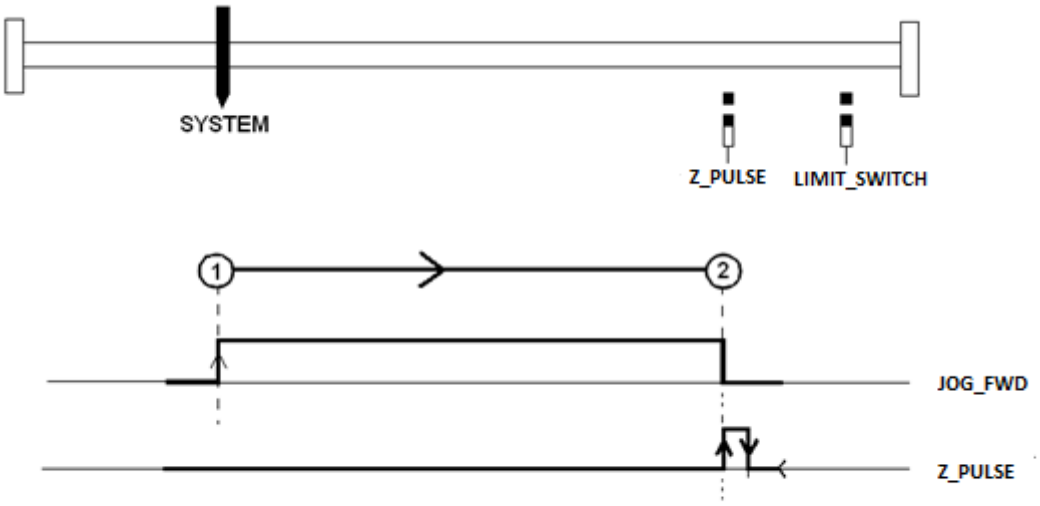
At the beginning, system is located at point 1 and limit switch is not active yet. When SOLAR_MODE_HOMING is enabled, JOG_BWD is set to TRUE. As soon as Z_PULSE shows rising edge, home position has been reached and system stops its movement at point 2.

If system is located between Z_ENCODER and LIMIT_SWITCH positions, SOLAR_MODE_HOMING operates as figure below shows:



Type 2: Using encoder reference point Z_PULSE mechanical limit switch to determinate home position.

First movement: Positive direction (right):



At the beginning, system is located at point 1 and limit switch is not active yet. When SOLAR_MODE_HOMING is enabled, JOG_FWD is set to TRUE. As soon as Z_PULSE shows rising edge, home position has been reached and system stops its movement at point 2.

If system is located between Z_ENCODER and LIMIT_SWITCH positions, SOLAR_MODE_HOMING operates as figure below shows:

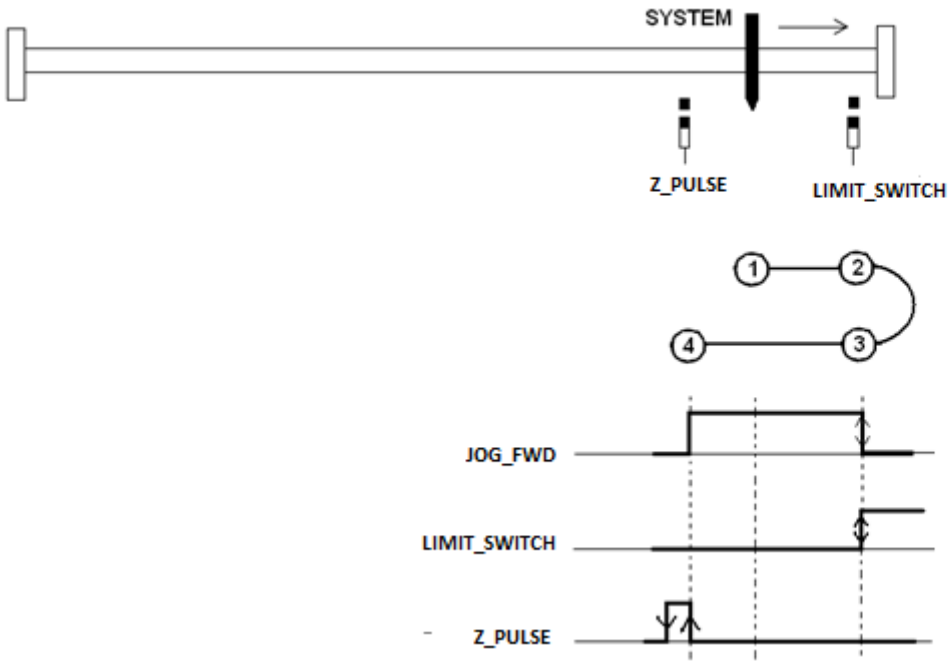


Figure below shows the logical sequence that implements SOLAR_MODE_HOMING Type 1 & Type 2:

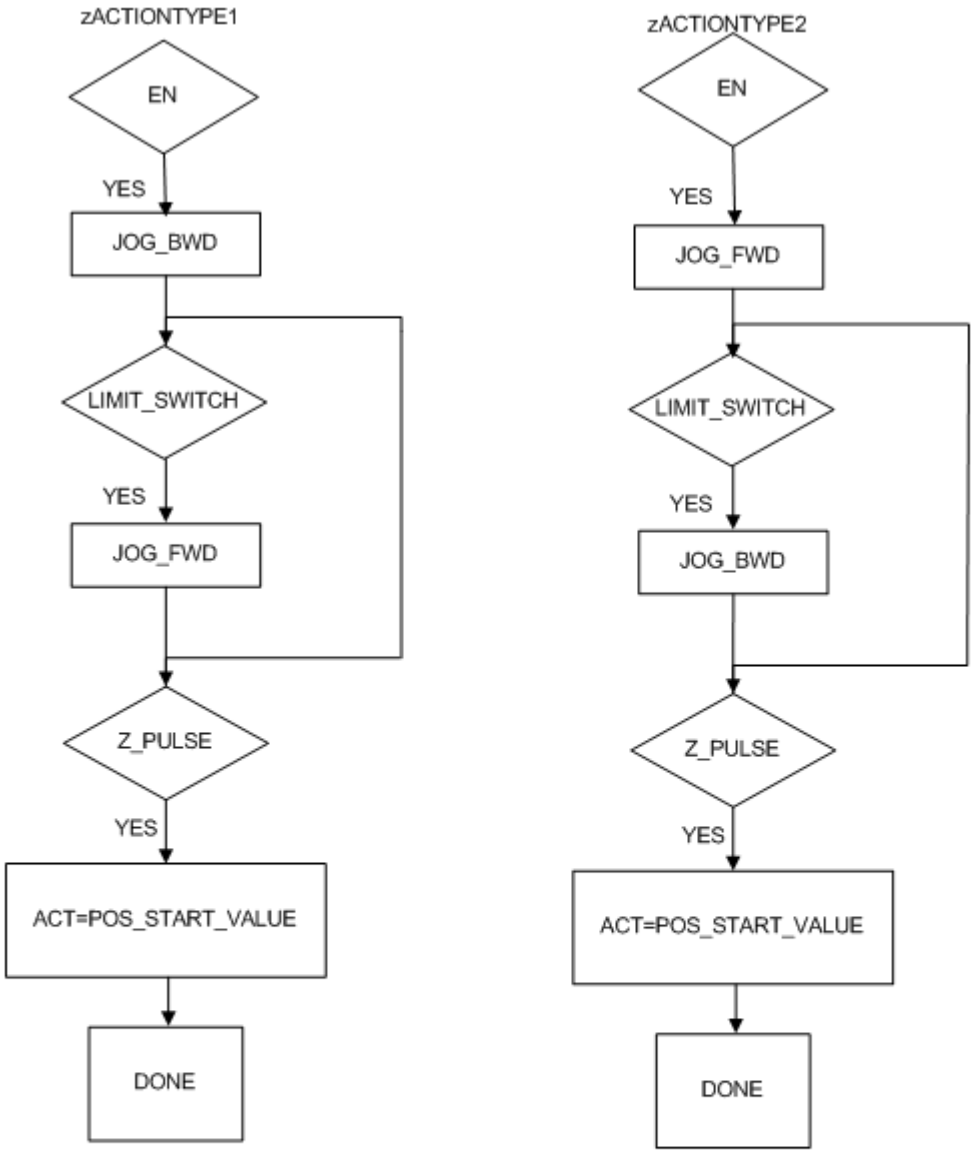
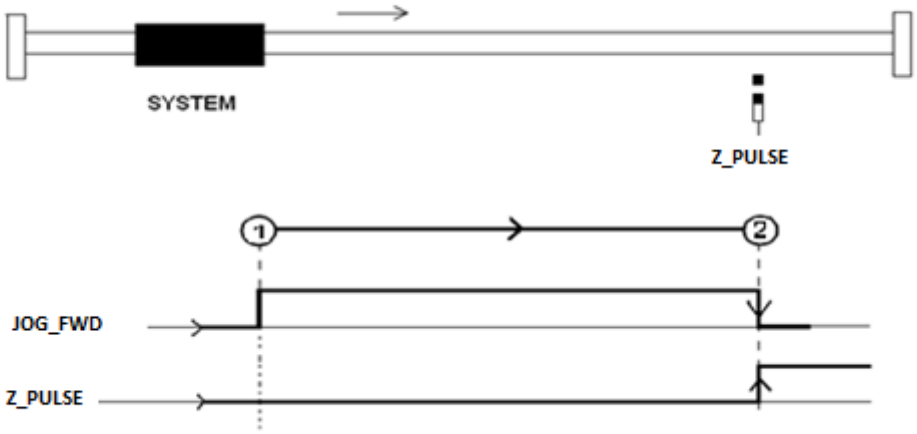
NEGATIVE Direction (left)	POSITIVE Direction (right)

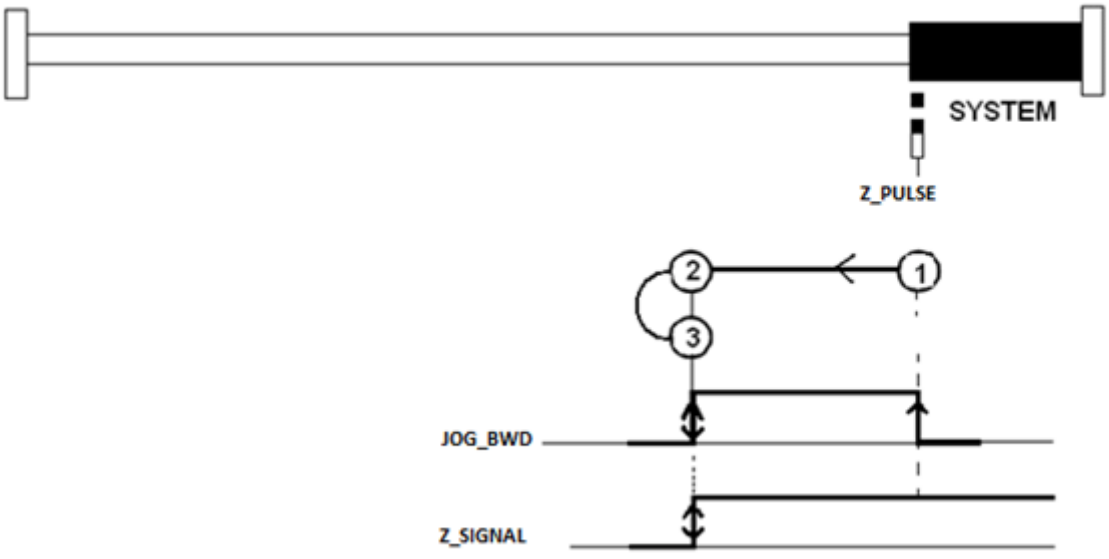


Type 3: Using Z_PULSE and cam switch to determinate home position.

First movement: Positive direction (right):

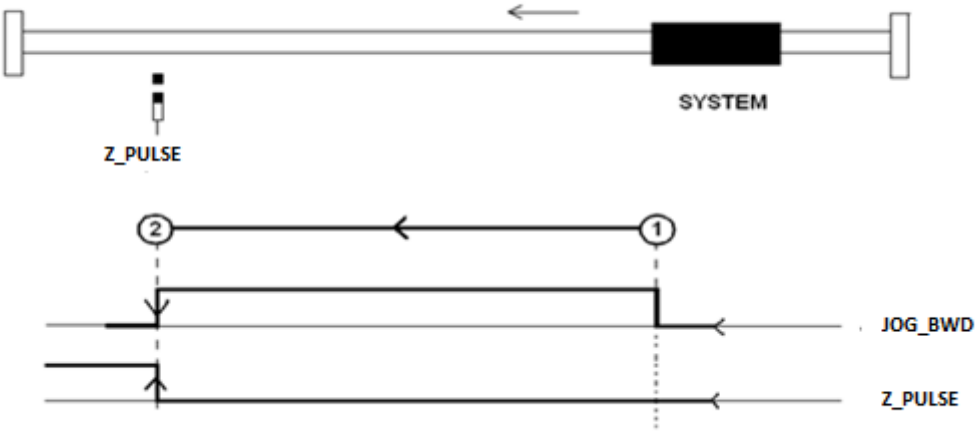


Home position has been reached when rising edge of the signal Z_PULSE is detected. Then, movement is stopped. On the other hand, if system is located at the end of its movement range and cam switch signal is set to TRUE (see figure below) home position is reached as follow:



Type 4: Using a cam switch to determinate home position.

First movement: Negative direction (left):



Home position has been reached when rising edge of the signal Z_PULSE is detected. Then, movement is stopped. On the other hand, if system is located at the end of its movement range and cam switch signal is set to TRUE (see figure below) home position is reached as follow:

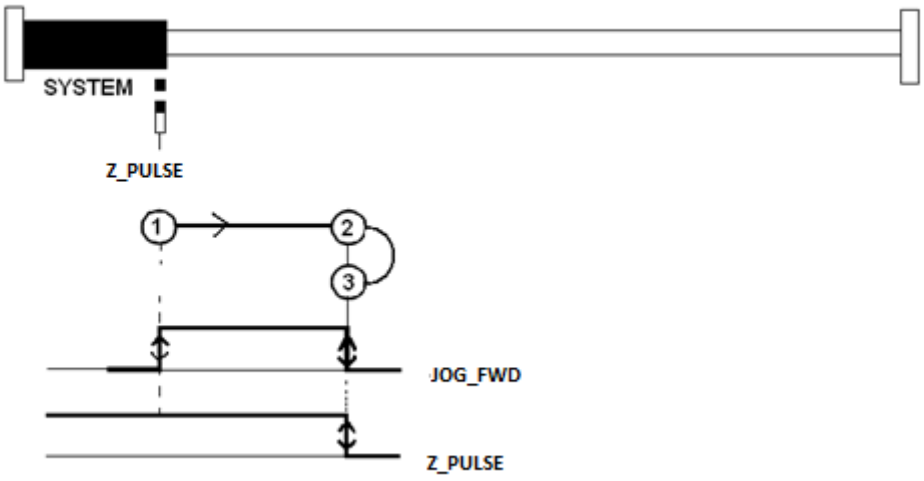


Figure below shows the logical sequence that implements SOLAR_MODE_HOMING Type 3 & Type 4:

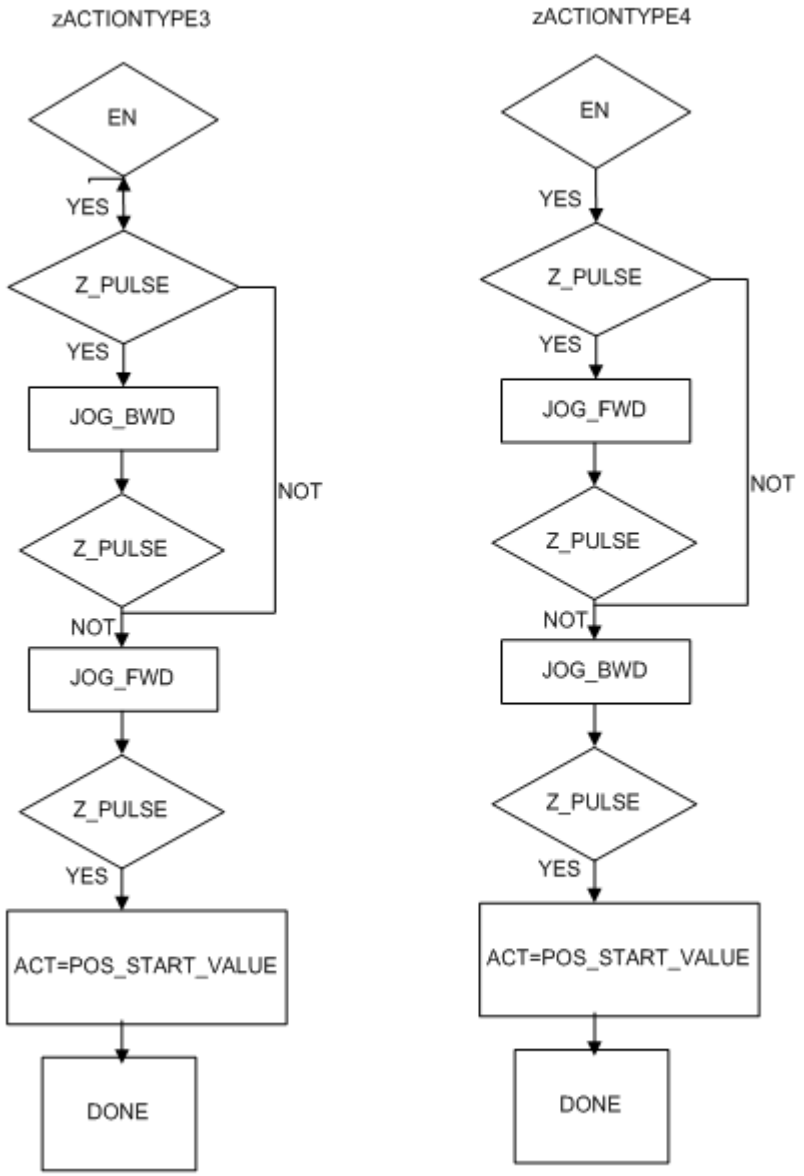
POSITIVE Direction (right)	NEGATIVE Direction (left)



Input description

EN BOOL (enable block)

Homing process starts as soon as rising edge is detected at signal EN.

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The block is not processed if input EN = FALSE.

While input EN is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

TYPE_MODE BYTE (type mode)

This input indicates which kind of configuration sensors are going to be used to determinate home positions (see figures above).

1 -> Z_Sensor is only one pulse signal. First movement: backward.

2 -> Z_Sensor is only one pulse signal. First movement: forward.

3 -> Z_Sensor uses cam switch. First movement: forward.

4 -> Z_Sensor uses cam switch. First movement: backward.

Z_PULSE BOOL (z pulse)

Boolean expression that indicates the positioning device has reached its Z position.

TYPE 1 & 2 -> Z_PULSE = RDY_SYNC (output variable of encoders function).

TYPE 3 & 4 -> Z_PULSE = Z_PULSE (variable that indicates the state of input Z).

LIMIT_SWITCH BOOL (limit switch)

Boolean expression that indicates home position has been reached. It is used in Type 1 & Type 2.

TYPE 1 -> LIMIT_SWITCH = LIMIT_SWITCH_MIN

TYPE 2 -> LIMIT_SWITCH = LIMIT_SWITCH_MAX

GO_TO_POS_REF BOOL (go to position reference)

Boolean expression that enables position control block.

POS_REF REAL (position_reference)

Desired position to locate the tracker.

JOG_FWD BOOL (jog forward)

In order to move manually the system forward, input JOG_FWD has to be set to TRUE.

JOG_BWD BOOL (jog backward)

In order to move manually the system backward, input JOG_BWD has to be set to TRUE.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

HOMING_DONE
BOOL
(homing done)

Boolean expression that enables synchronization process and giving homing done signal to subsequent blocks.

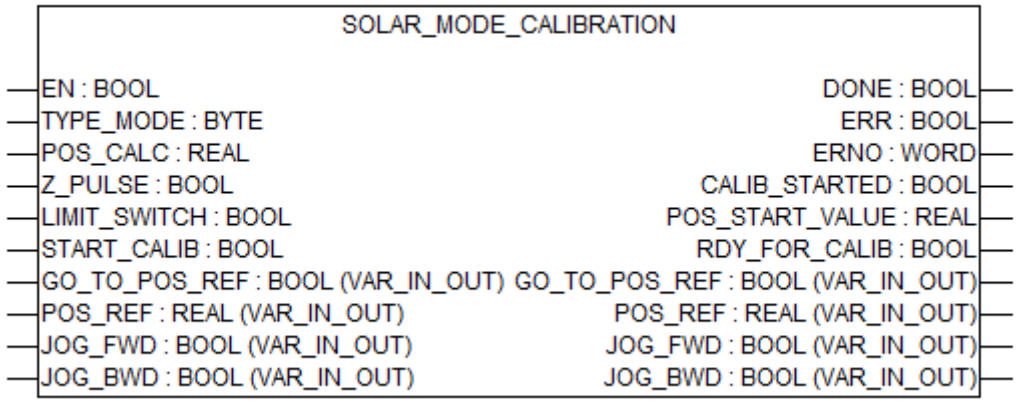
SOLAR_MODE_CALIBRATION



Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function block without historical values
Group	Package of function blocks for different control modes

This function block represents an operation mode that allows to calibrate the tracker reference point.

This function is necessary to calibrate the reference point (Z) when incremental encoders are used for the first time.

Sequence of the calibration process.

Option 1:

1. Move the tracker by using SOLAR_MODE_MANUAL to a position that let you to measure that position easily.
2. Get the angular position by using a high accuracy measurement device. Store this value in POS_CALC variable.
3. Enabling function block to start calibrating process, then:
   - System will be moved automatically towards reference point.
   - System will stop as soon as reference point (Z) is reached. Encoders position function will stored the calibrating value at Z_VALUE.

   ⇨ Calibrating process finished.

Option 2:

On the other hand, if you are not able to determinate tracker position by using a high accuracy measurement device, it is possible to use a simple solar radiation sensor to determinate the correct tracker position.

Proceed as follow:

1. Move the tracker using SOLAR_MODE _MANUAL to a position ahead of the sun.
2. Using a solar radiation sensor, you have to wait until tracker will be focused. At this moment you store the calculated position of the sun (obtained by using a sun position algorithm).
3. Enabling function block to start calibrating process, then:
   - System will be moved automatically towards reference point.
   - System will stop as soon as reference point (Z) is reached. Encoders position function will stored the calibrating value at Z_VALUE.

   ⇨ Calibration process finished.

Option 2 needs a sunny day to complete the process.

Figure below shows the logical sequence that implements both options:

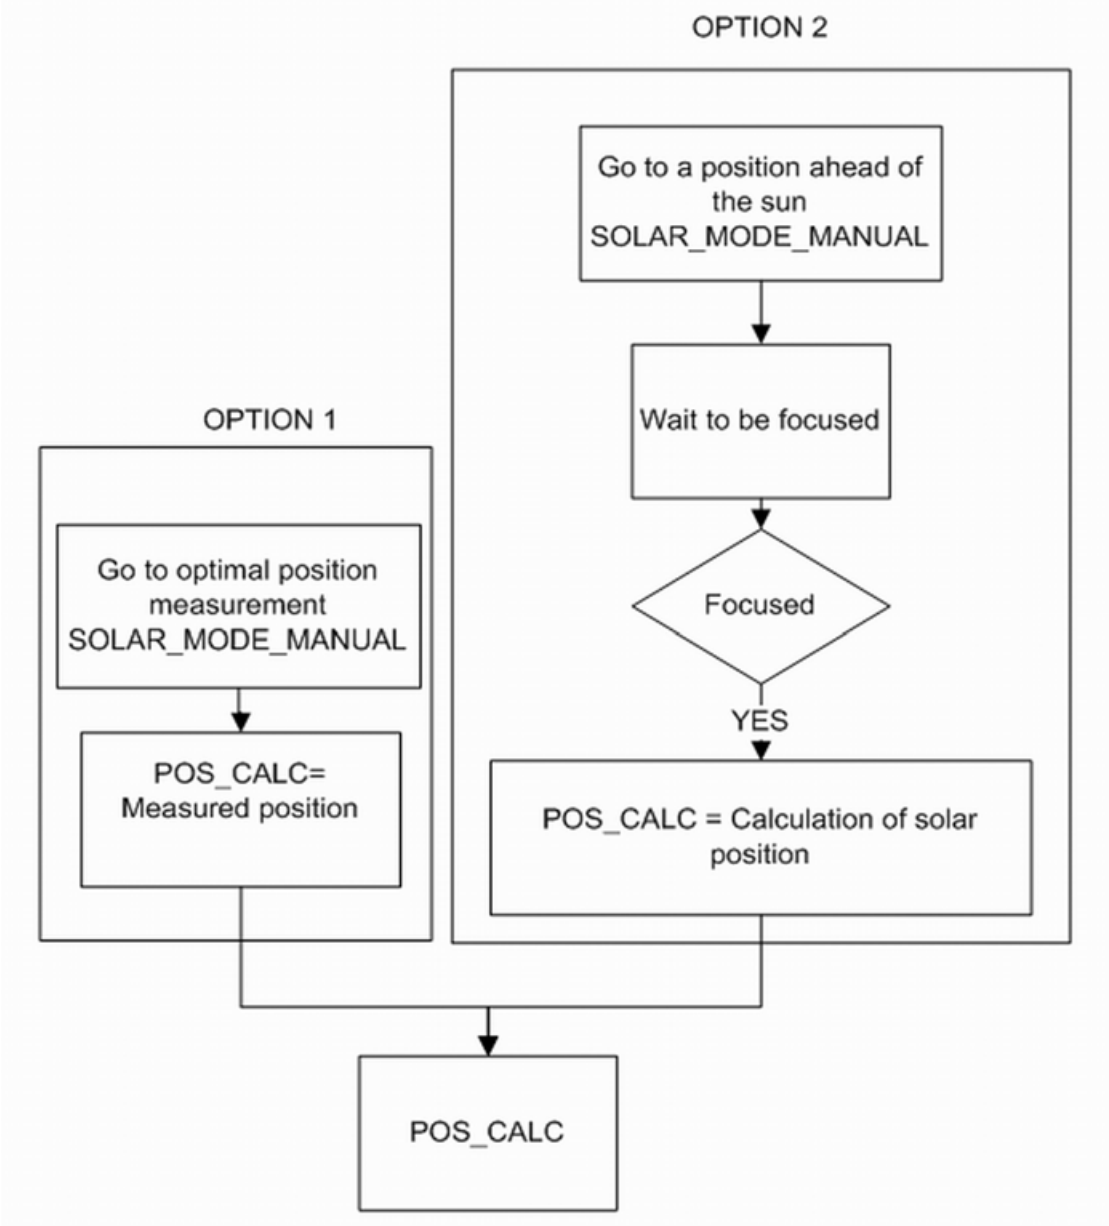


Figure below shows the logical sequence that implements SOLAR_MODE_CALIBRATION for Type 1 & Type 2:

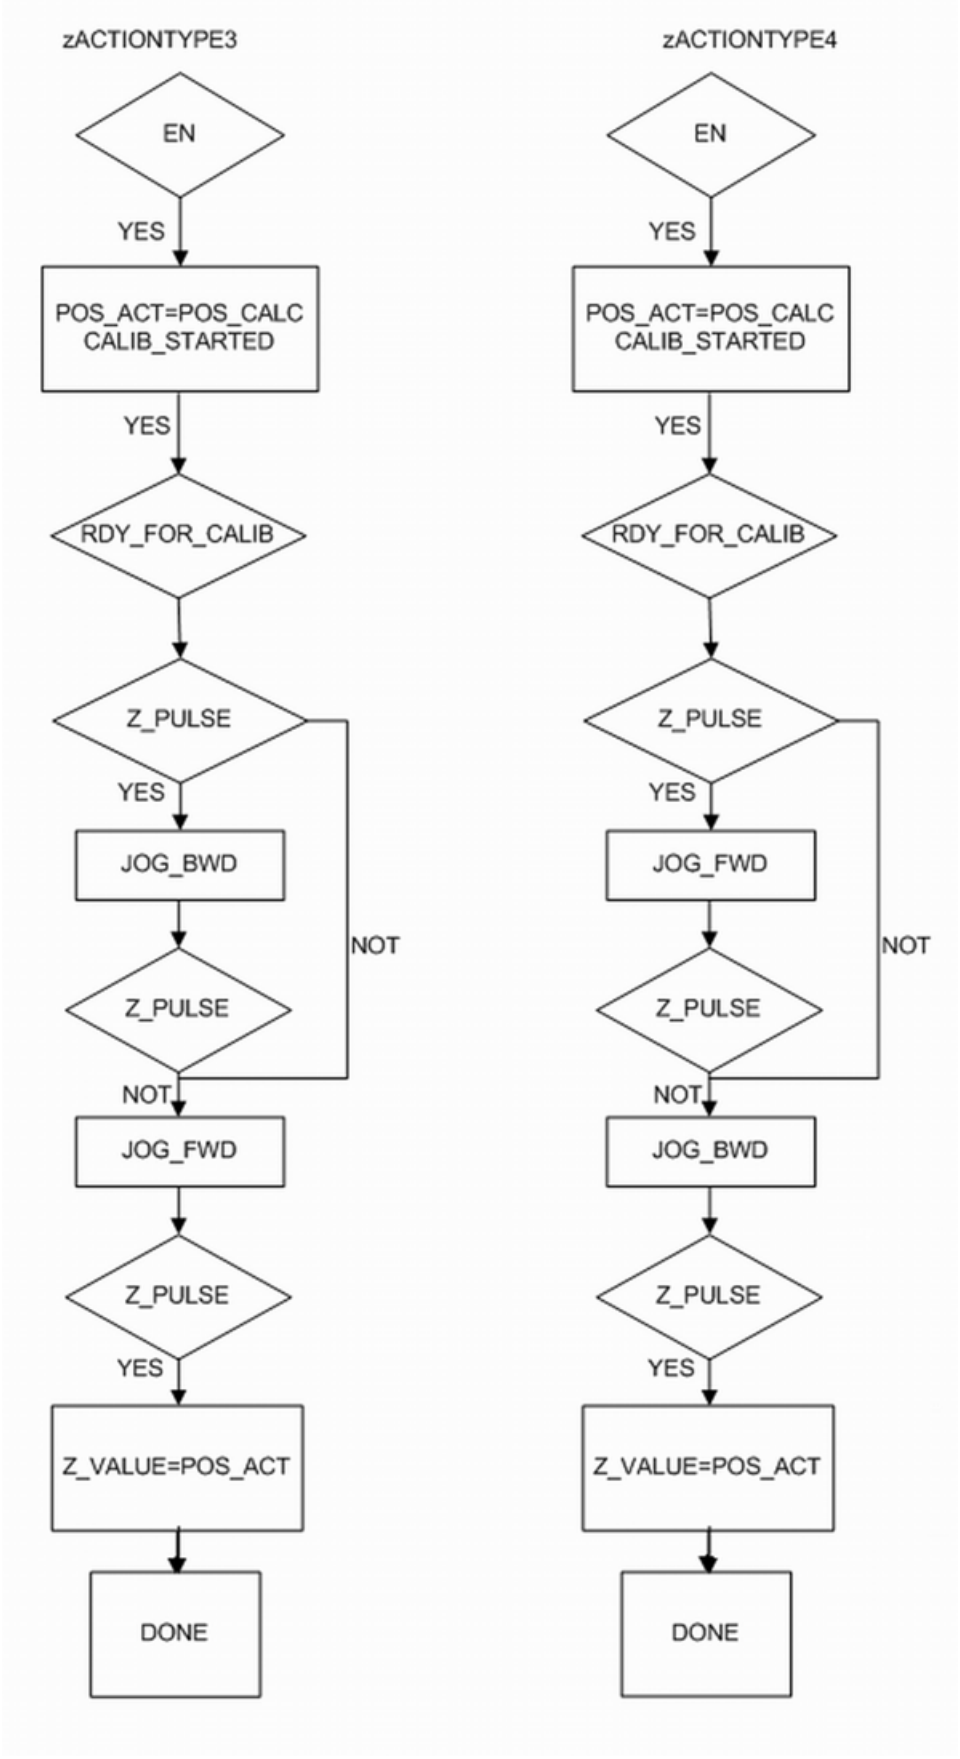
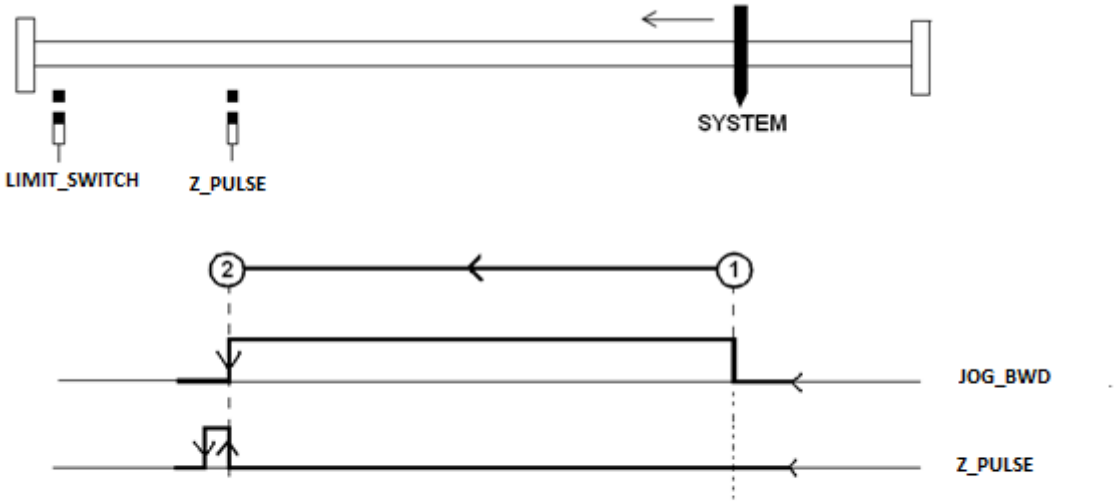
Figure below shows the logical sequence that implements SOLAR_MODE_CALIBRATION for Type 3 & Type 4:



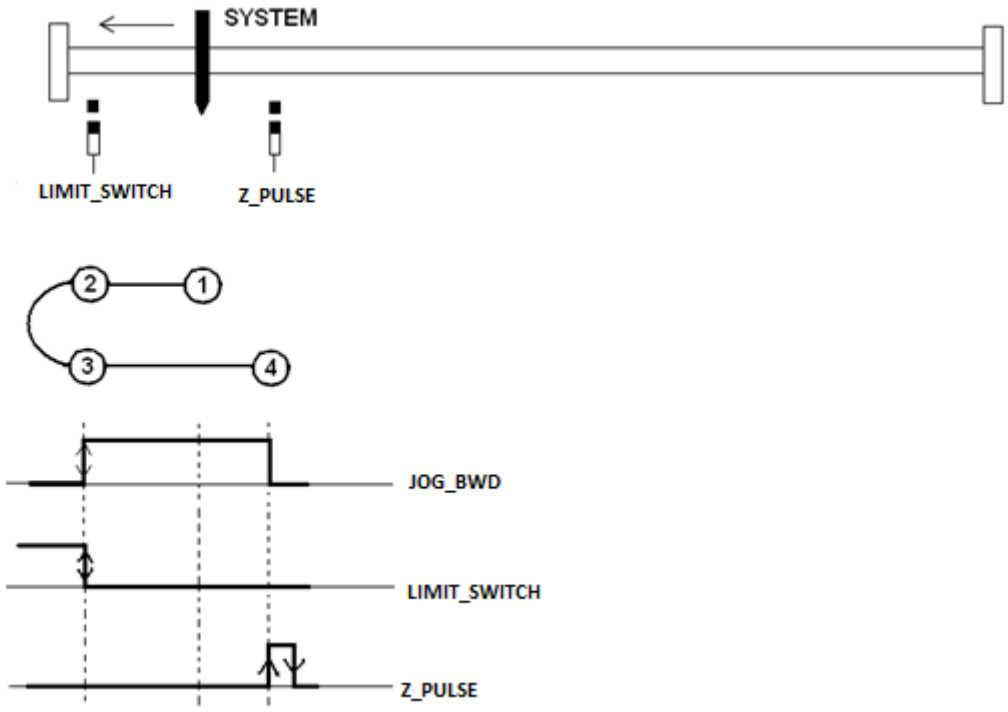
Type 1: Using encoder reference point Z_PULSE to determinate home position.

First movement: Negative direction (left):



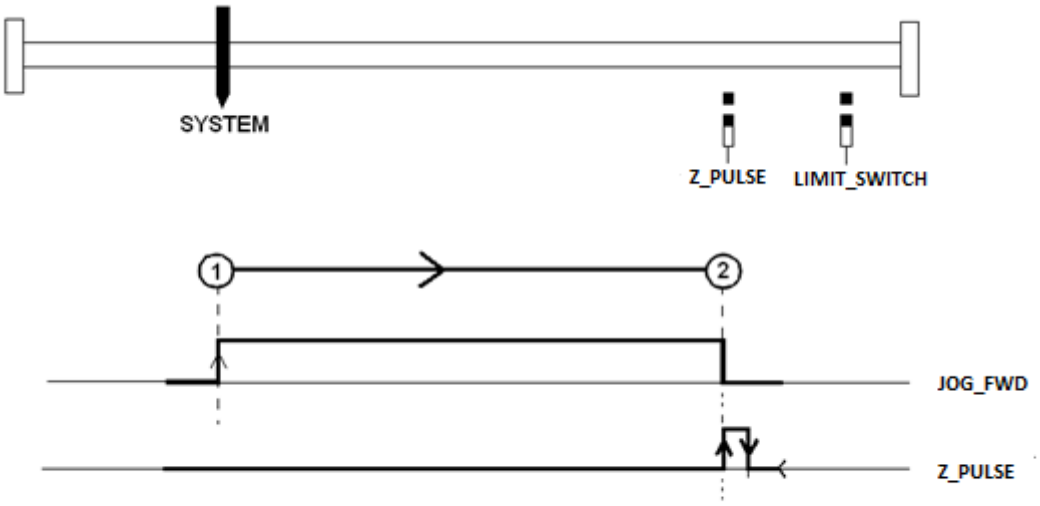
At the beginning, system is located at point 1 and limit switch is not active yet. When zACTION-TYPE1 is enabled, JOG_BWD is set to TRUE. As soon as shows rising edge, home position has been reached and system stops its movement at point 2.

If system is located between Z_PULSE and LIMIT_SWITCH positions, SOLAR_MODE_CALI-BRATION operates as figure below shows:



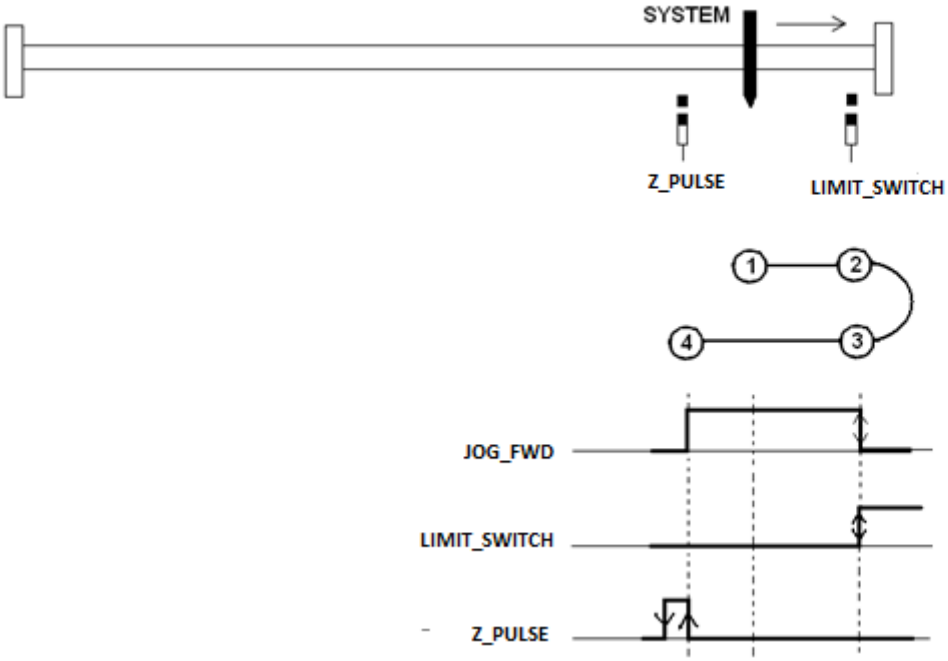
Type 2: Using encoder reference point Z_PULSE to determinate home position.

First movement: Positive direction (right):



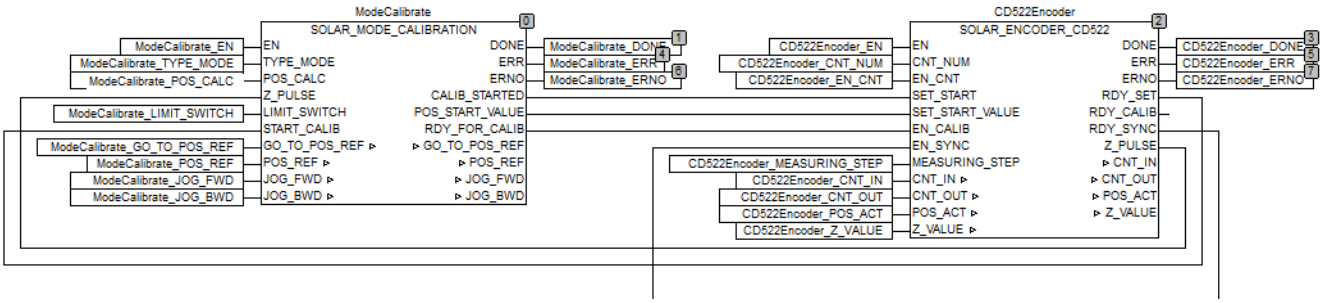
At the beginning, system is located at point 1 and Z_PULSE is not active yet. When SOLAR_MODE_HOMING is enabled, JOG_FWD is set to TRUE. As soon asZ_PULSE shows rising edge, home position has been reached and system stops its movement at point 2.

If system is located between Z_PULSE and LIMIT_SWITCH positions, SOLAR_MODE_CALIBRATION operates as figure below shows:



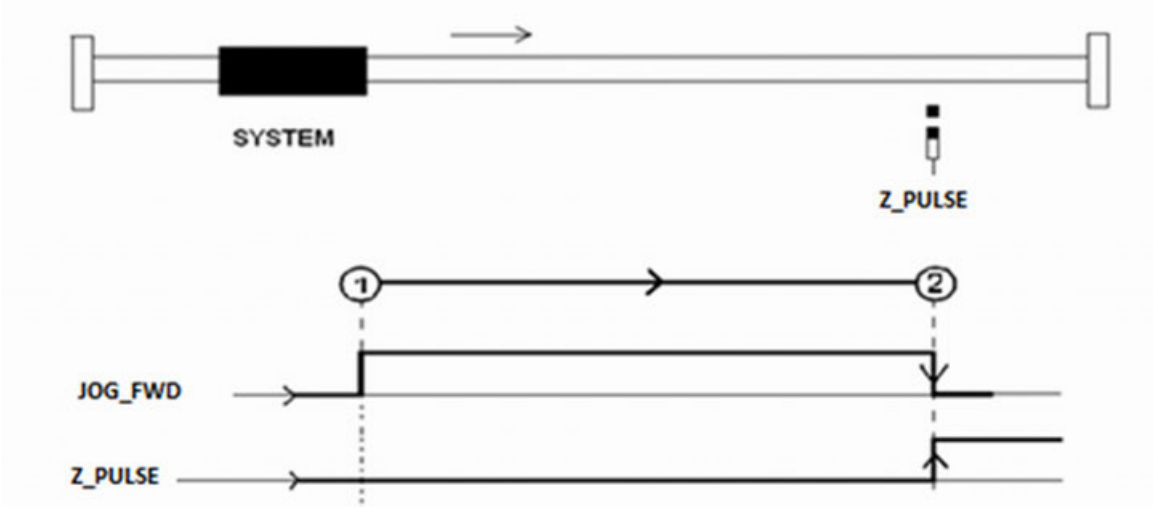
Example: SOLAR_MODE_CALIBRATION + Encoder

ModeCalibrate.Z_PULSE = CD522Encoder.RDY_TO_CALIB

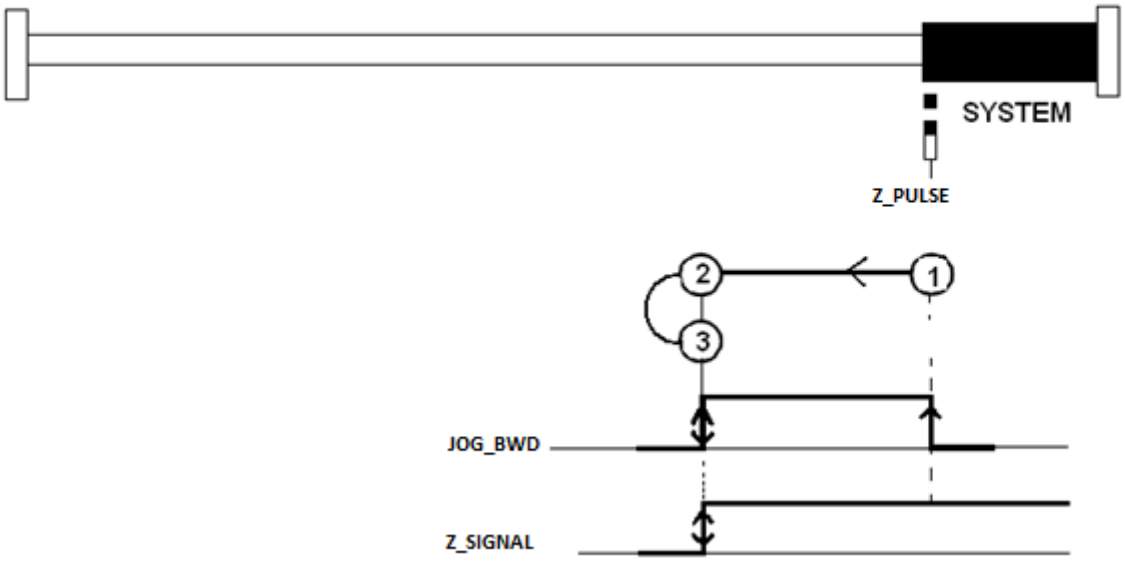


Type 3: Using Z_PULSE and cam switch to determinate home position.

First movement: Positive direction (right):

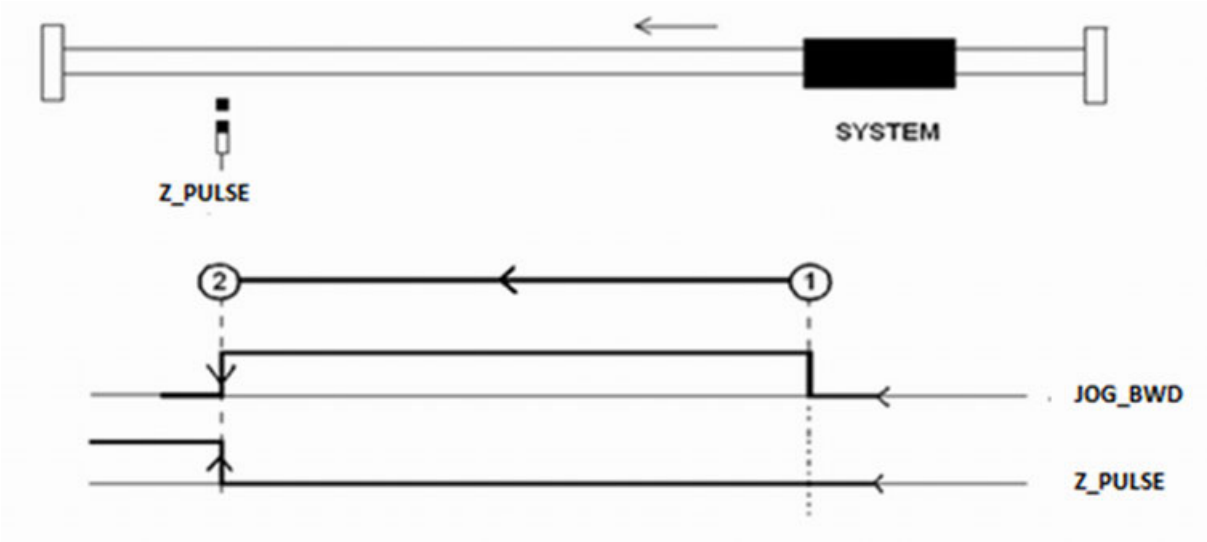


Home position has been reached when rising edge of the signal Z_PULSE is detected. Then, movement is stopped. On the other hand, if system is located at the end of its movement range and Z_PULSE signal is set to TRUE (see figure below) home position is reached as follow:

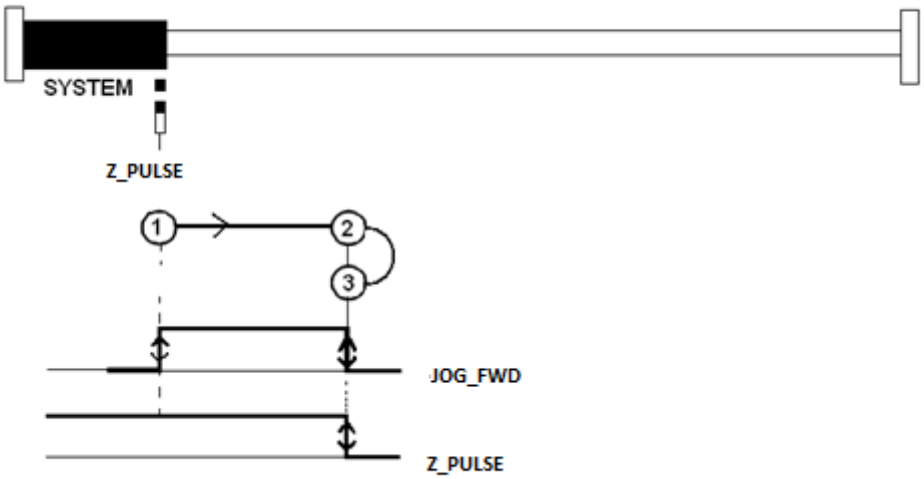


Type 4: Using Z_PULSE and cam switch to determinate home position.

First movement: Negative direction (left).

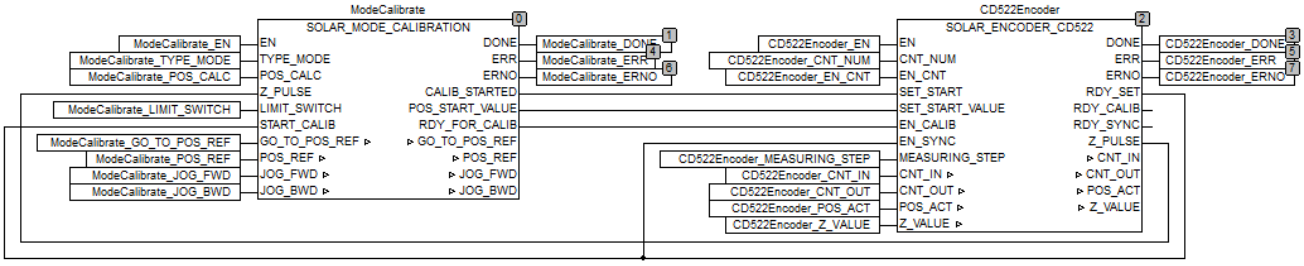


Home position has been reached when rising edge of the signal Z-PULSE is detected. Then, movement is stopped. On the other hand, if system is located at the end of its movement range and Z_PULSE signal is set to TRUE (see figure below) home position is reached as follow:



Example: SOLAR_MODE_CALIBRATION + Encoder.

> *ModeCalibrate.Z_PULSE = CD522Encoder.Z_PULSE*



Input description

EN BOOL (enable block)

Calibrating process starts as soon as rising edge is detected at signal EN.

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The block is not processed if input EN = FALSE.

While input EN is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

TYPE_MODE BYTE (type mode)

This input indicates which kind of configuration sensors are going to be used to determinate home positions (see figures above).

1 -> Z_Sensor is only one pulse signal. First movement: backward.

2 -> Z_Sensor is only one pulse signal. First movement: forward.

3 -> Z_Sensor uses cam switch. First movement: forward.

4 -> Z_Sensor uses cam switch. First movement: backward.

POS_CALC REAL (position calculated)

Calculated tracker position using a high accuracy measurement device or a sun position algorithm.

Z_PULSE BOOL (z pulse)

Boolean expression that indicates the positioning device has reached its Z position.

TYPE 1 & 2 -> Z_PULSE = RDY_CALIB (output variable of encoders function).

TYPE 3 & 4 -> Z_PULSE = (variable that indicates the state of input Z).

LIMIT_SWITCH BOOL (limit switch)

Boolean expression that indicates home position has been reached. It is used in Type 1 & Type 2.

TYPE 1 -> LIMIT_SWITCH = LIMIT_SWITCH_MIN

TYPE 2 -> LIMIT_SWITCH = LIMIT_SWITCH_MAX

START_CALIB BOOL (start calibration)

Boolean expression that indicates reading process of the encoder has finished (see SOLAR_Encoder_CD522_RDY_SET ↳ *Chapter 1.5.11.2.4.2 “SOLAR_ENCODER_CD522” on page 3194*).

POS_ACT = POS_CALC.

GO_TO_POS_REF BOOL (go to position reference)

Boolean expression that enables position control block.

POS_REF REAL (position_reference)

Desired position to locate the tracker.

JOG_FWD BOOL (jog forward)

In order to manually move the system forward, input JOG_FWD has to be set to TRUE.

JOG_BWD BOOL (jog backward)

In order to manually move the system backward, input JOG_BWD has to be set to TRUE.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

CALIB_STARTED BOOL (Calibration_Started)

Output CALIB_STARTED indicates calibrating process has started.

POS_START_VALUE REAL (position start value)

The counter can be set to a start value. This value must be applied to the input POS_START_VALUE.

If input CALIB_STARTED = TRUE, the counter takes this value.

RDY_FOR_CALIB BOOL (ready for calibration)

Boolean expression that enables calibrating process.

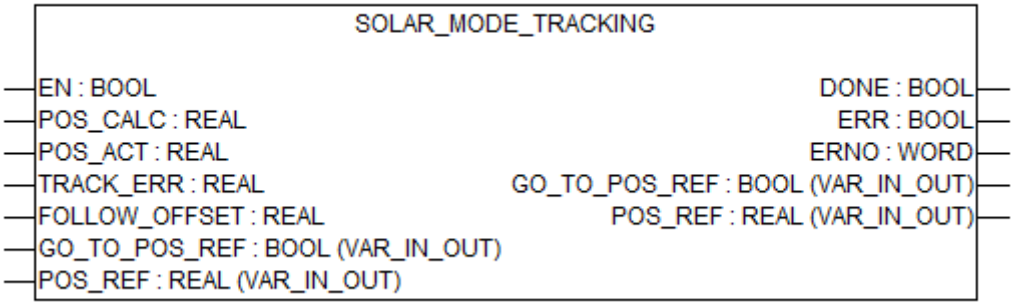
SOLAR_MODE_TRACKING



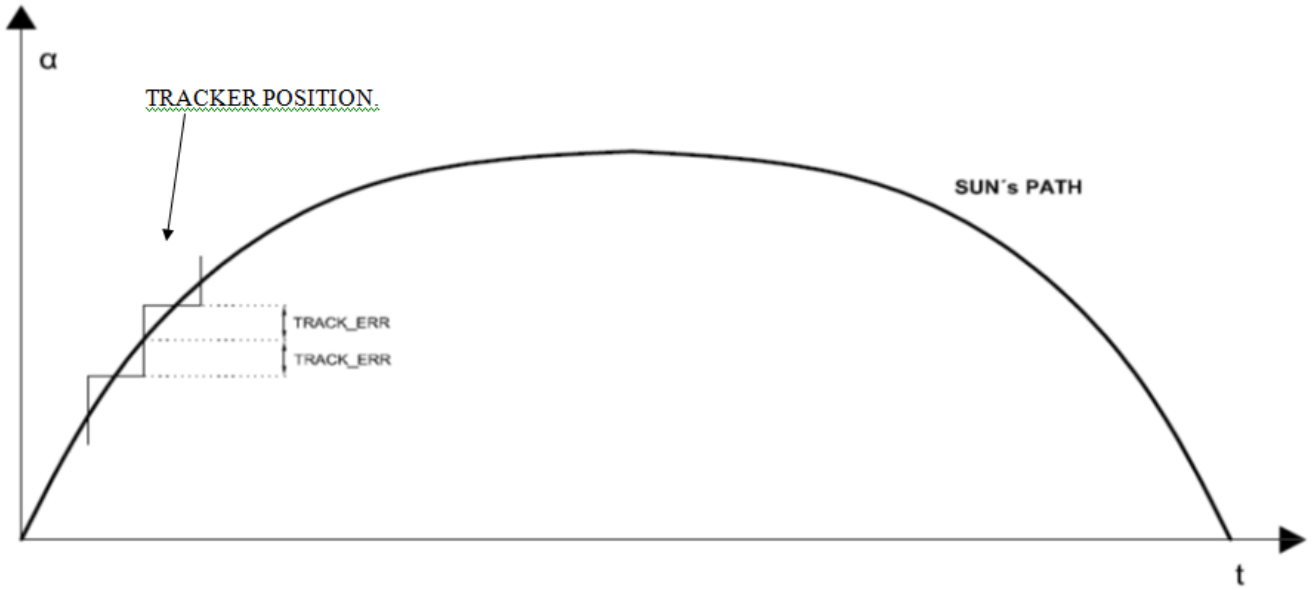
Available as of runtime system:	V1.3 and above
Included in library:	Solar_AC500_V22.lib
Type	Function block without historical values
Group	Package of function blocks for different control modes

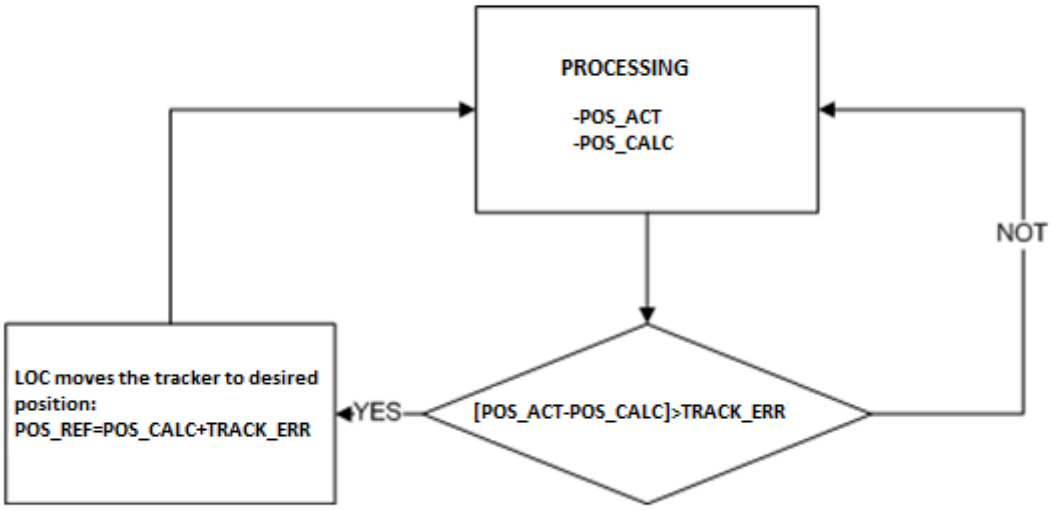
This function block represents an operation mode that allows to track the sun based on a calculated position of the sun. This position is given by an SOLAR_NOAA algorithm depending on date, latitude and longitude.

This function block calculates the absolute difference between the calculated position of the sun and the actual tracker position. If the result is greater than the value of track error (TRACK_ERR), system moves to the calculated position. Otherwise, system is stopped.

The figure below shows how this operation mode works.

Figure below shows the logical sequence that implements SOLAR_MODE_TRACKING:





It is possible to follow sun´s path with an offset. This value is indicated by the parameter FOLLOW_OFFSET.

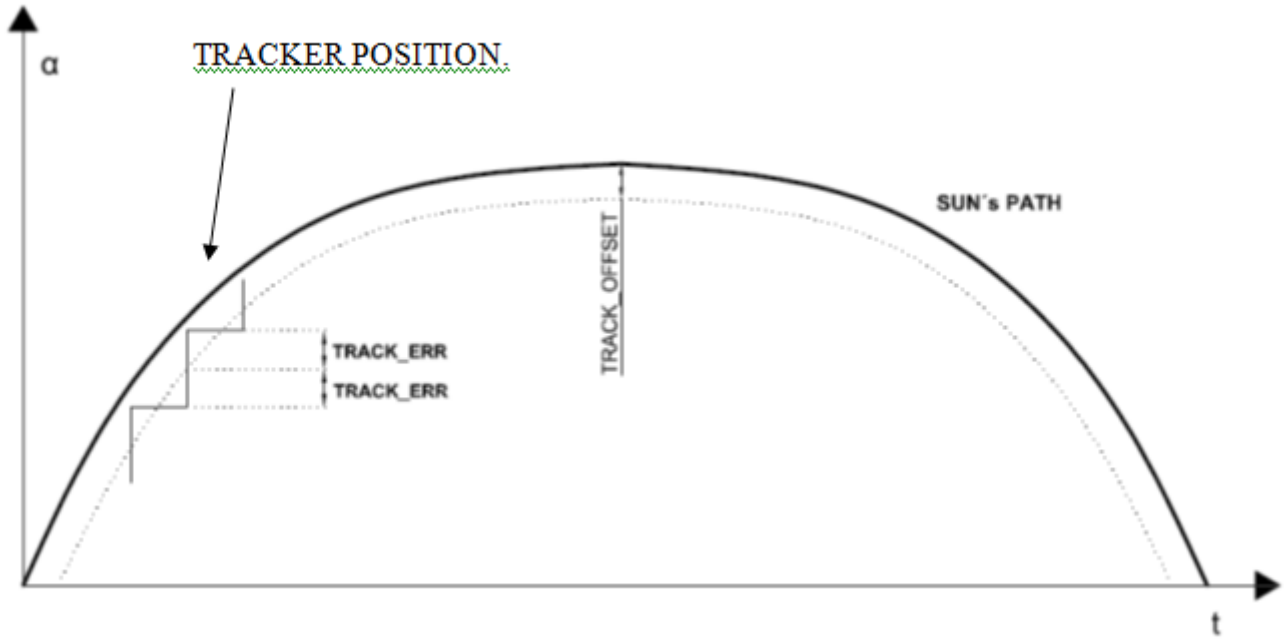


Figure below shows the logical sequence that implements SOLAR_MODE_TRACKING adding an offset value.

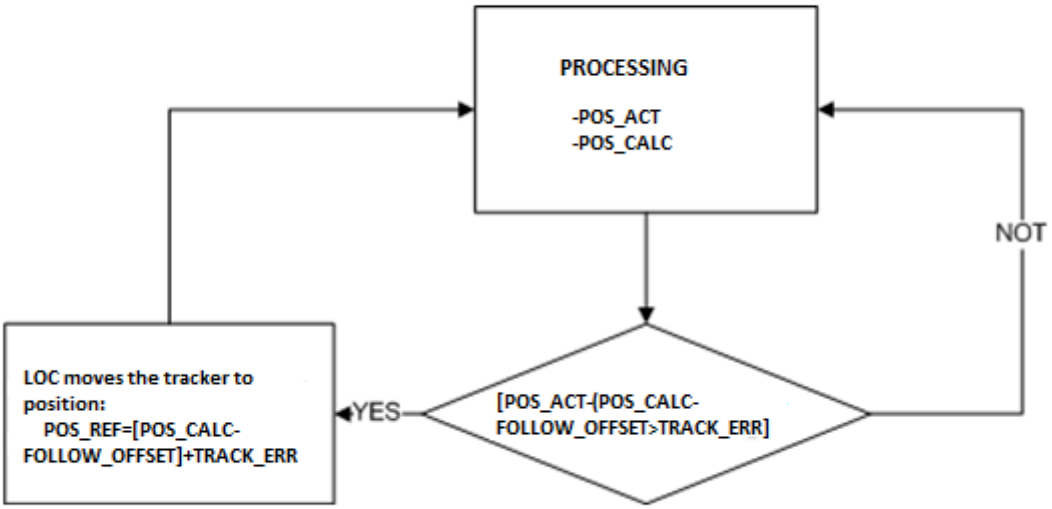
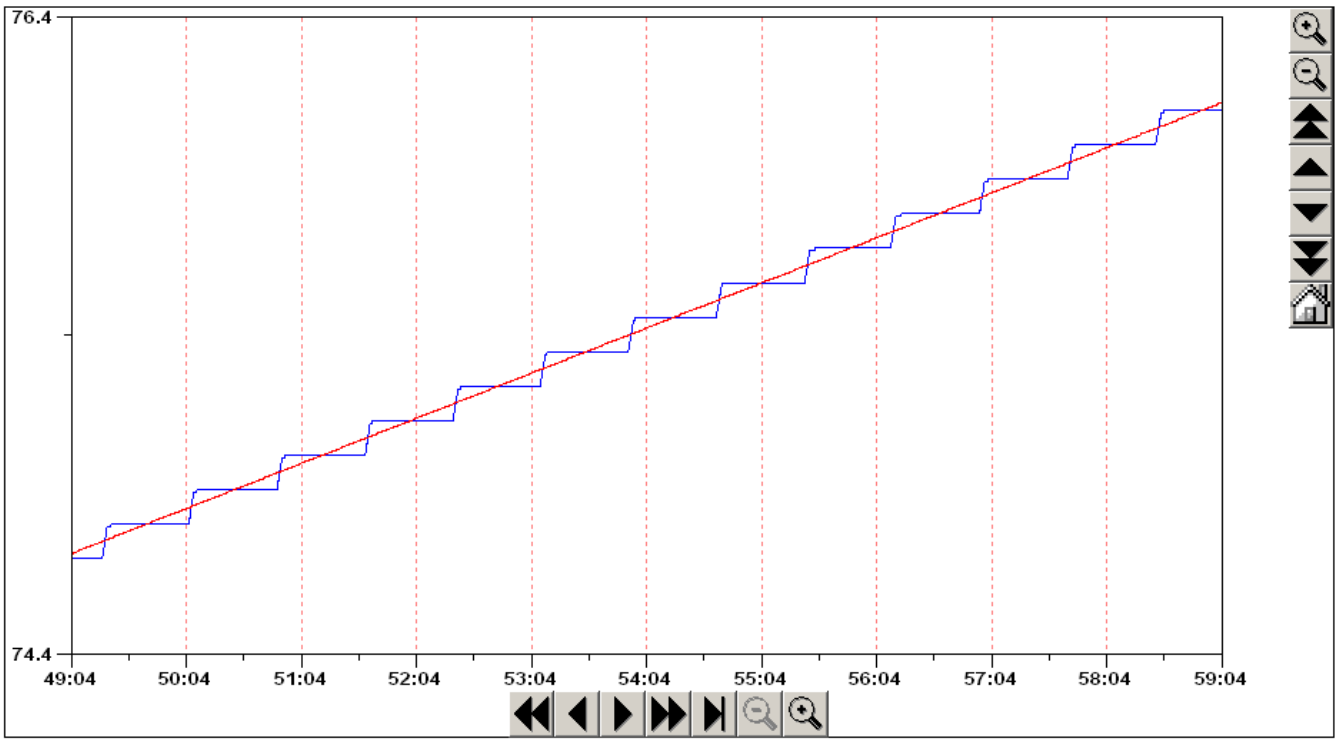


Tracker follows the sun by using a discontinuous movement. It is a step by step movement in order to save energy from actuators.

Chart below shows real behavior of azimuth tracker when is enabled SOLAR_MODE_TRACKING. In this case TRACK_ERROR = 0,05°.



Red line -> Calculated position using SOLAR_NOAA algorithm.

Blue line -> Actual axis position.

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

POS_CALC REAL (position_calculated)

Calculated position of the sun.

POS_ACT REAL (position actual)

Actual position of Solar Tracker.

TRACK_ERR REAL (track error)

Value of track error allowed.

FOLLOW_OFFSET REAL (follow offset)

Indicates that tracking has an offset concerning to real calculated position of the sun.

GO_TO_POS_REF BOOL (go to position reference)

Boolean expression that enables position control block.

POS_REF REAL (position_reference)

Desired position to locate the tracker.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

1.5.11.3 Solar_NREL library

1.5.11.3.1 Preconditions for the use of the Solar_NREL library

The blocks contained in the Solar_NREL library can only be executed in RUN mode of the PLC, but not in simulation mode. NREL stands for National Renewable Energy Laboratory and SPA stands for Solar Position Algorithm.

The function blocks of the library SolarNREL_AC500_V22.lib Version 0.4 are available in AC500 control systems with a runtime system of version V1.3 or higher and S500 I/O devices (DC551) with firmware version V1.11 or higher.

Because of the complexity of the algorithm, this library is recommended to be used with a PM583 at least.

NOTICE!

Notice about the algorithm

This computer software is code in development prepared by Midwest Research Institute, (hereinafter the "Contractor"), under Contract DE-AC-99G010337 (Contract) with the Department of Energy (DOE). The United States Government has been granted for itself and others acting on its behalf a paid-up, non-exclusive, irrevocable, worldwide license in the Software to reproduce, prepare derivative works, and perform publicly and display publicly. Beginning five (5) years after the date permission to assert copyright is obtained from the DOE, and subject to any subsequent five (5) year renewals, the United States Government is granted for itself and others acting on its behalf a paid-up, non-exclusive, irrevocable, worldwide license in the Software to reproduce, prepare derivative works, distribute copies to the public, perform publicly and display publicly, and to permit others to do so. If the Contractor ceases to make this computer software available, it may be obtained from DOE's Office of Scientific and Technical Information's Energy Science and Technology Software Center (ESTSC) at P.O. Box 1020, Oak Ridge, TN 37831-1020. THIS SOFTWARE IS PROVIDED BY THE CONTRACTOR "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE CONTRACTOR OR THE U.S. GOVERNMENT BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER, INCLUDING BUT NOT LIMITED TO CLAIMS ASSOCIATED WITH THE LOSS OF DATA OR PROFITS, WHICH MAY RESULT FROM AN ACTION IN CONTRACT, NEGLIGENCE OR OTHER TORTIOUS CLAIM THAT ARISES OUT OF OR IN CONNECTION WITH THE ACCESS, USE OR PERFORMANCE OF THIS SOFTWARE.

The Application Version of the library Solar_AC500_V22.lib is tested with the equipment and configuration used in the attached example programm "Example_Solar_2Axis_ACS3XX.pro".

This example uses a PM583 with a CD522 counter module.

ABB ACS355 drive is used with AC500 PLC via Modbus RTU communication.

This example also has option to connect DC541 or DC522 as encoder module.

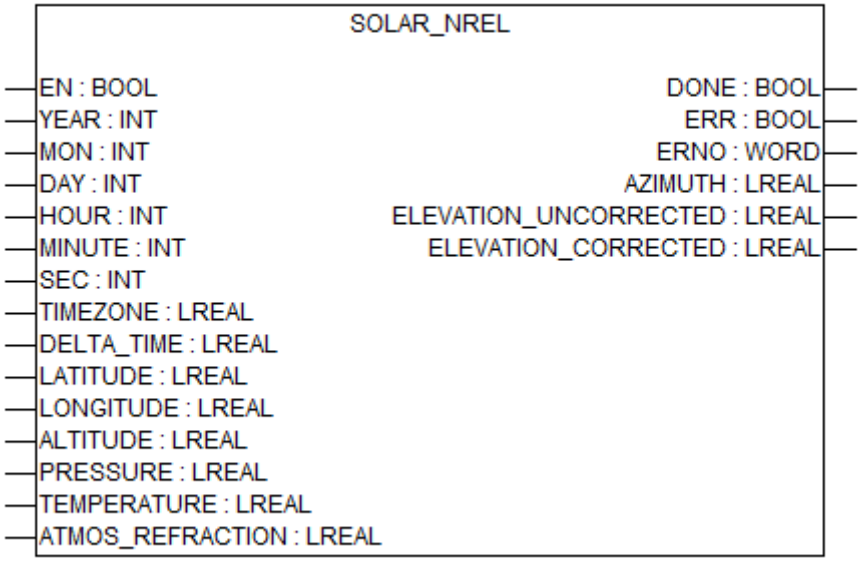
Any other combination with AC500 or drives equipment should work, but is not tested and might however not work properly.

1.5.11.3.2 Special characteristics of the Solar_NREL library

The Solar_NREL library contains all blocks necessary to calculate the position of the sun (azimuth and elevation) depending on the date, time and local environment.

A detailed description of the AC500 PLC configuration, can be found in the chapter *Chapter 1.6.5 “Configuration in Automation Builder for AC500 V2 products” on page 5757*.

1.5.11.3.3 SOLAR_NREL



Available as of runtime system:	V1.3 and above
Included in library:	SolarNREL_AC500_V22.lib
Type	Function block without historical values
Group	Package of function blocks to get the position of the sun

This function block calculates the position of the sun depending on the date, time, and localization. It also includes a function that corrects the value of the elevation thanks to the local pressure, temperature and refraction of atmosphere at sunrise and sunset. This function embeds the NREL's algorithm which can be found on the NERLs website: *http://rredc.nrel.gov/solar/codesandalgorithms/spa*.

The limitation of this function is the number of outputs which are the azimuth, elevation (uncorrected) and corrected elevation. These outputs are the topocentric coordinates of the sun which use the observer's location as the center of the coordinate system.

The end-user may use the RTC of the AC500 system by using the CLOCK function block of the library named SysExt_AC500_V10.lib or may use any other source to calculate the position of the sun.

Any additional information about the algorithm can be found on the NREL website: *http://www.nrel.gov/*

Table 197: Size of used data for NREL function block and execution time for each CPU type

	PM583	**PM591**	**PM564**
Data Size	4731 bytes	4731 bytes	4731 bytes
Program Size	79706 bytes	43270 bytes	80406 bytes
Execution Time	65 ms	1 ms	120 ms

In case of a PM58x and PM5X4 CPU´s, the program which calls this function block must be integrated in a dedicated task with a correct value of watchdog (or with watchdog disabled).

Input description

EN BOOL (enable block) In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The block is not processed if input EN = FALSE.

When calling the block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

YEAR INT (year) Range of values: from 2000 to 6000.

MON INT (month) Range of values: from 1 to 12.

DAY INT (day) Range of values: from 1 to 31.

HOUR INT (hour) Range of values: from 0 to 24.

MINUTE INT (minute) Range of values: from 0 to 59.

SEC INT (second) Range of values: from 0 to 59.

TIMEZONE LREAL (time-zone) Observer time zone (negative west of Greenwich) in hours and parts of hours.

Range of values: from -12 to 12.

DELTA_TIME LREAL (ΔT) ΔT = Terrestrial Time (TT) - Universal Time (UT) [seconds].

Difference between the earth rotation time and the terrestrial time. It is derived from observation only and it is reported in this bulletin, where _T = 32.184 + (TAI-UTC) + _UT1.

LATITUDE LREAL (lati-tude) Observer latitude (negative south of equator) in degrees.

Range of values: from -90 to 90.

LONGITUDE LREAL (longi-tude) Observer longitude (negative west of Greenwich) in degrees.

Range of values: from -180 to 180.

ALTITUDE LREAL (alti-tude) Observer elevation.

Range of values: -5000 to 5000

PRESSURE LREAL (pressure)
Local pressure in millibars.
Range of values: from 0 to 5000.

TEMPERATURE LREAL (temperature)
Local temperature in degrees Celsius.
Range of values: from -273 to 6000.

ATMOS_REFRACTION LREAL (atmosphere refraction)
Atmospheric refraction at sunrise and sunset in degrees.
Range of values: from -5 to 5. Typical: 0.5667

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

AZIMUTH LREAL (azimuth)
Topocentric azimuth angle (eastward from north) in degrees.
Range of values: from 0 to 360.
Error : ± 0,0004°.

ELEVATION_UNCORRECTED LREAL (elevation uncorrected)
Topocentric elevation angle (uncorrected) in degrees.
Range of values: from -90° to 90°.
Error : ± 0,0004°.

ELEVATION_CORRECTED LREAL (elevation corrected)
Topocentric elevation angle (corrected) in degrees. This value includes the effects of: refraction, pressure and temperature.
Range of values: from -90° to 90°.
Error : ± 0,0004°.

1.5.11.4 Examples

Example projects for the libraries can be found in the folder: \Users\Public\Documents\AutomationBuilder\Examples

1.5.12 Temperature control library

1.5.12.1 System technology

1.5.12.1.1 Introduction

The Temperature Control library package contains several parts and is overall designed for the demand of advanced temperature control for critical processes. It needs precise temperature control and e.g. adaptive tuning for ease of handling and changing environmental or process conditions.

The package consists of the following components:

- Libraries:
  - TECT_TEMP_CONTROL_AC500_V24 library
  - ADCTRL_AC500_V24 library (internal, automatically referenced and loaded)
  - TECT_EXT_AC500_V24 library (internal, automatically referenced and loaded)
- One example project, consisting of four examples (incl. one advanced CB610 Panel project)
- Documentation
- License code for starting the licensing procedure

Examples for use can be found in many different applications, where processing at controlled temperature levels has to be done, e.g. in extrusion and plastics but also in food & beverage or chemical applications. Especially demanding are extrusion applications, where you can find many temperature zones (up to 50) in different parts of the machinery and the overall process. For those system there will also be requirement of handling several zones in a group and several groups in a system in a structured way.

These processes require typically precise temperature control and therefore require PID instead of simple 2- or 3-point control. For example, plastics processing and especially extrusion requires the temperature to be controlled within +/- 0.5 degrees Celsius. High temp deviation can deteriorate the product quality. As PID settings need to be different, depending on the temperature zone's position along the process, e.g. the extruder screw, the adaptive option helps greatly.

Lots of machines are still using costly and difficult to setup dedicated and decentralized temperature controllers, i.e. separate controller for each zone. Due to this approach, it is not possible centrally monitoring, controlling and using data acquisition or alarm handling in a simple way. Often even the PID settings of the temperature zones need to be changed, based on the currently produced product. The decentralized system takes a much long time to make these settings and needs more attendance and skilled persons during the production.

Main purpose of TECT_TEMP_CONTROL_AC500_V24 library

TECT_TEMP_CONTROL_AC500_V24 Library gives centralized control of all the temperature zones using AC500 PLC.

TECT_TEMP_CONTROL_AC500_V24 is the main library, which provides the centralized control and auxiliary functions for all the temp zones. It also provides the AutoTune functionality for the individual zones and includes differentiation for the often different heating and cooling behavior. The blocks of this library internally call blocks of two other internal libraries (added automatically).

As this library provides centralized control, also Log and recipe functions are implemented for better user interaction and data collection. Process data can be logged on SD cardin “csv” format, which can process further for better understanding and monitoring of the system. The RECIPE function helps to store/select parameters setting for the different products.

This library also provides the option of a simplified interface to HMI´s for the CP600 Panels, which allows in a structured, modular and simple way the configuration and monitoring of all temperature zones.

1.5.12.1.2 Requirements

Hardware

The TECT_TEMP_CONTROL_AC500_V24 library is meant to run on AC500 CPUs and CPU firmware 2.4 or higher.

The number of temperature zones and auxiliary blocks, which can be used, is limited of course by memory available for program and data. Therefore on the smaller AC500 eCo typically only 3 temperature zones are possible.

Further needed are an memory card for the logging, a battery for buffering and a CP635 Panel if the panel project should be used.

Software

For TECT_TEMP_CONTROL_AC500_V24 library Automation Builder 1.2 or higher is required for programming purposes.

1.5.12.1.3 Control principle

State machine

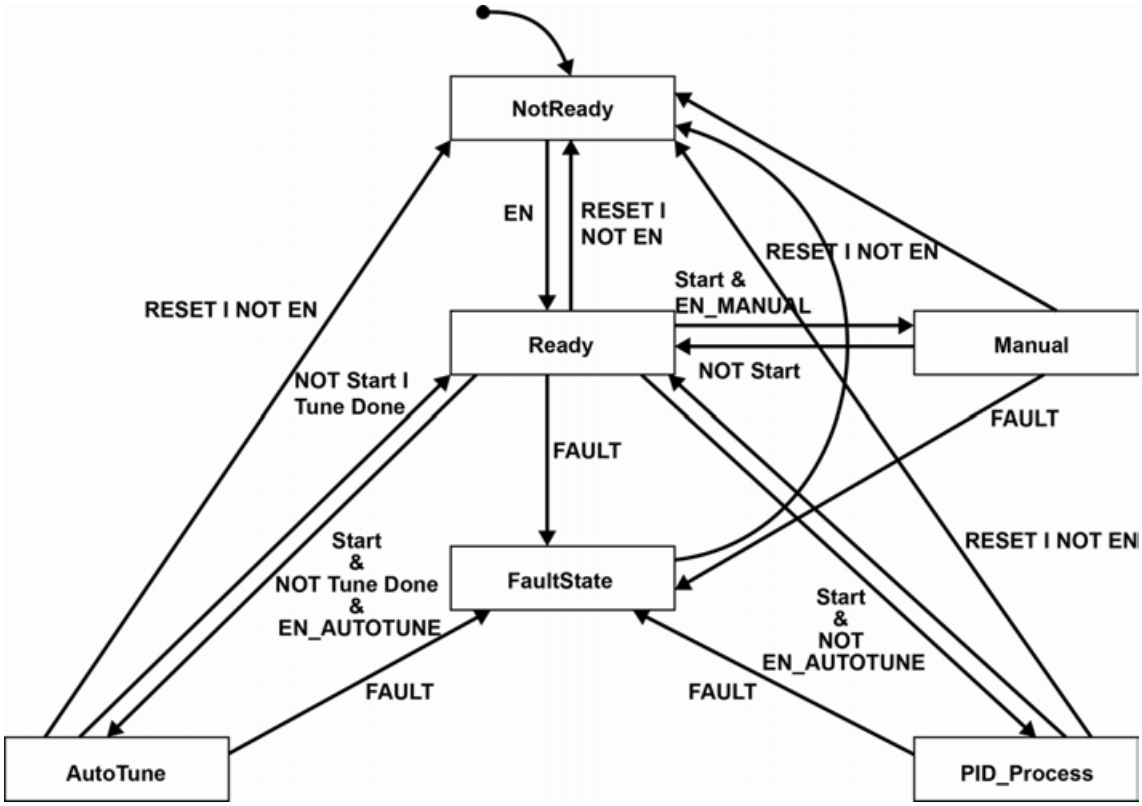

Fig. 579: Control Principle of State Machine

The PS564 Temperature Control library uses a state machine to accomplish all work, including:

- Automatic PID control (state PID_Process): Normal operation (see Automatic PID Control ↳ *Chapter 1.5.12.1.3.2 “Automatic PID control” on page 3270*)
- Auto tuning procedure (state AutoTune): Can be used during the commissioning phase to calculate the optimized parameters for PID controller. (see Auto Tuning ↳ *Chapter 1.5.12.1.3.3 “Auto tuning” on page 3271*)
- Manual Control (state Manual): Open loop control with directly change of duty cycle
- Alarm handling

Automatic PID control

PID controller principle

A proportional-integral-derivative controller (PID controller) is a closed-loop control method, widely used in industrial control systems. A PID controller manipulates a control variable to minimize the error between process actual value and a desired process set point.

The PID controller algorithm involves three parameters: The proportional, the integral and derivative values, abbreviated as P, I, and D.

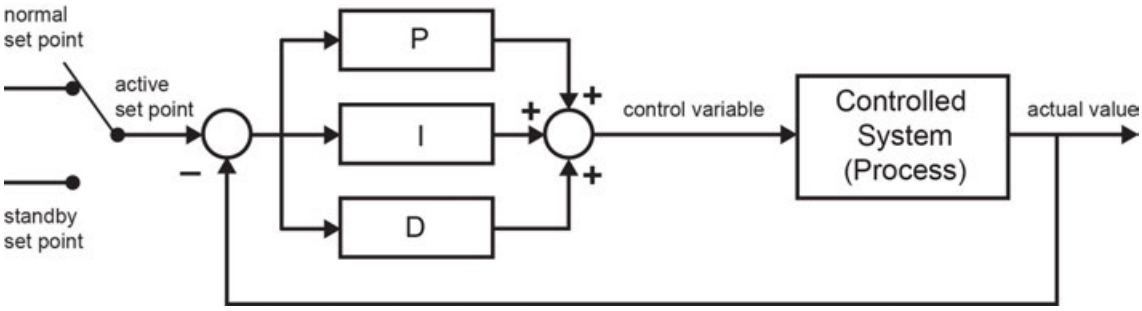

Fig. 580: PID Controller Principle

In the PS564 temperature control library, a PID controller with the first order delay T1 is used to prevent spike of derivative part D.

In the world of temperature control, set point is the desired temperature of the process, actual value is the actual temperature, and control variable is the PWM signal for controlling the heater and cooler.

In the PS564 Temperature Control library, the PWM signal is presented in means of digital value (binary outputs) as well as analogous value (duty cycle).

Set point selection

In the PS564 Temperature Control library are 3 set points available:

- Normal set point: For normal operation.
- Standby set point: For standby operation with a lower temperature to save energy, e.g. during lunch time.
- Tune set point: For auto tuning.

The first two set points use the same PID controller and the same parameters (see figure "Control Principle of State Machine"Fig. 579). The tune set point skip the PID controller and is used during an auto tuning procedure (see Auto Tuning ↳ *Chapter 1.5.12.1.3.3 “Auto tuning” on page 3271*).

Auto tuning

A controller with adaptive functionality helps the user to find out the optimized controller parameters of an unknown system using auto tuning procedure. This simplifies the machine commissioning and thus the user saves time and cost to reach an optimized result.

Function principle

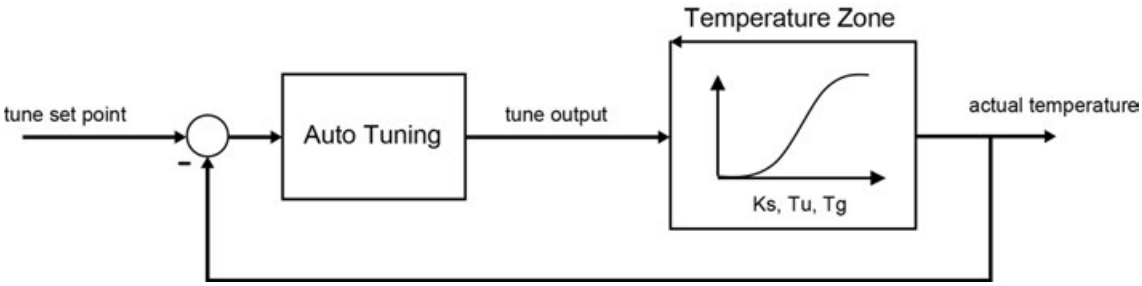

Fig. 581: Function principle of Auto Tuning

The auto tuning process serves to determine optimized controller parameters for the PID controller. The auto tuning identifies the parameters of one temperature zone (controlled system) and calculates the optimized controller parameters for that zone. The dynamic behavior of these thermal processes can be approximately acquired by means of the following characteristic quantities, which can be defined on the basis of the transfer function:

- Tu: Delay time
- Tg: Stabilization time
- Ks: Transfer factor (controlled system gain)

At the end of the auto tuning process, the actual progression of the transfer function is replaced by the linear-progressing reversing tangent placed at its turning point.

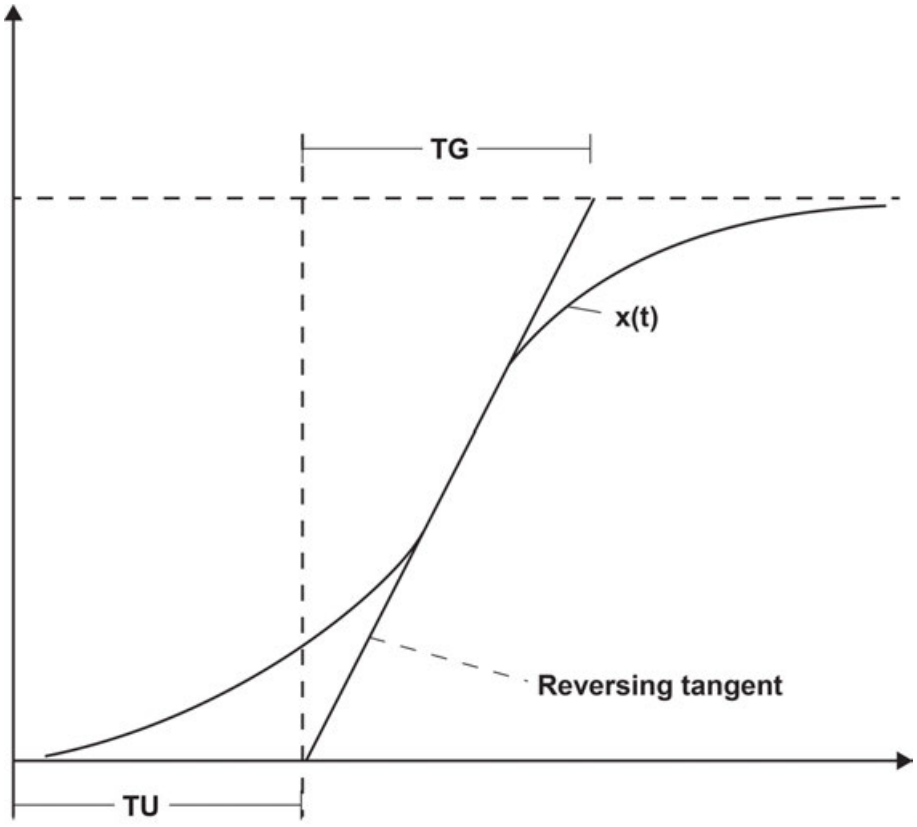

Fig. 582: Function principle of Auto Tuning

The figure above represents the transfer function, the reversing tangent and the resulting characteristic quantities for a temperature control process. As long as Tu, Tg, Ks are acquired, PID controller parameters like KP, TI, TD and T1 will be calculated.

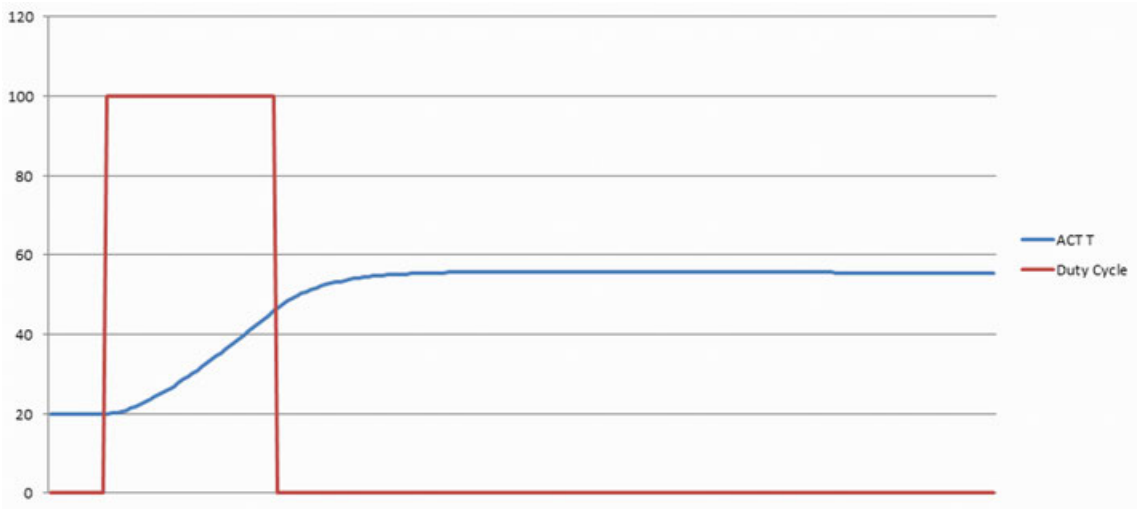
Auto tuning is only allowed when the actual temperature has reached its steady state. The auto tuning can be executed both during process start-up (initial settings) and when the value of the desired set point changes. This allows auto tuning of the control parameters in case of a process which must be operated at different set points and where the initially fixed control parameters may lead to undesired control response due to set point change. In both cases, the relative change should be as large as possible to ensure a precise measurement during the auto tuning, thus a good result of PID parameters.

Continuous auto retuning of the controller parameters is not built in.

Auto tuning for heating and cooling

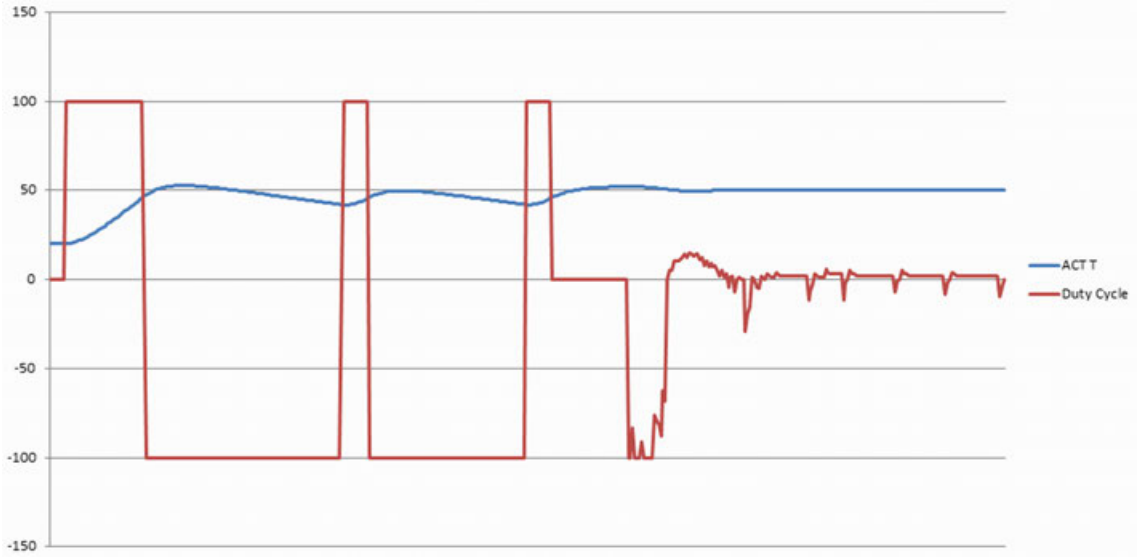
There are two possibilities for heating and cooling during auto tuning process:

Only heating



- System will be heated up with predefined Tune Output (100% duty cycle as default) until the tune set point is reached.
- Control parameters KP, TI, TD, T1 will be calculated using the temperature change (ACT T curve) during the auto tune.
- User can decide, if he would accept the auto tune result or not.
- After that he can change the KP, TI, TD, T1 parameters manually for fine tuning.

Heating and cooling



- System will be heated up with predefined Tune Output (100% duty cycle as default) until the tune set point is reached.
- Then the system will be cooled down with predefined Tune Output (-100% duty cycle as default) until the internal defined threshold is reached.
- Control parameters KP, TI, TD, T1 will be calculated for heat and a cool factor related to heat will be calculated for cool.
- The user can decide if he would accept the auto tune result or not.
- After that he can change the KP, TI, TD, T1 parameters and cool factor manually for fine tuning.

Alarm handling

In the PS564 library are two categories of alarm:

- Fault: leads to stop of the process
- Warning: process continues with warning indication

Fault is triggered if something serious happens, which must stop the process, otherwise the machine as well as the production material can be damaged.

In practice, the user can use the individual alarm bit to do some control or give some indication out of PLC, e.g. switching off a contactor or switch on an alarm light.

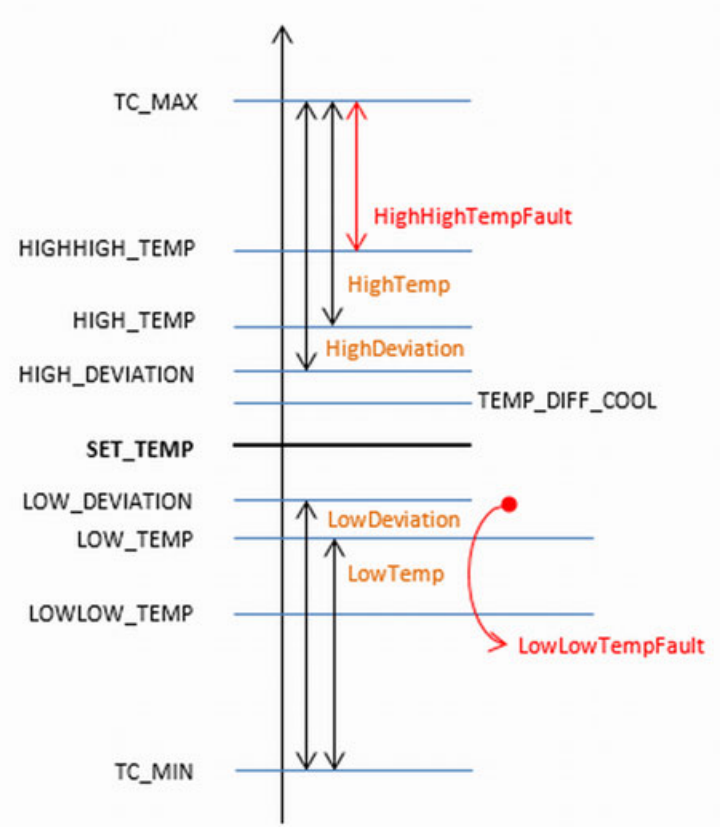
Faults

The following faults are specified:

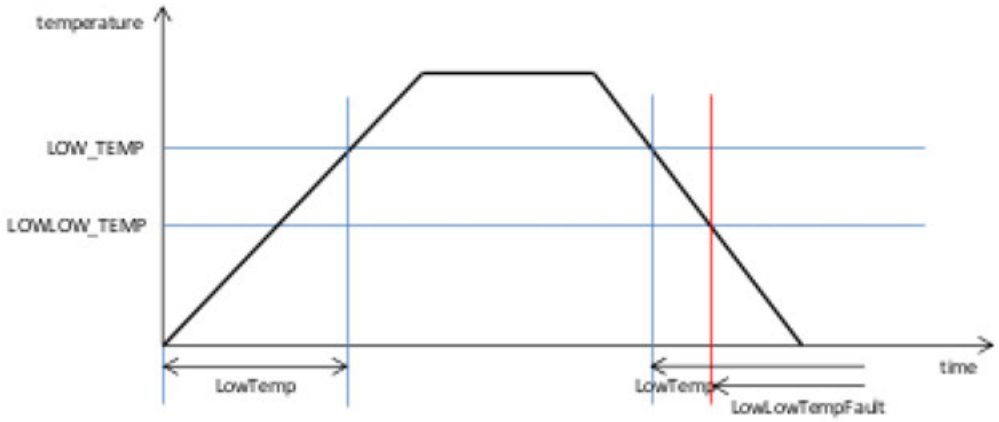
- Tune Fault
  This happens, when there is something wrong during the tune process, e.g. the temperature change is too small to calculate reasonable PID parameters.
- Thermal Coupler Fault 1
  Plausibility check of the temperature value, if it is inside the plausible range for case like wire cut.
- Thermal Coupler Fault 2
  Plausibility check of the temperature change to avoid e.g. inverted connection of two sensors.
- HighHigh Temperature Fault
  Check, if the actual temperature reaches the allowed up limit of the process.
- LowLow Temperature Fault
  Check, if the actual temperature reaches the allowed down limit of the process.

Temperature limits

There are different temperature limits for the process. They will trigger fault (red in following figures) or warning (orange in following figures) depending on the severity.

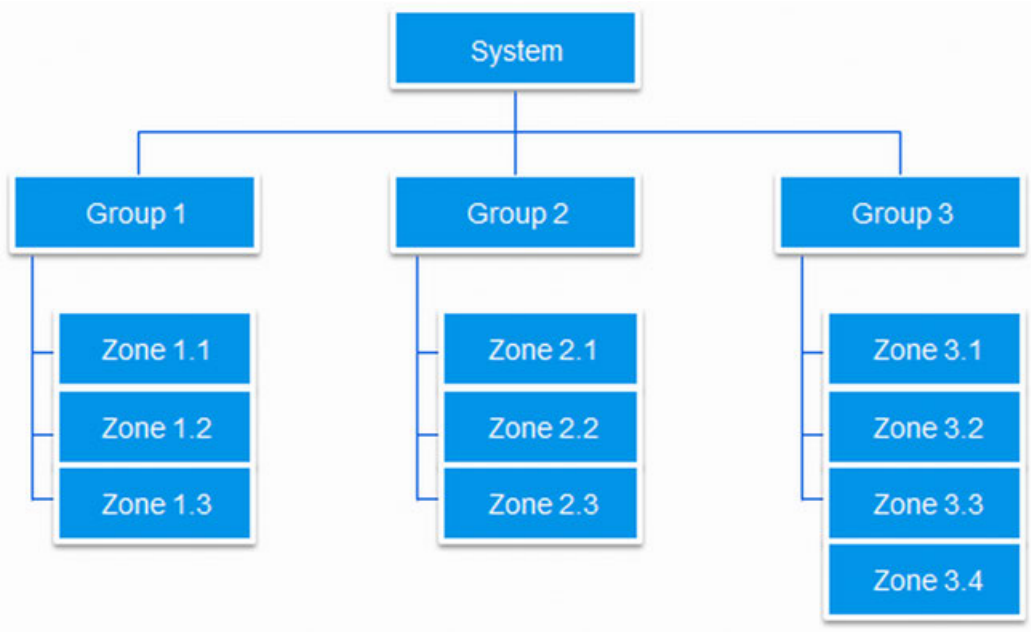


LOWLOW_TEMP check will only be active after the actual temperature has already exceeded the LOW_TEMP limit.



1.5.12.1.4 Zone management

Overview



Beside the Temperature Control process, a concept of 3-level zone management is offered by the PS564 library.

In this concept, a Temperature Control system consists of up to 255 groups, and each group consists of up to 255 zones.

The system refers to the whole machine. On the system level, it offers convenient monitoring as well as operating.

The groups are also the physical groups of the process which are normally close to each other. On the group level, several major functions are realised:

- Convenient monitoring as well as operating at group level.
- A group-wise programming of the control process (using function block TECT_GROUP) instead of programming the control process for each zone separately.
- Fault monitoring at group level.
- Coordinated output at group level.

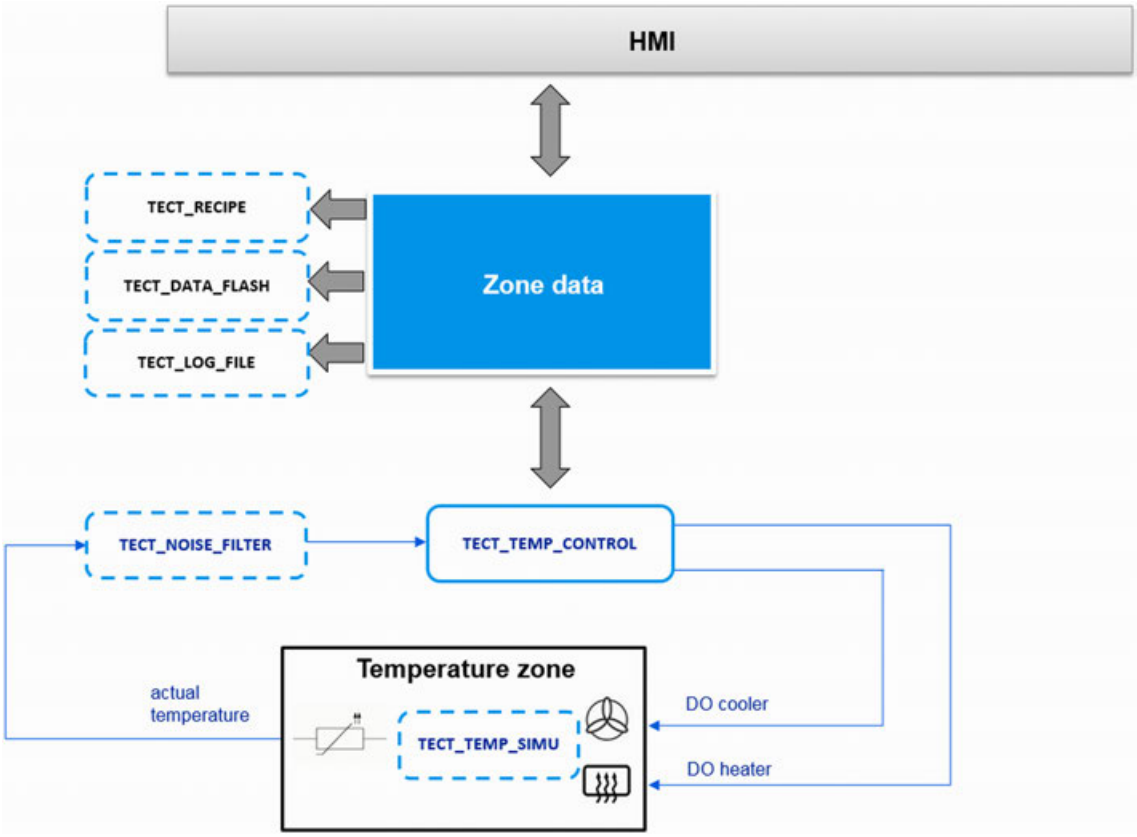
It is not mandatory to apply the zone management concept for the control process. Instead, the user can apply it with full flexiblilty: He can apply 3 levels (system-group-zone) for a large system, or 2 levels (group-zone) for a middle size system, or even 1 level (only zone) for a small machine. However the more zones a system contains, the bigger the benefit of the zone management concept will be experienced by the user.

One zone

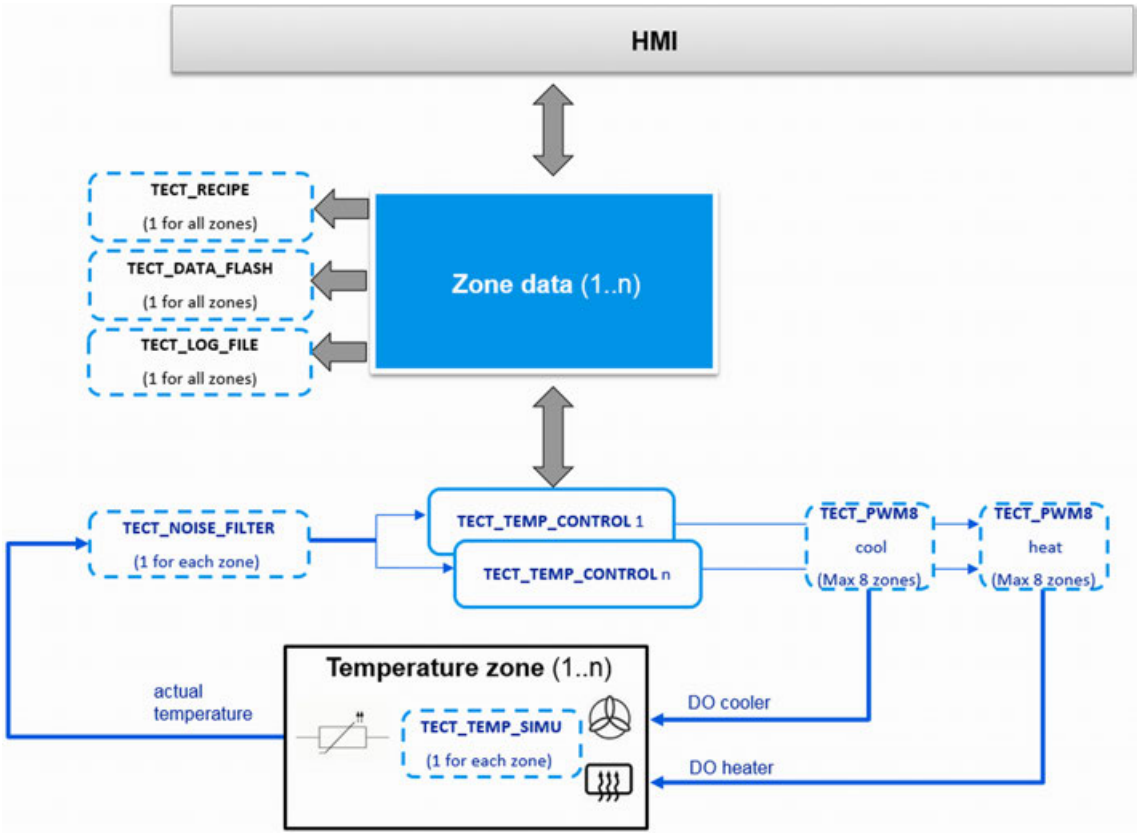
The TECT_TEMP_CONTROL is the kernel control function block, which does the control process. The input is the actual temperature feedback from the analogous sensor mounted inside the temperature zone. The outputs of the control is a PWM signal, which controls the process. It can be binary outputs, which switch the heater and cooler directly or analogous signal in duty cycle (%).

The zone data structure contains all set and status values, which are relevant for the process. The set values can be written from the user, whereas the status values can only be read, e.g. using a CP600 HMI operating panel. It is also the common interface for most of other function blocks in PS564 library.

The function block TECT_TEMP_SIMU can be used as one zone simulation instead of a real zone for test purpose.

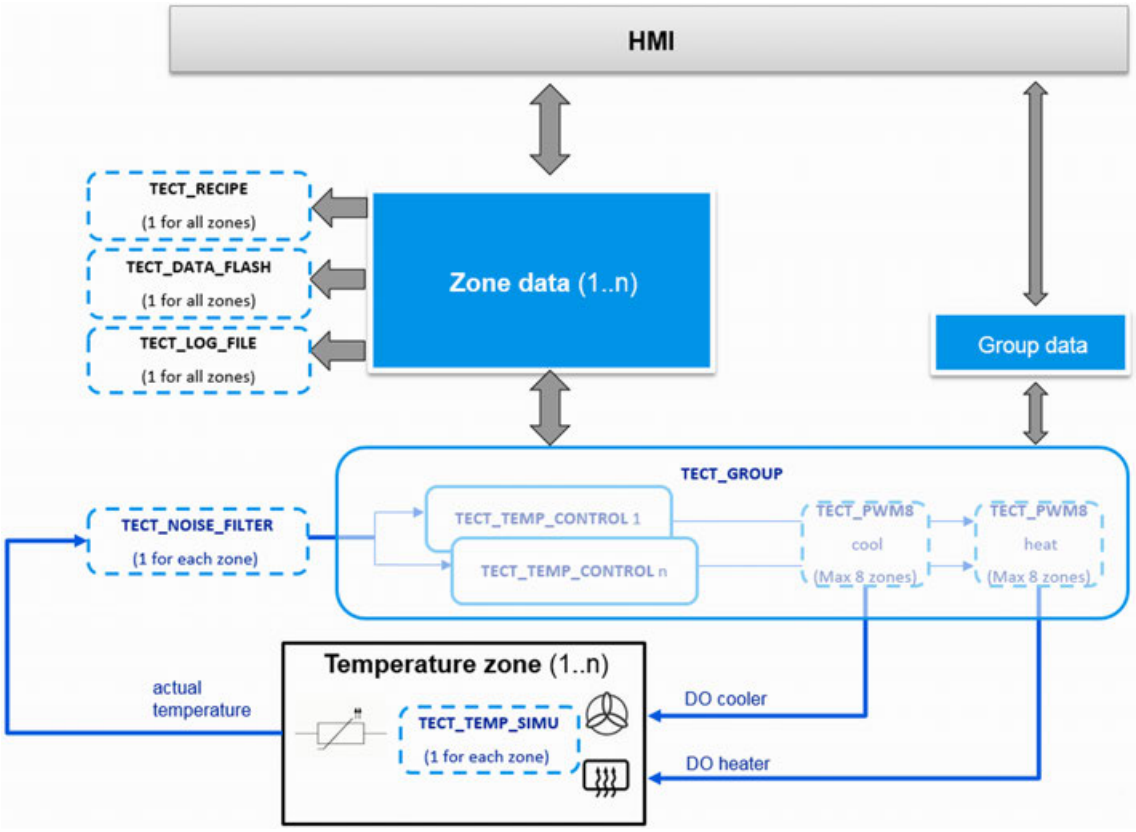


Multiple zones



For a multiple zones system, it just needs to duplicate the engineering of a one zone system. However, it is possible to use the TECT_PWM8 to coordinate the outputs.

One group



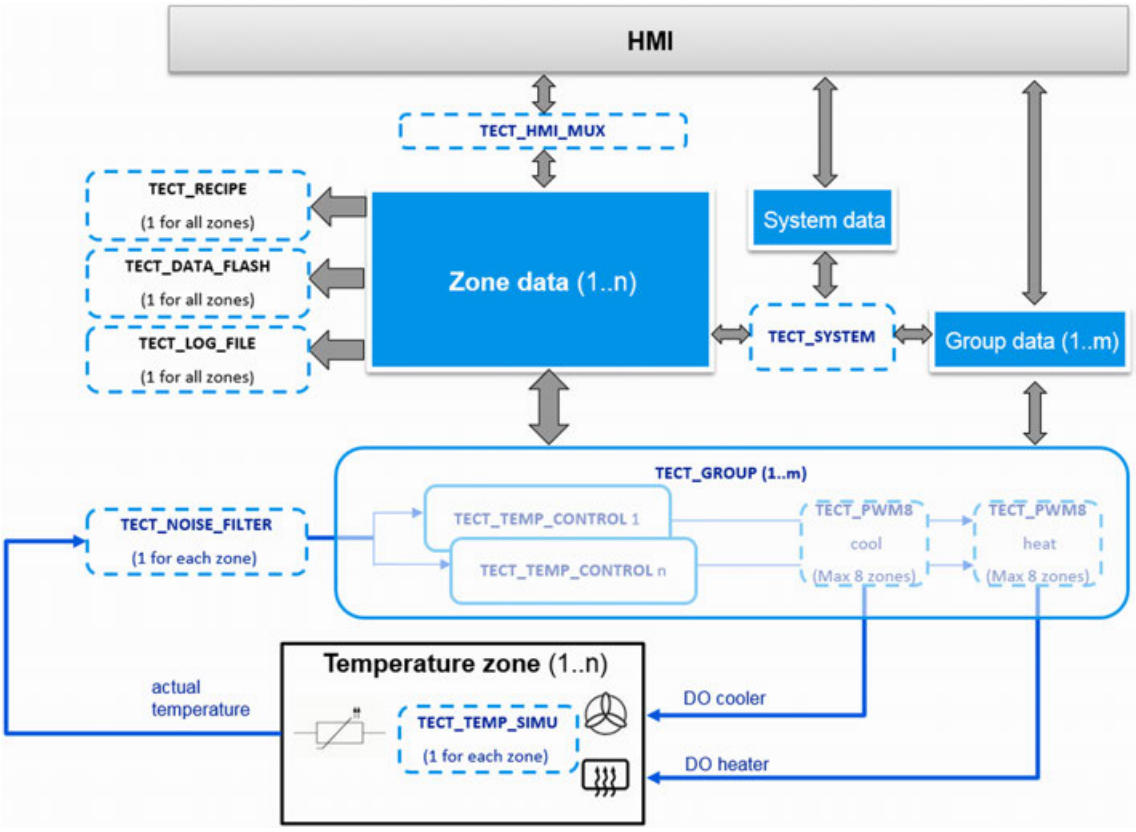
With TECT_GROUP the control function block TECT_TEMP_CONTROL is called internally multiple times for each zone.

A group data structure is needed, which contains the status of its zones as well as the control commands for the whole group, e.g. enable/disable process, enable/disable auto tune etc.

A zone data structure is always necessary to be defined for each zone.

It is possible to activate the TECT_PWM8 in TECT_GROUP internally to coordinate the outputs ↳ *Chapter 1.5.12.2.2 “TECT_GROUP” on page 3316*.

Multiple groups within a system



For a multiple groups system, it just needs to duplicate the engineering of a one group system. However, it is necessary to call TECT_SYSTEM function block and define a system data structure, which contains the status of its groups as well as the control commands for the whole system, e.g. enable/disable process, enable/disable auto tune etc.

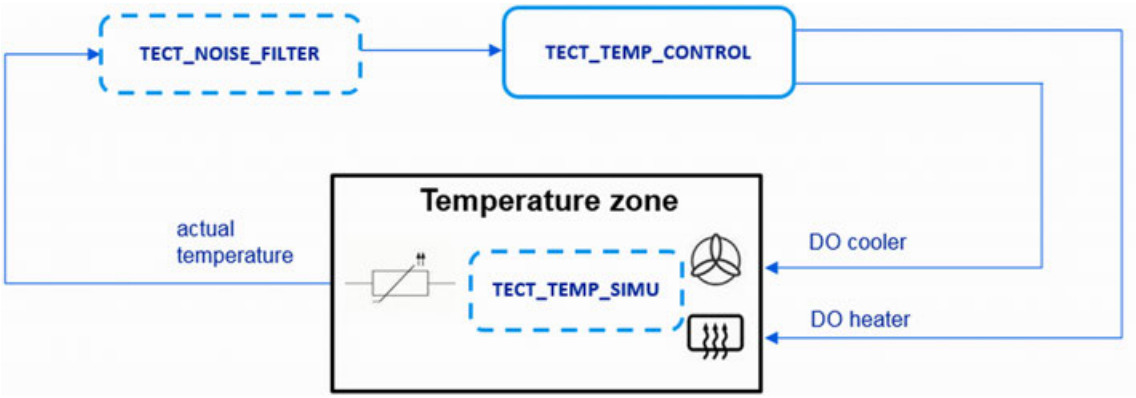
In this configuration, a TECT_HMI_MUX function block can be used as the direct communication interface to a HMI. It has the multiplexer principle and passes only one group of zone data from AC500 PLC to HMI to reduce the communication load. The usage of TECT_HMI_MUX will only make sense if more than 2 groups are defined.

1.5.12.1.5 How to realize in a program

This chapter tries to help the user to understand and combine the function blocks to realize his application. This chapter explains the principle of how to use the function blocks. The diagrams used in this chapter only demonstrate the principle instead of showing programming in the program editor. For detailed explanation of each function block please refer to another document Function Blocks Description. For how to program the application please refer to the example document.

Interface for sensors and actuators

The temperature control with PS564 is a closed loop control, as shown in the figure, the control function block TECT_TEMP_CONTROL sets the outputs as PWM signals for heater and cooler for the temperature zone. The actual temperature is connected to the input of TECT_TEMP_CONTROL as feedback.



Use a real zone

For a real zone, there are two methods for output:

- digital outputs
  Two digital outputs are available, one for heater and another for cooler. They can be connected to AC500 digital modules which has transistor outputs.
- analogous output
  o Duty Cycle as analogous output. It can be connected to AC500 analogous modules which has analogous outputs.

As feedback, a temperature sensor, e.g. thermocouple or resistance temperature detectors (RTDs), will be used. It can be connected to AC500 analog modules which supporting temperature sensor input.

Use zone simulation function block

The PS564 library has a simulation function block which can be used to simulate a temperature zone.

Consider zone management

The zone management is a feature which not only helps the user to manage his system but also give some add on functionality. But from another side, the zone management functionality as well as any further functionality will need more resource in PLC.

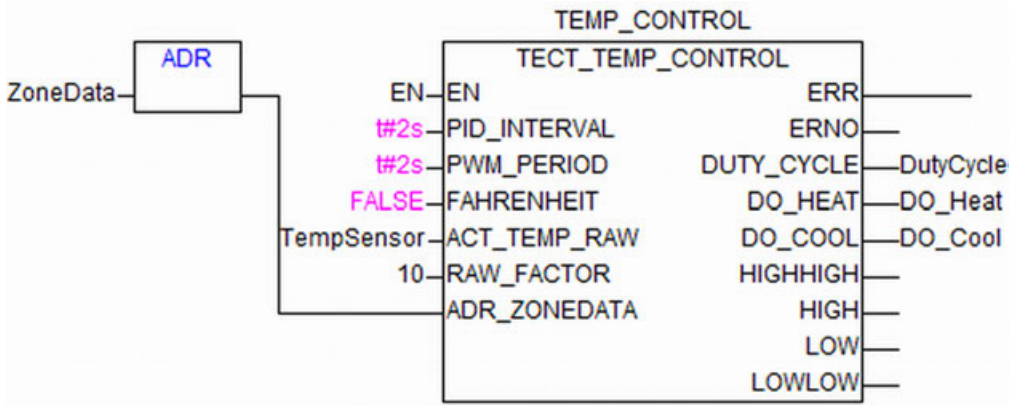
There are several criteria to decide how many levels the user should apply as zone management:

- Total number of zones
- Complexity of the machine
- The PLC type used (due to resources available in PLC)

Zone level programming

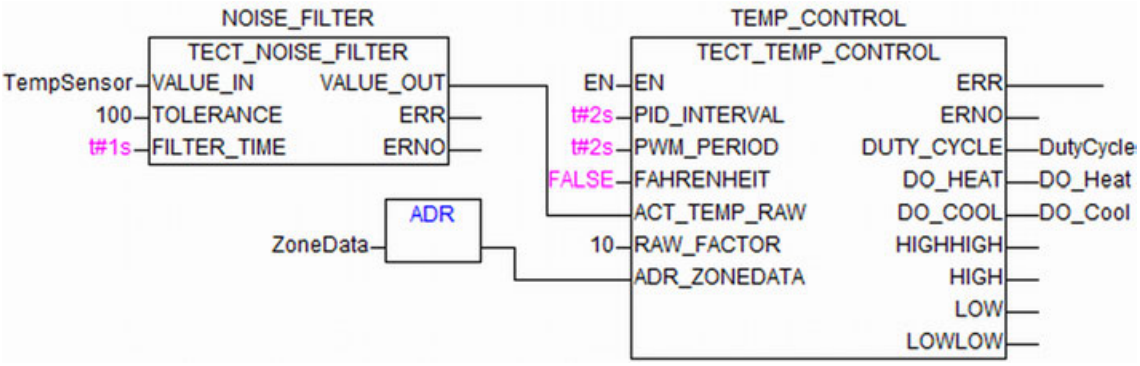
If the system has up to 5 zones, or if PLC type PM554 or PM564 is used, then only one level is recommended.

For zone level programming, the function block TECT_TEMP_CONTROL is used for each zone in the programming. The Zone Data which contains the important information of a zone needs to be connected to the function block.



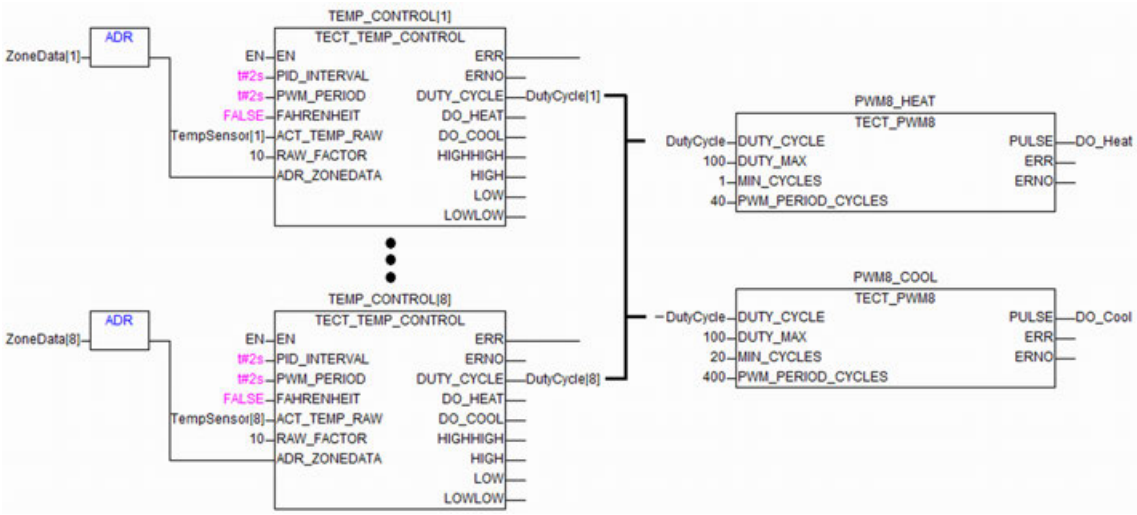
For each zone, the digital outputs DO_HEAT and DO_COOL as well as the analogous output DUTY_CYCLE can be used to connect to the output module. The temperature sensor feedback is connected to function block input ACT_TEMP_RAW.

For each zone, it is possible to add a noise filter to prevent short disturbances.



For multiple zones, it is just a multiplication of the one zone application.

Another function block TECT_PWM8 can be connected up to 8 TECT_TEMP_CONTROL function blocks to coordinate the outputs in time behavior. They have not to be switched on at the same time to avoid undesired voltage drop in the power supply system. At the same time, it compensates the error between digital outputs and duty cycle due to CPU task cycle (as resolution of digital outputs duration). For heating and cooling separate instances of this block have to be used.

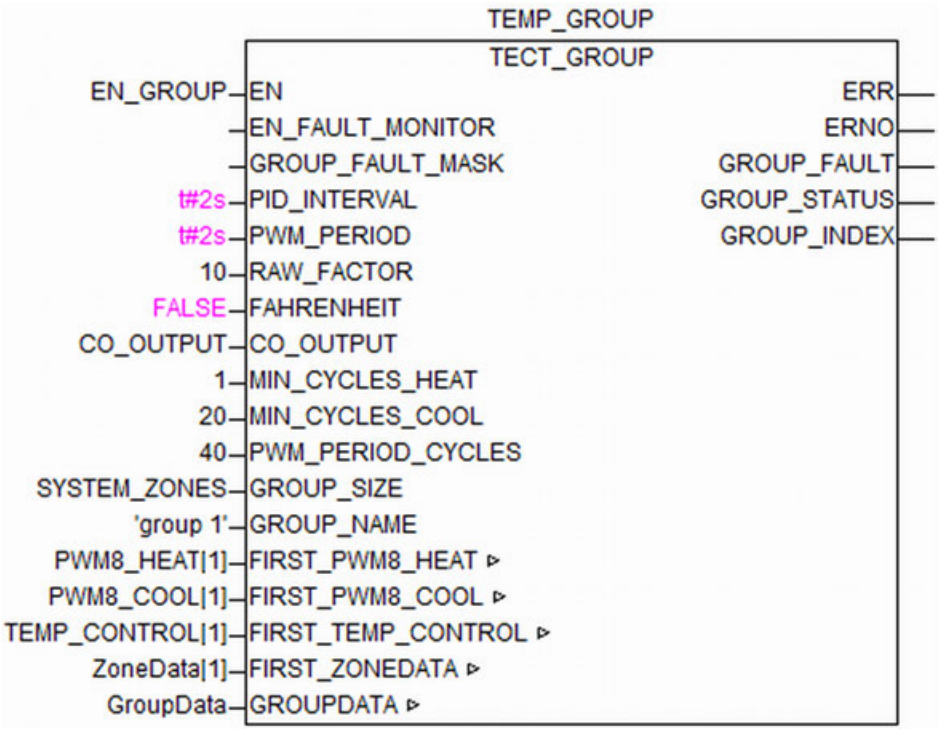


Group level programming

With group level, it will be possible to control as well as monitor the zones on group level.

Using the group level programming, one instance of function block TECT_GROUP is called in the program code instead of multiple calls of multiple zones in that group.

The first Zone Data and the Group Data structures need to be connected to the TECT_GROUP function block. Beside those, an array of TECT_TEMP_CONTROL for all zones in the group is to be declared and connected to the function block. Thus the TECT_TEMP_CONTROL function blocks will be called internally in the TECT_GROUP.



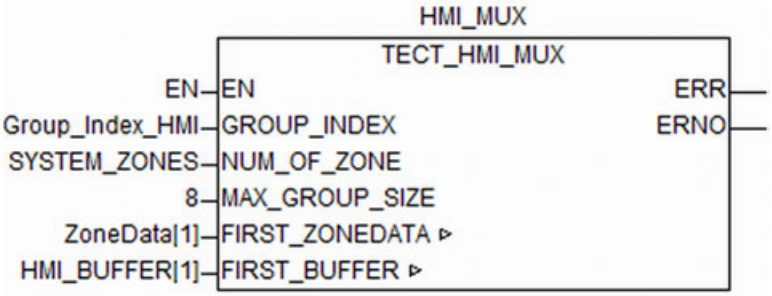
With TECT_GROUP, TECT_PWM8 function block is called internally:

- The instance for heating and cooling needs to be defined. Each instance supports 8 zones. For more than 8 zones, an array of TECT_PWM8 needs to be declared.
- This function can be enabled or disabled with input CO_OUTPUT. If it is disabled, then a dummy instance of TECT_PWM for each FIRST_PWM8_HEAT and FIRST_PWM8_COOL should be connected.
- The parameters for TECT_PWM8 are to be defined by inputs. For heating instance, MIN_CYCLES_HEAT, PWM_PERIOD_CYCLES are used. For cooling instance, MIN_CYCLES_COOL and PWM_PERIOD_CYCLES x rPeriod_Fact (in Machine Set of Zone Data structure) as PWM period.

Besides that, the user can enable the group fault monitor with input EN_FAULT_MONITOR with defined GROUP_FAULT_MASK. This function will set all zones in the group to fault state as soon as one zone in the group has fault (according to GROUP_FAULT_MASK).

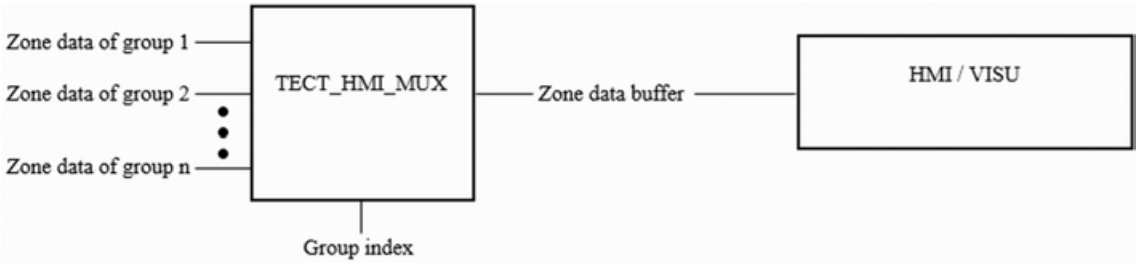
For multiple groups, it is just a multiplication of the one group application.

Another function block TECT_HMI_MUX can be used for multiple groups to reduce communication data as well as reduced engineering effort for Panel project.



It works as a multiplexer, group index decides the zone data of which group will be active for user, so that it can be read to buffer as well as be written from buffer.

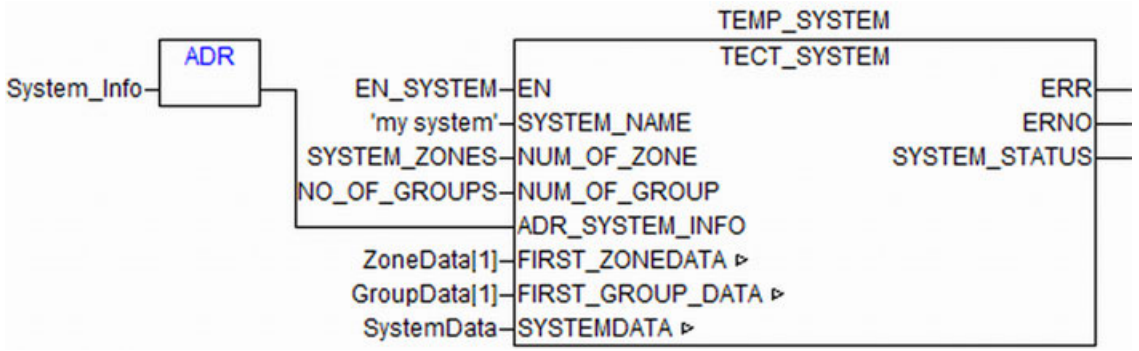
In this way, the communication data between AC500 and HMI can be reduced from n group to one group. At the same time the HMI project can also be programmed for one group instead of n groups.



System level programming

With system level, it will be possible to control as well as monitor all the zones on system level. This makes it convenient by a system with a lot of zones.

When using system level programming, the group function block TECT_GROUP will still be applied as in group level programming. Also the TECT_HMI_MUX can be used. Thus the functionalities on group level are still available.



The ADR_SYSTEM_INFO points to the ZONE_INFO which contains the actual temperature and error word. They will be used directly in the HMI for alarm handling and trends because they should be delivered to HMI without interruption by TECT_HMI_MUX.

Data and settings

Data structure

Depending on which level of zone management is applied, zone data, group data or system data will be used for saving the status and settings of control.

Zone Data structure is essential structure which contain all information for a zone. It is highly recommended to save zone data as retain variable for power safe. It has five sub structures:

- Internal status: status which is used internally in the function block, e.g. control state, group and zone index
- Machine status: machine specific status, e.g. PID parameters calculated from AutoTune.
- Process status: process specific status, e.g. actual temperature, status word, error word, duty cycle.
- Machine set values: machine specific set values, e.g. PID parameters, HighHigh and LowLow temperature limits
- Process set values: process specific values, e.g. control word, set point, High and Low limits.
- All status can only be read whereas all set values can be read and written by the user.

For group level, there is group data which contains the status of the group (e.g. control state of the whole group) and the control value of the group (e.g. enable / disable process of the zones in the group).

For system level, there is system data which contains the status of the system (e.g. control state of the whole system) and the control value of the system (e.g. enable / disable process of the zones in the system).

Initial zone data settings

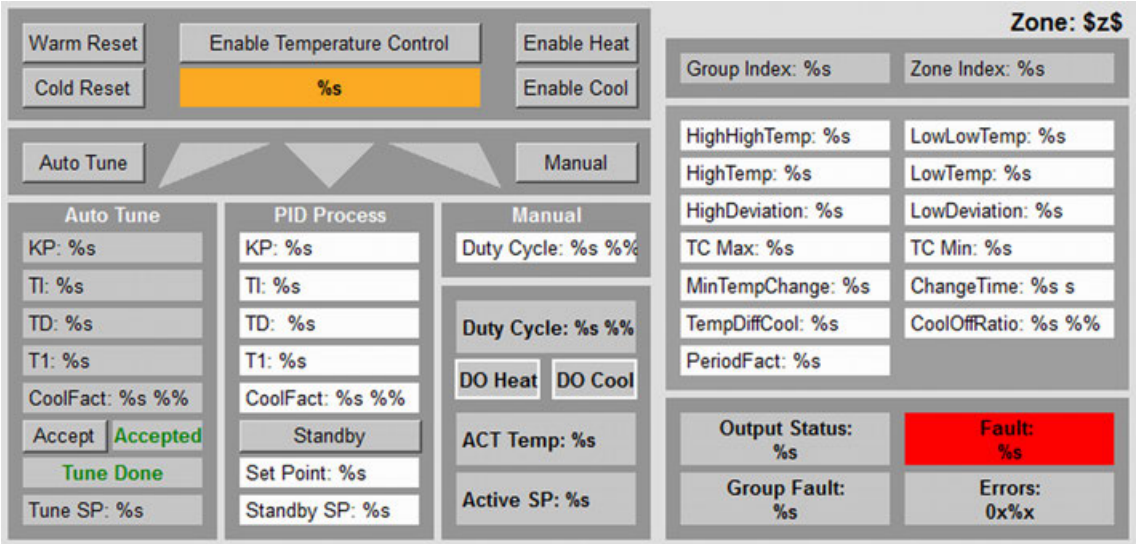
To simplify the start process of temperature control, it is highly recommended to have an initialization procedure of relevant zone data values, as those values are necessary for starting the process. Otherwise those values need to be set using HMI. For example:

- Set point:
  ZoneData.tsProcessSet.rsetpoint:=55;
- Hysteresis to switch on and off cooling: ZoneData.tsMachineSet.rTemp_diff_cool:=1; (*If value> 0: cooling will be ON with 100% when ACT_TEMP > set point + rtemp_diff_cool x iCool_Off_Ratio. If value = 0: rtemp_diff_cool is deactivated, PID controller will be active for cooling*)
- Values for Thermal Coupler Fault 2: ZoneData.tsMachineSet.uiMIN_TEMP_CHANGE:=1; ZoneData.tsMachineSet.uiCHANGE_TIME:=60;
  (*Inside uiCHANGE_TIME in seconds, a temperature change of 1 of raw value from sensor should be detected, otherwise fault will be triggered*)
- Values for Thermal Coupler Fault 1:
  ZoneData.tsMachineSet.rTC_max:=400;
  ZoneData.tsMachineSet.rTC_min:=-50;
  (*Measuring range of thermal sensor, e.g. -50°C to 400°C. If the detected sensor value is out of *)
- Limits for temperature:
  ZoneData.tsMachineSet.rhighhigh_temp:=120;
  ZoneData.tsMachineSet.rlowlow_temp:=0;
  ZoneData.tsProcessSet.rhigh_temp:=ZoneData.tsProcessSet.rsetpoint+10;
  ZoneData.tsProcessSet.rlow_temp:=ZoneData.tsProcessSet.rsetpoint-10;
  ZoneData.tsProcessSet.rhigh_deviation:=0.5;
  ZoneData.tsProcessSet.rlow_deviation:=0.5;
- Necessary temperature change to do AutoTune: ZoneData.tsMachineSet.iTune_Step:=500;
  (*This is a raw sensor value, for a RAW_FACTOR 10, it will be 50 degree.*)
- Set control bits:
  ZoneData.tsProcessSet.wcontrolWord.1:=TRUE;(*heat enabled*)
  ZoneData.tsProcessSet.wcontrolWord.2:=TRUE;(*cool enabled*)
  ZoneData.tsProcessSet.wcontrolWord.6:=TRUE;(* accept autotune result*)

Please refer to the example for the detailed realization of this data initialization part.

1.5.12.1.6 How to start control process

To have a better overview of the control process, the zone data visualization element can be used.



Do AutoTune

Prepare the settings

Before start the auto tuning process, the following points should be made clear:

- Auto tuning only for heating or for both heating and cooling.

If only heating is enabled for auto tuning, the following values should be set:

- Control bit: ZoneData.tsProcessSet.wControlWord.1:=TRUE;(*heat enabled*)
- ZoneData.tsProcessSet.wControlWord.2:=FALSE;(*cool disabled*),
  Or if cooling enabled with hysteresis:
  ZoneData.tsProcessSet.wControlWord.2:=TRUE;(*cool enabled*)
  ZoneData.tsMachineSet.rTemp_diff_cool>0;

If both heating and cooling are enabled for auto tuning, the following values should be set:

- Control bits: ZoneData.tsProcessSet.wControlWord.1:=TRUE;(*heat enabled*)
  ZoneData.tsProcessSet.wControlWord.2:=TRUE;(cool enabled*)
- Cooling with hysteresis must be disabled with:
  ZoneData.tsMachineSet.rTemp_diff_cool:=0;

Besides that, the necessary temperature change to do AutoTune needs to be checked: ZoneData.tsMachineSet.iTune_Step:=500; (*This is a raw sensor value, for a RAW_FACTOR 10, it will be 50 degree.*) The larger the value, the better the result will be. It is recommended to have 500 as raw sensor value.

Start AutoTune

Enable the control bit ZoneData.tsProcessSet.wControlWord.5 to enable AutoTune, and enable the control bit ZoneData.tsProcessSet.wControlWord.0 to start the control process.

As long the AutoTune is started, the control state machine ZoneData.tsInternalStatus.ControlState will change from Ready to AutoTune. The tune setpoint ZoneData.tsInternalStatus.rTune_SetPoint will be set internally: as long as the process set point ZoneData.tsProcessSet.rsetpoint fulfills the necessary temperature change, namely the different against actual temperature is greater than ZoneData.tsMachineSet.iTune_Step, then the AutoTune will take the process set point as tune setpoint and transfer it to the active setpoint ZoneData.tsProcessStatus.rActive_SetPoint. Otherwise it will set a higher tune setpoint, which is not lower than the HighHigh temperature limit.

AutoTune needs a long time depending on the system. If the cooling is also activated, then it will be even longer.

AutoTune done

If the AutoTune is done with success, a status bit ZoneData.tsProcessStatus.wStatusWord.6 for tune done is set and the PID parameters (KP, TI, TD, T1) will be calculated and the control state will change back to ready. If the control bit ZoneData.tsProcessSet.wControlWord.6 (accept AutoTune result) is TRUE, then the PID values will be copied from AutoTune result to PID values for automatic PID process with an indication ZoneData.tsProcessStatus.wStatusWord.7 (AutoTune accepted) and at the same time the automatic process will start with changing control state to PID_Process.

After accepting the AutoTune result, the control bit ZoneData.tsProcessSet.wControlWord.6 can be disabled for a fine tuning of the PID parameters.

Even if the zone data is saved as retain variable, it is recommended to save the AutoTune results and PID parameters into PLC internal flash or as a recipe file directly after AutoTune is done. Because the values can be reset by cold resetting the PLC or by downloading new PLC program. Please refer to the chapters for those two functionalities.

If AutoTune cannot be completed due to tune fault, the control state will change to Fault state with fault bit ZoneData.tsProcessStatus.wStatusWord.15 and error code TECT_TuneFault in ZoneData.tsProcessStatus.wErrors and ZoneData.tsProcessStatus.Latest_Error. To reset the fault, the enable AutoTune control bit needs to be disabled first and a warm reset with ZoneData.tsProcessSet.wControlWord.13 of process is necessary.

The AutoTune fault can happen if the temperature change between actual temperature and set point is not big enough. For such case, the user needs to wait until the machine temperature has been cooled down.

Restart AutoTune

To restart AutoTune, the cold reset of process is necessary. The cold reset resets not only the fault state but also the tune status including status bit tune done and tune accepted. After that, a new AutoTune process can be started again.

Do PID Process

PID process is an automatic process with a PID controller which outputs control variables according to actual temperature as feedback. To start PID process, the valid PID parameters (KP, TI, TD, T1) are necessary. Internally, it check the following conditions for valid parameters:

- KP > 0,
- TI >= 0,
- (TD>0 AND T1>0) OR (TD=0)

If the values are not valid, then the PID process cannot be started with a warning: NoPIDProcess.

The PID parameters can be accepted from AutoTune result, can be set during fine tuning or can even be set manually without AutoTune process.

If the user has already write the PID parameters into internal flash or a recipe file, then they can be read back from flash or a recipe file.

For PID process, two set points are possible. Normal set point for production and standby set point for energy saving. The switch between both is done with a control bit ZoneData.tsProcessSet.wControlWord.4 (enable standby set point). The currently used set point will be transferred to active set point.

Do manual control

The process can be controlled manually by changing duty cycle directly. The manual control can even interrupt the AutoTune and PID process.

To start manual control, the control bit ZoneData.tsProcessSet.wControlWord.3 (enable manual control) is set and the control state will change to Manual. After that, the manual duty cycle ZoneData.tsProcessSet. iManual_DutyCycle can be changed to output the control value directly.

Observe the status

There are different status which indicate what is exactly going on in the process.

Process status

Control state ZoneData.tsInternalStatus.ControlState is the main state machine for the whole process.

Status word ZoneData.tsProcessStatus.wStatusWord for general status, e.g. tune done and tune accepted.

Output status ZoneData.tsProcessStatus.OutputStatus indicates the status of PWM output, e.g. the output is in automatic heat or manual cool.

Errors (Error Word) ZoneData.tsProcessStatus.wErrors indicates all the errors (warnings and faults) which are active.

Latest error ZoneData.tsProcessStatus.Latest_Error shows only the latest activated error out of error word.

There are two levels of errors: faults (ZoneData.tsProcessStatus.wStatusWord.15=TRUE) and warnings (ZoneData.tsProcessStatus.wStatusWord.14=TRUE). Both will set the bits in error word and latest error.

The difference is: Faults will interrupt the control state and change it to Fault state. To resume the process, the control process needs to be warm reset to go to ready state first.

Warnings are only indications for the user and do not interrupt a running process.

Nevertheless, each bit in the error word can be programmed individually to control user defined functions, e.g. to control a contactor / relay or switch on a warning light.

Besides the errors for an individual zone, it is also possible to combine the zone faults to group faults.

This function will set all zones in the group to fault state and group fault bit (ZoneData.tsProcessStatus.wStatusWord.13) to TRUE as soon as one zone in the group has fault. Please refer to TECT_GROUP description for more details.

Function block status

For the function blocks in the library, there are different outputs for status of the function block, e.g. DONE, ERR, ERNO and BUSY. For ERNO (function block error numbers), please refer to that function block description. For certain special internal functionalities, e.g. CAA File Library or Flash operation, there will be a link for the original error description of those part.

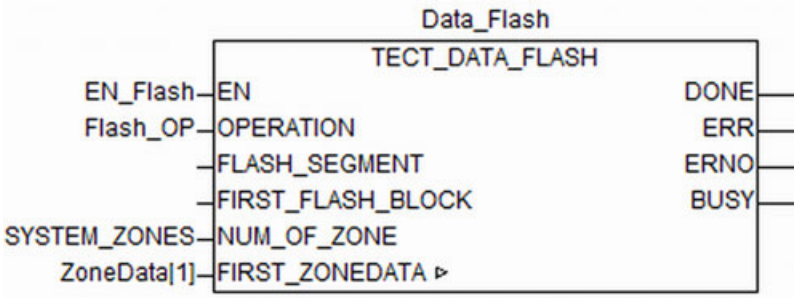
1.5.12.1.7 How to save control data

It is highly recommended to save the set values of zone data in case of power failure or reset of PLC, especially the result of AutoTune and the process PID parameters. For this purpose, there are to function blocks with different PLC resource demands are available for different function range:

TECT_DATA_FLASH: saves/loads AutoTune result and PID parameters into/from internal flash.

TECT_RECIPE: saves/loads all relevant control parameters and settings into/from recipe file in CSV format.

Save AutoTune and PID parameters into flash



Each PLC in AC500 range has a power safe internal flash data area which can be written, read and deleted from AC500 program. TECT_DATA_FLASH uses the internal flash to save and load the AutoTune results and PID parameters including:

- Internal parameters: rKS, rTU, rTG and wCoolFact_Tune
- Machine set parameters: wCoolFact, rKP, rTI, rTD, rT1

The user can perform the following operations by using this function block in the flash memory: Read, Write, Delete, Check Read, Delete Write and Check Write.

WRITE The user can save the above variables into flash by the WRITE operation by selecting the flash segment. When the WRITE command is enabled the parameters, which are listed above, will be copied and stored in the flash memory of the PLC. If the PLC is restarted or a cold reset is done these data will still be retained. Before a fresh set of data is written to the flash memory, it has to be cleared. Hence delete operation has to be executed before rewrite of the flash data.

READ The user can copy the data from the flash memory of PLC into the structure TEMPZONE_DATA by this command. When the READ operation is used, based on the flash block and segment configuration, it will read the data from a respective location. This is useful to restore/ load the settings of tune values.

DELETE This operation will clear all the data in the flash memory. It will delete data in the complete selected flash segment. Before a fresh set of data is written to the flash memory, it has to be cleared. Hence delete operation has to be executed before rewrite of the flash data.

DELETE_WRITE This operation is a combination of operation DELETE and WRITE. It will clear the complete segment first and then write the set of data into flash.

CHECK_READ This operation is used, when data read has to be restricted. It will check if the values of AutoTune results in Zone Data are valid. Only if they are invalid, it will read the values from flash memory to the Zone Data structure, otherwise the operation will do nothing.

CHECK_WRITE This operation is a combination of above two operations CHECK_READ and DELETE_WRITE. When this operation is executed, it will check if the values of AutoTune results in Zone Data are valid. Only if they are invalid, it will read the values from flash memory to the Zone Data structure. After that, it clears the flash with DELETE operation and write the set of data into flash.

In total they are 32 bytes which a data block in the flash is used for one zone. As one segment has 1927 data blocks, the maximum number of zones supported for the TECT_DATA_FLASH is 1927.

For a new data write processing to flash, the flash needs to be deleted first. This can be done with TECT_DELETE before TECT_WRITE is to be executed. As an alternative, TECT_DELETE_WRITE combines the two operations in one. *Chapter 1.5.12.2.9 “TECT_DATA_FLASH” on page 3338*

Save set values as recipe file

Function principle

The function block TECT_RECIPE can save/write the necessary control settings to a CSV file and load/read the settings from the CSV file. The files can be accessed via an FTP client connected to AC500 FTP server. After the configuration the data can be saved into a CSV file by a WRITE operation. The same CSV file can be used in other configurations where similar initializsation is required.

Work with recipe

The Recipe function block can READ/WRITE the following parameters into the CSV file: Group_Name, Zone Index, Set temperature, Standby Set temperature, ControlWord, KS, TU, TG, KP, TI, TD, T1, CoolFact, PeriodFact, HighHigh temperature, High temperature, Low temperature, LowLow temperature, High deviation, Low deviation, Change time, Minimum temperature change, TCmax, TCmin, Temperature difference cool, Cool off ratio, Max output, Tune setpoint, Tune output, Tune min KP, Tune max KP, Tune KP Scaling and Thermocouple offset. Only one TECT_RECIPE is necessary for the whole system.

When the WRITE operation is selected, it will make a single copy of parameters listed above for the whole system into a recipe file in CSV format. The file name can be decided by the input FILE_PATH and SET_NO. If a folder is defined at FILE_PATH, e.g. ‘sdcard/Recipe’, the recipe file will be created as TZD*.csv, * stands for SET_NO. If the user wants to define his own recipe name, then a csv file name with folder needs to be defined at FILE_PATH, e.g. ‘sdcard/Recipe/MyRecipe.csv’.

The first line of the CSV file will have all the variable names and below lines list values of each variable zone by zone (see figure below).

Fig. 583: Recipe data in the CSV file after WRITE operation

This function block can be used to save the dedicated settings of a Temperature Control system. Furthermore, as its name says, it can also be used to manage multiple sets of control settings using multiple recipe sets

Configure access to memory card through FTP client in the Automation Builder.

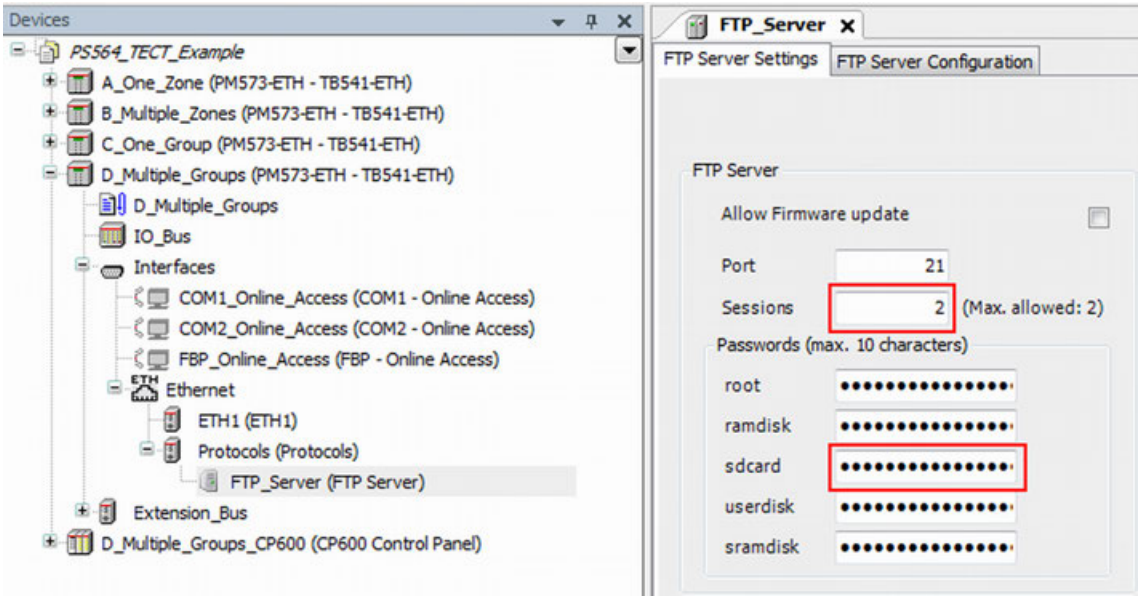

Fig. 584: Configuration of memory card access through FTP client in Automation Builder

For READ and WRITE operation on the memory card the access needs to be configured in the Automation Builder using FTP client. At this place the password for the memory card access is set.

For the following activities the tool "File Zilla" is used to access the memory card. But it is also possible to use other FTP client tools.

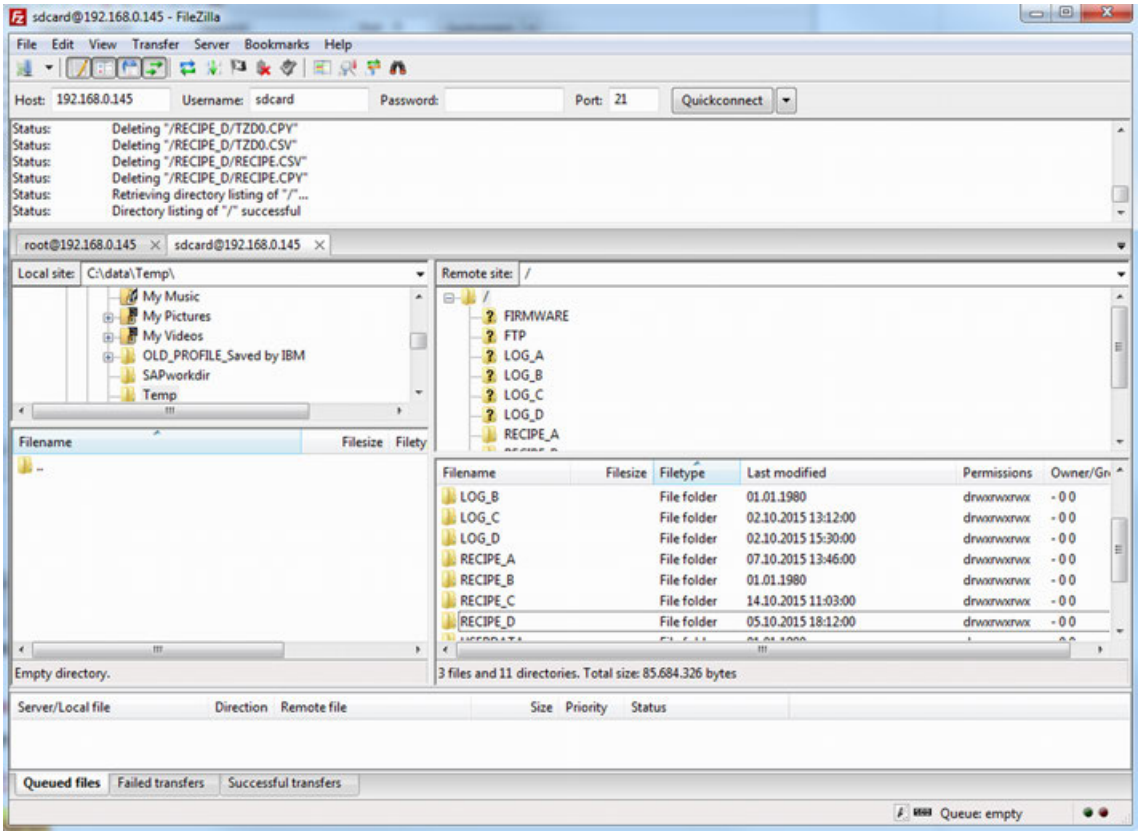

Fig. 585: Access of memory card through FTP client

Enter the PLC IP address as Host, sdcard as Username, password which is configured in the Automation Builder tool and Port number configured (default is 21).

After press “Quickconnect” button, the user can access the memory card data.

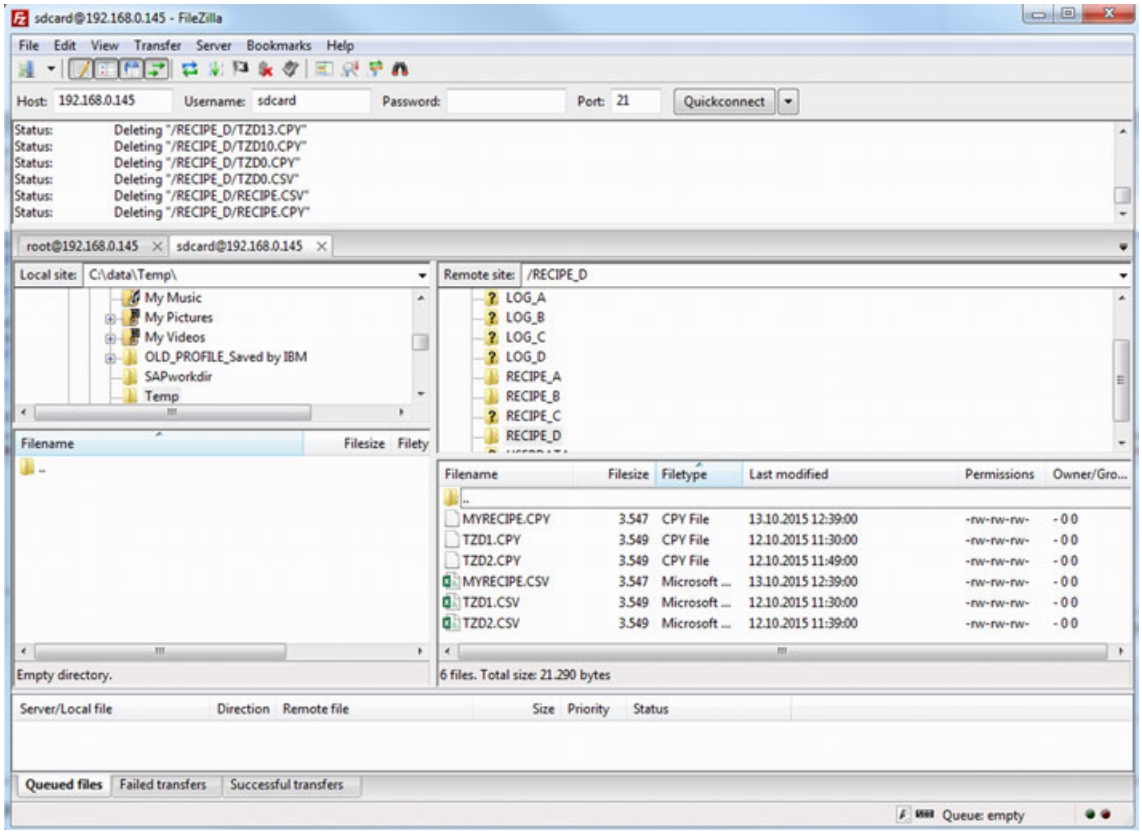

Fig. 586: Recipe files created in memory card accessed using FTP client

When the READ operation is selected, there must be a recipe file present in the Memory card in .CSV format. The name of the file must be as per the Recipe function block guideline. The Recipe block will copy the values of each variable to respective zone data structure. This will help the user to configure the system faster after a restart.

The CSV file is generated, in which all the data is added into a single line for each zone, separated by a semicolon (;) (see figure "Recipe files created in memory card accessed using FTP client"

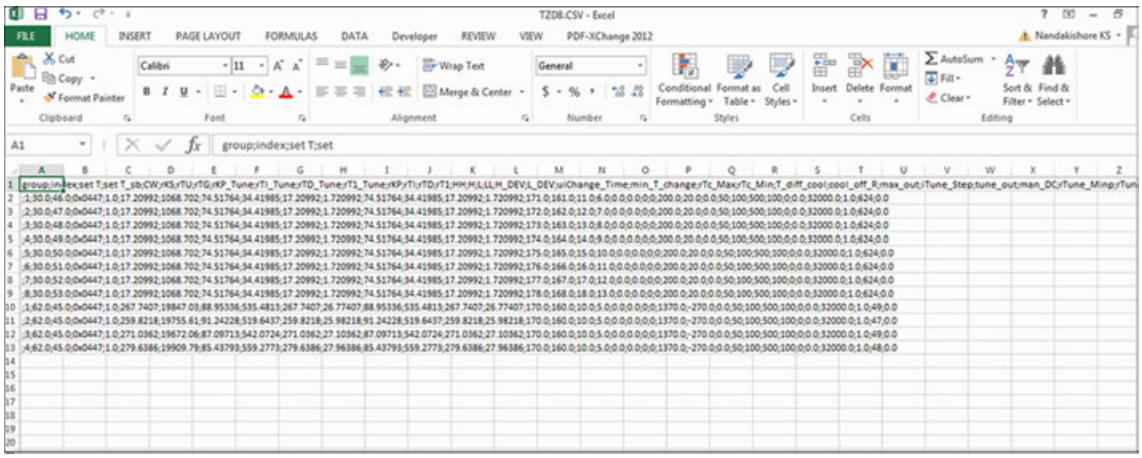

Fig. 587: Open CSV file without delimited

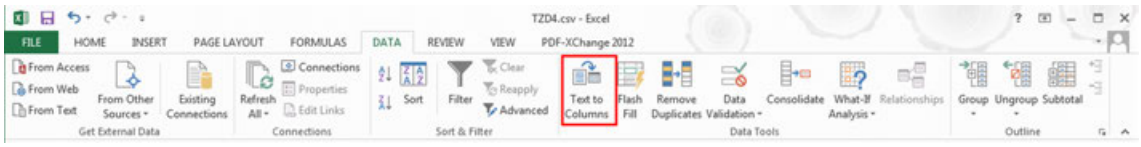
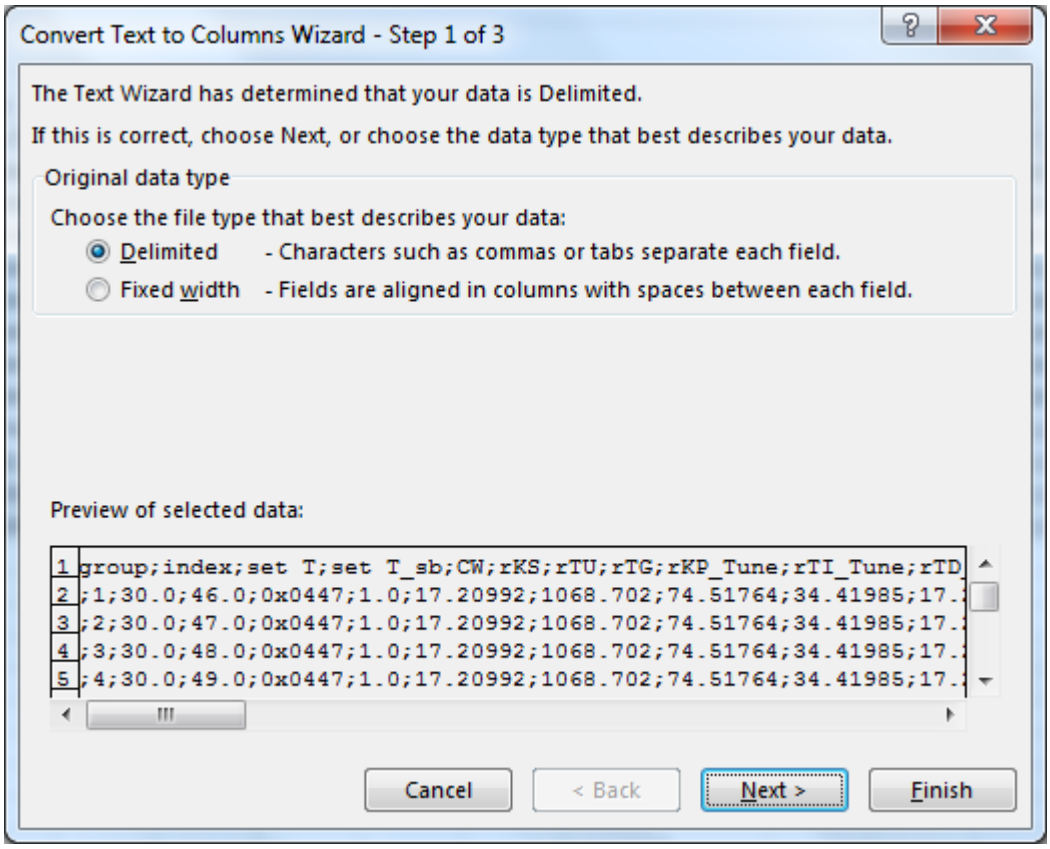
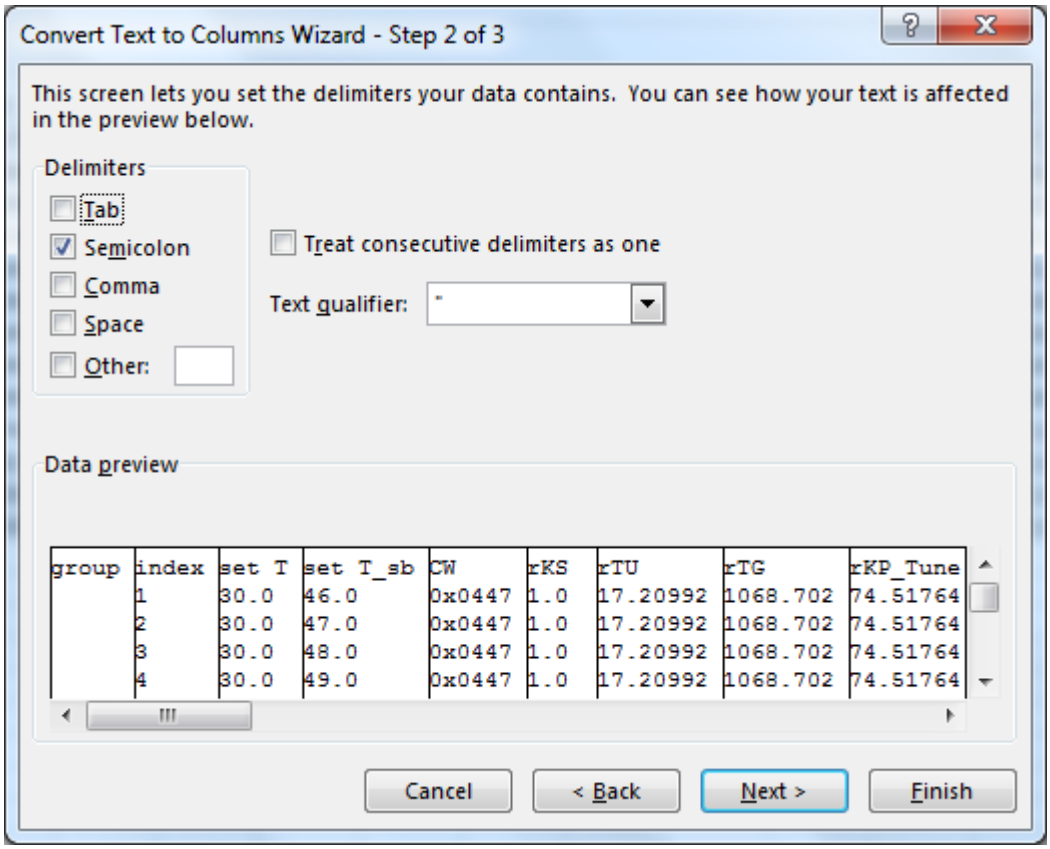
This CSV file can be displayed with separate columns using option “Text to Columns”:



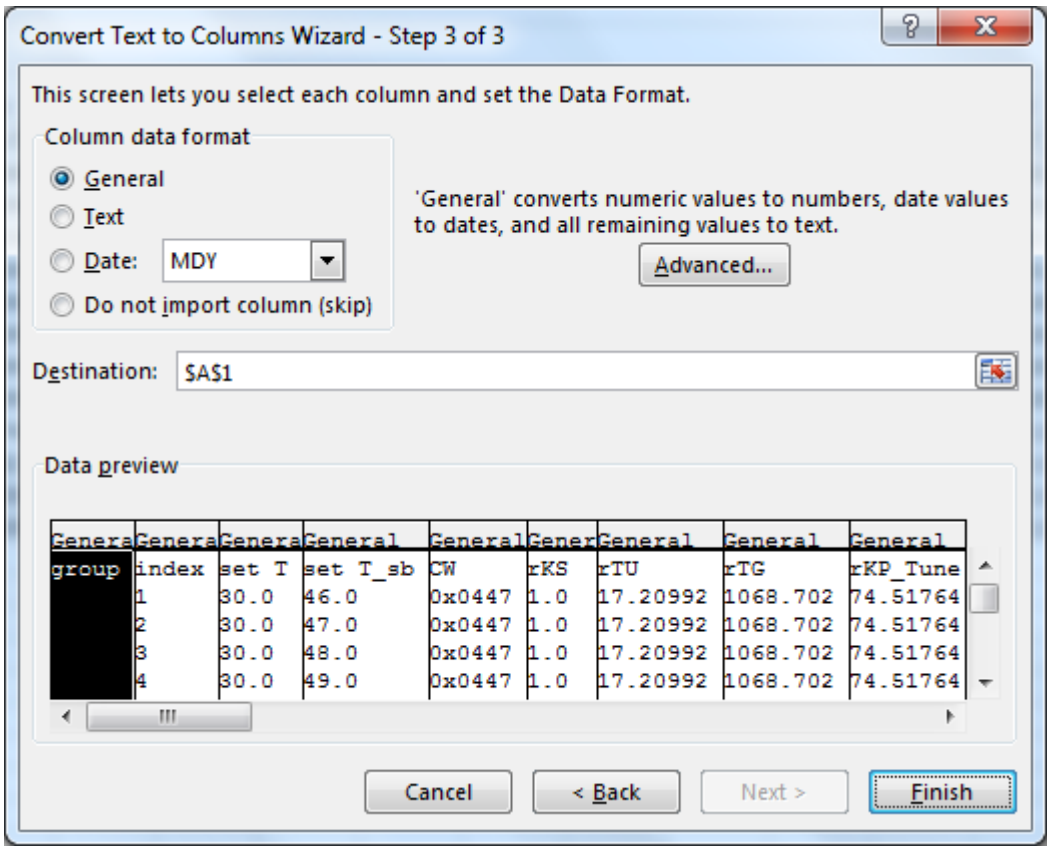
Then follow the following steps:



1. To choose the data type, choose "Delimited- Characters such as commas or tabs separate each field"



2. To set the delimiters, tick the box "Semicolon".



3. To set the data format, choose "General".

⇨ As a result:

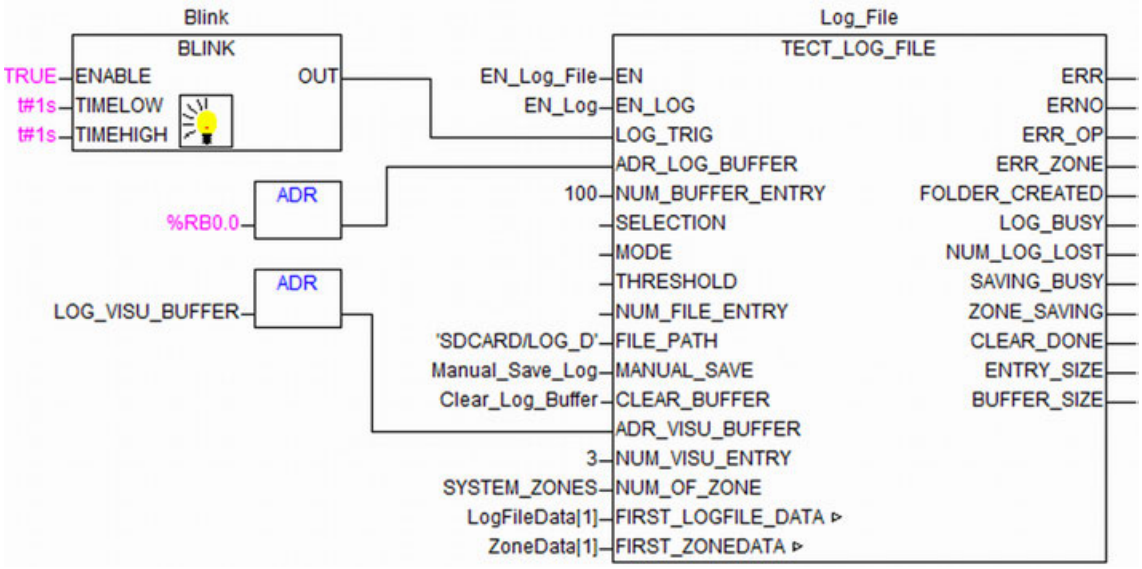
1.5.12.1.8 How to do data logging

Function principle



The TECT_LOG_FILE function block can log the predefined process status and values together with time stamp in a logging buffer as long as the trigger (LOG_TRIG as well as internal trigger if enabled) has a rising edge.

The predefined process status and values logged are:

Control Word, Status Word, SET_TEMP, ACT_TEMP, Duty Cycle, Control State, Output Status, Latest Error and Errors (Error Word).

The function block contains two major functionalities: logging data into a CSV file and live data logging in the visualization.

For the live data logging visualization, all data will be displayed in the visualization as soon as a trigger signal is active.

For logging data into a CSV file, the data based on the mode and selection set by the user will be logged.

There is a logging buffer for the system with a size of NUM_BUFFER_ENTRY (number of entries) for each zone. As long as the logging entry reaches the end of logging buffer, the entries in the logging buffer will be saved into a log file in .csv format under a user defined folder. The file name is generated automatically from the zone index, its group index and the month and date value while saving. This log file can be opened in e.g. Excel with semicolon as delimiter and can be analyzed. When the TECT_LOG_FILE function block is enabled, the user has to configure SELECTION input, where he can select which data is to be logged. There are different modes of logging, which can be selected.

Logging data into a CSV file

There are some steps to start with logging data into a CSV file:

- Define what to be logged:
  Input SELECTION types are: Selection of predefined values to be logged: bit 0 to bit 7 are used for the current version. Bit x=TRUE: the corresponding value will be logged.
  - Bit 0: Control Word
  - Bit 1: Status Word
  - Bit 2: SET_TEMP
  - Bit 3: ACT_TEMP
  - Bit 4: Duty Cycle
  - Bit 5: Control State
  - Bit 6: Output State
  - Bit 7: Latest Error
  - Bit 8: Errors (Error Word)
- Define the log trigger:
  - Define an external trigger with LOG_TRIG, it is recommended to use a timer, e.g. BLINK function block. The LOG_TRIG should be defined greater than 1s, otherwise log data could get lost.
  - Additional to LOG_TRIG, an internal trigger can be activated with bit 4 of input MODE, which creates a trigger if and there is change in Control word or Status word.
- Define when to log data:
  - With bit 1 and bit 0 of input MODE, it can be defined when to log data if log trigger is active. This setting can be used to optimize the storage size for data logging by reducing the number of data sets to be logged. Bit 1, Bit 0:
    00: Log all items as long as log trigger is active.
    01: Log, if one of the log values changes, when trigger is active.
    11: Log, if CW or SW changes or ACT_TEMP changes out of threshold (+/- THRESHOLD), when trigger is active.
  - With above mode 11, the input THRESHOLD needs to be defined also.
- Define the log buffer:
  A log buffer in data area needs to be defined for all zones to collect the log data before data is written to a log file. The log buffer contains continuous area for each zone individually. The first address of the log buffer needs to be assigned to input ADR_LOG_BUFFER. It is recommended to use a data area with fixed address, e.g. %R or %M area.
  The input NUM_BUFFER_ENTRY specifies the size of a log area for each zone in number of log entries. A log entry stands for a data set containing the predefined log values with input SELECTION. The total amount of log entries of the entire log buffer will be NUM_BUFFER_ENTRY x NUM_OF_ZONE.

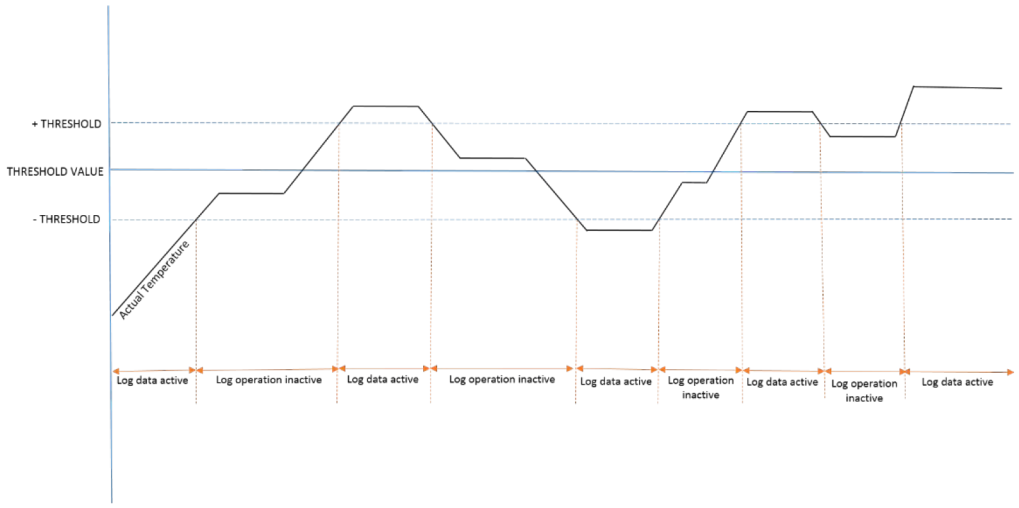


Fig. 588: Input THRESHOLD

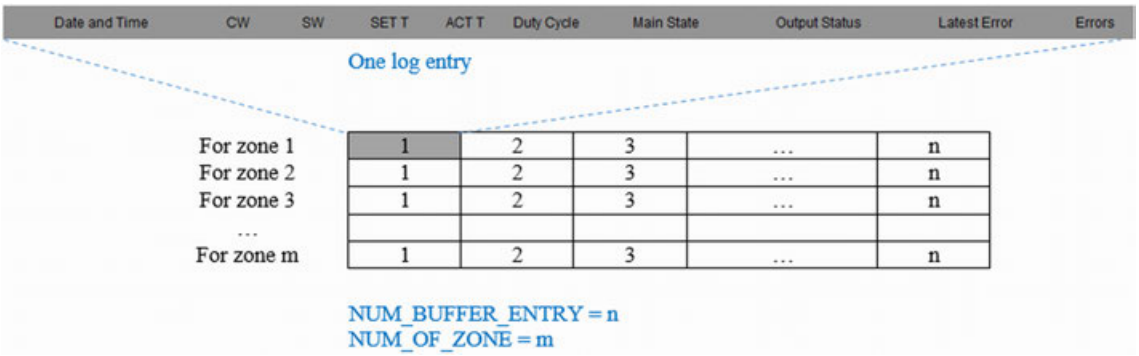


The NUM_BUFFER_ENTRY should be defined as large as possible to reduce the frequency of saving the log buffer into log files, thus reducing CPU load. It is recommended to define NUM_BUFFER_ENTRY > NUM_OF_ZONE x 2, otherwise log data could get lost.

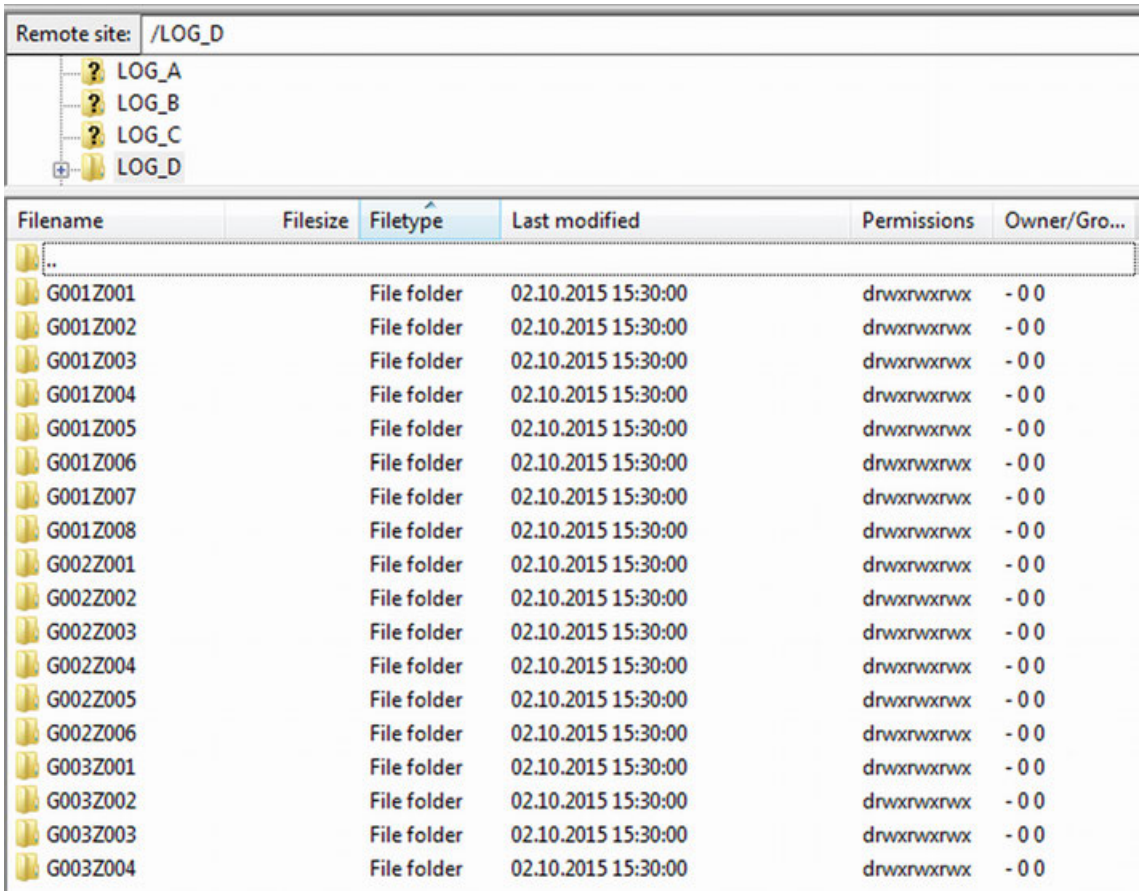
The data size of a log entry depends on the input SELECTION, the size can be about 20 bytes to 100 bytes. This information can be got at run time from the output ENTRY_SIZE and the total size of the log buffer is displayed at output BUFFER_SIZE.

It is very important to check the BUFFER_SIZE output to make sure that enough data area is available for the defined log buffer, otherwise undesired behavior can happen in PLC. The following table shows the available %M and %R area of different CPU types (status of 10.2015).

Memory Area [kB]	PM554	PM564	PM556	PM572	PM573	PM582	PM583	PM590	PM591	PM592	PM595
%M area	2	2	64	4	128	128	128	512	512	512	1024
%R area	1	1	1	4	128	128	128	512	512	512	1024

- Define where to save the log files:
  It is recommended to save log files on memory card. For CPU types PM592 and PM595 it is possible to be saved on the Flashdisk.
  The folder for saving is to be specified at input FILE_PATH, e.g. ‘SDCARD/folder’. The physical disk like SDCARD or FLASHDISK must be specified in the FILE_PATH. The folder following will be created if it does not exist yet as long as the function block is enabled with EN input. But only one folder level will be created, this means the parent folder must already exist.
  Bit 8 and bit 9 of input MODE can be used to specify the subfolder.
  – Bit 8: FALSE: Create subfolder automatically; TRUE: Do not create subfolder.
  – Bit 9: Valid, if bit 8 is FALSE.
    FALSE: subfolder name with index in DECIMAL.
    For example, for group 10, index 3, subfolder name is G010Z003.

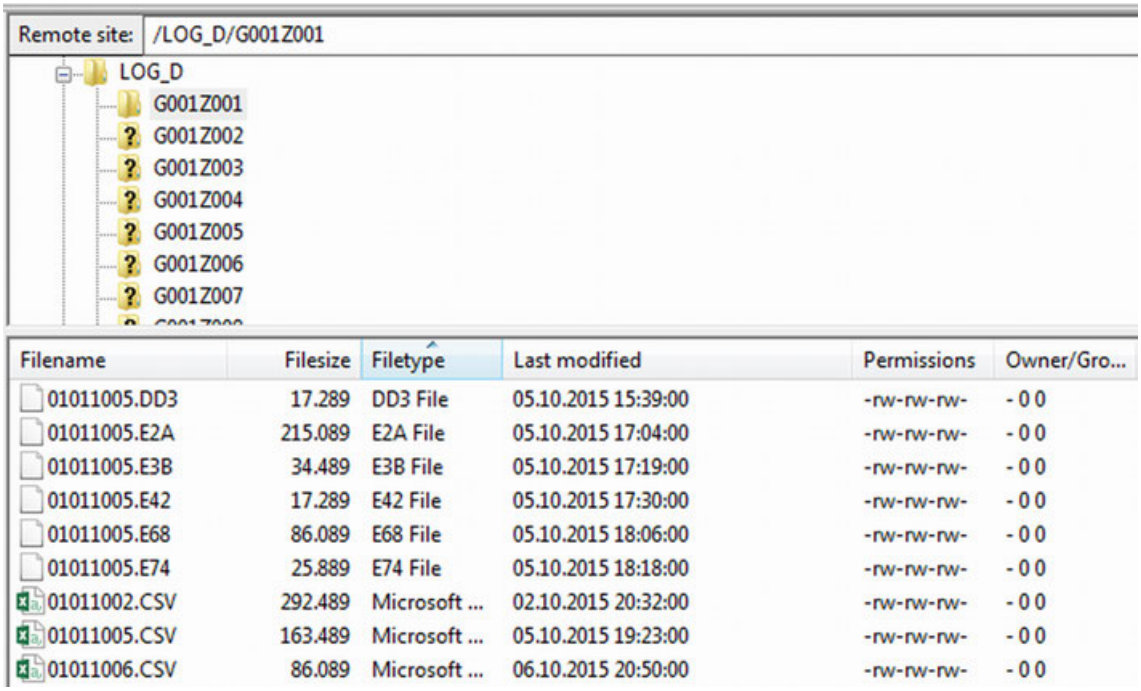
Following is an example of FILE_PATH = ‘SDCARD/LOG_D’ and Bit 8 = FALSE, Bit 9 = FALSE:



Filename	Filesize	Filetype	Last modified	Permissions	Owner/Gro...
..					
G001Z001		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G001Z002		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G001Z003		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G001Z004		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G001Z005		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G001Z006		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G001Z007		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G001Z008		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G002Z001		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G002Z002		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G002Z003		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G002Z004		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G002Z005		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G002Z006		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G003Z001		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G003Z002		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G003Z003		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0
G003Z004		File folder	02.10.2015 15:30:00	drwxrwxrwx	- 0 0

- Define when to create a new log file:
  The function block creates individual log files for each zone.
  As soon as the log area for each zone is full, that area will be written into a CSV file in the predefined folder. The file name contains the group and zone index as well as date information: ggzzmmdd.csv. Where:
  – ‘gg’ for group index in hexadecimal
  – ‘zz’ for zone index in hexadecimal
  – ‘mm’ for month of the year
  – ‘dd’ for day of the month

  At input NUM_FILE_ENTRY is to be defined how many entries a log files can have before creating a new log file. Before creating a new log file, the existing one will be backed up in changing the file extension without changing the name. For example, change ggzzmmdd.csv into ggzzmmdd.E74. The extension is composed of the last three hexadecimal numbers of current time without seconds. In this way, the file overwriting is avoid and all the log history is still available.
  If NUM_FILE_ENTRY is 0, then a new log file will be created daily.
  Following is an example of saved log files:



Filename	Filesize	Filetype	Last modified	Permissions	Owner/Gro...
01011005.DD3	17.289	DD3 File	05.10.2015 15:39:00	-rw-rw-rw-	- 0 0
01011005.E2A	215.089	E2A File	05.10.2015 17:04:00	-rw-rw-rw-	- 0 0
01011005.E3B	34.489	E3B File	05.10.2015 17:19:00	-rw-rw-rw-	- 0 0
01011005.E42	17.289	E42 File	05.10.2015 17:30:00	-rw-rw-rw-	- 0 0
01011005.E68	86.089	E68 File	05.10.2015 18:06:00	-rw-rw-rw-	- 0 0
01011005.E74	25.889	E74 File	05.10.2015 18:18:00	-rw-rw-rw-	- 0 0
01011002.CSV	292.489	Microsoft ...	02.10.2015 20:32:00	-rw-rw-rw-	- 0 0
01011005.CSV	163.489	Microsoft ...	05.10.2015 19:23:00	-rw-rw-rw-	- 0 0
01011006.CSV	86.089	Microsoft ...	06.10.2015 20:50:00	-rw-rw-rw-	- 0 0

- Common inputs:
  NUM_OF_ZONE: Number of zones to be logged into the .csv file or displayed in visualization. If TECT_GROUP is used, then the range is 1…65535. If TECT_GROUP is not used, then the range is 1…255. It is recommended to use one TECT_LOG_FILE for the whole system.
  FIRST_ZONEDATA: First structure of process data and parameters for the zone. See function block description for details.
- Manual operations:
  – Save the log buffer into files manually: with a rising edge at input MANUAL_SAVE all the data in the log buffer will be saved into the log files immediately.
  – Clear log buffer: with a rising edge at input CLEAR_BUFFER all data in the log buffer will be cleared. But before clearing, the new entries in the logging buffer are written into the .csv file first. Then the .csv file is renamed into a backup file with the same file name but different extension, which is composed of the last three hexadecimal numbers of current time without seconds. In this way, even after a clear log buffer action, the history in the buffer will not get lost.
- How to reduce the value of output NUM_LOG_LOST(number of logs which are lost):
  – Don’t create subfolder (MODE.bit8=TRUE) or first enable the function block with EN=TRUE until all folders are created (FOLDER_CREATED=TRUE) then start logging with EN_LOG=TRUE.
  – Increase the interval of LOG_TRIG if possible (recommendation: not less than 2 seconds).
  – Reduce the SELECTION to the necessity and increase the NUM_BUFFER_ENTRY if possible.
  – Increase the size of the second buffer (i2ndNEntry of TECT_LOGFILE_DATA_TYPE). Recommendation: 0…4.

The second buffer will allocate dynamic memory on PLC. Depending on the application, it could cause system error if the second buffer is so large that the system cannot allocate memory any more.

Live data logging in the visualization

All available status in the logger will be displayed with log visualization, thus input SELECTION has no influence on log visualization.

The buffer for visualization is to be defined, which is independent of the log buffer for logging data into CSV files. The first data address of visualization buffer needs to be assigned to input ADR_VISU_BUFFER.

The size of each visualization buffer is specified at input NUM_VISU_ENTRY as number of visualization entries.

The total size of the visualization buffer is depending on how many entries should be displayed in the visualization and how many zones are defined.

For example, if there are 4 zones to be logged and each zone has 10 log visualization entries, then a one dimensional or two dimensional array can be defined as the type “TECT_LOG-INFO_TYPE”:

visu_array : ARRAY[1..40] OF TECT_LOGINFO_TYPE; (in one dimensional array).

visu_array : ARRAY[1..4, 1..10] OF TECT_LOGINFO_TYPE; (in two dimensional array).

In the library, there are two predefined visualization elements:

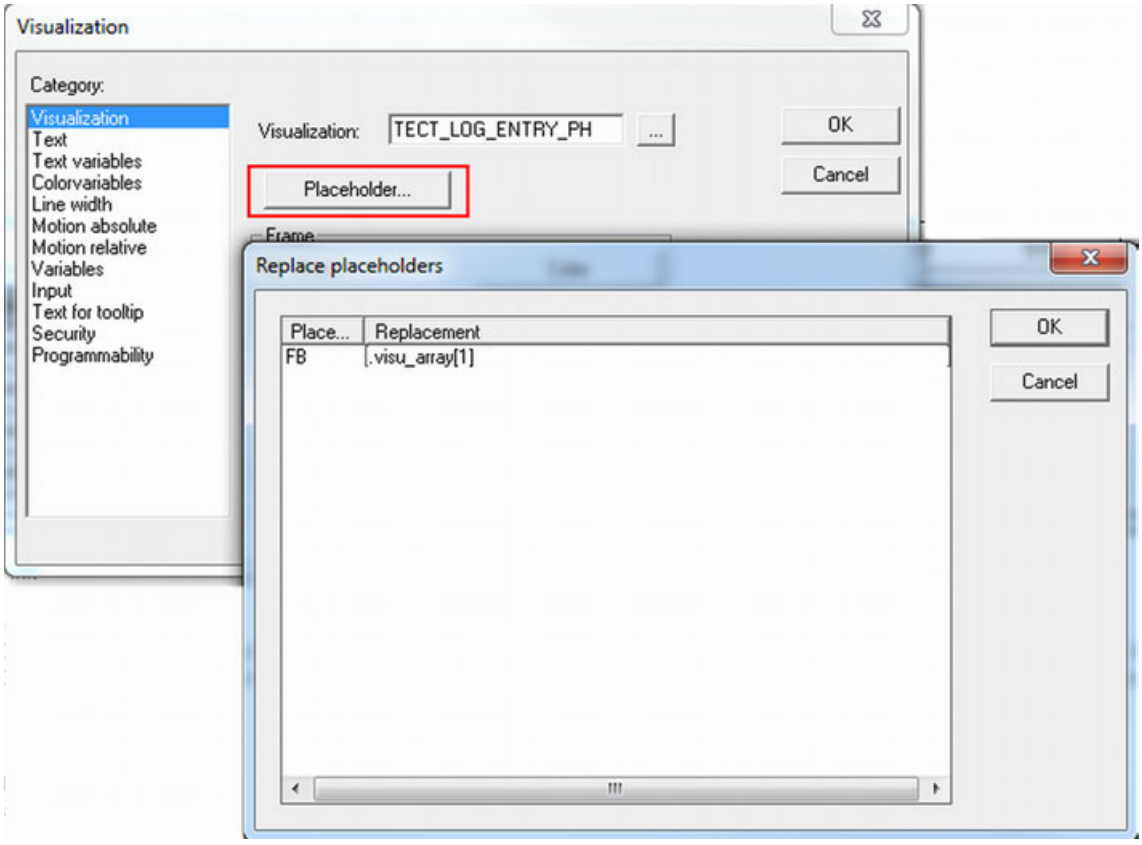
Log header:

Date and Time	CW	SW	SET T	ACT T	Duty Cycle	Main State	Output Status	Latest Error	Errors

Log entry:

%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s	0x%x

Each entry needs to be attach to one element of the defined visu_array[i] as place holder.



Then the user can build his own log visualization according to his demand. For example one zone with 5 log visualization entries:

Date and Time	CW	SW	SET T	ACT T	Duty Cycle	Main State	Output Status	Latest Error	Errors
DT#2015-10-22-15:46:23	0x6	0x4001	0	20	0	TECT_Ready	TECT_Disabled	TECT_LowTemp	0x100
DT#2015-10-22-15:46:21	0x6	0x4001	0	20	0	TECT_Ready	TECT_Disabled	TECT_LowTemp	0x100
DT#2015-10-22-15:46:19	0x6	0x4001	0	20	0	TECT_Ready	TECT_Disabled	TECT_LowTemp	0x100
DT#2015-10-22-15:46:17	0x6	0x4001	0	20	0	TECT_Ready	TECT_Disabled	TECT_LowTemp	0x100
DT#2015-10-22-15:46:15	0x6	0x4001	0	20	0	TECT_Ready	TECT_Disabled	TECT_LowTemp	0x100

Another variable FIRST_LOGFILE_DATA needs to be defined as an array of type “TECT_LOG-FILE_DATA_TYPE” in size NUM_OF_ZONE. This variable contains internal log settings and values for each zone individually.

Work with log file

The log files can be downloaded using a FTP client, e.g. FileZilla. For detailed operation of FTP please refer to the chapter for recipe functionality.

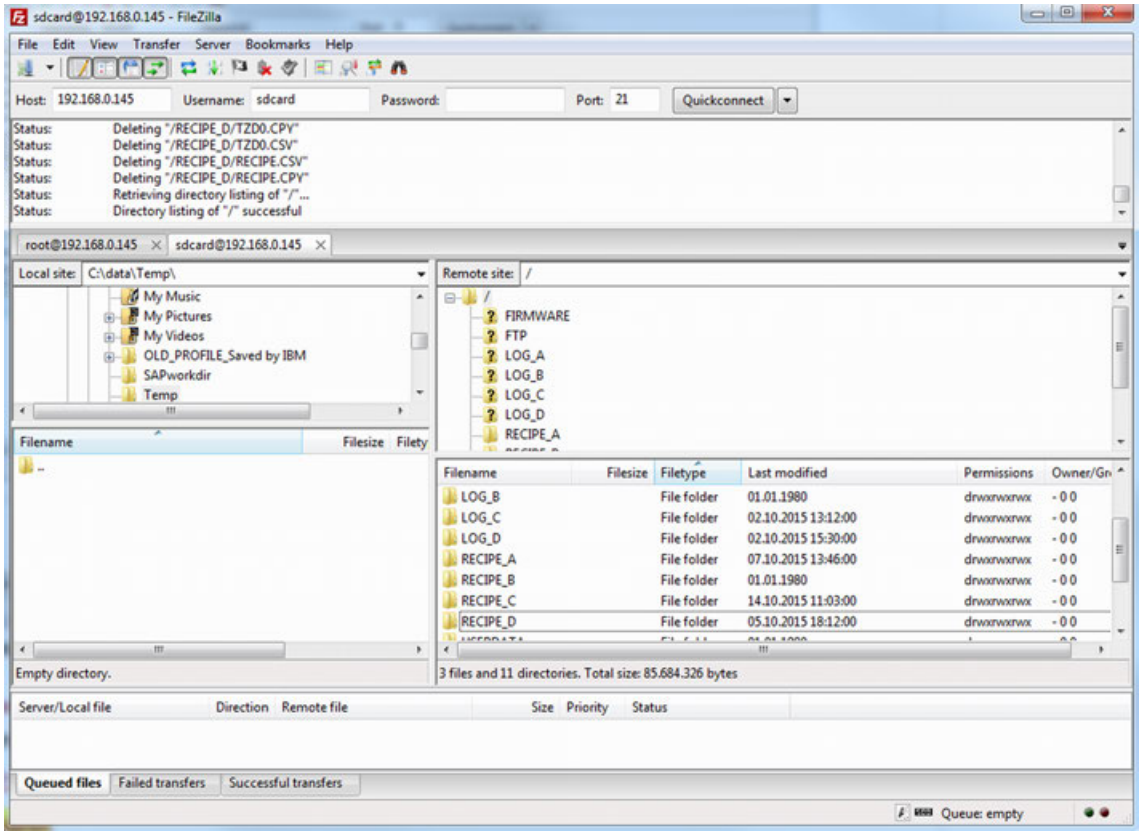


Fig. 589: Log files created in memory card accessed using FTP client

After a log file downloaded to PC, it can be opened with Excel in separate columns (delimited by semicolon) ↬ *Chapter 1.5.12.1.7.2 “Save set values as recipe file” on page 3289*.

For the backup files (files without .CSV extension), they can be renamed into CSV file and be opened with Excel. For example, can be 01011005.E42 renamed into 01011005.E42.CSV (keeping the original extension to avoid duplicated file name).

	A	B	C	D	E	F	G	H	I	J
1	Date and Time	CW	SW	SET T	ACT T	Duty Cycle	Main State	Output Status	Latest Error	Errors
2	2015-10-23-09:22:37	0x0006	0x4001	0	20	0	Ready	Disabled	LTemp	0x0100
3	2015-10-23-09:22:39	0x0006	0x4001	0	20	0	Ready	Disabled	LTemp	0x0100

15	2015-10-23-09:23:03	0x0067	0x4003	50	20.8	100	Tune	Tuning	LTemp	0x0100
16	2015-10-23-09:23:05	0x0067	0x4003	50	20.9	100	Tune	Tuning	LTemp	0x0100
17	2015-10-23-09:23:07	0x0067	0x4003	50	21.1	100	Tune	Tuning	LTemp	0x0100

Fig. 590: Log file example opened in Excel

The log data can be analyzed more easily with Excel, e.g. using line chart.

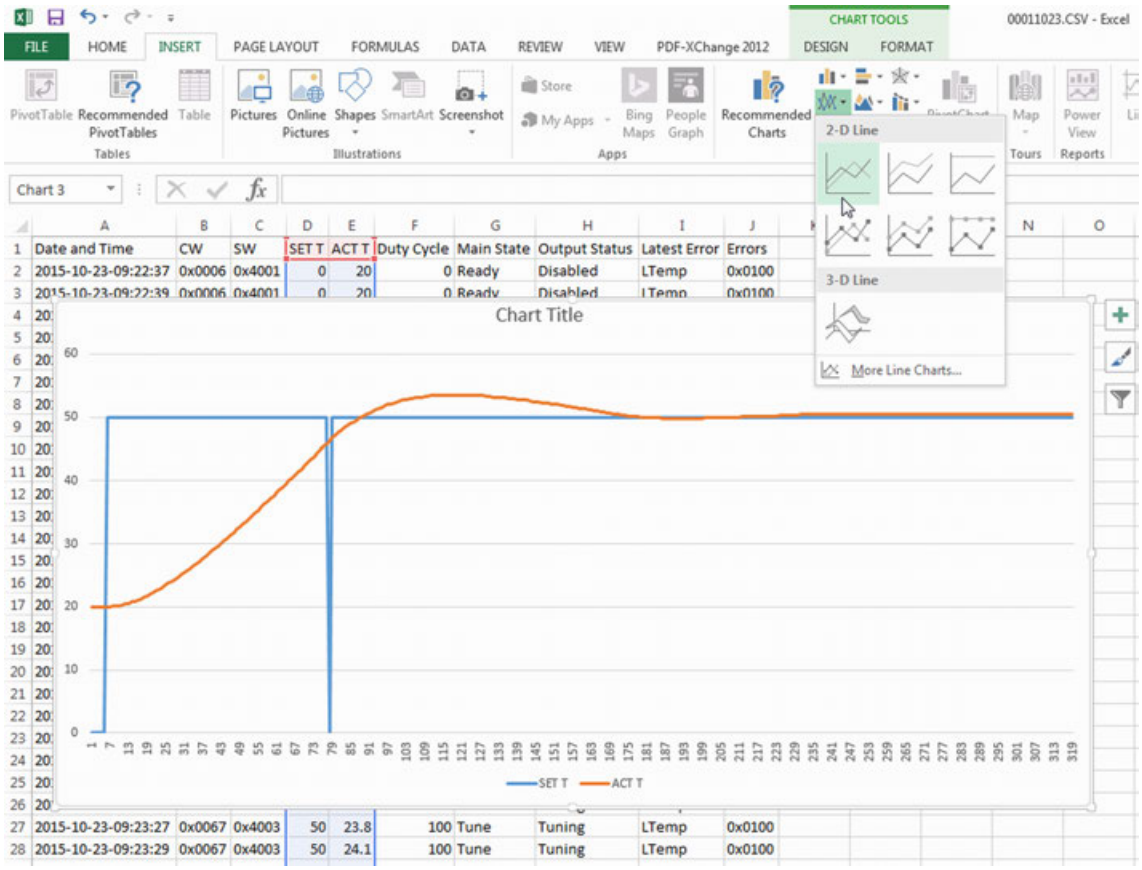

Fig. 591: Log file example opened in Excel with line chart

After editing the log file, it can be saved in .xlsx format to keep the line chart.

1.5.12.1.9 Current monitoring

Current monitoring feature is available with TECT_GROUP function block. Current can be measured using common current sensor for all zones in the group or individual current sensor for each zone. Single or three phase heaters system can be selected by user.

Industry uses resistive heaters for acquiring desired process temperature. Resistive heaters either become open or short circuited due to overheating and age over prolonged use. These conditions can be detected and respective error message generated using current sensors. Current sensors measures circuit current and sends it to AC500, which in turn compares it with rated current of heaters. On faulty condition one of the following error generated for the zone.

Open circuit

Most of the time heater coil breaks due to continuous / overheating and causes open circuit. In open circuit condition current will not flow. Hence we can safely assume a condition of open circuit, if current is measurement is zero.

Short circuit

If heater coil comes in contact with its metal container, then it causes short circuit. In short circuit condition, heater will try to draw max current capacity of the input supply. E.g. it will draw a max current of the SSR / MCB.

Control circuit failure

If there is no supply at the input side of SSR and still we are able to measure current at the output side, then it means there some problem in the control circuit.

Single or common current sensors

Advantage of common current sensor: is less costs, as single current sensor is used for all zones in the group. It also leads to less maintenance cost.

Disadvantage of common current sensor is slower recognition of faults, as single current sensor is used for all zones in the group. Single current sensor will measure current for one zone at a time. Once measurement is done sensor measure current for next zone.

Example: Circuit diagrams for individual and common current sensors

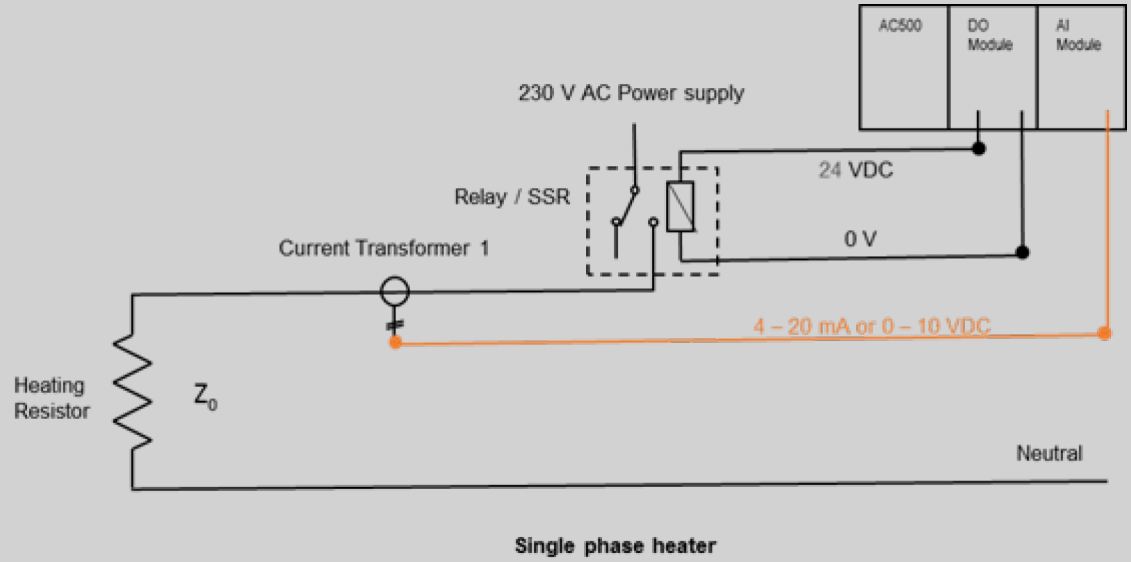

Fig. 592: Individual current sensor for single phase heater

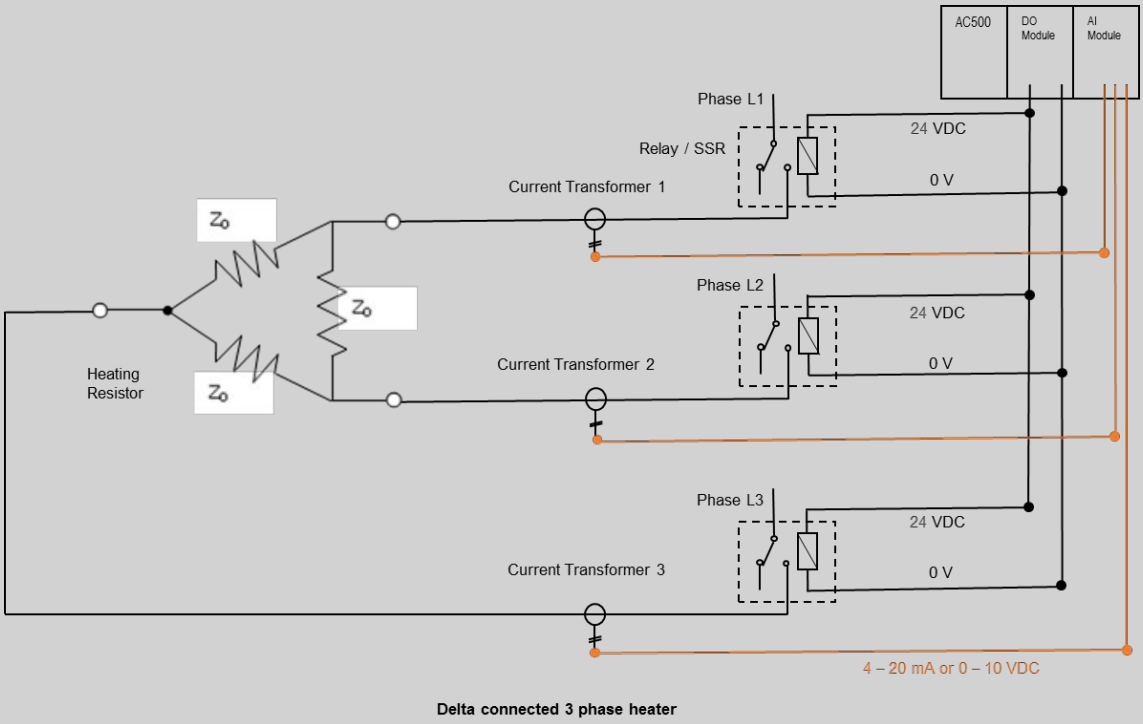

Fig. 593: Individual current sensor for Delta connected three phase heater

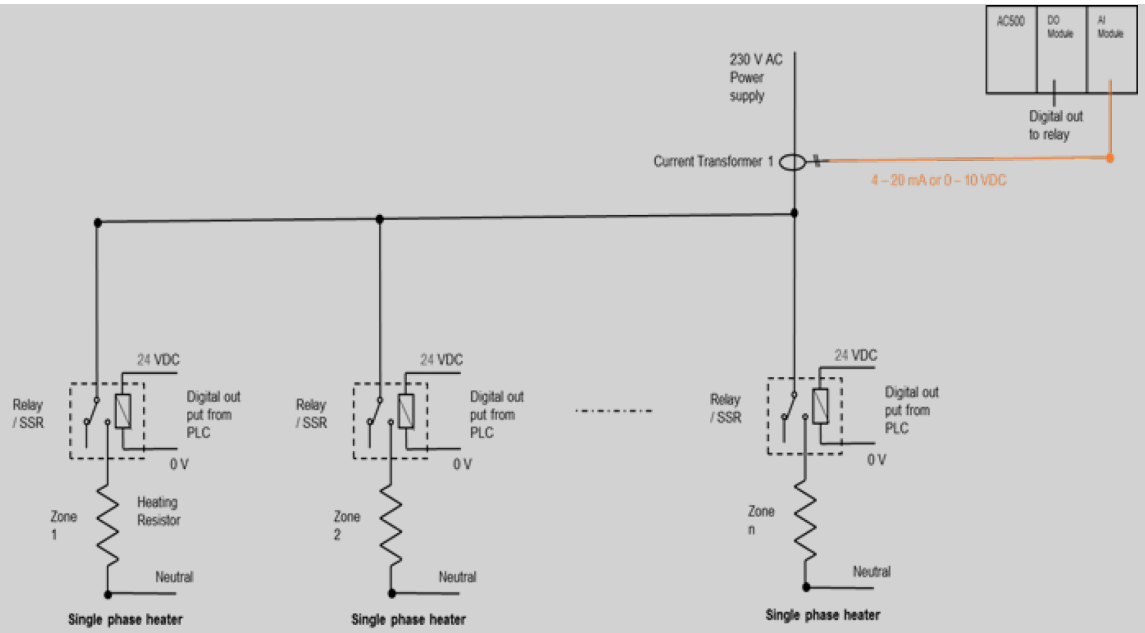

Fig. 594: Common current sensor for single phase heaters

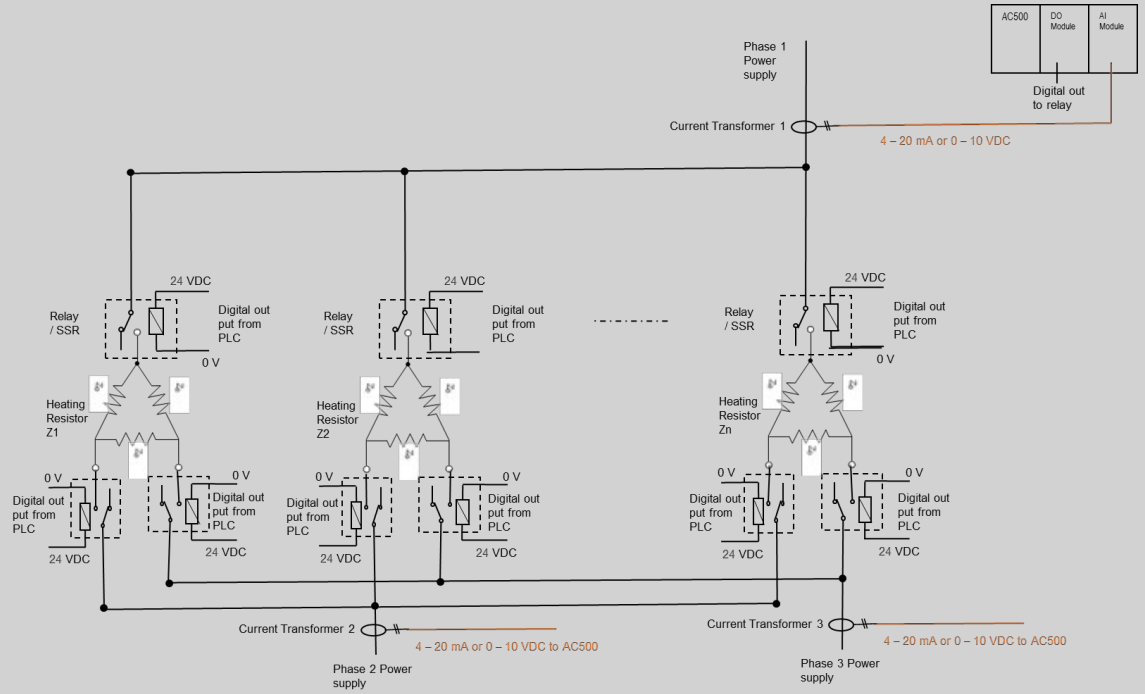

Fig. 595: Common current sensor for Delta connected three phase heater

Individual current sensor monitoring

Individual current sensor is connected to each zone. If three phase zone is used then three current sensors are required for zone, one for each phase. User needs to define following variables for individual current monitoring.

Selecting single or three phase current monitoring:

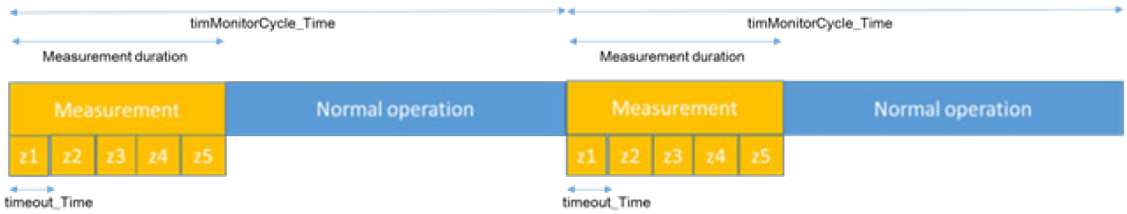
System will understand whether single or three phase heaters are used using “TECT_PROCESS_SET_TYPE“ structure “wControlWord“ variable bit 14. If this bit is turned ON then it means three phase current monitoring is selected else single phase current monitoring is selected.

xEn_Indivi_Monitor: User must set “xEn_Indivi_Monitor“ variable TRUE in the group data to turn on current monitoring feature for individual current sensor.

rRated_Current: User should use this variable from “TECT_MACHINE_SET_TYPE “ structure for connecting rated current of the heater. For 3 phase heaters same rating is used for balancing. Hence only one varaible for rated current is sufficient for all three phases.

arActual_Current: User should use this variable from “TECT_MACHINE_STATUS_TYPE“ structure for connecting actual current measured from the sensor. If single phase heater is used then only first array element should be connected. For 3 phase heaters sensor input needs to be connected to 3 array elements respectively.

timMonitorCycle_Time: Monitor cycle can be defined in seconds by user in “ TECT_GROUP_DATA_TYPE“ structure variable. At the start of this duration Zones enter in current monitoring function. One after another zones are checked until all zones are checked. After this monitoring function is stopped, and control of the zones goes back to process till “timMonitorCycle_Time“ elapsed. On next cycle function will start monitoring from zone 1 again.



It is recommended that user should set a value around 150-300 seconds.

Each zone takes approx. 5 seconds time for current monitoring. Each monitoring cycle has 2 parts: current monitoring and process. It is recommended that process time should be at least twice the current monitoring. As a thumb rule we can calculate minimum monitoring time as timMonitorCycle_Time := Number of zones * 5 * 3

wErrors2: This variable in TECT_PROCESS_STATUS_TYPE structure shows current monitoring status of the zone. If error is condition is removed, then error will be removed and it does not require RESET.

timLastMeasurement: This variable in “TECT_GROUP_DATA_TYPE“ structure shows time taken by all the zones to complete monitoring function in the last measurement.

Common current sensor monitoring

Common current sensor is used for all the zones in the group. If three phase zones are used then three current sensors are required for each phase. User needs to define following variables for common sensor current monitoring.

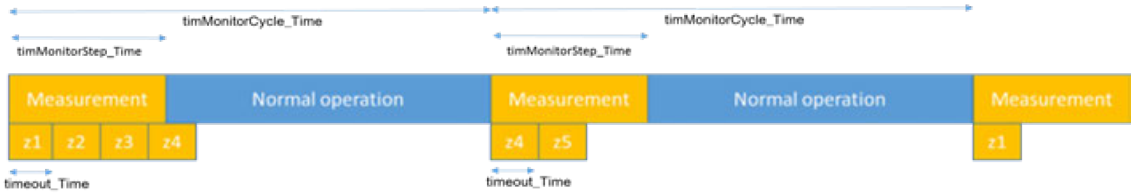
Selecting single or three phase current monitoring: System will understand whether single or three phase heaters are used using “TECT_PROCESS_SET_TYPE“ Structure “wControlWord“ variable bit 14. If this bit is turned on then it means three phase current monitoring is selected else single phase current monitoring is selected.

xEn_Co_Monitor: User can must set “xEn_Co_Monitor“ variable TRUE in the group data to turn on current monitoring feature for common current sensor.

rRated_Current: User should use this variable from “TECT_MACHINE_SET_TYPE “ structure for connecting rated current of the heater. For 3 phase heaters same rating is used for balancing. Hence only one variable for rated current is sufficient for all three phases.

arActual_Current: User should use this variable from “ TECT_GROUP_DATA_TYPE“ structure for connecting actual current measured from the sensor. If single phase heater is used then only first array element should be connected. For 3 phase heaters sensor input needs to be connected to 3 array elements respectively.

timMonitorCycle_Time: Monitor cycle can be defined in seconds by user in “ TECT_GROUP_DATA_TYPE“ structure varaiblevariable. At the start of this duration Zones enter in current monitoring function. One after another zones are checked untilluntil “timMonitorStep_Time“ is elapsed. After this monitoring function is stopped, zone number is stored internally and control of the zones goes back to process till “timMonitorCycle_Time“ elapsed. On next cycle monitoring function starts from internally stored zone number. Once all zones are checked, function will start monitoring from zone 1 again.



It is recommended that user should set a value around 150-300 seconds.

timMonitorStep_Time: Monitor cycle can be defined in seconds by user in “ TECT_GROUP_DATA_TYPE“ structure variable. In the monitoring cycle when this time is elapsed current monitoring function stops and control of the zones goes back to process.

wErrors2: This variable in TECT_PROCESS_STATUS_TYPE structure shows current monitoring status of the zone. If error is condition is removed, then error will be removed and it does not require RESET.

timLastMeasurement This variable in “TECT_GROUP_DATA_TYPE“ structure shows time taken by all the zones to complete monitoring function in the last measurement.

1.5.12.1.10 Explanation of zone data structure

Overview

Zone data values have been grouped into machine and process set, machine and process status, and internal status. This chapter contains details for the initial configurationset values of the Temperature Control system.

Set values / parameters

Process set values / parameters

TECT_PROCESS_SET_TYPE structure contains all the process related parameters.

This structure contains process set parameters of the zone data. User can define all parameters which are related to the process, i.e. parameters which are set as per process properties. These parameters will be changed continuously as per process requirement, e.g. in structure Control Word.

PID Set Point, Control Word, High Temp, Low Temp settings comes under this structure.

Control Word (wControlWord)

The Control Word setting will define the working of the machine / process. The user needs to set the Control Word bits per requirements .These settings will decide the working philosophy of the machine. The user also needs to decide which parameters he want to set permanently and which parameter he wants to change frequently.

E.g. Heat_en and Cool_en can be set permanently and Enable can be used to turn on and off the temperature zone.

- Enable (Bit 0):
  When this is TRUE, it will enable the process of temperature control. If this bit is FALSE, the complete process will stop and wait for next on command in Ready State.
- Heat_en (Bit 1):
  It will enable the zone as heat zone and the heating process starts when the duty cycle is greater than 0.
- Cool_en (Bit 2):
  It will enable the zone as a cooling zone and the cooling process starts when duty cycle is greater than 0.
- Manual_en (Bit 3):
  This is the highest priority mode. When this is TRUE, all the other modes are disabled and the manual control becomes active.
- Standby_en (Bit 4):
  When this bit is TRUE, the Standby set point becomes an active set point for the process.
- Tune_en (Bit 5):
  It will enable the auto tune process for the system using a tune step. It will start the tuning of the zone and calculate the optimal KP, TI, TD and T1 values.
- Accept_auto_tune (Bit 6):
  If the TRUE system will accept the calculated auto tune parameters.
- Co_Output (Bit 7):
  When this bit is TRUE, it will consider coordinated output for the particular group. It avoids switching on all zones simultaneously, thus avoiding a voltage drop in the power supply system. At the same time, it compensates the error between digital outputs and duty cycle due to CPU task cycle.
- Control Optimization (Bit 10, Bit 9):
  A combination of these two bits decide the working principle for the PID control.
  – 00 – APERIODIC:
  – 01 – OVERSHOOT:
  – 10 – DEADTIME COMPENSATION:
  – 11 – Default: APERIODIC
- Warm_Reset (Bit 13):
  When this bit is TRUE, it will reset the all alarms and process in the zone, but it will retain the auto tune status.
- En_3Phase_Monitor (Bit 14):
  When this bit is true, 3 phase current monitoring is enabled. If false, then single phase current monitoring is enabled.
- Cold_Reset (Bit 15):
  When this bit is TRUE, it will reset everything in the control process and the Status Word of the process will become zero. Auto tune has be carried out once again for the zone, as auto tune values have been reseted by cold reset.

PWM output in Manual mode. The Manual duty cycle needs to be set by the user when the manual mode (i.e. control word bit 3) is enabled for the process.

In the Manual mode the Manual duty cycle is passed on as a process duty cycle. That means the process duty cycle is not dependent on the set point and actual temperature. If not monitored properly, this can lead to accident.

Set Point (rSet-Point):

This is a secondary process set point which has to be set by the user. This value is considered for the process when Standby_en (control word bit 4) is TRUE.

Standby set point: (rStandBy_Set-Point): This is a secondary process set point which has to be set by the user, this value is considered for the process when Standby_en (control word bit 4) is TRUE

High Temperature (rHigh_Temp): The High Temperature value has to be set by the user as per process requirement. If the actual temperature becomes more than a High temperature, then the heat output is disabled and an alarm is generated.

Low Temperature (rLow_Temp): The Low Temperature value has to be set by the user as per process requirement. If the actual temperature becomes less than Low temperature, cool output is disabled and an alarm is generated.

High Deviation (rHigh_Deviation): If a difference between the actual value and the set value is more than the High Deviation, then an alarm is generated.

Low Deviation (rLow_Deviation): If a difference between the actual value and the set value is less than Low Deviation, then an alarm is generated.

Machine set values / parameters

TECT_MACHINE_SET_TYPE structure contains all the process related parameters.

This structure contains machine set parameters of the zone data. The user can define all parameters which are related to the machine, i.e. parameters which are set as per machine properties and will be defined only once at the time of commissioning. These parameters need to be changed, only when some machine property has changed, e.g. the temperature sensor has changed.

PID parameter, HighHigh, LowLow temp, and temperature sensors settings come under this structure.

Cool Factor (wCoolFact): Cool factor in percentage.

KP (rKP): PID parameter for the machine, P in Real value.

TI (rTI): PID parameter for control: I in seconds.

TD (rTD): PID parameter for control: Filter for D in seconds.

HighHigh Temperature (rHigh-High_Temp): This is the highest value of temperature the machine can reach and beyond that it could damage the system / machine. When this value is reached HighHigh Temperature fault will be generated, the control state will be in Fault state and all the outputs are disabled.

LowLow Temperature (rLowLow_Temp): This is the lowest value of temperature the machine can reach and below that value it can damage the system / the machine. When this value is reached, LowLow Temperature error is generated, the control state will be in Fault state and all the outputs are disabled.

Change time (uiChange_Time): For the TC_FAULT_2 the time (in seconds) is taken to register the Minimum temperature change when the duty cycle is greater than or equal to tune output value.

Minimum Temperature Change (uiMin_Temp_Change):	For the TC_FAULT_2 the Minimum Temperature Change, that can happen in the change time, is assigned when the duty cycle is greater than or equal to tune output value.
TC_Max (rTc_Max):	It corresponds to the maximum measurement range of the temperature sensor. When the temperature of the zone reaches this value the fault TC_FAULT_1 is generated.
TC_Min (rTc_Min):	It corresponds to the minimum measurement range of the temperature sensor. When the temperature of the zone reaches this value the fault TC_FAULT_1 is generated.
Temperature Difference Cool (rTemp_Diff_Cool):	If value > 0: cooling will be ON with 100% when ACT_TEMP > set point + rtemp_diff_cool, and will be OFF when ACT_TEMP < set point + rtemp_diff_cool x iCool_Off_Ratio. If value = 0: rtemp_diff_cool is deactivated, PID controller will be active for cooling.
Cool Off Ratio (iCool_Off_Ratio):	To be used with rTemp_Diff_Cool. ↳ *"Temperature Difference Cool (rTemp_Diff_Cool):" on page 3309*
Maximum Output (iMax_Output):	This input defines the maximum value of the duty cycle for the respective zone.
Tune Setpoint (iTune_Step):	Necessary temperature change in raw sensor value for auto tune process.
Tune Output (iTune_Output):	PWM duty cycle which is used during tuning.
Tune Minimum P (rTune_MinP):	Minimum allowable KP value for the auto tune to accept.
Tune Maximum P (rTune_MaxP)	Maximum allowable KP value for the auto tune to accept.
Tune P Multiplier (rTune_PMult):	Scaling for calculating KP value after tuning.
TC Offset (rTc_Offset):	Compensation for the thermocouple in degree.
Period Factor (rPeriod_Fact):	Period factor for cooling against heating.
Minimum Cool on Time (timMin_Cool_On):	Minimum time for which xDO_Cool output is ON.
Feed Forward Time Ratio (iFF_Time_Ratio):	Feed forward time ratio in percentage for internal set point ramp generator. The smaller the value, the steeper is the ramp.
Rated current (rRated_Current):	Rated current of phase 1, 2 and 3 of zone. Heaters have same current rating for all 3 phases.

1.5.12.2 Function blocks

Overview of the PS564-TEMPCTRL package

The temperature control library package (PS564-TEMP_CTRL) designed for the demand of advanced temperature control for critical processes, which need precise temperature control and e.g. adaptive tuning for ease of handling and changing environmental or process conditions. The package consists of libraries and examples. This document describes the function blocks of the main library TECT_TEMP_CONTROL_V24.lib. All other library files: (ADCTRL_AC500_V24.lib, TECT_EXT_AC500_V24.lib and TECT_EXT_AC500_V24…obj) are internal and need not be called by the end user.

Table 198: Overview of function blocks

Function Block	Description	Use Range
TECT_TEMP_CONTROL	Temperature control function block.	For one zone
TECT_LOG_FILE	Logging of process value change.	For entire system
TECT_TEMP_SIMU	Temperature zone simulation.	For one zone
TECT_NOISE_FILTER	Filter for short time noise.	For one zone
TECT_GROUP	Temperature control function block for a group	For one group
TECT_PWM8	Coordination of PWM outputs up to 8 zones.	For up to 8 zones
TECT_RECIPE	Read/Write recipe data in a file.	For entire system
TECT_DATA_FLASH	Read/Write/Delete AutoTune data on flash.	For entire system
TECT_HMI_MUX	Manage data transfer of active group to be monitored on operating HMI.	For entire system
TECT_SYSTEM	Function block for system fault monitoring, system control and zone information.	For entire system

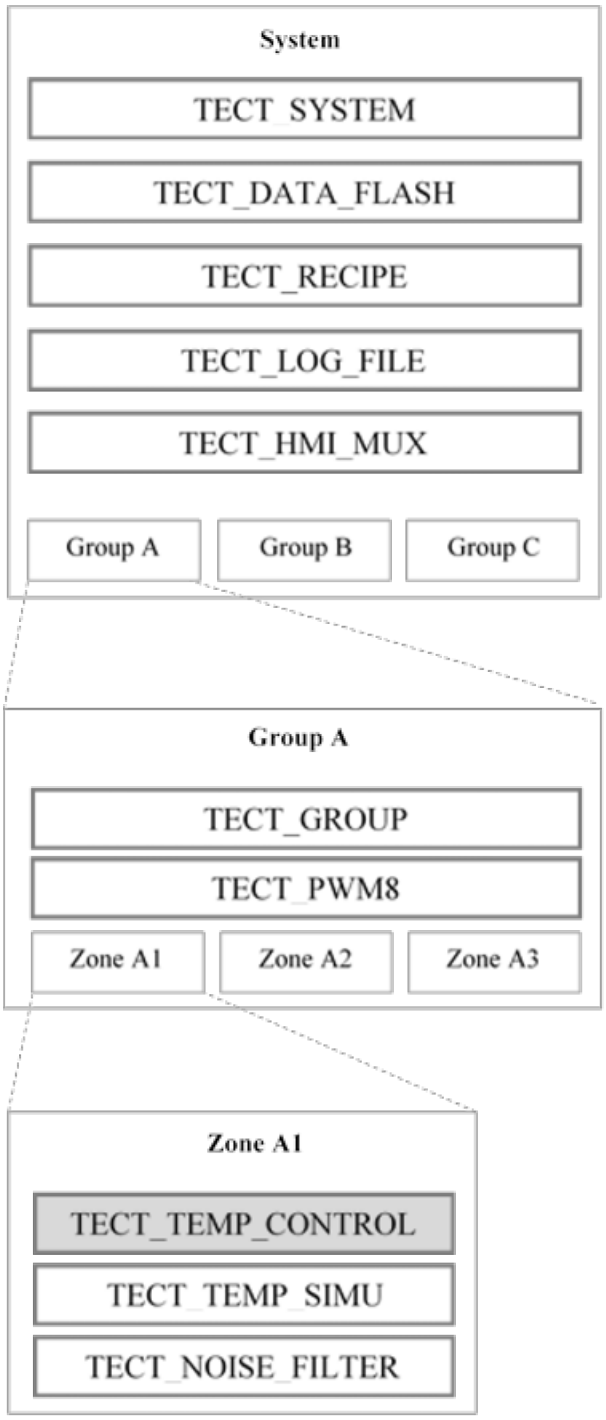


Fig. 596: Overview: Function blocks

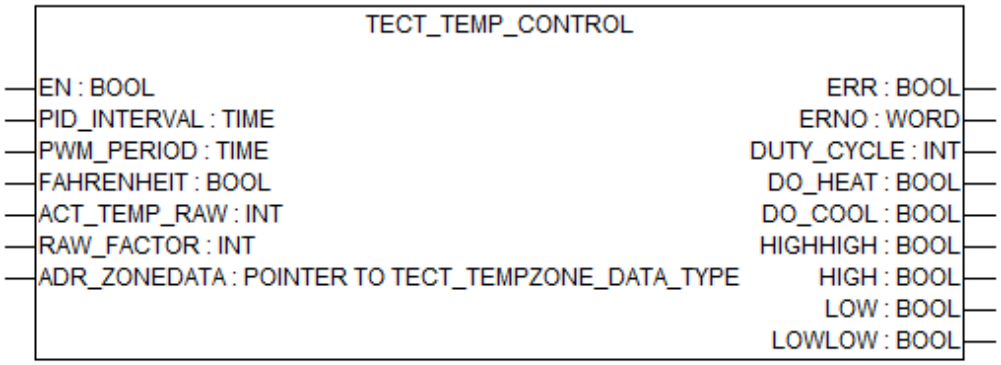
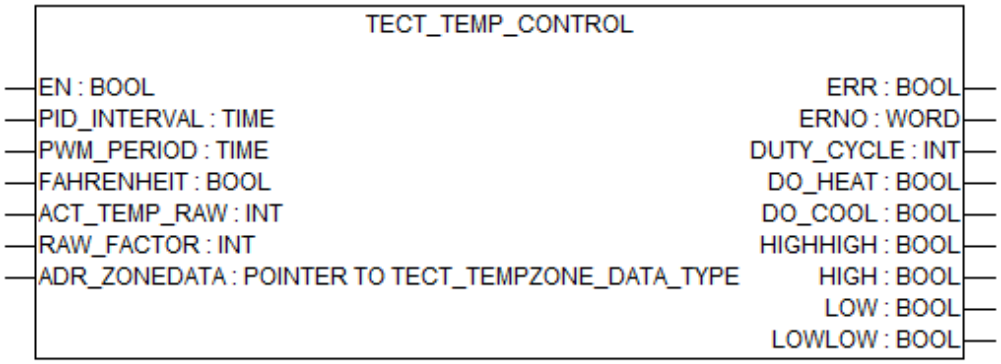
- Function blocks must be used.
- Optional function blocks.

1.5.12.2.1 TECT_TEMP_CONTROL



TECT_TEMP_CONTROL is the main control function block of temperature control process. An input variable ADR_ZONEDATA saves all relevant parameters, settings and values for one temperature zone. All function block for the zone interact with each other through ADR_ZONEDATA variable.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PID_INTERVAL Data type: TIME, Range: > 1 ms, Default value: 2 s.

Interval of PID and AutoTune process.

For PID process: The interval time, at which the PID updates the duty cycle of output based PWM_PERIOD.

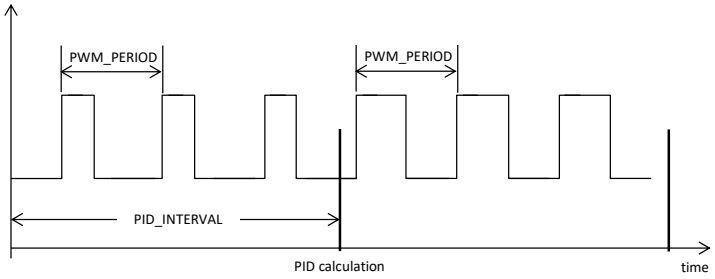


Fig. 597: PID Interval time

PWM_PERIOD Data type: TIME, Range: > 1 ms, Default value: 2 s.

Pulse Width Modulation (PWM) output period.

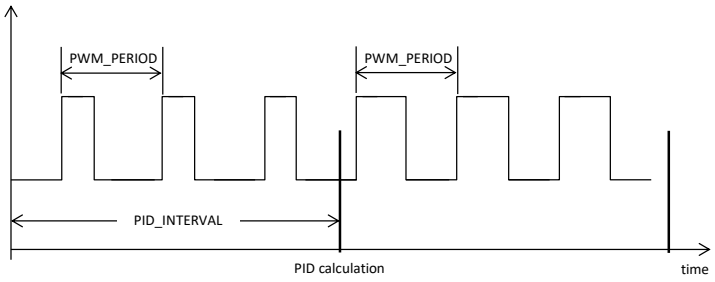

Fig. 598: PWM output period

> *PWM_PERIOD should be always less than or equal to PID_INTERVAL.*

FAHRENHEIT Data type: BOOL

A TRUE at the input FAHRENHEIT of the Funktion Block displays the temperature in Fahrenheit, a FALSE displays the temperature in Celsius.

ACT_TEMP_RAW Data type: INT

Actual raw temperature value from analogous input sensor.

RAW_FACTOR Data type: INT, Default value: 10.

Sensor provides the the ACT_TEMP_RAW, this value doesn't match to the temperature in Celcius. Hence RAW_FACTOR is necessary to scale the temperature into Celsius scale.

Example for RAW_FACTOR If ACT_TEMP_RAW is 200 which indicates 20 degree, then the RAW_FACTOR will be 200 / 20 = 10.

> *The RAW_FACTOR should not be zero.*

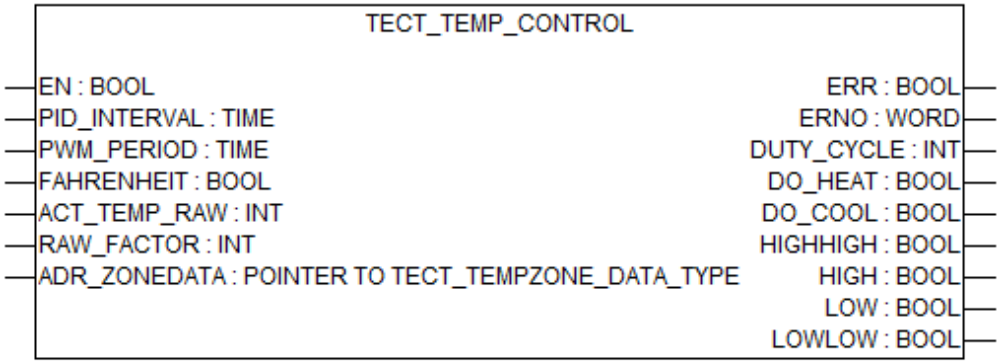
ADR_ZONE-DATA

Data type: POINTER TO TECT_TEMPZONE_DATA_TYPE

POINTER TO ZONEDATA defined as TECT_TEMPZONE_DATA_TYPE.

Input as POINTER TO ZoneData. This variable can be connected to the output signal of the ADR-Block. An input variable ZoneData saves all relevant parameters, settings and values for one temperature zone. All function blocks for the zone interact with each other through ZoneData variable *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*.

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

DUTY_CYCLE

Data type: INT

PWM (Pulse Width Modulation) output DUTY_CYCLE is displayed in percentage.

Positive value indicates heating, negative value indicates cooling.

DO_HEAT

Data type: BOOL

Pulse output for heating process. This variable can be connected to the digital output signal.

DO_COOL

Data type: BOOL

Pulse output for cooling process. This variable can be connected to the digital output signal.

HIGHHIGH Data type: BOOL

This variable is TRUE, when output HIGHHIGH temperature error is active. The limit value is declared in the data type TECT_TEMPZONE_DATA_TYPE. *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

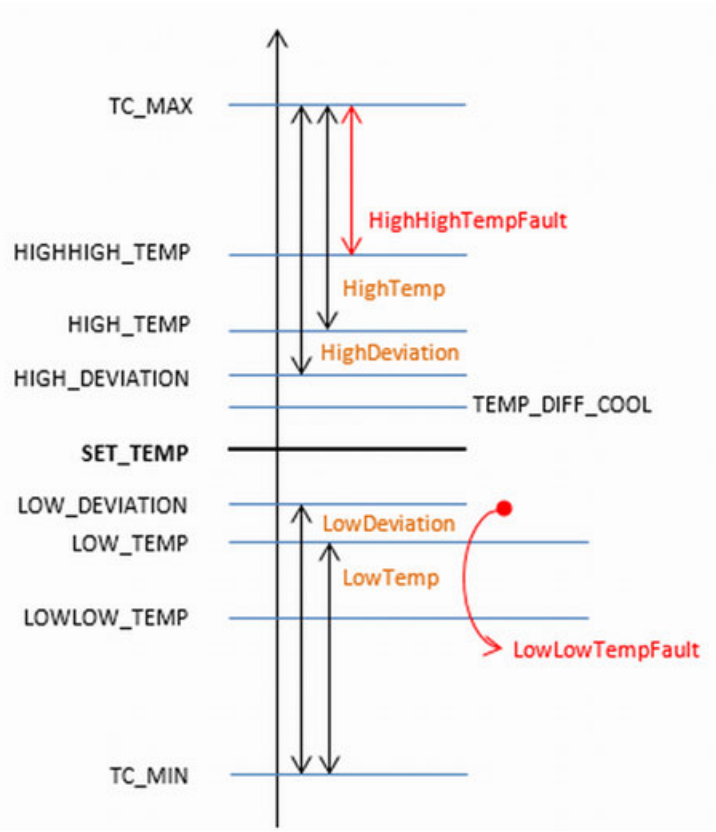


Fig. 599: High temperature alarm and HighHigh temperature fault.

HIGH Data type: BOOL

This output variable is TRUE, when HIGH temperature alarm is active. The limit value is declared in the data type TECT_TEMPZONE_DATA_TYPE. *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

LOW Data type: BOOL

This output variable is TRUE, when low temperature alarm (LOW_TEMP) is active. The limit value is declared in the data type TECT_TEMPZONE_DATA_TYPE. *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

Example for LowTemp alarm and LowLowTempFault alarm.

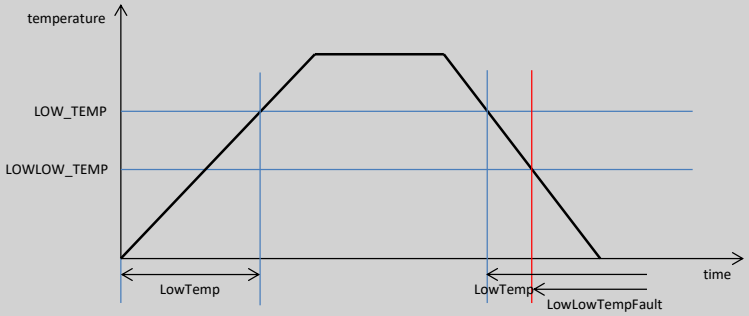

Fig. 600: LowTemp alarm, LowLowTempFault alarm

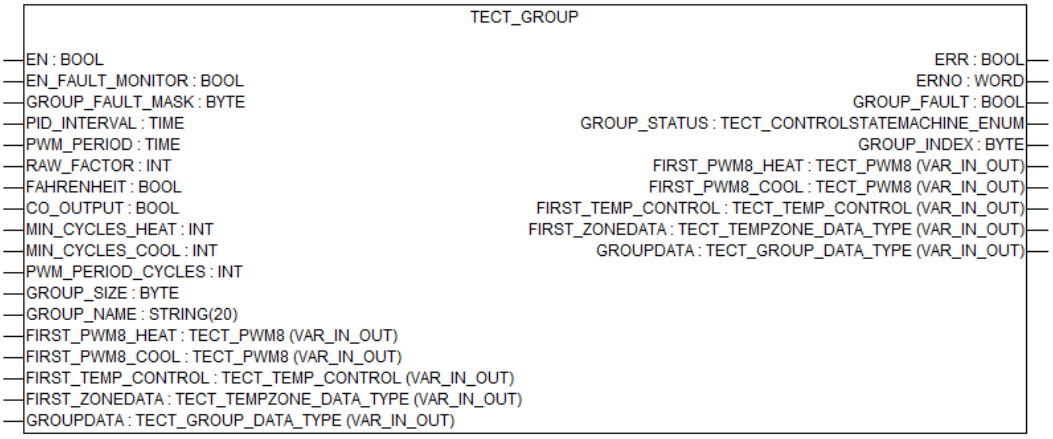
LOWLOW Data type: BOOL

This output variable is TRUE, when LOWLOW temperature error is active. Limit value is declared in the data type TECT_TEMPZONE_DATA_TYPE. ↳ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

1.5.12.2.2 TECT_GROUP

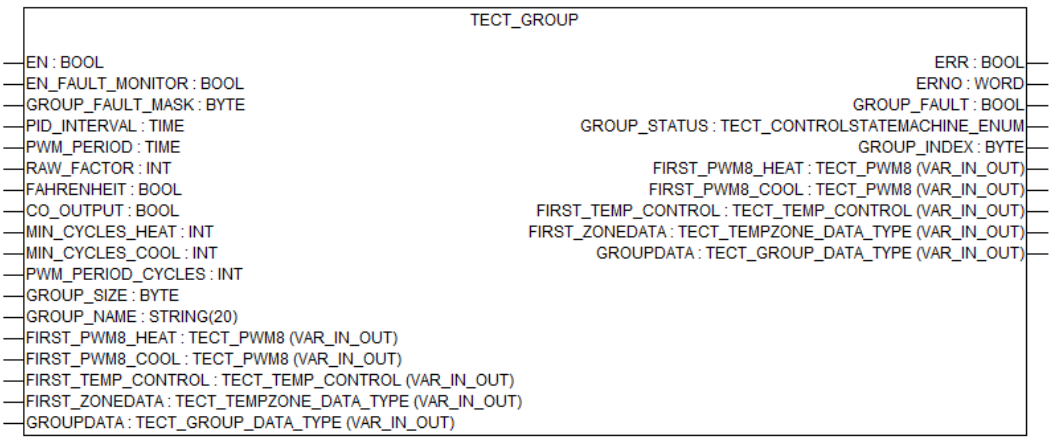


Function block TECT_GROUP realizes the following functions:

- Group fault monitoring.
- Group control: enable process, reset process, enable AutoTune.
- Coordinated output of the zones in the group.

Function block TECT_GROUP calls the function block TECT_TEMP_CONTROL for each zone internally. Thus a separate call of function block TECT_TEMP_CONTROL for each zone is not necessary. Function block TECT_GROUP also calls separately Funktion Block TECT_PWM8 for heating and cooling.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

EN_FAULT_MONITOR

Data type: BOOL

A TRUE at the input enables group fault monitoring.

A FALSE at the input disables group fault monitoring.

Group monitoring of faults is predefined through input GROUP_FAULT_MASK.

GROUP_FAULT_MASK

Data type: BYTE, Default value: 2#00001111

The first four Bits stand for four different error sources:

Bit 0: TC_Fault 1

Bit 1: TC_Fault2

Bit 2: HighHighTempFault

Bit 3: LowLowTempFault

This means, all of the four faults are monitored as group fault. Before enabling the group of zones of the function block TECT_GROUP, define the faults to be masked.

PID_INTERVAL

Data type: TIME, Range: > 1 ms, Default value: 2 s.

Interval of PID and AutoTune process.

For PID process: The interval time, at which the PID updates the duty cycle of output based PWM_PERIOD.

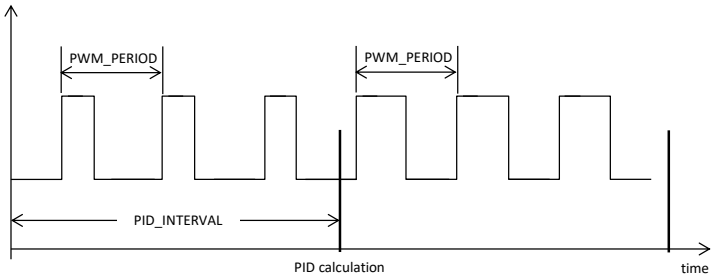


Fig. 601: PID Interval time

PWM_PERIOD

Data type: TIME, Range: >T#1 ms, Default value: T#2 s.

Pulse Width Modulation (PWM) output period.

PWM_PERIOD should be always less than or equal to PID_INTERVAL.

RAW_FACTOR Data type: INT, Default value: 10.

Sensor provides the the ACT_TEMP_RAW, this value doesn't match to the temperature in Celcius. Hence RAW_FACTOR is necessary to scale the temperature into Celsius scale.

Example for RAW_FACTOR If ACT_TEMP_RAW is 200 which indicates 20 degree, then the RAW_FACTOR will be 200 / 20 = 10.

The RAW_FACTOR should not be zero.

FAHRENHEIT Data type: BOOL

A TRUE at the input FAHRENHEIT of the Funktion Block displays the temperature in Fahrenheit, a FALSE displays the temperature in Celsius.

CO_OUTPUT Data type: BOOL

The Input CO_OUTPUT enables coordinated output for PWM8 output of a group. It avoids switching on all zones simultaneously, thus avoiding a voltage drop in the power supply system. At the same time, it compensates the error between digital outputs and duty cycle due to CPU task cycle (as resolution of digital outputs duration). The coordination is realized with function block TECT_PWM8 , called internally.

Input FIRST_PWM8_HEAT and FIRST_PWM8_COOL define the data area of the FIRST_TECT_PWM8 input for heating and cooling. Each function block TECT_PWM8 supports maximum 8 zones. For more than 8 zones, two arrays of function block TECT_PMW8 must be defined for heating and cooling accordingly. If CO_OUTPUT is not used (FALSE), then one dummy variable still needs to be defined for both Inputs FIRST_PWM8_HEAT and FIRST_PWM8_COOL.

MIN_CYCLES_HEAT Data type: INT, Default value = 1, Range: > 0.

Minimum length of ON and OFF time of PWM signal in number of CPU task cycles for heating.

Example Minimum length = 100 ms; CPU task cycle = 50 ms, then the number of cycles for heating is T_MIN_TZ_HEAT = 100 ms / 50 ms = 2.

MIN_CYCLES_COOL Data type: INT, Default value = 2, Range: > 0.

Minimum length of ON and OFF time of PWM signal in number of CPU task cycles for cooling.

Example Minimum length = 100 ms; CPU task cycle = 50 ms, then the number of cycles for heating is T_MIN_TZ_HEAT = 100 ms / 50 ms = 2.

PWM_PERIOD_CYCLES Data type: INT, Default value = 20, Range: > MIN_CYCLES HEAT and MIN_CYCLES_COOL.

Duration of PWM signal period in number of CPU task cycles.

Example	PWM_PERIOD = 1 s, CPU task cycle = 50 ms, then the number of task cycles is PERIOD_TZ = 1 s / 50 ms = 20.

GROUP_SIZE Data type: BYTE, Default value: 1, Range: > 0.

Size of the group or total number of zones in the particular group.

GROUP_NAME Data type: STRING[20]

The name of the group. It will be saved in TECT_TEMPZONE_DATA_TYPE structure.
↳ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

FIRST_PWM8_HEAT Data type: TECT_PWM8

First instance of function block TECT_PWM8 for heating in the declaration. Each instance supports maximum 8 zones. The function block TECT_PWM8 is called internally. If more instances are needed for one group, they must be defined in an array. If the coordinated output is not used, a dummy instance is still needed. Please see also description of input CO_OUTPUT
↳ *Chapter 1.5.12.2.6 “TECT_PWM8” on page 3327*.

All instances must be defined without memory break. It is highly recommended to define them in an array.

FIRST_PWM8_COOL Data type: TECT_PWM8

First instance of function block TECT_PWM8 for cooling in the declaration. Each instance supports maximum 8 zones. The function block TECT_PWM8 is called internally. If more instances are needed for one group, they must be defined in an array. If the coordinated output is not used, a dummy instance is still needed. Please see also description of CO_OUTPUT ↳ *Chapter 1.5.12.2.6 “TECT_PWM8” on page 3327*.

All instances must be defined without memory break. It is highly recommended to define them in an array.

FIRST_TEMP_CONTROL data type: TECT_TEMP_CONTROL

First instance of function block TECT_TEMP_CONTROL in the declaration. Each zone in the group needs one instance. The function block TECT_TEMP_CONTROL is called internally. Thus a separate call of function block TECT_TEMP_CONTROL for each zone is not necessary
↳ *Chapter 1.5.12.2.1 “TECT_TEMP_CONTROL” on page 3312*.

All instances must be defined without memory break. It is highly recommended to define them in an array.

FIRST_ZONE-DATA Data type: TECT_TEMPZONE_DATA_TYPE

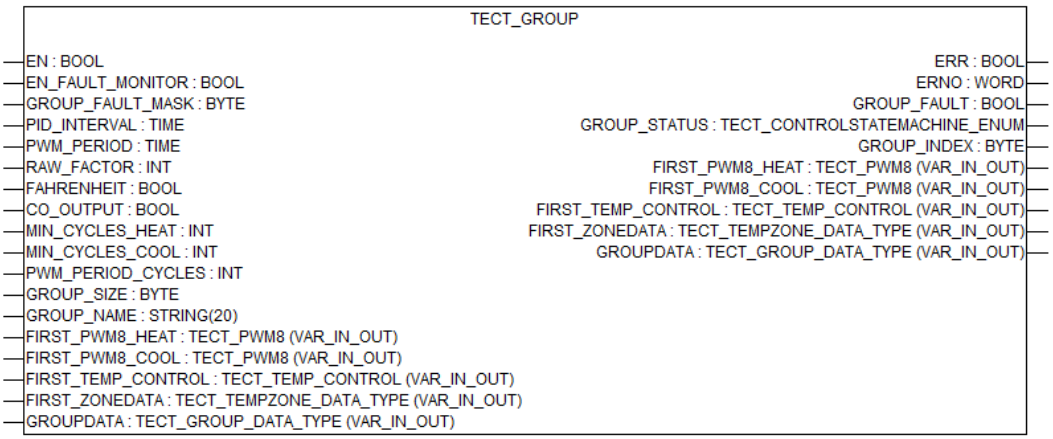
Monitoring of the first zone data structure of the zone group. ↳ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

> *All zones must be declared one after another without break. It is highly recommended to define an array of TECT_TEMPZONE_DATA_TYPE for the whole system.*

GROUPDATA Data type: TECT_GROUP_DATA_TYPE

This inout structure of the group will have variables related to the complete group *Chapter 1.5.12.3.4 “TECT_GROUP_DATA_TYPE” on page 3352*.

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

GROUP_FAULT Data type: BOOL

A TRUE at the output activates GROUP_FAULT. This will be TRUE only when input EN_FAULT_MONITOR is enabled. It leads to disable the outputs of the whole group.

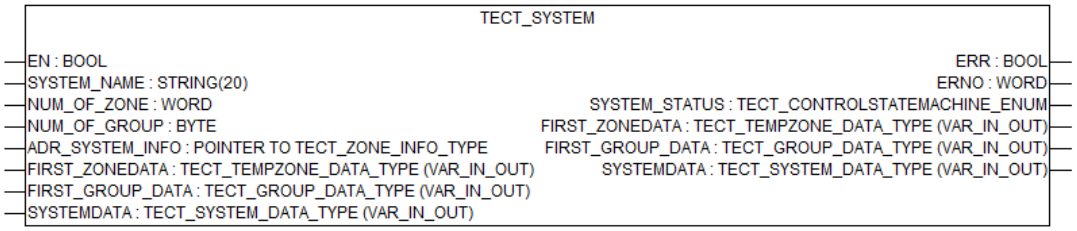
GROUP_STATUS Data type: TECT_CONTROLSTATEMACHINE_ENUM

All status related to the group will be updated to each zone by the enumeration TECT_CONTROLSTATEMACHINE_ENUM *Chapter 1.5.12.3.7 “TECT_CONTROLSTATEMACHINE_ENUM” on page 3357*.

GROUP_INDEX Data type: BYTE

This is the variable which differentiate each group by unique number.

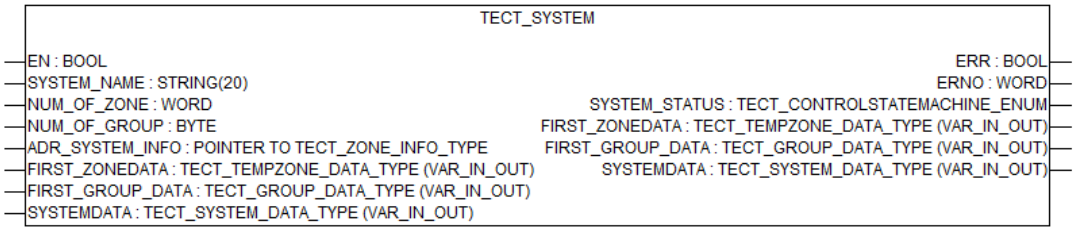
1.5.12.2.3 TECT_SYSTEM



The inputs marked with a triangle are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

The function block TECT_SYSTEM can be used to configure and monitor all groups and zones in the temperature control system. Status of the groups and zones in the system can be monitored. Using the structure TECT_SYSTEM_DATA *Chapter 1.5.12.3.5 “TECT_SYSTEM_DATA_TYPE” on page 3355* different operations for all groups/zones can also be configured.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SYSTEM_NAME Data type: STRING[20]

Configuration of system name. The name does not exceed 20 characters.

NUM_OF_ZONE Data type: WORD, Default value: 1, Range: > 0.

Total number of zones in the system.

NUM_OF_GROUP Data type: BYTE, Default value: 1, Range: > 0.

Number of groups to be operated in the system.

ADR_SYSTEM_INFO Data type: POINTER TO TECT_ZONE_INFO_TYPE.

It will point to the structure TECT_ZONE_INFO_TYPE ↳ *Chapter 1.5.12.3.6 “TECT_ZONE_INFO_TYPE” on page 3356*.

All zones must be declared one after another without break. It is highly recommended to define an array of TECT_ZONE_INFO_TYPE for one groupthe whole system, Maximum size of the array should be total number of zones in the system.

FIRST_ZONE-DATA Data type: TECT_TEMPZONE_DATA_TYPE

Monitoring of the first zone data structure of the zone group. ↳ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

All zones must be declared one after another without break. It is highly recommended to define an array of TECT_TEMPZONE_DATA_TYPE for the whole system.

FIRST_GROUP-DATA Data type: TECT_GROUP_DATA_TYPE

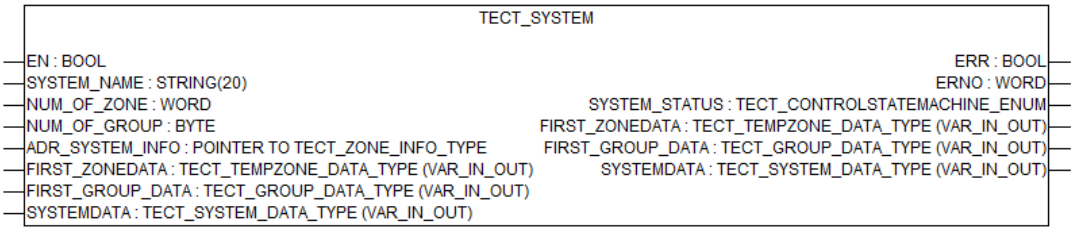
First GROUPDATA of the system in the declaration. All groups must be declared one after another without break ↳ *Chapter 1.5.12.3.4 “TECT_GROUP_DATA_TYPE” on page 3352*.

All groups must be declared one after another without break. It is highly recommended to define an array of TECT_GROUP_DATA_TYPE for one system.

SYSTEMDATA Data type: TECT_SYSTEM_DATA_TYPE

Declaration of data which is common to the complete system ↳ *Chapter 1.5.12.3.4 “TECT_GROUP_DATA_TYPE” on page 3352*.

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

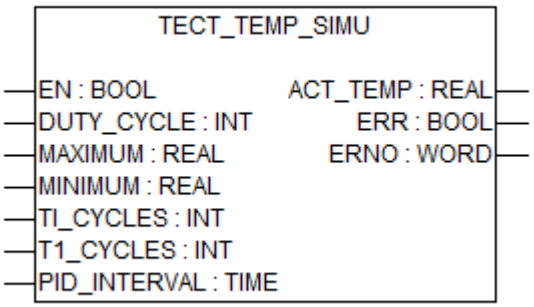
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

SYSTEM_STATUS

Data type: TECT_CONTROLSTATEMACHINE_ENUM

The status of the system including its zones and groups is updated to the enumeration TECT_CONTROLSTATEMACHINE_ENUM *Chapter 1.5.12.3.7 “TECT_CONTROLSTATE-MACHINE_ENUM” on page 3357*.

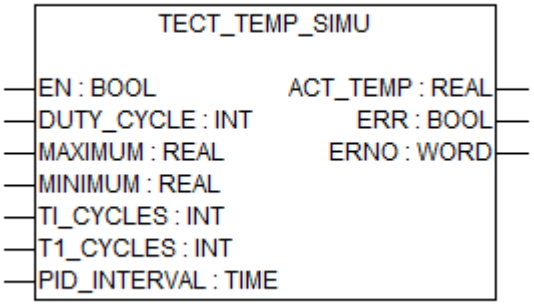
1.5.12.2.4 TECT_TEMP_SIMU



The function block TECT_TEMP_SIMU simulates a temperature zone, e.g. for simulation of the behavior during commissioning.

Connect DUTY_CYCLE input to DUTY_CYCLE output of TECT_TEMP_CONTROL function block. The ACT_TEMP outputs data of the simulated zone temperature.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

DUTY_CYCLE Data type: INT, Range: -100 ... +100, Default value: 0

The PWM duty cycle is for one temperature zone. The structure TECT_TEMP-ZONE_DATA_TYPE defines the duty cycle parameters. ↳ *Chapter 1.5.12.3.1 “TECT_TEMP-ZONE_DATA_TYPE” on page 3343*

MAXIMUM Data type: REAL, Default value: 0

Preset maximum temperature allowed for the simulation. The raw temperature value should be used as in function block TECT_TEMP_CONTROL.

> *Input MAXIMUM should be greater than input MINIMUM.*

MINIMUM Data type: REAL, Default value: 0

Preset minimum temperature allowed for the simulation. The raw temperature value should be used as in function block TECT_TEMP_CONTROL.

> *Input MINIMUM should be less than input MAXIMUM.*

TI_CYCLES Data type: INT

Internal control parameter for simulation. It has similar value as TU from structure TECT_INTERNAL_STATUS_TYPE. ↳ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

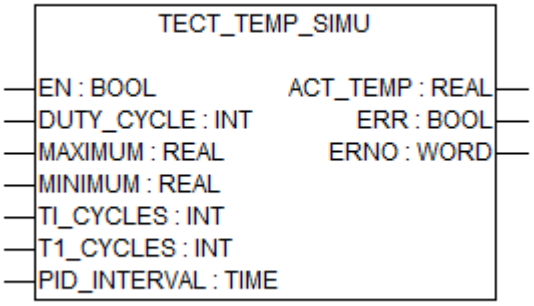
T1_CYCLES Data type: INT, Range: > 0, Default value: 20

Internal control parameter for simulation. It has a similar value as TG from structure TECT_INTERNAL_STATUS_TYPE. *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

PID_INTERVAL Data type: TIME, Range: >0 ms, Default value: 2 s

Interval of internal simulation control. Do the setting in the same way as for input PID_INTERVAL from function block TECT_TEMP_CONTROL *Chapter 1.5.12.2.1 “TECT_TEMP_CONTROL” on page 3312*.

Output description



ACT_TEMP (actual temperature) Data type: REAL

The output simulates the actual temperature.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

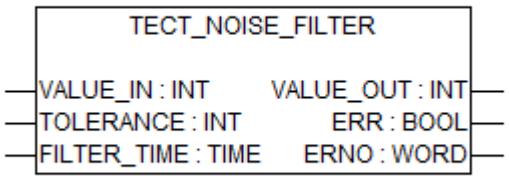
It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

1.5.12.2.5 TECT_NOISE_FILTER



The function block TECT_NOISE_FILTER can be used to filter the short disturbance on the sensor input. The VALUE_IN will be ignored, if the change of the value is greater than TOLERANCE for less than FILTER_TIME.

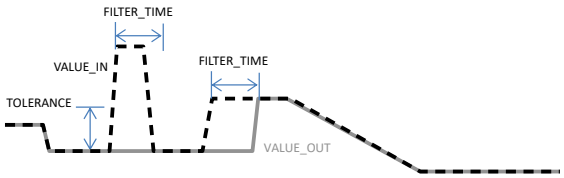


Fig. 602: Noise Filter

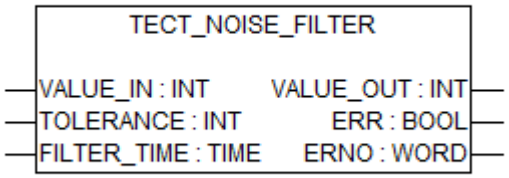
Input description



VALUE_IN Data type: INT

Input value from sensor to be filtered.

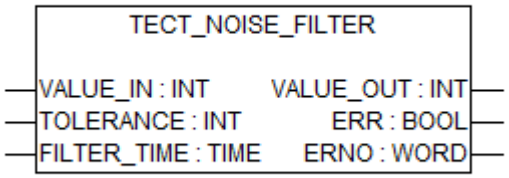
TOLERANCE Data type: INT, Default value: 0.

Tolerance for input value.

FILTER_TIME Data type: TIME, Default value: 0 s, Range: ≥ 0 ms.

Filter time.

Output description



VALUE_OUT Data type: INT

Output value after filtering. It is the input value for ACT_TEMP_RAW in function block TECT_TEMP_CONTROL .

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

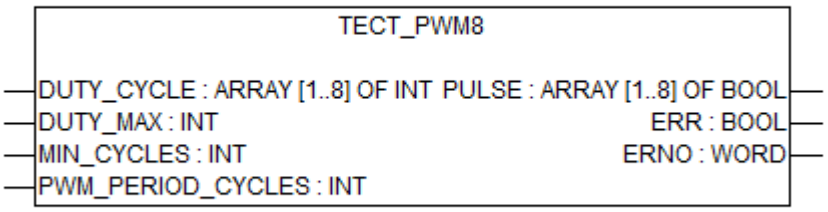
It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

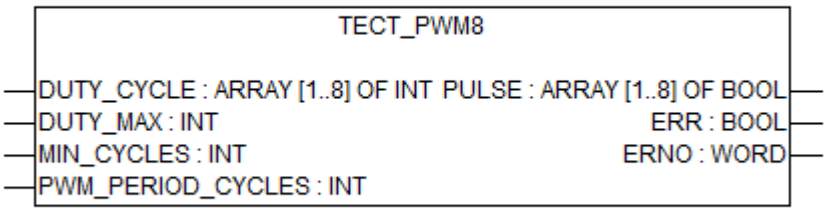
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

1.5.12.2.6 TECT_PWM8



The function block TECT_PWM8 coordinates up to 8 PWM signals in time behavior. They have not to be switched on at the same time to avoid undesired voltage drop in the power supply system. At the same time, it compensates the error between digital outputs and duty cycle due to CPU task cycle (as resolution of digital outputs duration). For heating and cooling separate instances of this block have to be used.

Input description



DUTY_CYCLE Data type: ARRAY[1..8] OF INT, Range: 0…100

PWM DUTY_CYCLE coordinates maximum 8 zones in a group. If there are more than 8 zones in one group, more function blocks can be used.

DUTY_MAX Data type: INT, Default value: 100, Range: +10 ... + 100.

Maximum value for a duty cycle.

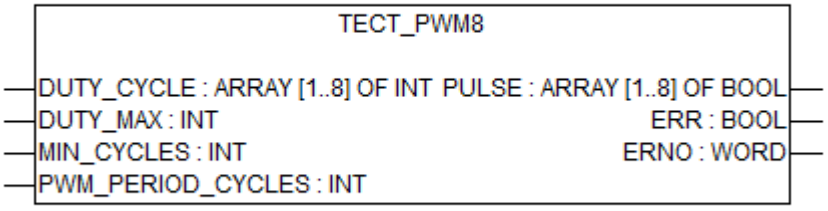
MIN_CYCLES Data type: INT, Default value: 1, Range: > 1.

Minimum length of ON and OFF time of PWM signal in number of CPU task cycles.

PWM_PERIOD_CYCLES Data type: INT, Default value: 20, Range: > MIN_CYCLES

Duration of PWM signal period in number of CPU task cycles.

Output description



PULSE Data type: ARRAY[1..8] OF BOOL

PWM signals for 8 zones.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

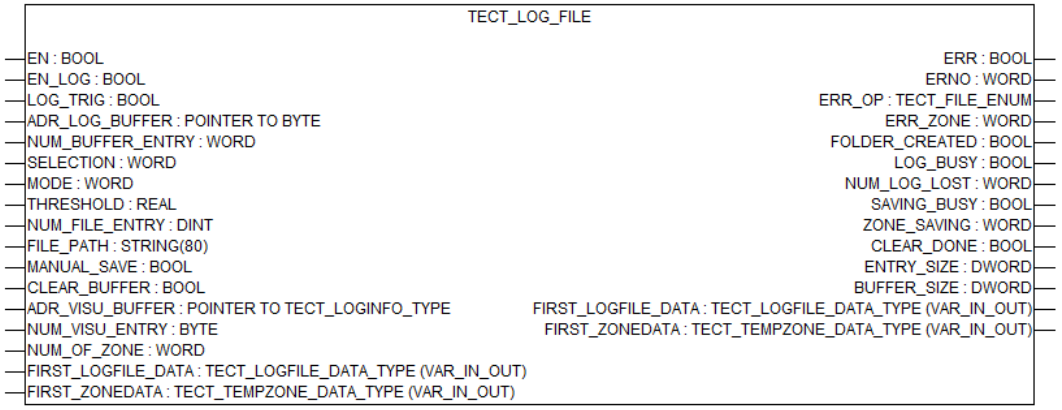
It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

1.5.12.2.7 TECT_LOG_FILE



Function block TECT_LOG_FILE logs the predefined process status and values together with time stamp in a logging buffer when trigger LOG_TRIG has a rising edge. To execute this block memory card is recommended for saving log files. The predefined process status and values are:

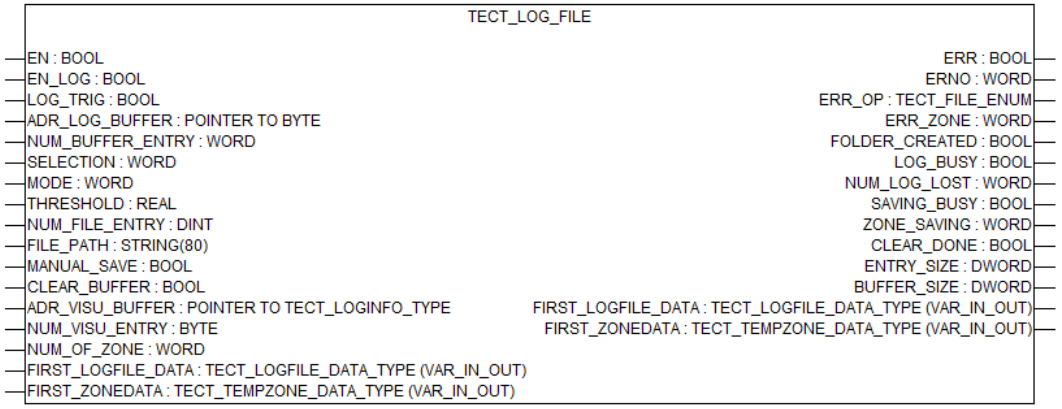
- Control Word
- Status Word
- SET_TEMP
- ACT_TEMP
- Duty Cycle
- Control State
- Output Status
- Latest Error
- Errors (Error Word).

Please see “Description of Structure TECT_TEMPZONE_DATA_TYPE” for details of the process status. *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

The logging buffer has a size of NUM_BUFFER_ENTRY (number of entries) for each zone. As long as the logging entry reaches the end of logging buffer, the entries in logging buffer will be saved as a log file in .csv format under a user defined folder. The file name is generated automatically from the zone index, its group index and the month and date value while saving. This log file can be opened in e.g. Excel with comma as delimiter and can be analyzed.

The second function of this function block is to display entries in logging buffer using CODESYS visualization as live log. This function block can be used not only to monitor the process but also for system diagnosis.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type: BOOL

The function block is activated by a TRUE at the input EN. It enables live logging visualization. With a rising edge, the folder to save log file is created. Depending on the MODE, a subfolder will be created for each zone. With a falling edge, clear logging buffer action is executed and backup file is created. After that, FOLDER_CREATED is reset to FALSE. See CLEAR_BUFFER and FOLDER_CREATED for details.

EN_LOG

Data type: BOOL

A TRUE at the input will enable logging to the buffer and copying of files from buffer to .csv file when buffer is full.

LOG_TRIG

Data Type: BOOL

A TRUE at the input executes logging a data entry into logging buffer with a rising edge.

ADR_LOG_BUFFER

Data type: POINTER TO BYTE

Start address of the logging buffer since this is POINTER TO BYTE. It is recommended to connect the input through ADR and point it to %RB area.

NUM_BUFFER_ENTRY

Data type: WORD, Range: 1 ... 65535, Default value: 100.

The size of logging buffer for each zone is the number of entries.

Following conditions to be checked to avoid data loss while logging in the buffe:

- *NUM_BUFFER_ENTRY should always be greater than NUM_OF_ZONE. Recommendation: NUM_BUFFER_ENTRY > NUM_OF_ZONE x 2.*
- *Interval of trigger for logging LOG_TRIG must be greater than one second.*
- *Monitor the output NUM_LOG_LOST for the logs/data lost in the buffer as indication of possible adaptation of log configuration.*

SELECTION Data type: WORD, Default value: 2#11111111.

Selection of predefined values to be logged: bit 0 to bit 8 indicates the current version.

Bit x = TRUE: the corresponding value will be logged.

- Bit 0: Control Word,
- Bit 1: Status Word,
- Bit 2: SET_TEMP,
- Bit 3: ACT_TEMP,
- Bit 4: Duty Cycle,
- Bit 5: Control State,
- Bit 6: Output State,
- Bit 7: Latest Error.
- Bit 8: Errors

MODE Data type: WORD, Default value: 2#00

Define different mode of logging.

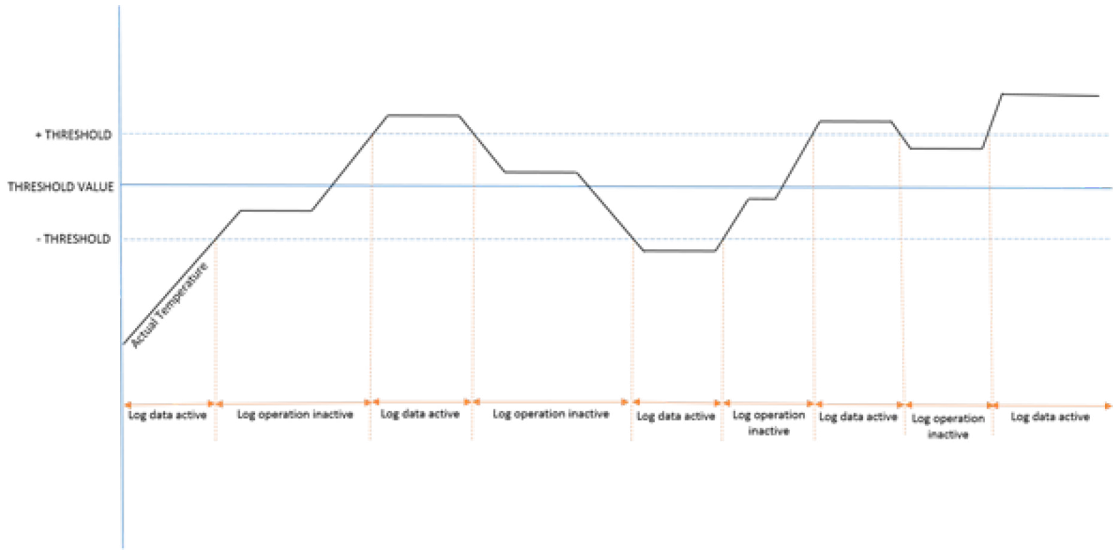
This table defines the different modes of logging:

- Bit 1, Bit 0: Log mode
  - 00: Log all items as long as log trigger is active.
  - 01: Log, if one of the log values changes, when trigger is active.
  - 11: Log, if CW or SW changes or ACT_TEMP changes out of threshold (+/- THRESHOLD), when trigger is active.
- Bit 4: Internal log trigger, TRUE: It will provide internal trigger to log the files. When Bit 4 is TRUE and there is change in Control word or Status word, a trigger signal will be created. It is a trigger additional to LOG_TRIG.
-
- Bit 8: FALSE: Create subfolder automatically; TRUE: Do not create subfolder.
- Bit 9: Valid, if bit 8 is FALSE.
  - FALSE: subfolder name with index in DECIMAL.
    For example, for group 10, index 3, subfolder name is G010Z003.
  - TRUE: subfolder name with index in HEXADECIMAL.
    For example, for group 10, zone 12, subfolder name is G0AZ0C.

THRESHOLD Data type: REAL

Threshold of actual temperature. Set the value in combination with MODE (log mode). Log operation will be active when acutal temperature is out of +/- of the Threshold value. See the below figure which explains when is active or inactive.

Bit 1-0: 11: Threshold of actual temperature.



NUM_FILE_ENTRY Data type: DINT, Range: >= 0, Default value: 0

The logging of data depends on the value of NUM_FILE_ENTRY input is assigned.

- If NUM_FILE_ENTRY = 0, then a new log file is created daily, previous day file is backed up with the same file name but a different suffix. The suffix is the last three HEX numbers of current time (without second).
- If NUM_FILE_ENTRY >0, a new file is created when number of log entries is equal to NUM_FILE_ENTRY defined. Old file will be backed up with the same file name but a different suffix. The suffix is the last three HEX numbers of current time (without second).
- If NUM_FILE_ENTRY <0, it is a invalid condition and function block will generate error 16#4090.

FILE_PATH Data type: STRING[80]

File Pathfor saving log file (followed with or without '/'), e.g. 'SDCARD/folder'. The physical disk like SDCARD or FLASHDISK must be specified in the FILE_PATH. The folder following will be created if it does not exist yet. But only one folder level will be created, this means the parent folder must already exist.

For Bit 8 of input MODE: FALSE: a subfolder will be created for each zone. The log files will be saved under FILE_PATH/subfolder. See MODE, bit 8 and bit 9 for details. It is recommended to save the log file on memory card.

MANUAL_SAVE Data type: BOOL

A rising edge at the input will save logging buffer to .csv log file manually.

CLEAR_BUFFER Data type: BOOL

A rising edge at the input clears the logging buffer: New entries in the logging buffer are written into the .csv file. The .csv file is renamed into a backup file with same file name but different extension. The extension is composed of the last three HEX Numbers of current time without seconds.

ADR_VISU_BUFFER Data type: POINTER TO TECT_LOGINFO_TYPE

Start address of the log visualization data. It is recommended to define the log visualization data in array. This can be used only with CODESYS visualization. For example, if there are 4 zones to be logged and each zone has 10 log visualization entries, then a one dimensional or two dimensional array can be defined ↬ *Chapter 1.5.12.3.3 "TECT_LOGINFO_TYPE" on page 3351*:

visu_array : ARRAY[1..40] OF TECT_LOGINFO_TYPE; (in one dimensional array).

visu_array : ARRAY[1..4, 1..10] OF TECT_LOGINFO_TYPE; (in two dimensional array).

NUM_VISU_ENTRY Data type: BYTE, Default value: 10.

Number of log entries displayed in log visualization for one zone.

NUM_OF_ZONE Data type: WORD, Default value: 1.

If TECT_GROUP is used, then Range: 1…65535. If TECT_GROUP is not used, then Range: 1…255.

Number of zones to be logged into the .csv file or displayed in visualization.

FIRST_LOG-FILE_DATA Data type: TECT_LOGFILE_DATA_FILE

First structure of data logging internal settings and values *Chapter 1.5.12.3.2 “TECT_LOG-FILE_DATA_TYPE” on page 3350*.

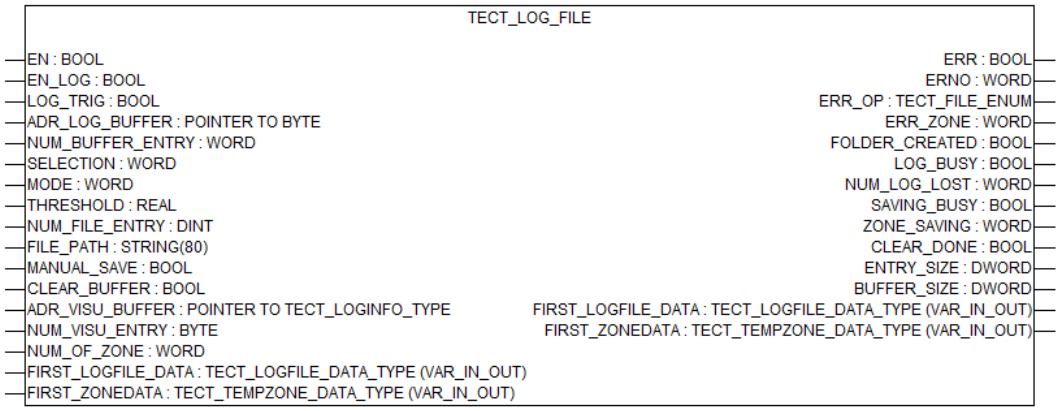
> *It is highly recommended to define an array of TECT_LOGFILE_DATA_TYPE for this input. The size of the array must be the same as the input MUM_OF_ZONE.*

FIRST_ZONE-DATA Data type: TECT_TEMPZONE_DATA_TYPE

First structure of process data and parameters for the zone. *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

> *All zones must be declared one after another without break. It is highly recommended to define an array of TECT_TEMPZONE_DATA_TYPE for the whole system.*

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

ERR_OP

Data type: TECT_FILE_ENUM

Display the logging operation, during which the error occurs *Chapter 1.5.12.3.9 “TECT_FILE_ENUM” on page 3358*.

ERR_ZONE

Data type: WORD

Indicate the zone in which error is generated.

FOLDER_CREATED

Data type: BOOL

This output variable is TRUE, if folder and subfolder have been created. Each time input EN has a rising edge, creating folder action will be executed. Depending on the number of zones and MODE 8, it could take some seconds to some minutes to create the folder and subfolders. If the folder already exists, the files inside will be kept untouched. It is recommended to enable logging (EN_LOG = TRUE) after FOLDER_CREATED is TRUE. Otherwise it could cause a loss of log data.

LOG_BUSY

Data type: BOOL

This output variable is TRUE, as long as input EN is TRUE and input EN_LOG is TRUE.

This output variable is FALSE, if input EN is TRUE and input EN_LOG is FALSE (pause), or if input EN has a falling edge. Then LOG_BUSY will be FALSE as soon as the backup of all log files have been created.

NUM_LOG_LOST

Data type: WORD

Number of log entries lost in the logging buffer due to busy of file operation, e.g. log saving operation of other zones.

SAVING_BUSY

Data type: BOOL

This output variable is TRUE, as long as log files are getting saved to the log folder.

This output variable is FALSE, if no saving of files to log folder is ongoing.

ZONE_SAVING

Data type: WORD

The particular zone, for which the file operation is executing (require: SAVING_BUSY is TRUE)

CLEAR_DONE

Data type: BOOL

Clear logging buffer is done.

ENTRY_SIZE Data type: DWORD

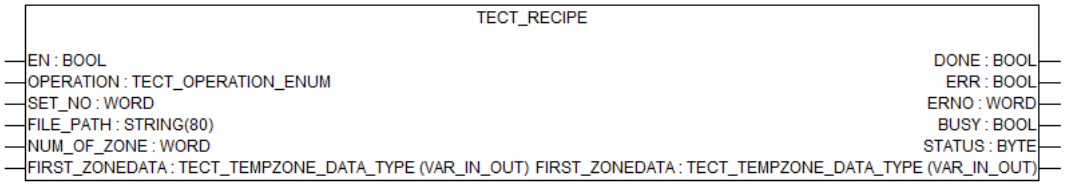
Size of one log entry in byte. The size depends on input data SELECTION.

BUFFER_SIZE Data type: DWORD

Size of whole buffer for all zones in byte. The size depends on output data ENTRY_SIZE and input data NUM_BUFFER_ENTRY and NUM_OF_ZONE.

> *Check this value to make sure the BUFFER_SIZE doesn't exceed the available size of specified data area.*

1.5.12.2.8 TECT_RECIPE



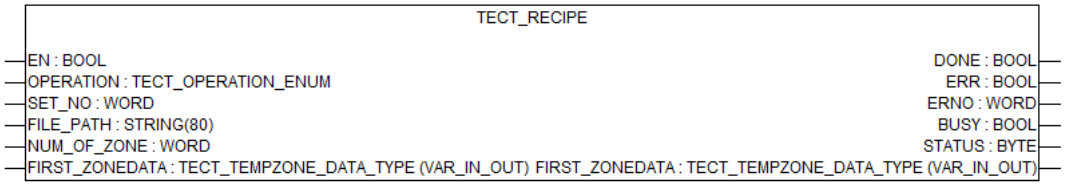
> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

The function block can save/write the necessary control settings to a CSV file. It also can load/read the settings from the CSV file.

This block will read/write from a file system, e.g. memory card. The files can be accessed via an FTP client connected to AC500 FTP server. A backup copy of the CSV file will be created with the same file name but with suffix .cpy after a WRITE operation and before a READ operation. In case of file corruption, the CPY file can be renamed into CSV file manually.

This function block can be used to save the dedicated control settings and settings for a temperature control system. Furthermore, it can also be used to manage recipes (multiple sets of control settings).

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

OPERATION Data type: TECT_OPERATION_ENUM

1: READ operation.

2: WRITE operation ↳ *Chapter 1.5.12.3.10 “TECT_OPERATION_ENUM” on page 3359*.

SET_NO Data type: WORD, Default value: 0, Range: 0 ... 65535

Recipe set number. This number will be used in the recipe CSV file name. See description of FILE_PATH.

FILE_PATH Data type: STRING[80]

There are two possibilities to define FILE_PATH, thus two methods to define the recipe file name:

- Default recipe file name: define a folder for saving recipe file (followed with or without ‘\’). The recipe file will be saved under FILE_PATH with a default name TZD*.csv (* stands for SET_NO).
  For example, if SET_NO = 3, FILE_PATH = SDCARD\RECIPE, then a recipe file TZD3.csv will be created (OPERATION = WRITE) or read (OPERATION = READ) under SDCARD\RECIPE.
- User defined recipe file name: define folder with CSV file name. In this case SET_NO has no meaning.
  For example, if FILE_PATH = SDCARD\RECIPE\myRecipe.csv, then a recipe file MYRECIPE.csv will be created (OPERATION = WRITE) or read (OPERATION = READ) under SDCARD\RECIPE.

The recipe file and the last level of the folder can be created by the function block, but the parent folder must already exist.

For example, if FILE_PATH = SDCARD\Level1\Level2\Level3 or FILE_PATH = SDCARD\Level1\Level2\Level3\myRecipe.csv, then SDCARD\Level1\Level2 must already exist but \Level3 can be created by the function block.

NUM_OF_ZONE Data type: WORD, Default value: 1, Range: > 0.

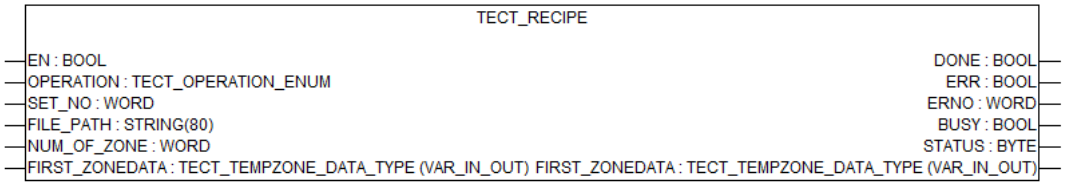
Total number of zones in the system.

FIRST_ZONE-DATA Data type: TECT_TEMPZONE_DATA_TYPE

Monitoring of the first zone data structure of the zone group. ↳ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

All zones must be declared one after another without break. It is highly recommended to define an array of TECT_TEMPZONE_DATA_TYPE for the whole system.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

BUSY

Data type: BOOL

TRUE: Will indicate that recipe operation READ/WRITE is ongoing and system is busy.

STATUS

Data type: BYTE

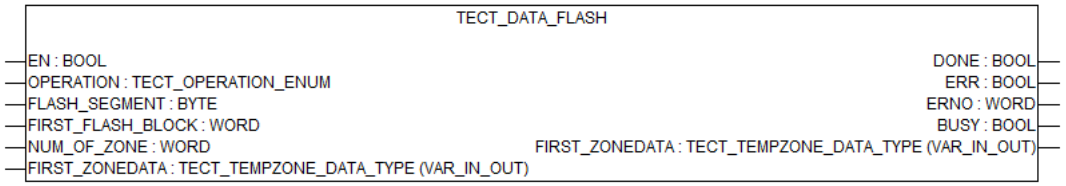
Output of this block indicates status of the process in the recipe function block. This input is helpful in displaying process status in the HMI.

Table 199: Function block TECT_RECIPE - STATUS description

STATUS	Description
0	Function block is disabled or no process running.
1	Recipe function block is BUSY, either READ or WRITE process going on
2	Recipe process is complete
3	Wrong parameter at input OPERATION
4	Wrong parameter at input NUM_OF_ZONE
5	Timeout of the recipe operation state
6	Read data failed: no correct format of data items.

STATUS	Description
7	Mismatch in number of zones declared and zone data in recipe.
8	CAA file error: Time limit exceeded
9	CAA file error: Order has been aborted by activating input xAbort
10	CAA file error: Invalid handle
11	CAA file error: Directory or file does not exist
12	CAA file error: Directory or file already exists
13	CAA file error: No further entries are available
14	CAA file error: File or directory is not empty
15	CAA file error: Drive, file or directory is write-protected
16	CAA file error: Wrong parameter(s) at function block
17	CAA file error: Unknown Error
18	CAA file error: Not all data has been written
19	CAA file error: Function not supported
20	CAA file error: No file handles or user tasks available (too many files open or tasks accessing file system)
21	CAA file error: Volume is full
22	CAA file error: Cannot open disk or no valid disk present
23	CAA file error: File/directory could not be accessed to execute operation
24	CAA file error: Internal or not further specified error
25	CAA file error: Source file could not be opened to execute required operation
26	CAA file error: Destination file could not be opened to execute required operation
27	CAA file error: Data could not be written to destination file
28	CAA file error: Data could not be read from source file
29	CAA file error: Formatting operation has not been confirmed as xEnable before activation the Function block with xExecute.

1.5.12.2.9 TECT_DATA_FLASH



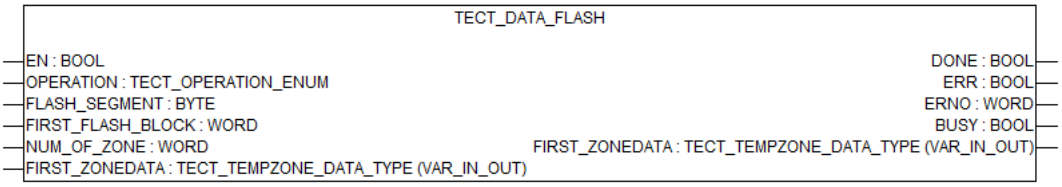
The function block TECT_DATA_FLASH can be used to save following data on flash:

- Internal parameters: rKS, rTU, rTG and wCoolFact_Tune *Chapter 1.5.12.3.1.1 “TECT_INTERNAL_STATUS_TYPE” on page 3343*).
- Machine set parameters: wCoolFact, rKP, rTI, rTD, rT1 *Chapter 1.5.12.3.1.2 “TECT_MACHINE_SET_TYPE” on page 3344*.

The main purpose of the flash operation is to save the parameters calculated from AutoTune, as they need a long time to be calculated. This function block is used as the second safety copy of AutoTune parameters besides saving as retain variables.

To rewrite the content on the flash, current data needs to be deleted before write operation. One instance of this function block has to be called for the complete system.

Input description



> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

OPERATION

Data type: TECT_OPERATION_ENUM

1: Enable READ operation: READ data from flash to TECT_TEMPZONE_DATA_TYPE.

2: Enable WRITE operation: WRITE data from TECT_TEMPZONE_DATA_TYPE to flash.

> *Each function block can only be written once. For a second WRITE action, the whole flash segment needs to be deleted first.*

3: Enable DELETE operation: Delete the whole flash segment.

4: Enable CHECK_READ operation: Check, if there are already valid parameters (KS>0) in TECT.

5: Enable DELETE_WRITE operation: Before write data from TECT_TEMPZONE_DATA_TYPE to flash, delete the whole flash segment first. It is used to avoid error 4101 by WRITE: Block was already written.

6: Enable CHECK_WRITE operation: Combination of CHECK_READ and DELETE_WRITE.

FLASH_SEGMENT

Data type: BYTE, Default value: 1, Range: 1 or 2

Number of the data segment. Each segment has 1927 blocks (0 ... 1926).

FIRST_FLASH_BLOCK Data type: WORD, Default value: 0, Range: 0 ... 1926.

Each segment has 1927 blocks (0…1926). Each block has 32 bytes. Each temperature zone needs one block (ie. 32 bytes).

The first block is assigned for FIRST_ZONEDATA.

NUM_OF_ZONE Data type: WORD, Default value: 1, Range: > 0.

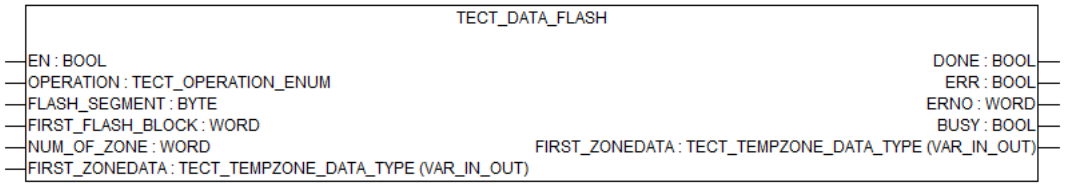
Number of zones in the entire system.

FIRST_ZONE-DATA Data type: TECT_TEMPZONE_DATA_TYPE.

Monitoring of the first zone data structure of the zone group.

> *All zones must be declared one after another without break. It is highly recommended to define an array of TECT_TEMPZONE_DATA_TYPE for the whole system.*

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

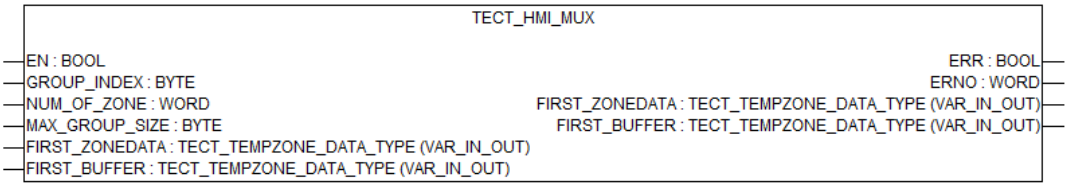
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

BUSY Data type: BOOL

TRUE: Will indicate that flash operation READ/WRITE/DELETE is ongoing and system is busy.

1.5.12.2.10 TECT_HMI_MUX

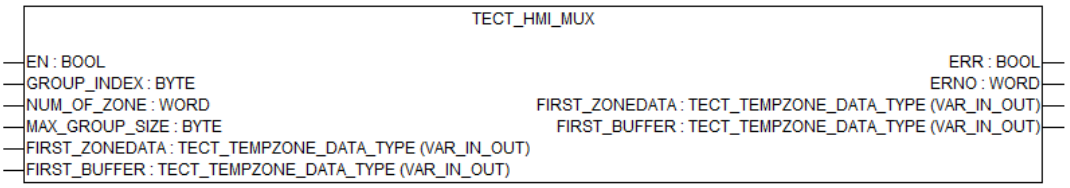


The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

The function block TECT_HMI_MUX

- helps to reduce the communication effort by reducing the data exchanged between PLC and HMI. It will also reduce the engineering efforts in configuring the panel projects. This function block can be used to commission CP600 projects or CODESYS visualization tool. When TECT_HMI_MUX function block is used in the program, BUFFER inout variable must be used for interface between PLC and HMI or visulaization.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

GROUP_INDEX Data type: BYTE, Default value: 1, Range: > 0.

Index of active Group on HMI, set from HMI. Group Index will be changed while navigating through HMI pages.

NUM_OF_ZONE Data type: WORD, Default value: 1, Range: > 0.

Total number of zones.

MAX_GROUP_SIZE Data type: Byte, Default value: 1, Range: > 0.

Size of the largest group in the system.

FIRST_ZONE-DATA Data type: TECT_TEMPZONE_DATA_TYPE

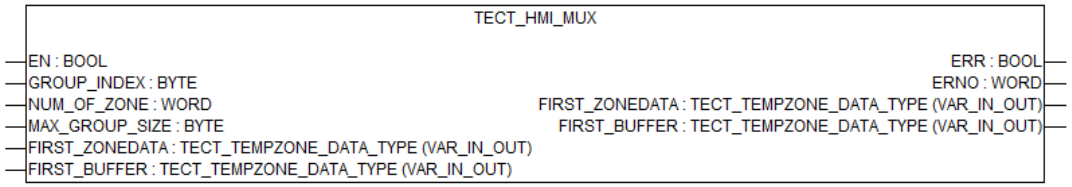
Monitoring of the first zone data structure of the zone group. ↳ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

> *All zones must be declared one after another without break. It is highly recommended to define an array of TECT_TEMPZONE_DATA_TYPE for the whole system.*

FIRST_BUFFER Data type: TECT_TEMPZONE_DATA_TYPE

The first ZONEDATA of the buffer in the declaration. Buffer exchanges the data between page/screens of HMI with the respective zones.

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see ↳ *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

Table 200: Function block TECT_HMI_MUX - Error code description

DEC	HEX	Error Description
16416	16#4020	GROUP_INDEX is less than or equal to zero
16432	16#4030	NUM_OF_ZONE is less than or equal to zero
16448	16#4040	MAX_GROUP_SIZE is less than or equal to zero
29330	16#7292	Zone_size and zone_index are not assigned

1.5.12.3 Structures and enumerator

The PS564-TEMP_CTRL package (the package containing TECT_TEMP_CONTROL_AC500_V24 library) contains the following structures:

- TECT_TEMPZONE_DATA_TYPE ,
- TECT_LOGFILE_DATA_TYPE,
- TECT_LOGINFO_TYPE,
- TECT_GROUP_DATA_TYPE,
- TECT_SYSTEM_DATA_TYPE,
- TECT_ZONE_INFO_TYPE.

Most variables in the structure cannot be accessed directly from the function blocks. All of them can be read and some can be written directly.

The PS564-TEMP_CTRL package (the package containing TECT_TEMP_CONTROL_AC500_V23 library) contains the following enumerator:

- TECT_CONTROLSTATEMACHINE_ENUM,
- TECT_ERRORCODE_ENUM,
- TECT_FILE_ENUM,
- TECT_OPERATION_ENUM,
- TECT_OUTPUTSTATUS_ENUM.

1.5.12.3.1 TECT_TEMPZONE_DATA_TYPE

TECT_TEMPZONE_DATA_TYPE (Temperature Zone Data) is a structure, which defines the control words, status words, limits and parameters for temperature zone control process.

It is recommmeded to declare TECT_TEMPZONE_DATA_TYPE as retain variables for power safe. All zones must be declared one after another without break. A zone group must be declared together without break. It is recommended to define an array of TECT_TEMPZONE_DATA_TYPE for one group.

Example: If there are three groups with group 1, 2 and 3 having 8, 6 and 4 zones, then TECT_TEMPZONE_DATA_TYPE has to be declared or attached into the function block TECT_GROUP as follows: In global retain variable as tsZonedata := ARRAY[1..18] OF TECT_TEMPZONE_DATA_TYPE. For group 1 as tsZonedata[1], for group 2 as tsZonedata[9] and for group 3 as tsZonedata[15] as the first zone for respective group.

The structure TECT_TEMPZONE_DATA_TYPE consist of 5 internal structures. These substructures are defined as per function of the parameters.

- TECT_INTERNAL_STATUS_TYPE,
- TECT_MACHINE_SET_TYPE,
- TECT_MACHINE_STATUS_TYPE,
- TECT_PROCESS_SET_TYPE,
- TECT_PROCESS_STATUS_TYPE.

TECT_INTERNAL_STATUS_TYPE

This structure contains internal status of the zone data. User can define group size and group name. User can also read control status and auto tune parameters.

No	Name	Data Type	Unit	Initial Value	Description	Access
1	ControlState	TECT_CONTROLSTATEMACHINE *Chapter 1.5.12.3.7 “TECT_CONTROLSTATEMACHINE_ENUM” on page 3357*		Not-Ready	Control state of the machine	FB
2	iRaw_Factor	INT	Raw Value	10	Factor of ACT_TEMP_RAW to actual temperature in °Celsius	FB
3	pGroupData	POINTER TO TECT_GROUP_DATA_TYPE *Chapter 1.5.12.3.4 “TECT_GROUP_DATA_TYPE” on page 3352*			GROUPDATA values	RO
4	byGroup_Size	BYTE		0	Group Size	RW
5	byGroup_Index	BYTE		0	Group Index	RO
6	byZone_Index	BYTE		0	Zone Index	RO
7	rTune_SetPoint	REAL		0	Auto tune setpoint to be calculated	RW
8	rKS	REAL		0	Internal PID parameter KS calculated by tuning	FB
9	rTU	REAL		0	Internal PID parameter TU calculated by tuning	FB
10	rTG	REAL		0	Internal PID parameter TG calculated by tuning	FB
11	wCoolFact_Tune	WORD		1000	Cool factor tune in percentage	FB

TECT_MACHINE_SET_TYPE

This structure contains machine set parameters of the zone data. User can define all parameters which are related to the machine, i.e. parameters which are set as per machine properties and will be defined only once at the time of commissioning. These parameters need to be changed only when some machine properties have changed, e.g. when a temperature sensor changed.

No	Name	Data Type	Unit	Initial Value	Description	Access
1	wCoolFact	WORD		1000	Cool factor in percentage	RW
2	rKP	REAL		0	PID parameter for control P in REAL value	RW

No	Name	Data Type	Unit	Initial Value	Description	Access
3	rTI	REAL		0	PID parameter for control I in seconds	RW
4	rTD	REAL		0	PID parameter for control D in seconds	RW
5	rT1	REAL		0	PID parameter for control filter for D in seconds	RW
6	rHigh-High_Temp	REAL		32767	HighHigh temperature alarm - disables all outputs	RW
7	rLowLow_Temp	REAL		- 32767	LowLow temperature alarm - disables all outputs	RW
8	uiChange_Time	UINT		0	For TC_Fault_2: time in second used to register min_temp_change when duty_cycle ≥ tune_output	RW
9	uiMin_Temp_Change	UINT		0	For TC_Fault_2: minimum temperature change in change_time when duty_cycle ≥ tune_output	RW
10	rTc_Max	REAL		32767	For TC_Fault_1: maximum plausible rActual_Temp	RW
11	rTc_Min	REAL		0	For TC_Fault_1: minimum plausible rActual_Temp	RW
12	rTemp_Diff_Cool	REAL		0	> 0: if temperature is temp_diff_cool higher than setpoint, then cooling is 100% ON until the temp_diff_cool*cool_off_ratio/100 over setpoint is reached. = 0: cooling is controlled as PID	RW
13	iCool_OFF_Ratio	INT		50	In percentage, if temp_diff_cool is active, see temp_diff_cool > 0	RW
14	iMax_Output	INT		100	Maximum allowable duty cycle	RW
15	iTune_Step	INT		500	Set point change in RAW value to be reached during auto tune process	RW
16	iTune_Output	INT		100	PWM duty cycle used during tuning	RW
17	rTune_MinP	REAL		0	Minimum allowable KP value for auto accept	RW
18	rTune_MaxP	REAL		32000	Maximum allowable KP value for auto accept	RW
19	rTune_PMult	REAL		1	Scaling for KP value	RW

No	Name	Data Type	Unit	Initial Value	Description	Access
20	rTc_Offset	REAL		0	Thermocouple compensation in degree (Celsius or Fahrenheit) - if required	RW
21	rPeriod_Fact	REAL		10	Period factor between cooling and heating	RW
22	timMin_Cool_ON	TIME		t# 3 s	Minimum time for which xDO_Cool output to be ON	RW
23	iFF_Time_Ratio	INT		125	>=100, Feedforward time ratio in percentage: for internal set point ramp generator. The smaller the value, the steeper the ramp	R/W
24	rRated_Current	REAL		0	Rated heater current of the Zone. It is always same for all 3 phases.	R/W

TECT_MACHINE_STATUS_TYPE

This structure contains machine status parameters of the zone data. It contains all the AutoTune parameters.

No	Name	Data Type	Unit	Initial Value	Description	Access
1	rKP_TUNE	REAL		0	PID parameter for control P in REAL value calculated by tuning	RO
2	rTI_Tune	REAL		0	PID parameter for control I in seconds calculated by tuning	RO
3	rTD_Tune	REAL		0	PID parameter for control D in seconds calculated by tuning	RO
4	rT1_Tune	REAL		0	PID parameter for control filter for D in seconds calculated by tuning	RO
5	arActual_Current	ARRAY [1..3] OF REAL			Actual heater current of phase 1,2 and 3 of the Zone	R/W

TECT_PROCESS_SET_TYPE

This structure contains process set parameters of the zone data. User can define all parameters which are related to the process, i.e. parameters which are set as per process properties. These parameters will be changing continuously as per process requirement, e.g. Control word.

PID setpoint, control word, high and low temp settings come under this structure.

No	Name	Data Type	Unit	Initial Value	Description	Access
1	wControlWord	WORD		0	Control word	RW
	enable:	BOOL			Bit 0: enable Process.	
	heat_en:	BOOL			Bit 1: enable zone as heat zone. If both heat_en and cool_en are FALSE then zone is monitor only	
	cool_en:	BOOL			Bit 2: enable zone as cooling zone. If both heat_en and cool_en are FALSE then zone is monitored only	
	manual_en:	BOOL			Bit 3: manual mode - highest priority mode, disable all other modes.	
	standby_en:	BOOL			Bit 4: standby setpoint is used.	
	tune_en:	BOOL			Bit 5: enable auto tune with large setpoint step.	
	accept_auto_tune:	BOOL			Bit 6: accept or reject tuning parameters.	
	co_output:	BOOL			Bit 7: coordinated output of one group.	
	Reserved	BOOL			Bit 8: Reserved	
	Control_Optimization:	BOOL			Bit 10, Bit 9: - 00: APERIODIC, - 01: OVERSHOOT, - 10: DEADTIME COMPENSATION, - 11: NO OPTIMIZATION .	
	warm_reset:	BOOL			Bit 13: reset the alarm and process but not AutoTune status.	
	en_3phase_Monitor	BOOL			Bit 14 - True :3phase current monitoring False: single phase monitoring	
	cold_reset:	BOOL			Bit 15: reset all in control process.	
2	iManual_Duty_Cycle	INT		0	PWM output in manual mode.	RW
3	rSetPoint	REAL		0	Process setpoint.	RW
4	rStandBy_SetPoint	REAL		0	Secondary process setpoint for standby.	RW
5	rHigh_Temp	REAL		32767	High temperature alarm, disables heat output.	RW
6	rLow_Temp	REAL		- 32767	Low temperature alarm, disables cool output.	RW

No	Name	Data Type	Unit	Initial Value	Description	Access
7	rHigh_Deviation	REAL		0	High deviation alarm, relative to setpoint.	RW
8	rLow_Deviation	REAL		0	Low deviation alarm, relative to setpoint.	RW

TECT_PROCESS_STATUS_TYPE

This structure contains process status parameters of the zone data. User can read all parameters which are related to the process. These parameters will be changing continuously as per process status, e.g. Status word.

Act temp, status word, error come under this structure.

No	Name	Data Type	Unit	Initial Value	Description	Access
1	rActive_SetPoint	REAL		0	Active setpoint currently used by process.	RO
2	rActual_Temp	REAL		0	Actual value from the Thermocouple.	RO
3	wStatusWord	WORD			Status WORD	RO
					Bit 0: reserved	
					Bit 1: reserved	
					Bit 2: reserved	
					Bit3: reserved	
	standby_on:	BOOL			Bit 4: StandBy mode active.	
	fahrenheit_on:	BOOL			Bit 5: TRUE: Fahrenheit	
	tune_done:	BOOL			Bit 6: AutoTune complete.	
	tune_ accepted:	BOOL			Bit 7: AutoTune values accepted.	
	tune_ state	BOOL			Bit 8: FALSE: start AutoTune with heat. TRUE: start AutoTune with cool.	
	hmi_visible:	BOOL			Bit 12: TRUE: Zone is visible in the HMI. FALSE: zone is invisible.	

No	Name	Data Type	Unit	Initial Value	Description	Access
	group_fault:	BOOL			Bit 13: Group fault active. All zones in that group: Outputs disabled. Process stopped.	
	warning:	BOOL			Bit 14: Warning active, only displayed. Process going on.	
	fault:	BOOL			Bit 15: Fault active, outputs disabled. Process stopped.	
4	OutputStatus	TECT_OUTPUTSTATUS_ENUM *Chapter 1.5.12.3.11 "TECT_OUTPUTSTATUS_ENUM" on page 3359*			Status Code of PWM output.	RO
5	iTune_Status	INT		0	Present tuned value output.	RO
6	Latest Error	TECT_ERRORCODE_ENUM *Chapter 1.5.12.3.8 "TECT_ERRORCODE_ENUM" on page 3357*			Error code of latest error.	RO
7	wErrors	WORD		0	All active errors.	RO
8	wErrors2	WORD		0	Second error word	RO
	ShortCircuit	BOOL		FALSE	Bit 0- Short Circuit Detected in the power circuit	
	OpenCircuit	BOOL		FALSE	Bit 1- Open Circuit Detected in the heater power circuit	
	ControlCircuitFailure	BOOL		FALSE	Bit 2- Control circuit failure detected	
	ZeroRatedCurrentAssigned	BOOL		FALSE	Zero rated current assigned for zone	
9	xDO_Heat	BOOL		FALSE	PWM output for heat cycle.	RO
10	xDO_Cool	BOOL		FALSE	PWM output for cool cycle.	RO
11	iDuty_Cycle	INT		0	Output duty cycle in per cent (%)	RO

1.5.12.3.2 TECT_LOGFILE_DATA_TYPE

TECT_ LOGFILE_DATA_TYPE is a structure which is used for the data of TECT_LOG_FILE function block. It contains all information of zone log data including status of the log process. E.g., user can check the status of folder: / csv file name, save status, file token information.

No	Name	Data Type	Unit	Initial Value	Description	Access
1	diFileEntries	DINT		- 1	1: File not yet created.	RO
2	iNewEntries	INT		0	No of new entries.	RO
3	stFileName	String[12]			\' + 8.3 file name	RO
4	stSubFolder	String[9]			Subfolder name	RO
5	xErr	BOOL		FALSE	TRUE: Error is generated. FALSE: No error.	RO
6	wErno	WORD		0	Error number	RO
7	Err_Op	TECT_FILE_ENUM ↳ *Chapter 1.5.12.3.9 “TECT_FILE_ENUM” on page 3358*			Error operation to the internal structure TECT_FILE_ENUM.	RO
8	bySaveState	TECT_FILE_ENUM ↳ *Chapter 1.5.12.3.9 “TECT_FILE_ENUM” on page 3358*		TECT_NO_OPERATION	Save state to TECT_FILE_ENUM structure.	RO
9	wMyFileToken	WORD		0	Current file token.	RO
10	xSave	BOOL		FALSE	Start save into file.	RO
11	xDirCreated	BOOL		FALSE	TRUE: Directory created.	RO
12	xLogBusy	BOOL		FALSE	TRUE: Log process ongoing.	RO
13	xInit	BOOL		FALSE	One execution after restart/ reset program: to backup (rename) the existing file.	RO
14	xNewFile	Bool		FALSE	To create a new file.	RO
15	xInThreshold	Bool		FALSE	TRUE: Act_temp is in threshold range.	RO
16	wRetryCycle	WORD		0	Number of CPU cycles have been passed after saving failed.	RO
17	xSaveFailed	BOOL		FALSE	Save (write) to file failed.	RO
18	x2ndBuffer	BOOL		FALSE	Second buffer allocated.	RO
19	i2ndNEntry	INT		0	Size of 2nd buffer in number of entries.	RO

No	Name	Data Type	Unit	Initial Value	Description	Access
20	i2ndEntryPosLog	INT		0	Position of current entry in 2nd buffer: 0.. i2ndNEntry-1.	RO
21	ptr2ndBuffer	POINTER TO BYTE			Pointer to begin of the 2nd buffer.	RO
22	wNumLogLost	WORD		0	Number of log lost for the zone	RO
23	ptrLogBuffer	POINTER TO BYTE			Pointer to begin of the zone log buffer.	RO
24	ptrEntryLog	POINTER TO BYTE			Pointer to current entry to be logged in buffer.	RO
25	iEntryPosLog	INT		0	Position of current buffer entry: 0.. NUM_BUFFER_ENTRY-1.	RO
26	iEntryPosWrite	INT		0	Position of buffer entry before which the data has been written into file: 0.. NUM_BUFFER_ENTRY-1.	RO
27	wOldStatus	Array[1..2] OF Word		2 (0)	Old status of the log.	RO

1.5.12.3.3 TECT_LOGINFO_TYPE

TECT_LOGINFO_TYPE is a structure which defines the log info for the log visualization. It contains all information of Log visualization including control word, status word, and control status. User can use visualization to observe this data.

No	Name	Data Type	Unit	Initial Value	Description	Access
1	timtimestamp	DT			Date and time stamp.	RO
2	wControlWord	WORD		0	Control word	RO
3	wStatusWord	WORD		0	Status word	RO
4	rActive_SetPoint	REAL		0	Active setpoint currently used by process.	RO
5	rActual_Temp	REAL		0	Actual value from the Thermocouple.	RO
6	iDuty_Cycle	INT		0	Output Duty Cycle in per cent (%).	RO

No	Name	Data Type	Unit	Initial Value	Description	Access
7	ControlState	TECT_CONTROLSTATEMACHINE_ ENUM *Chapter 1.5.12.3.7 “TECT_CONTROLSTATEMACHINE_ENUM” on page 3357*			Control State of the machine.	RO
8	OutputStatus	TECT_OUTPUTSTATUS_ENUM *Chapter 1.5.12.3.11 “TECT_OUTPUTSTATUS_ENUM” on page 3359*			Status code of PWM output.	RO
9	Latest_Error	TECT_ERRORCODE_ENUM *Chapter 1.5.12.3.8 “TECT_ERRORCODE_ENUM” on page 3357*			Error code of latest error.	RO
10	wErrors	WORD		0	All active errors.	RO
11	wErrors2	WORD		0	Second error word.	RO

1.5.12.3.4 TECT_GROUP_DATA_TYPE

TECT_GROUP_DATA_TYPE structure has the data related to each group in the system. It has all the status of TECT_GROUP function block.

No	Name	Data Type	Unit	Initial Value	Description	Access
1	stGroup_Name	STRING[20]			Name of the group.	RW
2	byGroup_Index	BYTE		0	Group index	RO
3	byGroup_Size	BYTE		0	Size of the group.	RW
4	ControlState	TECT_CONTROLSTATEMACHINE_ ENUM *Chapter 1.5.12.3.7 “TECT_CONTROLSTATEMACHINE_ENUM” on page 3357*		TECT_NotReady	Control state of the machine.	RO
5	byZones_Not_Ready	BYTE		0	Number of zones at Not-Ready status.	RO
6	byZones_Ready	BYTE		0	Number of zones at Ready status.	RO

No	Name	Data Type	Unit	Initial Value	Description	Access
7	byZones_Manual	BYTE		0	Number of zones at Manual status.	RO
8	byZones_AutoTune	BYTE		0	Number of zones at AutoTune status.	RO
9	byZones_PID_Process	BYTE		0	Number of zones at PID process status.	RO
10	byZones_Fault	BYTE		0	Number of zones at Fault status.	RO
11	xEn_Process	BOOL		FALSE	Enable process for all zones.	RW
12	xEn_Heat	BOOL		FALSE	Enable Heat process for all zones.	RW
13	xEn_Cool	BOOL		FALSE	Enable Cool process for all zones.	RW
14	xEn_Standby	BOOL		FALSE	Enable Standby for all zones.	RW
15	xEn_AutoTune	BOOL		FALSE	Enable Auto-Tune process for all zones.	RW
16	xEn_Accept_Auto-Tune	BOOL		FALSE	Accept Auto-Tune values for all zones.	RW
17	xReset_Warm	BOOL		FALSE	Reset Warm for all zones.	RW
18	xReset_Cold	BOOL		FALSE	Reset Cold for all zones.	RW
19	xDisable_Process	BOOL		FALSE	Disable process for all zones.	RW
20	xDisable_Heat	BOOL		FALSE	Disable Heat process for all zones.	RW
21	xDisable _Cool	BOOL		FALSE	Disable Cool process for all zones.	RW
22	xDisable _Standby	BOOL		FALSE	Disable Standby for all zones.	RW

No	Name	Data Type	Unit	Initial Value	Description	Access
23	xDisable _Autotune	BOOL		FALSE	Disable Auto-Tune process for all zones.	RW
24	xDisable _Accept_Autotune	BOOL		FALSE	Disable Auto-Tune values for all zones.	RW
25	byControlByte	BYTE		0	Group Control Byte	RW
	Transfer	BOOL			Bit 0 - Enables command transfer from group to indvidual zones	RW
26	arActual_Current	ARRAY [1..3] OF REAL			Actual current of phase L1,2 and 3 of the group	RW
27	timMonitor-Cycle_Time	TIME		T#600s	Current monitoring cycle time	RW
28	timMonitor-Step_Time	TIME		T#10s	Current monitoring step time in the cycle	RW
29	timSettling_Time	TIME		T#800ms	Settling time allocated for current sensor	RW
30	timLastMeasure-ment	TIME		T#0s	Time taken to complete current measurement of all the zones for last measurement	RW
31	xEn_Co_Monitor	BOOL		FALSE	Enable common sensor current monitoring for all zones	RW
32	xEn_Indivi_Monitor	BOOL		FALSE	Enable individual sensor current monitoring for all zones	RW
33	xControl_Circuit_Failure	BOOL		FALSE	Control circuit failure of one of the zone e.g. SSR failure	RW

No	Name	Data Type	Unit	Initial Value	Description	Access
34	byMaxPercentage	BYTE	%	150	Maximum percentage current allowed for current monitoring	RW
35	byMinPercentage	BYTE	%	50	Minimum percentage current allowed for current monitoring	RW
36	byZeroDetectPercentage	BYTE	%	10	Percentage current to detect control circuit failure	RW

1.5.12.3.5 TECT_SYSTEM_DATA_TYPE

No	Name	Data Type	Unit	Initial value	Description	Access
1	stSystem_Name	STRING[20]			Name of the system.	RW
2	bySystem_Size	BYTE		0	Size of the system.	RW
3	ControlState	TECT_CONTROLSTATEMACHINE_ENUM *Chapter 1.5.12.3.7 “TECT_CONTROLSTATEMACHINE_ENUM” on page 3357*(		TECT_NotReady	Control state of the machine.	RO
4	byGroups_Not_Ready	Byte		0	Number of groups NotReady status.	RO
5	byGroups_Ready	Byte		0	Number of groups Ready status.	RO
6	byGroups_Manual	Byte		0	Number of groups Manual status.	RO
7	byGroups_Autotune	Byte		0	Number of groups Autotune status.	RO
8	byGroups_PID_Process	Byte		0	Number of Groups PID Process status.	RO
9	byGroups_Fault	Byte		0	Number of groups Fault status.	RO
10	byGroups_Mixed_State	Byte		0	Number of groups Mixed status.	RO
11	xEn_Process	BOOL		FALSE	Enable process for all groups.	RW

No	Name	Data Type	Unit	Initial value	Description	Access
12	xEn_Heat	BOOL		FALSE	Enable Heat process for all groups.	RW
13	xEn_Cool	BOOL		FALSE	Enable Cool process for all groups.	RW
14	xEn_Standby	BOOL		FALSE	Enable Standby process for all groups.	RW
15	xEn_Autotune	BOOL		FALSE	Enable Autotune process for all groups.	RW
16	xEn_Accept_Autotune	BOOL		FALSE	Accept Autotune values for all zones.	RW
17	xReset_Warm	BOOL		FALSE	Reset Warm process for all groups.	RW
18	xReset_Cold	BOOL		FALSE	Reset Cold process for all groups.	RW
19	xDisable_Process	BOOL		FALSE	Disable process for all groups.	RW
20	xDisable_Heat	BOOL		FALSE	Disable Heat process for all groups.	RW
21	xDisable_Cool	BOOL		FALSE	Disable Cool process for all groups.	RW
22	xDisable_Standby	BOOL		FALSE	Disable Standby process for all groups.	RW
23	xDisable_Autotune	BOOL		FALSE	Disable Autotune process for all groups.	RW
24	xDisable_Accept_Autotune	BOOL		FALSE	Disable Autotune values for all zones.	RW

1.5.12.3.6 TECT_ZONE_INFO_TYPE

No	Name	Data Type	Unit	Initial Value	Description	Access
1	rActual_Temp	REAL		0	Actual value from the Thermocouple.	RO
2	wErrors	WORD		0	First error word	RO

No	Name	Data Type	Unit	Initial Value	Description	Access
3	wErrors2	WORD		0	Second error word	
4	byGroup_Index	BYTE		0	Group index	RO
5	byZone_Index	BYTE		0	Zone index	RO

1.5.12.3.7 TECT_CONTROLSTATEMACHINE_ENUM

The structure TECT_CONTROLSTATEMACHINE_ENUM enumeration gives the Control status of function block TECT_TEMP_CONTROL State machine action status.

No	Name	Description
1	TECT_NotReady	State machine is not ready.
2	TECT_Ready	State machine is in Ready state.
3	TECT_Manual	State machine is in Manual mode.
4	TECT_AutoTune	Automatic mode in PID process with standby setpoint - Heating.
5	TECT_PID_Process	State machine PID process is running.
6	TECT_FaultState	State machine is in Fault state.
7	TECT_MixedState	State machine is in Mixed state.
8	DummyState	DummyState = 256, to ensure the TECT_CONTROLSTATEMACHINE_ENUM has two bytes.

1.5.12.3.8 TECT_ERRORCODE_ENUM

The structure TECT_ERRORCODE_ENUM enumeration is to save and display all the special errors and warnings.

No	Name	Description
1	TECT_NoError	No Error
2	TECT_TuneFault	Bit 0: TuneFault: Tuning failed - Outputs disabled, check TECT_TEMPZONE_DATA_TYPE ↳ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*
3	TECT_TC_Fault_1	Bit 1: TC Fault_1: Bad thermocouple reading - outputs disabled.
4	TECT_TC_Fault_2	Bit 2: TC Fault_2: Plausability check not passed - outputs disabled.
5	TECT_HighHighTempFault	Bit 3: HighHighTempFault: HighHigh Temperature alarm - outputs disabled.
6	TECT_LowLowTempFault	Bit 4: LowLowTempFault: LowLow Temperature alarm - outputs disabled.
7	TECT_HighTemp	Bit 7: HighTemp: High Temperature alarm.
8	TECT_LowTemp	Bit 8: LowTemp: Low Temperature alarm.

No	Name	Description
9	TECT_HighDeviation	Bit 9: HighDeviation: High Deviation alarm
10	TECT_LowDeviation	Bit 10: LowDeviation: Low Deviation alarm.
11	TECT_NoHighHighLowLow	Bit 11: NoHighHighLowLow: No HighHighTemp/ LowLowTemp limit is defined.
12	TECT_WrongLimits	Bit 12: WrongLimits is configured, HighTemp/Low temp and HighHighTemp/LowLowTemp values are not plausible.
13	Reserved	Bit 13: Reserved
14	TECT_NoAutoTune	Bit 14: NoAutoTune: Auto tune cannot be started.
15	TECT_NoPIDProcess	Bit 15: NoPIDProcess: PID process cannot be started or parameters KP, TN, TV, TD are not valid.
16	TECT_ShortCircuit	Bit 16: Short Circuit detected in the heater power circuit.
17	TECT_OpenCircuit	Bit 17: Open Circuit detected in the heater power circuit.
18	TECT_ControlCircuitFailure	Bit 18: Heater power Control Circuit failure detected.
19	TECT_NoRatedCurrent	Bit 19: No valid rated current defined for current monitoring

1.5.12.3.9 TECT_FILE_ENUM

The structure TECT_FILE_ENUM enumeration will give the current status of TECT_LOG_FILE function block operation.

Value	Name	Description
0	TECT_NO_OPERATION	No operation is active in TECT_LOG_FILE function block.
5	TECT_CREATE_SUBFOLDER	Subfolder creation is active in TECT_LOG_FILE function block.
20	TECT_WAIT FOR TOKEN	Waiting for token in TECT_LOG_FILE function block.
40	TECT_OPEN_FILE	Opening file is active in TECT_LOG_FILE function block.
45	TECT_GET_POSITION	Get position is active in TECT_LOG_FILE function block.
50	TECT_WRITE_HEADER	Writing header is active in TECT_LOG_FILE function block.
60	TECT_WRITE_ENTRY	Writing entry is active in TECT_LOG_FILE function block.
80	TECT_CLOSE_FILE	Close file is active in TECT_LOG_FILE function block.
90	TECT_CREATE_BACKUP	Creating backup is active in TECT_LOG_FILE function block.
100	TECT_RENAME_FILE	Renaming is active in TECT_LOG_FILE function block.

Value	Name	Description
105	TECT_RETRY_RENAME	Retrying rename is active in TECT_LOG_FILE function block.
200	TECT_RELEASE_TOKEN	Releasing token is active in TECT_LOG_FILE function block.
- 5	TECT_CREATE_FOLDER	Folder creation is active in TECT_LOG_FILE function block. (*<0: creating FOLDER, not for saving log data state.)

1.5.12.3.10 TECT_OPERATION_ENUM

The structure TECT_OPERATION_ENUM enumeration is to configure operations in function block TECT_DATA_FLASH and function block TECT_RECIPE.

Value	Name	Description
1	TECT_READ	Read data from RECIPE/DATA_FLASH to TECT_TEMPZONE_DATA_TYPE. ↯ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*
2	TECT_WRITE	Write data to RECIPE/DATA_FLASH from TECT_TEMPZONE_DATA_TYPE. ↯ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*
3	TECT_DELETE	Delete data written into DATA_FLASH.
4	TECT_CHECK_READ	Check, if there are already valid parameters (KS > 0) in TECT_TEMPZONE_DATA_TYPE. ↯ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343* Read data only from DATA_FLASH, if KS ≤ 0.
5	TECT_DELETE_WRITE	First delete the whole flash segment. Then write data from TECT_TEMPZONE_DATA_TYPE to flash. ↯ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343* It is used to avoid error 4101 by WRITE: Block was already written.
6	TECT_CHECK_WRITE	First read data from flash to TECT_TEMPZONE_DATA_TYPE, if KS ≤ 0. ↯ *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343* Then delete the flash. It is a combination of CHECK_READ and DELETE_WRITE.

1.5.12.3.11 TECT_OUTPUTSTATUS_ENUM

The structure TECT_OUTPUTSTATUS_ENUM enumeration will give the status of the PWM output.

Value	Name	Description
0	TECT_Disabled	Process disabled.
1	TECT_AutoHeat	Automatic mode in PID process with setpoint: Heating.
2	TECT_AutoCool	Automatic mode in PID process with setpoint: Cooling.
3	TECT_AutoHeat Standby	Automatic mode in PID process with standby setpoint: Heating.

Value	Name	Description
4	TECT_AutoCool Standby	Automatic mode in PID process with standby setpoint: Cooling.
5	TECT_ManualHeat	Manual mode: Heating
6	TECT_ManualCool	Manual mode: Cooling
7	TECT_TuneActive	AutoTune is active. Heating with tune_output.
8	TECT_TuneComplete	AutoTune is complete. Waiting for accept of AutoTune results. No PWM output.
9	TECT_Inactive	Duty cycle = 0. No PWM output.
10	TECT_NoOutput	NoOutput: Monitor Only
11	TECT_CoMonitorActive	Common sensor current monitoring is active
12	TECT_CoMonitorWait	Common sensor current monitoring is in waiting mode
13	TECT_IndiviMonitor	Individual sensor current monitoring is active
256	TECT_DummyStatus	DummyStatus := 256 to ensure the TECT_OUTPUT-STATUS_ENUM has two bytes

1.5.12.4 Visualization

1.5.12.4.1 Visualization

Visualization gives an opportunity to the user to monitor and control function blocks. Some template are also created for ease of operation.

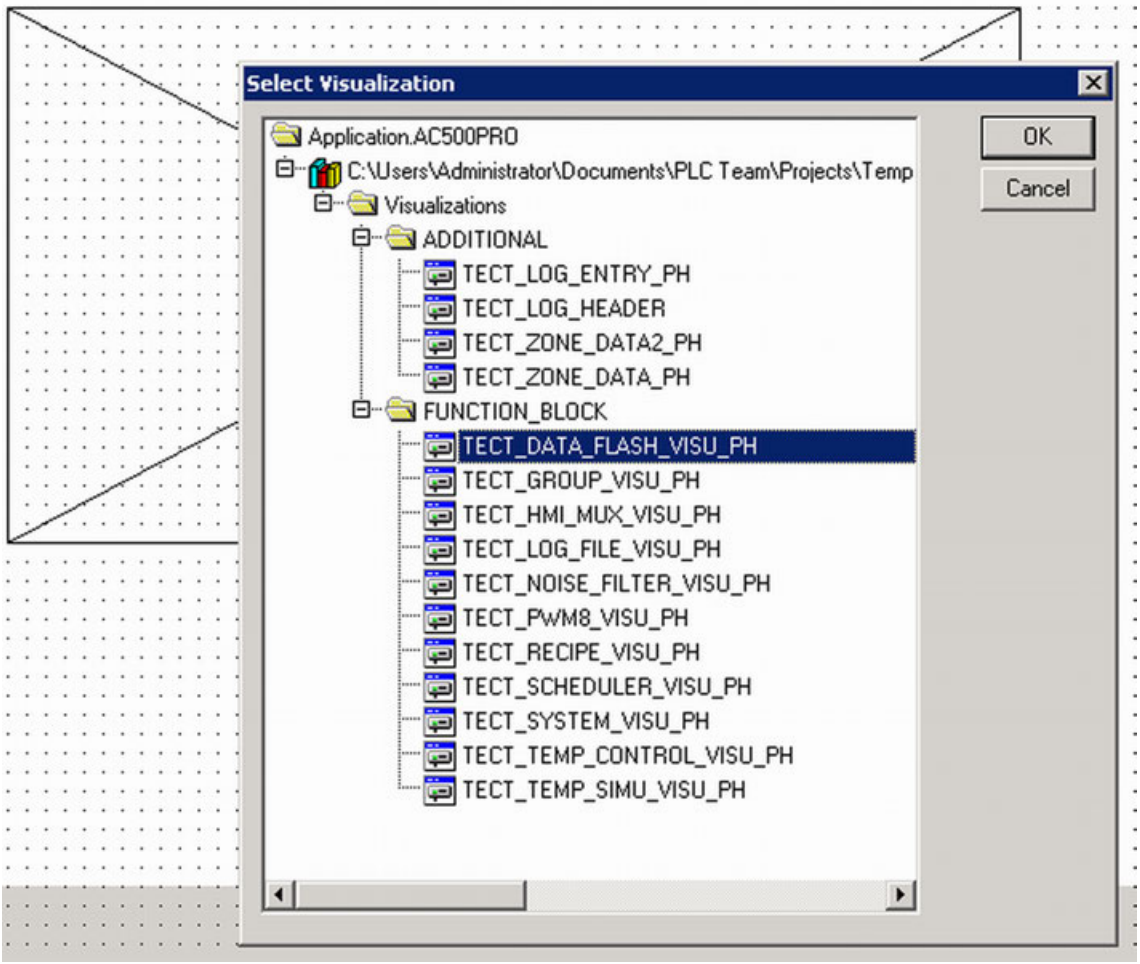


Fig. 603: TECT visualization list

TECT_ZONE_DATA_PH

TECT_ZONE_DATA_PH can be used as template for zone data. The most important values of a zone data during the control process can be monitored out of here. Each instance of this visualization has to be attached with respective zones to read and write the parameters to the particular zone. In the placeholder attach corresponding array element of the variable declared for structure TECT_TEMPZONE_DATA_TYPE. *Chapter 1.5.12.3.1 “TECT_TEMPZONE_DATA_TYPE” on page 3343*

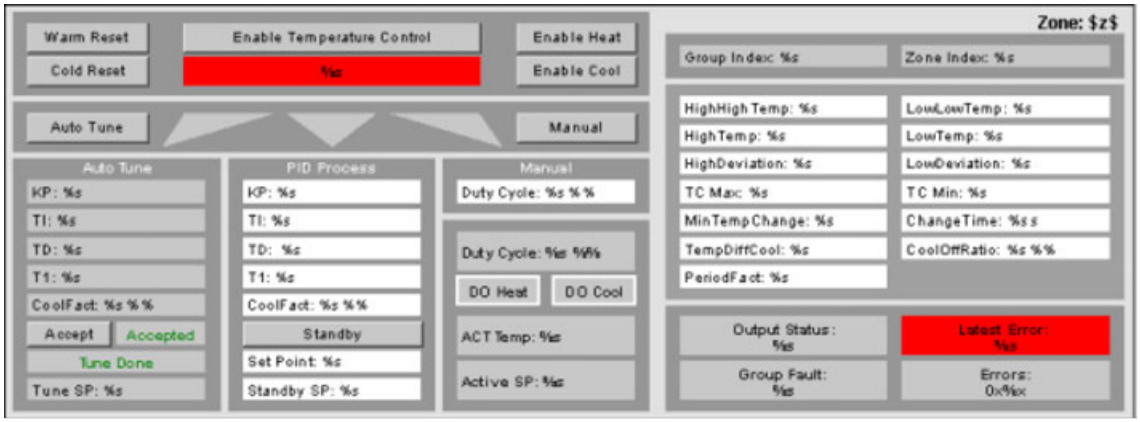

Fig. 604: TECT_ZONE_DATA_PH template in offline mode

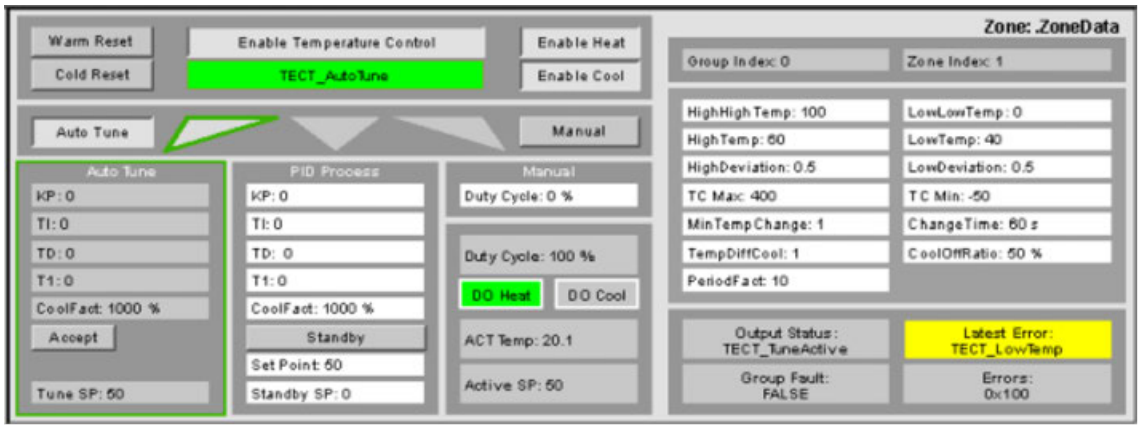

Fig. 605: TECT_ZONE_DATA_PH template in online mode

TECT_LOG_ENTRY_PH

The items of data TECT_LOG_ENTRY_PH array in logging buffer can be displayed in CODESYS Visualization, using dedicated visualization template. The following example shows how to realize it.

Visualization example of logging buffer

Definition of TECT_LOG_ENTRY_PH array

1. Define an array of TECT_LOG_ENTRY_PH with the size in number of entries (NUM_VISU_ENTRY = 10) to be displayed.

   ptsLog_Visu: ARRAY[1...10] of TECT_LOGINFO_TYPE ↳ *Chapter 1.5.12.3.3 “TECT_LOGINFO_TYPE” on page 3351*

   Visu_array: ARRAY[1...10] of Visu_LogEntry

VISU_BUFFER

2. Data type: POINTER TO TECT_LOGINFO_TYPE

   Start address of the log visualization data. It is recommended to define the log visualization data in array. This can be used only with CODESYS visualization. For example, if there are 4 zones to be logged and each zone has 10 log visualization entries, then a one dimensional or two dimensional array can be defined (see TECT_LOGINFO_TYPE: ↳ *Chapter 1.5.12.3.3 “TECT_LOGINFO_TYPE” on page 3351*

   visu_buffer: ARRAY[1..40] OF TECT_LOGINFO_TYPE; (in one dimensional array).

   visu_buffer: ARRAY[1..4, 1..10] OF TECT_LOGINFO_TYPE; (in two dimensional array).

NUM_VISU_ENTRY

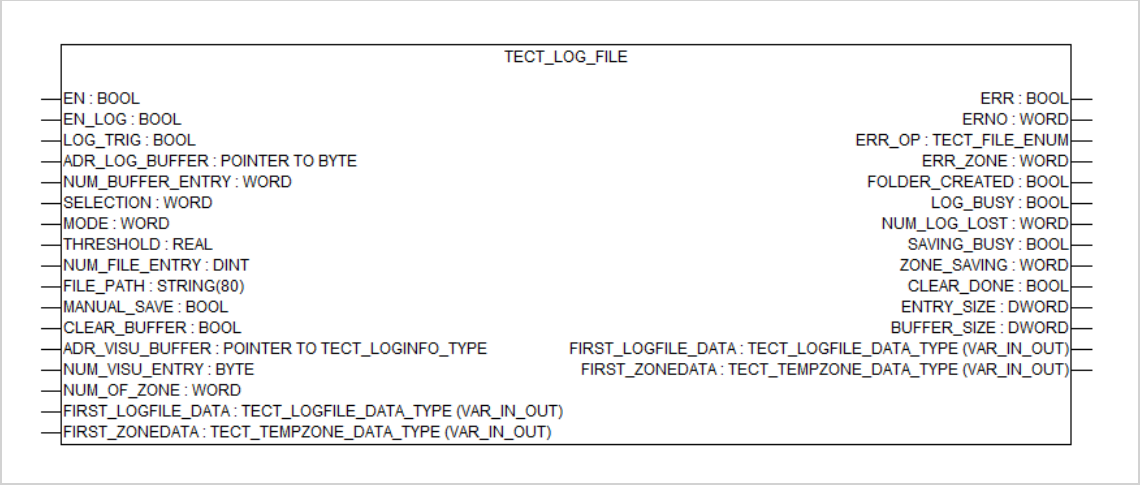

Fig. 606: FB_TECT_LOG_FILE 2

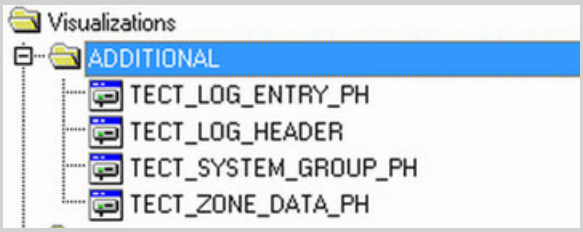
3. Data type: BYTE, Default value: 10

   Number of log entries displayed in log visualization for one zone.

Creation of VISU element of type TECT_LOG_HEADER



4. Create a VISU element of type TECT_LOG_HEADER.

Creation of VISU element of type TECT_LOG_ENTRY_PH

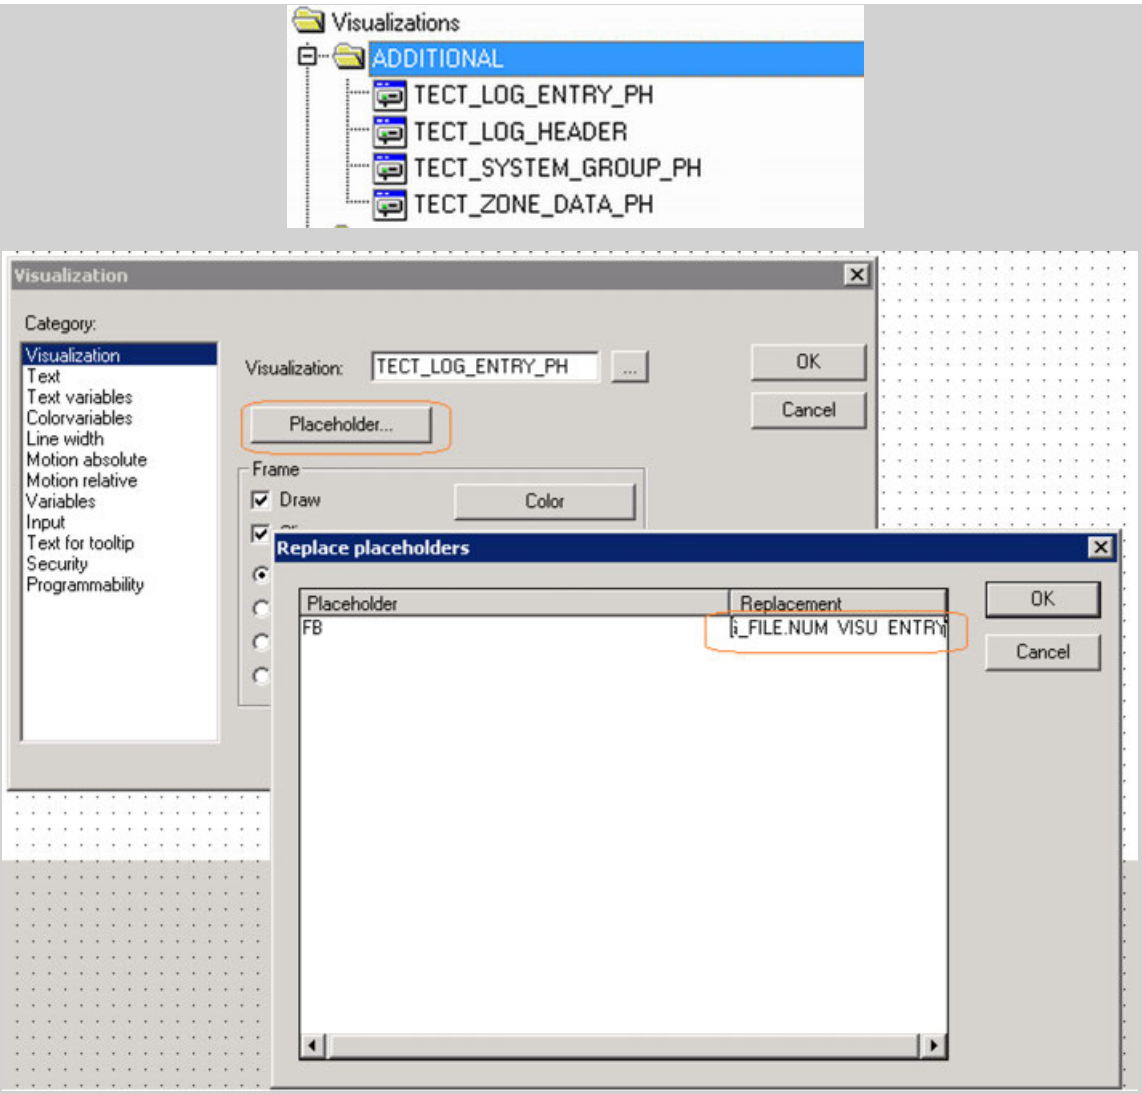


Fig. 607: TECT_LOG_ENTRY_PH placeholder

Date and Time	CW	SW	SET T	ACT T	Duty Cycle	Control State	Output Status	Error Status
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s

5. Create a VISU element of type TECT_LOG_ENTRY_PH. Set the Visu_buffer [1] as replacement for the VISU placeholder.

   Resize the VISU element as the same size of TECT_LOG_HEADER.

Creation of more VISU elements of type TECT_LOG_ENTRY_PH

6. Create more 9 VISU elements of type TECT_LOG_ENTRY_PH (or create 9 copies of the first TECT_LOG_ENTRY_PH item).

   Set the visu_buffer [2] to visu_buffer [10] as replacement for the placeholders to the 9 VISU items.

Organization of VISU items

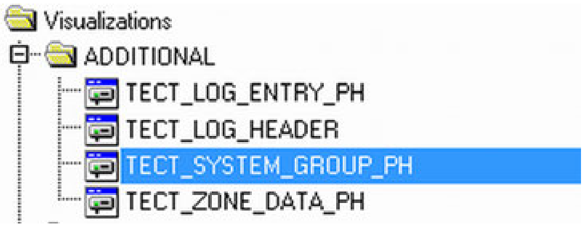
Date and Time	CW	SW	SET T	ACT T	Duty Cycle	Control State	Output Status	Error Status
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s
%s	0x%x	0x%x	%s	%s	%s	%s	%s	%s

Fig. 608: TECT_LOG_ENTRY_PH order place

7. Place the 10 VISU items in an ascending order (the oldest entry Visu_array[1] on the top) or a descending order (the newest entry Visu_array[10] on the top).

TECT_SYSTEM_GROUP_PH

TECT_SYSTEM_GROUP_PH can be used as template to control and monitor complete system.



Using this visualization user can enable or disable the process, start or stop autotune process, aceept the autotune parameters for the complete system. It also has option to Cold reset and Warm reset the process for complete system.

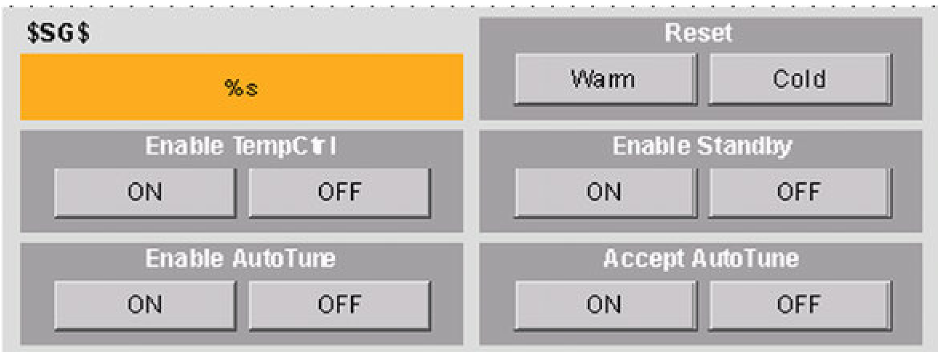


Fig. 609: TECT_SYSTEM_GROUP_PH in offline mode

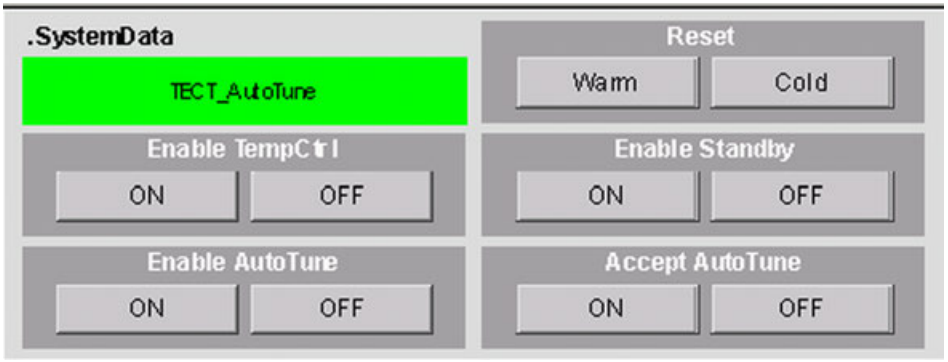

Fig. 610: TECT_SYSTEM_GROUP_PH in online mode

TECT_TEMP_CONTROL_VISU_PH

Description

Visualization element TECT_TEMP_CONTROL_VISU_PH is used to show the actual values of all inputs and outputs of the instance of TECT_TEMP_CONTROL_VISU_PH. The visualization is also used to control the function block by those inputs, which are not connected inside the program. The figures show the visualization in offline and online mode.

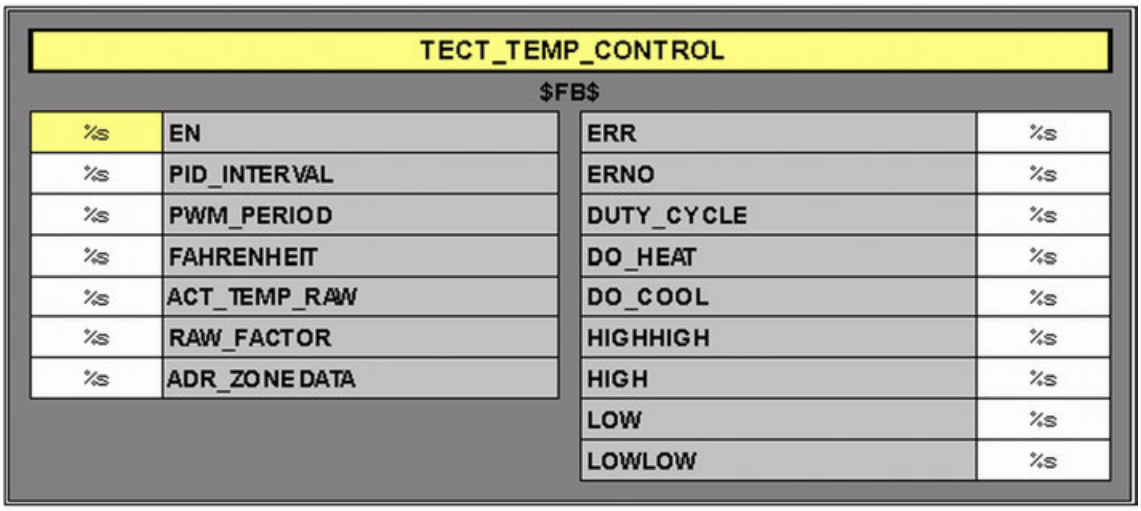

Fig. 611: TECT_TEMP_CONTROL_VISU_PH template in offline mode

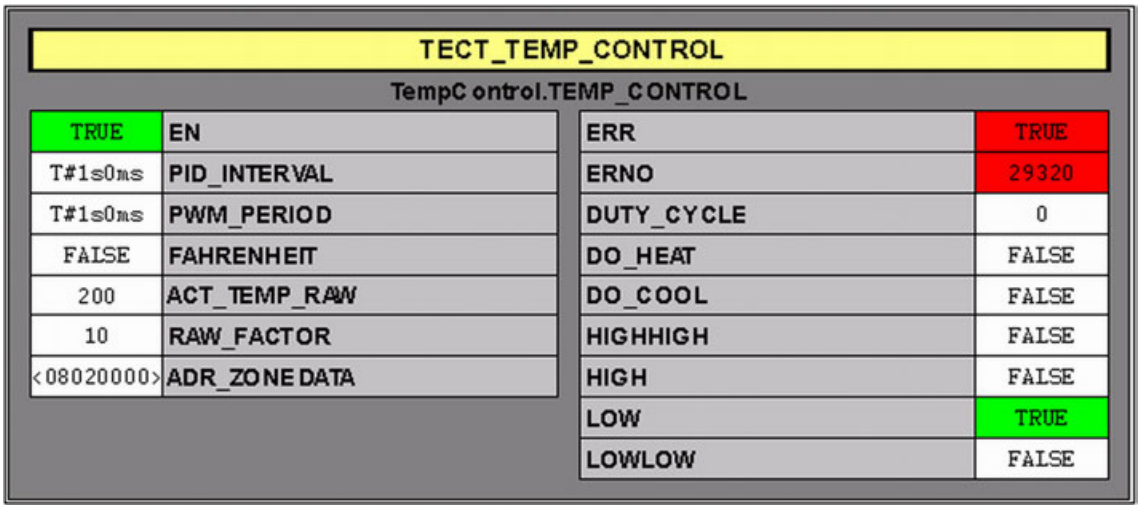

Fig. 612: TECT_TEMP_CONTROL_VISU_PH template in online mode

Colors

The color of the variables has the following meaning:

- WHITE: Actual FALSE and should be FALSE in normal operation
- GREEN: Actual TRUE and should be TRUE in normal operation
- YELLOW: Actual FALSE, but should be TRUE in normal operation
- RED: Actual TRUE, but should be FALSE in normal operation

Visualization parameters

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	Enable function block by TRUE level at input EN
PID_INTERVAL	R/W	Keypad	Interval time for PID processing
PWM_PERIOD	R/W	Keypad	PWM Period. It should not be greater than PID_INTERVAL
FAHREN-HEIT	R/W	Toggle	Converts process temperature into Fahrenheit when TRUE
ACT_TEMP_RAW	R/W	Numpad	TC sensor input as actual temperature in raw value: Celsius with RAW_FACTOR
RAW_FACTOR	R/W	Numpad	Factor of ACT_TEMP_RAW to actual temperature in Celsius
ADR_ZONE-DATA	R		Pointer to Zone Data defined as TECT_TEMP-ZONE_DATA_TYPE
ERR	R		Error occured during execution when output ERR = TRUE
ERNO	R		Error codes
DUTY_CYCLE	R		Output duty cycle
DO_HEAT	R		Pulse for heating
DO_COOL	R		Pulse for cooling
HIGHHIGH	R		HighHigh alarm active
HIGH	R		High alarm active
LOW	R		Low alarm active
LOWLOW	R		LowLow alarm active

All inputs of TECT_TEMP_CONTROL function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

The color of the background can be changed by writing a value to the global variable dwTect-ControlVisuBackgroundColor. The color of the title can be changed by writing a value to the global variable dwTectControlVisuTitleColor.

TECT_GROUP_VISU_PH

Description

Visualization element TECT_GROUP_VISU_PH is used to show the actual values of all inputs and outputs of the instance of TECT_GROUP_VISU_PH. The visualization is also used to control the function block by those inputs which are not connected inside the program.

The figures show the visualization in offline and online mode.

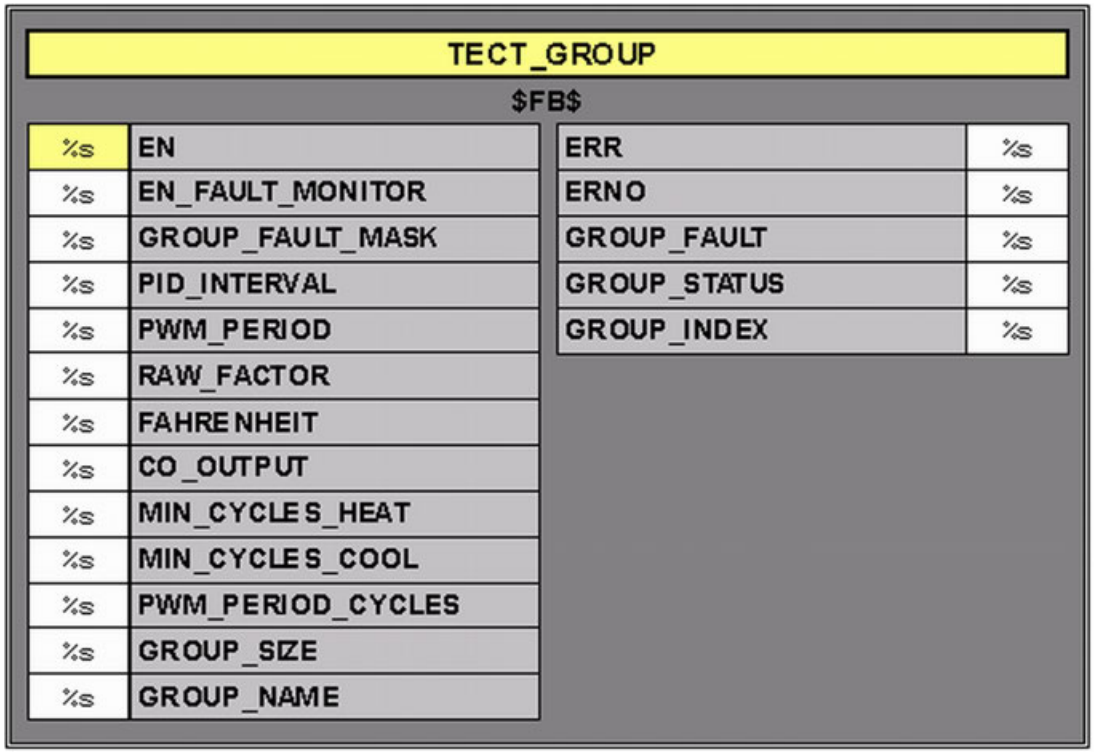

Fig. 613: TECT_GROUP_VISU_PH template in offline mode

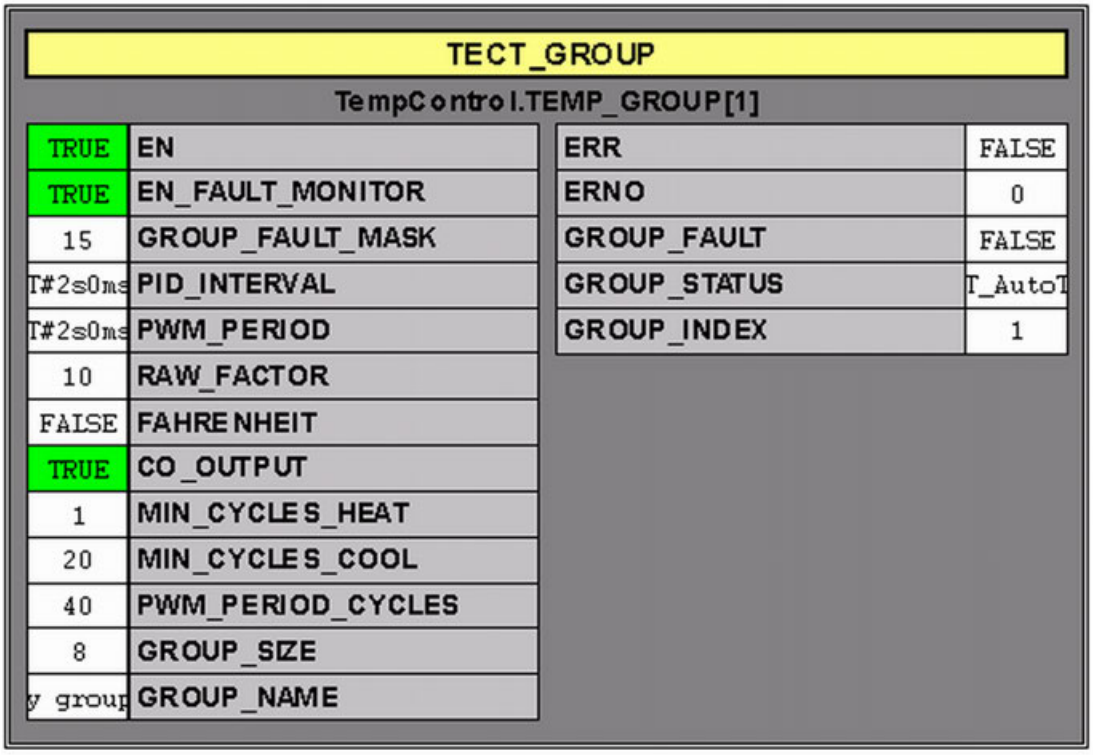

Fig. 614: TECT_GROUP_VISU_PH template in online mode

Colors

The color of the variables has the following meaning:

- WHITE: Actual FALSE and should be FALSE in normal operation
- GREEN: Actual TRUE and should be TRUE in normal operation
- YELLOW: Actual FALSE, but should be TRUE in normal operation
- RED: Actual TRUE, but should be FALSE in normal operation

Visualization parameters

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	Enable function block by TRUE level at input EN
EN_FAULT_MONITOR	R/W	Toggle	It enables the Fault monitoring function when TRUE
GROUP_FAULT_MASK	R/W	Numpad	It enables masking of the Group Fault for the bits which are with value 1
PID_INTERVAL	R/W	Keypad	Interval time for PID processing
PWM_PERIOD	R/W	Keypad	PWM Period. It should not be greater than PID_INTERVAL
RAW_FACTOR	R/W	Numpad	Factor of ACT_TEMP_RAW to actual temperature in Celsius
FAHRENHEIT	R/W	Toggle	Converts process temperature into Fahrenheit when TRUE
ACT_TEMP_RAW	R/W	Numpad	TC sensor input as actual temperature in raw value: Celsius with RAW_FACTOR
CO_OUTPUT	R/W	Toggle	Enables coordinated output
MIN_CYCLES_HEAT	R/W	Numpad	ON or OFF Period should have a minimum length in number of CPU cycles
MIN_CYCLES_COOL	R/W	Numpad	ON or OFF Period should have a minimum length in number of CPU cycles
PWM_PERIOD_CYCLES	R/W	Numpad	Period duration referred to number of CPU cycles
GROUP_SIZE	R/W	Numpad	Size of the group
GROUP_NAME	R/W	Keypad	Name of the Group upto 20 characters
ERR	R		Error occured during execution when output ERR = TRUE
ERNO	R		Error codes
GROUP_FAULT	R		Group fault active
GROUP_STATUS	R		Status of the group
GROUP_INDEX	R		Group Index

All inputs of TECT_GROUP function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

The color of the background can be changed by writing a value to the global variable dwTectControlVisuBackgroundColor. The color of the title can be changed by writing a value to the global variable dwTectControlVisuTitleColor.

TECT_SYSTEM_VISU_PH

Description

Visualization element TECT_SYSTEM_VISU_PH is used to show the actual values of all inputs and outputs of the instance of TECT_SYSTEM_VISU_PH. The visualization is also used to control the function block by those inputs, which are not connected inside the program.

The figures show the visualization in offline and online mode.

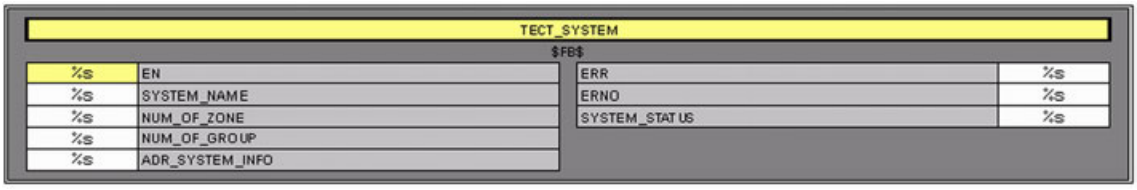

Fig. 615: TECT_SYSTEM_VISU_PH template in offline mode

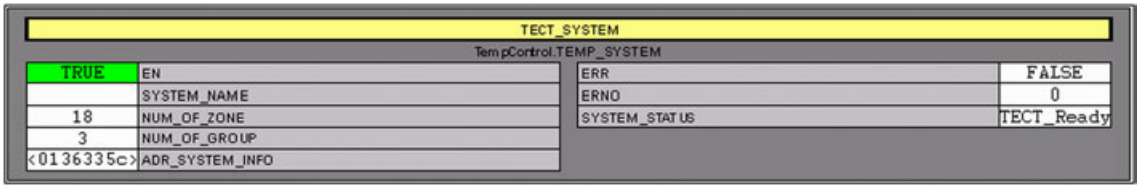

Fig. 616: TECT_SYSTEM_VISU_PH template in online mode

Colors

The color of the variables has the following meaning:

- WHITE: Actual FALSE and should be FALSE in normal operation
- GREEN: Actual TRUE and should be TRUE in normal operation
- YELLOW: Actual FALSE, but should be TRUE in normal operation
- RED: Actual TRUE, but should be FALSE in normal operation

Visualization parameters

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	Enable function block by TRUE level at input EN
SYSTEM_NAME	R/W	Text	Name of the System upto 20 characters
NUM_OF_ZONE	R/W	Numpad	Number of zones in the system to be operated
NUM_OF_GROUP	R/W	Numpad	Interval time for PID processing
ADR_SYSTEM_INFO	R		Pointer to Zone info defined as TECT_ZONE_INFO_TYPE
ERR	R		Error occured during execution when output ERR = TRUE
ERNO	R		Error codes
SYSTEM_STATUS	R		System state machine status

All inputs of TECT_SYSTEM function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

The color of the background can be changed by writing a value to the global variable dwTect-ControlVisuBackgroundColor.

TECT_TEMP_SIMU_VISU_PH

Description

Visualization element TECT_TEMP_SIMU_VISU_PH is used to show the actual values of all inputs and outputs of the instance of TECT_TEMP_SIMU_VISU_PH. The visualization is also used to control the function block by those inputs, which are not connected inside the program.

The figures show the visualization in offline and online mode.

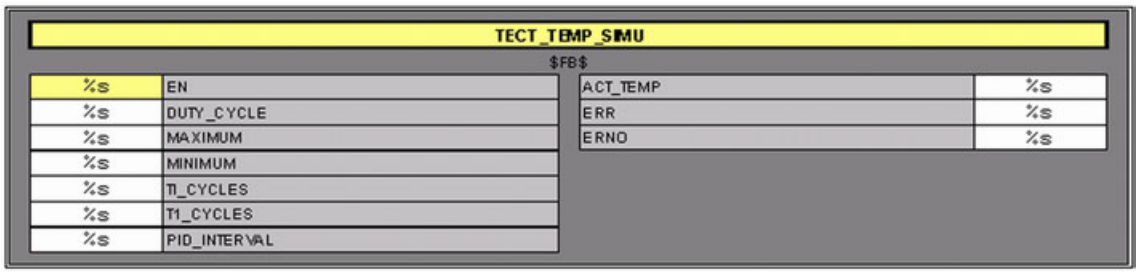

Fig. 617: TECT_TEMP_SIMU_VISU_PH template in offline mode

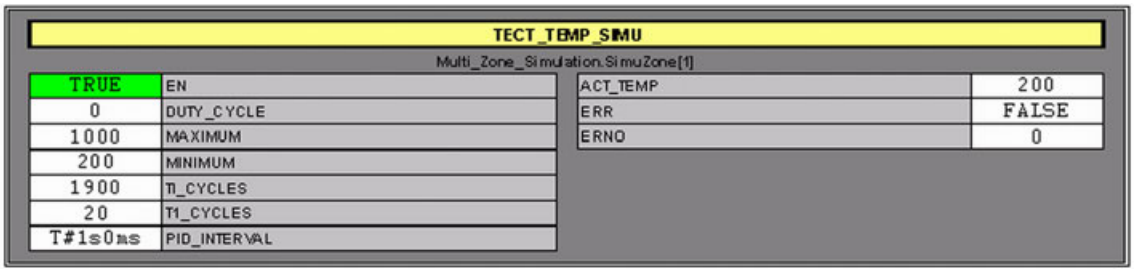

Fig. 618: TECT_TEMP_SIMU_VISU_PH template in online mode

Colors

The color of the variables has the following meaning:

- WHITE: Actual FALSE and should be FALSE in normal operation
- GREEN: Actual TRUE and should be TRUE in normal operation
- YELLOW: Actual FALSE, but should be TRUE in normal operation
- RED: Actual TRUE, but should be FALSE in normal operation

Visualization parameters

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	Enable function block by TRUE level at input EN
DUTY_CYCLE	R/W	Numpad	PWM duty cycle for a temperature zone
MAXIMUM	R/W	Numpad	Maximum temperature allowed for the simulation
MINIMUM	R/W	Numpad	Minimum temperature allowed for the simulation
TI_CYCLES	R/W	Numpad	Internal control parameter for simulation
T1_CYCLES	R/W	Numpad	Internal control parameter for simulation
PID_INTERVAL	R/W	Keypad	Interval time for PID processing
ACT_TEMP	R		Simulated actual temperature
ERR	R		Error occured during execution when output ERR = TRUE
ERNO	R		Error codes

All inputs of TECT_TEMP_SIMU function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

The color of the background can be changed by writing a value to the global variable dwTectControlVisuBackgroundColor. The color of the title can be changed by writing a value to the global variable dwTectControlVisuTitleColor.

TECT_NOISE_FILTER_VISU_PH

Description

Visualization element TECT_NOISE_FILTER_VISU_PH is used to show the actual values of all inputs and outputs of the instance of TECT_NOISE_FILTER_VISU_PH. The visualization is also used to control the function block by those inputs, which are not connected inside the program.

The figures show the visualization in offline and online mode.

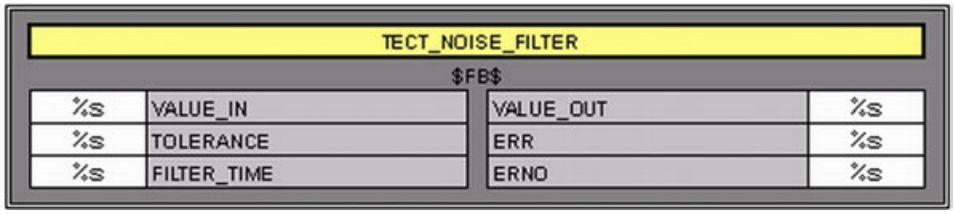

Fig. 619: TECT_NOISE_FILTER_VISU_PH template in offline mode

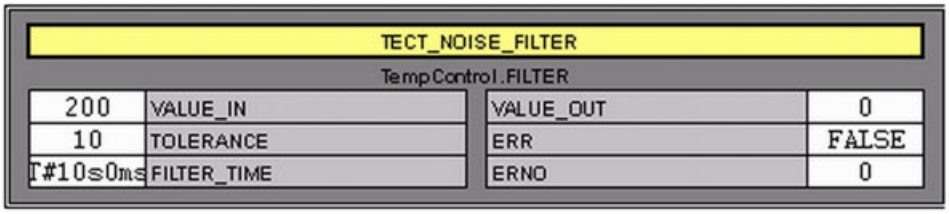

Fig. 620: TECT_NOISE_FILTER_VISU_PH template in online mode

Colors

The color of the variables has the following meaning:

- WHITE: Actual FALSE and should be FALSE in normal operation
- GREEN: Actual TRUE and should be TRUE in normal operation
- YELLOW: Actual FALSE, but should be TRUE in normal operation
- RED: Actual TRUE, but should be FALSE in normal operation

Visualization parameters

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
VALUE_IN	R/W	Numpad	Input value to be filtered
TOLERANCE	R/W	Numpad	Tolerance for the input value
FILTER_TIME	R/W	Keypad	Filter time
VALUE_OUT	R		Output value after filtering
ERR	R		Error occured during execution when output ERR = TRUE
ERNO	R		Error codes

All inputs of TECT_NOISE_FILTER function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

The color of the background can be changed by writing a value to the global variable dwTectControlVisuBackgroundColor. The color of the title can be changed by writing a value to the global variable dwTectControlVisuTitleColor.

TECT_PWM8_VISU_PH

Description

Visualization element TECT_PWM8_VISU_PH is used to show the actual values of all inputs and outputs of the instance of TECT_PWM8_VISU_PH. The visualization is also used to control the function block by those inputs which are not connected inside the program.

The figures show the visualization in offline and online mode.

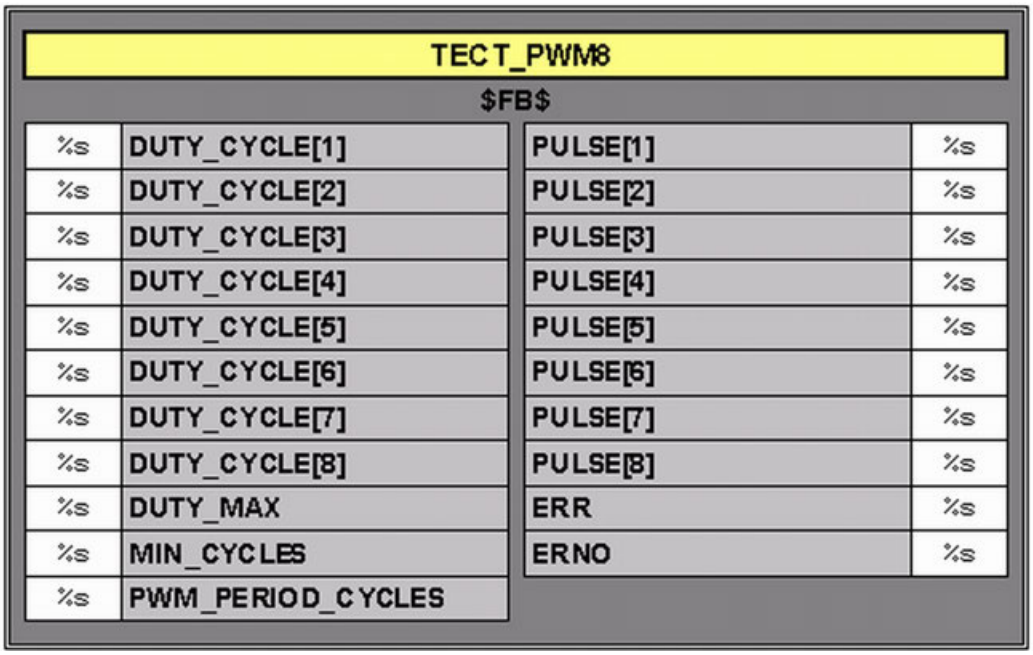

Fig. 621: TECT_PWM8_VISU_PH template in offline mode

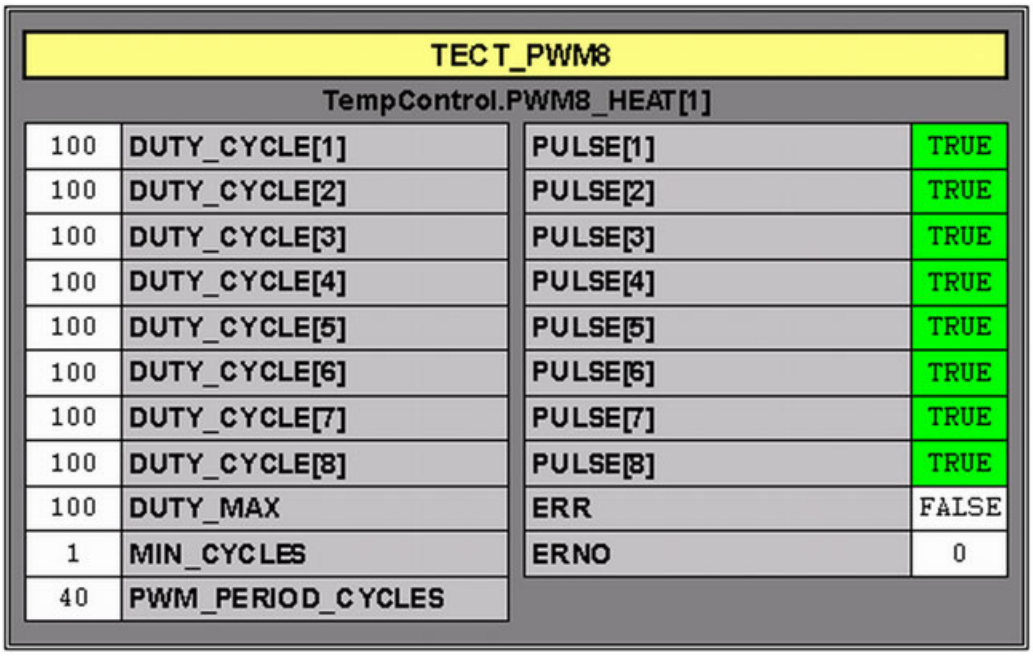

Fig. 622: TECT_PWM8_VISU_PH template in online mode

Colors

The color of the variables has the following meaning:

- WHITE: Actual FALSE and should be FALSE in normal operation
- GREEN: Actual TRUE and should be TRUE in normal operation
- YELLOW: Actual FALSE, but should be TRUE in normal operation
- RED: Actual TRUE, but should be FALSE in normal operation

Visualization parameters

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
DUTY_CYCLE[1]	R/W	Numpad	PWM duty cycle for a first zone
DUTY_CYCLE[2]	R/W	Numpad	PWM duty cycle for a second zone
DUTY_CYCLE[3]	R/W	Numpad	PWM duty cycle for a third zone
DUTY_CYCLE[4]	R/W	Numpad	PWM duty cycle for a fourth zone
DUTY_CYCLE[5]	R/W	Numpad	PWM duty cycle for a fifth zone
DUTY_CYCLE[6]	R/W	Numpad	PWM duty cycle for a sixth zone
DUTY_CYCLE[7]	R/W	Numpad	PWM duty cycle for a seventh zone
DUTY_CYCLE[8]	R/W	Numpad	PWM duty cycle for a eighth zone
DUTY_MAX	R/W	Numpad	Max value for DUTY_CYCLE
MIN_CYCLES	R/W	Numpad	ON or OFF Period should have a minimum length in number of CPU cycles
PWM_PERIOD_CYCLES	R/W	Numpad	Internal control parameter for simulation
PULSE[1]	R		Pulse duration modulated signal of first zone
PULSE[2]	R		Pulse duration modulated signal of second zone
PULSE[3]	R		Pulse duration modulated signal of third zone
PULSE[4]	R		Pulse duration modulated signal of fourth zone
PULSE[5]	R		Pulse duration modulated signal of fifth zone
PULSE[6]	R		Pulse duration modulated signal of sixth zone
PULSE[7]	R		Pulse duration modulated signal of seventh zone
PULSE[8]	R		Pulse duration modulated signal of eighth zone
ERR	R		Error occured during execution when output ERR = TRUE
ERNO	R		Error codes

All inputs of TECT_PWM8 function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

The color of the background can be changed by writing a value to the global variable dwTectControlVisuBackgroundColor. The color of the title can be changed by writing a value to the global variable dwTectControlVisuTitleColor.

TECT_LOG_FILE_VISU_PH

Description

Visualization element TECT_LOG_FILE_VISU_PH is used to show the actual values of all inputs and outputs of the instance of TECT_LOG_FILE_VISU_PH. The visualization is also used to control the function block by those inputs, which are not connected inside the program.

The figures show the visualization in offline and online mode.

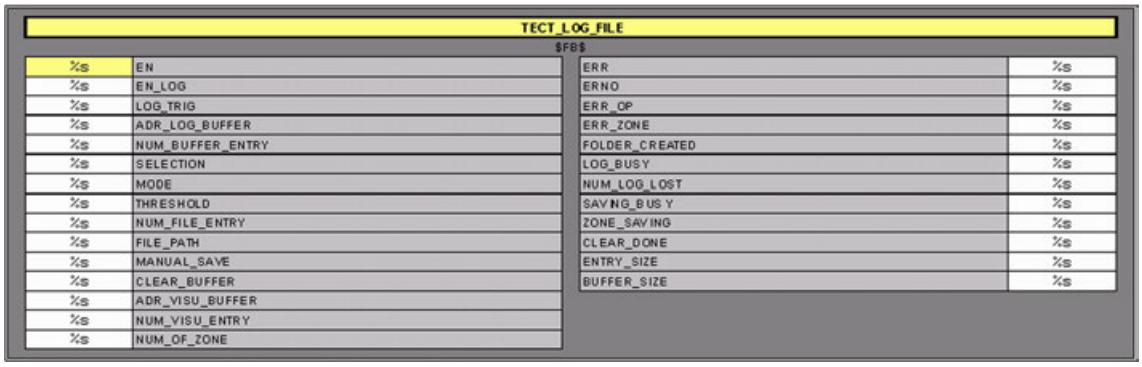

Fig. 623: TECT_LOG_FILE_VISU_PH template in offline mode

Fig. 624: TECT_LOG_FILE_VISU_PH template in online mode

Colors

The color of the variables has the following meaning:

- WHITE: Actual FALSE and should be FALSE in normal operation
- GREEN: Actual TRUE and should be TRUE in normal operation
- YELLOW: Actual FALSE, but should be TRUE in normal operation
- RED: Actual TRUE, but should be FALSE in normal operation

Visualization parameters

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	Enable function block by TRUE level at input EN
EN_LOG	R/W	Toggle	Enable logger and save log buffer to file automatically
LOG_TRIG	R/W	Toggle	Execute log with rising edge
ADR_LOG_BUFFER	R		Start address of the logging buffer
NUM_BUFFER_ENTRY	R/W	Numpad	Size of logging buffer: number of entries
SELECTION	R/W	Numpad	Selection of predefined values to be logged
MODE	R/W	Numpad	To select the different modes for logging
THRESHOLD	R/W	Numpad	Value needs to be set in combination of MODE: MODE.Bit2-0 = 101
NUM_FILE_ENTRY	R/W	Numpad	Value needs to be set in combination of MODE: MODE.Bit7-6 = 01
FILE_PATH	R/W	Text	Folder for saving log file, should not be empty, one level will be created

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
MANUAL_SAVE	R/W	Toggle	Save log buffer to file manually
CLEAR_BUFFER	R/W	Toggle	Clear log buffer
ADR_VISU_BUFFER	R		First address of data type TECT_TYPLOGINFO_TYPE
NUM_VISU_ENTRY	R/W	Numpad	Number of log entries displayed in VISU
NUM_OF_ZONE	R/W	Numpad	Number of zones in the system to be operated
ERR	R		Error occured during execution when output ERR = TRUE
ERNO	R		Error codes
ERR_OP	R		Error operation, combined with ERR and ERNO
ERR_ZONE	R		Error zone, zone which causes the error
FOLDER_CREATED	R		Folder and subfolder created
LOG_BUSY	R		Logging entry in buffer is busy
NUM_LOG_LOST	R		Number of logs lost
SAVING_BUSY	R		Save logging buffer to file is busy
ZONE_SAVING	R		The zone of which the file operation is executing
CLEAR_DONE	R		Clear logging buffer is done
ENTRY_SIZE	R		Size of one log entry in byte, depending on SELECTION
BUFFER_SIZE	R		Size of whole buffer for all zones in byte, depending on ENTRY_SIZE, NUM_BUFFER_ENTRY and NUM_OF_ZONE

All inputs of TECT_LOG_FILE function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

The color of the background can be changed by writing a value to the global variable dwTectControlVisuBackgroundColor. The color of the title can be changed by writing a value to the global variable dwTectControlVisuTitleColor.

TECT_RECIPE_VISU_PH

Description

Visualization element TECT_RECIPE_VISU_PH is used to show the actual values of all inputs and outputs of the instance of TECT_RECIPE_VISU_PH. The visualization is also used to control the function block by those inputs, which are not connected inside the program.

The figures show the visualization in offline and online mode.

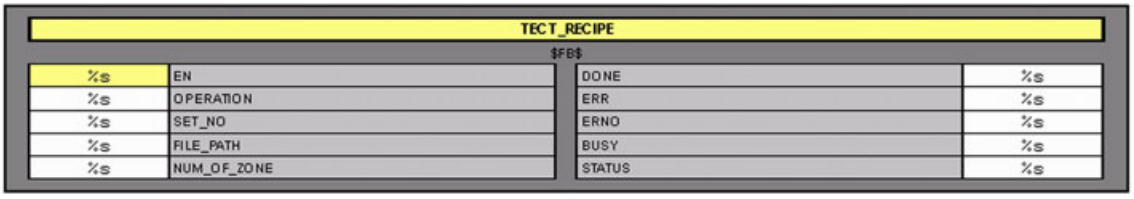

Fig. 625: TECT_RECIPE_VISU_PH template in offline mode

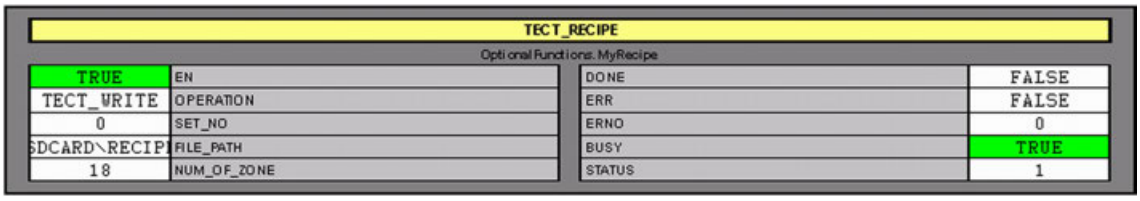

Fig. 626: TECT_RECIPE_VISU_PH template in online mode

Colors

The color of the variables has the following meaning:

- WHITE: Actual FALSE and should be FALSE in normal operation
- GREEN: Actual TRUE and should be TRUE in normal operation
- YELLOW: Actual FALSE, but should be TRUE in normal operation
- RED: Actual TRUE, but should be FALSE in normal operation

Visualization parameters

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	Enable function block by TRUE level at input EN
OPERATION	R/W	Numpad	Operation type := 1: READ, 2: WRITE.
SET_NO	R/W	Numpad	Recipe set number: 0..65535
FILE_PATH	R/W	Text	1. Folder name: default file will be created. 2. folder+file name: user defined file will be created.
NUM_OF_ZONE	R/W	Numpad	Number of zones in the system to be operated
DONE	R		Execution finished, when output DONE = TRUE
ERR	R		Error occured during execution when output ERR = TRUE
ERNO	R		Error codes
BUSY	R		Recipe operation busy
STATUS	R		Status of the recipe block

All inputs of TECT_RECIPE function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

The color of the background can be changed by writing a value to the global variable dwTect-ControlVisuBackgroundColor. The color of the title can be changed by writing a value to the global variable dwTectControlVisuTitleColor.

TECT_DATA_FLASH_VISU_PH

Description

Visualization element TECT_DATA_FLASH_VISU_PH is used to show the actual values of all inputs and outputs of the instance of TECT_DATA_FLASH_VISU_PH. The visualization is also used to control the function block by those inputs, which are not connected inside the program. The figures show the visualization in offline and online mode.

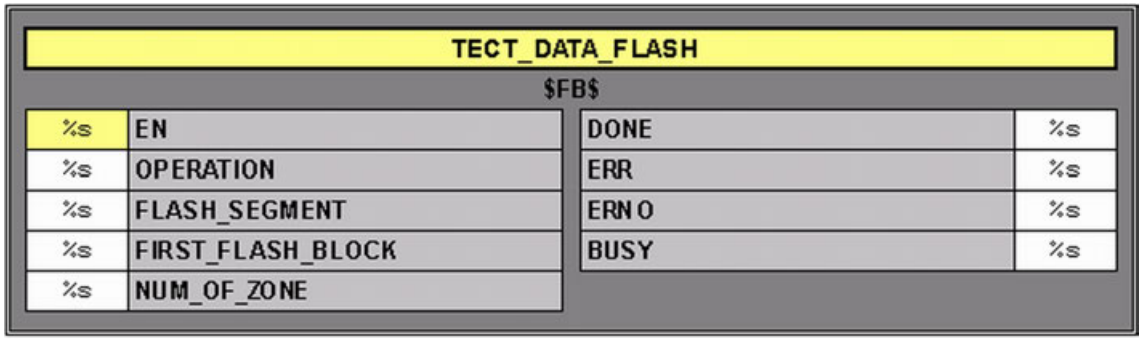

Fig. 627: TECT_DATA_FLASH_VISU_PH template in offline mode

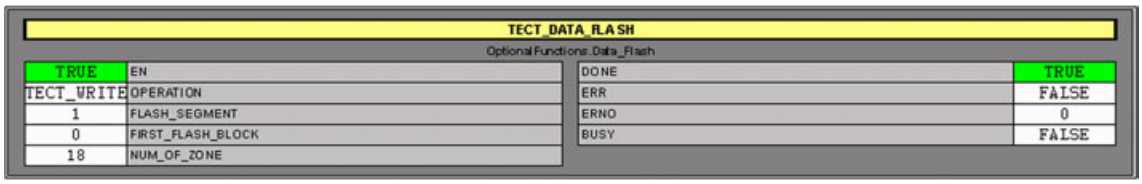

Fig. 628: TECT_DATA_FLASH_VISU_PH template in online mode

Colors

The color of the variables has the following meaning:

- WHITE: Actual FALSE and should be FALSE in normal operation
- GREEN: Actual TRUE and should be TRUE in normal operation
- YELLOW: Actual FALSE, but should be TRUE in normal operation
- RED: Actual TRUE, but should be FALSE in normal operation

Visualization parameters

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	Enable function block by TRUE level at input EN
OPERATION	R/W	Numpad	Operation type := 1: READ, 2: WRITE.
FLASH_SEGMENT	R/W	Numpad	Number of the data segment; 1 or 2
FIRST_FLASH_BLOCK	R/W	Numpad	Number of the flash block within the data segment: 0...1926
NUM_OF_ZONE	R/W	Numpad	Number of zones in the system to be operated
DONE	R		Execution finished, when output DONE = TRUE
ERR	R		Error occured during execution when output ERR = TRUE
ERNO	R		Error codes
BUSY	R		Recipe operation busy

All inputs of TECT_DATA_FLASH function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

The color of the background can be changed by writing a value to the global variable dwTectControlVisuBackgroundColor. The color of the title can be changed by writing a value to the global variable dwTectControlVisuTitleColor.

TECT_HMI_MUX_VISU_PH

Description

Visualization element TECT_HMI_MUX_VISU_PH is used to show the actual values of all inputs and outputs of the instance of TECT_HMI_MUX_VISU_PH. The visualization is also used to control the function block by those inputs, which are not connected inside the program.

The figures show the visualization in offline and online mode.

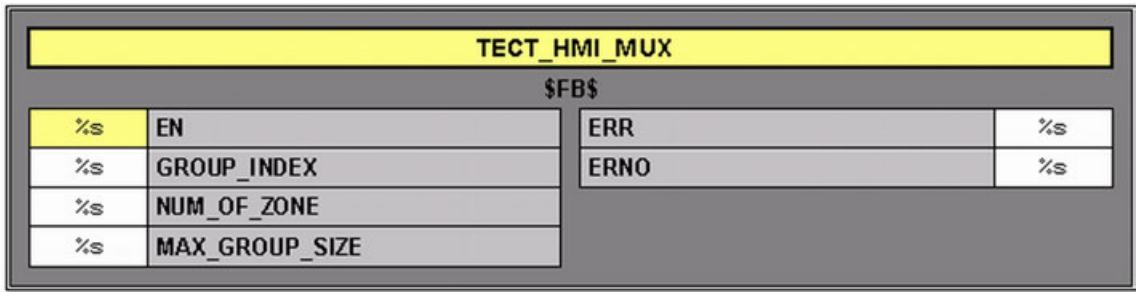

Fig. 629: TECT_HMI_MUX_VISU_PH template in offline mode

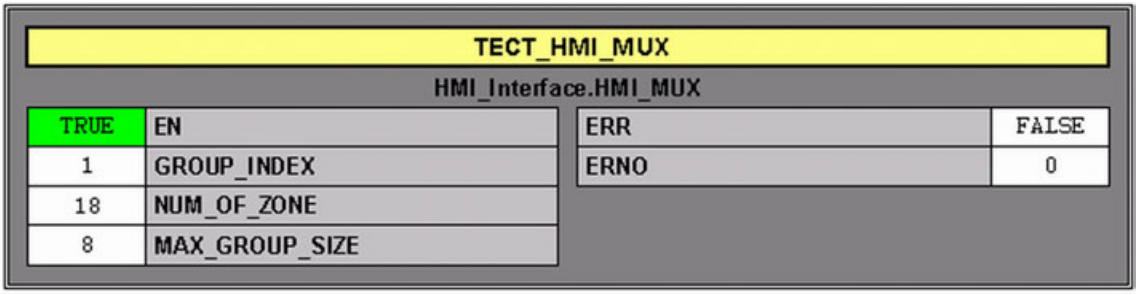

Fig. 630: TECT_HMI_MUX_VISU_PH template in online mode

Colors

The color of the variables has the following meaning:

- WHITE: Actual FALSE and should be FALSE in normal operation
- GREEN: Actual TRUE and should be TRUE in normal operation
- YELLOW: Actual FALSE, but should be TRUE in normal operation
- RED: Actual TRUE, but should be FALSE in normal operation

Visualization parameters

Variable Element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	Enable function block by TRUE level at input EN
GROUP_INDEX	R/W	Numpad	Index of active Group on HMI, it will be set from HMI and should be >0
NUM_OF_ZONE	R/W	Numpad	Number of zones in the system to be operated and should be >0
MAX_GROUP_SIZE	R/W	Numpad	Size of the largest group in the system and should be >0
ERR	R		Error occured during execution when output ERR = TRUE
ERNO	R		Error codes

All inputs of TECT_HMI_MUX function block, which are not connected to a variable (left open), can be written from this faceplate. The function block can be controlled from the visualization as long as the inputs are left open.

The color of the background can be changed by writing a value to the global variable dwTect-ControlVisuBackgroundColor. The color of the title can be changed by writing a value to the global variable dwTectControlVisuTitleColor.

1.5.12.5 Examples

Example projects for the libraries can be found in the folder: \Users\Public\Documents\AutomationBuilder\Examples

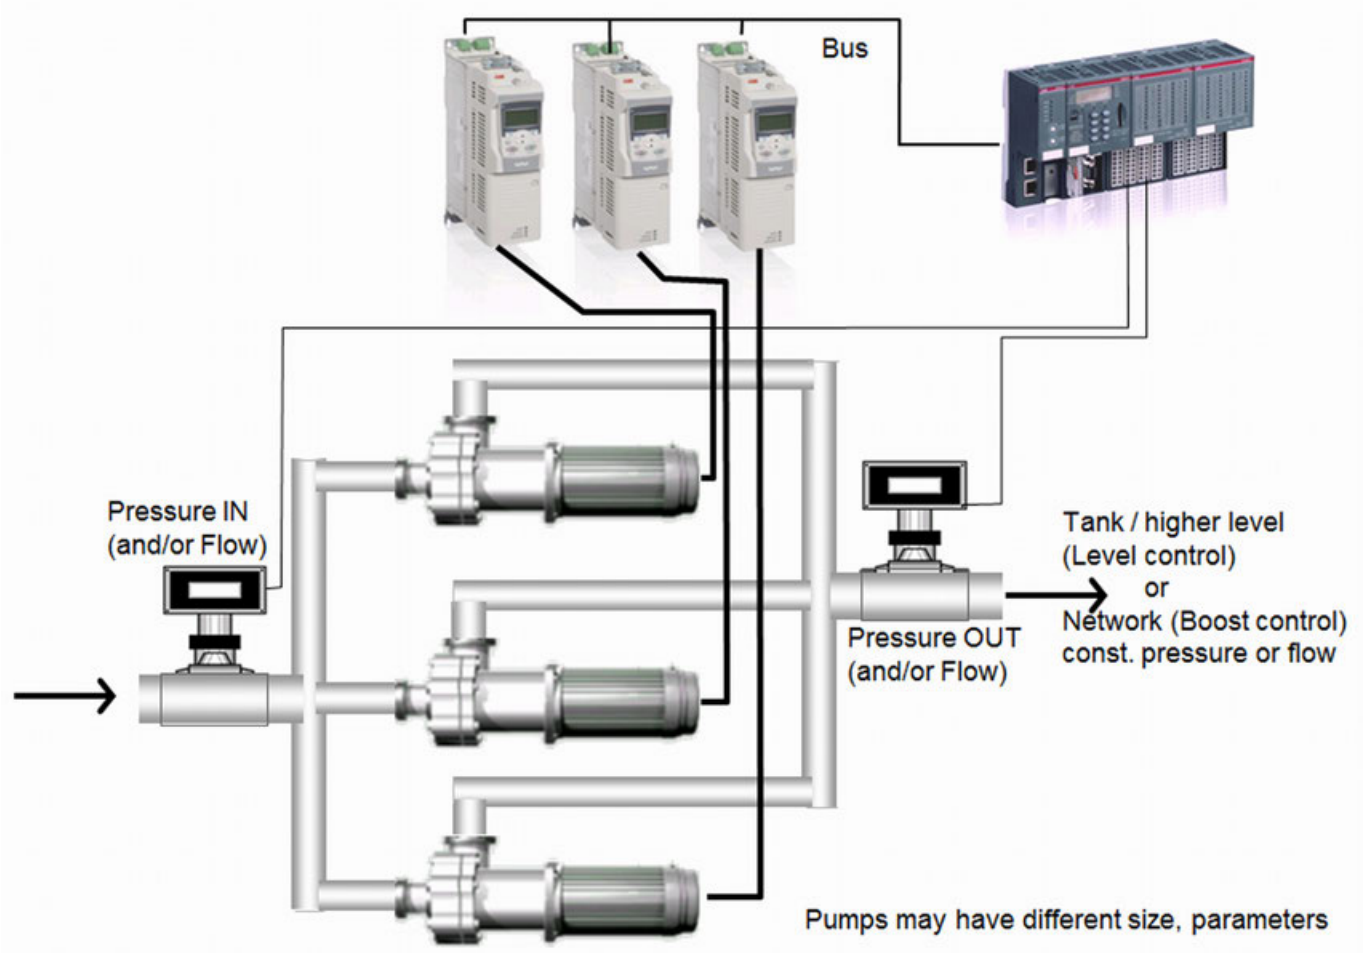
1.5.13 Water library

1.5.13.1 Pumping library

1.5.13.1.1 Overview

The Pumping Library is intended for smaller pump stations (or pump skids) and medium sized stations. It contains the block for the basic functionalities as well as advanced functions for very different applications.

This version named PUMP_AC500_V23.lib for Control Builder Plus V2.3 is usable for 1-3 pumps and is intended for configurations as it can be seen in the below figure It is best suited for the use of frequency converters/drives for each pump but also for the traditional setup with one drive and 1-2 switched outputs for the pumps.



The minimal sensor equipment for boost control applications is a pressure or flow sensor, for level control a level sensor. The pressure sensor can be at input and or/output, the flow sensor should be at the output. Often additionally also at the input a sensor, typically pressure, is placed for advanced protection and diagnosis.

The two main pumping applications in water and waste water are:

- Boost, typically pressure boost control: Used in network feeding, but also flow boost control for irrigation, water transport, cooling and washing applications.
- Level control: Used for tank or reservoir filling or emptying applications e.g. also lift applications e.g. in waste water networks.

For both applications a special application block is available, which has all the needed basic functionality, so that with minimal programming and mainly configuration an application can be setup.

Further auxiliary and optimization Function Blocks are part of the library, which help in putting additional advanced functionality with again minimal programming effort.

This function block type concept helps in always having the necessary functionality without using too much PLC resources (memory) and keeping the applications as simple as possible. Therefore the Pumping Library can be used throughout the AC500 Platform, starting from the small AC500-eCo.

Example

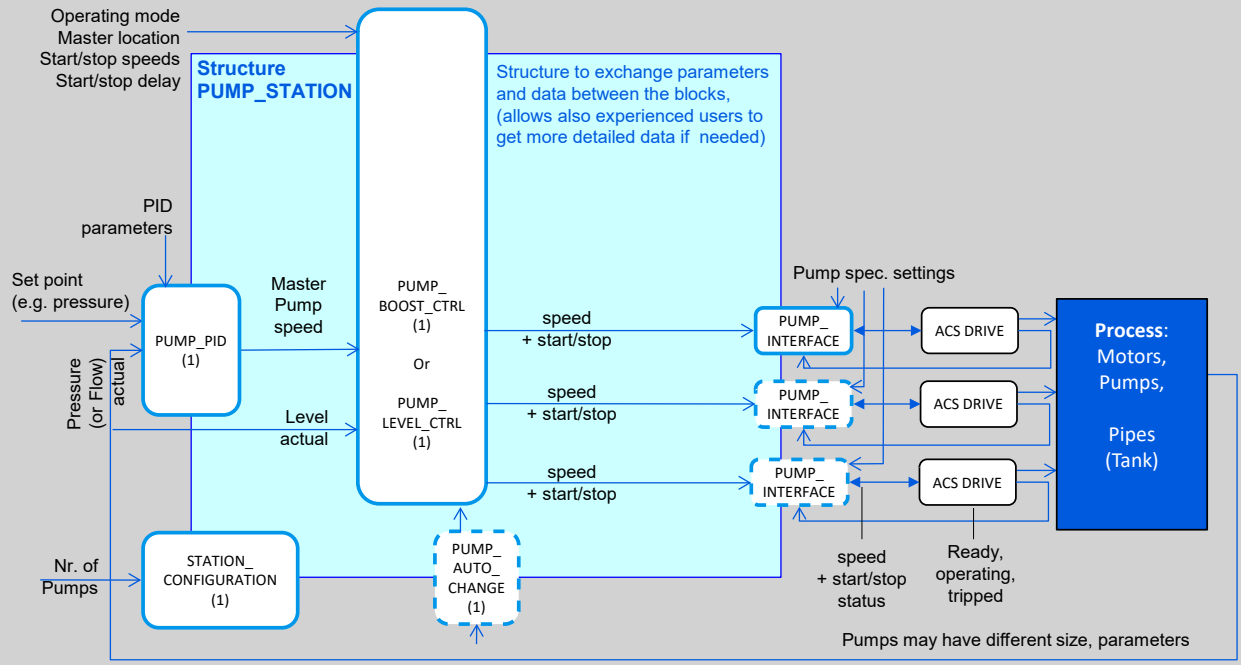


Fig. 631: A simple but typical application for small pump station or pump-skid (suitable e.g. also for AC500-eCo with 3 pumps)

→ Other specific parameters
(x) x shows how often a function block is used in a setup with 3 pumps
- - - Optional function blocks depending on the application

The station itself is configured by the function block STATION_CONFIGURATION with an ID, name and number of used pumps.

The main application Function Block is PUMP_BOOST_CTRL or PUMP_LEVEL_CTRL.

When using the function block PUMP_BOOST_CTRL: The actual pressure is read from the sensor and sent to the function block PUMP_PID. The PID corrections are given to the function block PUMP_BOOST_CTRL.

When using the PUMP_LEVEL_CTRL: The actual level is read from the sensor. It is not sent to PUMP_PID, it is sent directly to the function block PUMP_LEVEL_CTRL which does a fill or an empty operation.

The function block PUMP_INTERFACE is used for detailed configuration of each pump and for interfacing to the drives/actuators. The function blocks PUMP_INTERFACE allow a variety of actuators: One drive with direct-on-line "DOL" pumps, hard- or soft-switched; all drive controlled pumps; discrete or bus connection to the drives.

The number of function blocks PUMP_INTERFACE is depending on the number of pumps. 1 pump = 1 function block PUMP_INTERFACE, 2 pumps = 2 function blocks PUMP_INTERFACE etc.

The parameter and status exchange between the different blocks is done by a structured variable (symbolized by the light blue layer in the above figure which is connected to all blocks with control functionality. It contains substructures depending on the function and use.

This concept minimizes memory usage, the connection work and still allows advanced diagnosis if necessary.

Function blocks

Application function blocks

These are main application and control function blocks.

- The boost-control function block works with a closed loop control signal, typically coming from a PID controller with a pressure (or flow) sensor, see ↳ *Chapter 1.5.13.1.6 “PUMP_BOOST_CTRL Boost Control” on page 3404*. The PID gives a speed set-point for the boost pumping station. The boost control block then distributes start/stop and speed commands, depending on its chosen operating mode and parameters, to e.g. a multi-pump setup.

  The boost application is typically used with drives on all pumps and for:
  - Network feeding to control a pressure in the network over a wide range of flow, which is given by the varying demand in the network.
  - Irrigation, where either pressure or the flow is controlled to achieve a uniform and controlled irrigation.
  - Transport, cooling and washing applications (more flow control).
- The level-control function block works with discrete definable levels to switch the pumps and set appropriate fixed speeds, see ↳ *Chapter 1.5.13.1.8 “PUMP_LEVEL_CTRL Level Control” on page 3414*. Due to this fixed speed operation level control may also be used with the secondary pumps being switched.

Auxiliary function blocks

The auxiliary Function Blocks provide necessary additional functionality in a modular way to further minimize programming needs and mainly do configuration instead.

- PID control with extended functions for pumping applications with this library.
  ↳ *Chapter 1.5.13.1.7 “PUMP_PID” on page 3410*.
- Autochange functionality (ensures distribution of operation hours on the pumps).
  ↳ *Chapter 1.5.13.1.9 “PUMP_AUTOCHANGE” on page 3422*.
- Station configuration and pump interface function blocks to simplify configuration and interfacing to the drives.
  ↳ *Chapter 1.5.13.1.2 “PUMP_STATION_CFG” on page 3384*.
  ↳ *Chapter 1.5.13.1.3 “PUMP_INTERFACE” on page 3386*.
- The retain Function block stores selected values which have to sustain through power failures.
  ↳ *Chapter 1.5.13.1.4 “PUMP_RETAIN_DATA” on page 3391*.

Optimization function blocks

The optimization Function Blocks help in further optimizing the pumping station operation by providing additional information or functionality to save energy and protect the equipment (pumps, pipes, tanks).

- The Flow Calculation block estimates with the help of the drives measured power output and few pump curve data points of the PQ curve the actual flow, which can save a separate instrument and its integration work.
  Chapter 1.5.13.1.11 “PUMP_FLOW_CALC” on page 3430
- The Energy Calculation block totalizes the flows and energy consumptions and provides Efficiency values. If no flow meter is there, the Flow calculation block can be used.
  Chapter 1.5.13.1.14 “PUMP_ENERGY_CALC” on page 3450
- The Sleep function helps to save energy in PID operation if demand is low (e.g. at night in a network) and works closely together with PID and boost block.
  Chapter 1.5.13.1.12 “PUMP_SLEEP” on page 3435
- The Protection block provides advanced protections features for pump, pipe and tank based on the available information in the station.
  Chapter 1.5.13.1.13 “PUMP_PROTECTION” on page 3442
- The Anti-Jam block provides a configurable cleaning function per used pump with a drive.
  Chapter 1.5.13.1.10 “PUMP_ANTIJAM” on page 3426

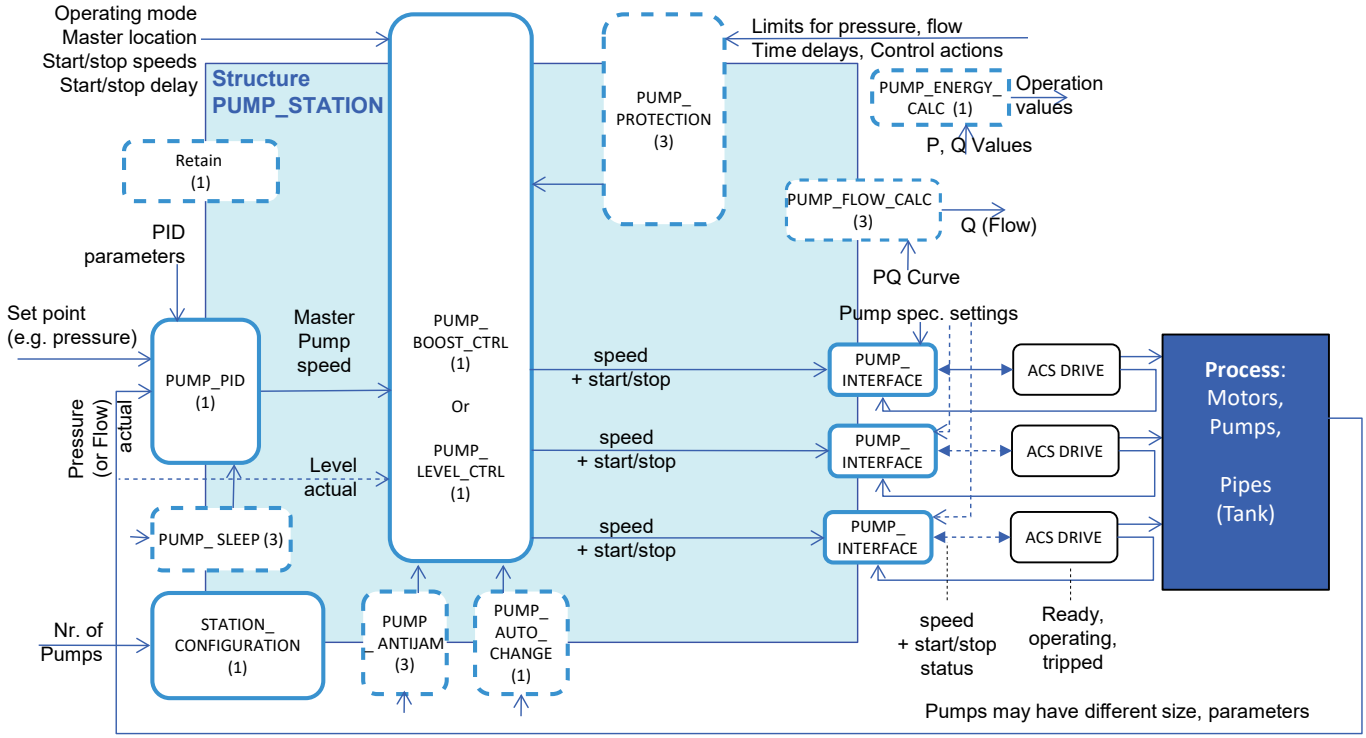

Fig. 632: Overview of the concept and its options with the Pumping Library, including auxiliary and optimization blocks.

There are further blocks provided enabling a simple simulation of the process (DOL, Drive, TANK) to try out an application program without hardware.

For further details please check the application examples and their documentation which are provided with the PS563-WATER library product package. Please check also if a more up to date version or comments exist as download on *www.abb.com/PLC*.

Preconditions for the use of the pumping library

Examples for this library can be found in C:\Users\Public\Documents\AutomationBuilder\Examples\PS563-WATER. Alternative is to go to *“Automation Builder ➔ Help ➔ Project Examples ➔ Examples”*.

The function blocks of the Pumping Library are only working in the RUN mode of the PLC. Usage of these libraries in the simulation mode may not provide any valid or usable diagnosis information.

For compatibility of the library PUMP_AC500_V23.lib please check the latest release notes.

1.5.13.1.2 PUMP_STATION_CFG

This function block must be called before all other function blocks of the library in the task configuration.

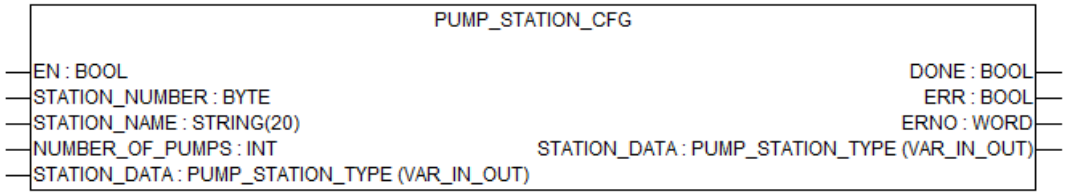

Fig. 633: Function block PUMP_STATION_CFG

Table 201: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

This function block is used to configure a pump station. Number of pumps, station name and number is configured.

Input description

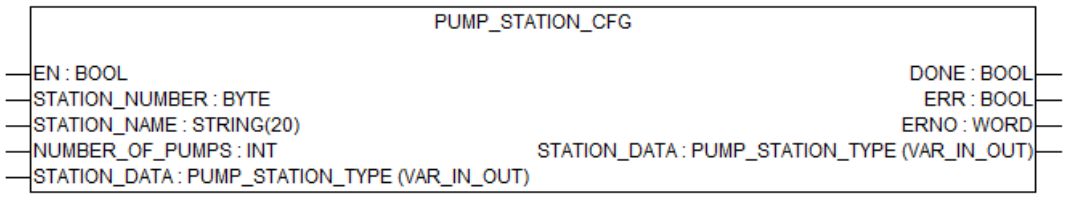

Fig. 634: Function block PUMP_STATION_CFG

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

STATION_NUMBER (station number)

Data type: BYTE, default value: 1, range: > 0

Number assigned to the station.

STATION_NAME (station name)

Data type: STRING

This input stores the station number, which is used as a unique identification number when there are more than one stations configured in a single PLC .

NUMBER_OF_PUMPS (number of pumps)

Data type: INT, default value: 1, range: 1-3

Total number of pumps used in the application.

STATION_DATA (station data structure)

Data type: PUMP_STATION_TYPE

This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

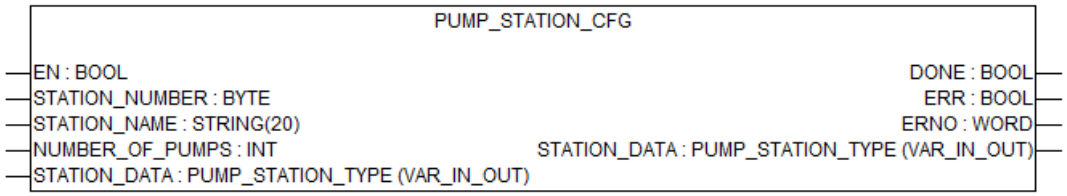

Fig. 635: Function block PUMP_STATION_CFG

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error
16416	4020	Value of STATION_NUMBER is erroneous
16448	4040	Value of NUMBER_OF_PUMPS is erroneous

1.5.13.1.3 PUMP_INTERFACE

All the instances of the function block PUMP_INTERFACE must be called after the function block PUMP_STATION_CFG and before all other function blocks of the pumping library.

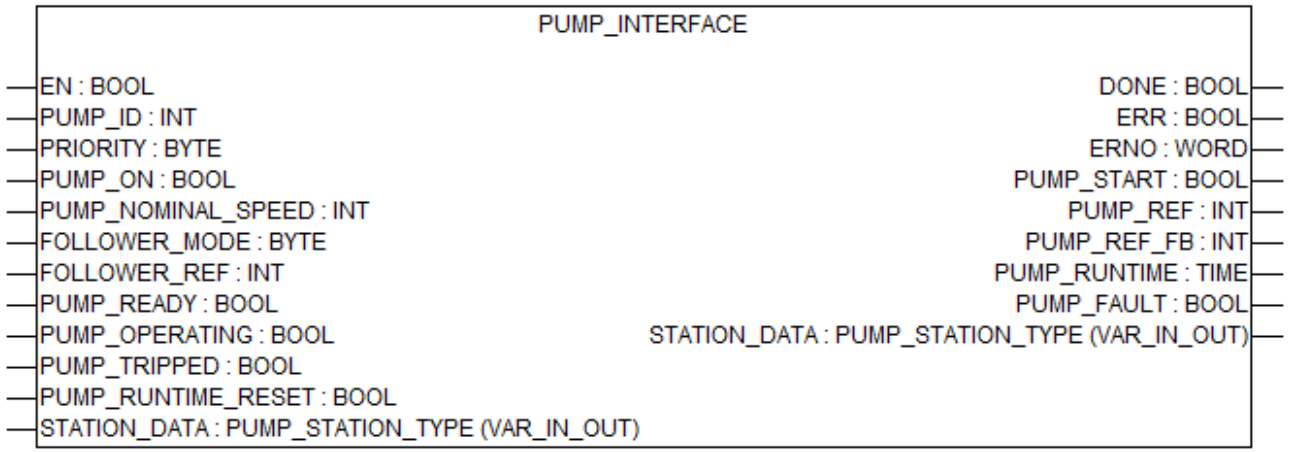

Fig. 636: Function block PUMP_INTERFACE

Table 202: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

Pump_Interface function block receives Pump ID, priority, follower mode and status of the drive and process this data. It gives out pump start,pump reference and pump actual runtime data. Follower drive behavior is defined using follower mode and follower reference and should be set to the same mode for all pumps of one pump station

1.The follower modes in each of the three function blocks PUMP_INTERFACE should be set to the same mode.

2. Each pump must have a unique PUMP_ID.

ACS Drives behavior:

- *When the ON command is withdrawn from the drive, AND it receives an ON command again (rising edge) before it has halted, the drive will not start. To restart the drive, the ON command needs to be made FALSE, let the drive come to halt and then made again TRUE.*

This case can occur by following ways:

- *Momentary power withdrawal from the drive, communication cable disturbance, or Pump_ON is made - FALSE then immediately TRUE again from the PUMP_INTERFACE e.g. during commissioning by manual operation in the engineering or by addition manual buttons around the application.*
- *This is not occurring in the normal operation. Nnevertheless it could be changed by selecting the drive on-the fly restart functionality, if deemed necessary and appropriate.*

Input description

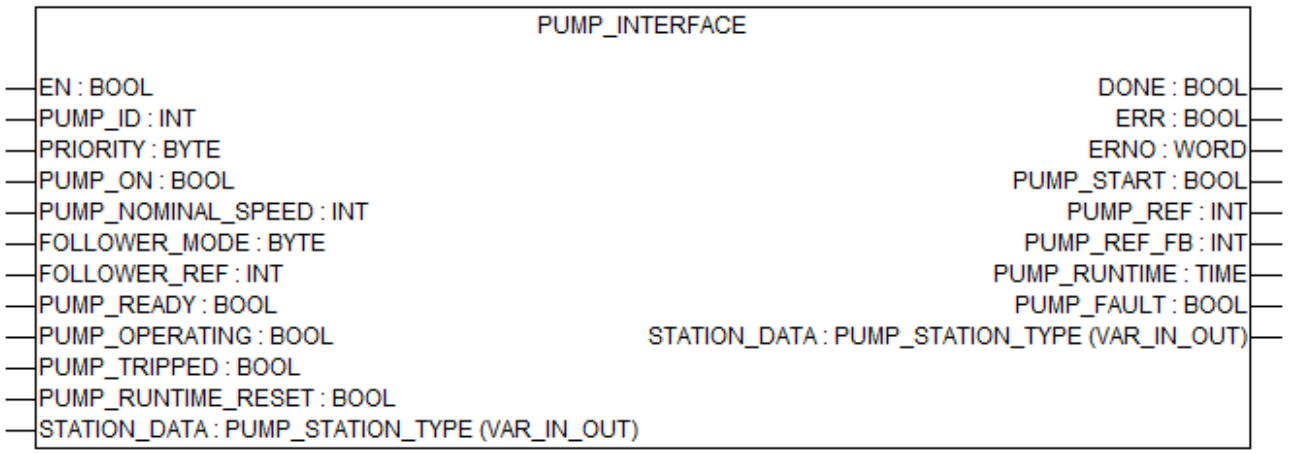

Fig. 637: Function block PUMP_INTERFACE

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PUMP_ID (pump ID)

Data type: INT

Pump identification number for which this function block to be called. Range of values: from 1 to 3 .

PRIORITY (priority)

Data type: BYTE

Pump Priority is used to decide, which drives need to be turn on demand increases.

PUMP_ON (pump on)

Data type: BOOL

This input turns the pump on or off running in boost control or level control. In case of a FALSE value, the user can remove the pump from the auto mode operations such as boost control or level control. Then the user can perform a manual task, such as manual anti-jam, or any other stand alone manual maintenance related job which actually are not part of the library. This input can also be configured using an external digital input signal.

PUMP_NOMINAL_SPEED (pump nominal speed in rpm)

Data type: INT

It stores the nominal value of the speed of the pump. This nominal value is put in the internal structure.

Example

STATION_DATA.atsPump[1].tsConfiguration.iPumpMaxSpeed

This is used to scale the field bus speed setpoint in the scale of -20000 to +20000. This data is also used in the flow calculations.

FOLLOWER_MODE (follower mode)

Data type: BYTE

Follower drives are started and stopped by the control logic. When flow demand increases , new pumps are started. Behavior of the follower pumps are defined by follower mode.

Follower mode	Speed	Explanation
0	Fixed constant speed	Follower starts at pre-defined fixed speed of master and runs at follower reference.
1	Copy master	Follower drives follows the same start/stop commands and speed reference like masterFig. 647.
2	Master speed	Follower starts at pre-defined fixed speed levels of master speed and then runs at the same master reference speed.

FOLLOWER_REF (follower reference)

Data type: INT

The speed reference in RPM for the pumps when the follower mode = 0 is selected.

PUMP_READY (pump ready)

Data type: BOOL

Input to attach the ready status of the drive of the pump.

PUMP_OPERATING (pump operating)

Data type: BOOL

Input to attach the operating status of the drive of the pump.

PUMP_TRIPPED (pump tripped)

Data type: BOOL

Input to attach the fault status of the drive of the pump.

PUMP_RUNTIME_RESET (pump runtime reset)

Data type: BOOL

TRUE value is used to reset the run time of the pump.

STATION_DATA (station data structure)

Data type: PUMP_STATION_TYPE

This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

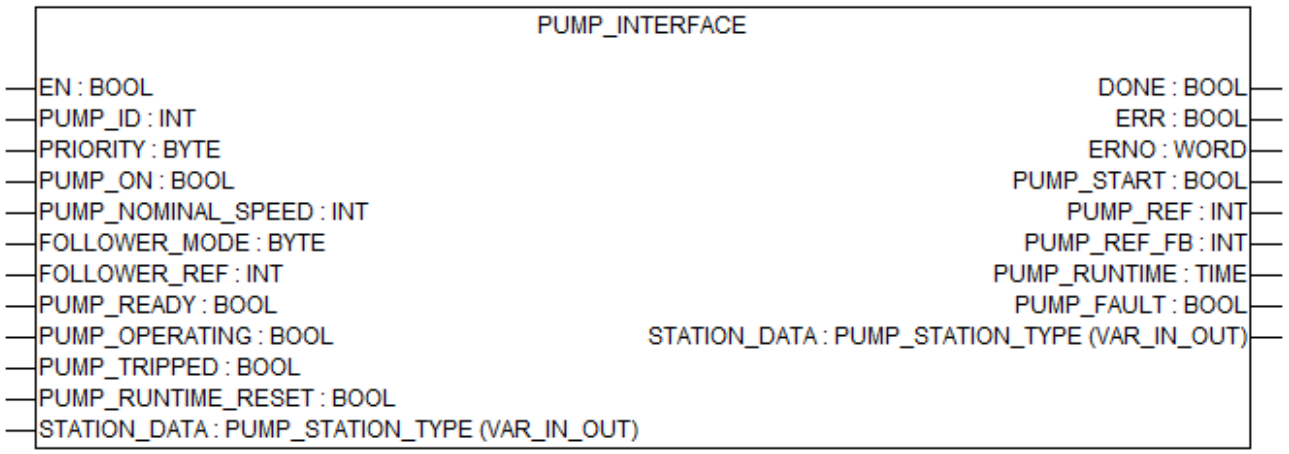

Fig. 638: Function block PUMP_INTERFACE

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

PUMP_START (pump start)

Data type: BOOL

On command to the pump.

PUMP_REF (pump reference)

Data type: INT

Speed reference to the pump in terms of RPM.

PUMP_REF_FB (pump reference field bus)

Data type: INT

Field bus speed reference to the pump in the range of -20000 to 20000.

PUMP_RUN-TIME (pump runtime)

Data type: TIME

Runtime value for the pump.

PUMP_FAULT (pump fault)

Data type: BOOL

TRUE when the pump encountered a fault. This fault can be because of drive tripped, pump protection fault, or due to PUMP_ON=FALSE when the boost control or the level control is running.

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error.
16416	4020	Value of PUMP_ID is erroneous.
16432	4030	Value of PRIORITY is erroneous.
16464	4050	Value of PUMP_NOMINAL_SPEED is erroneous.
16480	4060	Value of FOLLOWER_MODE is erroneous.
16483	4063	All pumps do not have same FOLLOWER_MODE.
16496	4070	Value of FOLLOWER_REF is erroneous.

1.5.13.1.4 PUMP_RETAIN_DATA

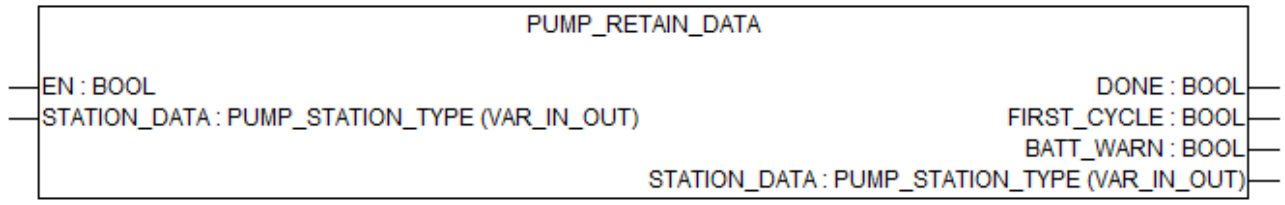

Fig. 639: Function block PUMP_RETAIN_DATA

General Information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block with historical values.

This function block is used to retain important data in the event of power failure or the PLC reboot. It stores the actual run time of the pump, last operating sequence of the pumps, total flow of the pump, total energy consumed.

Input description

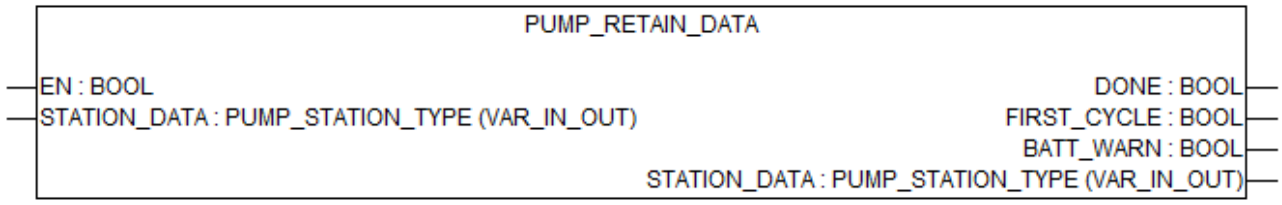

Fig. 640: Function block PUMP_RETAIN_DATA

The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

STATION_DATA (station data structure)

Data type: PUMP_STATION_TYPE

This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

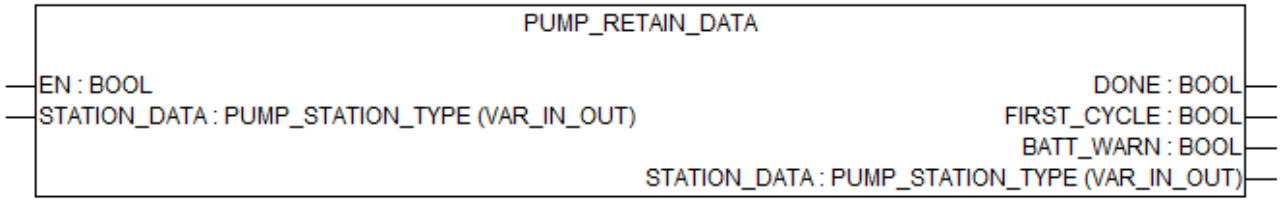

Fig. 641: Function block PUMP_RETAIN_DATA

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

FIRST_CYCLE (error)

Data type: BOOL

Indicates FIRST_CYCLE after download, reset, repower or stop running - set for only the FIRST_CYCLE.

BAT-TERY_WARN (battery warning)

Data type: BOOL

TRUE when battery is not inserted or less than minimum load reached.

1.5.13.1.5 STRUCTURE (PUMP_STATION_TYPE)

This structure is used to transfer and receive data in all function blocks. This is used as an in-out parameter to all function blocks. Every function block receives data, process it and modifies data of this structure. This structure is divided in substructure as per functions of the data. This structure basically stores values and parameters which are coming from the different function blocks of the library. Therefore these might be explained in more detail at the blocks where this parameters are entered or where the values are created.

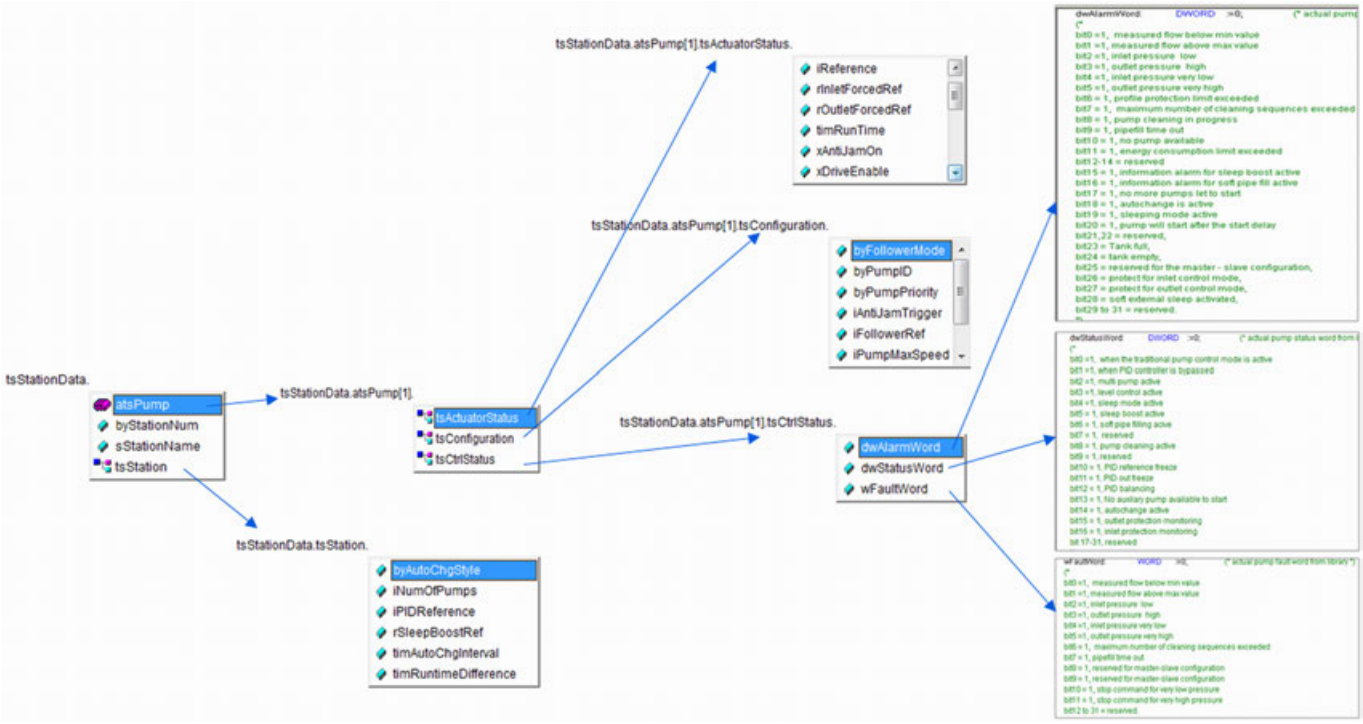

Fig. 642: Quick overview of the concept

PUMP_STATION_TYPE

byStationNum (station number)

Data type: BYTE, default value: 1, range: > 0

If more than one pump station are programmed, then byStationNum can be used to differentiate the stations.

sStationName (station name)

Data type: STRING(20)

If more than one pump station are programmed, then sStationName can be used to differentiate the stations in a "speaking" way and e.g. use for HMI purposes.

tsStation (station data)

Data type: zPUMP_STATION_DATA_TYPE

This structure stores station data.

atsPump (pumps data)

Data type: ARRAY[1..3] OF zPUMP_DATA_TYPE

An array is created for each pump. All pump information is stored in this structure.

byStationOpMode (station operating mode)

Data type: BYTE, default value: 2, range: 0-2

This variable stores the operating mode of the pumping station.

byMasterLoc (master location)

Data type: BYTE, default value: 1, range: 0-1

This variable stores the master location of the pumping station.

zPUMP_STATION_DATA_TYPE Station Configuration Data

iNumOfPumps (number of pumps)

Data type: INT

This variable defines the number of pumps in the station.

byAutoChgStyle (autochange style)

Data type: BYTE

Style	Short description	Description
0	None	Autochange function disabled.
1	Fixed	The starting sequence is shifted periodically at pre-defined intervals Autochg interval. In traditional pump control.
2	Run-time diff	The starting sequence is rearranged when the difference between the run times of two pumps exceed a limit, run-time difference. In the new sequence, the pump with the lowest run time will be started first, the pump with the highest run time will be started last.
3	All stop	The starting sequence is shifted every time the pump stops.

timAutoChgInterval (auto change interval time)

Data type: TIME

Time interval to elapse for the fixed autochange to activate.

timRuntimeDifference (run-time difference time)

Data type: TIME

Maximum permited runtime diff between the two pumps in the network.

rSleepBoostRef (sleep boost reference)

Data type: REAL

Speed step from the sleep function block. This step is used as additional setpoint to the pump before going to sleep mode.

byOperationMode (operation mode)

Data type: BYTE

Stores the operating mode of the pump boost control.

zPUMP_STATION_DATA_TYPE Station Actual Status

iPIDReference (pid reference)

Data type: INT

Value of speed correction coming from the PID function block.

xBoostEn (boost enable)

Data type: BOOL, default value: FALSE

Gives the true value when the pump boost enabled.

xBoostStart (boost start)

Data type: BOOL

Gives the true value when the pump boost starts.

xLevelCtrlEn (level control enable)
Data type: BOOL, default value: FALSE
Gives the TRUE value when the pump level control is enabled

xLevelCtrlStart (level control start)
Data type: BOOL
Gives the true value when the level control starts.

iStationMode (station mode)
Data type: BYTE
0 = none, 1 = pump bosst mode, 2 = level control mode.

aiSequenceID (sequence ID)
Data type: ARRAY[1..3] OF INT
Stores the sequence of the pumps operating in the station.

aiOriginalID (original ID)
Data type: ARRAY[1..3] OF INT
Stores the sequence of the pumps operating in the station without any sorting.

xSleepModeActive (sleep mode active)
Data type: BOOL
True value indicates that the sleep mode has been activated.

xSoftFillActive (soft fill active)
Data type: BOOL
True value indicates that the soft fill has been activated.

xAutoChgLevelCtrl (Autochange in the level control)
Data type: BOOL, default value: FALSE
When the auto change occurs in the level control, xAutoChgLevelCtrl becomes true for one scan cycle to ensure the changeover between the pumps.

xAssign3 (xAssign3)
Data type: BOOL, default value: FALSE
True value indicates the interface function block to assign the data in the structure

xAssign2 (xAssign2)
Data type: BOOL, default value: FALSE
True value indicates the interface function block to assign the data in the structure

xAssign1 (xAssign1)
Data type: BOOL, default value: FALSE
True value indicates the interface function block to assign the data in the structure

xAutoChgRunning (auto change running)
Data type: BOOL
True values indicates that auto change is running state.

zPUMP_DATA_TYPE

tsConfiguration (configuration structure)
Data type: zPUMP_CONFIGURATION_TYPE
This structure stores configuration data of pump.

tsActuator-Status (actuator status structure)
Data type: zPUMP_ACTUATOR_STATUS_TYPE
This structure stores actual values of pump.

tsCtrlStatus (actuator status structure)
Data type: zPUMP_CTRL_STATUS_TYPE
This structure stores control values of pump.

zPUMP_CONFIGURATION_TYPE

byPumpID (pump ID)
Data type: INT
This variable denotes Pump identification number.

byPumpPriority (pump priority)
Data type: BYTE
This variable denotes pump priority.

xPumpOn (pump on)
Data type: BOOL
By using FALSE value for this variable the user can remove this pump from the network in case of any problem/fault.

iPumpMax-Speed (pump max speed)
Data type: INT
This variable denotes maximum speed of the pump.

byFollowerMode (follower mode)
Data type: BYTE
0 = fixed, 1 = copy master, 2 = master speed.

iFollowerRef (follower reference)
Data type: INT
Follower speed ref in RPM for a pump, when follower mode is fixed.

xResetRuntime (reset run time)
Data type: BOOL
To reset the runtime value of the pump.

iAntiJamTrigger (antijam trigger)
Data type: INT
Trigger to clean the pump. 0 = not enabled, 1 = master enabled, 2 = follower enabled, 3 = at start, 4 = manual.

zPUMP_ACTUATOR_STATUS_TYPE

xDriveEnable (drive enable)
Data type: BOOL
This variable gives start command to the drive.

iReference (reference)
Data type: INT
Speed reference of the pump.

xMasterStatus (master status)
Data type: BOOL
TRUE value indicates that the pump is a MASTER and the FALSE value indicates that the pump is FOLLOWER.

xStopMode (stop mode)
Data type: BOOL
This identifies that the drive has to stop in the protection mode.

xInletRedSpeed-Mode (inlet reduced speed mode)
Data type: BOOL
This identifies that the pump has to run at the inlet reduced speed in the protection mode.

xOutletRed-SpeedMode (outlet reduced speed mode)
Data type: BOOL
This identifies that the drive has to run at the outlet reduced speed in the protection mode.

xReady (ready)
Data type: BOOL
True value tells that the pump is in ready state.

xOperating (operating)
Data type: BOOL
True value tells that the pump is in running state.

xFault (fault)
Data type: BOOL
True value indicates the fault in a pump.

xPumpProtec-tionFault (pump protection fault)
Data type: BOOL, default value: FALSE
True value indicates the fault generated by the protection bit.

xDriveFault (drive fault)
Data type: BOOL
True value indicates the drive fault.

xStandBy (standby)
Data type: BOOL
True value indicates that the pump is at standby state.

xRFGDisable (RFG disable)
Data type: BOOL
To disable the RFG of the drive of the pump.

xAntiJamOn (antijam on)
Data type: BOOL
On command to the pump in the manual mode of antijam function.

iAntiJamSpeed (antijamspeed)
Data type: INT
Speed reference to the pump in the manual mode of antijam function.

timRunTime(run time)
Data type: TIME
This variable stores the current run time of the pump.

rInletForcedRef (inlet forced reference) Data type: REAL

Forced speed ref when inlet mode=3, from pump_protection function block.

rOutletForcedRef (outlet forced reference) Data type: REAL

Forced speed ref when outlet mode=3, from pump_protection function block.

zPUMP_CTRL_STATUS_TYPE

dwStatusWord (status word) Data type: DWORD

Pump status word.

bit	Description
bit0 =1	When the traditional pump control mode is active.
bit1 =1	When PID controller is bypassed.
bit2 =1	Multi pump active.
bit3 =1	Level control active.
bit4 =1	Sleep mode active.
bit5 =1	Sleep boost active.
bit6 =1	Soft pipe filling active.
bit7 =1	Reserved
bit8 =1	Pump cleaning active.
bit9 =1	Reserved
bit10 =1	PID reference freeze.
bit11 =1	PID out freeze.
bit12 =1	PID balancing.
bit13 =1	No auxilary pump available to start.
bit14 =1	Autochange active.
bit15 =1	Outlet protection monitoring.
bit16 =1	Inlet protection monitoring.
bit17-31	Reserved

dwAlarmWord (alarm word)

Data type: DWORD

Pump alarm word.

bit	Description
bit0 =1	Measured flow below min value.
bit1 =1	Measured flow above max value.
bit2 =1	Inlet pressure low.
bit3 =1	Outlet pressure high.
bit4 =1	Inlet pressure low.
bit5 =1	Outlet pressure high.
bit6 =1	Profile protection limit exceeded.
bit7 =1	Maximum number of cleaning sequences exceeded.
bit8 =1	Pump cleaning in progress.
bit9 =1	Pipefill time out.
bit10 =1	No pump available.
bit11 =1	Energy consumption limit exceeded.
bit12-14 =1	Reserved.
bit15 =1	Information alarm for sleep boost active.
bit16 =1	Information alarm for soft pipe fill active.
bit17 =1	No more pumps let to start.
bit18 =1	Autochange is active.
bit19 =1	Sleeping mode active.
bit20 =1	Pump will start after the start delay.
bit21,22 =1	Reserved
bit23 =1	Tank full.
bit24 =1	Tank empty.
bit25 =1	Reserved for the master-slave configuration.
bit26 =1	Protect for inlet control mode.
bit27 =1	Protect for outlet control mode.
bit28-31	Reserved

wFaultWord (fault word)

Data type: WORD

Pump fault word.

bit	Description
bit0 =1	Measured flow below min value.
bit1 =1	Measured flow above max value.
bit2 =1	Inlet pressure low.
bit3 =1	Outlet pressure high.
bit4 =1	Inlet pressure very low.
bit5 =1	Outlet pressure very high.
bit6 =1	Maximum number of cleaning sequences exceeded.
bit7 =1	Pipefill time out.
bit8,9 =1	Reserved for master-slave configuration.
bit10 =1	Stop command for very low pressure.
bit11 =1	Stop command for very high pressure.
bit12-31	Reserved

Fig. 644: Structure Mapping 2

1.5.13.1.6 PUMP_BOOST_CTRL Boost Control

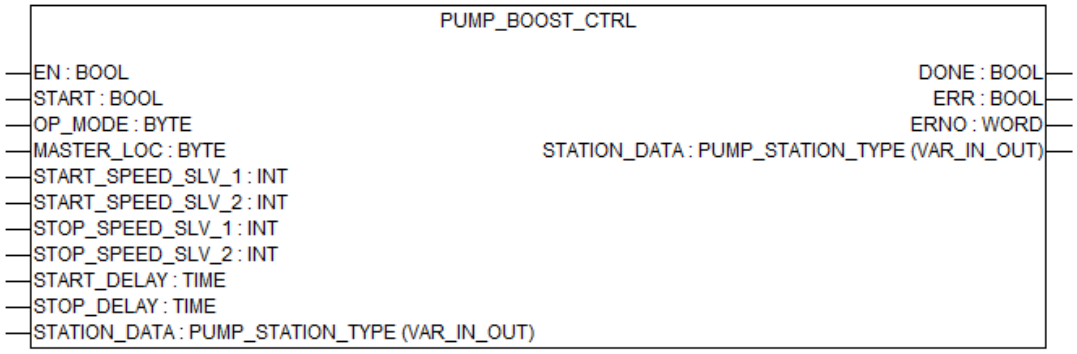

Fig. 645: Function block PUMP_BOOST_CTRL

Table 203: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

This application Function Block provides a typical logic for pump boost operations with several pumps - where the user can select the operation mode i.e. single pump, multi pump or traditional pumping for up to three pumps. The switching on and off of further pumps is triggered via start and stop speeds.

With this function block the

- traditional / conventional (only one pump with drives, other DOL* motors) and
- advanced (all pumps operated by drive-motors) pumping stations can be configured and operated. (* DOL = direct online: Motor without a drive but a switch or soft-starter connected to e.g. 50Hz AC line voltage).

PUMP_PID uses the speed reference based on the process demands to PUMP_BOOST_CTRL. PUMP_BOOST_CTRL controls the start/stop sequence for the pumps based on the start and stop speeds to fullfill process requirements.

Follower modes in boost operation

The following figures show the different control modes, resulting in different criteria how to run the followers. The follower mode itself is set in each PUMP_INTERFACE Block.

The follower modes in each of the three PUMP_INTERFACE Blocks have to be set to the same mode.

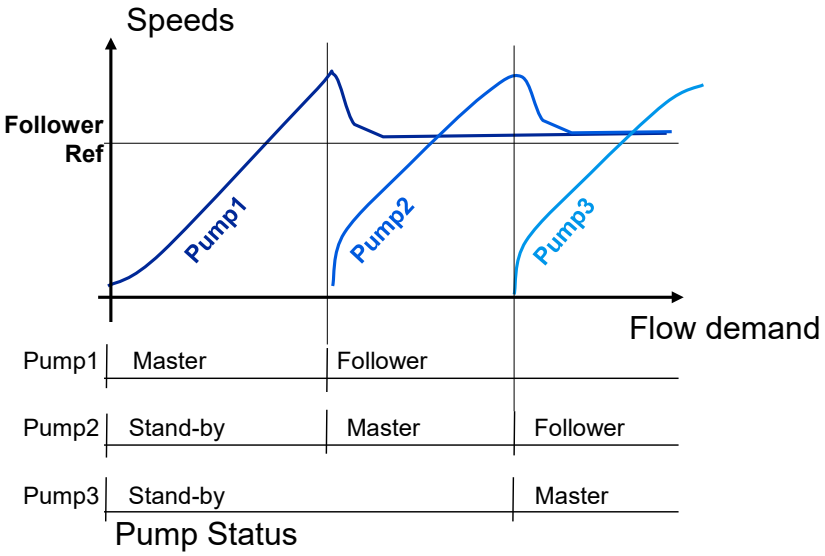

Fig. 646: Constant speed

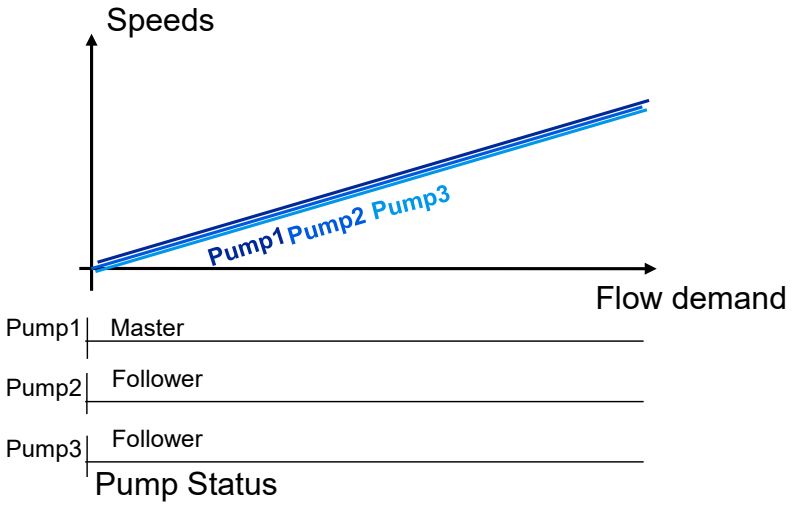

Fig. 647: Copy of “Master”/direct follower

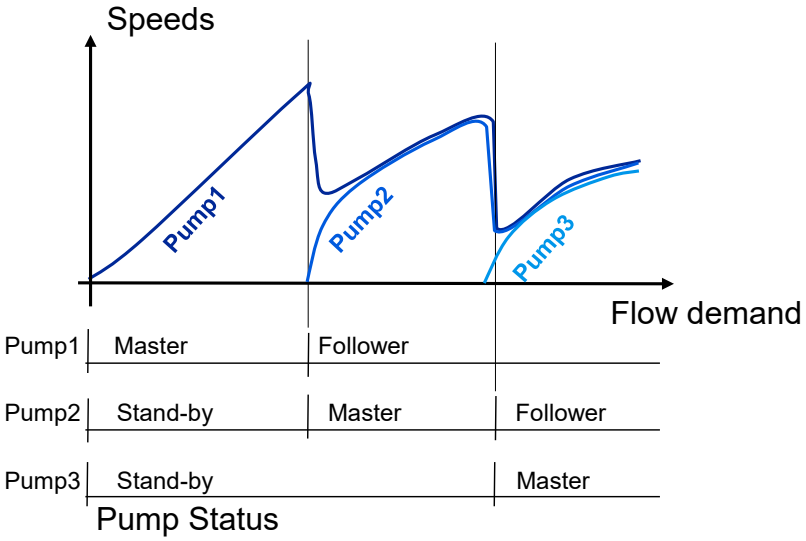

Fig. 648: "Master" Speed

Input description

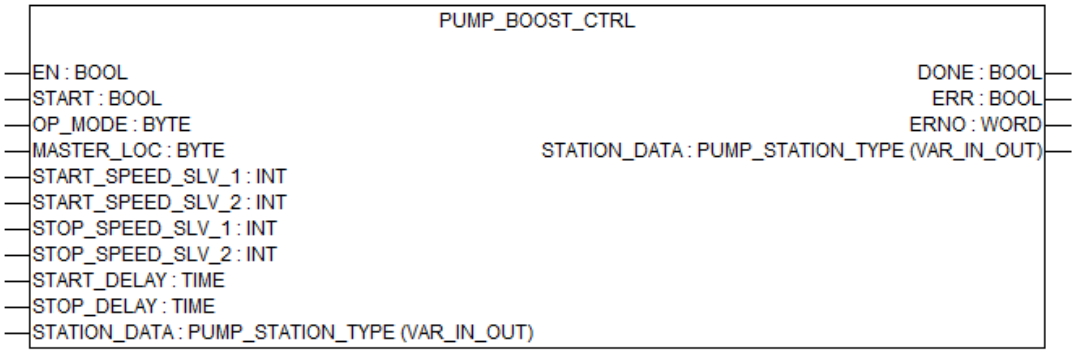

Fig. 649: Function block PUMP_BOOST_CTRL

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START (start command)

Data type: BOOL

To start the boost control operation with the TRUE value of the START variable. When START = FALSE, all the pumps stop.

OP_MODE (operation mode)

Data type: BYTE, default value: 0, range: 0-2

This input sets the operating mode of the pumping station.

Operation mode	Short description	Description
0	single pump	Operated by the drive.
1	traditional pump	One pump is driven by the drive and others are auxiliaries driven by contactors.
2	multi pump	The pumps are controlled by the drives.

Range of values: from 0 to 2

MASTER_LOC (master location of the pumping station)

Data type: BYTE, default value: 0, range: 0-1

This input defines the master location.

MASTER_LOC value	MASTER_LOC type	Description
0	INSTART	The master in the network is not fixed and "in the start" phase the last started pump in the network will be master. Master means basically it is the only pump which always takes the speed given by the PID. The followers speed depends on the chosen follower mode. Example in the input OP_MODE = 2 (Multi-pump): When the pumping station is started, Pump1 (ID=1) will start as a master. Demand increase will prompt the Pump2 also to start and it becomes the master and the Pump1 is a follower (whose operation is decided by the follower mode set on function block PUMP_INTERFACE). If the demand increases further, also Pump3 is started and becomes the master. If the demand then decreases again, Pump3 is stopped first (as per the sequence 1-2-3). Now Pump1 (follower) and Pump2 is again the master. Demand further decreases, Pump2 stops next and Pump1 now runs as the master. Remember if the start sequence is 1-2-3 the stop sequence is always 3-2-1.
1	FIXED	Master is always fixed, follower changes. In this mode the first pump in the sequence is and stays always the master. Example: When the pumping station is started, Pump1 (ID=1) will start as a master. Demand increase will prompt the Pump2 also to start as a follower. If the demand further increases, Pump3 also starts and take the follower speeds based on the chosen FOLLOWER _Mode. Here the Pump1 always remains the master. When the demand was high (3 pumps running) and the demand decreases, Pump3 will stop first (as per the sequence 1-2-3), then Pump2 will also stop if the demand decreases even further. But Pump1 stays always master. Principle: If the start sequence is 1-2-3, the stop sequence is always 3-2-1.

Range of values: from 0 to 1.

START_SPEED_SLV_1 (start speed for slave 1)

Data type: INT, default value: 0, range: ≥ 0, unit: rpm

The speed of the master at which the first follower pump must start in the follower mode 0 and 2.

START_SPEED_SLV_2 (start speed for slave 2)

Data type: INT, default value: 0, range: ≥ 0, unit: rpm

The speed of the master which the second follower pump must start in the follower mode 0 and 2.

STOP_SPEED_SLV_1 (stop speed for slave 1)

Data type: INT, default value: 0, range: ≥ 0, unit: rpm

The speed of master at which the first follower pump must stop in the follower mode 0 and 2.

STOP_SPEED_SLV2 (stop speed for slave 2)

Data type: INT, default value: 0, range: ≥ 0, unit: rpm

The speed of master at which the second follower pump must stop in the follower mode 0 and 2.

START_DELAY (start delay)

Data type: TIME, default value: 10, range: > 0, unit: s

This input is a time delay in seconds. The next pump starts only when the condition to start this pump has stayed for the duration mentioned in this time delay. This input is to be given when the operating mode is 1 or 2.

STOP_DELAY (stop delay)

Data type: TIME, default value: 10, range: > 0, unit: s

This input is atime delay in seconds. When the condition to stop the pump has stayed for the duration mentioned in this input, the pump stops. This input is to be given when the operating mode is 1 or 2.

STATION_DATA (station data structure)

Data type: PUMP_STATION_TYPE

This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

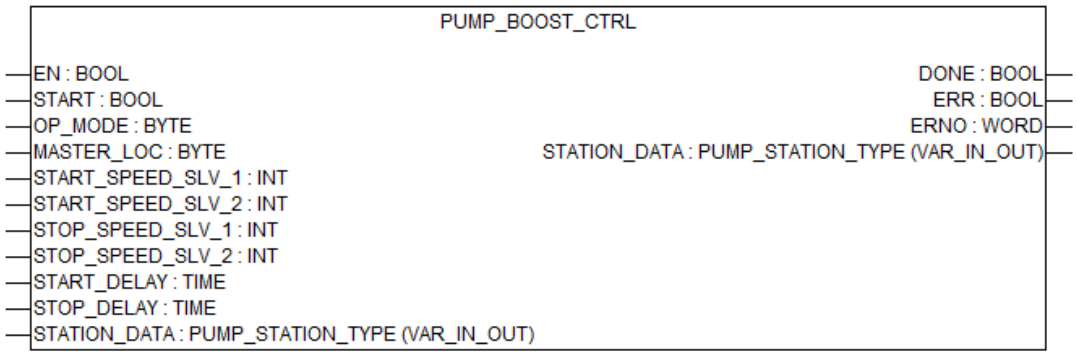

Fig. 650: Function block PUMP_BOOST_CTRL

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error.
16403	4013	EN signal for boost control given, although the pump level control is enabled.
16432	4030	Value of OP_MODE erroneous.
16448	4040	Value of MASTER_LOC erroneous.
16464	4050	Value of START_SPEED_SLV_1 erroneous.
16480	4060	Value of START_SPEED_SLV_2 erroneous.
16496	4070	Value of STOP_SPEED_SLV_1 is erroneous.
16512	4080	Value of STOP_SPEED_SLV_2 is erroneous.

1.5.13.1.7 PUMP_PID

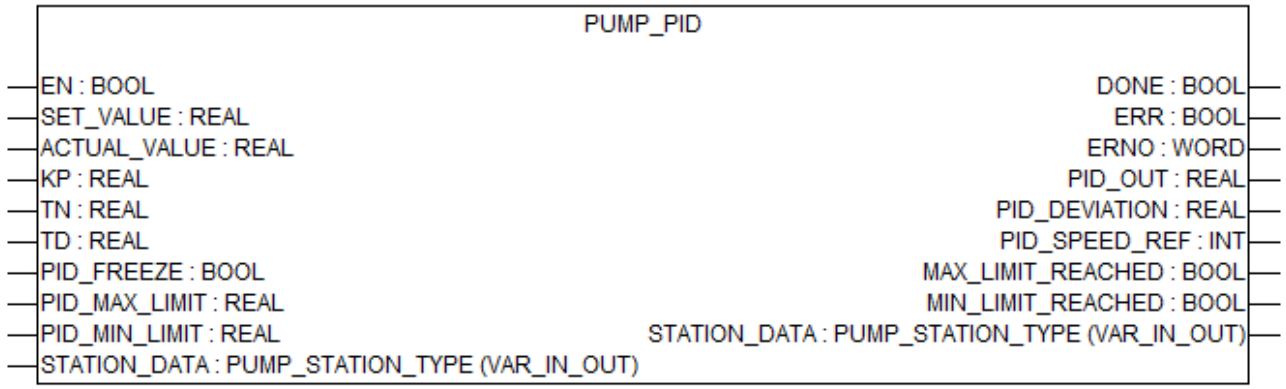

Fig. 651: Function block PUMP_PID

Table 204: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

This function block is used for closed loop control of the process parameter such as pressure.

The setpoint and the actual value are compared and error value is given as input to the PID. PID output is calculated based on the Proportional Gain KP, Integral Time TN, and Derivative Time TD.

Y = KP *(e +1/TN ∫e dt + TD de/dt) with

Y =PID_OUTPUT

e =Error between SET_VALUE – ACTUAL_VALUE

The PID output is then scaled and converted into required speed reference to the drive of the pump. The output PID_SPEED_REF is internally attached via structures to the PUMP_BOOST_CTRL.

Input description

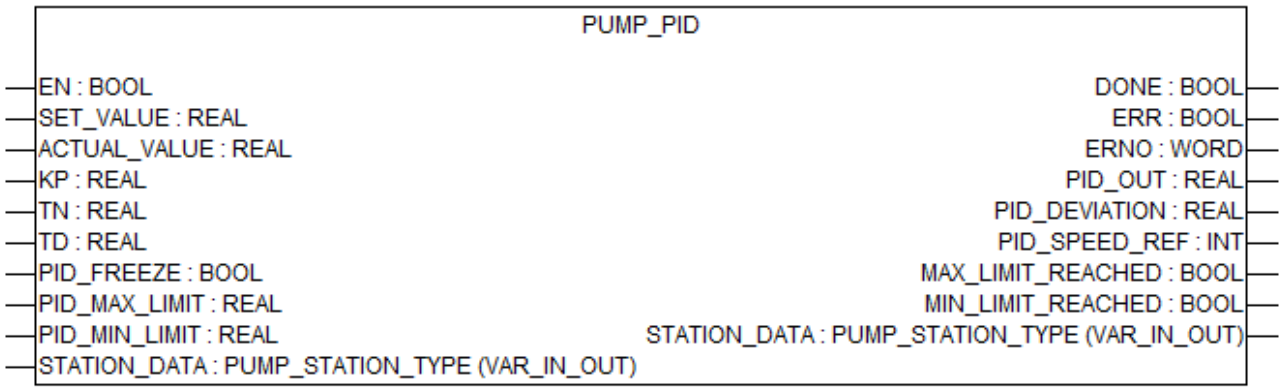

Fig. 652: Function block PUMP_PID

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SET_VALUE (set point of the PID)

Data type: REAL, default value: 0, range: ≥ 0, unit: %

Set value of the process variable.

Range of values: from 0 to 100 .

ACT_VALUE (actual point of the PID)

Data type: REAL, default value: 0, range: ≥ 0, unit: %

Actual value of the process variable. User need to scale actual value as percentage and attached to this variable.

Range of values: from 0 to 100.

KP (proportional gain)

Data type: REAL, default value: 0, range: ≥ 0

Proportional gain of the PID.This value has to be manually tuned as per system requirements.

TN (integration time)

Data type: REAL, default value: 0, range: ≥ 0, unit: ms

Integral time of the PID in terms of milliseconds. If the value entered is 500.0, it is taken as 500 ms.This value has be manually tuned as per system requirements.

TD (derivative time)

Data type: REAL, default value: 0, range: ≥ 0, unit: ms

Derivative time of the PID in terms of milliseconds. If the value entered is 500.0, it is taken as 500 ms.This value has be manually tuned as per system. Erroneous setting of derivative time can results in overshooting of the PID-OUT value.

PID_FREEZE (PID freeze)

Data type: BOOL

For the TRUE value the setpoint to the PID block is frozen. Actual value is overwritten to the setpoint.

PID_MAX-IMUM_LIMIT (pid maximum limit value)

Data type: REAL, default value: 100, range: 0-100, unit: %

Maximum permitted value of the PID output. Using the minimum and maximum limits, it is possible to restrict the operation range of the PID.

PID_MIN-IMUM_LIMIT (pid minimum limit value)

Data type: REAL, default value: 0, range: -100.0 to +100.0, unit: %

Minimum permitted value of the PID output. Using the minimum and maximum limits, it is possible to restrict the operation range of the PID.

STATION_DATA (station data structure)

Data type: PUMP_STATION_TYPE

This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

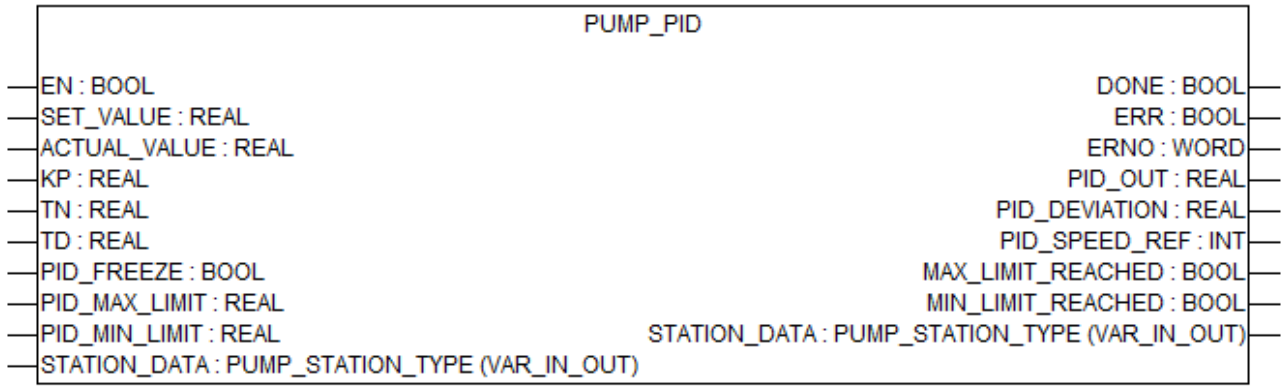

Fig. 653: Function block PUMP_PID

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

PID_OUT (pid output value)

Data type: REAL, default value: 0, range: -100 to +100, unit: %

Output PID_OUT after the manipulation.

PID_DEVIATION (deviation of set value from actual value)

Data type: REAL, default value: 0, range: -100 to +100, unit: %

Deviation of set value from actual value. It is also known as PID error.

PID_SPEED_REF (pid speed reference)

Data type: INT, default value: 0, range: -20000 to +20000

Speed reference as a correction to the main speed reference, calculated by the PID. This variable is meant for the user. The PID_SPEED_REF is also internally attached with the PUMP_BOOST_CTRL function block to process the start/stop of the pumps.

MAXIMUM_LIMIT_REACHED (maximum limit reached)

Data type: BOOL

Indicates that the PID output reached the MAXIMUM limit.

MINIMUM_LIMIT_REACHED (minimum limit reached)

Data type: BOOL

Indicates that the PID output reached the MINIMUM limit.

1.5.13.1.8 PUMP_LEVEL_CTRL Level Control

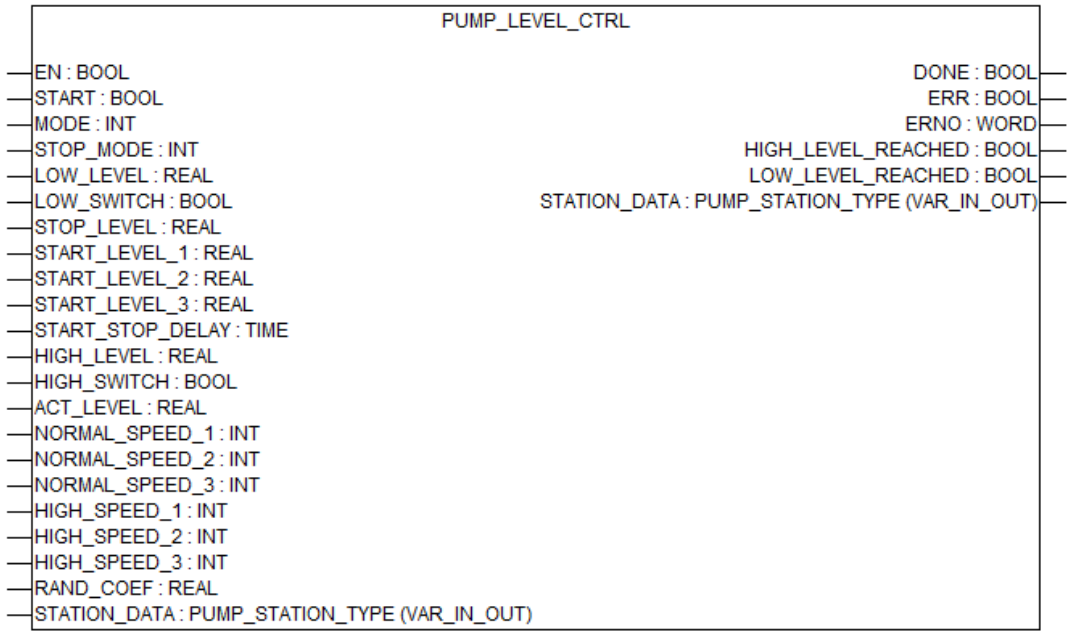

Fig. 654: Function block PUMP_LEVEL_CTRL

Table 205: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

The level control macro is designed for controlling a station of 1 to 3 pumps that is used for either emptying or filling a container. The level control functionality is activated by setting parameter level mode to emptying or filling. The start levels for the pumps (as well as the alarm levels) are set by parameters.

Filling mode

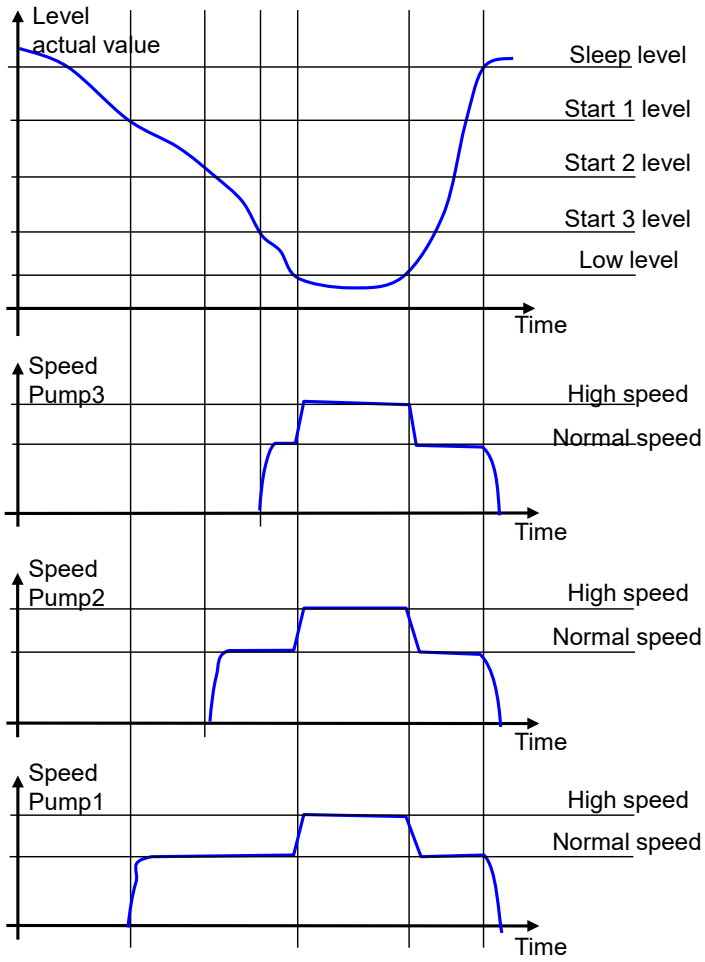

Fig. 655: Behavior and meaning of the parameters if the “Filling Mode” is set

The pump station above is used for filling a tank, decreasing its level due to a larger outlet flow. The diagram shows the start, stop and supervision levels for filling. Parameter “Stopping mode” is assumed to be set to “Common stop”; “Start stop delay” is assumed to be set to 0.

A larger outlet flow e.g. to a fresh water network via a supply tank / reservoir:	The pumps need to pump fresh water to keep the level possibly constant to feed a network with constant pressure.

Emptying mode

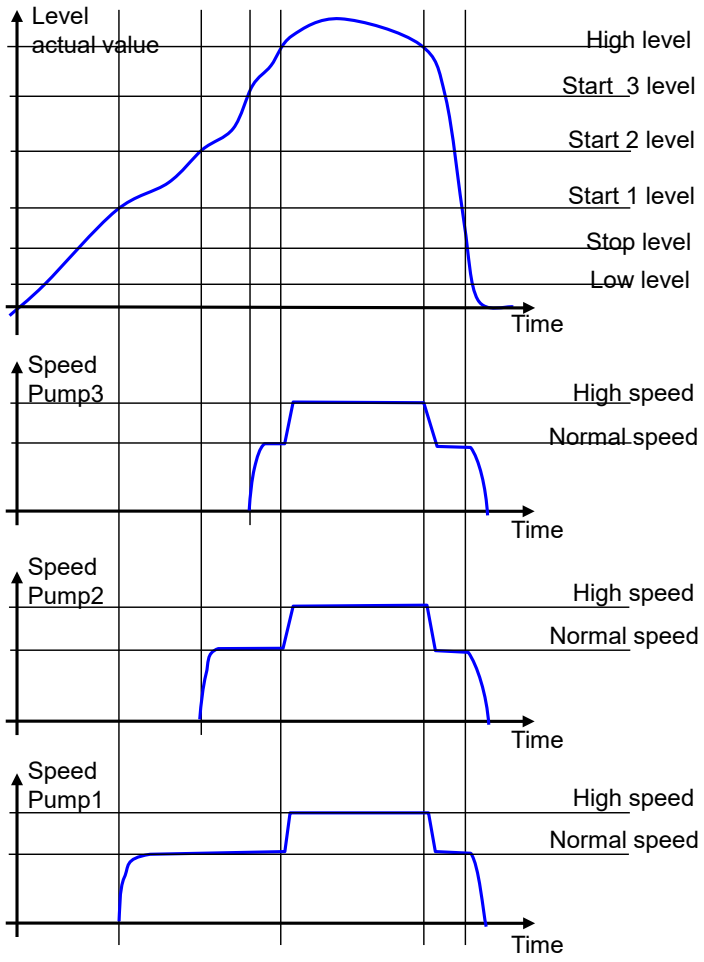

Fig. 656: Pump station using for emptying a container, increasing its level due to inflow

The diagram above shows the start, stop and supervision levels for emptying mode. Parameter “stopping mode” is assumed to be set to “common stop”; “start stop delay” is assumed to be set to 0.

Example is a reservoir or tank with a larger inlet flow (e.g. in a waste water lift stations):	The pumps need to work in emptying mode, meaning to pump waste water further to avoid spilling of the reservoir.

Input description

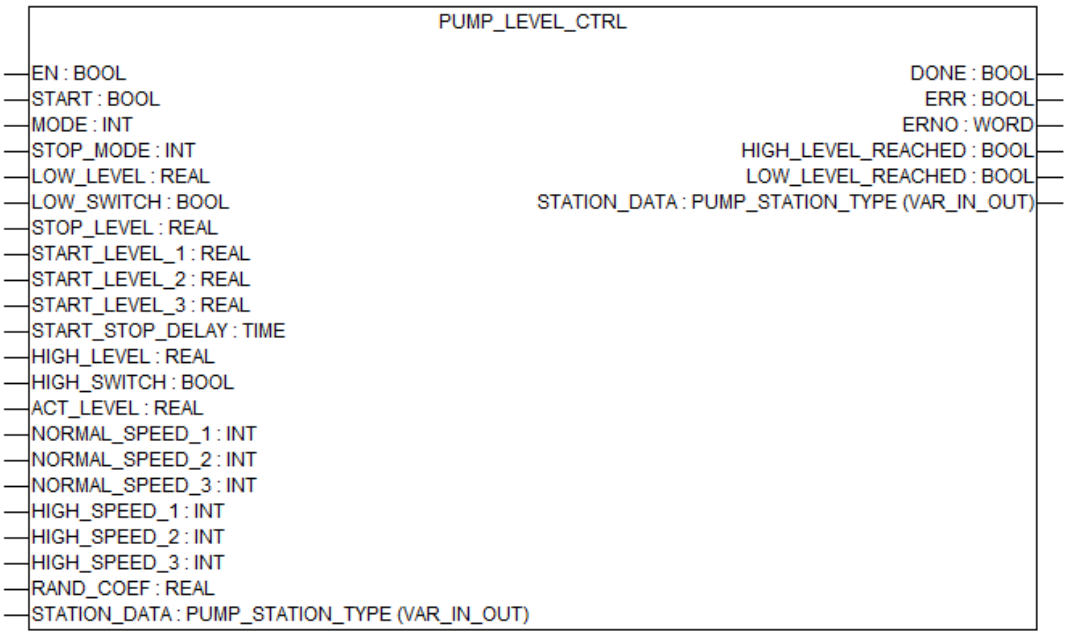

Fig. 657: Function block PUMP_LEVEL_CTRL

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START (start block)

Data type: BOOL

To start the level controller.

MODE (mode) Data type: INT, default value: 1, range: 0-2

To select the mode of operation.

Mode	Short description	Description
0	Off	Level control disabled.
1	Emptying	Pump station is used for emptying a container.
2	Filling	Pump station is used for filling a container.

STOP_MODE (stop mode) Data type: INT, default value: 0, range: 0-1

Mode	Description
0	Stable stop. Stops the pump at individual defined stop levels. For example in the fill mode if the START_LEVEL_1 is defined 60%. Now if the actual level reaches on or above 60%, the pump 1 would stop.
1	Common stop. Stops all the pumps together at defined level STOP_LEVEL. Which means, both in the emptying and filling mode, the pumps start at their respective start levels, but they stop when they reach the STOP_LEVEL.

LOW_SWITCH (low switch) Data type: BOOL, default value: FALSE

Digital input with TRUE indicates that the low level has reached.

STOP_LEVEL (stop level) Data type: REAL, default value: 10.0, range: >0, unit: %

Stop level defines the level at which all the pumps would stop, when the STOP_MODE = 1. This can occur while filling when the actual level is more than the stop level. In emptying mode all pumps stop when the actual level reaches below the stop level.

START_LEVEL_1 (start level 1) Data type: REAL, default value: 70, range: > 0, unit: %

Defines the start level for pump 1 in terms of full tank capacity. The same level is used to stop the pump when actual level comes back at this level. Refer the figure in the above section.

START_LEVEL_2 (start level 2) Data type: REAL, default value: 50, range: > 0, unit: %

Defines the start level for pump 2 in terms of full tank capacity. The same level is used to stop the pump when actual level comes back at this level. Refer the figure in the above section.

START_LEVEL_3 (start level 3) Data type: REAL, default value: 30, range: > 0, unit: %

Defines the start level for pump 3 in terms of full tank capacity. The same level is used to stop the pump when actual level comes back at this level. Refer the figure in the above section.

START_STOP_DELAY (start stop delay) Data type: TIME, default value: 10, range: ≥ 0, unit: s

Defines the time delay for pump to start and stop when respective level is reached.

HIGH_LEVEL (high level)
Data type: REAL, default value: 95, range: > 0, unit: %
Defines the high level in terms of full tank capacity.

HIGH_SWITCH (high switch)
Data type: BOOL
Digital input which with TRUE indicates that the high level has reached.

ACT_LEVEL (actual level)
Data type: REAL, default value: 0, range: ≥ 0, unit: %
Actual level read from the analog input of level sensor.

NORMAL_SPEED_1 (normal speed for pump 1)
Data type: INT, default value: 1100, range: ≥ 0, unit: rpm
Normal operating speed of the pump 1 while Filling/Emptying.

NORMAL_SPEED_2 (normal speed for pump 2)
Data type: INT, default value: 1100, range: ≥ 0, unit: rpm
Normal operating speed of the pump 2 while Filling/Emptying.

NORMAL_SPEED_3 (normal speed for pump 3)
Data type: INT, default value: 1100, range: ≥ 0, unit: rpm
Normal operating speed of the pump 3 while Filling/Emptying.

HIGH_SPEED_1 (high speed for pump 1)
Data type: REAL, default value: 1500, range: ≥ 0, unit: rpm
Defines the speed of the pump 1 for:
- Filling pump level falls below LOW_LEVEL,
- Emptying pump level rises above the HIGH_LEVEL.

HIGH_SPEED_2 (high speed for pump 2)
Data type: REAL, default value: 1500, range: ≥ 0, unit: rpm
Defines the speed of the pump 2 for:
- Filling pump level falls below LOW_LEVEL,
- Emptying pump level rises above the HIGH_LEVEL.

HIGH_SPEED_3 (high speed for pump 3)
Data type: REAL, default value: 1500, range: ≥ 0, unit: rpm
Defines the speed of the pump 3 for:
- Filling pump level falls below LOW_LEVEL,
- Emptying pump level rises above the HIGH_LEVEL.

RAND_COEF (random coefficient)
Data type: REAL, default value: 0, range: ≥ -10 to +10, unit: %
Random coefficient randomizes the start levels to avoid cake formation.

STATION_DATA (station data structure)
Data type: PUMP_STATION_TYPE
This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

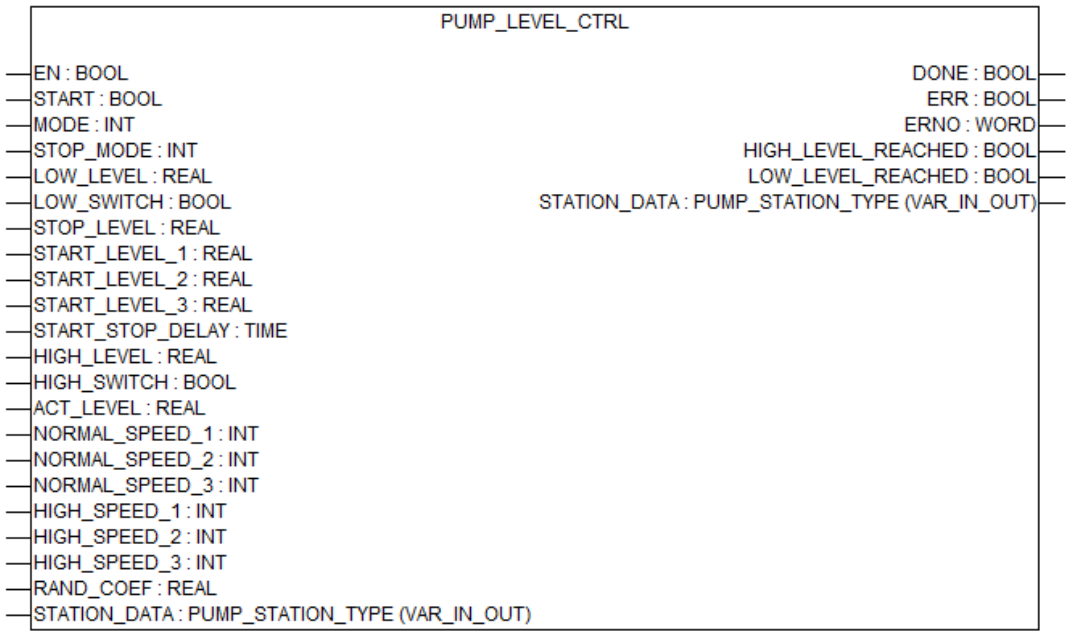

Fig. 658: Function block PUMP_LEVEL_CTRL

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

HIGH_LEVEL_REACHED (high level reached)

Data type: BOOL

TRUE value indicates that the actual level is more than the high level.

LOW_LEVEL_REACHED (low level reached)

Data type: BOOL

TRUE value indicates that the actual level is below the low level.

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error.
16403	4013	EN signal for level control given, although the pump boost control is enabled.
16432	4030	Value of MODE is erroneous.
16435	4033	Value of MODE level settings is erroneous.
16448	4040	Value of STOP_MODE is erroneous.
16464	4050	Value of LOW_LEVEL is erroneous.
16480	4060	Value of STOP_LEVEL is erroneous.
16512	4080	Value of START_LEVEL_1 is erroneous.
16528	4090	Value of START_LEVEL_2 is erroneous.
16544	40A0	Value of START_LEVEL_3 is erroneous.
16576	40C0	Value of HIGH_LEVEL is erroneous.
16608	40E0	Value of ACT_LEVEL is erroneous.
16624	40F0	Value of NORMAL_SPEED_1 is erroneous.
16640	4100	Value of NORMAL_SPEED_2 is erroneous.
16656	4110	Value of NORMAL_SPEED_3 is erroneous.
16672	4120	Value of HIGH_SPEED_1 is erroneous.
16688	4130	Value of HIGH_SPEED_2 is erroneous.
16704	4140	Value of HIGH_SPEED_3 is erroneous.
16720	4150	Value of RAND_COEF is erroneous.

1.5.13.1.9 PUMP_AUTOCHANGE

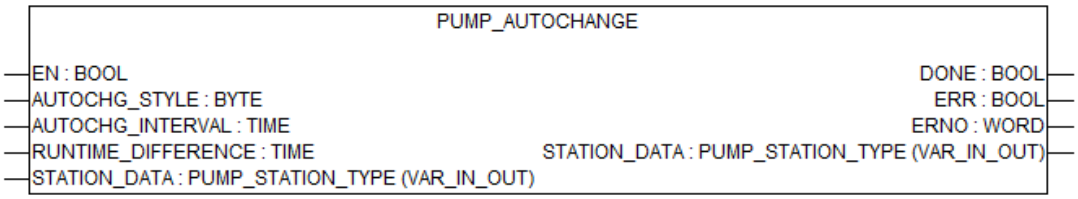

Fig. 659: Function block PUMP_AUTOCHANGE

Table 206: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

The Autochange function can be used to equalize duty time between multiple pumps, by varying the sequence in which pumps are started.

There are three autochange modes selectable by parameter autochange style:

- Fixed intervals: The starting sequence is shifted periodically at pre-defined intervals Autochange interval,
- Runtime equalization (hours count): The starting sequence is rearranged when the difference between the run times of two pumps exceed a limit, run-time difference. In the new sequence, the pump with the lowest run time will be started first. The pump with the highest run time will be started last,
- Autochange when stopped (all stop): The starting sequence for the next start is shifted every time the pump stops.

Example of a change in the sequence by AUTOCHANGE

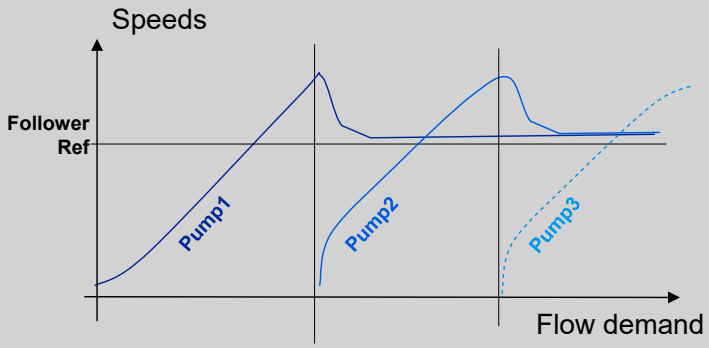

Fig. 660: Before sequence change: 2 pumps run

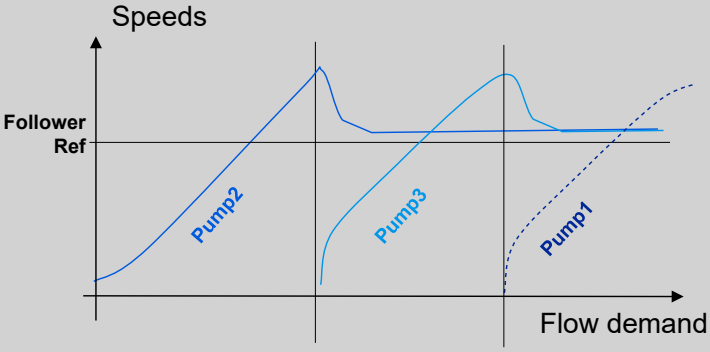

Fig. 661: After sequence change: Pump 1 was "oldest" →standby, 2 pumps run

Input description

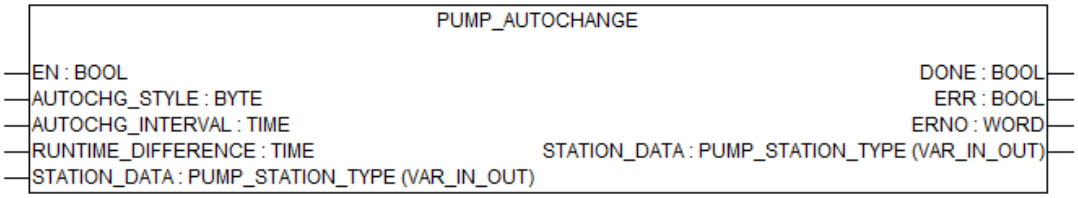

Fig. 662: Function block PUMP_AUTOCHANGE

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

AUTOCHG_STYLE (auto change style)

Data type: BYTE, default value: 0, range: 0-3

Mode	Short description	Description
0	None	Autochange function disabled.
1	Fixed	The starting sequence is shifted periodically at pre-defined intervals Autochange interval. For the Autochange to occur in this mode, it is necessary that atleast one pump is in standby condition. With this, when the Autochange occurs the pump with the maximum run time would stop and the new pump would start.
2	Runtime diff	The starting sequence is rearranged when the difference between the runtimes of two pumps exceed a limit, run-time difference. In the new sequence, the pump with the lowest runtime will be started first, the pump with the highest run time will be started last. For the autoch-ange to occur in this mode, it is necessary that atleast one pump is in standby condition. With this, when the autochange occurs the pump with the maximum run time would stop and the new pump would start.
3	All stop	The starting sequence is shifted every time the pump stops. This mode is also available to operate in the traditional pumping station.

AUTOCHG_INTERVAL (auto change interval)

Data type: TIME, default value: 60, range: > 0, unit: s

Time delay to elapse for the fixed Autochange to activate when the Autochange style selected is = 1.

RUNTIME_DIFFERENCE (run-time difference)

Data type: TIME, default value: 60, range: > 0, unit: s

Maximum permitted run-time difference between the two pumps in the network when the Autochange style selected is = 2.

STATION_DATA (station data structure)

Data type: PUMP_STATION_TYPE

This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

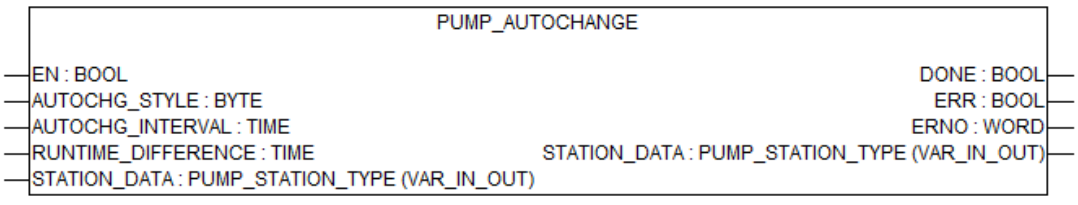

Fig. 663: Function block PUMP_AUTOCHANGE

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error.
16416	4020	Value of AUTOCHG_STYLE is erroneous.
16419	4023	Value of AUTOCHG_STYLE and related setting is erroneous.

1.5.13.1.10 PUMP_ANTIJAM

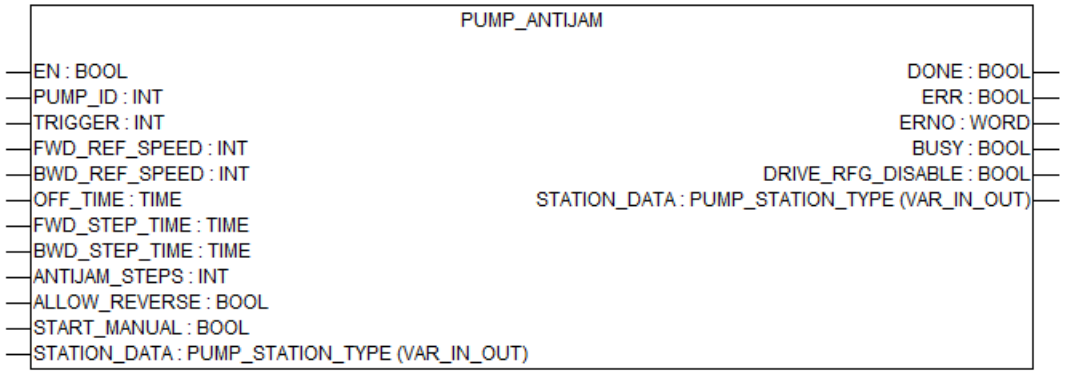

Fig. 664: Function block PUMP_ANTIJAM

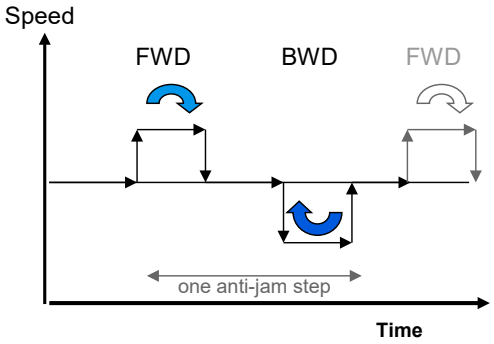
Table 207: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

Performs the pump antijam/cleaning functionality by running the pump at high speeds without any ramp up/down time. For the cleaning function to be performed properly it is important to disable the drive ramp function generator. This can be done if the programmer latches the DRIVE_RFG_DISABLE output with the corresponding bit in the drive control word.

Pump cleaning function can be used to prevent solids from building up on pump impellers or piping. The function consists of a programmable sequence of forward and reverse runs of the pump to shake off any residue on the impeller or piping. This is especially useful with booster and wastewater pumps.

The cleaning sequence can be programmed to occur at suitable intervals, or whenever certain triggering conditions are met.



Not all pumps can be rotated in the reverse direction.

> *For the cleaning function to be performed properly it is important to disable the drive ramp function generator. This can be done if the programmer latches the DRIVE_RFG_DISABLE output with the corresponding bit in the drive control word.*

Input description

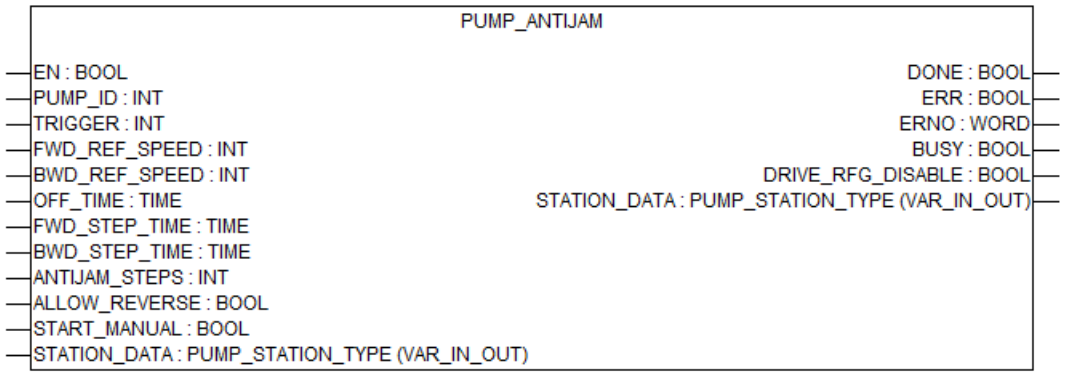


Fig. 665: Function block PUMP_ANTIJAM

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PUMP_ID (id of pump to be cleaned)

Data type: INT, default value: 1, range: 1-3

Enter ID of the pump which is to be cleaned.

TRIGGER (trigger)

Data type: INT, default value: 0, range: 0-4

Trigger to clean the pump.

Mode	Short description	Description
0	Not enbaled	Cleaning sequence is disabled.
1	Master enabled	Cleaning sequence is allowed when the drive is master.
2	Follower enabled	Cleaning sequence is allowed when the drive is follower.
3	At start	Cleaning sequence is performed at every start.
4	Manual mode	Cleaning sequence is performed manually. To operate the ANTIJAM in the manual mode, START_MANUAL has to be made FALSE →TRUE.

FWD_REF_SPEED (forward reference speed)

Data type: INT, default value: 1, range: ≥ 0, unit: rpm

Speed reference to clean the pump in the forward direction.

BWD_REF_SPEED (backward reference speed)

Data type: INT, default value: 1, range: ≥ 0, unit: rpm

Speed reference to clean the pump in the backward direction.

OFF_TIME (off time)

Data type: TIME, default value: 10, range: > 0, unit: s

Time delay between the forward and the reverse movement in antijam.

FWD_STEP_TIME (forward step time)

Data type: TIME, default value: 10, range: > 0, unit: s

Time duration of one clean-step for which the pump moves in the forward direction.

BWD_STEP_TIME (backward step time)

Data type: TIME, default value: 10, range: > 0, unit: s

Time duration of one clean-step for which the pump moves in the backward direction.

ANTIJAM_STEPS (antijam steps)

Data type: INT, default value: 1, range: 1-5

Number of steps to be performed in an antijam process. One step of antijam is shown in the figure above.

ALLOW_REVERSE (allow reverse direction)

Data type: BOOL

True value means the pump can also move in the reverse direction to perform the antijam.

START_MANUAL (manual mode)

Data type: BOOL

For the TRUE value it runs the antijam in the manual mode.

STATION_DATA (station data structure)

Data type: PUMP_STATION_TYPE

This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

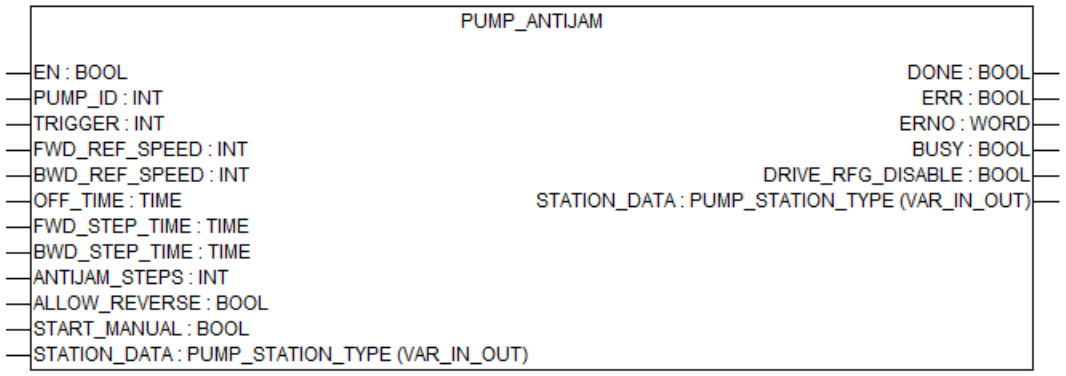

Fig. 666: Function block PUMP_ANTIJAM

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

BUSY (busy)

Data type: BOOL

TRUE value indicates that the function is running.

DRIVE_RFG_DISABLE (drive ramp function generator disable)

Data type: BOOL

Option given to the user bypass the ramp function generator.

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error.
16416	4020	Value of PUMP_ID is erroneous.
16419	4023	Value of PUMP_ID and related setting is erroneous.
16432	4030	Value of TRIGGER is erroneous.
16448	4040	Value of FWD_REF_SPEED is erroneous.
16464	4050	Value of BWD_REF_SPEED is erroneous.
16528	4090	Value of ANTIJAM_STEPS is erroneous.

1.5.13.1.11 PUMP_FLOW_CALC

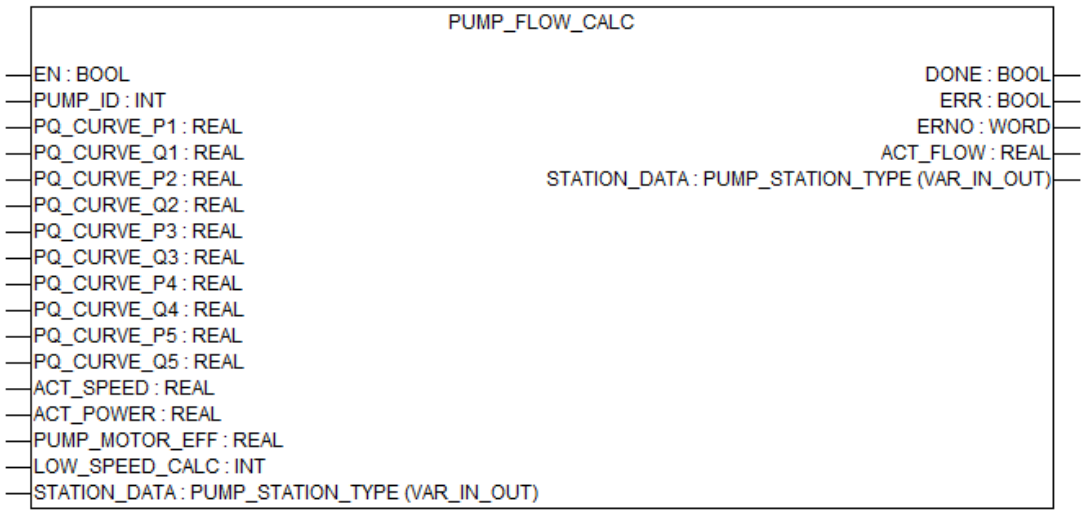

Fig. 667: Function block PUMP_FLOW_CALC

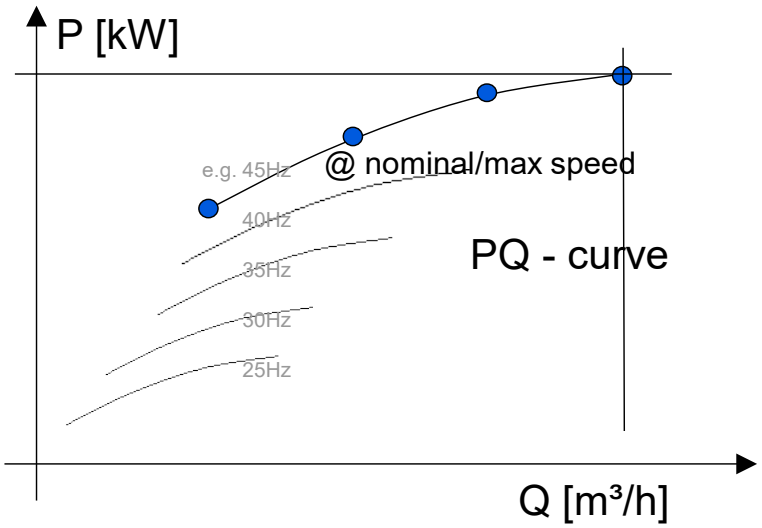
Table 208: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

The flow Calculation Function provides a reasonably accurate (typically ±3…6%) calculation of the flow without the installation of a separate flow meter. The flow is calculated on the basis of pump characteristics.

This function block must be called cyclically with the cycle time of 50ms in the task configuration.

The user can define a PQ (power/flow) performance curve of the pump for the Flow Calculation function. The P (power input) and Q (flow rate) coordinates of five points on the curve are entered. The values are provided by the pump manufacturer. All points defined should lie within the practical operating range of the pump. The points are taken at max operation speed (as entered in the PUMP_INTERFACE block for this pump → the value comes via the connected STATION structure), and scaled down by the block according to the actual speed. By this a good accuracy is achieved with limited parameterization effort.



- *The Flow Calculation function is not to be used for invoicing purposes,*
- *The Flow Calculation function cannot be used outside the normal operating range of the pump given by the pump curves.*

Input description

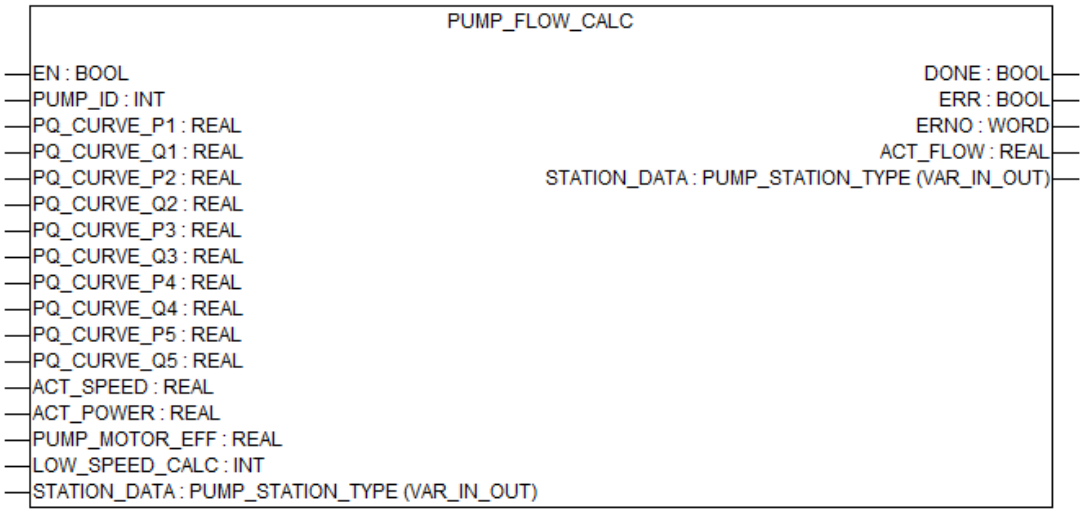


Fig. 668: Function block PUMP_FLOW_CALC

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PUMP_ID (pump number)

Data type: INT, default value: 1, range: 1-3

Pump identification number for which this function block to be called.

PQ_CURVE_P1 (PQ curve P1)

Data type: REAL, default value: 1, range: > 0, unit: kW

Power input of pump at point 1 on the PQ performance curve.

PQ_CURVE_Q1 (PQ curve Q1)

Data type: REAL, default value: 1, range: > 0, unit: m^3/h

Flow rate at point 1 on the PQ performance curve.

PQ_CURVE_P2 (PQ curve P2)

Data type: REAL, default value: 1, range: > 0, unit: kW

Power input of pump at point 2 on the PQ performance curve.

PQ_CURVE_Q2 (PQ curve Q2) Data type: REAL, default value: 1, range: > 0, unit: m^3/h
Flow rate at point 2 on the PQ performance curve.

PQ_CURVE_P3 (PQ curve P3) Data type: REAL, default value: 1, range: > 0, unit: kW
Power input of pump at point 3 on the PQ performance curve.

PQ_CURVE_Q3 (PQ curve Q3) Data type: REAL, default value: 1, range: > 0, unit: m^3/h
Flow rate at point 3 on the PQ performance curve.

PQ_CURVE_P4 (PQ curve P4) Data type: REAL, default value: 1, range: > 0, unit: kW
Power input of pump at point 4 on the PQ performance curve.

PQ_CURVE_Q4 (PQ curve Q4) Data type: REAL, default value: 1, range: > 0, unit: m^3/h
Flow rate at point 4 on the PQ performance curve.

PQ_CURVE_P5 (PQ curve P5) Data type: REAL, default value: 1, range: > 0, unit: kW
Power input of pump at point 5 on the PQ performance curve.

PQ_CURVE_Q5 (PQ curve Q5) Data type: REAL, default value: 1, range: > 0, unit: m^3/h
Flow rate at point 4 on the PQ performance curve.

ACT_SPEED (actual speed) Data type: REAL, default value: 1, range: ≥ 0, unit: rpm
Actual speed of the motor.

ACT_POWER (actual power) Data type: REAL, default value: 1, range: ≥ 0, unit: kW
Actual power of the motor.

PUMP_MOTOR_EFF (pump motor efficiency) Data type: REAL, default value: 1, range: ≥ 0
Pump and the motor combined efficiency.

LOW_SPEED_CALC (low speed calculation) Data type: INT, default value: 1, range: ≥ 0, unit: rpm
Speed below which the calculation will not take place.

STATION_DATA (station data structure) Data type: PUMP_STATION_TYPE
This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

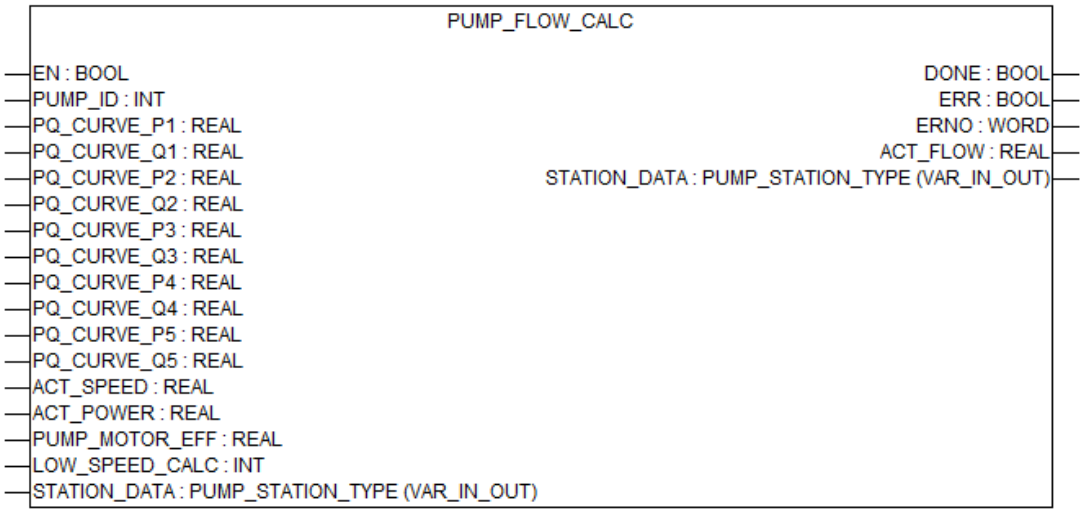

Fig. 669: Function block PUMP_FLOW_CALC

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

ACT_FLOW (actual flow)

Data type: REAL, default value: 0, range: ≥ 0, unit: m^3/h

Calculated actual flow of the pump. It is calculated using PQ (power/flow) performance curve of the pump.

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error.
16416	4020	Value of PUMP_ID is erroneous.
16435	4033	Value of PQ_CURVE_P1 to PQ_CURVE_P5 is erroneous.
16541	4043	Value of PQ_CURVE_Q1 to PQ_CURVE_Q5 is erroneous.
16640	4100	Value of PUMP_MOTOR_EFF is erroneous.
16656	4110	Value of LOW_SPEED_CALC is erroneous.

1.5.13.1.12 PUMP_SLEEP

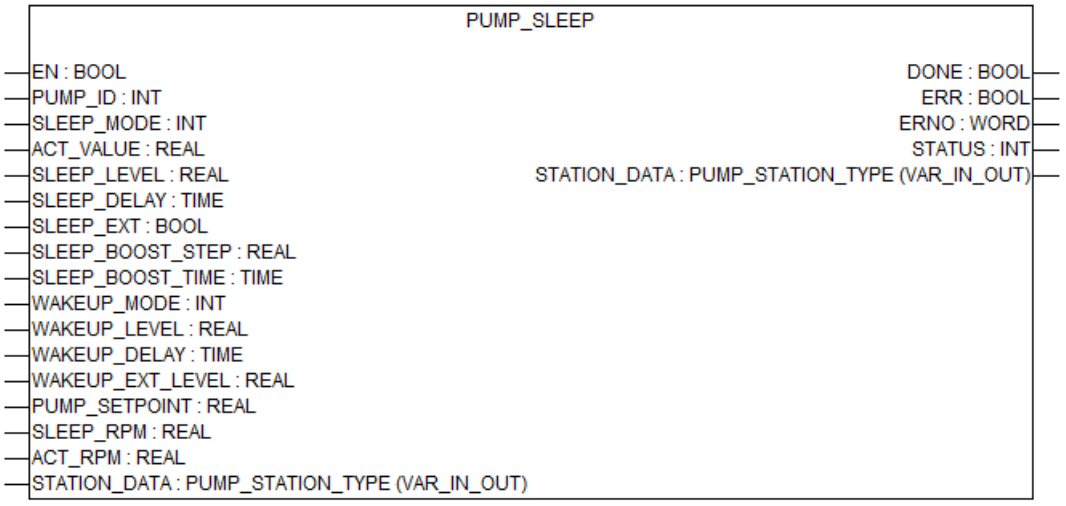

Fig. 670: Function Block PUMP_SLEEP

Table 209: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

The sleep function is suitable for PID control applications where the consumption varies, such as clean water pumping systems. When used, it stops the pump completely during low demand, instead of running the pump slowly below its efficient operating range.

The water consumption falls at night. As a consequence, the process PID controller decreases the motor speed. However, due to natural losses in the pipes and the low efficiency of the centrifugal pump at low speeds, the motor would never stop rotating. The sleep function detects the slow rotation and stops the unnecessary pumping after the sleep delay has passed. The drive shifts into sleep mode, still monitoring the pressure. The pumping resumes when the pressure falls under the predefined minimum level and the wake-up delay has passed.

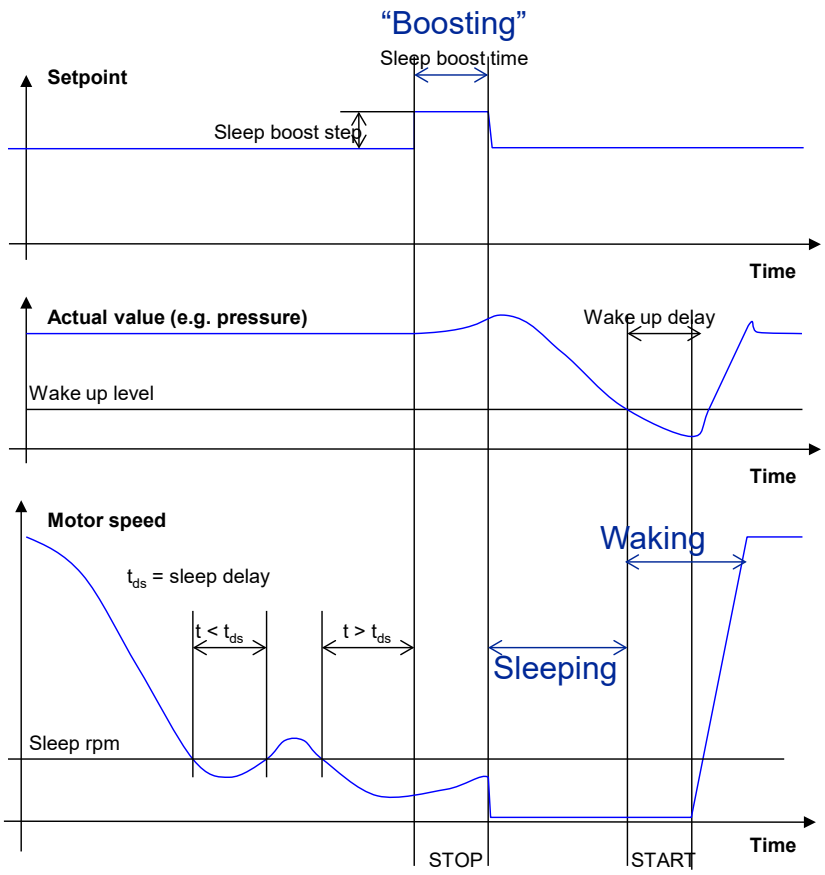

Fig. 671: Visualization of operation and parameters

Input description

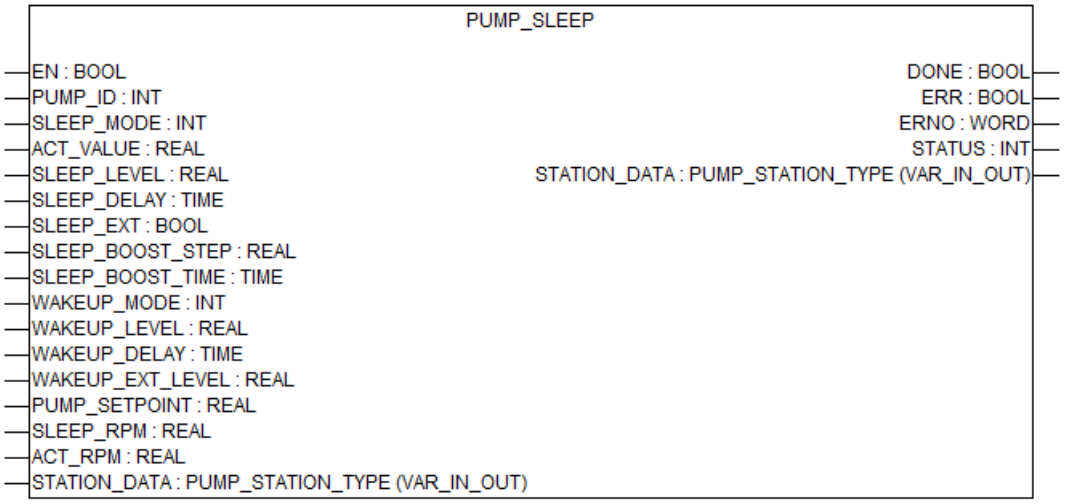

Fig. 672: Function block PUMP_SLEEP

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PUMP_ID (pump number)

Data type: INT, default value: 1, range: 1-3

Pump identification number for which this function block to be called.

SLEEP_MODE Data type: INT, default value: 1, range: 0-4

Table 210: Sleep mode

Mode	Short description	Description
0	Not Used	
1	Internal	Actual value compared with sleep level and if sleep delay is elapsed then pump goes in sleep mode.
2	External	Sleep function is activated using sleep external parameter value.
3	Internal and External	If Sleep_External is true, the Sleep Mode will follow the Internal Mode.
4	Soft External	If Sleep_External is true, the input of the PID controller will be set to 0. After the pump enters sleep mode, it will not wake up until the Sleep_External becomes false.

ACT_VALUE (actual value input of PID block)

Data type: REAL, default value: 1, range: 0-100, unit: %

Actual value of the process variable. This value is scaled as percentage values and attached to this variable. This is the same input which goes as the actual value into the PID.

SLEEP_LEVEL (sleep level)

Data type: REAL, default value: 1, range: 0-100, unit: %

This input defines the level to activate the sleep function. When actual value is equal to sleep level and pump rpm is below sleep rpm, then system waits for sleep delay. Once sleep delay is elapsed pump goes in sleep.

SLEEP_DELAY (sleep delay)

Data type: TIME, default value: 5, range: ≥ 0, unit: s

Time delay for the sleep function to activate. If the actual RPM value is below the parameter input SLEEP_RPM, the system will check if this condition stays for the duration of SLEEP_DELAY and then goes in to sleep-mode (shuts off).

SLEEP_EXTERNAL (sleep external)

Data type: BOOL

This input is used to enable the sleep function externally via a digital input signal

SLEEP_BOOST_STEP (sleep boost step)

Data type: REAL, default value: 1, range: 0-100, unit: %

If the drive enters sleep mode, the setpoint will be increased by this percentage for the time defined by sleep boost time. This allows the optimization of the resulting duty cycle by the sleep function.

SLEEP_BOOST_TIME (sleep boost time)

Data type: TIME, default value: 5, range: ≥ 0, unit: s

Time for which the sleep boost step will be used as an additional setpoint to the pump.

WAKEUP_MODE (wakeup mode) Data type: INT, default value: 1, range: 0-3

Table 211: Wakeup mode

Mode	Short description	Description
0	Wake >Ref	If the actual value remains below setpoint multiplied by the wakeup level for longer than the wakeup delay, the pump will wake up.
1	Wake <Ref	If the actual value remains above setpoint multiplied by the wakeup level for longer than the wakeup delay, the pump will wake up.
2	Wake >Ext	If the wakeup external level remains below actual value for longer than the wakeup delay, the pump will wake up.
3	Wake <	If the wakeup external level remains above actual value for longer than the wakeup delay, the pump will wake up.

WAKEUP_LEVEL (wakeup level) Data type: REAL, default value: 1, range: 0-100, unit: %

Defines the level to activate the wakeup function. It is a percentage of setpoint.

WAKEUP_DELAY (wakeup delay time) Data type: TIME, default value: 5, range: ≥ 0, unit: s

Time delay for the wakeup function to activate.

WAKEUP_EXTERNAL_LEVEL (wakeup external level) Data type: REAL, default value: 1, range: 0-100, unit: %

Wakeup external level. For wake up mode 2 and 3. This value is compared by actual value.

PUMP_SET-POINT (pump set point) Data type: REAL, default value: 1, range: 0-100, unit: %

Process setpoint - the same setpoint connected in the PUMP_PID function block.

SLEEP_RPM (sleep rpm) Data type: REAL, default value: 100, range: ≥ 0, unit: rpm

Pump RPM below which pump should go in to the sleep mode. At very low speed pump efficiency is very low and piping losses are large. By setting this parameter, we can initiate sleep function at lower pump RPM.

ACT_RPM (actual rpm) Data type: REAL, default value: 1, range: ≥ 0, unit: rpm

Actual RPM of the pump. This is compared by sleep RPM to initiate sleep function.

STATION_DATA (station data structure) Data type: PUMP_STATION_TYPE

This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

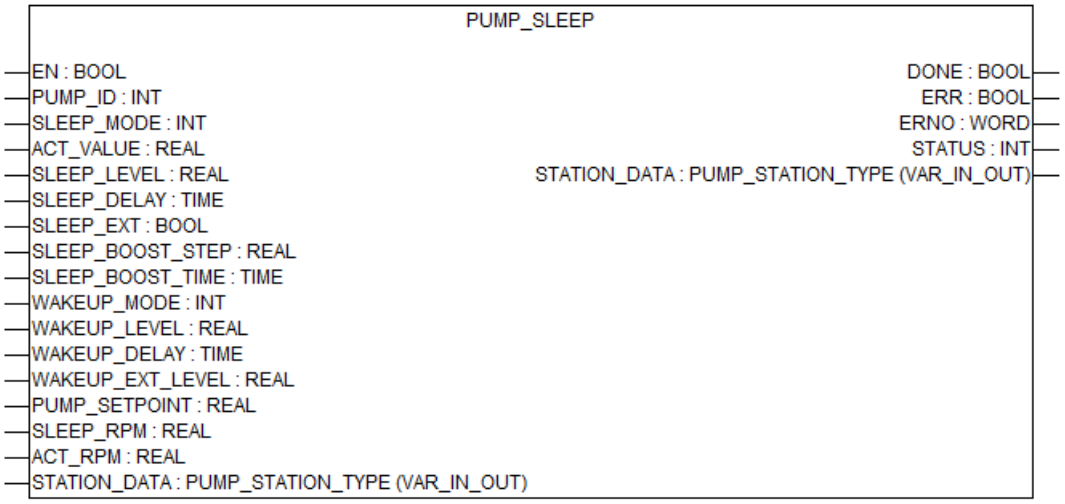

Fig. 673: Function block PUMP_SLEEP

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during data reception. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

STATUS (status) Data type: INT, default value: 0, range: 0-3

Table 212: Status of Sleep Function

Mode	Description
0	Function is inactive.
1	Sleep Function is active.
2	Boost Function is active.
3	Wakeup Function is active.

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error.
16416	4020	Value of PUMP_ID is erroneous
16432	4030	Value of SLEEP_MODE is erroneous.
16448	4040	Value of ACT_VALUE is erroneous.
16464	4050	Value of SLEEP_LEVEL is erroneous.
16480	4060	Value of SLEEP_DELAY is erroneous.
16512	4080	Value of SLEEP_BOOST_STEP is erroneous.
16528	4090	Value of SLEEP_BOOST_TIME is erroneous.
16544	40A0	Value of WAKEUP_MODE is erroneous.
16560	40B0	Value of WAKEUP_LEVEL is erroneous.
16576	40C0	Value of WAKEUP_DELAY is erroneous.
16592	40D0	Value of WAKEUP_EXTERNAL_LEVEL is erroneous.
16608	40E0	Value of PUMP_SETPOINT is erroneous.
16624	40E0	Value of SLEEP_RPM is erroneous.

1.5.13.1.13 PUMP_PROTECTION

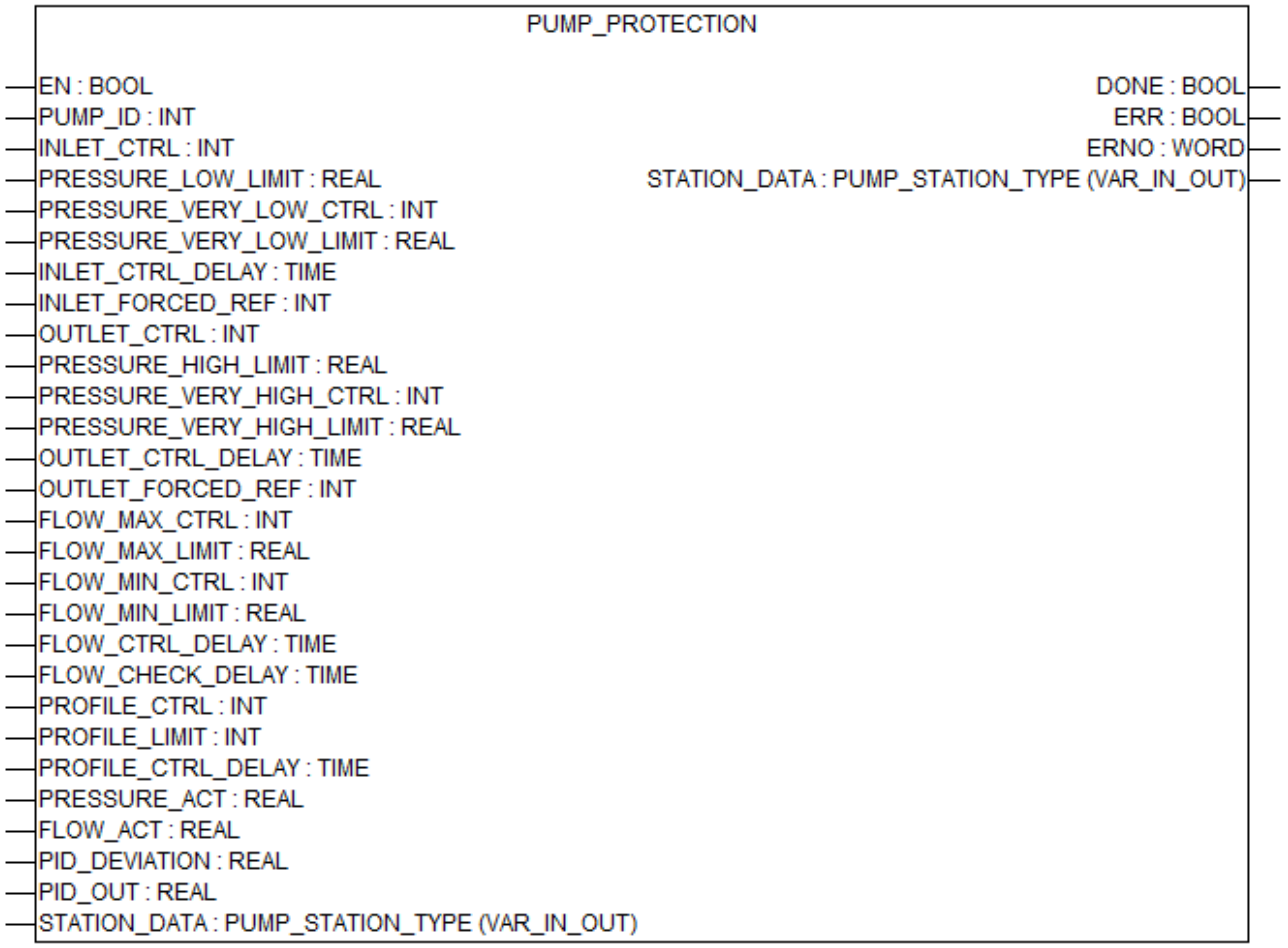

Fig. 674: Function block PUMP_PROTECTION

Table 213: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

This function block contains two level protection for the inlet and outlet pressure monitoring. The actual pressure for the comparison is an analog input. In the first level primary protection, the drive indicates depending on the chosen mode: A warning, trips on a fault, or starts to follow a predefined reference. In the second level secondary protection, the drive either will stop or trip on a fault. For flow and the profile monitoring there is only one level of protection, in which the drive responds as per the control selected.

Example

If for the inlet the primary (first limit) protection for the low pressure is set, the INLET_CTRL mode is set to 3. Lower pressures than given in the limit are measured: The station will run in the reduced speed mode. In that case the PID output is frozen (in the PID). The current master gets the reduced speed INLET_FORCED_REF. This new ref speed of the master will decide whether to run followers or not.

Flow Monitoring

The control program has a monitoring function for flow that can be configured to generate an alarm or a fault whenever the flow falls below or rises above predefined limits. The flow can either be calculated or measured using a flow meter connected to, for example, an analog input.

Application Profile Monitoring

The application profile monitoring function can be used for long-term supervision of an actual signal. If the selected signal remains above the supervision limit for a specified time, an alarm will be generated.

Input description

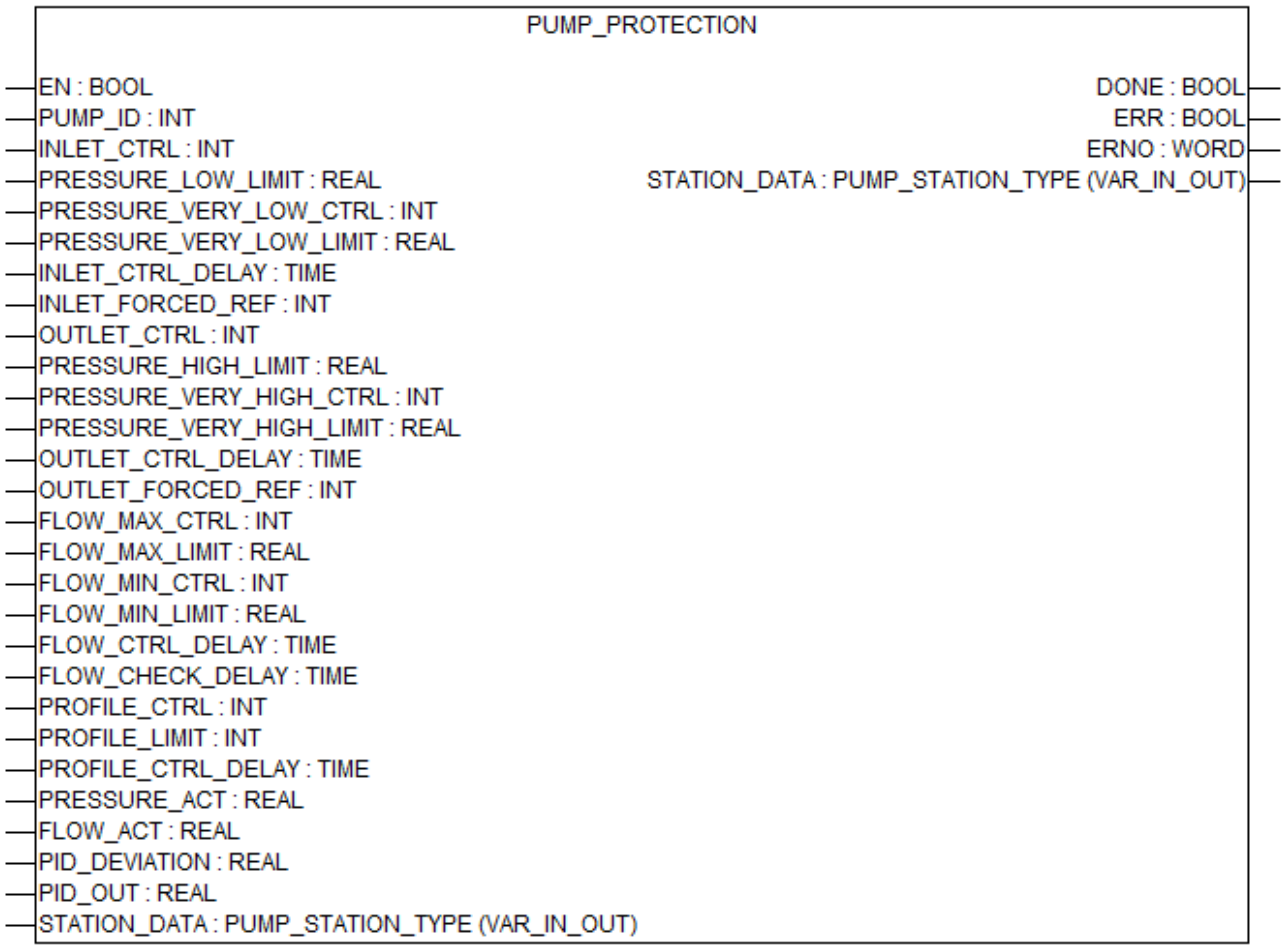

Fig. 675: Function block PUMP_PROTECTION

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PUMP_ID (pump identification number)

Data type: INT, default value: 1, range: 1-3

Identifies which function block instance is used for which physical pump.

INLET_CTRL (inlet control)

Data type: INT, default value: 0, range: 0-3

Table 214: To enable primary protection

Mode	Short description	Description
0	Disabled	Primary inlet pressure supervision is not used.
1	Alarm	Detection of low inlet pressure produces an alarm after the inlet control delay.
2	Fault	Detection of low inlet pressure trips drive after the inlet control delay.
3	Reduced speed	Detection of low inlet pressure produces an alarm after the inlet control delay. The Pump speed is reduced to the speed specified in inlet forced reference.

PRESSURE_LOW_LIMIT (pressure low limit)

Data type: REAL, default value: 1, range: 0-100, unit: %

Low pressure level limit for primary protection.

PRESSURE_VERY_LOW_CTRL (pressure very low control)

Data type: INT, default value: 1, range: 0-2

Table 215: To enable pressure very low

Mode	Short description	Description
0	Disabled	Secondary inlet pressure supervision is not used.
1	Fault	Detection of very low inlet pressure trips drive.
2	Stop	Detection of very low inlet pressure stops drive. The drive will restart, if pressure rises above PRESSURE_VERY_LOW_LIMIT value.

PRESSURE_VERY_LOW_LIMIT (pressure very low limit)

Data type: REAL, default value: 1, range: 0-100, unit: %

Very low pressure level limit at secondary protection.

INLET_CTRL_DELAY (inlet control delay)

Data type: TIME, default value: 1, range: 0-600, unit: s

Delay for primary (actual pressure less than the low pressure limit) and secondary supervision (actual pressure less than the very low pressure limit) of pump inlet pressure.

Range: 0 to 600 seconds .

INLET_FORCED_REF (inlet forced reference)

Data type: INT, default value: 1, range: ≥ 0, unit: rpm

Inlet forced reference for very low pressure. Detection of low inlet pressure produces an alarm after the inlet control delay. The pump speed is reduced to the speed specified in inlet forced reference.

OUTLET_CTRL (outlet control)

Data type: INT, default value: 1, range: 0-3

Table 216: To enable outlet protection

Mode	Short description	Description
0	Disabled	Primary outlet pressure supervision is not used.
1	Alarm	Detection of high outlet pressure produces an alarm after the outlet control delay.
2	Fault	Detection of high outlet pressure trips drive after the outlet control delay.
3	Reduced speed	Detection of high outlet pressure produces an alarm after the outlet control delay. Pump speed: Reduced to the speed specified in outlet forced reference.

PRESSURE_HIGH_LIMIT (pressure high limit)

Data type: REAL, default value: 1, range: 0-100, unit: %

High pressure level limit for primary protection.

PRESSURE_VERY_HIGH_CTRL (pressure very high control)

Data type: INT, default value: 1, range: 0-2

Table 217: To enable pressure very high control

Mode	Short description	Description
0	Disabled	Secondary outlet pressure supervision is not used.
1	Fault	Detection of very high outlet pressure trips drive.
2	Stop	Detection of very high outlet pressure stops drive. The drive will restart, if pressure rises above limit.

PRESSURE_VERY_HIGH_LIMIT (pressure very high limit)

Data type: REAL, default value: 1, range: 0-100, unit: %

Very high pressure level limit at secondary protection.

OUTLET_CTRL_DELAY (outlet control delay)

Data type: TIME, default value: 1, range: 0-600, unit: s

Delay for primary and secondary supervision of pump outlet pressure.

OUTLET_FORCED_REF (outlet forced reference)

Data type: INT, default value: 1, range: ≥ 0, unit: rpm

Outlet Forced Reference for very high pressure. Detection of high outlet pressure produces an alarm after the outlet control delay. The Pump speed is reduced to the speed specified in Outlet Forced Reference.

FLOW_MAX_CTRL (flow maximum control) Data type: INT, default value: 1, range: 0-2

Mode	Description
0	Protection from high flow rates disabled.
1	Alarms generated – minimum flow.
2	Fault generated - minimum flow, drive trips.

FLOW_MAX_LIMIT (flow maximum limit) Data type: REAL, default value: 0, range: 0-32767, unit: m^3/h

Value of max flow rate limit in m3/h.

FLOW_MIN_CTRL (flow minimum control) Data type: REAL, default value: 1, range: 0-2

Mode	Description
0	Protection from low flow rates disabled.
1	Alarms generated – minimum flow.
2	Fault generated - minimum flow, drive trips.

FLOW_MIN_LIMIT (flow minimum limit) Data type: INT, default value: 0, range: 0-32767, unit: m^3/h

Value of minimum flow rate limit.

FLOW_CTRL_DELAY (flow control delay) Data type: TIME, default value: 1, range: 0-12600, unit: s

Delay before executing the control due to low or high flow rates.

FLOW_CHECK_DELAY (flow check delay) Data type: TIME, default value: 1, range: 0-12600, unit: s

Delay after the start of the pump before monitoring the flow rates.

PROFILE_CTRL (profile control) Data type: INT, default value: 1, range: 0-2

Mode	Description
0	Protection from high flow rates disabled.
1	Alarms generated – maximum flow.
2	Fault generated - maximum flow, drive trips.

PROFILE_LIMIT (profile limit) Data type: INT, default value: 1, range: 0-32767

Value of profile protection limit.

PROFILE_CTRL_DELAY (profile control delay) Data type: TIME, default value: 1, range: ≥ 0, unit: s

Time delay before the Profile Control activates.

PRESSURE_ACT (actual pressure)	Data type: INT, default value: 1, range: 0-100, unit: % Actual pressure of the system.
FLOW_ACT (actual flow)	Data type: INT, default value: 1, range: ≥ 0, unit: m^3/h Actual flow of the pump.
PID_DEVIATION (pid deviation)	Data type: REAL, default value: 0.0, range 0-100.0, unit % Deviation of Set value from actual value. It is also known as PID error.
PID_OUT (pid out)	Data type: REAL, default value: 1, range: -100 to +100, unit: % PID Out is generated by PUMP_PID function block. PID control process error value gives output.
STATION_DATA (station data structure)	Data type: PUMP_STATION_TYPE This structure contains pumping station data. All the function blocks receive some data, process it and write it back to the structure.

Output description

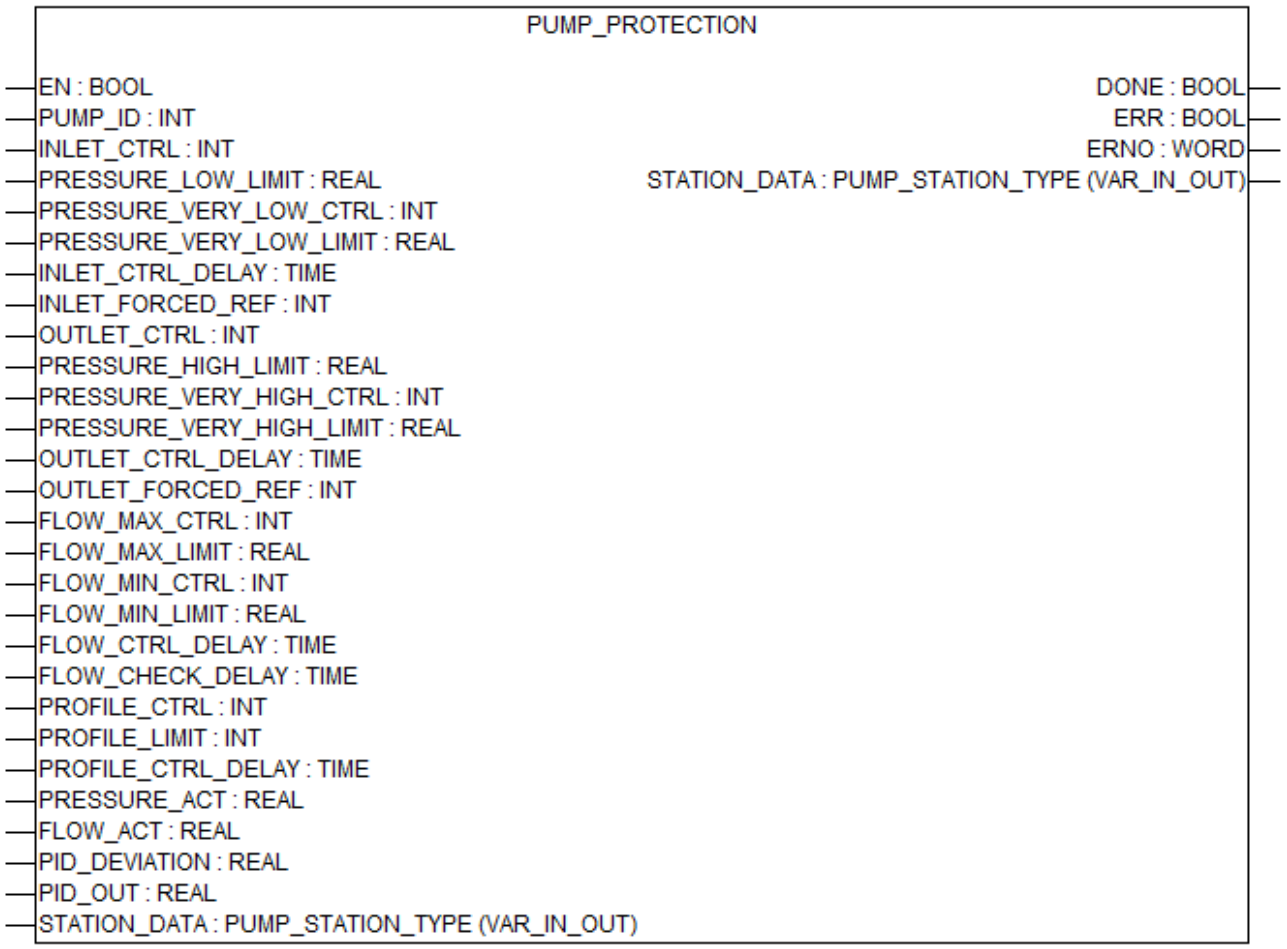

Fig. 676: Function block PUMP_PROTECTION

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error.
16416	4020	Value of PUMP_ID is erroneous.
16432	4030	Value of INLET_CTRL is erroneous.
16448	4040	Value of PRESSURE_LOW_LIMIT is erroneous.
16451	4043	Value of either PRESSURE_LOW_LIMIT or PRESSURE_VERY_LOW_LIMIT is erroneous.
16464	4050	Value of PRESSURE_VERY_LOW_CTRL is erroneous.
16480	4060	Value of PRESSURE_VERY_LOW_LIMIT is erroneous.
16496	4070	Value of INLET_CTRL_DELAY is erroneous.
16512	4080	Value of INLET_FORCED_REF is erroneous.
16528	4090	Value of OUTLET_CTRL is erroneous.
16544	40A0	Value of PRESSURE_HIGH_LIMIT is erroneous.
16547	40A3	Value of either PRESSURE_HIGH_LIMIT or PRESSURE_VERY_HIGH_LIMIT is erroneous.
16560	40B0	Value of PRESSURE_VERY_HIGH_CTRL is erroneous.
16576	40C0	Value of PRESSURE_VERY_HIGH_LIMIT is erroneous.
16592	40D0	Value of OUTLET_CTRL_DELAY is erroneous.
16608	40E0	Value of OUTLET_FORCED_REF is erroneous.

Dec	Hex	Error Description
16624	40F0	Value of FLOW_MAX_CTRL is erroneous.
16640	4100	Value of FLOW_MAX_LIMIT is erroneous .
16643	4103	Value of either FLOW_MAX_LIMIT or FLOW_MIN_LIMIT is erroneous.
16656	4110	Value of FLOW_MIN_CTRL is erroneous.
16672	4120	Value of FLOW_MIN_LIMIT is erroneous.
16688	4130	Value of FLOW_CTRL_DELAY is erroneous.
16704	4140	Value of FLOW_CHECK_DELAY is erroneous.
16720	4150	Value of PROFILE_CTRL is erroneous.
16736	4160	Value of PROFILE_LIMIT is erroneous.
16752	4170	Value of PROFILE_CTRL_DELAY is erroneous.

1.5.13.1.14 PUMP_ENERGY_CALC

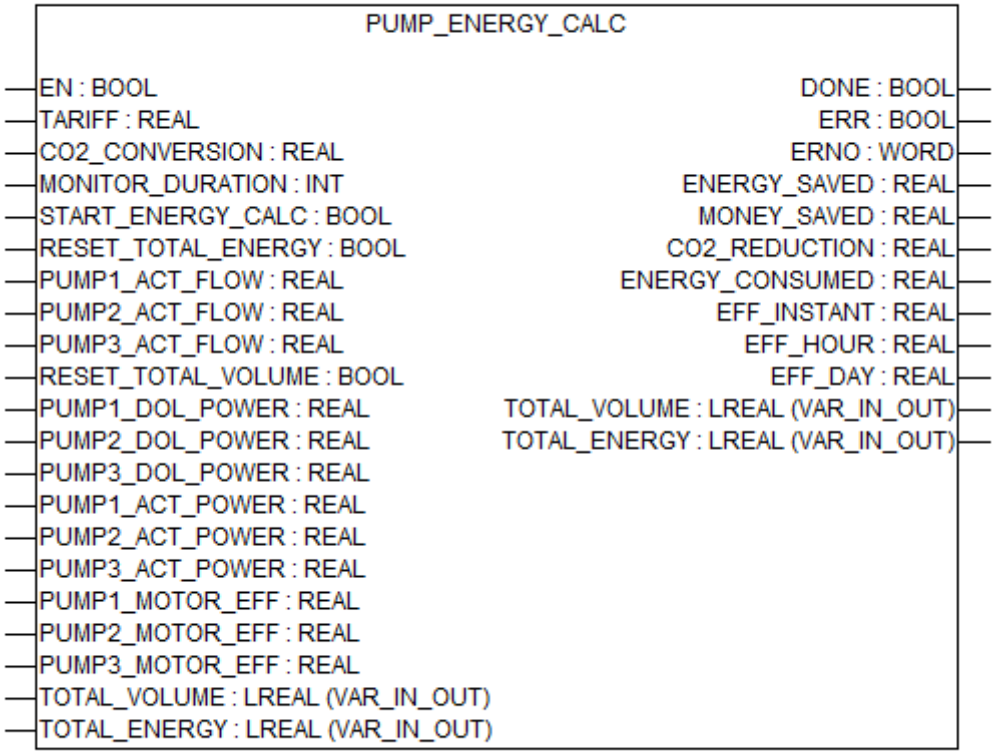

Fig. 677: Function block PUMP_ENERGY_CALC

Table 218: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

This function block calculates energy consumed by direct on line pumps and drive connected pumps. This is then used to calculate saved energy by using drives. Based on energy saved the CO_2 emission reductions and money saved is also computed.

It also calculates efficiency of total flow (= volume) per total power (energy) in m^3/kWh. Instant, hourly and 24 hourly (daily) efficiency are calculated continuously.

Total volume and total energy is calculated and connected as in or out parameter to the function block.

This function block must be called cyclically with the cycle time of 50 ms in the task configuration.

To retain this data, global retain variables need to be connected in the user program.

Input description

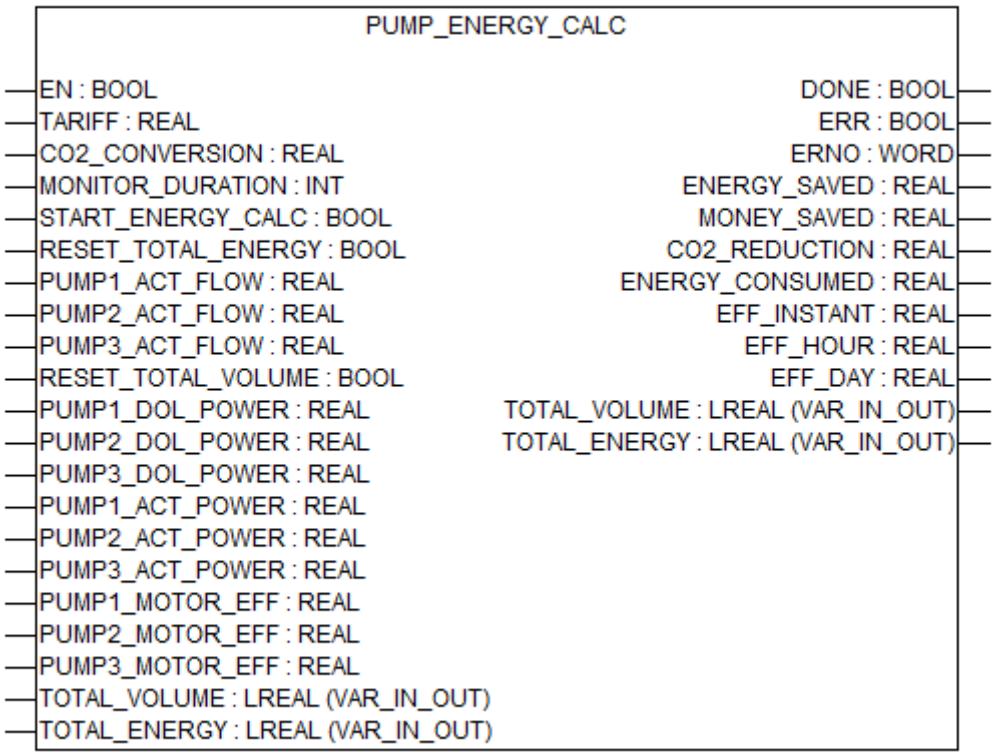

Fig. 678: Function block PUMP_ENERGY_CALC

> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

TARIFF (tariff) Data type: REAL, default value: 0, range: ≥ 0, unit: currency (e.g. Dollar, Euro) /kWh

This is used with energy saved to calculate money saved by using drives (instead of DOL).

CO2_CONVERSION (CO_2 conversion) Data type: REAL, default value: 0, range: ≥ 0

Factor which helps in converting the energy consumed in terms of CO_2 emission tn/MWh.

MONITOR_DURATION (monitor duration)
Data type: INT, default value: 0, range: > 0, unit: min
Time duration to calculate the energy consumed.

START_ENERGY_CALC (start energy calculation)
Data type: BOOL
The energy calculation will start if the input is TRUE. If the input becomes FALSE the energy calculation will stop.

RESET_TOTAL_ENERGY (reset total energy)
Data type: BOOL
If this input is TRUE it will reset all the stored values zero. If this input is FALSE the stored values will get updated continuously.

PUMP1_ACT_FLOW (pump 1 actual flow)
Data type: REAL, default value: 0, range: ≥ 0, unit: m^3/h
Actual flow of PUMP 1 is connected to this parameter. Actual flow can be measured using standard flow meters or theoretically calculated using PQ curves of function block PUMP_FLOW_CALC.

PUMP2_ACT_FLOW (pump 2 actual flow)
Data type: REAL, default value: 0, range: ≥ 0, unit: m^3/h
Actual flow of PUMP 2 is connected to this parameter. Actual flow can be measured using standard flow meters or theoretically calculated using PQ curves of function block PUMP_FLOW_CALC.

PUMP3_ACT_FLOW (pump 3 actual flow)
Data type: REAL, default value: 0, range: ≥ 0, unit: m^3/h
Actual flow of PUMP 3 is connected to this parameter. Actual flow can be measured using standard flow meters or theoretically calculated using PQ curves of function block PUMP_FLOW_CALC.

RESET_TOTAL_VOLUME (reset total volume)
Data type: BOOL
Total volume is calculated using the flow of the available pumps. If this input is TRUE it will reset stored total volume value to zero. If this input is FALSE the stored values will get updated continuously.

PUMP1_DOL_POWER (pump 1 dol power)
Data type: REAL, default value: 0, range: ≥ 0, unit: kW
Pump1 Direct On Line power, if directly connected to the motor.

PUMP2_DOL_POWER (pump 2 dol power)
Data type: REAL, default value: 0, range: ≥ 0, unit: kW
Pump2 Direct On Line power, if directly connected to the motor.

PUMP3_DOL_POWER (pump 3 dol power)
Data type: REAL, default value: 0, range: ≥ 0, unit: kW
Pump3 Direct On Line power, if directly connected to the motor.

PUMP1_ACT_POWER (pump 1 actual power)
Data type: REAL, default value: 0, range: ≥ 0, unit: kW
Pump1 actual power read from the drive.

PUMP2_ACT_POWER (pump 2 actual power)
Data type: REAL, default value: 0, range: ≥ 0, unit: kW
Pump2 actual power read from the drive.

PUMP3_ACT_POWER (pump 3 actual power)
Data type: REAL, default value: 0, range: ≥ 0, unit: kW
Pump3 actual power read from the drive.

PUMP1_MOTOR_EFF (pump 1 motor efficiency)
Data type: REAL, default value: 0, range: 0-100.0, unit: %
Motor efficiency in % of Pump1.

PUMP2_MOTOR_EFF (pump 2 motor efficiency)
Data type: REAL, default value: 0, range: 0-100.0, unit: %
Motor efficiency in % of Pump2.

PUMP3_MOTOR_EFF (pump 3 motor efficiency)
Data type: REAL, default value: 0, range: 0-100.0, unit %
Motor efficiency in % of Pump3.

TOTAL_VOLUME (total volume)
Data type: LREAL, default value: -, range: ≥ 0, unit: m^3
Total volume is consumed, which is calculated using flow of all the pumps. It is cumulative and the user can connect global retain variable in program can retain this value.

TOTAL_ENERGY (total energy)
Data type: LREAL, default value: -, range: ≥ 0, unit: kWh
Total energy which was consumed, calculated using actual power of all pumps. It is cumulative and the user should connect global retain variable in program to retain this value.

Output description

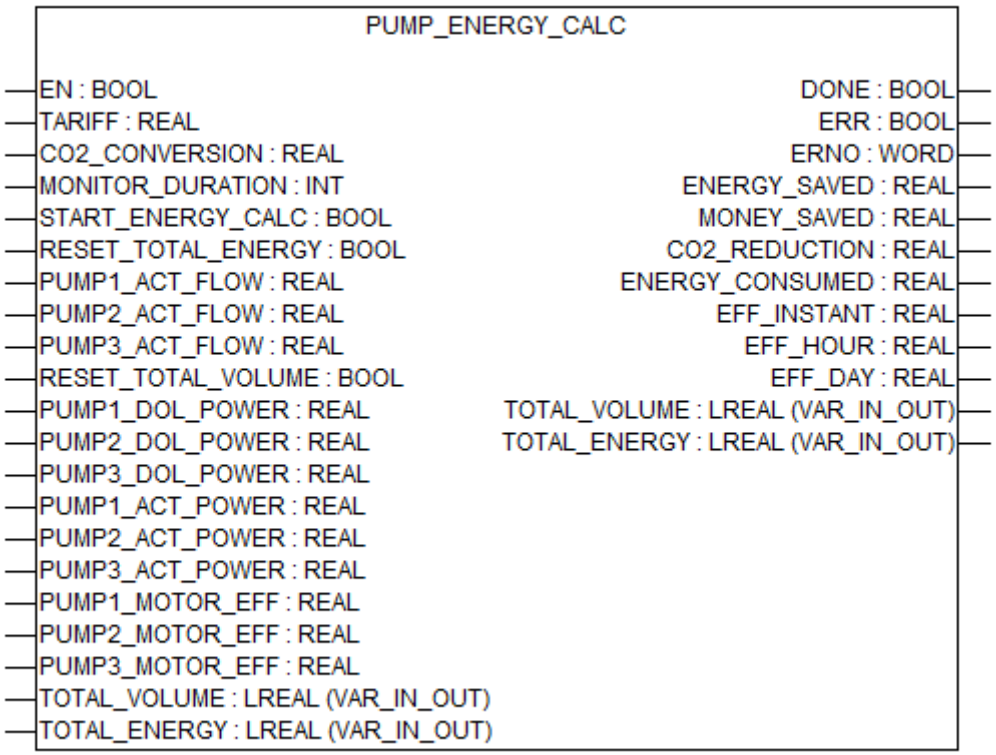

Fig. 679: Function block PUMP_ENERGY_CALC

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

ENERGY_SAVED (energy saved)

Data type: REAL, default value: 0, range: ≥ 0, unit: kWh

Stores the energy saved.

Difference of the energy consumed, considering the pumps motor connected directly to the grid (DOL), compared to the using a drive to control the motor.

MONEY_SAVED (money saved)

Data type: REAL, default value: 0, range: ≥ 0, unit: currency (e.g. Dollar, Euro)

Money saved is calculated by multiplying ENERGY_SAVED and TARIFF. Its unit is the same unit as TARIFF.

CO2_REDUCTION (CO_2 reduction)

Data type: REAL, default value: 0, range: ≥ 0, unit: t/kWh

Indicates the reduction in carbon dioxide emissions.

ENERGY_CONSUMED (energy consumed)

Data type: REAL, default value: 0, range: ≥ 0, unit: kWh

Indicates the value of energy consumed in the monitoring duration. While input TOTAL_ENERGY indicates cumulative value of energy consumed.

EFF_INSTANT (instant efficiency)

Data type: REAL, default value: 0, range: ≥ 0

Instant flow power efficiency of the system in m^3/kWh.

EFF_HOUR (hourly efficiency)

Data type: REAL, default value: 0, range: ≥ 0

Hourly flow power efficiency of the system in m^3/kWh.

EFF_DAY (daily efficiency)

Data type: REAL, default value: 0, range: ≥ 0

Daily flow power efficiency of the system in m^3/kWh.

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error.
16416	4020	Value of TARIFF is erroneous.
16432	4030	Value of CO2_CONVERSION is erroneous.

Dec	Hex	Error Description
16448	4040	Value of MONITOR_DURATION is erroneous.
16560	40B0	Value of PUMP1_DOL_POWER is erroneous.
16576	40C0	Value of PUMP2_DOL_POWER is erroneous.
16592	40D0	Value of PUMP3_DOL_POWER is erroneous.
16656	4110	Value of PUMP1_MOTOR_EFF is erroneous.
16672	4120	Value of PUMP2_MOTOR_EFF is erroneous.
16688	4130	Value of PUMP3_MOTOR_EFF is erroneous.

1.5.13.1.15 Pump_DOL_SIMU

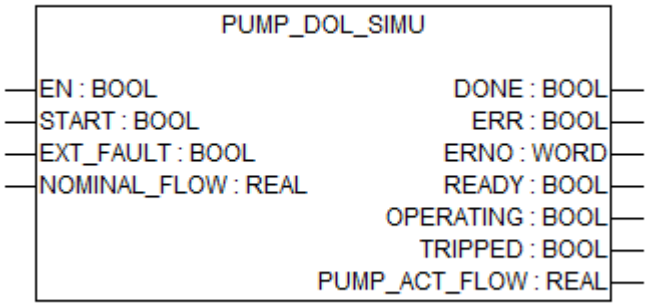

Fig. 680: Function block PUMP_DOL_SIMU

Table 219: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

This function block simulates a Direct Online Pump (DOL) without a drive . The function block generates the feedback signals READY, OPERATING and TRIPPED which have to be connected to the PUMP_INTERFACE function block . The trip signal is simulated by forcing the input EXT_FAULT. The input value “NOMINAL_FLOW" is the nominal (rated) flow of the pump which is forwarded to the output “PUMP_ACT_FLOW” if the pump is in operating condition. The output “PUMP_ACT_FLOW” is zero if the pump is off or tripped.

The function block simulates a Direct Online (DOL) pump in boost control applications traditional pumping

The function block simulates the pump only in general behavior. The behavior in the real process may be slightly different Outputs of this function block may or may not be as accurate as real process.

Input description

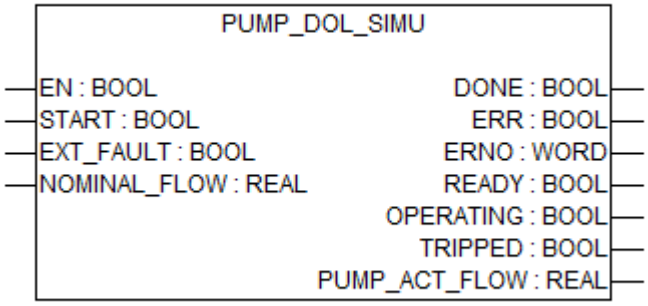

Fig. 681: Function block PUMP_DOL_SIMU

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START (start)

Data type: BOOL, default value: FALSE

The input is connected to the pump start command. The start command is activated by the PUMP_START output of the PUMP_INTERFACE function block.

TRUE starts the DOL pump and the output “OPERATING” is TRUE. FALSE stops the pump and the output “OPERATING” is FALSE The output “READY” keeps TRUE independent of the input state.

EXT_FAULT (external fault)

Data type: BOOL, default value: FALSE

This input simulates the trip condition. The user can trigger the input signal “EXT_FAULT".

TRUE activate a pump trip; the output ”TRIPPED” is TRUE and stops the pump; the output “OPERATING” is FALSE; the output “READY” is FALSE

FALSE deactivate a trip the output “TRIPPED” is FALSE.

NOM-INAL_FLOW (nominal flow)

Data type: REAL, default value: 0, range >0, unit: m^3/ h

This input parameter has to be designed according the nominal flow of the pump.

Output description

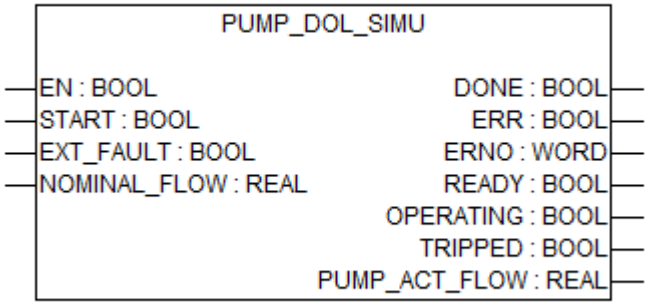

Fig. 682: Function block PUMP_DOL_SIMU

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

READY (ready)

Data type: BOOL

TRUE indicates that the pump is ready to start and there is no fault (input “EX_FAULT” is FALSE).

OPERATING (operating)

Data type: BOOL

TRUE indicates that the pump is operating.

TRIPPED (tripped)

Data type: BOOL

TRUE indicates the pump is tripped (input “EX_FAULT” is TRUE)

PUMP_ACT_FLOW (pump actual flow)

Data type: REAL, unit: m^3/h

Actual flow of the Direct Online (DOL) pump.

The output value corresponds to the input parameter “NOMINAL FLOW” if the pump is running.

The output value is zero if the pump is stopped.

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error
16448	4040	NOMINAL_FLOW is less than zero

1.5.13.1.16 PUMP_DRIVE_SIMU

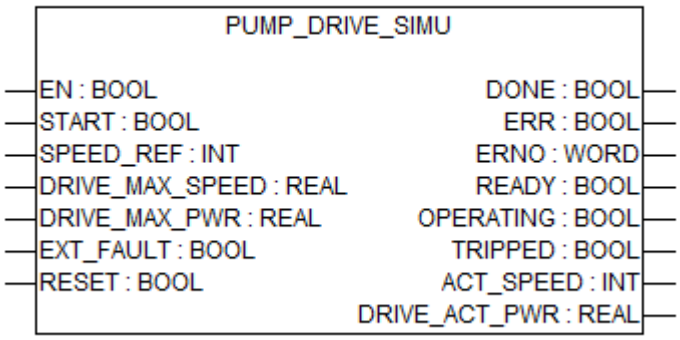

Fig. 683: Function block PUMP_DRIVE_SIMU

Table 220: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

This function block simulates a drive. In combination with the function block PUMP_FLOW_CALC a drive controlled pump can be simulated.

The function block generates the feedback signals READY, OPERATING and TRIPPED which have to be connected to the PUMP_INTERFACE function block. The output ACT_SPEED and DRIVE_ACT_PWR can be connected to the PUMP_FLOW_CALC function block. The trip signal is simulated by forcing the input EXT_FAULT

> *The function block simulates a Drive controlled pump in level control or boost control applications multimode or traditional pumping*
>
> *The function block simulates the Drive controlled pump only in general behavior. The behavior in the real process may be slightly different.*

Input description

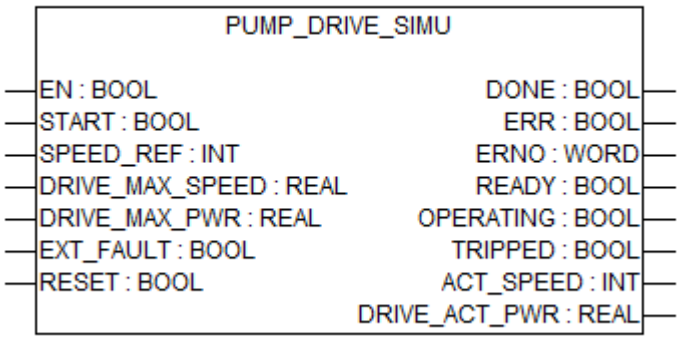

Fig. 684: Function block PUMP_DRIVE_SIMU

EN (enable)

Data type: BOOL, default value: FALSE

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The block is not processed if input EN = FALSE. While input is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

START (start)

Data type: BOOL, default value: FALSE

The input is connected to the pump start command. The start command is activated by the PUMP_INTERFACE function block.

TRUE starts the pump and the output “OPERATING” is TRUE.

FALSE stops the pump the output “OPERATING” is FALSE.

The output “READY” keeps TRUE independent of the input state.

SPEED_REF (speed reference)

Data type: INT, default value: 0, range: > 0, unit: RPM

The input is connected to the pump reference speed.

The pump reference speed is generated by the application and connected from the PUMP_INTERFACE function block.

DRIVE_MAX_SPEED (drive maximum speed) Data type: REAL, default value: 1500, range: > 0, unit: RPM

This input parameter has to be designed according the nominal speed of the pump.

DRIVE_MAX_PWR (drive maximum power) Data type: REAL, default value: 5, range: > 0, unit: kW

This input parameter has to be designed according the nominal power of the pump.

Maximum rated power of the drive.

EXT_FAULT (external fault) Data type: , BOOL, default value: FALSE

This input simulates the trip condition. The user can trigger the input signal “EXT_FAULT”

TRUE activate a pump trip; the output ”TRIPPED” is TRUE and stops the pump; the output “OPERATING” is FALSE;

When the input signal “EXT_FAULT” changes back to FALSE it does not deactivate the TRIPPED status. This can only be done using the RESET input explained below.

RESET (reset) Data type: , BOOL, default value: FALSE

This input can be used to reset the TRIPPED status on the drive.

When the RESET changes from FALSE to TRUE, the output TRIPPED becomes FALSE in the absence of EXT_FAULT. However RESET does not deactivate the TRIPPED status when the EXT_FAULT is already present

Output description

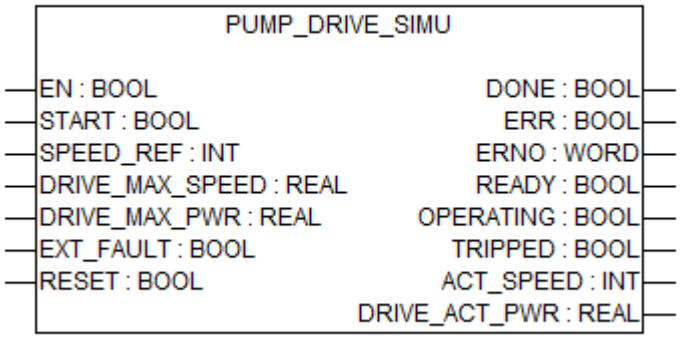

Fig. 685: Function block PUMP_DRIVE_SIMU

DONE (done) Data type: BOOL

Output DONE indicates the processing state of the block. After completion or abortion of processing (due to an error), DONE is set to TRUE for one cycle. This output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during data reception. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD, default value: 0, range: ≥ 0

Output ERNO provides an error identifier if an invalid value was applied to an input. ERNO always has to be considered together with the output ERR. The value output at ERNO is only valid if ERR is TRUE. The error messages encoding at output ERNO are explained at the table below.

READY (ready)

Data type: BOOL

TRUE indicates that the drive is ready to start and there is no fault.

(input “EX_FAULT” is FALSE)

OPERATING (operating)

Data type: BOOL

TRUE indicates that the drive is operating.

TRIPPED (tripped)

Data type: BOOL

TRUE indicates the pump is tripped (input “EX_FAULT” is TRUE).

ACT_SPEED (actual speed)

Data type: REAL , unit: RPM

Actual speed of the drive.

DRIVE_ACT_PWR (drive actual power)

Data type: REAL, unit: kW

Drive calculated power. It is based on the DRIVE_MAX_SPEED and DRIVE_MAX_PWR inputs.

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error
16432	4030	SPEED_REF is less than zero.
16448	4040	DRIVE_MAX_SPEED is less or equal than zero.
16464	4050	DRIVE_MAX_PWR is less or equal than zero.

1.5.13.1.17 PUMP_TANK_SIMU

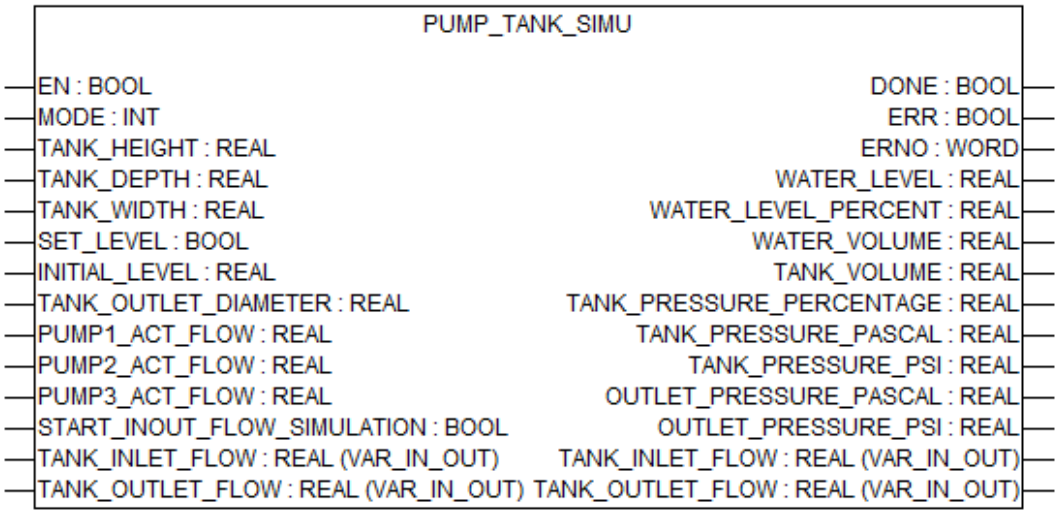

Fig. 686: Function block PUMP_TANK_SIMU

Table 221: General information

Available as of runtime system	V1.3 and above
Included in library	PUMP_AC500_V23.lib
Type	Function block without historical values.

This function block simulates a simple tank in a water pumping process. User can configure the tank size and attach the flow calculated from the PUMP_FLOW_CALC function block. Based on the user configuration, either emptying or filling mode of tank can be implemented. This function block outputs Water level or Pressure can be used as inputs to the level control or boost control application respectively.

The function block will be used to simulate tank behavior in level control and boost control applications.

The function block simulates the tank behavior only in general. The behavior in the rael process may be slightly different.

Input description

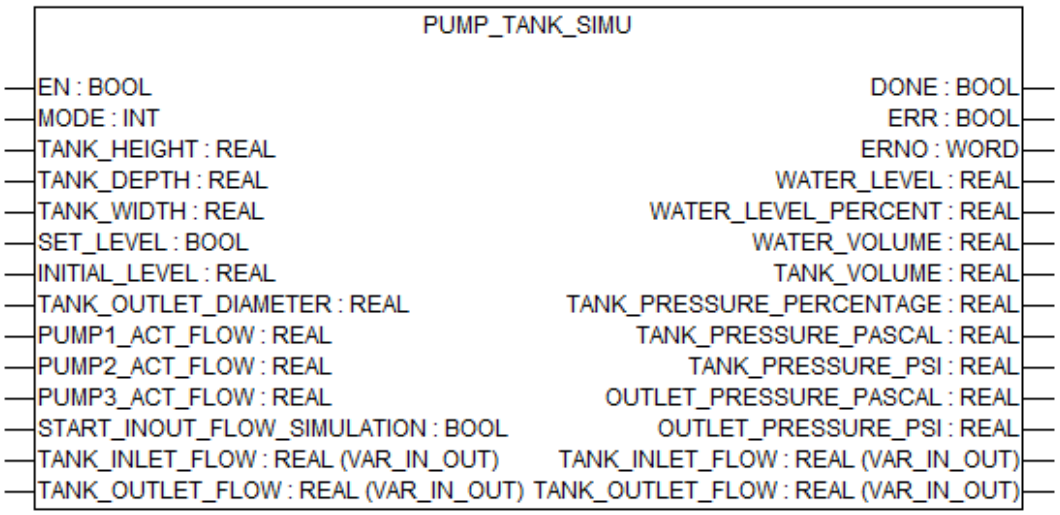

Fig. 687: Function block TANK_SIMU

EN (enable) Data type: BOOL, default value: FALSE

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The block is not processed if input EN = FALSE. While input is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

MODE (mode) Data type: INT, default value: 1, range: 1 or 2.

The input parameter selects the tank operation mode

1 – Emptying of the tank

2 – Filling of the tank

TANK_HEIGHT (tank height) Data type: REAL, default value: 0, range: ≥ 0, unit: m

The input parameter specifies the tank height.

TANK_DEPTH (tank depth) Data type: REAL, default value: 0, range: ≥ 0, unit: m

The input parameter specifies the tank depth.

TANK_WIDTH (tank width) Data type: REAL, default value: 0, range: ≥ 0, unit: m

The input parameter specifies the tank width.

SET_LEVEL (set level) Data type: , BOOL, default value: FALSE

The user can trigger the input and set the tank initial value for simulation TRUE set the initial tank level as declared in the input INITIAL_LEVEL.

FALSE starts the simulation considering zero level in the tank.

INITIAL_LEVEL (initial level)

Data type: REAL, default value: 1, range: > 0, unit: m

The input parameter specifies the initial tank level to start the simulation. This input value will be considered for the tank simulation only if input SET_LEVEL is made TRUE.

TANK_OUTLET_DIAMETER (tank outlet diameter)

Data type: REAL, default value: 1, range: > 0, unit: m

The input parameter specifies the diameter of the outlet pipe.

PUMP1_ACT_FLOW (pump 1 actual flow)

Data type: REAL, default value: 0, range: >0, unit: m^3/h

Actual flow from the pump 1.

For simulation process, the calculated ACT_FLOW output from the PUMP_FLOW_CALC function block is used.

PUMP2_ACT_FLOW (pump 2 actual flow)

Data type: REAL, default value: 0, range: >0, unit: m^3/h

Actual flow from the pump 2.

For simulation process,

- the calculated ACT_FLOW output from the PUMP_FLOW_CALC function block is used if the pump is simulated by the PUMP_DRIVE_SIMU .
- the ACT_FLOW output from the PUMP_DOL_SIMU function block is used if the pump is simulated by the PUMP_DOL_SIMU.

PUMP3_ACT_FLOW (pump 3 actual flow)

Data type: REAL, default value: 0, range: >0, unit: m^3/h

Actual flow from the pump 3.

For simulation process,

- the calculated ACT_FLOW output from the PUMP_FLOW_CALC function block is used. if the pump is simulated by the PUMP_DRIVE_SIMU.
- the ACT_FLOW output from the PUMP_DOL_SIMU function block is used if the pump is controlled by the PUMP_DOL_SIMU.

START_INOUT_FLOW_SIMULATION (start input flow simulation)

Data type: BOOL, default value: FALSE

TRUE value starts the simulation of filling or emptying of a tank.

FALSE stopps the simulation of filling or emptying of a tank.

TANK_INLET_FLOW

Data type: REAL, default value: 0, range: >0, unit: m^3/h

Simulates the filling flow of the tank in emptying mode.

TANK_OUTLET_FLOW

Data type: REAL, default value: 0, range: >0, unit: m^3/h

Simulates the discharge flow of the tank in filling mode.

Output description

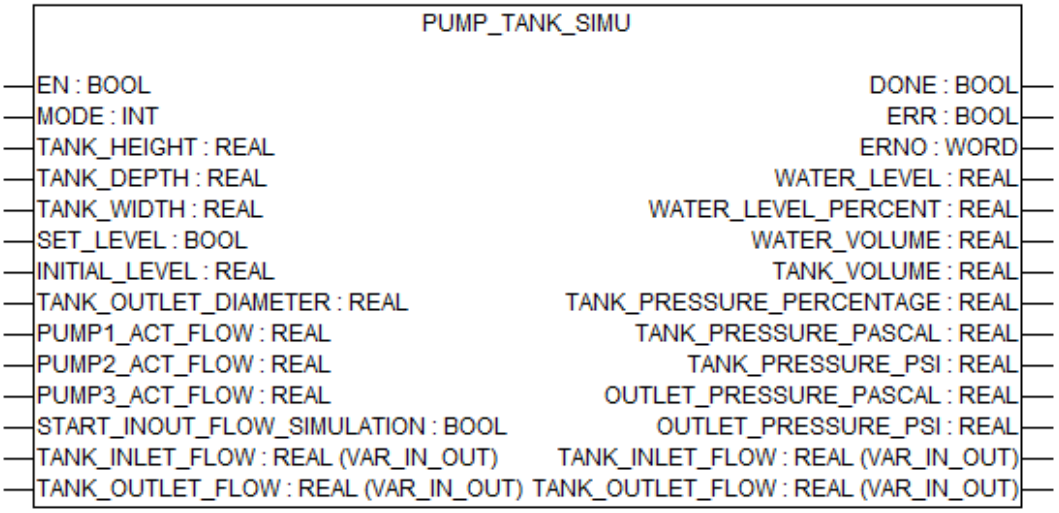

Fig. 688: Function block TANK_SIMU

DONE (done) Data type: BOOL

Output DONE indicates the processing state of the block. After completion or abortion of processing (due to an error), DONE is set to TRUE for one cycle. This output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL Output ERR indicates whether an error occurred during data reception. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD, default value: 0, range: ≥ 0

Output ERNO provides an error identifier if an invalid value was applied to an input. ERNO always has to be considered together with the output ERR. The value output at ERNO is only valid if ERR is TRUE. The error messages encoding at output ERNO are explained at the table below.

WATER_LEVEL (water level) Data type: REAL, unit: m

Level of the water tank.

WATER_LEVEL_PERCENT (water level percent) Data type: REAL, unit: %, range: 0-100

Level of the water tank in percentage.

WATER_VOLUME (water volume) Data type: REAL, unit: m^3

Actual volume of water in the tank .

TANK_VOLUME (tank volume) Data type: REAL, unit: m^3

Total volume of the tank.

TANK_PRESSURE_PERCENTAGE (tank pressure percentage)
Data type: REAL, unit: %, range: 0-100
Total pressure in the tank in percentage.

TANK_PRESSURE_PASCAL (tank pressure Pascal)
Data type: REAL, unit: Pa
Pressure at the bottom of tank.

TANK_PRESSURE_PSI (tank pressure psi)
Data type: REAL, unit: PSI
Pressure at the bottom of the tank.

OUTLET_PRESSURE_PASCAL (outlet pressure pascal)
Data type: REAL, unit: PSI
Pressure at the outlet pipe.

OUTLET_PRESSURE_PSI (outlet pressure psi)
Data type: REAL, unit: PSI
Pressure at the outlet pipe.

4000hex...4FFFhex - Block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

Dec	Hex	Error Description
0	0000	No error
16416	4020	MODE input value is less than 1 or greater than 2
16432	4030	TANK_HEIGHT is less than or equal to zero.
16448	4040	TANK_LEN is less than or equal to zero.
16464	4050	TANK_WIDTH is less than or equal to zero.
16496	4070	INITIAL_LEVEL is less than zero.
16512	4080	TANK_OUTLET_DIAMETER is less than or equal to zero.
16528	4090	PUMP1_ACT_FLOW is less than zero.
16544	40A0	PUMP2_ACT_FLOW is less than zero.
16560	40B0	PUMP3_ACT_FLOW is less than zero.

1.5.13.1.18 Visualizations

Every visualization element can be used to show the actual values of all inputs and outputs of the instance of the corresponding function block. In the application program, the programmer can add the visualization object in his project. In this object the programmer needs to add the faceplate of the required function block.

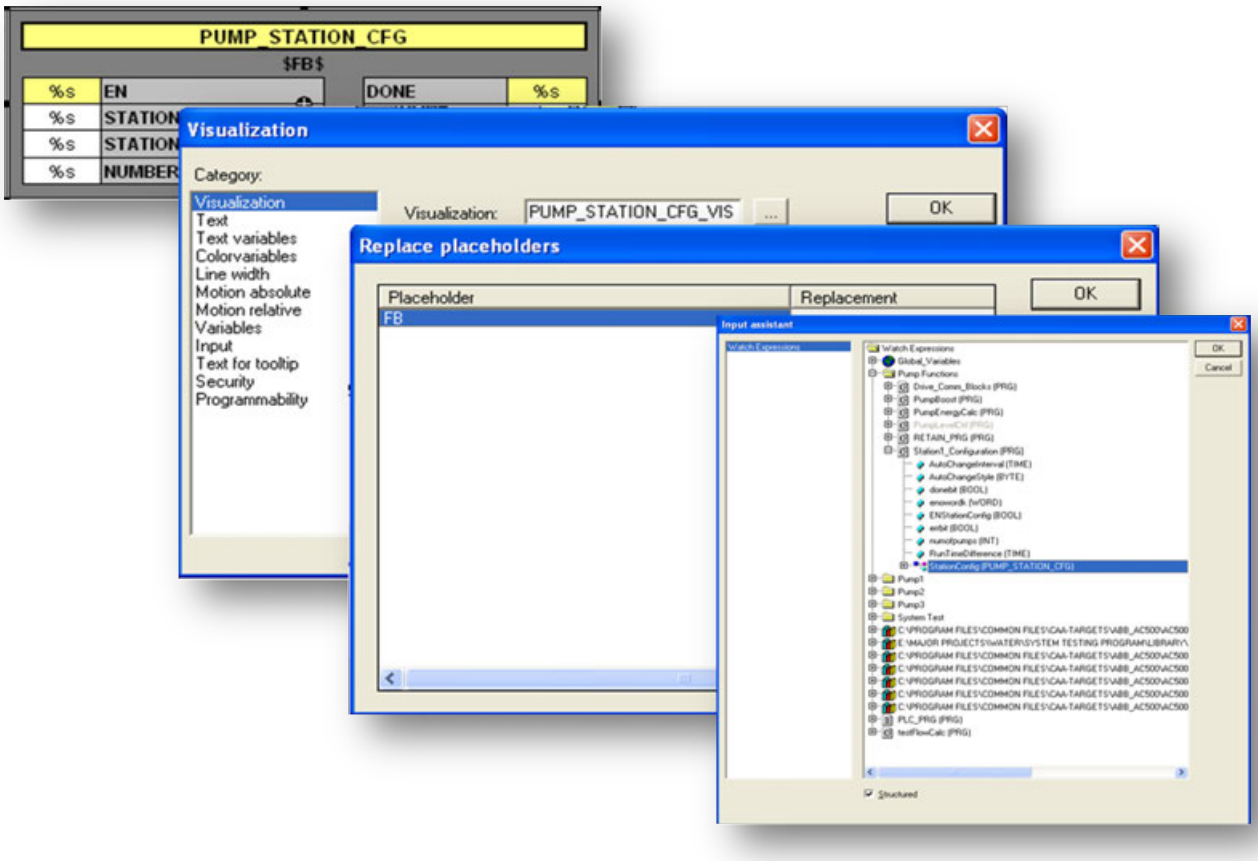

Fig. 689: Adding the faceplate of the required function block in the visualization object.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

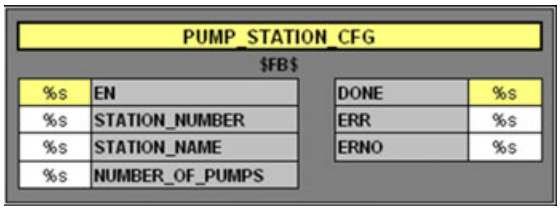
All inputs of the corresponding function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open.

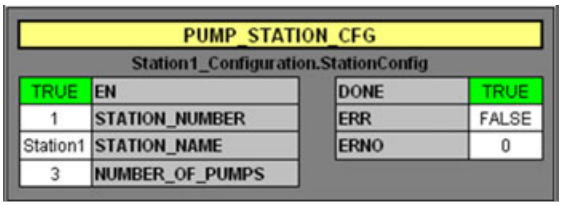
The color of the background can be changed by writing a value to the global variable `dwAcsVisuBackgroundColor`.

The color of the title can be changed by writing a value to the global variable `dwAcsVisuTitleColor`.

PUMP_STATION_CFG_VISU_PH

Faceplate for the function block PUMP_STATION_CFG.





Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 222: Colors of the variables

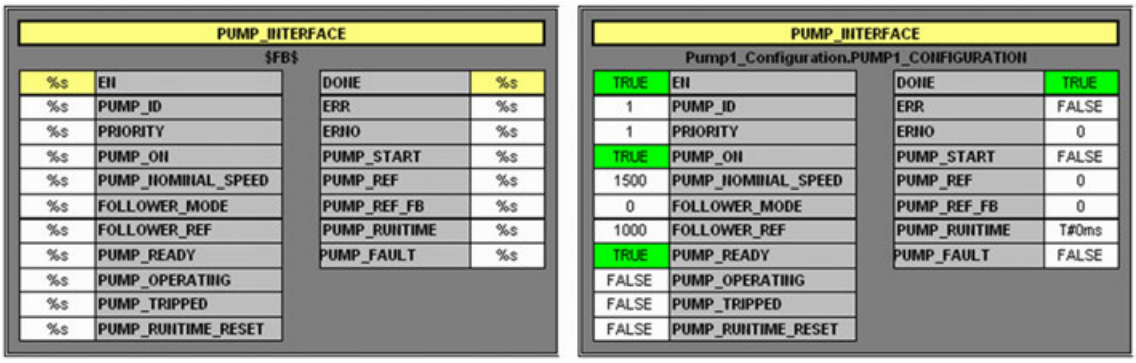
Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

Table 223: Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
STATION_NUMBER	R/W	Numpad – value 1 onwards	Station number as a unique identification for the station.
STATION_NAME	R/W	Text	Name of the pumping station.
NUMBER_OF_PUMPS	R/W	Numpad – value 1 to 3	Number of pumps in the pumping station.
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.
ENO	R		Error code.

PUMP_INTERFACE_VISU_PH

Faceplate for the function block PUMP_INTERFACE.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 224: Colors of the variables

Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

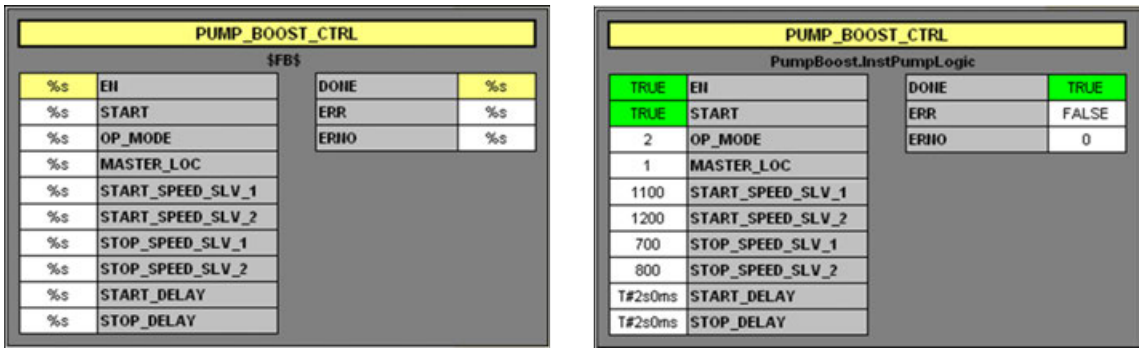
Table 225: Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
PUMP_ID	R/W	Numpad – value 1 to 3	To enter the ID of the pump.
PRIORITY	R/W	Numpad – value 1 to 3	To enter the priority of the pump.
PUMP_ON	R/W	Toggle	To switch off/On the pump individually. For the FALSE value the user can remove this pump from the network in case of any problem/fault.
PUMP_NOMINAL_SPEED	R/W	Numpad – value 0 onwards	To enter the nominal speed of the pump motor.
FOLLOWER_MODE	R/W	Numpad – value 0 to 2	Follower mode to decide at what speed the follower pumps must move. 0= Fixed, 1=copy master, 2=master speed.
FOLLOWER_REF	R/W	Numpad – value 0 onwards	follower speed reference in RPM, when FOLLOWER_MODE =0, i.e. fixed.
PUMP_READY	R/W	Toggle	Input to attach the ready status of the drive of the pump.
PUMP_OPERATING	R/W	Toggle	Input to attach the operating status of the drive of the pump.
PUMP_TRIPPRED	R/W	Toggle	Input to attach the fault status of the drive of the pump.

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
PUMP_RUNTIME_RESET	R/W	Toggle	TRUE value of this variable resets the actual run time to Zero value.
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.
ENO	R		Error code.
PUMP_START	R		On command to the pump.
PUMP_REF	R		Speed reference to the pump in RPM.
PUMP_REF_FB	R		Field bus speed reference to the pump in the range of -20000 to 20000.
PUMP_RUNTIME	R		Actual run time of the pump.

PUMP_BOOST_CTRL_VISU_PH

Faceplate for the function block PUMP_BOOST_CTRL.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 226: Colors of the variables

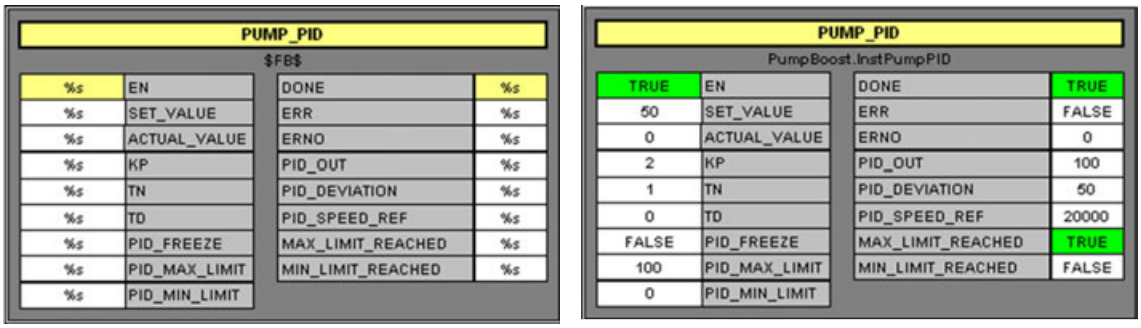
Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

Table 227: Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
START	R/W	Toggle	To start the Boost control functionality.
OP_MODE	R/W	Numpad – value 0 to 2	Operation mode of the station, 0= single pump, 1=traditional pump, 2=multi pump.
MASTER_LOC	R/W	Numpad – value 0 to 1	Defines the master location. INSTART: youngest pump in the network is the master. 1- STABLE: master is always fixed.
START_SPEED_SLV_1	R/W	Numpad- value 0 onwards	Speed of master in RPM at which the follower pump 1 starts.
START_SPEED_SLV_2	R/W	Numpad- value 0 onwards	Speed of master in RPM at which the follower pump 2 starts.
STOP_SPEED_SLV_1	R/W	Numpad- value 0 onwards	Speed of master in RPM at which the follower pump 1 stops.
STOP_SPEED_SLV_2	R/W	Numpad- value 0 onwards	Speed of master in RPM at which the follower pump 2 stops.
START_DELAY	R/W	Numpad- value 0 onwards	Time delay in seconds for starting the pump.
STOP_DELAY	R/W	Numpad- value 0 onwards	Time delay in seconds for stopping the pump.
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.
ENO	R		Error code.

PUMP_PID_VISU_PH

Faceplate for the function block PUMP_PID.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 228: Colors of the variables

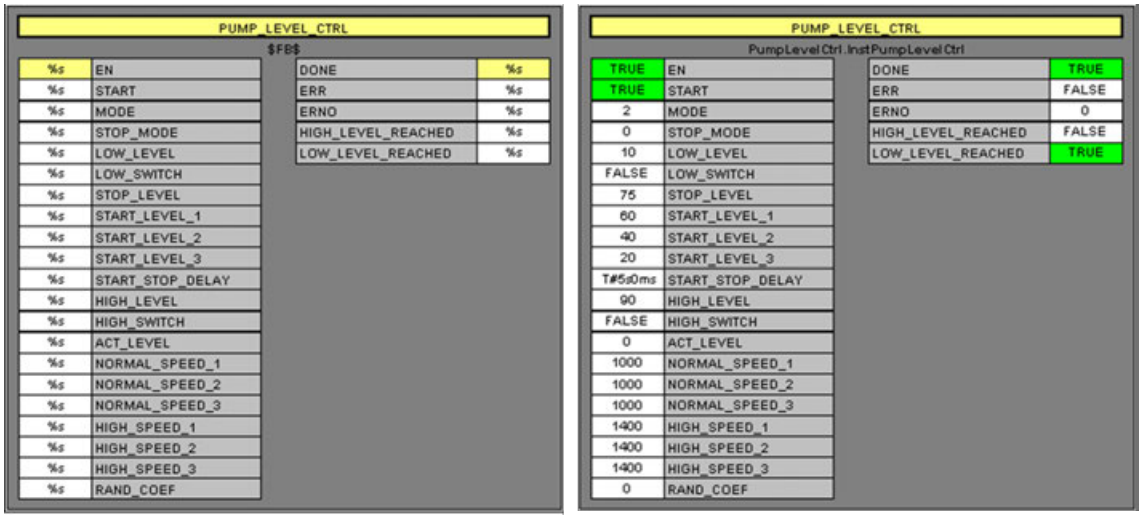
Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

Table 229: Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
SET_VALUE	R/W	Numpad – value 0.0 to 100.0	Set value of the process variable in terms of percentage.
ACTUAL_VALUE	R/W	Numpad – value 0.0 to 100.0	Actual value of the process variable in terms of percentage.
KP	R/W	Numpad – value 0.0 to 100.0	Proportional gain of the PID.
TN	R/W	Numpad – value 0.0 to 100.0	Integral time of the PID in terms of seconds.
TD	R/W	Numpad – value 0.0 to 100.0	Derivative time of the PID in terms of seconds.
PID_FREEZE	R/W	Toggle	For the TRUE value the setpoint to the PID block is frozen. Actual value is then attached to the setpoint.
PID_MAX_LIMIT	R/W	Numpad – value 0.0 to 100.0	Limit for the maximum PID Output.
PID_MIN_LIMIT	R/W	Numpad – value 0.0 to 100.0	Limit for the minimum PID Output.
PUMP_RUN-TIME_RESET	R/W	Toggle	TRUE value of this variable resets the actual run time to Zero value.
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.
ENO	R		Error code.
PID_OUT	R		PID output after the manipulation in terms of percentage.
PID_DEVIATION	R		Deviation of Set value from actual value. It is also known as PID error.
PID_SPEED_REF	R		Speed reference as a correction to the main speed reference, calculated by the PID - in the range of 0 to 20000.
MAX_LIMIT_REACHED	R		Indicates if the PID output touches the MAXIMUM limit.
MIN_LIMIT_REACHED	R		Indicates if the PID output touches the MINIMUM limit.

PUMP_LEVEL_CTRL_VISU_PH

Faceplate for the function block PUMP_LEVEL_CTRL.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 230: Colors of the variables

Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

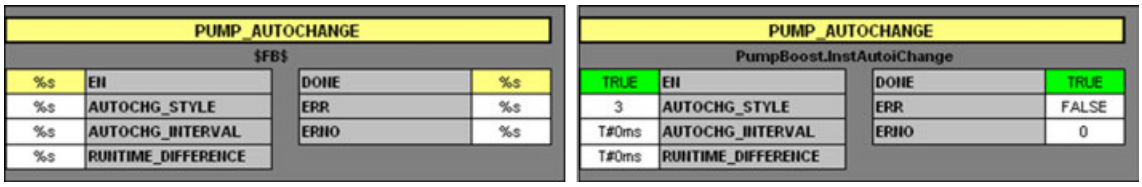
Table 231: Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
START	R/W	Toggle	To start the level control functionality.
MODE	R/W	Numpad – value 1 to 2	To select the mode of operation. 1 = emptying, 2= filling.
STOP_MODE	R/W	Numpad – value 0 to 1	Defines the stop mode stage stop. stops the pump at individual defined start stop levels. 1, common stop. stops all the pump as common stop at defined STOP_LEVEL.
LOW_LEVEL	R/W	Numpad- value 0.0 to 100.0	Defines the low level in terms of % of full tank capacity.
LOW_SWITCH	R/W	Toggle	Digital input with TRUE indicates that the low level has reached.
STOP_LEVEL	R/W	Numpad- value 0.0 to 100.0	Defines the stop level in terms of % of full tank capacity.
START_LEVEL_1	R/W	Numpad- value 0.0 to 100.0	Defines the start level for pump 1 in terms of % of full tank capacity.

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
START_LEVEL_2	R/W	Numpad- value 0.0 to 100.0	Defines the start level for pump 2 in terms of % of full tank capacity.
START_LEVEL_3	R/W	Numpad- value 0.0 to 100.0	Defines the start level for pump 3 in terms of % of full tank capacity.
START_STOP_DELAY	R/W	Numpad- value 0 onwards	Defines the time delay for pump to start and stop when respective level is reached.
HIGH_LEVEL	R/W	Numpad- value 0.0 to 100.0	Defines the high level in terms of % of full tank capacity.
HIGH_SWITCH	R/W	Toggle	Digital input with TRUE indicates that the high level has reached.
ACT_LEVEL	R/W	Numpad- value 0.0 to 100.0	Actual level in % - read from the analog input of level sensor.
NORMAL_SPEED_1	R/W	Numpad- value 0 onwards	Normal operating speed of the pump1 while Filling/Emptying.
NORMAL_SPEED_2	R/W	Numpad- value 0 onwards	Normal operating speed of the pump2 while Filling/Emptying.
NORMAL_SPEED_3	R/W	Numpad- value 0 onwards	Normal operating speed of the pump3 while Filling/Emptying.
HIGH_SPEED_1	R/W	Numpad- value 0 onwards	Defines the speed of the pump1 for : - Filling- pump level falls below LOW_LEVEL/ Emptying - pump level rises above the HIGH_LEVEL.
HIGH_SPEED_2	R/W	Numpad- value 0 onwards	Defines the speed of the pump2 for : - Filling- pump level falls below LOW_LEVEL/ Emptying – pump3 level rises above the HIGH_LEVEL.
HIGH_SPEED_3	R/W	Numpad- value 0 onwards	Defines the speed of the pump for : - Filling- pump level falls below LOW_LEVEL/ Emptying - pump level rises above the HIGH_LEVEL.
RAND_COEF	R/W	Numpad – value -10.0 to + 10.0	Random coefficient randomizes the start levels to avoid cake formation. Value between -10.0 to 10.0. Value 1.0 means 1.0%.
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.
ENO	R		Error code.
HIGH_LEVEL_REACHED	R		TRUE value indicates that the actual level is more than the high level.
LOW_LEVEL_REACHED	R		TRUE value indicates that the actual level is below the low level.

PUMP_ AUTOCHANGE _VISU_PH

Faceplate for the function block PUMP_ AUTOCHANGE.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 232: Colors of the variables

Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

Table 233: Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
AUTOCHG_STYLE	R/W	Numpad- value 0 to 3	Mode of auto change. 0=None, 1=fixed, 2=runtime difference, 3=all stop.
AUTOCHG_INTERVAL	R/W	Numpad- value 0 onwards	Time delay after which the autochange starts when AUTOCHG_STYLE =1.
RUNTIME_DIFFERENCE	R/W	Numpad- value 0 onwards	Maximum permited run-time difference between the two pumps after which the autochange starts when AUTOCHG_STYLE =2.
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.
ENO	R		Error code.

PUMP_ ANTIJAM _VISU_PH

Faceplate for the function block PUMP_ ANTIJAM.

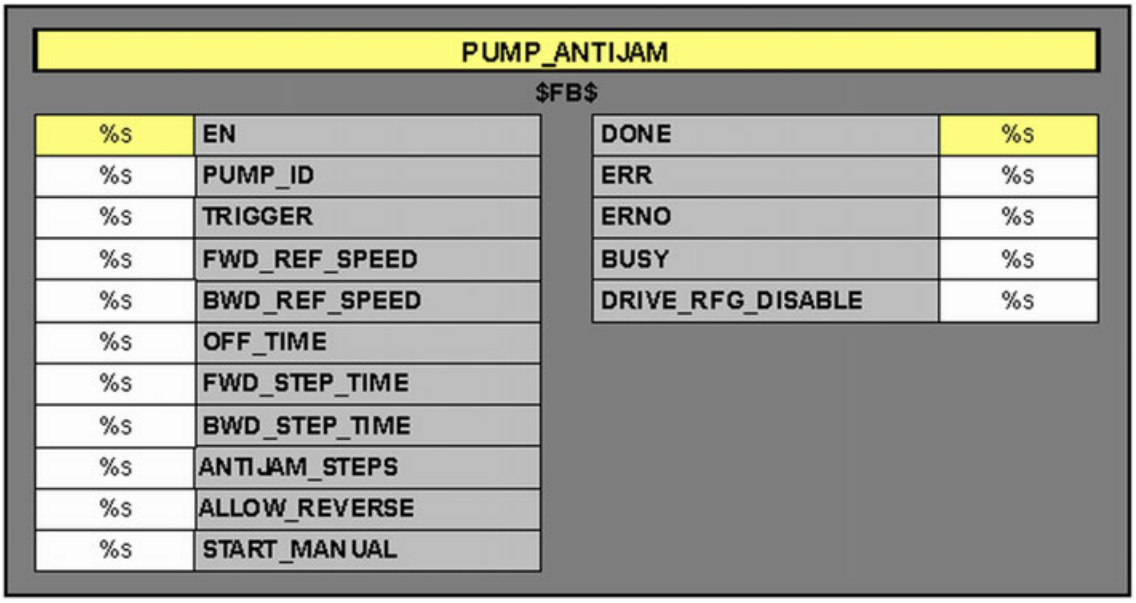


Fig. 690: Visualization in offline mode.

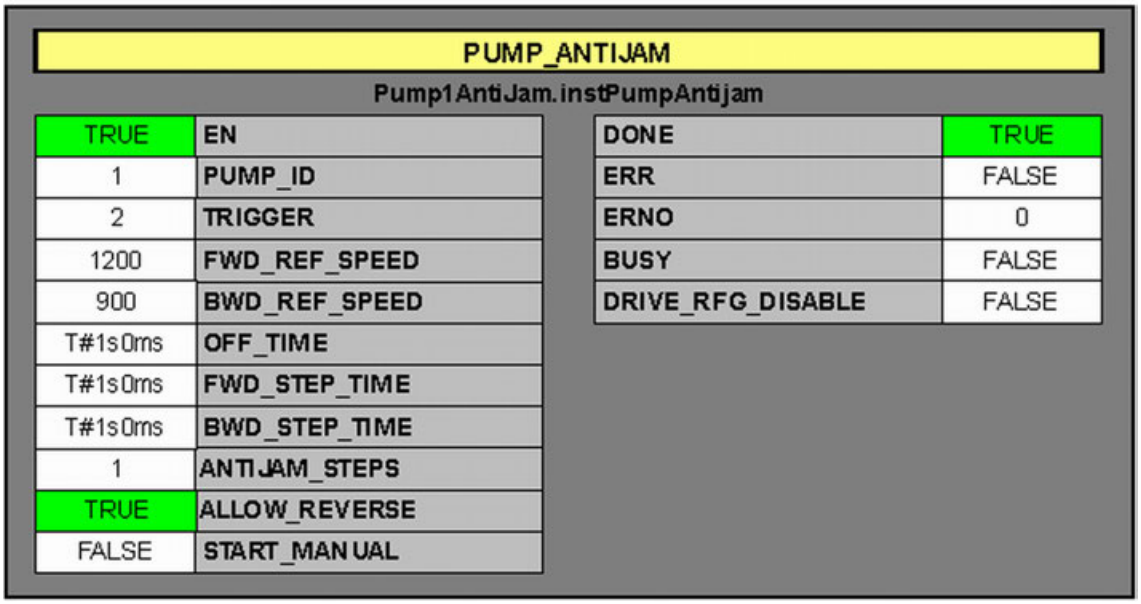

Fig. 691: Visualization in online mode.

Table 234: Colors of the variables

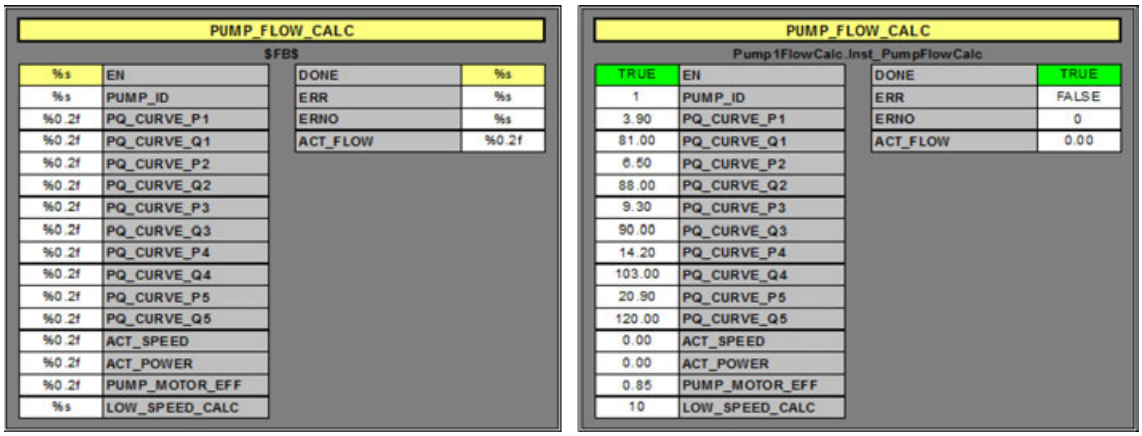
Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

Table 235: Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
PUMP_ID	R/W	Numpad- value 1 to 3	To enter the ID of the pump which is to be cleaned
TRIGGER	R/W	Numpad- value 0 to 4	Trigger to clean the pump. 0=not enabled, 1=master enabled, 2=follower enabled, 3=at start, 4=manual mode
FWD_REF_SPEED	R/W	Numpad- value 0 onwards	Speed reference to clean the pump in the forward direction
BWD_REF_SPEED	R/W	Numpad- value 0 onwards	Speed reference to clean the pump in the backward direction
OFF_TIME	R/W	Numpad- value 0 onwards	Time delay in seconds between the forward and the backward movement in anti-jam
FWD_STEP_TIME	R/W	Numpad- value 0 onwards	Time duration in seconds for which the pump moves in the forward direction in anti-jam
BWD_STEP_TIME	R/W	Numpad- value 0 onwards	Time duration in seconds for which the pump moves in the reverse direction in anti-jam
ANTIJAM_STEPS	R/W	Numpad- value 1 onwards	Number of steps to be performed in an anti-jam process
ALLOW_REVERSE	R/W	Toggle	True value means the pump can also move in the reverse direction to perform the anti jam
START_MANUAL	R/W	Toggle	For the TRUE anti-jam is performed in the manual mode i.e. TRIGGER =4
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.
ENO	R		Error code.

PUMP_ FLOW_CALC_VISU_PH

Faceplate for the function block PUMP_ FLOW_CALC.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 236: Colors of the variables

Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

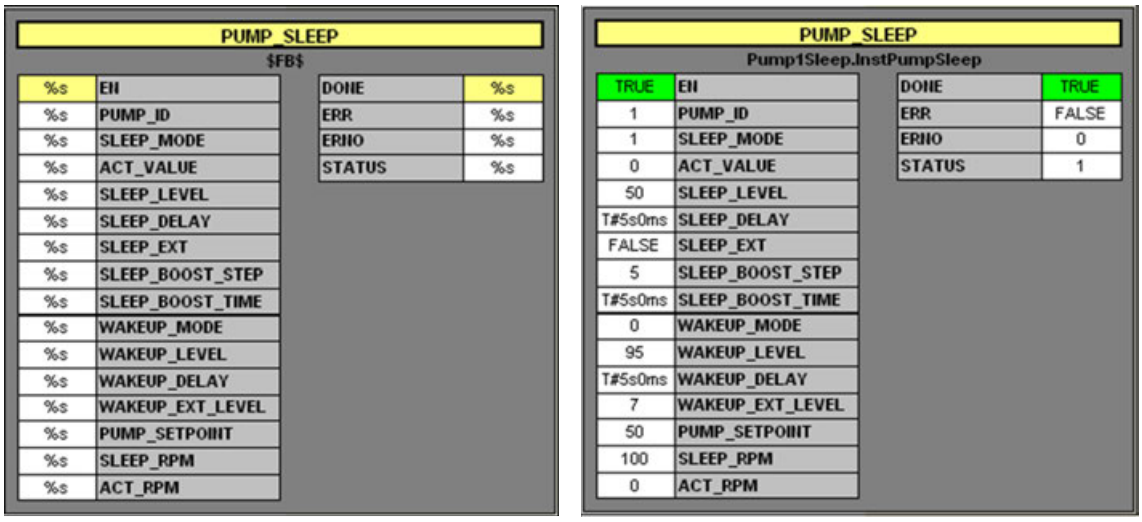
Table 237: Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
PUMP_ID	R/W	Numpad- value 1 to 3	To enter the ID of the pump which is to be cleaned.
PQ_CURVE_P1	R/W	Numpad- value 0 onwards	Pump PQ curve P1.
PQ_CURVE_Q1	R/W	Numpad- value 0 onwards	Pump PQ curve Q1.
PQ_CURVE_P2	R/W	Numpad- value 0 onwards	Pump PQ curve P2.
PQ_CURVE_Q2	R/W	Numpad- value 0 onwards	Pump PQ curve Q2.
PQ_CURVE_P3	R/W	Numpad- value 0 onwards	Pump PQ curve P3.
PQ_CURVE_Q3	R/W	Numpad- value 0 onwards	Pump PQ curve Q3.
PQ_CURVE_P4	R/W	Numpad- value 0 onwards	Pump PQ curve P4.
PQ_CURVE_Q4	R/W	Numpad- value 0 onwards	Pump PQ curve Q4.
PQ_CURVE_P5	R/W	Numpad- value 0 onwards	Pump PQ curve P5.

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
PQ_CURVE_Q5	R/W	Numpad- value 0 onwards	Pump PQ curve Q5.
NOMINAL_POWER		Numpad- value 0 onwards	Nominal power of the motor in kW.
ACT_SPEED	R		Actual speed of the motor in RPM is connected to the input.
ACT_POWER	R		Actual power of the motor in kW.
PUMP_MOTOR_EFF			Combined efficiency of the motor and the pump set.
LOW_SPEED_CALC			Speed below which the calculation will not take place.
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.
ENO	R		Error code.
ACT_FLOW	R		Calculated flow of the pump.

PUMP_ SLEEP _VISU_PH

Faceplate for the function block PUMP_ SLEEP.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 238: Colors of the variables

Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

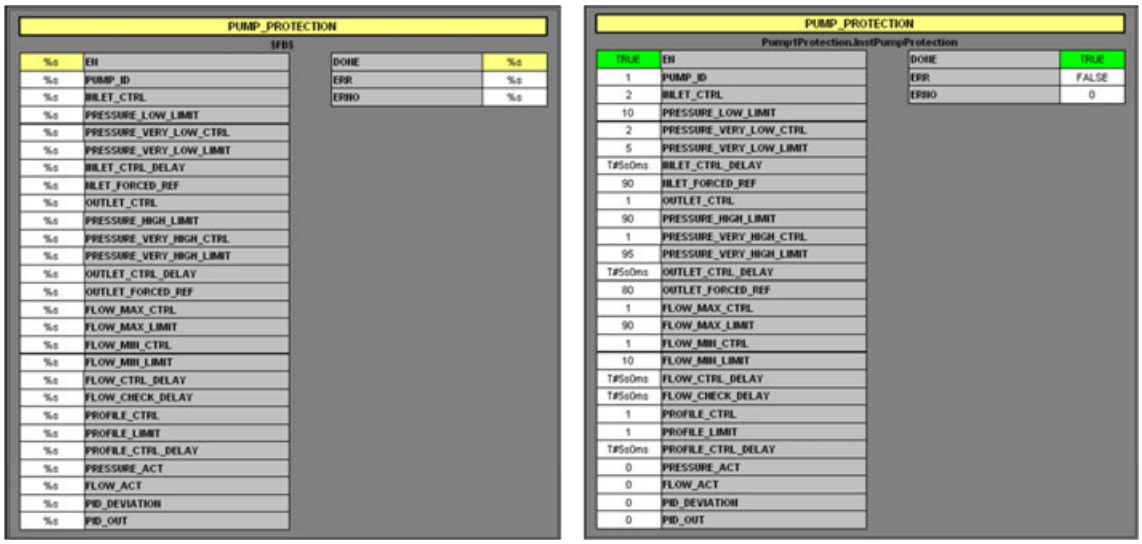
Table 239: Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
PUMP_ID	R/W	Numpad- value 1 to 3	To enter the ID of the pump which is to be cleaned.
SLEEP_MODE	R/W	Numpad- value 0 to 4	SLEEP MODE: 0= Not Used, 1= Internal, 2 = External, 3 = Int+Ext, 4 = Soft Ext.
ACT_VALUE	R/W	Numpad- value 0 to 100.0	Actual process value which is compared with the sleep level.
SLEEP_LEVEL	R/W	Numpad- value 0 to 100.0	Defines the level to active the sleep function.
SLEEP_DELAY	R/W	Numpad- value 0 onwards	Time delay for the sleep function to get activated.
SLEEP_EXT	R/W	Toggle	To enable the sleep function externally.
SLEEP_BOOST_STEP	R/W	Numpad- value 0 to 100.0	The setpoint is increased by boost step percentage for the time defined by sleep boost time.
SLEEP_BOOST_TIME	R/W	Numpad- value 0 onwards	Time in seconds for which sleep boost is to be operational.
WAKEUP_MODE	R/W	Numpad- value 0 to 3	Wake up mode: 0= wake > ref, 1= wake < ref , 2 = wake > Ext, 3 = wake < Ext.
WAKEUP_LEVEL	R/W	Numpad- value 0 to 100.0	Defines the level to active the wake up function. It is a percentage of setpoint.
WAKEUP_DELAY	R/W	Numpad- value 0 onwards	Time delay for the wake up function to activate.
WAKEUP_EXT_LEVEL	R/W	Numpad- value 0 to 100.0	Wake up external level. For wake up mode 2 and 3, this value is compaired with actual value.
PUMP_SETPOINT	R/W	Numpad- value 0 to 100.0	Process setpoint - the same setpoint connected in the PUMP_PID function block.
SLEEP_RPM	R/W	Numpad- value 0 onwards	Pump RPM below which pump should go in to the sleep mode.
ACT_RPM	R/W	Numpad- value 0 onwards	Actual RPM of the pump.
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
ENO	R		Error code.
STATUS	R		Status of sleep function. 0 = Function is inactive 1 = Sleep Function is active 2 = Boost Function is active 3 = Wake up Function is active

PUMP_PROTECTION_VISU_PH

Faceplate for the function block PUMP_PROTECTION.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 240: Colors of the variables

Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

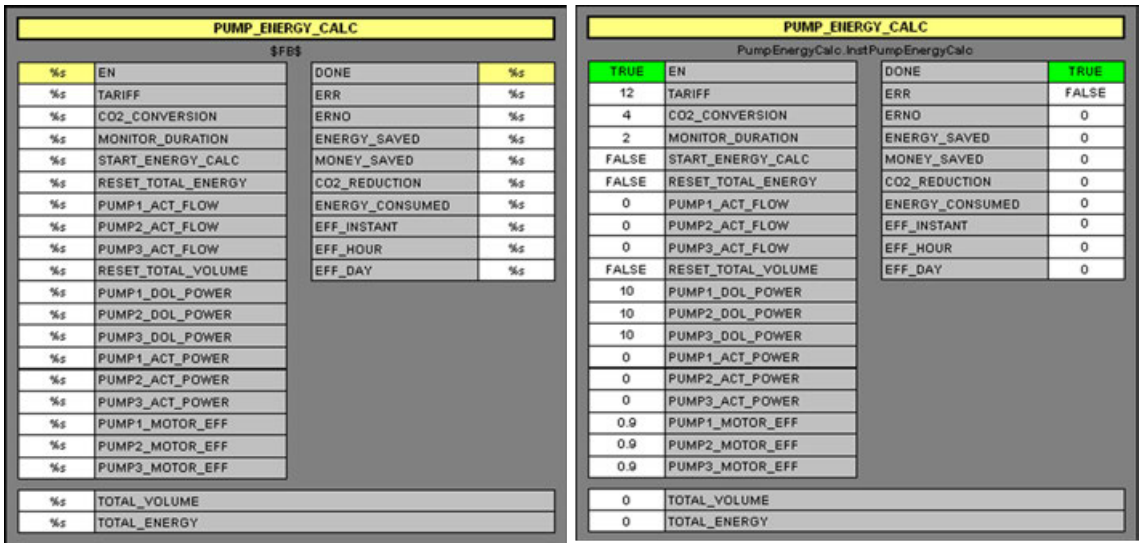
Table 241: Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
PUMP_ID	R/W	Numpad- value 1 to 3	ID of the pump for which the function block is to be called.
INLET_CTRL	R/W	Numpad – value 0 to 3	To enable control for primary protection against low inlet pressure: 0 = disabled, 1 = alarm, 2 = Fault, 3 = reduced speed.
PRESSURE_LOW_LIMIT	R/W	Numpad – value 0.0 to 100.0	Low pressure level limit for primary protection.
PRESSURE_VERY_LOW_CTRL	R/W	Numpad – value 0 to 2	To enable control for secondary protection against very low inlet pressure: 0 = disabled, 1 = fault, 2 = stop.
PRESSURE_VERY_LOW_LIMIT	R/W	Numpad – value 0.0 to 100.0	Very low pressure level limit for secondary protection.
INLET_CTRL_DELAY	R/W	Numpad – value 0 onwards	Delay in seconds for primary and secondary supervision to start. 0-600 s.
INLET_FORCED_REF	R/W	Numpad – value 0 onwards	Safe speed reference for the drive when the INLET_CTRL = 3 i.e. reduced speed mode.
OUTLET_CTRL	R/W	Numpad – value 0 to 3	To enable control for primary protection against high outlet pressure: 0 = disabled, 1 = alarm, 2 = fault, 3 = reduced speed.
PRESSURE_HIGH_LIMIT	R/W	Numpad – value 0.0 to 100.0	High pressure level limit for primary protection.
PRESSURE_VERY_HIGH_CTRL	R/W	Numpad – value 0 to 2	To enable control for secondary protection against very high outlet pressure: 0 = disabled, 1 = fault, 2 = stop.
PRESSURE_VERY_HIGH_LIMIT	R/W	Numpad – value 0.0 to 100.0	Very high pressure level limit at for secondary protection.
OUTLET_CTRL_DELAY	R/W	Numpad – value 0 onwards	Delay in seconds for primary and secondary supervision to start.
OUTLET_FORCED_REF	R/W	Numpad – value 0 onwards	Safe speed reference for the drive when the OUTLET_CTRL = 3 i.e. reduced speed mode.
FLOW_MAX_CTRL	R/W	Numpad – value 0 to 2	To enable control for protection against maximum flow condition: 0 – Disabled, 1 – Alarms, 2 – fault.
FLOW_MAX_LIMIT	R/W	Numpad – value 0 to 32767	Value of max flow rate limit in m^3/h.

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
FLOW_MIN_CTRL	R/W	Numpad – value 0 to 2	To enable control for protection against minimum flow condition: 0 – Disabled, 1 – Alarms, 2 – fault.
FLOW_MIN_LIMIT	R/W	Numpad – value 0 to 32767	Value of min flow rate limit in m^3/h.
FLOW_CTRL_DELAY	R/W	Numpad – value 0 onwards	Delay in seconds before executing the control due to low or high flow rates.
FLOW_CHECK_DELAY	R/W	Numpad – value 0 onwards	Delay in seconds after the start of the pump before monitoring the flow rates.
PROFILE_CTRL	R/W	Numpad – value 0 to 2	0 – profile protection disabled. 1 – PID deviation, generates alarm , PROFILE HIGH, if PID deviation exceeds PROFILE_LIMIT. 2 – PID output, generates alarm , PROFILE HIGH, if PID output exceeds PROFILE_LIMIT.
PROFILE_LIMIT	R/W	Numpad – value 0 to 32767	Value of profile protection limit.
PROFILE_CTRL_DELAY	R/W	Numpad – value 0 onwards	Time delay in seconds before the Profile Ctrl activates.
PRESSURE_ACT	R/W	Numpad – value 0.0 to 100.0	Actual pressure of the system.
FLOW_ACT	R/W	Numpad – value 0.0 to 100.0	Actual flow of the pump.
PID_DEVIATION	R/W	Numpad – value 0.0 to 100.0	PID deviation generated by PUMP_PID function block.
PID_OUT	R/W	Numpad – value 0.0 to 100.0	PID ouput generated by PUMP_PID function block.
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.
ENO	R		Error code.

PUMP_ ENERGY_CALC_VISU_PH

Faceplate for the function block PUMP_ ENERGY_CALC.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 242: Colors of the variables

Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

Table 243: Visualization parameters

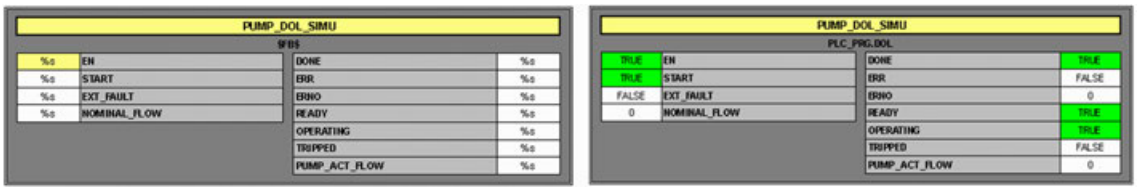
Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
TARIFF	R/W	Numpad- value 0 onwards	Per kwhr tariff rate.
CO2_CONVERSION	R/W	Numpad- value 0 onwards	Factor which helps in converting the energy consumed in terms of CO2 emission tn/Mwh.
MONITOR_DURATION	R/W	Numpad- value 0 onwards	Time duration in minutes to monitor the energy consumption.
START_ENERGY_CALC	R/W	Toggle	To enable energy calculation.
RESET_TOTAL_ENERGY	R/W	Toggle	Resets total energy value.
PUMP1_ACT_FLOW	R	Numpad- value 0 onwards	Calculated Actual flow of PUMP1 in m^3/hr.
PUMP2_ACT_FLOW	R	Numpad- value 0 onwards	Calculated Actual flow of PUMP2 in m^3/hr.

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
PUMP3_ACT_FLOW	R	Numpad- value 0 onwards	Calculated Actual flow of PUMP3 in m^3/hr.
RESET_TOTAL_VOLUME	R/W	Toggle	Reset Total volume.
PUMP1_DOL_POWER	R/W	Numpad- value 0 onwards	Pump1 Direct On Line power, if directly connected to the motor in kW.
PUMP2_DOL_POWER	R/W	Numpad- value 0 onwards	Pump2 Direct On Line power, if directly connected to the motor in kW.
PUMP3_DOL_POWER	R/W	Numpad- value 0 onwards	Pump3 Direct On Line power, if directly connected to the motor in kW.
PUMP1_ACT_POWER	R/W	Numpad- value 0 onwards	Pump1 Actual power in kW.
PUMP2_ACT_POWER	R/W	Numpad- value 0 onwards	Pump2 Actual power in kW.
PUMP3_ACT_POWER	R	Numpad- value 0 onwards	Pump3 Actual power in kW.
PUMP1_MOTOR_EFF	R/W	Numpad- value 0 to 1.0	Pump1 motor combined efficiency.
PUMP1_MOTOR_EFF	R/W	Numpad- value 0 to 1.0	Pump2 motor combined efficiency.
PUMP1_MOTOR_EFF	R/W	Numpad- value 0 to 1.0	Pump3 motor combined efficiency.
DONE	R		Execution finished when output DONE = TRUE.
ERR	R		Error occurred during execution when output ERR = TRUE.
ENO	R		Error code.
ENERGY_SAVED	R		Stores the energy saved. Difference of the energy consumed by pump with drive and the energy consumed if the pump was connected to the DOL motor.
MONEY_SAVED	R		Saving in terms of money.
CO2_REDUCTION	R		Reduction in terms of carbon dioxide emissions.
ENERGY_CONSUMED	R		Stores the energy consumed in the monitoring duration.
EFF_INSTANT	R		Instant flow vs power efficiency of the station.
EFF_HOUR	R		Hourly flow vs power efficiency of the station.
EFF_DAY	R		Daily flow vs power efficiency of the station.

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
TOTAL_VOLUME	R		Total volume which is calculated using flow of all the pumps.
TOTAL_ENERGY			Total actual energy which is calculated using actual power of all the pumps.

PUMP_DOL_SIMU _VISU_PH

Faceplate for the function block PUMP_DOL_SIMU.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 244: Colors of the variables

Color	Description

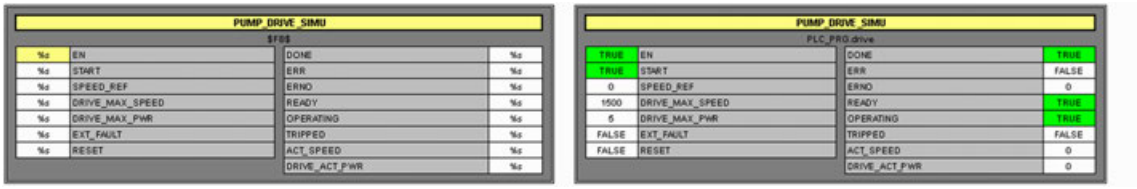
PUMP_DRIVE_SIMU _VISU_PH

Faceplate for the function block PUMP_DRIVE_SIMU.



Left figure Visualization in offline mode.
Right figure Visualization in online mode.

Table 245: Colors of the variables

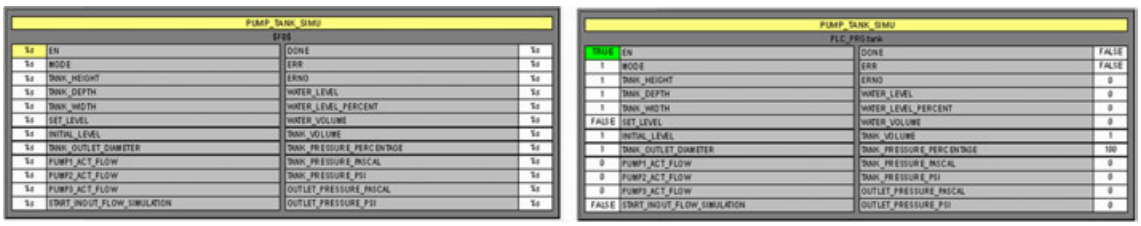
Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value.
START	R/W	Toggle	Start the simulation drive is operating.
SPEED_REF	R/W	Numpad – value 0 onwards	Speed reference from the PUMP_INTERFACE FB in RPM
DRIVE_MAX_SPEED	R/W	Numpad – value 0 onwards	Maximum speed of the drive in RPM
DRIVE_MAX_PWR	R/W	Numpad – value 0 onwards	Maximum power of the drive in kW
EXT_FAULT	R/W	Toggle	To force the fault externally to check the fault condition.
RESET	R/W	Toggle	Reset drive fault and reset ERNO output
DONE	R	-	Execution finished when output DONE = TRUE.
ERR	R	-	Error occurred during execution when output ERR = TRUE.
ENO	R	-	Error code.
READY OPERATING TRIPPED ACT_SPEED DRIVE_ACT_PWR	R R R R R	- - - - -	Pump is in ready state for operation Pump is Operating Pump is tripped Actual speed in RPM Actual power of drive in kW

PUMP_TANK_SIMU _VISU_PH

Faceplate for the function block PUMP_TANK_SIMU.



Right figure Visualization in online mode.

Table 246: Colors of the variables

Color	Description
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

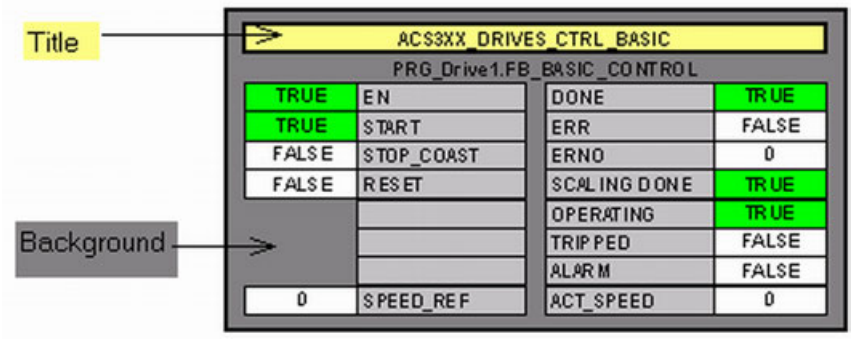
Visualization parameters

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
EN	R/W	Toggle	To enable the function block with the true value
MODE	R/W	Numpad – 1 or 2	To select the mode of operation. 1 = emptying, 2= filling
TANK_HEIGHT	R/W	Numpad – value 0 onwards	Height of Tank in m
TANK_DEPTH	R/W	Numpad – value 0 onwards	Depth of tank in m
TANK_WIDTH	R/W	Numpad – value 0 onwards	Width of tank in m
SET_LEVEL	R/W	Toggle	TRUE: Sets INITIAL_LEVEL as initial value of tank volume in m^3
INITIAL_LEVEL	R/W	Numpad – value 0 onwards	Initial value of tank level in m^3
TANK_OUTLET_DIAMETER	R/W	Numpad – 0 value onwards	Outlet diameter of pipe in m
PUMP1_ACT_FLOW	R/W	Numpad – 0 value onwards	Calculated Actual flow of PUMP1 in m^3/h
PUMP2_ACT_FLOW	R/W	Numpad – 0 value onwards	Calculated Actual flow of PUMP2 in m^3/h
PUMP3_ACT_FLOW	R/W	Numpad – 0 value onwards	Calculated Actual flow of PUMP3 in m^3/h
START_INOUT_FLOW_SIMUALTION	R/W	Toggle	Start filling or emptying flow flow simulation
DONE	R	-	Execution finished when output DONE = TRUE.
ERR	R	-	Error occurred during execution when output ERR = TRUE.
ENO	R	-	Error code.
WATER_LEVEL	R	-	Level of the tank in m

Variable element	Access	Access via	Description (all elements refer to the function block instance, replaced for the placeholder FB)
WATER_LEVEL_PERCENT	R	-	Level of the tank in percentage
WATER_VOLUME	R	-	Actual water volume in m^3
TANK_VOLUME	R	-	Total tank volume in m^3
TANK_PRESSURE_PERCENTAGE	R	-	Pressure in percentage at the bottom of tank
TANK_PRESSURE_PASCAL	R	-	Pressure at the tank bottom in PASCAL
TANK_PRESSURE_PSI	R	-	Pressure at the tank bottom in PSI
OUTLET_PRESSURE_PASCAL	R	-	Pressure at the outlet pipe in PASCAL
OUTLET_PRESSURE_PS	R	-	Pressure at the outlet pipe in PSI

1.5.13.1.19 Global variables

The background color and the color of the title in the visualization elements of the library can be changed with the two global variables dwAcsVisuBackgroundColor and dwAcsVisuTitleColor.



1.5.13.1.20 Glossary

BOOL Variables of the type BOOL can have the values TRUE and FALSE. For this, 8 bit of memory space are reserved.

Integer data types

BYTE, DINT, DWORD, INT, WORD

The different numerical types are responsible for a different numerical range. Due to this, it is possible that information are lost when converting greater data types to smaller data types.

Table 247: For integer data types the following range limits are valid:

Type	BYTE	INT	DINT	WORD	DWORD
Lower limit	0	-32768	-2147483648	0	0
Upper limit	255	32767	2147483647	65535	4294967295
Memory space	8 bits	16 bits	32 bits	16 bits	32 bits

Functions

Functions are subroutines which have multiple input parameters and return exactly one result element. The returned result can be of an elementary or a derived data type. Due to this, a function may also return an array, a structure, an array of structures and so on. For the same input parameters, functions always return the same result (they do not have an internal memory).

Therefore, the following rules can be derived:

- Within functions, global variables can neither be read nor written.
- Within functions, absolute operands can neither be read nor written.
- Within functions, function 'Function Blocks' must not be called.

Function blocks

Function blocks are subroutines which can have as many inputs, outputs and internal variables as required. They are called from a program or from another function block. As they can be used several times (with different data records), function blocks (code and interface) can be considered as type. When assigning an individual data record (declaration) to the function block, a function block instance is generated. In contrast to functions, function blocks can contain statically local data which are saved from one call to the next. Therefore e.g. counters can be realized which may not forget their counter value. I.e. function blockscan have an internal memory.

Functions and function blocks differ in two essential points:

- A function block has multiple output parameters, a function only one. The output parameters of functions and function blocks differ syntactically.
- In contrast to a function, a function block can have an internal memory.

Function blocks with historical values (memory)

For function blocks with historical values it has to be observed that instance names may not be defined several times if different data sets should be called.

Function blocks without historical values (memory)

For function blocks without historical values only one instance has to be defined for the function block type. This instance can be used for several calls of the function block (also with different I/O values).

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

1.5.13.1.21 Examples

Example projects for the libraries can be found in the folder: \Users\Public\Documents\AutomationBuilder\Examples

1.5.13.2 Datalogging library

1.5.13.2.1 Overview

The Datalogging function block Library contains five function blocks for the purpose of advanced time-stamped data logging for different use cases. In typical use cases the AC500 application program generates data which are normally transmitted to a telecontrol system for storage and further processing or displaying to the end user. Typically, these may be remote applications like water pumping stations or solar power plants where the connection between the remote station (AC500) and a central SCADA/telecontrol station is not always stable or only sporadically connected. Sporadically connected can be by intention e.g. to save communication costs or open ports/connections to be handled by a control station. Then the Datalogging function blocks can store data in case of a broken or intentionally interrupted connection between AC500 and the telecontrol system.

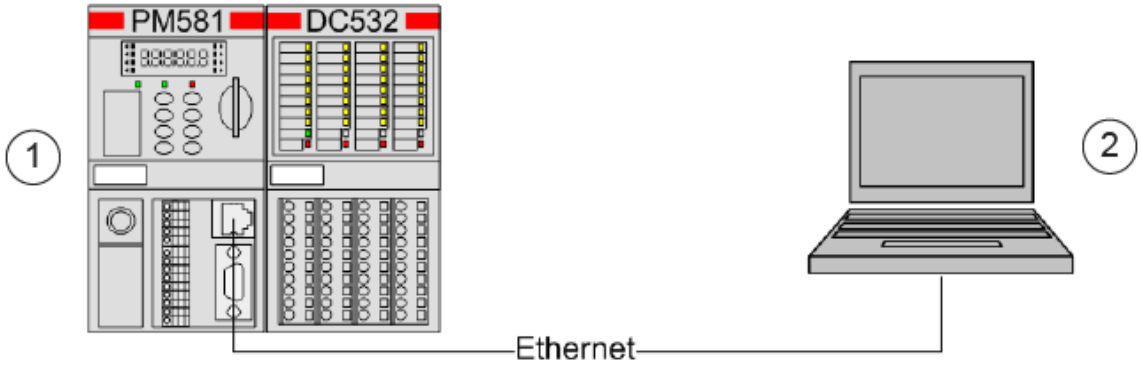


Fig. 692: Overview

1 AC500 application
2 telecontrol

- The Datalogging Library can be used as an event recorder. In this special mode data is continuously recorded in a ring buffer which can be read out after a certain event x (e.g. outage) in order to analyze the values especially before but also after the event x.
  OR
- Data can be logged only and on command transferred to the ftp area to be analyzed offline or taken out via the memory card.

The following figure gives an overview of the described interaction of the Datalogging function blocks. There is always an input function block needed which transfers the input data into data sets with timestamp for use by the Datalogger. An output function block receives the current or retrieved data from the Datalogger in case of communication or further processing. The input function blocks "LOG_xxx_INPUT", the function block "LOG_HANDLING" and the output function blocks "LOG_xxx_OUTPUT" communicate via SRAM FIFOin and FIFOout areas (defined in %M/%R area) in the memory. This SRAM FIFOs are intermediate buffers and help in decoupling time wise and speeding up the necessary write/read operations on the logging file structures significantly. These read/write operations on the files are done in blocks of data sets, enabling a comparably fast interaction with the otherwise slow file system.

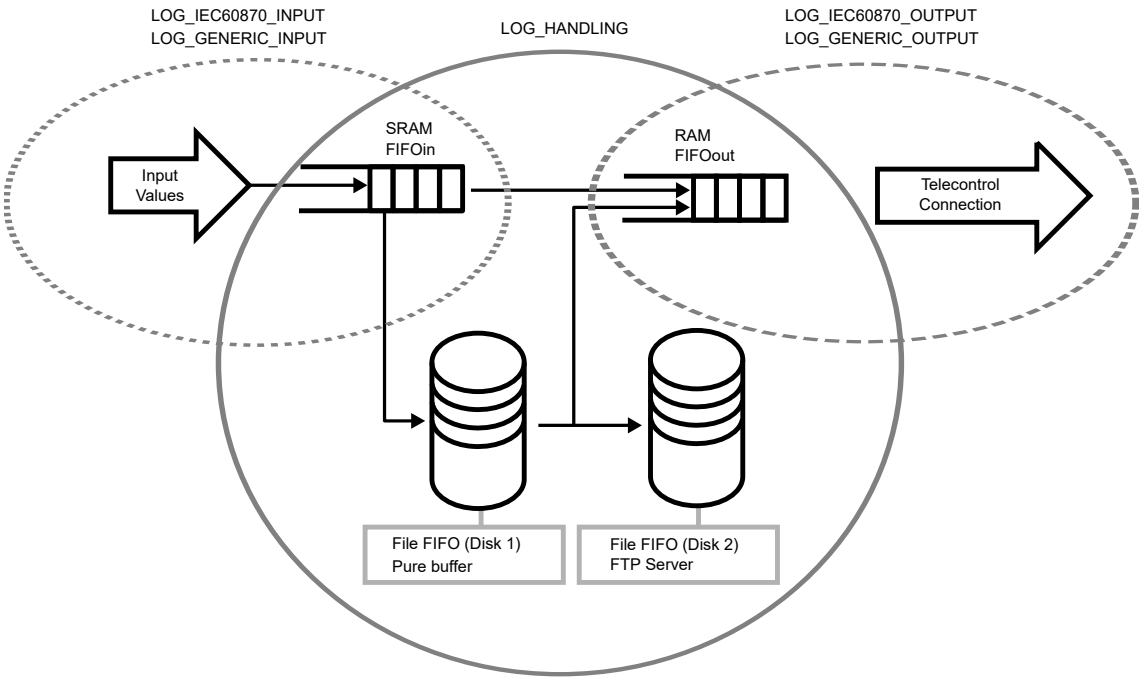

Fig. 693: Overview function blocks

Each Datalogging application requires the main function block LOG_HANDLING, one of the input function blocks to provide data to be logged and one output function block to retrieve the data.

As input and output function blocks two different types exist:

- For logging data of an interrupted IEC60870 communication, the function blocks LOG_IEC60870_INPUT and LOG_IEC60870_OUTPUT are provided. The IEC60870 Datalogging function blocks support the IEC data types and work internally with the standard AC500 IEC60870 Library. The IEC Datalogger output function block does not need special handling or control/inputs.
- For other types of general data LOG_GENERIC_INPUT and LOG_GENERIC_OUTPUT are provided. The generic Datalogging function blocks support an even larger variety of data types. The generic output function block needs to be hand-shaked with for each data set, in order to retrieve the data from the Datalogging files. Therefore the generic function blocks can also be used to integrate the data logging into any other protocol, e.g. Modbus.

The function block LOG_HANDLING ensures that also several consecutive and fast interruptions can be handled without losing data. While the log file is replayed, arriving new data is stored in the SRAM FIFOin and added to the Datalogging files (File FIFO) if the SRAM FIFOin becomes full (during that short time the log file replay is paused). Nevertheless any data send to a control station via a communication is always with the oldest data first (FIFIO = "First In First Out").

As it takes up to 30 seconds before a communication break is detected (e.g. with TCP/IP protocols by the AC500 hardware/firmware), the data rate at which data should be logged in case of a communication break has to be calculated and limited.

As an improvement a ping mechanism can be implemented in the substation. This was done in the example program for the IEC logger. With this ping the interruption is already detected after 1-2 seconds (can be configured in the example program).

As the SRAM FIFO has to store data during this time its size limits the data rate. The SRAM FIFO size is 160 data sets. This means the data rate should be lower than approximately max. datarate = 160 datasets/2 seconds => <5 data sets/second

The data rates for storing only without this detection can be much higher and depends on the CPU and memory type chosen. The data is always logged in directly readable csv format ↬ *Chapter 1.5.13.2.1.5 “CSV file formats” on page 3500*. Depending on the input function block and data type, the log file contains only one or up to 32 data variables per timestamped data set. The Datalogging files can be configured (up to 65k data sets, up to 999 concsecutive log files, name format).

Operating modes

This chapter describes the different operating modes of the Datalogging and their behavior.

- Mode 0/1: Buffer and disposal in chronologic order
  - Mode 0: Limited storage (keeps oldest, but stops if full)
  - Mode 1: Endless (ring buffer) operation modes (deletes oldest)
- Mode 2: Buffer and disposal via FTP, Log file(s) copied to ftp server area for further use
- Mode 3: Events Recorder, logs data before and after an event.

Mode 0/1: Buffer and disposal in chronologic order

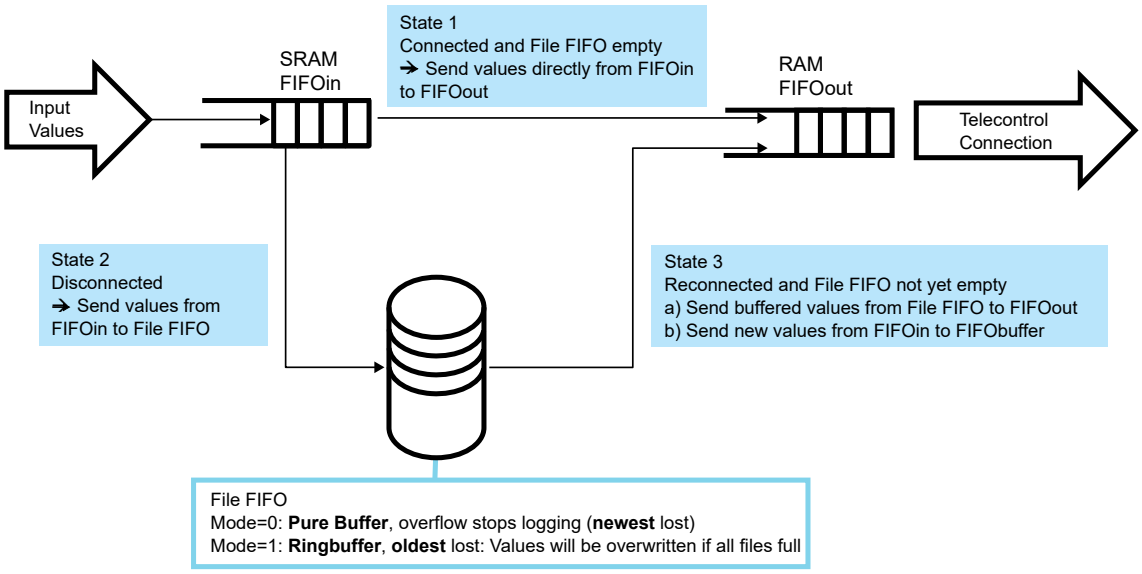

Fig. 694: Overview Mode 0/1

Mode 0/1 is for buffering the values from the AC500 application in case of a broken or intentionally interrupted connection between AC500 and telecontrol. In the normal state 1 the values are directly sent from the FIFOin (input values from application) to FIFOout (telecontrol connection). As soon as the connection is interrupted, the Datalogger changes to working state 2. The values are sent to the File FIFO instead. When the File FIFO is full, the Datalogging is stopped (Mode 0) or the oldest data will be overwritten (Mode 1 = ringbuffer). When the connection is established again and the RELEASE_HISTORY pin is triggered, the Datalogger changes to working state 3. It cares for disposal of the values in chronological order. The buffered values are written to FIFOout (working state 3a). This may take some time during which new values are coming from the application and stored into FIFOin. Before the FIFOin overflows the Datalogger switches to working state 3b and buffers the new values. After that it can continue with working state 3a. Only if the File FIFO is empty (all files deleted) the Datalogger changes back to normal state 1.

The advantage of Mode 0/1 is that all values (directly and buffered) are sent to telecontrol in strictly chronological order which is expected by most control stations (SCADA systems/historians).

As it takes up to 30 seconds before a communication break is detected (e.g. with TCP/IP protocols by the AC500 hardware/firmware), the data rate at which data should be logged in case of a communication break has to be calculated and limited.

Mode 2: Buffer and disposal via FTP

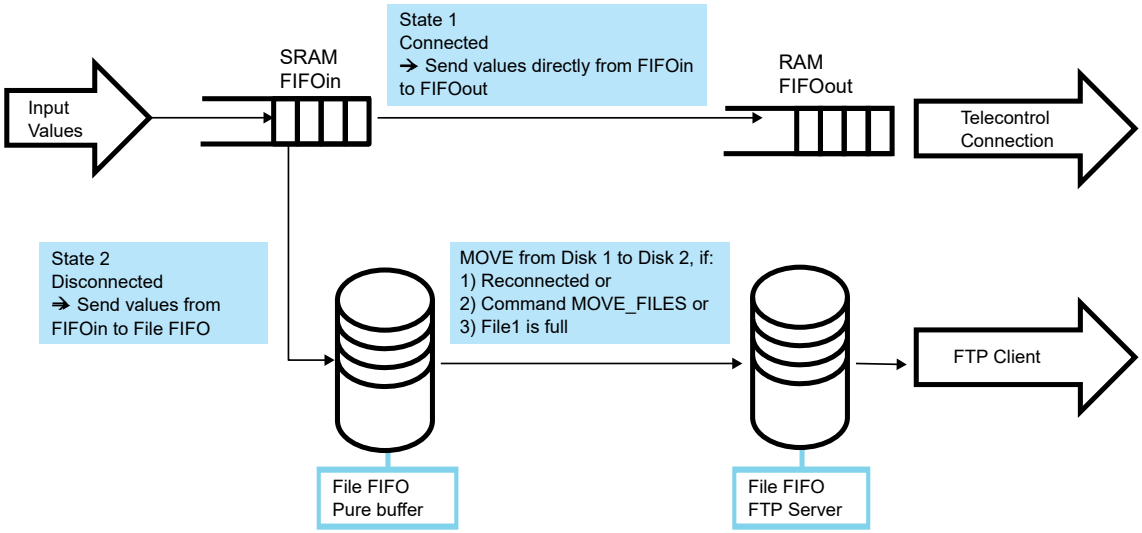

Fig. 695: Overview Mode 2

Mode 2 is also used for buffering the values from AC500 application in case of a broken connection between AC500 and telecontrol. State 1 and state 2 are similar to Mode 0/1. The difference is the disposal. When the connection is established again the Datalogger changes directly back to state 1 and the input values in FIFOin are directly sent to FIFOout (telecontrol connection). The buffered values in File FIFO are internally moved from disk 1 to disk 2 which can then be accessed or used by FTP (client or server). This move action can also be triggered by the command MOVE_FILES, or when file 1 is full. The advantage of Mode 2 is the immediate availability of the latest and all current values after an outage.

Mode 3: Events recorder

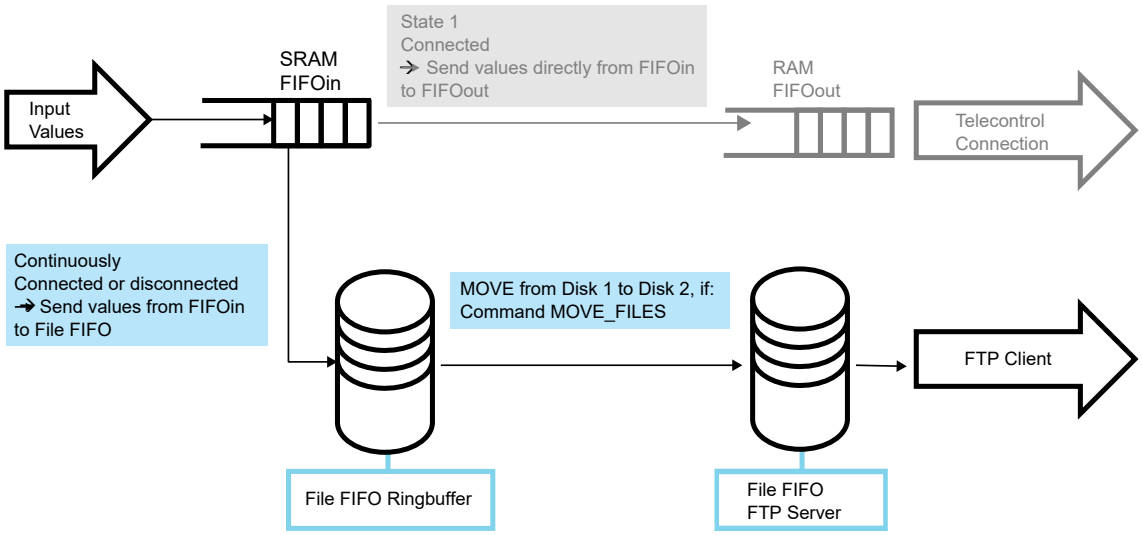

Fig. 696: Overview Mode 3

Mode 3 is used to record data values around an event, before and after the event x, e.g. outage of a part of the plant. The values are continuously recorded into the File FIFO file system independent of the connection status to telecontrol. If the File FIFO is full the oldest values are overwritten (ring buffer). Thus the File FIFO always contains the values from the past period n, which is depending on the amount of values per second and on the size of the File FIFO. When a certain event x occurs, the command MOVE_FILES can be given directly or after the period m. With the command MOVE_FILES the values in File FIFO are internally moved from disk1 to disk 2 and can be read out by an FTP action (client or server) when required.

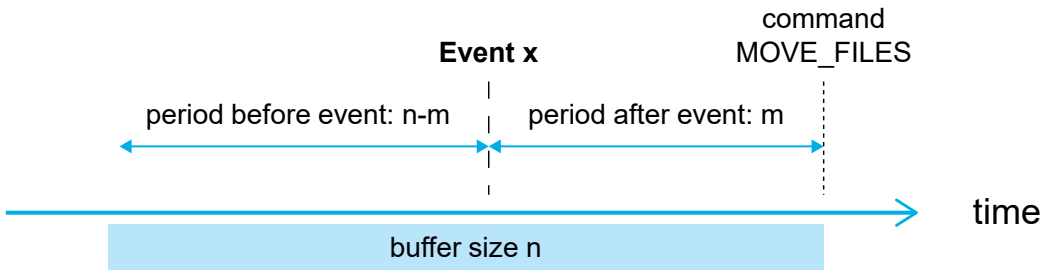

Fig. 697: The buffered values represent the time before the event (n-m) and after the event (m).

The advantage of mode 3 is that the values from the time period before the event (n-m) and after the event (m) are recorded and can help to reconstruct the cause and effect of the event.

Technical details

Parameter	Value
IEC 60870-5-104 protocol integrated in Datalogging, IEC data types	SinglePoint SP1/16, DoublePoint DP, IntegratedTotal IT1/16, MeasurementValue ME1/16
Generic logging to file(s); AC500 data types	BIN, BYTE, INT, DINT, WORD, DWORD, REAL
Trigger	Cyclic, event, tolerance
File format	CSV, including local timestamp. Generic Logging with separate ID (max. 8 characters), IEC Logging with IEC addresses. Timestamped data sets contain 1-16 values (IEC) depending on type logged. Generic contain different number of values, depending on type logged. BINARY: max. 58 BYTE: max. 88 INT: max. 50 WORD: max. 58 DINT: max. 29 DWORD: max. 31 REAL: max. 27
Datalogging target	Internal flashdisk or memory card, power fail input for memory card (from USV)
Datalogging file sizes and storage depth	FIFO storage in file system, Datalogging depth only limited by memory size
Configurable File FIFO	Number of files (max. 999); number of data sets per file (max. 65565)
Internal SRAM FIFO size	160 data sets
Block write mode into files	Up to 50 data sets/second per max. 88 values

Parameter	Value
Operation modes	Mode 0: Buffer and disposal in chronologic order Limited storage (keeps oldest, but stops if full) Mode 1: Buffer and disposal in chronologic order Endless (ring buffer) operation modes (deletes oldest) Mode 2: Buffer and disposal via FTP, Log file(s) copied to ftp server area for further use Mode 3: Events Recorder, logs data before and after an event.
Suppported software/firmware	V2.3 or higher
Current restrictions	One logger per PLC One IEC 60870 connection only: While log file is replayed, no other current information via IEC available Usable solutions: ● Delay replay of log file after connection returned to allow a “general inquiry” ● Use of Mode 2

File names

File names are renamed according to storing time with an accuracy of 100ms. The files are renamed from "filename.csv" to a file name with timestamp and with or without file extension, according to input DISK2_EXTENSION *“DISK2_EXTENTION (DISK2 extention)” on page 3507*.

File name with timestamp	02281448.593 = February 28th, 2:48pm (14:48), 59s, 300ms
File name with timestamp and file extension	02281448.csv = February 28th, 2:48pm (14:48)

Preconditions

The Datalogging Library supports CPU PM573 or higher.

The Datalogging Library does not support CPUs of the AC500-eCo-series.

CAUTION!
Failure in Processing of the function blocks.
– The function blocks LOGxxxxxx_INPUT, LOG_HANDLING and LOGxxxxxx_OUTPUT must be put in the same task.

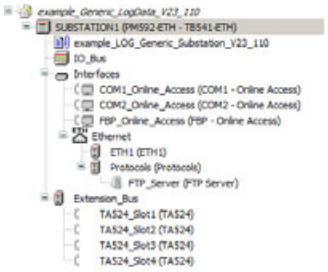
CPU firmware must be V 2.3.3 or higher.

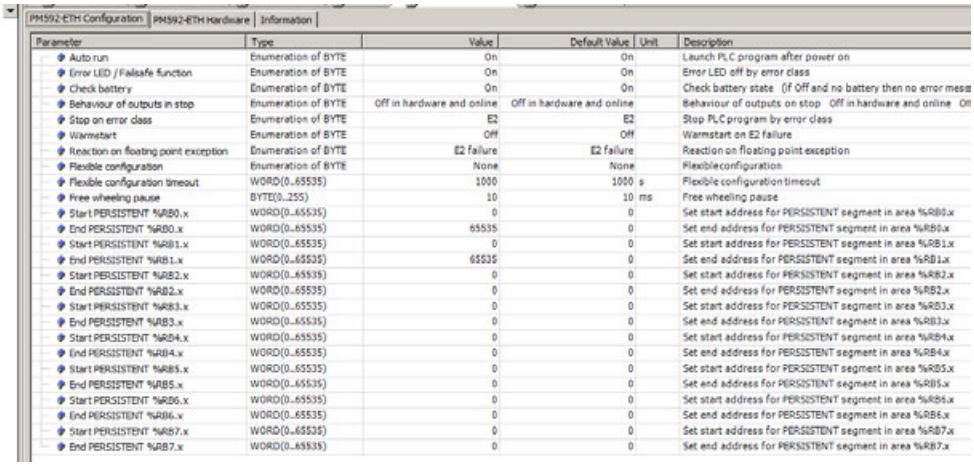
Use memory card from ABB with sufficient free space, at least 1,5 x file size as configured (file size is depending on input MAX_DS_IN_FILE (Log_Handling)).

Maximum number of files (input of FBLOG_HANDLING) is limited to 500 (ABB memory card is formatted with FAT).

The %R area must be set to PERSISTANT.

▷ Do the following settings in the AC500 configuration:





Automatically the following areas in the global %R/%M area are occupied:

- In the segment 0 of the %R/%M-area only the upper part is occupied in each case, %R starting at %RD13000, %M starting at %MD16370.
- The segment 1 is occupied completely in each case.

```
VAR_GLOBAL
(*
*************************************************************Segment
0 %R ************************************************************ *)
    RD0.0 ... RD0.12999 free for user - e.g.  MODBUS
(*
*************************************************************Segment
0 %M ************************************************************ *)
    MD0.0 ... MD0.16369 free for user - e.g.  MODBUS
```

Fig. 700: Explanation of the file formats

Table 248: 1 data set consists of the following parameters

Parameter	Explanation
IEC_TYPE =	IEC_TYPE of LOG_IEC60870_INPUT (1…7)
Slot/Con/Idx/NoDP =	PINGROUP of LOG_IEC60870_INPUT (1…7)
Quality_Bits(Byte) =	IV/NT/SB/BL/CA/CY/QOV (packed in 1 byte) of LOG_IEC60870_INPUT (1…7)
Quality (SQ) =	SQ of LOG_IEC60870_INPUT (1…7)
GADU =	calculated internally, from CBP-Configurator (Gadu1+Gadu2)
IAD3/2/1(n) =	calculated internally, for every datapoint separately, from CBP-Configurator (IAD1+IAD2+IAD3)
n =	1 or 16, in case of DP is n=2
VAR(n) =	variable

IEC type	Values	Meaning
SP1	-	SinglePoint 1
SP16	-	SinglePoint 16
DP	-	DoublePoint
IT1	-	IntegratedTotal 1
IT1616	-	IntegratedTotal 16
ME1	-	MeasurementValue 1

IEC type	Values	Meaning
ME16	-	MeasurementValue 16
Quality_Bits(Byte):	Quality.0 := IV;	Quality with quality invalid
	Quality.1 := NT;	Quality not topical
	Quality.2 := SB;	Quality substituted
	Quality.3 := BL;	Quality blocked
	Quality.4 := CA;	Quality with quality carry
	Quality.5 := CY;	Quality with quality counter adjusted
	Quality.6 := QOV;	Quality Overflow Quality
	Quality.7 := Reserve;	(*Reserve - Quality*)
Quality SQ(Byte)	SQ	Quality sequence number

Example

1.5.13.2.2 LOG_HANDLING

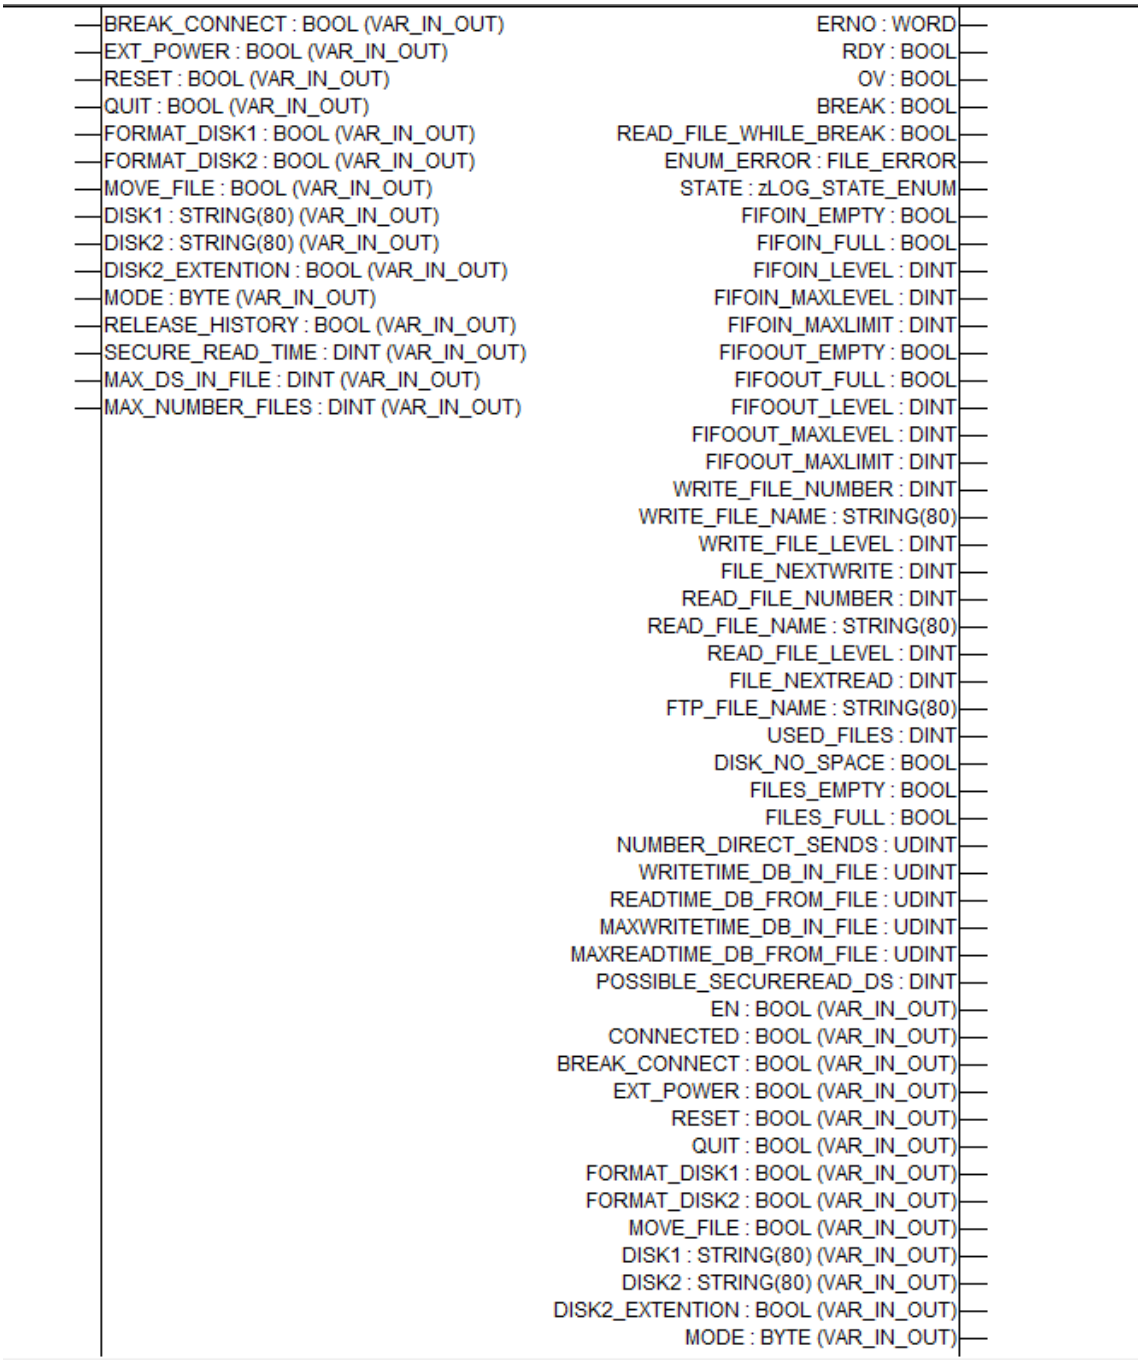

Table 249: General information

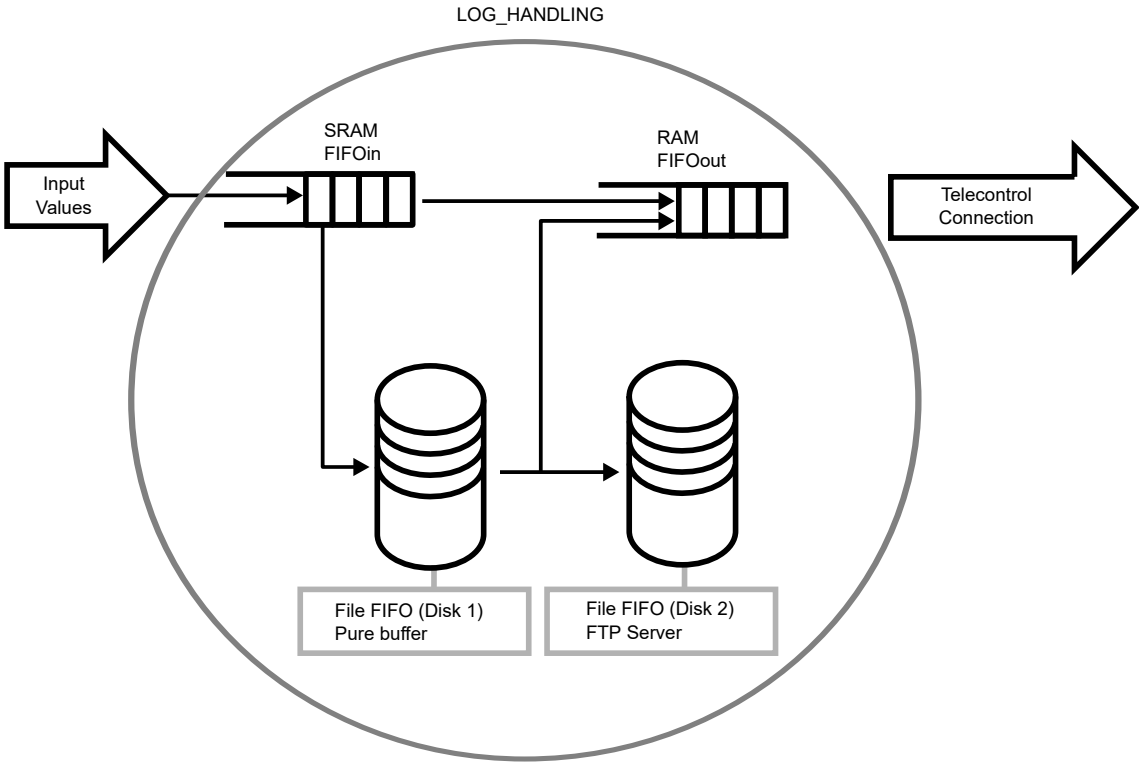
Available as of runtime system	V2.3 and above
Included in library	LogData_AC500_V23.lib
Type	Function block with historical values

Depending on the selected mode this function block is used to

- directly transfer data messages in IEC60870 format or in generic format from SRAM_FIFOin to the RAM_FIFOout in case of an existing communication.
- store data sets in IEC60870 format or in generic format in files on flash disk or memory card for other use or because a communication line is broken.
- provide these logged data sets at the RAM_FIFOout output in case of recurring communication with higher priority than the current data traffic or via FTP server of the PLC.

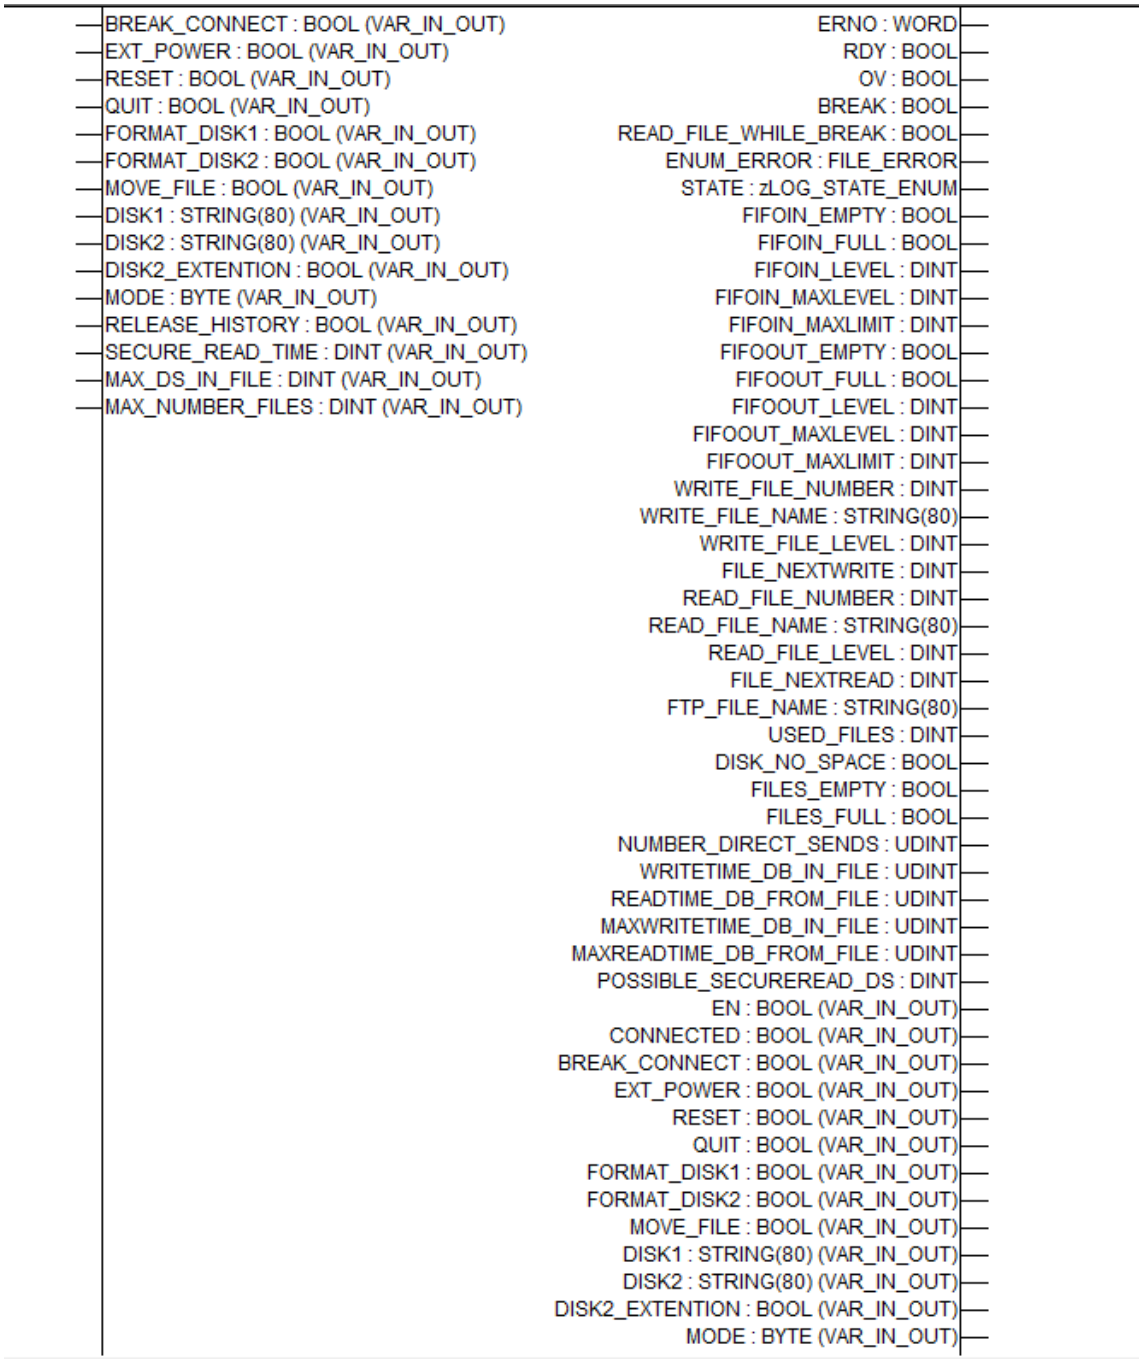


Depending on the mode the function block can have three main working states:

- State 1: Existing communication (CONNECT) und empty FILE-FIFO: Data sets are written into SRAM_FIFOin (First In First Out), which are either from LOG_IEC60870_INPUT or LOG_GENERIC_INPUT (cannot be mixed), and are transported to RAM_FIFOout (First In First Out). There they are either
  - decoded by LOG_IEC60870_OUTPUT and transmitted or
  - decoded by LOG_GENERIC_OUTPUT and provided on its outputs as real data for further transmission (dependant on the chosen input variant: IEC or generic).
- State 2: Communication failure (DISCONNECT): Data sets, which were written either by LOG_IEC60870_INPUT or LOG_GENERIC_INPUT (cannot be mixed) into the SRAM_FIFOin, will be transmitted into the FILE-FIFO (First In First Out) and stored.
- State 3: Write/Read Modes and FTP Modes *Chapter 1.5.13.2.1.1 “Operating modes” on page 3496*

This function block realises writing and reading of max. 999 files with max. 65535 data sets in a FIFO principle. Data storage can be either the FLASHDISK of a PM59x (with SafeFAT), or an SDCARD (without SafeFAT). In case of SDCARD it must be ensured that after main power failure, for approximately 3...5 sec the 24 V supply is maintained (input extPower = FALSE), in order to close open files properly.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CONNECTED (connected)

Data type: BOOL

Input signal, if the connection with the receiving/control station is established.

It is irrelevant in FTP Mode (Mode 3) because in FTP Mode no data is send by the function block to the control station.

BREAK_CONNECT (break connect)

Data type: BOOL

For testing purposes. TRUE indicates to the function block that the connection to the other station is interrupted.

It is irrelevant in FTP Mode (Mode 3) because in FTP Mode no data is send by the function block to the control station.

EXT_POWER (external power)

Data type: BOOL

External power/opener. FALSE: the function block completes the last write and read actions, closes all open files and goes to an idle-state. This is signaled at the DONE output. On the output STATE the text „zLOG_NO_EXTERNAL_POWER“ is given out.

RESET (reset)

Data type: BOOL

Complete reset of all data fields, historical data and actual status of the function block. During this action the output STATE shows the text „zLOG_RESET_ACTIVE“. The end of this action is signaled on the output DONE.

QUIT (quit)

Data type: BOOL

The input will acknowledge at an 0/1 edge the error message of the function block, if the message is not active anymore.

FORMAT_DISK1 (format DISK1)

Data type: BOOL

At an 0/1 edge the input formats the drive given on DISK1. During this action the output STATE shows the text „zLOG_DISK1_FORMAT_ACTIVE“. The end of this action is signaled on the output DONE. On the output STATE the text „zLOG_DISK_HAS_BEEN_FORMATTED“ is shown.

FORMAT_DISK2 (format DISK2)

Data type: BOOL

At an 0/1 edge the input formats the drive given on DISK2. During this action the output STATE shows the text „zLOG_DISK2_FORMAT_ACTIVE“. The end of this action is signaled on the output DONE. On the output STATE the text „zLOG_DISK_HAS_BEEN_FORMATTED“ is shown.

MOVE_FILE (move file)

Data type: BOOL

Only active in Mode 2 and Mode 3. At an 0/1 edge the input closes and moves the file (Mode 2) or multiple files (Mode 3) currently written on primary DISK1 into the folder FTP of the secondary DISK2 (both DISKs can be identical). The folder FTP is created automatically. The files are renamed.

After read-out via FTP client the moved and renamed files can be deleted on the FTP server by the user. During the action the output STATE shows the text „zLOG_MOVE_ACTIVE“. The end of this action is signaled on the output DONE.

DISK1 (DISK1)

Data type: STRING

Name of the primary drive ("flashdisk" or "sdcard") which is used for File FIFO buffer. DISK1 and DISK2 can be identical. Internally the primary drive is used with "file1...file999..." (Mode 0/1/3) or with "file1" (Mode 2) which the function block automatically creates and deletes.

DISK2 (DISK2)

Data type: STRING

Name of the secondary drive ("flashdisk" or "sdcard") which is used for File FIFO FTP Server. DISK1 and DISK2 can be identical.

DISK2_EXTENTION (DISK2 extention)

Data type: BOOL

Extention-Switch for the naming of the files to be moved to the FTP folder. The files stored in the FTP folder are renamed with a name representing a timestamp, in order to clearly be able to see the timely order when reading or processing the files.

Possible are:

- DISK2_EXTENTION = FALSE
- DISK2_EXTENTION = TRUE

CAUTION!

Accidentially overwritten files

When DISK2_EXTENSION = TRUE and the creation time between two files is too short to be visible in the name (< 1 minute), the first file is overwritten.

MODE (mode)

Data type: BYTE

- Mode 0 *Chapter 1.5.13.2.1.1 “Operating modes” on page 3496*
- Mode 1 *Chapter 1.5.13.2.1.1 “Operating modes” on page 3496*
- Mode 2 *Chapter 1.5.13.2.1.1 “Operating modes” on page 3496*
- Mode 3 *Chapter 1.5.13.2.1.1 “Operating modes” on page 3496*

RELEASE_HISTORY (release historical data transfer)

Data type: BOOL

External release for reading out the saved data from storage. This input is necessary when using IEC60870 logging. After communication is established again, the input keeps historical data back until control station sends a general interogation to get the current status. If this function is not needed, input=TRUE.

SECURE_READ_TIME (secure read time in ms)

Data type: DINT

Estimation of time (in ms) which passes after the failure of a connection until this failure is detected and the output CONNECT changes to FALSE. Under circumstances a communication failure can only be detected after a longer time without data transfer. Therefore in normal operation a measurement should be done for getting the average number of data sets arriving to the SRAM-FIFOin by SECURE_READ_TIME. In case of Connection fault this amount of data sets in the SRAM-FIFOin is taken from past and additionally stored into the FILE-FIFO, in order to avoid data losses by the delayed Connection fault recognition. At "0" no SecureRead is done.

MAX_DS_IN_FILE (max number of data sets in one file)

Data type: DINT

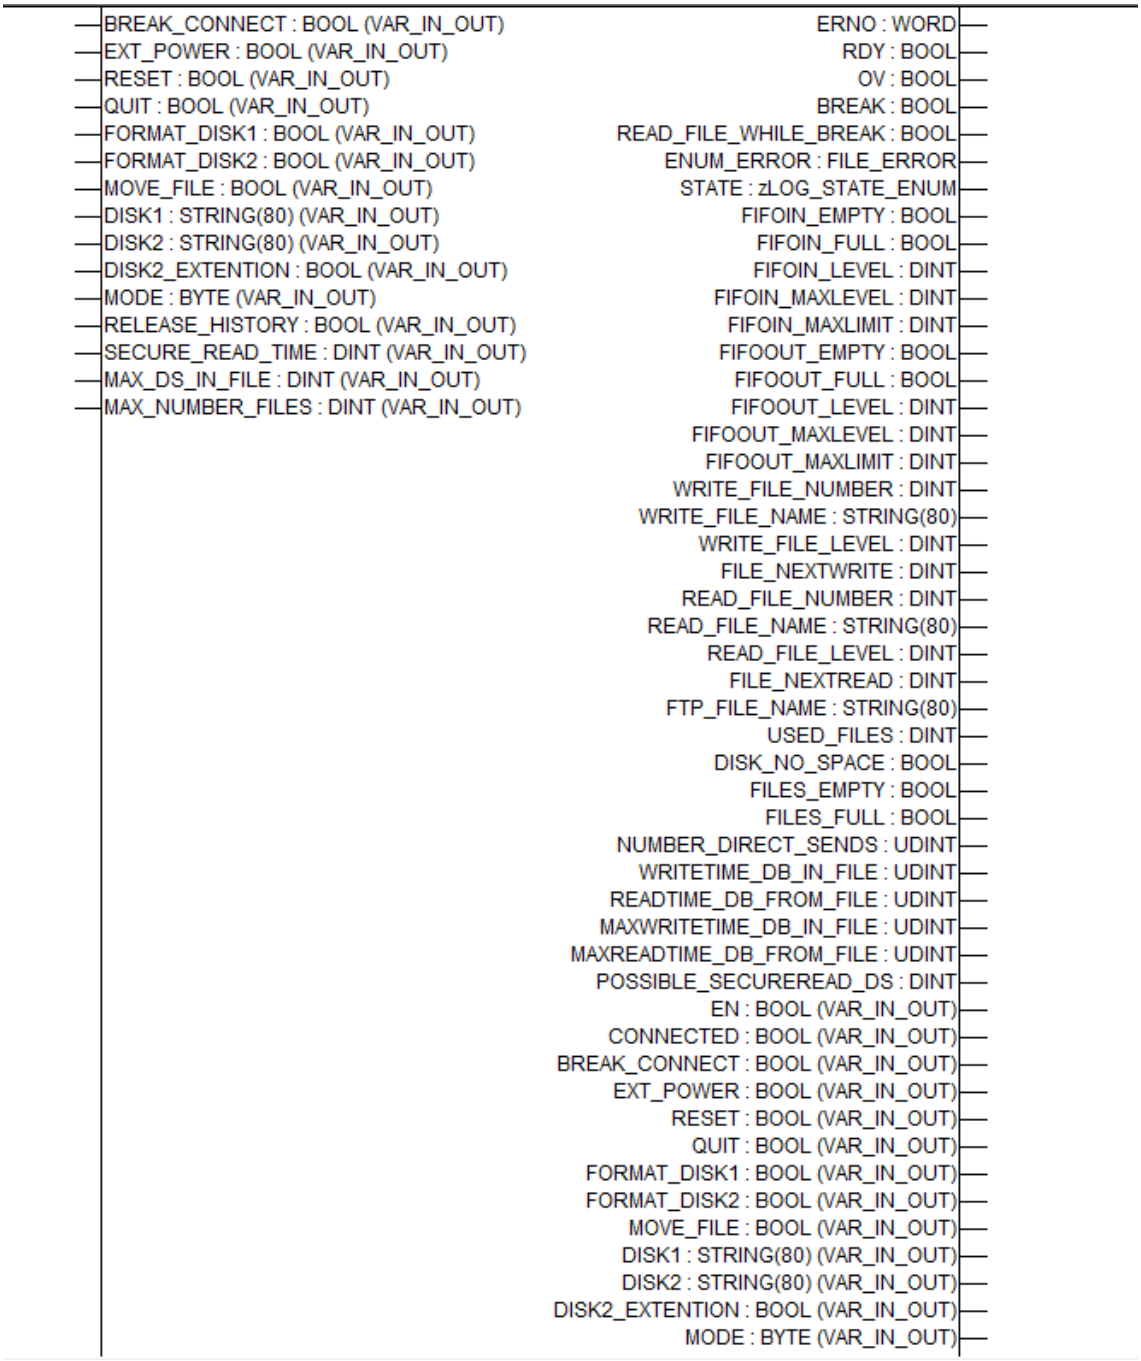
After reaching this limit the file is closed and a new file is opened. The configurable upper limit is 65535. An error is created if the input value is higher. A change of this value after start of the Datalogger is not allowed and will lead to faults in Mode 0 and Mode 1 when reading back values.

MAX_NUMBER_FILES (max number of files)

Data type: DINT

After reaching this limit no further data sets can be stored. If further data sets are arriving OV is signaled. The adjustable limit is 999. An error will be created if the input value is higher. A change of this value after start of the Datalogger is not allowed and will lead to faults in Mode 0 and Mode 1 when reading back values. An exception is Mode 3, no values are read back and therefore a change in operation is allowed, e.g. to obtain flexible timing.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

In addition, if errors occur while executing the IEC standard function blocks which are used internally, on the output ERNO a related error code *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529* will be given (ERR = TRUE).

RDY (ready)

Data type: BOOL

Output will be TRUE, if all external triggered activities of the function block are processed (FORMAT, MOVE, RESET, QUIT). Blinks if input EXT_POWER is missing.

OV (overrun)

Data type: BOOL

Output will be TRUE, if an overflow occurs. On this output a rising edge (FALSE -> TRUE) shows that communication/logging request occurred too fast and therefore the SRAM-FIFOin is full.

BREAK (break connect)

Data type: BOOL

Active, while available connection and while reading of historical values the SRAM-FIFOin is nearly full with new data sets. If BREAK is active, the SRAM-FIFOin-data will be written to FILE-FIFO despite CONNECT, in order to widely avoid OV of the SRAM-FIFOin. However, if incoming data sets arrive faster as they can be written to files, the system will reach a limit. Then an OV stop cannot be avoided.

READ_FILE_WHILE_BREAK (read file while break)

Data type: BOOL

Safety function: Output will be active, if all available files are full during CONNECT and BREAK. In this case primarily the oldest file of the FILE-FIFO is read out, regardless of OV.

ENUM_ERROR (eError from CAA Library)

Data type: FILE_ERROR

Detailed error messages of the used CAA_File function block Library. Output will be flagged, if an error occurs while execution of the function block. For error messages refer to chapter 'Error Messages' of the CAA_File function block Library.

STATE (enumeration of type zLOG_STATE_ENUM)	Data type: zLOG_STATE_ENUM Clear text messages of errors and states. The output uses the enumeration of the data type zLOG_STATE_ENUM declared in "data types".
FIFOIN_EMPTY (FIFOin empty)	Data type: BOOL SRAM-FIFOin is empty.
FIFOIN_FULL (FIFOin full)	Data type: BOOL SRAM-FIFOin is full (maximum 161 data sets).
FIFOIN_LEVEL (FIFOin level)	Data type: DINT Output represents the current level of SRAM-FIFOin %R area (zLOG_FIFOIN_LEVEL).
FIFOIN_MAX-LEVEL (FIFOin max level)	Data type: DINT Maximum SRAM-FIFOin filling level since EN=TRUE.
FIFOIN_MAX-LIMIT	Data type: DINT Standard value = 161.
FIFOOUT_EMPTY (FIFOout empty)	Data type: BOOL RAM-FIFOout is empty.
FIFOOUT _FULL (FIFOout full)	Data type: BOOL RAM-FIFOout is full (max 161 data sets).
FIFOOUT _LEVEL (FIFOout level)	Data type: DINT RAM-FIFOout filling level. Output represents current level of SRAM-FIFOin %R area (stored value).
FIFOOUT _MAX-LEVEL (FIFOout max level)	Data type: DINT Maximum RAM-FIFOout filling level since EN=TRUE.
FIFOOUT_MAX-LIMIT	Data type: DINT Standard value = 161.
WRITE_FILE_NUMBER (number of current file written to)	Data type: DINT Number of the current file written to (1…999).
WRITE_FILE_NAME (name of current file written to)	Data type: STRING Name of the current file written to (e.g. file1…file999).

WRITE_FILE_LEVEL (level of current file written to)
Data type: DINT
Filling level of the file currently written to.

FILE_NEXT-WRITE (next write position in current file written to)
Data type: DINT
Next write position in current file written to.

READ_FILE_NUMBER (number of current file)
Data type: DINT
Number of current file read from (1…999).

READ_FILE_NAME (name of current file)
Data type: STRING
Name of current file read from (for example file1…file999).

READ_FILE_LEVEL (level of current file)
Data type: DINT
Filling level of current file read from.

FILE_NEXT-READ (next read position in current file)
Data type: DINT
Next read position in current file read from.

FTP_FILE_NAME (name of current file written to)
Data type: STRING
Complete current path and name of the file which will be transferred to the folder FTP (e.g. "flashdisk\FTP\02141149.545") in Mode 2 in the following cases:

- file 1 is full
- communication returns
- per external trigger by setting the input MOVE_FILE

In Mode 3 the move is triggered only by setting input MOVE_FILE.

USED_FILES (currently used files)
Data type: DINT
Number of files written to.

DISK_NO_SPACE (disk no space)
Data type: BOOL
Data storage is full.

FILES_EMPTY (files empty)
Data type: BOOL
All files are empty.

FILES_FULL (files full)
Data type: BOOL
All files are full. No further data sets can be stored.

NUMBER_DIRECT_SENDS (number of direct sent data sets
Data type: UDINT
Number of the current data sets sent to the control station side since EN=TRUE and coming from SRAM-FIFO (without storing in FILE-FIFO).

WRITE-TIME_DB_IN_FILE (current time to write one data set in file)

Data type: UDINT

Current time for writing one data set into the file. When this time is growing over time, this is a sign of a growing fragmentation of the disk. In Mode 0 and Mode 1 and "flashdisk", the flash disk is defragmented automatically (FORMAT) as soon as all the historical data has been sent to the control station. In Mode 2 this may not happen as under circumstances files are stored in the FTP folder and have not been picked up by FTP yet.

In case of a memory card as storage medium, a FORMAT is basically locked because otherwise it may cause incompatibility between PLC and PC. That means a memory card defragmented via FORMAT in the PLC is possibly no longer readable on a PC.

READ-TIME_DB_FROM_FILE (current time to read one data set from file)

Data type: UDINT

Current time for reading a data set from the file. When this time is growing over time, this is a sign of a growing fragmentation of the disk. In Mode 0 and Mode 1 and "flashdisk," the flash disk is defragmented automatically (FORMAT) as soon as all the historical data has been sent to the control station. In Mode 2 this may not happen as under circumstances files are stored in the FTP folder and have not been picked up by FTP yet.

In case of a memory card as storage medium, a FORMAT is basically locked because otherwise it may cause incompatibility between PLC and PC. That means a memory card defragmented via FORMAT in the PLC is possibly no longer readable on a PC.

MAXWRITE-TIME_DB_IN_FILE (max time to write one data block in file since EN)

Data type: UDINT

Maximum time needed until now to write one data block in the file. When this time is growing over time, this is a sign of a growing fragmentation of the disk. In Mode 0 and Mode 1 and "flashdisk," the flash disk is defragmented automatically (FORMAT) as soon as all the historical data has been sent to the control station. In Mode 2 this may not happen as under circumstances files are stored in the FTP folder and have not been picked up by FTP yet.

In case of a memory card as storage medium, a FORMAT is basically locked because otherwise it may cause incompatibility between PLC and PC. That means a memory card defragmented via FORMAT in the PLC is possibly no longer readable on a PC.

MAXREAD-TIME_DB_FROM_FILE (max time to read one data block from file since EN)

Data type: UDINT

Maximum time needed until now to read one data block from the file. When this time is growing over time, this is a sign of a growing fragmentation of the disk. In Mode 0 and Mode 1 and "flashdisk," the flash disk is defragmented automatically (FORMAT) as soon as all the historical data has been sent to the control station. In Mode 2 this may not happen as under circumstances files are stored in the FTP folder and have not been picked up by FTP yet.

In case of a memory card as storage medium, a FORMAT is basically locked because otherwise it may cause incompatibility between PLC and PC. That means a memory card defragmented via FORMAT in the PLC is possibly no longer readable on a PC.

POSSIBLE_SECURE READ_DS (possible secure read data sets)

Data type: UDINT

Number of data sets delivered to SRAM-FIFOin (during the time indicated on input "SECURE_READ_TIME" in ms). In case of connection fault this number of past data sets in SRAM-FIFOin are taken additionally into account for writing to FILE-FIFO in order to avoid data losses caused by the delayed connection fault – recognition.

Integrated visualization

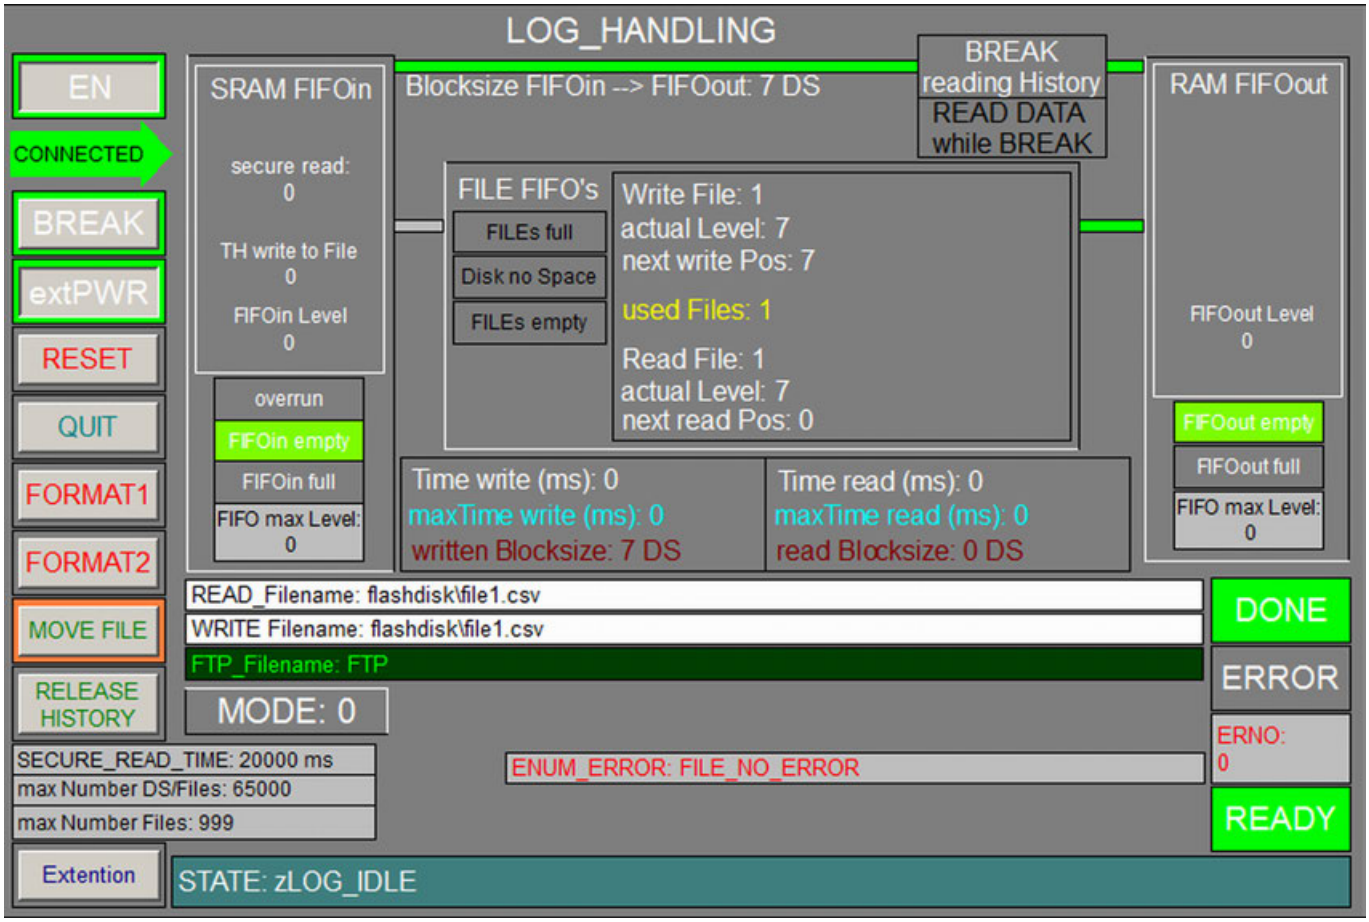


Fig. 702: Visualization

1.5.13.2.3 LOG_IEC60870_INPUT

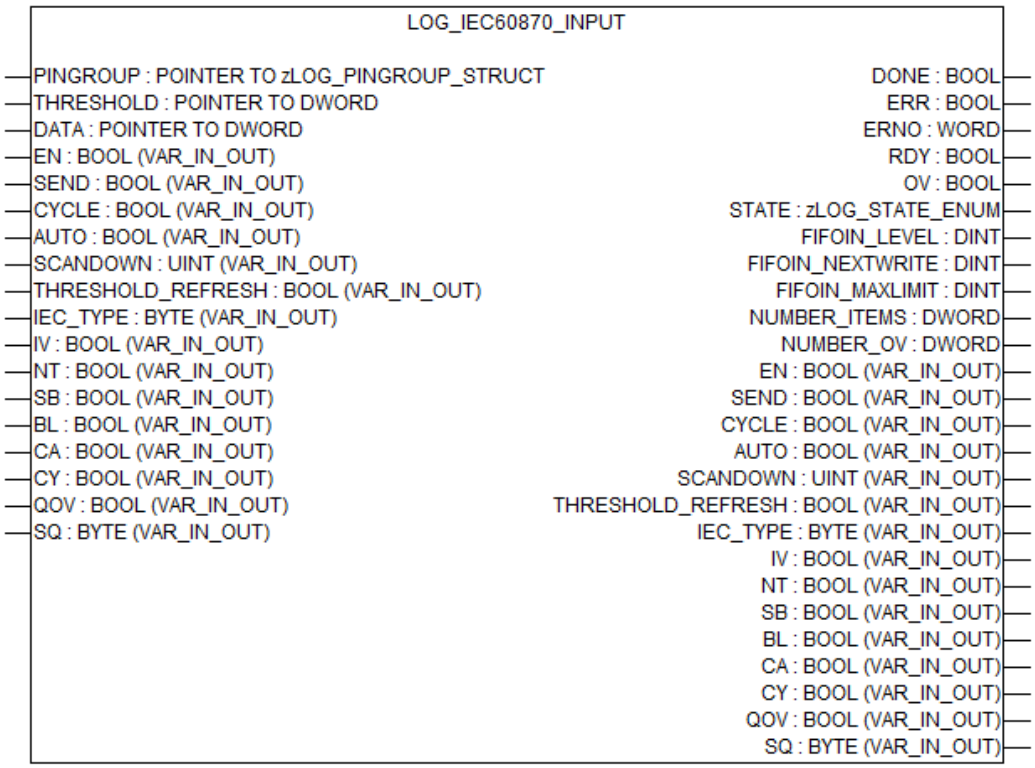

Table 250: General information

Available as of runtime system	V2.3 and above
Included in library	LogData_AC500_V23.lib
Type	Function block with historical values

The function block is used for writing data sets into the SRAM-FIFOin of the Datalogger according to IEC 60870-5-104 protocol. According to the corresponding data type up to 16 data points of this data type can be written at the same time.

The data sets are written in format *.csv as two-dimensional ARRAY. Every part of each data set is separated by SEMICOLON. Each data set is ended with a CR/LF. Every segment of the %R area of the SRAM-FIFOin contains maximum one ARRAY[0..160] OF ARRAY[0..399] OF BYTE. The ARRAY reserves the complete segment 1 of the %R area of the controler.

A complete segment (segment 1 of the %R-area) is used for the SRAM-FIFOin (zLOG_CONST_FIFOLIMIT =160).

Here, the function block is used to write the data sets into the SRAM-FIFOin of the PLC CPU and not to be sent directly to the control station. This is done with function block LOG_IEC60870_OUTPUT which uses the above mentioned function blocks.

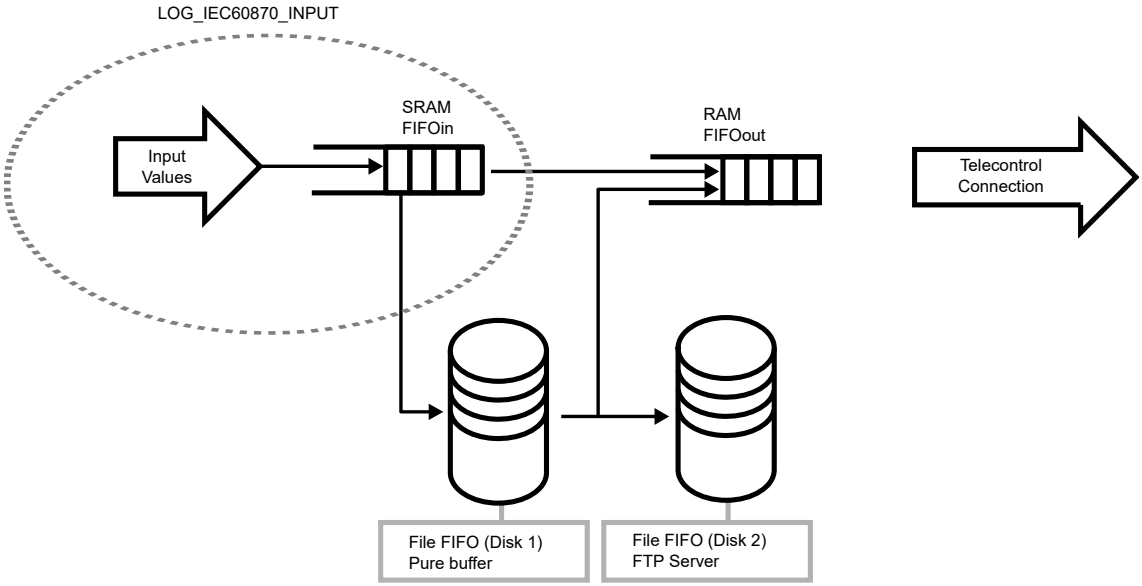

Fig. 703: Functionality

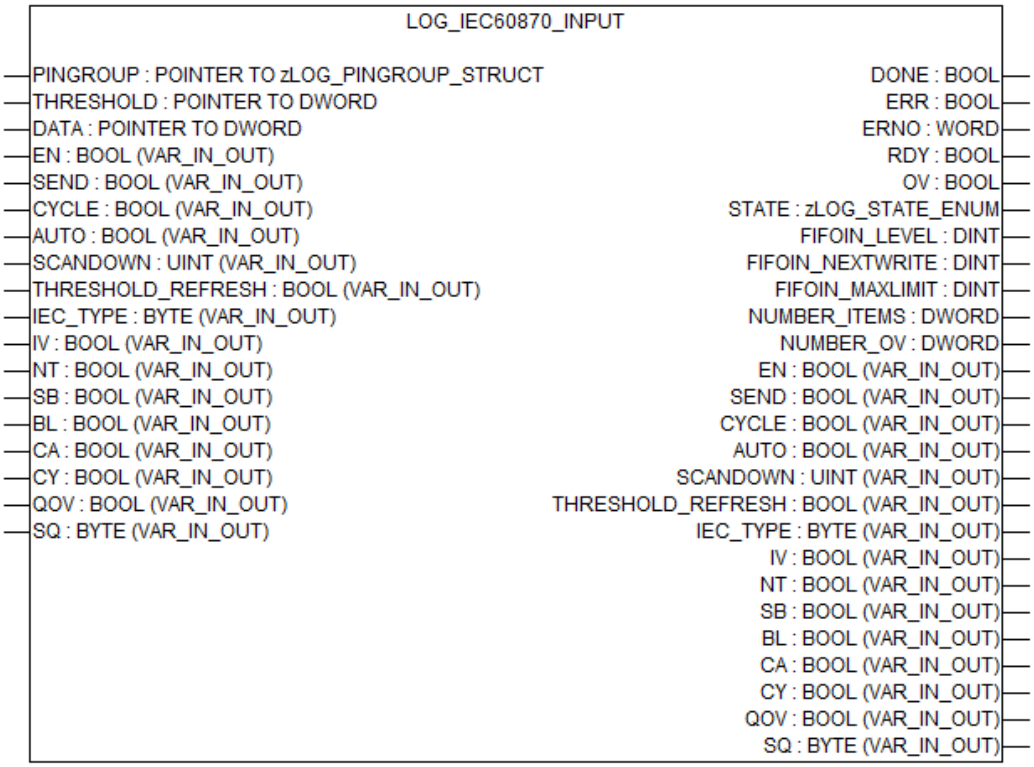
CAUTION!
Each used instance of the function block needs only one cycle for writing the data into FIFOin. For "n" succeeding instances called in the same cycle, "n" entrances/data sets are entered into FIFOin. Consider that FIFOin is limited by the limit of the segments of the %R area. That means, the upper limit of entries to FIFOin at the same time (in the same cycle) is 160.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

PINGROUP (pin group via ADR-Operator)

Data type: POINTER TO zLOG_IEC60870_FIFO_ENTRY

On this input the data point is set which should be received by the function block. The Pin-Group of e.g. the data type IEC60870_MeasuredValue relates to the one defined by the Control-/substation in the global address list of Automation Builder defined data type (see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*). After the declarations in Automation Builder are done, the data type is available in the global variable list in CODESYS (command list, Command(CONSTANT)). The IEC 60870 data are send or received to the data point defined by the address in Automation Builder. The sent address data point must be the same as the received data point (see *Chapter 1.6.5.3.2.3.4 “Data points” on page 6131*). As the input is a POINTER TO it has to be connected to an preceding ADR-Operator, to which any PINGROUP can be put.

THRESHOLD (threshold via ADR-Operator)

Data type: POINTER TO DWORD

When exceeding or falling below a threshold, a writing operation of a data set into the FIFOin is started. After this operation, either only the single threshold difference (between input and threshold) is deleted (TH_REFRESH=FALSE) or all differences (TH_REFRESH=TRUE). As the input is a POINTER TO, it has to be connected to an preceding ADR-Operator, to which any available input-type can be provided: BOOL, BYTE, INT, WORD, DINT, DWORD, REAL or an ARRAY of these data types. Make sure that THRESHOLD is always of the same type as in IN. E.g. if IN is an ARRAY[0..n] OF BYTE, THRESHOLD has to be an ARRAY[0..n] OF BYTE, too.

This input is only relevant for IEC_TYPE's 4(IT1), 5(IT16), 6(ME1) und 7(ME16), not for bool/digital. For the BOOL type inputs, THRESHOLD is not needed.

DATA (input via ADR-Operator)

Data type: POINTER TO DWORD

Input value as single value or as ARRAY for the possible 0 to 16 values. As the input is a POINTER TO, it has to be connected to a preceding ADR-Operator, to which any available input-type can be provided: BOOL, BYTE, INT, WORD, DINT, DWORD, REAL or an ARRAY of these data types.

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SEND (send)

Data type: BOOL

At a rising edge, this input writes a data set into the FIFOin

CYCLE (cycle)

Data type: BOOL

This input writes all SCANDOWN cycles of a data set into FIFOin. At SCANDOWN=0 a data set is written in each cycle.

AUTO (auto)

Data type: BOOL

With each change of an input value or exceeding/falling down of THRESHOLD, this input writes a data set into FIFOin.

SCANDOWN (scandown)

Data type: UINT

This input will be valid if input CYCLE = TRUE. Then cyclical writing is only executed within each scandown cycle.

Example

SCANDOWN=100: In one out of 100 cycles a data set is written to FIFOin.

SCANDOWN=0: In every cycle a data set is written.

THRESHOLD_REFRESH (threshold refresh)

Data type: BOOL

FALSE: Deletion of the threshold value difference of each input value after its overwriting of the threshold level. All other differences will be ignored if they have not yet been rising above their threshold. A higher trigger rate can be expected.

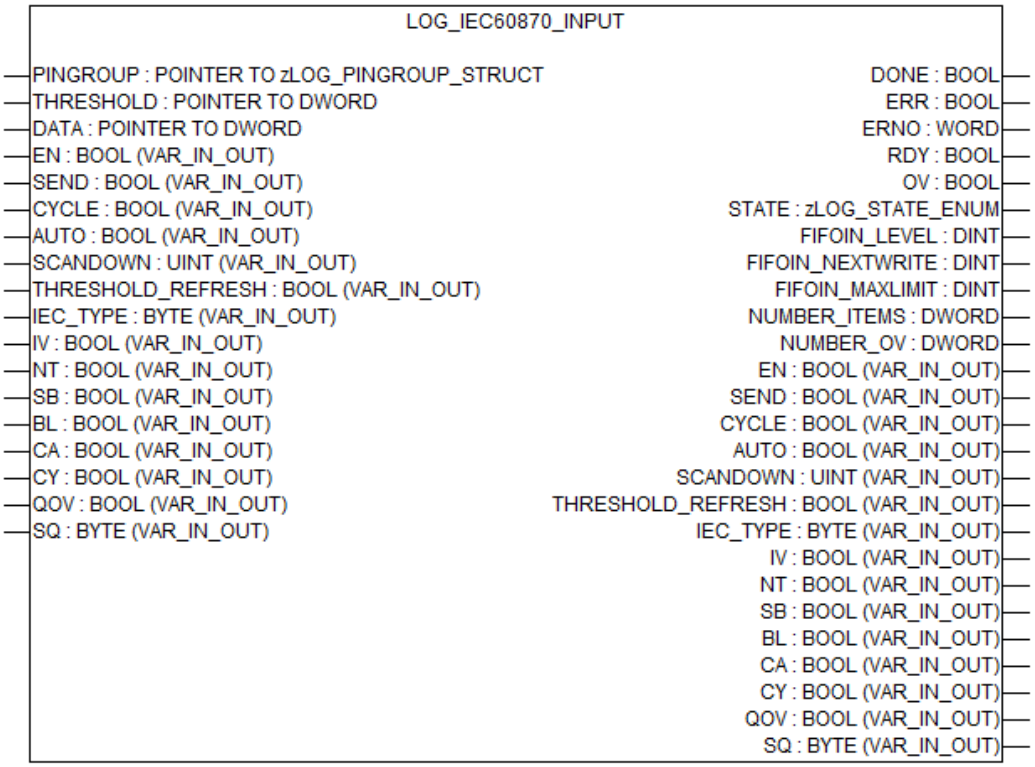
TRUE: Deletion of all threshold value differences after exceeding one of the thresholds. All other differences will also be cleared even if they have not yet been exceeded the threshold. A lower trigger rate can be expected. As always all data of the Funciton Block are sent, the data values are anyway always up to date.

This input is only relevant for IEC_TYPE's 2(SP16), 3(DP), 5(IT16) and 7(ME16), more than 1 input.

For the IEC_TYPE's 2(SP16) und 3(DP) BOOL the input TRESHOLD has no effect, as the inputs are of the type BOOL and therefore cannot have a threshold.

IEC_TYPE (IEC60870 Type)	Data type: BYTE 1=SP1, 2=SP16, 3=DP, 4=IT1, 5=IT16, 6=ME1, 7=ME16
IV (invalid)	Data type: BOOL Quality: invalid (SP1, SP16, DP, IT1, IT16, ME1, ME16)
NT (not topical)	Data type: BOOL Quality: not topical (SP1, SP16, DP, ME1, ME16)
SB (substituted)	Data type: BOOL Quality: substituted (SP1, SP16, DP, ME1, ME16)
BL (blocked)	Data type: BOOL Quality: blocked (SP1, SP16, DP, ME1, ME16)
CA (carry)	Data type: BOOL Quality: carry (IT1, IT16)
CY (counter adjusted)	Data type: BOOL Quality: counter adjusted (IT1, IT16)
QOV (overflow quality)	Data type: BOOL Quality: overflow (ME1,ME16)
SQ (sequence number)	Data type: BYTE Quality: sequence number (IT1,IT16)

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

RDY (ready)

Data type: BOOL

Output will be TRUE, if a command is been received. As this is only true for one cycle, also RDY = TRUE for one cycle only.

OV (overrun)

Data type: BOOL

Output will be TRUE, if an overflow occurs. On this output a rising edge (FALSE -> TRUE) shows that the transmit requests are coming too fast and thereby the SRAM-FIFOin is fully filled.

STATE (enumeration of type zLOG_STATE_ENUM)

Data type: zLOG_STATE_ENUM

Clear text messages of errors and states. The output uses the enumeration of the data type zLOG_STATE_ENUM declared in "data types".

FIFOIN_LEVEL (FIFOin level)

Data type: DINT

Output represents the current level of SRAM-FIFOin %R area (zLOG_FIFOIN_LEVEL).

FIFOIN_NEXTWRITE (next write position in FIFOin)

Data type: DINT

Shown is the next write position in SRAM-FIFOin %R area (zLOG_FIFOIN_NEXTWRITE).

FIFOIN_MAXLIMIT (max number of data sets in FIFOin)

Data type: DINT

Shows the value of the constant FIFOLIMIT of the data sets in SRAM-FIFOin %R area (zLOG_CONST_FIFOLIMIT).

NUMBER_ITEMS (max number of items)

Data type: DINT

Shows the executed write operation into the SRAM-FIFO since EN=TRUE.

NUMBER_OV (max number of overflow-items)

Data type: DINT

Shows the not executed write operations into the SRAM-FIFO since EN=TRUE.

1.5.13.2.4 LOG_IEC60870_OUTPUT

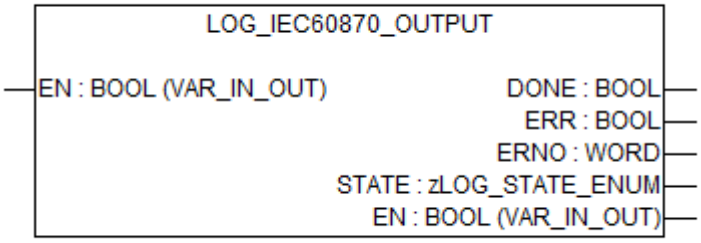

Table 251: General information

Available as of runtime system	V2.3 and above
Included in library	LogData_AC500_V23.lib
Type	Function block with historical values

This function block decodes a data set formated in *.csv and sends the current data type from the RAM-FIFOout of the Datalogger to the control station.

If enabled the function block automatically reads the oldest data set at a filling level of FIFOout > 0 and existing communication connection. Then the function block decodes the data set from *.csv format, sends the data via internal call of IEC function blocks and shows status at output STATE = zLOG_OUTPUT_DATA_HAS_BEEN_SENT. This happens until FIFOOUT_LEVEL=0 and the function block signals "EMPTY". At the same time at output STATE the message "zLOG_FIFOOUT_EMPTY" is given. While existing communication and exhausted FILE-FIFO,

the data sets, newly written by LOG_IEC60870_INPUT to the (in the %R area residing) FIFOin, are continuosly copied by LOG_HANDLING directly to the (in the %M-area residing) FIFOout, as soon as there is space in the FIFOout for new data sets. For this the FIFOout should not be empty (EMPTY). It is different when FILE-FIFO is not empty. In this case at first FIFOout is fully decremented until FIFOOUT_LEVEL=0 and the function block signals "EMPTY". After that a new data set block is copied from FILE-FIFO into FIFOout. The capacity of the RAM-FIFOout per segment of the %M-area is at max ARRAY[0..160] OF ARRAY[0..399] OF BYTE. The ARRAY ocupies the complete segment 1 in the %M-area of the CPU.

A complete segment (segment 1 of the %R-area) is used for the SRAM-FIFOin (zLOG_CONST_FIFOLIMIT =160).

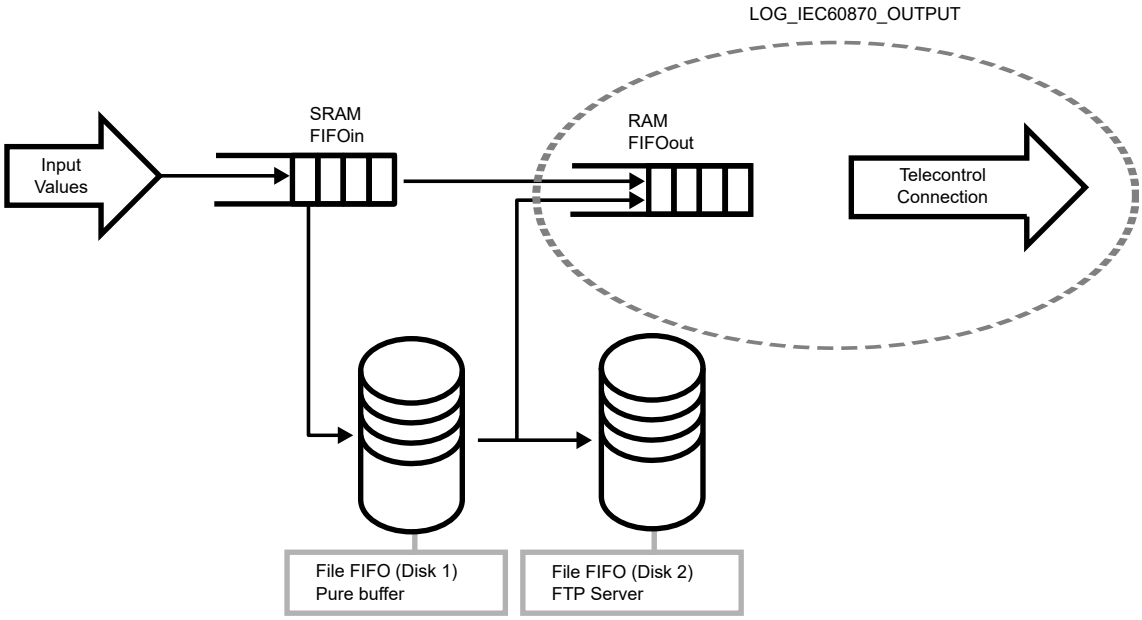

Fig. 707: Functionality

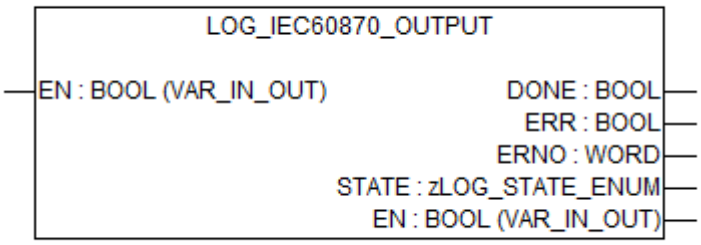
Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN

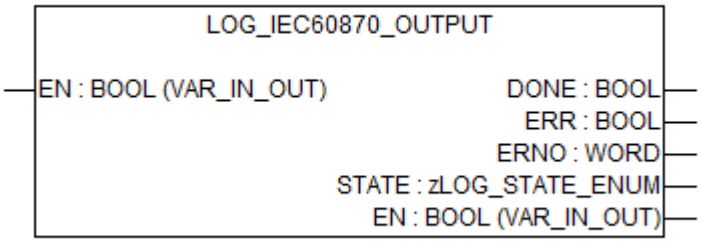
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE (done)

Data type: BOOL

On this output the status of the function block execution is shown. DONE = TRUE if a new data set is given to the remote control list of the CPU. By this the sending of the data set is considered.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

STATE (enumeration of type zLOG_STATE_ENUM)

Data type: zLOG_STATE_ENUM

Clear text messages of errors and states. The output uses the enumeration of the data type zLOG_STATE_ENUM declared in "data types".

Integrated visualization

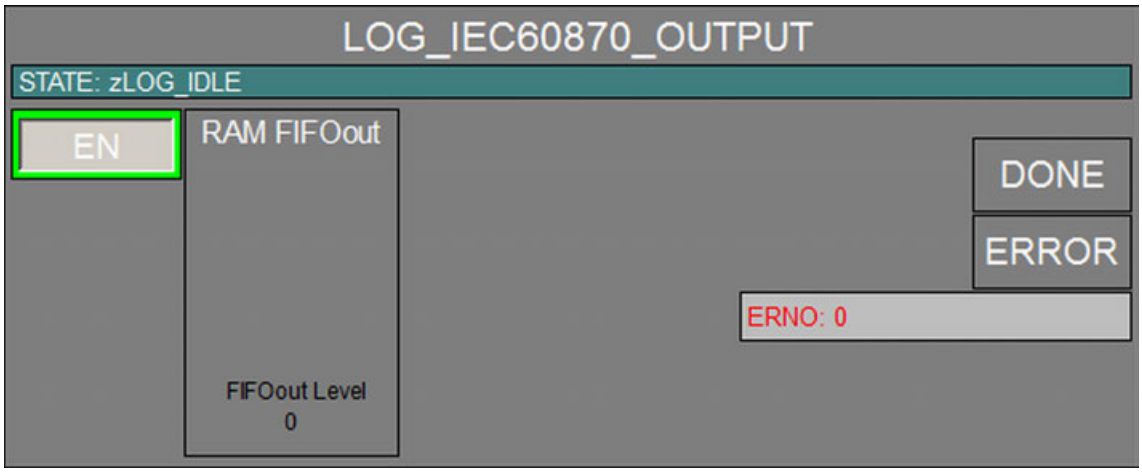


Fig. 708: Visualization

1.5.13.2.5 LOG_GENERIC_INPUT

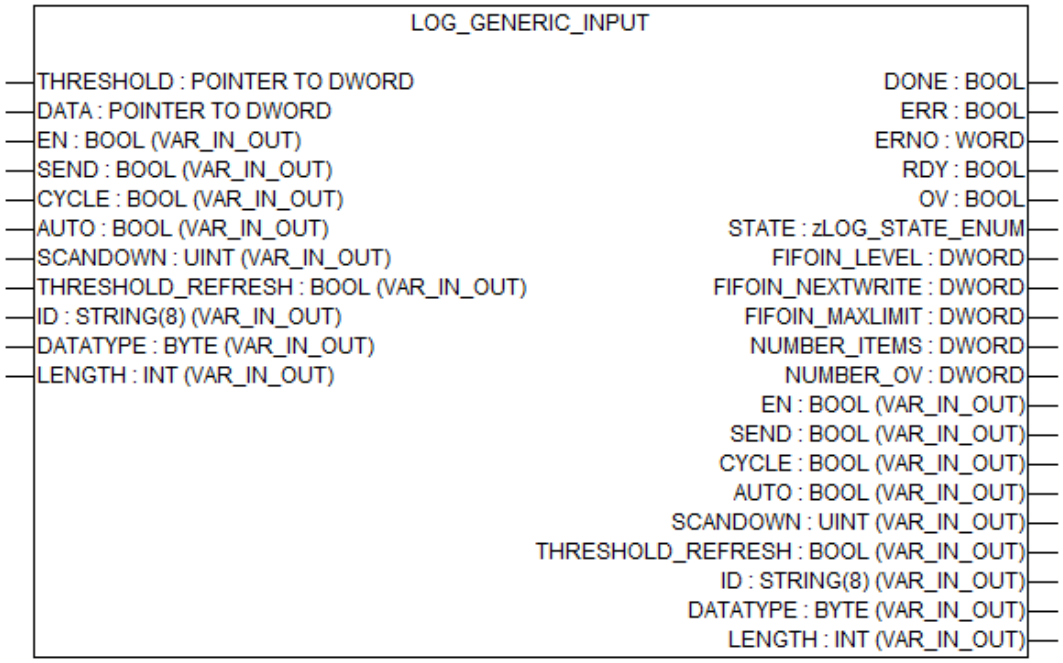

Table 252: General information

Available as of runtime system	V2.3 and above
Included in library	LogData_AC500_V23.lib
Type	Function block with historical values

At the same time, this function block writes data sets of the data types 1=BOOL, 2=BYTE, 3=INT, 4=WORD, 5=DINT, 6=DWORD, 7=REAL with a max length of 32 values into the SRAM-FIFOin of the Datalogger.

The data sets are written in format *.csv as two-dimensional ARRAY. Every part of each data set is separated by SEMICOLON. Each data set is ended with a CR/LF. Every segment of the %R area of the SRAM-FIFOin contains maximum one ARRAY[0..160] OF ARRAY[0..399] OF BYTE. The ARRAY reserves the complete segment 1 of the %R area of the controler.

A complete segment (segment 1 of the %R-area) is used for the SRAM-FIFOin (zLOG_CONST_FIFOLIMIT =160).

The function block writes data sets in the SRAM-FIFOin of the controller and doesn't send them directly to a central control station. This is done by the user. With the function block LOG_GENERIC_OUTPUT the data to be sent are provided as an interface.

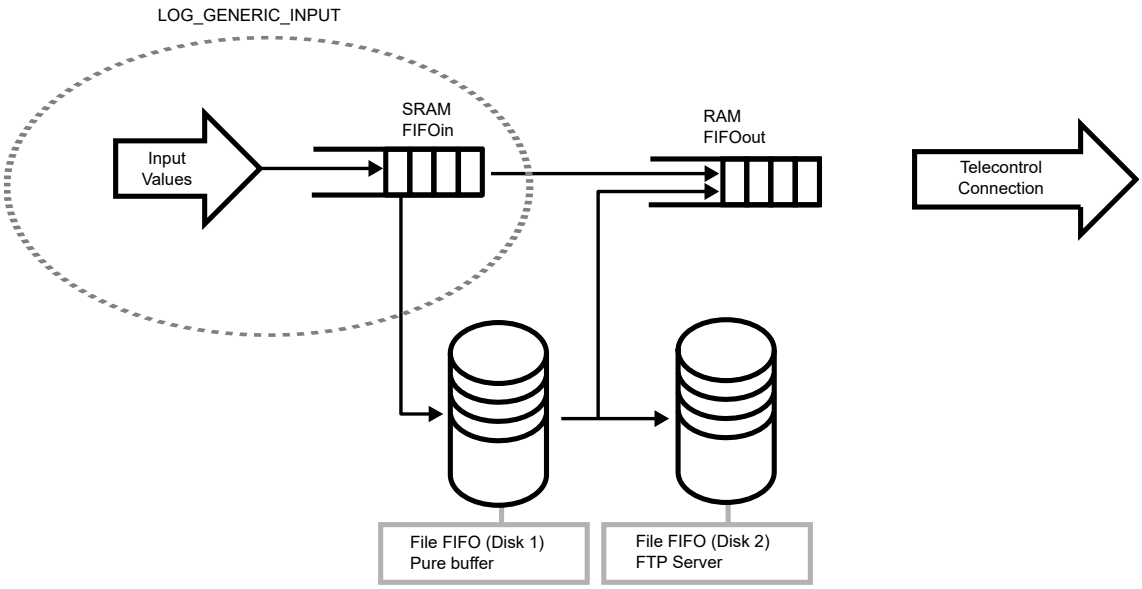

Fig. 709: Functionality

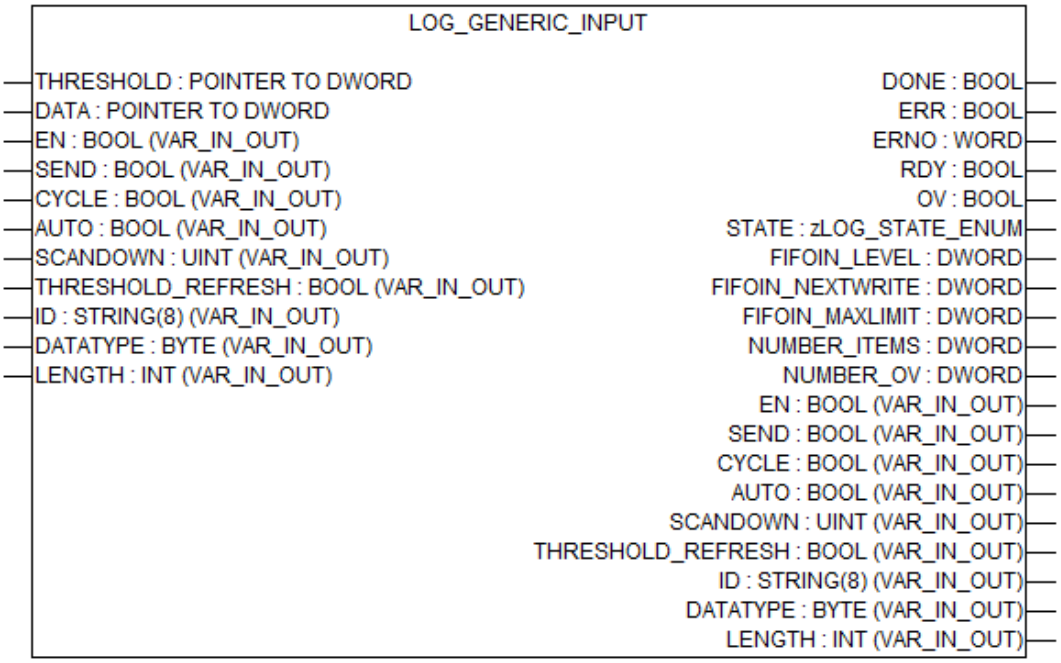
CAUTION!
Each used instance of the function block needs only one cycle for writing the data into FIFOin. For "n" succeeding instances called in the same cycle, "n" entrances/data sets are entered into FIFOin. Consider that FIFOin is limited by the limit of the segments of the %R area. That means, the upper limit of entries to FIFOin at the same time (in the same cycle) is 160.

Input Description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

THRESHOLD (threshold via ADR-Operator)

Data type: POINTER TO DWORD

When exceeding or falling below a threshold, a writing operation of a data set into the FIFOin is started. After this operation, either only the single threshold difference (between input and threshold) is deleted (TH_REFRESH=FALSE) or all differences (TH_REFRESH=TRUE). As the input is a POINTER TO, it has to be connected to an preceding ADR-Operator, to which any available input-type can be provided: BOOL, BYTE, INT, WORD, DINT, DWORD, REAL or an ARRAY of these data types. Make sure that THRESHOLD is always of the same type as in IN. E.g. if IN is an ARRAY[0..n] OF BYTE, THRESHOLD has to be an ARRAY[0..n] OF BYTE, too.

The input is only relevant for IN_TYPE's 2=BYTE, 3=INT, 4=WORD, 5=DINT, 6=DWORD, 7=REAL, not for bool/digital. For the IN_TYPE 1=BOOL, TRESHOLD has no effect, as the inputs are of the type BOOL and therefore cannot have a threshold.

DATA (input via ADR-Operator)

Data type: POINTER TO DWORD

Input value as single value or as ARRAY for the possible 0 to 31 values. As the input is a POINTER TO, it has to be connected to a preceding ADR-Operator, to which any available input-type can be provided: BOOL, BYTE, INT, WORD, DINT, DWORD, REAL or an ARRAY of these data types.

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SEND (send)

Data type: BOOL

At a rising edge, this input writes a data set into the FIFOin

CYCLE (cycle)

Data type: BOOL

This input writes all SCANDOWN cycles of a data set into FIFOin. At SCANDOWN=0 a data set is written in each cycle.

AUTO (auto)

Data type: BOOL

With each change of an input value or exceeding/falling down of THRESHOLD, this input writes a data set into FIFOin.

SCANDOWN (scandown)

Data type: UINT

This input will be valid if input CYCLE = TRUE. Then cyclical writing is only executed within each scandown cycle.

Example	SCANDOWN=100: In one out of 100 cycles a data set is written to FIFOin. SCANDOWN=0: In every cycle a data set is written.

THRESHOLD_REFRESH (threshold refresh)

Data type: BOOL

FALSE: Deletion of the threshold value difference of each input value after its overwriting of the threshold level. All other differences will be ignored if they have not yet been rising above their threshold. A higher trigger rate can be expected.

TRUE: Deletion of all threshold value differences after exceeding one of the thresholds. All other differences will also be cleared even if they have not yet been exceeded the threshold. A lower trigger rate can be expected. As always all data of the Funciton Block are sent, the data values are anyway always up to date.

The input is only relevant for IN_TYPE’s 2=BYTE, 3=INT, 4=WORD, 5=DINT, 6=DWORD, 7=REAL, not for bool/digital.

For the IN_TYPE 1=BOOL the input TRESHOLD has no effect, as the inputs are of the type BOOL and therefore cannot have a threshold.

ID (identity)

Data type: STRING

Free selectable name/text for identification of this data set. Maximum 8 characters.

DATATYPE (Datatype)

Data type: BYTE

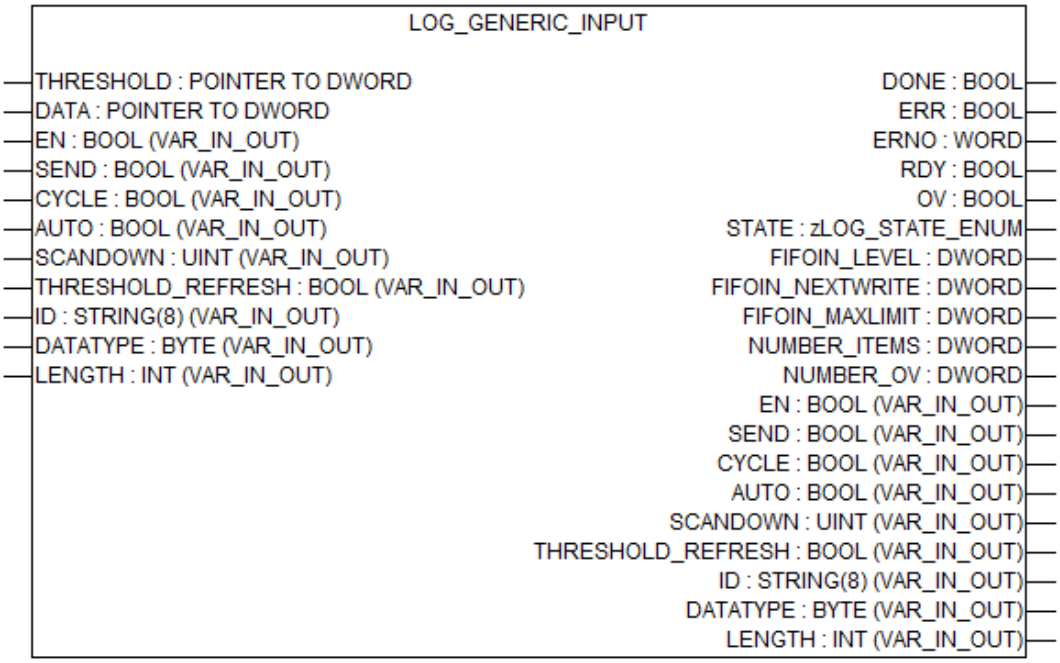
1=BOOL, 2=BYTE, 3=INT, 4=WORD, 5=DINT, 6=DWORD, 7=REAL

LENGTH (length of valid values)

Data type: INT

Number of valid values (maximum 88 values, depending of type).

Output Description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

Monitoring of the global constant diconFIFOmaxLimit defined in the the segment 0 of the %R area. Error in case of diconFIFOmaxLimit < 1 or diconFIFOmaxLimit > 1120.

RDY (ready)

Data type: BOOL

Output will be TRUE, if a command is been received. As this is only true for one cycle, also RDY = TRUE for one cycle only.

OV (overrun)

Data type: BOOL

Output will be TRUE, if an overflow occurs. On this output a rising edge (FALSE -> TRUE) shows that the transmit requests are coming too fast and thereby the SRAM-FIFOin is fully filled.

STATE (enumeration of type zLOG_STATE_ENUM)

Data type: zLOG_STATE_ENUM

Clear text messages of errors and states. The output uses the enumeration of the data type zLOG_STATE_ENUM declared in "data types".

FIFOIN_LEVEL (FIFOin level)

Data type: DINT

Output represents the current level of SRAM-FIFOin %R area (zLOG_FIFOIN_LEVEL).

FIFOIN_NEXTWRITE (next write position in FIFOin)

Data type: DINT

Shown is the next write position in SRAM-FIFOin %R area (zLOG_FIFOIN_NEXTWRITE).

FIFOIN_MAXLIMIT (max number of data sets in FIFOin)

Data type: DINT

Shows the value of the constant FIFOLIMIT of the data sets in SRAM-FIFOin %R area (zLOG_CONST_FIFOLIMIT).

NUMBER_ITEMS (max number of items)

Data type: DINT

Shows the executed write operation into the SRAM-FIFO since EN=TRUE.

NUMBER_OV (max number of overflow-items)

Data type: DINT

Shows the not executed write operations into the SRAM-FIFO since EN=TRUE.

Integrated Visualization

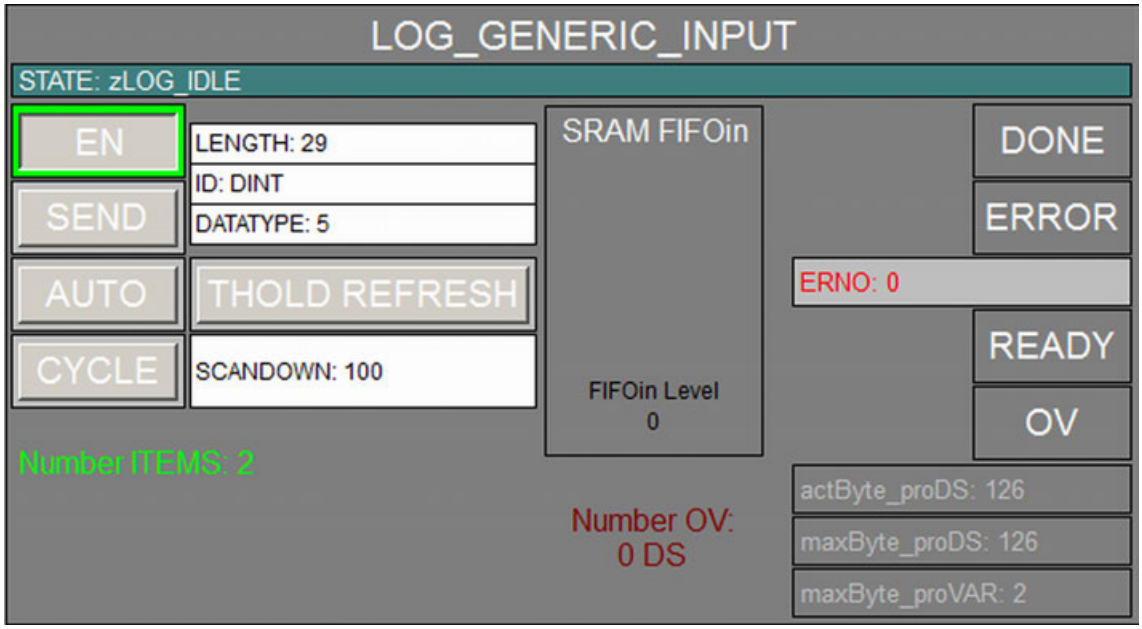

Fig. 712: Visualization

1.5.13.2.6 LOG_GENERIC_OUTPUT

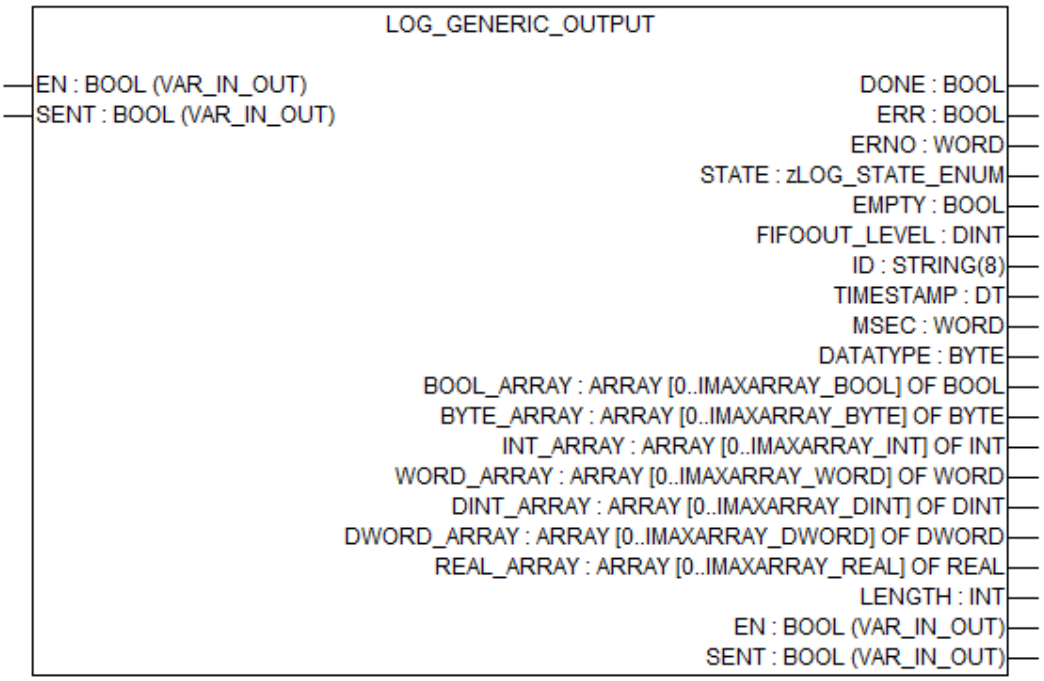

Table 253: General information

Available as of runtime system	V2.3 and above
Included in library	LogData_AC500_V23.lib
Type	Function block with historical values

This function block provides a decoded data set of the corresponding data types from the SRAM-FIFOout of the Datalogger. The function block does not cover the transmission of the data set. But it provides an interface for the user on which the data can be read and send according to application specific requirements and protocols.

The function block automatically reads the oldest data set at a filling level of FIFOout > 0. Then the function block decodes the data set from *.csv format and provids it to the outputs. The function block signals its availability through DONE = TRUE and STATE = zLOG_OUTPUT_DATA_AVAILABLE. If this data set is processed by the user, the user will have to signal this by SENT = TRUE to the function block. By the edge 0/1 the RAM-FIFOout is decremented by the value 1, DONE changes to "FALSE" and on the output STATE the text "zLOG_OUTPUT_DATA_HAS_BEEN_SENT" appears. By a 1/0 edge on SENT the function block reads the next data set (which is the same as the self triggered read without command, as long as SENT = false). This happens until FIFOOUT_LEVEL=0" and the function block signals "EMPTY". At the same time at output STATE the message "zLOG_FIFOOUT_EMPTY" is given and all output values are deleted. While existing communication and exhausted FILE-FIFO the data sets, newly written by LOG_GENERIC_INPUT to the (in the %R area residing) FIFOin are continuously copied by the LOG_HANDLING directly to the (in the %M-area residing) FIFOout, as soon as there is space in the FIFOout for new data sets. For this the FIFOout should not be empty (EMPTY). It is different when FILE-FIFO is not empty. In this case at first FIFOout is fully decremented until FIFOOUT_LEVEL=0 and the function block signals "EMPTY". After that a new data set block is copied from FILE-FIFO into FIFOout. The capacity of the RAM-FIFOout per segment of the %M-area is at max ARRAY[0..160] OF ARRAY[0..399] OF BYTE. The ARRAY ocupies the complete segment 1 in the %M area of the CPU.

A complete segment (segment 1 of the %R-area) is used for the SRAM-FIFOin (zLOG_CONST_FIFOLIMIT =160).

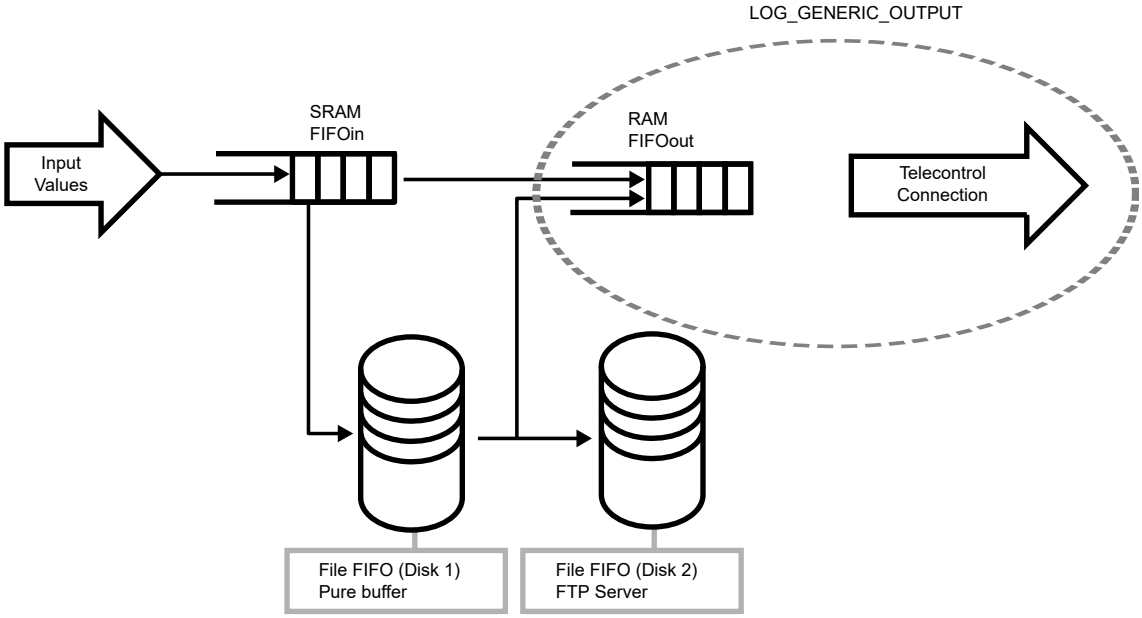

Fig. 713: Functionality

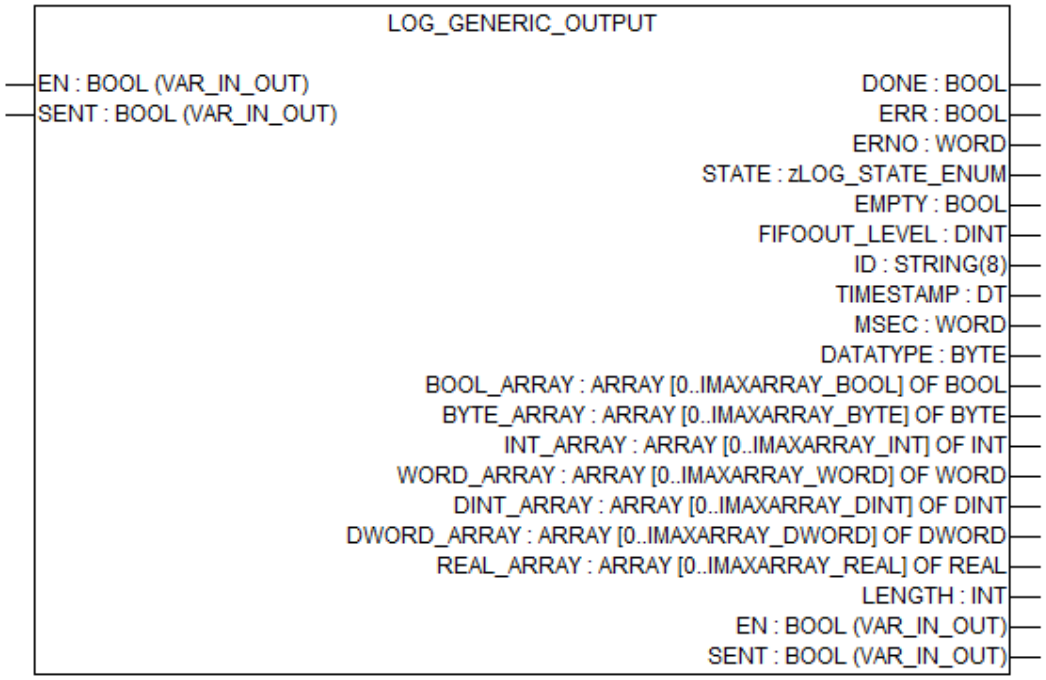
Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

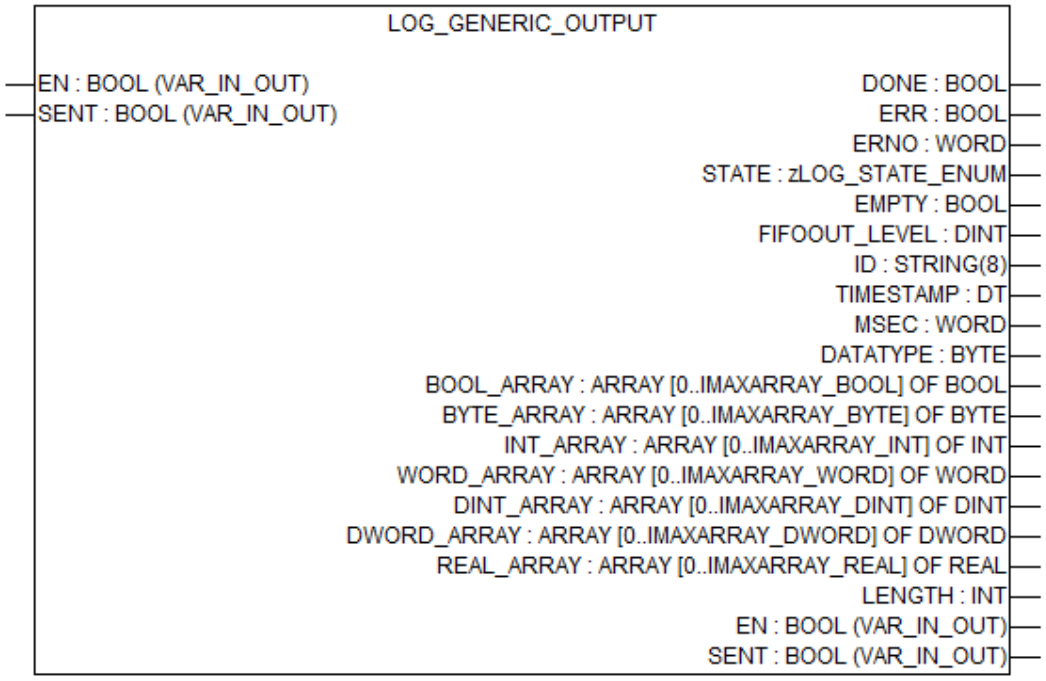
While it is executed its inputs are continuously evaluated.

SENT (output data were sent)

Data type: BOOL

Feedback from the user program that the currently provided data set was sent. By the 0/1 edge the RAM-FIFOout is decremented by a value of 1 (FIFOOUT_LEVEL -1). DONE changes to "FALSE" and on the output STATE the text "zLOG_OUTPUT_DATA_HAS_BEEN_SENT" appears. By the 1/0 edge on SENT the function block reads the next data set (it is the same as the automatic reading without a command, as long as SENT = FALSE).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

STATE (enumeration of type zLOG_STATE_ENUM)

Data type: zLOG_STATE_ENUM

Clear text messages of errors and states. The output uses the enumeration of the data type zLOG_STATE_ENUM declared in "data types".

EMPTY (empty)

Data type: BOOL

FIFOout "EMPTY" is shown.

FIFOOUT_LEVEL (level FIFOout)

Data type: DINT

The current level of RAM-FIFOout %M area (zLOG_FIFOOUT_LEVEL) is displayed.

ID (identity)

Data type: STRING(8)

Output of the ID or name of the data set as string chain (no special characters), maximum 8 characters.

TIMESTAMP (timestamp)

Data type: DT

Output of the time stamp of the data set in the format year-month-day-hour-minute-second.

MSEC (milliseconds of timestamp)

Data type: WORD

Output of the milliseconds of the time stamp of the data set.

DATATYPE (data type of data set)

Data type: BYTE

Output of the data set data type: 1=BOOL, 2=BYTE, 3=INT, 4=WORD, 5=DINT, 6=DWORD, 7=REAL.

BOOL_ARRAY (array 0..57 of bool)

Data type: ARRAY[0..57] OF BOOL

Output of the data set as ARRAY OF BOOL (max 58 values).

BYTE_ARRAY (array 0..87 of byte)
Data type: ARRAY[0..87] OF BYTE
Output of the data set as ARRAY OF BYTE (max 88 values).

INT_ARRAY (array 0..49 of int)
Data type: ARRAY[0..49] OF INT
Output of the data set as ARRAY OF INT (max 48 values).

WORD_ARRAY (array 0..57 of word)
Data type: ARRAY[0..57] OF WORD
Output of the data set as ARRAY OF WORD (max 58 values).

DINT_ARRAY (array 0..28 of dint)
Data type: ARRAY[0..28] OF DINT
Output of the data set as ARRAY OF DINT (max 29 values).

DWORD_ARRAY (array 0..30 of dword)
Data type: ARRAY[0..30] OF DWORD
Output of the data set as ARRAY OF DWORD (max 31 values).

REAL_ARRAY (array 0..26 of real)
Data type: ARRAY[0..26] OF REAL
Output of the data set as ARRAY OF REAL (maximum 27 values).

LENGTH (length of valid values)
Data type: INT
Number of valid values (maximum 88 values, depending of type).

1.5.14 Pumping library 2

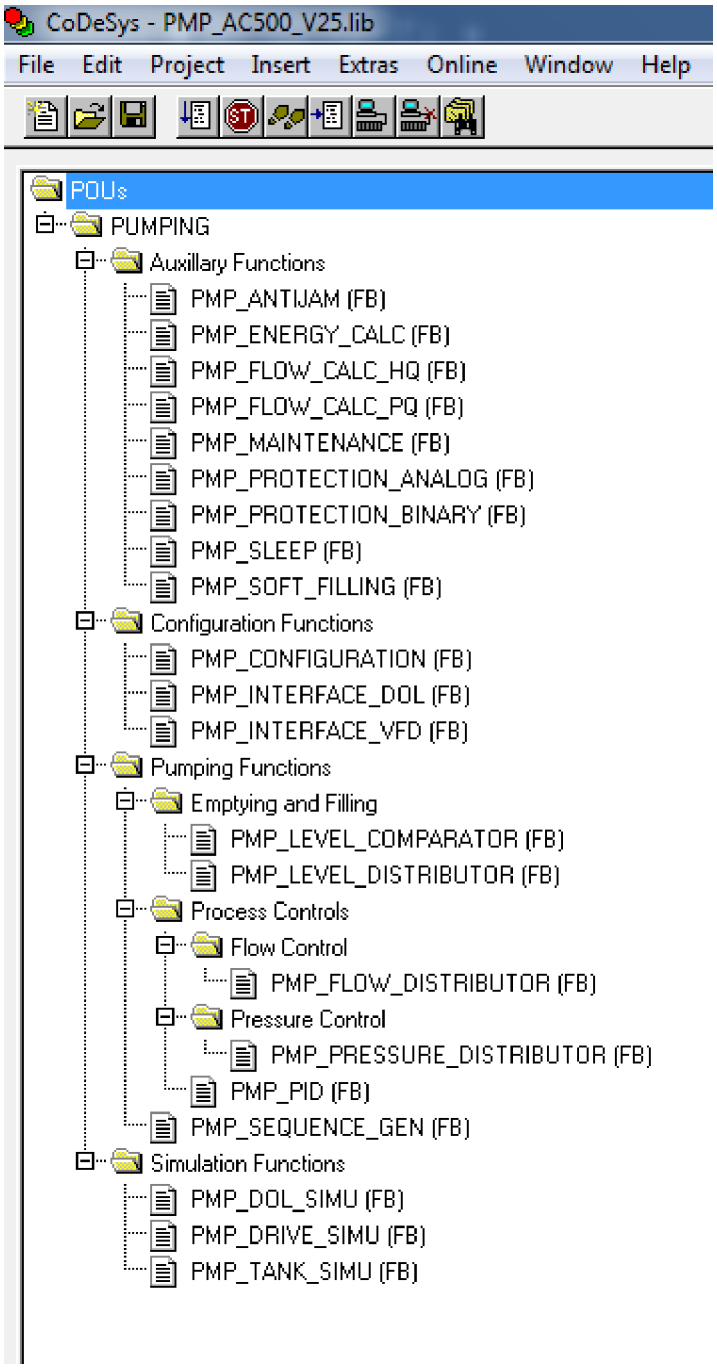
1.5.14.1 System technology

1.5.14.1.1 Components of pumping library

Overview

> *The pumping library, AC500_PMP_V25.lib is the extension and improvement in the library AC500_PUMP_V23.lib.*

The pumping library functions are categorized as follows. Refer to the figure below from the library itself.



The library contains function blocks needed for functions of pumping application (pressure control, flow control or level control).

It also contains function blocks for some advanced functions needed for different applications.

Compatibility

The library is compatible with following versions.

Type	Version
Pumping Library	**PMP_AC500_V25.lib**
Automation Builder	V2.0 and later

Required sensors

A minimal sensor equipment is required for the following measurements:

- Actual pressure measurement for pressure control.
- Actual flow measurement for flow control.
- Actual level measurement for level control.

The pressure sensor can be at the input and/or at the output. The flow sensor should be only at the output.

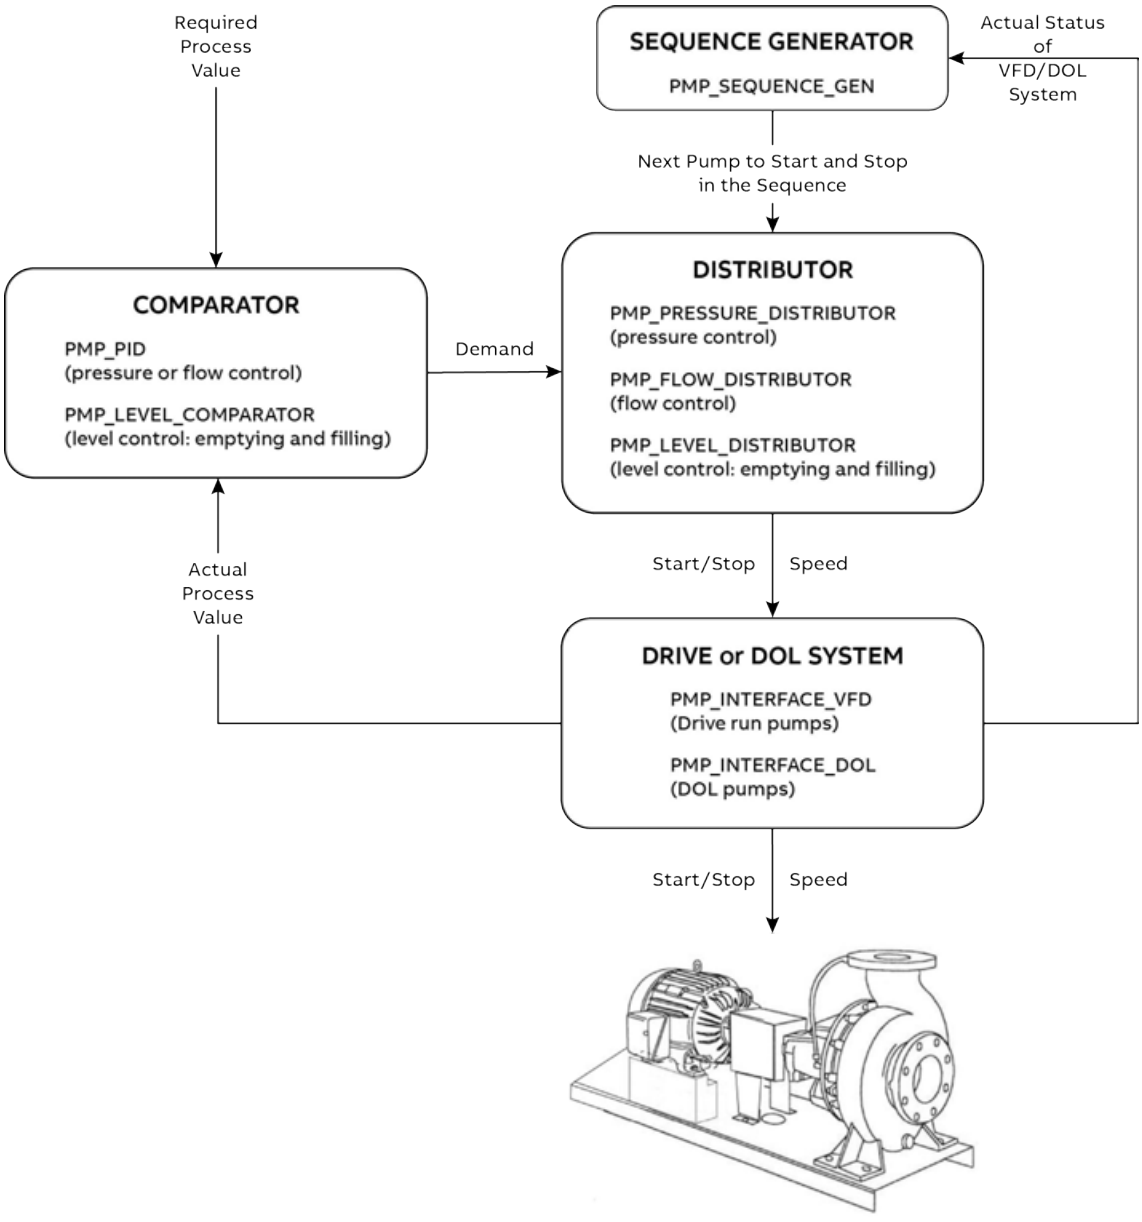
Often, at the input a sensor, typically pressure, is placed for advanced protection and diagnosis.

1.5.14.1.2 Control philosophy of pumping library

The Pumping library is used for controlling the following three water pumping processes:

- Pressure control
- Flow control
- Level control – Emptying or filling

The figure below gives an overview of the pumping library and explains how the library processes the data from the user and then controls the processes.



To run any process, the pumping library follows the four stages described below:

Stage 1: Comparator

The set process value (e.g., pressure in psi, flow rate in m^3/h) is compared with the measured actual value. The distributor uses the output of the comparator to decide the number of pumps and their operating speeds to meet the demand.

- **Pressure control and Flow control:**
  In pressure and flow controls, the function block PMP_PID acts as a comparator which gives the PID_OUT in [%] to the function block PMP_PRESSURE_DISTRIBUTOR or PMP_FLOW_DISTRIBUTOR. In the distributor the PID output is then converted as reference speed set point to the pumps.
- **Emptying or Filling mode:**
  In emptying or filling modes, the function block PMP_LEVEL_COMPARATOR is used to compare the actual level of the tank with the set levels to start or stop the pumps. This information is sent to the distributor by the output N_DEMAND. For example, in filling mode, at lower actual level more pumps are needed to run to fill the tank.

Stage 2: Sequence generator

The PMP_SEQUENCE_GEN function block is used. The following functions are included:

- Decides which pump is ready to run in the auto mode.
- Decides which pump to start in the sequence, based on the least actual runtime hours.
  Exception – when the pump station is traditional type (with master pump on VFD, rest on DOL), then the pump ID = 1 which is attached to the VFD will always run as master and is first to start and last to stop.
- Decides which pump to stop in the sequence, based on the highest actual runtime hours.
  Exception – when the pump station is traditional type (with master pump on VFD, rest on DOL), then the pump ID = 1 which is attached to the VFD will always run as master and is first to start and last to stop.
- Assigns a master status to the pump in the sequence.
- Indicates how many pumps are ready for automation and how many are running.

The figure below explains a use case where the demand increases and then decreases. The sequence is generated based on this criteria by the function block PMP_SEQUENCE_GEN.

DEMAND	1	2	3	4	5	6	7	8	7	6	5	4	3	2	1
Master	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
Next Pump to Start	2	3	4	5	6	7	8		2	Whichever pump has minimum runtime will start next					
Next Pump to Stop	1	2	2	2	2	2	2	2	3	4	5	6	7	8	1
Pumps running	1	1, 2	1, 2, 3	1, 2, 3, 4	1, 2, 3, 4, 5	1, 2, 3, 4, 5, 6	1, 2, 3, 4, 5, 6, 7	1, 2, 3, 4, 5, 6, 7, 8	1, 3, 4, 5, 6, 7, 8	1, 4, 5, 6, 7, 8	1, 5, 6, 7, 8	1, 6, 7, 8	1, 7, 8	1, 8	1

Stage 3: Distributor

The distributor function block distributes the start/ stop command and speed reference to all VFD operated pumps.

- • Pressure control: For pressure control, the function block PMP_PRESSURE_DISTRIBUTOR is used. The PID output coming from the function block PMP_PID (comparator) is converted as reference speed setpoint to the master pump. The function works based on the reference speed of the master pump. If the reference speed is higher, more number of pumps are needed to meet the demand. If the reference speed is lower, the already running pumps in the network need to be stopped. The function block:
  - Calculates the speed reference of the master pump and then starts/ stops the follower pumps based on the settings in the inputs START_SPEED_FWR or STOP_SPEED_FWR.
  - Distributes the speed references to VFD follower pumps based on the settings in the input FOLLOWER_MODE.
- Flow control: For flow control, the function block PMP_FLOW_DISTRIBUTOR is used.
  - In the flow distributor the number of pumps to run is decided by the following ratio: FLOW_SETPOINT/ (NUMBER OF PUMPS IN STATION * NOMINAL FLOW OF PUMP).
  - The function block distributes the speed references to VFD follower pumps based on the settings in the input FOLLOWER_MODE.
- Emptying/Filling mode: For emptying or filling operation, the function block PMP_LEVEL_DISTRIBUTOR is used. The function block starts/ stops the pumps based on the input N_DEMAND (demand) which it receives from function block PMP_LEVEL_COMPARATOR.
  - If the actual level is in the normal range, then the speed reference of the pumps are based on the input NORMAL_SPEED.
  - If for example while filling the actual level reaches below the LOW_LEVEL, then all pumps run at HIGH_SPEED, to quickly fill the pump. Similar analogy is followed when the pump is in emptying mode.

Stage 4: DRIVE or DOL system

The output of the distributors (AUTO_START_CMD and AUTO_SPEED_REF) are connected to function block PMP_INTERFACE_VFD and PMP_INTERFACE_DOL. The function blocks establish the link between library and field devices i.e. pumps.

- For pumps driven by VFD motors, the function block PMP_INTERFACE_VFD can be connected with the drives communication function blocks to establish communication and control with the VFD.
- For pumps driven by DOL motor, the function block PMP_INTERFACE_DOL can be used for start/stop controls.

For more information, see the detailed controlled philosophy in the following sections.

1.5.14.1.3 Application functions

There are three main application and control function blocks:

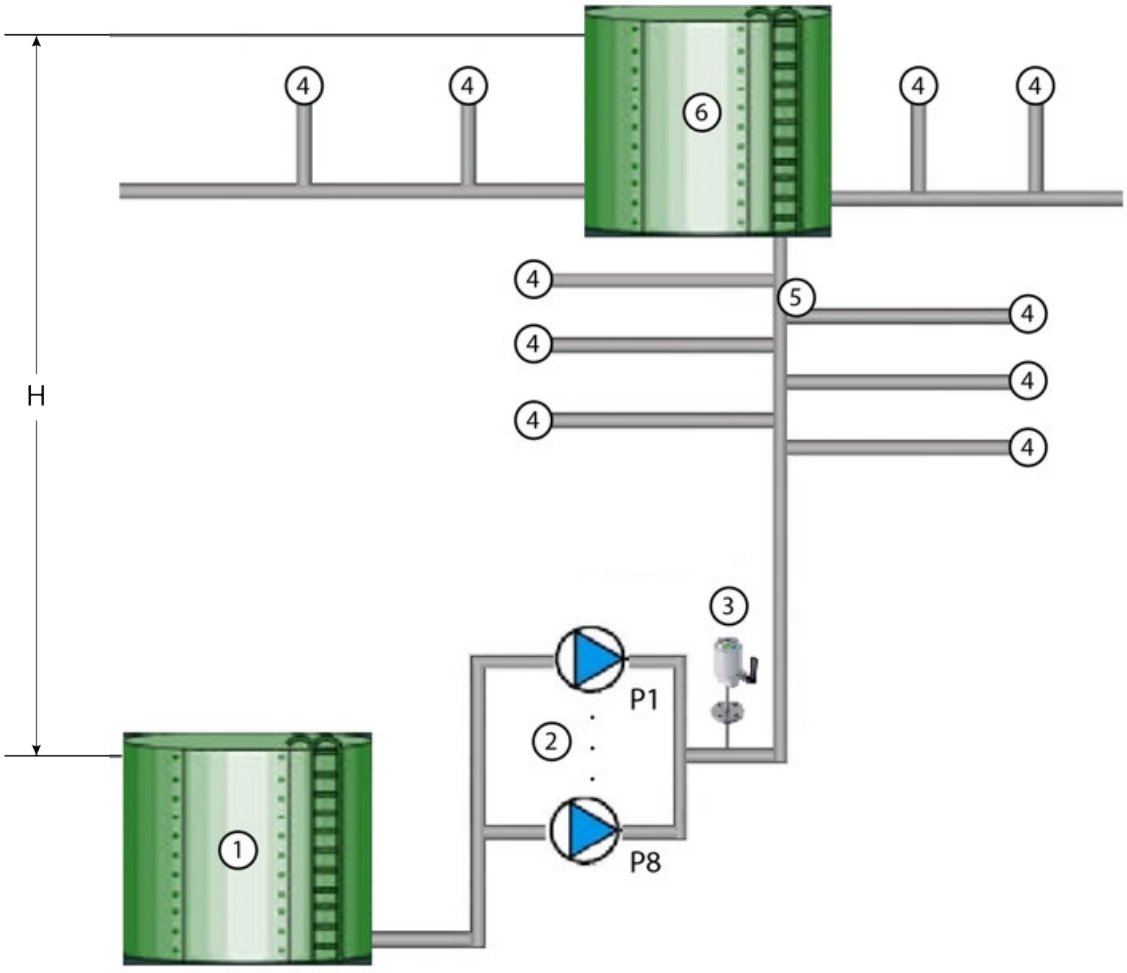
- Pressure control function blocks
- Flow control function blocks
- Level-control function block

Pressure control function block

Pressure control process flow diagram

Pressure control is used in applications with individual or multiple water consumers.

A typical pressure control application diagram is shown below.



1 Suction tank
2 Parallel operating pumps P1 ... P8
3 Pressure setpoint, discharge pressure
4 Consumer
5 Water distribution network
6 Water tower buffer tank
H Water head between the levels in the suction tank and water tower buffer tank

Using pressure control

Pressure control in the pumping library can help in the following operations:

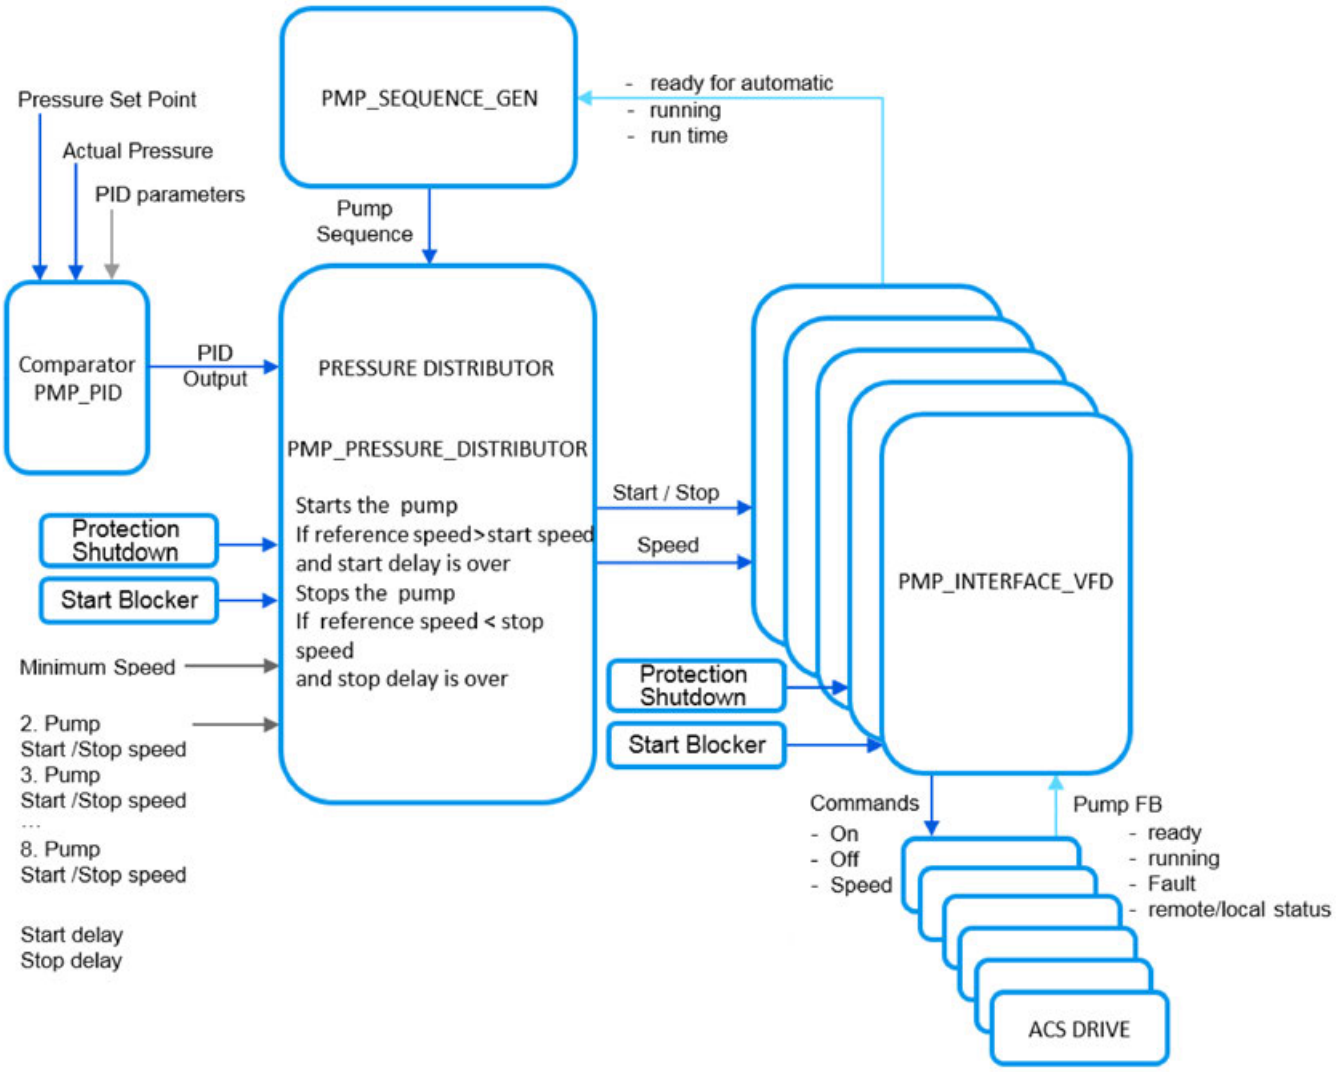
- Water consumption fluctuates always and may be discontinuous over a time period, because of which it is difficult to have a continuous flow rate like in the flow control process.
- The number of pumps and the pump speed is decided by the water consumption in the water distribution system.
- Water is supplied to the pump station through suction pipeline from a suction tank.
- The pumps may be operating in parallel.
- The discharge pressure is measured in the discharge pipeline. The measured discharge pressure is controlled according to the pressure set point.
- Each pump must be started with a minimum speed to build up the pressure which is required to produce a minimum flow.
- The pressure to deliver a minimum flow depends of the water head (H) between the water levels in the suction tank and target tank.
- If there is pump station shutdown due to protection shutdown input, the pumps must be stopped sequentially to prevent water hammering.
- Variable speed drives should be stopped through a speed ramp. Otherwise the water hammering will quickly wear out the pipeline connections and the pump station equipment.

Pump combinations for pressure control

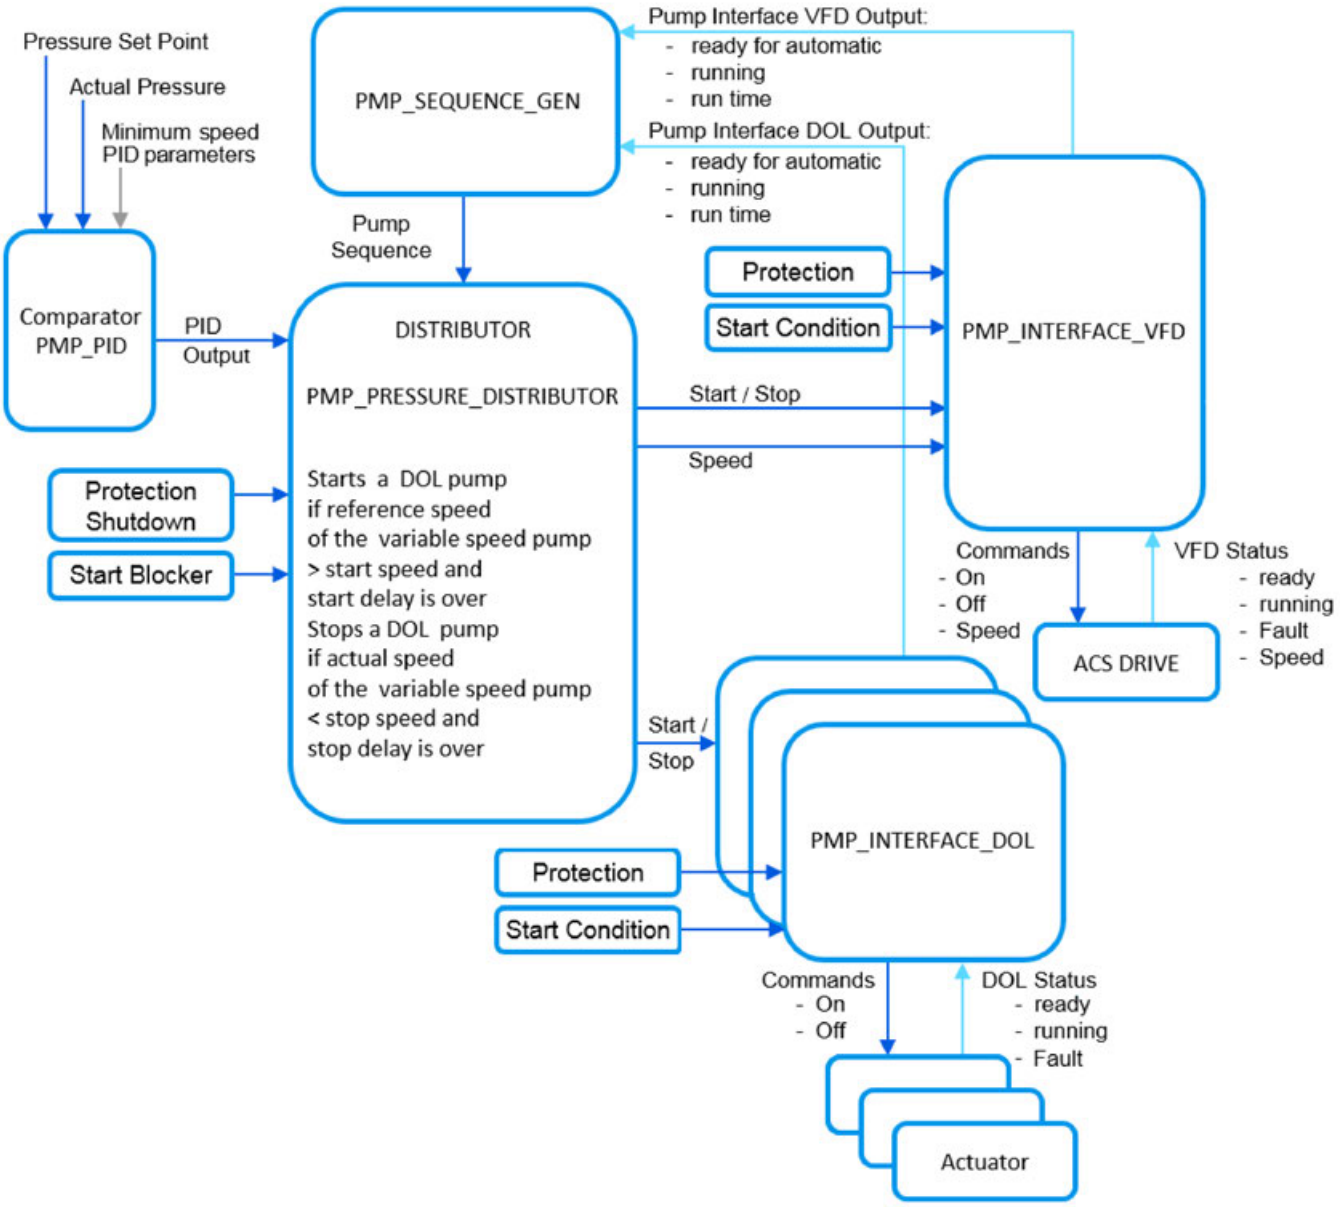
Pressure control mode works for two types of pump combinations: Multi pump and traditional pump.

The combination of function blocks to execute a pressure control is shown in the figures below.

- Multi pump – In this mode all pumps are run using VFDs.



- Traditional pump – In this mode only one pump is run using the VFD and the rest of the pumps are run using the Direct On Line (DOL) motors.



Pressure control mode is not supported by DOL pump.

The combination with any VFD pump is necessary.

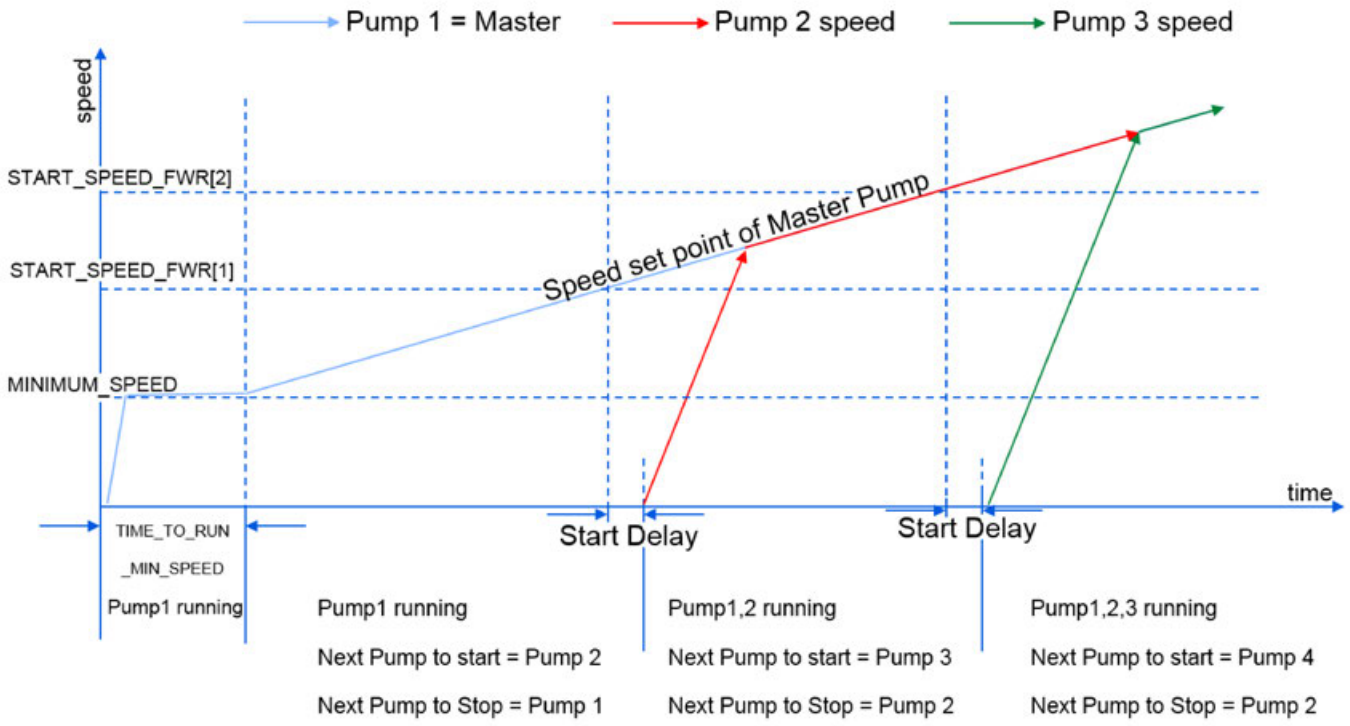
Control philosophy of pressure control mode

The pressure control mode follows this sequence of operation:

1. When the process is started, the first pump runs at MINIMUM_SPEED for the time defined in the TIME_TO_RUN_MIN_SPEED duration. With this process the pipe starts filling gradually and then the normal operation of PID control takes over.
2. The PID compares the required pressured and the actual pressure to generate the output in terms of percentage. This output must be connected to the function block PMP_PRESSURE_DISTRIBUTOR.

3. The function block PMP_PRESSURE_DISTRIBUTOR receives the PID_OUT. The distributor converts the PID output in terms of speed for the master pump.
4. The function block PMP_SEQUENCE_GEN has the MASTER_PUMP information.
5. The PID_OUT is scaled in terms of speed in this method:

   Speed reference of MASTER_PUMP = (NOMINAL_SPEED of MASTER_PUMP) * (PID_OUT/100)
6. As the PID output increases, the speed of the master pump increases. A higher PID output indicates a high demand. In case one pump is not able to cater the requirement, then more pump (followers) are needed to start and supply water to maintain the pressure.
7. If speed reference of the MASTER_PUMP increases such that it is more than the START_SPEED_FWR[1], then the first follower in the network will start. The information about which pump to start comes from function block PMP_SEQUENCE_GEN at the output PNSTART.
8. If the speed reference of the MASTER_PUMP increases further such that it is more than START_SPEED_FWR[2], then second follower pump starts. This sequence is followed till there is an increase in demand. See the timing diagram below.



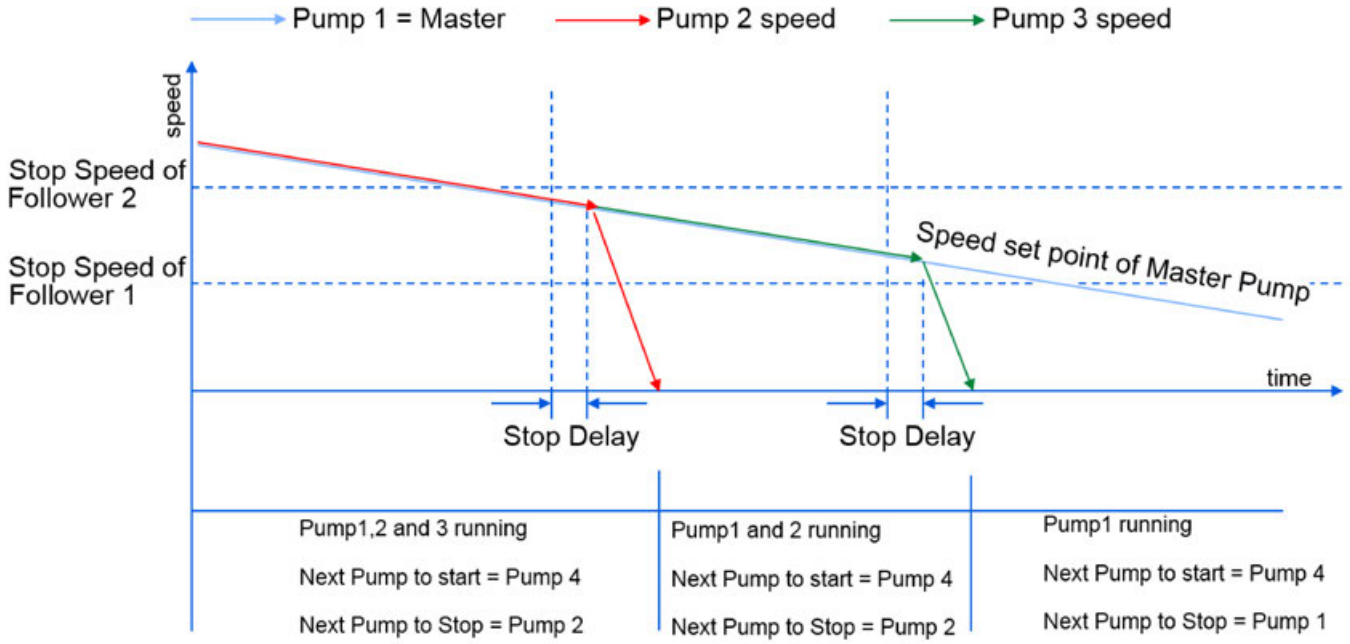
Speed setpoint of Master Pump = PID_OUT % * Nominal speed of master Pump

Start Delay: Delay time [s] to start the next pump

9. Similar when the demand decreases, the speed reference of master decreases. See the timing diagram below. As the speed reference of the master pump goes below STOP_SPEED_FWR[1], the first follower stops. The ID of next pump to stop comes from PMP_SEQUENCE_GEN as PNSTOP.

   If the speed reference of the MASTER_PUMP decreases further such that it is less than STOP_SPEED_FWR[2], then second follower pump stops. This sequence is followed till there is a decrease in demand.

> *The follower pumps in the above figure is considered to be in the FOLLOWER_MODE = 1, copy master speed. They can also run at their individual speed if FOLLOWER_MODE = 2, fixed speed.*



Speed setpoint of Master Pump = PID_OUT % * Nominal speed of master Pump

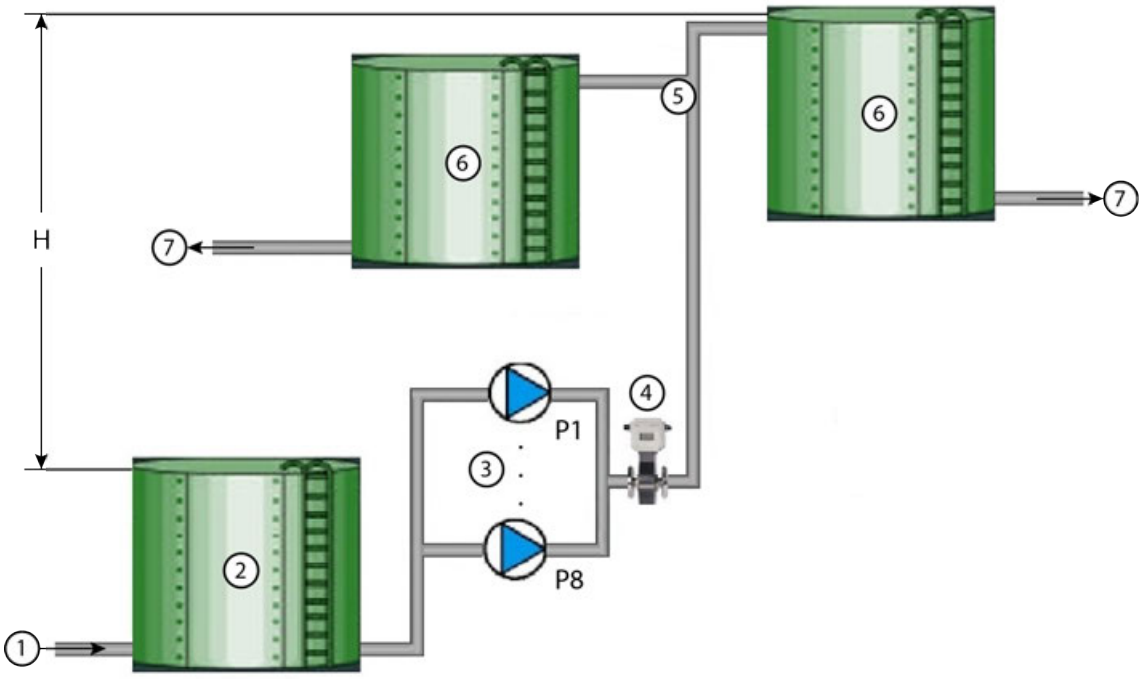
Stop Delay: Delay time [s] to stop the next pump

Flow control function block

Flow control process flow diagram

Flow control is used in applications where continuous flow distribution to one or more target tanks or reservoirs is needed.

A typical flow control application diagram is shown below.



1 From supply station
2 Suction tank
3 Parallel operating pumps P1 ... P8
4 Flow setpoint, discharge pressure
5 Water distribution network
6 Target tank/Reservoir
7 To next station or distribution network
H Water head between the levels in the suction tank and target tank

Using flow control

Flow control in the pumping library can help in followings pumping operations:

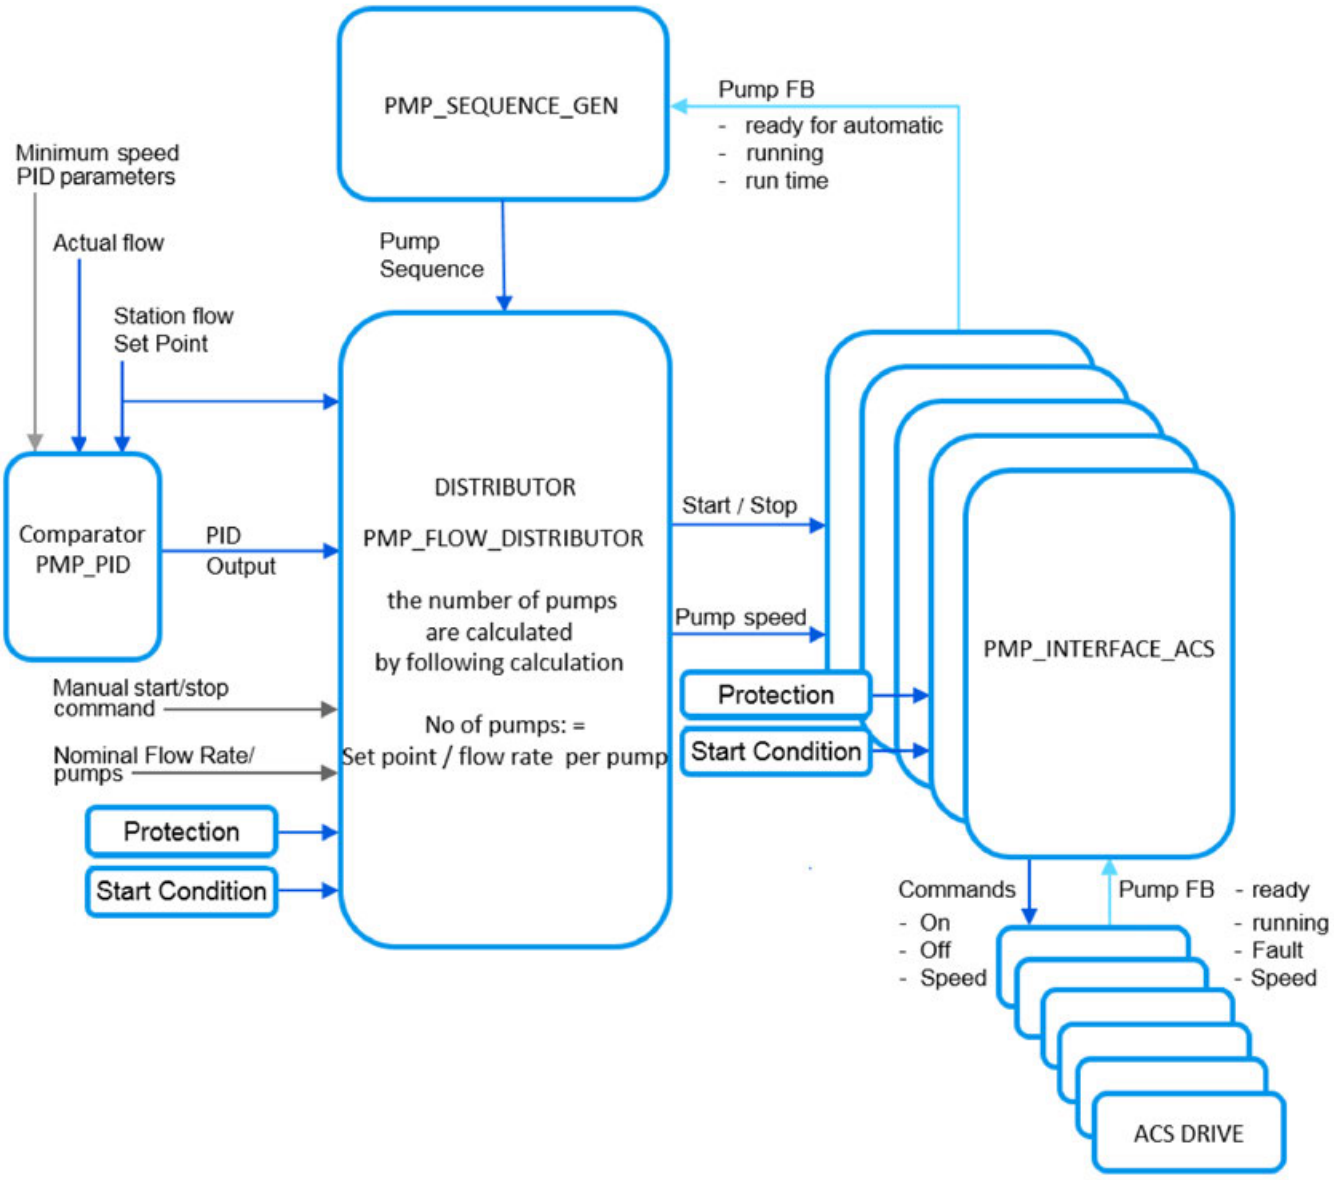
- Supplying water to the pump station through the suction pipeline from a suction tank.
- Operating pumps in parallel.
- Controlling continuous water flow over a time period.
- Measuring the discharge flow in the discharge pipeline.
- Defining the number of pumps and pump speed based on water flow demand (flow set point).
- Starting each pump with minimum speed to build up the pressure required to produce a minimum flow.

  The pressure depends on the water head (H) between the water levels in the suction tank and the target tank.
- In case of station shutdown stops the pumps sequentially to prevent water hammering.
- Stops variable speed drives through a speed ramp.

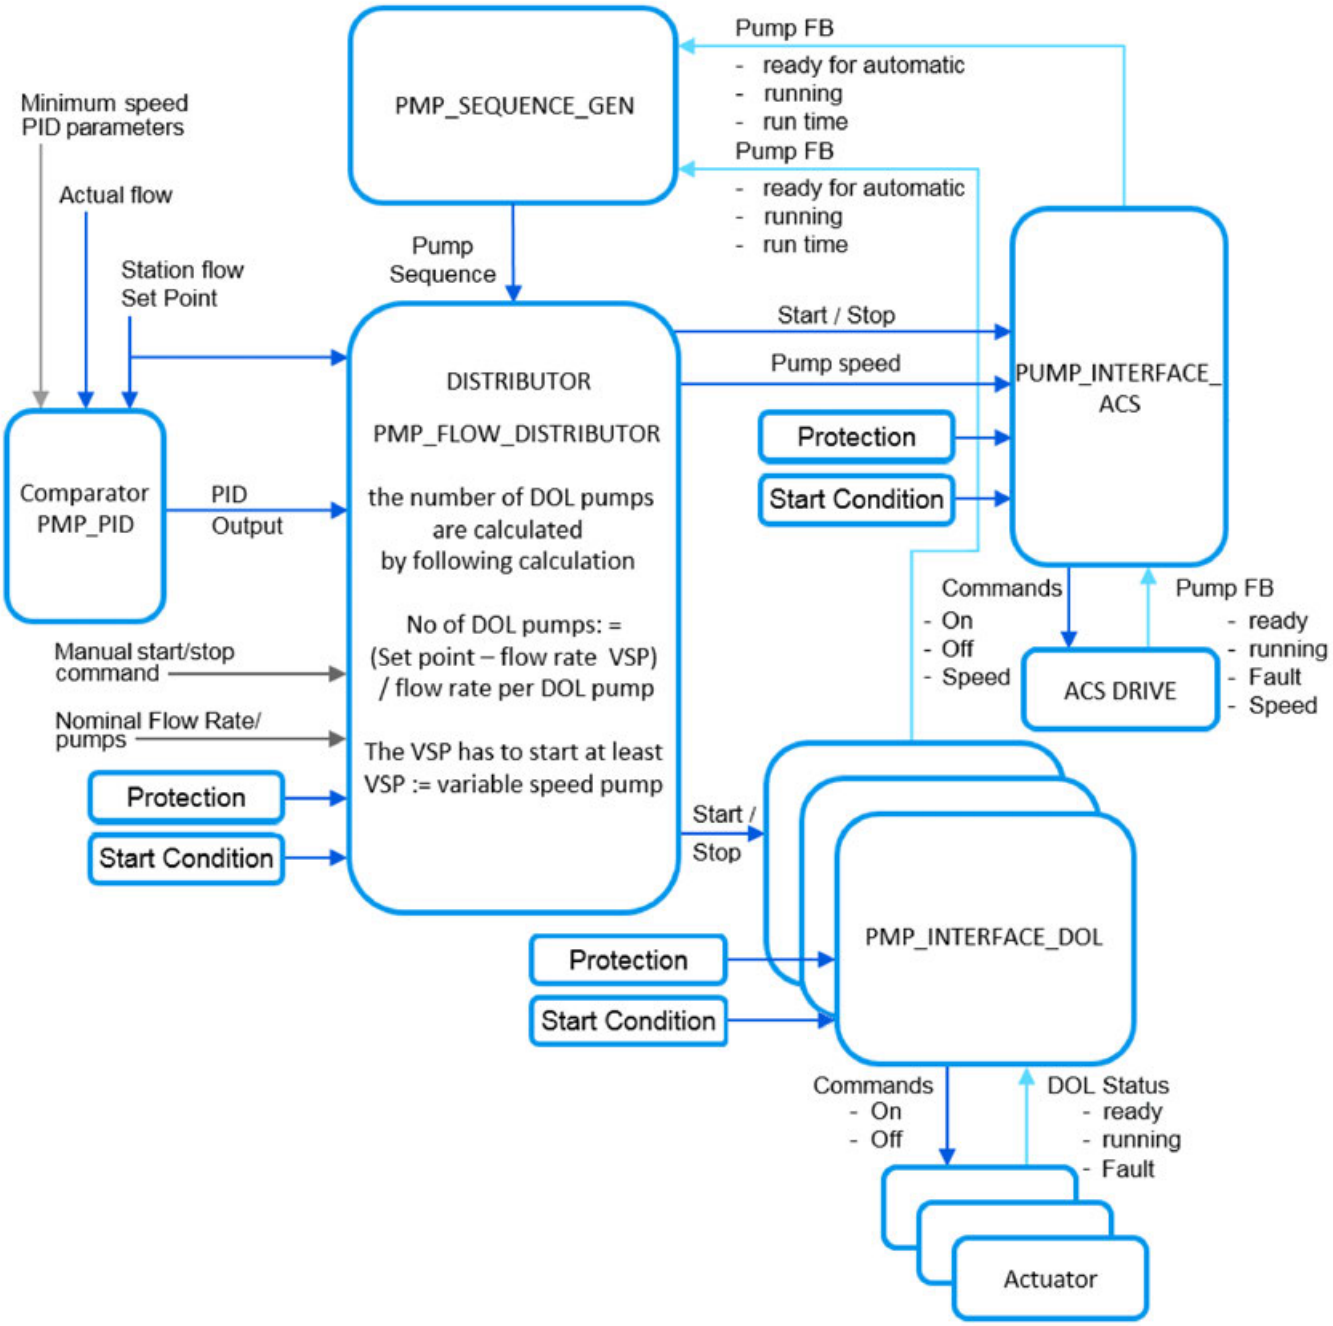
Pump combinations for flow control

Flow control works for all the three types of pump combinations: Multi pump, traditional pump, and DOL pump.

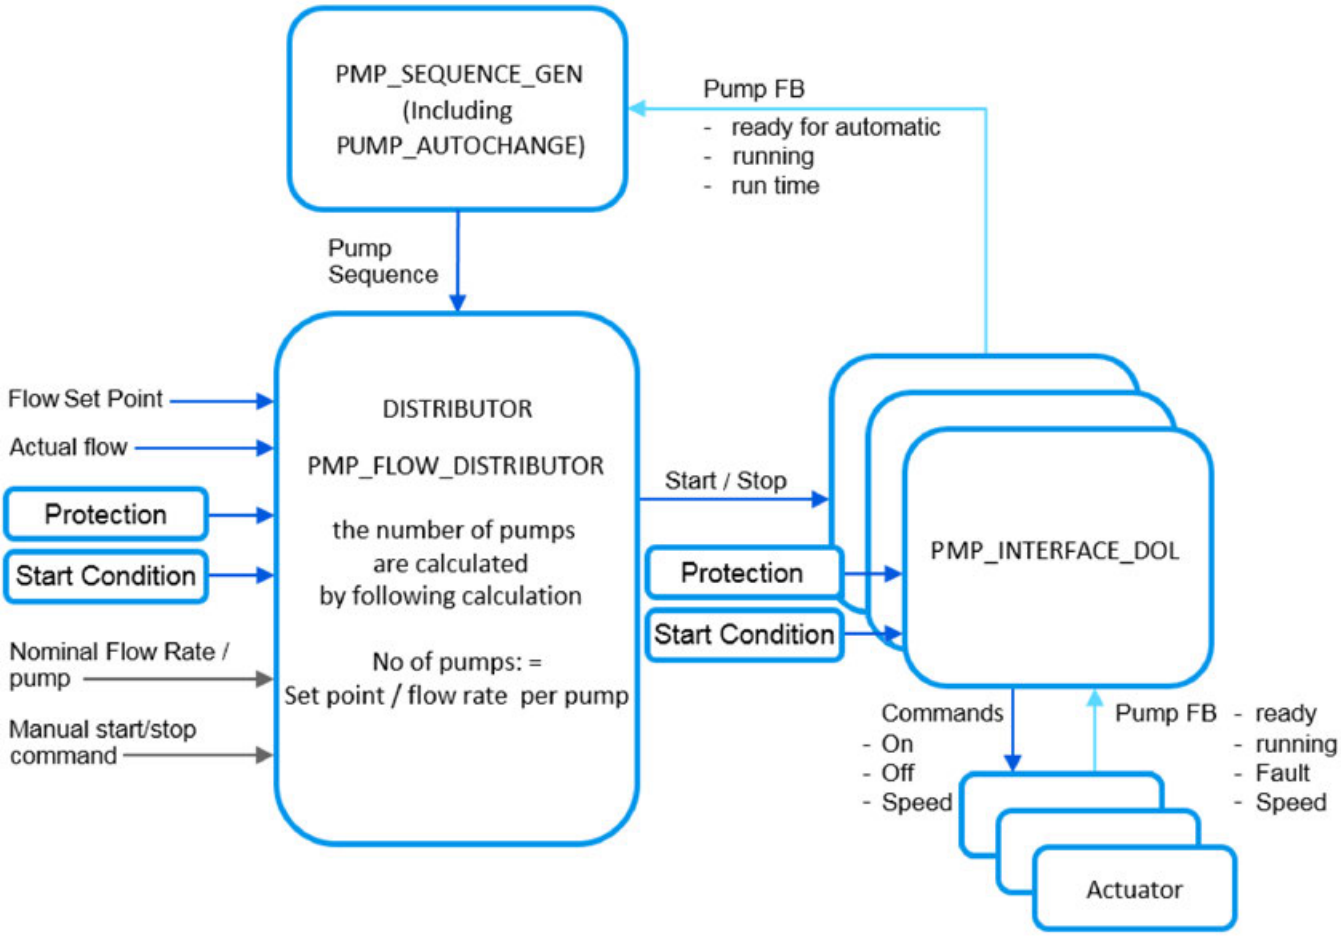
- Multi pump – In this mode all pumps are run using VFDs. See the example diagram below.



- Traditional pump – In this mode only one pump is run using the VFD and rest are run using the Direct On Line (DOL) motors. See the example diagram below.



- DOL Pump – In this mode all the pumps are operated by DOL motors. The function block PMP_PID is not configured as there is no possibility to change the speed of the pump. See the example diagram below.



Control philosophy of flow control mode

The above figures show the combination of function blocks to execute the flow control. As it can be seen,

- When the process is started, the first pump runs at the MINIMUM_SPEED for the time defined in the TIME_TO_RUN_MIN_SPEED duration. This is to gradually start filling the pipe. After this the normal operation of PID control takes over.
- The PID acts as a comparator: the PID compares the required flow and the actual flow to generate output in terms of percentage. This needs to be connected to the PMP_FLOW_DISTRIBUTOR.
- PMP_ FLOW _DISTRIBUTOR takes the PID_OUT. Then converts this output in terms of speed for the master pump. The information of master pump comes from the MASTER_PUMP of the PMP_SEQUENCE_GEN. The scaling of the PID_OUT in terms of speed is done in following ways.

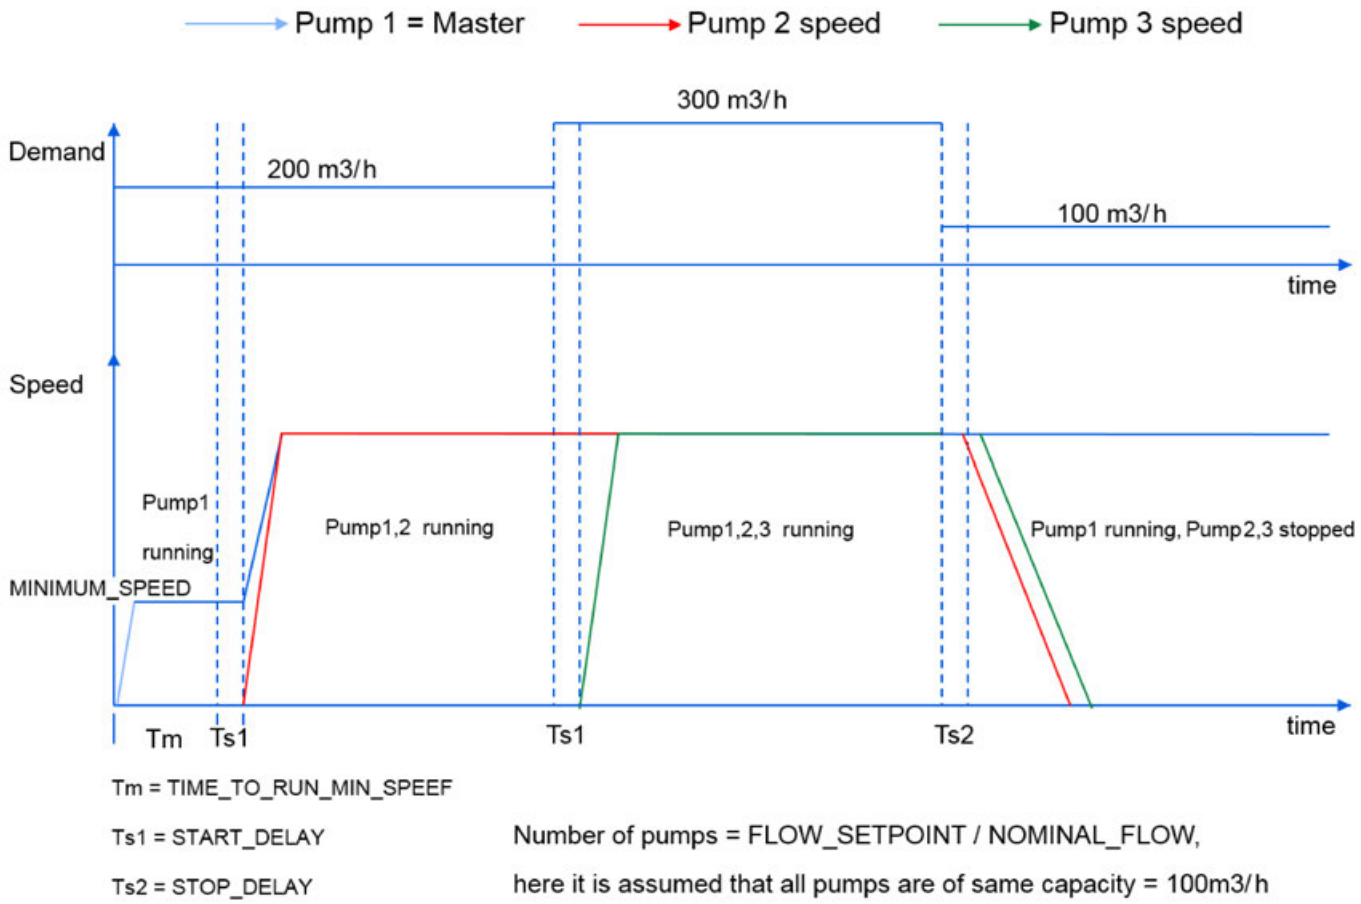
  Speed reference MASTER_PUMP = (NOMINAL_SPEED of MASTER_PUMP) * (PID_OUT/100)
- This speed reference is given to the master and the follower (if FOLLOWER_MODE = 1). If FOLLOWER_MODE = 2, then follower pumps will run at their fixed speed given in the input FOLLOWER_SPEED[1..8].
- The distributor then decides about the number of pumps to operate based on the following formula,

  Number of pumps = FLOW_SETPOINT / NOMINAL_FLOW, here it is assumed that all pumps are of same rating.

It is assumed that all the pumps are of same capacity.

- As the flow set point increases, the demand of pumps increases.
- Example: if each pump is of capacity = 100 cubic meters per hour and the flow set point is 400 cubic meters per hour, then four pumps will start together. This is unlike the pressure control where the pumps do not start together but based on speed reference of the master pump.

Flow control with distributor



- Similarly when the demand decreases, the speed reference of the master decreases. As the speed reference of the master pump goes below than STOP_SPEED_FWR[1], the first follower stops. The ID of next pump to stop comes from PMP_SEQUENCE_GEN as PNSTOP.
- If the speed reference of the MASTER_PUMP decreases further such that it is less than STOP_SPEED_FWR[2], then second follower pump stops. This sequence is follows till there is a decrease in demand.

The follower pumps in the above figures are considered to be in the FOLLOWER_MODE = 1, copy master speed.

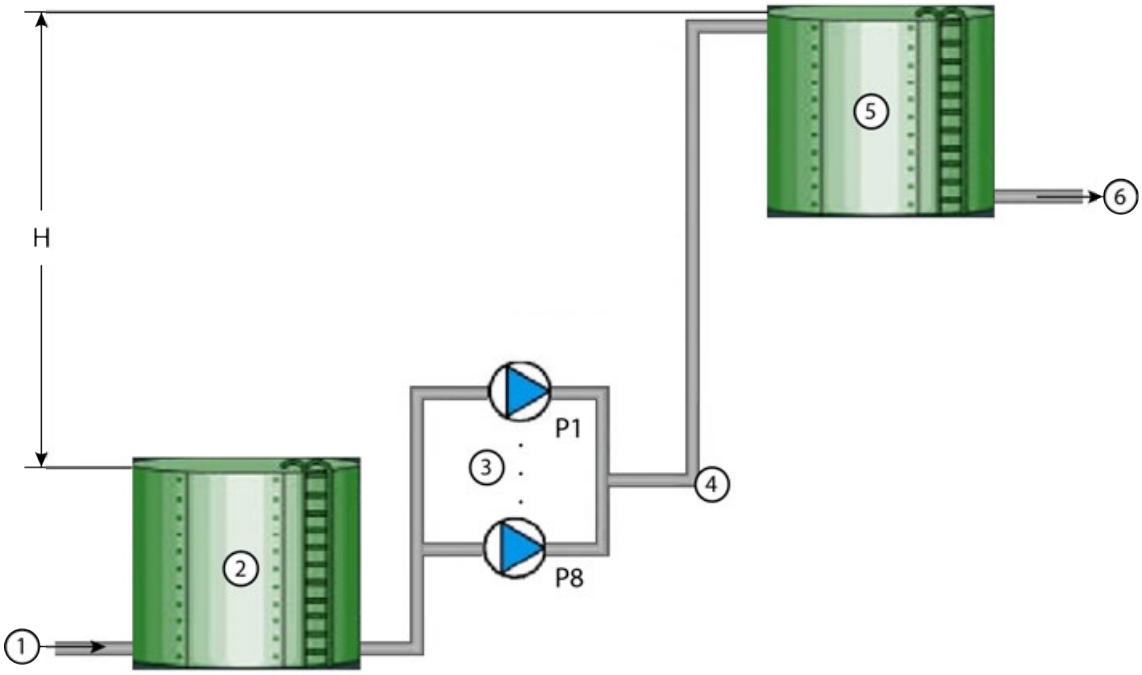
They can also run at their individual speed if FOLLOWER_MODE = 2, fixed speed.

Level control – Emptying or filling

Level control process flow diagram

Level control is used in applications where continuous flow distribution into one target tank or reservoir is needed.

A typical flow control application diagram is shown below.



1 From supply station
2 Suction tank
3 Parallel operating pumps P1 ... P8
4 Water distribution network
5 Target tank/Reservoir
6 To next station or distribution network
H Water head between the levels in the suction tank and target tank

Using level control

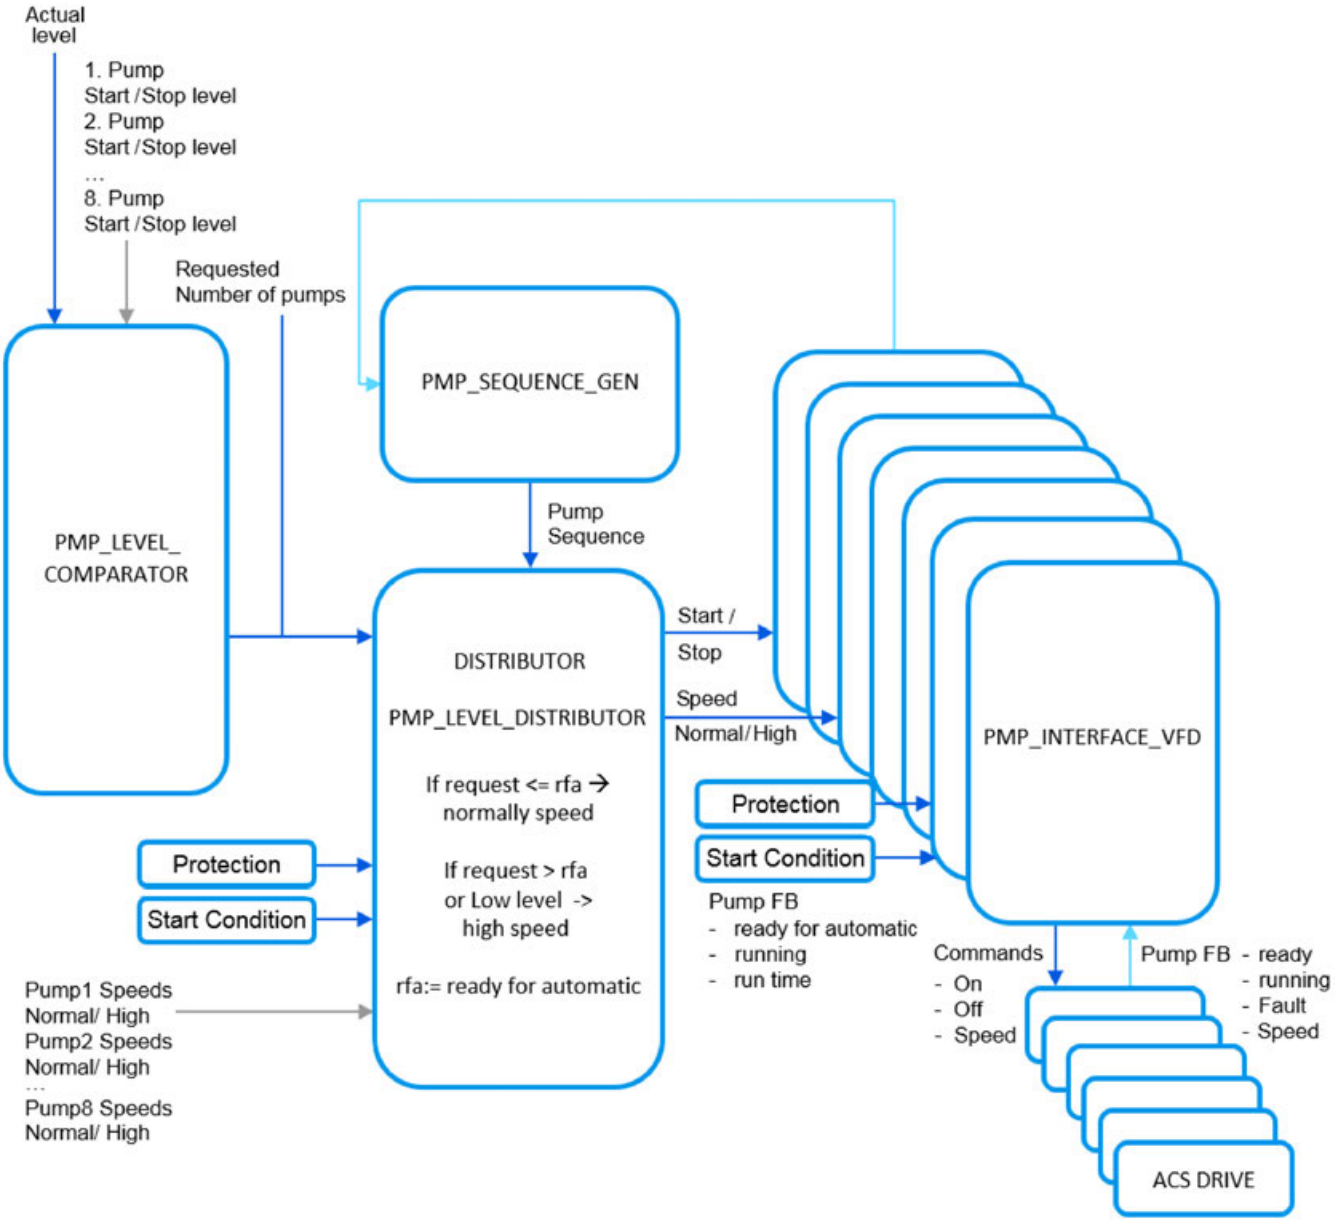
Level control in the pumping library can help in followings pumping operations:

- Emptying the target tank/reservoir by the next pump station or water distribution network.
- Filling the suction tank from a supply station.
- Defining the number of running pumps based on water level in the water tank.
- Start/stop the pumps with predefined start/stop levels.
- In case of a station shutdown, stop pumps sequentially to prevent water hammering.

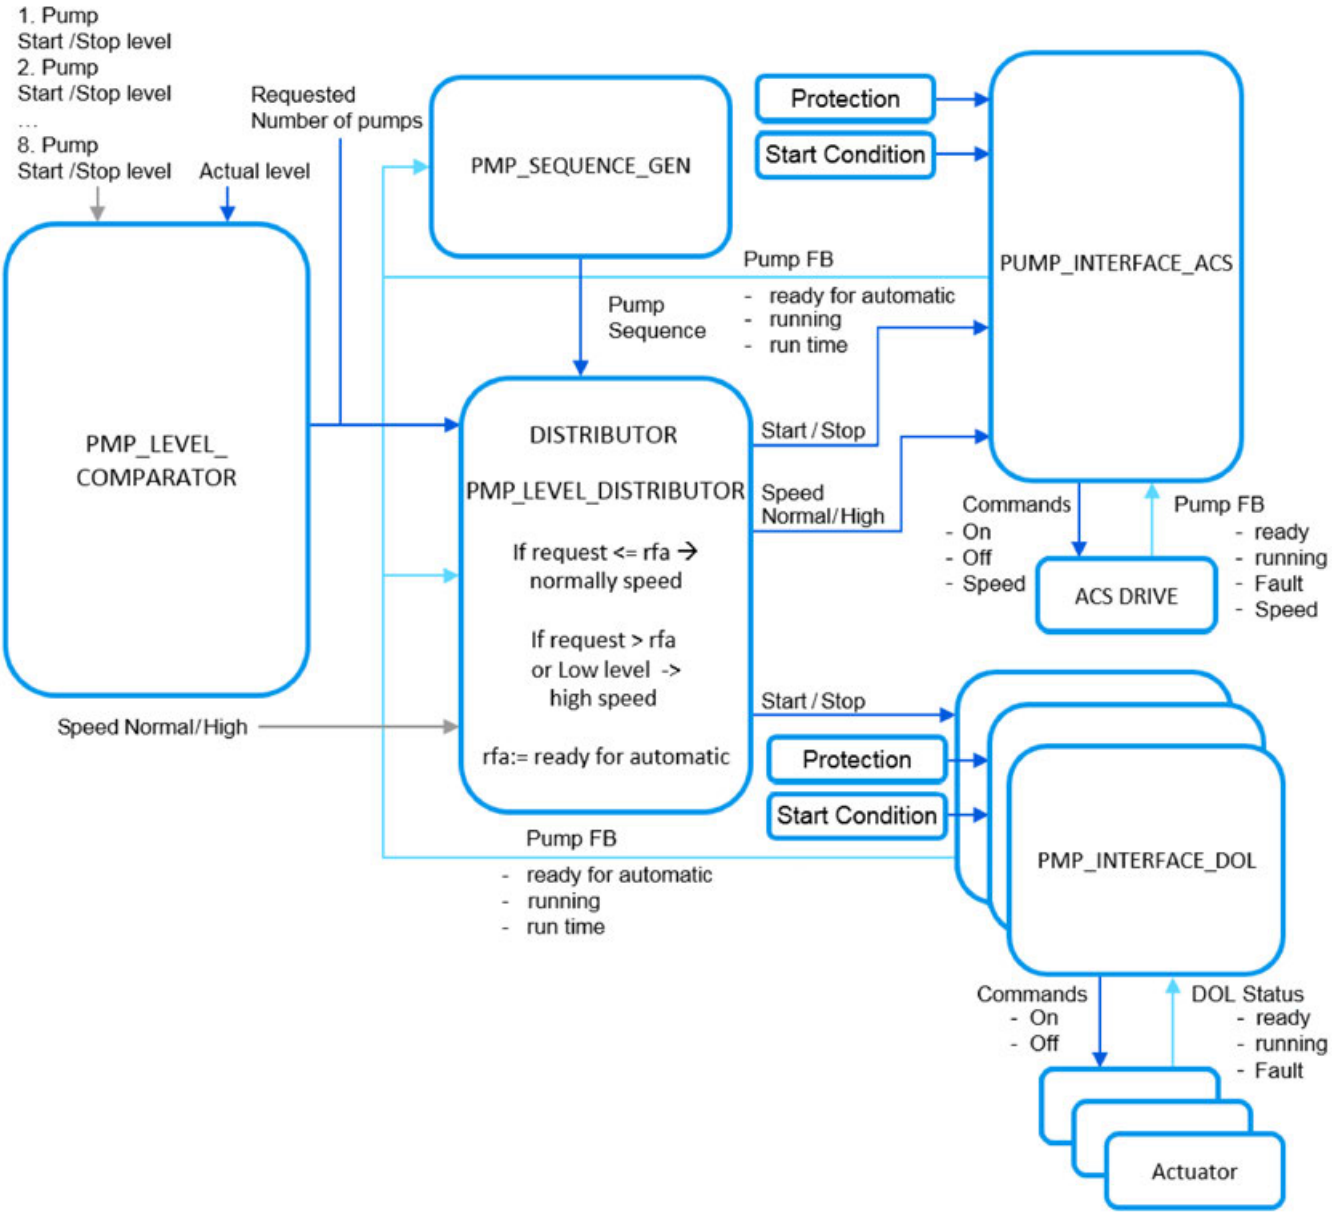
Pump combinations for level control

Level control works for all the three types of pump combinations: Multi pump, traditional pump, and DOL pump.

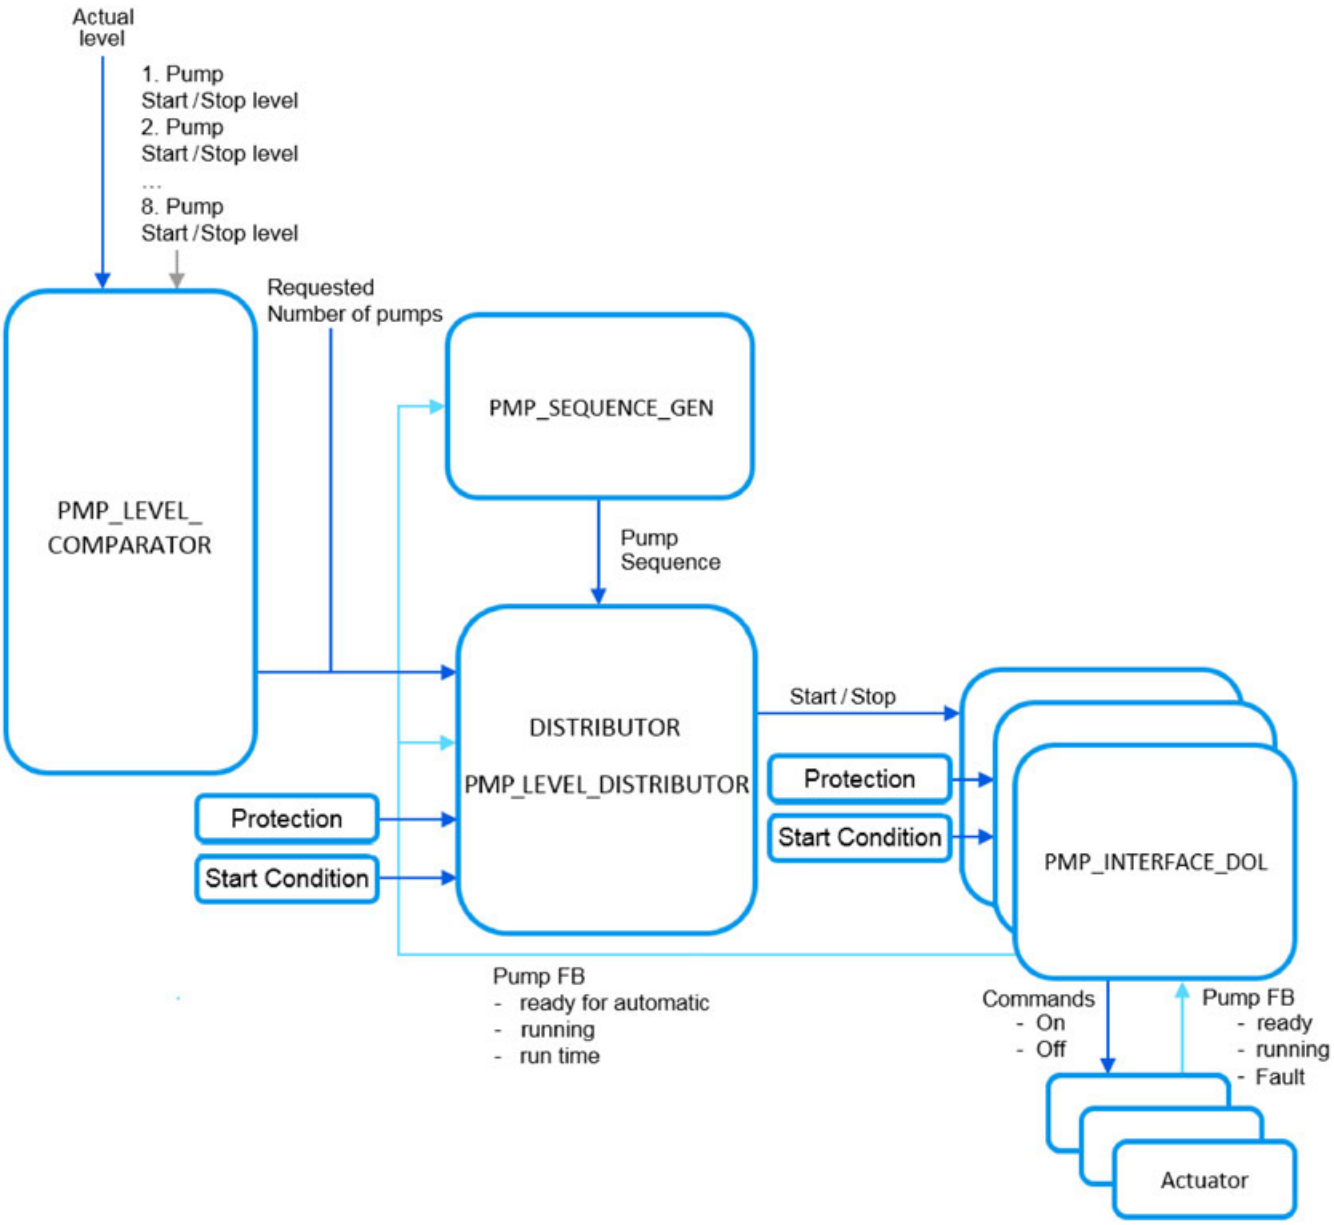
- Multi pump – In this mode all pumps are run using VFDs. See the example diagram below.



- Traditional pump – In this mode only one pump is run using the VFD and rest using the Direct On Line (DOL) motors. See the example diagram below.



- DOL Pump – In this mode all the pumps are operated by DOL motors. In this case the PMP_PID is not configured as there is no possibility to change the speed of the pump. See the example diagram below.



Control philosophy of level control mode

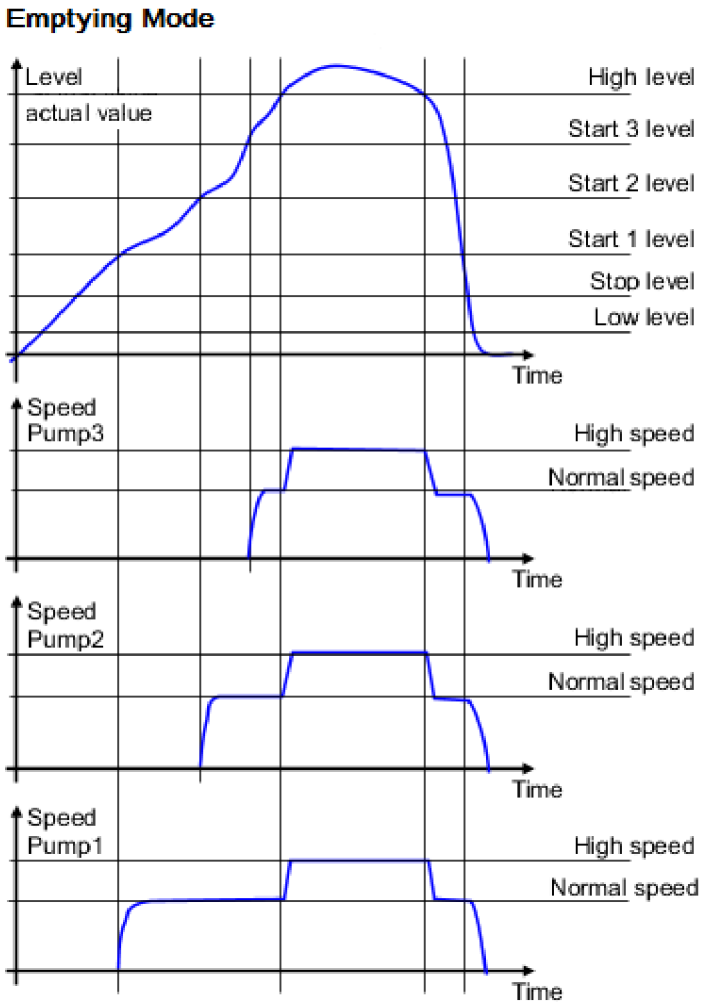
The level control is based on two modes.

- Emptying mode
- Filling mode

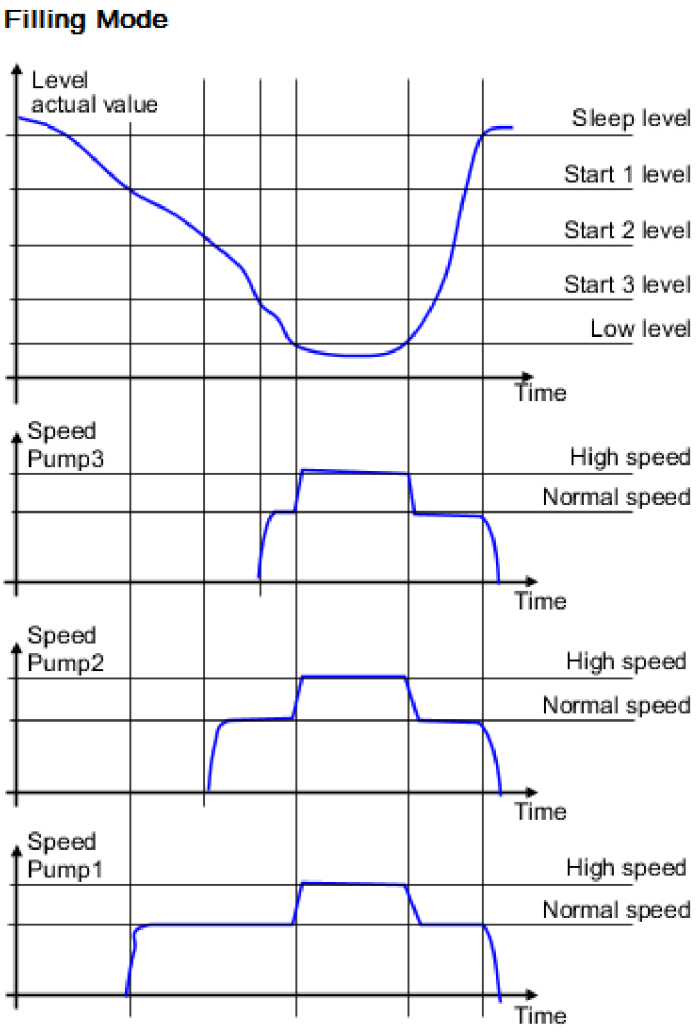
The level control mode follows this sequence of operation:

- The PMP_LEVEL_COMPARATOR compares the actual level (ACT_LEVEL) with the set start levels (START_LEVEL [1...8]). Based on which the comparator decides the demand (N_DEMAND). This demand goes as an input information to the PMP_ LEVEL _DISTRIBUTOR.
- The PMP_LEVEL_DISTRIBUTOR then starts the required pumps. In case the pumps are driven by VFD, the distributor also gives the speed reference to each pump. The information of which pump to start in the sequence is given to the distributor by PMP_SEQUENCE_GEN.

Time diagram: Emptying mode

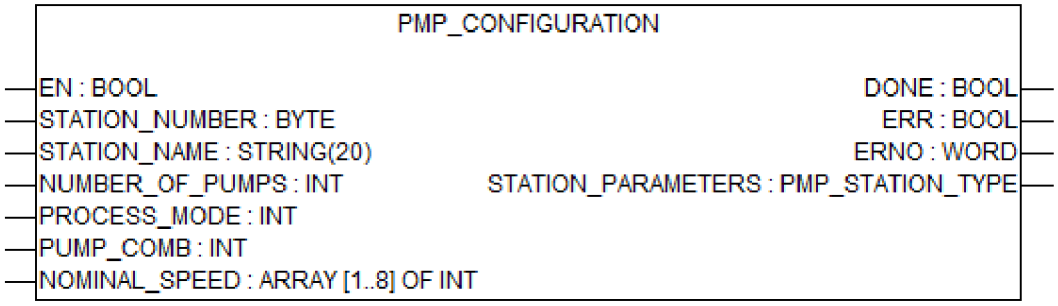


Time diagram:
Filling mode



1.5.14.2 Function block description

1.5.14.2.1 PMP_CONFIGURATION

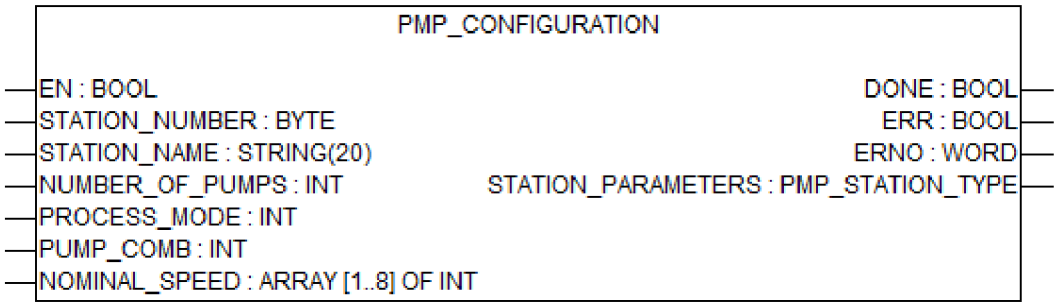


The function block PMP_CONFIGURATION configures the pump station. The function block receives the pumping station details (e.g., station name, station number) and stores in the structure PMP_STATION_TYPE.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

STATION_NUMBER

Data type	Default value	Range	Unit
BYTE	1	> 0	-

The input STATION_NUMBER defines the assigned station number, which is used as a unique identification number when more than one station is configured in a single PLC.

STATION_NAME

Data type	Default value	Range	Unit
STRING(20)	'Station1'	20 characters	-

The input STATION_NAME input defines the configured station name.

NUMBER_OF_PUMPS

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input NUMBER_OF_PUMPS defines the number of pumps used in the pumping station.

PROCESS_MODE

Data type	Default value	Range	Unit
INT	1	1 ... 3	-

The input PROCESS_MODE selects the process control mode for pump operation. The function block contains following control modes:

1 = Pressure control: for pressure stabilization

2 = Flow control: for maintaining the required flow in the process

3 = Level control: for emptying or filling the tank

PUMP_COMB

Data type	Default value	Range	Unit
INT	1	1 ... 3	-

The input PUMP_COMB selects the process combination mode for pump operation. The function block contains following modes:

1 = Multimode: this mode drives all pumps fed by VFDs.

2 = Traditional mode: in this mode only one pump is fed by VFD and rest of the pumps are fed by DOL motors.

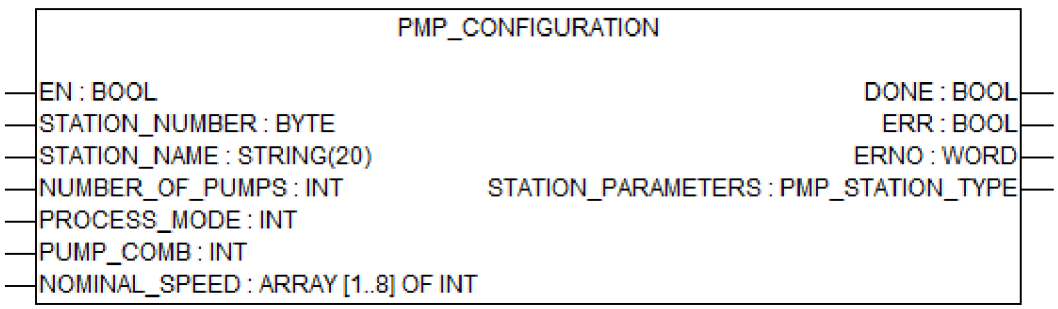
3 = DOL mode: in this mode all pumps are fed by DOL motors.

NOMINAL_SPEED

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	8(1500)	-	rpm

The input NOMINAL_SPEED defines the rated pump speed in rpm. This input is an array where the first index is meant for PUMP_ID = 1 in the interface function blocks PMP_INTERFACE_DOL and PMP_INTERFACE_VFD.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

STATION_ PARAMETERS

Data type	Default value	Range	Unit
PMP_STA-TION_TYPE	-	-	-

The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control

Parameter	Data type	Default value	Description
iPump_Combination	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

Error codes

The error codes of function block PMP_CONFIGURATION are listed below:

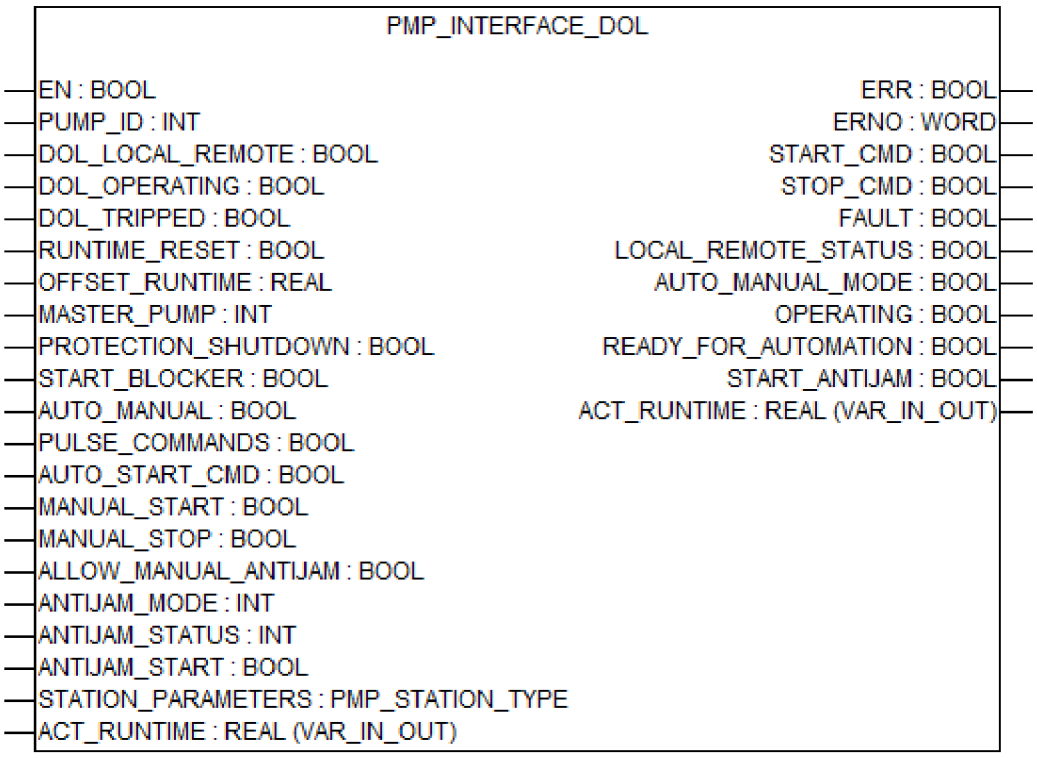
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16417	4021	Value of STATION_NUMBER is less than 1
16449	4041	Value of NUMBER_OF_PUMPS is less than 1
16450	4042	Value of NUMBER_OF_PUMPS is beyond 8
16465	4051	Value of PROCESS_MODE is less than 1
16466	4052	Value of PROCESS_MODE is beyond 3
16481	4061	Value of PUMP_COMB is less than 1
16482	4062	Value of PUMP_COMB is beyond 3
16483	4063	PUMP_COMB cannot be = 3 for the PROCESS_MODE = 1
16497	4071	Value of NOMINAL_SPEED is less than or equal to 0

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.2 PMP_INTERFACE_DOL

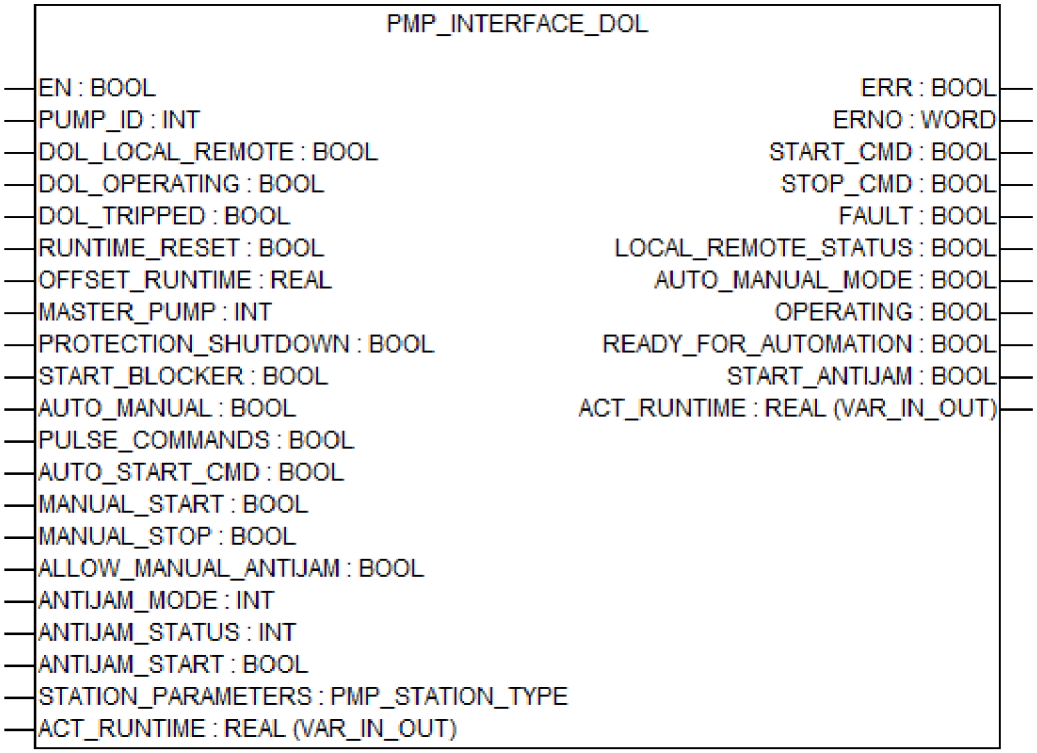


The function block PMP_INTERFACE_DOL is used to communicate with all pumps in the field that are run by direct online (DOL) motor. The function block configures pump settings and gives the status of pump operation. This function block is effective only for pumps fed by DOL motors.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PUMP_ID

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PUMP_ID defines the pump identification number.

DOL_LOCAL_REMOTE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input DOL_LOCAL_REMOTE connects the local or remote mode status of the DOL system. The function block uses this information to decide whether the pump is ready for automation.

- When input is TRUE, pump operates in LOCAL mode.
- When input is FALSE, pump operates in REMOTE mode.

DOL_ OPERATING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input DOL_OPERATING connects the operating status of the DOL system. The function block uses this information to decide whether the pump is ready for automation.

- When input is TRUE, pump is operating.
- When input is FALSE, pump is not ready for operation.

DOL_TRIPPED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input DOL_TRIPPED connects the faulty/healthy status of the DOL system. The function block uses this information to decide whether the pump is ready for automation.

- When input is TRUE, pump has tripped due to fault.
- When input is FALSE, pump operation is healthy.

RUNTIME_ RESET

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input RUNTIME_RESET resets the actual run time in the output ACTUAL_RUNTIME with value in the input OFFSET_RUNTIME for the pump.

- When input is TRUE, output ACTUAL_RUNTIME is reset to value in input OFFSET_RUNTIME.
- When input is FALSE, pump continues operation in current run time.

OFFSET_ RUNTIME

Data type	Default value	Range	Unit
REAL	1.0	-	-

The input OFFSET_RUNTIME defines offset run time of the pump that overwrites actual run time in the output ACTUAL_RUNTIME when input RUNTIME_RESET = TRUE.

MASTER_PUMP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input MASTER_PUMP receives the identification number of the master pump in the sequence. The input comes from the output MASTER_PUMP of the function block PMP_SEQUENCE_GEN.

PROTECTION_ SHUTDOWN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input PROTECTION_SHUTDOWN receives a digital signal to shut down the pump station for protection. The input comes from the output PROTECTION_SHUTDOWN of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

- When input is TRUE, pump station is shutdown.
- When input is FALSE, pump station operation continues.

START_ BLOCKER

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START_BLOCKER receives a digital signal to prevent the starting of pump station for protection. The input comes from the output START_BLOCKER of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

The input START_BLOCKER will not stop the already running pump.

- When input is TRUE, pump start is not allowed.
- When input is FALSE, pump start is allowed.

AUTO_MANUAL

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input AUTO_MANUAL selects the operating mode of the pump.

- When input is TRUE, pump operates in automatic mode.
- When input is FALSE, pump operates in manual mode.

PULSE_ COMMANDS

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input PULSE_COMMANDS selects the Start/Stop command type of the pump run by DOL motor.

- When input is TRUE, pump starts with the pulse input of start command.
- When input is FALSE, pump starts with the continuous start command.

AUTO_START_ CMD

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input AUTO_START_CMD receives the start command of the pump to start in automatic mode. The input comes from the output AUTO_START_CMD of function block PMP_FLOW_DISTRIBUTOR or PMP_PRESSURE_DISTRIBUTOR. Automatic start works only when input AUTO_MANUAL = TRUE.

- When input is TRUE, pump starts in automatic mode.
- When input is FALSE, pump stops if running in automatic mode.

MANUAL_ START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input MANUAL_START receives the start command to start the pump in manual mode.

This manual start function applies only for a pump fed by DOL motor. The function works only when input AUTO_MANUAL = FALSE.

The function also depends on the input PULSE_COMMANDS:

If input PULSE_COMMANDS = FALSE i.e. continuous mode is selected.

- When input MANUAL_START = TRUE, pump starts in manual mode.
- When input MANUAL_START = FALSE, pump stops if running in manual mode.

If input PULSE_COMMANDS = TRUE i.e. pulse mode is selected.

- Pump starts in manual mode at the rising edge i.e. FALSE ➨ TRUE.

MANUAL_STOP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

This input MANUAL_STOP stops the pump under following conditions:

- Input PULSE_COMMANDS = TRUE i.e. pulse mode is selected.
- Inputs AUTO_MANUAL = FALSE and MANUAL_STOP = TRUE.

This manual stop function applies only for a pump fed by DOL motor.

ALLOW_ MANUAL_ ANTIJAM

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input ALLOW_MANUAL_ANTIJAM allows antijam operation of the pump in manual mode. The input is effective only when the input AUTO_MANUAL = FALSE and ANTIJAM_MODE = Manual mode.

- When input is TRUE, antijam operation is allowed.
- When input is FALSE, antijam operation is not allowed.

ANTIJAM_ MODE

Data type	Default value	Range	Unit
INT	0	0 ... 3	-

The input ANTIJAM_MODE indicates the selected antijam mode.

0 = Disable antijam

1 = Master enabled

2 = At start

3 = Manual mode

The input ANTIJAM_MODE receives the antijam mode. The input comes from the output ANTIJAM_MODE of the function block PMP_ANTIJAM.

ANTIJAM_ STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 2	-

The input ANTIJAM_STATUS receives the antijam operation status of the pump. The input comes from the output ANTIJAM_STATUS of the function block PMP_ANTIJAM.

0 = Not started (Antijam operation has not started)

1 = Busy (Antijam operation has started)

2 = Done (Antijam operation is completed)

ANTIJAM_ START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output ANTIJAM_START of the function block PMP_ANTIJAM starts the antijam operation. This output is connected with the input ANTIJAM_START of the function blocks PMP_INTERFACE_VFD and PMP_INTERFACE_DOL.

- When output is TRUE, antijam operation starts.
- When output is FALSE, antijam operation stops if running.

STATION_ PARAMETERS

Data type	Default value	Range	Unit
PMP_STATION_TYPE	-	-	-

The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

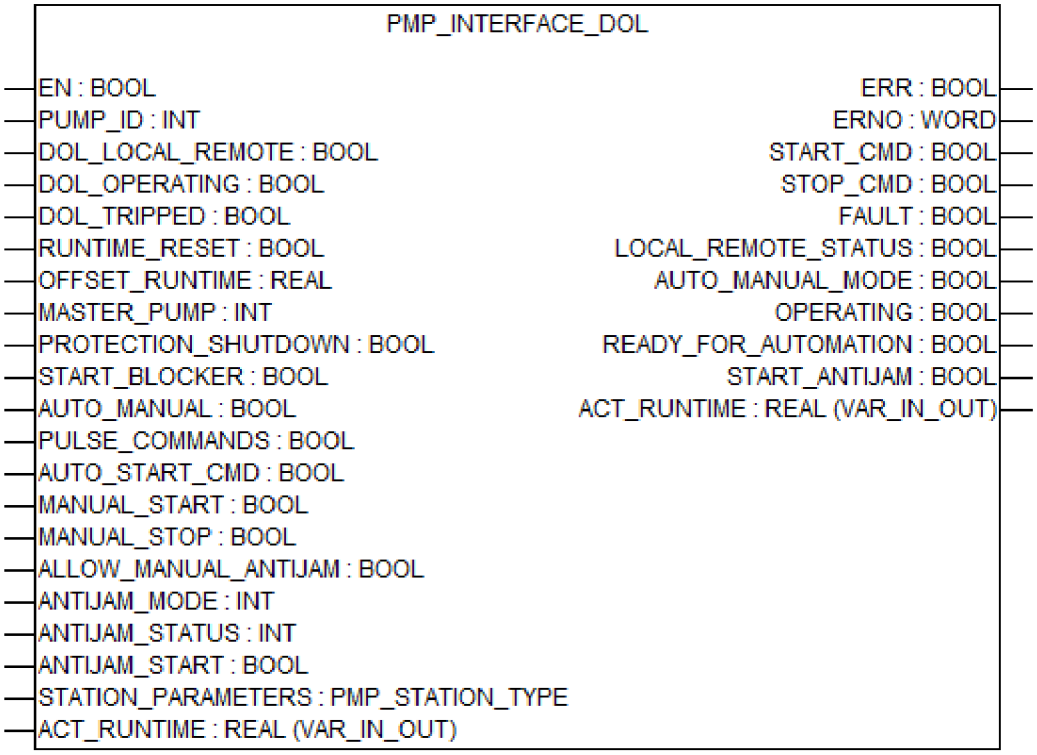
Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combination	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

ACT_RUNTIME

Data type	Default value	Range	Unit
REAL	-	-	h

The input ACT_RUNTIME defines the actual run time of pump in hours.

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

START_CMD

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output START_CMD is the command to start the pump fed by DOL motor. The command works only when input PULSE_COMMANDS = FALSE, i.e. continuous mode is selected.

- When output is TRUE, pump starts running.
- When output is FALSE, pump stops if already running.

When input PULSE_COMMANDS = TRUE, the command generates a single pulse to start the motor.

STOP_CMD

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output STOP_CMD is the command to stop the pump fed by DOL motor. The output works based on the value in input PULSE_COMMANDS.

- If PULSE_COMMANDS = FALSE, the output will stay FALSE and unused.
- If PULSE_COMMAND = TRUE, the output generates a single pulse to stop the motor.

FAULT

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output FAULT indicates a fault in the pump. The fault may be in the pump protection blocks.

- When output is TRUE, pump fault occurred.
- When output is FALSE, pump operation is healthy.

LOCAL_ REMOTE_ STATUS

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output LOCAL_REMOTE_STATUS indicates the operating mode of the pump system (DOL/VFD).

- When output is TRUE, pump system is in local mode.
- When output is FALSE, pump system is in remote mode.

AUTO_MANUAL _MODE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output AUTO_MANUAL_MODE indicates the operation mode of the pump.

- When output is TRUE, pump is in automatic mode.
- When output is FALSE, pump is in manual mode.

OPERATING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output OPERATING indicates that the device is operating.

- When output is TRUE, device is operating.
- When output is FALSE, device is not operating.

READY_FOR_AUTOMATION

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output READY_FOR_AUTOMATION of the pump interface function block indicates that the pump is ready for operation in automatic mode. This function is effective only when the function block is connected to the input READY_FOR_AUTOMATION of the following function blocks: PMP_SEQUENCE_GEN, PMP_FLOW_DISTRIBUTOR, PMP_LEVEL_DISTRIBUTOR and PMP_PRESSURE_DISTRIBUTOR.

- When output is TRUE, pump is ready for operation in automatic mode.
- When output is FALSE, pump is not ready for operation in automatic mode.

START_ANTIJAM

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output START_ANTIJAM starts antijam operation in manual mode. This function is effective only when the function block is connected to input START_MANUAL of function block PMP_ANTIJAM.

- When output is TRUE, antijam operation starts in manual mode.
- When output is FALSE, antijam operation stops if running.

Error codes

The error codes of function block PMP_INTERFACE_DOL are listed below:

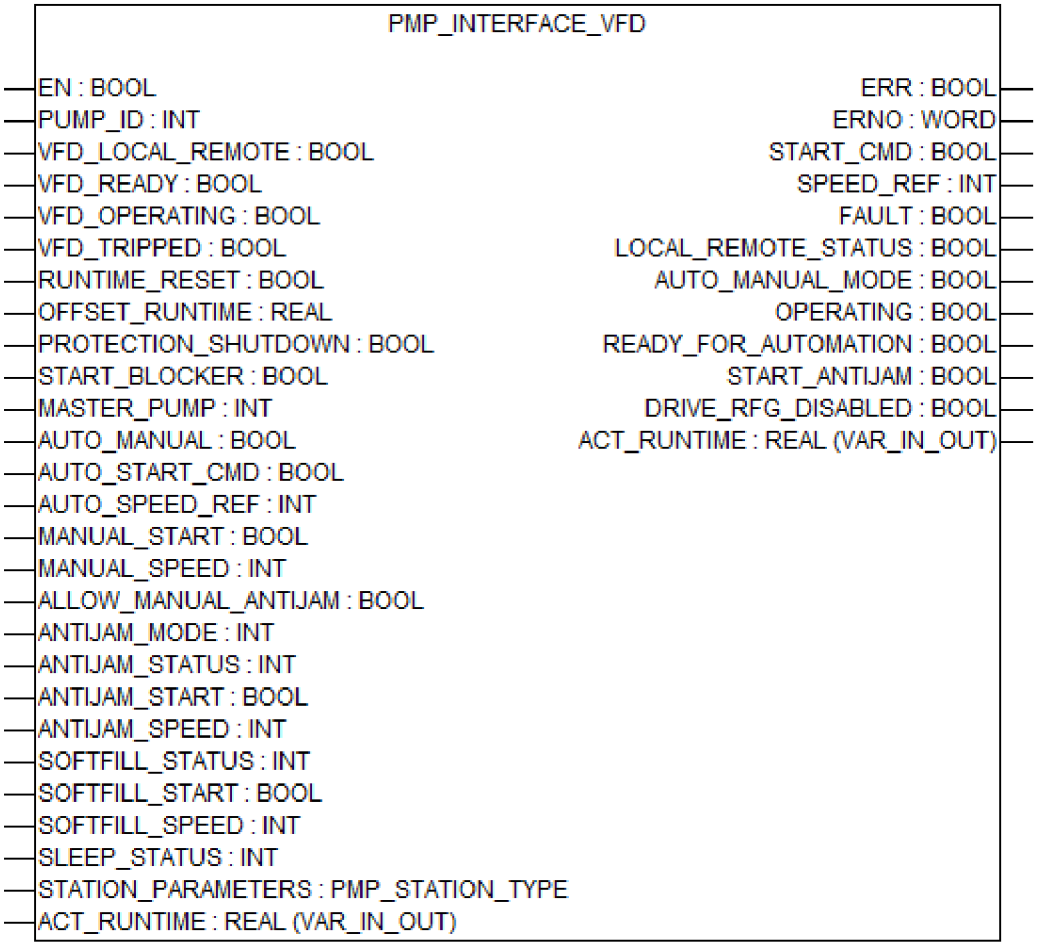
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16417	4021	Value of PUMP_ID is less than 1
16418	4022	Value of PUMP_ID is greater than NUMBER_OF_PUMPS in PMP_CONFIGURATION
16641	4101	Value of ANTIJAM_MODE is less than 0
16642	4102	Value of ANTIJAM_MODE is greater than 3
16657	4111	Value of ANTIJAM_STATUS is less than 0
16658	4112	Value of ANTIJAM_STATUS is greater than 2
16611	40E3	Value of MANUAL_START and ALLOW_MANUAL_ANTIJAM is TRUE simultaneously. Either one operation is allowed at a time in manual mode, i.e. manual pump start or manual antijam.

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.3 PMP_INTERFACE_VFD



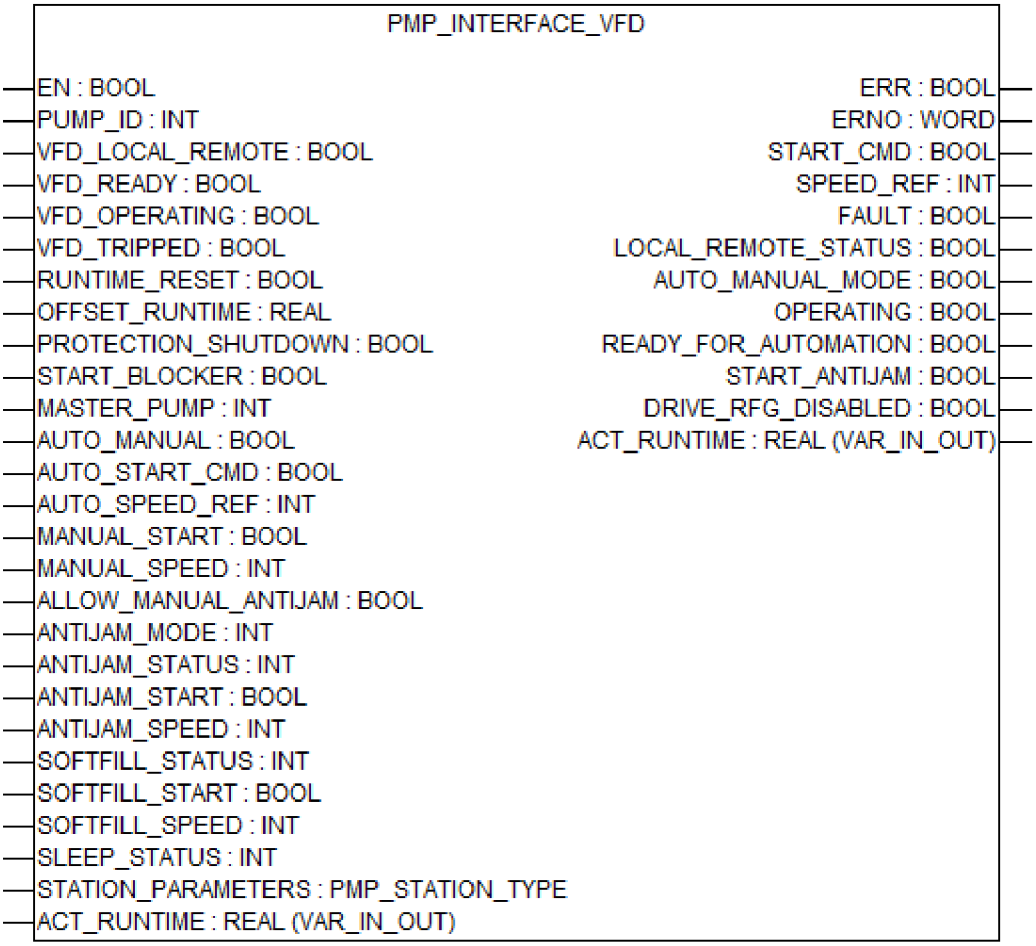
The function block PMP_INTERFACE_VFD enables communication within all connected pumps in the field run by VFD motors. The function block configures pump settings and gives the status of pump operation. This function block is effective only for pumps fed by VFD motors.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

The function block PMP_INTERFACE_VFD checks the status of variable frequency drives (VFDs) and sends the ON/OFF command and speed signals back to the drives.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PUMP_ID

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PUMP_ID defines the pump identification number.

VFD_LOCAL_REMOTE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input VFD_LOCAL_REMOTE receives the operating mode of the variable frequency drive.

- When input is TRUE, drive is operating in LOCAL mode.
- When input is FALSE, drive is operating in REMOTE mode.

VFD_READY

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input VFD_READY receives the ready for operation status of the variable frequency drive.

- When input is TRUE, drive is ready for operation.
- When input is FALSE, drive is not ready for operation.

VFD_OPERATING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input VFD_OPERATING receives the operating status of the variable frequency drive.

- When input is TRUE, drive is operating.
- When input is FALSE, drive is not operating.

VFD_TRIPPED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input VFD_TRIPPED receives the tripped status of the variable frequency drive.

- When input is TRUE, drive has tripped due to a fault.
- When input is FALSE, drive is healthy.

RUNTIME_RESET

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input RUNTIME_RESET resets the actual run time in the output ACTUAL_RUNTIME with value in the input OFFSET_RUNTIME for the pump.

- When input is TRUE, output ACTUAL_RUNTIME is reset to value in input OFFSET_RUNTIME.
- When input is FALSE, pump continues operation in current run time.

OFFSET_RUNTIME

Data type	Default value	Range	Unit
REAL	1.0	-	-

The input OFFSET_RUNTIME defines offset run time of the pump that overwrites actual run time in the output ACTUAL_RUNTIME when input RUNTIME_RESET = TRUE.

PROTECTION_SHUTDOWN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input PROTECTION_SHUTDOWN receives a digital signal to shut down the pump station for protection. The input comes from the output PROTECTION_SHUTDOWN of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

- When input is TRUE, pump station is shutdown.
- When input is FALSE, pump station operation continues.

START_BLOCKER

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START_BLOCKER receives a digital signal to prevent the starting of pump station for protection. The input comes from the output START_BLOCKER of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

The input START_BLOCKER will not stop the already running pump.

- When input is TRUE, pump start is not allowed.
- When input is FALSE, pump start is allowed.

MASTER_PUMP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input MASTER_PUMP receives the identification number of the master pump in the sequence. The input comes from the output MASTER_PUMP of the function block PMP_SEQUENCE_GEN.

AUTO_MANUAL

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input AUTO_MANUAL selects the operating mode of the pump.

- When input is TRUE, pump operates in automatic mode.
- When input is FALSE, pump operates in manual mode.

AUTO_START_CMD

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input AUTO_START_CMD receives the start command of the pump to start in automatic mode. The input comes from the output AUTO_START_CMD of function block PMP_FLOW_DISTRIBUTOR or PMP_PRESSURE_DISTRIBUTOR. Automatic start works only when input AUTO_MANUAL = TRUE.

- When input is TRUE, pump starts in automatic mode.
- When input is FALSE, pump stops if running in automatic mode.

AUTO_SPEED_REF

Data type	Default value	Range	Unit
INT	0	-	rpm

The input AUTO_SPEED_REF defines the speed reference of the pump run by variable frequency drive in automatic mode. The input comes from the output AUTO_SPEED_REF of function blocks PMP_FLOW_DISTRIBUTOR/ PMP_PRESSURE_DISTRIBUTOR/ PMP_LEVEL_DISTRIBUTOR, depending on the process selected in the function bock PMP_CONFIGURATION.

MANUAL_START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input MANUAL_START gives the start command to start the pump run by variable frequency drive in manual mode. This input is effective only when input AUTO_MANUAL = FALSE.

- When input is TRUE, pump starts in manual mode.
- When input is FALSE, pump stops if running in manual mode.

MANUAL_SPEED

Data type	Default value	Range	Unit
INT	0	> 0	rpm

The input MANUAL_SPEED defines the speed reference of the pump run by variable frequency drive in manual mode. Manual speed works only when input AUTO_MANUAL = FALSE.

ALLOW_MANUAL_ANTIJAM

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input ALLOW_MANUAL_ANTIJAM allows antijam operation of the pump in manual mode. The input is effective only when the input AUTO_MANUAL = FALSE and ANTIJAM_MODE = Manual mode.

- When input is TRUE, antijam operation is allowed.
- When input is FALSE, antijam operation is not allowed.

ANTIJAM_MODE

Data type	Default value	Range	Unit
INT	0	0 ... 3	-

The input ANTIJAM_MODE indicates the selected antijam mode.

0 = Disable antijam

1 = Master enabled

2 = At start

3 = Manual mode

The input ANTIJAM_MODE receives the antijam mode. The input comes from the output ANTIJAM_MODE of the function block PMP_ANTIJAM.

ANTIJAM_ STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 2	-

The input ANTIJAM_STATUS receives the antijam operation status of the pump. The input comes from the output ANTIJAM_STATUS of the function block PMP_ANTIJAM.

0 = Not started (Antijam operation has not started)

1 = Busy (Antijam operation has started)

2 = Done (Antijam operation is completed)

ANTIJAM_ START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output ANTIJAM_START of the function block PMP_ANTIJAM starts the antijam operation. This output is connected with the input ANTIJAM_START of the function blocks PMP_INTERFACE_VFD and PMP_INTERFACE_DOL.

- When output is TRUE, antijam operation starts.
- When output is FALSE, antijam operation stops if running.

ANTIJAM_ SPEED

Data type	Default value	Range	Unit
INT	0	-	rpm

The output ANTIJAM_SPEED of the function block PMP_ANTIJAM indicates the speed for antijam operation. This output is connected to the input ANTIJAM_SPEED of the function block PMP_INTERFACE_VFD.

SOFTFILL_ STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 4	-

The input SOFTFILL_STATUS indicates the status of softfilling function.

0 = Disable the softfill (Softfill operation is disabled)

1 = Ready to start (Softfill operation is ready to start)

2 = Softfill in progress (Softfill operation has started)

3 = Softfill completed (Softfill operation is completed)

4 = Softfill with fault (Softfill operation stopped due to a fault)

SOFTFILL_ START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output SOFTFILL_START of the used pump distributor starts the soft filling operation. This function is effective only when this output is connected to the input START of the function block PMP_SOFT_FILLING.

- When input is TRUE, softfill function starts.
- When input is FALSE, softfill function stops if running.

SOFTFILL_SPEED

Data type	Default value	Range	Unit
INT	0	> 0	rpm

The output SOFTFILL_SPEED of the function block PMP_SOFT_FILLING indicates the speed reference for soft filling function. The output must be connected to the input SOFTFILL_SPEED of the interface function block PMP_INTERFACE_VFD.

SLEEP_STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 3	-

The output SLEEP_STATUS of the function block PMP_SLEEP indicates the sleep status of the pump.

0 = Inactive/Wakeup inactive

1 = Boost activated

2 = Sleep mode active

3 = Wakeup function active

STATION_PARAMETERS

Data type	Default value	Range	Unit
PMP_STATION_TYPE	-	-	-

The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

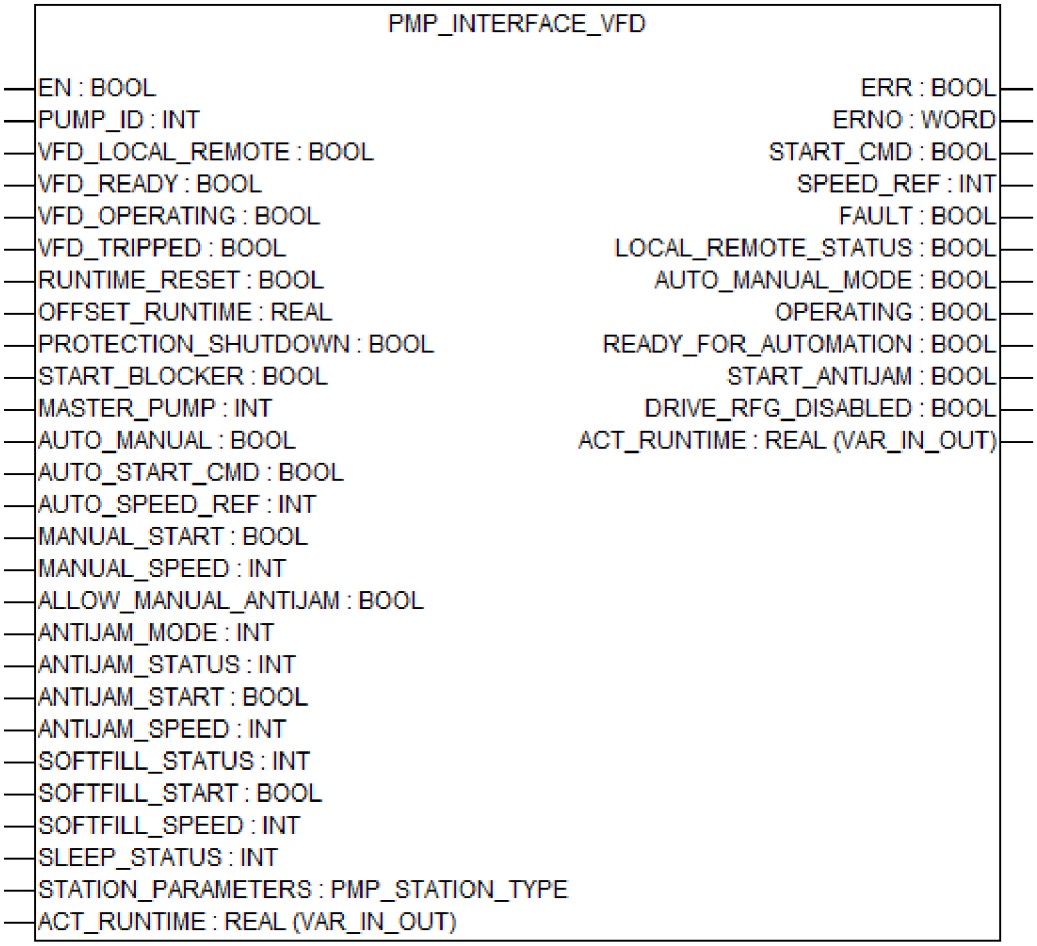
Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combination	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

ACT_RUNTIME

Data type	Default value	Range	Unit
REAL	-	-	h

The input ACT_RUNTIME defines the actual run time of pump in hours.

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

START_CMD

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output START_CMD is the start command to start the pump fed by variable frequency drive (VFD).

The VFD can run only if is connected to the on command of the VFD.

This can be done using the PLC - VFD communication library, which is not in the scope of the pump library.

- When output is TRUE, pump starts running.
- When output is FALSE, pump stops if already running.

SPEED_REF

Data type	Default value	Range	Unit
INT	0	> 0	rpm

The output SPEED_REF of the interface function block PMP_INTERFACE_VFD shows the speed reference of the variable frequency drive (VFD) in rpm.

The speed reference can be given to the drive only if it is connected to the correct parameter.

This can be done using the PLC - VFD communication library, which is not in the scope of the pump library.

The input SPEED_REF of the function block PMP_DRIVE_SIMU comes from the output SPEED_REF of the interface function block PMP_INTERFACE_VFD.

FAULT

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output FAULT indicates a fault in the pump. The fault may be in the pump protection blocks.

- When output is TRUE, pump fault occurred.
- When output is FALSE, pump operation is healthy.

LOCAL_ REMOTE_ STATUS

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output LOCAL_REMOTE_STATUS indicates the operating mode of the pump system (DOL/VFD).

- When output is TRUE, pump system is in local mode.
- When output is FALSE, pump system is in remote mode.

AUTO_MANUAL _MODE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output AUTO_MANUAL_MODE indicates the operation mode of the pump.

- When output is TRUE, pump is in automatic mode.
- When output is FALSE, pump is in manual mode.

OPERATING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output OPERATING indicates that the device is operating.

- When output is TRUE, device is operating.
- When output is FALSE, device is not operating.

READY_FOR_ AUTOMATION

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output READY_FOR_AUTOMATION of the pump interface function block indicates that the pump is ready for operation in automatic mode. This function is effective only when the function block is connected to the input READY_FOR_AUTOMATION of the following function blocks: PMP_SEQUENCE_GEN, PMP_FLOW_DISTRIBUTOR, PMP_LEVEL_DISTRIBUTOR and PMP_PRESSURE_DISTRIBUTOR.

- When output is TRUE, pump is ready for operation in automatic mode.
- When output is FALSE, pump is not ready for operation in automatic mode.

START_ ANTIJAM

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output START_ANTIJAM starts antijam operation in manual mode. This function is effective only when the function block is connected to input START_MANUAL of function block PMP_ANTIJAM.

- When output is TRUE, antijam operation starts in manual mode.
- When output is FALSE, antijam operation stops if running.

DRIVE_RFG_ DISABLED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output DRIVE_RFG_DISABLED bypasses the ramp function generator (RFG) during Antijam operation. The output is effective only when connected to the control word (CW) of the drive.

- When output is TRUE, drive bypasses RFG during antijam operation.
- When output is FALSE, antijam operation runs without bypassing RFG.

Error codes

The error codes of function block PMP_INTERFACE_VFD are listed below:

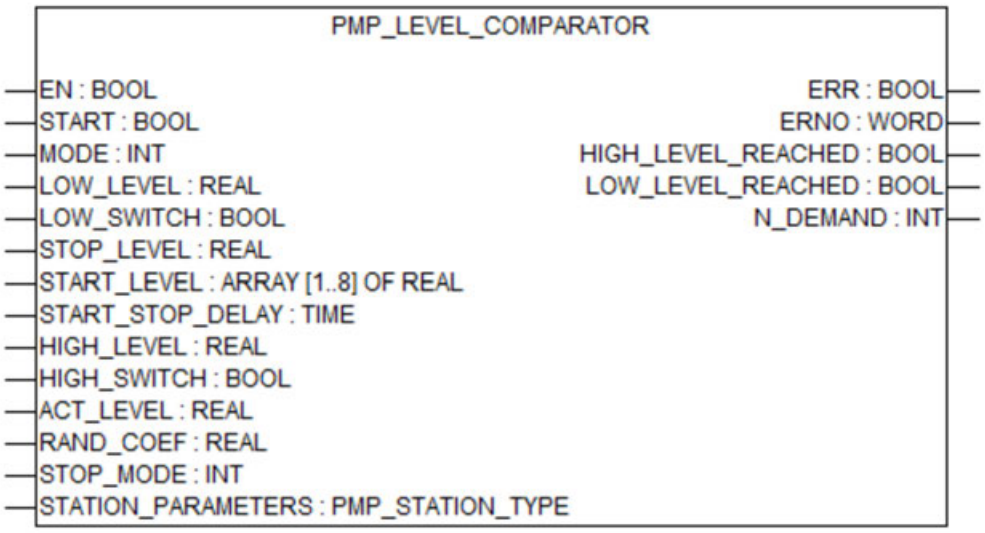
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16417	4021	Value of PUMP_ID is less than 1
16418	4022	Value of PUMP_ID is greater than NUMBER_OF_PUMPS in PMP_CONFIGURATION
16561	40B1	Value of MASTER_PUMP is less than 1
16562	40B2	Value of MASTER_PUMP is greater than NUMBER_OF_PUMPS in PMP_CONFIGURATION
16609	40E1	Value of AUTO_SPEED_REF is less than 0
16641	4101	Value of MANUAL_SPEED is less than 0
16673	4121	Value of ANTIJAM_MODE is less than 0
16674	4122	Value of ANTIJAM_MODE is greater than 3
16689	4131	Value of ANTIJAM_STATUS is less than 0
16690	4132	Value of ANTIJAM_STATUS is greater than 2
16737	4161	Value of SOFTFILL_STATUS is less than 0
16738	4162	Value of SOFTFILL_STATUS is greater than 4
16769	4181	Value of SOFTFILL_SPEED is less than 0
16785	4191	Value of SLEEP_STATUS is less than 0
16786	4192	Value of SLEEP_STATUS is greater than 3
16627	40F3	Value of MANUAL_START and ALLOW_MANUAL_ANTIJAM is TRUE simultaneously. Either one operation is allowed at a time in manual mode, i.e., manual pump start or manual antijam.

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.4 PMP_LEVEL_COMPARATOR



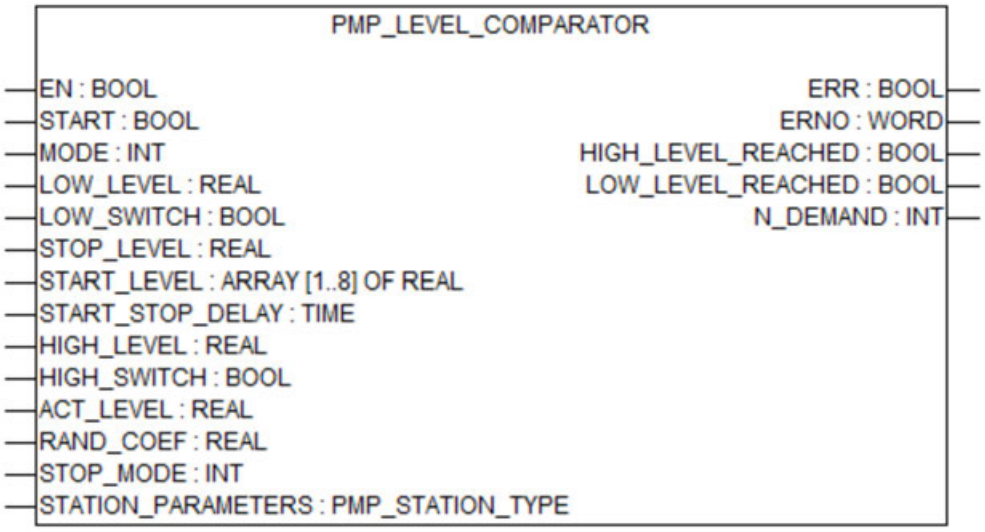
The function block PMP_LEVEL_COMPARATOR compares the actual level with the set level and generates a demand for the function block PMP_LEVEL_DISTRIBUTOR. The function block is used for tank filling or emptying operations.

> *The function block is used with function block PMP_LEVEL_DISTRIBUTOR, when the function block PMP_CONFIGURATION has the input PROCESS_MODE = 3 (Level control).*

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START starts the execution of the function block.

- When input is TRUE, the execution starts.
- When input is FALSE, the execution stops if running.

MODE

Data type	Default value	Range	Unit
INT	1	1 ... 2	-

The input MODE selects the pumping operation mode.

1 = Emptying.

2 = Filling.

LOW_LEVEL

Data type	Default value	Range	Unit
REAL	10.0	0.0 ... 100.0	%

The input LOW_LEVEL defines the low level limit in percentage of full tank capacity.

LOW_SWITCH

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input LOW_SWITCH receives a digital signal from the pumping process when a low level has reached. The input is effective only when the sensor is present in the system, otherwise the default value is FALSE.

- When input is TRUE, pumping process has reached low level.
- When input is FALSE, pumping process is above low level.

STOP_LEVEL

Data type	Default value	Range	Unit
REAL	90.0	0.0 ... 100.0	%

The input STOP_LEVEL defines the stop level limit in percentage of full tank capacity.

START_LEVEL

Data type	Default value	Range	Unit
ARRAY[1..8] of REAL	-	0.0 ... 100.0	%

The input START_LEVEL defines the array of start level limits in percentage of full tank capacity.

START_STOP_DELAY

Data type	Default value	Range	Unit
TIME	10	-	s

The input START_STOP_DELAY defines the delay time to start or stop the pump when the respective start/stop levels have reached.

HIGH_LEVEL

Data type	Default value	Range	Unit
REAL	95.0	0.0 ... 100.0	%

The input HIGH_LEVEL defines the high level limit in percentage of full tank capacity.

HIGH_SWITCH

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input HIGH_SWITCH receives a digital signal from the pumping process when a high level has reached. The input is effective only when the sensor is present in the system, otherwise the default value is FALSE.

- When input is TRUE, pumping process has reached high level.
- When input is FALSE, pumping process is below high level.

ACT_LEVEL

Data type	Default value	Range	Unit
REAL	0.0	0.0 ... 100.0	%

The input ACT_LEVEL shows the actual level in percentage of full tank capacity. The value is read from the analog input level sensor.

Scaling of analog input is not in the scope of this library, but is done in the application program.

RAND_COEF

Data type	Default value	Range	Unit
REAL	0.0	-10.0 ... 10.0	%

The input RAND_COEF defines the random coefficient in percentage for randomizing the start level to avoid cake formation.

STOP_MODE

Data type	Default value	Range	Unit
INT	1	1 ... 2	-

The input STOP_MODE selects the appropriate stop mode.

Stop mode 1 = used in filling and emptying operation to stop each running pump.

- In filling operation, pump is stopped when input ACT_LEVEL > START_LEVEL.
- In emptying operation, pump is stopped when input ACT_LEVEL < START_LEVEL.

Stop mode 2 = common stop mode that stops all pumps with the level defined in input STOP_LEVEL.

STATION_ PARAMETERS

Data type	Default value	Range	Unit
PMP_STA-TION_TYPE	-	-	-

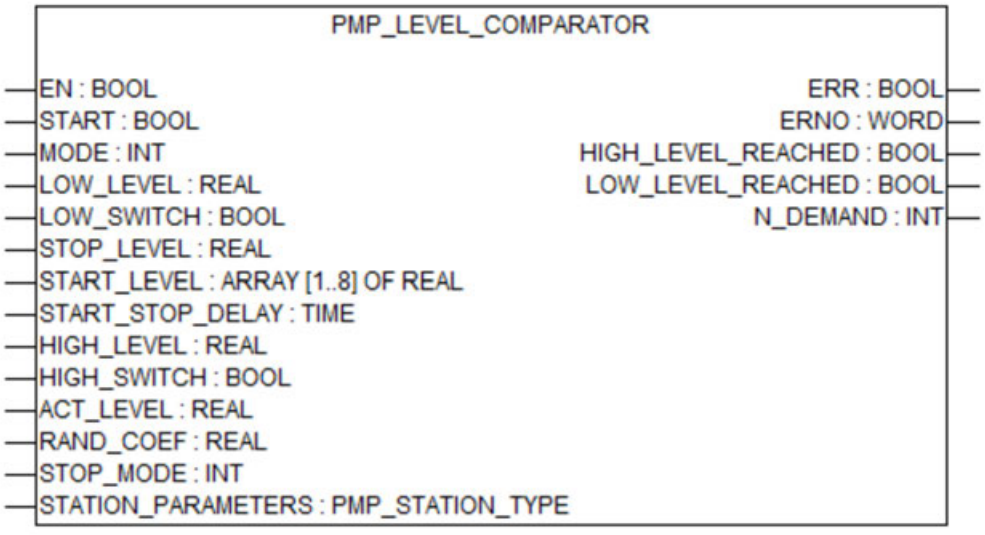
The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

> *All function blocks will receive some data, process it and write it back to the structure.*

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combina-tion	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

HIGH_LEVEL_ REACHED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output HIGH_LEVEL_REACHED of the function block PMP_LEVEL_COMPARATOR indicates that actual level is more than high level. This function is effective only when this output is connected to the input HIGH_LEVEL_REACHED of the function block PMP_LEVEL_DISTRIBUTOR.

- When output is TRUE, actual level is more than high level.
- When output is FALSE, actual level is less than high level.

LOW_LEVEL_ REACHED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output LOW_LEVEL_REACHED of the function block PMP_LEVEL_ COMPARATOR indicates that actual level is less than low level. This function is effective only when this output is connected to the input LOW_LEVEL_REACHED of the function block PMP_LEVEL_ DISTRIBUTOR.

- When output is TRUE, actual level is less than low level.
- When output is FALSE, actual level is more than low level.

N_DEMAND

Data type	Default value	Range	Unit
INT	0	1 ... 8	-

The input N_DEMAND of the function block PMP_LEVEL_DISTRIBUTOR receives the number of pumps demanded to run. This input comes from the output N_DEMAND of the function block PMP_LEVEL_COMPARATOR.

Error codes

The error codes of function block PMP_LEVEL_COMPARATOR are listed below:

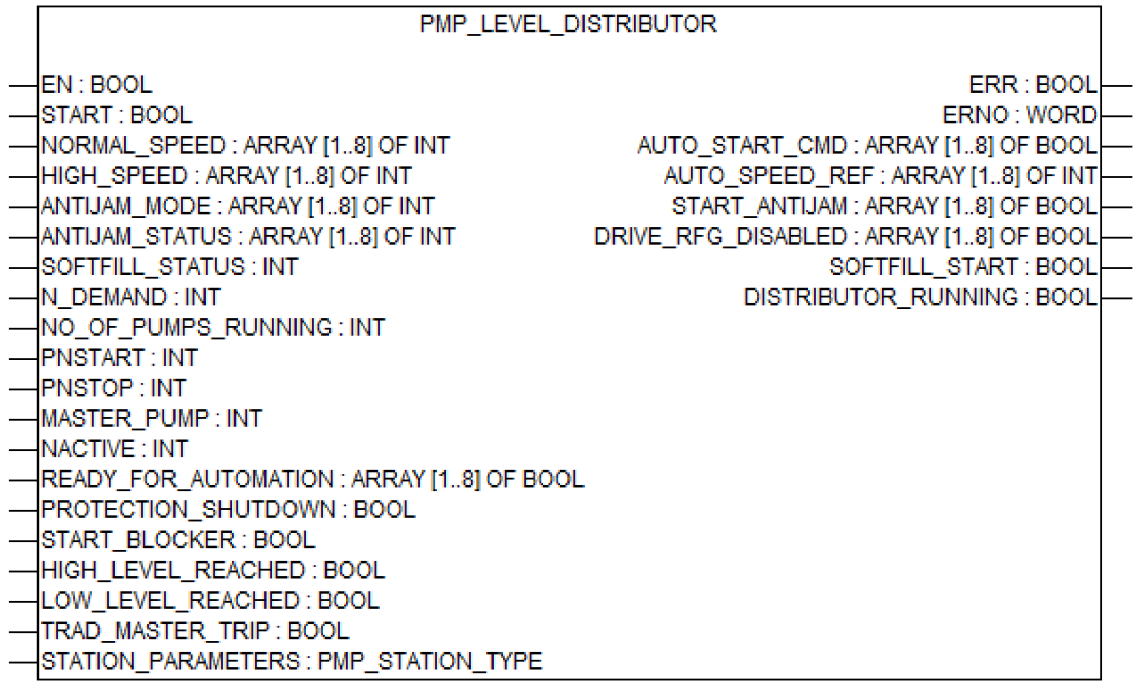
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16433	4031	Value of MODE is less than 1
16434	4032	Value of MODE is greater than 2
16449	4041	Value of LOW_LEVEL is less than 0.0
16450	4042	Value of LOW_LEVEL is greater than 100.0
16481	4061	Value of STOP_LEVEL is less than 0.0
16482	4062	Value of STOP_LEVEL is greater than 100.0
16496	4070	If MODE = 1 (Emptying), the array of START_LEVEL values must be in ascending order If MODE = 2 (Filling), the array of START_LEVEL values must be in descending order
16499	4073	If MODE = 1 (Emptying), the order of values must be LOW_LEVEL < STOP_LEVEL < START_LEVEL [1] ... [8] < HIGH_LEVEL If MODE = 2 (Filling), the order of values must be LOW_LEVEL < START_LEVEL [8] ... [1] < STOP_LEVEL < HIGH_LEVEL
16529	4091	Value of HIGH_LEVEL is less than 0.0
16530	4092	Value of HIGH_LEVEL is greater than 100.0
16577	40C1	Value of RAND_COEF is less than -10.0
16578	40C2	Value of RAND_COEF is greater than 10.0
16593	40D1	Value of STOP_MODE is less than 1
16594	40D2	Value of STOP_MODE is greater than 2

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.5 PMP_LEVEL_DISTRIBUTOR



The function block PMP_LEVEL_DISTRIBUTOR generates start commands and pump speed references based on the demand raised by PMP_LEVEL_COMPARATOR.

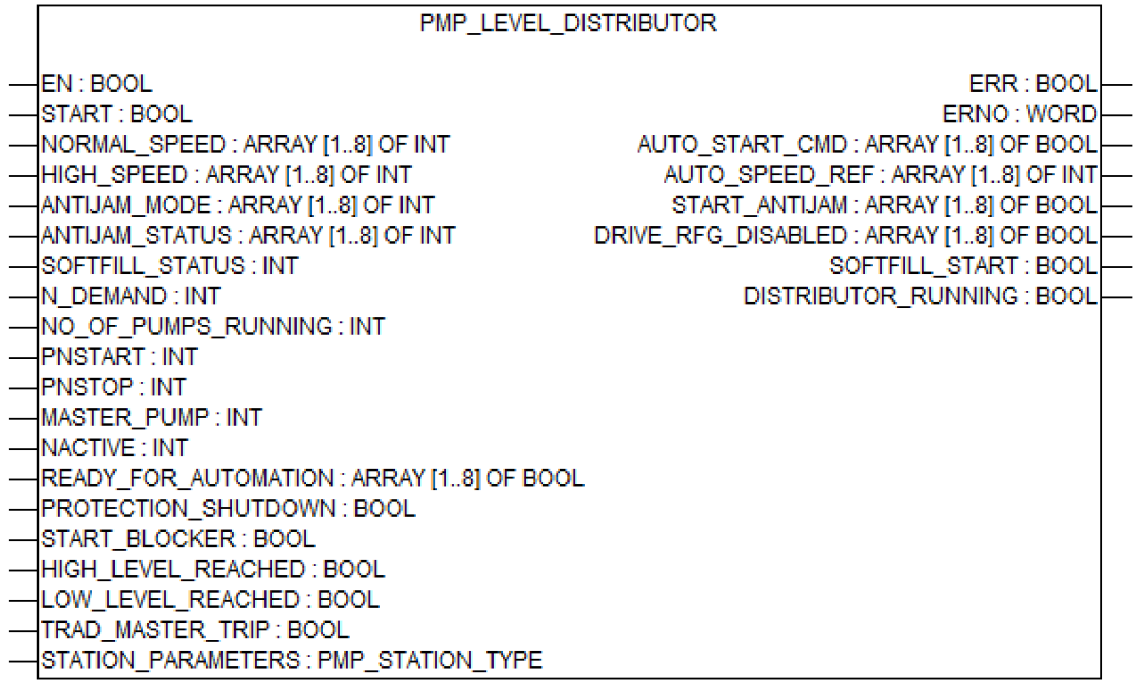
The function block receives the number of pumps in demand from the input N_DEMAND of function block PMP_LEVEL_COMPARATOR based on the process demand. The function block then sends pump ON/OFF command to function blocks PMP_INTERFACE_VFD or PMP_INTERFACE_DOL in the automatic mode of the pumping station. For the pumps run by variable frequency drive, the function block also sends speed references to function block PMP_INTERFACE_VFD.

> *This function block is used with function block PMP_LEVEL_COMPARATOR, when the function block PMP_CONFIGURATION has the input PROCESS_MODE = 3 (Level control).*

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START starts the execution of the function block.

- When input is TRUE, the execution starts.
- When input is FALSE, the execution stops if running.

NORMAL_SPEED

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	8 (1000)	> 0	rpm

The input NORMAL_SPEED defines the array of normal operating speed of all pumps for filling or emptying operations.

For e.g., the speed value in array index 1 points to PUMP_ID 1, and so on.

HIGH_SPEED

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	8 (1400)	> 0 ... NORMAL SPEED	rpm

The input HIGH_SPEED defines the array of speed values of all pumps for filling or emptying operations in the conditions below:

Filling – if pump level falls below the LOW_LEVEL

Emptying – if pump level rises above the HIGH_LEVEL.

For e.g., the speed value in array index 1 points to PUMP_ID 1, and so on.

ANTIJAM_ MODE

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	-	0 ... 3	-

The input ANTIJAM_MODE indicates the selected antijam mode.

0 = Disable antijam

1 = Master enabled

2 = At start

3 = Manual mode

The input ANTIJAM_MODE of the used pump distributor function block receives the antijam mode. This input comes from the output ANTIJAM_MODE of the function blocks PMP_ANTIJAM.

ANTIJAM_ STATUS

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	0	0 ... 2	-

The input ANTIJAM_STATUS receives the status of antijam operation. The input comes from the output ANTIJAM_STATUS of the function block PMP_ANTIJAM.

0 = Not started (Antijam operation has not started)

1 = Busy (Antijam operation has started)

2 = Done (Antijam operation is completed)

SOFTFILL_ STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 4	-

The input SOFTFILL_STATUS indicates the status of softfilling function.

0 = Disable the softfill (Softfill operation is disabled)

1 = Ready to start (Softfill operation is ready to start)

2 = Softfill in progress (Softfill operation has started)

3 = Softfill completed (Softfill operation is completed)

4 = Softfill with fault (Softfill operation stopped due to a fault)

N_DEMAND

Data type	Default value	Range	Unit
INT	0	1 ... 8	-

The input N_DEMAND of the function block PMP_LEVEL_DISTRIBUTOR receives the number of pumps demanded to run. This input comes from the output N_DEMAND of the function block PMP_LEVEL_COMPARATOR.

NO_OF_PUMPS_RUNNING

Data type	Default value	Range	Unit
INT	0	1 ... 8	-

The input NO_OF_PUMPS_RUNNING receives the number of pumps running. The input comes from the output NO_OF_PUMPS_RUNNING of the function block PMP_SEQUENCE_GEN.

PNSTART

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PNSTART receives the identification number of the next pump to start in the sequence. The input comes from the output PNSTART of the function block PMP_SEQUENCE_GEN.

PNSTOP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PNSTOP receives the identification number of the next pump to stop in the sequence. The input comes from the output PNSTOP of the function block PMP_SEQUENCE_GEN.

MASTER_PUMP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input MASTER_PUMP receives the identification number of the master pump in the sequence. The input comes from the output MASTER_PUMP of the function block PMP_SEQUENCE_GEN.

NACTIVE

Data type	Default value	Range	Unit
INT	0	1 ... 8	-

The input NACTIVE receives the number of pumps active for operation in automatic mode. The input comes from the output NACTIVE of the function block PMP_SEQUENCE_GEN.

READY_FOR_AUTOMATION

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	FALSE	TRUE/FALSE	-

The input READY_FOR_AUTOMATION receives an array of pumps ready for automatic operation. The input comes from the output READY_FOR_AUTOMATION of the function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL.

The READY_FOR_AUTOMATION[1] connects to the PUMP ID = 1. This pattern must be followed for all pump IDs.

- When input is TRUE, pump is ready for operation in automatic mode.
- When input is FALSE, pump is not ready for operation in automatic mode.

PROTECTION_ SHUTDOWN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input PROTECTION_SHUTDOWN receives a digital signal to shut down the pump station for protection. The input comes from the output PROTECTION_SHUTDOWN of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

- When input is TRUE, pump station is shutdown.
- When input is FALSE, pump station operation continues.

START_ BLOCKER

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START_BLOCKER receives a digital signal to prevent the starting of pump station for protection. The input comes from the output START_BLOCKER of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

The input START_BLOCKER will not stop the already running pump.

- When input is TRUE, pump start is not allowed.
- When input is FALSE, pump start is allowed.

HIGH_LEVEL_ REACHED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output HIGH_LEVEL_REACHED of the function block PMP_LEVEL_COMPARATOR indicates that actual level is more than high level. This function is effective only when this output is connected to the input HIGH_LEVEL_REACHED of the function block PMP_LEVEL_DISTRIBUTOR.

- When output is TRUE, actual level is more than high level.
- When output is FALSE, actual level is less than high level.

LOW_LEVEL_ REACHED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output LOW_LEVEL_REACHED of the function block PMP_LEVEL_ COMPARATOR indicates that actual level is less than low level. This function is effective only when this output is connected to the input LOW_LEVEL_REACHED of the function block PMP_LEVEL_ DISTRIBUTOR.

- When output is TRUE, actual level is less than low level.
- When output is FALSE, actual level is more than low level.

TRAD_MASTER _TRIP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Indicates that the master pump in the traditional pump combination has tripped. This input comes from the output TRAD_MASTER_TRIP of the function block PMP_SEQUENCE_GEN.

STATION_ PARAMETERS

Data type	Default value	Range	Unit
PMP_STATION_TYPE	-	-	-

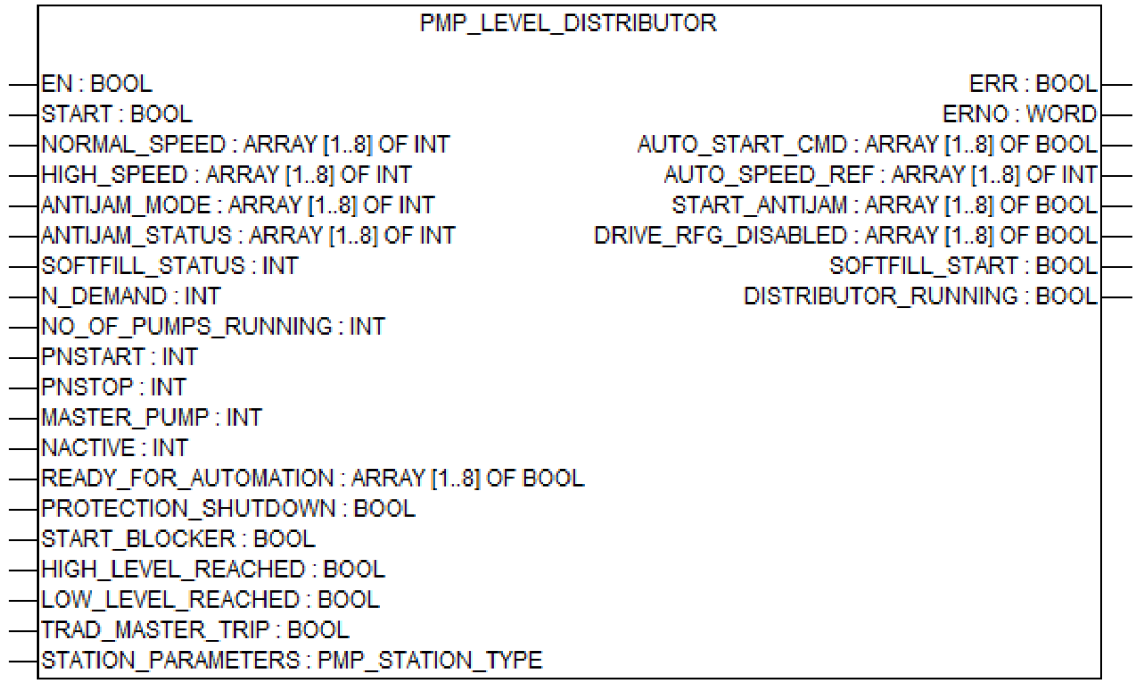
The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combination	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

AUTO_START_CMD

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	-	TRUE/FALSE	-

The output AUTO_START_CMD sends the automatic start command to the input AUTO_START_CMD of interface function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL for the required pump ID.

The output AUTO_START_CMD[1] must be connected to the input AUTO_START_CMD of function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL with PUMP ID = 1. This pattern must be followed for all pump IDs.

AUTO_SPEED_REF

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	-	-	-

The output AUTO_SPEED_REF sends the automatic speed reference value in rpm to the input PUMP_AUTO_SPEED_REF of interface function block PMP_INTERFACE_VFD of the required pump ID.

The output AUTO_SPEED_REF[1] must be connected to the input AUTO_SPEED_REF of function block PMP_INTERFACE_VFD with PUMP ID = 1. This pattern must be followed for all pump IDs.

START_ANTIJAM

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	-	TRUE/FALSE	-

The output START_ANTIJAM starts the antijam operation in automatic mode. The operation is effective only when the output is connected to the input START_AUTO of the function block PMP_ANTIJAM of the required pump ID.

The output START_ANTIJAM[1] must be connected to the input START_AUTO of function block PMP_ANTIJAM with PUMP ID = 1. This pattern must be followed for all pump IDs.

DRIVE_RFG_DISABLED

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	-	TRUE/FALSE	-

The output DRIVE_RFG_DISABLED bypasses the ramp function generator (RFG) during antijam operation. The output is effective only if the function block is connected to the control word (CW) of the drive.

SOFTFILL_START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output SOFTFILL_START of the used pump distributor starts the soft filling operation. This function is effective only when this output is connected to the input START of the function block PMP_SOFT_FILLING.

- When input is TRUE, softfill function starts.
- When input is FALSE, softfill function stops if running.

DISTRIBUTOR_RUNNING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input DISTRIBUTOR_RUNNING indicates the running status of the distributor.
This input is connected to the output DISTRIBUTOR_RUNNING of any of the the distributor function blocks PMP_LEVEL_DISTRIBUTOR, PMP_FLOW_DISTRIBUTOR or PMP_PRESSURE_DISTRIBUTOR.

- When output is TRUE, distributor is running.
- When output is FALSE, distributor is not running.

Error codes

The error codes of function block PMP_LEVEL_DISTRIBUTOR are listed below:

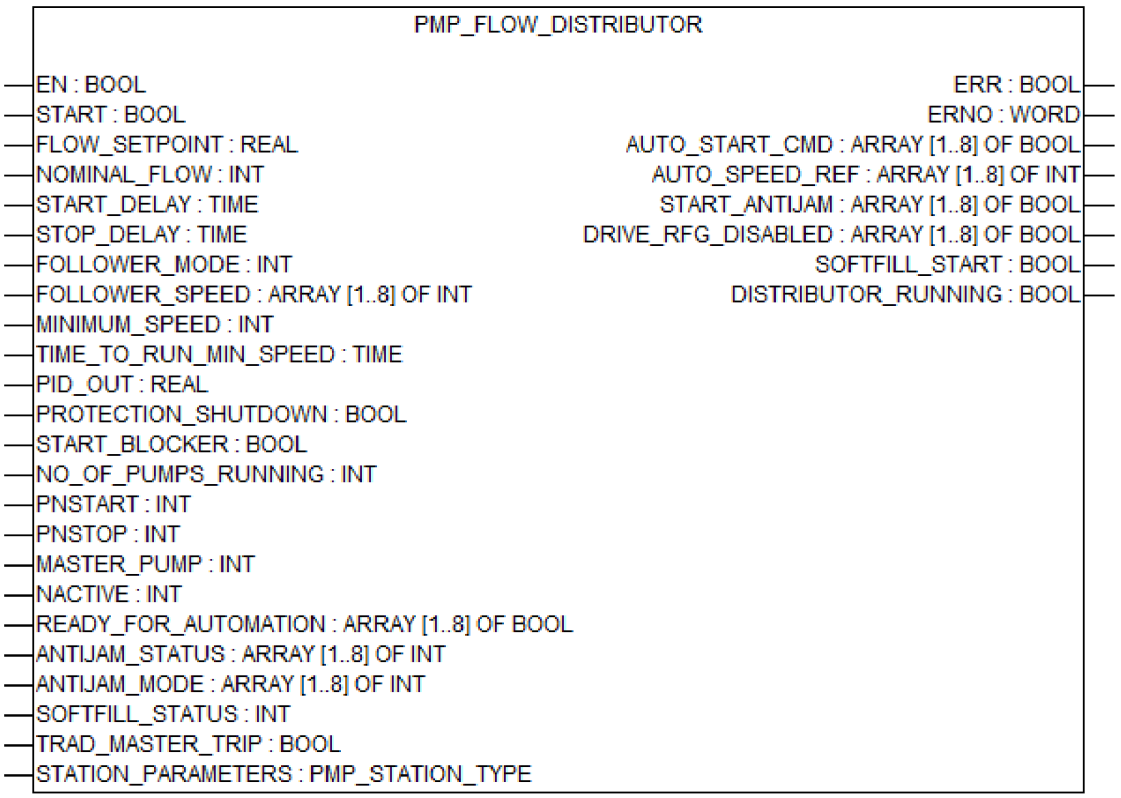
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16400	4010	Flow control can run only when the PROCESS_MODE in PMP_CONFIGURATION = 2
16433	4031	Value of FLOW_SET_POINT is less than 0
16449	4041	Value in NOMINAL_FLOW is less than or equal to 0
16450	4042	Value of HIGH_SPEED is more than NORMAL_SPEED
16465	4051	Value of ANTIJAM_MODE is less than 0
16466	4052	Value of ANTIJAM_MODE is greater than 3
16481	4061	Value of ANTIJAM_STATUS is less than 0
16482	4062	Value of ANTIJAM_STATUS is greater than 2
16497	4071	Value of SOFTFILL_STATUS is less than 0
16498	4072	Value of SOFTFILL_STATUS is greater than 3
16513	4081	Value of N_DEMAND is less than 1
16514	4082	Value of N_DEMAND is greater than NUMBER_OF_PUMPS in PMP_CONFIGURATION
16529	4091	Value of NO_OF_PUMPS_RUNNING is less than 0
16530	4092	Value of NO_OF_PUMPS_RUNNING is greater than NUMBER_OF_PUMPS in PMP_CONFIGURATION
16545	40A1	Value of PNSTART is less than 1
16546	40A2	Value of PNSTART is greater than NUMBER_OF_PUMPS in PMP_CONFIGURATION
16561	40B1	Value of PNSTOP is less than 1
16562	40B2	Value of PNSTOP is greater than NUMBER_OF_PUMPS in PMP_CONFIGURATION
16577	40C1	Value of MASTER_PUMP is less than 1
16578	40C2	Value of MASTER_PUMP is greater than NUMBER_OF_PUMPS in PMP_CONFIGURATION
16593	40D1	Value of NACTIVE is less than 1
16594	40D2	Value of NACTIVE is greater than NUMBER_OF_PUMPS in PMP_CONFIGURATION

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.6 PMP_FLOW_DISTRIBUTOR



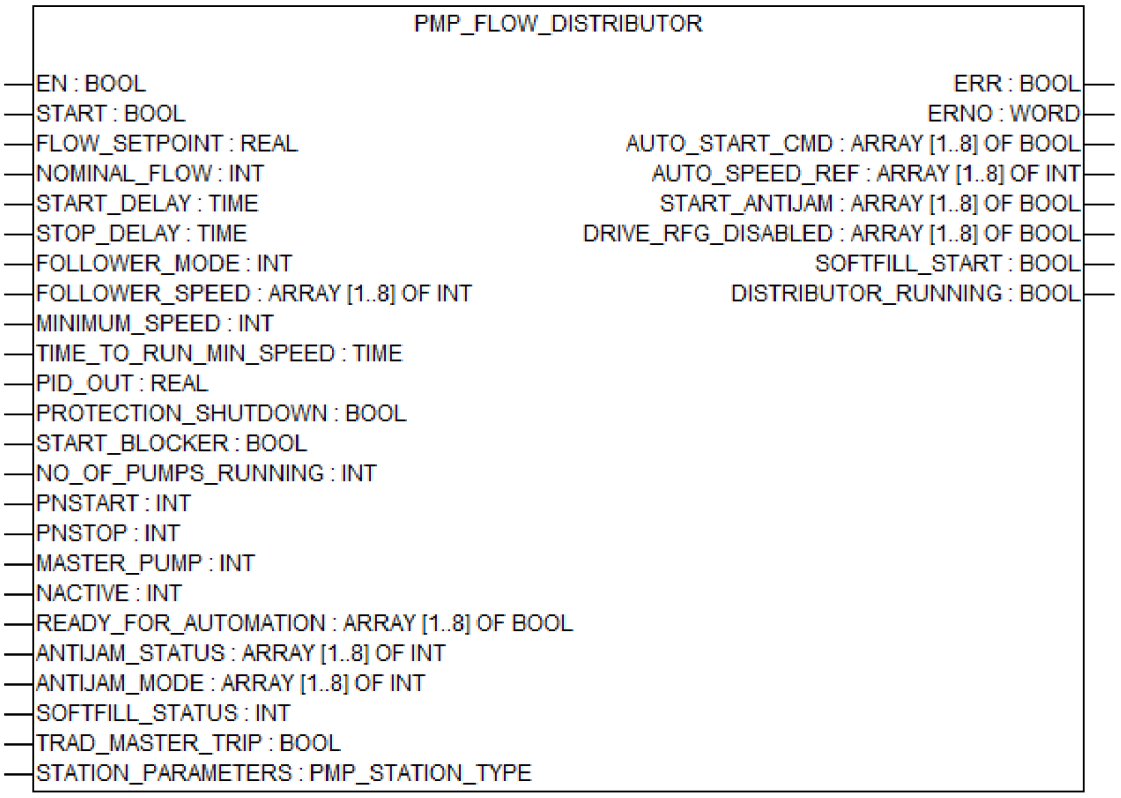
The function block PMP_FLOW_DISTRIBUTOR is used to maintain the flow in the network. The function block sends the pump ON/OFF command to the function blocks PMP_INTERFACE_VFD or PMP_INTERFACE_DOL in the automatic mode of the pumping station. For the pumps run by variable frequency drive, the function block also sends speed references to function block PMP_INTERFACE_VFD.

This function block is effective only when the input PROCESS_MODE = 2 (Flow control) in the function block PMP_CONFIGURATION.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START starts the execution of the function block.

- When input is TRUE, the execution starts.
- When input is FALSE, the execution stops if running.

FLOW_SETPOINT

Data type	Default value	Range	Unit
REAL	0.0	-	m^3/h

The input FLOW_SETPOINT defines the flow setpoint in cubic meters per hour.

NOMINAL_FLOW

Data type	Default value	Range	Unit
INT	100	-	m^3/h

The input NOMINAL_FLOW defines the nominal flow in cubic meters per hour for each pump. The input is effective in pumps of the same capacity.

START_DELAY

Data type	Default value	Range	Unit
TIME	0	-	s

The input START_DELAY defines the delay time to start the follower pumps.

STOP_DELAY

Data type	Default value	Range	Unit
TIME	0	-	s

The input STOP_DELAY defines the delay time to stop the follower pumps.

FOLLOWER_MODE

Data type	Default value	Range	Unit
INT	1	1 ... 2	-

The input FOLLOWER_MODE selects the follower mode of the follower pumps.

1 = Copy master mode to run at the master pump speed

2 = Fixed speed mode to run at its own speed

FOLLOWER_SPEED

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	-	> 0	rpm

The input FOLLOWER_SPEED defines the follower speed in rpm for each pump when the input FOLLOWER_MODE = 2 (Fixed speed mode to run at its own speed).

MINIMUM_SPEED

Data type	Default value	Range	Unit
INT	100	> 0	rpm

The input MINIMUM_SPEED defines the minimum speed in rpm at which the pump should run to maintain the minimum flow.

TIME_TO_RUN_MIN_SPEED

Data type	Default value	Range	Unit
TIME	5	-	s

The input TIME_TO_RUN_MIN_SPEED defines the time limit at which the pump should run at the value in the input MINIMUM_SPEED. After this time duration has elapsed the PID control take over the control of flow or pressure and the pumps start running based on the PID output and the follower mode speed.

PID_OUT

Data type	Default value	Range	Unit
REAL	0.0	-	%

The input PID_OUT of the function block PMP_SLEEP indicates the PID output in percentage. The value is the same as the output PID_OUT of the function blocks PMP_PID.

PROTECTION_ SHUTDOWN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input PROTECTION_SHUTDOWN receives a digital signal to shut down the pump station for protection. The input comes from the output PROTECTION_SHUTDOWN of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

- When input is TRUE, pump station is shutdown.
- When input is FALSE, pump station operation continues.

START_ BLOCKER

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START_BLOCKER receives a digital signal to prevent the starting of pump station for protection. The input comes from the output START_BLOCKER of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

The input START_BLOCKER will not stop the already running pump.

- When input is TRUE, pump start is not allowed.
- When input is FALSE, pump start is allowed.

NO_OF_PUMPS _RUNNING

Data type	Default value	Range	Unit
INT	0	1 ... 8	-

The input NO_OF_PUMPS_RUNNING receives the number of pumps running. The input comes from the output NO_OF_PUMPS_RUNNING of the function block PMP_SEQUENCE_GEN.

PNSTART

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PNSTART receives the identification number of the next pump to start in the sequence. The input comes from the output PNSTART of the function block PMP_SEQUENCE_GEN.

PNSTOP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PNSTOP receives the identification number of the next pump to stop in the sequence. The input comes from the output PNSTOP of the function block PMP_SEQUENCE_GEN.

MASTER_PUMP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input MASTER_PUMP receives the identification number of the master pump in the sequence. The input comes from the output MASTER_PUMP of the function block PMP_SEQUENCE_GEN.

NACTIVE

Data type	Default value	Range	Unit
INT	0	1 ... 8	-

The input NACTIVE receives the number of pumps active for operation in automatic mode. The input comes from the output NACTIVE of the function block PMP_SEQUENCE_GEN.

READY_FOR_ AUTOMATION

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	FALSE	TRUE/FALSE	-

The input READY_FOR_AUTOMATION receives an array of pumps ready for automatic operation. The input comes from the output READY_FOR_AUTOMATION of the function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL.

The READY_FOR_AUTOMATION[1] connects to the PUMP ID = 1. This pattern must be followed for all pump IDs.

- When input is TRUE, pump is ready for operation in automatic mode.
- When input is FALSE, pump is not ready for operation in automatic mode.

ANTIJAM_ STATUS

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	0	0 ... 2	-

The input ANTIJAM_STATUS receives the status of antijam operation. The input comes from the output ANTIJAM_STATUS of the function block PMP_ANTIJAM.

0 = Not started (Antijam operation has not started)

1 = Busy (Antijam operation has started)

2 = Done (Antijam operation is completed)

ANTIJAM_ MODE

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	-	0 ... 3	-

The input ANTIJAM_MODE indicates the selected antijam mode.

0 = Disable antijam

1 = Master enabled

2 = At start

3 = Manual mode

The input ANTIJAM_MODE of the used pump distributor function block receives the antijam mode. This input comes from the output ANTIJAM_MODE of the function blocks PMP_ANTIJAM.

SOFTFILL_ STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 4	-

The input SOFTFILL_STATUS indicates the status of softfilling function.

0 = Disable the softfill (Softfill operation is disabled)

1 = Ready to start (Softfill operation is ready to start)

2 = Softfill in progress (Softfill operation has started)

3 = Softfill completed (Softfill operation is completed)

4 = Softfill with fault (Softfill operation stopped due to a fault)

TRAD_MASTER _TRIP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Indicates that the master pump in the traditional pump combination has tripped. This input comes from the output TRAD_MASTER_TRIP of the function block PMP_SEQUENCE_GEN.

STATION_ PARAMETERS

Data type	Default value	Range	Unit
PMP_STA-TION_TYPE	-	-	-

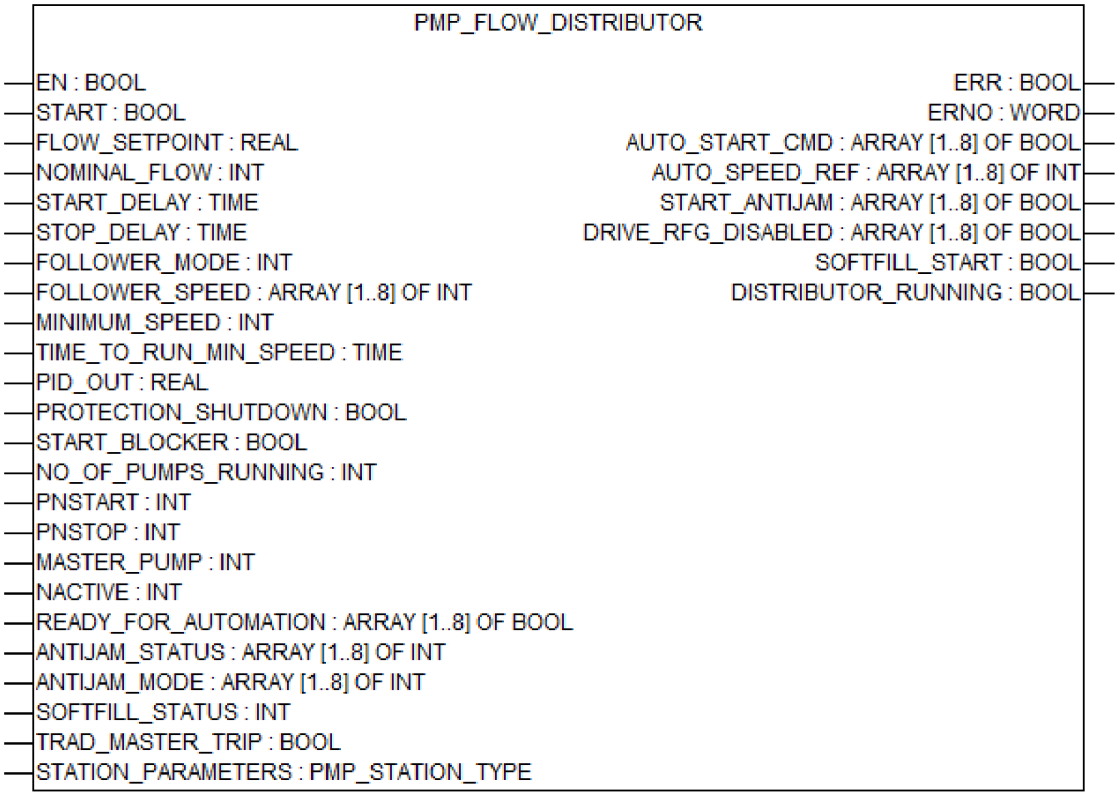
The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combina-tion	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

AUTO_START_CMD

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	-	TRUE/FALSE	-

The output AUTO_START_CMD sends the automatic start command to the input AUTO_START_CMD of interface function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL for the required pump ID.

> *The output AUTO_START_CMD[1] must be connected to the input AUTO_START_CMD of function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL with PUMP ID = 1. This pattern must be followed for all pump IDs.*

AUTO_SPEED_REF

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	-	-	-

The output AUTO_SPEED_REF sends the automatic speed reference value in rpm to the input PUMP_AUTO_SPEED_REF of interface function block PMP_INTERFACE_VFD of the required pump ID.

The output AUTO_SPEED_REF[1] must be connected to the input AUTO_SPEED_REF of function block PMP_INTERFACE_VFD with PUMP ID = 1. This pattern must be followed for all pump IDs.

START_ANTIJAM

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	-	TRUE/FALSE	-

The output START_ANTIJAM starts the antijam operation in automatic mode. The operation is effective only when the output is connected to the input START_AUTO of the function block PMP_ANTIJAM of the required pump ID.

The output START_ANTIJAM[1] must be connected to the input START_AUTO of function block PMP_ANTIJAM with PUMP ID = 1. This pattern must be followed for all pump IDs.

DRIVE_RFG_DISABLED

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	-	TRUE/FALSE	-

The output DRIVE_RFG_DISABLED bypasses the ramp function generator (RFG) during antijam operation. The output is effective only if the function block is connected to the control word (CW) of the drive.

SOFTFILL_START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output SOFTFILL_START of the used pump distributor starts the soft filling operation. This function is effective only when this output is connected to the input START of the function block PMP_SOFT_FILLING.

- When input is TRUE, softfill function starts.
- When input is FALSE, softfill function stops if running.

DISTRIBUTOR_RUNNING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input DISTRIBUTOR_RUNNING indicates the running status of the distributor.
This input is connected to the output DISTRIBUTOR_RUNNING of any of the the distributor function blocks PMP_LEVEL_DISTRIBUTOR, PMP_FLOW_DISTRIBUTOR or PMP_PRESSURE_DISTRIBUTOR.

- When output is TRUE, distributor is running.
- When output is FALSE, distributor is not running.

Error codes

The error codes of function block PMP_FLOW_DISTRIBUTOR are listed below:

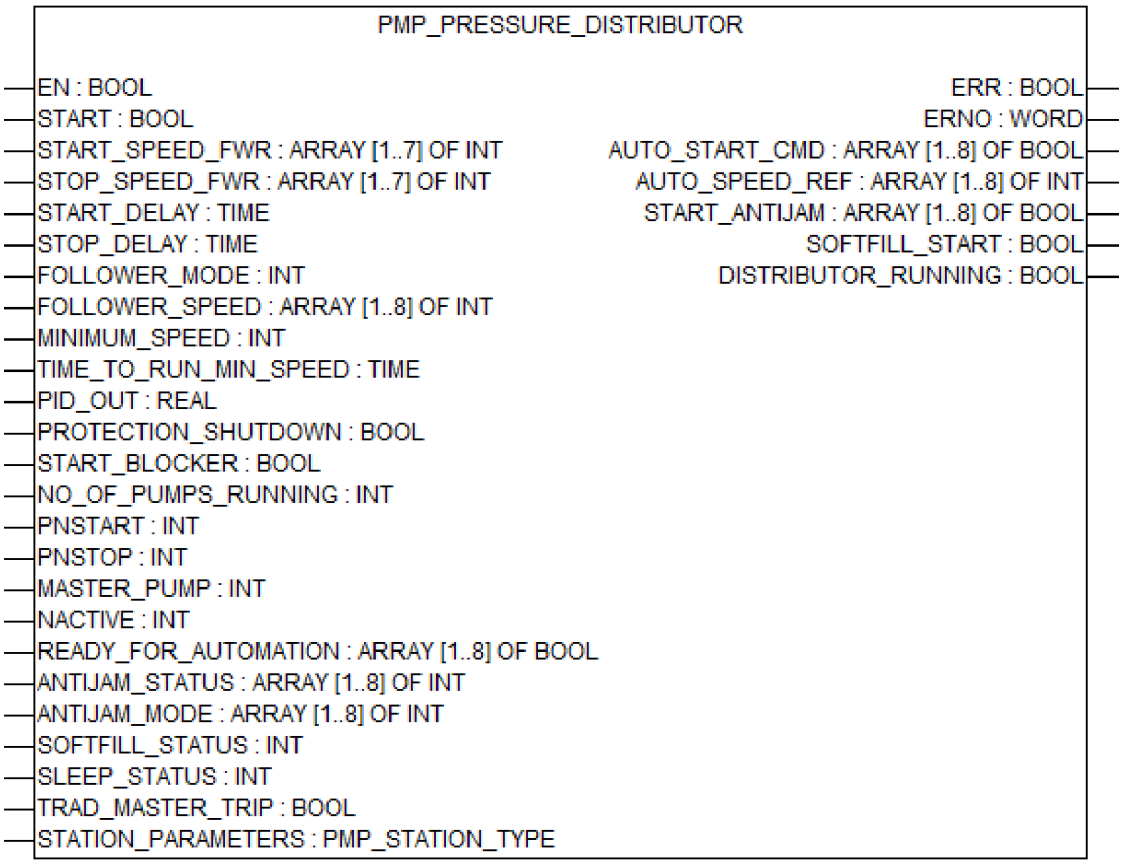
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16400	4010	Flow control can run only when the PROCESS_MODE in PMP_CONFIGURATION = 2
16433	4031	Value of FLOW_SET_POINT is less than 0
16449	4041	Value in NOMINAL_FLOW is less than or equal to 0
16497	4071	Value in FOLLOWER_MODE is less than 1
16498	4072	Value in FOLLOWER_MODE is greater than 2
16512	4080	Array in FOLLOWER_SPEED is less than or equal to 0
16529	4091	Value in MINIMUM_SPEED is less than 0

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.7 PMP_PRESSURE_DISTRIBUTOR



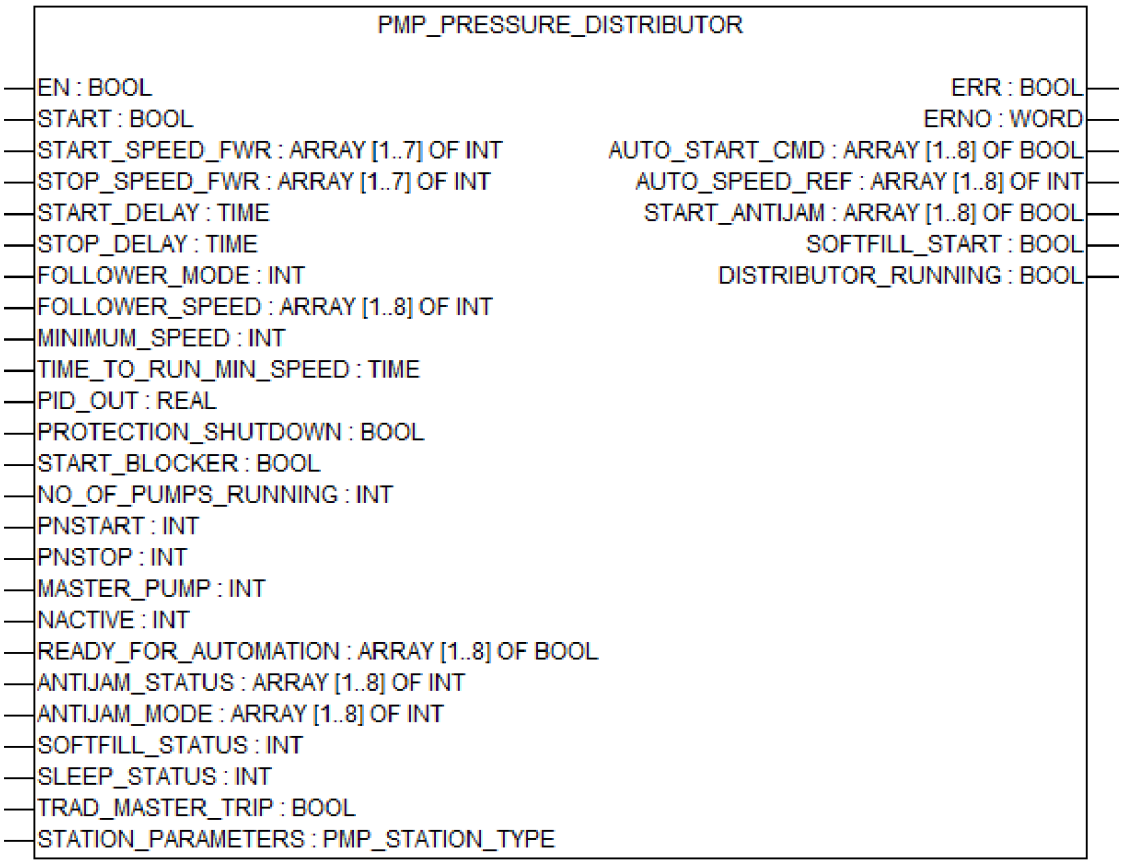
The function block PMP_PRESSURE_DISTRIBUTOR is used to stabilize pressure in the network. The function block is used together with function block PMP_PID to stabilize pressure in the network. The function block then sends pump ON/OFF command to the function blocks PMP_INTERFACE_VFD or PMP_INTERFACE_DOL in the automatic mode of the pumping station. For pumps run by variable frequency drive, the function block also sends speed references to function block PMP_INTERFACE_VFD.

> *This function block is effective only when the input PROCESS_MODE = 1 (Pressure control) in function block PMP_CONFIGURATION.*

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START starts the execution of the function block.

- When input is TRUE, the execution starts.
- When input is FALSE, the execution stops if running.

START_SPEED_FWR

Data type	Default value	Range	Unit
ARRAY[1..7] of INT	-	-	rpm

The input START_SPEED_FWR defines the start speed in rpm for the seven follower pumps.

STOP_SPEED_FWR

Data type	Default value	Range	Unit
ARRAY[1..7] of INT	-	-	rpm

The input STOP_SPEED_FWR defines the stop speed in rpm for the seven follower pumps.

START_DELAY

Data type	Default value	Range	Unit
TIME	0	-	s

The input START_DELAY defines the delay time to start the follower pumps.

STOP_DELAY

Data type	Default value	Range	Unit
TIME	0	-	s

The input STOP_DELAY defines the delay time to stop the follower pumps.

FOLLOWER_MODE

Data type	Default value	Range	Unit
INT	1	1 ... 2	-

The input FOLLOWER_MODE selects the follower mode of the follower pumps.

1 = Copy master mode to run at the master pump speed

2 = Fixed speed mode to run at its own speed

FOLLOWER_SPEED

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	-	> 0	rpm

The input FOLLOWER_SPEED defines the follower speed in rpm for each pump when the input FOLLOWER_MODE = 2 (Fixed speed mode to run at its own speed).

MINIMUM_SPEED

Data type	Default value	Range	Unit
INT	100	> 0	rpm

The input MINIMUM_SPEED defines the minimum speed in rpm at which the pump should run to maintain the minimum flow.

TIME_TO_RUN_MIN_SPEED

Data type	Default value	Range	Unit
TIME	5	-	s

The input TIME_TO_RUN_MIN_SPEED defines the time limit at which the pump should run at the value in the input MINIMUM_SPEED. After this time duration has elapsed the PID control take over the control of flow or pressure and the pumps start running based on the PID output and the follower mode speed.

PID_OUT

Data type	Default value	Range	Unit
REAL	0.0	-	%

The input PID_OUT of the function block PMP_SLEEP indicates the PID output in percentage. The value is the same as the output PID_OUT of the function blocks PMP_PID.

PROTECTION_ SHUTDOWN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input PROTECTION_SHUTDOWN receives a digital signal to shut down the pump station for protection. The input comes from the output PROTECTION_SHUTDOWN of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

- When input is TRUE, pump station is shutdown.
- When input is FALSE, pump station operation continues.

START_ BLOCKER

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START_BLOCKER receives a digital signal to prevent the starting of pump station for protection. The input comes from the output START_BLOCKER of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

The input START_BLOCKER will not stop the already running pump.

- When input is TRUE, pump start is not allowed.
- When input is FALSE, pump start is allowed.

NO_OF_PUMPS _RUNNING

Data type	Default value	Range	Unit
INT	0	1 ... 8	-

The input NO_OF_PUMPS_RUNNING receives the number of pumps running. The input comes from the output NO_OF_PUMPS_RUNNING of the function block PMP_SEQUENCE_GEN.

PNSTART

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PNSTART receives the identification number of the next pump to start in the sequence. The input comes from the output PNSTART of the function block PMP_SEQUENCE_GEN.

PNSTOP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PNSTOP receives the identification number of the next pump to stop in the sequence. The input comes from the output PNSTOP of the function block PMP_SEQUENCE_GEN.

MASTER_PUMP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input MASTER_PUMP receives the identification number of the master pump in the sequence. The input comes from the output MASTER_PUMP of the function block PMP_SEQUENCE_GEN.

NACTIVE

Data type	Default value	Range	Unit
INT	0	1 ... 8	-

The input NACTIVE receives the number of pumps active for operation in automatic mode. The input comes from the output NACTIVE of the function block PMP_SEQUENCE_GEN.

READY_FOR_ AUTOMATION

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	FALSE	TRUE/FALSE	-

The input READY_FOR_AUTOMATION receives an array of pumps ready for automatic operation. The input comes from the output READY_FOR_AUTOMATION of the function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL.

The READY_FOR_AUTOMATION[1] connects to the PUMP ID = 1. This pattern must be followed for all pump IDs.

- When input is TRUE, pump is ready for operation in automatic mode.
- When input is FALSE, pump is not ready for operation in automatic mode.

ANTIJAM_ STATUS

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	0	0 ... 2	-

The input ANTIJAM_STATUS receives the status of antijam operation. The input comes from the output ANTIJAM_STATUS of the function block PMP_ANTIJAM.

0 = Not started (Antijam operation has not started)

1 = Busy (Antijam operation has started)

2 = Done (Antijam operation is completed)

ANTIJAM_ MODE

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	-	0 ... 3	-

The input ANTIJAM_MODE indicates the selected antijam mode.

0 = Disable antijam

1 = Master enabled

2 = At start

3 = Manual mode

The input ANTIJAM_MODE of the used pump distributor function block receives the antijam mode. This input comes from the output ANTIJAM_MODE of the function blocks PMP_ANTIJAM.

SOFTFILL_ STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 4	-

The input SOFTFILL_STATUS indicates the status of softfilling function.

0 = Disable the softfill (Softfill operation is disabled)

1 = Ready to start (Softfill operation is ready to start)

2 = Softfill in progress (Softfill operation has started)

3 = Softfill completed (Softfill operation is completed)

4 = Softfill with fault (Softfill operation stopped due to a fault)

SLEEP_STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 3	-

The output SLEEP_STATUS of the function block PMP_SLEEP indicates the sleep status of the pump.

0 = Inactive/Wakeup inactive

1 = Boost activated

2 = Sleep mode active

3 = Wakeup function active

TRAD_MASTER _TRIP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Indicates that the master pump in the traditional pump combination has tripped. This input comes from the output TRAD_MASTER_TRIP of the function block PMP_SEQUENCE_GEN.

STATION_ PARAMETERS

Data type	Default value	Range	Unit
PMP_STA-TION_TYPE	-	-	-

The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

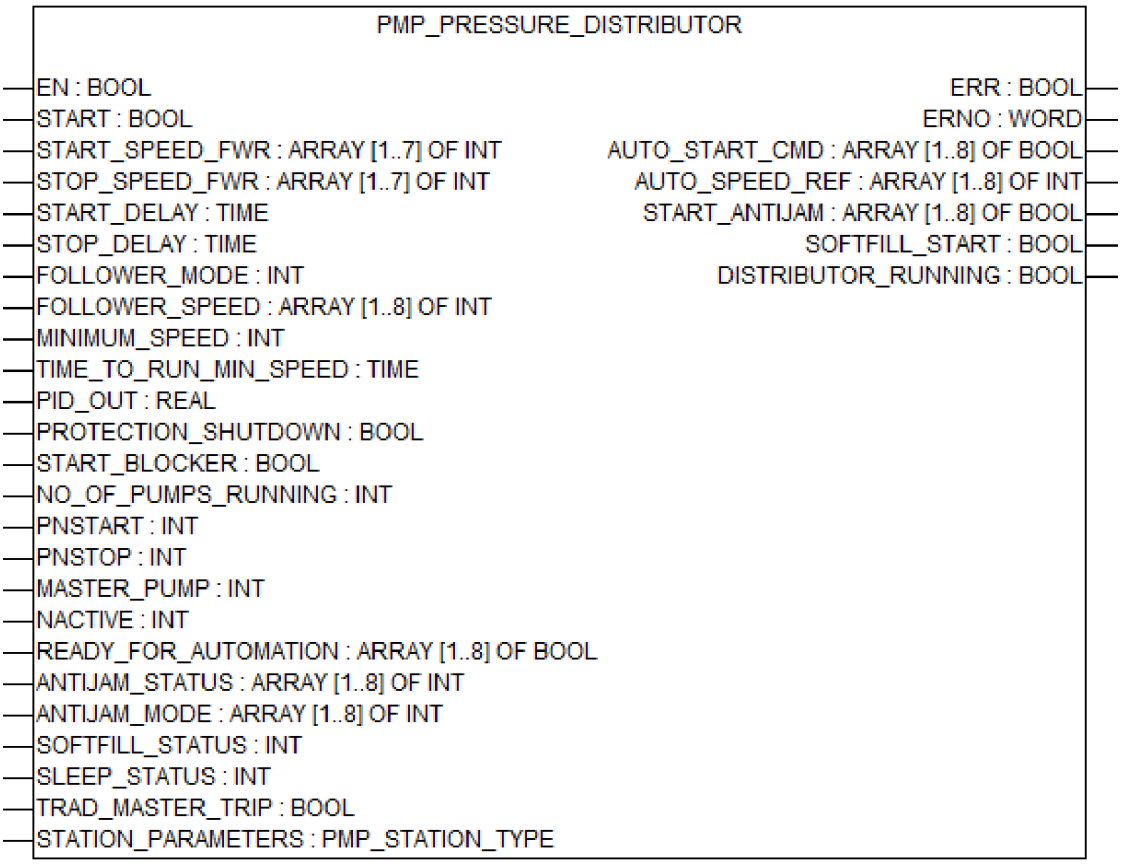
All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station

Parameter	Data type	Default value	Description
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combina-tion	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

AUTO_START_CMD

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	-	TRUE/FALSE	-

The output AUTO_START_CMD sends the automatic start command to the input AUTO_START_CMD of interface function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL for the required pump ID.

The output AUTO_START_CMD[1] must be connected to the input AUTO_START_CMD of function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL with PUMP ID = 1. This pattern must be followed for all pump IDs.

AUTO_SPEED_REF

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	-	-	-

The output AUTO_SPEED_REF sends the automatic speed reference value in rpm to the input PUMP_AUTO_SPEED_REF of interface function block PMP_INTERFACE_VFD of the required pump ID.

The output AUTO_SPEED_REF[1] must be connected to the input AUTO_SPEED_REF of function block PMP_INTERFACE_VFD with PUMP ID = 1. This pattern must be followed for all pump IDs.

START_ANTIJAM

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	-	TRUE/FALSE	-

The output START_ANTIJAM starts the antijam operation in automatic mode. The operation is effective only when the output is connected to the input START_AUTO of the function block PMP_ANTIJAM of the required pump ID.

The output START_ANTIJAM[1] must be connected to the input START_AUTO of function block PMP_ANTIJAM with PUMP ID = 1. This pattern must be followed for all pump IDs.

SOFTFILL_START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output SOFTFILL_START of the used pump distributor starts the soft filling operation. This function is effective only when this output is connected to the input START of the function block PMP_SOFT_FILLING.

- When input is TRUE, softfill function starts.
- When input is FALSE, softfill function stops if running.

DISTRIBUTOR_RUNNING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input DISTRIBUTOR_RUNNING indicates the running status of the distributor. This input is connected to the output DISTRIBUTOR_RUNNING of any of the the distributor function blocks PMP_LEVEL_DISTRIBUTOR, PMP_FLOW_DISTRIBUTOR or PMP_PRESSURE_DISTRIBUTOR.

- When output is TRUE, distributor is running.
- When output is FALSE, distributor is not running.

Error codes

The error codes of function block PMP_FLOW_DISTRIBUTOR are listed below:

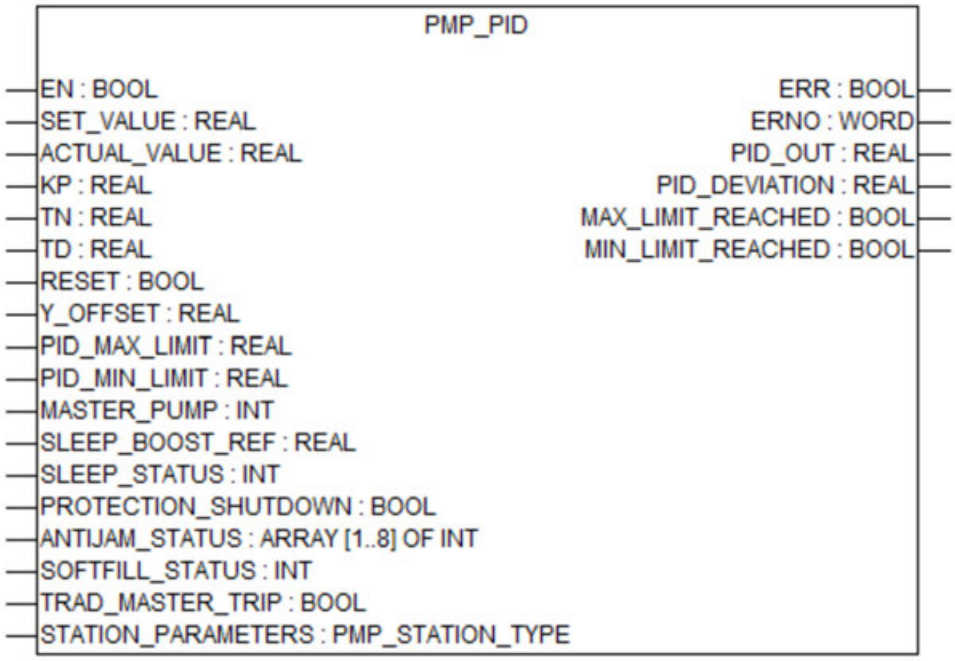
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16400	4010	Flow control can run only when the PROCESS_MODE in PMP_CONFIGURATION = 2
16432	4030	Value in START_SPEED_SLV is not in ascending order
16448	4040	Value in STOP_SPEED_SLV is not in ascending order
16451	4043	Value in START_SPEED_SLV[1] is not greater than STOP_SPEED_SLV[1] and so on for the rest of the pumps
16497	4071	Value in FOLLOWER_MODE is less than 1
16498	4072	Value in FOLLOWER_MODE is greater than 2
16512	4080	Array in FOLLOWER_SPEED is not in ascending order
16529	4091	Value in MINIMUM_SPEED is less than the minimum limit

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.8 PMP_PID

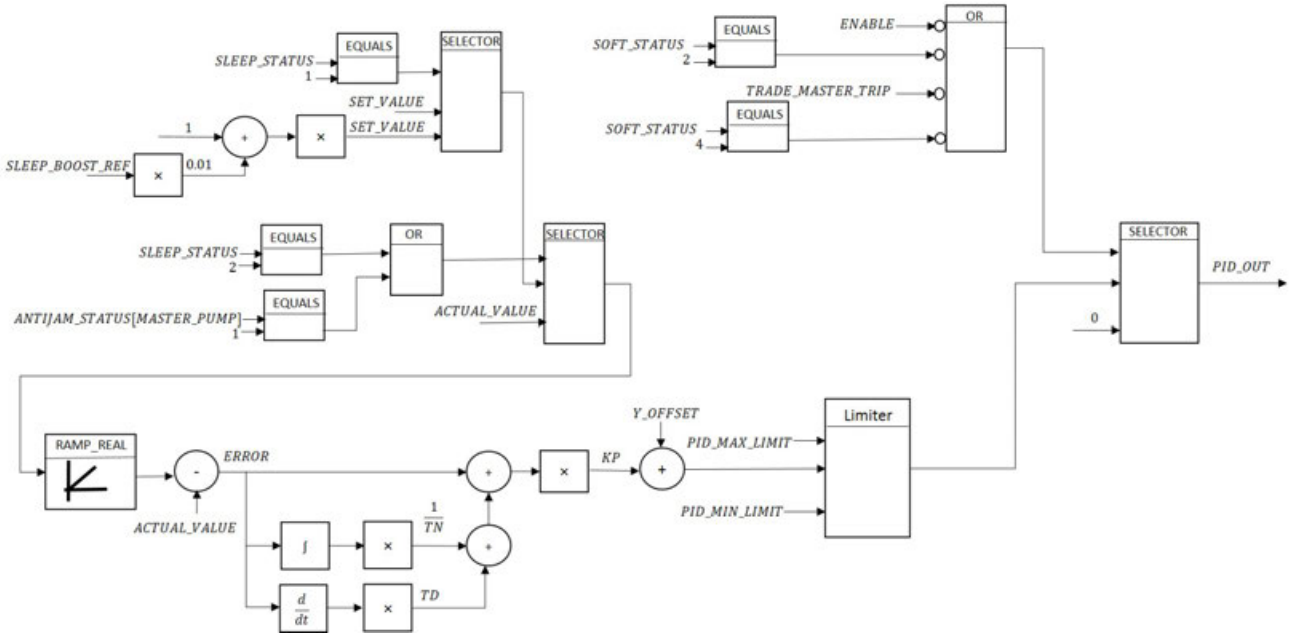


The function block PMP_PID is used for closed loop control of pressure or flow in the network.

The function block receives the set value and actual value from the process and does the closed loop control. The function block is used to control pressure or flow when the input PROCESS_MODE of function block PMP_CONFIGURATION is selected as either pressure control (1) or flow control (2) in the multi pumping and traditional pumping station.

> *This function is not used on DOL pumping stations.*

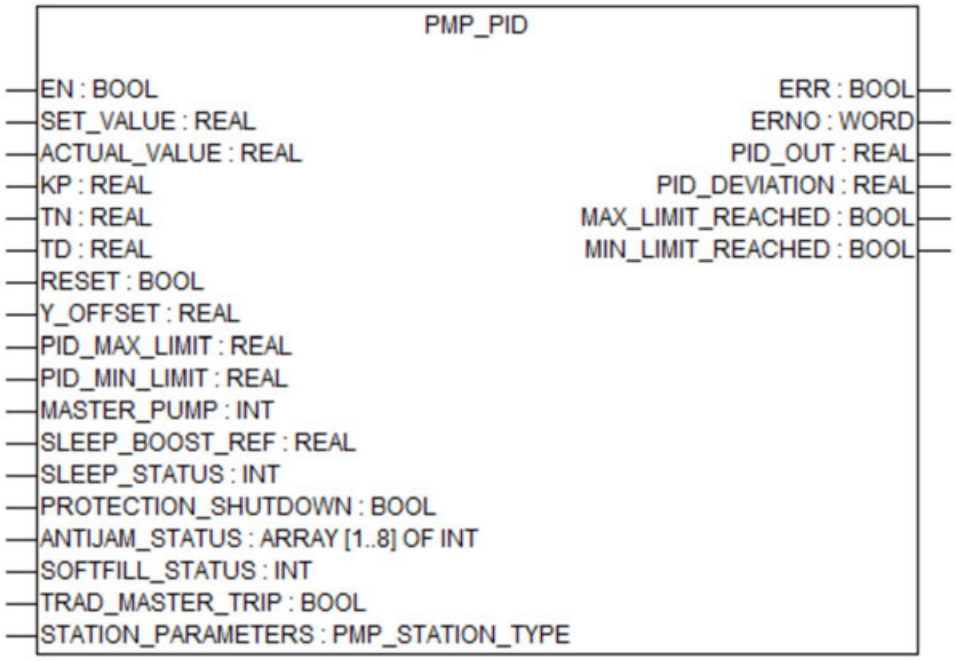
Functionality The functionality of the PMP_PID is explained in the figure below.



General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SET_VALUE

Data type	Default value	Range	Unit
REAL	1.0	> 0.0	Pressure: bar Flow: m^3/h

The input SET_VALUE defines the set value of process variable in real values, e.g.,

bar for pressure,

cubic meters per hour for flow.

ACTUAL_ VALUE

Data type	Default value	Range	Unit
REAL	0.0	> 0.0	Pressure: bar Flow: m^3/h

The input ACTUAL_VALUE defines the actual value of process variable in real values. The unit is same as the unit in the input SET_VALUE.

KP

Data type	Default value	Range	Unit
REAL	0.1	> 0.0	

The input KP defines the proportional gain of the PID.

TN

Data type	Default value	Range	Unit
REAL	1.0	> 0.0	s

The input TN defines the integral time of the PID in seconds.

TD

Data type	Default value	Range	Unit
REAL	0.0	> 0.0	s

The input TD defines the derivative time of the PID in seconds.

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input RESET resets the output of the PID and works as AntiWind Up.

- When input is TRUE, PID output is reset.
- When input is FALSE, PID output is not reset.

Y_OFFSET

Data type	Default value	Range	Unit
REAL	0.0	0.0 ... 200.0	-

The input Y_OFFSET adds the offset to the PID output.

PID_MAX_LIMIT

Data type	Default value	Range	Unit
REAL	100.0	0.0 ... 200.0	-

The input PID_MAX_LIMIT defines the maximum limit of the PID output.

PID_MIN_LIMIT

Data type	Default value	Range	Unit
REAL	0.0	0.0 ... 200.0	-

The input PID_MIN_LIMIT defines the minimum limit of the PID output.

MASTER_PUMP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input MASTER_PUMP receives the identification number of the master pump in the sequence. The input comes from the output MASTER_PUMP of the function block PMP_SEQUENCE_GEN.

SLEEP_ BOOST_REF

Data type	Default value	Range	Unit
REAL	0.0	> 0.0	-

The output SLEEP_BOOST_REF of the function block PMP_SLEEP indicates the sleep boost reference. This output is connected as input into PMP_PID function block.

SLEEP_STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 3	-

The output SLEEP_STATUS of the function block PMP_SLEEP indicates the sleep status of the pump.

0 = Inactive/Wakeup inactive

1 = Boost activated

2 = Sleep mode active

3 = Wakeup function active

PROTECTION_ SHUTDOWN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input PROTECTION_SHUTDOWN receives a digital signal to shut down the pump station for protection. The input comes from the output PROTECTION_SHUTDOWN of the protection function blocks PMP_PROTECTION_ANALOG and PMP_PROTECTION_BINARY.

- When input is TRUE, pump station is shutdown.
- When input is FALSE, pump station operation continues.

ANTIJAM_ STATUS

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	0	0 ... 2	-

The input ANTIJAM_STATUS receives the status of antijam operation. The input comes from the output ANTIJAM_STATUS of the function block PMP_ANTIJAM.

0 = Not started (Antijam operation has not started)

1 = Busy (Antijam operation has started)

2 = Done (Antijam operation is completed)

SOFTFILL_ STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 4	-

The input SOFTFILL_STATUS indicates the status of softfilling function.

0 = Disable the softfill (Softfill operation is disabled)

1 = Ready to start (Softfill operation is ready to start)

2 = Softfill in progress (Softfill operation has started)

3 = Softfill completed (Softfill operation is completed)

4 = Softfill with fault (Softfill operation stopped due to a fault)

TRAD_MASTER _TRIP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Indicates that the master pump in the traditional pump combination has tripped. This input comes from the output TRAD_MASTER_TRIP of the function block PMP_SEQUENCE_GEN.

STATION_ PARAMETERS

Data type	Default value	Range	Unit
PMP_STA-TION_TYPE	-	-	-

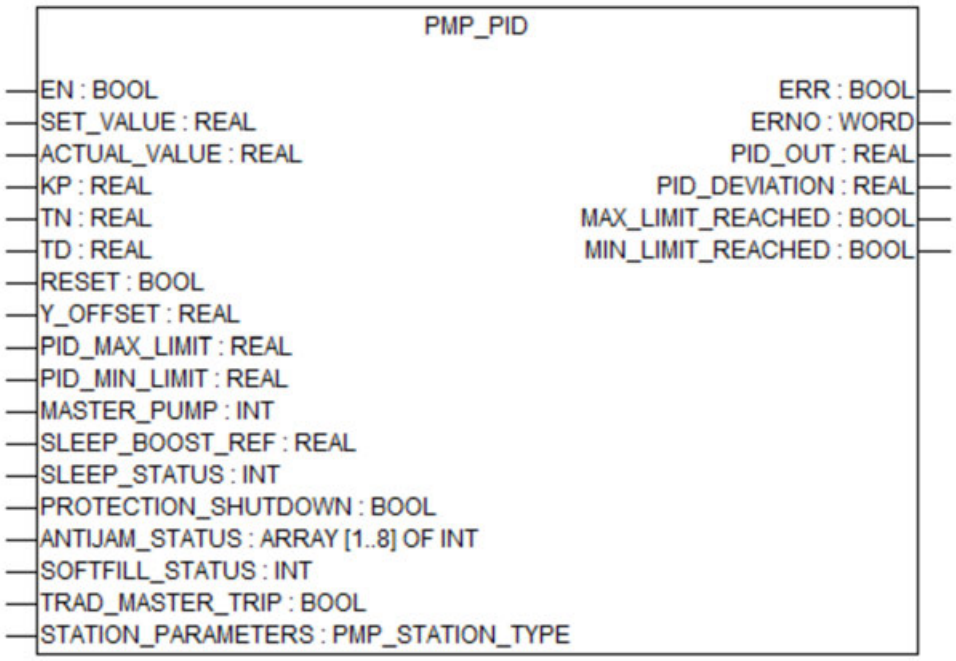
The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combina-tion	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

PID_OUT

Data type	Default value	Range	Unit
REAL	0.0	-	%

The input PID_OUT of the function block PMP_SLEEP indicates the PID output in percentage. The value is the same as the output PID_OUT of the function blocks PMP_PID.

PID_DEVIATION

Data type	Default value	Range	Unit
REAL	0.0	-	%

The output PID_DEVIATION indicates PID error which is deviation of set value from actual value.

MAX_LIMIT_ REACHED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output MAX_LIMIT_REACHED indicates that the PID output has reached the maximum limit.

- When output is TRUE, PID output has reached maximum limit.
- When output is FALSE, PID output is below the maximum limit.

MIN_LIMIT_ REACHED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output MIN_LIMIT_REACHED indicates that the PID output has reached the minimum limit.

- When output is TRUE, PID output has reached minimum limit.
- When output is FALSE, PID output is above the minimum limit.

Error codes

The error codes of function block PMP_PID are listed below:

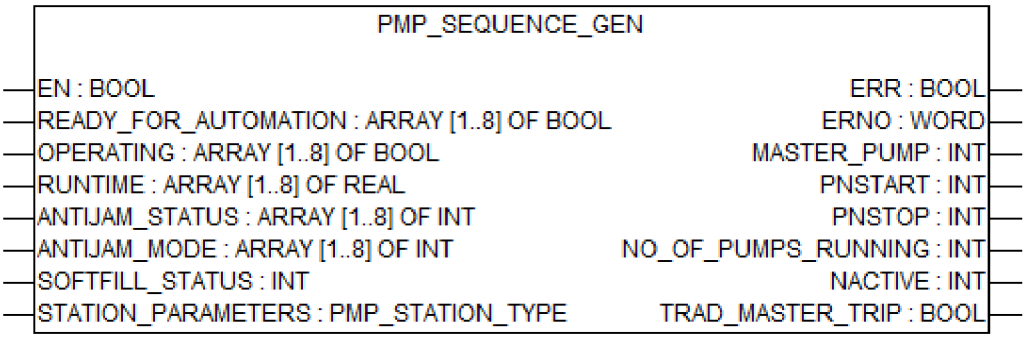
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16417	4021	Value in input SET_VALUE is less than 0.0
16433	4031	Value in input ACTUAL_VALUE is less than 0.0
16449	4041	Value in input KP is less than 0.0
16465	4051	Value in input TN is less than 0.0
16481	4061	Value in input TD is less than 0.0
16513	4081	Value in input Y_OFFSET is less than 0.0
16514	4082	Value in input Y_OFFSET is more than PID_MAX_LIMIT.
16529	4091	Value in input PID_MAX_LIMIT is less than PID_MIN_LIMIT
16530	4092	Value in input PID_MAX_LIMIT is greater than 200.0
16545	40A1	Value in input PID_MIN_LIMIT is less than 0.0
16577	40C1	Value in input SLEEP_BOOST_REF is less than 0.0
16593	40D1	Value in input SLEEP_STATUS is less than 0
16594	40D2	Value in input SLEEP_STATUS is greater than 3
16625	40F1	Value in input ANTIJAM_STATUS is less than 0
16626	40F2	Value in input ANTIJAM_STATUS is greater than 2
16641	4101	Value in input SOFTFILL_STATUS is less than 0
16642	4102	Value in input SOFTFILL_STATUS is greater than 4

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.9 PMP_SEQUENCE_GEN



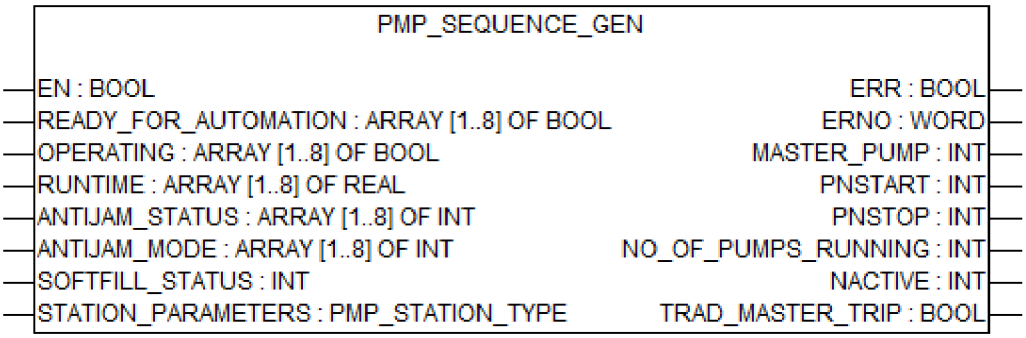
The function block PMP_SEQUENCE_GEN is used to generate the pump start and stop sequence. The function block executes the following start and stop sequence functions:

- Decides the sequence of the pumps based on the process demand.
- Decides the sequence in which a pump should start and stop next.
- Indicates the pump that is least run in the network to start next.
- Indicates the pump that has run maximum in the network to stop next.
- Sends the start and stop sequence information to the distributor function blocks.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

READY_FOR_AUTOMATION

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	FALSE	TRUE/FALSE	-

The input READY_FOR_AUTOMATION receives an array of pumps ready for automatic operation. The input comes from the output READY_FOR_AUTOMATION of the function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL.

The READY_FOR_AUTOMATION[1] connects to the PUMP ID = 1. This pattern must be followed for all pump IDs.

- When input is TRUE, pump is ready for operation in automatic mode.
- When input is FALSE, pump is not ready for operation in automatic mode.

OPERATING

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	-	TRUE/FALSE	-

The input OPERATING receives the operating status of all pumps (both variable frequency drives and direct online motors). The array is created from the output PUMP_OPERATING of the interface function blocks PMP_INTERFACE_VFD and PMP_INTERFACE_DOL.

RUNTIME

Data type	Default value	Range	Unit
ARRAY[1..8] of REAL	-	-	-

The input RUNTIME receives the actual runtime of all pumps (both variable frequency drives and direct online motors) in hours. The array is created from the output ACT_RUNTIME of the interface function blocks PMP_INTERFACE_VFD and PMP_INTERFACE_DOL.

ANTIJAM_ STATUS

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	0	0 ... 2	-

The input ANTIJAM_STATUS receives the status of antijam operation. The input comes from the output ANTIJAM_STATUS of the function block PMP_ANTIJAM.

0 = Not started (Antijam operation has not started)

1 = Busy (Antijam operation has started)

2 = Done (Antijam operation is completed)

ANTIJAM_ MODE

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	-	0 ... 3	-

The input ANTIJAM_MODE indicates the selected antijam mode.

0 = Disable antijam

1 = Master enabled

2 = At start

3 = Manual mode

The input ANTIJAM_MODE of the used pump distributor function block receives the antijam mode. This input comes from the output ANTIJAM_MODE of the function blocks PMP_ANTIJAM.

SOFTFILL_ STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 4	-

The input SOFTFILL_STATUS indicates the status of softfilling function.

0 = Disable the softfill (Softfill operation is disabled)

1 = Ready to start (Softfill operation is ready to start)

2 = Softfill in progress (Softfill operation has started)

3 = Softfill completed (Softfill operation is completed)

4 = Softfill with fault (Softfill operation stopped due to a fault)

STATION_ PARAMETERS

Data type	Default value	Range	Unit
PMP_STA-TION_TYPE	-	-	-

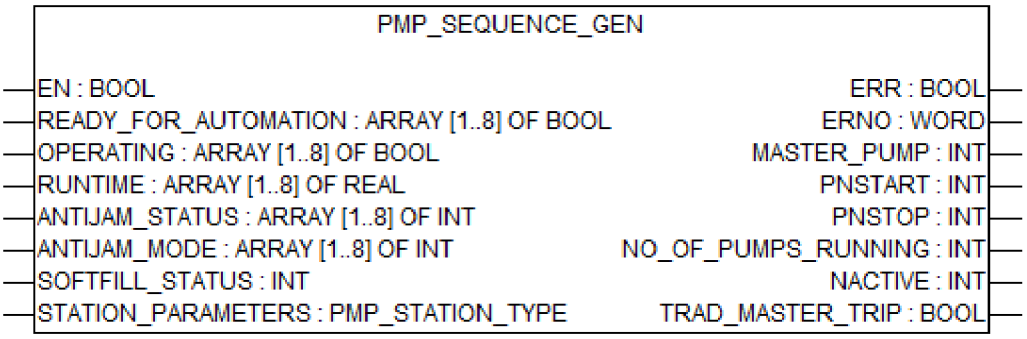
The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combination	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

MASTER_PUMP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input MASTER_PUMP receives the identification number of the master pump in the sequence. The input comes from the output MASTER_PUMP of the function block PMP_SEQUENCE_GEN.

PNSTART

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PNSTART receives the identification number of the next pump to start in the sequence. The input comes from the output PNSTART of the function block PMP_SEQUENCE_GEN.

PNSTOP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PNSTOP receives the identification number of the next pump to stop in the sequence. The input comes from the output PNSTOP of the function block PMP_SEQUENCE_GEN.

NO_OF_PUMPS_RUNNING

Data type	Default value	Range	Unit
INT	0	1 ... 8	-

The input NO_OF_PUMPS_RUNNING receives the number of pumps running. The input comes from the output NO_OF_PUMPS_RUNNING of the function block PMP_SEQUENCE_GEN.

NACTIVE

Data type	Default value	Range	Unit
INT	0	1 ... 8	-

The input NACTIVE receives the number of pumps active for operation in automatic mode. The input comes from the output NACTIVE of the function block PMP_SEQUENCE_GEN.

TRAD_MASTER_TRIP

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Indicates that the master pump in the traditional pump combination has tripped. This input comes from the output TRAD_MASTER_TRIP of the function block PMP_SEQUENCE_GEN.

Error codes

The error codes of function block PMP_SEQUENCE_GEN are listed below:

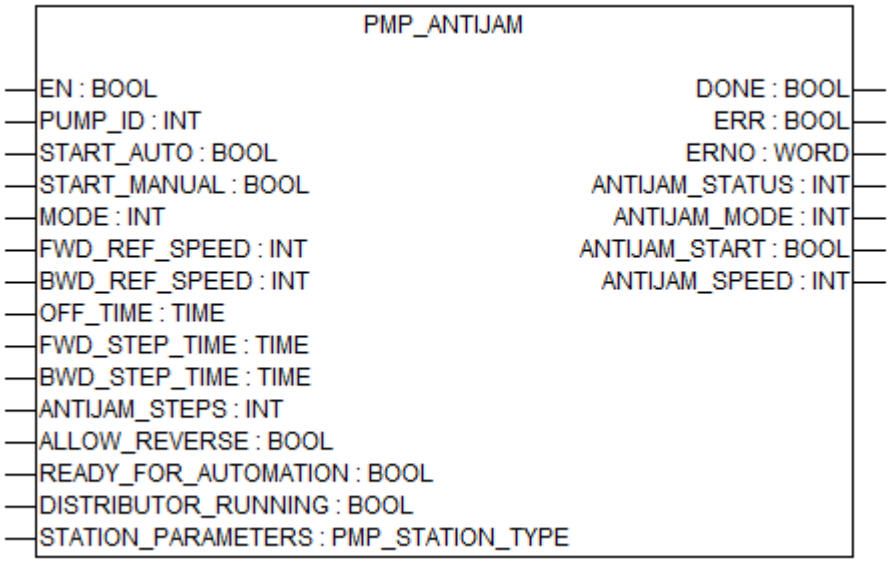
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16449	4041	Value of RUNTIME is less than 0
16465	4051	Value in input ANTIJAM_STATUS is less than 0
16466	4052	Value in input ANTIJAM_STATUS is greater than 2
16481	4061	Value in input ANTIJAM_MODE is less than 0
16482	4062	Value in input ANTIJAM_MODE is greater than 3
16497	4071	Value in input SOFTFILL_STATUS is less than 0
16498	4072	Value in input SOFTFILL_STATUS is greater than 4

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

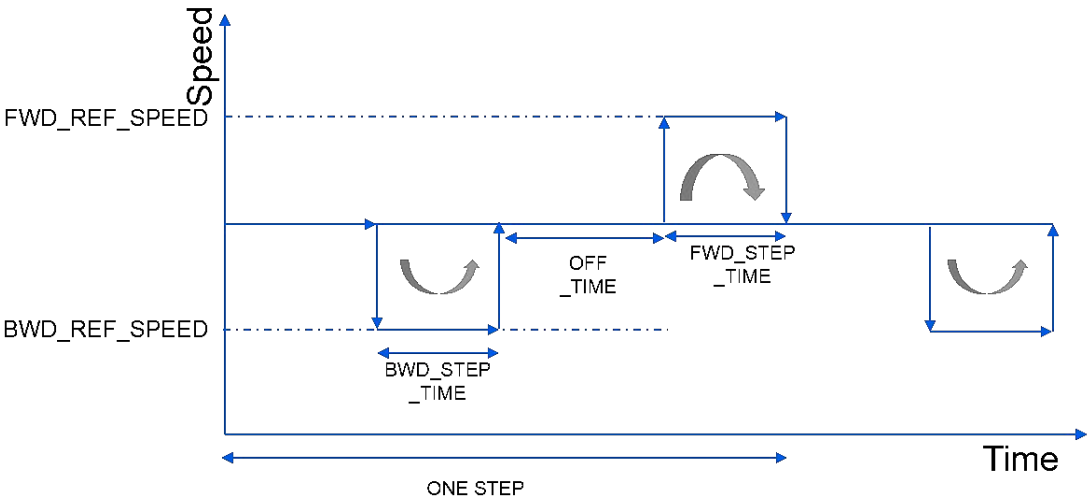
X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.10 PMP_ANTIJAM



Antijam overview

The pump antijam function is used to prevent building up of solids on the pump impellers or piping. The function consists of a programmable sequence of forward and reverse runs of the pump to shake off any residue on the impeller or piping. See timing diagram below. This function is mostly used with booster and wastewater pumps.



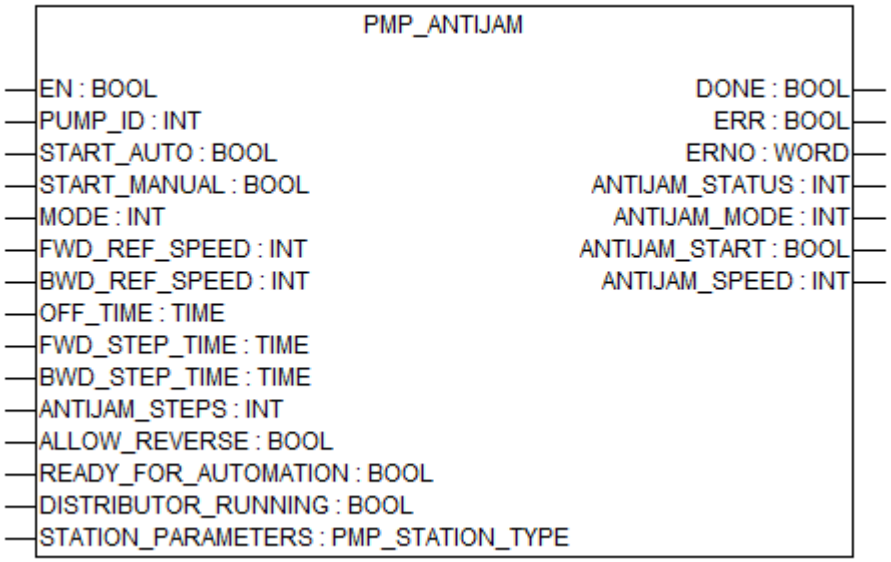
Function block description

The function block PMP_ANTIJAM performs the antijam function by running the pump at high speeds without any ramp up/down time.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PUMP_ID

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input PUMP_ID defines the pump identification number.

START_AUTO

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START_AUTO receives a digital signal to start antijam operation in automatic mode. The input comes from the output START_ANTIJAM of function blocks PMP_LEVEL_DISTRIBUTOR, PMP_FLOW_DISTRIBUTOR and PMP_PRESSURE_DISTRIBUTOR. The input is not effective if the value in input MODE = 3 (Manual mode).

The input START_AUTO of PUMP_ID = 1 must be connected to the output START_ANTIJAM[1] of distributors. This pattern must be followed for all pump IDs.

- When input is TRUE, antijam operation starts in automatic mode.
- When input is FALSE, antijam operation stops if running.

START_ MANUAL

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START_MANUAL receives a digital signal to start antijam operation in manual mode. The input comes from the output START_ANTIJAM of function blocks PMP_INTERFACE_VFD and PMP_INTERFACE_DOL. The input is effective only when value in input MODE = 3 (Manual mode).

- When input is TRUE, antijam operation starts in manual mode.
- When input is FALSE, antijam operation stops if running.

MODE

Data type	Default value	Range	Unit
INT	0	0 ... 3	-

The input MODE selects the antijam operation mode.

0 = Disable antijam

1 = Master enabled

2 = At start

3 = Manual mode

FWD_REF_ SPEED

Data type	Default value	Range	Unit
INT	100	> 0	rpm

The input FWD_REF_SPEED defines the forward direction speed reference in rpm to clean the pump.

BWD_REF_ SPEED

Data type	Default value	Range	Unit
INT	100	> 0	rpm

The input BWD_REF_SPEED defines the backward direction speed reference in rpm to clean the pump.

This input is effective only if the input ALLOW_REVERSE = TRUE.

OFF_TIME

Data type	Default value	Range	Unit
TIME	10	-	s

The input OFF_TIME defines the time period for which antijam operation will pause after either a forward or backward movement is completed.

FWD_STEP_ TIME

Data type	Default value	Range	Unit
TIME	10	-	s

The input FWD_STEP_TIME defines the time duration for which the pump moves in forward direction for antijam operation.

BWD_STEP_ TIME

Data type	Default value	Range	Unit
TIME	10	-	s

The input BWD_STEP_TIME defines the time duration for which the pump moves in backward direction for antijam operation.

ANTIJAM_ STEPS

Data type	Default value	Range	Unit
INT	1	> 0	-

The input ANTIJAM_STEPS defines the number of steps in forward or backward movement to be performed in antijam operation.

ALLOW_ REVERSE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input ALLOW_REVERSE allows the pump run by variable frequency drive to move in reverse direction to perform antijam operation.

The input ALLOW_REVERSE is not effective for DOL pumps.

- When input is TRUE, pump with VFD performs antijam operation in the reverse direction.
- When input is FALSE, pump with VFD stops antijam operation in the reverse direction.

READY_FOR_ AUTOMATION

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input comes from the output READY_FOR_AUTOMATION of the function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL.

- When input is TRUE, pump is ready for operation in automatic mode.
- When input is FALSE, pump is not ready for operation in automatic mode.

DISTRIBUTOR_ RUNNING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input DISTRIBUTOR_RUNNING indicates the running status of the distributor.
This input is connected to the output DISTRIBUTOR_RUNNING of any of the the distributor function blocks PMP_LEVEL_DISTRIBUTOR, PMP_FLOW_DISTRIBUTOR or PMP_PRESSURE_DISTRIBUTOR.

- When output is TRUE, distributor is running.
- When output is FALSE, distributor is not running.

STATION_ PARAMETERS

Data type	Default value	Range	Unit
PMP_STA-TION_TYPE	-	-	-

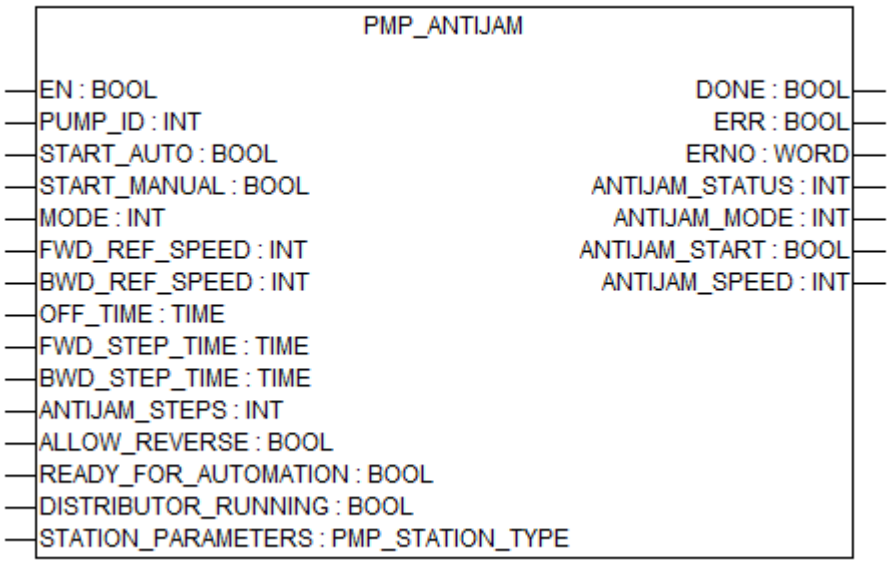
The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combination	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

ANTIJAM_ STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 2	-

The input ANTIJAM_STATUS receives the antijam operation status of the pump. The input comes from the output ANTIJAM_STATUS of the function block PMP_ANTIJAM.

0 = Not started (Antijam operation has not started)

1 = Busy (Antijam operation has started)

2 = Done (Antijam operation is completed)

ANTIJAM_ MODE

Data type	Default value	Range	Unit
INT	0	0 ... 3	-

The input ANTIJAM_MODE indicates the selected antijam mode.

0 = Disable antijam

1 = Master enabled

2 = At start

3 = Manual mode

The input ANTIJAM_MODE receives the antijam mode. The input comes from the output ANTIJAM_MODE of the function block PMP_ANTIJAM.

ANTIJAM_ START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output ANTIJAM_START of the function block PMP_ANTIJAM starts the antijam operation. This output is connected with the input ANTIJAM_START of the function blocks PMP_INTERFACE_VFD and PMP_INTERFACE_DOL.

- When output is TRUE, antijam operation starts.
- When output is FALSE, antijam operation stops if running.

ANTIJAM_SPEED

Data type	Default value	Range	Unit
INT	0	-	rpm

The output ANTIJAM_SPEED of the function block PMP_ANTIJAM indicates the speed for antijam operation. This output is connected to the input ANTIJAM_SPEED of the function block PMP_INTERFACE_VFD.

Error codes

The error codes of function block PMP_ANTIJAM are listed below:

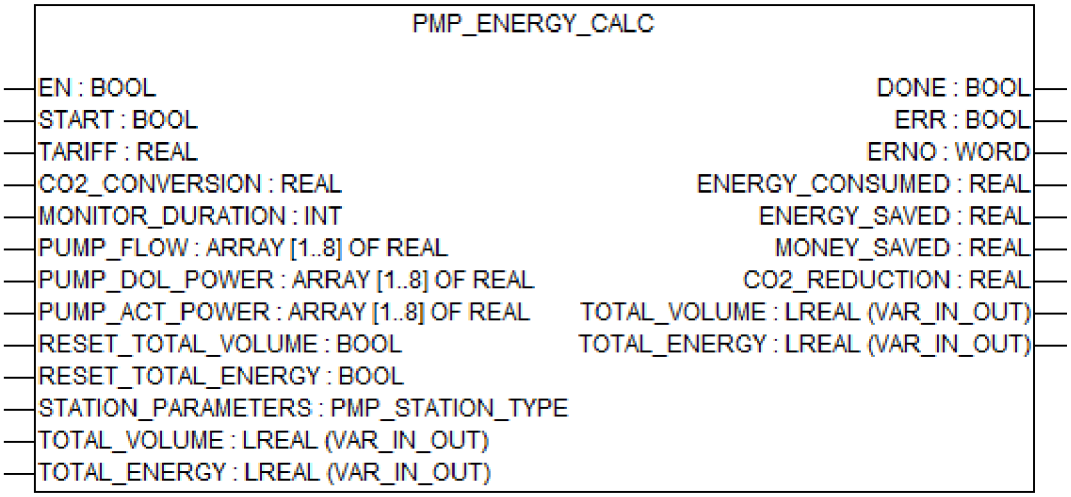
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16417	4021	Value of PUMP_ID is less than 0
16418	4022	Value of PUMP_ID is greater than NUMBER_OF_PUMPS in PMP_CONFIGURATION
16435	4033	Value of START_AUTO = TRUE when MODE = 3
16451	4043	Value of START_MANUAL = TRUE when MODE is not 3
16465	4051	Value of MODE is less than 0
16466	4052	Value of MODE is more than 3
16481	4061	Value of FWD_REF_SPEED is less than 0
16497	4071	Value of BWD_REF_SPEED is less than 0
16561	40B1	Value of ANTIJAM_STEPS is less than 0
16579	40C3	Value of ALLOW_REVERSE = TRUE for the pump fed by DOL motor

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.11 PMP_ENERGY_CALC



The function block PMP_ENERGY_CALC calculates the energy consumption of the pumping station run by variable frequency drive and gives the information on cumulative flow in cubic meters. The function includes following calculations:

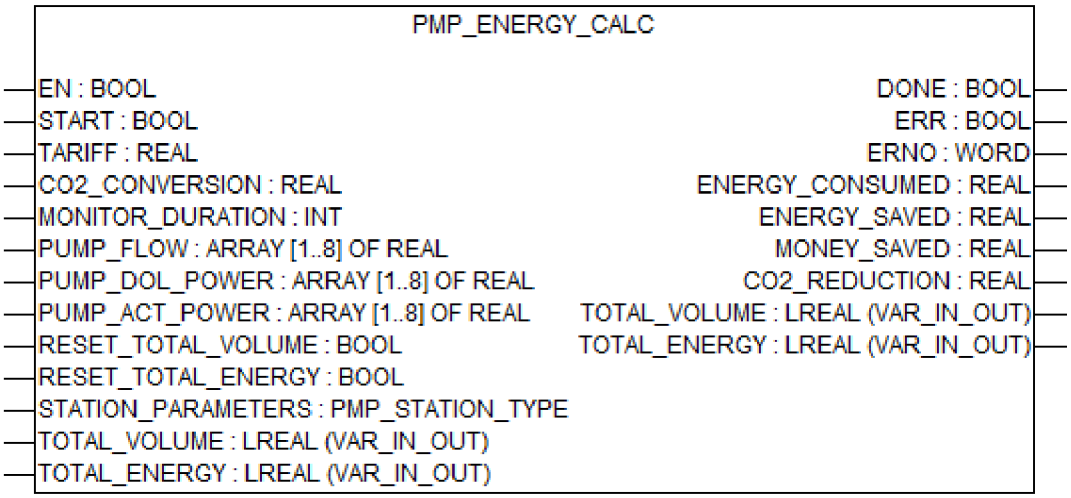
- Total energy consumed
- Total energy saved
- Total cost saved
- Reduced CO_2 emission

> *For correct calculations this function block must be called in the task manager with 50 ms cyclic time.*

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START starts the execution of the function block.

- When input is TRUE, the execution starts.
- When input is FALSE, the execution stops if running.

TARIFF

Data type	Default value	Range	Unit
REAL	1.0	> 0.0	-

The input TARIFF defines the tariff rate per kWh in different currencies, e.g., Dollar, Euro, etc.

CO2_ CONVERSION

Data type	Default value	Range	Unit
REAL	1.0	> 0.0	t/MWh

The input CO2_CONVERSION defines the factor to convert the energy consumed in CO_2 emission in t/MWh.

MONITOR_ DURATION

Data type	Default value	Range	Unit
INT	10	> 0	h

The input MONITOR_DURATION defines the time duration in hours to monitor the energy consumption.

PUMP_FLOW

Data type	Default value	Range	Unit
ARRAY[1..8] of REAL	-	-	m^3/h

The input PUMP_FLOW receives the actual flow of each pump in cubic meters per hour (m3/h).

The index 1 array is connected to the PUMP_ID = 1. This pattern follows for all pump IDs.

PUMP_DOL_ POWER

Data type	Default value	Range	Unit
ARRAY[1..8] of REAL	-	-	kW

The input PUMP_DOL_POWER defines the direct online power of each pump in kW, if the pumps are directly connected to the motor. The nominal power of the motor is connected to the pump.

PUMP_ACT_POWER

Data type	Default value	Range	Unit
ARRAY[1..8] of REAL	-	-	kW

The input PUMP_ACT_POWER defines the actual power of each pump in kW. The power is read from the variable frequency drive.

RESET_TOTAL_VOLUME

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input RESET_TOTAL_VOLUME resets the total volume.

- When input is TRUE, total volume is reset.
- When input is FALSE, pump continues with total volume.

RESET_TOTAL_ENERGY

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input RESET_TOTAL_ENERGY resets the total energy value.

- When input is TRUE, total energy value is reset.
- When input is FALSE, pump continues with total energy value.

STATION_PARAMETERS

Data type	Default value	Range	Unit
PMP_STATION_TYPE	-	-	-

The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control

Parameter	Data type	Default value	Description
iPump_Combination	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

TOTAL_VOLUME

Data type	Default value	Range	Unit
LREAL	-	-	m^3

The variable input/output TOTAL_VOLUME indicates the cumulative flow volume in cubic meters.

The total volume is calculated by combining the flow of all pumps in cubic meters.

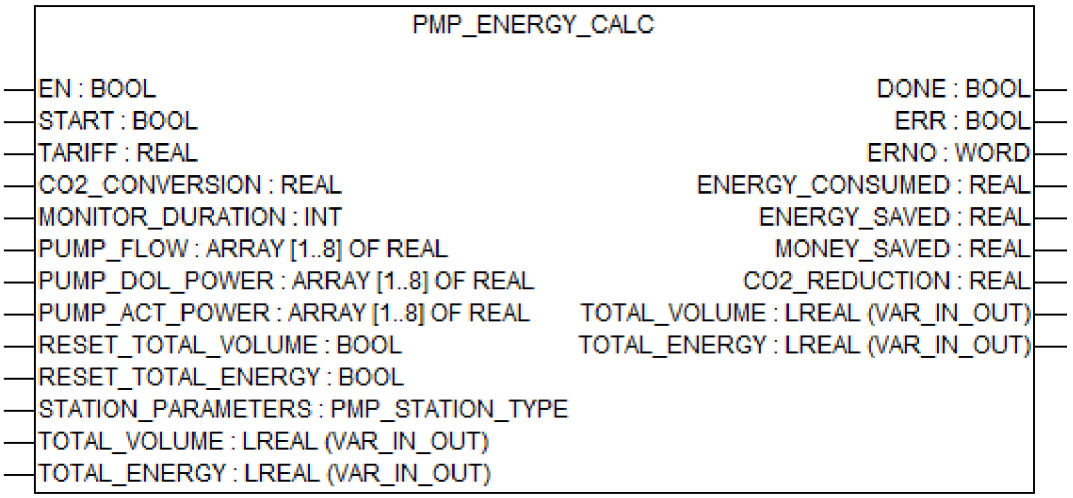
TOTAL_ENERGY

Data type	Default value	Range	Unit
LREAL	-	-	kWh

The variable input/output TOTAL_ENERGY indicates the total actual energy in kWh.

The total energy is calculated by combining the actual power of all pumps in kW in a hour.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

ENERGY_ CONSUMED

Data type	Default value	Range	Unit
REAL	0.0	-	kWh

The output ENERGY_CONSUMED indicates the energy consumed (kWh) in the monitoring duration.

ENERGY_ SAVED

Data type	Default value	Range	Unit
REAL	0.0	-	kWh

The output ENERGY_SAVED indicates the saved energy in kWh. Saved energy is the difference of energy consumed with VFD pump and energy consumed if it was a DOL pump.

MONEY_SAVED

Data type	Default value	Range	Unit
REAL	0.0	-	-

The output MONEY_SAVED indicates the money saved in tariff units.

CO2_ REDUCTION

Data type	Default value	Range	Unit
REAL	0.0	-	t/MWh

The output CO2_REDUCTION indicates the reduction of CO2 emission in t/MWh.

Error codes

The error codes of function block PMP_ENERGY_CALC are listed below:

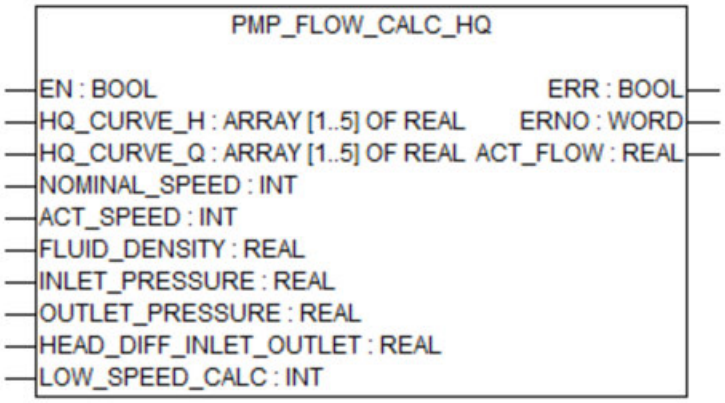
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16433	4031	Value of TARIFF is less than the minimum limit
16449	4041	Value of CO2_CONVERSION is less than the minimum limit
16465	4051	Value of MONITOR_DURATION is less than or equal to 0
16497	4071	Value of PUMP_DOL_POWER is less than or equal to 0.0

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.12 PMP_FLOW_CALC_HQ

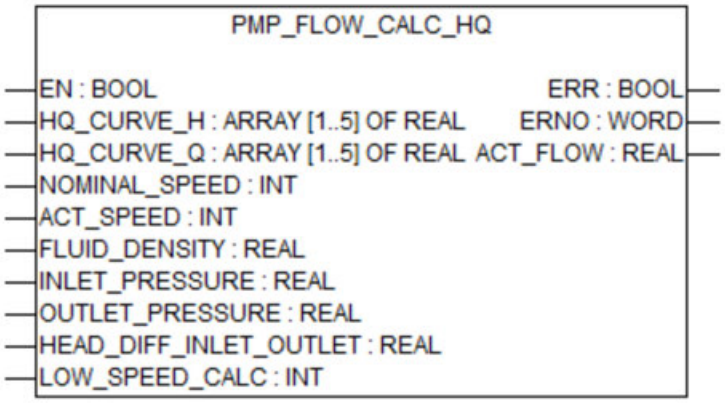


The function block PMP_FLOW_CALC_HQ calculates the flow rate of pumps using the pump head flow (HQ) curve characteristics. This function is applicable only for pumps run by variable frequency drives.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

HQ_CURVE_H

Data type	Default value	Range	Unit
ARRAY[1..5] of REAL	-	-	m

The input HQ_CURVE_H defines an array of head values for the HQ curve of pumps run by variable frequency drives. The values are in meters. HQ parameters are available in the pump characteristics of manufacturer’s specification.

HQ_CURVE_Q

Data type	Default value	Range	Unit
ARRAY[1..5] of REAL	-	-	m^3/h

The input HQ_CURVE_Q defines an array of flow rate values for HQ curve of pumps run by variable frequency drives. The values are in cubic meters per hour. HQ parameters are available in the pump characteristics of manufacturer’s specification.

NOMINAL_ SPEED

Data type	Default value	Range	Unit
INT	1400	> 0	rpm

The input NOMINAL_SPEED defines the rated speed in rpm of the pump run by variable frequency drive.

ACT_SPEED

Data type	Default value	Range	Unit
INT	10	> 1	rpm

The input ACT_SPEED indicates the actual speed of the variable frequency drive (VFD) in rpm.

FLUID_DENSITY

Data type	Default value	Range	Unit
REAL	1000.0	> 0.0	kg/m^3

The input FLUID_DENSITY defines the fluid density in kg/m3.

INLET_ PRESSURE

Data type	Default value	Range	Unit
REAL	0.0	-	-

The input INLET_PRESSURE receives the inlet pressure from the sensor that measures suction pressure.

OUTLET_ PRESSURE

Data type	Default value	Range	Unit
REAL	0.0	-	-

The input OUTLET_PRESSURE receives the outlet pressure from the sensor that measures discharge pressure.

HEAD_DIFF_ INLET_OUTLET

Data type	Default value	Range	Unit
REAL	0.0	-	m

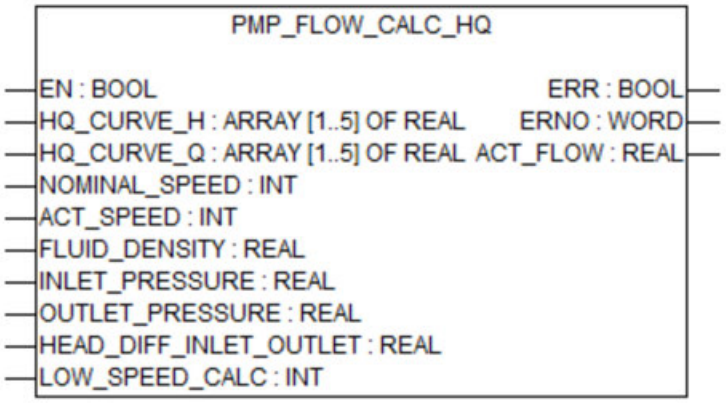
The input HEAD_DIFF_INLET_OUTLET defines the differential pressure of inlet and outlet head values in meters. The input is used only when direct measurement of differential pressure is available. If direct measurement of differential pressure is not available, then this input must be left as unassigned.

LOW_SPEED_ CALC

Data type	Default value	Range	Unit
INT	50	-	rpm

The input LOW_SPEED_CALC defines the low speed limit in rpm. This function block calculates the actual flow only when input ACTUAL_SPEED is more than this value.

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

ACT_FLOW

Data type	Default value	Range	Unit
INT	0	-	m^3/h

The output ACT_FLOW indicates the calculated actual flow in cubic meters per hour.

Error codes

The error codes of function block PMP_FLOW_CALC_HQ are listed below:

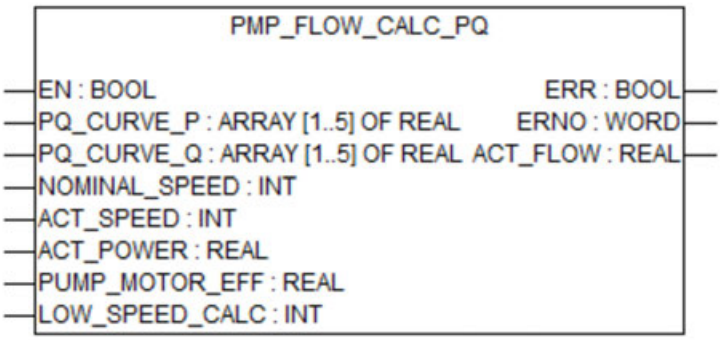
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16416	4020	Array of values in HQ_CURVE_H are not in ascending order
16432	4030	Array of values in HQ_CURVE_Q are not in ascending order
16449	4041	Value of NOMINAL_SPEED is less than 0
16481	4061	Value of INLET_PRESSURE is less than 0
16497	4071	Value of OUTLET_PRESSURE is less than 0
16499	4073	Value of INLET_PRESSURE is greater than OUTLET_PRESSURE
16513	4081	Value of FLUID_DENSITY is less than or equal to 0
16529	4091	Value of HEAD_DIFF_INLET_OUTLET is less than 0
16545	40A1	Value of LOW_SPEED_CALC is less than 0
16547	40A3	Value of LOW_SPEED_CALC is greater than or equal to NOMINAL_SPEED

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.13 PMP_FLOW_CALC_PQ

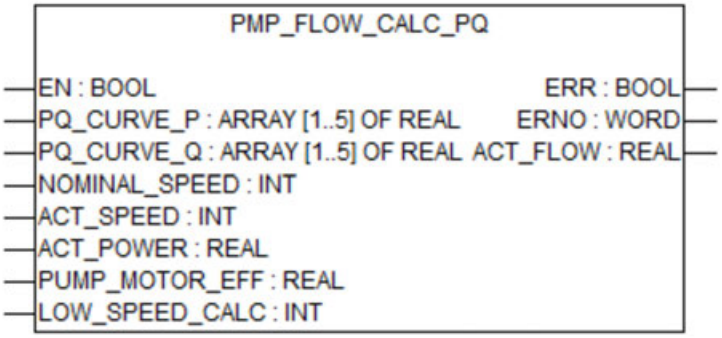


The function block PMP_FLOW_CALC_PQ calculates the flow rate of pumps using the pump pressure flow rate (PQ) curve characteristics. This function is applicable only for pumps run by variable frequency drives.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PQ_CURVE_P

Data type	Default value	Range	Unit
ARRAY[1..5] of REAL	-	-	m

The input PQ_CURVE_P defines an array of input power for PQ curve of pumps run by variable frequency drives. The values are in meters. PQ parameters are available in the pump characteristics of manufacturer’s specification.

HQ_CURVE_Q

Data type	Default value	Range	Unit
ARRAY[1..5] of REAL	-	-	m^3/h

The input HQ_CURVE_Q defines an array of flow rate values for HQ curve of pumps run by variable frequency drives. The values are in cubic meters per hour. HQ parameters are available in the pump characteristics of manufacturer’s specification.

PQ_CURVE_Q

Data type	Default value	Range	Unit
ARRAY[1..5] of REAL	-	-	m^3/h

The input PQ_CURVE_Q defines an array of flow rate values for PQ curve of pumps run by variable frequency drives. The values are in cubic meters per hour. PQ parameters are available in the pump characteristics of manufacturer’s specification.

NOMINAL_ SPEED

Data type	Default value	Range	Unit
INT	1400	> 0	rpm

The input NOMINAL_SPEED defines the rated speed in rpm of the pump run by variable frequency drive.

ACT_SPEED

Data type	Default value	Range	Unit
INT	10	> 1	rpm

The input ACT_SPEED indicates the actual speed of the variable frequency drive (VFD) in rpm.

ACT_POWER

Data type	Default value	Range	Unit
REAL	1.0	-	kW

The input ACT_POWER defines the actual power of the motor in kW. The value is read from the drive parameters.

PUMP_MOTOR_ EFF

Data type	Default value	Range	Unit
REAL	0.85	0.00 ... 1.00	-

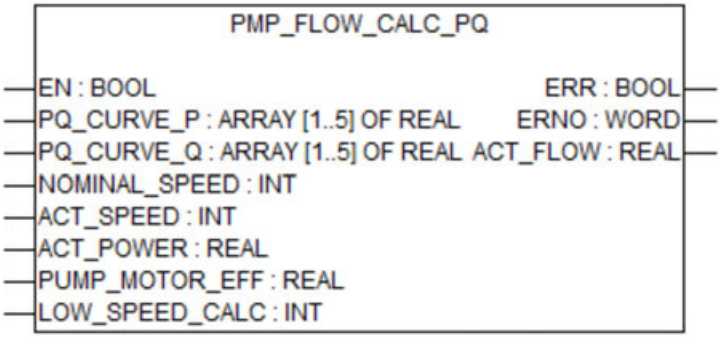
The input PUMP_MOTOR_EFF defines the combined efficiency of motor and pump set.

LOW_SPEED_ CALC

Data type	Default value	Range	Unit
INT	50	-	rpm

The input LOW_SPEED_CALC defines the low speed limit in rpm. This function block calculates the actual flow only when input ACTUAL_SPEED is more than this value.

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

ACT_FLOW

Data type	Default value	Range	Unit
INT	0	-	m^3/h

The output ACT_FLOW indicates the calculated actual flow in cubic meters per hour.

Error codes

The error codes of function block PMP_FLOW_CALC_PQ are listed below:

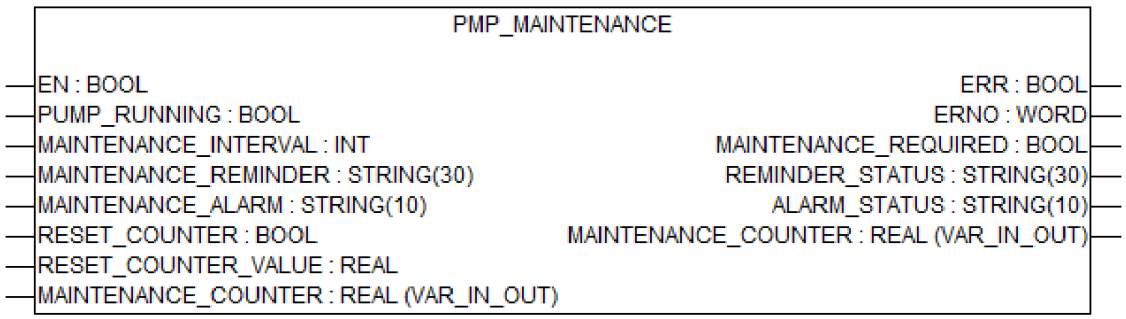
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16416	4020	Array of values in PQ_CURVE_P are not in ascending order
16432	4030	Array of values in PQ_CURVE_Q are not in ascending order
16449	4041	Value of NOMINAL_SPEED is less than or equal to 0
16497	4071	Value of MOTOR_EFF is less than or equal to 0.00
16498	4072	Value of MOTOR_EFF is greater than 1.00
16513	4081	Value of LOW_SPEED_CALC is less than 0
16515	4083	Value of LOW_SPEED_CALC is greater than the NOMINAL_SPEED

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.14 PMP_MAINTENANCE

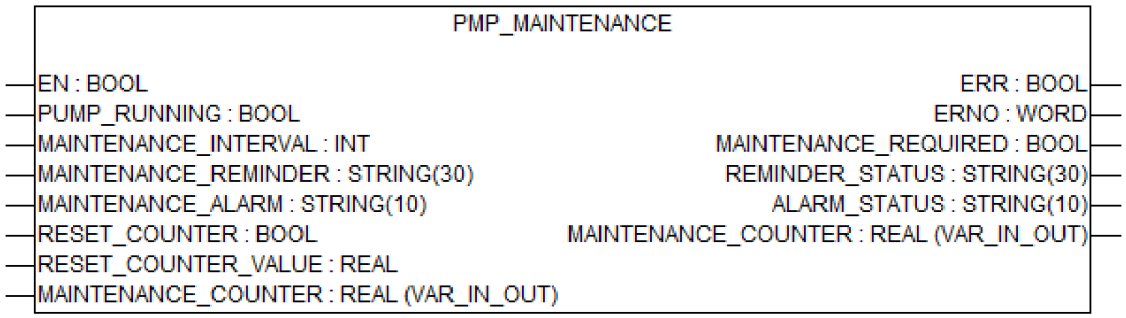


The function block PMP_MAINTENANCE is used to record the maintenance schedule of the pump. The function block maintains an hourly counter to track the pump maintenance interval and generates timely reminders and alarms.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PUMP_ RUNNING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input PUMP_RUNNING receives the pump running status. The input comes from the output PUMP_OPERATING of the function blocks PMP_INTERFACE_VFD/ PMP_INTERFACE_DOL.

- When input is TRUE, pump is operating.
- When input is FALSE, pump is not operating.

MAINTENANCE_ INTERVAL

Data type	Default value	Range	Unit
INT	1	0 ... 32767	-

The input MAINTENANCE_INTERVAL defines the pump maintenance interval in hours. When specific maintenance intervals are reached, function block generates reminders and alarms.

MAINTENANCE_ REMINDER

Data type	Default value	Range	Unit
STRING (30)	-	-	-

The input MAINTENANCE_REMINDER defines the user-defined reminder message for service maintenance.

MAINTENANCE_ALARM

Data type	Default value	Range	Unit
STRING (10)	-	-	-

The input MAINTENANCE_ALARM defines the user-defined alarm message for any maintenance activity.

RESET_COUNTER

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input RESET_COUNTER resets the output MAINTENANCE_COUNTER to the value in the input RESET_COUNTER_VALUE.

- When input is TRUE, value in input RESET_COUNTER_VALUE overwrites value in output MAINTENANCE_COUNTER.
- When input is FALSE, no reset is initiated.

RESET_COUNTER_VALUE

Data type	Default value	Range	Unit
INT	0	0 ... 32767	-

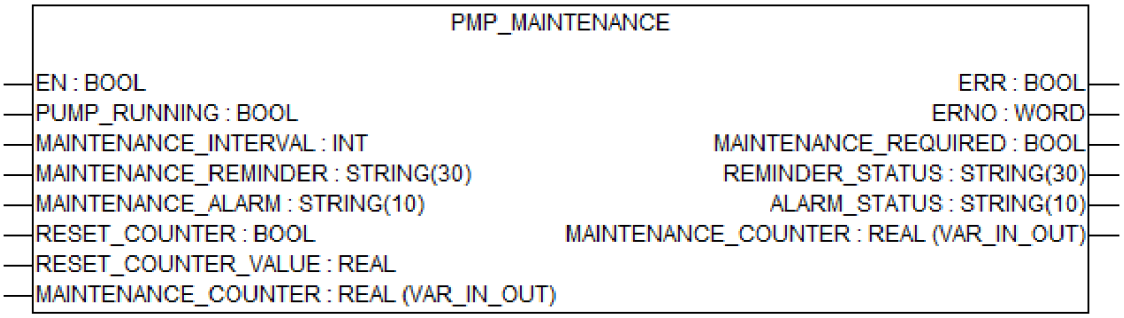
The input RESET_COUNTER_VALUE defines the counter value that is used to overwrite the output MAINTENANCE_COUNTER. The input is effective only when input RESET_COUNTER = TRUE.

MAINTENANCE_COUNTER

Data type	Default value	Range	Unit
REAL	-	-	-

The variable input/output MAINTENANCE_COUNTER provides the count of hourly activity. The count is overwritten by value in the input RESET_COUNTER_VALUE, when input RESET_COUNTER = TRUE

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

MAINTENANCE_REQUIRED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE / FALSE	-

The output MAINTENANCE_REQUIRED indicates that maintenance is required.

- When output is TRUE, maintenance is required.
- When output is FALSE, no maintenance required.

REMINDER_STATUS

Data type	Default value	Range	Unit
STRING (30)	-	-	-

The output REMINDER_STATUS indicates the status of service reminder message defined in the input MAINTENANCE_REMINDER.

ALARM_STATUS

Data type	Default value	Range	Unit
STRING (10)	-	-	-

The output ALARM_STATUS indicates the status of maintenance alarm message defined in the input MAINTENANCE_ALARM.

Error codes

The error codes of function block PMP_MAINTENANCE are listed below:

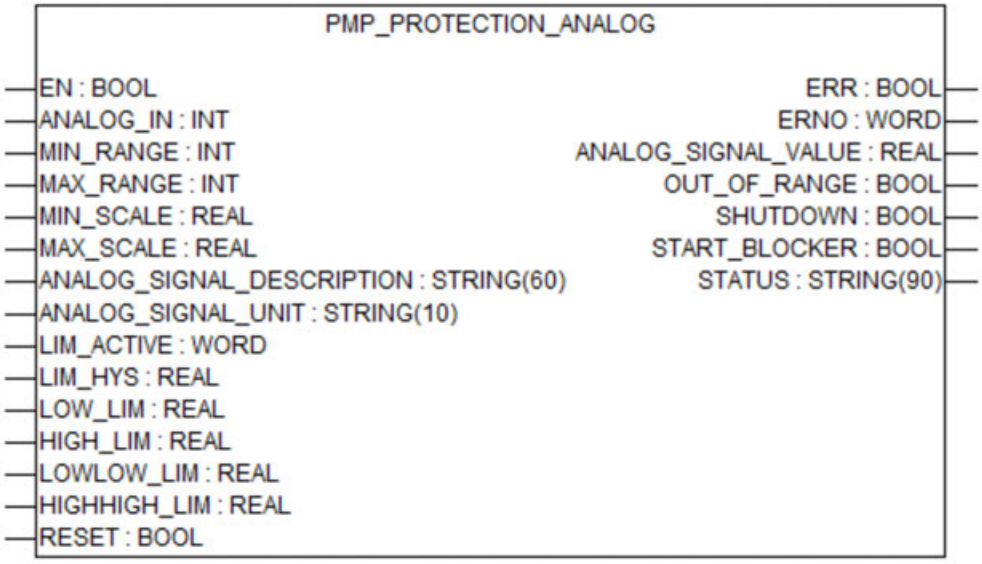
Error code		Error Description
Decimal	Hexadecimal	
0	0000	No error occurred
16432	4030	Value in MAINTENANCE_INTERVAL is less than or equal to 0
16496	4070	Value in RESET_COUNTER_VALUE is less than 0

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.15 PMP_PROTECTION_ANALOG



The function block PMP_PROTECTION_ANALOG monitors analog inputs and generates signals to shut down or to block the starting of pump or the process. The function block sends the signals to shut down or to block the starting of pump through inputs PROTECTION_SHUTDOWN or START_BLOCKER of these distributor and pump interface function blocks: PMP_LEVEL_DISTRIBUTOR, PMP_FLOW_DISTRIBUTOR, PMP_PRESSURE_DISTRIBUTOR, PMP_INTERFACE_VFD, and PMP_INTERFACE_DOL.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Pump protection configuration example

The function block PMP_PROTECTION_ANALOG can be used for:

- Process specific protection or
- Pump specific protection

Process specific protection with many such sensors

The function block can be used to configure the alarm (start blocker) or fault (protection shutdown) for the process value coming from an analog input (sensor). The actual process value from the analog input is compared with the limits. See the example diagram below.

- If high/low limits are breached, the alarm start blocker is generated.
- If highhigh/lowlow limits are breached the protection shutdown is generated.

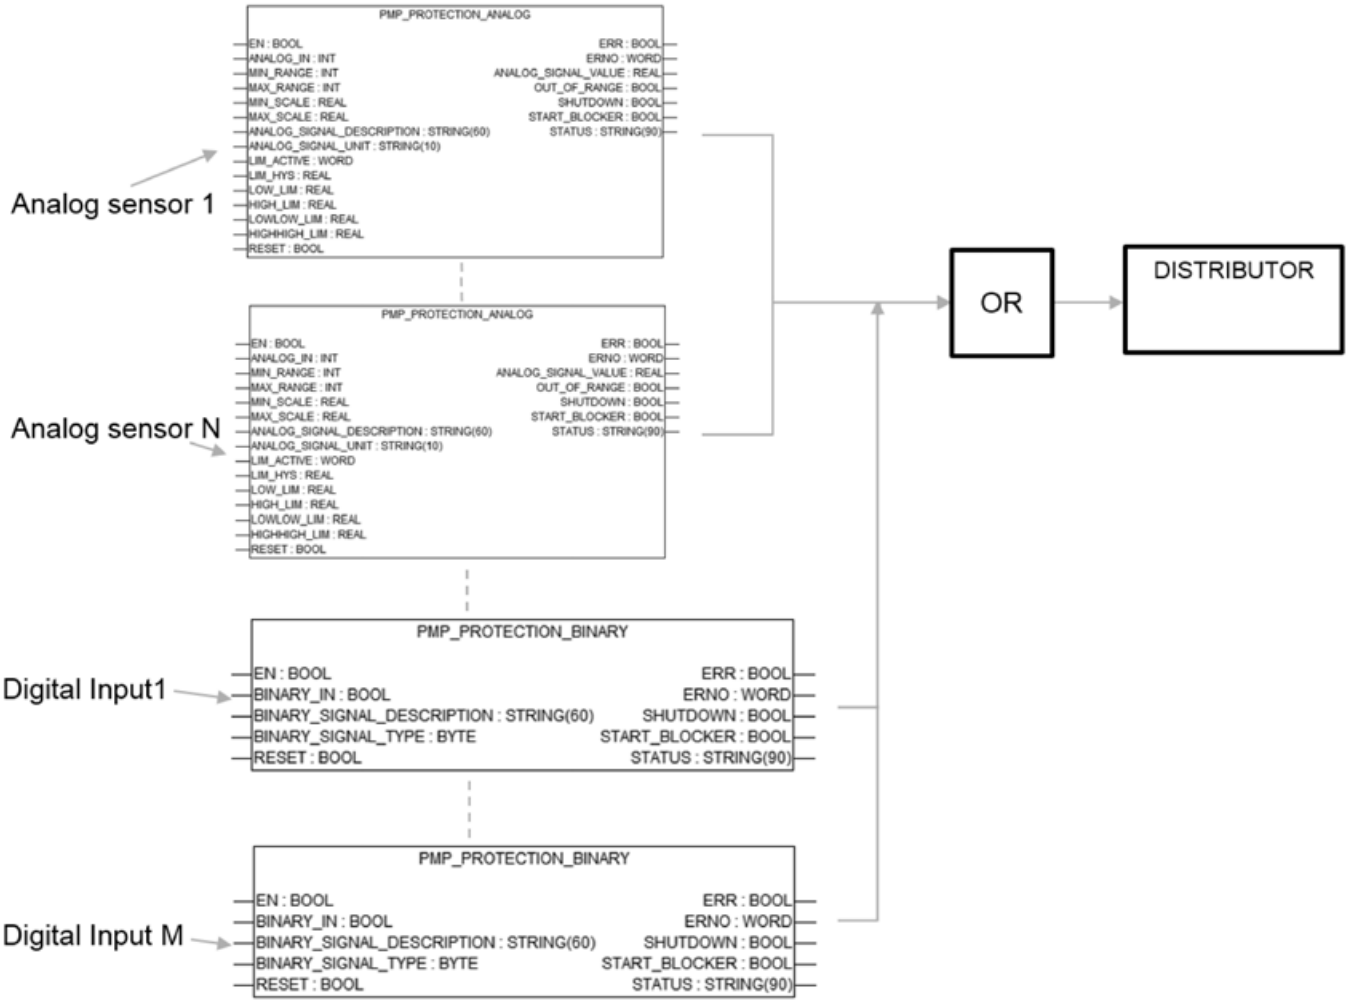


Fig. 715: Analog/Digital FB - process specific protection

Pump specific protection with many such sensors

The function block is flexible and can be used based on the pump specific requirements. If more than one sensor is used, then configure the function block for each sensor. The outputs of each function block can be logically OR'ed in the application program, as shown below.

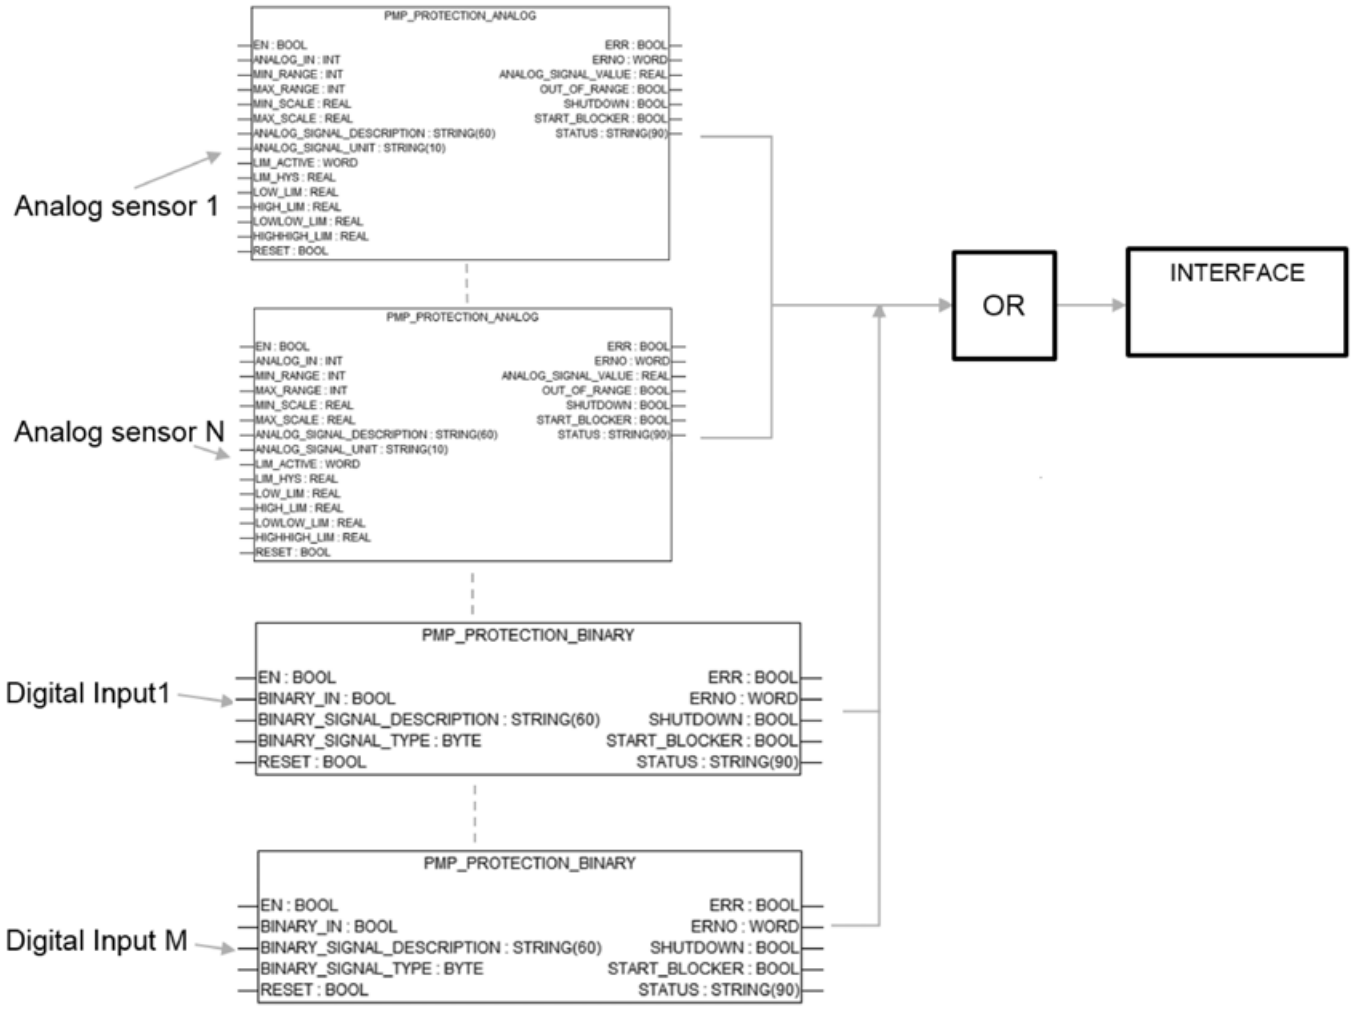

Fig. 716: Analog/Digital FB - pump specific protection

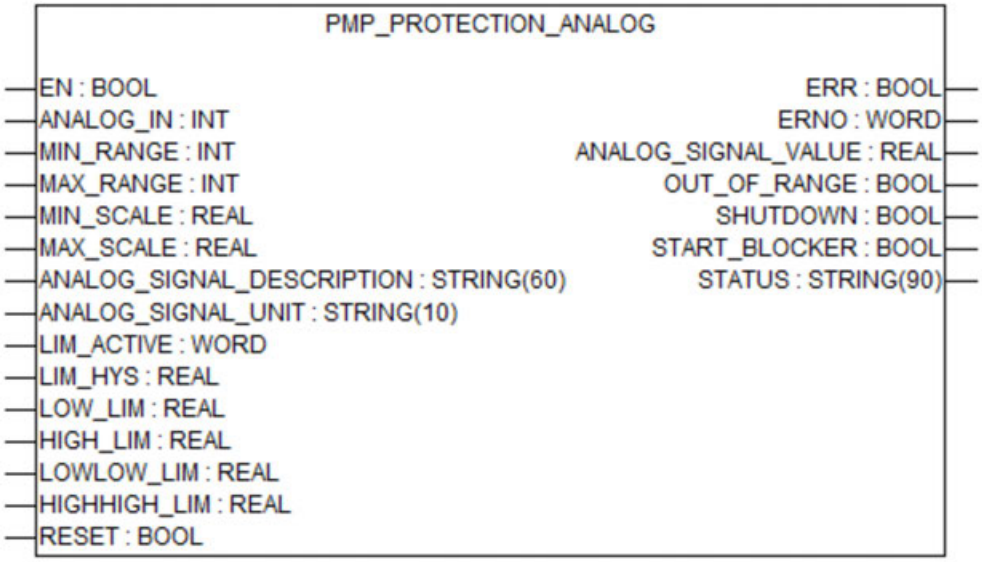
Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

ANALOG_IN

Data type	Default value	Range	Unit
INT	10	-	-

The input ANALOG_IN receives analog input from the process. The process input is compared with the limits to perform the protection function.

MIN_RANGE

Data type	Default value	Range	Unit
INT	0	-	-

The input MIN_RANGE defines the minimum range of the analog input signal.

MAX_RANGE

Data type	Default value	Range	Unit
INT	27648	-	-

The input MAX_RANGE defines the maximum range of the analog input signal.

MIN_SCALE

Data type	Default value	Range	Unit
REAL	0.0	-	-

The input MIN_SCALE defines the minimum scale of the analog input signal in the physical unit, e.g., 1 bar.

MAX_SCALE

Data type	Default value	Range	Unit
REAL	100.0	-	-

The input MAX_SCALE defines the maximum scale of the analog input signal in physical unit, e.g., 5 bar.

ANALOG_ SIGNAL_ DESCRIPTION

Data type	Default value	Range	Unit
STRING (60)	-	-	-

The input ANALOG_SIGNAL_DESCRIPTION allows the user to add the description of analog input signal. e.g., actual pressure.

ANALOG_ SIGNAL_UNIT

Data type	Default value	Range	Unit
STRING (10)	-	-	-

The input ANALOG_SIGNAL_UNIT allows the user to declare the unit of analog input signal. e.g., PSI

LIM_ACTIVE

Data type	Default value	Range	Unit
WORD	2#1111	-	-

The input LIM_ACTIVE selects the active limit of the analog input signal.

bit 0: Low limit active

bit 1: High limit active

bit 2: Low low limit active

bit 3: High high limit active

The selected limit only will be compared with the actual process values to generate the PROTECTION_SHUTDOWN or START_BLOCKER signal.

LIM_HYS

Data type	Default value	Range	Unit
REAL	0.0	-	-

The input LIM_HYS allows the user to declare the hysteresis limit of analog input signal. This value is the percent of the limits mentioned in LOW_LIM/ LOWLOW_LIM/ HIGH_LIM/ HIGHHIGH_LIM.

The limit ± hysteresis is compared with the actual process value.

LOW_LIM

Data type	Default value	Range	Unit
REAL	10.0	-	-

The input LOW_LIM declares the low limit of the analog input.

HIGH_LIM

Data type	Default value	Range	Unit
REAL	80.0	-	-

The input HIGH_LIM declares the high limit of the analog input.

LOWLOW_LIM

Data type	Default value	Range	Unit
REAL	5.0	-	-

The input LOWLOW_LIM declares the very low limit of the analog input.

HIGHHIGH_LIM

Data type	Default value	Range	Unit
REAL	90.0	-	-

The input HIGHHIGH_LIM declares the very high limit of the analog input.

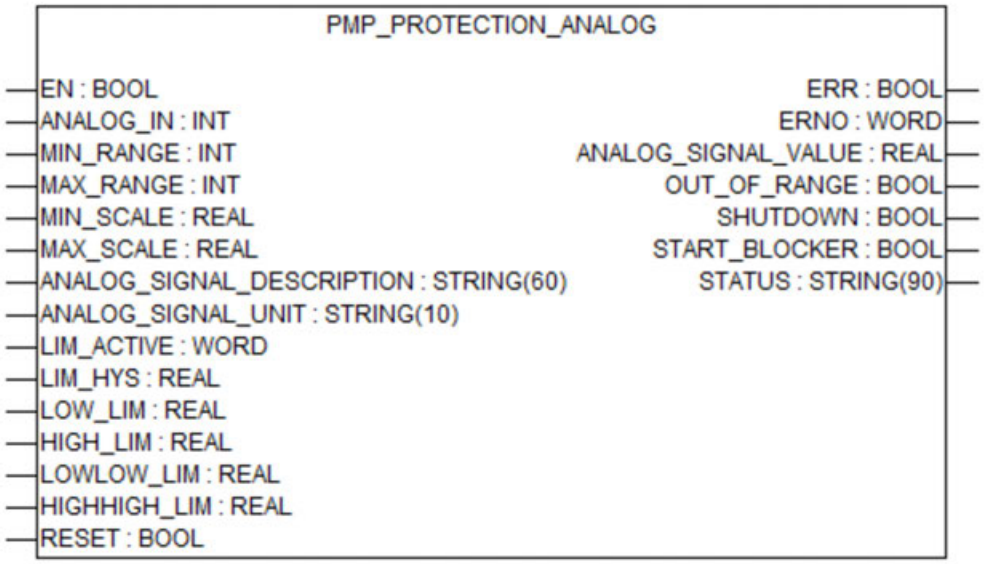
RESET

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input RESET resets any active alarm/fault and alarm messages generated by analog or binary input signal.

- When output is TRUE, alarm/fault and alarm message are reset.
- When output is FALSE, no reset.

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

ANALOG_ SIGNAL_VALUE

Data type	Default value	Range	Unit
REAL	0.0	-	-

The output ANALOG_SIGNAL_VALUE indicates the actual value of the analog input signal in physical units, e.g., bar.

OUT_OF_ RANGE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE / FALSE	-

The output OUT_OF_RANGE indicates that the analog input is out of range.

- When output is TRUE, analog input is out of range.
- When output is FALSE, analog input is within the range.

SHUTDOWN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE / FALSE	-

The output SHUTDOWN indicates pump shutdown depending on the analog or binary input signal.

- If the requirement is to stop the complete process, then the output must be connected to the input PROTECTION_SHUTDOWN of the distributor function blocks.
- If the requirement is stop only a particular pump, then the output must be connected to the input PROTECTION_SHUTDOWN of the interface function blocks.

The output is generated when actual process value is compared with the limits in the input HIGHHIGH_LIM and/or LOWLOW_LIM.

- When output is TRUE, pump station or pump is shutdown.
- When output is FALSE, pump station or pump’s operation continues.

START_ BLOCKER

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE / FALSE	-

The output START_BLOCKER of the protection function blocks PMP_PROTECTION_ANALOG and/or PMP_PROTECTION_BINARY stops the pump from starting depending on the analog or binary input signal.

- If the requirement is to block starting of the complete process, then the output must be connected to the input START_BLOCKER of the distributor function blocks.
- If the requirement is block the starting of only a particular pump, then the output must be connected to the input START_BLOCKER of the interface function blocks.

The output is generated when actual process value is compared with the limits in the input HIGH_LIM and/or LOW_LIM.

- When input is TRUE, pump start is not allowed.
- When input is FALSE, pump start is allowed.

The input START_BLOCKER will not stop the already running pump.

STATUS

Data type	Default value	Range	Unit
STRING (90)	-	-	-

The output STATUS indicates the status of fault/alarm messages generated by this function block.

Error codes

The error codes of function block PMP_PROTECTION_ANALOG are listed below:

Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16433	4031	Value in MIN_RANGE is less than 0
16449	4041	Value in MAX_RANGE is less than or equal to 0
16451	4043	Value in MAX_RANGE is less than or equal to MIN_RANGE
16481	4051	Value in MIN_SCALE is less than 0
16481	4061	Value in MAX_ SCALE is less than or equal to 0
16483	4063	Value in MAX_ SCALE is less than or equal to MIN_ SCALE
16528	4090	LIM_ACTIVE is changed when EN is TRUE
16545	40A1	Value in LIM_HYS is less than 0
16546	40A2	Value in LIM_HYS is greater than 100
16563	40B3	HIGH_LIM ≤ LOW_LIM or HIGHHIGH_LIM ≤ LOW_LIM
16595	40D3	HIGHHIGH_LIM ≤ LOWLOW_LIM or HIGH_LIM ≤ LOWLOW_LIM
16611	40E3	HIGHHIGH_LIM ≤ HIGH_LIM or HIGHHIGH_LIM ≤ 0 or HIGH_LIM < 0

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.16 PMP_PROTECTION_BINARY

The function block PMP_PROTECTION_BINARY monitors binary inputs and generates signals to shut down or to stop the starting of pump. The function block sends the signals to shut down or to stop the pump start through inputs PROTECTION_SHUTDOWN or START_BLOCKER of these distributor and pump interface function blocks: PMP_LEVEL_DISTRIBUTOR, PMP_FLOW_DISTRIBUTOR, PMP_PRESSURE_DISTRIBUTOR, PMP_INTERFACE_VFD, and PMP_INTERFACE_DOL.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Pump protection configuration example

The function block PMP_PROTECTION_BINARY can be used for:

- Process specific protection or
- Pump specific protection

Process specific protection with many such sensors

The function block can be used to configure the alarm (start blocker) or fault (protection shutdown) for the digital input signal. The input coming from the digital sensor can be used to generate the alarm (start blocker) or fault (protection shutdown) using the settings in the function block. See example diagram below:

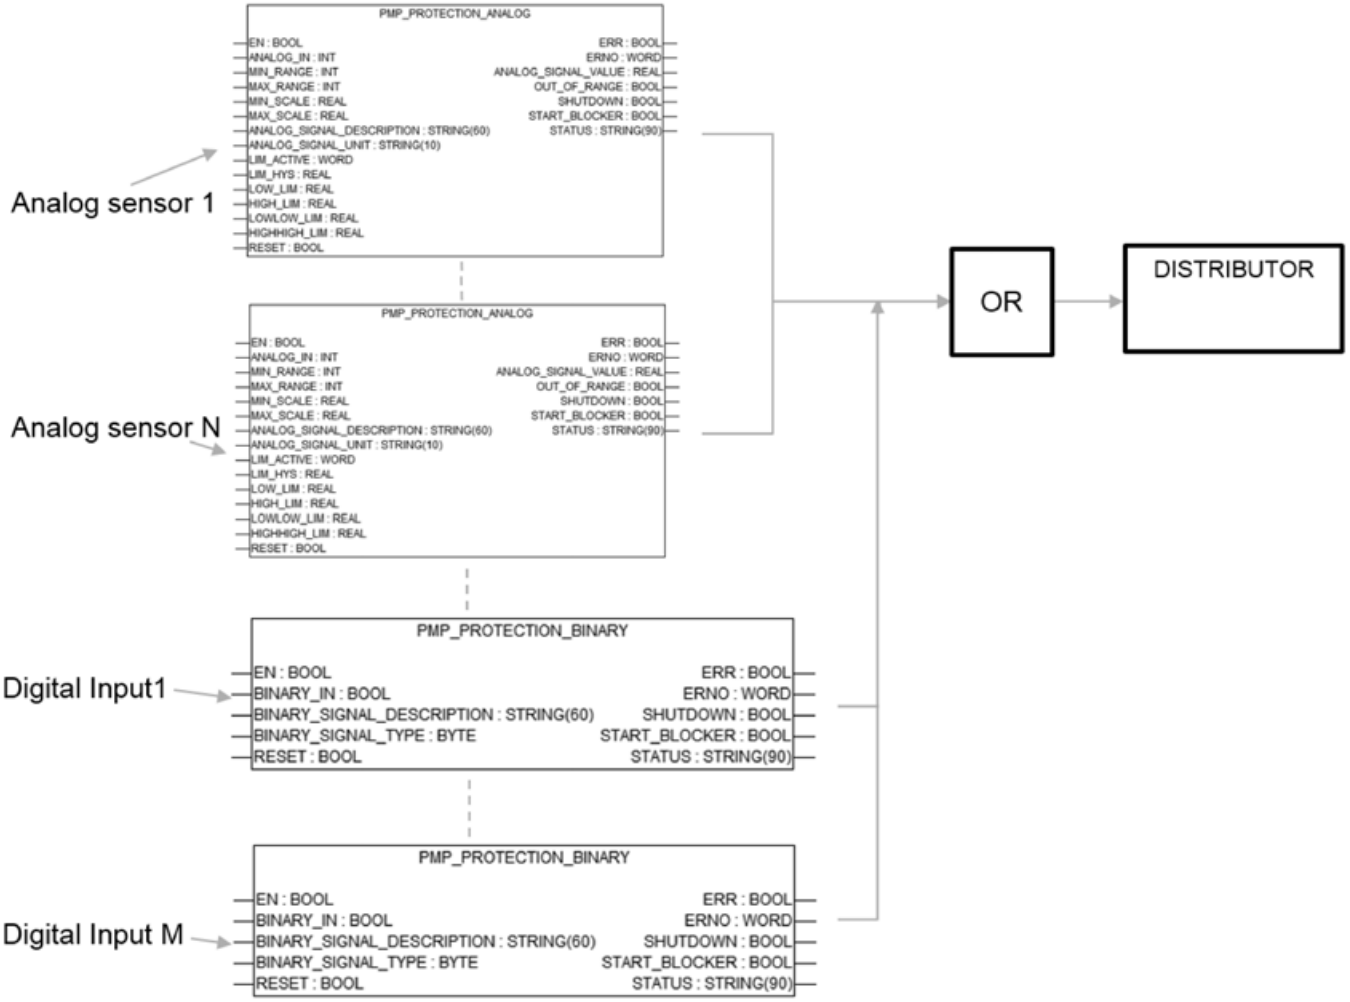


Fig. 717: Analog/Digital FB - process specific protection

Pump specific protection with many such sensors

The function block is flexible and can be used based on the requirements. If more than one sensor is used, then configure the function block for each digital sensor. The outputs of each function block can be logically OR'ed in the application program, as shown below.

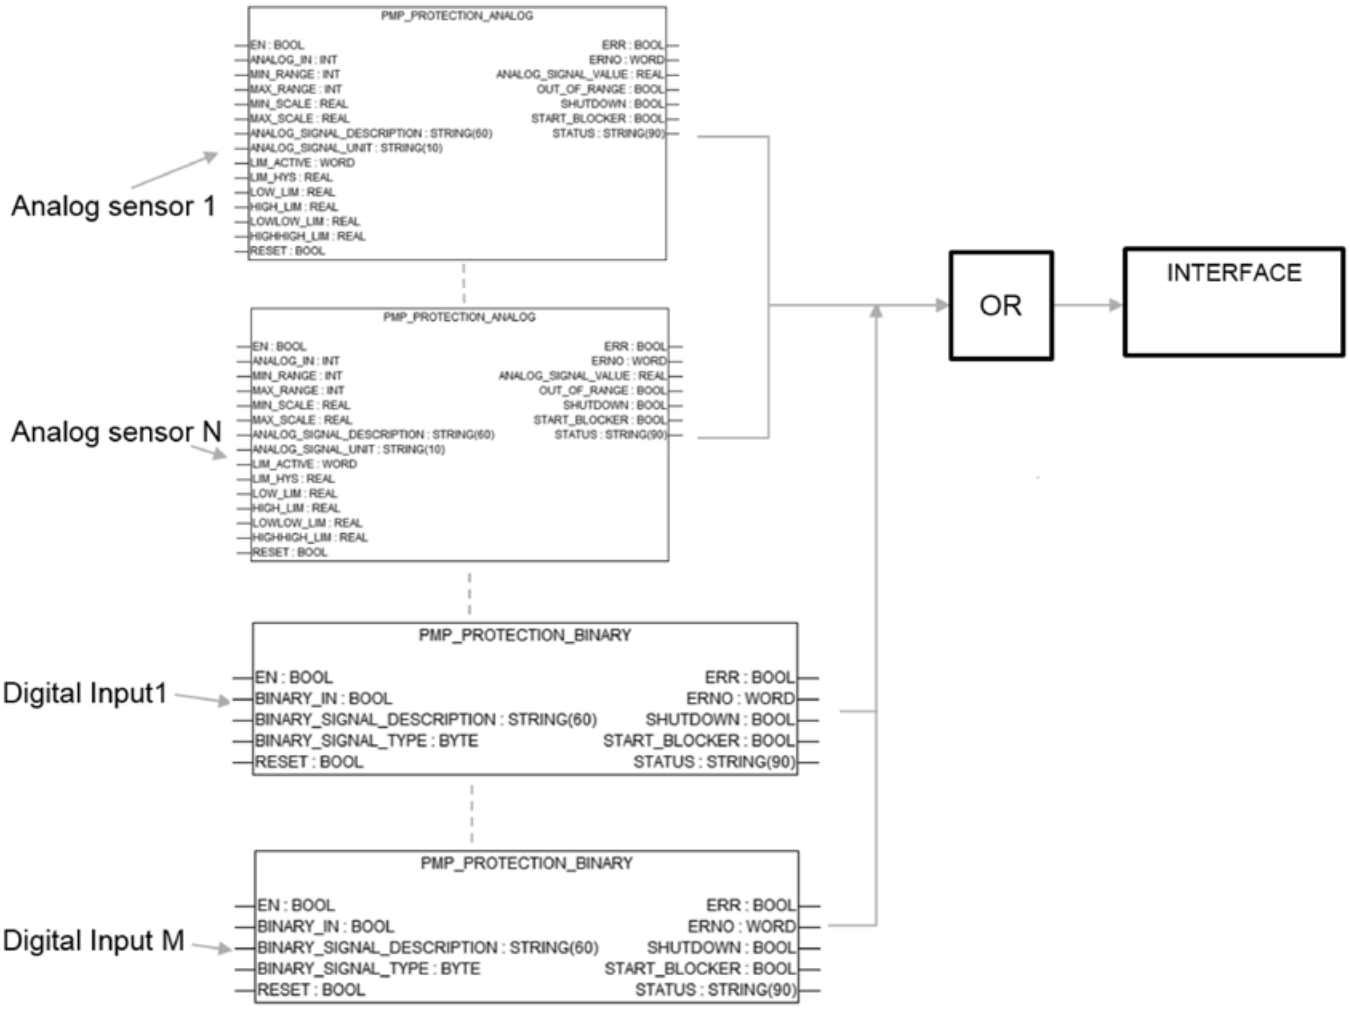

Fig. 718: Analog/Digital FB - pump specific protection

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

BINARY_IN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input BINARY_IN receives the binary input from the process.

- When input is TRUE, binary input received.
- When input is FALSE, no input received.

BINARY_ SIGNAL_ DESCRIPTION

Data type	Default value	Range	Unit
STRING (60)	-	-	-

The input BINARY_SIGNAL_DESCRIPTION allows the user to add the description of the binary input signal.

BINARY_ SIGNAL_TYPE

Data type	Default value	Range	Unit
BYTE	0	0 ... 2	-

The input BINARY_SIGNAL_TYPE selects the type of the binary input signal.

0 = Not used (no input signal)

1 = To generate alarm (binary input signal to generate an alarm)

2 = To generate fault (binary input signal to indicate a fault)

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input RESET resets any active alarm/fault and alarm messages generated by analog or binary input signal.

- When output is TRUE, alarm/fault and alarm message are reset.
- When output is FALSE, no reset.

Output description

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

SHUTDOWN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE / FALSE	-

The output SHUTDOWN indicates pump shutdown depending on the analog or binary input signal.

- If the requirement is to stop the complete process, then the output must be connected to the input PROTECTION_SHUTDOWN of the distributor function blocks.
- If the requirement is stop only a particular pump, then the output must be connected to the input PROTECTION_SHUTDOWN of the interface function blocks.

The output is generated when actual process value is compared with the limits in the input HIGHHIGH_LIM and/or LOWLOW_LIM.

- When output is TRUE, pump station or pump is shutdown.
- When output is FALSE, pump station or pump’s operation continues.

START_ BLOCKER

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE / FALSE	-

The output START_BLOCKER of the protection function blocks PMP_PROTECTION_ANALOG and/or PMP_PROTECTION_BINARY stops the pump from starting depending on the analog or binary input signal.

- If the requirement is to block starting of the complete process, then the output must be connected to the input START_BLOCKER of the distributor function blocks.
- If the requirement is block the starting of only a particular pump, then the output must be connected to the input START_BLOCKER of the interface function blocks.

The output is generated when actual process value is compared with the limits in the input HIGH_LIM and/or LOW_LIM.

- When input is TRUE, pump start is not allowed.
- When input is FALSE, pump start is allowed.

The input START_BLOCKER will not stop the already running pump.

STATUS

Data type	Default value	Range	Unit
STRING (90)	-	-	-

The output STATUS indicates the status of fault/alarm messages generated by this function block.

Error codes

The error codes of function block PMP_PROTECTION_BINARY are listed below:

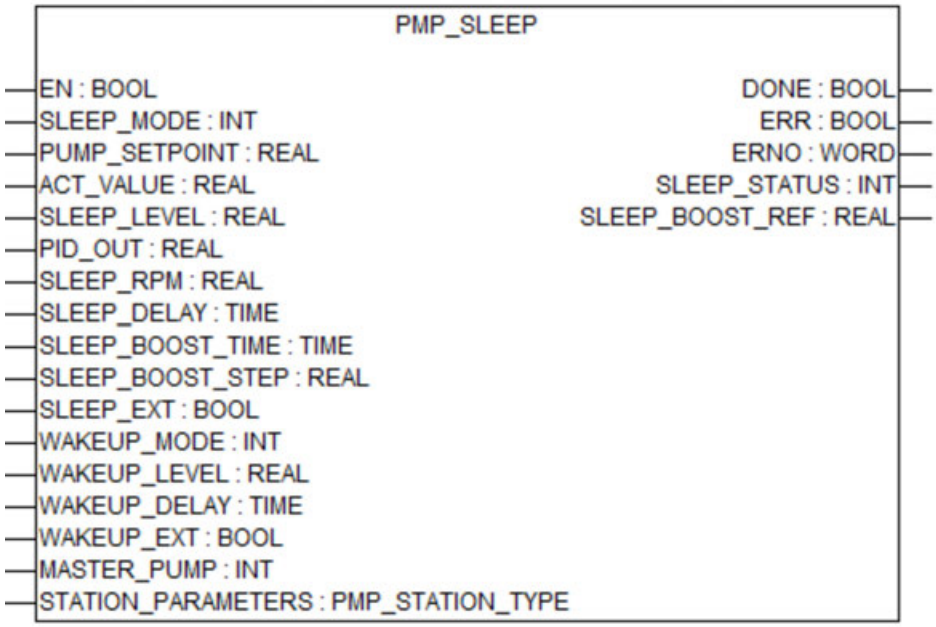
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16449	4041	Value in BINARY_SIGNAL_TYPE is less than 0
16450	4042	Value in BINARY_SIGNAL_TYPE is greater than 2

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.17 PMP_SLEEP



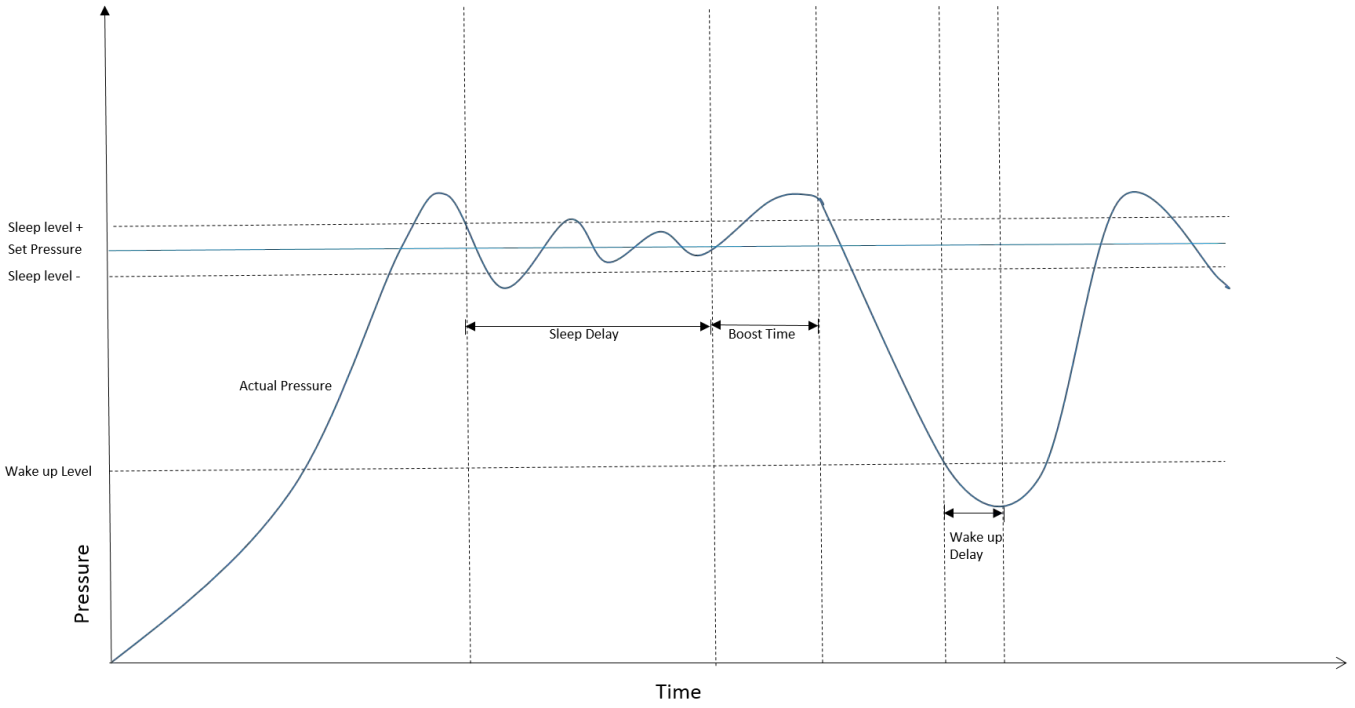
The function block PMP_SLEEP stops all pumps in the pressure control process during low demand. The function works only for pressure control (when function block PMP_CONFIGURATION has the input PROCESS_MODE = 1 (Pressure control) with multi pump station or traditional pump station.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Key features

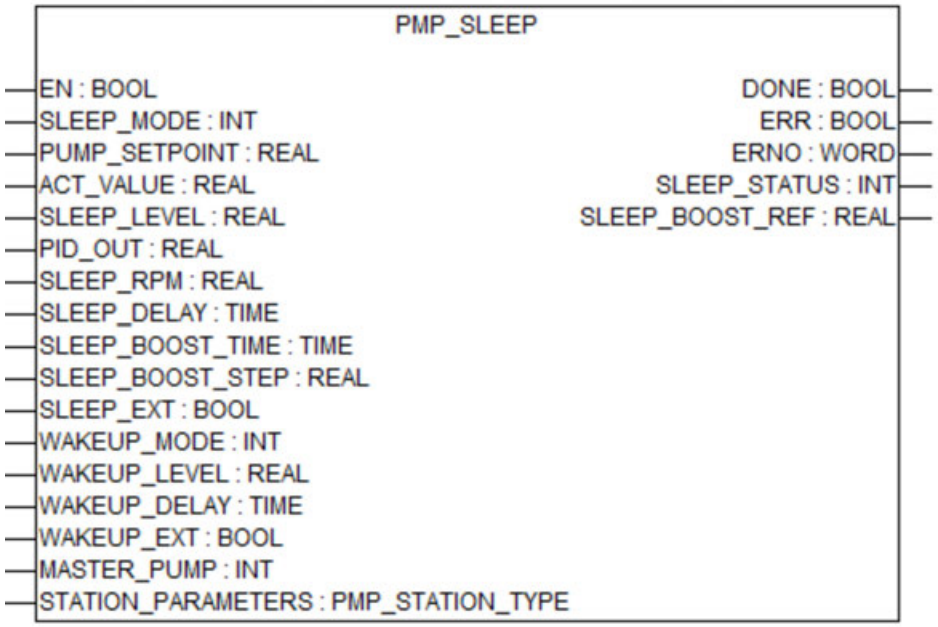
- The function block is used to conserve energy when the demand is very low and the pump is running at very less RPM
- For Sleep_Mode = 1
  - Absolute difference between set and actual pressure must be less than sleep level. Sleep level is defined as percentage of set point e.g. sleep level 10 means 10 % of set value.
  - Master pump RPM must be less than SLEEP_RPM.
  - If above both conditions are true for more than SLEEP_DELAY time then only pump gets ready to go to sleep.
  - Process increases set point by SLEEP_BOOST_STEP in terms of percentage for the time duration SLEEP_BOOST_TIME. This allows actual pressure to increase and in turn increases sleep duration.
  - Once SLEEP_BOOST_TIME is over, master pump goes in sleep and its ON command is removed.
  - When the actual pressure goes below WAKEUP_LEVEL then the wake up function starts. It waits for WAKEUP_DELAY and then the ON command is issued to the master drive and the pressure distributor process takes over.



This figure shows the sleep and wake up sequence based on the change in the actual pressure with time.

Sleep_Mode = 2 has not been implemented yet in this version.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLEEP_MODE

Data type	Default value	Range	Unit
INT	0	1 ... 2	-

The input SLEEP_MODE selects the sleep mode.

0 = Disabled

1 = Internal

2 = External

PUMP_SETPOINT

Data type	Default value	Range	Unit
REAL	1.0	> 0	-

The input PUMP_SETPOINT defines the pressure setpoint. The value is same as the input SET_VALUE of the function block PMP_PID.

ACT_VALUE

Data type	Default value	Range	Unit
REAL	1.0	-	

The input ACT_VALUE defines the actual pressure value.

SLEEP_LEVEL

Data type	Default value	Range	Unit
REAL	5.0	1.0 ... 100.0	%

The input SLEEP_LEVEL defines the sleep activation level, which is a percentage of the input PUMP_SETPOINT.

PID_OUT

Data type	Default value	Range	Unit
REAL	0.0	-	%

The input PID_OUT of the function block PMP_SLEEP indicates the PID output in percentage. The value is the same as the output PID_OUT of the function blocks PMP_PID.

SLEEP_RPM

Data type	Default value	Range	Unit
REAL	100.0	> 0.0	rpm

The input SLEEP_RPM defines the speed in rpm below which the pump should go to sleep mode.

SLEEP_DELAY

Data type	Default value	Range	Unit
TIME	5	-	s

The input SLEEP_DELAY defines the delay time in seconds at which the sleep function must be activated.

SLEEP_ BOOST_TIME

Data type	Default value	Range	Unit
TIME	5	-	s

The input SLEEP_BOOST_TIME defines the time period in seconds for which the sleep boost must be operated.

SLEEP_ BOOST_STEP

Data type	Default value	Range	Unit
REAL	5.0		%

The input SLEEP_BOOST_STEP defines the step limit in percentage at which the input PUMP_SETPOINT must increase for the time duration defined in the input SLEEP_BOOST_TIME.

SLEEP_EXT

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input SLEEP_EXT enables sleep function externally, when input SLEEP_MODE = 2 (External).

- When input is TRUE, sleep function is enabled externally.
- When input is FALSE, sleep function is disabled or continues in the current mode.

WAKEUP_MODE

Data type	Default value	Range	Unit
INT	1	1 ... 2	-

The input WAKEUP_MODE selects the wake up mode.

1 = Internal

2 = External

WAKEUP_LEVEL

Data type	Default value	Range	Unit
REAL	7.0	1.0 ... 100.0	%

The input WAKEUP_LEVEL defines the wake up activation level in percentage of the setpoint defined in the input PUMP_SETPOINT.

WAKEUP_DELAY

Data type	Default value	Range	Unit
TIME	5	-	s

The input WAKEUP_DELAY defines the delay time in seconds to activate the wake up function.

WAKEUP_EXT

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input WAKEUP_EXT receives a digital signal to wake up the system when the input WAKEUP_MODE = 2 (External).

MASTER_PUMP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input MASTER_PUMP receives the identification number of the master pump in the sequence. The input comes from the output MASTER_PUMP of the function block PMP_SEQUENCE_GEN.

STATION_PARAMETERS

Data type	Default value	Range	Unit
PMP_STATION_TYPE	-	-	-

The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

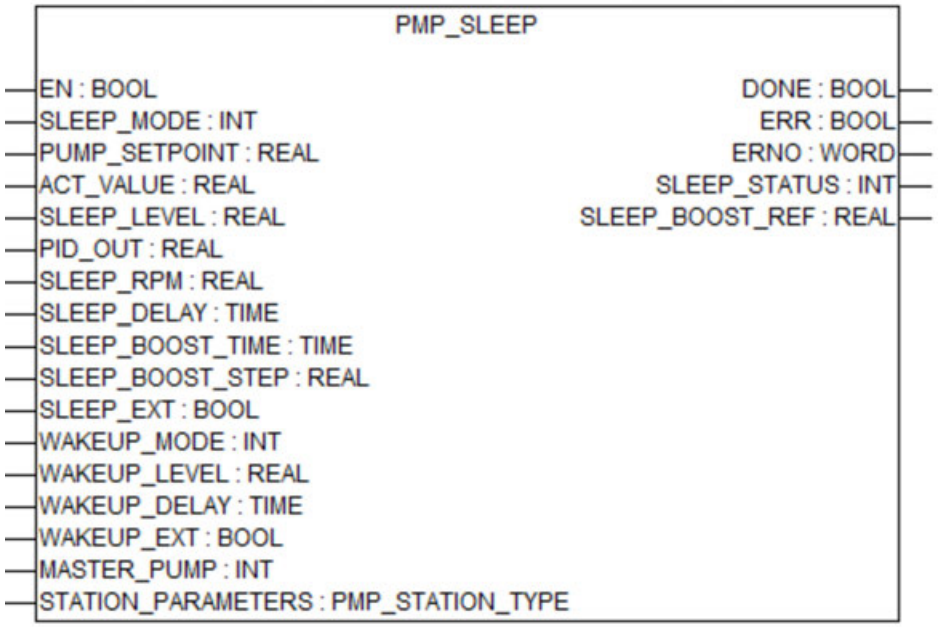
All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations

Parameter	Data type	Default value	Description
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combina-tion	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

SLEEP_STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 3	-

The output SLEEP_STATUS of the function block PMP_SLEEP indicates the sleep status of the pump.

0 = Inactive/Wakeup inactive

1 = Boost activated

2 = Sleep mode active

3 = Wakeup function active

SLEEP_ BOOST_REF

Data type	Default value	Range	Unit
REAL	0.0	> 0.0	-

The output SLEEP_BOOST_REF of the function block PMP_SLEEP indicates the sleep boost reference. This output is connected as input into PMP_PID function block.

Error codes

The error codes of function block PMP_SLEEP are listed below:

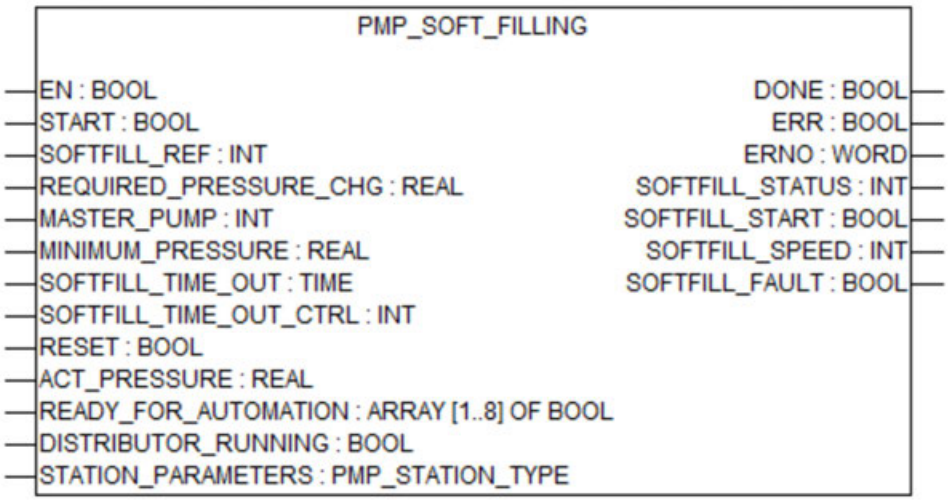
Error code		Error Description
Decimal	Hexadecimal	
0	0000	No error occurred
16403	4013	Sleep function is active only when input PROCESS_MODE = 1 in function block PMP_CONFIGURATION
16417	4021	Value of SLEEP_MODE is less than 0
16418	4022	Value of SLEEP_MODE is more than 2
16433	4031	Value of PUMP_SETPOINT is less than 0
16465	4051	Value of SLEEP_LEVEL is less than or equal to 0
16497	4071	Value of SLEEP_RPM is less than 0
16577	40C1	Value of WAKEUP_MODE is less than 0
16578	40C2	Value of WAKEUP_MODE is greater than 2
16593	40D1	Value of WAKEUP_LEVEL is less than 0.0

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.18 PMP_SOFT_FILLING



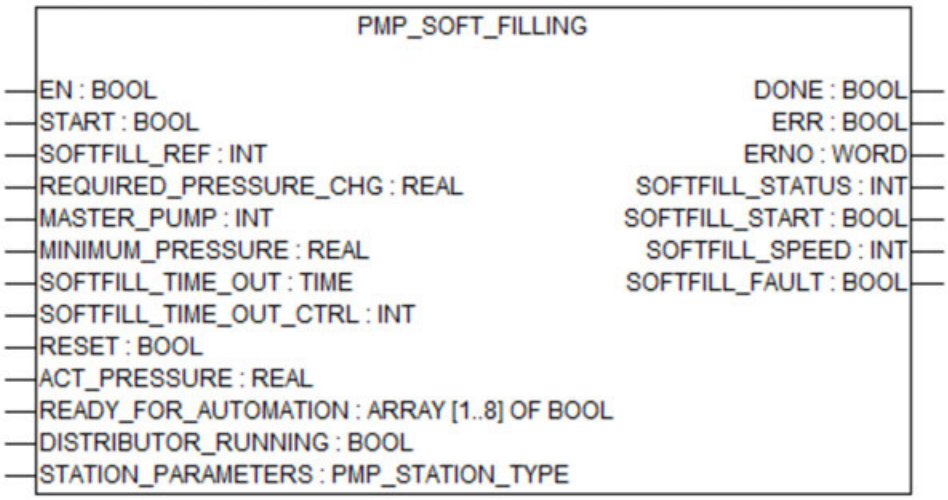
The function block PMP_SOFT_FILLING enables slow filling operation in pipes in the beginning of the process to avoid damages. If this operation is selected, it is executed before the actual process control takes over.

This function block cannot run when the PUMP_COMB = 3, DOL mode in PMP_CONFIGURATION. Soft filling needs the VFD drive to run and execute gradual filling of water.

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START receives the soft filling start command from the output SOFTFILL_START of the function blocks PMP_LEVEL_DISTRIBUTOR, PMP_FLOW_DISTRIBUTOR or PMP_PRESSURE_DISTRIBUTOR.

- When input is TRUE, the soft filling starts.
- When input is FALSE, the soft filling stops if running.

SOFTFILL_REF

Data type	Default value	Range	Unit
INT	100	0 ... 20 % of master pump nominal speed	rpm

The input SOFTFILL_REF defines the softfill speed reference in rpm.

REQUIRED_ PRESSURE_ CHG

Data type	Default value	Range	Unit
REAL	0.0	0.0 ... 100.0	%

The input REQUIRED_PRESSURE_CHG defines the percentage change in the actual pressure during soft filling operation.

MASTER_PUMP

Data type	Default value	Range	Unit
INT	1	1 ... 8	-

The input MASTER_PUMP receives the identification number of the master pump in the sequence. The input comes from the output MASTER_PUMP of the function block PMP_SEQUENCE_GEN.

MINIMUM_ PRESSURE

Data type	Default value	Range	Unit
REAL	0.0	≥ 0	-

The input MINIMUM_PRESSURE defines the minimum pressure above which the soft filling operation is disabled.

SOFTFILL_ TIME_OUT

Data type	Default value	Range	Unit
TIME	10	-	s

The input SOFTFILL_TIME_OUT defines the time limit in seconds after which the soft filling operation is stopped, regardless of the minimum pressure limit in input MINIMUM_PRESSURE.

SOFTFILL_ TIME_OUT_ CTRL

Data type	Default value	Range	Unit
INT	1	1 ... 2	s

The input SOFTFILL_TIME_OUT_CTRL selects the pump behavior when softfill operation stopped because of input SOFTFILL_TIME_OUT. The function will stop the process if already running. This indicates a leakage in the pipe and due to which the minimum pressure is not established.

1 = Keep running normal PID operation

2 = Fault trips the station

RESET

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The input RESET resets the output SOFTFILL_FAULT.

- When output is TRUE, softfill fault is reset.
- When output is FALSE, no reset.

ACT_ PRESSURE

Data type	Default value	Range	Unit
REAL	0.0	-	-

The input ACT_PRESSURE receives the actual pressure in physical units, e.g. bar, as measured by the pressure sensor.

READY_FOR_AUTOMATION

Data type	Default value	Range	Unit
ARRAY[1..8] of BOOL	FALSE	TRUE/FALSE	-

The input READY_FOR_AUTOMATION receives an array of pumps ready for automatic operation. The input comes from the output READY_FOR_AUTOMATION of the function block PMP_INTERFACE_VFD or PMP_INTERFACE_DOL.

The READY_FOR_AUTOMATION[1] connects to the PUMP ID = 1. This pattern must be followed for all pump IDs.

- When input is TRUE, pump is ready for operation in automatic mode.
- When input is FALSE, pump is not ready for operation in automatic mode.

DISTRIBUTOR_RUNNING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input DISTRIBUTOR_RUNNING indicates the running status of the distributor.
This input is connected to the output DISTRIBUTOR_RUNNING of any of the the distributor function blocks PMP_LEVEL_DISTRIBUTOR, PMP_FLOW_DISTRIBUTOR or PMP_PRESSURE_DISTRIBUTOR.

- When output is TRUE, distributor is running.
- When output is FALSE, distributor is not running.

STATION_PARAMETERS

Data type	Default value	Range	Unit
PMP_STATION_TYPE	-	-	-

The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

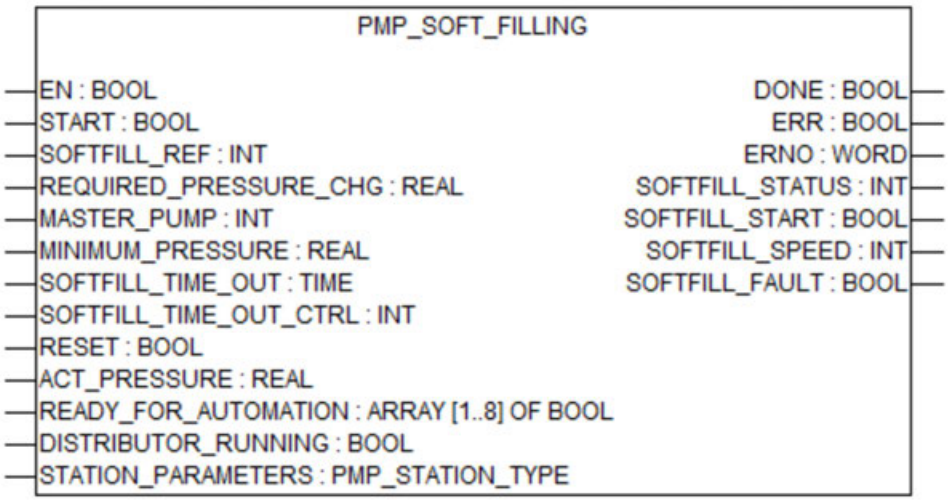
All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control

Parameter	Data type	Default value	Description
iPump_Combination	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

SOFTFILL_ STATUS

Data type	Default value	Range	Unit
INT	0	0 ... 4	-

The input SOFTFILL_STATUS indicates the status of softfilling function.

0 = Disable the softfill (Softfill operation is disabled)

1 = Ready to start (Softfill operation is ready to start)

2 = Softfill in progress (Softfill operation has started)

3 = Softfill completed (Softfill operation is completed)

4 = Softfill with fault (Softfill operation stopped due to a fault)

SOFTFILL_ START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output SOFTFILL_START of the used pump distributor starts the soft filling operation. This function is effective only when this output is connected to the input START of the function block PMP_SOFT_FILLING.

- When input is TRUE, softfill function starts.
- When input is FALSE, softfill function stops if running.

SOFTFILL_ SPEED

Data type	Default value	Range	Unit
INT	0	> 0	rpm

The output SOFTFILL_SPEED of the function block PMP_SOFT_FILLING indicates the speed reference for soft filling function. The output must be connected to the input SOFTFILL_SPEED of the interface function block PMP_INTERFACE_VFD.

SOFTFILL_ FAULT

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output SOFTFILL_FAULT indicates a fault in the soft filling function. The fault occurs when actual pressure in input ACT_PRESSURE has not reached PID_ENABLE_PRESSURE in the time limit defined in the input SOFTFILL_TIME_OUT.

- When output is TRUE, softfill fault occurred.
- When input is FALSE, no fault occurred.

Error codes

The error codes of function block PMP_SOFT_FILLING are listed below:

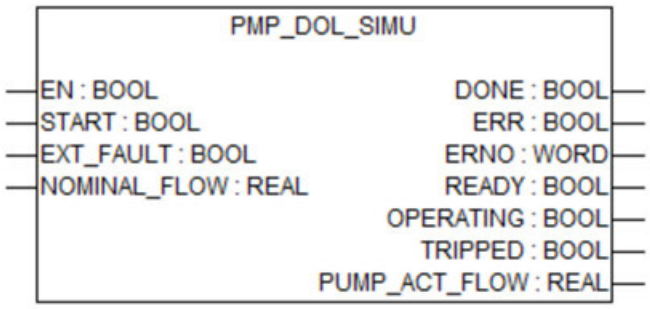
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16403	4013	Softfill function is incorrectly activated when the PUMP_COMB = 3, DOL type station in PMP_CONFIGURATION
16433	4031	Value of SOFTFILL_REF is less than 0
16435	4033	SOFTFILL_REF is greater than 20 % of master pumps nominal speed
16449	4041	Value of REQUIRED_PRESSURE_CHG is less than 0.0
16465	4051	Value of MASTER_PUMP is less than 1
16466	4052	Value of MASTER_PUMP is more than NUMBER_OF_PUMPS in the PMP_CONFIGFURATION function block
16481	4061	Value of MINIMUM_PRESSURE is less than 0.0
16513	4081	Value of SOFTFILL_TIME_OUT_CTRL is less than 1
16514	4082	Value of SOFTFILL_TIME_OUT_CTRL is greater than 2

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.19 PMP_DOL_SIMU



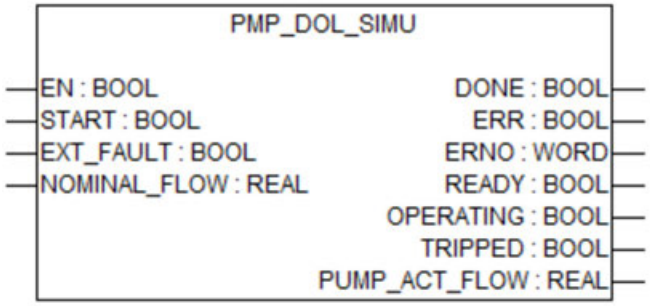
The function block PMP_DOL_SIMU is a simple simulation of the direct online pumps.

> *The outputs of the function block may or may not be as accurate as real process. Use this function block only for simulation testing and not on the actual system.*

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START starts the execution of the function block.

- When input is TRUE, the execution starts.
- When input is FALSE, the execution stops if running.

EXT_FAULT

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The input EXT_FAULT simulates the external fault condition.

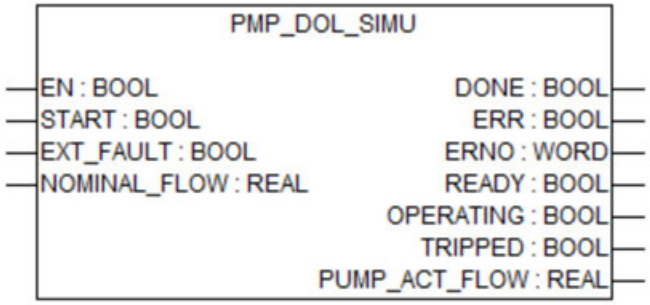
- When input is TRUE, external fault condition is simulated.
- When input is FALSE, no simulation.

NOMINAL_ FLOW

Data type	Default value	Range	Unit
REAL	100.0	> 0.0	m^3/h

The input NOMINAL_FLOW defines the nominal flow of the direct online (DOL) pump in cubic meters per hour.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

READY

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output READY indicates that the used system (DOL/VFD) is ready for operation.

- When output is TRUE, system is ready for operation.
- When output is FALSE, system is not ready for operation.

OPERATING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output OPERATING indicates that the device is operating.

- When output is TRUE, device is operating.
- When output is FALSE, device is not operating.

TRIPPED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output TRIPPED indicates that the used system (DOL/VFD) has tripped.

- When output is TRUE, system tripped.
- When output is FALSE, system is healthy.

PUMP_ACT_FLOW

Data type	Default value	Range	Unit
REAL	0.0	-	m^3/h

The output PUMP_ACT_FLOW indicates the actual flow of direct online pumps in cubic meters per hour.

Error codes

The error codes of function block PMP_DOL_SIMU are listed below:

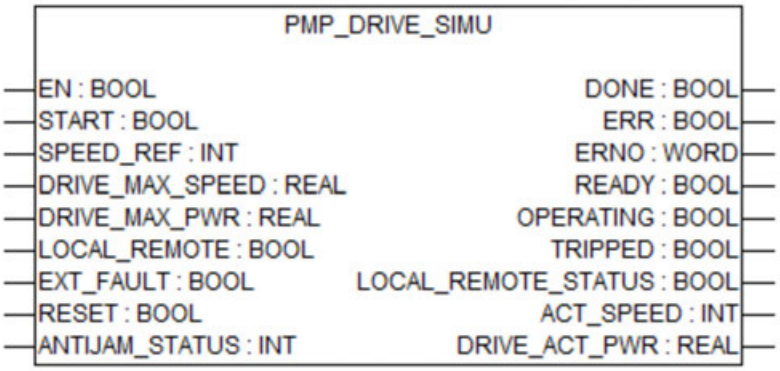
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16449	4041	Value in input NOMINAL_FLOW is less than or equal to 0.0

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.20 PMP_DRIVE_SIMU



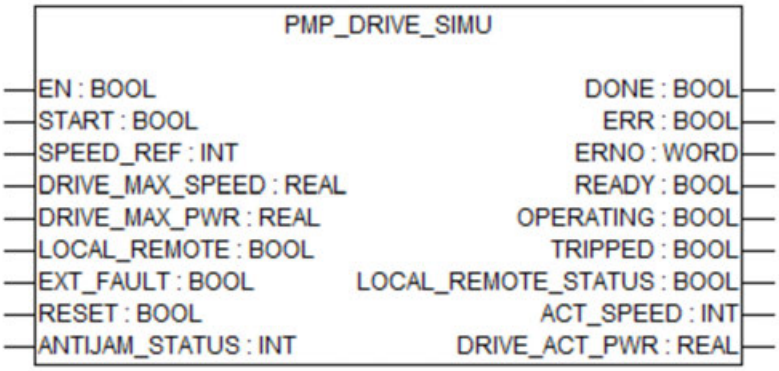
The function block PMP_DRIVE_SIMU is used to simulate the variable frequency drive (VFD) pumps and for PLC communication.

- *The function block is not similar to the PS553 drives library function block.*
- *The outputs of the function block may or may not be as accurate as real drive communication blocks.*
- *Use this function block only for simulation testing and not on the actual system.*

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

START

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input START starts the execution of the function block.

- When input is TRUE, the execution starts.
- When input is FALSE, the execution stops if running.

SPEED_REF

Data type	Default value	Range	Unit
INT	0	> 0	rpm

The output SPEED_REF of the interface function block PMP_INTERFACE_VFD shows the speed reference of the variable frequency drive (VFD) in rpm.

> *The speed reference can be given to the drive only if it is connected to the correct parameter.*
>
> *This can be done using the PLC - VFD communication library, which is not in the scope of the pump library.*

The input SPEED_REF of the function block PMP_DRIVE_SIMU comes from the output SPEED_REF of the interface function block PMP_INTERFACE_VFD.

DRIVE_MAX_SPEED

Data type	Default value	Range	Unit
REAL	1500.0	1.0 ... 1500.0	rpm

The input DRIVE_MAX_SPEED defines the maximum speed of the variable frequency drive (VFD) in rpm.

DRIVE_MAX_POWER

Data type	Default value	Range	Unit
REAL	5	0.1 ... 5.0	kW

The input DRIVE_MAX_POWER defines the maximum power of the variable frequency drive (VFD) in kW.

LOCAL_REMOTE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input LOCAL_REMOTE selects the variable frequency drive (VFD) operating mode.

- When input is TRUE, VFD is in local mode.
- When input is FALSE, VFD is in remote mode.

EXT_FAULT

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The input EXT_FAULT simulates the external fault condition.

- When input is TRUE, external fault condition is simulated.
- When input is FALSE, no simulation.

RESET

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The input RESET resets the variable frequency drive (VFD) fault and the value in output ERNO.

- When input is TRUE, softfill fault is reset.
- When input is FALSE, no reset.

ANTIJAM_STATUS

Data type	Default value	Range	Unit
ARRAY[1..8] of INT	0	0 ... 2	-

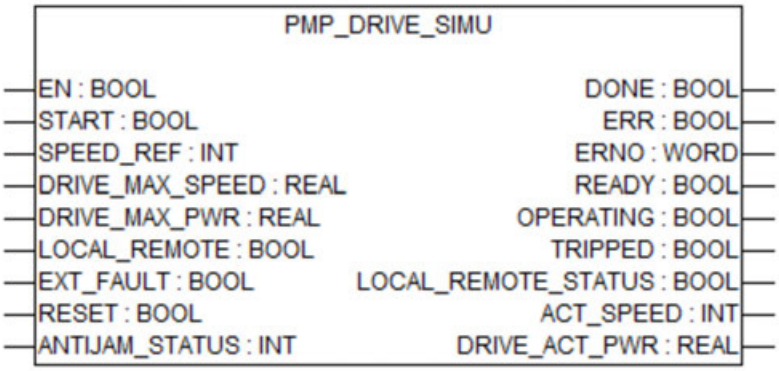
The input ANTIJAM_STATUS receives the status of antijam operation. The input comes from the output ANTIJAM_STATUS of the function block PMP_ANTIJAM.

0 = Not started (Antijam operation has not started)

1 = Busy (Antijam operation has started)

2 = Done (Antijam operation is completed)

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

READY

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output READY indicates that the used system (DOL/VFD) is ready for operation.

- When output is TRUE, system is ready for operation.
- When output is FALSE, system is not ready for operation.

OPERATING

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output OPERATING indicates that the device is operating.

- When output is TRUE, device is operating.
- When output is FALSE, device is not operating.

TRIPPED

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output TRIPPED indicates that the used system (DOL/VFD) has tripped.

- When output is TRUE, system tripped.
- When output is FALSE, system is healthy.

LOCAL_ REMOTE_ STATUS

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The output LOCAL_REMOTE_STATUS indicates the operating mode of the pump system (DOL/VFD).

- When output is TRUE, pump system is in local mode.
- When output is FALSE, pump system is in remote mode.

ACT_SPEED

Data type	Default value	Range	Unit
INT	10	> 1	rpm

The input ACT_SPEED indicates the actual speed of the variable frequency drive (VFD) in rpm.

DRIVE_ACT_ PWR

Data type	Default value	Range	Unit
REAL	0.0	> 0.0	kW

The output DRIVE_ACT_PWR indicates the actual power of the variable frequency drive (VFD) in kW.

Error codes

The error codes of function block PMP_DRIVE_SIMU are listed below:

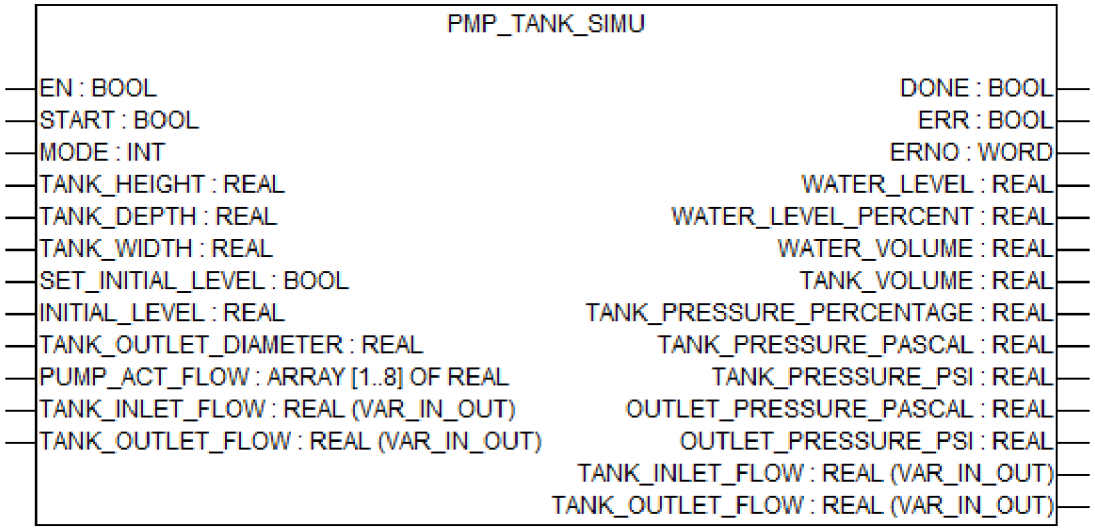
Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16449	4041	Value in input DRIVE_MAX_SPEED is less than or equal to 0
16465	4051	Value in input DRIVE_MAX_PWR is less than or equal to 0

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.2.21 PMP_TANK_SIMU



The function block PMP_TANK_SIMU is used to simulate the water tank.

This simulation can be used in all the three process control modes:

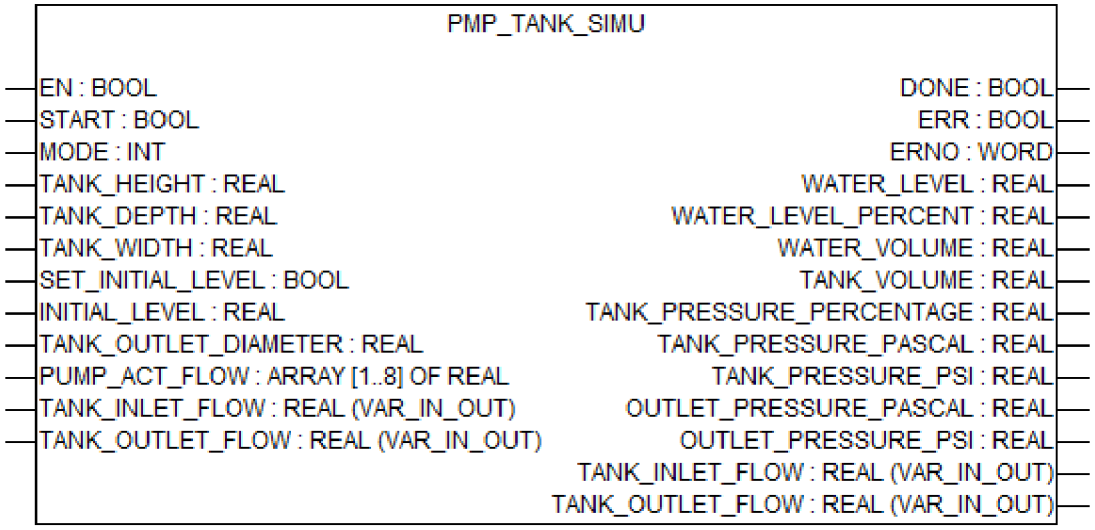
- Pressure
- Flow
- Level

> *Use this function block only for simulation testing and not with critical hardware in loop.*

General information

Runtime system version	V2.5 and later
Library version	**PMP_AC500_V25.lib**
Function block type	Function block without historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

MODE

Data type	Default value	Range	Unit
INT	1	1 ... 2	-

The input MODE selects the pumping operation mode.

1 = Emptying.

2 = Filling.

TANK_HIGHT

Data type	Default value	Range	Unit
REAL	20.0	> 1.0	m

The input TANK_HEIGHT defines the height of the tank in meters.

TANK_DEPTH

Data type	Default value	Range	Unit
REAL	10.0	> 1.0	m

The input TANK_DEPTH defines the depth of the tank in meters.

TANK_WIDTH

Data type	Default value	Range	Unit
REAL	5.0	> 1.0	m

The input TANK_WIDTH defines the width of the tank in meters.

SET_INITIAL_LEVEL

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input SET_INITIAL_LEVEL allows to set the initial level for tank simulation.

- When input is TRUE, initial level setting for tank simulation is allowed.
- When input is FALSE, initial level setting for tank simulation is not allowed.

INITIAL_LEVEL

Data type	Default value	Range	Unit
REAL	10.0	0.0 ... TANK_HEIGHT	m

The input INITIAL_LEVEL defines the initial level of tank in meters.

TANK_OUTLET_DIAMETER

Data type	Default value	Range	Unit
REAL	0.25	> 1.00	m

The input TANK_OUTLET_DIAMETER defines the outlet diameter of the tank pipe in meters.

PUMP_ACT_FLOW

Data type	Default value	Range	Unit
ARRAY[1..8] of REAL	-	> 0.0	m^3/h

The input PUMP_ACT_FLOW is an array of actual flow in cubic meters per hour.

At the first index of array PUMP_ACT_FLOW[1] connect the actual flow of the pump with PUMP ID = 1.

This pattern must be followed for all pump IDs.

TANK_INLET_FLOW

Data type	Default value	Range	Unit
REAL	-	-	m^3/h

The variable input/output TANK_INLET_FLOW defines the inlet flow of the tank in cubic meters per hour.

The inflow is assumed to be constant.

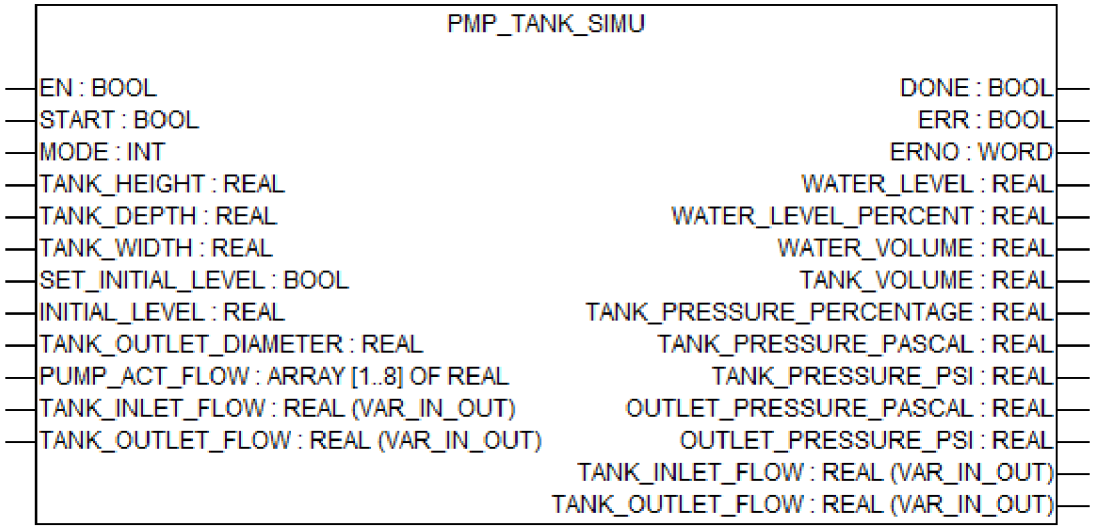
TANK_OUTLET_FLOW

Data type	Default value	Range	Unit
REAL	-	-	m^3/h

The variable input/output TANK_OUTLET_FLOW defines the outlet flow of the tank in cubic meters per hour.

The outflow is assumed to be constant.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.7.3.5 “Error messages of the AC500 V2 function block libraries” on page 6529*).

WATER_LEVEL

Data type	Default value	Range	Unit
REAL	0.0	-	m

The output WATER_LEVEL indicates the water level of the tank in meters.

WATER_LEVEL_PERCENT

Data type	Default value	Range	Unit
REAL	0.0	-	%

The output WATER_LEVEL_PERCENT indicates the percentage of water level in the tank.

WATER_ VOLUME

Data type	Default value	Range	Unit
REAL	0.0	-	m^3

The output WATER_VOLUME indicates the actual water volume in cubic meters.

TANK_VOLUME

Data type	Default value	Range	Unit
REAL	0.0	-	m^3

The output TANK_VOLUME indicates the total tank volume in cubic meters.

TANK_ PRESSURE_ PERCENTAGE

Data type	Default value	Range	Unit
REAL	0.0	0.0 ... 100	%

The output TANK_PRESSURE_PERCENTAGE indicates the pressure at the bottom of the tank in percentage.

TANK_ PRESSURE_ PASCAL

Data type	Default value	Range	Unit
REAL	0.0	-	Pa

The output TANK_PRESSURE_PASCAL indicates the pressure at the bottom of the tank in Pascal.

TANK_ PRESSURE_PSI

Data type	Default value	Range	Unit
REAL	0.0	-	psi

The output TANK_PRESSURE_PSI indicates the pressure at the bottom of the tank in psi (pounds per square inch).

OUTLET_ PRESSURE_ PASCAL

Data type	Default value	Range	Unit
REAL	0.0	-	Pa

The output OUTLET_PRESSURE_PASCAL indicates the pressure at the outlet pipe in Pascal.

OUTLET_ PRESSURE_PSI

Data type	Default value	Range	Unit
REAL	0.0	-	psi

The output OUTLET_PRESSURE_PSI indicates pressure at the outlet pipe in PSI.

Error codes

The error codes of function block PMP_TANK_SIMU are listed below:

Error code		Error Description
Decimal	**Hexadecimal**	
0	0000	No error occurred
16417	4021	Value in input MODE is less than 1
16418	4022	Value in input MODE is greater than 2
16433	4031	Value in input TANK_HEIGHT is less than or equal to 0
16449	4041	Value in input TANK_DEPTH is less than or equal to 0
16465	4051	Value in input TANK_WIDTH is less than or equal to 0
16497	4071	Value in input INITIAL_LEVEL is less than 0
16499	4073	Value in input INITIAL_LEVEL is greater than TANK_HEIGHT
16513	4081	Value in input TANK_OUTLET_DIAMETER is less than or equal to 0
16529	4091	Value in input PUMP1_ACT_FLOW is less than 0

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.14.3 Structures

PMP_STATION_TYPE

The structure PMP_STATION_TYPE contains information of pump station configuration parameters.

All function blocks will receive some data, process it and write it back to the structure.

See the parameters listed below:

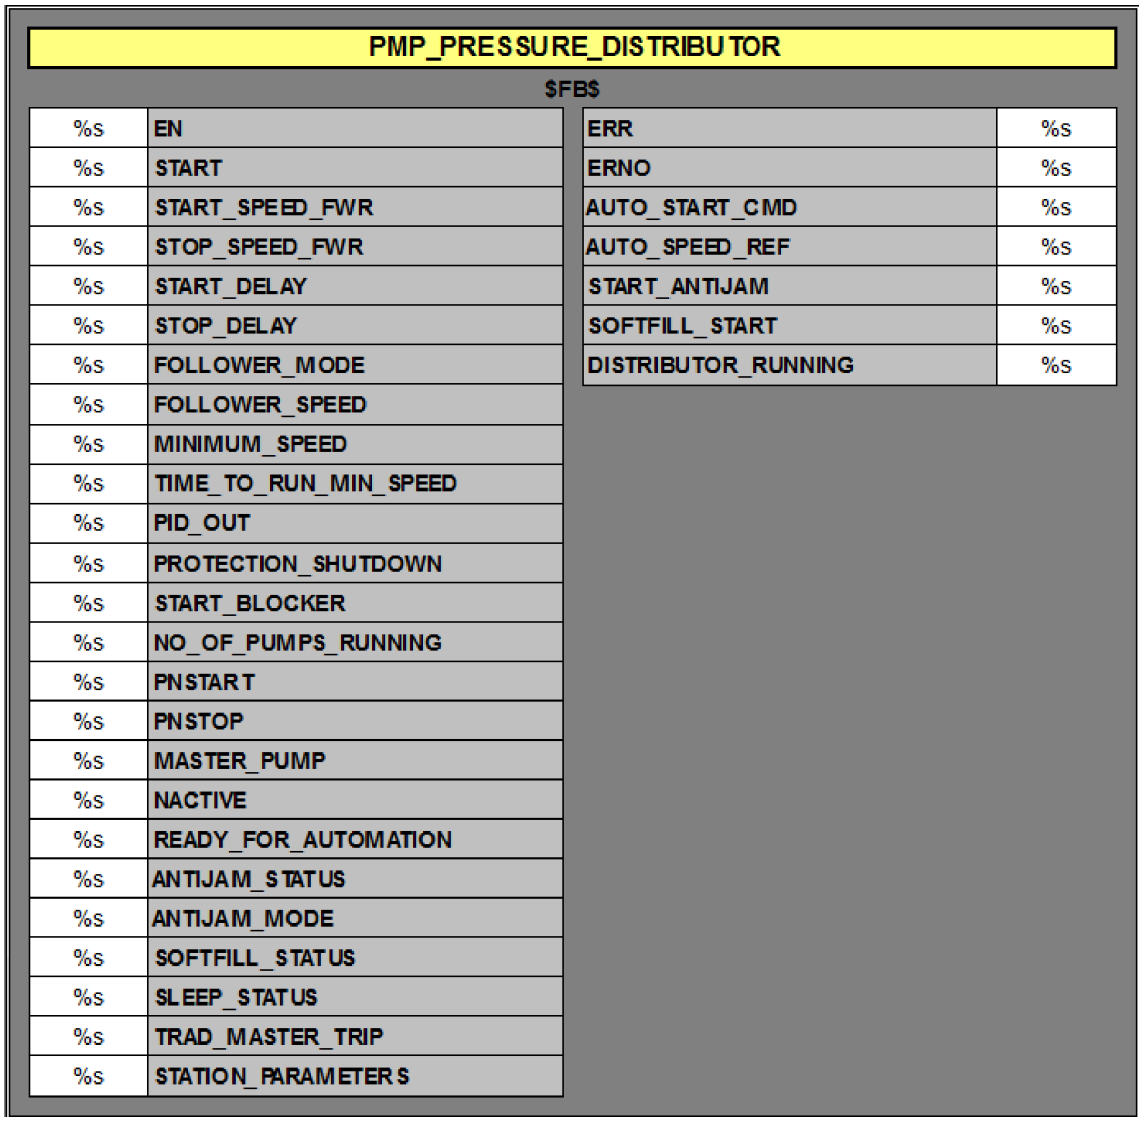
Parameter	Data type	Default value	Description
usiStation_Number	USINT	1	Corresponding station number
sStation_Name	STRING(20)	Station 1	Station name for visualizations
iNumber_of_Pumps	INT	1	Number of pumps in the pumping station
iProcess_Mode	INT	1	Selected process mode: 1 - Pressure control 2 - Flow control 3 - Level control
iPump_Combination	INT	1	Pump combination mode: 1 - Multimode 2 - Traditional mode 3 - DOL mode
aiNominalSpeed	ARRAY[1..8] of INT	8 (1500)	Array to store pump nominal speed values

1.5.14.4 Visualization

PMP_PRESSURE_DISTRIBUTOR_VISU_PH

Visualization element PMP_PRESSURE_DISTRIBUTOR_VISU_PH can be used to show the actual values of all inputs and outputs of the PMP_PRESSURE_DISTRIBUTOR function block. The visualization could also be used to control the function block by those inputs which are not connected inside the program.

The following figure demonstrates visualization in the offline mode:



For all the other function blocks in the library, similar visualizations are available.

All these visualization works same like the function block visualization defined above.

1.6 PLC integration (hardware)

1.6.1 PLC introduction

1.6.1.1 Safety instructions

The examples and diagrams in this manual are included solely for illustrative purposes. Because of the many variants and requirements associated with any particular installation, ABB cannot assume responsibility or liability for actual use based on the examples and diagrams.

No patent liability is assumed by ABB with respect to use of information, circuits, equipment or software described in this manual. No liability is assumed for the direct or indirect consequences of the improper use, improper application or inadequate maintenance of these devices. In no event will ABB be responsible or liable for indirect or consequential damages resulting from the use or application of this equipment.

PLC specific safety notices

The product family AC500 control system is designed according to EN 61131-2 IEC 61131-2 standards. Data, different from IEC 61131, are caused by the higher requirements of Maritime Services. Other differences are described in the technical data description of the devices.

NOTICE!

Avoidance of electrostatic charging

PLC devices and equipment are sensitive to electrostatic discharge, which can cause internal damage and affect normal operation. Observe the following rules when handling the system:

- Touch a grounded object to discharge potential static.
- Wear an approved grounding wrist strap.
- Do not touch connectors or pins on component boards.
- Do not touch circuit components inside the equipment.
- If available, use a static-safe workstation.
- When not in use, store the equipment in appropriate static-safe packaging.

NOTICE!

PLC damage due to operation conditions

Protect the devices from dampness, dirt and damage during transport, storage and operation!

NOTICE!

PLC damage due to wrong enclosures

Due to their construction (degree of protection IP 20 according to EN 60529) and their connection technology, the devices are suitable only for operation in enclosed switchgear cabinets.

Cleaning instruction

Do not use cleaning agent for cleaning the device.

Use a damp cloth instead.

Connection plans and user software must be created so that all technical safety aspects, legal regulations and standards are observed. In practice, possible shortcircuits and breakages must not be able to lead to dangerous situations. The extent of resulting errors must be kept to a minimum.

Do not operate devices outside of the specified, technical data!

Trouble-free functioning cannot be guaranteed outside of the specified data.

NOTICE!

PLC damage due to missing grounding

– Ensure to earth the devices.
– The grounding (switch cabinet grounding, PE) is supplied both by the mains connection (or 24 V supply voltage) and via DIN rail. The DIN rail must be connected to the ground before the device is subjected to any power. The grounding may be removed only if it is certain that no more power is being supplied to the control system.

In the description for the devices (operating manual or AC500 system description), reference is made at several points to grounding, galvanic isolation and EMC measures. One of the EMC measures consists of discharging interference voltages into the grounding via Y-type capacitors. Capacitor discharge currents must basically be able to flow off to the grounding (in this respect, see also VBG 4 and the relevant VDE regulations).

CAUTION!

Do not obstruct the ventilation for cooling!

The ventilation slots on the upper and lower side of the devices must not be covered.

CAUTION!

Run signal and power wiring separately!

Signal and supply lines (power cables) must be laid out so that no malfunctions due to capacitive and inductive interference can occur (EMC).

WARNING!

Labels on or inside the device alert people that dangerous voltage may be present or that surfaces may have dangerous temperatures.

WARNING!

Splaying of strands can cause hazards!

During wiring of terminals with stranded conductors, splaying of strands shall be avoided.

– Ferrules can be used to prevent splaying.

WARNING!

Removal/Insertion under power

The devices are not designed for removal or insertion under power. Because of unforeseeable consequences, it is not allowed to plug or unplug devices with the power being ON.

Make sure that all voltage sources (supply and process voltage) are switched off before you

– connect or disconnect any signal or terminal block
– remove, mount or replace a module.

Disconnecting any powered devices while energized in a hazardous location could result in an electric arc, which could create a flammable ignition resulting in fire or explosion.

Make sure that power is removed and that the area has been thoroughly checked to ensure that flammable materials are not present prior to proceeding.

The devices must not be opened when in operation. The same applies to the network interfaces.

Information on batteries

CAUTION!

Use only ABB approved lithium battery modules!

At the end of the battery's lifetime, always replace it only with a genuine battery module.

CAUTION!

Risk of explosion!

Do not open, re-charge or disassemble a lithium battery. Attempts to charge lithium batteries lead to overheating and possible explosions.

Protect them from heat and fire and store them in a dry place.

Never short-circuit or operate lithium batteries with the polarities reversed. The batteries are likely to overheat and explode. Avoid chance short circuiting and therefore do not store batteries in metal containers and do not place them on metallic surfaces. Escaping lithium is a health hazard.

Environment considerations

Recycle exhausted batteries. Dispose batteries in an environmentally conscious manner, in accordance to local-authority regulations.

Environment and enclosure information

This equipment is intended for use in a Pollution Degree 2 industrial environment, in overvoltage Category II applications (as defined in IEC publication 60664-1), at altitudes up to 2.000 meters without derating.

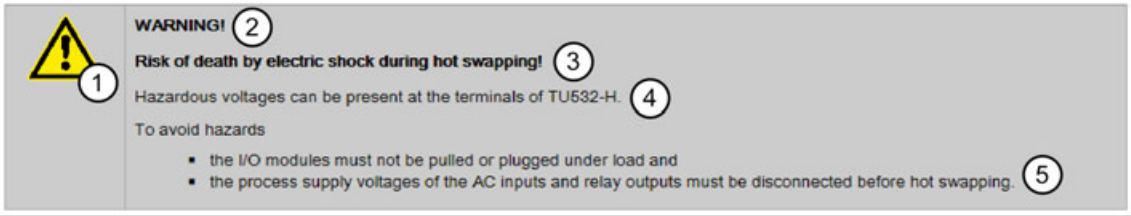
This equipment is considered Group 1, Class A industrial equipment according to IEC/CISPR Publication 11. Without appropriate precautions, there may be potential difficulties ensuring electromagnetic compatibility in other environments due to conducted as well as radiated disturbance.

This equipment is supplied as "open type" equipment. It must be mounted within an enclosure that is suitably designed for those specific environmental conditions that will be present and appropriately designed to prevent personal injury resulting from accessibility to live parts. The interior of the enclosure must be accessible only by the use of a tool. Subsequent sections of this publication may contain additional information regarding specific enclosure type ratings that are required to comply with certain product safety certifications.

Refer to NEMA Standards publication 250 and IEC publication 60529, as applicable, for explanations of the degrees of protection provided by different types of enclosure. Also see the appropriate sections in this manual.

1.6.1.1.1 Safety notice

Throughout the documentation we use the following types of safety and information notices according to ANSI Z535 make you aware of safety considerations or advice on AC500 products usage.



1 **Safety alert symbol** indicates the danger.
2 **Signal word** classifies the danger.
3 **Type and source of the risk** are mentioned.
4 **Possible consequences** of the risk are described.
5 **Measures to avoid these consequences** (enumerations).

Signal words

DANGER!
DANGER indicates a hazardous situation which, if not avoided, will result in death or serious injury.

Ensure to take measures to prevent the described impending danger.

WARNING!
WARNING indicates a hazardous situation which, if not avoided, could result in death or serious injury.

Ensure to take measures to prevent the described dangerous situation.

CAUTION!
CAUTION indicates a hazardous situation which, if not avoided, could result in minor or moderate injury.

Ensure to take measures to prevent the described dangerous situation.

NOTICE!
NOTICE is used to address practices not related to physical injury but might lead to property damage for example damage of the product.

Ensure to take measures to prevent the described dangerous situation.

NOTE provides additional information on the product, e.g. advices for configuration or best practice scenarios.

1.6.1.2 Cyber security

Cyber security disclaimer

This product is designed to be connected to and to communicate information and data via a network interface. It is your sole responsibility to provide and continuously ensure a secure connection between the product and your network or any other network (as the case may be). You shall establish and maintain any appropriate measures (such as but not limited to the installation of firewalls, application of authentication measures, encryption of data, installation of anti-virus programs, etc.) to protect the product, the network, its system and the interface against any kind of security breaches, unauthorized access, interference, intrusion, leakage and/or theft of data or information. ABB Ltd and its affiliates are not liable for damages and/or losses related to such security breaches, any unauthorized access, interference, intrusion, leakage and/or theft of data or information.

Although ABB provides functionality testing on the products and updates that we release, you should institute your own testing program for any product updates or other major system updates (to include but not limited to code changes, configuration file changes, third party software updates or patches, hardware exchanges, etc.) to ensure that the security measures that you have implemented have not been compromised and system functionality in your environment is as expected. This also applies to the operating system. Security measures (such as but not limited to the installation of latest patches, installation of firewalls, application of authentication measures, installation of anti-virus programs, etc.) are in your responsibility. You have to be aware that operating systems provide a considerable number of open ports that should be monitored carefully for any threats.

It has to be considered that online connections to any devices are not secured. It is your responsibility to assure that connections are established to the correct device (and e.g. not to an unknown device pretending to be a known device type). Furthermore you have to take care that confidential data exchanged with the PLC is either compiled or encrypted.

Security related deployment guidelines for industrial automation

Security details for industrial automation is provided in a *whitepaper* on ABB website.

Secure communication

Whenever possible, use an encrypted communication between AC500 V3 devices and third party devices, such as HMI devices. This is necessary to protect passwords and other data.

Frequently asked questions

For more information around cyber security please see our *FAQ*.

1.6.1.2.1 Defense in depth

The defense in depth approach implements multi-layer IT security measures. Each layer provides its special security measures. All deployed security mechanisms in the system must be updated regularly. It is also important to follow the system vendor's recommendations on how to configure and use these mechanisms. As a basis, the components must include security functions such as:

- Virus protection
- Firewall protection
- Strong and regularly changed passwords
- User management
- Using VPN tunnels for connections between networks

Additional security components such as routers and switches with integrated firewalls should be available. A defined user and rights concept managing access to the controllers and their networks is mandatory. Finally, the manufacturer of the components should be able to quickly discover weaknesses and provide patches.

Only used services/ports should be enabled (e.g. to enable the functionality of an FTPS server).

References: *CODESYS Security Whitepaper*

Security zones

IT resources vary in the extent to which they can be trusted. A common security architecture is therefore based on a layered approach that uses zones of trust to provide increasing levels of security according to increasing security needs. Less-trusted zones contain more-trusted zones and connections between the zones are only possible through secure interconnections such as firewallsFig. 719. All resources in the same zone must have the same minimum level of trust. The inner layers, where communication interaction needs to flow freely between nodes, must have the highest level of trust. This is the approach described in the IEC 62443 series of standards.

Firewalls, gateways, and proxies are used to control network traffic between zones of different security levels, and to filter out any undesirable or dangerous material. Traffic that is allowed to pass between zones should be limited to what is absolutely necessary because each type of service call or information exchange translates into a possible route that an intruder may be able to exploit. Different types of services represent different risks. Internet access, incoming e-mail and instant messaging, for example, represent very high risks.

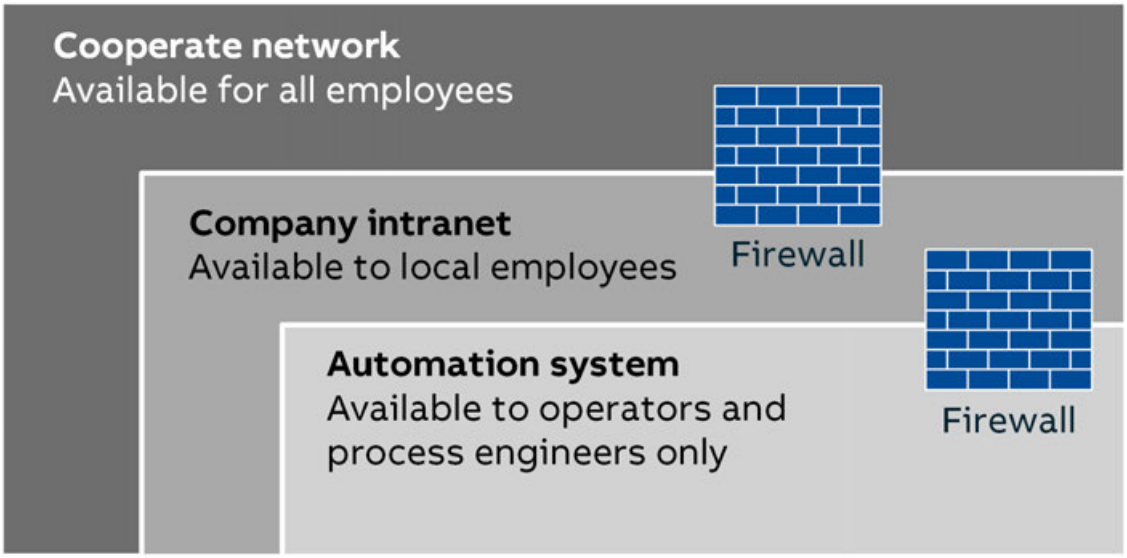


Fig. 719: Security zones

Fig. 719 shows three security zones, but the number of zones does not have to be as many or as few as three. The use of multiple zones allows access between zones of different trust levels to be controlled to protect a trusted resource from attack by a less trusted one.

High-security zones should be kept small and independent. They need to be physically protected, i.e. physical access to computers, network equipment and network cables must be limited by physical means to authorized persons only. A high-security zone should obviously not depend on resources in a less secure zone for its security. Therefore, it should form its own domain that is administered from the inside, and not depend on, e.g., a domain controller in a less secure network.

Even if a network zone is regarded as trusted, an attack is still possible: by a user or compromised resource that is inside the trusted zone, or by an outside user or resource that succeeds to penetrate the secure interconnection. Trust therefore depends also upon the types of measures taken to detect and prevent compromise of resources and violation of the security policy.

References: *Security for Industrial Automation and Control Systems*

1.6.1.2.2 Secure operation

The controller must be located in a protected environment in order to avoid accidental or intended access to the controller or the application.

A protected environment can be:

- Locked control cabinets without connection from outside
- No direct internet connection
- Use firewalls and VPN to separate different networks
- Separate different production areas with different access controls

To increase security, physical access protection measures such as fences, turnstiles, cameras or card readers can be added.

Follow these rules for the protected environment:

- Keep the trusted network as small as possible and independent from other networks.
- Protect the cross-communication of controllers and the communication between controllers and field devices via standard communication protocols (fieldbus systems) using appropriate measures.
- Protect such networks from unauthorized physical access.
- Use fieldbus systems only in protected environments. They are not protected by additional measures, such as encryption. Open physical or data access to fieldbus systems and their components is a serious security risk.

- Physically protect all equipment, i.e., ensure that physical access to computers, network equipment and cables, controllers, I/O systems, power supplies, etc., is limited to authorized persons
- When connecting a trusted network zone to outer networks, make sure that all connections are through properly configured secure interconnections only, such as a firewall or a system of firewalls, which is configured for “deny by default”, i.e., blocks everything except traffic that is explicitly needed to fulfill operational requirements.
- Allow only authorized users to log on to the system, and enforce strong passwords that are changed regularly.
- Continuously maintain the definitions of authorized users, user groups, and access rights, to properly reflect the current authorities and responsibilities of all individuals at all times. Users should not have more privileges than they need to do their job.
- Do not use the system for e-mail, instant messaging, or internet browsing. Use separate computers and networks for these functions if they are needed.
- Do not allow installation of any unauthorized software in the system.
- Restrict temporary connection of portable computers, USB memory sticks and other removable data carriers. Computers that can be physically accessed by regular users should have ports for removable data carriers disabled.
- If portable computers need to be connected, e.g., for service or maintenance purposes, they should be carefully scanned for viruses immediately before connection.
- All CDs, DVDs, USB memory sticks and other removable data carriers, and files with software or software updates, should also be checked for viruses before being introduced into the trusted zone.
- Continuously monitor the system for intrusion attempts.
- Define and maintain plans for incident response, including how to recover from potential disasters.
- Regularly review the organization as well as technical systems and installations with respect to compliance with security policies, procedures and practices.

A protected local control cabinet could look like in figure 720, page 3705. This network is not connected to any external network. Security is primarily a matter of physically protecting the automation system and preventing unauthorized users from accessing the system and from connecting or installing unauthorized hardware and software.

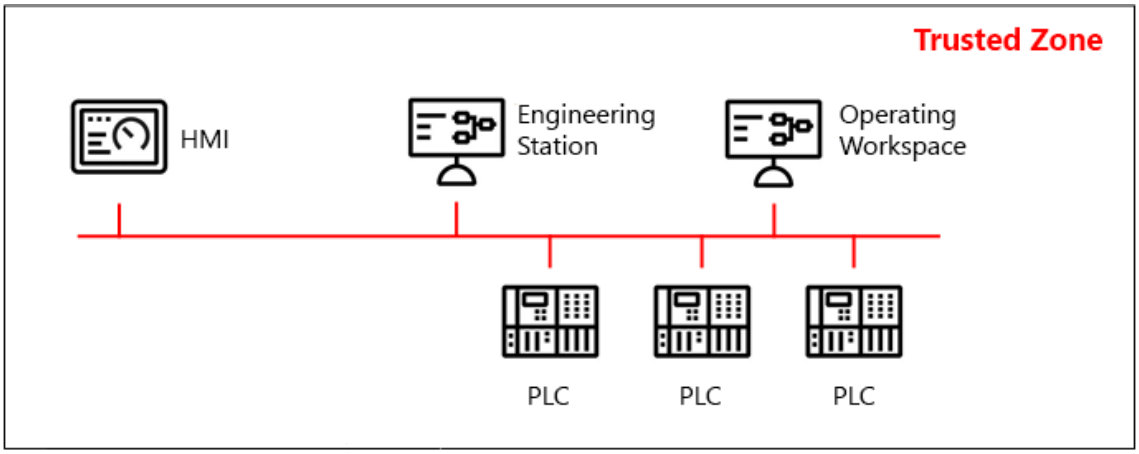

Fig. 720: Isolated automation system

Servers and workplaces that are not directly involved in the control and monitoring of the process should preferably be connected to a subnet that is separated from the automation system network by means of a router/firewall. This makes it possible to better control the network load and to limit access to certain servers on the automation system network. Note that servers and workplaces on this subnet are part of the trusted zone and thus need to be subject to the same security precautions as the nodes on the automation system network.

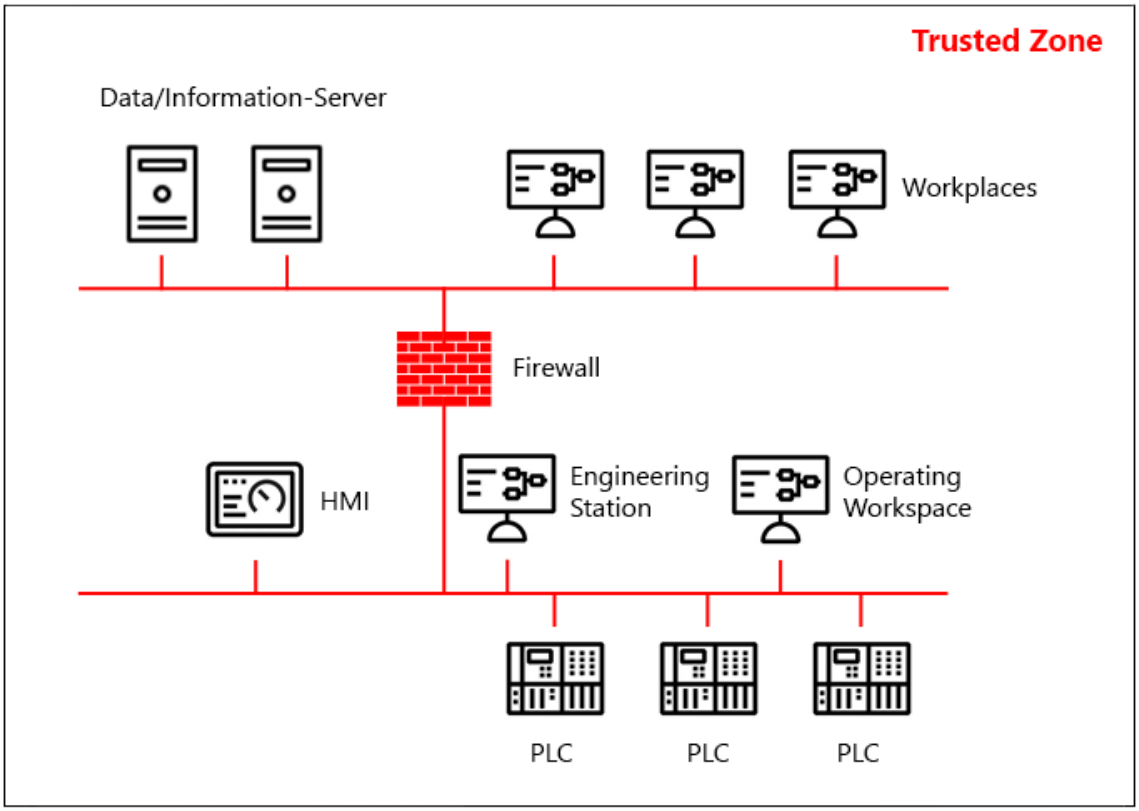

Fig. 721: Plant information network connected to an automation system

For the purposes of process control security, a general-purpose information system (IS) network should not be considered a trusted network, not the least since such networks are normally further connected to the Internet or other external networks. The IS network is therefore a different lower-security zone, and it should be separated from the automation system by means of a firewall. The IS and automation system networks should form separate domains.

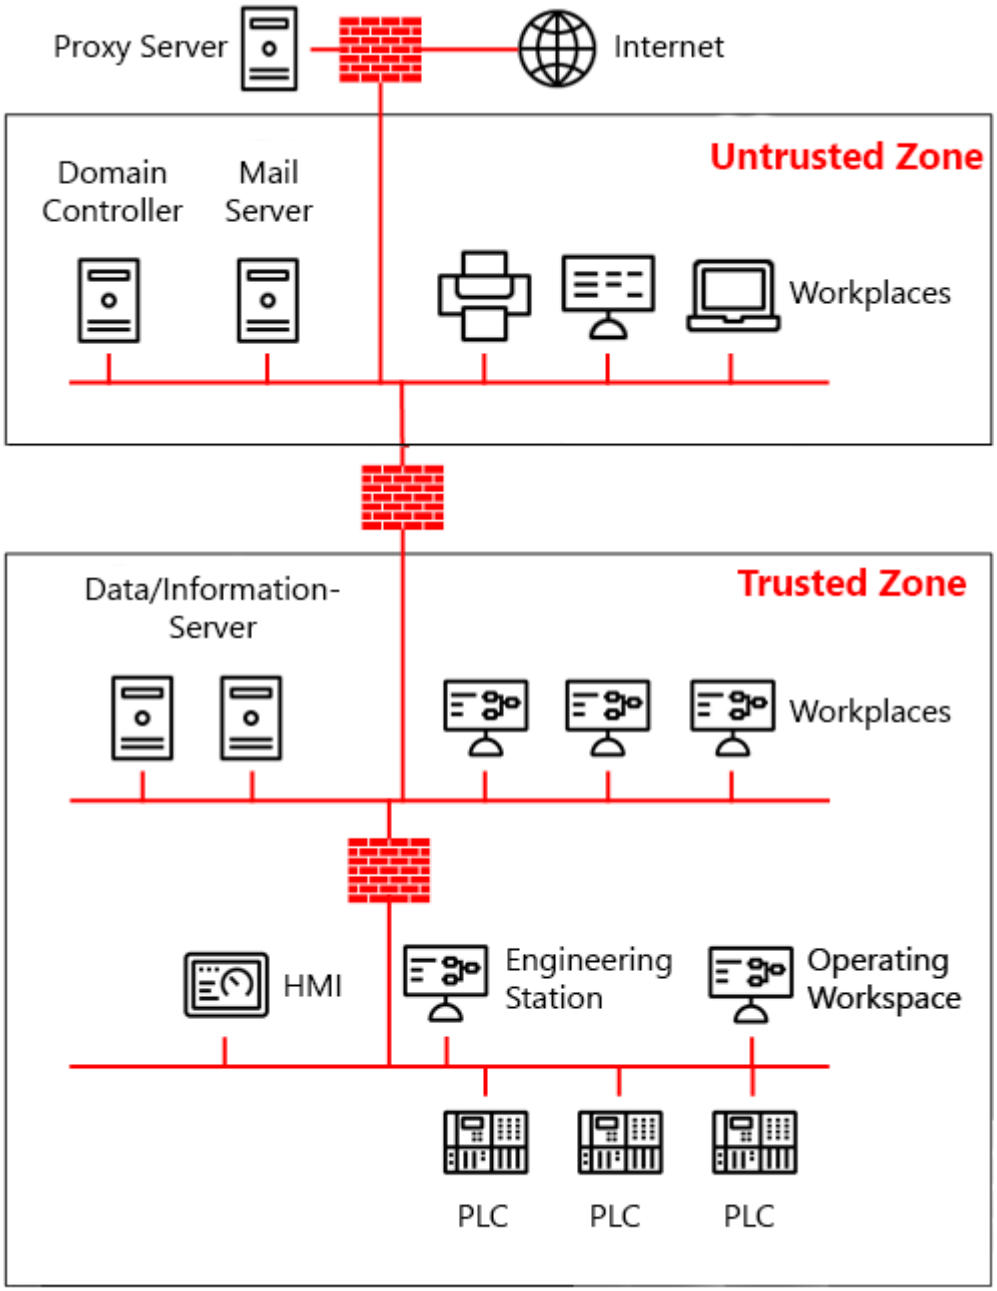

Fig. 722: Automation system and IS network

1.6.1.2.3 Hardening

System hardening means to eliminate as many security risks as possible. Hardening your system is an important step to protect your personal data and information. This process intends to eliminate attacks by patching vulnerabilities and turning off inessential services. Hardening a system involves several steps to form layers of protection.

Commissioning phase

- Protect the hardware from unauthorized access
- Be sure the hardware is based on a secure environment
- Disable unused software and services (network ports)
- Install firewalls
- Disallow file sharing among programs
- Install virus and spyware protection

- Use containers or virtual machines
- Create strong passwords by applying a strong password policy
- Create and keep backups
- Use encryption when possible
- Disable weak encryption algorithms
- Separate data and programs
- Enable and use disk quotas
- Strong logical access control
- Adjust default settings, especially passwords

Verification phase

- Verification of antivirus - Check antivirus is active and updated
- Verification of the identification - Check that test and unauthorized accounts are removed
- Verification of intrusion detection systems - Check malicious traffic is blocked
- Verification of audit logging - Check audit log is enabled
- You can use the checklist out of the *cyber security white paper*

Operation phase

- Keep software up-to-date, especially by applying security patches
- Keep antivirus up and running
- Keep antivirus definitions up-to-date
- Delete unused user accounts
- Lock an active session whenever it is unattended, e.g., lock the screen of the PC or of the control panel (HMI)

Decommissioning phase

- Delete all credentials stored in the device like certificates and user data *Chapter 1.6.3.4.6 “Decommissioning” on page 5233*.

1.6.1.2.4 Open Ports and Services

Overview of minimum cyber security requirements for open ports and services settings.

Port	Protocol	Description
1217	TCP	CODESYS Gateway V3
1210	TCP	CODESYS Gateway V2
1211	TCP	CODESYS Gateway V2
22350	TCP/UDP	CodeMeter License Server (runtime) – license
22352	HTTP	CodeMeter License Server (runtime) – WebAdmin
22353	HTTPS	CodeMeter License Server (runtime) – WebAdmin
11030	HTTP	Python editor server

1.6.1.3 License and third party information

Information on Automation Builder licensing and Third Party software can be found in the "About" window of the Automation Builder Installation Manager.

1.6.1.4 Regulations

Appropriate system setup

The following regulations have to be taken into due consideration:

- DIN VDE 0100: "Regulations for the Setting up of Power Installations"
- DIN VDE 0110 Part 1 and Part 2: "The Rating of Creepage Distances and Clearances"
- DIN VDE 0160 and DIN VDE 0660 Part 500: "The Equipment of Power Installations with Electrical Components"

To ensure project success and proper installation of all systems, customers must be familiar and proficient with the following standards and must comply with their directives:

- DIN VDE 0113 Part 1 & Part 200: "Working & Process Machinery"
- DIN VDE 0106 Part 100: "Close proximity to dangerous voltages"
- DIN VDE 0160, DIN VDE 0110 Part 1: "Protection against direct contact"

The user has to guarantee that the devices and the components are mounted following these regulations. For operating the machines and installations, other national and international relevant regulations, concerning prevention of accidents and using technical working means, also have to be met.

AC500 devices are designed according to IEC 1131 Part 2 under overvoltage category II per DIN VDE 0110 Part 2.

For direct connection of AC Category III overvoltages provide protection measures for overvoltage category II according to IEC-Report 664/1980 and DIN VDE 0110 Part 1.

Equivalent standards:

- DIN VDE 0110 Part 1 ↔ IEC 664
- DIN VDE 0113 Part 1 ↔ EN 60204 Part 1
- DIN VDE 0660 Part 500 ↔ EN 60439-1 ↔ IEC 439-1

All rights reserved to change design, size, weight, etc.

Qualified personnel

Both the control system AC500 and other components in the vicinity are operated with dangerous contact voltages. Touching parts, which are under such voltages, can cause grave damage to health.

In order to avoid such risks and the occurrence of material damage, persons involved with the assembly, starting up and servicing must possess pertinent knowledge of the following:

- Automation technology sector
- Dealing with dangerous voltages
- Using standards and regulations, in particular VDE, accident prevention regulations and regulations concerning special ambient conditions (e.g. areas potentially endangered by explosive materials, heavy pollution or corrosive influences).

1.6.1.5 Definitions: PLC system start-up

Cold start

The AC500-eCo V3 does not use a battery for buffering the operand areas specified below, hence the “cold start” mode does not exist in this product.

- A cold start is performed by switching power OFF/ON if no battery is connected.
- All RAM memory modules are checked and erased.
- If no user program is stored in the Flash EPROM, the default values (as set on delivery) are applied to the interfaces.
- If there is a user program stored in the Flash EPROM, it is loaded into RAM.
- The default operating modes set by the PLC configuration are applied.

Warm start

- A warm start is performed by switching power OFF/ON with a battery connected.
- All RAM memory modules are checked and erased except of the buffered operand areas and the RETAIN variables .
- If there is a user program stored in the Flash EPROM, it is loaded into RAM.
- The default operating modes set by the PLC configuration are applied.

RUN -> STOP

- RUN -> STOP means pressing the RUN function key on the PLC while the PLC is in run mode (AC500 PLC display "run", AC500-eCo PLC "RUN LED" is ON).
- If a user program is loaded into RAM, execution is stopped.
- All outputs are set to FALSE or 0.
- Variables keep their current values, i.e., they are not initialized.
- The AC500 PLC display changes from "run" to "StoP", AC500-eCo "RUN LED" changes from ON to OFF.

START -> STOP

- START -> STOP means stopping the execution of the user program in the PLC's RAM using the menu item "Online/Stop" in the programming system.
- All outputs are set to FALSE or 0.
- Variables keep their current values, i.e., they are not initialized.
- The AC500 PLC display changes from "run" to "StoP".

Reset

- Performs a START -> STOP process.
- Preparation for program restart, i.e., the variables (VAR) (exception: RETAIN variables) are set to their initialization values.
- Reset is performed using the menu item "Online/Reset" in the programming system or pressing the function key RUN for $\geq$ 5 s in STOP mode.

Reset (cold)

- Performs a START -> STOP process.
- Preparation for program restart, i.e., the variables (VAR) (also RETAIN variables) are set to their initialization values.
- Reset (cold) is performed using the menu item "Online/Reset (cold)" in the programming system.

Reset (original)

- Resets the controller to its original state (deletion of Flash, SRAM (%M, area, %R area, RETAIN, RETAIN PERSISTENT), Communication Module configurations and user program!).
- Reset (original) is performed using the menu item "Online/Reset (original)" in the programming system.

STOP -> RUN

- STOP -> RUN means short pressing the RUN function key on the PLC while the PLC is in STOP mode (AC500 PLC display "StoP", AC500-eCo "RUN LED" is ON). "RUN LED" is OFF of the toggle switch of an AC500-eCo CPU.
- If a user program is loaded into RAM, execution is continued, i.e., variables will not be set to their initialization values.
- The AC500 PLC display changes from "StoP" to "run", AC500-eCo "RUN LED" changes from OFF to ON.

STOP -> START

- STOP -> START means continuing the execution of the user program in the PLC's RAM using the menu item "Online/Start" in the programming system.
- If a user program is loaded into RAM, execution is continued, i.e., variables will not be set to their initialization values.
- The AC500 PLC display changes from "StoP" to "run", AC500-eCo PLC "RUN LED" changes from OFF to ON.

Download

- Download means loading the complete user program into the PLC's RAM. This process is started by selecting the menu item "Online/Download" in the programming system or after confirming a corresponding system message when switching to online mode (menu item "Online/Login").
- Execution of the user program is stopped.
- In order to store the user program to the Flash memory, the menu item "Online/Create boot project" must be called after downloading the program.
- Variables are set to their initialization values according to the initialization table.
- RETAIN variables can have wrong values as they can be allocated to other memory addresses in the new project!
- A download is forced by the following:
  - changed PLC configuration
  - changed task configuration
  - changed library management
  - changed compile-specific settings (segment sizes)
  - execution of the commands "Project/Clean all" and "Project/Rebuild All".

Online change

- After a project has changed, only these changes are compiled when pressing the key <F11> or calling the menu item "Project/Build". The changed program parts are marked with a blue arrow in the block list.
- The term Online Change means loading the changes made in the user program into the PLC's RAM using the programming system (after confirming a corresponding system message when switching to online mode, menu item "Online/Login").
- Execution of the user program is not stopped. After downloading the program changes, the program is re-organized. During re-organization, no further online change command is allowed. The storage of the user program to the Flash memory using the command "Online/Create boot project" cannot be initiated until re-organization is completed.
- Online Change is not possible after:
  - changes in the PLC configuration
  - changes in the task configuration
  - changes in the library management
  - changed compile-specific settings (segment sizes)
  - performing the commands "Project/Clean all" and "Project/Rebuild All".

Data buffering

- Data buffering, i.e., maintaining data after power ON/OFF, is only possible, if a battery is connected for AC500 CPU and the buffering will take place in FLASH with AC500-eCo V3 CPU. The following data can be buffered completely or in parts:
  - Data in the addressable flag area (%M area)
  - RETAIN variable
  - PERSISTENT variable (number is limited, no structured variables)
  - PERSISTENT area (%R area)
- In order to buffer particular data, the data must be excluded from the initialization process (see *Chapter 1.6.4.1.1.8 “Data backup and initialization” on page 5410*).

1.6.1.6 Definitions: RCOM

Terms

Do not confuse the RCOM services cold start / warm start and the corresponding PLC commands referring to the hardware state. In this section, the terms "cold start" and "warm start" always refer to the RCOM system services and therefore only affect the protocol state.

Cold start

A cold start service has to be performed after the initialization of the RCOM master. The cold start can be transmitted either by broadcast to all slaves simultaneously or to each slave individually.

A cold start requires reinitialization of the entire protocol mechanism and clearing of the event queue contents. For this, a special cold start event is triggered in the addressed RCOM slaves. This event is required when operating ABB MasterPiece systems. In case of pure Advant Controller networks, the event is only indicated when polling.

After a cold start, always normalization has to be performed. Otherwise it is not possible to transmit data sets.

Warm start

By executing a warm start service, it is possible to clear the event queue of a slave (or all slaves). A warm start can be used to resume communication after transmission errors. This permits master and slave to resynchronize.

After a warm start, always normalization has to be performed. Otherwise it is not possible to transmit data sets.

Normalization

A slave has to be normalized after a cold start or a warm start. Normalization enables the transmission of data sets and events. If a slave is not normalized, it cannot trigger events. The RCOM_TRANSMIT connection element then displays a corresponding error message.

If a master polls a non-normalized slave, the RCOM_POLL connection element signals a corresponding error.

1.6.1.7 Device lists

1.6.1.7.1 Device list: Terminal bases

Terminal bases for AC500 (Standard):

V2 products

Type	Description
TB511-ARCNET ↳ *Chapter 1.6.2.2.1 “TB51x-TB54x” on page 3786*	TB511-ARCNET, terminal base AC500, slots: 1 processor module, 1 communication module, ARCNET COAX connector
TB511-ETH ↳ *Chapter 1.6.2.2.1 “TB51x-TB54x” on page 3786*	TB511-ETH, terminal base AC500, slots: 1 processor module, 1 communication module, Ethernet RJ45 connector
TB511-ETH-XC ↳ *Chapter 1.6.2.2.1 “TB51x-TB54x” on page 3786*	TB511-ETH-XC, terminal base AC500, slots: 1 processor module, 1 communication module, Ethernet RJ45 connector, XC version
TB521-ARCNET ↳ *Chapter 1.6.2.2.1 “TB51x-TB54x” on page 3786*	TB521-ARCNET, terminal base AC500, slots: 1 processor module, 2 communication modules, ARCNET COAX connector
TB521-ETH ↳ *Chapter 1.6.2.2.1 “TB51x-TB54x” on page 3786*	TB521-ETH, terminal base AC500, slots: 1 processor module, 2 communication modules, Ethernet RJ45 connector
TB521-ETH-XC ↳ *Chapter 1.6.2.2.1 “TB51x-TB54x” on page 3786*	TB521-ETH-XC, terminal base AC500, slots: 1 processor module, 2 communication modules, Ethernet RJ45 connector, XC version

Type	Description
TB523-2ETH ↳ *Chapter 1.6.2.2.1 “TB51x-TB54x” on page 3786*	TB523-2ETH, terminal base AC500, slots: 1 processor module, 2 communication modules, 2 Ethernet RJ45 connector
TB541-ETH ↳ *Chapter 1.6.2.2.1 “TB51x-TB54x” on page 3786*	TB541-ETH, terminal base AC500, slots: 1 processor module, 4 communication modules, Ethernet RJ45 connector

PM595-4ETH-F ↳ *Chapter 1.6.2.3.2.2 "PM595-4ETH" on page 3863*	PM595-4ETH-F, processor module, user progr./data memory 16 MB / 16 MB, 1.3 GHz, 24 V DC, memory card slot, interfaces 2 RS232-485, 2 independent Ethernet interfaces (Progr., web server, IEC60870-5-104 protocol), 2 independent Ethernet based interfaces with 2-port switch (between fieldbus protocols PROFINET IO, EtherCAT and Ethernet)
PM595-4ETH-M-XC ↳ *Chapter 1.6.2.3.2.2 "PM595-4ETH" on page 3863*	PM595-4ETH-M-XC, processor module, user progr./data memory 16 MB / 16 MB, 1.0 GHz, 24 V DC, memory card slot, interfaces 2 RS232-485, 2 independent Ethernet interfaces (Progr., web server, IEC60870-5-104 protocol), 2 independent Ethernet based interfaces with 2-port switch (between fieldbus protocols PROFINET IO, EtherCAT and Ethernet), XC version

1.6.1.7.3 Device list: Communication modules

Type	Description
CM574-RCOM ↳ *Chapter 1.6.2.4.3.1 "CM574-RCOM for RCOM/RCOM+ " on page 4044*	CM574-RCOM, communication module, 2 serial RS-232/485, RCOM/RCOM+ protocol
CM574-RS ↳ *Chapter 1.6.2.4.4.1 "CM574-RS with 2 serial interfaces" on page 4049*	CM574-RS, communication module, 2 serial RS232/485, free configurable serial interface module
CM579-ETHCAT ↳ *Chapter 1.6.2.4.6.1 "CM579-ETHCAT - EtherCAT master" on page 4066*	CM579-ETHCAT, EtherCAT communication module
CM579-PNIO ↳ *Chapter 1.6.2.4.9.1 "CM579-PNIO - PROFINET IO RT controller" on page 4084*	CM579-PNIO, PROFINET communication module
CM579-PNIO-XC ↳ *Chapter 1.6.2.4.9.1 "CM579-PNIO - PROFINET IO RT controller" on page 4084*	CM579-PNIO-XC, PROFINET communication module, XC version

Type	Description
CM582-DP *Chapter 1.6.2.4.8.1 “CM582-DP - PROFIBUS DP slave” on page 4075*	CM582-DP, communication module PROFIBUS DP slave 12 Mbit/s
CM582-DP-XC *Chapter 1.6.2.4.8.1 “CM582-DP - PROFIBUS DP slave” on page 4075*	CM582-DP-XC, communication module PROFIBUS DP slave 12 Mbit/s, XC version
CM588-CN *Chapter 1.6.2.4.5.1 “CM588-CN - CANopen slave” on page 4053*	CM588-CN, communication module, CANopen slave
CM588-CN-XC *Chapter 1.6.2.4.5.1 “CM588-CN - CANopen slave” on page 4053*	CM588-CN-XC, communication module, CANopen slave, XC version
CM589-PNIO *Chapter 1.6.2.4.9.2 “CM589-PNIO(-4) - PROFINET IO RT with 4 devices” on page 4089*	CM589-PNIO, PROFINET communication module
CM589-PNIO-XC *Chapter 1.6.2.4.9.2 “CM589-PNIO(-4) - PROFINET IO RT with 4 devices” on page 4089*	CM589-PNIO-XC, PROFINET communication module, XC version
CM589-PNIO-4 *Chapter 1.6.2.4.9.2 “CM589-PNIO(-4) - PROFINET IO RT with 4 devices” on page 4089*	CM589-PNIO-4, PROFINET communication module
CM589-PNIO-4-XC *Chapter 1.6.2.4.9.2 “CM589-PNIO(-4) - PROFINET IO RT with 4 devices” on page 4089*	CM589-PNIO-4-XC, PROFINET communication module, XC version
CM592-DP *Chapter 1.6.2.4.8.2 “CM592-DP - PROFIBUS DP master” on page 4079*	CM592-DP, communication module PROFIBUS DP master 12 Mbit/s
CM592-DP-XC *Chapter 1.6.2.4.8.2 “CM592-DP - PROFIBUS DP master” on page 4079*	CM592-DP-XC, communication module PROFIBUS DP master 12 Mbit/s, XC version
CM597-ETH *Chapter 1.6.2.4.7.1 “CM597-ETH - Communication module Ethernet” on page 4070*	CM597-ETH, communication module Ethernet TCP/IP with integrated 2-port switch

Type	Description
CM597-ETH-XC ↳ *Chapter 1.6.2.4.7.1 “CM597-ETH - Communication module Ethernet” on page 4070*	CM597-ETH-XC, communication module Ethernet TCP/IP with integrated 2-port switch, XC version
CM598-CN ↳ *Chapter 1.6.2.4.5.2 “CM598-CN - CANopen master” on page 4060*	CM598-CN, communication module, CANopen master
CM598-CN-XC ↳ *Chapter 1.6.2.4.5.2 “CM598-CN - CANopen master” on page 4060*	CM598-CN-XC, communication module, CANopen master, XC version

1.6.1.7.4 Device list: Terminal units

Type	Description
TU507-ETH ↳ *Chapter 1.6.2.5.1 “TU507-ETH and TU508-ETH for Ethernet communication interface modules” on page 4095*	TU507-ETH, Ethernet terminal unit, 24 V DC, screw terminals
TU508-ETH ↳ *Chapter 1.6.2.5.1 “TU507-ETH and TU508-ETH for Ethernet communication interface modules” on page 4095*	TU508-ETH, Ethernet terminal unit, 24 V DC, spring terminals
TU508-ETH-XC ↳ *Chapter 1.6.2.5.1 “TU507-ETH and TU508-ETH for Ethernet communication interface modules” on page 4095*	TU508-ETH-XC, Ethernet terminal unit, 24 V DC, spring terminals, XC version
TU509 ↳ *Chapter 1.6.2.5.2 “TU509 and TU510 for communication interface modules” on page 4099*	TU509, communication interface module terminal unit, 24 V DC, screw terminals
TU510 ↳ *Chapter 1.6.2.5.2 “TU509 and TU510 for communication interface modules” on page 4099*	TU510, communication interface module terminal unit, 24 V DC, spring terminals
TU510-XC ↳ *Chapter 1.6.2.5.2 “TU509 and TU510 for communication interface modules” on page 4099*	TU510-XC, communication interface module terminal unit, 24 V DC, spring terminals, XC version

Type	Description
TU515 *Chapter 1.6.2.5.3 “TU515, TU516, TU541 and TU542 for I/O modules” on page 4103*	TU515, I/O terminal unit, 24 V DC, screw terminals
TU516 *Chapter 1.6.2.5.3 “TU515, TU516, TU541 and TU542 for I/O modules” on page 4103*	TU516, I/O terminal unit, 24 V DC, spring terminals
TU516-XC *Chapter 1.6.2.5.3 “TU515, TU516, TU541 and TU542 for I/O modules” on page 4103*	TU516-XC, I/O terminal unit, 24 V DC, spring terminals, XC version
TU516-H *Chapter 1.6.2.5.3 “TU515, TU516, TU541 and TU542 for I/O modules” on page 4103*	TU516-H, I/O terminal unit, hot swap, 24 V DC, spring terminals
TU516-H-XC *Chapter 1.6.2.5.3 “TU515, TU516, TU541 and TU542 for I/O modules” on page 4103*	TU516-H-XC, I/O terminal unit, hot swap, 24 V DC, spring terminals, XC version
TU517 *Chapter 1.6.2.5.4 “TU517 and TU518 for communication interface modules” on page 4109*	TU517, terminal unit for communication interface modules, 24 V DC, screw terminals
TU518 *Chapter 1.6.2.5.4 “TU517 and TU518 for communication interface modules” on page 4109*	TU518, terminal unit for communication interface modules, 24 V DC, spring terminals
TU518-XC *Chapter 1.6.2.5.4 “TU517 and TU518 for communication interface modules” on page 4109*	TU518-XC, terminal unit for communication interface modules, 24 V DC, spring terminals, XC version
TU520-ETH *Chapter 1.6.2.5.5 “TU520-ETH for PROFINET communication interface modules” on page 4112*	TU520-ETH, PROFINET I/O terminal unit, 24 V DC, spring terminals
TU520-ETH-XC *Chapter 1.6.2.5.5 “TU520-ETH for PROFINET communication interface modules” on page 4112*	TU520-ETH-XC, PROFINET I/O terminal unit, 24 V DC, spring terminals, XC version
TU531 *Chapter 1.6.2.5.6 “TU531 and TU532 for I/O modules” on page 4114*	TU531, I/O terminal unit, 230 V AC, relays, screw terminals

Type	Description
TU532 *Chapter 1.6.2.5.6 “TU531 and TU532 for I/O modules” on page 4114*	TU532, I/O terminal unit, 230 V AC, relays, spring terminals
TU532-XC *Chapter 1.6.2.5.6 “TU531 and TU532 for I/O modules” on page 4114*	TU532-XC, I/O terminal unit, 230 V AC, relays, spring terminals, XC version
TU532-H *Chapter 1.6.2.5.6 “TU531 and TU532 for I/O modules” on page 4114*	TU532-H, I/O terminal unit, hot swap, 230 V AC, relays, spring terminals
TU532-H-XC *Chapter 1.6.2.5.6 “TU531 and TU532 for I/O modules” on page 4114*	TU532-H-XC, I/O terminal unit, hot swap, 230 V AC, relays, spring terminals, XC version
TU541 *Chapter 1.6.2.5.3 “TU515, TU516, TU541 and TU542 for I/O modules” on page 4103*	TU541, I/O terminal unit, 24 V DC, screw terminals
TU542 *Chapter 1.6.2.5.3 “TU515, TU516, TU541 and TU542 for I/O modules” on page 4103*	TU542, I/O terminal unit, 24 V DC, spring terminals
TU542-XC *Chapter 1.6.2.5.3 “TU515, TU516, TU541 and TU542 for I/O modules” on page 4103*	TU542-XC, I/O terminal unit, 24 V DC, spring terminals, XC version
TU542-H *Chapter 1.6.2.5.3 “TU515, TU516, TU541 and TU542 for I/O modules” on page 4103*	TU542-H, I/O terminal unit, hot swap, 24 V DC, spring terminals
TU542-H-XC *Chapter 1.6.2.5.3 “TU515, TU516, TU541 and TU542 for I/O modules” on page 4103*	TU542-H-XC, I/O terminal unit, hot swap, 24 V DC, spring terminals, XC version
TU551-CS31 *Chapter 1.6.2.5.7 “TU551-CS31 and TU552-CS31 for CS31 communication interface modules” on page 4121*	TU551-CS31, CS31 bus terminal unit, 24 V DC, screw terminals

Type	Description
TU552-CS31 ↳ *Chapter 1.6.2.5.7 “TU551-CS31 and TU552-CS31 for CS31 communication interface modules” on page 4121*	TU552-CS31, CS31 bus terminal unit, 24 V DC, spring terminals
TU552-CS31-XC ↳ *Chapter 1.6.2.5.7 “TU551-CS31 and TU552-CS31 for CS31 communication interface modules” on page 4121*	TU552-CS31-XC, CS31 bus terminal unit, 24 V DC, spring terminals, XC version

1.6.1.7.5 Device list: S500-eCo I/O modules

Type	Description
AI561 ↳ *Chapter 1.6.2.6.2.1.1 “AI561 - Analog input module” on page 4351*	AI561, analog input module, 4 AI, U/I
AI562 ↳ *Chapter 1.6.2.6.2.1.2 “AI562 - Analog input module” on page 4362*	AI562, analog input module, 2 AI, RTD
AI563 ↳ *Chapter 1.6.2.6.2.1.3 “AI563 - Analog input module” on page 4373*	AI563, analog input module, 4 AI, thermocouple
AO561 ↳ *Chapter 1.6.2.6.2.1.4 “AO561 - Analog output module” on page 4385*	AO561, analog output module, 2 AO, U/I
AX561 ↳ *Chapter 1.6.2.6.2.1.5 “AX561 - Analog input/output module” on page 4394*	AX561, analog input/output module, 4 AI, 2AO, U/I
DC561 ↳ *Chapter 1.6.2.6.1.1.1 “DC561 - Digital input/output module” on page 4125*	DC561, digital input/output module, 16 configurable inputs/outputs, transistor output, interfast connection
DC562 ↳ *Chapter 1.6.2.6.1.1.2 “DC562 - Digital input/output module” on page 4133*	DC562, digital input/output module, 16 configurable inputs/outputs
DI561 ↳ *Chapter 1.6.2.6.1.1.3 “DI561 - Digital input module” on page 4144*	DI561, digital input module, 8 DI, 24 V DC
DI562 ↳ *Chapter 1.6.2.6.1.1.4 “DI562 - Digital input module” on page 4151*	DI562, digital input module, 16 DI, 24 V DC

Type	Description
DI571 ↳ *Chapter 1.6.2.6.1.1.5 “DI571 - Digital input module” on page 4159*	DI571, digital input module, 8 DI, 120 V AC...240 V AC
DI572 ↳ *Chapter 1.6.2.6.1.1.6 “DI572 - Digital input module” on page 4168*	DI572, digital input module, 16 DI, 100 V AC...240 V AC
DO561 ↳ *Chapter 1.6.2.6.1.1.7 “DO561 - Digital output module” on page 4177*	DO561, digital output module, 8 DO, transistor output
DO562 ↳ *Chapter 1.6.2.6.1.1.8 “DO562 - Digital output module” on page 4186*	DO562, digital output module, 16 DO, transistor output
DO571 ↳ *Chapter 1.6.2.6.1.1.9 “DO571 - Digital output module” on page 4195*	DO571, digital output module, 8 DO, relay output
DO572 ↳ *Chapter 1.6.2.6.1.1.10 “DO572 - Digital output module” on page 4205*	DO572, digital output module, 8 DO, triac output
DO573 ↳ *Chapter 1.6.2.6.1.1.11 “DO573 - Digital output module” on page 4215*	DO573, digital output module, 16 DO, relay output
DX561 ↳ *Chapter 1.6.2.6.1.1.12 “DX561 - Digital input/output module” on page 4227*	DX561, digital input/output module, 8 DI 24 V DC, 8 DO 24 V DC, transistor output
DX571 ↳ *Chapter 1.6.2.6.1.1.13 “DX571 - Digital input/output module” on page 4239*	DX571, digital input/output module, 8 DI 24 V DC, 8 DO, relay output

1.6.1.7.6 Device list: S500 I/O modules

Type	Description
AI523 ↳ *Chapter 1.6.2.6.2.2.2 “AI523 - Analog input module” on page 4433*	AI523, analog input module, 16 AI, U/I/Pt100, 12 bits + sign, 2-wires
AI523-XC ↳ *Chapter 1.6.2.6.2.2.2 “AI523 - Analog input module” on page 4433*	AI523-XC, analog input module, 16 AI, U/I/Pt100, 12 bits + sign, 2-wires, XC version
AI531 ↳ *Chapter 1.6.2.6.2.2.3 “AI531 - Analog input module” on page 4455*	AI531, analog input module, 8 AI, U/I/Pt100, TC, 15 bits + sign, 4-wires

Type	Description
AI531-XC ↯ *Chapter 1.6.2.6.2.2.3 “AI531 - Analog input module” on page 4455*	AI531-XC, analog input module, 8 AI, U/I/Pt100, TC, 15 bits + sign, 4-wires, XC version
AO523 ↯ *Chapter 1.6.2.6.2.2.4 “AO523 - Analog output module” on page 4487*	AO523, analog output module, 16 AO, U/I, 12 bits + sign, 2-wires
AO523-XC ↯ *Chapter 1.6.2.6.2.2.4 “AO523 - Analog output module” on page 4487*	AO523-XC, analog output module, 16 AO, U/I, 12 bits + sign, 2-wires, XC version
AX521 ↯ *Chapter 1.6.2.6.2.2.5 “AX521 - Analog input/output module” on page 4502*	AX521, analog input/output module, 4 AI, 4 AO, U/I/Pt100, 12 bits + sign, 2-wires
AX521-XC ↯ *Chapter 1.6.2.6.2.2.5 “AX521 - Analog input/output module” on page 4502*	AX521-XC, analog input/output module, 4 AI, 4 AO, U/I/Pt100, 12 bits + sign, 2-wires, XC version
AX522 ↯ *Chapter 1.6.2.6.2.2.6 “AX522 - Analog input/output module” on page 4525*	AX522, analog input/output module, 8 AI, 8 AO, U/I/Pt100, 12 bits + sign, 2-wires
AX522-XC ↯ *Chapter 1.6.2.6.2.2.6 “AX522 - Analog input/output module” on page 4525*	AX522-XC, analog input/output module, 8 AI, 8 AO, U/I/Pt100, 12 bits + sign, 2-wires, XC version
DA501 ↯ *Chapter 1.6.2.6.3.1.1 “DA501 - Digital/Analog input/output module” on page 4550*	DA501, digital/analog input/output module, 16 DI, 8 DC, 4 AI, 2 AO
DA501-XC ↯ *Chapter 1.6.2.6.3.1.1 “DA501 - Digital/Analog input/output module” on page 4550*	DA501-XC, digital/analog input/output module, 16 DI, 8 DC, 4 AI, 2 AO, XC version
DA502 ↯ *Chapter 1.6.2.6.3.1.2 “DA502 - Digital/Analog input/output module” on page 4585*	DA502, digital/analog input/output module, 16 DO, 8 DC, 4 AI, 2 AO
DA502-XC ↯ *Chapter 1.6.2.6.3.1.2 “DA502 - Digital/Analog input/output module” on page 4585*	DA502-XC, digital/analog input/output module, 16 DO, 8 DC, 4 AI, 2 AO, XC version
DC522 ↯ *Chapter 1.6.2.6.1.2.1 “DC522 - Digital input/output module” on page 4253*	DC522, digital input/output module, 16 DC, 24 V DC / 0.5 A, 2-wires
DC522-XC ↯ *Chapter 1.6.2.6.1.2.1 “DC522 - Digital input/output module” on page 4253*	DC522-XC, digital input/output module, 16 DC, 24 V DC / 0.5 A, 2-wires, XC version

Type	Description
DC523 *Chapter 1.6.2.6.1.2.2 “DC523 - Digital input/output module” on page 4264*	DC523, digital input/output module, 24 DC, 24 V DC / 0.5 A, 1-wire
DC523-XC *Chapter 1.6.2.6.1.2.2 “DC523 - Digital input/output module” on page 4264*	DC523-XC, digital input/output module, 24 DC, 24 V DC / 0.5 A, 1-wire, XC version
DC532 *Chapter 1.6.2.6.1.2.3 “DC532 - Digital input/output module” on page 4276*	DC532, digital input/output module, 16 DI, 16 DC, 24 V DC / 0.5 A, 1-wire
DC532-XC *Chapter 1.6.2.6.1.2.3 “DC532 - Digital input/output module” on page 4276*	DC532-XC, digital input/output module, 16 DI, 16 DC, 24 V DC / 0.5 A, 1-wire, XC version
DI524 *Chapter 1.6.2.6.1.2.5 “DI524 - Digital input module” on page 4298*	DI524, digital input module, 32 DI, 24 V DC, 1-wire
DI524-XC *Chapter 1.6.2.6.1.2.5 “DI524 - Digital input module” on page 4298*	DI524-XC, digital input module, 32 DI, 24 V DC, 1-wire, XC version
DO524 *Chapter 1.6.2.6.1.2.6 “DO524 - Digital output module” on page 4307*	DO524, digital output module, 32 DO, 24 V DC / 0.5 A, 1-wire
DO524-XC *Chapter 1.6.2.6.1.2.6 “DO524 - Digital output module” on page 4307*	DO524-XC, digital output module, 32 DO, 24 V DC / 0.5 A, 1-wire, XC version
DO526 *Chapter 1.6.2.6.1.2.7 “DO526 - Digital output module” on page 4317*	DO526, digital output module, 8 DO, 24 V DC / 2 A, 1-wire
DO526-XC *Chapter 1.6.2.6.1.2.7 “DO526 - Digital output module” on page 4317*	DO526-XC, digital output module, 8 DO, 24 V DC / 2 A, 1-wire, XC version
DX522 *Chapter 1.6.2.6.1.2.8 “DX522 - Digital input/output module” on page 4327*	DX522, digital input/output module, 8 DI, 24 V DC, 8 DO relays
DX522-XC *Chapter 1.6.2.6.1.2.8 “DX522 - Digital input/output module” on page 4327*	DX522-XC, digital input/output module, 8 DI, 24 V DC, 8 DO relays, XC version
DX531 *Chapter 1.6.2.6.1.2.9 “DX531 - Digital input/output module” on page 4339*	DX531, digital input/output module, 8 DI, 230 V AC, 4 DO relay, 2-wires

1.6.1.7.7 Device list: Function modules

Type	Description
CD522 ↳ *Chapter 1.6.2.7.2.1 “CD522 - Encoder, counter and PWM module” on page 4635*	CD522, encoder & PWM module, 2 encoder inputs, 2 PWM outputs, 2 digital inputs 24 V DC, 8 digital outputs 24 V DC
CD522-XC ↳ *Chapter 1.6.2.7.2.1 “CD522 - Encoder, counter and PWM module” on page 4635*	CD522-XC, encoder & PWM module, 2 encoder inputs, 2 PWM outputs, 2 digital inputs 24 V DC, 8 digital outputs 24 V DC, XC version
DC541-CM ↳ *Chapter 1.6.2.6.1.2.4 “DC541-CM - Digital input/output module” on page 4290*	DC541-CM, digital input/output module, 8 DC, 24 V DC / 0.5 A, 1-wire
DC541-CM-XC ↳ *Chapter 1.6.2.6.1.2.4 “DC541-CM - Digital input/output module” on page 4290*	DC541-CM-XC, digital input/output module, 8 DC, 24 V DC / 0.5 A, 1-wire, XC version
FM502-CMS ↳ *Chapter 1.6.2.7.2.2 “FM502-CMS - Analog measurements” on page 4658*	FM502-CMS for condition monitoring systems, 16 AI, 2 DI, 2 DC, 1 encoder (A, B, Z)
FM502-CMS-XC ↳ *Chapter 1.6.2.7.2.2 “FM502-CMS - Analog measurements” on page 4658*	FM502-CMS-XC for condition monitoring systems, 16 AI, 2 DI, 2 DC, 1 encoder (A, B, Z), XC version
AC500-eCo only:	
FM562 ↳ *Chapter 1.6.2.7.1.1 “FM562 for pulse train output” on page 4617*	FM562, pulse-train output module, 2 axes, RS-422, 4 DI 24 V DC

1.6.1.7.8 Device list: Communication interface modules

Table 254: CANopen

Type	Description
CI581-CN ↳ *Chapter 1.6.2.8.2.2 “CI581-CN” on page 4685*	CI581-CN, CANopen communication interface module, 8 DI, 8 DO, 4 AI and 2 AO
CI581-CN-XC ↳ *Chapter 1.6.2.8.2.2 “CI581-CN” on page 4685*	CI581-CN-XC, CANopen communication interface module, 8 DI, 8 DO, 4 AI and 2 AO, XC version

Type	Description
CI582-CN ↳ *Chapter 1.6.2.8.2.3 “CI582-CN” on page 4723*	CI582-CN, CANopen communication interface module, 8 DI, 8 DO and 8 DC
CI582-CN-XC ↳ *Chapter 1.6.2.8.2.3 “CI582-CN” on page 4723*	CI582-CN-XC, CANopen communication interface module, 8 DI, 8 DO and 8 DC, XC version

Table 255: ***CS31***

Type	Description
CI590-CS31-HA ↳ *Chapter 1.6.2.8.3.1 “CI590-CS31-HA” on page 4745*	CI590-CS31-HA, CS31 redundant communucation interface module, 16 DC
CI590-CS31-HA-XC ↳ *Chapter 1.6.2.8.3.1 “CI590-CS31-HA” on page 4745*	CI590-CS31-HA-XC, CS31 redundant communucation interface module, 16 DC, XC version
CI592-CS3 ↳ *Chapter 1.6.2.8.3.2 “CI592-CS31 - Digital and analog inputs and outputs” on page 4764*	CI592-CS31, CS31 communucation interface module, 8 DI, 8 DC, 4 AI, 2 AO

1.6.1.8 PLC system description

1.6.1.8.1 AC500 product family

AC500 programmable logic controllers (PLCs)

The AC500 (Standard), AC500-eCo, AC500-S and AC500-XC scalable PLC ranges provide solutions for small, middle and high-end applications. Our AC500 platform offers different performance levels and is the ideal choice for high availability, extreme environments or safety solutions. Our AC500 PLC platform offers interoperability and compatibility in hardware and software from compact PLCs up to high-end and safety PLCs.

Due to the flexible combinations of AC500 devices and components, AC500 PLCs can be used for controlling a wide variety of applications to fulfill your automation needs.

Features of AC500 PLCs

- Scalable and consistently expandable system
- Different performance classes of processor modules (CPUs) available
- Several field busses available
- Parallel connection to several field busses which can be combined arbitrarily

The AC500 product family consists of the product groups:

- AC500 (standard):
  AC500 standard PLCs offer a wide range of performance levels and scalability. The PLCs are highly capable of communication and extension for flexible application.
- AC500-eCo:
  AC500-eCo PLCs are cost-effective, high-performance compact PLCs that offer total interoperability with the core AC500 range and provide battery-free uninterrupted output. All I/O modules can be freely connected in a simple, stable and reliable manner.
- AC500-S:
  AC500-S PLCs are designed for safety applications involved in factory, process or machinery automation area.
- AC500-XC:
  AC500 (standard) and AC500-S provide devices with -XC extension as a product variant. These variants operate according to their product group and can, in addition, be operated under extreme conditions. AC500-XC PLCs can be used at high altitudes, extended operating temperature and in humid condition. Further, the devices provide immunity to vibration and hazardous gases. The AC500-XC series is consistent with standard devices in the overall dimensions, control function and software compatibility. *Chapter 1.6.3.7.1 “System data AC500-XC” on page 5389*.

The AC500 product family is characterized by functional modularity. As the complete AC500 product family shares the same hardware platform and programming software tool, the devices of the AC500 product groups can be flexibly combined.

S500 devices represent the I/O modules of the product group AC500 (standard), whereas S500-eCo devices represent the I/O modules of the product group AC500-eCo. Both S500 and S500-eCo devices can be combined with devices of the AC500 product family in a flexible way.

Extensions in the product name

AC500 devices support different protocols and technologies (e.g. Ethernet, PROFIBUS etc.) in variable number. AC500 devices with onboard interfaces for support of a certain protocol or technology can be identified easily by the extension in the product name of the AC500 device. For example the AC500 Communication Module PM592**-DP** provides onboard support for PROFIBUS DP, the AC500 processor module PM595**-4ETH** provides onboard support for four provided Ethernet interfaces.

Further extensions in AC500 device names:

- -ETH: Ethernet
- -ARC: ARCNET
- -DP: PROFIBUS DP
- -CAN: CAN/CANopen
- -ETHCAT: EtherCAT
- -PNIO: PROFINET

- -RCOM: RCOM/RCOM+
- -RS: Serial interface

1.6.1.8.2 AC500/S500 system structure

The AC500 product family provides a variety of modules and pluggable components for expanding the capabilities of the CPU with additional I/Os or other communication protocols. Depending on the features and functions of the processor module (CPU) compatible components can be added to a complete AC500 PLC system.

Example of an AC500 PLC system:

1 Processor module. In the example, without a LCD display or keypad.
2 Plug-in communication module (AC500-S)
3 Plug-in communication module (AC500 Standard)
4 Plug-in I/O module (AC500-S)
5 Plug-in I/O module (AC500 Standard)
6 Plug-in function module (AC500-eCo)

Centralized I/O extension

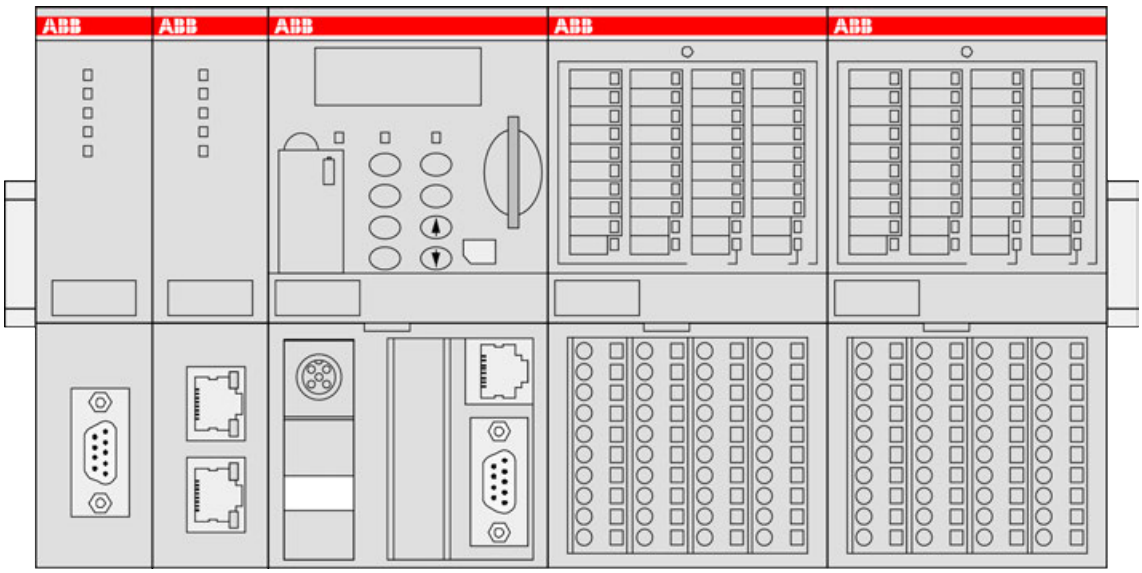

Fig. 723: S500 I/O modules directly connected to a processor module

Decentralized I/O extension

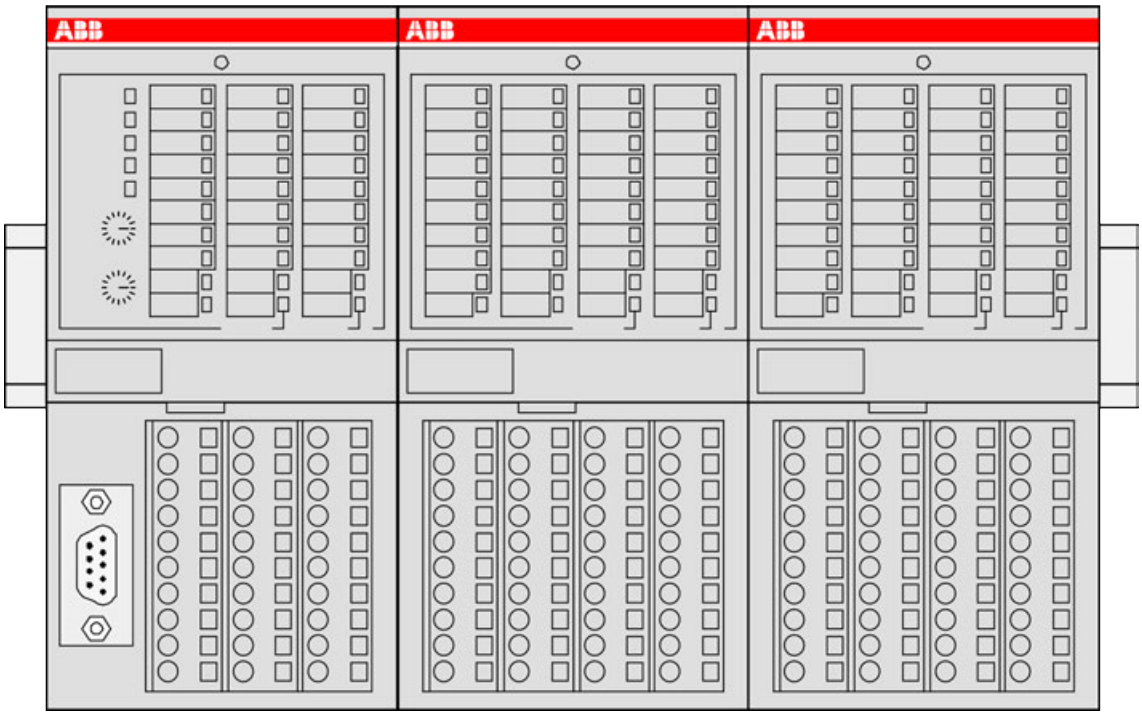

Fig. 724: S500 I/O modules connected via communication interface module

1.6.1.8.3 AC500-eCo/S500-eCo system structure

AC500-eCo/S500-eCo serie is fully compatible with AC500/S500. Customers can flexibly select S500-eCo I/O modules and S500 I/O modules to realize economical and upgradeable solutions.

The AC500-eCo processor module can run independently but also carry out centralized I/O extension, decentralized I/O extension and network extension.

Centralized I/O extension

Centralized I/O extension means that the processor module is connected with the I/O module via I/O bus on the side to increase control points and functions.

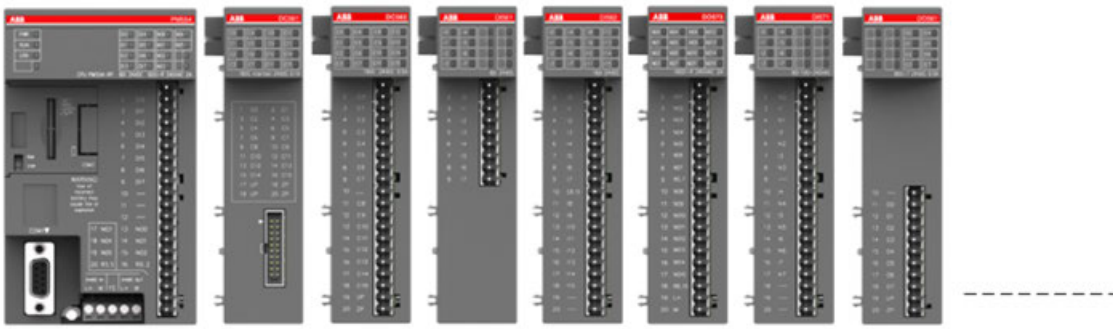

Fig. 725: I/O modules (S500-eCo) directly connected to a AC500-eCo processor module

Decentralized I/O extension

Usually, an AC500-eCo decentralized I/O station is realized with an CS31 module. As a master station, the processor module communicates with the CS31 slave station module (such as DC551) via the serial port COM1 connected to the bus.

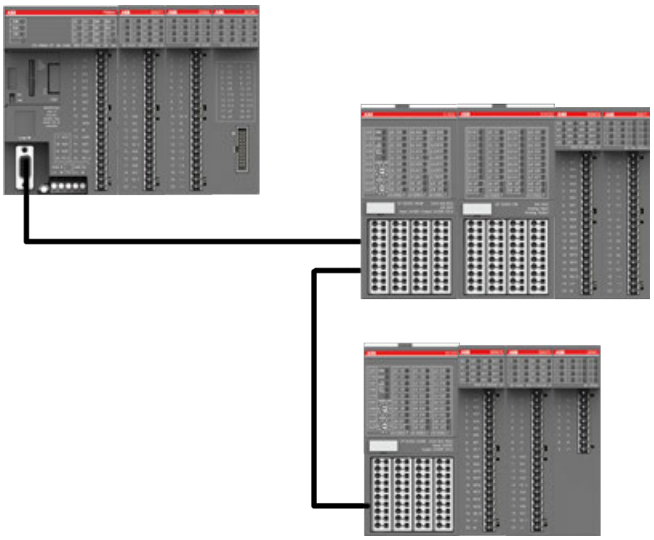

Fig. 726: I/O modules (S500-eCo) connected to a AC500-eCo processor module via CS31 bus

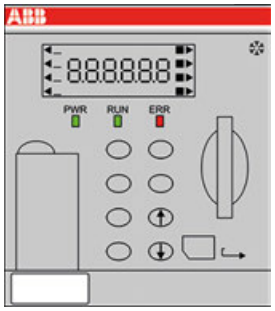
1.6.1.8.4 AC500/S500: Short description hardware

Processor modules



AC500 processor modules contains the CPU with the core component of the PLC. The CPU is connected with the user memory, input and output module, communication port and other units via system bus and performs tasks by means of system programs preset in the system memory. The CPU adopts the function preset by the system program to command the PLC for operation.

Its functions include:

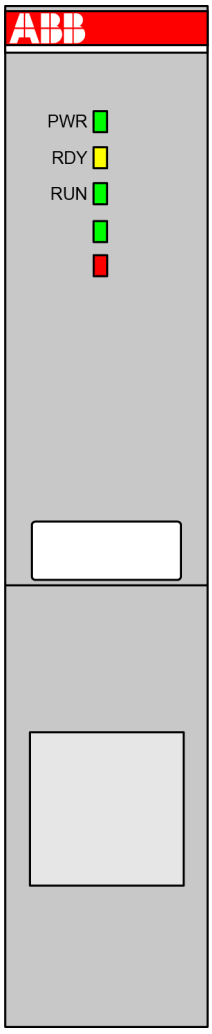
- To receive user program and data entered
- To diagnose work faults of the power supply and PLC circuit as well as syntax error in programming
- To receive the state or data of the site via the input interface and save it into the shadow register or data register
- To read the user program in the memory one by one and execute it after interpretation
- To update the state of related flag bits and output shadow register contents according to execution results and realize output control by means of output unit.

Processor modules are available in different performance classes. Only one processor module is required for a valid system architecture.

There are different types of processor module available that differ in the features and functions they provide, e.g. performance, LED display etc.

If required, processor modules are also available with an integrated Ethernet communication module (TCP/IP).

Communication modules



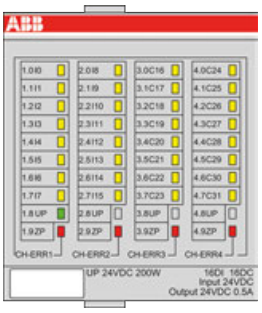
AC500 communication modules are required for

- a connection to standard field bus systems and
- for integration into existing networks.

AC500 communication modules

- enable communication on different field buses.
- are mounted on the left side of the processor module on the same terminal base.
- are directly powered via the internal communication module bus of the terminal base. A separate voltage source is not required.

I/O modules



The I/O modules are the input / output unit which connects the PLC with the industrial production site. The PLC can detect controlled object data via the input interface and the data is taken as the basis for PLC control on the controlled object. In addition, the PLC sends processing results via the output interface to the controlled object to realize the control purpose.

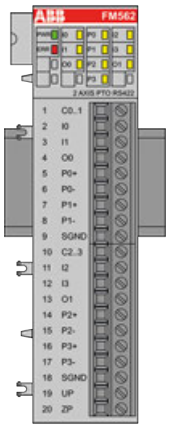
External input equipment and output equipment need various signal levels while the information processed by the CPU in the PLC only can be the standard level. In order to realize such conversion, the I/O interface generally shall perform optical isolation and filtering to improve interference immunity of the PLC. In addition, the I/O interface generally can indicate the working state to facilitate maintenance.

The PLC provides multiple I/O interface for operation level and drive capability to users for selection such as digital input, digital output, analog input, analog output, etc. I/O interfaces of the PLC have the number of input / output signals taken as the number of PLC I/O points. The number of I/O points is an important basis for PLC selection. If the system is insufficient in the I/O points, it can be expanded via the I/O extension interface of the PLC.

The I/O modules for digital and/or analog inputs and outputs are available in different versions and allow flexible use thanks to configurable channels.

The modules can be simply plugged onto a terminal unit for a centralized I/O extension or for a decentralized I/O extension via communication interface modules.

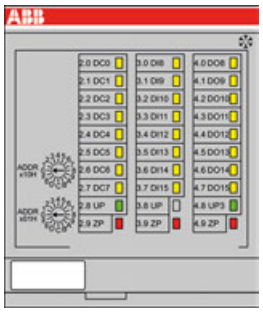
Function modules



Function modules extend the PLC system to perform special task control. Those modules often provide independent components such as a CPU, system programs, memory and interfaces connected with the PLC system bus.

It is connected with the PLC via the I/O bus to exchange data and independently work under cooperative management of the PLC.

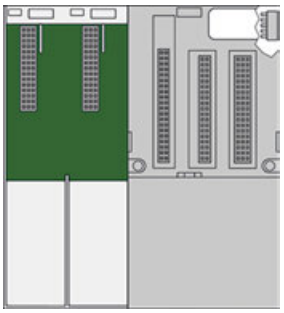
Communication interface modules



Communication interface modules enable a decentralized I/O station. It contains embedded digital I/Os and a fieldbus interface.

Communication interface modules act as I/O slave devices within a master-slave-arrangement.

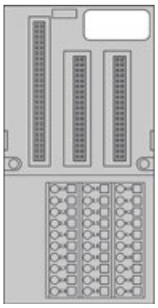
Terminal bases



On a terminal base the processor module and the communication modules are plugged.

> *For AC500-eCo processor modules and special AC500 (Standard) processor modules the terminal base cannot be removed.*

Terminal units



On a terminal unit the I/O modules are plugged.

Terminal units enable simple prewiring without electronics and are available for 24 V DC and 230 V AC, optionally for spring or screw-type terminals.

Memory

In the PLC, the memory is mainly used for saving system programs, user programs and work data. The following memory types can be distinguished:

- Volatile memory:
  All saved data will be lost after power failure of the memory but the memory can provide high access rate and unlimited programming cycles. Common volatile memories mainly include SRAM and DRAM (including common memories such as SDRAM).
- Nonvolatile memory:
  All saved data will not be lost after power failure of the memory, but the memory is subject to low read-write rate and limited rewrite cycles. Common nonvolatile memories mainly include NORflash, NANDflash, EEPROM, memory card, etc.

AC500 PLCs store all user programs in the nonvolatile memory to get protected from power failure. The programs are exported to the volatile memory under operation of the PLC to ensure high-speed and efficient operation. If user program debugging is finished, the programs can be fixed in the nonvolatile memory when they need no change. The work data is subject to frequent change and access in the PLC operation. It is saved in the volatile memory to meet the requirements for random access.

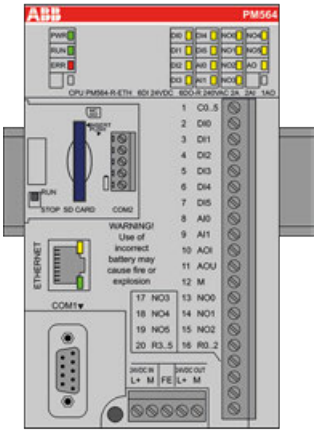
The work data memory of PLC has the memory area for input and output relay, auxiliary relay, timer, counter and other logic devices. The state of these devices depends on initial setting and operation of the user programs. Some data maintains existing state by using built-in supercapacitors or backup batteries in case of power failure. The memory area for data saving in case of power failure is called the data retention area.

Power supply

The PLC is equipped with a switch power supply for internal circuit. Compared with ordinary power supply, the PLC power supply has the higher stability and interference immunity. A number of PLC products provide 24 V DC stabilized voltage supply to meet external sensors.

1.6.1.8.5 AC500-eCo/S500-eCo: Short description hardware

Processor modules



AC500-eCo processor modules contains the CPU with the core microprocessor of the PLC. It is integrated with power supply, input channel and communication interface.

Functions:

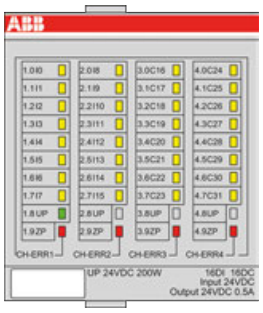
- To download user programs
- To run the CPU
- To execute user programs in loops
- To monitor program input and output devices.

Processor modules are available in different performance classes and provide different amounts onboard I/Os.

Only one processor module is required for a valid system architecture.

If required, processor modules are also available with Ethernet interface.

I/O modules



If the amount of onboard I/Os provided on the processor module is insufficient for a certain use case, the PLC can be expanded with I/O modules to meet the control requirements.

Memory

In the PLC, the memory is mainly used for saving system programs, user programs and work data. The following memory types can be distinguished:

- Volatile memory:
  All saved data will be lost after power failure of the memory but the memory can provide high access rate and unlimited programming cycles. Common volatile memories mainly include SRAM and DRAM (including common memories such as SDRAM).
- Nonvolatile memory:
  All saved data will not be lost after power failure of the memory, but the memory is subject to low read-write rate and limited rewrite cycles. Common nonvolatile memories mainly include NORflash, NANDflash, EEPROM, memory card, etc.

AC500 PLCs store all user programs in the nonvolatile memory to get protected from power failure. The programs are exported to the volatile memory under operation of the PLC to ensure high-speed and efficient operation. If user program debugging is finished, the programs can be fixed in the nonvolatile memory when they need no change. The work data is subject to frequent change and access in the PLC operation. It is saved in the volatile memory to meet the requirements for random access.

The work data memory of PLC has the memory area for input and output relay, auxiliary relay, timer, counter and other logic devices. The state of these devices depends on initial setting and operation of the user programs. Some data maintains existing state by using built-in supercapacitors or backup batteries in case of power failure. The memory area for data saving in case of power failure is called the data retention area.

Power supply

The CPU is equipped with a switch power supply for internal circuit. Compared with ordinary power supply, the PLC power supply has the higher stability and interference immunity. A number of PLC products provide 24VDC stabilized voltage supply to meet external sensors.

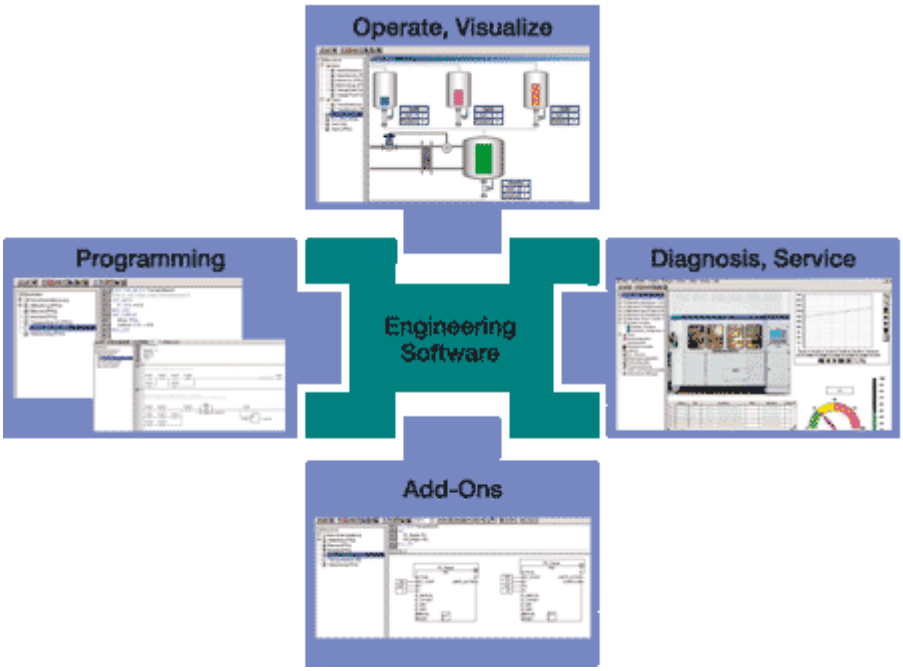
1.6.1.8.6 Short description software

Configuration and programming

Configuration and programming of all AC500 control systems (CPUs) is done by using Automation Builder software.

Features:

- Standardized programming according to IEC 61131-3 - five programming languages (Structured Text (ST), Function Block Diagram (FBD), Instruction List (IL), Ladder Diagram (LD), Sequential Function Chart (SFC)), free graphical function chart (CFC), debugging functions for program test
- Application programming in C/C++
- Online diagnosis
- Debugging functions for the program test: Single step, Single cycle, Breakpoint
- Offline simulation - simulate commands without PLC being connected
- Sampling trace - timing diagrams for process variables
- Recipe management and watch lists
- Visualization
- Configuration of the communication interface modules (for PROFINET, EtherCAT, CANopen, Ethernet, Modbus)
- Programming - serial or via Ethernet networks
- Comprehensive libraries
- Export and import interfaces for devices, signals, applications, visualization, etc.
- Multi-user support and project compare
- Project scripting



Offline simulation IEC 61131-3 commands can be simulated without a PLC being connected, including the relevant malfunctions. After the program test, the application can be downloaded to the control system.

Sampling trace Timing diagrams for process variables and storage of data in a ring buffer with event trigger.

Recipe management and watch lists Values of selected variables are displayed. Pre-defined values can be assigned to variables which can then be downloaded to the control system all at once ("Write recipe"). Actual values from the control system can also be pre-assigned for reading into the Watch and Recipe Manager, and stored in memory there ("Read recipe). These functions are also helpful, for example, for setting and entering control parameters.

Visualization Includes color change, moving elements, bitmaps, text display, allows input of setpoint values and display of process variables read from the PLC, dynamic bar diagrams, alarm and event management, function keys and ActiveX elements.

Programming Serial or via Ethernet networks.

Engineering interface Provides access from the programming system to an external project database in which the program source code of one or several automation projects is managed. Optionally, a version control system, such as Visual Source Safe, can be used in order to ensure data consistency of the program code for several different users and projects.

1.6.1.8.7 Control panels (HMI)

ABB control panels offer a wide range of features and functionalities for maximum operability. The panels are distinguished by their robustness and easy usability, providing all the relevant information from production plants and machines at a single touch.

HMI - human control and operation of machines and processes.

Individual solutions for each application - this enables an operator at any time to have an overview on a profitable production and intervene manually if necessary.

Control panels with TFT graphical display and touch screen.

Available in various resolutions.

1.6.1.9 AC500-S

The AC500-S safety user manual must be read and understood before using safety configuration and programming tools of Automation Builder / PS501 Control Builder Plus. Only qualified personnel shall be allowed to work with AC500-S safety PLCs.

In order to have always the latest version and due to a different lifecycle compared to Automation Builder help, the *AC500-S safety user manual* is only available on our website.

The AC500-S safety PLC includes the following safety-relevant hardware components.

- SM560-S / SM560-S-FD-1 / SM560-S-FD-4
- DI581-S
- DX581-S
- AI581-S
- TU582-S

1.6.1.10 AC500-eCo starter kit

This AC500-eCo Starter kit helps you to get familiar with ABB AC500 PLC offerings and the engineering tool. For that purpose, this manual explains how to connect and setup the components provided in the starter kit and how to program the AC500-eCo CPU by means of several simple example applications.

Contents of the AC500-eCo starter kit:

- 1 x AC500-eCo CPU PM554-TP-ETH with 2 terminal blocks plugged on the CPU: 1 x 11 pin, 1 x 9 pin
- 1 x digital input simulator
- 1 x programming cable

1.6.1.10.1 Preparing the AC500 CPU

Enclosed to the CPU, you find the installation instructions. Refer to these installation instructions for assembling the CPU.

Connecting the input simulator

Enclosed to the input simulator, you find the installation instructions. Refer to these installation instructions to connect the input simulator to the CPU.

Connection of the AC500 CPU

DANGER!

Risk of death by electric shock.

Before using the CPU refer to the “Regulations Concerning the Setting up of Installations” for safety instructions. *http://search-ext.abb.com/library/Download.aspx?DocumentID=3ADR025003*&Action=Launch*

CAUTION!

Risk of damaging the PLC modules.

The CPU can be damaged by overvoltages and short circuits. Make sure that all voltage sources (supply and process voltage) are switched off before you begin with operations on the system.

The CPU needs to be powered by 24 V DC. Use the 5-pin screw-type terminal block for connecting the power.

CAUTION!

Risk of damaging the CPU and the connected modules.

Voltages > 35 V DC can destroy the CPU and the connected modules. Make sure that the supply voltage never exceeds 35 V DC.

Connecting the programming cable

Plug in the provided programming cable to the CPU and your PC.

Set-up communication parameters in Windows

Set-up communication parameters

To set-up the communication between the PC and the PLC, e.g., for downloading the compiled program, you have to set-up the communication parameters.

The IP address of your PC must be in the same class as the IP address of the CPU.

The factory setting of the IP address of the CPU is 192.168.0.10.

The IP address of your PC should be 192.168.0.X. Avoid X = 10 in order to prevent an IP conflict with the CPU.

Subnet mask should be 255.255.255.0.

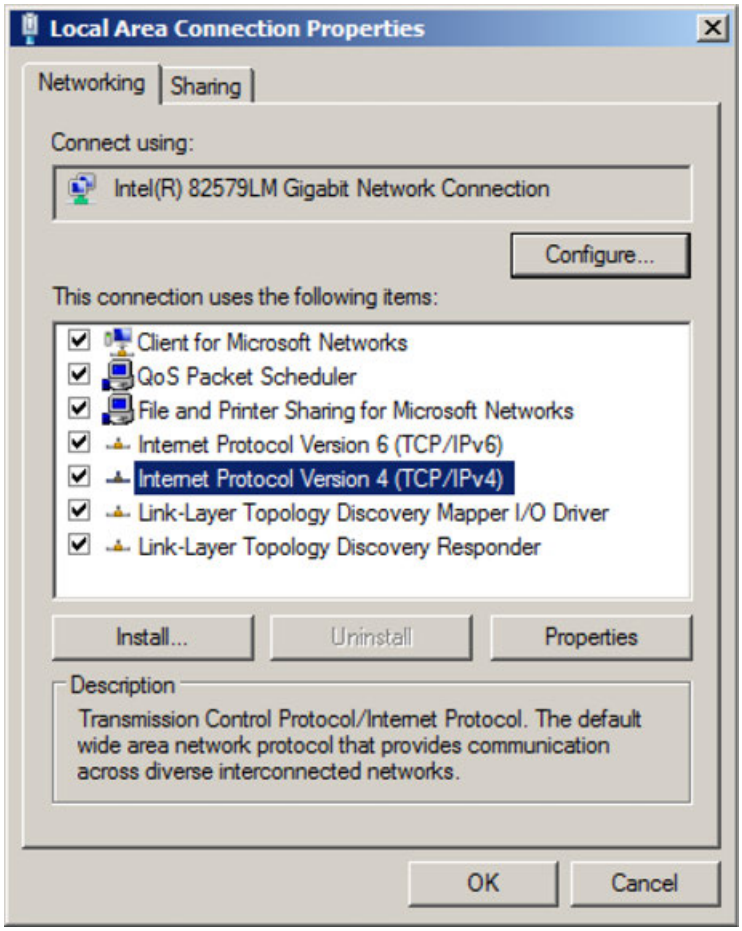
Change the IP address

1. Open Windows **Control Panel**. Click *“Network and Internet ➔ Network and Sharing Center”*.
2. Click **Change adapter settings**.

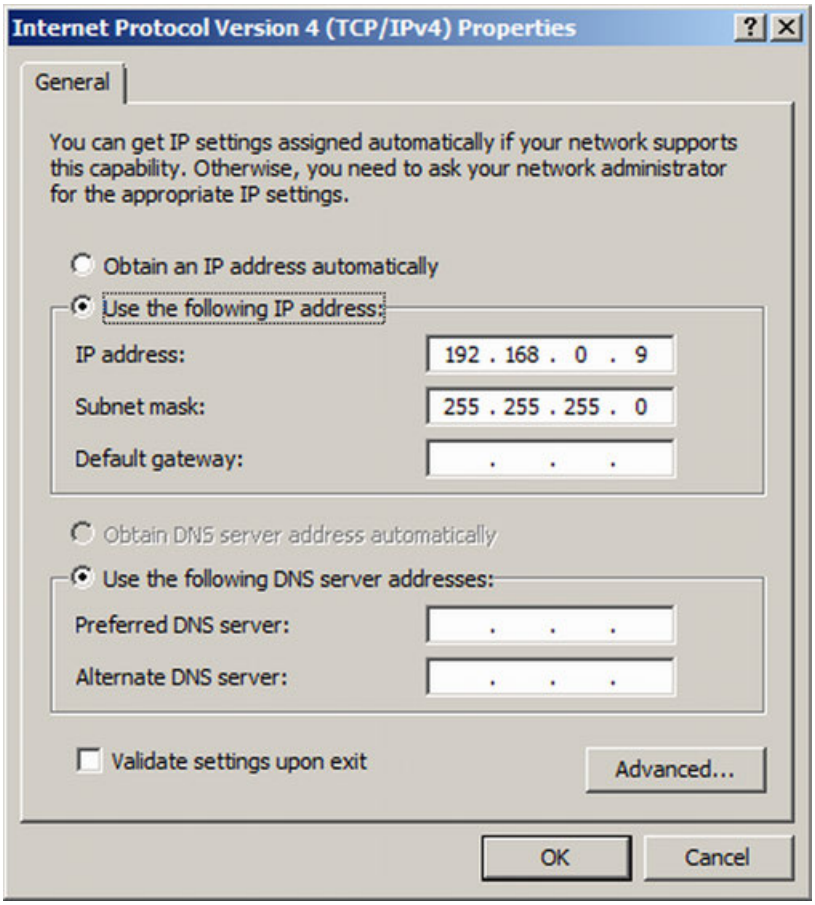
⇨

If using existing network with several devices, please pay attention on given network rules or contact your system administrator.

3. Right-click **Local Area Connection (Ethernet)** and select **Properties**.



4. Double-click **Internet Protocol Version 4 (TCP/IPv4)**.



5. Enter your desired IP address and subnet mask.

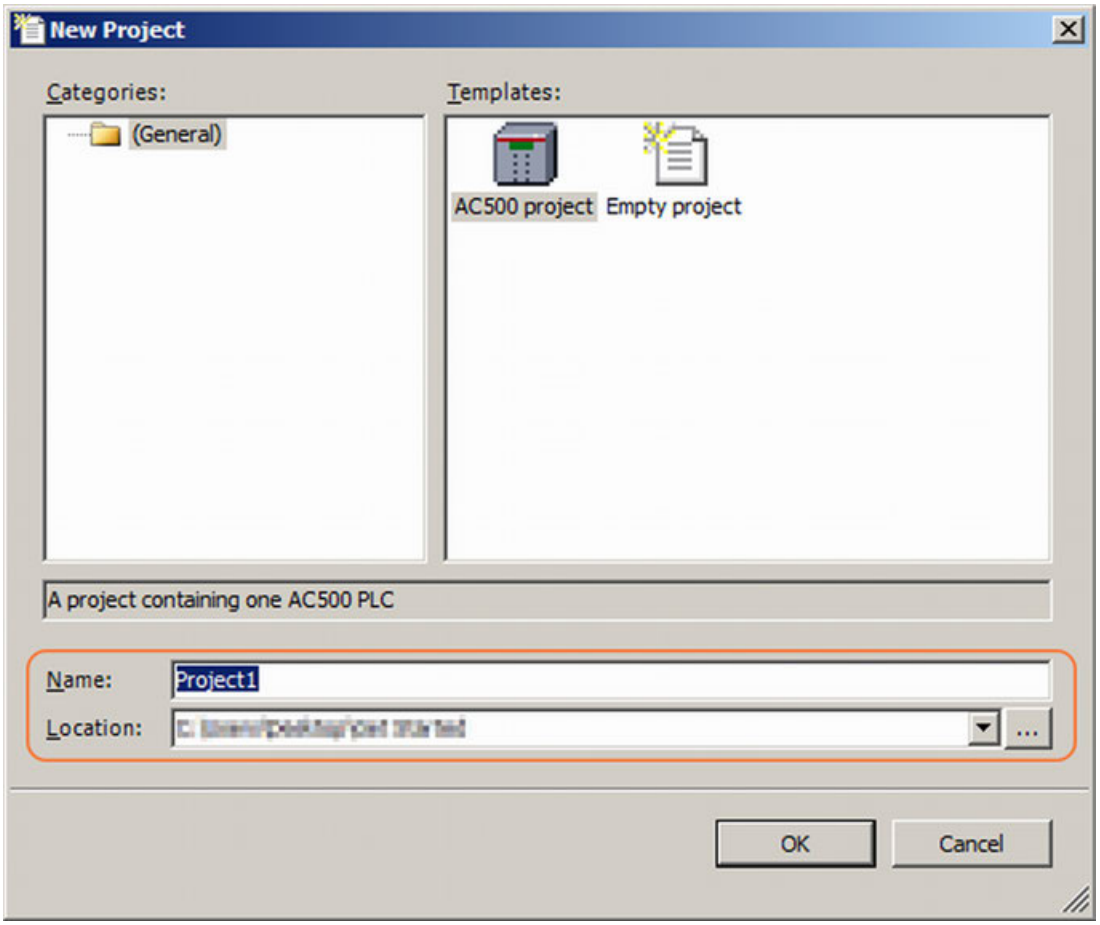
1.6.1.10.2 Step-by-Step introduction to Automation Builder

The following example gives you a brief step-by-step introduction to Automation Builder software and to the programming basics for AC500 PLCs. You will develop and start up a very simple application project with a logical AND function in the programming language Function Block Diagram (FBD).

Configurating the hardware

1. In Automation Builder, from the **File** menu, select **New Project**.
2. Under **Name** enter the project name.

   Under **Location** enter where you want to store the project.



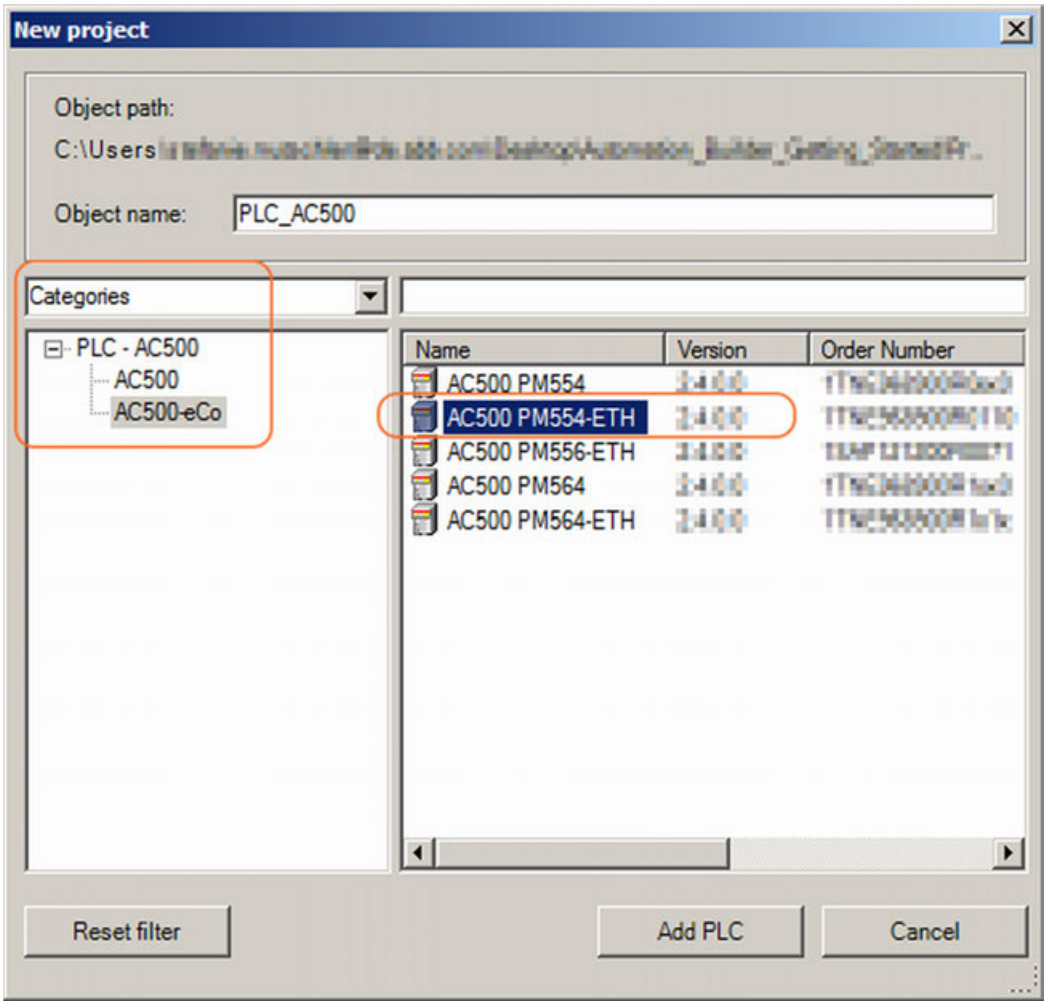
3. Click **OK**.

4. Under **Categories -> PLC - AC500** select **AC500-eCo**.

> *To expand the list, click on the plus sign.*

Select **AC500 PM554-ETH**.

Click **Add PLC**.



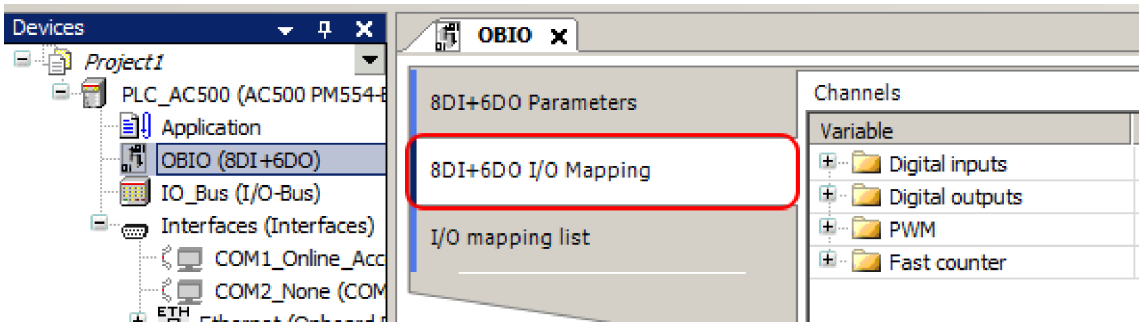
Creating I/O variables

To specify the hardware configuration, you have to define the I/Os and their symbolic names.

> *If you made a mistake during the process, you can always undo. In the CODESYS menu select "Edit ➔ Undo".*

1. Double-click **OBIO** (onboard inputs and outputs).
   ⇨ The **OBIO** tab opens on the right side with several child tabs.

2. Select the **8DI+6DO I/O Mapping** tab.

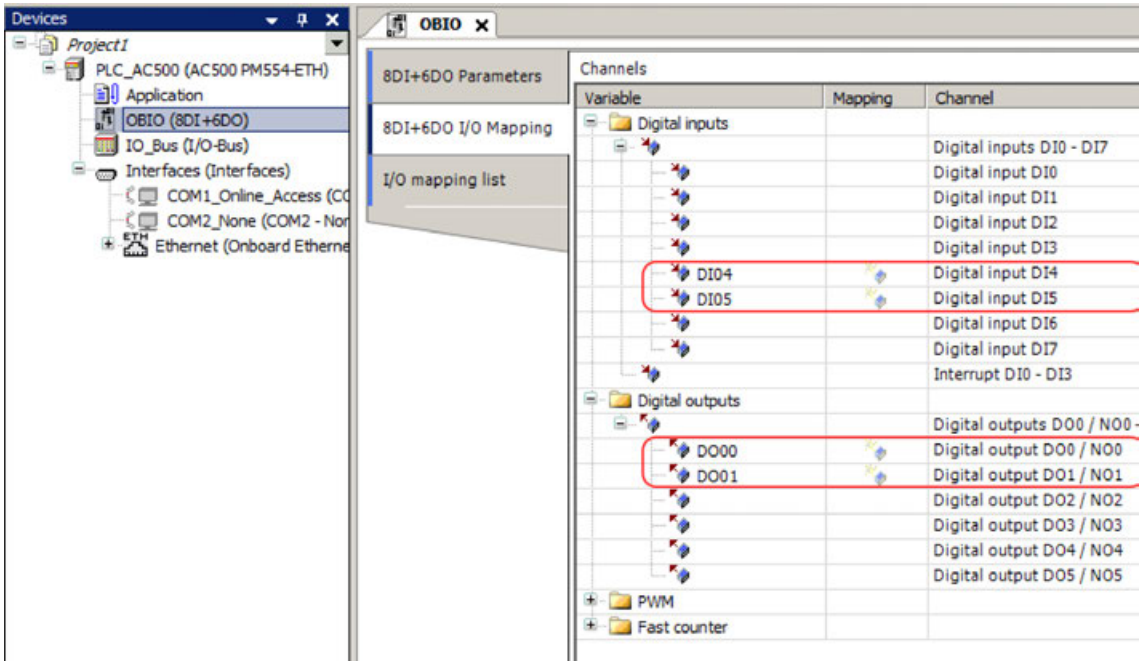


⇨

> *To expand the list, click on the plus sign.*

3. In the **Variable** column, insert the text **DI04** and **DI05** at the corresponding inputs and insert the text **DO00** and **DO01** at the corresponding outputs.

> *To see the number of the inputs and outputs, expand the width of the **Channel** column.*

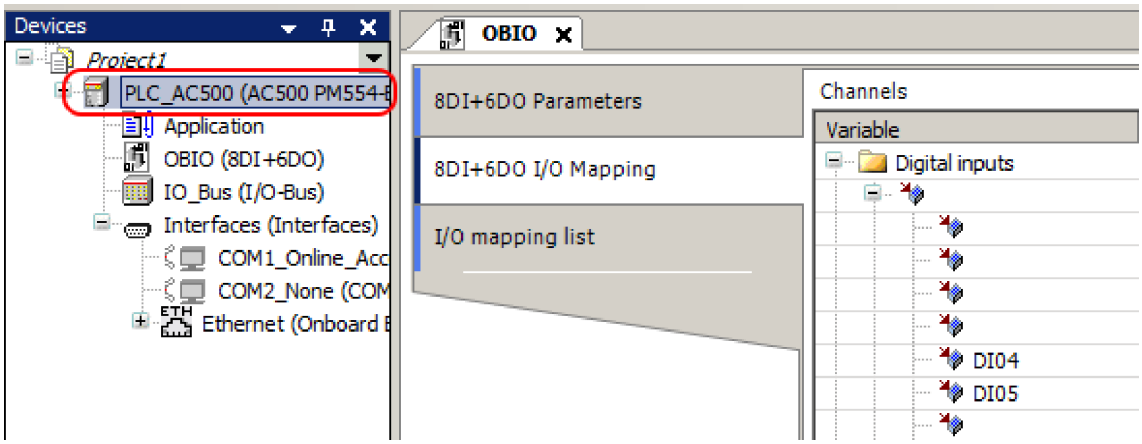


⇨ You added two digital inputs and two digital outputs to your AC500-eCo CPU.

Behavior of the error LED

If the Automation Builder software version and the AC500-eCo CPU firmware version are different, the red Error LED will go on. This has no influence on running your example program on your AC500-eCo CPU. The example program can be executed with any firmware version of the AC500-eCo CPU. In Automation Builder you can define if the Error LED is enabled or disabled.

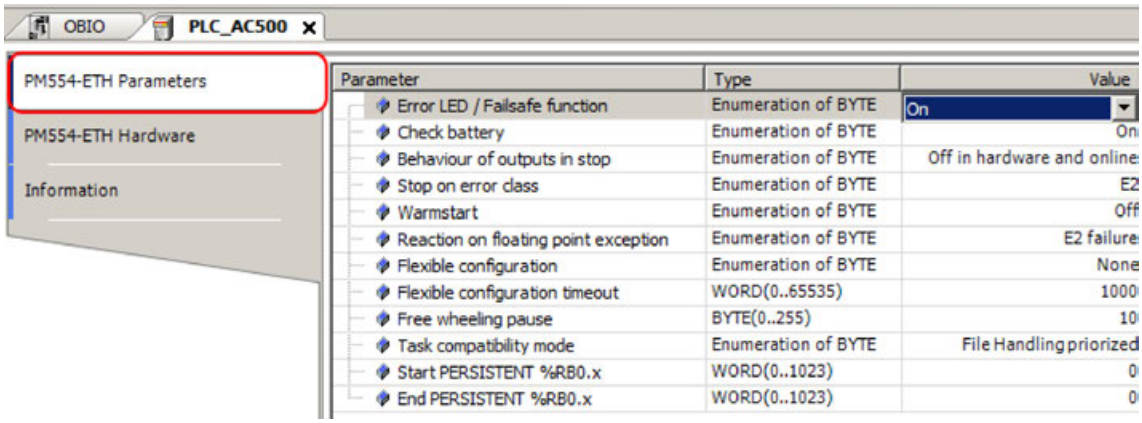
1. Double-click **PLC_AC500**.



⇨ The **PLC_AC500** tab opens on the right side with several child tabs.

2. Select the **PM554-ETH Configuration** tab.

   In the **Error LED / Failsafe function** row, double-click on the entry of the **Value** column.



3. Select **Off by E4** to disable the Error LED.

   Select **On** to enable the Error LED.

4. Close the **PLC_AC500** tab.

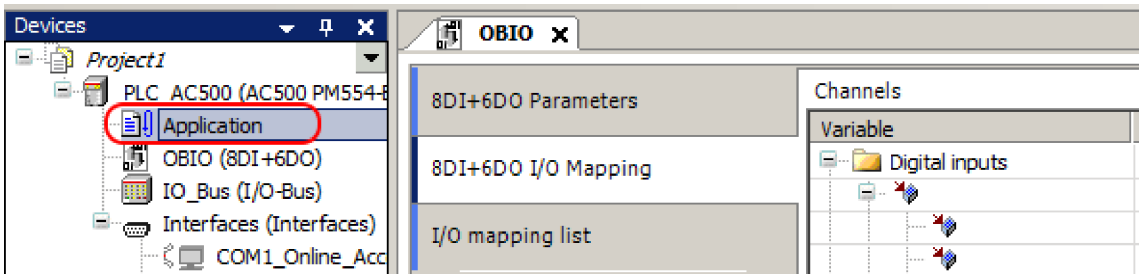
Programming your project

You write the program code in a separate IEC 61131-3 editor (CODESYS). You can open CODESYS out of Automation Builder.

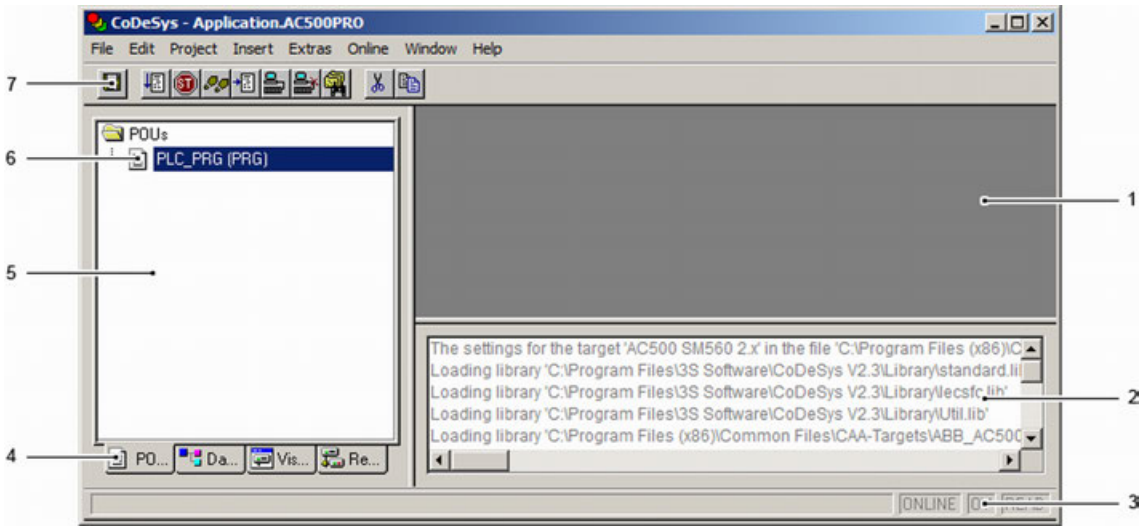
Supported programming languages:

- ST (Structured Text)
- IL (Instruction List)
- FBD (Function Block Diagram)
- LD (Ladder Diagram)
- SFC (Sequential Function Chart)
- CFC (Continuous Function Chart)

▷ To open CODESYS, double-click **Application**.



⇨ CODESYS opens in a new window.



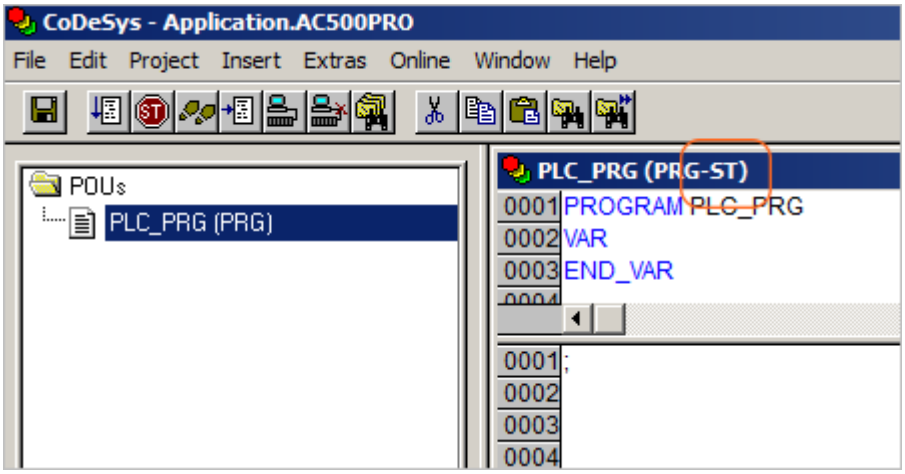
1 Work space
2 Message window
3 Status bar
4 Register cards: POUs (Program Organization Units), Data types, Visualizations, Resources
5 Object organizer
6 Automatically generated POU
7 Toolbar

Change the programming Language into FBD

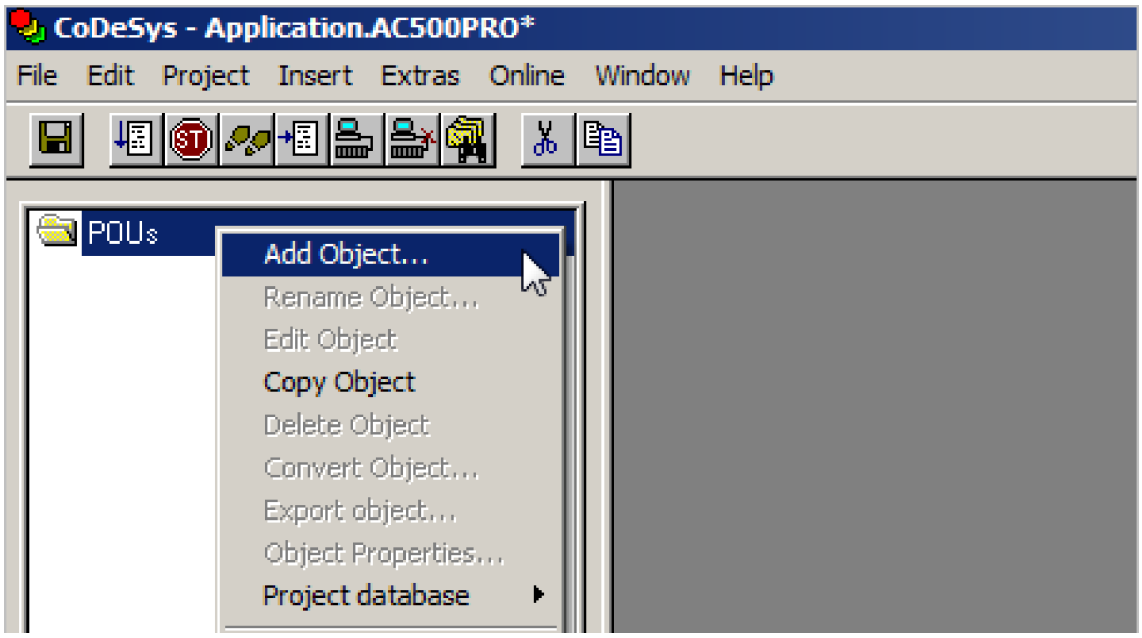
Default programming language is ST.

1. Select *“PLC_PRG (PRG)”* and press *[DELETE]*.

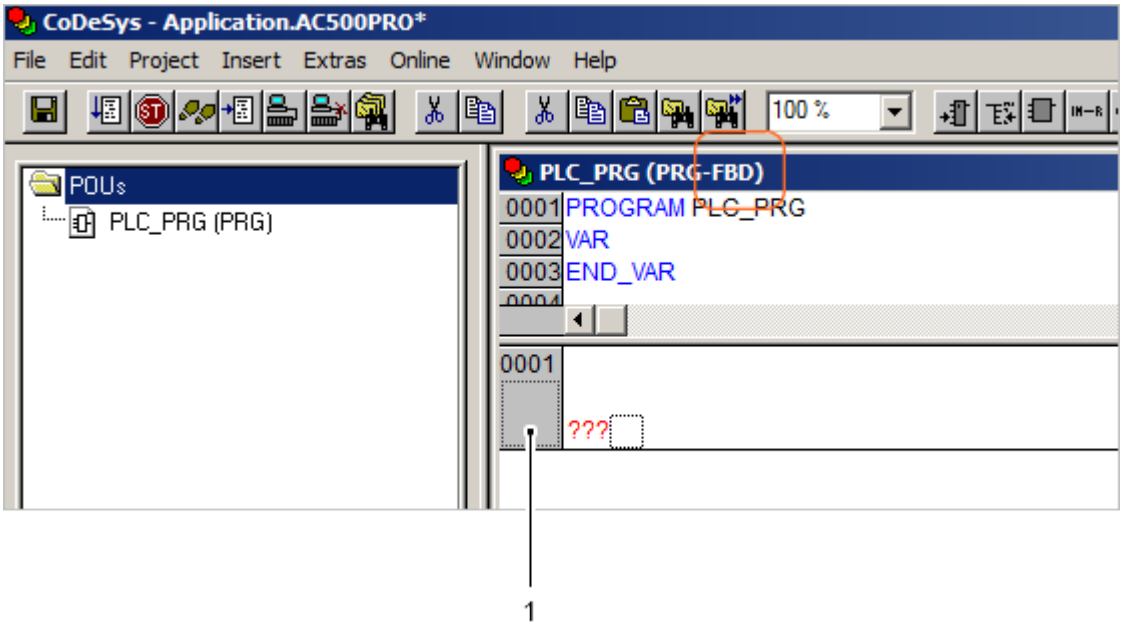
> *If you made a mistake during the process, you can always undo. In the CODESYS menu select “Edit ➔ Undo”.*



2. Right-click **POUs** and select **Add Object**.



3. Under **Language of the POU**, select **FBD**. Click **OK**.
   ⇨ A newly generated POU opens. The programming language of the POU is FBD.

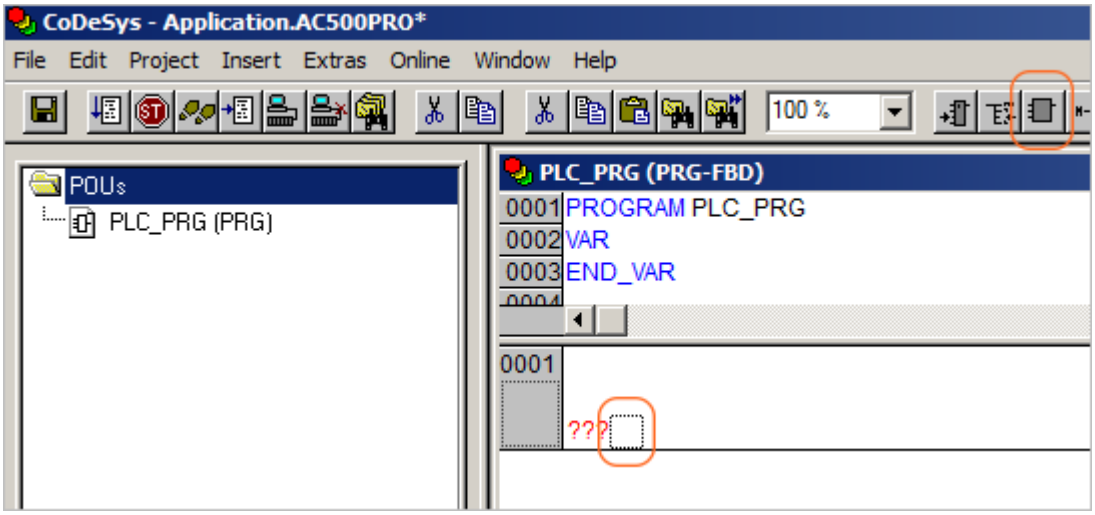


1 Network (here network number 0001)

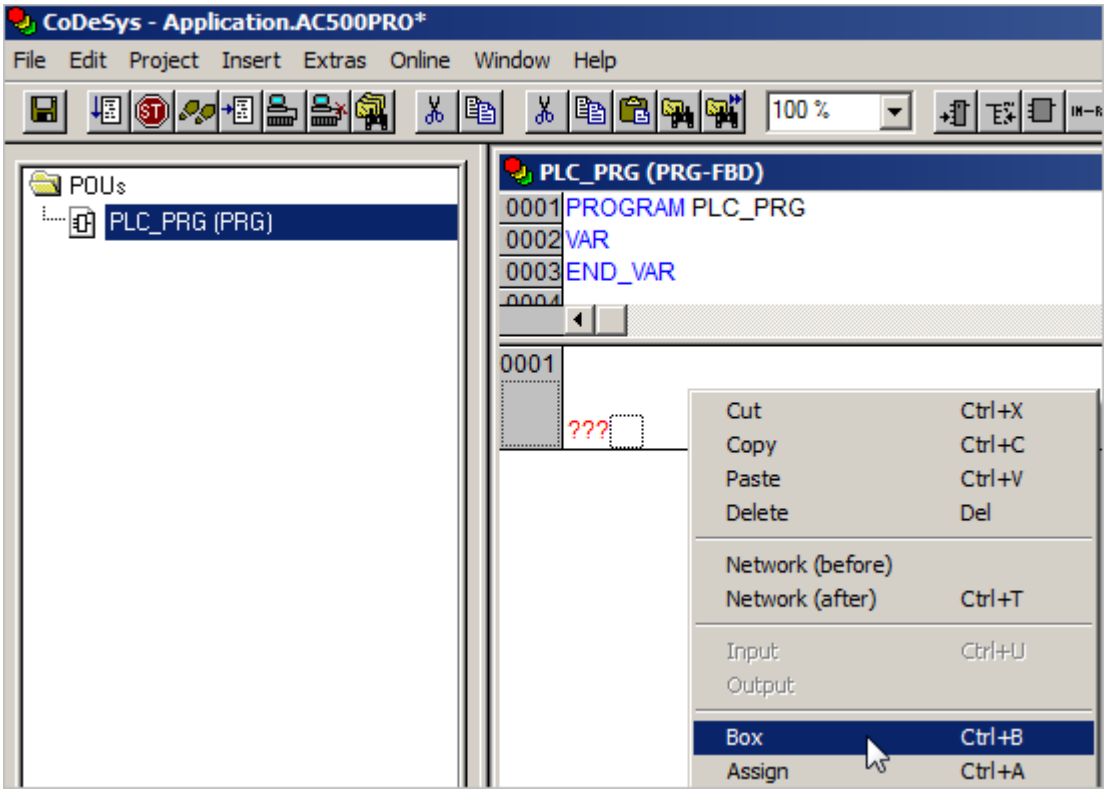
4. Click on the **Save** button.

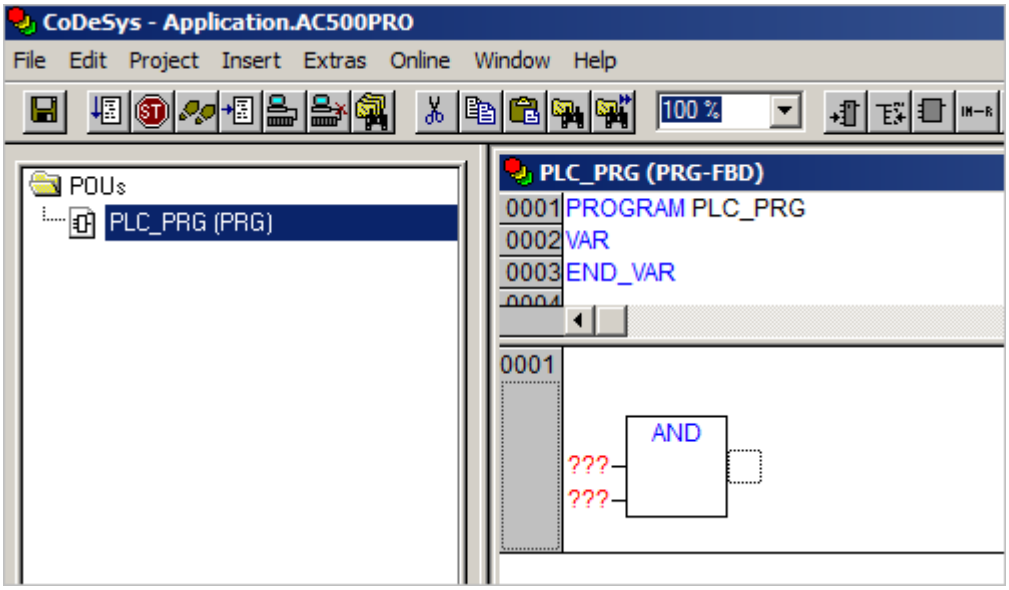
Creating an AND operator

1. Click on the dotted rectangle behind *"???"*. From the toolbar, click on the **Box** icon.
   The dotted rectangle represents the cursor position in this network.



2. Alternatively, right-click on the dotted rectangle and select **Box**.



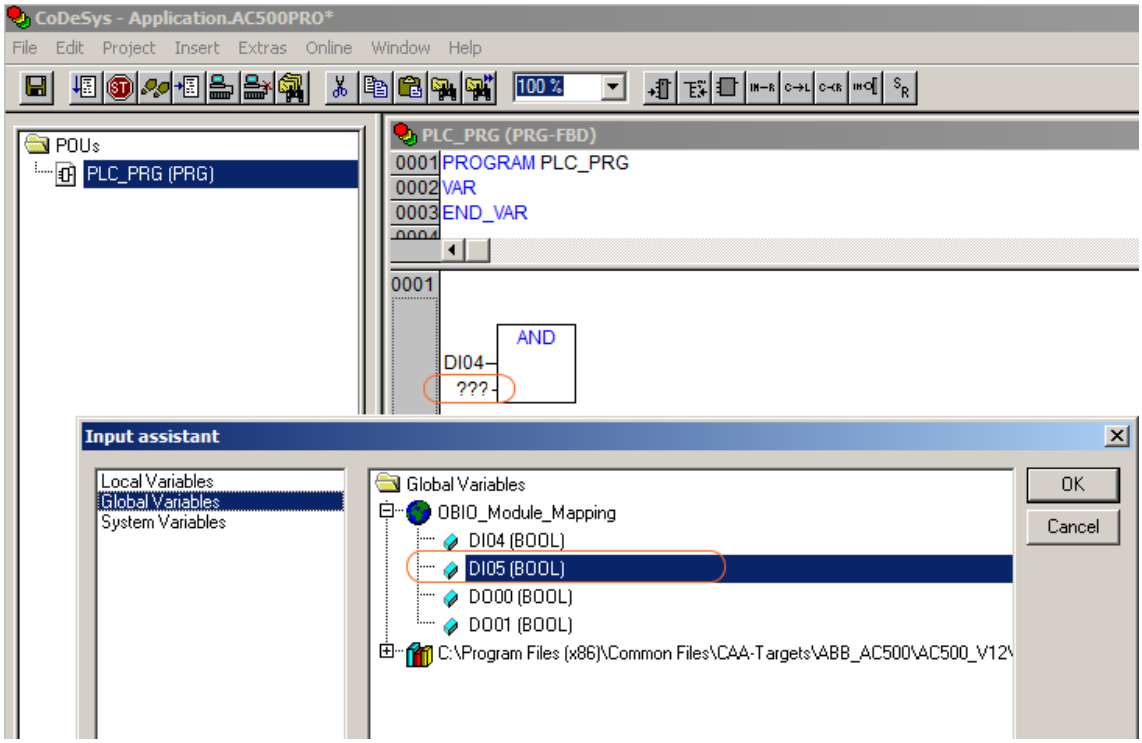


⇨

> *When inserting a new box, it always appears as an AND operator. You can change the type of the box at any time. Click on the AND text and type another name. Or click on the AND text and press F2. You will get an overview of all accepted operators, functions and function blocks.*

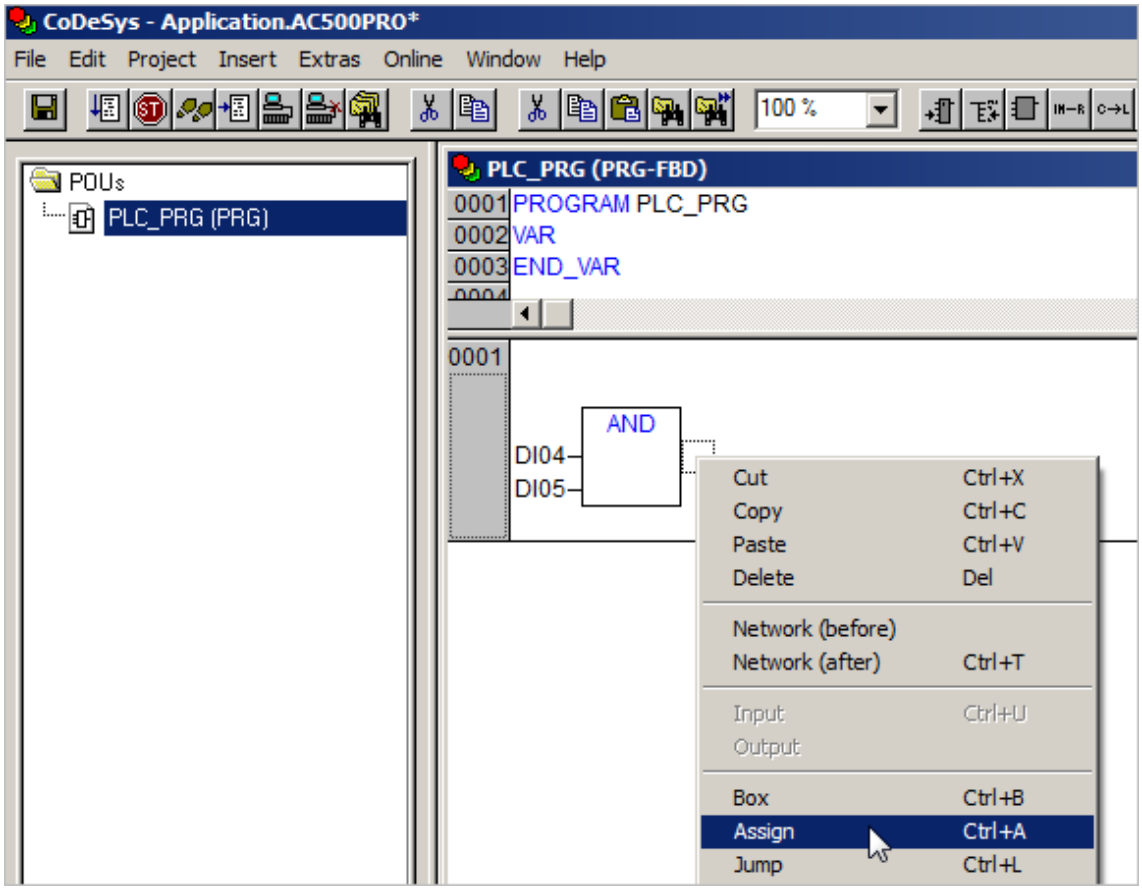
3. Click on *"???"* and press F2.
   ⇨ The input assistant opens.

4. Select **Global Variables**. Select the variable you want to assign.

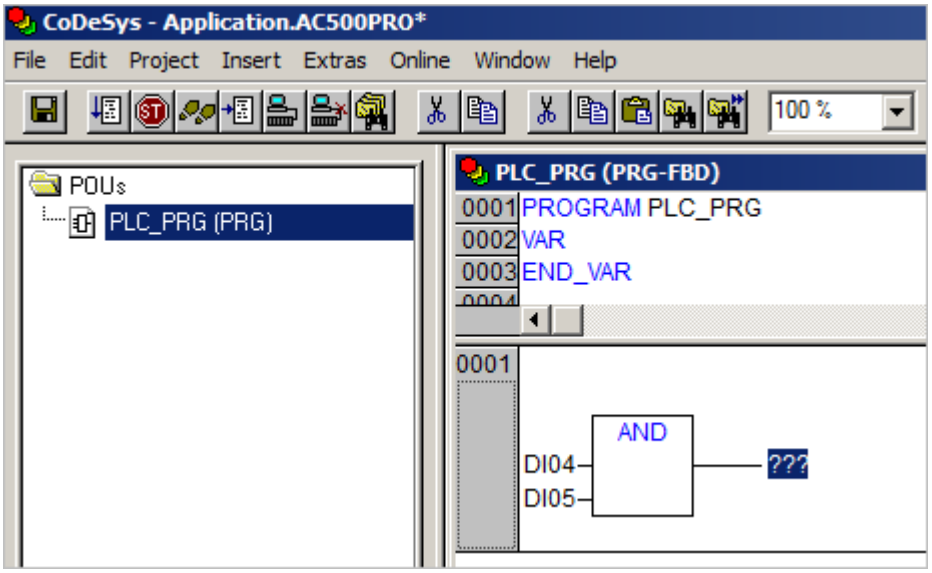


5. Alternatively, click on *"???"* and type DI04 for input 1 and DI05 for input 2.

6. To assign an output: Click on the right side of the AND operator. Right-click on the dotted rectangle and select **Assign**.



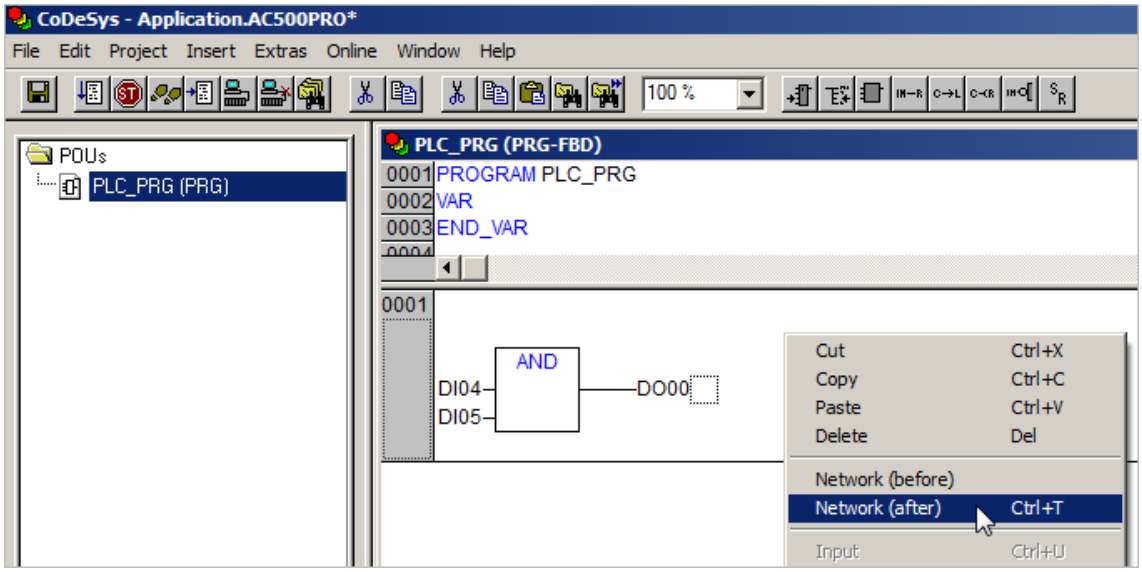
⇨ You assigned an output.



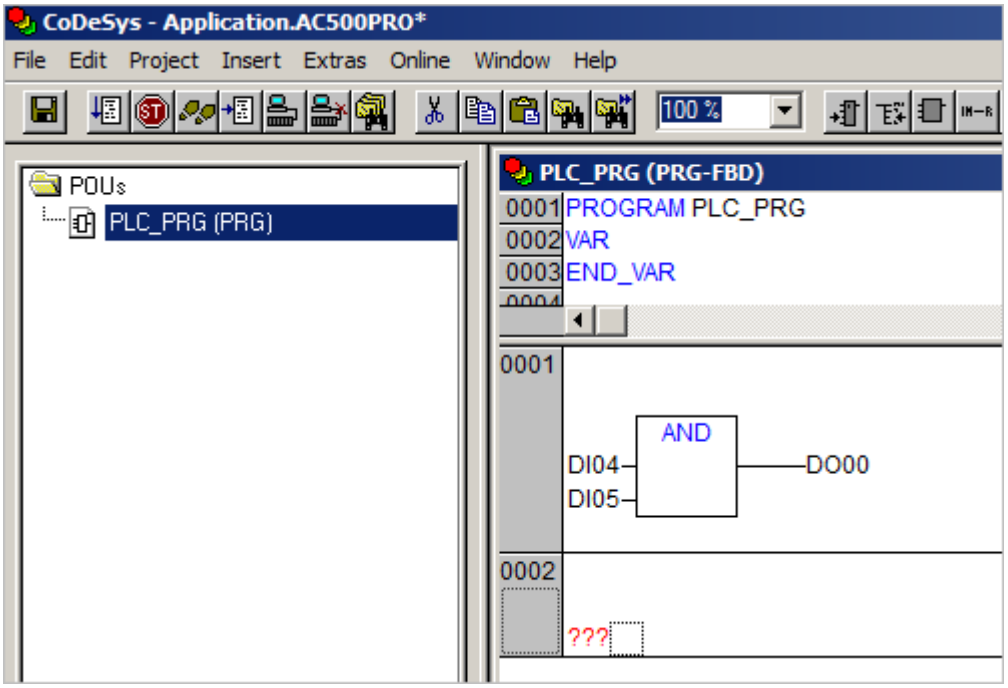
7. Type DO00 for the output. Or press F2 for opening the input assistant.

Add a new network

▷ Right-click on network 0001 and select *“Network (after)”*.



⇨ You added a new network after network 0001. The new network number is 0002.

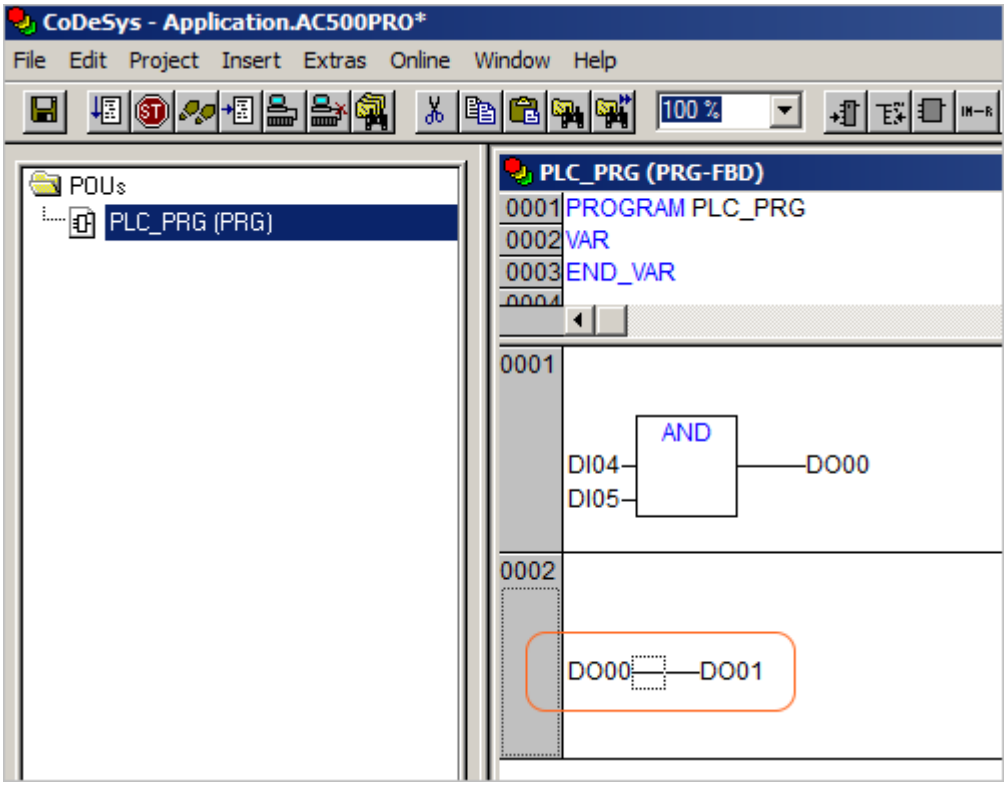


Insert a Negation

1. Right-click on the dotted rectangle and select *“Assign”*.
2. Type DO00 for input and DO01 for output.

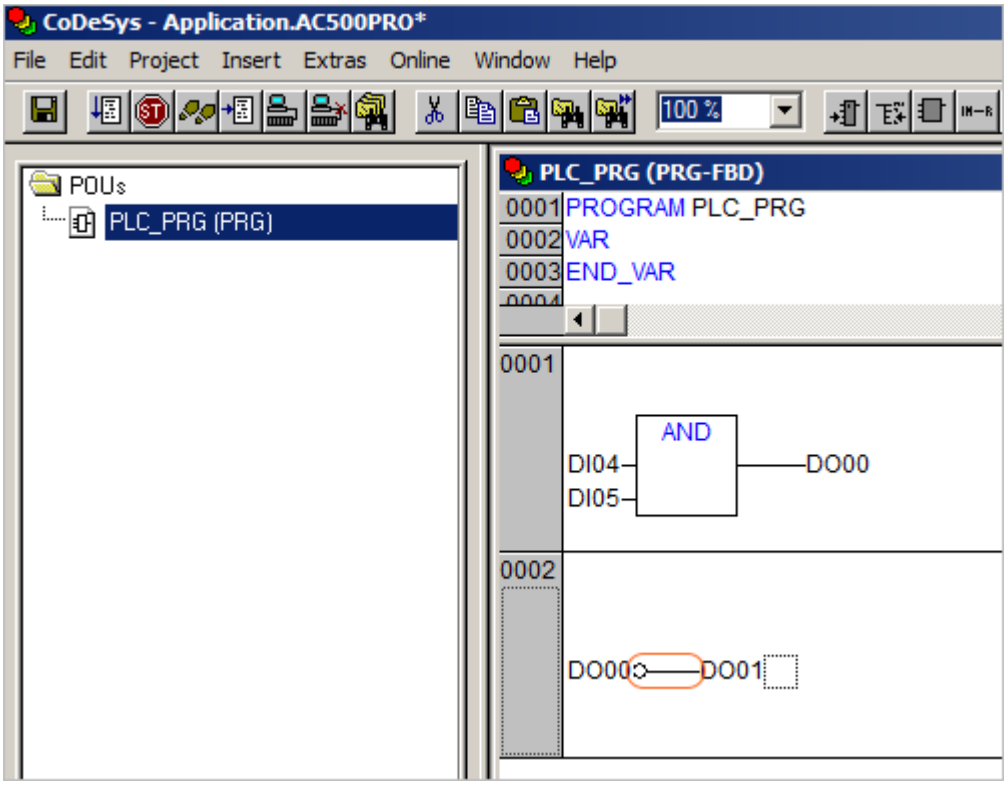
3. Click behind the input DO00.

   ⇨ The dotted rectangle represents the cursor position. The cursor position is behind DO00.



4. Right-click on the dotted rectangle and select **Negate**.

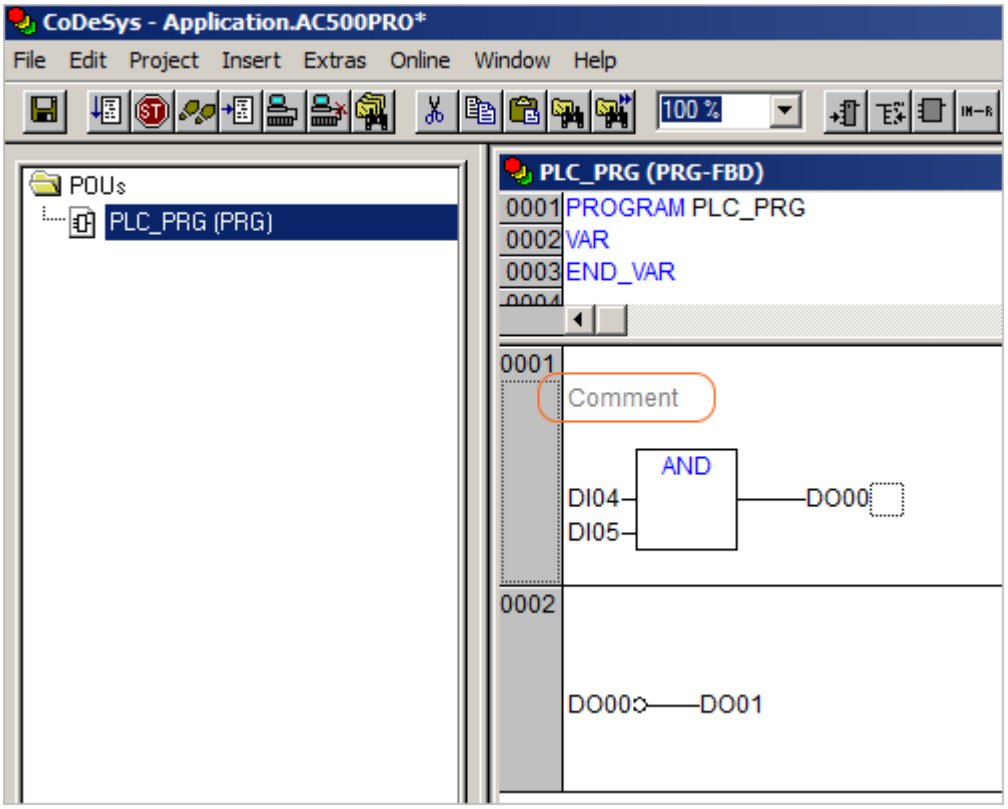
   ⇨ You inserted a negation between DO00 and DO01.



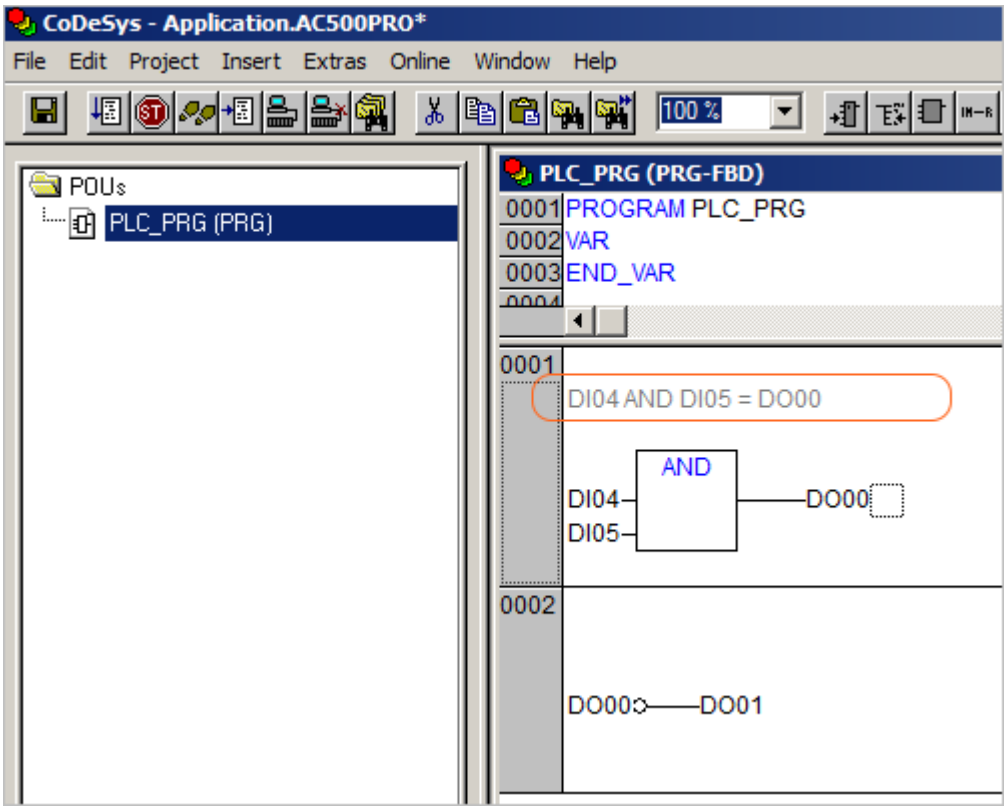
Insert a Comment

1. Right-click on network 0001 and select *"Comment"*.

   ⇨ The text *Comment* appears gray colored on first position in network 0001.

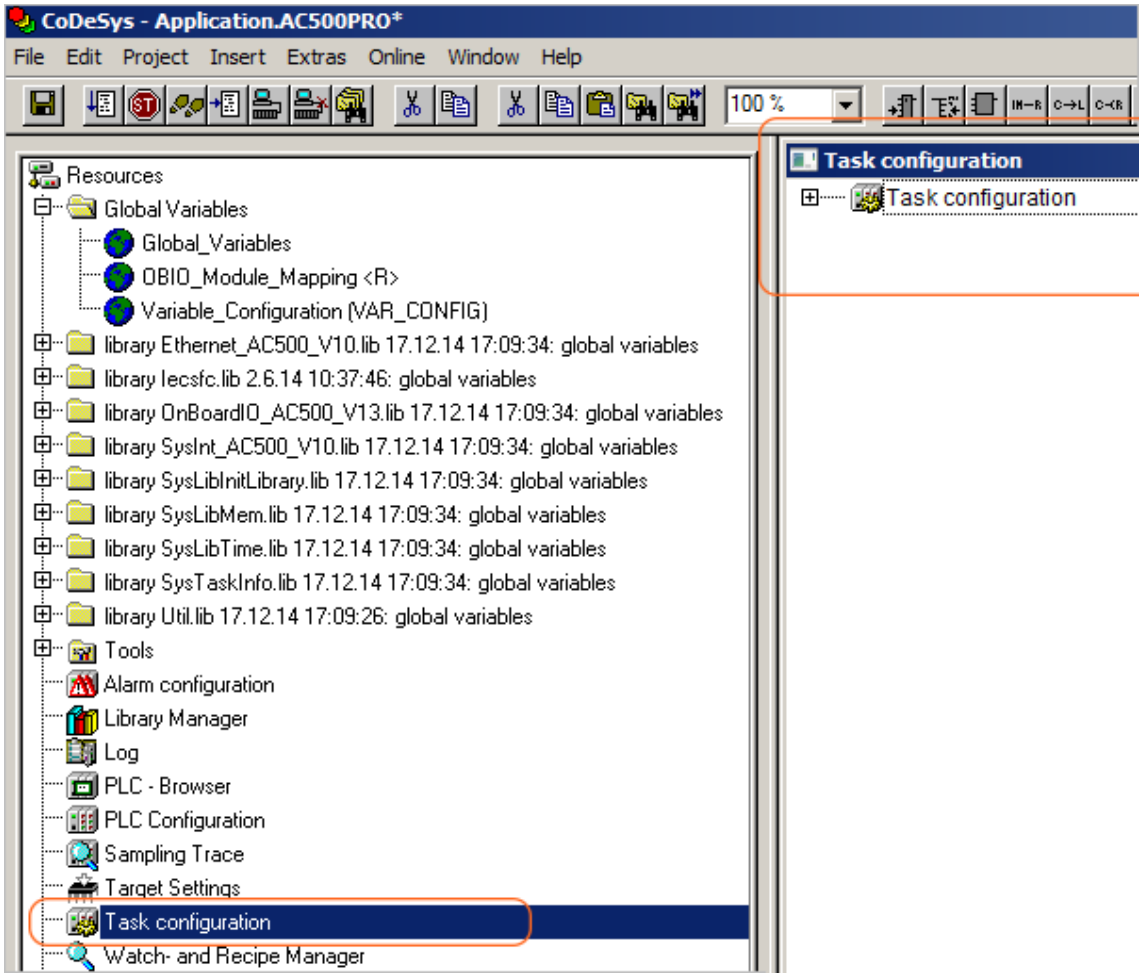


2. Double-click on *Comment* and insert *DI04 AND DI05 = DO00*.

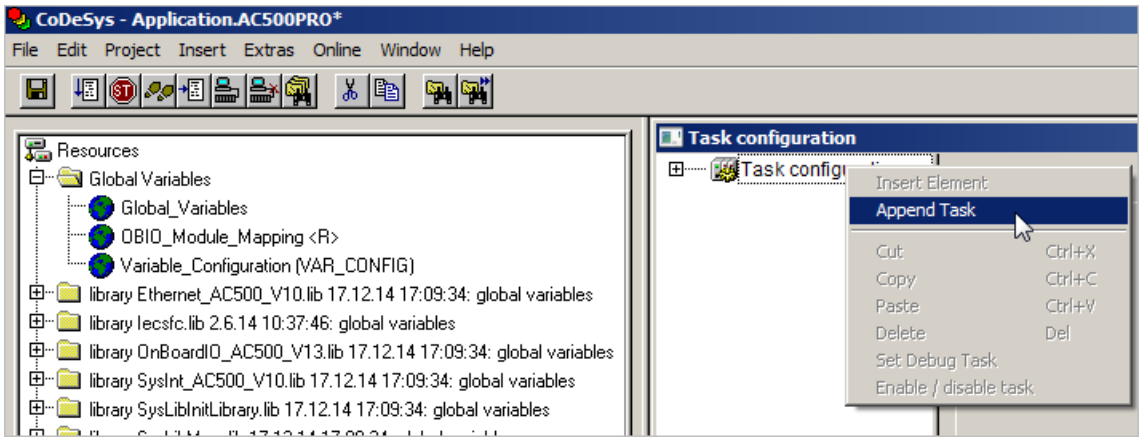


Create a Task Configuration

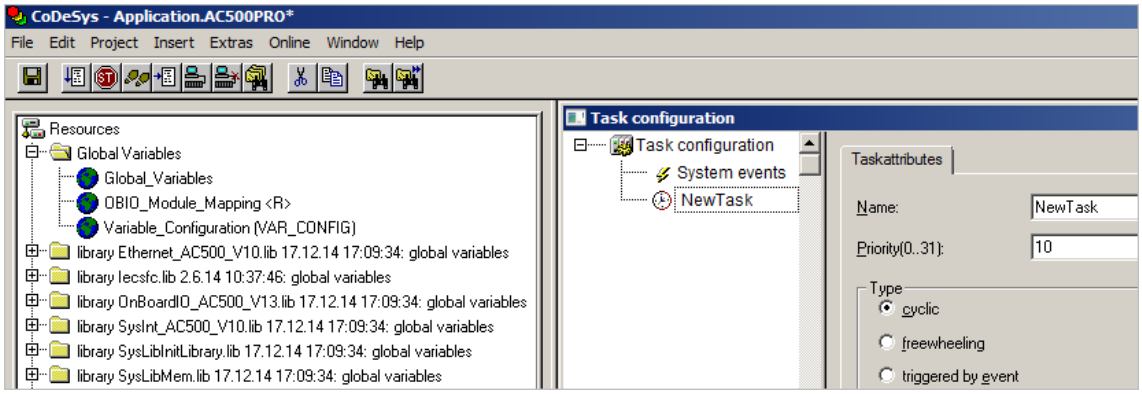
1. In the **Resources** register card, double-click **Task configuration**.
   ⇨ In work space the **Task configuration** window opens.



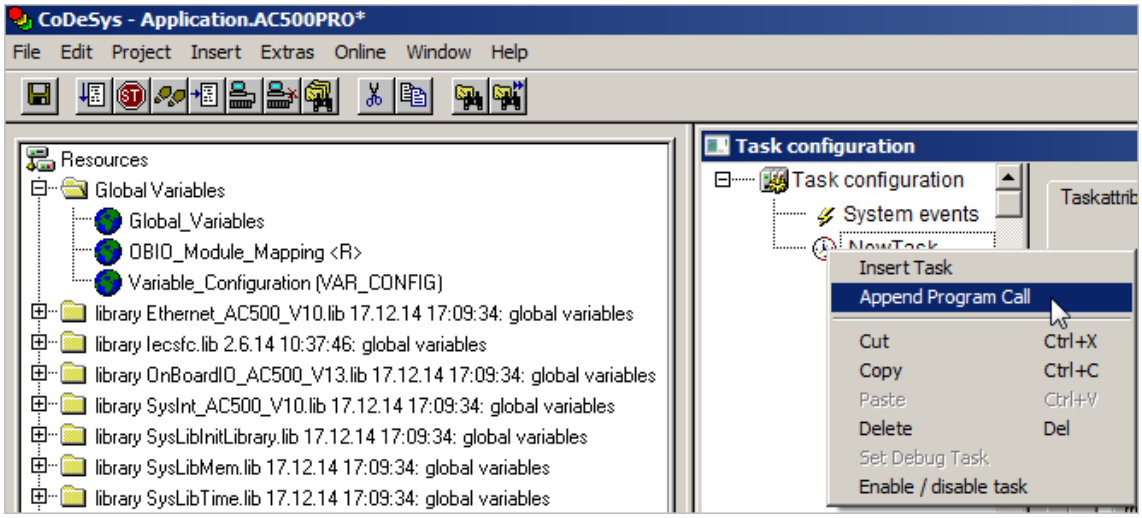
2. Right-click on **Task configuration** and select **Append Task**.



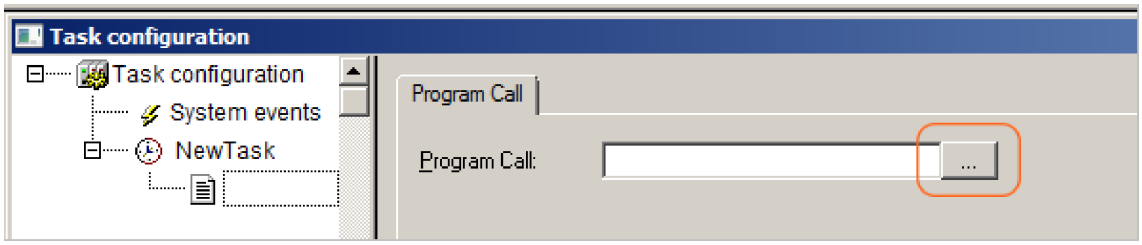
3. Under *"Properties ➔ Interval"*, enter *10*.



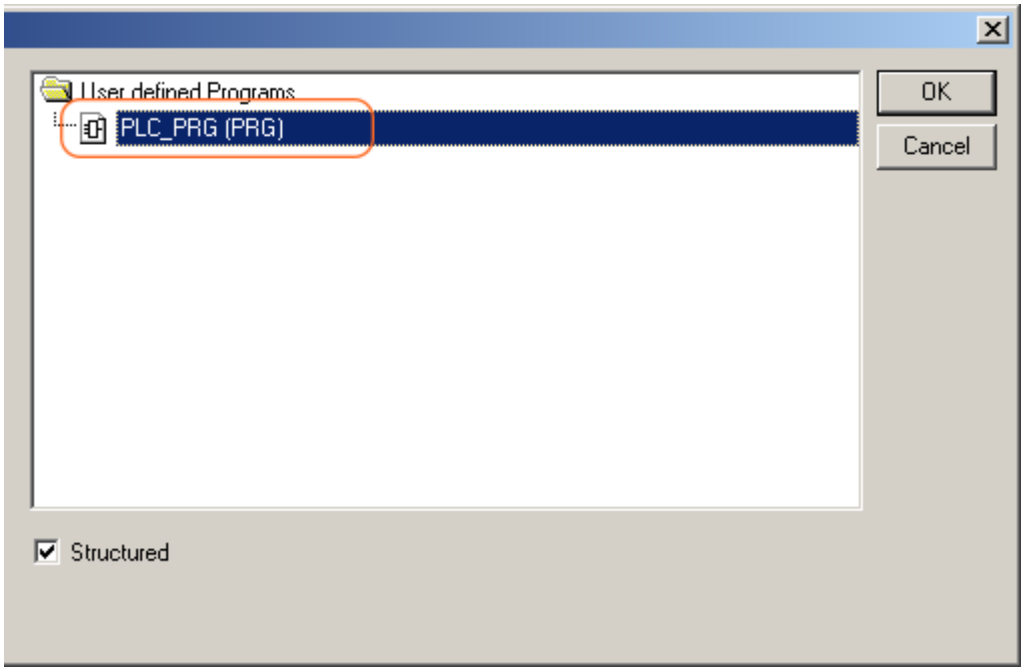
4. Right-click on the watch icon and select **Append Program Call**.

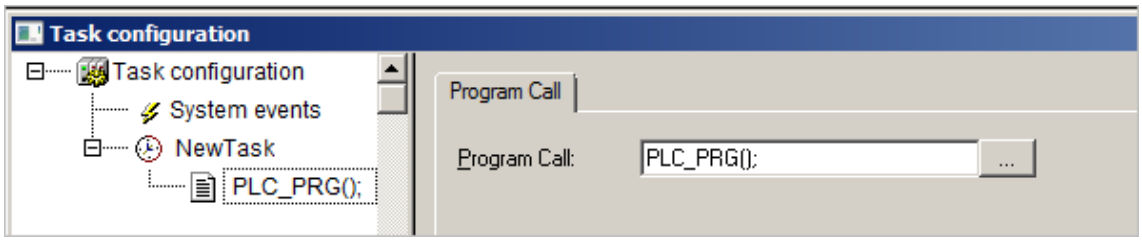


5. Click on **...** to open the input assistant.



6. Double-click on **PLC_PRG (PRG)**.





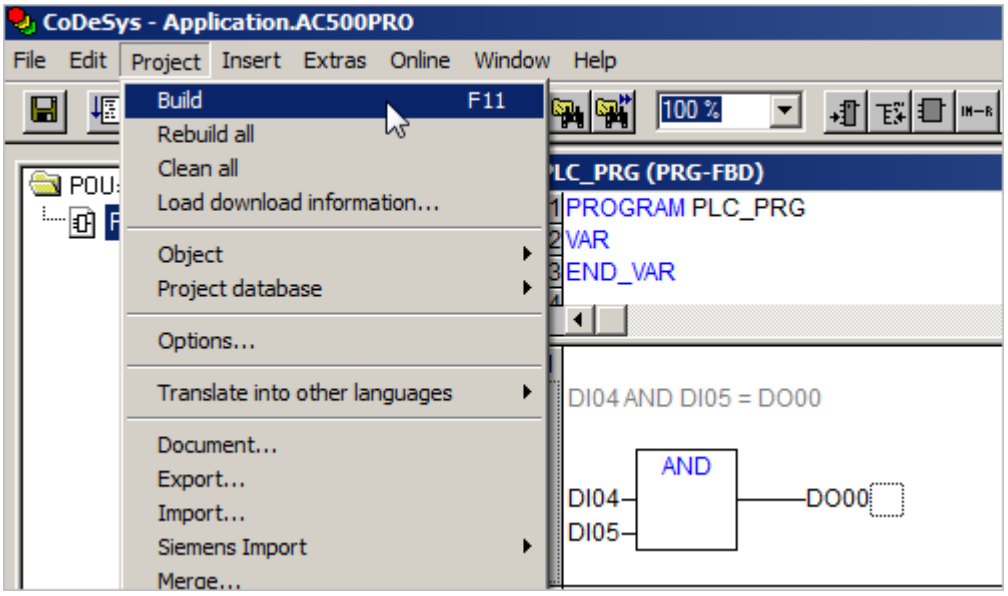
7. You finished the task configuration.

   You can close the **Task configuration** window.

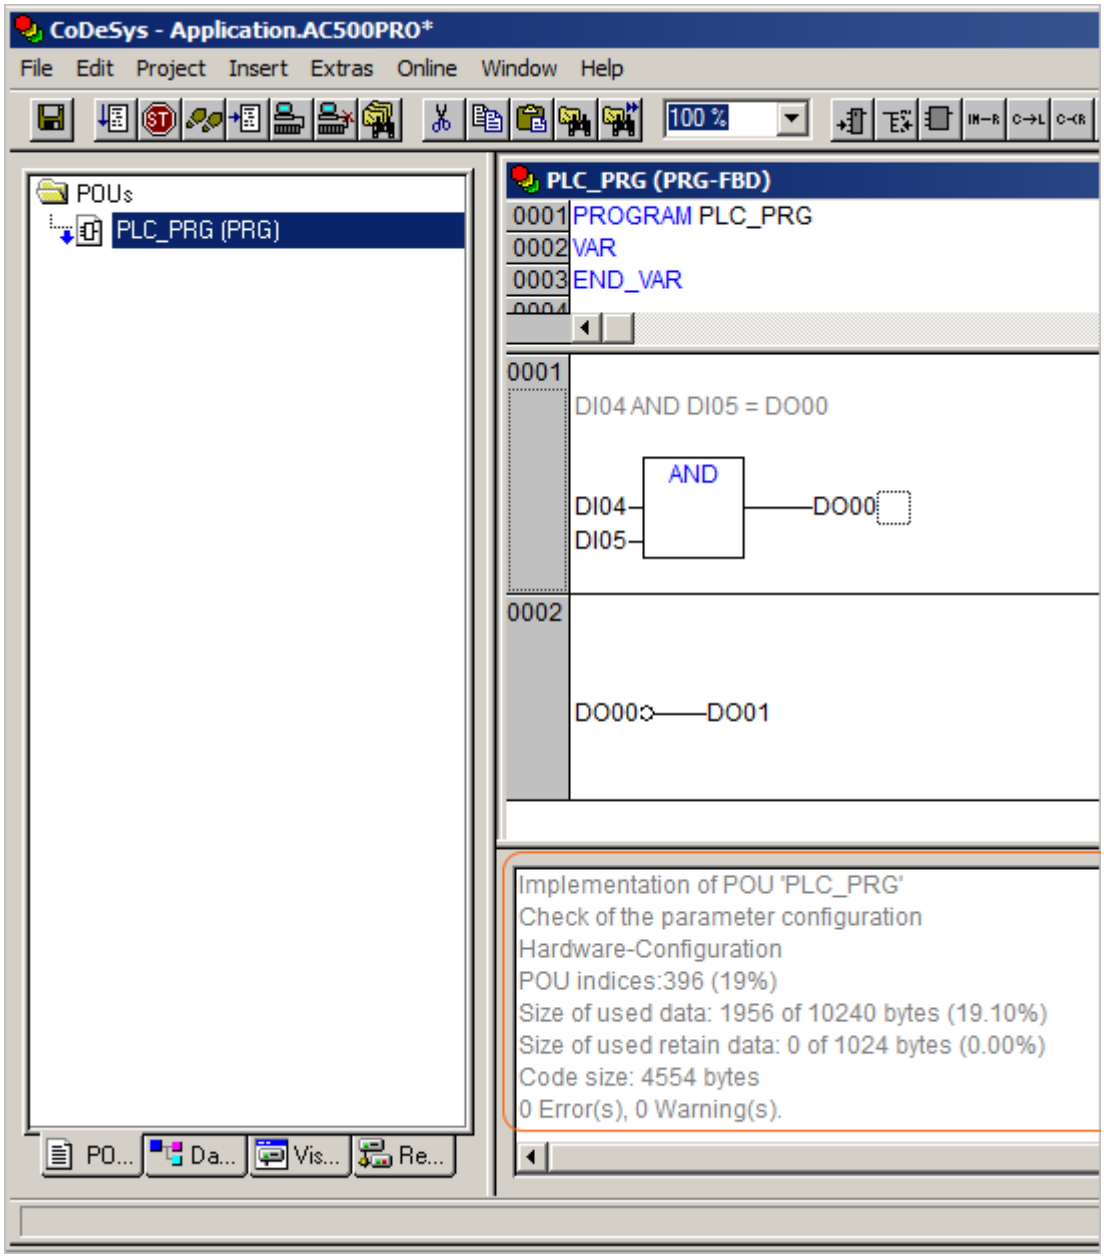
1. **Compile your Project.**

   Click on the **Save** button.

2. From the **Project** menu, click **Build**.



⇨ During compilation a message window opens. The message window shows the progress of the compilation process and any errors and warnings. Double-click on the error message to open the window that contains the error.

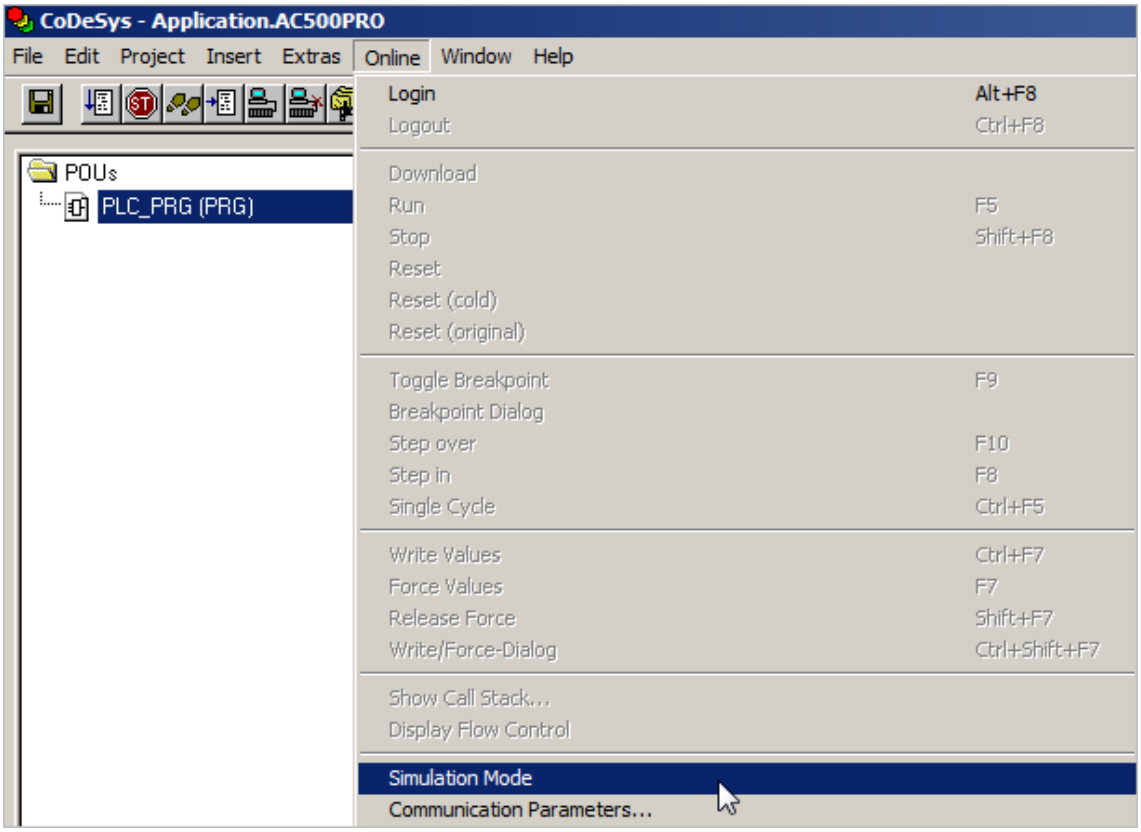


Size of used data:	Total variable that you have declared and used in your program.
Size of used retain data:	Total retain variable that you have declared and used in your program.

Testing your project without connecting the hardware

You can test your program in simulation mode. No hardware is required for simulation mode.

1. From the **Online** menu, select **Simulation Mode**.



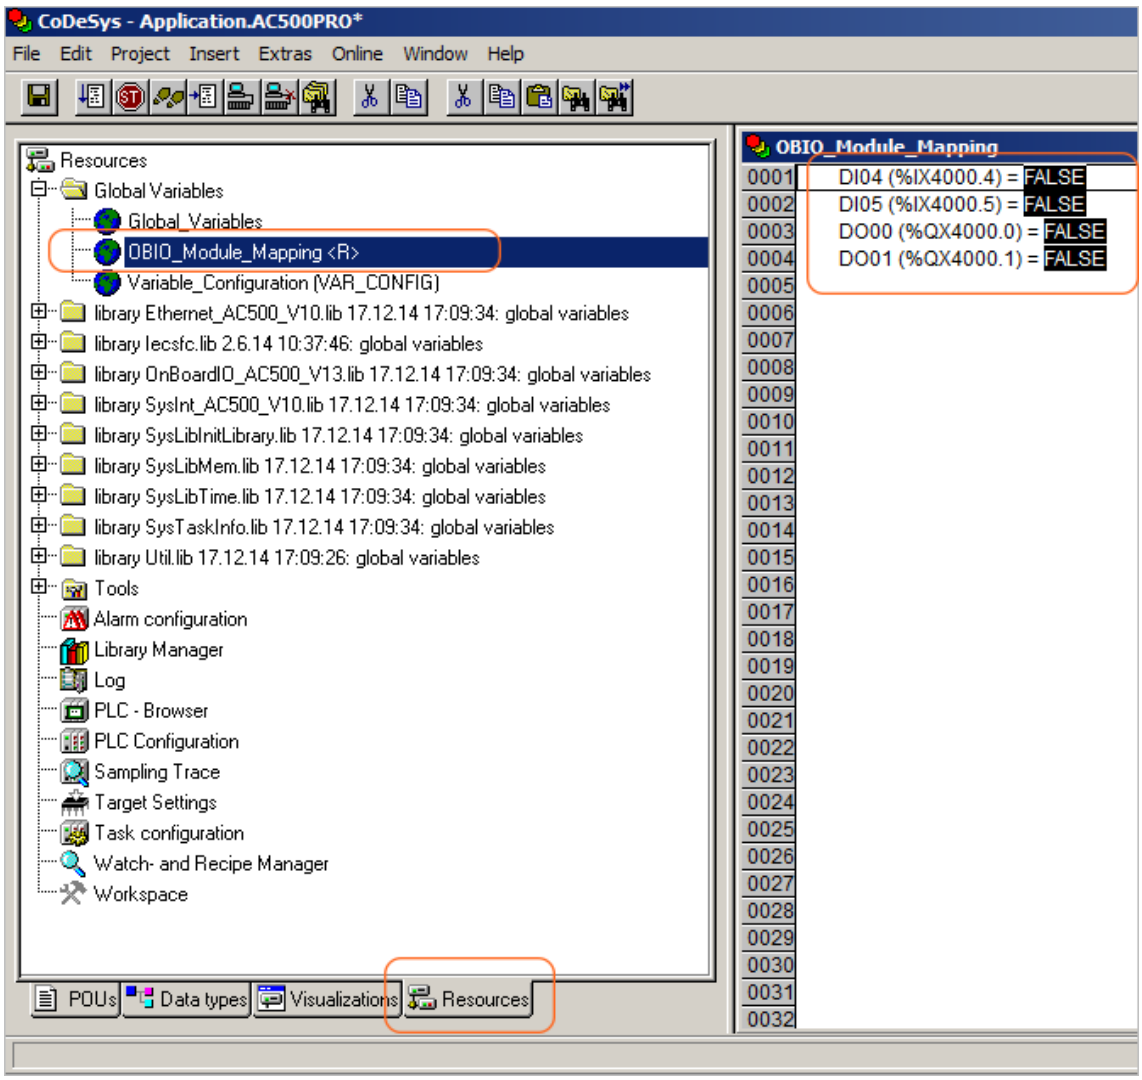
2. From the **Online** menu, select **Login**.

   You can see that **Simulation Mode** is checked.

   ⇨ In the status bar ONLINE and SIM are highlighted in black color.

3. From the **Resources** register card, double-click *“Global Variables ➔ OBIO_Module_Mapping <R>”*.

   ⇨ In work space a window opens. The window shows all declared inputs and outputs.

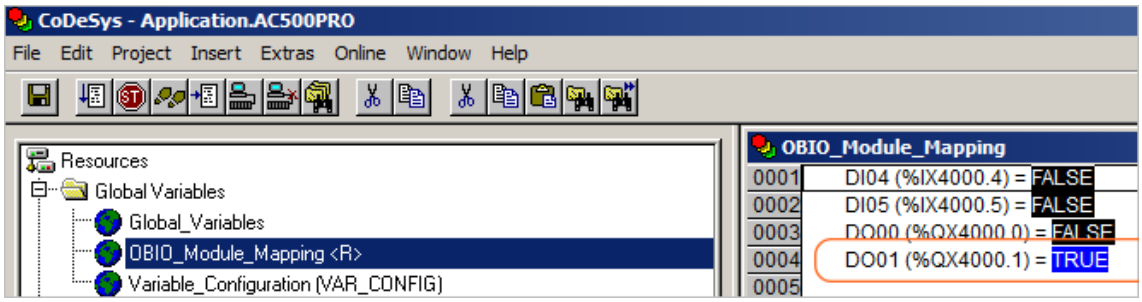


You see the status of every input and output. FALSE is highlighted on black background. TRUE is highlighted on blue background.

4. **Simulate the Starting of the CPU.**

   From the **Online** menu, select **Run**.

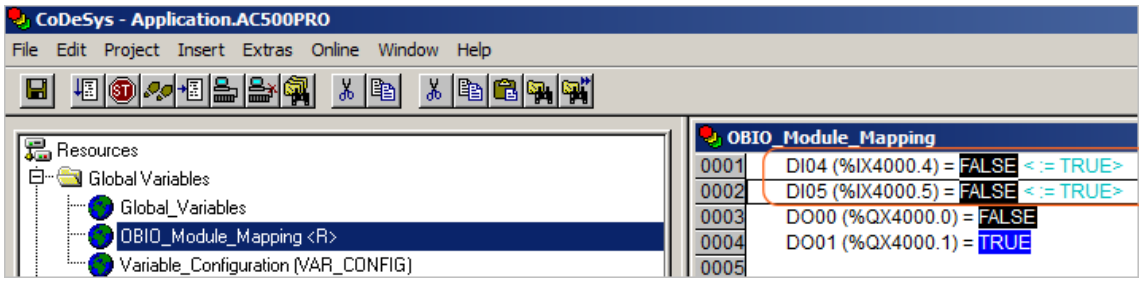
   ⇨ The status of DO01 changes from FALSE to TRUE.



5. **Change the Status of an Input.**

   Double-click FALSE of input DI04 and input DI05.

   ⇨ The change value is shown in green color behind FALSE.

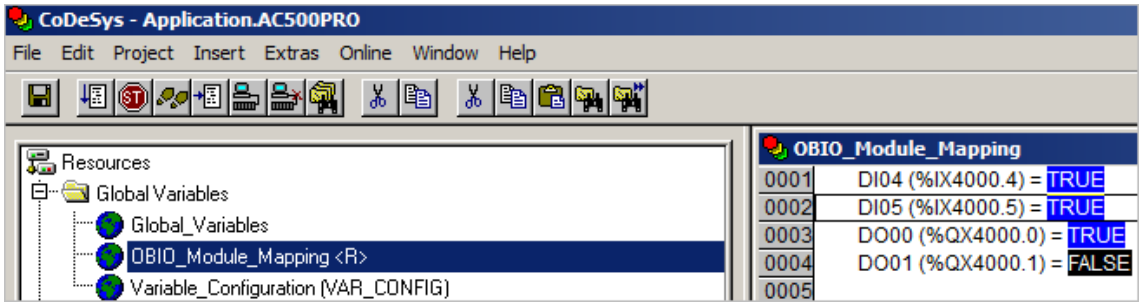


6. From the **Online** menu, select **Write Values** or **Force Values**.

   Write Values: One time effect.

   Force Values: Writes the value in every program cycle.

   ⇨ The status of the inputs and outputs is changed.



Stop simulation mode

1. From the **Online** menu, select **Logout**.
2. From the **Online** menu, select **Simulation Mode**.

   ⇨ **Simulation Mode** is unchecked.

Running your program on the AC500-eCo CPU

☑ Preconditions:

☑ The input simulator is connected to the AC500-eCo CPU ↳ *Chapter 1.6.1.10.1.1 “Connecting the input simulator” on page 3742*.

☑ The AC500-eCo CPU is connected to power supply ↳ *Chapter 1.6.1.10.1.2 “Connection of the AC500 CPU” on page 3742*.

☑ The programming cable is connected between AC500-eCo CPU and your PC ↳ *Chapter 1.6.1.10.1.3 “Connecting the programming cable” on page 3742*.

☑ The RUN/STOP switch of the AC500-eCo CPU is in RUN position. See the installation instruction which is enclosed to the AC500-eCo CPU.

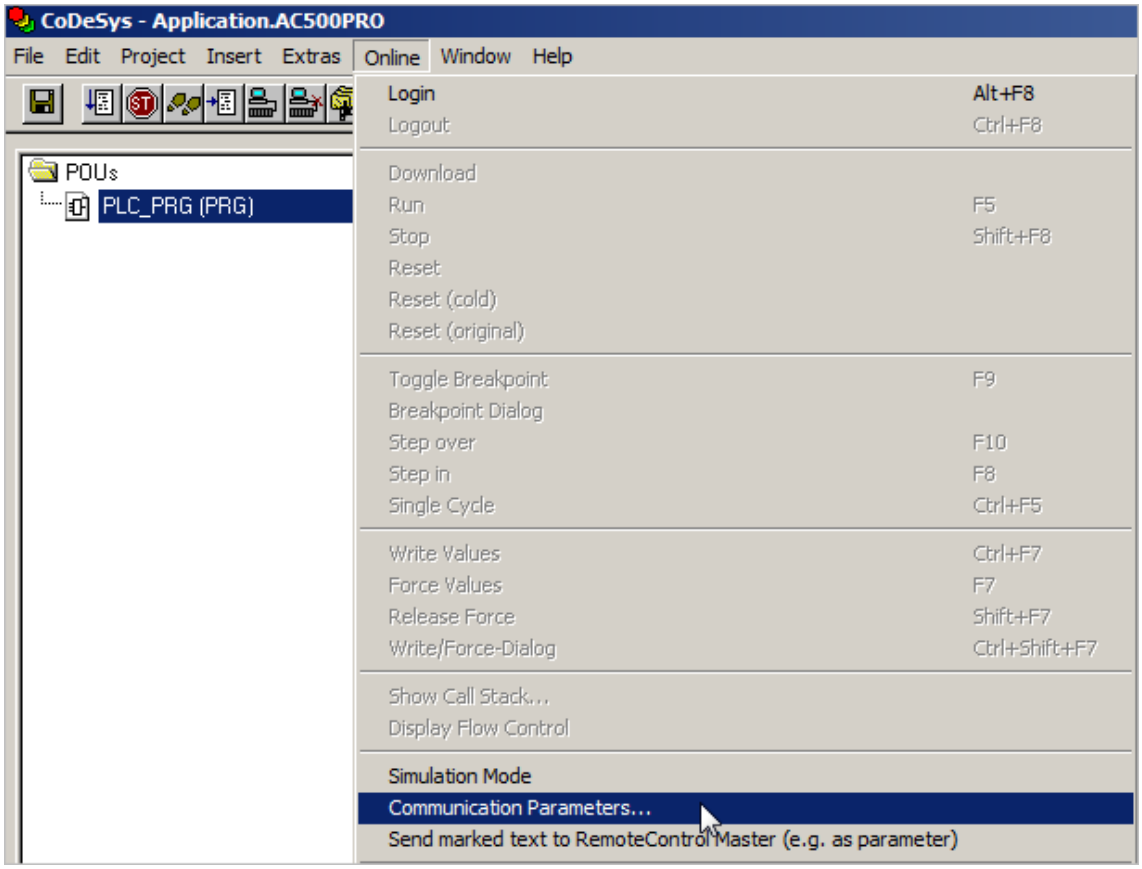
☑ The communication parameters in Windows are set ↳ *Chapter 1.6.1.10.1.4 “Set-up communication parameters in Windows” on page 3742*.

☑ The project is compiled successfully ↳ *Instruction on page 3749*.

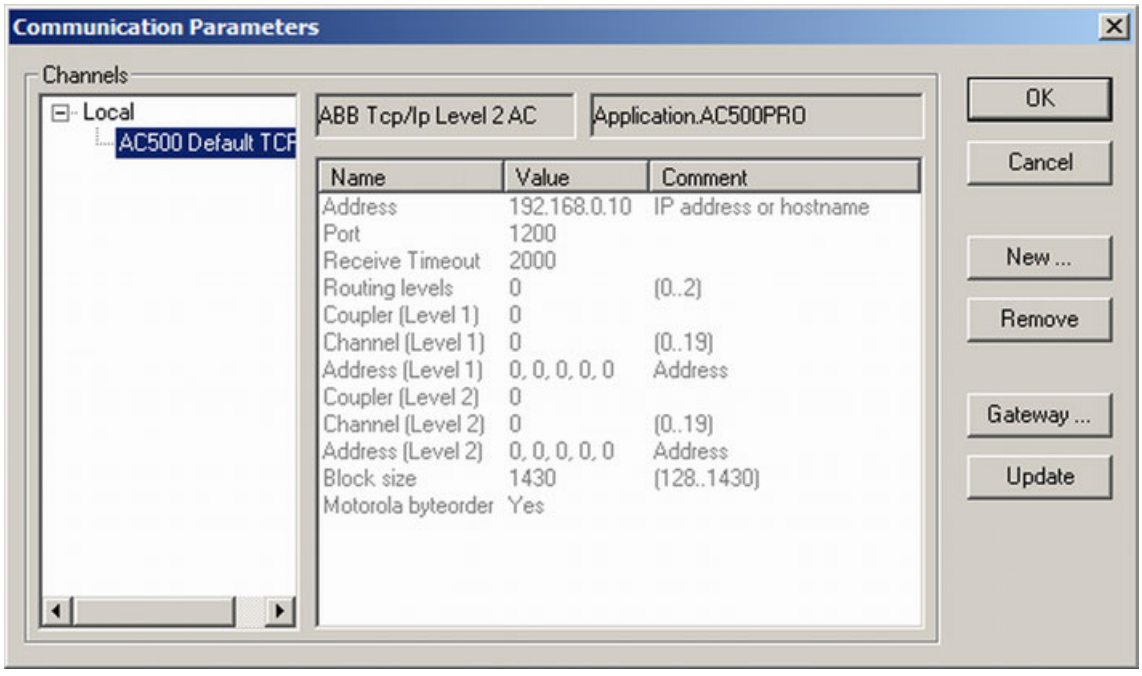
☑ The **Simulation Mode** is unchecked ↳ *“Stop simulation mode” on page 3766*.

1. Set the Communication Parameters in CODESYS

   From the **Online** menu, select **Communication Parameters**.



2. From **Channels**, select **AC500 Default TCP-IP**. Click **OK**.



3. **Download your Program to the AC500-eCo CPU.**

   From the **Online** menu, select **Login**.

4. The upcoming dialog informs you that no program is on the AC500-eCo CPU. You are asked if you want to download your program to the AC500-eCo CPU. Click **Yes**.

   ⇨ If the Automation Builder software version and the AC500-eCo CPU firmware version are different, a message is displayed in the status bar. This has no influence on running your example program on your AC500-eCo CPU. The example program can be executed with any firmware version of the AC500-eCo CPU.

5. **Create a Boot Project: Save RAM to ROM.**

   The application project is stored in the volatile memory of a CPU. You can enable the CPU to automatically load and execute the application project after a restart. Then the downloaded program will be stored in a non-volatile memory (flash memory). Otherwise, the program has to be reloaded manually (here: downloaded) each time the CPU is powered up.

   From the **Online** menu, select **Create boot project**.

> *Once the program is stored in the non-volatile memory, it can only be overwritten by another program or deleted with the delappl command*
> *↳ "Delete a program" on page 3768.*

6. From the **Online** menu, select **Run**.

   ⇨ In the status bar, ONLINE and RUNNING are highlighted in black color.

7. Use the toggles of the input simulator to change the status of input DI04 and DI05.

   ⇨ The LEDs of the inputs and outputs go on and off.

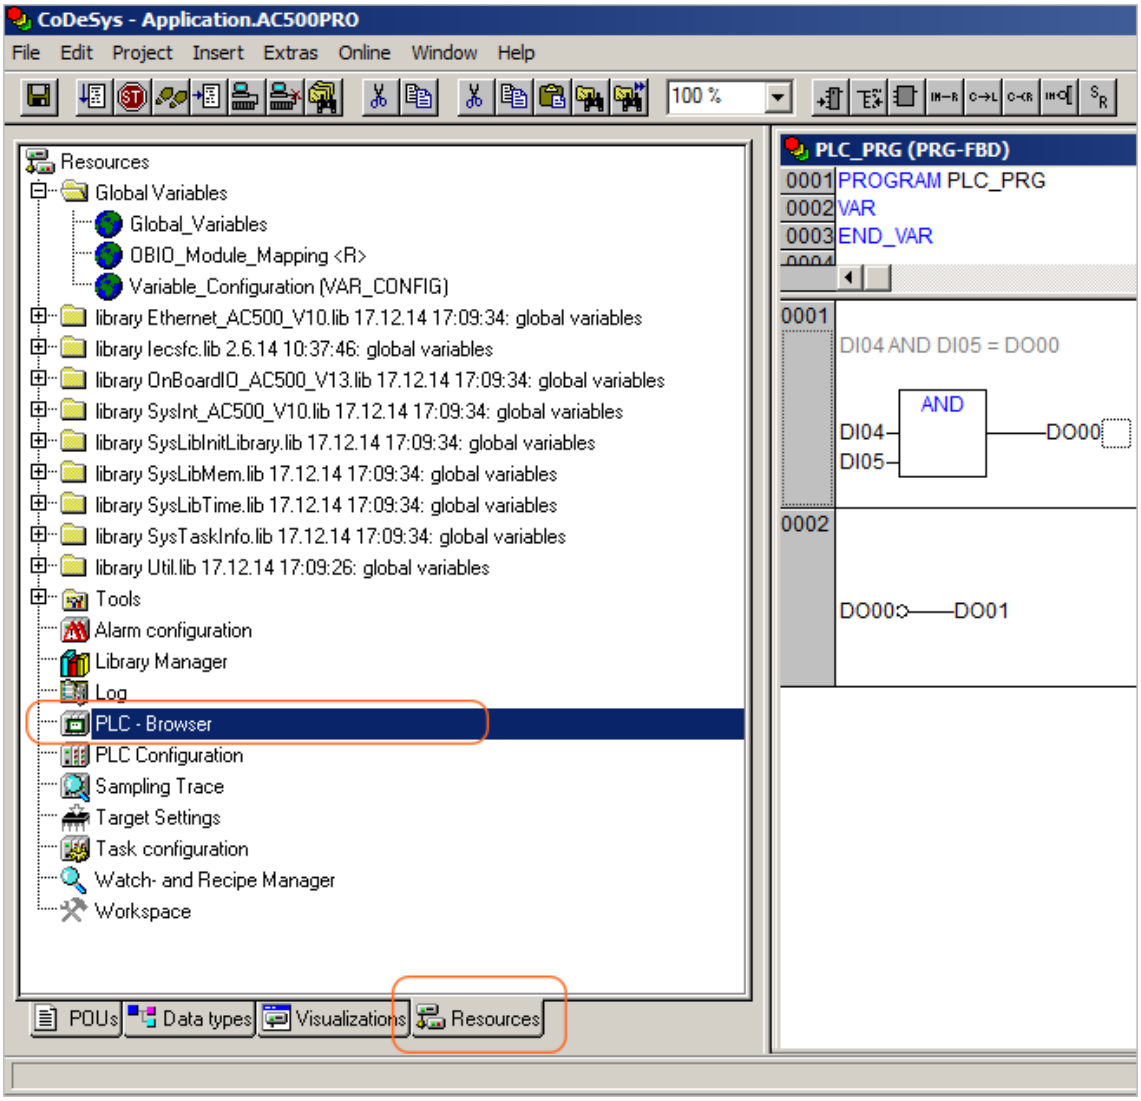
8. Stop the Connection to the AC500-eCo CPU.

   From the **Online** menu, select **Logout**.

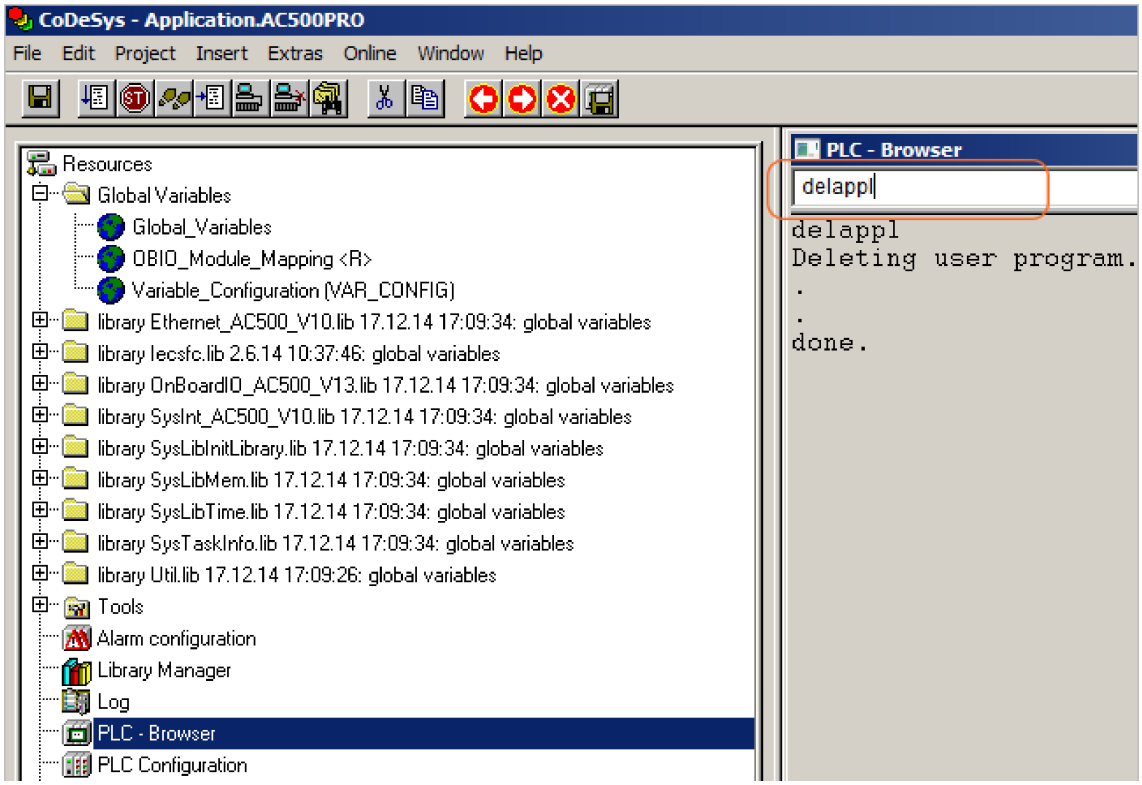
Delete a program

Once the program is stored in the non-volatile memory, it can only be overwritten by another program or deleted with the delappl command.

1. In the **Resources** register card, double-click **PLC-Browser**.



2. In the command line type *delappl*. Press ENTER.



3. The deletion is effective after power cycling.

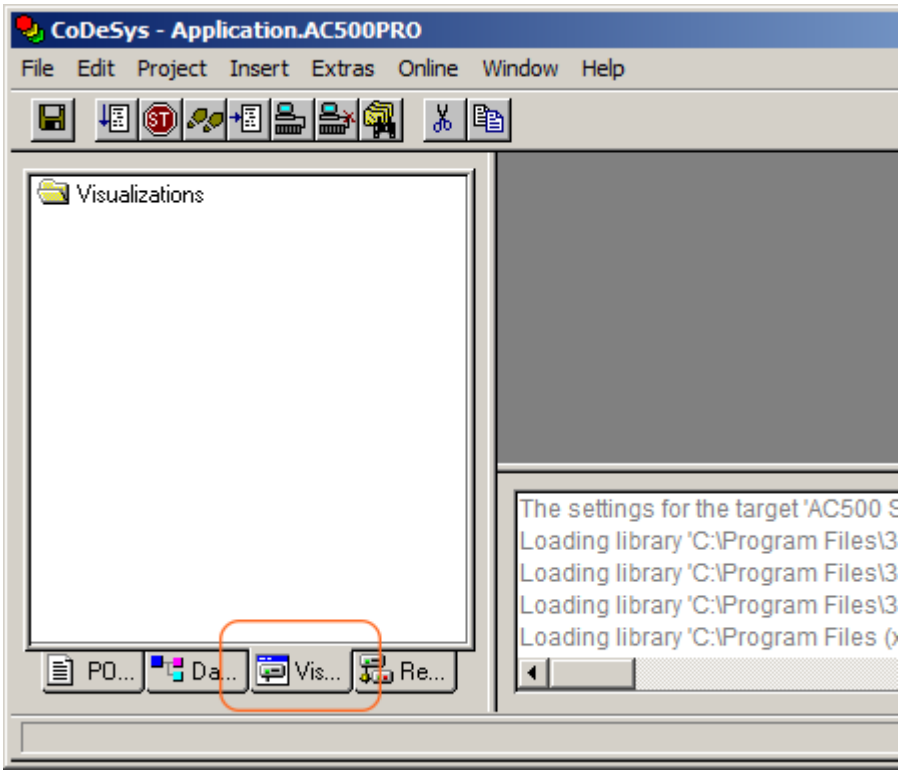
Program visualization

The visualization allows designing a graphical representation of project variables. In online mode, the graphical elements can change, for example, their color, size or position according to the actual variable status.

☑ Preconditions:

☑ The AC500-eCo CPU is disconnected. In the status bar, ONLINE is gray colored
↳ *Chapter 1.6.1.10.2.3 "Testing your project without connecting the hardware" on page 3762*.

1. Select the **Visualizations** register card.



2. **Insert a new Visualization Object.**

   From the **Project** menu, select *"Object ➔ Add"*.
