INSTRUCTIONS FOR USE

PLC Automation

Automation Builder, AC500

Automation Builder 2.5.0, AC500 V2, AC500-eCo V2, AC500-XC V2

Table of contents

1 PLC Automation with V2 CPUs

1.1 About this document

1.1.1 Documentation structure

Chapter 1.1.4 “Use the "magic button" to display your current position in the table of contents” on page 12.

See also chapter " Your tasks - documentation from the user's point of view" on page 10.

Table 1: Guidance for this documentation: Main chapters

Getting started Basic information to start with Automation Builder and AC500 PLC, e.g., licensing, GUI explanations, example projects.	*Chapter 1.2 “Getting started” on page 12*
Automation Builder installation manager Add, remove or modify software packages in Automation Builder.	*Chapter 1.3 “Automation Builder installation manager” on page 138*
Programming with CODESYS Information about IEC programming in Automation Builder, including description of CODESYS libraries.	*Chapter 1.4 “Programming with CODESYS” on page 145*
Libraries and solutions ABB libraries. Overview and description of integrated standard libraries and solution libraries available as library packages. Explanation of the concept of solution libraries ("system technology"). Description of the library elements, like function blocks and functions.	*AC500 V3 library descriptions: Chapter 1.5 " Libraries and solutions" on page 735*
PLC integration (hardware) Hardware description and specifications. Overview on module variants, connections, technical data, order data, assembly of modules. Device configuration in Automation Builder. Explanation of system behavior ("system technology"), interaction between PLC behavior (firmware), configuration, programming and use cases.	*Chapter 1.6 “PLC integration (hardware)” on page 3697*
Diagnosis and debugging Explanation of the diagnosis system in the PLC, the display of error messages at the CPU and in IEC applications. Online diagnosis in Automation Builder. List of diagnosis and error messages.	*Chapter 1.7 “Diagnosis and debugging for AC500 V2 products” on page 6365*
Engineering interfaces and tools Information on add-on packages, e.g., for security static analysis or Project Version Control. Mainly for advanced users.	*Chapter 1.8 “Engineering interfaces and tools” on page 6550*
Human machine interface (HMI) Information on HMI with Automation Builder. Configuration of HMI devices in Automation Builder.	*Chapter 1.9 “Human machine interface” on page 6628*
Contact ABB Contact information about our sales and support teams.	*Chapter 1.10 “Contact ABB” on page 6640*

1.1.2 Your tasks - documentation from the user's point of view

All information about **AC500**, **AC500-XC** and **AC500-eCo** is available in this manual.

All information about **AC500-S** and **AC500-S-XC** is available online in the *safety user manual*.

1.1.4 Use the "magic button" to display your current position in the table of contents

☑ Documentation is opened in a PDF reader. PDF readers often provide a button to synchronize with the table of contents. Usually, you can find the "magic button" in the bookmarks tab. For example, it looks like this: /

▷ Select the "magic button".

⇨ Your current position will be highlighted in the bookmark tab.

1.2 Getting started

ABB Automation Builder - One holistic suite

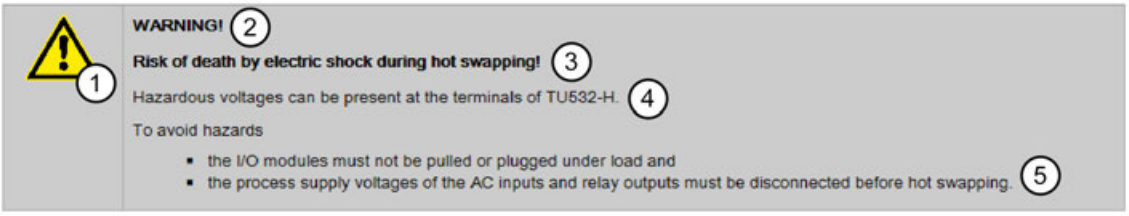
ABB Automation Builder is the integrated software suite for machine builders and system integrators wanting to automate their machines and systems in a productive way. Combining the tools required for configuring, programming, debugging and maintaining automation projects from a common intuitive interface, Automation Builder addresses the largest single cost element of most of today's industrial automation projects: software. ABB Automation Builder covers the engineering of ABB PLCs, Safety PLCs, control panels, drives, motion and robots.

Automation Builder ReadMe

Before starting Automation Builder configuration read the version specific information provided in the Automation Builder readme file. It describes new features and functions as well as workarounds on known problems. The readme file is stored in the installation directory of Automation Builder, however can be downloaded as well from ABB website http://new.abb.com/plc/automationbuilder.

1.2.1 Safety notice

Throughout the documentation we use the following types of safety and information notices according to ANSI Z535 make you aware of safety considerations or advice on AC500 products usage.



1 **Safety alert symbol** indicates the danger.
2 **Signal word** classifies the danger.
3 **Type and source of the risk** are mentioned.
4 **Possible consequences** of the risk are described.
5 **Measures to avoid these consequences** (enumerations).

Signal words

DANGER!
DANGER indicates a hazardous situation which, if not avoided, will result in death or serious injury.

Ensure to take measures to prevent the described impending danger.

WARNING!
WARNING indicates a hazardous situation which, if not avoided, could result in death or serious injury.

Ensure to take measures to prevent the described dangerous situation.

CAUTION!
CAUTION indicates a hazardous situation which, if not avoided, could result in minor or moderate injury.

Ensure to take measures to prevent the described dangerous situation.

NOTICE!
NOTICE is used to address practices not related to physical injury but might lead to property damage for example damage of the product.

Ensure to take measures to prevent the described dangerous situation.

NOTE provides additional information on the product, e.g. advices for configuration or best practice scenarios.

1.2.2 Cyber security

Cyber security disclaimer

This product is designed to be connected to and to communicate information and data via a network interface. It is your sole responsibility to provide and continuously ensure a secure connection between the product and your network or any other network (as the case may be). You shall establish and maintain any appropriate measures (such as but not limited to the installation of firewalls, application of authentication measures, encryption of data, installation of anti-virus programs, etc.) to protect the product, the network, its system and the interface against any kind of security breaches, unauthorized access, interference, intrusion, leakage and/or theft of data or information. ABB Ltd and its affiliates are not liable for damages and/or losses related to such security breaches, any unauthorized access, interference, intrusion, leakage and/or theft of data or information.

Although ABB provides functionality testing on the products and updates that we release, you should institute your own testing program for any product updates or other major system updates (to include but not limited to code changes, configuration file changes, third party software updates or patches, hardware exchanges, etc.) to ensure that the security measures that you have implemented have not been compromised and system functionality in your environment is as expected. This also applies to the operating system. Security measures (such as but not limited to the installation of latest patches, installation of firewalls, application of authentication measures, installation of anti-virus programs, etc.) are in your responsibility. You have to be aware that operating systems provide a considerable number of open ports that should be monitored carefully for any threats.

It has to be considered that online connections to any devices are not secured. It is your responsibility to assure that connections are established to the correct device (and e.g. not to an unknown device pretending to be a known device type). Furthermore you have to take care that confidential data exchanged with the PLC is either compiled or encrypted.

Security related deployment guidelines for industrial automation

Security details for industrial automation is provided in a *whitepaper* on ABB website.

Secure communication

Whenever possible, use an encrypted communication between AC500 V3 devices and third party devices, such as HMI devices. This is necessary to protect passwords and other data.

Frequently asked questions

For more information around cyber security please see our *FAQ*.

1.2.2.1 Defense in depth

The defense in depth approach implements multi-layer IT security measures. Each layer provides its special security measures. All deployed security mechanisms in the system must be updated regularly. It is also important to follow the system vendor’s recommendations on how to configure and use these mechanisms. As a basis, the components must include security functions such as:

- Virus protection
- Firewall protection
- Strong and regularly changed passwords
- User management
- Using VPN tunnels for connections between networks

Additional security components such as routers and switches with integrated firewalls should be available. A defined user and rights concept managing access to the controllers and their networks is mandatory. Finally, the manufacturer of the components should be able to quickly discover weaknesses and provide patches.

> *Only used services/ports should be enabled (e.g. to enable the functionality of an FTPS server).*

References: *CODESYS Security Whitepaper*

Security zones

IT resources vary in the extent to which they can be trusted. A common security architecture is therefore based on a layered approach that uses zones of trust to provide increasing levels of security according to increasing security needs. Less-trusted zones contain more-trusted zones and connections between the zones are only possible through secure interconnections such as firewallsFig. 1. All resources in the same zone must have the same minimum level of trust. The inner layers, where communication interaction needs to flow freely between nodes, must have the highest level of trust. This is the approach described in the IEC 62443 series of standards.

Firewalls, gateways, and proxies are used to control network traffic between zones of different security levels, and to filter out any undesirable or dangerous material. Traffic that is allowed to pass between zones should be limited to what is absolutely necessary because each type of service call or information exchange translates into a possible route that an intruder may be able to exploit. Different types of services represent different risks. Internet access, incoming e-mail and instant messaging, for example, represent very high risks.

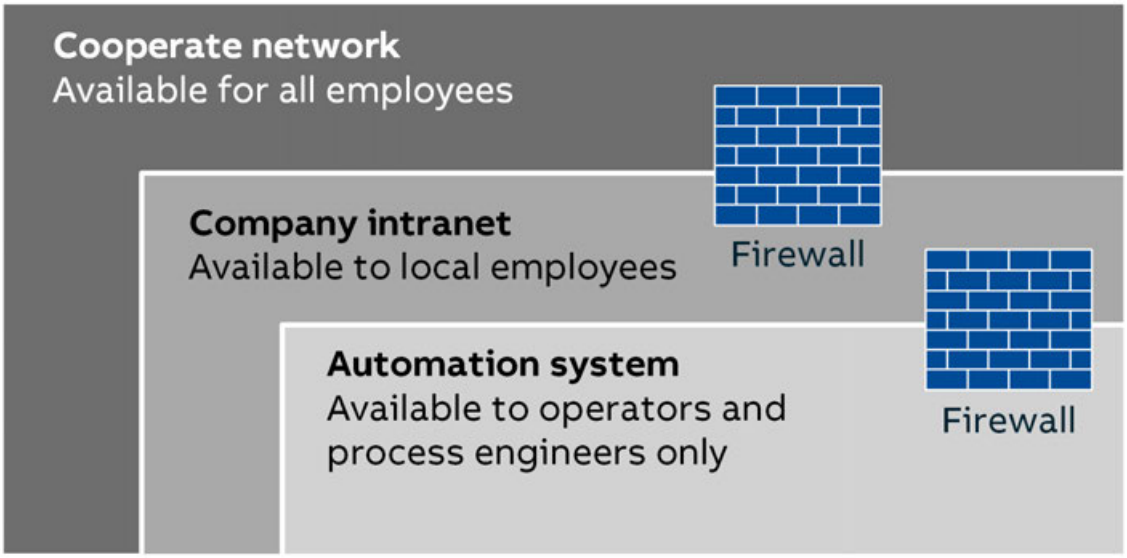


Fig. 1: Security zones

Fig. 1 shows three security zones, but the number of zones does not have to be as many or as few as three. The use of multiple zones allows access between zones of different trust levels to be controlled to protect a trusted resource from attack by a less trusted one.

High-security zones should be kept small and independent. They need to be physically protected, i.e. physical access to computers, network equipment and network cables must be limited by physical means to authorized persons only. A high-security zone should obviously not depend on resources in a less secure zone for its security. Therefore, it should form its own domain that is administered from the inside, and not depend on, e.g., a domain controller in a less secure network.

Even if a network zone is regarded as trusted, an attack is still possible: by a user or compromised resource that is inside the trusted zone, or by an outside user or resource that succeeds to penetrate the secure interconnection. Trust therefore depends also upon the types of measures taken to detect and prevent compromise of resources and violation of the security policy.

References: *Security for Industrial Automation and Control Systems*

1.2.2.2 Secure operation

The controller must be located in a protected environment in order to avoid accidental or intended access to the controller or the application.

A protected environment can be:

- Locked control cabinets without connection from outside
- No direct internet connection
- Use firewalls and VPN to separate different networks
- Separate different production areas with different access controls

To increase security, physical access protection measures such as fences, turnstiles, cameras or card readers can be added.

Follow these rules for the protected environment:

- Keep the trusted network as small as possible and independent from other networks.
- Protect the cross-communication of controllers and the communication between controllers and field devices via standard communication protocols (fieldbus systems) using appropriate measures.
- Protect such networks from unauthorized physical access.
- Use fieldbus systems only in protected environments. They are not protected by additional measures, such as encryption. Open physical or data access to fieldbus systems and their components is a serious security risk.
- Physically protect all equipment, i.e., ensure that physical access to computers, network equipment and cables, controllers, I/O systems, power supplies, etc., is limited to authorized persons
- When connecting a trusted network zone to outer networks, make sure that all connections are through properly configured secure interconnections only, such as a firewall or a system of firewalls, which is configured for “deny by default”, i.e., blocks everything except traffic that is explicitly needed to fulfill operational requirements.
- Allow only authorized users to log on to the system, and enforce strong passwords that are changed regularly.
- Continuously maintain the definitions of authorized users, user groups, and access rights, to properly reflect the current authorities and responsibilities of all individuals at all times. Users should not have more privileges than they need to do their job.
- Do not use the system for e-mail, instant messaging, or internet browsing. Use separate computers and networks for these functions if they are needed.
- Do not allow installation of any unauthorized software in the system.
- Restrict temporary connection of portable computers, USB memory sticks and other removable data carriers. Computers that can be physically accessed by regular users should have ports for removable data carriers disabled.
- If portable computers need to be connected, e.g., for service or maintenance purposes, they should be carefully scanned for viruses immediately before connection.
- All CDs, DVDs, USB memory sticks and other removable data carriers, and files with software or software updates, should also be checked for viruses before being introduced into the trusted zone.
- Continuously monitor the system for intrusion attempts.
- Define and maintain plans for incident response, including how to recover from potential disasters.
- Regularly review the organization as well as technical systems and installations with respect to compliance with security policies, procedures and practices.

A protected local control cabinet could look like in figure 2, page 17. This network is not connected to any external network. Security is primarily a matter of physically protecting the automation system and preventing unauthorized users from accessing the system and from connecting or installing unauthorized hardware and software.

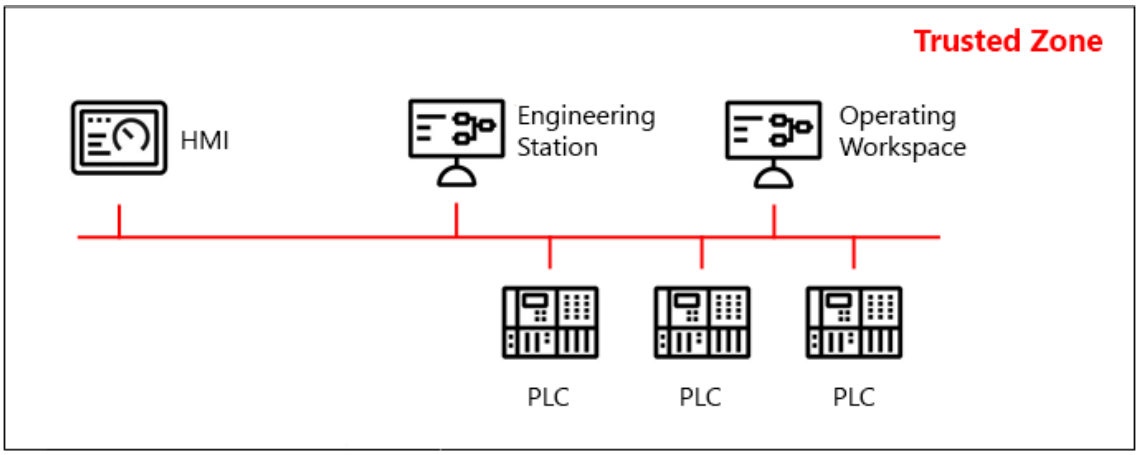

Fig. 2: Isolated automation system

Servers and workplaces that are not directly involved in the control and monitoring of the process should preferably be connected to a subnet that is separated from the automation system network by means of a router/firewall. This makes it possible to better control the network load and to limit access to certain servers on the automation system network. Note that servers and workplaces on this subnet are part of the trusted zone and thus need to be subject to the same security precautions as the nodes on the automation system network.

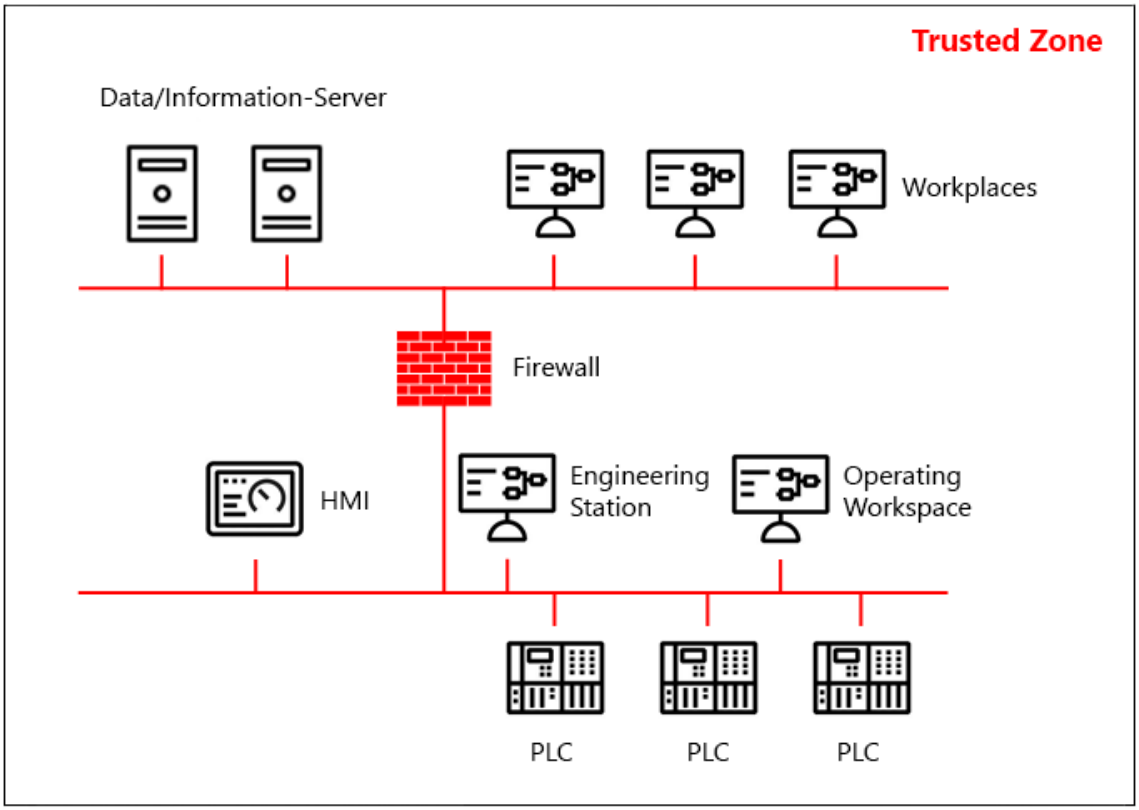

Fig. 3: Plant information network connected to an automation system

For the purposes of process control security, a general-purpose information system (IS) network should not be considered a trusted network, not the least since such networks are normally further connected to the Internet or other external networks. The IS network is therefore a different lower-security zone, and it should be separated from the automation system by means of a firewall. The IS and automation system networks should form separate domains.

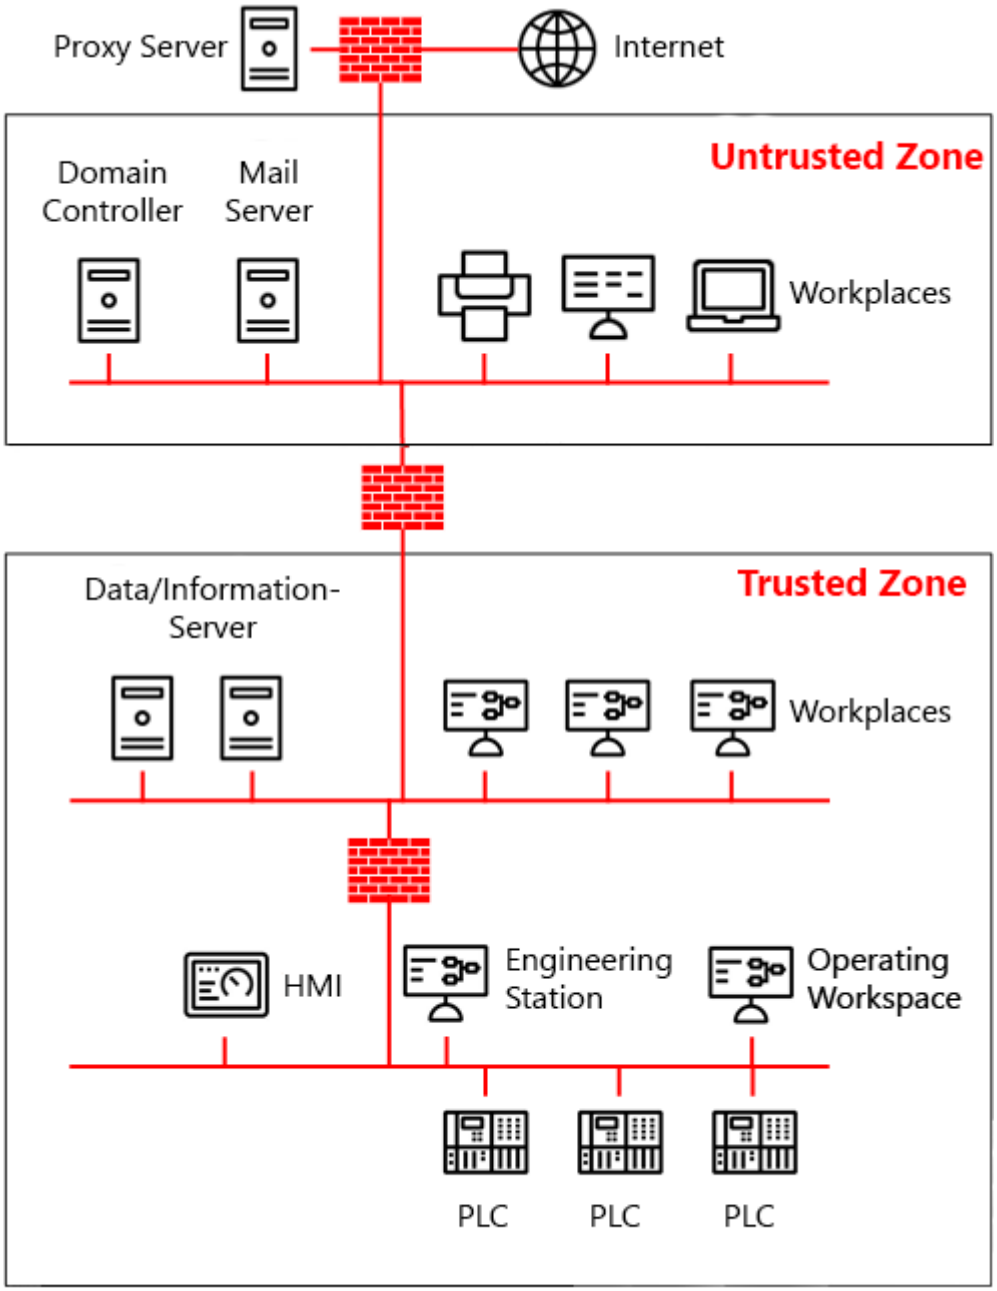

Fig. 4: Automation system and IS network

1.2.2.3 Hardening

System hardening means to eliminate as many security risks as possible. Hardening your system is an important step to protect your personal data and information. This process intends to eliminate attacks by patching vulnerabilities and turning off inessential services. Hardening a system involves several steps to form layers of protection.

Commissioning phase

- Protect the hardware from unauthorized access
- Be sure the hardware is based on a secure environment
- Disable unused software and services (network ports)
- Install firewalls
- Disallow file sharing among programs
- Install virus and spyware protection

- Use containers or virtual machines
- Create strong passwords by applying a strong password policy
- Create and keep backups
- Use encryption when possible
- Disable weak encryption algorithms
- Separate data and programs
- Enable and use disk quotas
- Strong logical access control
- Adjust default settings, especially passwords

Verification phase

- Verification of antivirus - Check antivirus is active and updated
- Verification of the identification - Check that test and unauthorized accounts are removed
- Verification of intrusion detection systems - Check malicious traffic is blocked
- Verification of audit logging - Check audit log is enabled
- You can use the checklist out of the *cyber security white paper*

Operation phase

- Keep software up-to-date, especially by applying security patches
- Keep antivirus up and running
- Keep antivirus definitions up-to-date
- Delete unused user accounts
- Lock an active session whenever it is unattended, e.g., lock the screen of the PC or of the control panel (HMI)

Decommissioning phase

- Delete all credentials stored in the device like certificates and user data *Chapter 1.6.3.4.6 “Decommissioning” on page 5233*.

References: *Hardening in Wikipedia (2021)*

1.2.2.4 Open Ports and Services

Overview of minimum cyber security requirements for open ports and services settings.

Port	Protocol	Description
1217	TCP	CODESYS Gateway V3
1210	TCP	CODESYS Gateway V2
1211	TCP	CODESYS Gateway V2
22350	TCP/UDP	CodeMeter License Server (runtime) – license
22352	HTTP	CodeMeter License Server (runtime) – WebAdmin
22353	HTTPS	CodeMeter License Server (runtime) – WebAdmin
11030	HTTP	Python editor server

1.2.3 Automation Builder update notification

A notification dialog will be shown if there are any updates available for the currently installed version on every launch of the Automation Builder.

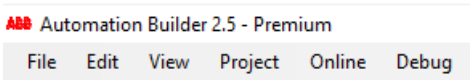
Chapter 1.3.3 “Automation Builder update notification” on page 141

1.2.4 Managing your licenses

After installing and licensing the Automation Builder you can manage your licenses in various ways.

1.2.4.1 Identifying the installed license

Since Automation Builder Version 1.1.1 the title bar or Automation Builder shows a license information:



Be aware of the following rule for this information:

The info in the menubar is taken in this order from the first found license

- local licenses (on PC)
- on dongle (USB key)
- network licenses (since AB1.2)

So if a local license is only basic and a dongle with premium is inserted:

- the information in the menubar is basic
- the functionality is premium (the highest available)

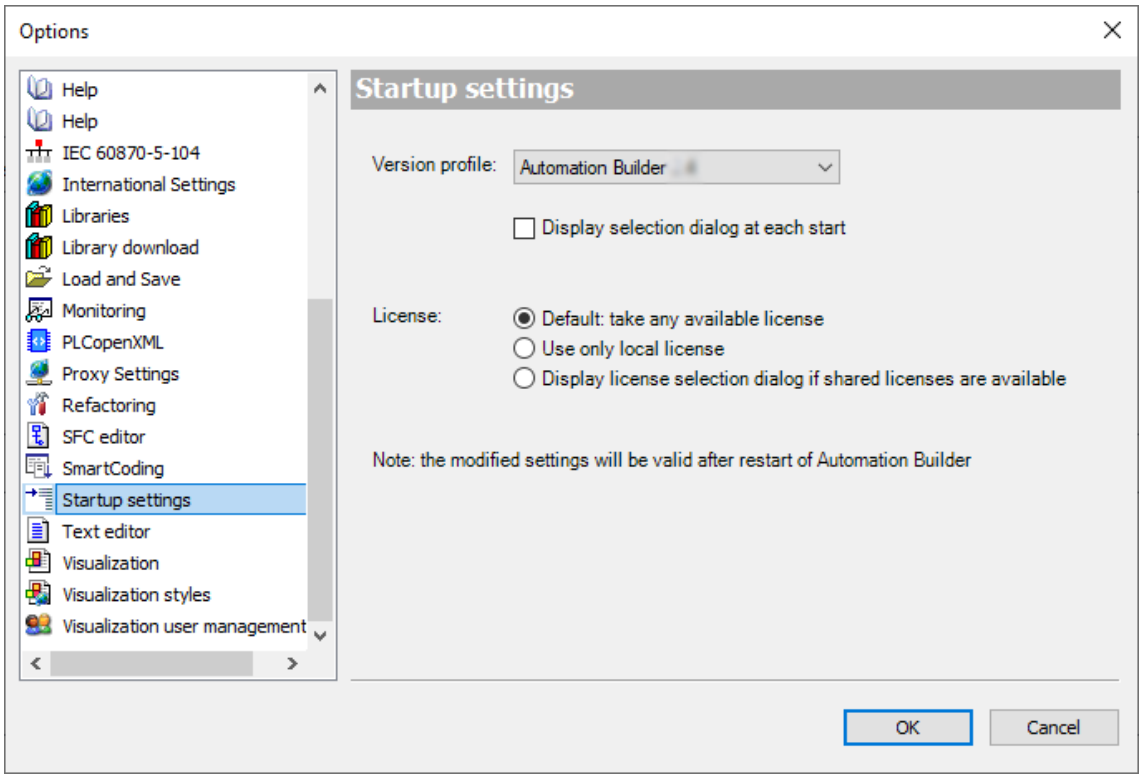
To check your installed licenses, the CodeMeter Control Center tool can be used ↳ *Chapter 1.2.4.3 “Checking licenses with CodeMeter control center” on page 22*.

1.2.4.2 Selecting the license used on Automation Builder startup

You can select, which license the Automation Builder should use on startup.

To select which license should be used:

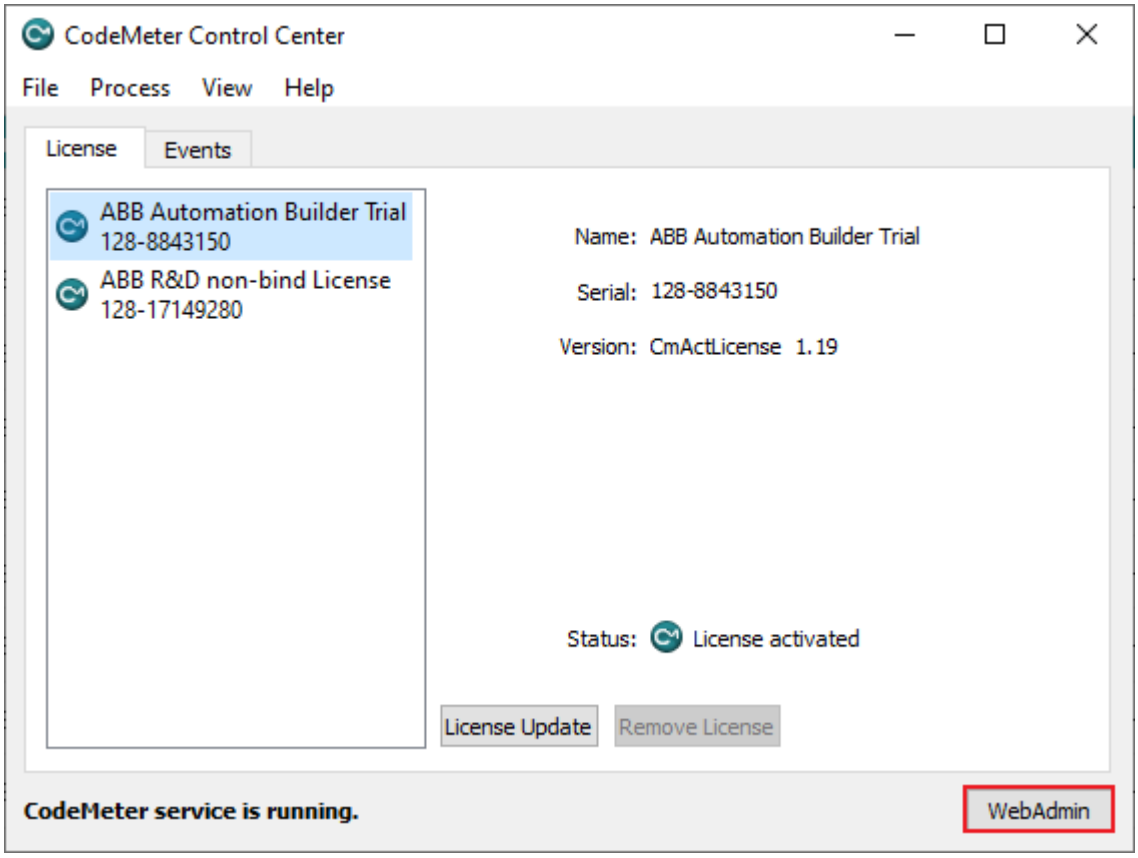
1. In the Automation Builder menu select *“Tools ➔ Options”*.
   ⇨ The Options window is opened.
2. In *“Startup settings”* under *“License”* select which license should be used.
   - Default: The most comprehensive available license will be selected
   - Use only local license: Network licenses will never be selected
   - Display licenses selection dialog if shared licenses are available: On every Automation Builder startup, you will be asked to select a license



3. To apply the setting select *“OK”*.

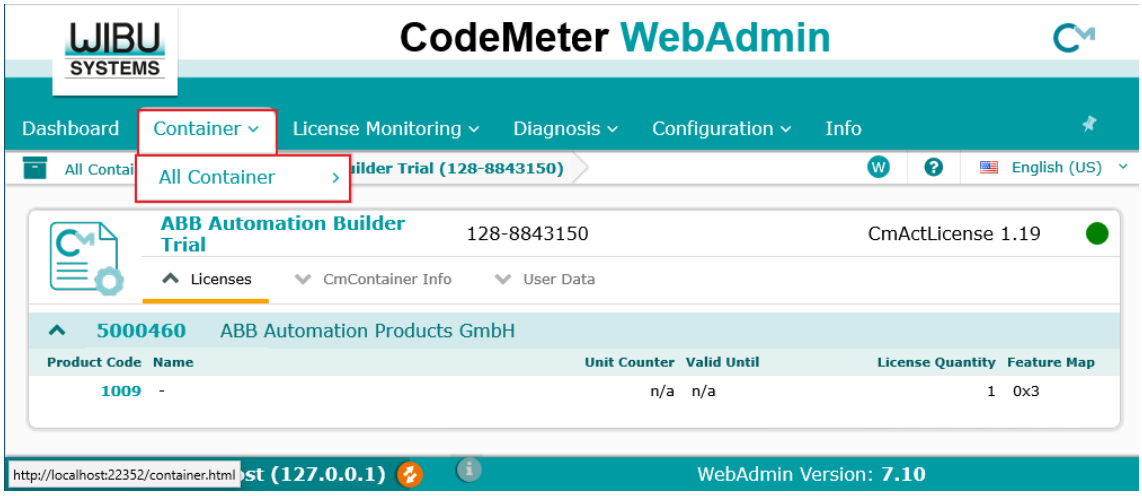
1.2.4.3 Checking licenses with CodeMeter control center

1. Open the CodeMeter Control Center via the *“Windows start menu ➔ CodeMeter ➔ CodeMeter Control Center”*.



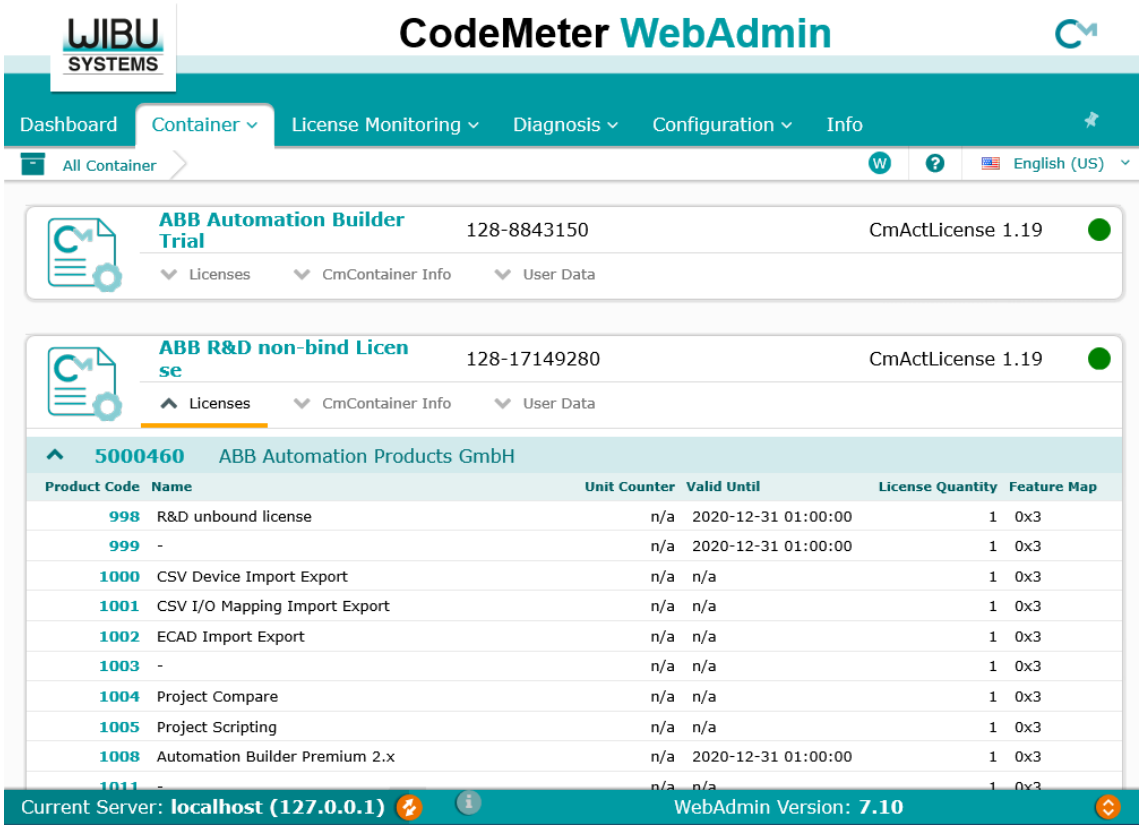
2. In the CodeMeter Control Center window you can see the different license “tickets” / “CmContainers” that are installed on your PC.

   To see more details, open the CodeMeter WebAdmin by selecting *“WebAdmin”*



3. Select *“Container ➔ All Container”*

   ⇨ Here the details of the license containers can be checked.

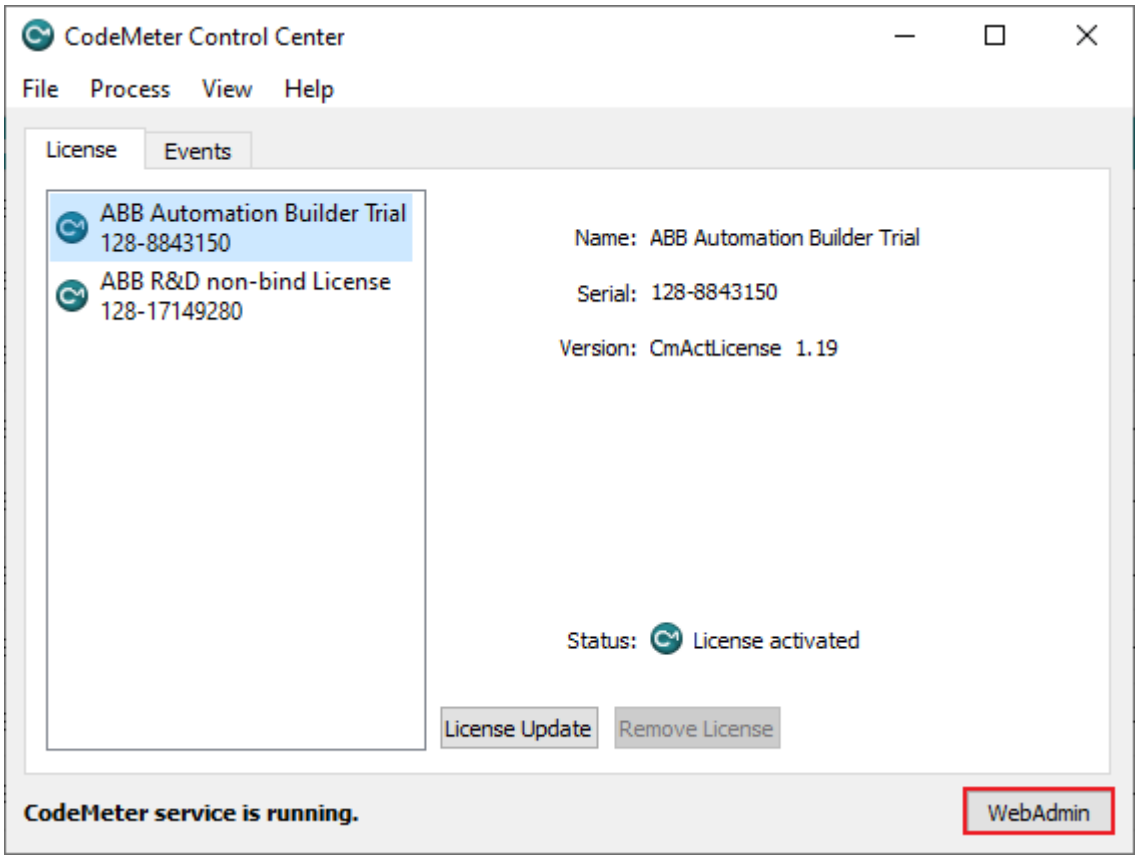


1.2.4.4 Setting dedicated network servers in search list

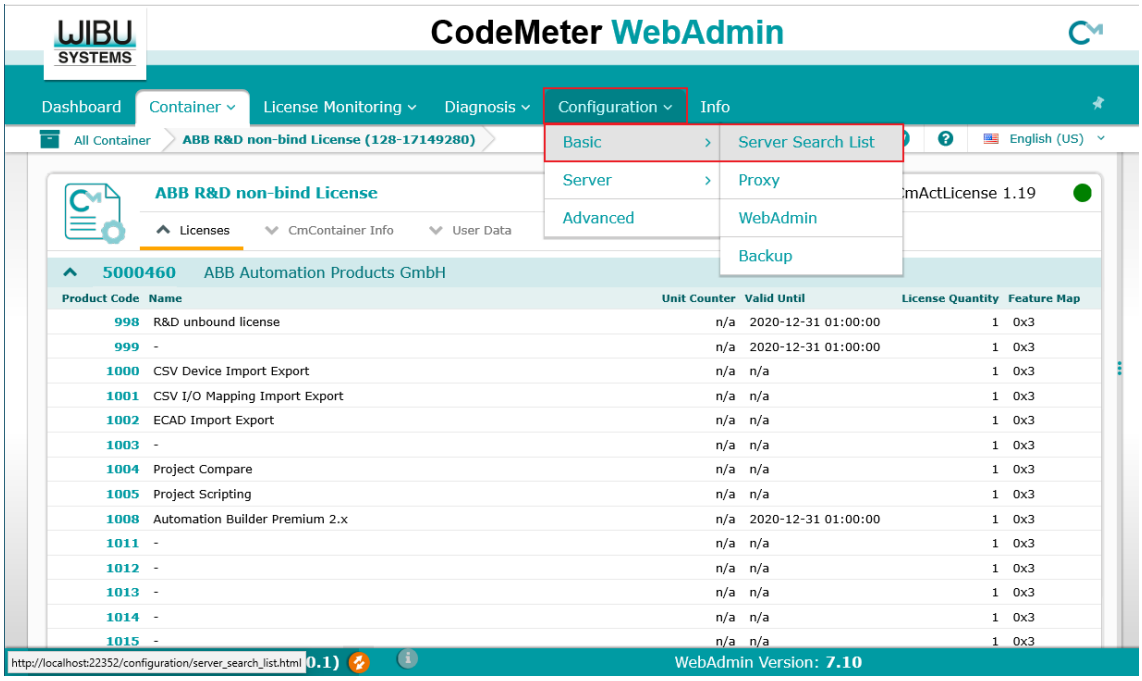
In case of a new installation CodeMeter will check for licenses also in the network. If there is a run-out or wrongly installed license found, the service is closed without any further hint. This looks like Automation Builder starts and closes after a few moments.

To set the search for licenses to your local machine only follow these steps:

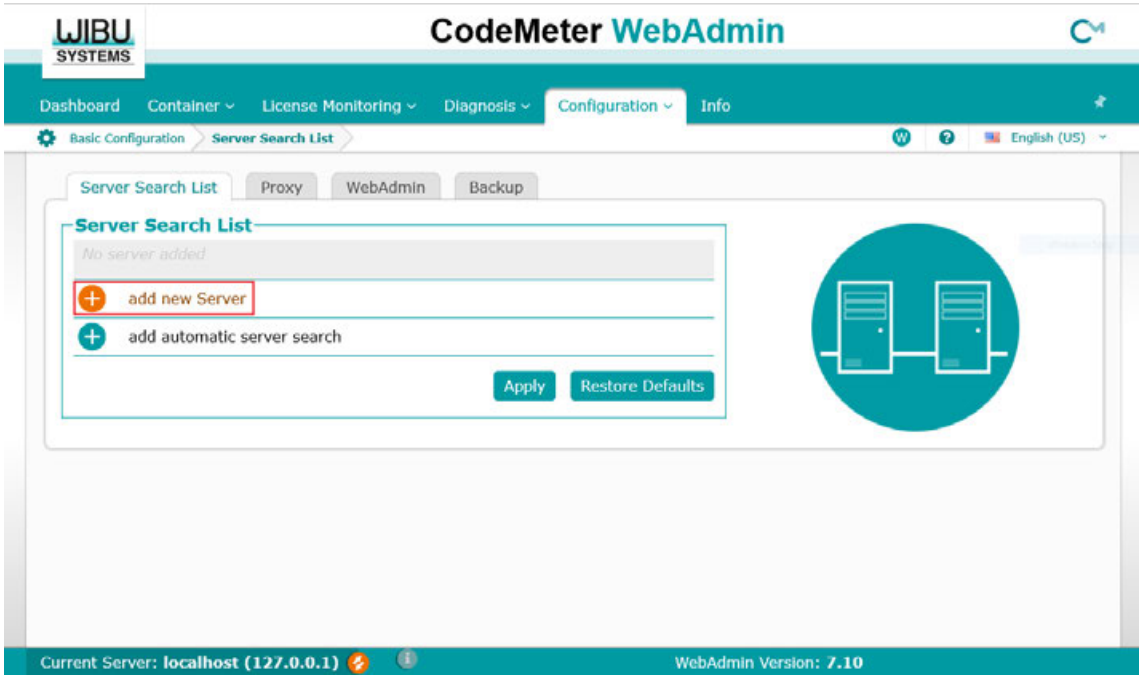
1. Open the CodeMeter Control Center. See ↳ *Chapter 1.2.4.3 “Checking licenses with CodeMeter control center” on page 22*
2. Open the CodeMeter WebAdmin by selecting *“WebAdmin”*



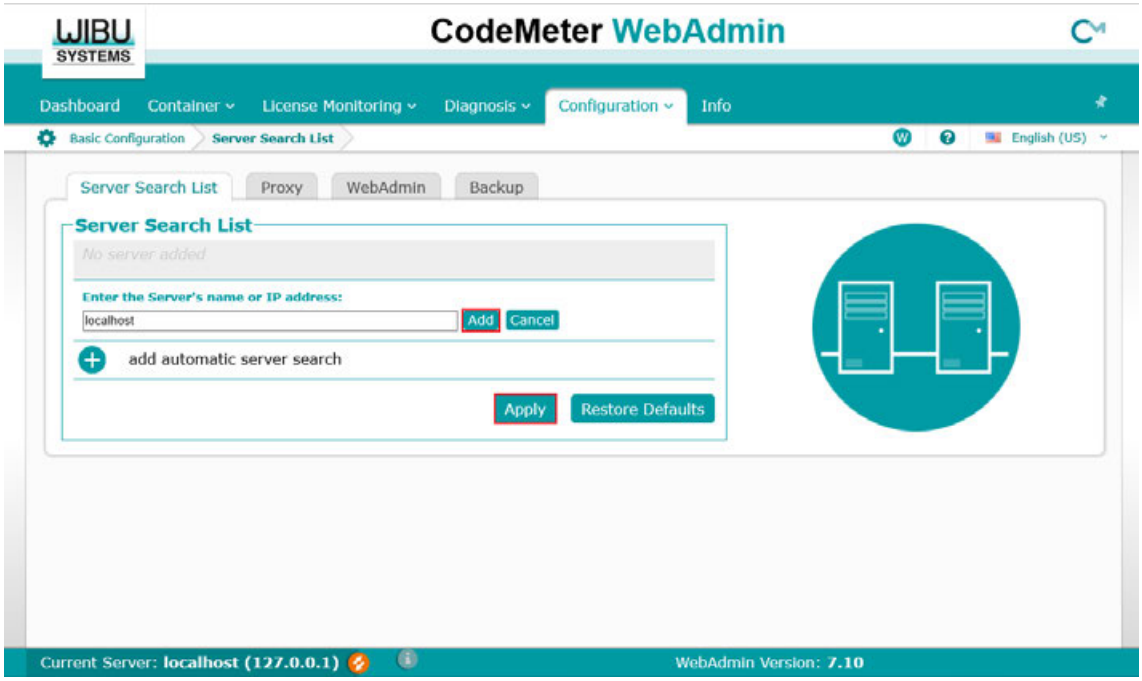
3. Select *"Configuration ➔ Basic ➔ Server Search List"*



4. Select *"add new Server"*



5. Enter "localhost" in the Server's names field
6. Select *“Add”*
7. Confirm by selecting *“Apply”*
   ⇨ The "localhost" is added to the Server Search List

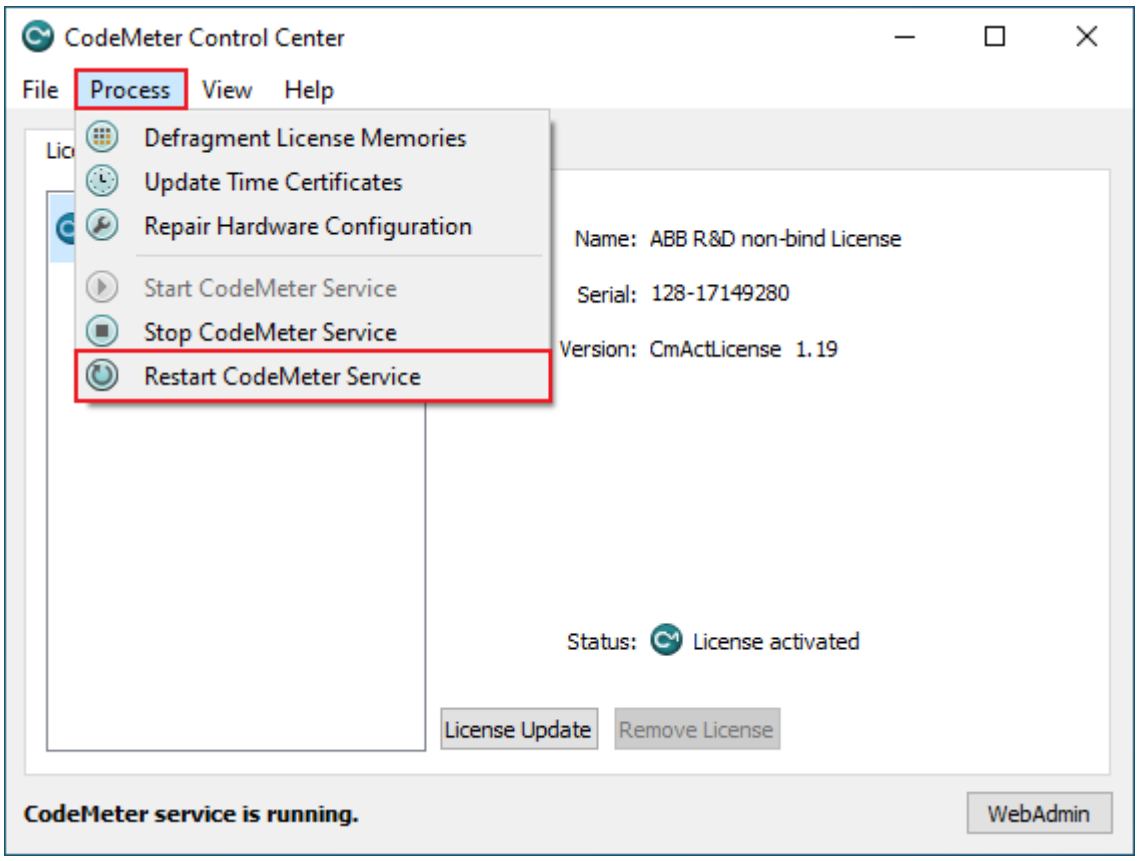


8. Restart the license check
9. Add more servers to the search list by entering the IP-Adress or name of the license servers you know.

1.2.4.5 Restarting license check with a dongle bound license

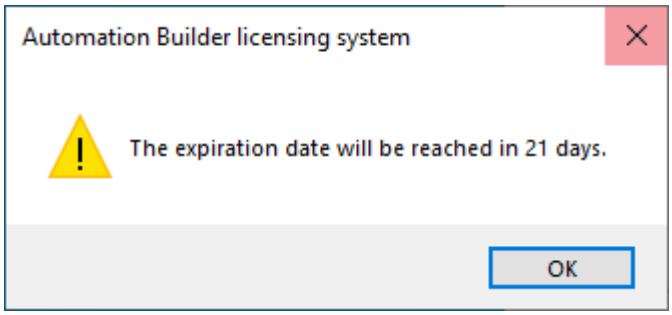
In case of using a dongle bound license it might be necessary to restart the check for license on the PC, e.g. if the dongle was removed and reinserted.

1. Open the CodeMeter Control Center. See *Chapter 1.2.4.3 “Checking licenses with CodeMeter control center” on page 22*
2. Select *“Process ➔ Restart CodeMeter Service”*



1.2.4.6 Removing trial license to remove expiring message

If an unlimited license is installed after having a trial license activated, the warning message for expiring date of the trial license still pops up at the Startup of the Automation Builder.

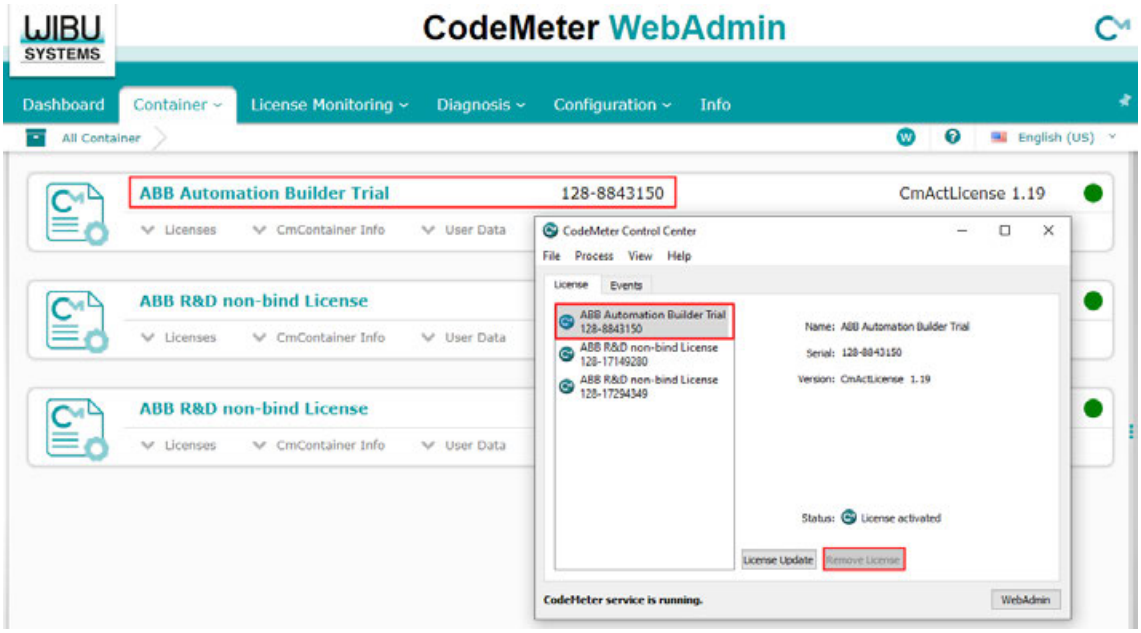


To avoid this message the trial license can be removed.

CAUTION!

- If you remove a license from your PC it will be permanently lost.
- Be aware that the trial license includes all premium functionalities, which will not be available any more if your unlimited license is not a premium license, e.g. standard.

1. Check for the Trial CmContainer number in CodeMeter WebAdmin InterfaceCheck for the Trial CmContainer number in CodeMeter WebAdmin Interface
2. Search CmContainer number in CodeMeter Control Center



3. Remove this selected license in CodeMeter Control Center

1.2.4.7 Network licenses

Starting from Automation Builder 1.2.0 network licenses can be used with Automation Builder.

This allows sharing of licenses between team members, easy switchover between several workstations with a single license and allows centralized administration (ordering, registration, activation).

The Automation Builder License Manager and CodeMeter need to be used to configure the Network server.

- *In a typical office LAN (Local Area Network) setup on Client side the default settings of the Automation Builder (and CodeMeter) are sufficient to get the Network Licenses working.*
- *If an opened Automation Builder is loosing contact to the network server (e.g. due to network problems) Automation Builder will prompt the user to restore the network. After 30 minutes without connection to the network server Automation Builder will fall back to basic edition. Opened editors for non-basic features stay open and usable. So your work will not be lost in case of troubles with the network.*

1.2.4.7.1 Setting up a network license

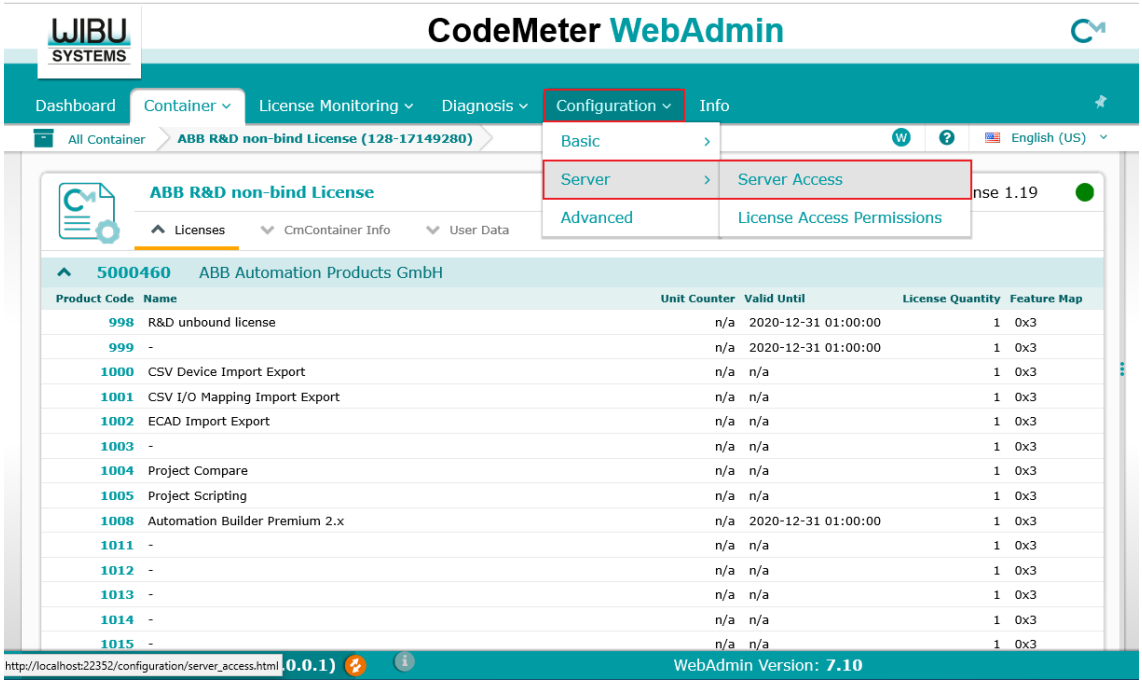
The following setup works in typical environments.

Configuring a network license server

☑ Network license must be registered.

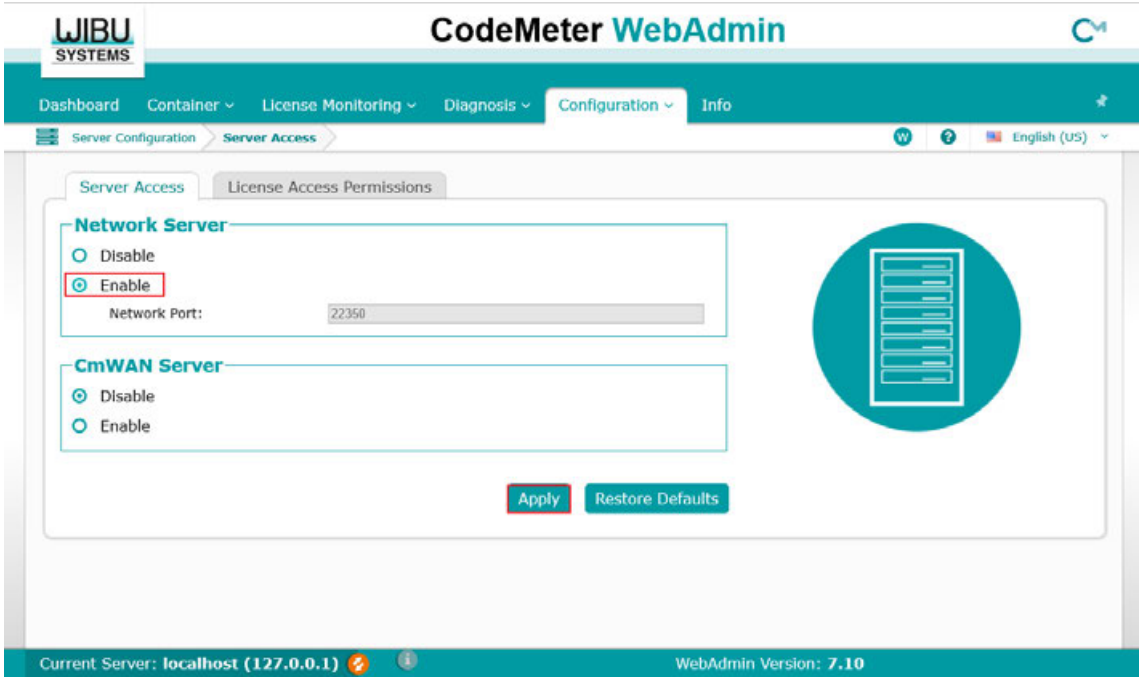
☑ Automation Builder license must be activated.

1. Launch CodeMeter WebAdmin as described in *Chapter 1.2.4 "Managing your licenses" on page 20*
2. Select *"Configuration ➔ Server ➔ Server Access"*



3. Enable Network Server

   Keep the default port settings. These should work in most cases.
4. Select *"Apply"*



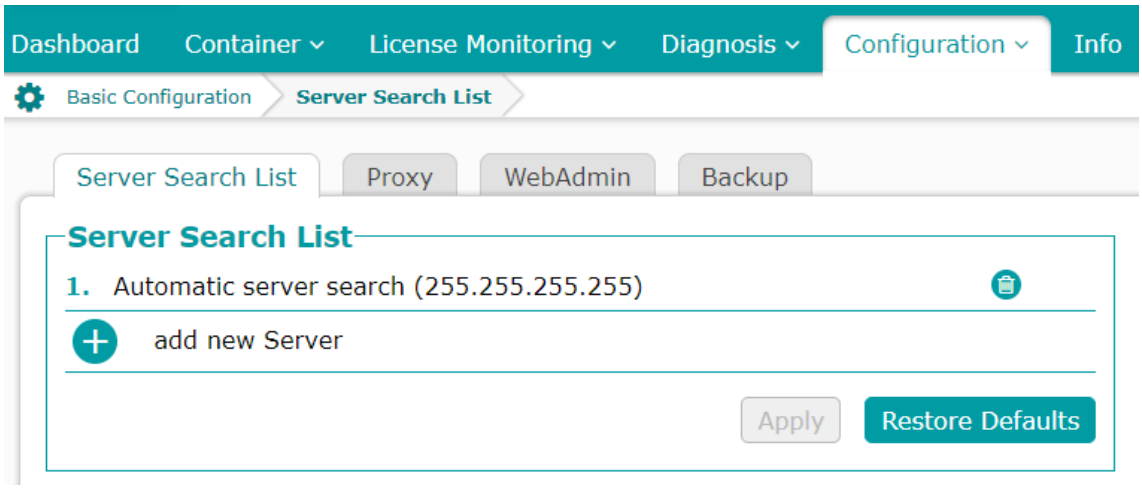
5. For the changes to take effect, restart CodeMeter Control Center see *Chapter 1.2.4.5 "Restarting license check with a dongle bound license" on page 25*

NOTICE!

– In case you want to control usage of network licenses please refer to
↳ *Chapter 1.2.4.7.3 “View network server license usage” on page 30*
– Activation keys for network licenses are valid for one network license each. This one license can be shared among many people but only one Automation Builder instance at the same time. If you want to run more than one Automation Builder instance at the same time you have to activate more than one network license. This means you have to purchase and enter more than one activation key (one per license).

Configuring the client side

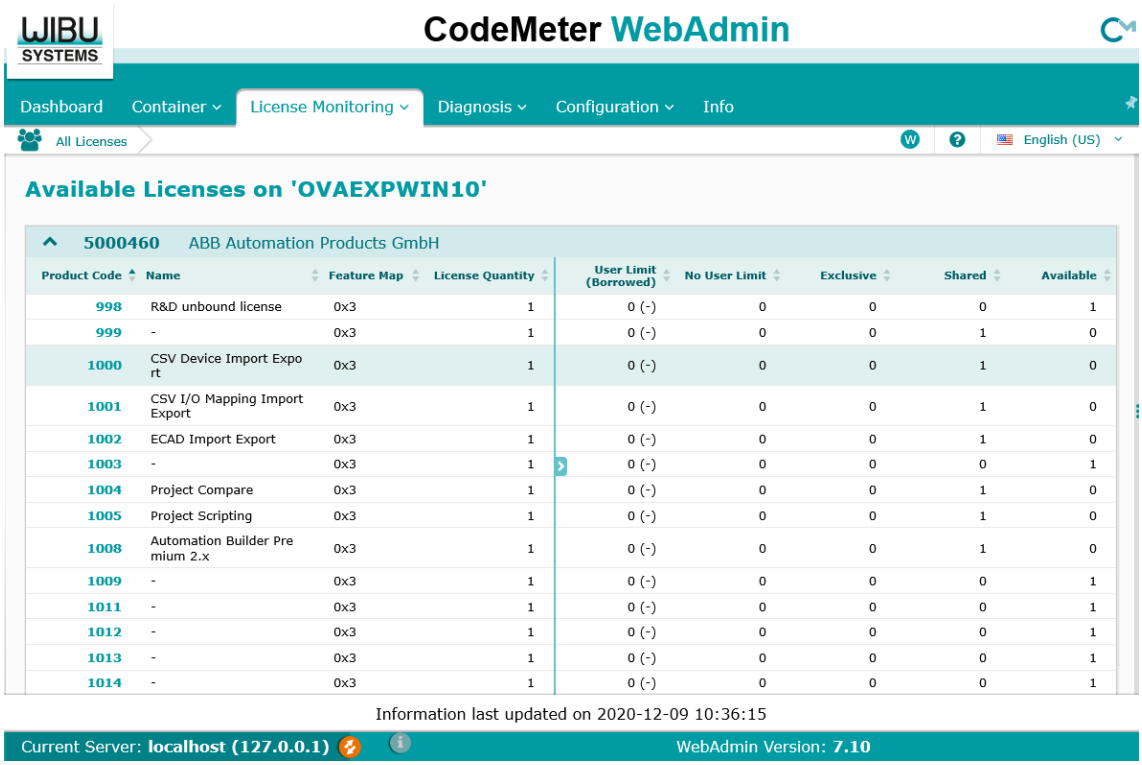
The default settings of Automation Builder and the CodeMeter (on client side) are sufficient in most cases to get the network licenses working. In case of problems accessing the network license, please set the server search list on the client side.



1.2.4.7.2 View network server licenses

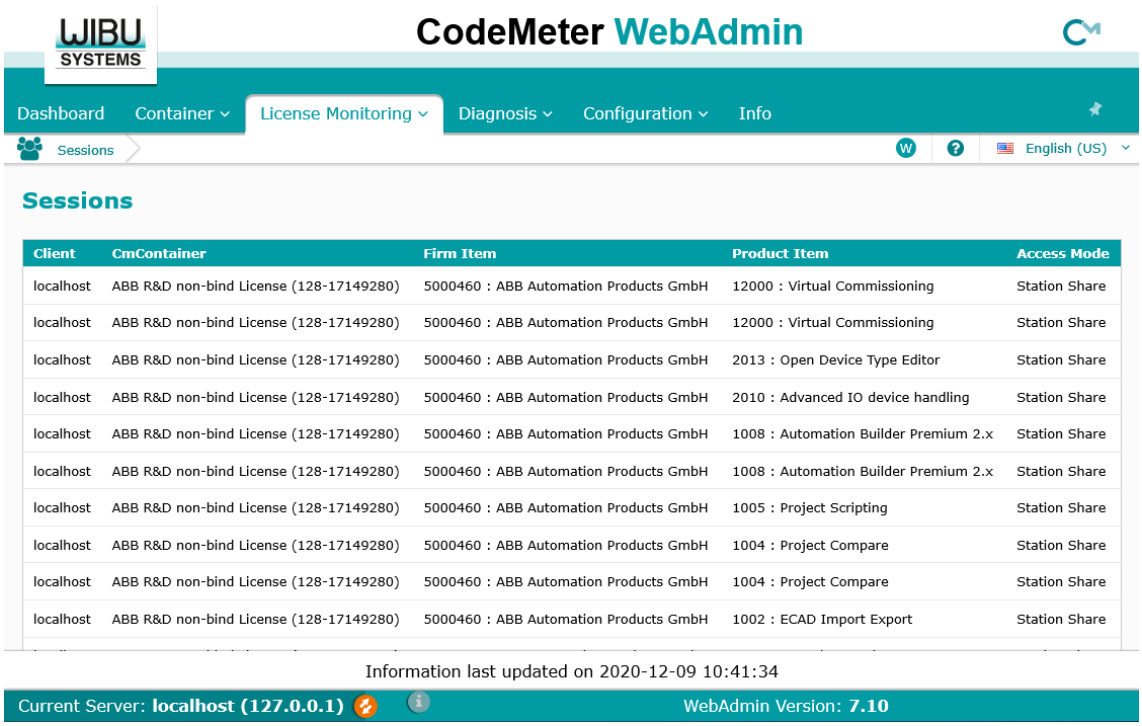
On the Network Server side you can find information on existing network licenses and their current allocation.

1. Launch CodeMeter WebAdmin. See ↳ *Chapter 1.2.4.3 "Checking licenses with CodeMeter control center" on page 22*
2. Select *"License Monitoring ➔ All Licenses "*



1.2.4.7.3 View network server license usage

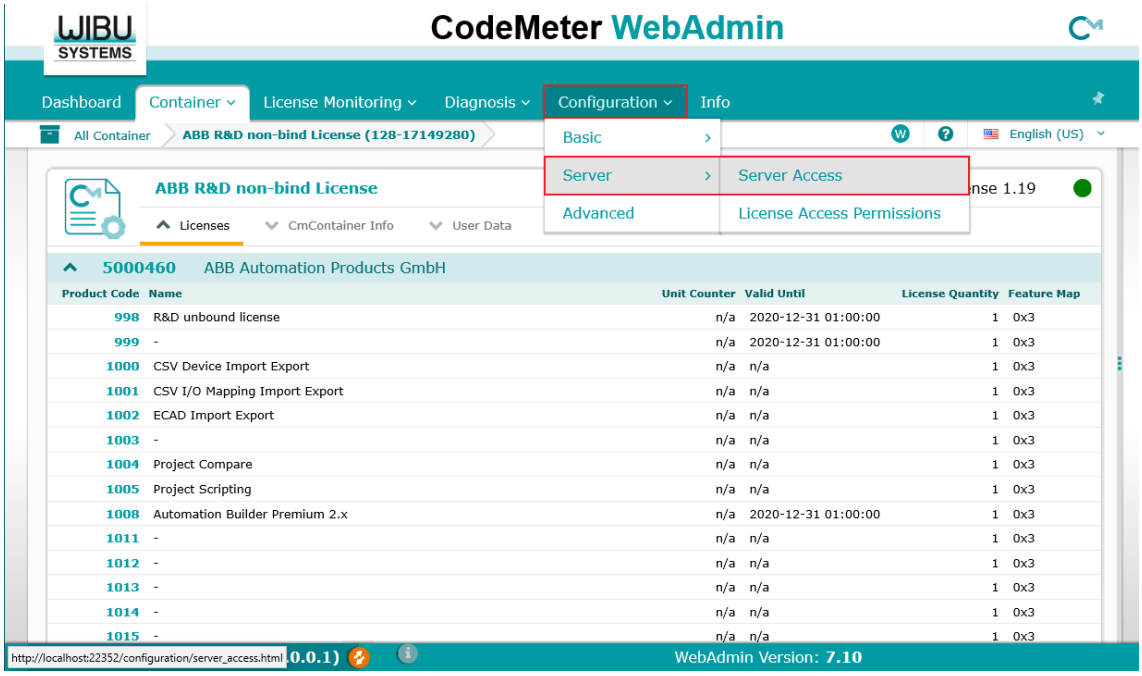
1. Launch CodeMeter WebAdmin. See ↳ *Chapter 1.2.4.3 "Checking licenses with CodeMeter control center" on page 22*
2. Select *"License Monitoring ➔ Sessions "*



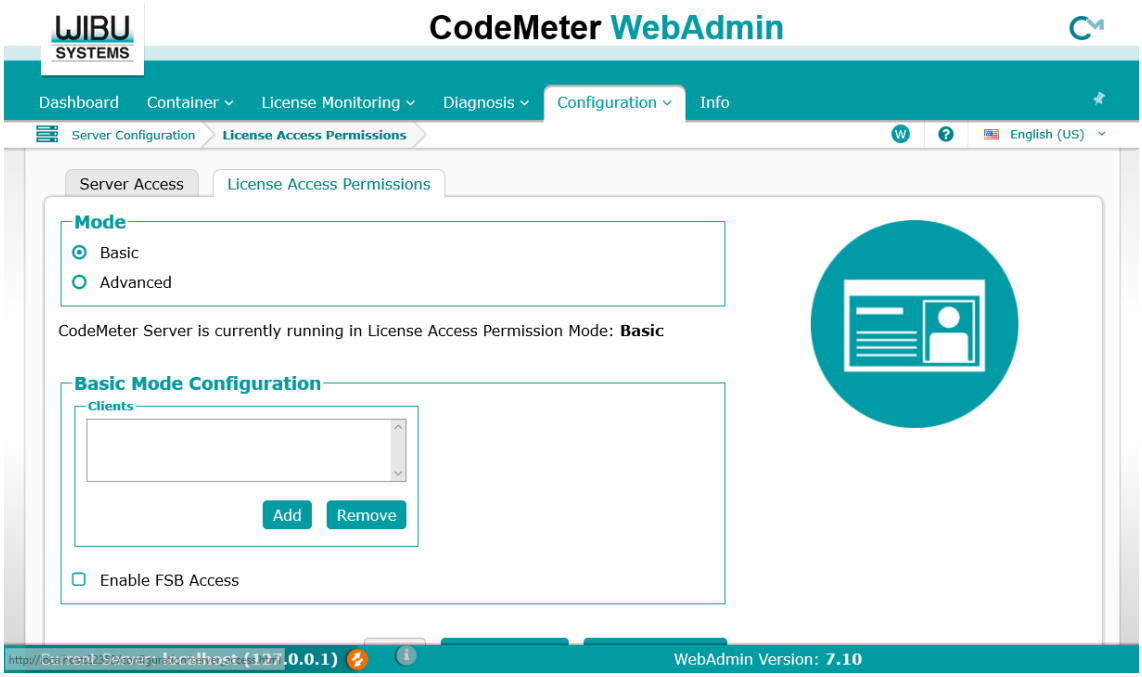
1.2.4.7.4 Controlling network server license usage

On the Network Server side you can define settings managing the client access to CodeMeter License Server on a network.

1. Launch CodeMeter WebAdmin. See *Chapter 1.2.4.3 "Checking licenses with CodeMeter control center" on page 22*
2. Select *"Configuration ➔ Server ➔ Server Access"*



3. Add entries of PCs you want to share licenses with by adding client computers and IP addresses for accessing CodeMeter License Server on a network.



1.2.4.8 License borrowing manager

The license borrowing manager allows you, to borrow a network license for offline use and return it.

> *The license borrowing manager is not part of the default software distribution, but will be handed out on request.*

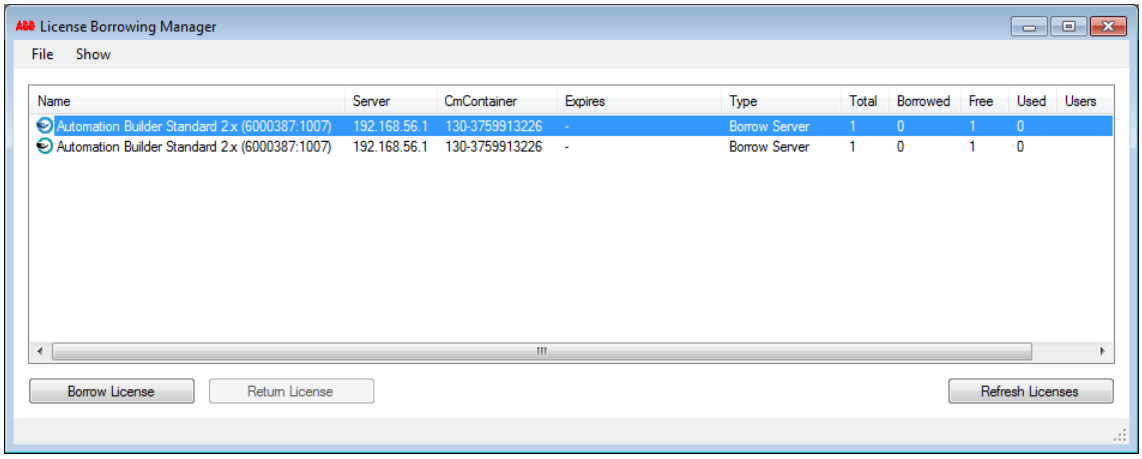
> *The license borrowing manager is only supported by Automation Builder 2.2.3 and later.*

1.2.4.8.1 Borrowing a network license

☑ Network access to the license server required.

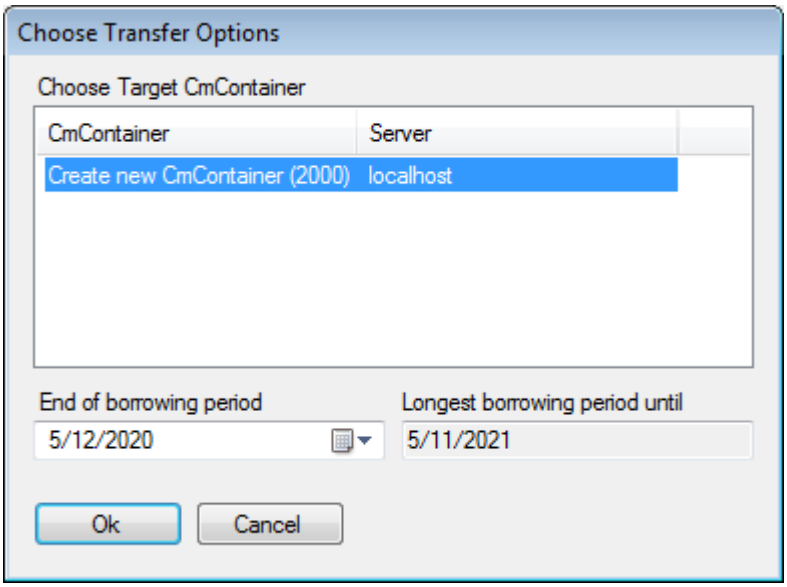
☑ Opened the license borrowing manager.

1. Select the license you want to borrow.



2. Select *“Borrow License”*.
3. Select the taget CmContainer.

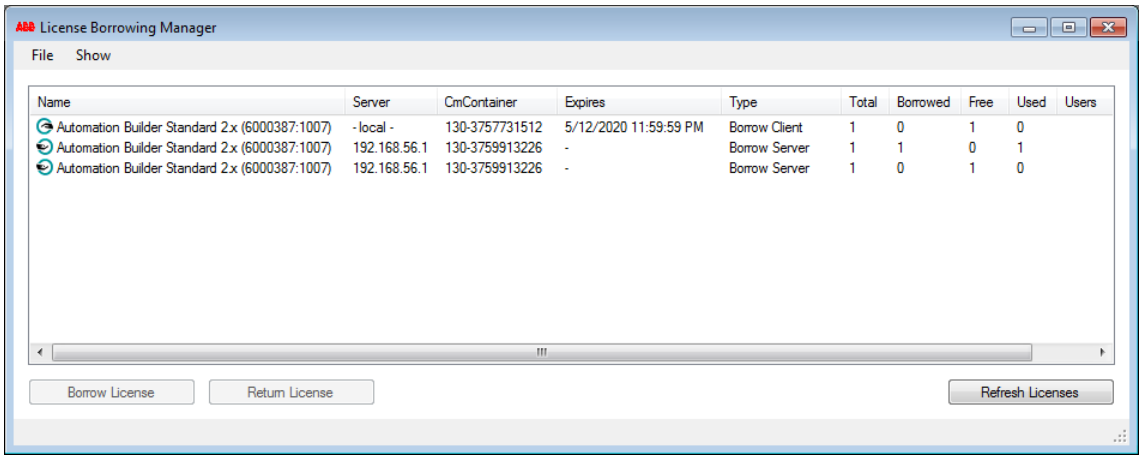
   Alternatively a new CmContainer can be created.
4. Select the end of the borrowing period.



5. Select *“OK”*.

   ⇨ The license has sucessfully been borrowed.

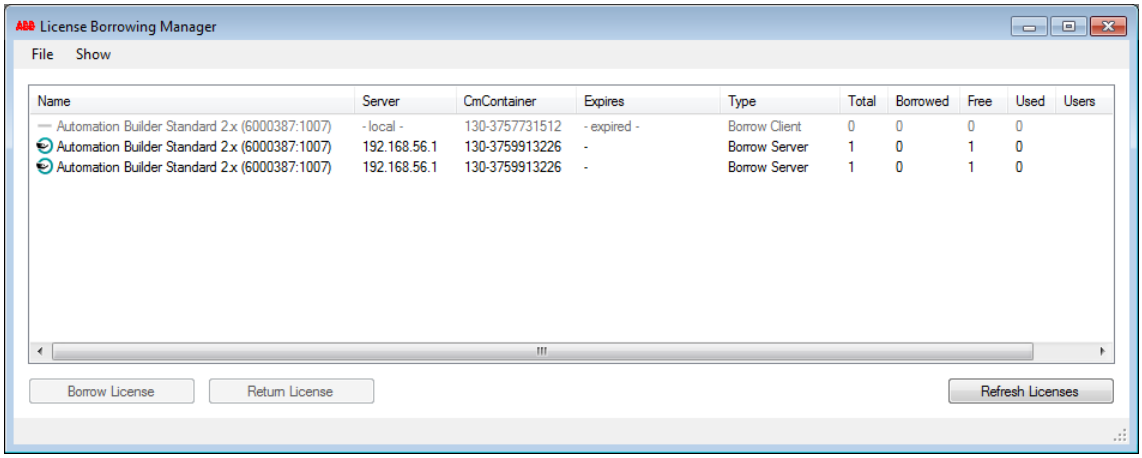
   The list of available licenses has been updated.



1.2.4.8.2 Returning a network license

Automatical return of a license

Network licenses will be returned automatically after the expiration of the maximum borrwoing period. No licenses server access is required.



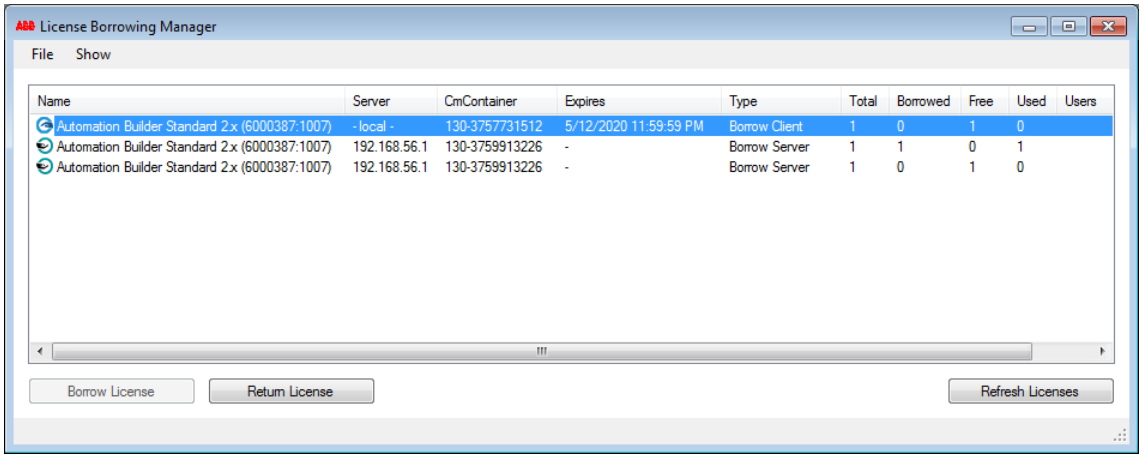
Manual return of a network license

Network licenses can be returned anytime manually.

☑ Network access to the license server required.

☑ Opened the license borrowing manager.

1. Select a borrowed license.



2. Select *“Return License”*

   ⇨ The license has sucessfully been returned.

1.2.4.9 Transfering an Automation Builder license

1.2.4.9.1 General

It is possible to transfer normal licenses from a PC to another PC or dongle (DM-Key).

This is not possible for ABB internal or temporary licenses, e.g. the 30 day Trial license.

The process consists of two main steps:

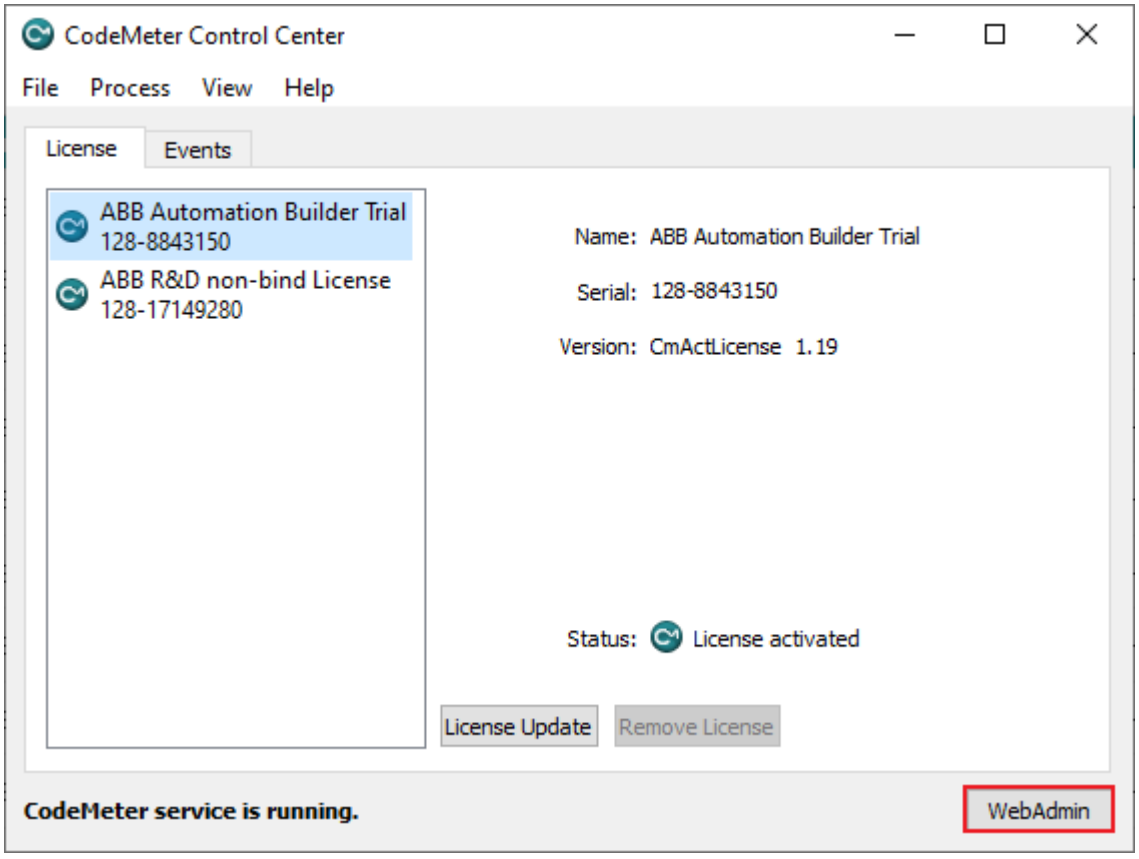
1. Return the actual license from the actual PC
2. Reactivate the license on the new PC

1.2.4.9.2 Getting activation code

For all license transfer processes the activation code is required. It is available from the license paper from purchasing the license.

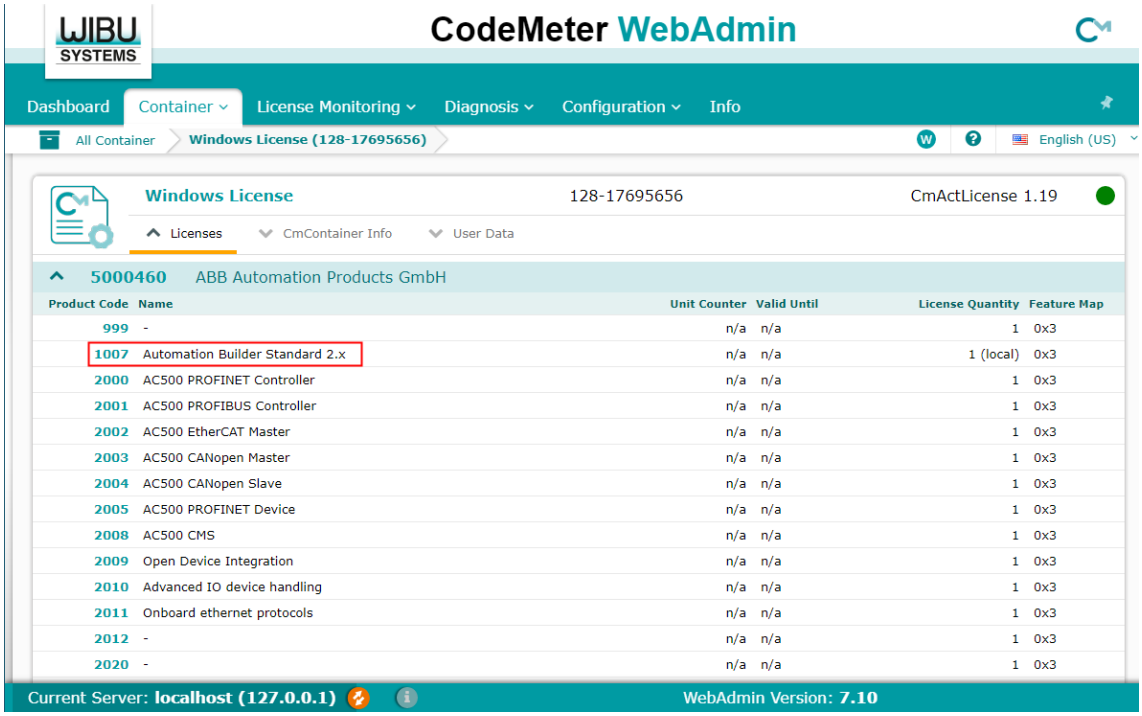
For Automation Builder licenses purchased April 2020 or later, the activation code is available from the activated license:

1. Open CodeMeter Control Center and navigate to the *"WebAdmin"*.

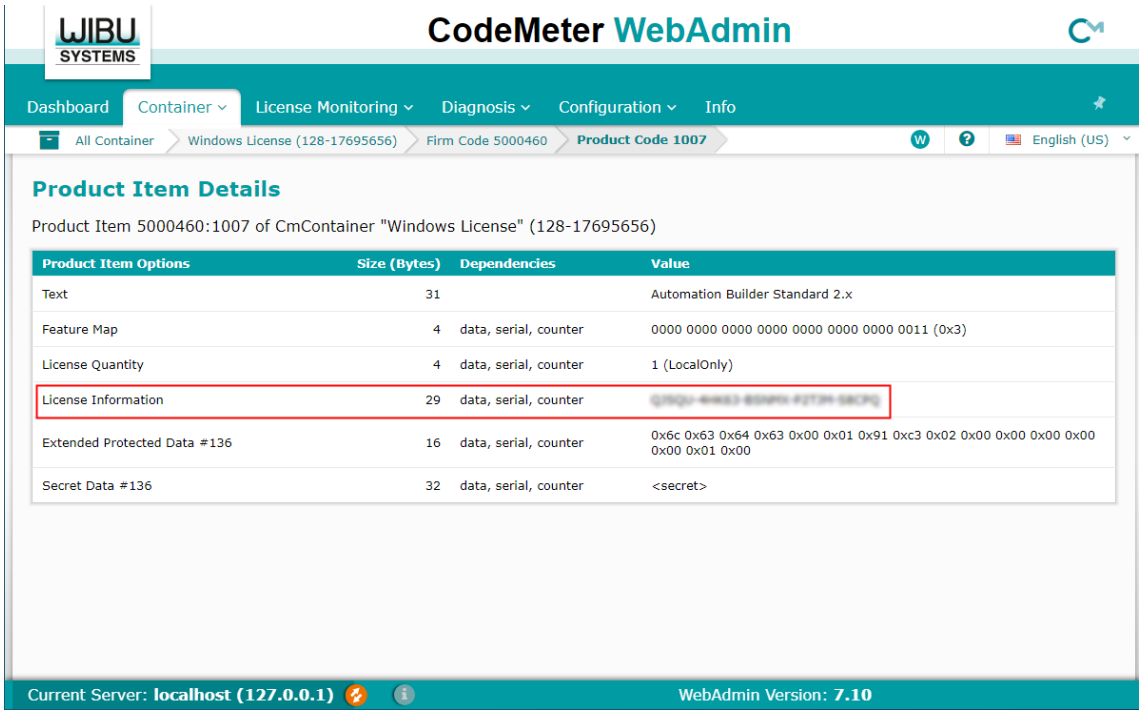


2. Identify the right product code.

   Automation Builder editions consist of multiple product codes. The activation ID is available from the product code containing the edition name, e.g. "Automation Builder Standard".



3. Select product code to access the product code details. Under *"License Information"* you can find the activation code.



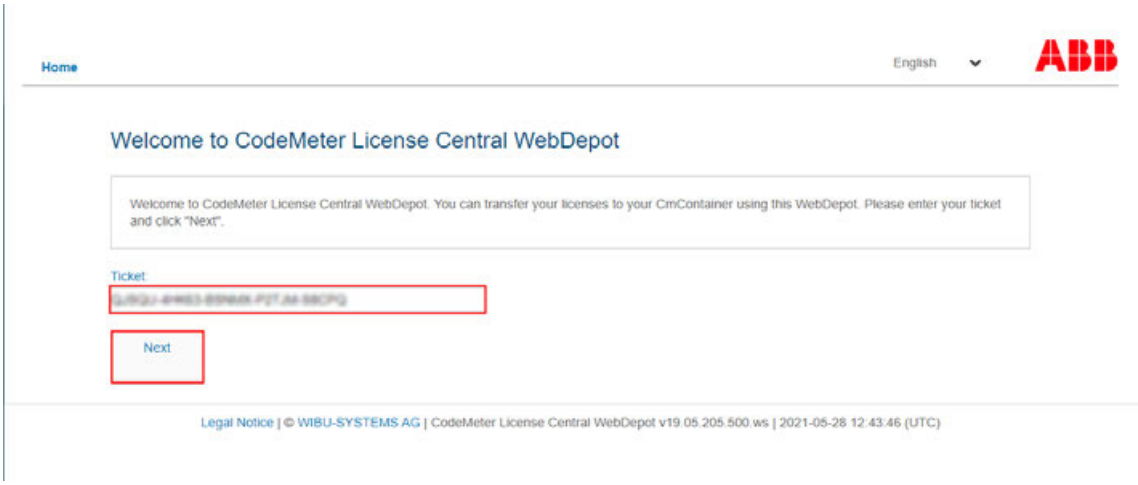
1.2.4.9.3 Returning an Automation Builder license

☑ You need the License Activation code of the license you want to return.

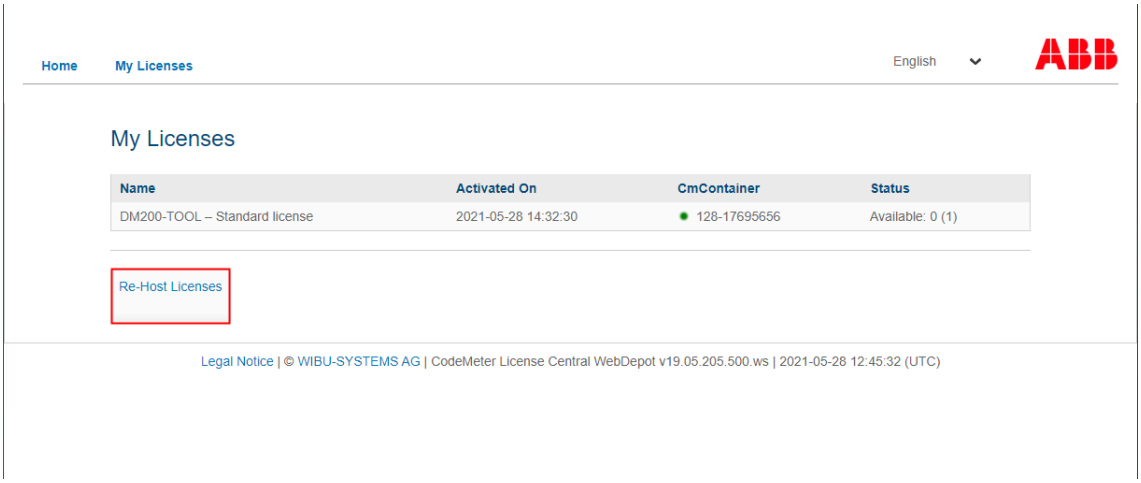
1. Go to the following website: *http://lc.codemeter.com/32838/depot-return/index.php*

> *The website is also availaible through the Automation Builder menu under "Help ➔ Return of Automation Builder license".*

2. Insert your Activation code in the field "Ticket"
3. Select *"Next"*



4. Select *"Re-Host License"*



⇨ If the CmContainer is found, continue with Online licenses transfer ↯ *Chapter 1.2.4.9.3.1 "Online license transfer" on page 37*

⇨ If the CmContainer is not found, continue with Offline license transfer ↯ *Chapter 1.2.4.9.3.2 "Offline license transfer" on page 39*

Online license transfer

▷ Wait till the CmContainer is found, then select *"Deactivate Selected License Now"*

My Licenses
English
Re-Hostable Licenses
To re-host licenses from one CmContainer to another CmContainer:
1. Make sure that the CmContainer with Serial 128-17695656 is connected to this computer. If this CmContainer is not connected to this computer, connect it now and click "Rescan for CmContainer".
2. Select the licenses you want to re-host.
3. Click "Deactivate Selected Licenses Now".
4. After the successful deactivation of the selected licenses, you can activate them again in another CmContainer.

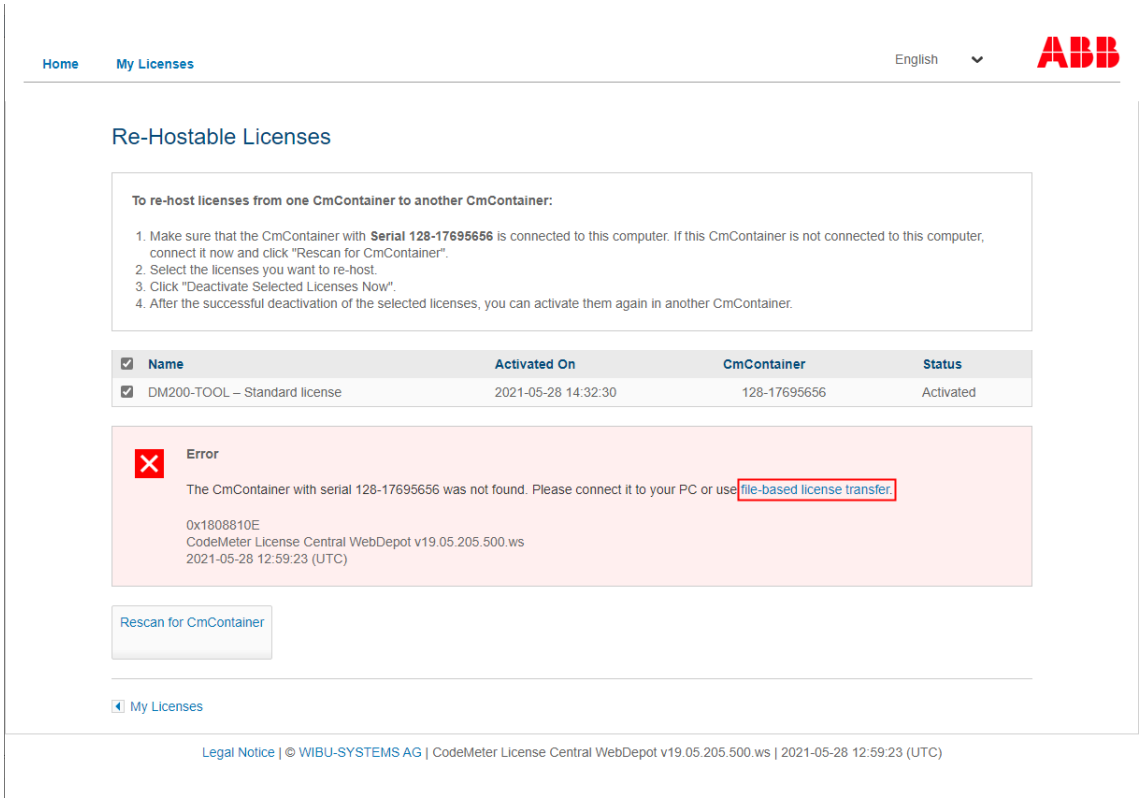
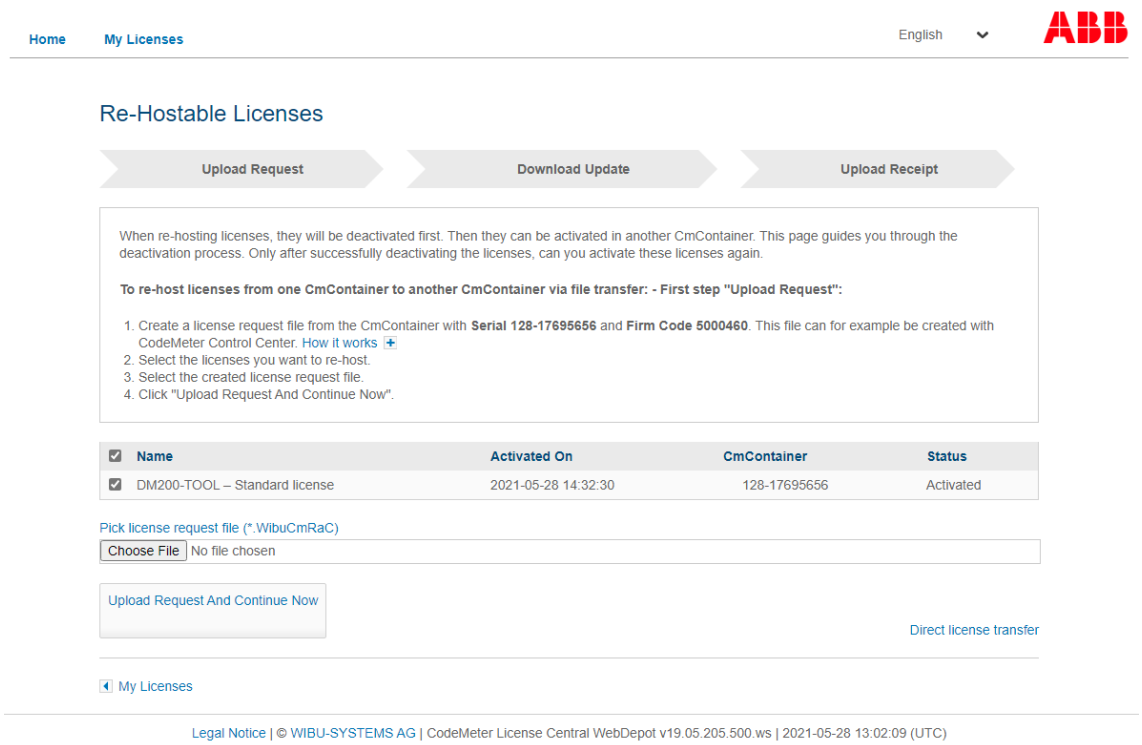
Online License Transfer
Starting license transfer.
Creating license request.
Downloading license update.
Importing license update to CmContainer.
Creating receipt.
Uploading receipt.
License transfer completed successfully!
OK

Offline license transfer

▷ If the CmContainer is not found on this PC, select file-based license transfer workflow.

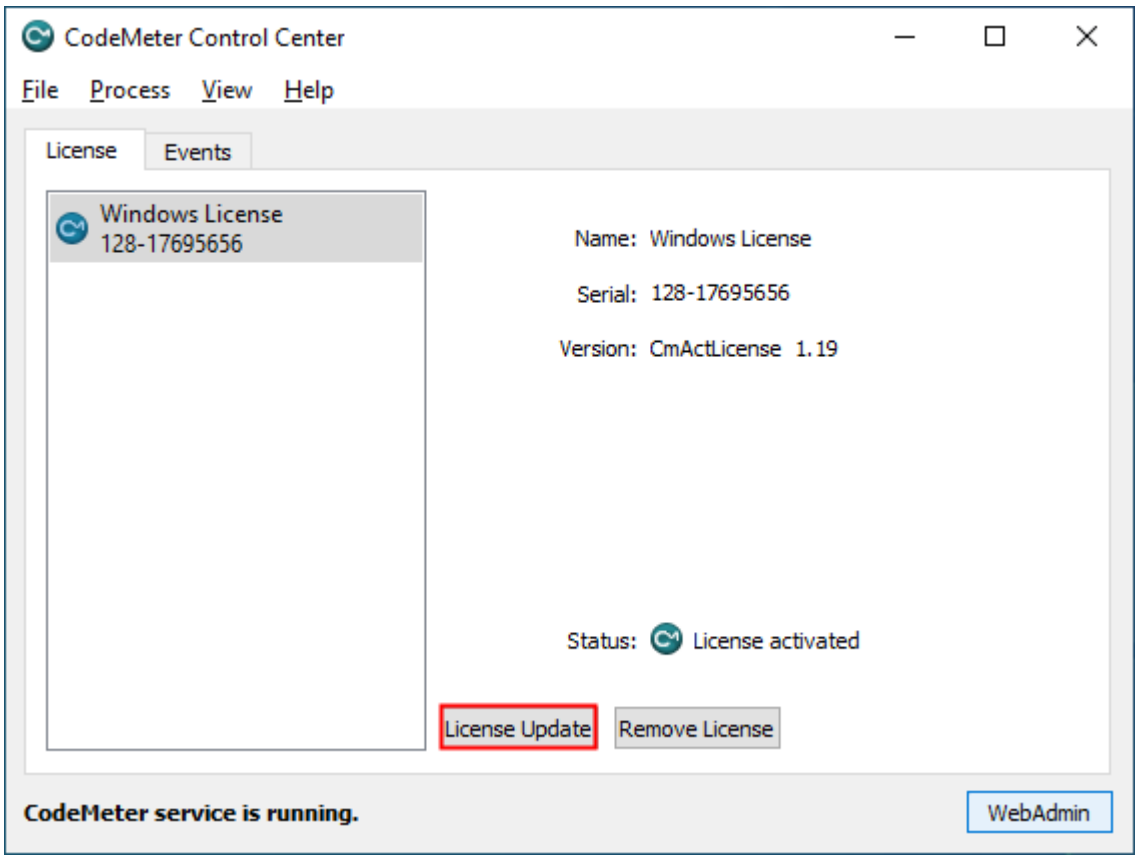


⇨ The following dialog opens

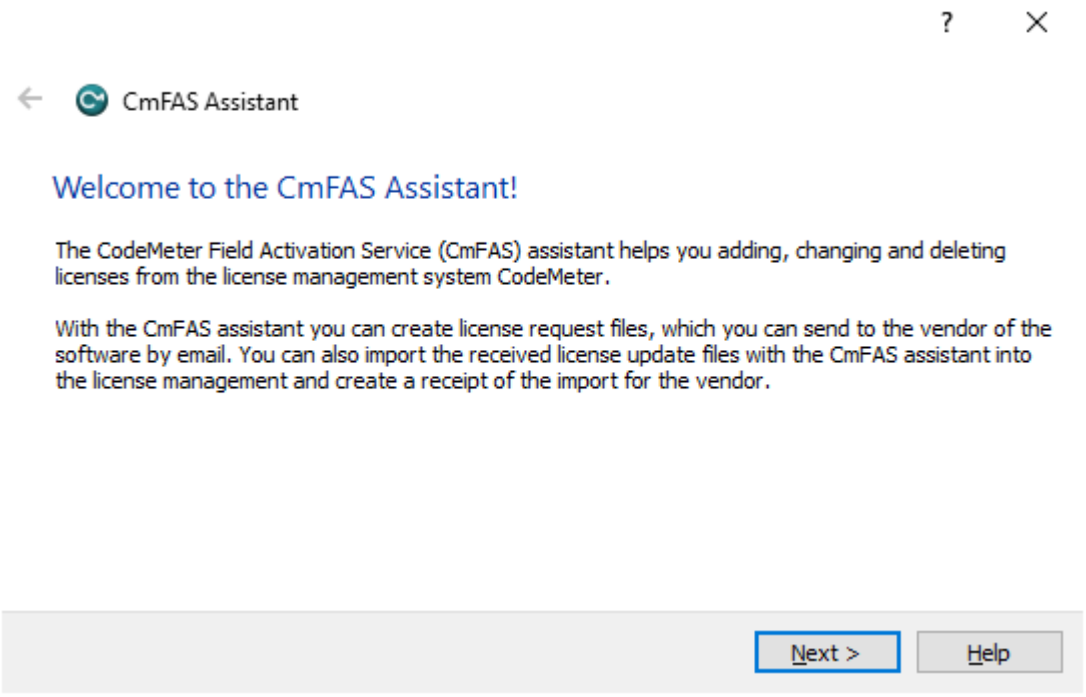


The instructions will lead you through the main steps of the offline license transfer:

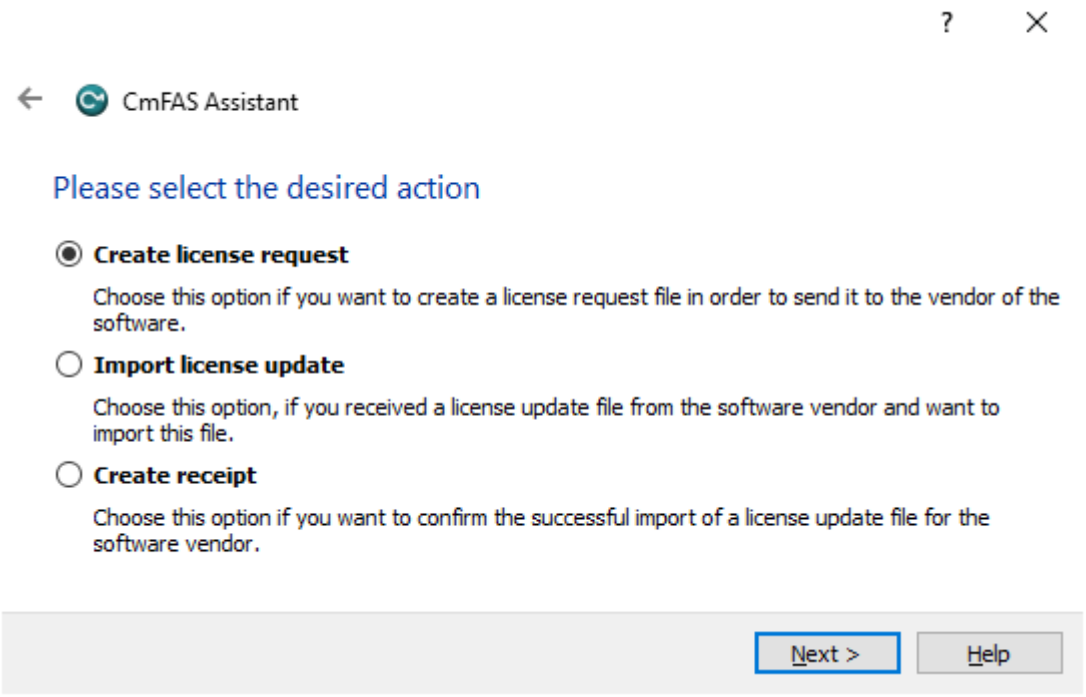
1. On the offline PC open the CodeMeter Control Center.
2. Select *“License Update”*.



⇨ The CmFAS Assistant opens.

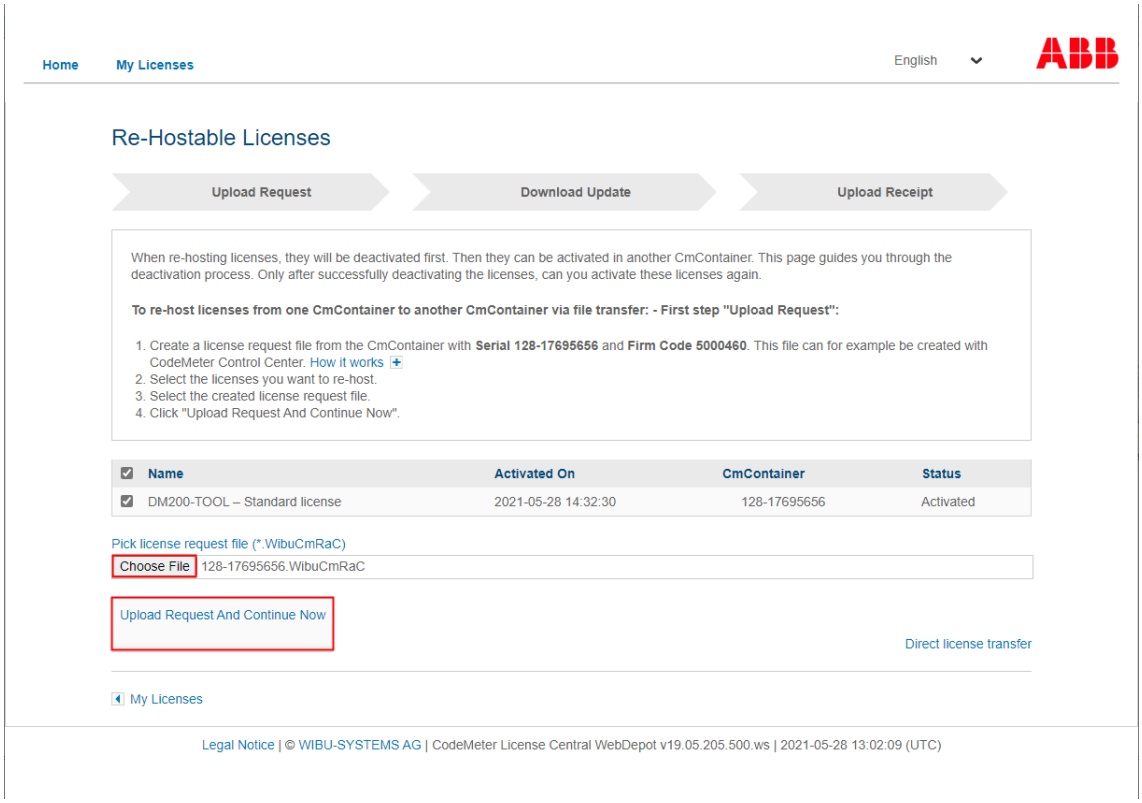


3. Select *“Create a license request file”*.

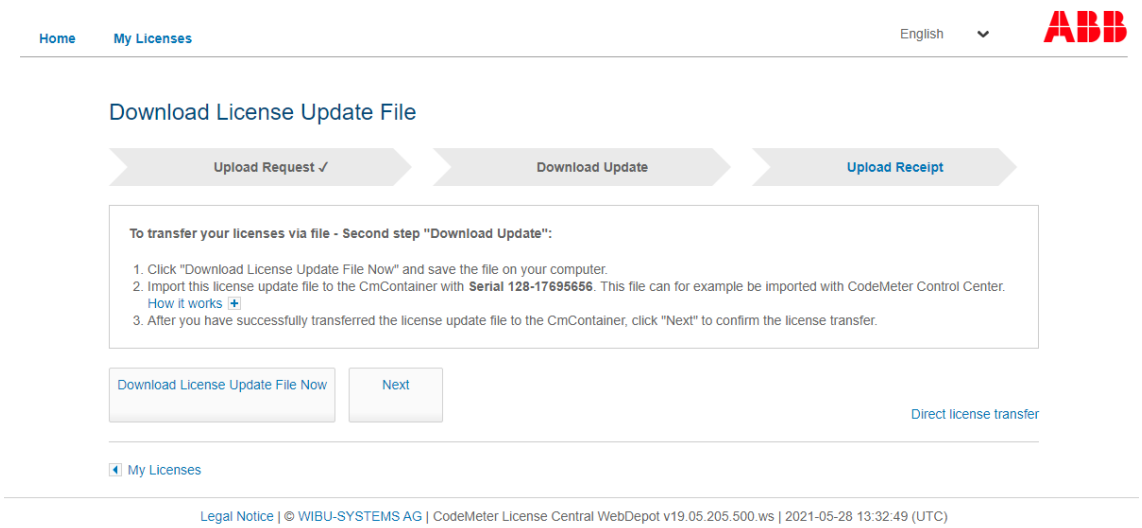


4. Select a location to store the license request file.
5. Transfer the license request file from the offline PC to an online PC.

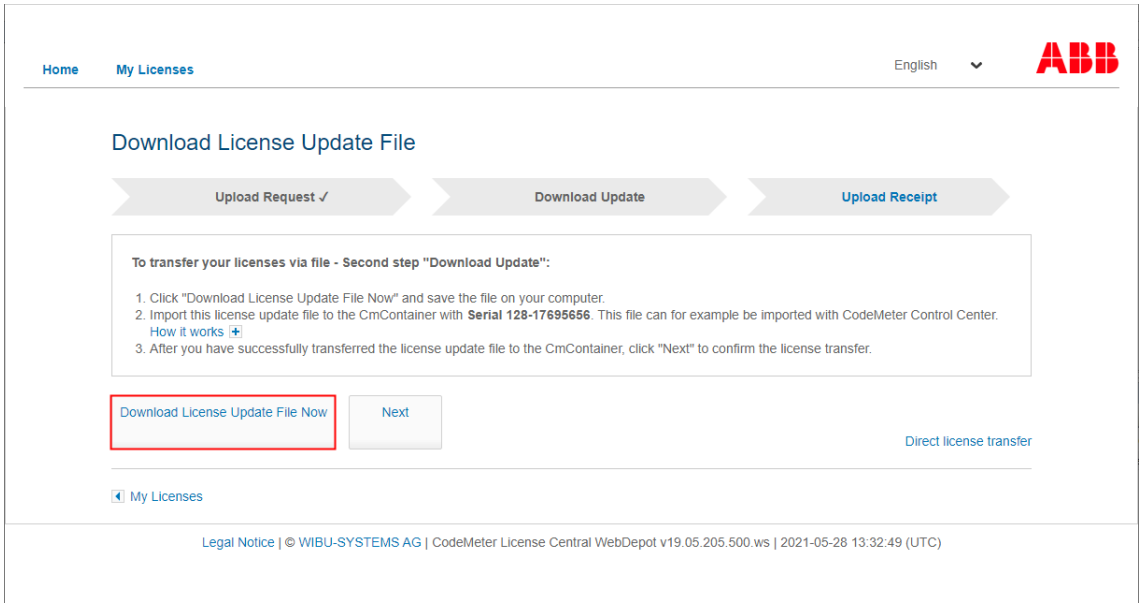
6. On the online PC choose the license request file and select *“Upload Request And Continue Now”*.



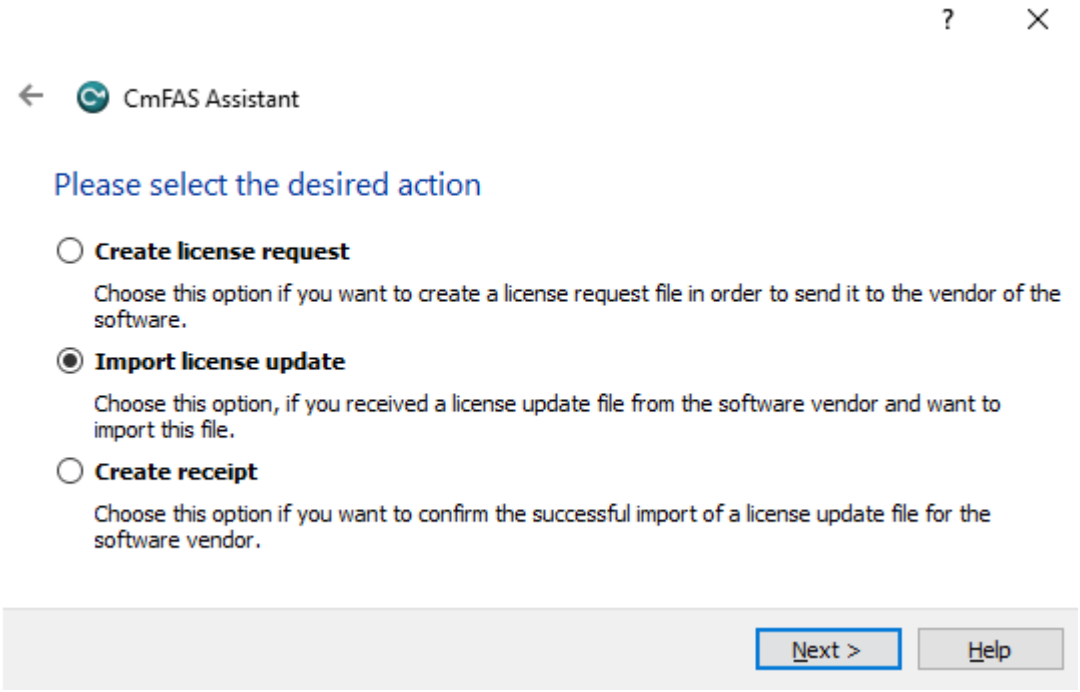
⇨ The next dialog is opened



7. Select *“Download License Update File Now”*.

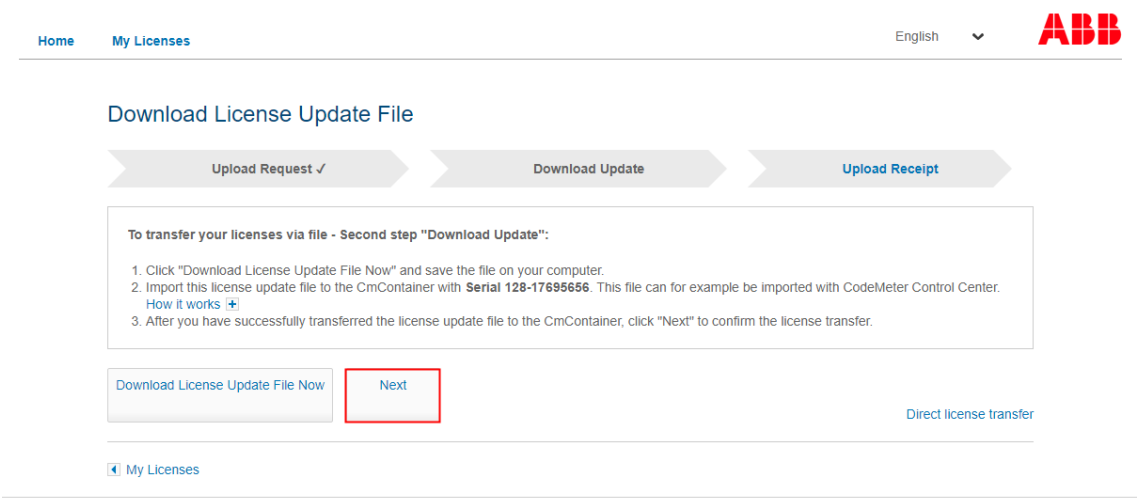


8. Save the license update file to a location on your computer.
9. Transfer the license upate file from the online PC to the offline PC.
10. On the offline PC open the CmFAS Assistant.
11. Select *“Import license update”*.

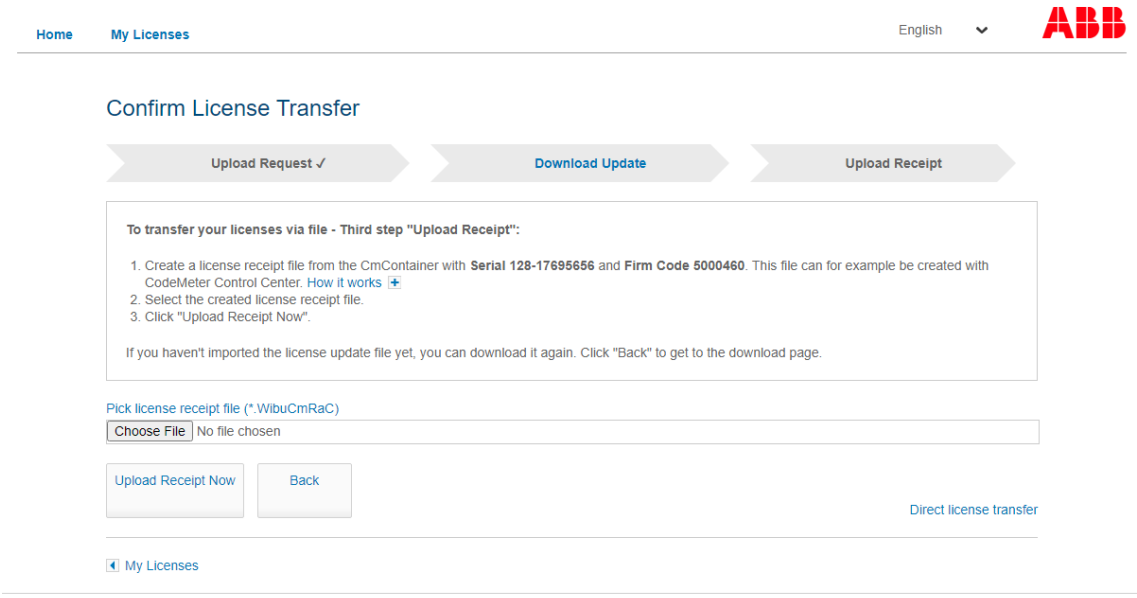


12. Select the license update file, to import the new license to the offline PC

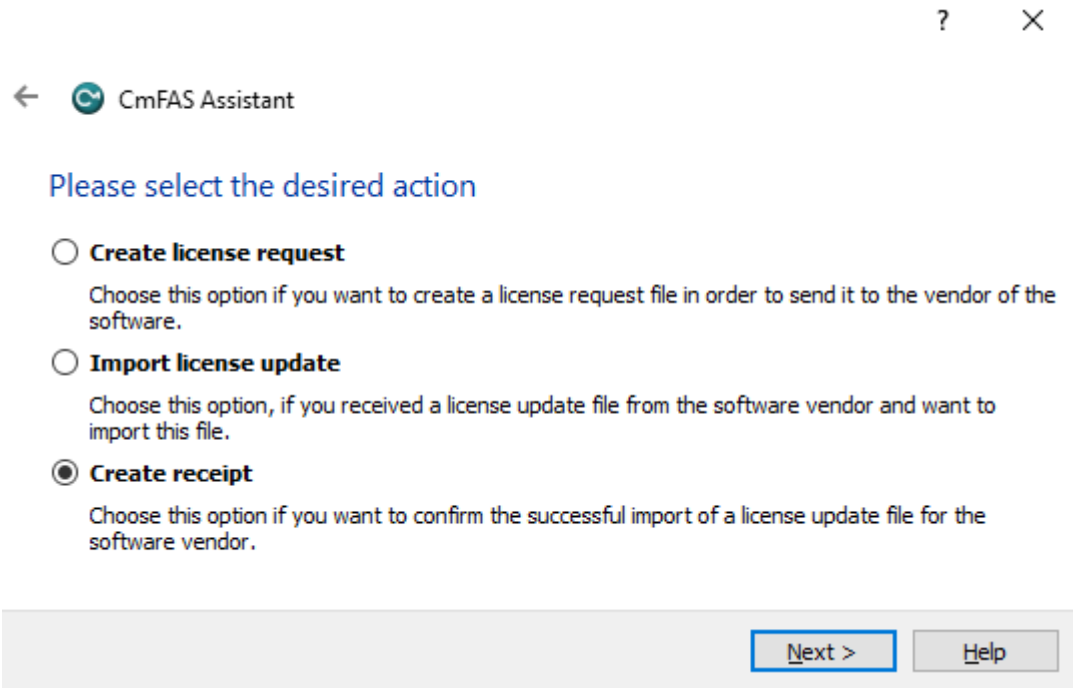
13. To confirm a succesful license transfer return to the online PC and select *“Next”*.



⇨ The last dialog is opened

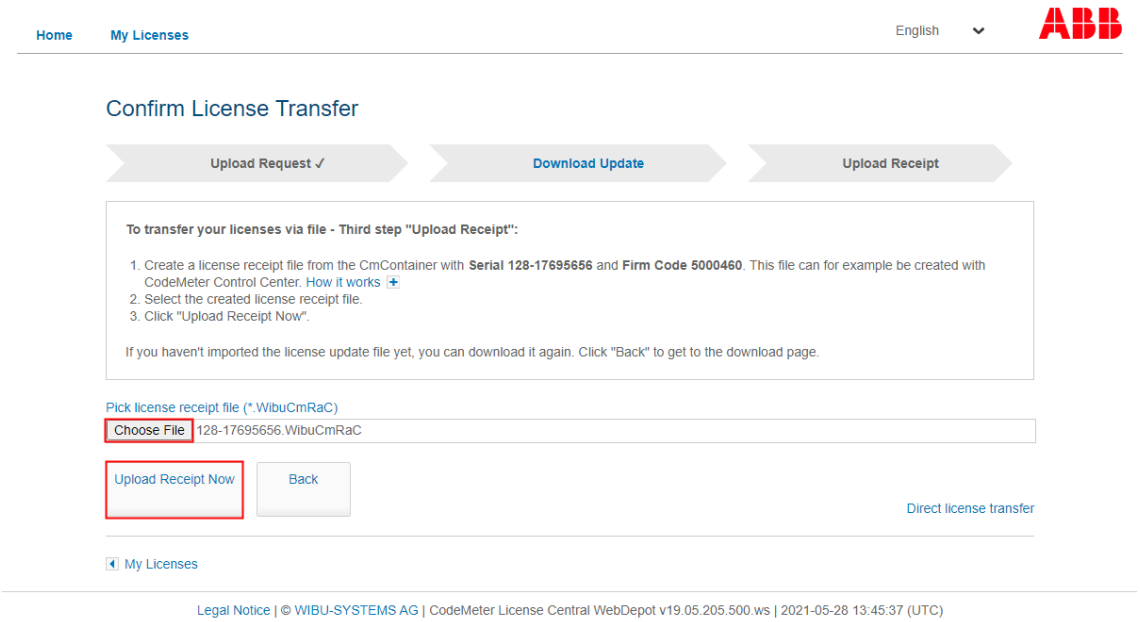


14. On the offline PC open the CmFAS Assistant.
15. Select *“Create receipt”*.

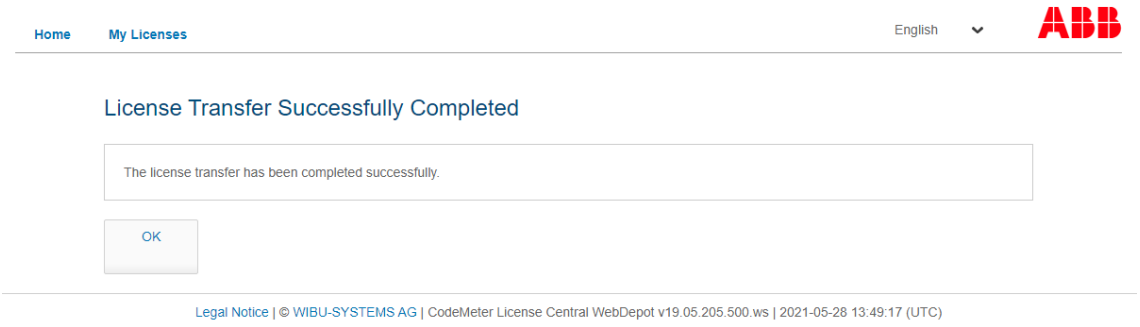


16. Choose a location to save the license receipt file.
17. Transfer the license receipt file from the offline PC to the online PC.

18. On the online PC choose the license receipt file and select *“Upload Receipt Now”*.



⇨ After a succesful license transfer you will receive the following message



1.2.4.10 Generating license information file for support

To create a license information file which includes all license information for the support:

1. Select *“Windows start menu* ➔ *CodeMeter* ➔ *Tools* ➔ *DmDust”*.
   ⇨ The explorer window opens and shows the folder where the created log file *“CmDust-Result.log”* is stored.
2. Please attach this file to any support request regarding your licenses.

1.2.4.10.1 Log files

Sometimes more detailed log files are needed to analyse a situation.

Then please also zip the following folder and attach it to your support request.

C:\ProgramData\CodeMeter\Logs

This folder includes

- CmActDiagLogyyyy-mm-dd-hhmmss.log
- CodeMeteryyyy-mm-dd-hhmmss.log

To make it easier to distinguish when the files were created, they are named as follows:

- yyyy – year, mm – month, hh – hour; mm – minutes, ss – seconds.

1.2.5 Set-up communication parameters in Windows

Set-up communication parameters

To set-up the communication between the PC and the PLC, e.g., for downloading the compiled program, you have to set-up the communication parameters.

The IP address of your PC must be in the same class as the IP address of the CPU.

The factory setting of the IP address of the CPU is 192.168.0.10.

The IP address of your PC should be 192.168.0.X. Avoid X = 10 in order to prevent an IP conflict with the CPU.

Subnet mask should be 255.255.255.0.

Change the IP address

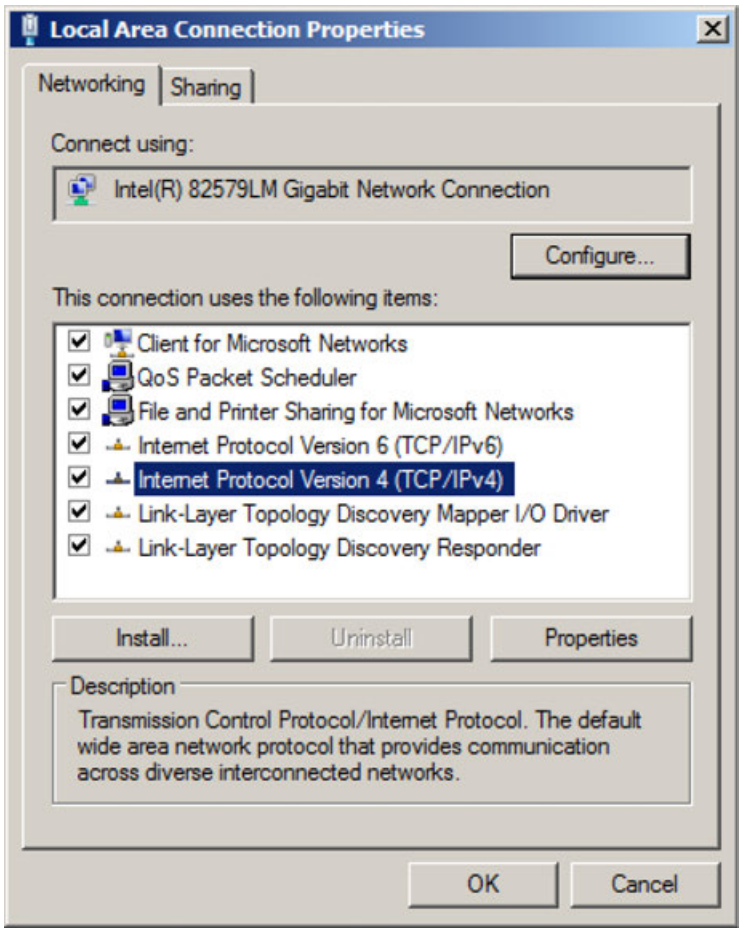
1. Open Windows **Control Panel**. Click *“Network and Internet ➔ Network and Sharing Center”*.
2. Click **Change adapter settings**.

   ⇨

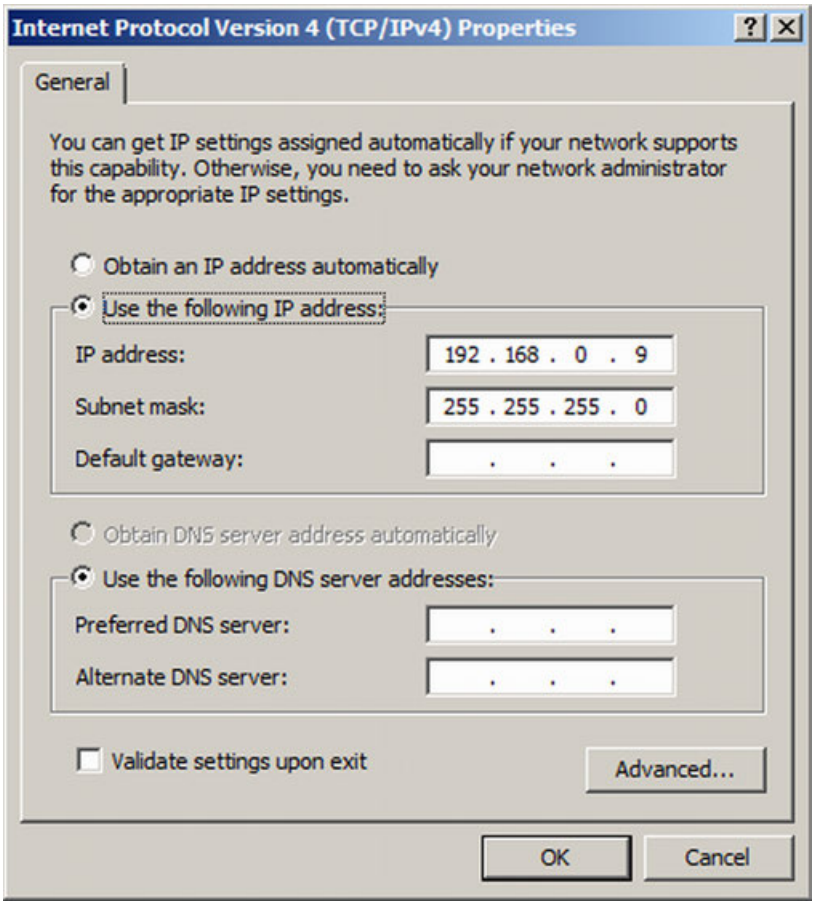
   

   If using existing network with several devices, please pay attention on given network rules or contact your system administrator.

3. Right-click **Local Area Connection (Ethernet)** and select **Properties**.



4. Double-click **Internet Protocol Version 4 (TCP/IPv4)**.



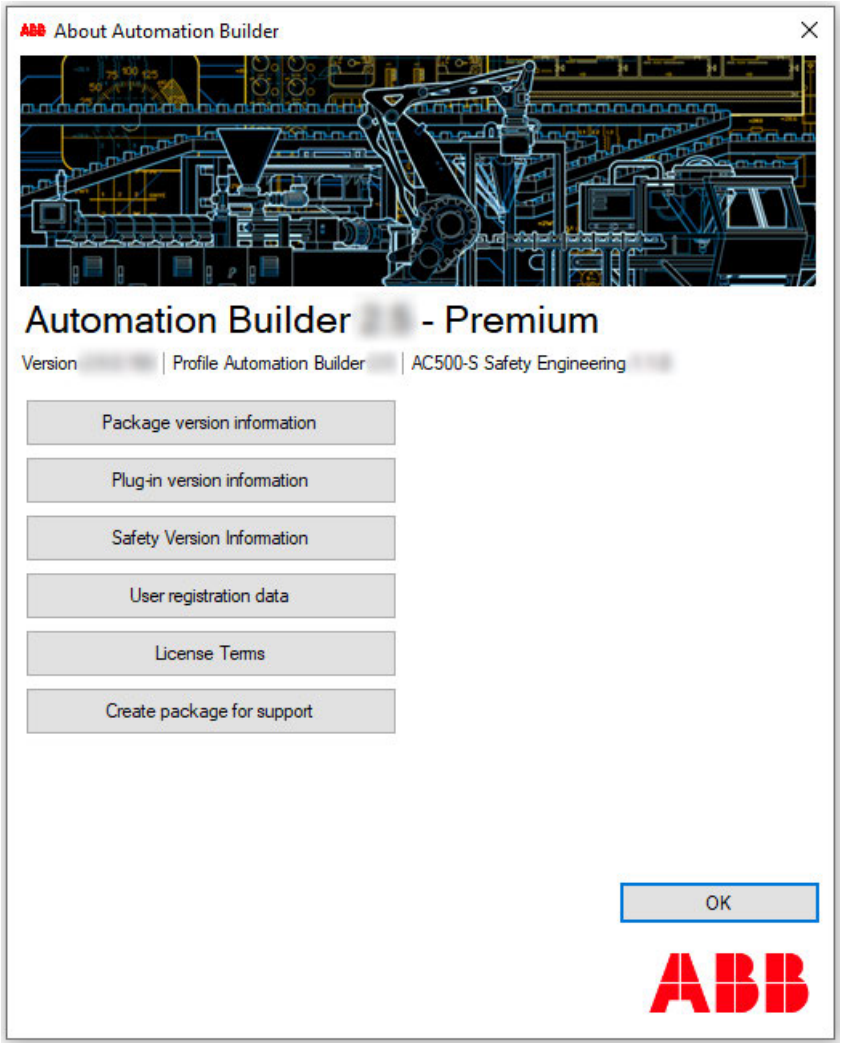
5. Enter your desired IP address and subnet mask.

1.2.6 Further information

Further information on the installed Automation Builder version such as installed packages or license terms can be found on the "About" page (help menu).

Safety Version is visible if safety option is installed. Safety Version Information shows the versions of all safety components.

- Package version information: Further information about all installed package versions is shown.
- Plug-in version infromation: Further information about all installed plug-in versions is shown.
- Safety version infromation: Further information about all safety component versions is shown.
- User registration data: Enter or change your registration data.
- License Terms: Information about the license terms.
- Create package for support: Creates a package which can be saved or sent to support
  ↳ *Chapter 1.2.7 “Create log files for support” on page 50*.



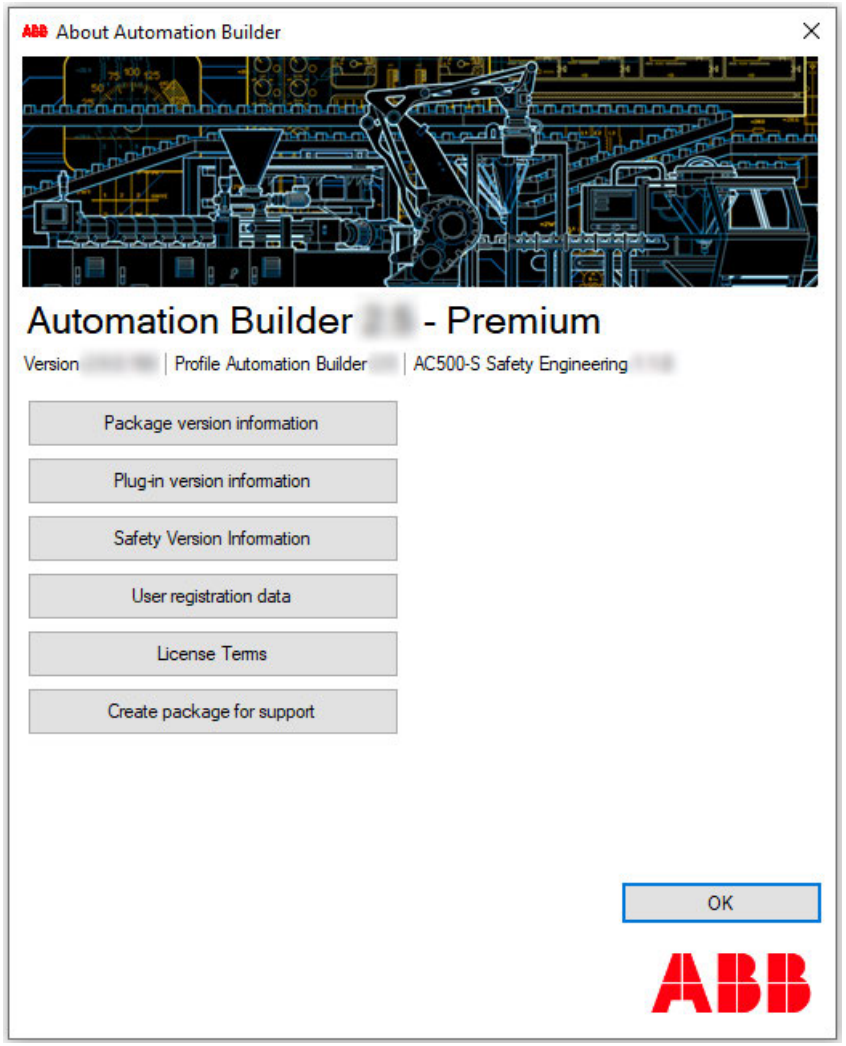
It is possible to either continue working with a project on an older Automation Builder version or to update a project to the latest Automation Builder version.

1.2.7 Create log files for support

Professional support requires some information about the project and the devices.

To collect this information proceed as follows:

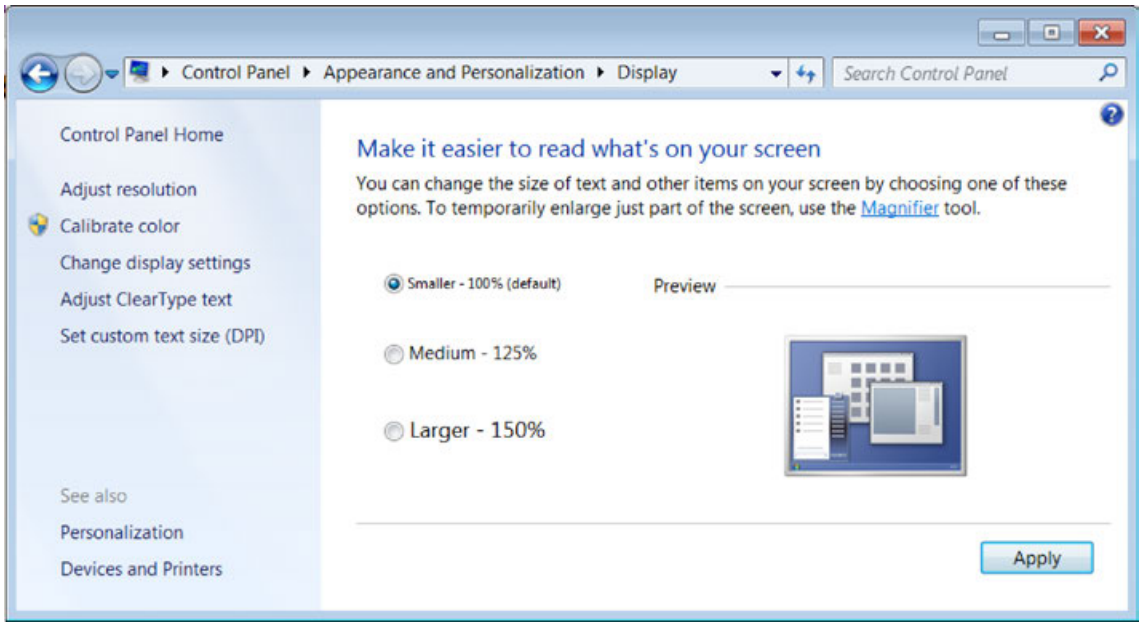
1. Click *"Help ➔ About"* in the main menu of Automation Builder.



2. Click *[Create package for support]* and wait until a list of log files is displayed.
3. Click *[Save package]* to store the zipped log files to your disk, or click *[Send package]* to send the zipped log files to ABB support.
4. Click *[OK]*.

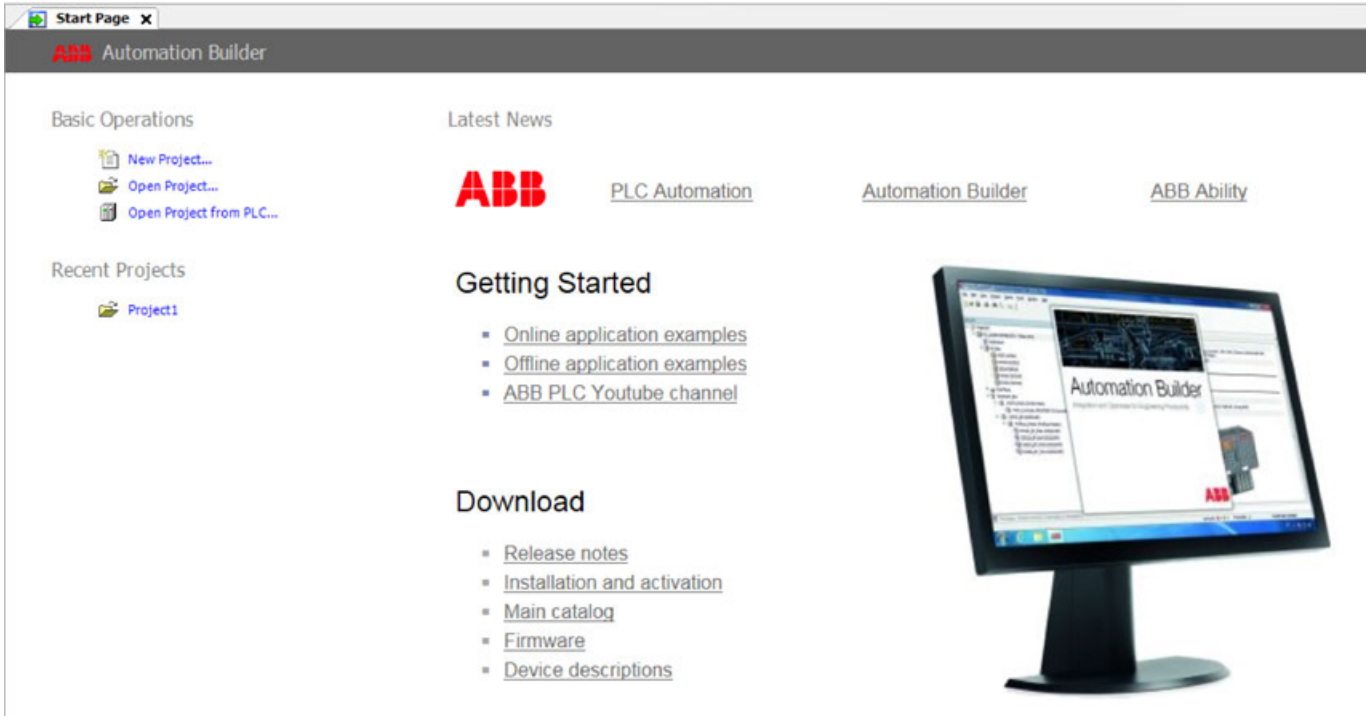
1.2.8 Menues, views, windows

Ensure the full display of Automation Builder editors by choosing the option Smaller - 100 % (default) in "Start ➔ Control Panel ➔ Appearance and Personalization ➔ Display".



1.2.8.1 Start page and menus

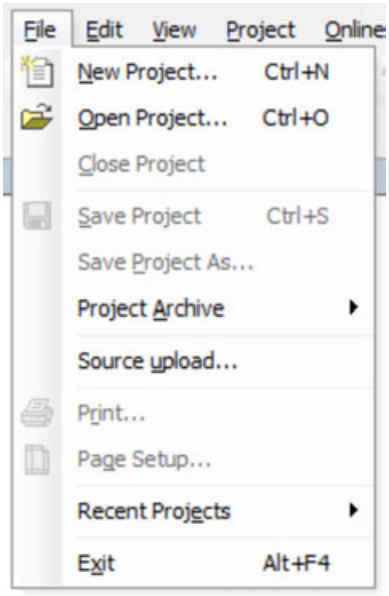
After start-up of Automation Builder software the start page is displayed.



All items of the Automation Builder user interface are described in the CODESYS documentation:

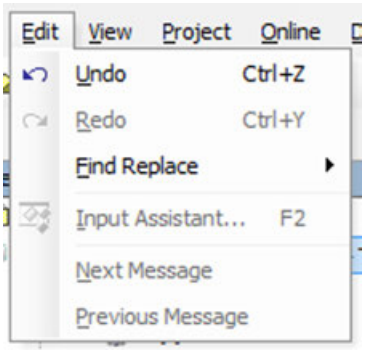
- *Chapter 1.4.1 “Development system” on page 145*

“ File” menu:



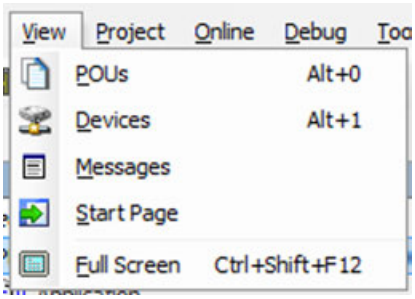
Command	Description
New Project	Creating a new project with the dialog New Project. ↳ *Chapter 1.6.5.1.1 “Project handling” on page 5757*
Open Project	Opening an existing project file.
Close Project	Closing a project file while Automation Builder keeps running. If the current projects keeps information which have not been saved before, you will be asked if the changes should be saved or not.
Save Project	Saving the project at the currently defined location. It is only available if changes have been done to the project since the last saving. This is indicated by an * (asterisk) behind the project name in title bar.
Save Project As	Saving the project whereby project name and location can be defined in a dialog box.
Project Archive	Creating a project archive. ↳ *Chapter 1.6.5.1.1 “Project handling” on page 5757*
Source upload	This command loads the project source code.
Print	Printing the content of the tab which is currently shown in editor window.
Page Setup	Opening the Page setup dialog where the page setup can be configured for printing.
Recent Projects	Reopening the most recently worked projects. The number of projects kept in the list can be defined.
Exit	Closing Automation Builder. If the current projects keeps information which have not been saved before, you will be asked if the changes should be saved or not.

“Edit” menu:



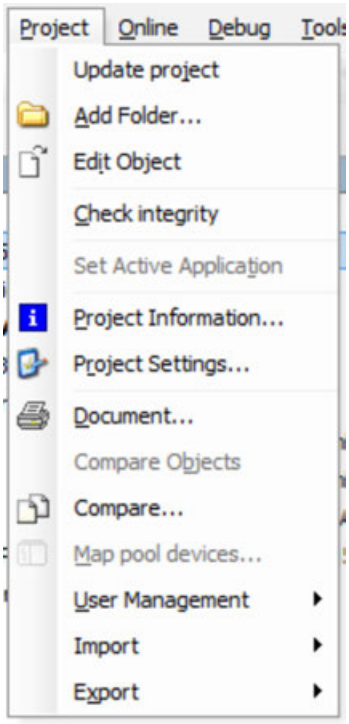
Command	Description
Undo	The last action is reversed.
Redo	A reversed action is redone.
Find Replace	Full text search and text replacement functions.
Input Assistant	This command opens the “Input Assistant” dialog box, guiding you in inserting a program element valid at the current cursor position.
Next Message	This command selects the next message in the messages view.
Previous Message	This command selects the previous message in the messages view.

“View” menu:



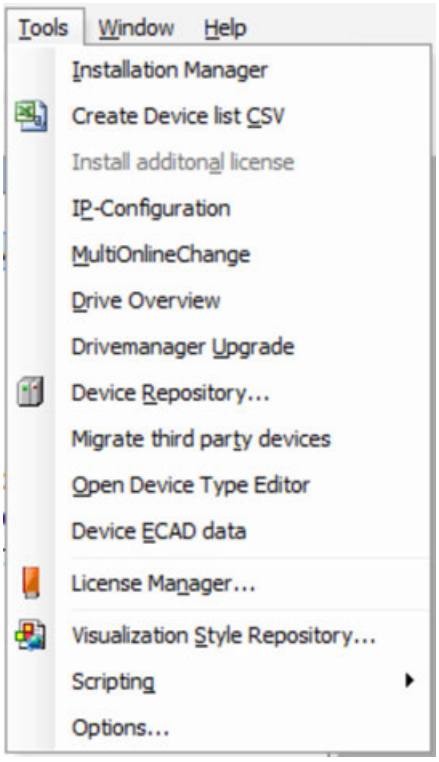
Command	Description
POUs	This command opens the “POUs” view in the CODESYS main window. POUs located here are available in the entire project.
Devices	Displaying the device tree on the left side of Automation Builder.
Messages	Displaying the Messages window.
Start Page	Displaying the Start Page tab. It shows the recently used projects, links to useful commands and the ABB PLC Product Website.
Full Screen	Effecting that CODESYS frame window is displayed in full screen mode. Use *[Ctrl]* + *[Shift]* + *[F12]* to toggle back to normal mode.

“Project” menu:



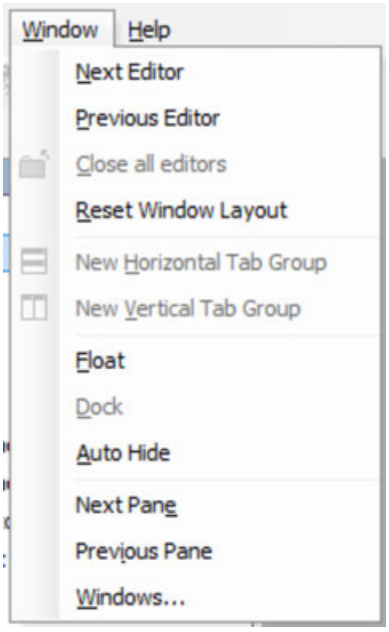
Command	Description
Update project	Updates the project
Add Folder	This command opens a dialog box for defining a new folder in the Devices or POUs view.
Edit Object	This command opens the object in its editor.
Project Information	Opening the "Project Information" dialog window which shows detailed information of the currently opened project.
Project Settings	This command opens the “Project settings” dialog box.
Document	This command opens the “Document Project” dialog box, where you can define the project documentation. This includes the selection of objects in the open project that you want to print.
Compare	This command opens the “Project compare” dialog. In this dialog, you define the reference project to compare with the current project. You configure the comparison process by means of options. When the dialog is exited, the comparison starts and the result is shown in the view “Project Compare - Differences”.
Import	This command opens a dialog box for importing objects from an XML file.
Export	This command opens a dialog box for exporting objects from a project to an XML file.

“Tools” menu:



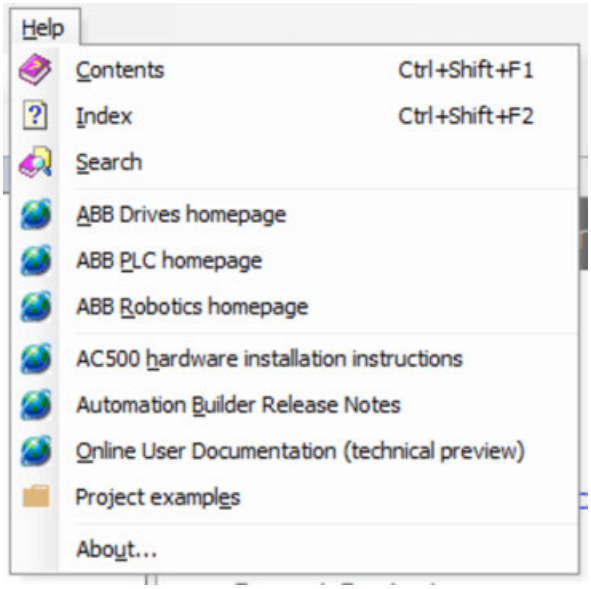
Command	Description
Installation Manager	Installation Manager allows installation and maintenance of Automation Builder packages.
Create Device list CSV	Creates an Exel file with a device list.
Install additional license	Allows to install an additional license.
IP-Configuration	Allows to configure the IP address.
Drive Overview	Shows a Drive overview
Drivemanager Upgrade	Allows a Drivemanager upgrade
Device Repository	Opening the Device Repository. This is a database for all devices which have been installed on the local system for Automation Builder. The default settings are defined by the current profile.
Options	Opening the "Options" dialog. This dialog contains sub-dialogs for configuring the appearance and behavior of Automation Builder. The default settings are defined by the current profile.

“Window” menu:



Command	Description
Next Editor	Opening the next editor window
Previous Editor	Opening the previous editor window
Close All Editors	Closing all opened editor windows and showing the start page of Automation Builder.
Reset Window Layout	This command resets all currently open windows and views to their default positions. You are prompted for a confirmation before the command is executed.
New Horizontal Tab Group	Adding a horizontal aligned tab view. Editor windows can be placed on the different views by drag-and-drop.
New Vertical Tab Group	Adding a vertical aligned tab view. Editor windows can be placed on the different views by drag-and-drop.
Float	This command releases a docked view from its frame in the user interface and repositions it on the screen as a floating window.
Dock	This command returns a floating window, which was released by the “Float” command, to the frame of the user interface.
Auto Hide	This command shows or hides a view.
Next Pane	This command sets the focus on the next pane.
Previous Pane	This command sets the focus on the previous pane.
Windows	Opening the Windows dialog box. This dialog box provides a list of active editor windows which can be accessed via button Activate or closed with button Close window(s). It is possible to close several windows.

“Help” menu:



Command	Description
Contents	Opening the table of contents of Automation Builder online help
Index	Opening the index of Automation Builder online help
Search	Opening the full-text search of Automation Builder online help
ABB Drives / PLC / Robotics home page	Opening the product specific home page
Automation Builder Release Notes	Opening the Release Notes of the current Automation Builder version
Online User Documentation	Opening the Automation Builder webhelp
Project examples	Opening the directory in which project examples are stored
About	Showing the about dialog with details of version

1.2.8.2 'All Messages' window

Errors, warning and success messages are written to the *“All messages”* window:

1.2.9 Device repository

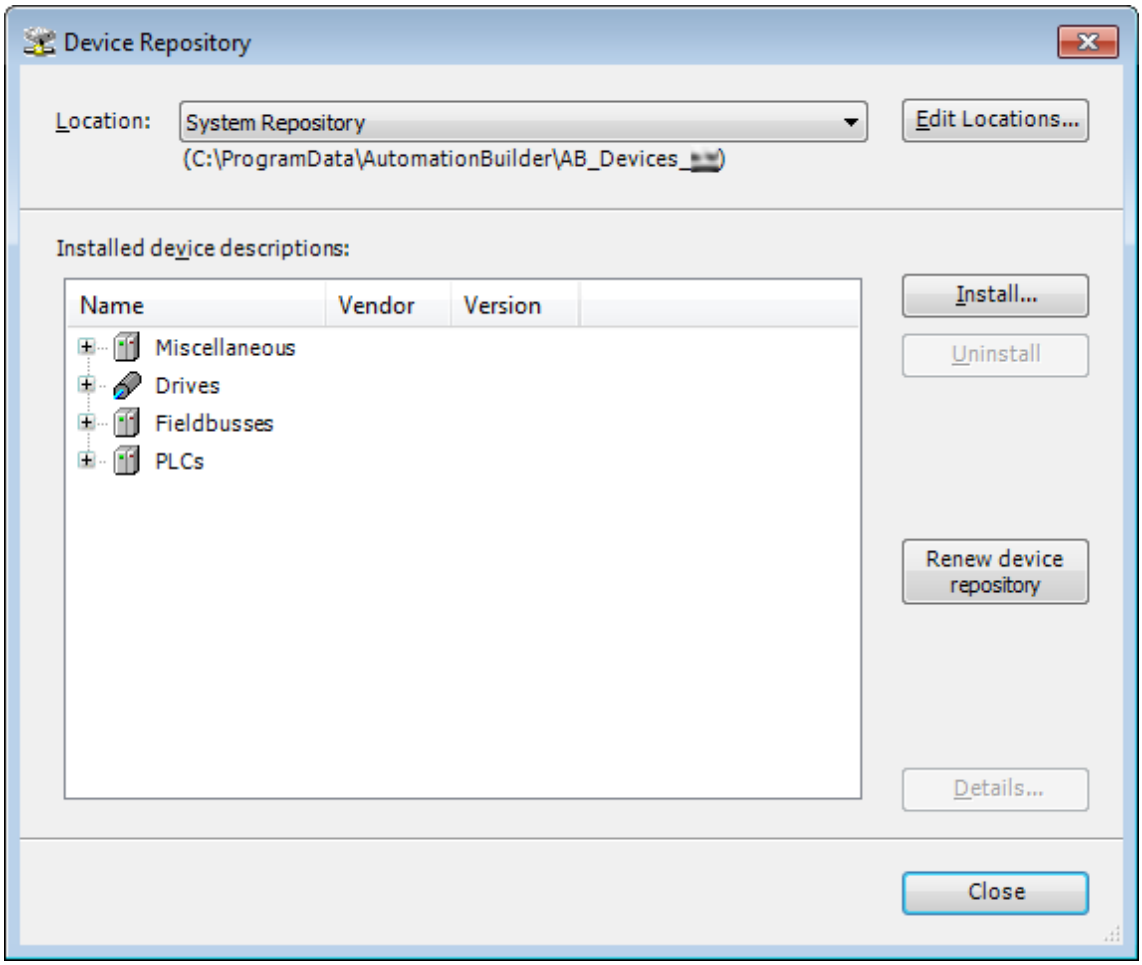
The Device Repository of Automation Builder manages the pool of devices that can be used in the PLC configuration.

You install or uninstall devices in the *"Device Repository"* dialog box. The system installs a device by reading the device description files, which define the device properties for configurability, programmability, and possible connections to other devices.

You can use the devices provided in the device repository by adding them to the device tree of your project.

Dialog device repository

1. Click *"Tools ➔ Device Repository"*.
   ⇨ The *"Device Repository"* dialog box opens.



[Edit Locations]: Changes the default repository location. The devices can be managed at different locations.

[Install] / *[Uninstall]*: Installs or uninstalls devices.

[Renew device repository]: Updates the device list, e.g. after uninstallation of a device.

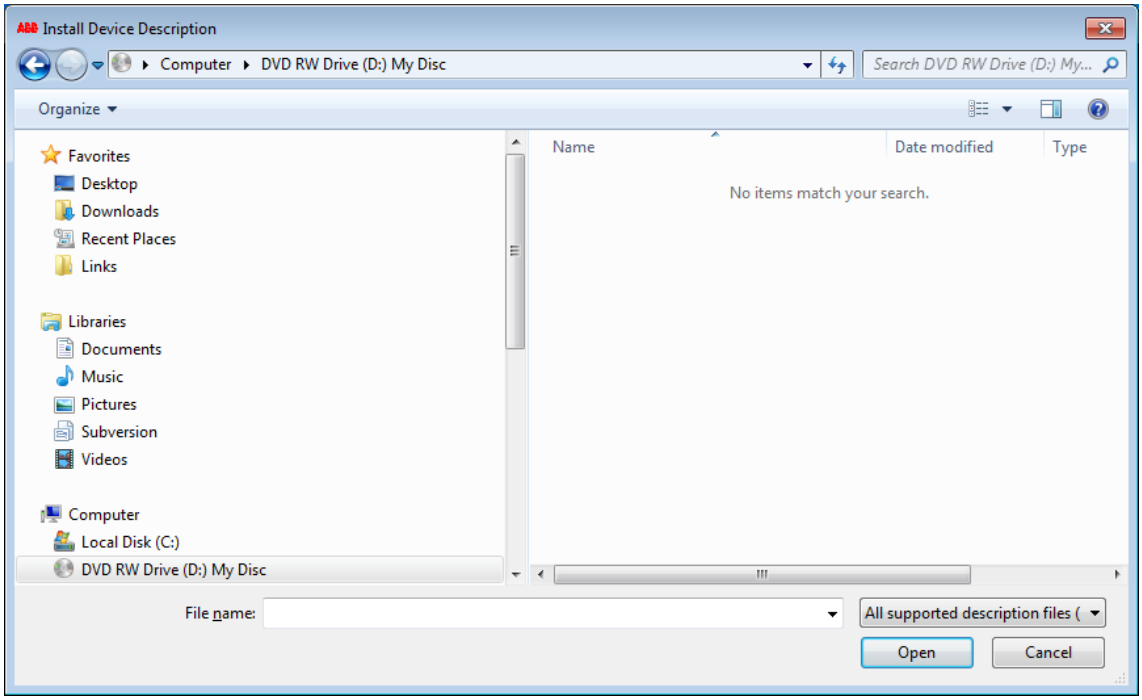
[Details]: Provides technical details on the selected device.

2. Select the install location. *"System Repository"* is set by default.

Installing devices

The device repository cannot be changed manually, e.g. by copying or deleting files. Use always the Device Repository dialog to add or remove devices.

1. Click *[Install]* and select the appropriate file format.
   ⇨ The *"Install Device Description"* dialog box opens.



2. Select the file path of the device description.
3. Select the file type filter of the required device description.
   ⇨ All device descriptions of the selected file type are listed.
4. Select the required device description and click *"Open"*.
   ⇨ Automation Builder adds the device description to the matching category of your device repository.

   If errors occur during installation (for example, missing files that are referenced by the device description), then Automation Builder displays them in the lower part of the device repository dialog box.

> *During the installation the device description files and all additional files referenced by that description will be copied to an internal location. Altering the original files will have no further effects to an internal location.*
>
> *The changes take only effect after reinstalling the corresponding device(s). The version number shown in the information section of the device should be verified.*

Uninstalling devices

Select the device you want to remove and click *[Uninstall]*.

The device is removed from the list.

> *Uninstalled devices which are used in existing projects are indicated by the symbol ❓. The device will not be configured properly.*

1.2.10 Creating and configuring projects

What is a project?

- A project contains the objects which are necessary to create a controller program ("application"):
  - Pure POUs, for example programs, function blocks, functions, and GVLs.
  - Objects that are also required to be able to run the application on a PLC. For example, task configuration, Library Manager, symbol configuration, device configuration, visualizations, and external files.
- In a project, you can program multiple applications and connect multiple controller devices.
- CODESYS manages device-specific and application-specific POUs in the *"Devices"* view ("device tree") and project-wide POUs in the *"POUs"* view.
- For the creation of projects, there are templates that already contain certain objects.
- Basic configurations and information for the project are defined in the *"Project Settings"* and *"Project Information"*. For example:
  - Compiler settings
  - User management
  - Author
  - Data about the project file

  There are settings for the version compatibility of the project in the configuration dialogs in the *"Project Environment"*.
- You save a project as a file in the file system. As an option, you can pack it together with project-relevant files and information into a project archive. It is also possible to save files in a source code management system such as SVN.
- Each project contains the information about the CODESYS version with which it was created. When you open it in another version, CODESYS will notify you about possible or necessary updates regarding file format, library versions, etc.
- You can compare, import/export projects, and create documentation for them.
- You can protect a project from being changed, or even completely protect it from being read. By using user management, you can selectively control the access to the project and even to individual objects in the project.

Handling of AC500 projects such as project creation, export/import, comparison of projects etc. is described in the sections for AC500 V2 products.

Chapter 1.6.5.1.1 "Project handling" on page 5757

1.2.11 Handling of AC500 projects

Handling of AC500 projects such as project creation, export/import, comparison of projects etc. is described in the sections for AC500 V2 products.

Chapter 1.6.5.1.1 "Project handling" on page 5757

Copy-and-paste from one project to another project in two different Automation Builder instances is possible. After copying parts of a project to a higher Automation Builder version the copied components have to be updated.

It is not possible to downgrade a project to an earlier Automation Builder version.

- *Import of export files is only allowed in the same profile version.*
- *Copy-and-paste of configurations must not be used to copy objects to an earlier version.*

> *Automation Builder performs an integrity check for the PLC configuration before generating the configuration.*

Project archive

Automation Builder supports the creation and the import of project archive files. Archive files contain all relevant project data including the PLC configuration, the CODESYS project files and all device descriptions. This allows exchanging Automation Builder projects without taking care of the target environment General Settings. *Chapter 1.6.5.1 “General settings” on page 5757*

User and access rights of a project

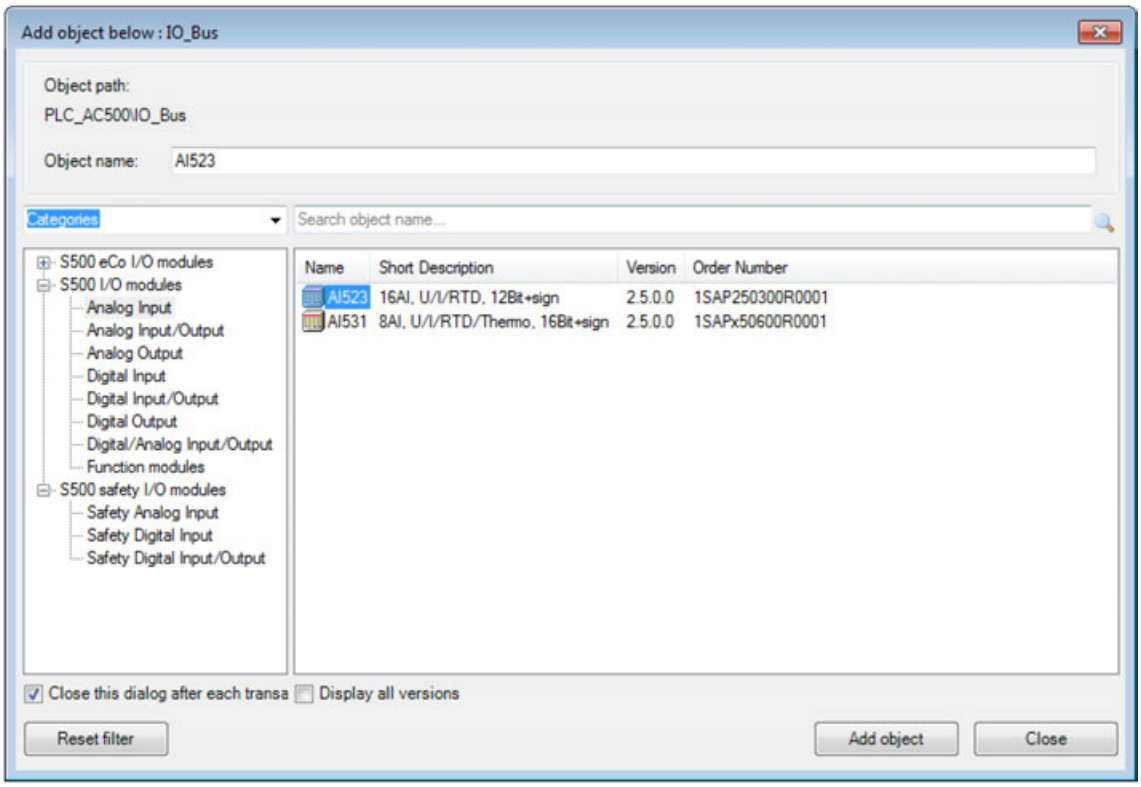
The 'User Management' provides functions for defining user accounts and configure the access rights within a project. The rights to access project objects via specified actions are assigned only to user groups, not to a single user account. So each user must be member of a group General Settings. *Chapter 1.6.5.1 “General settings” on page 5757*

1.2.12 Connection of devices

1.2.12.1 Configuring devices

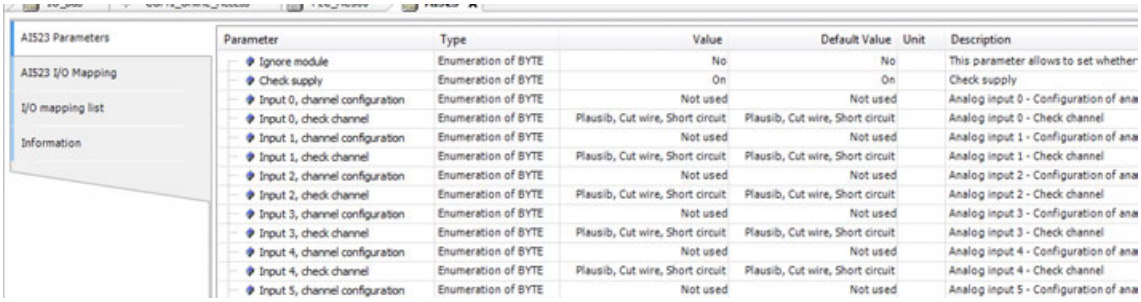
Modify your Automation Builder project by adding device objects. Preset items can be replaced in the same way.

1. In the device tree, right-click an item node. Select *“Add object”*.



2. Select the desired object and click *[Add object]*.

3. Double-click the new object in the device tree to configure the device settings. Depending on the selected item different configuration tabs are available.



1.2.12.2 Symbolic names for variables, inputs and outputs

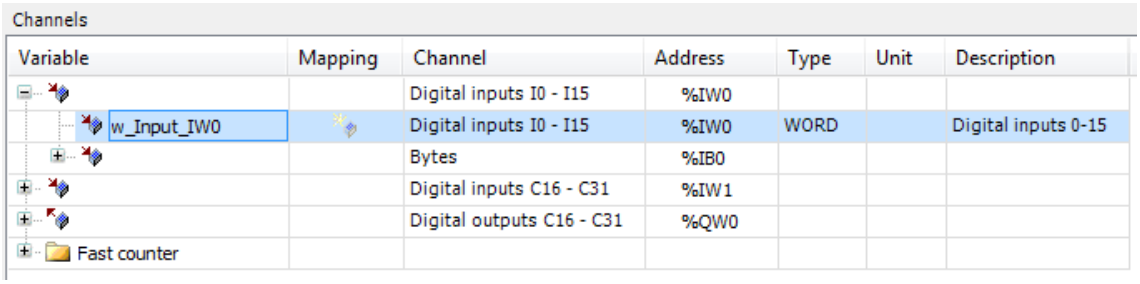
> *The IEC naming rules are not checked during input in Automation Builder.*

Input and output mapping

Devices with I/Os provide an I/O Mapping tab in their configuration editor where the available I/O channels can directly be mapped to a global variable.

The corresponding variable declarations are automatically created in a global variables object in a subfolder of the Global Variables section in the CODESYS project.

All available I/O channels can easily be assigned to a variable.

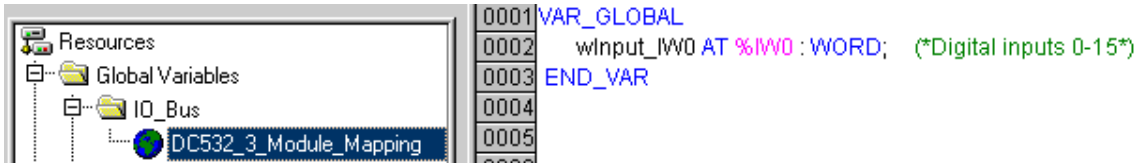


The variable is automatically added to the Global Variables in the CODESYS project after recreating the configuration data *Chapter 1.2.15.1 “Creating configuration data” on page 65*.

> *AC500 uses Motorola Byte Order (Big Endian).*
>
> *The numbers in column Channel correspond to the channel numbers only and not to the bit position inside the WORD variable.*

> *Only entries with a data type set in column "Type" can be mapped. These entries can be expanded to show the available I/O channels.*
>
> *If the project has been imported from a previous Automation Builder version, all variables should be checked to avoid inconsistencies concerning the I/O mapping.*

The variable is automatically added to the global variables in the CODESYS project after (re)creating the configuration data:



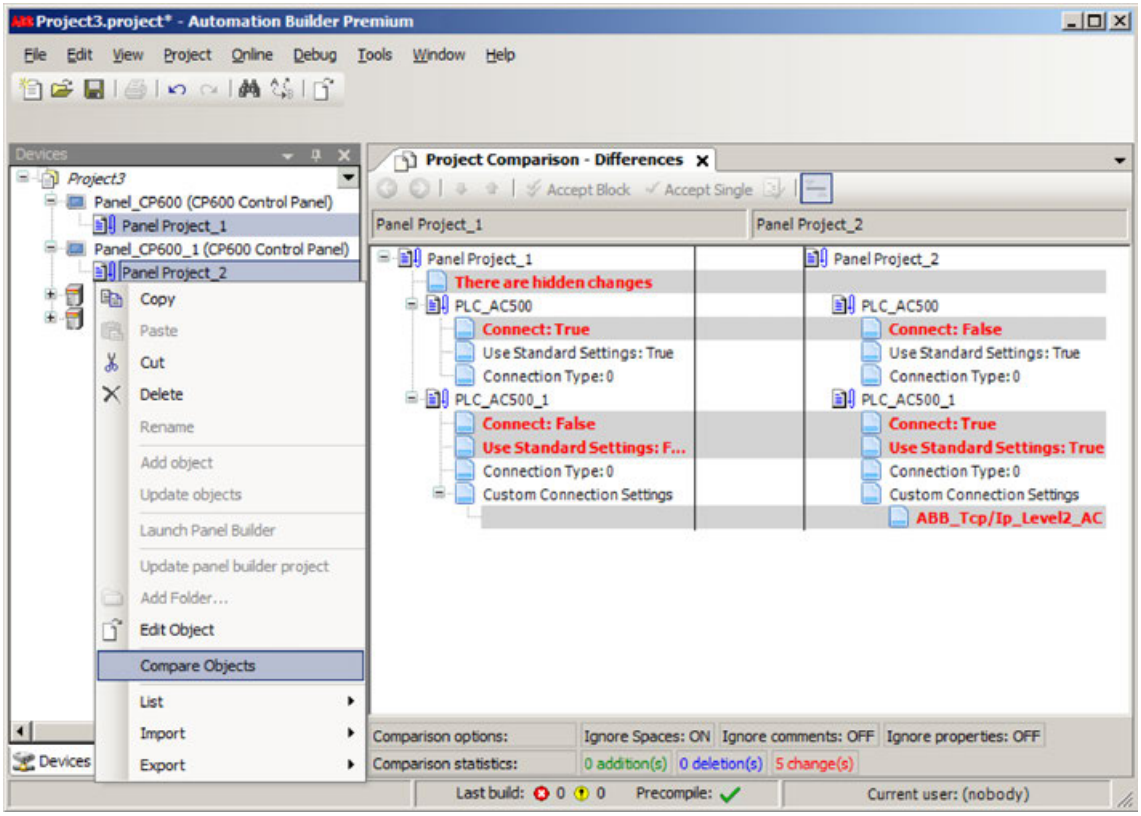
An additional GVL (Global Variables List) can be created and transferred to CODESYS V2.3. Editing of lists created in CODESYS V2.3 is not possible.

1.2.12.3 Update of AC500 devices

Perform a firmware update to update AC500 V2 devices. *Chapter 1.6.5.1.7 “Firmware identification and update” on page 5786*

1.2.12.4 Comparing objects

To compare similar objects within a project (such as the project configuration) select both objects. Right-click and select **Compare Objects** to see the differences.



1.2.13 Connection of serial interfaces

Depending on the device type, the configuration of serial interfaces is different.

AC500 V2 Products: *Chapter 1.6.5.2.11 “Serial interfaces COM1 and COM2” on page 6098*

1.2.13.1 Programming of applications

To create an application program which can be run on the controller, you fill POUs with declarations and implementation code (source code), establish the link from the controller I/Os to application variables, and configure the task assignment. After checking and debugging, the CODESYS compiler creates the application code which can be downloaded to the controller.

The programming of the application POUs is supported by the programming language editors and other features such as text lists, image pools, alarm configurations, pragmas, refactoring, and ready-to-use POUs from CODESYS Development System or libraries.

There are features for syntax checking and code analysis, for achieving data persistence, and for encrypting the application code which is downloaded to the controller.

1.2.14 I/O mapping

For all connected I/O devices perform an I/O Mapping.

↬ *Chapter 1.6.5.1.4 “I/O mapping list” on page 5781*

1.2.15 Data transfer and CODESYS programming

1.2.15.1 Creating configuration data

☑ If the setup of all devices has been finished, you can create the configuration file.

▷ Right-click on *“Application”* and select *“Create configuration data”* from context menu.

⇨ The generation process starts. The progress is shown in the status bar of Automation Builder.

Check integrity

Within a Automation Builder version only device versions of this Automation Builder version can be used. By following the use case described in the chapter Use Cases the system takes care about this project integrity. Additionally Automation Builder performs an integrity check for the selected PLC before generating the configuration.

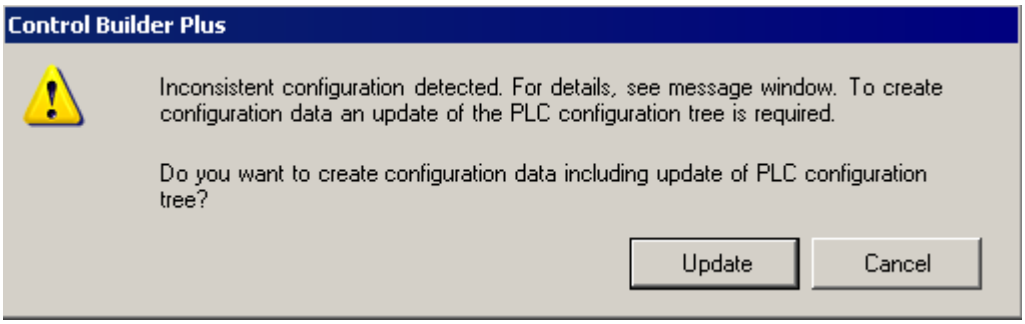
The integrity check can manually be called for the complete project:

1. Select the menu item *“Project ➔ Check integrity”*.

   ⇨ Automation Builder checks the project integrity for the complete project ("Project integrity" checks if all devices in the device tree are installed in the device repository).

   If the integrity check was successful a success message is displayed.

   If the integrity check was not successful the following message is displayed:



2. Click *“Update”* button:

   ⇨ Automation Builder updates the configuration to the latest version, creates configuration data and starts CODESYS V2.3.

3. Click *“Cancel”* button:

   ⇨ Creates configuration data and Automation Builder does not start CODESYS V2.3.

If the integrity check fails the Message Window displays further details.

> *In case of inconsistent configuration data update correct your project. Update all devices and install all 3rd party devices as used in the project.*

Following error messages indicating that devices are not installed properly: "The device XXXXXX was not found in the device repository! Please reinstall this device using the menu item *"Tools ➔ DeviceRepository"*.

Install the device. *Chapter 1.2.9 "Device repository" on page 58*.

"The version of device XXXXXX is not compatible with the current version."

Update to new version.

1.2.15.2 Launching programming system CODESYS V2.3.9.x

In your PLC project, double-click on *"Application"* to open the CODESYS V2.3.9.x project.

CAUTION!

Risk of damaged Automation Builder projects!

Projects created with Automation Builder are incompatible with CODESYS V2.3.9.x. Opening these projects directly with CODESYS V2.3.9.x may cause corrupted projects. Always use Automation Builder to open these projects.

> *If several instances of CODESYS V2.3.9.x are opened, double-clicking on the target item brings the corresponding CODESYS V2.3.9.x instance to the front.*

CPU name

The name of the used AC500 CPU is shown in the main node of the device tree.

The names of the devices can be edited by selecting the corresponding entry and clicking the entry. The name must be unique and cannot be reused in the same project. Automation Builder automatically appends double entries with an up counting number as an suffix.

> *The IEC naming rules are not checked during input in Automation Builder.*

1.2.15.3 Source download/upload in Automation Builder

Source download

The *"Source download"* downloads and stores the current project as a Zip-file on the PLC's memory card.

- Right-click *"PLC_AC500_V2 <...>"* node and click *"Source download"*.

Source upload

The *"Source upload"* retrieves a previously downloaded project from memory card to a selectable directory on the Automation Builder PC and optionally opens Automation Builder with this uploaded project.

- Click *"File"* in the main menu of Automation Builder and click *"Source upload"*.

Internally both commands are invoking a hidden instance of CODESYS V2.3 which is then working in batch mode to accomplish the download/upload.

Most of the error messages which could occur during the process are raised by CODESYS V2.3 and will then be displayed in Automation Builder as a result message box (the language of the message box is the installed language of CODESYS V2.3, the messages are sometimes quite "basic").

Before using the commands, check the following:

- *No CODESYS V2.3 instance started from within Automation Builder on the same PLC node should be running.*
- *To perform the download/upload, CODESYS V2.3 must be able to log in/on to the PLC. Therefore the gateway settings should be correct and saved to project file. It is recommended to test once the ability of CODESYS V2.3 to log in/on to the PLC.*
- *A formatted memory card must be mounted in the PLC's memory card slot.*

1.2.16 AC500 PLC configuration

See Getting Started for AC500 V2 products. *Chapter 1.2.18.1.1 "Hardware AC500 V2" on page 67*

See Starter Kit for AC500-eCo products. *Chapter 1.6.1.10 "AC500-eCo starter kit" on page 3741*

1.2.17 Converting an AC500 V2 project to an AC500 V3 project

A project that has been configured for an AC500 V2 PLC can be converted to a project for an AC500 V3 PLC.

Essentially, the conversion is done in Automation Builder, however, some additional actions have to be executed manually. The complete procedure is described in the application example

Instructions on how to convert a V2 project to a V3 project and differences between V2 and V3.

1.2.18 Example projects

1.2.18.1 Example projects for AC500 V2

1.2.18.1.1 Hardware AC500 V2

Configuration for example projects

The example projects require a small PLC configuration with I/O devices, e.g., as available in the training case TA515-CASE. *https://to.abb/AfO9-ftT*

Table 2: Modules for example projects to get started with AC500 V2 PLC

Product name	Type	First project ↳ *Chapter 1.2.18.1.2 "Example project for central I/O expansion" on page 70*	Second project ↳ *Chapter 1.2.18.1.3 "Example project for remote I/O expansion with PROFINET" on page 109*
PM585-ETH	AC500 V2 CPU	x	x
TB521-ETH	terminal base for CPU	x	x
DA501	analog/digital mixed input/output (I/O) module	x	x
TU516-H	terminal unit for I/O module	x	x
CM579-PNIO	PROFINET communication module	--	x
CI502-PNIO	PROFINET communication interface module	--	x
TU508-ETH	terminal unit for communication interface module	--	x
TA524	blind cap for terminal base	x	x

Connections

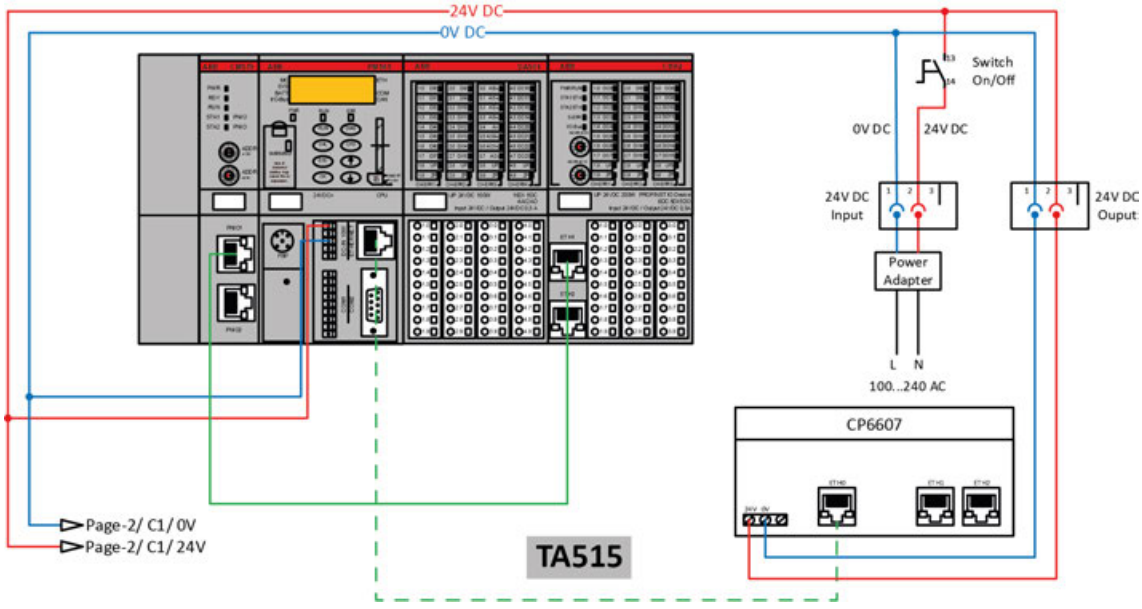


Fig. 5: Training case TA515

In the training case, the control panel CP6607 is included. A control panel is not needed for the example projects.

For testing the example project some inputs require to be connected as follows:

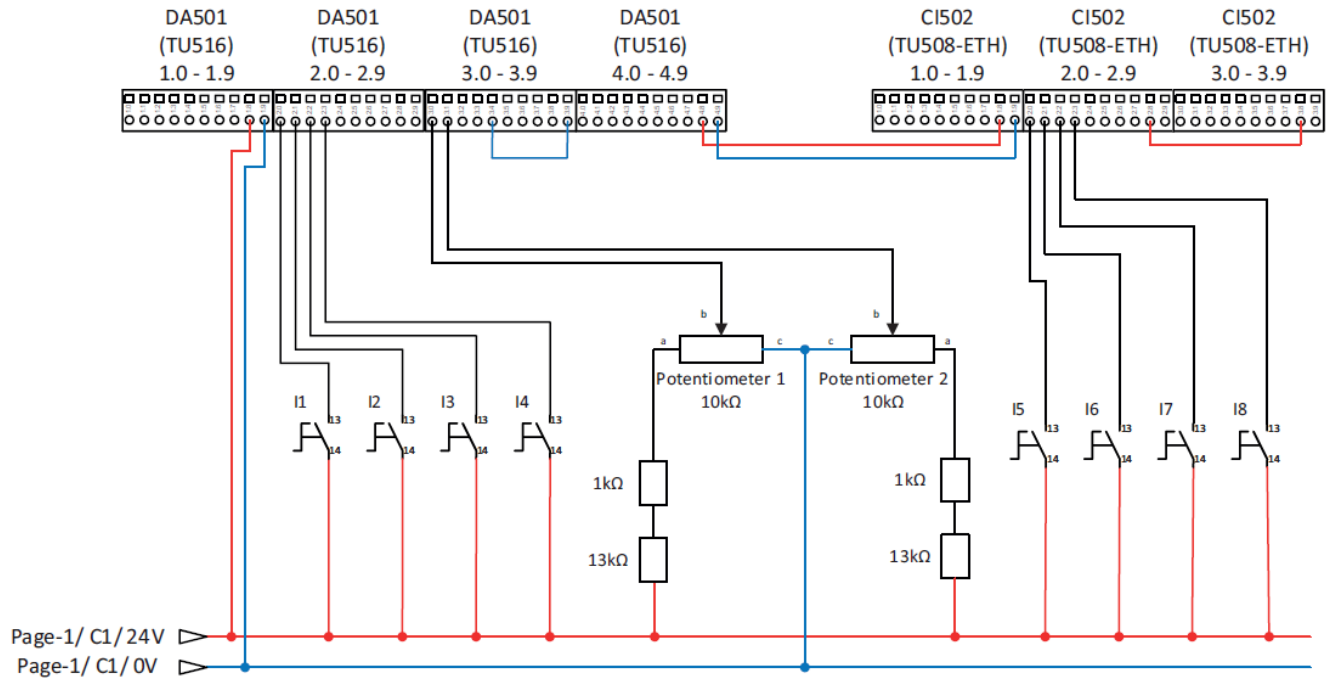

Fig. 6: Wiring of training case

> *For the example projects, not all input switches and none of the potentiometers included in training case are necessary.*
>
> *You will need switch I1 for the example project for central I/O expansion.*
>
> *You will need switch I5 for the example project for remote I/O expansion.*

System assembly, construction and connection

> **NOTICE!**
>
> **Avoidance of electrostatic charging**
>
> PLC devices and equipment are sensitive to electrostatic discharge, which can cause internal damage and affect normal operation. Observe the following rules when handling the system:
>
> – Touch a grounded object to discharge potential static.
> – Wear an approved grounding wrist strap.
> – Do not touch connectors or pins on component boards.
> – Do not touch circuit components inside the equipment.
> – If available, use a static-safe workstation.
> – When not in use, store the equipment in appropriate static-safe packaging.

You can mount AC500 PLC either to DIN rail or to a metal plate ↬ *Chapter 1.6.3.6.3 “Mounting and demounting” on page 5325*. Here, we recommend to mount on DIN rail.

1. Snap the terminal base onto DIN rail.
2. Snap the additional terminal units for I/O modules onto DIN rail.
3. Make the sensor/actuator wire connections according to the dedicated electronic module you want to use. Provide external process power supply as required.
4. If required, make the fieldbus connections according to the dedicated master communication module you want to use.

5. Plug the appropriate electronic and I/O modules in the correct locations (processor module, communication modules on terminal base, and eventually also communication interface modules and I/O modules onto dedicated terminal units).
6. Connect a programming cable (Ethernet cable between ETH port of CPU and PC with engineering software).

1.2.18.1.2 Example project for central I/O expansion

The following steps show how to set-up an application project and configure the hardware. A simple logic is used as example to introduce in programming and commissioning of the PLC. The workflow for creation of a visualization is explained, as well as how to set-up a web server for visualization.

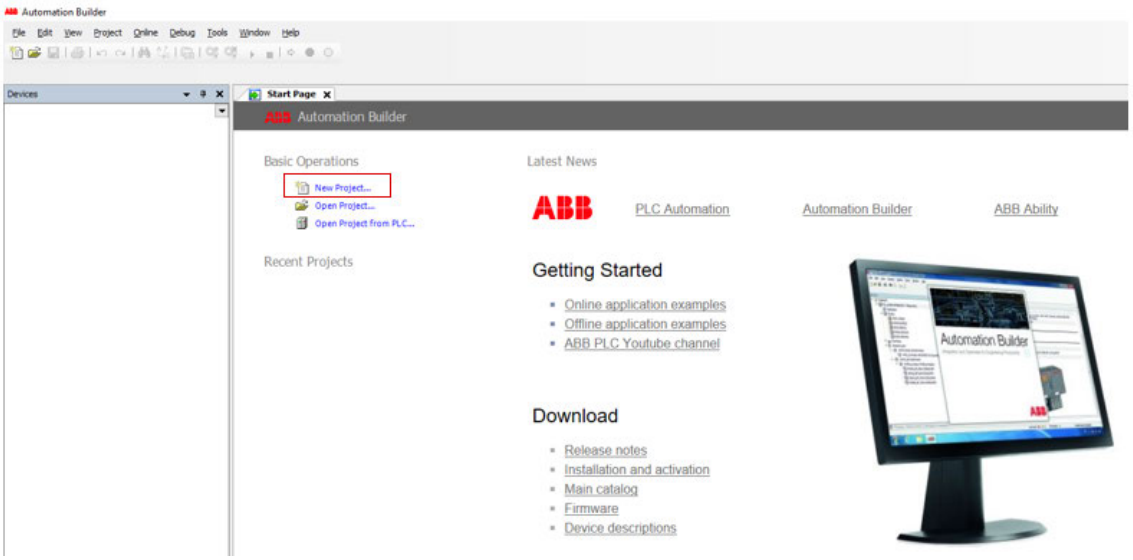
Preconditions

- Automation Builder is installed and licensed as, at least, basic edition ↬ *Chapter 1.2.4 "Managing your licenses" on page 20*.
- AC500 V2 CPU is assembled and connected to the PC ↬ *Chapter 1.2.18.1.1 "Hardware AC500 V2" on page 67*.

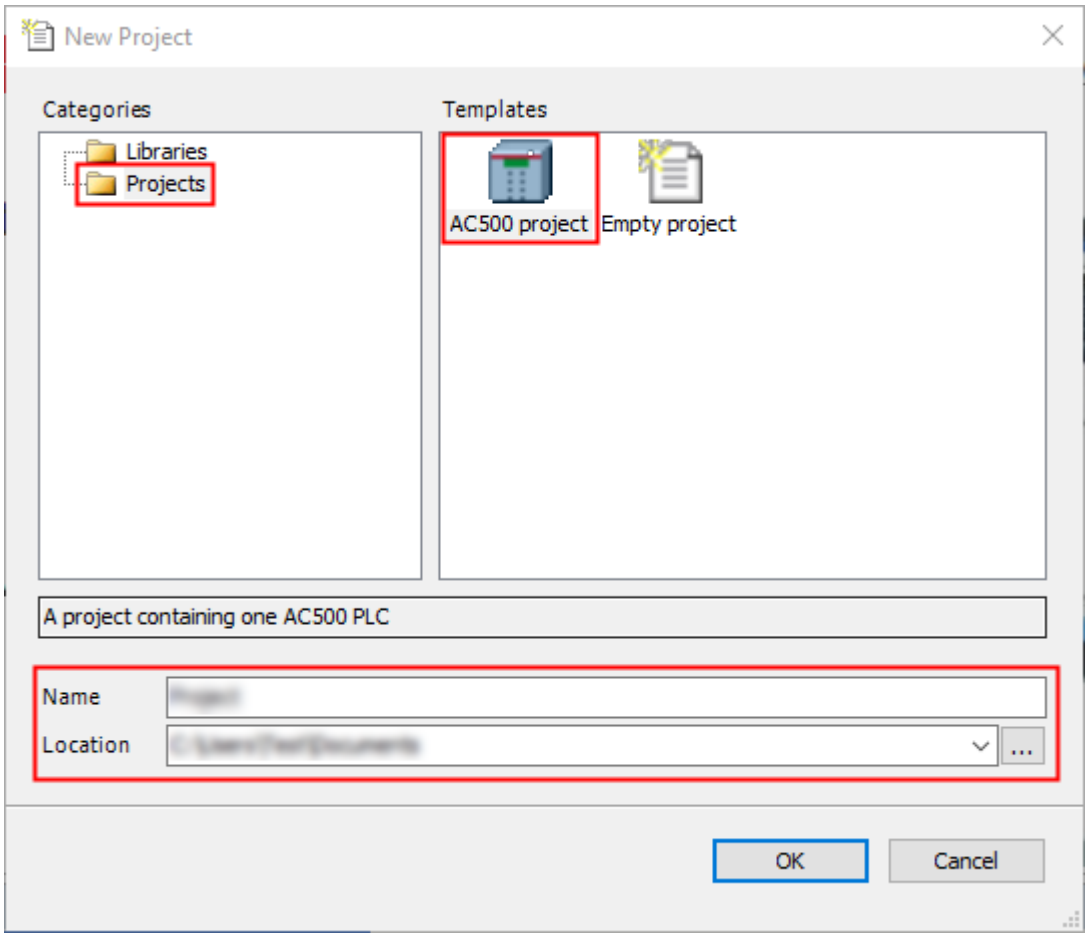
Create, set-up and save your AC500 V2 project

Create a project

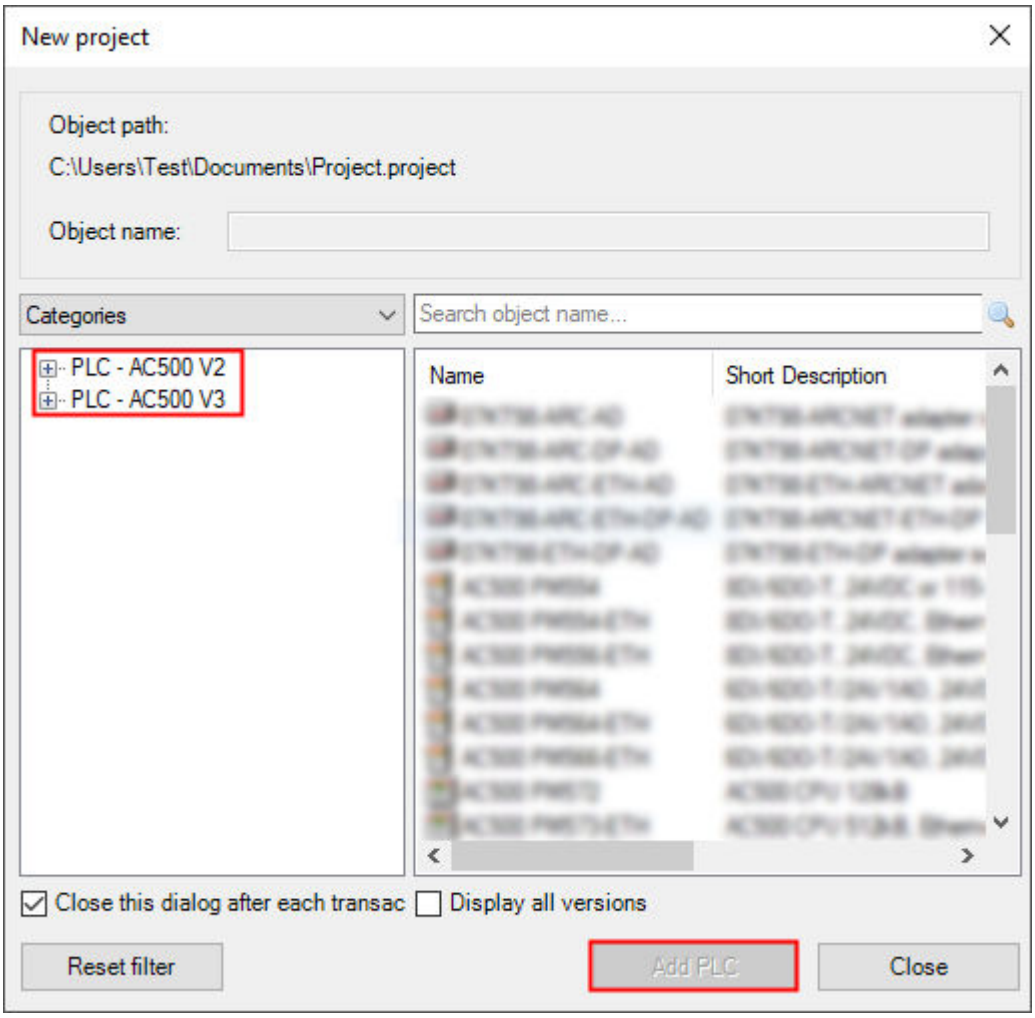
1. Launch Automation Builder either out of the desktop icon or out of the Windows menu.



2. Select *"New Project"* or go to menu *"File ➔ New Project"*.

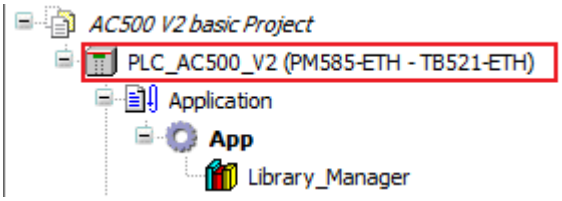


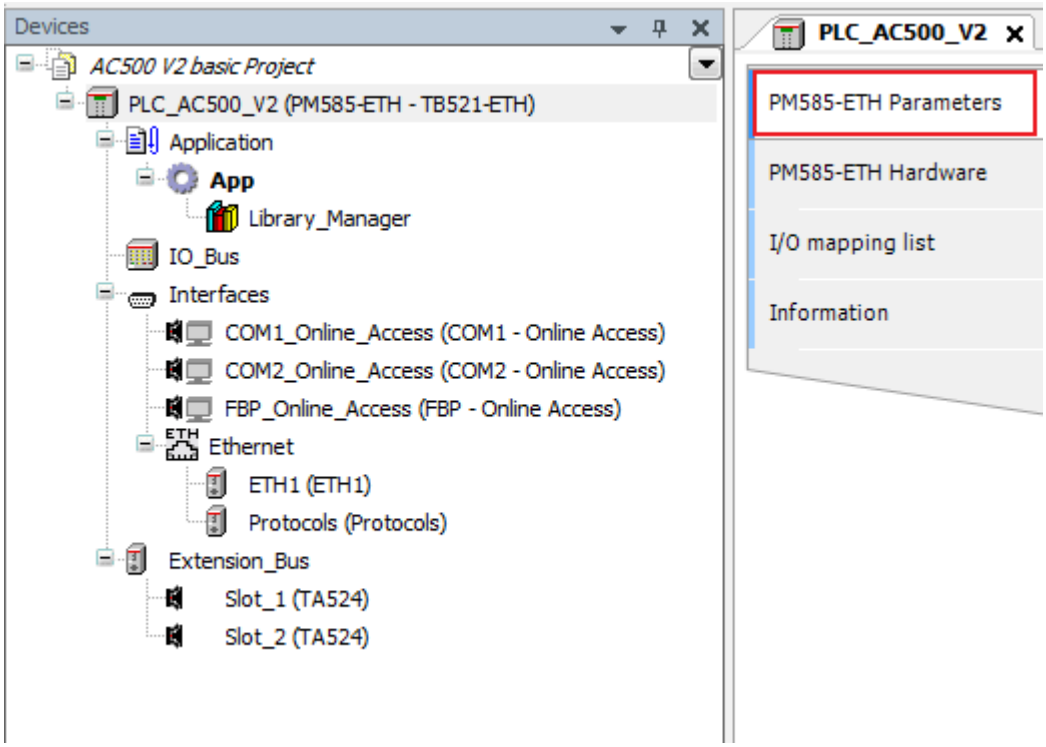
3. Select *“Projects”*.
4. Select *“AC500 project”*.
5. Fill in project name.
6. Choose a location to save the project to.
7. Select *“OK”*.
8. Select *“PLC - AC500 V2”*.
9. Select the CPU according to your hardware set-up.



10. Select *"Add PLC"* to add the CPU to your application.

Configure your CPU

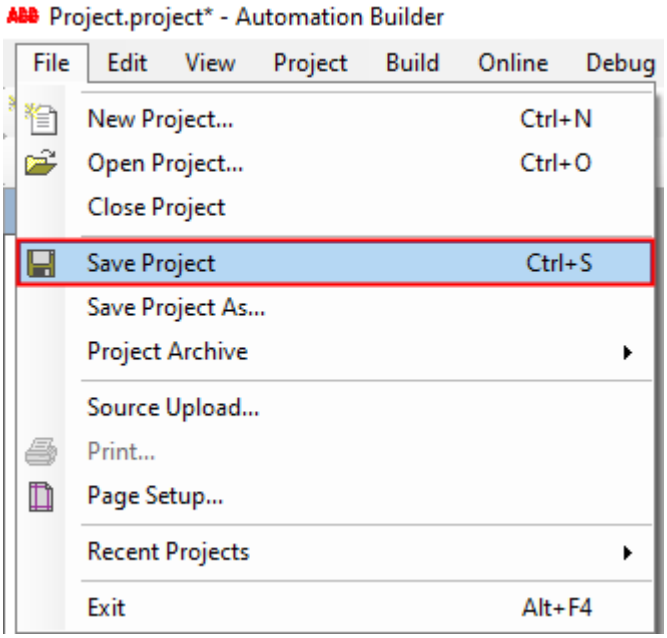




Parameter	Type	Value	Default Value
Auto run	Enumeration of BYTE	On	On
Error LED / Failsafe function	Enumeration of BYTE	On	On
Check battery	Enumeration of BYTE	On	On

1. Double-click *“PLC_AC500_V2”*.
   ⇨ A tab opens in the editor view.
2. Select *“CPU-Parameters Parameters”*.
3. Under parameter *“Check battery”*, choose the value *“Off”* since there is no battery present inside the CPU module.
4. Keep the default values for all other parameters.

Save the project



▷ Select menu *"File ➔ Save Project"*.

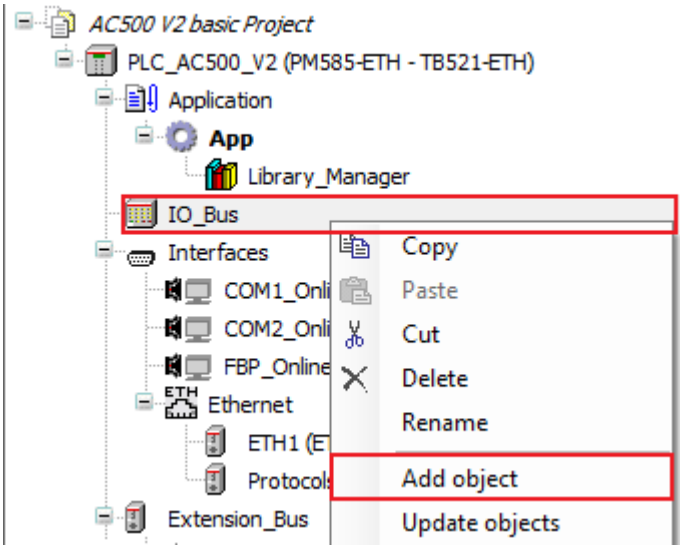
Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl]* + *[S]*.

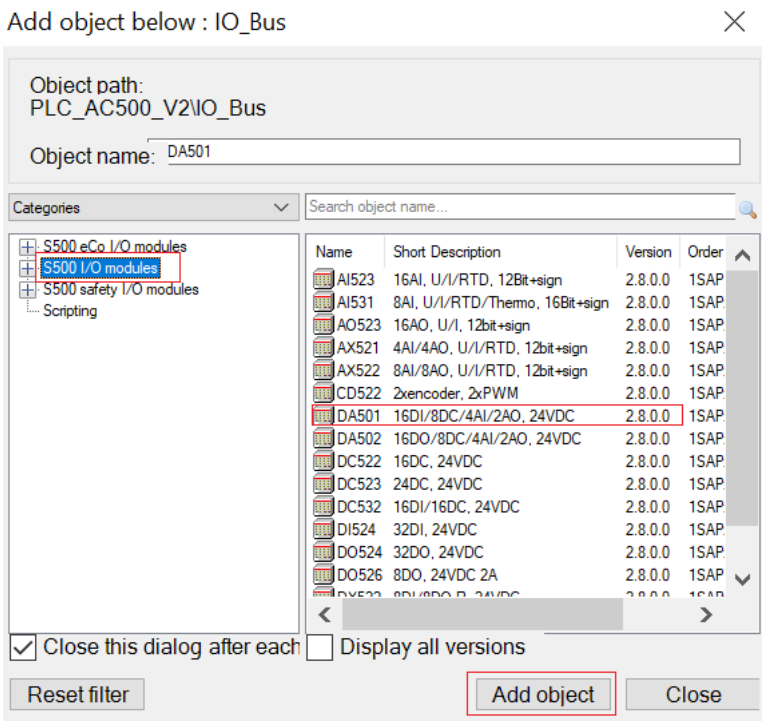
Configure the I/O module

- The types and order of modules in the Automation Builder project must match the real hardware configuration.
- The position of the modules in the device tree can be changed by drag and drop.

Add an I/O bus module

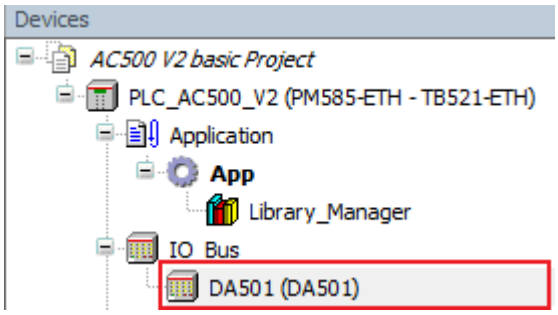


1. Right-click *"IO_Bus"* in the device tree.
2. Select *"Add object"*.

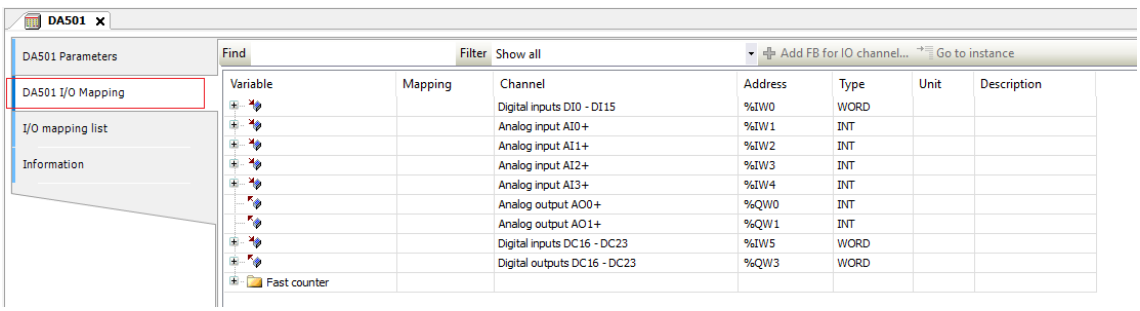


3. Select *“S500 I/O modules”*.
4. Select *“DA501”* module.
5. Select *“Add object”* to add the module to the I/O bus.

DA501 variable mapping

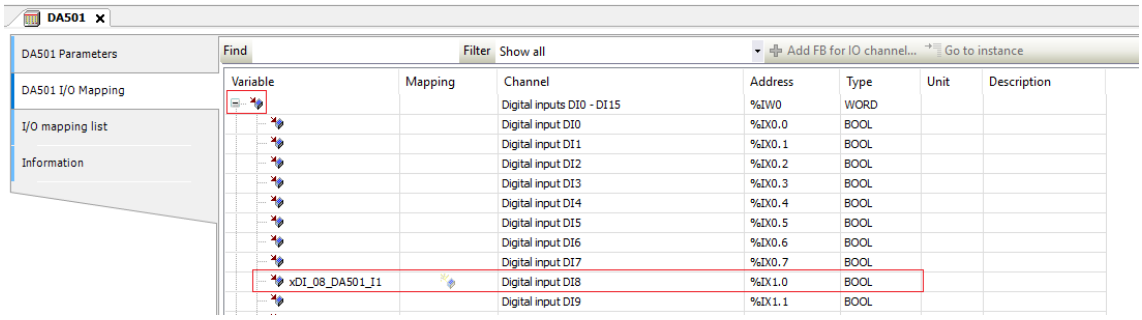


1. Double-click *“DA501”* in the device tree.
   ⇨ A tab opens in the editor view.
2. Select *“DA501 I/O Mapping”*
   ⇨ Here, you will map variable names (symbols) for the channels you will need in the program.



The suggested name convention is based on "Hungarian notation". A name prefix is describing variable type: e.g., "x" = variable of type BOOL, "w" = WORD, "i" = INT (integer) etc. This increases the code readability and is helpful for program analysis.

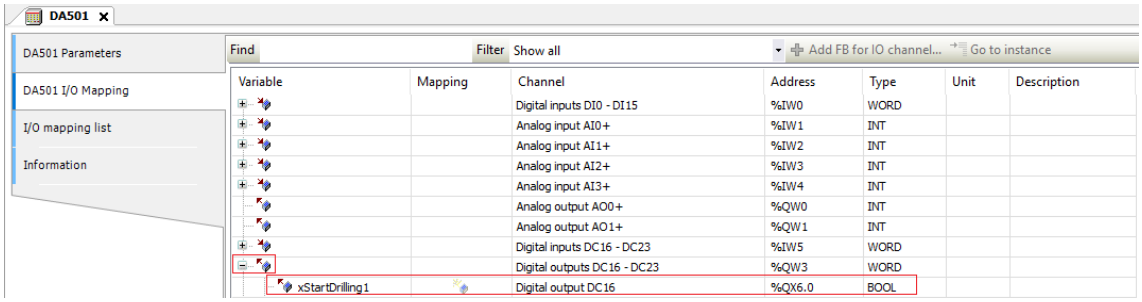
Handle the digital input variables



1. Open the list of the digital inputs.
2. Fill in the variable names:

Channel	Type	Variable
Digital input DI8	BOOL	xDI_08_DA501_I1

Handle the digital output variables



1. Open the list of the digital outputs.
2. Fill in the variable names:

Channel	Type	Variable
Digital output DC16	BOOL	xStartDrilling1

Programming and compiling

You write the program code in a separate IEC 61131-3 editor (CODESYS). You can open CODESYS out of Automation Builder.

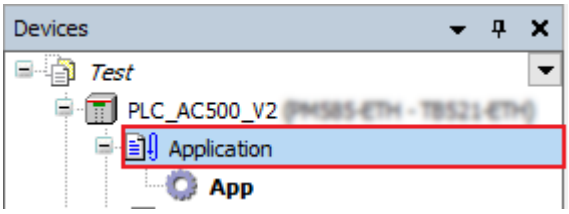
Supported programming languages:

- ST (Structured Text)
- IL (Instruction List)
- FBD (Function Block Diagram)
- LD (Ladder Diagram)
- SFC (Sequential Function Chart)
- CFC (Continuous Function Chart)

Starting the IEC 61131 programm editor CODESYS

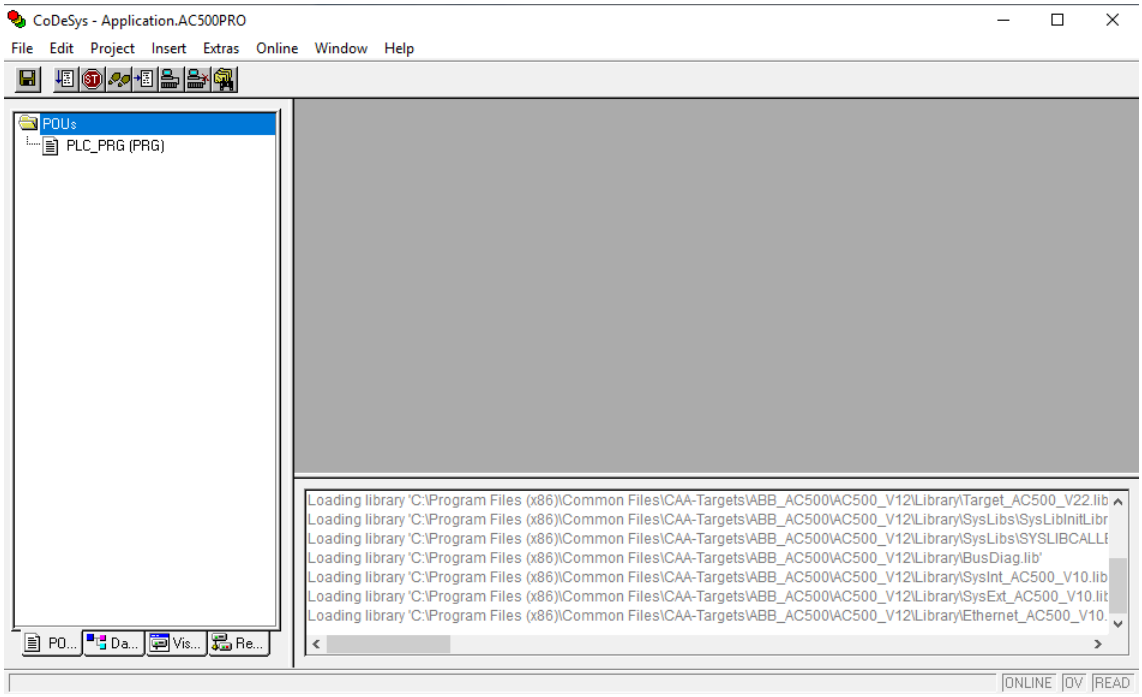
To start the IEC 61131 programm editor CODESYS:

☑ Open an AC500 V2 project in Automation Builder



▷ In the Automation Builder device tree double-click *“Application”*

⇨ This will start the IEC 61131 programm editor CODESYS



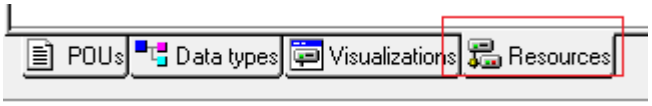
Task configuration

A task is a time unit in the processing of a user program (IEC application), which defines by parameters the way and the speed the CPU is executing the user program.

For this project you will use only one cycling task.

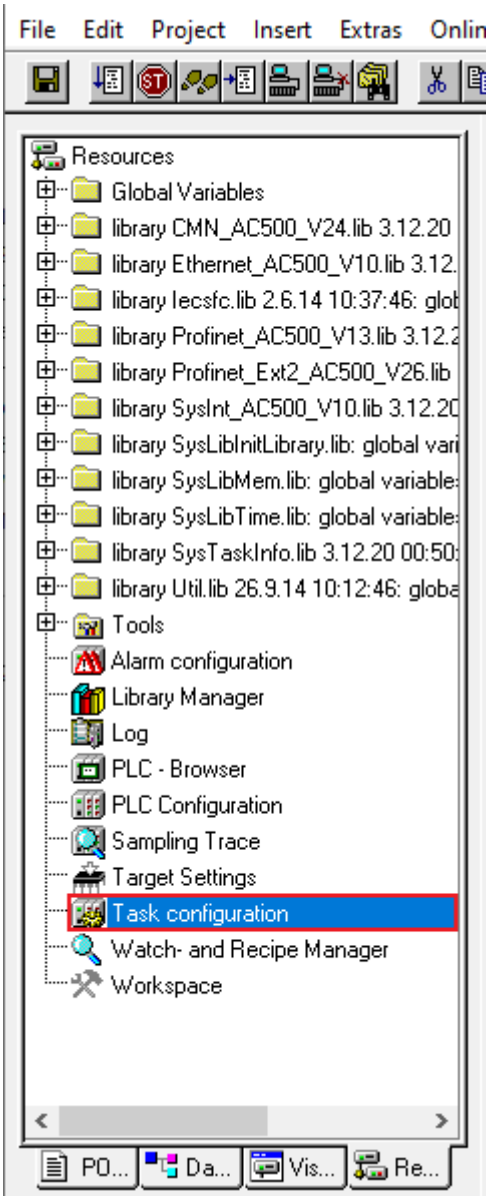
☑ Open CODESYS editor ↳ *Chapter 1.2.18.1.2.4.1 “Starting the IEC 61131 programm editor CODESYS” on page 77*

1. In the CODESYS editor menu select the *“Resources”* tab.

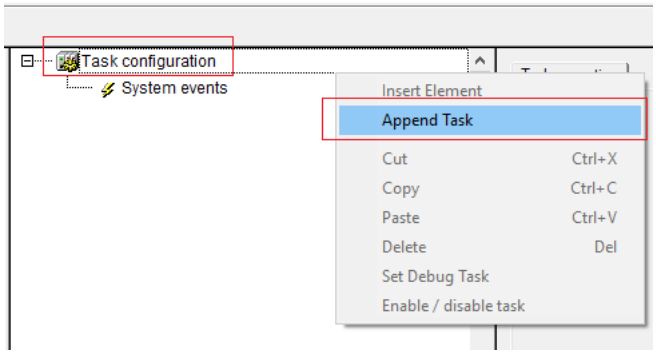


2. Double click *“Task configuration”*.

⇨ The Task configuration window opens.

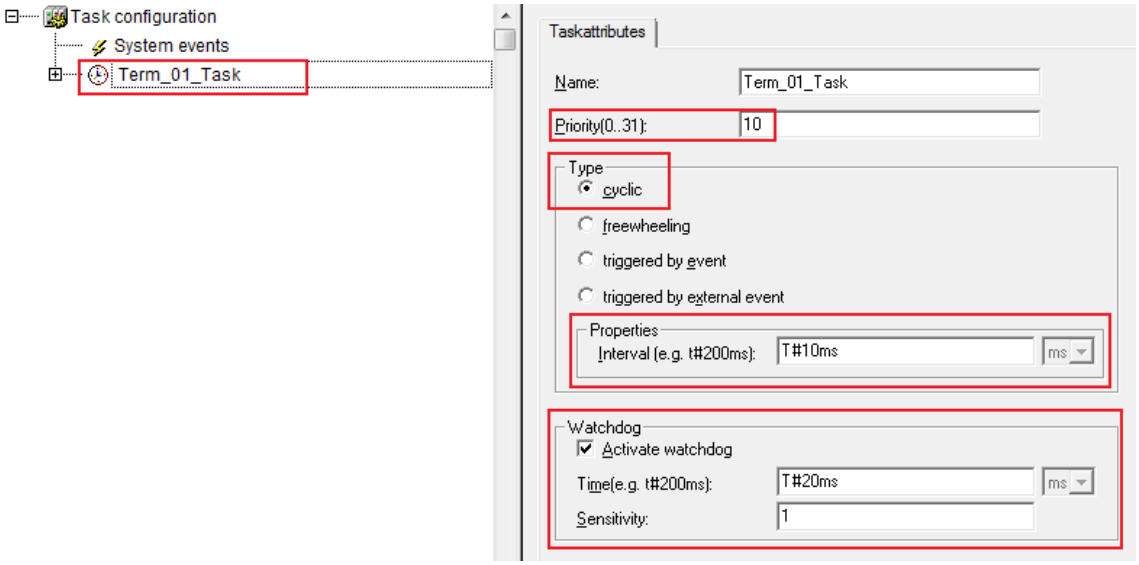


3. Right-click on *"Task configuration"*.
4. Select *"Append Task"*.



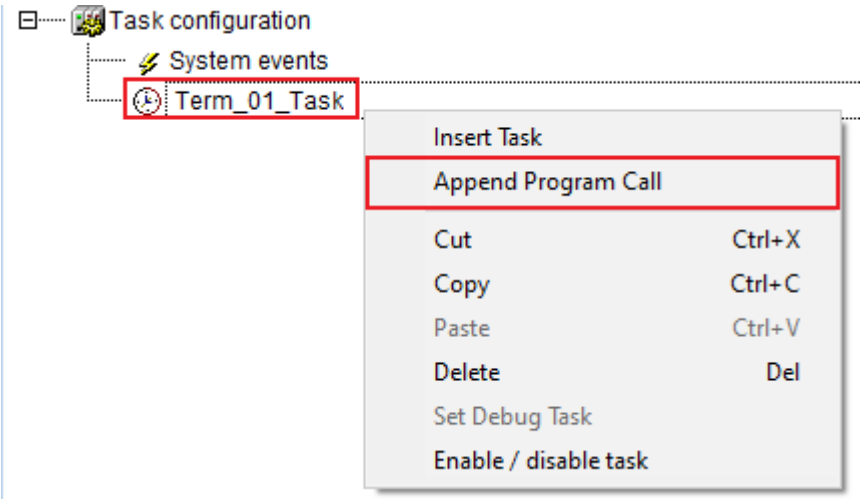
5. Enter a name.
6. Set *"Priority"* to 15
7. Set *"Type"* to *"cyclic"*.
8. Set *"Interval"* to *"T#10ms"*.

9. Activate Watchdog.
10. Set *“Time”* to *“T#20ms”*.

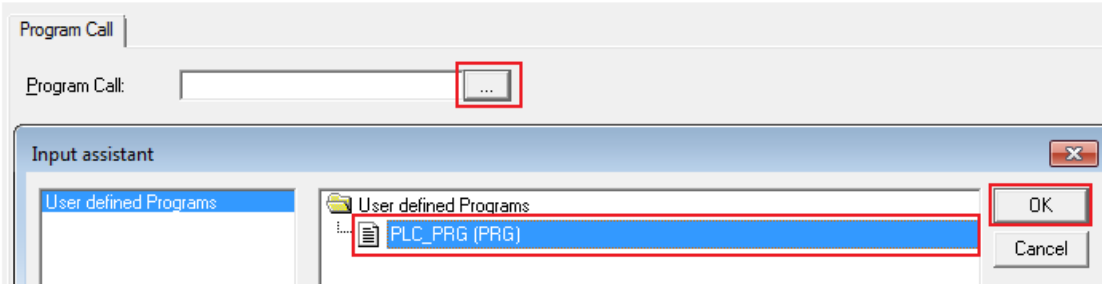


Priority type interval	This is how the CPU prioritizes the task, when more than one task is defined. Type In the CPU you can run tasks dependent on the demands of the process Interval For cyclic tasks you can set the cyclical execution time. It is usually set in milliseconds with IEC time syntax
Watchdog calls	To keep track of the time it takes to complete the task Calls You can call in one or more program POUs in one single task

11. Right click the watch icon next to *“Term_01_Task”*.
12. Select *“Append Program Call”*.

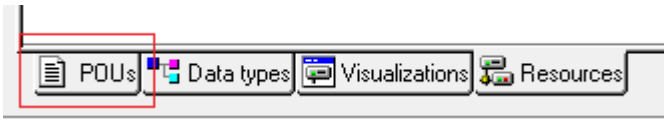


13. Select *“[…]”*.
    ⇨ The input assistant opens.
14. Select *“PLC_PRG (PRG)”*.
15. Select *“OK”*.
    ⇨ The task has been appended.

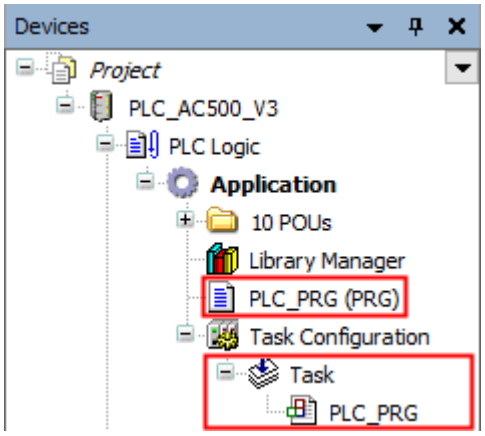


Main program PLC_PRG

In CODESYS menu select tab POUs, there is one call of a POU (program organization unit) i.e. "PLC_PRG".



In your project the "PLC_PRG" will become a main program containing calls to other programs (POUs) which you will create one by one.



The PLC_PRG POU has been defined by default in ST (Structured Text) editor. Keep this setting because of good visibility of the instructions at a glance and good handling for trouble-shooting.

Boolean logic "NOT"

Application example "driller"

Recognizing of a driller by a photo sensor. "TRUE" input signal from sensor indicates that a driller is broken. If driller has been found correct, then start drilling.

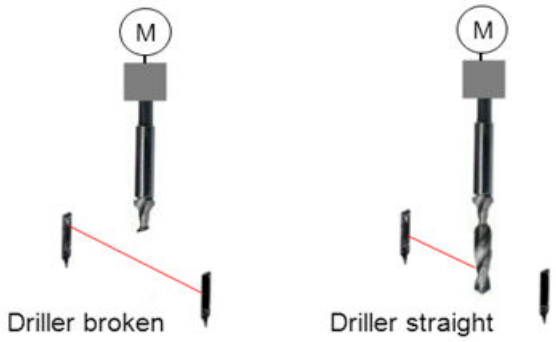


Table 3: Required behavior

Signal from photo sensor	Required signal of motor ON
FALSE	TRUE
TRUE	FALSE

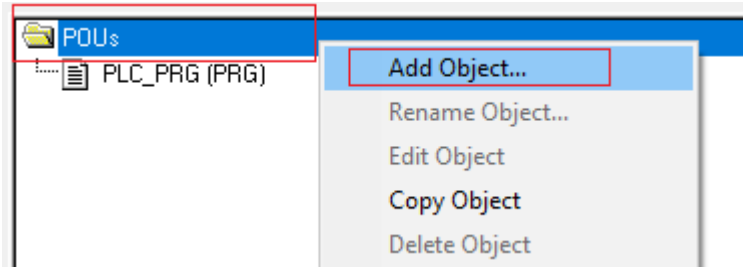
Table 4: Hardware set-up

Element	HW channel	Symbol	Description
Switch I1	DA501 DI8	xDI_08_DA501_I1	Photo sensor
LED output DC16	DA501 DC16	xStartDrilling1	Motor on

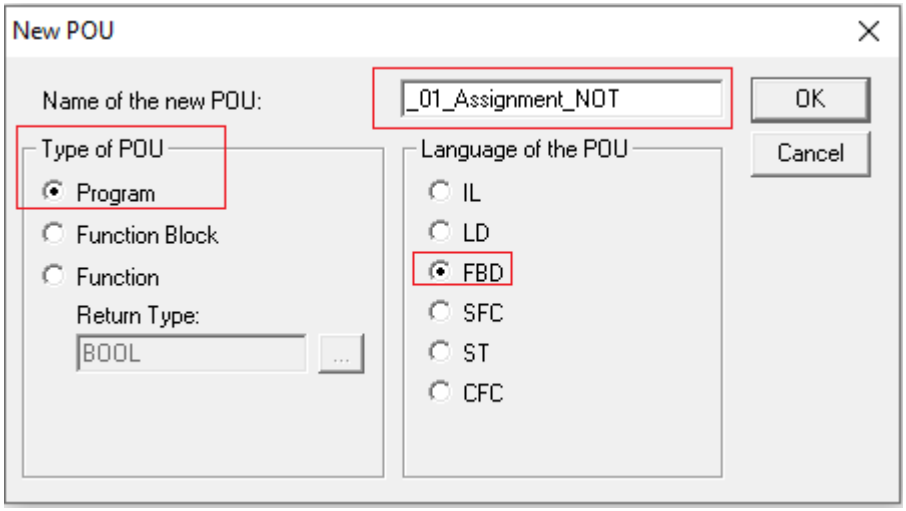
Implementation

Create a new program POU in the project

1. In the CODESYS menu select POUs
2. Select *“Add object”*

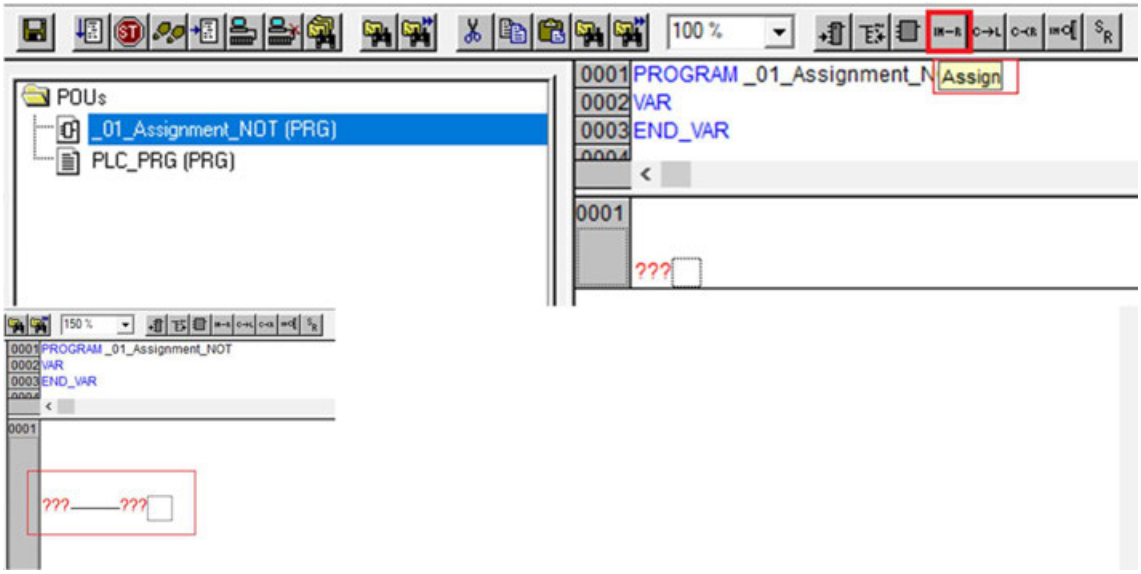


3. Enter *“_01_Assignment_NOT”*.
4. Set *“Type of POU”* to *“Program”*.
5. Set *“Language of the POU”* to Function Block Diagram *“FBD”*.
6. Select *“OK”*.
   ⇨ POU has been added.

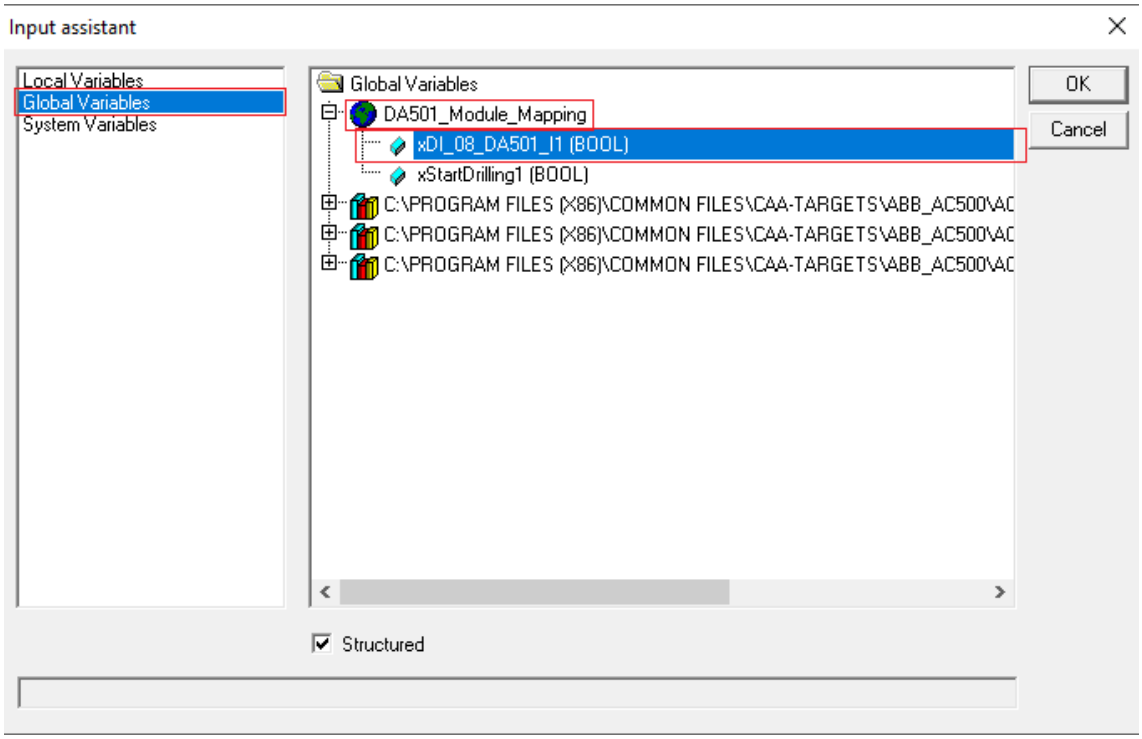


Assign the hardware DI signals to local variables

1. In the CODESYS device tree double-click POU *"_01_Assignement_NOT"*.
2. Click inside of the first Network.
3. Select *"Assign"* from Tools.

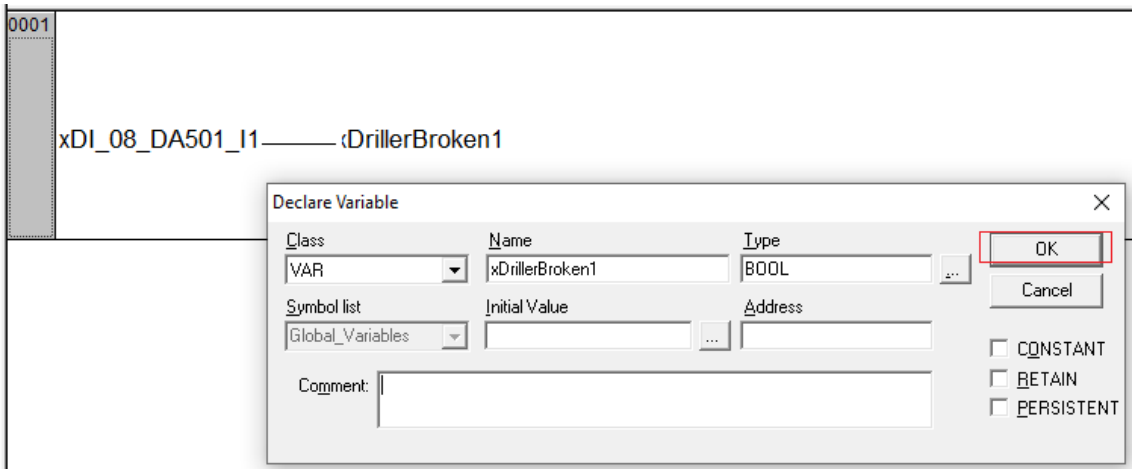


4. Select *"???"* on the left side of the assignment and press *[F2]*.
   ⇨ *"Input Assistant"* opens.
5. Under *"Global Variables"* open *"DA501_Module_Mapping"*.



6. Select *"xDI_08_DA501_I1"*.
7. Select *"???"* on the right side of the assignment connector.
8. Create a new local variable by typing in *"xDrillerBroken1"* which will replace the *"???"*.
9. Press *[Enter]*.

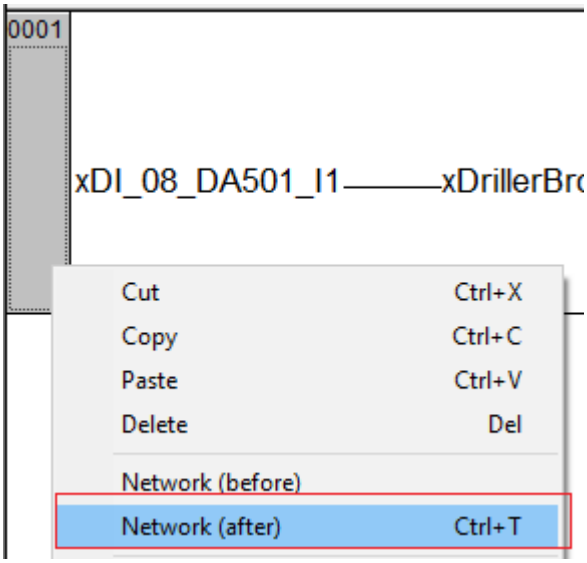
   ⇨ *"Declare Variable"* opens. You see the written variable name and the data type BOOL. The scope is "VAR". It means it is a local variable within this POU.



10. Select *"[OK]"* to accept the entries.

11. Right-click on network 1 and select Network (after)

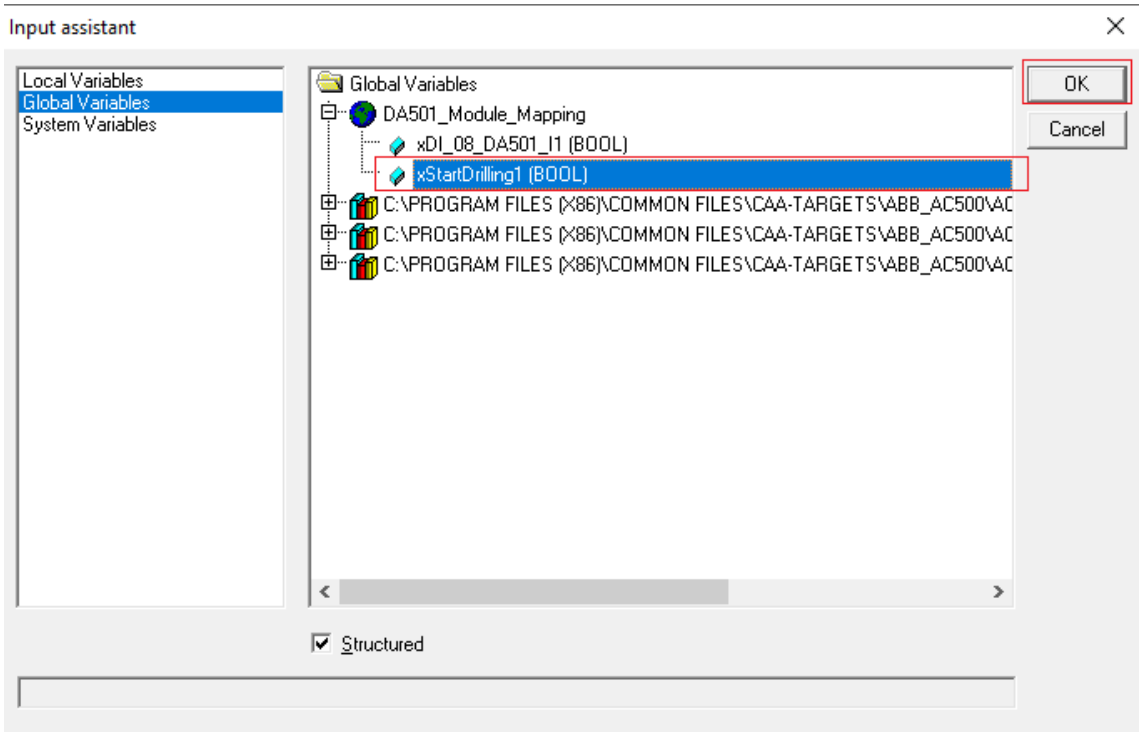
    ⇨ You added a network *“2”* below network 1.



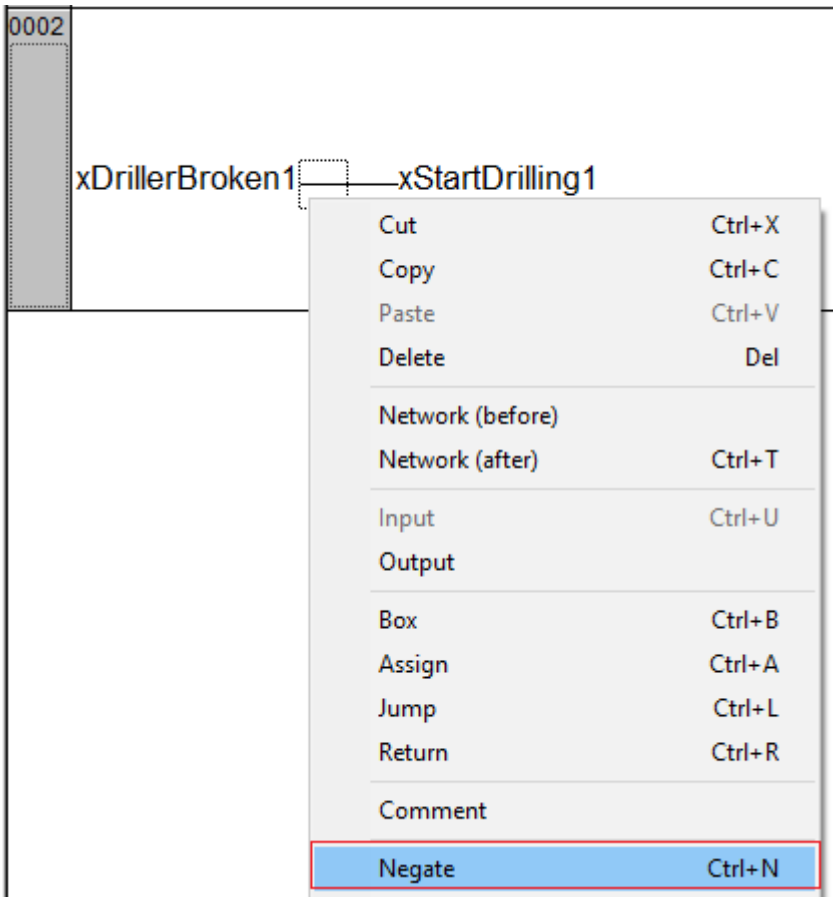
Add assignments and a Boolean NOT to the DO signals

1. Add an assingment from the Tools.
2. Type in or copy & paste "xDrillerBroken1" to the left side of the instruction line.
3. Select *“???”* on the right side of the instruction line, then press F2.

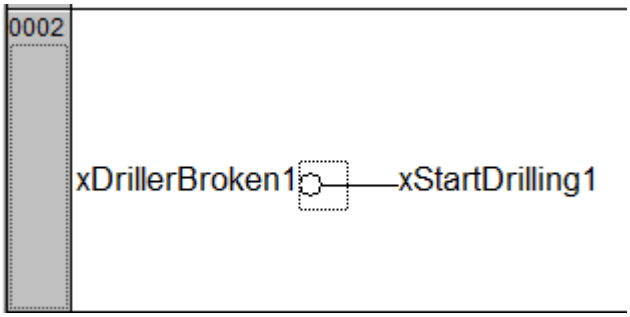
    ⇨ *“Input Assistant”* opens.
4. Under “Global Variables” open “DA501_Module_Mapping”
5. Select *“xStartDrilling1”*
6. Select *“[OK]”* to close the dialog.



7. Right-click the left side of assignment PIN.

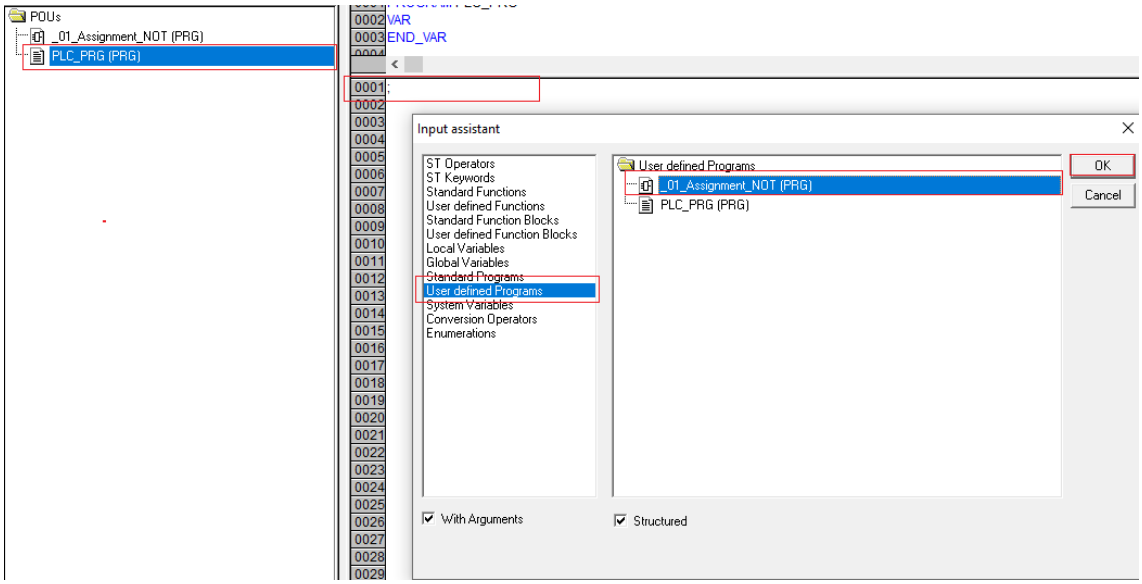


8. Select *“Negate”* to add a negation to the assignment



Call the POU in the PLC_PRG

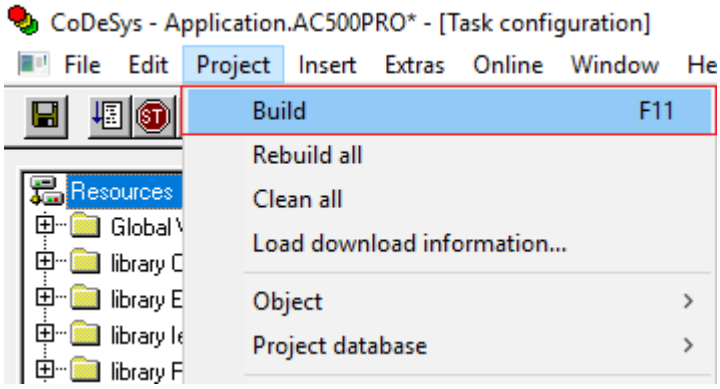
1. Double-click *“PLC_PRG”*.
2. Select the first line in *“PLC_PRG”* and press *[F2]*
   ⇨ *“Input Assistant”* opens.



3. Open *“User defined Program”*
4. Select *“_01_Assignment_NOT”*
5. Select *“OK”* to close the dialog

Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

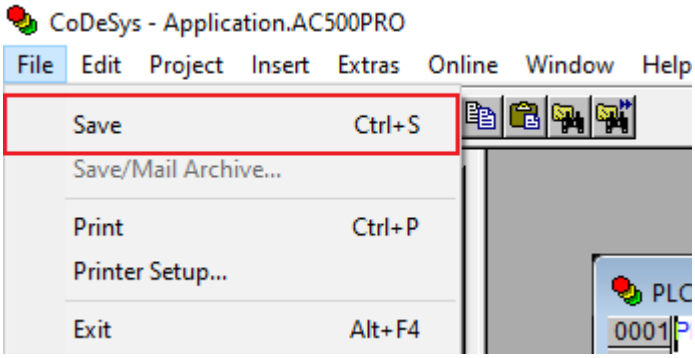


▷ In the CODESYS editor menu select *“Project ➔ Build”*

⇨ The result of the compiling is shown in the *“Messages”* field at the bottom of the screen.

If you skip the compiling and select *“Login”*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save CODESYS project



▷ In the CODESYS editor menu select *"File ➔ Save"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl]* + *[S]*.

Set-up the communication gateway

Set-up communication parameters

To set-up the communication between the PC and the PLC, e.g., for downloading the compiled program, you have to set-up the communication parameters.

The IP address of your PC must be in the same class as the IP address of the CPU.

The factory setting of the IP address of the CPU is 192.168.0.10.

The IP address of your PC should be 192.168.0.X. Avoid X = 10 in order to prevent an IP conflict with the CPU.

Subnet mask should be 255.255.255.0.

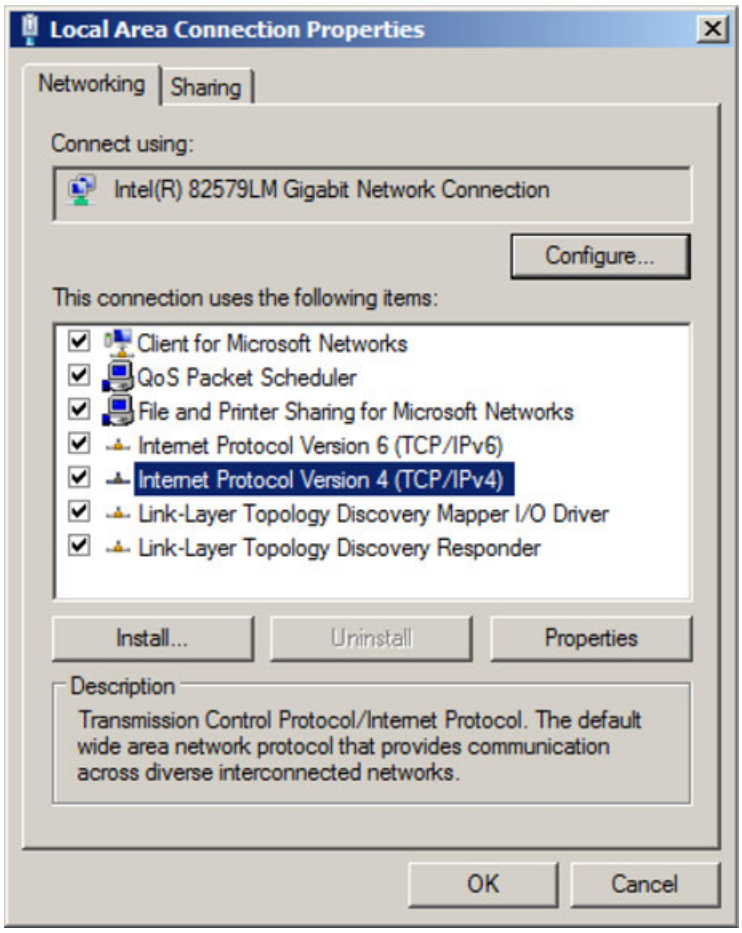
Change the IP address

1. Open Windows **Control Panel**. Click *"Network and Internet ➔ Network and Sharing Center"*.
2. Click **Change adapter settings**.

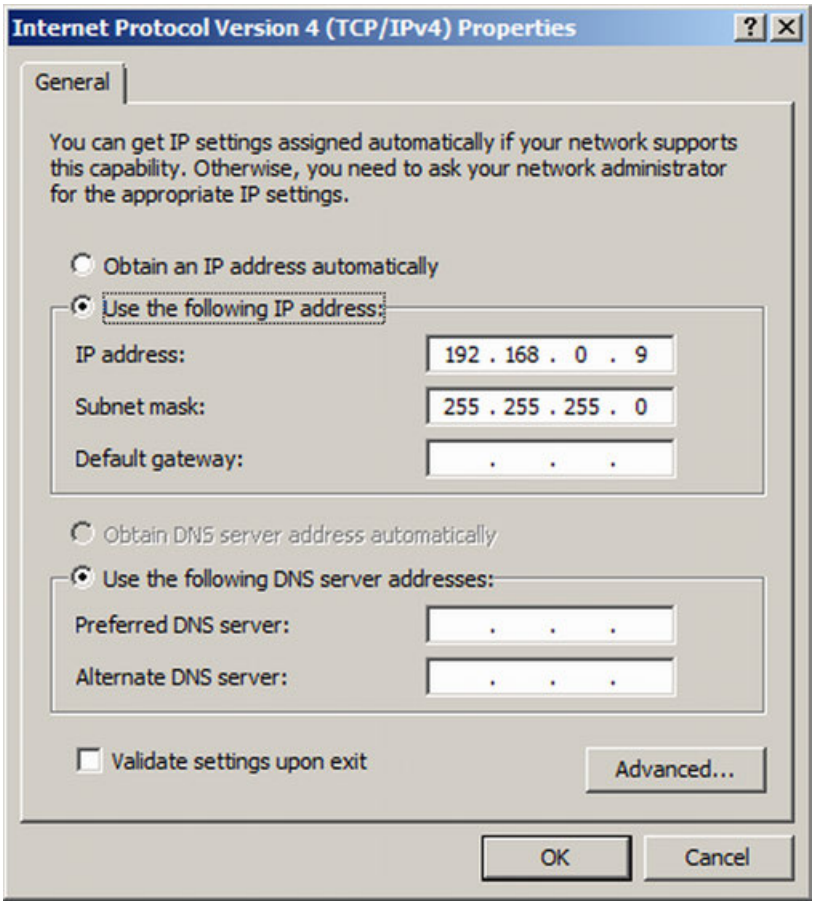
⇨

> *If using existing network with several devices, please pay attention on given network rules or contact your system administrator.*

3. Right-click **Local Area Connection (Ethernet)** and select **Properties**.



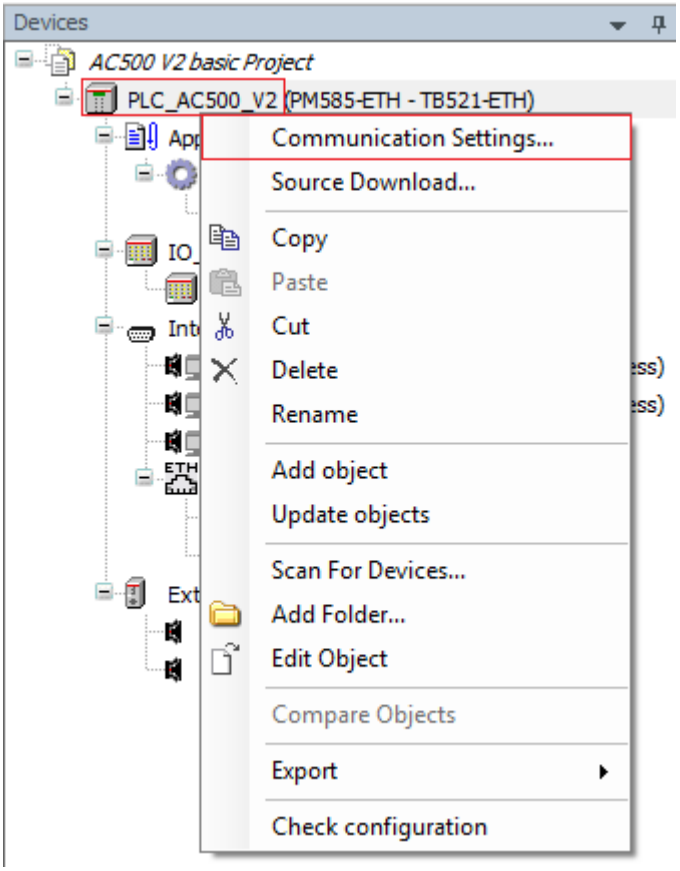
4. Double-click **Internet Protocol Version 4 (TCP/IPv4)**.



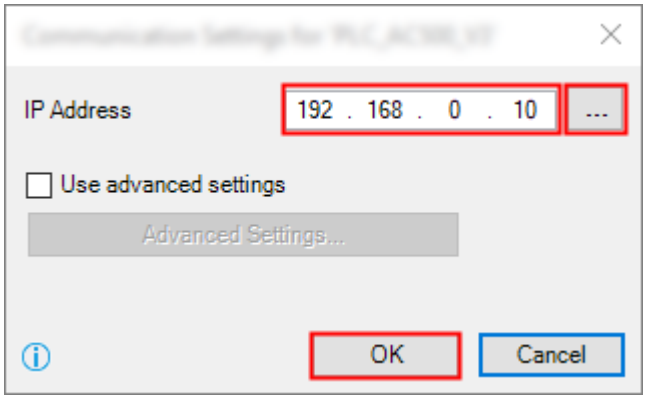
5. Enter your desired IP address and subnet mask.

Set-up the communication gateway

☑ CPU and PC are connected with an Ethernet cable.

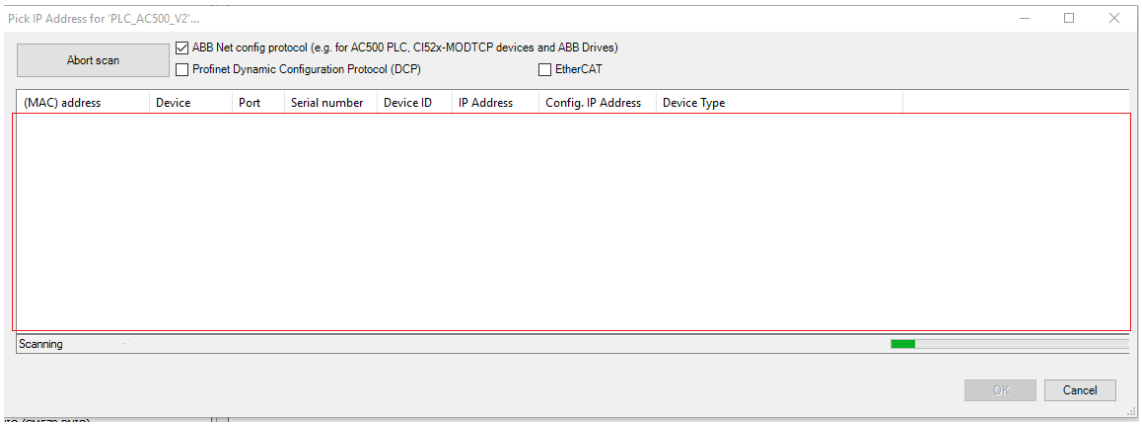


1. In the Automation Builder device tree right-click *"PLC_AC500_V2"*.
2. Select *"Communication Settings"*.



3. Keep the default value in the IP address of the CPU or type in the current IP address, if differs.

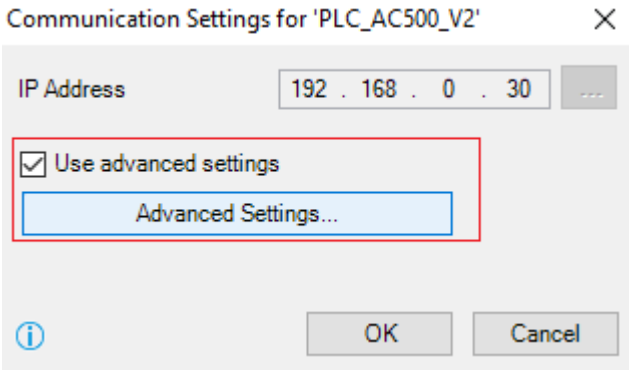
> *The standard (default) IP address of the port ETH1 is: 192.168.0.10*
> *The standard (default) IP address of the port ETH2 is: 192.168.1.10*

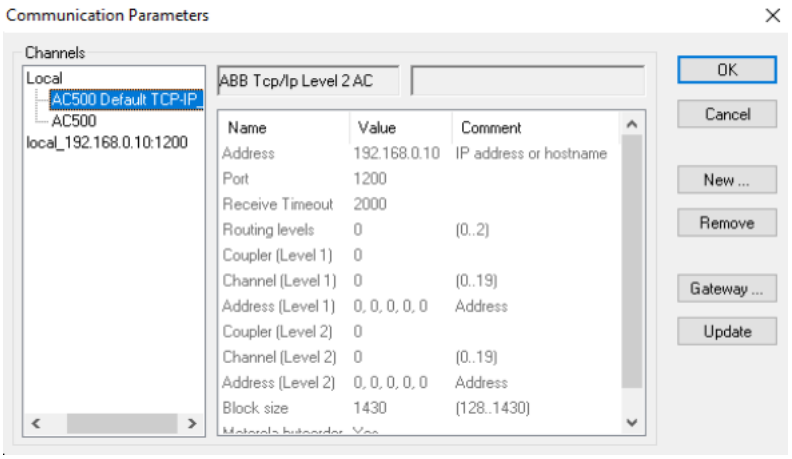


4. Select *"OK"* to implement the IP address.

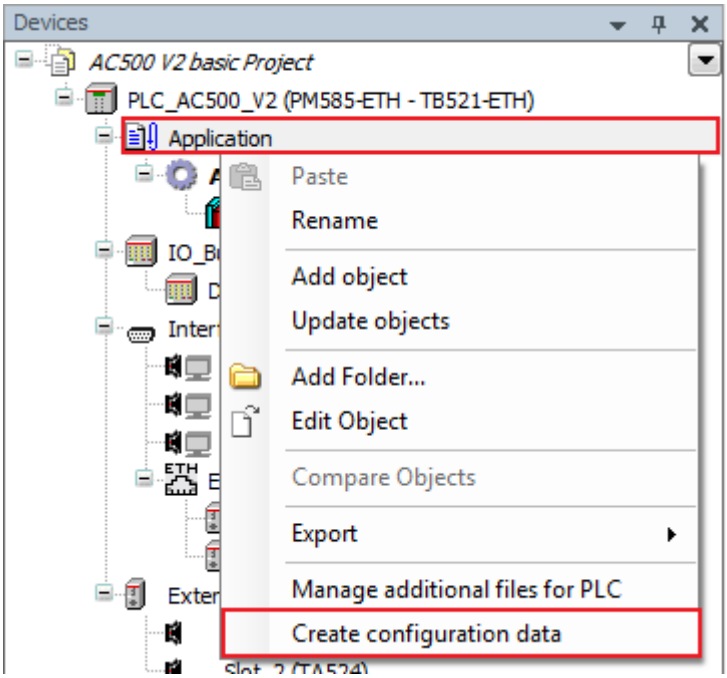
Check communication settings

If you need to check the communications settings or if you want to see more information about the current selected CPU.



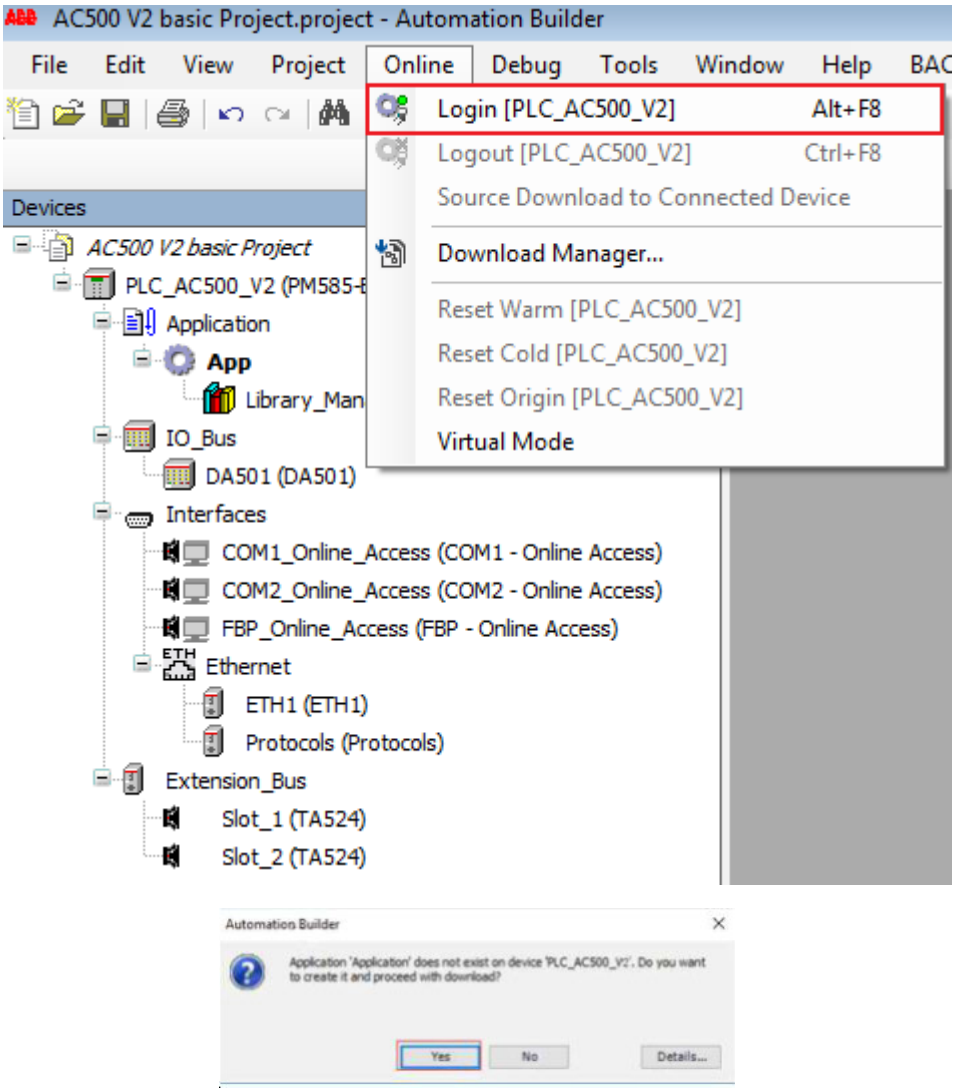


After changing the IP Address either double click the Application or right-click and *"Create Configuration Data"*



Log-in to CPU and download the program

Logging-in to the CPU will load the project into the AC500 V2 CPU. The first log-in will also load the hardware set-up.



1. In the Automation Builder menu select *“Online ➔ Login [PLC_AC500_V2]”*.

   ⇨ A pop-up will appear.

2. Select *“Yes”* to download the application to the AC500V2 CPU.

   ⇨ PLC is in "stop" mode.

3. Start the PLC ↳ *Chapter 1.2.18.1.2.7.1 “Start the program execution” on page 94*.

> *Generally, if the CPU is in RUN mode, i.e. in program execution mode, a download will always cause the mode change to "stop". In stop mode the CPU is not controlling the system!*
>
> *Always, after selecting the "Login" command, read carefully the dialog box text to ensure that you are aware of the CPU's behavior after the command confirmation.*

By default, a download generates following actions in the CPU:

- The project is stored in the RAM memory.
- The project is stored in the flash EEPROM, if boot application was created.

Test the program

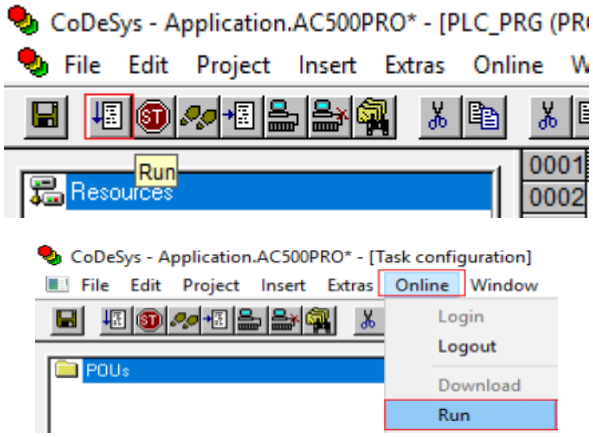
Start the program execution

☑ You are logged in the CPU.

☑ An executable project is loaded to the CPU.

☑ The CPU is in "stop" mode.

☑ Open CODESYS *Chapter 1.2.18.1.2.8.1 "Starting the IEC 61131 programm editor CODESYS" on page 97*.



▷ In the CODESYS editor menu select *"Online ➔ Run"*

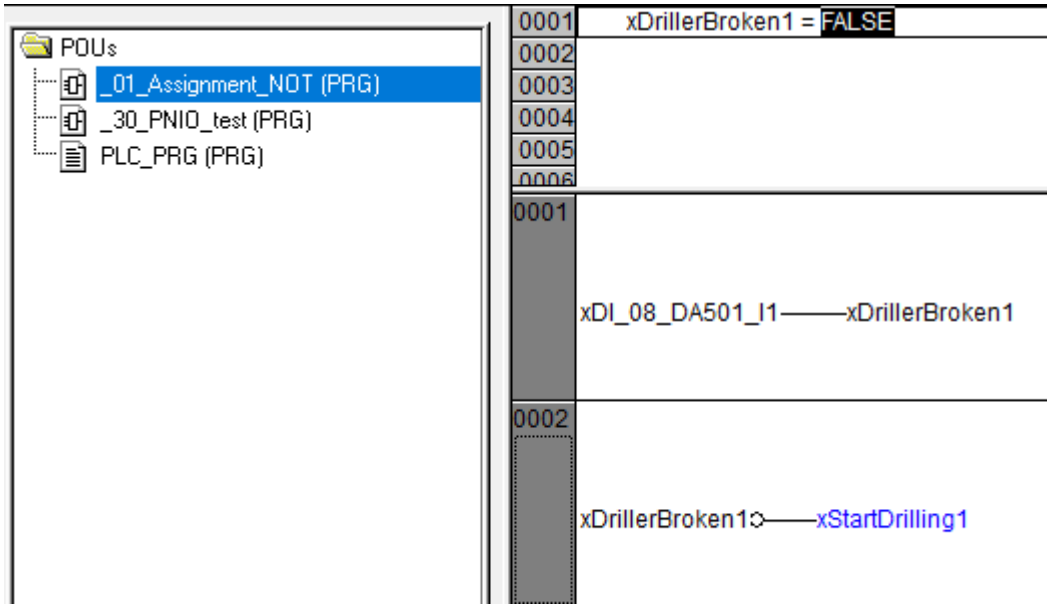
Alternatively, select the "run" icon in the tool bar.

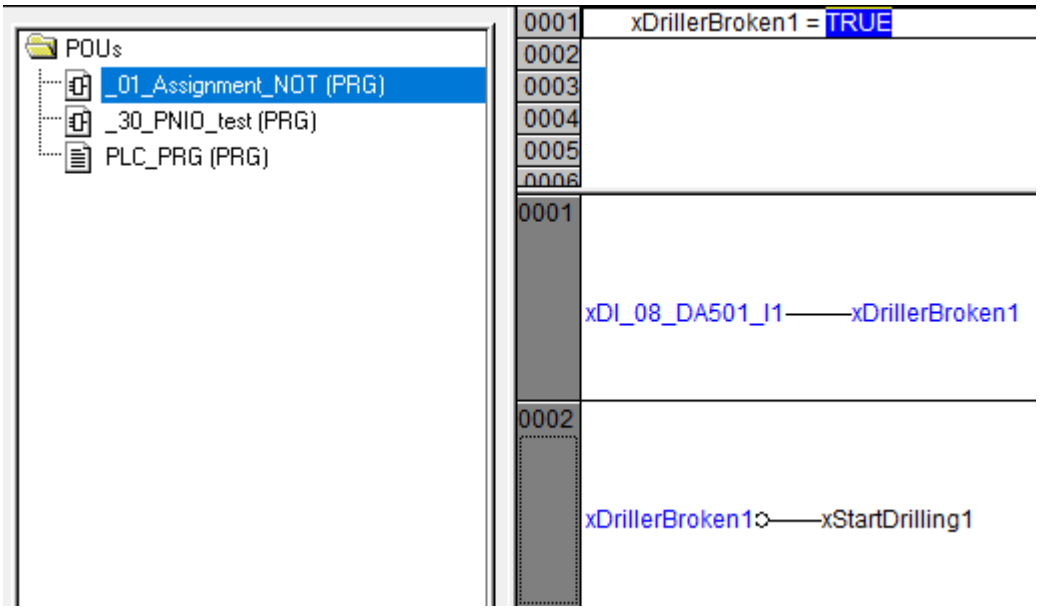
Alternatively, press *[F5]*.

Test the function

▷ Operate the switch I1 and in the CODESYS editor observe:

- The online status of inputs and outputs within the POU.



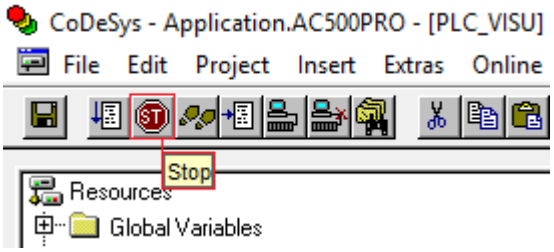


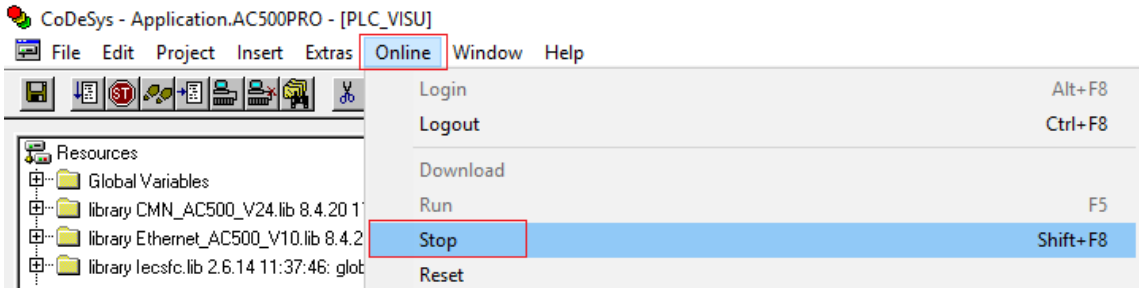
Stop the program execution

☑ You are logged in the CPU.

☑ An executable project is loaded to the CPU.

☑ The CPU is in RUN mode.





▷ In the CODESYS editor menu select *“"Online ➔ Stop [PLC_AC500_V2]"”*

Alternatively, select the "stop” icon in the tool bar.

Alternatively, press *[Shift]* + *[F8]*.

Set-up visualization

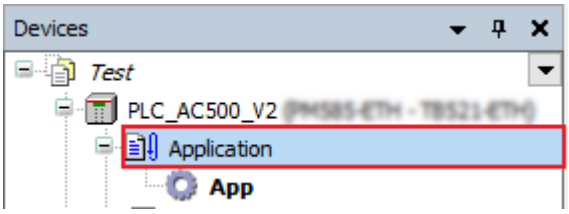
The visualization allows designing a graphical representation of project variables. In online mode, the graphical elements can change, for example, their color, size or position according to the actual variable status.

Visualization for your project is done via CODESYS editor.

Starting the IEC 61131 programm editor CODESYS

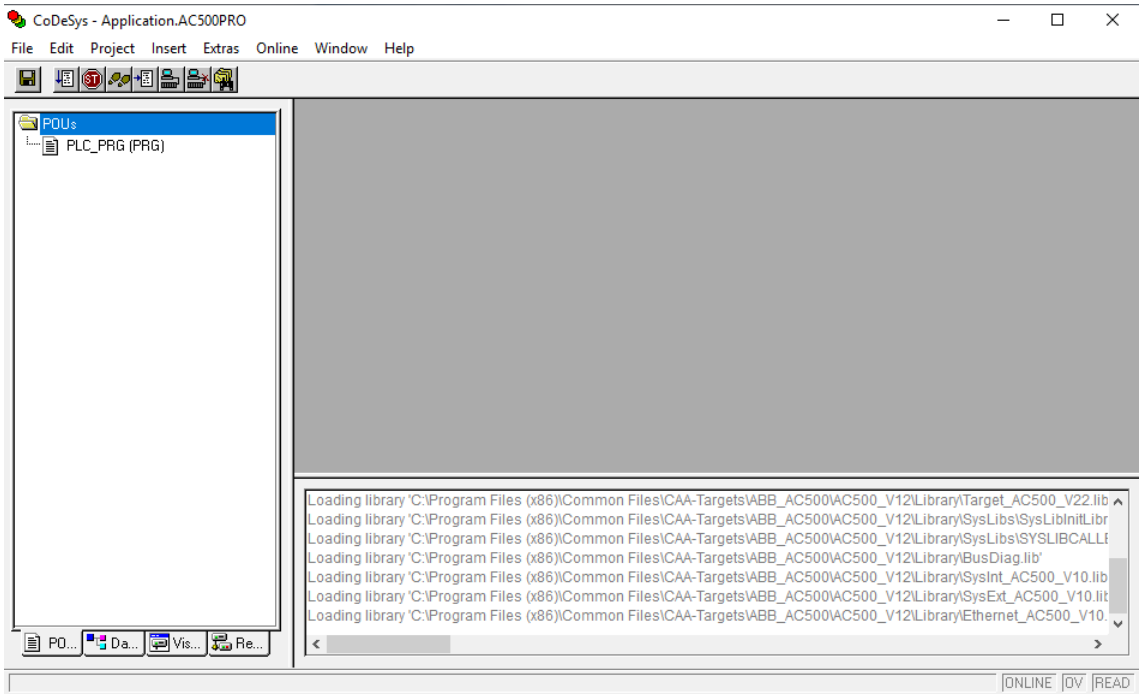
To start the IEC 61131 programm editor CODESYS:

☑ Open an AC500 V2 project in Automation Builder



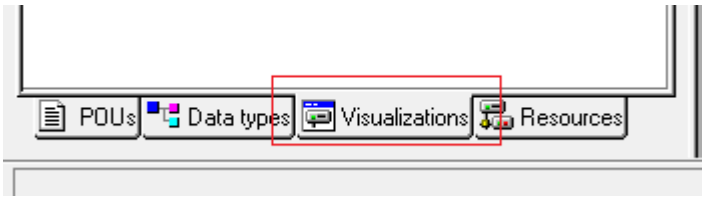
▷ In the Automation Builder device tree double-click *“Application”*

⇨ This will start the IEC 61131 programm editor CODESYS

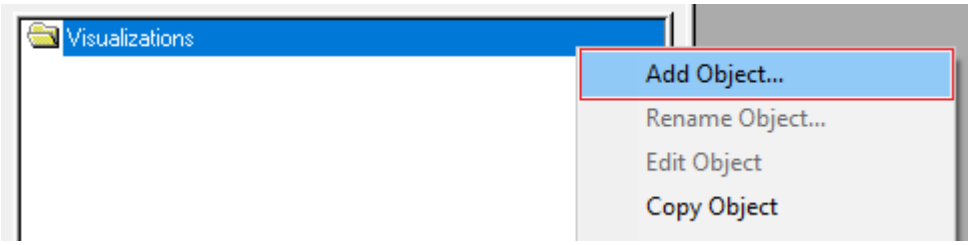


Insert visualization object

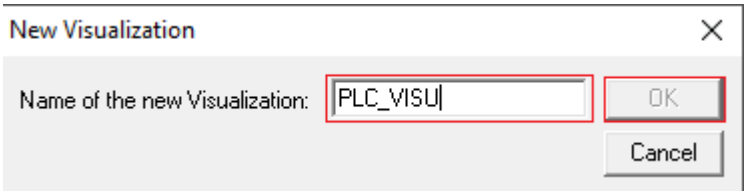
1. In the CODESYS menu select *“Visualization”*



2. Right-click Visualizations.
3. Select *“Add object”*.



4. Type in *“PLC_VISU”*
5. Select *“OK”* to add Visualization

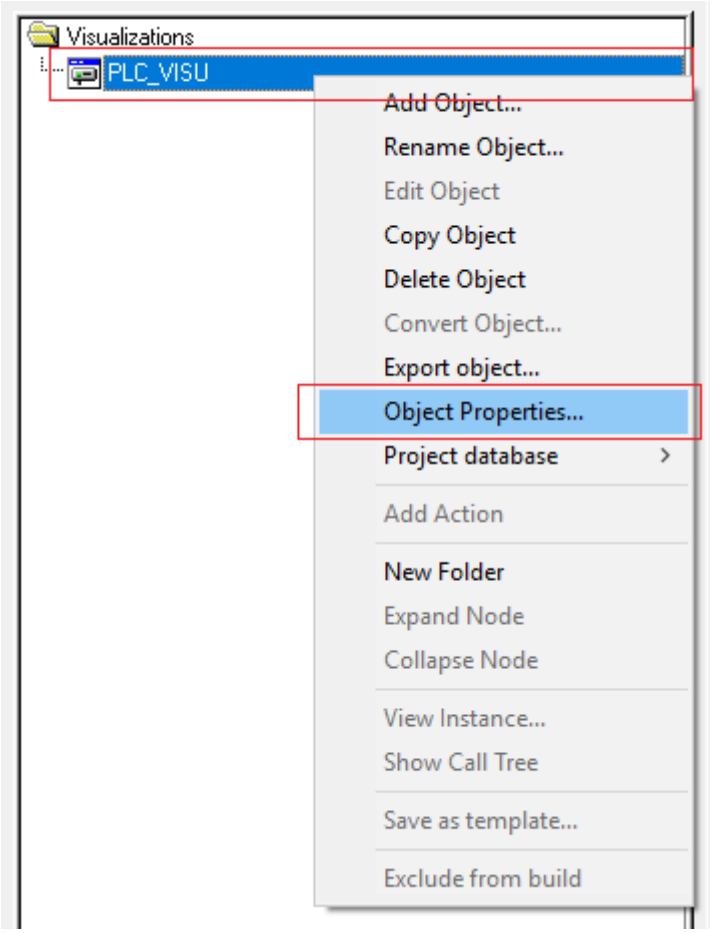


⇨ The new visualization object is inserted.

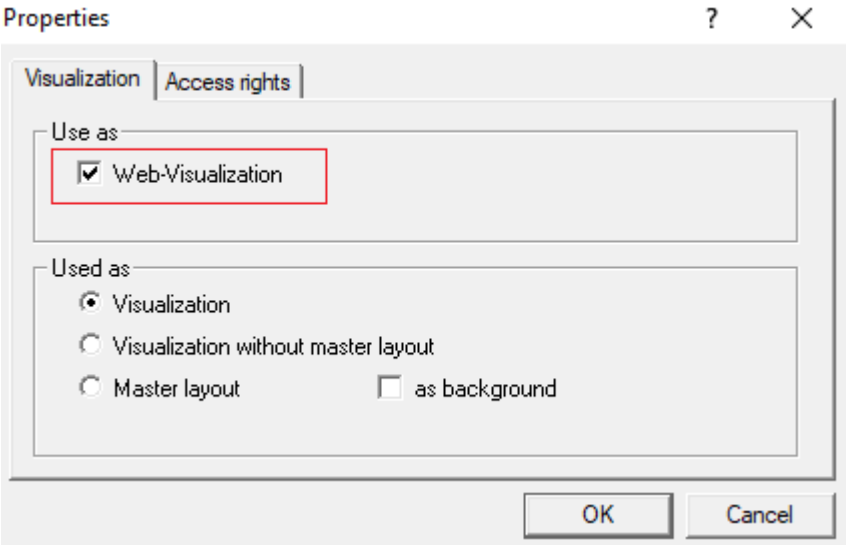
The name "PLC_VISU" has been chosen, because it is the default name for a home screen in a web visualization. If you have more than one visualization object in your project, it will be useful to choose another name, e.g. "_01_Assignment_NOT_v" and to choose "PLC_VISU" as a home screen to access all available visualization screens. The name of a visualization object can be modified afterwards.

Creating and configuring of visualization

1. In the CODESYS device tree right-click *“PLC_VISU”*
2. Select *“Object Properties”*



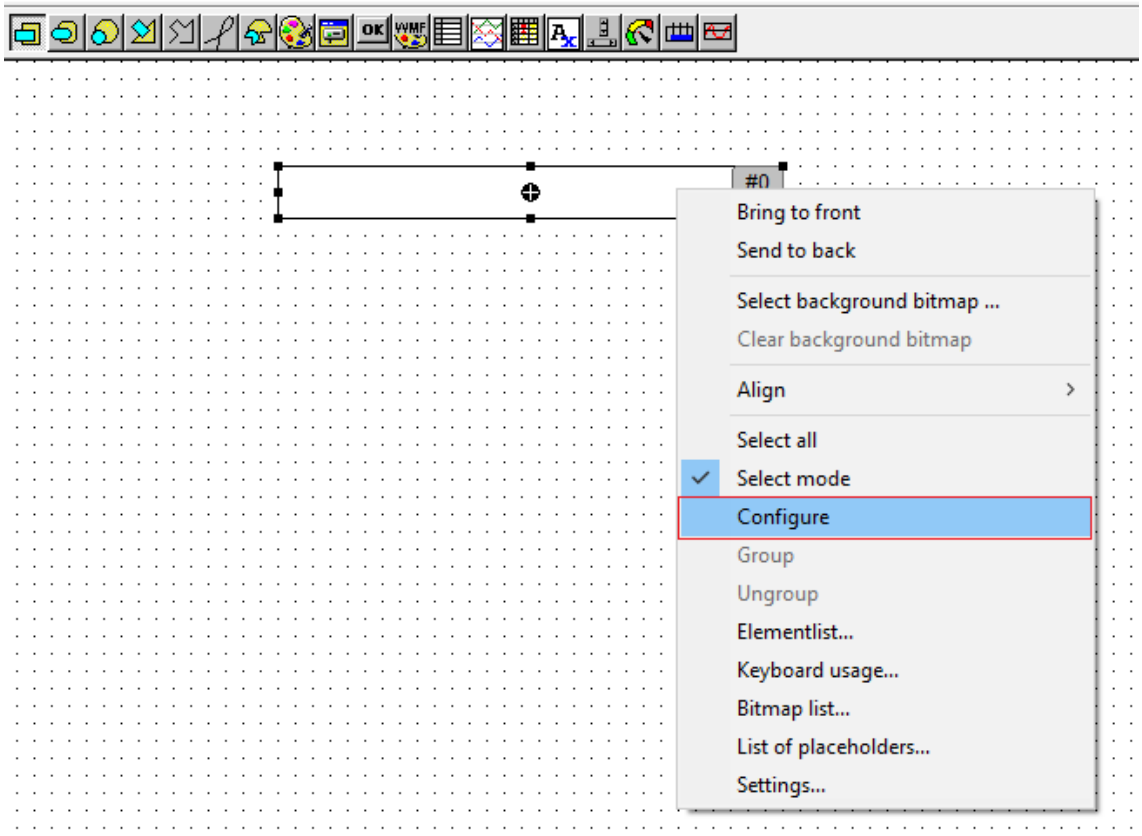
3. Enable *"Web-Visualization"*



Add a screen title

1. In the CODESYS editor toolbar select *“Rectangle”*.

2. Now by dragging your mouse anywhere on the Visualization you can create a rectangle.



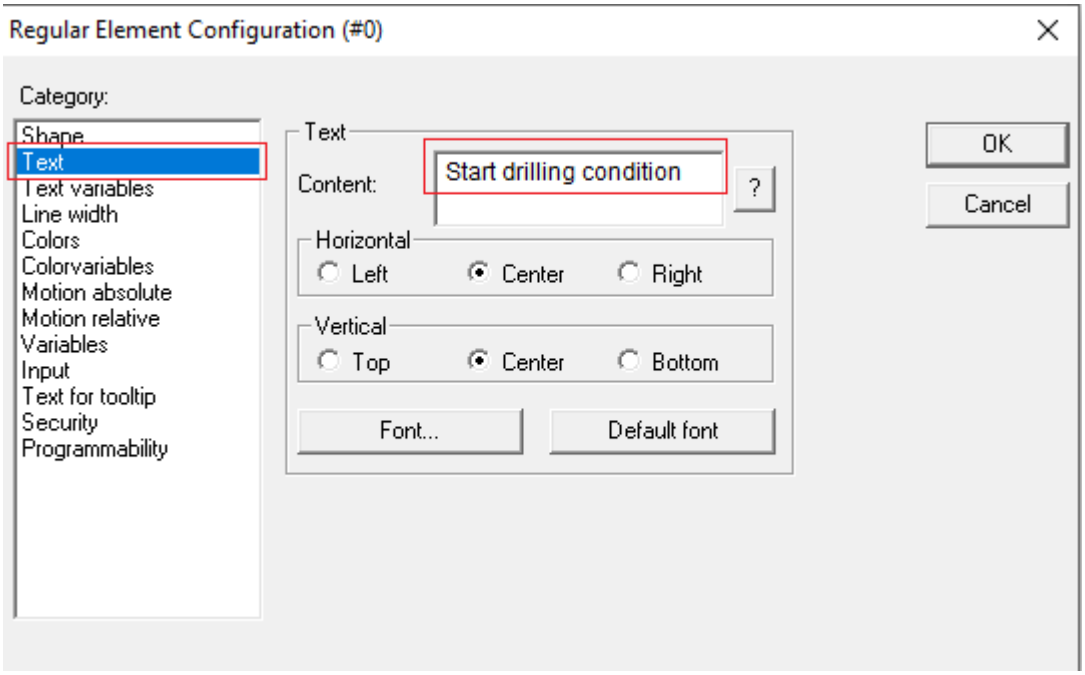
3. Double-click the shape.

   Alternatively right-click and then select *“Configure”*

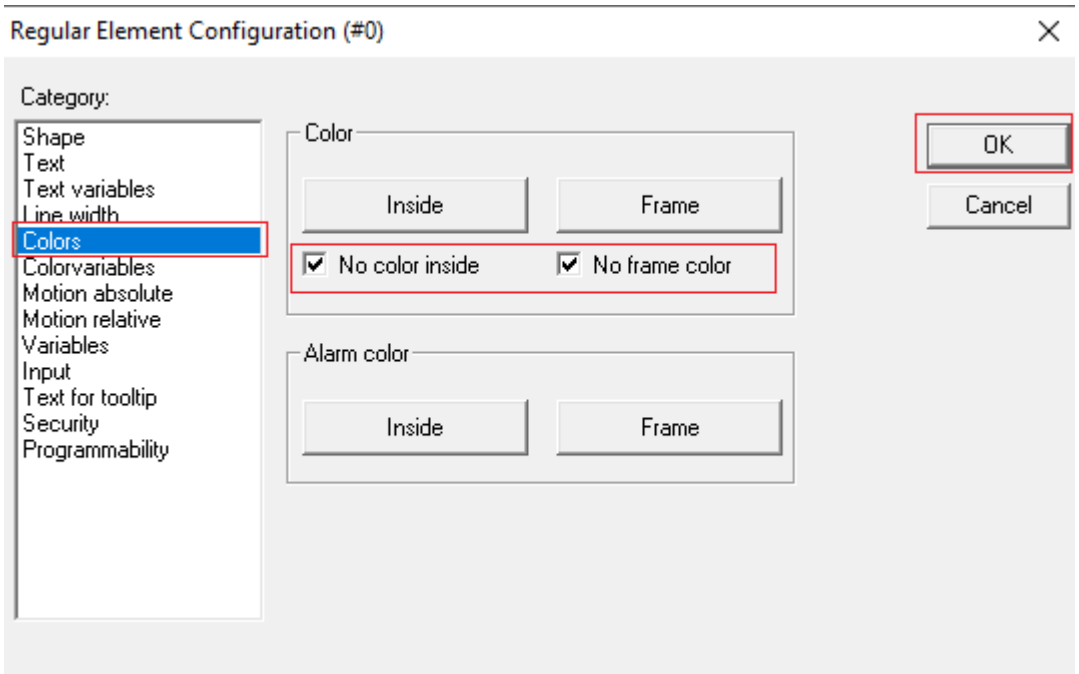
   ⇨ The *“Regular Element Configuration”* window opens.

4. Under *“Category”* select *“Text”*

5. Under *“Content”* type in *“Start drilling condition”*

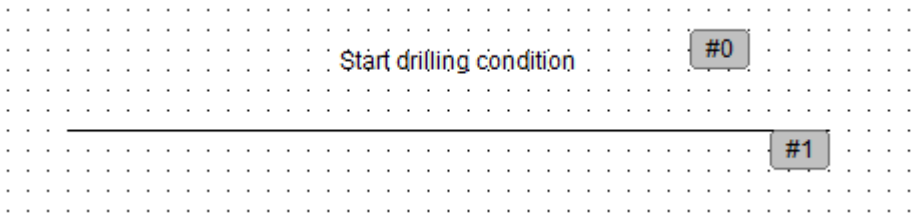


6. Under Category select *“Colors”*.
7. Under *“Color”* enable *“No color inside”* and *“No frame color”* this will help create a cleaner look later on
8. Select *“[OK]”* to implement changes.

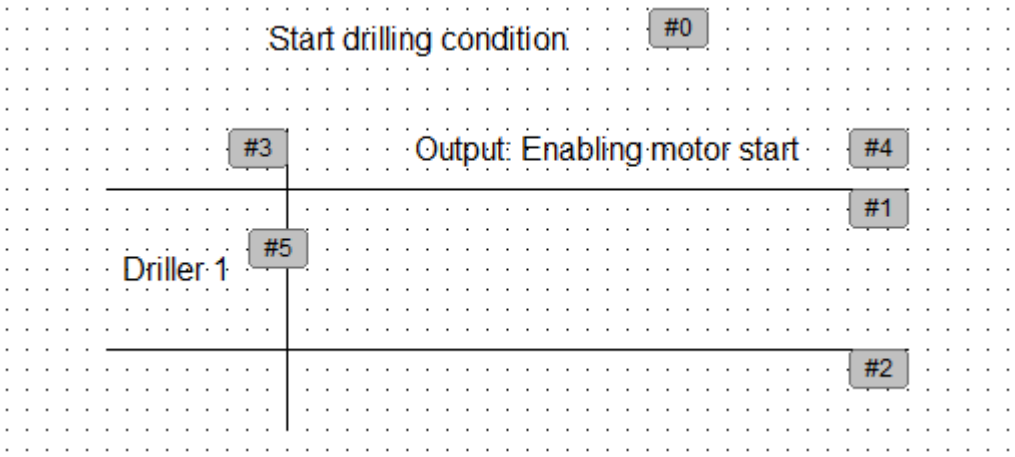


Further lines and labels

1. In the CODESYS editor toolbox select *“Polyline”*
2. Create a line by left-clicking and holding the mouse button. Drag the line to your desired lenght then double-click to end the line.

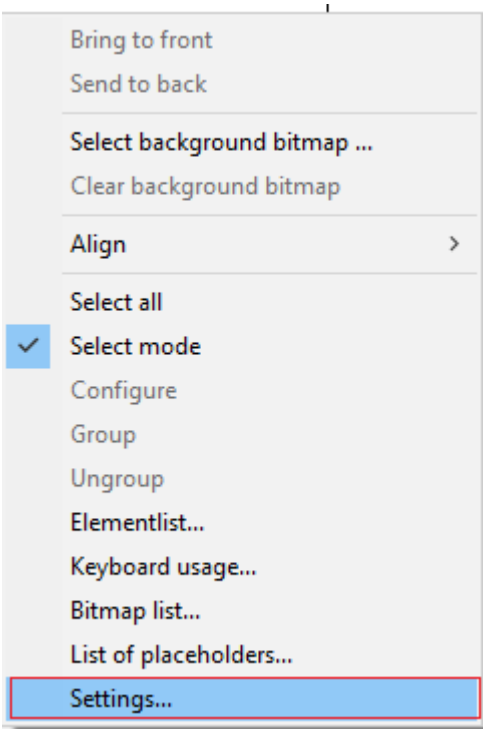


3. Follow the same procedure to create the other shapes and labels.

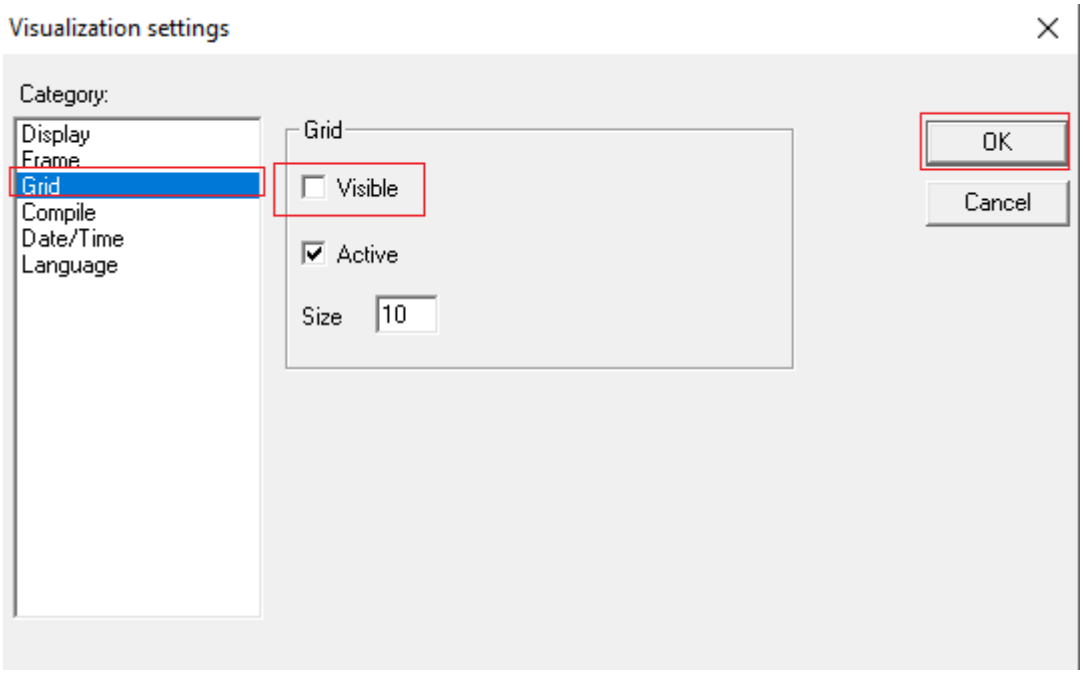


Disable Grid and check Settings

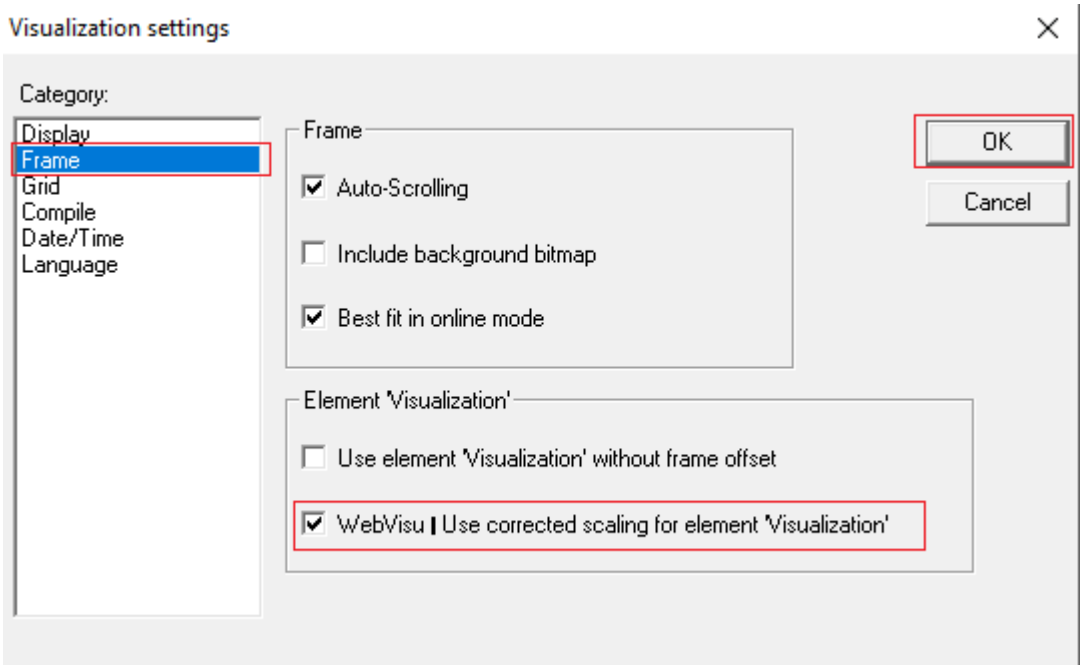
1. In the CODESYS editor right-click anywhere on the visualization and select *“Settings”*.

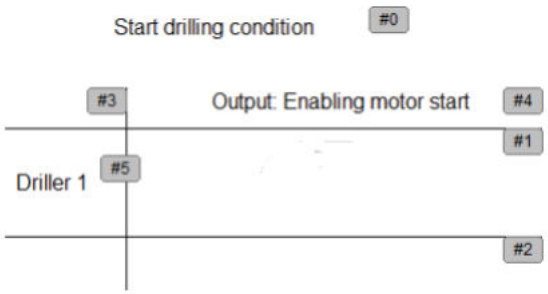


2. Select *“Grid”* and unmark *“Visible”*.



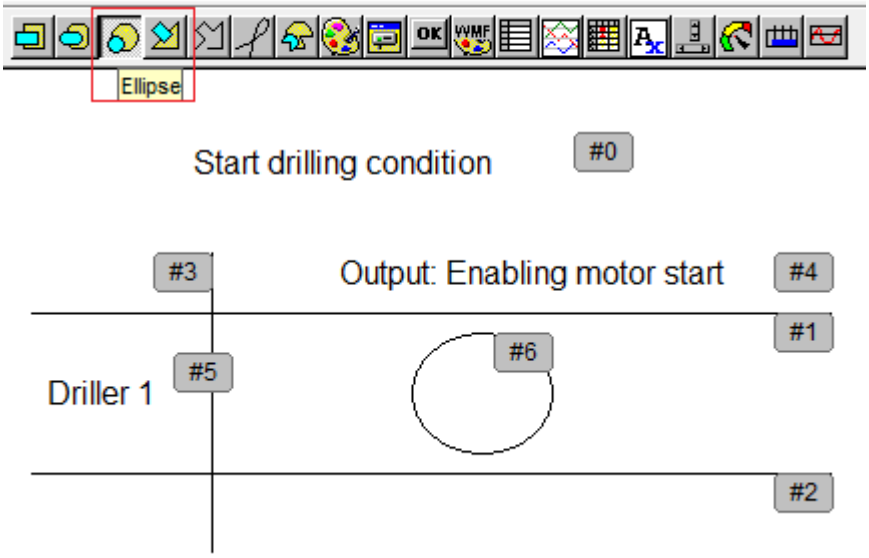
3. Select *"Frame"* and make sure *"WebVisu"* is activated.



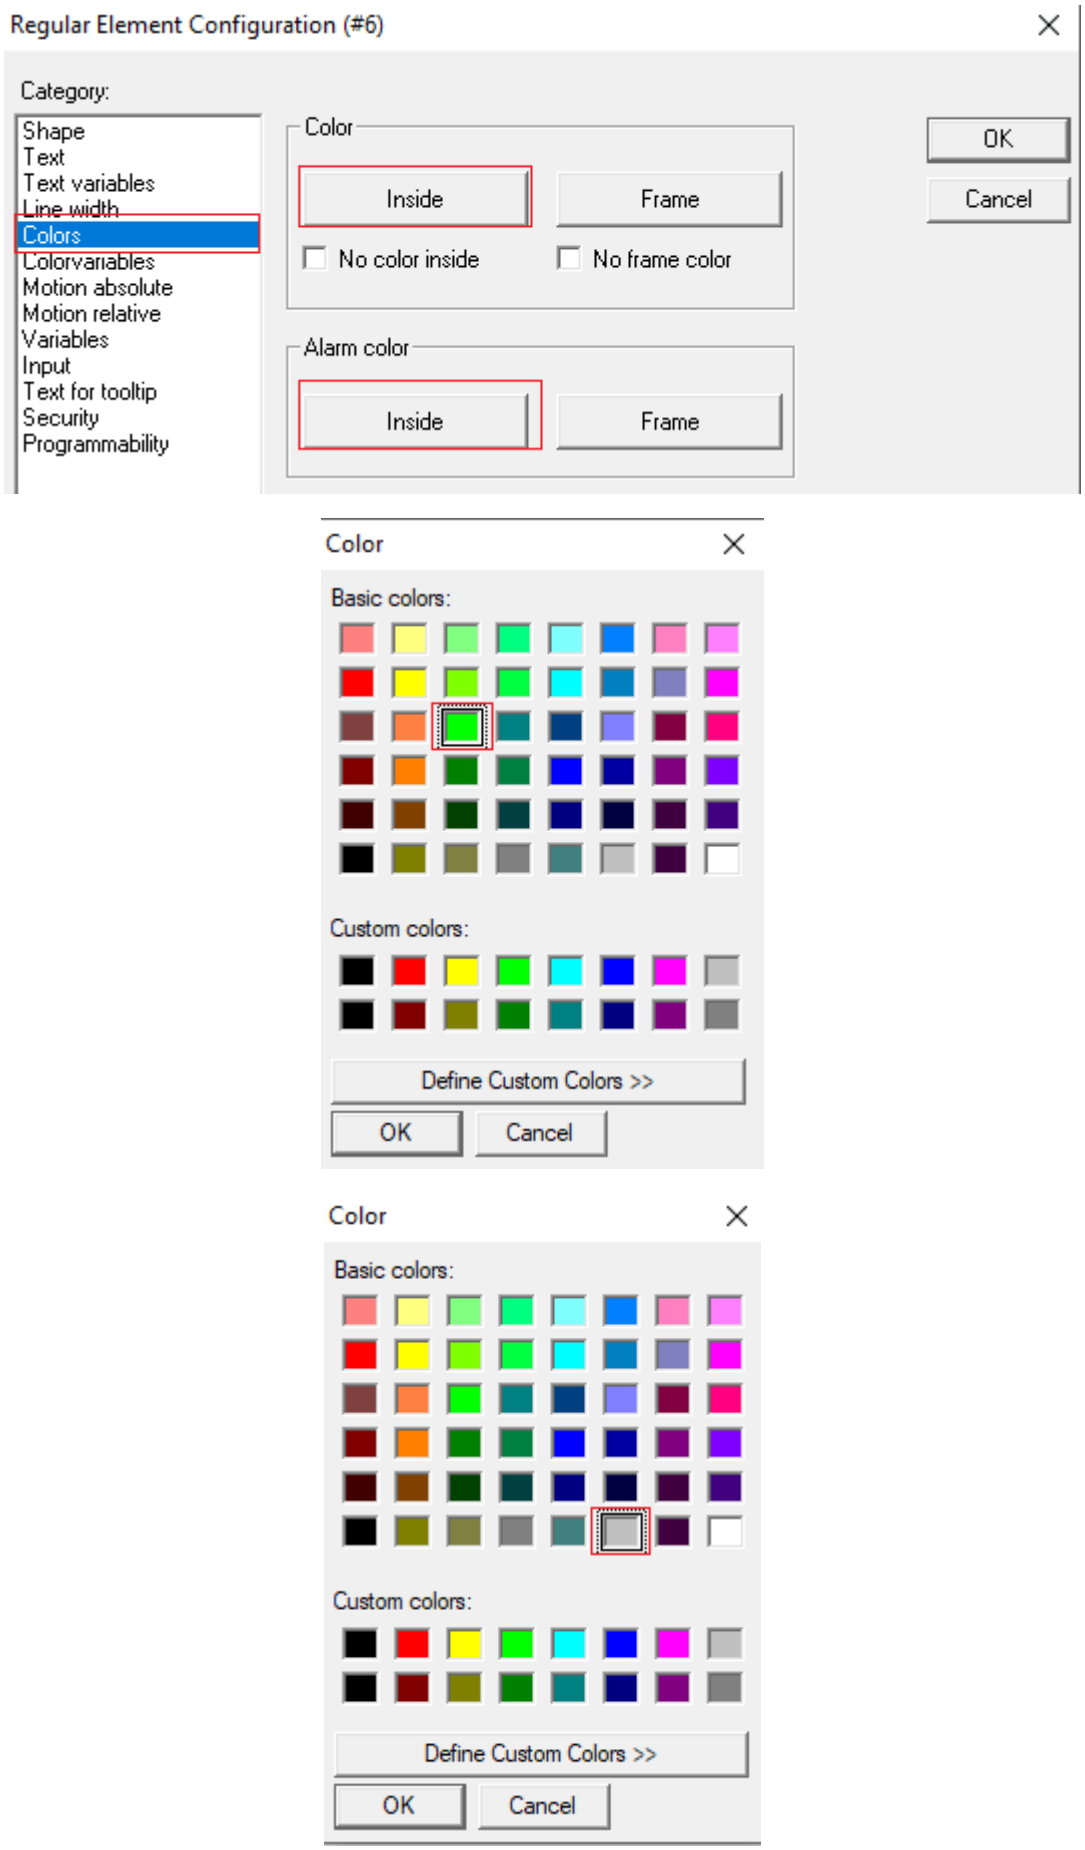


Lamp element for signal indication

1. In the CODESYS editor tool bar select Ellipse and adapt size, if required.
2. Double-click on the ellipse to open the configuration.

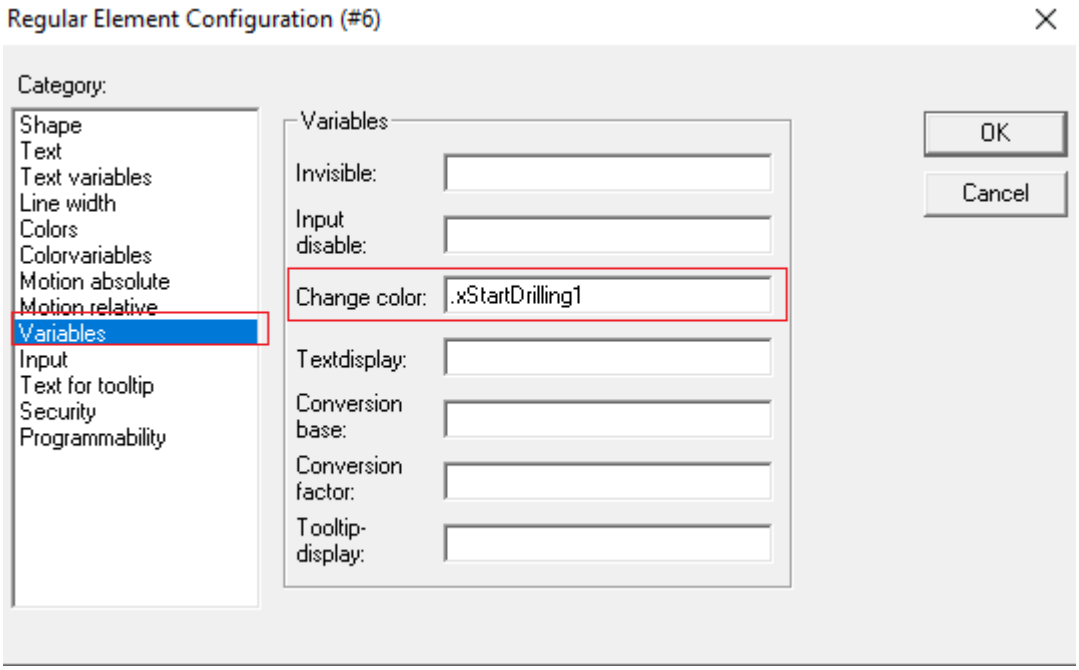


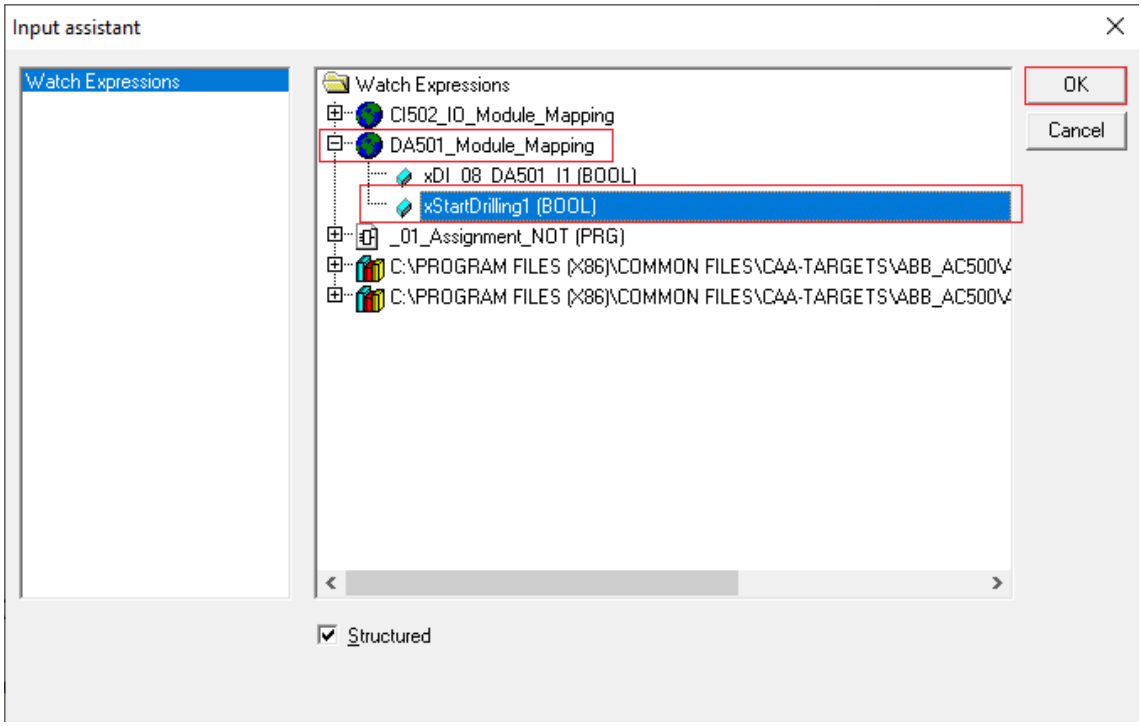
3. Select *“Colors”* and set two different colors for "Color" and "Alarm color".



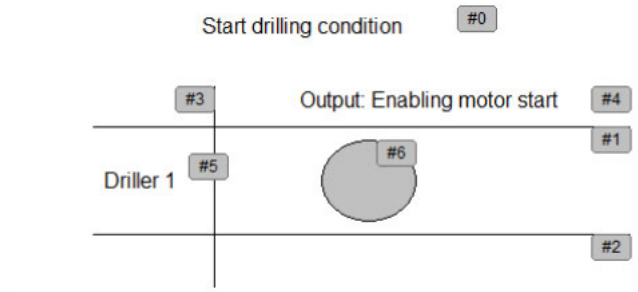
4. Open Variables and left-click *"Change color"*.

5. Press *[F2]*, this will open the *"Input assistant"*.



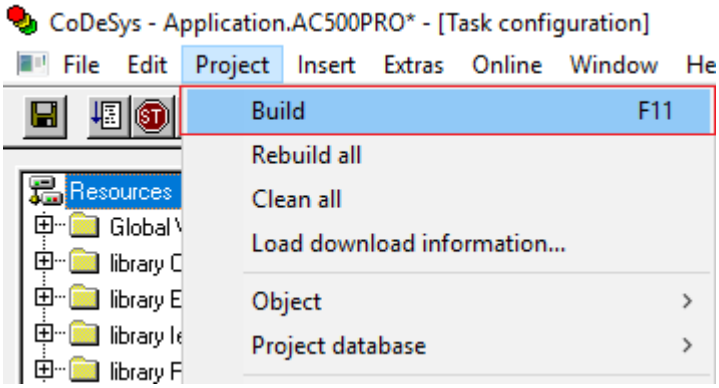


6. In *"DA501_Module_Mapping"* select *"xStartDrilling1"*
7. Select *"[OK]"*



Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

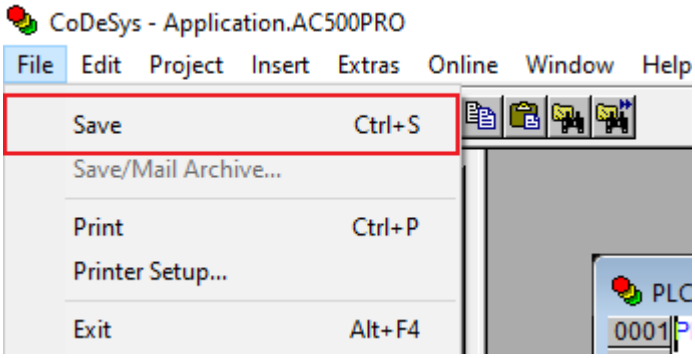


▷ In the CODESYS editor menu select *"Project ➔ Build"*

⇨ The result of the compiling is shown in the *"Messages"* field at the bottom of the screen.

If you skip the compiling and select *"Login"*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save CODESYS project



▷ In the CODESYS editor menu select *"File ➔ Save"*.

Alternatively, select the save icon in the tool bar.

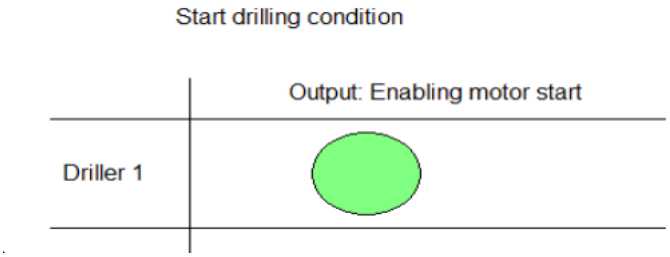
Alternatively, press *[Ctrl]* + *[S]*.

Loading the project to the CPU

▷ Download the project to the CPU ↬ *as described in Chapter 1.2.18.1.2.6 , on page 92*.

Test the program

Operate the switches and observe the visualization screen.



Reset the CPU

Reset values and parameters

In some cases, it could be required to do a CPU reset, e.g., for resetting of counter values, parameters etc.

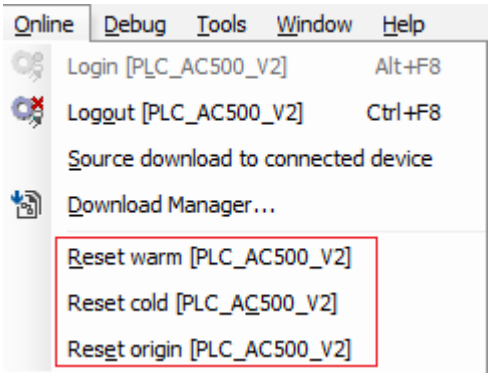


Fig. 7: Reset commands in “Online” menu

Reset warm	All variables are reset, except R% variables.
Reset cold	Causes initialization of all variables, except PERSISTENT variables. By recommended creation of remanent variables always with both properties: PERSISITENT and RETAIN, this command resets all variables, except R% variables.
Reset origin	All variables and the application project are reset.

Table 5: Behavior of variables of type VAR (local or global) and variables of type PERSISTENT RETAIN

	VAR	VAR PERSISTENT RETAIN
After online command 'Online change'	no change	no change
After online command 'Download'	initialization	no change
After online command 'Reset warm'	initialization	no change
After online command 'Reset cold'	initialization	no change
After online command 'Reset origin'	initialization	initialization
After power supply off	initialization	no change

1.2.18.1.3 Example project for remote I/O expansion with PROFINET

This example introduces the configuration of the PLC with remote I/O. The use of I/O channels in a program and commissioning of the configuration is shown.

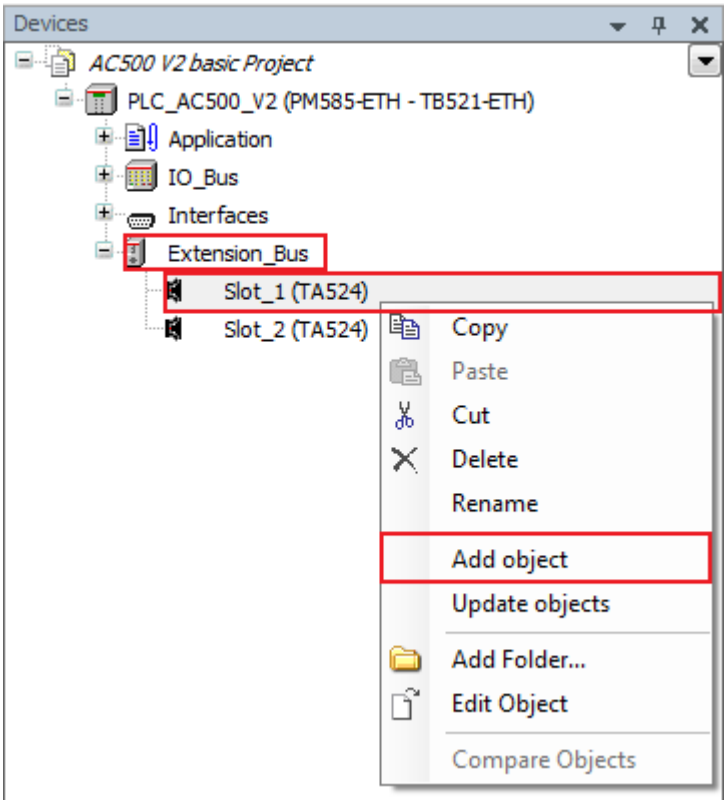
Preconditions

- Automation Builder is installed and licensed as, at least, standard edition ↳ *Chapter 1.2.4 "Managing your licenses" on page 20*.
- AC500 V2 CPU is assembled and connected to the PC ↳ *Chapter 1.2.18.1.1 "Hardware AC500 V2" on page 67*.
- Configuration and programming of this example project will be made in the existing example project for central I/O expansion ↳ *Chapter 1.2.18.1.2 "Example project for central I/O expansion" on page 70*.
- CM579-PNIO communication module is inserted in terminal base and connected to the PLC ↳ *Chapter 1.2.18.1.1 "Hardware AC500 V2" on page 67*.
- CI502-PNIO communication interface module is inserted in terminal unit and connected to the PLC ↳ *Chapter 1.2.18.1.1 "Hardware AC500 V2" on page 67*.

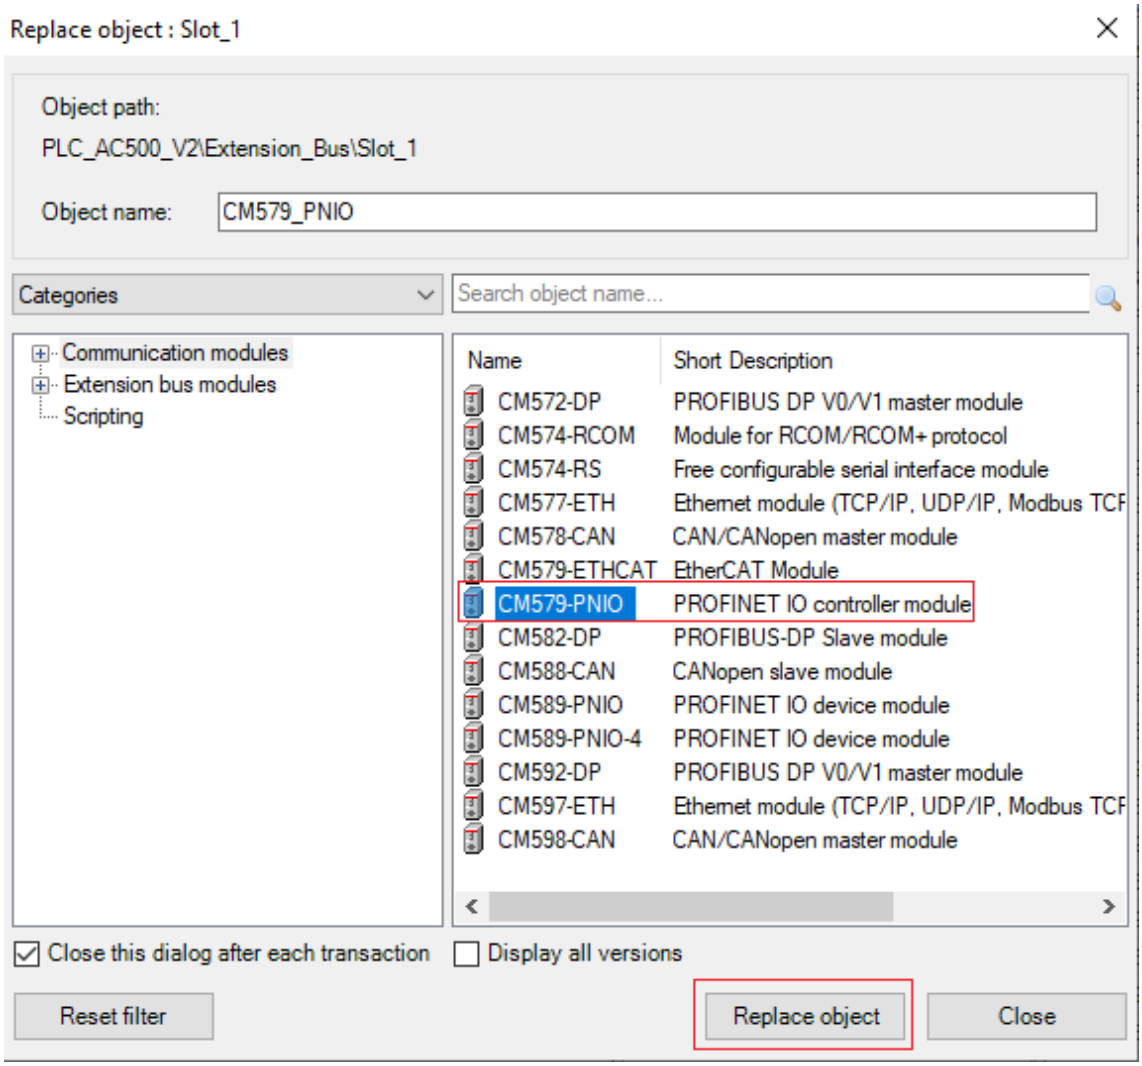
Set-up PROFINET controller

Add the CM579-PNIO to the device tree

1. In the Automation Builder device tree under *"Extension_Bus"*, right-click *"Slot_1"*.
2. Select *"Add object"*.

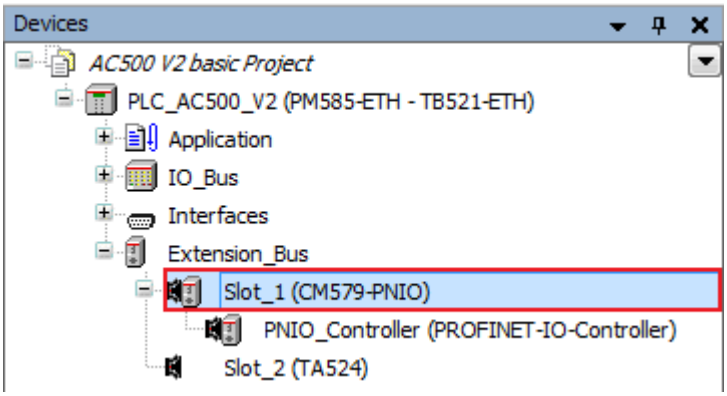


3. Select *"CM579-PNIO"*.



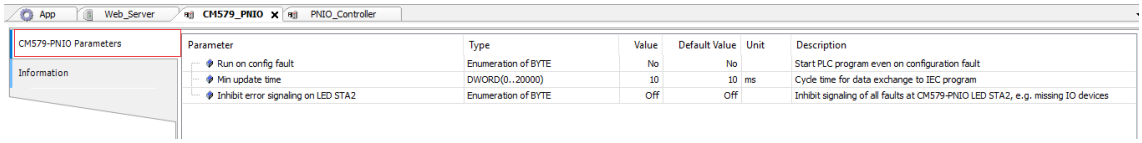
4. Select *“Replace object”* to add the CM579-PNIO.

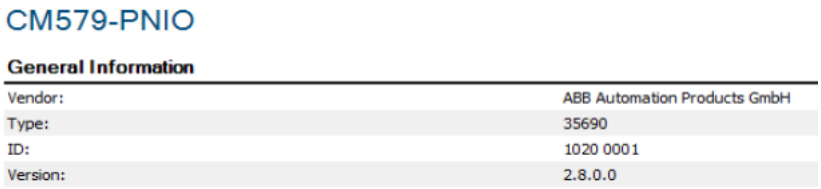
Set-up the general behavior



1. Under *“Extension_Bus”*, double-click *“CM579_PNIO”* in the device tree.
   ⇨ A tab opens in the editor view.

2. Select *“CM579-PNIO Parameters”*.

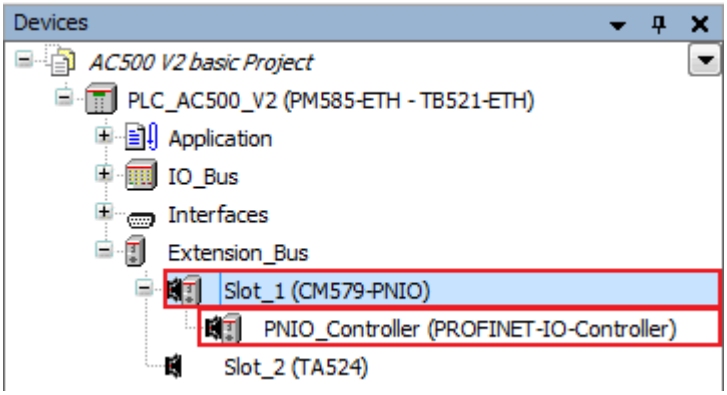




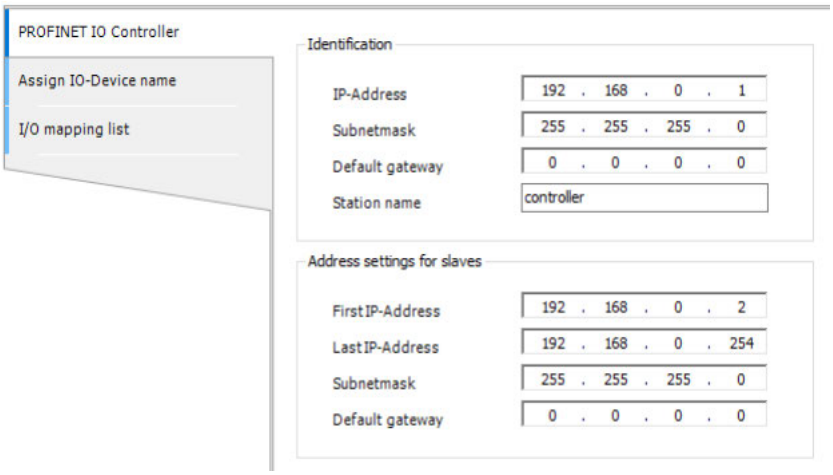
3. Select *“Information”*.
   ⇨ This page contains general information about the CM579-PNIO.
4. For the example project, you can keep the default settings.

Set-up the PROFINET IO controller

☑ To edit settings for the controller, you must not be logged-in to the PLC.



1. Under *“CM579_PNIO”*, double-click *“PNIO_Controller”* in the device tree.
   ⇨ A tab opens in the editor view.
2. Select *“PROFINET IO CONTROLLER”*



3. Here, you can set-up the way, IP addresses are distributed out to the industrial bus network. You can even set, what IP-address and DNS name (station name) the PROFINET controller has.

   For the example project, keep the default settings.

Set-up PROFINET device

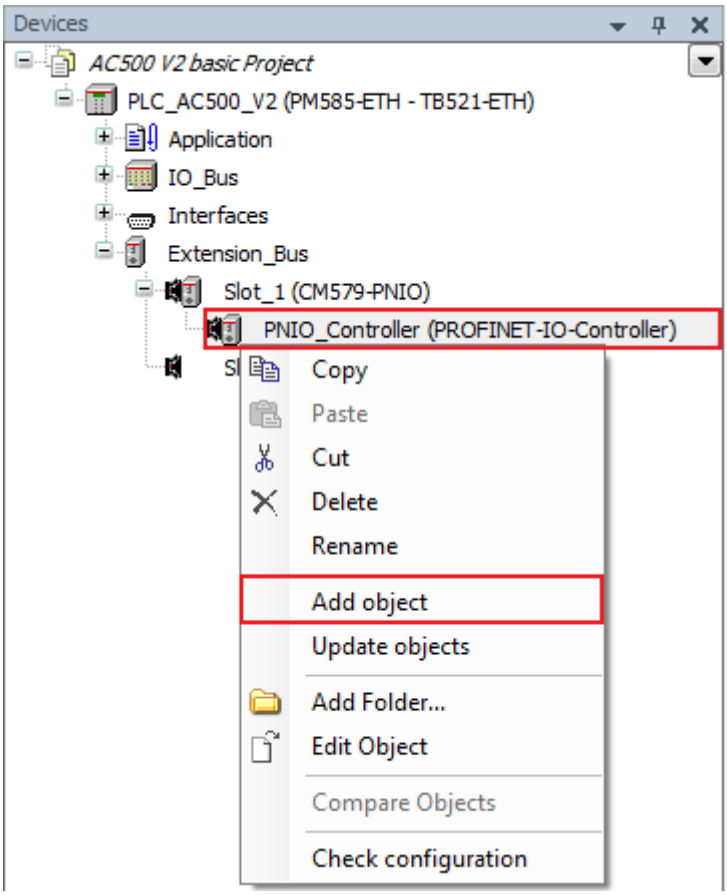
Hardware preparation

1. Switch off the power supply of your PLC.

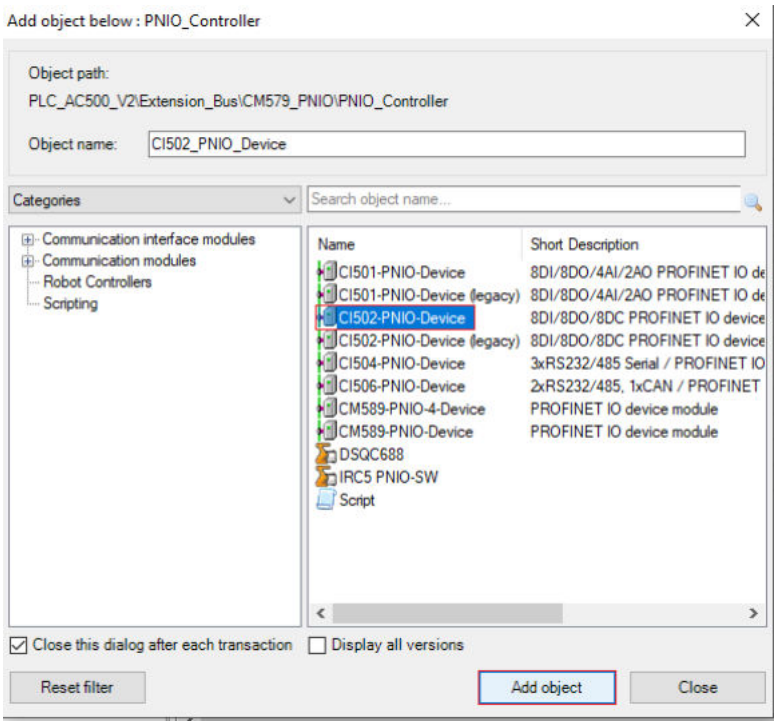
2. Use a screw driver to set the CI502 module address to "02" by positioning of the upper rotary switch to "0" and lower switch to "2". Note, that the numbers have hexadecimal format.
3. Switch on the power supply.

Add the CI502-PNIO to the device tree

1. Right-click *“PNIO_Controller”* in the device tree.
2. Select *“Add object”*.



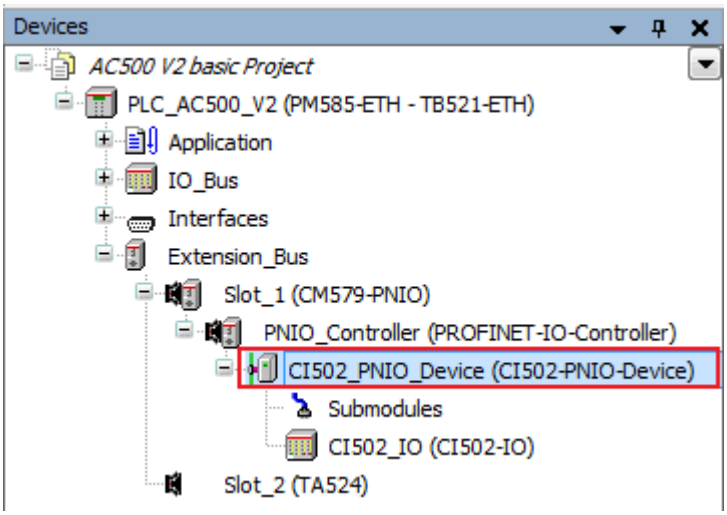
3. Select *"CI502-PNIO-Device"*.



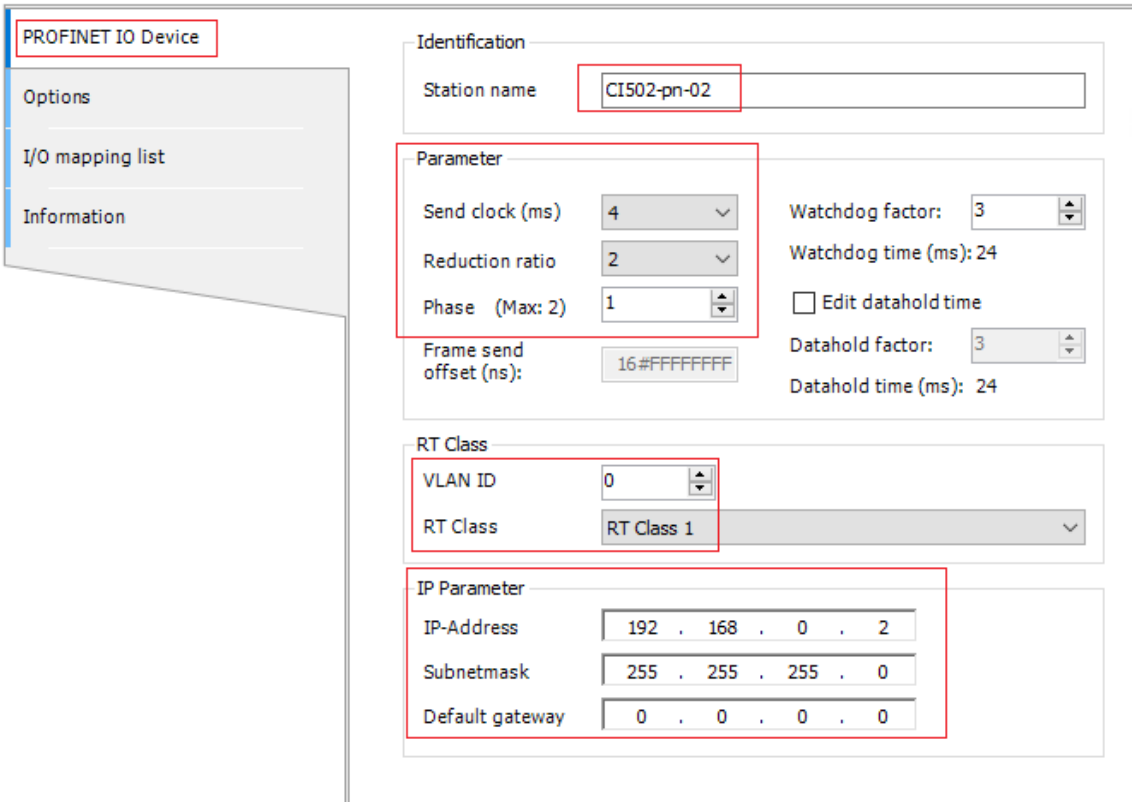
4. Select *"Add object"* to add the device.

Configure the CI502-PNIO device

Configure the CI502-PNIO PROFINET IO device



1. Double-click *“CI502_PNIO_Device”*.
   ⇨ A tab opens in the editor view.
2. Select *“PROFINET IO Device”*.



Station name	Default station name
Parameter	Communication time set-up
VLAN	Virtual local area network ID
RT Class	PROFINET IO RT (real time) type settings
IP Parameter	IP-addressing parameters of the node. If modifications are required for *“IP Parameter”*, they must be done also for CM579-PNIO and all other devices in this PROFINET line.

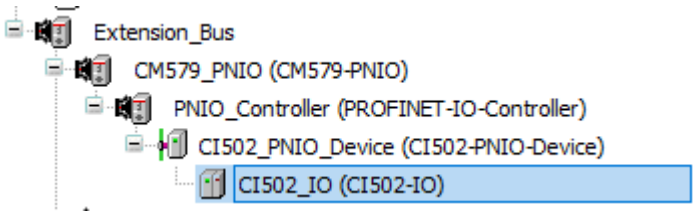
3. Set station name to "ci502-pn-02" according to hardware settings.

   For numbers greater than 09 always make sure, that the last two **decimal** digits of the node's *"Station Name"* in Automation Builder correspond to the position of module's rotary switches (**hexadecimal** values): e.g., "ci502-pn-10" <-> "0A" or "ci502-pn-16" <-> "10".

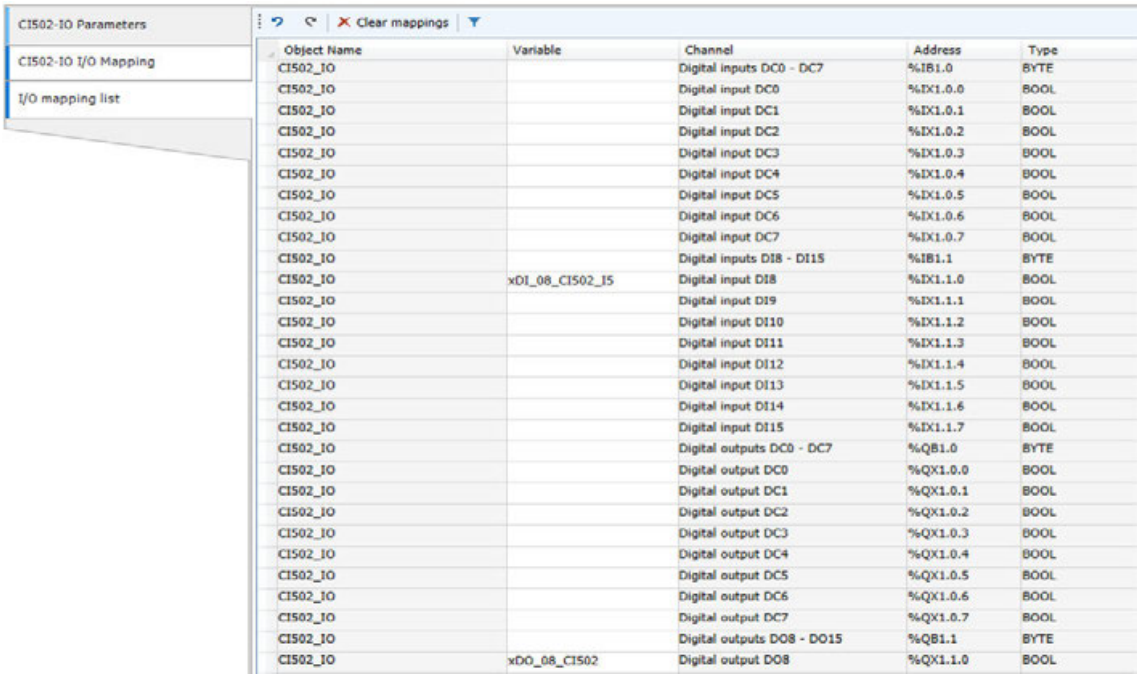
4. Leave the default settings for *"IP Parameter"*.
5. Adjust the communication time settings to get a Watchdog (ms) 24:
   - *"Send clock (ms)"*: 4
   - *"Reduction ratio"*: 2
   - *"Phase"*: 1
6. Leave the default settings for *"VLAN ID"*.
7. Leave the default settings for *"RT Class"*.

> *If the node has the same device address (the last two digits of the device name) as set by means of the rotary switches on the module, all the node parameters will be loaded automatically upon initialization scan of the CI50x module. This allows, e.g., the module exchange without an engineering tool.*

Create CI502-PNIO I/O mapping to symbols



1. Double-click *"CI502_IO"*.



Object Name	Variable	Channel	Address	Type
CI502_IO		Digital inputs DC0 - DC7	%IB1.0	BYTE
CI502_IO		Digital input DC0	%IX1.0.0	BOOL
CI502_IO		Digital input DC1	%IX1.0.1	BOOL
CI502_IO		Digital input DC2	%IX1.0.2	BOOL
CI502_IO		Digital input DC3	%IX1.0.3	BOOL
CI502_IO		Digital input DC4	%IX1.0.4	BOOL
CI502_IO		Digital input DC5	%IX1.0.5	BOOL
CI502_IO		Digital input DC6	%IX1.0.6	BOOL
CI502_IO		Digital input DC7	%IX1.0.7	BOOL
CI502_IO		Digital inputs DI8 - DI15	%IB1.1	BYTE
CI502_IO	xDI_08_CI502_I5	Digital input DI8	%IX1.1.0	BOOL
CI502_IO		Digital input DI9	%IX1.1.1	BOOL
CI502_IO		Digital input DI10	%IX1.1.2	BOOL
CI502_IO		Digital input DI11	%IX1.1.3	BOOL
CI502_IO		Digital input DI12	%IX1.1.4	BOOL
CI502_IO		Digital input DI13	%IX1.1.5	BOOL
CI502_IO		Digital input DI14	%IX1.1.6	BOOL
CI502_IO		Digital input DI15	%IX1.1.7	BOOL
CI502_IO		Digital outputs DC0 - DC7	%QB1.0	BYTE
CI502_IO		Digital output DC0	%QX1.0.0	BOOL
CI502_IO		Digital output DC1	%QX1.0.1	BOOL
CI502_IO		Digital output DC2	%QX1.0.2	BOOL
CI502_IO		Digital output DC3	%QX1.0.3	BOOL
CI502_IO		Digital output DC4	%QX1.0.4	BOOL
CI502_IO		Digital output DC5	%QX1.0.5	BOOL
CI502_IO		Digital output DC6	%QX1.0.6	BOOL
CI502_IO		Digital output DC7	%QX1.0.7	BOOL
CI502_IO		Digital outputs DO8 - DO15	%QB1.1	BYTE
CI502_IO	xDO_08_CI502	Digital output DO8	%QX1.1.0	BOOL

2. Select *"PNIO Module I/O Mapping"*.

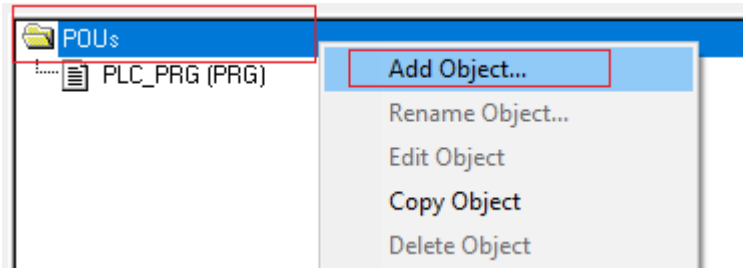
3. Fill in the variable names:

Element	Hardware channel	Symbol
Switch I5	CI502 DI8	xDI_08_CI502_I5
LED output DO8	CI502 DO 8	xDO_08_CI502

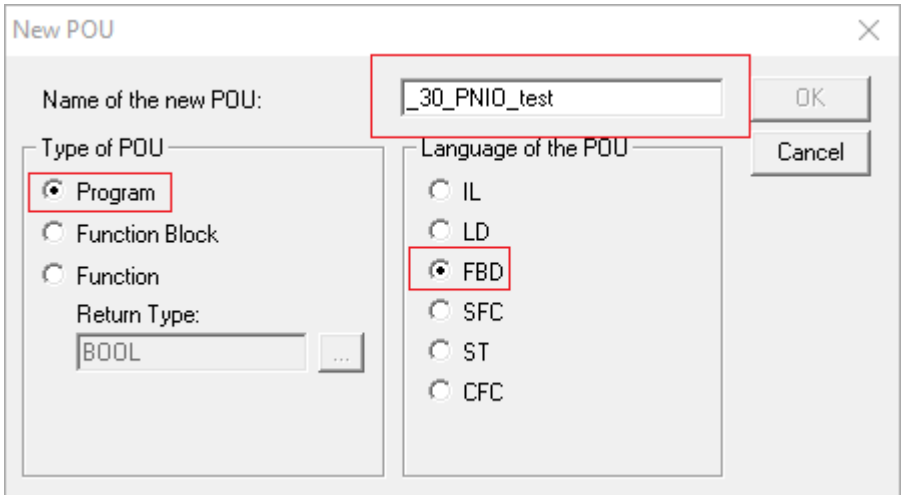
Add remote I/O expansion to project

Add a program POU to the project

1. Double click *“Application”* in the device tree to create the application file.
   ⇨ This will open the IEC 61131 programm editor CODESYS (A configuration file will be created.)(*Chapter 1.2.18.2.2.4.1 “Starting the IEC 61131 programm editor CODESYS” on page 127*).
2. In the CODESYS editor device tree right-click “POUs”.
3. Select *“Add object”*.

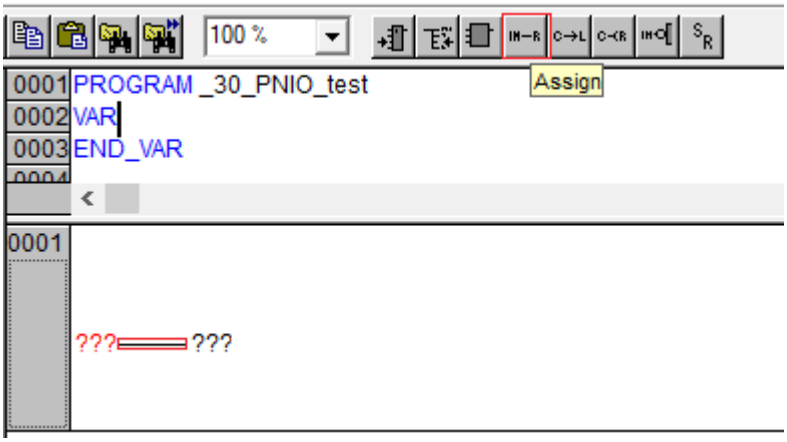


4. Enter *“_30_PNIO_test”*.
5. Select *“Program”*.
6. Select Function Block Diagram *“FBD”*.
7. Select *“[OK]”* to add POU.

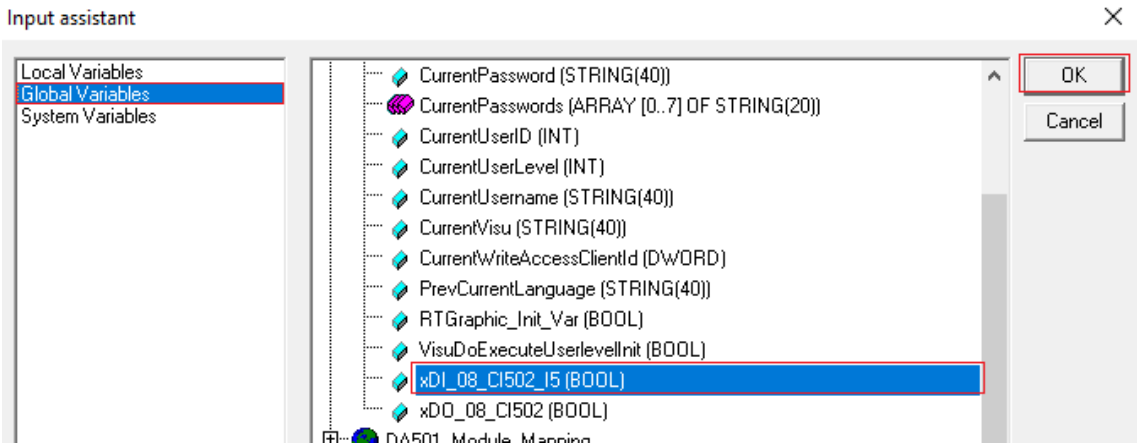


Create POU logic

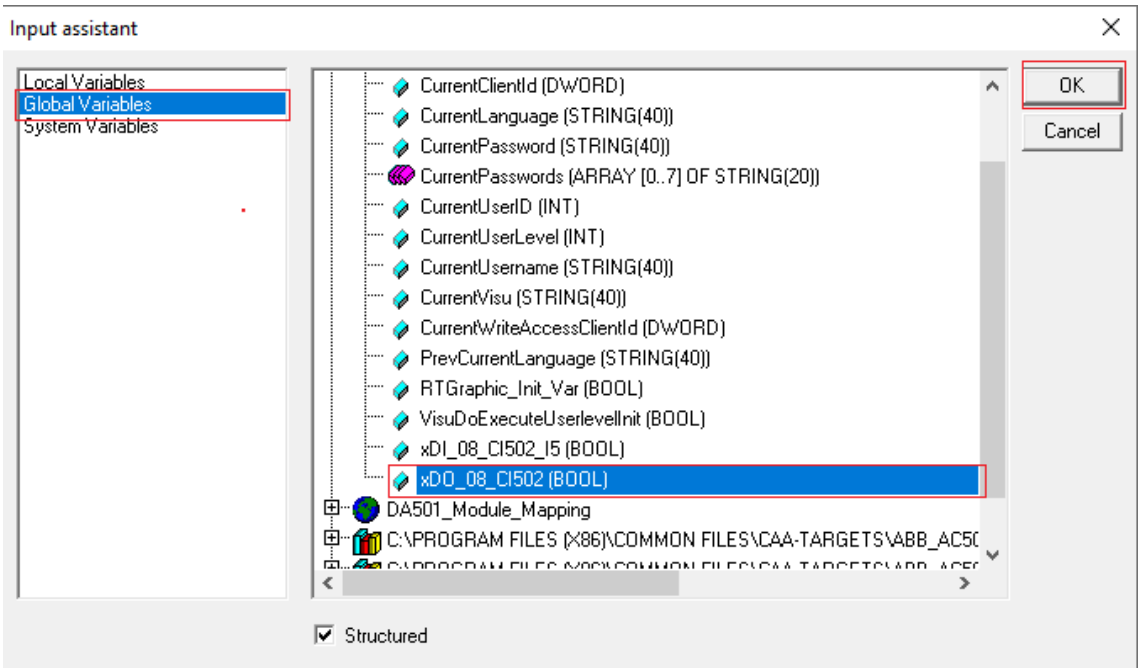
1. In the CODESYS editor device tree double-click *“_30_PNIO_test”*
2. Select *“Assign”* from Tools.



3. Select *"???"* on the left side of the assignment, press *[F2]*.
4. Select *"Global Variables"*.
5. In *"CI502_IO_Module_Mapping"* list, select *"xDI_08_CI502_I5"*.
6. Select *"[OK]"* to add this variable to the left side of the assignment connector.

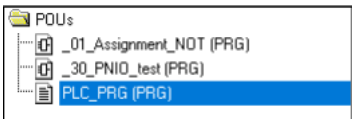


7. Select *"???"* on the right side of the assignment, then press *[F2]*.
8. In *"CI502_IO_Module_Mapping"* list" , select *"xDO_08_CI502"*.
9. Select *"[OK]."*

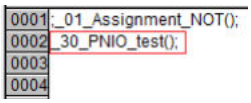


Call the POU in PLC_PRG

1. In the CODESYS editor device tree double-click *“PLC_PRG”*.

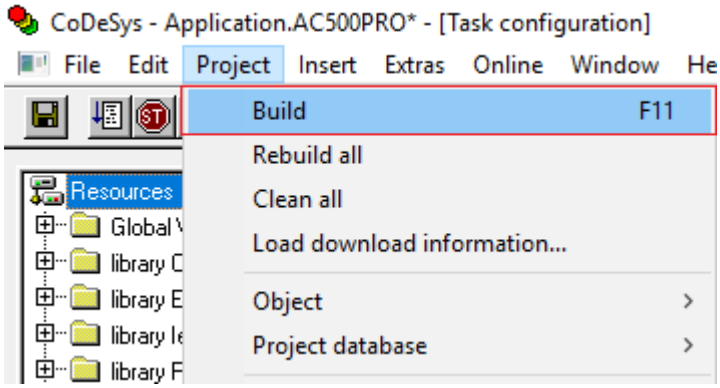


2. Select the next free line in *“PLC_PRG”* and press *[F2]*.
   ⇨ *“Input Assistant”* opens.
3. Select *“User defined Program”*.
4. Select *“_30_PNIO test”*.
5. Select *“[OK]”* to close the dialog.



Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

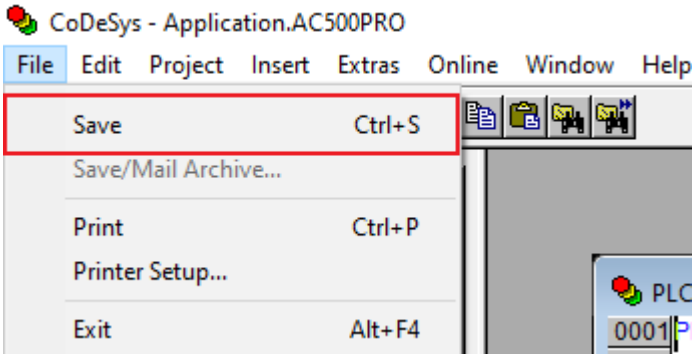


▷ In the CODESYS editor menu select *"Project ➔ Build"*

⇨ The result of the compiling is shown in the *"Messages"* field at the bottom of the screen.

If you skip the compiling and select *"Login"*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save CODESYS project



▷ In the CODESYS editor menu select *"File ➔ Save"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl]* + *[S]*.

Loading the project to the CPU

▷ Download the project to the CPU ↬ *as described in Chapter 1.2.18.2.2.5 , on page 135*.

Test the program

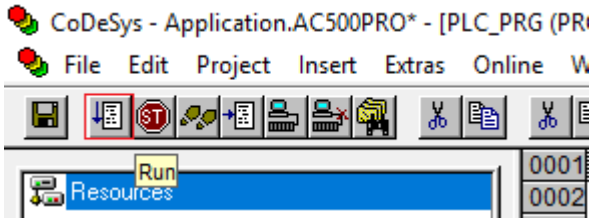
Start the program execution

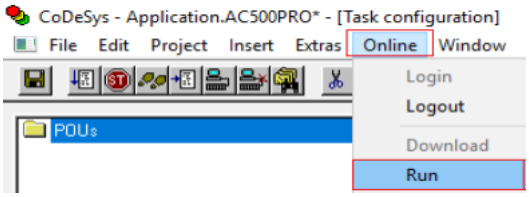
☑ You are logged in the CPU.

☑ An executable project is loaded to the CPU.

☑ The CPU is in "stop" mode.

☑ Open CODESYS ↬ *Chapter 1.2.18.2.2.4.1 “Starting the IEC 61131 programm editor CODESYS” on page 127*.





▷ In the CODESYS editor menu select *“Online ➔ Run”*

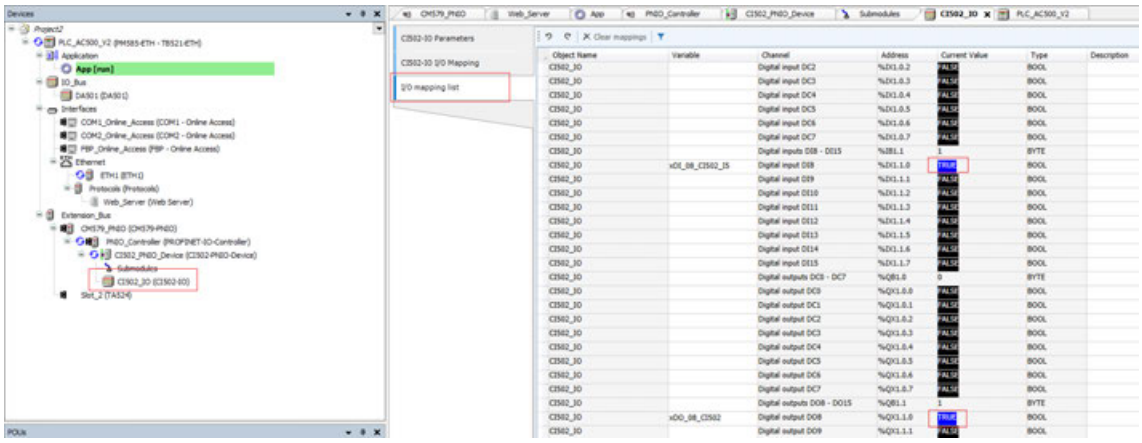
Alternatively, select the "run" icon in the tool bar.

Alternatively, press *[F5]*.

Test the function

▷ Operate the switch I5 and observe:

- The LEDs of the relevant CI502 inputs and outputs.
- The online status of inputs and outputs within the POU.



Reset the CPU

Reset values and parameters

In some cases, it could be required to do a CPU reset, e.g., for resetting of counter values, parameters etc.

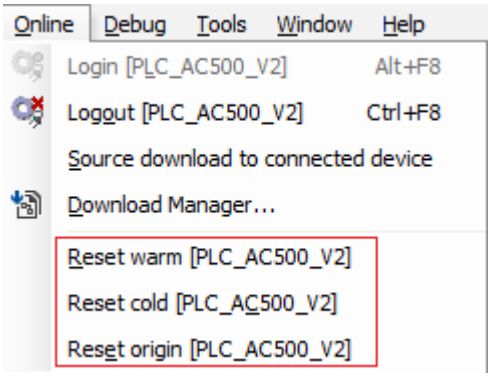


Fig. 8: Reset commands in “Online” menu

Reset warm All variables are reset, except R% variables.
Reset cold Causes initialization of all variables, except PERSISTENT variables. By recommended creation of remanent variables always with both properties: PERSISITENT and RETAIN, this command resets all variables, except R% variables.
Reset origin All variables and the application project are reset.

Table 6: Behavior of variables of type VAR (local or global) and variables of type PERSISTENT RETAIN

	VAR	VAR PERSISTENT RETAIN
After online command 'Online change'	no change	no change
After online command 'Download'	initialization	no change
After online command 'Reset warm'	initialization	no change
After online command 'Reset cold'	initialization	no change
After online command 'Reset origin'	initialization	initialization
After power supply off	initialization	no change

1.2.18.2 Example projects for AC500-eCo V2

1.2.18.2.1 Hardware AC500-eCo V2

Contents of the AC500-eCo V2 starter kit:

- 1 x AC500-eCo V2 CPU PM554-TP-ETH with 2 terminal blocks plugged on the CPU: 1 x 11 pin, 1 x 9 pin
- 1 x digital input simulator
- 1 x programming cable

System assembly, construction and connection

1. Assemble the CPU.

   Enclosed to the CPU, you find the installation instructions. Refer to these installation instructions for assembling the CPU.

2. Connect the input simulator to the CPU.

   Enclosed to the input simulator, you find the installation instructions. Refer to these installation instructions to connect the input simulator to the CPU.

DANGER!

Risk of death through electric shock.

Before using the CPU refer to the “Regulations Concerning the Setting up of Installations” for safety instructions. *http://search-ext.abb.com/library/Download.aspx?DocumentID=3ADR025003*&Action=Launch*

CAUTION!

Risk of damaging the PLC modules.

The CPU can be damaged by overvoltages and short circuits. Make sure that all voltage sources (supply and process voltage) are switched off before you begin with operations on the system.

3. The CPU needs to be powered by 24 V DC. Connect the CPU to the power, by using the 5-pin screw-type terminal block.

CAUTION!

Risk of damaging the CPU and the connected modules.

Voltages > 35 V DC can destroy the CPU and the connected modules. Make sure that the supply voltage never exceeds 35 V DC.

4. Plug the programming cable into the CPU and your PC.

1.2.18.2.2 Example project

The following steps show how to set-up an application project and configure the hardware. A simple logic is used as example to introduce in programming and commissioning of the PLC. The workflow for creation of a visualization is explained, as well as how to set-up a web server for visualization.

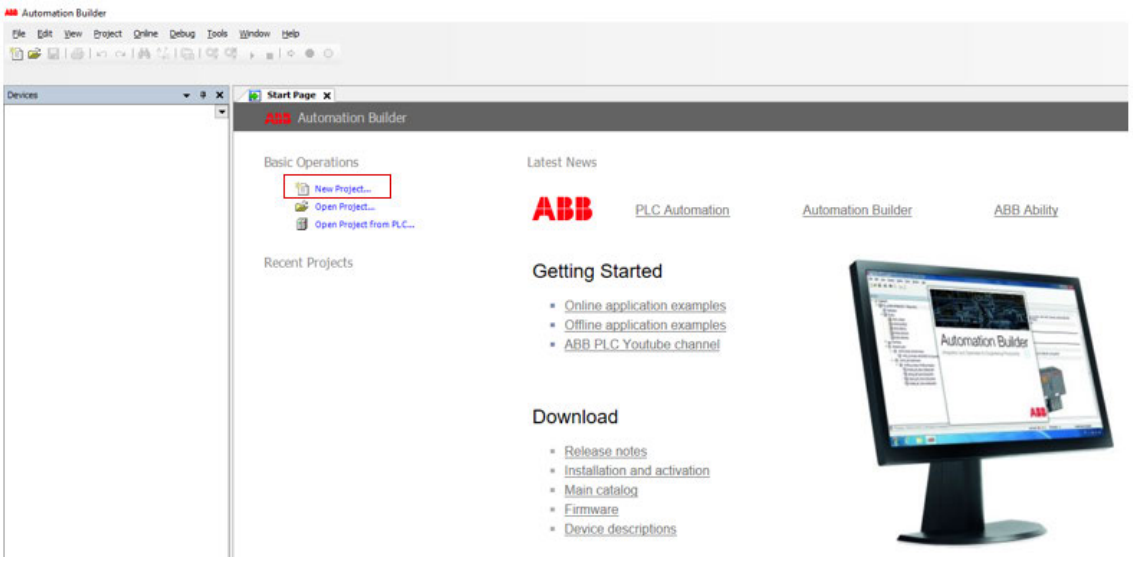
Preconditions

- Automation Builder is installed and licensed as, at least, basic edition ↬ *Chapter 1.2.4 “Managing your licenses” on page 20*.
- AC500 V2 CPU is assembled and connected to the PC ↬ *Chapter 1.2.18.2.1 “Hardware AC500-eCo V2” on page 121*.

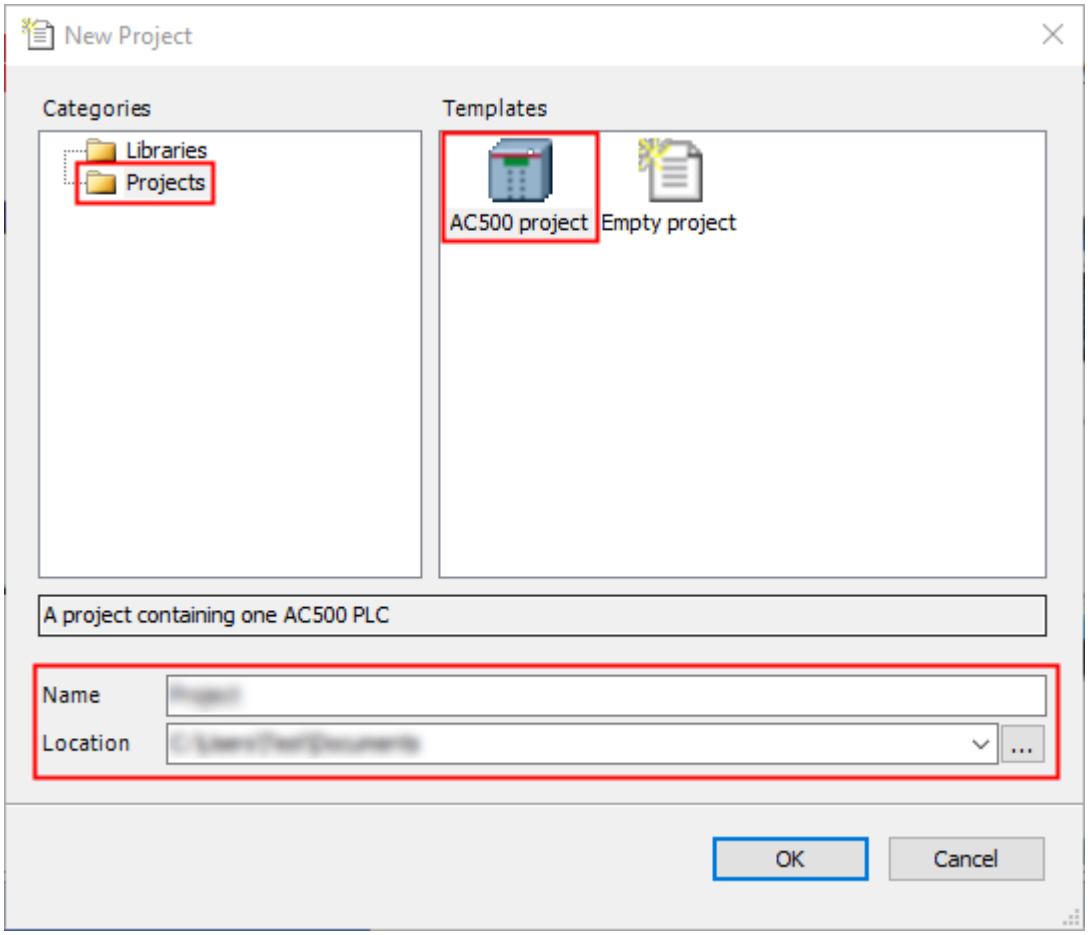
Create, set-up and save your AC500 V2 project

Create a project

1. Launch Automation Builder either out of the desktop icon or out of the Windows menu.

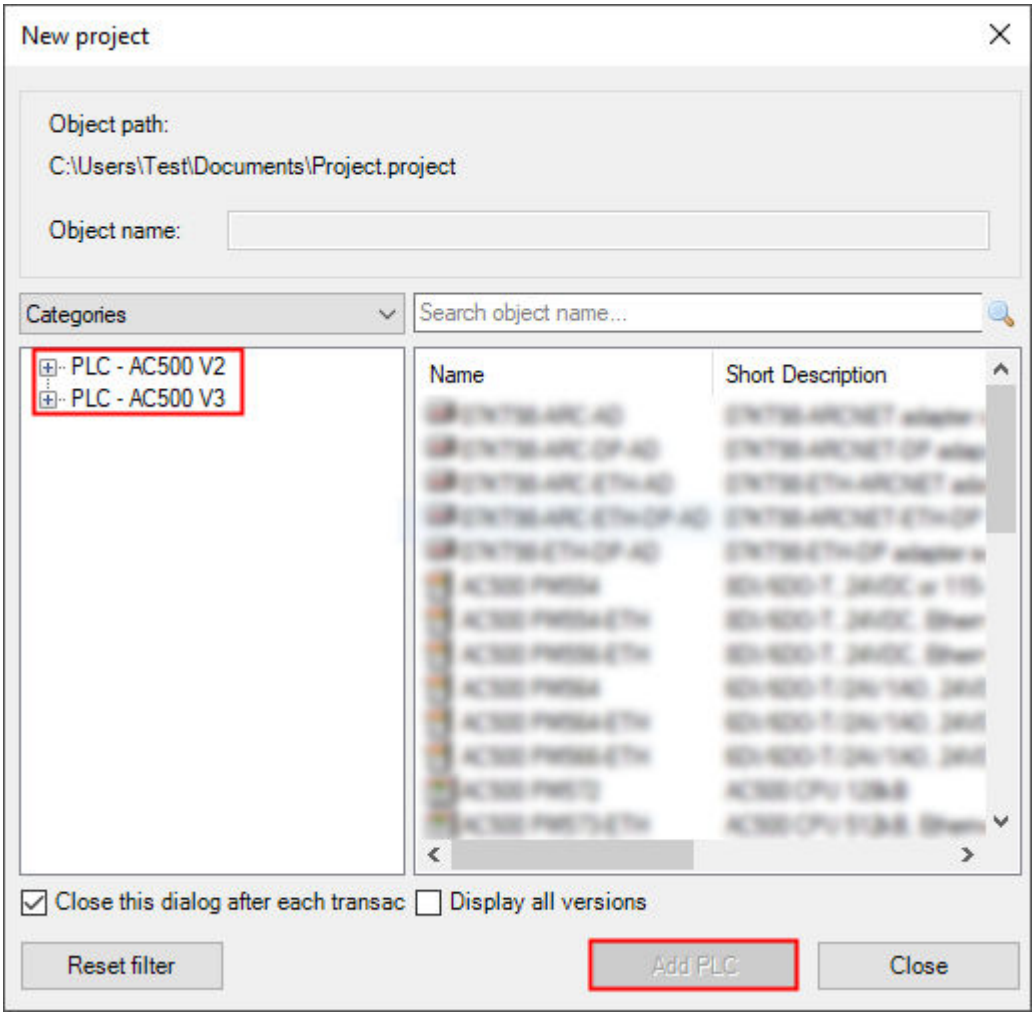


2. Select *"New Project"* or go to menu *"File ➔ New Project"*.



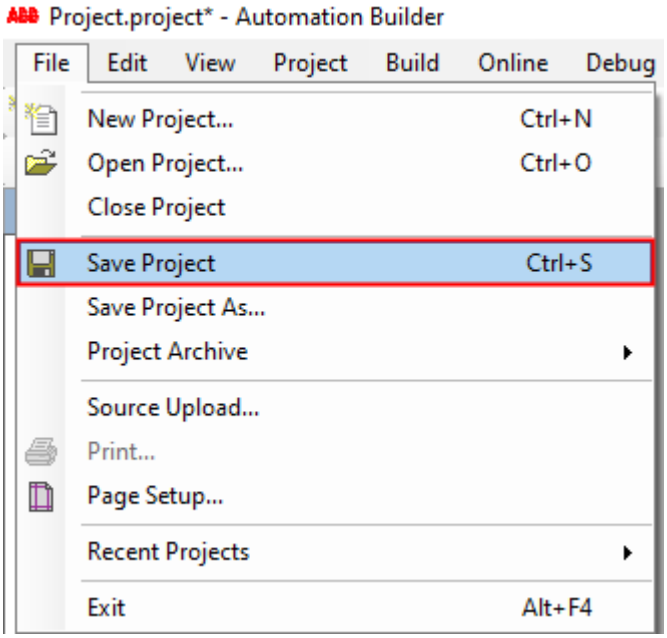
3. Select *"Projects"*.
4. Select *"AC500 project"*.
5. Fill in project name.
6. Choose a location to save the project to.

7. Select *“OK”*.
8. Select *“PLC - AC500 V2”*.
9. Select the CPU according to your hardware set-up.



10. Select *“Add PLC”* to add the CPU to your application.

Save the project



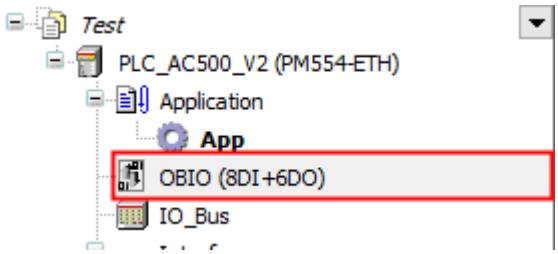
▷ Select menu *"File ➔ Save Project"*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl]* + *[S]*.

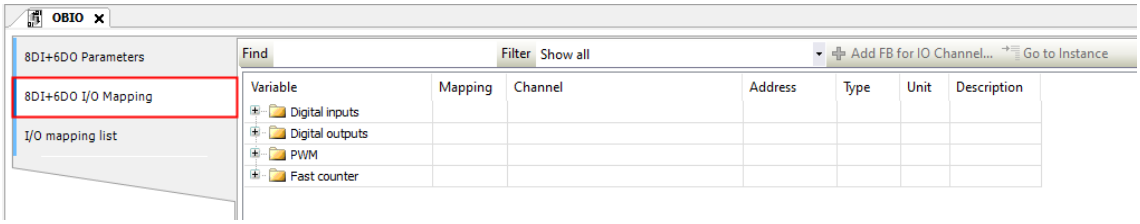
Configure the onboard I/O channels

Onboard I/O variable mapping



1. Double-click *"OBIO"* in the device tree.

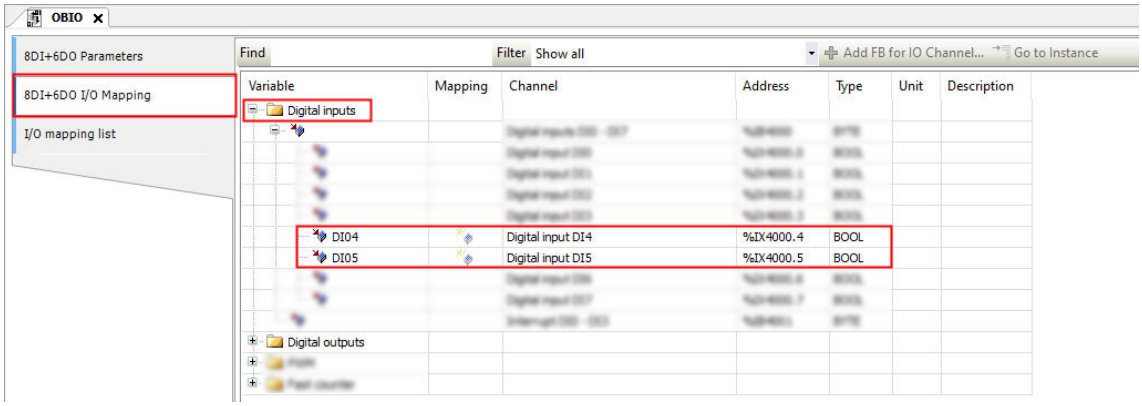
   ⇨ A tab opens in the editor view.



2. Select *"8DI+6DO I/O Mapping"*.

   ⇨ Here, you will map variable names (symbols) for the channels you will need in the program.

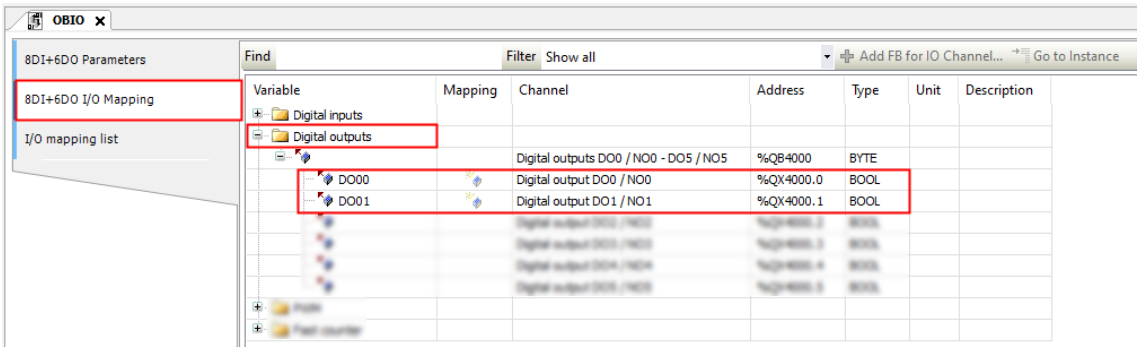
Handle the digital input variables



1. Open the list of the digital inputs.
2. Fill in the variable names:

Channel	Type	Variable
Digital input DI4	BOOL	DI04
Digital input DI5	BOOL	DI05

Handle the digital output variables



1. Open the list of the digital outputs.
2. Fill in the variable names:

Channel	Type	Variable
Digital output DO0 / NO0	BOOL	DO00
Digital output DO1 / NO1	BOOL	DO01

Programming and compiling

You write the program code in a separate IEC 61131-3 editor (CODESYS). You can open CODESYS out of Automation Builder.

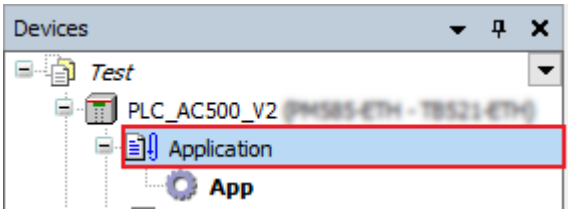
Supported programming languages:

- ST (Structured Text)
- IL (Instruction List)
- FBD (Function Block Diagram)
- LD (Ladder Diagram)
- SFC (Sequential Function Chart)
- CFC (Continuous Function Chart)

Starting the IEC 61131 programm editor CODESYS

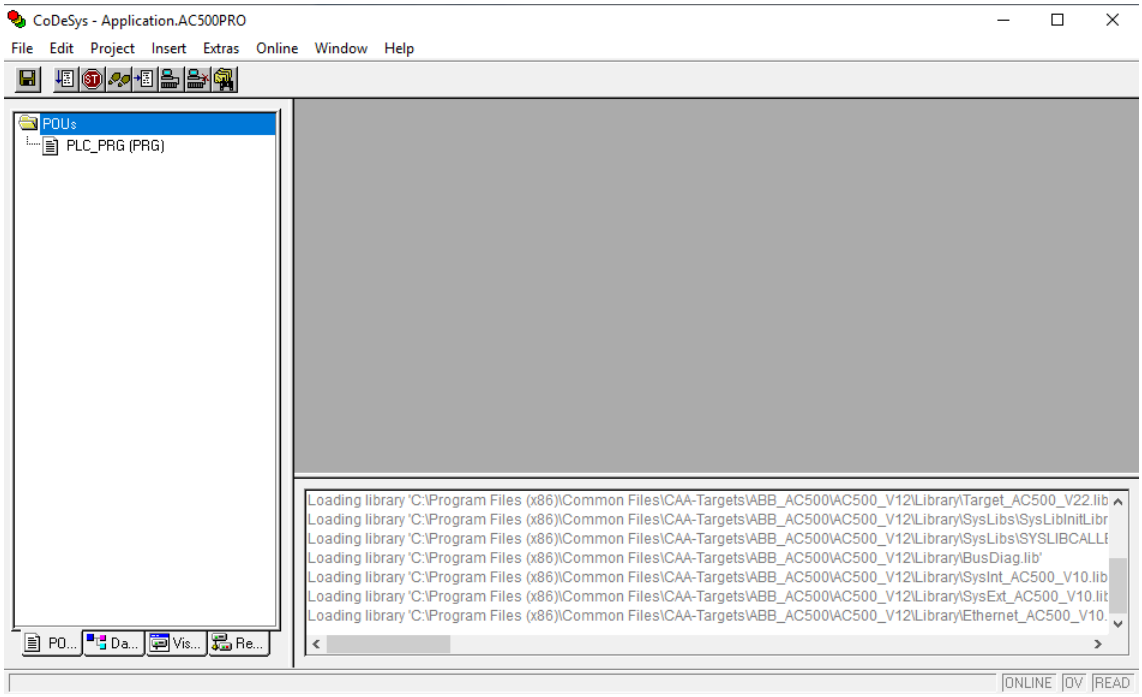
To start the IEC 61131 programm editor CODESYS:

☑ Open an AC500 V2 project in Automation Builder



▷ In the Automation Builder device tree double-click *“Application”*

⇨ This will start the IEC 61131 programm editor CODESYS

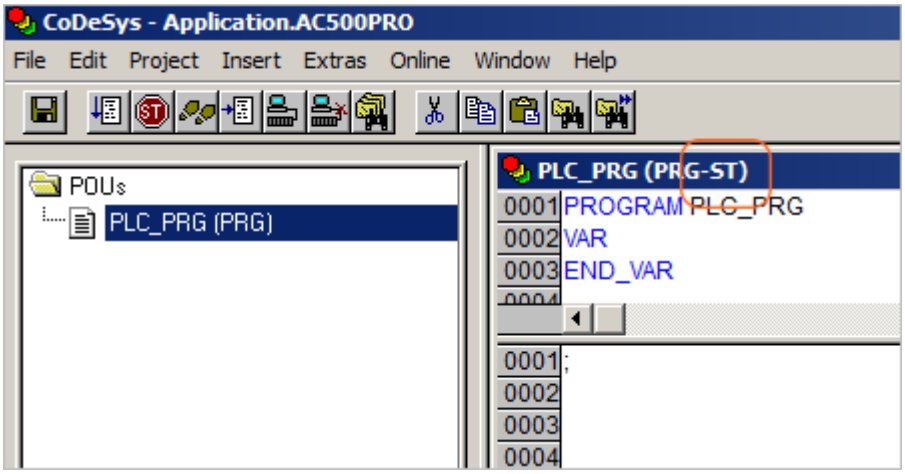


Change the programming language into FBD

The default programming language is ST.

1. Select *“PLC_PRG (PRG)”*.

> *If you made a mistake during the process, you can always undo. In the CODESYS menu select “Edit ➔ Undo”.*

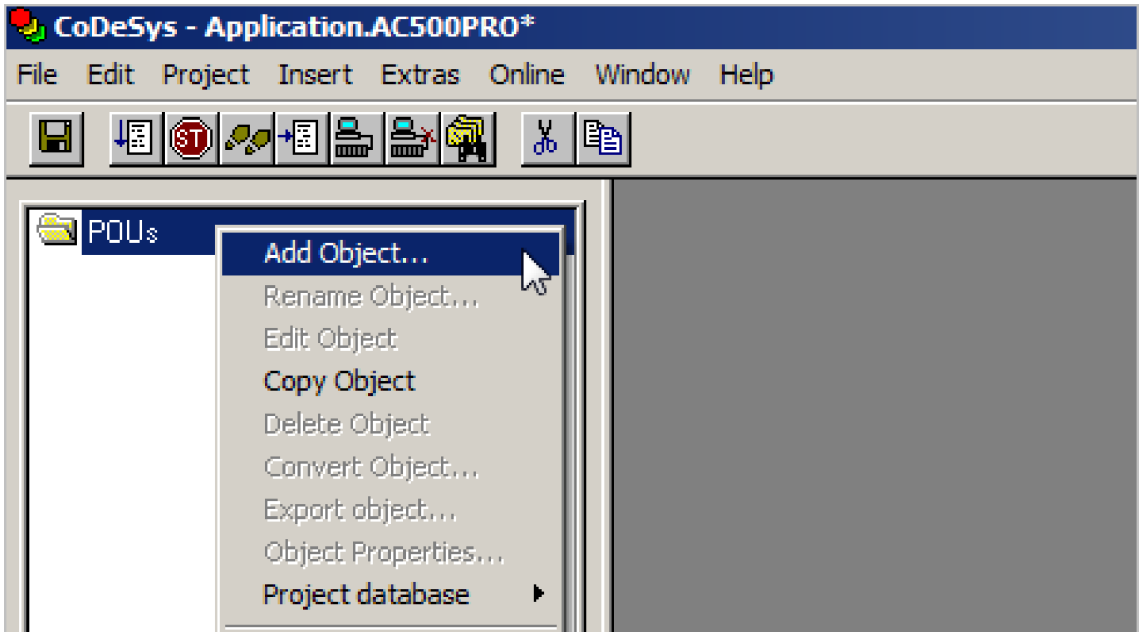


2. Press *[DELETE]*.

   ⇨ *“PLC_PRG (PRG)”* has been removed.

3. Right-click *“POUs”*.

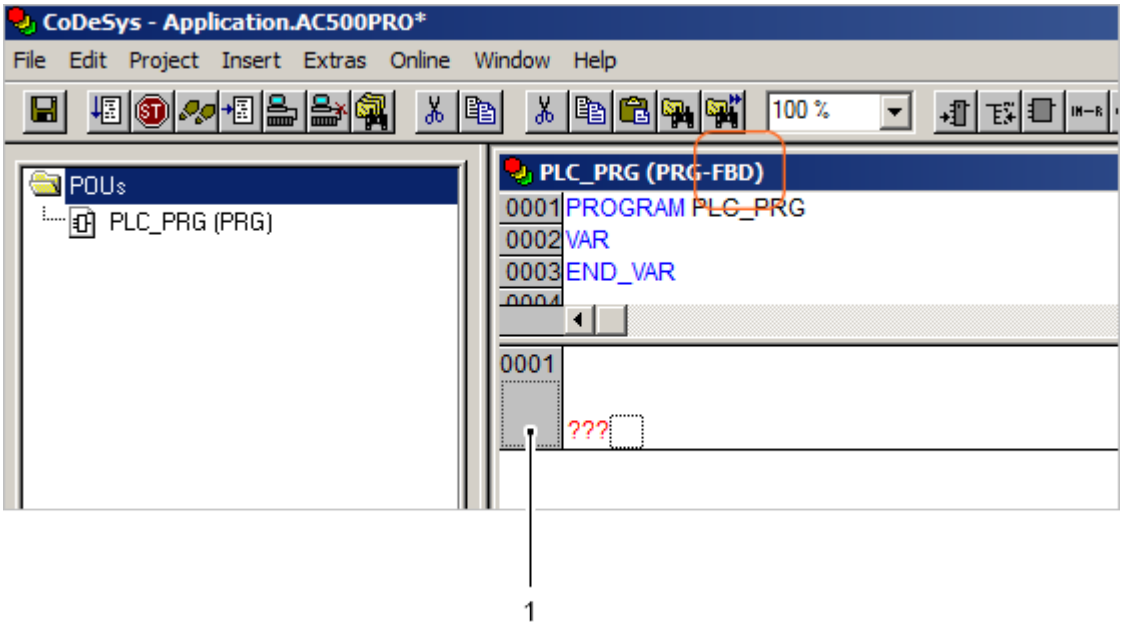
   Select *“Add Object”*.



4. Under *“Language of the POU”* select *“FBD”*.

5. Select *“OK”*.

   ⇨ A newly generated POU opens. The programming language of the POU is FBD.



1 Network (here network number 0001)

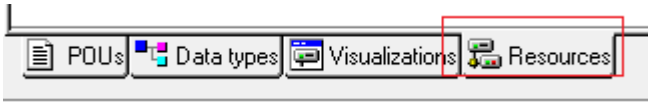
Task configuration

A task is a time unit in the processing of a user program (IEC application), which defines by parameters the way and the speed the CPU is executing the user program.

For this project you will use only one cycling task.

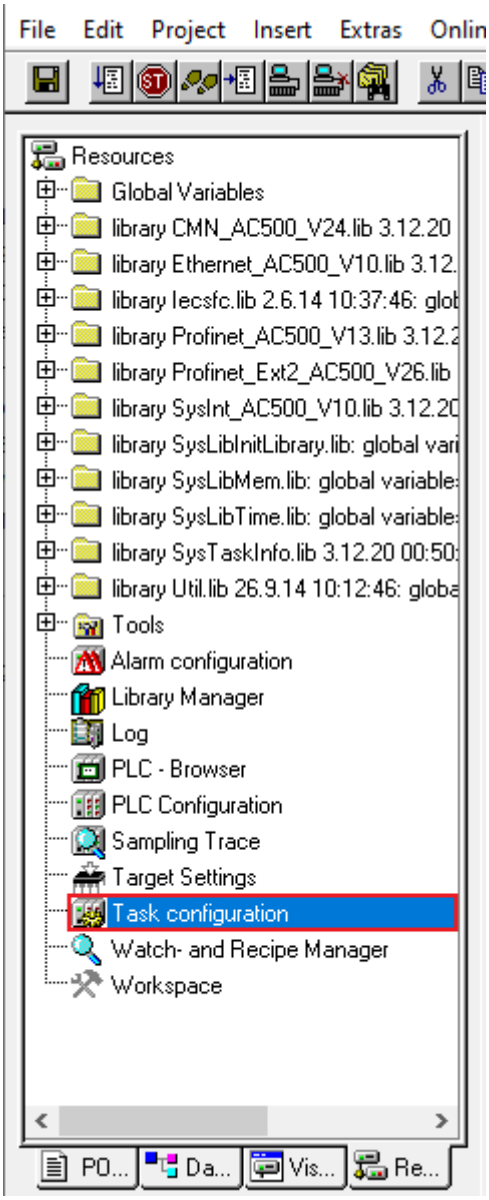
☑ Open CODESYS editor ↯ *Chapter 1.2.18.2.2.4.1 “Starting the IEC 61131 programm editor CODESYS” on page 127*

1. In the CODESYS editor menu select the *“Resources”* tab.

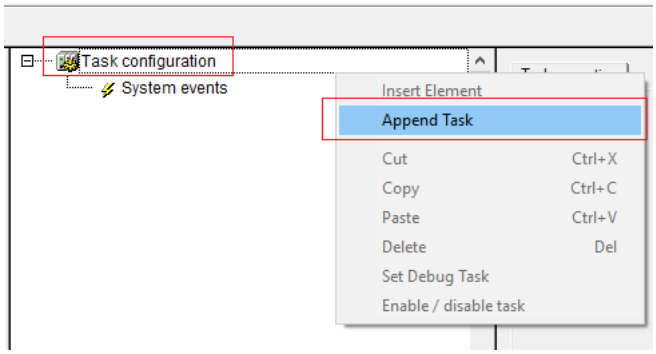


2. Double click *“Task configuration”*.

   ⇨ The Task configuration window opens.

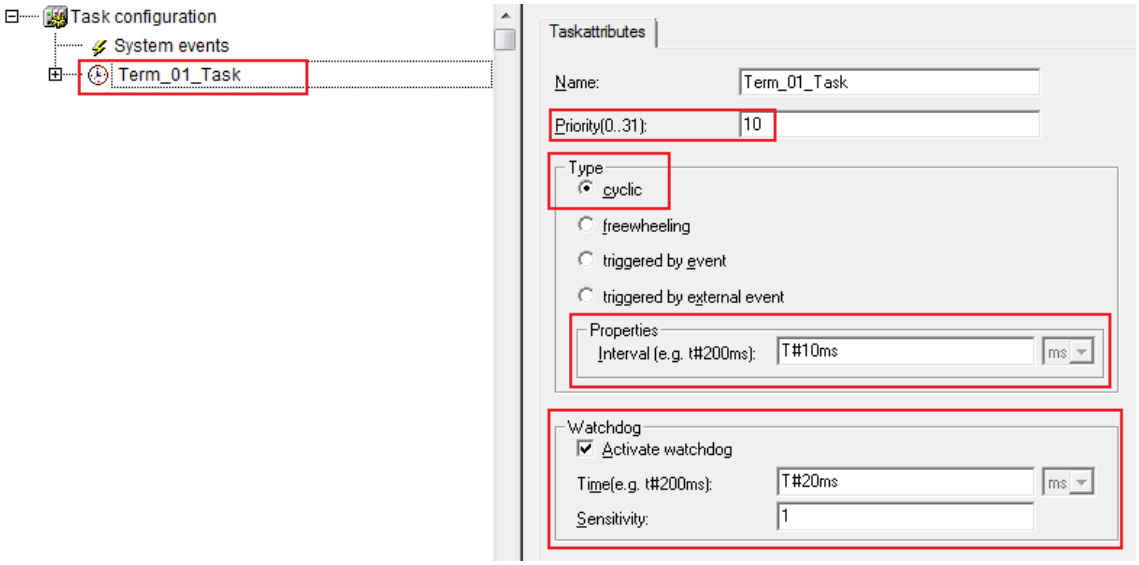


3. Right-click on *"Task configuration"*.
4. Select *"Append Task"*.



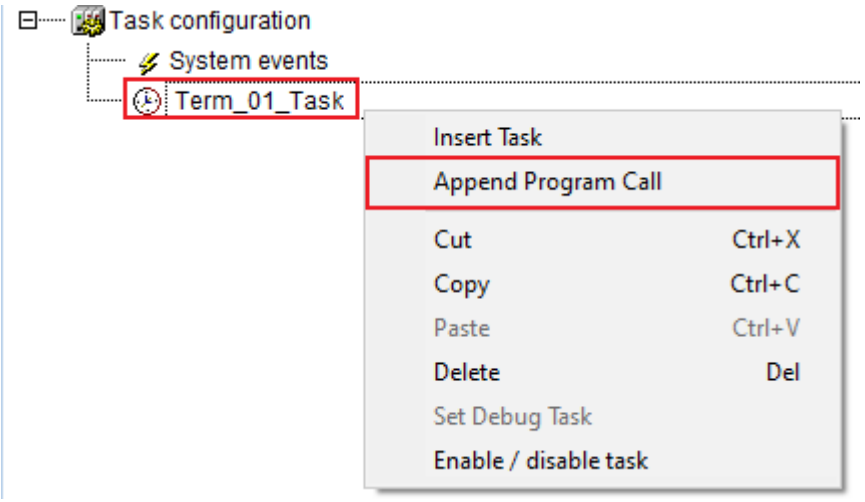
5. Enter a name.
6. Set *"Priority"* to 15
7. Set *"Type"* to *"cyclic"*.
8. Set *"Interval"* to *"T#10ms"*.

9. Activate Watchdog.
10. Set *“Time”* to *“T#20ms”*.

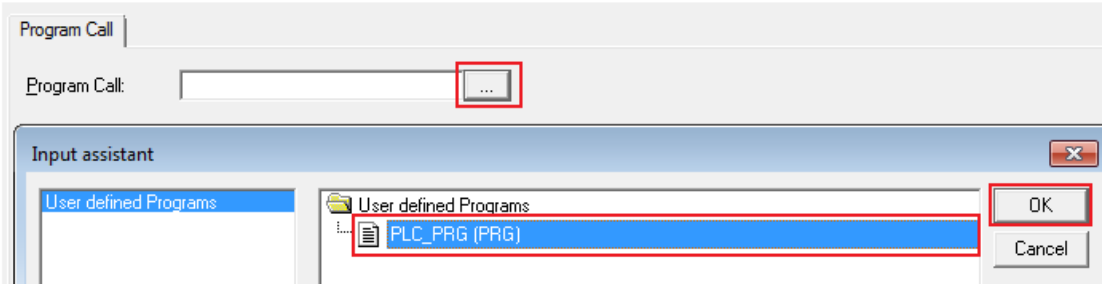


Priority type interval	This is how the CPU prioritizes the task, when more than one task is defined. Type In the CPU you can run tasks dependent on the demands of the process Interval For cyclic tasks you can set the cyclical execution time. It is usually set in milliseconds with IEC time syntax
Watchdog calls	To keep track of the time it takes to complete the task Calls You can call in one or more program POUs in one single task

11. Right click the watch icon next to *“Term_01_Task”*.
12. Select *“Append Program Call”*.

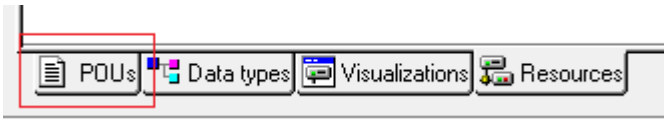


13. Select *“[…]”*.
    ⇨ The input assistant opens.
14. Select *“PLC_PRG (PRG)”*.
15. Select *“OK”*.
    ⇨ The task has been appended.

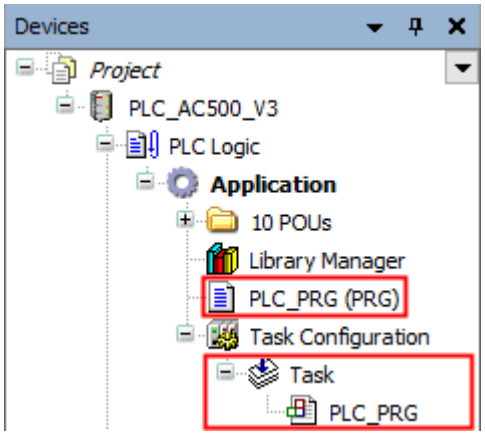


Main program PLC_PRG

In CODESYS menu select tab POUs, there is one call of a POU (program organization unit) i.e. "PLC_PRG".



In your project the "PLC_PRG" will become a main program containing calls to other programs (POUs) which you will create one by one.



The PLC_PRG POU has been defined by default in ST (Structured Text) editor. Keep this setting because of good visibility of the instructions at a glance and good handling for trouble-shooting.

Boolean logic AND

Implementation

Add Boolean "AND"

1. Select the dotted rectangle behind“ *???*”. The dotted rectangle represents the cursor position in this network.
2. In the toolbar select the Box icon.

   ⇨ A box with the AND operator will be added to your network.

When inserting a new box, it always appears as an AND operator. To change the type of the box click on the AND text and enter another name.

To get an overview of all accepted operators, functions and function blocks click on the AND text and press [F2].

Assign input and output variables to the AND operator

Assign input variables to the AND operator

The *"???"* on the left side of the AND operator represent your two inputs.

To assign variables to each input:

1. Select *"???"*.
2. Press *[F2]*.
   ⇨ The input assistant opens.
3. Under Global Variables open *"OBIO_Module_Mapping"*.
4. For each *"???"* select *"DI04"* and *"DI05"*.

Assign output variable to the AND operator

The *"???"* on the right side of the AND operator represent your output.

To assign a variable to the output:

1. Select *"???"*.
2. Press *[F2]*.
   ⇨ The input assistant opens.
3. Under Global Variables open *"OBIO_Module_Mapping"*.
4. Select *"DO00"*.

Add another network

To add another network:

1. Right-click on network 0001.
2. Select *"Network (after)"*.
   ⇨ You added a new network after network 0001. The new network number is 0002.

Add assignments and variables

To add an assignments to your network:

▷ From the toolbar select the assign symbol.

Alternatively right-click on the dotted rectangle and select *"Assign"*.

⇨ You added another assignment to the network.

To add variables to your assignments:

1. Select *"???"*.
2. Press *[F2]*.
   ⇨ The input assistant opens.

3. Under Global Variables open *“OBIO_Module_Mapping”*.
4. For the input select DO00.

   For the output select DO01.

Add Boolean NOT

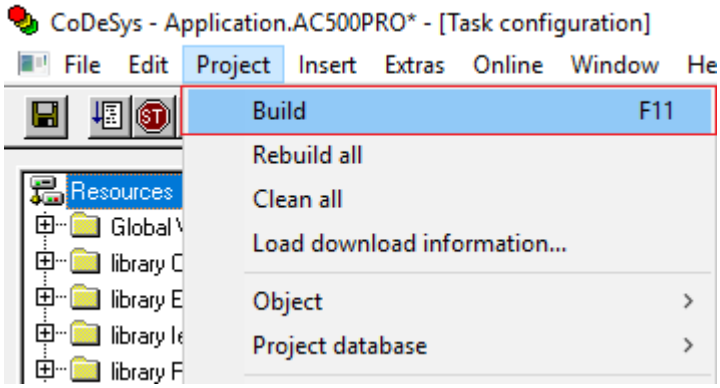
To negate the function:

1. Select the line behind the input. The dotted rectangle represents the cursor postion.
2. Right click on the dotted rectangle and select Negate.

   ⇨ You inserted a negation between your assignments.

Compile the project

Before logging-in to the CPU, you need to compile the complete code without any errors.

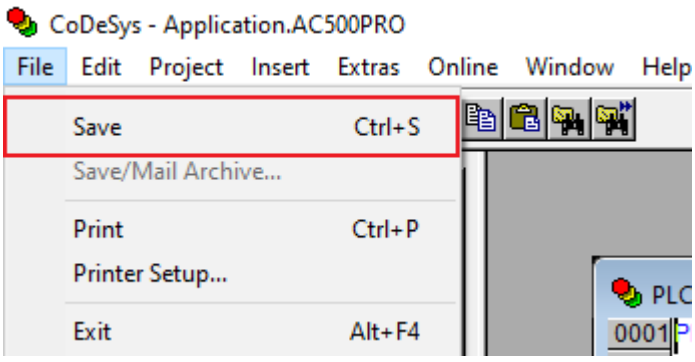


▷ In the CODESYS editor menu select *“Project ➔ Build”*

⇨ The result of the compiling is shown in the *“Messages”* field at the bottom of the screen.

If you skip the compiling and select *“Login”*, the Automation Builder will automatically trigger compiling in advance to logging-in.

Save CODESYS project



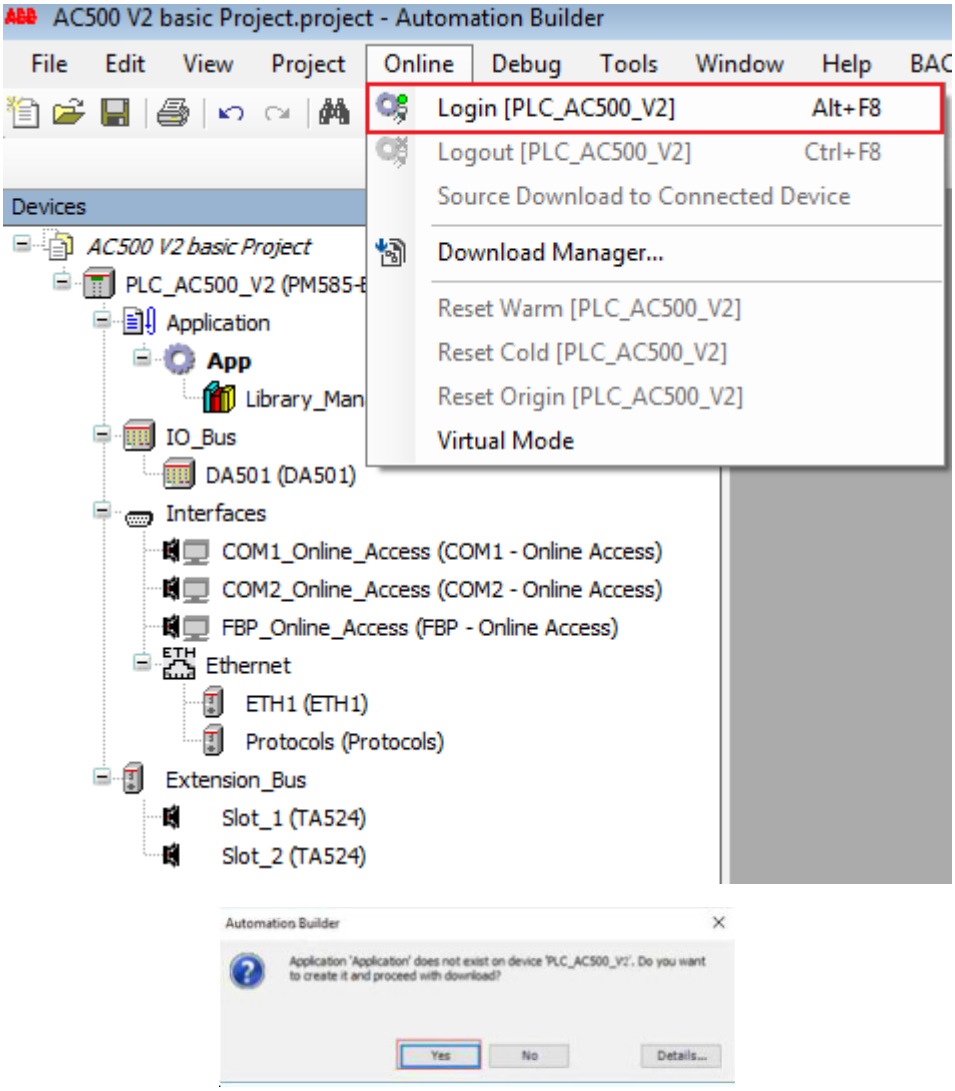
▷ In the CODESYS editor menu select *“File ➔ Save”*.

Alternatively, select the save icon in the tool bar.

Alternatively, press *[Ctrl] + [S]*.

Log-in to CPU and download the program

Logging-in to the CPU will load the project into the AC500 V2 CPU. The first log-in will also load the hardware set-up.



1. In the Automation Builder menu select *“Online ➔ Login [PLC_AC500_V2]”*.

   ⇨ A pop-up will appear.

2. Select *“Yes”* to download the application to the AC500V2 CPU.

   ⇨ PLC is in "stop" mode.

3. Start the PLC ↳ *Chapter 1.2.18.2.2.6.1 “Start the program execution” on page 136*.

> *Generally, if the CPU is in RUN mode, i.e. in program execution mode, a download will always cause the mode change to "stop". In stop mode the CPU is not controlling the system!*
>
> *Always, after selecting the "Login" command, read carefully the dialog box text to ensure that you are aware of the CPU's behavior after the command confirmation.*

By default, a download generates following actions in the CPU:

- The project is stored in the RAM memory.
- The project is stored in the flash EEPROM, if boot application was created.

Test the program

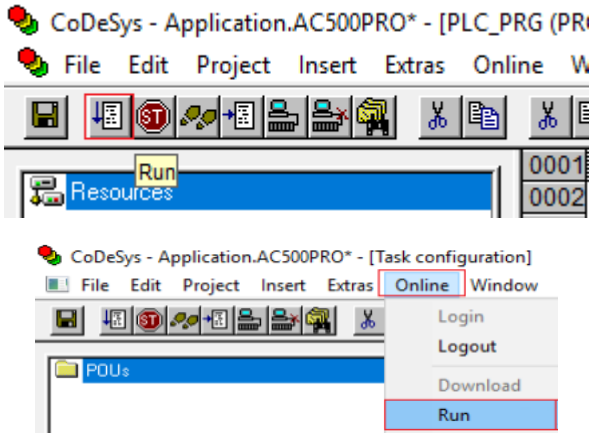
Start the program execution

☑ You are logged in the CPU.

☑ An executable project is loaded to the CPU.

☑ The CPU is in "stop" mode.

☑ Open CODESYS *Chapter 1.2.18.2.2.4.1 "Starting the IEC 61131 programm editor CODESYS" on page 127*.



▷ In the CODESYS editor menu select *"Online ➔ Run"*

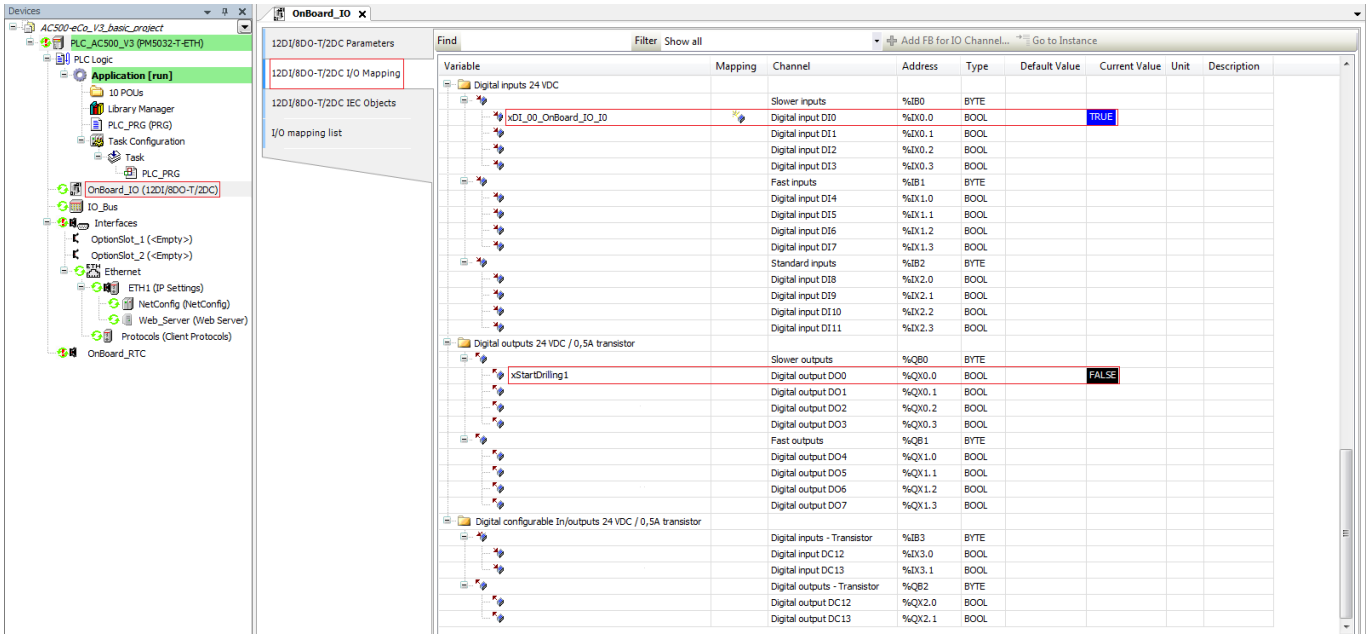
Alternatively, select the "run" icon in the tool bar.

Alternatively, press *[F5]*.

Test the function

▷ Operate the switch I1 and observe:

- The LEDs of the relevant onboard I/O inputs and outputs.
- The online status of inputs and outputs within the POU.

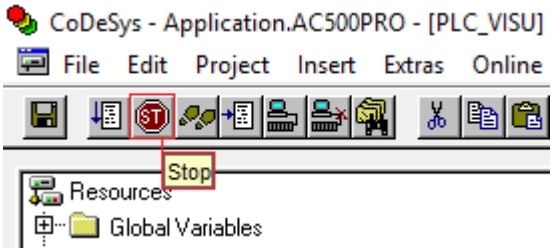


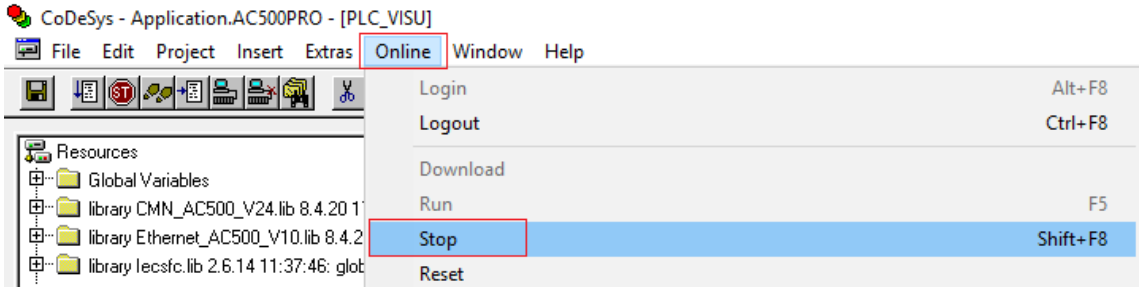
Stop the program execution

☑ You are logged in the CPU.

☑ An executable project is loaded to the CPU.

☑ The CPU is in RUN mode.





▷ In the CODESYS editor menu select *“"Online ➔ Stop [PLC_AC500_V2]"”*

Alternatively, select the "stop” icon in the tool bar.

Alternatively, press *[Shift]* + *[F8]*.

Reset the CPU

Reset values and parameters

In some cases, it could be required to do a CPU reset, e.g., for resetting of counter values, parameters etc.

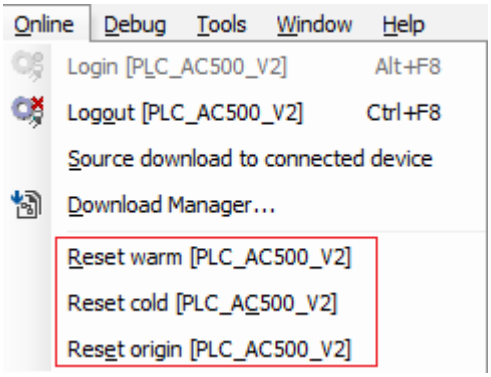


Fig. 9: Reset commands in “Online” menu

Reset warm — All variables are reset, except R% variables.
Reset cold — Causes initialization of all variables, except PERSISTENT variables. By recommended creation of remanent variables always with both properties: PERSISITENT and RETAIN, this command resets all variables, except R% variables.
Reset origin — All variables and the application project are reset.

Table 7: Behavior of variables of type VAR (local or global) and variables of type PERSISTENT RETAIN

	VAR	VAR PERSISTENT RETAIN
After online command 'Online change'	no change	no change
After online command 'Download'	initialization	no change
After online command 'Reset warm'	initialization	no change
After online command 'Reset cold'	initialization	no change
After online command 'Reset origin'	initialization	initialization
After power supply off	initialization	no change

1.3 Automation Builder installation manager

Automation Builder installation manager allows you to install customer specific software packages, modify the existing installation, update installation information and to uninstall Automation Builder software packages in a comfortable and flexible way.

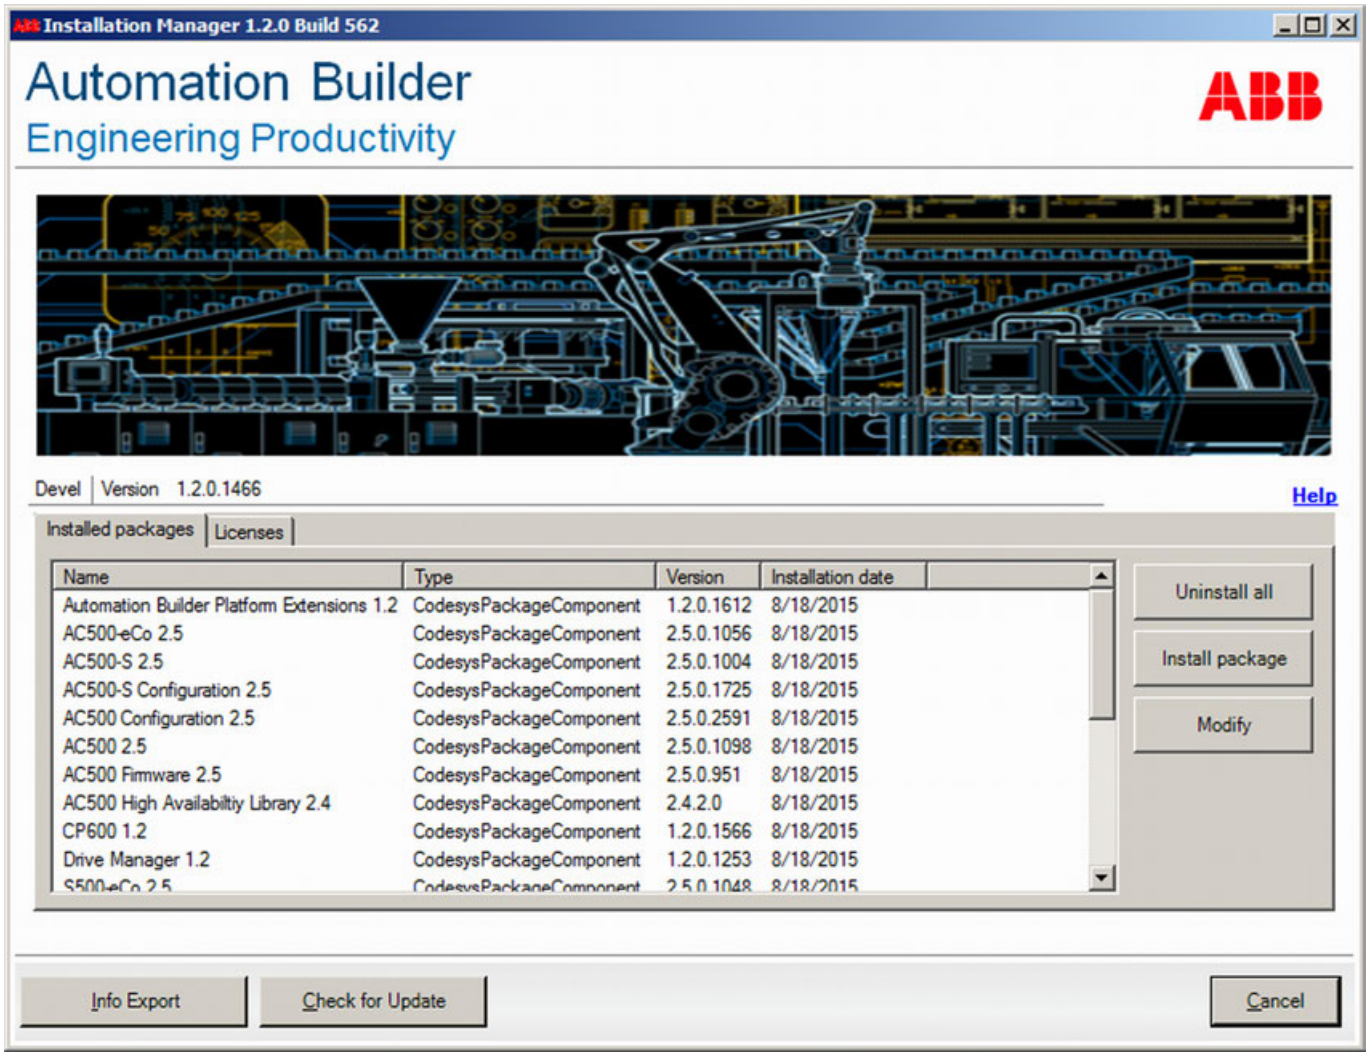
You can launch installation manager from the main menu of Automation Builder or from Windows start menu.

1. Open Automation Builder software.

   From the **Tools** menu, select **Installation Manager**.

2. As an alternative, launch installation manager from Windows start menu: *"Start menu ➔ All Programs ➔ ABB ➔ Automation Builder ➔ ABB Automation Builder Installation Manager"*.

   ⇨ Installation manager starts.



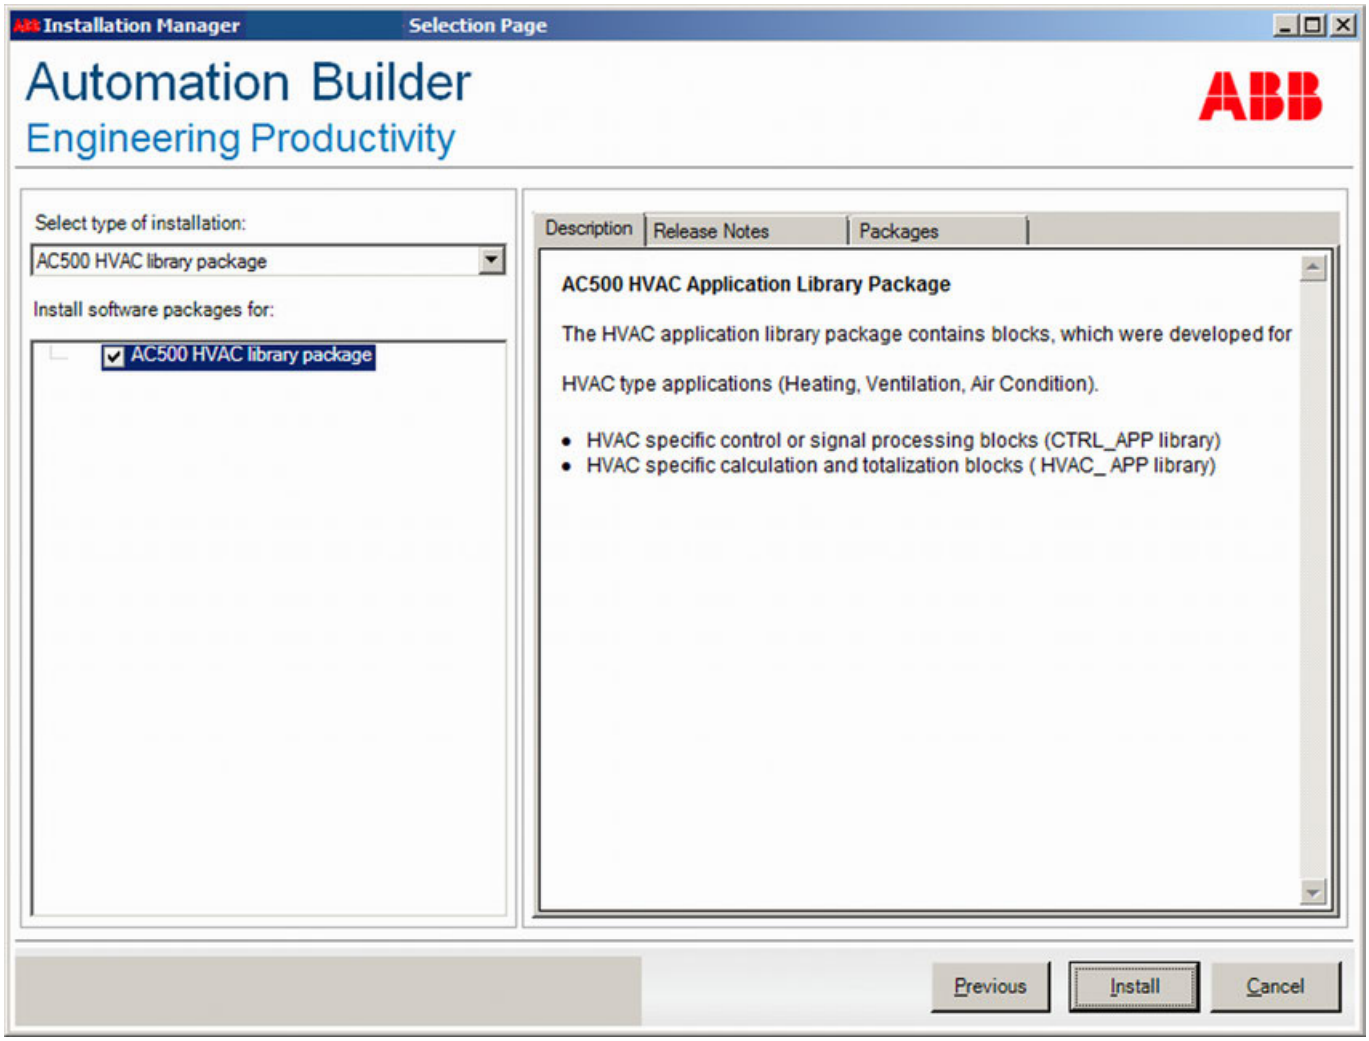
Options:

- **Installed packages**: Shows all installed packages of Automation Builder.
- **Licenses**: Displays the detailed license information of installed Automation Builder packages in the CodeMeter WebAdmin page. For more information, see *http://localhost:22350/$help/CmUserHelp/us/index.html?controlcenter.htm*.
- **Uninstall all**: Uninstalls the currently installed Automation Builder software.
- **Install Package**: Installs customer specific software packages.
- **Modify**: Adds or removes installed software packages.
- **Info Export**: Exports detailed information of installed packages in a notepad.
- **Check for Update**: Checks if your installed version of Automation Builder is up to date and checks for updates.

1.3.1 Installing customer specific package

Installation manager allows you to install customer specific software packages (CABPKG files). These packages are separately distributed to the customer based on the customer requirement.

1. In the installation manager, click **Install Package**.
2. Select the package to be installed (.cabpkg file) from the file system.



3. Select the components to be installed.
4. Click **Install**.

   ⇨ Data installation starts.
5. Successfully installed components are indicated with .

   Errors during data download are indicated with . Errors during download of any package component aborts the installation. In this case click **Show Log** and save the log data. Send the log file to ABB support team.

   Click **Finish** to end the wizard.

1.3.2 Adding or removing installed software packages

1. In the installation manager, click **Modify**.

   ⇨ The selection page opens.

   The selected software packages are installed already.

   The not selected software packages are not installed.

2. Select the software packages you want to install.

   Unselect the software packages you want to uninstall.

   > *You cannot unselect the main **ABB Automation Builder** software package.*

   If also an older Automation Builder version or Control Builder Plus version shall be installed for compatibility reasons, select the appropriate options under **Install also previous product versions**. This allows to open and edit a corresponding project in the original version without a previous project upgrade.

3. Click **Continue**.

   The following three cases are possible:

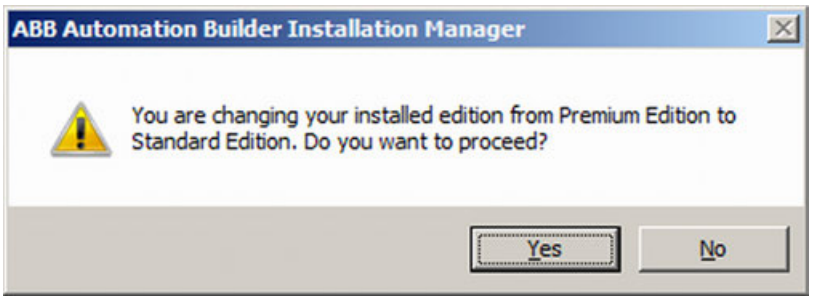
   - The selected software package starts downloading and installing.
   - The unselected software package will uninstall.
   - The unselected software package will uninstall first and then download and install the selected software package.

4. Successfully downloaded components are indicated with .

   Errors during data download are indicated with . Errors during download of any package component aborts the installation. In this case click **Show Log** and save the log data. Send the log file to ABB support team.

   Click **Finish** to end the wizard.

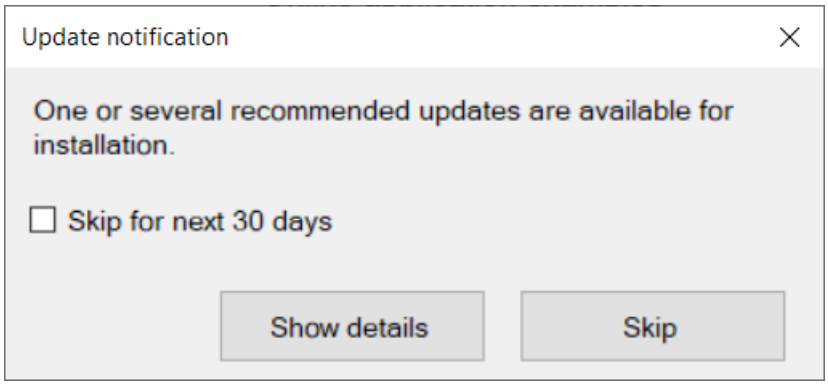
If you modify the type of installed edition, a warning message is displayed.



1.3.3 Automation Builder update notification

An update notification dialog will be shown during Automation Builder startup in case there are any updates available for the currently installed version.

- Notification on available major, minor, or service release version
- Notification on recommend software updates (Bug fixes, CM FW, V2 FW, LIB updates, documentation updates, ...), Automation Builder 2.5 and next future versions will show notification on updates.

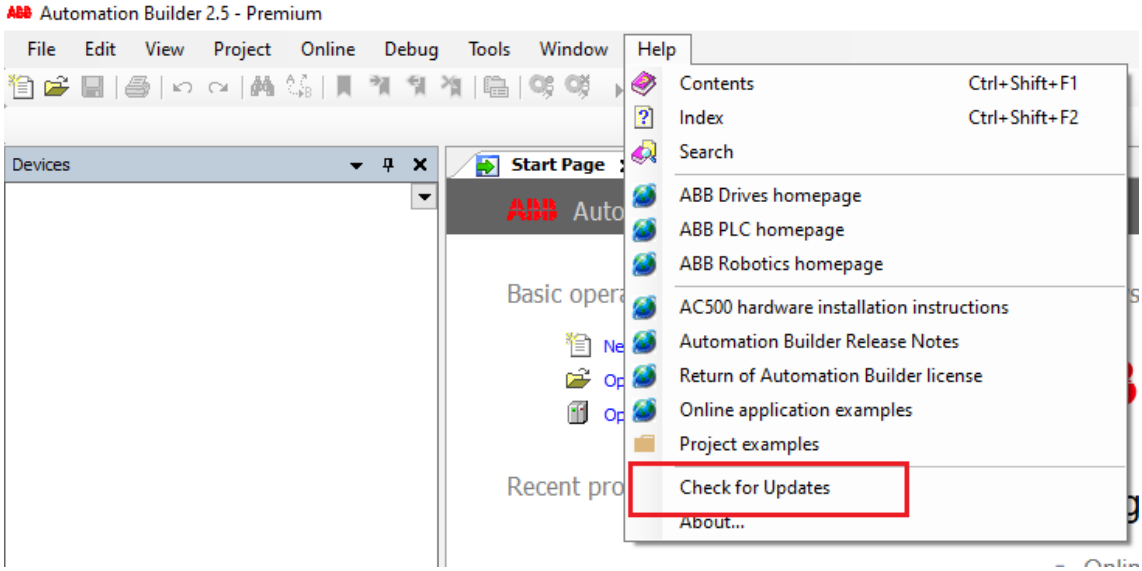


Skip of next 30 days + Skip:	Close the notification dialog. Notification dialog will not be shown for next 30 days.
Show details:	Show details will show the updates details page.
Skip:	Close the notification dialog. Next time launch of Automation Builder will show the notification dialog.

Update notifications will only be shown in the latest installed Automation Builder version profile.

"Help" - "Check for Updates" menu item

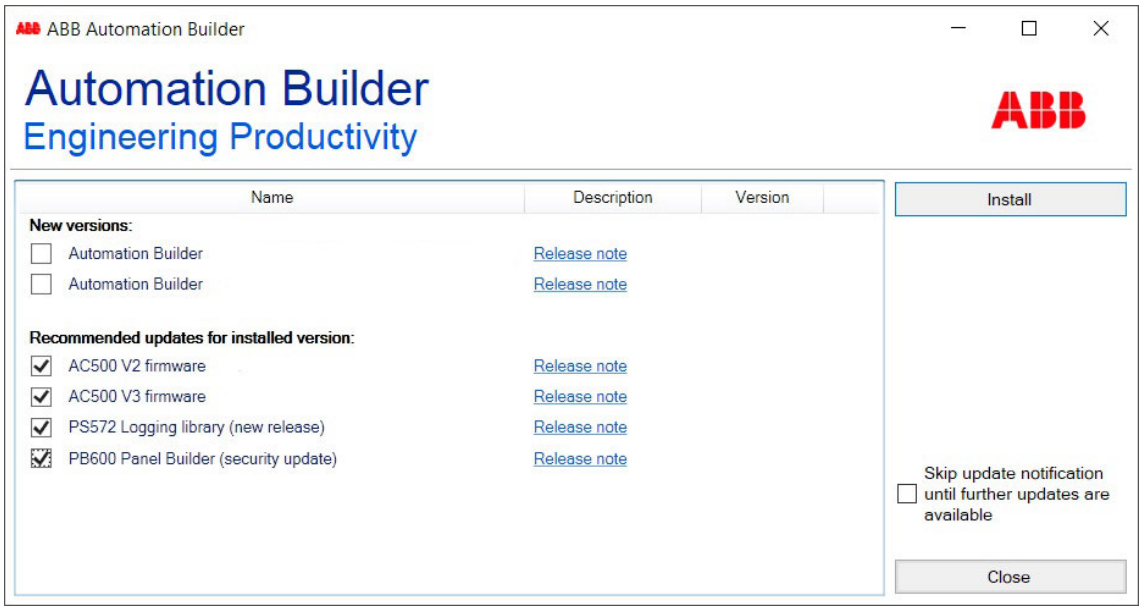
The *"Check for Updates"* menu item has been added to the *"Help"* menu. The user has the possibility to check for updates manually.



Check for Updates: Will launch the Automation Builder update details window.

Automation Builder update details window

The Automation Builder update window provides information about all available updates for the currently installed Automation Builder version and features. Detailed information is provided via the description links.



Skip update notification until further updates are available:	If this option is selected and the update details page is *"Close"*, no notification is displayed at startup until new updates are available.
New versions:	New releases of Automation Builder will be shown this section which will list hotfix version for the currently installed version or recent major version released, if any.
Recommended updates for installed version:	Updates for the currently installed options will be shown.

User can only select any one of the new versions and install.

Installed updates in the Installation Manager start page

All the installed updates will be shown in the Installation Manager start page in the *"Installed updates"* tab.

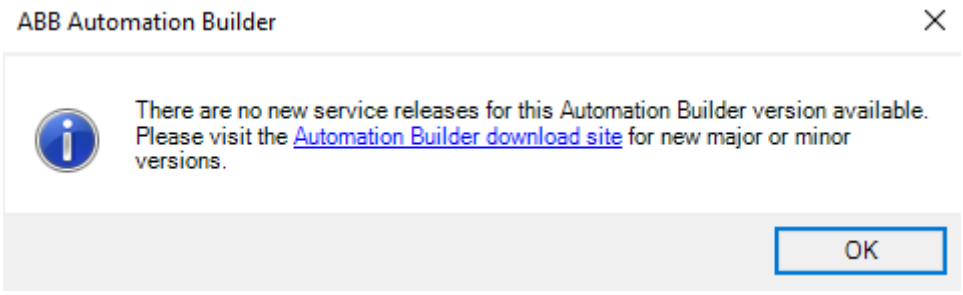
Installation Manager selection page

All the newly installed updates package version information will be updated and shown in the packages tab.

1.3.4 Checking for updates

▷ In the installation manager, click *“Check for new service release”*.

⇨ If the installed Automation Builder version is up-to-date, the following message will appear.



If a newer Automation Builder version is available, you will get an option to download and install the new version.

> *Create a project archive before updating Automation Builder. Project archives contain all project data, including data that is not stored with a *.project file, e.g. device description files for third party devices.*
>
> *Chapter 1.6.5.1.1.7.1 “Creation of an archive ” on page 5768*

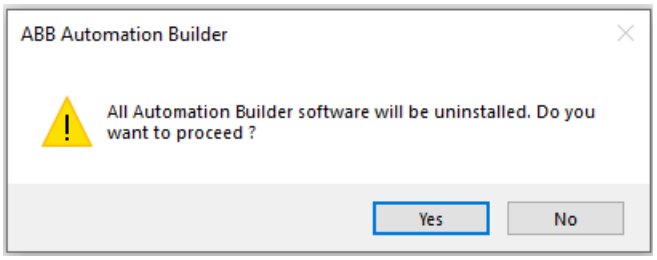
1.3.5 Uninstalling Automation Builder

Installation manager offers a comfortable way to uninstall Automation Builder software. This will uninstall all related packages of Automation Builder platform as well, such as Mint Plug-in, Automation Builder Extensions, Drive Manager etc.

1. In the installation manager, click *“Uninstall all”*.

⇨ A warning message is displayed to uninstall Automation Builder software.

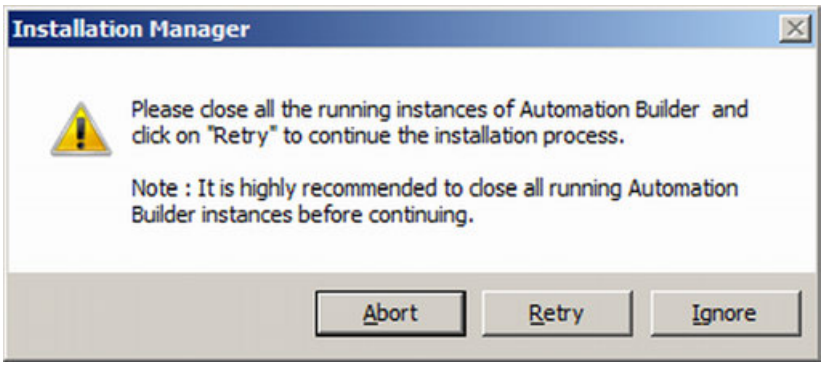
Click **Yes** to continue.



2. If Automation Builder instances are running, a warning message is displayed.

   Close running instances of Automation Builder and click **Retry** to continue uninstallation.

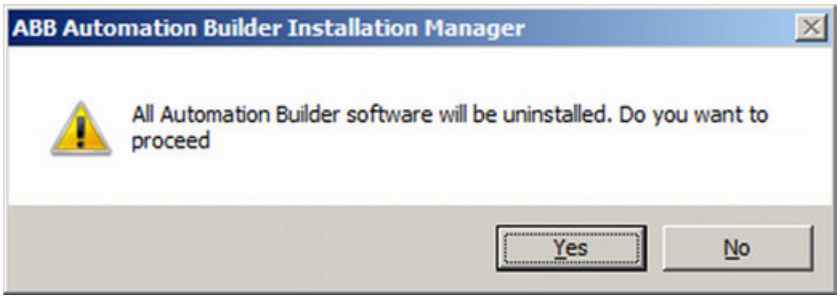
   With **Abort** uninstallation of the current package is stopped. Uninstallation is continued with the next package. With **Ignore**, uninstallation is forced. As this can lead to an erroneous uninstallation, we recommend you, *not* to use this option.



3. If installation manager was launched with *"Tools ➔ Installation Manager"*, the following message is displayed as Automation Builder is still running:

   With **Yes** Automation Builder software is closed to continue uninstallation procedure.

   With **No** uninstallation of the current package is stopped. Uninstallation is continued with the next package.



4. For each of the packages being uninstalled, system may prompt to continue uninstallation.
5. Successfully uninstalled components are indicated with ✔.

   Errors during uninstallation are indicated with ✖. Errors during uninstallation of any package component aborts the uninstallation. In this case click **Show Log** and save the log data. Send the log file to ABB support team.

   Click **Finish** to end the wizard.

1.4 Programming with CODESYS

1.4.1 Development system

1.4.1.1 Overview

1.4.1.1.1 How is a project structured?

A project is put into a file named after the project ↳ *Chapter 1.4.1.1.9.1 "Project" on page 151*. The first program organization unit created in a new project will automatically be named PLC_PRG ↳ *Chapter 1.4.1.1.9.2 "POU (program organization unit)" on page 151* ↳ *Chapter 1.4.1.1.9.8 "PLC_PRG" on page 158*. The process begins here (in compliance with the main function in a C program), and other POUs can be accessed from the same point: programs, function blocks and functions ↳ *Chapter 1.4.1.1.9.7 "Program" on page 156* ↳ *Chapter 1.4.1.1.9.4 "Function block" on page 153* ↳ *Chapter 1.4.1.1.9.3 "Function" on page 151*.

Once you have defined a Task Configuration, it is no longer necessary to create a program named PLC_PRG ↳ *Chapter 1.4.1.4.8.1 "Overview" on page 390*. You will find more about this in the Task Configuration chapter.

There are different kinds of objects in a project: POUs, data types, display elements (visualizations) and resources.

The Object organizer contains a list of all the objects in your project *Chapter 1.4.1.2.1.3 “Object organizer” on page 199*.

1.4.1.1.2 How do I set up my project?

First you should configure your PLC in order to check the accuracy of the addresses used in the project.

Then you can create the POUs needed to solve your problem.

Now you can program the POUs you need in the desired languages.

Once the programming is complete, you can compile the project and remove errors should there be any.

1.4.1.1.3 How can I test my project?

Once all errors have been removed, activate the simulation, log in to the simulated PLC and "load" your project in the PLC *Chapter 1.4.1.1.11.8 “Simulation” on page 184*. Now you are in Online mode.

Now open the window with your PLC Configuration and test your project for correct sequence. To do this, enter input variables manually and observe whether outputs are as expected. You can also observe the value sequence of the local variables in the POUs. In the 'Watch and Recipe Manager' you can configure data records whose values you wish to examine.

1.4.1.1.4 Comparing projects

You can compare the currently open project with another project – a reference project. The differences in contents, properties, or access rights are detected and shown in a comparison view.

Clicking *“Project ➔ Compare”* opens the *“Project Compare”* dialog for you to configure and run the comparison. Then the result is shown in the comparison view *“Project Compare - Differences”* where the objects are aligned in a tree structure. Objects that indicate differences from the respective reference object are identified by colors and symbols. This is how you detect whether or not the contents, properties, or access rights are different.

For differences in the contents, you can also open the detailed compare view *“Project Compare - <object name> Differences”* in order to zoom into the object. In the detailed compare view, the contents of the object and reference object are displayed or their source code aligned. The detected differences are marked. Previously opened views are not closed. In this way, you can have any number of comparison views open and read them, in addition to the project compare view.

You can accept the detected differences from the reference project into the current project. This is possible only from the reference project into the open project. To do this, you activate differences (for example in the code) that should be accepted in the current project with the commands , , or in the active comparison view for accepting. These positions are highlighted in yellow. Make sure that any other open compare views are inactive (write-protected, read-only). therefore, you can activate differences to be accepted in exactly one comparison view only. When exiting the active compare view, if you confirm that the differences that are activated for acceptance are actually accepted into the current project, then the current project is modified.

In order to exit the project comparison completely, close the project compare view.

Creating a comparison view

Requirement: You have made changes in your current project and wish, for example, to compare it with the last-saved version. In the meantime, for example, you have added further POUs, removed a POU, changed single lines of code or the object properties in function blocks.

1. Select the command *"Project ➔ Compare"*.
   ⇨ The *"Project Comparison"* dialog box opens.
2. Enter the path to the reference project, for example the path to the last-saved version of your current project.
3. Leave the activation of the comparison option *"Ignore Spaces"* as it is.
4. Click on *"OK"*.
   ⇨ The comparison view opens. Title: *" Project Comparison – Differences"*. The Device trees of the current project and the reference project are displayed alongside each other and the changed objects are marked in color.
5. Select an object marked in blue in the tree of the reference project (right). The current project no longer contains this object.
   Click on *"Accept Single"*
   ⇨ The object is added to the tree of the current project (left). The line has a yellow background. appears in the middle column.
6. Select an object marked in green in the tree of the current project (left). The reference project does not contain this object.
   Click on *"Accept Single"*
   ⇨ The object is removed again from the tree of the current project (left). The line has a yellow background. appears in the middle column.
7. If changes are detected in the content of an object that is contained in both the current project and the reference project, this is indicated by red lettering. You can then switch to the detailed comparison view for the object by double-clicking on the object.
8. Close the comparison view and answer the query whether the changes made are to be saved with *"Yes"*.
   ⇨ The changes become effective in the project.

Opening the detailed compare view

Requirement: For example, a user modified the code in a POU of the current project. You have performed the project comparison by clicking *"Project ➔ Compare"*. The project compare view shows this POU highlighted in red in the aligned in the project tree.

1. Double-click the line of the aligned POU versions.
   ⇨ The compare view switches to the detailed compare view of the POU. The modified code lines are highlighted in gray and written in red.
2. Click .
   ⇨ Code lines with changes (red) are extended by two lines: an line with insert (left, green) and a line with delete (right, blue).
3. Click again.
   ⇨ The code line is marked again as modified.
4. Move the mouse pointer to the code line marked as modified and click *"Accept Single"*.
   ⇨ The code line from the reference project is activated for acceptance into the current project.

5. Click .
   ⇨ The project compare view opens for the entire project. It is write-protected (read-only) to prevent you from activating differences for acceptance. The link highlighted in yellow above the tree view also indicates this.
6. Click the link: *“Project compare view is read only because there are uncommitted changes in another view. Click here to switch to the modified view.”*
   ⇨ The detailed compare view opens again. The unconfirmed changes are highlighted in yellow.
7. Click ✕ in the tab of the view and confirm that the changes should be saved.
   ⇨ The detail project view is closed and the POU is overwritten. Now it corresponds to the POU of the reference project. The project view is active again so that you can continue working with project compare.

If you do not click the link, but click ✕ instead to close the editor of the project compare view, then you will also confirm the acceptance of changes into the current project. The detail changes are accepted and then the project compare is closed completely.

See also

- *Chapter 1.6.5.1.1.6 “Comparing projects” on page 5765*
- *Chapter 1.4.1.1.4.1 “Creating a comparison view” on page 147*

1.4.1.1.5 Debugging

In case of a programming error you can set a breakpoint *Chapter 1.4.1.1.11.3 “Breakpoint” on page 182*. If the process stops at such a breakpoint, you can examine the values of all project variables at this point in time. By working through sequentially (single step) you can check the logical correctness of your program.

1.4.1.1.6 Additional online functions

Further debugging functions:

You can set program variables and inputs and outputs at certain values.

You can use the flow control to check which program lines have been run.

A window log records operations, user actions and internal processes during an online session in a chronological order *Chapter 1.4.1.4.4.2 “'Window' 'Log'” on page 374*.

If activated in the target settings the Sampling Trace allows you to trace and display the actual course of variables over an extended period of time.

Also a target specific function is the PLC Browser which can serve to request certain information from the PLC.

Once the project has been set up and tested, it can be downloaded to the hardware and tested as well. The same online functions as you used with the simulation will be available.

1.4.1.1.7 Additional features

The entire project can be documented or exported to a text file at any time.

For communication purposes there is a symbolic interface and a DDE interface. A gateway server plus OPC server and DDE server are components of the standard installation packet.

A visualization can be processed target specifically to be available as web visualization and/or target visualization. This allows to run and view the visualization via internet or on a PLC monitor.

1.4.1.1.8 File types

The following file types can be created:

File extension	Example	Description	Format	Path (default)
*.pro	project01.pro	Project file	binary	project directory
*.ci	project01<number>.ci	Information on the last build (compilation) of the project → incremental compile possible; only created when project gets saved	number: coded target ID	binary
project directory	*.eci	project01<number>.eci	external Compile-Information; Subset of the ci-file in eci-format; can be read via an access-dll	number: coded target ID
PE	project directory	*.cic	project01<number>.cic	target-dependant information on the last build (compilation) of the project -> incremental compile possible; only created when project gets saved
number: coded target ID	binary	project directory	*.cit	project01<number>.cit
temporary *.ci-file; created at target change, transformed to a ci-file at next save of the project	number: coded target ID	binary	project directory	*.ri
project01<number>.ri	information on the last download, important for Online Change; created at each download	number: coded target ID	binary	project directory
*.exp	project01.exp, PLC_PRG.exp	export file ('Project' 'Export')	Export format (Text)	project directory
*.tlt	*.txt	project01.tlt	project01.txt	translation file (defined in 'Project' 'Translate in another language')
Text		*.sym	project01.sym	symbol file
Text	project directory	*.sdb	project01.sdb	symbol file
binary	project directory	*.sym_xml	project01.sym_xml	symbol file
XML	project directory	*.asd	project01.asd	save file (temporary, 'Auto save', 'Auto save before compile')

File extension	Example	Description	Format	Path (default)
binary	project directory	*.asl	lib01.asl	save file for a library opened as project (temporary, 'Auto save', 'Auto save before compile')
binary	library resp. project directory	*.bak	project01.bak	backup file for project (permanent, 'Create backup')
binary	project directory	*.prg	*.bin	default.prg
project01.prg	boot project, file name depending on target	binary	target system (created online)	project directory (created offline)
*.chk		default.chk	project01.chk	checksum for boot projekt code
binary	target system (created online)	project directory (created offline)	*.ini	codesys.ini
ini-file for various settings	Text	with codesys.exe	*.dfr	default.dfr
project01.dfr	frame file (Printer setup)	binary	with codesys.exe	*.asm
code386.asm	assembler-Listing of the created project code	Text	compile directory	*.lst
project01.lst	assembler-Listing of the created project code	Text	compile directory	
*.bpl	project01.bpl	debug-files (breakpoint-information)	Text	compile directory
	*.st	PLC_PRG.st	debug-files, implicit ST-code	Text
compile directory		*.map	project01.map	map-file; information on memory organization and variable locations
Text	compile directory		*.hex	*.h86
project01.hex (Output) resp. standard.hex (Lib)	.hex for Intel or Motorola, .h86 for Intel; compiler output or input for external library	Intel or Motorola hex-files	compile directory	resp. library directory
*.trd	projectxy0.trd	trend logging (number befor the dot is counted up, if file is full and another must be created)	Text	project directory
*.log	projectxy.log	log file (Log)	binary	project directory
*.wtc	projx_watch1.wtc	watch list (Watch- and Recipe-Manager)	Text	user defined directory

File extension	Example	Description	Format	Path (default)
*.alm	alarmlog0.alm	alarm log-file		user defined directory resp. download-directory of the controller
*.zip	projectxy.zip	project archive file; zip-file with files belonging to the project , 'File' 'Save/ Mail Archive'		user defined directory
*.trc	project01_tr1.trc	trace recording	binary	with codesys.exe
*.mon	project01_tr1.mon	trace recording	XML	with codesys.exe
*.tcf	project01_tr1.tcf	trace configuration	binary	with codesys.exe

1.4.1.1.9 Project components

Project

A project contains all of the objects in a PLC program. A project is saved in a file named after the project. The following objects are included in a project:

POUs (program organization units), data types, visualizations, resources, and libraries.

POU (program organization unit)

Functions, function blocks, and programs are POUs which can be supplemented by actions.

Each POU consists of a declaration part and a body. The body is written in one of the IEC programming languages which include IL, ST, SFC, FBD, LD or CFC. All IEC standard POUs are supported. If you want to use these POUs in your project, you must include the library standard.lib in your project.

POUs can call up other POUs. However, recursions are not allowed.

Function

A function is a POU, which yields exactly one data element (which can consist of several elements, such as fields or structures) when it is processed, and whose call in textual languages can occur as an operator in expressions.

When declaring a function do not forget that the function must receive a type. This means, after the function name, you must enter a colon followed by a type.

Example A correct function declaration can look like this:

```
FUNCTION Fct: INT
```

In addition, a result must be assigned to the function. That means that function name is used as an output variable.

A function declaration begins with the keyword FUNCTION. Regard the recommendations on the naming *Chapter 1.4.1.3.9.2.1 “Recommendations on the naming of identifiers” on page 297*.

Example of a function Fct in IL, in which three input variables are declared:

The first both input variables get multiplicated and then divided by the third one. The function returns the result of this operation:

Declaration part:

```
FUNCTION Fct: INT
VAR_INPUT
PAR1:INT;
PAR2:INT;
PAR3:INT;
END_VAR
```

Implementation part:

```
LD PAR1
MUL PAR2
DIV PAR3
ST Fct
```

Calling a function:

In ST a function call can be used as operand in an expression.

In SFC a function call can only take place within actions of a step or a transition.

CODESYS allows using global variables within a function. This intentionally deviates from the IEC61131-3 standard, which prescribes that return value of a function only will be modified by the input parameters. Thus the difference between functions and programs is just, that functions return only one return value and that their parameters and return values are handled over the stack.

Examples for calling the above described function Fct:

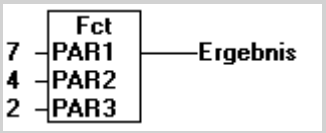
In IL:

```
LD 7
Fct 2,4
ST  Ergebnis
```

In ST:

```
Ergebnis := Fct(7, 2, 4);
```

In FUP:



NOTICE!

If a local variable in a function is declared as RETAIN, this will be without any effect. The variable will not be saved in the Retain area!

- *If you define a function in your project with the name CheckBounds, you can use it to check for range overflows in arrays ↳ Chapter 1.4.1.8.2.1 “ARRAY” on page 445.*
- *If you define functions in your project with the names CheckDivByte, CheckDivWord, CheckDivDWord and CheckDivReal, you can use them to check the value of the divisor if you use the operator DIV, for example to avoid a division by 0 ↳ Chapter 1.4.1.6.2.4 “DIV” on page 408.*
- *If you define functions with the names CheckRangeSigned and CheckRangeUnsigned, then range exceeding of variables declared with subrange types can be intercepted ↳ Chapter 1.4.1.8.2.7 “Subrange types” on page 450.*

All these check function names are reserved for the described usage.

Function block

A function block is a POU which provides one or more values during the procedure.

As opposed to a function, a function block provides no return value ↳ *Chapter 1.4.1.1.9.3 “Function” on page 151*.

A function block declaration begins with the keyword FUNCTION_BLOCK. Regard the recommendations on the naming ↳ *Chapter 1.4.1.3.9.2.1 “Recommendations on the naming of identifiers” on page 297*.

Reproductions or instances (copies) of a function block can be created ↳ *Chapter 1.4.1.1.9.5 “Function block instances” on page 153*.

The call of a function block is done via a function block instance ↳ *Chapter 1.4.1.1.9.6 “Calling a function block” on page 154*.

Example in IL of a function block with two input variables and two output variables:

One output (iMulErg) is the product of the two inputs, the other (xVergl) is a comparison for equality:

Declaration part:

```
FUNCTION_BLOCK FUB
VAR_INPUT
    iPar1:INT;
    iPar2:INT;
END_VAR
VAR_OUTPUT
    iMulErg:INT;
    xVergl:BOOL;
END_VAR
```

Implementation part in IL:

```
LD iPar1
MUL iPar2
ST iMulErg

LD iPar1
EQ iPar2
ST xVergl
```

Function block instances

Reproductions or instances (copies) of a function block can be created ↳ *Chapter 1.4.1.1.9.4 “Function block” on page 153*.

Each instance possesses its own identifier (the Instance name), and a data structure which contains its inputs, outputs, and internal variables. Instances are declared locally or globally as variables, whereas the name of the function block is indicated as the type of an identifier.

Regard the Recommendations on the naming *Chapter 1.4.1.3.9.2.1 “Recommendations on the naming of identifiers” on page 297*.

Example

Example of an instance with the name INSTANCE of the FUB function block:

```
fubInstance: FUB;
```

Function blocks are always called through the instances described above.

Only the input and output parameters can be accessed from outside of an function block instance, not its internal variables.

Example for accessing an input variable

The function block FB has an input variable in1 of the type INT.

```
PROGRAM prog

VAR
fbinst1:fb;
END_VAR

LD 17
ST fbinst1.in1
CAL fbinst1

END_PROGRAM
```

The declaration parts of function blocks and programs can contain instance declarations *Chapter 1.4.1.1.9.4 “Function block” on page 153*. Instance declarations are not permitted in functions *Chapter 1.4.1.1.9.3 “Function” on page 151*.

Access to a function block instance is limited to the POU in which it was declared unless it was declared globally.

The instance name of a function block instance can be used as the input for a function or a function block.

All values are retained after processing a function block until the next it is processed. Therefore, function block calls with the same arguments do not always return the same output values!

If at least one of the function block variables is a retain variable, the total instance is stored in the retain area.

Calling a function block

The input and output variables of a function block can be accessed from another POU by setting up an instance of the function block and specifying the desired variable using the following syntax *Chapter 1.4.1.1.9.5 “Function block instances” on page 153*:

<Instance name>.<Variable name>

Assigning parameters at call:

If you would like to set input and/or output parameters when you call the function block, you can do this in the text languages IL and ST by assigning values to the parameters after the instance name of the function block in parentheses (for input parameters this assignment takes place using ":=" just as with the initialization of variables at the declaration position, for output parameters "=>" is to be used) ↳ *Chapter 1.4.1.3.9.11 “Variables declaration” on page 303*.

If the instance is inserted via input assistant (<F2>) with option With arguments in the implementation window of a ST or IL POU, it will be displayed automatically according to this syntax with all of its parameters. But you not necessarily must assign these parameters.

Example:

FBINST is a local variable of type of a function block, which contains the input variable xx and the output variable yy. When FBINST is inserted in a ST program via input assistant, the call will be displayed as follows and then can be supplemented with the desired values: FBINST1(xx:= , yy=>);

InOutVariables at call:

Please regard, that the InOutVariables (VAR_IN_OUT) of a function block are handed over as pointers. For this reason in a call of a function block no constants can be assigned to VAR_IN_OUTs and there is no read or write access from outside to them.

Example

Calling a VAR_IN_OUT variable inout1 of function block fubo in a ST module:

```
VAR
 fuboinst:fubo;
 iVar1:int;
END_VAR
iVar1:=2;
fuboinst(iInOut1:=iVar1);
```

not allowed in this case: "fuboinst(iInOut1:=2);" or "fuboinst.iInOut1:=2;"

Examples for calling function block FUB:

Declaration part:

```
FUNCTION_BLOCK FUB
VAR_INPUT
    iPAR1:INT;
    iPAR2:INT;
END_VAR
VAR_OUTPUT
  iMELERG:INT;
  xVERGL:BOOL;
END_VAR
```

Implementation part in AWL:

```
LD iPar1
MUL iPar2
ST iMulErg

LD iPar1
EQ iPar2
ST xVergl
```

The multiplication result is saved in the variable ERG, and the result of the comparison is saved in QUAD. An instance of FUB with the name INSTANCE is declared.

Calling FUB in IL:

Declaration part:

```
PROGRAM AWLaufruf
VAR
      xQuad :      BOOL;
      fubinstanz : FUB;
      iErg:        INT:=0;
END_VAR
```

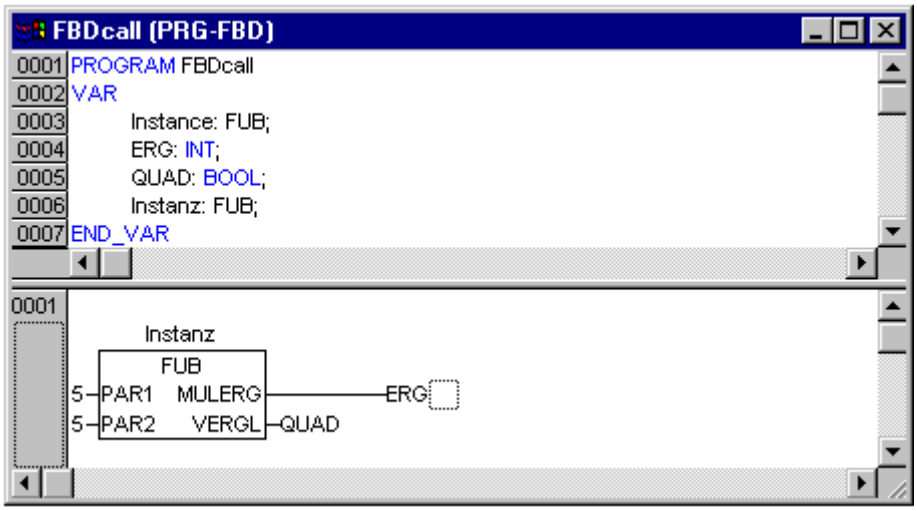
Implementation part:

```
CAL  fubinstanz(iPar1:=5;iPar2:=5);
LD    fubinstanz.xVergl
ST    xQuad
LD    fubinstanz.iMulErg
ST    iErg
```

Calling FUB in ST (declaration part as shown above for IL):

```
PROGRAM STaufruf
fubinstanz(iPar1:=5;iPar2:=5);   bzw. fubinstanz;
QUAD:=fubinstanz.xVergl;
ERG:=funbinstanz.iMulErg;
```

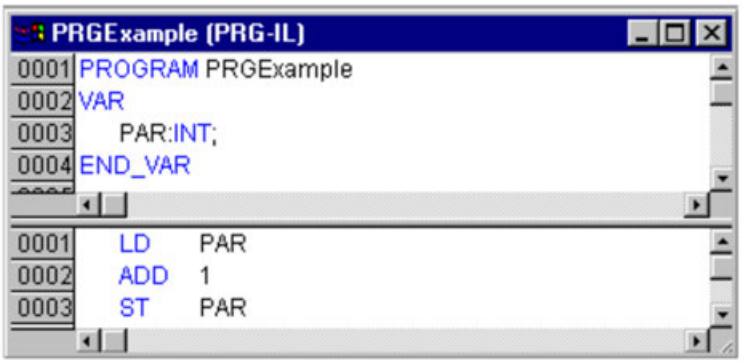
Calling FUB in FBD (declaration part as shown above for IL):



In SFC function block calls can only take place in steps.

Program

A program is a POU which returns several values during operation. Programs are recognized globally throughout the project. All values are retained from the last time the program was run until the next.



Programs can be called. A program call in a function is not allowed. There are also no instances of programs ↳ *Chapter 1.4.1.1.9.3 “Function” on page 151*.

If a POU calls a program, and if thereby values of the program are changed, then these changes are retained the next time the program is called, even if the program has been called from within another POU.

This is different from calling a function block. There only the values in the given instance of a function block are changed.

These changes therefore play a role only when the same instance is called.

A program declaration begins with the keyword PROGRAM. Regard the Recommendations on the naming of identifiers ↳ *Chapter 1.4.1.3.9.2.1 “Recommendations on the naming of identifiers” on page 297*.

If you would like to set input and/or output parameters when you call the program, you can do this in the text languages IL and ST by assigning values to the parameters after the program name in parentheses (for input parameters this assignment takes place using ":=" just as with the initialization of variables at the declaration position, for output parameters "=>" is to be used) ↳ *Chapter 1.4.1.3.9.11 “Variables declaration” on page 303*.

If the program is inserted via input assistant (<F2>) with option With arguments in the implementation window of a ST or IL POU, it will be displayed automatically according to this syntax with all of its parameters. But you not necessarily must assign these parameters.

Examples for program calls

In IL

```
CAL PRGexample2

LD PRGexample2.out_var

ST  ERG

or with assigning the parameters (input assistant "With arguments",
see above):

CAL PRGexample2(in_var:=33, out_var=>erg )
```

In ST

```
PRGexample2;

Erg := PRGexample2.out_var;

or with assigning the parameters (input assistant "With arguments",
see above):

PRGexample2(in_var:=33, out_var=>erg );
```

In FBD

In IL

```
CAL PRGexample2

LD PRGexample2.out_var

ST  ERG

or with assigning the parameters (input assistant "With arguments",
see above):

CAL PRGexample2(in_var:=33, out_var=>erg )
```

Example for a possible call sequence for PLC_PRG

See the program PRGexample shown in the picture at top of this chapter:

```
LD 0

ST  PRGexample.PAR (*Default setting for PAR is 0*)

CAL IL call (*ERG in IL call results in 1*)

CAL ST call (*ERG in ST call results in 2*)

CAL FBD call (*ERG in FBD call results in 3*)
```

If the variable PAR from the program PRGexample is initialized by a main program with 0, and then one after the other programs are called with above named program calls, then the ERG result in the programs will have the values 1, 2, and 3. If one exchanges the sequence of the calls, then the values of the given result parameters also change in a corresponding fashion.

PLC_PRG

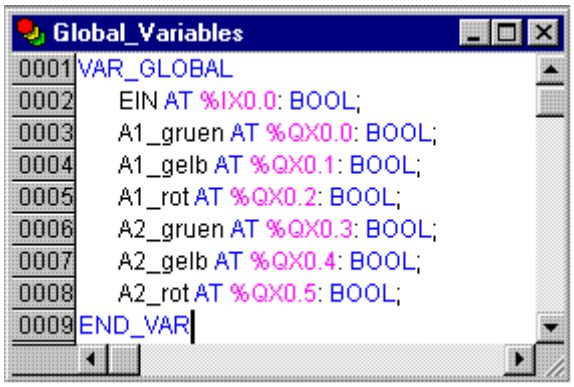
We have defined and correlated the time sequencing of the phases for both sets of traffic lights in the block SEQUENCE. Since, however, we see the traffic lights system as a module of a bus system, e.g. CAN bus, we have to make input and output variables available in the block PLC_PRG. We want to start-up the traffic lights system over an ON switch and we want to send each of the six lamps (each traffic light red, green, yellow) the corresponding "signal command" for each step of the SEQUENCE. We are now declaring appropriate Boolean variables for these six outputs and one input, before we create the programme in the editor, and are allocating them, at the same time, to the corresponding IEC addresses.

The next step is declare the variables Light1 and Light2 of the type Phases in the declaration editor.

These deliver the Boolean value of each of the six lights to the above mentioned six outputs for each step of the block SEQUENCE. We are not, however, declaring the output variables which are foreseen within the PLC_PRG block but under Resources for Global Variables instead. The Boolean input variable IN, which is used to set the variable START in the block SEQUENCE to TRUE, can be set in the same way. ON is also allocated to an IEC address.

Select the tab Resources and open the list Global Variables.

Make the declaration as follows:



The name of the variable (e.g. IN) is followed, after AT, by a percent sign which begins the IEC address. I stands for input, Q for output, B (used in the example) stands for byte and the individual bits of the module are addressed using 0.0 (0.1, 0.2, etc.). We will not do the needed controller configuration here in the example, because it depends on which target package you have available on your computer.

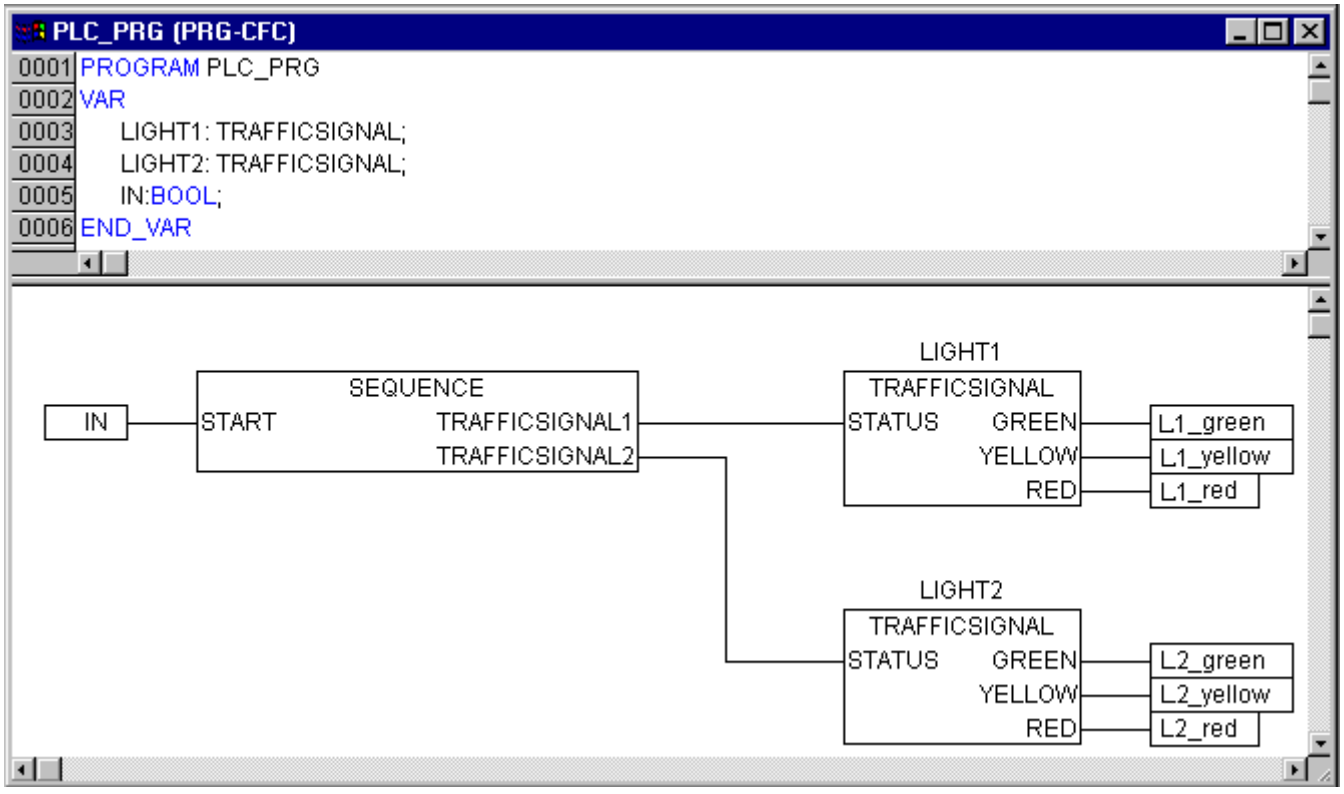
We now want to finish off the block PLC_PRG.

For this we go into the editor window. We have selected the Continuous Function Chart editor and we consequently obtain, under the menu bar, a CFC symbol bar with all of the available elements.

Click on the right mouse key in the editor window and select the element Box. Click on the text AND and write "SEQUENCE" instead. This brings up the block SEQUENCE with all of the already defined input and output variables. Insert two further block elements which you name PHASES. Phases is a function block and this causes you to obtain three red question marks over the block which you replace with the already locally declared variables LIGHT1 and LIGHT2. Now set an element of the type Input, which award the title ON and six elements of the type Output which you award variable names to, as described, namely L1_green, L1_yellow, L1_red, L2_green, L2_yellow, L2_red.

All of the elements of the programme are now in place and you can connect the inputs and outputs, by clicking on the short line at the input/output of an element and dragging this with a constantly depressed mouse key to the input/output of the desired element.

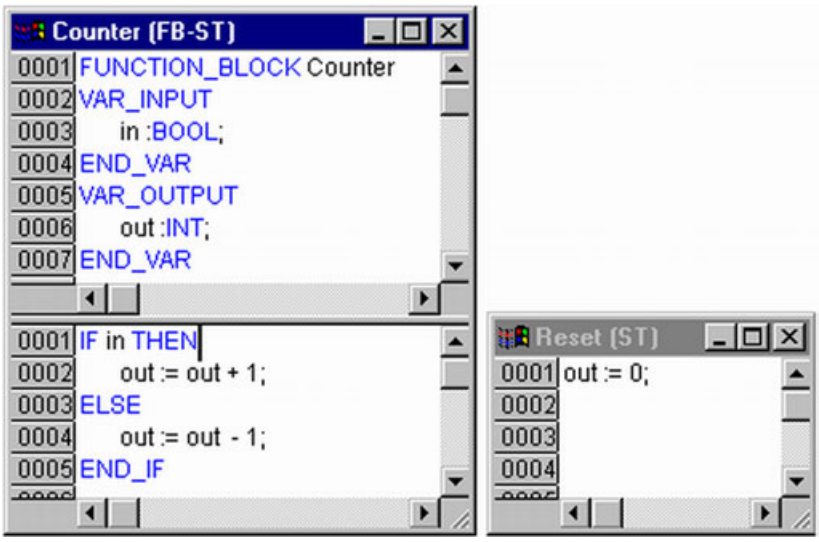
Your program should finally look like the example shown here.



Action

Actions can be defined and assigned to function blocks and programs ↳ *Chapter 1.4.1.1.9.4 “Function block” on page 153* ↳ *Chapter 1.4.1.1.9.7 “Program” on page 156* ↳ *Chapter 1.4.1.2.4.14 “'Project' 'Add action'” on page 263*. The action represents a further implementation which can be entirely created in another language as the "normal" implementation. Each action is given a name.

An action works with the data from the function block or programme which it belongs to. The action uses the same input/output variables and local variables as the "normal" implementation uses.



In the example given, calling up the function block Counter increases or decreases the output variable "out", depending on the value of the input variable "in". Calling up the action Reset of the function block sets the output variable to zero. The same variable "out" is written in both cases.

Calling an action:

An action is called up with <Program_name>.<Action_name> or <Instance_name>.<Action_name>. Regard the notation in FBD (see example below) ! If it is required to call up the action within its own block, one just uses the name of the action in the text editors and in the graphic form the function block call up without instance information ↳ *Chapter 1.4.1.1.9.5 “Function block instances” on page 153*.

Examples for calls of the above described action from another POU

Declaration for all examples:

```
PROGRAM PLC_PRG
  VAR
   Inst : Counter;
  END_VAR
```

Call of action 'Reset' in another POU, which is programmed in IL:

```
CAL Inst.Reset(In := FALSE)
  LD Inst.out
  ST  ERG
```

Call of action 'Reset' in another POU, which is programmed in ST:

```
Inst.Reset(In := FALSE);
  Erg := Inst.out;
```

Call of action 'Reset' in another POU, which is programmed in FBD:

Actions play an important role in blocks in sequential function charts. The IEC standard does not recognise actions other than actions of the sequential function chart (SFC) ↳ *Chapter 1.4.1.1.10.5.1 “Overview” on page 171.*

Resources

You need the resources for configuring and organizing your project and for tracing variable values:

- Global variables which can be used throughout the project or network
- Library manager for adding libraries to the project ↳ *Chapter 1.4.1.4.3.1 “Overview” on page 371*
- Log for recording the actions during an online session ↳ *Chapter 1.4.1.4.4.1 “Overview” on page 374*
- Alarm configuration for the configuration of the alarm handling in the project ↳ *Chapter 1.4.1.4.2.1 “Overview” on page 363*
- PLC configuration for configuring your hardware
- Task configuration for guiding your program through tasks ↳ *Chapter 1.4.1.4.8.1 “Overview” on page 390*
- Watch and receipt manager for displaying variable values and setting default variable values ↳ *Chapter 1.4.1.4.9.1 “Overview” on page 395*
- Target settings for selection and if necessary final configuration of the target system ↳ *Chapter 1.4.1.4.7.1 “Overview” on page 387*
- Workspace as an image of the project options ↳ *Chapter 1.4.1.2.1.5 “Workspace” on page 199*

Depending on the target system and on the target settings further resources might be available in your project. ↳ *Chapter 1.4.1.4 “The 'Resources' tab” on page 357*

Libraries

You can include in your project a series of libraries whose POUs, data types, and global variables you can use just like user-defined variables. The libraries standard.lib and util.lib are standard parts of the program and are always at your disposal *Chapter 1.4.1.4.3.1 “Overview” on page 371*.

Data types

Along with the standard data types the user can define his own data types. Structures, enumeration types and references can be created *Chapter 1.4.1.8.1.1 “Data types” on page 443*.

Visualization

With visualizations you can display your project variables. You can plot geometric elements off-line with the help of the visualization. In Online mode, these can then change their form/color/text output in response to specified variable values.

A visualization can be used as a pure operating interface for a PLC with HMI or as a web visualization or target visualization running via internet resp. directly on the PLC *Chapter 1.4.3.1 “Overview” on page 636*.

1.4.1.1.10 Languages

Supported languages

All languages described by the standard IEC-61131 are supported.

Textual languages:

- Instruction list (IL) *Chapter 1.4.1.1.10.3.1 “Overview” on page 163*
- Structured Text (ST) *Chapter 1.4.1.1.10.4.1 “Overview” on page 165*

Graphic languages:

- Sequential function chart (SFC) *Chapter 1.4.1.1.10.5.1 “Overview” on page 171*
- Function Block Diagram (FBD) *Chapter 1.4.1.1.10.2 “Function Block Diagram (FBD)” on page 162*
- Ladder Diagram (LD) *Chapter 1.4.1.1.10.7.1 “Overview” on page 176*

Additionally, there is available the graphic continuous function chart (CFC), based on the Function Block Diagram *Chapter 1.4.1.1.10.6 “The continuous function chart (CFC)” on page 176*.

Function Block Diagram (FBD)

The Function Block Diagram is a graphically oriented programming language. It works with a list of networks whereby each network contains a structure which represents either a logical or arithmetic expression, the call of a function block, a jump, or a return instruction *Chapter 1.4.1.1.9.4 “Function block” on page 153*.

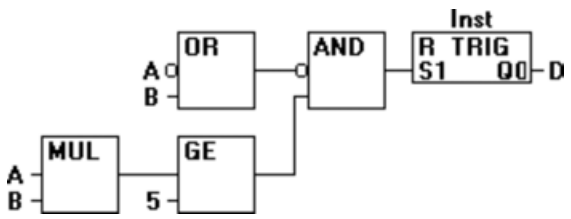


Fig. 10: Example of a network in the Function Block Diagram

See also:

- The graphic editors *Chapter 1.4.1.3.11.1 “Overview” on page 314*
- The Function Block Diagram Editor *Chapter 1.4.1.3.11.7.1 “Overview” on page 317*

Instruction list (IL)

Overview

An instruction list (IL) consists of a series of instructions. Each instruction begins in a new line and contains an operator and, depending on the type of operation, one or more operands separated by commas.

In front of an instruction there can be an identification mark (label) followed by a colon (:).

A comment must be the last element in a line. Empty lines can be inserted between instructions.

Example:

```
LD 17
ST lint (* Kommentar *)
GE 5
JMPC next
LD idword
EQ istruct.sdword
STN test
next:
```

See also:

Modifiers and operators in IL *Chapter 1.4.1.1.10.3.2 “Modifiers and operators in IL” on page 163*

Modifiers and operators in IL

In the IL language the following operators and modifiers can be used.

Table 8: Modifiers

C	with JMP, CAL, RET:	The instruction is only then executed if the result of the preceding expression is TRUE.
N	with JMPC, CALC, RETC:	The instruction is only then executed if the result of the preceding expression is FALSE.
N	otherwise:	Negation of the operand (not of the accumulator) Below you find a table of all operators in IL with their possible modifiers and the relevant meaning:

Table 9: Operators in IL

Operator	Modifiers	Meaning
LD	N	Make current result equal to the operand
ST	N	Save current result at the position of the operand
S		Then put the Boolean operand exactly at TRUE if the current result is TRUE
R		Then put the Boolean operand exactly at FALSE if the current result is TRUE
AND	N,(	Bitwise AND
OR	N,(	Bitwise OR
XOR	N,(	Bitwise exclusive OR
ADD	(	Addition
SUB	(	Subtraction
MUL	(	Multiplication
DIV	(	Division
GT	(	>
GE	(	>=
EQ	(	=
NE	(	<>
LE	(	<=
LT	(	<
JMP	CN	Jump to the label
CAL	CN	Call programor function block or
RET	CN	Leave POU and return to caller.
)		Evaluate deferred operation

Example of an IL program while using some modifiers:

LD	TRUE	(*load TRUE in the accumulator*)
ANDN	BOOL1	(*execute AND with the negated value of the BOOL1 variable*)
JMPC	mark	(*if the result was TRUE, then jump to the label "mark"*)
LDN	BOOL2	(*save the negated value of *)
ST	ERG	(*BOOL2 in ERG*)
label:		
LD	BOOL2	(*save the value of *)
ST	ERG	*BOOL2 in ERG*)

It is also possible in IL to put parentheses after an operation. The value of the parenthesis is then considered as an operand.

Example

```
LD  2
MUL 2
ADD 3
Erg
```

Here is the value of Erg 7. However, if one puts parentheses:

```
LD 2
MUL (2
ADD 3
)
ST Erg
```

The resulting value for Erg is 10, the operation MUL is only then evaluated if you come to ")"; as operand for MUL 5 is then calculated.

Structured Text (ST)

Overview

The Structured Text consists of a series of instructions which, as determined in high level languages, ("IF..THEN..ELSE") or in loops (WHILE..DO) can be executed.

Example

```
If value < 7 THEN
 WHILE value < 8 DO
  value:=value+1;
 END_WHILE;
END_IF;
```

Identifier

An identifier is a sequence of letters, numbers, and underscores that begins with a letter or an underscore.

The variable identifier may not contain any blank spaces or special characters, may not be declared more than once and cannot be the same as any of the keywords. Capitalization is not recognized which means that VAR1, Var1, and var1 are all the same variable. The underscore character is recognized in identifiers (e.g., "A_BCD" and "AB_CD" are considered two different identifiers). An identifier may not have more than one underscore character in a row. The first 32 characters are significant.

Expressions

An expression is a construction which returns a value after its evaluation.

Expressions are composed of operators and operands. An operand can be a constant, a variable, a function call, or another expression.

Valuation of expressions

The evaluation of expression takes place by means of processing the operators according to certain binding rules. The operator with the strongest binding is processed first, then the operator with the next strongest binding, etc., until all operators have been processed.

Operators with equal binding strength are processed from left to right.

Table 10: ST operators in the order of their binding strength

Operation	Symbol	Binding strength
Put in parentheses	(expression)	Strongest binding
Function call	Function name (parameter list)	
Exponentiation	EXPT	
Negate Building of complements	- NOT	
Multiply Divide Modulo	* / MOD	
Add Subtract	+ -	
Compare	<,>,<=,>=	
Equal to Not equal to	= <>	
Boolean AND	AND	
Boolean XOR	XOR	
Boolean OR	OR	Weakest binding

Table 11: Instructions in ST

Instruction type	Example
Assignment	A:=B; CV := CV + 1; C:=SIN(X);
Calling a function block and use of the FB output	CMD_TMR(IN := %IX5, PT := 300); A:=CMD_TMR.Q
RETURN	RETURN;

IF	D:=B*B;
	IF D<0.0 THEN
	C:=A;
	ELSIF D=0.0 THEN
	C:=B;
	ELSE
	C:=D;
	END_IF;

CASE	CASE INT1 OF 1: BOOL1 := TRUE; 2: BOOL2 := TRUE; ELSE BOOL1 := FALSE; BOOL2 := FALSE; END_CASE;

FOR	J:=101;
	FOR I:=1 TO 100 BY 2 DO
	IF ARR[I] = 70 THEN
	J:=I; EXIT;
	END_IF;
	END_FOR;

WHILE	J:=1; WHILE J<= 100 AND ARR[J] <> 70 DO J:=J+2; END_WHILE;
REPEAT	J:=-1; REPEAT J:=J+2; UNTIL J= 101 OR ARR[J] = 70 END_REPEAT;
EXIT	EXIT;
Empty instruction	;

Assignment operator

On the left side of an assignment there is an operand (variable, address) to which is assigned the value of the expression on the right side with the assignment operator :=

Example:

```
Var1 := Var2 * 10;
```

After completion of this line Var1 has the tenfold value of Var2.

Calling function blocks in ST

A function block is called in ST by writing the name of the instance of the function block and then assigning the values of the parameters in parentheses *Chapter 1.4.1.1.9.4 “Function block” on page 153* *Chapter 1.4.1.1.9.5 “Function block instances” on page 153*. In the following example a timer is called with assignments for the parameters IN and PT. Then the result variable Q is assigned to the variable A.

The result variable, as in IL, is addressed with the name of the function block, a following point, and the name of the variable:

```
CMD_TMR(IN := %IX5, PT := 300);
A:=CMD_TMR.Q
```

RETURN instruction

The RETURN instruction can be used to leave a POU, for example depending on a condition.

IF instruction

With the IF instruction you can check a condition and, depending upon this condition, execute instructions.

Syntax:

```
IF <Boolean_expression1> THEN
    <IF_instructions>
{ELSIF <Boolean_expression2> THEN
    <ELSIF_instructions1>
.
.
ELSIF <Boolean_expression n> THEN
    <ELSIF_instructions n-1>
ELSE
<ELSE_instructions>}
END_IF;
```

The part in braces {} is optional.

If the <Boolean_expression1> returns TRUE, then only the <IF_Instructions> are executed and none of the other instructions.

Otherwise the Boolean expressions, beginning with <Boolean_expression2>, are evaluated one after the other until one of the expressions returns TRUE. Then only those instructions after this Boolean expression and before the next ELSE or ELSIF are evaluated.

If none of the Boolean expressions produce TRUE, then only the <ELSE_instructions> are evaluated.

Example:

```
IF temp<17
THEN heating_on := TRUE;
ELSE heating_on := FALSE;
END_IF;
```

Here the heating is turned on when the temperature sinks below 17 degrees. Otherwise it remains off.

CASE instruction

With the CASE instructions one can combine several conditioned instructions with the same condition variable in one construct.

Syntax:

```
CASE <Var1> OF
<Value1>: <Instruction 1>
<Value2>: <Instruction 2>
<Value3, Value4, Value5>: <Instruction 3>
<Value6 .. Value10>: <Instruction 4>

...

<Value n>: <Instruction n>
ELSE <ELSE instruction>
END_CASE;
```

A CASE instruction is processed according to the following model:

- If the variable in <Var1> has the value <Value i>, then the instruction <Instruction i> is executed.
- If <Var 1> has none of the indicated values, then the <ELSE Instruction> is executed.
- If the same instruction is to be executed for several values of the variables, then one can write these values one after the other separated by commas, and thus condition the common execution.
- If the same instruction is to be executed for a range of values of a variable, one can write the initial value and the end value separated by two dots one after the other. So you can condition the common condition.

Example:

```
CASE INT1 OF
1, 5: BOOL1 := TRUE;
 BOOL3 := FALSE;
2: BOOL2 := FALSE;
 BOOL3 := TRUE;
10..20: BOOL1 := TRUE;
 BOOL3:= TRUE;
ELSE
 BOOL1 := NOT BOOL1;
 BOOL2 := BOOL1 OR BOOL2;
END_CASE;
```

FOR loop

With the FOR loop one can program repeated processes.

Syntax:

```
INT_Var :INT;
FOR <INT_Var> := <INIT_VALUE> TO <END_VALUE> {BY <Step size>} DO
  <Instructions>
END_FOR;
```

The part in braces {} is optional.

The <Instructions> are executed as long as the counter <INT_Var> is not greater than the <END_VALUE>. This is checked before executing the <Instructions> so that the <instructions> are never executed if <INIT_VALUE> is greater than <END_VALUE>.

When <Instructions> are executed, <INT_Var> is always increased by <Step size>. The step size can have any integer value. If it is missing, then it is set to 1. The loop must also end since <INT_Var> only becomes greater.

Example:

```
FOR Counter:=1 TO 5 BY 1 DO
Var1:=Var1*2;
END_FOR;
Erg:=Var1;
```

Let us assume that the default setting for Var1 is the value 1. Then it will have the value 32 after the FOR loop.

<END_VALUE> must not be equal to the limit value of the counter <INT_VAR>. For example: If the variable Counter is of type SINT and if <END_VALUE> is 127, you will get an endless loop.

WHILE loop

The WHILE loop can be used like the FOR loop with the difference that the break-off condition can be any Boolean expression. This means you indicate a condition which, when it is fulfilled, the loop will be executed.

Syntax:

```
WHILE <Boolean expression>
```

<Instructions>

```
END_WHILE;
```

The <Instructions> are repeatedly executed as long as the <Boolean_expression> returns TRUE. If the <Boolean_expression> is already FALSE at the first evaluation, then the <Instructions> are never executed. If <Boolean_expression> never assumes the value FALSE, then the <Instructions> are repeated endlessly which causes a relative time delay.

The programmer must make sure that no endless loop is caused. He does this by changing the condition in the instruction part of the loop, for example, by counting up or down one counter.

Example:

```
WHILE counter<>0 DO
Var1 := Var1*2;
Counter := Counter-1;
END_WHILE
```

The WHILE and REPEAT loops are, in a certain sense, more powerful than the FOR loop since one doesn't need to know the number of cycles before executing the loop. In some cases one will, therefore, only be able to work with these two loop types. If, however, the number of the loop cycles is clear, then a FOR loop is preferable since it allows no endless loops.

REPEAT loop

The REPEAT loop is different from the WHILE loop because the break-off condition is checked only after the loop has been executed. This means that the loop will run through at least once, regardless of the wording of the break-off condition.

Syntax:

```
REPEAT
```

<Instructions>

```
UNTIL <Boolean expression>
END_REPEAT;
```

The <Instructions> are carried out until the <Boolean expression> returns TRUE.

If <Boolean expression> is produced already at the first TRUE evaluation, then <Instructions> are executed only once. If <Boolean_expression> never assumes the value TRUE, then the <Instructions> are repeated endlessly which causes a relative time delay.

The programmer must make sure that no endless loop is caused. He does this by changing the condition in the instruction part of the loop, for example by counting up or down one counter.

Example:

```
REPEAT
Var1 := Var1*2;
Counter := Counter-1;
UNTIL
Counter=0
END_REPEAT;
```

EXIT instruction

If the EXIT instruction appears in a FOR, WHILE, or REPEAT loop, then the innermost loop is ended, regardless of the break-off condition.

Sequential function chart (SFC)

Overview

The sequential function chart (SFC) is a graphically oriented language which makes it possible to describe the chronological order of different actions within a program. For this the actions are assigned to step elements and the sequence of processing is controlled by transition elements.

Action

An action can contain a series of instructions in IL or in ST, a lot of networks in FBD or in LD, or again in Sequential Function Chart (SFC) ↳ *Chapter 1.4.1.1.10.2 “Function Block Diagram (FBD)” on page 162* ↳ *Chapter 1.4.1.1.10.7.1 “Overview” on page 176*.

With the simplified steps an action is always connected to a step. In order to edit an action, click twice with the mouse on the step to which the action belongs. Or select the step and select the menu command 'Extras' 'Zoom Action/Transition' ↳ *Chapter 1.4.1.3.11.9.18 “'Extras' 'Zoom Action/Transition'” on page 333*. In addition, one input or output action per step is possible.

Actions of IEC steps hang in the Object Organizer directly under their SFC-POU and are loaded with a doubleclick or by pressing <Enter> in their editor ↳ *Chapter 1.4.1.1.10.5.6 “IEC step” on page 172*. New actions can be created with 'Project' 'Add action' ↳ *Chapter 1.4.1.2.4.14 “'Project' 'Add action'” on page 263*. You can assign max. nine actions to one IEC step.

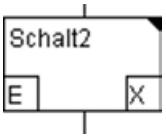
Entry or exit action

Additional to a step action you can add an entry action and an exit action to a step. An entry action is executed only once, right after the step has become active. An exit action is executed only once before the step is deactivated.

A step with entry action is indicated by an "E" in the lower left corner, the exit action by an "X" in the lower right corner.

The entry and exit action can be implemented in any language. In order to edit an entry or exit action, doubleclick in the corresponding corner in the step with the mouse.

Example of a step with entry and exit action:



Transition / Transition condition

Between the steps there are so-called transitions.

A transition condition must have the value TRUE or FALSE. Thus it can consist of either a boolean variable, a boolean address or a boolean constant. It can also contain a series of instructions having a boolean result, either in ST syntax (e.g. (i<= 100) AND b) or in any language desired ↳ *Chapter 1.4.1.3.11.9.18 “'Extras' 'Zoom Action/Transition'” on page 333*. But a transition may not contain programs, function blocks or assignments!

In the SFC-Editor a transition condition can be written directly at the transition symbol or an own editor window can be opened for entering the condition ↳ *Chapter 1.4.1.3.11.9.18 “'Extras' 'Zoom Action/Transition'” on page 333*. Regard that the instructions entered in the editor window will take precedence!

> *Besides transitions, inching mode can also be used to skip to the next step.*

Active step

After calling the SFC POU, the action (surrounded by a double border) belonging to the initial step is executed first ↳ *Chapter 1.4.1.1.10.5.2 “Action” on page 171*. A step, whose action is being executed, is called active. In Online mode active steps are shown in blue.

In a control cycle all actions are executed which belong to active steps. Thereafter the respective following steps of the active steps become active if the transition conditions of the following steps are TRUE ↳ *Chapter 1.4.1.1.10.5.4 “Transition / Transition condition” on page 172*. The currently active steps will be executed in the next cycle.

> *If the active step contains an output action, this will only be executed during the next cycle, provided that the transition following is TRUE.*
>
> *Note the possibility to use implicit variables for scanning the status and time of steps or actions ↳ Chapter 1.4.1.1.10.5.7 “Implicit variables in SFC” on page 174.*

IEC step

Along with the simplified steps the standard IEC steps in SFC are available.

In order to be able to use IEC steps, you must link the special SFC library Iecsfc.lib into your project.

Not more than nine actions can be assigned to an IEC step *Chapter 1.4.1.1.10.5.2 “Action” on page 171*. IEC actions are not fixed as input, step or output actions to a certain step as in the simplified steps, but are stored separately from the steps and can be reused many times within a POU. For this they must be associated to the single steps with the command 'Extras''Associate action'.

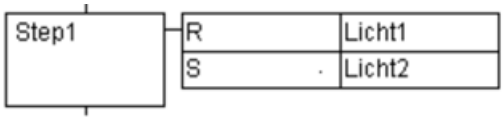
Along with actions, Boolean variables can be assigned to steps.

The activation and deactivation of actions and boolean variables can be controlled using so-called Qualifier. Time delays are possible. Since an action can still be active, if the next step has been processed, for example through the qualifier S (Set), one can achieve concurrent processes.

An associated boolean variable is set or reset with each call of the SFC block. That means, that at each call the variable gets re-assigned value TRUE resp. FALSE.

The actions associated with an IEC step are shown at the right of the step in a two-part box. The left field contains the qualifier, possibly with time constant, and the right field contains the action name respectively boolean variable name.

An example for an IEC step with two actions:



In order to make it easier to follow the processes, all active actions in online mode are shown in blue like the active steps. After each cycle a check is made to see which actions are active.

Pay attention here also to the restrictions on the use of time-qualifiers in actions that are repeatedly re-used within the same cycle.

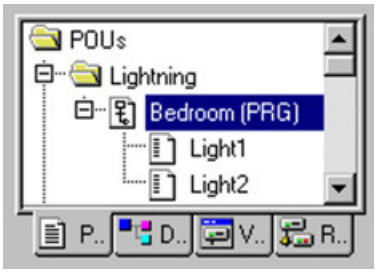
If an action has been inactivated, it will be executed once more. That means, that each action is executed at least twice (also an action with qualifier P).

In case of a call first the deactivated actions, then the active actions are executed, in alphabetical order each time.

Whether a newly inserted step is an IEC step depends upon whether the menu command 'Extras' 'Use IEC-Steps' has been chosen.

In the Object Organizer the actions hang directly underneath their respective SFC POUs. New actions can be created with 'Project' 'Add Action' *Chapter 1.4.1.2.4.14 “'Project' 'Add action'” on page 263*.

In order to use IEC steps you must include in your project the special SFC library Iecsfc.lib .



Implicit variables in SFC

In SFC implicitly declared variables ("flags") can be used to scan the status of steps and actions as well as the time of steps. These flags each are set at the beginning of a cycle. For IEC steps and IEC actions they are provided by the library iecsfc.lib (structures SFCStepType and SFCActionType), which is included automatically in a project *Chapter 1.4.1.1.10.5.6 “IEC step” on page 172* *Chapter 1.4.1.1.10.5.2 “Action” on page 171*.

Scan of the step or action status via boolean variables:

- For IEC steps: <stepname>.x resp. <stepname>._x: <StepName>.x shows the current activation status. <StepName>._x shows the activation status for the next cycle. If <StepName>.x=TRUE, the step will be executed in the current cycle. If <StepName>._x=TRUE and <StepName>.x=FALSE, the step will be executed in the following cycle, i.e. <StepName>._x gets copied to <StepName>.x at the beginning of a cycle.
- For simplified steps: <stepname> resp. _<stepname>: If <StepName>=TRUE, the step will be executed in the current cycle. If _<StepName>=TRUE, the step will be executed in the following cycle, i.e. <StepName> gets copied to _<StepName> at the beginning of a cycle.
- For IEC-actions: <actionname>.x gets TRUE as soon as the action gets active (<actionname>._x is only for internal purposes, not for a status scan).

Time of a step via TIME variables:

The following implicit variables give the current time span which has passed since the step had got active; this is only for steps which have a minimum time configured in the step attributes *Chapter 1.4.1.3.11.9.20 “'Extras' 'Step Attributes'” on page 334*.

- For IEC steps: <stepname>.t (<stepname>._t not usable for external purposes)
- For simplified steps: _time<stepname>. BUT: If this implicit variable should be used for scan purposes, it also must be declared explicitly as a TIME variable; e.g. "_timeStep1 : TIME;"
- For IEC actions: the implicit time variables are not used.

These status flags can be used in each action and transition of the SFC module. But they can also be accessed from other programs:

Example: boolvar1:=sfc.step1.x;

step1.x in the example is an implicit boolean variable showing the status of IEC step "step1" in POU "sfc1".

SFC flags

For controlling the operation of SFC POUs flags can be used, which are created implicitly during running the project. To read this flags you have to define appropriate global or local variables as inputs or outputs. Example: If in a SFC POU a step is active for a longer time than defined in the step attributes, then a flag will be set, which is accessible by using a variable "SFCError" (SFCError gets TRUE in this case).

The following flag variables can be defined:

- SFCEnableLimit: This variable is of the type BOOL. When it has the value TRUE, the timeouts of the steps will be registered in SFCError. Other timeouts will be ignored.
- SFCInit: When this boolean variable has the value TRUE the sequential function chart is set back to the Init step. The other SFC flags are reset too (initialization). The Init step remains active, but is not executed, for as long as the variable has the value TRUE. It is only when SFCInit is again set to FALSE that the block can be processed normally.
- SFCReset: This variable, of type BOOL, behaves similarly to SFCInit. Unlike the latter, however, further processing takes place after the initialization of the Init step. Thus for example the SFCReset flag could be re-set to FALSE in the Init step.

As from compiler version 2.3.7.0 SFCReset also can be used to reset boolean actions associated to IEC steps, which was not possible before.

- SFCQuitError: Provided that the Execution of the SFC diagram is stopped for as long as this boolean variable has the value TRUE whereby a possible timeout in the variable SFCError is reset. All previous times in the active steps are reset when the variable again assumes the value FALSE. It is a pre-condition that the flag SFCError has been defined also, which registers any timeout in the SFC.
- SFCPause: Execution of the SFC diagram is stopped for as long as this boolean variable has the value TRUE.
- SFCError: This Boolean variable is TRUE when a timeout has occurred in a SFC diagram. If another timeout occurs in a program after the first one, it will not be registered unless the variable SFCError is reset first. It is a pre-condition that SFCError is defined, if you want to use the other time-controlling flags (SFCErrorStep, SFCErrorPOU, SFCQuitError, SFCErrorAnalyzation).
- SFCTrans: This boolean variable takes on the value TRUE when a transition is actuated.
- SFCErrorStep: This variable is of the type STRING. If SFCError registers a timeout, in this variable is stored the name of the step which has caused the timeout. It is a pre-condition that the flag SFCError has been defined also, which registers any timeout in the SFC.
- SFCErrorPOU: This variable of the type STRING contains the name of the block in which a timeout has occurred. It is a pre-condition that the flag SFCError has been defined also, which registers any timeout in the SFC.
- SFCCurrentStep: This variable is of the type STRING. The name of the step is stored in this variable which is active, independently of the time monitoring. In the case of simultaneous sequences the step is stored in the branch on the outer right. No further timeout will be registered if a timeout occurs and the variable SFCError is not reset again.
- SFCErrorAnalyzationTable: This variable of type ARRAY [0..n] OF ExpressionResult provides the result of an analyzation of a transition expression. For each component of the expression, which is contributing to a FALSE of the transition and thereby to a timeout of the preceding step, the following information is written to the structure ExpressionResult: name, address, comment, current value.

  This is possible for maximum 16 components (variables), thus the array range is max. 0..15).

  The structure ExpressionResult as well as the implicitly used analyzation modules are provided with the library AnalyzationNew.lib. The analyzation modules also can be used explicitly in other POUs, which are not programmed in SFC.

  It is a pre-condition for the analyzation of a transition expression, that a timeout is registered in the preceding step. So a time monitoring must be implemented there and also the variable SFCError (see above) must be defined in the declaration window.
- SFCTip, SFCTipMode: This variables of type BOOL allow inching mode of the SFC. When this is switched on by SFCTipMode=TRUE, it is only possible to skip to the next step if SFCTip is set to TRUE. As long as SFCTipMode is set to FALSE, it is possible to skip even over transitions.

Regard also the implicit variables usable for scanning the status and time of steps/ actions ↳ *Chapter 1.4.1.1.10.5.7 “Implicit variables in SFC” on page 174.*

Alternative branch

Two or more branches in SFC can be defined as alternative branches. Each alternative branch must begin and end with a transition ↳ *Chapter 1.4.1.2.3.43 “'Project' 'Passwords for user groups'” on page 250*. Alternative branches can contain parallel branches and other alternative branches ↳ *Chapter 1.4.1.1.10.5.10 “Parallel branch” on page 176*. An alternative branch begins at a horizontal line (alternative beginning) and ends at a horizontal line (alternative end) or with a jump ↳ *Chapter 1.4.1.1.10.5.11 “Jump” on page 176*.

If the step which precedes the alternative beginning line is active, then the first transition of each alternative branch is evaluated from left to right. The first transition from the left whose transition condition has the value TRUE is opened and the following steps are activated ↳ *Chapter 1.4.1.1.10.5.5 “Active step” on page 172*.

Parallel branch

Two or more branches in SFC can be defined as parallel branches. Each parallel branch must begin and end with a step. Parallel branches can contain alternative branches or other parallel branches. A parallel branch begins with a double line (parallel beginning) and ends with a double line (parallel end) or with a jump. It can be provided with a jump label.

If the parallel beginning line of the previous step is active and the transition condition after this step has the value TRUE, then the first steps of all parallel branches become active *Chapter 1.4.1.2.3.43 “'Project' 'Passwords for user groups'” on page 250* *Chapter 1.4.1.1.10.5.5 “Active step” on page 172*. These branches are now processed parallel to one another. The step after the parallel end line becomes active when all previous steps are active and the transition condition before this step produces the value TRUE.

Jump

A jump is a connection to the step whose name is indicated under the jump symbol. Jumps are required because it is not allowed to create connections which lead upward or cross each other.

The continuous function chart (CFC)

The continuous function chart bases on the Function Block Diagram language. However it does not operate with networks, but rather with freely placeable elements. This allows feedback, for example.

Ladder Diagram (LD)

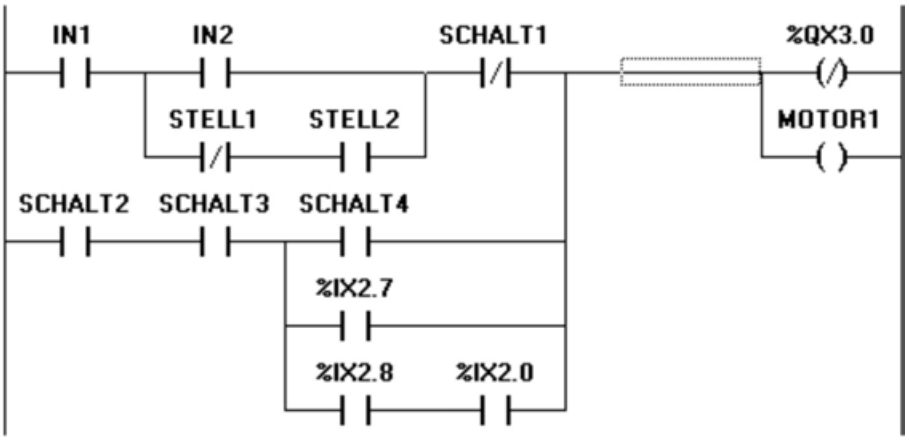
Overview

The Ladder Diagram is also a graphics oriented programming language which approaches the structure of an electric circuit.

On the one hand, the Ladder Diagram is suitable for constructing logical switches, on the other hand one can also create networks as in FBD. Therefore the LD is very useful for controlling the call of other POUs.

The Ladder Diagram consists of a series of networks. A network is limited on the left and right sides by a left and right vertical current line. In the middle is a circuit diagram made up of contacts, coils, and connecting lines.

Each network consists on the left side of a series of contacts which pass on from left to right the condition "ON" or "OFF" which correspond to the Boolean values TRUE and FALSE. To each contact belongs a Boolean variable. If this variable is TRUE, then the condition is passed from left to right along the connecting line. Otherwise the right connection receives the value OFF.



See also:

The Graphic Editors ↳ *Chapter 1.4.1.3.11.1 “Overview” on page 314*

The Ladder Editor ↳ *Chapter 1.4.1.3.11.8.1 “Overview” on page 323*

Contact

Each network in LD consists on the left side of a network of contacts (contacts are represented by two parallel lines: | |) which from left to right show the condition "On" or "Off".

These conditions correspond to the Boolean values TRUE and FALSE. A Boolean variable belongs to each contact. If this variable is TRUE, then the condition is passed on by the connecting line from left to right, otherwise the right connection receives the value "Out".

Contacts can be connected in parallel, then one of the parallel branches must transmit the value "On" so that the parallel branch transmits the value "On"; or the contacts are connected in series, then contacts must transmit the condition "On" so that the last contact transmits the "On" condition. This therefore corresponds to an electric parallel or series circuit.

A contact can also be negated, recognizable by the slash in the contact symbol: |/| ↳ *Chapter 1.4.1.3.11.8.25 “'Extras' 'Negate' in LD” on page 329*. Then the value of the line is transmitted if the variable is FALSE.

Coil

On the right side of a network in LD there can be any number of so-called coils which are represented by parentheses:( ). They can only be in parallel. A coil transmits the value of the connections from left to right and copies it in an appropriate Boolean variable. At the entry line the value ON (corresponds to the Boolean variable TRUE) or the value OFF (corresponding to FALSE) can be present.

Contacts and coils can also be negated (in the example the contact SWITCH1 and the coil %QX3.0 is negated). If a coil is negated (recognizable by the slash in the coil symbol: (/)), then it copies the negated value in the appropriate Boolean variable. If a contact is negated, then it connects through only if the appropriate Boolean value is FALSE.

Function blocks in the Ladder Diagram

Along with contacts and coils you can also enter function blocks and programs In the network they must have an input and an output with Boolean values and can be used at the same places as contacts, that is on the left side of the Ladder Diagram network ↳ *Chapter 1.4.1.1.10.7.2 “Contact” on page 177* ↳ *Chapter 1.4.1.1.10.7.3 “Coil” on page 177* ↳ *Chapter 1.4.1.1.9.4 “Function block” on page 153*.

Set/Reset coils

Coils can also be defined as set or reset coils. One can recognize a set coil by the "S" in the coil symbol: (S)) It never writes over the value TRUE in the appropriate Boolean variable. That is, if the variable was once set at TRUE, then it remains so.

One can recognize a reset coil by the "R" in the coil symbol: (R)) It never writes over the value FALSE in the appropriate Boolean variable: If the variable has been once set on FALSE, then it remains so.

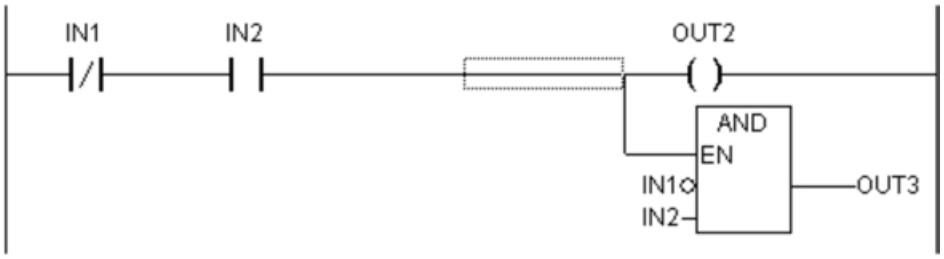
LD as FBD

When working with LD it is very possible that you will want to use the result of the contact switch for controlling other POUs. On the one hand you can use the coils to put the result in a global variable which can then be used in another place. You can, however, also insert the possible call directly into your LD network. For this you introduce a POU with EN input.

Such POUs are completely normal operands, functions, programs, or function blocks which have an additional input which is labeled with EN. The EN input is always of the BOOL type and its meaning is: The POU with EN input is evaluated when EN has the value TRUE.

An EN POU is wired parallel to the coils, whereby the EN input is connected to the connecting line between the contacts and the coils. If the ON information is transmitted through this line, this POU will be evaluated completely normally.

Starting from such an EN POU, you can create networks similar to FBD.



Reserved keywords

The following strings are reserved as keywords, i.e. they cannot be used as identifiers for variables or POUs:

ABS *Chapter 1.4.1.6.10.1 “ABS” on page 430*

ACOS *Chapter 1.4.1.6.10.10 “ACOS” on page 433*

ACTION (only used in the Export Format)

ADD *Chapter 1.4.1.6.2.1 “ADD” on page 407*

ADR *Chapter 1.4.1.6.7.1 “ADR” on page 421*

1.4.1.1.11 Debugging, online functions

Sampling trace

The sampling trace allows you to trace the value sequence of variables, depending upon the so-called trigger event. This is the rising edge or falling edge of a previously defined Boolean variable (trigger variable). The tracing of up to 20 variables is permitted. 500 values can be traced for each variable.

Debugging

The debugging functions make it easier for you to find errors.

In order to debug, run the command *“Project ➔ Options”* and in the dialog box that pops up under the *“Build”* options select activate option *“Debugging”*↳ *Chapter 1.4.1.2.2.9 “Options for build” on page 209*.

Breakpoint

A breakpoint is a place in the program at which the processing is stopped. Thus it is possible to look at the values of variables at specific places within the program.

Breakpoints can be set in all editors. In the text editors breakpoints are set at line numbers, in FBD and LD at network numbers, in CFC at POUs and in SFC at steps. No breakpoints can be set in function block instances.

WARNING!
Runtime system CODESYS SP 32 bit Full will deactivate the watchdog function of the concerned task as soon as the execution of the program currently is stopped at a breakpoint.

Single step

Single step means:

- In IL: Execute the program until the next CAL, LD or JMP command.
- In ST: Execute the next instruction.
- In FBD, LD: Execute the next network.
- In SFC: Continue the action until the next step.

By proceeding step by step you can check the logical correctness of your program.

Single cycle

If Single cycle has been chosen, then the execution is stopped after each cycle.

Change values online

During operations variables can be set once at a certain value or also described again with a certain value after each cycle ↳ *write value* ↳ *force value*. In online mode one also can change the variable value by double click on the value. By that boolean variables change from TRUE to FALSE or the other way round, for each other types of variables one gets the dialog Write Variable xy, where the actual value of the variable can be edited.

Monitoring

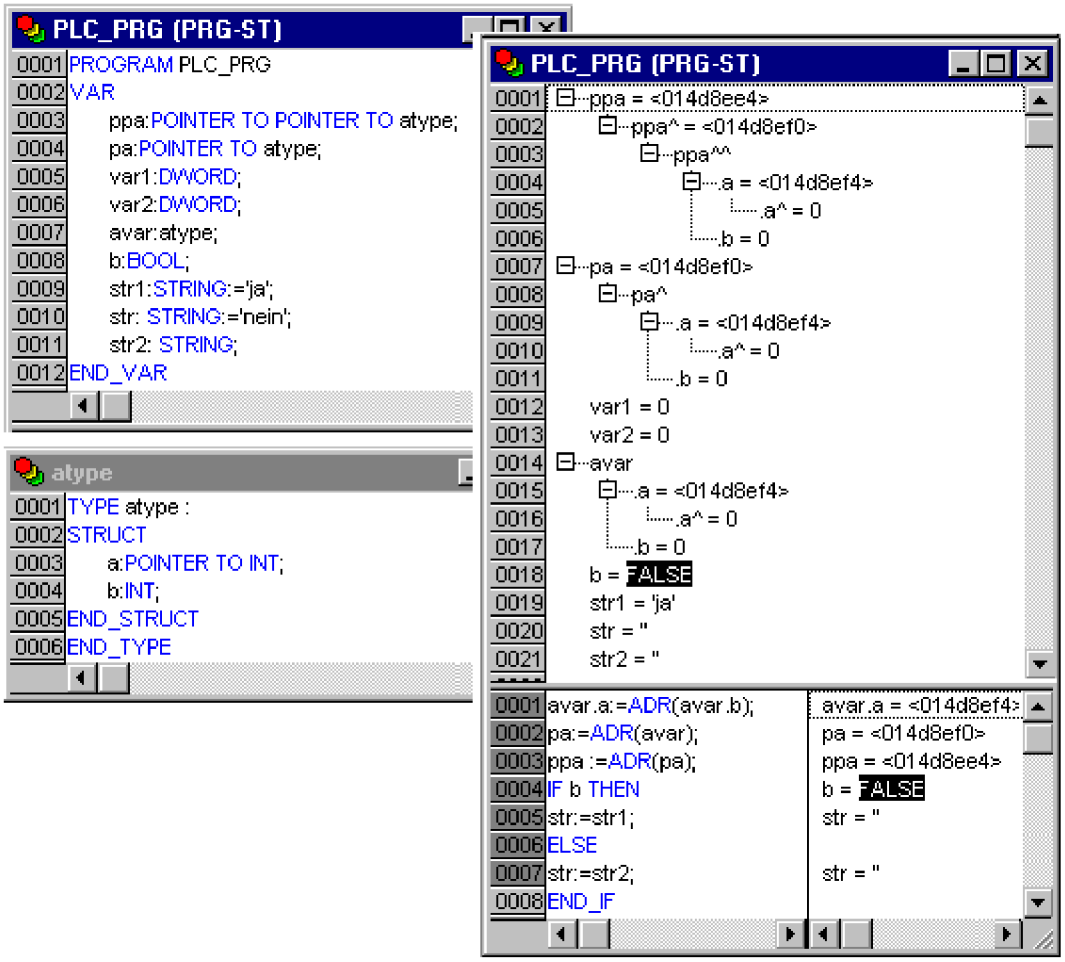
In Online mode, all displayable variables are read from the controller and displayed in real time. You will find this display in the declarations and program editor; you can also read out current values of variables in the watch and receipt manager and in a visualization. If variables from instances of function blocks are to be monitored, the corresponding instance must first be opened.

In monitoring VAR_IN_OUT variables, the de-referenced value is output.

In monitoring pointers, both the pointer and the de-referenced value are output in the declaration portion. In the program portion, only the pointer is output:

+ --pointervar = '<'pointervalue'>'

POINTERs in the de-referenced value are also displayed accordingly. With a simple click on the cross or a double-click on the line, the display is either expanded or truncated.



In the implementations, the value of the pointer is displayed. For de-referencing, however, the de-referenced value is displayed.

Monitoring of ARRAY components: In addition to array components indexed by a constant, components are also displayed which are indexed by a variable:

anarray[1] = 5

anarray[i] = 1

If the index consists of an expression (e.g. [i+j] or [i+1]), the component can not be displayed.

> *If the maximum number of variables which can be monitored, has been reached, for each further variable instead of the current value the string "Too many monitoring variables" will be displayed.*

Simulation

During the simulation the created PLC program is not processed in the PLC. All online functions are available. That allows you to test the logical correctness of your program without PLC hardware.

POUs of external libraries do not run in simulation mode.

Log

The log chronologically records user actions, internal processes, state changes and exceptions during Online mode processing ↳ *Chapter 1.4.1.1.10.5.4 “Transition / Transition condition” on page 172*. It is used for monitoring and for error tracing ↳ *Chapter 1.4.1.2.6.1 “Overview” on page 278*.

1.4.1.1.12 We write a little program

Controlling a traffic signal unit

Let us now start to write a small example program. It is for a simple traffic signal unit which is supposed to control two traffic signals at an intersection. The red/green phases of both traffic signals alternate and, in order to avoid accidents, we will insert yellow or yellow/red transitional phases. The latter will be longer than the former.

In the example you will see how time dependent programs can be shown with the language resources of the IEC1131-3 standard, how one can edit the different languages of the standard, and how one can easily connect them while becoming familiar with the simulation ↳ *Chapter 1.4.1.1.11.8 “Simulation” on page 184*.

Create POU

Choose *“File ➔ New”*↳ *Chapter 1.4.1.2.3.1 “'File' 'New'” on page 222*.

In the dialog box which appears, the first POU has already been given the default name PLC_PRG. Keep this name, and the type of POU should definitely be a program. Each project needs a program with this name. In this case we choose as the language of this POU the Continuous Function Chart Editor (CFC).

Now create three more objects with the command 'Project' 'Object Add' with the menu bar or with the context menu (press right mouse button in the Object Organizer) ↳ *Chapter 1.4.1.2.4.6 “'Project' 'Object' ' Add'” on page 258*. A program in the language Sequential Function Chart named SEQUENCE, a function block ↳ *Chapter 1.4.1.1.9.4 “Function block” on page 153* in the language Function Block Diagram named TRAFFICSIGNAL, along with a POU WAIT, also of the type function block, which we want to program as an Instruction List ↳ *IL* ↳ *Chapter 1.4.1.1.10.5.1 “Overview” on page 171* ↳ *Chapter 1.4.1.1.10.2 “Function Block Diagram (FBD)” on page 162*.

What does TRAFFICSIGNAL do?

In the POU TRAFFICSIGNAL we will assign the individual trafficsignal phases to the lights, i.e. we will make sure that the red light is lit red in the red phase and in the yellow/red phase, the yellow light in the yellow and yellow/red phases, etc.

What does WAIT do?

In WAIT we will program a simple timer which as input will receive the length of the phase in milliseconds, and as output will produce TRUE as soon as the time period is finished.

What does SEQUENCE do?

In SEQUENCE all is combined so that the right light lights up at the right time for the desired time period.

What does PLC_PRG do?

In PLC_PRG the input start signal is connected to the traffic lights' sequence and the "color instructions" for each lamp are provided as outputs.

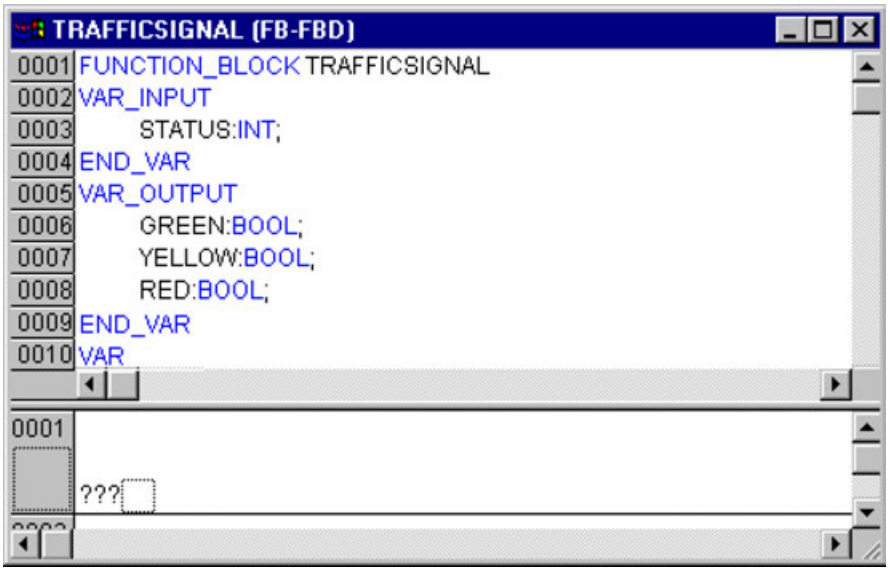
TRAFFICSIGNAL simulation

Now test your program in simulation mode. Compile ("Project" "Build") and load ("Online" "Login") it. Start the program by "Online" "Start", then set variable ON to TRUE, e.g. by a double-click on the entry "ON" in the input box of the CFC editor. This will mark the variable as prepared to be set to <TRUE>. Then press <Ctrl><F7> or command "Online" "Write values", to set the value. Now variable START in ABLAUF (which we had set to TRUE manually in the first extension level of the program) gets this value by variable ON, which is used in PLC_PRG. This will make run the traffic light cycles. PLC_PRG has changed to a monitoring window. Click twice on the plus sign in the declaration editor, the variable display drops down, and you can see the values of the individual variables.

"TRAFFICSIGNAL" declaration

Let us now turn to the POU TRAFFICSIGNAL. In the declaration editor you declare as input variable (between the keywords VAR_INPUT and END_VAR) a variable named STATUS of the type INT. STATUS will have four possible conditions, that is one for the TRAFFICSIGNAL phases green, yellow, yellow/red andred.

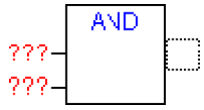
Correspondingly our TRAFFICSIGNAL has three outputs, that is RED, YELLOW and GREEN. You should declare these three variables. Then the declaration part of our TRAFFICSIGNAL will look like this *Chapter 1.4.1.1.9.4 “Function block” on page 153*:



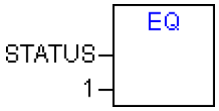
"TRAFFICSIGNAL" body

Now we determine the values of the output variables depending on the input STATUS of the POU. To do this go into the body of the POU. Click on the field to the left beside the first network (the gray field with the number 0001). You have now selected the first network. Choose the menu item 'Insert' 'Box' *Chapter 1.4.1.3.11.7.7 "'Insert' 'Box' in FBD" on page 319*.

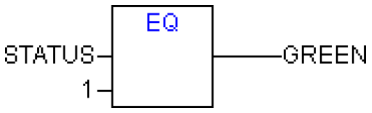
In the first network a box is inserted with the operator AND and two inputs:



Click on the text AND, so that it appears selected and change the text into EQ. Select then for each of the two inputs the three question marks and overwrite them with "STATUS" respectively "1".

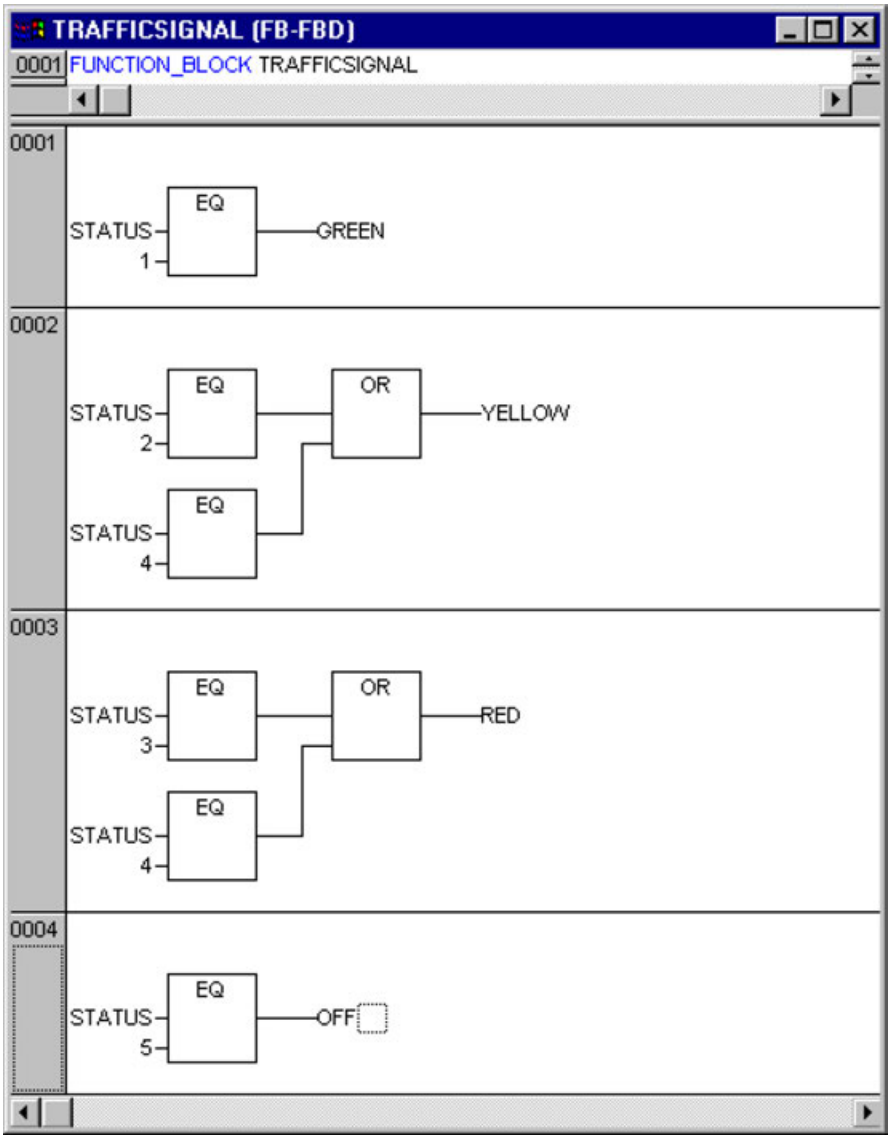


Click now on a place behind the EQ Box. Now the output of the EQ operation is selected. Choose 'Insert' 'Assign' in FBD *Chapter 1.4.1.3.11.7.4 "'Insert' 'Assign'in FBD" on page 318*. Change the three question marks ??? to GREEN. You now have created a network with the following structure:



STATUS is compared with 1, the result is assigned to GREEN. This network thus switches to GREEN if the preset state value is 1.

For the other TRAFFICSIGNAL colors we need two more networks. To create the first one execute command 'Insert' 'Network (after)' and insert an EQ-Box like described above. Then select the output pin of this box and use again command 'Insert' 'Box'. In the new box replace "AND" by "OR". Now select the first output pin of the OR-box and use command 'Insert' 'Assign' to assign it to "YELLOW". Select the second input of the OR-box by a mouse-click on the horizontal line next to the three question marks, so that it appears marked by a dotted rectangle. Now use 'Insert' 'Box' to add a further EQ-box like described above. Finally the network should look like shown in the following:



In order to insert an operator in front of another operator, you must select the place where the input to which you want to attach the operator feeds into the box.

Then use the command 'Insert' 'Box' *Chapter 1.4.1.3.11.7.7 “'Insert' 'Box' in FBD” on page 319*. Otherwise you can set up these networks in the same way as the first network.

Now our first POU has been finished. TRAFFICSIGNAL, according to the input of the value STATUS, controls whichever light color we wish.

Connecting the standard.lib

For the timer in the POU WAIT we need a POU from the standard library. Therefore, open the library manager with 'Window' 'Library Manager' *Chapter 1.4.1.4.3.1 “Overview” on page 371*. Choose 'Insert' 'Additional library' *Chapter 1.4.1.4.3.4 “'Insert' 'Additional Library'” on page 373*. The dialog box appears for opening files. From the list of the libraries choose standard.lib.

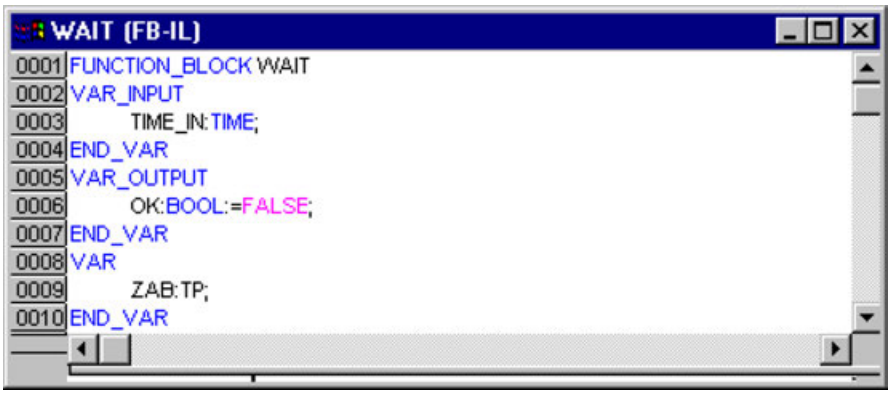
"WAIT" declaration

Now let us turn to the POU WAIT. This POU is supposed to become a timer with which we can determine the length of the time period of each TRAFFICSIGNAL phase. Our POU receives as input variable a variable TIME of the type TIME, and as output it produces a Boolean value which we want to call OK and which should be TRUE when the desired time period is finished. We set this value with FALSE by inserting at the end of the declaration (before the semicolon, however) " := FALSE ".

For our purposes we need the POU TP, a clock generator. This has two inputs (IN, PT) and two outputs (Q, ET). TP does the following:

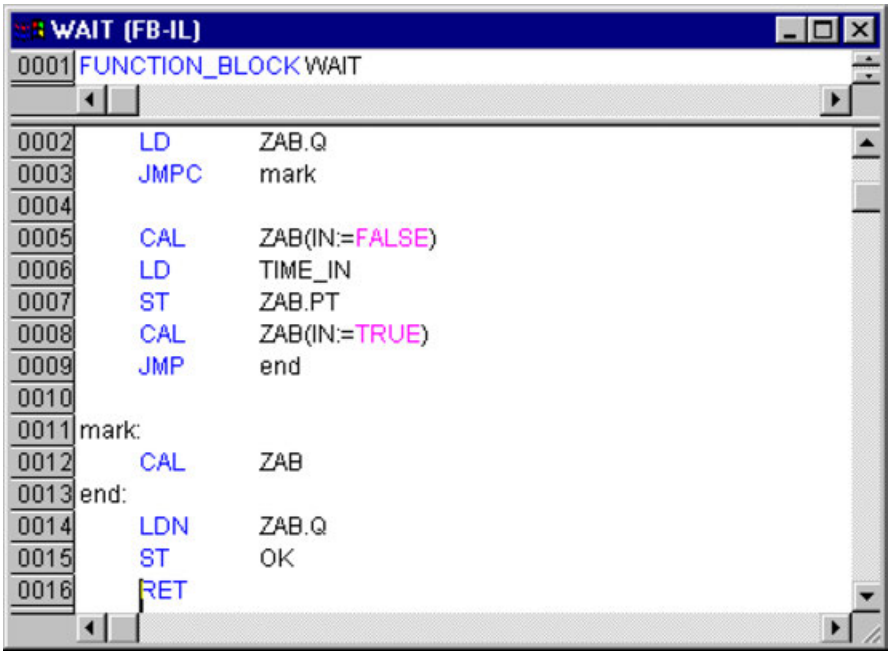
As long as IN is FALSE, ET is 0 and Q is FALSE. As soon as IN provides the value TRUE, the time is calculated at the output ET in milliseconds. When ET reaches the value PT, then ET is no longer counted. Meanwhile Q produces TRUE as long as ET is smaller than PT. As soon as the value PT has been reached, then Q produces FALSE again. See the chapter on the standard library for short descriptions of all POUs.

In order to use the POU TP in the POU WAIT we must create a local instance from TP. For this we declare a local variable ZAB (for elapsed time) of the type TP (between the keywords VAR, END_VAR). The declaration part of WAIT thus looks like this:



"WAIT" body

In order to create the desired timer, the body of the POU must be programmed as follows:



At first it is checked whether Q has already been set at TRUE (as though the counting had already been executed), in this case we change nothing with the occupation of ZAB, but we call the function block ZAB without input (in order to check whether the time period is already over) ↳ *Chapter 1.4.1.1.9.4 “Function block” on page 153*.

Otherwise we set the variable IN in ZAB at FALSE, and therefore at the same time ET at 0 and Q at FALSE. In this way all variables are set at the desired initial condition. Now we assign the necessary time from the variable TIME into the variable PT, and call ZAB with IN:=TRUE. In the function block ZAB the variable ET is now calculated until it reaches the value TIME, then Q is set at FALSE.

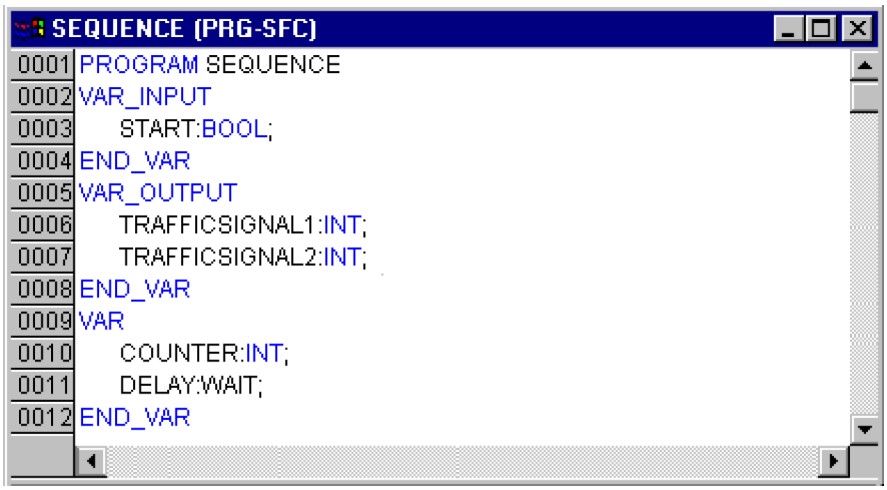
The negated value of Q is saved in OK after each execution of WAIT. As soon as Q is FALSE, then OK produces TRUE.

The timer is finished at this point. Now it is time to combine our two function blocks WAIT and SEQUENCE in the main program ↳ *Chapter 1.4.1.1.12.1.17 “PLC_PRG” on page 194*.

"SEQUENCE" first expansion level

First we declare the variables we need. They are: an input variable START of the type BOOL, two output variables TRAFFICSIGNAL1 and TRAFFICSIGNAL2 of the type INT and one of the type WAIT (DELAY as delay). The program SEQUENCE now looks like shown here.

Program SEQUENCE, First Expansion Level, Declaration Part:



Create a SFC diagram

The beginning diagram of a POU in SFC always consists of an action "Init" of a following transition "Trans0" and a jump back to Init ↳ *Chapter 1.4.1.1.10.5.4 “Transition / Transition condition” on page 172*. We have to expand that.

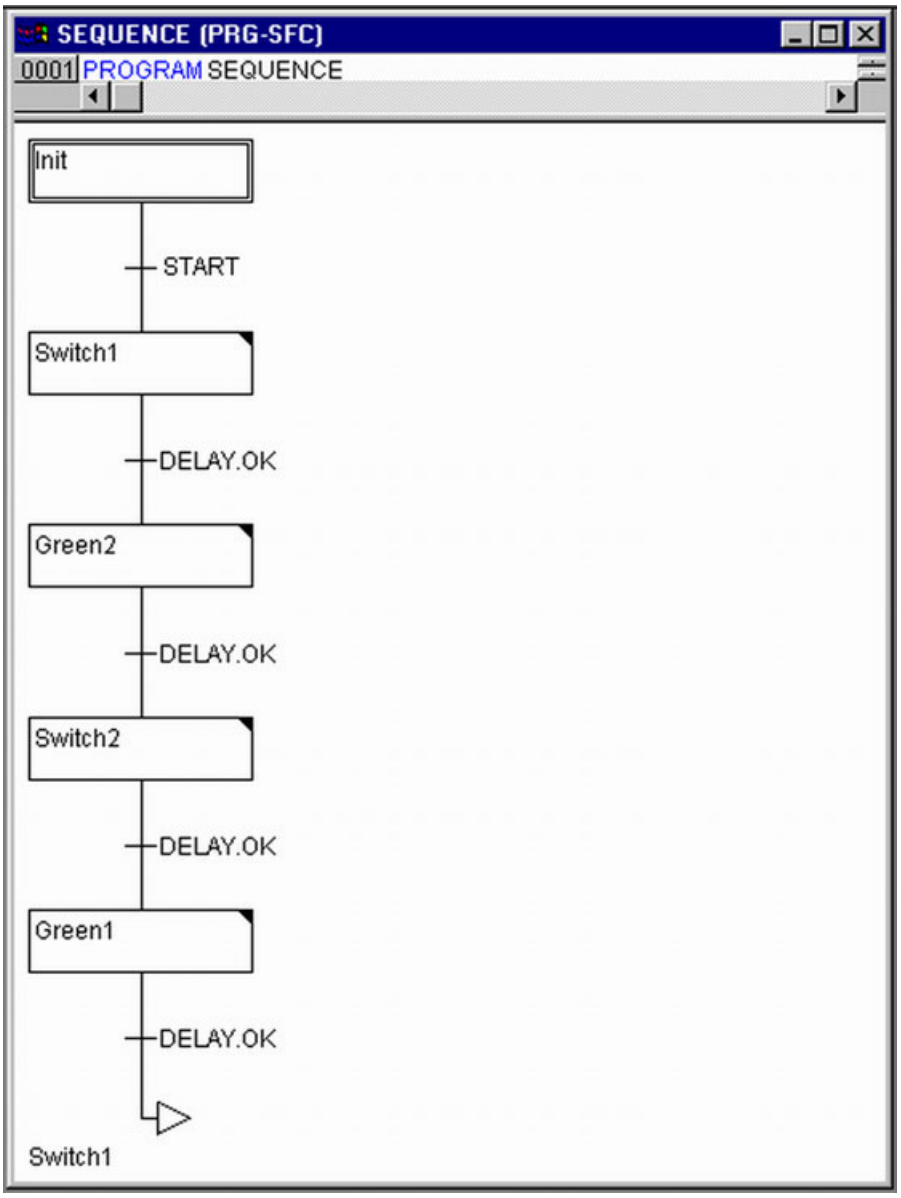
Before we program the individual action and transitions let us first determine the structure of the diagrams. We need one step for each trafficsignal phase. Insert it by marking Trans0 and choosing "Insert" "Step transition (after)". Repeat this procedure three more times.

If you click directly on the name of a transition or a step, then this is marked and you can change it. Name the first transition after Init "START", and all other transitions "DELAY.OK".

The first transition switches through when START is TRUE and all others switch through when DELAY in OK produces TRUE, i.e. when the set time period is finished.

The steps (from top to bottom) receive the names Switch1, Green2, Switch2, Green1, whereby Init of course keeps its Name. "Switch" should include a yellow phase, at Green1 TRAFFIC-SIGNAL1 will be green, at Green2 TRAFFICSIGNAL2 will be green. Finally change the return address of Init after Switch1. If you have done everything right, then the diagram should look like in the following figure:

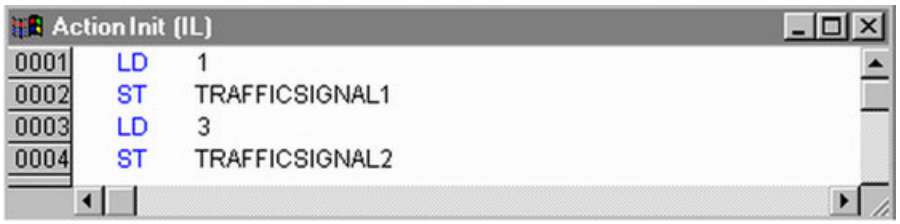
Program SEQUENCE, First Expansion Level, Instruction Part



Now we have to finish the programming of the individual steps. If you doubleclick on the field of a step, then you get a dialog for opening a new action ↳ *Chapter 1.4.1.1.10.5.2 “Action” on page 171*. In our case we will use IL (Instruction List).

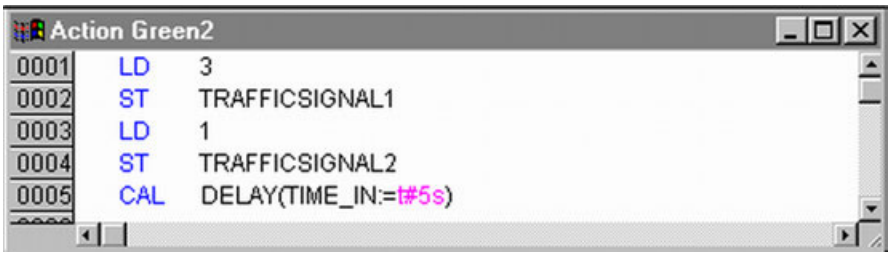
Actions and transition conditions

In the action of the step 'Init' the variables are initialized, the STATUS of TRAFFICSIGNAL1 should be 1 (green) ↳ *Chapter 1.4.1.1.10.5.2 “Action” on page 171*. The state of TRAFFIC-SIGNAL2 should be 3 (red). The action Init then looks like in the following figure:



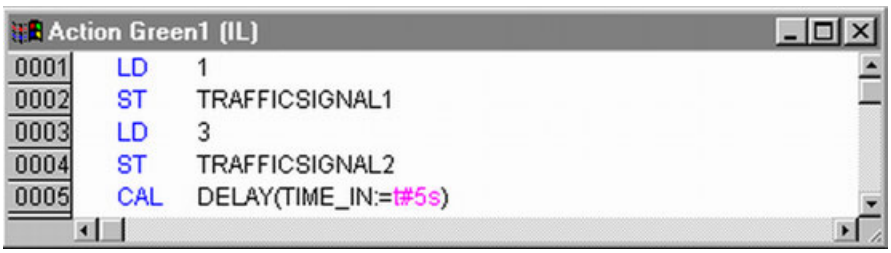
Switch1 changes the sate of TRAFFICSIGNAL1 to 2 (yellow), and that of TRAFFICSIGNAL2 to 4 (yellow-red). In addition, a time delay of 2000 milliseconds is set. The action is now as follows:

With Green2 TRAFFICSIGNAL1 is red (STATUS:=3), TRAFFICSIGNAL2 green (STATUS:=1), and the delay time is 5000 milliseconds.



At Switch2 the STATUS of TRAFFICSIGNAL1 changes to 4 (yellow-red), that of TRAFFIC-SIGNAL2 to 2 (yellow). A time delay of 2000 milliseconds is now set.

With Green1 TRAFFICSIGNAL1 is green (STATUS:=1), TRAFFICSIGNAL2 is red (STATUS:=3), and the time delay is set to 5000 milliseconds.



The first expansion phase of our program is completed.

If you want to do a first test of POU ABLAUF in simulation mode, perform the following steps:

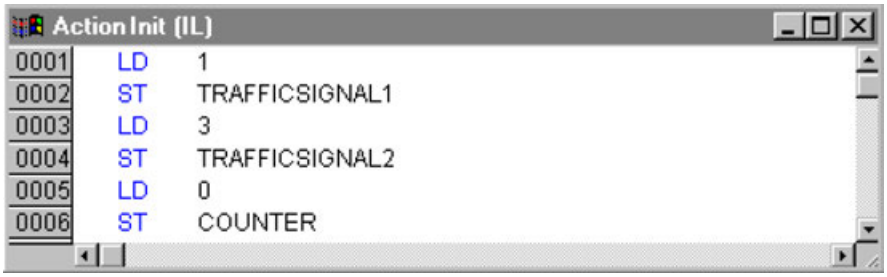
1. Open POU PLC_PRG. Each project starts running with PLC_PRG. In order to be able to provisionally start POU ABLAUF, insert a box and replace "AND" by "ABLAUF". Remain the inputs and outputs unassigned for the moment.
2. Compile the project via 'Project' 'Build'. In the message window you should get "0 Errors, 0 Warnings". Now check if option 'Online' 'Simulation' is activated and use command 'Online' 'Login' to get into simulation mode. Start program with 'Online' 'Start'. Open POU ABLAUF by a double-click on entry "ABLAUF" in the Object Organizer. The program is started now, but to get it run, variable START must be TRUE. Later this will be set by PLC_PRG but at the moment we have to set it manually within the POU. To do that, perform a double-click on the line in the declaration part, where START is defined (START=FALSE). This will set the option "<:=TRUE>" behind the variable in turquoise color. Now select command 'Online' 'Write values' to set this value. Thereupon START will be displayed in blue color in the sequence diagram and the processing of the steps will be indicated by a blue mark of the currently active step.

When you have finished this intermediate test use command 'Online' 'Logout' to leave the simulation mode and to continue programming.

"SEQUENCE" second expansion level

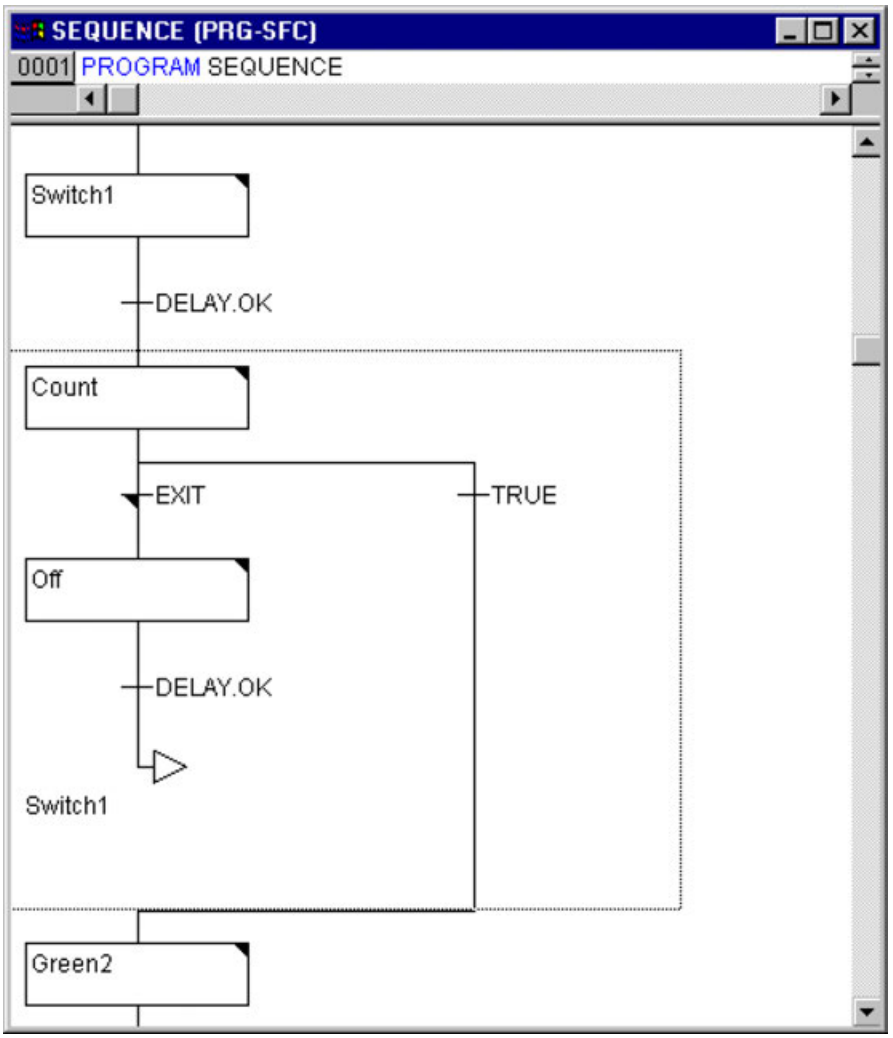
In order to ensure that our diagram has at least one alternative branch, and so that we can turn off our traffic light unit at night, we now include in our program a counter which, after a certain number of TRAFFICSIGNAL cycles, turns the unit off.

At first we need a new variable COUNTER of the type INT. Declare this as usual in the declaration part of SEQUENCE, and initialize it in Init with 0.

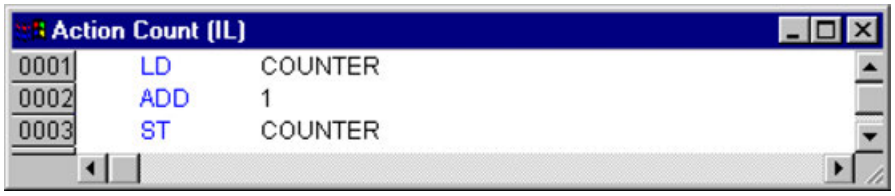


Now select the transition after Switch1 and insert a step and then a transition ↬ *Chapter 1.4.1.1.10.5.4 “Transition / Transition condition” on page 172*. Select the resulting transition and insert an alternative branch to its left. After the left transition insert a step and a transition. After the resulting new transition insert a jump after Switch1.

Name the new parts as follows: the upper of the two new steps should be called "Count" and the lower "Off". The transitions are called (from top to bottom and from left to right) EXIT, TRUE and DELAY.OK. The new part should look like the part marked with the black border in the following figure:

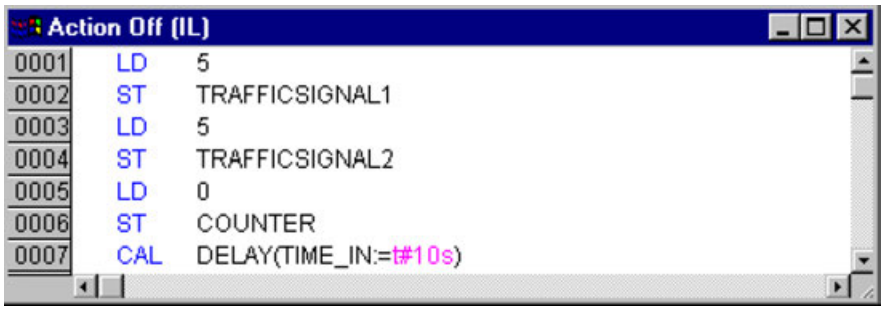


Now two new actions and a new transition condition are to be implemented ↳ *Chapter 1.4.1.1.10.5.2 “Action” on page 171* ↳ *Chapter 1.4.1.1.10.5.4 “Transition / Transition condition” on page 172*. At the step Count the variable COUNTER is increased by one:



The EXIT transition checks whether the counter is greater than a certain value, for example 7:

At Off the state of both lights is set at 5(OFF), (or each other number not equal 1,2,3 or 4) the COUNTER is reset to 0, and a time delay of 10 seconds is set:



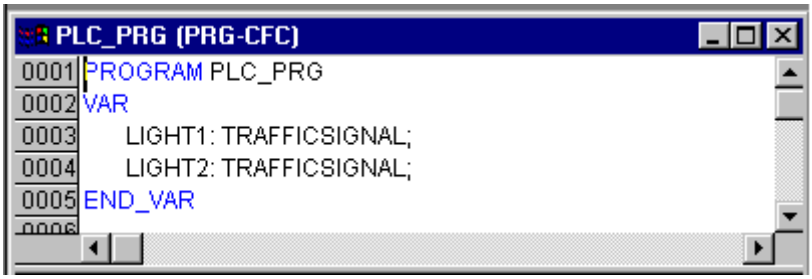
The result

In our hypothetical situation, night falls after seven trafficsignal cycles, for ten seconds the trafficsignal turns itself off, then we have daylight again, the traffic light unit turns itself on again, and the whole process starts again from the beginning. If you like, do another test of the current version of your program in simulation mode before we go on to create the POU PLC_PRG.

PLC_PRG

We have defined and correlated the time sequencing of the phases for both sets of traffic lights in the block SEQUENCE. Since, however, we see the traffic lights system as a module of a bus system, e.g. CAN bus, we have to make input and output variables available in the block PLC_PRG. We want to start-up the traffic lights system over an ON switch and we want to send each of the six lamps (each traffic light red, green, yellow) the corresponding "signal command" for each step of the SEQUENCE. We are now declaring appropriate Boolean variables for these six outputs and one input, before we create the programme in the editor, and are allocating them, at the same time, to the corresponding IEC addresses.

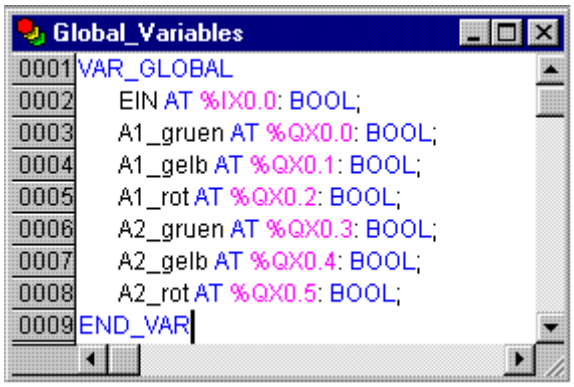
The next step is declare the variables Light1 and Light2 of the type Phases in the declaration editor.



These deliver the Boolean value of each of the six lights to the above mentioned six outputs for each step of the block SEQUENCE. We are not, however, declaring the output variables which are foreseen within the PLC_PRG block but under Resources for Global Variables instead. The Boolean input variable IN, which is used to set the variable START in the block SEQUENCE to TRUE, can be set in the same way. ON is also allocated to an IEC address.

Select the tab Resources and open the list Global Variables.

Make the declaration as follows:



The name of the variable (e.g. IN) is followed, after AT, by a percent sign which begins the IEC address. I stands for input, Q for output, B (used in the example) stands for byte and the individual bits of the module are addressed using 0.0 (0.1, 0.2, etc.). We will not do the needed controller configuration here in the example, because it depends on which target package you have available on your computer.

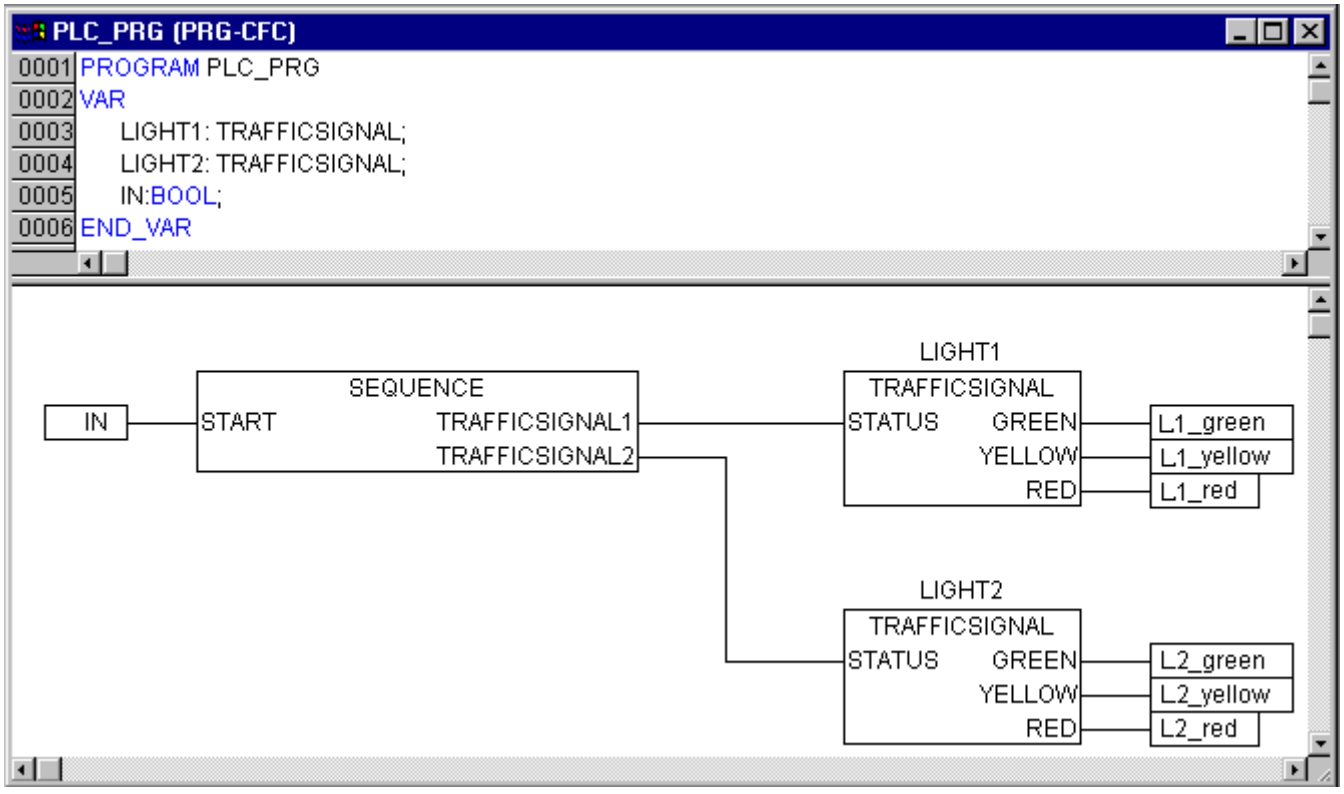
We now want to finish off the block PLC_PRG.

For this we go into the editor window. We have selected the Continuous Function Chart editor and we consequently obtain, under the menu bar, a CFC symbol bar with all of the available elements.

Click on the right mouse key in the editor window and select the element Box. Click on the text AND and write "SEQUENCE" instead. This brings up the block SEQUENCE with all of the already defined input and output variables. Insert two further block elements which you name PHASES. Phases is a function block and this causes you to obtain three red question marks over the block which you replace with the already locally declared variables LIGHT1 and LIGHT2. Now set an element of the type Input, which award the title ON and six elements of the type Output which you award variable names to, as described, namely L1_green, L1_yellow, L1_red, L2_green, L2_yellow, L2_red.

All of the elements of the programme are now in place and you can connect the inputs and outputs, by clicking on the short line at the input/output of an element and dragging this with a constantly depressed mouse key to the input/output of the desired element.

Your program should finally look like the example shown here.



TRAFFICSIGNAL simulation

Now test your program in simulation mode. Compile ("Project" "Build") and load ("Online" "Login") it. Start the program by "Online" "Start", then set variable ON to TRUE, e.g. by a double-click on the entry "ON" in the input box of the CFC editor. This will mark the variable as prepared to be set to <TRUE>. Then press <Ctrl><F7> or command "Online" "Write values", to set the value. Now variable START in ABLAUF (which we had set to TRUE manually in the first extension level of the program) gets this value by variable ON, which is used in PLC_PRG. This will make run the traffic light cycles. PLC_PRG has changed to a monitoring window. Click twice on the plus sign in the declaration editor, the variable display drops down, and you can see the values of the individual variables.

Visualizing a traffic signal unit

Creating a new visualization

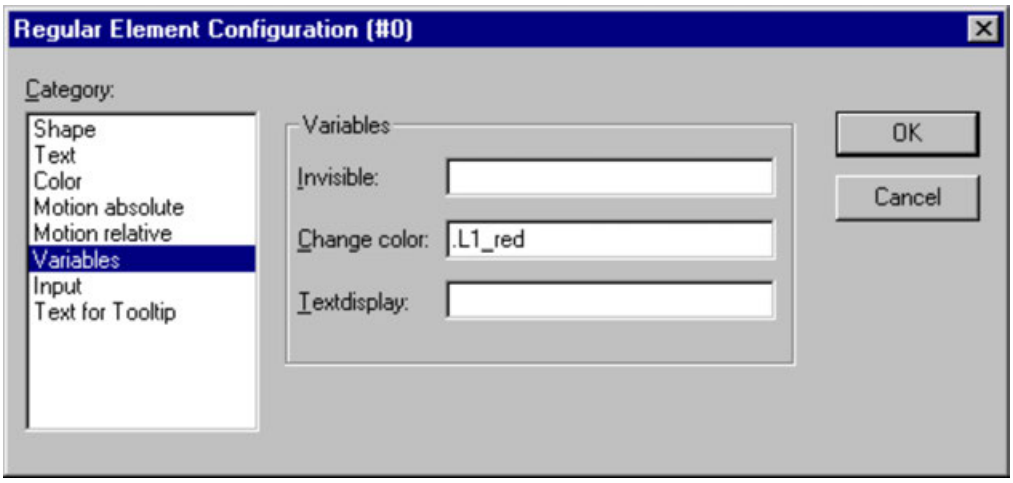
In order to create a visualization you must first select the range of Visualization in the Object Organizer. First click on the lower edge of the window on the left side with the POU on the register card with this symbol and the name Visualization. If you now choose the command 'Project' 'Object Add', then a dialog box opens *Chapter 1.4.1.2.4.6 "'Project' 'Object' ' Add'" on page 258*.

Enter here any name. When you confirm the dialog with OK, then a window opens in which you can set up your new visualization.

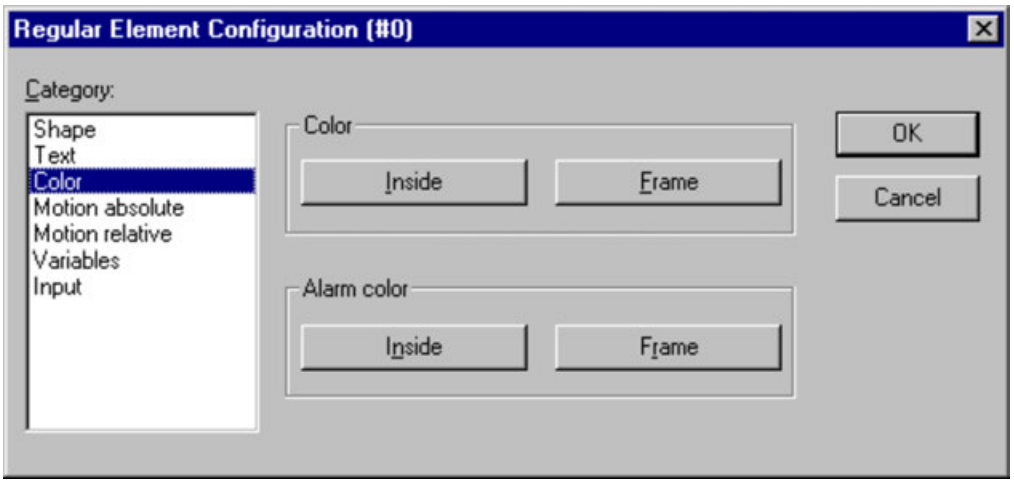
Insert element in visualization

For our TRAFFICSIGNAL visualization you should proceed as follows:

- Give the command 'Insert' 'Ellipse'.Insert..Ellipse.>Proc and try to draw a medium sized circle (?2cm). For this click in the editor field and draw with pressed left mouse button the circle in its length.
- Now doubleclick the circle. The dialog box for editing visualization elements opens
- Choose the category Variables and in the field Change color enter the variable name .L1_red or "L1_red". That means that the global variable L1_red will cause the color change as soon as it is set to TRUE. The dot before the variable name indicates that it is a global variable, but it is not mandatory.



- Then choose the category Color and click on the button Inside in the area Color. Choose as neutral a color as possible, such as black.
- Now click on the button within in the area Alarm color and choose the red which comes closest to that of a red light.



The resulting circle will normally be black, and when the variable RED from TRAFFICSIGNAL1 is TRUE, then its color will change to red. We have therefore created the first light of the first trafficsignal!

The other traffic lights

Now enter the commands 'Edit' 'Copy' (<Ctrl>+<C>) and then twice 'Edit' 'Paste' (<Ctrl>+<V>) ↳ *Chapter 1.4.1.2.5.5 “'Edit' 'Copy'” on page 273* ↳ *Chapter 1.4.1.2.5.6 “'Edit' 'Paste'” on page 274* . That gives you two more circles of the exact same size lying on top of the first one. You can move the circles by clicking on the circle and dragging it with pressed left mouse button. The desired position should, in our case, be in a vertical row in the left half of the editor window. Doubleclick on one of the other two circles in order to open the configuration dialog box again. Enter in the field Change Color of the corresponding circle the following variables:

- for the middle circle: L1_yellow
- for the lowest circle: L1-green

Now choose for the circles in the category 'Color' and in the area 'Alarm color' the corresponding color (yellow or green).

The TRAFFICSIGNAL case

Now enter the command 'Insert' 'Rectangle', and insert in the same way as the circle a rectangle which encloses the three circles. Once again choose as neutral a color as possible for the rectangle and give the command 'Extras' 'Send to back' so that the circles are visible again.

If simulation modeis not yet turned on, you can activate it with the command 'Online' 'Simulation' ↳ *Chapter 1.4.1.2.6.22 “'Online' 'Simulation'” on page 291*.

If you now start the simulation with the commands 'Online' 'Login' and 'Online' 'Run', then you can observe the color change of the first traffic signal ↳ *Chapter 1.4.1.2.6.2 “'Online' 'Login'” on page 279* ↳ *Chapter 1.4.1.2.6.6 “'Online' 'Run'” on page 283*.

The second traffic signal

The simplest way to create the second traffic signal is to copy all of the elements of the first traffic signal. For this you select all elements of the first traffic signal and copy them (as before with the lights of the first traffic signal) with the commands 'Edit' 'Copy' and 'Edit' 'Paste'. You then only have to change the text "TRAFFICSIGNAL1" in the respective dialog boxes into "TRAFFICSIGNAL2", and the visualization of the second traffic signal is completed.

The ON switch

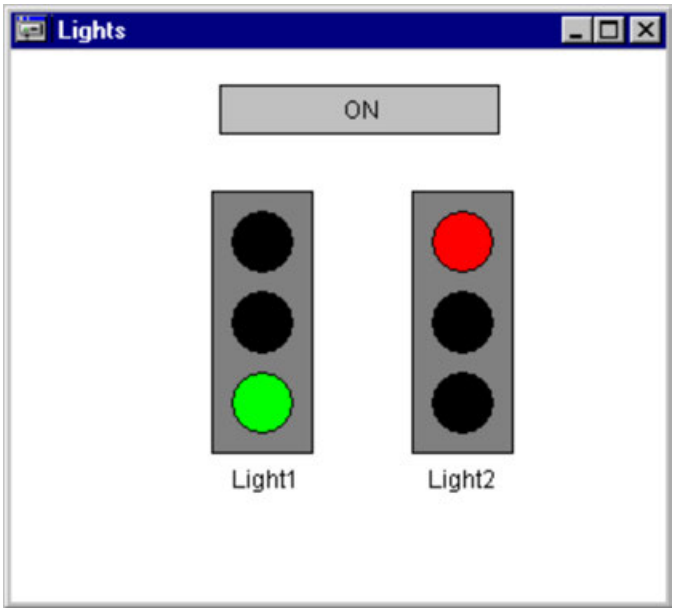
Insert a rectangle and award it, as described above, a colour for a traffic light of your choice and enter .ON at *“Variables”* for the *“Change color”*. Enter "ON" in the input field for *“Content”* in the category Text.

In order to set the variable ON to TRUE with a mouse click on the switch, activate option 'Toggle variable' in category 'Input' and enter variable name ".ON" there. Variable keying means that when a mouse click is made on the visualization element the variable .ON is set to the value TRUE but is reset to the value FALSE when the mousekey is released again (we have created hereby a simple switch-on device for our traffic lights program).

Font in the visualization

In order to complete the visualization you should first insert two more rectangles which you place underneath the traffic signals.

In the visualizations dialog box set white in the category Color for Frame and write in the category Text in the field Contents "Light1" or "Light2". Now your visualization looks like this:



1.4.1.2 The individual components

1.4.1.2.1 The main window

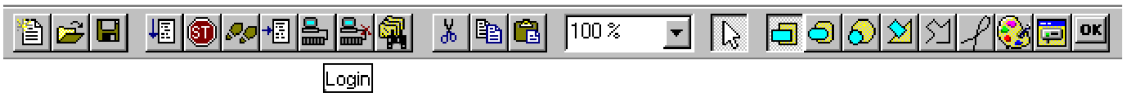
Menu bar

The menu bar is located at the upper edge of the main window. It contains all menu commands.

Tool bar

By clicking with the mouse on a symbol you can select a menu command more quickly. The choice of the available symbols automatically adapts itself to the active window.

The command is only carried out when the mouse button is pressed on the symbol and then released. If you hold the mouse pointer for a short time on a symbol in the tool bar, then the name of the symbol is shown in a Tooltip. In order to see a description of each symbol on the tool bar, select in *"Help"* the editor about which you want information and click on the tool bar symbol in which you are interested. The display of the tool bar is optional.



Object organizer

The Object Organizer is always located on the left side of the program. At the bottom there are four register cards with symbols for the four types of objects:

- POUs
- Data types
- Visualizations
- Resources

In order to change between the respective object types click with the mouse on the corresponding register card or use the left or right arrow key.

Screen divider

The screen divider is the border between two non-overlapping windows. There are screen dividers between the object organizer and the of the main window, between the interface (declaration part) and the implementation (instruction part) of POUs and between the work space and the message window ↳ *Chapter 1.4.1.2.1.3 "Object organizer" on page 199* ↳ *Chapter 1.4.1.2.1 "The main window" on page 198* ↳ *Chapter 1.4.1.3.9.2 "Declaration part" on page 297*.

You can move the screen divider with the mouse pointer. You do this by moving the mouse with the left mouse button pressed.

Make sure the screen divider always remains at its absolute position, even when the window size has been changed. If it seems that the screen divider is no longer present, then simply enlarge your window.

Workspace

This object in the 'Resources' tab provides an figure of the currently set project options. If you open it, you get the project options dialog with the know categories ↳ *Chapter 1.4.1.2.2.1 "'Project' 'Options'" on page 200*.

Message window

The message window is separated by a screendivider underneath the workspace in the main window ↳ *Chapter 1.4.1.2.1.4 “Screen divider” on page 199* ↳ *Chapter 1.4.1.2.1.5 “Workspace” on page 199*.

It contains all messages from the previous compilations, checks or comparisons. Search results and the cross-reference list can also be output here.

If you doubleclick with the mouse in the message window on a message or press *[Enter]*, the editor opens with the object. The relevant line of the object is selected. With the commands 'Edit' 'Next error' and 'Edit' 'Previous error' you can can quickly jump between the error messages.

Status bar

The status bar at the bottom of the window frame of the main window gives you information about the current project and about menu commands.

If an item is relevant, then the concept appears on the right side of the status bar in black script, otherwise in gray script.

When you are working in online mode, the concept Online appears in black script. If you are working in the offline mode it appears in gray script.

In Online mode you can see from the status bar whether you are in the simulation (SIM), the program is being processed (RUNS), a breakpoint is set (BP), or variables are being forced (FORCE) ↳ *Chapter 1.4.1.1.11.8 “Simulation” on page 184*.

With the text editor the line and column number of the current cursor position is indicated (e.g. Line:5, Col.:11). In online mode 'OV' is indicated black in the status bar. Pressing the *[Ins]* key switches between Overwrite and Insert mode.

If the mouse point is in a visualization, the current X and Y position of the cursor in pixels relative to the upper left corner of the screen is given. If the mouse pointer is on an Element, or if an element is being processed, then its number is indicated. If you have an element to insert, then it also appears (e.g. Rectangle).

If you have chosen a menu command but haven't yet confirmed it, then a short description appears in the status bar.

Context menu

Shortcut: *[Shift]* + *[F10]*

Instead of using the menu bar for executing a command, you can use the right mouse button. The menu which then appears contains the most frequently used commands for a selected object or for the active editor. The choice of the available commands adapts itself automatically to the active window.

1.4.1.2.2 Project options

'Project' 'Options'

With this command the dialog box for setting options is opened. The options are divided into different categories. Choose the desired category on the left side of the dialog box by means of a mouse click or using the arrow keys and change the options on the right side.

An image of the options which are set for the current project, will be found in the Resources tab in component Workspace ↳ *Chapter 1.4.1.2.1.5 “Workspace” on page 199*.

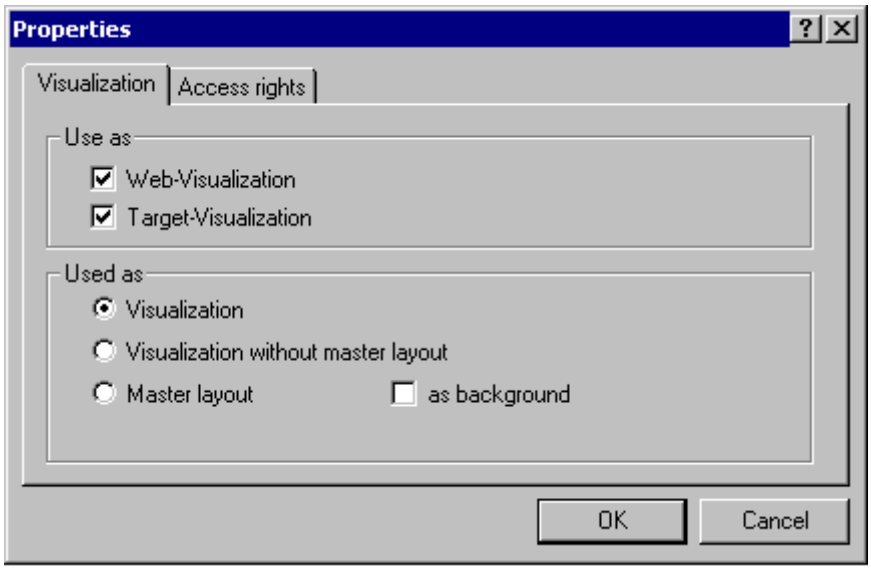
The settings amongst other things serve to configure the view of the main window. They are, unless determined otherwise, saved in the file "codesys.ini" and restored at the next startup.

You have at your disposal the following categories:

Category	Stored in CODESYS	Stored in project
Load & Save ↯ *Chapter 1.4.1.2.2.2 “Options for load & save” on page 201*	x	
User information ↯ *Chapter 1.4.1.2.2.3 “Options for user information” on page 203*	x	
Editor ↯ *Chapter 1.4.1.2.2.4 “Options for editor” on page 203*	x	
Desktop ↯ *Chapter 1.4.1.2.2.5 “Options for the desktop” on page 205*	x	
Color ↯ *Chapter 1.4.1.2.2.6 “Options for colors” on page 206*	x	
Directories ↯ *Chapter 1.4.1.2.2.7 “Options for directories” on page 207*	Cat. Common	Cat. Project
Log ↯ *Chapter 1.4.1.2.2.8 “Options for log” on page 208*	x	
Build ↯ *Chapter 1.4.1.2.2.9 “Options for build” on page 209*		
Passwords ↯ *Chapter 1.4.1.2.2.10 “Passwords” on page 211*		
Source download ↯ *Chapter 1.4.1.2.2.11 “'Source download'” on page 212*	x	
Symbol configuration ↯ *Chapter 1.4.1.2.2.12 “Options for 'Symbol configuration'” on page 214*	x	
Project Source Control ↯ *Chapter 1.4.1.2.2.13 “Options for 'Project source control'” on page 216*		x
Macros ↯ *Chapter 1.4.1.2.2.16 “Options for 'Macros'” on page 220*		x

Options for load & save

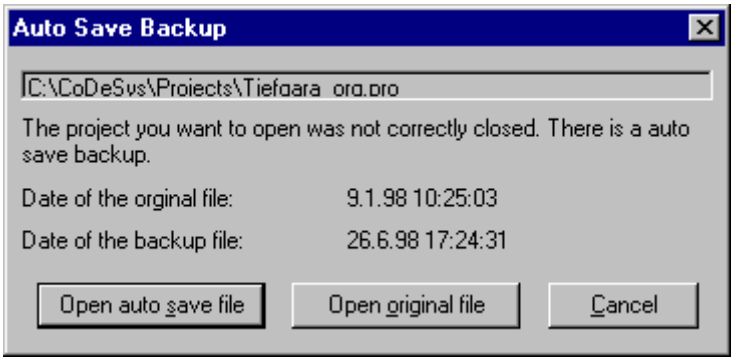
If you choose this category in the Options dialog box , then you get the following dialog box:



When activating an option, a check icon appears before the option.

Create Backup: a backup file is created at every save with the extension ".bak". Contrary to the *.asd-file (see below, 'Auto Save') this *.bak-file is kept after closing the project. So you can restore the version you had before the last project save.

Auto Save: While you are working, your project is saved according to a defined time interval (Auto Save Interval) to a temporary file with the extension ".asd" in the projects directory. This file is erased at a normal exit from the program. If for any reason Automation Builder is not shut down "normally" (e.g. due to a power failure), then the file will not get erased. When you open the file again the following message appears:



You can now decide whether you want to open the original file or the auto save file.

If a library *.lib is opened as project, a corresponding auto-save-file "*.asl" will be created.

Auto save before compile: The project will be saved before each compilation. In doing so a file with the extension ".asd" resp. ".asl" will be created, which behaves like described above for the option 'Auto Save'.

Ask for project info: When saving a new project or saving a project under a new name, the project info is automatically called. You can visualize the project info with the command 'Project' 'Project info' and also process it.

Auto Load: At the next start the last open project is automatically loaded. Loading of a project at the start of Automation Builder can also take place by entering the project in the command line.

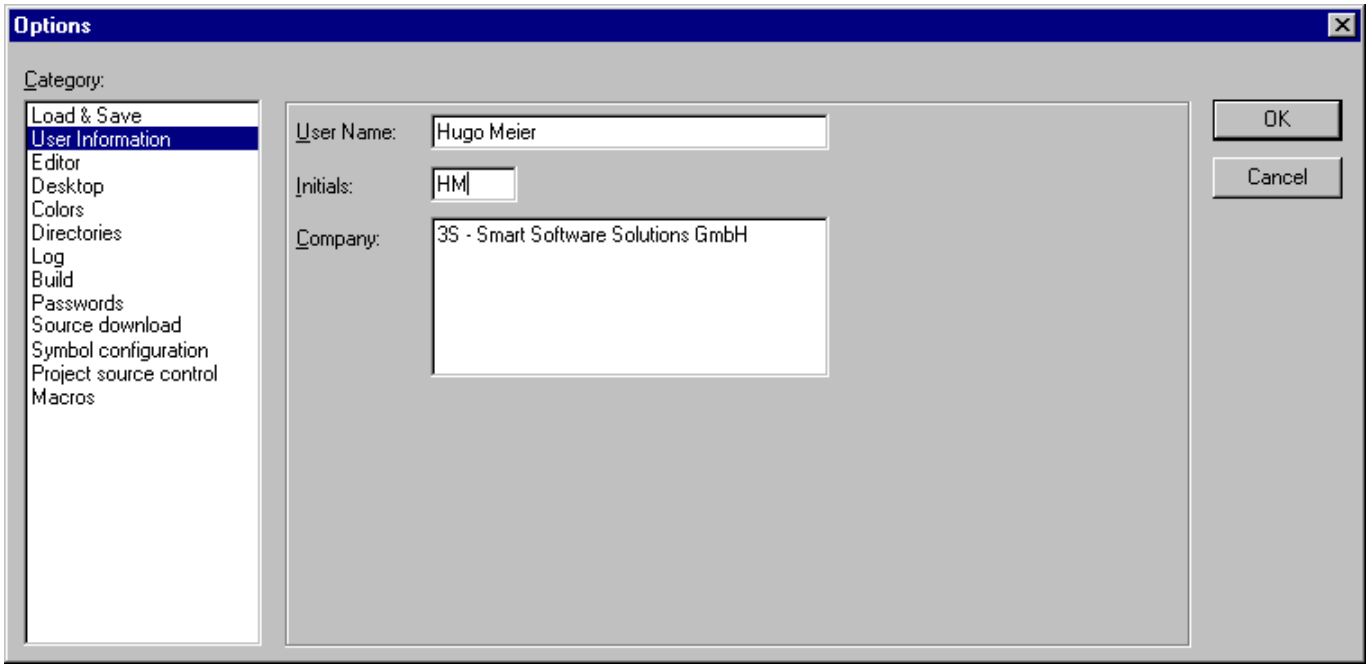
Remind of boot project on exit: If the project has been modified and downloaded without creating a new boot project since the last download of a boot project, then a dialog will advise the user before leaving the project: "No boot project created since last download. Exit anyway ?".

Save ENI credentials: User name and Password, as they might be inserted in the Login dialog for the ENI data base, will be saved. Concerning the access data, entered once by the user at 'Open project from source code manager' ('File' 'Open') in this case additionally username and password will be saved in the codesys.ini file.

The settings will be stored in CODESYS.

Options for user information

If you choose this category in the Options dialog box, then you get the following dialog box:

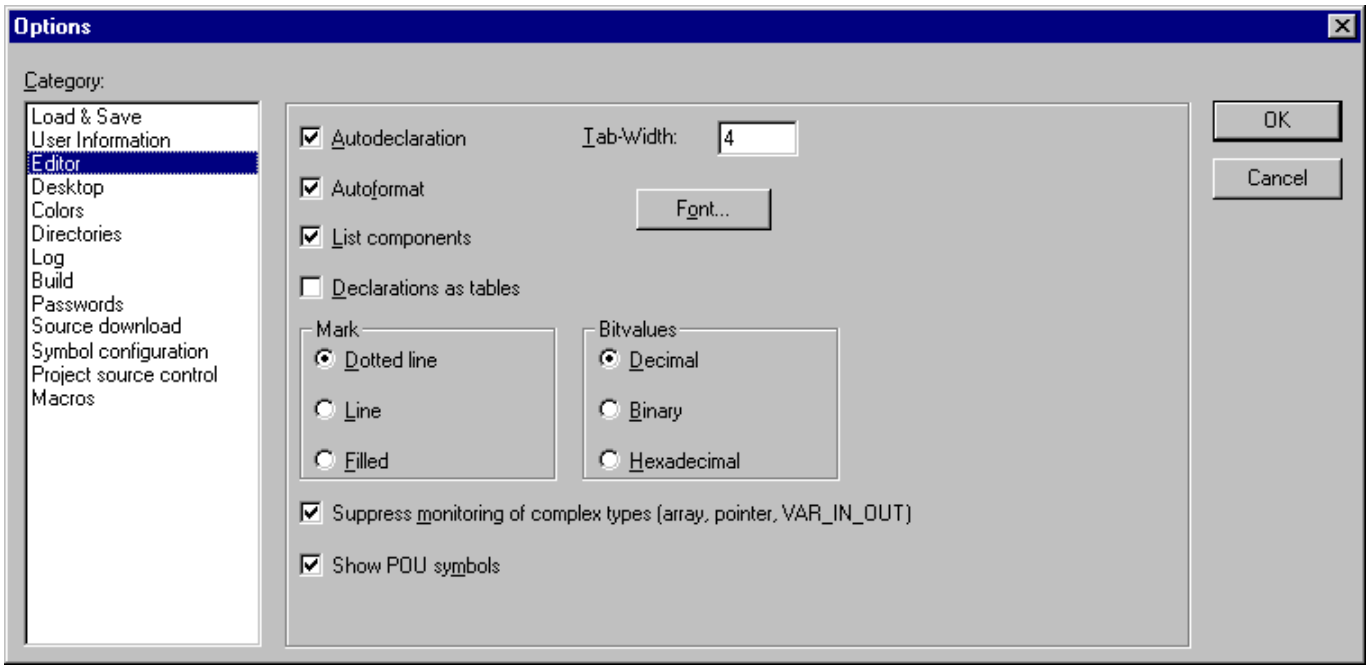


To User information belong the name of the user, his initials and the company for which he works. Each of the entries can be modified.

The settings will be stored in CODESYS.

Options for editor

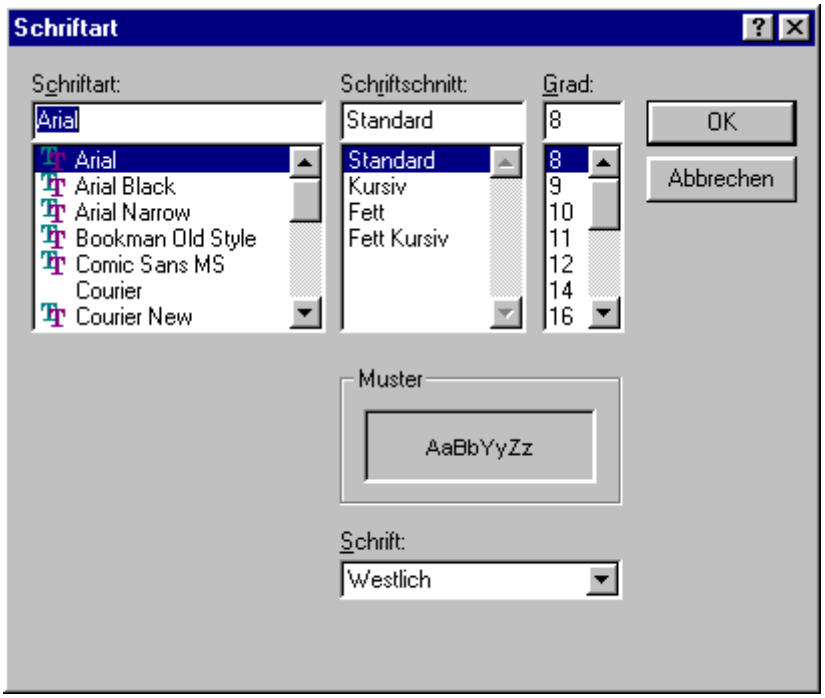
If you choose this category in the *“Options”* dialog box, then you get the following dialog box:



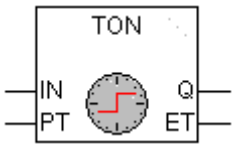
You can make the following settings for the Editors:

- Autodeclaration: If this option is activated , then after the input of a not-yet-declared variable a dialog box will appear in all editors with which this variable can be declared.
- Autoformat: If this option is activted, then automatic formatting is executed in the IL editor and in the declaration editor. When you finish with a line, the following formatting is made: 1.Operators written in small letters are shown in capitals; Tabs are inserted to that the columns are uniformly divided.
- List components: If this option is activated, then the Intellisense functionality will be available to work as an input assistant. This means that if you insert a dot at a position where a identifier should be inserted, then a selection list will open, offering all global variables which are found in the project. If you insert the name of a function block instance, then you will get a selection list of all inputs and outputs of the instanced function block. The Intellisense function is available in editors, in the Watch- and Receiptmanager, in visualizations and in the Sampling Trace.
- Declarations as tables: If this option is activated, then you can edit variables in a table instead of using the usual declaration editor. This table is sorted like a card box, where you find tabs for input variables, output variables local variables and in_out variables. For each variable there are edit fields to insert Name,Address, Type, Initial and Comment.
- Tab-Width: In the field Tab-Width in the category Editor of the Options dialog box you can determine the width of a tab as shown in the editors. The default setting is four characters, whereby the character width depends upon the font which is chosen.
- Font: By clicking on the button Font in the category Editor of the Options dialog box you can choose the font in all editors. The font size is the basic unit for all drawing operations. The choice of a larger font size thus enlarges the printout, even with each editor.

  After you have entered the command, the font dialog box opens for choosing the font, style and font size.



- Mark: When choosing Mark in the Editor category in the Options dialog box you can choose whether the current selection in your graphic editors should be represented by a dotted rectangle (Dotted), a rectangle with continuous lines (Line) or by a filled-in rectangle (Filled). In the last case the selection is shown inverted.
- Bitvalues: When choosing Bitvalues in the category Editor of the Options dialog box you can choose whether binary data (type BYTE, WORD, DWORD) during monitoring should be shown Decimal, Hexadecimal, or Binary.
- Suppress monitoring of complex types (Array, Pointer, VAR_IN_OUT): If this option is activated, complex data types like arrays, pointers, VAR_IN_OUTs will not get displayed in the monitoring window in online mode.
- Show POU symbols: If this option is activated, in the module boxes which are inserted to a graphic editor, additionally symbols will get displayed, if those are available in the library folder as bitmaps. The name of the bitmap-file must be composed of the name of the module and the extension ".bmp". Example: For module TON there is a symbol file TON.bmp available. The box will be displayed as follows:



The settings will be stored in CODESYS.

Options for the desktop

When an option is activated, a check appears in front of it.

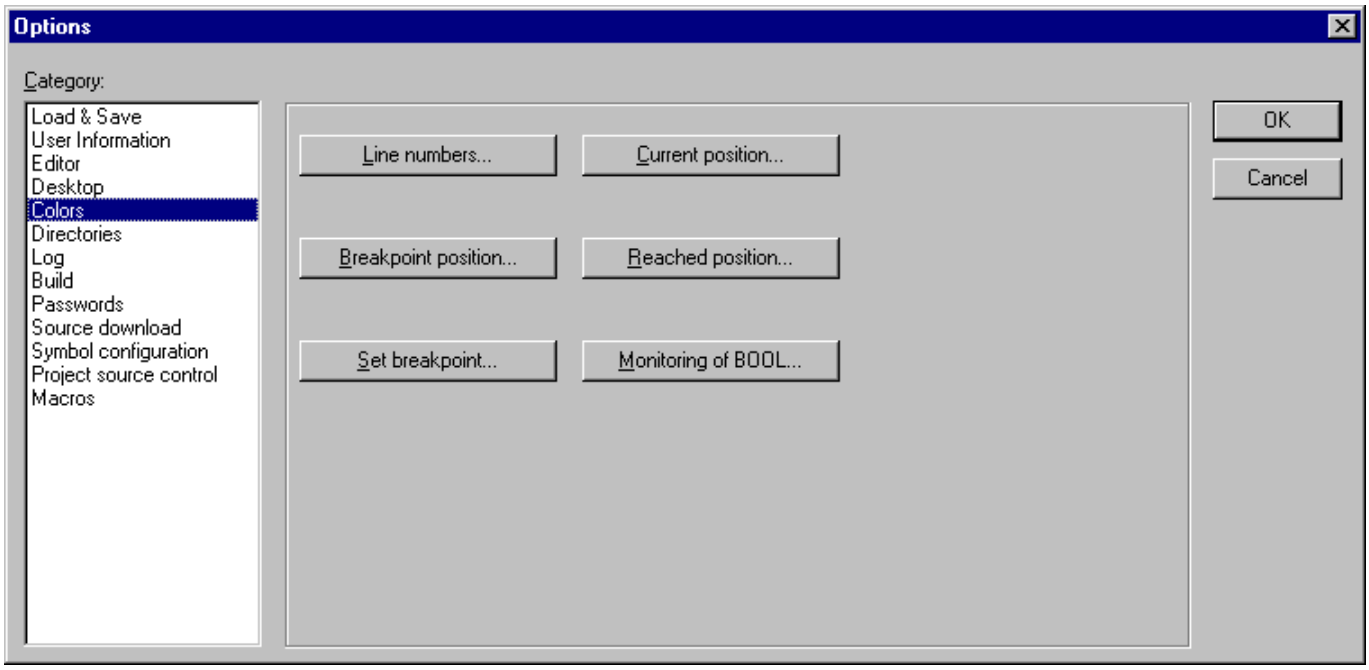
- Tool bar: The tool bar with the buttons for faster selection of menu commands becomes visible underneath the menu bar.
- Status bar: The status bar at the lower edge of the main window becomes visible.

- Online in Securitymode: In Online mode a dialog box appears with the confirmation request whether the command should really be executed. If supported by the target system, an extended dialog might be available when you want to load the actual project from the programming system to the PLC If there is already a project on the PLC, this dialog will display the project information of that project as well as the information of the project currently to be loaded. This project information also will be available in case of creating a boot project when there is already one on the PLC. This option is saved with the project.
- Query communication parameters before login: As soon as the command 'Online' 'Login' is executed, first the communication parameters dialog will open. To get in online mode you must first close this dialog with OK.
- Do not save communication parameters in project: The settings of the communication parameters dialog ('Online' 'Communication Parameters') will not be saved with the project.
- Show print area margins:In every editor window, the limits of the currently set print range are marked with red dashed lines. Their size depends on the printer characteristics (paper size, orientation) and on the size of the "Content" field of the set print layout (menu: 'File" "Documentation Settings").
- F4 ignores warnings:After compilation, when F4 is pressed in a message window, the focus jumps only to lines with error messages; warning messages are ignored.
- MDI representation: Per default this option (Multiple-Document-Interface) is activated and thus several windows can be opened at the same time. If the option is deactivated (SDI mode) only one window can be opened and will be displayed in full screen mode. Exception: The action of a program and the program itself can be displayed side by side even in MDI mode.
- Communications timeout [ms]: for standard communication services: Time span in milliseconds, after which the communication to the target system will be terminated if no more activity is detected. Possible values: 1-10000000 ms.
- Communications timeout for download [ms]: for long lasting communication services (program download, file up- and download, boot project creation and check): Time span in milliseconds after which the communication to the target system will be terminated if no more activity is detected (Download Wait Time). Possible values: 1-10000000 ms.
- XML-Encoding: The format for XML-exports can be selected. The default setting is "ISO 8859-1". This concerns the communication via ENI, Message Interface and COM Automation Interface, as well as each user-triggered XML-export. An exception is the XML-export of the Licensing Manager.
- Language: Define here, in which language the menu and dialog texts should be displayed.

The settings will be stored in CODESYS.

Options for colors

If you choose this category in the Options dialog box , then you get the following dialog box:



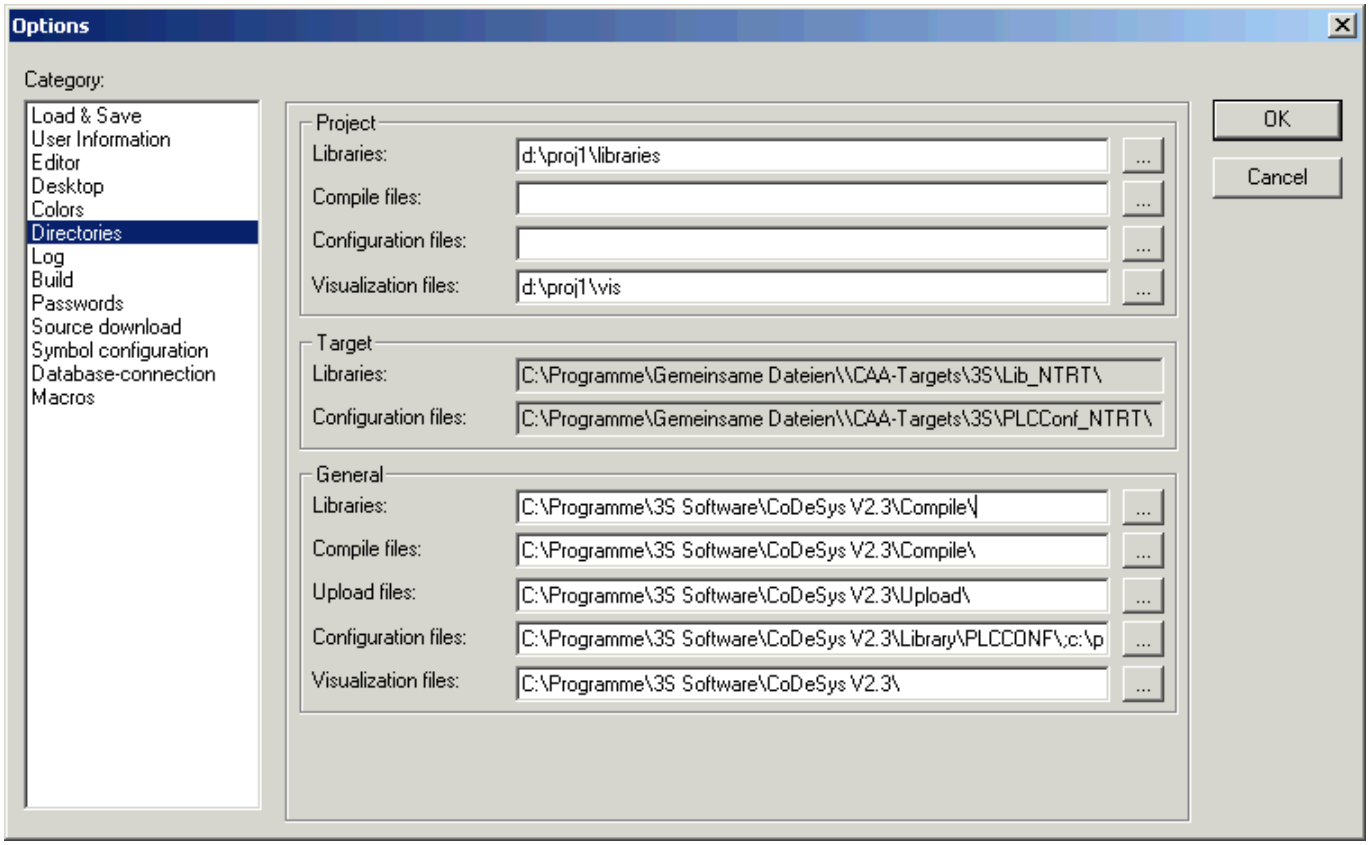
You can edit the default color setting of CODESYS. You can choose whether you want to change the color settings for Line numbers (default presetting: light gray), for Breakpoint positions (dark gray), for a Set breakpoint (light blue), for the Current position (red), for the Reached Positions (green) or for the Monitoring of Boolean values (blue).

If you have chosen one of the indicated buttons, the dialog box for the input of colors opens.

The settings will be stored in CODESYS.

Options for directories

If you choose this category in the Options dialog box, then you get the following dialog box:



Directories can be entered in the Project and Common areas for CODESYS to use in searching for Libraries, controller Configuration and Visualization files (bitmaps, XML file for dynamic texts etc.) iles, as well as for storing Compile and source-Upload files. (Compile files for example are map- and list-files, not however e.g. symbol files ! The latter will be saved in the project directory.) If you activate the button (...) behind a field, the directory selection dialog opens. For library and configuration files, several paths can be entered for each, separated by semicolons ";".

> *Please regard: Library paths can be entered based on the project file's path by prefixing a dot ".". If e.g. ".\libs" is entered, the libraries will be searched in 'C:\programs\projects\libs', if the current project is in 'C:\programs\projects'. For information on library paths see also: 'Insert' 'Additional Library'.*
>
> *Please regard: Do not use empty spaces and special characters except for "_" in the directory pathes.*

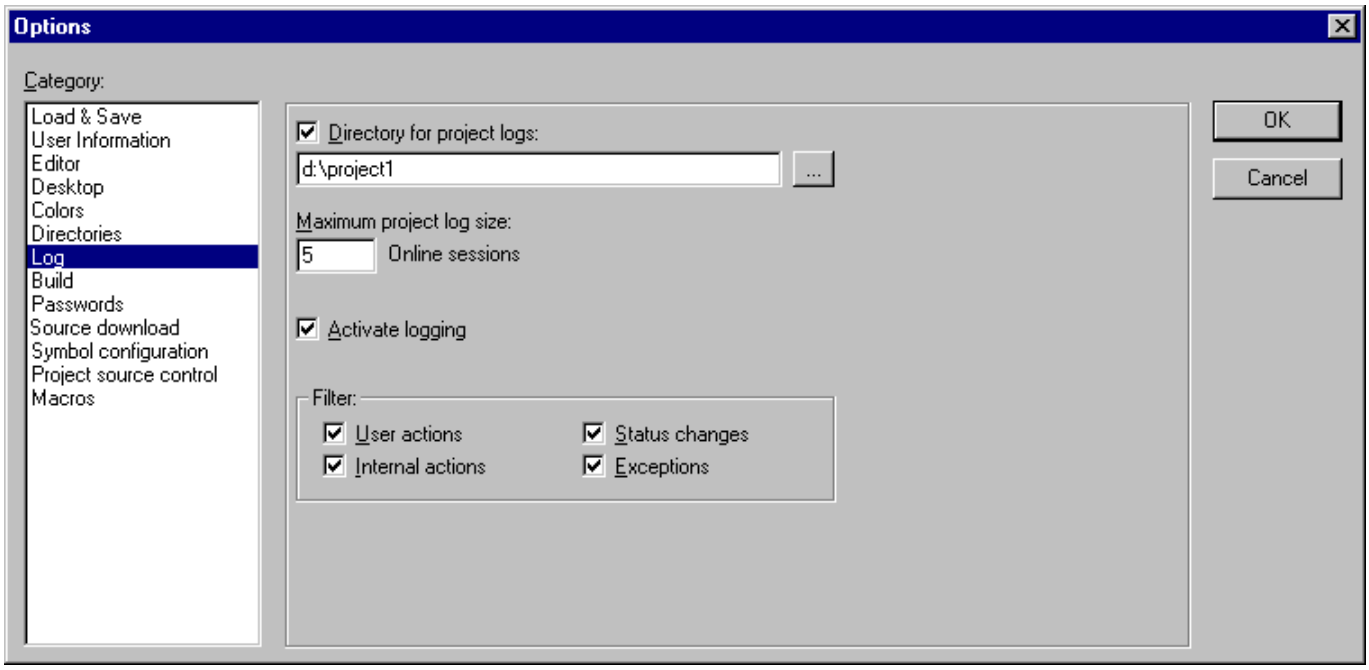
The Target area just displays the directories for libraries and configuration files set in the target system, e.g. through entries in the Target file. These fields cannot be edited, but an entry can be selected and copied (right mouse button context menu).

CODESYS generally searches first in the directories entered in 'Project', then in those in 'Target' (defined in the Target file), and finally those listed under 'Common'. If two files with identical names are found, the one in the directory that is browsed first will be used.

> *The settings for area Common will be stored in CODESYS, those for area Project in the project..*

Options for log

If you choose this category in the Options dialog box, then you get the following dialog box:



In this dialog, you can configure a file that acts as a project log, recording all user actions and internal processes during Online mode processing (see also: Log).

If an existing project is opened for which no log has yet been generated, a dialog box opens which calls attention to the fact that a log is now being set up that will receive its first input after the next login process.

The log is automatically stored as a binary file in the project directory when the project is saved. If you prefer a different target directory, you can activate the option Directory for project logs: and enter the appropriate path in the edit field. Use the button to access the "Select Directory" dialog for this purpose:

The log file is automatically assigned the name of the project with the extension .log. The maximum number of Online sessions to be recorded is determined by Maximum project log size. If this number is exceeded while recording, the oldest entry is deleted to make room for the newest.

The Log function can be switched on or off in the Option field Activate logging.

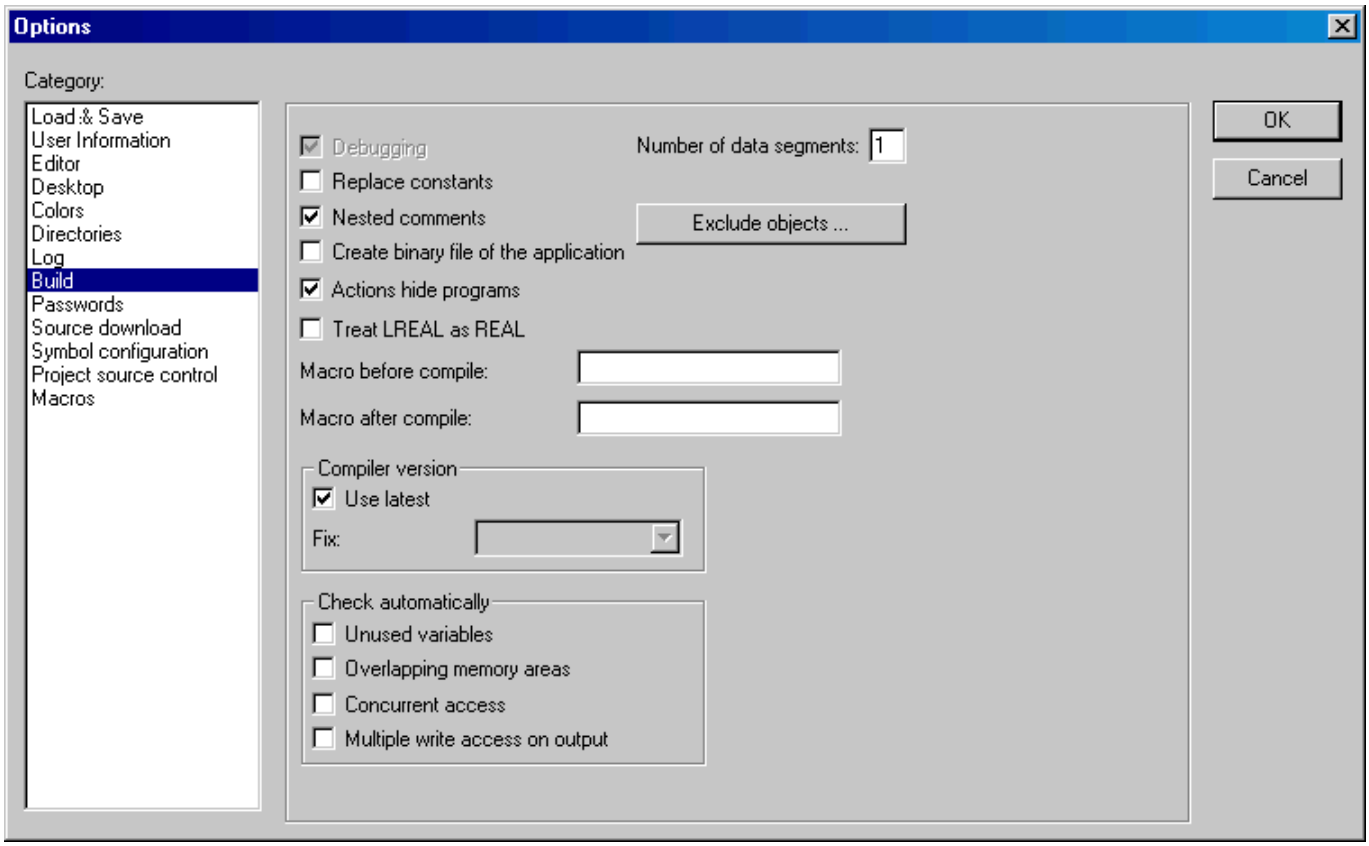
You can select in the Filter area which actions are to be recorded: User actions, Internal actions, Status changes, Exceptions. Only actions belonging to categories checked here will appear in the Log window and be written to the Log file.

The Log window can be opened with the command 'Window' 'Log'.

The settings will be stored in CODESYS.

Options for build

If you choose this category in the Options dialog box , then you get the following dialog box:



- Debugging: It depends on the target descriptions whether this option can be activated/deactivated by the user resp. which is the given setting . If it is activated, additional debugging code is created, that is the code can become considerably larger. The debugging code is needed in order to make use of the debugging functions (e.g. breakpoints). When you switch off this option, project processing becomes faster and the size of the code decreases. The option is stored with the project.
- Replace constants: The value of each constant of scalar type (thus not for strings, arrays and structures) is loaded directly, and in Online mode the constants are displayed in green. Forcing, writing and monitoring of a constant is then no longer possible. If the option is deactivated, the value is loaded into a storage location via variable access (this does in fact allow writing the variable value, but implies longer processing time).
- Nested comments: Comments can be placed within other comments.

  Example:

  (*
  a:=inst.out; (* to be checked *)
  b:=b+1;
  *)

  Here the comment that begins with the first bracket is not closed by the bracket following "checked," but only by the last bracket.

  Attention: Currently this option must be used carefully: If the setting in the project does not match the setting chosen in a library which also has been created in CODESYS and now is used is the project, compiler errors will occur, which are hard to interpret by the user and often cannot be cleared!
- Create binary file of the application: A binary image of the generated code (boot project) is created in the project directory during compilation. File name: <project_name>.bin. By comparison, the command *“Online ➔ Create boot project”* sets up the boot project on the controller *Chapter 1.4.1.2.6.25 “'Online' 'Create boot project'” on page 291*.
- Actions hide programs: This option is activated per default, when a new project is created. It means: If a local action has the same name like a global variable or a program, the following hierarchy is valid: local variable before local action before global variable before program.

  Regard: If an existing project is opened, which has been created with a previous version of CODESYS, the option will be deactivated per default. Thus the previously vlid hierarchy (local varaible before global variable before program before local action) can be kept.

- Treat LREAL as REAL: If this option is activated, (availability depends on the runtime system, default: not activated), the compile will handle LREAL values as REAL values. This can be used for creating platform independent projects.
- Number of data segments: Here you define how many memory segments should be allocated in the PLC for the project data. This space is needed to make possible online changes even if new variables have been added. If during compilation you get the message "Out of global data memory...", enter a higher number. In this regard local program variables will be handled like global variables ↳ *Chapter 1.4.1.2.6.2 “'Online' 'Login'” on page 279*.
- Exclude objects: This button opens the dialog Exclude objects from build: In the tree of project components select those POUs which should not be regarded during compilation and activate option Exclude. Hereupon the excluded POUs will be displayed green-colored in the selection tree. Press button Exclude unused, if you just want to get displayed those POUs which are currently used in the program. Regard that a single object which is selected in the Object Organizer can also be excluded from build by using the command 'Exclude from build' from the context menu.
- Compiler Version: Here you define the compiler version to be used. CODESYS versions after V2.3.3 (version, service pack, patch) will include besides the actual compiler version also the previous compiler versions (back to V2.3.3). If you want to get the project compiled with the latest compiler version in any case, activate option Use latest. In this case however it will be checked whether the currently opened programming system is also of that version. If this is not true, the compiler version matching the actually used programming system version will be used!. If the project should be compiled with a specific version, define this via the selection list at Fix.

  In order to exert control over the compilation process you can set up two macros:

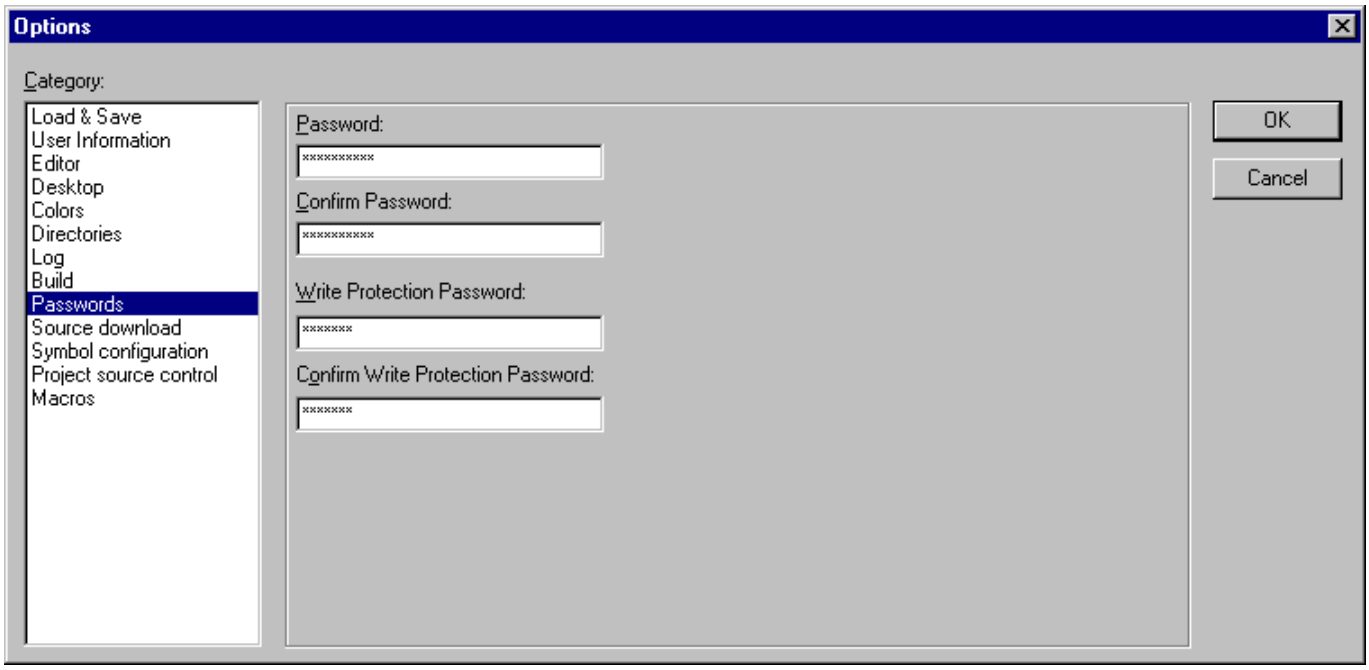
  The macro in the Macro before compile field is executed before the compilation process; the macro in the Macro after compile field afterwards. The following macro commands can not, however, be used here: file new, file open, file close, file save as, file quit, online, project compile, project check, project build, project clean, project rebuild, debug, watchlist.
- Check automatically: In order to get the semantic correctness checked at each compilation of the project the following options can be activated:
  – Unused variables
  – Overlapping memory areas
  – Concurrent access
  – Multiple write access on output

  The results will be displayed in the message window. These checks also can be initiated by the respective commands of the 'Check' submenu in the 'Project' menu. If supported by the target system, negative check results will produce compiler errors.

All entries in the Build Options dialog are stored with the project.

Passwords

If you choose this category in the Options dialog box, then you get the following dialog box:



To protect your files from unauthorized access use a password to protect against your files being opened or changed.

Enter the desired password in the field Password. For each typed character an asterisk (*) appears in the field. You must repeat the same word in the field Confirm Password. Close the dialog box with OK. If you get the message:

```
"The password does not agree with the confirmation",
```

then you made a typing error during one of the two entries. In this case repeat both entries until the dialog box closes without a message.

If you now save the file and then reopen it, then you get a dialog box in which you are requested to enter the password. The project can then only be opened if you enter the correct password.

Along with the opening of the file, you can also use a password to protect against the file being changed. For this you must enter a password in the field Write Protection Password and confirm this entry in the field underneath.

A write-protected project can be opened without a password. For this, press the button Cancel, if a message is prompted to enter the write protection password when opening a file. Now you can compile the project, load it into the PLC, simulate, etc., but you cannot change it.

The passwords are saved with the project.

In order to create differentiated access rights you can define user groups and 'Passwords for user groups').

Additionally regard the extended possibilities to protect a project by encryption which for example can help to protect a library from getting used without having entered a key.

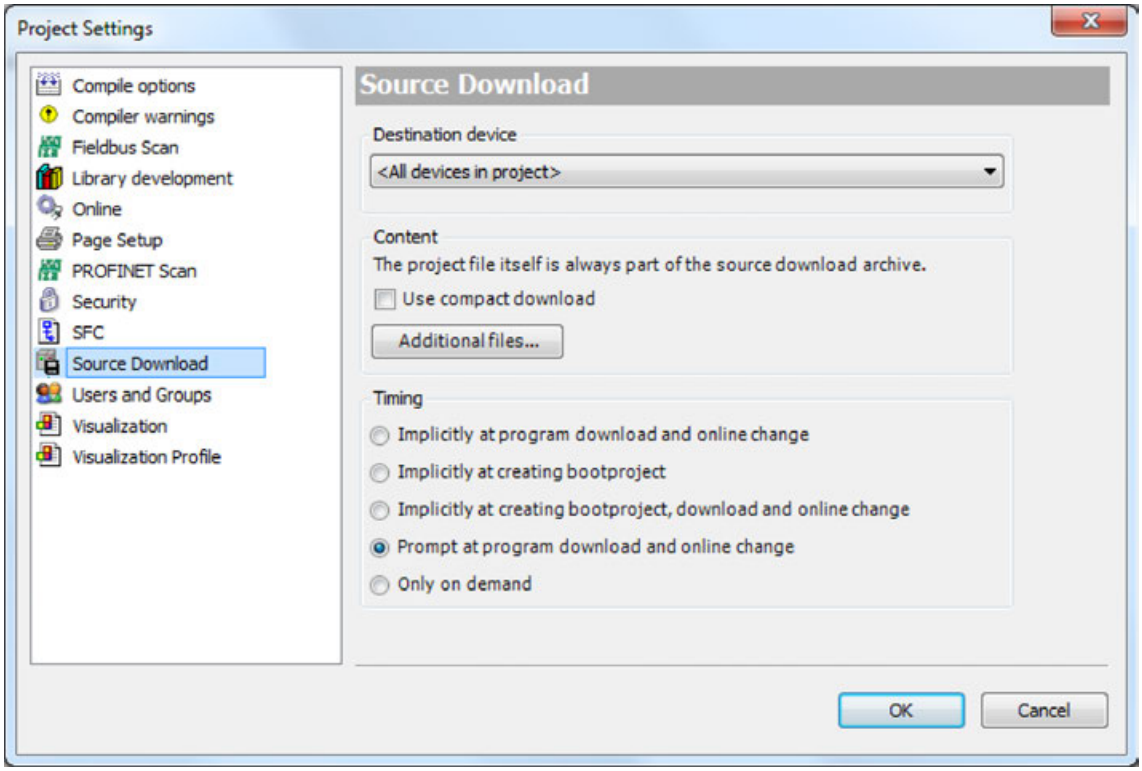
The settings will be stored in the project.

'Source download'

The user can configure a source code download (i.e. the project archive of the open project) to an memory card of any V2 PLC defined in the project. This ensures that the project on a PLC matches the current application, i.e. for maintenance purposes the project can be uploaded directly from the PLC.

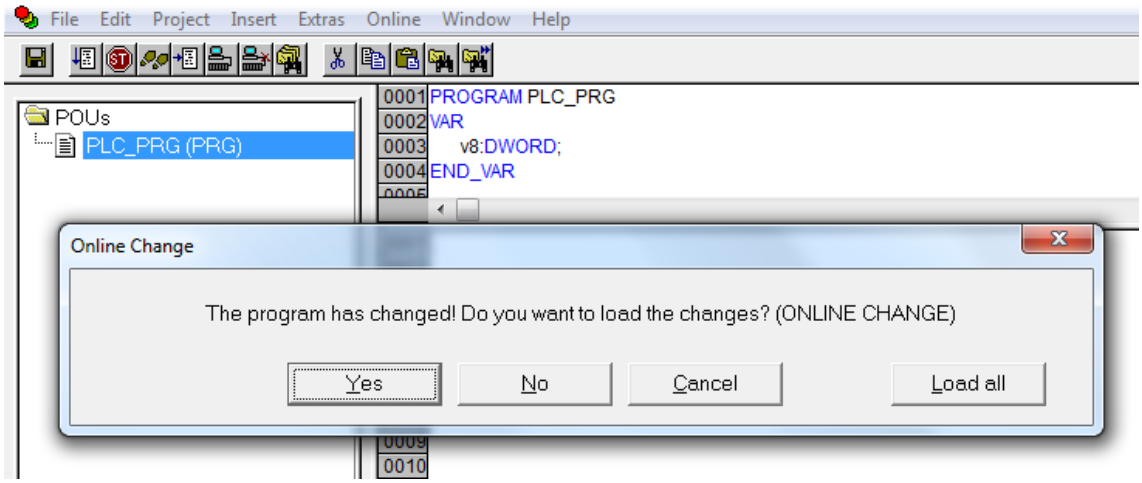
The automatic source code download ensures that the V2 PLC always has the up-to-date project archive on its memory card. With each online change or download of the application program (that can be triggered via Automation Builder or via CODESYS editor) the Automation Builder will send the current project archive to the PLCs memory card.

Enable one of the given project options in the 'Timing' section to trigger an automatic source code download on each online change or application download.



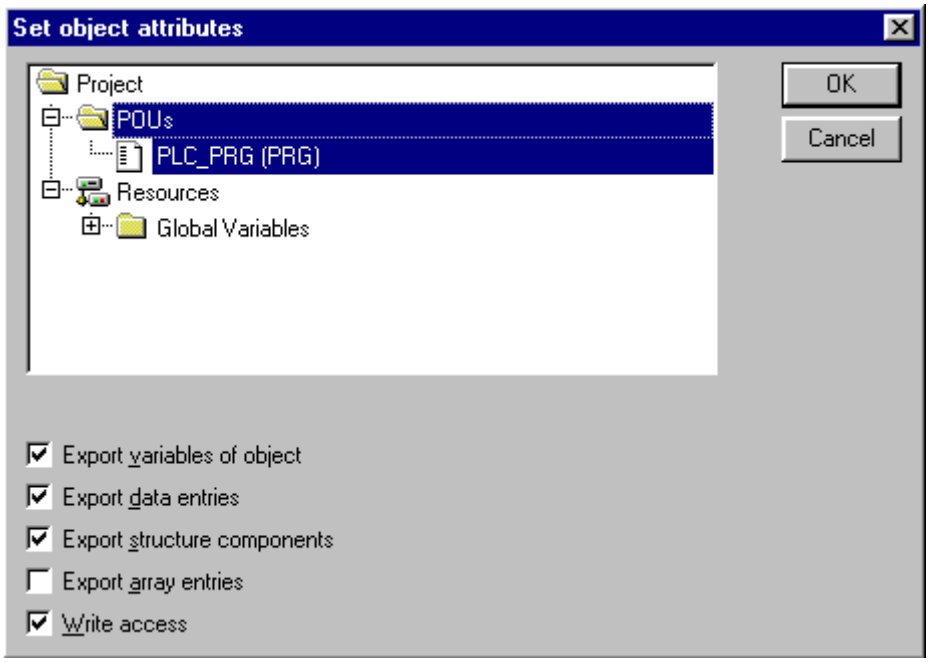
- *The option ‘Only on demand’ will never trigger any automatic download.*
- *The option ‘Prompt at program download and online change’ will prompt a dialog before downloading the source code. Only one dialog is prompted, even if multiple consecutive actions in CODESYS might have triggered a download. By this, a user can finish configuring all required changes in the application program before Automation Builder finally downloads all changes to the PLCs memory card.*
- *If no memory card is inserted in the PLC, the download fails with an error message.*

A source code download can be triggered from the CODESYS editor via online login after any change in the application program:



With a source code download always the complete project archive is downloaded. This might lead to inconsistencies between the applications and the project archive if an AC500-S device is envolved. For example, if there are recent changes in a non-safety PLC that have not been downloaded yet, while performing a download to the AC500-S PLC.

Options for 'Symbol configuration'



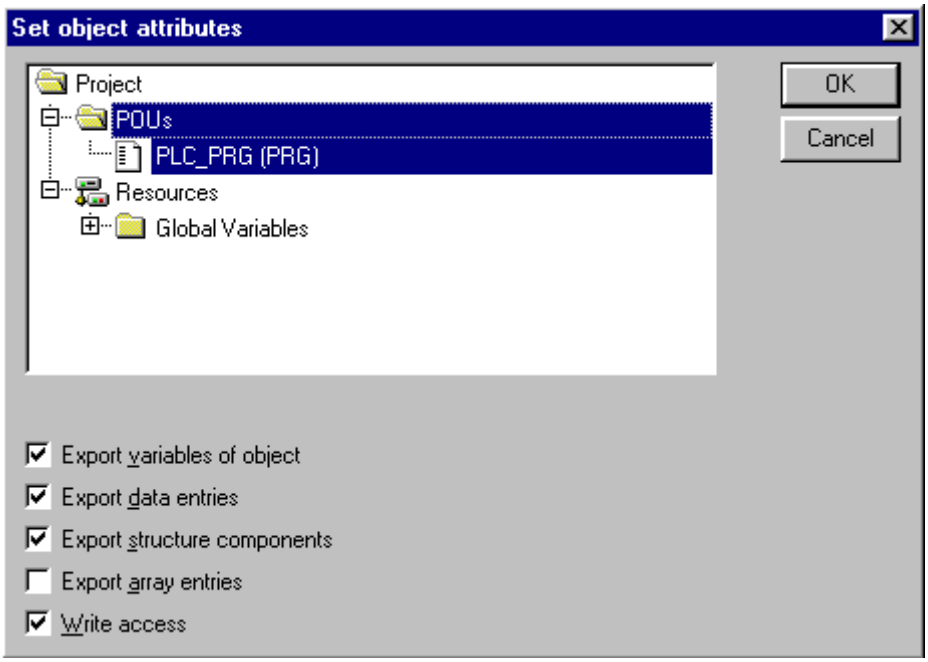
The dialog presented here is used for configuring the symbol file which will be created during each compilation of the project. The symbol file is created as a text file <project name>.sym respectively as a binary file <project name>.sdb (the format is depending on the used gateway version) in the project directory. The file is needed for data exchange with the controller via the symbolic interface and will be used for that purpose e.g. by OPC- or GatewayDDE-Server.

If the option Create symbol entries is activated, then symbol entries for the project variables will be automatically written to the symbol file. Otherwise only version info about file and project is contained.

If additionally the option Dump XML symbol table is activated, then also an XML file containing the symbol information will be created in the project directory. It will be named <project name>.SYM_XML.

Regard the following when configuring the symbol entries:

- If option 'Symbol config from INI-file' is activated in the target settings, then the symbol configuration will be read from the codesys.ini file or from another ini-file which is defined there. (In this case the dialog 'Set object attributes' cannot be edited.)
- If option 'Symbol config from INI-file' is not activated, the symbol entries will be generated in accordance with the settings you can make in the 'Set object attributes' dialog. You get there using the Configure symbol file button:



Use the tree-structured selection editor to mark the variables which should be entered in the symbol file. For this purpose you can select a POU's entry (e.g. Global Variables) which automatically will mark all variables belonging to this POU, or you can select particular variables. For the selected set of entries then activate the desired options in the lower part of the dialog box by mouse-clicks on the corresponding option boxes. Activated options are displayed checked. The following options can be set:

Export variables of object: The variables of the selected object are exported into the symbol file.

The following options can take effect only if the Export variables of object option is activated:

Export data entries: Entries for access to the global variables are created for object's structures and arrays.

Export structure components: An individual entry is created for each variable component of object's structures.

Export array entries: An individual entry is created for each variable component of object's arrays.

Write Access: Object's variables may be changed by the OPC server.

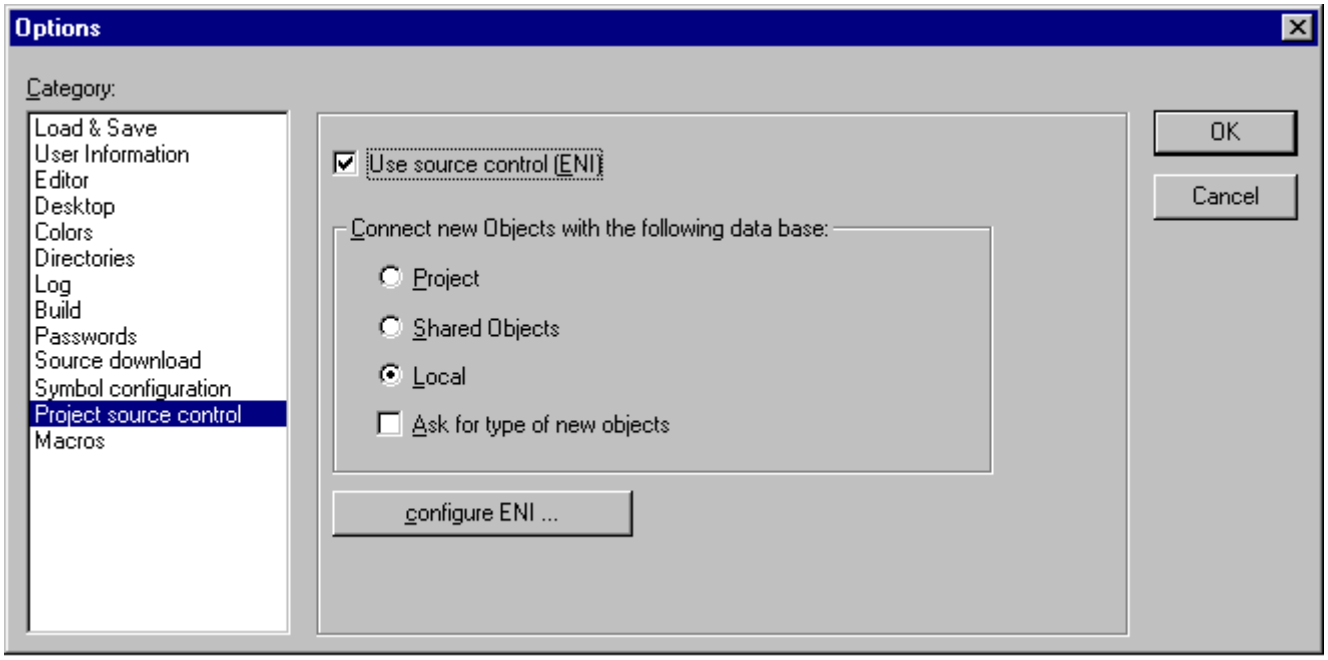
Once the option settings for the currently selected variables are complete, other POUs can be also be selected - without closing the dialog before - and given an option configuration. This can be carried out for any desired number of POU selections, one after the other.

When the dialog box is closed by selecting OK, all configurations carried out since the dialog box was opened are applied.

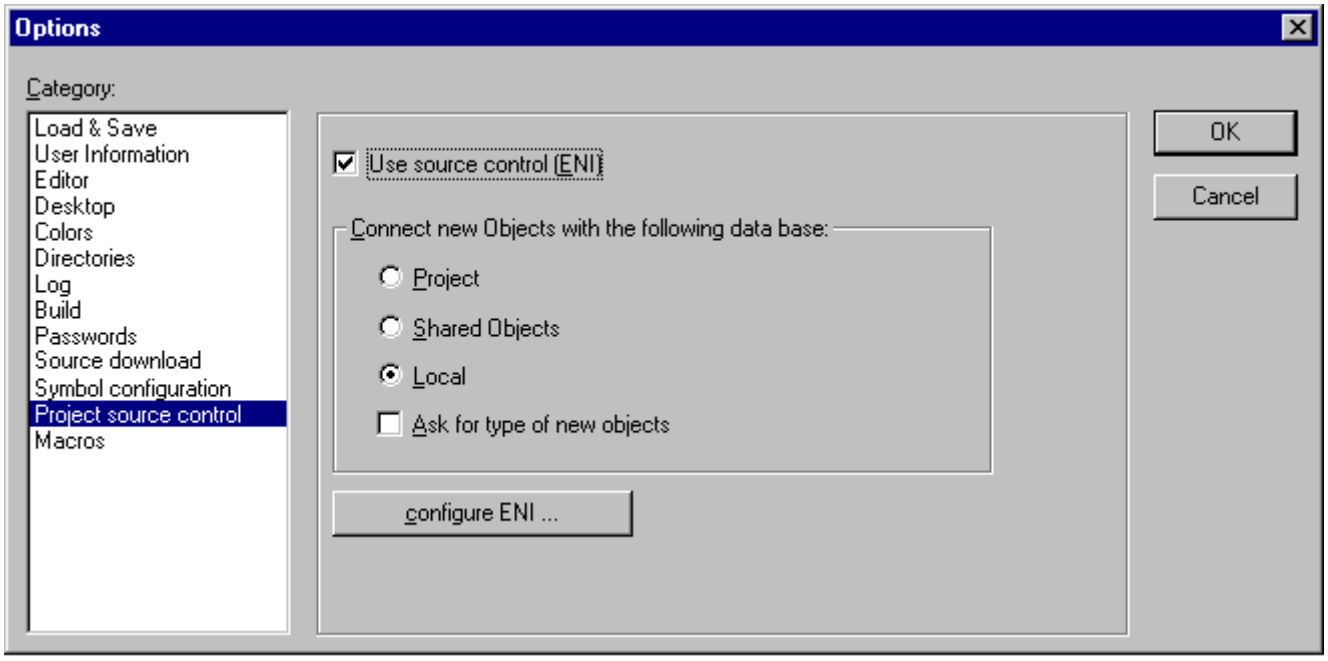
Note: Regard the possibility of using pragmas in the declaration of a variable, which define that the variable is taken to the symbol file with restricted access or that it is excluded from the symbol file.

The settings will be stored in CODESYS.

Options for 'Project source control'



This dialog is used to define whether the project should be managed in a project data base and to configure the ENI interface correspondingly.



Use source control (ENI): Activate this option, if you want to access a project data base via the ENI Server in order to administer all or a selection of POUs of the project in this data base. Preconditions: ENI Server and data base must be installed and you must be registered as an user in the database. See also the documentation for the ENI-Server resp. in chapter 'ENI'.

If the option is activated, then the data base functions (Check in, Get last version etc.) will be available for handling the project POUs. Then some of the data base functions will run automatically like defined in the options dialogs, and in the menu 'Project' 'Data Base Link' you will find the commands for calling the functions explicitly. Besides that a tab 'Data base-connection' will be added in the dialog Properties, where you can assign a POU to a particular data base catetory.

Connect new objects with the following data base:

Here you set a default: If a new object is inserted in the project ('Project' 'Object' 'Add'), then it will automatically get assigned to that object category which is defined here. This assignment will be displayed in the object properties dialog ('Project' 'Object' 'Properties') and can be modified there later. The possible assignments:

- Project: The POU will be stored in that data base folder which is defined in the dialog ENI configuration/Project objects in the field 'Project name'.
- Shared Objects: The POU will be stored in that data base folder which is defined in the dialog ENI configuration/Shared objects in the field 'Project name'.
- Local: The POU will not be managed in a ENI data base, but only will be stored locally in the project.

Besides 'Project objects' and 'Shared objects' there is a third data base category 'Compile files' for such objects which are not created until the project has been compiled. Therefore this category is not relevant for the current settings.

Ask for type of new objects: If this option is activated, then whenever a new object is added to the project, the dialog 'Object' 'Properties' will open, where you can choose to which of the three object categories mentioned above the POU should be assigned. By doing so the standard setting can be overwritten.

configure ENI: This button opens the first of three ENI configuration dialogs:

Each object of a project, which is determined to get managed in the ENI data base, can be assigned to one of the following data base categories: 'Project objects', 'Shared objects' or 'Compile files'. For each of these categories a separate dialog is available to define in which data base folder it should be stored and which presettings should be effective for certain data base functions:

- *Chapter 1.4.1.2.2.14 “Options for project objects and shared objects regarding the project data” on page 217*
- *Chapter 1.4.1.2.2.15 “Options for compile files regarding the project data base” on page 220*

Each object will be stored also locally (with project) in any case.

The dialog will open one after the other if you are doing a primary configuration. In this case a Wizard (Button Next) will guide you and the settings entered in the first dialog will be automatically copied to the other ones, so that you just have to modify them if you need different parameter values.

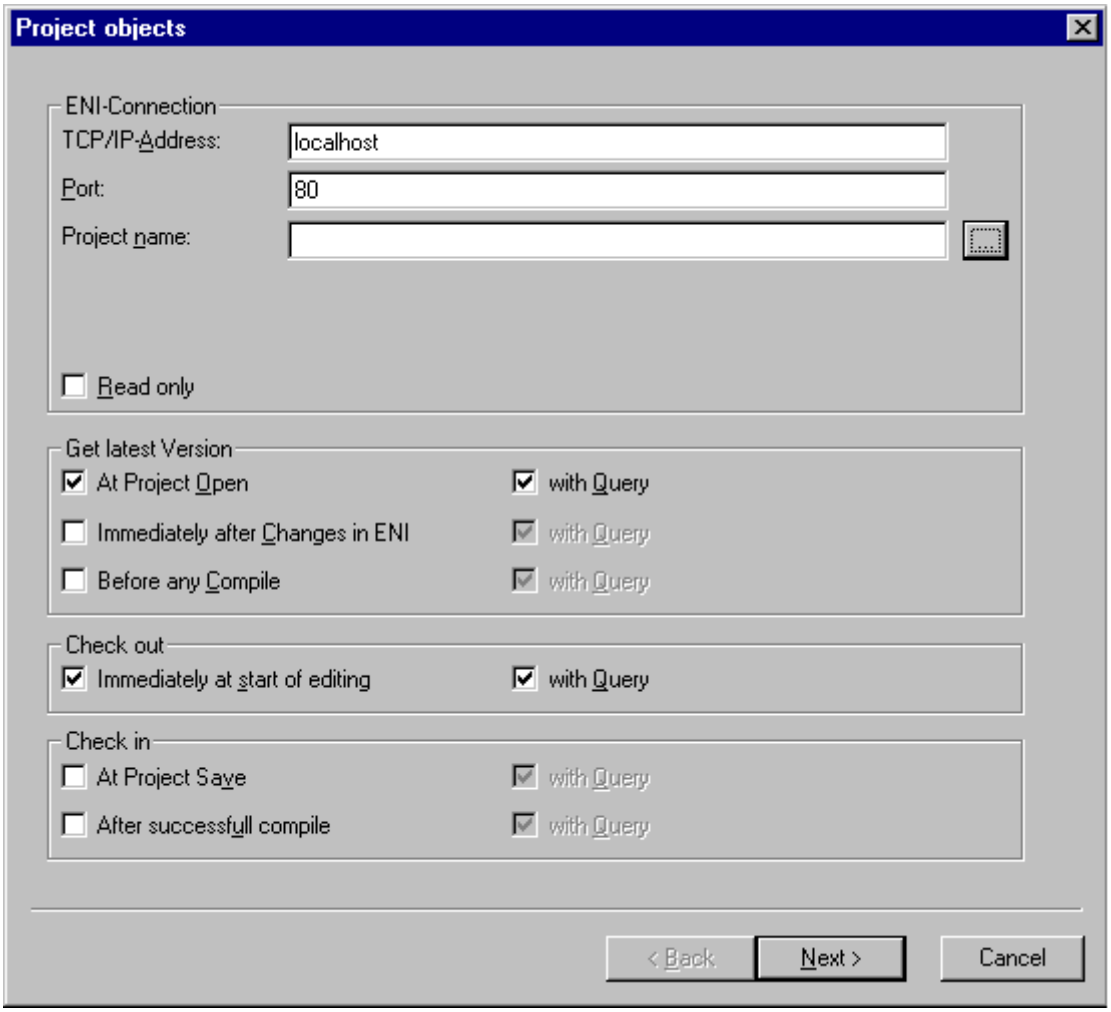
If you want to modify an existing configuration, then the three dialogs are combined in one window (three tabs).

If you have not yet logged in successfully to the data base before, then the Login dialog will be opened automatically.

The settings will be stored in the project.

Options for project objects and shared objects regarding the project data

These dialogs are part of the configuration of the project data base options ('Project' 'Options' 'Project source control'). Here you define the access parameters for the data base categories 'Project objects' und 'Shared objects'. Both dialogs contain the same items. (A third dialog is available for the configuration of the access to the data base category Compile files.



ENI-Connection

TCP/IP-Address:	Address of the computer where the ENI-Server is running
Port:	Default: 80; must be the same as set in the configuration parameters of the ENI Server
Project name:	Name of the data base folder where the objects of this category should be stored. Press button ... to open a folder tree of the already existing data base projects. If the desired folder already exists, you can select it in this tree and it will be entered in the 'Project name' edit field. If you had not logged in to the ENI Server until you try to open the folder tree by button ..., then you will first get the Login dialog where you must enter 'User name' and 'Password' as defined in your ENI user account to get access to the three data base categories.
Read only	If this option is activated, then only read access is possible to the above defined data base folder.

Get latest version

The data base function 'Get latest Version' (Menu 'Project' 'Data Base Link' copies the actual version of POUs from the above defined data base folder to the currently opened project, whereby the local version of objects will be overwritten. This will be done automatically for all objects, for which the version found in the data base differs from that in the project, as soon as one of the chosen timing conditions will meet. Choose the options by setting a check mark:

At Project Open	As soon as the project is opened in CODESYS
Immediately after Changes in ENI	As soon as a newer version of the POU is checked in to the data base (e.g. by another user); then the POU will be updated in the current project immediately and an appropriate message will pop up.
Before any Compile	Before any compile process in CODESYS

Check out

The data base function 'Check out' means that the POU will be marked as 'in the works' and will be locked for other users until it will be de-blocked again by a 'Check in' or 'Undo check out'.

If the option Immediately at start of editing is activated, then an object will be checked out automatically as soon as you start to edit it. If the object is currently already checked out by another user (indicated by a red cross before the object name in the object organizer of CODESYS), then a message will pop up.

Check in

The data base function 'Check in' means, that a new version of the object will be created in the data base. The older versions will be kept anyway.

You can activate one or both of the following options to define the time of automatic Checking in:

At Project Save	as soon as the project is saved
After successfull compile	as soon as the project has been compiled without errors

For each of the options 'Get last version', 'Check out' and 'Check in' additionally the option with Query can be activatd. In this case, before the corresponding action is carried out, a dialog opens where you still can decide to cancel the action or otherwise confirm it.

The items of the dialog 'Shared objects' are the same like in the dialog 'Project objects' described above. The settings apply to all objects which are assigned to the data base category 'Shared objects'.

If you do a primary configuration, the configuration dialogs will appear one after the other and you will be guided by a wizard (button Next). The settings made in the first dialog will automatically be inherited to the other ones. So those just have to be edited if modificiations are necessary.

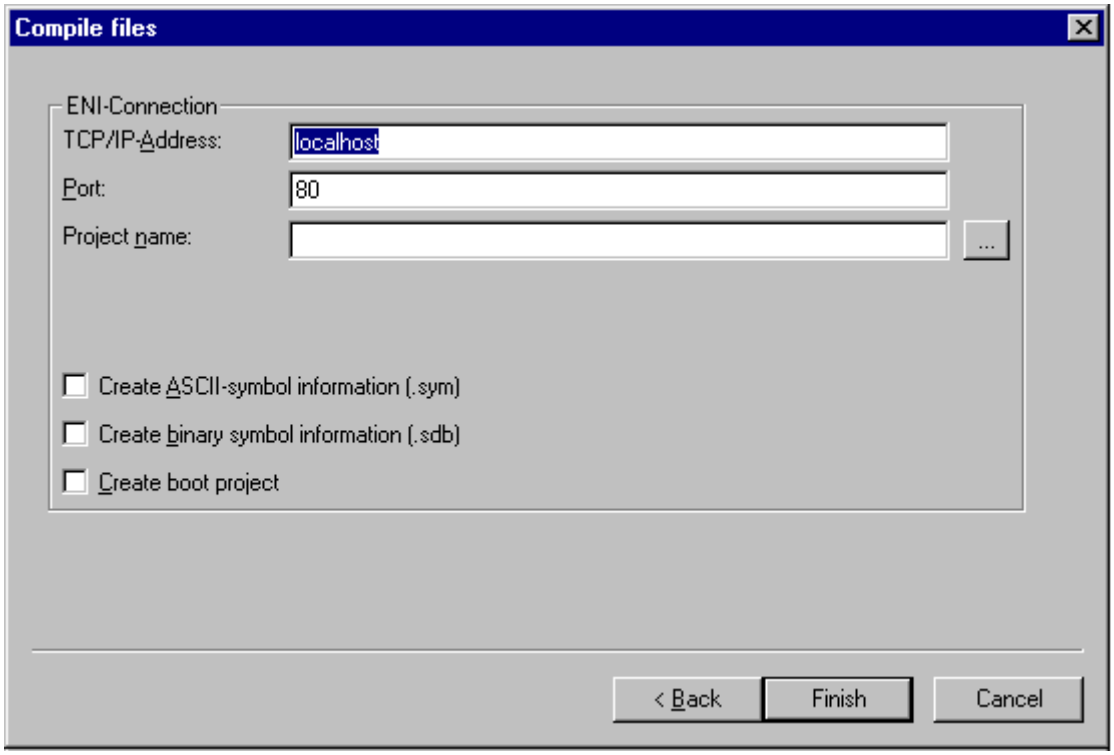
Cancel will close the dialog without saving the done modifications in the currently opened dialog. You return to the main dialog 'Options' 'Project source control'.

If an already existing configuration has been modified, then the new settings (for all three dialogs) can be saved by pressing OK. After that the dialog will be closed and you return to the main dialog 'Options' 'Project source control'.

The settings will be stored in the project.

Options for compile files regarding the project data base

This dialog is part of the option settings for the project data base ('Project' 'Options' 'Project source control'). Here you define how the objects of category 'Compile files' will be handled in the data base. (Besides that two further dialogs are available to define this for objects of category 'Project objects' and 'Shared objects'.)



For the input fields TCP/IP-Address, Port, Project namesee the description of dialog Project objects/Shared objects.

If you do a primary configuration, the configuration dialogs will appear one after the other, guided by a wizard (button Next). The settings made in the first dialog will automatically be inherited to the other ones. So those just have to be edited if modificiations are necessary.

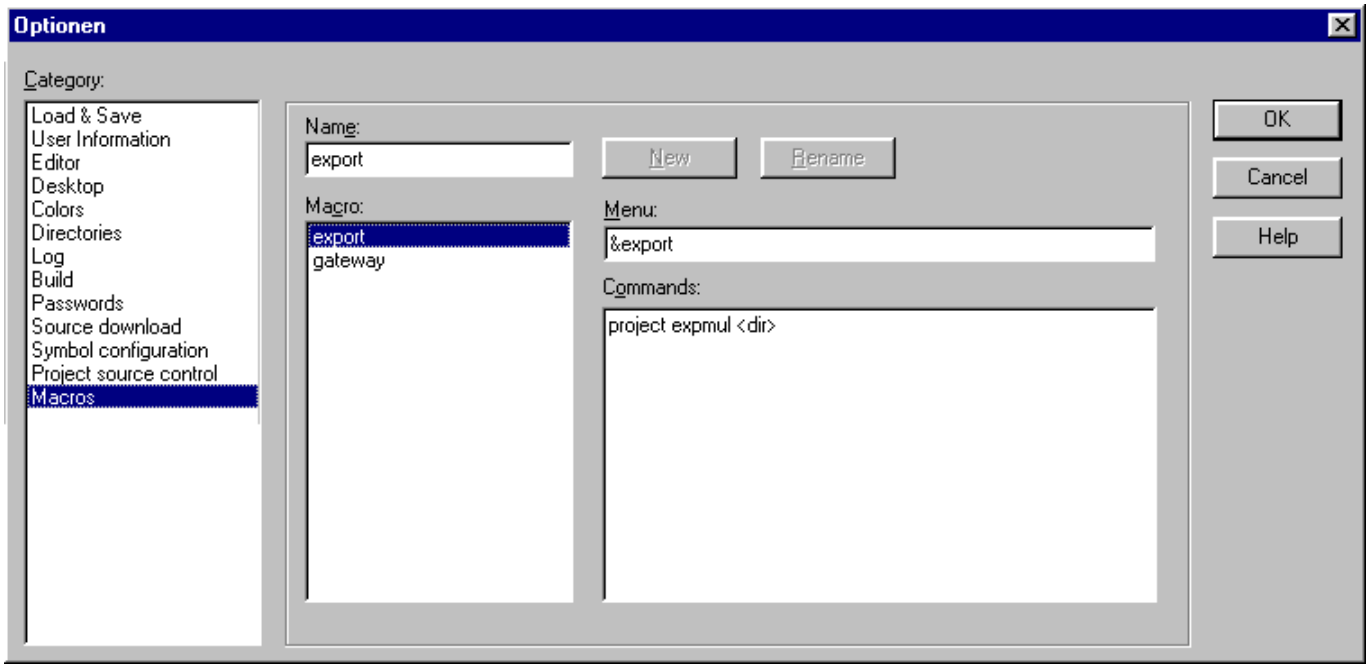
Cancel will close the dialog without saving the done modifications in the currently opened dialog (the settings made in the previous dialogs will be kept anyway). You return to the main dialog 'Options' 'Project source control'.

If an already existing configuration has been modified, then the new settings (for all three dialogs) can be saved by pressing OK. After that the dialog will be closed and you return to the main dialog 'Options' 'Project source control'.

The settings will be stored in the project.

Options for 'Macros'

If you choose this category in the Options dialog, the following dialog box opens:



In this dialog, macros can be defined using the commands of the batch mechanism, which can then be called in the 'Edit' 'Macros' menu.

Perform the following steps to define a new macro:

- In the input field Name, you enter a name for the macro to be created. After the New button is pressed, this name is transferred into the Macrolist field and marked as selected there. The macro list is represented in a tree structure. The locally defined macros are positioned one below the other. If macro libraries (see below) are integrated, then the library names will be listed and by a mouse-click on the plus- resp. minus-signs in front of those entries you can open or close a list of the library elements.
- The Menu field is used to define the menu entry with which the macro will appear in the 'Edit' 'Macros' menu. In order to be able to use a single letter as a short-cut, the letter must be preceded by the symbol '&'. Example: the name "Ma&cro 1" generates the menu entry "Macro 1". Example: the name "Ma&cro 1" will create a menu item "Macro 1".
- In the editor field Commands you define and/or edit the commands that are to constitute the newly created or selected macro. All the commands of the batch mechanism and all keywords which are valid for those are allowed. You can obtain a list by pressing the Help button. A new command line is started by pressing <Ctrl><Enter>. The context menu with the common text editor functions is obtained by pressing the right mouse button. Command components that belong together can be grouped using quotation marks.
- If you want to create further macros, perform steps 1-3 again, before you close the dialog by pressing the OK-button.

If you want to delete a macro, select it in the macro list and press button <Del>.

If you want to rename a macro, select it in the macro list, insert a new name in the edit field 'Name' and then press button Rename.

To edit an existing macro, select it in the macro list and edit the fields 'Menu' and/or 'Commands'. The modifications will be saved when pressing the OK-button.

As soon as the dialog is closed by pressing the OK-button the actual description of all macros will be saved in the project.

The macro menu entries in the 'Edit' 'Macros' menu are now displayed in the order in which they were defined. The macros are not checked until a menu selection is made.

Macro libraries: Macros can be saved in external macro libraries. These libraries can be included in other projects.

- Creating a macro library containing the macros of the currently opened project:
  Press button Create. You get the dialog Merge project, where all available macros are listed. Select the desired entries and confirm with OK. The selection dialog will close and dialog Save Macrolibrary will open. Insert here a name and path for the new library and press button Save. The library will be created named as <library name>.mac and the dialog will be closed.
- Including a macro library <library name>.mac in the currently opened project:
  Press button Include. The dialog Open Macrolibrary will open, which shows files with extension *.mac. Select the desired library and press button Open. The dialog will be closed and the library will be added to the tree of the Macrolist.

Hint: The macros of a project also can be exported ↳ *Chapter 1.4.1.2.3.22 “'Project' 'Export'” on page 239*.

The settings will be stored in the project.

1.4.1.2.3 Managing projects

'File' 'New'

Symbol: 

With this command you create an empty project with the name "Untitled". This name must be changed when saving.

'File' 'New from template'

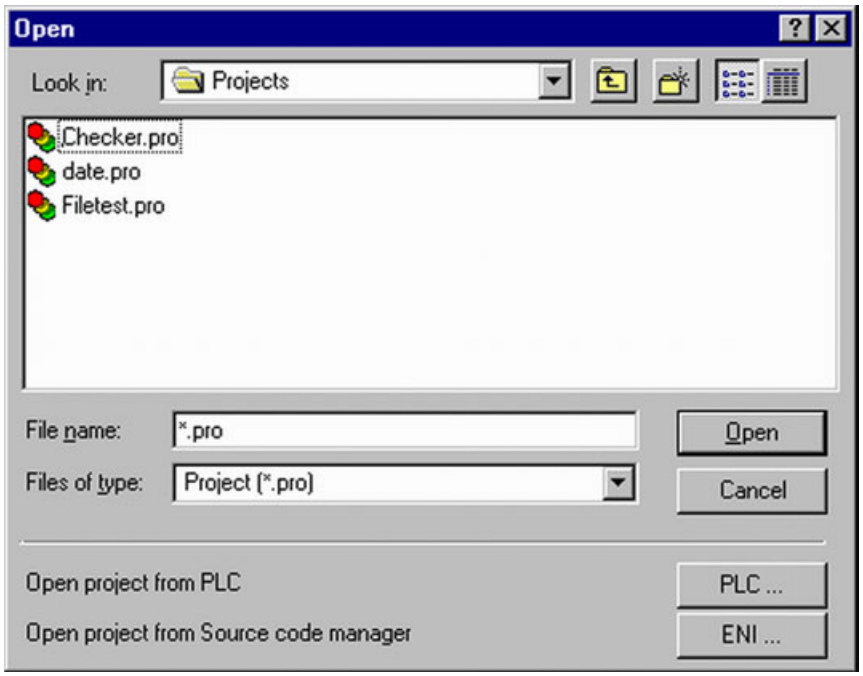
Use this command to open any desired project as a "template" project. The dialog for opening a project file will be available and the selected project will be opened with project name "Unknown" ↳ *Chapter 1.4.1.2.3.3 “'File' 'Open'” on page 222*.

'File' 'Open'

Symbol: 

With this command you open an already existing project. If a project has already been opened and changed, then you are asked whether this project should be saved or not.

The dialog box for opening a file appears, and a project file with the extension "*.pro" or a library file with the extension "*.lib" must be chosen. This file must already exist ↳ *Chapter 1.4.1.4.3.1 “Overview” on page 371*. It is not possible to create a project with the command "Open".



Open a project from the PLC

To upload a project file from the PLC, press PLC at Open project from PLC. You will obtain, as next, the dialog Communication parameters (see menu 'Online' 'Communication parameters') for setting the transmission parameters when no connection exists yet to the PLC. Once an on-line connection has been created, the system checks whether the same named project files already exist in the directory on your computer hard disc. When this is the case you receive the dialogue Load the project from the controller where you can decide whether the local files should be replaced by those being used by the controller. (This sequence is the reverse of the sequence of 'Online' 'Load source code', with which the project source file is stored in the controller. Do not confuse with 'Create Boot project'!)

Please note, that you in any case have to give a new name to a project, when you load it from the PLC to your local directory, otherwise it is unnamed. If supported by the target system, a 'Title' entered in the project info will be pre-defined as new project file name ↬ Chapter 1.4.1.2.3.34 "'Project' 'Project info'" on page 246. In this case at loading the project from the PLC the dialog for saving a file will open, where the new file name automatically is entered and can be confirmed or modified.

If there has not yet been loaded a project to the PLC, you get an error message.

↬ *Chapter 1.4.1.2.2.11 "'Source download'" on page 212*'

Open a project from Source code manager (ENI data base)

To open a project which is stored in a ENI project data base, activate option Open project from Source code manager can be used . It is a precondition that you have access to an ENI Server which serves the data base. Press button ENI..., to get a dialog where you can connect to the server concerning the data base category 'Project objects'.

Insert the appropriate access data (TCP/IP-Address, Port, Username, Password, Read only) and the data base folder (Project name) from which the objects should be get and confirm with Next. The dialog will be closed and another one will open where you have to insert the access data for the data base category 'Shared objects'. If you press button Finish the dialog will be closed and the objects of the defined folders will automatically be retrieved and displayed in the Object manager. If you want to continue to keep the project objects under data base control, then open the Project options to set the desired parameters.

The access data are stored in the codesys.ini file, username and password however only if the project option 'Save ENI credentials' is activated.

Most recently opened files

The most recently opened files are listed in the Files menu below the command 'File' 'Exit'. If you choose one of them, then this project is opened.

If passwords or User groups have been defined for the project, then a dialog box appears for entering the password.

'File' 'Close'

With this command you close the currently-open project. If the project has been changed, then you are asked if these changes are to be saved or not. If the project to be saved carries the name "Untitled", then a name must be given to it *Chapter 1.4.1.2.3.6 “'File' 'Save as'” on page 224*.

'File' 'Save'

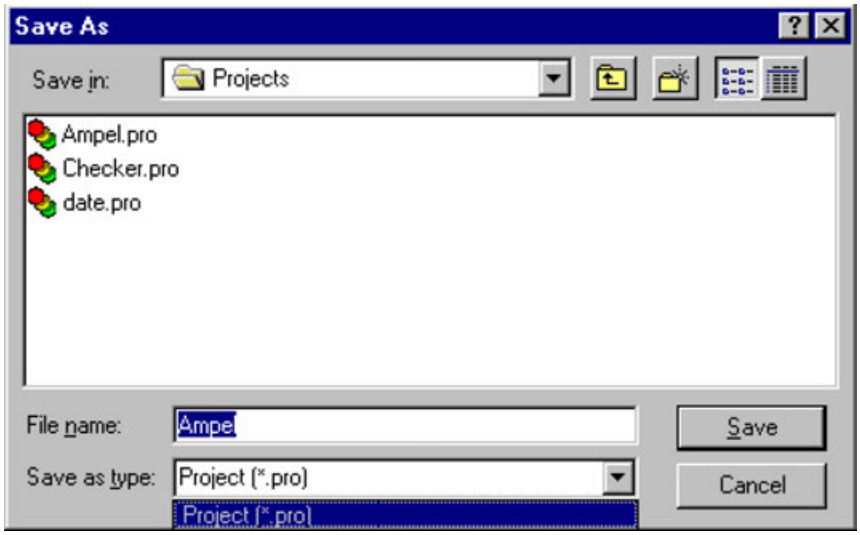
Symbol: Shortcut: <Ctrl>+<S>

With this command you save any changes in the project. If the project to be saved is called "Untitled", then you must give it a name *Chapter 1.4.1.2.3.6 “'File' 'Save as'” on page 224*.

'File' 'Save as'

With this command the current project can be saved in another file or as a library. This does not change the original project file.

After the command has been chosen the Save dialog box appears. Choose either an existing File name or enter a new file name and choose the desired file type.



If the project is to be saved under a new name, then choose the file type Project (*.pro).

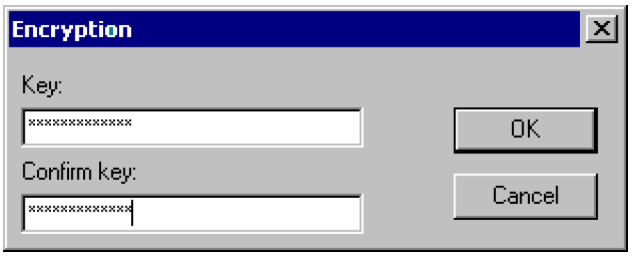
If you choose the file type Project Version 1.5 (*.pro), 2.0 (*.pro), 2.1 (*.pro) or 2.2 (*.pro), then the current project is saved as if it were created with the version 1.5, 2.0, 2.1 or 2.2. Specific data of the version 2.3 can thereby be lost! However, the project can be executed with the version 1.5, 2.0, 2.1 or 2.2.

You can also save the current project as a library in order to use it in other projects. Choose the file type Internal library (*.lib) if you have programmed your POUs in CODESYS.

Choose the file type External library (*.lib) if you want to implement and integrate POUs in other languages (e.g. C). This means that another file is also saved which receives the file name of the library, but with the extension "*.h". This file is constructed as a C header file with the declarations of all POUs, data types, and global variables. If external libraries are used, in the simulation mode the implementation, written for the POUs in CODESYS, will be executed. Working with he real hardware the implementation written in C will be executed.

Encryption of a project

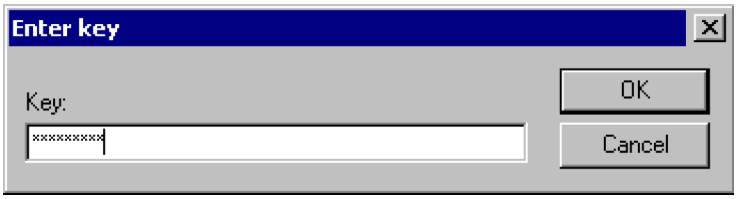
In order to save the project as an encrypted project or library, choose option Encrypted Project (*.pro) resp. Encrypted internal library (*.lib) or Encrypted external library (*.lib). In this case you get the 'Encryption' dialog , where you can define and confirm a key. The project later cannot be opened esp. a library cannot be used without this key:



The encryption extends the protection of a project, which up to now was only possible via the assignment of passwords for access and write protection ↳ *Chapter 1.4.1.2.2.10 “Passwords” on page 211*. These possibilities will exist further on, but note that they e.g. cannot avoid that a library is included in a project without the need of entering a library password (key).

A key once defined will be saved with any further savings of the project. To modify that key, you have to use again the 'Save as' dialog.

If an encrypted project should be opened resp. if an encrypted library sShould be used in a project, the dialog asking for the key will appear.



Licensing a library:

If you want save the project as a licensed library, you can add the appropriate licensing information in the dialog 'Edit Licensing Information'. Open the dialog by pressing the button Edit license info.

After having done all settings, press OK. The current project will be saved in the indicated file. If the new file name already exists, then you are asked if you want to overwrite this file.

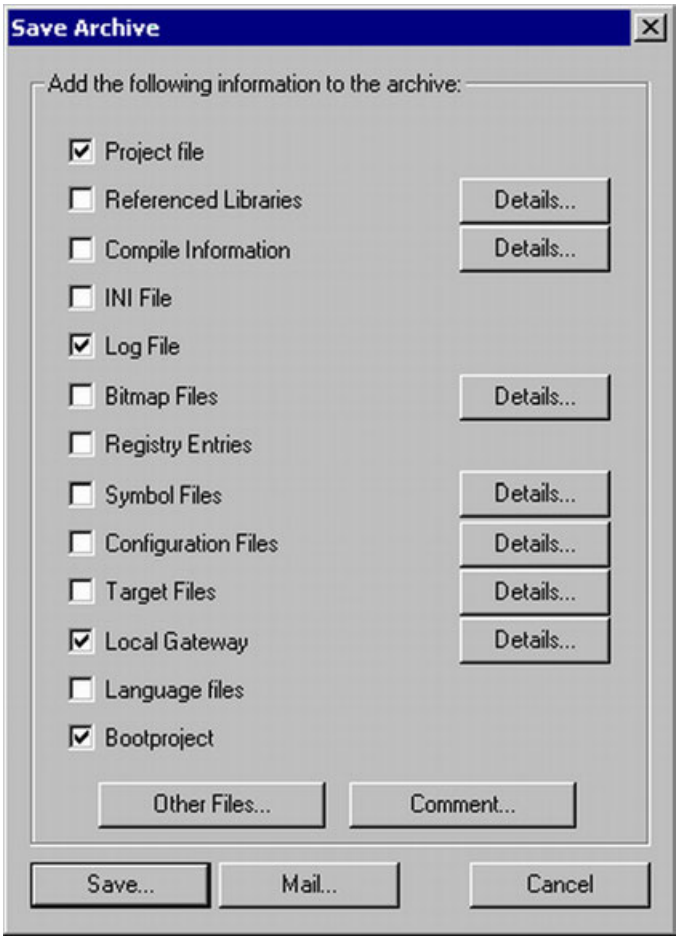
When saving as a library, the entire project is compiled. If an error occurs thereby, then you are told that a correct project is necessary in order to create a library. The project is then not saved as a library.

'File' 'Save/Mail archive'

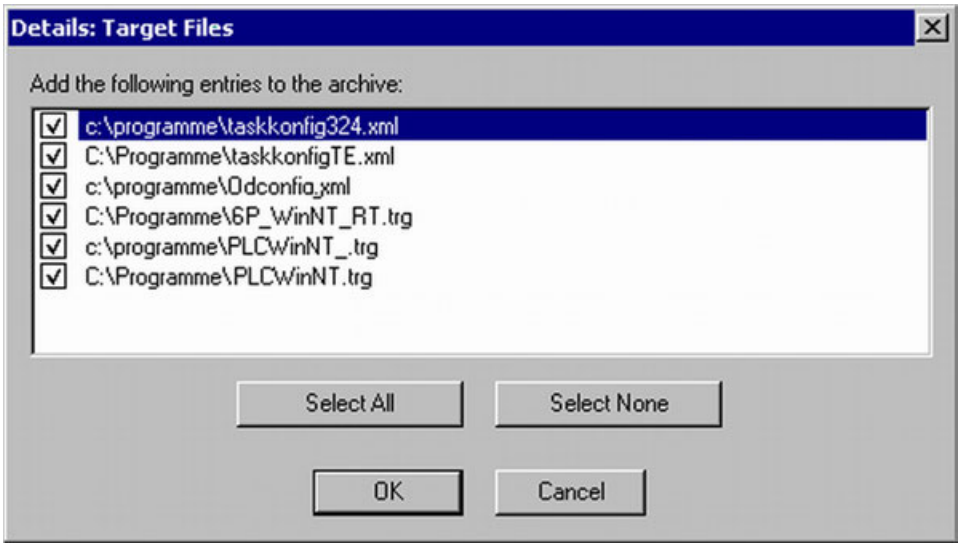
This command is used to set up and create a project archive file. All files which are referenced by and used with a CODESYS project can be packed in a compressed zip file. The zip file can be stored or directly can be sent in an email. This is useful if you want to give forward a set of all project relevant files.

The archive function is not practical for restoring a project environment. It is designated for an easy packing of all files belonging to a project. When unpacking an archive the paths of the particular files must be adapted to the actual environment!

When the command is executed, the dialog box 'Save Archive' opens:



Here you can define which file categories should be added to the archive zip file: Select or deselect a category by activating/deactivating the corresponding checkbox. Do this by a single mouseclick in the checkbox or by a doubleclick on the category name. If a category is marked with ☑, all files of this category will be added to the zip file, if it is marked with ☐, none of the files will be added. To select single files of a category press the corresponding button Details. The dialog 'Details' will open with a list of available files:



The dialog shows a list of all files which are available for the category: Automatically alle files are selected, an exception is category 'Target Files' where only the files are selected which are relevant for the currently set target system. For modifying the selection activate resp. deactivate the desired files. With the button 'Select All' all files of the list are selected, with 'Select None' none of them. A single file can be selected/deselected by a mouseclick in the checkbox, also by a doubleclick on the list entry or by pressing the spacebar when the list entry is marked.

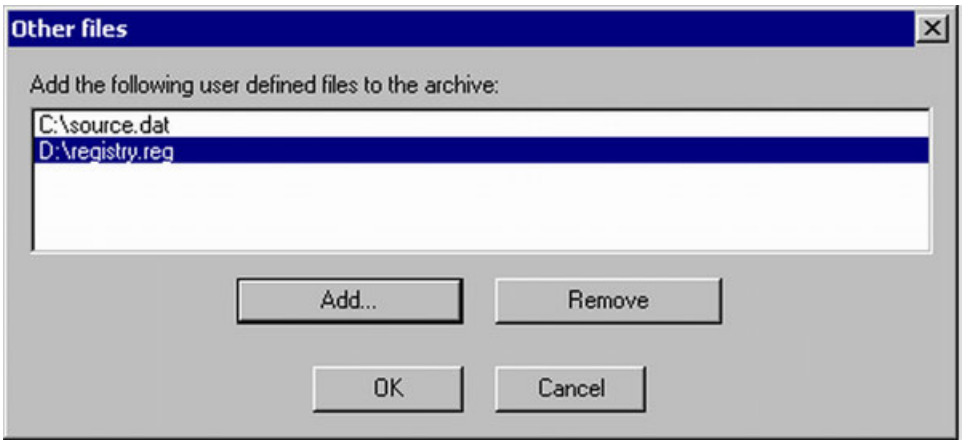
Close the Details dialog with 'Save' to store the new settings.

In the main dialog the checkbox of categories, for which not all files are selected, will appear with a grey background color ☑.

The following file categories are available, the right column of the table shows which files can be added to the zip file:

Category	Files
Project File	projectname.pro (the project file)
Referenced Libraries	*.lib, *.obj, *.hex (libraries and if available the corresponding object and hex-files)
Compile Information	*.ci (compile information) *.ri (download/reference information) <temp>.* (temporary compile and download files) also for simulation
INI File	Codesys.ini
Log File	*.log (project log file)
Bitmap Files	*.bmp (bitmaps for project POUs and visualizations)
Registry Entries	Registry.reg (Entries for Automation Alliance, Gateway and SPS; the following subtrees will be packed: HKEY_LOCAL_MACHINE\SOFTWARE\3S-Smart Software Solutions HKEY_LOCAL_MACHINE\SOFTWARE\AutomationAlliance"
Symbol Files	*.sdb, *.sym (symbolic information)
Configuration files	files used for PLC configuration (configuration files, device files, icons etc.): e.g. *.cfg, *.con, *.eds, *.dib, *.ico ....
Target Files	*.trg (target files in binary format for all installed targets) *.txt (target files for the installed targets in text format, if available)
Local Gateway	Gateway.exe, GatewayDDE.exe, GClient.dll, GDrvBase.dll, GDrvStd.dll, GHandle.dll, GSymbol.dll, GUtil.dll, further DLLs in the gateway directory if available
Language Files	language files used for visualizations (*.vis, *.xml)
Boot project	Boot project files <project name>.prg, <project name>.chk resp. the target specific boot project files.

To add any other files to the zip, press the button 'Other Files'. The dialog 'Other files' will open where you can set up a list of desired files.



Press the button Add to open the standard dialog for opening a file, where you can browse for a file. Choose one and confirm with Open. The file will be added to the list in the 'Other files' dialog. Repeat this for each file you want to add. To delete entries from the list, press the button Remove. When the list of selected files is ok, close the dialog with OK.

To add a readme file to the archive zip, press the button 'Comment'. A text editor will open, where you can enter any text. If you close the dialog with OK, during creation of the zip file a readme.txt file will be added. Additionally to the entered comments it will contain information about the build date and version of CODESYS.

If all desired selections have been made, in the main dialog press:

- Save... to create and save the archive zip file: The standard dialog for saving a file will open and you can enter the path, where the zip should be stored. The zip file per default is named <projectname>.zip. Confirm with Save to start building it. During creation the current progress status is displayed and the subsequent steps are listed in the message window. There also a message will be displayed if any file could not not been found.
- Mail... to create a temporary archive zip and to automatically generate an empty email which contains the zip as an attachment. This feature only works if the MAPI (Messaging Application Programming Interface) has been installed correctly on the system, otherwise an error message is generated. During setup of the email the progressing status is displayed and the steps of the action are listed in the message window. The temporary zip file will be removed automatically after the action has been finished.
- Cancel to cancel the action; no zip file will be generated.

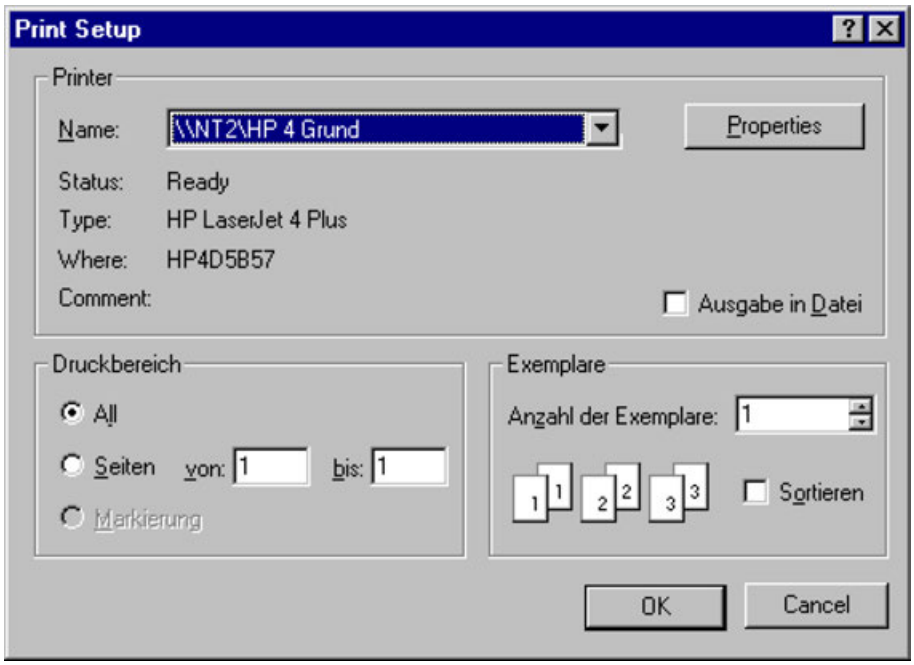
After unpacking the archive zip on a different system it might be necessary to adapt the file paths!

'File' 'Print'

Shortcut: <Ctrl>+<P>

With this command the content of the active window is printed.

After the command has been chosen, then the Print dialog box appears. Choose the desired option or configure the printer and then click OK. The active window is printed. Color output is available from all editors.



You can determine the number of the copies and print the version to a file.

With the button 'Properties' you open the dialog box to set up the printer.

You can determine the layout of your printout with the command 'File' 'Printer setup' *Chapter 1.4.1.2.3.9 “'File' 'Printer setup'” on page 229*.

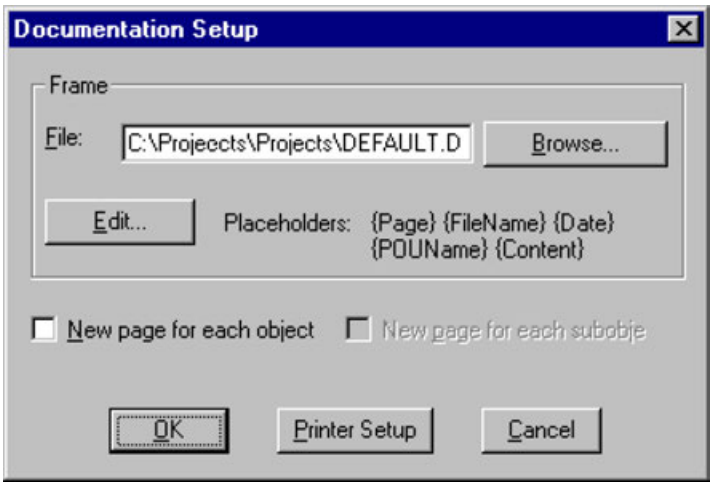
During printing the dialog box shows you the number of pages already printed. When you close this dialog box, then the printing stops after the next page.

In order to document your entire project, use the command 'Project' 'Document' *Chapter 1.4.1.2.3.21 “'Project' 'Document'” on page 238*.

If you want to create a document frame for your project, in which you can store comments regarding all the variables used in the project, then open a global variables list and use the command 'Extras' 'Make docuframe file'.

'File' 'Printer setup'

With this command you can determine the layout of the printed pages. The following dialog box is now opened:

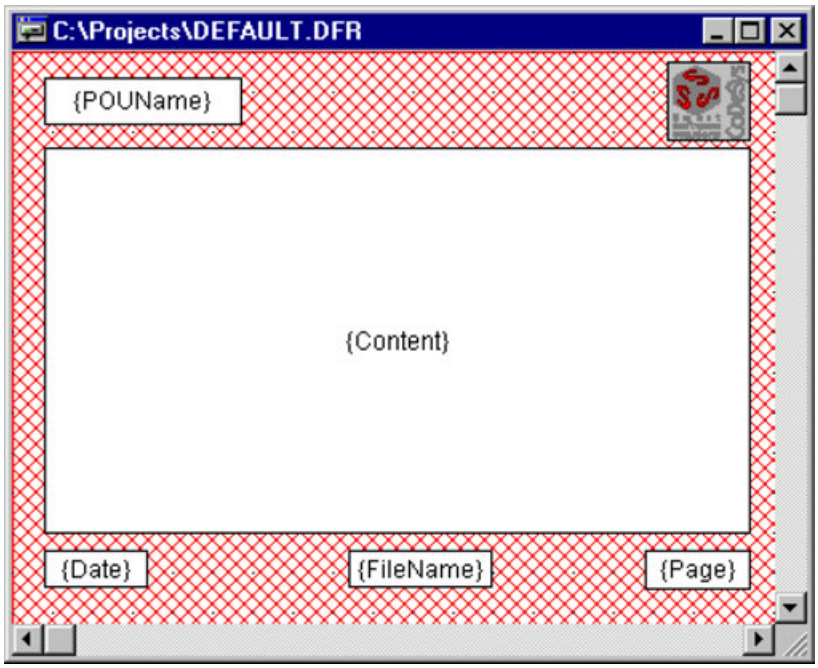


In the field File you can enter the name of the file with the extension ".dfr" in which the page layout should be saved. The default destination for the settings is the file DEFAULT.DFR.

If you would like to change an existing layout, then browse through the directory tree to find the desired file with the button 'Browse'.

You can also choose whether to begin a new page for each object and for each subobject. Use the 'Printer Setup' button to open the printer configuration.

If you click on the 'Edit' button, then the frame for setting up the page layout appears. Here you can determine the page numbers, date, file name and POU name, and also place graphics on the page and the text area in which the documentation should be printed.



With the menu item 'Insert' 'Placeholder' and subsequent selection among the five placeholders (Page, POU name, File name, Date, and Content), insert into the layout a so-called placeholder by dragging a rectangle the layout while pressing the left mouse button. In the printout they are replaced as follows:

Command	Placeholder	Effect
Page	{Page}	Here the current page number appears in the printout.
POU name	{POU Name}	Here the current name of the POU appears.
File name	{File Name}	Here the name of the project appears.
Date	{Date}	Here the current date appears.
Contents	{Contents}	Here the contents of the POU appear.

In addition, with 'Insert' 'Bitmap' you can insert a bitmap graphic (e.g. a company logo) in the page. After selecting the graphic, a rectangle should also be drawn here on the layout using the mouse. Other visualization elements can be inserted ↳ *Chapter 1.4.3 “Visualization” on page 636*.

If the template was changed, then you are asked when the window is closed if these changes should be saved or not.

> *In order to be aware of the page format which will be valid for printouts, define the layout as described above and additionally activate option 'Show print area margins' in the project options, category Desktop.*

'File' 'Exit'

Shortcut: <Alt>+<F4>

With this command you exit from CODESYS.

If a project is opened, then it is closed *Chapter 1.4.1.2.3.5 "'File' 'Save'" on page 224*.

'Project' 'Build'

Shortcut: <F11>

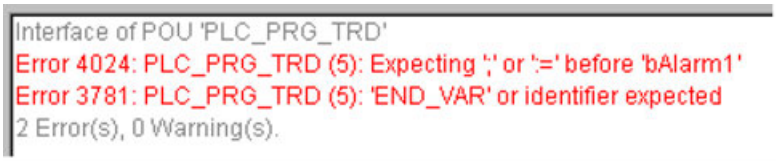
The project is compiled using 'Project' 'Build'. The compilation process is basically incremental, that is only changed POUs are recompiled. The necessary information about the last compilation is stored in a *.ci-file when the project is saved. A non-incremental compilation can also be obtained if the command 'Project' 'Clear all' is first executed.

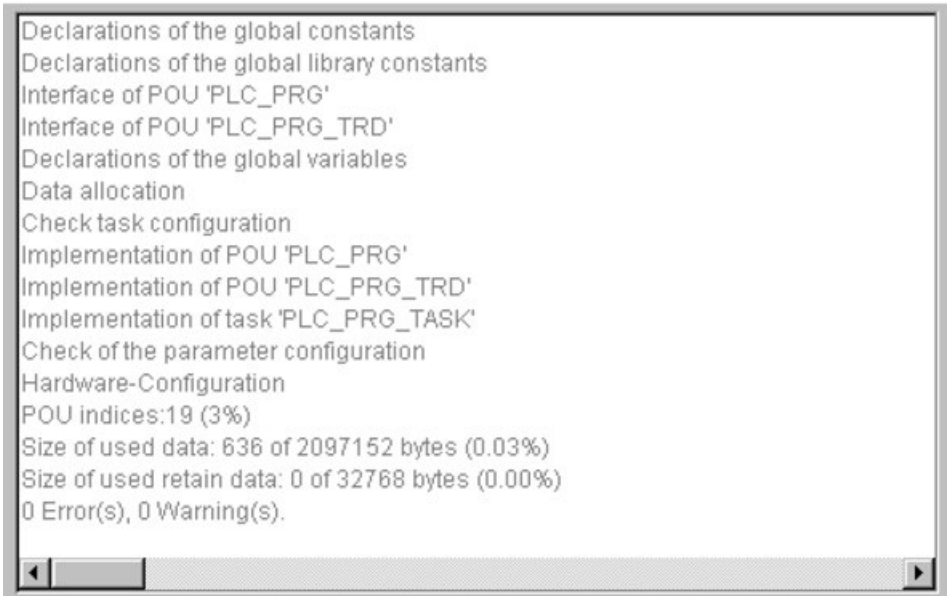
For target systems that support Online Change, all POUs that will be loaded into the controller on the next download are marked with a blue arrow in the Object Organizer after compilation.

The compilation process that is carried out with 'Project' 'Build' occurs automatically if the controller is logged-in via 'Online' 'Login' *Chapter 1.4.1.2.6.2 "'Online' 'Login'" on page 279*.

See online login for a diagram showing the relations between Project-Build, Project-Download, Online Change and Login on the target systemFig. .

During compilation a message window is opened which shows the progress of the compilation process, any errors and warnings which may occur during compilation as well as information on the used POU indices and memory space (number and percentage). Errors and warnings are marked with numbers. Using F1 you get more information about the currently selected error.





See the listing of all available error messages and warnings ↳ *Chapter 1.4.1.10.2.1 “1100” on page 478*.

If the option 'Save before compilation' is selected in the options dialog of the Load & Save category, the project is stored before compilation.

An object, or several objects, selected in the Object Organizer can be excluded from compilation by command 'Exclude from build' which is available in the context menu, or via an appropriate configuration ('Exclude objects') in the Options for Build.

Cross references are created during compilation and are stored with the compilation information. In order to be able to use the command 'Show Call Tree', and to get up to date results with the commands 'Show Cross Reference' and 'Unused variables', 'Overlapping memory areas', '', 'Multiple Writes to output', rebuild the project after any change ↳ *Chapter 1.4.1.2.4.16 “'Project' 'Show call tree'” on page 264* ↳ *Chapter 1.4.1.2.4.17 “'Project' 'Show cross reference'” on page 264* ↳ *Chapter 1.4.1.2.3.41 “Concurrent access” on page 249* ↳ *Chapter 1.4.1.2.3.37 “'Project' 'Check'” on page 248.*

'Project' 'Rebuild all'

With 'Project' 'Rebuild all', unlike the incremental compilation, the project is completely recompiled ↳ *Chapter 1.4.1.2.3.11 “'Project' 'Build'” on page 231*. Download information is not discarded, however, as is the case with the command 'Project' 'Clean all' ↳ *Chapter 1.4.1.2.3.13 “'Project' 'Clean all'” on page 232* ↳ *Chapter 1.4.1.2.3.14 “'Project' 'Load download information'” on page 232*. Note the possibility to exclude objects from compilation ↳ *Chapter 1.4.1.2.2.9 “Options for build” on page 209*.

See 'Online' 'Login' for a diagram showing the relations between Project-Build, Project-Download, Online Change and Login on the target systemFig. .

'Project' 'Clean all'

With this command, all the information from the last download and from the last compilation is deleted.

After the command is selected a dialog box appears, reporting that Login without new download is no longer possible ↳ *Chapter 1.4.1.2.6.2 “'Online' 'Login'” on page 279*. At this point the command can either be cancelled or confirmed.

Note: After having done a 'Clean all', an online change on the PLC project is only possible if the *.ri file with the project information from the last download was first renamed or saved outside the project directory and can now be loaded explicitly prior to logging-in ↳ *Chapter 1.4.1.2.6.2 “'Online' 'Login'” on page 279* ↳ *Chapter 1.4.1.2.3.14 “'Project' 'Load download information'” on page 232*.

See Online Login for a diagram showing the relations between Project-Build, Project-Download, Online Change and Login on the target systemFig. .

'Project' 'Load download information'

With this command the Download-Information belonging to the project can get reloaded. After choosing the command the standard dialogue 'File Open' opens.

The Download-Information is saved automatically at each download and, dependent on the target system, potentially also at each offline creation of a boot project to a file, which is named <project name><target identifier>.ri and which is put to the project directory *Chapter 1.4.1.2.6.5 “'Online' 'Download'” on page 283*. This file gets reloaded each time the project is reopened and at login it is used to check the code of which POUs has been changed. Only these POUs will then be loaded to the PLC during online change procedure. Thus the *.ri file is a precondition for an online change *Chapter 1.4.1.2.6.2 “'Online' 'Login'” on page 279*.

*Using command 'Project' 'Clean all' the *.ri file belonging to the current project automatically gets deleted from the projects directory, so that no online change will be possible until the *.ri file can be reloaded from another directory or from a renamed *.ri file Chapter 1.4.1.2.3.13 “'Project' 'Clean all'” on page 232.*

See online login for a diagram showing the relations between Project-Build, Project-Download, Online Change and Login on the target systemFig. .

'Project' 'Translate into another language'

This menu item is used for translating the current project file into another language. This is carried out by reading in a translation file that was generated from the project and externally enhanced in the desired national language with the help of a text editor. The project can be just displayed or really get translated into one of the generated language versions.

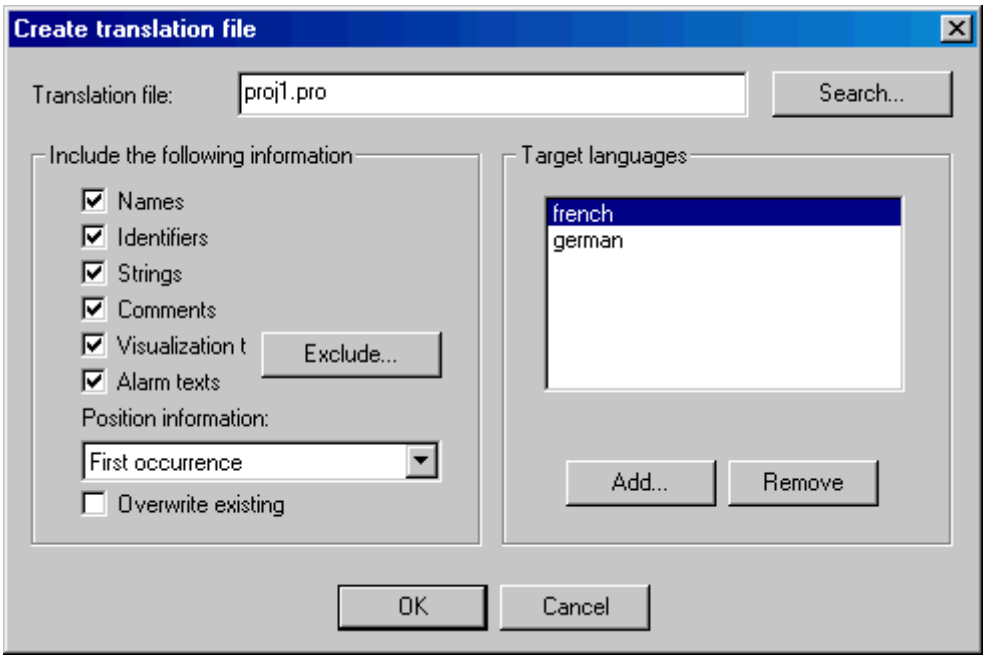
The following menu sub-items are present:

- Create translation file *Chapter 1.4.1.2.3.16 “Create translation file” on page 233*
- Translate project *Chapter 1.4.1.2.3.18 “Translate project (into another language)” on page 237*
- Show project translated *Chapter 1.4.1.2.3.19 “Show project translated” on page 238*
- Toggle translation *Chapter 1.4.1.2.3.20 “'Toggle translation'” on page 238*
- See also: 'Editing of the translation file' *Chapter 1.4.1.2.3.17 “Editing of the translation file” on page 236*

Create translation file

This command in the 'Project' 'Translate into another language' menu leads to the 'Create translation file' dialog.

Dialog for creating a translation file



In the Translation file field, enter a path that shows where the file is to be stored. The default file extension is *.tlt; this is a text file. You also can use the extension *.txt, which is recommended, if you want to work on the file in EXCEL or WORD, because in this case the data are organized in table format.

If there already exists a translation file which you want to process, give the path of this file or use the Search button to reach the standard Windows file selection dialog.

The following information from the project can optionally be passed to the translation file that is being modified or created, so that they will be available for translation: Names (names, e.g. the title 'POUs' in Object Organizer), Identifiers, Strings, Comments, Visualisation texts, Alarm texts. In addition, Position information for these project elements can be transferred.

If the corresponding options are checked, the information from the current project will be exported as language symbols into a newly created translation file or added to an already existing one. If the respective option is not selected, information belonging to the pertinent category, regardless of which project it came from, will be deleted from the translation file.

The option "Visualisation texts" only concerns 'Text' and 'Tooltip-Text' of a visualization element. Regard the following items when using a translation file for visualization texts:

- A *.tlt- or *.txt translation file only can be used with CODESYS or CODESYS HMI, not however with target visualization or web visualization. It might be better to use a special visualization language file *.vis.
- Switching to another language is only possible in online mode. This means that the visualization texts will not be translated by command 'Translate into another language' ↳ *Chapter 1.4.1.2.3.15 “'Project' 'Translate into another language'” on page 233*. A language change can only occur in Online mode if the corresponding language is entered in the 'Extras' 'Settings' dialog.
- If a *.tlt- or *.txt-file should be used for visualization texts ('Text' and 'Text for Tooltip'), the texts must be bracketed by two "#" symbols in the configuration dialog of the visualization element (e.g. #text#) in order to be transferred to the translation file.
- Language switching in visualizations ↳ *Chapter 1.4.3.6.1 “'Extras' 'Settings'” on page 700*.

Position information: This describes with the specifications file path, POU and line the position of the language symbol made available for translation. Three options are available for selection:

'None':	No position information is generated.
'First appearance':	The position on which the element first appears is added to the translation file.
'All':	All positions on which the corresponding element appears are specified.

If a translation file created earlier is to be edited which already contains more position information than that currently selected, it will be correspondingly truncated or deleted, regardless of which project it was generated from.

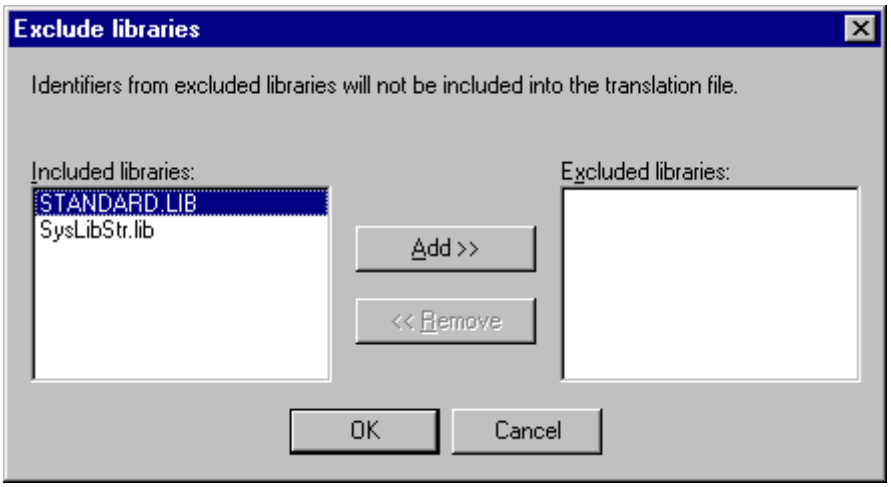
A maximum of 64 position specifications will be generated per element (language symbol), even if the user has selected "All" under "Position Information" in the 'Create Translation File' dialog.

Overwrite existing: Existing position information in the translation file, that is currently being processed, will be overwritten, regardless of which project generated it.

Target languages: This list contains identifiers for all languages which are contained in the translation file, as well as those to be added upon completion of the 'Create translation file' dialog.

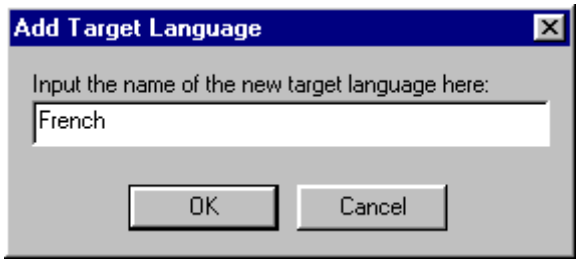
The Exclude button opens the 'Exclude libraries' dialog. Here, libraries included to the project can be selected, whose identifier information is not to be transferred to the translation file. To accomplish this, the corresponding entry in the table Included libraries on the left is selected with the mouse and placed in the Excluded libraries table to the right using the Add button. Likewise, entries already placed there can be removed using the Remove button. OK confirms the setting and closes the dialog.

Dialog for excluding library information for the translation file:



The Add button opens the 'Add Target Language' dialog:

Dialog for adding a target language (Project, Translate into Another Language):



A language identifier must be entered into the editor field; it may not have a space or an umlaut character (ä, ö, ü) at either the beginning or the end.

OK closes the 'Add Target Language' dialog and the new target language appears in the target language list.

The Remove button removes a selected entry from the list.

You may also confirm the "Create translation file" dialog via OK, in order to generate a translation file.

If a translation file of the same name already exists you will get the following confirmation message to be answered Yes or No:

" The specified translation file already exists. It will now be altered and a backup copy of the existing file will be created. Do you want to continue?"

No returns you without action to the 'Create translation file' dialog. If Yes is selected, a copy of the existing translation file with the filename "Backup_of_<translation file>.xlt" will be created in the same directory and the corresponding translation file will be modified in accordance with the options that have been entered.

The following takes place when a translation file is generated:

- For each new target language, a placeholder ("##TODO") is generated for each language symbol to be displayed *Chapter 1.4.1.2.3.17 “Editing of the translation file” on page 236*.
- If an existing translation file is processed, file entries of languages that appear in the translation file, but not in the target language list, are deleted, regardless of the project from which they were generated.

Editing of the translation file

The translation file must be opened and saved as a text file. The signs ## mark keywords. The ##TODO-placeholders in the file can be replaced by the valid translation. For each language symbol a paragraph is generated which starts and ends with a type identifier. For example ##NAME_ITEM and ##END_NAME_ITEM include a section for the name of an object as used in the object organizer. (COMMENT_ITEM marks sections for comments, IDENTIFIER_ITEM those for identifiers, STRING_ITEM those for strings and VISUALTEXT_ITEM those for visualization texts).

See in the following an example of a translation file paragraph which handles the name of one of the POUs of the project. ST_Visu. The target languages shall be English(USA) and French. In the example the position information of the project element which should be translated has been added:

before translation:

Example

```
##NAME_ITEM
[D:\codesys\projects\Bspdt_22.pro::ST_Visualisierung::0]
ST_Visualisierung
##English :: ##TODO
##French :: ##TODO
##END_NAME_ITEM
```

after translation:

The ##TODOs have been replaced by the English resp. French word for 'Visualisierung':

Example

```
##NAME_ITEM
[D:\codesys\projects\Bspdt_22.pro::ST_Visualisierung::0]
ST_Visualisierung
##English :: ST_Visualization
##French :: ST_Visu
##END_NAME_ITEM
```

Please check that the translated Identifier and Names remain valid concerning the standard and that strings and comments are in correct brackets. Example: For a comment (##COMMENT_ITEM) which is represented with "(* Kommentar 1)" in the translation file, the "##TODO" behind "##English" must be replaced by a "(* comment 1 *)". For a string (##STRING_ITEM) represented with "zeichenfolge1" the "##TODO" must be replaced by "string1".

The following parts of a translation file should not be modified without detailed knowledge: Language block, Flag block, Position information, Original texts.

Translate project (into another language)

This command in the 'Project' 'Translate into Another Language' menu opens the 'Translate Project into Another Language' dialog.

The current project can be translated into another language if an appropriate translation file is used.

If you want to save the version of the project in the language in which it was originally created, save a copy of the project prior to translation under a different name. The translation process cannot be undone. Consider in this context the possibility just to display the project in another language (in this display version then however not editable).

In the field Translation file, provide the path to the translation file to be used. By pressing Search you may access the standard Windows file selection dialog.

The field Target language contains a list of the language identifiers entered in the translation file, from which you can select the desired target language.

OK starts the translation of the current project into the chosen target language with the help of the specified translation file. During translation, a progress dialog is displayed, as well as error messages, if any. After translation, the dialog box and all open editor windows of the project are closed.

Cancel closes the dialog box without modification to the current project.

If the translation file contains erroneous entries, an error message is displayed after OK is pressed, giving the file path and the erroneous line, e.g.: "[C:\Programs\codesys\projects\visu.tlt (78)]; Translation text expected"

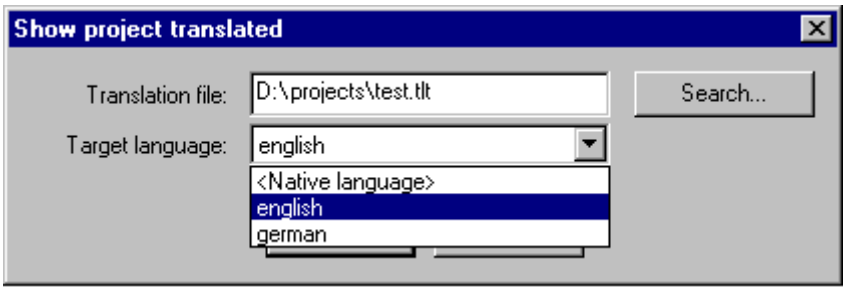
Regard the specialities for texts in visualizations.

Show project translated

If there is a translation file available for the project, you can display one of the language versions defined there, without overwriting the original language version of the project.

(Regard this possibility in comparison to the "real" translating of a project, which you would do with the command 'Translate Project', and which would mean to create a new version of the project !)

The command 'Translate this project' in menu 'Project' 'Translate into another language' opens the dialog 'Translate project into another language'.



In field Translation file insert the path of the translation file, you want to use. You can receive assistance by the standard dialog for opening a file which is opened by button Browse.

In field Target language you find a selection list, which besides the entry "<Native language>" also offers the language identifiers which are defined by the currently set translation file. The original language is that one, which is currently saved with the project. (It only could be changed by a 'Project' 'Translate'.) Choose one of the available languages and confirm the dialog with OK. Thereupon the project will be displayed in the chosen language, but cannot be edited in this view !

If you want to change back to viewing the project in its original language, use command 'Switch translation'.

Regard the specialities for texts in visualizations.

'Toggle translation'

If you have got displayed the project (not editable) in another language by command 'Show project translated', you can now switch between this language version and the (editable) original version by using the command 'Switch translation' of menu 'Project' 'Translate (into another Language)' .

Regard the specialities for texts in visualizations.

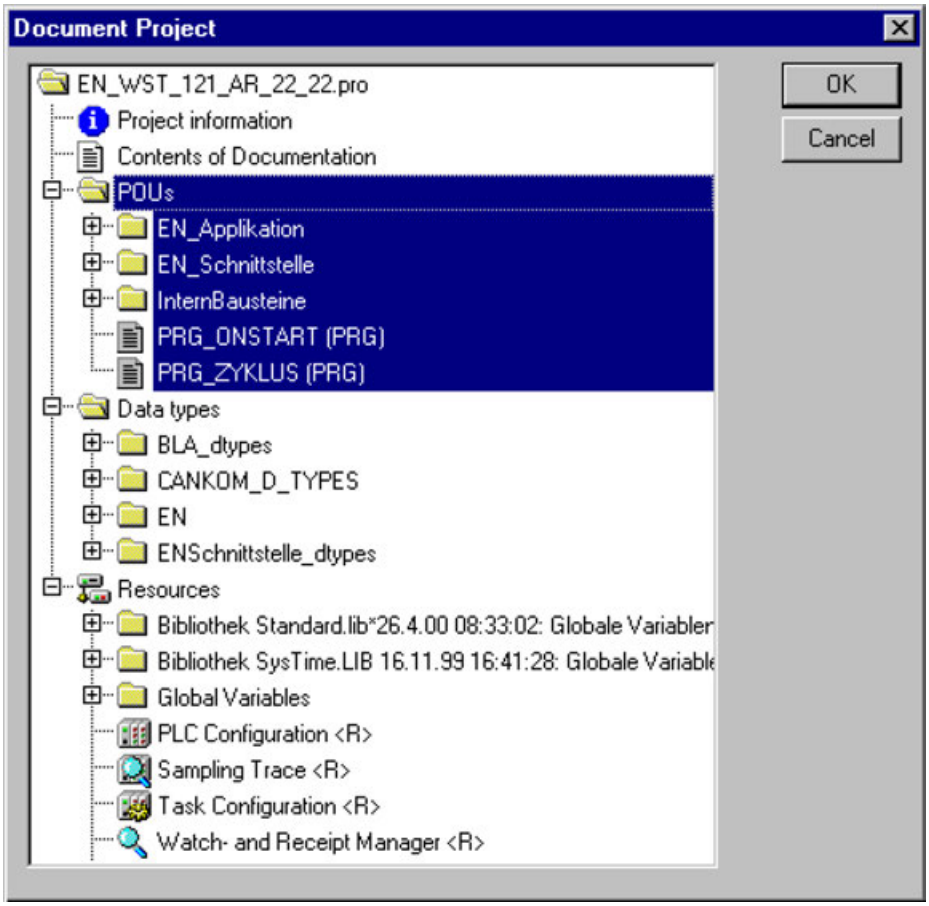
'Project' 'Document'

This command lets you print the documentation of your entire project. The elements of a complete documentation are:

- The POUs,
- the contents of the documentation,
- the datatypes *Chapter 1.4.1.8.1.1 “Data types” on page 443*,
- the visualizations *Chapter 1.4.3.1 “Overview” on page 636*,

- the resources, global variables, variables configuration, the Sampling Trace, the PLC Configuration, the Task Configuration, the Watch and Receipt Manager),
- the call trees ↳ *Chapter 1.4.1.2.4.16 “'Project' 'Show call tree'” on page 264* of POUs and data types, as well as
- the cross-reference list ↳ *Chapter 1.4.1.2.4.17 “'Project' 'Show cross reference'” on page 264*.

For the last two items the project must have been built without errors.



Only those areas highlighted in blue in the dialog box are printed.

If you want to select the entire project, then select the name of your project in the first line.

If, on the other hand, you only want to select a single object, then click on the corresponding object or move the dotted rectangle onto the desired object with the arrow key. Objects which have a plus sign in front of their symbols are organization objects which contain other objects. With a click on a plus sign organization object is expanded, and with a click on the resulting minus sign it can be closed up again. When you select an organization object, then all relevant objects are also selected. By pressing the <Shift> key you can select a group of objects, and by pressing the <Ctrl> key you can select several individual objects.

Once you have made your selection, then click on 'OK'. The Print dialog box appears. You can determine the layout of the pages to be printed with 'File' 'Printer setup' ↳ *Chapter 1.4.1.2.3.9 “'File' 'Printer setup'” on page 229*.

'Project' 'Export'

Projects can be exported or imported ↳ *Chapter 1.4.1.2.3.23 “'Project' 'Import'” on page 240*. That allows you to exchange programs between different IEC programming systems.

There is a standardized exchange format for POUs in IL, ST, and SFC (the Common Elements format of IEC 1131-3). For the POUs in LD and FBD and the other objects, CODESYS has its own filing format since there is no text format for this in IEC 1131-3.

The selected objects are written to an ASCII file.

POUs, data types, visualizations, and the resources can be exported. In addition, entries in the library manager, that is the linking information to the libraries, can be exported (not the libraries themselves!).

WARNING!
Re-importing an exported FBD or LD POU results in an error if a comment in the graphic editor contains a single quotation mark ('), as this will be interpreted as the beginning of a string!

Once you have made your selection in the dialog box window (the same way as with 'Project' 'Document' *Chapter 1.4.1.2.3.21 “'Project' 'Document'” on page 238*), you can decide, whether you want to export the selected parts to one file or to export in separate files, one for each object. Switch on or off the option One file for each object then click on OK. The dialog box for saving files appears. Enter a file name with the expansion ".exp" respectively a directory for the object export files, which then will be saved there with the file name <objectname.exp>.

'Project' 'Import'

In the resulting dialog box for opening files select the desired export file *Chapter 1.4.1.2.3.22 “'Project' 'Export'” on page 239*.

The data is imported into the current project. If an object with the same name already exists in the same project, then a dialog box appears with the question "Do you want to replace it?": If you answer Yes, then the object in the project is replaced by the object from the import file. If you answer No, then the name of the new objects receives as a supplement an underline and a digit ("_0", "_1", ..). With Yes, all or No, all this is carried out for all objects.

If the information is imported to link with a library, the library will be loaded and appended to the end of the list in the library manager. If the library was already loaded into the project, it will not be reloaded. If, however, the export file that is being imported shows a different storage time for the library, the library name is marked with a "*" in the library manager (e.g. standard.lib*30.3.99 11:30:14), similar to the loading of a project. If the library can not be found, then an information dialog appears: "Cannot find library {<path>\}<name> <date> <time>", as when a project is loaded.

In the message window the import is registered.

'Project' 'Compare'

This command is used to compare two projects or to compare the actual version of one project with that which was saved last.

Definitions:

- actual project: Project, which you are currently working on.
- reference project: Project, which should be compared with the actual project.
- compare mode: in this mode the project will be displayed after the command 'Project' 'Compare' has been executed.
- unit: Smallest unit which can be compared. Can be a line (declaration editor, ST editor, IL editor), a network (FBD editor, LD editor) or a element/POU (CFC editor, SFC editor).

In compare mode the actual project and the reference project will be presented in a bipartited window. The names of the POUs, for which differences have been found, are marked by color. For editor POUs also the content of the POUs is displayed in a vis-a-vis way. The results and the way of presenting in compare mode depend on: 1. what filters have been activated for the compare run, affecting the consideration of whitespaces and comments during comparison; 2. whether modification within lines or networks or elements are evaluated as a completely new inserting of a POU or not.

The version of the reference project can be accepted for single differences or for 'all equally marked' differences. To accept means that the version of the reference project is taken over to the actual project.

> *In compare mode (see status bar: COMPARE) the project cannot get edited!*

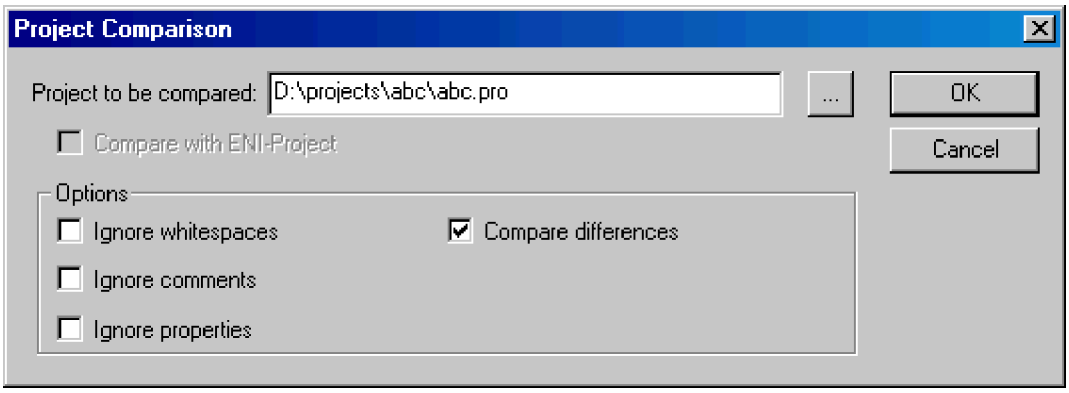
See also:

Chapter 1.4.1.2.3.25 “Execute comparison” on page 241

Chapter 1.4.1.2.3.26 “Representation of the comparison result” on page 242

Execute comparison

After executing the command 'Project' 'Compare' the dialog Project Comparison opens:



Insert the path of the reference project at Project to compare *Chapter 1.4.1.2.3.24 “'Project' 'Compare'” on page 240*. Press button if you want to use the standard dialog for opening a project. If you insert the name of the actual project, the current version of the project will be compared with the version which was saved last.

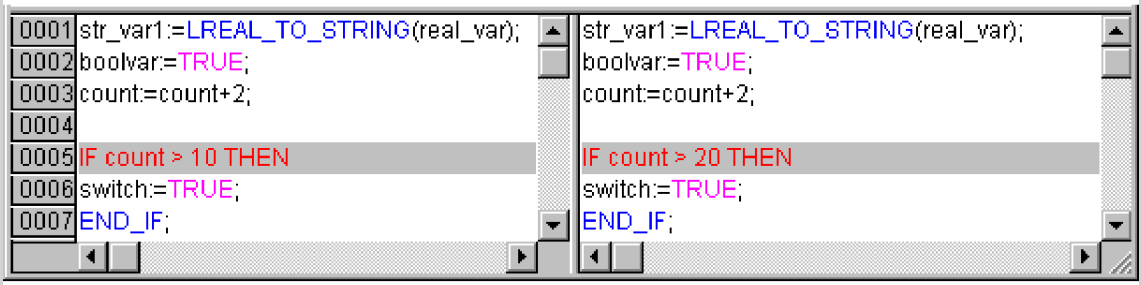
If the project is under source control in an ENI data base, then the local version can be compared with the actual version found in the data base. For this activate option Compare with ENI-Project.

The following options concerning the comparison can be activated:

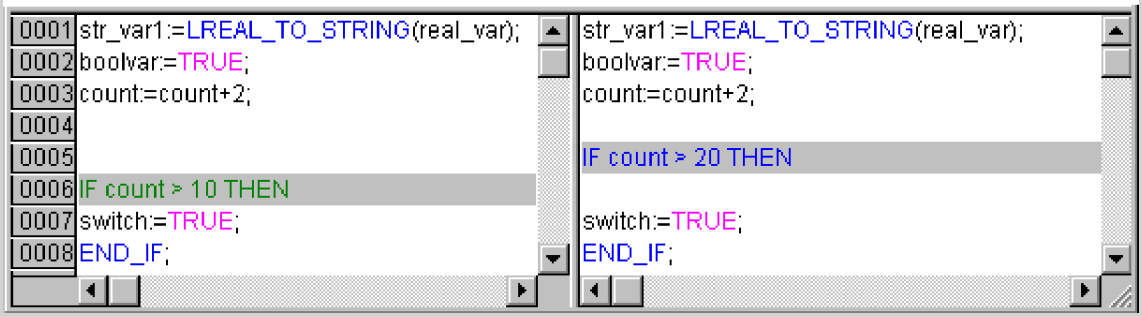
- Ignore whitespaces: There will be detected no differences which consist in a different number of whitespaces.
- Ignore comments: There will be detected no differences in comments.
- Ignore properties: There will be detected no differences in object properties.
- Compare differences: If a line, a network or an element within a POU has been modified, in compare mode it will be displayed in the bipartited window directly opposite to the version of the other project (marked red, see below). If the option is deactivated, the corresponding line will be displayed in the reference project as 'deleted' and in the actual project as 'inserted' (blue/green, see below). This means it will not be displayed directly opposite to the same line in the other project.

Example: Line 0005 has been modified in actual project (left side).

Option 'Oppose differences' activated:



Option 'Oppose differences' not activated:



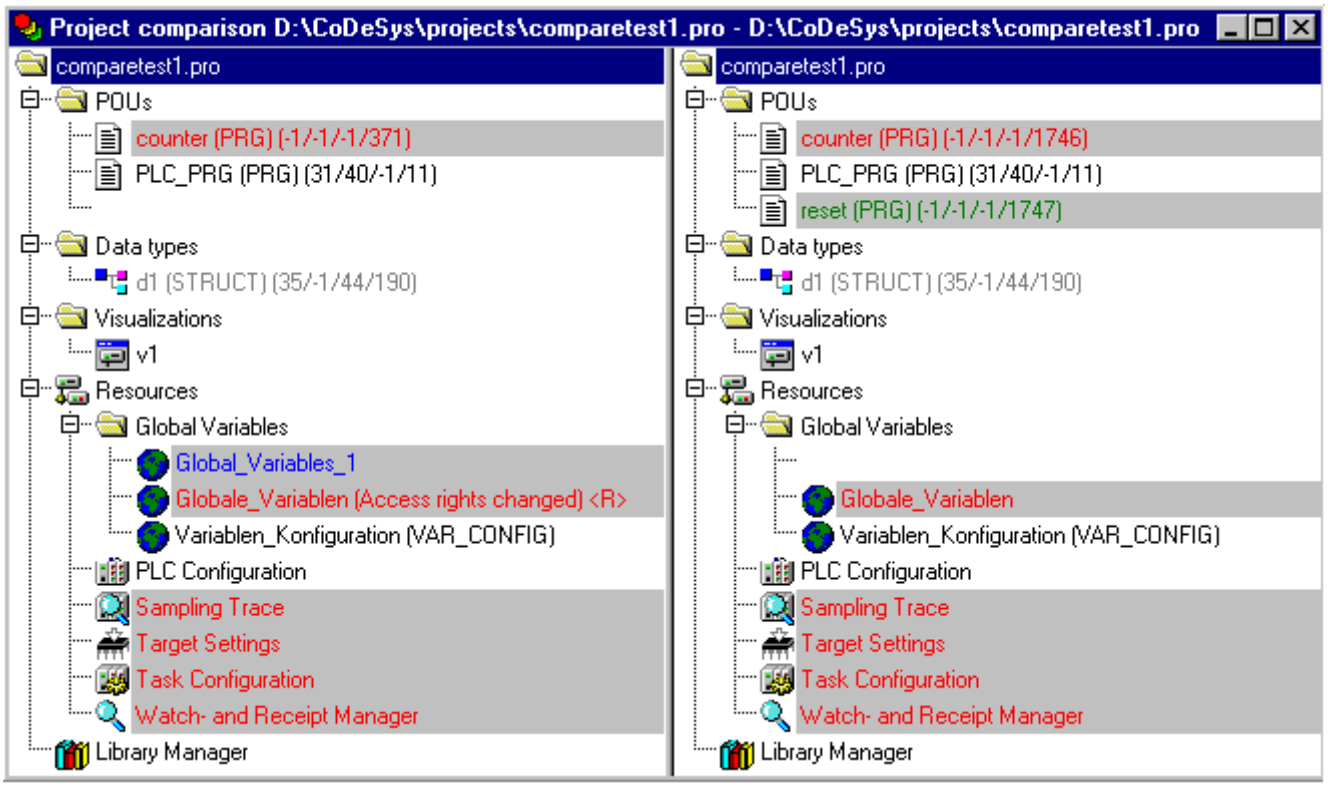
When the dialog 'Project Comparison' is closed by pressing OK, the comparison will be executed according to the settings.

Representation of the comparison result

First the structure tree of the project, titled with "Project Comparison", will be opened to display the results of the comparison. Here you can select particular POUs to see the found differences in detail.

1. Project overview in compare mode:

After the project compare has been executed, a bipartited window opens which shows the project in compare mode. In the title bar you find the project paths: "Project comparison <path of actual project> - <path of reference project>". The actual project is represented In the left half of the window, the reference project in the right one. Each structure tree shows the projects' name at the uppermost position, apart from that it corresponds to the the object organizer structure.



POUs which are different, are marked in the structure tree by a shadow, a specific color and eventually by an additional text :

- Red: Unit has been modified; is displayed with red colored letters in both partitions of the window.
- Blue: Unit only available in compare project; a gap will be inserted at the corresponding place in the structure overview of the actual project.
- Green: Unit only available in actual project; a gap will be inserted at the corresponding place in the structure overview of the actual project.
- Black: Unit for which no differences have been detected.

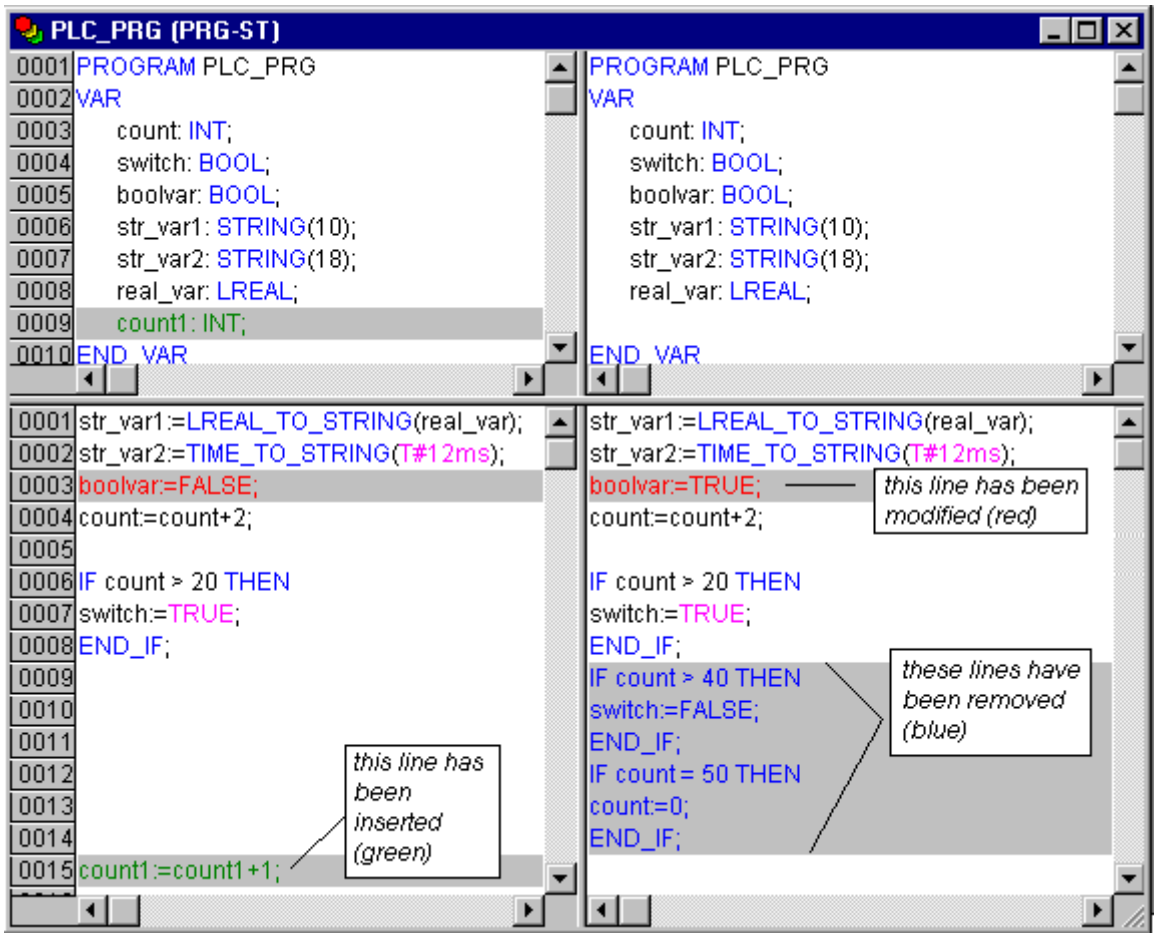
"(Properties changed)": This text is attached to the POU name in the project structure tree, if differences in the properties of the POU have been detected.

"(Access rights changed)": This text is attached to the POU name in the project structure tree, if differences in the access rights of the POU have been detected.

2. POU contents in compare mode:

By a double click on a line in the structure overview, which is marked red because of a modification, the POU is opened.

- If it is a text or graphic editor POU, it will be opened in a bipartited window. The content of the reference project (right side) is set opposite to that of the actual project (left side). The smallest unit which will be regarded during comparison, is a line (declaration editor, ST, IL), a network (FBD, LD) or an element (CFC, SFC). The same coloring will be used as described above for the project overview.
  Example:



- If it is not a editor POU, but the task configuration, the target settings etc., then the POU version of the actual and the reference project can be opened in separate windows by a double click on the respective line in the project structure. For those project POUs no further details of differences will be displayed.

'Extras' 'Next difference'

Shortcut: <F7>

This command is available in the compare mode *Chapter 1.4.1.2.3.24 "'Project' 'Compare'" on page 240*.

The cursor jumps to the next unit, where a difference is indicated. (line in project overview, line/network/element in POU)

'Extras' 'Previous difference'

Shortcut: <Shift><F7>

This command is available in the compare mode *Chapter 1.4.1.2.3.24 "'Project' 'Compare'" on page 240*.

The cursor jumps to the previous unit, where a difference is indicated (line in project overview, line/network/element in POU) .

'Extras' 'Accept change'

Shortcut: <Space>

This command is available in the compare mode ↳ *Chapter 1.4.1.2.3.24 “'Project' 'Compare'” on page 240*.

For all units, which are cohering with that one where the cursor currently is placed, and which have the same sort of difference marking, (e.g. subsequent lines), the version of the reference project will be accepted for the actual project (only possible in this direction!) ↳ *Chapter 1.4.1.2.3.25 “Execute comparison” on page 241*. The corresponding units will be shown (with the corresponding coloring) in the left side of the window.

For accepting changes of particular units please use 'Accept changed item' ↳ *Chapter 1.4.1.2.3.30 “'Extras' 'Accept changed item'” on page 245*.

The acceptance of different project parts (differences) or access right properties is only possible from the reference project of the actual project, not vice versa.

'Extras' 'Accept changed item'

Shortcut: <Ctrl> <Spacebar>

This command is available in the compare mode ↳ *Chapter 1.4.1.2.3.24 “'Project' 'Compare'” on page 240*.

Only the single unit (line, network, element) where the cursor is currently placed, will be accepted for the actual version ↳ *Chapter 1.4.1.2.3.25 “Execute comparison” on page 241*. The corresponding units will be shown (with the corresponding coloring) in the left side of the window.

If for a POU, which has got marked red-colored in the structure tree because of a change of its content, this change gets accepted, then the POU will be indicated by yellow coloring in the actual project.

POUs which are only available in the current project because of 'Accept changed item', also will be indicated by yellow coloring. POUs which have been removed from the current project because of 'Accept changed item', will be indicated by yellow coloring in the reference project ↳ *Chapter 1.4.1.2.3.25 “Execute comparison” on page 241*.

The acceptance of different project parts (differences) or access right properties is only possible from the reference project of the actual project, not vice versa.

'Extras' 'Accept properties'

This command is available in the compare mode ↳ *Chapter 1.4.1.2.3.24 “'Project' 'Compare'” on page 240*.

The object properties for the POU, where the cursor is currently placed, will be accepted for the actual project as they are set in the ence version ↳ *Chapter 1.4.1.2.3.25 “Execute comparison” on page 241*.

The acceptance of different project parts (differences) or access right properties is only possible from the reference project of the actual project, not vice versa.

'Extras' 'Accept access rights'

This command is available in the compare mode only in project overview *Chapter 1.4.1.2.3.24 "'Project' 'Compare'" on page 240*.

The object access rights for the POU, where the cursor is currently placed, will be accepted for the actual project as they are set in the reference version *Chapter 1.4.1.2.3.25 "Execute comparison" on page 241*.

'Project' 'Merge'

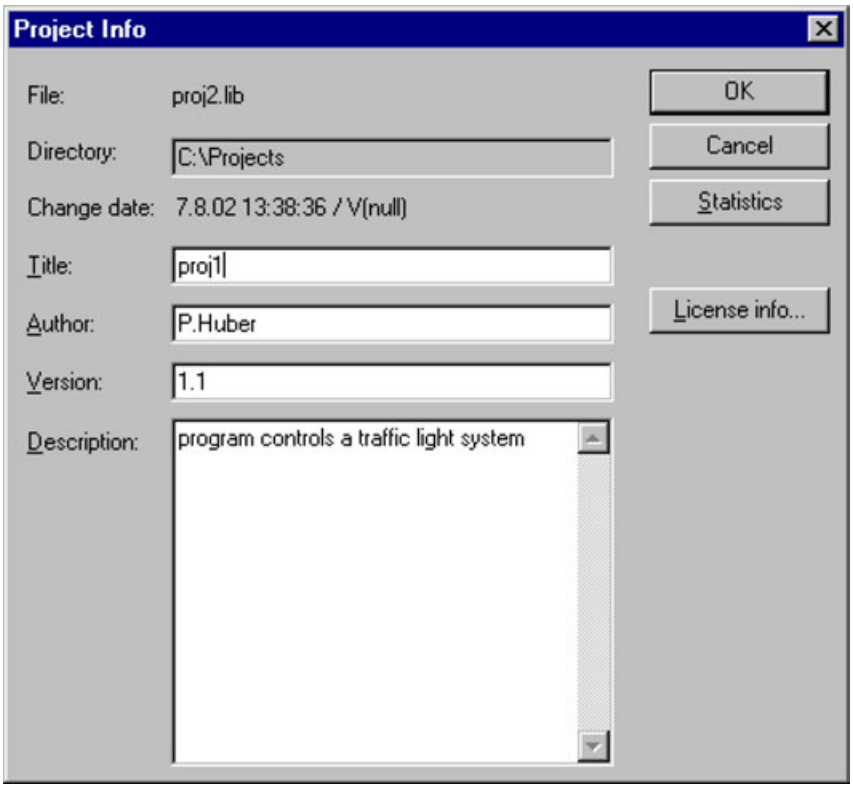
With this command you can merge objects (POUs, data types, visualizations, and resources) as well as links to libraries from other projects into your project.

When the command has been given, first the standard dialog box for opening files appears. When you have chosen a file there, a dialog box appears in which you can choose the desired object. The selection takes place as described with 'Project' 'Document' *Chapter 1.4.1.2.3.21 "'Project' 'Document'" on page 238*.

If an object with the same name already exists in the project, then the name of the new object receives the addition of an underline and a digit ("_1", "_2" ...).

'Project' 'Project info'

Under this menu item the information about your project can be saved. When the command has been given, then the following dialog box opens:



The following project information is displayed:

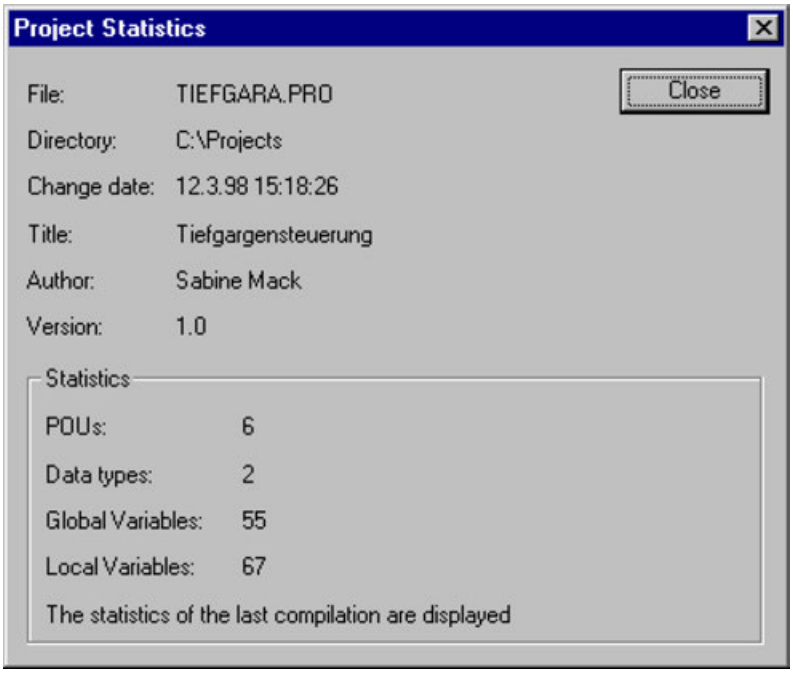
- File name
- Directory path
- The time of the most recent change (Change date)

This information cannot be changed. In addition, you can add the following information:

- A Title of the project: Please regard: If supported by the target system, this title automatically will be proposed as project file name, when the project gets loaded by command 'File' 'Open project from PLC' (In this case the dialog for saving a file will open).
- the name of the Author,
- the Version number, and
- a Description of the project.

This information is optional. When you press the button Statistics you receive statistical information about the project.

It contains information such as the number of the POUs, data types, and the local and global variables as they were traced at the last compilation.



The button 'License info' will be available, if you work on a project, which had been saved already with licensing information by the command 'File' 'Save as' *Chapter 1.4.1.2.3.6 "'File' 'Save as'" on page 224*. In this case the button opens the dialog 'Edit Licensing Information', where you can modify or remove the license.

If you choose the option 'Ask for project info' in the category 'Load & Save' in the Options dialog box, then while saving a new project, or while saving a project under a new name, the project info dialog is called automatically.

'Project' 'Global search'

With this command you can search for the location of a text in POUs, data types, or in the objects of the global variables.

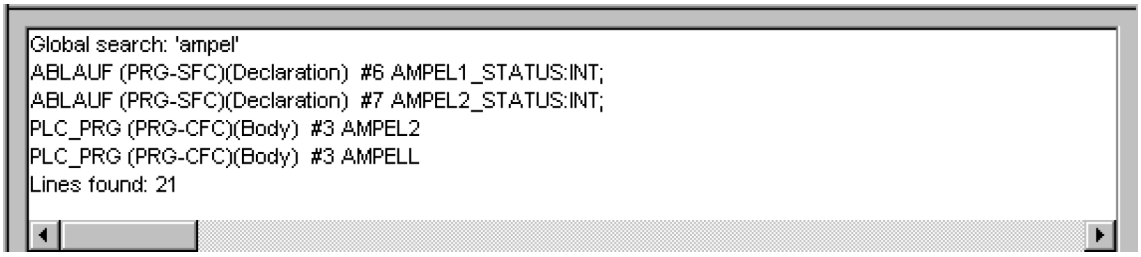
When the command is entered, a dialog box opens in which you can choose the desired object. The selection is made as in the 'Project' 'Document' description *Chapter 1.4.1.2.3.21 "'Project' 'Document'" on page 238*.

If the selection is confirmed with 'OK', the standard dialog for Search will be opened. This appears immediately when the command 'Global Search' is invoked via the symbol in the menu bar; the search is then automatically carried out in all searchable parts of the project. The most recently entered search strings can be selected through the combo box of the 'Search for' field. If a text string is found in an object, the object is loaded into the corresponding editor or in the library manager and the location where the string was found is displayed. The display of the text that is found, as well as the search and find next functions behave similarly to the command 'Edit' 'Search'.

If you select the 'In message window' button, all locations where the series of symbols searched for appears in the selected object will be listed line by line in tabular form in the message window. Afterward, the number of locations found will be displayed.

If the report window was not opened, it will be displayed. For each location that is found, the following will be displayed:

- Object name
- Location of the find in the Declaration (Decl) or in the Implementation (Impl) portion of a POU
- Line and network number if any
- The full line in the text editors
- Complete text element in the graphic editors



If you double-click the mouse on a line in the message window or press <Enter>, the editor opens with the object loaded. The line concerned in the object is marked. You can jump rapidly between display lines using the function keys <F4> and <Shift>+<F4>.

'Project' 'Global replace'

With this command you can search for the location of a text in POUs, data types, or the objects of the global variables and replace this text by another. This is executed in the same way as with 'Project' 'Global search' or 'Edit' 'Replace' ↳ *Chapter 1.4.1.2.3.35 “'Project' 'Global search'” on page 247* ↳ *Chapter 1.4.1.2.5.10 “'Edit' 'Replace'” on page 275*. The libraries, however, are not offered for selection and no display in the message window is possible.

Results are displayed in the message window.

'Project' 'Check'

This command provides commands for checking the semantic correctness of the project. The status of the most recent compilation will be regarded. If you have changed the project in the mean time, do a recompilation in order to get an up to date check result. Otherwise you will get an appropriate warning in the message window.

The results will be displayed in the message window.

In the project options, category 'Build', you can define these semantic checks to be done at each compilation of the project automatically.

Unused variables

This function in the 'Project' 'Check' menu searches for variables that have been declared but not used in the program. They are outputted by POU name and line, e.g.: PLC_PRG (4) – var1. Variables in libraries are not examined. Results are displayed in the message window.

Overlapping memory areas

This function in the 'Project' 'Check' menu tests whether in allocation of variables via the "AT" declaration overlaps have arisen at specific memory areas. For example, an overlap occurs when allocating the variables "var1 AT %QB21: INT" and "var2 AT %QD5: DWORD" because they both use byte 21. The output then appears as follows:

%QB21 is referenced by the following variables:

PLC_PRG (3): var1 AT %QB21

PLC_PRG (7): var2 AT %QD5

Results are displayed in the message window.

Multiple write acces on output

This function of the 'Project' 'Check' menu searches for memory areas to which a single project gains write access at more than one place. The output then appears as follows:

%QB24 is written to at the following locations:

PLC_PRG (3): %QB24

PLC_PRG.POU1 (8): %QB24

Results are displayed in the message window.

Concurrent access

This function in the 'Project' 'Check' menu searches for memory areas of IEC addresses which are referenced in more than one task ↬ *Chapter 1.4.1.2.3.37 “'Project' 'Check'” on page 248*. No distinction is made here between read and write access. The output is for example:

%MB28 is referenced in the following tasks :

Task1 – PLC_PRG (6): %MB28 [read-only access]

Task2 – POU1.ACTION (1) %MB28 [write access]

Results are displayed in the message window.

User groups

Up to eight user groups with different access rights to the POUs, data types, visualizations, and resources can be set up. Access rights for single objects or all of them can be established. Only a member of a certain user group can open a project. A member of such a user group must identify himself by means of a password.

The user groups are numbered from 0 to 7, whereby the Group 0 has the administrator rights, i.e. only members of group 0 may determine passwords and access rights for all groups and/or objects.

When a new project is launched, then all passwords are initially empty. Until a password has been set for the 0 group, one enters the project automatically as a member of the 0 group.

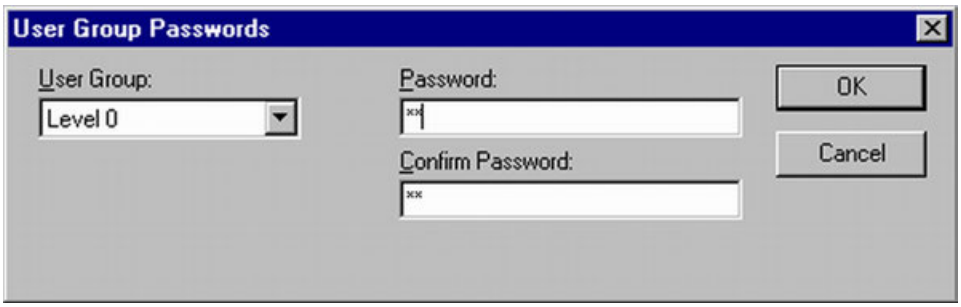
If a password for the user group 0 is existing while the project is loaded, then a password will be demanded for all groups when the project is opened.

In the combobox User group on the left side of the dialog box, enter the group to which you belong and enter on the right side the relevant password. Press OK. If the password does not agree with the saved password, then the message appears: "The password is not correct."

Only when you have entered the correct password the project can be opened. With the command 'Passwords for user group' you can assign the passwords, and with 'Object' 'Access rights' you can define the rights for single objects or for all of them.

'Project' 'Passwords for user groups'

With this command you open the dialog box for password assignment for user groups. This command can only be executed by members of group 0. When the command has been given, then the following dialog box appears:



In the left combobox 'User group' you can select the group. Enter the desired password for the group in the field 'Password'. For each typed character an asterisk (*) appears in the field. You must repeat the same password in the field 'Confirm password'. Close the dialog box after each password entry with 'OK'. If you get the message:

```
"The password does not agree with the confirmation",
```

then you made a typing error during one of the two entries. In this case repeat both entries until the dialog box closes without a message.

Then, if necessary, assign a password for the next group by calling the command again.

WARNING!
If passwords are not assigned to all user groups, a project can be opened by way of a group to which no password was assigned!

Use the command 'Object' 'Access rights' to assign the rights for single objects or all of them ↳ *Chapter 1.4.1.2.4.13 “'Project' 'Object access rights'” on page 262*.

Concerning the protection of a project see also the following:

Encryption of a project at project saving ↳ *Chapter 1.4.1.2.3.6 “'File' 'Save as'” on page 224*

'Project' 'Project database'

Overview

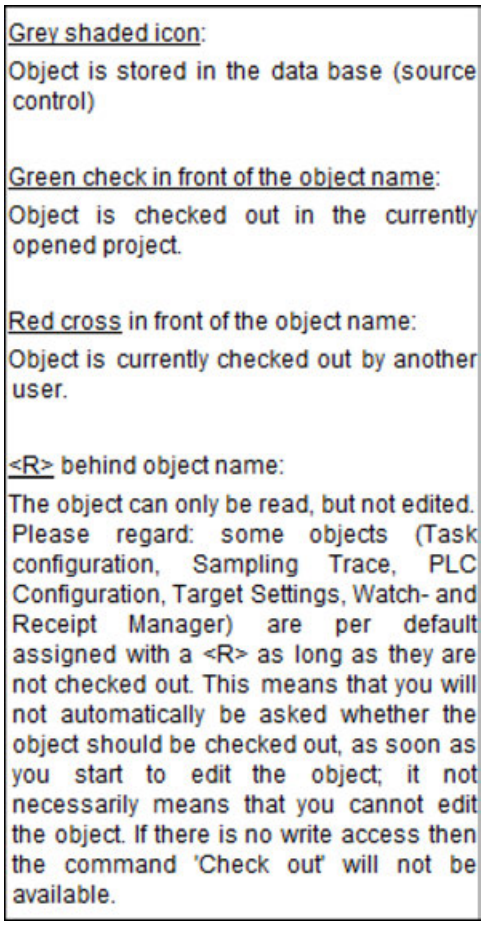
This menu item is only available if you have activated the option 'Use source control (ENI)' in the project options dialog for category 'Project source control'. A submenu is attached where you find the following commands for handling the object resp. the project in the currently connected ENI data base:

Login (The user logs in to the ENI Server)

If an object is marked in the Object Organizer and the command Data Base Link is executed (from the context menu, right mouse button), then several commands will be available for executing the corresponding data base actions. If the user had not logged in successfully to the ENI Server before, then the dialog 'Data base Login' will open automatically and the chosen command will not been executed until the login was successful.

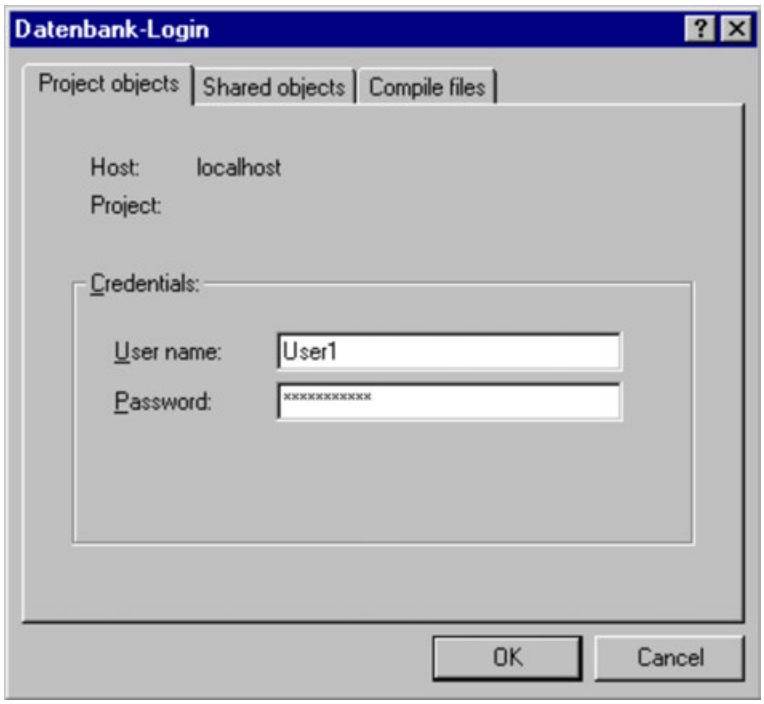
If the command 'Data Base Link' in the 'Project' menu is activated, then additional menu items will be available, which concern all objects of the project.

How the status of an object's handling in the data base is displayed in the Object Organizer:



Login

This command will open the dialog 'Login' where you can enter the access data for the ENI data base via the ENI Server. The access data also have to be defined in the ENI Server (ENI Admin, User Management) and – depending on the currently used data base – also in the user management of the data base. After the command has been executed, first the Login dialog for category 'Project objects' will open.



The following items are displayed:

- Data base: project objects
- Host: address of the computer where the ENI Server is running (must match with the entry in field 'TCP/IP address' in the project options dialog for 'Project source control').
- Project: Name of the data base project (must match with the entry in field 'Project name' in the project options dialog for 'Project source control'/category 'Project Objects').

Credentials:

- Insert username and password.
- When option Use as default for this project is activated, then the above entered access data will automatically be used for any further communication between the actual project and the data base concerning objects of the actual category.
- Press OK to confirm the settings. The dialog will be closed and automatically the Login dialog for 'Shared objects' will open. Enter the access data in the same way as described for the 'Project objects' and confirm with OK. Do the same in the third Login dialog which will be opened for category 'Compile files'.
- The Login dialog will always open as soon as you try to access the data base before having logged in successfully as described above.

If you want to save the access data with the project, activate option 'Save ENI credentials' in the project options, category 'Load & Save'.

Define

Command: 'Project' 'Data Base Link' 'Define'

Here you can define, whether the object which is currently marked in the Object organizer should be kept in the data base or just locally in the project. A dialog will open, where you can choose one of the two database categories 'Project' or 'Shared objects', or the category 'Local'.

The icons of all objects which are managed in the data base will be displayed grey-shaded in the Object organizer. Shared objects are displayed with turquoise letters.

Get latest version

Command: 'Project' Data Base Link'Get Latest Version'

The current version of the object which is marked in the Object organizer will be copied from the data base and will overwrite the local version. In contrast to the Check Out action the object will not be locked for other users in the data base *Chapter 1.4.1.2.3.44.5 “Check out” on page 253*.

Check out

Command: 'Project' 'Data Base Link' 'Check Out'

The object which is marked in the Object organizer will be checked out from the data base and by that will be locked for other users.

When executing the command the user will get a dialog 'Check out object'. A comment can be added there which will be stored in the version history of the object in the data base. Line breaks are inserted by <Ctrl>+<Enter>. If the version of the object differs from that in the local project, an appropriate message will be displayed and the user can decide whether the object should be checked out anyway.

After the dialog has been closed with OK, the checked-out object will be marked with a green check in the object organizer of the local project. For other users it will be appear marked with a red cross and will not be editable by them.

Check in

Command: 'Project' 'Data Base Link' 'Check In'

The object which is marked in the Object organizer will be checked in to the data base. Thereby a new version of the object will be created in the data base. The old versions will be kept anyway.

When executing the command the user will get a dialog 'Check in object'. There a comment can be added which will be stored in the version history of the object in the data base. Line breaks are inserted by <Ctrl>+<Enter>.

After the dialog has been closed with OK the green check in front of the object name in the Object organizer will be removed.

Undo check out

Command: 'Project' 'Data Base Link' 'Undo Check Out'

Use this command to cancel the Checking out of the object which is currently marked in the Object organizer. Thereby also the modifications of the object which have been made locally, will be canceled. No dialog will appear. The unchanged last version of the object will be kept in the data base and it will be accessible again for other users. The red cross in front of the object name in the Object organizer will disappear.

Show differences

Command: 'Project' 'Data Base Link' 'Show Differences'

The object which is currently open will be displayed in a window which is divided up in two parts. There the local version, which is currently edited by the local user, will be opposed to the last (actual) version which is kept in the data base. The differences of the versions will be marked like described for the project comparison (see 'Project' 'Compare').

Show version history

Command: 'Project' 'Data Base Link' 'Show Version History'

For the currently marked object in the Object organizer a dialog Version history of <object name> will be opened. There all versions of the object are listed which have been checked in to the data base or which have been labeled there:

The following information is given:

Version: Data base specific numbering of the versions of the object which have been checked in one after the other. Labeled versions get no version number but are marked by a label-icon.

User: Name of the user, who has executed the check-in or labeling action

Date: Date and time stamp of the action

Action: Type of the action which has been executed. Possible types: 'created' (the object has been checked in to the data base for the first time), 'checked in' (all check-ins of the object excluding the first one) and labeled with <label> (a label has been assigned to this version of the object)

The buttons:

Close: The dialog will be closed.

Display: The version which is currently marked in the table will be opened. The title bar shows: ENI: <name of the project in the data base>/<object name>

Details: The dialog 'Details of Version History' will open:

File (name of the project and the object in the data base), Version (see above), Date (see above), User (see above), Comment (Comment which has been inserted when the object has been checked in resp. has been labeled). Use the buttons Next resp. Previous to jump to the details window of the next or previous entry in the table in dialog 'Version history of ..'.

Get latest version: The version which is marked in the table will be loaded and there will overwrite the local version.

Differences: If in the table only one version of an object is marked, then this command will cause a comparison of this version with the latest (actual) data base version. If two versions are marked, then those will be compared. The differences are displayed in a bipartited window like it is done at the project comparison.

Reset version: The version which is marked in the table will be set as latest version. All versions which have been checked in later will be deleted ! This can be useful to restore an earlier status of an object.

Labels only: If this option is activated, then only those versions of the object will be displayed in the table, which are marked by a label.

Selection box below the option 'Labels only': Here you find the names of all users which have executed any data base actions for objects of the current project. Select 'All' or one of the names if you want to get the version history concerning all users or just for a certain one.

Multiple define

Command 'Project' 'Data Base Link' 'Multiple Define'

Use this command if you want to assign several objects at a single blow to a certain data base category. The dialog 'Properties' will open like described for command 'Define'. Choose the desired category and close the dialog with OK. After that the dialog 'ENI-Selection' will open, listing all POUs of the project which are considered for the chosen category (Example: if you choose category 'shared objects' then the selection window will only offer the POUs of the Resources tab). The POUs are presented in a tree structure complying to that of the Object Organizer. Select the desired POUs and confirm with OK.

Get all latest versions

Command 'Project' 'Data Base Link' 'Get All Latest Versions'

The latest version of each object of the currently opened project, which is kept under source control, will be called from the data base. Consider the following:

- If in the meantime additional objects have been stored to the data base project folder, then those will now be added to the local project.
- If objects have been deleted in the data base in the meantime, those will not be deleted in the local project, but they will automatically get assigned to category 'Local'.
- The latest version of objects of category 'Shared Objects' will only be called, if these objects are already available in the local project. For further information see command 'Get latest version' *Chapter 1.4.1.2.3.44.4 “Get latest version” on page 253*.

Multiple check out

Command 'Project' 'Data Base Link' 'Multiple Check Out'

You can check out several objects at a single blow. For this the dialog 'ENI-Selection' will open, listing all POUs of the project. Select those which should be checked out and confirm with OK. For further information see command 'Check Out'.

Multiple check in

Command 'Project' 'Data Base Link' 'Multiple Check In'

You can check in several objects at a single blow. For this the dialog 'ENI-Selection' will open, listing all POUs of the project. Select those which should be checked in and confirm with OK. For further information see command 'Check In'.

Multiple undo check out

Command 'Project' 'Data Base Link' Undo Multiple Check Out'

You can undo the check out action for several objects at a single blow. For this the dialog 'ENI-Selection' will open, listing all POUs of the project. Select those for which you want to cancel the check out and confirm with OK. For further information see command 'Undo Check Out'.

Project version history

Command 'Project' 'Data Base Link' 'Project Version History

If the chosen data base system supports that functionality, you can use this command to view the version history for the currently opened project.

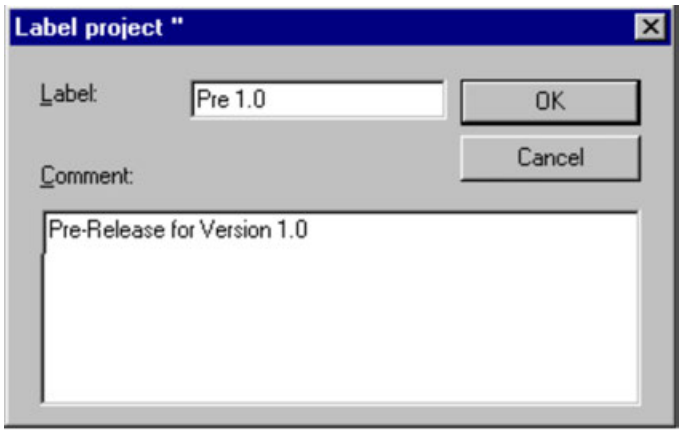
The dialog 'History of <data base project name>' will open. It shows the actions (create, check in, label) which have been performed for the particular objects of the project in a chronological order. The total number of objects is displayed behind Version history. The dialog can be handled like described for command 'Show Version History', but regard the following:

- The command 'Reset Version' is only available for single objects.
- The command 'Get latest version' means that all objects of the version of the currently marked object will be called to the local project! That means, that the objects in CODESYS will be overwritten with the older version. But: Local objects, which were not yet part of the project in that older version, will not be removed from the local project ! If a labeled version is called, which contains Shared Objects, then the user will get a dialog where he can decide whether those Shared Objects should be called also or not.

Label version

Command 'Project' 'Data Base Link' 'Label Version'

This command is used to put a "label" on the actual version of each object of a project, so that exactly this project version can be recalled later. A dialog 'Label <data base project name>' will open. Insert a label name (Label) (e.g. "Release Version") and optionally a Comment. When you confirm with OK, the dialog will close and the label and the action "labeled with <label name>" will appear in the table of the version history, as well in the history for a single object as in the history of the project. Shared Objects which are part of the project will also get that label. A labeled version of the project does not get a version number, but is just marked with a label icon in the column 'Version'. If the option 'Labels only' is activated in the Version History dialog, then only labeled versions will be listed.

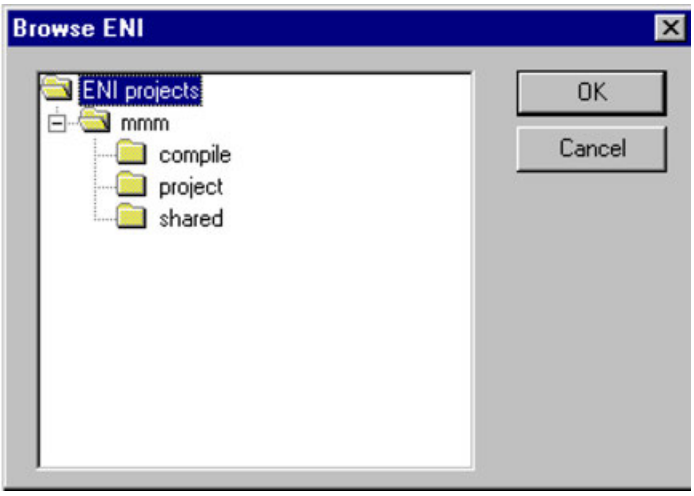


Add shared objects

Command 'Project' 'Data Base Link' 'Add Shared Objects'

Use this command if you explicitly want to add new objects of data base category 'Shared Objects' to the locally opened project. For objects of category 'Project Objects' this is not necessary, because the command 'Get (all) latest version(s)' automatically calls all objects which are found in the data base project folder, even if there are some which not yet available in the local project. But for objects of category 'Shared Objects' in this case just those objects will be called which are already available in the local project.

So execute the command 'Add Shared Objects' to open the dialog 'Browse ENI'. A list in the right part of the window shows all objects which are available in the data base folder which is currently selected in the list on the left side. Choose the desired object and press OK or do a doubleclick on the entry to insert the object to the currently opened project.



Refresh status

Command 'Project' 'Data Base Link' 'Refresh Status'

Use this command to update the display in the Object Organizer, so that you can see the actual status of the objects concerning the source control of the project.

1.4.1.2.4 Managing objects in a project

Object

POUs, data types, visualizations and the resources global variables, the variable configuration, the Sampling Trace, the PLC Configuration, the Task Configuration, and the Watch and Receipt Manager are all defined as "objects". The folders inserted for structuring the project are partially involved. All objects of a project are in the Object Organizer.

If you hold the mouse pointer for a short time on a POU in the Object Organizer, then the type of the POU (Program, Function or Function block) is shown in a Tooltip. For the global variables the tooltip shows the keyword (VAR_GLOBAL, VAR_CONFIG).

With drag & drop you can shift objects (and also folders, see 'Folder') within an object type. For this, select the object and shift it to the desired spot by holding down the left mouse button. If the shift results in a name collision, the newly introduced element will be uniquely identified by an appended, serial number (e.g. "Object_1").

Folder

In order to keep track of larger projects you should group your POUs, data types, visualizations, and global variables systematically in folders.

You can set up as many levels of folders as you want. If a plus sign is in front of a closed folder symbol  , then this folder contains objects and/or additional folders. With a click on the plus sign the folder is opened and the subordinated objects appear. With a click on the minus (which has replaced the plus sign) the folder can be closed again. In the context menu you find the commands 'Expand nodes' and 'Collapse nodes' with the same functions *Chapter 1.4.1.2.4.4 “'Expand nodes' 'Collapse nodes'” on page 258*.

With Drag&Drop you can move the objects as well as the folders within their object type. For this select the object and drag it with pressed left mouse button to the desired position.

You can create more folders with the command 'New folder' *Chapter 1.4.1.2.4.3 “'New folder'” on page 258*.

Folders have no influence on the program, but rather serve only to structure your project clearly.

'New folder'

With this command a new folder is inserted as a structural object *Chapter 1.4.1.2.4.2 “Folder” on page 257*. If a folder has been selected, then the new one is created underneath it. Otherwise it is created on the same level. If an action is selected, the new folder will be inserted at the level of the POU to which the action belongs.

The context menu of the 'Object Organizer' which contains this command appears when an object or the object type has been selected and you have pressed the right mouse button or <Shift>+<F10> *Chapter 1.4.1.2.1.3 “Object organizer” on page 199*.

The newly inserted folder initially has the designation 'New Folder'. Observe the following naming convention for folders:

- Folders at the same level in the hierarchy must have distinct names.
- Folders on different levels can have the same name. A folder can not have the same name as an object located on the same level.

If there is already a folder with the name "New Folder" on the same level, each additional one with this name automatically receives an appended, serial number (e.g. "New Folder 1"). Renaming to a name that is already in use is not possible.

'Expand nodes' 'Collapse nodes'

With the Expand nodes command the objects which are located in the selected object are visibly unfolded. Collapse nodes hides the subordinate objects.

With folders you can open or close them with a double mouse click or by pressing <Enter> *Chapter 1.4.1.2.4.2 “Folder” on page 257*.

This command appears in the context menu of the Object Organizer when you right-click on an object, or press <Shift>+<F10>.

'Project' 'Object' 'Delete'

Shortcut: <Delete>

With this command the currently selected object (a POU, a data type, a visualization, or global variables), or a folder with the subordinated objects is removed from the Object Organizer and is thus deleted from the project. Deleting of an object can be reversed by the command 'Edit' 'Undo'.

You can get back the deleted objects by using the command 'Edit' 'Undo'.

If the editor window of the object was open, then it is automatically closed.

If you delete with the command 'Edit' 'Cut', then the object is parked on the clipboard *Chapter 1.4.1.2.5.4 “'Edit' 'Cut'” on page 273*.

'Project' 'Object' ' Add'

Shortcut: <Insert>

With this command you create a new object. The type of the object (POU, data type, visualization, or global variables) depends upon the selected register card in the Object Organizer. Note that in doing so possibly a template will be used for objects of type 'Global Variables', 'Data types', 'Function', 'Function Block' or 'Program' ., see below, chapter 'Save as template' *Chapter 1.4.1.2.4.7 “'Save as template'” on page 259*.

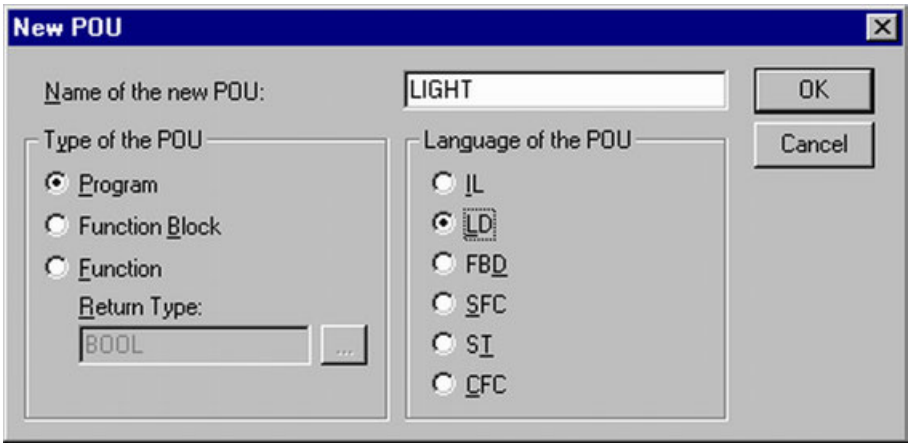
Enter the 'Name of the new POU' in the dialog box which appears. Remember that the name of the object may not have already been used.

Take note of the following restrictions:

- The name of a POU can not include any spaces
- A POU can not have the same name as another POU, a data type and should not have the same as a visualization in order to avoid problems with visualization changes.
- A data type can not receive the same name as another data type or a POU.
- A global variable list can not have the same name as another global variable list.
- An action can not have the same name as another action in the same POU.
- A visualization can not have the same name as another visualization and should not have the same as a POU in order to avoid problems with visualization changes.

In all other cases, identical naming is allowed. Thus for example actions belonging to different POUs can have the same name, and a visualization may have the same as a POU.

In the case of a POU, the POU type (program, function or function block) and the language in which it is programmed must also be selected. 'Program' is the default value of 'Type of the POU', while that of 'Language of the POU' is that of most recently created POU. If a POU of the function type is created, the desired data type must be entered in the 'Return Type' text input field. Here all elementary and defined data types (arrays, structures, enumerations, aliases) are allowed. Input assistance (e.g. via <F2>) can be used.



After pressing 'OK', which is only possible if there is no conflict with the naming conventions described above, the new object is set up in the Object Organizer and the appropriate input window appears.

If the command 'Edit' 'Insert' is used, the object currently in the clipboard is inserted and no dialog appears. If the name of the inserted object conflicts with the naming conventions (see above), it is made unique by the addition of a serial number appended with a leading underline character (e.g. "Rightturnsig_1").

If the project is under source control in an ENI data base, it may be (depends on the settings in the Project options dialog for 'Project source control') that you will be automatically asked in which data base category you want to handle the new object ↯ *Chapter 1.4.1.2.2.13 “Options for 'Project source control'” on page 216*. In this case the dialog 'Properties' will open where you can assign the object to one of the database object categories.

'Save as template'

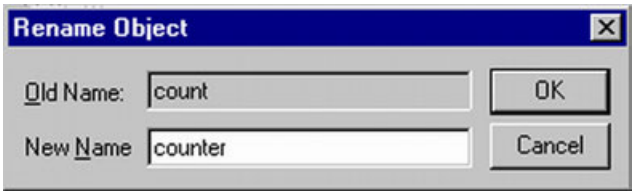
Objects of type 'Global Variables', 'Data types', 'Function', 'Function Block' or 'Program' can be saved as templates. Select the object in the Object Organizer and choose command 'Save as template' in the context menu (right mouse button). Hereupon each further new object of the same type will automatically initially get the declaration part of the template ↯ *Chapter 1.4.1.2.4.6 “'Project' 'Object' ' Add'” on page 258*. The last created template for an object type will be used.

'Project' 'Object' 'Rename'

Shortcut: <Spacebar>

With this command you give a new name to the currently-selected object or folder ↳ *Chapter 1.4.1.2.4.2 “Folder” on page 257*. Remember that the name of the object may not have already been used.

If the editing window of the object is open, then its title is changed automatically when the name is changed.



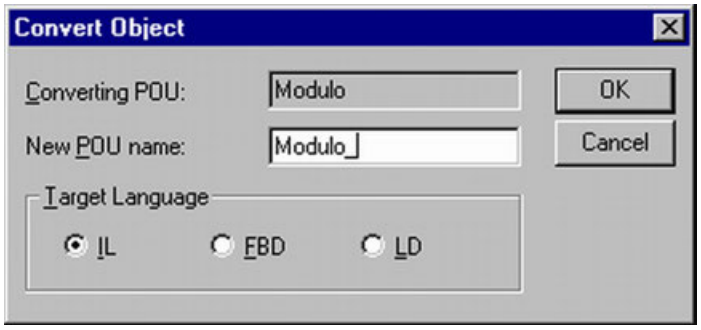
'Project' 'Object' 'Convert'

This command can only be used with POUs. You can convert POUs from the languages SFC, ST, FBD, LD, and IL into one of the three languages IL, FBD, and LD.

For this the project must be compiled. Choose the language into which you want to convert and give the POU a new name. Remember that the name of the POU may not have already been used. Then press 'OK', and the new POU is added to your POU list.

The type of processing that occurs during conversion corresponds to that which applies to compilation.

NOTICE!
Actions cannot be converted.

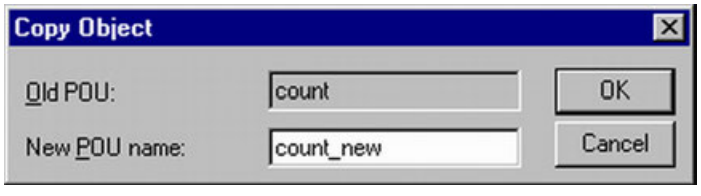


Note the following possibility: A POU which has been created in the FBD-Editor can, using the command 'Extras' 'View' be displayed and edited in the KOP-Editor as well without any conversion ↳ *Chapter 1.4.1.3.11.7.12 “'Extras' 'View'” on page 321*.

'Project' 'Object' 'Copy'

With this command a selected object is copied and saved under a new name. Enter the name of the new object in the resulting dialog box. Remember that the name of the object may not have already been used.

If, on the other hand, you used the command 'Edit' 'Copy', then the object is parked on the clipboard, and no dialog box appears.



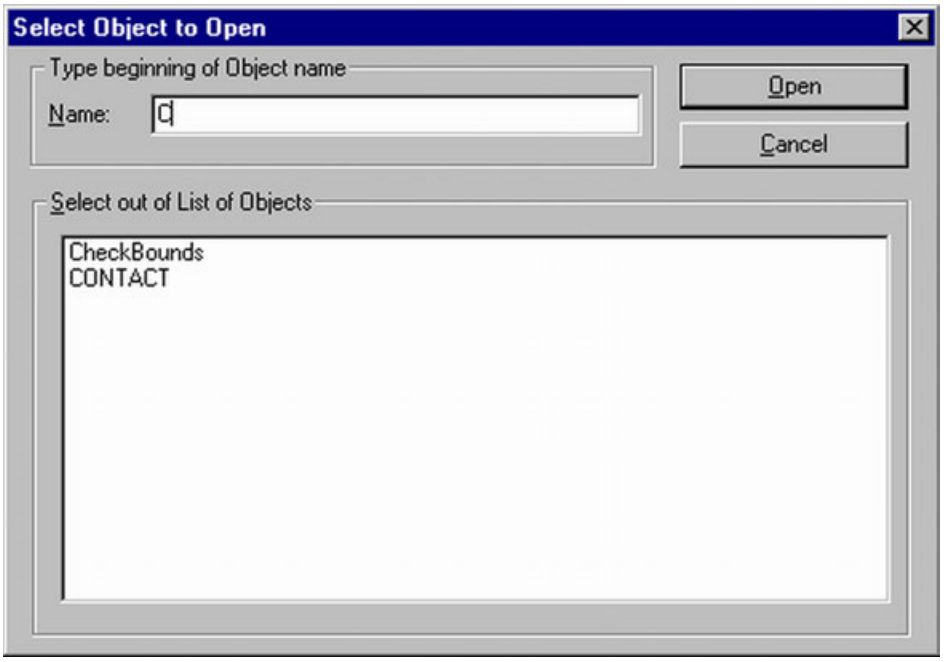
'Project' 'Object' 'Open'

Shortcut: <Enter>

With the command you load a selected object within the 'Object Organizer' into the respective editor *Chapter 1.4.1.2.1.3 “Object organizer” on page 199*. If a window with this object is already open, then it gets a focus, is moved into the foreground and can now be edited.

There are two other ways of opening an object:

- Doubleclick with the mouse on the desired object
- in the Object Organizer, type the first letter of the object name. This will open a dialog box in which all objects of the available object types which have this initial letter are shown. Actions are listed with the notation <POU name>.<action name>. Due to the fact that the objects in the object selection dialog are listed alphabetically, the actions of a POU always get positioned below this POU. Select the desired object and click on the button 'Open' in order to load the object in its edit window. Hereupon the object gets also marked in the object organizer and all folders which are hierarchically placed above the object will get expanded. This option is supported with the object type 'Resources' only for global variables.



'Project' 'Object properties'

This command will open the dialog 'Properties' for that object which is currently marked in the Object organizer.

On the tab 'Access rights' you find the same dialog as you get when executing the command 'Project' 'Object access rights' *Chapter 1.4.1.2.4.13 “'Project' 'Object access rights'” on page 262*.

It depends on the object and the project settings, whether there are additional tabs available where you can define object properties:

Global variable list: In the tab 'Global variable list' the parameters concerning the actualization of the list and concerning the data exchange of network variables are displayed and can be modified here. This dialog also will be opened if you create a new global variable list by selecting one of the entries in section 'Global Variables' in the Object Organizer and executing the command 'Add Object' *Chapter 1.4.1.4.1.3.1 “Create a global variable list” on page 358*.

Visualization: In the tab 'Visualization' you can define for the visualization object, how it should be used *Chapter 1.4.3 “Visualization” on page 636*:

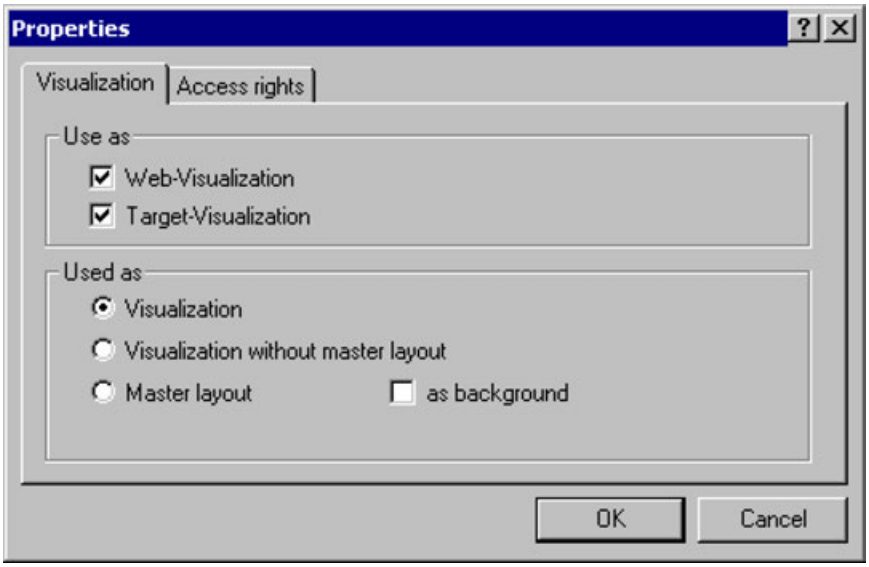
Use as:

If in the target settings the option 'web visualization' or 'target visualization' is activated, then you can choose here whether the object should be part of the web visualization or target visualization *Chapter 1.4.1.4.7.3 “Target settings in category visualization” on page 388*.

Used as:

Activate one of these settings referring to the possibility of using "Master layouts":

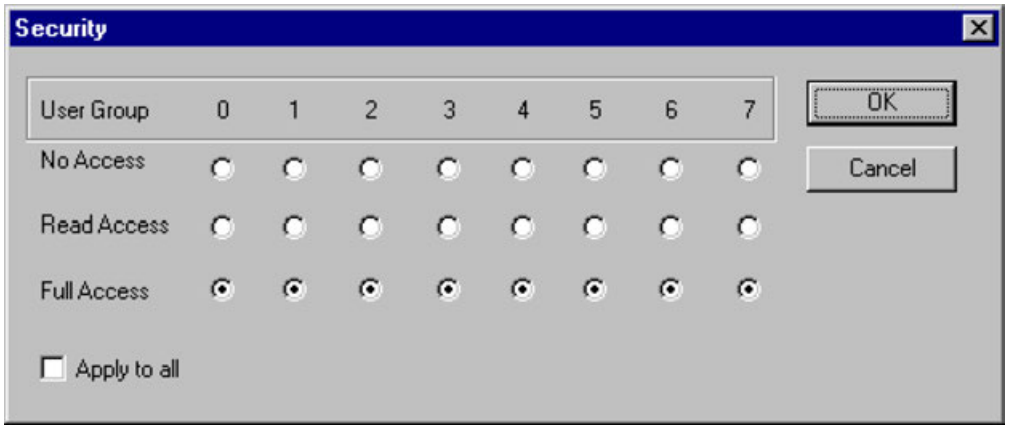
- Visualization: The object is used as a normal visualization.
- Visualization without master layout: If a Master Layout is defined in the project, it will not be applied to this visualization object.
- Master layout: The object will be used as Master Layout. Per default the master layout always will be in the foreground of a visualization, except the option as background is activated.



Database-connection: If the project is connected to an ENI data base, then a tab 'Database-connection' will be available *Chapter 1.4.1.2.2.13 “Options for 'Project source control'” on page 216*. Here you can display and modify the current assignment of the object to one of the data base categories resp. to the category 'Local'.

'Project' 'Object access rights'

With this command you open the dialog box for assigning access rights to the different 'user groups' *Chapter 1.4.1.2.3.42 “User groups” on page 249*. The following dialog box appears:



Members of the user group 0 can now assign individual access rights for each user group. There are three possible settings:

- No Access: the object may not be opened by a member of the user group.
- Read Access: the object can be opened for reading by a member of the user group but not changed.
- Full Access: the object may be opened and changed by a member of the user group.

The settings refer either to the currently-selected object in the 'Object Organizer' or, if the option 'Apply to all' is chosen, to all POUs, data types, visualizations, and resources of the project ↳ *Chapter 1.4.1.2.1.3 “Object organizer” on page 199*.

The assignment to a user group takes place when opening the project through a password request if a password was assigned to the user group 0.

Please regard also the possibility to assign access rights concerning the operation of visualization elements (Visualization, Security).

'Project' 'Add action'

This command is used to generate an action allocated to a selected block in the 'Object Organizer' ↳ *Chapter 1.4.1.2.1.3 “Object organizer” on page 199*. One selects the name of the action in the dialog which appears and also the language in which the action should be implemented.

The new action is placed under your block in the Object Organiser. A plus sign appears in front of the block. A simple mouse click on the plus sign causes the action objects to appear and a minus sign appears in front of the block. Renewed clicking on the minus sign causes the actions to disappear and the plus sign appears again. This can also be achieved over the context menu commands 'Expand Node' and 'Collapse Node' ↳ *Chapter 1.4.1.2.4.4 “'Expand nodes' 'Collapse nodes'” on page 258*.

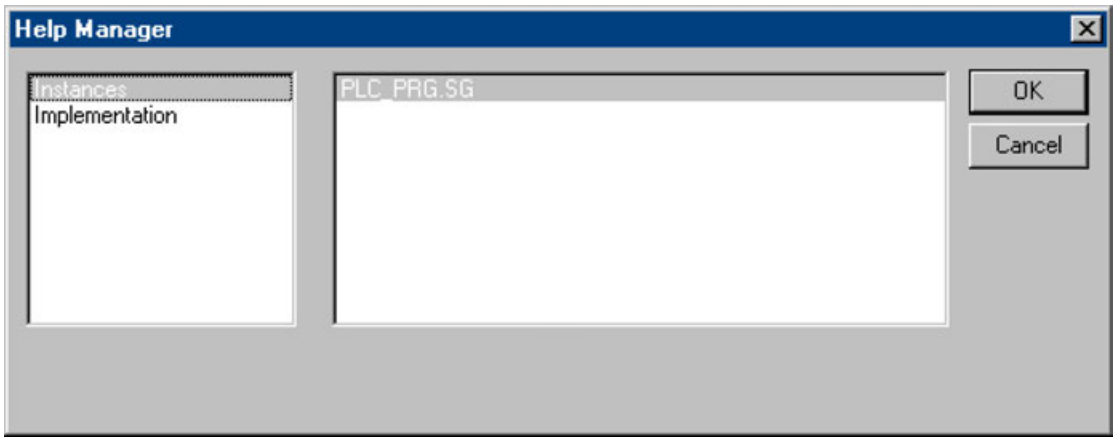
See also:

Calling actions ↳ *Chapter 1.4.1.1.9.9 “Action” on page 160*

Action in the Sequential Function Chart ↳ *Chapter 1.4.1.1.10.5.2 “Action” on page 171*

'Project' 'View instance'

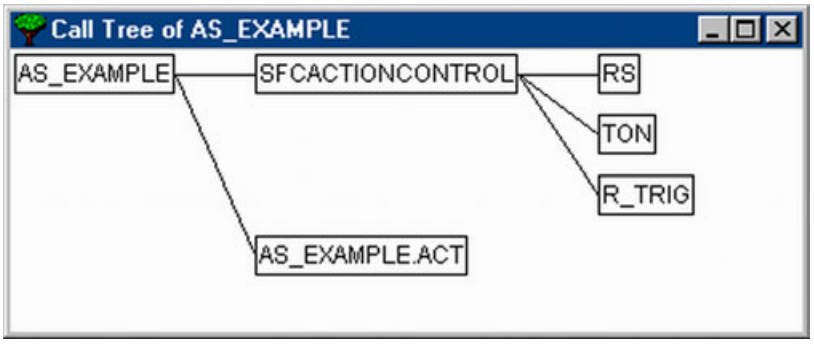
With this command it is possible to open and display the instance of the function block which is selected in the Object Organizer. In the same manner, a double click on the function block in the Object Organizer gives access to a selection dialog in which the instances of the function block as well as the implementation are listed. Select here the desired instance or the implementation and confirm using OK. The desired item is then displayed in a window.



If you want to view instances, you first have to log in! (The project has been compiled with no errors and downloaded to the PLC with 'Online' 'Login').

'Project' 'Show call tree'

With this command you open a window which shows the call tree of the object chosen in the 'Object Organizer' ↳ *Chapter 1.4.1.2.1.3 “Object organizer” on page 199*. Before this the project must have been compiled without any error ↳ *Chapter 1.4.1.2.3.12 “'Project' 'Rebuild all'” on page 232*. The call tree contains both calls for POUs and references to data types.



'Project' 'Show cross reference'

With this command you open a dialog box which makes possible the output of all application points for a variable, address, or a POU. For this the project must be compiled ↳ *Chapter 1.4.1.2.3.11 “'Project' 'Build'” on page 231*.

At 'name' enter the name (e.g. "ivar") or path (e.g. "PLC_PRG.fbi.ivar") of the element for which you want to get listed the cross references (input assistant <F2> can be used). If you specify "*", all elements will be regarded. Also just a partial string followed by "*", e.g. "INT_*" can be specified in order to get listed all elements, the names of which start with this string.

If the project has been changed since the last compile, the term "(Not up to date)" will be displayed in the title bar of the dialog. In this case any cross references which have been created recently will not be regarded in the list unless you do a re-compile!

By clicking on the button 'Cross References' you get the list of all application points. Along with the POU and the line or network number, the variable name and the address binding, if any, are specified.

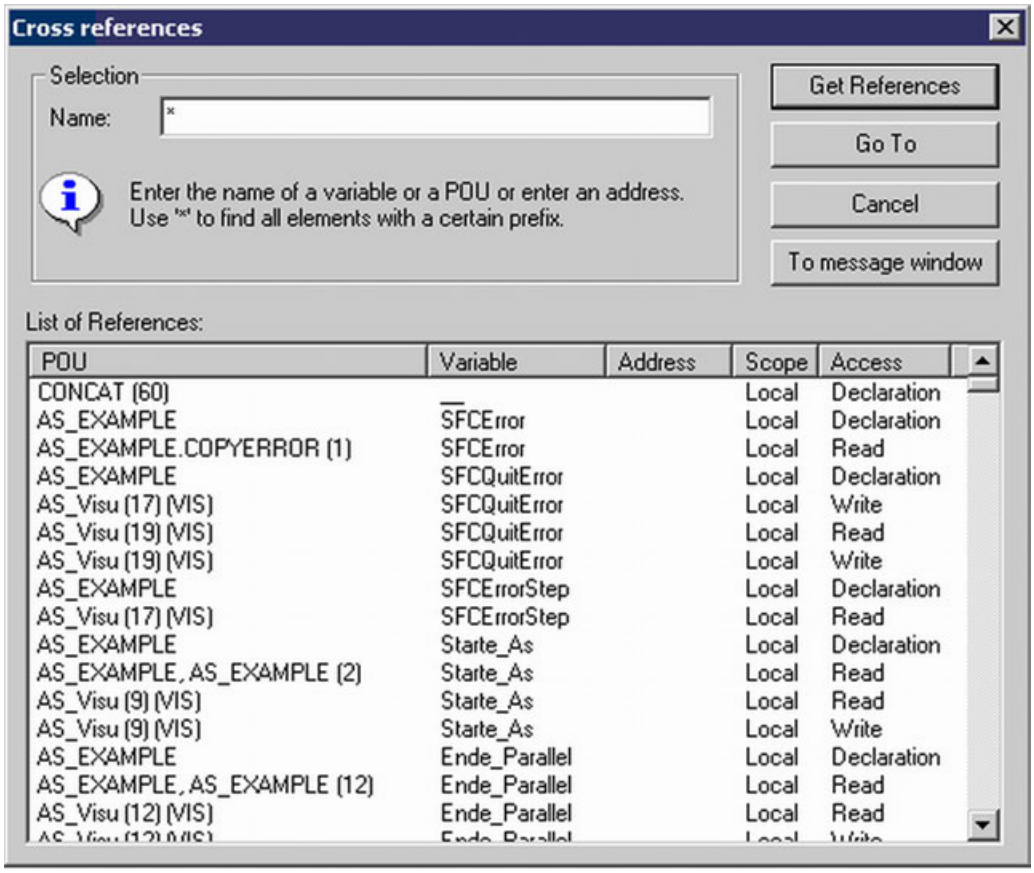
The Domain space shows whether this is a local or a global variable; the Access column shows whether the variable is to be accessed for 'reading' or 'writing' at the current location.

If the element is used within the address range of a structure or an array, this position will also be listed (Example: A variable wVar of type WORD is assigned to %MW2. A variable arrVar of type ARRAY [0..2] OF WORD is assigned to %MW0. If you call the cross-reference list for wVar, arrVar[2] will be found). The same is true for structures.

If an element is used within a visualization, the visualization name will be shown in column "POU". However note the following concerning placeholders within a visualization: The cross-reference list only regards variable name strings, which are already entered in the configuration of a visualization element, not however any names, which are generated during compilation of the project due to placeholder replacements !!

When you select a line of the cross-reference list and press the button 'Go To' or doubleclick on the line, then the POU is shown in its editor at the corresponding point. In this way you can jump to all application points without a time-consuming search.

In order to make processing easier, you can use the 'Send to message window' button to bring the current cross-reference list into the message window and from there change to the respective POU ↳ *Chapter 1.4.1.2.1.6 “Message window” on page 200*.



Direct call of a cross-reference list out of a POU editor or a watchlist:

The cross-reference list can be generated directly out of the editor (ST, FUP, KOP, AWL, CFC, AS), which is used to work on a POU, or out of a watchlist ↳ *Chapter 1.4.1.4.9.1 “Overview” on page 395*. In this case in online as well as in offline mode the command 'Show cross references' is available in the context or "Extras" menu, when a variable is selected in the editor or the watchlist ↳ *Chapter 1.4.1.3.7 “Show cross references” on page 295*.

'Project' 'Project database'

Overview

This menu item is only available if you have activated the option 'Use source control (ENI)' in the project options dialog for category 'Project source control'. A submenu is attached where you find the following commands for handling the object resp. the project in the currently connected ENI data base:

Login (The user logs in to the ENI Server)

If an object is marked in the Object Organizer and the command Data Base Link is executed (from the context menu, right mouse button), then several commands will be available for executing the corresponding data base actions. If the user had not logged in successfully to the ENI Server before, then the dialog 'Data base Login' will open automatically and the chosen command will not been executed until the login was successful.

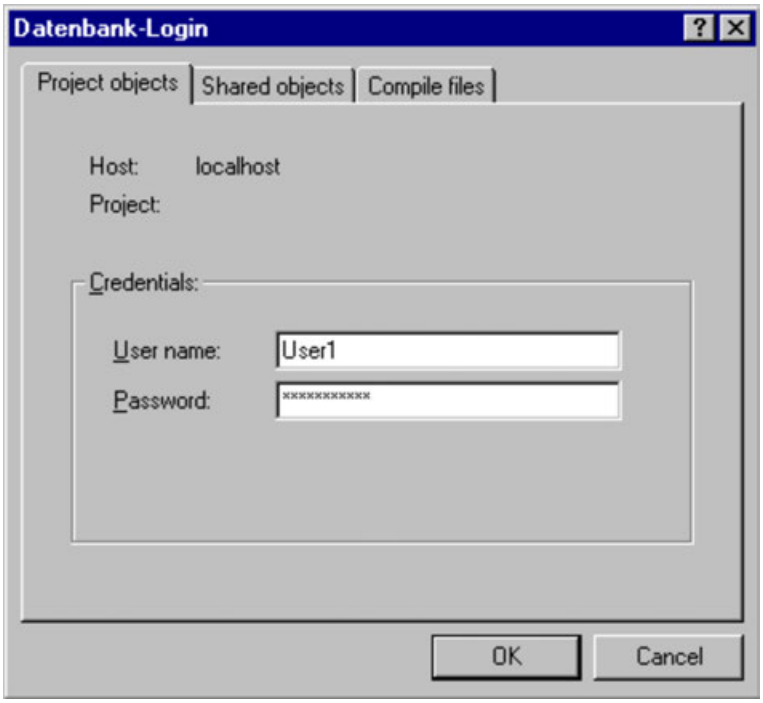
If the command 'Data Base Link' in the 'Project' menu is activated, then additional menu items will be available, which concern all objects of the project.

How the status of an object's handling in the data base is displayed in the Object Organizer:

Grey shaded icon: Object is stored in the data base (source control) Green check in front of the object name: Object is checked out in the currently opened project. Red cross in front of the object name: Object is currently checked out by another user. <R> behind object name: The object can only be read, but not edited. Please regard: some objects (Task configuration, Sampling Trace, PLC Configuration, Target Settings, Watch- and Receipt Manager) are per default assigned with a <R> as long as they are not checked out. This means that you will not automatically be asked whether the object should be checked out, as soon as you start to edit the object; it not necessarily means that you cannot edit the object. If there is no write access then the command 'Check out' will not be available.

Login

This command will open the dialog 'Login' where you can enter the access data for the ENI data base via the ENI Server. The access data also have to be defined in the ENI Server (ENI Admin, User Management) and – depending on the currently used data base – also in the user management of the data base. After the command has been executed, first the Login dialog for category 'Project objects' will open.



The following items are displayed:

- Data base: project objects
- Host: address of the computer where the ENI Server is running (must match with the entry in field 'TCP/IP address' in the project options dialog for 'Project source control').
- Project: Name of the data base project (must match with the entry in field 'Project name' in the project options dialog for 'Project source control'/category 'Project Objects').

Credentials:

- Insert username and password.
- When option Use as default for this project is activated, then the above entered access data will automatically be used for any further communication between the actual project and the data base concerning objects of the actual category.
- Press OK to confirm the settings. The dialog will be closed and automatically the Login dialog for 'Shared objects' will open. Enter the access data in the same way as described for the 'Project objects' and confirm with OK. Do the same in the third Login dialog which will be opened for category 'Compile files'.
- The Login dialog will always open as soon as you try to access the data base before having logged in successfully as described above.

If you want to save the access data with the project, activate option 'Save ENI credentials' in the project options, category 'Load & Save'.

Define

Command: 'Project' 'Data Base Link' 'Define'

Here you can define, whether the object which is currently marked in the Object organizer should be kept in the data base or just locally in the project. A dialog will open, where you can choose one of the two database categories 'Project' or 'Shared objects', or the category 'Local'.

The icons of all objects which are managed in the data base will be displayed grey-shaded in the Object organizer. Shared objects are displayed with turquoise letters.

Get latest version

Command: 'Project' Data Base Link'Get Latest Version'

The current version of the object which is marked in the Object organizer will be copied from the data base and will overwrite the local version. In contrast to the Check Out action the object will not be locked for other users in the data base *Chapter 1.4.1.2.4.18.5 “Check out” on page 268*.

Check out

Command: 'Project' 'Data Base Link' 'Check Out'

The object which is marked in the Object organizer will be checked out from the data base and by that will be locked for other users.

When executing the command the user will get a dialog 'Check out object'. A comment can be added there which will be stored in the version history of the object in the data base. Line breaks are inserted by <Ctrl>+<Enter>. If the version of the object differs from that in the local project, an appropriate message will be displayed and the user can decide whether the object should be checked out anyway.

After the dialog has been closed with OK, the checked-out object will be marked with a green check in the object organizer of the local project. For other users it will be appear marked with a red cross and will not be editable by them.

Check in

Command: 'Project' 'Data Base Link' 'Check In'

The object which is marked in the Object organizer will be checked in to the data base. Thereby a new version of the object will be created in the data base. The old versions will be kept anyway.

When executing the command the user will get a dialog 'Check in object'. There a comment can be added which will be stored in the version history of the object in the data base. Line breaks are inserted by <Ctrl>+<Enter>.

After the dialog has been closed with OK the green check in front of the object name in the Object organizer will be removed.

Undo check out

Command: 'Project' 'Data Base Link' 'Undo Check Out'

Use this command to cancel the Checking out of the object which is currently marked in the Object organizer. Thereby also the modifications of the object which have been made locally, will be canceled. No dialog will appear. The unchanged last version of the object will be kept in the data base and it will be accessible again for other users. The red cross in front of the object name in the Object organizer will disappear.

Show differences

Command: 'Project' 'Data Base Link' 'Show Differences'

The object which is currently open will be displayed in a window which is divided up in two parts. There the local version, which is currently edited by the local user, will be opposed to the last (actual) version which is kept in the data base. The differences of the versions will be marked like described for the project comparison (see 'Project' 'Compare').

Show version history

Command: 'Project' 'Data Base Link' 'Show Version History'

For the currently marked object in the Object organizer a dialog Version history of <object name> will be opened. There all versions of the object are listed which have been checked in to the data base or which have been labeled there:

The following information is given:

Version: Data base specific numbering of the versions of the object which have been checked in one after the other. Labeled versions get no version number but are marked by a label-icon.

User: Name of the user, who has executed the check-in or labeling action

Date: Date and time stamp of the action

Action: Type of the action which has been executed. Possible types: 'created' (the object has been checked in to the data base for the first time), 'checked in' (all check-ins of the object excluding the first one) and labeled with <label> (a label has been assigned to this version of the object)

The buttons:

Close: The dialog will be closed.

Display: The version which is currently marked in the table will be opened. The title bar shows: ENI: <name of the project in the data base>/<object name>

Details: The dialog 'Details of Version History' will open:

File (name of the project and the object in the data base), Version (see above), Date (see above), User (see above), Comment (Comment which has been inserted when the object has been checked in resp. has been labeled). Use the buttons Next resp. Previous to jump to the details window of the next or previous entry in the table in dialog 'Version history of ..'.

Get latest version: The version which is marked in the table will be loaded and there will overwrite the local version.

Differences: If in the table only one version of an object is marked, then this command will cause a comparison of this version with the latest (actual) data base version. If two versions are marked, then those will be compared. The differences are displayed in a bipartited window like it is done at the project comparison.

Reset version: The version which is marked in the table will be set as latest version. All versions which have been checked in later will be deleted ! This can be useful to restore an earlier status of an object.

Labels only: If this option is activated, then only those versions of the object will be displayed in the table, which are marked by a label.

Selection box below the option 'Labels only': Here you find the names of all users which have executed any data base actions for objects of the current project. Select 'All' or one of the names if you want to get the version history concerning all users or just for a certain one.

Multiple define

Command 'Project' 'Data Base Link' 'Multiple Define'

Use this command if you want to assign several objects at a single blow to a certain data base category. The dialog 'Properties' will open like described for command 'Define'. Choose the desired category and close the dialog with OK. After that the dialog 'ENI-Selection' will open, listing all POUs of the project which are considered for the chosen category (Example: if you choose category 'shared objects' then the selection window will only offer the POUs of the Resources tab). The POUs are presented in a tree structure complying to that of the Object Organizer. Select the desired POUs and confirm with OK.

Get all latest versions

Command 'Project' 'Data Base Link' 'Get All Latest Versions'

The latest version of each object of the currently opened project, which is kept under source control, will be called from the data base. Consider the following:

- If in the meantime additional objects have been stored to the data base project folder, then those will now be added to the local project.
- If objects have been deleted in the data base in the meantime, those will not be deleted in the local project, but they will automatically get assigned to category 'Local'.
- The latest version of objects of category 'Shared Objects' will only be called, if these objects are already available in the local project. For further information see command 'Get latest version' *Chapter 1.4.1.2.4.18.4 “Get latest version” on page 268*.

Multiple check out

Command 'Project' 'Data Base Link' 'Multiple Check Out'

You can check out several objects at a single blow. For this the dialog 'ENI-Selection' will open, listing all POUs of the project. Select those which should be checked out and confirm with OK. For further information see command 'Check Out'.

Multiple check in

Command 'Project' 'Data Base Link' 'Multiple Check In'

You can check in several objects at a single blow. For this the dialog 'ENI-Selection' will open, listing all POUs of the project. Select those which should be checked in and confirm with OK. For further information see command 'Check In'.

Multiple undo check out

Command 'Project' 'Data Base Link' Undo Multiple Check Out'

You can undo the check out action for several objects at a single blow. For this the dialog 'ENI-Selection' will open, listing all POUs of the project. Select those for which you want to cancel the check out and confirm with OK. For further information see command 'Undo Check Out'.

Project version history

Command 'Project' 'Data Base Link' 'Project Version History

If the chosen data base system supports that functionality, you can use this command to view the version history for the currently opened project.

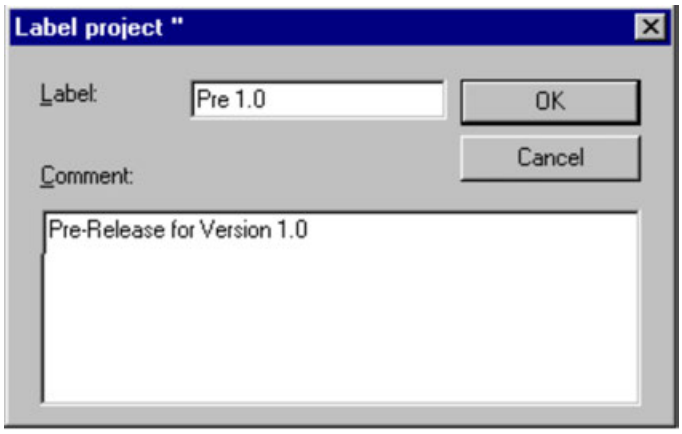
The dialog 'History of <data base project name>' will open. It shows the actions (create, check in, label) which have been performed for the particular objects of the project in a chronological order. The total number of objects is displayed behind Version history. The dialog can be handled like described for command 'Show Version History', but regard the following:

- The command 'Reset Version' is only available for single objects.
- The command 'Get latest version' means that all objects of the version of the currently marked object will be called to the local project! That means, that the objects in CODESYS will be overwritten with the older version. But: Local objects, which were not yet part of the project in that older version, will not be removed from the local project ! If a labeled version is called, which contains Shared Objects, then the user will get a dialog where he can decide whether those Shared Objects should be called also or not.

Label version

Command 'Project' 'Data Base Link' 'Label Version'

This command is used to put a "label" on the actual version of each object of a project, so that exactly this project version can be recalled later. A dialog 'Label <data base project name>' will open. Insert a label name (Label) (e.g. "Release Version") and optionally a Comment. When you confirm with OK, the dialog will close and the label and the action "labeled with <label name>" will appear in the table of the version history, as well in the history for a single object as in the history of the project. Shared Objects which are part of the project will also get that label. A labeled version of the project does not get a version number, but is just marked with a label icon in the column 'Version'. If the option 'Labels only' is activated in the Version History dialog, then only labeled versions will be listed.

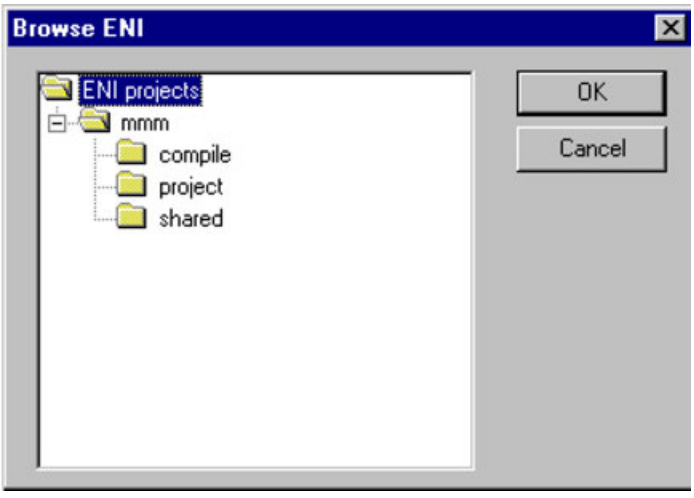


Add shared objects

Command 'Project' 'Data Base Link' 'Add Shared Objects'

Use this command if you explicitly want to add new objects of data base category 'Shared Objects' to the locally opened project. For objects of category 'Project Objects' this is not necessary, because the command 'Get (all) latest version(s)' automatically calls all objects which are found in the data base project folder, even if there are some which not yet available in the local project. But for objects of category 'Shared Objects' in this case just those objects will be called which are already available in the local project.

So execute the command 'Add Shared Objects' to open the dialog 'Browse ENI'. A list in the right part of the window shows all objects which are available in the data base folder which is currently selected in the list on the left side. Choose the desired object and press OK or do a doubleclick on the entry to insert the object to the currently opened project.



Refresh status

Command 'Project' 'Data Base Link' 'Refresh Status'

Use this command to update the display in the Object Organizer, so that you can see the actual status of the objects concerning the source control of the project.

1.4.1.2.5 General editing functions

Overview

You can use the following commands in all editors and some of them in the Object Organizer. The commands are located under the menu item 'Edit' and in the context menu that is opened with the right mouse button.

If the IntelliPoint-Software is installed on the computer, all functions of the MS IntelliMouse are supported. In all editors with zoom functionality: To magnify press the <Strg> key while rolling the wheel of the mouse, to reduce roll backwards while the <Ctrl> key is pressed.

↳ *Chapter 1.4.1.2.5.16 “'Edit' 'Previous error'” on page 278*
↳ *Chapter 1.4.1.2.5.17 “'Edit' 'Macros'” on page 278*

'Edit' 'Undo'

Shortcut: <Ctrl>+<Z>

This command undoes the action which was most recently executed in the currently-open editor window or in the Object Organizer; repeated use undoes all actions back to the time that the window was opened. This applies to all actions in the editors for POUs, data types, visualizations and global variables and in the Object Organizer.

With 'Edit' 'Redo' ↳ *Chapter 1.4.1.2.5.3 “'Edit' 'Redo'” on page 273* you can restore an action which you have undone.

The commands Undo and Redo apply to the current window. Each window carries its own action list. If you want to undo actions in several windows, then you must activate the corresponding window. When undoing or redoing in the Object Organizer the focus must lie here.

'Edit' 'Redo'

Shortcut: <Ctrl>+<Y>

With the command in the currently-open editor window or in the 'Object Organizer' you can restore an action you have undone *Chapter 1.4.1.2.1.3 “Object organizer” on page 199* *Chapter 1.4.1.2.5.2 “'Edit' 'Undo'” on page 272*.

As often as you have previously executed the command 'Undo' , you can also carry out the command 'Redo'.

The commands 'Undo' and 'Redo' apply to the current window. Each window carries its own action list. If you want to undo actions in several windows, then you must activate the corresponding window. When undoing or redoing in the Object Manager must lie there.

'Edit' 'Cut'

Symbol:  Shortcut: <Ctrl>+<X> or <Shift>+<Delete>

This command transfers the current selection from the editor to the clipboard. The selection is removed from the editor.

In the 'Object Organizer' this similarly applies to the selected object, whereby not all objects can be deleted, e.g. the PLC Configuration *Chapter 1.4.1.2.1.3 “Object organizer” on page 199* *Chapter 1.4.1.2.5.10 “'Edit' 'Replace'” on page 275*.

Remember that not all editors support the cut command, and that its use can be limited in some editors.

The form of the selection depends upon the respective editor:

In the text editors IL, ST, and declarations the selection is a list of characters.

In the FBD and LD editors the choice is a number of networks which are indicated by a dotted rectangle in the network number field or a box with all preceding lines, boxes, and operands.

In the SFC editor the selection is a part of a series of steps surrounded by a dotted rectangle *Chapter 1.4.1.3.11.9.1 “Overview” on page 330*.

In order to paste the content of the clipboard you use the command 'Edit' 'Paste' *Chapter 1.4.1.2.5.6 “'Edit' 'Paste'” on page 274*. In the SFC editor you can also use the commands 'Extras' 'Insert parallel branch (right)' or 'Extras' 'Paste after' *Chapter 1.4.1.1.9.4 “Function block” on page 153* *Chapter 1.4.1.3.11.9.17 “'Extras' 'Paste after'” on page 333*.

In order to remove a selected area without changing the clipboard, use the command 'Edit' 'Delete' *Chapter 1.4.1.2.5.7 “'Edit' 'Delete'” on page 274*.

'Edit' 'Copy'

Symbol:  Shortcut: <Ctrl>+<C>

This command copies the current selection from the editor to the clipboard. This does not change the contents of the editor window.

In the 'Object Organizer' this similarly applies to the selected object, whereby not all objects can be deleted, e.g. the PLC configuration *Chapter 1.4.1.2.1.3 “Object organizer” on page 199* *Chapter 1.4.1.2.5.10 “'Edit' 'Replace'” on page 275*

Remember that not all editors support copying and that it can be limited with some editors.

For the type of selection the same rules apply as with 'Edit' 'Cut'.

The form of the selection depends upon the respective editor:

In the text editors (IL, ST, and declarations) the selection is a list of characters.

In the FBD and LD editors the choice is a number of networks which are indicated by a dotted rectangle in the network number field or a box with all preceding lines, boxes, and operands.

In the SFC editor the selection is a part of a series of steps steps surrounded by a dotted rectangle *Chapter 1.4.1.3.11.9.1 “Overview” on page 330*.

In order to paste the content of the clipboard you use the command 'Edit' 'Paste' *Chapter 1.4.1.2.5.6 “'Edit' 'Paste'” on page 274*. In the SFC editor you can also use the commands 'Extras' 'Insert parallel branch (right)' or 'Extras' 'Paste after' *Chapter 1.4.1.1.9.4 “Function block” on page 153* *Chapter 1.4.1.3.11.9.17 “'Extras' 'Paste after'” on page 333*.

In order to delete a selected area and simultaneously put it on the clipboard, use the command 'Edit' 'Cut' *Chapter 1.4.1.2.5.4 “'Edit' 'Cut'” on page 273*.

'Edit' 'Paste'

Symbol: Shortcut: <Ctrl>+<V>

Pastes the content of the clipboard onto the current position in the editor window. In the graphic editors the command can only be executed when a correct structure results from the insertion *Chapter 1.4.1.3.11.1 “Overview” on page 314*.

With the object organizer the object is pasted from the clipboard *Chapter 1.4.1.2.1.3 “Object organizer” on page 199*.

Remember that pasting is not supported by all editors and that its use can be limited in some editors.

The current position can be defined differently according to the type of editor:

With the text editors (and declarations) the current position is that of the blinking cursor (a vertical line) which you place by clicking with the mouse *IL, ST,*.

In the FBD and LD editors the current position is the first network with a dotted rectangle in the network number area *Chapter 1.4.1.3.11.7.1 “Overview” on page 317* *Chapter 1.4.1.3.11.8.1 “Overview” on page 323*. The contents of the clipboard are inserted in front of this network. If a partial structure has been copied, then it is inserted in front of the selected element.

In the SFCeditor the current position is determined the selection which is surrounded by a dotted rectangle *Chapter 1.4.1.3.11.9.1 “Overview” on page 330*. Depending upon the selection and the contents of the clipboard, these contents are inserted either in front of the selection or into a new branch (parallel or alternative) to the left of the selection.

In SFC the commands 'Extras' 'Insert parallel branch (right)' or 'Extras' 'Paste after' can be used in order to insert the contents of the clipboard *Chapter 1.4.1.1.9.4 “Function block” on page 153* *Chapter 1.4.1.3.11.9.17 “'Extras' 'Paste after'” on page 333*.

In order to copy a selection onto the clipboard without deleting it, use the command 'Edit' 'Copy' *Chapter 1.4.1.2.5.5 “'Edit' 'Copy'” on page 273*.

In order to remove a selected area without changing the clipboard, use the command 'Edit' 'Delete' *Chapter 1.4.1.2.5.7 “'Edit' 'Delete'” on page 274*.

'Edit' 'Delete'

Shortcut: <Del>

Deletes the selected area from the editor window. This does not change the contents of the clipboard.

In the 'Object Organizer' this similarly applies to the selected object, whereby not all objects can be deleted, e.g. the PLC Configuration *Chapter 1.4.1.2.1.3 “Object organizer” on page 199* *Chapter 1.4.1.2.5.10 “'Edit' 'Replace'” on page 275*.

For the type of selection the same rules apply as with 'Edit' 'Cut'.

The form of the selection depends upon the respective editor:

In the text editors (IL, ST, and declarations) the selection is a list of characters.

In the FBD and LD editors the choice is a number of networks which are indicated by a dotted rectangle in the network number field.

In the SFC editor the selection is a part of a series of steps surrounded by a dotted rectangle ↳ *Chapter 1.4.1.3.11.9.1 “Overview” on page 330*.

In the 'library manager' the selection is the currently selected library name ↳ *Chapter 1.4.1.4.3.1 “Overview” on page 371*.

In order to delete a selected area and simultaneously put it on the clipboard, use the command 'Edit' 'Cut' ↳ *Chapter 1.4.1.2.5.4 “'Edit' 'Cut'” on page 273*.

'Edit' 'Find'

Symbol: 

With this command you search for a certain text passage in the current editor window. The Find dialog box opens. It remains opens until the button Cancel is pressed.

In the field 'Find what' you can enter the series of characters you are looking for.

In addition, you can decide whether the text you are looking for 'Match whole word only' or not, or also whether 'Match case' is to be considered, and whether the search should proceed 'Up' or 'Down' starting from the current cursor position.

The button 'Find next' starts the search which begins at the selected position and continues in the chosen search direction. If the text passages is found, then it is highlighted. If the passage is not found, then a message announces this. The search can be repeated several times in succession until the beginning or the end of the contents of the editor window has been reached. In the CFC editor the geometrical order of the elements will be regarded, the search will run from the left upper corner of the window to the right upper corner. Please regard that FBD POUs are processed from the right to the left!

Find dialog box:

'Edit' 'Find next'

Symbol:  Shortcut: <F3>

With this command you execute a search with the same parameters as with the most recent action 'Edit' 'Find' ↳ *Chapter 1.4.1.2.5.8 “'Edit' 'Find'” on page 275*. Please note that FBD POUs are processed from the right to the left!

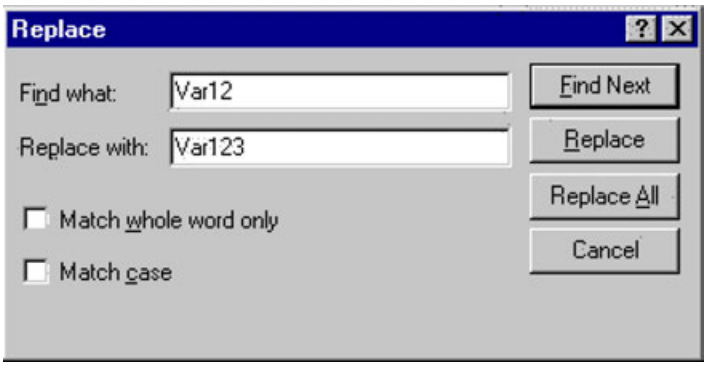
'Edit' 'Replace'

With this command you search for a certain passage just as with the command 'Edit' 'Find', and replace it with another ↳ *Chapter 1.4.1.2.5.8 “'Edit' 'Find'” on page 275*. After you have chosen the command the dialog box for find and replace appears. This dialog box remains open until the button 'Cancel' or 'Close' is pressed.

In the field behind 'Find' automatically that string will be inserted which you have marked before in the editor. You also can enter the search string manually. Pressing button 'Replace' will replace the current selection with the string which is given in the field 'Replace with'. Use the button 'Find Next' to get to the next passage where the string is found. Please regard, that FBD POUs are processed from the right to the left!

The button 'Replace all' replaces every occurrence of the text in the field 'Find next' after the current position with the text in the field 'Replace with'. At the end of the procedure a message announces how many replacements were made.

Dialog box for find and replace:



'Edit' 'Input assistant'

Shortcut: <F2>

This command provides a dialog box for choosing possible inputs at the current cursor position in the editor window. In the left column choose the desired input category, select the desired entry in the right column, and confirm your choice with OK. This inserts your choice at this position.

The categories offered depend upon the current cursor position in the editor window (e.g. variables, operators, POUs, conversions, watch variables etc.).

If the option 'With arguments' is active, then when the selected element is inserted, the arguments to be transferred are specified with it, for example: function block fu1 selected, which defines the input variable var_in: fu1(var_in:=);

Insertion of function func1, which uses var1 and var2 as transfer parameters: func1(var1,var2)

It is basically possible to switch between structured and unstructured display of the available elements ↳ *Chapter 1.4.1.2.5.13 “Stuctured display” on page 277* ↳ *Chapter 1.4.1.2.5.12 “Unstructured display” on page 276*. This occurs through activation/deactivation of the 'Structured Display' option.

For inserting identifiers you also can use the intellisense functionality ↳ *Chapter 1.4.1.3.6 “Intellisense function” on page 295.*

Unstructured display

In the left part of the window always those categories of elements are listed which are relevant for the current insert position,. e.g. ST Operators, Local Variables, Global Variables, Standard Programs, Defined Programs, Watch Expressions etc. In the right part of the window the elements of the selected category are listed simply linearly sorted in alphabetical order.

At various places (e.g. in the Watch List), multi-stage variable names are required. In that event the input assistant displays the available variables with a preceded POU name, resp. in case of structured variables and function block instances additionally with the FB name resp. data type name. Examples: PLC_PRG.ivar, PLC_PRG.Structure1.Component1. For global variables no POU name is added.

The desired element must be selected and then will be inserted at the insert position by OK.

When the non-structured input assistant is used in the Watch- and Recipe Manager, then the range of offered watch variables (Watch Expressions) can be reduced by a filter.

You can switch to structured display through activation of the Structured Display

Stuctured display

If Structured display is selected, the POUs, variables or data types will be sorted hierarchically. This is possible for standard programs, standard functions, standard function blocks, defined programs, defined functions, defined function blocks, global variables, local variables, defined types, watch variables. The visual and hierarchical display corresponds to that of the 'Object Organizer'; if elements in a library are referred to, these are inserted in alphabetical order at the very top and the pertinent hierarchy is displayed as in the Library Manager.

The in- and output variables of function blocks which are declared as local or global variables are listed in the category 'Local Variables' or 'Global Variables' under the instance name (e.g. Inst_TP ET, Inst_TP IN,...). To get there, select the instance name (e.g. Inst_TP) and confirm with OK.

If the instance of a function block is selected here, the option With arguments may be selected. In the text languages ST and IL as well as during task configuration, the instance name and the input parameters of the function block are then inserted.

For example, if Inst (DeklarationInst: TON;) is selected, the following is inserted:

Inst(IN:= ,PT:=)

If the option is not selected, only the instance name will be inserted. In the graphical languages or in the Watch window, only the instance name is generally inserted.

Components of structures are displayed in an analog fashion to function block instances.

For enumerations, the individual enumeration values are listed under the enumeration type. The order is: enumerations from libraries, enumerations from data types, local enumerations from POUs.

The general rule is that lines containing sub-objects are not selectable (except instances, see above), but can only have their hierarchy display expanded or contracted by one level, as for multi-stage variable names.

If input assistant is invoked in the Watch and Receipt Manager or in the selection of trace variables in the trace configuration dialog, it is possible to make a multiple selection. When the <Shift> key is pressed, you can select a range of variables; when the <Ctrl> key is pressed you can select many individual variables. The selected variables are so marked. If, during range selection lines are selected that do not contain valid variables (e.g. POU names), these lines will not be included in the selection. When individual selections are made, such lines can not be marked.

In the watch window and in trace configuration it is possible to transfer structures, arrays or instances from the Input Assistant dialog. As a double click with the mouse button is associated with the extension or contraction of the element's hierarchy display, selection in these cases can only be confirmed by OK.

Thereafter, the selected variables are inserted line by line in the watch window, that is each selected variable is written on a separate line. In the case of trace variables, each variable is inserted in a separate line of the trace variables list.

If the maximum number of trace variables, 20, is exceeded during insertion of the selected variables, the error message "A maximum of 20 variables is allowed" appears. Further selected variables are then not inserted in the list.

Some entries (e.g. Global Variables) are only updated in the input assistant dialog after compilation.

You can switch to unstructured display through deactivation of option Structured.

'Edit' 'Autodeclare'

Shortcut: <Shift>+<F2>

This command opens the dialog for the declaration of a variable *Chapter 1.4.1.3.9.11 “Variables declaration” on page 303*. This dialog also opens automatically when the option 'Project' 'Options' 'Editor' 'Autodeclaration' is switched on and when a new undefined variable is used the declaration editor *Chapter 1.4.1.3.9.17 “Autodeclaration” on page 306*.

'Edit' 'Next error'

Shortcut: <F4>

After the incorrect compilation of a project this command can show the next error. The corresponding editor window is activated and the incorrect place is selected. At the same time in the message window the corresponding error message is shown *Chapter 1.4.1.2.1.6 “Message window” on page 200*.

'Edit' 'Previous error'

Shortcut: <Shift>+<F4>

After the incorrect compilation of a project this command shows the previous error. The corresponding editor window is activated and the incorrect place is selected. At the same time in the message window the corresponding error message is shown *Chapter 1.4.1.2.1.6 “Message window” on page 200*.

'Edit' 'Macros'

This menu item leads to a list of all macros, which are defined for the project. (For info on generating macros see 'Project' 'Options' 'Macros' *Chapter 1.4.1.2.2.16 “Options for 'Macros'” on page 220*). When an executable macro is selected the dialog 'Process Macro'. The name of the macro and the currently active command line are displayed. The button Cancel can be used to stop the processing of the macro. In that event the processing of the current command will be finished anyway. Then an appropriate message is displayed in the message window and in the log during Online operation: "<Macro>: Execution interrupted by user".

Macros can be executed offline and online, but in each case only those commands are executed which are available in the respective mode.

1.4.1.2.6 General online functions

Overview

The available online commands are assembled under the menu item 'Online'. The execution of some of the commands depends upon the active editor.

The online commands become available only after logging in. See the book 'General Online Functions..' in the Contents tab of this online help.See the following chapters for a description.

Thanks to 'Online Change' functionality you have the possibility of making changes to programs on the running controller. See in this connection 'Online' 'Login' ↳ *Chapter 1.4.1.2.6.2 "'Online' 'Login'" on page 279*.

See 'Online' 'Login' for a diagram showing the relations between Project-Build, Project-Download, Online Change and Login ↳ *"Relations between Login - Build - Download - Online Change" on page 280*.

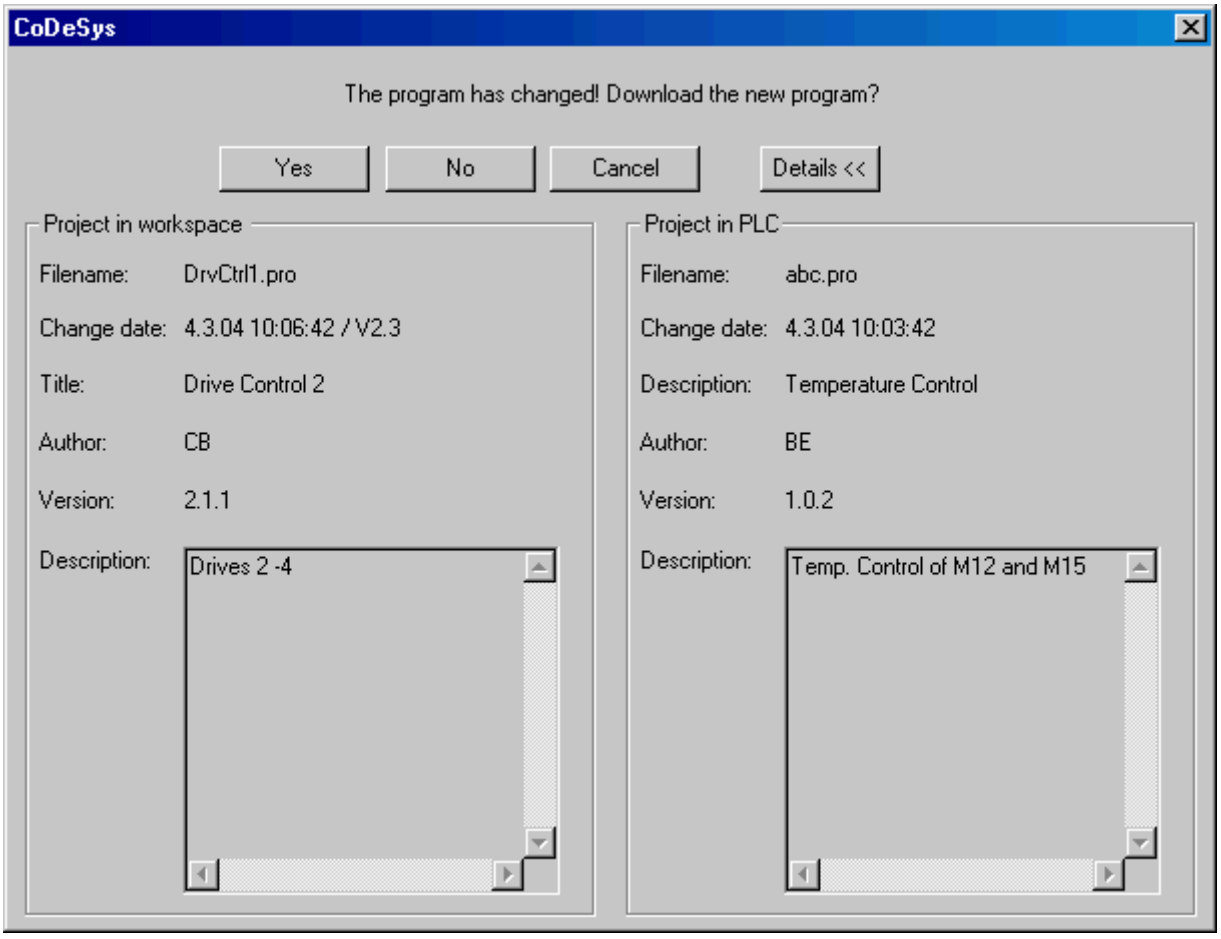
'Online' 'Login'

Symbol: Shortcut: <Alt>+<F8>

This command combines the programming system with the PLC (or starts the simulation program) and changes into the online mode ↳ *Chapter 1.4.1.1.11.8 "Simulation" on page 184*.

If the current project has not been compiled since opening or since the last modification, then it is compiled now ↳ *Chapter 1.4.1.2.3.11 "'Project' 'Build'" on page 231*. If errors occur during compilation, then Automation Builder does not change into Online mode.

If the current project was changed on the controller since the last download, but not closed, and if the last download information was not deleted with the command 'Project' 'Clear all', then after the command 'Login' a dialog opens with the question ↳ *Chapter 1.4.1.2.6.5 "'Online' 'Download'" on page 283*: "The program has been changed. Load changes? (Online Change)". By answering 'Yes' you confirm that, on log-in, the modified portions of the project are to be loaded onto the controller. (Concerning this see below a diagram on the relations between Project-Build, Project-Download, Online Change and Login and also some hints on Online Change). 'No' results in a log-in without the changes made since the last download being loaded onto the controller. 'Cancel' cancels the command. <Load all> causes the entire project to be reloaded onto the controller.



If in the project options, category Desktop, the option 'Online in security mode' is activated and if the target system supports the functionality, in the Login dialog automatically also the Project information will be displayed. This is the project information of the project which is currently opened in Automation Builder and which is already available on the controller. Via button 'Details <<' you can close this information part of the dialog. If the 'Online in security mode' option is not activated, you can explicitly open the project information display in the dialog via button 'Details >>'.

It depends on the target which button is set as default button.

Online Change does not cause a re-initialization of the variables, thus modifications of the initialization values will not be regarded ! Retain variables keep their values when an Online Change is done, they won't do that at a re-download of the project (see below, 'Online' 'Download').

After a successful login all online functions are available (if the corresponding settings in 'Project' 'Options' category have been entered ↳ *'Build'*). The current values are monitored for all visible variable declarations ↳ *Chapter 1.4.1.3.9.11 “Variables declaration” on page 303*.

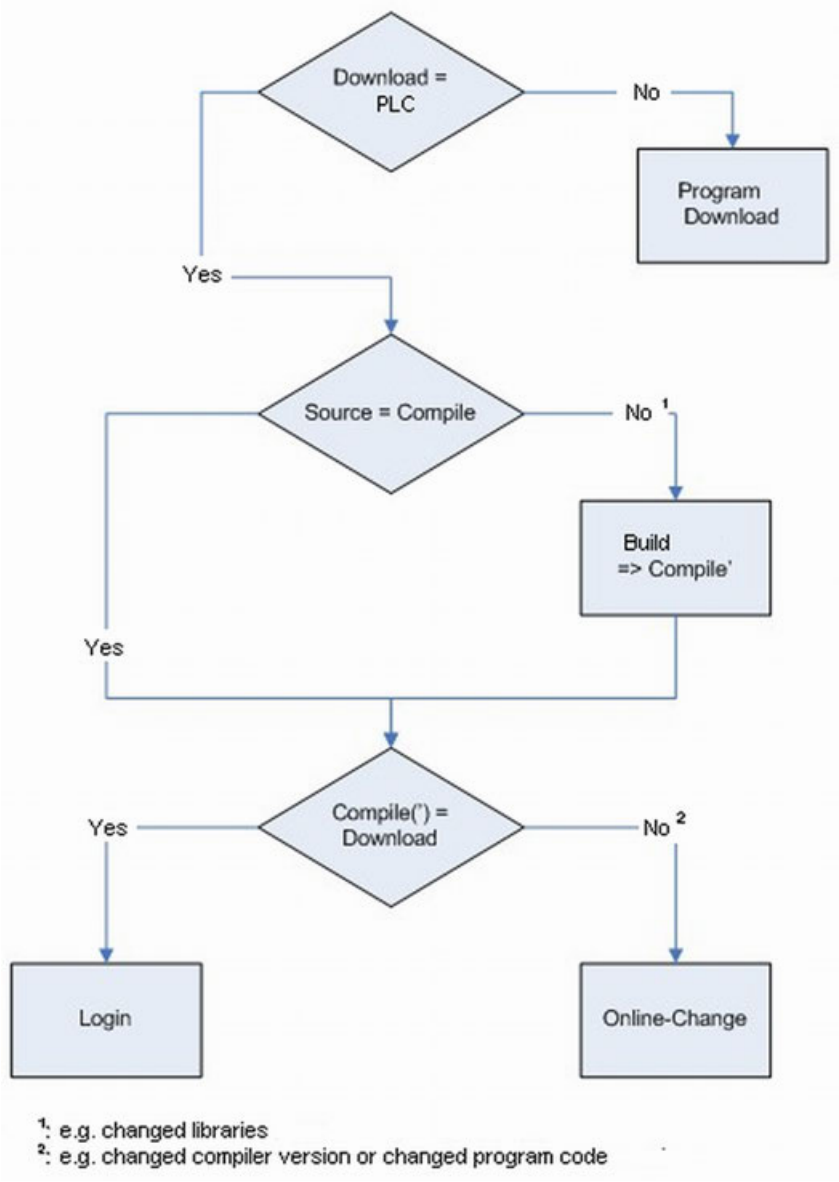
Use the 'Online' 'Logout' command to change from online back to offline mode ↳ *Chapter 1.4.1.2.6.4 “'Online' 'Logout'” on page 283*.

Relations between Login - Build - Download - Online Change

See below a diagram which shows the relations between Login, Build (Compilation), Download and Online Change:

The following terms are used:

Source	Current Automation Builder project (*.pro-file, local PC)
Compile	Compile information from the last build process, is needed for incremental compilation (*.ci-file, local PC)
Download	Information on what was loaded to the PLC at the last download (*.ri file, local PC)
PLC	Project currently available on the PLC (*.prg-file, target system)



Hints on Online Change

- Online Change is not possible after modifications in the Task or PLC Configuration, after inserting a library and after performing 'Project' 'Clean all' (see below).
- If the download Information (file <projectname><targetidentifier>.ri), which had been created at the last download (might have been an Online Change also) of the project, has been deleted meanwhile (e.g. via command 'Project' 'Clean all', then no Online Change will be possible further on, except for ↳ *Chapter 1.4.1.2.6.5 “'Online' 'Download'” on page 283* ↳ *Chapter 1.4.1.2.3.13 “'Project' 'Clean all'” on page 232*: The .ri file has been saved at another location or has been renamed and therefore now is still available and can be loaded explicitly by command 'Project' 'Load download information' ↳ *Chapter 1.4.1.2.3.14 “'Project' 'Load download information'” on page 232*. Concerning this see also below 'Online Change for a project....'.
- Online Change does not cause a re-initialization of the variables, thus modifications of the initialization values will not be regarded !
- retain variables keep their values when an Online Change is done, they won't do that at a re-download of the project ↳ *Chapter 1.4.1.3.9.7 “Remanent variables” on page 302* ↳ *Chapter 1.4.1.2.6.5 “'Online' 'Download'” on page 283*.

Online Change for a project which is running on several PLCs:

If you want to run a project 'proj.pro' on two identical controllers PLC1 and PLC2 (same target system) and want to make sure that an update of the project on both controllers can be done via online change, do the following:

(1) Loading and starting project on PLC1, save download information for PLC1:

1. Connect the Automation Builder project proj.pro to controller PLC1 (Online/Communication parameters) and load proj.pro on PLC1 (Online/Login, Download). At the download the file proj00000001.ri will be created in the projects directory, containing download information.
2. Rename proj00000001.ri, e.g. to proj00000001_PLC1.ri. This save of the file with another file name is necessary because at a further download of proj.pro the file proj00000001.ri on another PLC would be overwritten with new download information and thus the information belonging to the download on PLC1 would be lost.
3. Start the project on PLC1 and then log out ('Online' 'Start', 'Online' 'Logout').

(2) Loading and starting project on PLC2, save download information for PLC2:

1. Now connect to controller PLC2 (using same target as PLC1) and download proj.pro on PLC2. Thus again a file proj00000001.ri will be created in the projects directory, now containing the information on the currently done download.
2. Rename the new proj00000001.ri e.g. to proj00000001_PLC2.ri in order to store it explicitly.
3. Start the project on PLC2 and log out ('Online' 'Start', 'Online' 'Logout'.

(3) Change project in Automation Builder:

Do the modifications in proj.pro which you afterwards want to transfer via Online Change to the program running on the both PLCs.

(4) Online Change on PLC1, Re-saving download information for PLC1:

In order to make possible the Online Change for proj.pro on PLC1, first the download information referring to the download of proj.pro on PLC1 must be restored. At login Automation Builder is looking for a file proj00000001.ri. But you have stored the appropriate download information in file proj00000001_PLC1.ri.

Now you have 2 possibilities:

- You can rename proj00000001_PLC1.ri again to proj00000001.ri. Thus at a login on PLC1 automatically the appropriate download information is available and Automation Builder will ask you whether you want to do an Online Change.
- Instead of this you explicitly can load the file proj00000001_PLC1.ri before login by using command 'Project' 'Load Download Information'. In this case no renaming of the .ri file is necessary.

(5) Online Change on PLC2, Re-saving download information for PLC2:

In order to make possible an Online Change concerning the modifications in proj.pro done in (3) also on PLC2 please perform the corresponding steps for proj00000001_PLC2.ri as described in step (4) .

If the system reports

Error:

```
"The selected controller profile does not match that of the target system..."
```

Check that the target system entered in the target system settings (Resources) matches the parameters entered in 'Online' 'Communications parameters'.

Error:

"Communication error. Log-out has occurred"

Check whether the controller is running. Check whether the parameters entered in 'Online' 'Communications parameters' match those of your controller. In particular, you should check whether the correct port has been entered and whether the baud rates in the controller and the programming system match. If the gateway server is used, check whether the correct channel is set.

Error:

"The program has been modified! Should the new program be loaded?"

The project which is open in the editor is incompatible with the program currently found in the PLC (or with the simulation mode program being run *Chapter 1.4.1.2.6.22 “'Online' 'Simulation'” on page 291*). Monitoring and debugging is therefore not possible *Chapter 1.4.1.1.11.2 “Debugging” on page 182*. You can either choose "No," logout, and open the right project, or use "Yes" to load the current project in the PLC.

Message:

"The program has been changed. Load changes? (ONLINE CHANGE)".

The project is running on the controller. The target system supports 'Online Change' and the project has been altered on the controller with respect to the most recent download or the most recent Online Change. You may now decide whether these changes should be loaded with the controller program running or whether the command should be cancelled. You can also, however, load the entire compiled code by selecting the Load all button.

'Online' 'Logout'

Symbol:  Shortcut <Ctrl>+<F8>

The connection to the PLC is broken, or the simulation mode program is ended and is shifted to the offline mode *Chapter 1.4.1.2.6.22 “'Online' 'Simulation'” on page 291*.

Use the 'Online' 'Login' command to change to the online mode *Chapter 1.4.1.2.6.2 “'Online' 'Login'” on page 279*.

'Online' 'Download'

This command loads the compiled project in the PLC.

During compilation the Download-Information gets saved in a file called <project-name>0000000ar.ri , which is used during online change to compare the current program with the one most recently loaded onto the controller, so that only changed program components are reloaded *Chapter 1.4.1.2.6.2 “'Online' 'Login'” on page 279*. This file is erased by the command 'Project' 'Clean all' *Chapter 1.4.1.2.3.13 “'Project' 'Clean all'” on page 232*! Concerning Online Change on several PLCs please see 'Online' 'Login' *Chapter 1.4.1.2.6.2 “'Online' 'Login'” on page 279*. Note that the *.ri file also gets updated during an Online Change.

Depending on the target system settings at each creation of a boot project in offline mode the *.ri file might be regenerated *Chapter 1.4.1.2.6.25 “'Online' 'Create boot project'” on page 291*.

Only persistent variables keep their values even after a download *Chapter 1.4.1.3.9.7 “Remanent variables” on page 302*.

See 'Online' 'Login' for a diagram showing the relations between Project-Build, Project-Download, Online Change and Login on the target system *Table on page 280*.

'Online' 'Run'

Symbol:  Shortcut: <F5>

This command starts the program in the PLC or in simulation mode *Chapter 1.4.1.2.6.22 “'Online' 'Simulation'” on page 291*.

This command can be executed immediately after the 'Online' 'Download' command, or after the user program in the PLC has been ended with the 'Online' 'Stop' command, or when the user program is at a break point, or when the 'Online' 'Single cycle' command has been executed *Chapter 1.4.1.2.6.7 “'Online' 'Stop'” on page 284* *Chapter 1.4.1.2.6.15 “'Online' 'Single cycle'” on page 286*.

'Online' 'Stop'

Symbol: Shortcut <Shift>+<F8>

Stops the execution of the program in the PLC or in simulation mode between two cycles *Chapter 1.4.1.2.6.22 “'Online' 'Simulation'” on page 291*.

Use the 'Online' 'Run' command to continue the program *Chapter 1.4.1.2.6.6 “'Online' 'Run'” on page 283*.

'Online' 'Reset'

This command resets – with exception of the retain variables (VAR RETAIN) - all variables to that specific value, with which they have got initialized (also those variables which have been declared as VAR PERSISTENT!). If you have initialized the variables with a specific value, then this command will reset the variables to the initialized value. All other variables are set at a standard initialization (for example, integers at 0). As a precautionary measure, you must confirm your decision before all of the variables are overwritten. The situation is that which occurs in the event of a power failure or by turning the controller off, then on (warm restart) while the program is running.

Use the 'Online' 'Run' command to restart the program *Chapter 1.4.1.2.6.6 “'Online' 'Run'” on page 283*.

See also 'Online' 'Reset (original)', 'Online' 'Reset (cold)' and - for an overview on reinitialization - Remanent variables *Chapter 1.4.1.2.6.10 “'Online' 'Reset (original)'” on page 284* *Chapter 1.4.1.2.6.9 “'Online' 'Reset (cold)'” on page 284* *Chapter 1.4.1.3.9.7 “Remanent variables” on page 302*.

'Online' 'Reset (cold)'

This command corresponds to 'Online' 'Reset', but besides of "normal" and persistent variables also sets back retain variables (!) to their initialization values *Chapter 1.4.1.2.6.8 “'Online' 'Reset'” on page 284*. The situation is that which occurs at the start of a program which has been downloaded just before to the PLC (cold start). See in this connection also 'Online' 'Reset' *Chapter 1.4.1.2.6.8 “'Online' 'Reset'” on page 284*, 'Online' 'Reset (original)' *Chapter 1.4.1.2.6.10 “'Online' 'Reset (original)'” on page 284*, and - for an overview on reinitialization - Remanent variables *Chapter 1.4.1.3.9.7 “Remanent variables” on page 302*.

'Online' 'Reset (original)'

This command resets all variables including the remanent ones (VAR RETAIN and VAR PERSISTENT) to their initialization values and erases the user program on the controller. The controller is returned to its original state *Chapter 1.4.1.3.9.7 “Remanent variables” on page 302*. See in this connection also 'Online' 'Reset' *Chapter 1.4.1.2.6.8 “'Online' 'Reset'” on page 284*, 'Online' 'Reset (cold)' *Chapter 1.4.1.2.6.9 “'Online' 'Reset (cold)'” on page 284* and - for an overview on reinitialization - Remanent variables *Chapter 1.4.1.3.9.7 “Remanent variables” on page 302*.

'Online' 'Toggle breakpoint'

Symbol: image\ebx_946809370.gif Shortcut: <F9>

This command sets a breakpoint in the present position in the active window ↳ *Chapter 1.4.1.1.11.3 “Breakpoint” on page 182*. If a breakpoint has already been set in the present position, that breakpoint will be removed.

The position at which a breakpoint can be set depends on the language in which the POU in the active window is written.

In the text editors (IL, ST), the breakpoint is set at the line where the cursor is located, if this line is a breakpoint position (recognizable by the dark-gray color of the line number field) ↳ *Chapter 1.4.1.3.12.1 “Overview” on page 352*. You can also click on the line number field to set or remove a breakpoint in the text editors.

In FBD and LD, the breakpoint is set at the currently selected network. In order to set or remove a breakpoint in the FBD or LD Editor, you can also click on the network number field.

In SFC, the breakpoint is set at the currently selected step ↳ *Chapter 1.4.1.3.11.9.1 “Overview” on page 330*. In SFC you can also use <Shift> with a doubleclick to set or remove a breakpoint.

If a breakpoint has been set, then the line number field or the network number field or the step will be displayed with a light-blue background color. If a breakpoint is reached while the program is running, the program will stop, and the corresponding field will be displayed in a red background color. In order to continue the program, use the 'Online' 'Run', 'Online' 'Step in', or 'Online' 'Step over' commands ↳ *Chapter 1.4.1.2.6.6 “'Online' 'Run'” on page 283* ↳ *Chapter 1.4.1.2.6.14 “'Online' 'Step in'” on page 286* ↳ *Chapter 1.4.1.2.6.13 “'Online' 'Step over'” on page 286*.

You can also use the Breakpoint dialog box to set or remove breakpoints.

'Online' 'Breakpoint dialog box'

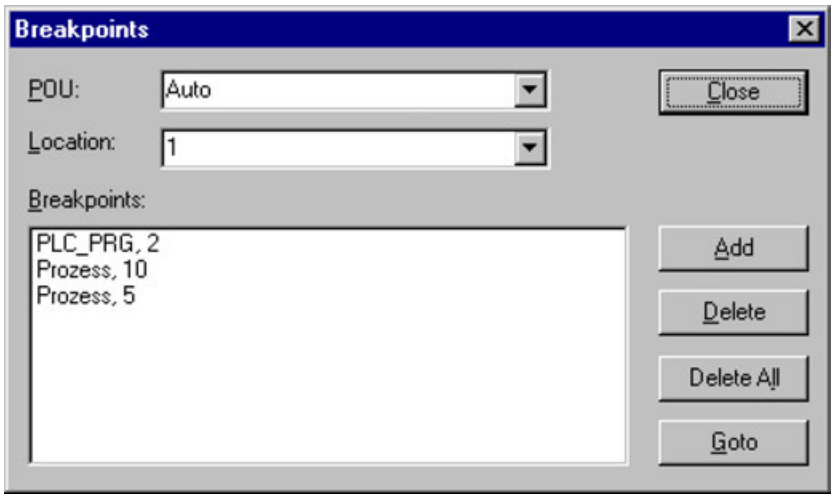
This command opens a dialog box to edit breakpoints throughout the entire project ↳ *Chapter 1.4.1.1.11.3 “Breakpoint” on page 182*. The dialog box also displays all breakpoints presently set.

In order to set a breakpoint, choose a POU in the POU combobox and the line or the network in the Location combobox where you would like to set the breakpoint; then press the Add button. The breakpoint will be added to the list.

In order to delete a breakpoint, highlight the breakpoint to be deleted from the list of the set breakpoints and press the Delete button.

The Delete All button can be used to delete all the breakpoints.

In order to go to the location in the editor where a certain breakpoint was set, highlight the respective breakpoint from the list of set breakpoints and press the Go to button.



To set or delete breakpoints, you can also use the 'Online' 'Toggle Breakpoint' command.

'Online' 'Step over'

Symbol: Shortcut: <F10>

This command causes a single step to execute *Chapter 1.4.1.1.11.4 “Single step” on page 182*. If a POU is called, the program stops after its execution. In SFC a complete action is executed *Chapter 1.4.1.1.10.5.2 “Action” on page 171*.

If the present instruction is the call-up of a function or of a function block, then the function or function block will be executed completely. Use the 'Online' 'Step in' command, in order to move to the first instruction of a called function or function block *Chapter 1.4.1.2.6.14 “'Online' 'Step in'” on page 286*.

If the last instruction has been reached, then the program will go on to the next instruction in the POU.

'Online' 'Step in'

Shortcut: <F8>

A single step is executed *Chapter 1.4.1.1.11.4 “Single step” on page 182*. The program is stopped before the first instruction of a called POU.

If necessary, there will be a changeover to an open POU.

If the present position is a call-up of a function or of a function block, then the command will proceed on to the first instruction in the called POU.

In all other situations, the command will function exactly as 'Online' 'Step over' *Chapter 1.4.1.2.6.13 “'Online' 'Step over'” on page 286*.

'Online' 'Single cycle'

Shortcut: <Ctrl>+<F5>

This command executes a single PLC Cycle and stops after this cycle *Chapter 1.4.1.1.11.5 “Single cycle” on page 182*.

This command can be repeated continuously in order to proceed in single cycles.

The Single Cycle ends when the 'Online' 'Run' command is executed *Chapter 1.4.1.2.6.6 “'Online' 'Run'” on page 283*.

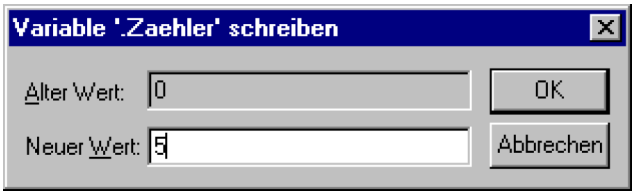
'Online' 'Write values'

Shortcut: <Ctrl>+<F7>

With this command, one or more variables are set – one time only! – to user defined values at the beginning of a cycle (see 'Online' 'Force values' for setting permanently *Chapter 1.4.1.2.6.17 “'Online' 'Force values'” on page 287*).

The values of all single-element variables can be changed, so long as they are also visible in Monitoring.

Before the command 'Write values' can be executed, a variable value must be ready to be written: For non-boolean variables a double mouse click in performed on the line in which a variable is declared, or the variable is marked and the <Enter> key is pressed. The dialog box 'Write variable <x>' then appears, in which the value to be written to the variable can be entered.



For boolean variables, the value is toggled (switched between TRUE and FALSE, with no other value allowed) by double-clicking on the line in which the variable is declared; no dialog appears.

The value set for Writing is displayed in brackets and in turquoise colour behind the former value of the variable. e.g. a=0 <:=34>.

Exception: In the FBD and LD Editor the value is shown turquoise without brackets next to the variable name.

Set the values for as many variables as you like.

The values entered to be written to variables can also be corrected or deleted in the same manner. This is likewise possible in the 'Online' 'Write/Force dialog' (see below).

The values to be written that were previously noticed are saved in a writelist (Watchlist), where they remain until they are actually written, deleted or transferred to a forcelist by the command 'Force values'.

The command to Write Values can be found at two places:

- Command 'Write Values' in the menu 'Online'.
- Button 'Write Values' in the dialog ↳ *'Editing the writelist and the forcelist'*.

When the command 'Write values' is executed, all the values contained in the writelist are written, once only , to the appropriate variables in the controller at the beginning of the cycle, then deleted from the writelist. (If the command 'Force values' is executed, the variables in question are also deleted from the writelist, and transferred to the forcelist! ↳ *Chapter 1.4.1.2.6.17 "'Online' 'Force values'" on page 287*)

In the sequential function chart language, the individual values from which a transition expression is assembled cannot be changed with 'Write values' ↳ Chapter 1.4.1.1.10.5.1 "Overview" on page 171. This is due to the fact that in monitoring the 'Total value' of the expression, not the values of the individual variables are displayed (e.g. "a AND b" is only displayed as TRUE if both variables actually have the value TRUE).

In FBD, on the other hand, only the first variable in an expression, used for example as input to a function block, is monitored ↳ *Chapter 1.4.1.1.10.2 "Function Block Diagram (FBD)" on page 162*. Thus a 'Write values' command is only possible for this variable.

'Online' 'Force values'

Shortcut: <F7>

With this command, one or more variables are permanently set (see 'Online' 'Write values' for setting only once at the beginning of a cycle ↳ *Chapter 1.4.1.2.6.16 "'Online' 'Write values'" on page 286*) to user-defined values.

The setting occurs in the runtime system, both at the beginning and at the end of the cycle. The time sequence in one cycle: 1.Read inputs, 2. Force values 3. Process code, 4. Force values 5. Write outputs.

The function remains active until it is explicitly suspended by the user (command 'Online' 'Release force') or the programming system is logged-out.

For setting the new values, a 'writelist' is first created, just as described under 'Online' 'Write values' *Chapter 1.4.1.2.6.16 “'Online' 'Write values'” on page 286*. The variables contained in the writelist are accordingly marked in Monitoring. The writelist is transferred to a 'forcelist' as soon as the command 'Online' 'Force values' is executed. It is possible that an active forcelist already exists, in which case it is updated as required. The writelist is then emptied and the new values displayed in red as 'forced'. Modifications of the forcelist are transferred to the program with the next 'Force values' command.

Note: The forcelist is created at the first forcing of the variables contained in the writelist, while the writelist existed prior to the first writing of the variables that it contains.

The command for forcing a variable, which means that it will be entered into the forcelist can be found at the following places:

- Command 'Force Values' in the menu 'Online'.
- Button 'Force Values' in the dialog *'Editing the writelist and the forcelist'*.

In the sequential function chart language, the individual values from which a transition expression is assembled cannot be changed with 'Force values'. This is due to the fact that in monitoring the 'Total value' of the expression, not the values of the individual variables are displayed (e.g. "a AND b" is only displayed as TRUE if both variables actually have the value TRUE).

In FBD, on the other hand, only the first variable in an expression, used for example as input to a function block, is monitored. Thus a 'Force values' command is only possible for this variable.

'Online' 'Release force'

Shortcut: <Shift>+<F7>

This command ends the forcing of variable values in the controller. The variable values change again in the normal way.

Forced variables can be recognized in Monitoring by the red color in which their values are displayed. You can delete the whole forcelist, but you can also mark single variables for which the forcing should be released.

To delete the whole forcelist, which means to release force for all variables, choose one of the following ways:

- Command 'Release Force' in menu 'Online'.
- Button 'Release Force' in dialog *'Editing the writelist and the forcelist'*
- Delete the whole forcelist using the command 'Release Force' in the dialog 'Remove Write-/Forcelist'. This dialog opens if you choose the command 'Release Force' while also a writelist exists *Chapter 1.4.1.2.6.16 “'Online' 'Write values'” on page 286*.
- To release force only for single variables you have to mark these variables first. Do this in one ways described in the following. After that the chosen variables are marked with an turquoise extension <Release Force>:

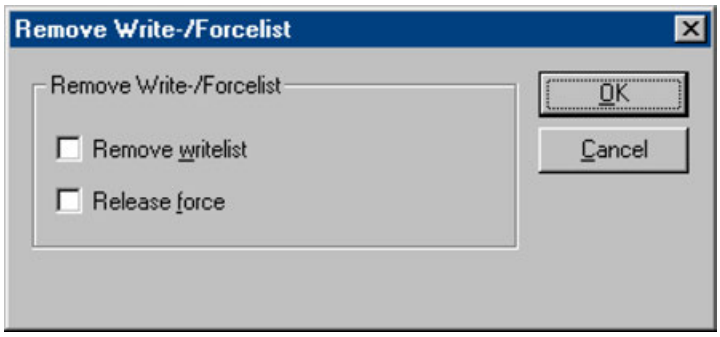
  - A double mouse click on a line, in which a non boolean variable is declared, opens the dialog 'Write variable <x>' *Chapter 1.4.1.2.6.16 “'Online' 'Write values'” on page 286*. Press button <Release Force for this variable>.

  - Repeat double mouse clicks on a line in which a boolean variable is declared to toggle to the display <Release Force> at the end of the line.

  - In the menu 'Online' open the Write/Force-Dialog and delete the value in the edit field of the column 'Forced value'.

When for all desired variables the setting "<Release Force>" is shown in the declaration window, choose the command 'Force values' to transfer the modifications of the forcelist to the program *Chapter 1.4.1.2.6.17 “'Online' 'Force values'” on page 287*.

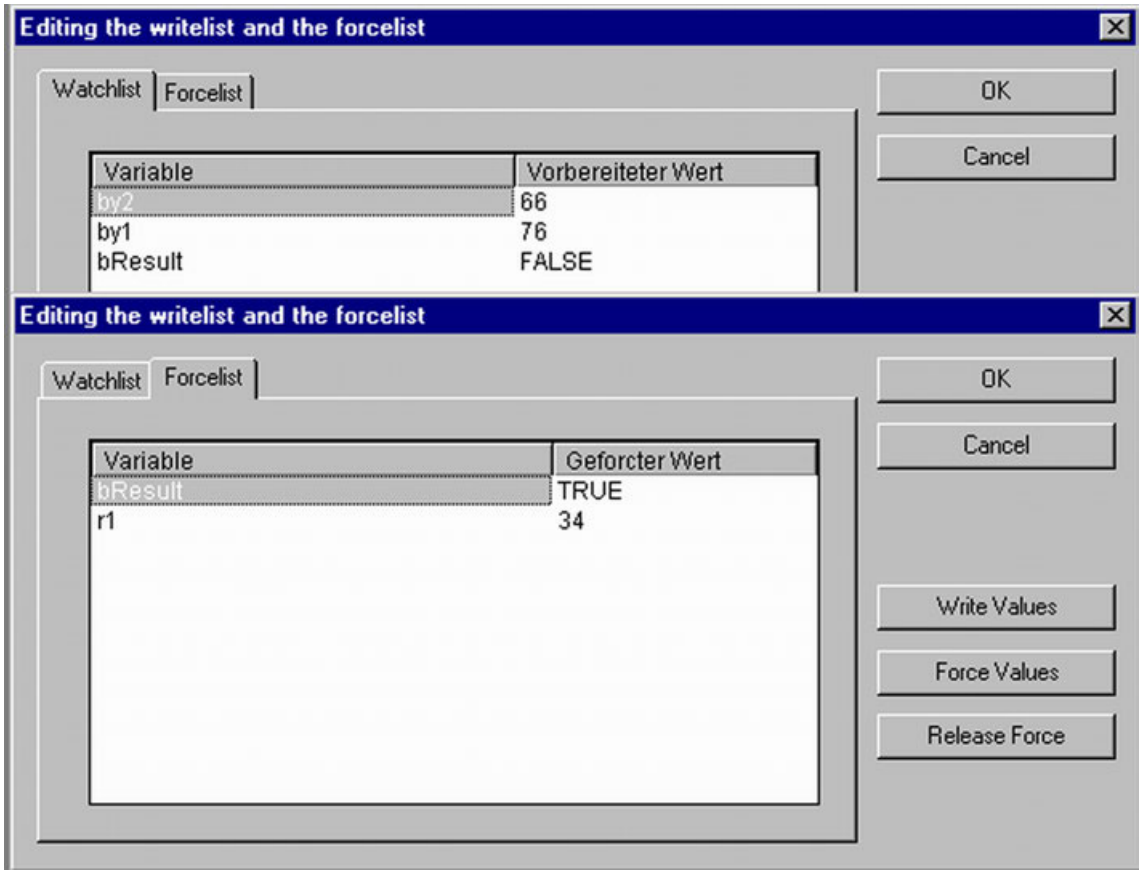
If the current writelist is not empty while you execute the command 'Release Force', the dialog 'Remove Write-/Forcelist' will be opened *Chapter 1.4.1.2.6.16 “'Online' 'Write values'” on page 286*. There the user has to decide whether he just wants to Release Force or additionally wants to Remove the writelist or if he wants to remove both lists.



'Online' 'Write/Force' Dialog'

Shortcut: <Ctrl>+<Shift>+<F7>

This command leads to a dialog which displays in two registers the current writelist (Watchlist) and forcelist (Forcelist). Each variable name and the value to be written to it or forced on it are displayed in a table.



The variables reach the watchlist via the commands 'Online' 'Write values' and are transferred to the forcelist by the command 'Online' 'Force values' ↳ *Chapter 1.4.1.2.6.16 “'Online' 'Write values'” on page 286* ↳ *Chapter 1.4.1.2.6.17 “'Online' 'Force values'” on page 287*. The values can be edited here in the "Prepared Value" or "Forced Value" columns by clicking the mouse on an entry to open an editor field. If the entry is not type-consistent, an error message is displayed. If a value is deleted, it means that the entry is deleted from the writelist or the variable is noticed for suspension of forcing as soon as the dialog is closed with any other command than Cancel.

The following commands, corresponding to those in the Online menu, are available via buttons:

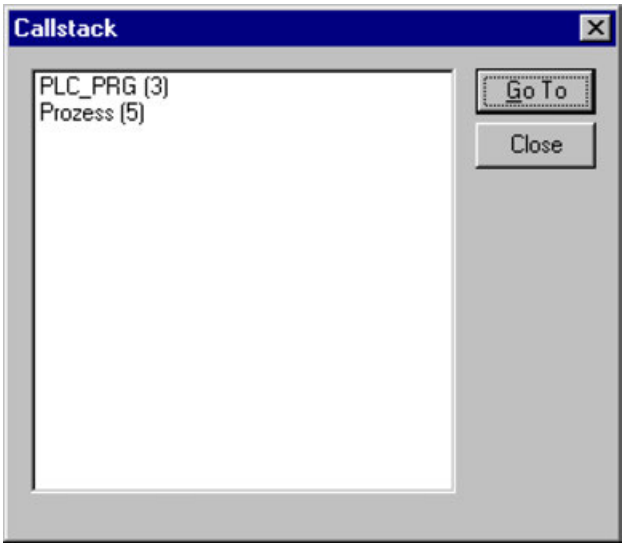
Force Values ↳ *Chapter 1.4.1.2.6.17 “'Online' 'Force values'” on page 287*: All entries in the current writelist are transferred to the forcelist, that is the values of the variables in the controller are forced. All variables marked with 'Release Force' are no longer forced. The dialog is then closed.

Write Values ↳ *Chapter 1.4.1.2.6.16 “'Online' 'Write values'” on page 286*: All entries in the current writelist are written once only to the corresponding variables in the controller. The dialog is then closed.

Release Force ↳ *Chapter 1.4.1.2.6.18 “'Online' 'Release force'” on page 288*: All entries in the forcelist will be deleted or, if a writelist is present, the dialog "Delete write-/forcelist" comes up, in which the user must decide whether he only wants to release forcing or discard the writelist, or both. The dialog will close at that point, or after the selection dialog is closed as the case may be.

'Online' 'Show call stack'

You can run this command when the simulation mode stops at a breakpoint ↳ *Chapter 1.4.1.2.6.22 “'Online' 'Simulation'” on page 291* ↳ *Chapter 1.4.1.2.3.9 “'File' 'Printer setup'” on page 229*. You will be given a dialog box with a list of the POU Call Stack.



The first POU is always PLC_PRG, because this is where the executing begins ↳ *Chapter 1.4.1.1.9.2 “POU (program organization unit)” on page 151*.

The last POU is always the POU being executed.

After you have selected a POU and have pressed the 'Go to' button, the selected POU is loaded in its editor, and it will display the line or network being processed.

'Online' 'Display flow control'

Depending on the target system settings the user can activate resp. deactivate the Flow Control function. If it is activated, a check (✓) will appear in front of the menu item. Following this, every line or every network will be marked which was executed in the last PLC Cycle.

The line number field or the network number field of the lines or networks which just run will be displayed in green. An additional field is added in the IL editor in which the present contents of the accumulator are displayed ↳ *Chapter 1.4.1.3.12.1 “Overview” on page 352*. In the graphic editors for the Function Block Diagram and Ladder Diagram, an additional field will be inserted in all connecting lines not transporting any Boolean values ↳ *Chapter 1.4.1.3.11.1 “Overview” on page 314* ↳ *Chapter 1.4.1.3.11.7.1 “Overview” on page 317* ↳ *Chapter 1.4.1.3.11.8.1 “Overview” on page 323*. When these Out- and Inputs are verified, then the value that is transported over the connecting line will be shown in this field. Connecting lines that transport only Boolean values will be shaded blue when they transport TRUE. This enables constant monitoring of the information flow.

1. The run time of a program will be increased by using flow control. This might cause timeouts in time-cyclic programs with high load.

2. At active breakpoint positions there is no flow control display.

3. If a watchdog has been defined for the concerned task, this will be switched off when the flow control is active ↳ Chapter 1.4.1.4.8.2 “'Insert' 'Insert Task' or 'Insert' 'Append Task'” on page 391.

'Online' 'Simulation'

If Simulation Mode is chosen, then a check (✓) will appear in front of the menu item.

In the simulation mode, the user program runs on the same PC under Windows. This mode is used to test the project. The communication between the PC and Simulation Mode uses the Windows Message mechanism.

If the program is not in simulation mode, then the program will run on the PLC. The communication between the PC and the PLC typically runs over the serial interface.

The status of this flag is stored with the project.

POUs of external libraries will not run in simulation mode.

'Online' 'Communication parameters'

You are offered a special dialog for setting communication parameters when the communication between the local PC and the runtime system is running over a gateway server in your system. (If the OPC or DDE server is used, the same communications parameters must be entered in its configuration).

'Online' 'Sourcecode download'

This command loads the source code for the project into the controller system. This is not to be confused with the Code that is created when the project is compiled! You can enter the options that apply to Download (time, size) in the 'Project' 'Options' 'Source download' dialog *↳ Chapter 1.4.1.2.2.1 “'Project' 'Options'” on page 200 ↳ Chapter 1.4.1.2.2.11 “'Source download'” on page 212*.

'Online' 'Create boot project'

With this command, the compiled project is set up on the controller in such a way that the controller can load it automatically when restarted. Storage of the boot project occurs differently depending on the target system. For example, on 386 systems three files are created: default.prg contains the project code, default.chk contains the code's checksum, default.sts contains the controller status after restart (start/stop).

The command 'Online' 'Create boot project' is also available in offline mode if the project has been built without errors. In this case the following files are created in the projects directory: <projektname>.prg for the boot project code, and <projektname>.chk for the checksum. These files can be renamed as necessary and then be copied to a PLC.

Depending on the target system settings at the creation of a boot project in offline mode a new *.ri file (download information) might be created *Chapter 1.4.1.2.6.5 “'Online' 'Download'” on page 283*. Also depending on the target setting a dialog will appear if this file is already existing.

If the project option "Implicit at create boot project" (category Source download) is activated, then the selected sources will be loaded automatically into the controller on the command 'Online' 'Create boot project' *Chapter 1.4.1.2.2.11 “'Source download'” on page 212.*

'Online' 'Write file to PLC'

This command is used for loading any desired file onto the controller. It opens the dialog for 'Write file to controller' in which you can select the desired file.

After the dialog is closed using the 'Open' button, the file is loaded into the controller and stored there under the same name. The loading process is accompanied by a progress dialog.

With the command 'Online' 'Load file from PLC' you can retrieve a file previously loaded on the controller *Chapter 1.4.1.2.6.27 “'Online' 'Load file from PLC'” on page 292*.

'Online' 'Load file from PLC'

With this command, you can retrieve a file previously loaded into the controller using 'Online' 'Write file to PLC' *Chapter 1.4.1.2.6.26 “'Online' 'Write file to PLC'” on page 292*. You receive the 'Load file from controller' dialog. Under Filename, provide the name of the desired file, and in the selection window enter the directory on your computer into which it is to be loaded as soon as the dialog is closed with the "Save" button.

1.4.1.2.7 Window setup

'Window' 'Tile horizontal'

With this command you can arrange all the windows horizontally in the work area so that they do not overlap and will fill the entire work area.

'Window' 'Tile vertical'

With this command you can arrange all the windows vertically in the work area so that they do not overlap and will fill the entire work area.

'Window' 'Cascade'

With this command you can arrange all the windows in the work area in a cascading fashion, one behind another.

'Window' 'Arrange symbols'

With this command you can arrange all of the minimized windows in the work area in a row at the lower end of the work area.

'Window' 'Close all'

With this command you can close all open windows in the work area.

'Window' 'Messages'

Shortcut: <Shift>+<Esc>

With this command you can open or close the Message window with the messages from the last compiling, checking, or comparing procedure *Chapter 1.4.1.2.1.6 “Message window” on page 200*.

If the messages window is open, then a check (✓) will appear in front of the command.

1.4.1.2.8 Help

'Help' 'Contents and search'

With the commands Contents or Search in the Help menu you can open the help topics window, which will be displayed via the HTML Help Viewer.

The Contents tab shows the contents tree. The books can be opened and closed by a double-click or via the plus and minus signs. That page which is currently selected in the contents tree will be displayed in the right part of the window. Hyperlinks from the text to other help pages resp. expanding hotspots are marked by a different color and an underline. A mouse-click on such texts will open the linked page resp. will show the expanded text or a figure. For example you can click on "Help Topic Window" at the end of this page in order to get displayed a figure of a help window, or you can click on the hyperlink "Context Sensitive Help" in order to get to the respective help page.

In the Index tab you can look for help pages on specific items, in the Search tab a full-text search on all help pages can be done. Follow the instructions in the register cards.

See also: Context sensitive help *Chapter 1.4.1.2.8.2 “Context sensitive help” on page 293*.

Context sensitive help

Shortcut: <F1>

You can use the <F1> key in an active window, in a dialog box, or above a menu command in order to open the 'Help' 'Contents and search' *Chapter 1.4.1.2.8.1 “'Help' 'Contents and search'” on page 293*. When you perform a command from the menu, the help for the command called up at that time is displayed. You can also highlight a text (for example, a key word or a standard function) and press <F1> to have the help displayed for that item.

1.4.1.3 Editors

1.4.1.3.1 Components of an editor

All editors for POUs (Program Organization Units) consist of a declaration part and a body. The body can consist of other a text or a graphic editor; the declaration portion is always a text editor. Body and declaration part are separated by a screen divider that can be dragged, as required, by clicking it with the mouse and moving it up or down.

1.4.1.3.2 Print margins

The vertical and horizontal margins that apply when the editor contents are printed, are shown by red dashed lines if the 'Show print range' option in the project options in the dialog 'Workspace' was selected. The properties of the printer that was entered apply, as well as the size of the print layout selected in the 'File' 'Printer Setup' menu *Chapter 1.4.1.2.3.9 “'File' 'Printer setup'” on page 229*. If no printer setup or no print layout is entered, a default configuration is used (Default.DFR and default printer). The horizontal margins are drawn as if the options 'New page for each object' or 'New page for each sub-object' were selected in 'Documentation settings'. The lowest margin is not displayed.

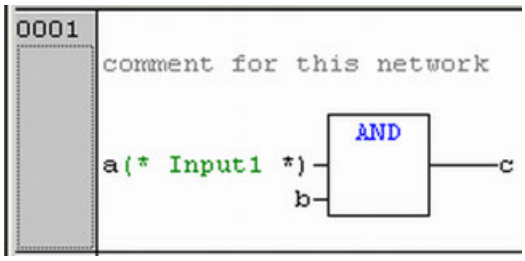
An exact display of the print margins is only possible when a zoom factor of 100% is selected.

1.4.1.3.3 Comment

User comments must be enclosed in the special symbol sequences (* and *). Example: (*This is a comment.*)

- Comments are allowed in all text editors, at any location desired, that is in all declarations, in the IL and ST languages and in self-defined data types *Chapter 1.4.1.1.10.3.1 “Overview” on page 163* *Chapter 1.4.1.1.10.4.1 “Overview” on page 165*. If the project is printed out using a template, the comment that was entered during variable declaration appears in text-based program components after each variable.
- In the FBD and LD graphic editors, comments can be entered for each network *Chapter 1.4.1.1.10.2 “Function Block Diagram (FBD)” on page 162* *Chapter 1.4.1.1.10.7.1 “Overview” on page 176*. To do this, search for the network on which you wish to comment and activate 'Insert' 'Comment'.
- Besides that comments always can be added where variable names are inserted.

  Example in FBD for a network comment and for a comment placed behind an input variable:



In KOP a comment also can be added to each contact resp. each coil, if this is configured accordingly in the display options in menu 'Extras' 'Options' *Chapter 1.4.1.3.11.9.22 “'Extras' 'Options'” on page 336*.

- In the Ladder Editor additionally a comment for each particular contact and coil can be added, if the corresponding options are activated in the menu 'Extras' 'Options'.
- In CFC there are special Comment POUs which can be placed at will *Chapter 1.4.1.1.10.6 “The continuous function chart (CFC)” on page 176* *Chapter 1.4.1.3.11.10.9 “'Insert' 'Comment' in CFC” on page 341*.
- In SFC, you can enter comments about a step in the dialog for editing step attributes *Chapter 1.4.1.1.10.5.1 “Overview” on page 171* *Chapter 1.4.1.3.11.9.20 “'Extras' 'Step Attributes'” on page 334*.

Nested comments are also allowed if the appropriate option in the 'Project' 'Options' 'Build Options' dialog is activated *Chapter 1.4.1.2.2.9 “Options for build” on page 209*.

In Online mode, if you rest the mouse cursor for a short time on a variable, the type and if applicable the address and comment of that variable are displayed in a tooltip.

1.4.1.3.4 Zoom to a POU

Shortcut: <Alt>+<Enter>

With this command a selected POU is loaded into its editor. The command is available in the context menu (<F2>) or in the 'Extras' menu, if the cursor is positioned on the name of a POU in a text editor or if the POU box is selected in a graphic editor.

If you are dealing with a POU from a library, then the library manager is called up, and the corresponding POU is displayed.

1.4.1.3.5 Open instance

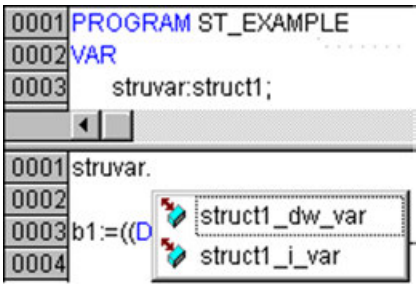
This command corresponds to the 'Project' 'View instance' command *Chapter 1.4.1.2.4.15 “'Project' 'View instance'” on page 263*.

It is available in the context menu (<F2>) or in the "Extras" menu, if the cursor is positioned on the name of a function block in a text editor or if the function block box is selected in a graphic editor.

1.4.1.3.6 Intellisense function

If the option List components is activated in the project options dialog for category 'Editor' , then the "Intellisense" functionality will be available in all editors, in the Watch- and Recipe manager, in the Visualization and in the Sampling Trace *Chapter 1.4.1.2.2.4 “Options for editor” on page 203*:

- If you insert a dot "." instead of an identifier, a selection box will appear, listing all local and global variables of the project. You can choose one of these elements and press 'Return' to insert it behind the dot. You can also insert the element by a doubleclick on the list entry.
- If you enter a function block instance or a structure variable followed by a dot, then a selection box listing all input and output variables of the corresponding function block resp. listing the structure components will appear, where you can choose the desired element and enter it by pressing 'Return' or by a doubleclick *Chapter 1.4.1.1.9.5 “Function block instances” on page 153* *Chapter 1.4.1.8.2.5 “Structures” on page 449*.
  Example: Insert "struvar." -> the components of structure struct1 will be offered:



- If you enter any string and press <Ctrl> + <Space Bar>, a selection box will appear listing all POUs and global variables available in the project. The list entry starting with the given string will be selected and can be entered to the program by pressing the <Enter> key.

1.4.1.3.7 Show cross references

Shortcut: <Strg>+<F3>

If a variable identifier is selected in an editor, then this command "Show cross references" will be available in the 'Extras' menu or the context menu. It can be used to get a list of all positions within the project where the variable is used. For information on this cross-reference list see: 'Project' 'Show cross reference'.

1.4.1.3.8 Add variables to watchlist

If one or several variables or elements are selected in one of the POU editors, these can be inserted in a new or existing watchlist via appropriate commands in the context menu. For details see Creating Watch Lists, Recipes *Chapter 1.4.1.4.9.2 “Creating watch lists, recipes” on page 397*.

1.4.1.3.9 Declaration editor

Overview

The declaration editor is used to declare variables of POUs and global variables, for data type declarations, and in the Watch and Receipt Manager. It gives access to the usual Windows functions, and even those of the IntelliMouse can be used if the corresponding driver is installed.

In Overwrite mode, 'OV' is shown in black on the status bar; switching between Overwrite and Insert modes can be accomplished with the <Ins> key.

The declaration of variables is supported by syntax coloring *Chapter 1.4.1.3.9.15 “Syntax coloring” on page 305*.

The most important commands are found in the context menu (right mouse button or <Ctrl>+<F10>).

Consider the possibility of using pragmas to affect the properties of a variable concerning the compilation resp. precompilation process Chapter 1.4.1.3.10.1 “Pragmas, overview” on page 309.

'Insert' 'NewDeclaration' *Chapter 1.4.1.3.9.19 “'Insert' 'New declaration'” on page 307*

Declaration editors in online mode ↳ *Chapter 1.4.1.3.9.21 “Declaration editors in online mode” on page 308*

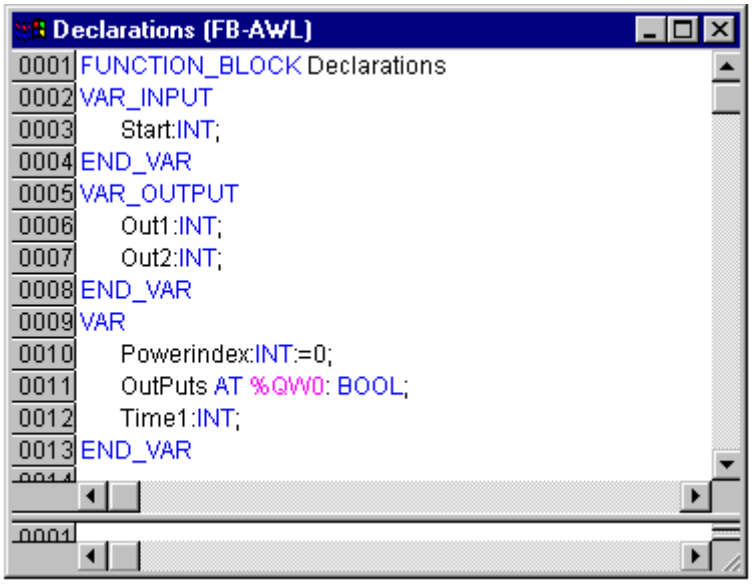
Declaration part

All variables to be used only in this POU are declared in the declaration part of the POU. These can include: input variable, output variable , input/output variables, local variables, remanent variables and constants ↳ *Chapter 1.4.1.3.9.3 “Input variable” on page 301* ↳ *Chapter 1.4.1.3.9.4 “Output variable” on page 301* ↳ *Chapter 1.4.1.3.9.5 “Input and output variables” on page 301* ↳ *Chapter 1.4.1.3.9.6 “Local variables” on page 301* ↳ *Chapter 1.4.1.3.9.7 “Remanent variables” on page 302* ↳ *Chapter 1.4.1.3.9.8 “Constants, typed literals” on page 302*. The declaration syntax is based on the IEC61131-3 standard.

Regard the possibility of using templates for objects of type 'Global Variables', 'Data types', 'Function', 'Function Block' or 'Program' ↳ *Chapter 1.4.1.2.4.7 “'Save as template'” on page 259*.

> *Regard the possibility of using pragmas to affect the properties of a variable concerning the compilation resp. precompilation process ↳ pragmas.*

An example of a correct declaration of variables in the editor:



Recommendations on the naming of identifiers

Identifiers are defined at the declaration of variables (variable names), user-defined data types and at the creation of POUs (functions, function blocks, programs) and visualizations. You might follow the following recommendations concerning the naming of identifiers in order to make it as unique as possible.

(1) Variable names

The naming of variables in applications and libraries as far as possible should follow the Hungarian notation:

For each variable a meaningful, short description should be found, the base name. The first letter of each word of a base name should be a capital letter, the others should be small ones (Example: FileSize). If needed additionally an translation file for other languages can be created.

Before the base name, corresponding to the data type of the variable, prefix(es) are added in small letters.

Data type	Lower limit	Upper limit	Information content	Prefix	Comment
BOOL	FALSE	TRUE	1 bit	x*	
				b	reserved
BYTE			8 bit	by	Bit string, not for arithm. operations
WORD			16 bit	w	Bit string, not for arithm. operations
DWORD			32 bit	dw	Bit string, not for arithm. operations
LWORD			64 bit	lw	not for arithm. operations
SINT	-128	127	8 bit	si	
USINT	0	255	8 bit	usi	
INT	-32.768	32.767	16 bit	i	
UINT	0	65.535	16 bit	ui	
DINT	-2.147.483.648	2.147.483.647	32 bit	di	
UDINT	0	4.294.967.295	32 bit	udi	
LINT	-2^{63}	$2^{63} - 1$	64 bit	li	
ULINT	0	$2^{64} - 1$	64 bit	uli	
REAL			32 bit	r	
LREAL			64 bit	lr	
STRING				s	
TIME				tim	
TIME_OF_DAY				tod	
DATETIME				dt	
DATE				date	
ENUM				16 bit	
e			POINTER		
	p		ARRAY		
		a			

* pointedly for BOOLean variables x is chosen as prefix, in order to differentiate from BYTE and also in order to accommodate the perception of an IEC-programmer (see addressing %IX0.0).

Examples:

```
bySubIndex: BYTE;
sFileName: STRING;
udiCounter: UDINT;
```

In nested declarations the prefixes are attached to each other in the order of the declarations:

Example:

```
pabyTelegramData: POINTER TO ARRAY [0..7] OF BYTE;
```

Function block instances and variables of user-defined data types as a prefix get a shortcut for the FB- resp. data type name (Examle: sdo).

Example:

```
cansdoReceivedTelegram: CAN_SDOTelegram;
TYPE CAN_SDOTelegram :  (* prefix: sdo *)
STRUCT
wIndex:WORD;
bySubIndex:BYTE;
byLen:BYTE;
aby: ARRAY [0..3] OF BYTE;
END_STRUCT
END_TYPE
```

Locale contants (c) start with prefix c and an attached underscore, followed by the type prefix and the variable name.

Example:

```
VAR CONSTANT
c_uiSyncID: UINT := 16#80;
END_VAR
```

For Global variables (g) and Global constants (gc) an additional prefix + underscore is attached to the library prefix:

Examples:

```
VAR_GLOBAL
CAN_g_iTest: INT;
END_VAR
VAR_GLOBAL CONSTANT
CAN_gc_dwExample: DWORD;
END_VAR
```

(2) User-defined data types (DUT)

The name of each structure data type consists of a library prefix (Example: CAN), an underscore and a preferably short expressive description (Example: SDOTelegram) of the structure. The associated prefix for used variables of this structure should follow directly after the colon.

Example:

```
TYPE CAN_SDOTelegram :   (* prefix: sdo *)
STRUCT
wIndex:WORD;
bySubIndex:BYTE;
byLen:BYTE;
abyData: ARRAY [0..3] OF BYTE;
END_STRUCT
END_TYPE
```

Enumerations start with the library prefix (Example: CAL), followed by an underscore and the identifier in capital letters..

Regard that in previous versions of CODESYS ENUM values > 16#7FFF have caused errors, because they did not get converted automatically to INT values. For this reason ENUMs always should be defined with correct INT values.

Example:

```
TYPE CAL_Day :(
CAL_MONDAY,
CAL_TUESDAY,
CAL_WEDNESDAY,
CAL_THIRSDAY,
CAL_FRIDAY,
CAL_SATURDAY,
CAL_SUNDAY);
Declaration:
eToday: CAL_Day;
```

(3) Functions, Function blocks, Programs (POU)

The names of functions, function blocks and programs consist of the library prefix (Example: CAN), an underscore and an expressive short name of the POU (Example: SendTelegram). Like with variables always the first letter of a word of the POU name should be a capital letter, the others should be small letters. It is recommended to compose the name of the POU of a verb and a substantive.

Example:

```
FUNCTION_BLOCK CAN_SendTelegram (* prefix: canst *)
```

In the declaration part a short description of the POU should be provided as a comment. Further on all inputs and outputs should be provided with comments. In case of function blocks the associated prefix for set-up instances should follow directly after the name.

Actions get no prefix; just actions which should be called only internally, i.e. by the POU itself, start with prv_.

Each function - for the reason of compatibility with previous CODESYS versions - must have at least one parameter. External functions must not use structures as return values.

(4) Identifiers for Visualizations

Note: Currently you must avoid that a visualization has the same name like another POU in the project. This would lead to problems in case of changes between visualizations.

Input variable

Between the key words VAR_INPUT and END_VAR, all variables are declared that serve as input variables for a POU. That means that at the call position, the value of the variables can be given along with a call.

Example:

```
VAR_INPUT
 iIn1:INT (* 1. Inputvariable*)
END_VAR
```

Output variable

Between the key words VAR_OUTPUT and END_VAR, all variables are declared that serve as output variables of a POU. That means that these values are carried back to the POU making the call. There they can be answered and used further.

Example:

```
VAR_OUTPUT
 iOut1:INT; (* 1. Outputvariable*)
END_VAR
```

Input and output variables

Between the key words VAR_IN_OUT and END_VAR, all variables are declared that serve as input and output variables for a POU.

NOTICE!
With this variable, the value of the transferred variable is changed ("transferred as a pointer", Call-by-Reference). That means that the input value for such variables cannot be a constant. For this reason, even the VAR_IN_OUT variables of a function block can not be read or written directly from outside via <functionblockinstance><in/outputvariable>.

Example:

```
VAR_IN_OUT
 iInOut1:INT; (* 1. Inputoutputvariable *)
END_VAR
```

Local variables

Between the keywords VAR and END_VAR, all of the local variables of a POU are declared. These have no external connection; in other words, they can not be written from the outside.

Example:

```
VAR
 iLoc1:INT; (* 1. Local Variable*)
END_VAR
```

Remanent variables

Remanent variables can retain their value throughout the usual program run period. These include Retain variables and Persistent variables.

Example:

```
VAR RETAIN
 iRem1:INT; (* 1. Retain variable*)
END_VAR
```

- Retain variables are identified by the keyword RETAIN. These variables maintain their value even after an uncontrolled shutdown of the controller as well as after a normal switch off and on of the controller (corresponding to command Online Reset). When the program is run again, the stored values will be processed further. A concrete example would be an piece-counter in a production line, that recommences counting after a power failure. All other variables are newly initialized, either with their initialized values or with the standard initializations.
  Retains are reinitialized at Reset (cold) and Reset (original) and - contrary to Persistent variables - at a new download of the program.
- Persistent variables are identified by the keyword PERSISTENT. Unlike Retain variables, these variables retain their value only after a re-download, but not after an Online Reset, Online Reset (original) or Online Reset (cold), because they are not saved in the "retain area". If also persistent variables should maintain their values after a uncontrolled shutdown of the controller, then they have to be declared additionally as VAR RETAIN variables. A concrete example of "persistent Retain-Variables" would be a operations timer that recommences timing after a power failure.

x = value will be retained

- = value gets reinitialized

after Online command	VAR	VAR RETAIN	VAR PERSISTENT	VAR RETAIN PERSISTENT VAR PERSISTENT RETAIN
Reset	-	x	-	x
Reset cold	-	-	-	-
Reset origin	-	-	-	-
Download	-	-	x	x
Online Change	x	x	x	x

- *If a local variable in a program is declared as VAR RETAIN, then exactly that variable will be saved in the retain area (like a global retain variable).*
- *If a local variable in a function block is declared as VAR RETAIN, then the complete instance of the function block will be saved in the retain area (all data of the POU), whereby only the declared retain variable will be handled as a retain.*
- *If a local variable in a function is declared as VAR RETAIN, then this will be without any effect. The variable will not be saved in the retain area ! If a local variable is declared as PERSISTENT in a function, then this will be without any effect also!*

Constants, typed literals

Constants are identified by the key word CONSTANT. They can be declared locally or globally.

Syntax:

VAR CONSTANT

<Identifier>:<Type> := <initialization>;

END_VAR

Example:

```
VAR CONSTANT
 c_iCon1:INT:=12; (* 1. Constant*)
END_VAR
```

See 'Operands' for a listing of possible constants *Chapter 1.4.1.7.1 “Overview” on page 435*. See there also regarding the possibility of using typed constants *Chapter 1.4.1.7.2.9 “Typed literals” on page 437*.

External variables

Global variables which are to be imported into the POU are designated with the keyword EXTERNAL. They also appear in the Watch window of the declaration part in Online mode.

If the VAR_EXTERNAL declaration does not match the global declaration in every respect, the following error message appears: "Declaration of '<var>' does not match global declaration!"

If the global variable does not exist, the following error message appears: "Unkown global variable: '<var>'!"

Example:

```
VAR EXTERNAL
 iVarExt1:INT:=12; (* 1st external variable *)
END_VAR
```

Keywords

Keywords are to be written in uppercase letters in all editors *Chapter 1.4.1.3.9.13 “'Insert' 'Declaration keywords'” on page 304*. Keywords may not be used as variables. Examples for keywords: VAR, VAR_CONSTANT, IF, NOT, INT *Chapter 1.4.1.1.10.8 “Reserved keywords” on page 178*.

Variables declaration

A variables declaration has the following syntax:

<Identifier> {AT <Address>}:<Type> {:=<initialization>};

The parts in the braces {} are optional.

Regarding the identifier, that is the name of a variable, it should be noted that it may not contain spaces or umlaut characters, it may not be declared in duplicate and may not be identical to any keyword. Upper/lowercase writing of variables is ignored, in other words VAR1, Var1 and var1 are not different variables. Underlines in identifiers are meaningful, e.g. A_BCD and AB_CD are interpreted as different identifiers. Multiple consecutive underlines at the beginning of an identifier or within a identifier are not allowed. The length of the identifier, as well as the meaningful part of it, are unlimited.

All declarations of variables and data type elements can include initialization. They are brought about by the ":=" operator. For variables of elementary types, these initializations are constants. The default-initialization is 0 for all declarations.

Example: iVar1:INT:=12; (* Integer variable with initial value of 12*)

If you wish to link a variable directly to a definite address, then you must declare the variable with the keywordAT.

For faster input of the declarations, use the shortcut mode.

In function blocks you can also specify variables with incomplete address statements. In order for such a variable to be used in a local instance, there must be an entry for it in the variable configuration.

Pay attention to the possibility of an automatic declaration.

Regard the possibility of using pragmas to affect the properties of a variable concerning the compilation resp. precompilation process.

AT Declaration

If you wish to link a variable directly to a definite address, then you must declare the variable with the keyword AT. The advantage of such a procedure is that you can assign a meaningful name to an address, and that any necessary changes of an incoming or outgoing signal will only have to be made in one place (e.g., in the declaration).

Notice that variables requiring an input cannot be accessed by writing.

Examples:

```
xCounterHeat7 AT %QX0.0: BOOL;
wLightcabinetimpulse AT %IW2: WORD;
xDownload AT %MX2.2: BOOL;
```

If boolean variables are assigned to a Byte, Word or DWORD address, they occupy one byte with TRUE or FALSE, not just the first bit after the offset!

'Insert' 'Declaration keywords'

You can use this command to open a list of all the keywords that can be used in the declaration part of a POU. After a keyword has been chosen and the choice has been confirmed, the word will be inserted at the present cursor position *Chapter 1.4.1.1.10.8 “Reserved keywords” on page 178*.

You also receive the list when you open the input assistant (<F2>) and choose the Declarations category *Chapter 1.4.1.2.5.11 “'Edit' 'Input assistant'” on page 276*.

'Insert' 'Type'

With this command you will receive a selection of the possible types for a declaration of variables. You also receive the list when you access the input assistant (<F2>).

The types are divided into these categories:

- Standard types BOOL, BYTE, etc.
- Defined types Structures, enumeration types, etc.
- Standard function blocks for instance declarations
- Defined function blocks for instance declarations

All standard types of IEC1131-3 are supported *Chapter 1.4.1.8.2.1 “ARRAY” on page 445*.

Syntax coloring

In all editors you receive visual support in the implementation and declaration of variables. Errors are avoided, or discovered more quickly, because the text is displayed in color.

A comment left unclosed, thus annotating instructions, will be noticed immediately; keywords will not be accidentally misspelled, etc.

Table 12: Used color highlighting

Color	HIghlighted text
Blue	Keywords
Green	Comments in the text editors
Pink	Special constants (e.g. TRUE/FALSE, T#3s, %IX0.0)
Red	Input error (for example, invalid time constant, keyword, written in lower case,...)
Black	Variables, constants, assignment operators, ...

Shortcut mode

The declaration editor allows you to use the shortcut mode. This mode is activated when you end a line with <Ctrl><Enter>

Supported shortcuts:

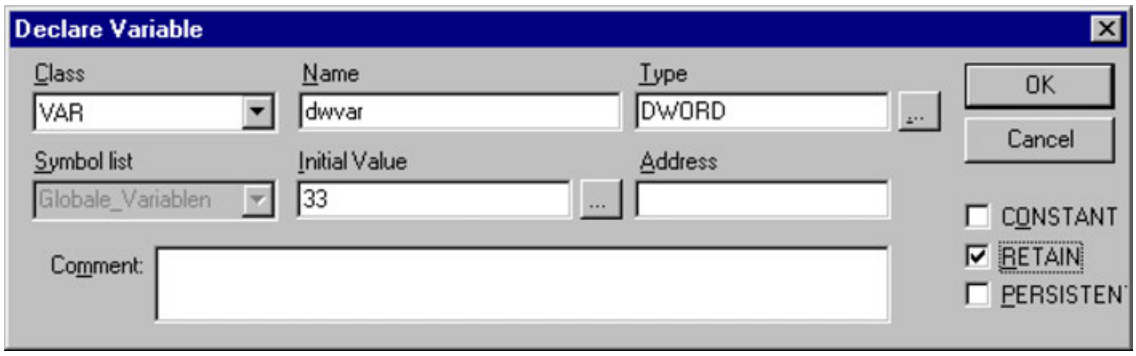
- All identifiers up to the last identifier of a line will become declaration variable identifiers
- The type of declaration is determined by the last identifier of the line. In this context, the following will apply:
  - B or BOOL gives the result - BOOL
  - I or INT gives the result - INT
  - R or REAL gives the result - REAL
  - S or string gives the result - STRING
- If no type has been established through these rules, then the type is BOOL and the last identifier will not be used as a type (Example 1.).
- Every constant, depending on the type of declaration, will turn into an initialization or a string (Examples 2. and 3.).
- An address (as in %MD12) is extended around the ATATDeclaration>Proc... attribute (Example 4.).
- A text after a semicolon (;) becomes a comment (Example 4.).
- All other characters in the line are ignored (e.g., the exclamation point in Example 5.).

Examples

Shortcut	Declaration
A	A: BOOL;
A B I 2	A, B: INT := 2;
ST S 2; A string	ST:STRING(2); (* A string *)
X %MD12 R 5 Real Number	X AT %MD12: REAL := 5.0;(* Real Number *)
B !	B: BOOL;

Autodeclaration

If the Autodeclaration option has been chosen in the Editor category of the Options dialog box , then a dialog box will appear in all editors after the input of a variable that has not yet been declared:



With the help of this dialog box, the variable can now be declared.

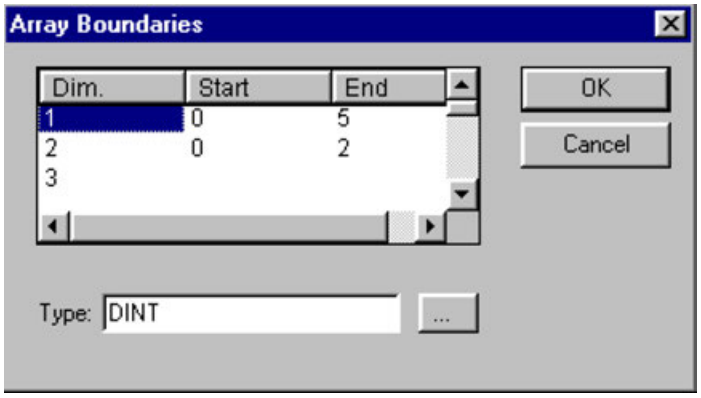
With the help of the Class combobox, select whether you are dealing with a local variable (VAR), input variable((VAR_INPUT), output variable (VAR_OUTPUT), input/output variable (VAR_INOUT), or a global variable (VAR_GLOBAL).

With the CONSTANT, RETAIN, PERSISTENT options, you can define whether you are dealing with a constant or a retain variable ↬ *Chapter 1.4.1.3.9.7 “Remanent variables” on page 302*.

The variable name you entered in the editor has been entered in the Name field, BOOL has been placed in the Type field. The … button opens the input assistant dialog which allows you to select from all possible data types.

Declaration of Arrays

If ARRAY is chosen as the variable type, the dialog for entering array boundaries appears:



For each of the three possible dimensions (Dim.), array boundaries can be entered under Start and End by clicking with the mouse on the corresponding field to open an editing space. The array data type is entered in the Type field. In doing this, the … button can be used to call up an input assistant dialog.

Upon leaving the array boundaries dialog via the OK button, variable declarations in IEC format are set up based on the entries in the Type field in the dialog. Example: ARRAY [1..5, 1..3] OF INT

In the field Initial value, you may enter the initial value of the variable being declared. If this is an array or a valid structure, you can open a special initialization dialog via the … button or <F2>, or open the input assistant dialog for other variable types.

In the initialization dialog for an array you are presented a list of array elements; a mouse click on the space following ":="opens an editing field for entering the initial value of an element.

In the initialization dialog for a structure, individual components are displayed in a tree structure. The type and default initial value appear in brackets after the variable name; each is followed by ":=". A mouse click on the field following ":=" opens an editing field in which you can enter the desired initial value. If the component is an array, then the display of individual fields in the array can be expanded by a mouse click on the plus sign before the array name and the fields can be edited with initial values.

After leaving the initialization dialog with OK, the initialization of the array or the structure appears in the field Initial value of the declaration dialog in IEC format.

Example: x:=5,field:=2,3,struct2:=(a:=2,b:=3)

In the Address field, you can bind the variable being declared to an IEC address (AT declaration).

If applicable, enter a Comment. The comment can be formatted with line breaks by using the key combination <Ctrl> + <Enter>.

By pressing OK, the declaration dialog is closed and the variable is entered in the corresponding declaration editor in accordance to the IEC syntax.

The dialog box for variable declaration you also get by the command 'Edit' 'Declare Variable' ↳ *Chapter 1.4.1.2.5.14 “'Edit' 'Autodeclare'” on page 278*. *If the cursor is resting on a variable in Online mode, the Autodeclare window can be opened with <Shift><F2> with the current variable-related settings displayed.*

Line numbers in the declaration editor

In offline mode, a simple click on a special line number will mark the entire text line.

In the online mode, a single click on a specific line number will open up or close the variable in this line, in case a structural variable is involved.

'Insert' 'New declaration'

With this command you bring a new variable into the declaration table of the declaration editor ↳ *Chapter 1.4.1.3.9.20 “Declarations as table” on page 307*. If the present cursor position is located in an field of the table, then the new variable will be pasted in the preceding line; otherwise, the new variable is pasted at the end of the table. Moreover, you can paste a new declaration at the end of the table by using the right arrow key or the tab key in the last field of the table.

You will receive a variable that has "Name" located in the Name field, and "Bool" located in the Type field, as its default setting. You should change these values to the desired values. Name and type are all that is necessary for a complete declaration of variables.

Declarations as table

If the Declarations as tables option is activated in the Project Options (category ‘Editor’) or - if you already are working in the declaration editor - in the context menu, the declaration editor looks like a table. As in a card-index box, you can select the register cards of the respective variable types and edit the variables.

For each variable you are given the following entry fields.

Name:	Input the identifier of the variable.
Address:	If necessary, input the address of the variable ↳ *Chapter 1.4.1.3.9.12 “AT Declaration” on page 304*
Type:	Input the type of the variable. (Input the function block when instantiating a function block)
Initial:	Enter a possible initialization of the variable (corresponding to the ":= " assignment operator).
Comment:	Enter a comment here.

Both of the display types of the declaration editor can be changed without causing any problems. In the online mode, there are no different display types.

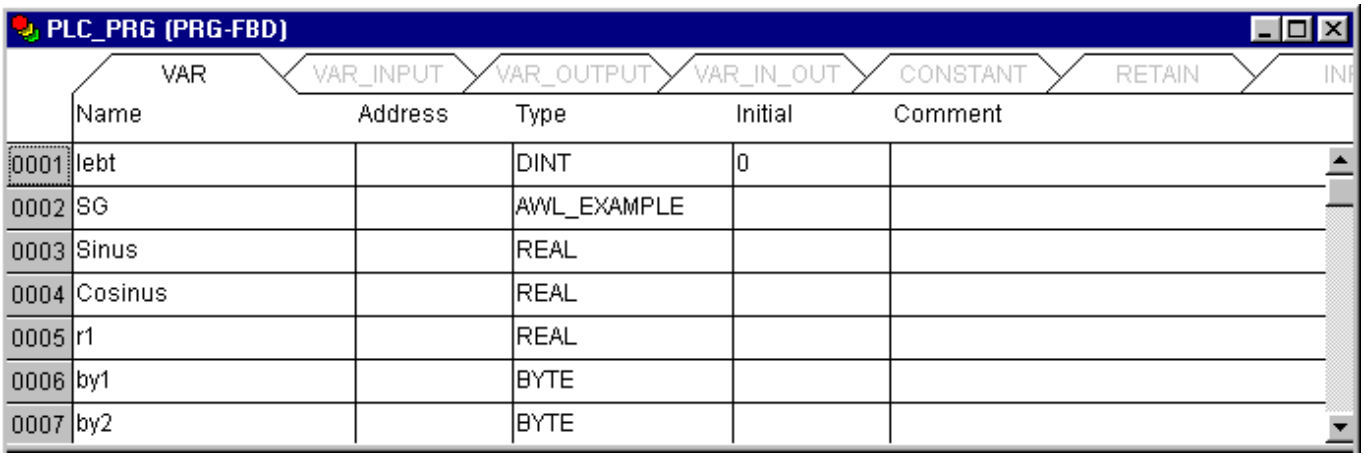
Insert new declaration:

In order to edit a new variable, select the 'Insert' 'New Declaration' command ↳ *Chapter 1.4.1.3.9.19 “'Insert' 'New declaration'” on page 307*.

Sorting the declarations:

In order to sort the table entries, set the cursor to the line number bar at the left border of the editor window and choose one of the following commands in the context menu:

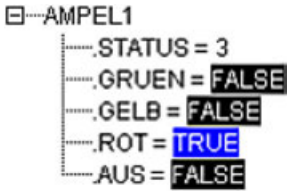
- Sort by name: All lines are sorted alphabetically according to the identifier names in column ‘Name’.
- Sort by address: All lines are sorted alphabetically according to the address entries in column ‘Address’.
- Sort by type: All lines are sorted alphabetically according to the type names in column ’Type’.
- Original order: The lines are displayed in the order in which they had been entered originally.



Declaration editors in online mode

In online mode , the declaration editor changes into a monitor window ↳ *Chapter 1.4.1.3.9.1 “Overview” on page 296*. In each line there is a variable followed by the equal sign (=) and the value of the variable. If the variable at this point is undefined, three question marks (???) will appear. For function blocks, values are displayed only for open instances (command: 'Project' 'Open instance').

In front of every multi-element variable there is a plus sign. By pressing <Enter> or after doubleclicking on such a variable, the variable is opened up. In the example, the traffic signal structure would be opened up.



When a variable is open, all of its components are listed after it. A minus sign appears in front of the variable. If you doubleclick again or press <Enter>, the variable will be closed, and the plus sign will reappear.

Pressing <Enter> or doubleclicking on a single-element variable will open the dialog box to write a variable. Here it is possible to change the present value of the variable. In the case of Boolean variables, no dialog box appears; these variables are toggled.

The new value is displayed after the variable, in pointed brackets and in turquoise color, and remains unchanged. If the 'Online' 'Write values' command is given, then all variables are placed in the selected list and are once again displayed in black ↳ *Chapter 1.4.1.2.6.16 “'Online' 'Write values'” on page 286*.

If the 'Online' 'Force values' command is given, then all variables will be set to the selected values, until the 'Release force' command is given ↳ *Chapter 1.4.1.2.6.17 “'Online' 'Force values'” on page 287* ↳ *Chapter 1.4.1.2.6.18 “'Online' 'Release force'” on page 288*. In this event, the color of the force value changes to red.

1.4.1.3.10 Pragma instructions

Pragmas, overview

The pragma instruction is used to affect the properties of a variable concerning the compilation resp. precompilation process. It can be used in with supplementary text in a program line of the declaration editor or in its own line ↳ *Chapter 1.4.1.3.9.1 “Overview” on page 296*.

The pragma instruction is enclosed in curly brackets, upper- and lower-case are ignored:
{ <Instruction text> }

If the compiler cannot meaningfully interpret the instruction text, the entire pragma is handled as a comment and read over. A warning will be issued in this case.

Depending on the type and contents of pragma, the pragma either operates on the line in which it is located or on all subsequent lines until it is ended by an appropriate pragma, or the same pragma is executed with different parameters, or the end of the file is reached. By file we mean here: declaration part, implementation portion, global variable list, type declaration.

The opening bracket may immediately follow a variable name. Opening and closing brackets must be located on the same line.

The following pragmas are currently available:

↳ *“Pragma {flag} for Initialization, Monitoring, Creation of symbols:” on page 310*

↳ *“Pragma {bitaccess...} for the Bitaccess” on page 312*

↳ *“Pragma {link} for linking a POU during code generation” on page 312*

↳ *Chapter 1.4.1.3.10.3 “Pragmas for controlling the display of library declaration parts” on page 312*

↳ *Chapter 1.4.1.3.10.4 “Pragma for nonpersistent data types” on page 313*

Pragma instructions for initialization, monitoring, creation of symbols, bitaccess, linking

Pragma {flag} for Initialization, Monitoring, Creation of symbols:

{flag [<flags>] [off|on]}

<flags> can be a combination of the following flags:

Flag	Description
noini	The variable will not be initialized.
nowatch	The variable can not be monitored
noread	The variable is exported to the symbol file without read permission
nowrite	The variable is exported to the symbol file without write permission
noread, nowrite	The variable will not get exported to the symbol file

With the "on" modifier, the pragma operates on all subsequent variable declarations until it is ended by the pragma {flag off}, or until overwritten by another {flag <flags> on} pragma.

Without the "on" or "off" modifier, the pragma operates only on the current variable declaration (that is the declaration that is closed by the next semicolon).

Example for use of pragma {flag}: Initialization and monitoring of variables

The variable a will not be initialized and will not be monitored. The variable b will not be initialized:

```
VAR
 a : INT {flag noinit, nowatch};
 b : INT {flag noinit };

END_VAR

VAR
 {flag noinit, nowatch on}
 a : INT;
 {flag noinit on}
 b : INT;
 {flag off}

END_VAR
```

Neither variable will be initialized:

```
{flag noinit on}

VAR
a : INT;
b : INT;

END_VAR

{flag off}

VAR
{flag noinit on}
a : INT;

b : INT;

{flag off}

END_VAR
```

Example for use of pragma {flag}: Getting variables to the symbol file

The flags "noread" and "nowrite" are used, in a POU that has read and/or write permission, to provide selected variables with restricted access rights. The default for the variable is the same as the setting for the POU in which the variable is declared. If a variable has neither read nor write permission, it will not be exported into the symbol file.

If the POU has read and write permission, then with the following pragmas variable a can only be exported with write permission, while variable b can not be exported at all:

```
VAR
 a : INT {flag noread};
 b : INT {flag noread, nowrite};

END_VAR

VAR
 { flag noread on}
 a : INT;
 { flag noread, nowrite on}
 b : INT;
 {flag off}

END_VAR
```

Neither variable a nor b will be exported to the symbol file:

```
{ flag noread, nowrite on }
VAR
 a : INT;
 b : INT;
END_VAR
{flag off}

VAR
 { flag noread, nowrite on}
 a : INT;
 b : INT;
 {flag off}
END_VAR
```

The pragma operates additively on all subsequent variable declarations.

Example: (all POUs in use will be exported with read and write permission)

```
a : afb;

...

FUNCTION_BLOCK afB
VAR
 b : bfb {flag nowrite};
 c : INT;
END_VAR

...

FUNCTION_BLOCK bfB
VAR
 d : INT {flag noread};
 e : INT {flag nowrite};
END_VAR
```

"a.b.d": Will not be exported

"a.b.e": Will be exported only with read permission

"a.c": Will be exported with read and write permission.

Pragma {bitaccess...} for the Bitaccess

This pragma can be used to get a correct display of a variable, which is doing a bitaccess with the help of a global constant, in the input assistant, in the intellisense function and at monitoring in the declaration window. Furtheron it will effect that, when this variable is monitored in the declaration window of the particular POU, the used global constants are shown below the respective structure variable.

Please regard: The project option 'Replace constants' (category Build) must be activated !

The pragma must be inserted in the declaration of the structure in a separate line. The line is not terminated by a semicolon.

Syntax: {bitaccess <Global Constant> <Bitnumber> '<comment>'}

<Global Constant> : Name of the global constant, which must be defined in a global variables list.

<Bitnumber> : Value of the global constant, as defined in the global variables list.

Pragma {link} for linking a POU during code generation

Normally a POU (program, function, function block) or a data unit type definition (DUT) which is not called within the project, will not be linked during code generation. But it might be desired that a function, e.g. included in the project via a library, should be available after download on the runtime system even if it is not used by the application program directly (e.g. for any check operations). For this purpose you can add the {link} pragma at any desired position in the declaration part of a POU or in a DUT in order to force a linking of the POU anyway.

Pragmas for controlling the display of library declaration parts

During creation of a library in CODESYS you can define via pragmas which parts of the declaration window should be visible resp. not visible in the Library Manager later when the library will be included in a project. The display of the implementation part of the library will not be affected by that.

Thus comments or any variables declarations can be concealed from the user. The pragmas {library private} and {library public} each affect the rest of the same line resp. the subsequent lines, as long as they are not overwritten by the each other one.

Syntax: {library public} The subsequent test will be displayed in the Library Manager. {library private} : he subsequent test will be not displayed.

Example: Declaration part of a library created in CODESYS

The comment "(* this is for all *)" should be displayed in the Library Manager after having included the library in a project., the comment "(* but this is not for all ")" however should not be displayed. The variables local and in2 also should not be displayed:

```
{library public}(* this is for all *) {library private} (* this is
not for all *)
{library public}
FUNCTION afun : BOOL
VAR_INPUT
in: BOOL;
END_VAR
{library private}
VAR
local: BOOL;
END_VAR
{library public}
VAR_INPUT
in2: BOOL;
{library private}
in3: BOOL;
{library public}
END_VAR
```

Pragma for nonpersistent data types

Normally the following is valid: Even if only one local variable in a function block or a structure is declared persistent, at usage of an instance automatically all components will be stored in the persistent information (persist.dat) on the runtime system. In order to save space you can use the pragma

{nonpersistent}

in the declaration of the function block resp. the structure. It effects that only those components of the function block resp. structure, which are declared as "persistent", will be entered to the persistent info.

Example

If an instance of the following function block is declared as persistent, only variables local and fblevel3 will be written to the persistent info. Without pragma {nonpersistent} all function block variables would be stored there.

```
FUNCTION_BLOCK FB_Level_2
{nonpersistent}
VAR_INPUT
bvar_in : BOOL;
END_VAR
VAR_OUTPUT
bvar_out : BOOL;
END_VAR
VAR
ivar2 : INT;
END_VAR
VAR PERSISTENT
local : INT := 33;
fblevel3 : FB_Level_3;
END_VAR
```

1.4.1.3.11 The graphic editors

Overview

The editors of the graphically oriented languages, Sequential Function Chart SFC, Ladder Diagram LD and Function Block Diagram FBD and of free graphic Function Block Diagram have many points in common. In the following paragraphs these features will be summarized; the specific descriptions of LD, FBD an CFC, as well as the Sequential Function Chart language SFC follow in separate sections. The implementation in the graphics editors is supported by syntax coloring.

Zoom to a POU

Shortcut: <Alt>+<Enter>

With this command a selected POU is loaded into its editor. The command is available in the context menu (<F2>) or in the 'Extras' menu, if the cursor is positioned on the name of a POU in a text editor or if the POU box is selected in a graphic editor.

If you are dealing with a POU from a library, then the library manager is called up, and the corresponding POU is displayed.

Network

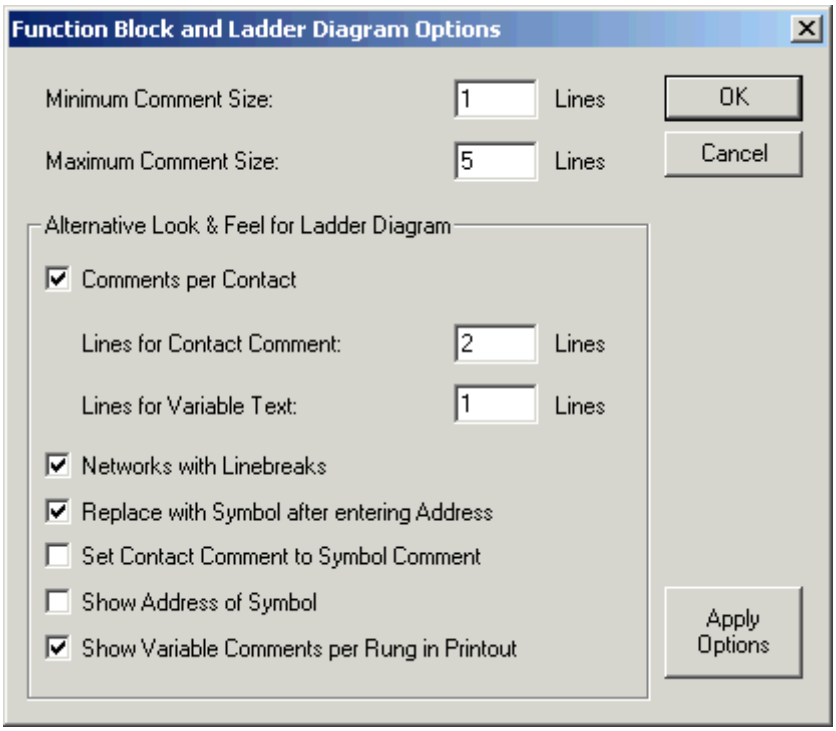
In the LD and FBD editors, the program is arranged in a list of networks. Each network is designated on the left side by a serial network number and has a structure consisting of either a logical or an arithmetic expression, a program, function or function block call, and a jump or a return instruction.

Label

Each network has a label that can optionally be left empty. This label is edited by clicking the first line of the network, directly next to the network number. Now you can enter a label, followed by a colon.

Comments, networks with linebreaks, 'Extras' 'Options'

Every network can be supplied with a multi-lined comment. In the dialog 'Function Block and Ladder Diagram Options', which can be opened by executing the command 'Extras' 'Options', you can do settings concerning comments and linebreaks.



Maximum Comment Size: Maximum number of lines to be made available for a network comment (The default value here is 4.)

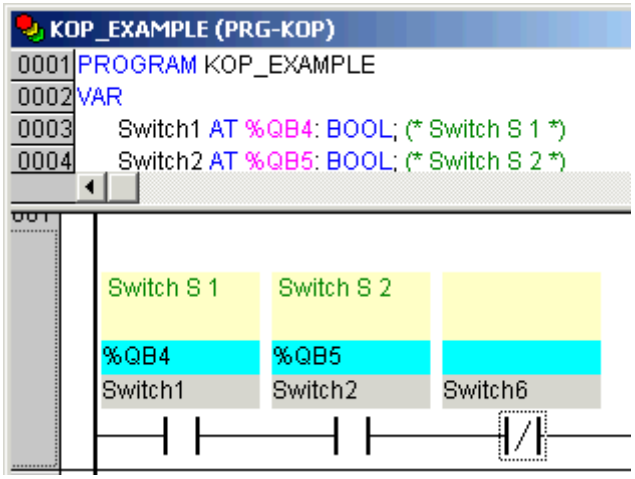
Minimum Comment Size: Number of lines that generally should be reserved for comments. If, for example, the number 2 is entered, then, at the start of each network there will be two empty lines after the label line. The default value here is 0, which has the advantage of allowing more networks to fit in the screen area.

If the minimal comment size is greater than 0, then in order to enter a comment you simply click in the comment line and then enter the comment. Otherwise you first must select the network to which a comment is to be entered, and use 'Insert' 'Comment' to insert a comment line. In contrast to the program text, comments are displayed in grey.

Alternative Look & Feel: The following options allow to define an alternative look of the networks.

Comments per Contact (only for Ladder editor): If this option is activated, you can assign an individual comment to each contact or coil . In the edit field Lines for Variable Comment enter the number of lines which should be reserved and displayed for the comment. If this setting is done, a comment field will be displayed in the editor above each contact and coil where you can insert text.

If Comments per Contact is activated, then in the Ladder editor also the number of lines (Lines for Variable Text:) can be defined which should be used for the variable name of the contact resp. coil. This is used to display even long names completely by breaking them into several lines. In the following example 2 lines are defined for the variable comment and 1 line for the variable text:



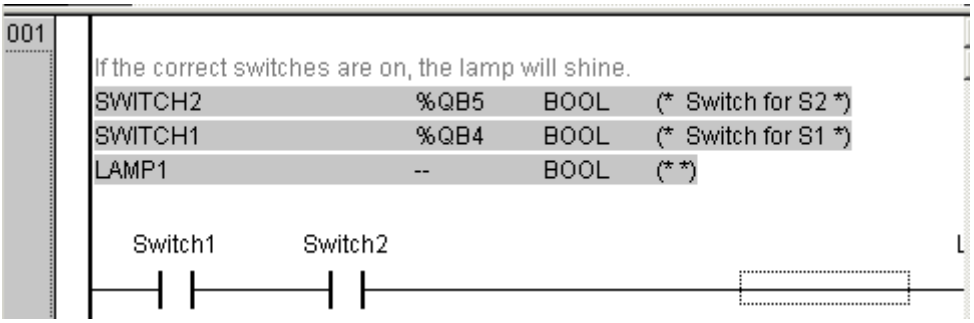
Networks with Linebreaks (only for Ladder editor): If this option is activated, linebreaks will be forced in the networks as soon as the network length exceeds the given window size and some of the elements would not be visible.

Replace with Symbol after entering Address: (only for Ladder editor): If this option is activated, you can enter an address at a box resp. at a contact or coil (e.g. "%QB4") and this address will be replaced immediately by the name of the variable which is assigned to the address. If there is no variable assigned to the entered address, the address remains displayed unchangedly.

Set Contact Comment to Symbol Comment: If this option is activated, in the comment field of a contact resp. a coil that comment will be displayed which has been defined at the declaration of the variable used for the contact or coil. The comment then can be edited. (see example in the subsequent figure). For this purpose however the option 'Comments per Contact' also must be activated. Regard that a comment which has been entered already locally at a contact or coil will be replaced automatically by the variable comment in any case, even if the variable has not got a comment in its declaration!

Show Address of Symbol: (only for Ladder editor): If this option is activated and a variable assigned to a contact or coil is assigned to an address, the address will be displayed above the variable name (see example in the figure above).

Show Variable Comments per Rung in Printout: If this option is activated, in each network for each variable used in that network there will be displayed a line showing the name, address, data type and comment for this variable, as defined in the variables declaration. This might be of useful for a documentation (printout) of the project. Example:



OK: Press this button to apply the settings on the actual POU and to close the options dialog.

Apply options: Press this button to apply the settings on the whole project. A dialog will open asking you where you have explicitly to confirm that you want to do that.

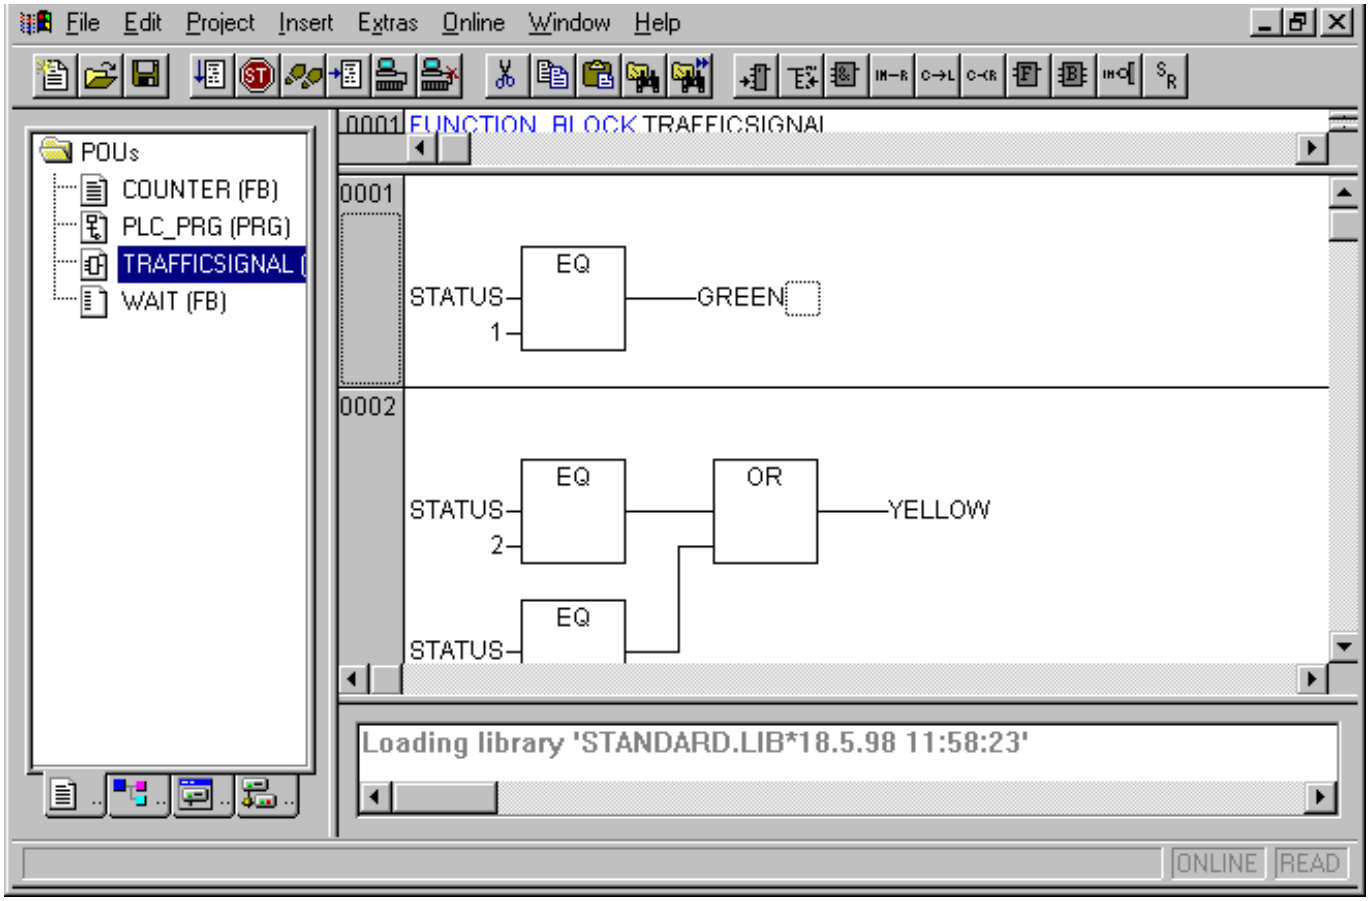
'Insert' 'Network (after)' or 'Insert' 'Network (before)'

Shortcut: <Shift>+<T> (Network after)

In order to insert a new network in the FBD or the LD editor, select the 'Insert' 'Network (after)' or the 'Insert' 'Network (before)' command, depending on whether you want to insert the new network before or after the present network. The present network can be changed by clicking the network number. You will recognize it in the dotted rectangle under the number. With the <Shift key> and a mouse click you can select from the entire area of networks, from the present one to the one clicked.

The Function Block Diagram Editor

Overview



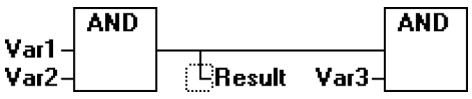
The Function Block Diagram Editor is a graphic editor. It works with a list of networks, in which every network contains a structure that displays, respectively, a logical or an arithmetical expression, the calling up of a function block, a function, a program, a jump, or a return instruction. The most important commands are found in the context menu (right mouse button or <Ctrl>+<F10>).

Cursor positions in FBD

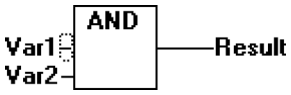
Every text is a possible cursor position. The selected text is on a blue background and can now be changed.

You can also recognize the present cursor position by a dotted rectangle. The following is a list of all possible cursor positions with an example:

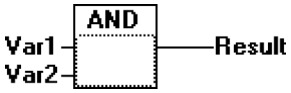
1) Every text field (possible cursor positions framed in black):



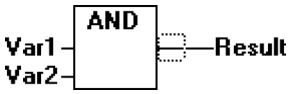
2) Every input:



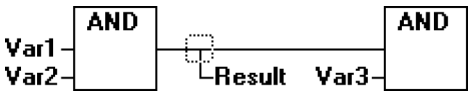
3) Every operator, function, or function block:



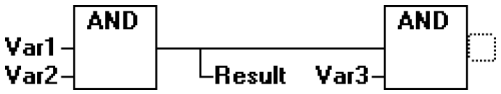
4) Outputs, if an assignment or a jump comes afterward:



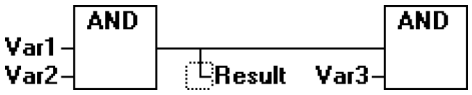
5) The lined cross above an assignment, a jump, or a return instruction:



6) Behind the outermost object on the right of every network ("last cursor position," the same cursor position that was used to select a network):



7) The lined cross directly in front of an assignment:



How to set the cursor in FBD

The cursor can be set at a certain position by clicking the mouse, or with the help of the keyboard.

Using the arrow keys, you can jump to the nearest cursor position in the selected direction at any time. All cursor positions, including the text fields, can be accessed this way. If the last cursor position is selected, then the <up> or <down> arrow keys can be used to select the last cursor position of the previous or subsequent network.

An empty network contains only three question marks "???". By clicking behind these, the last cursor position is selected.

'Insert' 'Assign'in FBD

Symbol: Shortcut: <Ctrl>+<A>

This command inserts an assignment.

Depending on the selected position, insertion takes place directly in front of the selected input (Cursor Position 2), directly after the selected output (Cursor Position 4) or at the end of the network (Cursor Position 6) *Chapter 1.4.1.3.11.7.2 “Cursor positions in FBD” on page 317*.

For an inserted assignment, a selection can be made accompanying the entered text "???", and the assignment can be replaced by the variable that is to be assigned. For this you can also use the input assistant *Chapter 1.4.1.2.5.11 “'Edit' 'Input assistant'” on page 276*. For the possibility to enter an address instead of the variable name please see the description of the options dialog.

In order to insert an additional assignment to an existing assignment, use the 'Insert' 'Output' command.

'Insert' 'Jump' in FBD

Symbol: Shortcut: <Ctrl>+<L>

This command inserts a jump. Depending on the selected position, insertion takes place directly in front of the selected input (Cursor Position 2), directly after the selected output (Cursor Position 4) or at the end of the network (Cursor Position 6) *Chapter 1.4.1.3.11.7.2 “Cursor positions in FBD” on page 317*.

For an inserted jump, a selection can be made accompanying the entered text "???", and the jump can be replaced by the label to which it is to be assigned.

'Insert' 'Return' in FBD

Symbol: Shortcut: <Ctrl>+<R>

This command inserts a RETURN instruction. Depending on the selected position, insertion takes place directly in front of the selected input (Cursor Position 2),directly after the selected output (Cursor Position 4), directly before the selected line cross (Cursor Position 5), or at the end of the network (Cursor Position 6) *Chapter 1.4.1.3.11.7.2 “Cursor positions in FBD” on page 317*.

'Insert' 'Box' in FBD

Symbol: Shortcut: <Ctrl>+<B>

With this command, operators, functions, function blocks and programs can be inserted. First of all, it is always inserted an "AND" operator. This can be converted by Selection and Overwrite of the type text („AND") into every other operator, into every function, into every function block and every program. You can select the desired POU by using Input Assistant (<F2>). If the new selected block has another minimum number of inputs, these will be attached. If the new block has a smaller highest number of inputs, the last inputs will be deleted.

In functions and function blocks, the formal names of the in- and outputs are displayed.

In function blocks there exists an editable instance field above the box. If another function block that is not known is called by changing the type text, an operator box with two inputs and the given type is displayed. If the instance field is selected, input assistant can be obtained via <F2> with the categories for variable selection.

The newest POU is inserted at the selected position *Chapter 1.4.1.3.11.7.2 “Cursor positions in FBD” on page 317*:

- If an input is selected (Cursor Position 2), then the POU is inserted in front of this input. The first input of this POU is linked to the branch on the left of the selected input. The output of the new POU is linked to the selected input.
- If an output is selected (Cursor Position 4), then the POU is inserted after this output. The first input of the POU is connected with the selected output. The output of the new POU is linked to the branch with which the selected output was linked.
- If a POU, a function, or a function block is selected (Cursor Position 3), then the old element will be replaced by the new POU.
- As far as possible, the branches will be connected the same way as they were before the replacement. If the old element had more inputs than the new one, then the unattachable branches will be deleted. The same holds true for the outputs.
- If a jump or a return is selected, then the POU will be inserted before this jump or return. The first input of the POU is connected with the branch to the left of the selected element. The output of the POU is linked to the branch to the right of the selected element.
- If the last cursor position of a network is selected (Cursor Position 6), then the POU will be inserted following the last element. The first input of the POU is linked to the branch to the left of the selected position.

All POU inputs that could not be linked will receive the text "???". This text must be clicked and changed into the desired constant or variable.

If there is a branch to the right of an inserted POU, then the branch will be assigned to the first POU output. Otherwise the outputs remain unassigned.

'Insert' 'Input'

Symbol: Shortcut: <Ctrl>+<U>

This command inserts an operator input. With many operators, the number of inputs may vary. (For example, ADD can have 2 or more inputs.)

In order to extend such an operator by an input, you need to select the input in front of which you wish to insert an additional input (Cursor Position 1); or you must select the operator itself (Cursor Position 3), if a lowest input is to be inserted *Chapter 1.4.1.3.11.7.2 “Cursor positions in FBD” on page 317*.

The inserted input is allocated with the text "???". This text must be clicked and changed into the desired constant or variable. For this you can also use the input assistant. For the possibility to enter an address instead of the variable name please see the description of the options dialog.

'Insert' 'Output'

Symbol:

This command inserts an additional assignment into an existing assignment. This capability serves the placement of so-called assignment combs; i.e., the assignment of the value presently located at the line to several variables.

If you select the lined cross above an assignment (Cursor Position 5) or the output directly in front of it (Cursor Position 4), then there will be another assignment inserted after the ones already there *Chapter 1.4.1.3.11.7.2 “Cursor positions in FBD” on page 317*.

If the line cross directly in front of an assignment is selected (Cursor Position 4), then another assignment will be inserted in front of this one.

The inserted output is allocated with the text "???". This text must be clicked and changed into the desired variable. For this you can also use the input assistant. For the possibility to enter an address instead of the variable name please see the description of the options dialog.

'Extras' 'Negation'

Symbol: Shortcut: <Ctrl>+<N>

With this command you can negate the inputs, outputs, jumps, or RETURN instructions. The symbol for the negation is a small circle at a connection.

If an input is selected (Cursor Position 2), then this input will be negated *Chapter 1.4.1.3.11.7.2 “Cursor positions in FBD” on page 317*.

If an output is selected (Cursor Position 4), then this output will be negated.

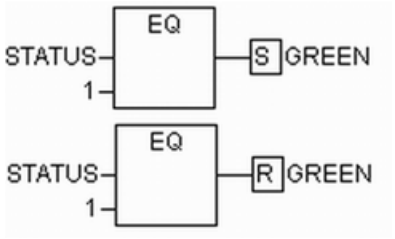
If a jump or a return is marked, then the input of this jump or return will be negated.

A negation can be canceled through renewed negation.

'Extras' 'Set/Reset'

Symbol:

With this command you can define outputs as Set or Reset Outputs. A grid with Set Output is displayed with [S], and a grid with Reset Output is displayed with [R] :



An Output Set is set to TRUE, if the grid belonging to it returns TRUE. The output now maintains this value, even if the grid jumps back to FALSE.

An Output Reset is set to FALSE, if the grid belonging to it returns FALSE. The output maintains its value, even if the grid jumps back to FALSE.

With multiple executions of the command, the output will alternate between set, reset, and normal output.

'Extras' 'View'

Using this command for a POU created in the FBD-Editor you can choose, whether it should be displayed in the LD- (ladder logic) or in the FBD-Editor (Function Block Diagram). This is possible in offline as well as in online mode.

Open instance

This command corresponds to the 'Project' 'View instance' Command ↬ *Chapter 1.4.1.2.4.15 “'Project' 'View instance'” on page 263*.

It is available in the context menu (<F2>) or in the 'Extras' menu, if the cursor is positioned on the name of a function block in a text editor or if the function block box is selected in a graphic editor.

Cutting, copying, pasting, and deleting in FBD

The commands used to 'Cut', 'Copy', 'Paste', and 'Delete' are found under the 'Edit' menu item.

If a line cross is selected (Cursor Position 5), then the assignments, jumps, or RETURNS located below the crossed line will be cut, deleted, or copied ↬ *Chapter 1.4.1.3.11.7.2 “Cursor positions in FBD” on page 317*.

If a POU is selected (Cursor Position 3), then the selected object itself, will be cut, deleted, or copied, along with all of the branches dependent on the inputs, with the exception of the first (highest position) branch. Otherwise, the entire branch located in front of the cursor position will be cut, deleted, or copied.

After copying or cutting, the deleted or copied part is located on the clipboard and can now be pasted, as desired.

In order to do so, you must first select the pasting point. Valid pasting points include inputs and outputs.

If a POU has been loaded onto the clipboard (As a reminder: in this case all connected branches except the first are located together on the clipboard), the first input is connected with the branch before the pasting point.

Otherwise, the entire branch located in front of the pasting point will be replaced by the contents of the clipboard.

In each case, the last element pasted is connected to the branch located in front of the pasting point.

The following problem is solved by cutting and pasting: A new operator is inserted in the middle of a network. The branch located on the right of the operator is now connected with the first input, but should be connected with the second input. You can now select the first input and perform the command "'Edit' 'Cut'". Following this, you can select the second input and perform the command "'Edit' 'Paste'". This way, the branch is dependent on the second input.

The Function Block Diagram in the online mode

In the Function Block Diagram, breakpoints can only be set to networks. If a breakpoint has been set to a network, then the network numbers field will be displayed in blue. The processing then stops in front of the network where the breakpoint is located. In this case, the network numbers field will become red. Using stepping (single step), you can jump from network to network ↳ *Chapter 1.4.1.4 "The 'Resources' tab" on page 357*.

The current value is displayed for each variable. Exception: If the input to a function block is an expression, only the first variable in the expression is monitored.

Doubleclicking on a variable opens the dialog box for writing a variable. Here it is possible to change the present value of the variable. In the case of Boolean variables, no dialog box appears; these variables are toggled.

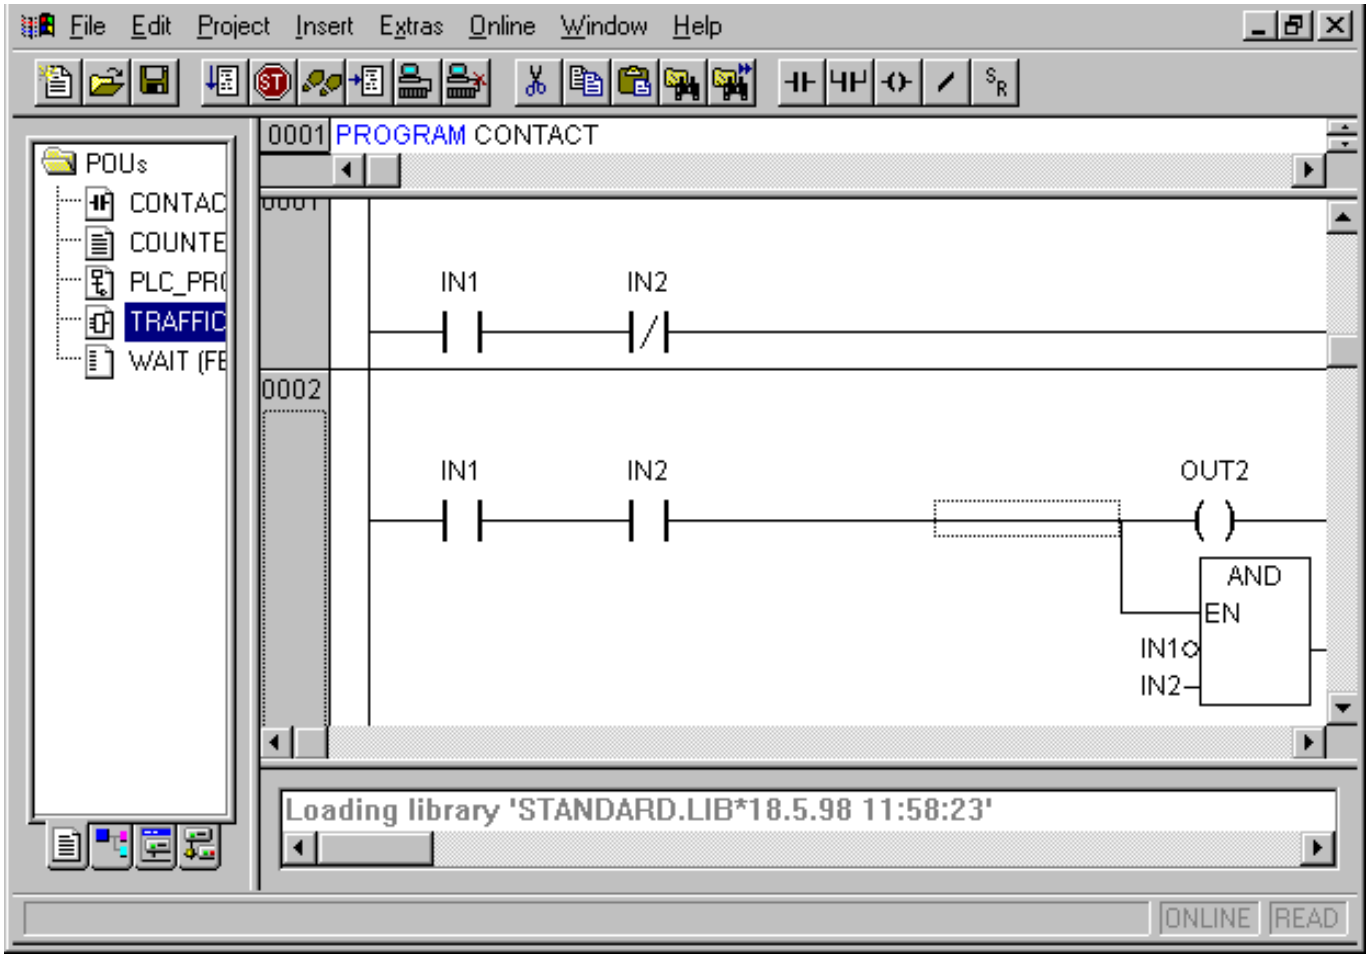
The new value will turn red and will remain unchanged. If the 'Online' 'Write values' command is given, then all variables are placed in the selected list and are once again displayed in black ↳ *Chapter 1.4.1.2.6.16 "'Online' 'Write values'" on page 286*.

The flow control is started with the 'Online' 'Flow control' command Using the flow control, you can view the present values that are being carried in the networks over the connecting lines ↳ *Chapter 1.4.1.2.6.21 "'Online' 'Display flow control'" on page 290*. If the connecting lines do not carry Boolean values, then the value will be displayed in a specially inserted field. If the lines carry Boolean values, then they will be shaded blue in the event that they carry TRUE. By this means, you can accompany the flow of information while the PLC is running.

If you place the mouse pointer briefly above a variable, then the type, the address and the comment about the variable will be displayed in a Tooltip.

The ladder editor

Overview



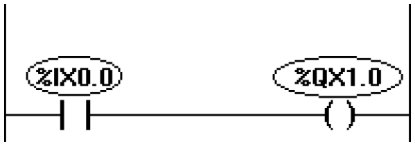
All editors for POUs consist of a declaration part and a body. These are separated by a screen divider.

The LD editor is a graphic editor. The most important commands are found in the context menu (right mouse button or <Ctrl>+<F10>).

Cursor positions in the LD editors

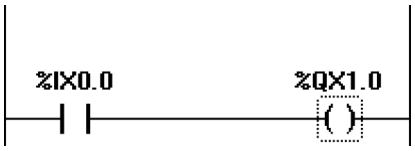
The following locations can be cursor positions, in which the function block and program accessing can be handled as contacts. POUs with EN inputs and other POUs connected to them are treated the same way as in the Function Block Diagram.

1. Every text field (possible cursor positions framed in black):

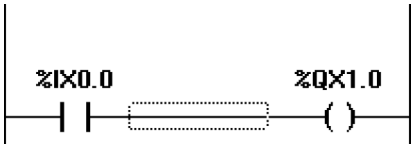


2. Every contact *Chapter 1.4.1.1.10.7.2 “Contact” on page 177* or function block:

3. Every Coil:



4. The Connecting Line between the Contacts and the Coils:



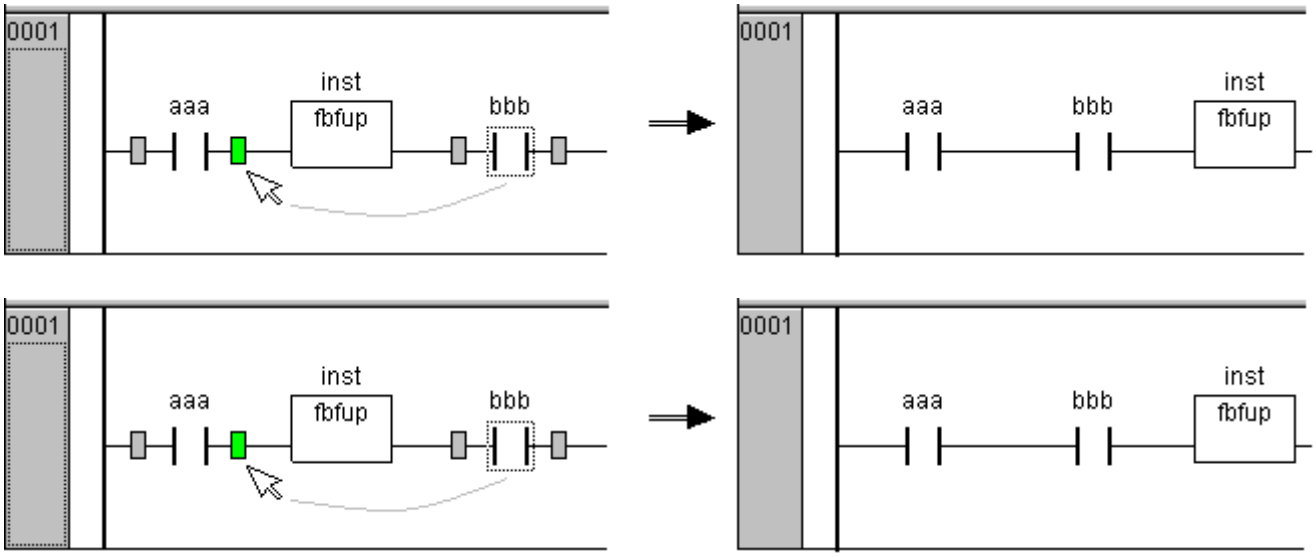
The Ladder Diagram uses the following menu commands in a special way.

Move elements or names in the LD-editor

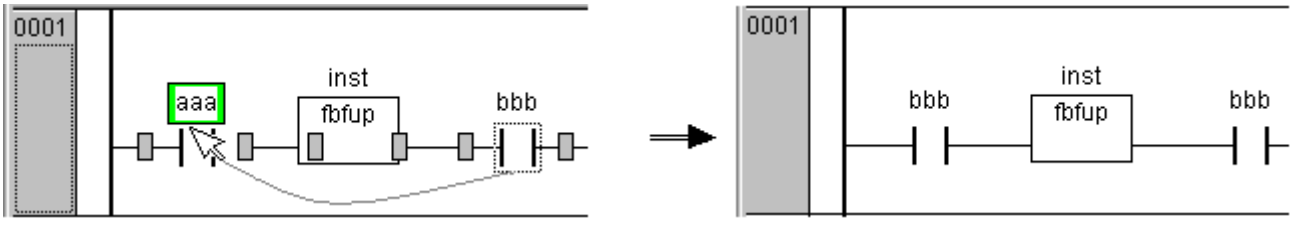
An element or just the name (variable name, address, comment) of an element can be moved to a different position within a LD POU by "drag&drop".

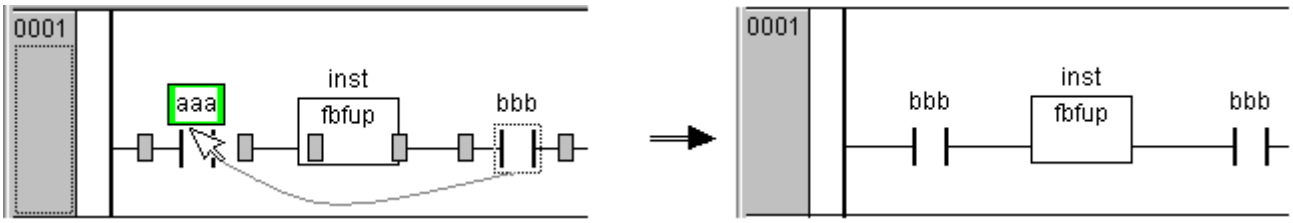
In order to do this select the desired element (contact, coil, function block) and drag it - keeping the mouse key pressed - away from the current position. Thereupon all possible positions within all networks of the POU, to which the element might be moved, will be indicated by grey-filled rectangles.

Move the element to one of these positions and let off the mouse key: the element will be inserted at the new position.



If you however move the element to the name (variable name) of another element, the name field will be shaded green. If you then let off the mouse key, the previous name will be replaced by the "dragged" one. If additionally address and comment are displayed (options), the copying also will apply to those.





'Insert' 'Network (before)' in LD

Symbol:

This command inserts a network in the Ladder editor. If there are already networks, the new one will be inserted before the currently focused.

'Insert' 'Network (after)' in LD

Symbol:

This command inserts a network in the Ladder editor. If there are already networks, the new one will be inserted after the currently focused.

'Insert' 'Contact' in LD

Symbol: Shortcut: <Ctrl>+<K>

Use this command in the LD editor in order to insert a contact in front of the marked location in the network ↳ *Chapter 1.4.1.1.10.7.2 “Contact” on page 177*.

If the marked position is a coil or the connecting line between the contacts and the coils, then the new contact will be connected serially to the previous contact connection ↳ *Chapter 1.4.1.3.11.8.2 “Cursor positions in the LD editors” on page 323* ↳ *Chapter 1.4.1.1.10.7.3 “Coil” on page 177*.

The contact is preset with the text "???". You can click on this text and change it to the desired variable or the desired constant. For this you can also use the input assistant ↳ *Chapter 1.4.1.2.5.11 “'Edit' 'Input assistant'” on page 276*. Note the possibility of entering an address instead of the variable name, if this is configured appropriately in the Function Block and Ladder Diagram Options.

Also in the options dialog you can activate the options Comments per Contact and Lines for variable comment and reserve a certain number of lines for the variable name. This might be useful, if long variable names are used, to keep the network short.

Also note the option 'Networks with linebreaks', which you also can activate in the Ladder Diagram Options.

'Insert' 'Contact (negated)' in LD

Symbol: Shortcut: <Ctrl> + <G>

This command inserts a negated contact ↳ *Chapter 1.4.1.1.10.7.2 “Contact” on page 177*. The same is true as for the commands 'Insert' 'Contact' in LD and 'Extras' 'Negate' in LD, which in combination also could be used to insert a negated contact ↳ *Chapter 1.4.1.3.11.8.6 “'Insert' 'Contact' in LD” on page 325* ↳ *Chapter 1.4.1.3.11.8.25 “'Extras' 'Negate' in LD” on page 329*.

'Insert' 'Parallel contact' in LD

Symbol: Shortcut: <Ctrl>+<R>

Use this command in the LD editor to insert a contact parallel to the marked position in the network ↳ *Chapter 1.4.1.1.10.7.2 “Contact” on page 177*.

If the marked position is a coil or the connection between the contacts and the coils, then the new contact will be connected in parallel to the entire previous contact connection ↳ *Chapter 1.4.1.3.11.8.2 “Cursor positions in the LD editors” on page 323* ↳ *Chapter 1.4.1.1.10.7.3 “Coil” on page 177*.

The contact is preset with the text "???". You can click on this text and change it to the desired variable or the desired constant. For this you can also use the input assistant ↳ *Chapter 1.4.1.2.5.11 “'Edit' 'Input assistant'” on page 276*.

For the possibility of entering addresses, of linebreaks for variable names and of comments per contact or coil please see the description of the Ladder Options dialog.

'Insert' 'Parallel contact (negated)' in LD

Symbol: Shortcut: <Ctrl> + <D>

This command inserts a negated parallel contact ↳ *Chapter 1.4.1.1.10.7.2 “Contact” on page 177*. The same is true as for the commands 'Insert' 'Parallel contact' in LD and 'Extras' 'Negate' in LD, which in combination also could be used to insert a negated parallel contact ↳ *Chapter 1.4.1.3.11.8.8 “'Insert' 'Parallel contact' in LD” on page 325* ↳ *Chapter 1.4.1.3.11.8.25 “'Extras' 'Negate' in LD” on page 329*.

'Insert' 'Coil' in LD

Symbol: Shortcut: <Ctrl>+<L>

You can use this command in the LD editor to insert a coil in parallel to the previous coils ↳ *Chapter 1.4.1.1.10.7.3 “Coil” on page 177*.

If the marked position is a connection between the contacts and the coils, then the new coil will be inserted as the last ↳ *Chapter 1.4.1.3.11.8.2 “Cursor positions in the LD editors” on page 323* ↳ *Chapter 1.4.1.3.11.8.6 “'Insert' 'Contact' in LD” on page 325*. If the marked position is a coil, then the new coil will be inserted directly above it.

The coil is given the text "???" as a default setting. You can click on this text and change it to the desired variable. For this you can also use the input assistant ↳ *Chapter 1.4.1.2.5.11 “'Edit' 'Input assistant'” on page 276*.

For the possibility of entering addresses, of linebreaks for variable names and of comments per coil please see the description of the Ladder Options dialog.

'Insert' 'Set' coil' in LD

Symbol: Shortcut: <Ctrl> + <I>

This command inserts a set coil ↳ *Chapter 1.4.1.1.10.7.5 “Set/Reset coils” on page 178*. The same is true as for the commands 'Insert' 'Coil' in LD and 'Extras' 'Set/Reset' in LD, which in combination also could be used to get a set coil ↳ *Chapter 1.4.1.3.11.8.10 “'Insert' 'Coil' in LD” on page 326* ↳ *Chapter 1.4.1.3.11.8.26 “'Extras' 'Set/Reset' in LD” on page 329*.

'Insert' 'Reset' coil' in LD

Symbol:

This command inserts a reset coil ↳ *Chapter 1.4.1.1.10.7.5 “Set/Reset coils” on page 178*. The same is true as for the commands 'Insert' 'Coil' in LD and 'Extras' 'Set/Reset', which in combination also could be used to get a reset coil ↳ *Chapter 1.4.1.3.11.8.10 “'Insert' 'Coil' in LD” on page 326* ↳ *Chapter 1.4.1.3.11.7.11 “'Extras' 'Set/Reset'” on page 320*.

'Insert' 'Function Block' in LD

Symbol: Shortcut: <Ctrl>+<B>

Use this command in order to insert an operator, a function block, a function or a program as a POU. For this, the connection between the contacts and the coils, or a coil, must be marked. The new POU at first has the designation AND. If you wish, you can change this designation to another one. For this you can also use the input assistant *Chapter 1.4.1.2.5.11 “'Edit' 'Input assistant'” on page 276*. Both standard and self-defined POUs are available.

The first input to the POU is placed on the input connection, the first output on the output connection; thus these variables must definitely be of type BOOL. All other in- and outputs of the POU are filled with the text "???". These prior entries can be changed into other constants, variables or addresses. For this you can also use the input assistant *Chapter 1.4.1.2.5.11 “'Edit' 'Input assistant'” on page 276*.

For the possibility of entering addresses, of linebreaks for variable names and of comments per contact, coil or function block please see the description of the Ladder Options dialog *Chapter 1.4.1.3.11.5 “Comments, networks with linebreaks, 'Extras' 'Options'” on page 314*.

POUs with EN inputs

If you want to use your LD network as a PLC for calling up other POUs , then you must merge a POU with an EN input. Such a POU is connected in parallel to the coils. Beyond such a POU you can develop the network further, as in the Function Block Diagram. You can find the commands for insertion at an EN POU under the menu item 'Insert' 'Insert at Blocks'.

An operator, a function block, a program or a function with EN input performs the same way as the corresponding POU in the Function Block Diagram, except that its execution is controlled on the EN input. This input is annexed at the connecting line between coils and contacts. If this connection carries the information "On", then the POU will be evaluated.

If a POU has been created once already with EN input, then this POU can be used to create a network. This means that data from usual operators, functions, and function blocks can flow in an EN POU and an EN POU can carry data to such usual POUs.

If, therefore, you want to program a network in the LD editor, as in FBD, you only need first to insert an EN operator in a new network. Subsequently, from this POU, you can continue to construct from your network, as in the FBD editor. A network thus formed will perform like the corresponding network in FBD.

'Insert' 'Box with EN in LD'

Symbol:

Use this command to insert a function block, an operator, a function or a program with EN input into a LD network.

The marked position must be the connection between the contacts and the coils (Cursor Position 4) or a coil (Cursor Position 3). The new POU is inserted in parallel to the coils and underneath them; it contains initially the designation "AND". If you wish, you can change this designation to another one. For this you can also use the input assistant *Chapter 1.4.1.2.5.11 “'Edit' 'Input assistant'” on page 276*.

'Insert' 'Insert at blocks in LD

With this command you can insert additional elements into a POU that has already been inserted (also a POU with EN input). The commands below this menu item can be executed at the same cursor positions as the corresponding commands in the Function Block Diagram.

With 'Input' you can add a new input to the POU.

With 'Output' you can add a new output to the POU.

With 'POU', you insert a new POU. The procedure is similar to that described under 'Insert' 'POU'.

With 'Assign' you can insert an assignment to a variable. At first, this is shown by three question marks "???", which you edit and replace with the desired variable. Input assistance is available for this purpose.

'Insert' 'Rising edge detection' in LD

Symbol: 

This commands inserts a R_TRIG function block, which serves to detect a rising edge (FALSE -> TRUE) at the incoming signal. The same is true as for command 'Insert' 'Function Block' in LD which can be used to insert any available function block *Chapter 1.4.1.3.11.8.13 “'Insert' 'Function Block' in LD” on page 327*.

'Insert' 'Falling edge detection' in LD

Symbol: 

This commands inserts a F_TRIG function block, which serves to detect a rising edge (TRUE -> FALSE) at the incoming signal. The same is true as for command 'Insert' 'Function Block' in LD which can be used to insert any available function block *Chapter 1.4.1.3.11.8.13 “'Insert' 'Function Block' in LD” on page 327*.

'Insert' 'Timer (TON)' in LD

Symbol: 

This command inserts a timer Function Block of type TON. This serves to get a turn-on delay (delayed passing on of the incoming signal). For the inserting the same is true as for command 'Insert' 'Function Block' in LD, which also could be used to insert a TON module *Chapter 1.4.1.3.11.8.13 “'Insert' 'Function Block' in LD” on page 327*.

'Insert' 'Jump' in LD

With this command you can insert a parallel jump in the selected LD editor, in parallel, at the end of the previous coils *Chapter 1.4.1.1.10.7.3 “Coil” on page 177*. If the incoming line delivers the value "On", then the jump will be executed to the indicated label.

The marked position must be the connection between the contacts and the coils or a coil *Chapter 1.4.1.3.11.8.2 “Cursor positions in the LD editors” on page 323*.

The jump is present with the text "???". You can click on this text and make a change in the desired label.

'Insert' 'Return' in LD

In the LD editor, you can use this command to insert a Return instruction in parallel at the end of the previous coils. If the incoming line delivers the value "On," then the processing of the POU in this network is broken off.

The marked position must be the connection between the contacts and the coils or a coil *Chapter 1.4.1.3.11.8.2 “Cursor positions in the LD editors” on page 323*.

'Extras' 'Paste after' in LD

Use this command in the LD editor to paste the contents of the clipboard as serial contact below the marked position. This command is only possible if the contents of the clipboard and the marked position are networks comprised of contacts.

'Extras' 'Paste below'in LD

Use this command in the LD editor to insert the contents of the clipboard as parallel contact below the marked position. This command is only possible if the contents of the clipboard and the marked position are networks comprised of contacts.

'Extras' 'Paste above' in LD

Use this command in the LD editor to insert the contents of the clipboard as parallel contact above the marked position. This command is only possible if the contents of the clipboard and the marked position are networks comprised of contacts.

'Extras' 'Negate' in LD

Symbol: Shortcut: <Ctrl>+<N>

Use this command to negate a contact, a coil, a jump or return instruction, or an input or output of EN POUs at the present cursor position *Chapter 1.4.1.3.11.8.2 “Cursor positions in the LD editors” on page 323*.

Between the parentheses of the coil or between the straight lines of the contact, a slash will appear ((/) or |/|) *Chapter 1.4.1.1.10.7.3 “Coil” on page 177* *Chapter 1.4.1.1.10.7.2 “Contact” on page 177*. If there are jumps, returns, or inputs or outputs of EN POUs, a small circle will appear at the connection, just as in the FBD editor.

The coil now writes the negated value of the input connection in the respective Boolean variable. Right at this moment, a negated contact switches the status of the input to the output, if the respective Boolean variable carries the value FALSE.

If a jump or a return is marked, then the input of this jump or return will be negated.

A negation can be canceled through renewed negation.

'Extras' 'Set/Reset' in LD

Symbol:

If you execute this command on a coil, then you will receive a set coil *Chapter 1.4.1.1.10.7.3 “Coil” on page 177* *Chapter 1.4.1.1.10.7.5 “Set/Reset coils” on page 178*. Such a coil never overwrites the value TRUE in the respective Boolean variable. This means that once you have set the value of this variable to TRUE, it will always remain at TRUE. A Set Coil is designated with an "S" in the coil symbol.

If you execute this command once again, then you will be given a Reset coil. Such a coil never overwrites the value FALSE in the respective Boolean variable. This means that once you have set the value of this variable to FALSE, it will always remain at FALSE. A Reset Coil is designated with an "R" in the coil symbol.

If you execute this command repeatedly, the coil will alternate between set, reset and normal coil.

The Ladder Diagram in the online mode

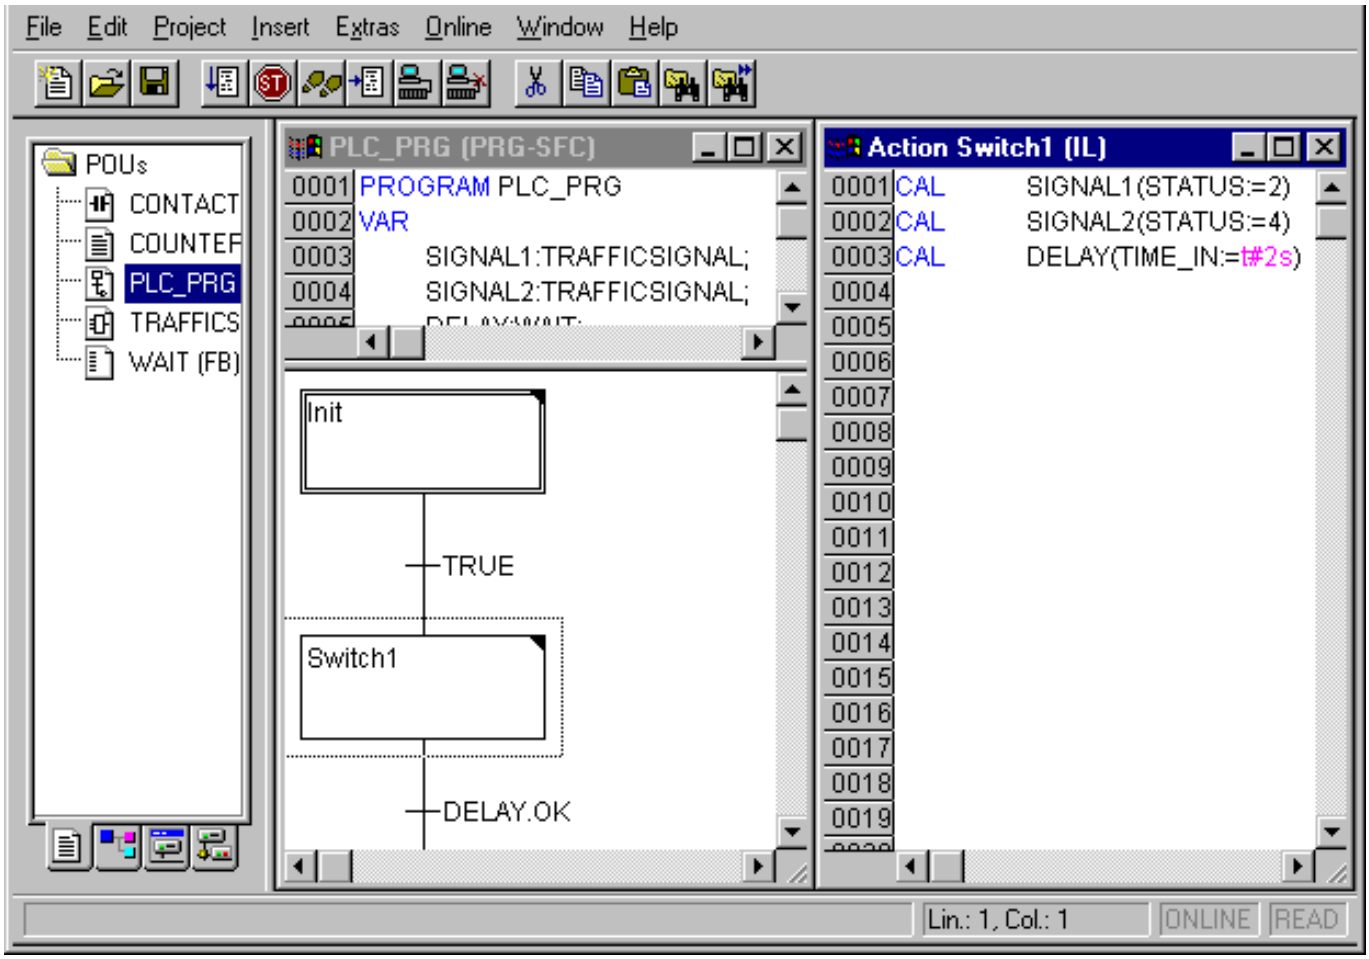
In Online mode, the contacts and coils in the Ladder Diagram that are in the "On" state are colored blue. Likewise, all lines over which the "On" is carried are also colored blue. At the inputs and outputs of function blocks, the values of the corresponding variables are indicated ↳ *Chapter 1.4.1.1.9.4 “Function block” on page 153*.

Breakpoints can only be set on networks; by using stepping, you can jump from network to network ↳ *Chapter 1.4.1.1.11.3 “Breakpoint” on page 182*.

If you place the mouse pointer briefly above a variable, then the type, the address and the comment about the variable will be displayed in a Tooltip.

The sequential function chart editor

Overview



All editors for POUs consist of a declaration part and a body. These are separated by a screen divider.

The Sequential Function Chart editor is a graphic editor. The most important commands are found in the context menu (right mouse button or <Ctrl><F10>). Tooltips show in Offline as well as in Online mode and in the zoomed state the full names or expressions of steps, transitions, jumps, jump labels, qualifiers or associated actions.

Marking blocks in the SFC

A marked block is a bunch of SFC elements that are enclosed in a dotted rectangle.

You can select an element (a step, a transition, or a jump) by pointing the mouse on this element and pressing the left mouse button, or you can use the arrow keys. In order to mark a group of several elements, press <Shift> for a block already marked, and select the element in the lower left or right corner of the group. The resulting selection is the smallest cohesive group of elements that includes both of these elements.

Please regard, that a step can only be deleted together with the preceding or the succeeding transition *Chapter 1.4.1.3.11.9.5 “Delete step and transition” on page 331*!

'Insert' 'Step Transition (before)'

Symbol: Shortcut: <Ctrl>+<T>

This command inserts a step in the SFC editor followed by a transition in front of the marked block.

You can select and replace the automatically specified step name "Step_<x>" by another string, also the transition name.

When renaming a step note that no comment may be added. Example: "Step_xy (counter *)" is not allowed!*

'Insert' 'Step Transition (after)'

Symbol: Shortcut: <Ctrl>+<E>

This command inserts a step in the SFC editor followed by a transition after the first transition in the marked block.

Concerning step name and transition name please see 'Insert' 'Step Transition (before)' *Chapter 1.4.1.3.11.9.3 “'Insert' 'Step Transition (before)'” on page 331*.

Delete step and transition

A step can only be deleted together with the preceding or the succeeding transition. For this purpose put a selection frame around step and transition and choose command 'Edit' 'Delete' or press the <Del> key.

'Insert' 'Alternative Branch (right)'

Symbol: Shortcut: <Ctrl>+<A>

This command inserts an alternative branch in the SFC editor as a right branch of the marked block. For this the marked block must both begin and end with a transition. The new branch is then made up of one transition.

'Insert' 'Alternative Branch (left)'

Symbol:

This command inserts an alternative branch in the SFC editor as the left branch of the marked block. For this the marked block must both begin and end with a transition. The new branch is then made up of one transition.

'Insert' "Parallel Branch (right)"

Symbol: Shortcut: <Ctrl>+<L>

This command inserts a parallel branch in the SFC editor as the right branch of the marked block. For this the marked block must both begin and end with a step. The new branch is then made up of one step. To allow jumps to the parallel branches that have been created, these must be provided with a jump label.

'Insert' 'Parallel Branch (left)'

Symbol: This command inserts a parallel branch in the SFC editor as the left branch of the marked block. For this the marked block must both begin and end with a step. The new branch is then made up of one step. To allow jumps to the parallel branches that have been created, these must be provided with a jump label *Chapter 1.4.1.3.11.9.15 “'Extras' 'Add label to parallel branch'” on page 333*.

'Insert' 'Jump'

'This command inserts a jump in the SFC editor at the end of the branch, to which the marked block belongs. For this the branch must be an alternative branch.

The inserted text string 'Step' in the inserted jump can then be selected and replaced by the step name or the jump label of a parallel branch to be jumped to.

Concerning the step name please see 'Insert' 'Step Transition (before)' *Chapter 1.4.1.3.11.9.3 “'Insert' 'Step Transition (before)'” on page 331*.

'Insert' 'Transition-Jump'

Symbol:

This command inserts a transition in the SFC editor, followed by a jump at the end of the selected branch. For this the branch must be a parallel branch.

The inserted text string 'Step' in the inserted jump can then be selected and replaced by the step name or the jump label of a parallel branch to be jumped to.

Concerning step name and transition name please see 'Insert' 'Step Transition (before)' *Chapter 1.4.1.3.11.9.3 “'Insert' 'Step Transition (before)'” on page 331*.

'Insert' 'Add Entry-Action'

With this command you can add an entry action to a step *Chapter 1.4.1.1.10.5.2 “Action” on page 171*. An entry-action is only executed once, right after the step has become active *Chapter 1.4.1.1.10.5.5 “Active step” on page 172*. The entry-action can be implemented in a language of your choice.

A step with an entry-action is designated by an "E" in the bottom left corner.

'Insert' 'Add Exit-Action'

With this command you can add an exit-action to a step *Chapter 1.4.1.1.10.5.3 “Entry or exit action” on page 172*. An exit-action is only executed once, before the step is deactivated. The exit-action can be implemented in a language of your choice.

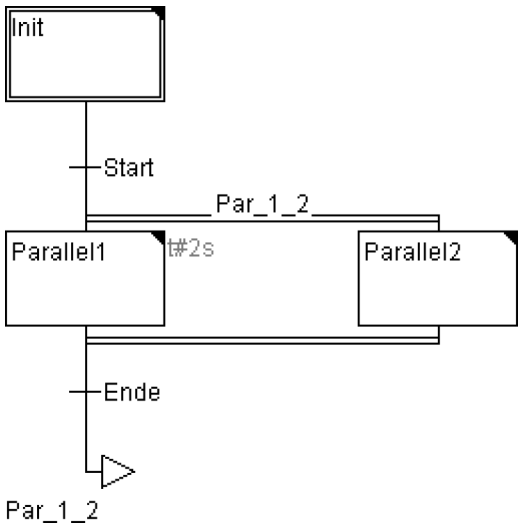
A step with an exit-action is designated by an "X" in the lower right corner.

'Extras' 'Paste Parallel Branch (right)'

This command pastes the contents of the clipboard as a right parallel branchof the marked block ↳ *Chapter 1.4.1.1.10.5.10 “Parallel branch” on page 176*. For this the marked block must both begin and end with a step. The contents of the clipboard must, likewise, be an SFC block that both begins and ends with a step.

'Extras' 'Add label to parallel branch'

In order to provide a newly inserted parallel branch with a jump label, the transition occurring before the parallel branching must be marked and the command 'Add label to parallel branch' must be executed. At that point, the parallel branch will be given a standard name consisting of "Parallel" and an appended serial number, which can be edited according to the rules for identifier names. In the following example, "Parallel" was replaced by "Par_1_2" and the jump to the transition "End" was steered to this jump label.



Delete a label

A jump label can be deleted by deleting the label name.

'Extras' 'Paste after'

This command pastes the SFC block on the clipboard after the first step or the first transition of the marked block. (Normal copying pastes it in front of the marked block.) This will now be executed, if the resulting SFC structure is correct, according to the language norms.

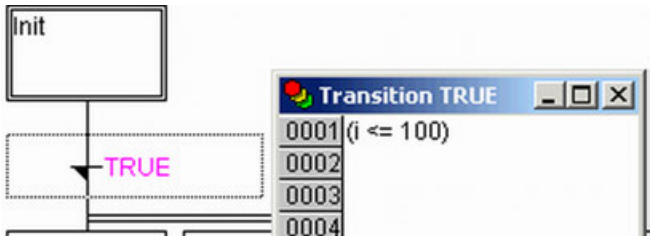
'Extras' 'Zoom Action/Transition'

Shortcut: <Alt>+<Enter>

The action of the first step of the marked block or the transition body of the first transition of the market block is loaded into the editor in the respective language, in which it has been written ↳ *Chapter 1.4.1.1.10.5.2 “Action” on page 171*. If the action or the transition body is empty, then the language must be selected, in which it has been written.

Note that the transition condition which is written within the editor window will take precedence over a condition which might be written directly at the transition mark.

Example: If here i>100, then the transition condition will be FALSE, although TRUE has been entered at the mark!



'Extras' 'Clear Action/Transition'

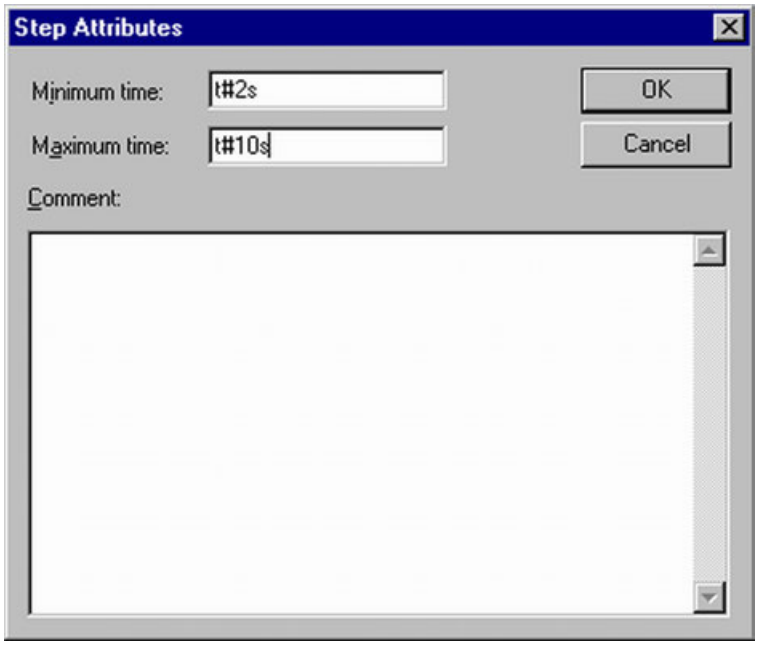
With this command you can delete the actions of the first step of the marked block or of the transitions body of the first transition ↳ *Chapter 1.4.1.1.10.5.2 “Action” on page 171*.

If, during a step, you implement either only the action, the entry-action, or the exit-action, then the same will be deleted by the command. Otherwise a dialog box appears, and you can select which action or actions are to be deleted.

If the cursor is located in the action of an IEC step, then only this association will be deleted ↳ *Chapter 1.4.1.1.10.5.6 “IEC step” on page 172*. If an IEC step with an associated action is selected, then this association will be deleted ↳ *Chapter 1.4.1.1.10.5.2 “Action” on page 171*. During an IEC step with several actions, a selection dialog box will appear.

'Extras' 'Step Attributes'

With this command you can open a dialog box in which you can edit the attributes for the marked step.



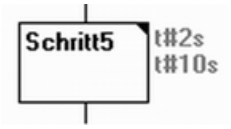
You can take advantage of three different entries in the step attribute dialog box. Under 'Minimum Time', you enter the minimum length of time that the processing of this step should take. Under the 'Maximum Time', you enter the maximum length of time that the processing of this step should take. Note that the entries are of the TIME type, so you use a TIME constant (i.e. T#3s) or a variable of the TIME type.

The time settings are also accessible in dialog 'Extras' 'Time Overview' ↳ *Chapter 1.4.1.3.11.9.21 “'Extras' 'Time Overview'” on page 335*.

Under 'Comment' you can insert a comment to the step. In the 'Sequential function chart options' dialog which you open under 'Extras' 'Options', you can then define whether comments, the time setting or nothing is displayed for the steps in the SFC editor. On the right, next to the step, either the comment or the time setting or none of both will appear.

Those attributes which are not displayed because of the options settings, can - additionally to the step name - be displayed in a tooltip, which appears when the cursor is placed on the upper resp. lower right corner of the step box *Chapter 1.4.1.3.11.9.22 “'Extras' 'Options'” on page 336*.

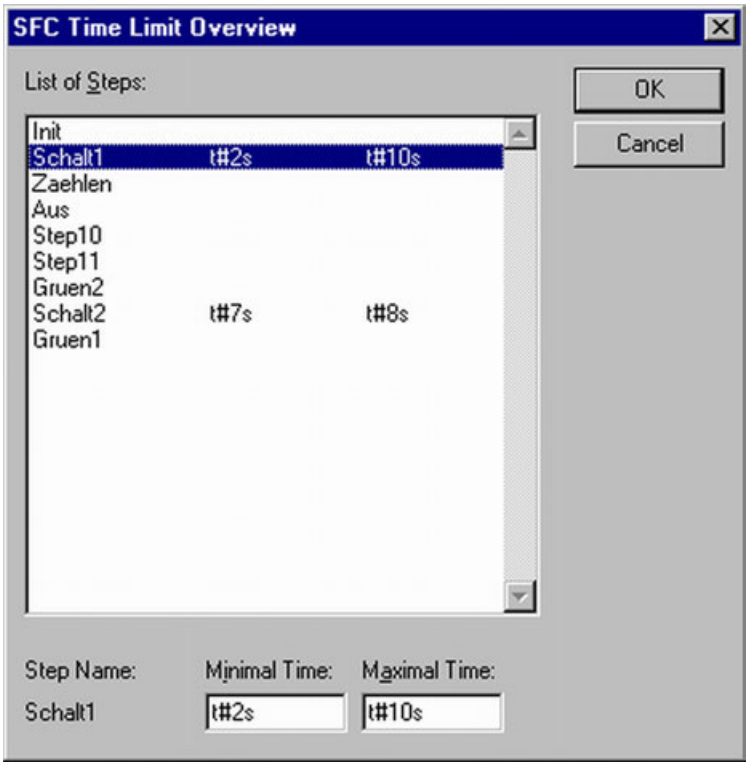
If the maximum time is exceeded, SFC flags are set which the user can query *Chapter 1.4.1.1.10.5.8 “SFC flags” on page 174*.



The example shows a step whose execution should last at least two, and at the most, ten seconds. In Online mode, there is, in addition to these two times, a display of how long the step has already been active.

'Extras' 'Time Overview'

With this command you can open a window in which you can edit the time settings of your SFC steps:



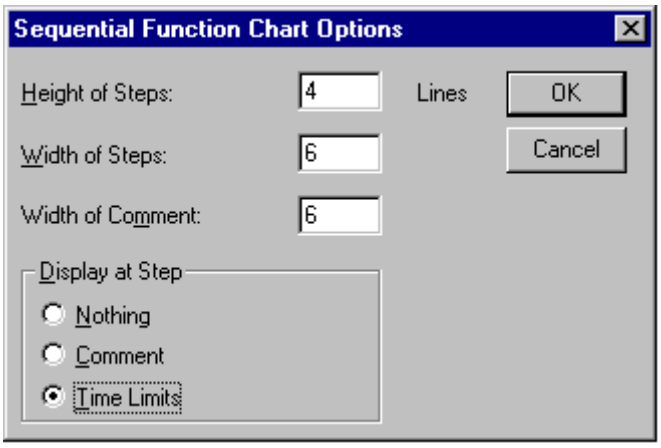
In the time boundaries overview, all steps of your SFC POU are displayed. If you have entered a time boundary for a step, then the time boundary is displayed to the right of the step (first, the lower limit, then the upper limit) *Chapter 1.4.1.3.11.9.20 “'Extras' 'Step Attributes'” on page 334*. You can also edit the time boundaries. To do so, click on the desired step in the overview. The name of the step is then shown below in the window. Go to the 'Minimum Time' or 'Maximum Time' field, and enter the desired time boundary there. If you close the window with OK, then all of the changes will be stored.

In the example, steps 2 and 6 have a time boundary. Shift1 lasts at least two, and at most, ten seconds. Shift2 lasts at least seven, and at most, eight seconds.

'Extras' 'Options'

With this command you open a dialog box in which you can set different options for your SFC POU.

Dialog Box for Sequential Function Chart Options:



Under 'Step Height', you can enter how many lines high an SFC step can be in your SFC editor. 4 is the standard setting here. Under 'Step Width', you can enter how many columns wide a step should be. 6 is the standard setting here.

You can also preset the 'Display at Step', i.e. which of the attributes, defined 'Extras' 'Step Attributes' should be displayed next to the step ↳ *Chapter 1.4.1.3.11.9.20 “'Extras' 'Step Attributes'” on page 334*. Either choose Comment, Time Limits, or Nothing:

- If "Nothing" is set, the defined comment and the time limits nevertheless can be shown in a tooltip, which appears when the cursor is placed on the lower right corner of the step box.
- If "Comment" is set, the defined comment and the time limits can be shown in a tooltip, which appears when the cursor is placed on the upper right corner of the step box.
- If "Time Limits" is set, the defined comment and the time limits nevertheless can be shown in a tooltip, which appears when the cursor is placed on the lower right corner of the step box.

'Extras' 'Associate Action'

With this command actions and Boolean variables can be associated with IEC steps ↳ *Chapter 1.4.1.1.10.5.2 “Action” on page 171* ↳ *Chapter 1.4.1.1.10.5.6 “IEC step” on page 172*.

To the right of, and next to the IEC step, an additional divided box is attached, for the association of an action. It is preset in the left field with the qualifier "N" and the name "Action." Both presets can be changed. For this you can use the input assistant ↳ *Chapter 1.4.1.2.5.11 “'Edit' 'Input assistant'” on page 276*.

Maximum nine actions can be assigned to an IEC step.

New actions for IEC steps are created in the Object Organizer for an SFC POU with the 'Project' 'Add Action' command.

'Extras' 'Use IEC-Steps'

Symbol:

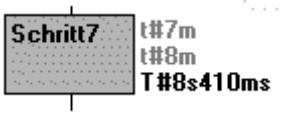
If this command is activated (denoted by a check in front of the menu item and a printed symbol in the Tool bar), then IEC steps will be inserted instead of the simplified steps upon insertion of step transitions and parallel branches ↳ *Chapter 1.4.1.1.10.5.6 “IEC step” on page 172* ↳ *Chapter 1.4.1.1.10.5.4 “Transition / Transition condition” on page 172* ↳ *Chapter 1.4.1.1.10.5.10 “Parallel branch” on page 176*.

If this option is switched on, the Init step is set as an IEC step when you create a new SFC POU.

These settings are saved in the file "codesys.ini" and are restored when CODESYS gets started again.

Sequential function chart in online mode

With the Sequential Function Chart editor in Online mode, the currently active steps will be displayed in blue. If you have set it under 'Extras' 'Options', then the time management is depicted next to the steps ↳ *Chapter 1.4.1.3.11.9.22 “'Extras' 'Options'” on page 336*. Under the lower and upper bounds that you have set, a third time indicator will appear from which you can read how long the step has already been active.



In the figure above the step depicted has already been active 8 seconds and 410 milliseconds. The step must, however, be active for at least 7 minutes before the step will be left.

With 'Online' 'Toggle Breakpoint' a breakpoint can be set on a step, or in an action at the locations allowed by the language in use. Processing then stops prior to execution of this step or before the location of the action in the program. Steps or program locations where a breakpoint is set are marked in light blue.

If several steps are active in a parallel branch, then the active step whose action will be processed next is displayed in red.

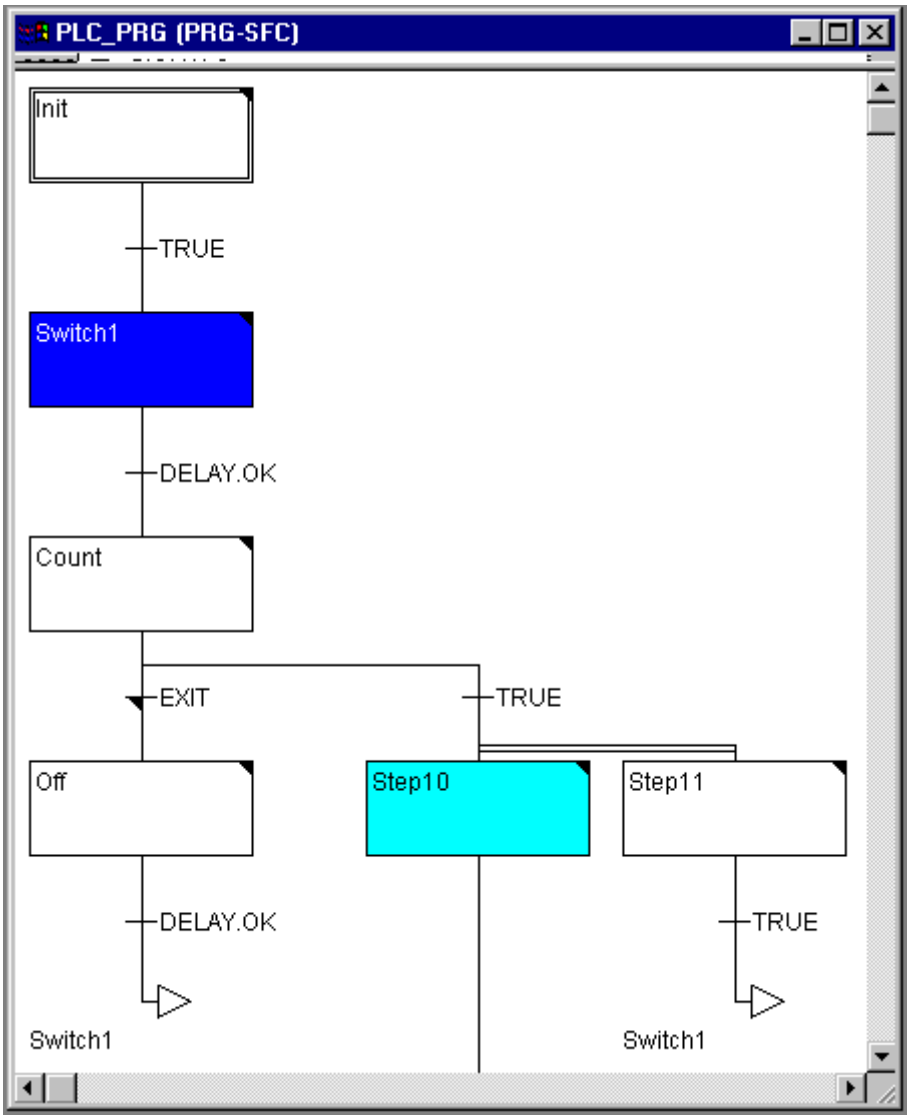
If IEC step has been used, then all active actions in Online mode will be displayed in blue ↳ *Chapter 1.4.1.1.10.5.6 “IEC step” on page 172*.

With the command 'Online' 'Step over' it is stepped always to the next step which action is executed. If the current location is:

- a step in the linear processing of a POU or a step in the rightmost parallel branch of a POU, execution returns from the SFC POU to the caller. If the POU is the main program, the next cycle begins.
- a step in a parallel branch other than the rightmost, execution jumps to the active step in the next parallel branch.
- the last breakpoint location within an action, execution jumps to the caller of the SFC.
- the last breakpoint location within an IEC action, execution jumps to the caller of the SFC.
- the last breakpoint position within an input action or output action, execution jumps to the next active step.

With 'Online' 'Step in' even actions can be stepped into. If an input, output or IEC action is to be jumped into, a breakpoint must be set there. Within the actions, all the debugging functionality of the corresponding editor is available to the user.

If you rest the mouse cursor for a short time on a variable in the declaration editor, the type, the address and the comment of the variable will be displayed in a tooltip.



If you rename a step and perform an Online Change while this step is active, the program will be stopped in undefined status !

Processing order of elements in a sequence:

- First, all Action Control Block flags in the IEC actions that are used in this sequence are reset (not, however, the flags of IEC actions that are called within actions).
- All steps are tested in the order which they assume in the sequence (top to bottom and left to right) to determine whether the requirement for execution of the output action is provided, and this is executed if that is the case.
- All steps are tested in the order which they assume in the sequence to determine whether the requirement for the input action is provided, and this is executed if that is the case.
- For all steps , the following is done in the order which they assume in the sequence:
  - If applicable, the elapsed time is copied into the corresponding step variable.
  - If applicable, any timeout is tested and the SFC error flags are serviced as required.
  - For non-IEC steps, the corresponding action is now executed.

- IEC actions that are used in the sequence are executed in alphabetical order. This is done in two passes through the list of actions. In the first pass, all the IEC actions that are deactivated in the current cycle are executed. In the second pass, all the IEC actions that are active in the current cycle are executed.
- Transitions are evaluated: If the step in the current cycle was active and the following transition returns TRUE (and if applicable the minimum active time has already elapsed), then the following step is activated.

The following must be noted concerning implementation of actions:

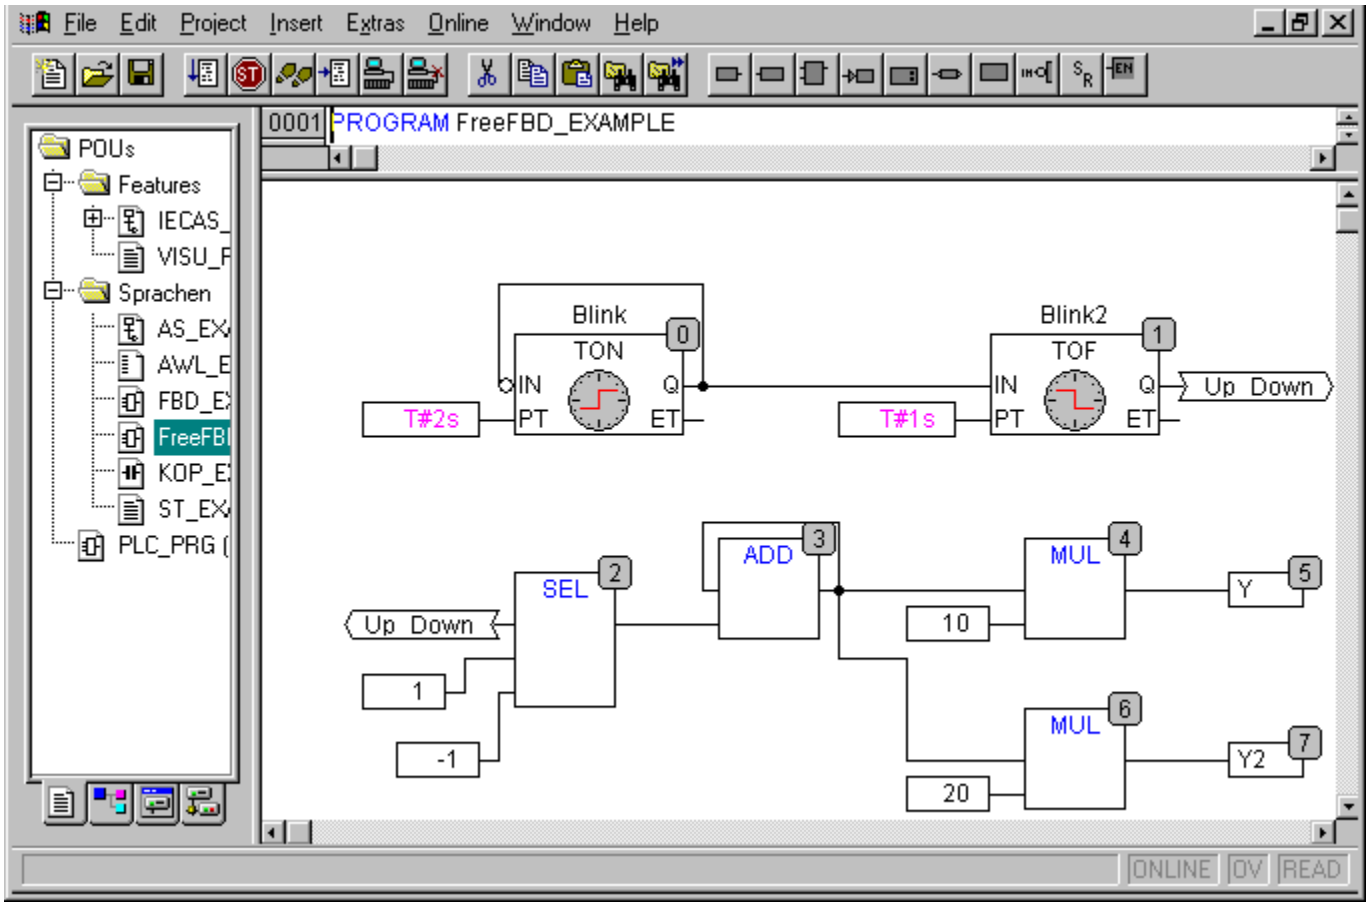
It can come about that an action is carried out several times in one cycle because it is associated with multiple sequences. (For example, an SFC could have two IEC actions A and B, which are both implemented in SFC, and which both call IEC action C; then in IEC actions A and B can both be active in the same cycle and furthermore in both actions IEC action C can be active; then C would be called twice).

If the same IEC action is used simultaneously in different levels of an SFC, this could lead to undesired effects due to the processing sequence described above. For this reason, an error message is issued in this case. It can possibly arise during processing of projects created with older versions of CODESYS.

> *In monitoring expressions (e.g. A AND B) in transitions, only the "Total value" of the transition is displayed.*

The continuous function chart editor (CFC)

Overview



No snap grid is used for the continuous function chart editor so the elements can be placed anywhere. Elements of the sequential processing list include boxes, input, output, jump, label, return and comments. The inputs and outputs of these elements can be connected by dragging a connection with the mouse. The connecting line will be drawn automatically. The shortest possible connection line is drawn taking into account existing connections. The connecting lines are automatically adjusted when the elements are moved. If the case arises where a connecting line cannot be drawn simply because of lack of space, a red line will be shown between the input and the associated output instead. This line will be converted into a connecting line just as soon as space is available.

One advantage of the continuous function chart as opposed to the usual Function Block Diagram Editor is the fact that feedback paths can be inserted directly.

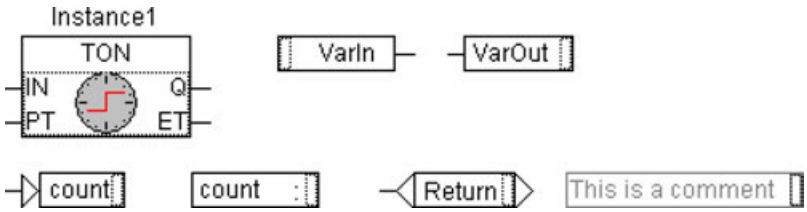
The most important commands can be found in the context menu.

Cursor positions in the CFC

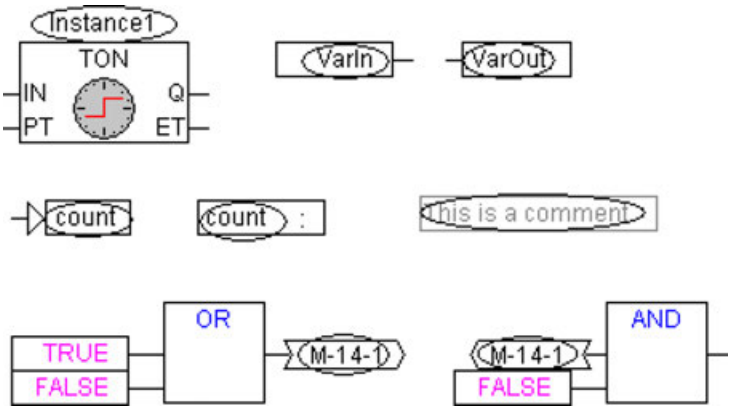
Each text is a possible cursor position. The selected text is shaded in blue and can be modified.

In all other cases the current cursor position is shown by a rectangle made up of points. The following is a list of all possible cursor positions with examples:

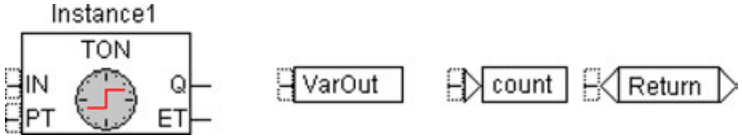
1. Trunks of the elements box, input, output, jump, label, return and comments:



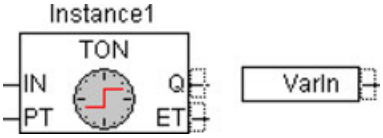
2. Text fields for the elements box, input, output, jump, label, return and comments as well as text fields for connection marker:



3. Inputs for the elements box, input, output, jump and return:



4. Outputs for the elements box and input:



'Insert' 'Box' in the CFC

Symbol: Shortcut: <Ctrl>+<B>

This command can be used to paste in operators, functions, function blocks and programs. First of all, it is always inserted an "AND" operator. This can be converted by Selection and Overwrite of the text into every other operator, into every function, into every function block and every program. The input assistance serves to select the desired block from the list of supported blocks. If the new block has another minimum number of inputs, these will be attached. If the new block has a smaller highest number of inputs, the last inputs will be deleted.

'Insert' 'Input' in CFC

Symbol: Shortcut: <Ctrl>+<E>

This command is used to insert an input. The text offered "???" can be selected and replaced by a variable or constant. The input assistance can also be used here.

'Insert' 'Output' in CFC

Symbol: Shortcut: <Ctrl>+<A>

This command is used to insert an output. The text offered "???" can be selected and replaced by a variable. The input assistance can also be used here. The value which is associated with the input of the output is allocated to this variable.

'Insert' 'Jump' in CFC

Symbol: Shortcut: <Ctrl>+<J>

This command is used to insert a jump. The text offered "???" can be selected and replaced by the jump label to which the program should jump.

The jump label is inserted using the command 'Insert 'Label'.

'Insert' 'Label' in CFC

Symbol: Shortcut: <Ctrl>+<L> This command is used to insert a label. The text offered "???" can be selected and replaced by the jump label. In Online mode a RETURN label for marking the end of POU is automatically inserted.

The jump is inserted using the command 'Insert 'Jump'.

'Insert' 'Return' in CFC

Symbol: Shortcut: <Ctrl>+<R>

This command is used to insert a RETURN command. Note that in Online mode a jump label with the name RETURN is automatically inserted in the first column and after the last element in the editor; in stepping, it is automatically jumped to before execution leaves the POU.

'Insert' 'Comment' in CFC

Symbol: Shortcut: <Ctrl> + <K>

This command is used to insert a comment. You obtain a new line within the comment with <Ctrl> + <Enter>.

'Insert' 'Input of box' in CFC

Shortcut: <Ctrl>+<U>

This command is used to insert an input at a box. The number of inputs is variable for many operators (e.g. ADD can have two or more inputs).

To increase the number of inputs for such an operator by one, the box itself must be selected.

Insert' 'In-Pin' in CFC, 'Insert' 'Out-Pin'

Symbol: 

These commands are available as soon as a macro is opened for editing. They are used for inserting in- or out-pins as in- and outputs of the macro. They differ from the normal in- and outputs of POUs by the way they are displayed and in that they have no position index.

'Extras' 'Negate' in CFC

Symbol:  Shortcut: <Ctrl> + <N>

This command is used to negate inputs, outputs, jumps or RETURN commands. The symbol for the negation is a small cross on the connection.

The input of the element block, output, jump or return is negated when it is selected.

The output of the element block or input is negated when it is selected (Cursor position 4).

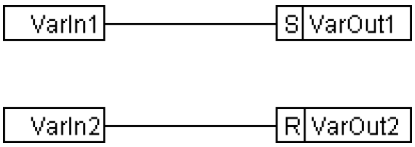
A negation can be deleted by negating again.

'Extras' 'Set/Reset' in CFC

Symbol:  Shortcut: <Ctrl> + <T>

This command can only be used for selected inputs of the element output .

The symbol for Set is S and for Reset is R.



VarOut1 is set to TRUE, if VarIn1 delivers TRUE. VarOut1 retains this value, even when VarIn1 springs back to FALSE.

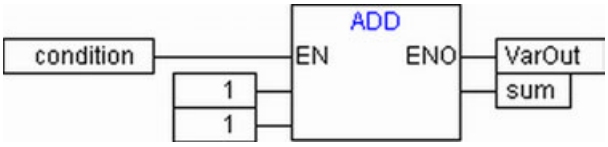
VarOut2 is set to FALSE, if VarIn2 delivers TRUE. VarOut2 retains this value, even when VarIn2 springs back to FALSE.

Multiple activation of this command causes the output to change between Set, Reset and the normal condition.

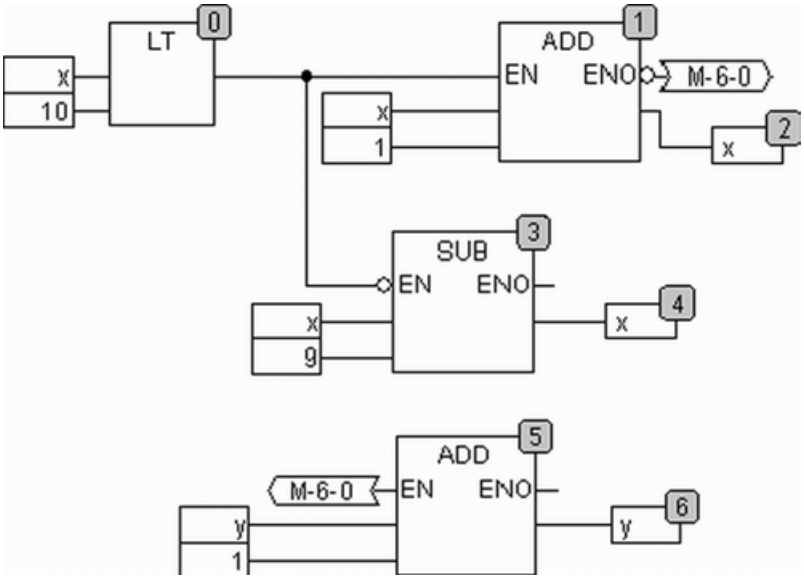
'Extras' 'EN/ENO' in CFC

Symbol:  Shortcut: <Ctrl> + <I>

This command is used to give a selected block (Cursor position 3) an additional Boolean enable input EN (Enable In) and a Boolean output ENO (Enable Out).



ADD is only executed in the example when the Boolean variable "condition" is TRUE. VarOut will also be set to TRUE after the execution of ADD. But if afterwords condition changes to FALSE, ADD will not be executed any more and thus VarOut remains TRUE! The example below shows how the value ENO can be used for further blocks:

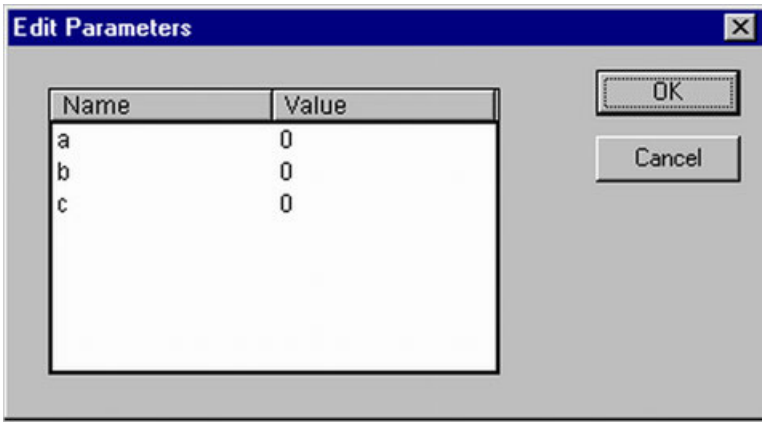


x should initialised to 1 and y initialised to 0. The numbers in the right corner of the block indicate the order in which the commands are executed.

x will be increased by one until it reaches the value 10. This causes the output of the block LT(0) to deliver the value FALSE and SUB(3) and ADD(5) will be executed. x is set back to the value 1 and y is increased by 1. LT(0) is executed again as long as x is smaller than 10. y thus count the number of times x passes though the range of values 1 to 10.

'Extras' 'Properties...' in CFC

Constant input parameters (VAR_INPUT CONSTANT) from functions ↳ *Chapter 1.4.1.2.3.34 “'Project' 'Project info'” on page 246* and function blocks ↳ *Chapter 1.4.1.1.9.4 “Function block” on page 153* are not shown directly in the continuous function chart editor. These can be shown and their value can be changed when one selects the trunk of the block in question and then selects the command 'Extras' 'Properties' or simply double clicks on the trunk. The 'Edit parameters' dialog opens:



The values of the constant input parameter (VAR_INPUT CONSTANT) can be changed. Here it is necessary to mark the parameter value in the column Value. Another mouse click or pressing on the space bar allows this to be edited. Confirmation of the change to the value is made by pressing the <Enter> key or pressing <Escape> rejects the changes. The button 'OK' stores all of the changes which were made.

This functionality and the associated declaration of variables with keyword "VAR_INPUT CONSTANT" is only of impact for the CFC editor. In the FBD editor always all INPUT variables will be displayed at a box, no matter whether declared as VAR_INPUT or VAR_INPUT CONSTANT. Also for text editors this does not make any difference.

Moving/Copying elements in CFC

One or more selected elements can be moved with the arrow keys + <Shift> key. Another possibility is to move elements using a depressed left mousekey. These elements are placed by releasing the left mousekey in as far as they do not cover other elements or exceed the foreseen size of the editor. The marked element jumps back to its initial position in such cases and a warning tone sounds.

One or more selected elements can be copied with the command 'Edit' 'Copy' and inserted with the command 'Edit' 'Paste'.

Creating connections

An input of an element can be precisely connected to the output of another element. An output of an element can be connected to the inputs of a number of other elements.

There are a number of possibilities to connect the input of an element E2 with the output of an element E1.

Place the mouse on the output of element E1, click with the left mousekey, hold the left mousekey down and drag the mouse cursor onto the input of element E2 and let the left mousekey go. A connection is made from the output of element E1 to the mouse cursor during this dragging operation with the mouse.

Place the mouse on the input of element E2, click with the left mousekey, hold the left mousekey down and drag the mouse cursor onto the output of element E1 and let the left mousekey go.

Move one of the elements E1 or E2 and place it in such a way by letting go of the left mousekey that the output of element E2 and the input of element E1 touch.

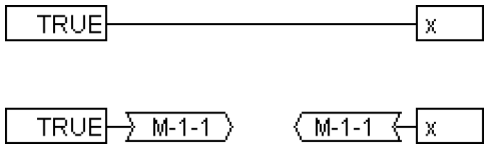
Where element E2 is a block with a free input, a connection can also be made by dragging the mouse from an output from E1 to the trunk of E2. A connection with the free input at the highest position on E2 will be created when the mousekey is released. In the case where block E2 does not have a free input but is an operator which can have an input added to it, a new input will be automatically generated.

The output and input of a block can be connected together (feedback path) by using this method. To establish a connection between two pins, click with the left mouse button on one pin, hold the button down and thus drag the connection to the desired pin, where you then release the button. If during the dragging of the connection extends outside working area of the editor, scrolling occurs automatically. For simple data types, type testing is carried out during the connection. If the types of the two pins are not compatible, the cursor changes to "Forbidden". For complex data types, no testing takes place.

'Extras' 'Connection marker'

Connections can also be represented by a connector (connection marker) instead of a connecting line. Here the output and the associated input have a connector added to them which is given a unique name.

Where a connection already exists between the two elements which should now be represented by connectors, the output of the connecting line is marked and the menu point 'Extras' 'Connection marker' is selected. The following diagram shows a connection before and after the selection of this menu point.



A unique name is given as standard by the program which begins with M, but which can be changed The connector name is stored as an output parameter, but can be edited both at the input and at the output.

It is important to know that the connector name is associated with a property of the output of a connection and is stored with it.

1. Edit the connector at the output: 
If the text in the connector is replaced, the new connector name is adopted by all associated connectors at the inputs. One cannot, however, select a name which already belongs to another connection marker since the uniqueness of the connector name would be violated.

2. Edit the connector at the input: 
If the text in a connector is replaced, it will also be replaced in the corresponding connection marker on the other POU. Connections in connector representations can be converted to normal connections in that one marks the output of the connections (Cursor position 4) and again selects the menu point 'Extras' 'Connection marker'.

Changing connections

A connection between the output of an element E1 and the input of an element E2 can easily be changed into a connection between the output of element E1 and the input of element E3. The mouse is clicked on the input of E2, the left mousekey is kept depressed, the mouse cursor is moved to the input of E3 and then released.

Deleting connections

There are a number of possibilities for removing the connection between the output of an element E1 and the input of an element E2:

- Select the output of element E1 and press the <Delete> key or execute the command 'Edit' 'Delete'. Several connections will be removed at the same if the output of E1 is connected to more than one of inputs.
- Select the input of element E2 and press the <Delete> key or execute the command 'Edit' 'Delete'.
- Select the input of E2 with the mouse, hold the left mousekey depressed and drag the connection from the input to E2 away. The connection is removed when the left mousekey is released in a free area of the screen.

Insert inputs/outputs on the fly

If exactly one input or output pin of an element is selected, then the corresponding input- or output- element can be directly inserted and its editor field filled with a string by entering the string at the keyboard.

Order of execution

The elements block, output, jump, return and label each possess a number indicating the order in which they are executed. In this sequential order the individual elements are evaluated at run time.

When pasting in an element the number is automatically given according to the topological sequence (from left to right and from above to below). The new element receives the number of its topological successor if the sequence has already been changed and all higher numbers are increased by one.

The number of an element remains constant when it is moved.

The sequence influences the result and must be changed in certain cases.

If the sequence is displayed, the corresponding sequential execution number is shown in the upper right hand corner of the element.

'Extras' 'Order' 'Show Order'

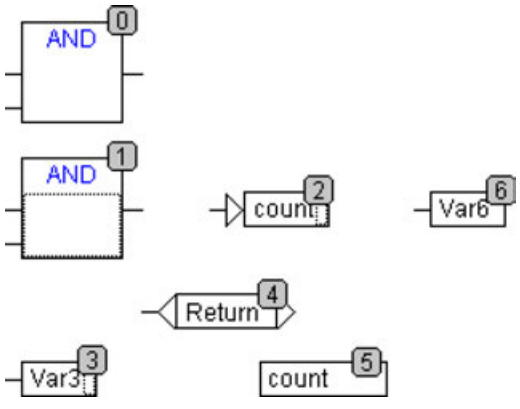
This command switches the display of the order of execution on and off. The default setting is to show it (recognised by a tick (✓) in front of the menu point).

The relevant order of execution number appears in the upper right hand corner for the elements block, output, jump, return and label.

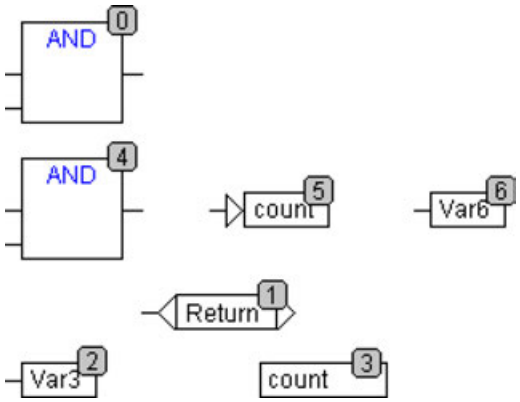
'Extras' 'Order' 'Order topologically'

Elements are ordered in a topological sequence when the execution takes place from left to right and from above to below, that is the number increases from left to right and from above to below for topologically arranged elements. The connections are not relevant, only the location of the elements is important.

All selected elements are topologically arranged when the command 'Extras' 'Order' 'Order topologically' is executed. All elements in the selection are taken out of the sequential processing list by this process. The elements are then entered into the remaining sequential processing list individually from bottom right through to upper left. Each marked element is entered into the sequential processing list before its topological successor, i.e. it is inserted before the element that in a topological sequencing would be executed after it, when all elements in the editor were sequenced according to a topological sequencing system. This will be clarified by an example.



The elements with numbers 1, 2 and 3 are selected. If the command 'Order topologically' is selected the elements are first taken out of the sequential processing list. Var3, the jump and the AND-operator are then inserted again one after the other. Var3 is placed before the label and receives the number 2. The jump is then ordered and receives the number 4 at first but this then becomes 5 after the AND is inserted. The new order of execution which arises is:



When a newly generated block is introduced it will be placed by default in front of its topological successor in the sequential processing list.

'Extras' 'Order' 'One up'

With this command all selected elements with the exception of the element which is at the beginning of the sequential processing list are moved one place forwards in the sequential processing list.

'Extras' 'Order' 'One down'

With this command all selected elements with the exception of the element which is at the end of the sequential processing list are moved one place backwards in the sequential processing list.

'Extras' 'Order' 'Start'

With this command all selected elements will be moved to the front of the sequential processing list whereby the order within the group of selected elements is maintained. The order within the group of unselected elements also remains the same.

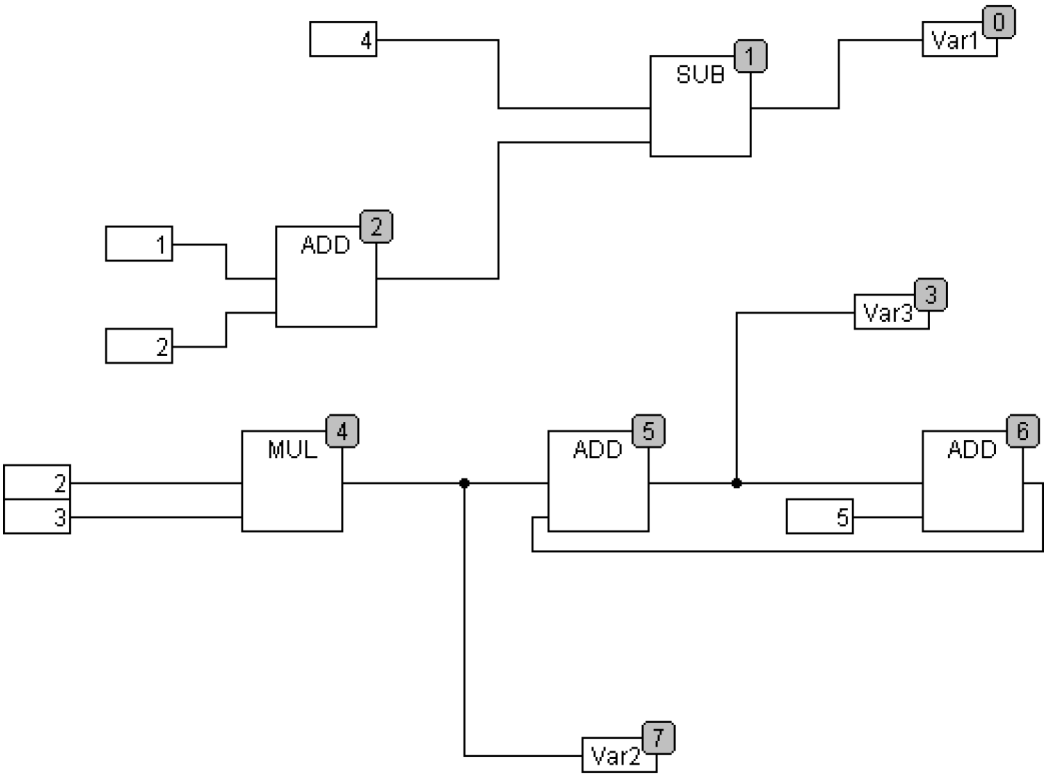
'Extras' 'Order' 'End'

With this command all selected elements will be moved to the end of the sequential processing list whereby the order within the group of selected elements is maintained. The order within the group of unselected elements also remains the same.

'Extras' 'Order' 'Order everything according to data flow'

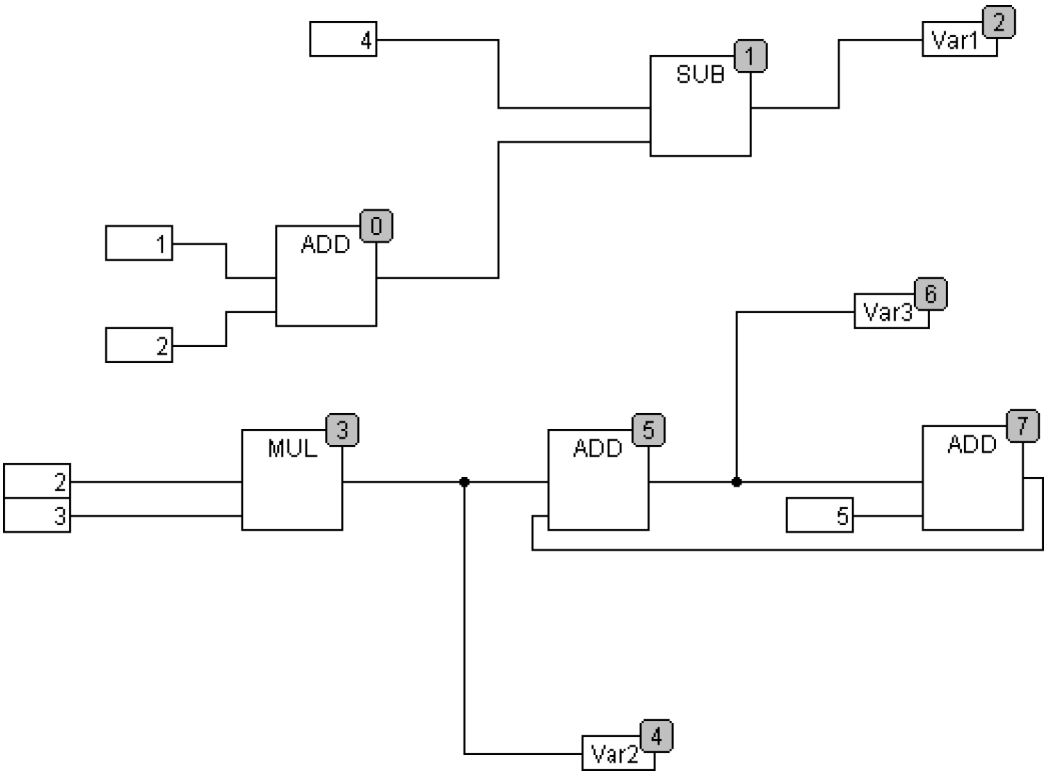
This command effects all elements. The order of execution is determined by the data flow of the elements and not by their position. The diagram below shows elements which have been ordered topographically.

Sequence before the ordering according to data flow:



The following arrangement exists after selecting the command.

Sequence after the ordering according to data flow:



When this command is selected the first thing to happen is that the elements are ordered topographically. A new sequential processing list is then created. Based on the known values of the inputs, the computer calculates which of the as yet not numbered elements can be processed next. In the above "network" the block AND, for example, could be processed immediately since the values at its inputs (1 and 2) are known. Block SUB can only then be processed since the result from ADD must be known first, etc.

Feedback paths are inserted last *Chapter 1.4.1.3.11.10.34 “Feedback paths in CFC” on page 350*.

The advantage of the data flow sequencing is that an output box which is connected to the output of a block comes immediately after it in the data flow sequencing system which by topological ordering would not always be the case. The topological ordering can deliver another result in some cases than ordering by data flow, a point which one can recognise from the above example.

'Extras' 'Create macro"

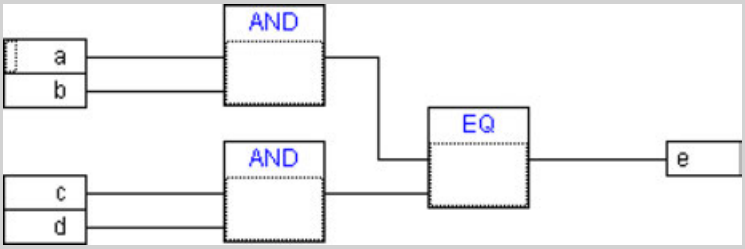
Symbol: 

With this command, several POUs that are selected at the same time can be assembled into a block, which can be named as a macro. Macros only can be reproduced by Copy/Paste, whereby each copy becomes a separate macro whose name can be chosen independently. Macros are thus not references. All connections that are cut by the creation of a macro generate in- or out-pins on the macro. Connections to inputs generate an in-pin. The default name appears next to the pin in the form In<n>. For connections to outputs, Out<n> appears. Affected connections which had connection markers prior to the creation of the macro, retain the connection marker on the PIN of the macro.

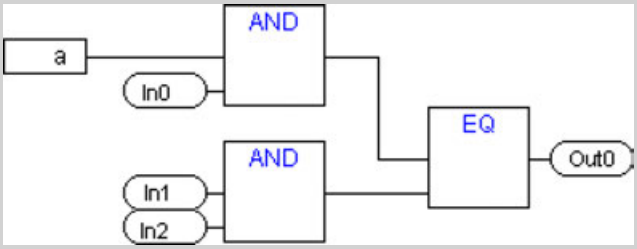
At first, a macro has the default name "MACRO". This can be changed in the Name field of the macro use. If the macro is edited, the name of the macro will be displayed in the title bar of the editor window appended to the POU name.

Example:

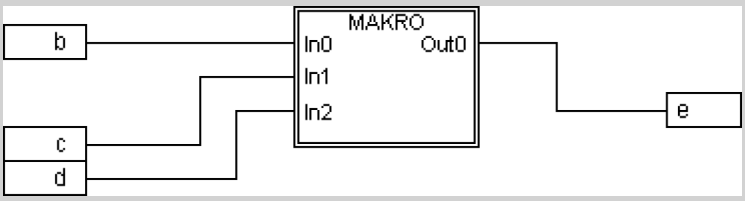
Selection:



Macro:



In the editor:



'Extras' 'Edit Macro'

Symbol: 

By this command, or by double clicking on the body of the macro, the macro is opened for editing in the editor window of the associated POU *Chapter 1.4.1.3.11.10.30 “'Extras' 'Create macro'” on page 349*. The name of the macro is displayed appended to the POU name in the title bar.

The pin boxes generated for the in- and outputs of the macro during creation can be handled like normal POU in- and outputs. They can also be moved, deleted, added, etc. They differ only in how they are displayed and have no position index. For adding you can use the buttons  (input) or  (output), which are available in the menu bar. Pin boxes have rounded corners. The text in the pin-box matches the name of the pin in the macro display.

The order of the pins in the macro box follows the order of execution of the elements of the macro. A lower order index before a higher one, higher pin before lower.

The processing order within the macro is closed, in other words the macro is processed as a block, at the position of the macro in the primary POU. Commands for manipulating the order of execution therefore operate only within the macro.

'Extras' 'Expand macro'

With this command, the selected macro is re-expanded and the elements contained in it are inserted in the POU at the macro's location *Chapter 1.4.1.3.11.10.30 “'Extras' 'Create macro'” on page 349*. The connections to the pins of the macro are again displayed as connections to the in- or outputs of the elements. If the expansion of the macro can not occur at the location of the macro box for lack of space, the macro is displaced to the right and down until enough space is available.

If the project is saved under project version number 2.1, the macros will likewise all be expanded. All macros will also be expanded before conversion into other languages.

'Extras' 'Back one macro level', 'Extras' 'Back all macro level'

Symbols: 

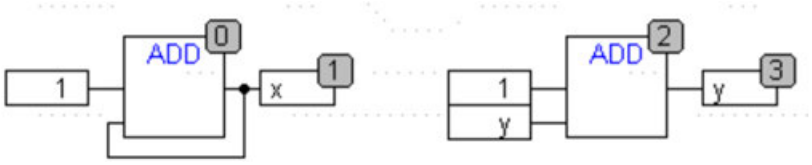
These commands are also available in the toolbar, as soon as a macro is opened for editing *Chapter 1.4.1.3.11.10.30 “'Extras' 'Create macro'” on page 349*. If macros are nested within one another, it is possible to switch to the next higher or to the highest display level.

Feedback paths in CFC

Feedback paths can only be displayed directly in the continuous function chart editor and not in the usual Function Block Diagram Editor. Here it should be observed that the output of a block always carries an internal intermediate variable. The data type of the intermediate variable results, for operators, from the largest data type of the inputs.

The data type of a constant is obtained from the smallest possible data type, that is the constant '1' adopts the data type SINT. If now an addition with feedback and the constant '1' is executed, the first input gives the data type SINT and the second is undefined because of the feedback. Thus the intermediate variable is also of the type SINT. The value of the intermediate variable is only then allocated to the output variable.

The diagram below shows an addition with feedback and an addition with a variable. The variables x and y should be of the type INT here.



There are differences between the two additions:

The variable y can be initialised with a value which is not equal to zero but this is not the case for intermediate variable for the left addition.

The intermediate variable for the left addition has the data type SINT while that on the right has the data type INT. The variables x and y have different values after the 129th call up. The variable x, although it is of the type INT, contains the value 127 because the intermediate variable has gone into overflow. The variable y contains the value 129, on the other hand.

Zoom to POU

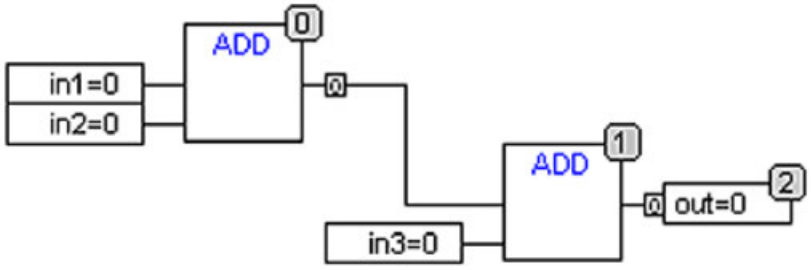
Shortcut: <Alt>+<Enter>

With this command a selected POU is loaded into its editor. The command is available in the context menu (<F2>) or in the 'Extras' menu, if the cursor is positioned on the name of a POU in a text editor or if the POU box is selected in a graphic editor.

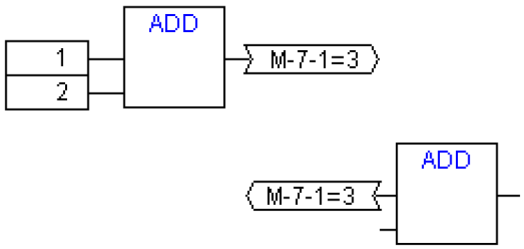
If you are dealing with a POU from a library, then the library manager is called up, and the corresponding POU is displayed.

CFC in Online mode

Monitoring: The values for inputs and outputs are displayed within the input or output boxes. Constants are not monitored. For non-boolean variables, the boxes are expanded to accommodated the values displayed. For boolean connections, the variable name as well as the connection are displayed in blue if the value is TRUE, otherwise they remain black. Internal boolean connections are also displayed Online in blue in the TRUE state, otherwise black. The value of internal non-boolean connections is displayed in a small box with rounded corners on the output pin of the connection.



Pins in macros are monitored like in- or output boxes.



Non-boolean connections with connection markers display their value within the connection marker. For boolean connections, the lines as well as the marker names are displayed in blue if the line is carrying the value TRUE, otherwise black.

Flow control: When flow control is switched on, the connections that have been traversed are marked with the color selected in the project options.

Breakpoints: Breakpoints can be set on all elements that also have a processing sequence order index ↳ *Chapter 1.4.1.1.11.3 “Breakpoint” on page 182*. The processing of the program will be halted prior to execution of the respective element, that is for POUs and outputs before the assignment of inputs, for jump labels before execution of the element with the next index. The processing sequence index of the element is used as the breakpoint position in the Breakpoint dialog.

The setting of breakpoints on a selected element is accomplished with the F9 key or via the menu item 'Breakpoint on/off' in the 'Online' or 'Extras' menu or in the editor's context menu. If a breakpoint is set on an element, then this will be erased and reversed the next time the command 'Breakpoint on/off' is executed. In addition, the breakpoint on an element can be toggled by double-clicking on it.

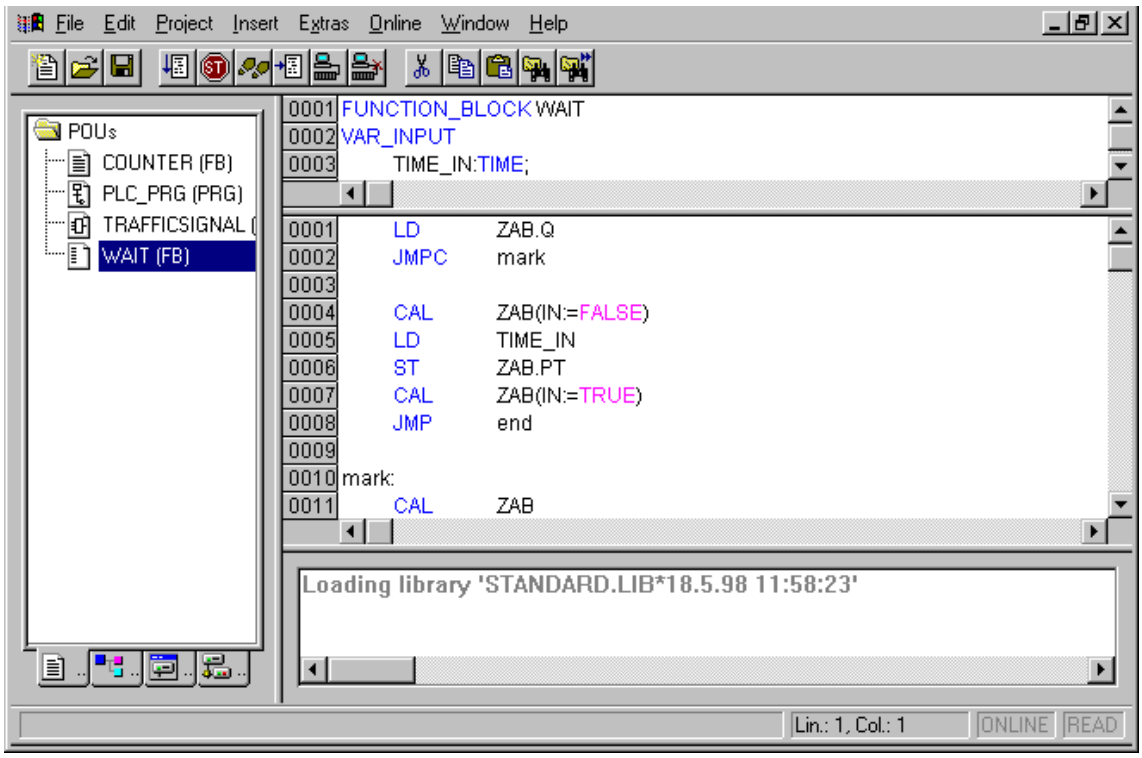
Breakpoints are displayed in the colors entered in the project options.

RETURN label: In Online mode, a jump label with the name „RETURN" is automatically generated in the first column and after the last element in the editor. This label marks the end of the POU and is jumped to when stepping just before execution leaves the POU. No RETURN marks are inserted in macros.

Stepping: When using 'Step over' the element with the next-higher order index will always be jumped to ↳ *Chapter 1.4.1.2.6.13 “'Online' 'Step over'” on page 286*. If the current element is a macro or a POU, then its implement branches when 'Step in' is in effect ↳ *Chapter 1.4.1.2.6.14 “'Online' 'Step in'” on page 286*. If a 'Step over' is executed from there, the element whose order index follows that of the macro is jumped to.

1.4.1.3.12 The text editors

Overview



The text editors used for the implementation portion (the Instruction List editor and the Structured Text editor) provide the usual Windows text editor functions.

The implementation in the text editors is supported by syntax coloring.

In Overwrite mode the status bar shows a black OV. You can switch between Overwrite mode and Insert mode by key <Ins>

The most important commands are found in the context menu (right mouse button or <Ctrl>+<F10>).

'Insert''Operators'

With this command all of the operators available in the current language are displayed in a dialog box.

If one of the operators is selected and the list is closed with OK, then the highlighted operator will be inserted at the present cursor position. (This is managed here just as it is in the input assistant).

'Insert' 'Operand'

With this command all variables in a dialog box are displayed. You can select whether you would like to display a list of the global, the local, or the system variables.

If one of the operands is chosen, and the dialog box is closed with OK, then the highlighted operand will be inserted at the present cursor position. (This is managed here just as it is in the input assistant).

'Insert' 'Function'

With this command all functions will be displayed in a dialog box ↳ *Chapter 1.4.1.1.9.3 “Function” on page 151*. You can choose whether to have a list displaying user-defined or standard functions.

If one of the functions is selected and the dialog box is closed with OK, then the highlighted function will be inserted at the current cursor position. (The management will proceed, as in the input selection.)

If the 'With arguments' option was selected in the dialog box, then the necessary input and output variables will also be inserted.

'Insert' 'Function Block'

With this command all function blocks are displayed in a dialog box ↳ *Chapter 1.4.1.1.9.4 “Function block” on page 153*. You can choose whether to have a list displaying user-defined or standard function blocks.

If one of the function blocks is selected and the dialog box is closed with OK, then the highlighted function block will be inserted at the current cursor position. (This is managed here just as it is in the input assistant).

If the 'With arguments' option was selected in the dialog box, then the necessary input variables of the function block will also be inserted. However you are not forced to assign these parameters.

Calling POUs with output parameters in text editors

The output parameters of a called POU can be directly assigned upon being called in the text languages IL and ST.

Example: Output parameter out1 of afbinst is assigned variable a.

IL:

```
CAL afbinst(in1:=1, out1=>a)
```

ST:

```
afbinst(in1:=1, out1=>a);
```

If the POU is inserted via input assistant (<F2>) with option 'With arguments' in the implementation window of a ST or IL POU, it will automatically be displayed with all parameters in this syntax. However you are not forced to assign these parameters.

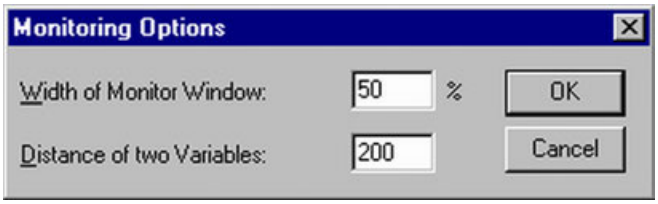
'Extras' 'Monitoring Options'

With this command you can configure your monitoring window. In the text editors, the window is divided into two halves during monitoring. The program is located in the left half. In the right half, all variables that are located in the corresponding program line are monitored.

You can specify the Monitor Window Width and which Distance two variables should have in a line. An distance declaration of 1 corresponds, in this case, to a line height in the selected font.

Regard that the width of the window halves also can be modified by drawing the divider with the mouse.

Monitoring Options Dialog Box:



Breakpoint positions

Breakpoint positions include all positions in a program at which values of variables can change or where the program flow branches off. (Exception: function calls. If necessary, a breakpoint in the function must be set here.) At the positions lying inbetween, a breakpoint would not even make sense, since nothing has been able to change in the data since the preceding breakpoint position.

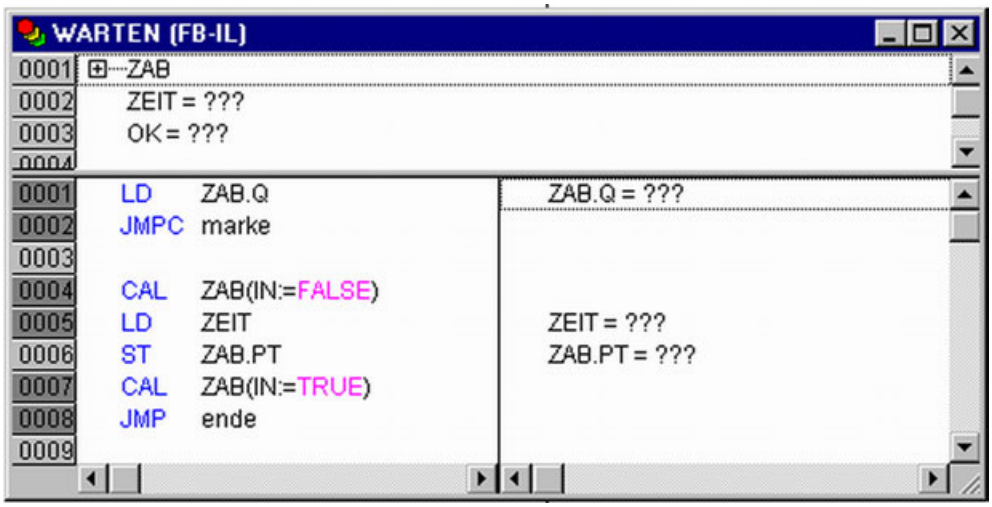
This results in the following breakpoint positions in the IL:

- At the start of the POU
- At every LD, LDN (or, in case a LD is located at a label, then at the label)
- At every JMP, JMPC, JMPCN
- At every label
- At every CAL, CALC, CALCN
- At every RET, RETC, RETCN
- At the end of the POU

Structured Text accommodates the following breakpoint positions:

- At every assignment
- At every RETURN and EXIT instruction
- in lines where conditions are being evaluated (WHILE, IF, REPEAT)
- At the end of the POU

Breakpoint positions are marked by darker line number fields (in the color which is set in the project options):



How do you set a breakpoint?

In order to set a breakpoint, click the line number field of the line where you want to set a breakpoint. If the selected field is a breakpoint position, then the color of the line numbers field will change from dark gray to light blue, and the breakpoint will be activated in the PLC.

Deleting breakpoints

Correspondingly, in order to delete a breakpoint, click on the line number field of the line with the breakpoint to be deleted.

Setting and deleting of breakpoints can also be selected via the menu ('Online' 'Toggle Breakpoint'), via the function key <F9>, or via the symbol in the tool bar ↬ *Chapter 1.4.1.2.6.11 "'Online' 'Toggle breakpoint'" on page 285*.

Line number of the text editor

The line numbers of the text editor give the number of each text line of an implementation of a POU.

In Off-line mode, a simple click on a special line number will mark the entire text line.

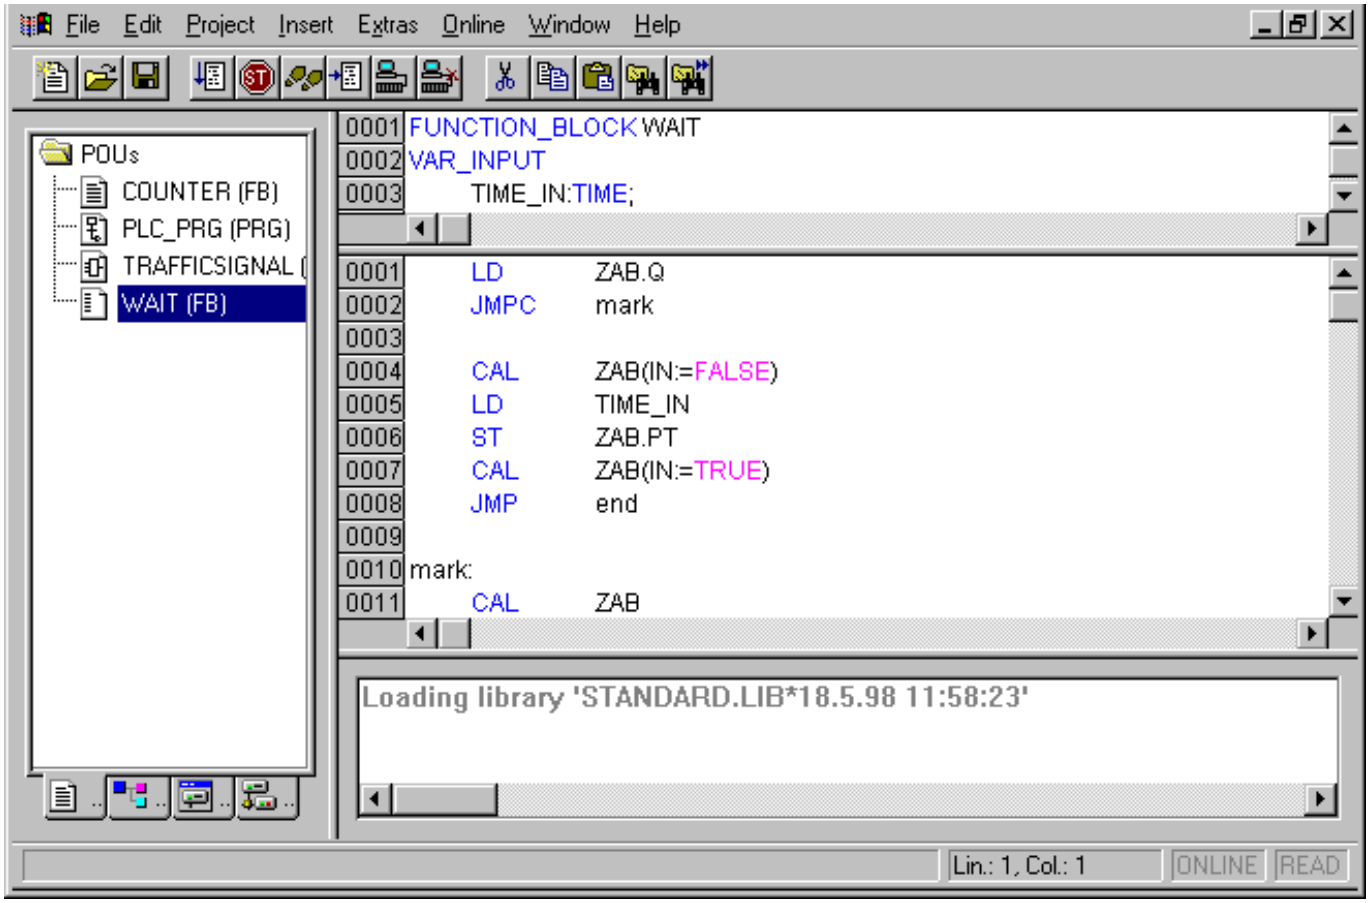
In Online mode, the background color of the line number indicates the breakpoint status of every line. The standard settings for the colors are

- dark gray: This line is a possible position for a breakpoint.
- light blue: a breakpoint has been set in this line.
- red: The program has reached this point.

In Online mode, simply clicking the mouse will change the breakpoint status of this line.

The instruction list editor

Overview



All editors for POUs consist of a declaration part and a body. These are separated by a screen divider.

The Instruction List editor is a text editor with the usual capabilities of Windows text editors. The most important commands are found in the context menu (right mouse button or <Ctrl>+<F10>). Multiline POU calls are also possible.

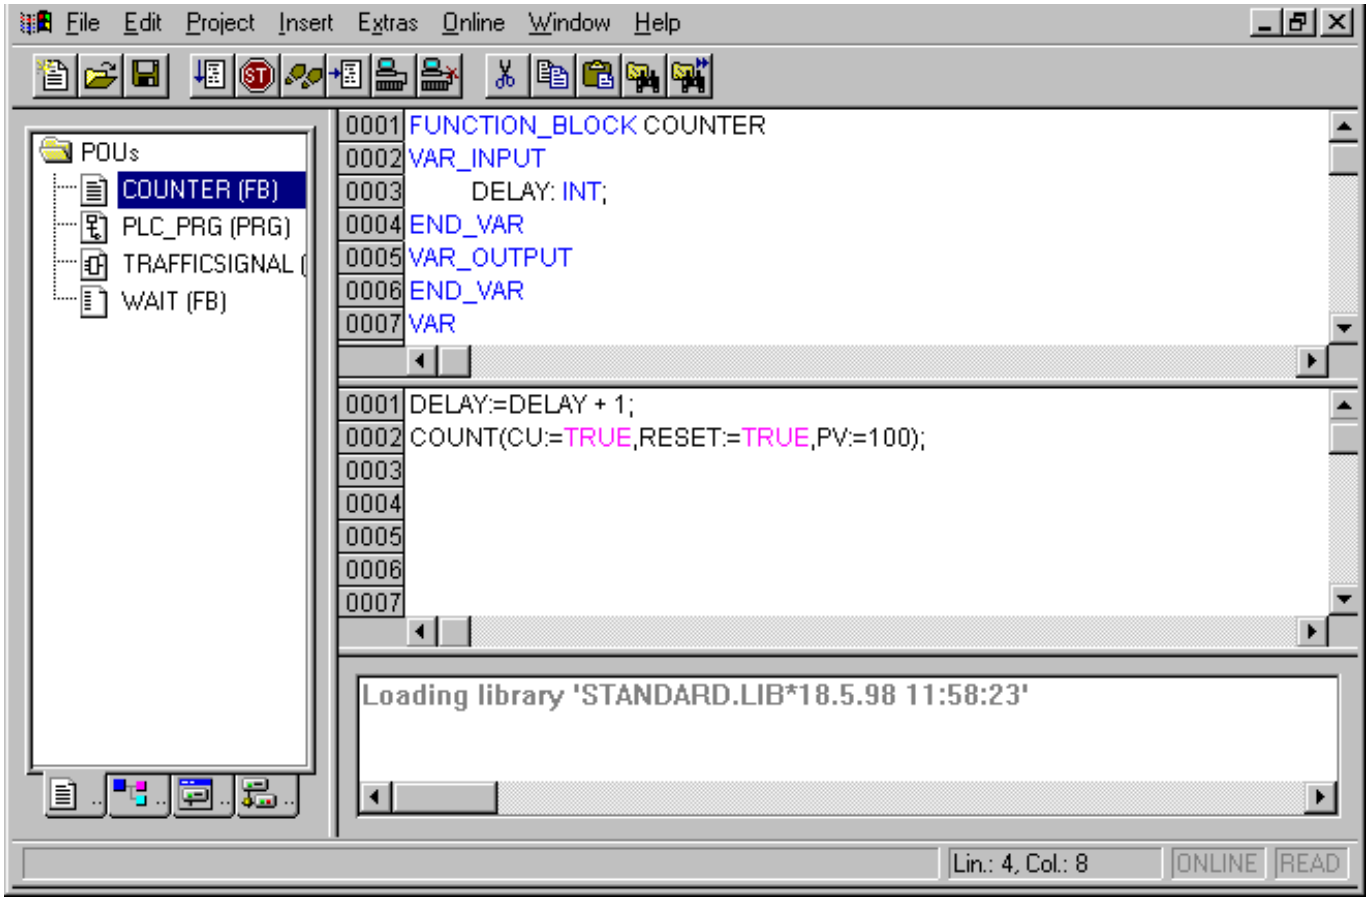
Example

```
CAL CTU_inst(
CU:=%IX10,
PV:=(
LD A
ADD 5
)
)
```

IL in online mode

With the 'Online' 'Flow control' command ↳ *Chapter 1.4.1.2.6.21 “'Online' 'Display flow control'” on page 290*, an additional field in which the accumulator contents is displayed is inserted in the IL editor on the left side of every line.

The structured text editor



All editors for POUs consist of a declaration part and a body. These are separated by a screen divider.

The editor for Structured Text is a text editor with the usual capabilities of Windows text editors. The most important commands are found in the context menu (right mouse button or <Ctrl>+<F10>).

1.4.1.4 The 'Resources' tab

1.4.1.4.1 Global variables, variable configuration, document frame

'Global Variables' folder

Objects in 'Global Variables' folder

In the Object Organizer, you will find two objects in the *“Resources”* register card in the *“Global Variables”* folder (default names of the objects in parentheses).

- Global Variables ↯ *Chapter 1.4.1.4.1.2 “Global variables” on page 357*
- Variables Configuration ↯ *Chapter 1.4.1.4.1.4.1 “Overview” on page 361*

All variables defined in these objects are recognized throughout the project. If the Global Variables folder is not opened, you can open it with a double-click *[Enter]* in the line.

Select the corresponding object. The *“'Object Open'”* command opens a window with the previously defined global variables. The editor for this works the same way as the declaration editor.

Global variables

Normal variables, constants or remanent variables that are known throughout the project can be declared as global variables.

In a project you can define a local variable which has the same name as a global variable. In this case within a POU the locally defined variable will be used.

It is not allowed to name two global variables identically. For example, you will get a compiler error if you have defined a variable "var1" in the PLC Configuration as well as in a global variables list.

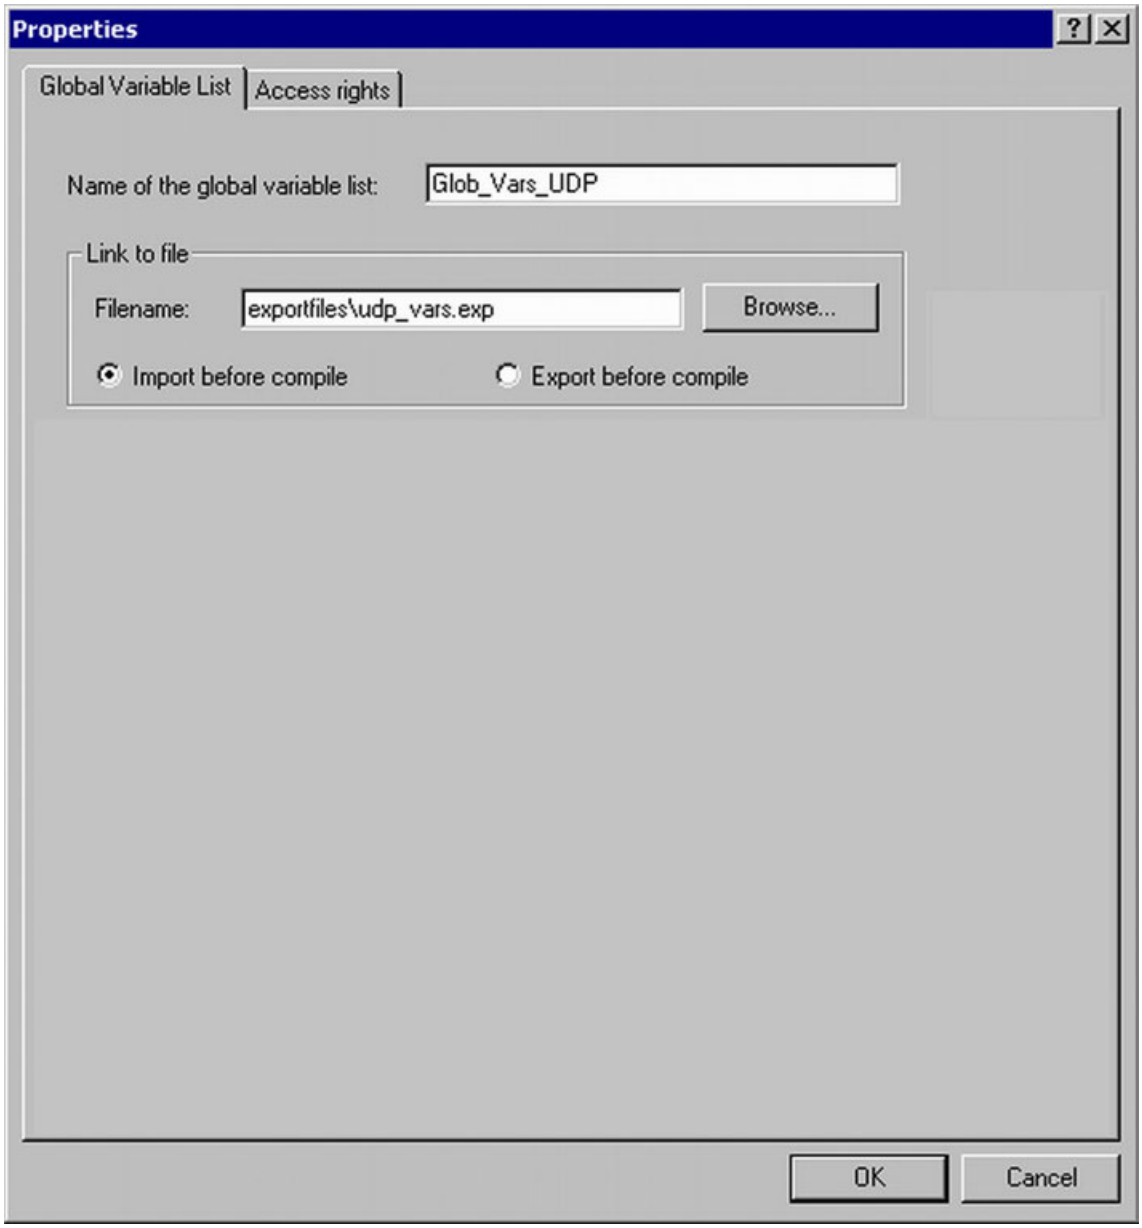
Global variable lists

Create a global variable list

To create a Global Variable List, open the register 'Resources' in the Object Organizer and select the entry 'Global Variables' or select an already existing list. Then choose the command 'Project' 'Object' 'Add'to open the dialog Global variable list ↬ *Chapter 1.4.1.2.4.6 “'Project' 'Object' ' Add'” on page 258*.

This dialog can also be opened by the command 'Project' 'Object' 'Properties' which is available if an existing Global Variable List is marked in the object organizer ↬ *Chapter 1.4.1.2.4.12 “'Project' 'Object properties'” on page 261*. It shows the configuration of this list.

Dialog to create a new Global Variable List:



Name of the global variable list: Insert a list name.

Link to file:

Filename: If you have an export file (*.exp) or a DCF file, which contains the desired variables, you can set up a link to this file. To do this, insert the path of the file in the field Filename resp. press the button Browse to get the standard dialog 'Select text file'. DCF files are converted to ICE syntax when they are read in.

Activate option Import before compile, if you wish that the variable list will be read from the external file before each compilation of the project. Activate the option Export before compile, if you want the variable list to be written to the external file before each compilation of the project.

If you close the 'Global variable list' dialog with OK, the new object is created. Global variables lists can be recognized in the Object Organizer by the symbol . With the command 'Project' 'Object' 'Properties' you can re-open the 'Global variable list' configuration dialog for the entry marked in the Object Organizer.

Several variables lists

Global variables, global network variables (VAR_GLOBAL) and variable configurations (VAR_CONFIG) must be defined in separate objects.

If you have declared a large number of global variables, and you would like to structure your global variables list better, then you can create further variables lists.

In the Object Organizer, select the Global Variables folder or one of the existing objects with global variables. Then execute the 'Project' 'Object Add' command. Give the object that appears in the dialog box a corresponding name. With this name an additional object will be created with the key word VAR_GLOBAL. If you prefer an object a variable configuration, change the corresponding key word to VAR_CONFIG.

Editing global variable lists

The editor for global variables works similar to the declaration editor. But note that you cannot edit in this editor a list, which is an figure of an linked external variable list. External variable lists only can be edited externally and they will be read at each opening and compiling of the project.

Syntax:

```
VAR_GLOBAL
 (* Variables declarations *)
END_VAR
```

Editing remanent global variables lists

If they are supported by the runtime system, remanent variables may be processed. There are two types of remanent global variables:

- Retain variables remain unchanged after an uncontrolled shutdown of the runtime system (off/on) or an 'Online' 'Reset' *Chapter 1.4.1.2.6.8 “'Online' 'Reset'” on page 284*.
- Persistent variables remain only unchanged after a program download *Chapter 1.4.1.2.6.5 “'Online' 'Download'” on page 283*.

Persistent variables are not automatically also Retain variables !

Remanent variables are additionally assigned the keyword RETAIN and/or PERSISTENT.

Syntax:

```
VAR_GLOBAL RETAIN
 (* Variables declarations *)
END_VAR
VAR_GLOBAL PERSISTENT
 (* Variables declarations *)
END_VAR
```

For the combination of retain and persistent properties both keywords are used:

```
 VAR_GLOBAL RETAIN PERSISTENT
```

or

```
 VAR_GLOBAL PERSISTENT RETAIN
```

Global constants

Global constants additionally get the keyword CONSTANT.

Syntax:

```
VAR_GLOBAL CONSTANT
 (* Variables declarations *)
END_VAR
```

Variable configuration

Overview

In function blocks it is possible to specify addresses for inputs and outputs that are not completely defined, if you put the variable definitions between the key words VAR and END_VAR. Addresses not completely defined are identified with an asterisk.

Example

```
FUNCTION_BLOCK locio
VAR
 loci AT %I*: BOOL := TRUE;
 loco AT %Q*: BOOL;
END_VAR
```

Here two local I/O-variables are defined, a local-In (%I*) and a local-Out (%Q*).

If you want to configure local I/Os for variables configuration in the Object Organizer in the Resources register card, the object Variable_Configuration will generally be available. The object then can be renamed and other objects can be created for the variables configuration.

The editor for variables configuration works like the declaration editor.

Variables for local I/O-configurations must be located between the key words VAR_CONFIG and END_VAR.

The name of such a variable consists of a complete instance path through which the individual POUs and instance names are separated from one another by periods. The declaration must contain an address whose class (input/output) corresponds to that of the incompletely specified address (%I*, %Q*) in the function block. Also the data type must agree with the declaration in the function block.

Configuration variables, whose instance path is invalid because the instance does not exist, are also denoted as errors. On the other hand, an error is also reported if no configuration exists for an instance variable. In order to receive a list of all necessary configuration variables, the "All Instance Paths" menu item in the 'Insert' menu can be used.

Example for a variable configuration

Assume that the following definition for a function block is given in a program:

```
VAR
Hugo: locio;
Otto: locio;
END_VAR
```

Then a corrected variable configuration would look this way:

```
VAR_CONFIG
PLC_PRG.Hugo.loci AT %IX1.0 : BOOL;
PLC_PRG.Hugo.loco AT %QX0.0 : BOOL;
PLC_PRG.Otto.loci AT %IX1.0 : BOOL;
PLC_PRG.Otto.loco AT %QX0.3 : BOOL;
END_VAR
```

'Insert' 'All Instance Paths'

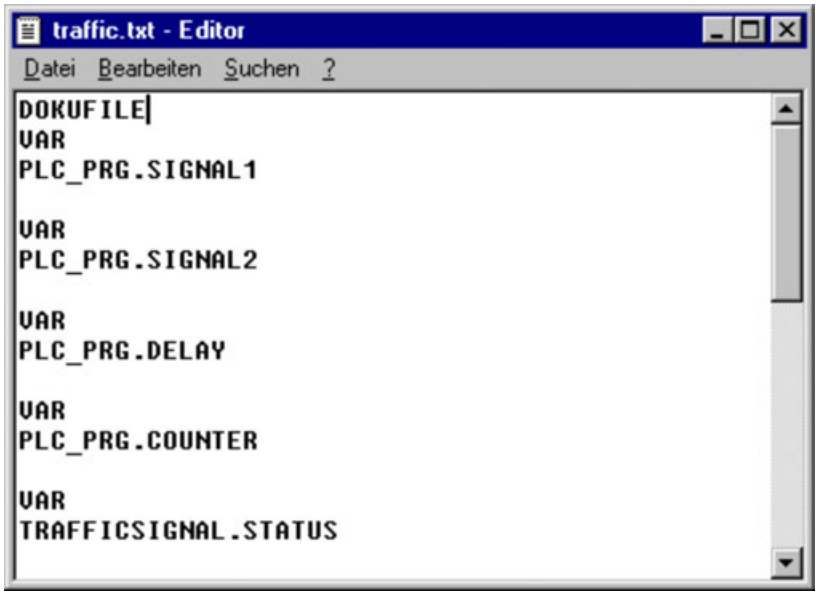
With this command a VAR_CONFIG - END_VAR-block is generated that contains all of the instance paths available in the project. Declarations already on hand do not need to be reinserted in order to contain addresses already in existence. This menu item can be found in the window for configuration of variables if the project is compiled ↳ *Chapter 1.4.1.2.3.12 "'Project' 'Rebuild all'" on page 232*.

Document frame

Overview

If a project is to receive multiple documentations, perhaps with German and English comments, or if you want to document several similar projects that use the same variable names, then you can save yourself a lot of work by creating a docuframe with the 'Extras' 'Make Docuframe File' command *Chapter 1.4.1.4.1.5.2 “'Extras' 'Make Docuframe File'” on page 362*.

The created file can be loaded into a desired text editor and can be edited. The file begins with the DOCUFILE line. Then a listing of the project variables follows in an arrangement that assigns three lines to each variable: a VAR line that shows when a new variable comes; next, a line with the name of the variable; and, finally, an empty line. You can now replace this line by using a comment to the variable. You can simply delete any variables that you are unable to document. If you want, you can create several document frames for your project.



In order to use a document frame, give the 'Extras' 'Link Docu File' command *Chapter 1.4.1.4.1.5.3 “'Extras' 'Link Docu File'” on page 362*. Now if you document the entire project, or print parts of your project, then in the program text, there will be an insertion of the comment produced in the docuframe into all of the variables. This comment only appears in the printout!

'Extras' 'Make Docuframe File'

Use this command to create a document frame. The command is at your disposal, whenever you select an object from the global variables. A dialog box will open for saving files under a new name. In the field for the name file, the *.txt extension has already been entered. Select a desired name. Now a text file has been created in which all the variables of your project are listed.

'Extras' 'Link Docu File'

With this command you can select a document frame.

The dialog box for opening files is opened. Choose the desired document frame and press OK. Now if you document the entire project, or print parts of your project, then in the program text there will be an insertion of the comment produced in the docuframe into all of the variables. This comment only appears in the printout!

To create a document frame, use the 'Extras' 'Make Docuframe File' command *Chapter 1.4.1.4.1.5.2 “'Extras' 'Make Docuframe File'” on page 362*.

1.4.1.4.2 Alarm configuration

Overview

The alarm system allows to detect critical process states, to record them and to visualize them for the user with the aid of a visualization element. The alarm handling can be done in Automation Builder or alternatively in the PLC. For alarm handling in the PLC please see the target settings in category 'Visualization' ↳ *Chapter 1.4.1.4.7.3 “Target settings in category visualization” on page 388*.

If supported by the target system, the dialogs for 'Alarm configuration' are available in the 'Resources' tab.

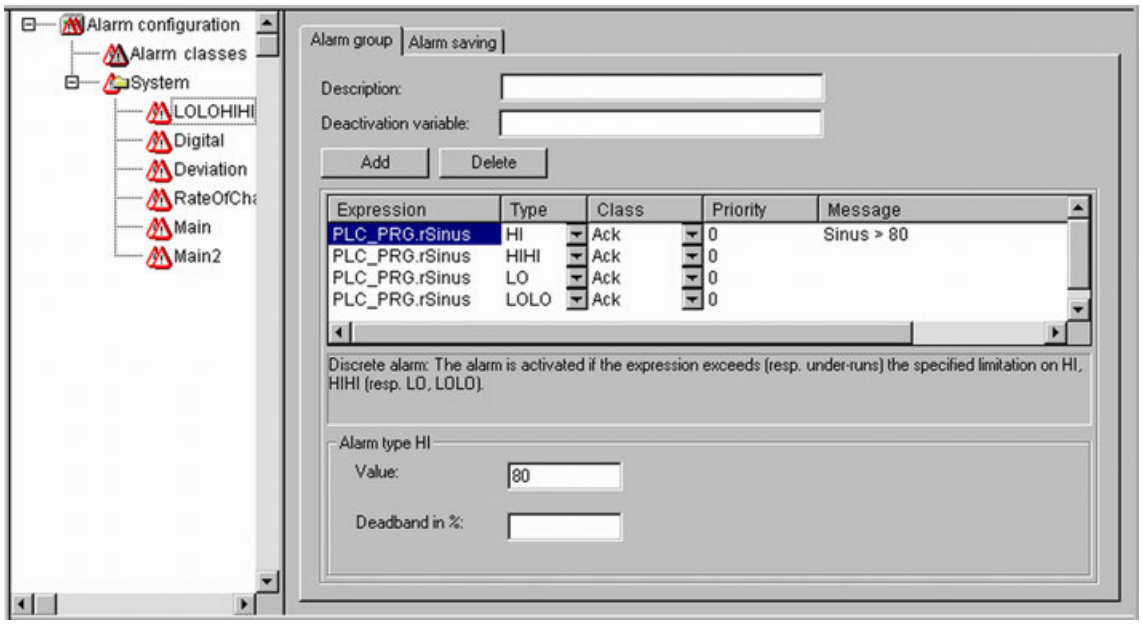
Here you define alarm classes and alarm groups. An alarm class serves for the typing of an alarm, that means it assigns certain parameters to the alarm. An alarm group serves for the concrete configuration of one or several alarms (which get assigned a certain class and further parameters) for the use in the project. Thus a class is useful for structuring the available alarms. The different alarm groups are defined by the user by inserting appropriate entries below the header 'System' in the configuration tree.

For the visualization of alarms the alarm table element is available in the visualization ↳ *Chapter 1.4.3.5.26 “Alarm table” on page 684*. Using this table the user can watch and acknowledge alarms. The language of the displayed alarm message texts might be switched dynamically.

If a history, i.e. recording of alarm events should be written to a log-file, such a file must be defined and for each alarm group the saving behavior must be defined.

When you open the 'Alarm configuration' in the Resources tab, the dialog 'Alarm configuration' opens with a bi-partited window, which concerning the mode of operation is similar to that of the PLC Configuration or Task configuration. In the left part the configuration tree is displayed, in the right part the appropriate configuration dialog will be opened.

Example of an Alarm configuration :



Open by a mouse-click on the plus sign at the entry 'Alarm configuration' the currently available configuration tree. If you are going to create a new configuration, this tree only will show the entries 'Alarm classes' and 'System'.

See also:

↳ *Chapter 1.4.1.4.2.2 “General information on alarms, terms” on page 364*

↳ *Chapter 1.4.1.4.2.3 “Alarm classes” on page 364*

↳ *Chapter 1.4.1.4.2.4 “Alarm groups” on page 368*

↳ *Chapter 1.4.1.4.2.5 “Alarm saving” on page 369*

General information on alarms, terms

The usage of an alarm system obeys the following universal descriptions and definitions concerning alarms:

- Alarm: Generally an alarm is regarded as a special condition (expression value).
- Priority: The priority, also named "severity", of an alarm describes how important (severe) the alarm condition is. The highest priority is "0", the lowest valid priority value is "255".
- Alarm state: An expression/variable configured for the alarm control can have the following states: NORM (no alarm), INTO (alarm just has come), ACK (alarm has come and has been acknowledged by the user), OUTOF (alarm state has been terminated, alarm "has gone", but not yet acknowledged !)
- Sub-State: An alarm condition can have limits (Lo, Hi) and "extreme" limits (LoLo, HiHi). Example: The value of an expression ascends and first will transit the HI-limit, thus causing the coming of an HI-alarm. If the value continues ascending and exceeds also the HIHI-limit before the alarm gets acknowledged by the user, then the HI-alarm will get acknowledged automatically and just the HIHI-alarm remains in the alarm list (which is an internal list used for alarm administration). The HI-state in this case is named sub-state.
- Acknowledgement of alarms: The main purpose of alarms is to inform the user on alarm situations. In doing so it often is necessary to make sure that the user has noticed this information (see possible actions assigned to an alarm in the alarm class configuration). The user must acknowledge the alarm in order to get the alarm removed from the alarm list.
- Alarm Event: An alarm event must not be mixed up with an alarm condition. While an alarm condition can be valid for a longer period of time, an alarm event just describes the momentary occurrence of an change, e.g. a change from the normal state to the alarm state. In the alarm configuration for the three types of events and the corresponding alarm states the same names are used (INTO, ACK, OUTOF).

Supported features:

- Deactivation of the alarm generation for single alarms as well as for alarm groups
- Selection of the alarms which should be displayed by defining alarm groups and priorities
- Saving of all alarm events in an alarm table
- Visualization element 'Alarm table' in the visualization

See also:

Alarm configuration overview ↳ *Chapter 1.4.1.4.2.1 “Overview” on page 363*

Alarm classes ↳ *Chapter 1.4.1.4.2.3 “Alarm classes” on page 364*

Alarm groups ↳ *Chapter 1.4.1.4.2.4 “Alarm groups” on page 368*

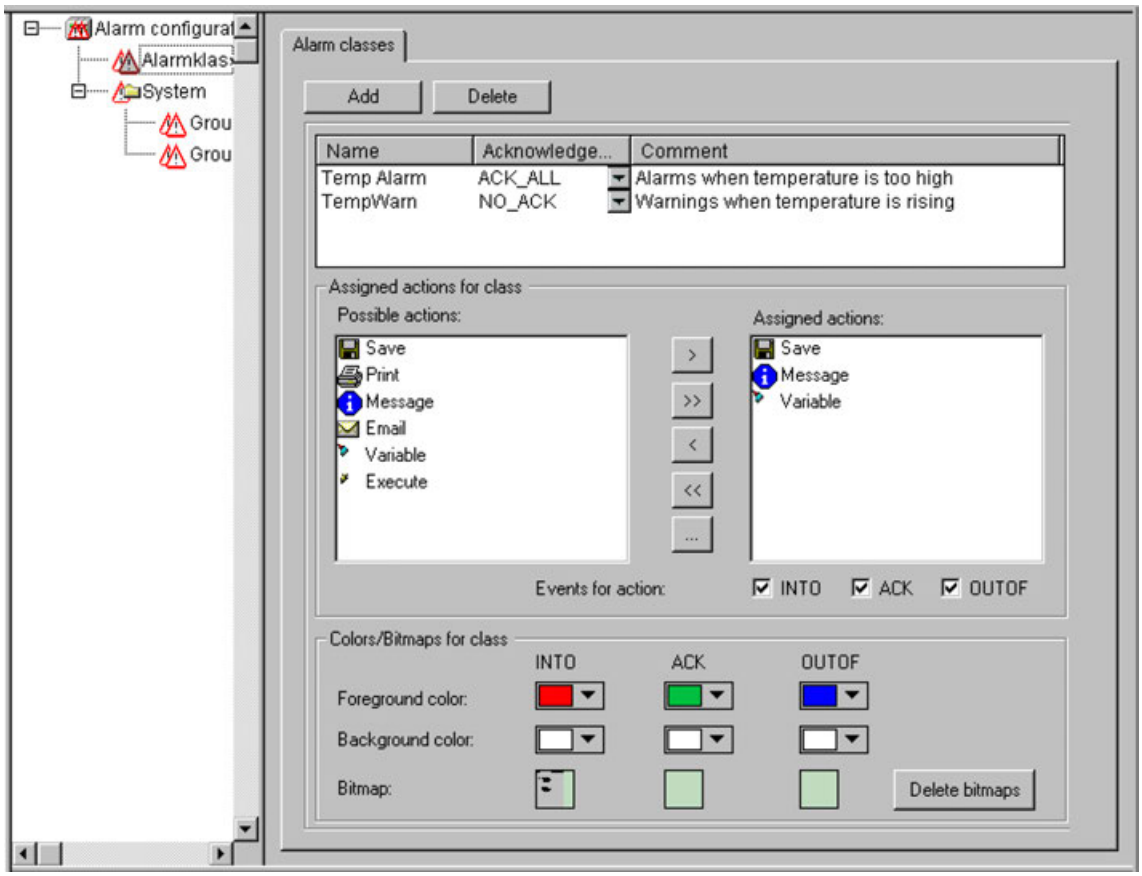
Alarm saving ↳ *Chapter 1.4.1.4.2.5 “Alarm saving” on page 369*

Alarm classes

Alarm classes are used for the general description of certain alarm criteria, such as how to handle acknowledgements (confirmation of an alarm by the user), which actions should automatically run as soon as a particular alarm state has been detected and which colors and bitmaps are to be used for a visualization of an alarm table ↳ *Chapter 1.4.1.4.2.2 “General information on alarms, terms” on page 364*↳ *Chapter 1.4.3.5.26 “Alarm table” on page 684*. Alarm classes are defined globally in the alarm configuration and are then available as a base configuration when configuring alarm groups ↳ *Chapter 1.4.1.4.2.1 “Overview” on page 363* ↳ *Chapter 1.4.1.4.2.4 “Alarm groups” on page 368*.

Configuration of alarm classes

Select entry 'Alarm classes' in the alarm configuration tree. The configuration dialog 'Alarm classes' gets opened:



Press button 'Add' in order to create a new alarm class. Thereupon in the upper window a line will be inserted, primarily only with an entry "NOACK" (no acknowledgement) in the 'Acknowledgement' column. Define a name for the alarm class in the corresponding field in the 'Name' column (open an edit frame by a mouse-click on the field) and if necessary modify the acknowledgement type in column 'Acknowledgement'. The following acknowledgements are available:

- NO_ACK: No acknowledgement of the alarm by the user is required
- ACK_INTO: A "come" alarm condition (status "INTO", alarm occurs) must be confirmed by the user.
- ACK_OUTOF: A "gone alarm" (status "OUTOF", alarm terminated) must be confirmed by the user.
- ACK_ALL: Gone and come alarm conditions must be confirmed by the user ↳ *Chapter 1.4.1.4.2.2 “General information on alarms, terms” on page 364*.

Additionally you can enter a Comment.

Entries for further alarm classes each will be added at the end of the list.

Use button Delete to remove the currently selected entry from the list.

Assigned actions for class <class name>

Each alarm class defined in the upper window can get assigned a list of actions, which should be performed as soon as an alarm event occurs ↳ *Chapter 1.4.1.4.2.2 “General information on alarms, terms” on page 364*.

In the list of Possible actions select one and press button ">" to get it into the field Assigned actions. This field will finally contain the selection of actions assigned to the alarm class. Via button ">>" you can add all actions at a single blow. Via "<" resp.. "<<" you can remove one or all actions from the done existing selection. If an action is marked in the 'Assigned actions' list, via "..." a corresponding dialog can be opened to define the desired E-Mail settings, the printer settings, the process variable resp. the executable program and, if applicable, a message text.

The following action types (Possible actions) are supported (for a definition of a message text see below):

Action	Description	Settings to be done in the corresponding dialog
Save	The alarm event will be saved internally, in order to be given out e.g.in a log-file ↳ *Chapter 1.4.1.4.2.5 “Alarm saving” on page 369*. Please note: In this case the log-file must be defined in the configuration of the alarm groups ↳ *Chapter 1.4.1.4.2.4 “Alarm groups” on page 368*!	The settings are done in the Alarm group definition in the Alarm saving dialog ↳ *Chapter 1.4.1.4.2.5 “Alarm saving” on page 369*
Print	A message text is sent to a printer.	Printer: Select one of the printers defined on the local system; Outputtext: Message text (see below) which should be printed out ● Please note that this function is not supported for target visualization!
Message	In the current visualization of the alarm a message window will be opened showing the defined text ↳ *Chapter 1.4.3.5.26 “Alarm table” on page 684*.	Message: Message text to be displayed in the message window ● Please note that this function is not supported for target visualization!
E-Mail	An E-Mail containing the defined message will be sent.	From: E-Mail address of sender; To: E-Mail address of recipient; Subject: any subject; Message: Message text (see below); Server: Name of the E-Mail server
Variable	A variable of the program will get the alarm status resp. a message text string.	Variable: Variable name: You can select project variables via the input assistant (<F2>): A boolean variable will indicate the alarm states NORM =0 and INTO=1, an integer variable will indicate the alarm states NORM =0, INTO =1, ACK =2, OUTOF =4; a string variable will get the message text defined in field; Message (see below)
Execute	An executable file will be started as soon as the alarm event occurs.	Executable file: name of the file to be executed (e.g. notepad.exe, you can use the "..." button to get the standard dialog for selecting a file; Parameter: appropriate parameter(s) which should be attached to the call of the exe-file

Definition of the message text

For action types 'Message', 'Print', 'Email' or 'Variable' you can define a message text which should be output in case of an Alarm Event. Line breaks at the text definitions in 'Message', 'Email' or 'Variable' can be inserted by <Ctrl>+<Enter>.

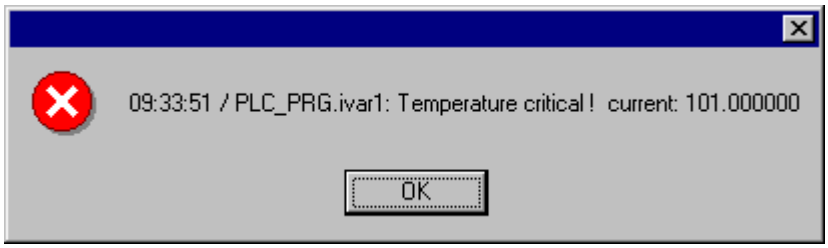
The following placeholders can be used when defining the alarm message:

MESSAGE	The message text which is defined for the particular alarm in the configuration of the alarm group will be used ↳ *Chapter 1.4.1.4.2.4 “Alarm groups” on page 368*.
DATE	Date, when the alarm status was reached (INTO).
TIME	Time of alarm entry.
EXPRESSION	Expression (defined in alarm group) which has caused the alarm.
PRIORITY	Priority of the alarm (defined for alarm group.)
VALUE	Current value of the expression (see above).
TYPE	Alarm type (defined in alarm group)
CLASS	Alarm class (defined in alarm group)
TARGETVALUE	Target value for alarm types DEV+ and DEV- (defined in alarm group)
DEADBAND	Tolerance of the alarm (defined in alarm group)
ALLDEFAULT	Any information on the alarm will be output, like described for the line entries in a log file (History).

Example of defining an alarm message:

For a definition of a message box enter the following in the message window:

Further on when defining the alarm in the alarm group enter in column 'Message' the following: "Temperature critical !". The output of the final alarm message will be like follows:



Note for translation to other languages: The message text will also be affected in case of a change of the project language if it is included in a *.vis-file or a translation file *.tlt ↳ *Chapter 1.4.1.2.3.16 “Create translation file” on page 233*. BUT: In this case - like texts referring to a visualization it has to be set between two "#"-characters (e.g. in the example shown above : "#Temperature critical !#" and "TIME /EXPRESSION: MESSAGE #current#: VALUE", in order to get the text entered in the translation file as ALARMTEXT_ITEMs.)

A log file for action 'Save' is to be defined in the configuration of the alarm group ↳ *Chapter 1.4.1.4.2.4 “Alarm groups” on page 368*.

Alarm events for actions

For each action you define, at which alarm events it should be started ↳ *Chapter 1.4.1.4.2.2 “General information on alarms, terms” on page 364*.

Activate the desired events:

INTO The alarm occurs. Status = INTO.

ACK Acknowledgement by the user has been done. Status = ACK.

OUTOF Alarm state terminated. Status = OUTOF.

Colors/Bitmaps for class <class name>

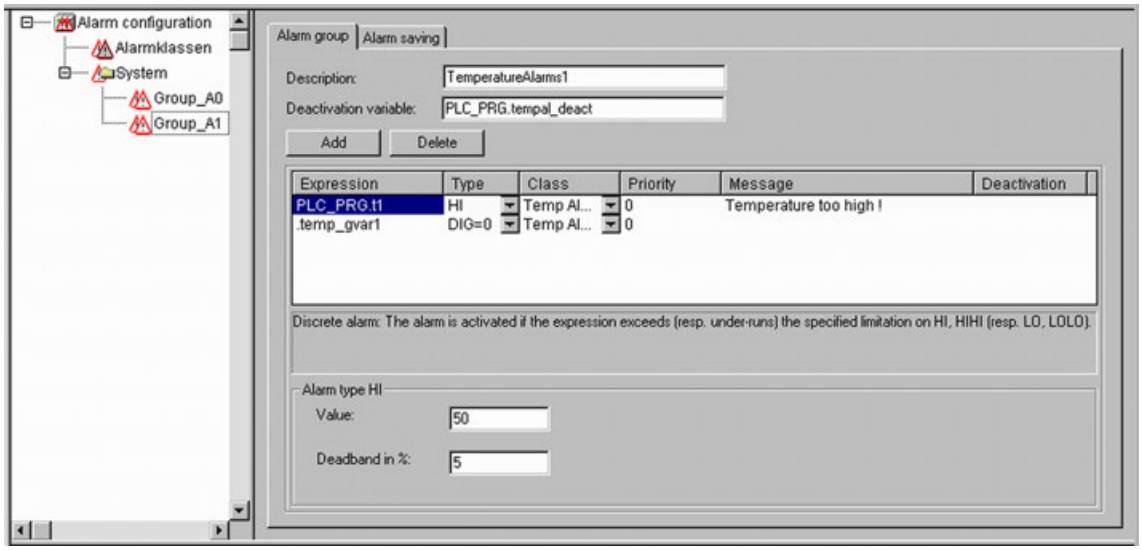
Each alarm class can get assigned own colors and bitmaps, which will be used for the differentiation of the alarms in the visualization element alarm table ↳ *Chapter 1.4.3.5.26 “Alarm table” on page 684*. Select a Foreground color and Background color for the possible events INTO, ACK and OUTOF.

The standard dialog for selecting a color will open as soon as you perform a mouse-click on the color symbol. For selecting a bitmap a mouse-click on the grey rectangle will open the standard dialog for selecting a file.

Alarm groups

Alarm groups are used for organizing the available alarms. Each alarm is definitely assigned to right one alarm group and is managed by this group. All alarms of a group can get assigned a common deactivation variable and common parameters regarding the alarm saving. Regard that even a single alarm must be configured within an alarm group.

A hierarchical structure of alarm groups can be defined via Folder elements. When a alarm group is selected in the configuration tree, automatically the dialog Alarm group will be displayed:



In the field *“Description”* you can enter a name for the alarm group.

As *“Deactivation variable”* a boolean project variable can be defined. At a rising edge on this variable the alarm creation for all alarms of the group will be deactivate, at a falling edge it will be re-activated.

Via button *[Add]* an alarm can be added to the group. A new line in the table window will be inserted and there the following parameters are to be set:

Expression: Enter here the project variable or an expression (e.g. "a + b") to which the alarm should refer. It is recommended to use the input assistant <F2> or the "Intellisense" function for a correct entry ↳ *Chapter 1.4.1.3.6 “Intellisense function” on page 295*.

Type: The alarm types listed in the following can be used. For each type regard the appropriate comment regarding the definitions to be done in the area beyond the table !

- DIG=0 Digital alarm, active as soon as the expression gets FALSE.
- DIG=1 Digital alarm, active as soon as the expression gets TRUE.
- LOLO Analog alarm, active as soon as the value of the expression falls below the Value defined for Alarm type LOLO. You can define a tolerance (Deadband). As long as the expression value is within the dead band, no alarm will be activated, even if the LOLO-value has been falling below the limit.
- LO corresponding to LOLO
- HI Analog alarm, active as soon as the expression exceeds the Value defined for Alarm type HIHI. You can define a tolerance (Deadband). As long as the expression value is within the dead band, no alarm will be activated, even if the HI value has exceeded the limit.
- HIHI corresponding to HI
- DEV- Deviation from the target value; Alarm gets active as soon as the value of the expression falls below the value defined for Alarm type DEV- plus the percentage deviation. Percentage deviation = target value * (deviation in %) / 100.
- DEV+ Deviation from the target value); Alarm gets active as soon as the value of the expression exceeds the value defined for Alarm type DEV+ plus the percentage deviation. Percentage deviation = target value * (deviation in %) / 100.
- ROC Rate of Change per time unit; Alarm gets active as soon as the expression deviates strongly from the previous value. The limit value for activating an alarm is defined by the number of value changes (Rate of changes) per second, minute or hour (units per).

Class: Choose the desired alarm class. The selection list will offer all classes which have been defined in the alarm class configuration before the last saving of the project ↳ *Chapter 1.4.1.4.2.3 “Alarm classes” on page 364*.

Priority: Here you can define a priority level 0-152. 0 is the highest priority. The priority will impinge on the sorting of the alarms within the alarm table.

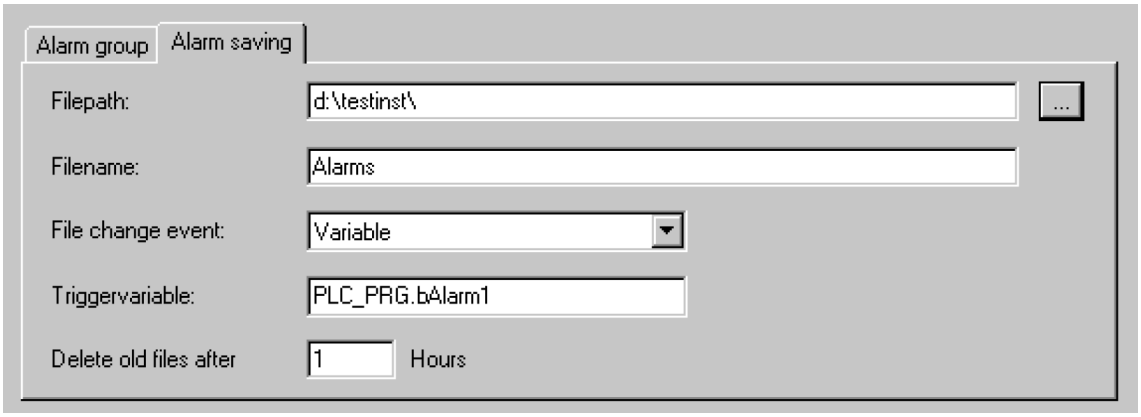
Message: Define here the text for the message box, which will appear in case of an alarm. This box must be confirmed by the user with OK, but this OK will not automatically acknowledge the alarm ! For confirming (acknowledge) the alarm the alarm table must be accessed. This is possible via the visualization element alarm table or via the date of the alarm entry in the table. This date can be read from a log file which can be created optionally. Regard that, when visualizing the alarms in an alarm table element in a visualization, the message text defined here might be overwritten by a corresponding text entry from an language file in xml-format, which is specified in the visualization for the purpose of dynamic language switching ↳ *Chapter 1.4.3.8.3 “Dynamic language switching” on page 709*.

Deactivation: Here a project variable can be entered, which at a rising edge will deactivate any creation of the alarm. Regard however, that this setting Alarm group' will be overwritten by the entry which might be found in the field 'Deactivation variable'.

Alarm saving

For each alarm group a file can be defined, in which the alarm events are stored, if (!) a 'Save' action has been assigned to the class in the alarm class configuration dialog ↳ *Chapter 1.4.1.4.2.3 “Alarm classes” on page 364*.

Select the alarm group in the configuration tree and open the dialog tab 'Alarm saving':



The following definitions are possible:

- Filepath: Directories path of the file which is defined in Filename; via button "..." you get the standard dialog for selecting a directory. If the target-specific option 'Alarmhandling on PLC' is activated, this path will be ignored an the file will be saved in the download directory of the PLC *Chapter 1.4.1.4.7.3 “Target settings in category visualization” on page 388*.
- Filename: Name of the file which should save the alarm events (e.g. "alarmlog"). Automatically a file will be created which gets the name defined here plus an attached digit and which has the extension ".alm". The digit indicates the version of the log-file. The first file gets a "0"; each further file, which will be created according to the defined File change event, will be numbered with 1, 2 etc. (Examples: "alarmlog0.alm", "alarmlog1.alm).
- File change event: Define here the event which will cause the creation of a new file for alarm-saving. Possible entries: Never, after one Hour, after one Day, after one Week, after one Month, at a rising edge of the variable defined in field Triggervariable, when the number of records in the file as defined in Number of records gets exceeded.
- Triggervariable resp. Number of records: see above, File change event.
- Delete old files after .. Hours: Number of days since the day of creation, after which all alarm log-files except from the actual one should be deleted.

The log-file (History) contains the following entries:

See the column types and exemplary entries for two alarms.

Date/ Time in DWORD	Date	Time	Event	Expression	Alarm type	Limit	Tolerance	Current value	Class	Priority	Message
10469 63332	6.3.03	16:08: 52	INTO	PLC_ PRG. b	LO	-30	5	-31	Alarm _high	0	Tem- pera- ture !
10469 63333	6.3.03	16:08: 53	ACK	PLC_ PRG. n	HIHI	35			Warnn g	9	Rising Temp. !

Example appearance of the log-file	1046963332,6.3.03 16:08:52,INTO,PLC_PRG.ivar5,HIHI,,,, 9.00,a_class2,0, 1046963333,6.3.03 16:08:53,INTO,PLC_PRG.ivar4,ROC,2,,, 6.00,a_class2,2, 1046963333,6.3.03 16:08:53,INTO,PLC_PRG.ivar3,DEV-,,,, -6.00,a_class2,5, 1046963334,6.3.03 16:08:54,INTO,PLC_PRG.ivar2,LOLO,-35,,3, -47.00,warning,10,warning: low temperature ! 1046963334,6.3.03 16:08:54,INTO,PLC_PRG.ivar1,HI,20,,5, 47.00,a_class1,2,temperature to high ! Acknowledge !

Alarm configuration 'Extras' 'Settings'

The dialog Alarm configuration settings opens on the command 'Extras' 'Settings' in the Alarm Configuration:

Category date/ time

Here you set the formatting for the representation of the alarms in the log-file. Define the format according to the following syntax. Dashes and colons are to be set in inverted commas:

for date: dd'-'MM'-'yyyy -> e.g. "12.Jan-1993"

for time: hh':'mm':'ss (12-hours format) -> e.g. "01:10:34" or HH':'mm':'ss (24-hours format) -> e.g. "13:10:34"

Language

The usage of this dialog corresponds to that used for doing the language settings of a visualization object ↳ *Chapter 1.4.3.8 “Language switching” on page 706*.

Choose here a language file (*.vis or *.tlt) which should be used for the alarm configuration texts when the Option for the desktop is changed ↳ *Chapter 1.4.1.2.2.5 “Options for the desktop” on page 205*. Make sure that for this purpose the language file i.a. contains the translations for the text strings of the alarm configuration. See also: 'Project' 'Translate into another language' ↳ *Chapter 1.4.1.2.3.15 “'Project' 'Translate into another language'” on page 233*.

Alternatively you can define dynamic language switching by specifying a special language file in xml-format, like it is used for visualization elements. Note however that the actual settings only concern the display of the alarm messages. If the alarm configuration is visualized by an alarm table element in a visualization object, there the separate visualization language settings will be valid!

Online

Deactivate alarm evaluation in online mode: If this online setting is set, there will be no alarm handling in online mode. This means that no alarm evaluation corresponding to the current alarm configuration will be done and no alarms will be displayed. This might be desired in certain environments in order to save computing time.

1.4.1.4.3 Library manager

Overview

The library manager shows all libraries that are connected with the current project. The POUs, data types, and global variables of the libraries can be used the same way as user-defined POUs, data types, and global variables.

The library manager is opened with the 'Window' 'Library Manager' command. Information concerning included libraries is stored with the project and can be viewed in the dialog 'Informations about external library'. To open this dialog select the corresponding library name in the library manager and execute the command 'Extras' 'Properties'.

Libraries can contain pragma instructions in the declaration part, which effect that when the library is included in a project, not the complete declaration part gets displayed ↳ *Chapter 1.4.1.3.10.3 “Pragmas for controlling the display of library declaration parts” on page 312*. Thus particular variable declarations or comments can be "concealed" from the user.

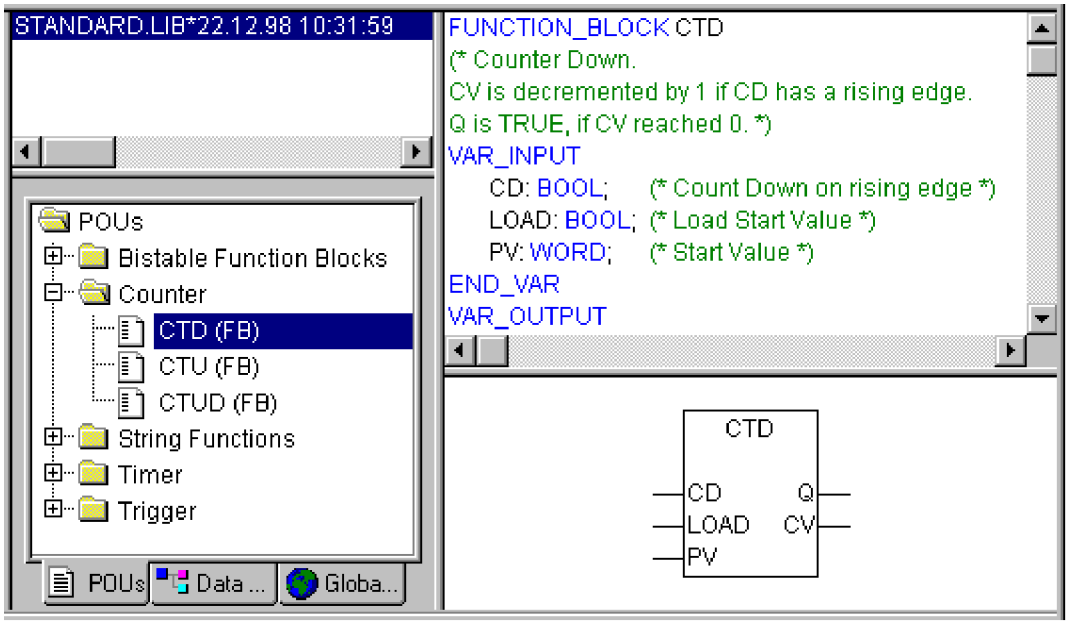
The window of the library manager is divided into areas by screen dividers. The libraries attached to the project are listed in the upper left area.

Depending on which register card has been selected, there is a listing of the POUs , Data types, Visualizations or Global variables of the library selected in the upper area. Folders are opened and closed by doubleclicking the line or pressing <Enter>.

There is a plus sign in front of closed folders, and a minus sign in front of opened folders.

If a POU is selected by clicking the mouse or selecting with the arrow keys then the declaration of the POU will appear in the upper right area of the library manager; and in the lower right is the graphic display in the form of a black box with inputs and outputs.

With data types and global variables, the declaration is displayed in the right area of the library manager.



See also:

Standard library *Chapter 1.4.1.4.3.2 “Standard library” on page 372*

User-defined libraries *Chapter 1.4.1.4.3.3 “User-defined libraries” on page 372*

'Insert' 'Additional Library' *Chapter 1.4.1.4.3.4 “'Insert' 'Additional Library'” on page 373*

Standard library

The library with "standard.lib" is always available. It contains all the functions and function blocks which are required from the IEC61131-3 as standard POUs for an IEC programming system. The difference between a standard function and an operator is that the operator is implicitly recognized by the programming system, while the standard POUs must be tied to the project (standard.lib).

The code for these POUs exists as a C-library.

User-defined libraries

If a project is to be compiled in its entity and without errors, then it can be saved in a library with the 'Save as' command in the 'File' menu. The project itself will remain unchanged. An additional file will be generated, which has the default extension ".lib". This library afterwards can be used and accessed like e.g. the standard library.

For the purpose to have available the POUs of a project in other projects, save the project as an Internal Library *.lib. This library afterwards can be inserted in other projects using the library manager.

Regard the possibility to define via pragmas to what extent the declaration part of the library should be visible in the Library Manager when the library has been included in a project.

If you have implemented POUs in other programming languages, e.g. C, and want to get them into a library, then save the project using data type External Library *.lib). You will get the library file but additionally a file with the extension "*.h". This file is structured like a C header file and contains the declarations of all POUs, data types and global variables, which are available with the library. If an external library is used in a project, then in simulation mode that implementation of the POUs will be executed; but on the target the C-written implementation will be processed.

If you want to add licensing information to a library, then press button Edit license info... and insert the appropriate settings in the dialog 'Edit Licensing Information'.

'Insert' 'Additional Library'

With this command you can attach an additional library to your project.

The command opens the dialog for opening a file. If the currently set directory does not contain the desired library, you can select another directory in field Library directory where all directories will be offered, which are defined in 'Project' 'Options' 'Directories' 'Libraries' (File type "*.lib"). Choose the desired library - multiple selection is possible - and confirm with OK. The dialog will close and the library gets inserted to the Library Manager. Now you can use the objects of the library in the project like user-defined objects.

Library paths

Regard which libraries directories are currently defined in the project options ↳ *Chapter 1.4.1.2.2.7 “Options for directories” on page 207*. If you insert a library from a directory which is not defined there, the library will be entered with the respective path.

Example: You insert library standard.lib from directory "D:\codesys\libraries\standard".

- If this directory is defined in the project options, the entry in the library manager will be: "standard.lib <date and time of file>".
- If in the project options there is just defined a directory "D:\codesys\libraries", then the entry in the library manager will be: "standard\standard.lib <date and time of file>".
- If no matching directory at all is defined in the project options, then the complete path will be entered: "D:\codesys\libraries\standard\standard.lib <date and time of file>".

When re-opening the project the libraries will be searched according to entries in the library manager. So for example, if just the library file name is entered there, the library will be searched in the libraries directories defined in the project options.

If libraries are not found when opening a project, you will be asked whether you want to change the library directory defined in the project options. If you say no, a dialog will open providing information on the libraries not found and the respective entries in the Library Manager will be displayed red-colored. In this case you can select a red entry and choose command *“Search”* from the context menu. Thus you will get the dialog for opening a file where you can browse for the missing library and reload it immediately.

Licensing

As soon as you include a library for which a license is needed and no valid license is found, you may get a message that the library is only available in demo mode or that the library is not licensed for the currently set target. You can ignore this message at that time or start appropriate actions concerning the license. An invalid license will produce an error during compile ↳ *Chapter 1.4.1.2.3.11 “'Project' 'Build'” on page 231*. In this case a doubleclick on the error message resp. <F4> will open the dialog 'License information' where you can start the appropriate actions guided by a wizard ↳ *Chapter 1.4.6.1 “Overview” on page 733*.

1.4.1.4.4 Log

Overview

The log stores in chronological order actions that occur during an Online session. For this purpose a binary log file (*.log) is set up. Afterward, the user can store excerpts from the appropriate project log in an external log.

The log window can be opened in either Offline or Online mode and can thus serve as a direct monitor online.

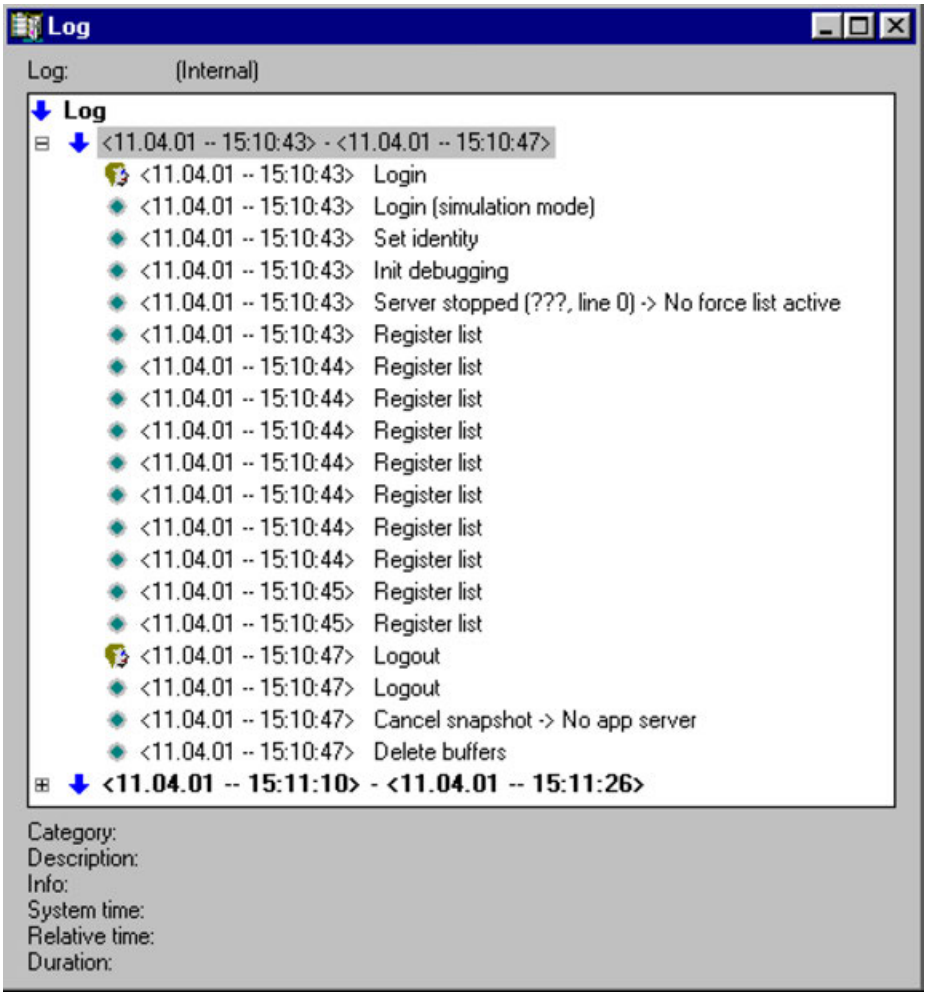
See also:

'Window' 'Log' ↳ *Chapter 1.4.1.4.4.2 “'Window' 'Log'” on page 374*

Menu Log ↳ *Chapter 1.4.1.4.4.3 “Menu log” on page 375*

'Window' 'Log'

To open, select the menu item 'Window' 'Log' or select entry 'Log' in the Resources tab.



In the log window, the file name of the currently displayed log appears after Log. If this is the log of the current project, the word "(Internal)" will be displayed.

Registered entries are displayed in the log window. The newest entry always appears at the bottom.

Only actions belonging to categories that have been activated in the 'Filter' field of the menu 'Project' 'Options' 'Log' will be displayed ↳ *Chapter 1.4.1.2.2.8 “Options for log” on page 208*.

Available information concerning the currently selected entry is displayed below the log window.

Category: The category to which the particular log entry belongs. The following four categories are possible:

- User action: The user has carried out an Online action (typically from the Online menu).
- Internal action: An internal action has been executed in the Online layer (e.g. Delete Buffers or Init debugging).
- Status change: The status of the runtime system has changed (e.g. from Running to Break, if a breakpoint is reached).
- Exception: An exception has occurred, e.g. a communication error.

Description: The type of action. User actions have the same names as their corresponding menu commands; all other actions are in English and have the same name as the corresponding `OnlineXXX()` function.

Info: This field contains a description of an error that may have occurred during an action. The field is empty if no error has occurred.

System time: The system time at which the action began, to the nearest second.

Relative time: The time measured from the beginning of the Online session, to the nearest millisecond.

Duration: Duration of the action in milliseconds.

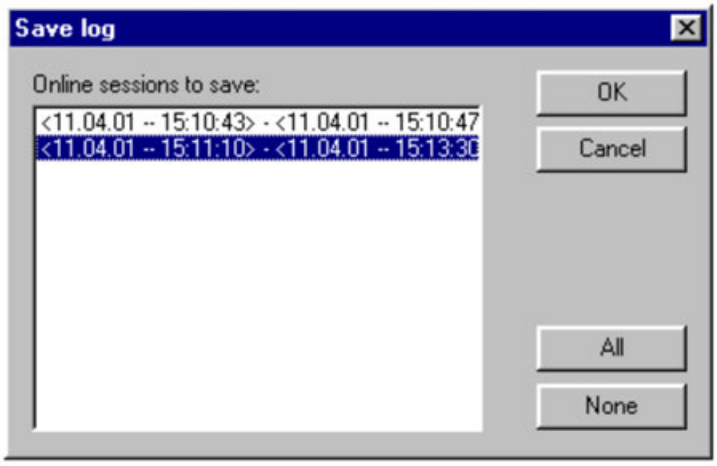
Menu log

When the log window has the input focus, the menu option Log appears in the menu bar instead of the items 'Extras' and 'Options'.

The menu includes the following items:

Load: An external log file *.log can be loaded and displayed using the standard file open dialog. The log that is present in the project will not be overwritten by the command. If the log window is closed and later opened again, or a new Online session is started then the version that is loaded will again be replaced by the project log.

Save: This menu item can only be selected if the project log is currently displayed. It allows an excerpt of the project log to be stored in an external file. For that, the following dialog will be displayed, in which the Online sessions to be stored can be selected:



After successful selection, the standard dialog for storing a file opens ('Save Log').

Display Project Log: This command can only be selected if an external log is currently displayed. It switches the display back to the project log

1.4.1.4.5 PLC browser

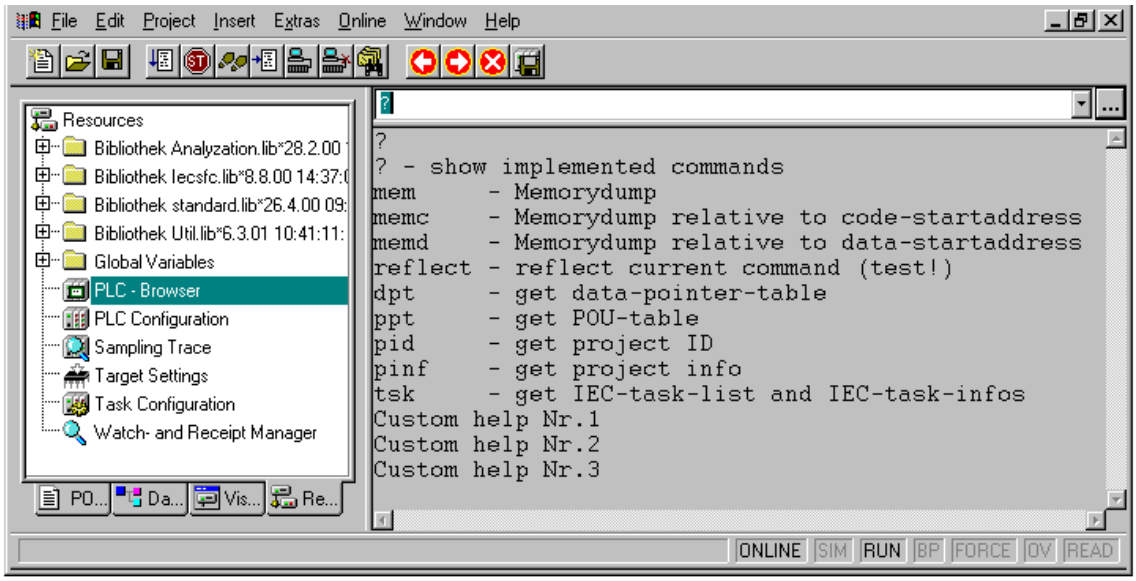
Overview

The PLC browser is a text-based control monitor (terminal). Commands for the request of specific information from the controller are entered in an entry line and sent as string to the controller. The returned response string is displayed in a result window of the browser. This functionality serves diagnostic- and debugging purposes.

↳ *Chapter 1.4.1.4.5.3 “Command entry in the PLC browser” on page 376*

General remarks concerning PLC browser operation

Select the entry PLC-Browser in the Resources tab-control. It will be available there if it is activated in the current target settings (category networkfunctionality).



The browser consists of a command entry line and a result/display window.

In a selection box the input line displays a list of all the commands entered since the start of the project (input history). They are available for re-selection until the project is closed. Only commands, which differ from those already existing, are added to the list.

The entered command is sent to the controller with *[Enter]*. If there is no Online connection, the command is displayed in the result window in the same way as it is sent to the controller, otherwise the response from the controller is shown there. If a new command is sent to the controller, the content of the result window is deleted.

Commands can be entered in the form of command strings, the use of macros is possible as well ↳ *Chapter 1.4.1.4.5.3 “Command entry in the PLC browser” on page 376* ↳ *Chapter 1.4.1.4.5.4 “Use of macros during the command entry in PLC-browser” on page 378*.

Command entry in the PLC browser

Basically the PLC browser makes available the standard commands hard-coded in the runtime system. It is concerned with functions for direct memory manipulation, for the output of project- and status functions as well as for runtime monitoring. They are described in the browser's ini-file, which is an integral part of the Target Support Package. These standard commands can be further supplemented by specialized ones, e.g. self-diagnostic functions or other status messages of the control application. The expansion of the command list must be carried out both in the customer interface in the runtime system as well as through additional entries in the Browser ini-file.

When opening the project the command list available in the PLC browser is generated based on the entries in the Browser ini-file. It can be accessed as input help using the *[...]* key in the dialog "Insert standard command" or using *[F2]*. Also the command 'Insert' 'Standard commands' can be used to get the command list. A command can be typed in manually to the command line or it can be selected from the list by a double-click on the appropriate entry.

The general command syntax is:

<KEYWORD><LEER><KEYWORD-DEPENDEND PARAMETERS>

The keyword is the command. With which parameters it can be expanded is described in the respective tooltip in the entry help window.

The command, which has been sent, is repeated in the output data window, the controller's response appears below it.

Example

Request for the project Id from the controller with the command "pid"

Entry in command line:

```
pid
```

Output in result window:

```
pid
Project-ID: 16#0025CFDA
```

A help text can be supplied for each standard command with ?<BLANK><KEYWORD>. This is similarly defined in the ini-file.

The following commands are firmly integrated in the runtime system and contained in the ini-file with the corresponding entries for entry help, tooltips and help:

Command	Description
?	The runtime system supplies a list of the available commands. The list is independent of the status of the description files of the target system.
mem	Hexdump of a memory area Syntax 1: mem <start address> <end address> Addresses can be entered decimal, hexadecimal (Prefix 16#) or as a macro.
memc	Hexdump relative to the start address of the code in the controller; like mem, the data are added to the code area start address.
memd	Hexdump relative to the data base address in the controller; like mem, the data are added to the data area start address.
reflect	Reflect current command line, for test purposes.
dpt	Read and display data-pointer table.
ppt	Read and display POU table.
pid	Read and display project Id.
pinf	Read and display project info (see 'Project' 'Project Info').
tsk	Show list of IEC-tasks incl. task infos defined in the project.
startprg	Start PLC program ('Online' 'Start').
stopprg	Stop PLC program ('Online' 'Stop').
resetprg	Reset PLC program. Only not-retentive data get initialized. ('Online' 'Reset).

Command	Description
resetprgcold	Reset PLC program cold. Retentive data also get initialized. ('Online' 'Reset (cold)').
resetprgorg	Reset PLC program original. The current application program as well as all data (incl. retentive and persistent) are deleted.
('Online' 'Reset (origin)').	
reload	Reload boot project.
getprgprop	Read and display program properties (Name, title, version author, date).
getprgstat	Read and display program status (e.g. "run", "stop", last error, flags)
filedir	File command "dir". List of files in the PLC directory.
filecopy	Copy file [from] [to]. Example: "filecopy filename.txt filename2.txt".
filerename	Rename files on PLC [old] [new]. Example: filerename oldname.txt newname.txt".
filedelete	Delete file on PLC; Example: "filedelete file.xml".
saveretain	Save retain variables. The name of the save file will be displayed afterwards.
restoreretain	Load retain variables. The name of the save file, from which the variables values are restored, will be displayed.
setpwd	Set password on controller; Syntax: setpwd <password> [level], e.g. "setpwd abcde 0" <level> can be "0" (default) just valid concerning logins from the programming system, or "1" valid for all applications
delpwd	Delete password on PLC.

Please regard:

- The first word of the command sequence entered is interpreted as keyword (<KEYWORD>).
- If the first word of the command entry is not recognized by the controller, the response 'Keyword not found' will appear in the result window.
- If a keyword is preceded by a "?<SPACE>" (e.g. "? mem"), the ini-file will be searched for the existence of a help section to this keyword. If one is available, nothing is sent to the controller, but only the help text is displayed in the output data window.

Use of macros during the command entry in PLC-browser

If a command associated with a macro is entered in the command line, this is expanded before it is sent to the controller. Then the response in the result window appears in a similarly expanded form.

The entry syntax is: <KEYWORD><macro>

<KEYWORD> is the command.

Macros

%P<NAME>	If NAME is a POU-name, the expression is expanded to <POU-Index>, otherwise there is no alteration
%V<NAME>	If NAME is a variable name, the expression is expanded to #<INDEX>:<OFFSET>, otherwise there is no alteration (this notation #<INDEX>:<OFFSET> is interpreted by the controller as a memory address)
%T<NAME>	If NAME is a variable name, the expression is expanded to <VARIABLENTYP>, otherwise there is no alteration.
%S<NAME>	If NAME is a variable name, the expression is expanded to <SIZEOF(VAR)>, otherwise there is no alteration.

The % character is ignored if the escape symbol \ (Backslash) is placed in front. The escape symbol as such is only transmitted if written \\.

Example

Entry in command line: (memory dump of the variable .testit ?)

```
mem %V.testit
```

Output in result window:

```
mem #4:52
03BAAA24 00 00 00 00 CD CD CD CD ....ÍÍÍÍ
```

Further PLC browser options

In the 'Extras' menu or in the PLC browser's toolbar there are the following commands for handling the command entry or history list:

With 'History forward' and 'History backward' you scroll backwards and forwards through the query results already carried out. The history recording is continued until you leave the project.

With 'Cancel' you break off a query which has been initiated.

With 'Save history list' you save the query results carried out up until that point in an external text file. The dialogue 'Save file as' will appear, in which you can enter a file name with the extension „.bhl" (Browser History List).

'Print last command' opens the standard dialogue to print. The current query plus the output data in the message window can be printed.

1.4.1.4.6 Sampling trace

Overview and configuration

Overview

Sample tracing will be available as an object in the resources, if it is activated in the target settings (category 'General'). It can be used to trace the progression of values for variables is traced over a certain time. These values are written in a ring buffer (trace buffer). If the memory is full, then the "oldest" values from the start of the memory will be overwritten. As a maximum, 20 variables can be traced at the same time. A maximum of 500 values can be traced per variable.

Since the size of the trace buffer in the PLC has a fixed value, in the event of very many or very wide variables (DWORD), fewer than 500 values can be traced.

Example

If 10 WORD variables are traced and if the memory in the PLC is 5000 bytes long, then, for every variable, 250 values can be traced.

In order to be able to perform a trace, open the object for a 'Sampling Trace' in the 'Resources' register card in the Object Organizer *Chapter 1.4.1.2.1.3 “Object organizer” on page 199*. Create or load an appropriate trace configuration and define the variables to be traced.

After you have created the configuration and have started the trace in the PLC with 'Start Trace', then the values of the variables will be traced. With 'Read Trace', the final traced values will be read out and displayed graphically as curves *Chapter 1.4.1.4.6.2.1 “'Extras' 'Start Trace'” on page 382* *Chapter 1.4.1.4.6.2.2 “'Extras' 'Read Trace'” on page 382.

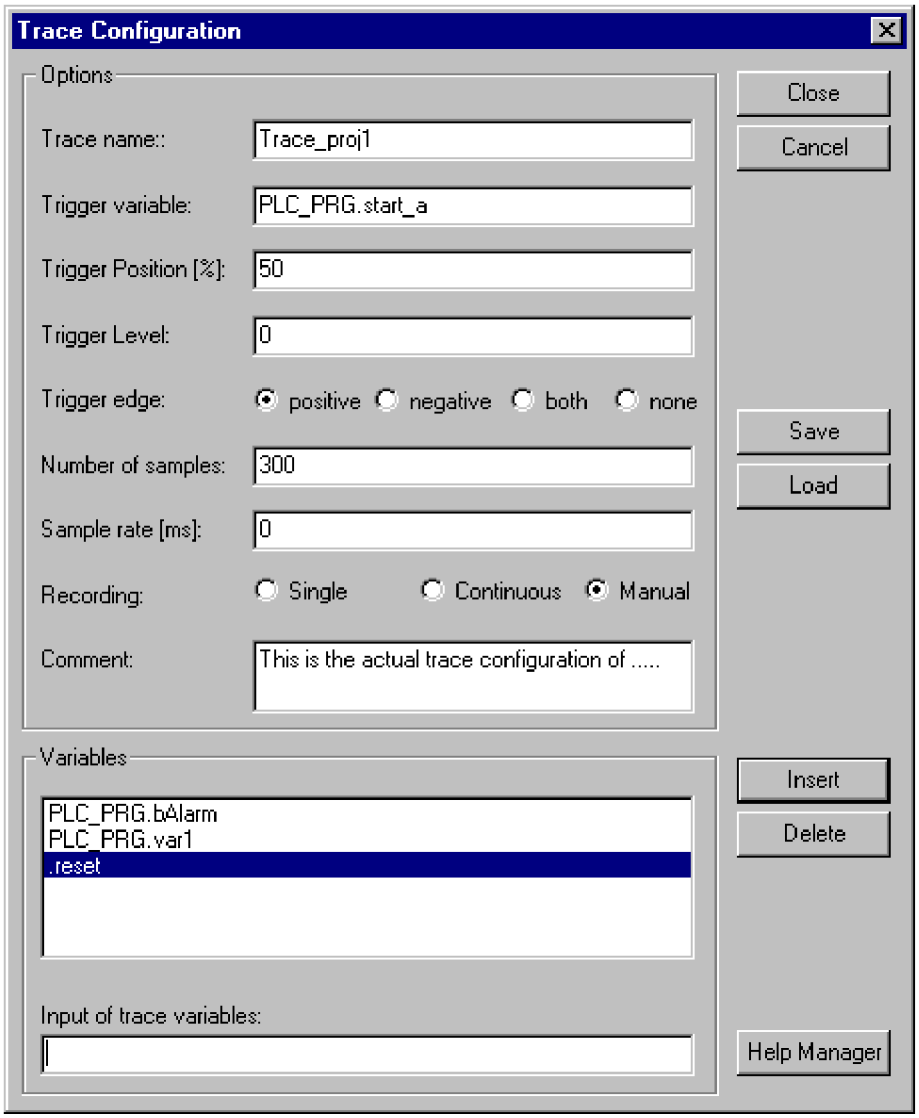
A Trace (variable values and configuration) can be saved and reloaded in project format (*.trc) or in XML format (*.mon). Just the configuration can be stored and reloaded via a *.tcf-file.

Various traces can be available in a project for getting displayed. They are listed in a selection list ('Trace') in the upper right corner of the trace window. You can select one of those to be the currently used trace configuration.

If a task configuration is used for controlling the program, the trace functionality refers to the debug task *Chapter 1.4.1.4.8.1 “Overview” on page 390.*

'Extras' 'Trace Configuration'

With this command you will be given the dialog box for entering the variables to be traced, as well as diverse trace parameters for the Sampling Trace. The dialog can also be opened by a double click in the grey area of the dialog Sampling Trace.



First define a name for the trace configuration (Trace Name). This name will be added to the selection list 'Trace' in the upper right corner of the Trace window, as soon as you have confirmed and closed the configuration dialog with OK. Optionally enter a comment.

The list of the Variables to be traced is initially empty. In order to append a variable the variable must be entered in the field under the list. Following this, you can use the Add button or the *[Enter]* to append the variable to the list. You can also use the input assistant ↬ *Chapter 1.4.1.2.5.11 "'Edit' 'Input assistant'" on page 276*. The use of enumeration variables is possible.

A variable is deleted from the list when you select the variable and then press the *[Delete]* button.

A Boolean or analog variable (also an enumeration variables) can be entered into the field Trigger Variable. The input assistance can be used here. The trigger variable describes the termination condition of the trace.

In Trigger Level you enter the level of an analog trigger variable at which the trigger event occurs. You also can use an ENUM constant here. When Triggeredgepositive is selected the trigger event occurs after an ascending edge of the Boolean trigger variable or when an analog variable has passed through the trigger level from below to above. Negative causes triggering after a descending edge or when an analog variable went from above to below. Both causes triggering for both descending and ascending edges or by a positive or negative pass, whereas none does not initiate a triggering event at all.

Trigger Position is used to set the percentage of the measured value which will be recorded before the trigger event occurs. If, for example, you enter 25 here then 25% of the measured values are shown before the triggering event and 75% afterwards and then the trace is terminated.

The field Sample Rate is used set the time period between two recordings in milliseconds resp., if supported by the target system, in microseconds. The default value "0" means one scanning procedure per cycle.

Select the mode for recalling the recorded values: With Single the Number of the defined samples are displayed one time. With Continuous the reading of the recording of the defined number of measured values is initiated anew each time. If, for example, you enter the number '35' the first display contains the first measured values 1 to 35 and the recording of the next 35 measured values (36-70) will then be automatically read, etc.Manual selection is used to read the trace recordings specifically with 'Extras' 'Read Trace' ↳ *Chapter 1.4.1.4.6.2.2 “'Extras' 'Read Trace'” on page 382*.

The recall mode functions independently of whether a trigger variable is set or not. If no trigger variable is set the trace buffer will be filled with the defined number of measured values and the buffer contents will be read and displayed on recall.

[Save] is used to store the trace configuration which has been created in a file. The standard window "File save as" is opened for this purpose.

Stored trace configurations can be retrieved using *[Load]*. The standard window "File open" is opened for this purpose.

[Save] and [Load] in the configuration dialog only relates to the configuration, not to the values of a trace recording (in contrast to the menu commands 'Save Values' and 'Load Trace' ↳ *Chapter 1.4.1.4.6.4.1 “'Save Values'” on page 385 ↳ Chapter 1.4.1.4.6.4.2 “'Load Values'” on page 385**).*

If the field Trigger Variable is empty, the trace recording will run endlessly and can be stopped by 'Extras' 'Stop Trace' ↳ *Chapter 1.4.1.4.6.2.4 “'Extras' 'Stop Trace'” on page 383*.

Selection of the variables to be displayed

The comboboxes to the right, next to the window for displaying curves trace variables defined in the trace configuration. If a variable is selected from the list, then after the trace buffer has been read the variable will be displayed in the corresponding color (Var 0 green, etc.). Variables can also be selected if curves are already displayed.

A maximum of up to eight variables can be observed simultaneously in the trace window.

Generating a trace sampling

'Extras' 'Start Trace'

Symbol:

With this command the trace configuration is transferred to the PLC and the trace sampling is started in the PLC.

'Extras' 'Read Trace'

Symbol

With this command the present trace buffer is read from the PLC, and the values of the selected variables are displayed.

'Extras' 'Auto Read'

With this command the present trace buffer is read automatically from the PLC, and the values are continuously displayed.

If the trace buffer is automatically read, then a check (ü) is located before the menu item.

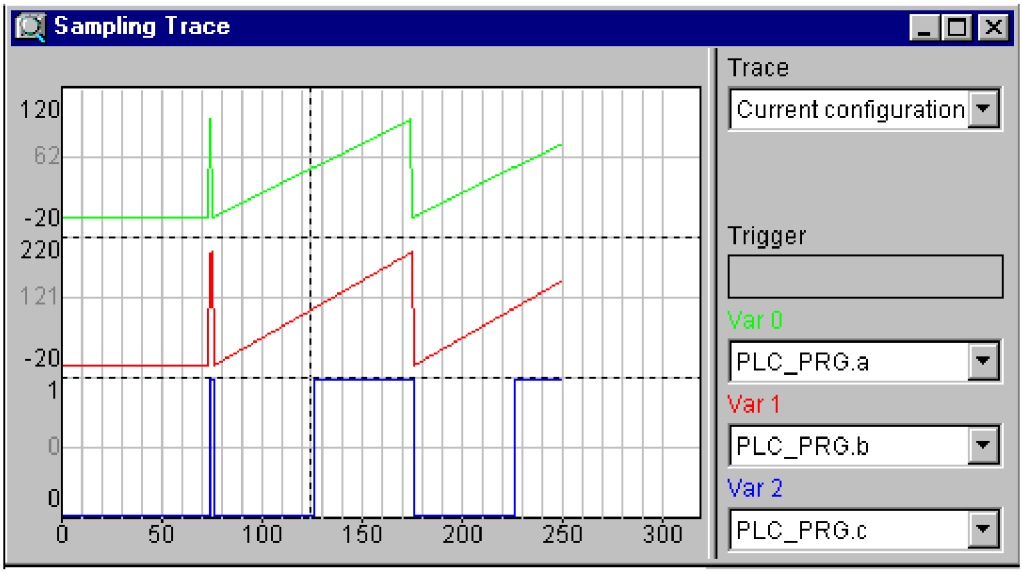
'Extras' 'Stop Trace'

Symbol:

This command stops the Sampling Trace in the PLC.

Looking at the trace sampling

Display of the sampling trace



If a trace buffer is loaded (), then the values of all variables to be displayed can be read out ('Extras' 'Read Trace' or 'Extras' 'AutoRead') and will be displayed accordingly ↳ *Chapter 1.4.1.4.6.2.1 "'Extras' 'Start Trace'" on page 382* ↳ *Chapter 1.4.1.4.6.2.2 "'Extras' 'Read Trace'" on page 382* ↳ *Chapter 1.4.1.4.6.2.3 "'Extras' 'Auto Read'" on page 382*. If no scan frequency has been set, then the X axis will be inscribed with the continuous number of the traced value. The trace buffer will be deleted as soon as the trace sampling is stopped ↳ *Chapter 1.4.1.4.6.2.4 "'Extras' 'Stop Trace'" on page 383*.

The status indicator of the trace window (first line) indicates whether the trace buffer is full and when the trace is completed.

If a value for the scan frequency was specified, then the x axis will specify the time of the traced value. The time is assigned to the "oldest" traced value. In the example, e.g., the values for the last 25 seconds are indicated.

The Y axis is inscribed with values in the appropriate data type. The scaling is laid out in a way that allows the lowest and the highest value to fit in the viewing area. In the example, Var 0 has taken on the lowest value of 6, and the highest value of 100: hence the setting of the scale at the left edge.

If the 'Extras' 'Trace Configuration' ↳ *Chapter 1.4.1.4.6.1.2 "'Extras' 'Trace Configuration'" on page 380* is met, then a vertical dotted line is displayed at the interface between the values before and after the appearance of the trigger requirement.

'Extras' 'Cursor Mode'

The easiest way to set a cursor in the monitoring area is to click there with the left mouse button. A cursor appears and can be moved by the mouse. At the top of the monitoring window the current x-position of the cursor is displayed. In the fields next to 'Var 0', 'Var 1', ..., 'Var n' the value of the respective variable is shown.

Another way is the command 'Extras' 'Cursor mode'. With this command two vertical lines will appear in the Sampling Trace. First they are laying one on the other. One of the lines can be moved to the right or to the left by the arrow keys. By pressing *[Ctrl]* + *[left]* or *[Ctrl]* + *[right]* the speed of the movement can be increased by factor 10.

If additionally *[Shift]* is pressed, the second line can be moved, showing the difference to the first one.

'Extras' 'Multi Channel'

With this command you can alternate between single-channel and multi-channel display of the Sampling Trace. In the event of a multi-channel display, there is a check (ü) in front of the menu item.

The multi-channel display has been preset. Here the display window is divided into as many as eight display curves. For each curve the maximum and the minimum value are displayed at the edge.

In a single-channel display, all curves are displayed with the same scaling factor and are superimposed. This can be useful when displaying curve abnormalities.

'Extras' 'Show grid'

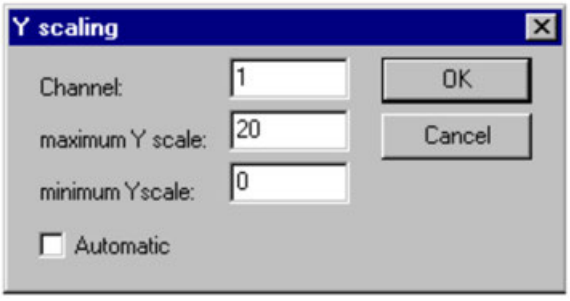
With this command you can switch on and off the grid in the graphic window. When the grid is switched on, a check symbol will appear next to the menu item.

'Extras' 'Y Scaling'

With this command you can change the preset Y scaling of a curve in the trace display. By doubleclicking on a curve you will also be given the dialog box 'Y-scaling'.

As long as option Automatic is activated, the default scaling will be used, which depends on the type of the used variable. In case of enumeration variables the enumeration values will be displayed at the scale. In order to change the scaling, deactivate option 'Automatic' and enter the number of the respective curve (Channel) and the new maximum (maximum y scale) and the new minimum value (minimum y scale) on the y axis.

The channel and the former value are preset.



'Extras' 'Stretch'

Symbol:

With this command you can stretch (zoom) the values of the Sampling Trace that are shown. The beginning position is set with the horizontal picture adjustment bar. With repeated stretches that follow one-after-another, the trace section displayed in the window will increasingly shrink in size.

This command is the counterpart to 'Extras' 'Compress' ↳ *Chapter 1.4.1.4.6.3.7 “'Extras' 'Compress'” on page 385*.

'Extras' 'Compress'

Symbol:

With this command the values shown for the Sampling Trace are compressed; i.e., after this command you can view the progression of the trace variables within a larger time frame. A multiple execution of the command is possible.

This command is the counterpart to 'Extras' 'Stretch' ↳ *Chapter 1.4.1.4.6.3.6 “'Extras' 'Stretch'” on page 384*.

'Extras' 'Save trace values'

Use the commands of this menu to save traces (configuration + values) to files resp. to reload them from files to the project. Besides that a trace can be saved in a file in ASCII format.

*Regard the alternative way of storing and reloading traces by using the commands of menu 'Extras' 'External Trace Configurations' (XML format, *.mon-Datei)* ↳ *Chapter 1.4.1.4.6.5 “'Extras' 'External Trace Configurations'” on page 386!*

'Save Values'

With this command you can save a Sampling Trace (values + configuration data). The dialog box for saving a file is opened. The file name receives the extension "*.trc".

Be aware, that here you save the traced values as well as the trace configuration, whereas Save trace in the configuration dialog only concerns the configuration data.

The saved Sampling Trace can be loaded again with 'Load Trace' ↳ *Chapter 1.4.1.4.6.4.2 “'Load Values'” on page 385*.

Regard the alternative way of saving a trace by using the commands of menu 'Extras' 'External Trace Configurations' ↳ *Chapter 1.4.1.4.6.5 “'Extras' 'External Trace Configurations'” on page 386.*

'Load Values'

With this command a saved Sampling Trace (traced values + configuration data) can be reloaded. The dialog box for opening a file is opened. Select the desired file with the "*.trc" extension.

With 'Save Values' you can save a Sampling Trace ↳ *Chapter 1.4.1.4.6.4.1 “'Save Values'” on page 385*.

'Trace in ASCII-File'

With this command you can save a Sampling Trace in an ASCII file. The dialog box for saving a file is opened. The file name receives the extension "*.txt". The values are deposited in the file according to the following scheme:

BODAS Trace

D:\BODAS\PROJECTS\TRAFFICSIGNAL.PRO

Cycle PLC_PRG.COUNTER PLC_PRG.LIGHT1

0 2 1

1 2 1

2 2 1

.....

If no frequency scan was set in the trace configuration, then the cycle is located in the first column; that means one value per cycle has been recorded at any given time. In the other respects, the entry here is for the point in time in ms at which the values of the variables have been saved since the Sampling Trace has been run.

In the subsequent columns, the corresponding values of the trace variables are saved. At any given time the values are separated from one another by a blank space.

The appertaining variable names are displayed next to one another in the third line, according to the sequence (PLC_PRG.COUNTER, PLC_PRG.LIGHT1).

'Extras' 'External Trace Configurations'

Use the commands of this menu to save or reload traces (configuration + trace values) in files resp. from files, to load a trace from the controller to the project or to set a certain trace as that which should be used in the project.

*Regard the alternative way of storing and reloading traces by using the commands of menu 'Extras' 'Save trace values' (project format, *.trc-file, ASCII)*
↳ Chapter 1.4.1.4.6.4 “'Extras' 'Save trace values'” on page 385!

'Save to file'

With this command a trace (configuration + values) can be saved in a file in XML format. For this purpose the standard dialog for saving a file opens. Automatically the file extension *.mon will be used.

A *.mon-file can be reloaded to a project with command 'Load from file' *↳ Chapter 1.4.1.4.6.5.2 “'Load from File'” on page 386*.

*Regard the alternative way of storing and reloading traces by using the commands of menu 'Extras' 'Save trace values' (Project format, *.trc-Datei, ASCII)*
↳ Chapter 1.4.1.4.6.4 “'Extras' 'Save trace values'” on page 385!

'Load from File'

With this command a trace (configuration + values), which is available in a file in XML format (*.mon, can be loaded into the project. The dialog for opening a file will open and you can browse for files with extension *.mon. The loaded trace will be displayed and added to the selection list in field 'Trace in the configuration dialog. If you want to set it as currently used project trace configuration, use command 'Set as project configuration' *↳ Chapter 1.4.1.4.6.5.5 “Set as project configuration” on page 387*.

A *.mon-file can be created by using command 'Save to file' *↳ Chapter 1.4.1.4.6.5.1 “'Save to file'” on page 386*.

Regard the alternative way of saving a trace by using the commands of menu 'Extras' 'Save trace values' *Chapter 1.4.1.4.6.4 “'Extras' 'Save trace values'” on page 385.*

'Save to Target'

With this command in online mode a trace configuration, which is available in a file in XML format (*.mon), can be loaded into the controller (target).

The standard dialog for opening a file will be available, where per default files with extension *.mon will be displayed. Regard in this concern the possibility to save trace configurations in *.mon-files (XML format) *Chapter 1.4.1.4.6.5.1 “'Save to file'” on page 386*.

'Load from Target'

With this command the trace (configuration + values) which is currently used on the controller can be loaded to the project. It will be displayed in the trace window and can be set as project configuration *Chapter 1.4.1.4.6.5.5 “Set as project configuration” on page 387*.

Set as project configuration

With this command the trace configuration which is currently selected in the list of available traces (field 'Trace' in the trace window) can be set as active configuration within the project.

The selection list besides the currently used (top position) offers all traces which have been loaded to the project by command 'Load from file' from *.mon-files (e.g. for the purpose of viewing) *Chapter 1.4.1.4.6.5.2 “'Load from File'” on page 386*.

1.4.1.4.7 Target settings

Overview

The "Target Settings" is an object of the 'Resources'. Here you define, which target shall be used for the project and how it will be configured. If a new project is started with 'Project' 'New', a dialog will open where the target, that means a predefined configuration for a target, has to be set.

Dialog 'Target Settings'

The dialog 'Target Settings' will open automatically, when a new project is created. It also can be opened by selecting the menu item 'Target Settings' in the register 'Resources' in the Object Organizer.

Choose one of the target configurations offered at Configuration.

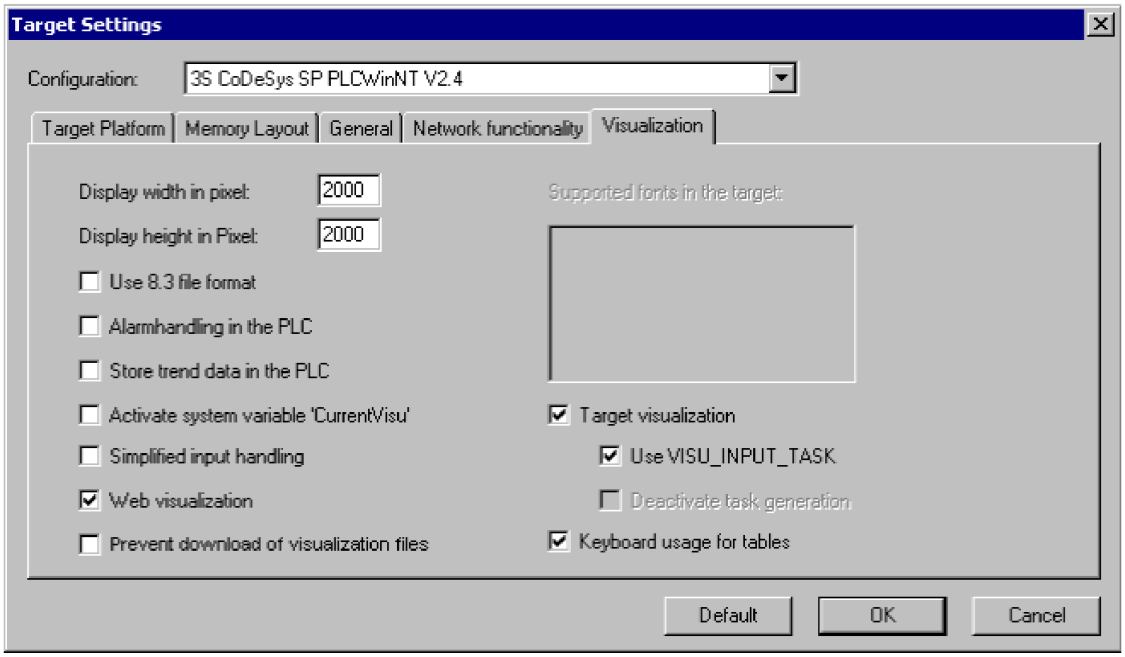
If you choose one of the installed configurations it depends on the entries in the target files, which possibilities are left to customize this configuration in the dialogs.

If a configuration is selected, which is provided with the entry "HideSettings" in the corresponding target file, you only can see the name of the configuration. Otherwise you can use the visualization dialog to modify the given configuration *Chapter 1.4.1.4.7.3 “Target settings in category visualization” on page 388*.

Please be aware, that each modification of the predefined target configuration can cause severe changes in performance and behavior of the target!

Press <Default> if you want to reset the target settings to the standard configuration given by the target file.

Target settings in category visualization



The items described for this tab can be available for each standard target.

Dialog item	Meaning
Display width in pixel Display height in pixel	An area of the given width and height will be displayed in the editor window when editing a visualization. Thus e.g. the size of the screen on which the target visualization will run later, can be regarded when positioning the visualization elements. Use 8.3 file format The file names of the bitmaps and language files which are used in the visualization will be shortened to the 8.3-notation format and loaded to the PLC in this format.
Alarmhandling in the PLC	The task ALARM_TASK will be inserted automatically in the task configuration. It will process an implicitely created ST-code evaluating the status of the particular alarms and if applicable executing the associated actions ↬ *Chapter 1.4.1.4.2.1 “Overview” on page 363*. The ST-code needs auxiliary functions of library SysLibAlarmTrend.lib. This library will be loaded automatically. Additionally the implicitely needed libraries SysLibSockets.lib, SysLibMem.lib, SysLibTime.lib, SysLibFile.lib are loaded. These libraries must be supported by the target system. Hint: The 'Alarm handling in the PLC' can be used even if no web visualization has been activated. Even then the required ST-code will be generated.
Store trend data in the PLC	The trend handling in the PLC will be activated. The task TREND_TASK will be inserted automatically in the task configuration It will process an implicitely created ST-code for recording the trend data in a ring buffer and - if option History is activated in the trend element - for storing the values in a file system. The ST-code needs auxiliary functions of library SysLibAlarmTrend.lib. This library will be loaded automatically. Additionally the implicitely needed libraries SysLibSockets.lib, SysLibMem.lib, SysLibTime.lib, SysLibFile.lib are loaded. These libraries must be supported by the target system. Hint: 'Store Trend data....' can be used even if no web visualization has been activated. Even then the required ST-code will be generated.
Activate system variable 'CurrentVisu'	The system variable can be used for switching between visualizations ↬ *Chapter 1.4.3.11 “System variables” on page 717*.
Supported fonts in the target	List of fonts which are supported by the target system.
Simplified input handling	If activated: In 'Operation over the keyboard' the input handling in visualizations is simplified ↬ *Chapter 1.4.3.9.2 “Operation over the keyboard” on page 715*: *[Tab]* and *[Space]* are not needed to get from one input field to the next one. The selection is automatically given forward to the next field after having terminated an input by *[Return]*. An input field also can be reached via the arrow or *[Tab]* keys and then immediately an input can be entered. If not activated: *[Tab]* and *[Space]* must be used to get to the next input field and to select this field for making possible an input.
Web visualization	If activated: All visualisation objects of the project are compiled for the usage as Web-Visualization objects ↬ *Chapter 1.4.5.1 “Overview” on page 721*.

Dialog item	Meaning
Compression	If activated: The following files for the web visualization, which are to be transferred to the web server/ PLC, will be transferred in a packed format (zip-Format); otherwise in original format: ● XML visualization files ● image files (only *.bmp, because with others no compression effect) ● language files (*.xml for dynamic texts, *.tlt, *.vis) The files additionally to the existing file name get the extension ".zip". The dot in the existing name will be replaced by an underscore (example: "PLC_VISU.xml" will be renamed to "PLC_VISU_xml.zip") No compression is done for the Java-archives (minml.jar, webvisu.jar) and the main page webvisu.htm.
Prevent download of visualization files	If activated: When the project is downloaded, all files which are used in the current visualization will not be downloaded to the target system. Visualization files are only downloaded for web visualization and can be bitmaps, language files and for web visualization also XML description files. Keyboard usage for tables If this option is activated, in online mode the keyboard usage of tables in the visualization (CODESYS HMI or web visualization) is possible. Switching off this option will effect that no code is generated for the key functions.

1.4.1.4.8 Task configuration

Overview

In addition to declaring the special PLC_PRG program, you can also control the processing of your project using the task management.

A Task is a time unit in the processing of an IEC program. It is defined by a name, a priority and by a type determining which condition will trigger the start of the task. This condition can be defined by a time (cyclic, freewheeling) or by an internal or external event which will trigger the task; e.g. the rising edge of a global project variable or an interrupt event of the controller.

For each task you can specify a series of programs that will be started by the task. If the task is executed in the present cycle, then these programs will be processed for the length of one cycle.

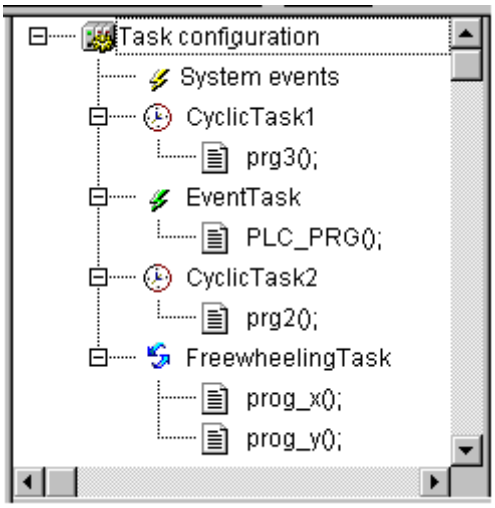
The combination of priority and condition will determine in which chronological order the tasks will be executed.

Each task can be enabled or disabled explicitly.

For each task you can configure a watch dog (time control); the possible settings depend on the target system.

Additionally there is the possibility to link System events (e.g. Start, Stop, Reset) directly with the execution of a project POU.

The Task Configuration is found as an object in the Resources tab of the Object Organizer. The Task editor is opened in a bipartited window.



In the left part of the window the tasks are represented in a configuration tree. At the topmost position you will always find the entry 'Taskconfiguration'. Below there are the entry 'System events' and the entries for the particular tasks, represented by the task name. Below each task entry the assigned program calls are inserted. Each line is preceded by an icon.

In the right part of the window a dialog will be displayed which belongs to the currently marked entry in the configuration tree. Here you can configure the tasks (Task properties), program calls (Program call) resp. define the linking of system events (System events). It depends on the target which options are available in the configuration dialogs. They are defined by a description file which is referenced in the target file. If the standard descriptions are extended by customer specific definitions, then those will be displayed in an additional tab 'Parameter' in the right part of the window.

Please do not use the same string function (see standard.lib) in several tasks, because this may cause program errors by overwriting.

Which task is being processed?

For the execution, the following rules apply:

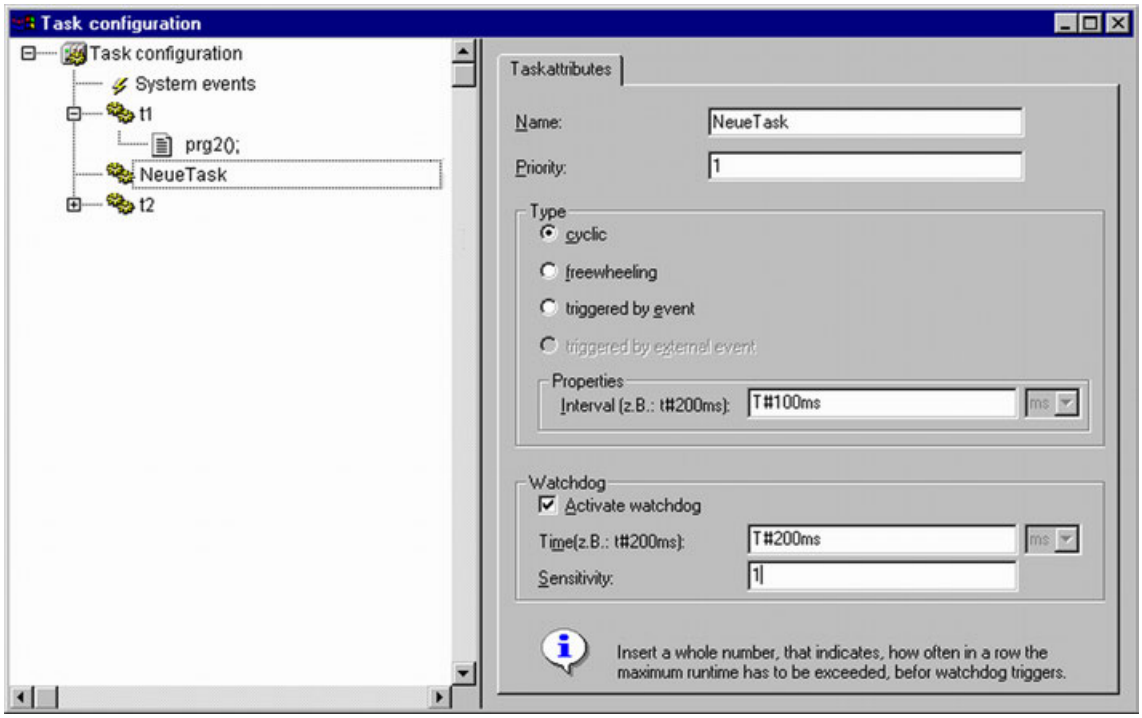
- That task is executed, whose condition has been met; i.e., if its specified time has expired, or after its condition (event) variable exhibits a rising edge.
- If several tasks have a valid requirement, then the task with the highest priority will be executed.
- If several tasks have valid conditions and equivalent priorities, then the task that has had the longest waiting time will be executed first.
- The processing of the program calls will be done according to their order (top down) in the task editor.
- Depending on the target system PLC_PRG might get processed in any case as a free-wheeling task, without being inserted in the task configuration tree.

'Insert' 'Insert Task' or 'Insert' 'Append Task'

With this command you can insert a new task into the Task Configuration. The entries each consist of a symbol and the task name.

If a task or the entry 'System events' is selected, then the 'Insert Task' command will be at your disposal. The new task will be inserted after the selected one. If the entry 'Task Configuration' is selected, then the 'Append Task' is available, and the new task will be appended to the end of the existing list. The maximum number of tasks is defined by the target system. Please regard that a certain number of tasks already might be reserved for modules of the PLC Configuration (defined in the *.cfg file).

When inserting a task, the dialog for setting the Task attributes will be opened:



Insert the desired attributes:

Name: a name for the task; with this name the task is represented in the configuration tree; the name can be edited there after a mouseclick on the entry or after pressing the <Space> key when the entry is selected.

Priority (0-31): a number between 0 and 31; 0 is the highest priority, 31 is the lowest

Types:

- cyclic (): The task will be processed cyclic according to the time definition given in the field 'Interval' (see below).
- freewheeling (): The task will be processed as soon as the program is started and at the end of one run will be automatically restarted in a continuous loop. There is no cycle time defined.
- triggered by event (): The task will be started as soon as the variable, which is defined in the Event field gets a rising edge.
- triggered by external event (): The task will be started as soon as the system event, which is defined in the Event field, occurs. It depends on the target, which events will be supported and offered in the selection list. (Not to be mixed up with system events

Properties for event triggered tasks:

- Interval (for Type 'cyclic' or 'triggered by external event' if the event requires a time entry): the period of time, after which the task should be restarted. If you enter a number, then you can choose the desired unit in the selection box behind the edit field: milliseconds [ms] or microseconds [µs]. Inputs in [ms]-format will be shown in the TIME format (e.g. "t#200ms") as soon as the window gets repainted; but you also can directly enter the value in TIME format. Inputs in [ms] will always be displayed as a pure number (e.g. "300").
- Event (for Type 'triggered by event' or 'triggered by external event'): a global variable which will trigger the start of the task as soon as a rising edge is detected. Use button ... or the input assistant <F2> to get a list of all available global variables.

Possibly the target system defines Singleton-Events. These are events, which only allow to start one single task. Whether such an event starts several tasks will be checked during compilation of the project. The check regards the data address of the event variable, not on the name.
For example: If the target system defines %MX1.1 and %IB4 as Singleton-Events, using the following variables as event variables will produce two errors (a and b as well as c and d each have the same address).

```
 VAR_GLOBAL
a AT %MX1.1: BOOL;
b AT %MX1.1: BOOL;
c AT %MB4: BOOL;
d AT %MD1: BOOL;
END_VAR
```

If there is no entry in both fields 'Interval' and 'Event', then the task interval will depend on which runtime system is used (see run time documentation); e.g. in this case for CODESYS SP NT V2.2 and higher an interval of 10 ms will be used).

Watchdog

For each task a time control (watchdog) can be configured. If the target system supports an extended watchdog configuration, possibly there are predefined upper and lower limits and a default for the watchdog time are defined, as well as a time definition in percent.

Activate watchdog: When this option is activated (☑) then regarding the currently set sensitivity (see below), the task will be terminated in error status as soon as the processing takes longer than defined in the 'Time' field (see below).

> **NOTICE!**
> Target system CODESYS SP 32-bit Full switches off the watchdog function when the flow control is active or when the execution currently is stopped at a breakpoint.

Time (e.g.: t#200ms): Watchdog time; after the expiration of this term, regarding the currently set sensitivity (see below), the watchdog will be activated unless the task has not been terminated already. Depending on the target system the time has to be entered as percent of the task interval. In this case the unit selection box is greyed and shows "%".

Sensitivity: Here you can enter in integer numbers at which overrun of the watchdog time an error should be generated. The default entry is "1", i.e. at the first overrun of the watchdog time an error occurs. Attention: If "0" is entered, the watchdog will be deactivated!

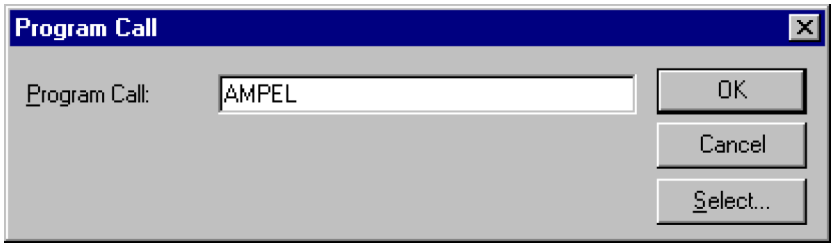
Manufacturer specific attributes:

Additionally to these standard attributes for the currently selected task manufacturer specific attributes might be displayed in a second tab "Parameters". This will be the case if it is defined in the target-specific description file for the task configuration.

'Insert' 'Insert Program Call' or 'Insert' 'Append Program Call'

With these commands you will open the dialog box for entering a program call to a task in the Task Configuration. Each entry in the task configuration tree consists of a symbol () and the program name.

With 'Insert Program Call', the new program call is inserted before the selected program call, and with 'Append Program Call' the program call is appended to the end of the existing list or program calls.



In the field 'program call' specify a valid program name out of your project or open the input assistant with the Select button to select a valid program name ↳ *Chapter 1.4.1.2.5.11 "'Edit' 'Input assistant'" on page 276*. The program name later also can be modified in the configuration tree. For this select the entry and press the <Space> key or just perform a mouseclick to open an editor field. If the selected program requires input variables, then enter these in their usual form and of the declared type (for example, prg(invar:=17)).

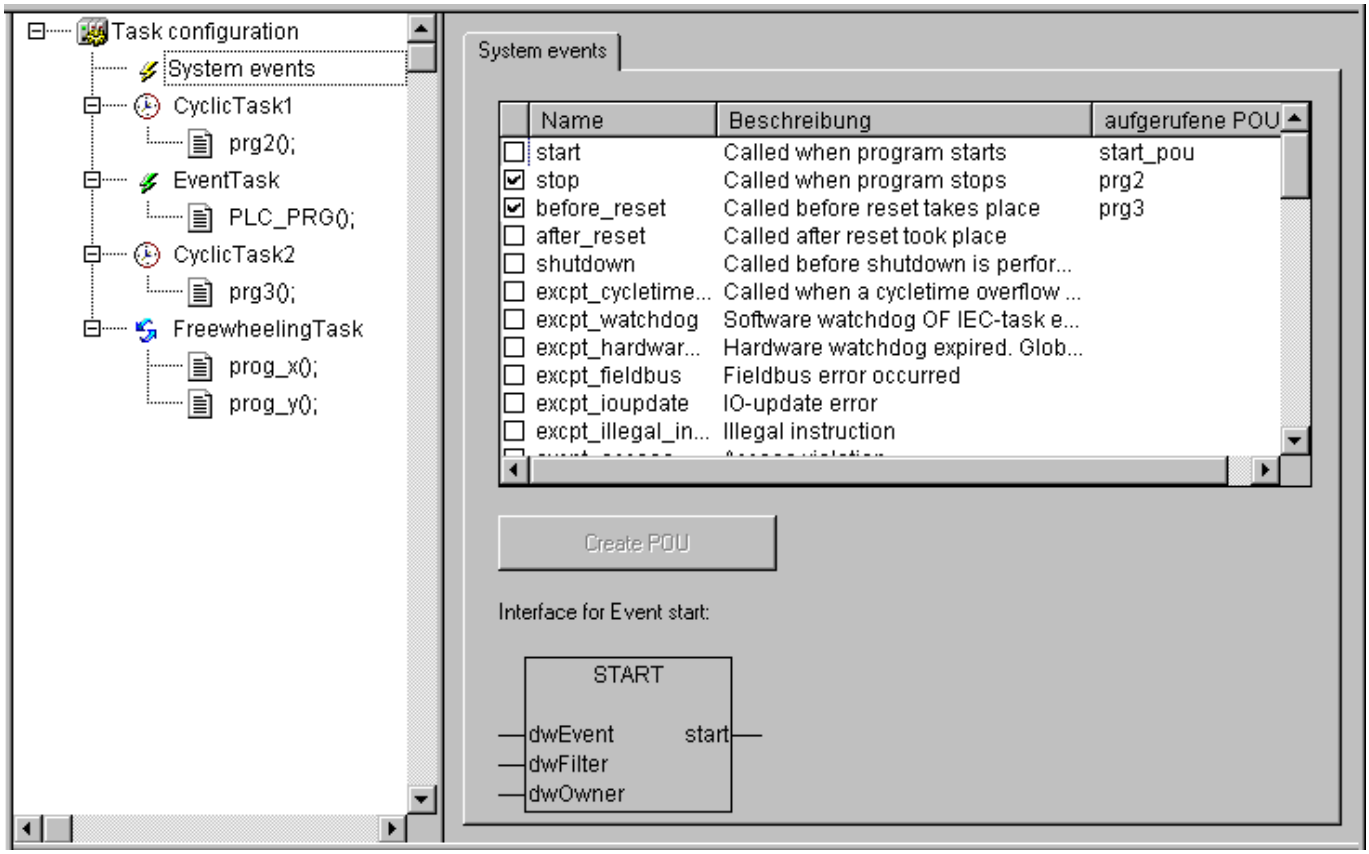
The processing of the program calls later in online mode will be done according to their order (top down) in the task editor.

Do not use the same string function in several tasks, because in this case values might be overwritten during processing of the tasks ↳ *Chapter 1.4.1.4.3.2 "Standard library" on page 372.*

System events

Instead of a "task" also a "system event" can be used to call a POU of your project. The available system events are target specific (definition in target file). The list of the standard events of the target may be extended by customer specific events. Possible events are for instance: Stop, Start, Online Change.

The assignment of system events to POUs is also done in the Task configuration editor. Use the dialog 'Events', which will be opened as soon as the entry " System-events" is selected in the task configuration tree:



Each event is represented in a line: Name and Description are displayed as defined in the target file, in the column called POU you can enter the name of the project POU which should be called and processed as soon as the event occurs.

For this use the input assistant (<F2>) or enter manually the name of an already existing POU (e.g. "PLC_PRG" or "PRG.ACT1"), or insert a name for a not yet existing POU.

In order to get a new POU (function) created in the project, press button Create POU. Hereupon the POU will be inserted in the Object Organizer. The input and output parameters which are required by the event will automatically be defined in the declaration part of the POU. Below the assignment table the currently selected event is displayed in a picture, showing the required parameters.

If you actually want the POU to be called by the event, activate the entry in the assignment table.

Activating/deactivating is done by a mouseclick on the control box.

'Extras' 'Set Debug Task'

With this command a debugging task can be set in Online mode in the task configuration ↬ *Chapter 1.4.1.4.8.3 “'Insert' 'Insert Program Call' or 'Insert' 'Append Program Call'” on page 393*. The text [DEBUG] will appear after the set task. The debugging capabilities apply, then, only to this task. In other words, the program only stops at a breakpoint if the program is gone through by the set task.

'Extras' 'Enable / disable task'

With this command the task which is currently marked in the task configuration can be disabled or re-enabled. A disabled task will not be regarded during processing of the program. In the configuration tree it is indicated by a grayed entry.

'Extras' 'Callstack'

This command is available in the Extras menu in the task configuration. If the program is stopped at a breakpoint during debugging, it can be used to show the callstack of the corresponding POU. For this purpose the debug task must be selected in the task configuration tree of ↬ *Chapter 1.4.1.4.8.5 “'Extras' 'Set Debug Task'” on page 395*. The window 'Callstack of task <task name>' will open. There you get the name of the POU and the breakpoint position (e.g. "prog_x (2)" for line 2 of POU prog_x) . Below the complete call stack is shown in backward order. If you press button 'Go To', the focus will jump to that position in the POU which is currently marked in the callstack.

1.4.1.4.9 Watch- and recipe manager

Overview

Function

In the Watch- and Recipe Manager (Resources tab of the Object Organizer) the current values of specified variables can be viewed in so-called "watch lists (Monitoring).

Further on the variables listed in a watch list can be preset with constant values and this set of values, named "Recipe" be transferred to the PLC. Also the current values of the variables of a watch list can be read from the PLC to the Watch and Recipe Manager as a preset/recipe. In this context regard the possibility to save recipes in files and to reload them to the Recipe Manager when required. See further information on the usage of recipes in: 'Creating Watch Lists, Recipes' ↬ *Chapter 1.4.1.4.9.2 “Creating watch lists, recipes” on page 397*.

In online mode watch lists as well can be used to write and force variables ↬ *Chapter 1.4.1.2.6.16 “'Online' 'Write values'” on page 286* ↬ *Chapter 1.4.1.2.6.17 “'Online' 'Force values'” on page 287*.

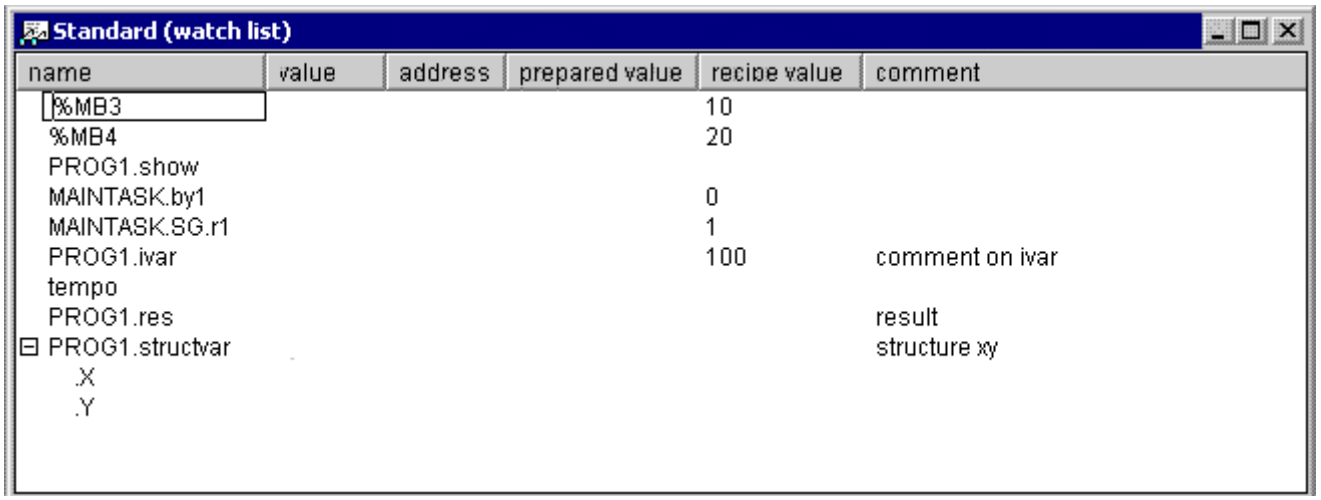
All these functions for example can be used for logging and setting of control parameters.

Editor

Tabular editor

Each watch list is viewed in a separate tabular editor window and multiple windows can be opened at the same time. In this case the available watch lists will be shown as entries in the "Resources" tab indented below the Watch and Recipe Manager. Each can be opened by a doubleclick on the entry.

The tabular editor contains columns for name, address, value, prepared value, recipe value and comment of the watch variable.



name: Here a variable identifier according to the following syntax must be entered of an address in standard format:

<POU name>.<variable name>

In case of global variables the POU name is dropped. The variable name can be multilevel. Addresses can be entered directly (e.g. "%IB0.0").

Example for a multilevel variable:	PLC_PRG.Instance1.Instance2.Structure.Component

Example for a global variable:	globalvar.component1

address, comment: As specified in the declaration of the variable.

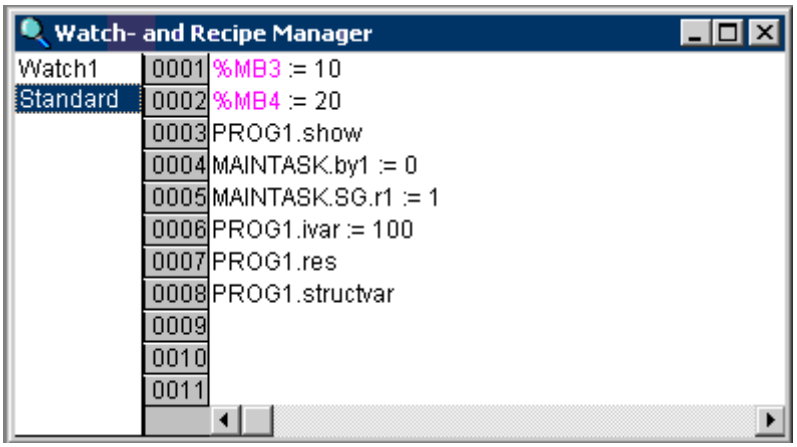
value: In online mode here the current value of the variable is displayed (Monitoring).

recipe value: Here a value can be entered, which will be transferred to the PLC when command 'Extras' 'Write Recipe' is applied on the whole watch list ↳ *Chapter 1.4.1.4.9.14 “'Extras' 'Write Recipe'” on page 401*. The recipe values of all variables of the list can be replaced by the current values from the PLC by using command 'Extras' 'Read Recipe' ↳ *Chapter 1.4.1.4.9.15 “'Extras' 'Read Recipe'” on page 402*.

In case of function block instances and structured variables a plus respectively minus sign appears in front of the name in the first column. It serves to expand resp. collapse the list of components. For function block variables the context menu is extended by the items 'Open function block' and 'Open instance'.

By a double-click on a non-editable position within the editor window, the table gets adapted to the window width and the column widths get optimized.

1-window-editor There is only one bipartite editor window, in the left part of which you find all available watch lists. For the list currently selected the right part of the window shows the associated variables. This editor view is opened via object 'Watch- and Recipe Manager' in the 'Resources' tab in the Object Organizer. The watch variables are entered line by line and a recipe value can be assigned to each by ":=".



Adding variables to watch lists is possible in offline mode by typing, or in online mode directly out of the POU editors. See 'Creating Watch Lists, Recipes' ↳ *Chapter 1.4.1.4.9.2 “Creating watch lists, recipes” on page 397*.

A 'cross-reference list' can be called directly from a watch list, when one of the watch variables is selected. In this case the command 'Show cross references' in the Extras menu or in the context menu is available ↳ *Chapter 1.4.1.3.7 “Show cross references” on page 295*. On cross-reference list see: 'Project' 'Show cross reference' ↳ *Chapter 1.4.1.2.4.17 “'Project' 'Show cross reference'” on page 264*.

Creating watch lists, recipes

By default in each project an empty watch list "Standard" is automatically created. See in the following how further lists can be created and filled with watch variables and how recipes can be defined. Partly this depends on which (target dependant) variant of the Watch- and Recipe Manager is used:

Creating watch lists Create a new, empty list - in offline or online mode:

If entry 'Watch- and Recipe Manager' is selected in the 'Resources' tab, then in the tabular editor via command 'Object' 'Add' (menu 'Project' - 'Object', or context menu) a new, primarily empty watch list can be created ↳ *Chapter 1.4.1.4.9.1 “Overview” on page 395* ↳ *Chapter 1.4.1.2.4.6 “'Project' 'Object' ' Add'” on page 258*. In the 1-Window-Editor for this purpose the command 'New Watch List' (menu 'Insert' or context menu) is available ↳ *Chapter 1.4.1.4.9.1 “Overview” on page 395* ↳ *Chapter 1.4.1.4.9.3 “'Insert' 'New Watch List'” on page 399*. Each a dialog for entering an unique watch list name opens. After confirmation the new list will be immediately added in the Resources tree (tabular editor) resp. in the left part of the 1-Window-Editor.

Fill new list with watch variables out of the POU editors, resp. add variables to existing lists:

Only possible in online mode. It is not necessary to deactivate monitoring for this purpose ↳ *Chapter 1.4.1.4.9.13 “'Extras' 'Monitoring Active'” on page 401*.

Tabular Editor and 1-Window-Editor:

- If one or multiple variables or elements are selected in one of the POU editors, they can be directly entered in a new watch list by command 'Into new watch list' (menu 'Extras' or context menu) *Chapter 1.4.1.4.9.8 “'Extras' 'Into new watch list'” on page 400*. The new list will be added automatically as "Watch<n>" in the Resources tab below the Watch- and Recipe Manager and opened in the editor window. Renaming of the list is only possible in offline mode *Chapter 1.4.1.4.9.10 “'Extras' 'Rename Watch List'” on page 401*.
- If one or multiple variables or elements are selected in one of the POU editors, the variables can be directly added to one of the existing watch lists by command 'Add to watch list' (menu 'Extras' or context menu) *Chapter 1.4.1.4.9.7 “'Extras' 'Add to watch list'” on page 400*.
- Instead of a variable identifier an address in standard format can be entered in a watch list *Chapter 1.4.1.7.4.2 “Address” on page 441*. Command 'Insert address range' (menu 'Extras' or context menu) allows to add all addresses of a specified address range at one go *Chapter 1.4.1.4.9.9 “'Insert address range'” on page 400*.

Fill a list manually:

Possible in online and offline mode; for the syntax see: Overview, Editor *Chapter 1.4.1.4.9.1.2 “Editor” on page 396*

Tabular editor:

- If the watch list is opened, via commands 'Insert watch variable' or 'Insert' 'Attach watch variable'further variables can be added *Chapter 1.4.1.4.9.4 “'Insert' 'Insert watch variable'” on page 399* *Chapter 1.4.1.4.9.5 “'Insert' 'Attach watch variable'” on page 399*. Existing entries can be selected and removed by 'Delete watch variable' resp. <Del> *Chapter 1.4.1.4.9.6 “'Delete watch variable'” on page 400*.

1-Window-Editor:

- For entering variables in a watch list, the list must be selected in the left part of the Watch- and Recipe Manager Window. Then variables are added in the right part at the current cursor position line by line, either with the help of the input assistant <F2> (see Note on using the input assistant... below) or by typing. See Overview, Editor for the requested syntax *Chapter 1.4.1.4.9.1.2 “Editor” on page 396*. If the variables should be entered in online mode, previously the monitoring must be deactivated. Via command 'Monitoring active' in the 'Extras' or the context menu you can switch between activated and deactivated *Chapter 1.4.1.4.9.13 “'Extras' 'Monitoring Active'” on page 401*.

Note on using the input assistant in the watch- and recipe manager:

The non-structured view of the Input Assistant offers additional filter functions for selecting watch variables *Chapter 1.4.1.2.5.12 “Unstructured display” on page 276*: In the Filter input field you can enter a string and additionally specify whether this string must be found at the beginning of a variable name (Prefix), at the end of a variable name (Suffix), or at an arbitrary position within the variable name in order to get the watch variables offered for selection.

Working with recipes

The variables of a watch list can be preset with constant values. In the tabular editor this is possible via column recipe value, in the 1-Window-Editor by an assignment via ":=". Then the watch list can be used as a so-called "recipe".

If the presetting should be done automatically with the current values read from the PLC, then command 'Read Recipe' can be used.

In the 1-Window-Editor variant of the Watch- and Recipe Manager the recipe values must be assigned according to the following example:

Example: PLC_PRG.TIMER:=50

Here variable PLC_PRG.TIMER is preset with 50.

Note the following for variables of type array, structure or function block instance: The particular elements resp. instance variables must be entered explicitly in order to be able to preset them with values. Example: Let's assume that a structure STRU is defined with components a, b,c, and a structure variable struvar is declared in program PLC_PRG. In order to preset a,b,c with values, the following must be entered in the watch list:

PLC_PRG.struvar.a:=<value>

PLC_PRG.struvar.b:=<value>

PLC_PRG.struvar.c:=<value>

Correspondingly the presetting of elements of an array must be done: Example for an array variable arr_var of type ARRAY[0...6]

PLC_PRG.arr_var[0]:=<value>

PLC_PRG.arr_var[1]:=<value>

If a function block FB contains the variables x,y and an instance variable fb_inst of type fb is declared in PLC_PRG, then x and y can be preset as follows:

PLC_PRG.fb_inst.x:=<value>

PLC_PRG.fb_inst.y:=<value>

Recipes can be saved externally in a file via command *“Extras ➔ Save watch list”* and they can be loaded back to the editor via *“Extras ➔ Load watch list”*. In online mode the recipe values can be written to the variables on the PLC via *“Extras ➔ Write recipe”*.

↳ *Chapter 1.4.1.4.9.11 “'Extras' 'Save Watch List'” on page 401*

↳ *Chapter 1.4.1.4.9.12 “'Extras' 'Load Watch List'” on page 401*

↳ *Chapter 1.4.1.4.9.14 “'Extras' 'Write Recipe'” on page 401*

'Insert' 'New Watch List'

This command is only available, if the 1-Window-Editor view of the Watch- and Recipe Manager is opened ↳ *“Tabular editor” on page 396*. Then in offline as well as in online mode a new watch list can be created. A dialog for entering the watch list name will be opened for this purpose.

'Insert' 'Insert watch variable'

This command is only available in the tabular editor view of a watch list ↳ *Chapter 1.4.1.4.9.1.2 “Editor” on page 396*. It appends a new line at the end of the list and and opens an edit field in column "name" for entering a new watch variable via the input assistant (see the note in Creating Watch Lists, Recipes ↳ *“Note on using the input assistant in the watch- and recipe manager:” on page 398*) or by typing ↳ *Chapter 1.4.1.4.9.2 “Creating watch lists, recipes” on page 397*.

'Insert' 'Attach watch variable'

This command is only available in the tabular editor view of a watch list ↳ *Chapter 1.4.1.4.9.1.2 “Editor” on page 396*. It appends a new line at the end of the list and and opens an edit field in column "name" for entering a new watch variable via the input assistant (see the note in Creating Watch Lists, Recipes ↳ *“Note on using the input assistant in the watch- and recipe manager:” on page 398*) or by typing ↳ *Chapter 1.4.1.4.9.2 “Creating watch lists, recipes” on page 397*.

'Delete watch variable'

This command is only available in the tabular editor view of a watch list *Chapter 1.4.1.4.9.1.2 “Editor” on page 396*. It removes the currently focused line and corresponds to using the <Del> key.

'Extras' 'Add to watch list'

Short key: <Alt>+<X>+<W>

Out of the POU editors in the project you can directly add variables to a watch list.

When one or multiple variables or elements are selected in an editor, they can directly be added to one of the existing watch lists via command 'Add to watch list' ('Extras' menu or context menu). It is not necessary to deactivate the monitoring for this purpose *Chapter 1.4.1.4.9.13 “'Extras' 'Monitoring Active'” on page 401*.

For function blocks the command only will be available, if the full instance path of a variable within the POU is known.

Notes on the element selection in the POU editors:

Basically particular variables can be selected like usual for the respective editor. Additionally the following is true:

- In the FBD editor all elements on the left of a selected element will automatically be selected too. For example also the inputs a and b of an AND box will be selected when you select the AND box.
- In the Ladder editor multiple elements can be selected by keeping the <Shift> key pressed while clicking on the desired elements.
- In the ST and IL editor in the right part of the window a single variable can be selected. In the left part multiple lines can be selected in order to get all included variables added to the watch list.
- In the SFC editor you can select multiple successive elements in order to get all included variables added to the watch list.
- In the declaration parts of GVLs and POUs only particular variables can be selected.

'Extras' 'Into new watch list'

Short key: <Alt>+<X>+<N>

This command inserts the variable(s) currently selected in a POU editor to a new watch list. This list will automatically be created with name "Watch<n>", whereby n is a running number starting with 0 and used in a way that the name will be unique.

Furthermore for this command the same is true like for 'Extras' 'Add to watch list' *Chapter 1.4.1.4.9.7 “'Extras' 'Add to watch list'” on page 400*.

'Insert address range'

Instead of a variable name an address in standard format can be entered in column "name" of a watch list *Chapter 1.4.1.7.4.2 “Address” on page 441*.

The command allows to insert all addresses of a defined address range to the watch list at one go. For this purpose a dialog opens where you can specify the start address and the number of addresses. If you define for example name="%MW0" and number = "10", then the addresses %MW0 to %MW9 will be inserted in the watch list.

'Extras' 'Rename Watch List'

This command will only be available, if the 1-Window-Editor view of the Watch- and Recipe Manager is opened (target-dependent!) ↳ *"Tabular editor" on page 396*.

It opens a dialog for specifying the new watch list name.

If the tabular view is used, the watch list can be renamed in the Object Organizer via command 'Project' 'Object' 'Rename' ↳ *Chapter 1.4.1.2.4.8 "'Project' 'Object' 'Rename'" on page 259.*

'Extras' 'Save Watch List'

With this command you can save a watch list ↳ *Chapter 1.4.1.4.9.1 "Overview" on page 395*. The dialog box for saving a file is opened. The file name is preset with the name of the watch list and is given the extension "*.wtc".

The saved watch list can be loaded again with 'Extras' 'Load Watch List' ↳ *Chapter 1.4.1.4.9.12 "'Extras' 'Load Watch List'" on page 401*.

For example this allows to manage various recipes for the same set of variables, which can be loaded to the PLC as currently required ↳ *Chapter 1.4.1.4.9.2 "Creating watch lists, recipes" on page 397*.

'Extras' 'Load Watch List'

With this command you can reload a saved watch list, for example in order to reload a certain recipe to the editor, so that it can be written to the PLC ↳ *Chapter 1.4.1.4.9.2 "Creating watch lists, recipes" on page 397*. The dialog box for opening a file will be opened. Select the desired file with the "*.wtc" extension. In the dialog box that appears, you can give the watch list a new name. The file name is preset without an extension.

With 'Extras' 'Save Watch List', you can save a watch list ↳ *Chapter 1.4.1.4.9.11 "'Extras' 'Save Watch List'" on page 401*.

'Extras' 'Monitoring Active'

Short key: <Alt>+<X>+<M>

This command turns off resp. on the display of the values in the Watch- and recipe manager ↳ *Chapter 1.4.1.4.9.1 "Overview" on page 395*. If the Monitoring is activated, a check (✓) appears in front of the menu item.

'Extras' 'Write Recipe'

With this command in the online mode of the Watch- and Recipe Manager you can write the preset values () into the variables ↳ *recipe values*.

The command only concerns the values of that watch list, which is currently selected in the Watch- and Recipe Manager!

'Extras' 'Read Recipe'

With the command, in the Online Mode of the Watch- and Recipe Manager, you can replace the presetting of the variables with the present value of the variables.

Example: `PLC_PRG.Counter [:= <present value>] = <present value>`

The command only concerns the values of that watch list, which is currently selected in the Watch- and Recipe Manager!

Force and write values in the watch- and recipe manager

In online mode in each watch list you can force values and write values ↳ *Chapter 1.4.1.2.6.17 “'Online' 'Force values'” on page 287* ↳ *Chapter 1.4.1.2.6.16 “'Online' 'Write values'” on page 286*.

In the tabular editor you can enter a value in column prepared value and thus prepare that value for forcing or writing on the PLC. For this purpose select the respective cell (mouseclick resp. navigation within the table via the arrow keys) and by a mouseclick or the <Enter> key open a dialog for entering the value. If they have the same data type, also the cells of multiple variables can be selected at once in order to get the same value prepared for all these variables. For multiselection of the cells just keep the <Shift> button pressed while selecting the particular cells.

In the 1-Window-Editor by a mouseclick on an specified variable value you also can open a corresponding dialog for entering the value which should be forced or written.

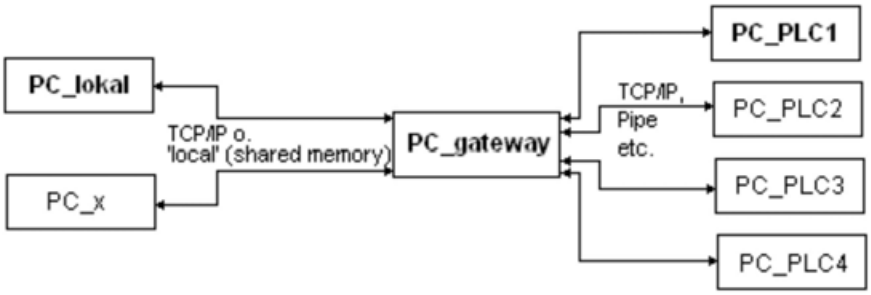
1.4.1.4.10 Workspace

This object in the 'Resources' tab provides an figure of the currently set project options. If you open it, you get the project options dialog with the know categories ↳ *Chapter 1.4.1.2.2.1 “'Project' 'Options'” on page 200*.

1.4.1.5 Principle of a gateway system

1.4.1.5.1 Overview

A gateway server can be used to allow your local PC to communicate with one or more runtime systems. The setting concerning which runtime systems can be addressed, which is specifically configured for each gateway server, and the connection to the desired gateway server, is made on the local PC. Here it is possible that both the gateway server and the runtime system(s) can run together on the local PC. If we are dealing with a gateway server which is running on another PC we must ensure that it has been started there. If you are selecting a locally installed gateway server, it automatically starts when you log onto the target runtime system. You can recognize this through the appearance of a symbol on the bottom right in the task bar. This symbol lights up as long as you are connected to the runtime system over the gateway. The menu points Info and Finish are obtained by clicking with the right mousekey on the symbol. Finish is used to switch off the gateway.



PC_local is your local PC, PC_x is another PC, which gateway addresses. PC_gateway is the PC on which the gateway server is installed, PC_PLC1 through to PC_PLC4 are PCs on which the runtime systems are running. The diagram shows the modules as separated but it is fully possible for the Gateway server and / or runtime systems to be installed together on the local PC.

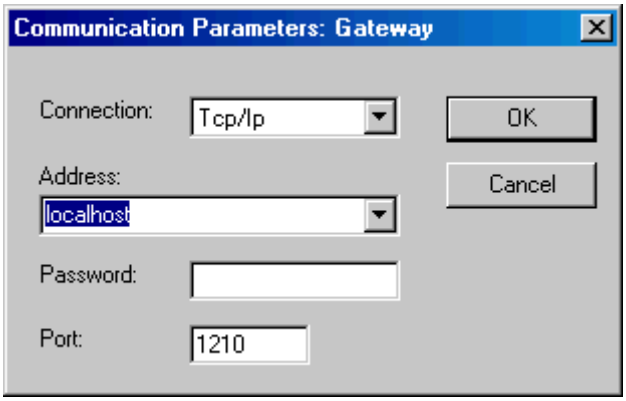
Please note that a connection to gateway is only possible over TCP/IP so make sure that your PC is configured appropriately.

The connections from gateway to the various runtime computers can, on the other hand, run over different protocols (TCP/IP, Pipe, etc.).

1.4.1.5.2 Setting up the desired gateway server and channel

Setting up the desired gateway server and channel in the communication parameters dialog

To define the connection to the desired gateway server we open the dialog 'Communication Parameters Gateway' by pressing the button Gateway.



Here you can enter and/or edit the following:

- The type of connection from your computer to the computer on which the gateway server that you want to use is running. If the gateway server is running on the local computer, connection via shared memory ("local") or via TCP/IP is possible; if connection to a different computer is needed, only TCP/IP can be used.
- The address of the computer, on which the gateway server that you want to use is running: IP address or the appropriate symbolic name such as e.g. localhost. Regard that leading zeros added to the address range number however are not allowed.

  Example: not possible: '010.107.084.050', must be entered as '10.107.84.50'). On initial setup, the standard 'localhost' is offered as the computer name (address), which means that the locally installed gateway would be accessed. The name 'localhost' is set to be identical to the local IP address 127.0.0.1 in most cases, but you may in some cases have to enter this directly into the Address field. If you want to access a gateway server on another computer, you must replace 'localhost' with its name or IP address.
- The password for the selected gateway server, if it is on a remote computer. If it is incorrectly entered, or not entered at all, an error message appears.

  Note in this connection: you can give the locally installed gateway server a password with the following procedure: click with the right mouse button on the gateway symbol in the lower right portion of the toolbar and select "Change password". A dialog comes up for changing or entering a password. If you access the gateway server locally any password that is entered will not be asked for.
- The computer’s port on which the gateway server that you wish to use is running, as a rule the correct value for the selected gateway is already given.

If the dialog is closed with OK, the corresponding entry (computer address) appears in the Channels field at the top of the 'Communication parameters' dialog, and below it the channels available on this gateway server.

Setting up the desired channel on the selected gateway server

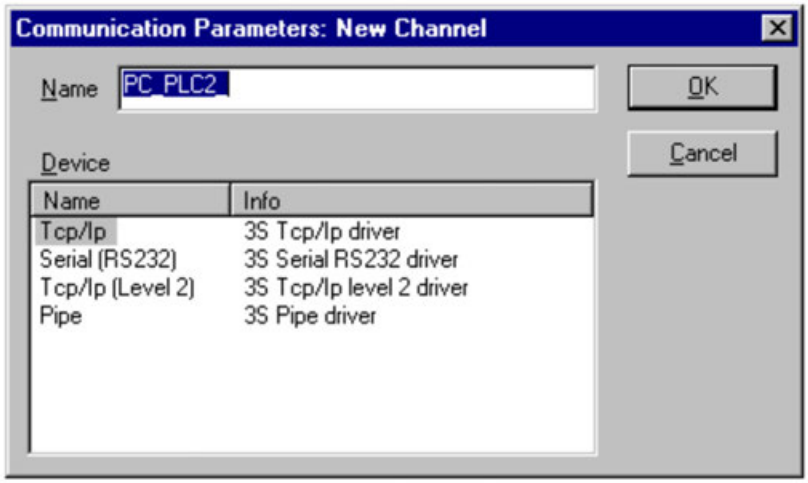
Now select one of the channels by clicking on an entry with the mouse. The corresponding parameters will then be shown in the table. If no connection can be established to the selected gateway address possibly because it has not been started or the address is incorrect "" the phrase 'not connected' appears in brackets after the address and a message 'No gateway with these settings could be found' appears. In this connection perform a quick check ↬ *Chapter 1.4.1.5.6 “Quick check in the event of unsuccessful connection attempt to the gateway” on page 407*.

Once the desired channel is set up, close the dialog using OK. The settings are saved with the project.

1.4.1.5.3 Setting up a new channel for the local gateway server

You can set up new channels for the currently connected gateway server, which are then available for establishing further connection from the server, a connection to a controller for example. The options that you have in this regard depend on the particular choice of the number of device drivers installed on your computer.

Press the New button in the 'Online' 'Communication Parameters' dialog ↬ *Chapter 1.4.1.2.6.23 “'Online' 'Communication parameters'” on page 291*. The dialog 'Communication Parameters: New Channel' comes up.



- The input field Name automatically contains the name used for the last inputted channel. If no channel has yet been defined, the current gateway name will be offered, followed by an underline character , e.g. 'localhost_'. You can edit the channel name at this point. The channel name is purely informative, it does not have to be a unique name but it is recommended to use one.
- The device drivers available on the gateway computer are listed in the table under Device. In the Name column, select by mouse click one of the available drivers; the corresponding comment, if any, appears in the Info column.

If you close the 'New Channel' dialog with OK, the newly defined channel appears in the 'Communication Parameters' dialog as a new entry in Channels at the lowest position under the minus sign. So far, it is only stored locally in the project. At this point you can edit the Value column. Now confirm the entered parameters with OK, thus leaving the 'Communication Parameters' dialog.

In order for the newly entered gateway channel and its parameters to also be known to the gateway server xy, and thus also to make it available to other computers that access this gateway xy, you must log into the runtime system. If you then re-open the 'Online' 'Communication parameters' dialog, the new channel appears in the „channel tree“, not only in its previous position but also indented under the address or name of the gateway server xy. This indicates that it is known to the network. You can now open the Communication Parameter dialog on a computer other than the local one, select gateway xy and use its new channel.

If a communication error occurs when logging in, it is possible that the interface cannot be opened (e.g. COM1 for a serial connection) possibly because it is being used by another device. It is also possible that the controller is not running.

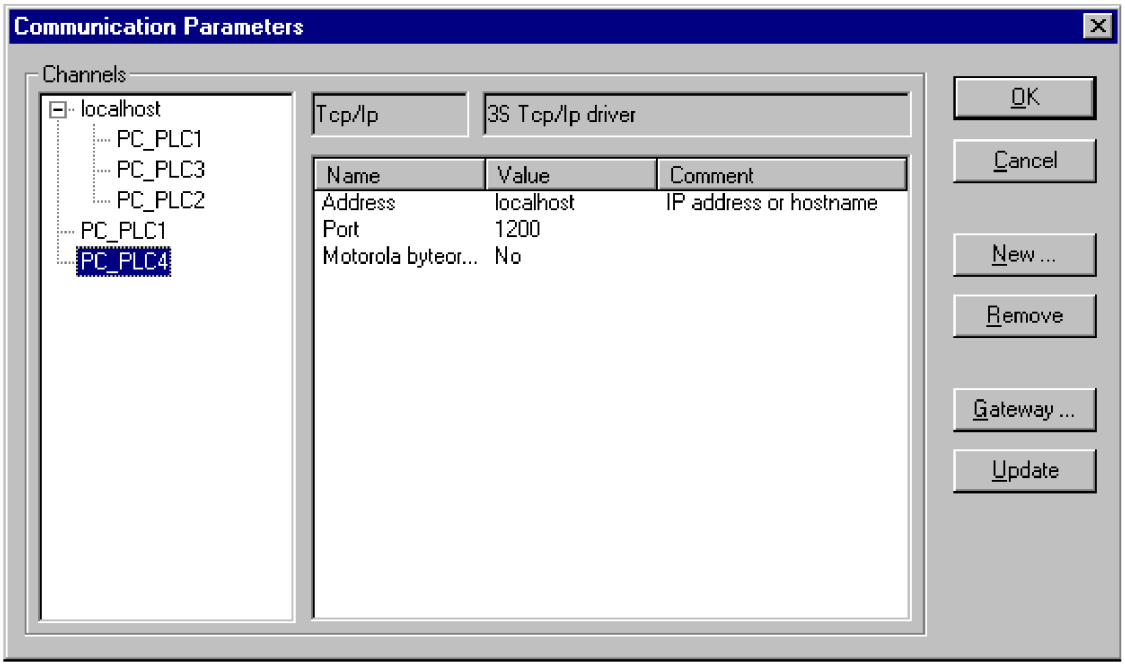
The parameters for a channel already known by the gateway server can no longer be edited in the configuration dialog. The parameter fields appear grey. You can, however, delete the connection as long as it is not active.

The deletion of a channel is not reversible. It occurs at the moment that you press on the button [Remove]!

1.4.1.5.4 What the communications parameters dialog on the local PC shows

This dialog is used to select a gateway server for the communication with a PLC. Furtheron there can be set up new channels for a gateway server which is installed on the local PC so that these channels can be used by other computers which are part of the network.

The current settings can be called up at any time using the button Update. A dialog will appear if the communications parameters have already been configured according to the example in Principle of a gateway system ↳ *Chapter 1.4.1.5.1 “Overview” on page 402*.



The Heading Channels lists two categories of connections:

- On the one hand all of the connections are shown which are installed on the currently connected gateway server called 'localhost'. Here the address or the name of this gateway is located on the upper position behind the minus sign, which in our example is running on the local computer. The appropriate address 'localhost' corresponds in the normal case to the IP address 127.0.0.1 of the local computer (PC_local). Below, indented to the right, are three addresses of runtime computers which the gateway channels are set-up to (PC_PLC1 to 3). They could have been configured both from the local PC or from the other PCs (PC_x) which are or were connected to the gateway server.
- The second category of the channels describes includes all connections to the gateway which can be set up from your local PC, over this configuration dialog for example. They create the "branch" which leads from the minus sign directly below to PC_PLC1 and PC_PLC4. These channel addresses do not necessarily have to be known yet at the gateway. For PC_PLC4 in the example described above, the configuration parameters are stored locally in the project, but they will first be known to the gateway the next time log-in to the runtime system occurs ↬ *Chapter 1.4.1.2.6.6 "'Online' 'Run'" on page 283*. This has already occurred for PC_PLC1 since the associated gateway address has appeared as an additional "sub-branch" to the "channel tree".

In the central part of the dialog one finds the designation, in each case, of the left selected channel and the associated parameter under Name, Value and Comment.

1.4.1.5.5 Tips for editing the parameters in the communications parameters dialogue

You can only edit the text fields in the column Value.

Select a text field with the mouse, and get into the editing mode by double clicking or by pressing the space bar. The text input is finished by pressing the <Enter> key.

You can use <Tabulator> or <Shift> + <Tabulator> to jump to the next or the previous switching or editing possibility.

To edit numerical values it is possible with the arrow keys or the Page Up/Down keys to change the value by one or ten units respectively. A double click with the mouse also changes the value by increasing by one unit. A typing check is installed for numerical values: <Ctrl> + <Home> or <Ctrl> + <End> deliver the lowest or the highest value respectively for the possible input values for the type of parameter in question.

1.4.1.5.6 Quick check in the event of unsuccessful connection attempt to the gateway

You should make the following checks if the connection to the selected gateway computer is not successful. (You get the message „not connected" in the Communication Parameters dialog behind the gateway server address in the field Channels):

- Has the gateway server been started (the three-color symbol appears in the bottom right portion of the toolbar) ?
- Is the IP address that you entered in the 'Gateway: Communication Parameters' dialog really that of the computer on which the gateway is running ? (use „ping" to check)
- Is the TCP/IP connection working locally? The error may possibly lie with TCP/IP.

1.4.1.6 IEC operators and additional, norm-extending functions

1.4.1.6.1 Overview

All IEC operators are supported. In contrast with the standard functions (see Appendix D of the Standard library ↬ *Chapter 1.4.1.4.3.2 “Standard library” on page 372*), these operators are recognized implicitly throughout the project.

Besides the IEC operators also the following operators are supported which are not prescribed by the standard: INDEXOF and SIZEOF (see 'Arithmetic Operators'Link auf obsoletes Modul ↬ *Chapter 1.4.1.6.2 “Arithmetic operators” on page 407*), ADR and BITADR (see 'Address Operators' ↬ *Chapter 1.4.1.6.7 “Address operators” on page 421*).

Operators are used like functions in POU.

1.4.1.6.2 Arithmetic operators

ADD

IEC operator ↬ *Chapter 1.4.1.6.1 “Overview” on page 407*: Addition of variables of the types: BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL and LREAL.

Two TIME variables can also be added together resulting in another time (e.g., t#45s + t#50s = t#1m35s)

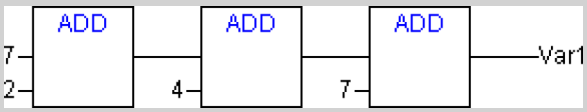
Example in IL:

```
LD  7
ADD 2,4,7
ST  Var1
```

Example in ST:

```
var1 := 7+2+4+7;
```

Example in FBD:



MUL

IEC operator ↬ *Chapter 1.4.1.6.1 “Overview” on page 407*: Multiplication of variables of the types: BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL and LREAL.

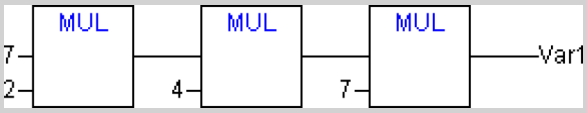
Example in IL:

```
LD 7
MUL 2,4,7
ST Var1
```

Example in ST:

```
var1 := 7*2*4*7;
```

Example in FBD:



SUB

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Subtraction of one variable from another of the types: BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL and LREAL.

A TIME variable may also be subtracted from another TIME variable resulting in third TIME type variable. Note that negative TIME values are undefined.

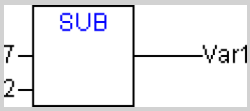
Example in IL:

```
LD  7
SUB 2
ST  Var1
```

Example in ST:

```
var1 := 7-2;
```

Example in FBD:



DIV

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Division of one variable by another of the types: BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL and LREAL.

Example in IL:

```
LD  8
DIV 2
ST  Var1 (* Result is 4 *)
```

Example in ST:

```
var1 := 8/2;
```

Example in FBD:

If you define functions in your project with the names CheckDivByte, CheckDivWord, CheckDivDWord and CheckDivReal, you can use them to check the value of the divisor if you use the operator DIV, for example to avoid a division by 0. The functions must have the above listed names.

NOTICE!
Note that different target systems may behave differently concerning a division by zero!

MOD

IEC operator *Chapter 1.4.1.6.1 "Overview" on page 407*: Module Division of one variable by another of the types: BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT. The result of this function will be the remainder of the division. This result will be a whole number.

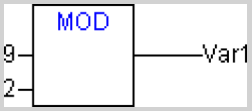
Example in IL:

```
LD 9
MOD 2
ST Var1 (* Result is 1 *)
```

Example in ST:

```
var1 := 9 MOD 2;
```

Example in FBD:

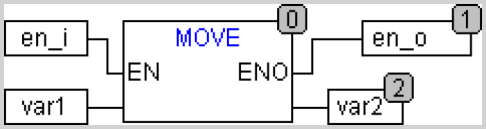


MOVE

IEC operator *Chapter 1.4.1.6.1 "Overview" on page 407*: Assignment of a variable to another variable of an appropriate type. As MOVE is available as a box in the graphic editors LD, CFC, there the (unlocking) EN/EN0 functionality can also be applied on a variable assignment. In the FBD editor this is not possible however.

Example in CFC in conjunction with the EN/EN0 function:

Only if en_i is TRUE, var1 will be assigned to var2.



Example in IL:

```
LD ivar1
MOVE
ST ivar2 (* Result: ivar2 gets assigned value of ivar1 *)
```

You get the same result with:

```
LD ivar1
ST ivar2
```

Example in ST:
```
ivar2 := MOVE(ivar1);
```
You get the same result with: ivar2 := ivar1;

INDEXOF

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: This function is not prescribed by the standard IEC61131-3.

Perform this function to find the internal index for a POU.

Example in ST:
```
var1 := INDEXOF(POU2);
```

SIZEOF

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: This function is not prescribed by the standard IEC 61131-3.

Perform this function to determine the number of bytes required by the given variable.

Example in IL:
```
arr1:ARRAY[0..4] OF INT;
Var1 INT
LD arr1
SIZEOF
ST Var1 (* Result is 10 *)
```

Example in ST:
```
var1 := SIZEOF(arr1);
```

1.4.1.6.3 Bitstring operators

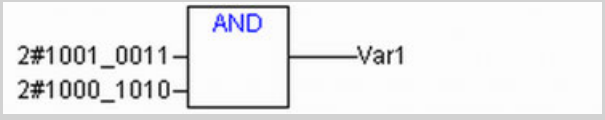
AND

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Bitwise AND of bit operands. The operands should be of the type BOOL, BYTE, WORD or DWORD.

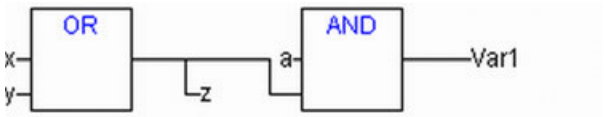
Example in IL:
```
Var1 BYTE
LD 2#1001_0011
AND 2#1000_1010
ST Var1 (* Result is 2#1000_0010 *)
```

Example in ST:
```
var1 := 2#1001_0011 AND 2#1000_1010
```

Example in FBD:



If you have a program step in the SFC like the following and if you use 68xxx generators, please note the following: The allocation of the value of the second input variable at the AND operator module to variable z will not be executed! This is due to the optimized processing in the SFC in case of value FALSE at the input variable.



OR

IEC operator ↳ *Chapter 1.4.1.6.1 "Overview" on page 407*: Bitwise OR of bit operands. The operands should be of the type BOOL, BYTE, WORD or DWORD.

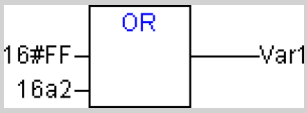
Example in IL:

```
var1 :BYTE;
LD 2#1001_0011
OR 2#1000_1010
ST  var1 (* Result is 2#1001_1011 *)
```

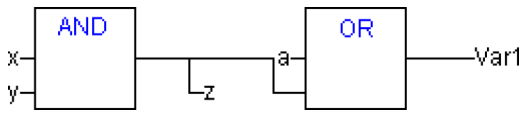
Example in ST:

```
Var1 := 2#1001_0011 OR 2#1000_1010
```

Example in FBD:



If you have a program step in the SFC like the following and if you use 68xxx generators, please note the following: The allocation of the value of the second input variable at the OR operator module to variable z will not be executed! This is due to the optimized processing in the SFC in case of value FALSE at the input variable.



XOR

IEC operator ↳ *Chapter 1.4.1.6.1 "Overview" on page 407*: Bitwise XOR of bit operands. The operands should be of the type BOOL, BYTE, WORD or DWORD.

Note the behavior of the XOR function in extended form, that means if there are more than 2 inputs. The inputs will be checked in pairs and the particular results will then be compared again in pairs (this complies with the standard, but may not be expected by the user).

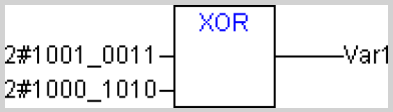
Example in IL:

```
Var1 :BYTE;
LD 2#1001_0011
XOR 2#1000_1010
ST  Var1 (* Result is 2#0001_1001 *)
```

Example in ST:

```
Var1 := 2#1001_0011 XOR 2#1000_1010
```

Example in FBD:



NOT

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Bitwise NOT of a bit operand. The operand should be of the type BOOL, BYTE, WORD or DWORD.

Example in IL:

```
Var1 :BYTE;
LD 2#1001_0011
NOT
ST  Var1 (* Result is 2#0110_1100 *)
```

Example in ST:

```
Var1 := NOT 2#1001_0011
```

Example in FBD:

1.4.1.6.4 Bit-Shift operators

SHL

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Bitwise left-shift of an operand : erg:= SHL (in, n)

in gets shifted to the left by n bits. If n > data type width, for BYTE, WORD and DWORD will be filled with zeros. But if signed data types are used, like e.g. INT, then an arithmetic shift will be executed in such cases, that means it will be filled with the value of the topmost bit.

> *The amount of bits used for the arithmetic operation is determined by the data type of the input variable! If the input variable is a constant the smallest possible data type is used. The data type of the output variable has no effect at all on the arithmetic operation.*

See in the following example in hexadecimal notation that you get different results for erg_byte and erg_word depending on the data type of the input variable (BYTE or WORD), although the values of the input variables in_byte and in_word are the same.

Example in IL:

```
LD  16#45
SHL 2
ST  erg_byte
```

Example in ST:

```
PROGRAM shl_st
VAR
in_byte : BYTE:=16#45;
in_word : WORD:=16#45;
erg_byte : BYTE;
erg_word : WORD;
n: BYTE :=2;
END_VAR
erg_byte:=SHL(in_byte,n); (* Result is 16#14 *)
erg_word:=SHL(in_word,n); (* Result is 16#0114 *)
```

Example in FBD:

SHR

IEC operator *Chapter 1.4.1.6.1 “Overview” on page 407*: Bitwise righ-shift of an operand : erg:= SHL (in, n)

in gets shifted to the right by n bits. If n > data type width, for BYTE, WORD and DWORD will be filled with zeros. But if signed data types are used, like e.g. INT, then an arithmetic shift will be executed in such cases, that means it will be filled with the value of the topmost bit.

> *The amount of bits used for the arithmetic operation is determined by the data type of the input variable! If the input variable is a constant the smallest possible data type is used. The data type of the output variable has no effect at all on the arithmetic operation.*

See in the following example in hexadecimal notation that you get different results for erg_byte and erg_word depending on the data type of the input variable (BYTE or WORD), although the values of the input variables in_byte and in_word are the same.

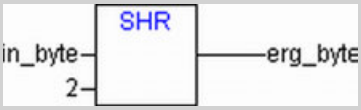
Example in IL:

```
LD  16#45
SHR 2
ST  erg_byte
```

Example in ST:

```
PROGRAM shr_st
VAR
in_byte : BYTE:=16#45;
in_word : WORD:=16#45;
erg_byte : BYTE;
erg_word : WORD;
n: BYTE :=2;
END_VAR
erg_byte:=SHR(in_byte,n); (* Result is 11 *)
erg_word:=SHR(in_word,n); (* Result is 0011 *)
```

Example in FBD:



ROL

IEC operator ↳ *Chapter 1.4.1.6.1 "Overview" on page 407*: Bitwise rotation of an operand to the left: erg:= ROL (in, n)

erg, in and n should be of the type BYTE, WORD or DWORD. in will be shifted one bit position to the left n times while the bit that is furthest to the left will be reinserted from the right.

> *The amount of bits used for the arithmetic operation is determined by the data type of the input variable! If the input variable is a constant the smallest possible data type is used. The data type of the output variable has no effect at all on the arithmetic operation.*

In the following example in hexadecimal notation you get different results for erg_byte and erg_word depending on the data type of the input variable (BYTE or WORD), although the values of the input variables in_byte and in_word are the same.

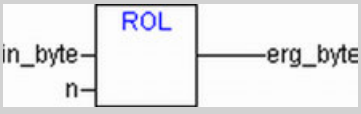
Example in IL:

```
LD  16#45
ROL 2
ST erg_byte
```

Example in ST:

```
PROGRAM rol_st
VAR
in_byte : BYTE:=16#45;
in_word : WORD:=16#45;
erg_byte : BYTE;
erg_word : WORD;
n: BYTE :=2;
END_VAR
erg_byte:=ROL(in_byte,n); (* Result is 16#15 *)
erg_word:=ROL(in_word,n); (* Result is 16#0114 *)
```

Example in FBD:



ROR

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Bitwise rotation of an operand to the right: erg:= ROL (in, n)

erg, in and n should be of the type BYTE, WORD or DWORD. in will be shifted one bit position to the right n times while the bit that is furthest to the right will be reinserted from the left.

The amount of bits used for the arithmetic operation is determined by the data type of the input variable! If the input variable is a constant the smallest possible data type is used. The data type of the output variable has no effect at all on the arithmetic operation.

In the following example in hexadecimal notation you get different results for erg_byte and erg_word depending on the data type of the input variable (BYTE or WORD), although the values of the input variables in_byte and in_word are the same.

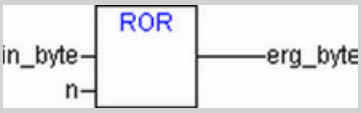
Example in IL:

```
LD 16#45
ROR 2
ST erg_byte
```

Example in ST:

```
PROGRAM ror_st
VAR
in_byte : BYTE:=16#45;
in_word : WORD:=16#45;
erg_byte : BYTE;
erg_word : WORD;
n: BYTE :=2;
END_VAR
erg_byte:=ROR(in_byte,n); (* Result is 16#51 *)
erg_word:=ROR(in_word,n); (* Result is 16#4011 *)
```

Example in FBD:



1.4.1.6.5 Selection operators

Overview

All selection operations can also be performed with variables. For purposes of clarity we will limit our examples to the following which use constants as operators.

See also:

SEL ↳ *Chapter 1.4.1.6.5.2 “SEL” on page 416*

MAX ↳ *Chapter 1.4.1.6.5.3 “MAX” on page 416*

MIN ↳ *Chapter 1.4.1.6.5.4 “MIN” on page 417*

LIMIT ↳ *Chapter 1.4.1.6.5.5 “LIMIT” on page 417*

MUX ↳ *Chapter 1.4.1.6.5.6 “MUX” on page 418*

SEL

IEC operator *Chapter 1.4.1.6.1 “Overview” on page 407*: Binary selection.

```
OUT := SEL(G, IN0, IN1) means:
OUT := IN0 if G=FALSE;
OUT := IN1 if G=TRUE
```

IN0, IN1 and OUT can be any type of variable, G must be BOOL. The result of the selection is IN0 if G is FALSE, IN1 if G is TRUE.

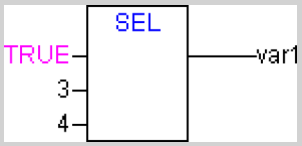
Example in IL:

```
LD  TRUE
SEL 3,4   (* IN0 = 3, IN1 =4 *)
ST  Var1  (* Result is 4 *)
LD  FALSE
SEL 3,4
ST  Var1  (* Result is 3 *)
```

Example in ST:

```
Var1:=SEL(TRUE,3,4); (* Result is 4 *)
```

Example in FBD:



An expression occurring ahead of IN1 or IN2 will not be processed if IN0 is TRUE.

MAX

IEC operator *Chapter 1.4.1.6.1 “Overview” on page 407*: Maximum function. Returns the greater of the two values.

```
OUT := MAX(IN0, IN1)
```

IN0, IN1 and OUT can be any type of variable.

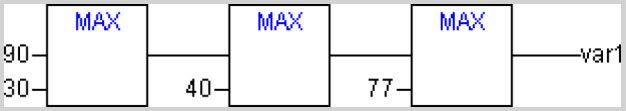
Example in IL:

```
LD 90
MAX 30
MAX 40
MAX 77
ST Var1 (* Result is 90 *)
```

Example in ST:

```
Var1:=MAX(30,40); (* Result is 40 *)
Var1:=MAX(40,MAX(90,30)); (* Result is 90 *)
```

Example in FBD:



MIN

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Minimum function. Returns the lesser of the two values.

```
OUT := MIN(IN0, IN1)
```

IN0, IN1 and OUT can be any type of variable.

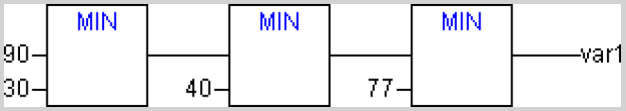
Example in IL:

```
LD 90
MIN 30
MIN 40
MIN 77
ST Var1 (* Result is 30 *)
```

Example in ST:

```
Var1:=MIN(90,30); (* Result is 30 *);
Var1:=MIN(MIN(90,30),40); (* Result is 30 *);
```

Example in FBD:



LIMIT

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Limiting

```
OUT := LIMIT(Min, IN, Max) means:
OUT := MIN (MAX (IN, Min), Max)
```

Max is the upper and Min the lower limit for the result. Should the value IN exceed the upper limit Max, LIMIT will return Max. Should IN fall below Min, the result will be Min.

IN and OUT can be any type of variable.

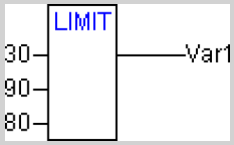
Example in IL:

```
LD 90
LIMIT 30,80
ST Var1 (* Result is 80 *)
```

Example in ST:

```
Var1:=LIMIT(30,90,80); (* Result is 80 *);
```

Example in FBD:



MUX

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Multiplexer.

```
OUT := MUX(K, IN0,...,INn) means:
OUT := INK
```

IN0, ...,INn and OUT can be any type of variable. K must be BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT or UDINT. MUX selects the Kth value from among a group of values.

Example in IL:

```
LD 0
MUX 30,40,50,60,70,80
ST Var1 (* Result is 30 *)
```

Example in ST:

```
Var1:=MUX(0,30,40,50,60,70,80); (* Result is 30 *);
```

An expression occurring ahead of an input other than INK will not be processed to save run time! Only in simulation mode all expressions will be executed.

1.4.1.6.6 Comparison operators

GT

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Greater than.

A Boolean operator which returns the value TRUE when the value of the first operand is greater than that of the second. The operands can be BOOL, BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL, LREAL, TIME, DATE, TIME_OF_DAY, DATE_AND_TIME and STRING.

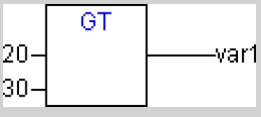
Example in IL:

```
LD 20
GE 30
ST  Var1 (* Result is FALSE *)
```

Example in ST:

```
VAR1 := 20 > 30 > 40 > 50 > 60 > 70;
```

Example in FBD:



LT

↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Less than.

A Boolean operator that returns the value TRUE when the value of the first operand is less than that of the second. The operands can be BOOL, BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL, LREAL, TIME, DATE, TIME_OF_DAY, DATE_AND_TIME and STRING.

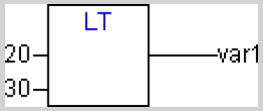
Example in IL:

```
LD 20
LT 30
ST Var1 (* Result is TRUE *)
```

Example in ST:

```
VAR1 := 20 < 30;
```

Example in FBD:



LE

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Less than or equal to.

A Boolean operator that returns the value TRUE when the value of the first operand is less than or equal to that of the second. The operands can be BOOL, BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL, LREAL, TIME, DATE, TIME_OF_DAY, DATE_AND_TIME and STRING.

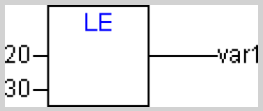
Example in IL:

```
LD 20
LE 30
ST  Var1 (* Result is TRUE *)
```

Example in ST:

```
VAR1 := 20 <= 30;
```

Example in FBD:



GE

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Greater than or equal to.

A Boolean operator that returns the value TRUE when the value of the first operand is greater than or equal to that of the second. The operands can be BOOL, BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL, LREAL, TIME, DATE, TIME_OF_DAY, DATE_AND_TIME and STRING.

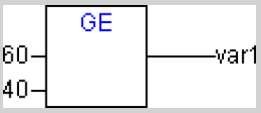
Example in IL:

```
LD 60
GE 40
ST  Var1 (* Result is TRUE *)
```

Example in ST:

```
VAR1 := 60 >= 40;
```

Example in FBD:



EQ

IEC operator *Chapter 1.4.1.6.1 “Overview” on page 407*: Equal to

A Boolean operator that returns the value TRUE when the operands are equal. The operands can be BOOL, BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL, LREAL, TIME, DATE, TIME_OF_DAY, DATE_AND_TIME and STRING.

Example in IL:

```
LD 40
EQ 40
ST Var1 (* Result is TRUE *)
```

Example in ST:

```
VAR1 := 40 = 40;
```

Example in FBD:

NE

IEC operator *Chapter 1.4.1.6.1 “Overview” on page 407*: Not equal to

A Boolean operator that returns that value TRUE when the operands are not equal. The operands can be BOOL, BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL, LREAL, TIME, DATE, TIME_OF_DAY, DATE_AND_TIME and STRING.

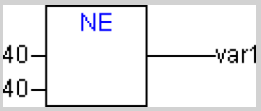
Example in IL:

```
LD 40
NE 40
ST Var1 (* Result is FALSE *)
```

Example in ST:

```
VAR1 := 40 <> 40;
```

Example in FBD:



1.4.1.6.7 Address operators

ADR

IEC operator: Address function not prescribed by the standard IEC 61131-3 ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*.

dwVar:=ADR(bVAR);

Example in IL:

```
LD bVar
ADR
ST dwVar
man_fun1
```

> **NOTICE!**
> After an online change there might be changes concerning the data on certain addresses. Please regard this in case of using pointers on addresses.

ADRINST

Operator: Address function not prescribed by the standard IEC 61131-3 ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*.

ADRINST can be used within a function block instance to return the address of this instance in a DWORD.

Examples in ST (within a function block instance):

```
dvar:=ADRINST();   (* Address of the instance is written to
variable dvar *)
fun(a:=ADRINST()); (* The instance address is given to input
parameter a of function fun *)
```

Examples in IL:

```
ADRINST
ST dvar

ADRINST
fun
```

BITADR

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Address function not prescribed by the standard IEC 61131-3.

BITADR returns the bit offset within the segment in a DWORD. Note that the offset value depends on whether the option byte addressing in the target settings is activated or not.

```
VAR
 var1 AT %IX2.3:BOOL;
 bitoffset: DWORD;
END_VAR
```

Example in ST:

```
bitoffset:=BITADR(var1); (* Result if byte addressing=TRUE: 19, if
byte addressing=FALSE: 35 *)
```

Example in IL:

```
LD Var1
BITADR
ST Var2
```

NOTICE!
After an Online Change there might be changes concerning the data on certain addresses. Please regard this in case of using pointers on addresses.

Content operator

IEC operator *Chapter 1.4.1.6.1 “Overview” on page 407*: A pointer can be dereferenced by adding the content operator "^" after the pointer identifier.

Example in ST:

```
pt:POINTER TO INT;
var_int1:INT;
var_int2:INT;
pt := ADR(var_int1);
var_int2:=pt^;
```

NOTICE!
After an Online Change there might be changes concerning the data on certain addresses. Please regard this in case of using pointers on addresses.

1.4.1.6.8 Calling operators

CAL

IEC operator *Chapter 1.4.1.6.1 “Overview” on page 407*: Calling a function block or a program

Use CAL in IL to call up a function block instance. The variables that will serve as the input variables are placed in parentheses right after the name of the function block instance.

Example: Calling up the instance Inst from a function block where input variables Par1 and Par2 are 0 and TRUE respectively.

```
CAL INST(PAR1 := 0, PAR2 := TRUE)
```

1.4.1.6.9 Type conversion

Type conversion functions

Its is forbidden to implicitly convert from a "larger" type to a "smaller" type (for example from INT to BYTE or from DINT to WORD). Special type conversions are required if one wants to do this. One can basically convert from any elementary type to any other elementary type.

Syntax:

`<elem.Typ1>_TO_<elem.Typ2>`

Please note that at ...TO_STRING conversions the string is generated left-justified. If it is defined to short, it will be cut from the right side.

See also:

- BOOL_TO conversions *Chapter 1.4.1.6.9.2 “BOOL_TO conversions” on page 423*
- TO_BOOL conversions *Chapter 1.4.1.6.9.3 “TO_BOOL conversions” on page 424*
- Conversion between integral number types *Chapter 1.4.1.6.9.4 “Conversion between integral number types” on page 425*
- REAL_TO-/ LREAL_TO conversions *Chapter 1.4.1.6.9.5 “REAL_TO-/ LREAL_TO conversions” on page 426*
- TIME_TO/TIME_OF_DAY conversions *Chapter 1.4.1.6.9.6 “TIME_TO/TIME_OF_DAY conversions” on page 426*
- DATE_TO/DT_TO conversions *Chapter 1.4.1.6.9.7 “DATE_TO/DT_TO conversions” on page 427*
- STRING_TO conversions *Chapter 1.4.1.6.9.8 “STRING_TO conversions” on page 428*

BOOL_TO conversions

Conversion from type BOOL to any other type:

For number types the result is 1, when the operand is TRUE, and 0, when the operand is FALSE.

For the STRING type the result is 'TRUE' or 'FALSE'.

Examples in IL:

```
(*Result is 1 *)
LD TRUE
BOOL_TO_INT
ST i

(*Result is 'TRUE' *)
LD TRUE
BOOL_TO_STRING
ST str

(*Result is T#1ms *)
LD TRUE
BOOL_TO_TIME
ST t

(*Result is TOD#00:00:00.001 *)
LD TRUE
BOOL_TO_TOD
ST

(*Result is D#1970-01-01 *)
LD FALSE
BOOL_TO_DATE
ST dat

(*Result is DT#1970-01-01-00:00:01 *)
LD TRUE
BOOL_TO_DT
ST dandt
```

Examples in ST:

```
(* Result is 1 *)
i:=BOOL_TO_INT(TRUE);

(* Result is "TRUE" *)
str:=BOOL_TO_STRING(TRUE);

(* Result is T#1ms *)
t:=BOOL_TO_TIME(TRUE);

(* Result is TOD#00:00:00.001 *)
tof:=BOOL_TO_TOD(TRUE);

(* Result is D#1970 *)
dat:=BOOL_TO_DATE(FALSE);

(* Result is DT#1970-01-01-00:00:01 *)
dandt:=BOOL_TO_DT(TRUE);
```

Examples in FBD:

	`Result is 1`
	`Result is "TRUE"`
	`Result is T#1ms`
	`Result is TOD#00:00:00.001`
	`Result is D#1970-01-01`
	`Result is DT#1970-01-01-00:00:01`

TO_BOOL conversions

Conversion from another variable type to BOOL:

The result is TRUE when the operand is not equal to 0. The result is FALSE when the operand is equal to 0.

The result is true for STRING type variables when the operand is "TRUE", otherwise the result is FALSE.

Examples in IL:

```
(*Result is TRUE *)
LD 213
BYTE_TO_BOOL
ST b

(*Result is FALSE *)
LD 0
INT_TO_BOOL
ST b

(*Result is TRUE *)
LD T#5ms
TIME_TO_BOOL
ST b

(*Result is TRUE *)
LD 'TRUE'
STRING_TO_BOOL
ST b
```

Examples in ST:

```
(* Result is TRUE *)
b := BYTE_TO_BOOL(2#11010101);

(* Result is FALSE *)
b := INT_TO_BOOL(0);

(* Result is TRUE *)
b := TIME_TO_BOOL(T#5ms);

(* Result is TRUE *)
b := STRING_TO_BOOL('TRUE');
```

Examples in FBD:

	Result is TRUE
	Result is FALSE
	Result is TRUE
	Result is TRUE

Conversion between integral number types

Conversion from an integral number type to another number type:

When you perform a type conversion from a larger to a smaller type, you risk losing some information. If the number you are converting exceeds the range limit, the first bytes for the number will be ignored.

Example in ST:

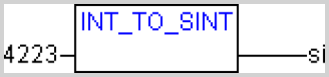
```
si := INT_TO_SINT(4223); (* Result is 127 *)
```

If you save the integer 4223 (16#107f represented hexadecimally) as a SINT variable, it will appear as 127 (16#7f represented hexadecimally).

Example in IL:

```
LD 2
INT_TO_REAL
MUL
```

Example in FBD:



REAL_TO-/ LREAL_TO conversions

Converting from the variable type REAL or LREAL to a different type:

The value will be rounded up or down to the nearest whole number and converted into the new variable type. Exceptions to this are the variable types STRING, BOOL, REAL and LREAL.

Please note at a conversion to type STRING that the total number of digits is limited to 16. If the (L)REAL-number has more digits, then the sixteenth will be rounded. If the length of the STRING is defined to short, it will be cut beginning from the right end.

When you perform a type conversion from a larger to a smaller type, you risk losing some information.

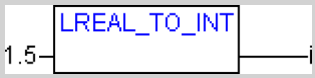
Examples in IL:

```
LD 2.7
REAL_TO_INT
GE %MW8
```

Examples in ST:

```
i := REAL_TO_INT(1.5); (* Result is 2 *)
j := REAL_TO_INT(1.4); (* Result is 1 *)
i := REAL_TO_INT(-1.5); (* Result is -2 *)
j := REAL_TO_INT(-1.4); (* Result is -1 *)
```

Examples in FBD:



TIME_TO/TIME_OF_DAY conversions

Converting from the variable type TIME or TIME_OF_DAY to a different type:

The time will be stored internally in a DWORD in milliseconds (beginning with 12:00 A.M. for the TIME_OF_DAY variable). This value will then be converted.

When you perform a type conversion from a larger to a smaller type, you risk losing some information.

For the STRING type variable, the result is a time constant.

Examples in IL:

```
(*Result is 'T#12ms' *)
LD T#12ms
TIME_TO_STRING
ST str

(*Result is 300000 *)
LD T#300000ms
TIME_TO_DWORD
ST dw

(*Result is 12 *)
LD TOD#00:00:00.012
TOD_TO_SINT
ST si
```

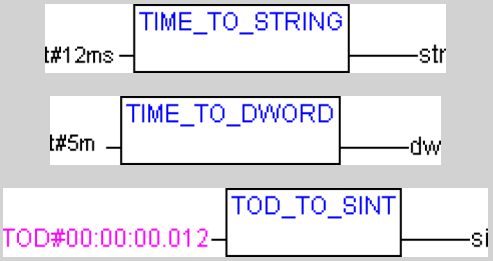
Examples in ST:

```
(* Result is T#12ms *)
#str :=TIME_TO_STRING(T#12ms);

(* Result is 300000 *)
dw:=TIME_TO_DWORD(T#5m);

(* Result is 12 *)
si:=TOD_TO_SINT(TOD#00:00:00.012);
```

Examples in FBD:



DATE_TO/DT_TO conversions

Converting from the variable type DATE or DATE_AND_TIME to a different type:

The date will be stored internally in a DWORD in seconds since Jan. 1, 1970. This value will then be converted.

When you perform a type conversion from a larger to a smaller type, you risk losing some information.

For STRING type variables, the result is the date constant.

Examples in IL:

```
(* Result is FALSE *)
LD D#1970-01-01
DATE_TO_BOOL
ST b

(* Result is 29952 *)
LD D#1970-01-15
DATE_TO_INT
ST i

(* Result is 129 *)
LD DT#1970-01-15-05:05:05
DT_TO_BYTE
ST byt

(* Result is 'DT#1998-02-13-14:20' *)
LD DT#1998-02-13-14:20
DT_TO STRING
ST str
```

Examples in ST:

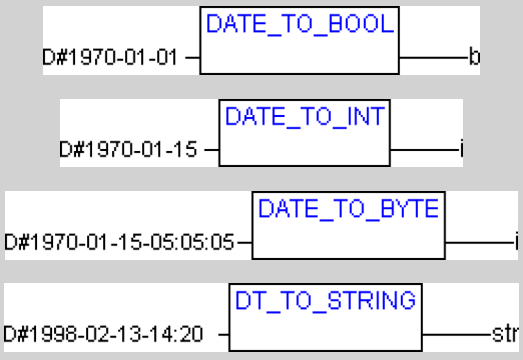
```
(* Result is FALSE *)
b :=DATE_TO_BOOL(D#1970-01-01);

(* Result is 29952 *)
i :=DATE_TO_INT(D#1970-01-15);

(* Result is 129 *)
byt :=DT_TO_BYTE(DT#1970-01-15-05:05:05);

(* Result is 'DT#1998-02-13-14:20' *)
str:=DT_TO_STRING(DT#1998-02-13-14:20);
```

Examples in FUP:



STRING_TO conversions

Converting from the variable type STRING to a different type:

The operand from the STRING type variable must contain a value that is valid in the target variable type, otherwise the result will be 0.

Examples in IL:

```
(* Result is TRUE *)
LD 'TRUE'
STRING_TO_BOOL
ST b

(* Result is 0 *)
LD 'abc34'
STRING_TO_WORD
ST w

(* Result is T#127ms *)
LD 't#127ms'
STRING_TO_TIME
ST t
```

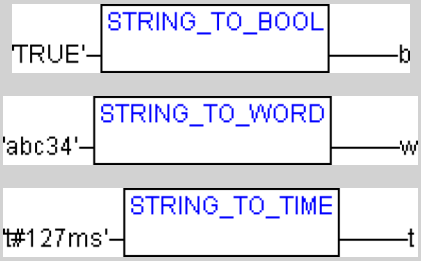
Examples in ST:

```
(* Result is TRUE *)
b :=STRING_TO_BOOL('TRUE');

(* Result is 0 *)
w :=STRING_TO_WORD('abc34');

(* Result is T#127ms *)
t :=STRING_TO_TIME('T#127ms');
```

Examples in FBD:



TRUNC

IEC operator *Chapter 1.4.1.6.1 “Overview” on page 407*: Converting from REAL to INT. The whole number portion of the value will be used.

When you perform a type conversion from a larger to a smaller type, you risk losing some information.

Example in IL:

```
LD 2.7 TRUNC GE %MW8
```

Examples in ST:

```
i:=TRUNC(1.9); (* Result is 1 *)
i:=TRUNC(-1.4); (* Result is -1 *)
```

1.4.1.6.10 Numeric operators

ABS

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the absolute value of a number. ABS(-2) equals 2.

The following type combinations for input and output variables are possible:

IN	OUT
INT	INT, REAL, WORD, DWORD, DINT
REAL	REAL
BYTE	INT, REAL, BYTE, WORD, DWORD, DINT
WORD	INT, REAL, WORD, DWORD, DINT
DWORD	REAL, DWORD, DINT
SINT	REAL
USINT	REAL
UINT	INT, REAL, WORD, DWORD, DINT, UDINT, UINT
DINT	REAL, DWORD, DINT
UDINT	REAL, DWORD, DINT, UDINT

Example in IL:

```
LD  -2
ABS
ST  i  (* Result is 2 *)
```

Example in ST:

```
i:=ABS(-2);
```

Example in FBD:

SQRT

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the square root of a number.

IN can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT. OUT must be type REAL.

Example in IL:

```
LD  16
SQRT
ST  q  (* Result is 4 *)
```

Example in ST:

```
q:=SQRT(16);
```

Example in FBD:

LN

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the natural logarithm of a number.

IN can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT.

OUT must be type REAL.

Example in IL:

```
LD 45
LN
ST  q (* Result is 3.80666 *)
```

Example in ST:

```
q:=LN(45);
```

Example in FBD:

LOG

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the logarithm of a number in base 10.

IN can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT.

OUT must be type REAL.

Example in IL:

```
LD 314.5
LOG
ST  q (* Result is 2.49762 *)
```

Example in ST:

```
q:=LOG(314.5);
```

Example in FBD:

EXP

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the exponential function.

IN can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT, OUT must be type REAL.

Example in IL:

```
LD  2
EXP
ST  q (* Result is 7.389056099 *)
```

Example in ST:

```
q:=EXP(2);
```

Example in FBD:

SIN

IEC operator *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the sine of a number. The result is calculated in radians.

IN can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT, OUT must be type REAL.

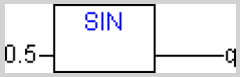
Example in IL:

```
LD  0.5
SIN
ST  q  (* Result is 0.479426 *)
```

Example in ST:

```
q:=SIN(0.5);
```

Example in FBD:



COS

IEC operator *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the cosine of a number. The result is calculated in radians.

IN can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT, OUT must be type REAL.

Example in IL:

```
LD  0.5
COS
ST  q  (* Result is 0.877583 *)
```

Example in ST:

```
q:=COS(0.5);
```

Example in FBD:

TAN

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the tangent of a number. The value is calculated in radians.

IN can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT, OUT must be type REAL.

Example in IL:

```
LD  0.5
TAN
ST  q  (* Result is 0.546302 *)
```

Example in ST:

```
q:=TAN(0.5);
```

Example in FBD:

ASIN

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the arc sine (inverse function of sine) of a number.

IN can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT, OUT must be type REAL.

Example in IL:

```
LD  0.5
ASIN
ST  q  (* Result is 0.523599 *)
```

Example in ST:

```
q:=ASIN(0.5);
```

Example in FBD:

ACOS

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the arc cosine (inverse function of cosine) of a number. The value is calculated in radians.

IN can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT, OUT must be type REAL.

Example in IL:

```
LD 0.5
ACOS
ST q  (* Result is 1.0472 *)
```

Example in ST:

```
q:=ACOS(0.5);
```

Example in FBD:

ATAN

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Returns the arc tangent (inverse function of tangent) of a number.

IN can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT. The result OUT is calculated in radians and must be type REAL.

Example in IL:

```
LD  0.5
ATAN
ST  q  (* Result is 0.463648 *)
```

Example in ST:

```
q:=ATAN(0.5);
```

Example in FBD:

EXPT

IEC operator ↳ *Chapter 1.4.1.6.1 “Overview” on page 407*: Exponentiation of a variable with another variable:

IN1 and IN2 can be type BYTE, WORD, DWORD, INT, DINT, REAL, SINT, USINT, UINT, UDINT, OUT must be type REAL.

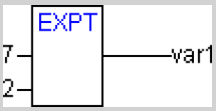
Example in IL:

```
LD  7
EXPT 2
ST  Var1 (* Result is 49 *)
```

Example in ST:

```
var1 := EXPT(7,2);
```

Example in FBD:



1.4.1.6.11 Initialization operator

INI operator

The INI operator can be used to initialize retain variables which are provided by a function block instance used in the POU.

The operator must be assigned to a boolean variable.

Syntax: <bool-Variable> := INI(<FB-instance, TRUE|FALSE)

If the second parameter of the operator is set to TRUE, all retain variables defined in the function block FB will be initialized.

Example in ST: fbinst is the instance of function block fb, in which a retain variable retvar is defined.

Declaration in POU:

```
fbinst:fb;
b:bool;
```

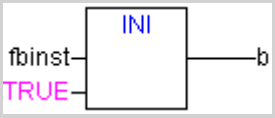
Implementation part:

```
b := INI(fbinst, TRUE);
ivar:=fbinst.retvar  (* => retvar gets initialized *)
```

Example of operator call in IL:

```
LD fbinst
INI TRUE
ST b
```

Example of operator call in FUP:



1.4.1.7 Operands

1.4.1.7.1 Overview

In constants, variables, addresses and possibly function calls can appear as operands.

1.4.1.7.2 Constants

BOOL constants

BOOL constants are the logical values TRUE and FALSE.

TIME constants

TIME constants can be declared. These are generally used to operate the timer in the standard library. A TIME constant is always made up of an initial "t" or "T" (or "time" or "TIME" spelled out) and a number sign "#".

This is followed by the actual time declaration which can include days (identified by "d"), hours (identified by "h"), minutes (identified by "m"), seconds (identified by "s") and milliseconds (identified by "ms").

Please note that the time entries must be given in this order according to length (d before h before m before s before m before ms) but you are not required to include all time increments.

Examples of correct TIME constants in a ST assignment:	TIME1 := T#14ms; TIME1 := T#100S12ms; (*The highest component may be allowed to exceed its limit*) TIME1 := t#12h34m15s; The following would be incorrect: TIME1 := t#5m68s; (*limit exceeded in a lower component*) TIME1 := 15ms; (*T# is missing*) TIME1 := t#4ms13d; (*Incorrect order of entries*)

DATE constants

These constants can be used to enter dates. A DATE constant is declared beginning with a "d", "D", "DATE" or "date" followed by "#". You can then enter any date with format Year-Month-Day.

Examples:	DATE#1996-05-06 d#1972-03-29

TIME_OF_DAY constants

Use this type of constant to store times of the day. A TIME_OF_DAY declaration begins with "tod#", "TOD#", "TIME_OF_DAY#" or "time_of_day#" followed by a time with the format: Hour:Minute:Second.

You can enter seconds as real numbers or you can enter fractions of a second.

Examples:	TIME_OF_DAY#15:36:30.123 tod#00:00:00

DATE_AND_TIME constants

Date constants and the time of day can also be combined to form so-called DATE_AND_TIME constants. DATE_AND_TIME constants begin with "dt#", "DT#", "DATE_AND_TIME#" or "date_and_time#".

Place a hyphen after the date followed by the time.

Examples:	DATE_AND_TIME#1996-05-06-15:36:30 dt#1972-03-29-00:00:00

Number constants

Number values can appear as binary numbers, octal numbers, decimal numbers and hexadecimal numbers. If an integer value is not a decimal number, you must write its base followed by the number sign (#) in front of the integer constant. The values for the numbers 10-15 in hexadecimal numbers will be represented as always by the letters A-F.

You may include the underscore character within the number.

Examples	14 (decimal number) 2#1001_0011 (dual number) 8#67 (octal number) 16#A (hexadecimal number)

These number values can be from the variable types BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL or LREAL. Implicit conversions from "larger" to "smaller" variable types are not permitted. This means that a DINT variable cannot simply be used as an INT variable. You must use the type conversion.

REAL/LREAL constants

REAL / LREAL constants can be given as decimal fractions and represented exponentially ↳ *Chapter 1.4.1.8.1.4 “REAL / LREAL” on page 443*. Use the standard American format with the decimal point to do this.

Example	7.4 instead of 7,4 1.64e+009 instead of 1,64e+009

STRING constants

A string is a sequence of characters. STRING constants are preceded and followed by single quotation marks. You may also enter blank spaces and special characters (umlauts for instance). They will be treated just like all other characters.

In character sequences, the combination of the dollar sign ($) followed by two hexadecimal numbers is interpreted as a hexadecimal representation of the eight bit character code. In addition, the combination of two characters that begin with the dollar sign are interpreted as shown below when they appear in a character sequence:

$$	Dollar signs
$'	Single quotation mark
$L or $l	Line feed
$N or $n	New line
$P or $p	Page feed
$R or $r	Line break
$T or $t	Tab

Examples	'w1Wüß?' ' Abby and Craig ' ':-)'

Typed literals

Basically, in using IEC constants, the smallest possible data type will be used. If another data type must be used, this can be achieved with the help of typed literals without the necessity of explicitly declaring the constants. For this, the constant will be provided with a prefix which determines the type.

This is written as follows: <Type>#<Literal>

<Type> specifies the desired data type; possible entries are: BOOL, SINT, USINT, BYTE, INT, UINT, WORD, DINT, UDINT, DWORD, REAL, LREAL. The type must be written in uppercase letters.

<Literal> specifies the constant. The data entered must fit within the data type specified under <Type>.

Example	var1:=DINT#34;

If the constant can not be converted to the target type without data loss, an error message is issued:

Typed literals can be used wherever normal constants can be used.

1.4.1.7.3 Variables

Overview

Variables can be declared either locally in the declaration part of a POU or in a global variable list.

In a project you can define a local variable which has the same name like a global variable. In this case within a POU the locally defined variable will be used. It is not allowed however to name two global variables identically. For example you will get a compiler error, if you have defined a variable "var1" in the PLC Configuration as well as in a global variables list.

The variable identifier may not contain any blank spaces or special characters, may not be declared more than once and cannot be the same as any of the keywords. Capitalization is not recognized which means that VAR1, Var1, and var1 are all the same variable. The underscore character is recognized in identifiers (e.g., "A_BCD" and "AB_CD" are considered two different identifiers). An identifier may not have more than one underscore character in a row. The length of the identifier, as well as the meaningful part of it, are unlimited.

Variables can be used anywhere the declared type allows for them.

You can access available variables through the input assistant.

System flags

System flags are implicitly declared variables that are different on each specific PLC. To find out which system flags are available in your system, use the command 'Insert' 'Operand'. An input assistant dialog box pops up, select the category 'System Variable'.

Accessing variables for arrays, structures and POUs

Two-dimensional array components can be accessed using the following syntax:

```
<Fieldname>[Index1, Index2]
```

Structure variables can be accessed using the following syntax:

```
<Structurename>.<Variablenname>
```

Function block and program variables can be accessed using the following syntax:

```
<Functionblockname>.<Variablename>
```

Addressing bits in variables

In integer variables individual bits can be accessed. For this, the index of the bit to be addressed is appended to the variable, separated by a dot. The bit-index can be given by any constant. Indexing is 0-based.

Bitaccess in Direct variables is not allowed Chapter 1.4.2.4.4 “The library SysLibDirect.lib” on page 570.

Example

```
a : INT;
b : BOOL;
...
a.2 := b;
```

The third bit of the variable a will be set to the value of the variable b.

If the index is greater than the bit width of the variable, the following error message is issued: Index '<n>' outside the valid range for variable '<var>'!

Bit addressing is possible with the following variable types: SINT, INT, DINT, USINT, UINT, UDINT, BYTE, WORD, DWORD.

If the variable type does not allow it, the following error message is issued: "Invalid data type '<type>' for direct indexing"

A bit access must not be assigned to a VAR_IN_OUT variable!

Bitaccess via a global constant:

If you have declared a global constant, which defines the bit-index, you can use this constant for a bitaccess.

The project option 'Replace constants' (category Build) must be activated.

See in the following examples for such a bitaccess on a variable resp. a structure variable:

Declaration in global variables list for both examples:

Variable enable defines which bit should be accessed:

```
VAR_GLOBAL CONSTANT
enable:int:=2;
END_VAR
```

Example 1, Bitaccess on an integer variable:

Declaration in POU:

```
VAR
xxx:int;
END_VAR
```

Bitaccess:

```
xxx.enable:=true;
```

The third bit in variable xxx will be set TRUE.

Example 2, Bitaccess on an integer structure component:

Declaration of structure stru1:

```
TYPE stru1 :
STRUCT
bvar:BOOL;
rvar:REAL;
wvar:WORD;
{bitaccess enable 42 'Start drive'}
END_STRUCT
END_TYPE
```

Declaration in POU:

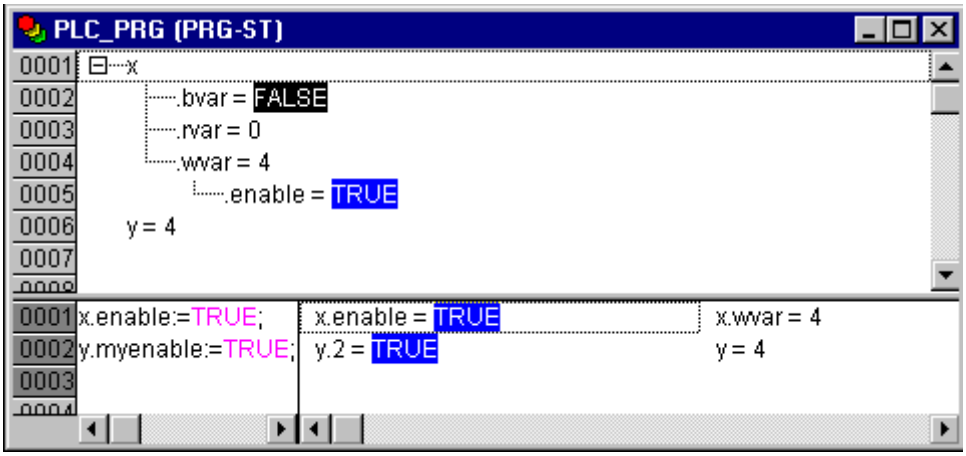
```
VAR
x:stru1;
END_VAR
```

Bitaccess:

```
x.enable:=true;
```

This will set TRUE the 42. bit in variable x. Since bvar has 8 bits and rvar has 32 bits, the bitaccess will be done on the second bit of variable wvar, which as a result will get value 4.

If a variable, which does a bitaccess on a structure variable with the aid of a global constant, should be displayed correctly in the input assistant, at monitoring in the declaration window and in the intellisense function. Please use pragma {bitaccess} which is shown in the example ↬ Chapter 1.4.1.3.10.2 “Pragma instructions for initialization, monitoring, creation of symbols, bitaccess, linking” on page 310. Then in addition you get displayed the global constant beyond the respective structure variable during monitoring in the declaration window:



1.4.1.7.4 Addresses

Addresses, note

> *Online Change might change the contents on addresses.*
>
> *Please regard this when using pointers on addresses. See Pointer and Address ↳ Chapter 1.4.1.8.2.3 “Pointer” on page 447 ↳ Chapter 1.4.1.7.4.2 “Address” on page 441.*

Address

The direct display of individual memory locations is done through the use of special character sequences. These sequences are a concatenation of the percent sign "%", a range prefix, a prefix for the size and one or more natural numbers separated by blank spaces.

The following range prefixes are supported:

I	Input
Q	Output
M	Memory location

The following size prefixes are supported:

Examples:

%QX7.5 and %Q7.5	Output bit 7.5
%IW215	Input word 215
%QB7	Output byte 7
%MD48	Double word in memory position 48 in the memory location.
%IW2.5.7.1	depending on the PLC Configuration
ivar AT %IW0 : WORD;	Example of a variable declaration including an address assignment

The current PLC Configuration for the program determines whether or not an address is valid.

Boolean values will be allocated bytewise, if no explicit single-bit address is specified.

Example: A change in the value of varbool1 AT %QW0 affects the range from QX0.0 to QX0.7.

Online Change might change the contents on addresses.

Please regard this when using Pointer on addresses *Chapter 1.4.1.8.2.3 “Pointer” on page 447.*

Memory location

You can use any supported size to access the memory location.

For example, the address %MD48 would address bytes numbers 192, 193, 194, and 195 in the memory location area (48 * 4 = 192). The number of the first byte is 0.

You can access words, bytes and even bits in the same way: the address %MX5.0 allows you to access the first bit in the fifth word (Bits are generally saved wordwise).

Online Change might change the contents on addresses.

Please regard this when using pointers on addresses.

1.4.1.7.5 Functions

In ST a function call can also appear as an operand.

Example:	Result := Fct(7) + 3;

TIME()-Function

This function returns the time (based on milliseconds) which has been passed since the system was started. The data type is TIME.

Example in IL:	TIME ST systime (* Result e.g.: T#35m11s342ms *)

Example in ST:	systime:=TIME();

Example in FUP:	
1.4.1.8 Data types

1.4.1.8.1 Standard data types

Data types

You can use standard data types and user-defined data types when programming. Each identifier is assigned to a data type which dictates how much memory space will be reserved and what type of values it stores.

BOOL

BOOL type variables may be given the values TRUE and FALSE. 8 bits of memory space will be reserved.

See also: BOOL constants ↳ *Chapter 1.4.1.7.2.1 “BOOL constants” on page 435*

Integer data types

BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, and UDINT are all integer data types.

Each of the different number types covers a different range of values. The following range limitations apply to the integer data types:

Type	Lower limit	Upper limit	Memory space
BYTE	0	255	8 bit
WORD	0	65535	16 bit
DWORD	0	4294967295	32 bit
SINT	-128	127	8 bit
USINT	0	255	8 bit
INT	-32768	32767	16 bit
UINT	0	65535	16 bit
DINT	-2147483648	2147483647	32 bit
UDINT	0	4294967295	32 bit

As a result when larger types are converted to smaller types, information may be lost.

See also: Number constants ↳ *Chapter 1.4.1.7.2.6 “Number constants” on page 436*

REAL / LREAL

REAL and LREAL are so-called floating-point types. They are required to represent rational numbers. 32 bits of memory space is reserved for REAL and 64 bits for LREAL.

Valid values for REAL: 1.175494351e-38 to 3.402823466e+38

Valid values for LREAL: 2.2250738585072014e-308 to 1.7976931348623158e+308

See also: REAL/LREAL constants ↳ *Chapter 1.4.1.7.2.7 “REAL/LREAL constants” on page 437*

STRING

A STRING type variable can contain any string of characters. The size entry in the declaration determines how much memory space should be reserved for the variable. It refers to the number of characters in the string and can be placed in parentheses or square brackets. If no size specification is given, the default size of 80 characters will be used.

The string length basically is not limited, but string functions only can process strings of 1 - 255 characters!

Example of a String Declaration with 35 characters:

```
str:STRING(35):='This is a String';
```

See also: STRING constants ↬ *Chapter 1.4.1.7.2.8 “STRING constants” on page 437*

Time data types

The data types TIME, TIME_OF_DAY (abb. TOD), DATE and DATE_AND_TIME (abb. DT) are handled internally like DWORD.

Time is given in milliseconds in TIME and TOD, time in TOD begins at 12:00 A.M.

Time is given in seconds in DATE and DT beginning with January 1, 1970 at 12:00 A.M.

See in the following the time data formats used to assign values for time constants:

TIME constants: always made up of an initial "t" or "T" (or "time" or "TIME" spelled out) and a number sign "#".

This is followed by the actual time declaration which can include days (identified by "d"), hours (identified by "h"), minutes (identified by "m"), seconds (identified by "s") and milliseconds (identified by "ms"). Please note that the time entries must be given in this order according to length (d before h before m before s before m before ms) but you are not required to include all time increments.

Maximum value: 49d17h2m47s295ms (4194967295 ms)

Examples of correct TIME constants in a ST assignment:

TIME1 := T#14ms;	
TIME1 := T#100S12ms;	(*The highest component may be allowed to exceed its limit*)
TIME1 := t#12h34m15s;	

the following would be incorrect:

TIME1 := t#5m68s;	(*limit exceeded in a lower component*)
TIME1 := 15ms;	(*T# is missing*)
TIME1 := t#4ms13d;	(*Incorrect order of entries*)

DATE constants: A date constant begins with a "d", "D", "DATE" or "date" followed by "#". You can then enter any date with format Year-Month-Day. Possible values: 1970-00-00 to 2106-02-06.

Examples:

```
DATE#1996-05-06
d#1972-03-29
```

TIME_OF_DAY constants, for storing times of the day: begin with "tod#", "TOD#", "TIME_OF_DAY#" or "time_of_day#" followed by a time with the format: Hour:Minute:Second. Seconds can be entered as real numbers or you can enter fractions of a second. Possible values: 00:00:00 bis 23:59:59.999.

Examples:

```
TIME_OF_DAY#15:36:30.123
tod#00:00:00
```

DATE_AND_TIME constants, combination of date and the time of day: begin with "dt#", "DT#", "DATE_AND_TIME#" or "date_and_time#". Place a hyphen after the date followed by the time. Possible values: 1970-00-00-00:00:00 to 2106-02-06-06:28:15.

Examples:

```
DATE_AND_TIME#1996-05-06-15:36:30
dt#1972-03-29-00:00:00
```

1.4.1.8.2 Defined data types

ARRAY

One-, two-, and three-dimensional fields (arrays) are supported as elementary data types. Arrays can be defined both in the declaration part of a POU and in the global variable lists. Maximum 9 dimensions may result from nesting of arrays ("ARRAY[0..2] OF ARRAY[0..3] OF …").

Syntax:

```
<Field_Name>:ARRAY [<ll1>..<ul1>,<ll2>..<ul2>] OF <elem. Type>.
```

ll1, ll2, ll3 identify the lower limit of the field range; ul1, ul2 and ul3 identify the upper limit. The limit values must be integers and must match the DINT range of values.

Example:

```
Card_game: ARRAY [1..13, 1..4] OF INT;
```

Initializing arrays:

Example for complete initialization of an array:

```
arr1 : ARRAY [1..5] OF INT := 1,2,3,4,5;
arr2 : ARRAY [1..2,3..4] OF INT := 1,3(7); (* short for 1,7,7,7 *)
arr3 : ARRAY [1..2,2..3,3..4] OF INT := 2(0),4(4),2,3; (* short for
0,0,4,4,4,4,2,3 *)
```

Example of the initialization of an array of a structure:

```
TYPE STRUCT1
STRUCT
p1:int;
p2:int;
p3:dword;
END_STRUCT
ARRAY[1..3] OF STRUCT1:= (p1:=1,p2:=10,p3:=4723),
(p1:=2,p2:=0,p3:=299),(p1:=14,p2:=5,p3:=112);
```

Example of the partial initialization of an array:

```
arr1 : ARRAY [1..10] OF INT := 1,2;
```

Elements to which no value is pre-assigned are initialized with the default initial value of the basic type. In the example above, the elements anarray[6] to anarray[10] are therefore initialized with 0.

Accessing array components: Array components are accessed in a two-dimensional array using the following syntax:

```
<Field_Name>[Index1,Index2]
```

Example:

```
Card_game [9,2]
```

If you define a function in your project with the name CheckBounds, you can use it to check for range overflows in your project (see chapter 'How is a project structured?' ↳ *Chapter 1.4.1.1.1 “How is a project structured?” on page 145)*
↳ *Chapter 1.4.1.8.2.2 “Function CheckBounds” on page 446.*

Function CheckBounds

If you define a function in your project with the name CheckBounds, you can automatically check for out-of-range errors in arrays ↳ *Chapter 1.4.1.8.2.1 “ARRAY” on page 445*. The name of the function is fixed and can only have this designation.

Example for the function CheckBounds:

```
FUNCTION CheckBounds : DINT
VAR_INPUT
 index, lower, upper: DINT;
END_VAR
IF  index < lower THEN
 CheckBounds := lower;
ELSIF  index > upper THEN
 CheckBounds := upper;
ELSE  CheckBounds := index;
END_IF
```

The following sample program for testing the CheckBounds function exceeds the bounds of a defined array. The CheckBounds function allows the value TRUE to be assigned, not to location A[10], but to the still valid range boundary A[7] above it. With the CheckBounds function, references outside of array boundaries can thus be corrected.

Test program for the function CheckBounds:

```
PROGRAM PLC_PRG
VAR
 a: ARRAY[0..7] OF BOOL;
 b: INT:=10;
END_VAR
a[b]:=TRUE;
```

NOTICE!
The CheckBounds-function provided by the Check.Lib library is just a sample solution! Before using that library module check whether the function is working in your sense, or implement an appropriate function directly as a POU in your project.

Pointer

Variable or function block addresses ↳ *Addresses* are saved in pointers while a program is running.

Pointer declarations have the following syntax:

```
<Identifier>: POINTER TO <Datatype/Functionblock>;
```

A pointer can point to any data type or function block even to user-defined types.

The function of the Address Operator ADR is to assign the address of a variable or function block to the pointer.

A pointer can be dereferenced by adding the content operator "^" after the pointer identifier.

A pointer is counted up bytewise ! You can get it counted up like it is usual in the C-Compiler by using the instruction p=p+SIZEOF(p^);.

Example:

```
pt:POINTER TO INT;
var_int1:INT := 5;
var_int2:INT;
pt := ADR(var_int1);
var_int2:= pt^; (* var_int2 is now 5 *)
```

Checking pointer accesses at run time

For checking pointer accesses during run time you can create check functions, which will be called automatically before each access on the address of a pointer. For this purpose the respective function must be available in the project, directly or via a library. The following functions are supported:

- Function CheckPointer: checks whether the address currently stored at the pointer is within the valid memory range,
- Function CheckPointerAligned: implicates the functionality of CheckPointer and additionally checks the memory alignment.

The functions must exactly have the mentioned names. They return the address which is used for dereferencing the pointer, thus at best that which has been passed on as the first input parameter (dwAddress in the example shown below).

See in the following example of a CheckPointerAligned function, which input parameters are processed. The parameter names are examples too. A CheckPointer function must look the same, except that there may be no parameter for the granularity of the pointer access:

`FUNCTION CheckPointerAligned : DWORD`	(* The data type of the function (return value) must be the same as used for pointers in the currently set target system; i.e. DWORD for systems using 32-bit pointers, WORD for systems using 16-bit pointers *)
`VAR_INPUT`	
`dwAddress : DWORD;`	(* Target address of the pointer; the data type must be the same as used for pointers in the currently set target system, see above: return value *)
`iSize : DINT;`	(* Size of pointer access; the data type must be integer-compatible and must cover the maximum potential data size stored at the pointer address *)
`iGran : DINT;`	(* ! not to be used in CheckPointer functions ! : Granularity of the access, e.g. "2", if INT is the smallest not-structured datatype used on the given address; the data type must be integer-compatible *)
`bWrite: BOOL;`	(*Access type: Read or Write; TRUE=read access; the data type must be BOOL *)
`END_VAR`	

If there are a CheckPointer function and a CheckPointerAligned function in the project, CheckPointerAligned will be called.

Enumeration

Enumeration is a user-defined data type that is made up of a number of string constants. These constants are referred to as enumeration values.

Enumeration values are recognized in all areas of the project even if they were declared within a POU. It is best to create your enumerations as objects in the Object Organizer under the register card Data types. They begin with the keyword TYPE and end with END_TYPE.

Syntax:

```
TYPE <Identifier>:(<Enum_0> ,<Enum_1>, ...,<Enum_n>);
END_TYPE
```

A variable of the type <Identifier> can take on one of the enumeration values and will be initialized with the first one. These values are compatible with whole numbers which means that you can perform operations with them just as you would with INT. You can assign a number x to the variable. If the enumeration values are not initialized, counting will begin with 0. When initializing, make certain the initial values are increasing. The validity of the number will be reviewed at the time it is run.

Example:

```
TYPE TRAFFIC_SIGNAL: (Red, Yellow, Green:=10); (*The initial value
for each of the colors is red 0, yellow 1, green 10 *)
END_TYPE
TRAFFIC_SIGNAL1 : TRAFFIC_SIGNAL;
TRAFFIC_SIGNAL1:=0; (* The value of the traffic signal is red*)
FOR i:= Red TO Green DO
 i := i + 1;
END_FOR;
```

The same enumeration value may not be used twice within an enumeration or within all enumerations used in the same POU.

Example:

```
TRAFFIC_SIGNAL: (red, yellow, green);
COLOR: (blue, white, red);
Error: red may not be used for both TRAFFIC_SIGNAL and COLOR.
```

Structures

Structures are created as objects in the Object Organizer under the register card Data types. They begin with the keywords TYPE and STRUCT and end with END_STRUCT and END_TYPE.

The syntax for structure declarations is as follows:

```
TYPE <Structurename>:
STRUCT
 <Declaration of Variables 1>
 .
 .
 <Declaration of Variables n>
END_STRUCT
END_TYPE
```

<Structurename> is a type that is recognized throughout the project and can be used like a standard data type.

Interlocking structures are allowed. The only restriction is that variables may not be placed at addresses (the AT declaration is not allowed!).

Example for a structure definition named Polygonline:

```
TYPE Polygonline:
STRUCT
 Start:ARRAY [1..2] OF INT;
 Point1:ARRAY [1..2] OF INT;
 Point2:ARRAY [1..2] OF INT;
 Point3:ARRAY [1..2] OF INT;
 Point4:ARRAY [1..2] OF INT;
 End:ARRAY [1..2] OF INT;
END_STRUCT
END_TYPE
```

Example for the initialization of a structure:

```
Poly_1:polygonline := ( Start:=3,3, Point1 =5,2, Point2:=7,3,
Point3:=8,5, Point4:=5,7, End := 3,5);
```

Initializations with variables are not possible. See an example of the initialization of an array of a structure under 'Arrays'.

Access on structure components:

You can gain access to structure components using the following syntax:

```
<Structure_Name>.<Componentname>
```

So for the above mentioned example of the structure 'polygonline' you can access the component 'start' by `Poly_1.Start`.

References

You can use the user-defined reference data type to create an alternative name for a variable, constant or function block.

Create your references as objects in the Object Organizer under the register card Data types. They begin with the keyword TYPE and end with END_TYPE.

Syntax:

```
TYPE <Identifier>: <Assignment term>;
END_TYPE
```

Example:

```
TYPE message:STRING[50];
END_TYPE;
```

Subrange types

A subrange type is a type whose range of values is only a subset of that of the basic type. The declaration can be carried out in the data types register, but a variable can also be directly declared with a subrange type:

Syntax for the declaration in the 'Data types' register:

```
TYPE <Name> : <Inttype> (<ug>..<og>) END_TYPE;
```

<Name>	must be a valid IEC identifier,
<Inttype>	is one of the data types SINT, USINT, INT, UINT, DINT, UDINT, BYTE, WORD, DWORD (LINT, ULINT, LWORD).
<ug>	Is a constant which must be compatible with the basic type and which sets the lower boundary of the range types. The lower boundary itself is included in this range.
<og>	Is a constant that must be compatible with the basic type, and sets the upper boundary of the range types. The upper boundary itself is included in this basic type.

Example:

```
TYPE
 SubInt : INT (-4095..4095);
END_TYPE
```

Direct declaration of a variable with a subrange type:

```
VAR
 i : INT (-4095..4095);
 ui : UINT (0..10000);
END_VAR
```

If a constant is assigned to a subrange type (in the declaration or in the implementation) that does not fall into this range (e.g. 1:=5000), an error message is issued.

In order to check for observance of range boundaries at run time, the functions CheckRangeSigned or CheckRangeUnsigned must be introduced. In these, boundary violations can be captured by the appropriate method and means (e.g. the value can be cut out or an error flag can be set.). They are implicitly called as soon as a variable is written as belonging to a subrange type constructed from either a signed or an unsigned type.

Example:

In the case of a variable belonging to a signed subrange type (like i, above), the function CheckRangeSigned is called; it could be programmed as follows to trim a value to the permissible range:

```
FUNCTION CheckRangeSigned : DINT
VAR_INPUT
 value, lower, upper: DINT;
END_VAR
IF (value < lower) THEN
 CheckRangeSigned := lower;
ELSIF(value > upper) THEN
 CheckRangeSigned := upper;
ELSE
 CheckRangeSigned := value;
END_IF
```

In calling up the function automatically, the function name CheckRangeSigned is obligatory, as is the interface specification: return value and three parameters of type DINT

When called, the function is parameterized as follows:

-
- - value: the value to be assigned to the range type
- - lower: the lower boundary of the range
- - upper: the upper boundary of the range
- - Return value: this is the value that is actually assigned to the range type

An assignment i:=10*y implicitly produces the following in the example:

```
i := CheckRangeSigned(10*y, -4095, 4095);
```

Even if y for example has the value 1000, then i still has only the value 4095 after this assignment.

The same applies to the function CheckRangeUnsigned: function name and interface must be correct.

```
FUNCTION CheckRangeUnsigned : UDINT
VAR_INPUT
 value, lower, upper: UDINT;
END_VAR
```

WARNING!
If neither of the functions CheckRangeSigned or CheckRangeUnsigned is present, no type checking of subrange types occurs during run time! The variable i could then take on any value between 32768 and 32767 at any time!

NOTICE!
If neither of the functions CheckRangeSigned or CheckRangeUnsigned is present like described above, there can result an endless loop if a subrange type is used in a FOR loop. This will happen when the range given for the FOR loop is as big or bigger than the range of the subrange type!

NOTICE!
The CheckRangeSigned-function provided with the Check.Lib library is just a sample solution! Before using the library module check whether the function is working as requested for your project, or implement an appropriate CheckRange-function directly as a POU in the project.

Example:

```
VAR
 ui : UINT (0..10000);
END_VAR

FOR ui:=0 TO 10000 DO
...
END_FOR
```

The FOR loop will never be finished, because ui cannot get bigger than 10000.

Also take care of the definition of the CheckRange functions when you define the incremental value of a FOR loop!

1.4.1.8.3 Overview operators and library elements

The table shown below shows an overview on the operators, which are available in CODESYS or in the libraries Standard.lib and Util.lib. You find there the notation for ST and IL. For IL also the supported modificators are listed.

Take note that for the 'IL operator' column: Only the line in which the operator is used will be displayed. A prerequisite is that the (first) required operand have been successfully loaded in the preceding line (e.g. LD in).

Table 13: The 'Mod. IL' column shows the possible modifiers in IL:

C	The command is only executed if the result of the preceding expression is TRUE.
N	for JMPC, CALC, RETC: The command is only executed if the result of the preceding expression is FALSE.
N	otherwise: negation of the operand (not of the accumulator)
(	Operator enclosed in brackets: only after the closing bracket is reached will the operation preceding the brackets be carried out.

Please obtain a detailed description of usage from the appropriate appendices concerning IEC operators.

Operators in CODESYS:

in ST	in AWL	Mod. AWL	Description
'			String delimiters (e.g. 'string1')
.. [ ]			Size of Array range (e.g. ARRAY[0..3] OF INT)
:			Delimiter between Operand and Type in a declaration (e.g. var1 : INT;)
;			Termination of instruction (e.g. a:=var1;)
^			Dereferenced Pointer (e.g. pointer1^)
	LD var1	N	Load value of var1 in buffer
:=	ST var1	N	Store actual result to var1
	S boolvar		Set boolean operand boolvar exactly then to TRUE, when the actual result is TRUE
	R boolvar		Set boolean operand boolvar exactly then to FALSE, when the actual result is TRUE

in ST	in AWL	Mod. AWL	Description
	JMP label	CN	Jump to label
<Program name>	CAL prog1	CN	Call program prog1
<Instance name>	CAL inst1	CN	Call function block instance inst1
<Fctname>(vx, vy,..)	<Fctname> vx, vy	CN	Call function fctname and transmit variables vx, vy
RETURN	RET	CN	Leave POU and go back to caller
	(		The value following the bracket is handled as operand, the operation before the bracket is not executed before the expression in the brackets.

in ST	in AWL	Mod. AWL	Description
	)		Now execute the operation which has been set back
AND	AND	N,(	Bitwise AND
OR	OR	N,(	Bitwise OR
XOR	XOR	N,(	Bitwise exclusive OR
NOT	NOT		Bitweise NOT
+	ADD	(	Addition
-	SUB	(	Subtraction
*	MUL	(	Multiplication
/	DIV	(	Division
>	GT	(	Greater than
>=	GE	(	Greater or equal
=	EQ	(	Equal
<>	NE	(	Not equal
<=	LE	(	Less or equal
<	LT	(	Less than
MOD(in)	MOD		Modulo Division
INDEXOF(in)	INDEXOF		Internal index of POU in1; [INT]
SIZEOF(in)	SIZEOF		Number of bytes required for the given data type of in
SHL(K,in)	SHL		Bitwise left-shift of operator in by K
SHR(K,in)	SHR		Bitwise right-shift of operator in by K
ROL(K,in)	ROL		Bitwise rotation to the left of operator in by K
ROR(K,in)	ROR		Bitwise rotation to the right of operator in by K
SEL(G,in0,in1)	SEL		Binary selection between 2 operands in0 (G is FALSE) and in1 (G is TRUE)
MAX(in0,in1)	MAX		Returns the greater of 2 values
MIN(in0,in1)	MIN		Returns the lesser of 2 values in0 and in1
LIMIT(MIN,in,Max)	LIMIT		Limits the range of values (in is set back to MIN or MAX in case of exceeding the range)

in ST	in AWL	Mod. AWL	Description
MUX(K,in0,...in_n)	MUX		Selecti the Kth value out of a group of values (in0 to In_n)
ADR(in)	ADR		Address of the operand in [DWORD]
ADRINST()	ADRINST()		Address of the function block instance from which you are calling that operator.
BITADR(in)	BITADR		Bitoffset of the operand in [DWORD]
BOOL_TO_<type>(in)	BOOL_TO_<type>		Type conversion of the boolean operand
<type>_TO_BOOL(in)	<type>_TO_BOOL		Type conversion to BOOL
INT_TO_<type>(in)	INT_TO_<type>		Type conversion of an INT Operand to another elementary type
REAL_TO_<type>(in)	REAL_TO_<type>		Type conversion of an REAL operand to another elementary type
LREAL_TO_<type>(in)	LREAL_TO_<type>		Type conversion of a LREAL operand to another elementary type
TIME_TO_<type>(in)	TIME_TO_<type>		Type conversion of a TIME operand to another elementary type
TOD_TO_<type>(in)	TOD_TO__<type>		Type conversion of a TOD operand to another elementary type
DATE_TO_<type>(in)	DATE_TO_<type>		Type conversion of a DATE operand to another elementary type
DT_TO_<type>(in)	DT_TO_<type>		Type conversion of a DT operand to another elementary type
STRING_TO_<type>(in)	STRING_TO_<type>		Type conversion of a string operand to another elementary type, in must contain valid value of desired type
TRUNC(in)	TRUNC		Conversion from REAL to INT
ABS(in)	ABS		Absolute value of operand in

in ST	in AWL	Mod. AWL	Description
SQRT(in)	SQRT		Square root of operand in
LN(in)	LN		Natural logarithm of operand in
LOG(in)	LOG		Logarithm of operand in, base 10
EXP(in)	EXP		Exponential function of operand in
SIN(in)	SIN		Sine of operand in
COS(in)	COS		Cosine of operand in
TAN(in)	TAN		Tangent of operand in
ASIN(in)	ASIN		Arc sine of operand in
ACOS(in)	ACOS		Arc cosine of operand in
ATAN(in)	ATAN		Arc tangent of operand in
EXPT(in,expt)	EXPT expt		Exponentation of operand in with expt

Elements of the Standard.lib

in ST	in AWL	Description
LEN(in)	LEN	String length of operand in
LEFT(str,size)	LEFT	Left inital string of given size of string str
RIGHT(str,size)	RIGHT	Right initial string of given size of string str
MID(str,size,pos)	MID	Partial string of str of given size at position pos
CONCAT('str1','str2')	CONCAT 'str2'	Concatenation of two subse-quent strings
INSERT('str1','str2',pos)	INSERT 'str2',p	Insert string str1 in String str2 at position pos
DELETE('str1',len,pos)	DELETE len,pos	Delete partial string (length len), start at position pos of str1
REPLACE('str1','str2',len,pos)	REPLACE 'str2',len,pos	Replace partial string of lenght len by str2, start at position pos of str1
FIND('str1','str2')	FIND 'str2'	Search for partial string str2 in str1
SR	SR	Bistable FB is set dominant
RS	RS	Bistable FB is set back
SEMA	SEMA	FB: Software Semaphor (interruptable)
R_TRIG	R_TRIG	FB: rising edge is detected
F_TRIG	F_TRIG	FB: falling edge is detected

in ST	in AWL	Description
CTU	CTU	FB: Counts upv
CTD	CTD	FB: Counts down
CTUD	CTUD	FB: Counts up and down
TP	TP	FB: trigger
TON	TON	FB: Timer On-Delay
TOF	TOF	FB: Timer Off-Delay
RTC	RTC	FB: Real-time clock

Elements of the Util.lib

Element	Description
BCD_TO_INT	Conversion of a Byte: BCD to INT format
INT_TO_BCD	Converstion of a Byte: INT to BCD format
EXTRACT(in,n)	The n-th bit of DWORD in is returned in BOOL
PACK	Up to 8 bits are packed into a byte
PUTBIT	A bit of a DWORD is set to a certain value
UNPACK	A byte is returned as single bits
DERIVATIVE	Local derivation
INTEGRAL	Integral
LIN_TRAFO	Transformation of REAL values
STATISTICS_INT	Min., Max., average values in INT format
STATISTICS_REAL	Min., Max., average in REAL format
VARIANCE	Variance
PD	PD controller
PID	PID controller
BLINK	Pulsating signal
FREQ_MEASURE	Measuring frequency of boolean input signal
GEN	Periodic functions
CHARCURVE	Linear functions
RAMP_INT	Limiting ascendance of descendance of the function beeing fed (INT)
RAMP_REAL	Limiting ascendance of descendance of the function beeing fed (REAL)
HYSTERESIS	Hysteresis
LIMITALARM	Watches whether input value exceeds limits of a defined range

1.4.1.9 Utilities

1.4.1.9.1 Command line-/Command file

Command line commands

When CODESYS is started you can add commands in the command line which will be asserted during execution of the program. These commands start with a "/". Capitalization / use of small letters is not regarded. The commands will be executed sequentially from the left to the right.

/online	Immediately after start, CODESYS tries to go online with the current project.
/run	After login, CODESYS starts the application program. Only valid in combination with /online.
/batch	CODESYS starts without user interface and returns the error code of the first error or the return value of the first command which is terminated with a warning. CODESYS will terminate immediately after the command file has been processed. The processing of the command file will be aborted as soon as the first command is processed with an error. Warnings do not terminate the processing. If neither errors nor warnings occur, the return value is S_OK.
/show ... /show hide /show icon /show max /show normal	Settings for the frame window of CODESYS can be made. The window will not be displayed, it also will not be represented in the task menu. The window will be minimized in display. The window will be maximized in display. The window will be displayed in the same status as it was during the last closing.
/out <outfile>	All messages are displayed in the message window and additionally are written in the file <outfile>.
/noinfo	No splash screen at start of CODESYS
/userlevel <group>	Definition of the user group (e.g. "/userlevel 0" for user group 0)
/password <password>	Direct input of the user group password (e.g. "/password abc")
/openfromplc	The project which is currently available on the connected target system, will be loaded.
/visudownload	If CODESYS HMI is started with a project, which does not match with the project currently available on the target system, a download will be offered. (Dialog, to be closed with YES or NO).
/notargetchange	A change of the target system only can be done via a command file ↬ *Table 31 “Select target system” on page 464*.
/targetfile <file>.trg	A target description file (*.trg) can be specified. So the already installed targets will not be regarded when CODESYS is started. The commands 'File' 'New', File' 'New from template...', 'File' 'Open...' and the list of recently opened projects will not be available. Additionally the selection list in the target settings configuration dialog will not usable.

/targetfilenosaveas <file>.trg	In addition to the effects described for the "/targetfile" option, see above, also the menu command 'File' 'Save as...' will not be available.
/cmd <cmdfile>	After starting the commands of the <cmdfile> get executed *Chapter 1.4.1.9.1.2 “Command file (cmdfile) commands” on page 459*.

Regard the following syntax for a command line:

"<Path of codesys.exe-file>" "<Path of the project>" /<command1> /<command2> ....

Example for a command line: The project ampel.pro gets opened, but no window opens. The commands included in the command file command.cmd will be executed.

```
"D:\dir1\codesys" "C:\projects\ampel.pro" /show hide /cmd command.cmd
```

Command file (cmdfile) commands

See the following tables for a list of commands which can be used in a command file (<cmdfile>). The command file you then can call by a command line *Chapter 1.4.1.9.1.1 “Command line commands” on page 457*. There is no case sensitivity. The command line will be displayed as a message in the message window and can be given out in a message file (see below) except the command is prefixed by a "@".

All signs after a semicolon (;) will be ignored (comment). Parameters containing blanks must be embraced by quotation marks. Umlauts only may be used if the command file is created in ANSI code. Keywords can be used in the command parameters. A list of the keywords you find subsequent to the following tables of command descriptions.

Table 14: Commands for controlling the subsequent commands

Command	Description
onerror continue	The subsequent commands will be executed even if an error occurs.
onerror break	The subsequent commands will not be executed any more if an error has been detected.

Table 15: Commands of the online menu

Command	Description
online login	Login with the loaded project ('Online Login')
online logout	Logout ('Online' 'Logout')
online run	Start of the application program ('Online' 'Run')
online stop	Stop application program ('Online' 'Stop')
online bootproject	Creation of a boot project. This command can be applied in offline and online mode! (See also description of command 'Online' 'Create boot project' *Chapter 1.4.1.2.6.25 “'Online' 'Create boot project'” on page 291*!)
online sourcecodedownload	Download of the source code of the project to the PLC ('Online' 'Sourcecode download')

Command	Description
online sim	Switch on of simulation mode 'Online' 'Simulation')
online sim off	Switch off of simulation mode ('Online' 'Simulation')

Table 16: Commands of the file menu

Command	Description
file new	A new project is created ('File' 'New')
file open <projectfile> possible additions:	The project <projectfile> will be loaded ('File' 'Open')
/readpwd:<readpassword>	The password for read access is given here so that no dialog asking for the password will appear when the read-protected project is opened.
/writepwd:<writepassword>	The password for full access is given here, so that no dialog asking for the password will appear when the project is openend.
file close	The current project will be closed ('File' 'Close')
file save	The current project will be stored ('File' 'Save')
file saveas <projectfile> optionally add: <type><version>	The current project will be saved with the file name <projectfile> ('File' 'Save as') Default: Project will be saved as <projectfile>.pro under the current version of CODESYS. If you want to save the project as an internal or external library or as project for an older version of CODESYS, add the respective command: Possible entries for <type>: "internallib" Save as internal library: "externallib" Save as external library: "pro" Save as project for older version: valid entries for <Version>: 15, 20, 21, 22 (product versions 1.5, 2.0, 2.1, 2.2) Example: "file save as lib_xy internallib22": The project "project xy.pro", which is created in the current version of CODESYS will be saved as "lib_xy.lib" for V2.2.
file saveas <projectfile>	The current project will be saved with the file name <projectfile> ('File' 'Save as')
file printersetup <filename>.dfr optionally add: pageperobject or pagepersubject	Define a document frame file ('File' Printer setup') and optionally define one of the print options 'New page per object' or 'New page per subobject'; these settings affect the printing of the document (project documentation, see below)
file archive <filename>.zip	The project will be archived in a zip-file with the given file name ('File' Save/Mail Archive')
file quit	CODESYS will be closed ('File' 'Exit')

Table 17: Commands of the project menu

Command	Description
project build	The project that is loaded will be incrementally compiled ('Project' 'Build')
project rebuild or project compile	The project that is loaded will be compiled in full ('Project' 'Rebuild')
project clean	Compilation information and Online Change information in the current project will be deleted ('Project' 'Clean Project')
project check	The project that is loaded will be checked ('Project' 'Check all')
project compile	The current project will be compiled by "Rebuild all" ('Project' 'Rebuild all')
project check	The current project will be checked ('Project' 'Check')
project build	The current project will be built ('Projekt' 'Build')
project import <file1> ... <fileN>	The files <file1> ... <fileN> get imported into the current project ('Project' 'Import'). Regard: Wildcards can be used, e.g. "project import C:\projects*.exp" will import all files with extension *.exp found in directory C:\projects.
project export <expfile>	The current project will be exported in the file <expfile> ('Project' 'Export')
project expmul	Each object of the current project will be exported in an own file, which gets the name of the object.
project documentation	The entire project will be printed on the default printer ('Project' 'Documentation', see also above "file printersetup")

Table 18: Commands for the control of the message file

Command	Description
out open <msgfile>	The file <msgfile> opens as message file. New messages will be appended
out close	The currently shown message file will be closed.
out clear	All messages of the currently opened message file will be deleted.

Table 19: Commands for the control of messages

Command	Description
echo on	The command lines will be displayed as messages.
echo off	The command lines will not be displayed as messages.
echo <text>	<text> will be displayed in the message window.

Table 20: Commands for the control of replace of objects respectively for the control of files for import, export, copy

Command	Description
replace yesall	Replace all (any 'query on' command will be ignored; no dialogs will open)
replace noall	Replace none (any 'query on' command will be ignored; no dialogs will open)
replace query	If a 'query on' command is set, then a dialog will open regarding the replacing of the objects even if there is a 'replace yesall' or 'replace noall' command

Table 21: Commands for the control of the default parameters of the dialogs

Command	Description
query on	Dialogs are displayed and need user input
query off ok	All dialogs respond as if the user had clicked on the 'OK' button
query off no	All dialogs respond as if the user had clicked on the 'No' button
query off cancel	All dialogs respond as if the user had clicked on the 'Cancel' button

Table 22: Command for calling command files as subprograms

Command	Description
call <parameter1> ... <parameter10>	Command files will be called as subprograms. Up to 10 parameters may be passed. In the file that is called, the parameters can be accessed with $0 - $9.
call <parameter1> ... <parameter10>	Command files are called as subroutines. Up to ten parameters can be consigned. In the subroutine called you can access the parameters using $0 - $9.

Table 23: Setting of used directories

Command	Description
dir lib <libdir>	Sets <libdir> as the library directory
dir compile <compiledir>	Sets <compiledir> as the directory for the compilation files
dir config <configdir>	Sets <configdir> as the directory for the configuration files
dir upload <uploaddir>	Sets <uploaddir> as the directory for the upload files

Remarks for settings of used directories:

Project options dialog, category 'Directories', subcategory 'General'

If several directories are defined with one of the following commands, these must be separated by a semicolon + emptyspace and the whole row of directories must be embraced by double quotation marks.

Example, two paths: `dir lib "D:\codesys\Libraries\Standard; D:\codesys\Libraries\NetVar"`

Table 24: Delaying processing of the CMDFILE

Command	Description
delay 5000	Waits 5 seconds

Table 25: Controlling the Watch and Receipt Manager

Command	Description
watchlist load <file>	Loads the Watchlist saved as <file> and opens the corresponding window ('Extras' 'Load Watchlist')
watchlist save <file>	Saves the current Watchlist as <file> ('Extras' 'Save Watchlist')
watchlist set <text>	The watchlist is set active (corresponds to selecting a watchlist in the left part of the Watch and Receipt Manager)
watchlist read	Updates the values of the Watch variables ('Extras' 'Read receipt')
watchlist write	Fills the Watch variables with the values found in the Watchlist ('Extras' 'Write receipt')

Table 26: Linking libraries

Command	Libraries
library add <library file1> <library file2> .. <library fileN>	Attaches the specified library file to the library list of the currently open project. If the file path is a relative path, the library directory entered in the project is used as the root of the path.
library delete [<library1> <library2> .. <libraryN>]	Deletes the specified libraries from the library list of the currently open project.

Table 27: Copying objects

Command	Description
object copy <source project file> <source path> <target path>	Copies objects from the specified path of the source project file to the target path of the already opened project.
If the source path is the name of an object, this will be copied. If it is a folder, all objects below this folder will be copied. In this case, the folder structure below the source folder will be duplicated.	If the target path does not yet exist, it will be created.

Table 28: Read-only access for particular objects

Command	Description
object setreadonly <TRUE|FALSE> <object type> | <object name>	Sets read-only access to a object; Define the object type and in case of object types pou, dut, gvl, vis also the name of the object.
Possible object types: pou, dut (data type), gvl (global variables list), vis (visualization), cnc (CNC object), liblist (Libraries), targetsettings, toolinstanceobject (particular Tools instance), toolmanagerobject (all instances in the Tools tree), customplconfig (PLC configuration), projectinfo (Project information), taskconfig (task configuration), trace, watchentrylist (Watch- and Recipe Manager), alarmconfig (Alarm configuration)	e.g. "object setreadonly TRUE pou plc_prg" will set the PLC_PRG to read-only access

Table 29: Entering communications parameters (gateway, device)

Command	Description
gateway local	Sets the gateway on the local computer as the current gateway.
gateway tcpip <Address> <Port>	Sets the gateway in the specified remote computer as the current gateway.
<Address>: TCP/IP address or hostname of the remote computer	<Port>: TCP/IP port of the remote gateway
Important: Only gateways that have no password set can be reached!	device guid <guid>
Sets the device with the specified GUID as the current device.	GUID must have the following format:
{01234567-0123-0123-0123-0123456789ABC}	The curly brackets and the hyphens must appear at the specified positions.
device instance <Instance name>	Sets the instance name for the current device to the name specified
device parameter <Id> <Value>	Assigns the specified value, which will then be interpreted by the device, to the parameter with the specified ID.

Table 30: System call

Command	Description
system <command>	Carries out the specified operating system command.

Table 31: Select target system

Command	Description
target <Id>	Sets the target platform for the current project. If CODESYS is getting started with command line option "/notargetchange", only by this command a target can be set.

Table 32: Query system state

Command	Description
state offline	Returns "S_OK", if currently there is no connection between programming system and target system (offline mode), otherwise "HRESULT[0x800441f0)" (online mode).
state online	Returns "S_OK", if currently there is a connection between programming system and target system (online mode), otherwise "HRESULT[0x800441f0)" (offline mode).

Table 33: Password for user group

user level	User group, the password for which is defined in the project and is given by the subsequent command "user password".
user password	Password for user group specified by the preceding command "user group".

With the password settings - when opening a project which is protected by user group passwords - you can enter the password for a certain user group. Thus, even if the display of the user input dialogs is switched off ("query off...", see above), a password-protected project can be opened via the command file. The entries for the user group and the password must be placed before the command "file open..."!

Example:

```
user level 0
user password aaa
file open "D:\codesys\projects\xxxx.pro"
query off ok
```

Table 34: Visualization settings

Command	Description
visual settings...	Corresponds to the possible settings which can be done for a visualization in 'Extras' 'Settings', category Language, or in the Target Settings, category Visualization
... language file on || off	Option 'Language file gets activated (on) or deactivated (off). In case of activation the option 'Dynamic texts' will be deactivated.
... set languagefile <path language file>	Specification of the language file to be used (.tlt or .vis). Example: "visual settings set languagefile proj1.tlt"
... dynamictexts on || off	Option 'Dynamic texts' will be deactivated (on) or deactivated (off). In case of activation the option Language file will be deactivated.
... dynamictextfiles <file path> | <file path> | ...	Specification of a list of language file paths to be used. The previous list will be deleted. Example: "visual settings D:\dynfiles\p1.xml D:\dynfiles\p2.xml"
... dynamictexthideelements on || off	Activation or deactivation of option 'Suppress elements if no text replacement has taken place'.

Command	Description
... language <language>	Specification of the language to be used; Example: "visual settings language German"
... tablekeyboardusage_web on || off	Activation or deactivation of option 'Keyboard usage for tables' in the web visualization (Target Settings).
... tablekeyboardusage_codesys on || off	Activation or deactivation of option 'Keyboard usage for tables'.
visual webvisuactivation on || off	Activation or deactivation of option web visualization.

Table 35: Commands concerning managing the project in the ENI project database

Command	Description
eni on eni off	The option 'Use source control (ENI)' will be activated or deactivated (Dialog 'Project' 'Options' 'Project source control')
eni project readonly on eni project readonly off	The option 'Read only' for the database category 'Project objects' will be activated or deactivated. (Dialog 'Project' 'Options' 'Project objects')
eni shared readonly on eni shared readonly off	The option 'Read only' for the database category 'Shared objects' will be activated or deactivated. (Dialog 'Project' 'Options' 'Shared objects')
eni set local <POUname>	The object will be assigned to category 'Local', i.e. it will not be stored in the project database. (Dialog 'Project' 'Object' 'Properties' 'Data base-connection')
eni set shared <POUname>	The object will be assigned to category 'Shared objects'. (Dialog 'Project' 'Object' 'Properties' 'Data base-connection')
eni set project <POUname>	The object will be assigned to category 'Project objects'. (Dialog 'Project' 'Object' 'Properties' 'Data base-connection')
eni <category> server <TCP/IP_Address> <Port> <Projectname> <Username> <Password>	Configures the connection to the ENI Server for the category 'Project objects'. (Dialog 'Project' 'Options' 'Project data base'); Example: `eni project server localhost 80 batchtest\project EniBatch Batch` (TCP/IP-Address = localhost, Port = 80, Project name = batchtest\project, User name = EniBatch, Password = Batch)

Command	Description
eni compile sym on eni compile sym off	The option 'Create ASCII symbol information (.sym)' for the objects of category 'Compile files' will be activated/deactivated. (Dialog 'Project' 'Options' 'Project source control' 'ENI settings' for 'Compile files')
eni compile sdb on eni compile sdb off	The option 'Create binary symbol information (.sym)' for the objects of category 'Compile files' will be activated/deactivated. (Dialog 'Project' 'Options' 'Project source control' 'ENI settings' for 'Compile files')
eni compile prg on eni compile prg off	The option 'Create boot project' for the objects of category 'Compile files' will be activated/deactivated. (Dialog 'Project' 'Options' 'Project source control' 'ENI settings' for 'Compile files')

In the description of the commands placeholders are used:

<category>: Replace by "project" or "shared" or "compile" depending on which of the following database categories is concerned: Project Objects, Shared Objects, Compile Files

<POUname>: Name of the object, corresponds to the object name which is used.

<Objecttype>: Replace by the shortcut, which is appended as an extension to the POU name of the object in the database, and which reflects the object type (defined by the list of object types, see ENI Administration, 'Object Types'). Example: Object "GLOBAL_1.GVL": the POU name is "GLOBAL_1", the object type is "GVL" (global variables list).

<comment>: Replace by a comment text (embraced by single quotation marks) which will be stored in the version history with the particular action.

Table 36: Commands of the menu 'Project' 'Data Base Link' for working with the database

Command	Description
eni set <category>	The object gets assigned to the named database category ('Define')
'eni set <category>set <Objecttype>:<POUname> <Objecttype>:<POUname> eni <category> getall	The objects which are listed separated by spaces will be assigned to the named database category. ('Multiple Define') Example: "`eni set project pou:as_fub pou:st_prg`" The objects (pou) as_fub and st_prg get assigned to category 'Project objects'
	The latest version of all objects of the named category will be called from the database ('Get All Latest Versions')
'eni <category>get <Objecttype>:<POUname> <Objecttype>:<POUname>	The objects of the named category, which are listed separated by spaces will be called from the database. ('Multiple Define'). ('Get latest version') Example: "`eni project get pou:as_fub gvl:global_1`" Tthe POU as_fub.pou and the global variables list global_1.gvl will be called from the database

Command	Description
eni <category> checkoutall "<comment>"	All objects of the named category will be checked out from the database. The defined comment will be stored with the check-out-action in the version history.
eni <category> checkout "<comment>" <Objecttype>:<POUname> <Objecttype>:<POUname>	All objects (Objecttype:POUname) which are listed separated by spaces will be checked out from the database. The defined comment will be stored with the check-out-action in the version history for each particular object. Example: "`eni project checkout "for working on xy" pou:as_fub gvl:global_1`" The POU as_fub and the global variables list global_1 will be checked out and the comment "for working on xy" will be stored with this action
eni <category>checkinall "<comment>"	All objects of the project, which are under source control in the project database, will be checked in. The defined comment will be stored with the check-in-action.
eni <category> checkin "<comment>" <Objecttype>:<POUname> <Objecttype>:<POUname>	All objects (Objecttype:POUname) which are listed separated by spaces will be checked in to the database. The defined comment will be stored with the check-in-action in the version history for each particular object. (see above: check out) The defined comment will be stored with the check-in-action in the version history for each particular object.

Keywords for the command parameters:

The following keywords, enclosed in "$", can be used in command parameters:

$PROJECT_NAME$	Name of the current project in CODESYS (file name without extension ".pro", e.g. "project_2.pro")
$PROJECT_PATH$	Path of the directory, where the current project file is (without indication of the drive and without a backslash at the end, e.g. "projects\sub1").
$PROJECT_DRIVE$	Drive, where the current project is (without backslash at the end, e.g. "D:")
$COMPILE_DIR$	Compile directory of the current project (with indiciation of the drive and without backslash at the end, e.g. "D:\codesys\compile")
EXE_DIR	Directory where the codesys.exe file is (with indication of the drive and without backslash at the end, e.g. D:\codesys)

Example of a command file:

A command file like shown below will open the project file ampel.pro, will then load a watch list, which was stored as w.wtc, will then start the application program and write after 1 second delay - the values of the variables into the watch list watch.wtc (which will be saved) and will finally close the project.

```
file open C:\projects\codesys_test\ampel.pro
  query off ok
  watchlist load c:\work\w.wtc
  online login
  online run
  delay 1000
  watchlist read
  watchlist save $PROJECT_DRIVE$\$PROJECT_PATH$\w_update.wtc
  online logout
  file close
```

This command file will open the project ampel.pro, will load an existing watchlist w.wtc, will start the application program, after 1 second will write the variables values to the watch list w_update.wtc, which will be saved in the directory "C:\projects\codesys_test" and then will close the project again.

A command file is called in a command line as shown here:

```
"<path of codesys.exe>" /cmd "<path of cmd file>"
```

1.4.1.9.2 Use of keyboard

Overview

If you would like to run the program using only the keyboard, you will find it necessary to use a few commands that are not found in the menu.

- The function key *[F6]* allows you to toggle back and forth within the open POU between the Declaration and the Instruction parts.
- *[Alt]* + *[F6]* allows you to move from an open object to the Object Organizer and from there to the Message window if it is open. If a Search box is open, *[Alt]* + *[F6]* allows you to switch from Object Organizer to the Search box and from the there back to the object.
- Press *[Ctrl]* + *[F6]* to move to the next open editor window, press *[Ctrl]* + *[Shift]* + *[F6]* to get to the previous
- Press *[Tab]* to move through the input fields and buttons in the dialog boxes.
- The arrow keys allow you to move through the register cards and objects within the Object Organizer and Library Manager.

All other actions can be performed using the menu commands or with the shortcuts listed after the menu commands. *[Shift]* + *[F10]* opens the context menu which contains the commands most frequently used for the selected object or for the active editor.

Key combinations

The following is an overview of all key combinations and function keys:

Function	Function Key	
General Functions		
Move between the declaration part and the instruction part of a POU	<F6>	
Context Menu	<Shift>+<F10>	
Shortcut mode for declarations	<Ctrl>+<Enter>	

Function	Function Key	
Move from a message in the Message window back to the original position in the editor	<Enter>	
Move to the next open editor window	<Ctrl>+<F6>	
Move to the previous open editor window	<Ctrl>+<Shift>+<F6>	
Open and close multi-layered variables	<Enter>	
Open and close folders	<Enter>	
Switch register cards in the Object Organizer and the Library Manager	<Arrow keys>	
Move to the next field within a dialog box	<Tab>	
Context sensitive Help	<F1>	
General Commands		
'File' 'Save'	<Ctrl>+<S>	
'File' 'Print'	<Ctrl>+<P>	
'File' 'Exit'	<Alt>+<F4>	
'Project' 'Build'	<F11>	
'Project' 'Delete Object'	<Del>	
'Project' 'Add Object'	<Ins>	
'Project' 'Rename Object'	<Spacebar>	
'Project' 'Open Object'	<Enter>	
'Edit' 'Undo'	<Ctrl>+<Z>	
'Edit' 'Redo'	<Ctrl>+<Y>	
'Edit' 'Cut'	<Ctrl>+<X> or <Shift>+<Del>	
'Edit' 'Copy'	<Ctrl>+<C>	
'Edit' 'Paste'	<Ctrl>+<V>	
'Edit' 'Delete'	<Del>	
'Edit' 'Find next'	<F3>	
'Edit' 'Input Assistant'	<F2>	
'Edit' 'Auto Declare'	<Shift>+<F2>	
'Edit' 'Next Error'	<F4>	
'Edit' 'Previous Error'	<Shift>+<F4>	
'Online' 'Log-in'	<Alt><F8>	
'Online' 'Logout'	<Ctrl>+<F8>	
'Online' 'Run'	<F5>	
'Online' 'Toggle Breakpoint'	<F9>	
'Online' 'Step over'	<F10>	
'Online' 'Step in'	<F8>	
'Online' 'Single Cycle'	<Ctrl>+<F5>	
'Online' 'Write Values'	<Ctrl>+<F7>	
'Online' 'Force Values'	<F7>	

Function	Function Key	
'Online' 'Release Force'	<Shift>+<F7>	
'Online' "Write/Force dialog'	<Ctrl><Shift>+<F7>	
'Window' 'Messages'	<Shift>+<Esc>	
FBD Editor Commands		
'Insert' 'Network (after)'	<Ctrl>+<T>	
'Insert' 'Assignment'	<Ctrl>+<A>	
'Insert' 'Jump'	<Ctrl>+<L>	
'Insert' 'Return'	<Ctrl>+<R>	
'Insert' 'Function Block'	<Ctrl>+<B>	
'Insert' 'Input'	<Ctrl>+<U>	
'Extras' 'Negate'	<Ctrl>+<N>	
'Extras' 'Zoom'	<Alt>+<Enter>	
CFC Editor Commands		
'Insert' 'POU'	<Ctrl>+<B>	
'Insert' 'Input'	<Ctrl>+<E>

1.4.1.9.3 Reserved keywords

The following strings are reserved as keywords, i.e. they cannot be used as identifiers for variables or POUs:

ABS *Chapter 1.4.1.6.10.1 “ABS” on page 430*

ACOS *Chapter 1.4.1.6.10.10 “ACOS” on page 433*

ACTION (only used in the Export Format)

ADD *Chapter 1.4.1.6.2.1 “ADD” on page 407*

ADR *Chapter 1.4.1.6.7.1 “ADR” on page 421*

ADRINST *Chapter 1.4.1.6.7.2 “ADRINST” on page 421*

AND *Chapter 1.4.1.6.3.1 “AND” on page 410*

ANDN *Chapter 1.4.1.1.10.3.2 “Modifiers and operators in IL” on page 163*

ARRAY *Chapter 1.4.1.8.2.1 “ARRAY” on page 445*

ASIN *Chapter 1.4.1.6.10.9 “ASIN” on page 433*

AT *Chapter 1.4.1.7.4.2 “Address” on page 441*

ATAN ↳ *Chapter 1.4.1.6.10.11 “ATAN” on page 434*
BITADR ↳ *Chapter 1.4.1.6.7.3 “BITADR” on page 421*
BOOL ↳ *Chapter 1.4.1.8.1.2 “BOOL” on page 443*
BY ↳ *Chapter 1.4.1.1.10.4.10 “FOR loop” on page 169*
BYTE ↳ *Chapter 1.4.1.8.1.3 “Integer data types” on page 443*
CAL ↳ *Chapter 1.4.1.6.8.1 “CAL” on page 422*
CALC ↳ *Chapter 1.4.1.1.10.3.2 “Modifiers and operators in IL” on page 163*
CALCN ↳ *Chapter 1.4.1.1.10.3.2 “Modifiers and operators in IL” on page 163*
CASE ↳ *Chapter 1.4.1.1.10.4.9 “CASE instruction” on page 169*
CONSTANT ↳ *Chapter 1.4.1.3.9.8 “Constants, typed literals” on page 302*
COS ↳ *Chapter 1.4.1.6.10.7 “COS” on page 432*
DATE ↳ *Chapter 1.4.1.8.1.6 “Time data types” on page 444*
DINT ↳ *Chapter 1.4.1.8.1.3 “Integer data types” on page 443*

TRUE ↳ *Chapter 1.4.1.8.1.2 “BOOL” on page 443*

TRUNC ↳ *Chapter 1.4.1.6.9.9 “TRUNC” on page 429*

TYPE ↳ *Chapter 1.4.1.8.2.4 “Enumeration” on page 448*

UDINT ↳ *Chapter 1.4.1.8.1.3 “Integer data types” on page 443*

UINT ↳ *Chapter 1.4.1.8.1.3 “Integer data types” on page 443*

ULINT ↳ *Chapter 1.4.1.8.1.3 “Integer data types” on page 443*

UNTIL ↳ *Chapter 1.4.1.1.10.4.12 “REPEAT loop” on page 170*

USINT ↳ *Chapter 1.4.1.8.1.3 “Integer data types” on page 443*

VAR ↳ *Chapter 1.4.1.3.9.6 “Local variables” on page 301*

VAR_ACCESS (only used very specifically, depending on the hardware)

VAR_CONFIG ↳ *Chapter 1.4.1.4.1.4.1 “Overview” on page 361*

VAR_CONSTANT ↳ *Chapter 1.4.1.3.9.8 “Constants, typed literals” on page 302*

VAR_EXTERNAL ↳ *Chapter 1.4.1.3.9.9 “External variables” on page 303*

VAR_GLOBAL ↳ *Chapter 1.4.1.4.1.3.2 “Several variables lists” on page 359*

VAR_IN_OUT ↳ *Chapter 1.4.1.3.9.5 “Input and output variables” on page 301*

VAR_INPUT ↳ *Chapter 1.4.1.3.9.3 “Input variable” on page 301*

VAR_OUTPUT ↳ *Chapter 1.4.1.3.9.4 “Output variable” on page 301*

WHILE ↳ *Chapter 1.4.1.1.10.4.11 “WHILE loop” on page 170*

WORD ↳ *Chapter 1.4.1.8.1.3 “Integer data types” on page 443*

WSTRING (IEC data type is not supported)

XOR ↳ *Chapter 1.4.1.6.3.3 “XOR” on page 411*

XORN ↳ *Chapter 1.4.1.1.10.3.2 “Modifiers and operators in IL” on page 163*

Additionally all conversion operators as listed in the 'Edit' 'Input assistant' are handled as keywords ↳ *Chapter 1.4.1.2.5.11 “'Edit' 'Input assistant'” on page 276*.

1.4.1.9.4 File types

The following file types can be created:

File extension	Example	Description	Format	Path (default)
*.pro	project01.pro	Project file	binary	project directory
*.ci	project01<number>.ci	Information on the last build (compilation) of the project → incremental compile possible; only created when project gets saved	number: coded target ID	binary
project directory	*.eci	project01<number>.eci	external Compile-Information; Subset of the ci-file in eci-format; can be read via an access-dll	number: coded target ID
PE	project directory	*.cic	project01<number>.cic	target-dependant information on the last build (compilation) of the project -> incremental compile possible; only created when project gets saved
number: coded target ID	binary	project directory	*.cit	project01<number>.cit
temporary *.ci-file; created at target change, transformed to a ci-file at next save of the project	number: coded target ID	binary	project directory	*.ri
project01<number>.ri	information on the last download, important for Online Change; created at each download	number: coded target ID	binary	project directory
*.exp	project01.exp, PLC_PRG.exp	export file ('Project' 'Export')	Export format (Text)	project directory
*.tlt	*.txt	project01.tlt	project01.txt	translation file (defined in 'Project' 'Translate in another language')
Text		*.sym	project01.sym	symbol file
Text	project directory	*.sdb	project01.sdb	symbol file
binary	project directory	*.sym_xml	project01.sym_xml	symbol file
XML	project directory	*.asd	project01.asd	save file (temporary, 'Auto save', 'Auto save before compile')
binary	project directory	*.asl	lib01.asl	save file for a library opened as project (temporary, 'Auto save', 'Auto save before compile')

File extension	Example	Description	Format	Path (default)
binary	library resp. project directory	*.bak	project01.bak	backup file for project (permanent, 'Create backup')
binary	project directory	*.prg	*.bin	default.prg
project01.prg	boot project, file name depending on target	binary	target system (created online)	project directory (created offline)
*.chk		default.chk	project01.chk	checksum for boot projekt code
binary	target system (created online)	project directory (created offline)	*.ini	codesys.ini
ini-file for various settings	Text	with codesys.exe	*.dfr	default.dfr
project01.dfr	frame file (Printer setup)	binary	with codesys.exe	*.asm
code386.asm	assembler-Listing of the created project code	Text	compile directory	*.lst
project01.lst	assembler-Listing of the created project code	Text	compile directory	
*.bpl	project01.bpl	debug-files (breakpoint-information)	Text	compile directory
	*.st	PLC_PRG.st	debug-files, implicit ST-code	Text
compile directory		*.map	project01.map	map-file; information on memory organization and variable locations
Text	compile directory		*.hex	*.h86
project01.hex (Output) resp. standard.hex (Lib)	.hex for Intel or Motorola, .h86 for Intel; compiler output or input for external library	Intel or Motorola hex-files	compile directory	resp. library directory
*.trd	projectxy0.trd	trend logging (number befor the dot is counted up, if file is full and another must be created)	Text	project directory
*.log	projectxy.log	log file (Log)	binary	project directory
*.wtc	projx_watch1.wtc	watch list (Watch- and Recipe-Manager)	Text	user defined directory
*.alm	alarmlog0.alm	alarm log-file		user defined directory resp. download-directory of the controller

File extension	Example	Description	Format	Path (default)
*.zip	projectxy.zip	project archive file; zip-file with files belonging to the project , 'File' 'Save/ Mail Archive'		user defined directory
*.trc	project01_tr1.trc	trace recording	binary	with codesys.exe
*.mon	project01_tr1.mon	trace recording	XML	with codesys.exe
*.tcf	project01_tr1.tcf	trace configuration	binary	with codesys.exe

1.4.1.10 Compiler errors and warnings

1.4.1.10.1 Remarks on compiler errors and warnings

If errors are detected during the compilation of the project, messages will be dumped in the message window. Also warnings might be displayed there. *[F4]* always allows to jump to the next message line in this window, whereby also the concerned POU will be opened. The error and warning messages are preceded by unique numbers. If a message line is selected in the message window, *[F1]* will open the corresponding online help window.

- *Chapter 1.4.1.2.1.6 “Message window” on page 200*
- *Chapter 1.4.1.2.5.15 “'Edit' 'Next error'” on page 278*
- *Chapter 1.4.1.2.8.1 “'Help' 'Contents and search'” on page 293*

1.4.1.10.2 Warnings

1100

"Unknown function '<name>' in library." An external library is used. Please check, whether all functions, which are defined in the .hex file, are also defined in the .lib file.

1101

"Unresolved symbol '<Symbol>'." The code generator expects a POU with the name <Symbol>. It is not defined in the project. Define a function/program with this name.

1102

"Invalid interface for symbol '<Symbol>'." The code generator expects a function with the name <Symbol> and exactly one scalar input, or a program with the name <Symbol> and no input or output.

1103

"The constant '<name>' at code address '<address>' overwrites a 16K page boundary!" A string constant exceeds the 16K page boundary. The system cannot handle this. It depends on the runtime system whether the problem could be avoided by an entry in the target file.

1200

"Task '<name>', call of '<name>' Access variables in the parameter list are not updated"

Variables, which are only used at a function block call in the task configuration, will not be listed in the cross-reference list.

1300

"File not found '<name>'"

The file, to which the global variable object is pointing, does not exist. Please check the path.

1301

"Analyze-Library not found! Code for analyzation will not be generated."

The analyze function is used, but the library analyzation.lib is missing. Add the library in the library manager.

1302

"New externally referenced functions inserted. Online Change is therefore no longer possible!"

Since the last download you have linked a library containing functions which are not yet referenced in the runtime system. For this reason you have to download the complete project.

1400

"Unknown Pragma '<Name>' is ignored!"

This pragma is not supported by the compiler. See 'Pragmas' for supported directives
↳ *Pragmas*.

1401

"The struct '<name>' does not contain any elements."

The structure does not contain any elements, but variables of this type allocate 1 Byte of memory.

1410

"'RETAIN' and 'PERSISTENT' do not have any effect in functions"

Remanent variables which are defined locally in functions are handled like normal local variables.

1411

"Variable '<name>' in the variable configuration isn't updated in any task"

The top level instance of the variable is not referenced by a call in any task. Thus it will not be copied from the process image.

Example:

```
Variable Configuration:
VAR_CONFIG
 plc_prg.aprg.ainst.in AT %IB0 : INT;
END_VAR
plc_prg:
index := INDEXOF(aprg);
```

The program aprg is referenced but not called. Thus plc_prg.aprg.ainst.in never will get the actual value of %IB0.

1412

"Unexpected token Name-Name in pragma {pragma name}"

You are using a pragma which is not written correctly or which cannot be used at this location. See *Pragmas*.

1413

"'<Name>' is not a valid key for list '<Name>'. The key will be ignored"

In the pragma a nonexistent parameter list is specified. Check the list name resp. have a look in the Parameter Manager for the currently available lists.

1414

Too many component definitions in pragma '<name>'

The Pragma contains more definitions (in square brackets) than there are elements in the corresponding array, function block or structure.

1415

'<Name>' (<Number>): The literal '<Number>' is assigned to more than one enumeration

In the declaration of enumeration <Name> the same number is assigned to more than one enumeration components (e.g. TYPE aenum (a:=1, b:=1); END_TYPE).

1500

"Expression contains no assignment. No code was generated."

The result of this expression is not used. For this reason there is no code generated for the whole expression.

1501

"String constant passed as 'VAR_IN_OUT': '<Name>' must not be overwritten!"

The constant may not be written within the POU, because there no size check is possible.

1502

"Variable '<Name>' has the same name as a POU. The POU will not be called!"	A variable is used, which has the same name like a POU.

Example:

```
PROGRAM a
...
VAR_GLOBAL
    a: INT;
END_VAR ...
a; (* Not POU a is called but variable a is loaded. *)
```

1503

"The POU '<name>' has no outputs. Box result is set to 'TRUE'."	The Output pin of a POU which has no outputs, is connected in FBD or KOP. The assignment automatically gets the value TRUE.

1504

"'<name>' ('<number>'): Statement may not be executed due to the evaluation of the logical expression"	Eventually not all branches of the logic expression will be executed.

Example:

```
IF a AND funct(TRUE) THEN ....
```

If a is FALSE then funct will not be called.

1505

"Side effect in '<Name>'! Branch is probably not executed !"	The first input of the POU is FALSE. For this reason the side branch, which may come in at the second input, will not be executed.

1506

"Variable '<name>' has the same name as a local action. The action will not be called!"	Rename the variable or the action.

1507

"Instance '<name>' has the same name as a function. The instance will not be called"	You call in ST an instance which has the same name as a function. The function will be called! Use different names.

1509

"'<name>' ('<number>'): Functions to be registered as callbacks have to start with 'Callback'."	You are using a callback function, the name of which does not start with "callback".This can cause unexpected effects on RISC resp. Motorola 68K controllers!

1510

"Operand to be rotated has no explicit type. Please use a typed literal, like 'DWORD#1'."	For the constant used in the ROL resp. ROR operation there must be a data type definition. For information on typed constants see Typed Literals ↳ *Typed Literals*.

1511

"Operand to be shifted has no explicit type. Please use a typed literal, like 'DWORD#1'."	For the constant used in the SHL resp. SHR operation there must be a data type definition. For information on typed constants see 'Typed Literals' ↳ *Typed Literals*.

1550

"Multiple calls of the POU '<Name>' in one network may lead to undesired side effects"	Check whether the multiple call of this POU is really necessary. By a multiple call unwanted value overstrikes may occur.

1600

"Open DB unclear (generated code may be erroneous)."	The original Siemens program does not tell, which POU is opened.

1700

"Input not connected."	An input box is used in CFC which has no assignment. For this no code will be generated.

1750

"Step '<Name>': the minimal time is greater than the maximal time!"	Open dialog 'Step attributes' for this step and correct the time definitions.

1751

"Caution with usage of variable '<name>'. This variable is used by implicit code and influences the behaviour of the step sequence."	We recommend to rename the variable, so that unique identifiers are used within the project and undesired side effects can be avoided.

1800

"<name>(element #<element number>): Invalid watchexpression '<name>'"	The visualization element contains an expression which cannot be monitored. Check variable name and placeholder replacements.

1801

"'<name> (number): No Input on Expression '<name>' possible"	In the configuration of the visualization object at field input a composed expression is used. Replace this by a single variable.

1802

"<Visualization object>(Element number): Bitmap '<name>' was not found"	Make sure that an external bitmap file is available in the path which is defined in the visualization configuration dialog.

1803

"'<name>'('<number>'): "The print action would not supported for web and target visualisation"	A print action is assigned to an alarm configured in the visualization. This will not be regarded in the web or target visualization.

1804

"'<name>'('<number>'): The font '<name>' is not supported by the target."	In the visualization you are using a font which is not supported by the target system. See in the target settings, category 'Visualization' for the supported fonts.

1807

"<name> (<number>): No message window for alarms for target visualization"	Note that action "message" is not supported for the target visualization!

1808

"'<name>'('<number>'): A polygon consists of to many points for target	Per default maximum 512 points are allowed, target-specifically another maximum number might be defined. By opening the configuration dialog the element will be optimized to the allowed number of points.

visualization. In case of a meter element, please open the configuration once."	
1809	
"'<name> ('<nummer>'): Invalid visualization as zoom target: '<number>'"	This visualization could not be found. Please check whether the visualization name is correct and that the visualization object is available.
1850	
"Input variable at %IB<number> is used in task '<name>' but updated in another task"	Please check which tasks are using this variable and whether the current programming is not causing undesirable effects. The update of the variable value usually is done in the task with the highest priority.
1851	
"Output variable at %IQ<number> is used in task '<name>' but updated in another task"	Please check which tasks are using this variable and whether the current programming is not causing undesirable effects. The update of the variable value usually is done in the task with the highest priority.
1852	
"CanOpen-Master might not be called cyclically in event task '<name>'! Set modul parameter UpdateTask!"	Currently the CanOpen Master is called by the named event task. If you want to get it called cyclically, specify an appropriate task via parameter UpdateTask in the PLC Configuration in dialog 'Module parameters'.
1853	
"A PDO (index: '<number>') might not be updated cyclically in event task '<name>'"	Currently the named PDO is controlled via the named event task. But if you want to get it called cyclically, you must assign an appropriate task to the PDO by shifting I/O-references to this task.
1900	
"POU '<name>' (main routine) is not available in the library"	The Start-POU (e.g. PLC_PRG) will not be available, when the project is used as library.
1901	
"Access Variables and Variable Configurations are not saved in a library!"	Access variables and variable configuration are not stored in the library.

1902

"'<Name>': is no Library for the current machine type!"	The .obj file of the library was generated for another device.

1903

"<Name>: is no valid Library"	The file does not have the format requested for the actual target.

1904

"The constant '<Name>' hides a constant of the same name in a library"	In your project you have defined a constant which has the same name as one which is defined in a linked library. The library variable will be overwritten!

1970

"Parameter manager: List '<Name>' , Column '<Name>', Value '<Name>' could not be imported!"	Check the Import-file *.prm for entries which do not match the current configuration (standard values resp. XML-description file) of the Parameter Manager.

1980

Global network variables '<Name>' '<Name>': simultaneous reading and writing may result in loss of data!"	In the configuration of the network variables list options 'Read' and 'Write' are activated (select list in the Resources tab and open dialog 'Global variables list' via command 'Properties' in the context menu). Note that this might result in data losses during communication.

1990

"No 'VAR_CONFIG' for '<name>'"	For this variable there is no address configuration available in the 'Variable Configuration' (VAR_CONFIG) ↳ *Chapter 1.4.1.4.1.4.1 “Overview” on page 361*. Open window Variable_Configuration in the Resources tab and insert the appropriate configuration (Command 'Insert' 'All Instance Paths' ↳ *Chapter 1.4.1.4.1.4.2 “'Insert' 'All Instance Paths'” on page 361*).

2500

"Task '<task name>': fno cycle time specified for cyclic task"	In the Task configuration a cyclic task has been created, for which no cycle time has been defined. Enter an appropriate time span in dialog 'Taskattributes' at "Interval".

4710

"'<name>' ('<number>'): A required expression has not been configured"	Check the configuration of the slider element in category 'Variables'. There must be defined a valid value for each of the fields 'Min.Value', 'Slider' and 'Max. Value'.

4711

"'<name>'('<number>'): The slider element is not supported by your SysLibTargetVisu."

Install and use the current version of the library SysLibTargetVisu.library.

4714

"'<name>'('<number>'): The type of the selection variable has to be a signed type compatible to INT"

Check and appropriately correct the configuration of the table element in category "Selection".

4715

"The current target does not support formatted display of time and date values"

Option "Formatted time display" is activated in the settings of a visualization ↳ *Chapter 1.4.3.6.1 "'Extras' 'Settings'" on page 700*. However this is not supported by the currently used target system.

4716

"The current target does not support simplified input handling"

In the target settings, in category 'Visualization' option 'Simplified input handling' is activated. Maybe it is not supported by the current target system, because an old version of the library SysLibTargetvisu.lib is used.

1.4.1.10.3 Errors

3100

"Code too large. Maximum size: '<number>' Byte (<number>K)"

The maximum program size is exceeded. Reduce project size.

3101

"Total data too large. Maximum size: '<number>' Byte (<number>K)"

Memory is exceeded. Reduce data usage of the application.

3110

"Error in Library '<Name>'."

The .hex file is not in INTEL Hex format.

3111

"Library '<Name>' is too large. Maximum size: 64K"

The .hex file exceeds the set maximum size.

3112

"Nonrelocatable instruction in library."	The .hex file contains an instruction which is not relocatable. The library code cannot be linked.

3113

"Library code overwrites function tables."	The ranges for code and function tables are overlapping.

3114

"Library uses more than one segment."	The tables and the code in the .hex file use more than one segment.

3115

"Unable to assign constant to VAR_IN_OUT. Incompatible data types."	The internal pointer format for string constants cannot get converted to the internal pointer format of VAR_IN_OUT, because the data are set "near" but the string constants are set " huge" or "far". If possible change these target settings.

3116

"Function tables overwrite library code or a segment boundary."	Code 166x: The external library cannot be used with the current target settings. These must be adapted resp. the library must be rebuilt with appropriate settings.

3117

"<Name> (<code>): Expression too complex. No more registers available"	The named expression is too complex to be handled by the available registers. Please try to reduce the expression by using interim variables.

3120

"Current code-segment exceeds 64K."	The currently generated code is bigger than 64K. Eventually too much initializing code is created.

3121

"POU too large."	A POU may not exceed the size of 64K.

3122

"Initialisation too large. Maximum size: 64K"	The initialisation code for a function or a structure POU may not exceed 64K.

3124

"String constant too large: '<number>' characters (maximum 253 characters)"	The given constant must be reduced in number of characters.

3130

"User-Stack too small: '<number>' DWORD needed, '<number>' DWORD available."	The nesting depth of the POU calls is too big. Enter a higher stack size in the target settings or compile build project without option 'Debug' (set in dialog 'Project' 'Options' 'Build').

3150

"Parameter <number> of function '<name>': Cannot pass the result of a IEC-function as string parameter to a C-function."	Use an intermediate variable, to which the result of the IEC function is assigned.

3160

"Can't open library file '<name>'."	A library <name> is included in the library manager for this project, but the library file does not exist at the given path.

3161

"Library '<name>' contains no code-segment"	An .obj file of a library must contain at least one C function. Insert a dummy function in the .obj file, which is not defined in the .lib file.

3162

"Could not resolve reference in Library '<name>'(Symbol '<name>', Class '<name>', Type '<name>')"	The .obj file contains an unresolvable reference to another symbol. Please check the settings of the C Compiler.

3163

"Unknown reference type in Library '<name>' (Symbol '<name>' , Class '<name>' , Type '<name>')"	The .obj file contains a reference type which is not resolvable by the code generator. Please check the settings of the C Compiler.

3200

"<name>: Boolean expression too complex"	The temporary memory of the target system is insufficient for the size of the expression. Divide up the expression into several partial expressions thereby using assignments to intermediate variables.

3201

"<name> (<network>): A network must not result in more than 512 bytes of code"	Internal jumps can not be resolved. Activate option "Use 16 bit jump offsets" in the 68k target settings.

3202

"Stack overrun with nested string/array/ structure function calls"	A nested function call CONCAT(x, f(i)) is used. This can lead to data loss. Divide up the call into two expressions.

3203

"Expression too complex (too many used address registers)."	Divide up the assignment into several expressions.

3204

"A jump exceeds 32k Bytes"	Jump distances may not be bigger than 32767 bytes.

3205

"Internal Error: Too many constant strings"	In a POU a maximum of 3000 string constants may be used.

3206

"Function block data exceeds maximal size"	A function block may produce maximum 32767 Bytes of code.

3207

"Array optimization"	The optimization of the array accesses failed because during index calculation a function has been called.

3208

"Conversion not implemented yet"	A conversion function is used, which is not implemented for the actual code generator.

3209

"Operator not implemented"	A operator is used which is not implemented for this data type and the actual code generator. MIN(string1,string2).

3210

"Function '<Name>' not found"	A function is called which is not available in the project.

3211

"Max string usage exceeded"	A variable of type string can be used in one expression 10 times at the most.

3212

"Wrong library order at POU <POU name>"	The order of libraries for this POU does not match with that in the cslib.hex file. Correct the order accordingly. (only for 68K targets, if the checking option is activated in the target file.)

3250

"Real not supported for 8 Bit Controller"	The target is currently not supported.

3251

"Date of day types are not supported for 8 Bit Controller"	The target is currently not supported.

3252

"Size of stack exceeds <number> bytes"	The target is currently not supported.

3253

"Could not find hex file: '<Name>' "	The target is currently not supported.

3254

"Call to external library function could not be resolved."	The target is currently not supported.

3255

"Pointers are not supported for 8 bit controllers."	Avoid using pointers in your program to get it running on the 8 bit system.

3260

"Function '<name>' has too many arguments: Increase the size of the argument stack in the target settings."	If possible, modify the size of the stack in dialog Target Platform in the Target Settings (Default: 40).

3400

"An error occured during import of Access variables"	The .exp file contains an incorrect access variables section.

3401

"An error occured during import of variable configuration"	The .exp file contains an incorrect configuration variables section.

3402

"An error occured during import of global variables"	The .exp file contains an incorrect global variables section.

3403

"Could not import <name>"	The section for object <name> in the .exp file is not correct.

3404

"An error occured during import of task configuration"	The section for the task configuration the .exp file is not correct.

3405

"An error occured during import of PLC configuration"	The section for the PLC configuration in the .exp file is not correct.

3406

"Two steps with the name '<name>'. Second step not imported."	The section for the SFC POU in the .exp file contains two steps with equal names. Rename one of the steps in the export file.

3407

"Predecessor step '<name>' not found"	The step <name> is missing in the .exp file.

3408

"Successor step '<name>' not found"	The step <name> is missing in the .exp file.

3409

"No successing transition for step '<´name>' "	In the .exp file a transition is missing, which requires step <name> as preceeding step.

3410

"No successing step for transition '<name>'"	In the .exp file a step is missing which requires the transition <name> as preceeding condition.

3411

"Step '<name>' not reachable from initial step"	In the .exp file the connection between step <name> and the initial step is missing.

3412

"Macro '<name>' not imported"	Check the export file.

3413

"Error during import of the CAMs."	You have imported an export file (*.exp) which contains erroneous information on a CAM. Check the export file.

3414

"Error during import of the CNC program list"	You have imported an export file (*.exp) which contains erroneous information on a CNC program. Check the export file.

3415

"Error during import of the Alarm configuration"	You have imported an export file (*.exp) which contains erroneous information on the Alarm Configuration. Check the export file.

3450

"PDO'<PDO-name>': Missing COB-Id!"	Click on the button 'Properties’ in the PLC configuration dialog for the module and enter a COB ID for the PDO <PDO Name>.

3451

"Error during load: EDS-File '<name>' could not be found, but is referenced in hardware configuration!"	The device file needed for the CAN configuration is not in the correct directory. Check the directory setting for configuration files in 'Project' 'Options' 'Directories'.

3452

"The module '<name>' couldn't be created!"	The device file for module <name> does not fit to the current configuration. It has been modified since the configuration has been set up or it is corrupted.

3453

"The channel '<name>' couldn't be created!"	The device file for channel <name> does not fit to the current configuration. It has been modified since the configuration has been set up or it is corrupted.

3454

"The address '<name>' points to an used memory!"	Option 'Check for overlapping addresses' is activated in the dialog 'Settings' of the PLC configuration and an overlap has been detected. Note that the area check is based on the size which results of the data types of the modules, not on the size which is given by the entry 'size' in the configuration file.

3455

"Error during load: GSD-File '<name>' could not be found, but is referenced in hardware configuration!"	The device file required by the PROFIBUS configuration is not in the correct directory. Check the directory setting for configuration files in 'Project' 'Options' 'Directories'.

3456

"The profibus device '<name>' couldn't be created!"	The device file for module <name> does not fit to the current configuration. It has been modified since the configuration has been set up or it is corrupted.

3457

"Error in module description!"	Please check the device file of this module.

3458

"The PLC-Configuration couldn't be created! Check the configuration files."	Check if all required configuration and device files are available in the correct path (see defined compile directory in 'Project' 'Options' /Directories).

3459

"The selected baudrate is not supported."	Change the setting in the CAN Parameter dialog. Check the specification of the baud rate given by the GSD file.

3460

3S_CanDrv.lib has the wrong version.	Make sure that the 3S_CanDrv.lib included in the project is up to date.

3461

"3S_CanOpenMaster.lib has the wrong version."	Make sure that the 3S_CanOpenMaster.lib included in the project is up to date.

3462

"3S_CanOpenDevice.lib has the wrong version."	Make sure that the 3S_CanOpenDevice.lib included in the project is up to date.

3463

"3S_CanOpenManager.lib has the wrong version."	Make sure that the 3S_CanOpenManager.lib included in the project is up to date.

3464

"3S_CanNetVar.lib has the wrong version."	Make sure that the 3S_CanNetVar.lib included in the project is up to date.

3465

"CanDevice: Sub indices have to be numerated sequentially"	In parameter lists used by the CanDevice the sub-indices must be numbered sequentially and without interruption. Check the corresponding list in the Parameter Manager.

3466

"CAN network variables: No CAN controller found in the PLC configuration"	There are network variables configured for a CAN network (Resources, Global Variables), but in the PLC Configuration there is no CAN Controller available.

3468

"CanDevice: Update task not available in the task configuration."	The update task (used for calling the CANdevice) which is defined in the Base Settings dialog of the CANdevice in the PLC Configuration, must be configured in the Task Configuraiton of the project.

3469

"The CanOpenMaster can not be called. Please assign a task manually."	Assign a task, which should call the master, via parameter UpdateTask in the Module parameters dialog in the PLC Configuration.

3470

"Invalid name in parameter UpdateTask"	Open the CanMasters Module parameter dialog in the PLC Configuration. Check parameter UpdateTask. The specified task must be available in the project. If you cannot set an appropriate task here, the device file must be checked for the corresponding value definitions for UpdateTask.

3500

"No 'VAR_CONFIG' for '<Name>'"	Insert a declaration for this variable in the global variable list which contains the 'Variable_Configuration'.

3501

"No address in 'VAR_CONFIG' for '<name>'."	Assign an address to this variable in the global variable list which contains the 'Variable_Configuration'.

3502

"Wrong data type for '<name>' in 'VAR_CONFIG"	In the global variables list which contains the 'Variable_Configuration' the variable is declared with a different data type than in the POU.

3503

"Wrong data type for '<name>' in 'VAR_CONFIG'"	In the global variables list which contains the 'Variable_Configuration' the variable is declared with a different address than in the POU.

3504

"Initial values are not supported for 'VAR_CONFIG"	A variable of the 'Variable_Configuration' is declared with address and initial value, but an initial value can only be defined for input variables without address assignment.

3505

"'<name>'is no valid instance path"	The Variable_Configuration contains a non-existent variable.

3506

"Access path expected"	In the global variable list for Access Variables the access path for a variable is not correct. Correct: <Identifier>:'<Access path>':<Type> <Access mode>.

3507

"No address specification for 'VAR_ACCESS'-variables"	The global variable list for Access Variables contains an address assignment for a variable. This is not allowed. Valid variable definition: <Identifier>:'<Access path>':<Type> <Access mode>

3550

"Duplicate definition of identifier '<name>'"	There are two tasks defined with identical names. Rename one of them.

3551

"The task '<name>' must contain at least one program call"	Insert a program call or delete the task.

3552

"Event variable '<name>' in task '<name>' not defined" There is an event variable set in the ‘Single’ field of the task properties dialog which is not declared globally in the project. Use another variable or define the variable globally.

3553

"Event variable '<name>' in task '<name>' must be of type 'BOOL'" Use a variable of type BOOL as event variable in the ‘Single’ field of the task properties dialog.

3554

"Task entry '<name>' must be a program or global function block instance" In the field 'Program call’ a function or an undefined POU is entered. Enter a valid program name.

3555

"The task entry '<name>' contains invalid parameters" In the field 'Append program call’ parameters are used which do not comply with the declaration of the program POU.

3556

"Tasks are not supported by the currently selected target" The currently defined task configuration cannot be used for the currently set target system. Change target or modify the task configuration correspondingly.

3557

"Maximum number of Tasks ('<number>') exceeded" The currently defined number of tasks exceeds the maximum number allowed for the currently set target system. Change target or modify the task configuration correspondingly. Attention: Do not edit the XML description file of the task configuration!

3558

"Priority of task '<name>' is out of valid range between '<lower limit>' and '<upper limit>'" The currently defined priority for the task is not valid for the currently set target system. Change target or modify the task configuration correspondingly.

3559

"Task '<name>': Interval-Tasks are not supported by the current target" The current task configuration contains an interval task. This is not allowed by the currently set target system. Change target or modify the task configuration correspondingly.

3560

"Task '<name>': free wheeling tasks are not supported by the current target"

The current task configuration contains a free wheeling task. This is not allowed by the currently set target system. Change target or modify the task configuration correspondingly.

3561

"Task '<name>': event tasks are not supported by the current target"

The current task configuration contains event tasks which are not supported by the currently set target system. Change target or modify the task configuration correspondingly.

3562

"Task '<name>': external event tasks are not supported by the current target"

The current task configuration contains external event tasks which are not supported by the currently set target system. Change target or modify the task configuration correspondingly.

3563

"The interval of task '<name>' is out of valid range between '<lower limit>' and '<upper limit>'"

Change the interval value in the configuration dialog for the task.

3564

"The external event '<name>' of task '<name>' is not supported by the current target"

The currently set target system does not support the external event which is defined in the task configuration for this task. Change target or modify the task configuration correspondingly.

3565

"Maximum number of event tasks ('<number>') exceeded"

The currently set target system does not allow as many event tasks as are defined at the moment. Change target or modify the task configuration correspondingly.

3566

"Maximum number of interval tasks ('<number>') exceeded"

The currently set target system does not allow as many interval tasks as defined at the moment. Change target or modify the configuration correspondingly.

3567

"Maximum number of free wheeling tasks ('<number>') exceeded"

The currently set target system does not allow as many free wheeling tasks as defined at the moment. Change target or modify the configuration correspondingly.

3568

"Maximum number of external interval tasks ('<number>') exceeded"

The currently set target system does not allow as many external interval tasks as defined at the moment. Change target or modify the configuration correspondingly.

3569

"POU '<name>' for system event '<name>' not defined"

The POU which should be called by the named system event, as defined in the task configuration, is not available in the project. Modify the task configuration correspondingly or make sure that the POU is available in the project.

3570

"The tasks '<name>' and '<name>' share the same priority"

Modify the task configuration so that each task has a different priority.

3571

"The library 'SysLibCallback' is not included in the project! System events can not be generated."

In order to create event tasks, the SysLibCallback.lib is needed. Link this library to the project in the library manager, or modify the task configuration (task attributes) so that there is no task triggered by an event.

3572

"Watchdog interval of task '<name>' is out of the valid range from <number>µs' to '<number>µs'"

In the task configuration in dialog 'Taskattributes' there is a watchdog time defined in microseconds, which is out of the valid range defined in the XML-description file ↳ *Chapter 1.4.1.4.8.1 “Overview” on page 390*.

3573

"Watchdog interval of task '<name>' is out of the valid range from <number>%' to

In the task configuration in dialog 'Taskattributes' there is a watchdog time defined in percents, which is out of the valid range defined in the XML-description file ↳ *Chapter 1.4.1.4.8.1 “Overview” on page 390*.

3574

"The event variable '<name>' respectively its direct address must not be used multiple times as an event"

A singleton event is used several times in the task configuration. For information on singleton events see the description in 'Insert' 'Insert task' or 'Insert' 'Append Task' ↳ *Chapter 1.4.1.4.8.2 “'Insert' 'Insert Task' or 'Insert' 'Append Task'” on page 391*.

3575

"Task '<name>': the cycle time has to be a multiple of '<number>' µs."	Correct the cycle time accordingly in the Taskattributes dialog for this task. The target system defines a base time and prescribes that the cycle time must be equal to or be a multiple of this base time.

3600

"Implicit variables not found!"	Use command 'Rebuild all'.

3601

"<name> is a reserved variable name"	The given variable is declared in the project, although it is reserved for the code generator. Rename the variable.

3610

" '<Name>' not supported"	The given feature is not supported by the current version of the programming system.

3611

"The given compile directory '<name>' is invalid"	There is an invalid directory given in the 'Project', 'Options', 'Directories' for the compile files.

3612

"Maximum number of POUs (<number>) exceeded! Compile is aborted."	Too many POUs and data types are used in the project. Modify the maximum number of POUs in the Target Settings / Memory Layout.

3613

"Build canceled"	The compile process was cancelled by the user.

3614

"Project must contain a POU named '<name>' (main routine) or a taskconfiguration"	Create an init POU of type Program (e.g. PLC_PRG) or set up a task configuration.

3615

"<Name> (main routine) must be of type program"	An init POU (e.g. PLC_PRG) is used in the project which is not of type Program.

3616

"Programs musn't be implemented in external libraries"	The project which should be saved as an external library contains a program. This will not be available when the library is used.

3617

"Out of memory"	Increase the virtual memory capacity of your computer.

3618

"BitAccess not supported in current code generator!"	The code generator for the currently set target system does not support bit access on variables.

3619

"Object file '<name>' and library '<name>' have different versions!"	Make sure that for the library there are available matching versions of *.lib and *.obj resp. *.hex files. These files must have the very same time stamp.

3620

"The POU '<name>' must not be present inside a library"	You want to save the project as a library of version 2.1. In this version a library may not contain a PLC_PRG object. Use a different POU name.

3621

"Cannot write compile file '<name>'"	Probably in the path which is specified for the compile file there is already a file of the same name, which is "read only". Remove that file or change the access rights.

3622

"The symbol file '<name>' could not be created"	Probably in the path which is specified for the symbol file (usually project directory) there is already a file of the same name, which is "read only". Remove that file or change the access rights.

3623

"Cannot write boot project file '<name>'"	Probably in the path which is specified for the symbol file (target specific) there is already a file of the same name, which is "read only". Remove that file or change the access rights.

3624

"Target setting <targetsetting1>=<set value> not compatible with <targetsetting2>=<set value>"	Check and correct these settings in the Target settings dialogs (Resources tab).

3700

"POU with name '<name>' is already in library '<name>'"	A POU name is used in the project, which is already used for a library POU. Rename the POU.

3701

"Name used in interface is not identical with POU Name"	Use command ‘Project’ ‘Rename object’ to rename the POU in the object organizer, or change the name of the POU in the declaration window. There the POU name has to be placed next to one of the keywords PROGRAM, FUNCTION or FUNCTIONBLOCK.

3702

"Overflow of identifier list"	Maximum 100 identifiers can be entered in one variable declaration.

3703

"Duplicate definition of identifier '<Name>'"	Take care that there is only one identifier with the given name in the declaration part of the POU.

3704

"Data recursion: "<POU 0> -> <POU 1> -> .. -> <POU 0>"	An instance of a function block is used which calls itself.

3705

"<Name>: VAR_IN_OUT in Top-Level-POU not allowed, if there is no Task-Configuration"	Create a task configuration or make sure that there are no VAR_IN_OUT variables used in PLC_PRG.

3706

"Modifier 'CONSTANT' allowed for 'VAR', 'VAR_INPUT', 'VAR_EXTERNAL' and 'VAR_GLOBAL' only"	Constants cannot be declared for this type of variable.

3720

"Address expected after 'AT'"	Add a valid address after the keyword AT or modify the keyword.

3721

"Only 'VAR' and 'VAR_GLOBAL' can be located to addresses"	Put the declaration to a VAR or VAR_GLOBAL declaration area.

3722

"Only 'BOOL' variables allowed on bit addresses"	Modify the address or modify the type of the variable to which the address is assigned.

3726

"Constants can not be laid on direct addresses"	Modify the address assignment correspondingly.

3727

"No array declaration allowed on this address"	Modify the address assignment correspondingly.

3728

"Invalid address: '<address>'"	This address is not supported by the PLC configuration. Check the PLC configuration or modify the address.

3729

"Invalid type '<name>' at address: '<Name>' "	The type of this variable cannot be placed on the given address. Example: For a target system working with ‘alignment 2’ the following declaration is not valid: var1 AT %IB1:WORD; This error message also might indicate that an array is assigned to the address of a direct variable, which is not allowed.

3740

"Invalid type: '<Name>' "	An invalid data type is used in a variable declaration.

3741

"Expecting type specification"	A keyword or an operator is used instead of a valid type identifier.

3742

"Enumeration value expected"	In the definition of the enumeration type an identifier is missing after the opening bracket or after a comma between the brackets.

3743

"Integer number expected"	Enumerations can only be initialized with numbers of type INT.

3744

"Enum constant '<name>' already defined"	Check if you have followed the rules for the definition of enumeration values: ● Within one enum definition all values have to be unique. ● Within all global enum definitions all values have to be unique. ● Within all local enum definitions all values have to be unique.

3745

"Subranges are only allowed on Integers!" Subrange types can only be defined for integer data types.

3746

"Subrange '<name>' is not compatible with Type '<name>'" One of the limits set for the range of the subrange type is out of the range which is valid for the base type.

3747

"Unknown string length: '<name>'" There is a not valid constant used for the definition of the string length.

3748

"More than three dimensions are not allowed for arrays" More than the allowed three dimensions are given in the definition of an array. If applicable use an ARRAY OF ARRAY.

3749

"Lower bound '<name>' not defined" There is an undefined constant used to define the lower limit for a subrange or array type.

3750

"Upper bound '<name>' not defined" There is an undefined constant used to define the upper limit for a subrange or array type.

3751

"Invalid string length '<number of characters>'" The defined string length exceeds the maximum value which is defined for the currently set target system.

3752

"More than 9 dimensions are not allowed for nested arrays" An array can be 1- 2- or 3-dimensional ↬ *Chapter 1.4.1.8.2.1 “ARRAY” on page 445*. The maximum number of dimensions reached by nesting of arrays is 9, e.g. "arr: ARRAY [0..2,0..2,0..2] OF ARRAY [0..2,0..2,0..2] OF ARRAY [0..2,0..2,0..2, 0..2] OF DINT". This maximum has been exceeded in the current error case. Reduce to a maximum of 9 dimensions.

3760

"Error in inital value" Use an initial value which corresponds to the type definition. To change the declaration you can use the declaration dialog for variables (Shift/F2 or 'Edit"Autodeclare').

3761

"'VAR_IN_OUT' variables must not have an initial value."

Remove the initialisation at the declaration of the VAR_IN_OUT variable.

3780

"'VAR', 'VAR_INPUT', 'VAR_OUTPUT' or 'VAR_IN_OUT' expected"

The first line following the name of a POU must contain one of these keywords.

3781

"'END_VAR' or identifier expected"

Enter a valid identifier or a END_VAR at the beginning of the given line in the declaration window.

3782

"Unexpected end"

In the declaration editor: Add keyword END_VAR at the end of the declaration part.

In the text editor of the programming part: Add an instruction which terminates the last instruction sequence (e.g. END_IF).

This error message already might be created together with error 3703, if there are two identical declarations at the end of the declaration part.

3783

"END_STRUCT' or identifier expected"

Ensure that the type declaration is terminated correctly.

3784

"The current target doesn't support attribute <attribute name>"

The target system does not support this type of variable (e.g. RETAIN, PERSISTENT).

3800

"The global variables need too much memory. Increase the available memory in the project options."

Increase the number of segments given in the settings in dialog 'Project', 'Options', 'Build'.

3801

"The variable '<name>' is too big. (<size> byte)"

The variable uses a type which is bigger than 1 data segment. The segment size is a target specific parameter and can be modified in the target settings/memory layout.

3802

"Out of retain memory. Variable '<name>', <number> bytes."	The memory space available for retain variables is exhausted. The size of the memory area can be set target-specific in the target settings / memory layout. If retain variables are used in a function block instance, the complete instance POU will be stored in the retain memory area.

3803

"Out of global data memory. Variable '<name>', '<number>' bytes."	The memory space available for global variables is exhausted. The size of the memory area can be set target-specific in the target settings / memory layout. If you do not find the settings field in the dialog, please contact your PLC manfacturer.

3804

"The current size of the persistent data description is <'number'> bytes and exceeds the maximum of <'number'> bytes."	Reduce the persistent data to the size allowed by the target system.

3820

"'VAR_OUTPUT' and 'VAR_IN_OUT' not allowed in functions"	In a function no output or in_output variables may be defined.

3821

"At least one input required for functions"	Add at least on input parameter for the function.

3840

"Unknown global variable '<name>'!"	In the POU a VAR_EXTERNAL variable is used, for which no global variable declared.

3841

"Declaration of '<name>' do not match global declaration!"	The type given in the declaration of the VAR_EXTERNAL variable is not the same as that in the global declaration.

3850

"Declaration of an unpacked struct '<name>' inside a packed struct '<name>' is not allowed!"	This structure definition leads to a misalignment in the memory. You must change the structure definition appropriately.

3900

"Multiple underlines in identifier"	Remove multiple underlines in the identifier name.

3901

"At most 4 numerical fields allowed in addresses"	There is a direct assignment to an address which has more than four levels, e.g. %QB0.1.1.0.1.

3902

"Keywords must be uppercase"	Use capital letters for the keyword or activate option 'Autoformat' in 'Project', 'Options'.

3903

"Invalid duration constant"	The notation of the constant does not comply with the IEC61131-3 format.

3904

"Overflow in duration constant"	The value used for the time constant cannot be represented in the internal format. The maximum value which is presentable is t#49d17h2m47s295ms.

3905

"Invalid date constant"	The notation of the constant does not comply with the IEC61131-3 format.

3906

"Invalid time of day constant"	The notation of the constant does not comply with the IEC61131-3 format.

3907

"Invalid date and time constant"	The notation of the constant does not comply with the IEC61131-3 format.

3908

"Invalid string constant"	The string constant contains an invalid character.

4000

"Identifier expected"	Enter a valid identifier at this position.

4001

"Variable '<Name>' not declared"	Declare variable local or global.

4010

"Type mismatch: Cannot convert '<Name>' to '<Name>'."	Check what data type the operator expects (Browse online help for name of operator) and change the type of the variable which has caused the error, or select another variable.

4011

"Type mismatch in parameter '<Name>' of '<Name>': Cannot convert '<Name>' to '<Name>'."	The data type of the actual parameter cannot be automatically converted to that of the formal parameter. Use a type conversion or use another variable type.

4012

"Type mismatch in parameter '<Name>' of '<Name>': Cannot convert '<Name>' to '<Name>'."	A value with the invalid type <Type2> is assigned to the input variable '<Name>'. Replace the variable or constant to one of type <Type1> or use a type conversion or a constant with type-prefix.

4013

"Type mismatch in output '<Name>' of '<Name>': Cannot convert '<Name>' to '<Name>'."	A value with the invalid type <Type2> is assigned to the output variable '<Name>'. Replace the variable or constant to one of type <Type1> or use a type conversion or a constant with type-prefix.

4014

"Typed literal: Cannot convert '<name>' to '<name>'"	The type of the constant is not compatible with the type of the prefix. Example: SINT#255

4015

"Data type '<name>' illegal for direct bit access"	Direct bit addressing is only allowed for Integer- and Bitstring datatypes and not for direct variables. You are using a variable var1 of type REAL/LREAL or a constant in bit access <var1>.<bit>, or you are trying a bit access on a direct variable.

4016

"Bit index '<number>' out of range for variable of type '<name>'"	You are trying to access a bit which is not defined for the data type of the variable.

4017

"'MOD' is not defined for 'REAL'"	The operator MOD can only be used for integer and bitstring data types.

4020

"Variable with write access or direct address required for 'ST', 'STN', 'S', 'R'"	Replace the first operand by a variable with write access.

4021

"No write access to variable '<name>' allowed"	Replace the variable by a variable with write access.

4022

"Operand expected"	Add an operand behind the command.

4023

"Number expected after '+' or '-'"	Enter a digit.

4024

"Expecting <Operator 0> or <Operator 1> or ... before <Name>'"	Enter a valid operand at the named position.

4025

"Expecting ':=' or '=>' before '<Name>'"	Enter one of the operators at the named position.

4026

"'BITADR' expects a bit address or a variable on a bit address"	Use a valid bit address (e.g. %IX0.1).

4027

"Integer number or symbolic constant expected"	Enter a integer number or the identifier of a valid constant.

4028

"'INI' operator needs function block instance or data unit type instance"	Check the data type of the variable for which the INI operator is used.

4029

"Nested calls of the same function are not possible."	In non-reentrant target systems and in simulation mode a function call may not contain a call to itself as a parameter.

Example:	`fun1(a,fun1(b,c,d),e);`
	Use an intermediate table.

4030

"Expressions and constants are not allowed as operands of 'ADR'"	Replace the constant or the expression by a variable or a direct address.

4031

"'ADR' is not allowed on bits! Use 'BITADR' instead."	Use BITADR. Please note that the BITADR function does not return a physical memory address.

4032

"'<number>' operands are too few for '<name>'. At least '<number>' are needed"	Check how many operands the named operator requires and add the missing operands.

4033

"'<number>' operands are too many for '<name>'. At least '<number>' are needed"	Check how many operands the named operator requires and remove the surplus operands.

4034

"Division by 0"	You are using a division by 0 in a constant expression. If you want to cause a runtime error then use, if applicable, a variable with the value 0.

4035

"ADR must not be applied on 'VAR CONSTANT' if 'replaced constants' is activated"	An address access on constants, for which the direct values are used, is not possible. If applicable, deactivate the option 'Replace Constants' in 'Project' 'Options' 'Build'.

4040

"Label '<name>' is not defined"	Define a label with the name <LabelName> or change the name <LabelName> to that of a defined label.

4041

"Duplicate definition of label '<name>'"	The label '<Name>' has multiple definitions in the POU. Rename the label or remove one of the definitions.

4042

"No more than <number> labels in sequence are allowed"	The number of jump labels is limited to '<number>'. Insert a dummy instruction.

4043

"Format of label invalid. A label must be a name optionally followed by a colon."	The label name is not valid or the colon is missing in the definition.

4050

"POU '%s' is not defined"	Define a POU with the name '<Name>' using the command ‘Project’ ‘Add Object’, or change '<Name>' to the name of a defined POU.

4051

"'%s' is no function"	Use instead of <name> a function name which is defined in the project or in the libraries.

4052

"'<name>' must be a declared instance of FB '<name>'"	Use an instance of data type '<Name>' which is defined in the project or change the type of <Instance name> to '<Name>'.

4053

"'<name>' is no valid box or operator"	Replace '<name>' by the name of a POU or an operator defined in the project.

4054

"POU name expected as parameter of 'INDEXOF'"	The given parameter is not a valid POU name.

4060

"'VAR_IN_OUT' parameter '<name>' of '<name>' needs variable with write access as input"	Variables with write access have to be passed to VAR_IN_OUT parameters, because a VAR_IN_OUT can be modified within the POU.

4061

"'VAR_IN_OUT' parameter '<name>' of '<name>' must be used."	A VAR_IN_OUT parameter must be passed a variable with write access, because a VAR_IN_OUT can be modified within the POU.

4062

"No external access to 'VAR_IN_OUT' parameter '<name>' of '<name>'."

VAR_IN_OUT parameter may be written or read only within the POU, because they are handed over by reference.

4063

"'VAR_IN_OUT' parameter '<name>' of '<name>' must not be used with bit addresses."

A bit address is not a valid physical address. Hand over a variable or a direct non-bit address.

4064

"'VAR_IN_OUT' must not be overwritten in local action call!"

Delete the parameters set for the VAR_IN_OUT variable in the local action call.

4070

"The POU contains a too complex expression"

Decrease nesting depth by dividing up the expression into several expressions. Use intermediate variables for this purpose.

4071

"Network too complex"

Divide up the network into several networks.

4072

"Inconsistent use of an action identifier in FB type ('<name>') and instance ('<name>')."

You have defined two actions of a function block FB: e.g. a1 and a2, but in the call of one of the actions in the FBD you are using a type (string within the box, e.g. fb.a1 different to that used in the instance-name (e.g. inst.a2, above box). Correct the name correspondingly into the name of the desired action.

4100

"'^' needs a pointer type"

You are trying to dereference a variable which is not declared as a pointer.

4110

"'[<index>]' needs array variable"

[<index>] is used for a variable which is not declared as an array with ARRAY OF.

4111

"Index expression of an array must be of type 'INT'"

Use an expression of the correct type or a type conversion.

4112

"Too many indexes for array"	Check the number of indices (1, 2, or 3) for which the array is declared and remove the surplus.

4113

"Too few indexes for array"	Check the number of indices (1, 2, or 3) for which the array is declared and add the missing ones.

4114

"One of the constant indices is not within the array range"	Make sure that the used indices are within the bounds of the array.

4120

"'.' needs structure variable"	The identifier on the left hand of the dot must be a variable of type STRUCT or FUNCTION_BLOCK or the name of a FUNCTION or a PROGRAM.

4121

"'<Name>' is not a component of <object name>"	The component '<Name>' is not included in the definition of the object <object name>.

4122

"'<name>' is not an input variable of the called function block"	Check the input variables of the called function block and change ‘<name>' to one of these.

4200

"'LD' expected"	Insert at least one LD instruction after the jump label in the IL editor.

4201

"IL Operator expected"	Each IL instruction must start with an operator or a jump label.

4202

"Unexpected end of text in brackets"	Insert a closing bracket after the text.

4203

"<name> in brackets not allowed"	The operator <name> is not valid in a IL bracket expression. Not valid are: 'JMP', 'RET', 'CAL', 'LDN', 'LD', 'TIME'.

4204

"Closing bracket with no corresponding opening bracket"	Insert an opening bracket or remove the closing one.

4205

"No comma allowed after ')'"	Remove comma after closing bracket.

4206

"Label in brackets not allowed"	Shift jump label so that it is outside of the brackets.

4207

"'N' modifier requires operand of type 'BOOL', 'BYTE', 'WORD' or 'DWORD'"	The N modifier requires a data type, for which a boolean negation can be executed.

4208

"Conditional Operator requires type 'BOOL'"	Make sure that the expression gives out a boolean result or use a type conversion.

4209

"Function name not allowed here"	Replace the function call by a variable or a constant.

4210

"'CAL', 'CALC' and 'CALN' require a function block instance as operand"	Declare an instance of the function block which you want to call.

4211

"Comments are only allowed at the end of line in IL"	Shift the comment to the end of the line or to an extra line.

4212

"Accumulator is invalid before conditional statement"	The accumulator is not defined. This happens if an instruction is preceeding which does not submit a result (e.g. 'CAL').

4213

"'S' and 'R' require 'BOOL' operand"	Use a boolean variable at this place.

4250

"Another 'ST' statement or end of POU expected"	The line does not start with a valid ST instruction.

4251

"Too many parameters in function '<name>'"	There are more parameters given than are declared in the definition of the function.

4252

"Too few parameters in function '<name>'"	There are fewer parameters given than are declared in the definition of the function.

4253

"'IF' or 'ELSIF' require 'BOOL' expression as condition"	Make sure that the condition for IF or ELSIF is a boolean expression.

4254

"'WHILE' requires 'BOOL' expression as condition"	Make sure that the condition following the ‘WHILE’ is a boolean expression.

4255

"'UNTIL' requires 'BOOL' expression as condition"	Make sure that the condition following the ‘UNTIL’ is a boolean expression.

4256

"'NOT' requires 'BOOL' operand"	Make sure that the condition following the ‘NOT’ is a boolean expression.

4257

"Variable of 'FOR' statement must be of type 'INT'"	Make sure that the counter variable is of an integer or bitstring data type (e.g. DINT, DWORD).

4258

"Expression in 'FOR' statement is no variable with write access"	Replace the counter variable by a variable with write access.

4259

"Start value in 'FOR' statement is no variable with write access"	The start value in the 'FOR' instruction must be compatible to the type of the counter variable.

4260

"End value of 'FOR' statement must be of type 'INT'"	The end value in the 'FOR' instruction must be compatible to the type of the counter variable.

4261

"Increment value of 'FOR' statement must be of type 'INT'"	The incremental value in the 'FOR' instruction must be compatible to the type of the counter variable.

4262

"'EXIT' outside a loop"	Use 'EXIT' only within 'FOR', 'WHILE' or 'UNTIL' instructions.

4263

"Expecting Number, 'ELSE' or 'END_CASE'"	Within a ‘CASE' expression you can only use a number or a 'ELSE' instruction or the ending instruction 'END_CASE'.

4264

"'CASE' requires selector of an integer type"	Make sure that the selector is of an integer or bitstring data type (e.g. DINT, DWORD).

4265

"Number expected after ','"	In the enumeration of the CASE selectors there must be inserted a further selector after a comma.

4266

"At least one statement is required"	Insert an instruction, at least a semicolon.

4267

"Function block call requires function block instance"	The identifier in the function block call is no instance. Declare an instance of the desired function block or use the name of an already defined instance.

4268

"Expression expected"	Insert an expression.

4269

"'END_CASE' expected after 'ELSE'-branch"	Terminate the 'CASE' instruction after the 'ELSE' part with an 'END_CASE'.

4270

"'CASE' constant '<name>' already used"	A 'CASE' selector may only be used once within a ‘CASE' instruction.

4271

"The lower border of the range is greater than the upper border."	Modify the area bounds for the selectors so that the lower border is less than the upper border.

4272

"Expecting parameter '<name>' at place <position> in call of '<name>'!"	You can edit a function call so that the parameter names are contained, not only the parameter values. But nevertheless the position (sequence) of the parameters must be the same as in the function definition.

4273

"Parts of the 'CASE'-Range '<range>' already used in Range '<range>'"	Make sure that the areas for the selectors which are used in the CASE instruction don’t overlap.

4274

"Multiple 'ELSE' branch in 'CASE' statement"	A CASE instruction may not contain more than one 'ELSE' instruction.

4300

"Jump requires 'BOOL' as input type"	Make sure that the input for the jump or the RETURN instruction is a boolean expression.

4301

"POU '<name>' need exactly <number> inputs"	The number of inputs does not correspond to the number of VAR_INPUT and VAR_IN_OUT variables which is given in the POU definition.

4302

"POU '<name>' need exactly %d outputs"	The number of outputs does not correspond to the number of VAR_OUTPUT variables which is given in the POU definition.

4303

"'<name>' is no operator"	Replace '<name>' with a valid operator.

4320

"Non-boolean expression '<name>' used with contact" The switch signal for a contact must be a boolean expression.

4321

"Non-boolean expression '<name>' used with coil" The output variable of a coil must be of type BOOL.

4330

"Expression expected at input 'EN' of the box '<name>' " Assign an input or an expression to the input EN of POU '<name>'.

4331

"Expression expected at input '<number>' of the box '<Name>' " The input <number> of the operator POU is not assigned.

4332

"Expression expected at input '<name>' of the box '<Name>'" The input of the POU is of type VAR_IN_OUT and is not assigned.

4333

"Identifier in jump expected" The given jump mark is not a valid identifier.

4334

"Expression expected at the input of jump" Assign a boolean expression to the input of the jump. If this is TRUE, the jump will be executed.

4335

"Expression expected at the input of the return" Assign a boolean expression to the input of the RETURN instruction. If this is TRUE, the jump will be executed.

4336

"Expression expected at the input of the output" Assign a suitable expression to the output box.

4337

"Identifier for input expected" Insert a valid expression or identifier in the input box.

4338

"Box '<name>' has no inputs"	None of the inputs of the operator POU '<name>' have been assigned a valid expression.

4339

"Type mismatch at output: Cannot convert '<name>' to '<name>'	The type of the expression in the output box is not compatible with that of the expression which should be assigned to it.

4340

"Jump requires 'BOOL' as input type"	Make sure that the input for the jump is a boolean expression.

4341

"Return needs a boolean input"	Make sure that the input for the RETURN instruction is a boolean expression.

4342

"Expression expected at input 'EN' of the box '<name>'"	Assign a valid boolean expression to the EN input of the box.

4343

"Values of Constants: '<name>'"	Input '<name>' of box '<name>' is declared as VAR_INPUT CONSTANT. But to this POU box an expression has been assigned in the dialog 'Edit Parameters' which is not type compatible.

4344

"'S' and 'R' require 'BOOL' operand"	Insert a valid boolean expression after the Set or Reset instruction.

4345

"Invalid type for parameter '<name>' of '<name>': Cannot convert '<type>' to '<type>'"	An expression is assigned to input '<name>' of POU box '<name>' which is not type compatible.

4346

"Not allowed to use a constant as an output"	You can only assign an output to a variable or a direct address with write access.

4347

"'VAR_IN_OUT' parameter needs variable with write access as input"	Only variables with write access can be passed to VAR_IN_OUT parameters, because these can be modified within the POU.

4348

"Invalid program name '<name>'. A variable with the same name exists already."	You have inserted a program box in the CFC editor which has the same name as a (global) variable already existing in your project. You must rename accordingly.

4349

Input or output in POU <name> has been deleted: Check all connections to the box. This error message disappears only after the CFC was edited	Error in CFC POU.

4350

"An SFC-Action can not be accessed from outside!"	SFC actions only can be called within the SFC POU in which they are defined. But this error also will be dumped if you call an action from within a SFC POU, which is allowed, but are not using IEC steps while the iecsfc.lib is still included in your project. In this case please remove the library in the library manager and rebuild the project.

4351

"Step name is no identifier: '<name>'"	Rename the step or choose a valid identifier as step name.

4352

"Extra characters following valid step name:'<Name>'"	Remove the invalid characters in the step name.

4353

"Step name duplicated: '<Name>'"	Rename one of the steps. This error also will be generated if a step has the same name as a non-boolean variable.

4354

"Jump to undefined Step: '<Name>'"	Choose an existing step name as a target for the jump, or insert a step with name '<name>'.

4355

"A transition must not have any side effects (Assignments, FB-Calls etc.)"	A transition must be a boolean expression.

4356

"Jump without valid Step Name: '<Name>'"	Use a valid identifier as the target of the jump.

4357

"IEC-Library not found"	Check whether the library iecsfc.lib is inserted in the library manager and whether the library paths defined in ‘Project’ ‘Options’ ‘Paths’ are correct.

4358

"Action not declared: '<name>'"	Make sure that in the object organizer the action of the IEC step is inserted below the SFC POU, and that in the editor the action name is inserted in the box on the right hand of the qualifier.

4359

"Invalid Qualifier: '<name>'"	In the box on the left hand of the action name enter a qualifier for the IEC action.

4360

"Time Constant expected after qualifier '<name>'"	Enter next to the box on the left hand of the action name a time constant behind the qualifier.

4361

"'<name>' is not the name of an action"	Enter next to the box on the right hand of the qualifier the name of an action or the name of a variable which is defined in the project.

4362

"Nonboolean expression used in action: '<name>'"	Insert a boolean variable or a valid action name.

4363

"IEC-Step name already used for variable: '<Name>'"	Please rename the step or the variable.

4364

"A transition must be a boolean expression"	The result of the transition expression must be of type BOOL.

4365

"Time constant expected after qualifier '<name>'"	Open dialog 'step attributes' for the step '<name>' and enter a valid time variable or time constant.

4366

"The label of the parallel branch is no valid identifier: '<Name>'"	Enter a valid identifier next to the triangle which marks the jump label.

4367

"The label '<name>' is already used"	There is already a jump label or a step with this name. Please rename correspondingly.

4368

"Action '<name>' is used in multiple step chains, where one is containing the other!"	The action '<name>' is used in the POU as well as in one or several actions of the POU.

4369

"Exactly one network required for a transition"	There are used several FBD or LD networks for a transition. Please reduce to 1 network.

4370

"Additional lines found after correct IL-transition"	Remove the unnecessary lines at the end of the transition.

4371

"Invalid characters following valid expression: '<name>"	Remove the unnecessary characters at the end of the transition.

4372

"Step '<name>': Time limit needs type 'TIME'"	Define the time limits of the step in the step attributes by using a variable of type TIME, or by a time definition in correct format (e.g "t#200ms").

4373

"IEC-actions are only allowed with SFC-POUs"	There is an action assigned to a non-SFC-POU (see the Object Organizer), which is programmed in SFC and which contains IEC actions. Replace this action by one which contains no IEC actions.

4374

"Step expected instead of transition '<name>'"	The SFC POU is corrupt, possibly due to any export-import actions.

4375

"Transition expected instead of step '<name>'"	The SFC POU is corrupt, possibly due to any export-import actions.

4376

"Step expected after transition '<name>'"	The SFC POU is corrupt, possibly due to any export-import actions.

4377

"Transition expected after step '<name>'"	The SFC POU is corrupt, possibly due to any export-import actions.

4400

"Import / conversion of POU '<name>' contains errors resp. is not complete."	The POU cannot be converted to IEC 61131-3 completely.

4401

"S5 time constant <number> seconds is too big (max. 9990s)."	There is no valid BCD coded time in the accumulator.

4402

"Direct access only allowed on I/Os."	Make sure that you only access variables which are defined as input or output.

4403

"STEP5/7 instruction invalid or not convertible to IEC 61131-3."	Some STEP5/7 commands are not convertible to IEC 61131-3, e.g. CPU commands like MAS.

4404

"STEP5/7 operand invalid or not convertible to IEC 61131-3."	Some STEP5/7 operands are not convertible to IEC 61131-3 or an operand is missing.

4405

"Reset of a STEP5/7 timer cannot be converted into IEC 61131-3."	The corresponding IEC timer has no reset input.

4406

"STEP5/7 counter constant out of range (max. 999)."	There is no valid BCD coded counter constant in the accu.

4407

"STEP5 instruction not convertible to IEC 61131-3."	Some STEP5/7 instructions cannot be converted to IEC 61131-3, e.g. DUF.

4408

"Bit access of timer or counter words not convertible into IEC 61131-3."	Special timer/counter commands are not convertible into IEC 61131-3.

4409

"Contents of ACCU1 or ACCU2 undefined, not convertible into IEC 61131-3."	A command, which connects the both accus, cannot be converted because the accu values are not defined.

4410

"Called POU not in project."	Import the called POU.

4411

"Error in global variable list."	Please check the SEQ file.

4413

"Error in format of line in data block"	In the code which should be imported there is an erroneous date.

4414

"FB/FX name missing."	In the original S5D file the symbolic name of an (extended) POU is missing.

4415

"Instruction after block end not allowed."	A protected POU cannot get imported.

4416

"Invalid command"	The S5/S7 command cannot be disassembled.

4417

"Comment not closed"	Close the comment with "*)".

4418

"FB/FX-Name too long (max. 8 characters)"	The symbolic name of an (extended) POU is too long.

4419

"Expected format of line ""(* Name: <FB/FX-Name> *)"" "	Correct the line correspondingly.

4420

"Name of FB/FX parameter missing"	Check the POUs.

4421

"Type of FB/FX parameter invalid"	Check the POUs.

4422

"Type of FB/FX parameter missing"	Check the POUs.

4423

"Invalid FB/FX call parameter"	Check the interface of the POU.

4424

"Warning: FB/FX for call either missing or parameters invalid or has '0' parameters"	The called POU is not imported yet, is not correct, or has no parameters (in the last case you can ignore the error message).

4425

"Definition of label missing"	The target (label) of the jump is not defined.

4426

"POU does not have a valid STEP 5 block name, e.g. PB10"	Modify the POU name.

4427

"Timer type not declared"	Add a declaration of the timer in the global variables list.

4428

"Maximum number of open STEP5 brackets exceeded"	You may not use more than seven open brackets.

4429

"Error in name of formal parameter"	The parameter name may not exceed four characters.

4430

"Type of formal parameter not IEC-convertible"	In IEC 61131-3 Timer, counter and POUs cannot be converted as formal parameters.

4431

"Too many 'VAR_OUTPUT' parameters for a call in STEP5 STL"	A POU may not contain more than 16 formal parameters as outputs.

4432

"Labels within an expression are not allowed"	In IEC 61131-3 jump labels may not be inserted at any desired position.

4434

"Too many labels"	A POU may not contain more than 100 labels.

4435

"After jump / call, a new expression must start"	After jump or call a Load command LD must follow.

4436

"Bit result undefined, not convertible to IEC 61131-3."	The command which is used by VKE cannot get converted, because the value of the VKE is not known.

4437

"Type of instruction and operand are not compatible"	A bit command is used for a word operand or the other way round.

4438

"No data block opened (insert instruction C DB before)"	Insert a "A DB".

4500

"Unrecognized variable or address"	The watch variable is not declared within the project. By pressing <F2> you get the input assistant which lists the declared variables.

4501

"Extra characters following valid watch expression"	Remove the surplus signs.

4520

"Error in Pragma: Flag expected before '<Name>'!"	The pragma is not correct. Check whether ‘<Name>' is a valid flag.

4521

"Error in Pragma: Unexpected element '<Name>'!"	Check whether pragma is composed correctly.

4522

"'flag off' pragma expected!"	Pragma has not been terminated, insert a 'flag off' instruction.

4523

"Pragma {<Pragma-name>} not allowed in interface of type '<Name>'"	The Pragma cannot be used at this location, see 'Pragmas, overview' for the correct use of pragmas ↬ *Chapter 1.4.1.3.10.1 “Pragmas, overview” on page 309*.

4550

"Index out of defined range : Variable OD "number>, Line <line number>."	Ensure that the index is within the area which is defined in the target settings/networkfunctionality.

4551

"Subindex out of defined range : Variable OD "number>, Line <line number>."	Ensure that the subindex is within the area which is defined in the target settings/network functionality.

4552

"Index out of defined range : Parameter OD "number>, Line <line number>."	Ensure that the index is within the area which is defined in the target settings/network functionality.

4553

"Subindex out of defined range : Parameter OD "number>, Line <line number>."	Ensure that the subindex is within the area which is defined in the target settings/network functionality.

4554

"Variable name invalid: Variable OD <number>, Line <line number>."	Enter a valid project variable in the field 'variable'. Use the syntax <POU name>.<variable name>, or for global variables .<variable name>

4555

"Empty table-entry, input not optional: Parameter OD <number>, Line <line number>	You must make an entry in this field.

4556

"Empty table-entry, input not optional: Variable OD <number>, Line <number>"	You must make an entry in this field.

4557

"The required parameter memory is too large"	The maximum size of data which can be loaded via parameter lists of type Parameters to the controller has been exceeded. This size is defined by the target system. Information on the data size is displayed in the message window at compilation. Reduce the parameter lists size.

4558

"The required variable memory is too large"	The maximum size of data which can be loaded via parameter lists of type Variables to the controller has been exceeded. This size is defined by the target system. Information on the data size is displayed in the message window at compilation. Reduce the parameter lists size.

4560

"Invalid value: Dictionary '<Name>', column '<Name>', line '<line number>'"	Check this entry. It depends on the currently used column (attribute) definition which entries are valid for this field. This definition is given by the target-specific XML description file of the Parameter Manager, or by the standard settings which will be used if there is no description file.

4561

"Column not defined: '<Name>'"	Entries in a column of the parameter list refer to another column which is not defined. The column definitions are given by the description file (XML) of the Parameter Manager for the current target. If a description file is not available, standard settings are used.

4562

"Index/subindex used already: Dictionary '<Name>', line '<Line Number>'"	The Index/Subindex-combination must be unique throughout all parameter lists, because it can be used for parameter access. Correct the indices correspondingly.

4563

"Identifier '<Name>' used already: Dictionary '<Name>', line '<Line Number>'"	The name must be unique throughout all parameter lists, because it can be used for parameter access.

4564

"Index '<Name>' is out of range: Dictionary '<Name>', line '<Line Number>'"	Enter an index which is within the range defined in the target settings, category network functionality in field 'Index range...' for the respective list types (Variables, Parameters, Mappings).

4565

"Subindex '<Name>' is out of range: Dictionary '<Name>', line '<Line Number>'"	Enter a subindex which is within the range defined in the target settings, category network functionality in field 'SubIndex range'.

4566

"An error occurred during import of the parameter manager"	You have imported an export file which contains erroneous information on the Parameter Manager. Check the *.exp file.

4600

"Network variables: '<name>' expression is not from type bool!"	Make sure that the variable defined in the properties dialog of the network variables list at option 'Transmit on event' is of type BOOL.

4601

"Network variables '<name>': No cyclic or freewheeling task for network variable exchange found"

There is no cyclic or free-wheeling task or PLC_PRG in the project where the network variables of type CAN or UDP of the given list are used (only declaration is not sufficient!). You must take care that the variables are used in an appropriate task or in PLC_PRG. If you want to use them in several tasks, note that at data exchange the task with the highest priority will be regarded.

4602

"'<name of network variables list>': The object uses UDP port '<port number>' instead of '<port number>'"

In the Settings 'Create a global variable list' of the named network variables list a port number is used which is not the same as that which is used in the first network variables list found in the global variables folder ↳ *Chapter 1.4.1.4.1.3.1 “Create a global variable list” on page 358*. Take care that all network variables lists are using the same port!

4604

"Network variables '<name>': Base identifier has been used more than once."

The same COB-ID is used in the configuration settings of multiple network variables lists. Assign unique IDs.

4605

"Network variables '<name>': Duplicate CAN COB id."

In the configuration of a network variables list a COB-ID is used which is also specified in the CAN PLC Configuration. Assign unique IDs.

4620

Unused variables have been found in the project ↳ *Chapter 1.4.1.2.3.38 “Unused variables” on page 248*. See the description for command 'Project' 'Check' ↳ *Chapter 1.4.1.2.3.37 “'Project' 'Check'” on page 248*.

4621

There are overlaps at the assignment of variables to memory areas via the "AT"-declaration ↳ *Chapter 1.4.1.2.3.39 “Overlapping memory areas” on page 249*. See the description of command 'Project' 'Check' ↳ *Chapter 1.4.1.2.3.37 “'Project' 'Check'” on page 248*.

4622

IEC addresses assigned to the same memory area are referenced in more than one task. See the description of command 'Project' 'Check' ↳ *Chapter 1.4.1.2.3.37 “'Project' 'Check'” on page 248* ↳ *Chapter 1.4.1.2.3.41 “Concurrent access” on page 249*.

4623

The project gains write access to the same memory area at more than one place. See the description of command ' ↳ *Chapter 1.4.1.2.3.37 “'Project' 'Check'” on page 248*' ↳ *Chapter 1.4.1.2.3.40 “Multiple write acces on output” on page 249*'.

4650

"AxisGroup '<Name>': Task '<Name>' does not exist."	In the PLC Configuration in the definition of the axis group (dialog 'Module parameters', column 'Value') there is a name defined for the task which is controlling the data transfer of this axis group. This task name is not known in the Task Configuration. Correct Task Configuration or PLC Configuration correspondingly.

4651

"AxisGroup '<Name>': Cycletime (dwCycle) not set."	In dialog 'Module parameters' of the axis group enter a value for the cycle time (dwCycle).

4652

"Drive '<name>': wDriveID exists already in this axis group"	In the PLC Configuration within the same axis group there is already a drive with the same Drive ID. Select the drive in the configuration tree and define an ID in configuration dialog 'Drive' which is unique within the axis group.

4656

"Drive '<name>': Scaling factor must not be 0."	Open the PLC Configuration and check the Scale entries in the configuration dialog of the drive. All fields must have entries not equal "0".

4670

"CNC program '<Name>': Global variable '<Name>' not found."	In the CNC program a global variable is used (e.g. $glob_var$), which is not defined in the project. Add the appropriate declaration or correct the assignment to the variable in the CNC program.

4671

"CNC program '<Name>': Variable '<Name>' has an incompatible type."	There is a variable assigned in an instruction of the CNC program, which is declared of a data type which is not valid in this place. Use another variable or correct the type specification.

4685

"CAM '<Name>': CAM table type unknown."	Check the data type which is specified in the CAM Editor dialog "Compile options.." for the equidistant or element optimized point table.

4686

"CAM '<Name>': CAM point exceeds datatype range."	CAM points are used which are out of the data range specified for the point table. For the current range definition see dialog 'Compile options..' in the CAM-Editor.

4700

"'<Number>' ('<Name>'): Watch expression '<Name>' is not a numeric variable."	In the configuration of the visualization a variable is used which is not a number, as required in this place (e.g. at the configuration of XOffset or Angle values etc.).

4701

"'<Name>' ('<Number>'): Watch expression '<name>' is not of type BOOL."	In the configuration of the visualization a variable is used which is not of type BOOL, as required in this place.

4702

"'<Name>' ('<Number>'): Watch expression '<name>' is not of type STRING."	The visualization contains a variable which is not of type STRING although this is required in this place (e.g. at the tooltip configuration).

4703

"'<Name>' ('<Number>'): Invalid watch expression '<Name>'"	The visualization contains an invalid variable.

4704

"'<Name>'('<Number>'): Invalid initial value in watchlist '<Name>'."	In this watchlist, used in a visualization (INTERN command in category Input), there is a erroneous initial value. Check the used list.

4705

"'<name>' ('<number>'): No valid alarm group assigned to alarm table."	Enter a valid alarm group in the configuration dialog of the alarm table (category Alarm table).

4706

"'<name>' ('<number>'): Use of alarm tables requires the target setting 'Alarmhandling in controller' to be activated."	Open the target settings in tab 'Resources', and in dialog 'Visualization' activate option 'Alarmhandling in the PLC'. Otherwise the alarm table element will not work in the target visualization which is currently activated also in the target settings.

4707

"'<name>' ('<number>'): Alarm tables are not supported by the	The target system does not support the processing of alarms (target setting 'Alarmhandling in the PLC' cannot be activated). Thus for running a target visualization (currently activated in the target settings in tab 'Visualization') the alarm table elements must be removed from the visualization.

current target. Please remove these elements from the target visualization."

4708

"'<name>' ('<number>'): Use of trends requires the target setting 'Trend recording in controller' to be activated."

Open the target settings in tab 'Resources' and in dialog 'Visualization' activate option 'Store trend data in the PLC'. Otherwise the trend element will not work in the target visualization which is currently activated also in the target settings.

4709

"'<name>' ('<number>'): Trends are not supported by the current target. Please remove these elements from the target visualization."

The target system does not support the processing of trend data (target setting 'Store trend data in the PLC' cannot be activated). Thus for running a target visualization (currently activated in the target settings in tab 'Visualization') the trend elements must be removed from the visualization.

4712

"'<Name>'('<number>'): The selected target does not support the output of passwords"

The text output in the visualization element is configured to work via dynamic texts or unicode texts. Additionally the option "Hidden" is activated in the "Input" category. This is not supported by the target visualization.

4900

"Invalid type for conversion"

You are using a type conversion which is not supported by the currently chosen code generator.

4901

"Internal error: Overflow in array access!"

The array bounds are too large for a 32-bit-variable. Reduce the array index range.

5100

"<Name> (<Number>): Expression too complex. No more registers available"

The named expression is to complex to be handled by the available registers. Please try to reduce the expression by using interim variables.

1.4.2 Libraries

1.4.2.1 Standard.library

Elements of the Standard.lib

in ST	in AWL	Description
LEN(in)	LEN	String length of operand in
LEFT(str,size)	LEFT	Left inital string of given size of string str

in ST	in AWL	Description
RIGHT(str,size)	RIGHT	Right initial string of given size of string str
MID(str,size,pos)	MID	Partial string of str of given size at position pos
CONCAT('str1','str2')	CONCAT 'str2'	Concatenation of two subsequent strings
INSERT('str1','str2',pos)	INSERT 'str2',p	Insert string str1 in String str2 at position pos
DELETE('str1',len,pos)	DELETE len,pos	Delete partial string (length len), start at position pos of str1
REPLACE('str1','str2',len,pos)	REPLACE 'str2',len,pos	Replace partial string of lenght len by str2, start at position pos of str1
FIND('str1','str2')	FIND 'str2'	Search for partial string str2 in str1
SR	SR	Bistable FB is set dominant
RS	RS	Bistable FB is set back
SEMA	SEMA	FB: Software Semaphor (interruptable)
R_TRIG	R_TRIG	FB: rising edge is detected
F_TRIG	F_TRIG	FB: falling edge is detected
CTU	CTU	FB: Counts upv
CTD	CTD	FB: Counts down
CTUD	CTUD	FB: Counts up and down
TP	TP	FB: trigger
TON	TON	FB: Timer On-Delay
TOF	TOF	FB: Timer Off-Delay
RTC	RTC	FB: Real-time clock

1.4.2.1.1 String functions

LEN

Provided by standard.lib.

Returns the length of a string. Input STR is of type STRING, the return value of the function is type INT.

Example in IL

```
LD 'SUSI'
LEN
ST VarINT1 (* Result is 4 *)
```

Example in FBD

Example in ST VarSTRING1 := LEN ('SUSI');

> *String functions are not "thread safe": When using tasks, string functions may only be used in a single task. If the same function is used in different tasks, there is a danger of overwriting.*

LEFT

Provided by standard.lib.

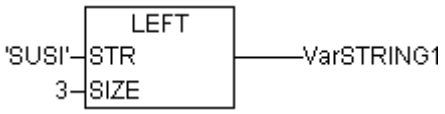
Left returns the left, initial string for a given string. Input STR is type STRING, SIZE is of type INT, the return value of the function is type STRING.

LEFT (STR, SIZE) means: Take the first SIZE character from the left in the string STR.

Example in IL

```
LD   'SUSI'
LEFT 3
ST   VarSTRING1 (* Result is 'SUS' *)
```

Example in FBD



Example in ST VarSTRING1 := LEFT ('SUSI',3);

> *String functions are not "thread safe": When using tasks, string functions may only be used in a single task. If the same function is used in different tasks, there is a danger of overwriting.*

RIGHT

Provided by standard.lib.

Right returns the right, initial string for a given string.

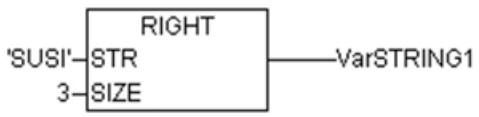
RIGHT (STR, SIZE) means: Take the first SIZE character from the right in the string STR.

Input STR is of type STRING, SIZE is of type INT, the return value of the function is of type STRING.

Example in IL

```
LD 'SUSI'
RIGHT 3
ST VarSTRING1 (* Result is 'USI' *)
```

Example in FBD



Example in ST VarSTRING1 := RIGHT ('SUSI',3);

> *String functions are not "thread safe": When using tasks, string functions may only be used in a single task. If the same function is used in different tasks, there is a danger of overwriting.*

MID

Provided by standard.lib.

Mid returns a partial string from within a string.

Input STR is type STRING, LEN and POS are type INT, the return value of the function is type STRING.

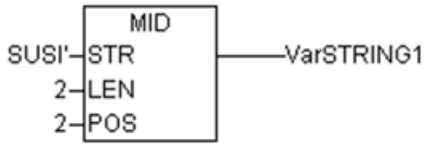
MID (STR, LEN, POS) means: Retrieve LEN characters from the STR string beginning with the character at position POS.

Example in IL LD 'SUSI'

MID 2,2

ST VarSTRING1 (* Result is 'US' *)

Example in FBD



Example in ST VarSTRING1 := MID ('SUSI',2,2);

> *String functions are not "thread safe": When using tasks, string functions may only be used in a single task. If the same function is used in different tasks, there is a danger of overwriting.*

CONCAT

Provided by standard.lib.

Concatenation (combination) of two strings.

The input variables STR1 and STR2 as well as the return value of the function are type STRING.

Example in IL LD 'SUSI'

CONCAT 'WILLI'

ST VarSTRING1 (* Result is 'SUSIWILLI' *)

Example in FBD

Example in ST VarSTRING1 := CONCAT ('SUSI','WILLI');

The CONCAT function does not work, if nested over more than five levels.

String functions are not "thread safe": When using tasks, string functions may only be used in a single task. If the same function is used in different tasks, there is a danger of overwriting.

INSERT

Provided by standard.lib.

INSERT inserts a string into another string at a defined point.

The input variables STR1 and STR2 are type STRING, POS is type INT and the return value of the function is type STRING.

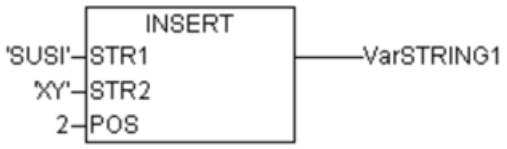
INSERT(STR1, STR2, POS) means: insert STR2 into STR1 after position POS.

Example in IL LD 'SUSI'

INSERT 'XY',2

ST VarSTRING1 (* Result is 'SUXYSI' *)

Example in FBD



Example in ST VarSTRING1 := INSERT ('SUSI','XY',2);

String functions are not "thread safe": When using tasks, string functions may only be used in a single task. If the same function is used in different tasks, there is a danger of overwriting.

DELETE

Provided by standard.lib.

DELETE removes a partial string from a larger string at a defined position.

The input variable STR is type STRING, LEN and POS are type INT, the return value of the function is type STRING.

DELETE(STR, L, P) means: Delete L characters from STR beginning with the character in the P position.

Example in IL

```
LD 'SUXYSI'
DELETE 2,3
ST Var1 (* Result is 'SUSI' *)
```

Example in FBD

Example in ST

```
Var1 := DELETE ('SUXYSI',2,3);
```

> *String functions are not "thread safe": When using tasks, string functions may only be used in a single task. If the same function is used in different tasks, there is a danger of overwriting.*

REPLACE

Provided by standard.lib.

REPLACE replaces a partial string from a larger string with a third string.

The input variable STR1 and STR2 are type STRING, LEN and POS are type INT, the return value of the function is type STRING.

REPLACE(STR1, STR2, L, P) means: Replace L characters from STR1 with STR2 beginning with the character in the P position.

Example in IL

```
LD 'SUXYSI'
REPLACE 'K',2,2
ST VarSTRING1 (* Result is 'SKYSI' *)
```

Example in FBD

Example in ST

```
VarSTRING1 := REPLACE ('SUXYSI','K',2,2);
```

> *String functions are not "thread safe": When using tasks, string functions may only be used in a single task. If the same function is used in different tasks, there is a danger of overwriting.*

FIND

Provided by standard.lib.

FIND searches for a partial string within a string.

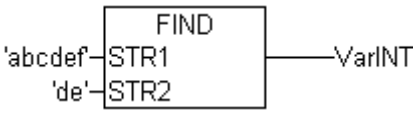
The input variable STR1 and STR2 are type STRING, the return value of the function is type STRING.

FIND(STR1, STR2) means: Find the position of the first character where STR2 appears in STR1 for the first time. If STR2 is not found in STR1, then OUT:=0.

Example in IL

```
LD   'abcdef'
FIND 'de'
ST   VarINT1 (* Result is '4' *)
```

Example in FBD



Example in ST

```
arINT1 := FIND ('abcdef','de');
```

Please note: String functions are not "thread safe": When using tasks, string functions may only be used in a single task. If the same function is used in different tasks, there is a danger of overwriting.

1.4.2.1.2 Bistable function blocks

SR

Provided by standard.lib.

Making bistable function blocks dominant:

Q1 = SR (SET1, RESET) means:

Q1 = (NOT RESET AND Q1) OR SET1

The input variables SET1 and RESET as well as the output variable Q1 are type BOOL.

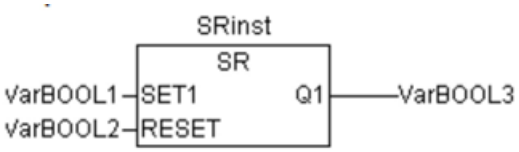
Declaration example

```
SRInst : SR ;
```

Example in IL

```
CAL SRInst(SET1 := VarBOOL1, RESET := VarBOOL2)
LD SRInst.Q1 ST VarBOOL3
```

Example in FBD



Example in ST

```
SRInst(SET1:= VarBOOL1 , RESET:=VarBOOL2 );
VarBOOL3 := SRInst.Q1 ;
```

RS

Provided by standard.lib.

Resetting bistable function blocks

Q1 = RS (SET, RESET1) means:

Q1 = NOT RESET1 AND (Q1 OR SET)

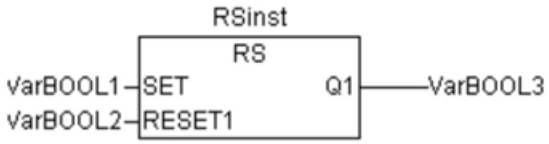
The input variables SET and RESET1 as well as the output variable Q1 are type BOOL.

Declaration example	RSInst : RS ;

Example in IL

```
CAL RSInst(SET:= VarBOOL1,RESET1:=VarBOOL2)
LD RSInst.Q1
ST VarBOOL3
```

Example in FBD



Example in ST

```
RSInst(SET:= VarBOOL1 , RESET1:=VarBOOL2 );
VarBOOL3 := RSInst.Q1 ;
```

SEMA

Provided by standard.lib.

A Software Semaphore (Interruptible)

BUSY = SEMA(CLAIM, RELEASE) means:

BUSY := X;

IF CLAIM THEN X:=TRUE;

ELSE IF RELEASE THEN BUSY := FALSE; X:= FALSE;

END_IF

X is an internal BOOL variable that is FALSE when it is initialized.

The input variables CLAIM and RELEASE as well as the output variable BUSY are type BOOL.

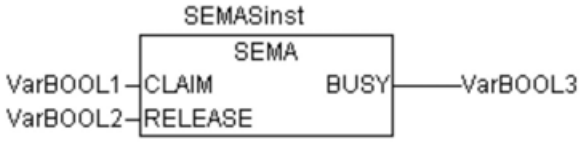
If BUSY is TRUE when SEMA is called up, this means that a value has already been assigned to SEMA (SEMA was called up with CLAIM = TRUE). If BUSY is FALSE, SEMA has not yet been called up or it has been released (called up with RELEASE = TRUE).

Declaration example	SEMAInst : SEMA ;

Example in IL

```
CAL SEMAInst(CLAIM:=VarBOOL1,RELEASE:=VarBOOL2)
LD SEMAInst.BUSY
ST VarBOOL3
```

Example in FBD



Example in ST

```
SEMAInst(CLAIM:= VarBOOL1 , RELEASE:=VarBOOL2 );
VarBOOL3 := SEMAInst.BUSY;
```

1.4.2.1.3 Trigger

R_TRIG

Provided by standard.lib.

The function block R_TRIG detects a rising edge.

```
FUNCTION_BLOCK R_TRIG
VAR_INPUT
 CLK : BOOL;
END_VAR
VAR_OUTPUT
 Q : BOOL;
END_VAR
VAR
 M : BOOL := FALSE;
END_VAR
 Q := CLK AND NOT M;
 M := CLK;
```

The output Q and the help variable M will remain FALSE as long as the input variable CLK is FALSE. As soon as CLK returns TRUE, Q will first return TRUE, then M will be set to TRUE. This means each time the function is called up, Q will return FALSE until CLK has falling edge followed by an rising edge.

Declaration example	RTRIGInst : R_TRIG ;

Example in IL

```
CAL RTRIGInst(CLK := VarBOOL1)
LD  RTRIGInst.Q
ST  VarBOOL2
```

Example in FBD

Example in ST

```
RTRIGInst(CLK:= VarBOOL1);
```

VarBOOL2 := RTRIGInst.Q;

F_TRIG

Provided by standard.lib.

The function block F_TRIG a falling edge.

FUNCTION_BLOCK F_TRIG

VAR_INPUT

CLK: BOOL;

END_VAR

VAR_OUTPUT

Q: BOOL;

END_VAR

VAR

M: BOOL := FALSE;

END_VAR

Q := NOT CLK AND NOT M;

M := NOT CLK;

The output Q and the help variable M will remain FALSE as long as the input variable CLK returns TRUE. As soon as CLK returns FALSE, Q will first return TRUE, then M will be set to TRUE. This means each time the function is called up, Q will return FALSE until CLK has a rising followed by a falling edge.

Declaration example	FTRIGInst : F_TRIG ;

Example in IL

CAL FTRIGInst(CLK := VarBOOL1)

LD FTRIGInst.Q

ST VarBOOL2

Example in FBD

Example in ST

FTRIGInst(CLK:= VarBOOL1);

VarBOOL2 := FTRIGInst.Q;

1.4.2.1.4 Counter

CTU

Provided by standard.lib.

Function block Incrementer:

The input variables CU and RESET as well as the output variable Q are type BOOL, the input variable PV and the output variable CV are type WORD.

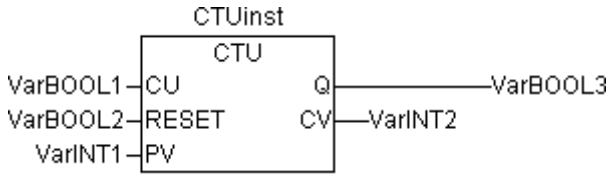
The counter variable CV will be initialized with 0 if RESET is TRUE. If CU has a rising edge from FALSE to TRUE, CV will be raised by 1.Q will return TRUE when CV is greater than or equal to the upper limit PV.

Declaration example	CTUInst : CTU ;

Example in IL

```
CAL  CTUInst(CU := VarBOOL1, RESET := VarBOOL2, PV := VarINT1)
LD   CTUInst.Q
ST   VarBOOL3
LD   CTUInst.CV
ST   VarINT2
```

Example in FBD



Example in ST

```
CTUInst(CU:= VarBOOL1, RESET:=VarBOOL2 , PV:= VarINT1);
VarBOOL3 := CTUInst.Q ;
VarINT2 := CTUInst.CV;
```

CTD

Provided by standard.lib.

Function block Decrementer:

The input variables CD and LOAD as well as the output variable Q are type BOOL, the input variable PV and the output variable CV are type WORD.

When LOAD_ is TRUE, the counter variable CV will be initialized with the upper limit PV. If CD has a rising edge from FALSE to TRUE, CV will be lowered by 1 provided CV is greater than 0 (i.e., it doesn't cause the value to fall below 0).

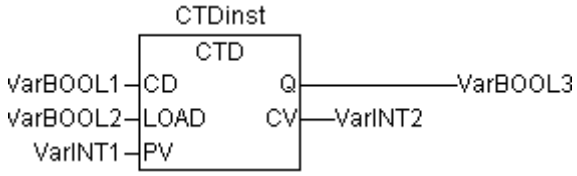
Q returns TRUE when CVis equal 0.

Declaration example	CTDInst : CTD ;

Example in IL

```
CAL  CTDInst(CD := VarBOOL1, LOAD := VarBOOL2, PV := VarINT1)
LD   CTDInst.Q
ST   VarBOOL3
LD   CTDInst.CV
ST   VarINT2
```

Example in FBD



Example in ST

```
CTDInst(CD:= VarBOOL1, LOAD:=VarBOOL2 , PV:= VarINT1);
VarBOOL3 := CTDInst.Q ;
VarINT2 := CTDInst.CV;
```

CTUD

Provided by standard.lib.

Function block Incrementer/Decrementer

The input variables CU, CD, RESET, LOAD as well as the output variables QU and QD are type BOOL, PV and CV are type WORD.

If RESET is valid, the counter variable CV will be initialized with 0. If LOAD is valid, CV will be initialized with PV.

If CU has a rising edge from FALSE to TRUE, CV will be raised by 1. If CD has a rising edge from FALSE to TRUE, CV will be lowered by 1 provided this does not cause the value to fall below 0.

QU returns TRUE when CV has become greater than or equal to PV.

QD returns TRUE when CV has become equal to 0.

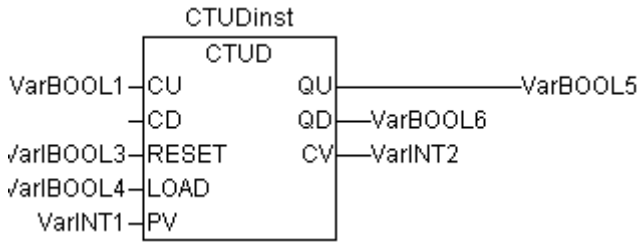
Declaration example:

```
CTUDInst : CUTD ;
```

Example in IL

```
CAL  CTUDInst(CU:=VarBOOL1, RESET:=VarBOOL3, LOAD:=VarBOOL4, PV:=VarINT1)
LD   CTUDInst.Q
ST   VarBOOL5
LD   CTUDInst.QD
ST   VarBOOL5
LD   CTUInst.CV
ST   VarINT2
```

Example in FBD



Example in ST

```
CTUDInst(CU := VarBOOL1, RESET := VarBOOL3, LOAD:=VarBOOL4 , PV:= VarINT1);
VarBOOL5 := CTUDInst.QU ;
VarBOOL6 := CTUDInst.QD ;
VarINT2 := CTUDInst.CV;
```

1.4.2.1.5 Timer

TP

Provided by standard.lib.

The function block Timer is a trigger. TP(IN, PT, Q, ET) means:

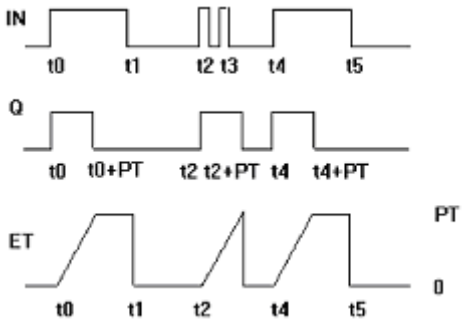
IN and PT are input variables of the BOOL and TIME types respectively. Q and ET are output variables of the BOOL and TIME types respectively. If IN is FALSE, Q is FALSE and ET is 0.

As soon as IN becomes TRUE, the time will begin to be counted in milliseconds in ET until its value is equal to PT. It will then remain constant.

Q is TRUE as from IN has got TRUE and ET is less than or equal to PT. Otherwise it is FALSE.

Q returns a signal for the time period given in PT.

Graphic Display of the TP Time Sequence



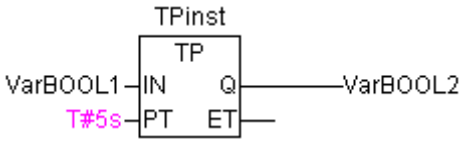
Declaration example:

```
TPInst : TP ;
```

Example in IL

```
CAL TPInst(IN := VarBOOL1, PT := T#5s)
LD  TPInst.Q
ST  VarBOOL2
```

Example in FBD



Example in ST

```
TPInst(IN := VarBOOL1, PT:= T#5s);
VarBOOL2 :=TPInst.Q;
```

TON

Provided by standard.lib.

The function block Timer On Delay implements a turn-on delay.

TON(IN, PT, Q, ET) means:

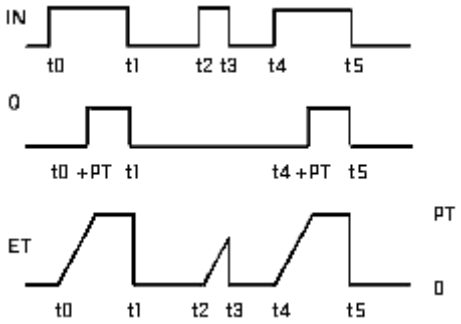
IN and PT are input variables of the BOOL and TIME types respectively. Q and ET are output variables of the BOOL and TIME types respectively. If IN is FALSE, Q is FALSE and ET is 0.

As soon as IN becomes TRUE, the time will begin to be counted in milliseconds in ET until its value is equal to PT. It will then remain constant.

Q is TRUE when IN is TRUE and ET is equal to PT. Otherwise it is FALSE.

Thus, Q has a rising edge when the time indicated in PT in milliseconds has run out.

Graphic display of TON behavior over time:

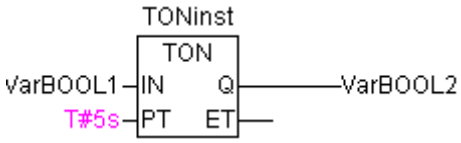


Declaration example:	TONInst : TON ;

Example in IL

```
CAL TONInst(IN := VarBOOL1, PT := T#5s)
LD  TONInst.Q
ST  VarBOOL2
```

Example in FBD



Example in ST

```
TONInst(IN := VarBOOL1, PT:= T#5s);
```

TOF

Provided by standard.lib.

The function block TOF implements a turn-off delay..

TOF(IN, PT, Q, ET) means:

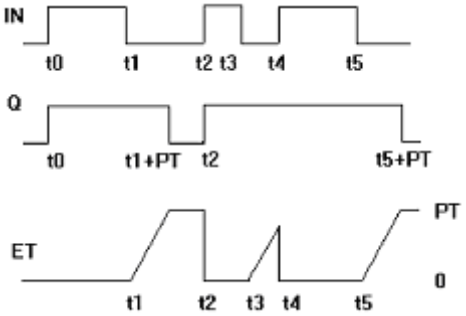
IN and PT are input variables type BOOL respectively TIME. Q and E are output variabls type BOOL respectively TIME. If IN is TRUE, the outputs are TRU respectively 0.

As soon as IN becomes FALSE, in ET the time will begin to be counted in milliseconds in ET until its value is equal to PT. It will then remain constant.

Q is FALSE when IN is FALSE und ET equal PT. Otherwise it is TRUE.

Thus, Q has a falling edge when the time indicated in PT in milliseconds has run out.

Graphic display of TOF behavior over time:

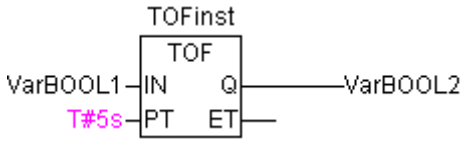


Declaration example	TOFInst : TOF ;

Example in IL

```
CAL TOFInst(IN := VarBOOL1, PT := T#5s)
LD TOFInst.Q
ST VarBOOL2
```

Example in FBD



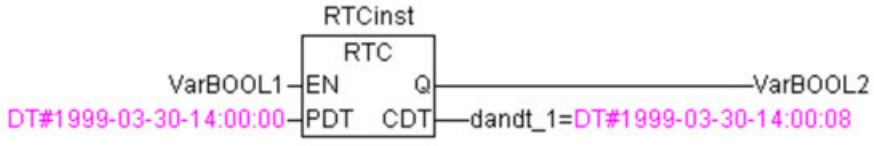
Example in ST

```
TOFInst(IN := VarBOOL1, PT:= T#5s);
VarBOOL2 :=TOFInst.Q;
```

RTC

Provided by standard.lib.

The function block run-time clock returns, starting at a given time, the current date and time.



RTC(EN, PDT, Q, CDT) means:

EN and PDT are input variables type TIME. Q and CDT are output variables type BOOL respectively DATE_AND_TIME. When EN is FALSE, the output variables Q und CDT are FALSE respectively DT#1970-01-01-00:00:00.

As soon as EN becomes TRUE, the time of PDT is set, is counted up in seconds and returned in CDT as long as EN is TRUE (see example in the picture above). As soon as EN is reset to FALSE, CDT is reset to the initial value DT#1970-01-01-00:00:00. Please note that the time in PDT is only set by a rising edge.

1.4.2.2 UTIL.library

Elements of the Util.lib

Element	Description
BCD_TO_INT	Conversion of a Byte: BCD to INT format
INT_TO_BCD	Converstion of a Byte: INT to BCD format
EXTRACT(in,n)	The n-th bit of DWORD in is returned in BOOL
PACK	Up to 8 bits are packed into a byte
PUTBIT	A bit of a DWORD is set to a certain value
UNPACK	A byte is returned as single bits
DERIVATIVE	Local derivation
INTEGRAL	Integral
LIN_TRAFO	Transformation of REAL values
STATISTICS_INT	Min., Max., average values in INT format
STATISTICS_REAL	Min., Max., average in REAL format
VARIANCE	Variance
PD	PD controller
PID	PID controller
BLINK	Pulsating signal
FREQ_MEASURE	Measuring frequency of boolean input signal
GEN	Periodic functions
CHARCURVE	Linear functions
RAMP_INT	Limiting ascendance of descendance of the function beeing fed (INT)
RAMP_REAL	Limiting ascendance of descendance of the function beeing fed (REAL)
HYSTERESIS	Hysteresis
LIMITALARM	Watches whether input value exceeds limits of a defined range

1.4.2.2.1 Overview

This library contains an additional collection of various blocks which can be used for BCD conversion, bit/byte functions, mathematical auxiliary functions, as controller, signal generators, function manipulators and for analog value processing.

As some of the functions and function blocks contain REAL variables, an accessory library named UTIL_NO_REAL exists in which these POUs are excluded.

1.4.2.2.2 BCD conversion

BCD conversion

Provided by util.lib.

A byte in the BCD format contains integers between 0 and 99. Four bits are used for each decimal place. The ten decimal place is stored in the bits 4-7. Thus the BCD format is similar to the hexadecimal presentation, with the simple difference that only values between 0 and 99 can be stored in a BCD byte, whereas a hexadecimal byte reaches from 0 to FF.

Example	The integer 51 should be converted to BCD format. 5 in binary is 0101, 1 in binary is 0001, which makes the BCD byte 01010001, which corresponds to the value $51=81.

BCD_TO_INT

Provided by util.lib.

This function converts a byte in BCD format into an INT value:

The input value of the function is type BYTE and the output is type INT.

Where a byte should be converted which is not in the BCD format the output is -1.

Examples in ST

```
i:=BCD_TO_INT(73); (* Result is 49 *)
k:=BCD_TO_INT(151); (* Result is 97 *)
l:=BCD_TO_INT(15); (* Output -1, because it is not in BCD format *)
```

INT_TO_BCD_

Provided by util.lib.

This function converts an INTEGER value into a byte in BCD format:

The input value of the function is type INT, the output is type BYTE.

The number 255 will be outputted where an INTEGER value should be converted which cannot be converted into a BCD byte.

Examples in ST

```
i:=INT_TO_BCD(49); (* Result is 73 *)
k:=BCD_TO_INT(97); (* Result is 151 *)
l:=BCD_TO_INT(100); (* Error! Output: 255 *)
```

1.4.2.2.3 Bit-/Byte functions

EXTRACT

Provided by util.lib.

Inputs to this function are a DWORD X, as well as a BYTE N. The output is a BOOL value, which contains the content of the N^{th} bit of the input X, whereby the function begins to count from the zero bit.

Examples in ST

```
FLAG:=EXTRACT(X:=81, N:=4); (* Result : TRUE, because 81 is binary 1010001, so the 4th bit is 1 *)
FLAG:=EXTRACT(X:=33, N:=0); (* Result : TRUE, because 33 is binary 100001, so the bit '0' is 1 *)
```

PACK

Provided by util.lib.

This function is capable of delivering back eight input bits B0, B1, ..., B7 from type BOOL as a BYTE.

The function block UNPACK is closely related to this function.

PUTBIT

Provided by util.lib.

The input to this function consists of a DWORD X, a BYTE N and a BOOLean value B.

PUTBIT sets the N^{th} bit from X on the value B, whereby it starts counting from the zero bit.

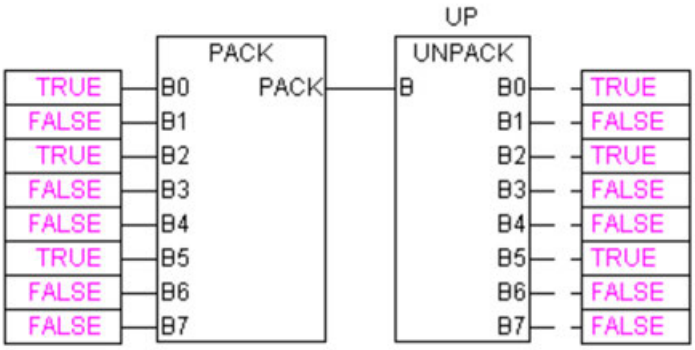
Example in ST

```
A:=38; (* binary 100110 *)
B:=PUTBIT(A,4,TRUE); (* Result : 54 = 2#110110 *)
C:=PUTBIT(A,1,FALSE); (* Result : 36 = 2#100100 *)
```

UNPACK

Provided by util.lib.

UNPACK converts the input B from type BYTE into 8 output variables B0,...,B7 of the type BOOL, and this is the opposite to PACK.



1.4.2.2.4 Mathematic auxiliary functions

DERIVATIVE

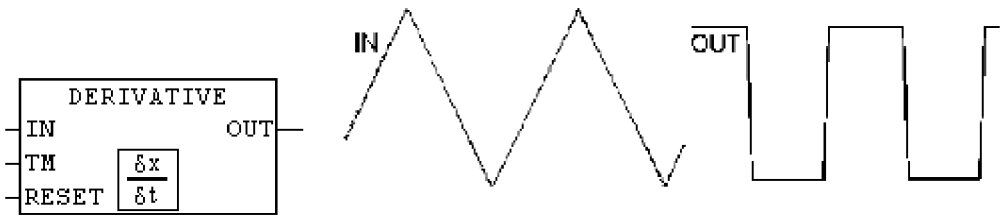
Provided by util.lib.

This function block approximately determines the local derivation.

The function value is delivered as a REAL variable by using IN. TM contains the time which has passed in ms in a DWORD and the input of RESET of the type BOOL allows the function block to start anew through the delivery of the value TRUE.

The output OUT is of the type REAL.

In order to obtain the best possible result, DERIVATIVE approximates using the last four values, in order to hold errors which are produced by inaccuracies in the input parameters as low as possible.



INTEGRAL

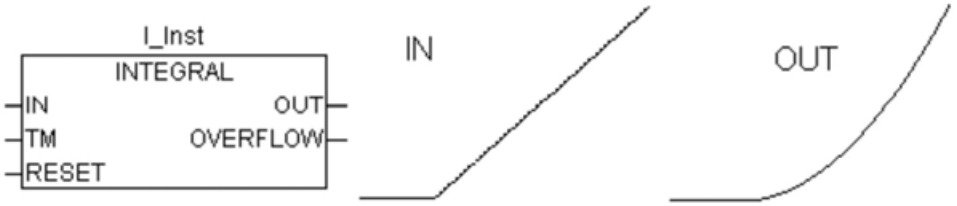
Provided by util.lib.

This function block approximately determines the integral of the function.

In an analog fashion to DERIVATIVE, the function value is delivered as a REAL variable by using IN. TM contains the time which has passed in ms in a DWORD and the input of RESET of the type BOOL allows the function block to start anew with the value TRUE.

The output OUT is of the type REAL. The integral is approximated by two step functions. The average of these is delivered as the approximated integral.

Example: Integration of a linear function:



LIN_TRAFO

This function block (util.lib. transforms a REAL-value, which lies in a range of values defined by a lower and upper limit value, to a REAL-value which lies correspondingly in another range also defined by a lower and upper limit. The following equation is basis of the conversion:

(IN - IN_MIN) : (IN_MAX - IN) = (OUT - OUT_MIN) : (OUT_MAX - OUT)

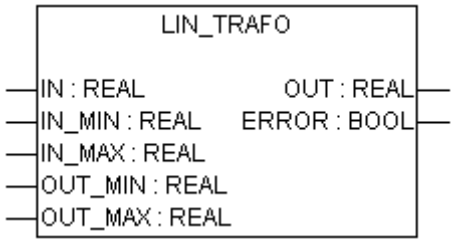


Table 37: Input variables

Variable	Data type	Description
IN	REAL	Input value
IN_MIN	REAL	Lower limit of input range of values
IN_MAX	REAL	Upper limit of input range of values
OUT_MIN	REAL	Lower limit of output value range
OUT_MAX	REAL	Upper limit of output value range

Table 38: Output variables

Variable	Data type	Description
OUT	REAL	Output value
ERROR	BOOL	Error occurred: TRUE, if IN_MIN = IN_MAX, or if IN is outside of the specified input range of values

Application example:

A temperature sensor provides Volt-values (input IN). These are to be converted to temperature values in degree celsius (output OUT). The input(Volt) range of values is defined by the limits IN_MIN=0 and IN_MAX=10. The output(degree celsius) range of values is defined by the limits OUT_MIN=-20 and OUT_MAX=40.

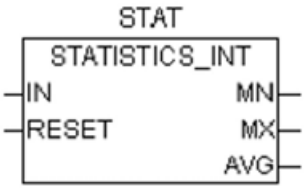
Thus for an input of 5 Volt a temperature of 10 degree celsius will result.

STATISTICS_INT

Provided by util.lib.

This function block calculates some standard statistical values:

The input IN is of the type INT. All values are initialised anew when the BOOLean input RESET is TRUE. The output MN contains the minimum, MX of the maximum value from IN. AVG describes the average, that is the expected value of IN. All three outputs are of the type INT.



STATISTICS_REAL

Provided by util.lib.

This function block corresponds to STATISTICS_INT, except that the input IN is of the type REAL like the outputs MN, MX, AVG.

VARIANCE

Provided by util.lib.

VARIANCE calculates the variance of the entered values.

The input IN is of the type REAL, RESET is of the type BOOL and the output OUT is again of the type REAL.

This block calculates the variance of the inputted values. VARIANCE can be reset with RESET=TRUE.

The standard deviation can easily be calculated as the square root of the VARIANCE.

1.4.2.2.5 Controllers

PD

The library util.lib provides the following PD controller function block:

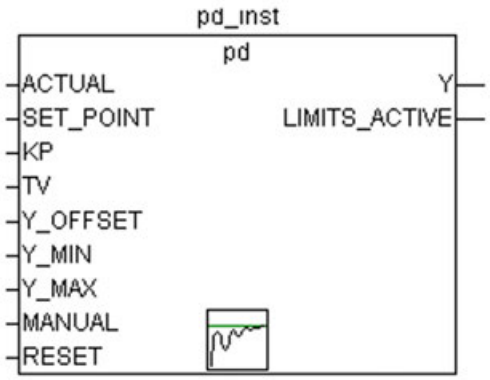


Table 39: Inputs of the function block

Variable	Data type	Description
ACTUAL	REAL	Current value of the controlled variable
SET_POINT	REAL	Desired value, command variable
KP	REAL	Coefficient of proportionality, unity gain of the P-part
TV	REAL	Derivative action time, unity gain of the D-part in seconds, e.g. "0.5" for 500 ms
Y_MANUAL	REAL	Defines output value Y in case of MANUAL = TRUE
Y_OFFSET	REAL	Offset for the manipulated variable Y
Y_MIN, Y_MAX	REAL	Lower resp. upper limit for the manipulated variable Y. If Y exceeds these limits, output LIMITS_ACTIVE will be set to TRUE and Y will be kept within the prescribed range. This control will only work if Y_MIN<Y_MAX.
MANUAL	BOOL	If TRUE, manual operation will be active, i.e. the manipulated value will be defined by Y_MANUAL.
RESET	BOOL	TRUE resets the controller; during reinitialization Y = Y_OFFSET.

Table 40: Outputs of the function block

Variable	Data type	Description
Y	REAL	Manipulated value, calculated by the function block (see below)
LIMITS_ACTIVE	BOOL	TRUE indicates that Y has exceeded the given limits (Y_MIN, Y_MAX).

Y_OFFSET, Y_MIN und Y_MAX are used for the transformation of the manipulated variable within a prescribed range.

MANUAL can be used to switch on and off manual operation. RESET serves to reset the controller.

In normal operation (MANUAL = RESET = LIMITS_ACTIVE = FALSE) the controller calculates the controller error e as difference SET_POINT - ACTUAL, generates the derivation with respect to time $\delta e/\delta t$ and stores these values internally.

The output, i.e. the manipulated variable Y is calculated as follows:

$Y = KP (\Delta + TV\ \delta\Delta/\delta t) + Y\_OFFSET$ whereby Δ = SET_POINT-ACTUAL

So besides the P-part also the current change of the controller error (D-part) influences the manipulated variable.

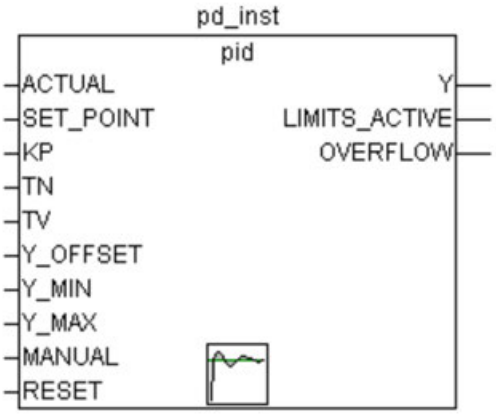
Additionally Y is limited on a range prescribed by Y_MIN and Y_MAX. If Y exceeds these limits, LIMITS_ACTIVE will get TRUE. If no limitation of the manipulated variable is desired, Y_MIN and Y_MAX have to be set to 0.

As long as MANUAL=TRUE, Y_MANUAL will be written to Y.

A P-controller can be easily created by setting TV=0.

PID

The library util.lib provides the following PID controller function block:



Unlike the PD controller, this function block contains a further REAL input TN for the readjusting time in sec (e.g. "0.5" for 500 ms).

Table 41: Inputs of the function block

Variable	Data type	Description
ACTUAL	REAL	Current value of the controlled variable
SET_POINT	REAL	Desired value, command variable
KP	REAL	Coefficient of proportionality, unity gain of the P-part
TN	REAL	Reset time, reciprocal unity gain of the I-part; given in seconds, e.g. "0.5" for 500 ms
TV	REAL	Derivative action time, unity gain of the D-part in seconds, e.g. "0.5" for 500 ms

Variable	Data type	Description
Y_MANUAL	REAL	Defines output value Y in case of MANUAL = TRUE
Y_OFFSET	REAL	Offset for the manipulated variable Y
Y_MIN, Y_MAX	REAL	Lower resp. upper limit for the manipulated variable Y. If Y exceeds these limits, output LIMITS_ACTIVE will be set to TRUE and Y will be kept within the prescribed range. This control will only work if Y_MIN<Y_MAX.
MANUAL	BOOL	If TRUE, manual operation will be active, i.e. the manipulated value will be defined by Y_MANUAL.
RESET	BOOL	TRUE resets the controller; during reinitialization Y = Y_OFFSET.

Table 42: Outputs of the function block

Variable	Data type	Description
Y	REAL	Manipulated value, calculated by the function block (see below)
LIMITS_ACTIVE	BOOL	TRUE indicates that Y has exceeded the given limits (Y_MIN, Y_MAX).
OVERFLOW	BOOL	TRUE indicates an overflow (see below)

Y_OFFSET, Y_MIN und Y_MAX serve for transformation of the manipulated variable within a prescribed range.

MANUAL can be used to switch to manual operation; RESET can be used to re-initialize the controller..

In normal operation (MANUAL = RESET = LIMITS_ACTIVE = FALSE) the controller calculates the controller error e as difference from SET_POINT "“ ACTUAL, generates the derivation with respect to time $\delta e/\delta t$ and stores these values internally.

The output, i.e. the manipulated variable Y unlike the PD controller contains an additional integral part and is calculated as follows:

$Y = KP (\Delta + 1/TN \int edt + TV\ \delta\Delta /\delta t) + Y\_OFFSET$

So besides the P-part also the current change of the controller error (D-part) and the history of the controller error (I-part) influence the manipulated variable.

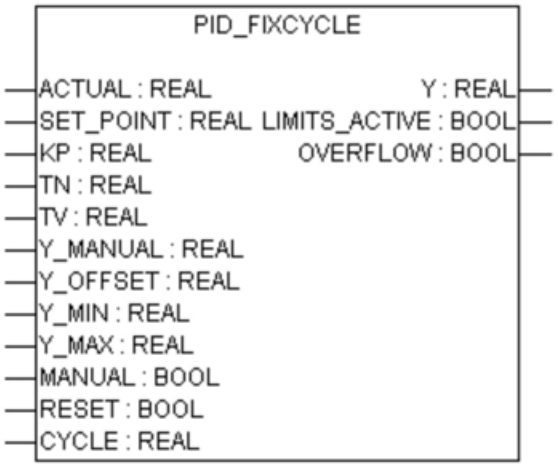
The PID controller can be easily converted to a PI-controller by setting TV=0.

Because of the additional integral part, an overflow can come about by incorrect parameterization of the controller, if the integral of the error D becomes to great. Therefore for the sake of safety a BOOLean output called OVERFLOW is present, which in this case would have the value TRUE. This only will happen if the control system is instable due to incorrect parameterization. At the same time, the controller will be suspended and will only be activated again by re-initialization.

PID_FIXCYCLE

Provided by util.lib.

The PID_FIXCYCLE controller function block:



This function block functionally corresponds to the PID controller with the exception that the cycle time is not measured autmatically by an internal function but is set by input CYCLE (in seconds).

1.4.2.2.6 Signal generators

BLINK

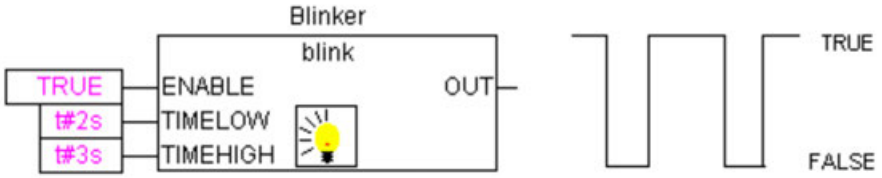
Provided by util.lib.

The function block BLINK generates a pulsating signal. The input consists of ENABLE of the type BOOL, as well as TIMELOW and TIMEHIGH of the type TIME. The output OUT is of the type BOOL.

If ENABLE is set to TRUE, BLINK begins to set the output for the time period TIMEHIGH to TRUE and afterwards to set it for the time period TIMELOW to FALSE.

When ENABLE is reset to FALSE, output OUT will not be changed, i.e. no further pulse will be generated. If you explicitly also want to get OUT FALSE when ENABLE is reset to FALSE, you might use "OUT AND ENABLE" (i.e. adding an AND box with parameter ENABLE) at the output.

Example in CFC:



FREQ_MEASURE

Provided by util.lib.

This function block measures the (average) frequency (Hz) of a boolean input signal. You can specify over how many periods it should be averaged. A period is the time between two rising edges of the input signal.

Table 43: Input variables

Variable	Data Type	Description
IN	BOOL	Input signal
PERIODS	INT	Number of periods, i.e. the time intervals between the rising edges, over which the average frequency of the input signal should be calculated. Possible values: 1 to 10
RESET	BOOL	Reset of all parameters to 0

Table 44: Output variables

Variable	Data Type	Description
OUT	REAL	Resulting frequency in [Hz]
VALID	BOOL	FALSE until the first measure has been finished, or if the period > 3*OUT (indicating something wrong with the inputs)

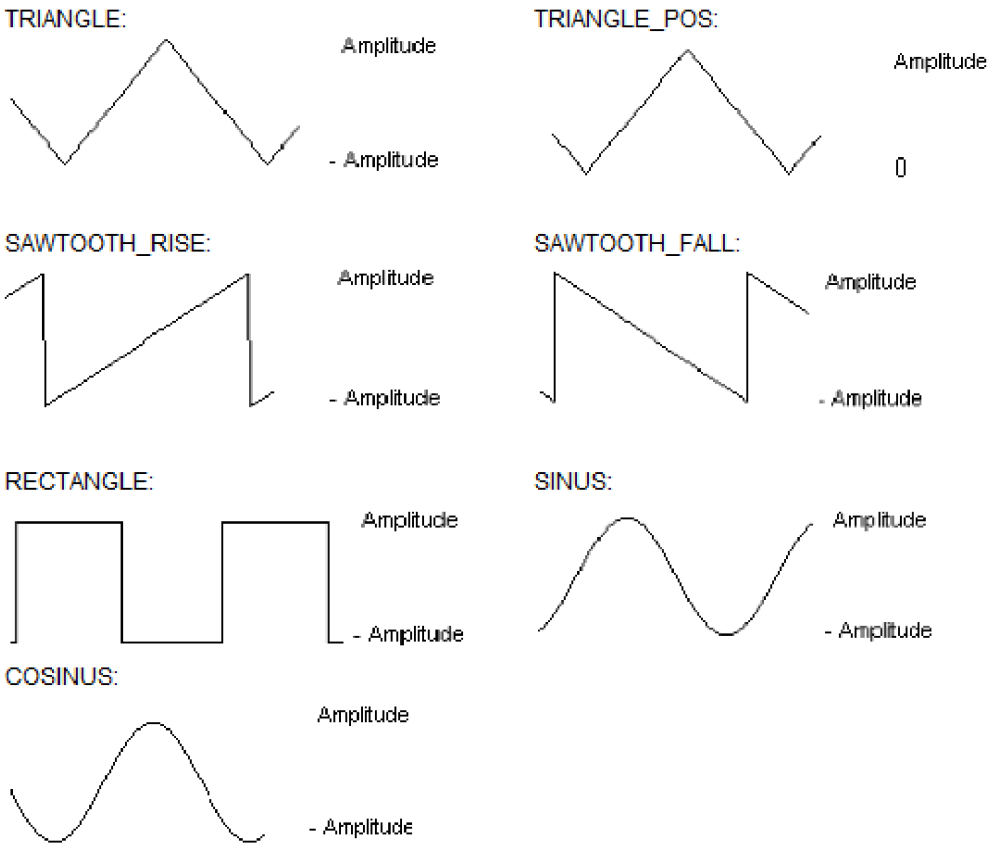
GEN

Provided by util.lib.

The function generator generates typical periodic functions:

The inputs are a composition consisting of MODE from the pre-defined counting type GEN_MODE, BASE of the type BOOL, PERIOD of the type TIME, of two INT values CYCLES and AMPLITUDE and of the BOOLean RESET input.

The MODE describes the function which should be generated, whereby the enumeration values TRIANGLE and TRIANGLE_POS deliver two triangular functions, SAWTOOTH_RISE an ascending, SAWTOOTH_FALL a descending sawtooth, RECTANGLE a rectangular signal and SINE and COSINE the sine and cosine:

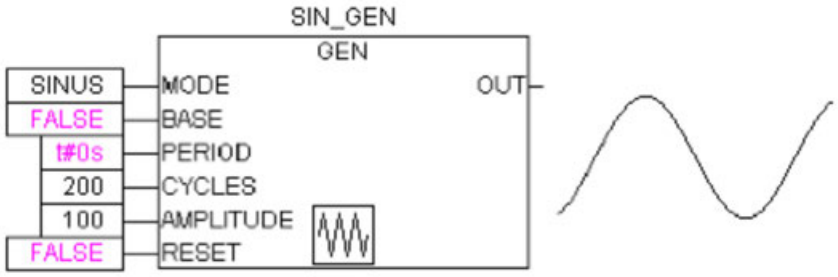


BASE defines whether the cycle period is really related to a defined time (BASE=TRUE) or whether it is related to a particular number of cycles, which means the number of calls of function block (BASE=FALSE).

PERIOD or CYCLES defines the corresponding cycle period.

AMPLITUDE defines, in a trivial way, the amplitude of the function to be generated.

The function generator is again set to 0 as soon as RESET=TRUE.

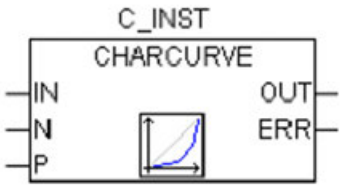


1.4.2.2.7 Function manipulators

CHARCURVE

Provided by util.lib.

This function block serves to represent values, piece by piece, on a linear function:



IN of the type INT is fed with the value to be manipulated. The BYTE N designates the number of points which defines the presentation function. This characteristic line is then generated in an ARRAY P[0..10] with P of the type POINT which is a structure based on two INT values (X and Y).

The output consists of OUT of the type INT, the manipulated value and BYTE ERR, which will indicate an error if necessary.

The points P[0]..P[N-1] in the ARRAY must be sorted according to their X values, otherwise ERR receives the value 1.

If the input IN is not between P[0].X and P[N-1].X, ERR=2 and OUT contains the corresponding limiting value P[0]. Y or P[N-1].Y.

If N lies outside of the allowed values which are between 2 and 11, then ERR=4.

Example in ST

First of all ARRAY P must be defined in the header:

```
VAR
...
CHARACTERISTIC_LINE:CHARCURVE;
KL:ARRAY[0..10] OF POINT:=(X:=0,Y:=0),(X:=250,Y:=50),
(X:=500,Y:=150),(X:=750,Y:=400),7((X:=1000,Y:=1000));
COUNTER:INT;
...
END_VAR
```

Then we supply CHARCURVE with for example a constantly increasing value:

```
COUNTER:=COUNTER+10;
CHARACTERISTIC_LINE(IN:=COUNTER,N:=5,P:=KL);
```

The subsequent tracing illustrates the effect:

RAMP_INT

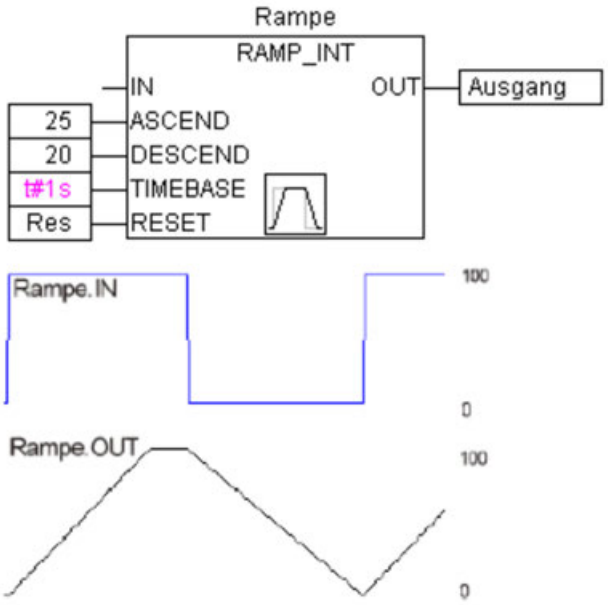
Provided by util.lib.

RAMP_INT serves to limit the ascendance or descendance of the function being fed:

The input consists on the one hand out of three INT values: IN, the function input, and ASCEND and DESCEND, the maximum increase or decrease for a given time interval, which is defined by TIMEBASE of the type TIME. Setting RESET to TRUE causes RAMP_INT to be initialised anew.

The output OUT of the type INT contains the ascend and descend limited function value.

When TIMEBASE is set to t#0s, ASCEND and DESCEND are not related to the time interval, but remain the same.



RAMP_REAL

Provided by util.lib.

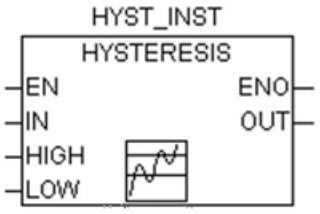
RAMP_REAL functions in the same way as RAMP_INT, with the simple difference that the inputs IN, ASCEND, DESCEND and the output OUT are of the type REAL.

1.4.2.2.8 Analog value processing

HYSTERESIS

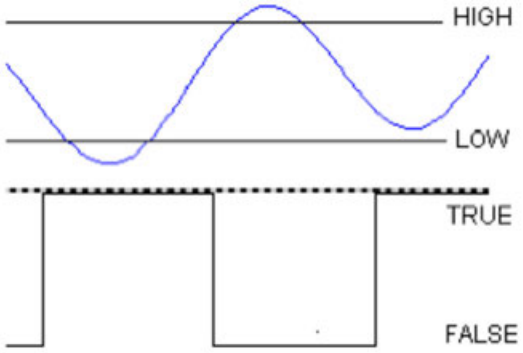
Provided by util.lib.

The input to this function block consists of three INT values IN, HIGH and LOW. The output OUT is of the type BOOL.



If IN goes below the limiting value LOW, OUT becomes TRUE. If IN goes over the upper limit HIGH, FALSE is delivered.

An illustrative example:



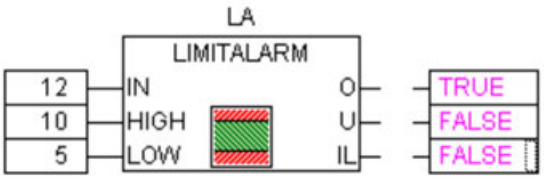
LIMITALARM

Provided by util.lib.

This function block specifies, whether the input value is within a set range and which limits it has violated if it has done so.

The input values IN, HIGH and LOW are each of the type INT, while the outputs O, U and IL are of the type BOOL. If the upper limit HIGH is exceeded by IN, O becomes TRUE, and when IN is below LOW, U becomes TRUE. IL is TRUE if IN lies between LOW and HIGH.

Result:



1.4.2.3 AnalyzationNew.library

1.4.2.3.1 Analysis of expression

This library provides modules for the analysis of expressions. If a composed expression is FALSE, those of its components can be evaluated which are adding to this result. In the SFC-Editor the flag uses this function implicitely for the analysis of expressions in transitions ↳ *Chapter 1.4.1.3.11.9.1 “Overview” on page 330* ↳ *SFCErrorAnalyzationTable*.

Example of an expression:

```
b OR NOT(y < x) OR NOT (NOT d AND e)
```

The functions: The following variables are used by all modules:

- InputExpr: BOOL, expression to be analysed
- DoAnalyze: BOOL, TRUE starts analysis
- ExpResult: BOOL, current value of the expression

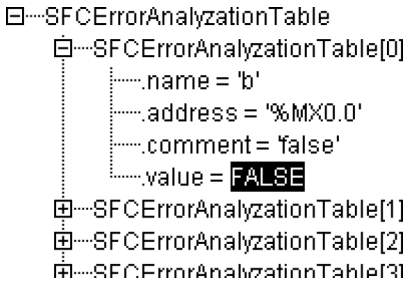
Different is the output of the result of the analyzation:

'AnalyzeExpression' returns in a string the components of the expression, which are adding to the total value FALSE. Function AppendErrorString is used for this purpose, separating the particular components in the output string by "|" characters:

OutString: STRING, Result of the analysis, Sequence of the concerned components of the expression (e.g. y < x | d)

'AnalyseExpressionTable' writes the components of the expression, which are adding to the total value FALSE, to an array. For each component the following information is provided by structure ExpressionResult: name, address, comment, (current)value:

OutTable: ARRAY [0..15] OF ExpressionResult; e.g..



'AnalyseExpressionCombined' combines the functionalities of AnalyzeExpression plus AnalyseExpressionTable

1.4.2.4 Protocol- and system libraries

1.4.2.4.1 The library SysLibCallback.lib

This library provides the functions SysCallbackRegister and SysCallbackUnregister, which serve to activate defined callback functions for runtime events.

Both functions are of type BOOL and return TRUE as soon as the required callback function successfully has been registered resp. de-registered.

The execution is synchronous.

Prototype of the callback function

The prototype of the callback function must look as follows:

```
FUNCTION Callback : DWORD
VAR_INPUT
 dwEvent:DWORD; // Event
 dwFilter:DWORD; // Filter
 dwOwner:DWORD; // Source
END_VAR
```

Attention for RISC and Motorola 68K target systems: The name of the callback function must start with "callback"!

The library functions SysCallbackRegister and SysCallbackUnregister each use the following parameters when calling the callback function which should be registered or de-registered:

Input-Variable	Data Type	Description
iPOUIndex	INT	POU Index of the callback function which should be (de)registered. The index must be accquired before with the aid of the operator INDEXOF(<function name>).
Event	RTS_EVENT	The runtime event, for which the callback function is called, is defined by a value of the enumeration RTS_EVENT, which also is contained in the library (see below).

The enumeration RTS_EVENT is defined as follows:

```
TYPE RTS_EVENT :
(
EVENT_ALL,
(* General events *)
EVENT_START,
EVENT_STOP,
EVENT_BEFORE_RESET,
EVENT_AFTER_RESET,
EVENT_SHUTDOWN,

(* Exceptions generated by run time *)
EVENT_EXCPT_CYCLETIME_OVERFLOW, (* Cycle time overflow *)
EVENT_EXCPT_WATCHDOG, (* Software watchdog OF IEC-task expired *)
EVENT_EXCPT_HARDWARE_WATCHDOG, (* Hardware watchdog expired. Global software error *)
EVENT_EXCPT_FIELDBUS, (* Fieldbus error occurred *)
EVENT_EXCPT_IOUPDATE, (* IO-update error *)

(* Exceptions generated BY system *)
EVENT_EXCPT_ILLEGAL_INSTRUCTION, (* Illegal instruction *)
EVENT_EXCPT_ACCESS_VIOLATION, (* Access violation *)
EVENT_EXCPT_PRIV_INSTRUCTION, (* Privileged instruction *)
EVENT_EXCPT_IN_PAGE_ERROR, (* Page error *)
EVENT_EXCPT_STACK_OVERFLOW, (* Stack overflow *)
EVENT_EXCPT_MISALIGNMENT, (* Datatype misalignment *)
EVENT_EXCPT_ARRAYBOUNDS, (* ARRAY bounds exceeded *)
EVENT_EXCPT_DIVIDEBYZERO, (* Division BY zero *)
EVENT_EXCPT_OVERFLOW, (* Overflow *)
EVENT_EXCPT_NONCONTINUABLE, (* Non continuable *)
EVENT_EXCPT_NO_FPU_AVAILABLE, (* FPU: No FPU available *)
```

```
EVENT_EXCPT_FPU_ERROR, (* FPU: Unspecified error *)
EVENT_EXCPT_FPU_DENORMAL_OPERAND, (* FPU: Denormal operand *)
EVENT_EXCPT_FPU_DIVIDEBYZERO, (* FPU: Division BY zero *)
EVENT_EXCPT_FPU_INVALID_OPERATION, (* FPU: Invalid operation *)
EVENT_EXCPT_FPU_OVERFLOW, (* FPU: Overflow *)
EVENT_EXCPT_FPU_STACK_CHECK, (* FPU: Stack check *)

(* IO events *)
EVENT_AFTER_READING_INPUTS,
EVENT_BEFORE_WRITING_OUTPUTS,

(* Miscellaneous events *)
EVENT_TIMER, (* Schedule tick (timer interrupt) *)
EVENT_DEBUG_LOOP, (* Debug loop at breakpoint *)

(* Online services *)
EVENT_ONLINE_SERVICES_BEGIN := 500,
EVENT_LOGIN,
EVENT_CUSTOM_SERVICES,

(* Interrupts *)
EVENT_INT_0:=1000,
EVENT_INT_1,
EVENT_INT_2,
EVENT_INT_3,
EVENT_INT_4,
EVENT_INT_5,
EVENT_INT_6,
EVENT_INT_7,
EVENT_INT_8,
EVENT_INT_9,
EVENT_INT_10,
EVENT_INT_11,
EVENT_INT_12,
EVENT_INT_13,
EVENT_INT_14,
EVENT_INT_15,
EVENT_INT_255:=1255,
EVENT_MAX
);
END_TYPE
```

1.4.2.4.2 The library SysLibCom.lib

Overview

This library supports the serial communication with a target system. If the target system provides the functionality, then the following library functions can be used to open or close a serial port and to read or write data via this port (The execution is synchronous.)

SysComOpen

This function serves to open a serial port.

The function returns a handle for the port, which can be passed on when calling other functions of the library. If the port cannot be opened, 0xFFFFFFFF will be returned as handle.

Input Variable	Data Type	Description
Port	PORTS	specifies the port which should be opened (COM1,..); Port number see below: Enumeration PORTS

Enumeration PORTS:

TYPE PORTS : (COM1:=1, COM2, COM3, COM4, COM5, COM6, COM7, COM8);

END_TYPE

SysComSetSettings

This function serves to set values like tranmission rate, stopbits, parity, function-timout, buffersize and scan-time for a serial port. The parameter value is of type POINTER TO COMSETTINGS; the structure COMSETTINGS is used.

As soon as the parameters could be set successfully, TRUE will be returned, otherwise FALSE.

Input Variable	Data Type	Description
ComSettings	POINTER TO COMSETTINGS;	Pointer to the structure COMSETTINGS; you can make use of the operator ADR (see below, example)
dwHandle	DWORD	Port handle, acquired by *Chapter 1.4.2.4.2.2 "SysComOpen" on page 564*

The structure COMSETTINGS, which is also part of the library, is defined as follows:

TYPE COMSETTINGS :

STRUCT

Port:PORTS;	Port number, see below: Enumeration PORTS
dwBaudRate:DWORD;	4800, 9600, 19200, 38400, 57600, 115200
byStopBits:BYTE;	0 = ONESTOPBIT, 1=ONE5STOPBITS, 2=TWOSTOPBITS

byParity:BYTE;	0 = NOPARITY, 1 = ODDPARITY, 2 = EVEN-PARITY
dwTimeout:DWORD;	Timeout of the interface in ms, Default = 0
dwBufferSize:DWORD;	Buffer size of the internal device buffer, Default = 0
dwScan:DWORD;	Polling time of the serial interface; should be set to 0

END_STRUCT

END_TYPE

Enumeration PORTS:

TYPE PORTS : (COM1:=1, COM2, COM3, COM4, COM5, COM6, COM7, COM8);

END_TYPE

SysComSetSettingsEx

This function of type BOOL with the parameters of type POINTER TO COMSETTINGSEX is used to set all relevant parameters of a serial communication port. Not only the parameters of the above function are set, but also the parameters for flowcontrol and character size can be set with this function. This is performed by filling them into the structure COMSETTINGSEX.

The return value of the function is true if the parameters were successfully set and false if the parameters could not be applied to the communication port. It is hardware-dependent whether the settings can be changed more often than one time after opening a port. It may be necessary to close and reopen the port before setting the parameters new.

Input Variable	Data Type	Description
ComSettingsEx	POINTER TO COMSET-TINGSEX;	Pointer to the structure COM-SETTINGSEX; Use the ADR operator to determine an address.
dwHandle	DWORD	Port handle, acquired by SysComOpen ↳ *Chapter 1.4.2.4.2.2 “SysComOpen” on page 564*

Structure COM-SETTINGSEX:

TYPE COMSETTINGSEX :

STRUCT

Size:INT;	(*The size in bytes of the structure. Use the sizeof() operator to fill in. Used for backward compatibility.*)
Port:PORTS;	(*Port number, see below: Enumeration PORTS *)
dwBaudRate:DWORD;	(* 4800, 9600, 19200, 38400, 57600, 115200 *)
byStopBits:BYTE;	(* 0 = ONESTOPBIT, 1=ONE5STOPBITS, 2=TWOSTOPBITS *)

byParity:BYTE;	(* 0 = NOPARITY, 1 = ODDPARITY, 2 = EVENPARITY *)
dwTimeout:DWORD;	(* Timeout of the port in ms, Default = 0 *)
dwBufferSize:DWORD;	(* Buffersize used by the driver, Default = 0 *)
dwScan:DWORD;	(* Poll-time of the serial driver. Should be set to 0. Only change if the documentation of the hardware-vendor tells so. *)
cByteSize : BYTE;	(*4...8: Character size in bits.*)
fOutxCtsFlow : BOOL;	(*Specifies whether the CTS (clear-to-send) signal is monitored for output flow control. If this member is TRUE and CTS is turned off, output is suspended until CTS is sent again. *)
fDtrControl : BYTE;	(*0:Disables the DTR line when the device is opened and leaves it disabled. 1:Enables the DTR line when the device is opened and leaves it on. 2:Enables DTR handshaking. *)
fDsrSensitivity : BOOL;	(*Specifies whether the communications driver is sensitive to the state of the DSR signal. If this member is TRUE, the driver ignores any bytes received, unless the DSR modem input line is high. *)
fRtsControl : BYTE;	(*0: Disables the RTS line when the device is opened and leaves it disabled. 1: Enables the RTS line when the device is opened and leaves it on. 2: Enables RTS handshaking. The driver raises the RTS line when the "type-ahead" (input) buffer is less than one-half full and lowers the RTS line when the buffer is more than three-quarters full. 3: Specifies the RTS line will be high if bytes are available for transmission. After all buffered bytes have been sent, the RTS line will be low. *)
fOutxDsrFlow : BOOL;	(*Specifies whether the DSR (data-set-ready) signal is monitored for output flow control. If this member is TRUE and DSR is turned off, output is suspended until DSR is sent again. *)

END_STRUCT

END_TYPE

Enumeration PORTS

TYPE PORTS : (COM1:=1, COM2, COM3, COM4, COM5, COM6, COM7, COM8);

END_TYPE

Example for the settings to perform a hardwarehandshake:

dwHandle: DWORD;

pt_comsettingsex:COMSETTINGSEX:=(Port:=COM1,

dwBaudRate:=38400,

byStopBits:=0,

dwTimeout:=5000,

cByteSize:=7,

byParity := 2,

fOutxCtsFlow := FALSE,

fOutxDsrFlow:=TRUE,

DtrControl := 2,

fRtsControl := 2);

Implementation:

pt_comsettingsex.Size := sizeof(pt_comsettingsex);

SysComSetSettingsEx(dwHandle := Handle, ComSettingsExt := ADR(pt_comsettingsex));

Where Handle is the returnvalue of a call to SysComOpen(COM1).

SysComClose

This function of type BOOL closes the COM port. For that purpose the port handle, which has been got by SysComOpen, must be given as input parameter. The return value will be TRUE after a successful operation, otherwise FALSE.

Input Variable	Data Type	Description
dwHandle	DWORD	Port handle, acquired by SysComOpen ↳ *Chapter 1.4.2.4.2.2 “SysComOpen” on page 564*

SysComWrite

This function of type DWORD writes the data to that port which is defined by the handle got by SysComOpen. Besides the handle also the address from which the data should be taken, the number of data which should be written and the timeout of the function must be passed on.

The function will return the number of actually written bytes.

Input Variable	Data Type	Description
dwHandle	DWORD	Port handle, acquired by SysComOpen ↳ *Chapter 1.4.2.4.2.2 “SysComOpen” on page 564*
dwBufferAddress	DWORD	Address from which the data should be taken and written to the port; you can use the ADR operator to get this address
dwBytesToWrite	DWORD	Number of bytes, which should be written
dwTimeout	DWORD	Time in [ms], after which the function will return at the latest

SysComRead

This function of type DWORD reads the data of COM-PORT. The input parameters are the port handle got by SysComOpen, the number of expected bytes and the timeout of the function. Besides that the address to which the read data should be copied, will be passed on.

The function will return the number of actually read bytes.

Input Variable	Data Type	Description
dwHandle	DWORD	Port handle, acquired by SysComOpen ↳ *Chapter 1.4.2.4.2.2 “SysComOpen” on page 564*
dwBufferAddress	DWORD	address, to which the read bytes should be copied after having been read from the port; (you can make use of the operator ADR to get this address)
dwBytesToRead	DWORD	Number of bytes, which should be read
dwTimeout	DWORD	Time in [ms], after that the function returns at the latest

SysComGetVersion2300

This function (type DWORD, always returns 0) is only used for an automatic internal version check and is not to be called explicitly in the application program.

1.4.2.4.3 The library SysLibDir.lib

Overview

If supported by the runtime system, you can use the functions of this library to handle a file directory system on the target system. Entries of the directory can be read and modified. The execution is synchronous.

SysDirCreate

This function of type BOOL can be used to create a new directory.

The return value is TRUE, if the directory has been created, or FALSE in case of error.

Input-Variable	Data type	Description
stName	STRING	Name of the directory

SysDirOpen

This function of type DWORD can be used, to open a directory in order to read the directory entries (files, subdirectories) via function SysDirRead ↳ *Chapter 1.4.2.4.3.4 “SysDirRead” on page 569*.

To close the directory, SysDirRead must be called until it returns 0.

The return value is a handle, which is required by function SysDirRead ↳ *Chapter 1.4.2.4.3.4 “SysDirRead” on page 569* as an input.

Input-Variable	Data type	Description
stDirectory	STRING	Directory name

SysDirRead

This function of type UDINT can be used to read directory entries.

Each time the function is called, one entry of the directory will be read. As long as "1" is returned, a further entry is in the directory. Thus for reading all entries the function must be called repeatedly until "0" is returned. In this case, the directory is closed and the handle is not valid any more. In every case, the function has to be called until it returns 0 to close the directory.

The information on the particular entries will be written to structure DIRECTORY_INFO.

Input-Variable	Data type	Description
hDir	DWORD	Handle of the directory; Returned by function SysDirOpen ↳ *Chapter 1.4.2.4.3.3 “SysDirOpen” on page 568*, which was called before for opening the directory.
stDirEntry	STRING	Name of an entry in the directory. Can be a file or another directory. Max. 80 characters.
pDirInfo	POINTER TO 'Structure DIRECTORY_INFO' ↳ *Chapter 1.4.2.4.3.7 “Structure DIRECTORY_INFO” on page 570*	Pointer on structure DIRECTORY_INFO, which will be filled with information on the read entry. You can enter "0" here if the information should not be read.

SysDirRemove

This function of type BOOL can be used to delete a directory.

TRUE will be returned if the directory could be removed, otherwise FALSE.

Input-Variable	Data type	Description
stName	STRING	Name of the directory to be removed

SysDirRename

This function of type BOOL can be used to rename a directory.

TRUE will be returned if the directory could be renamed, otherwise FALSE.

Input-Variable	Data type	Description
stOldName	STRING	old directory name
stNewName	STRING	new directory name

Structure DIRECTORY_INFO

This structure contains information on a directory, which is read via function SysDirRead ↳ *Chapter 1.4.2.4.3.4 “SysDirRead” on page 569*.

The components:

Variable	Data type	Description
ftTime	DIRFILETIME ↳ *Chapter 1.4.2.4.3.8 “Structure DIRFILETIME” on page 570*	Structure with information on creation date, change date, access date
dwSize	DWORD	Size of the directory entry (file)
bDirectory	BOOL	TRUE, if entry is a directory; FALSE, if the entry is a file

Structure DIRFILETIME

This structure contains data information for a directory entry. It is used by 'Structure DIRECTORY_INFO' ↳ *Chapter 1.4.2.4.3.7 “Structure DIRECTORY_INFO” on page 570*.

The components:

Variable	Data type	Description
dtCreation	DT	Date of creation
dtLastAccess	DT	Date of last access
dtLastModification	DT	Date of last modification

1.4.2.4.4 The library SysLibDirect.lib

The functions of this library serve to access variables by indices with which they are referenced in the runtime system. For detailed information see the description of the particular runtime system.

The user does not have to call a function! The functions will be called implicitely, according to the data type and the access mode of the variable, as soon as the library is linked to the project and a variable will be used in the program with the "#" like shown in the following:

iVar1 AT #MW17.4: INT;

The functions must be implemented in the runtime system as external C-functions.

The execution is synchronous.

1.4.2.4.5 The library SysLibEvent.lib

Overview

This library serves to synchronize and control the processing of two (IEC-) tasks.

A task waiting for an event can get re-activated by a second task which sets this event.

The functions are available to define, to delete and start an event resp. to set the timeout.

The execution is synchronous.

SysEventCreate

This function of type DWORD serves to create a new event and to name it. A handle will be returned, which is used by the other functions of the library to access the event.

Variable	Data Type	Description
stName	STRING	Name of the new event

SysEventDelete

This function of type BOOL deletes an event. The event is defined by the handle which was returned by the function SysEventCreate when creating the event. TRUE will be returned if as the event has been deleted successfully, otherwise FALSE.

Variable	Data Type	Description
DwHandle	DWORD	Event handle returned by SysEventCreate ↳ *Chapter 1.4.2.4.5.2 “SysEventCreate” on page 571*.

SysEventSet

This function of type DWORD is used to set an event. The event is defined by the handle which was returned by the function SysEventCreate when creating the event. TRUE will be returned if as the event has been set successfully, otherwise FALSE.

Variable	Data Type	Description
DwHandle	DWORD	Event handle returned by SysEventCreate ↳ *Chapter 1.4.2.4.5.2 “SysEventCreate” on page 571*.

SysEventWait

This function of type DWORD is used to set the timeout for an event. The event is defined by the handle which was returned by the function SysEventCreate when creating the event. TRUE will be returned if as the timeout has been set successfully, otherwise FALSE.

Variable	Data Type	Description
DwHandle	DWORD	Event handle returned by SysEventCreate *Chapter 1.4.2.4.5.2 “SysEventCreate” on page 571*.
dwTimeout	DWORD	Time in [ms], after which the function will return at the latest.

1.4.2.4.6 The library SysLibDPV1Hilscher.lib

Overview

Note: It depends on the target system, which system libraries can be used in the application program. Please see the document SysLibs_Overview.pdf.

This library supports the acyclic PROFIBUS DPV1, Class 1, Read- and Write-Services for the data transfer between master and slaves. The data are addressed within the slaves by slot and index. (Concerning this see the PB-DP standard.)

If supported by the target system the following function blocks are available:

- DPV1_Read, DPV1_ReadEx: Reading data
- DPV1_Write, DPV1_WriteEx: Writing data

Each module uses the following parameters:

Input variable	Data type	Description
ENABLE	BOOL	At a rising edge at this input the module starts processing.
Device	INT	Index of the Hilscher card, to which the request is given.
StationAddr	INT	Station address of the slave in the PROFIBUS.
Slot	INT	Data slot, for identification of the data within the slave.
Index	INT	Data index, for identification of the data within the slave.
Len	INT	Length of the data to be read/written in Bytes. Fed in the maximum length of the data buffer "buffer".
buffer	DWORD	Local address of the data. (Evaluate via using ADR().)

Output variable	Data type	Description
Ready	BOOL	The function block has finished processing.
State	V1State	Information on the state of the request (see below, Enumeration "V1State")
Size	INT	Length of the actually read/written data in case of successful execution.

Variable	Data type	Description
ENABLEOLD	BOOL	internal variable.
JobId	DWORD	internal variable.

Additionally the modules DPV1_ReadEx and DPV1_WriteEx have an output parameter Error, which tells about possibly occurred errors:

Output variable	Data type	Description
Error	ARRAY[0..7] OF BYTE;	Byte 1: Hilscher error code (see the documentation on the Hilscher PB-cards "Protocol Interface Manual PROFIBUS DP". Byte 2: Error class code. These values can be looked up in the PB standard. Bytes 3+4 (index 2+3): Slave-specific error information. These values can be looked up in the slave-specific documentation.

Enumeration V1State

This structure is used by the function blocks of the SysLibDPV1Hilscher.lib always in the output variable "state". It describes the current state of the request.

```
TYPE V1State :
(NotEnabled := 0, InvalidParam, Started, Done, DoneWithError );
END_TYPE
```

Meaning of the components:

NotEnabled := 0 - Function block currently not active

InvalidParam - Invalid input variable

Started - Function block has started execution

Done - Function block has terminated execution

DoneWithError - Function block has aborted execution with an error

1.4.2.4.7 The library SysLibFile.lib

Overview

This library supports a file system on the target computer. If the target supports the functionality, the library functions can be used to open, close, delete, rename, write to or read from files. Further functions are available for getting the file size or the date of the last access, as well as for reading or modifying the offset. The execution is synchronous.

If you are working with target system CODESYS SP RTE, please regard, that file access operations can affect the real-time behavior.

SysFileOpen

This function of type DWORD serves to open a file, which already exists or which should be created.

The return value is a file number, which will be used in the functions SysFileWrite, SysFileRead, SysFileClose as an input ('File'). In case of an error '0' will be returned resp. (watch out this exception!) '-1' by target CODESYS SP RTE.

Input-Variable	Data Type	Description
FileName	STRING	File name
Mode	STRING	Access mode: ● w write (File will be updated or created newly) ● r read (File will only be opened for reading; if the file does not exist, an error will be returned) ● rw read and write (File will be updated; if the file does not exist, an error will be returned) ● a append (File will be opened like described for 'w', but the written data will be appended at the end of the file)

SysFileWrite

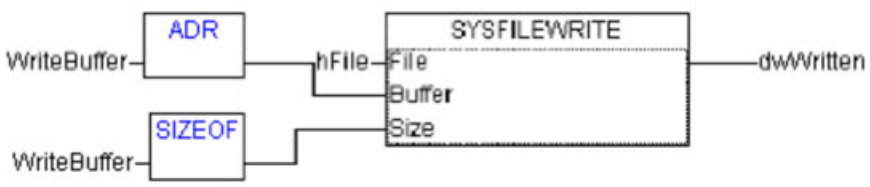
This function of type DWORD serves to write data to a file, which has been opened before by the function SysFileOpen. The return value is the number of successfully written bytes.

The return value is a file number, which will be used in the functions SysFileWrite, SysFileRead, SysFileClose as an input ('File'). In case of an error '0' will be returned resp. (watch out this exception!) '-1' by target CODESYS SP RTE.

Input-Variable	Data Type	Description
File	DWORD	File number ↳ *Chapter 1.4.2.4.7.2 "SysFileOpen" on page 573*
Buffer	DWORD	Address of the buffer (ascertainable by the ADR operator) of the file to which you want to write
Size	DWORD	Number of bytes, which you want to write to the file (ascertainable by the SIZEOF operator)

Example:

```
WriteBuffer : ARRAY[0..5] OF BYTE:=0,1,2,4,5,6;
DwWritten : DWORD;
hFile : DWORD;
```



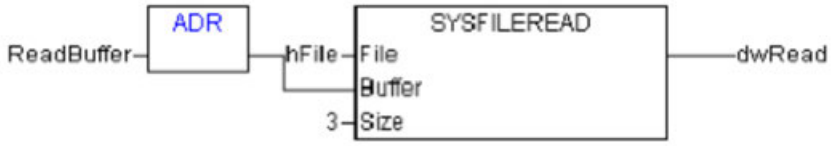
SysFileRead

This function of type DWORD serves to read a file, which has been opened before by SysFileOpen. The return value is the number of successfully read bytes.

Input-Variable	Data Type	Description
File	DWORD	File number ↳ *Chapter 1.4.2.4.7.2 “SysFileOpen” on page 573*
Buffer	DWORD	Address of the buffer which contains the data to be read (get this with the aid of the ADR operator)
Size	DWORD	Number of bytes to be read from the buffer

Example:

```
ReadBuffer : ReadBuffer:ARRAY[0..5] OF BYTE;
hFile : DWORD;
dwRead : DWORD;
```



SysFileClose

This function of type BOOL serves to close a file, which has been opened before by SysFileOpen. The return value is 1 (ok) or 0 (error).

Input-Variable	Data Type	Description
File	DWORD	File number ↳ *Chapter 1.4.2.4.7.2 “SysFileOpen” on page 573*

SysFileDelete

This function of type BOOL serves to delete a file. The return value is 1 (ok) or 0 (error).

Input-Variable	Data Type	Description
FileName	STRING	File name

SysFileCopy

This function of type UDINT serves to copy the file content to another file (different file name). It will return the number of actually copied bytes.

Input-Variable	Data Type	Description
FileDest	STRING	File to which you want to copy
FileSource	STRING	File from which you want to copy

SysFileEOF

This function of type BOOL will return 1, if the current offset is at the end of the file; it will return 0, if the end of file has not yet been reached.

Input-Variable	Data Type	Description
File	DWORD	File number ↳ *Chapter 1.4.2.4.7.2 “SysFileOpen” on page 573*

SysFileGetPos

This function of type DINT returns the currently set offset position in the file, which is identifed by the file number that you have got from the SysFileOpen function before ↳ *Chapter 1.4.2.4.7.2 “SysFileOpen” on page 573*.

Input-Variable	Data Type	Description
File	DWORD	File number ↳ *Chapter 1.4.2.4.7.2 “SysFileOpen” on page 573*

SysFileGetSize

This function of type DWORD returns the size of the file (in Bytes), which is identified by the file name.

Input-Variable	Data Type	Description
FileName	DWORD	File name

SysFileGetTime

This function of type BOOL returns the creation date, the date of last access and the date of the last modification of the file (which is identified by the file name). The used format is DT. You get these data by accessing elements of the structure FILETIME.

The return value is 1(ok) or 0 (error).

Input-Variable	Data Type	Description
FileName	STRING	File name
ftFileTime	POINTER TO FILETIME	Points to the structure FILE-TIME; the operator ADR can be used for this purpose.

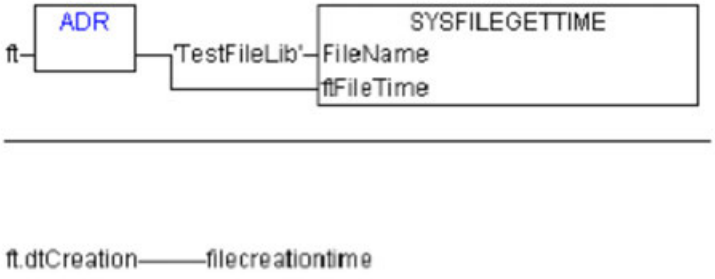
The structure FILETIME is defined as follows:

```
TYPE FILETIME
STRUCT
dtCreation:DT; (* Creation date *)
dtLastAccess:DT; (* Last access date; Attention: In VxWorks-systems possibly only day, without time! *)
dtLastModification:DT; (* Last modification date *)
END_STRUCT
END_TYPE
```

Example

For the file 'TestFile' the creation date is read:

```
Ft : FILETIME;
filecreationtime : DT;
```



SysFileRename

This function of type BOOL serves to rename a file.

It returns 1 (ok) or 0 (error).

Variable	Data Type	Description
FileOldName	STRING	Old file name
FileNewName	STRING	New file name

SysFileSetPos

This function of type BOOL serves to change the current offset (which can be read by the function SysFileGetPos ↳ *Chapter 1.4.2.4.7.9 “SysFileGetPos” on page 576*) for a file access. The file is identifed by the file number which has been got by SysFileOpen.

Input-Variable	Data Type	Description
File	DWORD	File number ↳ *Chapter 1.4.2.4.7.2 “SysFileOpen” on page 573*)
Pos	DWORD	Access offset within the file

1.4.2.4.8 The library SysLibFileAsync.lib

Overview

This library supports asynchronous file access from the IEC-application. If the target system supports the library, the following function blocks can be instanciated:

Attention: If you are working with target system CODESYS SP RTE, please regard, that file access operations can affect the real-time behavior!

The function blocks provided by this library have the following common parameters:

- Input parameter bEnable : BOOL

- Output parameter bDone : BOOL

- Output parameter bBusy : BOOL

- Output parameter bError : BOOL

- Output parameter wErrorId : WORD

All these function blocks start an action on a rising edge at the input parameter bEnable. After an action has been started, all these function blocks have to be called until the output parameter bDone is set. Now the outputs are valid.

The common parameters listed above will not explicitly be mentioned in the following descriptions of the particular function blocks.

The row I/O shows I for inputs, O for outputs.

SysFileOpenAsync

This function block is used for opening an existing file or creating a new one.

The output is hFile, a handle to the file. A file handle is an identifier for a file and is used as an input for other function blocks.

Input-Variable	Data type	Description
stFileName	STRING	File name
stMode	STRING	Mode to open the file: ● w write (file is created or overwritten) ● r read (file is only opened for reading if it exists) ● rw read and write (file is created if not existing, opened for reading if it exists) ● a append (file is opened for writing if it exists, created if it exists not, data is appended at the end always.)

SysFileCloseAsync

This function block is used to close a file. From now on the file handle is invalid and the file is free for other processes.

Variable	Datentyp	Beschreibung
hFile	DWORD	File's handle from SysFileOpenAsync ↳ *Chapter 1.4.2.4.8.2 "SysFileOpenAsync" on page 578*

SysFileWriteAsync

This function block is used for writing to a file. The file has to be opened with the function block SysFileOpenAsync ↳ *Chapter 1.4.2.4.8.2 "SysFileOpenAsync" on page 578*.

Variable	I/O	Data type	Description
hFile	E	DWORD	File identifier ↳ *Chapter 1.4.2.4.8.2 "SysFileOpenAsync" on page 578*)
pBuffer	E	DWORD	Address of the data to write (to be retrieved using ADR-operator)
dwSize	E	DWORD	Number of bytes to write (to be retrieved using SIZEOF-operator)
dwWrite	A	DWORD	Number of actually written bytes.

The data is written to the file in binary mode, means without any conversion.

SysFileReadAsync

This function block is used to read from an open file.

Variable	I/O	Data type	Description
hFile	I	DWORD	File identifier ↳ *Chapter 1.4.2.4.8.2 “SysFileOpenAsync” on page 578*)
pBuffer	I	DWORD	Address of the buffer to read to.
dwSize	I	DWORD	Number of bytes to read from the file to buffer.
dwRead	O	DWORD	Number of actually read bytes.

Parameter pBuffer must be evaluated via the ADR() operator. The files to be written are read binarily, i.e. without any conversion and copied to pBuffer.

SysFileDeleteAsync

This function block is used to delete a file.

Input-Variable	Data type	Description
stFileName	STRING	File name of the file to be deleted.

SysFileGetPosAsync

This function block retrieves the current read-/write position of the file.

Variable	Data type	Description
hFile	DWORD	File handle from SysFileOpenAsync ↳ *Chapter 1.4.2.4.8.2 “SysFileOpenAsync” on page 578*

SysFileSetPosAsync

This function block retrieves the current read-/write position of the file.

Variable	Data type	Description
hFile	DWORD	File number ↳ *Chapter 1.4.2.4.8.2 “SysFileOpenAsync” on page 578*)
dwPos	DWORD	Offset within the file which is valid for access.

SysFileEOFAsync

This function block is used to determine, whether the read-/write pointer has reached the end of the file.

Variable	I/O	Data type	Description
hFile	I	DWORD	File handle from SysFileOpenAsync
bEOF	O	DWORD	Tells if file handle is reached

SysFileGetSizeAsync

This function block is used to retrieve the size in bytes of a file.

Variable	I/O	Data type	Description
stFileName	I	STRING	File name
dwSize	O	DWORD	Size of the file in bytes

SysFileGetTimeAsync

This function block retrieves the modification times of a file.

Variable	I/O	Data type	Description
stFileName	I	STRING	File name
ftFileTime	O	POINTER TO FILETIME	Points to a FILETIMEAsync-structure; the ADR can be used

Structure FILETIMEASYNC (is included in the library):

```
TYPE FILETIMEASYNC
STRUCT
 dtCreation:DT;  (* Erstelldatum *)
 dtLastAccess:DT;  (* Datum letzter Zugriff *)
 dtLastModification:DT; (* Datum letzte Änderung *)
END_STRUCT
END_TYPE
```

SysFileCopyAsync

This function block is used to copy a file to another name/location.

Variable	I/O	Data type	Description
stFileDest	I	STRING	Name of destination file
stFileSource	I	STRING	Name of source file
dwCopied	O	DWORD	Number of copied bytes.

SysFileRenameAsync

This function block is used to rename a file.

Variable	Data type	Description
stFileOldName	STRING	Old file name
stFileNewName	STRING	New file name

SysFileCloseAllOpenAsync

With this function block one can close all currently open files, without knowing any handles or names. The system always knows these handles.

1.4.2.4.9 The library SysLibFileStream.lib

This library provides functions which correspond to ANSI C functions for file stream operations. The execution is synchronous.

The functions:

SysLibFileStream function	ANSI C Function	Data Type	Description
SysFileStreamFOpen	*fopen(char *file-name, char *mode);	DWORD	File with name file-name will be opened as stream; possible values for inputvari-able Mode: 'w' (write), 'r' (read), 'a' (append), '+', 'b', 't'
SysFileStream-Clearerr	clearerr(FILE* pFile);	DINT	internal error state of pFile will be deleted; always returns 1
SysFileStreamFClose	fclose(FILE *pFile);	DINT	all open streams will be closed (except for stdin, stdout, stderr). Returns SysFileS-treamFClose_EOF in case of error, other-wise 0.
SysFileStreamFEOF	*feof(FILE* pFile);	DINT	returns !=0, as soon as end of file in pFile is reached

SysLibFileStream function	ANSI C Function	Data Type	Description
SysFileStreamFError	ferror(FILE* pFile);	DINT	returns !=0, as soon as an error has been detected for pFile
SysFileStreamFFlush	fflush(FILE *pFile);	DINT	Characters which are still buffered internally, will be output
SysFileStreamRemove	remove(char* filename);	BOOL	File will be deleted; returns 1 for OK, 0 in case of an error
SysFileStreamRename	rename(char* filename);	BOOL	Renaming a file; returns 1 for OK, 0 in case of an error
SysFileStreamRewind	rewind(FILE* pFile);	DINT	sets file position to start and deletes internal error state; always returns 1
SysFileStreamFGetC	fgetc(FILE *pFile);	DINT	returns the next character in the stream (0--255, SYSFILESTREAM_EOF in case of an error
SysFileStreamFGetPos	*fgetpos(FILE* pFile, fpos_t * ptr);	DINT	writes current file position of pFile to ptr; fpos_t here defined as an unsigned long (32 bits)
SysFileStreamFSetPos	fsetpos(FILE* pFile, fpos_t * ptr);	DINT	sets file position of pFile according to ptr; fpos_t here is defined as unsigned long (32 bits); pFPos:DWORD; (* pointer !!*)
SysFileStreamFGetS	* fgets(char * str, int n, FILE * pFile);	POINTER TO STRING	Reads at most the next n-1 characters into the array s, (termination automatically with 0); Truncation at '\n', the '\n' will be taken over to s; Return value: s resp. 0 (at end of file or error)
SysFileStreamFPrintf_Int	fprintf(FILE* pFile, char* szFormat, intnArg);	DINT	formatted output in stream pFile; Restrictions compared to C:only 1argument of type INT/DINT etc. can be printed; szFormat should be e.g. '%d'

SysLibFileStream function	ANSI C Function	Data Type	Description
SysFileStreamF-Printf_Real	fprintf(FILE* pFile, char* szFormat, float fArg);	DINT	formatted output in stream pFile; Restrictions compared to C:only 1argument of type REAL etc. can be printed; szFormat should be e.g. '%f'
SysFileStreamF-Printf_String	fprintf(FILE* pFile, char* szFormat, char *pcArg);	DINT	formatted output in stream pFile; Restrictions compared to C:only 1argument of type STRING etc. can be printed; szFormat should be e.g. '%s'
SysFileStreamFPutC	fputc(int c, FILE *pFile);	DINT	Writing character (unsignedchar) c to stream pFile Returns c (converted to DINT) or SYSFI-LESTREAM_EOF in case of an error
SysFileStreamFPutS	fputs(char* str, FILE * pFile);	DINT	Writing string s in stream pFile Returns str (pointer to string) or SYSFI-LESTREAM_EOF in case of an error
SysFileStreamFRead	fread(void* ptr, size_t size, size_t nobj, FILE* pFile);	DWORD	nobj objects of size size will be read from pFile to ptr; Returns number of read objects
SysFileStreamFWrite	fwrite(void* ptr, size_t size, size_t nobj, FILE* pFile);	DWORD	nobj objects of size size wil lbe written from ptr to pFile; Returns number of written objects
SysFileStreamFS-canf_Int	fscanf(FILE* pFile, char* szFormat, int * pnArg);	DINT	formatted input from stream pFile; Restrictions compared to C: only 1 DINT argument can be read; szFormat should be e.g. '%d'
SysFileStreamFS-canf_String	fscanf(FILE* pFile, char* szFormat, char *pcArg);	DINT	formatted input from stream pFile; Restrictions compared to C: only 1 STRING argument can be read; szFormat should be e.g. '%s'

SysLibFileStream function	ANSI C Function	Data Type	Description
SysFileStreamFS-canf_Real	fscanf(FILE* pFile, char* szFormat, float* pfArg);	DINT	formatted input from stream pFile; Restrictions compared to C: only 1 REAL argument can be read; szFormat should be e.g. '%f'
SysFileStreamF-SeekÂ	fseek(FILE* pFile, long offset, int origin);	DINT	sets file position on offset Bytes based on origin; values for origin: SEEK_SET=Start of file, SEEK_CUR=current position; SEEK_END=End of file; 0=OK
SysFileStreamFTell	ftell(FILE* pFile);	DINT	returns current file position (based on file start) in Bytes (-1 in case of error)

1.4.2.4.10 The library SysLibGetAddress.lib

Overview

This library provides functions which - if supported by the target system - return the start address and the size of a data segment (Memory, Input, Output, Retain or Global) in a DWORD. The data segment is to be specified via its number, which is defined in the enumeration.

SysLibGetSize

This function returns the start address and the size of a data segment (Memory, Input, Output, Retain or Global) in a DWORD.

The data segment is to be specified via its number, which is defined in the enumeration ADDRESS_SEGMENTS.

Input-Variable	Data type	Description
iSegment	INT	Number of the data segment, see 'Enumeration ADDRESS_SEGMENTS' ↳ *Chapter 1.4.2.4.10.3 “Enumeration ADDRESS_SEGMENTS” on page 585*

Enumeration ADDRESS_SEGMENTS

This enumeration defines the number of a data segment (Memory, Input, Output, Retain or Global), which is needed as an input for the functions.

TYPE ADDRESS_SEGMENTS :

(

DATAID_MEMORY, (0)
DATAID_INPUT, (1)
DATAID_OUTPUT, (2)
DATAID_RETAIN, (3)
DATAID_GLOBVARS (4)
);
END_TYPE

1.4.2.4.11 The library SysLibIECTasks.lib

Overview

This library can be used to call information on the configuration of IEC tasks. To create, delete, prioritize, stop and restart a task you can use the library SysLibTasks.lib.

The execution is synchronous.

SysIECTaskGetConfig

This function of type BOOL serves to retrieve the configuration parameters of an IEC task.

The task is addressed by its name or its index, which it has got assigned in the task configuration. The structure SysIECTaskConfEntry contains all parameters which are used in the task configuration.

As soon as the task has been found, TRUE will be returned, otherwise FALSE.

Input Variable	Data Type	Description
udiTaskId	UDINT	Task Id (Index in the task configuration)
pTaskInfo	POINTER TO SYSIECTASK-CONFENTRY	Information on the task configuration (structure, see below)

Structure SysIECTaskConfEntry:

TYPE SYSIECTASKCONFENTRY :
STRUCT

byTaskNr	USINT;	(* Task Number *)
byPriority	USINT;	(* Priority, see Dialog 'Taskattributes' *)
lInterval	DINT;	(* Interval of cyclic tasks, see Dialog 'Taskattributes' *) (* (in this case ldrEvent has an invalid entry) *)
ldrEvent	LDATAREF_TYPE;	(* ldrEvent represents address of event variable (by POURef, offset and size) *)

wIndex	UINT;	(*If POU is called by task, then special wrapper _Call-Task<TaskName> (also POU) is created. *) (*Returned Index corresponds to index of this POU. *)
uiNameLen	UDINT;	(* ulNameLen has a max. length of 32 characters (max. task name length) *)
szName	STRING(80);	(* Name of the task, see Dialog 'Taskattributes' *)

END_STRUCT

END_TYPE

Structure LdataRef_Type:

TYPE LDATAREF_TYPE :

STRUCT

POURef	UINT;	POU-ID of the event variable
Offset	UDINT;	Offset for the event variable
Size	UDINT;	Size of the event variable

END_STRUCT

END_TYPE

SysIECTaskGetInfo

This function of type BOOL returns the current time values of an IEC task.

The task is identified by the task name or by the index, it has got in the task configuration.

As soon as the task has been found, TRUE will be returned, otherwise FALSE.

Input-Variable	Data Type	Description
stTaskName	STRING	Name of the task
pTaskInfo	POINTER TO SYSIECTAS-KINFO	Pointer to current data of the IEC task (structure, see below)

Structure SysIECTaskInfo:

TYPE SYSIECTASKINFO :

STRUCT

dwCount :	DWORD;	(* Number of cycles since start of task *)
dwCycleTime :	DWORD;	(* Current cycle time *)
dwCycleTimeMin :	DWORD;	(* Minimum cycle time *)
dwCycleTimeMax :	DWORD;	(* Maximum cycle time *)
dwCycleTimeAvg :	DWORD;	(* Average cycle time *)

wStatus :	WORD;	For cyclic task = 0 (PLC RUN) and for event triggered task wStatus = 1 (PLC STOP)
wMode :	WORD;	wMode = 1 (task mode running) for both tasks, although the event triggered task isn't running

END_STRUCT

END_TYPE

SysIECGetFctPointer

This auxiliary function of type DWORD returns a function pointer, which is required as input parameter for the function which is used to create a new task *Chapter 1.4.2.4.26.2 “SysTaskCreate” on page 629* *Chapter 1.4.2.4.26 “The library SysLibTasks.lib” on page 628*.

The function requires as an input parameter the internal index of the POU, which should be called by the task. This index can be acquired with the aid of the INDEXOF operator.

Input-Variable	Data Type	Description
wIndexOf	WORD	Internal index of the POU, which is to be called by the task.

SysIECTaskResetEvent

This auxiliary function of type BOOL resets the event variable of an event triggered IEC task.

The function has no input parameter. It is working on the current task. It returns TRUE in case of success, otherwise 0 FALSE (e.g. if the task is not an event triggered task).

The function sets the BOOLean IEC-variable, which is used as an event, to FALSE, and the internal flag of the runtime system task management to 0.

So it is achieved that a rising edge of the event variable will be regarded at the next cycle of the scheduler.

1.4.2.4.12 The library SysLibInit.lib

Overview

This library contains a function which can be used to initialize an external library, which is available as an obj-file. The execution is synchronous.

To use the functionality "Initializing of special external object libraries", include the library in the Automation Builder project. It is not necessary to call a function explicitely.

SysInitLibrary

This function of type BOOL can be used to initialize an external library. The index of the function <LibName>SetPointer will be handed over.

The function call is created automatically. Do not call the function explicitely. Include the library in the Automation Builder project.

TRUE is returned after the operation ha been finished successfully, otherwise FALSE.

Input Variable	Data Type	Description
index	DINT	Index of the function <Lib-Name>SetPointer.

1.4.2.4.13 The library SysLibInt.lib

Overview

If the target system supports this functionality you can use this library to set and remove an interrupt handler for a function. The execution is synchronous.

SysInstallHandler

This function of type BOOL sets the interrupt with a given number on the function which is identified by its address. This address can be retrieved by the SysIECGetFctPointer function (see Library SysLibIECTasks.lib) ↳ *Chapter 1.4.2.4.11.4 “SysIECGetFctPointer” on page 588*.

The return value is TRUE or FALSE depending on the success of the operation.

The interrupt handler can be removed by the SysRemoveIntHandler function.

Input Variable	Data Type	Description
iInterrupt	INT	Interrupt number
dwFctAddress	DWORD	Function pointer, retrieved with the aid of SysIEC-GetFctPointer (SysLibIEC-Tasks.lib) ↳ *Chapter 1.4.2.4.11.4 “SysIECGetFct-Pointer” on page 588*

SysRemoveHandler

This function of type BOOL removes the interrupt, which is identifed by the given number, for the function which is identified by its address. This address can be retrieved by the function SysIECGetFctPointer (Library SysLibIECTasks.lib). The interrupt handler is set by the SysInstallHandler function ↳ *Chapter 1.4.2.4.13.2 “SysInstallHandler” on page 589*.

The return value is TRUE or FALSE depending on the success of the operation.

Input Variable	Data Type	Description
iInterrupt	INT	Interrupt number
dwFctAddress	DWORD	Function pointer, retrieved with the aid of SysIEC-GetFctPointer (SysLibIEC-Tasks.lib) *Chapter 1.4.2.4.11.4 “SysIECGetFct-Pointer” on page 588*

1.4.2.4.14 The library SysLibMem.lib

Overview

This library can be used for memory management. The library functions are available to allocate, to free, to define, to compare memory locations and to copy, move or swap between different memory locations. The execution is synchronous.

SysMemAlloc

This function of type DWORD is used to dynamically allocate memory space.

The return value is either the pointer on the allocated memory location or it is 0, in case there is not as much space available as requested. This return value always should be checked, even if just a small memory area is to be allocated.

This function is not supported by CODESYS SP RTE.

Variable	Data Type	Description
dwSize	DWORD	Number of bytes to be allocated.

SysMemFree

This function of type BOOL is used to deallocate memory space.

The return value is TRUE or FALSE depending on the success of the operation.

This function is not supported by CODESYS SP RTE.

Variable	Data Type	Description
dwAddress	DWORD	Address of the memory space which is currently allocated ↳ *Chapter 1.4.2.4.14.2 “SysMemAlloc” on page 590*.
dwSize	DWORD	Number of bytes to get reallocated.

SysMemCmp

This function of type DWORD compares the content of two memory buffers of size dwCount. dwBuf1 and dwBuf2 each show the start address of the buffer.

The function returns the difference of the buffer area contents:

< 0 buf1 smaller than buf2

0 buf1 is of equal size as buf2

> 0 buf1 bigger than buf2

Variable	Data Type	Description
dwBuf1	DWORD	Address of memory buffer 1 (buf1)
dwBuf2	DWORD	Address of memory buffer 2 (buf2)
dwCount	DWORD	Number of memory bytes which should be compared

SysMemCpy

This function of type DWORD is used to copy a defined number of memory locations from one buffer to another. The function will return the pointer to the address of the destination buffer area.

The difference to SysMemMove is that you only can copy between two non-adjoining buffers.

Variable	Data Type	Description
dwDest	DWORD	Address of destination buffer
dwSrc	DWORD	Address of source buffer
dwCount	DWORD	Number of memory locations to be copied

SysMemMove

This function of type DWORD moves one memory buffer to another. The function will return the address of the destination buffer.

The difference to SysMemCpy is that this function allows to copy even memory areas which are adjoining or even overlapping.

Variable	Data Type	Description
dwDest	DWORD	Address of destination buffer
dwSrc	DWORD	Address of source buffer
dwCount	DWORD	Number of memory locations to be moved

SysMemSet

This function of type DWORD can be used to initialize a memory location with a defined value. It will return the address of the destination buffer.

Variable	Data Type	Description
dwDest	DWORD	Pointer to the address of the memory location which should be initialized
bCharacter	BYTE	Character or numeric value with which the memory location should be initialized
dwCount	DWORD	Number of memory locations in bytes

SysMemSwap

This function of type BOOL can be used to swap data.

It is used on Motorola byte order systems (PPC) to swap from Motorola to Intel byte order. On Intel systems (ARM, MIPS, SH, x86) the function has no effect. This allows to write portable libraries.

The function will return TRUE if the operation has been terminated successfully, otherwise FALSE.

The return value does not indicate whether the operation was performed or not.

Variable	Data Type	Description
dwAddress	DWORD	Address of the memory buffer to be swapped
diSwapSize	DINT	Number of locations to be swapped: 2,4,8
diSwapElements	DINT	Number of elements in the memory area to be swapped

1.4.2.4.15 The library SysLibPciCards.lib

Overview

This library is designed for access to a Pci card plugged to the Plc. If the system supports the functionality, the function SysPciGetCardInfo can be used to retrieve information about a Pci card *Chapter 1.4.2.4.15.2 “Function SysPciGetCardInfo” on page 593*.

Function SysPciGetCardInfo

This function is for retrieving information about a Pci card.

The return value is a pointer to a Structure PCI_INFO structure *Chapter 1.4.2.4.15.3 “Structure PCI_INFO” on page 593*. The structure is defined in the library too. The structure contains all the Pci configuration registers. If the specified card is not found, the function will return zero.

Input Variable	Data type	Description
usVendorId	WORD	The vendor ID of the card.
usDeviceId	WORD	The device ID of the card.
usCardIndex	WORD	The card’s index with the specified vendor ID and device ID. The index is zero-based. If there are more than one cards with this vendor and device ID, one can use the index to distinguish the cards.

Structure PCI_INFO

The structure has the following members:

Member	Data type
usVendorID	WORD
usDeviceID	WORD
usSubVendorID	WORD
usSubSystemID	WORD
ulBusNr	DWORD
SlotNr	DWORD
ulFunction	DWORD
ulBaseAddresses	ARRAY[0..5] OF DWORD
byInterrupt	BYTE
DeviceSpecific	ARRAY[0..191] OF BYTE

The structure is set up by the Pci Bios. The access is read-only, do never write to this structure.

1.4.2.4.16 The library SysLibPlcConfig.lib

Overview

This library supports the reading of the configuration data of the PLC Configuration. These data are also loaded to the controller at a download of the application and are written to structures by the runtime system. The library offers functions for getting pointers on these structures. The execution is synchronous.

Due to the fact that pointers on original structures of the runtime system are provided, the following is:

- The structure (pointer to sub-elements) may not be modified!
- If default values of parameters in the structures get modified, this will be of on effect!

CfgCCGetError

Currently not yet implemented in the runtime system. Error code always 0.

This function provides information on the errors which occur during the download of the PLC configuration.

The function returns a pointer to Structure CCLoadError ↳ *Chapter 1.4.2.4.16.7 “Structure CCLoadError” on page 595*.

CfgCCGetHeader

This function returns a pointer on the header structure of the PLC configuration ↳ *Chapter 1.4.2.4.16.8 “Structure CCHeader” on page 595*.

CfgCCGetRootModule

This function provides information on the root module of the PLC configuration. It returns a pointer to Structure CCLoadError ↳ *Chapter 1.4.2.4.16.9 “Structure CCModule” on page 595*.

CfgCCGetRootModuleByModuleId

This function provides information on the root module of the currently used PLC configuration, which is given by the module Id. The module Id is defined in the configuration file by entry "Id".

The function returns a pointer to Structure CCModule (see above, function CfgCCGetRoot-Module ↳ *Chapter 1.4.2.4.16.4 “CfgCCGetRootModule” on page 594*) ↳ *Chapter 1.4.2.4.16.9 “Structure CCModule” on page 595*.

Variable	Data Type	Description
ulModuleId	UDINT	Module id of the root module.

CfgCCGetRootModuleByNodeId

This function provides information on the root module of the currently used PLC configuration, which is given by the node Id. The node Id of the module normally results from the position of the module within the PLC Configuration.

The function returns a pointer to Structure CCModule (see above, function CfgCCGetRoot-Module ↳ *Chapter 1.4.2.4.16.4 “CfgCCGetRootModule” on page 594*) ↳ *Chapter 1.4.2.4.16.9 “Structure CCModule” on page 595*.

Variable	Data Type	Description
ulNodeId	UDINT	Node id of the root module.

Structure CCLoadError

This structure provides information on the last error during the download of the PLC configuration data. It is accessed by function CfgCCGetError ↳ *Chapter 1.4.2.4.16.2 “CfgCCGetError” on page 594*.

The components:

Variable	Data Type	Description
ulLastError	UDINT	Error code of the last error
ulAddInfo1	UDINT	According to ulLastError, the meaning changes.
ulAddInfo2	UDINT	According to ulLastError, the meaning changes.
szLastError	STRING(32)	Last error message. A possibility to make debugging easier

Structure CCHeader

This structure provides information on the header structure for the PLC configuration which has been loaded on the target system. It can be accessed by function CfgCCGetHeader ↳ *Chapter 1.4.2.4.16.3 “CfgCCGetHeader” on page 594*.

The components:

Variable	Data Type	Description
szTag	STRING(10)	zero-terminated STRING "CommConf"
cByteOrder	BYTE	The file data are in Intel ('I') or Motorola format ('M')
ulSize	UDINT	Size of the following data
lVersion	UDINT	Version number of the file

Structure CCModule

This structure provides information on the module, which e.g. can be accessd via function CfgCCGetRootModule ↳ *Chapter 1.4.2.4.16.4 “CfgCCGetRootModule” on page 594*.

The components:

Variable	Data Type	Description
ucEntryTag	BYTE	'M' = Module
ucDummy1	BYTE	
ucDummy3		
ulModuleId		Id of the module given in the configuration file *.cfg
sModuleNumber		Number of the module in the parent module (-1 if root)
usModuleTag		Describes the kind of the module (0=3S-Module, 1=DP-Master, 2=DP-Slave, 3=CAN-Master, 4=CAN-Slave, 5=DP-SingleSlave)
byDeviceDriver	BYTE	The module needs a device driver (0=FALSE, 1=TRUE)
ucDummy4	BYTE	
ucDummy5	BYTE	
ucDummy6	BYTE	
ulNodeId	UDINT	NodeId of the module
byDefinedWithStruct:	BYTE	The module was defined with a structure (0=FALSE, 1=TRUE)
ucDummy7	BYTE	
ucDummy8	BYTE	
ucDummy9	BYTE	
ulBitOffsetInput	UDINT	Offset of the modules input area
ulBitSizeInput	UDINT	Size of the modules input area in bit
ulBitOffsetOutput	UDINT	Offset of the modules output area
ulBitSizeOutput	UDINT	Size of the modules output area in bit
ulRefIdCommonDiag	UDINT	RefId of the modules common diagnosis area
ulBitOffsetCommonDiag		Offset of the modules common diagnosis area
ulBitSizeDiag	UDINT	Size of the modules diagnosis area in bit
usParameterCount	UINT	Number of parameters
usDummy	UINT	

Variable	Data Type	Description
ppccpModuleParams	POINTER TO POINTER TO ccParam	<ccParam [0..usParameter-Count]> a pointer to an array of pointers to CCMo-duleParam-structures. (Defini-tion of structure CCParam see below). Dereferencing the pointer with ppccpModuleParams^ gives you the pointer to the first parameter structure. (ppccpModuleParams+4)^ gives you the pointer to the next parameter structure. See also comment (*Read pointer to parameters *) in example project.
ulSizeOfSpecificData	UDINT	Size in bytes of the module specific data
pModuleData	POINTER TO BYTE	<MODULE_SPE-CIFIC_DATA> Here the data, according to usModuleTag is located: pModuleData is possible to be a pointer to PBSlave, CANSlave, PBMaster, PBSlave, PBSingleSlave, see definitions below.
usChannelCount:	UINT	Number of configured chan-nels
usModuleCount	UINT	Number of configured modules
In the following the Channels and Modules of this Module in the configured order are located! (DP-Slaves are ordered by the stationnumber!) This means, it is possible that another CCModule structure is inserted here.		

Variable	Data Type	Description
ppcccChannels	POINTER TO POINTER TO ccChannel;	<ccChannel [0..usChannelCount]> Definition of structure CCChannel see below * Dereferencing the pointer with ppccpChannels^ gives you the pointer to the first parameter structure. (ppccpChannels+4)^ gives you the pointer to the next parameter structure. See also comment "(*Read pointer to parameters *)" in example project.
ppccmSubModules	POINTER TO POINTER TO BYTE	<ccModule [0..usModuleCount]> Points to an array of variables of type POINTER TO ccModule. To view the contents, you have to assign the value to a variable of type "POINTER TO CCModule". Definition of structure CCModule see below. Dereferencing the pointer with ppccpSubModules^ gives you the pointer to the first parameter structure. (ppccpSubModules+4)^ gives you the pointer to the next parameter structure. See also comment "(*Read pointer to parameters *)" in example project.

Structure CCChannel

This structure provides information on the channel of a module; see usage in Structure CCModule ↳ *Chapter 1.4.2.4.16.9 “Structure CCModule” on page 595*.

Variable	Data Type	Description
ucEntryTag	BYTE	C' = Channel
ulChannelId	UDINT	Id of the channel given in the configuration file
usChannelNumber	UINT	Number of the channel in the parent module
ulRefId	UDINT	Direction of the channel (1=input, 2=output, 3=input AND output)
usChannelType	UINT	TYPE of the channel (coded as "TypeClass")
ulBitOffset	UDINT	Offset of the channel in in-/output area

Variable	Data Type	Description
usParameterCount	UINT	Number of parameters
ppccpParams	POINTER TO POINTER TO CCParam	PARAMETER[1..usParameterCount]> POINTER TO an ARRAY OF pointers TO Structure CCParam ↳ *Chapter 1.4.2.4.16.11 “Structure CCParam” on page 599*.

Structure CCParam

This structure provides information on a channel of the module; see usage in Structure CCModule and Structure CCChannel ↳ *Chapter 1.4.2.4.16.9 “Structure CCModule” on page 595* ↳ *Chapter 1.4.2.4.16.10 “Structure CCChannel” on page 598*.

Variable	Data Type	Description
ulParameterId	UDINT	Id of the parameter given in the configuration file *.cfg
usParameterNumber	UINT	Number of the parameter in the module
byReadOnly	BYTE	1=TRUE, 0=FALSE
byDummy	BYTE	
usParameterType	UINT	Type of the parameter; coded as "TypeClass"
usDummy	UINT	
ulSize	UDINT	Size of the parameter in bytes
byValue	BYTE	The memory representation of the parameter value starts with this byte. The other bytes follow immediately, if the size of the parameter value is bigger than 1.

1.4.2.4.17 The library SysLibPlcCtrl.lib

Overview

This library contains the following functions for controlling a PLC. The execution is synchronous.

- ↳ *Chapter 1.4.2.4.17.2 “SysStartPlcProgram” on page 600*
- ↳ *Chapter 1.4.2.4.17.3 “SysResetPlcProgram” on page 600*
- ↳ *Chapter 1.4.2.4.17.4 “SysStopPlcProgram” on page 600*
- ↳ *Chapter 1.4.2.4.17.5 “SysShutdownPlc” on page 600*
- ↳ *Chapter 1.4.2.4.17.6 “SysEnableScheduling” on page 601*
- ↳ *Chapter 1.4.2.4.17.7 “SysGetPlcLoad” on page 601*

Additionally there are functions to handle the retain variables:

- ↳ *Chapter 1.4.2.4.17.9 “SysRestoreRetains” on page 601*
- ↳ *Chapter 1.4.2.4.17.8 “SysSaveRetains” on page 601*

as well as a function for activating the watchdog:

- ↳ *Chapter 1.4.2.4.17.10 “SysWdgEnable” on page 602*

SysStartPlcProgram

This function of type BOOL can be used to start a PLC. It will return TRUE in case of success, otherwise FALSE.

Input-Variable	Data type	Description
bDummy	BOOL	Without function

SysResetPlcProgram

This function of type BOOL can be used to reset the PLC. The reset mode is set with the aid of the enumeration Reset_Mode. The function will return always TRUE.

This function is not synchronous, but it creates a task. The priority of the task is lower than the lowest user task.

The function may not be called in a callback, especially in no one where user tasks are created or destroyed, for example EVENT_BEFORE_RESET, EVENT_AFTER_RESET, EVENT_SHUTDOWN, EVENT_STOP.

Variable	Data type	Description
rmRESETMODE	RESET_MODE	Choose one of the enumeration values to give the desired reset command to the PLC:
0=RESET_WARM, 1=RESET_COLD, 2=RESET_HARD;	RESET_WARM corresponds with the 'Reset' command in the Online Menu, RESET_HARD corresponds with the 'Reset (original)'	

SysStopPlcProgram

This function of type BOOL can be used to stop the PLC. It will return TRUE in case of success, otherwise FALSE.

Input Variable	Data type	Description
bDummy	BOOL	Without function

SysShutdownPlc

This function of type BOOL can be used to shut down the PLC. It will return TRUE in case of success, otherwise FALSE.

Variable	Data type	Description
bDummy	BOOL	Without function.

SysEnableScheduling

This function of type DWORD can be used to enable resp. disable the scheduler for the IEC tasks in the PLC.

Variable	Data type	Description
bEnable	BOOL	Without function

SysGetPlcLoad

This function of type DWORD returns the current processor load of the IEC tasks.

Variable	Data type	Description
bDummy	BOOL	Without function

SysSaveRetains

This function of type DINT can be used to save the values of retain variables in a file. One of the following values will be returned:

1: OK

0: No program loaded

-1: The given file could not be opened

Input Variable	Data type	Description
stFileName	STRING	Name of the file where you want to save the retain variables

SysRestoreRetains

This function of type DINT can be used to to restore the values of retain variables, which have been saved in a file *Chapter 1.4.2.4.17.8 “SysSaveRetains” on page 601*. One of the following values will be returned:

1: OK

0: No program loaded

-1: The given file could not be opened

-2: The content of the file exceeds the size of the retain area

Input Variable	Data type	Description
stFileName	STRING	Name of the file which contains the retain variables *Chapter 1.4.2.4.17.8 “SysSaveRetains” on page 601*

SysWdgEnable

This function of type BOOL can be used to activate resp. deactivate the watchdog for a specified task. It will return TRUE in case of success, otherwise FALSE.

Variable	Data type	Description
bEnable	BOOL	if TRUE: The watchdog functionality gets activated if FALSE: The watchdog functionality gets deactivated
byIECTaskIndex	BYTE	Index of the IEC task, for which the watchdog should be activated/deactivated
stIECTaskName	POINTER TO STRING	Name of the IEC task, can be a pointer to zero

1.4.2.4.18 The library SysLibPorts.lib

Overview

This library can be used to communicate with external hardware devices via their port addresses; e.g. real-time clock, graphic controller etc. The port addresses can accessed reading and writing. The execution is synchronous.

SysPortIn

This function of type BYTE returns the byte value at that port address, which has been passed on by wPort.

Variable	Data Type	Description
wPort	WORD	Port address of the hardware device.

SysPortInW

This function of type WORD returns the byte value at that port address, which has been passed on by wPort.

Variable	Data Type	Description
wPort	WORD	Port address of the hardware device.

SysPortInD

This function of type DWORD returns the byte value at that port address, which has been passed on by wPort.

Variable	Data Type	Description
wPort	DWORD	Port address of the hardware device.

SysPortOut

This function of type BOOL writes the BYTE value which is passed on by byData to that port address which is passed on by wPort. The function returns TRUE if the operation has been terminated successfully, otherwise FALSE.

Variable	Data Type	Description
wPort	WORD	Port address of the hardware device.
byData	BYTE	Value to be written to the port address.

SysPortOutW

This function of type BOOL writes the WORD value which is passed on by byData to that port address which is passed on by wPort. The function returns TRUE if the operation has been terminated successfully, otherwise FALSE.

Variable	Data Type	Description
wPort	WORD	Port address of the hardware device.
byData	WORD	Value to be written to the port address.

SysPortOutD

This function of type BOOL writes the DWORD value which is passed on by byData to that port address which is passed on by wPort. The function returns TRUE if the operation has been terminated successfully, otherwise FALSE.

Variable	Data Type	Description
wPort	WORD	Port address of the hardware device.
byData	DWORD	Value to be written to the port address.

1.4.2.4.19 The library SysLibProjectInfo.lib

Overview

The functions contained in this library can be used to read the Menu 'Project' 'Project Info' respectively the function SysGetProjectID *Chapter 1.4.2.4.19.3 “Structure PROJECT_INFO” on page 604* *Chapter 1.4.2.4.19.4 “Function SysGetProjectID” on page 604.

The execution is synchronous.

Function SysGetProjectInfo

This function of type BOOL provides the components of the project info which was entered in the programming system ('Project' 'Project Info'); the structure PROJECT_INFO is used for that purpose.

TRUE is returned if the operation has been successful, otherwise FALSE.

Input Variable	Data type	Description
ProjectInfo	POINTER TO PROJECT_INFO	Pointer on the project information which is stored in the structure PROJECT_INFO *Chapter 1.4.2.4.19.3 “Structure PROJECT_INFO” on page 604* The ADR operator can be used to retrieve the offset

Structure PROJECT_INFO

The components of this structure show the project info ('Project' 'Project Info'). The structure is used by the function SysGetProjectInfo *Chapter 1.4.2.4.19.2 “Function SysGetProjectInfo” on page 604*.

Component	Data type	corresponding field in the dialog 'Project Info'
dtDate	DT	'Change date:'
stProject	STRING(255)	'File:'
stTitle	STRING(255)	'Title:'
stVersion	STRING(255)	'Version:'
stAuthor	STRING(255)	'Author'
stDescription	STRING(255)	'Description:'

Function SysGetProjectID

This function of type DWORD returns the project ID. It is used to determine whether the project in the editor and the project on the controller are identical, whether an online change can be performed, or whether they are different projects.

The project ID is also stored in the symbol file. Using this function a visualization can check if the symbol file fits to the project on the controller.

The return value contains the project ID.

The function is supported by runtime systems CSP32F 2.4.5.0 and newer.

Input Variable	Data type	Description
---	---	---

1.4.2.4.20 The library SysLibRtc.lib

The library SysLibRtc.lib

This library contains functions for accessing the real-time clock of the local system. If the target system is supporting the functionality, the real-time clock can be read and set; additionally the current hour display mode as well as the battery can be retrieved. The execution is synchronous.

In this context regard the RTC function, which is part of the standard.ibrary and which returns the running date and time referring to a given start time.

RTC is not a real real-time clock function because the start time must be set explicitly. But using RTC will save system operating time. Think about setting the start time for RTC with the aid of the SysRtcGetTime function *Chapter 1.4.2.4.20.4 “SysRtcGetTime” on page 605.*

SysRtcCheckBattery

This function of type BOOL checks the status of the battery of the computer, which is important for the exactness of the shown clock time.

The function returns 0, if the battery is not ok, otherwise 1.

Variable	Data Type	Description
bDummy	BOOL	TRUE starts the function.

SysRtcGetHourMode

This function of type BOOL can be used to read the display mode of the real-time clock of the local system.

The function returns 0 in case of 12-hour mode, it returns 1 in case of 24-hour mode .

Variable	Data Type	Description
bDummy	BOOL	TRUE starts the function.

SysRtcGetTime

This function of type DATE_AND_TIME returns the current time which is read from the PC clock.

Variable	Data Type	Description
dummy	BOOL	TRUE starts the function.

SysRtcSetTime

This function of type DATE_AND_TIME can be used to set the real-time clock of the local system. It returns 1, if the operation has been terminated successfully, otherwise 0.

Variable	Data Type	Description
ActDateAndTime	DATE_AND_TIME	Time to which the real-time clock of the computer should be set

1.4.2.4.21 The library SysLibSem.lib

Overview

This library can be used to create and use semaphores for the synchronization of tasks. The semaphores serve to avoid any concurrent access on critical data, which are used by several tasks. The target system must support this functionality. The execution is synchronous.

SysSemCreate

This function of type DWORD can be used to create a semaphore. The function returns a handle, which identifies the semaphore and which is required as input value for the other functions of the SysLibSem.lib.

Variable	Data Type	Description
bDummy	BOOL	If bDummy=TRUE, a semaphore will be created

SysSemDelete

This function of type BOOL deletes the semaphore which is identified by the handle retrieved by SysSemCreate. TRUE will be returned in case of success, otherwise FALSE.

Variable	Data Type	Description
dwHandle	DWORD	Handle of the semaphore; was returned by SysSemCreate ↳ *Chapter 1.4.2.4.21.2 “SysSemCreate” on page 606*.

SysSemEnter

This function of type BOOL must be called before a task accesses data which also are used by other tasks. Thus the data will be blocked for other tasks, which also use SysSemEnter until by function SysSemLeave *Chapter 1.4.2.4.21.5 “SysSemLeave” on page 607* the semaphore will be set free again.

The semaphore is identified by the handle which was returned by SysSemCreate. TRUE will be returned in case of success, otherwise FALSE.

Input Variable	Data Type	Description
dwHandle	DWORD	Handle of the semaphore; was returned by SysSemCreate *Chapter 1.4.2.4.21.2 “SysSemCreate” on page 606*.

SysSemLeave

This function of type BOOL must be called after an access on data, which also are used by other tasks. This is necessary to release the semaphore which has been blocked before the data access by SysSemEnter *Chapter 1.4.2.4.21.4 “SysSemEnter” on page 607*.

The semaphore is identified by the handle which was returned by SysSemCreate. TRUE will be returned in case of success, otherwise FALSE.

Input Variable	Data Type	Description
dwHandle	DWORD	Handle of the semaphore; was returned by SysSemCreate *Chapter 1.4.2.4.21.2 “SysSemCreate” on page 606*.

SysSemTry

If a semphore can be entered by SysSemTry(), TRUE will be returned. If not the function returns FALSE with the particular error code.

In contrast to SysSemEnter *Chapter 1.4.2.4.21.4 “SysSemEnter” on page 607* SysSemTry() is non-blocking.

Input Variable	Data Type	Description
dwHandle	DWORD	Handle of the semaphore; was returned by SysSemCreate *Chapter 1.4.2.4.21.2 “SysSemCreate” on page 606*.

1.4.2.4.22 The Library SysLibShm.lib

Overview

This library provides functions for accessing a memory area which is used in common by several processes resp. referencing a physical address (Shared-Memory, shortcut ShM).

The library functions can be used to open and to close the ShM and to read and write from it. The reading, writing and closing functions need the handle which is returned by the opening function.

The execution is synchronous.

SysShmOpen

This function of type DWORD opens a Shared Memory. It returns a handle for the ShM, which can be used as a pointer. The handle is required as input parameter for the other library functions.

Variable	Data Type	Description
stName	STRING	Name of the Shared Memory, can be set as desired dwPhysicalAddress DWORD
dwPhysicalAddress	DWORD	Set here one of the following: - the desired physical address of the ShM; must be valid! - 0, if the location of the ShM area can be arbitrary pdwSize DWORD
pdwSize	DWORD	Address of size of the area for the ShM - If the ShM is already existing, the actual size will be returned. - If the ShM does not yet exist, it will be created according to the given size. If you enter "0" here, the function will fail. Thus the function also can be used to check whether the ShM already has been created.

SysShmClose

This function of type BOOL closes the Shared Memory, which is identified by the handle returned by SysShmOpen. TRUE will be returned after successful operation, otherwise FALSE.

Variable	Data Type	Description
hShm	DWORD	Handle of the Shared Memory; was returned by SysShmOpen ↳ *Chapter 1.4.2.4.22.2 “SysShmOpen” on page 608*.

SysShmRead

This function of type DWORD can be used to read a defined number of bytes from a Shared Memory, starting at a certain offset. It will return the number of actually read bytes.

Variable	Data Type	Description
hShm	DWORD	Handle of the Shared Memory; was returned by SysShmOpen ↳ *Chapter 1.4.2.4.22.2 "SysShmOpen" on page 608*.
dwOffset	DWORD	Offset in the data area, where reading should start
pData	DWORD	Address of the data buffer to be read
dwSize	DWORD	Number of bytes to be read

SysShmWrite

This function of type DWORD can be used to write a defined number of bytes to a Shared Memory. It will return the number of actually written bytes.

Variable	Data Type	Description
hShm	DWORD	Handle of the Shared Memory; was returned by SysShmOpen ↳ *Chapter 1.4.2.4.22.2 "SysShmOpen" on page 608*.
dwOffset	DWORD	Offset in the data area where the writing of the data should start
pData	DWORD	Address of the data buffer to be written
dwSize	DWORD	Number of bytes to be written

1.4.2.4.23 The library SysLibSockets.lib

Overview

This library supports the access on sockets for the communication via TCP/IP and UDP.

UDP
- *For AC500 Firmware < 2.4 FreeUDP must be used.*
- *For AC500 Firmware ≥ 2.4 UDP is available.*

If the target system supports the functionality then the functions listed below are available, each calling the corresponding function of the operating system ↳ *Chapter 1.4.2.4.23.1.1 "Constraints for AC500 V2" on page 610*.

The execution is synchronous.

The behavior of the functions may differ target-specifically.

The opening/closing of sockets may take a long time if many sockets are to be opened/closed simultaneously.

Using the asynchronous functions is recommended (only AC500 V3).
Chapter 1.4.2.4.24 “The library SysLibSocketsAsync.lib” on page 625.

TCP specific:

- *Chapter 1.4.2.4.23.24.1 “SysSockRecv” on page 622*
- *Chapter 1.4.2.4.23.24.2 “SysSockSend” on page 623*

UDP specific:

- *Chapter 1.4.2.4.23.25.1 “SysSockRecvFrom” on page 623*
- *Chapter 1.4.2.4.23.25.2 “SysSockSendTo” on page 624*

Constraints for AC500 V2

The Implementation of the *SysLibSockets* library offers the opportunity to implement user specific communication protocols based on TCP/IP sockets on AC500 V2.

However, there are some restrictions for AC500 V2.

SysLibSocketsAsync
The SysLibSocketsAsync library is not supported.

SysSockIoctl

In order to minimize the influence on timing behavior, AC500 offers the user exclusively non-blocking stream sockets.

Changing such a socket to blocking is not possible for AC500 Firmware < 2.4. The function *SysSockIoctl* will return an error when trying to do so.

SysSockCreate

Opposing standard behavior, sockets are always created non-blocking by the function *SysSockCreate*.

The system offers a limited number of sockets. If the maximum number is reached, *SysSockCreate* and *SysSockAccept* return an error.

SysSockClose

The system tries to close all sockets that are created by the application, nevertheless, the user is advised to close all sockets he created using *SysSockClose*, even in case of of a reset or a download. The function *SysSockClose* might return an error, if the socket was already closed on network side. Please refer to the *SysCallbackRegister* calls in the example application.

SysSockGetLastErrorSync

The error codes returned by *SysSockGetLastErrorSync* refer to the values of the Winsock implementation by Microsoft. Thus, development of applications using *SysLibSockets* can be done on a *SoftPLC* as well.

SysSockShutdown

The function *SysSockShutdown* is not available.

A socket should only be used in the task where it was created. Avoid using sockets in different tasks.

For AC500 Firmware < 2.4, socket options can only be set before the socket is bound.

The returned values of functions *SysSockCreate* and *SysSockAccept* are socket handles. For these a value of 0 is valid, which is why those return values should be compared to SOCKET_INVALID (=-1) instead of comparison to Zero.

Restart needed

If a task that uses sockets is suspended by the system due to an error, this might lead to a leakage of system resources. This can lead to the need of restarting the system.

After a reset or a new download of the user program the PLC can not be set to run again. A power-cycle or a reboot is needed to restart the operating system.

AC500 V2 support overview

SysSockAccept	Supported for non-blocking sockets	Returns negative values, only -1 signals error
SysSockConnect	Supported for non-blocking sockets	
SysSockSelect	Supported for non-blocking sockets	
SysSockRecv (TCP only)	Supported for non-blocking sockets	
SysSockSend (TCP only)	Supported for non-blocking sockets	
SysSockBind	Supported for non-blocking sockets	
SysSockClose	Supported for non-blocking sockets	Might return failure, when socket was already closed
SysSockCreate	Supported for non-blocking sockets	Returns negative values, only -1 signals error, Sockets are non-blocking by default
SysSockListen	Supported for non-blocking sockets	Attention when Listen socket is closed all accepted sockets get closed.
SysSockShutdown	Not supported	
SysSockSendTo (UDP only)	Not supported for AC500 firmware < 2.4 (UDP)	
SysSockRecvFrom (UDP only)	Not supported for AC500 firmware < 2.4 (UDP)	
SysSockGetLastError	Supported	See above for codes
SysSockGetLastErrorSync	Supported	See above for codes
SysSockGetOption	Supported	See above for options
SysSockIoctl	Not allowed for AC500 firmware < 2.4	See above
SysSockSetOption	Supported	See Options above
SysSockGetHostByName	Not supported as requires DNS	
SysSockNtohl	Supported	
SysSockNtohs	Supported	

SysSockHtons	Supported	
SysSockHtonl	Supported	
SysSockGetHostName	Supported	Will return product name
SysSockInetAddr	Supported	
SysSockInetNtoa	Supported	
SysSockSetIPAddress	Not supported on AC500	

SysSockAccept

This function of type DINT calls the function accept of the operating system, which can accept a connection request to the socket. A new descriptor (handle) for the socket is returned. The orignal socket will be reset to the "listening" status ↳ *Chapter 1.4.2.4.23.16 “SysSockListen” on page 618*.

Variable	Data type	Description
diSocket	DINT	A descriptor identifying a socket that has been placed in a listening state with the listen function. The connection will actually be made with the socket that is returned by the SysSockListen function. The requested connection then will be made with that socket, for which the SysSockAccept function returned a handle. (corresponding parameter, e.g. in Win32:s)
pSockAddr	DWORD	Pointer on a variable of type SOCKADDR; will be filled with the address of the caller. (corresponding parameter, e.g. in Win32: addr)
piSocketAddrSize	DWORD	Pointer to a variable of type DINT. This variable has got assigned the length of the structure SockAddr (can be retrieved with the aid of the SIZEOF operator) (corresponding parameter, e.g. in Win32: addrlen)

Structure SOCKADDR:

sin_family : INT; (* Adress-family, defines address format *)

sin_port : UINT; (* Port of the connection requesting unit *)

sin_addr : UDINT; (* IP-address of the requesting unit *)

sin_zero : ARRAY [0..7] OF SINT; (* buffer *)

SysSockBind

This function of type BOOL calls the function bind of the operating system. This function will allocate a local address to the socket which was assigned before just to an address range by SysSockCreate *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614*.

Usually the "binding" will be done before functions like SysSockListen or SysSockAccept are called for a socket *Chapter 1.4.2.4.23.16 “SysSockListen” on page 618* *Chapter 1.4.2.4.23.2 “SysSockAccept” on page 612*.

In case of successful operation the function will return TRUE, otherwise FALSE.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
pSockAddr	DWORD	Pointer on a varialbe of type SOCKADDR; *Chapter 1.4.2.4.23.2 “SysSockAccept” on page 612*
diSockAddrSize	DINT	Lenght of the structure SOCKADDR (can be retrieved with the aid of the SIZEOF operator)

SysSockClose

This function of type BOOL calls the function closesocket of the operating system, in order to close a socket.

In case of successful operation the function will return TRUE, otherwise FALSE.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)

SysSockConnect

This function of type BOOL calls the function connect of the operating system. In case the socket has not yet been "bound" by the SysSockBind function, now automatically a local address will be assigned to it *Chapter 1.4.2.4.23.3 “SysSockBind” on page 613*. Afterwards the socket will be ready to send and /or receive data.

In case of successful operation the function will return TRUE, otherwise FALSE.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate ↳ *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
pSockAddr	DWORD	Pointer on a variable of type SOCKADDR; ↳ *Chapter 1.4.2.4.23.2 “SysSockAccept” on page 612*
diSockAddrSize	DINT	Length of the structure SOCKADDR; (can be retrieved with the aid of the SIZEOF operator)

Note for operating system VxWorks: There are systems on which function SysSockConnect returns FALSE even in case of success. Reason: The special behavior of connect under VxWorks.

SysSockCreate

This function of type DINT calls the function socket of the operating system. A new socket will be created and assigned to a Service Provider.

The function returns the descriptor of the new socket, which is used as input parameter in other functions of the library, e.g. SysSockBind, SysSockConnect.

Variable	Data type	Description
diAddressFamily	DINT	Address family (corresponding parameter e.g. in Win32: af)
diType	DINT	One of the following two types can be used e.g. for Windows Sockets 1.1: SOCK_STREAM, SOCK_DGRAM (corresponding parameter e.g. in Win32: type)
diProtocol	DINT	Protocol, depending on the chosen address family (corresponding parameter e.g. in Win32: protocol)

SysSockGetHostByName

This function of type DWORD ruft die Funktion hostGetByName (VxWorks)resp.gethostbyname (win32)of the operating system.

In case of successful operation the function will return the host address, otherwise SOCKET_INADDR_NONE (defined in the library as a global constant).

Variable	Data type	Description
stHostName	POINTER TO STRING	Name of the host (corresponding parameter e.g. in Win32: name)

SysSockGetHostName

This function of type BOOL calls the function gethostnameof the operating system and returns the host name.

In case of successful operation the function will return TRUE, otherwise FALSE.

Variable	Data type	Description
stHostName	STRING	Host name (corresponding parameter e.g. in Win32: name)
diNameLength	DINT	Length of the host name (corresponding parameter e.g. in Win32: buflen)

SysSockGetOption

This function of type BOOL calls the function getsockoptof the operating system, in order to get the value of a particular socket option.

In case of successful operation the function will return TRUE, otherwise FALSE.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate ↳ *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
diLevel	DINT	protocol specific level; possible values: SOL_SOCKET, IPPROTO_TCP (corresponding parameter e.g. in Win32: level)
diOption	DINT	Name of the option, for which you want to get the current value; see function SysSockSetOption for a list of the options ↳ *Chapter 1.4.2.4.23.21 “SysSockSetOption” on page 621* (corresponding parameter e.g. in Win32: optname)

Variable	Data type	Description
diOptionValue	DWORD	Pointer to the variable, to which the current value of the option should be written (corresponding parameter e.g. in Win32: optval)
diOptionLength	DWORD	Pointer to the size of the variable, to which the current value of the option should be written (corresponding parameter e.g. in Win32: optlen)

Note for operating system VxWorks: There are systems on which a multiple call of SysSockGetOption only at the first call returns a reasonable option value. This is especially true if an error has occurred just before.

Reason: The special behavior of getsockopt under VxWorks.

SysSockGetLastErrorSync

This function of type INT calls the function getlasterror of the operating system, which returns the error code of the last error occurred at the given socket.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate ↳ *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)

SysSockGetLastError

This function block calls the function getlasterror of the operating system, which returns the error code of the last error occurred at the given socket.

Input Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate ↳ *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
bEnable	BOOL	Rising edge: the function block starts the action.

Output Variable	Data type	Description
bDone	BOOL	TRUE indicates that the function block has completed processing.
bBusy	BOOL	TRUE indicates that the function block is still processing.
bError	BOOL	TRUE indicates that an error has occured.
wErrorId	WORD	Error number
dwLastError	DWORD	Return value of getlasterror of operating system.

SysSockHtons

This function of type WORD calls the function htons of the operating system, which converts a short value from host byte order to TCP/IP network order.

The function returns the converted value.

Variable	Data type	Description
wHost	WORD	Value to be converted.

SysSockInetAddr

This function of type DWORD calls the function inet_addr of the operating system, which converts a string, containing an internet address, in an address which can be used in the IN_ADDR structure.

The function returns the converted address.

Variable	Data type	Description
stIPAddr	STRING	IP address (dotted notation) (corresponding parameter e.g. in Win32: cp)

SysSockInetNtoa

This function of type BOOL calls the function inet_ntoa (Win32) resp.inet_ntoa_b (VxWorks), which converts an Internet network address in a string in Internet standard format..

In case of successful operation the function will return TRUE, otherwise FALSE.

Variable	Data type	Description
pInAddr	INADDR	Pointer to structure INADDR, which contains the Internet address, see below (corresponding parameter e.g. in Win32: in)
stIPAddr	STRING	IP address
diIPAddrSize	DINT	Size of the IP address

Structure INADDR:

S_addr : DWORD; (* Internet-Adresse als DWORD *)

SysSockIoctl

This function of type DINT calls the function ioctl of the operating system in order to control the I/O mode of the socket.

In case of successful operation the function will return TRUE, otherwise FALSE.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate ↯ *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
diCommand	DINT	Command which you want to apply on the socket. (corresponding parameter e.g. in Win32: cmd). Valid commands are: SOCKET_FIONBIO, SOCKET_FIONREAD.
piParameter	DWORD	Pointer to the command parameter (corresponding parameter e.g. in Win32: argp)

SysSockListen

This function of type BOOL calls the function listen of the operating system. This function will cause the socket to listen to connection requests and to queue them until they can be accepted by the SysSockAccept ↯ *Chapter 1.4.2.4.23.2 “SysSockAccept” on page 612* function.

In case of successful operation the function will return TRUE.

As soon as the maximum number of connection requests in the queue is exceeded the function will return FALSE.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
diMaxConnections	DINT	Maximum number of connection requests, which can be put in the input queue of the socket. (corresponding parameter e.g. in Win32: backlog)

SysSockNtohl

This function of type DWORD calls the function ntohl of the operating system, which converts a u_long value of the TCP/IP network order to the host byte order.

The function will return the value in host byte order.

Variable	Data type	Description
dwNet	DWORD	u_long value to be converted (corresponding parameter e.g. in Win32: netlong)

SysSockNtohs

Attention: Please regard the General Remarks on the library.

This function of type WORD calls the function ntohs of the operating system, which converts a u_short value from the TCP/IP network order to the host byte order.

The function will return the value in host byte order.

Variable	Data type	Description
wNet	WORD	u_short value to be converted (corresponding parameter e.g. in Win32: netshort

SysSockSelect

This function of type DINT calls the function select of the operating system to check whether one or several sockets are ready for certain communication actions. The group of sockets, to which this request should be applied, can be defined via the structure SOCKET_FD_SET.

The function will return the result of the select function.

Variable	Data type	Description
diWidth	DINT	Size of structure SOCKET_FD_SET.
fdRead	DWORD	Optionally a pointer to the structure defining the socket set for which the status of the read actions should be checked. You also can pass 0. Structure SOCKET_FD_SET see below (corresponding parameter e.g. in Win32: readfds)
fdWrite	DWORD	Optionally a pointer to the structure, defining the socket for which the status of the write actions should be checked. You also can pass 0. Structure SOCKET_FD_SET see below (corresponding parameter e.g. in Win32: writefds)
fdExcept	DWORD	Optionally a pointer to the structure, defining the socket for which the error status should be checked. You also can pass 0. Structure SOCKET_FD_SET see below (corresponding parameter e.g. in Win32: exceptfds)
ptvTimeout	DWORD	Maximum time which the SysSockSelect function will wait for an answer; Structure SOCKET_TIMEVAL, see below (corresponding parameter e.g. in Win32:timeout)

Structure SOCKET_FD_SET

fd_count:	UDINT;	(* Number of sockets *)
fd_array:	ARRAY [0..63] OF DINT;	(* Field with socket descriptors *)

Structure SOCKET_TIMEVAL:

tv_sec:	DINT;	(* seconds *)
tv_usec:	DINT;	(* microseconds *)

SysSockSetIPAddress

This function of type BOOL is only implemented for VxWorkstargets. It sets the IP address of the given card.

In case of successful operation the function will return TRUE, otherwise FALSE.

For other operating systems the function always will return FALSE.

Variable	Data type	Description
stCardName	STRING	Name of the network card
stIPAddress	STRING	IP address to be set

SysSockSetOption

This function of type BOOL calls the function getsockoptof the operating system in order to set particular socket options..

For a description of the getsockopt function please see the online help resp. documentation on the operating system.

In case of successful operation the function will return TRUE, otherwise FALSE.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
diLevel	DINT	Protocol specific level (corresponding parameter e.g. in Win32: level)
diOption	DINT	Name of the option: (corresponding parameter e.g. in Win32: optname) depends on the operating system
diOptionValue	DWORD	Option value; Deactivate boolean option values by setting a "0"; otherwise set the value (corresponding parameter e.g. in Win32: optval)
diOptionLength	DWORD	Length of the buffer for the option value (corresponding parameter e.g. in Win32: optlen)

SysSockShutdown

This function of type BOOL calls the function shutdown of the operating system in order to inhibit further send or receive actions. The function does not close the socket ! This must be done via SysSockClose *Chapter 1.4.2.4.23.4 “SysSockClose” on page 613*.

In case of successful operation the function will return TRUE, otherwise FALSE.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
diHow	DINT	Here you define, which type of communication actions should be inhibited (corresponding parameter e.g. in Win32: how)

SysSockHtonl

This function of type DWORD calls the function htonl of the operating system, which will convert a u_long value from host byte order to TCP/IP network order.

The function returns the converted value.

Variable	Data type	Description
dwHost	DWORD	Value to be converted.

TCP specific functions

SysSockRecv

This TCP/IP specific function of type DINT calls the function read (VxWorks) resp. recv (Win32) of the operating system in order to receive data which have been sent to the socket.

The function will return the number of read bits.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
pbyBuffer	DWORD	Address of the buffer from which the data should be read (corresponding parameter e.g. in Win32: buf)

Variable	Data type	Description
diBufferSize	DINT	Size of the buffer from which the data should be read (corresponding parameter e.g. in Win32: len)
diFlags	DINT	Defines in which way the function should be called; depending on the socket options. (corresponding parameter e.g. in Win32: flags)

If the socket has been "gracefully closed" , 0 will be returned, otherwise 1.

SysSockSend

This TCP/IP specific function of type DINT calls the function send of the operating system in order to send the data which are buffered at the socket.

The function will return the number of sent bits. If the socket has been "gracefully closed" , 0 will be returned, otherwise 1.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
pbyBuffer	DWORD	Address of the buffer from which the data should be send (corresponding parameter e.g. in Win32: buf)
diBufferSize	DINT	Size of the buffer from which the data should be send (corresponding parameter e.g. in Win32: len)
diFlags	DINT	Defines in which way the function should be called; depending on the socket options. (corresponding parameter e.g. in Win32: flags)

UDP specific functions

SysSockRecvFrom

This UDP specific function of type DINT calls the function recvfrom of the operating system, in order to read the data which have been sent to the socket.

The function will return the number of read bits. If the socket has been "gracefully closed" , 0 will be returned, otherwise 1.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate ↳ *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
pbyBuffer	DWORD	Address of the buffer from which the data should be received (corresponding parameter e.g. in Win32: buf)
diBufferSize	DINT	Size of the buffer from which the data should be received (corresponding parameter e.g. in Win32: len)
diFlags	DINT	Defines in which way the function should be called; depending on the socket options. (corresponding parameter e.g. in Win32: flags)
pSockAddr	DWORD	Pointer to a variable of type SOCKADDR; ↳ *Chapter 1.4.2.4.23.2 “SysSockAccept” on page 612*
diSockAddrSize	DINT	Length of structure SockAddr (can be retrieved via the SIZEOF operator) (corresponding parameter e.g. in Win32: iSockAddrSize)

SysSockSendTo

This UDP specific function of type DINT calls the function send of the operating system in order to send the data which are stored at the socket.

The function will return the number of read bits. If the socket has been "gracefully closed" , 0 will be returned, otherwise 1.

Variable	Data type	Description
diSocket	DINT	Descriptor of the socket, returned by SysSockCreate ↳ *Chapter 1.4.2.4.23.6 “SysSockCreate” on page 614* (corresponding parameter e.g. in Win32: s)
pbyBuffer	DWORD	Address of the buffer from which the data should be sent (corresponding parameter e.g. in Win32: buf)

Variable	Data type	Description
diBufferSize	DINT	Size of the buffer from which the data should be sent (corresponding parameter e.g. in Win32: en)
diFlags	DINT	Defines in which way the function should be called; depending on the socket options. (corresponding parameter e.g. in Win32: flags)
pSockAddr	DWORD	Pointer to a variable or type SOCKADDR; *Chapter 1.4.2.4.23.2 “SysSockAccept” on page 612*
diSockAddrSize	DINT	Length of the structure Sock-Addr (can be retrieved via the SIZEOF operator) (corresponding parameter e.g. in Win32: iSockAddrSize)

1.4.2.4.24 The library SysLibSocketsAsync.lib

This library offers the same functionality as 'The library SysLibSockets.lib', however function blocks instead of functions are used and the processing is asynchronous *Chapter 1.4.2.4.23.1 “Overview” on page 609*.

Restriction
This library is not supported for AC500 V2 devices.

- *The opening/closing of sockets may take a long time if many sockets are to be opened/closed simultaneously.*
- *Using the asynchronous functions is recommended.*

Corresponding to the parameters of the functions in SysLibSockets.lib the respective function blocks of SysLibSocketsAsync.lib have specific input parameters with identic impact.

Corresponding to the return values of the functions in SysLibSockets.lib the respective function blocks of SysLibSocketsAsync.lib have specific output parameters with identic impact.

Additionally the following input and output parameters are available in all function blocks:

Input:	bEnable	BOOL	Rising edge: the function block starts the action.
Outputs:	bDone	BOOL	TRUE indicates that the function block has completed processing.
	bBusy	BOOL	TRUE indicates that the function block is still processing.

	bError	BOOL	TRUE indicates that an error has occurred.
	wErrorId	WORD	Error number

Each function block will start the respective action as soon as a rising edge is detected at bEnable. Then it must be called cyclically until bDone=TRUE. Thereafter the outputs bError and wErrorId as well as the specific output parameters of the particular function block are in effect.

1.4.2.4.25 The library SysLibStr.lib

Overview

This library provides functions for string operations. If the target system is supporting the functionality, the library functions can be used to compare or copy strings or to retrieve the length of a string. The execution is synchronous.

SysStrCmp

This function of type DINT compares lexicographically two strings and returns one of the following values:

Return value < 0 String1 smaller than String2

Return value = 0 String1 = String2

Return value > 0 String1 bigger than String2

Variable	Data Type	Description
dwString1	STRING	First string (String1)
dwString2	STRING	Second string (String2)

SysStrCmpI

This function of type DINT checks whether two strings are identical and returns one of the following values:

Return value < 0 String1 smaller than String2

Return value = 0 String1 = String2

Return value > 0 String1 bigger than String2

Variable	Data Type	Description
dwString1	STRING	First string (String1)
dwString2	STRING	Second string (String2)

SysStrCmpN

This function of type DINT compares the size of two strings, whereby a defined number of characters counted from the beginning of the string will be considered. One of the following values will be returned:

Return value < 0 String1 smaller than String2

Return value = 0 String1 = String2

Return value > 0 String1 bigger than String2

Variable	Data Type	Description
sString1	STRING	First string (String1)
sString2	STRING	Second string (String2)
diChars	DINT	Number of locations for which (start counting from the beginning of the string) the size of the strings should be compared

SysStrCmpNI

This function of type DINT checks whether a defined number of characters of two strings (starting at the beginning of the string) are identical. One of the following return values will show the result:

Return value < 0 String1 smaller than String2

Return value = 0 String1 = String2

Return value > 0 String1 bigger than String2

Variable	Data Type	Description
sString1	STRING	First string (String1)
sString2	STRING	Second string (String2)
diChars	DINT	Number of characters starting at the beginning of the string, which will be checked for identical values in both strings

SysStrCpy

This function of type DWORD copies one string (Str1) to another (Str2). It will return a pointer to the target string Str2.

Variable	Data Type	Description
sString1	STRING	String, to which you want to copy (destination)
sString2	STRING	String, which should be copied (source)

SysStrLen

This function of type DINT acquires the length of a string. It will return the number of characters, excluding the "terminal NULL".

Variable	Data Type	Description
sString1	STRING	String, for which the length should be retrieved

1.4.2.4.26 The library SysLibTasks.lib

Overview

If the target system supports the functionality, then the library functions can be used to manage tasks. That means to generate, to delete, to modify priority level, to stop and restart tasks. The execution is synchronous.

These functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library SysLibSema in this case.

If you need functions to get information on the configuration of IEC-Tasks, use the library SysLibIECTasks.lib. ↳ *Chapter 1.4.2.4.11.1 “Overview” on page 586*.

Functions to be used within a task:

- ↳ *Chapter 1.4.2.4.26.9 “SysTaskSleep” on page 632*
- ↳ *Chapter 1.4.2.4.26.10 “SysTaskEnd” on page 633*
- ↳ *Chapter 1.4.2.4.26.11 “SysTaskGetCurrent” on page 633*

SysTaskCreate

This function of type UDINT creates a new task. It will return an unique Id number for the task, which is required as an input parameter for the other functions of SysLibTask.lib.

SysTask functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library SysLibSema in this case.

Input Variable	Data type	Description
stName	STRING	Name of the task
byPriority	BYTE	Priority of the Task; possible values : 0-255, Reserved: 0..31 for System IEC-Tasks: 32..63 Communication -Tasks: 64 and higher
udiInterval	UDINT	Task interval in milliseconds
pfFunction	DWORD	Function pointer, which must be acquired with the aid of the function SysIECGetFct-Pointer()
pArgument	DWORD	Pointer to parameters for the new task

SysTaskDestroy

This function of type BOOL can be used to delete a task. It will return TRUE, if the operation has succeeded, otherwise FALSE.

SysTask-functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library 'The library SysLibSem.lib' in this case ↳ *Chapter 1.4.2.4.21.1 “Overview” on page 606.*

Input Variable	Data type	Description
udiTaskId	UDINT	Id of the task, which should be deleted; Id is returned by Sys-TaskCreate ↳ *Chapter 1.4.2.4.26.2 “SysTaskCreate” on page 629*

SysTaskGetInfo

This function of type BOOL returns information on a task, which is identified by the task Id.

SysTask-functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library 'The library SysLibSem.lib' in this case *Chapter 1.4.2.4.21.1 “Overview” on page 606.*

Input Variable	Data type	Description
udiTaskId	UDINT	Id of the task, on which you want to get information; this Id was returned by SysTask-Create at creating the task *Chapter 1.4.2.4.26.2 “Sys-TaskCreate” on page 629*
pSysTaskInfo	POINTER TO SYSTASKINFO	Pointer on the structure Sys-TaskInfo, see below, which contains information on the task

Structure SysTaskInfo:

TYPE SYSTASKINFO :

STRUCT

dwHandle:	DWORD;	(* Operating system handle of the task *)
dwId:	DWORD;	(* Index of the task *)
dwSem:	DWORD;	(*Reserved, only use in the runtime system *)
wIECTaskNr:	WORD;	(* IEC task index in case it is an IEC task *)
stName:	STRING;	(* Name of the task *)

END_STRUCT

END_TYPE

SysTaskGetPriority

This function of type BYTE returns the priority of the task identified by the task Id.

The priority can be a value between 0 (=highest priority) and 255 (=lowest priority).

SysTask functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library 'The library SysLibSem.lib' in this case *Chapter 1.4.2.4.21.1 “Overview” on page 606.*

Input Variable	Data type	Description
udiTaskId	UDINT	Id of the task, of which you want to know the priority level; this Id was returned by SysTaskCreate during creation of the task *Chapter 1.4.2.4.26.2 “SysTaskCreate” on page 629*

SysTaskSetPriority

This function of type BOOL can be used to define the priority level for a task which is identified by the task Id. TRUE will be returned in case of a successful operation, otherwise FALSE.

The priority level can be a value between 0 (=highest priority) and 255 (=lowest priority).

SysTask functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library 'The library SysLibSem.lib' in this case Chapter 1.4.2.4.21.1 “Overview” on page 606.

Input Variable	Data type	Description
UdiTaskId	UDINT	Id of the task, for which the priority level should be set; this Id was returned by SysTaskCreate during creation of the task *Chapter 1.4.2.4.26.2 “SysTaskCreate” on page 629*
byPriority	BYTE	Priority ; possible values : 0 "“ 255 - Reserved for system: 0..31 - IEC-Tasks: 32..63 - Communication tasks: 64 and higher

SysTaskSuspend

This function of type BOOL can be used to stop a task during operation. The task will be identified by the task Id. (By calling the function SysTaskResume the processing can be continued later *Chapter 1.4.2.4.26.8 “SysTaskResume” on page 632*.)

TRUE will be returned in case of a successful stop of the task, otherwise FALSE.

SysTask functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library 'The library SysLibSem.lib' in this case Chapter 1.4.2.4.21.1 “Overview” on page 606.

Input Variable	Data type	Description
udiTaskId	UDINT	Id of the task, which should be stopped; this Id was returned by SysTaskCreate during creation of the task *Chapter 1.4.2.4.26.2 “SysTaskCreate” on page 629*

SysTaskResume

This function of type BOOL can be used to continue the processing of a task, which was stopped before by the function SysTaskSuspend *Chapter 1.4.2.4.26.7 “SysTaskSuspend” on page 631*.

TRUE will be returned in case of a successful stop of the task, otherwise FALSE.

SysTask functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library 'The library SysLibSem.lib' in this case Chapter 1.4.2.4.21.1 “Overview” on page 606.

Input Variable	Data type	Description
udiTaskId	UDINT	Id of the task, which should continue processing; this Id was returned by SysTaskCreate during creation of the task *Chapter 1.4.2.4.26.2 “SysTaskCreate” on page 629*

SysTaskSleep

This function of type BOOL can be used to interrupt the processing in a running task and to make it continue after a defined period of time.

TRUE will be returned, if the sleep function has been executed successfully, otherwise FALSE.

SysTask functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library 'The library SysLibSem.lib' in this case Chapter 1.4.2.4.21.1 “Overview” on page 606.

Input Variable	Data type	Description
udiMilliseconds	UDINT	Time in milliseconds after which the stopped (sleeping) task should continue to be processed

SysTaskEnd

This function of type BOOL should be called by a task as soon its processing has been terminated. Typically this should be done immediately before the task is left.

SysTask functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library 'The library SysLibSem.lib' in this case *Chapter 1.4.2.4.21.1 “Overview” on page 606.*

Input Variable	Data type	Description
udiExitCode	UDINT	Should be 0
udiTaskId	UDINT	Id of the task, which should be terminated; has been returned by SysTaskCreate during creation of the task *Chapter 1.4.2.4.26.2 “SysTaskCreate” on page 629*

SysTaskGetCurrent

This function of type UDINT can be called by the currently processing task in order to get returned the own task Id.

SysTask functions are not reentrant. This should be no problem in normal cases, but if in the application program a situation might occur, where several IEC-tasks create and manage additional tasks, the calls to these functions have to be synchronized. You can use the library 'The library SysLibSem.lib' in this case *Chapter 1.4.2.4.21.1 “Overview” on page 606.*

Input Variable	Data type	Description
bDummy	BOOL	TRUE starts the function

1.4.2.4.27 The library SysLibSymbols.lib

Overview

If supported by the target system (CSP32F as from Version 2.4.5.0), the function SysLibGetSymbolAddress1 provided by this library can be used to read the physical address of a symbol of an IEC project. The processing is done synchronously *Chapter 1.4.2.4.27.2 “Function SysLibGetSymbolAddress” on page 633*.

Function SysLibGetSymbolAddress

This function of type DWORD of the library 'The Library SysLibSymbols' returns the physical address for the given symbol. A variable must be specified by its full name, e.g. "PLC_PRG.a’ or "*.global_var’ *Chapter 1.4.2.4.27.1 “Overview” on page 633*.

As a precondition the symbol file must be available on the PLC and the symbol must be entered in the symbol file. The appropriate settings are to be done in the project options and in the target settings dialogs.

There is still the possibility to get the address of a variable by the ADR operator (e.g. ADR(PLC_PRG.a)). But in this case the symbol must be known already at compile time. The SysLibGetSymbolAddress function however allows to adapt the symbol name during run time ↳ *Chapter 1.4.2.4.27.2 “Function SysLibGetSymbolAddress” on page 633*.

The return value is the address of the variable or 0 in case the symbol could not be found.

Input Variable	Data Type	Description
pszSymbol	STRING	Name of the variable

1.4.2.4.28 The library SysLibTime.lib

Overview

This library provides function blocks for reading the real-time clock of the local system. The execution is synchronous.

- ↳ *Chapter 1.4.2.4.28.2 “CurTime” on page 634*
- ↳ *Chapter 1.4.2.4.28.3 “CurTimeEx” on page 634*

Used structures:

- ↳ *Chapter 1.4.2.4.28.4 “Structure SystemTimeDate” on page 635*
- ↳ *Chapter 1.4.2.4.28.5 “Structure SysTime64” on page 635*

CurTime

This function block provides the real time of the local system in microseconds; using the structure SysTime64.

VARINOUT Variable	Data type	Description
SystemTime	SysTime64	Value of the real-time clock of the local system in microseconds, see Structure SysTime64 ↳ *Chapter 1.4.2.4.28.5 “Structure SysTime64” on page 635*

CurTimeEx

This function block provides extended information on the real-time clock data on the local system.

VARINOUT Variable	Data type	Description
SystemTime	SysTime64	Value of the real-time clock in microseconds, see Structure SysTime64 ↳ *Chapter 1.4.2.4.28.5 “Structure SysTime64” on page 635*
TimeDate	SystemTimeDate	Detailed information on the value of the real-time clock, see Structure SystemTimeDate ↳ *Chapter 1.4.2.4.28.4 “Structure SystemTimeDate” on page 635*

Structure SystemTimeDate

This structure contains the following information on the real time given by the local system clock. It is used by the function block CurTimeEx ↳ *Chapter 1.4.2.4.28.3 “CurTimeEx” on page 634*.

Component	Data type	Description
dwLowMSecs	DWORD	The value of the real-time clock is returned in microseconds, using a Low DWORD plus a High DWORD, see Structure SysTime64 ↳ *Chapter 1.4.2.4.28.5 “Structure SysTime64” on page 635*
dwHighMsec	DWORD	
Year	UINT	Year, e.g. "2002"
Month	UINT	Month, e.g. "12"
Day	UINT	Day of month, e.g. "3"
Hour	UINT	Hour of the current day, e.g. "13"
Minute	UINT	Minutes of the current hour, e.g. "43"
Second	UINT	Seconds of the current minute, e.g. "15"
Milliseconds	UINT	Milliseconds of the current second, e.g. "649"
DayOfWeek	UINT	Day of the week, e.g. "2" (Sunday=0, Monday = 1...)

Structure SysTime64

This structure contains the real time of the local system in microseconds. A Low- plus a High-DWORD are used for that purpose, thus 64 bit are available. The structure is used by the function blocks CurTime and CurTimeEx ↳ *Chapter 1.4.2.4.28.2 “CurTime” on page 634* ↳ *Chapter 1.4.2.4.28.3 “CurTimeEx” on page 634*.

Component	Data type	Description
ulLow	DWORD	Low DWORD of the real-time value (microseconds)
ulHigh	DWORD	High DWORD of the real-time value (microseconds)

1.4.3 Visualization

1.4.3.1 Overview

A visualization is a graphical representation of the project variables which allows inputs to the PLC program in online mode via mouse and keypad. The integrated visualization provides graphic elements which can be arranged as desired and can be connected with project variables. Thereupon in online mode the look of the graphical elements will change depending on the variables values.

Simple example: In order to represent a fill level, which is calculated by the PLC program, draw a bar and connect it to the corresponding project variable, so that the length and color of the bar will show the current fill level value. Add a text field which will display the current value in a text string and a button for starting and stopping the program.

The properties of a single visualization element as well as of the whole visualization object will be defined in appropriate configuration dialogs and in the Object Properties dialog. There it is possible to set basic parameters by activating options as well as to define a dynamic parameterizing by entering project variables.

Additional special possibilities for configuring are given by the programmability of element properties via structure variables.

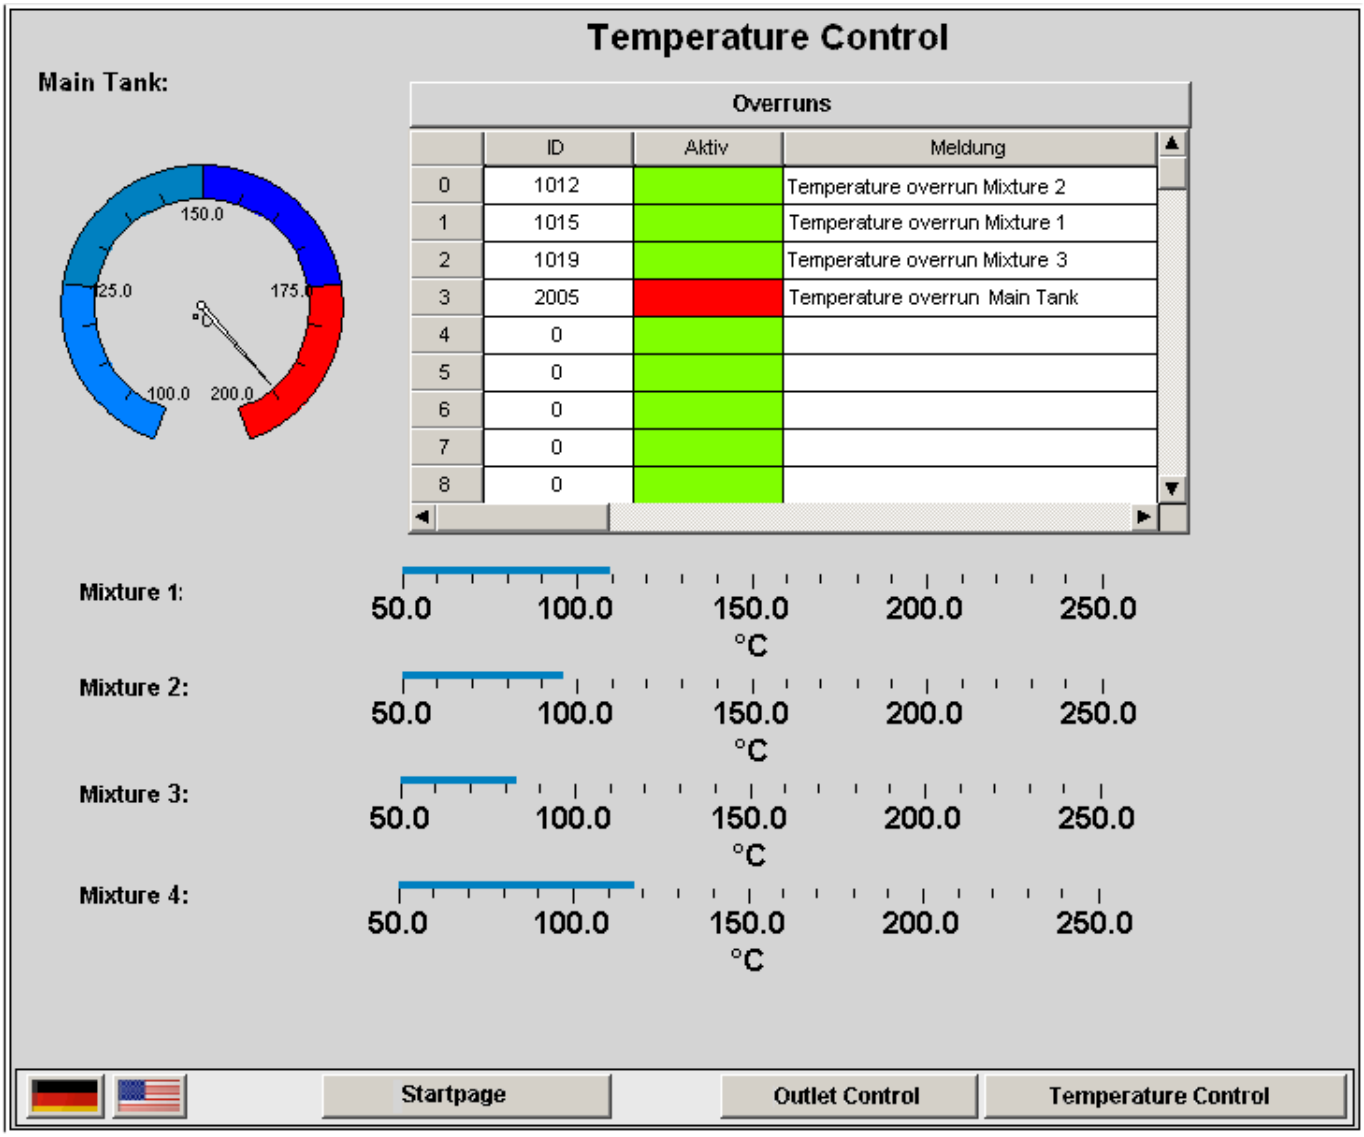
Using placeholders in the configuration dialogs may save a lot of effort in case you want to use the same visualization object several times with different configurations.

The visualization which is created in the programming system will in many cases be used as the only user interface available for controlling and watching the associated PLC program in online mode. For this purpose it must be possible to give inputs to the program solely by activating visualization elements. To reach this you can use special input possibilities during the configuration of the visualization and you have the option to define special hotkeys for each particular visualization.

A visualization can later be used in different ways:

- It can be made available on CODESYS HMI, a special runtime system for operating the visualization in full screen mode on a PLC computer.
- It can be made available as a web visualization, which allows to call and operate it via the Internet (useful for remote maintenance purposes)

Example of a visualization:



1.4.3.2 Create a new visualization

A visualization object is managed in the 'Visualization' register of the Object Organizer. It contains an arrangement of visualization elements and can get certain object properties. One or several visualization objects can be created in a Automation Builder project and might be linked with each other.

In order to create a visualization object in the Object Organizer, you must select the register card for Visualization in the Object Organizer.

Using the 'Project' 'Object Add' command, you can create a new visualization object. Open the 'New visualization' dialog, in which you can enter the name of the new visualization (see the remarks below). Once a valid entry is made, that is not a name that is already in use and no special characters used, you can close the dialog with OK. A window opens, in which you can edit the new visualization.

When the visualization object is marked in the Object Organizer, via command 'Project' 'Object' 'Properties' the properties dialog can be opened, where you can make settings concerning the usage of the object in a web visualization as well as concerning a Master layout ↳ *Chapter 1.4.1.2.4.12 “'Project' 'Object properties'” on page 261*.

When defining the name of the visualization object, please regard the following:

- A visualization named "PLC_VISU" per default automatically will be used as start visualization in a web visualization or in CODESYS HMI, if there not explicitly another visualization is configured for this.
- A visualization may not get the same name as another object within the project because this would result in problems when changing between visualizations.

If you want to use the implicit variable CurrentVisu (type STRING) for addressing the currently opened visualization object, with compiler versions < V2.3.7.0 and if the library SysLibStr.lib is not included in the project, you must use capital letters for the names of the visualization objects (e.g. PLC_VISU).

For information on implicit variables see 'System variables' ↳ *Chapter 1.4.3.11 “System variables” on page 717.*

1.4.3.3 Inserting visualization elements

A visualization element is a graphical element, which is used to fill a visualization object. The available elements are offered in the menu bar. Each element gets a separate configuration.

You can insert various geometric forms, as well as bitmaps, metafiles, buttons, various special elements and existing visualizations into your visualization. Regard the possibility of defining a special directory for visualization files in the Options for directories ↳ *Chapter 1.4.1.2.2.7 “Options for directories” on page 207*.

Go to the 'Insert' menu item and select freely from the following commands: 'Rectangle', 'Rounded Rectangle', 'Ellipse', 'Polygon', 'Polyline', 'Curve', 'Pie', 'Bitmap', 'Visualization', 'Button', 'Table', 'ActiveX-Element', 'Scrollbar', 'Meter', 'Bar Display', 'Histogram', 'Alarm table', 'Trend', 'WMF file'.

Alternatively you can use the tool bar.

If you then draw the mouse pointer to the editor window, the corresponding element symbol will be displayed at the pointer. Click on the desired starting point of your element and move the pointer with pressed left mouse key until the element has the desired dimensions.

If you want to create a polygon or a line, first click with the mouse on the position of the first corner of the polygon resp. on the starting point of the line, and then click on the further desired corner points. By doubleclicking on the last corner point you will close the polygon and it will be completely drawn respectively the line will be completed. If you want to create a curve (Bezier curves) determine the initial and two other points with mouse clicks to define the circumscribing rectangle. An arc is drawn after the third mouse click. You can then change the position of the end point of the arc by moving the mouse and can then end the process with a double click or add another arc with additional mouse clicks.

Furthermore pay attention to the status bar and the change from select and insert modes.

1.4.3.3.1 'Insert' 'Rectangle'

Symbol:

With the command you can insert a rectangle as an element into your present visualization ↳ *Chapter 1.4.3.3 “Inserting visualization elements” on page 638*.

1.4.3.3.2 'Insert' 'Rounded Rectangle'

Symbol:

With the command you can insert a rectangle with rounded corners as an element in your present visualization ↳ *Chapter 1.4.3.3 “Inserting visualization elements” on page 638*.

1.4.3.3.3 'Insert' 'Ellipse'

Symbol:

With the command you can insert a circle or an ellipse as an element in your present visualization ↳ *Chapter 1.4.3.3 “Inserting visualization elements” on page 638*.

1.4.3.3.4 'Insert' 'Polygon'

Symbol:

With the command you can insert a polygon as an element in your present visualization ↳ *Chapter 1.4.3.3 “Inserting visualization elements” on page 638*.

1.4.3.3.5 'Insert' 'Polyline'

Symbol:

With the command you can insert a line as an element into your current visualization ↳ *Chapter 1.4.3.3 “Inserting visualization elements” on page 638*.

1.4.3.3.6 'Insert' 'Curve'

Symbol:

With the command you can insert a Bezier curve as an element into your current visualization ↳ *Chapter 1.4.3.3 “Inserting visualization elements” on page 638*.

1.4.3.3.7 'Insert' 'Pie'

Symbol:

Use this command to insert a Pie Segment as an element into your current visualization.

While pressing the left mouse button, bring up an area in the desired size. An oval element including a line marking the radius at the 0° position will be displayed. As long as keeping the mouse button pressed you can immediately change size and position of the element by moving the mouse. A little black square is attended to the the element, indicating the corner of a virtual rectangle surronding the element.

In order to define the start and end angles of a Pie, select the end point of the radius line on the circular arc by a mouse-click. As soon as you, keeping the mouse button pressed, move the cursor, two small rectangles will be displayed, indicating the two angle positions. As from now those can be selected and moved seperately. If you want the angle values get defined dynamically by variables, open the configuration dialog category 'Angle' and enter the desired variable names *Chapter 1.4.3.5.5 “Angle” on page 650*.

You can resize or reshape the element later by either clicking on the centre point, the cursor getting displayed as diagonally crossed arrows, and moving the mouse while keeping the mouse button pressed (or using the arrow keys). Alternatively you can select and move the corner indicating little square outside of the element. In order to move the element to another position, click inside the element to get the cursor beeing displayed as vertically crossed arrows and then move the cursor.

1.4.3.3.8 'Insert' 'Bitmap'

Symbol:

With the command you can insert a bitmap as an element in your present visualization *Chapter 1.4.3.3 “Inserting visualization elements” on page 638*.

While pressing the left mouse button, bring up an area in the desired size. The standard dialog box for browsing for a file will be opened. You can use this dialog to select and enter a bitmap file from the local file system. In the configuration dialog of the inserted bitmap you then can define, whether a link to the bitmap file should be stored or the bitmap should be inserted as an element.

Alternatively you can specify a project variable to define which bitmap should be used. This allows a dynamic change of bitmaps in online mode. The variable must be entered in the configuration dialog of an already inserted bitmap element and it must contain the name of a bitmap file managed in the project-global *Chapter 1.4.3.7.1 “'Extras' 'Bitmap list'” on page 706*.

For a description on the configuration of a bitmap element please see 'Bitmap' *Chapter 1.4.3.5.19 “Bitmap” on page 669*.

1.4.3.3.9 'Insert' 'Visualization'

Symbol:

With the command you can insert an existing visualization as an element in your present visualization *Chapter 1.4.3.3 “Inserting visualization elements” on page 638*.

While pressing the left mouse button, bring up an area in the desired size. A selection list of existing visualizations opens. After you have selected the desired visualization, it will be inserted in the defined area. An inserted visualization will also be named "instance".

1.4.3.3.10 'Insert' 'Button'

Symbol:

This command is used to insert a button into your current visualization *Chapter 1.4.3.3 “Inserting visualization elements” on page 638*.

Drag the element to the desired size with the left mouse button held down.

If a toggle variable is configured for the button it displays the state of this variable by visually displaying whether it is pressed or not pressed. Conversely, the variable is toggled by "pressing" the button.

Like for a "Bitmap" element also for the filling of a button element an image file can be specified (static or dynamic use). See the description of the configuration dialog for 'Insert Bitmap' ↳ *Chapter 1.4.3.3.8 “'Insert' 'Bitmap'” on page 640*.

1.4.3.3.11 'Insert' 'WMF file'

Symbol:

This command is used to insert a Windows Metafile. The standard dialog for opening a file will appear, where you can select a file (extension *.wmf). After having closed the dialog with OK the file will be inserted as an element in the visualization. Please regard, that no link to a file will be saved, like it is done when you insert a bitmap, but the elements of the metafile will be inserted as a group ↳ *Chapter 1.4.3.3.8 “'Insert' 'Bitmap'” on page 640 ↳ Chapter 1.4.3.4.8 “Grouping elements” on page 644*.

1.4.3.3.12 'Insert' 'Table'

Symbol:

Use this command to insert a Table element as an element into your current visualization. It is used to display the current values of the elements of an array.

While pressing the left mouse button, bring up an area in the desired size. Before the element gets displayed the configuration dialog 'Configure Table' will be opened ↳ *Chapter 1.4.3.5.20 “Table” on page 671*. Here you will find additionally to the standard categories Tooltip and Security the categories 'Table', 'Columns', 'Rows' and 'Selection' where you can define contents and appearance of the table.

1.4.3.3.13 'Insert' 'ActiveX-Element'

Symbol:

Use this command to insert an ActiveX Control into your current visualization. It can be used later on Windows32 systems in CODESYS HMI. While pressing the left mouse button, bring up an area in the desired size. It will be inserted as a rectangle with the inscription "Control:".

To select a certain ActiveX Control and to configure the method calls and the display open the dialog 'Configure ActiveX-Control' by a double-click on the element resp. via command 'Extras' 'Configure' ↳ *Chapter 1.4.3.5.4 “'Extras' 'Configure'” on page 649*.

1.4.3.3.14 'Insert' 'Scrollbar'

Use this command to insert a Scrollbar element in the current visualization. In the configuration of that element you can assign a variable to the element, the value of which will be changed when the user moves the scrollbar slider in online mode ↳ *Chapter 1.4.3.5.22 “Scrollbar” on page 679*. Vice versa the slider position will reflect the current value of the variable if this value is given by any other input. In the target visualization the element will work only if it is supported by the target system.

Insert the element by drawing a rectangle in desired size. The shape of the rectangle determines whether the scrollbar will be entered vertically or horizontally .

1.4.3.3.15 'Insert' 'Meter'

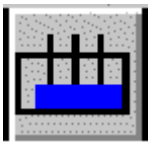
Symbol:

Use this command to insert a Meter as an element into your current visualization. It provides a scale which is defined as a sector of a circular arc, and a pointer element.

While pressing the left mouse button, bring up an area in the desired size. Before the element gets displayed the configuration dialog 'Meter' will be opened ↳ *Chapter 1.4.3.5.23 “Meter” on page 680*. Here you can define various parameters concerning the display of the element and a preview is available to check the configuration before really inserting the element by confirming the dialog.

1.4.3.3.16 'Insert' 'Bar Display'

Symbol:



Use this command to insert a Bar Display element into your current visualization. It is used to visualize the value of the assigned variable by a bar indicating the value by its length along a horizontal scale.

While pressing the left mouse button, bring up an area in the desired size. Before the element gets displayed the configuration dialog 'Configure bar display' will be opened ↳ *Chapter 1.4.3.5.24 “Bar display” on page 682*. Here you can define various parameters concerning the display of the element and a preview is available to check the configuration before really inserting the element by confirming the dialog.

1.4.3.3.17 'Insert' 'Histogram'

Symbol:

Use this command to insert a Histogram element into your current visualization. It is used to visualize the elements of an array by bars which are placed side by side each indicating the value of the element by its length.

While pressing the left mouse button, bring up an area in the desired size. Before the element gets displayed the configuration dialog 'Configure Histrogram' will be opened ↳ *Chapter 1.4.3.5.25 “Histogram” on page 683*. Here you can define various parameters concerning the display of the element and a preview is available to check the configuration before really inserting the element by confirming the dialog.

1.4.3.3.18 'Insert' 'Alarm table'

Symbol:

Use this command to insert an alarm table into your current visualization object.

While pressing the left mouse button, bring up an area in the desired size. Before the element gets displayed the configuration dialog 'Configure Alarm table' will open *Chapter 1.4.3.5.26 “Alarm table” on page 684*. Here you will find additionally to the standard categories Tooltip and Security the categories 'Alarmtable', 'Settings for sorting', 'Columns' and Settings for alarmtable' where you can define contents and appearance of the table.

An alarm table can be used to visualize the alarms, which have been defined in the Alarm configuration of the project.

1.4.3.3.19 'Insert' 'Trend'

Symbol:

Use this command to insert a trend element into your current visualization object.. While pressing the left mouse button, bring up an area in the desired size. The configuration (axes, variables, history) is done in the configuration dialog 'Trend' *Chapter 1.4.3.5.27 “Trend” on page 688*.

The trend element, also named oscilloscope element, is used to display variable values within a certain time period. It stores the data in a file on the client and displays them as a graph. As soon as a value changes, a new entry will be made in the file, showing date/time and the new value.

The trend element is drawn transparently. So you can assign any desired background (bitmap, color).

1.4.3.4 Positioning visualization elements

1.4.3.4.1 Selecting visualization elements

The selection mode is activated by default. In order to select an element, click with the mouse on the element. You can also select the first element of the elements list by pressing the <Tab> key and jump to the next by each further keystroke. If you press *[Tab]* while pressing *[Shift]*, you jump backwards in the order of the elements list.

In order to select elements, which are placed one upon the other, first select the top level element by a mouse-click. Then do further mouse-clicks while *[Ctrl]* + *[Shift]* are pressed, to reach the elements in the underlying levels .

In order to mark multiple elements, press and hold *[Shift]* and click the corresponding elements, one after another. Or while holding down the left mouse button, pull a window over the elements to be selected.

In order to select all the elements, use the 'Extras' 'Select All' *Chapter 1.4.3.4.4 “'Extras' 'Select All'” on page 644* command.

If you are in the element list (called by 'Extras' 'Element list'), you can select the concerned element in the visualization by selecting a line.

1.4.3.4.2 Changing the selection and insert mode

After the insertion of a visualization element, there is an automatic change back into the selection mode. If you want to insert an additional element the same way, you can once again select the corresponding command in the menu.

You can also quickly change between the selection mode and the insert mode by pressing *[Ctrl]* and the right mouse button simultaneously.

In the insert mode, the corresponding symbol will also appear at the mouse pointer, and the name will also be indicated in black in the status bar.

1.4.3.4.3 'Extras' 'Select'

This command is used to switch the selection mode on or off. This can also be achieved by pressing the right mouse-key while holding down the *[Ctrl]*key at the same time.

1.4.3.4.4 'Extras' 'Select All'

This command allows you to select all visualization elements within the current visualization object.

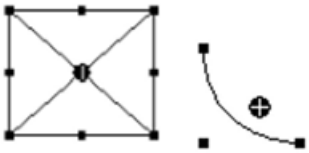
1.4.3.4.5 Copying visual elements

One or more selected elements can be inserted with the 'Edit' 'Copy'command, the *[Ctrl]* + *[C]* combination, or the corresponding copy symbol, and with 'Edit' 'Paste'.

A further possibility is to select the elements and to again click in one of these elements with *[Ctrl]* held down. If you now hold the left mouse button down, you can separate the elements thus copied from the original.

1.4.3.4.6 Modifying visualization elements

You can select an element which has already been inserted by a mouse click on the element or by pressing *[tab]*. A small black square will appear at each corner of each of the elements, (with ellipses at the corners of the surrounding rectangle). Except in the case of polygons, lines or curves further squares appear in the middle of the element edges between the corner points.



With a selected element, the turning point (balance point) is also displayed at the same time. You can then rotate the element around this point with a set motion/angle. The turning point is displayed as a small black circle with a white cross. You can drag the turning point with a pressed left mouse button.

You can change the size of the element by clicking on one of the black squares and, while keeping the left mouse button pressed, controlling the new outline.

With the selection of a polygon, you can drag each individual corner using the same technique. While doing this, if you press *[Ctrl]* then an additional corner point will be inserted at the corner point, an additional corner point will be inserted, which can be dragged by moving the mouse. By pressing *[Shift]* + *[Ctrl]*, you can remove a corner point.

1.4.3.4.7 Dragging visualization elements

One or more selected elements can be dragged by pressing the left mouse button or the arrow key.

1.4.3.4.8 Grouping elements

Elements can be grouped by selecting all desired elements and performing the command 'Extras' 'Group'. The group will behave like a single element:

- the grouped elements get a collective frame; when dragging the frame, depending on the current configuration all elements will be stretched, compressed or keep their original size; only the group can be moved to another position.
- the grouped elements get collective properties: inputs only can effect the group and not a single element. Thus the elements also get one collective configuration (category 'group'). The property 'Change color' can not be configured for a group!

To redefine a single element of a group, the grouping must be redone by the command 'Extras' 'Ungroup'. The configuration of the group will be lost in this case.

As soon as you save the project as program version 2.1 or lower, a group of visualization elements will be resolved automatically; that means that the elements of the group will be shown as single elements in the visualization.

1.4.3.4.9 'Extras' 'Send to Front'

Use this command to bring selected visualization elements to the front.

1.4.3.4.10 'Extras' 'Send to Back'

Use this command to send selected visualization elements to the back.

1.4.3.4.11 'Extras' 'Align'

Use this command to align selected visualization elements.

The following alignment options are available:

- Left: the left edge of each of the elements will be aligned to the element that is furthest to the left.
- the same is true for Right / Top / Bottom.
- Horizontal Center: each of the elements will be aligned to the average horizontal center of all elements.
- Vertical Center: each of the elements will be aligned to the average vertical center of all elements.

1.4.3.4.12 'Extras' 'Element list'

This command opens a dialog box containing a list of all visualization elements including their number, type and position. The element number will be displayed in the element in the editor view, if the corresponding option is activated in the visualization settings ↳ *Chapter 1.4.3.6.1 "'Extras' 'Settings'" on page 700*. The position is given according to the x and y position of the upper left (x1, y1) and the lower right (x2, y2) corner of the element.

When one or more items have been selected, the corresponding elements in the visualization are marked for visual control and if necessary the display will scroll to that section of the visualization that contains the elements.

Use the *[To front]* button to bring selected visualization elements to the front. Use the *[To behind]* button to move them to the back.

Below the elements list there you find depending on which element is currently selected - one of the following combinations of edit fields where you can modify size and position of the element:

- If a rectangle, rounded rectangle, ellipse, bitmap, visualization, button or a meta file is currently selected, then next to the text "Rectangle (x1, y1, x2, y2)" there are four edit fields, where the actual x/y positions are shown and can be modified.
- If a line, polygon or a curve is currently selected, a table will be available showing the actual X-Position and Y-Position of each of the black squares which mark the shape of the element, as soon as it is selected. These values can be edited here.

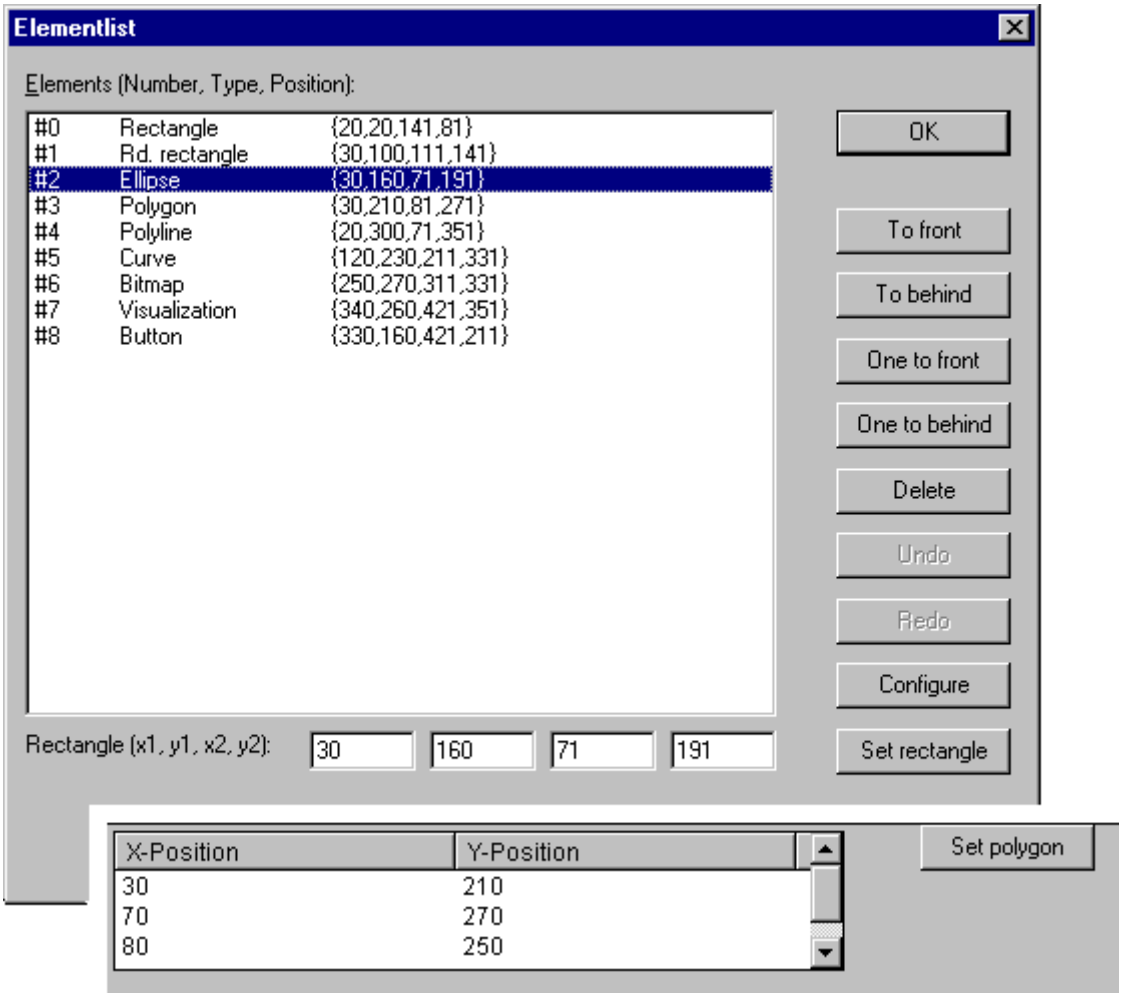
To set the modified position values in the elements list and in the visualization, press button *[Set rectangle]* (in case 1.) resp. *[Set polygon]* (in case 2.).

Use the Delete button to remove selected visualization elements.

Use the *[Undo]* and *[Redo]* buttons to undo or restore changes that have been made just as you would do with the commands 'Edit' 'Undo' and 'Edit' 'Redo' . In the dialog box, you can observe the changes that are being made.

Click on *[OK]* to close the dialog box and confirm the changes.

Use *“Configure”* to get the configuration dialog for the element.



1.4.3.4.13 Status bar in the visualization

If a visualization has the focus, the current X and Y position of the mouse cursor in pixels relative to the upper left corner of the image is displayed in the status bar. If the mouse pointer is located on an Element, or if the element is being processed, then the number of the element will be displayed. If you have selected an element to insert, then this element will also appear (for example, Rectangle).

1.4.3.5 Configuring visualization elements

1.4.3.5.1 Overview

In the configuration dialogs opened via the 'Extras' 'Configure' command the properties of an element or object are set either by activating options or dynamically by inserting project variables ↳ *Chapter 1.4.3.5.4 “'Extras' 'Configure'” on page 649*. Besides that the properties can be programmed via the components of a structure variable, which can be defined for each visualization element.

Regard the order of analysis, which will be followed in online mode:

- *The values which are given dynamically, i.e. via project variables, will overwrite the fix parameters defined for the same property.*
- *If an element property is defined by a "normal" project variable as well as by the component of a structure variable, then in online mode primarily the value of the project variable will be regarded.*

Please regard the possibility of using placeholders as well as the special input possibilities which are useful if the visualization should be used in CODESYS HMI or web visualization , that means if the visualization serves as the only user interface for a PLC program ↳ *Chapter 1.4.3.5.30 “Special input possibilities for operating versions” on page 695*.

Dialogs which include the configuration of Colors and Fonts for a visualization element, can look differently depending on the currently selected target system. Possibly instead of the standard dialog there is a dialog with restricted options. This might be reasonable for projects, which are designated for a use in target visualizations.

Also regard that in the project options a separate directory can be defined for visualization files ↳ *Chapter 1.4.1.2.2.7 “Options for directories” on page 207*.

1.4.3.5.2 Placeholder

At each location in the configuration dialog at which variables or text are entered, a placeholder can be set in place of the respective variable or text. This makes sense if the visualization object is not to be used directly in the program, but is created to be inserted in other visualization objects as an "instance". When configuring such an Instance, the placeholders can be replaced with variable names or with text (see Configuring an inserted visualization , there you also find an example for using placeholders ↳ *Chapter 1.4.3.5.28 “Visualization” on page 693*).

Any string enclosed in two dollar signs ($) is a valid placeholder (e.g. $variable1$, variable$x$). For each placeholder a „value group" can be defined as an input specification in the 'Placeholder list' dialog (called from 'Extras' 'List of placeholders'). With one of these values you can replace the placeholder when configuring an instance of the visualization object. A placeholder list will be available in the instance to do this replacements.

Example of an application of the placeholder concept

Instances of a function block can easily be displayed with the help of instances of the same visualization. For example, in configuring the visualization visu, which visualizes the variables of function block, one could begin each variable entry with the placeholder FUB (e.g. FUB.a). If an instance of visu is then used (by inserting visu in another visualization or by calling via 'Zoom to vis.'), then in the configuration of this instance the placeholder FUB can then be replaced with the name of the function block instance to be visualized. This might look like shown in the following: In the project define a function block containing the following declarations:

```
FUNCTION_BLOCK fu
VAR_INPUT
 changecol : BOOL; (* should cause a color change in the
visualization *`)
END_VAR
```

In PLC_PRG define two instances of 'fu':

```
inst1_fu : fu;
inst2_fu : fu;
```

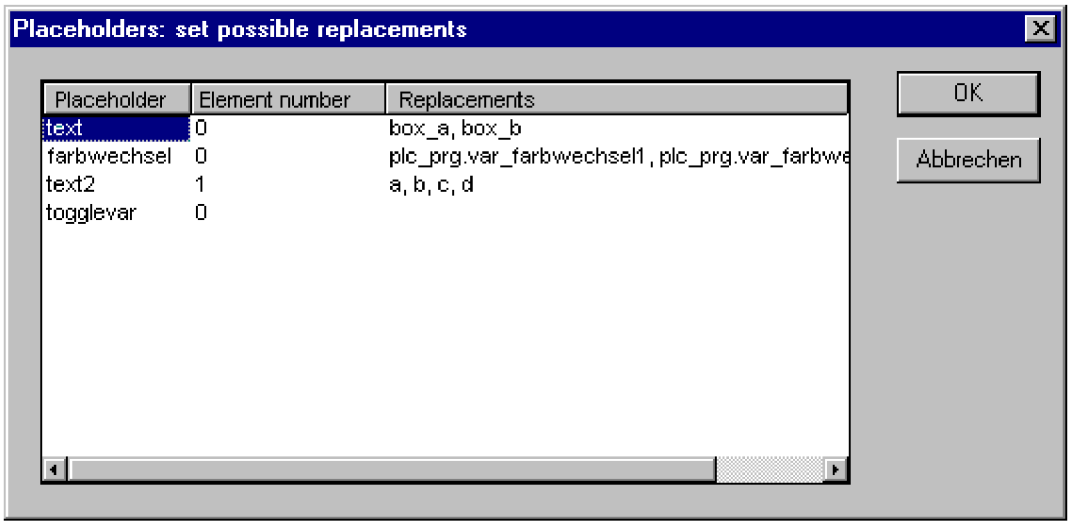
1. Create a visualization object 'visu'. Insert an element and open the configuration dialog, category 'Variables'. Enter in field 'Change color' the following: "FUB.changecol". Open category 'Input' and enter in field 'Tap Variable' "FUB.changecol". Open category 'Text' and enter"FUB - change color ".
2. Create another visualization object 'visu1'.
3. Insert visualization 'visu' twice in 'visu1' (two references of 'visu').
4. Mark the first reference of 'visu' and open the configuration dialog of category 'Visualization'. Press button 'Placeholder', so that the placeholder list will be displayed. There replace entry 'FUB' by 'PLC_PRG.inst_1'.
5. Now mark the second instance of 'visu' and (like described for the first one) replace 'FUB' by 'PLC_PRG.inst_2'.

   ⇨ In online mode, the values of the variables which are used to configure the two instances of 'fu' will be visualized in the corresponding instance of 'visu'. Of course the placeholder FUB can be used at all places in the configuration of 'visu' where variables or text strings are entered.

1.4.3.5.3 'Extras' 'List of Placeholders'

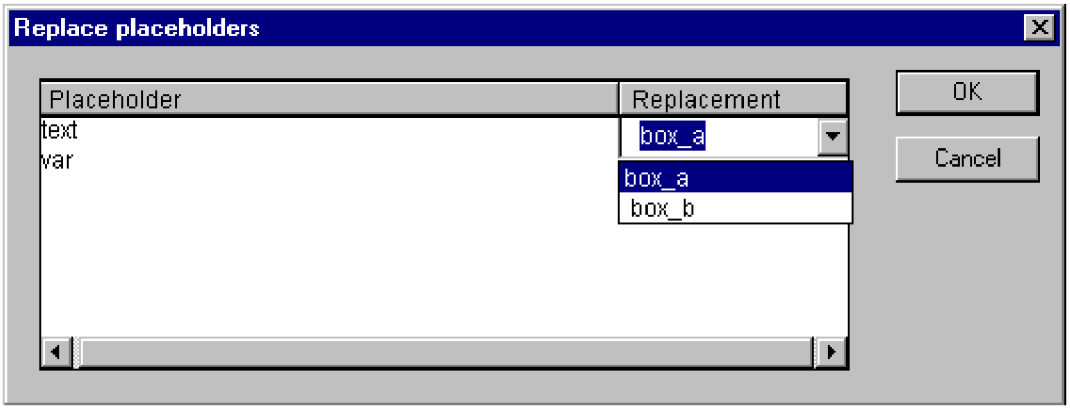
This list is used to manage placeholders and to configure them:

Primarily you use the list when configuring a visualization object, which later should be inserted, which means instanced, in other visualization(s). For this reason you will use placeholders instead of or additionally to variables and strings in the configuration dialogs. You can open the dialog 'Placeholders' by the command 'List of Placeholders' in the 'Extras' menu or in the context menu.



Column 'Placeholder' will list all placeholders, which are currently used in the configuration of the visualization object. Column 'Element number' shows the elements which contain a placeholder. In column 'Replacements' you can enter one or several strings (text, variable, expression) which you want to get available later when replacing a placeholder during the configuration of an instance of the visualization object. The elements of the selection must be entered separated by commas. If no or an impossible replacement string is specified, then the placeholder can be replaced with any desired text later during the configuration of the visualization's reference.

Later you use the list of placeholders when configuring an instance of the above mentioned visualization object, that means after this object has been inserted (as a 'reference') in another visualization by the command 'Insert' 'Visualization'. For this purpose do the following to open the dialog: Select the inserted visualization, execute command 'Extras' 'Configure' and press button 'Placeholders' in Category 'Visualization'. In this case the dialog will only contain two columns:



Column 'Placeholder' – like described above – shows all placeholders which have been defined for the primary visualization object. If additionally a selection of possible replacements had been defined, this list will now be available in column 'Replacement'. Select one of the entries to replace the placeholder in the present instance. If no replacements have been pre-defined then you can manually enter an expression or variable. For this purpose perform a mouse-click on the field in column Replacement to open an editor field.

1.4.3.5.4 'Extras' 'Configure'

With this command, the 'Configure element' dialog opens for configuring the selected visualization element ↬ *Chapter 1.4.3.4.1 “Selecting visualization elements” on page 643*. You are given the dialog box when you double-click on the element.

Select a category in the left area of the dialog box (available categories depending on element type) and fill out the requested information in the right area. This has to be done by activating options resp. by inserting the name of valid variables, whose values should define the property of the element.

There are also configuration dialogs available for a group of elements. Regard that the settings will be valid for the "element" group. If you want to configure the particular elements of the group, you have to resolve the group.

If you have defined an element property by a "static" setting as well as dynamically by a variable, then in online mode the variable will overwrite the static value (Example: "Alarm color Inside" can be defined statically in category 'Color' and additionally dynamically in category 'Colorvariables' by a variable). If the setting is controlled by a "normal" project variable as well as by a structure variable, then the value of structure variable also will be overwritten by the "normal" project variable.

Meter, Bar Display and Histogram must be re-grouped before!

At locations in the element configuration where variables are operative, the following Entries are possible:

- Variable names, for which input assistant is available.
- Expressions which are assembled from component accesses, field accesses with constant index, variables and direct addresses.
- Operators and constants, which can be combined at will with the aforementioned expressions.
- Placeholders instead of variable names or text strings.

Examples of permissible expressions	x + y 100*PLC_PRG.a TRUE NOT PLC_PRG.b 9*sin(x + 100)+cos(y+100)

Function calls are not possible. Invalid expressions result in an error message on login („Invalid Watch expression..."). Examples of invalid expressions: fun(88), a := 9, RETURN.

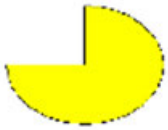
There are two possible ways in the configuration dialogs to write **global variables**: „.globvar" and „globvar" are equivalent. The style with a dot (which is that used in the Watch- and Receipt Manager) is not allowed within an assembled expression, however.

Regard also the possibility of using placeholders ↳ *Chapter 1.4.3.5.2 “Placeholder” on page 647*.

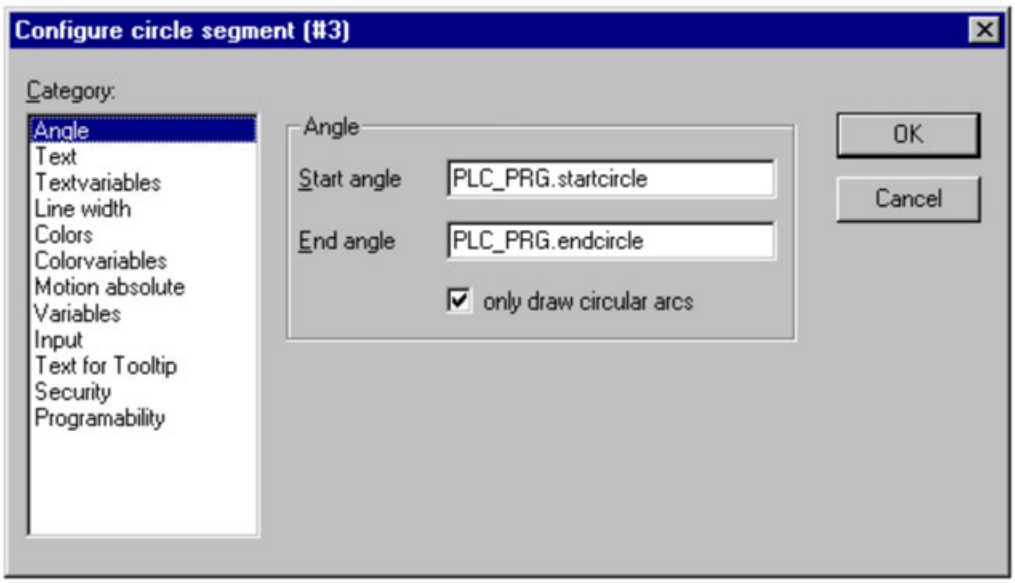
1.4.3.5.5 Angle

In the configuration dialog 'Configure Pie' in the Angle category you can each enter a value or a variable defining the start angle and the end angle of the sector element in degrees. The sector will be drawn clockwise from the start angle position to the end angle position.

Example:	Enter start angle: "90", end angle: "180"

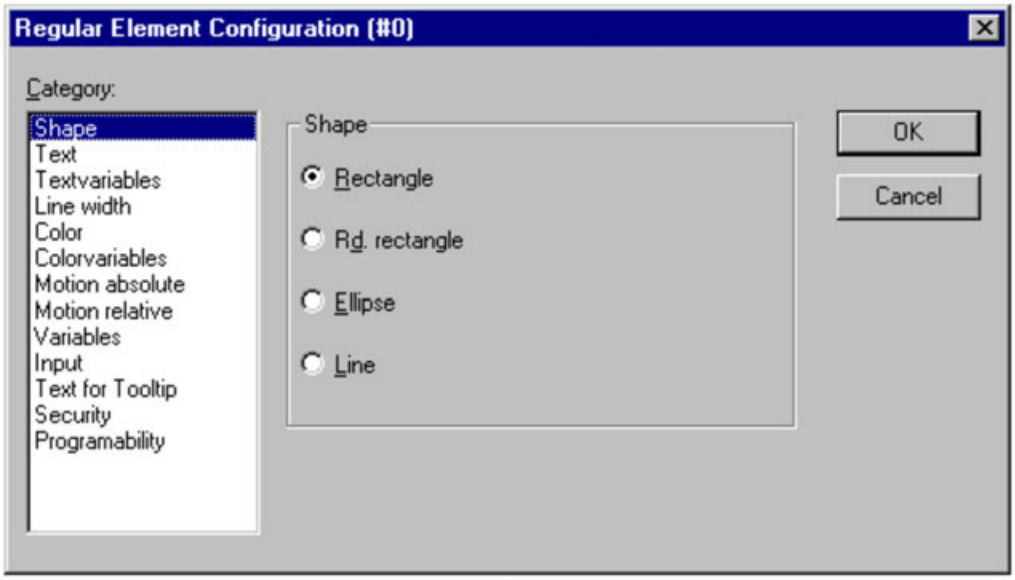


Dialog for Configuring a Pie



1.4.3.5.6 Shape

In the visualization element configuration dialog box, you can select in the 'Shape' category from among Rectangle, Rounded Rectangle, Line and Ellipse respectively Polygon, Line and Curve. The form will change into the size already set.

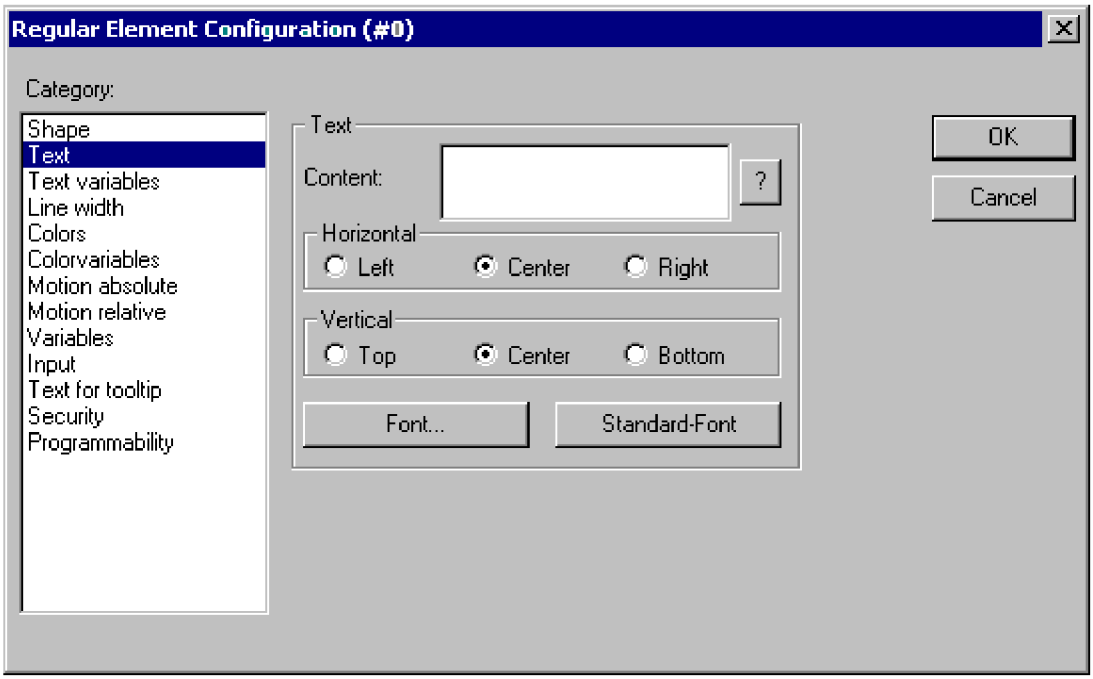


1.4.3.5.7 Text

In the dialog for configuring visualization elements, you can specify a text for the element in the Text category. This can be entered directly or/and a variable can be defined which will determine the text string. The usage of placeholders is possible ↳ *Chapter 1.4.3.5.2 “Placeholder” on page 647*. Also the default settings for font and alignment are done here.

> *As soon as text parameters are additionally provided dynamically, which means by a system or structure variable (see resp. 'Programmability'), the static definitions which are done in the currently opened dialog , will be overwritten*
> ↳ *Chapter 1.4.3.5.8 “Textvariables” on page 655!*

In case of multiple definition of an element property consider the specific order of precedence concerning according to which a value might be overwritten in online mode by another.



Enter the text in the Content field. With the key combination *[Ctrl]* + *[Enter]* you can insert line breaks, with *[Ctrl]* + *[Tab]*, tab stops. Besides the input of a pure text string you can use the following formatting sequences (via button the corresponding online help page can be opened):

- If you include "%s" into the text, then this location, in Online mode, will be replaced by the value of the variable from the Textdisplay field of the Variables category. Instead of "s" you also can use other formatting strings conforming with the standard C-library function 'sprintf': See here a sample list of strings and arguments:

Character	Argument / Output as
d,i	Decimal number
o	Unsigned octal number (without leading zerol)
x	Unsigned hexadecimal number (without leading 0x)
u	Unsigned decimal number
c	Single character

Character	Argument / Output as
s	String
f	REAL-values; syntax: `%|<alignment><minimal width><accuracy>|f` Accuracy defines the number of decimal places behind the comma (Default is 6). Example see below.

- If you want to get displayed a percent sign% combined with one of the formatting strings mentioned above, you must enter "%%". For example: Enter "Rate in %%: %s" to get displayed in online mode "Rate in %: 12" (if the text display variable currently is "12").

- Be careful with letter case: capital letters, i.e. %S instead of %s not acceptable."

The value of the variable will be displayed correspondingly in online mode. You can enter any IEC-conforming format strings, which fit to the type of the used variable.

It is not checked whether the type which is used in the formatting string matches with the type of the variable which is defined in the 'Text Output' field!

Example:

Input in the 'Content' field: `Fill level %2.5f mm`

Input in the 'Textdisplay' field (variable of type REAL), e.g.: `plc_prg.fvar1`

-> Output in online mode e.g.: `Fill level 32.8999 mm`

- If you enter "%t", followed by a certain sequence of special placeholders, then this location will be replaced in Online mode by the system time. The placeholders define the display format, see the following table.

Do not insert any other characters before %t in the 'Content' field (in contrast this is allowed for e.g. "%s", see above)

%a	Abbreviated weekday name
%A	Full weekday name
%b	Abbreviated month name
%B	Full month name
%c	Date and time representation appropriate for locale
%d	Day of month as decimal number (01 "“ 31)
%H	Hour in 24-hour format (00 "“ 23)
%I	Hour in 12-hour format (01 "“ 12)
%j	Day of year as decimal number (001 "“ 366)
%m	Month as decimal number (01 "“ 12)
%M	Minute as decimal number (00 "“ 59)

%p	Current locale’s A.M./P.M. indicator for 12-hour clock
%S	Second as decimal number (00 "“ 59)
%U	Week of year as decimal number, with Sunday as first day of week (00 "“ 53)
%w	Weekday as decimal number (0 "“ 6; Sunday is 0)
%W	Week of year as decimal number, with Monday as first day of week (00 "“ 53)
%x	Date representation for current locale
%X	Time representation for current locale
%y	Year without century, as decimal number (00 "“ 99)
%Y	Year with century, as decimal number
%z, %Z	Time-zone name or abbreviation; no characters if time zone is unknown
%%	Percent sign

Examples: %t%a %b %d.%m.%y %H:%M:%S

-> Display in online mode: Wed Aug 28.08.02 16:32:45

Between the placeholders you can insert any text strings:

%Today is %d.%m.%y

-> Display in online mode: Today is 28.08.02

If a text string is to be transferred into a translation file, which will then be used in Online mode to enable switching into another national language, it must be delimited at the beginning and end by #.

Examples: "#Pump 1#" or else even "#Pump# 1".

The second case might for example in the event of multiple occurrences of the text Pump (Pump 1, Pump 2, etc.), prevent multiple appearances in the translation.

- If you include"%<PREFIX>" into the text, you can enter instead of "PREFIX" a certain string, which will serve as an identifier concerning the use of dynamic texts. The prefix will be used together with an ID number, which is to be defined in the 'Variables' category of the configuration dialog in field 'Textdisplay'. The combination references to a certain text, which is defined in a XML file available for this purpose and listing all possible dynamic texts. Thus at run time the text which is indicated by the current ID-Prefix-combination will be displayed. For further information see also the description of Language Switching ↳ *Chapter 1.4.3.8 “Language switching” on page 706*. See there also information on the usage of Unicode-Format.

The configured text will appear online in the prescribed alignment within the element: horizontally left, center or right and vertically top, center or bottom.

Via button *“Font”* the dialog for font selection will appear. Choose the desired font and confirm with OK. (The list of offered fonts depends on the target system.) The Standard-Font button can be used to assign the currently valid standard font to the element. That is defined in the visualization settings in category Display ↳ *Chapter 1.4.3.6.1 “'Extras' 'Settings'” on page 700*.

1.4.3.5.8 Textvariables

In category 'Textvariables' of the dialog for configuring visualization elements you can specify a variable which should dynamically set color and font of that string which is defined in category 'Text' ↳ *Chapter 1.4.3.5.7 “Text” on page 652*. At best enter the variable name with the aid of the input assistant (*[F2]*).

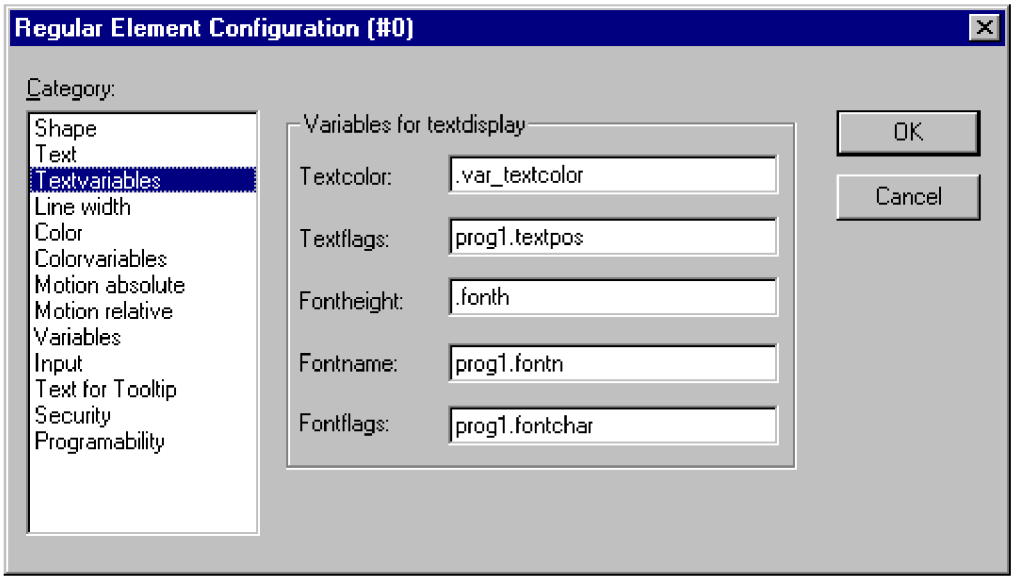
You can also use components of the structure VisualObjectType to set the text properties. For this see the description of category 'Programability' ↳ *Chapter 1.4.3.5.18 “Programmability” on page 665*; there you will find the possible values of the particular structure components and their effect.

If there are corresponding static definitions in category 'Text', these will be overwritten by the dynamic parameter values.

In case of multiple definition of an element property consider the specific order of precedence concerning according to which a value might be overwritten in online mode by another.

The parameters of the dialog:

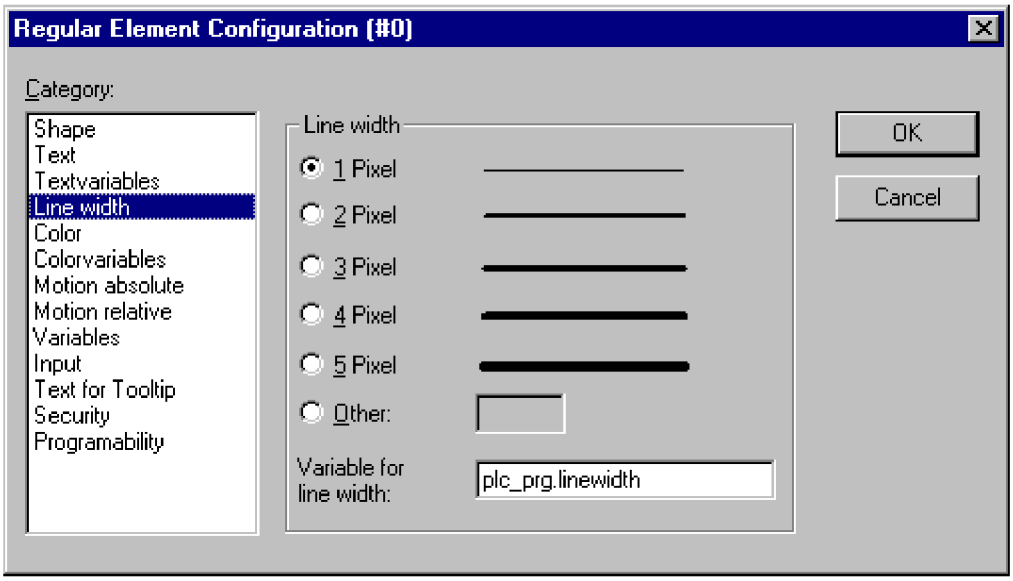
Parameter:	**Meaning:**	**Example entry of project variable:**	**Example Usage of variable in program:**	**corresponding component of structure VisualObjectType:**
Textcolor:	Text color	"plc_prg.var_textcolor"	var_textcolor=16#FF00FF -> Farbe	dwTextColor
Textflags:	Alignment (right, left, centered...)	"plc_prg.textpos"	textpos:=2 -> Text right justified	dwTextFlags
Fontheight:	Font height in Pixel	".fonth"	fonth:=16; -> Font height 16 pt	ntFontHeight
Fontname:	Font name	"vis1.fontn"	fontn:=arial; -> Arial is used	stFontName
Fontflags:	Font display (bold, underlined, italic...)	"plc_prg.fontchar"	fontchar:=2 -> Text will be displayed bold	dwFontFlags



1.4.3.5.9 Line width

In the dialog for configuring visualization elements, you can choose the line width for an element. As predefined options you find width settings from 1 to 5 pixel, additionally an other value can be entered manually (Other:), or a project variable (Variable for line width:) can be inserted. For the latter the input assistance (*[F2]*) can be used.

> *As soon as the parameter is additionally defined dynamically, i.e. by a structure variable, see category 'Programmability', the static setting will be overwritten in online mode* ↳ *Chapter 1.4.3.5.18 “Programmability” on page 665.*

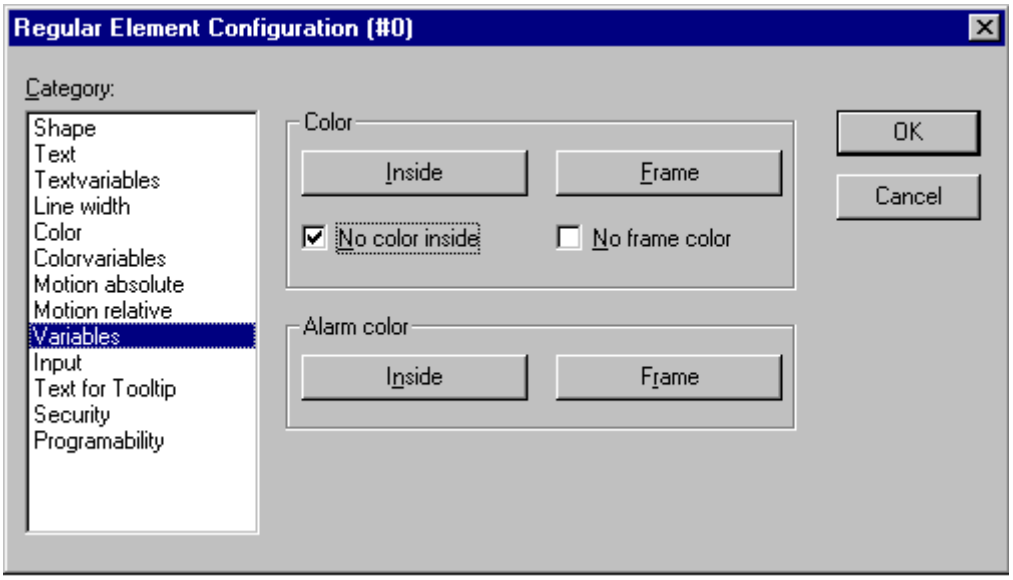


1.4.3.5.10 Colors

In the visualization element configuration dialog box, in the Color category you can select primary colors and alarm colors for the inside area and for the frame of your element. Choosing the options no color inside and no frame color you can create transparent elements.

As soon as the parameter is additionally defined dynamically by a variable, the static setting will be overwritten in online mode.

In case of multiple definition of an element property consider the specific order of precedence concerning according to which a value might be overwritten in online mode by another.



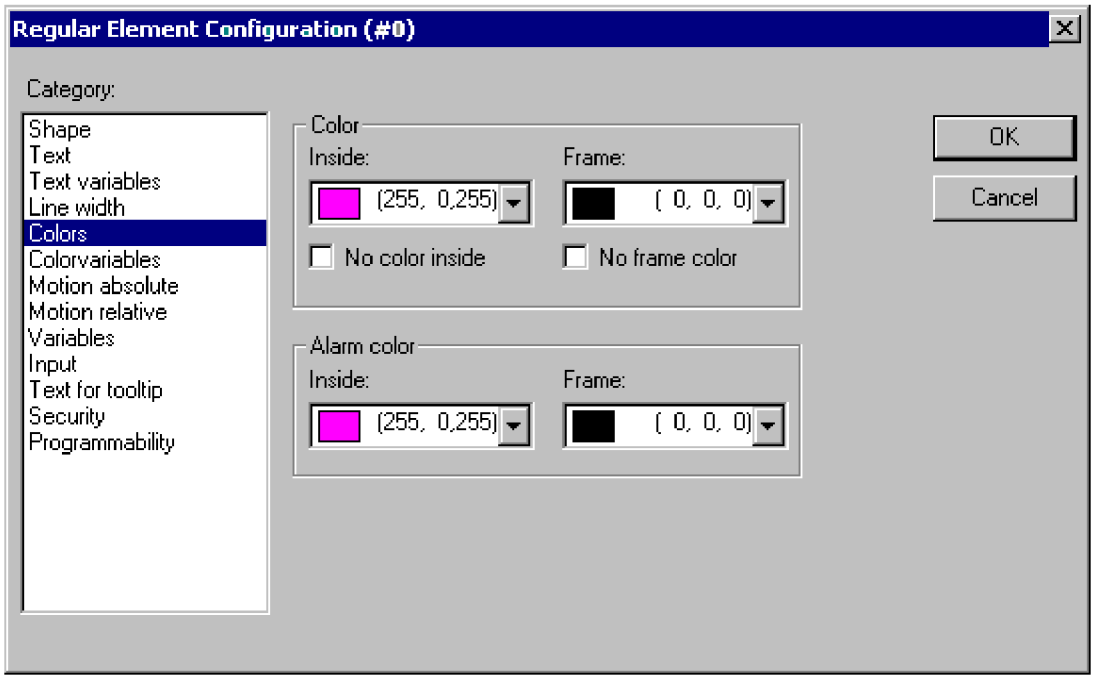
If you now enter a Boolean variable in the Variables category in the Change Color field, then the element will be displayed in the Color set, as long as the variable is FALSE. If the variable is TRUE, then the element will be displayed in its Alarm Color.

The change color function only becomes active, if the PLC is in Online Mode!

If you want to change the color of the frame, then press the Frame button, instead of the Inside button. In either case, the dialog box will open for selection of the color.

Here can to choose the desired hue from the primary colors and the user-defined colors. By pressing the Define Colors you can change the user-defined colors.

Depending on the target the dialog might offer only a restricted selection of colors. This can be reasonable for creating projects which are intended for target visualizations. In this case the colors are defined via selection lists.



1.4.3.5.11 Color variables

Here you can enter project variables (e.g. PLC_PRG.color_inside), which should determine the particular property in online mode: These property definitions also or additionally can be programmed with the aid of components of the structure VisualObjectType. Therefore see the description on the "Programmability" of a visualization element. There you will find a list of the possible values and their effects.

> *The variables, entered in the Color Variables dialog, in online mode will overwrite the static values given in the 'Color' category as well as corresponding values given by a structure variable.*

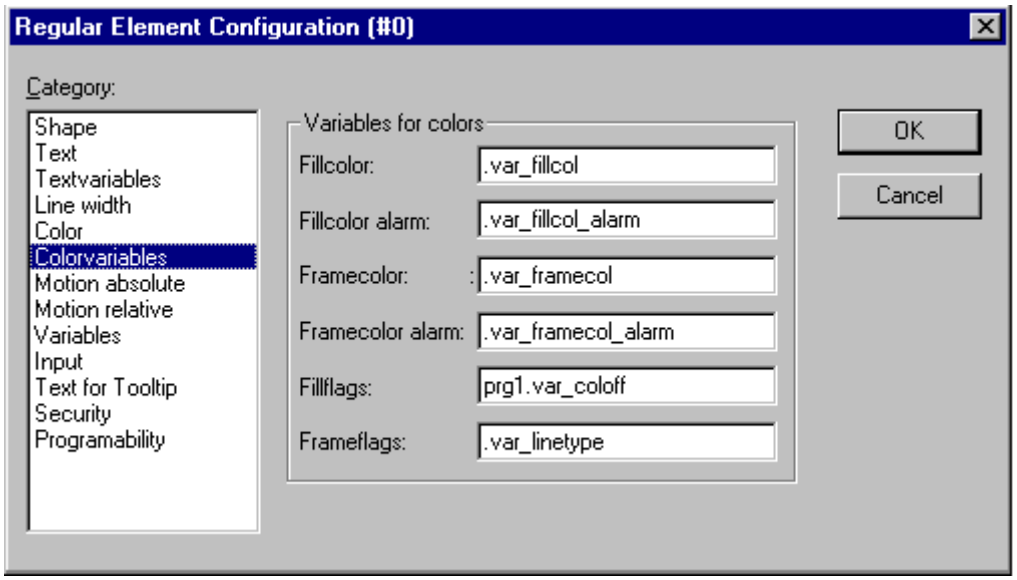
In case of multiple definition of an element property consider the specific order of precendence concerning according to which a value might be overwritten in online mode by another.

The parameters of the dialog:

Parameter	Description	Example of an entry	Example for using the variable in the program	corresponding component of structure VisualObjectType
Fillcolor:	fill color	"plc_prg.var_fillcol"	var_var_fillcol:=16#FF00FF -> fill color pink	dwFillColor
Fillcolor alarm:	fill color if the 'Change color' variable is TRUE (↳ *Chapter 1.4.3.5.10 “Colors” on page 656*)	"plc_prg.var_fillcol_a"	var_fillcol_a:=16#FF00FF -> alarm fill color pink	dwFillColorAlarm

Parameter	Description	Example of an entry	Example for using the variable in the program	corresponding component of structure VisualObjectType
Framecolor:	frame color	"plc_prg.var_framecol"	var_framecol::=16#FF00FF -> frame color pink	dwFrameColor
Framecolor alarm:	frame color if the 'Change color' variable is TRUE (*Chapter 1.4.3.5.10 "Colors" on page 656*)	"plc_prg.var_framecol"	var_framecol:=16#FF00FF -> alarm frame color farbe pink	dwFrameColorAlarm
Fillflags:	The current inside color configuration can be activated (FALSE) resp. deactivated (TRUE)	"plc_prg.var_col_off"	var_col_off:=1 -> the color definition for the fill color will not be regarded, that for the frame remains valid	dwFillFlags
Frameflags:	Display of the frame (solid, dotted etc.)	"plc_prg.var_linetype"	var_linetype:=2; -> frame will be displayed as dotted line	dwFrameFlags

Dialog Box for Configuring Visualization Elements (Category Colorvariables):



1.4.3.5.12 Motion absolute

In the visualization element configuration dialog box, in the Motion absolute category, X- or Y-Offset fields variables can be entered. These variables can shift the element in the X or the Y direction, depending on the respective variable value. A variable in the Scale field will change the size of the element linear to its current value. This value, which is used as scaling factor, will be divided by 1000 implicitely, so that it is not necessary to use REAL-variables in order to get a reduction of the element. The scaling always will refer to the balance point.

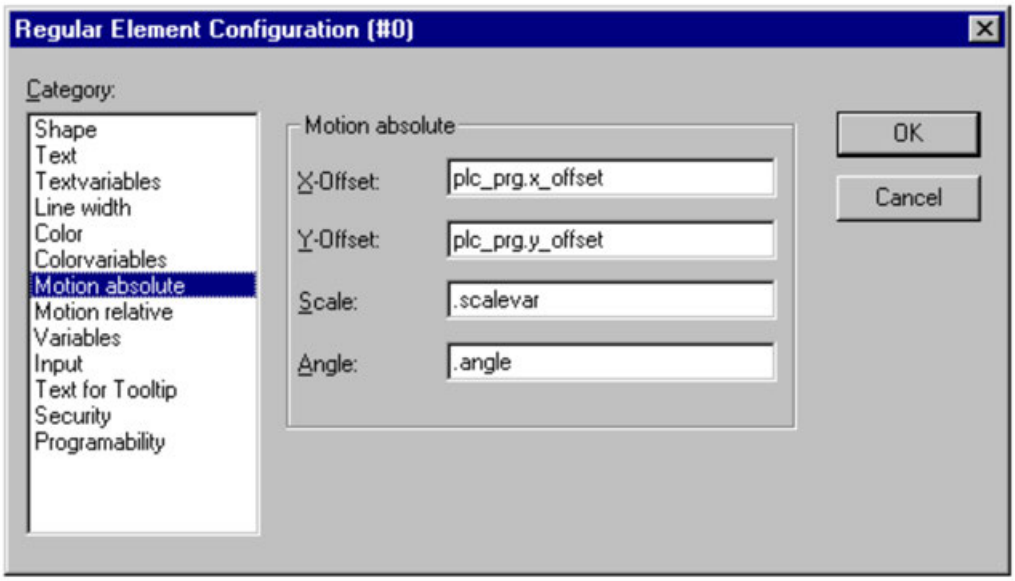
A variable in the Angle field causes the element to turn on its turning point, depending on the value of the variable. (Positive Value = Mathematic Positive = Clockwise). The value is evaluated in degrees. With polygons, every point rotates; in other words, the polygon turns. With all other elements, the element rotates, in such a way, that the upper edge always remains on top.

The turning point appears after a single click on the element, and is displayed as a small black circle with a white cross. You can drag the turning point with a pressed left mouse button.

> *In online mode the variables which are set in the 'Motion absolute' dialog will override the values of structure components which additionally might be used to define the same property ('Programability').*

In case of multiple definition of an element property consider the specific order of precedence concerning according to which a value might be overwritten in online mode by another.

Visualization Element Configuration Dialog Box (Motion Absolute Category)



1.4.3.5.13 Motion relative

In the dialog for configuring visualization elements in the Motion Relative category, you can assign variables to the individual element edges. Depending on the values of the variables, the corresponding element edges are then moved. The easiest way to enter variables into the fields is to use the Input Assistant (*[F2]*).

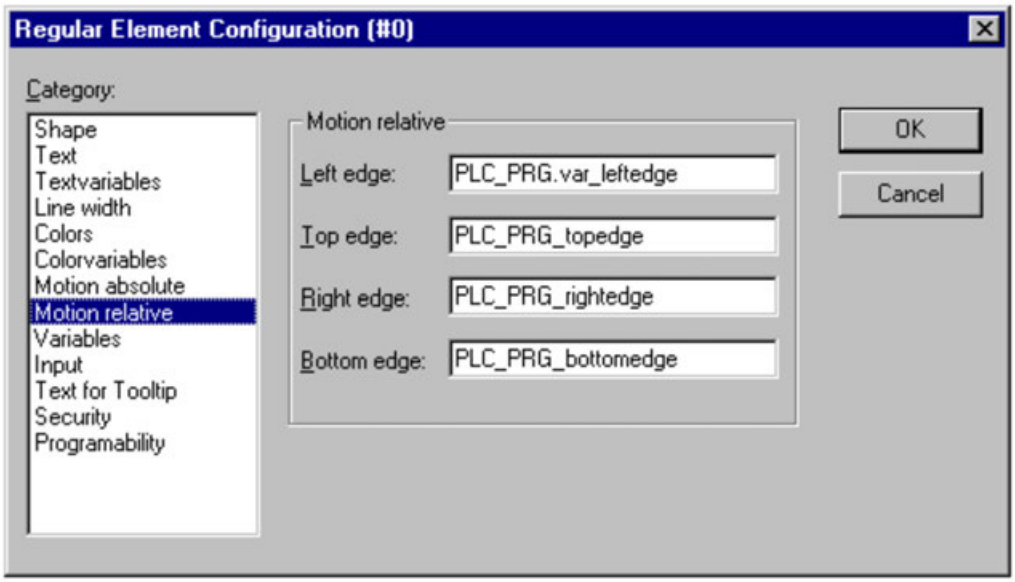
The four entries indicate the four sides of your element. The base position of the corners is always at zero. A new value in the variables, in the corresponding column, shifts the boundary in pixels around this value. Therefore, the variables that are entered ought to be INT variables.

> *Positive values shift the horizontal edges downward, or, the vertical edges, to the right!*

> *In online mode the variables which are set in the 'Motion absolute' dialog will override the values of structure components which additionally might be used to define the same property ('Programmability').*

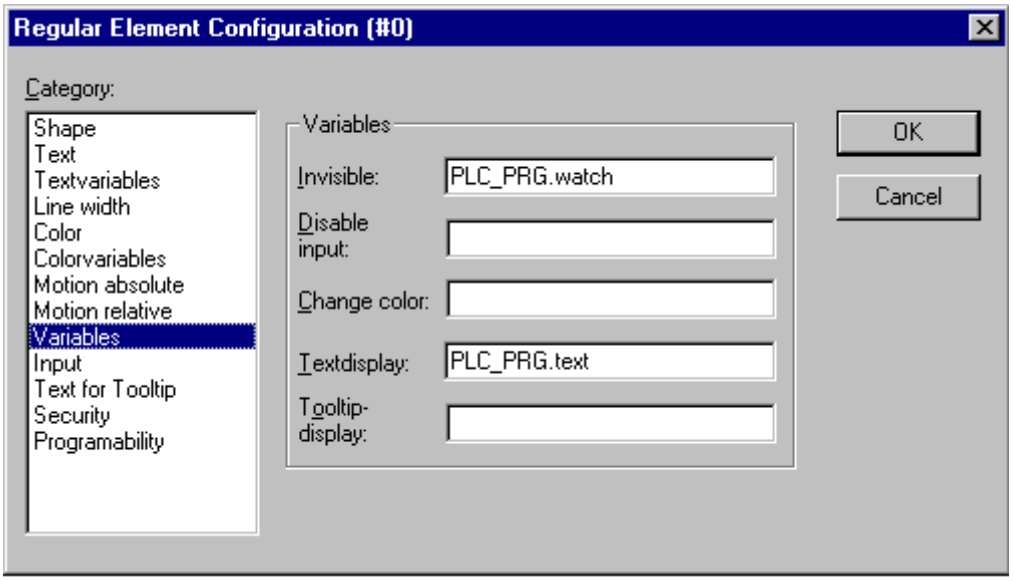
In case of multiple definition of an element property consider the specific order of precedence concerning according to which a value might be overwritten in online mode by another.

Dialog Box for Configuration of Visualization Elements (Motion Relative Category)



1.4.3.5.14 Variables

Visualization Element Configuration Dialog Box (Variables Category):



You can enter the variables that describe the status of the visualization elements in the Variable category within the dialog box for configuring visualization elements. The simplest way to enter variables in the fields is to use the Input Assistant.

> *In online mode the variables which are set in the 'Motion absolute' dialog will override the values of structure components which additionally might be used to define the same property ('Programmability').*

In case of multiple definition of an element property consider the specific order of precedence concerning according to which a value might be overwritten in online mode by another.

You can enter Boolean variables in the Invisible and Change color fields. The values in the fields determine their actions. If the variable of the Invisible field contains the value FALSE, the visualization element will be visible. If the variable contains the value TRUE, the element will be invisible.

Disable input: If the variable entered here is TRUE, all settings of category 'Input' will be ignored.

Change color: If the variable which is defined in this field, has the value FALSE, the visualization element will be displayed in its default color. If the variable is TRUE, the element will be displayed in its alarm color.

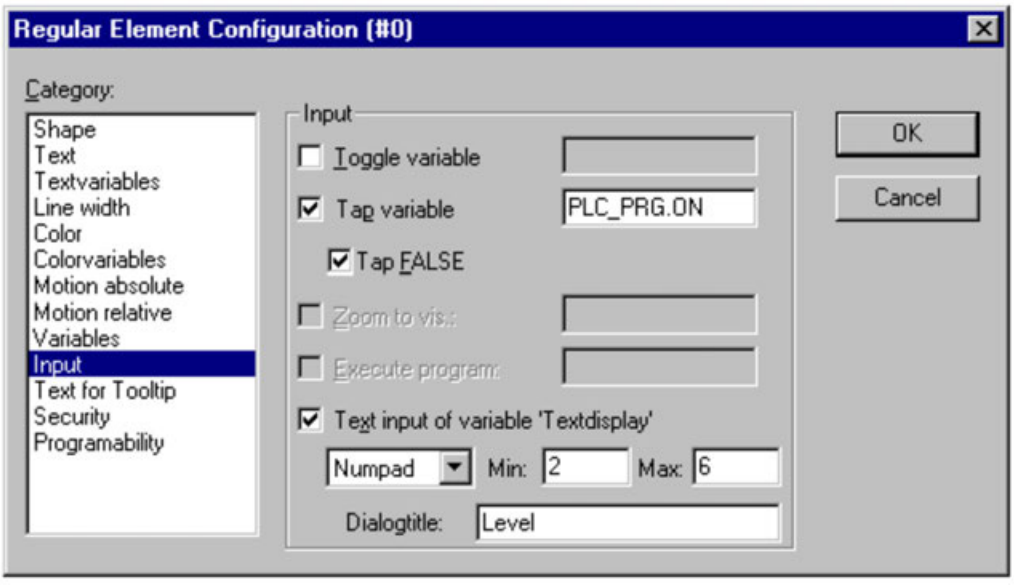
Textdisplay:

- If you have inserted a "%s" in the Content field of the Text category or if you have included "%s" in the textstring, then the value of the variable which is defined in 'Textdisplay' will be displayed in online mode in the visualization object. "%s" will be replaced by the value.
- If you have inserted resp. included a "%<PREFIX>" in the Content field of the Text category ("PREFIX" must be a sequence of letters), then the variable resp. the numeric value which is entered here in 'Textdisplay' will be interpreted as an ID, which in combination with the prefix serves as a reference on a text, which is described in a XML file. This text will be displayed in online mode instead of "%<PREFIX>" in the visualization object. Thus a dynamic modification of the text display is possible.
- If you want to edit the value of the variable in Online mode using the keyboard, you can do this via the 'Text input of variable' 'Textdisplay' in the Input category.

Tooltip-display: Here you can enter a string or a variable of type STRING, which defines the ID for a dynamic tooltip text. In combination with a prefix to be defined in category 'ToolTip' uniquely a certain text in a dynamic textlist can be called to be displayed as tooltip ↬ *Chapter 1.4.3.5.16 "Text for ToolTip" on page 664*. Thus dynamic text switching resp. language switching is also possible for tooltip texts.

1.4.3.5.15 Input

Dialog for configuring the visualization elements (Category Input):



Toggle variable: If this option is activated, in online mode you will toggle the value of the variables which are located in the input field by each mouse click on the visualization element. You can obtain input assistance for data entry via *[F2]*. The value of the Boolean variable changes with each mouse click from TRUE to FALSE and then back to TRUE again at the next mouse click, etc.

Tap Variable: If this option is activated, in online mode you can switch the value of the Boolean variable which is located in the input field, between TRUE and FALSE. Place the mouse cursor on the element, press the mouse-key and hold it depressed. If option Tap FALSE is activated, the value is set to FALSE as soon as the mouse key is pressed, otherwise it is set to TRUE at this moment. The variable changes back to its initial value as soon as you release the mouse key.

Zoom to Vis...: If this option is activated, you can enter in the edit field the name of a visualization object of the same project to which you want to jump by a mouse-click on the element in online mode. In this case always first the window of the target visualization will be opened before that of the current one will be closed.

The following entries are allowed:

- The name of a visualization object of the current project (see Object Organizer)
- If a visualization reference that contains placeholders is to be jumped to, the placeholders can be directly replaced by variable names or text when called up ↬ *Chapter 1.4.3.5.2 “Placeholder” on page 647*. For this pupose, conform to the following syntax:
  <Visuname>(<Placeholder1>:=<Text1>, <Placeholder2>:=<Text2>,..., <Placeholder n>:=<Textn>).
  Example:
  Calling the visualization visu1, whereby the placeholders var_ref1 and var_ref2 used in visu1 are replaced by the variables PLC_PRG.var1 and PROG.var1 respectively:
  visu1(var_ref1:=PLC_PRG.var1, var_ref2:=PROG.var1)
- If a program variable of the type STRING (e.g. PLC_PRG.xxx) has been entered instead of a visualization object, then this variable can be used to define the name of the visualization object (e.g. ‚visu1') which the system should change to when a mouse click occurs (e.g. xxx:= ‚visu1).
- If you issue the command „ZOOMTOCALLER" in the Zoom to vis. field, a backward jump into the calling visualization is achieved in Online mode by a mouse click on the element, if such a constellation was configured.

The implicit variable CurrentVisu (type STRING, for implicit (system) variables see here) describes the name of the currently opened visualization object. For example it can be used in the application to control which visualization should be opened resp. to see which is the currently opened.

Note: with compiler version < V2.3.7.0, and if the library SysLibStr.lib is not included in the project, this will only work if the names of the visualization objects are defined in capital letters.

Example: CurrentVisu:='PLC_VISU';

Execute program: If this option is activated you can enter ASSIGN- or special "INTERN"-commands in the input field, which will be executed in online mode as soon as you perform a mouse-click on the element. Press button "..." to get the dialog Configure programs where you can select the desired commands (Add) and arrange them in the desired order (Before, After).

This feature especially is important if the visualization will be the only operating interface of a system (pure operating version).

Text input of variable 'Textdisplay': If this option is activated, in online mode you can enter text in an edit field in this visualization element. This value upon pressing *[Enter]* will be written to the variable that appears in the textdisplay field of the 'Variables' category.

If option Hidden is activated, the text will be replaced by asterisks ("***") in the online display of the visualization element.

Select in the scroll box which kind of input should be possible later in online mode

Text: An edit field will open, where you can enter the value.

Numpad resp. Keypad: A window will open showing an image of the numeric resp. alphabetic keypad, where you can enter a value by activating the appropriate key elements. This might be useful if the visualization must be operatable via a touch screen. The range of valid input values can be restricted by defining a minimum and a maximum value in the edit fields 'Min' and 'Max'.

> *In case of using target visualization regard the possibility to get information on user inputs via mouse-clicks by special interface functions and to use that directly in the project.*

In case of multiple definition of an element property consider the specific order of precedence concerning according to which a value might be overwritten in online mode by another.

1.4.3.5.16 Text for ToolTip

The dialog Text for Tooltip offers an input field for text which appears in a text field as soon as the mouse cursor is passed over the object in online mode. The text can be formatted with line breaks by using the key combination *[Ctrl] + [Enter]*.

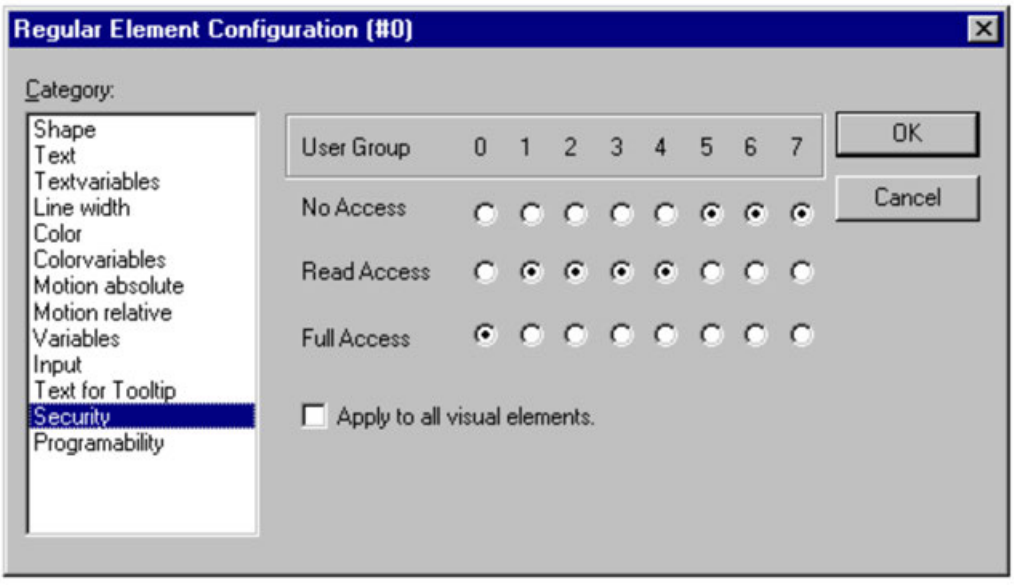
Dynamic language switching

If in field 'Content' you enter "%<PREFIX>" instead of a fix text string, "PREFIX" can be any string which serves as an identifier for the usage of dynamic texts. The prefix will be used in combination with an ID, which is to be specified in category 'Variables' in field 'Tooltip-display'. The combination prefix-ID references uniquely a certain text which is defined in a special language file in xml-format. Thus at run time always that text will be displayed which corresponds to the currently valid combination of prefix and ID. For further information see the description of the dialog 'Settings', category 'Language', and the help pages on Language Switching in the Visualization ↳ *Chapter 1.4.3.8 “Language switching” on page 706*.

Concerning the usage of Unicode format please also see the pages on Language Switching in the Visualization.

1.4.3.5.17 Security

It might be useful that different user groups get different operating possibilities and display of a visualization. This can be reached by assigning different access rights concerning particular visualization elements. You can do this for the eight user groups ↳ *Chapter 1.4.1.2.4.12 “'Project' 'Object properties'” on page 261* ↳ *Chapter 1.4.1.2.3.43 “'Project' 'Passwords for user groups'” on page 250*. The access rights can be assigned by activating the appropriate option in the configuration dialog 'Access rights' for a visualization element:



Access right	Effect in online mode
No Access	Element will not be visible
Read Access	Element will be visible but not operatable (no inputs allowed)
Full Access	Element is not visible and not operatable

If you want to assign the access rights also to all other elements of the visualization object, activate option 'Apply to all visual elements'.

Please regard, that the access rights which are set for the visualization object in the 'Project''Object' 'Properties' dialog, are independent on those of the particular visualization elements!

1.4.3.5.18 Programmability

Programability The properties of an visualization element can not only be defined by a static setting or by a "normal" project variable, but also by the components of a structure variable, which is exclusively used for programming visualization elements.

For this purpose the structure VisualObjectType is available in the library SysLibVisu.lib. Its components can be used to define most of the element properties.

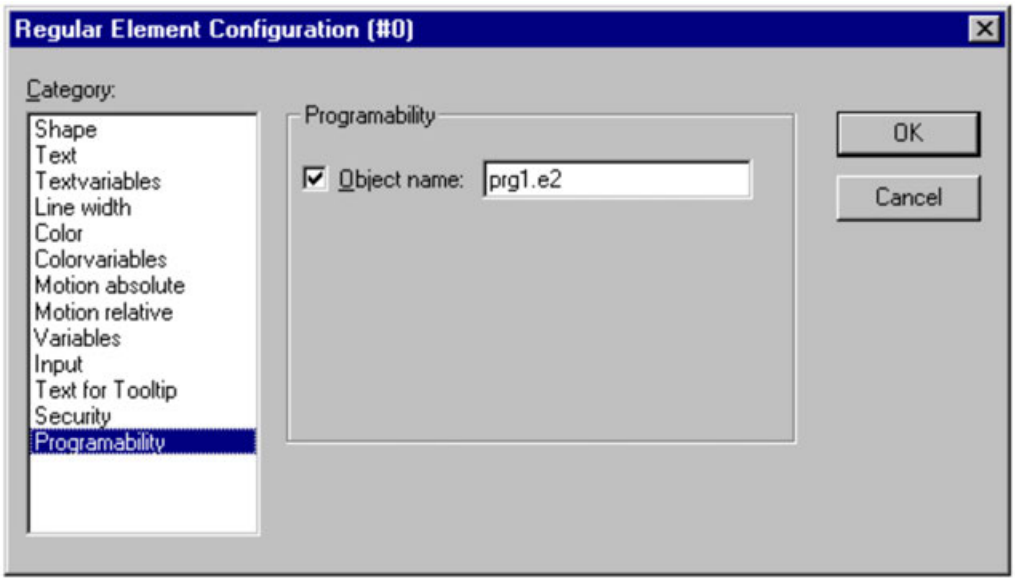
In case of multiple definition of a element property the value of the "normal" project variables will overwrite that of the structure variable and both will overwrite a static definition.

In order to configure the element properties by using a structure variable, do the following:

Open the configuration dialog, category 'Programmability' and enter a new, unique (!) variable name in the field 'Object Name'. For this purpose you must activate the option by a mouse-click in the checkbox. The variable automatically will be declared with type 'VisualObjectType', a structure which is contained in the library 'SysLibVisu.Lib'. The declaration is done implicitely and not visible for the user. Make sure that the library is included in the library manager.

After the next compile the newly assigned structure variable will be available in the project. (Hint: Activate the Intellisense functionality 'List components' in the project options, category Editor, in order to get the structure components in a selection list as soon as the variable name followed by a dot is entered).

Example: If you have defined a Object Name "visu1_line" for a visualization element, then you can program the line width of this element by e.g. "visu1_line.nLIneWidth:=4".



The structure VisualObject-Type

The following table will show you all components of the structure and references to the corresponding items in the different categories of the configuration dialog:

At the beginning of the component name the data type is integrated:

- n INT
- dw DWORD
- b BOOL
- st STRING

Component (+Data type)	Effect	Example (the Object Name "vis1" has been defined for the element)	corresponding entries in configuration dialog:
nXOffset : INT;	Shift element in X-direction	vis1.nXOffset:=val2; (element is set to position X=val2)	- Cat. Motion absolute: X-Offset
nYOffset : INT;	Shift element in Y-direction	vis1.nYOffset:=22; (element is set to position Y=val2)	- Cat. Motion absolute: Y-Offset
nScale : INT;	Change of the size	vis1.nScale:=plc_prg.scale_var; (element size changes linear with change of value of plc_prg.scale_var)	- Cat. Motion absolute: Scaling
nAngle : INT;	Rotating element around its center	vis1.anglevar:=15; (element rotates clockwise by 15)	- Cat. Motion absolute: angle
bInvisible : BOOL;	Element is visible / invisible	vis1.visible:=TRUE; (element is invisible)	- Cat. Color: No color inside + No frame color - Cat. Colorvariables: Fillcolor + Framecolor

Component (+Data type)	Effect	Example (the Object Name "vis1" has been defined for the element)	corresponding entries in configuration dialog:
stTextDisplay : STRING;	Text is displayed in element	vis1.TextDisplay:='ON / OFF'; element is inscribed with this text	- Cat. Text: entry at 'Content'
bToggleColor : BOOL;	color change when toggling between TRUE and FALSE	vis1.bToggleColor:=alarm_var; As soon as alarm_var gets TRUE, the element gets the color defined via the components dwFillColorAlarm, dwFrameColorAlarm resp. via the settings in category 'Colorvariables' or 'Color'.	- Cat. Input: Toggle variable + - Cat. Variables: Change color
bInputDisabled: BOOL;	if FALSE: Inputs in category 'Input' are ignored	vis1.bInputDisabled:=FALSE; (no input is possible for this elementt)	- Cat. Variables: 'Disable Input'
stTooltipDisplay:STRING;	Text of the tooltip	vis1.stTooltipDisplay:='Switch for .....';	- Cat. Text for Tooltip: Entry in 'Content:'
dwTextFlags:DWORD;	Text position: 1 left justified 2 right justified: 4 centered horizontally 8 top 10 bottom 20 centered vertically Note: Always set a horizontal and a vertical position (addition of values)!	vis1.dwTextFlags:=24; (Text will be placed in the center of the element (4 + 20)	- Cat. Text: Horizontal and Vertical options - Cat. Textvariables: Textflags
dwTextColor : DWORD;	Text color (definition of colors see subsequent to this table)	vis1.dwTextColor := 16#00FF0000; (Text is blue-colored)	- Cat. Text: Font | Color - Cat. Textvariables: Textcolor
nFontHeight : INT;	Font height in Pixel should be in range 10-96	vis1.nFontHeight:=16; (Text height is 16 pt)	- Cat. Text: Font | Grad - Cat. Textvariables: Font heigth

Component (+Data type)	Effect	Example (the Object Name "vis1" has been defined for the element)	corresponding entries in configuration dialog:
dwFontFlags : DWORD;	Font display. Available flags: 1 italic 2 fett 4 underlined 8 canceled + combinations by adding values	vis1.dwFont-Flags:=10; (Text is displayed blue and canceled)	- Cat. Text: Schrift | Schriftschnitt - Cat. Textvariables: Fontflags
stFontName : STRING;	Change font	vis1.stFontName:=’Arial’; (Arial is used)	- Cat. Text: Schrift | Schriftart - Cat. Textvariables: Fontname
nLineWidth : INT;	Line width of the frame (pixels)	vis1.nLWidth:=3; (Frame width is 3 Pixels)	- Cat. Line width
dwFillColor : DWORD;	Fill color (definition of colors see subsequent to this table)	vis1.dwFill-Color":=16#00FF0000; (Element ist im "Normalzustand" blau)	- Cat. Color: Color | Inside - Cat. Colorvariables: Inside
dwFillColorAlarm : DWORD;	Fill color as soon as bToggleColor gets TRUE, see above) (definition of colors see subsequent to this table)	vis1.dwFillColorAlarm:=16#00808080; (as soon as Variable togglevar gets TRUE, the element will be displayed grey-colored)	- Cat. Color: Alarm color | Inside - Cat. Colorvariables: Inside Alarm
dwFrameColor: DWORD;	Frame color (definition of colors see subsequent to this table)	vis1.dwFrame-Color:=16#00FF0000; (Frame is blue-colored)	- Cat. Color: Color | Frame - Cat. Colorvariables: Frame
dwFrameColorAlarm: DWORD;	Fill color as soon as bFrameColor gets TRUE, see above (definition of colors see subsequent to this table)	vis1.dwFrameColorAlarm:=16#00808080; (as soon as Variable vis1.bToggle-Color gets TRUE, the frame will be displayed grey-colored)	- Cat. Color: Alarm color | Frame - Cat. Colorvariables: Frame Alarm

Component (+Data type)	Effect	Example (the Object Name "vis1" has been defined for the element)	corresponding entries in configuration dialog:
dwFillFlags: DWORD;	Color, as defined by the color variables, can be displayed or ignored 0 = show color >0 = ignore setting	vis1.dwFillFlags:=1; (element gets invisible)	- Cat. Color: No color inside + No frame color - Cat. Colorvariables: Fillflags
dwFrameFlags: DWORD;	Display of frame: 0 full 1 dashed (---) 2 dotted ( ) 3 dash-point (_._._) 4 dash-point-point (_.._..) 8 blind out line	vis1.FrameFlags:=1; (Frame will be displayed as dashed line)	- Cat. Colorvariables: Frameflags

Defining color values

Example: e1.dwFillColor := 16#00FF00FF;

A color is entered as a hex number which is composed of the Blue/Green/Red (RGB) components. The first two zeros after "16#" should be set to in each case, to fill the DWORD size. For each color value 256 (0-255) colors are available.

- FF Blue component
- 00 Green component
- FF Red component

Example for a blinking visualization element

Define a global variable 'blink1' of type VisualObjectType in the configuration of a rectangle. In a program of function block the value of a component of the structure can be modified.

```
PROGRAM PLC_PRG
VAR
n:INT:=0;
bMod:BOOL:=TRUE;
END_VAR
(* Blinking element *)
n:=n+1;
bMod:= (n MOD 20) > 10;
IF bMod THEN
blinker.nFillColor := 16#00808080; (* Grau *)
ELSE blinker.nFillColor := 16#00FF0000; (* Blau *)
END_IF
```

1.4.3.5.19 Bitmap

You can do the following settings in category 'Bitmap' in the visualization element configuration dialog box:

Specify, which image file should be used. This specification can be static or dynamic. If there are entries both in the 'Bitmap' field and in the 'Bitmap Variable' field, then that in the 'Bitmap' field will be ignored:

Bitmap: Static definition: You can enter the path of an image file available in the local file system. Via button ... the standard dialog for browsing for a file will be opened, where you can select the desired file.

Bitmap variable: Dynamic definition: A project variable of type STRING can be entered here, containing the name of the image file currently to be used. This allows dynamic change of images in online mode, but only works with image files which are entered in the project-global "bitmap list" ↯ *Chapter 1.4.3.7.1 “'Extras' 'Bitmap list'” on page 706*. The string-variable always only must get assigned the file name, even if there is a full path specified in the bitmap list.

See in the following example 'stBitmap' as string-variable, which is got assigned various image files that are part of the global bitmap list.

```
CASE nId OF
0: stBitmap := 'background.bmp';
1: stBitmap := 'deutest.bmp';
2: stBitmap := 'alarm.bmp';
END_CASE
```

If stBitmap e.g. is declared in object PLC_PRG, it can be entered here in the configuration dialog in field 'Bitmap variable' like follows: "PLC_PRG.stBitmap".

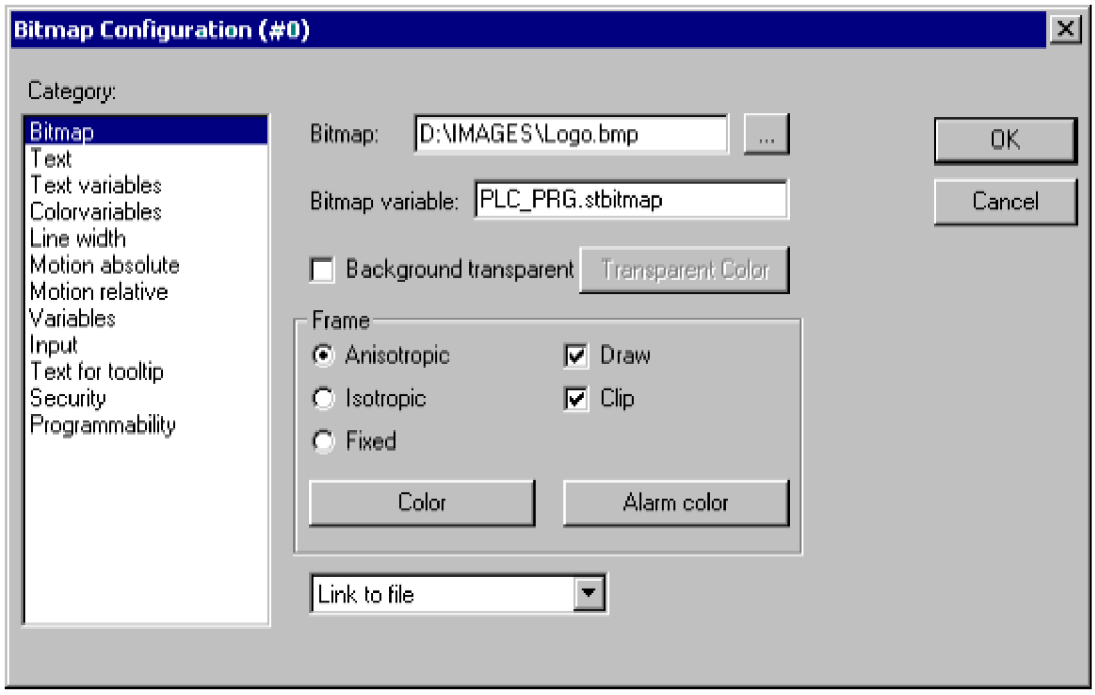
The following entries affect the frame of the bitmap:

By selecting Anisotropic, Isotropic or Fixed you specify how the bitmap should react to changes in the size of the frame. Anisotropic means that the bitmap remains the same size as the frame which allows you to change the height and width of the bitmap independently. Isotropic means that the bitmap retains the same proportions even if the overall size is changed (i.e., the relationship between height and width is maintained). If Fixed is selected, the original size of the bitmap will be maintained regardless of the size of the frame.

If the Clip option is selected together with the Fixed setting, only that portion of the bitmap that is contained within the frame will be displayed.

If you select the Draw option, the frame will be displayed in the color selected in the Color and Alarm color buttons in the color dialog boxes (standard or target-specific options). The alarm color will only be used if the variable in the Change Color field in the Variable category is TRUE.

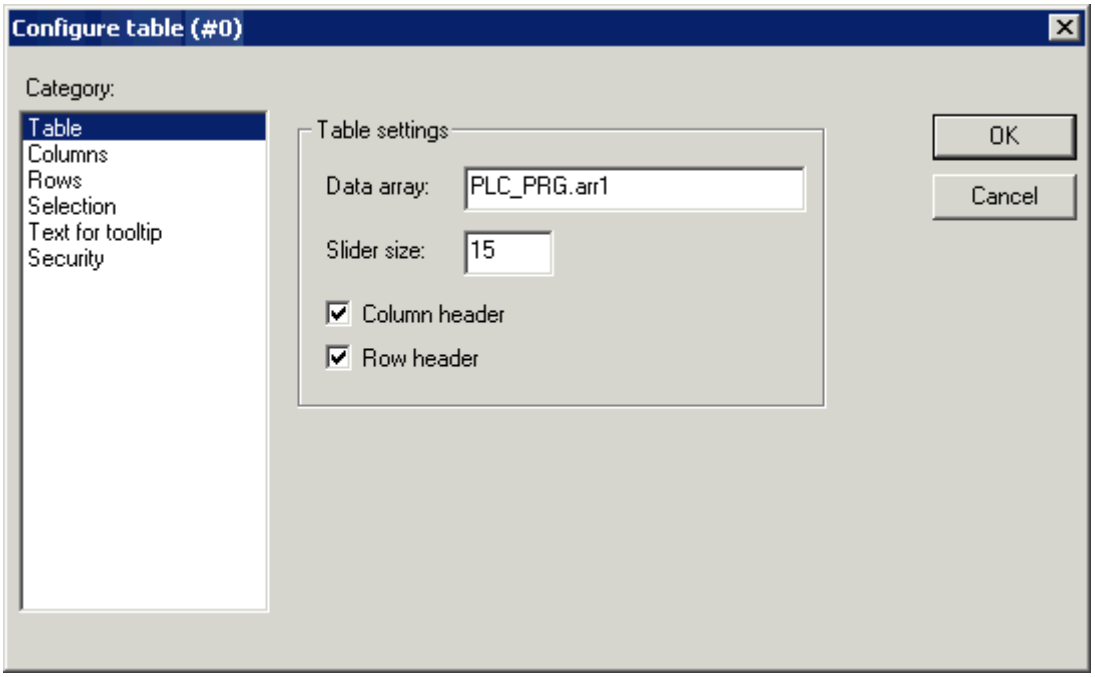
In the selection list in the lower part of the dialog you can define whether the bitmap should be inserted in the project (Embed) or whether just a link to an external bitmap-file (path as entered above in the 'Bitmap' field) should be created (Remember the link). It is reasonable to keep the bitmap file in the project directory, because then you can enter a relative path. Otherwise you would enter an absolute path and this might cause problems in case you want to transfer the project to another working environment.



1.4.3.5.20 Table

As soon as a table is inserted for the purpose of visualization of an array, the dialog Configure Table will be opened. Besides the categories 'Tooltip' and 'Security' which are also available for other visualization elements, the following categories will be available for configuring display and contents of the table.

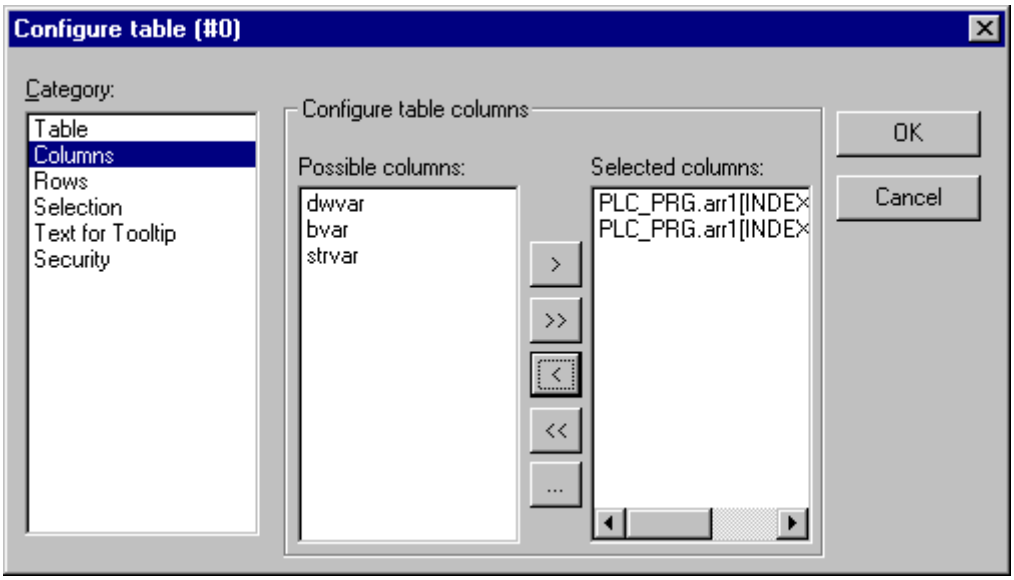
Category table:



Do the following table settings:

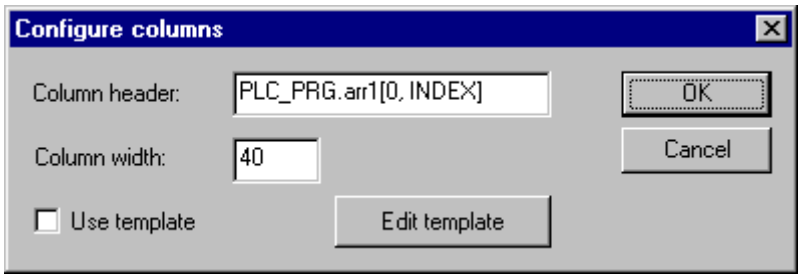
- Data array: Insert the name of an array which should be visualized in the table. It is recommended to use the input assistant (<F2>) resp. the Intellisense function.
- Slider size: Insert here the desired height of the slider which will appear at the bottom of the table element if the display of the array columns exceeds the element width.
- Column header, Line header: Activate these options if you want to get displayed the titles in the table. The line title reflects the array index (first column of the table), the column title can be defined in category 'Columns'.

Category columns:



Here you define the table elements. In the left window you get al list of all elements, which are handled in the array per index. In case of an array of a structure these would be the structure components.

Using the arrow button > you can transfer a selected component from the left window to the right window where you define the set of elements to be displayed in the table. Pressing button >> all elements will be transferred at a single blow. In the same manner you can remove elements from an already defined set (<, <<). In order to modify the default settings concerning the display of the table column for one of the elements, perform a double-click on the desired entry in the right part of the window, or press button '...' to open the dialog 'Configure columns':



Editing the column header and the column width:

Initially the edit field Column header will contain an automatically created title (e.g. "PLC_PRG.arr1[INDEX].iNo" in case of an array of structure for the column representing the structure component "iNo") which you can change. Further on the Column width (number of characters) can be set.

Editing configuration parameters for all elements of a column:

By default the table fields are displayed as simple rectangles and the entries are not editable. If you however activate button Edit template for the currently marked column, you can modify the parameters of the fields of this column, e.g. the line width, text input etc. The template affects all fields of the current column and can be edited via the known configuration dialog for a visualization element.

If you want to configure only one or several particular fields of the column, you can use the following placeholders determining the desired row and column: $ROWCONST$, $COLCONST$, INDEX. (INDEX has the same effect as $ROWCONST$).

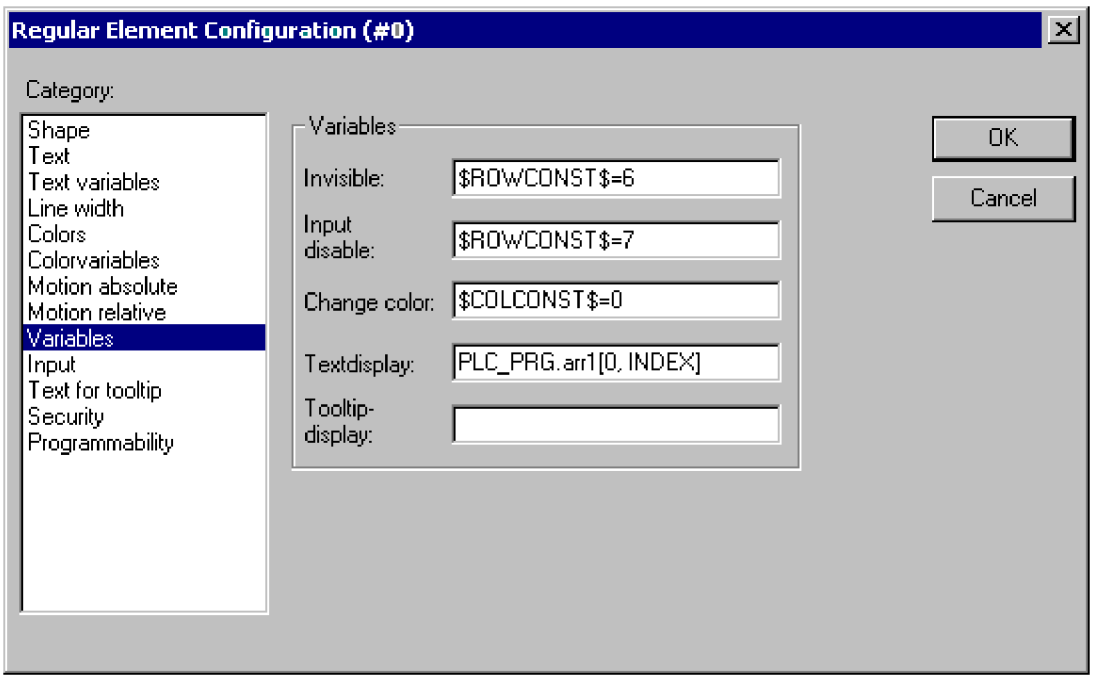
Examples for the use of placeholders in column-templates:

Example 1:

You visualize an array "arr1 [0..2] of BOOL" (table with 1 column) and you want, that in online mode by a mouse-click on a table cell the cell gets red-colored and the corresponding array element will be toggled and vice versa. To reach this activate 'Use template' in the configuration dialog for the column and define the template as follows: Category 'Input', Action 'Toggle variable': "PLC_PRG.arr1[INDEX]. Category 'Colors': Alarm color red. Category 'Variables', Action 'Change color': "PLC_PRG.arr1[INDEX].

Example 2:

The following template configuration has been created for a table column representing Index "0" of an array:



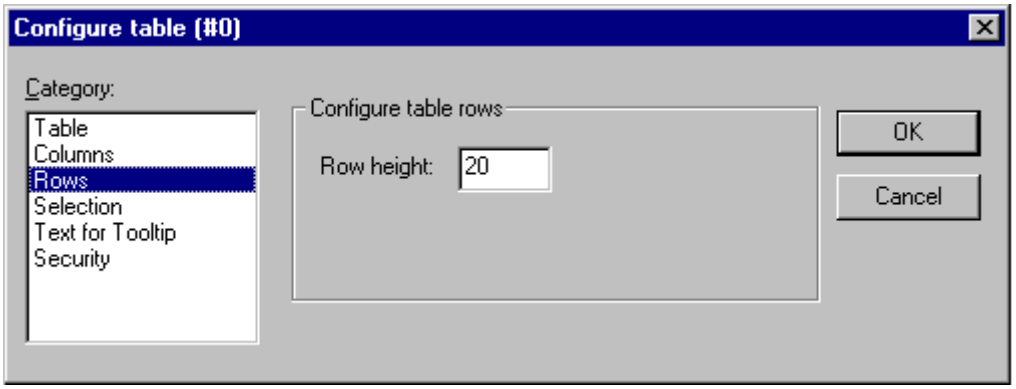
Meaning: For the concerned table column...

- the field in line 6 (line number, index) is invisible.
- in the field in line 7 no edit field can be opened.
- in all fields of column 0 the color will change to alarm color. The other fields of the column remain in base color.
- always entered automatically, but of course changeable, is the textdisplay configuration, which combined with the "%s" entry in category "Text" effects that the corresponding variable value will be displayed in the table field.

The placeholder entries can be connected with "AND" resp. "OR"; Example: "$ROWCONST$=1 OR $ROWCONST$=3" makes that both fields will get the respective setting.

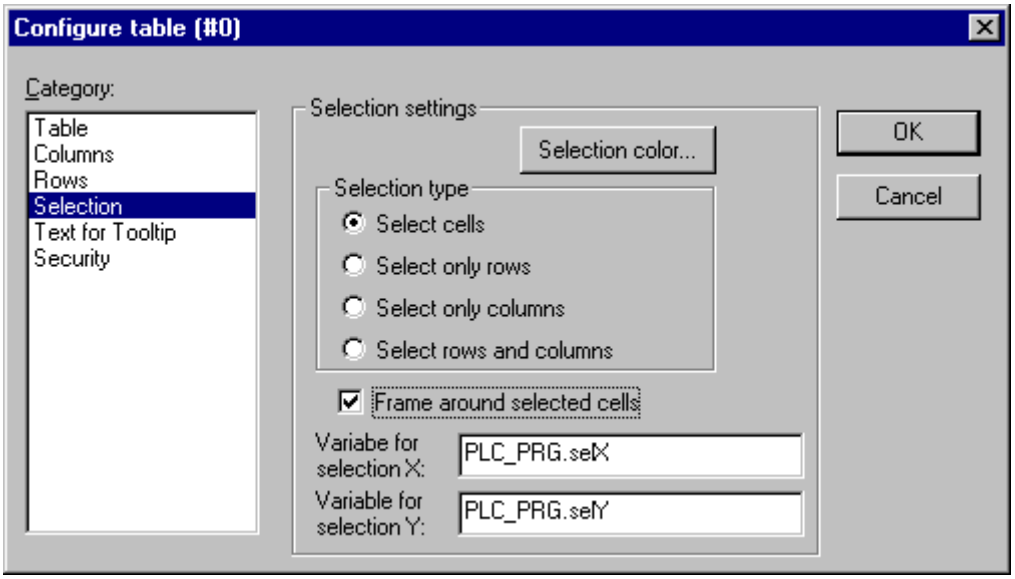
The use of the currently configured template can be activated or deactivated: Option Use template.

Category rows:



Row height: Insert the desired height in number of pixels.

Category selection:



Here you can set the following parameters concerning the selection behavior within the table:

- Selection color: Press this button to define a color for selected cells. You get the standard dialog for choosing a color or a color selection list.
- Selection type: Define which part of the table will be selected when you perform a mouse-click on one of the table fields in online mode:
  - Select single cells: Only the cell will be selected.
  - Select only rows: The whole line will be selected.
  - Select only columns: The whole column will be selected.
  - Select rows and columns: The whole column and line will be selected.
- Frame around selected cells: A selected cell gets surrounded by a frame.
- Variable for selection X, Variable for selection Y: Here you each can enter a project variable, which will indicate the X- resp. Y-Index of the selected table cell.

Example: Create a table element visualizing the array of a structure

```
TYPE strucTab :
STRUCT
iNo: INT; bDigi : BOOL; sText:STRING; byDummy: BYTE;
END_STRUCT END_TYPE
```

In PLC_PRG define the following array:

```
arr1:ARRAY [1..5] OF strucTab;
```

and the following variables:

```
selX:INT;
```

```
selY:INT;
```

Create a visualization object and insert a table element. Configure like follows:

Cat. Table: data array: "PLC_PRG.arr1"

Cat. Columns: Transfer the components iNo, bDigi, sText to the right window - In the right window perform a double-click on the first entry (PLC_PRG.arr1[INDEX].iNo) and in the dialog which will open, replace the default title by "Number". Confirm with OK and also define new column titles for the other two entries (e.g. "Value" and "Text").

Cat. 'Selection': Enter here at 'Variable Selection X': "PLC_PRG.selX" and at Variable Selection "Y: PLC_PRG.selY". Activate option 'Frame around selected cells'. Press button 'Selection color' and choose color 'yellow'. Close the configuration dialog with OK. The table element now should be displayed as shown in the following:

	Number	Value	Text
1			
2			
3			
4			
5			

At the left border the numbers of the array index, at the top the titles of the selected structure components. You can modify the column widths by placing the cursor on the separator between two columns and moving the mouse as soon as the cursor appears as a horizontal double-arrow. .

In online mode the current values of the array elements will be displayed in the table cells. As soon as you select a table cell by a mouse-click, it will get yellow-colored and surrounded by a frame. Example:

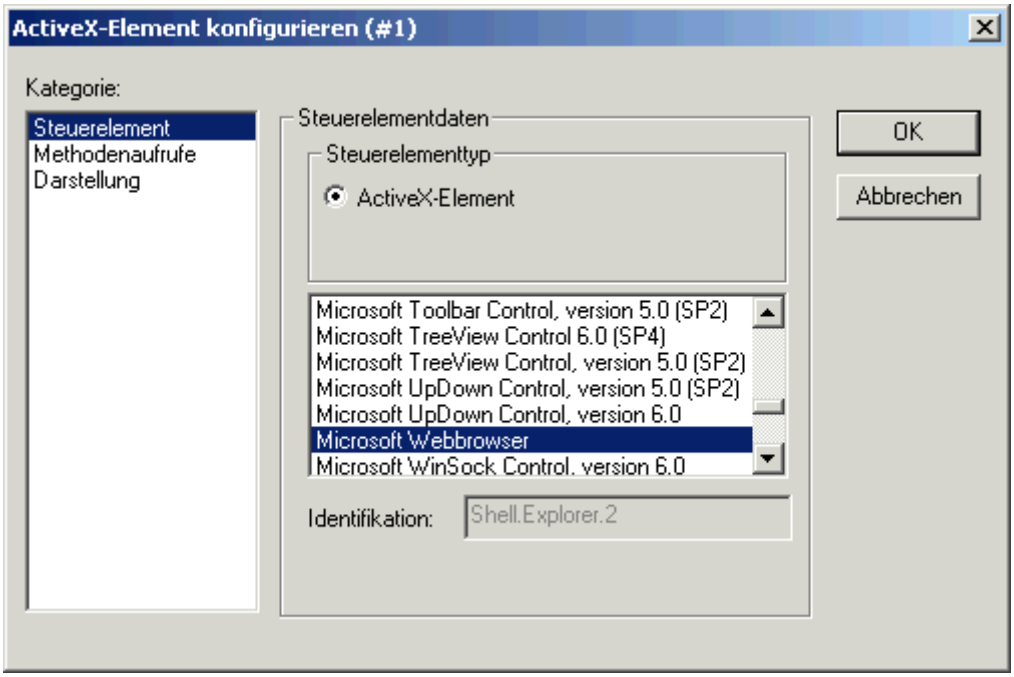
	Number	Value	Text
1	0	TRUE	text1
2	33	TRUE	text2
3	55	FALSE	abc
4	0	FALSE	
5	0	TRUE	

1.4.3.5.21 ActiveX element

The ActiveX element serves for displaying a passive ActiveX Control within a visualization. The element is usable on Windows32 based systems in CODESYS HMI.

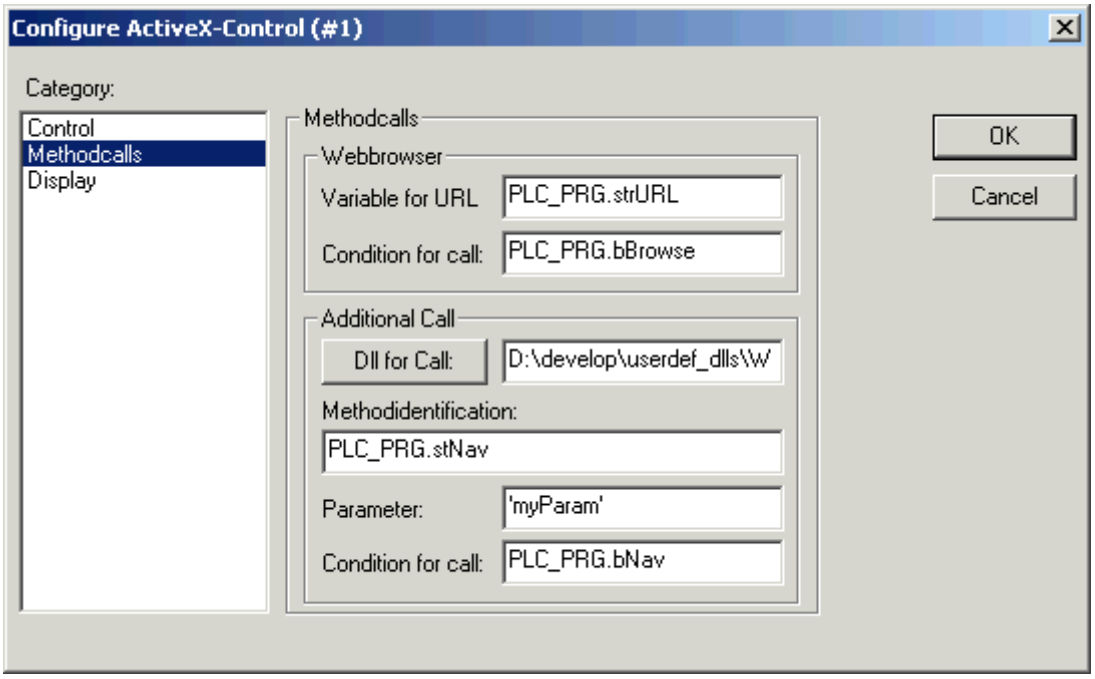
The configuration dialog is opened by a double-click on the Inserted element and offers three sub-dialogs, for selecting the control type, for defining method calls and for the configuration of the display:

Control:



In this dialog you can mark the desired ActiveX Control in the selection list offering all ActiveX Controls which are registered on your computer.

Methodcalls:



Here you configure the method calls for the chosen ActiveX Control:

Web browser:

These input fields only can be edited if you are configuring a control element which supports the 'IWebBrowser' interface (e.g. Internet Explorer or Mozilla Browser). In this case the method Navigate can be called (other method calls must be controlled via a user defined DLL, see below 'Additional Call').

Enter an URL as a parameter value in field Variable for URL (Input as a string between inverted commas) resp. a project variable of type STRING defining an URL. The browser will be called as soon as the variable entered in field Condition for call gets TRUE (rising edge). If no call condition is defined here, in the target visualization the browser will be called in each cycle of the visualization task!

Additional Call:

Via a user defined Windows-Dll you can define method calls for the ActiveX Control in order to control the behavior of the control at a call. For this purpose you must enter the DLL in the field at DLL for Call. If you press the button you get the File Open dialog to browse for a DLL. If the DLL is in the visualization files directory which is specified in the project options, just the path relative to this directory will be entered, otherwise the complete file path.

> *If the DLL is to be used on a runtime system with a target visualization, it must explicitly be copied there. When the Control is called in the target visualization, only the file name contained in the path will be regarded.*

The DLL is called as soon as the variable defined below in Condition for call gets TRUE (rising edge). If no condition is specified, in the target visualization it will be called in each cycle of the visualization task!

Regard the following when creating an appropriate DLL:

The DLL must export a method "ExecuteActiveXCall" with this function prototype :

```
void ExecuteActiveXCall(IUnknown* pUnk, char* pszId, char* pszParam,
char* pszReturnBuffer, int nReturnBufferSize, DWORD* pdwReturnFlag);
```

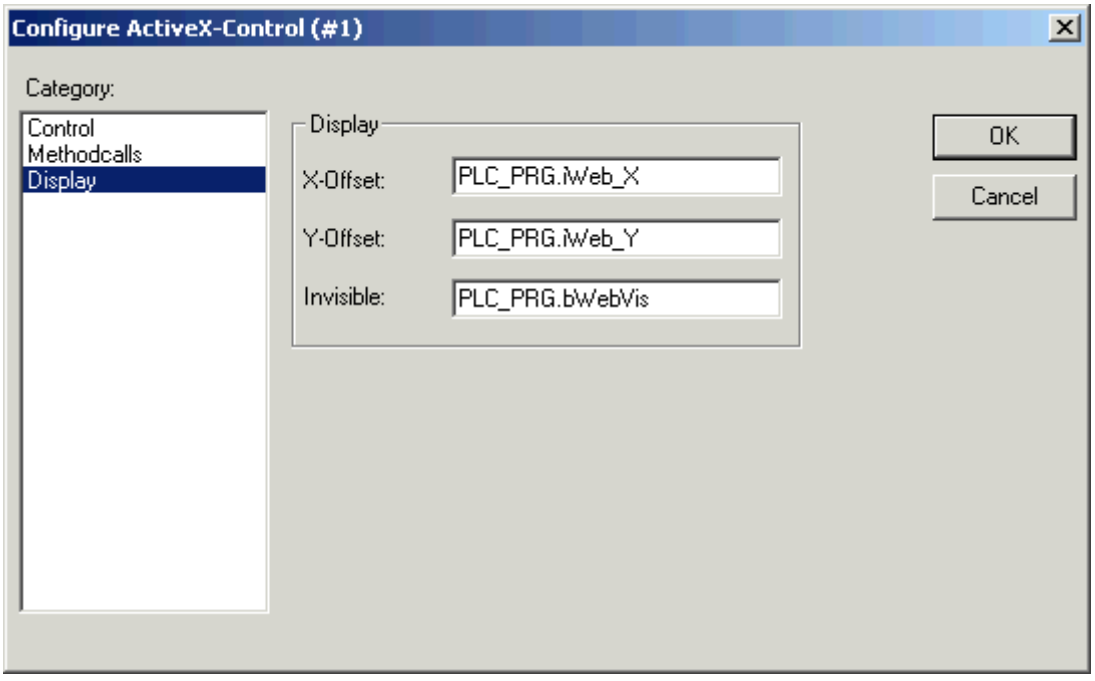
The function will be called with the following parameters which can be defined in the configuration dialog:

- pszId : string resp. string variable specified in field Methodidentification
- pszParam : value specified in field Parameter

The parameter pUnk allows a query of further Com(ActiveX-)interfaces. With these interfaces you can call any Method on your ActiveX-Control with any parameters packed in a string!

The parameters pszReturnBuffer, nReturnBufferSize and pdwReturnFlag currently are not used.

Display:



In this dialog you can specify the variables defining the position with X-Offset, Y-Offset (see ↳ *Chapter 1.4.3.5.12 “Motion absolute” on page 659*) and visibility of the control element Invisible (see ↳ *Chapter 1.4.1.7.3.1 “Overview” on page 438*).

Example of a DLL source file: This example DLL will only call the methods GoBack or GoForward of the control if it supports the 'IWebBrowser' interface.

The method is chosen by the parameter pszId.

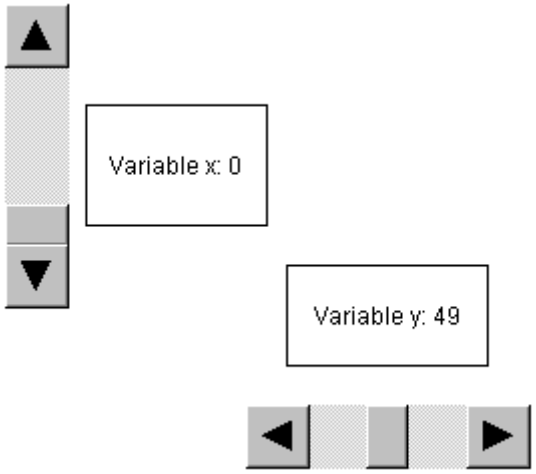
```
#include "stdafx.h"
#include <unknwn.h>
#include <exdisp.h>
BOOL APIENTRY DllMain( HANDLE hModule,
           DWORD  ul_reason_for_call,
            LPVOID lpReserved
)
{
    return TRUE;
}
extern "C" __declspec (dllexport) void ExecuteActiveXCall(IUnknown*
pUnk, char* pszId, char* pszParam,
  char* pszReturnBuffer, int nReturnBufferSize, DWORD* pdwReturnFlag)
{
if (strcmp(pszId, "IWebBrowser|GoBack") == 0)
{
IUnknown* pNewUnk;
IWebBrowser* pwb;
pUnk->QueryInterface(IID_IWebBrowser, (void**) &pNewUnk);
pwb = (IWebBrowser*) pNewUnk;
if (pwb)
{
pwb->GoBack();
pwb->Release();
}
}
else if (strcmp(pszId, "IWebBrowser|GoForward") == 0)
{
IUnknown* pNewUnk;
IWebBrowser* pwb;
pUnk->QueryInterface(IID_IWebBrowser, (void**) &pNewUnk);
pwb = (IWebBrowser*) pNewUnk;
if (pwb)
{
pwb->GoForward();
pwb->Release();
```

```
}
}
}
```

1.4.3.5.22 Scrollbar

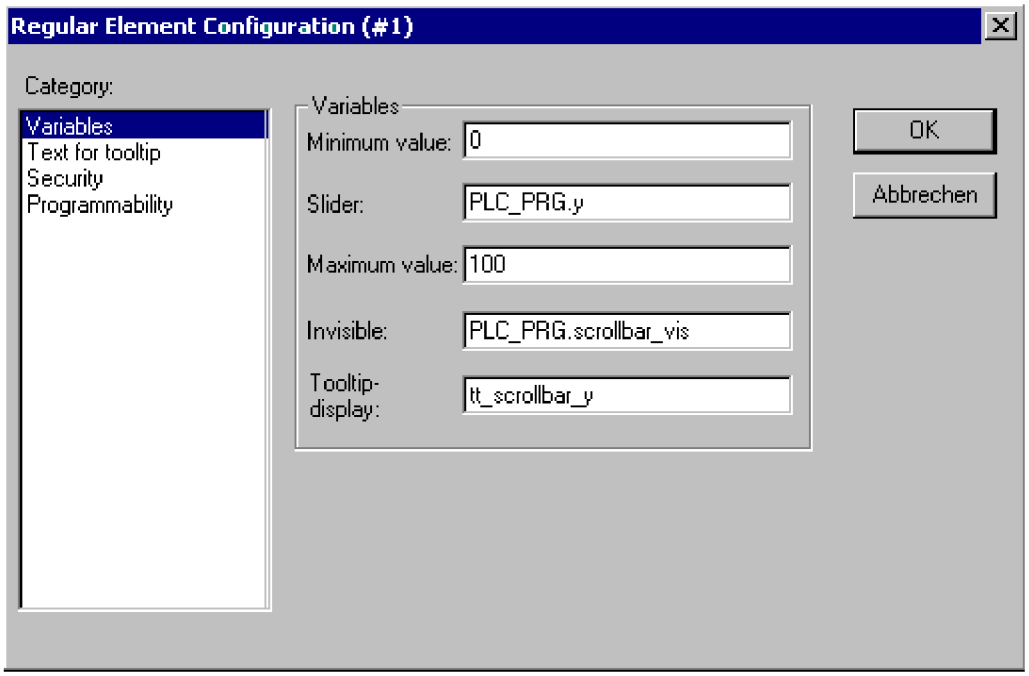
The scrollbar element can be used to modify the value of a variable (or vice versa). The slider position will correspond to the value of an assigned variable within a defined range of values.

The user can move the slider in online mode by clicking on the slider and then moving it by moving the mouse - or alternatively by clicking on one of the arrow symbols on the scrollbar, whereby each mouse-click will move the slider (and thus the variable value) by 1 in the respective direction: If the slider is moved to the right resp. up, the value will be increased, if the slider is moved to the left resp. down, the value will be decreased.



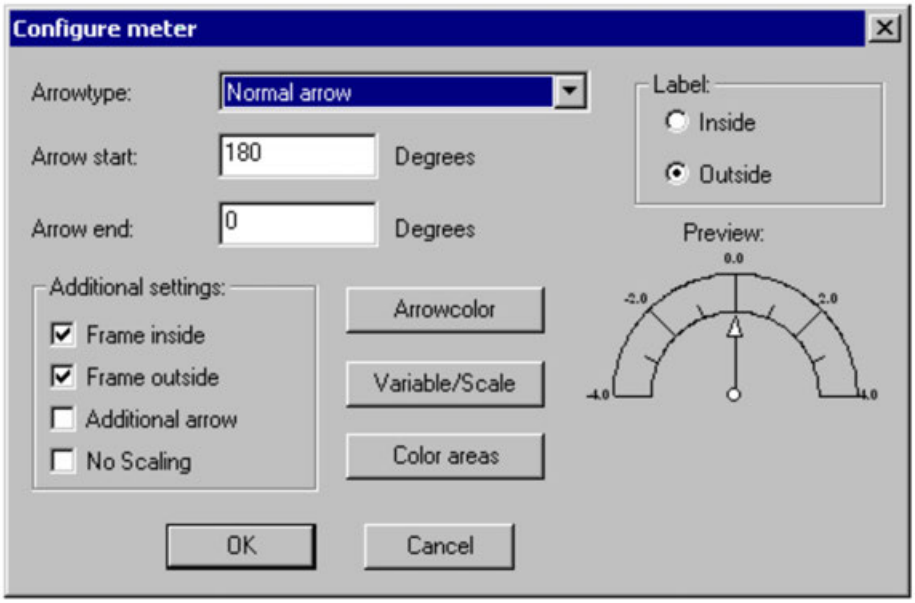
A vertical or horizontal display of the scrollbar can be reached by a respective shaping of the element (see 'Insert' 'Scrollbar').

The configuration dialog gets opened by a double-click on the element.



- Slider: Enter here the path of the project variable, the value of which should correspond to the slider position between the given Minimum value and Maximum value (e.g. "PLC_PRG.ivar"). So, when the slider gets moved in online mode, the value of the variable will change. Vice versa, if the variable gets modified by any other input the slider would get moved correspondingly.
- Minimum value, Maximum value: Boundaries for the range of values which can be displayed for the variable assigned to the slider. In horizontal scrollbars the minimum value corresponds to the left-most position of the slider, in vertically scrollbars to the bottom-most position. The values can be entered directly or via a project variable (e.g. "0", "200", "PLC_PRG.minvar").
- Invisible: The visibility of the element in online mode can be controlled dynamically, if here an appropriate boolean variable is entered, e.g. "PLC_PRG.bScrollbar_vis". A static definition is also possible ("TRUE", "FALSE" resp. "0", "1"). Default: visible.
- Tooltip-display: If "dynamic texts" should be used for the tooltip text, here the ID of the prefix-ID-combination must be entered, which uniquely references the desired text in a specific language file (xml-format). You can enter the ID directly (string, e.g. "tt_scrollbar1") or via a project variable of string format which gives the ID (e.g. "PLC_PRG.tt_ID"). Concerning this see the help pages on Tooltip and generally on Language Switching.

1.4.3.5.23 Meter



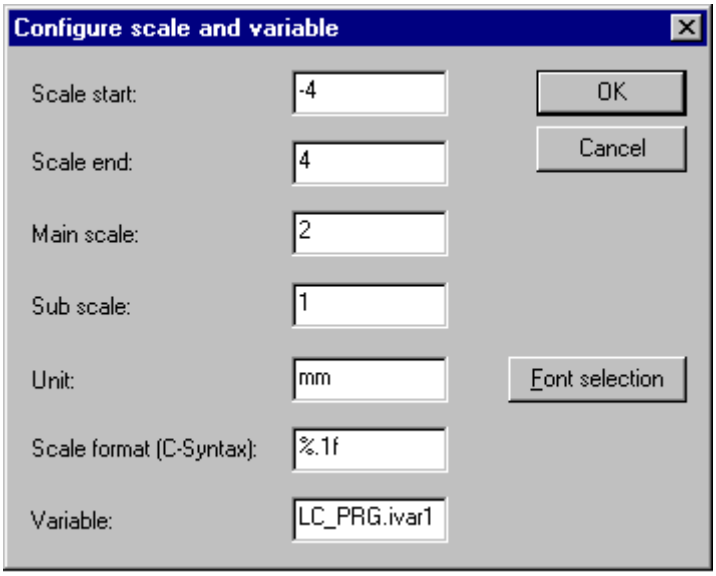
This dialog will open automatically as soon as you insert a Meter into a visualization object. A Preview is part of the dialog, immediately showing how the element will look as a result of the currently set parameters:

- Arrowtype: Define the type of the arrow which will point at the current value on the Meter. Possible types: Normal arrow, Thin arrow, Wide arrow, Thin needle.
- Arrow start, Arrow end: Here you define the start and the end positions of the scale on a virtual circular arc in ° Degrees (angle). (Example: a Start angle of 180° and an End angle of 0° will define a upturned semicircle).
- Arrow color: This button opens the standard dialog or a target-specific color selection list for choosing a color. Define the color of the pointer.
- Variable/Scale: This button opens the dialog *"Dialog 'Configure scale and variable'" on page 681*.
- Color areas: This button opens the dialog *"Dialog 'Configure color areas'" on page 681*: Here you can define a separate color for each partition of the scale.

Additional settings:

- Frame inside, Frame outside: If one or both of these options is/are activated, an inner or outer frame will be added to the scale arc.
- Additional arrow: In addition to the main pointer a little arrow will indicate the current value directly on the scale.
- No Scaling: If this option is activated, the inserted element cannot get resized.

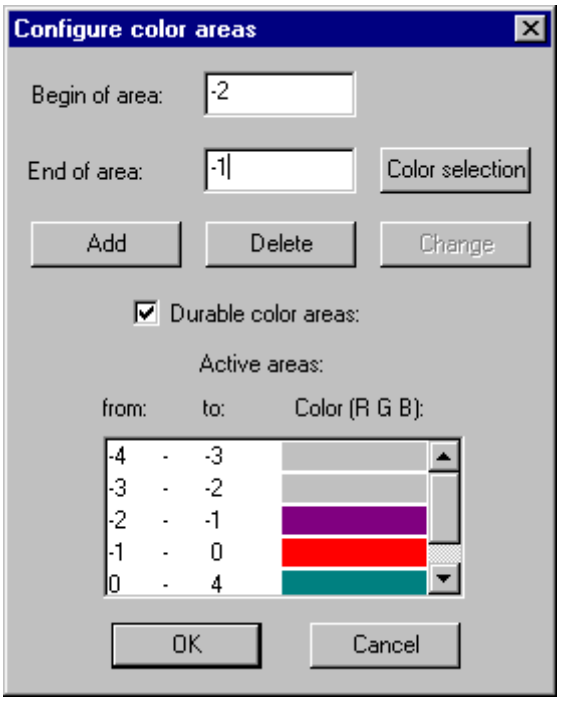
Dialog 'Configure scale and variable'



- Scale start, Scale end: lowest and highest value on the scale, e.g. "-4" and "4".
- Main scale: Define which intervals on the scale should be marked "with all", that means which should get a scale pitch and a label. If you insert e.g. "2", each second integer value will be indicated.
- Sub scale: In addtion to the main scale (Label + long pitch lines) here you can define a sub-scale which will be displayed as short pitch lines without any labels.
- Unit: Define here the scale unit, e.g. "cm" or "sec". The unit is indicated by a label at the origin of the pointer.
- Scale format (C-Syntax): According to the C-syntax you can define the display format of the scale labels; see the description concerning Category 'Text'. Example: If you insert "%1.1f" the scale values will be indicated by a floating point number with one decimal place before and one after the comma (e.g. "12.0")
- Variable: Here you can define a variable which is assigned to the pointer position. (e.g. "PLC_PRG.posvar")
- Font selection: This button will open the standard dialog for defining the font used in the Meter element (the selection list can be target-specific).

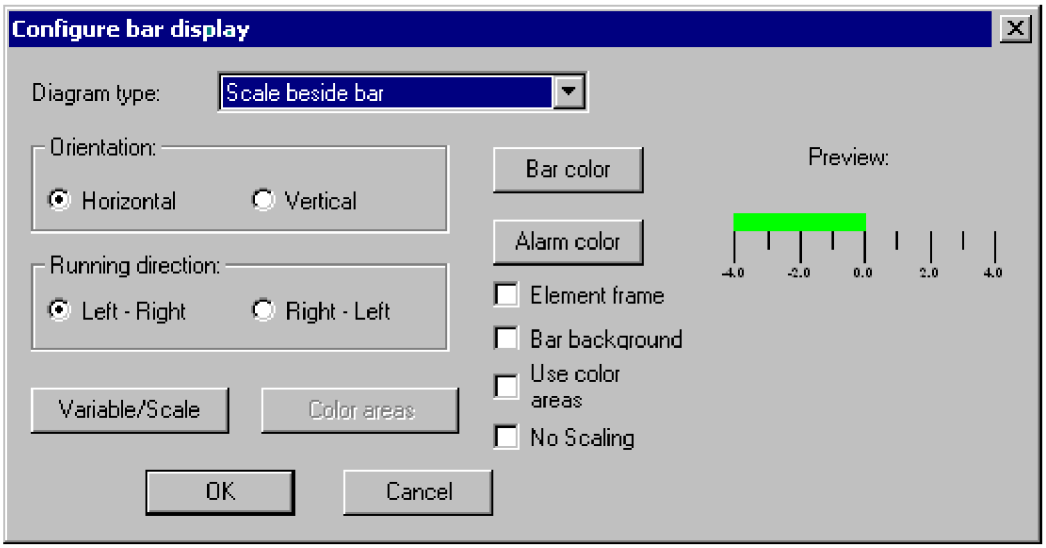
Dialog 'Configure color areas'

Dialog for the configuration of color areas for a Meter:



- Begin of area, End of area: Insert here the start and end values of the scale partition which should get the color defined in the following:
- Color selection: This button opens the standard dialog for choosing a color or a target-specific selection list. Confirm your selection with OK, which will close the dialog, and press button Add, whereupon the color and the assigned partition of the scale will be added to the window 'Active areas'. In order to remove an already defined area, select the entry and press Delete.
  If the option Durable color areas is activated, the defined color ranges will be displayed permanently, otherwise in online mode just that partition of the scale will be colored which contains the current value of the respective value.
- Label: Depending on which of the options is activated (inside or outside), the scale labels are placed at the inside or the outside of the circular arc of the scale.

1.4.3.5.24 Bar display

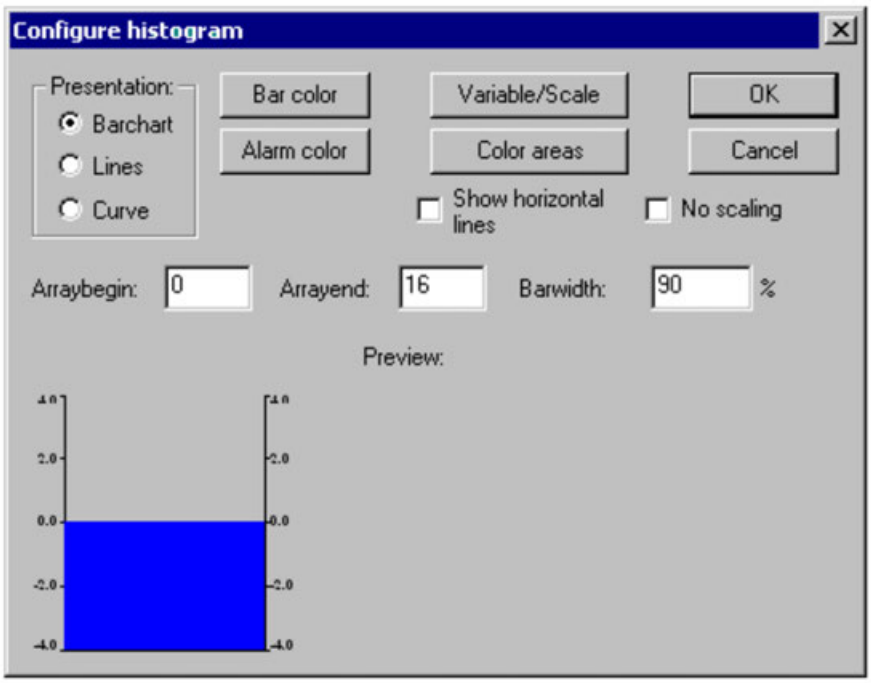


This dialog will be opened as soon as you insert a Bar Display element into a visualization object. A Preview is part of the dialog, immediately showing how the element will look as a result of the currently set parameters:

- Diagram type: Choose one of the options: 'Scale beside bar', 'Scale inside bar' and 'Bar inside scale'.
- Orientation: Define one of the options: Horizontal or Vertical bar.
- Running direction: Choose whether the bar should be elongated corresponding to a growing value of the assigned variable in Left "“ Right or in Right "“ Left direction.
- Bar color: This button opens the standard dialog for choosing a color. Define a color for the bar in normal state (no alarm). If option 'Use color areas' (see below) is activated, no entries are possible.
- Alarm color: This button opens the dialog 'Configure alarm', where you define at which value the bar will be displayed in alarm color and which is the alarm color: Insert the desired limit value in the edit field and activate one of the Conditions greater than or lower than, in order to define whether values higher or lower than the limit value should set off an alarm. Press button *“Alarm color”* to open the standard dialog or a target-specific color selection list for choosing the alarm color. Close both dialogs with OK in order to confirm the settings and to return to the main dialog for configuring the bar display. If the option 'Use color ranges' (see below) is activated, no entries are possible.
- Variable/Scale: This button opens the dialog 'Configure scale and variable', which corresponds to that used for the Meter element ↬ *Chapter 1.4.3.5.23 “Meter” on page 680*.
- Element frame: If this option is activated a frame will enclose the bar display.
- Bar background: If this option is activated, the whole display range will be indicated by a black bar in the background of the current values' bar, otherwise only the current values' bar will be displayed.
- Use color areas: If this option is activated, any settings defined in the dialogs for 'Bar color' and 'Alarm color' (see above) will not be valid. In this case the color area definitions will be used, which have been made in the dialog 'Configure color areas'. This dialog can be opened by pressing button 'Color areas' (see below)
- Color areas: This button opens the dialog 'Configure color areas' where you can define a separate color for each partition of the scale. These definitions will only be valid if the option 'Use color areas' (see above) is activated. Use the dialog as described for the Meter element ↬ *Chapter 1.4.3.5.23 “Meter” on page 680*.
- No Scaling: If this option is activated, the inserted element cannot get resized.

1.4.3.5.25 Histogram

A histogram element can be used to visualize an array. The values of the array elements will be represented by bars or lines side by side, indicating the current values of the element by their height.

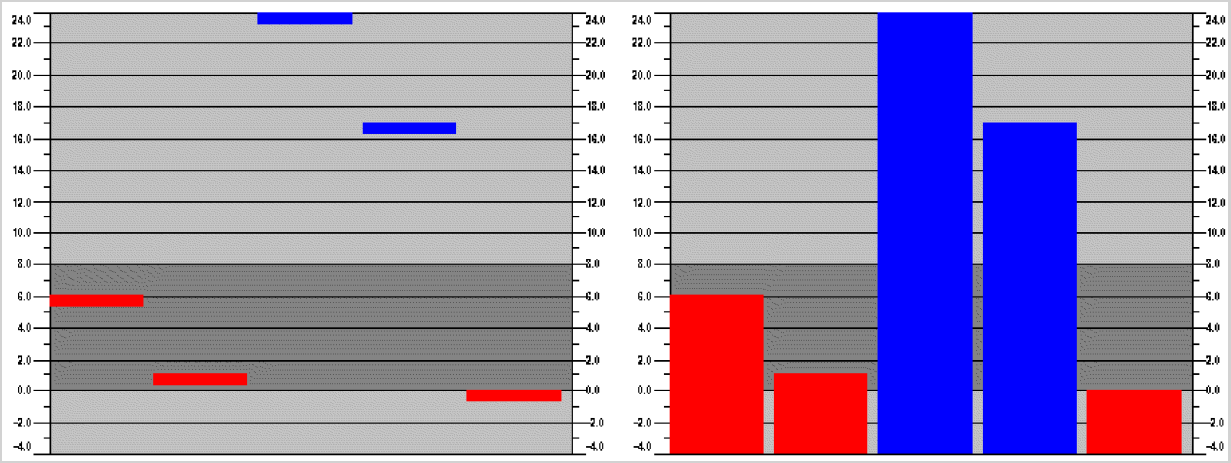


The configuration dialog will be opened as soon as you insert a histogram element into a visualization object. A preview is part of the dialog, immediately showing how the element will look as a result of the currently set parameters:

- Presentation: Activate one of the options Barchart or Lines.
- Show horizontal lines: If this option is activated, horizontal lines spanning the diagram will additionally display the scale gradation.
- No Scaling: If this option is activated, the inserted element cannot get resized.
- Alarm color: This button opens the dialog 'Configure alarm', where you define at which value the bar will be displayed in alarm color and which is the alarm color: Insert the desired threshold value in the edit field and activate one of the Conditions greater than or less than, in order to define whether values higher or lower than the limit value should set off an alarm. Press button *“Alarm color”* to open the standard dialog or a target-specific color selection list for choosing the alarm color. Close both dialogs with OK in order to confirm the settings and to return to the main dialog for configuring the histogram.
- Variable/Scale: This button opens the dialog 'Configure scale and variable', which can be filled like described for the Meter element ↳ *Chapter 1.4.3.5.23 “Meter” on page 680*.
- Color areas: This button opens the dialog 'Configure color areas': Here you can define a separate color for each partition of the scale. See the description of the Meter where the same dialog is available ↳ *Chapter 1.4.3.5.23 “Meter” on page 680*.
- Bar color: This button opens the standard dialog for choosing a color. Define a color for the bar in normal state (no alarm).

  Define which range of the array should be displayed:
  - Arraybegin: First array element to be displayed (Index).
  - Arrayend: Last array element to be displayed (Index).
- Barwidth: Define the width of the bars in percent by the total width available for one bar.

Example: See in the following picture an example of the online display (bars resp. lines) of a histogram which represents an array arr1 [0..4] of INT. The arraybegin was set to "0", the arrayend to "4", the scale start to "-4", the scale end to "24", the main graduation was set to "2", the sub-graduation to "1" and the scale range 0 "“ 8 has got assigned another color (dark grey) than the rest of the scale range. Furtheron the bars should be displayed alarm-colored (blue) as soon as the value of the corresponding array element exceeds "8". You see the array elements arr1[2] and arr1[3] currently being in alarm state:

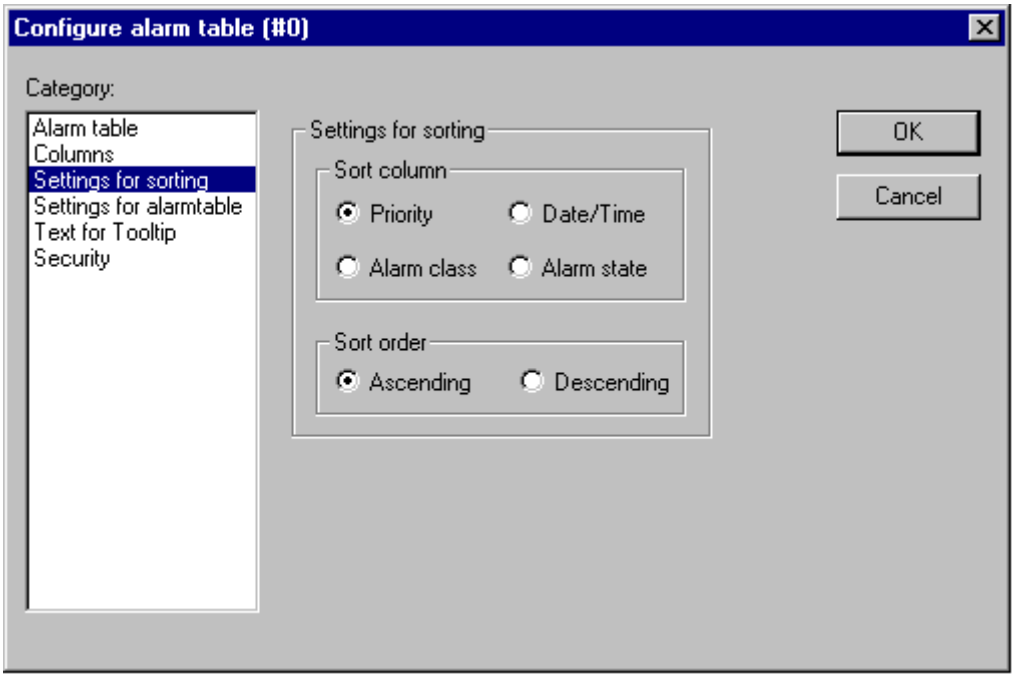


1.4.3.5.26 Alarm table

The element 'Alarm table' is used to visualize alarms, which must be defined before, see 'Alarm configuration, Overview' ↳ *Chapter 1.4.1.4.2.1 “Overview” on page 363*.

As soon as the element gets inserted in the visualization object, the dialog 'Configure alarm table'. Besides the known categories for configuration of tooltip and security the following settings concerning display and selection in the table can be made.

Category alarm table

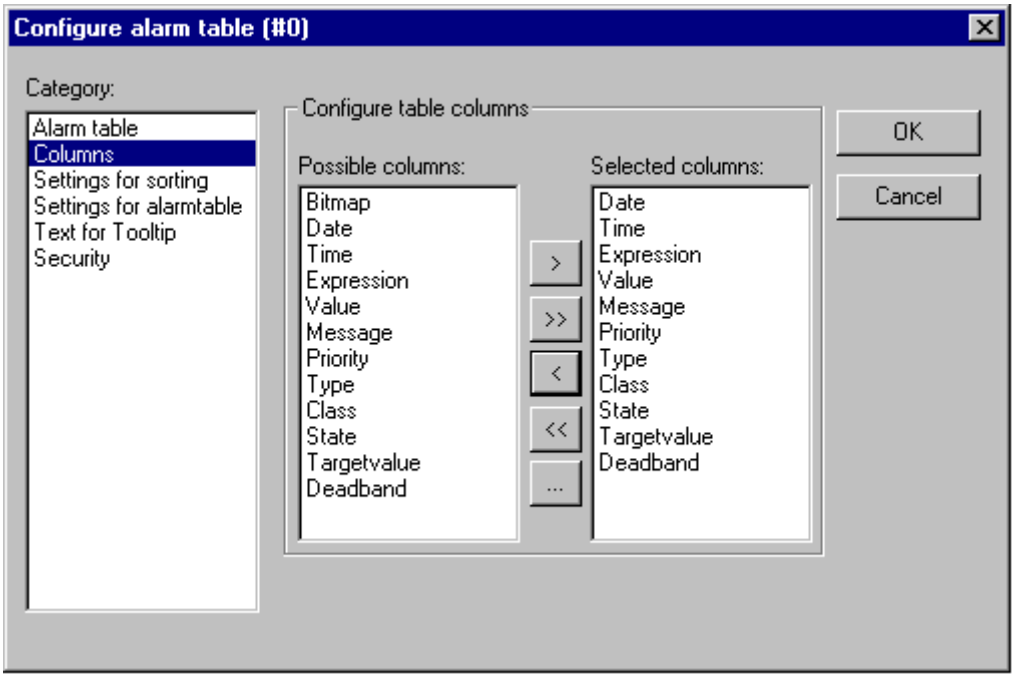


Define what you want to get displayed in the alarm table:

- Change alarm group: Press this button to get the selection tree of the alarm configuration, which offers all alarm groups currently defined. Choose the desired group (which even may contain just one alarm).

  Note: The name of the alarm group, as it is displayed here (e.g. "System/Alarmgroup1") can be used as PREFIX in a XML file for dynamic texts in order to get dynamic language switching for the message texts in the alarm table; the associated ID in this must be the number of that line in the Alarm group configuration table, that defines the respective message text.
- Priority: Define the priority for which you want to get displayed all alarms. Permissible range: 0 to 255.
- Alarm classes: Mark a class which you want to get displayed and press button Add to add the class to the list in the window 'Alarm classes'. Do this for all required classes. In order to remove a marked entry from the alarm classes window press button Delete.
- Activate options Column heading resp. Row heading, if the headings should be displayed in the alarm table.

Category settings for sorting

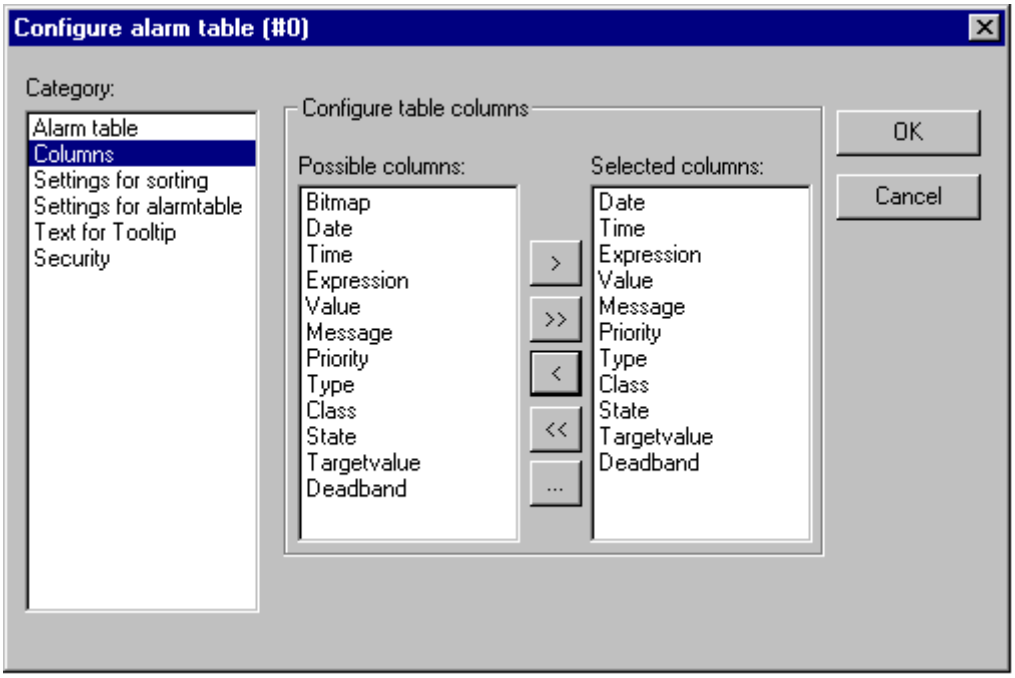


Define here according to which criteria the alarm table should be sorted:

- Sort column: Sorting according to Priority, Alarm class, Date/Time or Alarm state
- Sort order: Ascending or Descending;
  Example: Ascending according to priority means that the table will start with alarms of priority 0 (if available), followed by higher numbered priorities.

> *When using in a target visualization this settings are not regarded in the display of the alarm history. There the sorting always is descending according to the date.*

Category columns

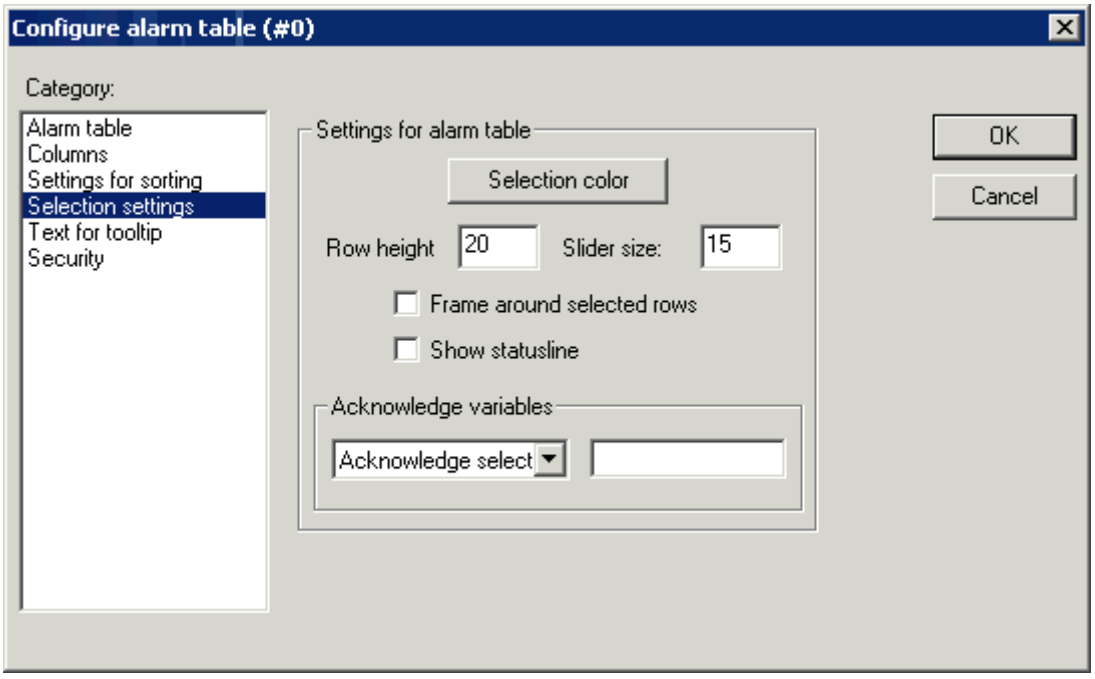


Define here, which of the columns (alarm parameters) should be displayed in the alarm table: The parameters are defined -- except for date and time (alarm is coming) and alarm state in the configuration of the alarm groups: Bitmap, Date, Time, Expression, Value, Message, Priority, Type, Class, State, Target value (for alarm types DEV+ and DEV-), Deadband.

Using the buttons ">", ">>", you can take single resp. all parameters from the left to the right window. The selection defined in the right window will be displayed in the alarm table. Using the buttons "<" resp. "<<" entries can be removed from the selection.

For each column you can open the dialog 'Configure columns' by a double-click on the entry in the right window. In this dialog Column header and Column width can be defined.

Category selection settings for alarm table



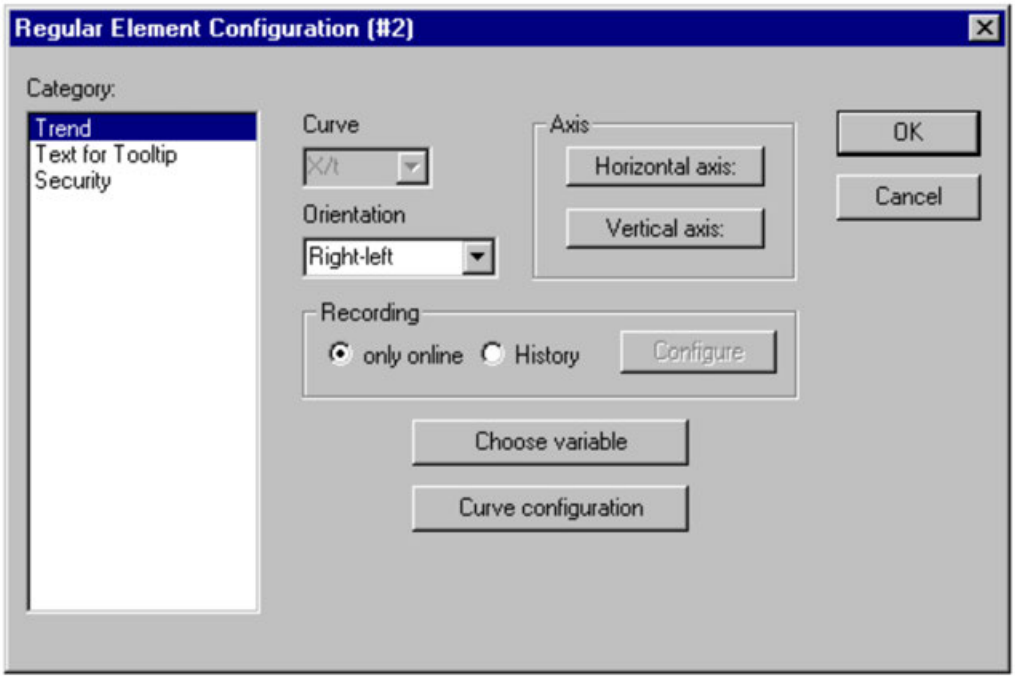
Define here some settings for the display for the chosen table fields:

- Selection color: This button opens the standard dialog or a target-specific selection list for choosing a color. Define the color in which selected fields should be displayed.
- Row height: Height of the table rows in Pixel.
- Slider size: Height of the slider (Pixel) at the bottom of the table.
- Frame around selected rows: If this option is activated, selected table rows will get a frame.
- Show statusline: If this option is activated, below the alarm table a status bar will be displayed providing the following buttons for the operation in online mode:
  - Acknowledge: All alarm entries marked in the alarm table get acknowledged.
  - Acknowledge all: All alarm entries listed in the alarm table get acknowledged.
  - History: If this button is pressed, instead of the current status of the alarms the table will show a complete list of all events which have occurred up to now (all transitions between any alarm stati). In this list no acknowledgement is possible ! Any new events will be added currently.

    If you have defined a record file, also there you will find this history for all alarm classes, for which the action 'Save' has been activated.
  - Start: cancels Stop (see below)
  - Stop: the current update of the list with newly occurring events will be stopped until it is restarted by pressing button 'Start'.
- Acknowledge variables: This option is only available as long as you have not chosen option 'Show statusline' (see above). If it is activated, the functions described above for the status string buttons can get controlled by variables. In order to define these variables, choose a function from the selection list and enter a project variable in the assigned edit field. Thus for example the acknowledgement of all alarms in online mode can be done by a rising edge of the assigned variable.

The web visualization might be configured in a way, that in online mode a tooltip will display the full string of a text entry, which is only partially visible in the alarm table.

1.4.3.5.27 Trend



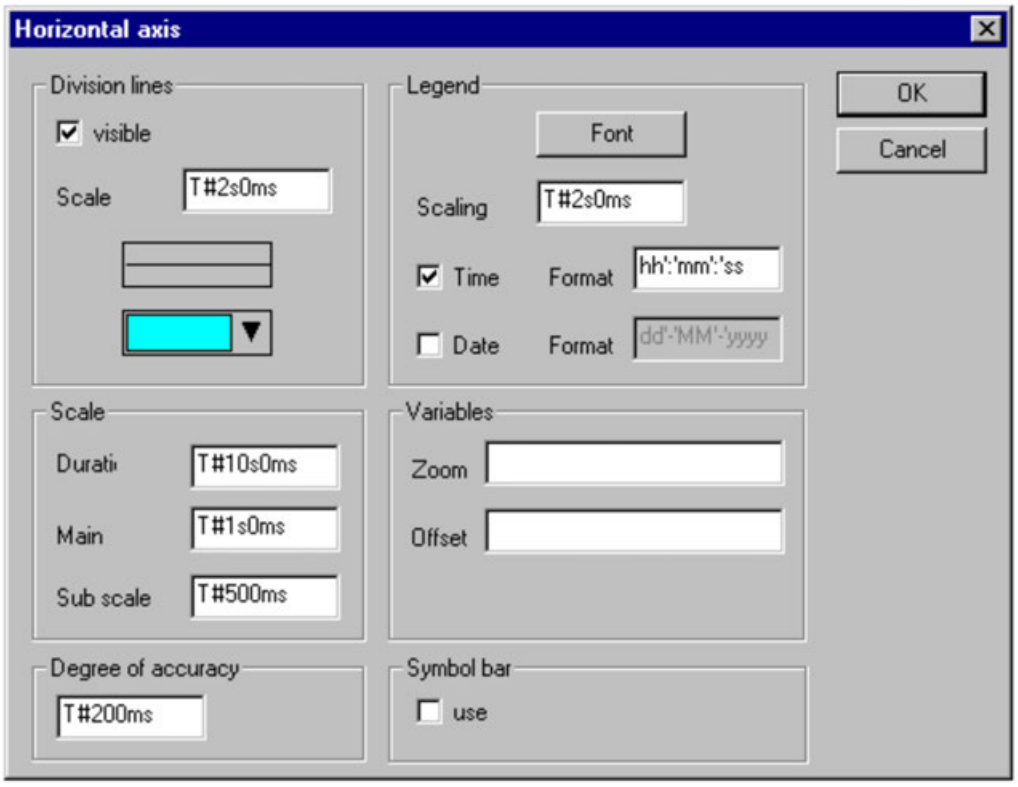
The Trend element can be used to log the time dependent behavior of variable values in the online mode. The online presentation is done in a diagram, in case of logging to a text file each of the values is written to a separate line.

In the dialog for configuring visualization elements in category 'Trend' you can do the following settings :

- Curve: X/t, horizontal axis = time axis, vertical axis = scale of values
- Orientation: Left-right or Right.-left: The latest value will be displayed on the left/right side;
- Axis:
  - Horizontal Axis *“Horizontal axis” on page 689*
  - Vertical Axis *“Vertical axis” on page 690*
- Recording: Define here whether the trend should be recorded 'only online', i.e. the time dependent behavior of the variable values will be displayed using the chosen range of the scale, or whether the record should be saved to history file, which can be configured after pressing the button History. The dialog corresponds to that which is used for the configuration of the alarm log file.

  In the log file for each time of measurement a separate line is written which contains the name and the values of all regarded variables. Each line starts with a unique identifier in DWORD format, which is built from the date of measuring.
- Choose variable *“Choose variable” on page 690*
- Curve configuration *“Curve configuration” on page 691*

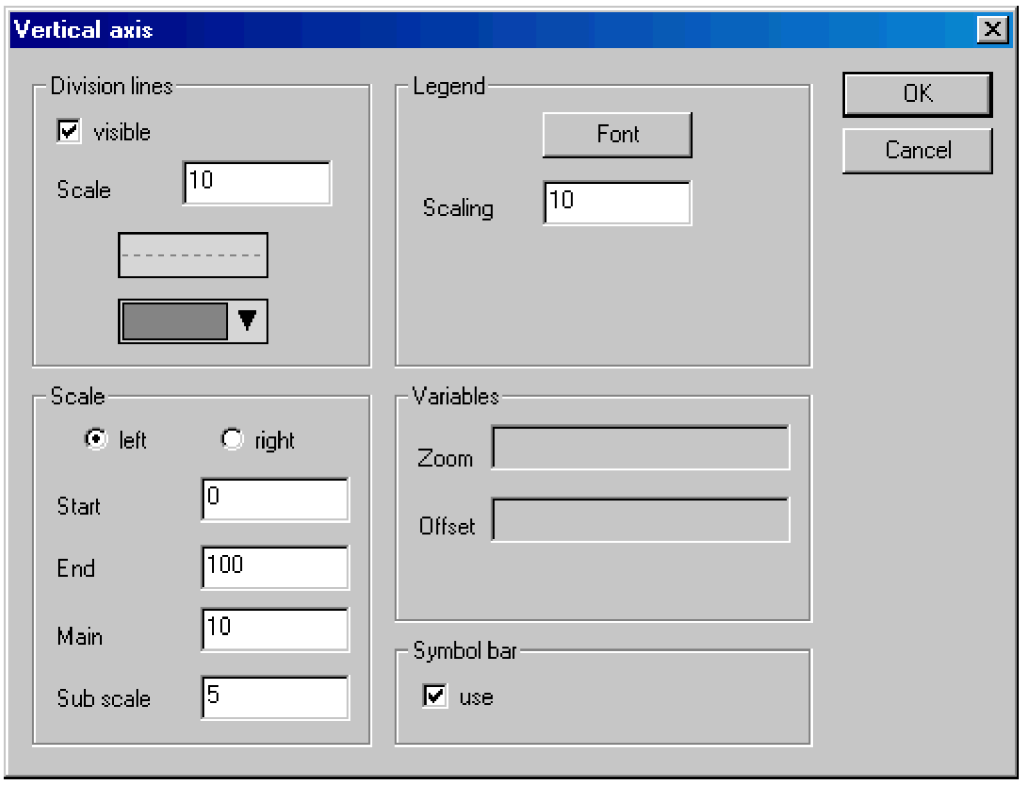
Horizontal axis



- Division lines: Activate option 'visible', if vertical division lines should be displayed which are elongating the scale marks. In this case define the 'Scale': The given number defines the interval between the division lines on the horizontal axis. Type (normal ___, dashed _ _ _, dotted ....., dashdotted _ . _ .) and color of the lines can be defined in dialogs which will open when you perform a mouse-click on the corresponding rectangle showing the currently set line type resp. color.
- Scale: The shown range of the scale is determined by the entry for Duration. If here e.g. " T#20s0ms" is defined, the scale will display a period of 20 seconds. The Main division and the Sub scale division, which will be displayed by the means of long and short marks are to be defined according to the same syntax.
- Degree of accuracy: Define here (in the standard format for dates, e.g. T#5ms) the interval for displaying the current values of the variables.

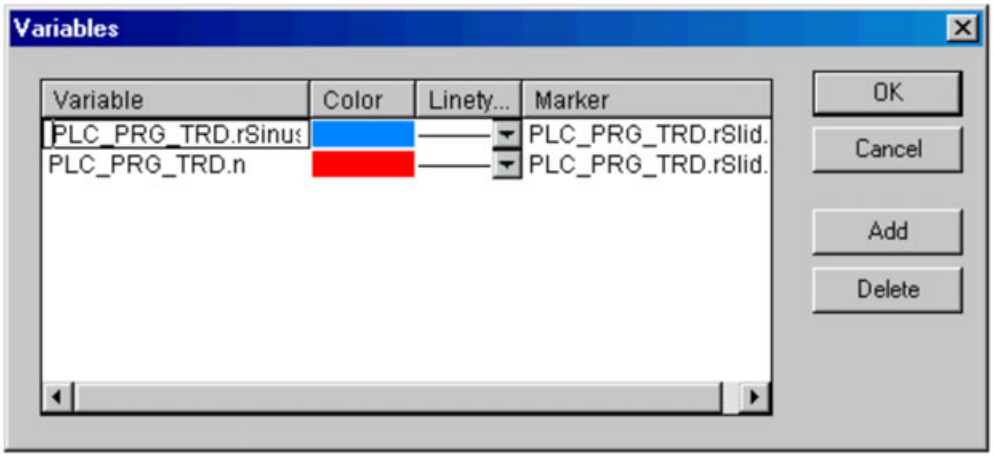
- Legend: Here you define the display of the legend. Via button Font the standard or a target-specific restricted dialog for setting the font will be opened. At Scaling define the distances between the particular letterings on the scale (e.g. T#4ms, if the scale markings should get a lettering each 4 milliseconds). The lettering will contain the Time and/or Date, depending on which options are activated. The desired format each can be defined in the field 'Format'. Regard that you can either set the 12-hour format ("hh") or the 24-hour format ("HH").
- Variables: Here you can define project variables, which contain the zoom values resp. offset values for the horizontal scale. For example the offset of the display range of the horizontal axis will be set to "10" as soon as the variable assigned here gets value 10.
- Symbol bar: If option use is activated, at the bottom of the element a horizontal symbol bar will be added, providing buttons for scrolling and zooming in online mode. The simple arrow buttons will move the displayed range along the time axis step by step, the double arrow buttons will shift it to the end resp. start of the record. The zoom buttons allow a zooming of the horizontal scale step by step. To get a possibility to restore the original settings concerning zoom and offset, define the vertical symbol bar to get the 'home' symbol.

Vertical axis



- Dialog for configuration of the vertical axis in the trend element
- Division lines: corresponding to the horizontal axis (see above)
- Scale: Define whether the scale should be displayed at the left or right border of the trend diagram. Choose the Start value (lower end) and End value (upper end) of the scale as well as the Main and Sub scale divisions (longer and shorter markings will be displayed in the here defined distances).
- Legend: Font and divisions; see above, horizontal axis
- Variables: see above, horizontal axis
- Symbol bar: see above, horizontal axis, additionally there is a "home" button for restoring the standard settings concerning zooming and offset of the axes.

Choose variable Choose variable: Press this button to get the dialog Variables, where you can configure the variables for which the trend record should be done and how they should be displayed:



Enter a project variable in column Variable (mouse-click on the field will open an edit frame). It is recommended to use the input assistant <F2> or Intellisense function.

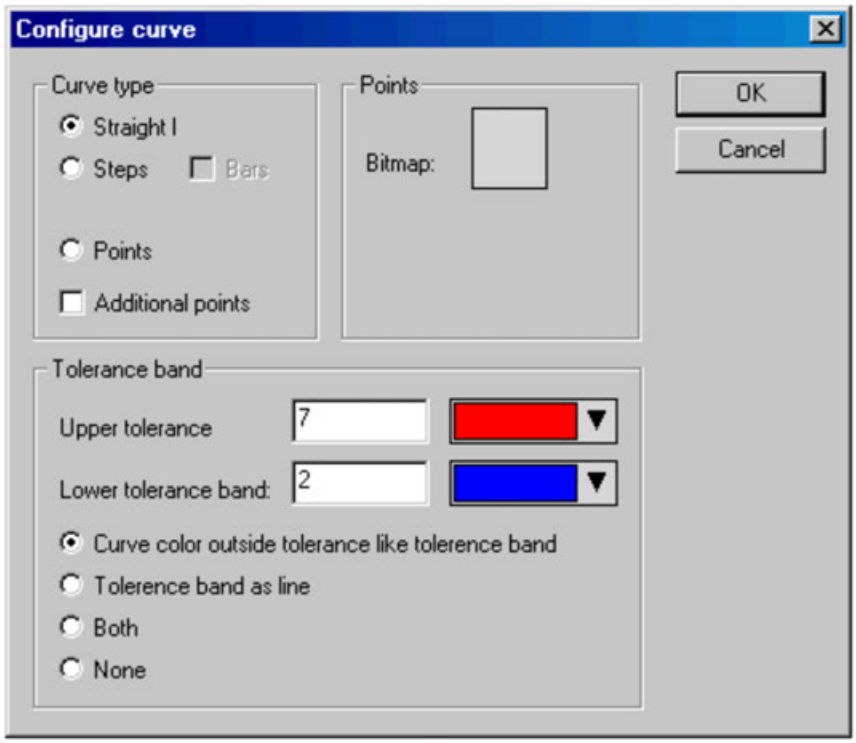
Color and Line type for the display of the variable in the record you can define by a mouse-click on the corresponding field in column Color (the standard dialog or a target-specific color selection list) resp. by selecting a line type in the corresponding field of column Line type (normal ___, dashed _ _ _, dotted ....., dashdotted _ . _ .).

In column Marker you can define a variable, which will provide the currently recorded value when you use the marker function in online mode. The marker will be displayed as a little grey triangle in the upper left corner of the diagram. If you click on the triangle and keep the mouse-button pressed, you can shift a vertical marker line along the horizontal time axis. The variable defined as 'marker' then will read the corresponding value from the record curve of the associated project variable.

Do the settings for all variables you want to record. Via button Add a further line will be added at the end of the list. A line can be deleted by button Delete.

Curve configuration

Curve configuration: This button opens the dialog Curve configuration. Here some settings concerning the trend curves can be done:



Curve type: Select one of the options Straight line, Steps or Points. For the first two types the display of Additional points can be defined. For displaying a point a bitmap can be defined, otherwise a filled rectangle (same color as curve) will be used as point symbol. Press the rectangle next to Bitmap to get the standard dialog for selecting a bitmap file. Via Delete the currently set bitmap can be removed from the configuration.

Tolerance band: You can define an upper and lower limit value on the vertical axis to be displayed as a tolerance band. For each band a color (Press the color rectangle to get the default resp. target-specific selection dialog) can be defined. If the bands should be displayed in online mode, activate option Tolerance band as line. If you want the curve to get displayed in the color defined for the respective band as soon as exceeding the tolerance value, activate Curve color outside tolerance like tolerance band. Activate Both or None if you want to activate both or none of the above described display options at a time.

Example: Display of a trend element in online mode

Declaration in program PLC_PRG:

```
VAR
n: INT;
rSinus:REAL;
rValue:REAL;
rSlider1:REAL; (*for marker function*)
rSlider2:REAL; (*for marker function*)
END_VAR
```

Programmteil von PLC_PRG:

```
n:=n+1;
rValue := rValue + 0.01;
rSinus:=SIN(rValue)*50 + 50;
IF n>100 THEN
n:=0;
END_IF
```

Configuration of a trend element in a visualization:

Orientation Left-Right, History activated

Horizontal axis: Division lines: T#2s, Duration: T#10s, Main: T#1s, Sub scale: T#500ms, Degree if accuracy: T#200ms, Legend: Time Format ('HH':'mm':'ss'), Scaling T#2s. Symbol bar activated.

Vertical axis: Division lines visible, Scale: 10, dotted, grey; Scale left, Start: 0, End: 100, Main: 10, Sub scale: 5; Legend: 10; Symbol bar activated.

Variables:

1. Variable PLC_PRG.rsinus, blue line, Marker: PLC_PRG_TRD.rSlider1;

2. Variable PLC_PRG.n, red line, Marker: PLC_PRG_TRD.rSlider2

Curve configuration: Straight line, no tolerance band

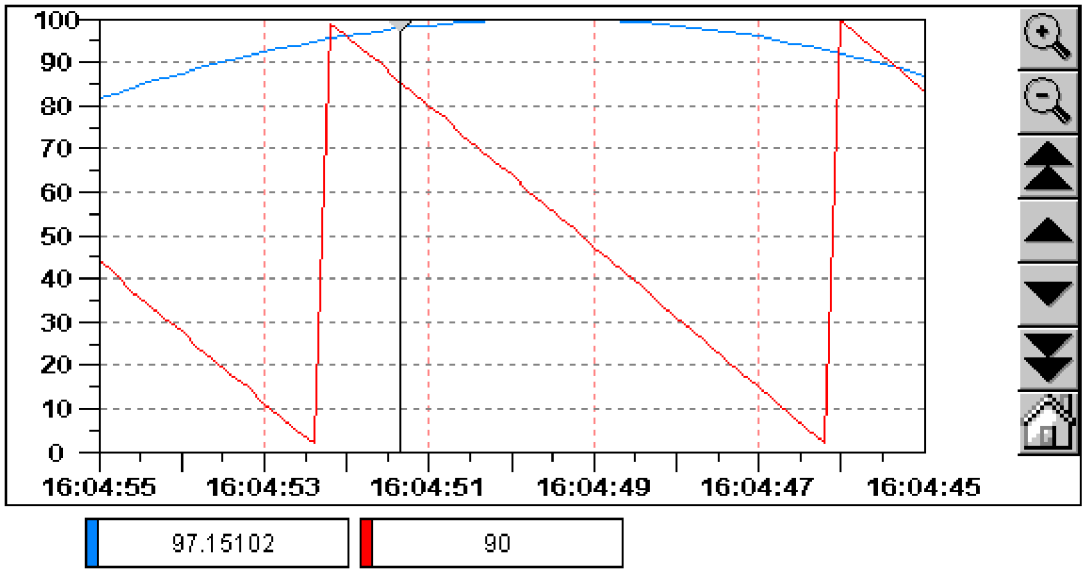
Configuration of two display fields for the current record values provided by the marker variables:

Rectangle element 1: Category Text: insert "%s" in the Content field; Category Variables: insert in field Textdisplay: PLC_PRG.rSlider1

Rectangle element 2: Category Text: insert "%s" in the Content field; Category Variables: insert in field Textdisplay: PLC_PRG.rSlider2

(additionally insert a rectangle element at the left border of the rectangle elements 1 and 2, showing the curve color of the corresponding record variable)

Result in online mode after login and start of the program:



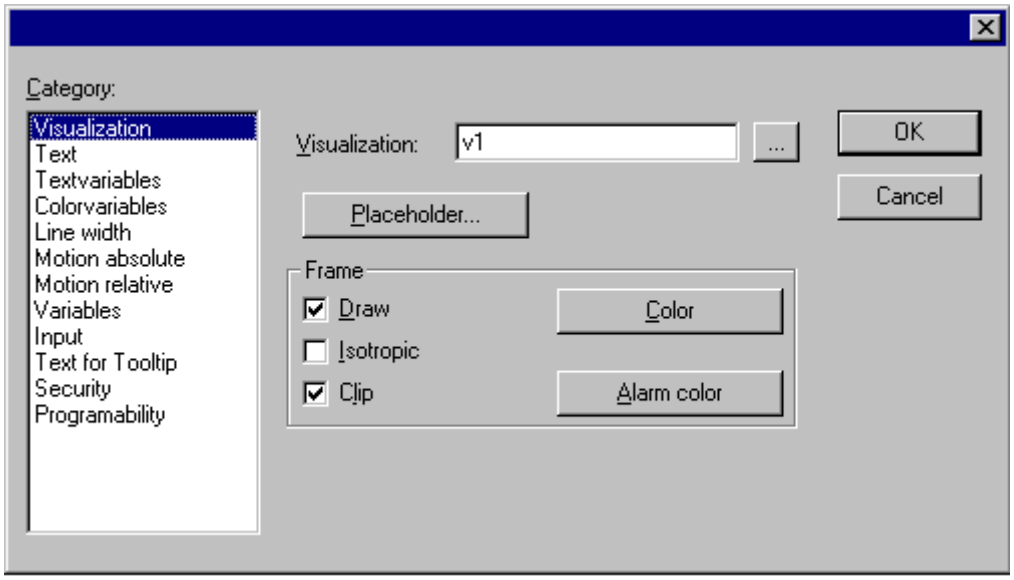
The record is running from the left to the right; the latest value is shown on the leftmost position; every 200 milliseconds the current value will be added to the display. The arrow buttons in the symbol bars allow shifting the displayed time range. Using the simple arrow buttons you can shift step by step, using the double arrows you get to the end resp. start of the record.

For example: if you go to the start of the record by pressing the double arrows pointing to the left, you get a still display of the former values. If you then move the marker (grey triangle in the upper left corner) along the time axis, you can read the exact values of each of the both recorded variables for each time in the rectangle elements below the diagram.

1.4.3.5.28 Visualization

When you insert a visualization as an element in another visualization, you are creating a "reference" of the visualization.

The configuration of this reference can be done in the Visualization category within the visualization element configuration dialog box.



Enter the object namefor the visualization, which should be inserted, in the Visualization field. Use the ... button to open a dialog box containing the visualizations available in this project. Any visualization may be used with the exception of the current one.

The possible settings concerning the visualization frame are the same as described for a bitmap (see above).

The *[Placeholder]* button leads to the 'Replace placeholder' dialog. It lists in the 'Placeholder' column all the placeholders which had been inserted in the configuration dialogs of the "mother"-visualization and offers in the 'Replacements' column the possibility of replacing these for the current reference with a definite value. Which replacements are possible in a given case depends on whether a value group was predefined in the 'Extras' 'Placeholder list' dialog in the "mother"-visualization. If this is the case, it will be displayed in a combo box for selection. If nothing was pre-defined, double clicking on the corresponding field in the Replacements column opens an editing field which can be filled in as desired.

A further possibility for replacing placeholders in references occurs directly when you define the call of a visualization by an entry into the **Zoom to vis**. option field in the configuration dialog ('Input' category).

No control of the chronological sequence of replacements is possible! Therefore no placeholders should be replaced with text that also contains placeholders!

When using placeholders it is no longer possible to check for invalid entries in the configuration of the visualization element immediately upon compilation of the project. Hence the appropriate error messages are first issued in Online mode (...Invalid Watch expression..).

Example of an application of the placeholder concept

Instances of a function block can easily be displayed with the help of references of the same visualization. For example, in configuring the visualization visu, which visualizes the variables of function block, one could begin each variable entry with the placeholder FUB (e.g. FUB.a). If a reference from visu is then used (by inserting visu in another visualization or by calling via 'Zoom to vis.'), then in the configuration of this reference the placeholder FUB can then be replaced with the name of the function block instance to be visualized.

This might look like shown in the following:

In the project define a function block containing the following declarations:

```
FUNCTION_BLOCK fu

VAR_INPUT

changecol : BOOL; (* should cause a color change in the visualization
*`)

END_VAR
```

In PLC_PRG define two instances of 'fu':

```
inst1_fu : fu;

inst2_fu : fu;
```

Create a visualization object 'visu'. Insert an element and open the configuration dialog, category 'Variables'. Enter in field 'Change color' the following: "FUB.changecol". Open category 'Input' and enter in field 'Tap Variable' "FUB.changecol". Open category 'Text' and enter"FUB - change color ". Define an alarm color in category 'Colors'.

Create another visualization object 'visu1'.

Insert visualization 'visu' twice in 'visu1' (two references of 'visu').

Mark the first reference of 'visu' and open the configuration dialog of category 'Visualization'. Press button 'Placeholder', so that the placeholder list will be displayed. There replace entry 'FUB' by 'PLC_PRG.inst1_fu'.

Now mark the second reference of 'visu' and (like described for the first one) replace 'FUB' by 'PLC_PRG.inst2_fu'.

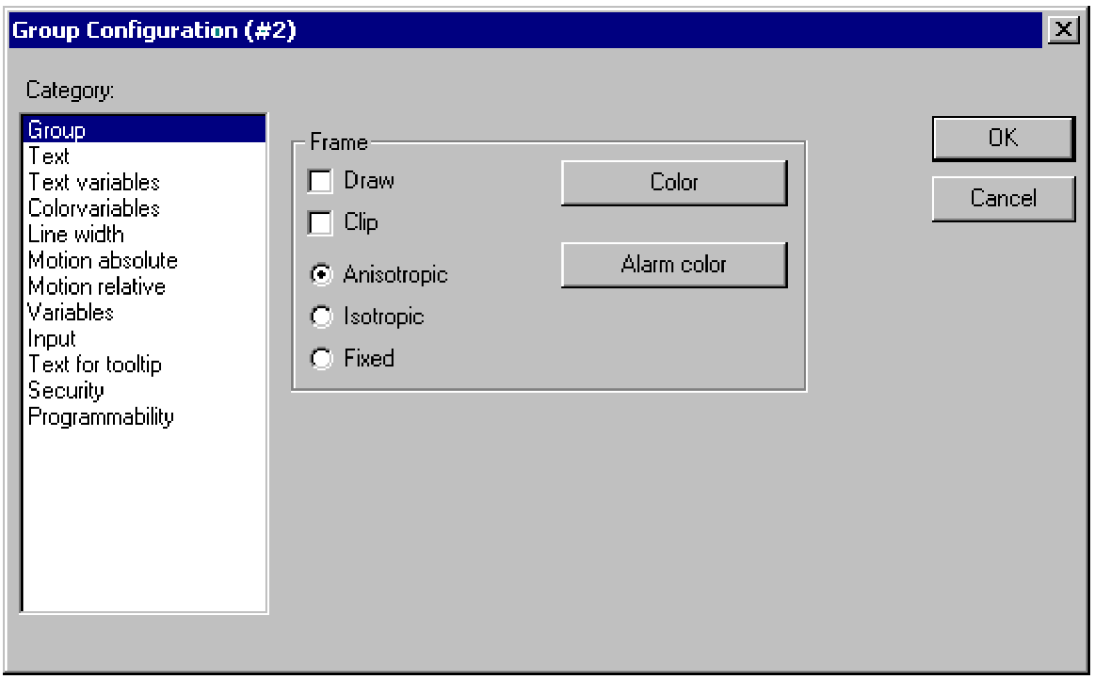
Now in online mode the values of the variables which are used to configure the two instances of 'fu' will be visualized in the corresponding reference of 'visu'.

Of course the placeholder FUB can be used at all places in the configuration of 'visu' where variables or text strings are entered.

> *Attention: Online behavior of a visualization reference: If you insert a visualization and then select and configure this reference, it will be regarded as a single object and in online mode will react to inputs correspondingly to its configuration. In contrast: if you do not configurate the reference, then in online mode its particular visualization elements will react exactly like those of the original visualization.*

1.4.3.5.29 Group

The configuration dialog for a group of visualization elements offers the same options Anisotropic, Isotropc,Fixed, Draw, Clip, Color and Alarm color in field 'Frame' as that for a Bitmap. For example regard the possibility to keep the size of the single elements of the group even when the frame gets stretched or compressed.



1.4.3.5.30 Special input possibilities for operating versions

The visualization can target specifically be used with CODESYS HMI or as web visualization as a mere operating interface. Then no menus and status and tool bars will be available to the user and no possibility to modify the code.

Thus, when a visualization is created with CODESYS for the purpose of being used as a 'operating version' the principal control and monitoring functions in a project must be assigned to visualization elements thus making them accessible via mouse click or keyboard in Online mode.

See in the following some special input possibilities to configure visualization elements for the purpose of being used in CODESYS HMI. They are available in the configuration dialog for a visualization element:

Enter internal commands in the field Execute program in the category Input according to the following syntax (The dialog 'Configure Programs' is available for this purpose):

INTERN <COMMAND> [PARAMETER]*

The following table shows the available internal commands. Some of them expect to receive several parameters, which are then entered separated by spaces. Optional parameters are enclosed in square brackets. For those commands which require that a Watch list be specified, a placeholder can be used instead of the direct name. If you enter several commands for one element, these are separated by commas.

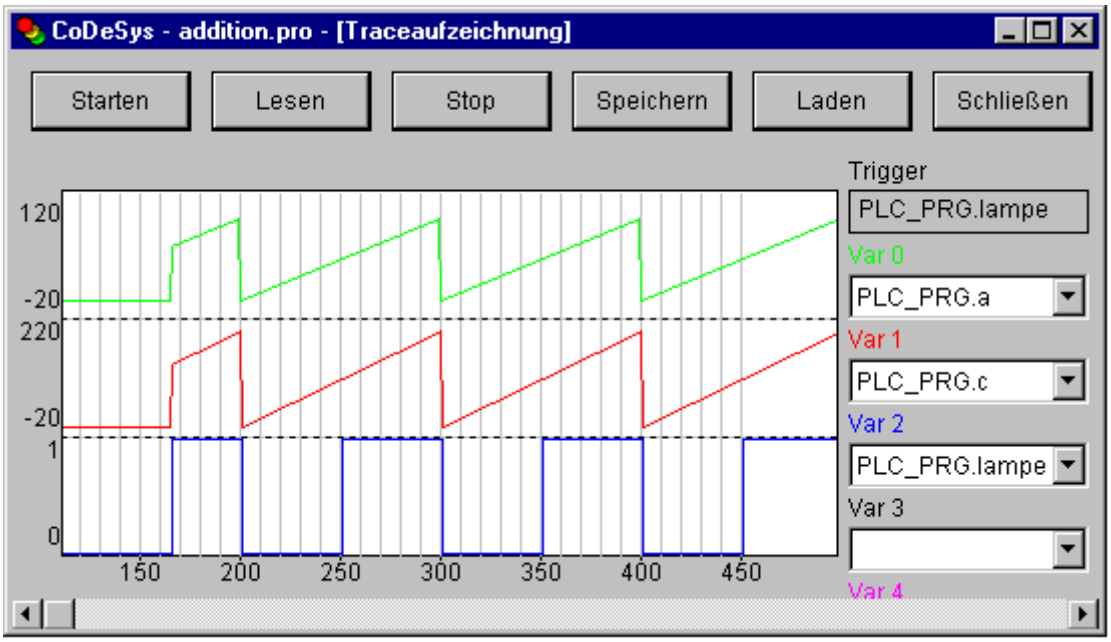
Command	**The equivalent in the programming version of CODESYS HMI**	**Explanation**
ASSIGN <Variable>:=<Expression>	Assignment	A variable or expression gets assigned to another variable. Example: INTERN ASSIGN PLC_PRG.ivar1:=PROG1.ivar +12;
<Path executable program> [Path of the file to be opened] 2)	Program call	The program will be executed. Example: C:\programms\notepad.exe text.txt
LANGUAGEDIALOG2)	'Extras' 'Settings' ↯ *Chapter 1.4.3.6.1 “'Extras' 'Settings'” on page 700*	The dialog for visualization settings which includes the category language gets opened.
LANGUAGE <language identifier as used in the currently set language file *.vis, *.tlt or *.txt> Attention: For visualizations it is recommended to use the *.vis language file.	'Extras' 'Settings' ↯ *Chapter 1.4.3.6.1 “'Extras' 'Settings'” on page 700*, Language	The desired language is set without using the dialog for visualization settings.
LANGUAGE DEFAULT <language identifier as used in the currently set language file>	'Extras' 'Settings' ↯ *Chapter 1.4.3.6.1 “'Extras' 'Settings'” on page 700*, Language	For dynamic texts the default language will be used, which is defined in the currently included XML file.
DELAY <delay time in milliseconds>[1) 2)]		The next command will not be executed before this time has elapsed. E.g. a delay of 500 ms is necessary between DEFINERECEIPT, READRECEIPT and SAVEWATCH.
DEFINERECEIPT <name of watch list>	Select watch lists	A watch list is selected from the receipt manager which enters your name (name) when the command is given. The variables in this watch list are registered and displayed.

Command	The equivalent in the programming version of CODESYS HMI	Explanation
READRECEIPT <name of watch list>	'Read receipt'	In the defined watch list the pre-definition of the variables will be replaced by the current values. Regard: The watch list must be defined before via DEFINERECEIPT and a delay of 500 ms must be inserted (see above: command DELAY).
WRITERECEIPT <name of watch list>	'Write receipts'	The name of a watch list of the receipt manager is expected. The receipt of this watch list will be written. A previous execution of DEFINERECEIPT is not necessary.
SAVEWATCH	'Save watch list'	The receipt will be read into the current watch list which will be stored in a file. Important: call a previous DEFINERECEIPT to define the current receipt and insert a delay of 500 ms (see above: command DELAY).
LOADWATCH	'Load watch list'+ 'Write receipt'	The standard window 'File open' appears, from which a previously stored receipt can be selected. This receipt will be immediately written into the controller system.
CHANGEUSERLEVEL	-	A dialog for setting the user group level will open. The eight user group levels are offered for selection.
CHANGEPASSWORD	cp. 'Project' 'User Group Passwords...'	A dialog for changing the user group password will appear.
SAVEPROJECT[1) 2)]	'File' 'Save'	The project will be saved.
EXITPROGRAM[1) 2)]	'File' 'Close'	The program will be exited.
PRINT[1) 2)]	'File' 'Print'	The current visualization will be printed out online.
HELP <name of help file>[1) 2)]	Call of a help file	Depending on which language is set for the visualization, a help file will be called which is entered for that language in the codesys.ini-file *Chapter 1.4.3.6.1 "'Extras' 'Settings'" on page 700*.

Command	The equivalent in the programming version of CODESYS HMI	Explanation
TRACE[1) 2)]	Resources, Sampling Trace	The window for trace recording (Sampling Trace) will be opened. The menu commands Trace Start, Read, Stop, Save, Load which are available in the full version are available in this window.
CAM[1) 2)]	Resources, CAMs	If there is a CAMs definition available in the project (Resources), the CAM-Editor will be opened. As soon as the editor will be closed again, it will be returned to the visualization.
CNC[1) 2)]	Resources, CNC program list	f there is a CNC program list available in the project (Resources), the CNC editor will be opened. As soon as the CNC editor will be closed again, it will be returned to the visualization.
[1)] not supported for target visualization [2)] not supported for web visualization		
Only for usage in a web visualization: The following commands can be used to give the write access in online mode on a visualization to a certain client. This is of interest if multiple clients at the same time might modify data on the PLC *Chapter 1.4.3.9.4 “Access protection for multi-client operations” on page 716*.		
REQUESTWRITEACCESS	Request for write access	
RELEASEWRITEACCESS	Deallocation of the write access which has been requested before	
GLOBALRELEASEWRITEACCESS	Global deallocation of the write access	
INTERN LINK <URL>	The web visualization will switch over within the browser to the defined URL (Unified resource location)	
INTERN LINK <HTTP file path>	The defined file will be opened.	

Command	The equivalent in the programming version of CODESYS HMI	Explanation
INTERN LINK mailto:<email address>	The entry mask for sending an EMail to the defined address will be opened; e.g. " INTERN LINK mailto:s.sdfjksk@compa-nyxy.com"	
INTERN CONNECT_TO <PLC name>|<Start-Visu>	The PLC (target) will be switched; Preconditions: The web server must be configured appropri-ately with the connection parameters for the respective target systems and a matching ini-file for the PLCHandler must be available. PLC name: Name of the target PLC, as defined in the PLCHandler ini-file. Start-Visu: Name of the desired start visualization page. The web server will establish the connection to the respective PLC automatically. Example: "INTERN CONNECT_TO PLC1|PLC_VISU"	

Dialog for the trace recording in the operating version:



1.4.3.6 Configuring visualization objects

Besides the configuration of the individual visualization elements also the visualization object as a whole can get configured. This is possible concerning the settings for frame, language, grid, background, placeholders etc. as well as the assignment of special hotkey definitions (keyboard usage), which should be valid for exactly one visualization object. These settings are done in the visualization editor via commands of the 'Extras' menu.

Besides that outside of the editor you can do some settings in the Properties dialog of the visualization object, which concern the usage as web visualization or as Master layout.

Regard that in the project options a separate directory can be defined for visualization files
↳ *Chapter 1.4.1.2.2.7 “Options for directories” on page 207*.

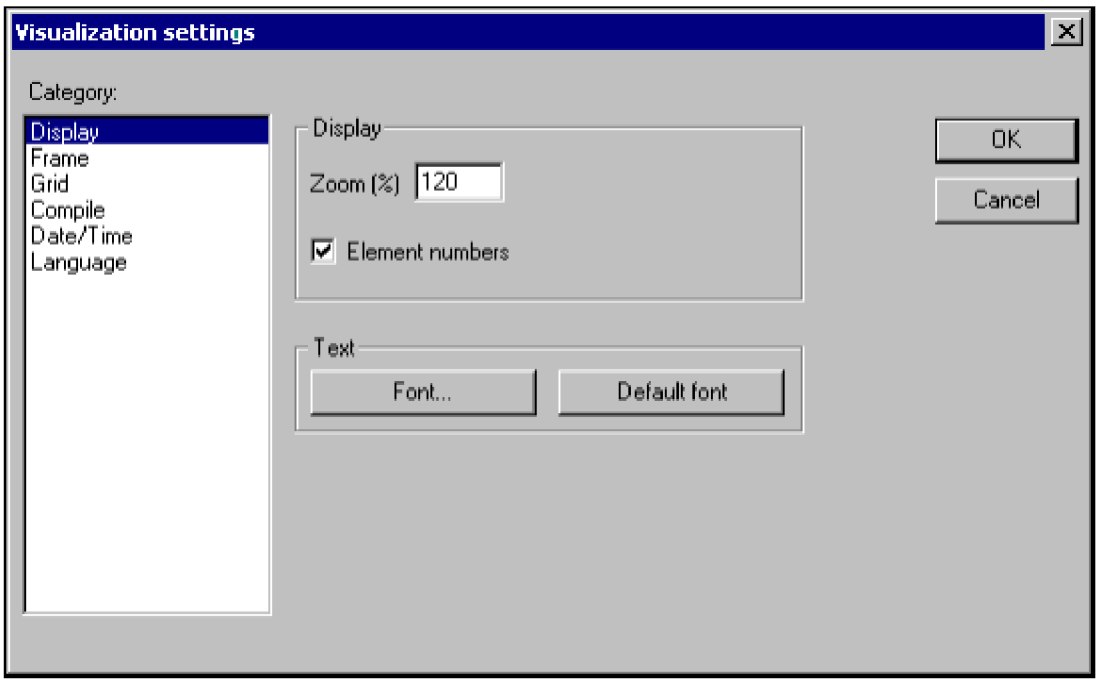
Image files can be used for the background (static) of a visualization in "bitmap" elements (static or dynamic use).

1.4.3.6.1 'Extras' 'Settings'

When this command is used, a dialog box will open in which you can make certain settings that affect the display and language in the visualization as well as the check of the visualization variables.

> *The categories Display, Frame and Language also can be edited in the online mode.*

- Category Display : Enter a zoom factor into the field Zoom of between 10 and 500 % in order to increase or decrease the size of the visualization display. If option 'Element numbers' is activated, in each visualization element its number will be displayed, via which it is managed in the Element List.
  In the 'Text' area via button *[Font]* the standard dialog for selecting a font can be used for defining the font for the current visualization. This font will be automatically applied to all visualization elements, which do not have got a different font explicitly assigned via the element configuration (category 'Text'). Via button *[Standard-Font]* the project font, which is defined in the Project Options, can be set as Visualization font, which also will only effect those elements without individual font definitions. Even those elements however can get assigned the currently valid standard font by the *[Standard-Font]* button in their element configuration dialog.



- Category Frame: If **Auto-scrolling** is selected, the visible portion of the visualization window will move automatically when you reach the edge while drawing or moving a visualization element. If *"Best fit in Onlinemode"* is selected, the entire visualization including all elements will be shown in the window in Online mode regardless of the size of the window. When *"Include Background Bitmap"* is selected, the background bitmap will be fitted into the window as well, otherwise only the elements will be considered.
- Category Grid: Define here whether the grid points are visible in the offline mode, whereby the spacing between the visible points is at least 10 even if the entered size is smaller than that. In this case the grid points only appear with a spacing which is a multiple of the entered size. Selecting *"Active"* causes the elements to be placed on the snap grid points when they are drawn and moved. The spacing of the grid points is set in the field Size.

- Category Compile: Per default the used variables get not checked for validity before going online with a project. If you want this check to be done already during a build run of the project (command 'Project ' 'Build' resp. 'Rebuild all'), then activate option *“Check visualization variable on compile”*. Invalid variables will be announced by a warning "... invalid watch expression..." in the message window.
- Category Time/Date: Here you can define in which format the date or time data outputs in a visualization should be displayed.
  If option *“Formatted time display”* is activated, outputs controlled by a variable of the corresponding time or date datatype (e.g. timevar:TIME;) will be displayed in that format which is defined in the respective edit field here in the dialog. If the option is not activated or if for a datatype no formatting is defined here, the output will be displayed in that format which is used when assigning values to date and time constants (e.g. "t#12h34m15s"), see 'Time data types' *Chapter 1.4.1.8.1.6 “Time data types” on page 444*.

During compilation as target visualization a warning will be displayed, if the functionality is not supported by the target system.

Settings for the following datatypes are possible: Format for TIME/TOD, Format for DATE, Format for DT.

You can use the formattings listed in the table stated below. Upper and lower case must be regarded. Empty spaces inserted in a formatting definition will be displayed in the output string at the same position. Additional characters, which should not be interpreted as format definition, must be embraced by single quotation marks.

Example: A project variable "timevar" of data type TIME is defined, which is configured to control the text output of a visualization element. In the Time/Date settings of this visualization, in the edit field at "Format for TIME/TOD" the data hh':'mm':'ss tt is entered. Output by the respective visualization element in online mode (e.g. if timevar has the value "t#12h34m15s"): 12:24:15 PM.

h	Hours as number, with no leading zero for single-digit hours; 12-hour clock
hh	Hours as number, with leading zero for single-digit hours; 12-hour clock
H	Hours as number, with no leading zero for single-digit hours; 24-hour clock
HH	Hours as number, with leading zero for single-digit; 24-hour clock
m	Minutes as number, with no leading zero for single-digit minutes
mm	Minutes as number, with leading zero for single-digit minutes
s	Seconds as number, with no leading zero for single-digit seconds
ss	Seconds as number, with leading zero for single-digit seconds
ms	Milliseconds as number, with no leading zero for single-digit microseconds
t	One-character time marker string; "A" (ante meridiem) for the time between 00:00 and 11:59, "P" (post meridiem) for the time between 12:00 and 23:59
tt	Two-character time marker string: "AM" (ante meridiem) for the time between 00:00 and 11:59, "PM" (post meridiem) for the time between 12:00 and 23:59
d	Day of the month as number, with no leading zero for single-digit days
dd	Day of the month as number, with leading zero for single-digit days
M	Month as number, with no leading zero for single-digit days
MM	Month as number, with leading zero for single-digit days
y	Year as last two digits, with no leading zero for years less than 10 (example: year 2007 is displayed as "7")

yy	Year as last two digits, with leading zero for years less than 10 (example: year 2007 is displayed as "07")
yyyy	Year represented by full four digits (example: year 2007 is displayed as "2007")

- Category Language: Here you can specify in which national language the text that you assigned to an element in the Text and Text for Tooltip options should be displayed. Additionally the option 'Dynamic Texts' allows a dynamic change of the displayed text.

The text display changes only in Online mode!

1.4.3.6.2 'Extras' 'Select Background Bitmap'

Use this command to open the dialog box for selecting files. Select a file with the extension "*.bmp". The selected bitmap will then appear as the background in your visualization.

The bitmap can be removed with the command 'Extras' 'Clear Background Bitmap'.

1.4.3.6.3 'Extras' 'Clear Background Bitmap'

Use this command to remove the bitmap as the background for the current visualization.

You can use the command 'Extras' 'Select Background Bitmap' to select a bitmap for the current visualization ↳ *Chapter 1.4.3.6.2 “'Extras' 'Select Background Bitmap'” on page 702*.

1.4.3.6.4 'Extras' 'Keyboard usage'

The use of hotkeys can optimize the pure keyboard operation of a visualization.

In the configuration of a visualization object you can define hotkeys which will cause actions like visualization elements do. For example you could define that "“ if visualization 'xy' is active "“ in online mode the hotkey <Strg><F2> will stop the program, which also will happen as soon as element 'z' of visu 'xy' gets an input (by mouse-click or via touch screen).

Anyway per default the keys <Tabulator> <Space> <Enter> will work in that way that in online mode each element of a visualization can be selected and activated.

The dialog 'Keyboard usage: set possible keystrokes' can be called in the menu 'Extras' or in the context menu:

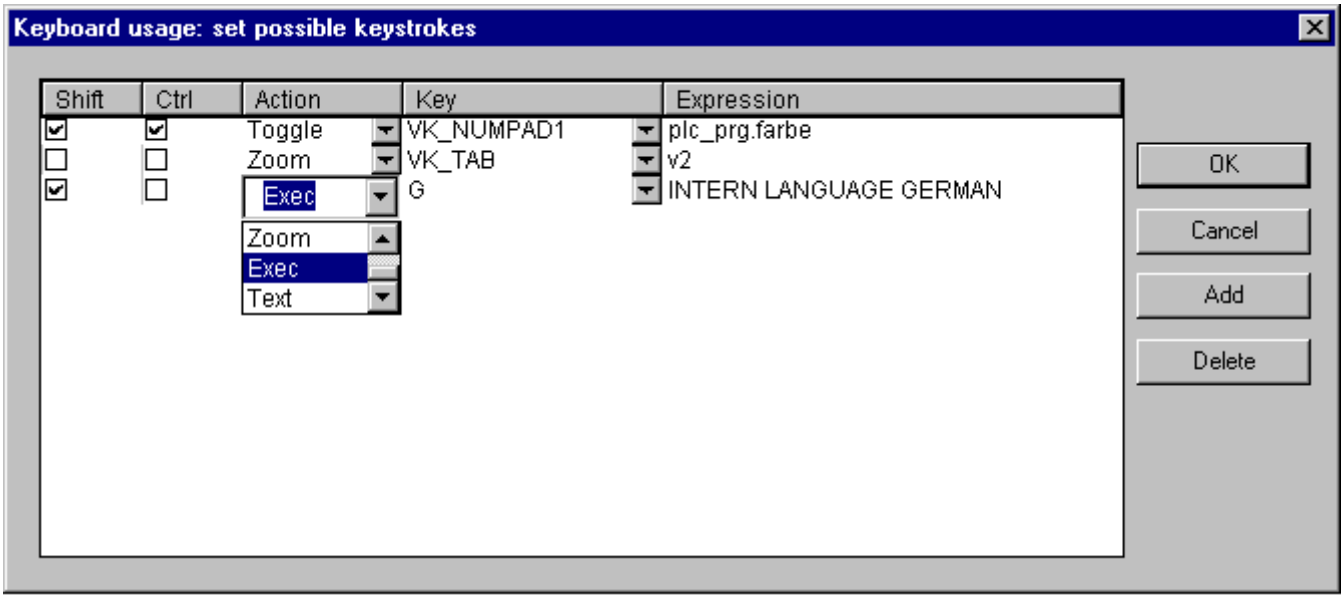


Fig. 11: Dialog 'Keyboard usage: set possible keystrokes'

In column Key a selection list offers the following keys to which an action can get assigned:

VK_TAB	Tab-Key
VK_RETURN	Enter-Key
VK_SPACE	Space-Key
VK_ESCAPE	Esc-Key
VK_INSERT	Insert-Key
VK_DELETE	Delete-Key
VK_HOME	Pos1-Key
VK_END	End-Key
VK_PRIOR	Bild-Key (previous)
VK_NEXT	Bild-Key (next)
VK_LEFT	Arrow-Key (to the left)
VK_RIGHT	Arrow-Key (to the right)
VK_UP	Arrow-Key (up)
VK_DOWN	Arrow-Key (down)
VK_F1-VK_F12	Function keys F1 to F12
0-9	Keys 0 to 9
A-Z	Keys A to Z
VK_NUMPAD0 - VK_NUMPAD9	Keys 0 to 9 of the numeric keypad
VK_MULTIPLY	Key* of the numeric keypad
VK_ADD	Key+ of the numeric keypad
VK_SUBTRACT	Key- of the numeric keypad
VK_DIVIDE	Key÷ of the numeric keypad

In the columns **Shift** and **Ctrl** you can add the *[Shift]*- and/or the *[Ctrl]*-key to the already chosen key, so that a key combination will result.

See the possible key combinations for the particular visualization variants ↬ *Chapter 1.4.3.12 “Possible key combinations for the particular visualization variants” on page 718*.

In column **Action** you define what should happen as soon as the key (combination) will be pressed. Select the desired action from the list and insert an appropriate expression. See in the following the available actions and valid expressions, corresponding to those which can be set in the configuration dialog of category 'Input':

Action	Meaning	Expression
Toggle	Toggle variable	Variable, e.g."plc_prg.tvar"
Tap true	Tap variable (set to TRUE)	Program variable, e.g. "plc_prg.svar"
Tap false	Tap variable (set to FALSE)	Program variable, e.g. "plc_prg.xvar"
Zoom	Zoom to Vis.	Name of the visualization object to which you want to jump, e.g. "Visu1"
Exec	Execute program	Name of the executable file, e.g. "notepad C:\help.txt" (notepad will start and open the file help.txt)
Text	Text input of variable 'Textdisplay'	Number of the element for which the text input is to be configured, e.g. "#2". Display of element numbers can be switched on in 'Extras' 'Settings'; also see 'Elementlist...'.

In column Expression you must enter "“ depending on the type of action "“ either a variable name, a INTERN-command, a visualization name of a text string, exactly like you would do in the configuration dialog of category 'Input' for the corresponding visualization element.

Use button *[Add]* to add another empty line at the end of the table. Use the *[Delete]* button to remove the line where the cursor is positioned currently. *[OK]* resp. *[Cancel]* will save resp. not save the done settings and close the dialog.

The keyboard usage can be configured separately for each visualization object. Thus the same key (combination) can start different actions in different visualization.

Example

The following key configurations have been done for the visualizations VIS_1 and VIS_2:

Table 45: VIS_1:

Shift	Ctrl	Action	Key	Expression
x		Toggle	A	PLC_PRG.automatic
	x	Zoom	Z	VIS_2

Table 46: VIS_2:

Shift	Ctrl	Action	Key	Expression
		Exec	E	INTERN LANGUAGE DEUTSCH
	x	Zoom	Z	PLC_VISU

If you now go online and set the focus to VIS_1, then pressing *[Shift]* + *[A]* will cause that variable PLC_PRG.automatic will be toggled. *[Ctrl]* + *[Z]* will cause a jump from Visu1 to VIS_2.

If VIS_2 is the active window, pressing key *[E]* will cause that the language within the visualization will switch to German. *[Ctrl]*+ *[Z]* here will cause a jump to visualization PLC_VISU.

1.4.3.6.5 Master layout

The usage of a "Master layout" in visualizations for example could be used to provide a dialog in various visualizations without the need to explicitly insert it in each of them. Whether and when the dialog will be displayed in online mode could be controlled via a variable which is defined in the Master layout configuration for the visibility of the dialog elements .

Use as master layout

If a visualization is defined as "Master layout", it will be inserted automatically in all other visualizations (if those are not explicitly excluded, see below) and will be available there with all its functions during online mode. It always will be inserted on the front level, if you however it always want to get it in the background, then activate option 'in background' in the properties dialog of the visualization element (see below). A master layout cannot be edited any longer in the visualization where it has been inserted. Modifications of the configuration only can be done in the master layout visualization itself.

Appointing a visualization to be the master layout is done in the Properties dialog, which can be opened for an object currently selected in the Object Organizer via command 'Project' 'Objectproperties' ↳ *Chapter 1.4.1.2.4.12 “'Project' 'Object properties'” on page 261*. Option Master layout must be activated for this purpose. If prior to this another visualization has been defined to be a master layout, that one will automatically be re-defined to be a "normal" visualization (option Visualization in the Properties dialog.

Visualization without master layout

Also in the Properties dialog of a visualization object you can define that it should be used as a Visualization without master layout.

1.4.3.6.6 Use as web visualization

If a project is created for a web visualization, for each visualization object you can define whether it should be used for this purpose or not ↳ *Chapter 1.4.5.1 “Overview” on page 721*.

There to select the visualization object in the Object Organizer and open the Properties dialog ↳ *Chapter 1.4.1.2.4.12 “'Project' 'Object properties'” on page 261*. If in the Target Settings the options web visualization are activated, in the Properties dialog the corresponding options use as web visualization automatically also will be activated. In order to explicitly exclude the object from the use in a web visualization deactivate the appropriate option.

1.4.3.7 Images in visualization

Image files can be used in a visualization object for the background as well as in visualization elements of type "Bitmap". The following formats are supported:

CODESYS HMI:	*.bitmap, *.jpg, *.tif
Web visualization:	*.bmp, *.jpg

In "Bitmap" elements a dynamic change of images can be reached by specifying the image file name by a project variable instead of using a definite file reference.

↳ *Chapter 1.4.3.5.19 “Bitmap” on page 669*

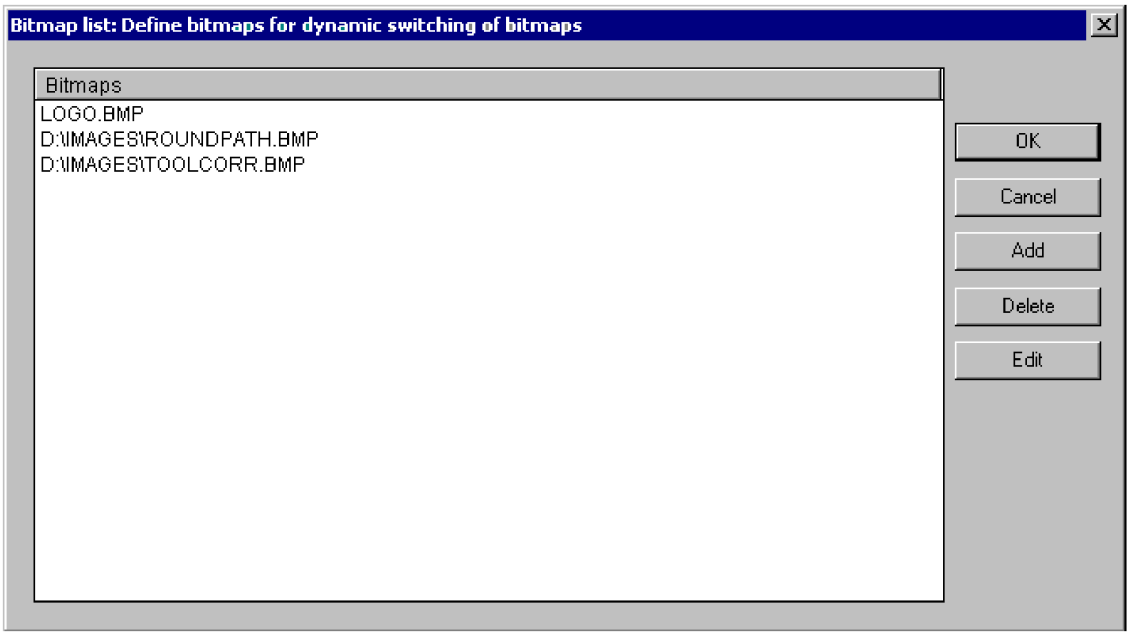
↳ *Chapter 1.4.3.7.1 “'Extras' 'Bitmap list'” on page 706*

The background image of a visualization can only be defined by a static file reference.

↳ *Chapter 1.4.3.6.2 “'Extras' 'Select Background Bitmap'” on page 702*

1.4.3.7.1 'Extras' 'Bitmap list'

In the 'Extras' menu which is available when the Visualization editor is active, command 'Bitmap list' opens dialog 'Bitmap list:...". Here you can enter image files, which then can be used in all visualization objects via a project variable defining the content of a "Bitmap" element. This allows a dynamic change of images in online mode - alternatively to the static use of image files, which for this purpose are not to be part of the bitmap list.



In order to enter an image file in the bitmap list, use button *[Add]*. The standard dialog for browsing for a file will be opened, where you can select an image file (*.bmp, *.tif, *.jpg, regard the supported file formats). If the chosen file is in the project directory, only the file name will be added to the list, otherwise the full path.

Via button *[Delete]* the currently selected entry (click by the right mouse-button) can be deleted.

In order to modify an entry, either edit it directly (click by the left mouse-button on the entry opens the edit frame), of use button *[Edit]* to open the standard dialog for browsing for a file. For the latter the entry first must be selected by a click with the right mouse-button.

[OK] saves the current list.

Each file name specified in the list now can be assigned to a variable of type STRING, which is entered in the bitmap configuration of a visualization element in order to define the image to be used ↳ *Chapter 1.4.3.5.19 “Bitmap” on page 669*.

1.4.3.8 Language switching

1.4.3.8.1 Overview

The language switching for texts, tooltips and alarm messages in a visualization can be done via static texts or via dynamic texts, which must be provided by a file ↳ *Chapter 1.4.3.8.2 “Static language switching” on page 707* ↳ *Chapter 1.4.3.8.3 “Dynamic language switching” on page 709*. Unicode format is only possible with dynamic texts.

How can a language switching be done:

In the configuration dialog ‘Visualization settings’ in the selection list below 'Language' you can choose one of the languages defined in the currently used language file, which should be used as '(start) language' in online mode; for the example shown below: german and english.

A language switch in online mode is done via an input on a visualization element. For this purpose the internal commands "INTERN LANGUAGE <language>" and "INTERN LANGUAGEDIALOG" are available, which can be used in the configuration dialog in category 'input' ↳ *Chapter 1.4.3.5.30 “Special input possibilities for operating versions” on page 695* ↳ *Chapter 1.4.3.5.15 “Input” on page 662*.

Example: Insert a button element which can be used to switch the visualization texts to German. For this purpose, label the element with ‘German’, in configuration category ‘Input’ activate option ‘Execute program’ and define a command "INTERN LANGUAGE <language>". "language" is to be replaced by the language shortcut used in the language file, thus for the vis-file example shown under 'Static Language Switching' ↳ *Chapter 1.4.3.8.2 “Static language switching” on page 707*: "INTERN LANGUAGE german". If the button will be operated in online mode the visualization texts will be displayed according to the entries which are available for "german" in the language file.

Unicode format: Unicode format is only possible with dynamic texts. An appropriate entry must be available in the XML language file. Additionally the following preconditions must be complied:

1. In the configuration of the visualization object a unicode-enabled font must be specified.

   Attention: Currently for tooltip texts this font must be specified in the codesys.ini file ("FaceTooltip=<font>") and is not read from the XML language file!

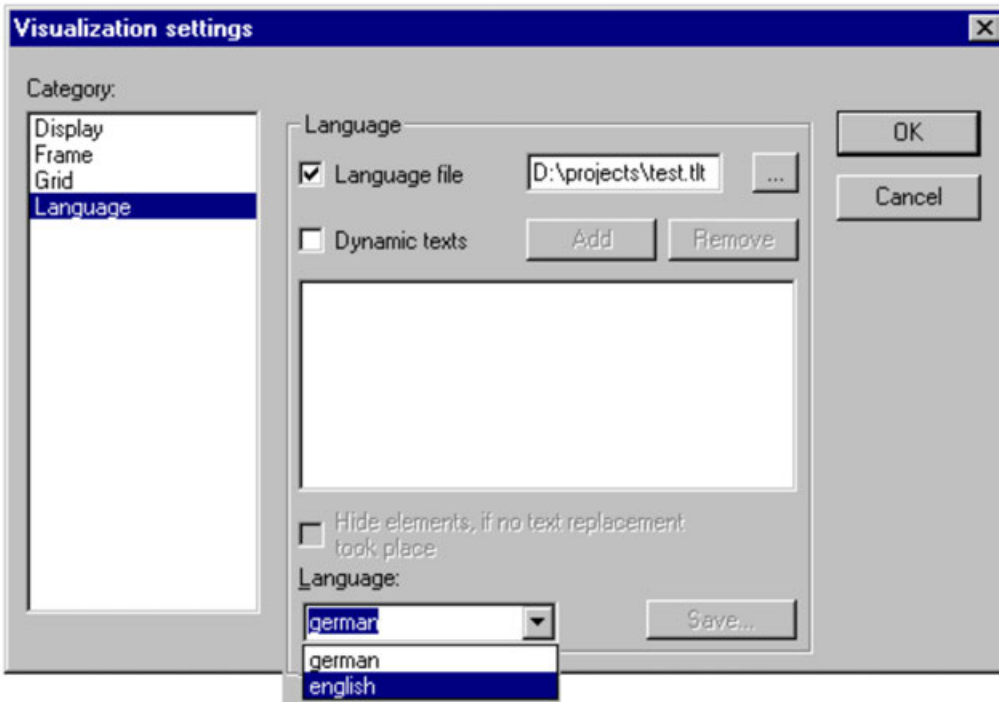
2. In order to get work the unicode font in the target visualization, it must be supported by the target system.
3. In order to get work the unicode font in the web visualization, the configuration entry TOOLTIPFONT in webvisu.htm must be set with a unicode-enabled font.

1.4.3.8.2 Static language switching

For a static switch of the language a language file (*.vis, *.tlt, *.txt) file can be used (for how to create see below). The difference to the dynamic language switching is that the language cannot be defined by a project variable during run time.

*For visualizations it is recommended to use the *.vis language file, because *.tlt- or *.txt-translation files only work for visualizations in CODESYS or CODESYS HMI and also in those not for the Meter, Bar display and Histogram elements.*

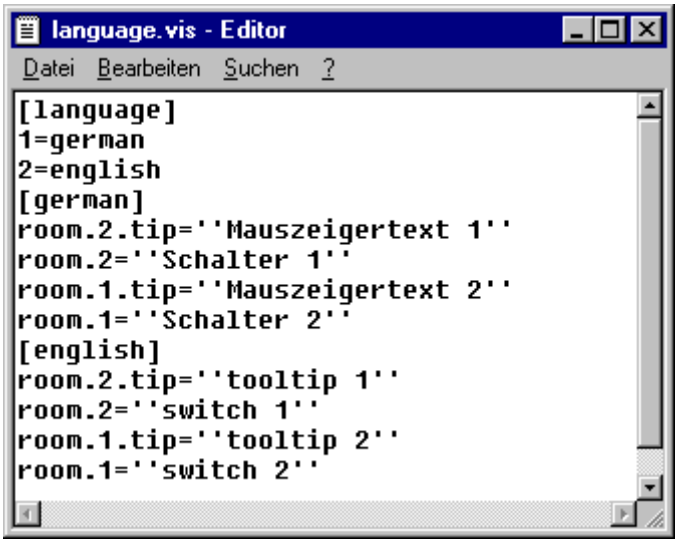
In dialog ‘Visualization settings’ you configure, which language file should be used with the project. In order to choose a translation (*.tlt, *.txt) or a pure visualization language file (*.vis), which contains the texts in the various languages, activate the Language file option and in the input field next to it enter the appropriate file path. Via the button you get the standard dialog for opening a file.



Regarding creating a translation file *.tlt, see 'Project' 'Translate into another language'
↳ *Chapter 1.4.1.2.3.15 “'Project' 'Translate into another language'” on page 233*.

For creating a special language file *.vis for the visualization, perform the following steps:

1. Open likewise the Settings Visualization dialog, Language category.
2. Choose option language file. In the associate input field enter where you want to store the file. The extension is .vis. If a language file with the extension .vis is already present, it will be offered to you here.
3. In the input field next to Language you fill in a keyword for the language which is currently used in the visualization, i.e."german" (or "D"). Then press the button *[Save]*.
4. A file with the extension .vis will be created, which now can be edited by a normal text editor. For example you can open the file by notepad. Example file:



5. You get a list of the text variables for the language currently used in the visualization. It includes a reference to the title of this list, for example "1=german" as reference to the title [german]. You can extend the list by copying all lines, then replacing the German by English text and setting a new title [english]. Beyond the line 1=german you accordingly have to add 2=english.

   To view the visualization in one of the prepared languages, open the dialog *“Language”* again. In the option field beyond *“Language”* now you can choose between german and english (for the example described above).

1.4.3.8.3 Dynamic language switching

Dynamic texts allow switching between different, always language-assigned text versions for a visualization element (texts, texts for tooltips, message texts in alarm tables). The difference to static text is that the definite text selection also can be done via a variable used in the application.

In the configuration of the element a Prefix-ID-combination is entered, which is assigned to a text in a XML files (also named "textlist" in the following). The ID can be defined by a project variable.

Example of application: The ID represents an error number, as Prefix e.g. "Error" is used. The language file provides via the Prefix-ID-combination an appropriate error message, which (depending on the currently set language) will be displayed in this language.

Please regard:

- The language files for dynamic texts can be created in Unicode (UTF-16) or ANSI (ISO-8859-1), e.g. " <?xml version='1.0' encoding='UTF-16'?>". For the preconditions for the usage of unicode-able fonts please see static language switching *Chapter 1.4.3.8.2 “Static language switching” on page 707.*

- For the target visualization the start language, the directory for the XML file to be used and a list of XML files can be defined by the target system. This allows to modify these parameters later without the need of creating a new boot project. Thus in an easy way existing textlists can be modified (start language, texts) resp. new languages can be added. If the target system is providing such a configuration, the textlists which are defined for the visualization, will not be regarded in online mode! If no target-specific configuration is available for the language switching, then after a modification of the textlists a project download must be done.

1.4.3.8.4 Configuration of dynamic language switching

You can control dynamically which text (also alarm message text in an alarm table) will be displayed in a visualization element resp. as tooltip of an element in online mode by using Prefix-ID-combinations, each pointing to another text defined in a XML file.

For this purpose a XML file describing the text assignments must be linked to the project in the configuration of the visualization (*Chapter 1.4.3.6.1 “'Extras' 'Settings'” on page 700*). The XML file must have a certain format. A language code is added to the particular texts, thus later you not only can switch between different text contents but also language switching is supported.

In the configuration of a visualization element, for which the text display should be switched dynamically, Prefix and ID are entered (see below) whereby the ID can be provided by a project variable. A default language can be defined via an INTERN command (LANGUAGE DEFAULT).

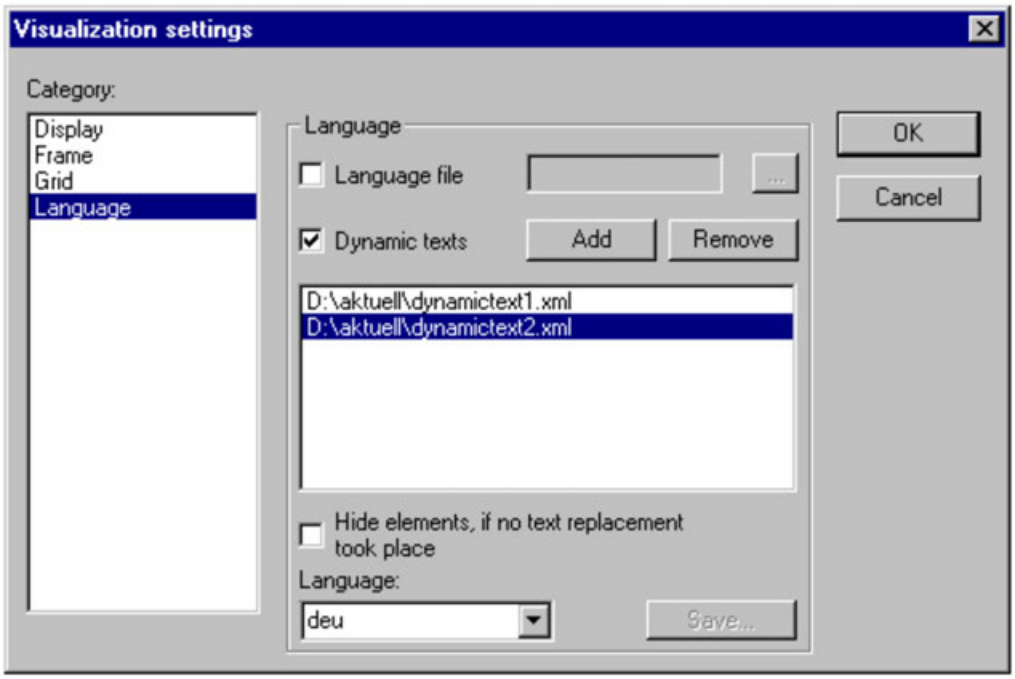
Set the following entries in the different configuration dialogs of a visualization:

1. Link the XML file(s) and choose the (start) language: Dialog 'Settings' category Language:

   Activate option *“Dynamic texts”* and press *[Add]*, in order to link one or several XML files, which are available on your system, to the project. The selected files will be listed in the window below the button. Press *[Delete]* if you want to remove a selected file from the list. If you want to get displayed just those visualization elements, for which a dynamic text replacement is done, then activate option *“Hide elements, if no text replacement took place”*.

   Selecting one of the language identifiers offered in the selection list at field *“Language”* will cause the display of those text versions (for the corresponding prefix-ID-combination) which are marked with that language identifier in the XML file.

   ⇨ Configuration dialog Settings, category Language, for dynamic texts:



2. Specify the ID (as used in the XML file) in configuration dialog 'Variables' in field 'Textdisplay' resp. 'Tooltip-display':

   Enter a value (number) resp. a project variable which should define the ID of a text (as used in the XML file).

   In case of message texts of an alarm table, the ID must match the respective line number in the table .

3. Define the text format in configuration dialog 'Text' resp. 'Text for tooltip':

   In the Content field, insert a placeholder "%<PREFIX>" at that position of the text, where you want to get displayed a dynamic text in online mode. Instead of "PREFIX" you can enter any string matching with a PREFIX-definition used in the XML textlist. See the description for the 'Text' configuration dialog.

For each prefix-ID-combination, which is found in a linked XML file, the assigned text will be displayed in the visualization element in online mode. If no appropriate entry is found, no replacement will be done.

1.4.3.8.5 XML file for dynamic texts

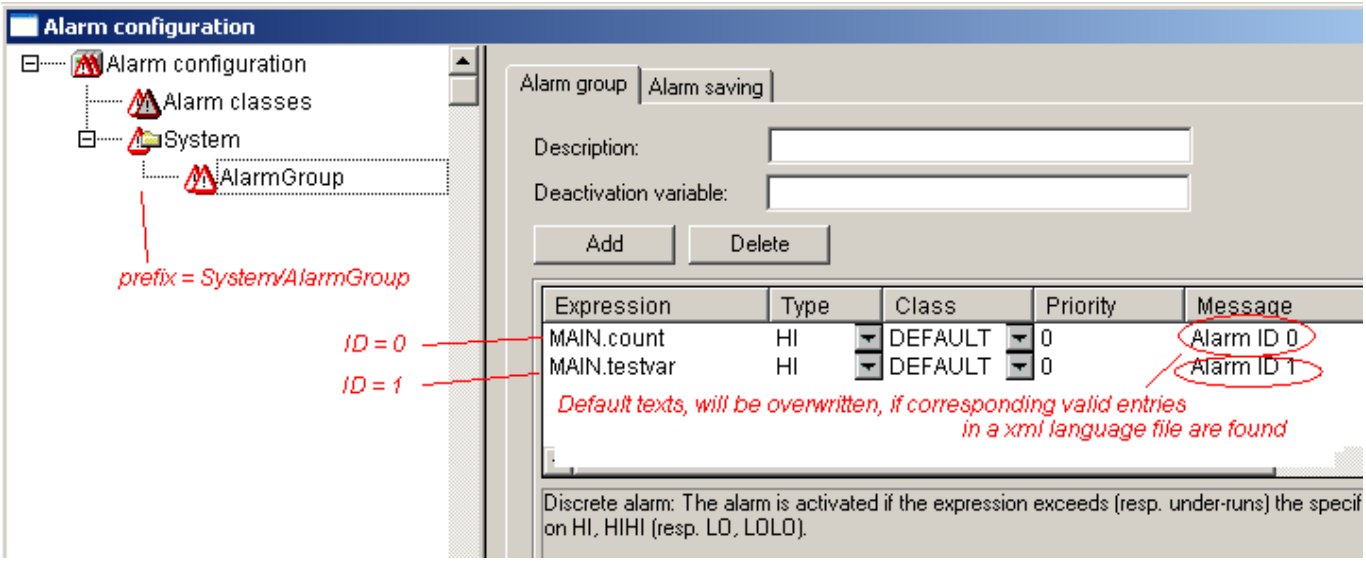
For a description how to use dynamic texts in the visualization see

'Dynamic Language Switching' *Chapter 1.4.3.8.3 “Dynamic language switching” on page 709*

'Configuration of Dynamic Language Switching' *Chapter 1.4.3.8.4 “Configuration of dynamic language switching” on page 709*

The basic file must be available in XML format (<file name>.xml). In this file texts are assigned to identifiers(which are a combination of a prefix and a ID). In case of normal texts and tootip texts these combinations can be entered in the configuration of a visualization element, in order to get displayed the respective text in online mode. In case of an alarm table the prefix and ID are given by the "path" of the alarm group in the alarm configuration (prefix) and the line number of the text definition in the alarm group configuration table (ID).

Example picture showing prefix and ID in an alarm configuration:



In the header section of the file a default language and a default font assigned to a language can be defined. See an example of an description file at the end of this page.

The descriptions in the XML file are enclosed by tag <dynamic-text> and <\dynamic_text> which have to be entered at the beginning resp. end of the file.

The language files for dynamic texts (as of program version V2.3.4.0) can be created in Unicode (UTF-16) or ANSI (ISO-8859-1). This is to be defined via the encoding syntax at the beginning of the XML file, e.g. " <?xml version='1.0' encoding='UTF-16'?>". For the preconditions for the usage of unicode-able fonts, see 'Language Switching' *Chapter 1.4.3.8 “Language switching” on page 706*.

To facilitate the creation of the language file the standard installation provides some Excel macros.

Primary formats of the XML file, which do not use the <dynamic_text>\<\dynamic_text> tags or the header section, will be supported further on.

Structure of the file:

The header section starts with <header> and is closed with <\header>. If you want to define a default language, use entry <default-language>. A default font which is assigned to a certain language, can be defined via entry <default-font>. These entries are optional. If they are missing, the dynamic text in the visualization will be displayed according to the local configuration settings of the visualization.

<header>	
<default-language><language></default-language>	Default language; that means that if there is no text entry available for the currently set language, that text will be used which is found within the same text entry for the default language. If also for the default language no text is found, "<PREFIX> <ID>" will be displayed. If multiple XML files are used, thus providing multiple headers, only that header section will be regarded, which is read at last. So it is reasonable to use only one header section ! The language token must correspond which one of that used in the text entries (see below). Note: In online mode the default language can be set explicitly via a visualization element configured with command INTERN LANGUAGE DEFAULT in category Input, Execute program.
<default-font>	Default font for <language>: The given font (e.g. "Arial" will automatically be used for all elements, which display dynamic texts in <language>. The language token must correspond which one of that used in the text entries (see below). For the preconditions for the usage of unicode-able fonts please see 'Language Switching' ↳ *Chapter 1.4.3.8 “Language switching” on page 706*.
<language><language></language>	
<font-name><font></font-name>	
</default-font>	
<default-font>	Further default fonts for other languages
<language>.....	
....	
</default-font>	
</header>	

The list of the assignments of the Prefix-ID combinations to texts must start with <text list> and end with </text list>. The particular text entries each start with <text prefix> and end with <\text>.

A text entry which is assigned to a Prefix-ID-combination must contain the following lines:

<text prefix>= "<PREFIX> id="<ID>"	"PREFIX" corresponds to the <PREFIX> used in the visualization element configuration (category Text or Tooltip); in case of an message text used in an alarm table the path of the *alarm group* within the alarm configuration starting at node "System" must be specified, e.g. "System/Alarmgroup_xy" "ID" corresponds to the entry in category 'Variables', Textdisplay or Tooltip-display; in case of an of an message text used in an alarm table the number of the line which defines that text in the 'Alarm groups' must be specified ↳ *Chapter 1.4.1.4.2.4 "Alarm groups" on page 368*.
<language> <!CDATA[<TEXT>]]</language>	Use any string as an 'language' identifier (e.g. "english"). This identifier then will be displayed in the 'Settings' dialog, category Language of the visualization element in the selection list at 'Language'; instead of "TEXT" insert any text which then will be displayed instead of the above defined ID-prefix-combination in the visualization element.
</text>	

For each prefix-ID-combination at least for 1 language a text entry must be available. E.g. see in the file example shown below: <deutsch> indicates the start of the german version of a text, </deutsch> terminates the text.

Dynamic texts on the one hand can serve to display Texts in different languages, but of course on the other hand they also can be used to change the content of a text (same language) display dynamically.

Example: You want to have two visualization elements, one for visualizing the current machine identification, the other for visualizing an error message according to a currently given error number:

1. Define in PLC_PRG the following variables: ivar of type INT, defining the current machine identification; errnum of type INT defining the current error number.
2. Configure a visualization element for displaying the current machine identification:

   - In category 'Text'' in the text field enter: "%<Maschine>"

   - In category 'Variables' at Textdisplay" enter: "PLC_PRG.ivar"
3. Configure another visualization element for displaying the error message for the currently occurred error:

   - In category 'Text' in the text field enter: "%<Error>"

   - In category 'Variables' at 'Textdisplay' enter: "PLC_PRG.errnum"
4. Create a XML file, e.g. with name dynamictextsample.xml, according to the syntax described above, which should look as followed for the current example: Sample XML file for dynamic texts ↳ *"Sample XML file for dynamic texts" on page 714*
5. In the visualization open dialog 'Settings', category Language: Activate option 'Dynamic Texts'; Add file dynamictextsample.xml, now available on your computer, to the file list.
6. Go online with the project.
7. In the visualization settings set language to "deutsch". Set PLC_PRG.ivar to "1" and PLC_PRG.errnum to "4711". Now in the visualization elements the following texts should be displayed: "Vorschub" resp. "Fehler an Position 4711". The texts will be displayed in Arial 13.
8. Set PLC_PRG.ivar to "2" and PLC_PRG.errnum to "2000". The texts will change to "Beschleunigung" and "Das ist ein Fehlertext über mehrere Zeilen".

9. In the visualization settings change the language to "english". Now the following texts will be displayed:

   "Acceleration" and "This is a error text over more than one line".

Sample XML file for dynamic texts

```
<dynamic-text>
    <header>
    <default-language>deutsch</default-language>
    <default-font>
      <language>english</language>
      <font-name>Arial</font-name>
      <font-color>0,0,0</font-color>
      <font-height>-13</font-height>
      <font-weight>700</font-weight>
      <font-italic>false</font-italic>
      <font-underline>false</font-underline>
      <font-strike-out>false</font-strike-out>
      <font-char-set>0</font-char-set>
    </default-font>
    </header>
  <text-list>
    <text prefix="ERROR" id="4711">
      <english>Error at position 4711</english>
    </text>
    <text prefix="ERROR" id="815">
      <english>Error at position 815</english>
    </text>
    <text prefix="ERROR" id="2000">
        <english>
          <![CDATA[
          This is a error text over more than
          one line
          ]]>
        </english>
    </text>
    <text prefix="MASCHINE" id="1">
        <english>
            <![CDATA[ Feed rate
          ]]>
        </english>
    </text>
    <text prefix="MASCHINE" id="2">
       <english>
           <![CDATA[ Acceleration
        ]]>
       </english>
    </text>
  </text-list>
</dynamic-text>
```

1.4.3.8.6 Calling up language-dependent online help via a visualization element

The calling of a different Help file with a visualization element can be tied in with the language currently entered for the visualization. For this purpose, the command INTERN HELP must be entered for this element in the configuration dialog in category 'Input' at the location 'Execute program', and a [Visu-Helpfiles] section must be present in the codesys.ini-file. Below this, the corresponding help files must be assigned to the languages available for selection in the visualization.

Example	[Visu-Helpfiles] German=C:\PROGRAMME\HELP\<hilfedatei_german>.chm English=C:\PROGRAMME\HELP\<hilfedatei_english>.chm

1.4.3.9 Visualization in online mode

1.4.3.9.1 Overview

Regard the following items concerning a visualization in online mode:

- Order of evaluation:
  - Dynamically defined element properties (by variables) will overwrite the (static) base settings defined by options in the configuration dialogs.
  - If an element property is defined by a "normal" project variable as well as by the component of a structure variable (programmability), then primarily the value of the project variable will be regarded.
  - A visualization can be configured in that way that in online mode it can be operated solely by inputs via keyboard. This is an important feature especially for using the visualization with CODESYS HMI, as web visualization.
- Before a download of the project regard the current setting of option 'Prevent download of visualization files' in the target settings. This concerns all files which are used in the current visualization. Visualization files are only downloaded for web visualization and can be bitmaps, language files and for web visualization also XML description files.
- The configuration settings for Display, Frame and Language can also be edited in online mode.
- As long as a visualization "reference" is not configured explicitly, the particular elements of the reference in online mode will react on inputs like those of the original visualization ("mother" of the references).
- When you switch the language ('Extras' 'Settings') this will only effect the display in online mode.
- A visualization can be printed in online mode.
- If a visualization is used as target visualization, information on user entries via mouse-clicks can be scanned with the help of special interface functions and thus be used in the project.

You can find descriptions on the online usage of some visualization elements, like e.g. Trend or Table, in the help page on the configuration of the respective element.

1.4.3.9.2 Operation over the keyboard

In order to get independent from the mouse or a touch screen, it is useful to configure a visualization in a way that allows pure keyboard operation:

Per default the following key (combinations) will work in online mode anyway (no special configuration necessary):

- Pressing the *[Tabulator]* key selects the first element in the element list for which an input is configured. Each subsequent pressing of the key moves one to the next element in the list. Within tables you will jump to the next table field. Pressing the key while keeping the *[Shift]* key depressed selects the previous element. Depending on the target a simplified input handling may be possible.
- The *[arrow]* keys can be used to change from a selected element to a neighbouring one in any direction.
- The *[Space bar]* is used to execute an activity on the selected visualization element. If the element is one which has a text output variable or if it is a table field, a text input field will be opened which displays the text contents of the variable resp. the field. Pressing the *[Enter]* key writes in this value.

Additional key (combinations) for the online operation can be defined in the configuration dialog 'Keyboard usage'. There also the keys *[Tab]*, *[Space]* and *[Enter]* can get assigned another functions than the above described standards.

The individual elements of references behave in Online mode identically to the corresponding ones in the visualization that is referenced. They will therefore react the same way as individual elements to inputs and operation by mouse and keyboard; the display of tooltips in references is also element-dependent. When processing the element list, as for instance when jumping from one input element to the next using the tabulator, the processing of all individual elements of a reference proceeds from the location of the reference in the element list before jumping to the next element of the list.

Operation over the keyboard in online mode is of greatest significance, if the visualization should be used with CODESYS HMI or web visualization. In the web visualization a specific setting in webvisu.htm allows to keep effective the operation over the keyboard even if currently an entry field is opened.

1.4.3.9.3 'File' 'Print'

'File' 'Print'is used to print out the contents of the visualization window in online mode. Visualizations which stretch over the border of the window can lead to inconsistencies particularly when there are moving elements in the visualization.

1.4.3.9.4 Access protection for multi-client operations

Due to the fact that it is possible to connect multiple visualization clients to one PLC (target and web visualization), multiple clients might access data in the PLC at the same time. If this is not desired, an access protection can be defined by certain INTERn commands, so that always only one client can write the data on the PLC.

The following INTERN commands are available for restricting the write access to one client:

REQUESTWRITEACCESS	The client requests write access on the visualization. Using the system variable CurrentWriteAccessClientId the client then can check whether it has got write access. This implicit variable stores the identification (ID) of the client which currently has write access. Each client has an unique ID "CurrentClientID".Thus the following expression can be used to allow a certain input on a visualization: CurrentWriteAccessClientId = CurrentClientId Example: The expression could be used in the configuration of an element to define its visibility : If the expression is TRUE, i.e. the client has write access, then the element is visible, i.e. allows input. The web server will check at each write request, whether the requesting client currently has write access.
RELEASEWRITEACCESS	The client deallocates its write access.
GLOBALRELEASEWRITEACCESS	The write access is deallocated client-independently.

Automatic deallocation of write access: If during monitoring it is detected that the client which has currently write access is not connected to the PLC any longer, variable CurrentWriteAccessClientId will be set to "-1", which means, that no client at all has write access. This also can be done via the application.

1.4.3.10 Visualizations in libraries

Visualizations can also be stored in libraries and thus be made available to projects in the form of library POUs. They can be inserted as references or they can be called up via the command „Zoom to vis." in the input configuration of another visualization which is part of the project.

Visualizations used in a project must have unique names. It can be problematic if for instance a visualization from a library is called or referenced which has the same name as one present in the project. Because, in processing references or visualization calls in the program, first the visualizations in the project, and only thereafter the ones in the loaded libraries will be implemented.

1.4.3.11 System variables

Implicit variables The following implicitely created system variables can be used to program a visualization:

Implicitely generated variable	Data type	Function	Currently usable in HMI	Currently usable in Simulation	Currently usable in Target Visu	Currently usable in Web-Visu
CurrentVisu	String[40]	Name of the currently opened visualization. If the name gets changed, a change to another visualization will be done. Note: With compiler versions < V2.3.7.0 the name string MUST be defined in capital letters. With compiler versions as from V2.3.7.0 the string can be defined in small letters IF the library SysLibStr.lib is included in the project. Depending on the target system this variable can be activated/deactivated in the Target Settings dialog, category Visualization.	x	x	x	x
CurrentCaller	String[40]	Name of the previously opened visualization. Is used for the ZOOMTOCALLER functionality. Only set and modified in TargetVisu.	-	-	x	-
CurrentLanguage	String[40]	Currently set language, available in the language file. The language. Only set and modified in TargetVisu.	-	-	x	-
CurrentUserLevel *	INT	Currently set user level 0..7.	x	x	x	x

Implicitely generated variable	Data type	Function	Currently usable in HMI	Currently usable in Simulation	Currently usable in Target Visu	Currently usable in Web-Visu
CurrentPasswords[0 .. 7] *	ARRAY [0..7] of String[20]	All passwords which are defined in "Usergroup passwords".	x	x	x	x
CurrentWriteAccessClientId	DWORD	ID of the visualization client which in a multi-client operation currently has the write access on the PLC data	-	-	x	x
CurrentClientId	DWORD	ID of the current visualization client	-	-	x	x

Implicit variables as remanent variables:

The implicit variables of a target visualization can be declared as remanent variables *Chapter 1.4.1.3.9.7 “Remanent variables” on page 302*:

For this purpose the variables must be declared explicitly as global variables. This declaration MUST be done in the topmost (alphabetic order) global variables list in folder 'Global Variables' in the Resources tab *Chapter 1.4.1.4.1.2 “Global variables” on page 357*. If the declaration is placed in another global variable list, a compile error will occur.

Example:

```
VAR_GLOBAL RETAIN
 VisuDoExecuteUserlevelInit : BOOL := TRUE;
 CurrentUserLevel : INT := 0;
 CurrentPasswords : ARRAY[0..7] OF STRING[20] := 'a','b','c','d','e','f','g','h';
END_VAR
```

* Regard for the variables CurrentUserLevel, CurrentPasswords[...]: Those must be of the same type (normal, RETAIN, PERSISTENT...)! If they are defined as remanent variables, additionally a variable "VisuDoExecuteUserlevelInit" of type BOOL must be declared as a RETAIN variable in the global variables list, initialized with TRUE (" VisuDoExecuteUserlevelInit : BOOL := TRUE;").

1.4.3.12 Possible key combinations for the particular visualization variants

The table below shows all possible key combinations which are supported for keyboard usage in the particular visualization variants.

The following abbreviations are used:

- C for CODESYS / CODESYS HMI
- TV for target visualization
- WV for web visualization

If an abbreviation is available in a column, the referring visualization variant supports the corresponding key combination.

Table 47: Comments for the particular lines

	no modifier	Shift	Ctrl	Shift+Ctrl	Comment
VK_TAB	C	C	C	C	K4
VK_RETURN	C / TV	C / TV	C / TV	C / TV	
VK_SPACE	C / WV	C / WV	C / WV	C / WV	K4; K5
VK_ESCAPE	C / TV / WV	C / TV / WV			K3
VK_INSERT	C / TV	C / TV	C / TV	C / TV	
VK_DELETE	C / TV	C / TV	C / TV	C / TV	
VK_HOME	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
VK_END	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
VK_PRIOR	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
VK_NEXT	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
VK_LEFT	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
VK_RIGHT	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
VK_UP	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
VK_DOWN	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
F1	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	K1
F2	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
F3	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
F4	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
F5	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
F6	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
F7	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
F8	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
F9	C / TV / WV	C / TV / WV	C / TV / WV	C / TV / WV	
F10	C / TV	C / TV	C / TV	C / TV	K2

K1: Additionally, the online help will be displayed

K2: In the web visualization and the IExplorer the File Menu will be focused

K3: Ctrl/Esc opens the start menu, Shift/Ctrl/Esc opens the Taskmanager

K4: Tab and Space have a different function in the target visualization

K5: Shift/Space opens the applet configuration

1.4.4 HMI

1.4.4.1 Overview

CODESYS HMI is a runtime system for the execution of visualizations which have been created with CODESYS. If a PLC program contains appropriate visualizations, those will be displayed in fullscreen mode after having started CODESYS HMI and the user can operate the control and watch functions, which are contained in the program by mouse-clicks and keyboard. This is possible, even if the Automation Builder project has got a read protection. The user has no possibility to edit the program, menues and function bars are not available, it is a pure operating version.

Thus the main control and watch functions of the project must be assigned to visualization elements which can be operated in online mode. For this purpose special input possibilities for CODESYS HMI are available in the configuration dialog of a visualization element ↳ *Chapter 1.4.3.5.30 “Special input possibilities for operating versions” on page 695*.

1.4.4.2 Installation, start and operation

Installation

CODESYS HMI can be installed with the standard Automation Builder setup. If no valid license is available, a time-limited demo version is available.

Start and operation

CODESYS HMI (*CoDeSysHMI.exe*) is started by a **command line**:

In each case at least the desired Automation Builder project has to be given in the command line. If no further parameters are set there, CODESYS HMI automatically will start with a visualization POU named PLC_VISU (if existant in the project) and on that target or simulation mode, which was set when the project had been saved last.

Additionally as well the known command line and command file commands as the following special parameters can be used:

- **"/simulation" resp. "/target"**
  Per default it will be started in that mode which was set when the project was saved last. Using the parameter "/simulation" resp. "/target" in the command line it can be set explicitely whether the project should run in simulation mode or on the target.
- **/visu <visualization POU>**
  If the project contains a visualization POU named PLC_VISU, it will start automatically with this one. If another POU should be the entrance, it has to be set in the command line with "/visu <name of visualization POU>".
- **/visudownload**
  Overrides the download lock: If the user tries to log in with a project, which is different to that on the PLC, per default a download of the new project (dialog) can be initiated. If however there is an entry "visudownload=0" in the *codesys.ini* file, then no download is possible. This lock can be overridden by the command line parameter "/visudownload".
- **/visucompactload**
  This parameter can be used for optimization at starting a project for which no download is required. If a download gets necessary anyway, e.g. effected by parameter "/visudownload", "/visucompactload" will be ignored.

Example for a command line

```
D:\PROGRAMME\CoDeSysHMI /simulation D:\PROJECTS\PROJECT.PRO /visu
overview
```

The project *project.pro* will start in simulation mode and with the visualization POU 'overview'.

Paths containing spaces must be bordered by quotation marks (").

The project will start in full screen mode with the entrance POU.

CODESYS HMI can be operated corresponding to the functions of the visualization elements via keyboard and mouse. If there is no visualization element configured with a corresponding function, CODESYS HMI at any time can be terminated by pressing *[Alt]* + *[F4]*.

1.4.5 Web visualization

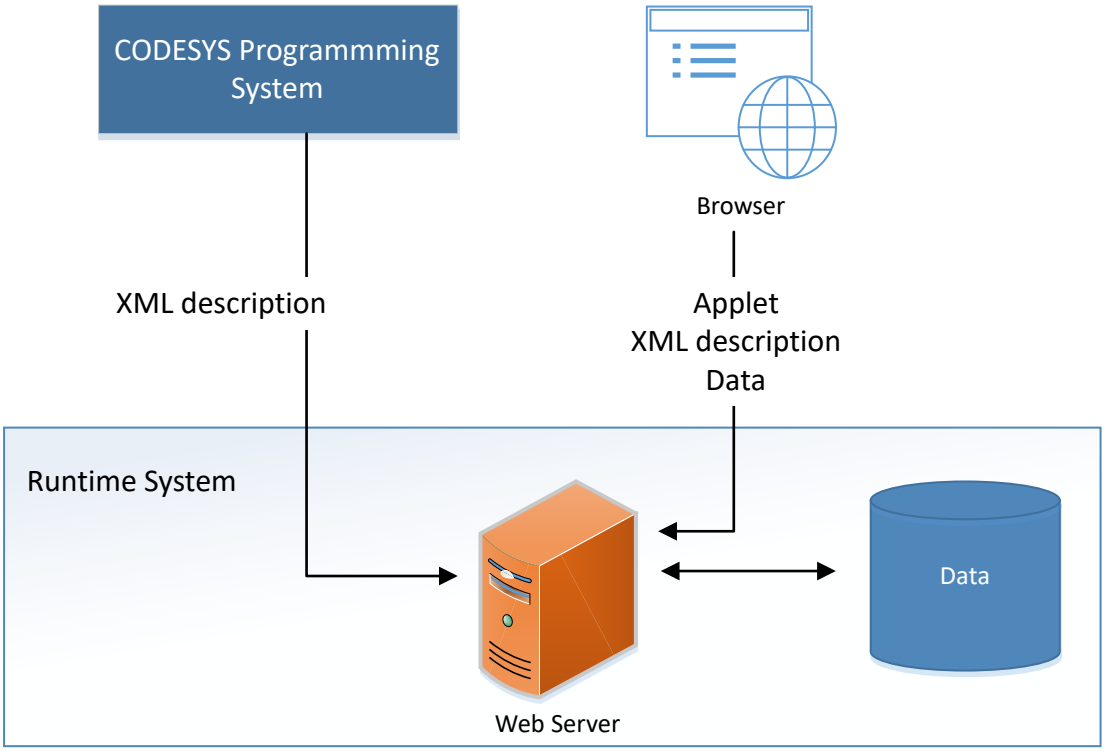
1.4.5.1 Overview

The web visualization is a target specific application of a visualization.

CODESYS can create XML descriptions of the visualization objects and download them to the PLC. There a web server will provide the PLC data in XML format too and thus can create a continuously updated visualization which can be opened in the web browser of any computer which is connected via Internet, independently from the target platform (e.g. useful for remote maintenance purposes).

Regard the Restrictions and Special Features when programming for a web visualization.

The web server can connect dynamically to several controllers if configured appropriately. Visualization elements can be configured in a way that they will effect a connection change to another target system.



Before a download regard the current setting of option 'Prevent download of visualization files' in the target settings. This concerns all files which are in the directory for visualization files!

1.4.5.2 Preconditions

In order to make a visualization created in CODESYS available as web visualization, the following preconditions must be fulfilled:

- the target system must support the functionality; that means that in the target settings the option 'web visualization' must be activated. If defined in the target file, this can be done by the user in the 'General' target settings.
- A correctly configured web server must be started. (see below)
- In order to get the web visualization displayed on a computer, a Web browser (IE-Explorer oder Netscape) is required.

- Operating system: Windows NT/2000, Windows CE, Linux, RTE
- Regard when using a HTTP-Proxy-Server: If the communication within the Internet browser is done via a HTTP-Proxy-Server, the monitoring of the visualization data might cause problems. If "USEFIXSOCKETCONNECTION" in WebVisu.htm is set TRUE, the telegram format used for the process data communication between applet and web server will not match the HTTP standard. In this case the HTTP Proxy will not forward the telegrams to the web server.

  A workaround is to configure a SOCKS-Proxy:.Clients behind a firewall which want to establish a connection to an external server, instead have to connect to a SOCKS-Proxy. This Proxy-Server checks whether the client is authorized to communicate with an external server and forwards the requests transparently to the server.

  The SOCKS protocol is an Internet-Proxy protocol, allowing client-server applications to transparently use the services of a firewall. SOCKS is an abbreviation for "SOCKets".

Before downloading the project regard the current setting of option 'Prevent download of visualization files' in the target settings. This concerns all files which are used in the current visualization. Those can be bitmaps, language files and for web visualization also XML description files.

1.4.5.3 Editing the WebVisu.htm file

During installation of Automation Builder the file WebVisu.htm (base-HTML-page for the web visualization) gets copied to the subdirectory "visu" in the installation directory. This is the basic html-page for the web visualization. Before it gets downloaded to the target system together with the web visualization project, it can be edited in a text editor in order to change the behavior of the web visualization:

Webvisu.htm per default contains the following:

```
<HTML>

<HEAD>

   <TITLE>Applet HTML Page</TITLE>

</HEAD>

<BODY>

<APPLET CODEBASE=. CODE=webvisu/WebVisu.class
archive="webvisu.jar,minml.jar" name="WebVisu" width="1600"
height="1200">

<param name="STARTVISU" value="PLC_VISU">

<param name="UPDATETIME" value="100">

<param name="USECURRENTVISU" value="FALSE">

</APPLET>

</BODY>

</HTML>
```

The following parameters are of meaning for an adaption of the behavior of the web visualization:

width, height	Definition of the size of the screen. Regard the possibility to make visible this size already during creating a visualization (Target Settings: Display width/height in pixel).
STARTVISU	Definition of the start POU (Default: PLC_VISU)
UPDATETIME	Definition of the monitoring interval (ms)
USECURRENTVISU	Definition whether an automatic change to another visualization will be done, as soon as the system variable 'CurrentVisu' is changed by the PLC program. For information on implicit (system) variables in the visualization see 'Implicit Variables' *Chapter 1.4.3.11 “System variables” on page 717*).

Optionally the file can be extended by the following entries in the APPLET definition part:

<param name="USEFIXSOCKETCONNECTION" value="FALSE or TRUE">	If this parameter is TRUE, a fix socket connection will be used for monitoring; if it is FALSE or if the entry is missing at all, for each monitoring request a new socket will be used. Default: FALSE. Attention: If parameter USEURLCONNECTION (see below) is used, USEFIXSOCKETCONNECTION may not be set TRUE.
<param name="FORCEDLOAD" value="Comma-separated list of visualization names">	The visualizations specified here will be loaded already when the web visualization is loaded, not just when they are opened for the first time. Thus time is saved at later changes of visualizations, because then the data not have to be transferred first by the web server. Examples: <param name="FORCEDLOAD" value="VISU_1, VISU_2, VISU_3 "> <param name="FORCEDLOAD" value="TREND">
<param name="COMPRESSEDFILES" value="FALSE or TRUE">	The files to be transferred for the web visualization to the web server can be provided in a packed format ("<filename>_<extension original format>.zip"). See 'Target settings in category visualization' *Chapter 1.4.1.4.7.3 “Target settings in category visualization” on page 388*. If parameter "COMPRESSEDFILES" is set "TRUE", the web visualization first will try to load from the web server all needed files which have got appended the extension ".zip"and to unzip those. If the request for a zip-file fails, it will be tried to load the original file. If parameter "COMPRESSEDFILES" is not available or is configured with value FALSE, any available zip-files will be ignored.

<param name="USEURLCONNECTION" value="URL">	If this parameter is available, the communication will be done via the specified URL-connection. Per default a simple socket connection is used. Attention: If parameter USEFIXSOCKETCONNECTION (see above) is set TRUE, USEFIXSOCKETCONNECTION may not be used additionally. Example: <param name="USEURLCONNECTION" value="http://192.168.100.19:8080/webvisu.htm"
<param name= "PLCSTATEINTERVAL" value="Time interval for cyclic status requests">	The status of the PLC will be requested according to this time interval (milliseconds). Default: 2000. See also: Status check, AutoReload, File error ini.xml.
<param name="FORCEDLOAD" value="comma-separated list of visualization names">	The visualizations specified here will be loaded already when the web visualization is loaded, not just when they are opened for the first time. Thus time is saved at later changes of visualizations, because then the data not have to be transferred first by the web server. Examples: <param name="FORCEDLOAD" value="VISU_1, VISU_2, VISU_3 "> <param name="FORCEDLOAD" value="TREND">
<param name="COMPRESSEDFILES" value="FALSE or TRUE">	The files to be transferred for the web visualization to the web server can be provided in a packed format ("<filename>_<extension original format>.zip"). See 'Target settings in category visualization' *Chapter 1.4.1.4.7.3 “Target settings in category visualization” on page 388*. If parameter "COMPRESSEDFILES" is set TRUE, the web visualization first will try to load from the web server all needed files which have got appended the extension ".zip"and to unzip those. If the request for a zip-file fails, it will be tried to load the original file. If parameter "COMPRESSEDFILES" is not available or is configured with value FALSE, any available zip-files will be ignored.
<param name="SELECTION" value="Line width|RED|GREEN|BLUE">	Here the line width and color for the display of the current selection can be defined. Syntax: LINEWIDTH|RED|GREEN|BLUE; Example: "4|0|0|255"
<param name="ERROR_SENSITIVITY" value="Number of trials to get a file transferred">	This parameter defines, how many trials will be done to get a visualization file transferred from the web server, before an applet error will appear.

<param name="KEYPADINDIALOGS" value="FALSE or TRUE">	If a touch screen is used for working with the web visualization, this parameter should be set TRUE in order to get an input possibility in any case for each dialog; if applicable via numpad/keypad.
<param name="KEYBOARDUSAGEFROM-DIALOGS" value="FALSE or TRUE">	If this parameter is set TRUE, the keyboard usage is always active, even if a modal dialog - like e.g. the numpad - is currently opened.
<param name="WRITEACCESSLOCK" value="FALSE or TRUE">	This parameter only should be set TRUE, if the web server supports multi-client processing and if an access lock for various clients is desired. Concerning access control in multi-client operation please see 'Access protection for multi-client operations' *Chapter 1.4.3.9.4 “Access protection for multi-client operations” on page 716*.
<param name="DEFAULTENCODING" value="FALSE or TRUE">	If this parameter is set TRUE and the language switching is done via ASCII language files, the default encoding - currently set in the system - will be used for the interpretation of the language file.
<param name="ENCODINGSTRING" value="encoding string">	If the default encoding of the system is not set as desired, you can define here the desired encoding by entering the appropriate string. Examples for encoding strings: German: "ISO-8859-1" Russian: "ISO-8859-5" Japanese: "MS932"
<param name="PLCSTATEINTERVAL" value="Zykluszeit">	Cycle time in milliseconds, according to which the web client will check the PLC status. It will be checked whether the PLC is in Start or Stop status and whether a download has been done.
<param name="ALARMUPDATEBLOCKSIZE" value="Number of alarm states to be updated per cycle">	This parameter can be set in order to change the update of the alarm states. Due to the fact that not all alarm states can be updated within one cycle, it might be useful to exactly defined the number of alarms which should be updated per cycle. This number can be specified as a numeric value.
<param name="SUPPORTTOOLTIPSINA-LARMTABLE" value="TRUE oder FALSE">	If this parameter is set TRUE, the tooltip functionality in the alarm table will be activated. This means: If any text entry in the alarm table cannot be displayed completely, a tooltip will be available showing the complete text string as soon as the mouse pointer is moved on the respective table cell.
<param name="TOOLTIPFONT" value="Schrifttyp|Schriftgröße">	This parameter serves to define the font for all tooltips. Syntax: Font|Size; Example: "Arial|11".
<param name="FILEOPENSAVEDIALOG-FONT" value="Schrifttyp|Schriftgröße ">	This parameter serves to define the font for the File-Open-dialog. Syntax: Font|Size; Example: "Arial|11".

<param name="ALARMTABLEFONT" value="NAME|HEIGHT|WEIGHT|CHARSET|ITALIC|HORZ_ALIGN|VERT_ALIGN">	This parameter serves to define the font for the alarm table. Syntax: NAME|HEIGHT|WEIGHT|CHARSET|ITALIC|HORZ_ALIGN|VERT_ALIGN Example: "Arial|11|0|0|false|left|center".
<param name="USECURRENTLANGUAGE" value="TRUE oder FALSE">	If this parameter is set TRUE, the current language setting always will be synchronized between web and target visualization (via implicit variable CurrentLanguage); i.e. at a language switch caused by an input in one of the both visualization types each in the other type the language will be switched too. The visualization currently is not included in this match.

1.4.5.4 Status check, auto-reload, file error_ini.xml

Status changes of the PLC or the visualization project are notified as messages in an error_ini.xml file. Usually in this case communication errors, start/stop of the PLC, breakpoint states, new download etc. will be reported in message boxes. The ini-file however also might define error messages like "page cannot be displayed", "too many variables to be monitored" or the like. Also as a reaction on a download or online change of the project an automatic reload of the web visualization might be defined.

The time interval for a cyclic status check can be defined in the file WebVisu.htm (PLCSTATEINTERVAL).

A communication failure during the monitoring of the web visualization will not be dumped as an error message, but will be displayed in the status line of the web browser.

1.4.5.5 Preparing a web visualization

- Create the visualization(s) for your PLC program as usual in CODESYS. If you want a certain visualization to be called as starting object, then name it 'PLC_VISU'. It will be loaded automatically as soon as the visualization is called via the Internet. Regard the effects of the currently active target settings, category Visualization.
- For visualization objects, which should not be part of the web version of the visualization, deactivate option web visualization' in the dialog 'Object' 'Properties' in category 'Visualization'.
- Regard the possibility to use visualization elements for the purpose of switching between several controllers, to which the web server then will connect automatically.
- If needed, modify the basic html-page ↯ *Chapter 1.4.5.3 “Editing the WebVisu.htm file” on page 723*. For example instead of PLC_VISU another visualization can be defined as start page of the web visualization.
- Perform command 'Project' 'Clean all', then 'Project' 'Build'. Before downloading the project regard the current setting of option in the target settings ↯ *Chapter 1.4.1.4.7.3 “Target settings in category visualization” on page 388*. This concerns all files which are used in the current visualization. Those can be bitmaps, language files and for web visualization also XML description files.
- Log in to the target system ('Project' 'Online' 'Login') and start the project on the PLC.

1.4.5.6 Configuration and start of the web server

- The web server must be available as an appropriate executable file (*.exe) for the used target system. It also can be installed and started as a sevice. The following command line parameters can be used for this purpose when webserver.exe is started:
  - i = web server gets installed as a service
  - u = web server service gets uninstalled
  - s = web server service gets started
  - e = web server service gets terminated
- The configuration of the server can be done by a configuration file or - restricted usable - by parameters added in the command line when calling the server-exe. The definitions given by a configuration file will overwrite those of the command line.

  The possible parameters:

webserver-port-nr	Port, on which the web server expects requests of the client (web browser)	Default: 80
target-port-nr	Port of the runtime system	Default: 1200
target-ip-address	IP address of the runtime system	Default: localhost
use-file-upload-dir	If this flag is set to TRUE, additionally the file-upload-directory (see below, file-upload-dir) must be defined, where the *.xml, *.bmp, *.jpg, etc. files of the web visualization are stored on the target system and from where they are uploaded to the browser.	Default:false
file-upload-dir	Directory for the web visualization files	Default:""
use-intel-byte-order	Type of byte-order (true or false): if "false, the data will get swapped (Motorola Byte-Order).	Default: true
The following entries refer to the use of a description file for the PLCHandler in order to be able to use the MultiPLC-functionality. If these entries are missing, automatically the TCP/IP-connection to the above specified target system will be used.		
plc-description-file	Path of the ini-file for the PLCHandler, describing the communication parameters for all PLCs (controllers) to which the web server then can connect via Gateway/PLCHandler. (Per default the ini-file is in the same directory as web server.exe). If the visualization (web client) via INTERN-command CONNECT_TO tells to which PLC a connection should be established, this connection will be built automatically by the server and will be maintained until the next change.	Default: ""

plc-entries	Section containing the entries <plc-entry> for the various PLCs	Default: ""
plc-entry	Entry for a PLC, contains PLC name and directory	Default: ""
plc-name	Name of the PLC, as defined in the PLCHandler.ini-file	Default: ""
plc-directory	Directory of the PLC files; can be defined absolutely or relatively to the file-upload directory (see above). Example: For the example configuration shown below a definition ".\FD" for the plc-directory results in the following location: "C:\Programme\codesysV23\FD"	Default: ""

If you define a "file-upload" directory, where the controller can store the visualization download files, then the visualization files will be automatically updated at each download. The advantage of this upload-directory is that the controller is not involved and thus not strained. The web server gets the files directly from the directory and by this the data transfer is much quicker. This is especially of impact in case of a big amount of data.

A configuration file for the web server must be available in XML-format and it must be named "webserver_conf.xml". It must be found in the directory where the webserver-exe is. If no configuration file is available, the above mentioned default settings will be used (if not changed by parameters added to the call of the server in a command line.)

Example configuration in the webserver_conf.xml file

```
<webserver-configuration>
    <webserver-port-nr> 8080 </webserver-port-nr>
    <target-port-nr> 1200 </target-port-nr>
    <target-ip-address> localhost </target-ip-address>
    <use-file-upload-dir> true </use-file-upload-dir>
    <file-upload-dir> C:\Programme\CoDeSysV23\ </file-upload-dir>
    <use-intel-byte-order> true </use-intel-byte-order>
    <plc-description-file> PlcHandler.ini </plc-description-file>
    <plc-entries>
        <plc-entry>
            <plc-name> MASTER </plc-name>
            <plc-directory> .\MASTER </plc-directory>
        </plc-entry>
        <plc-entry>
            <plc-name> FD </plc-name>
            <plc-directory> .\FD </plc-directory>
        </plc-entry>
        <plc-entry>
            <plc-name> DL </plc-name>
            <plc-directory> .\DL </plc-directory>
        </plc-entry>
     </plc-entries>
</webserver-configuration>
```

A call in a command line must use the following syntax:

```
WebServer [webserver-Port-nr] [target-port-nr] [target-IP-address] |
[file-upload-dir]
```

Only these parameters can be used in a command line. The others described above, concerning byte-order and multiPLC-functionality must come via the configuration file.

Thus a call corresponding to the above shown configuration example would look like follows, whereby the settings for <plc-description-file> and <plc-entries> must be available in a configuration file:

```
> webserver 8080 1200 localhost c:\Programme\codesysV23
```

The parameter settings in the command line are without any effect, if there is a valid configuration file available.

1.4.5.7 Calling a web visualization via internet

Insert the following address in the browser:

```
http://<IP-Adresse of the web server>:<Port of the web server>/
webvisu.htm
```

Example: `http://localhost:8080/webvisu.htm`

WebVisu is the default HTML-file. It contains a <applet> tag which will start the WebVisu-Applet so that the desired start page of the visualization will be displayed. Now you can start to operate the visualization.

If the browser accepts cookies (if necessary, activate this option) the current language setting for dynamic texts will be stored and at the next call of the web visualization will be re-used automatically. If the stored language is not available in the newly opened visualization, the default language of this visualization will be used. If no default language is defined, the visualization texts will not be translated until the language gets switched explicitly.

1.4.5.8 Restrictions and special features

Table 48: INTERN commands

PRINT	Printout of the current visualization is not supported for web visualization.
Execute external program	This command for the execution of an external program is not supported for web visualization.
LANGUAGEDIALOG	The command for calling the configuration dialog containing the category 'Language' is not supported for web visualization.
EXITPROGRAM	The command for exiting the program is not supported for web visualization. Can be realized via command INTERN LINK.
TRACE	The command for opening the Sampling Trace window is not supported for web visualization. This function will be taken by the Trend element.
SAVEPROJECT	The command for saving the project is not supported for web visualization.

↳ *Chapter 1.4.3.5.30 “Special input possibilities for operating versions” on page 695*

Table 49: Accessing variables

Dynamic indexing within an array ↳ *Chapter 1.4.1.8.2.1 “ARRAY” on page 445*	"Array1[Index].a" is not possible, however "Array1[10].a" is possible.
Replacing placeholders containing an expression	Placeholder: abc + 5 Replacement: PLC_PRG.n + 500 Should result in PLC_PRG.n + 500 + 5, this however is not possible in the web visualization.
Pointer variables ↳ *Chapter 1.4.1.8.2.3 “Pointer” on page 447*	Pointer variables like PLC_PRG.pdw2^ cannot be monitored.

Table 50: Others

Transparent bitmaps	Transparent bitmaps currently are not supported.

Table 51: Alarm handling

Actions	Action 'Print' currently is not supported.
Settings for sorting (history)	The sorting within the alarm table, displayed via button 'History', always is according to date. The settings as done in the configuration of the alarm table element are not regarded.
IEC operators ↳ *Chapter 1.4.1.6 “IEC operators and additional, norm-extending functions” on page 407*	The following IEC operators currently are not supported by the web visualization: Arithmetic operators: ● MOVE ● INDEXOF ● SIZEOF Bitstring operators: ● XOR Bitshift operators: ● SHL ● SHR ● ROL ● ROR Selection operators: ● LIMIT ● MUX Comparison operators: ● EQ ● NE All address operators All calling operators All conversion operators Numeric operators: ● SQRT ● LN ● LOG ● EXP ● ASIN ● ACOS ● ATAN ● EXPT

The following features are only suported by the web visualization:

Table 52: INTERN commands

INTERN LINK	Via "INTERN LINK <URL>" a change to another web page can be defined. Example: "INTERN LINK http://www.3s-software.com" "INTERN LINK <webaddress file>" opens a PDF file, which must be available on the server. Example: "INTERN LINK http://localhost:8080/test.pdf " "INTERN LINK <Email address>" opens a window for sending an Email. Example: "INTERN LINK mailto:support@3s-software.com"
INTERN CONNECT_TO <PLC-Name>|<Start-Visu>	The target PLC can be changed if the web server is configured appropriately with the connection parameters for multiple PLCs (see 'Configuration and start of the web server' *Chapter 1.4.5.6 “Configuration and start of the web server” on page 728*). PLC-Name: Name of the PLC, as defined in the ini file of the PLCHandler. Start-Visu: Name of the visualization which should be displayed at start of the web visualization. As soon as the web server gets the request for a PLC-change, it will automatically establish the connection to the respective PLC.

Chapter 1.4.3.5.30 “Special input possibilities for operating versions” on page 695

Language for dynamic texts

If the browser accepts cookies (if necessary, activate this option) the current language setting for dynamic texts will be stored and at the next call of the web visualization will be re-used automatically. See the note in 'Calling a web-visualization via internet' *Chapter 1.4.5.7 “Calling a web visualization via internet” on page 730*.

Using a HTTP-proxy-server

If a HTTP-Proxy-Server is used, additionally a SOCKS-Proxy-Server might be necessary in order to avoid monitoring problems. See 'Preconditions' *Chapter 1.4.5.2 “Preconditions” on page 722*.

1.4.6 License manager

1.4.6.1 Overview

The license manager

The *License Manager* is available to handle the licenses for modules, as well as licenses for modules for which an appropriate license information file is provided, on your computer. You can create a project and provide it as a licensed library. The Licensing Manager will be installed automatically with any module, which requires a license *Chapter 1.4.6.2 “Creating a licensed library” on page 734*.

1.4.6.2 Creating a licensed library

A project can be saved as a library. If you want to create a licensed library you have to add the appropriate license information. For this perform the command *“File ➔ Save as”*, choose data type 'Internal Library' or 'External Library' and press button *[Edit license info]*↳ *Chapter 1.4.1.2.3.6 “'File' 'Save as'” on page 224*.

In the dialog *“Edit Licensing Information”* enter the information described below. The license information will be added to the *“Project Info”*↳ *Chapter 1.4.1.2.3.34 “'Project' 'Project info'” on page 246*.

When later on the library will be included in a project, the license information can be checked up in the object properties dialog of the library in the*“library manager”* ↳ *Chapter 1.4.1.4.3.1 “Overview” on page 371*.

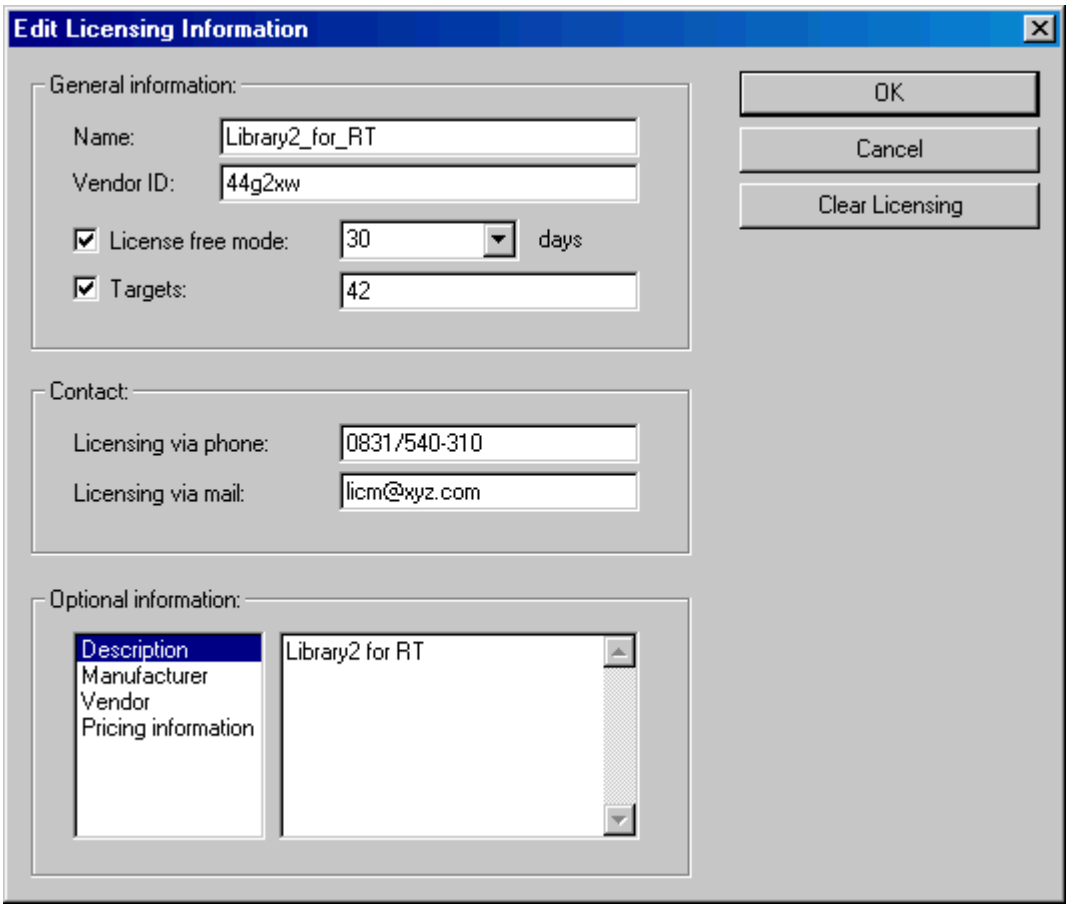


Fig. 12: Edit licensing information

Name	Enter a name for the library module which is used to represent it in the *Licensing Manager*. This input is mandatory.
Vendor-ID	A manufacturer identifier, depending on the manufacturer specific licensing management tool.
Targets	Enter here the target ID(s) of the target system(s) for which the license should be valid. You can enter multiple IDs separated by a semicolon or as a range. Example: "12;15-19;21"; herewith the IDs 12,15,16,17,18,19,21 are entered.
Licensing via phone / mail	Insert here the phone number resp. email address of the license provider. These inputs are mandatory.
Optional information	In the right window you can enter a text referring to the item currently marked in the left window: *“Description”*, *“Manufacturer”*, *“Vendor”*, *“Pricing information”*

It is reasonable to protect a library, which has been provided with licensing information, by a password↳ Chapter 1.4.1.2.2.10 “Passwords” on page 211. If you are going to save the project without password you will be pointed to that by a message box.

The licensing information of a library is stored internally with the library and will be registered on the computer automatically as soon as the library is included in a project. The license information of modules which are not provided must be provided in a separate description file in compatible XML format, which can be read by the Licensing Manager.

1.5 Libraries and solutions

1.5.1 Information on libraries

System libraries

When upgrading Automation Builder or an existing project, new AC500 V2 system libraries are installed automatically. Older library versions will be removed as coexistence of a new library version and an older library version is not possible. Check the available library version in the Library Manager.

Usually, when upgrading Automation Builder or an existing project, new AC500 V2 system libraries are installed automatically and older library versions are removed.

As an exception, for the CANopen device CM598-CN both library versions are available in the Library Manager due to compatibility reasons. However, coexistence of a new library version and an older library version is not possible. In order to avoid compile errors remove the older library version.

↳ *Chapter 1.2.17 “Converting an AC500 V2 project to an AC500 V3 project” on page 67*

Customer libraries

Target change from AC500 V2 to AC500 V3

After a target change from AC500 V2 to AC500 V3 the customer libraries have to be converted manually using the Library Converter . For further information see ↳ *Chapter 1.6.5.1.6 “Later change-over of a target system” on page 5782*.

Some Standard CODESYS libraries are automatically converted during the target change.

1.5.2 Reference to CODESYS (V2)

Note that CODESYS libraries are used. For further information see ↳ *Chapter 1.4.1 “Development system” on page 145*.

1.5.3 Error messages of the AC500 V2 function block libraries

1.5.3.1 0000hex...0FFFhex - telegram error

8191	1FFF	Not ready Flash..: The command is already executed by an other instance SD..: Command cannot be executed. Another instance is already active.

1.5.3.3 2000hex...2FFFhex - interface error

DEC	HEX	Error description
8193	2001	Invalid interface, Communication Module number or slot ID COM: Interface is not configured in the "free mode" HA: Wrong COM number at input COM ETH-MOD-MAST: Invalid interface or slot ID
8194	2002	Command not supported by the interface. The function is not supported by the device firmware. Block library newer than the device firmware.
8195	2003	Invalid interface or Communication Module type. Block is not suitable for this type.
8197	2005	HA..: CS31 Bus failure
8198	2006	Fault on both local and remote CPU.
8211	2013	Timeout COM_MOD_MAST: Slave did not respond within the specified time HA..: No Ethernet link, Error in DPRAM communication between CM574-RS and AC500 CPUs. ECAT_COE_READ, ECAT_COE_Write: Response timeout occurs
8212	2014	Framing error (incorrect transmission rate, number of stop bits and/or bits per character)
8213	2015	Parity error HA: Remote CS31 slave sync error. Difference in digital/ analog output buffer of PLC A and B
8214	2016	Idle error COM..: Character timeout occurred
8215	2017	Invalid length COM_MOD_MAST: Invalid data length received COM_REC: Received more data than expected
8216	2018	Checksum error
8217	2019	Handshake error

DEC	HEX	Error description
8218	201A	Service failed COM_REC: Unknown error message of the interface COM_SET_PROT: Interface hardware not accessible. Initialization already failed during system start-up. COM_MOD_SLV_SET_ADDR..: Internal error (e.g. wrong return value of internal function, null pointer received) CS31..: Internal error (e.g. CS31 communication failed) FC..: Internal error (e.g. null pointer received, wrong return value of internal function, no entry in config found) HA..: Internal error (e.g. null pointer received, wrong return value of internal function, no entry in configuration found)
8219	201B	Access error HA..: Remote CS31 Bus failure: Other CPUs' CS31 Bus is out of order IO..: Module number does not exist
8220	201C	Incorrect number (quantity) COM_SET_PROT: Invalid protocol index. Index is not supported by the device firmware. COM_MOD_SLV_SET_ADDR..: Invalid protocol index. HA..: Numbers of CI590-CS31-HA devices configured in line A and line B are different IO..: Invalid module number
8223	201F	Access denied COM..: Access to the interface is not possible at present. Automation Builder, OPC or another program is logged in via the interface.
8226	2022	COM_MOD_SLV_SET_ADDR..: Wrong configuration (No protocols configured). FC..: Wrong configuration (e.g. no Automation Builder configuration, no CS31 configured, no CS31 modules found). HA..: Overflow of HA_DATA reference table
8233	2029	● HA_CS31_CONTROL: – CI590-CS31-HA slave configuration not complete – CI590-CS31-HA slaves in Bus1 and Bus2 are mix-wired – Remote CI590-CS31-HA Failure – CS31 Master Cross Wired / No CS31 configuration / No submodules on CS31 bus ● HA_CS31_DIAG/ HA_CS31_DIAG_VIA_CM574-RS – CI590-CS31-HA slaves in line A and line B are mix-wired.
8234	202A	HA: configuration error: ● Wrong CM574-RS communication ● CM574-RS COM interface is not configured for shared communication ● CM574-RS not added to Communication Module slot ● Wrong configuration of DIAG blocks

1.5.3.4 3000hex...3FFFhex - protocol error

DEC	HEX	Error description
12289	3001	Unknown protocol or protocol not configured. MqttClient: The Network Connection has been made but the MQTT service is unavailable on the specified port.
12290	3002	Command not supported by the protocol. The function is not supported by the device firmware. Block library newer than the device firmware.
12291	3003	Another protocol is configured. FC_DC551: The selected interface (COMx) is not set to the CS31 protocol. COM_MOD_SLV_SET_ADDR..: The selected interface (COMx) is not set to the Multi protocol. COM_MOD_SLV_SET_ADDR..: Wrong protocol index (No Modbus protocol on specified index). HA: No CS31 protocol at COM. BACnet B-ASC: Multiple function block instances, one instance allowed only.
12292	3004	Operating mode error COM_MOD_MAST: Invalid operating mode (master/slave).
12293	3005	Protocol status error Fieldbus Communication Module .._SYS_DIAG: Master is not in the OPERATE state. ETH_SMTP_EMAIL_SEND: Internal error (ulHandle wrong). BACnet B-ASC: No device object instantiated.
12307	3013	IEC..: ACTCON timeout ETH_SMTP_EMAIL_SEND: Server timeout MqttClient: The timeout value for the communication has been exceeded.
12308	3014	IEC..: NACK received
12309	3015	ETH_SMTP_EMAIL_SEND: Syntax error in mail address
12310	3016	IEC..: Timeout
12311	3017	Incorrect length ARC..: Buffer is full CAN2..: Total length of all messages too high IEC..: Queue overrun ETH_UDP..: Buffer is full. MqttClient: Received topic or payload is too long.
12313	3019	IEC..: ACTERM timeout Wait answer ETH_SMTP_EMAIL_SEND: Could not connect to server. Not reachable or does not answer.

DEC	HEX	Error description
12314	301A	Execution failed COM_SET_PROT: Initialization of the protocol failed IEC..: Send failed due to queue deleted COM_MOD_SLV_SET_ADDR..: Internal error (e.g. null pointer received, wrong return value of internal function) ETH_SMTP_EMAIL_SEND: Internal error. Mail not sent. (e.g. out of resources) ETH_ICMP_PING: Target Host did not answer the ping echo request before the specified timeout MqttClient: MQTT broker did not answer the ping. MQTT client has passed the KeepAlive or MQTT broker is unreachable.
12315	301B	Access error ARC..: Buffer does not exist / is not specified CAN2..: Buffer does not exist / is not specified ETH_UDP..: Buffer does not exist / is not specified IEC..: Protocol access error IO..: There is no module in the selected slot
12316	301C	Wrong number IO..: Invalid module number > max.
12319	301F	Access denied COM..: Access to the interface is not possible at present. Automation Builder, OPC or another program is logged in via the interface. MqttClient: The Client identifier is correct UTF-8 but not allowed by the Server.
12320	3020	Error when opening ARC..: Error during protocol initialization. Protocol not yet ready. CAN2..: Error during protocol initialization. Protocol not yet ready. IEC..: Data type mismatch for this PIN when data arrived. ETH_UDP..: Error during protocol initialization. Protocol not yet ready. ETH_SMTP_EMAIL_SEND: ● File for attachment cannot be opened ● Server not ready (wrong port configured?) MqttClient: The Server does not support the level of the MQTT protocol requested by the Client.
12321	3021	ETH_SMTP_EMAIL_SEND: File for attachment not found CPU_PROD_ENTRY_READ: Entry not found

DEC	HEX	Error description
12325	3025	Address error COM_MOD_MAST: Receive telegram does not contain the expected register address. ETH_MOD_MAST: Cannot connect to server (IP address) OR response telegram contains wrong UNIT_ID (must be the same as in request). ETH_SMTP_EMAIL_SEND: Internal error (Could not bind sockets). ETH_UDP_REC: Wrong INDEX for connection. ETH_UDP_SEND: Wrong INDEX for connection or IP Destination does not contain a valid IP address. MqttClient: Connection refused, maybe the IP address is malformed.
12326	3026	Function error COM_MOD_MAST: The received FCT does not correspond to the sent FCT.
12327	3027	Invalid value COM_MOD_MAST: Receive telegram contains an unexpected value. MqttClient: Network error on MqttSubscribe/MqttUnsubscribe. Maybe the topic is not valid.
12328	3028	ETH_SMTP_EMAIL_SEND: Out of sockets. Mail not sent (resource starvation). ETH_ICMP_PING: Could not create internal Task (not enough resources). BACnet B-ASC: Protocol task start failed.
12329	3029	HA..: CI590-CS31-HA slave configuration is not complete.
12331	302B	Unspecified error MqttClient: Internal library returned an unspecified error.
12333	302D	No connection, sending not possible due to no connection, either closed or not established yet MqttClient: No connection to an MQTT Broker.
12540	30FC	ETH_SMTP_EMAIL_SEND: Mailbox unavailable or not found on target server. SMTP error by server.
12788	31F4	ETH_SMTP_EMAIL_SEND: Syntax Error. SMTP error by server.
12789	31F5	Syntax error in parameters or arguments.
12790	31F6	Command not implemented. SMTP error by server.
12791	31F7	The SMTP server has encountered a bad sequence of commands, or it requires an authentication.
12823	3217	ETH_SMTP_EMAIL_SEND: Wrong user login and/or password. Check configuration. SMTP Error by server. MqttClient: Authentication failed: Bad username, password OR client id.
12838	3226	ETH_SMTP_EMAIL_SEND
12839	3227	ETH_SMTP_EMAIL_SEND: Mailbox unavailable or not found on target server. SMTP Error by server.
12840	3228	ETH_SMTP_EMAIL_SEND: Exceeded mailbox storage on target server. SMTP Error by server.
12841	3229	ETH_SMTP_EMAIL_SEND: Mailbox name not allowed. SMTP Error by server.
12848	3230	MqttClient: Error on TLS handshake.

DEC	HEX	Error description
12849	3231	MqttClient: Server certificate not valid. Check if PLC date has been set correctly.
12850	3232	MqttClient: Server certificate format is not formatted as PEM.
12851	3233	MqttClient: Server certificate has expired.
12852	3234	MqttClient: Client certificate not valid. Check if PLC date has been set correctly.
12853	3235	MqttClient: Client certificate or client key format is not formatted as PEM.
12854	3236	MqttClient: Client certificate has expired.
16383	3FFF	Not ready. Resources currently not available. COM_MOD_MAST: Transmission is not possible at the moment. Another instance of the function block is already transmitting. COM_SEND: Transmission is not possible at the moment. Another instance of the function block is already transmitting. BACnet B-ASC: No memory for BACnet objects.

1.5.3.5 4000hex...4FFFhex - block input error

The error 4xxxhex is used in case of detected function block input parameter errors. The error is structured as follows:

4 X1 X2 X3 hex

X...	Value	Error Description
X1 + X2	1....FF	Number of the input
X3	0	Invalid value
	1	Value too low
	2	Value too high
	3	Wrong combination of the parameters

1.5.3.6 5000hex...5FFFhex - request error

DEC	HEX	Error description
20482	5002	The request is not supported (e.g. in the simulation mode of the Automation Builder).
20485	5005	Invalid internal state -> function block probably called in invalid manner/ sequence
20499	5013	Timeout error ECAT_COE_READ, ECAT_COE_Write: Request timeout occurs
20503	5017	Incorrect length ARC..: Invalid data length CAN2..: Invalid DLC in message ETH_UDP..: Invalid data length ECAT_COE_READ, ECAT_COE_Write: Request/ Response length invalid
20504	5018	Traceability data is corrupted.

DEC	HEX	Error description
20507	501B	Access error COM_MOD_MAST: Invalid memory address DATA or DATA + NB. At least one datum is outside of the access range of the user program. The range includes different flag ranges. ETH_MOD_MAST: Invalid memory address DATA or DATA + NB. At least one datum is outside of the access range of the user program. The range includes different flag ranges.
20508	501C	Invalid number (quantity) CAN2A_SEND: Invalid number of messages at input NUM COM_MOD_MAST: Invalid number of data at NB (0 or more than permitted). ETH_MOD_MAST: Invalid number of data at NB (0 or more than permitted).20515
20513	5021	IO_PROD_ENTRY_READ: I/O Module not found: input MODULE invalid
20515	5023	Failed to read traceability data from I/O Module.
20517	5025	Address error ARC..: Invalid IP address CAN2..: Invalid identifier in message COM_MOD_MAST: Invalid slave address. Broadcast not permitted in connection with the selected function code. ETH_MOD_MAST: Invalid slave address. Broadcast not permitted in connection with the selected function code. ETH_UDP..: Invalid IP address.
20518	5026	Function error COM_MOD_MAST: Invalid function code FCT. ETH_MOD_MAST: Invalid function code FCT.
20735	50FF	DIAG..: Simulation mode
24575	5FFF	Operation pending / busy -> wait and try again later

1.5.3.7 6000hex...6FFFhex - communication module errors

DEC	HEX	Error description
24577	6001	EtherCAT: Invalid command received PNIO: Creating a TLR-timer-packet in RPC task failed due to insufficient memory
24578	6002	EtherCAT: No link exists OR the watchdog expired CAN..: Service was rejected by the node with SDO abortion. Index/subindex not valid or no access to the specified node. DNM..: Resource not available or invalid class ID DPM../DPV1..: Resource not available. Free buffer memory in slave is not sufficient for the requested service. PNIO: Generic RPC-error code or not enough memory
24579	6003	EtherCAT: Error during reading the bus configuration OR the requested watchdog time is too small. DPM../DPV1..: Requested service (e.g. DPV1) is not active in the slave.

DEC	HEX	Error description
24580	6004	Communication Module does not support DPRAM message communication function blocks OR There is no receive function block active in IEC project of Communication Module. EtherCAT: Error during processing the bus configuration OR The requested watchdog time is too large.
24581	6005	EtherCAT: Existing bus does not match configured bus OR Error during reset (resetting watchdog).
24582	6006	EtherCAT: Not all slaves are available OR Error during reset (cleanup dynamic resources) DPM../DPV1..: Slave address not configured
24583	6007	EtherCAT: Error during reset (stopping the master) OR master is in critical error state, reset required.
24584	6008	EtherCAT: Error during reset (deinitializing the master) OR error activating the watchdog. DNM..: Service not available in module. Read/write function not supported by the selected class.
24585	6009	EtherCAT: Error during reset (cleanup the dynamic resources) OR size of configured input data is larger than cyclic DPM input data size. DNM..: Attribute invalid or not supported DPM../DPV1..: No data received from slave
24586	600A	EtherCAT: Master is in critical error state. Reset required OR size of configured output data is larger than DPM data output size.
24587	600B	EtherCAT: The requested bus cycle time is invalid DNM..: Request is already in progress
24588	600C	EtherCAT: Invalid parameter for broken slave behavior. DNM..: Conflict of the object status
24589	600D	EtherCAT: Master is in wrong internal state
24590	600E	EtherCAT: The watchdog expired DNM..: Attribute cannot be set or writing is not permitted
24591	600F	EtherCAT: Invalid SlaveID was used for CoE DNM..: Permission check faulty or access denied
24592	6010	EtherCAT: No available resources for CoE Transfer DNM..: Status conflict. Device prohibits execution
24593	6011	EtherCAT: Internal error during CoE usage CAN..: No response from the selected node DNM..: No response from the selected device DPM../DPV1..: No response received from slave.
24594	6012	EtherCAT: Invalid index on slave requested DPM../DPV1..: Master not in logical "token ring". PNIO: Internal error inside Communication Module's firmware
24595	6013	EtherCAT: Invalid bus communication state for CoE-usage CAN..: Selected node is not ready for operation DNM..: Not enough receive data

DEC	HEX	Error description
24596	6014	EtherCAT: Frame with CoE data is lost CAN..: Local resources are not available. Requested bus parameters are not available. Communication Module is not configured. DNM..: Local resources are not available. Requested bus parameters are not available. Communication Module is not configured. PNIO: Internal error inside Communication Module's firmware
24597	6015	EtherCAT: Timeout during CoE service CAN..: Parameter error DNM..: Parameter error
24598	6016	EtherCAT: Slave is not addressable (not on bus or power down) DNM..: Object does not exist
24599	6017	EtherCAT: Invalid list type requested Other Communication Modules: Received data length too big. Internal buffer too small.
24600	6018	EtherCAT: Data in slave response is to large for confirmation packet. PNIO: Internal error inside Communication Module's firmware
24601	6019	EtherCAT: Invalid access mask selected (during GetEntryDesc) DPM../DPV1..: Unexpected reaction of slave or reaction not in accordance with standard.
24602	601A	EtherCAT: Slave Working Counter error during CoE service PNIO: Another request is already running ETH2 not supported on AC500 CPU with Ethernet
24603	601B	EtherCAT: The service is already in use
24604	601C	EtherCAT: Command is not usable in this communication state
24605	601D	EtherCAT: Distributed Clocks must be activated for this command
24606	601E	EtherCAT: The scan is already running. It cannot be started twice at the same time
24607	601F	EtherCAT: Timeout during bus scan, but at least one link is established
24608	6020	EtherCAT: The bus scan was not started before or it is not finished yet
24609	6021	EtherCAT: The requested slave is invalid
24610	6022	EtherCAT: Internal error during CoE usage
24612	6024	PNIO: Internal error inside Communication Module's firmware
24615	6027	EtherCAT: Internal error of SDO protocol
24616	6028	EtherCAT: Internal error of SDO protocol
24617	6029	EtherCAT: Internal error of SDO protocol
24618	602A	EtherCAT: Internal error of SDO protocol
24619	602B	EtherCAT: Internal error of SDO protocol
24620	602C	EtherCAT: Internal error of SDO protocol
24621	602D	EtherCAT: Not enough memory
24622	602E	EtherCAT: Selected object could not be accessed
24623	602F	EtherCAT: Selected object is write only

DEC	HEX	Error description
24624	6030	EtherCAT: Selected object is read only CAN..: Function timeout DNM..: Device not configured PNIO: Internal error inside Communication Module's firmware
24625	6031	EtherCAT: Selected object does not exist PNIO: Internal error inside Communication Module's firmware
24626	6032	EtherCAT: PDO mapping failed DNM..: Format error in the received data ETH_UDP..: TCP/UDP task not available or IP task not ready. PNIO: Internal error inside Communication Module's firmware
24627	6033	EtherCAT: Selceted object is to large to be mapped to PDO CAN..: Maximum buffer size of the receive data exceeded ETH_UDP..: Internal task with configuration data not available PNIO: The ALPMR protocol-machine corresponding to the index in request packet is invalid
24628	6034	EtherCAT: General parameter error occured CAN..: Function not available. Code unknown. DNM..: Code unknown ETH_MOD..: Invalid parameter for "ServerConnection" ETH_UDP..: No MAC address available PNIO: The ALPMR protocol-machine is invalid for the current request
24629	6035	EtherCAT: Internal device error occured CAN..: Unknown area. Buffer exceeded. DNM..: Overflow of buffer length ETH_MOD..: Invalid parameter for "Task Timeout" ETH_UDP..: Waiting for warm start performed by the application
24630	6036	EtherCAT: Hardware error occured CAN..: Unknown function in HOST message or function still active DNM..: Other service still active ETH_MOD..: Invalid parameter for "OBM Timeout" ETH_UDP..: Unknown flag in start parameters DPM../DPV1..: Slave denied access to the requested data
24631	6037	EtherCAT: Invalid data type CAN..: Parameter error DNM..: Parameter error or MAC ID beyond the valid range ETH_MOD..: Invalid parameter for "Mode" ETH_UDP..: Invalid IP address in start parameters PNIO: The index of ALPMR protocol-machine is invalid
24632	6038	EtherCAT: Invalid data type ETH_MOD..: Invalid parameter for "Send Timeout" ETH_UDP..: Invalid subnet mask in start parameters

DEC	HEX	Error description
24633	6039	EtherCAT: Invalid data type CAN..: Sequence error DNM..: Sequence error or one MAC ID was multiple used in one network ETH_MOD..: Invalid parameter for "Connect Timeout" ETH_UDP..: Invalid gateway IP in start parameters
24634	603A	EtherCAT: Invalid sub-index ETH_MOD..: Invalid parameter for "Close Timeout".
24635	603B	EtherCAT: Invalid parameter value CAN..: Data error DNM..: Data error ETH_MOD..: Invalid parameter for "Swab" ETH_UDP..: Unknown device type
24636	603C	EtherCAT: Invalid parameter value CAN..: Node address configured twice DNM..: Display of total number of data sets incorrect ETH_MOD..: TCP task not ready ETH_UDP..: Access to IP address in the specified source failed
24637	603D	EtherCAT: Invalid parameter value CAN..: ADD table incorrect DNM..: ADD table incorrect ETH_MOD..: PLC task not ready ETH_UDP..: Initialization of the driver layer failed
24638	603E	EtherCAT: Invalid parameter value CAN..: Total length of the node parameters incorrect DNM..: Size of the I/O configuration table incorrect ETH_MOD..: Error during initialization ETH_UDP..: No source specified for IP address (BOOTP, DHCP, IP address parameter)
24639	603F	EtherCAT: Internal error of SDO protocol CAN..: Transmission type unknown DNM..: I/O configuration does not match with the ADD table
24640	6040	EtherCAT: Internal device error occured CAN..: Length of the PDO-cfg file too big DNM..: Parameter size incorrct or channel/handler already in use PNIO: Internal error inside Communication Module's firmware
24641	6041	EtherCAT: Internal device error occured CAN..: Unknown transmission rate DNM..: Number of defined inputs in the ADD table does not match with the I/O configuration PNIO: Internal error inside Communication Module's firmware

DEC	HEX	Error description
24642	6042	EtherCAT: Internal device error occured CAN..: COB-ID SYNC beyond the valid range DNM..: Number of defined outputs in the ADD table does not match with the I/O
24643	6043	EtherCAT: Internal device error occured CAN..: Value of the synchronization timer invalid DNM..: Unknown data type in the I/O configuration
24644	6044	EtherCAT: Unknown SDO protocol error CAN..: Input offset of the PDOs too big DNM..: Defined data type of an I/O module does not match with the defined data size
24645	6045	CAN..: Output offset of the PDOs too big DNM..: The configured output address of an I/O module is not within the permitted address range of 3584 bytes
24646	6046	CAN..: Inconsistency between the PDO and the ADD table DNM..: The configured input address of an I/O module is not within the permitted address range of 3584 bytes

1.5.3.8 7000hex...7FFFhex - product libraries

Table 53: Drives library

Dec	Hex	Error description
28672	7000	Any activity was NOT completed within an appropiate TIME
28673	7001	Read or write parameter could not be completed
28674	7002	A parameter at the function block is out of the possible range. This does not refer to the parameter range which is allowed for the drive but just to the 32-bit integer which is used for internal calculation
28675	7003	The field bus connection is faulty
28677	7005	Wrong PPO type
28678	7006	Wrong or no adapter type could be detected
28679	7007	Drive type does not match to function block
28680	7008	Function aborted
28681	7009	Error while reading scaling parameter for REF1
28682	700A	Wrong parameter number at read/write parameter
28683	700B	COM interface differs from others on same LINE_TOKEN variable
28684	700C	Profile type error
28685	700D	Function block Read_Parameters has been executed with error
28686	700E	Function block Write_Parameters has been executed with error
28687	700F	No connection to communication block, or error in communication block
28688	7010	Error at reading the drives communication profile value
28689	7011	Drive communication profile can not be used with this function block
28690	7012	PROFINET or PROFIBUS write packet size exceed 240 byte data limit

Table 54: Solar library

Dec	Hex	Error description
28928	7100	ALARM: Limit exceeded. System has moved more than POS_DEG_LIMIT distance without any moving command.
28929	7101	ALARM: Timeout. The system has not reached POS_DEG_LIMIT within the tolerance time (3 * t POS_TIME_LIMIT [ms]).
28930	7102	ALARM: Limit at wrong side reached. System has reached POS_DEG_LIMIT distance in the opposite DIR to actual movement order.
28931	7103	ALARM: Low Limit exceeded. Tracker position is less than VIRTUAL_LIMIT_MIN.
28932	7104	High Limit exceeded. Tracker position is more than VIRTUAL_LIMIT_MAX.
28933	7105	Warning: Interlocking. Try to move BACKWARD while STOP_BWD input is set.
28934	7106	Warning: Interlocking. Try to move FORWARD while STOP_FWD input is set.
28935	7107	Warning: Interlocking. Both STOP_BWD and STOP_FWD input are set.

Table 56: Temperature control library

Dec	Hex	Error description
29312	7280	Fault (TuneFault): "Tuning failed": outputs disabled, see Tune_Status Remedy: Check for tune set point and currrent temperatur
29313	7281	Fault (TC_Fault_1): "Bad Thermocouple reading": outputs disabled. Remedy: Bad Thermocouple reading: outputs disabled
29314	7282	Fault (TC_Fault_2): "Plausibility check not passed": outputs disabled. Remedy: Check for inverted connection of Thermocouple.
29315	7283	Fault (HighHighTempFalt): "HighHigh temperature alarm": outputs disabled. Remedy ● Check for defective cooling device. ● Check for correct setting of HIGHHIGH_TEMP and SET_TEMP.
29316	7284	Fault (LowLowTempFault): "LowLow temperature alarm": outputs disabled. Remedy ● Check for defective heating device. ● Check for correct setting of LOWLOW_TEMP and SET_TEMP.
29319	7287	High temperature alarm
29320	7288	Low temperature alarm
29321	7289	High deviation alarm
29330	7292	Zone_size and zone_index are not assigned
29335	7297	No group function block call possible: internal Group function call for TECT_TEMP_CONTROL or TECT_PWM8 failed.
29336	7298	TimeOut of one operation state.
29337	7299	Read data failed: no correct format of data items.

Dec	Hex	Error description
29322	728A	Low deviation alarm
29323	728B	Fault: (NoHighHighLowLow): "No plausible HighHigh or LowLow limit is defined" Remedy: Check the HighHighTemp and low low temp.
29324	728C	Fault (WrongLimits): "No plausible wrong limits defined" Remedy: Check the defined limits.
29325	728D	Heat and Cool are not enabled: Monitoring only.
29326	728E	Faut (NoAutoTune): "AutoTune cannot be started" Remedy: Process in Manual mode or Heat is not enabled
29327	728F	Fault (NoPIDProcess): "PID process cannot be started" Remedy: Process in Manual mode or no KS, TU, TG parameters are accepted.
29328	7290	Fault (Improper setting of HigHigh and High): HighHigh and High limits are not set correctly. Values are not taken by process/ADR_ZONEDATA. Remedy: Check parameter settings.
29329	7291	Fault (Improper setting of LowLow and Low): LowLow and Low limits are not set correct. Values are not taken by process/ADR_ZONEDATA. Remedy: Check parameter settings.
29330	7292	Fault (No assignment for zone index and size): Zone_size and zone_index are not assigned. Remedy: Check parameter settings.
29335	7297	Fault (No Group function possible):no Group function block call possible: internal Group function call for TECT_TEMP_CONTROL or TECT_PWM8 failed.
29336	7298	TimeOut of one operation state.
29337	7299	Fault (Reading failed):Read data failed: no correct format of data items. Remedy: Check parameter settings.
29338	729A	Fault (Incomplete log saving): Restart of the EN is required since last log saving is not complete
29339	729B	Fault (Less zone data available in RECIPE file than requested):Mismatch in number of zones declared and zone data in recipe. Remedy: Check the zone data in CSV file and Num_of_zones declared in RECIPE.

Table 57: CMS/FM502 library

Dec	Hex	Error description
29440	7300	Invalid file format.
29445	7305	Number of channels > 1, not supported by this version of library.
29440	7300	Invalid RIFF Chunk ID
29441	7301	Invalid WAV Chunk ID
29442	7302	Invalid FMT Chunk ID
29443	7303	Invalid DATA Chunk ID
29444	7304	Invalid LABL Chunk ID
29445	7305	Number of channels >1 , not supported by this version of library.
29504	7340	No Channel activated
29505	7341	Internal Error (Start)

Dec	Hex	Error description
29506	7342	Internal Error (Poll)
29507	7343	Internal Error (Finish)
29508	7344	Not possible because of measurement running
29519	734F	No Measurement possible. Device in Failure Loop.
29520	7350	Comunication Timeout to FM502
29521	7351	Internal File Error
29522	7352	Plausibility Check of Configuration wrong
29569	7381	Error in memory allocation to the input signal, due to insufficient memory available.
29571	7383	Wrong intermediate variable value
29572	7384	Error during reading wave file - check wave file for format compatibility.
29573	7385	Could not open indicated wave file.

1.5.4 Standard function block libraries AC500

1.5.4.1 ARCNET library

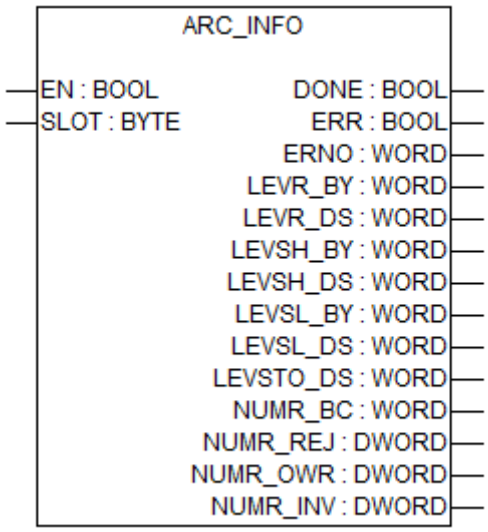
Library file name: **ARCNET_AC500_Vx.lib**

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

The use of the function blocks presupposes that the ARCNET Communication Module is configured in the ARCNET data exchange mode.

1.5.4.1.1 Function blocks

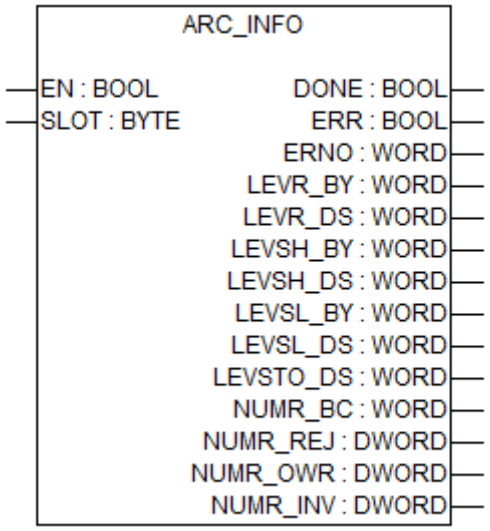
ARC_INFO



Parameter	Value
Included in library	ARCNET_AC500_V12.lib
Available as of firmware	V1.2
Type	Function block with historical values
Group	General

Using the ARC_INFO function block, various status information about the ARCNET processing can be read. This information can only be read if in the "ARCNET data exchange".

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

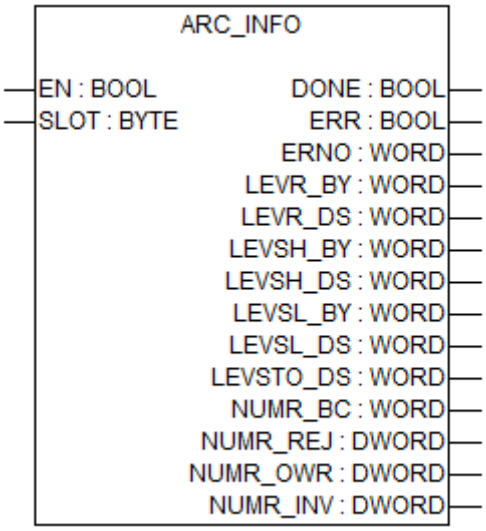
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEVR_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVR_BY displays the filling level of the receive buffer in bytes.

LEVR_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVR_DS displays the filling level of the receive buffer in data sets.

LEVSH_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSH_BY displays the filling level of the high priority send buffer in bytes.

LEVSH_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSH_DS displays the filling level of the high priority send buffer in data sets.

LEVSL_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSL_BY displays the filling level of the low priority send buffer in bytes.

LEVSL_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSL_DS displays the filling level of the low priority send buffer in data sets.

LEVSTO_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSTO_DS displays the filling level of the timeout buffer in data sets.

NUMR_BC

Data type	Default value	Range	Unit
DWORD	-	-	-

NUMR_BC outputs the number of broadcasts (data packets to all stations) which were received by this station.

NUMR_REJ

Data type	Default value	Range	Unit
DWORD	-	-	-

At output NUMR_REJ, the number of data sets is displayed which were discarded during reception due to a full receive buffer. Data sets are only discarded if this is set accordingly within the PLC configuration of the ARCNET processing.

NUMR_OWR

Data type	Default value	Range	Unit
DWORD	-	-	-

At output NUMR_OWR, the number of data sets is displayed which were overwritten during reception due to a full receive buffer. Data sets are only overwritten in the receive buffer, if this is set accordingly within the PLC configuration of the ARCNET processing.

NUMR_INV

Data type	Default value	Range	Unit
DWORD	-	-	-

NUMR_INV outputs the number of telegrams which were received faulty by this station.

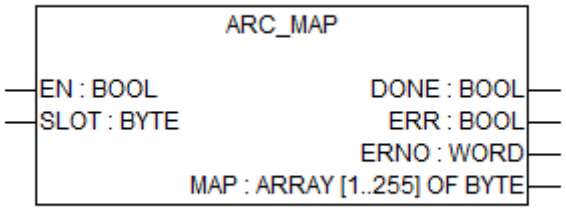
Info_NUMR_BC := Info.NUMR_BC;
Info_NUMR_REJ := Info.NUMR_REJ;
Info_NUMR_OWR := Info.NUMR_OWR;
Info_NUMR_INV := Info.NUMR_INV;
```

ARC_MAP

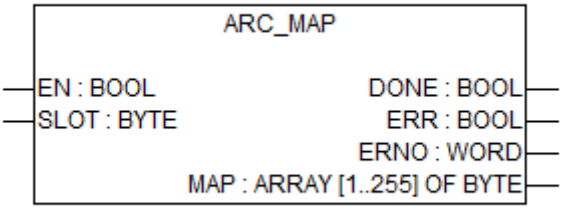


Parameter	Value
Included in library	ARCNET_AC500_V12.lib
Available as of firmware	V1.3
Type	Function block without historical values
Group	General

The function block ARC_MAP provides information about the ARCNET network map. The output MAP shows the status of every node. If the node is active, a "1" is shown at the corresponding output array. (Each possible node has an own byte at the array; e. g. nodes 2 and 3 are active -> array of Byte [2] = 1 and array of byte [3] = 1, the others have the value 0).

Every node of the ARCNET map is checked by the RTS for about 210 ms. So the complete cycle time for the whole map takes about 255*210 ms (If the map consists of 255 nodes. If the network consists of 5 nodes it takes about 1s).

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

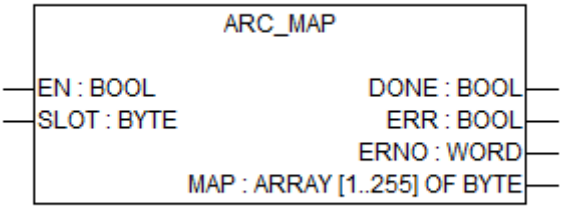
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

MAP

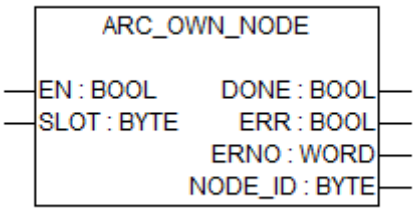
Data type	Default value	Range	Unit
ARRAY	-	-	-

As long as EN = TRUE and at least 2 nodes are active (a network consists of min 2 nodes), output array [1..255] of BYTE shows the status information of the network map.

Function call in ST

```
MAP (EN := MAP_EN,
SLOT := MAP_SLOT);
MAP_DONE := MAP.DONE;
MAP_ERR := MAP.ERR;
MAP_ERNO := MAP.ERNO;
MAP_MAP := MAP.MAP;
```

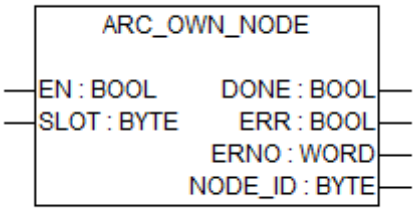
ARC_OWN_NODE



Parameter	Value
Included in library	ARCNET_AC500_V12.lib
Available as of firmware	V1.2
Type	Function block without historical values
Group	General

Prior to setting into operation an AC500 Communication Module, it must be configured using the system configuration of the Control Builder. One of the parameters of an ARCNET Communication Module is its own NODE_ID. Using the function block ARC_NODE_ID, the latest configured NODE ID of the device at SLOT can be read. If no ARCNET Communication Module is installed at SLOT, the corresponding error is generated and output at ERR and ERNO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

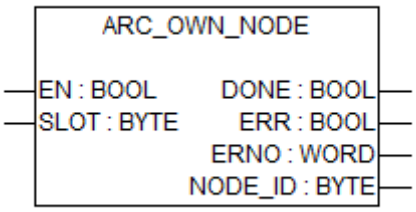
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NODE_ID

Data type	Default value	Range	Unit
BYTE	-	-	-

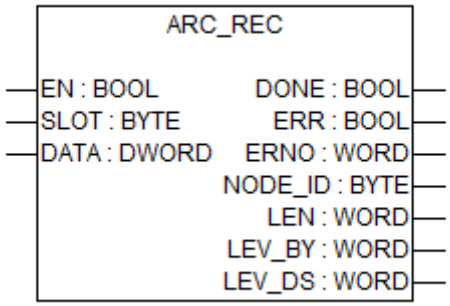
Output NODE_ID displays the own NODE ID of the Communication Module.

Function call in ST

```
ARC_OWN_NODE(EN := OwnNode_EN, SLOT := OwnNode_SLOT);

OwnNode_DONE := OwnNode.DONE;
OwnNode_ERR := OwnNode.ERR;
OwnNode_ERNO := OwnNode.ERNO;
  OwnNode_IP_ADR := OwnNode.NODE_ID;
```

ARC_REC



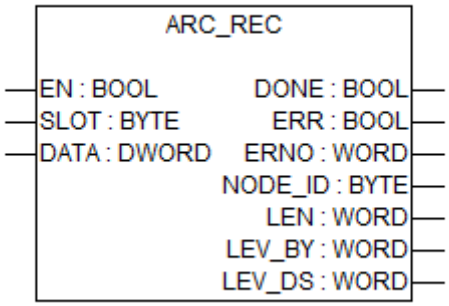
Parameter	Value
Included in library	ARCNET_AC500_V12.lib
Available as of firmware	V1.2
Type	Function block with historical values
Group	Data

The operating system reads the received ARCNET data packets from the ARCNET Communication Module and stores them in the receive buffer. The buffer size is determined using the ↳ *Chapter 1.6.5.2.3.6 "Parameters of PM5x1-ARCNET (onboard ARCNET)" on page 5846* of the CPU. The data packets are stored with variable lengths. For example, a data packet consisting of 16 bytes of user data occupies exactly 22 bytes in the receive buffer (4 bytes for the NODE ID of the sending device, 2 bytes for the packet length and 16 bytes of user data).

Using the ARC_REC function block, exactly one data packet is read. The user data are stored in the configured memory area (DATA). The NODE ID of the sending device and the data packet length are supplied at the outputs NODE_ID and LEN. DONE = TRUE and ERR = FALSE indicate that the reading process was successful. If an error was detected during Function Block processing, the error is additionally indicated at the outputs ERR and ERNO. Furthermore, the function block provides information about the receive buffer filling level displayed in bytes (LEVR_BY) and data records (LEVR_DS).

Before the ARC_REC function block can read data packets from the receive buffer, the setting "ARCNET data exchange" must have been selected in the ↳ *Chapter 1.6.5.2.3.6 "Parameters of PM5x1-ARCNET (onboard ARCNET)" on page 5846* of the CPU.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

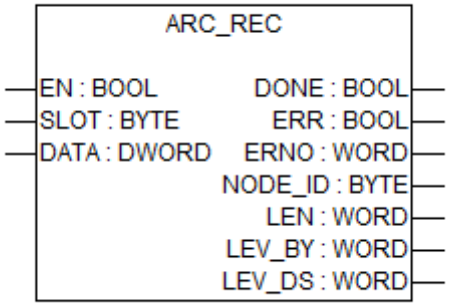
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. DATA must be the address of a variable of the type ARRAY or STRUCT.

CAUTION: Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NODE_ID

Data type	Default value	Range	Unit
BYTE	-	-	-

Output NODE_ID displays the own NODE ID of the Communication Module.

LEN

Data type	Default value	Range	Unit
WORD	-	-	byte

Output LEN displays the length of the received data package in bytes.

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY displays the filling level of the receive buffer in bytes. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 6 bytes in the receive buffer (4 bytes for the NODE ID of the sending device, 2 bytes for the specification of the length).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

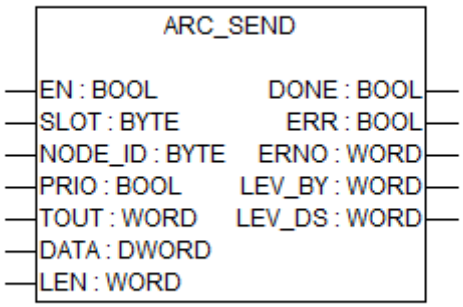
Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
REC  (EN := Rec_EN,
     SLOT := Rec_SLOT,
     DATA := ADR(Rec_DATA));

REC_DONE := Rec.DONE;
REC_ERR := Rec.ERR;
REC_ERNO := Rec.ERNO;
REC_NODE_ID := Rec.NODE_ID;
REC_LEN := Rec.LEN;
REC_LEVR_BY := Rec.LEV_BY;
REC_LEVR_DS := Rec.LEV_DS;
```

ARC_SEND

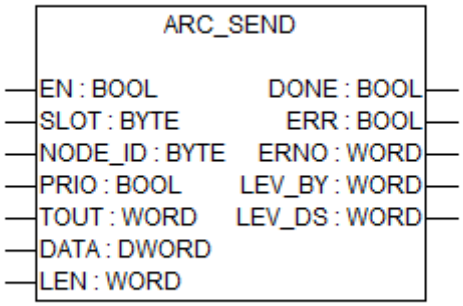


Parameter	Value
Included in library	ARCNET_AC500_V12.lib
Available as of firmware	V1.2
Type	Function block with historical values
Group	Data

The function block ARC_SEND is used to transmit data packets via the ARCNET Communication Module. The specified packages are stored in the transmit buffer which is selected by input PRIO. From there, the operating system hands over the data packets to the ARCNET Communication Module in order to transmit them to the target address specified at input NODE_ID. The transmit buffer size is determined using the PLC Configuration of the Control Builder. Using input TOUT, the timeout period can be specified. If TOUT <> 0, the ARCNET data exchange is automatically performed with receive acknowledgement. If TOUT = 0, no acknowledgement is expected. Output DONE indicates that the specified data packets has been stored in the transmit buffer or that an error occurred during Function Block processing. If an error was detected during Function Block processing, the error is additionally indicated at the outputs ERR and ERNO. In case of an error, the data packet has to be transmitted again.

Before the ARC_SEND function block can store data packets in the receive buffer, the setting "ARCNET data exchange" must have been selected in the *Chapter 1.6.5.2.3.6 “Parameters of PM5x1-ARCNET (onboard ARCNET)” on page 5846* of the CPU.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE_ID

Data type	Default value	Range	Unit
BYTE	-	-	-

Output NODE_ID displays the own NODE ID of the Communication Module.

PRIO

Data type	Default value	Range	Unit
BOOL	-	-	-

Input PRIO is used to specify the transmit priority of the data packet.

The following applies:

PRIO = FALSE

The specified data packet has low priority. Thus, it is stored in the low priority transmit buffer. All outputs refer to this buffer.

PRIO = TRUE

The specified data packet has high priority. Thus, it is stored in the high priority transmit buffer. All outputs refer to this buffer.

TOUT

Data type	Default value	Range	Unit
WORD	200ms	-	-

Using input TOUT, the timeout period can be specified. If TOUT <> 0, the ARCNET data exchange is automatically performed with receive acknowledgement. If a data packet cannot be transmitted within this period (no acknowledge telegram is received), transmission is aborted and the package is lost.

In this case, some distinctive bytes of the data packet (see also the PLC configuration of the Control Builder) are stored to the timeout buffer and can then be read using the function block ARC_STO.

If TOUT = 0, no acknowledgement is expected.

The following applies:

TOUT = 0 means: Default value for TOUT, given by PLC configuration, is used.

Data exchange without receive acknowledgement. No data are written to the timeout buffer.

TOUT <> 0:

Data exchange with receive acknowledgement. Each transmitted data record is acknowledged by the recipient. If no acknowledge telegram is received within the set timeout period (in ms), the data are written to the timeout buffer.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. DATA must be the address of a variable of the type ARRAY or STRUCT.

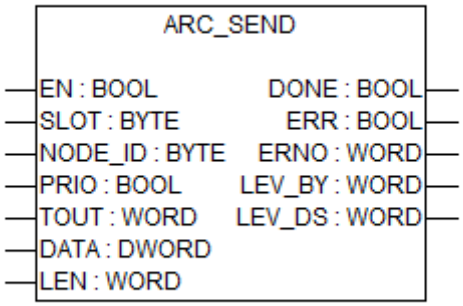
CAUTION: Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

LEN

Data type	Default value	Range	Unit
WORD	-	-	byte

Output LEN displays the length of the received data package in bytes.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY displays the filling level of the receive buffer in bytes. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 6 bytes in the receive buffer (4 bytes for the NODE ID of the sending device, 2 bytes for the specification of the length).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

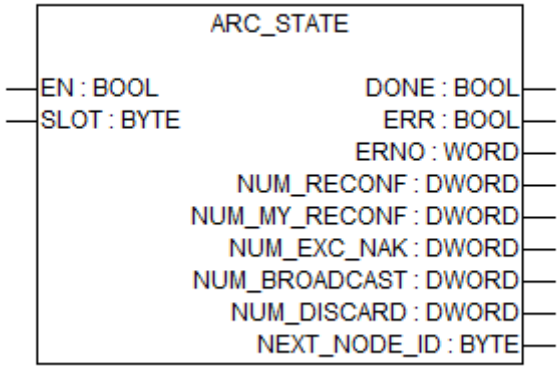
Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
Send (EN := Send_EN,
     SLOT := Send_SLOT,
     NODE_ID := Send_NODE_ID,
     PRIO := Send_PRIO,
     TOUT := Send_TOUT,
     DATA := ADR(Send_DATA),
     LEN := Send_LEN);

Send_DONE := Send.DONE;
Send_ERR := Send.ERR;
Send_ERNO := Send.ERNO;
Send_LEV_BY := Send.LEV_BY;
Send_LEV_DS := Send.LEV_DS;
```

ARC_STATE

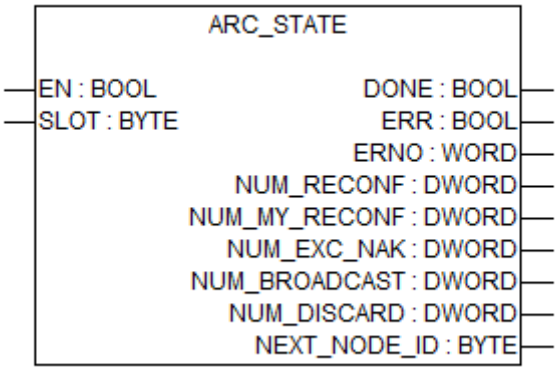


Parameter	Value
Included in library	ARCNET_AC500_V12.lib
Available as of firmware	V1.3
Type	Function block without historical values
Group	General

The function block ARC_STATE is used to get general status information about the ARCNET network. With this FB you get

- the number of reconfigurations (whole number and caused by this device),
- the number of excessive NAKs
- the number of broadcasts
- the number of discards
- the number of the next node ID.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

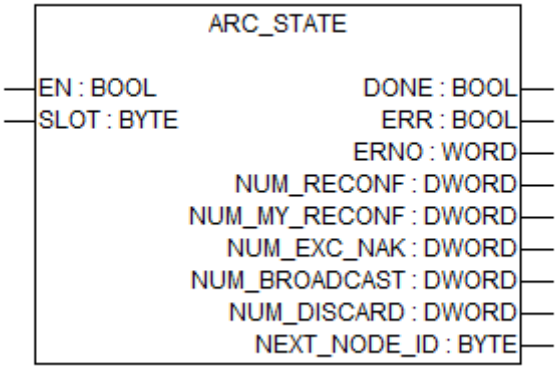
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_RECONF

Data type	Default value	Range	Unit
DWORD	-	-	-

Total number of reconfigurations

NUM_MY_RECONF

Data type	Default value	Range	Unit
DWORD	-	-	-

Number of reconfigurations caused by this device

NUM_EXC_NAK

Data type	Default value	Range	Unit
DWORD	-	-	-

Total number of excessive NAKs.

NUM_BROAD-CAST

Data type	Default value	Range	Unit
DWORD	-	-	-

NUM_DISCARD

Data type	Default value	Range	Unit
DWORD	-	-	-

Total number of receipts discarded due to no matching destination handle found.

NEXT_NODE_ID

Data type	Default value	Range	Unit
BYTE	-	-	-

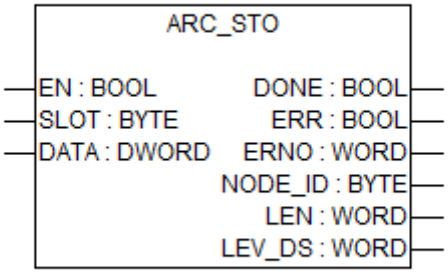
Next node ID.

Function call in ST

```
STATE (EN := STATE_EN,
SLOT := STATE_SLOT);

STATE_DONE := STATE.DONE;
STATE_ERR := STATE.ERR;
STATE_ERNO := STATE.ERNO;
STATE_NUM_RECONF := STATE.NUM_RECONF;
STATE_NUM_MY_RECONF:= STATE.NUM_MY_RECONF;
STATE_NUM_EXC_NAK := STATE.NUM_EXC_NAK;
STATE_NUM_BROADCAST:= STATE.NUM_BROADCAST;
STATE_NUM_DISCARD:= STATE.NUM_DISCARD;
STATE_NEXT_NODE_ID:= STATE.NEXT_NODE_ID;
```

ARC_STO



Parameter	Value
Included in library	ARCNET_AC500_V12.lib
Available as of firmware	V1.2
Type	Function block with historical values
Group	Data

During the transmission of a data packet, the success of the transmission is monitored by an adjustable timeout period. When this time is exceeded, distinctive information of the data packet is stored in the timeout buffer.

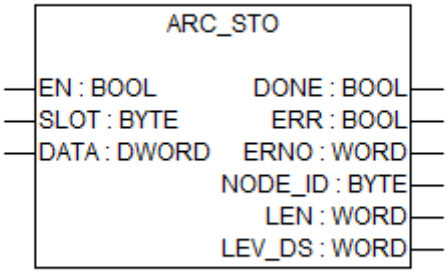
These are:

- the NODE ID of the receiver (4 bytes)
- the length of the involved data packet
- header data of the involved data set.

The length of the timeout buffer as well as the number of user data to be stored can be set for the ARCNET processing in the PLC configuration of the Control Builder. The buffer is constructed as a circular buffer (FIFO). If the buffer is full, the oldest entry in the buffer is overwritten. If the ARC_STO function block is enabled by EN = TRUE, it checks whether a data packet is stored in the buffer and provides the user with the above mentioned information as of the variable given at input DATA. At the outputs NODE_ID and LEN, the NODE ID and the original length of the telegram, which could not be sent, are available.

Before the ARC_STO function block can be used, the setting "ARCNET data exchange" has to be selected. Additionally, the input TOUT of the ARC_SEND function block must be >0.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

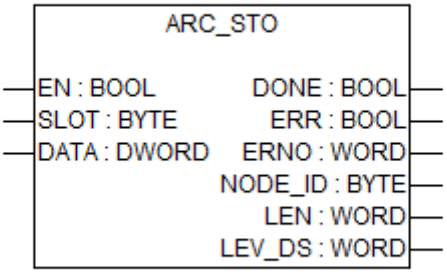
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. DATA must be the address of a variable of the type ARRAY or STRUCT.

CAUTION: Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NODE_ID

Data type	Default value	Range	Unit
BYTE	-	-	-

Output NODE_ID displays the own NODE ID of the Communication Module.

LEN

Data type	Default value	Range	Unit
WORD	-	-	byte

Output LEN displays the length of the received data package in bytes.

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
Sto  (EN := Sto_EN,
     SLOT := Sto_SLOT,
     DATA := ADR(Sto_DATA));

Sto_DONE := Sto.DONE;
Sto_ERR := Sto.ERR;
Sto_ERNO := Sto.ERNO;
Sto_NODE_ID := Sto.NODE_ID;
Sto_LEN := Sto.LEN;
Sto_LEV_DS := Sto.LEV_DS;
```

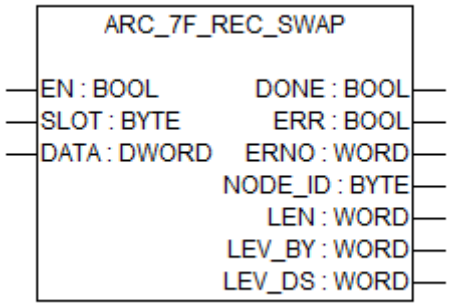
1.5.4.2 Extended ARCNET library

Library file name: **ARCNET_Ext_AC500_Vx.lib**

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

The use of the function blocks presupposes that the ARCNET Communication Module is configured in the ARCNET data exchange mode.

1.5.4.2.1 ARC_7F_REC_SWAP



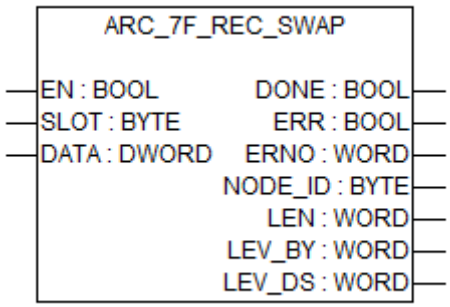
Parameter	Value
Included in library	ARCNETExt_AC500_V12.lib
Available as of firmware	V1.2
Type	Function block with historical values
Group	Data

The operating system reads the received ARCNET data packets from the ARCNET Communication Module and stores them in the receive buffer. The buffer size is determined using the *Chapter 1.6.5.2.3.6 “Parameters of PM5x1-ARCNET (onboard ARCNET)” on page 5846* of the CPU. The data packets are stored with variable lengths. For example, a data packet consisting of 16 bytes of user data occupies exactly 22 bytes in the receive buffer (4 bytes for the NODE ID of the sending device, 2 bytes for the packet length and 16 bytes of user data).

Using the ARC_7F_REC_SWAP function block, exactly one data packet is read. The user data are stored in the configured memory area (DATA). The NODE ID of the sending device and the data packet length are supplied at the outputs NODE_ID and LEN. DONE = TRUE and ERR = FALSE indicate that the reading process was successful. If an error was detected during Function Block processing, the error is additionally indicated at the outputs ERR and ERNO. Furthermore, the function block provides information about the receive buffer filling level displayed in bytes (LEVR_BY) and data records (LEVR_DS).

Before the ARC_REC function block can read data packets from the receive buffer, the setting "ARCNET data exchange" must have been selected in the *Chapter 1.6.5.2.3.6 “Parameters of PM5x1-ARCNET (onboard ARCNET)” on page 5846* of the CPU.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

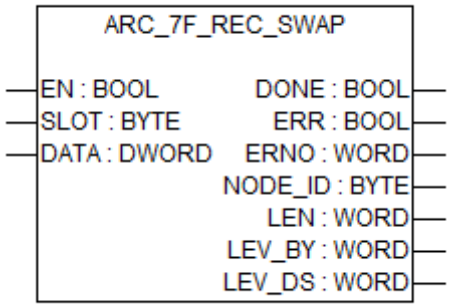
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. DATA must be the address of a variable of the type ARRAY or STRUCT.

CAUTION: Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NODE_ID

Data type	Default value	Range	Unit
BYTE	-	-	-

Output NODE_ID displays the own NODE ID of the Communication Module.

LEN

Data type	Default value	Range	Unit
WORD	-	-	byte

Output LEN displays the length of the received data package in bytes.

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY displays the filling level of the receive buffer in bytes. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

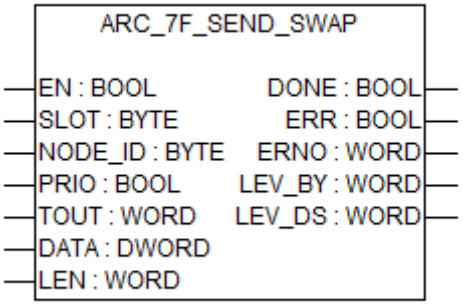
One data packet occupies output LEN + 6 bytes in the receive buffer (4 bytes for the NODE ID of the sending device, 2 bytes for the specification of the length).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

1.5.4.2.2 ARC_7F_SEND_SWAP

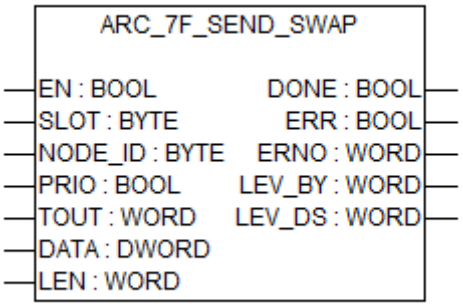


Parameter	Value
Included in library	ASCII_AC500_V12.lib
Available as of firmware	V1.2
Type	Function block with historical values
Group	Data

The function block ARC_7F_SEND_SWAP is used to transmit data packets via the ARCNET Communication Module. The specified packages are stored in the transmit buffer which is selected by input PRIO. From there, the operating system hands over the data packet to the ARCNET Communication Module in order to transmit them to the target address specified at input NODE_ID. The transmit buffer size is determined using the PLC Configuration ↳ *Chapter 1.6.5.2.3.6 “Parameters of PM5x1-ARCNET (onboard ARCNET)” on page 5846* of the Automation Builder. Using input TOUT, the timeout period can be specified. If TOUT <> 0, the ARCNET data exchange is automatically performed with receive acknowledgement. If TOUT = 0, no acknowledgement is expected. Output DONE indicates that the specified data packet has been stored in the transmit buffer or that an error occurred during Function Block processing. If an error was detected during Function Block processing, the error is additionally indicated at the outputs ERR and ERNO. In case of an error, the data packet has to be transmitted again.

Before the ARC_SEND function block can store data packets in the receive buffer, the setting "ARCNET data exchange" must have been selected in the *Chapter 1.6.5.2.3.6 “Parameters of PM5x1-ARCNET (onboard ARCNET)” on page 5846* of the CPU.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE_ID

Data type	Default value	Range	Unit
BYTE	-	-	-

Output NODE_ID displays the own NODE ID of the Communication Module.

PRIO

Data type	Default value	Range	Unit
BOOL	-	-	-

Input PRIO is used to specify the transmit priority of the data packet.

The following applies:

PRIO = FALSE

The specified data packet has low priority. Thus, it is stored in the low priority transmit buffer. All outputs refer to this buffer.

PRIO = TRUE

The specified data packet has high priority. Thus, it is stored in the high priority transmit buffer. All outputs refer to this buffer.

TOUT

Data type	Default value	Range	Unit
WORD	200ms	-	-

Using input TOUT, the timeout period can be specified. If TOUT <> 0, the ARCNET data exchange is automatically performed with receive acknowledgement. If a data packet cannot be transmitted within this period (no acknowledge telegram is received), transmission is aborted and the package is lost.

In this case, some distinctive bytes of the data packet (see also the PLC configuration of the Control Builder) are stored to the timeout buffer and can then be read using the function block ARC_STO.

If TOUT = 0, no acknowledgement is expected.

The following applies:

TOUT = 0 means: Default value for TOUT, given by PLC configuration, is used.

Data exchange without receive acknowledgement. No data are written to the timeout buffer.

TOUT <> 0:

Data exchange with receive acknowledgement. Each transmitted data record is acknowledged by the recipient. If no acknowledge telegram is received within the set timeout period (in ms), the data are written to the timeout buffer.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. DATA must be the address of a variable of the type ARRAY or STRUCT.

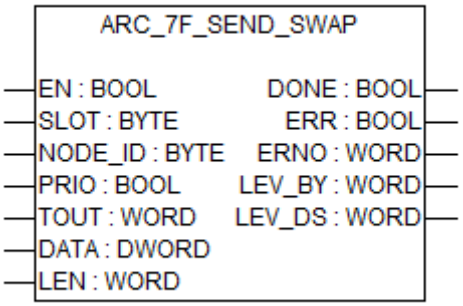
CAUTION: Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

LEN

Data type	Default value	Range	Unit
WORD	-	-	byte

Output LEN displays the length of the received data package in bytes.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY displays the filling level of the receive buffer in bytes. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 6 bytes in the receive buffer (4 bytes for the NODE ID of the sending device, 2 bytes for the specification of the length).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

1.5.4.3 ASCII communication library

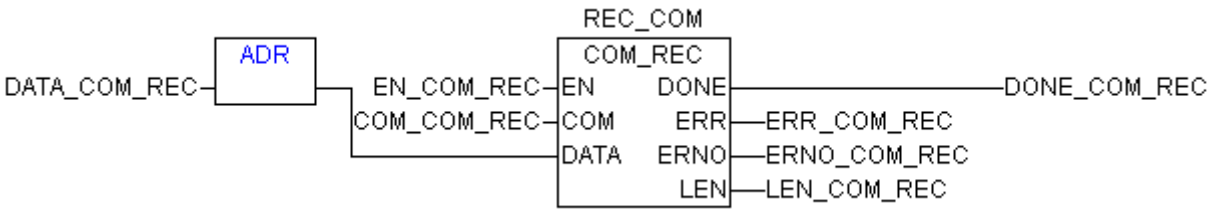
Library file name: **ASCII_AC500_Vx.lib**

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

There is no particular function block available for setting the communication interfaces in transmitting and receiving direction. This is done in the configuration within CODESYS.

1.5.4.3.1 Function blocks

COM_REC



Parameter	Value
Included in library	ASCII_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values
Group	ASCII communication

The function block COM_REC is used for receiving data via a serial interface in "free mode". The number of COM_REC function blocks within a project as well as their distribution (i.e. assignment) to different user tasks is not restricted. However, it has to be observed that the function blocks are mutually interlocked, i.e. it must be ensured that only one function block is active at the same time. To avoid the loss of telegram parts and to prevent that telegrams are evaluated incorrectly or not at all, a change of activity between two COM_REC function blocks should only occur if the function block to be deactivated has signalized the termination of the receive process by setting DONE = TRUE and if the received telegram has been evaluated. It is essential to ensure that all function block instances are inactive prior to initiating an activity change. Thus, it is strongly recommended to use only one COM_REC function block within a project. This way, any responsibility conflicts can be avoided.

With a FALSE -> TRUE edge at function block input EN, the function block checks the input values. If they are valid, the function block reads the receiving buffer of the corresponding COMx interface one-time.

By specifying the length of the memory address for the received data, the format of the telegram is not restricted in any way. The length of the received data block is limited to a maximum of 256 bytes and is output at LEN.

During project planning it has to be observed that enough free memory space is reserved starting at address DATA for storing the received data (e.g. ARRAY [1..256] OF BYTE).

If a valid received telegram is available in the memory area starting at DATA, this is always indicated by DONE = TRUE.

The inputs can neither be duplicated nor negated/inverted.

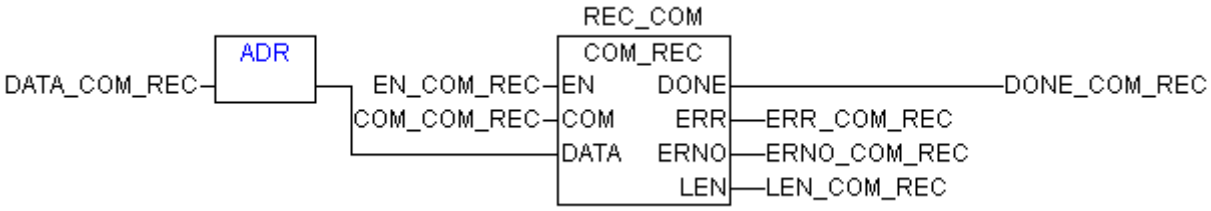
Receive error

Possible receive errors are detected by the function block and indicated by ERR = TRUE. In this case, an error number is output at ERNO. The function block recognizes overflow, parity and framing errors. In this case, the communication parameters (transmission rate, char length, no. of stop bits, parity) of the communication partners have to be checked.

Times

There is no particular function block available for setting the times in transmitting and receiving direction. This is done in AC500 controller configuration.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

At the COM input, the number of the serial interface is specified.

COM = 1: COM1

COM = 2: COM2

DATA

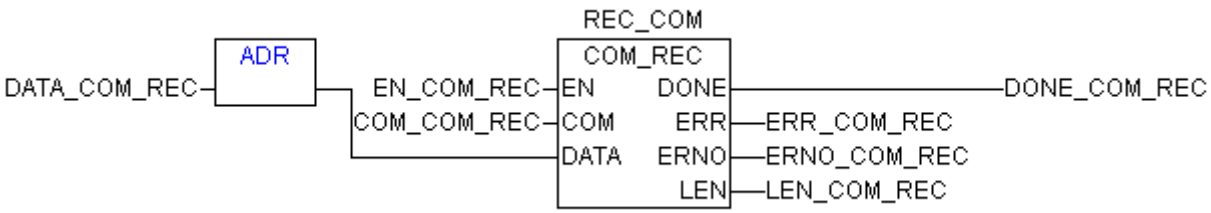
Data type	Default value	Range	Unit
DWORD	-	-	-

At input DATA, the start address for storing the received data is specified using an ADR operator. Received data can be stored in the operand area as well as in variables. Some peculiarities have to be observed when receiving binary values.

When using IEC bit operands as storage address, only operands are allowed which end with ".0" (e.g. %QX62.0 allowed, %QX62.1 forbidden).

When storing a received telegram within the IEC bit operand area, it has to be observed that a received byte describes 8 bit operands. However, if a received telegram is stored to a Boolean variable, this variable is considered as FALSE if the byte has the value 0 and TRUE for all other values of the byte.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEN

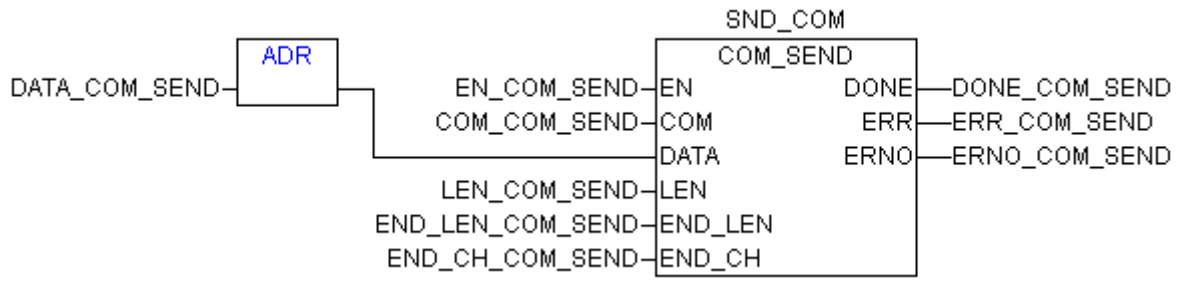
Data type	Default value	Range	Unit
WORD	-	-	-

LEN outputs the length of the received data (in bytes) including end character (if contained). LEN is only valid if DONE = TRUE. LEN has always to be considered together with output ERR.

Function call in ST

```
REC_COM
(EN := EN_COM_REC,
COM := COM_COM_REC,
DATA := ADR(DATA_COM_REC));
DONE_COM_REC := REC_COM.DONE;
ERR_COM_REC := REC_COM.ERR;
ERNO_COM_REC := REC_COM.ERNO;
LEN_COM_REC := REC_COM.LEN;
```

COM_SEND



Parameter	Value
Included in library	ASCII_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values
Group	ASCII communication

The function block COM_SEND is used for sending data via a serial interface. The number of COM_SEND function blocks in a project as well as their usage in (i.e. assignment to) different user tasks is not restricted. Transmission is triggered by a FALSE > TRUE edge at input EN. By specifying the length of the memory address for the data to be transmitted, the format of the telegram is not restricted in any way.

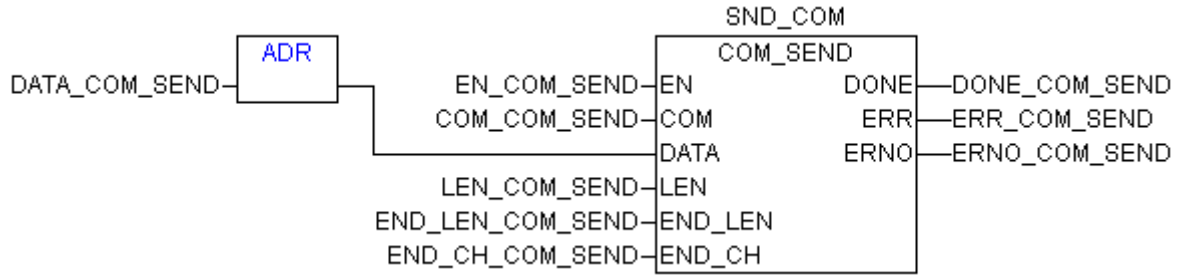
The length of the data block to be transmitted is not limited. It is recommended to write only data blocks up to a maximal size of 256 bytes into the transmit buffer, since data can only be transmitted if enough free memory space is available for the transmit buffer. If required, longer telegrams can be generated by using several COM_SEND function blocks following each other immediately without considering their individual DONE outputs.

The inputs can neither be duplicated nor negated/inverted.

Telegram length

The maximum length of a transmit telegram can be controlled by evaluating the output DONE. DONE = TRUE indicates an empty transmit buffer. If a transmission is only triggered if DONE = TRUE, one single telegram will be sent per COM_SEND. Theoretically, endless data streams can be generated by ignoring DONE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

At the COM input, the number of the serial interface is specified.

COM = 1: COM1

COM = 2: COM2

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

At input DATA, the start address for storing the received data is specified using an ADR operator. Received data can be stored in the operand area as well as in variables. Some peculiarities have to be observed when receiving binary values.

When using IEC bit operands as storage address, only operands are allowed which end with ".0" (e.g. %QX62.0 allowed, %QX62.1 forbidden).

When storing a received telegram within the IEC bit operand area, it has to be observed that a received byte describes 8 bit operands. However, if a received telegram is stored to a Boolean variable, this variable is considered as FALSE if the byte has the value 0 and TRUE for all other values of the byte.

LEN

Data type	Default value	Range	Unit
WORD	-	-	-

LEN outputs the length of the received data (in bytes) including end character (if contained). LEN is only valid if DONE = TRUE. LEN has always to be considered together with output ERR.

END_LEN

Data type	Default value	Range	Unit
BYTE	-	-	-

Number of end characters to be attached: 0, 1, 2 means none, one or two.

The inputs LEN and END_LEN have to be smaller than 256! Otherwise, an error will occur.

END_CH

Data type	Default value	Range	Unit
WORD	-	-	-

At input END_CH, the value of the telegram end character(s) must be specified which has (have) to be attached to the actual transmit data. END_CH is considered if input END_LEN of the COM_SEND function block is not 0. END_CH is applied with a FALSE > TRUE edge at EN. If required, the end character can vary within each telegram.

If, for example, a CR/LF shall be attached to a telegram, the value of END_CH is as follows: 16#0D0A and END_LEN: 2.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
SEND_COM
(EN := EN_COM_SEND,
COM := COM_COM_SEND,
DATA := ADR(DATA_COM_SEND),
LEN := LEN_COM_SEND,
END_CH := END_CH_COM_SEND,
END_LEN := END_LEN_COM_SEND);

DONE_COM_SEND := SEND_COM.DONE;

ERR_COM_SEND := SEND_COM.ERR;
ERNO_COM_SEND := SEND_COM.ERNO;
```

1.5.4.4 CAA_File library

Library file name: **CAA_File.lib**

The IEC61131 library CAA_FILE provides function blocks for accessing directories and files. File access is only supported in binary mode.

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

For usage of CAA_File Library, CPU firmware V2.1 or higher is needed.

CAA_File.lib requires the following additional libraries:

- CAA_ASYNCMAN.lib
- CAA_CALLBACK.lib
- CAA_TICK.lib
- CAA_TICKUTIL.lib
- CAA_TYPES.lib

Most input values of the function blocks are stored in local internal variables. This does not apply for the contents of memory structures where a pointer is passed on as an input e.g. pBuffer of FILE_Read or FILE_Write.

Differing from Standard ABB Libraries CAA function blocks set EITHER xDone (i.e. function block finished without error) OR xError (i.e. function block finished with error)!

1.5.4.4.1 Characteristics

CAA_FILENAME which is described in CAA_Types.lib should be usable for library CAA_File.lib in the following way:

- Separators in paths in CAA_FILENAME is the back-slash ("\").
- Only absolute paths are allowed to use for file operation: drivename\directory\file.ext
- File and directory names have to be in standard DOS 8.3 notation without \ / : * ? "< > |
- Directory and file names may not contain whitespaces and are not case-sensitive.

Available drives for the use with this library are:

- Userdisk
- Memory card
- Flash disk – only on PM592-ETH (PLC with internal mass storage)
- SRAM Disk – only PM57x, PM58x, PM59x

Restrictions for the use of the drives are:

- Maximum file names: 8.3 filenames, e.g.: abcdefgh.123
- Maximum total path length: 255 characters
- Maximum file size: 4 GB -1 Byte
- Maximum number of simultaneous user handles (directories + files): 6 (PM55x) or 12 (PM57x,PM58x,PM59x)
- Maximum number of files in the root directory is limited (depends on memory location).

Behavior of CAA_File on reset

A reset operation is executed if any user calls any online reset command or downloads a new application into the PLC. All file handles which are opened during execution of IEC application using FILE_Open and FILE_DirOpen will be closed after application reset. This assures that all handles opened by the user application will be closed and returned to the system. Please note that the application is not reset in case of a stop or an online change operation, so any file handle in IEC application is kept opened.

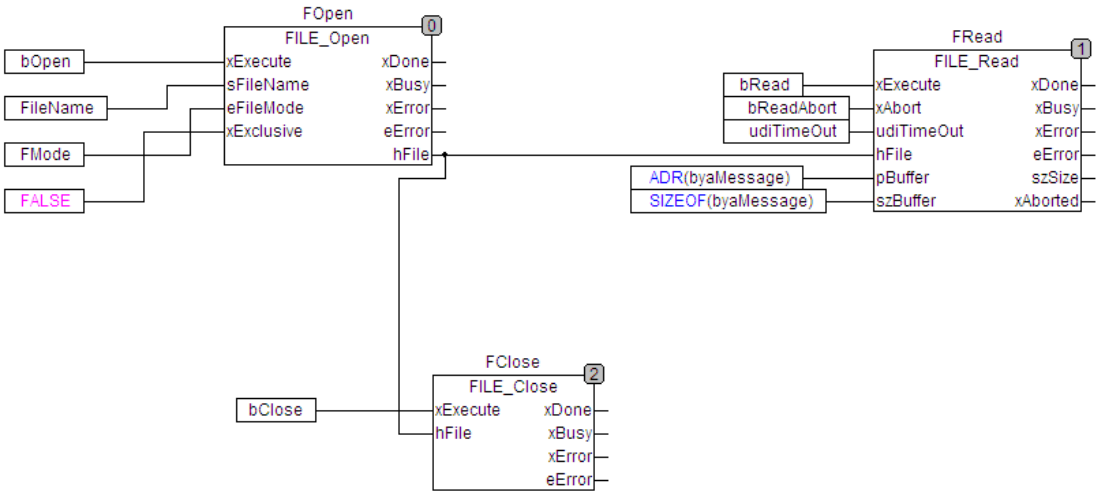
If a CAA_File function block is in BUSY state at the moment when reset command is executed the behavior of this function block is the following:

- If the request to file system which is executed by the function block is not yet processed by file system, the function block will be aborted. This means that the file operation will not be executed at all.
- If the file operation is already started and the corresponding function block does not support an abort command, the file operation will be finished and after that the corresponding file handle will be closed.
- If the file operation is already started and the corresponding function block supports an abort command (i.e. FILE_Write, FILE_Read, FILE_Copy) the file operation is aborted and after that the corresponding file handle is closed. Please refer to the description of abort for each function block for further details.

Usage of CAA_File function blocks and online changes

There are 2 function blocks in CAA_File.lib which use ADR operator to pass parameter from IEC application to function block. During design and maintenance of IEC application which uses these function block it is necessary to consider behavior of these function blocks during online changes.

Example of a simple program:

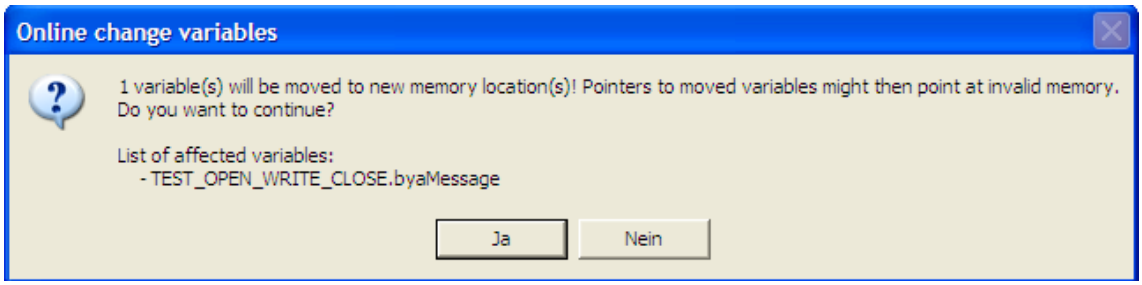


As known during online change variables in IEC application could be relocated to different memory position. In the example, variable byaMessage could be relocated as well. All file operations which are invoked by CAA_File function block are executed in separate low priority task and pointer to read buffer (byaMessage in the example) is saved in context of this task during all file operation.

It means that if operation FILE_Write is not finished before online change some data could be lost or damaged, because pointer to buffer which is used for execution of file operation is not valid anymore.

The following recommendation could be done how to use FILE_Write and FILE_Read function block to avoid any problems after online change:

- Global variable or variable which is declared inside POU Program is only relocated if size of variable is changed. Any variable which is declared in POU function block is relocated even if data structure of function block is changed, e.g. any new variable is added to function block, any variable is deleted etc. So it is recommended to use for read/write buffer global variables and keep their size constant during online change or use variables which are declared in function block, but keep the structure of function block data unalterable.
- If any variable in application is relocated during online change the following message appears



Please check if any variable in your project which is used as write or read buffer does not present in this list. If variable is nevertheless here please check that xBusy output of appropriate function block is set to FALSE. If so, then online change is absolutely safe, otherwise you may meet the problems which are described above and it is recommended to avoid online change and postpone it for a while, till xBusy will not be set to TRUE.

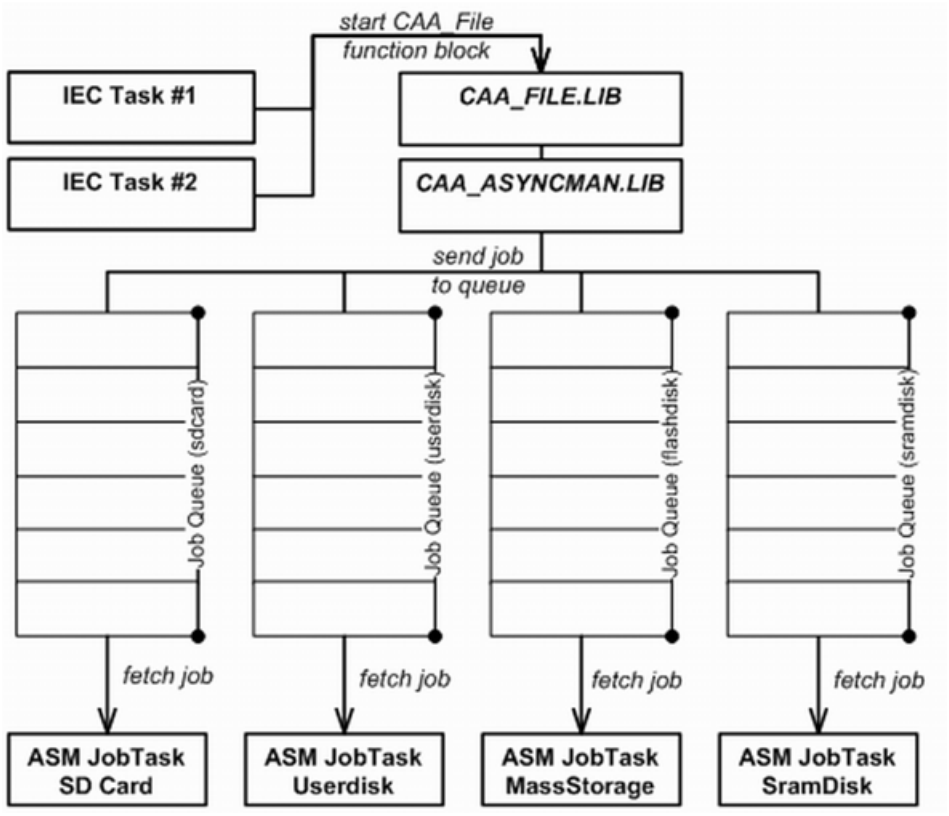
Implementation notes for CAA_File.lib

- Ensure that the file/directory handle is returned to the system (with FILE_Close/FILE_DirCLose) before discarding the local variable holding it.
- You cannot open a file with write access simultaneously.
- Only a successfully call to FILE_Close or FILE_Flush updates a file's representation (i.e. size & content) on a device completely and definitely.
- All outputs of all function blocks will be invalidated, if xExecute is set to FALSE, thus they have to be read previously.

- Differing from Standard ABB libraries, CAA function blocks set EITHER xDone (i.e. FB finished without error) OR xError (i.e. FB finished with error).
- The path separator is a single backslash („\“), not a double backslash („\\“) or a forward slash („/“).
- Both pointer and data contents handed over to read/write function blocks have to be stable during operation!
- CAA_File.lib works in binary mode, thus it reads and writes bytewise. There is no automatic null-termination of the data of any kind, i.e. everything is a byte array: You hand over the starting address of the array and the number of bytes you want to have read/written from/to the array with the given starting address. The interpretation of the read data is up to the user application.
- Files and directory handles are only auto-closed in case of a application download or reset. A stop or online change of the IEC application does NOT close any file handles.

Notes on CAA_AsyncMan .lib

CAA_File.lib requires the additional library CAA_AsyncMan.lib. This library provides the means to handle all CAA_File.lib function blocks completely asynchronous. For each call to a CAA_File function block a so called "job" will be created. One task handles the job requests sent by the IEC application for each file I/O module in the AC500 PLC. These tasks run with a low priority, so the available file throughput depends on the other tasks running on the PLC - i.e. If the PLC is already completely busy doing communication, handling I/O Modules or calculation IEC tasks, the file operations might not be carried out. If a file I/O module is currently busy with an ongoing job request, new requests are queued and executed in a FIFO (“first in, first out”) manner.



Thus to understand the AC500’s file access system behavior the user has to keep in mind that:

- Every file operation is done asynchronously in a separate worker task.
- There is one worker task per I/O module (e.g. userdisk, memory card,…).
- The worker tasks have a low priority and thus might be blocked by other PLC processes.
- Each worker task has a FIFO-queue for the incoming jobs (i.e. triggered function blocks) for its I/O module.
- Most jobs cannot be interrupted or aborted once they are started (exceptions see function block descriptions).

These aspects result in the danger of priority inversion:

If a low priority task already triggered a file access job and another task with higher priority tries to access the same I/O module, the task with higher priority still will have to wait for the task with low priority to complete its job, i.e. the task priorities are inverted.

CAA_AsyncMan.lib can handle a maximum of 20 active function blocks in parallel. In this context, "active" means function block instances triggered via a rising edge and not yet reset by a falling edge on their input xExecute. If this limit is exceeded, additional triggered function blocks will return with undefined errors (e.g. "Invalid error 5802").

1.5.4.4.2 Function blocks

Error messages

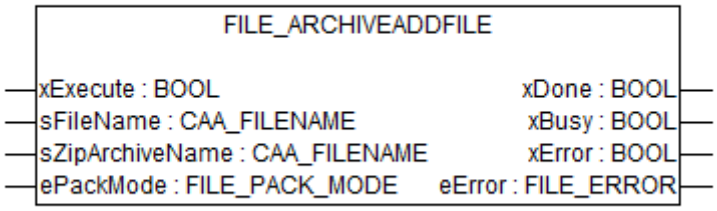
If a function block returns an "invalid" (i.e. internal) error code which is not listed here, check for a possible version mismatch between PLC firmware and the CAA File Libraries. If the function block is supported definitely by the firmware version in the PLC, the IEC application might have too many active function blocks in parallel (maximum number is 20).

Function blocks of CAA_File.lib can return the following error codes:

Value	Error Name	Description
0	FILE_NO_ERROR	No error
5101	FILE_TIME_OUT	Time limit exceeded
5102	FILE_ABORT	Order has been aborted by activating input xAbort
5103	FILE_HANDLE_INVALID	Invalid handle
5104	FILE_NOT_EXIST	Directory or file does not exist
5105	FILE_EXIST	Directory or file already exists
5106	FILE_NO_MORE_ENTRIES	No further entries are available
5107	FILE_NOT_EMPTY	File or directory is not empty
5108	FILE_READ_ONLY_CAA	Drive, file or directory is write-protected
5109	FILE_WRONG_PARAMETER	Wrong parameter(s) at function block
5110	FILE_ERROR_UNKNOWN	Unknown error
5111	FILE_WRITE_INCOMPLETE	Not all data has been written
5112	FILE_NOT_IMPLEMENTED	Function not supported
5113	FILE_NO_RESSOURCES	No file handles or user tasks available (too many files open or tasks accessing file system)
5114	FILE_NO_SPACE	Volume is full
5115	FILE_NO_DEVICE	Cannot open disk or no valid disk present
5151	FILE_CANT_BE_OPENED	File/directory could not be accessed to execute operation
5152	FILE_ERROR_OTHER	Internal or not further specified error
5153	FILE_SOURCE_CANT_BE_OPENED	Source file could not be opened to execute required operation
5154	FILE_DEST_CANT_BE_OPENED	Destination file could not be opened to execute required operation
5155	FILE_CANT_WRITE	Data could not be written to destination file

Value	Error Name	Description
5156	FILE_CANT_READ	Data could not be read from source file
5157	FILE_CONFIRM_FORMAT_OPERATION	Formatting operation has not been confirmed at xEnable before activating the function block with xExecute.

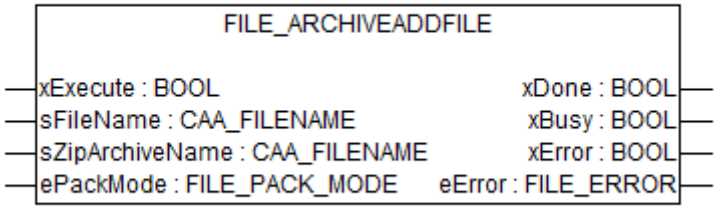
FILE_ArchiveAddFile



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Archive Services

FILE_ArchiveAddFile adds a file to an archive. If the archive does not exist a new one is created. The file is always added to the archive in uppercase.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

sFileName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sFileName specifies an absolute file name which has to be added to archive. The file name appears in archive in uppercase.

sZipArchive-Name

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sZipArchiveName specifies archive name to unpack.

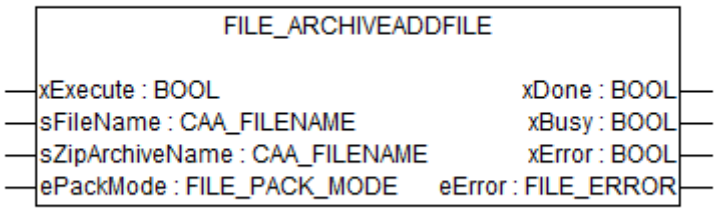
ePackMode

Data type	Default value	Range	Unit
FILE_PACK_MODE	-	-	-

Input ePackMode specifies the mode how a file is packed into archive.

FILE_MODE	Description
FILE_PACK_OVERWRITE	If file in archive already exists it is allowed to overwrite it.
FILE_PACK_WITHOUT_PATH	If this mode is defined then the file will be packed only with its name, otherwise absolute file name is saved in the archive.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

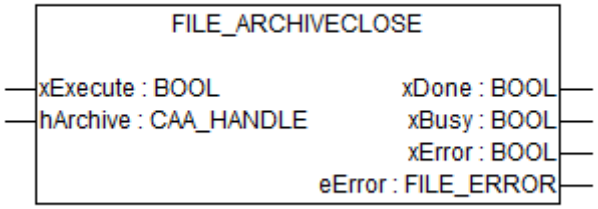
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

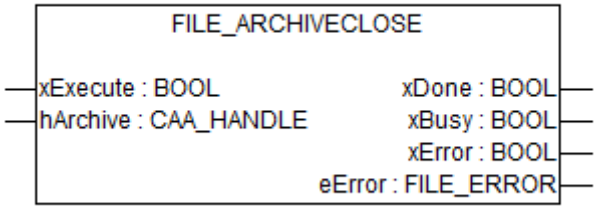
FILE_ArchiveClose



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Archive Services

FILE_ArchiveClose closes archive. After this operation archive is again available again for packing operation (FILE_ArchiveAddFile).

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

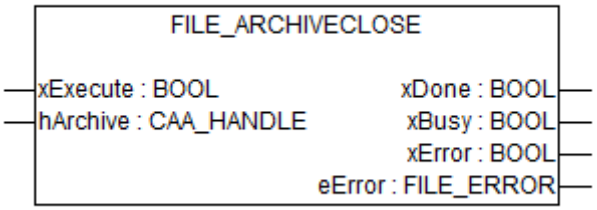
The function block is activated via a positive edge at this input.

hArchive

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

Input hArchive specifies archive handle which has to be closed.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

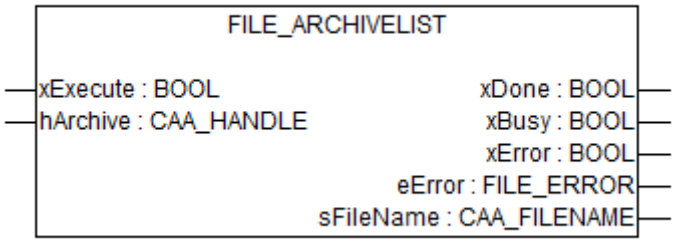
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

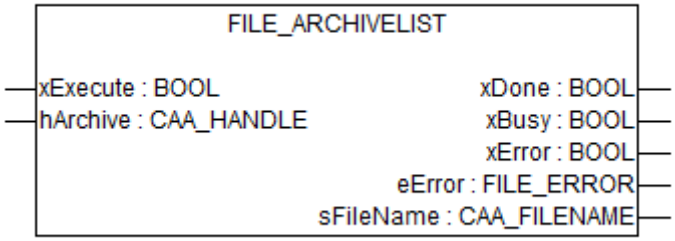
FILE_ArchiveList



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Archive Services

FILE_ArchiveList returns current file entry in archive. If the function block cannot find any further entries the error message FILE_NO_MORE_ENTRIES is generated. The functionality is similar to the function block FILE_DirList but instead of directory archive is accessed.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

hArchive

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

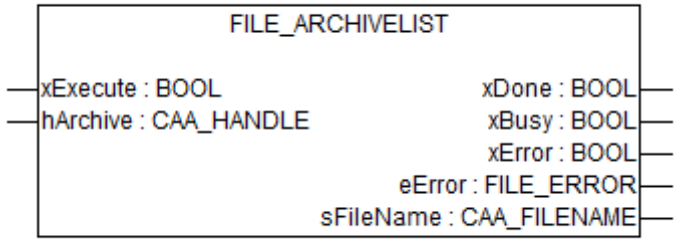
Input hArchive specifies archive handle which has to be closed.

sFileName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sFileName specifies an absolute file name which has to be added to archive. The file name appears in archive in uppercase.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

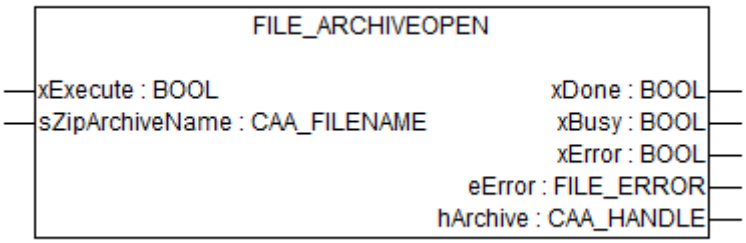
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

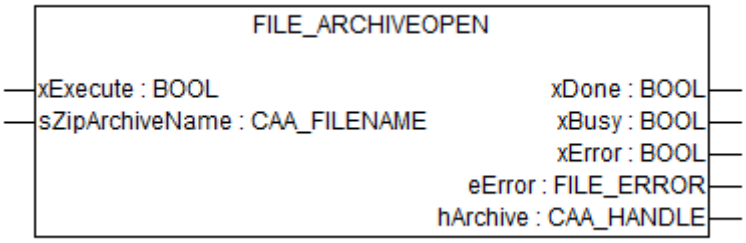
FILE_ArchiveOpen



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Archive Services

FILE_ArchiveOpen opens an archive and returns the archive handle. Afterwards it is possible to iterate over all files in archive. If archive is opened using this function block all unpack operations (FILE_ArchiveUnpackFile, FILE_ArchiveUnpackFile) could be executed on this archive. Packing operation (FILE_ArchiveAddFile) is not allowed. Archive must be closed first to execute packing operation.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

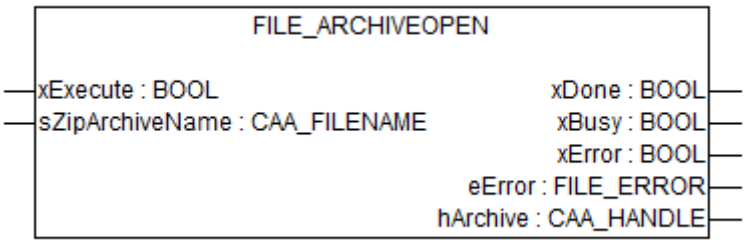
The function block is activated via a positive edge at this input.

sZipArchive-Name

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sZipArchiveName specifies archive name to unpack.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

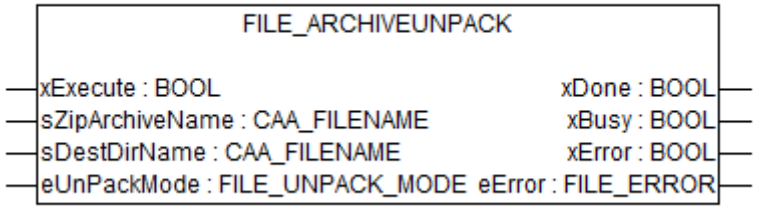
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

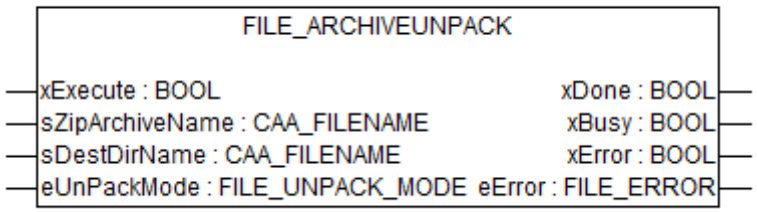
FILE_ArchiveUnpack



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Archive Services

FILE_ArchiveUnpack unpacks an archive. Function block iterates over all files in archive and unpacks each one. If it is not possible to unpack file error is generated but function block tries to unpack other files in archive. Function block returns error which corresponds to the last failed sub-operation. Only files which are stored with names with 8.3 format could be unpacked.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

sZipArchive-Name

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sZipArchiveName specifies archive name to unpack.

sDestDirName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sDestDirName specifies name of destination directory, where archive has to be unpacked.

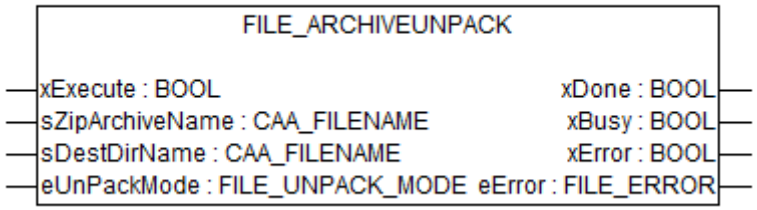
eUnpackMode

Data type	Default value	Range	Unit
FILE_UNPACK_MODE	-	-	-

Input eUnpackMode specifies the mode for archive unpacking operation.

FILE_MODE	Description
FILE_UNPACK_USE_ABSOLUTE_PATH_SAVED_IN_ARCHIVE	If this mode is defined then path to directory is saved in archive. That means sDestDirName is ignored and files are extracted in saved archive directory path, otherwise files are extracted to directory which is specified using sDestDirName. Destination drive name has to be always available in the specified path, i.e. path has to be absolute. If mode is defined but path for any file is not available in archive then this file is not extracted.
FILE_UNPACK_OVERWRITE	If any file in destination directory already exists it is allowed to overwrite it. Input is set to FALSE when only new files are added to destination directory.
FILE_UNPACK_CREATE_DIRS	If destination directory does not exist it will be automatically created. If mode is not set and destination directory does not exist function block returns error. Destination directory could be defined in archive itself if FILE_UNPACK_USE_ABSOLUTE_PATH_SAVED_IN_ARCHIVE is set.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

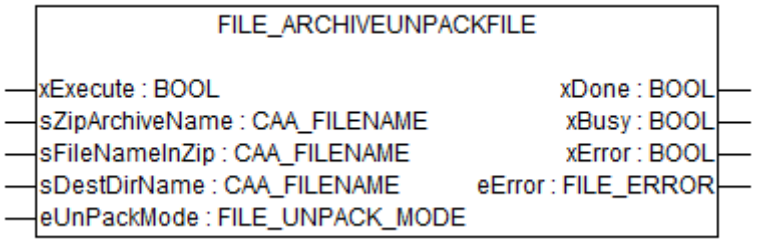
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

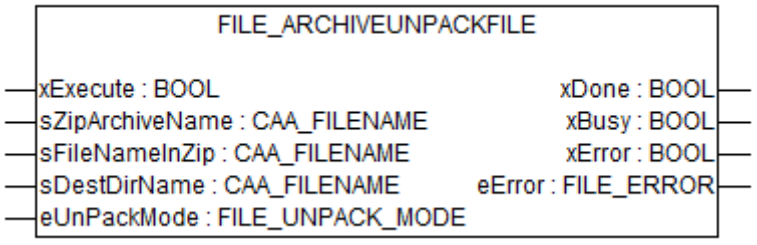
FILE_ArchiveUnpackFile



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Archive Services

FILE_ArchiveUnpackFile unpacks a specific file from an archive. The function block finds the file with name specified by end user and unpacks it to the destination directory sDestDirName. Only files which are stored with names with 8.3 format can be unpacked.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

sZipArchive-Name

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sZipArchiveName specifies archive name to unpack.

sDestDirName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sDestDirName specifies name of destination directory, where archive has to be unpacked.

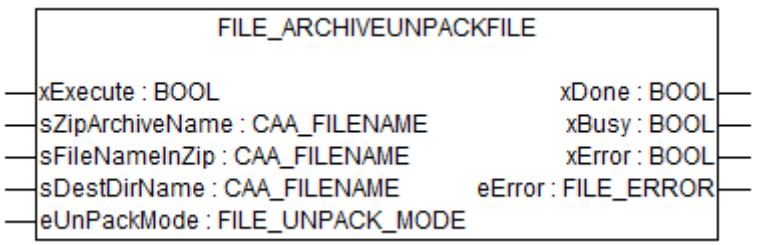
eUnpackMode

Data type	Default value	Range	Unit
FILE_UNPACK_MODE	-	-	-

Input eUnpackMode specifies the mode for archive unpacking operation.

FILE_MODE	Description
FILE_UNPACK_USE_ABSOLUTE_PATH_SAVED_IN_ARCHIVE	If this mode is defined then path to directory is saved in archive. That means sDestDirName is ignored and files are extracted in saved archive directory path, otherwise files are extracted to directory which is specified using sDestDirName. Destination drive name has to be always available in the specified path, i.e. path has to be absolute. If mode is defined but path for any file is not available in archive then this file is not extracted.
FILE_UNPACK_OVERWRITE	If any file in destination directory already exists it is allowed to overwrite it. Input is set to FALSE when only new files are added to destination directory.
FILE_UNPACK_CREATE_DIRS	If destination directory does not exist it will be automatically created. If mode is not set and destination directory does not exist function block returns error. Destination directory could be defined in archive itself if FILE_UNPACK_USE_ABSOLUTE_PATH_SAVED_IN_ARCHIVE is set.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

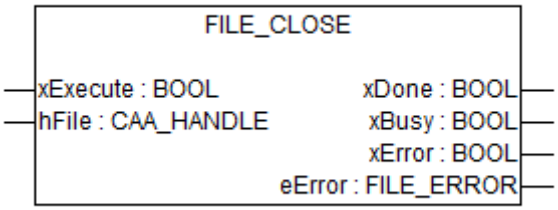
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' ↳ *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

FILE_Close

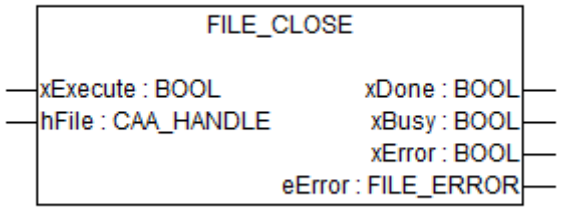


Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_Close terminates the file access, i.e. closes the file. If an operation (FILE_Read, FILE_Write, FILE_GetPos, FILE_SetPos) which uses the file handle to be closed is ongoing, it will be aborted before closing file.

Without a correct FILE_Close written data can be lost!

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

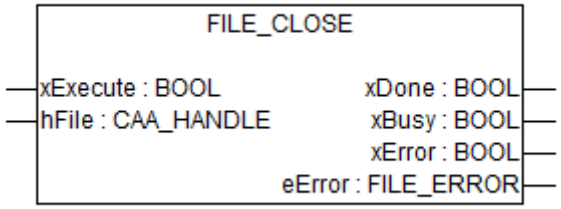
The function block is activated via a positive edge at this input.

hFile

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

File handle retrieved with CAA_Open.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

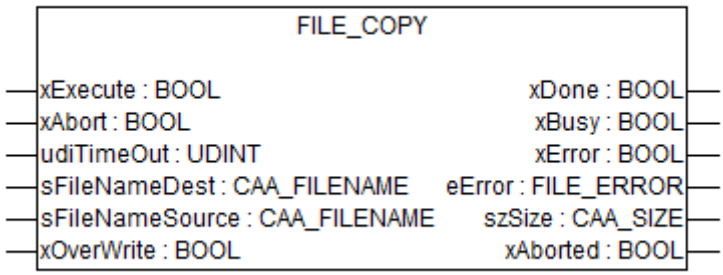
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

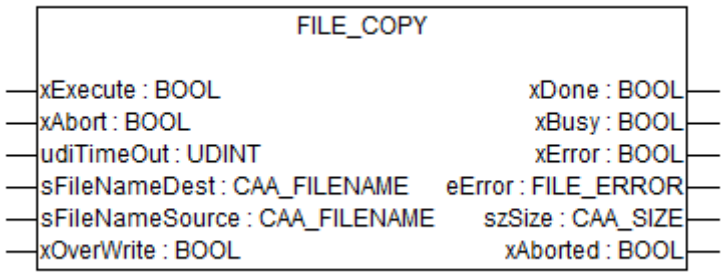
FILE_Copy



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_Copy copies a file. The target file is created or - if already existing - overwritten. During the operation a temporary file with the extension .tmp is created. If the copying is aborted by the user the .tmp file will remain on the device.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

xAbort

Data type	Default value	Range	Unit
BOOL	-	-	-

Input xAbort stops the Function Block's processing without waiting for it to finish.

udiTimeOut

Data type	Default value	Range	Unit
UDINT	-	-	-

Input udiTimeOut defines the time out in microseconds for the function block to wait on the operation to be finished. A value of 0 means no time out.

sFileNameDest

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Absolute Path of destination.

sFileName-Source

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

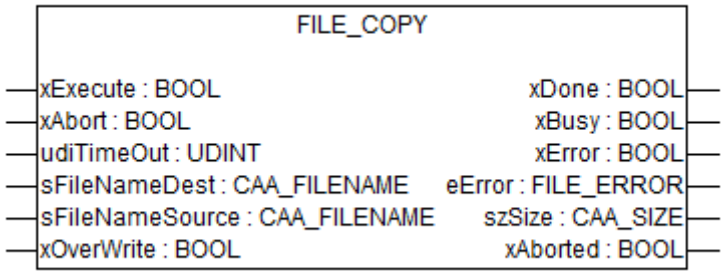
Absolute Path of source.

xOverWrite

Data type	Default value	Range	Unit
BOOL	-	-	-

If input xOverwrite is set to TRUE, the target file will be overwritten, if it exists. Otherwise an error is raised.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

szSize

Data type	Default value	Range	Unit
CAA_SIZE	-	-	-

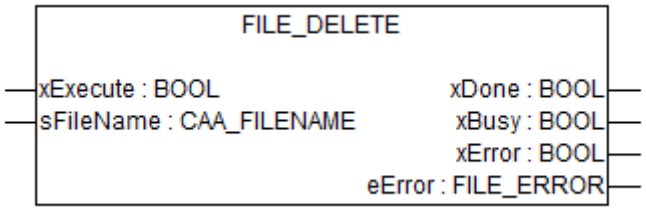
Output szSize is set to the number of bytes copied.

xAborted

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xAborted is set if the function block has been aborted.

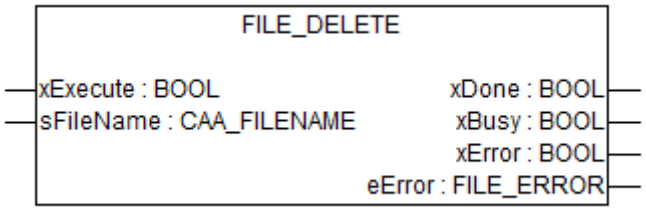
FILE_Delete



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_Delete deletes a file. This is not possible if the file is open via FILE_Open.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

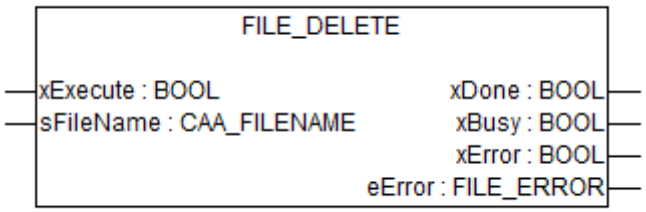
The function block is activated via a positive edge at this input.

sFileName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sFileName specifies an absolute file name which has to be added to archive. The file name appears in archive in uppercase.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

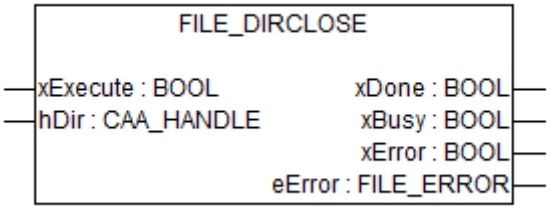
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

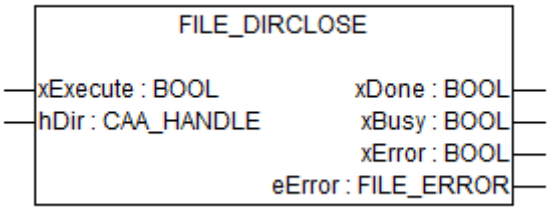
FILE_DirClose



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Directory

FILE_DirClose closes the access on the specified directory.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

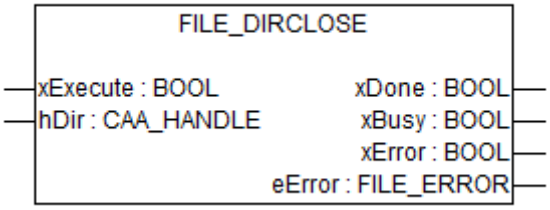
The function block is activated via a positive edge at this input.

hDir

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

Input hDir sets the handle of the directory to close.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

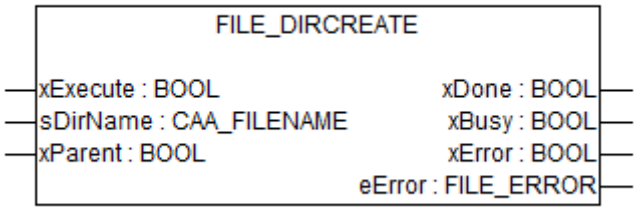
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

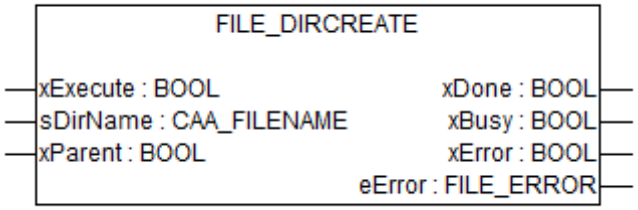
FILE_DirCreate



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Directory

FILE_DirCreate creates a directory. If the directory already exists, an error is generated.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

sDirName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

At input sDirName the absolute path and directory name of the new directory has to be specified.

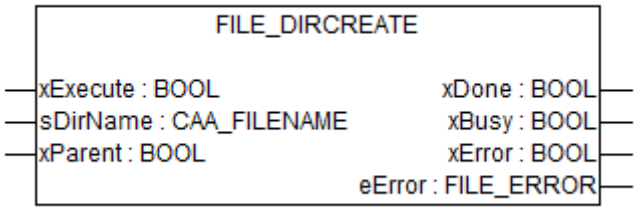
xParent

Data type	Default value	Range	Unit
BOOL	-	-	-

If input xParent = TRUE the full path specified at sDirName is created if it is not existing.

This input is not supported on the AC500 PLCs.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

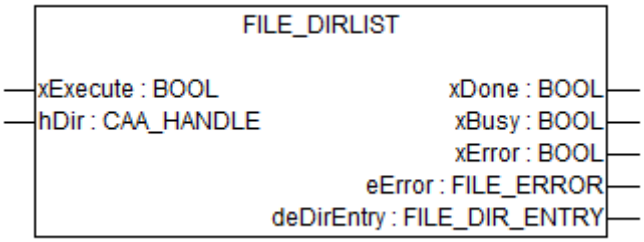
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' ↳ *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

FILE_DirList

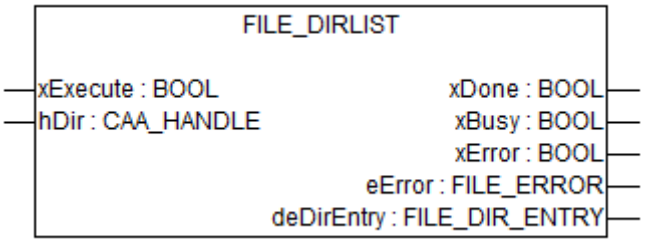


Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Directory

FILE_DirList reads directory or file properties. The function block needs a valid handle which identifies the directory as a transfer parameter. The information is written to structure deDirEntry of type FILE_DIR_ENTRY. If the function block cannot find any further entries the error message FILE_NO_MORE_ENTRIES is generated and the entries in the structure deDirEntry are deleted.

If FILE_DirList is called for an empty volume (e.g. just formatted), an empty file is returned which represents the volume entry of the device. Calling the function block again delivers an error return with code FILE_NO_MORE_ENTRIES.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

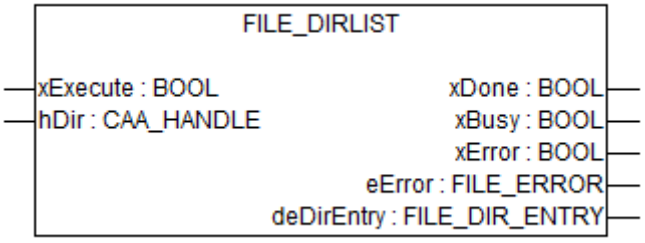
The function block is activated via a positive edge at this input.

hDir

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

Input hDir sets the handle of the directory to close.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' ↳ *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

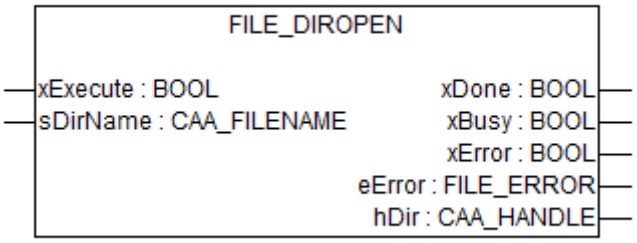
deDirEntry

Data type	Default value	Range	Unit
FILE_DIR_ENTRY	-	-	-

Output deDirEntry is filled with the information on the read directory or file entry:

FILE_DIR_ENTRY		
Element	**Type**	**Description**
sEntry	CAA_FILENAME	Name of the directory or file
szSize	CAA_SIZE	File size
xDirectory	BOOL	Directory or file: TRUE => Directory FALSE => File
xExclusive	BOOL	Access mode on file: TRUE => exclusive access on the file FALSE => multiple access on this file possible
dtLastModification	DT	Date and time of last modification

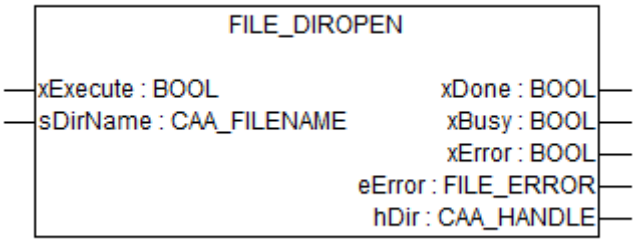
FILE_DirOpen



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Directory

FILE_DirOpen opens a directory which entries (files and sub-directories) should be read with the help of the function block FILE_DirList. The return value is a handle.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

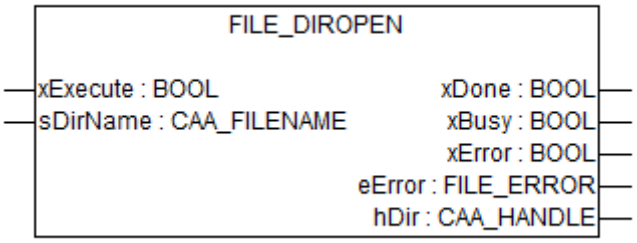
The function block is activated via a positive edge at this input.

sDirName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

At input sDirName the absolute path and directory name of the new directory has to be specified.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

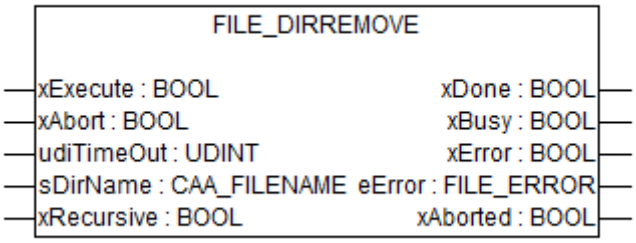
Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' ↳ *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

hDir

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

Input hDir sets the handle of the directory to close.

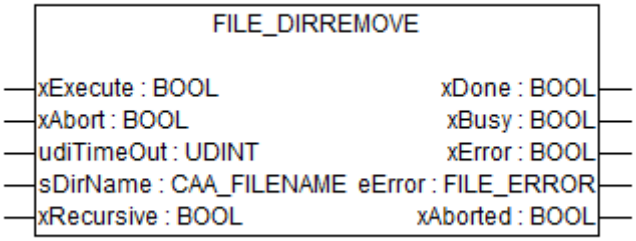
FILE_DirRemove



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Directory

FILE_DirRemove deletes a directory. The directory cannot be deleted if it is opened via FILE_DirOpen or if it is not empty.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

xAbort

Data type	Default value	Range	Unit
BOOL	-	-	-

Input xAbort stops the Function Block's processing without waiting for it to finish.

udiTimeOut

Data type	Default value	Range	Unit
UDINT	-	-	-

Input udiTimeOut defines the time out in microseconds for the function block to wait on the operation to be finished. A value of 0 means no time out.

sDirName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

At input sDirName the absolute path and directory name of the new directory has to be specified.

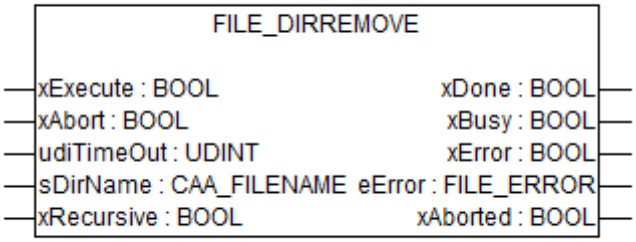
xRecursive

Data type	Default value	Range	Unit
BOOL	-	-	-

If Input xRecursive is set all files and sub-directories within the directory specified at sDirName will be deleted.

This input is not supported on the AC500 PLCs.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

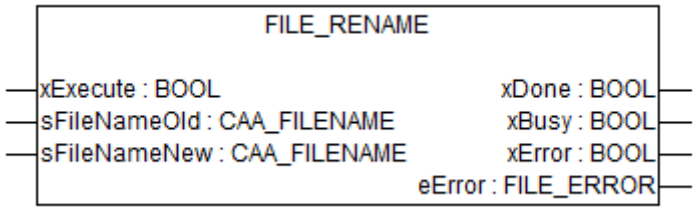
Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

xAborted

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xAborted is set if the function block has been aborted.

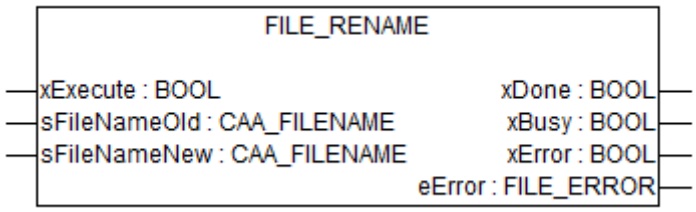
FILE_Rename



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_Rename modifies the file name. This does not work if the file is open via FILE_Open. The function block cannot be used to move files or directories!

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

sFileNameOld

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

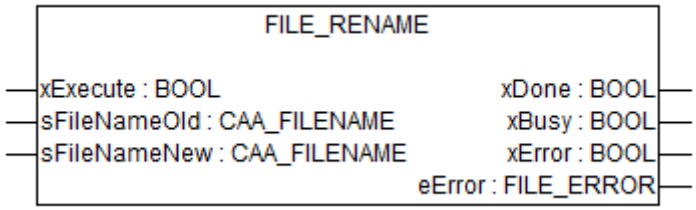
Absolute Path with current file name.

sFileNameNew

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Absolute Path with new file name.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

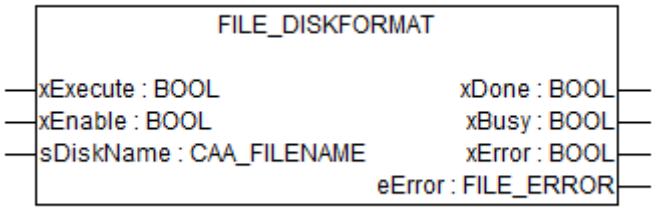
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' ↳ *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

FILE_DiskFormat



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.3
Type	Function block with historical values
Group	Storage Device Services

This function block formats a storage device, i.e. erasing all content on it and writing a new, clean file system to it.

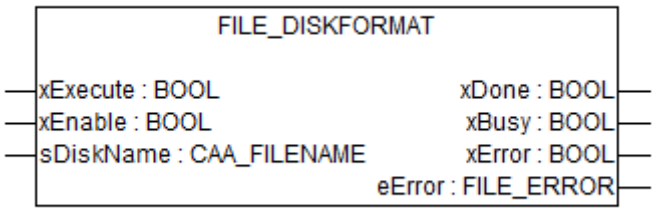
CAUTION!
The format protection (see *Chapter 1.6.5.4.3 “AC500-specific PLC browser commands” on page 6222*) is automatically unlocked and all data on the device will be lost!

The function block "FILE_DiskFormat" can format the "sramdisk", "userdisk" and "flashdisk".

It is not possible to format the "sdcard".

See also AC500 CPU Storage Devices for hints on memory location maintenance.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

xEnable

Data type	Default value	Range	Unit
BOOL	-	-	-

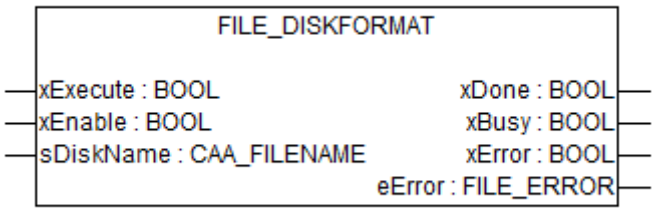
This input must be TRUE before the function block may be triggered via xExecute (i.e. "are you sure"-flag).

sDiskName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Name of storage device to format (e.g. "sramdisk" or "userdisk\").

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

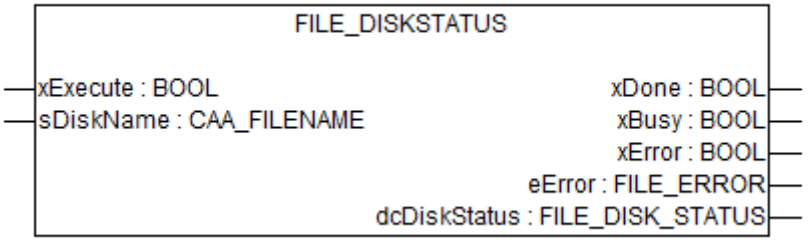
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

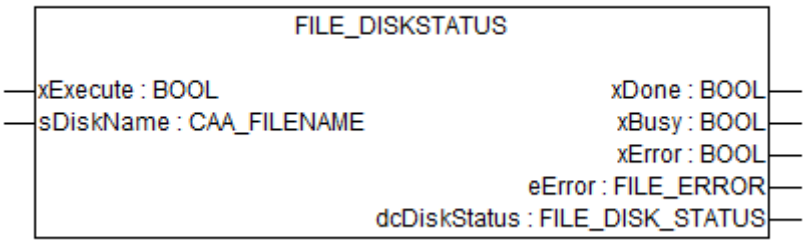
FILE_DiskStatus



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.3
Type	Function block with historical values
Group	Storage Device Services

This function block retrieves information about a storage device.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

sDiskName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

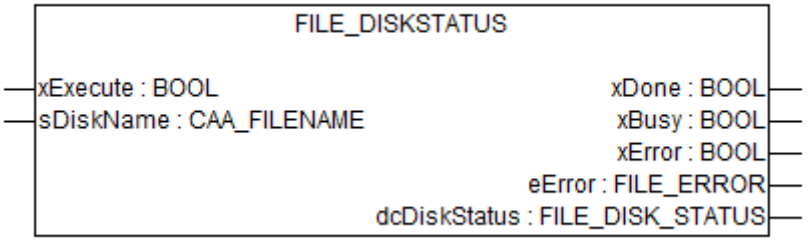
Name of storage device to format (e.g. "sramdisk" or "userdisk\").

sDiskName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Name of storage device to format (e.g. "sramdisk" or "userdisk\").

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

dcDiskStatus

Data type	Default value	Range	Unit
FILE_DISK_STATUS	-	-	-

Output dcDiskStatus contains all available information about the storage device:

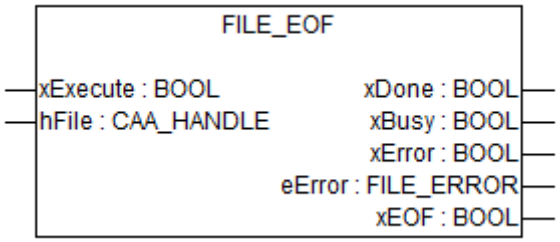
Free, used and total available space on the device, block size, cluster size, total cluster count and the device condition. The meaning of the decive conditions DC_GREEN, DC_YELLOW, DC_RED is storage device specific as shown in the following table:

state	userdisk	flashdisk	SRAM disk	memory card
GREEN	userdisk ready	flashdisk ready	SRAM disk ready	memory card ready
YELLOW	-	threshold exceeded	-	-
RED	userdisk not ready	flashdisk is read only	SRAM disk not ready	memory card not ready

To optimize the usage of a storage device try to fit your read/write operation's sizes and file sizes with the device's block and/or cluster sizes.

See also AC500 CPU Storage Devices for hints on memory location maintenance.

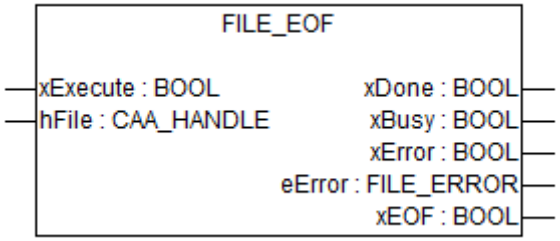
FILE_EOF



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_EOF sets xEOF to TRUE if the current offset is equal to the end of the file. If the end of the file has not yet been reached, FALSE is returned.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

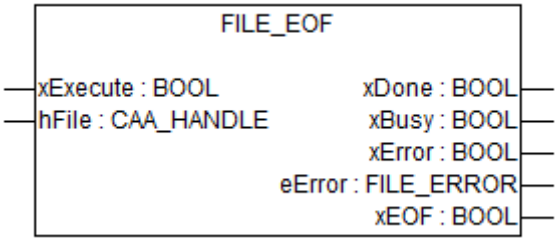
The function block is activated via a positive edge at this input.

hFile

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

File handle retrieved with CAA_Open.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

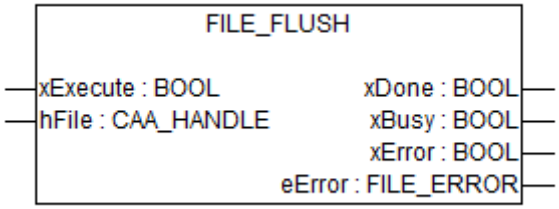
Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

xEOF

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xEOF is set if the current position of the file stream pointer is the end of the file.

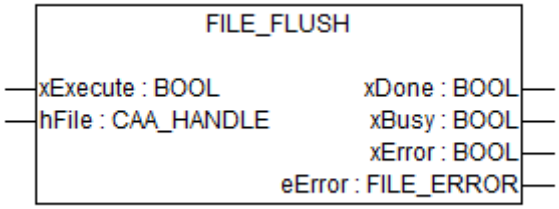
FILE_Flush



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_Flush flushes data from the file system cache to the disk for the file with given file handle hFile. Calling this Function Block guarantees that data will be stored on the disk.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

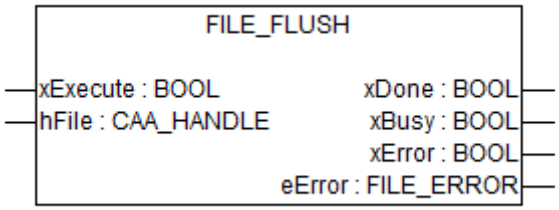
The function block is activated via a positive edge at this input.

hFile

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

File handle retrieved with CAA_Open.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

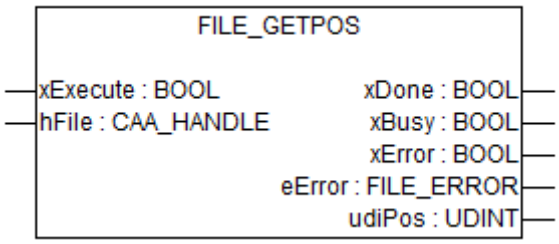
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

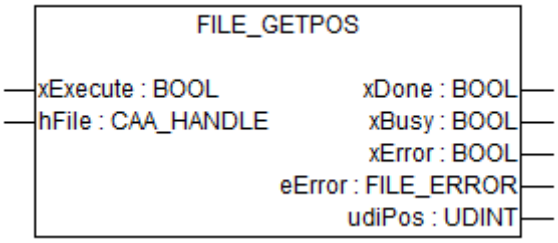
FILE_GetPos



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_GetPos returns the offset position of the file stream pointer currently set in the file. The file must be opened via FILE_Open.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

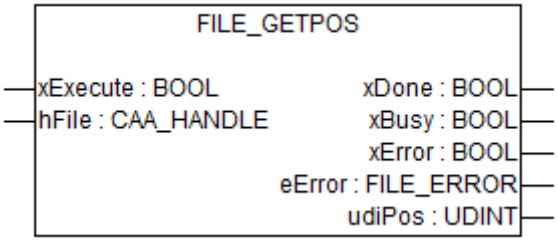
The function block is activated via a positive edge at this input.

hFile

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

File handle retrieved with CAA_Open.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

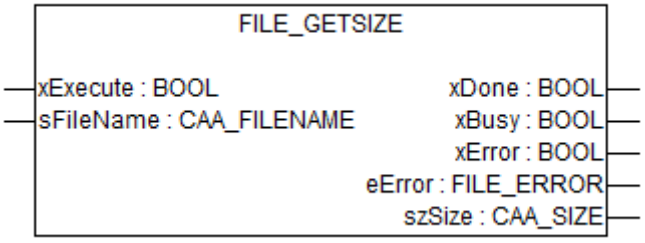
Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

udiPos

Data type	Default value	Range	Unit
UDINT	-	-	-

Output udiPos is set to the current offset position i.e. number of bytes from the start of the file.

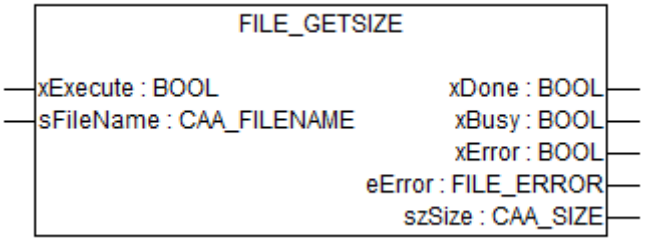
FILE_GetSize



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_GetSize returns the size of the file specified by sFileName. If the file is still open, it must be flushed or closed to get the actual size.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

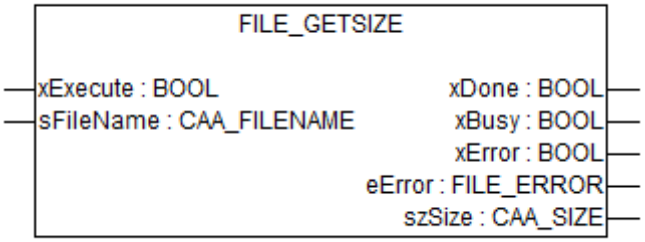
The function block is activated via a positive edge at this input.

sFileName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sFileName specifies an absolute file name which has to be added to archive. The file name appears in archive in uppercase.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

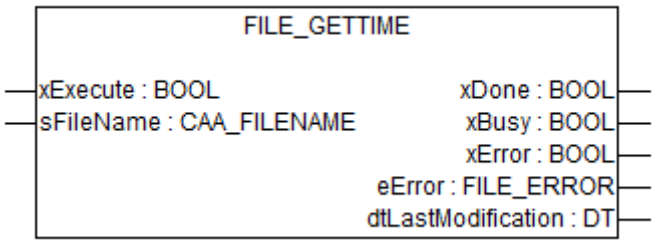
Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

szSize

Data type	Default value	Range	Unit
CAA_SIZE	-	-	-

Output szSize is set to the number of bytes copied.

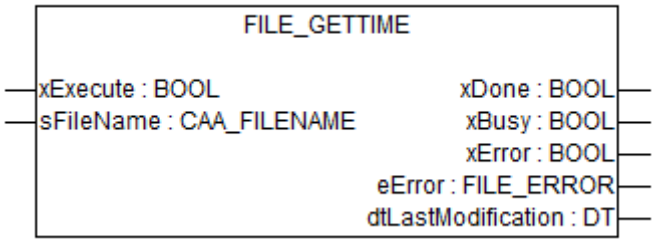
FILE_GetTime



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_GetTime returns date and time of the last modification of the file specified by sFileName.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

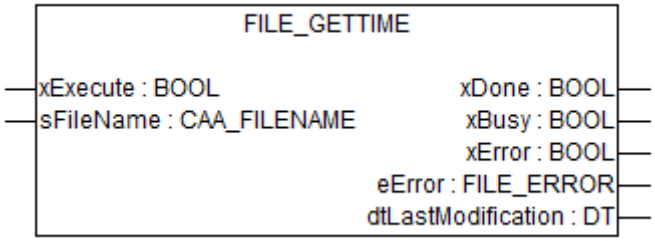
The function block is activated via a positive edge at this input.

sFileName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sFileName specifies an absolute file name which has to be added to archive. The file name appears in archive in uppercase.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

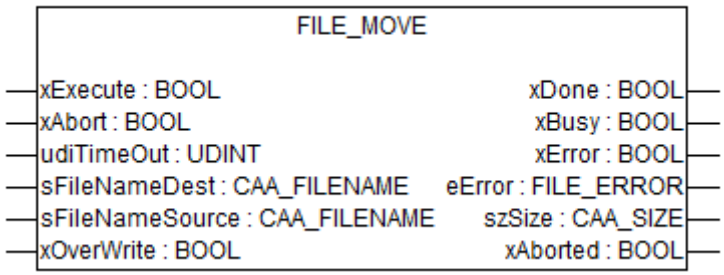
Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

dtLastModification

Data type	Default value	Range	Unit
DT	-	-	-

Output dtLastModification is set to the date and time of the last file modification (e.g. dt#2006-05-08-00:00:00).

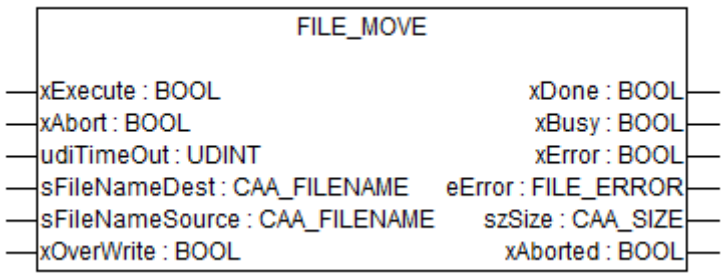
FILE_Move



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.3
Type	Function block with historical values
Group	File

This function block moves a file. The target file is created or - if already existent - overwritten. During the operation a temporary file with the extension .tmp is created. If the moving is aborted by the user the .tmp-file will remain on the device.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

xAbort

Data type	Default value	Range	Unit
BOOL	-	-	-

Input xAbort stops the Function Block's processing without waiting for it to finish.

udiTimeOut

Data type	Default value	Range	Unit
UDINT	-	-	-

Input udiTimeOut defines the time out in microseconds for the function block to wait on the operation to be finished. A value of 0 means no time out.

sFileNameDest

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Absolute Path of destination.

sFileName-Source

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

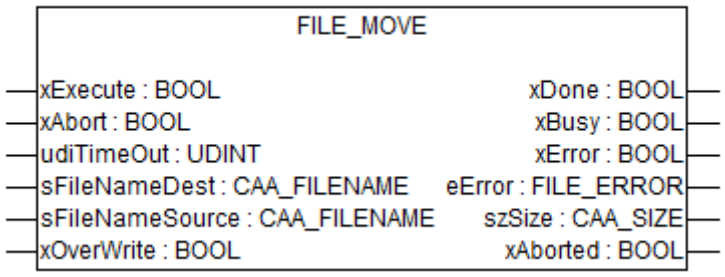
Absolute Path of source.

xOverWrite

Data type	Default value	Range	Unit
BOOL	-	-	-

If input xOverwrite is set to TRUE, the target file will be overwritten, if it exists. Otherwise an error is raised.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

szSize

Data type	Default value	Range	Unit
CAA_SIZE	-	-	-

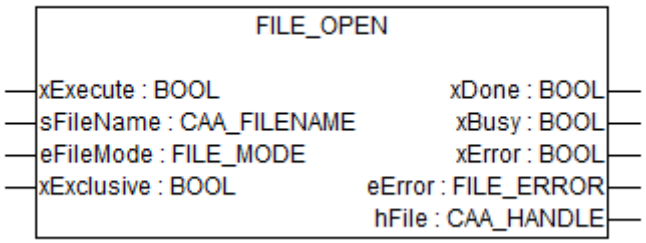
Output szSize is set to the number of bytes copied.

xAborted

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xAborted is set if the function block has been aborted.

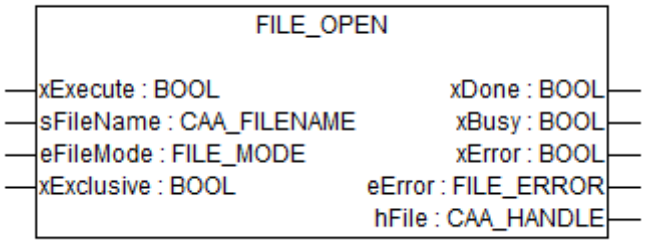
FILE_Open



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_Open retrieves a file handle from the drive's file system for further file operations. This function block opens an already existing file or creates a new one depending on the set FILE_MODE at input eFileMode. The return value is a file handle which can be used as an input hFile in the function blocks FILE_Read, FILE_Write, FILE_GetPos, FILE_SetPos, FILE_EOF and FILE_Close.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

sFileName

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

Input sFileName specifies an absolute file name which has to be added to archive. The file name appears in archive in uppercase.

eFileMode

Data type	Default value	Range	Unit
FILE_MODE	-	-	-

Input eFileMode determines the opening mode for the file.

"File lock" describes, if a file can be opened again, while it is still opened in one of the modi. "File size" defines how the file size is treated by the open-operation. "File pointer" describes the initial position of the pointer into the file after the open operation.

FILE_MODE	Description
FILE_MWRITE	"write only" - write data to a file. File lock: Cannot be reopened in any other mode. File size: File is createdor existing file content is deleted. File pointer: At beginning of file.
FILE_MREAD	"read only" - read data from a file. File lock: Can be reopened in read-mode. File size: Unchanged, no writing possible. File pointer: At beginning of file.

FILE_MODE	Description
FILE_MRDWR	"read and write" - read and write data to a file. File lock: Cannot be reopened in any other mode. File size: File is created or existing file content is deleted. File pointer: At beginning of file.
FILE_MAPPD	"append to a file" - read and write to a file. File lock: File can be reopened in read mode. File size: File is created (if not existing), existing file content kept. File pointer: At end of file.

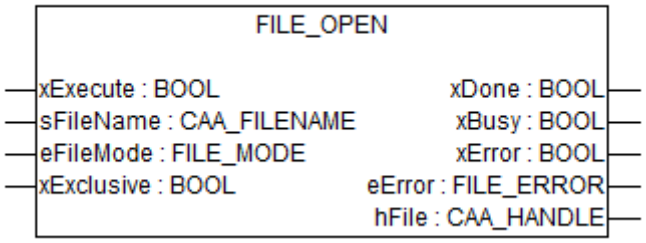
xEclusive

Data type	Default value	Range	Unit
BOOL	-	-	-

Additional input for file access mode.

This input is not supported on the AC500 PLCs.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

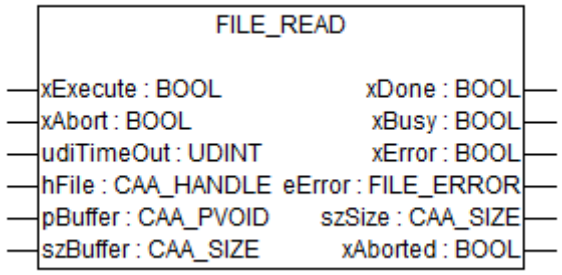
Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

hFile

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

File handle retrieved with CAA_Open.

FILE_Read

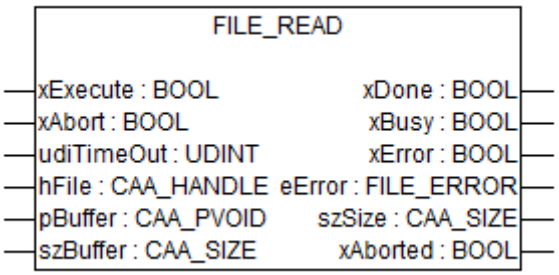


Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_Read reads the file which was previously opened via FILE_Open. If less characters can be read than specified in szBuffer, the function block returns an active xDone and indicates the current number of characters in szSize. The size of the target memory structure for the bytes to be read and the number of bytes to be read will not be checked.

The stability of the pointer on the data structures and their contents must be guaranteed if online change is executed. If pointer to data structure is changed during online changes operation could lead to damage of application data.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

xAbort

Data type	Default value	Range	Unit
BOOL	-	-	-

Input xAbort stops the Function Block's processing without waiting for it to finish.

udiTimeOut

Data type	Default value	Range	Unit
UDINT	-	-	-

Input udiTimeOut defines the time out in microseconds for the function block to wait on the operation to be finished. A value of 0 means no time out.

hFile

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

File handle retrieved with CAA_Open.

pBuffer

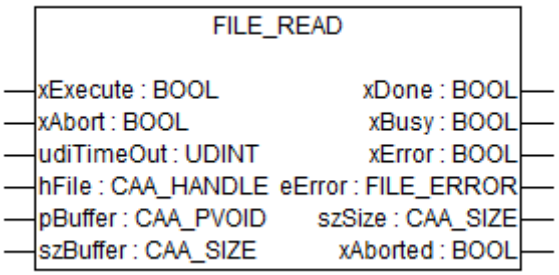
Data type	Default value	Range	Unit
CAA_PVOID	-	-	-

Target address of the buffer where read data will be copied to; can be retrieved via operator ADR.

szBuffer

Data type	Default value	Range	Unit
CAA_SIZE	-	-	-

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' ↳ *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

szSize

Data type	Default value	Range	Unit
CAA_SIZE	-	-	-

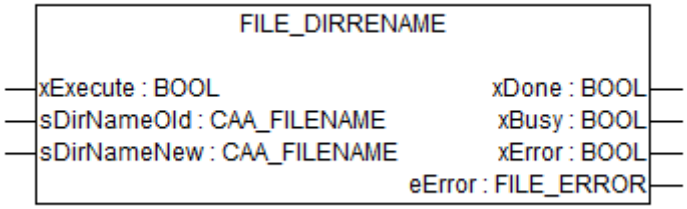
Output szSize is set to the number of bytes copied.

xAborted

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xAborted is set if the function block has been aborted.

FILE_DirRename

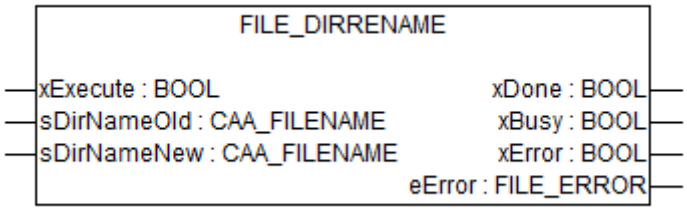


Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	Directory

FILE_DirRename modifies the directory name. This does not work if the directory is opened via FILE_DirOpen. The function block cannot be used to move directories!

CAA_DirRename only supported on the flash disk!

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

sDirNameOld

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

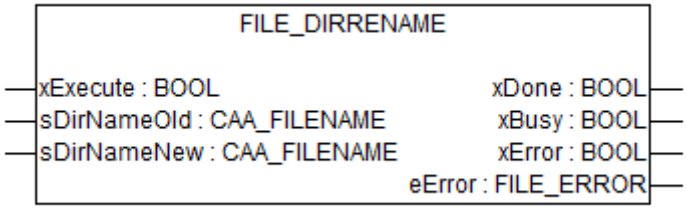
At input sDirNameOld the absolute path with current directory name is set.

sDirNameNew

Data type	Default value	Range	Unit
CAA_FILENAME	-	-	-

At input sDirNameNew the absolute path with new directory name is set.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

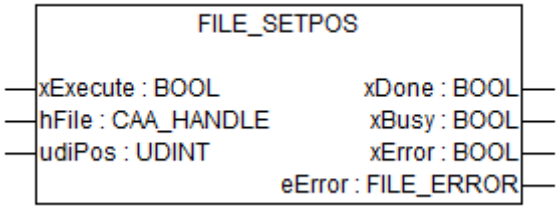
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

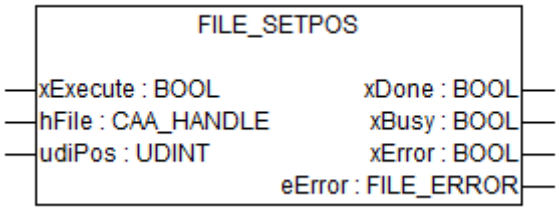
FILE_SetPos



Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_SetPos sets the offset position in bytes of the file stream in the file counting from the beginning of the file. The file must be opened via FILE_Open. If the new position would place the file stream pointer outside the file, an error is returned and the position is not changed.

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

hFile

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

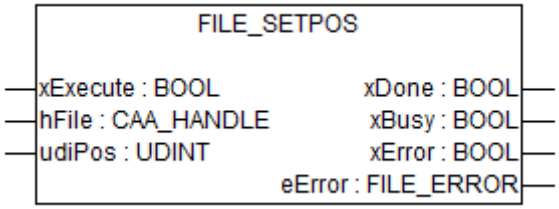
File handle retrieved with CAA_Open.

udiPos

Data type	Default value	Range	Unit
UDINT	-	-	-

Output udiPos is set to the current offset position i.e. number of bytes from the start of the file.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

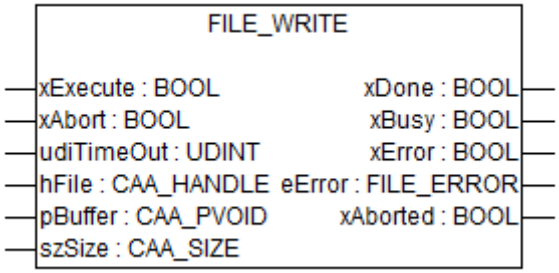
Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' ↳ *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

FILE_Write



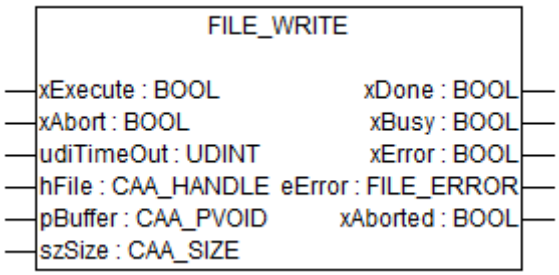
Parameter	Value
Included in library	CAA_File.lib
Available as of firmware	V2.1
Type	Function block with historical values
Group	File

FILE_Write writes data into the file which was previously opened via FILE_Open. The contents of the memory area indicated by pointer pBuffer should not be modified during the write action! The size of the structure of the memory containing the bytes to be written as well as the number of bytes to be written will not be checked. The stability of the pointer on the data structures and their contents must be guaranteed if online change is executed. If pointer to data structure is changed during online changes operation could lead to file damage.

For performance reasons the file system buffers written data. In effect only flushing or closing a file updates its representation on the device completely.

Without a correct FILE_Close written data will be lost!

Input description



xExecute

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated via a positive edge at this input.

xAbort

Data type	Default value	Range	Unit
BOOL	-	-	-

Input xAbort stops the Function Block's processing without waiting for it to finish.

udiTimeOut

Data type	Default value	Range	Unit
UDINT	-	-	-

Input udiTimeOut defines the time out in microseconds for the function block to wait on the operation to be finished. A value of 0 means no time out.

hFile

Data type	Default value	Range	Unit
CAA_HANDLE	-	-	-

File handle retrieved with CAA_Open.

pBuffer

Data type	Default value	Range	Unit
CAA_PVOID	-	-	-

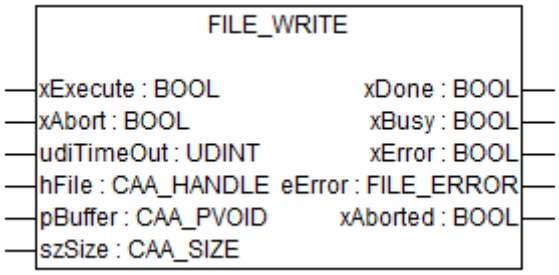
Target address of the buffer where read data will be copied to; can be retrieved via operator ADR.

szSize

Data type	Default value	Range	Unit
CAA_SIZE	-	-	-

Output szSize is set to the number of bytes copied.

Output description



xDone

Data type	Default value	Range	Unit
BOOL	-	-	-

If Output xDone changes to TRUE, the function block has finished its processing without an error and all other outputs become valid.

xBusy

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xBusy signals if a function block has been triggered and is TRUE as long it is processing.

xError

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xError is set if the function block finished and an error occurred during the Function Block processing. If xError is TRUE the error code can be read from output eError.

eError

Data type	Default value	Range	Unit
FILE_ERROR	-	-	-

Output eError is set if an error occurred during the function block processing. For error codes, see 'Error Messages of the CAA_File function blocks' ↳ *Chapter 1.5.4.4.2.1 “Error messages” on page 793*.

xAborted

Data type	Default value	Range	Unit
BOOL	-	-	-

Output xAborted is set if the function block has been aborted.

1.5.4.4.3 Data types

Data type	Base type	Description	Note
CAA_FILENAME	STRING(256)	Used for file names and paths	
FILE_ERROR	INT	Error codes of CAA_File.lib function blocks	See Error messages ↳ *Chapter 1.5.4.4.2.1 “Error messages” on page 793*
FILE_PACK_MODE	DWORD	Options for packing data to an archive	FILE_PACK_WITHOUT_PATH FILE_PACK_OVERWRITE
CAA_HANDLE	DWORD	File / directory handle for function block operations	-
FILE_UNPACK_MODE	DWORD	Options for unpacking data from an archive	FILE_UNPACK_USE_ABSOLUTE_PATH_SAVED_IN_ARCHIVE FILE_UNPACK_OVERWRITE FILE_UNPACK_CREATE_DIRS
CAA_SIZE	UDINT	File size type	In Bytes
FILE_DIR_ENTRY	STRUCT	Structure with information about directory entry	For details, see function block FILE_DirList ↳ *Chapter 1.5.4.4.2.13 “FILE_DirList” on page 815*
FILE_DISK_STATUS	STRUCT	Structure with information about status	For details, see function block FILE_DiskStatus ↳ *Chapter 1.5.4.4.2.18 “FILE_DiskStatus” on page 826*
FILE_MODE	ENUM	Mode for opening a file with function block FILE_OPEN ↳ *Chapter 1.5.4.4.2.25 “FILE_Open” on page 839*	FILE_MWRITE FILE_MREAD FILE_MRDWR FILE_MAPPD

Data type	Base type	Description	Note
FILE_ATTRIB	ENUM	File attribute	FILE_ARCHIVE FILE_HIDDEN FILE_NORMAL FILE_READONLY
FILE_DISK_CONDITION	ENUM	State of storage device	For details, see function block FILE_DiskStatus *Chapter 1.5.4.4.2.18 “FILE_DiskStatus” on page 826*

1.5.4.5 Camswitch library

Library file name: **CAMSWITCH_AC500_Vx.lib**

System requirements

Following libraries are needed:

- CODESYS 2.3.9.3 or later
- SysExt_AC500_V10.lib or later
- SysLibTime.lib Version 2.4.0.6 or later

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

The MC function blocks represent additional functionality. They are not required for normal EtherCAT operation.

The MC function blocks functionalities are used exclusively by CI511-ETHCAT and CI512-ETHCAT.

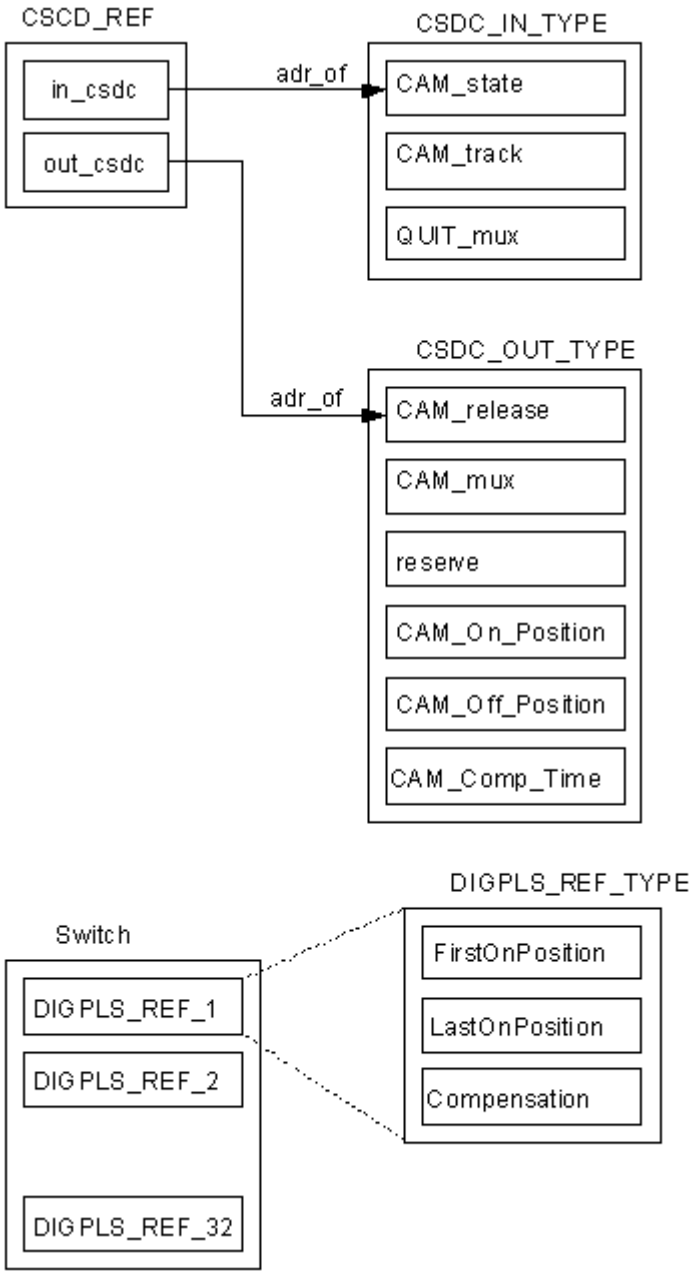


Fig. 13: Relation of the data types for the cam switch

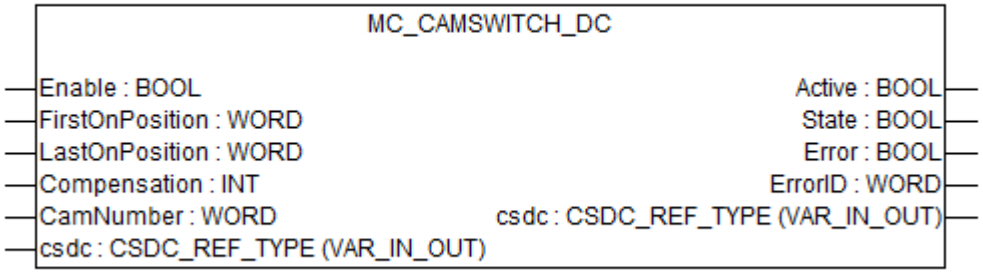
1.5.4.5.1 Function blocks

MC_CamSwitch_DC



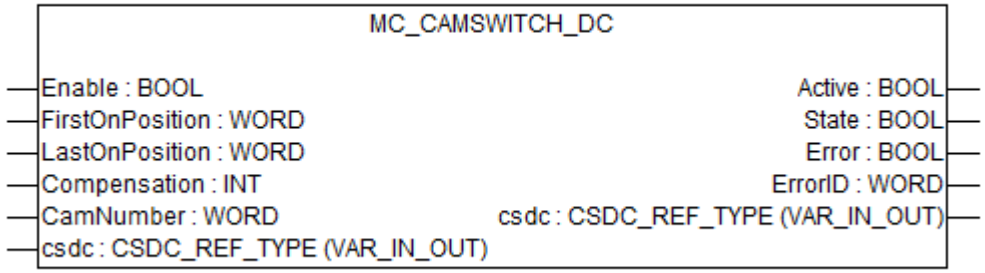
Parameter	Value
Included in library	CAMSWITCH_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	Group/Subgroup

Input description

MC_CamSwitch_DC provides the possibility to switch a cam on/off at projected positions. The position is given by an encoder, which must be available, if the cam switch functionality is to be used.

The switch-on-position and the switch-off-position are individually changeable online. Further more a compensation time in both directions can be added to the switch position. Compensation is applied to both switch-on-position and switch-off-position.

The actual state of the cam can also be monitored with the output “state”.



Enable

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

FirstOnPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOnPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOnPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOnPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

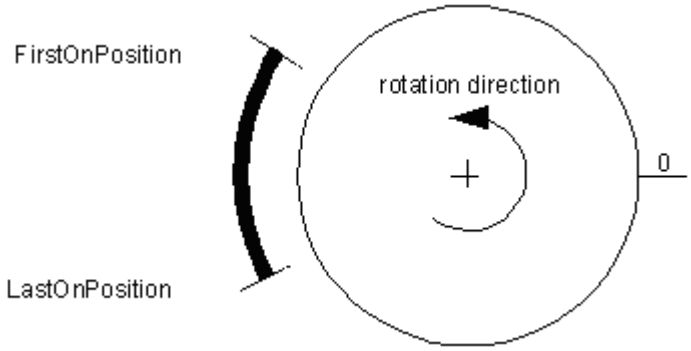
LastOnPosition

Data type	Default value	Range	Unit
WORD	-	-	-

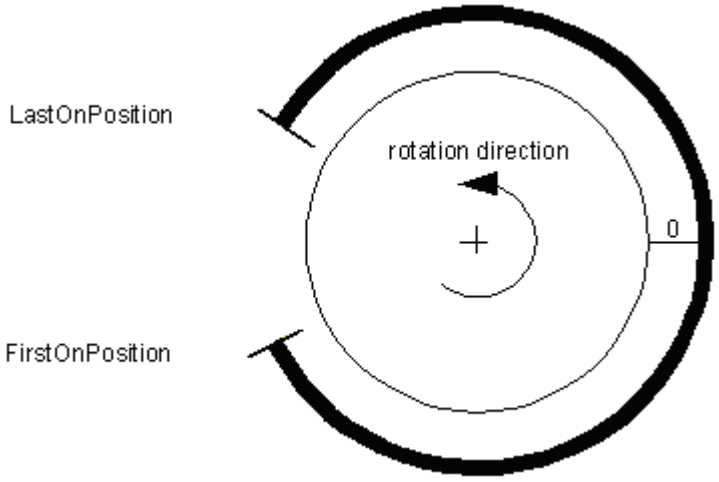
The value of LastOnPosition is automatically truncated to the resolution of the circle without notice. For example, all LastOnPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

LastOnPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

If FirstOnPosition is smaller than LastOnPosition, the cam is switched on between the values of FirstOnPosition and LastOnPosition of the same turn.



If FirstOnPosition is greater than LastOnPosition, the cam is switched on between the values of FirstOnPosition of the actual turn and LastOnPosition of the next turn.



If FirstOnPosition is equal to LastOnPosition, the cam is switched on for one interrupt cycle.

Compensation

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with Compensation:

- If Compensation is positive, the switch action will be delayed by the value of Compensation.
- If Compensation is negative, the switch action will be brought forward by the value of Compensation.

CamNumber

Data type	Default value	Range	Unit
WORD	-	-	-

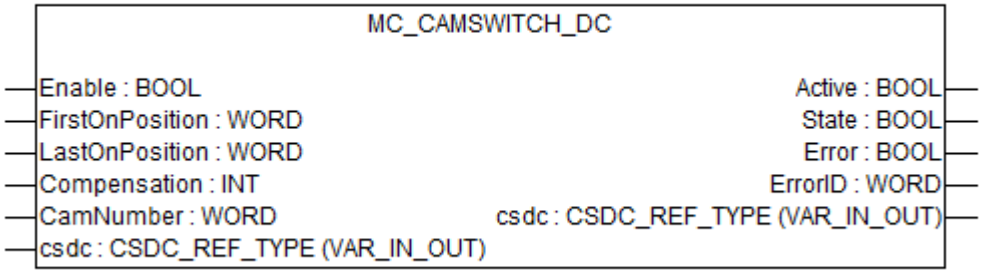
Number of the cam; the parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

csdc

Data type	Default value	Range	Unit
DWORD	-	-	-

See data type CSDC_REF_TYPE.

Ouput description



Active

Data type	Default value	Range	Unit
BOOL	-	-	-

Parameters (FirstOnPosition, LastOnPosition, Compensation) are transferred during active is TRUE.

State

Data type	Default value	Range	Unit
DWORD	-	-	bit

The 32 bits of state correspond to the states of 32 cams of a CI51x-ETHCAT Module. If a bit is set, the corresponding cam is on, otherwise the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	-	-

The output ERR=TRUE indicates that the communication to the device is not working properly.

ErrorID

Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

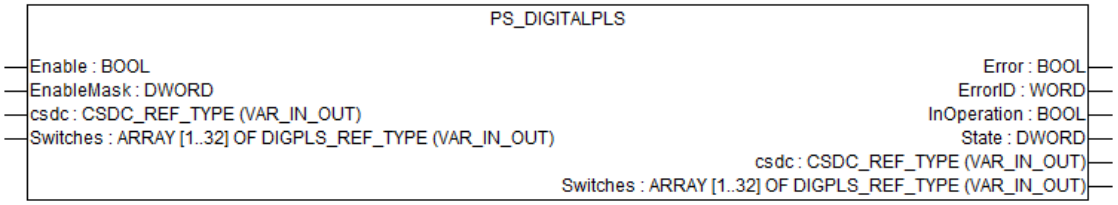
Function call in ST

```
cs1.in_csdc  := ADR(CI512_INPUTS_CAM_STATE);
cs1.out_csdc := ADR(CI512_OUTPUTS_CAM_RELEASE);

CAM1 (
cscd              := cs1,
FirstOnPosition   := CAM1_FirstOnPosition,
LastOnPosition    := CAM1_LastOnPosition,
Compensation      := CAM1_Compensation,
CamNumber         := CAM1_CamNumber);

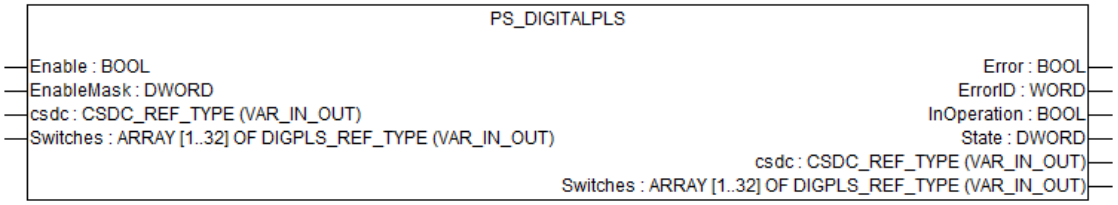
CAM1_Active      := CamSwitch.active;
CAM1_State       := CamSwitch.state;
CAM1_Error       := CamSwitch.error;
CAM1_ErrorID     := CamSwitch.error_id;
```

PS_DigitalPLS



Parameter	Value
Included in library	CAMSWITCH_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	Group/Subgroup

Input description



PS_DigitalPLS provides the possibility to control all the cams on an ABB CI51x-ECAT.

The switch-on and switch-off-position of each cam and the compensation time of each cam can be set individually via the input Switches. The position of the reference axis is given by an encoder, which must be available, if the cam switch functionality is to be used.

The switch-on position and the switch-off-position can be changed individually online. Furthermore, a compensation time in both directions can be added to the switch position. Compensation is applied to both switch-on-position and switch-off-position.

Individual cam can be disabled by clearing the corresponding bit in the EnableMask.

The actual state of the cams can also be monitored with the output “State”.

Enable

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

EnableMask

Data type	Default value	Range	Unit
DWORD	-	-	-

The 32 bits of EnableMask correspond to the 32 cams of a CI51x-ETHCAT device. Setting a bit will enable the corresponding cam.

csdc

Data type	Default value	Range	Unit
DWORD	-	-	-

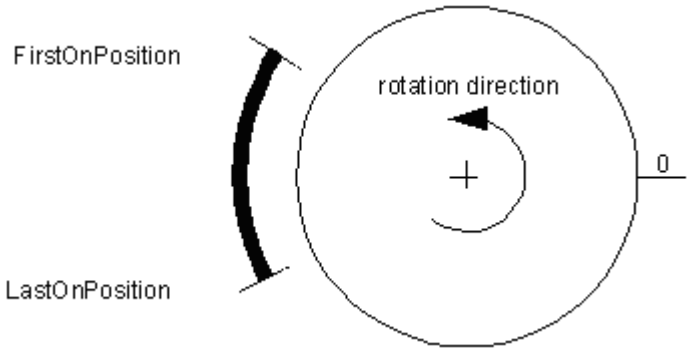
See data type CSDC_REF_TYPE.

Switches OF DIGPLS_REF_TYPE

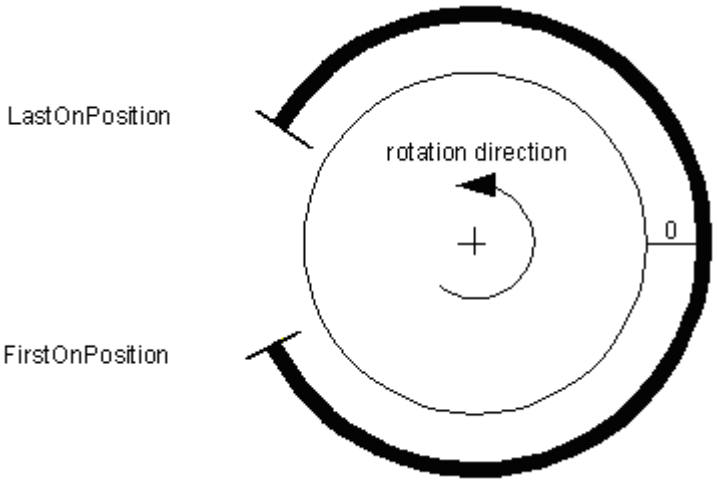
Data type	Default value	Range	Unit
ARRAY	-	1...32	-

See data type DIGPLS_REF_TYPE.

If FirstOnPosition is smaller than LastOnPosition, the cam is switched on between the values of FirstOnPosition and LastOnPosition of the same turn.



If FirstOnPosition is greater than LastOnPosition, the cam is switched on between the values of FirstOnPosition of the actual turn and LastOnPosition of the next turn.

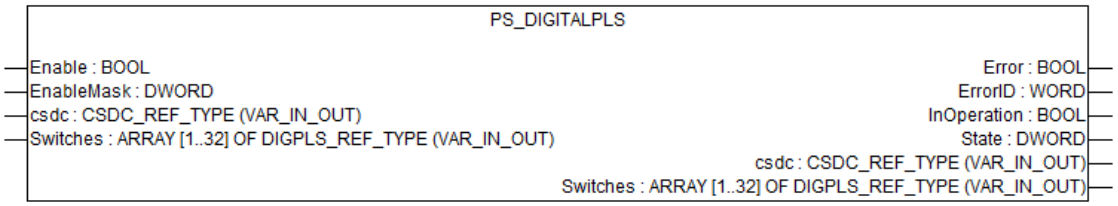


If FirstOnPosition is equal to LastOnPosition, the cam is switched on for one interrupt cycle.

The POU PS_DigitalPLS automatically truncates FirstOnPosition and LastOnPosition to the resolution of the circle without notice. For example, all FirstOnPosition/LastOnPosition which are greater than 36000 will be limited to 36000 (given that the default resolution of CI51x-ETHCAT cam is used).

The parameters FirstOnPosition, LastOnPosition and Compensation can be changed at any time. They will be immediately valid after sending to the CI51x-ETHCAT via the POU.

Output description



Error

Data type	Default value	Range	Unit
BOOL	-	-	-

The output ERR=TRUE indicates that the communication to the device is not working properly.

ErrorID

Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

InOperation

Data type	Default value	Range	Unit
BOOL	-	-	-

TRUE if the POU is running.

State

Data type	Default value	Range	Unit
DWORD	-	-	bit

The 32 bits of state correspond to the states of 32 cams of a CI51x-ETHCAT Module. If a bit is set, the corresponding cam is on, otherwise the cam is off.

Function call in ST

```
cs1.in_csdc := ADR(CI512_INPUTS_CAM_STATE);
cs1.out_csdc := ADR(CI512_OUTPUTS_CAM_RELEASE);

PLS1 (
Enable       := PLS1_Enable,
EnableMask   := PLS1_EnableMask,
cscd         := cs1,
Switches     := PLS1_Switches);

PLS1_Error := PLS1.Error;
PLS1_ErrorID := PLS1.ErrorID;
PLS1_InOperation := PLS1.InOperation;
PLS1_State := PLS1.State;
```

1.5.4.5.2 Data types

CSDC_REF_TYPE

The library contains the data type CSDC_REF_TYPE to facilitate access to the process data image of the I/O module, on which the cams are located. This data type is declared as follows:

```
TYPE CSDC_REF_TYPE :
STRUCT
number   : INT;
name     : STRING;
in_csdc  : POINTER TO CSDC_IN;
out_csdc : POINTER TO CSDC_OUT;
END_STRUCT
END_TYPE
```

number

Data type	Default value	Range	Unit
INT	-	-	-

Can optionally be used to identify the EtherCAT slave.

name

Data type	Default value	Range	Unit
INT	-	-	-

Can optionally be used to identify the EtherCAT slave.

in_csdc

Data type	Default value	Range	Unit
DWORD	-	-	-

in_csdc is the address of the first element of the input data. For the CI51x-ETHCAT it shall be initialized with the address of the parameter CAM_state (see type CSDC_IN_TYPE ↳ *Chapter 1.5.4.5.2.2 “CSDC_IN_TYPE” on page 861*).

out_csdc

Data type	Default value	Range	Unit
DWORD	-	-	-

out_csdc is the address of the first element of the output data. For the CI51x-ETHCAT it shall be initialized with the address of the parameter CAM_release (see type CSDC_OUT_TYPE ↳ *Chapter 1.5.4.5.2.3 “CSDC_OUT_TYPE” on page 861*).

CSDC_IN_TYPE

The library contains the data type CSDC_IN_TYPE, which contains all the parameters needed to realize the cam switch function. POU accesses to the required inputs in the process data image of the I/O module are performed with these parameters.

The application program shall not access the elements of this structure, so no detail descriptions of the structure elements are given.

Function call in ST

```
TYPE CSDC_IN_TYPE :
(*declaration of I/O-structures for CS-device*)
STRUCT
CAM_state : DWORD;
CAM_track : WORD;
QUIT_mux : BYTE;
END_STRUCT
END_TYPE
```

CSDC_OUT_TYPE

The library contains the data type CSDC_OUT_TYPE, which contains all the parameters needed to realize the cam switch function. Accesses to the required outputs in the process data image of the I/O module are performed with these parameters.

Application program shall not access the elements of this structure, so no detail descriptions of the structure elements are given.

```
TYPE CSDC_OUT_TYPE :
STRUCT
CAM_release      : DWORD;
CAM_mux          : BYTE;
reserve          : BYTE;
CAM_On_Position  : WORD;
CAM_Off_Position : WORD;
CAM_Comp_Time    : WORD;
END_STRUCT
END_TYPE
```

DIGPLS_REF_TYPE

Data type DIGPLS_REF_TYPE describes a cam.

LastOnPosition

Data type	Default value	Range	Unit
REAL	-	-	µs

Position of the referenced axis where the cam is switched off.

Compensation

Data type	Default value	Range	Unit
INT	-	-	µs

The switch action is rescheduled with Compensation:

- If Compensation is positive, the switch action will be delayed by the value of Compensation.
- If Compensation is negative, the switch action will be brought forward by the value of Compensation.

Function call in ST

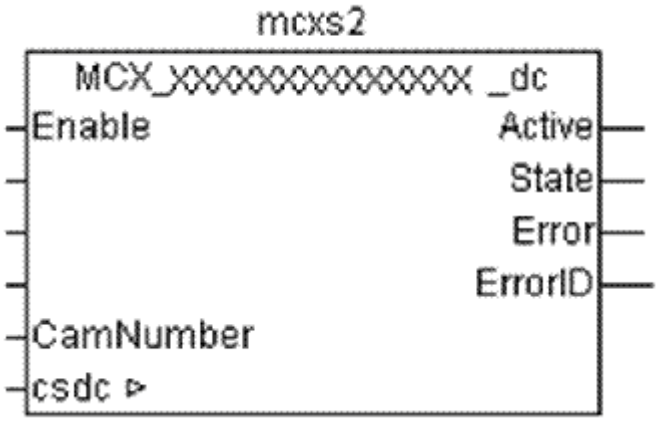
```
TYPE DIGPLS_REF_TYPE :
STRUCT
FirstOnPosition : REAL;
LastOnPosition  : REAL
Compensation    : INT;
END_STRUCT
END_TYPE
```

1.5.4.6 Extended camswitch library

Library file name: **MCX_AC500_Vx.lib**

All function blocks follow the same basic rules which are as follows:

- The “Enable” enables the cam switch. It will be switched off immediately with Enable = FALSE and the respective output will be switched off.
- Every function block has to be assigned to a certain cam switch by specifying the number at input CamNumber. CamNumber runs from 1..32.
- Every function block has to be assigned to a certain device. This is done by “csdc” which holds addresses of the devices process image
- The “active” output indicates that the specific function block communicates with the device. A complete pulse ensures the data has been transferred
- The “state” output indicates that the cam switch is “on” which means the output of the cam is on.



All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

System requirements

Following system requirements have to be fulfilled:

- CODESYS 2.3.9.3 or later
- SysExt_AC500_V10.lib or later
- SysLibTime.lib Version 2.4.0.6 or later

Restrictions

- Compensation time
  - The time is given in a resolution of µs, but the best achievable resolution is the cycle-time of the device (200 µs with 32 cams)
  - For times larger then 32767, the resolution will be increased internally. The user gives still a us-time in a DINT-value
  - Times which are larger then 524 ms will be transferred with a resolution of 512 µs. A compensation time up to 8 s could be reached.
- Best achievable resolution is cycle-time of the device (80 µs / 100 µs / 200 µs).

1.5.4.6.1 Architecture

Identification of binary inputs and outputs

The device has 8 inputs, 8 combined input/outputs (dc) and 8 outputs.

The cam controller holds up to 32 cams which could be assigned to the 8 outputs and 8 DCs. Several cams might be assigned to the same output. The BinaryReference and BinaryShift are assigned to the 8 digital inputs or to the 8 DCs. The inputs and outputs are numbered from 0 to 15, where 0..7 is a DC, the function decides if it is to be used as input or outputs, numbers 8..15 are inputs and outputs and it depends on the function if for example the input 8 or output 8 is used.

	DC (number)		Input (number)		Output (number)
1.0	0	2.0	8	3.0	8
1.1	1	2.1	9	3.1	9
1.2	2	2.2	10	3.2	10

	DC (number)		Input (number)		Output (number)
1.3	3	2.3	11	3.3	11
1.4	4	2.4	12	3.4	12
1.5	5	2.5	13	3.5	13
1.6	6	2.6	14	3.6	14
1.7	7	2.7	15	3.7	15
1.8		2.8			
1.9		2.9			

Architecture and possible composition

The following view shows the general architecture and possible assignments of different cams.

The general rules are:

- Output-cams are cams which are able to directly switch an output. They may be used as stand-alone Cam-Switch or may be combined with a trigger-cam. In this case, not just a position but the respective trigger event will release the cam.
- The output-cams are:
  - CamSwitchSimple (Type 0)
  - PulseSwitch (Type 1)
  - CamSwitchTimed (Type 2)
  - CamSwitchComfort (Type 3)
  - CamSwitchMulti (Type 6)
  - CamSwitchTimeTime (Type 7) (no stand-alone)
  - CamSwitchMultiTime (Type 9)
- The trigger-cams are
  - CamShift (Type 4)
  - Different blocks refer to cams with different types. The type is defined by the parameterization of the cam.
  - The output-cams are assigned to a binary output (by parameterization).
  - The trigger-cams are assigned to a binary input (by parameterization).
  - Trigger-cams are connected to output-cams by programming of the function block in PLC program.
  - The BinaryReference is assigned to a binary input (by parameterization).
  - The Puls-Switch is assigned to a binary output (by parameterization).
  - The logic is assigned to a cam and modifies the output which belongs to this cam.
  - BinaryShift (Type 5), refer to picture.

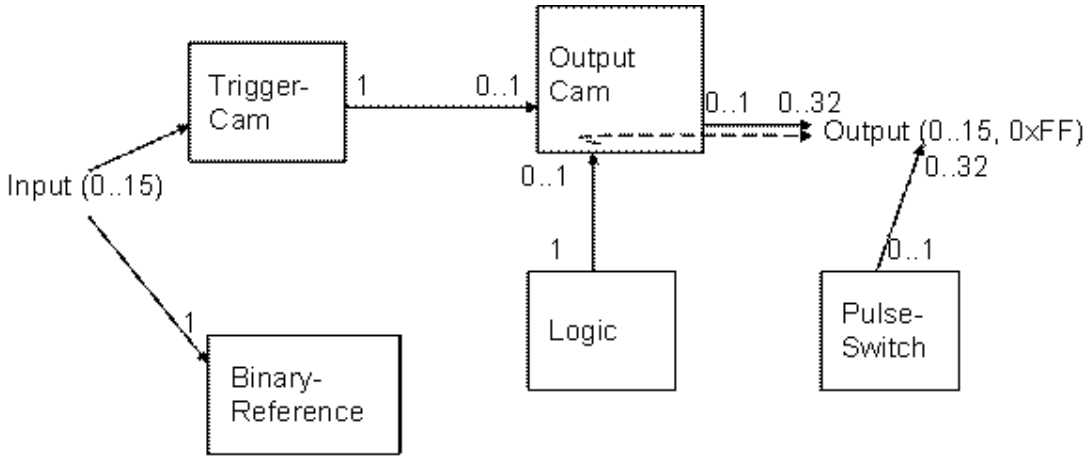


Fig. 14: BinaryShift (Type 5)

1.5.4.6.2 Controller

The device is based on the CI512-ETH and offers an cam controller functionality with the same basic functions. The configuration concerning EtherCAT communication and the usage from AC500 PLC is basically the same. The common features are

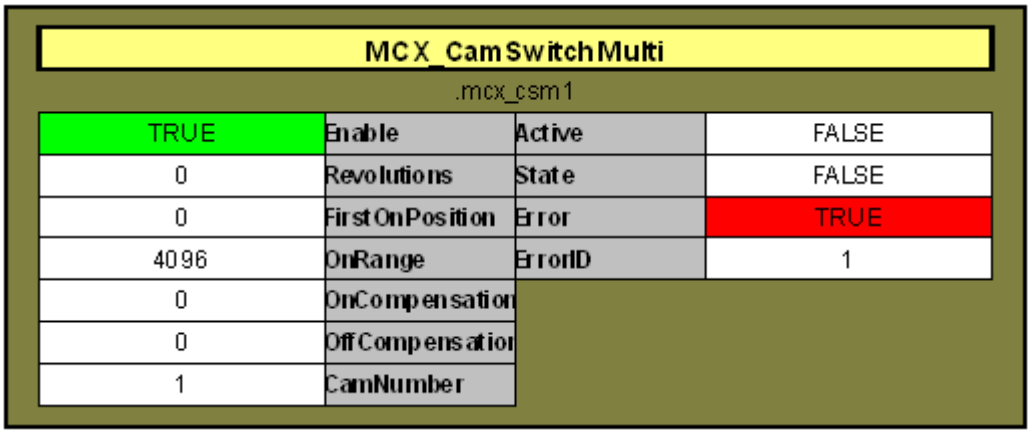
- Up to 32 cam switches with free assignment to the binary outputs
- Dynamic compensation for delay times
- Scan time from 80 µs to 200 µs

A number of additional features is available. The new features are accessible by defining a type for every cam (Parameterization) and by using a dedicated function block which relates to the cam and to the type defined. The respective functionality is explained in detail in the function block's documentation. The features of the different cam-types include:

- Different compensation times for on- and off- switching
- MXC_CamSwitchComfort_dc, MCX_CamSwitchMulti_dc
- Cams which work for a configurable numbers of revolutions
- MCX_CamSwitchMulti_dc, MCX_CamSwitchMultiTimed_dc
- Cams which are switched on for a certain time instead of certain position range.
- MCX_CamSwitchTimed_dc, MCX_CamSwitchMultiTimed_dc
- Cams which are triggered by binary inputs, by a combination of input and Cam or by combination of input and time.
- Trigger
- MCX_CamShift_dc, MCX_BinaryShift_dc
- Triggered
- MCX_CamSwitchSimple_dc, MCX_CamSwitchComfort_dc, MCX_CamSwitchTimed_dc, MCX_CamSwitchMulti_dc, MCX_camSwitchTimeTimed_dc, MCX_CamSwitchMulti-Timed_dc
- A cam which produces a certain frequency according to the velocity
- MCX_PulseSwitch_dc
- A cam which delivers information about binary inputs according to the position
- MCX_BinaryReference_dc
- A certain logic function which might be connected to the cam.
- MCX_CamLogic_dc

1.5.4.6.3 Visualization

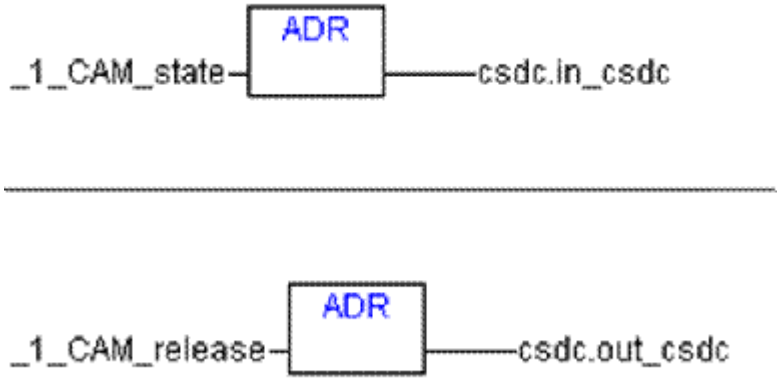
For each of the MCX… function block, the library provides an integrated visualization element. In the configuration of these visualization elements, the placeholder has to be configured with the name of the function block's instance. The visualization looks for example as follows:



The values for all inputs and outputs and as well the name of the instance are shown.

1.5.4.6.4 How to create cscd

1. Create a variable of type CSDCX_REF_TYPE
2. Write the address of the 1. input (process image) of the device to csdc.in_csdc
3. Write the address of the 1. output (process image) of the device to csdc.out_csdc



1.5.4.6.5 How to configure a cam

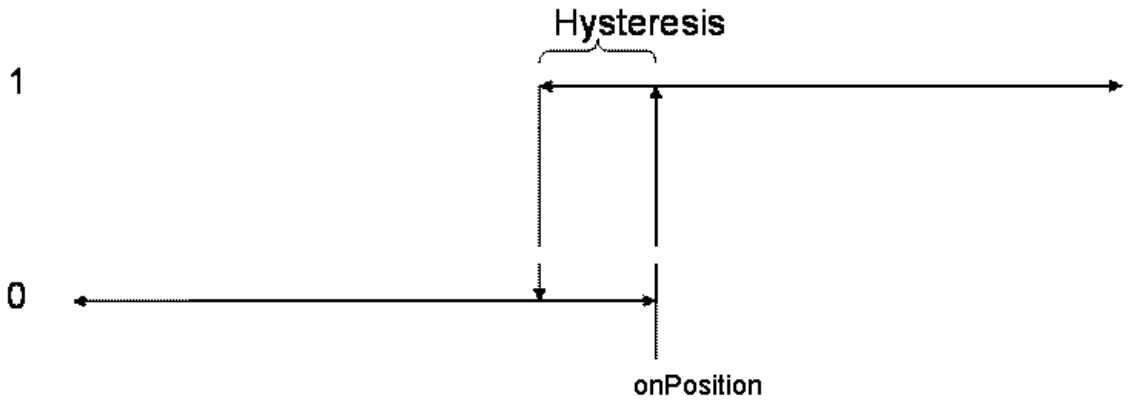
Every cam has 2 main parameters which need to be configured. This is done by the respective bus configuration tool. The parameters will be transferred by SDO during start up. (X runs from 00 to 31)

- camToTrackX 0..15
- connects the cam switch to an input or output, (input or output is determined by the type of cam switch)
- camTypeX 0..9
- selects the type of cam switch

All other data for a single cam switch is transferred by the respective function block

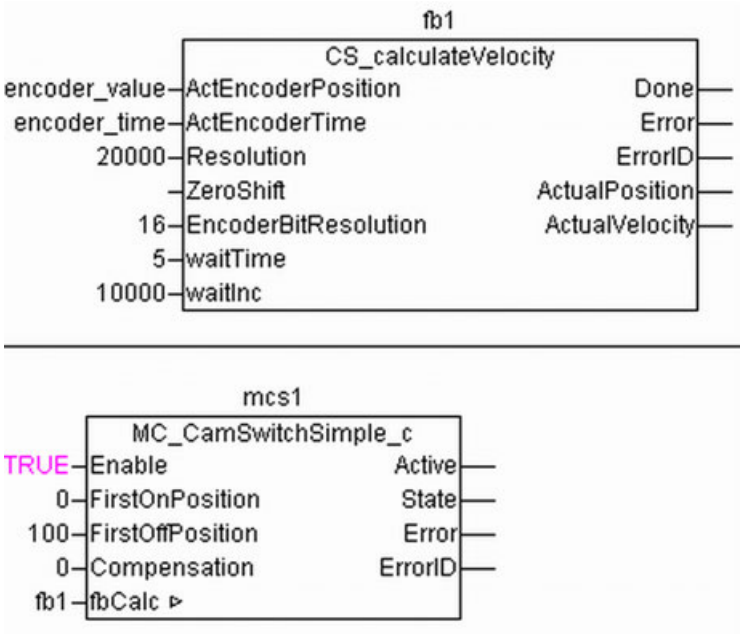
1.5.4.6.6 Hysteresis

- The PulseSwitch has an individually defined hysteresis per cam, applied to the On- and Off-Position.
- All other Cams have a common hysteresis, defined as parameter, which is applied to the „OnPosition”. The hysteresis would be just in use when the encoder would turn backwards or on standstill. Then it will prevent a jitter on the output.



1.5.4.6.7 Function blocks

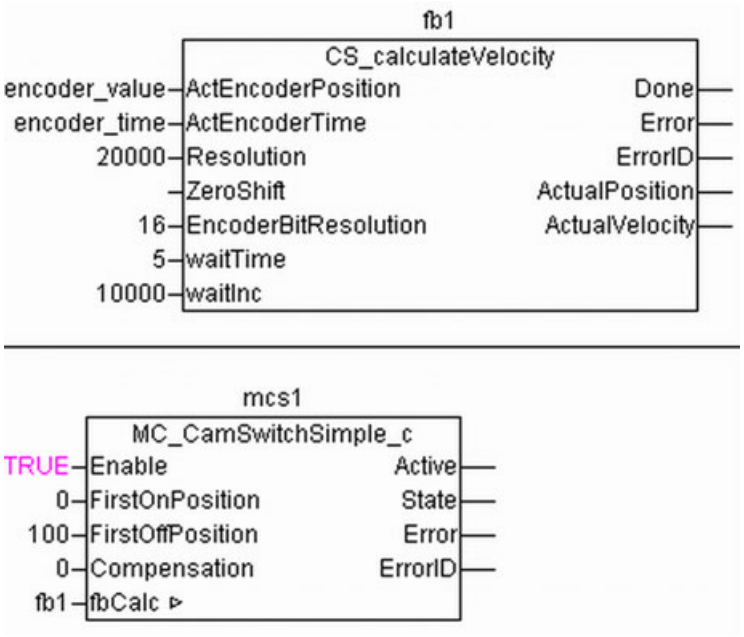
CS_calculateVelocity



Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

Input description

CS_CalculateVelocity is necessary to execute some pre-calculations which are needed for the MC_CamSwitchSimple_c. It needs the actual position and the time related to this position to calculate the velocity. In addition, the position and velocity are transferred to the units which are used from MC_CamSwitchSimple_c.



ActEncoderPosition

Data type	Default value	Range	Unit
DWORD	-	-	-

At input ActEncoderPosition, the position value of the encoder has to be given. It mus be a binary value.

ActEncoderTime

Data type	Default value	Range	Unit
DWORD	-	-	-

At input ActEncoderTime, the time value related to the ActEncoderPosition has to be given. The resolution is nanoseconds.

Resolution

Data type	Default value	Range	Unit
WORD	-	-	-

When the position should be used as it is, the value for resolution should be set to 0. Otherwise, resolution gives the value which is used to display 1 revolution.

For example, when to encoder provides 10 bits per revolution, the encoder value (ActEncoder-Position) would run from 0..1023.

- With resolution=360, the value would be converted to a 1° resolution and the positions for MC_CamSwitchSimple_c could run from 0..259.
- With resolution=0, the positions for MC_CamSwitchSimple_c could run from 0..1023.

ZeroShift

Data type	Default value	Range	Unit
DWORD	-	-	-

At input Zero Shift, an offset to adjust the value of ActEncoderPosition, can be specified.

EncoderBitResolution

Data type	Default value	Range	Unit
WORD	-	-	-

Number of bits which hold the relevant position for 1 revolution (8..32)

This parameter allows to adjust the calculation to different encoder resolutions. The encoder might deliver a single turn or multi turn value. The only requirement is to have a binary value which means 1 revolution should match 2^n increments. n is then the value for EncoderBitResolution.

waitTime

Data type	Default value	Range	Unit
WORD	-	-	-

At input waitTime the minimum time to wait between 2 calculations of velocity [µs] has to be specified.

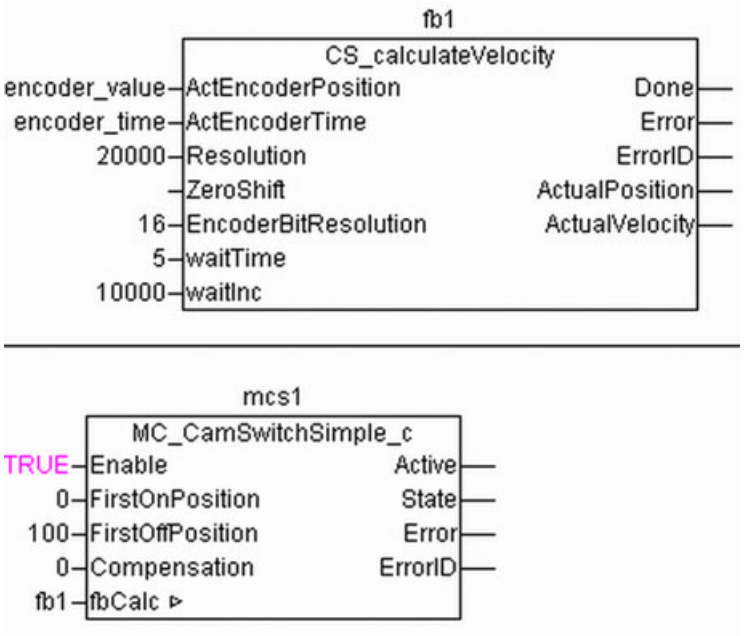
waitInc

Data type	Default value	Range	Unit
WORD	-	-	-

At input waitInc the minimum distance to wait between 2 calculations of velocity has to be specified.

When the velocity is low or the time between 2 measurements is very short, the velocity calculation with velocity = position/time will be imprecise. Therefore it is possible to give a minimum position distance (waitInc) and a minimum time distance (waitTime) which should be exceeded to perform a new calculation. The calculation will be executed when at least 1 of the 2 limits was exceeded. In addition, the velocity will be a average of 4 calculations.

Output description



Done

Data type	Default value	Range	Unit
BOOL	-	-	-

Function block has been executed at least once.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

ActualPosition

Data type	Default value	Range	Unit
DWORD	-	-	-

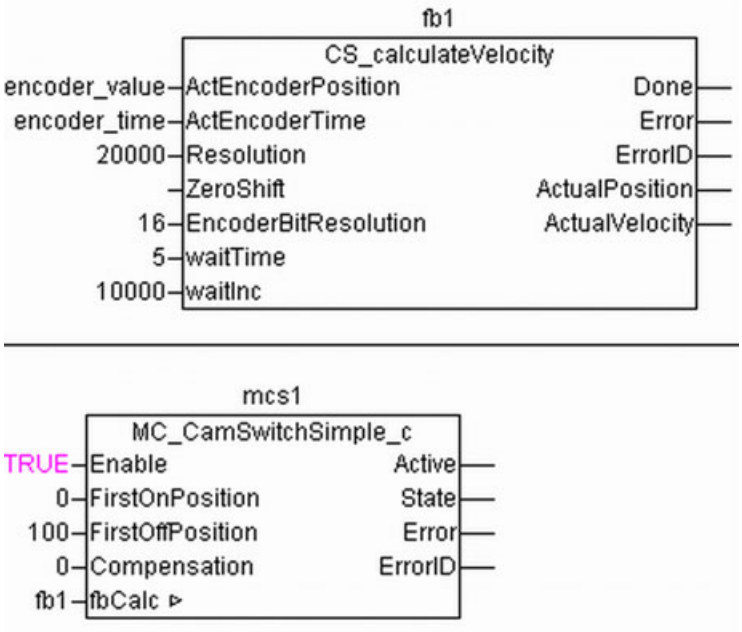
Actual position based on resolution.

ActualVelocity

Data type	Default value	Range	Unit
DINT	-	-	-

Actual velocity based on resolution and normalised with 0x10000.

MCX_CamSwitchSimple_c

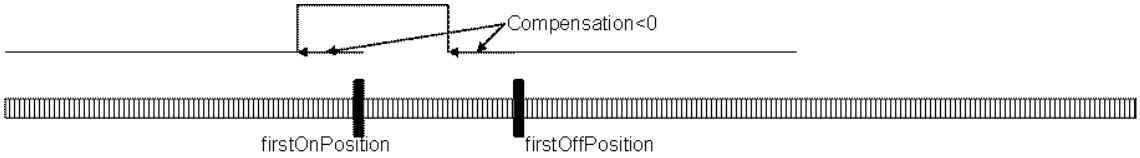


Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

Input description

MC_CamSwitchSimple_c provides the possibility to switch a cam on/off at projected positions. The position is given by a function block of type CS_calculateVelocity. This function block has to be executed every cycle and by the same task as the MC_CamSwitchSimple_c. MC_CamSwitchSimple_c could be used several times, there are no special hardware requirements.

The switch-on-position and the switch-off-position are individually changeable online. Further more a compensation time in both directions can be added to the switch position. Compensation is applied to both switch-on-position and switch-off-position.

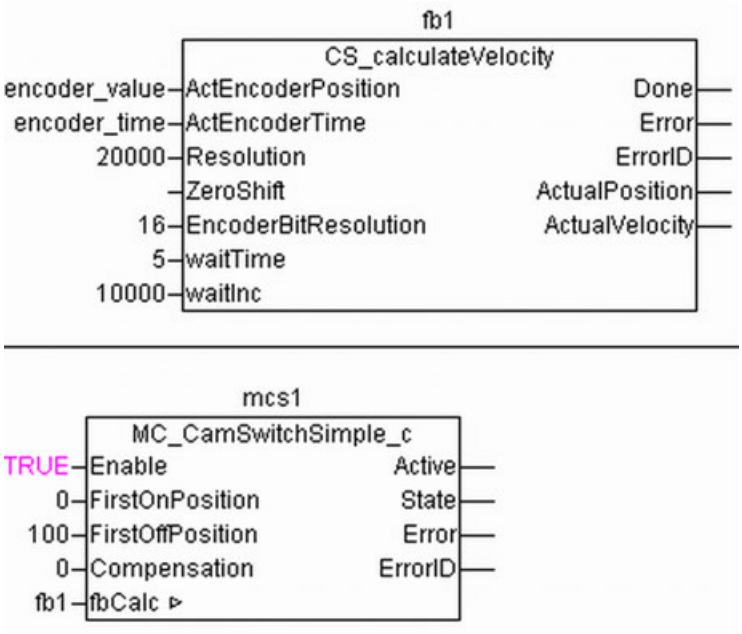


The compensation time makes the switch a “dynamic” switch. The position where to switch on and off is calculated according to the actual velocity, in a way that the output occurs a certain time before (negative compensation) or after (positive compensation) the position has been reached. The time is given at the input compensation, the distance is calculated. The accuracy of time to be reached depends on the stability of velocity, which means just on a constant velocity, the time will be correct.

```
Distance = velocity * compensation;
```

The switch will be switched on at “FirstOnPosition + distance” and switched off at “FirstOffPosition + distance”. While switched on, no new calculation of distance will be done.

The actual state of the cam can also be monitored with the output “state”.



Enable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

FirstOnPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOnPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOnPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOnPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

FirstOffPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOffPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOffPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOffPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

- *If FirstOnPosition is smaller than FirstOffPosition, the cam is switched on between the values of FirstOnPosition and FirstOffPosition of the same turn.*
- *If FirstOnPosition is greater than FirstOffPosition, the cam is switched on between the values of FirstOnPosition of the actual turn and FirstOffPosition of the next turn.*
- *If FirstOnPosition is equal to FirstOffPosition, the cam is switched on for one device cycle.*

Compensation

Data type	Default value	Range	Unit
DINT	-	-	µs

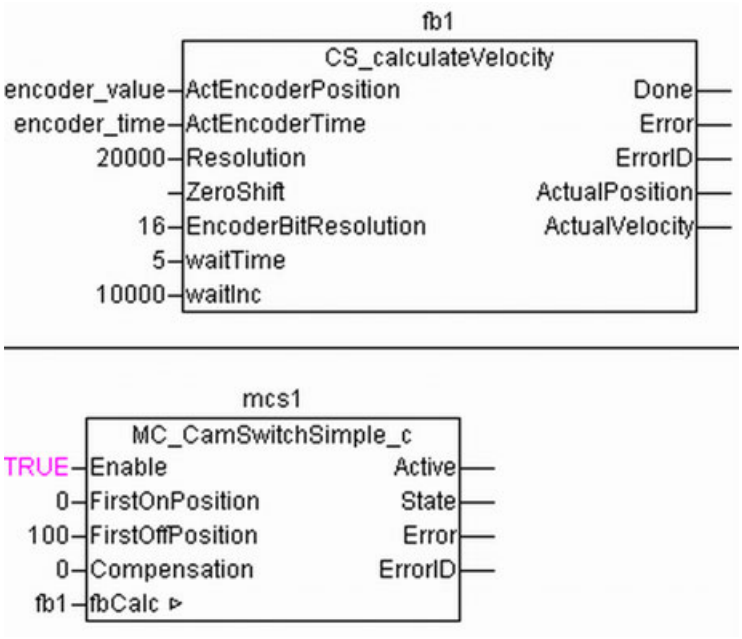
The switch action is rescheduled with Compensation:

- If Compensation is positive, the switch action will be delayed by the value of Compensation.
- If Compensation is negative, the switch action will be brought forward by the value of Compensation.

fbCalc CS_CalculateVelocity

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

Output description



active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

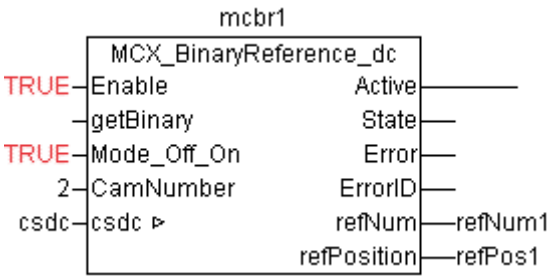
Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

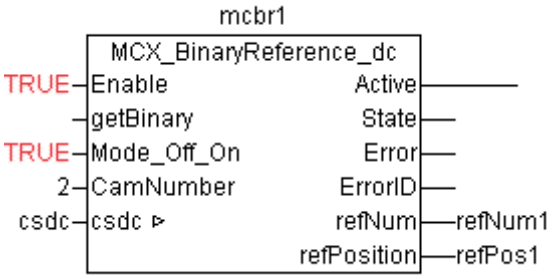
MCX_BinaryReference_DC



Read a Captured Position

Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Group	Camswitch Extended
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

Input description



MCX_BinaryReference_dc provides the possibility to read the encoder position related to an edge on a binary input. The master position is given by an encoder, which must be available, if the cam switch functionality is to be used.

The values for getBinary and Mode_On_Off are individually changeable online.

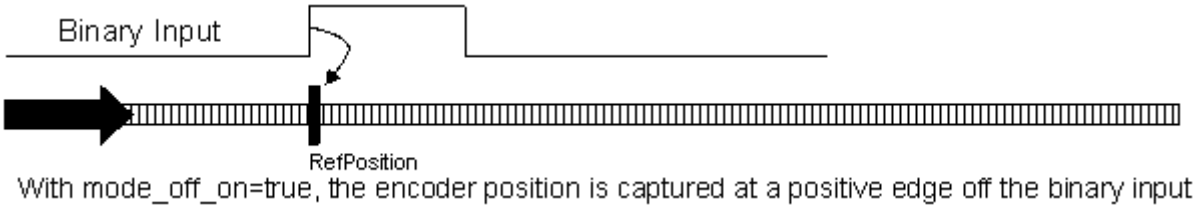
The function block is related to a binary input. It saves the actual encoder position as refPosition when an edge of the binary input has been received. Accuracy would be best when the cam is configured at a low number. The output refNum is counted up for each trigger, so this would also provide an information when more edges are triggered then could be transferred to the PLC.

- Mode_Off_On=FALSE
- a negative edge is used as trigger
- Mode_Off_On=TRUE
- a positive edge is used as trigger

The refPosition can be

- getBinary=TRUE
- the binary value as directly received from the encoder
- getBinary=FALSE
- the angle-value (position is converted by the angle resolution)

The values are transferred multiplexed, so it may take some time to receive them.



The actual state of the binary input can also be monitored with the output "state".

Enable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

getBinary

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

getBinary selects if a binary value or angle value should be triggered.

Mode_Off_On

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Mode_off_on selects if a positive or negative edge will be used as trigger.

CamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

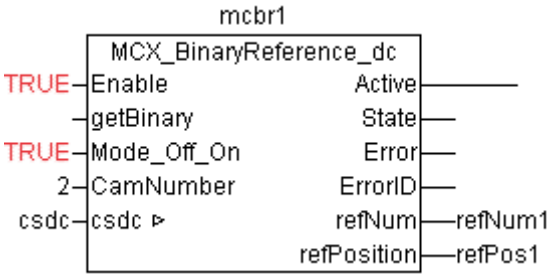
Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

csdc

Data type: CSDCX_REF_TYPE

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

Output description



active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

refNum

Data type	Default value	Range	Unit
WORD	-	0...255	-

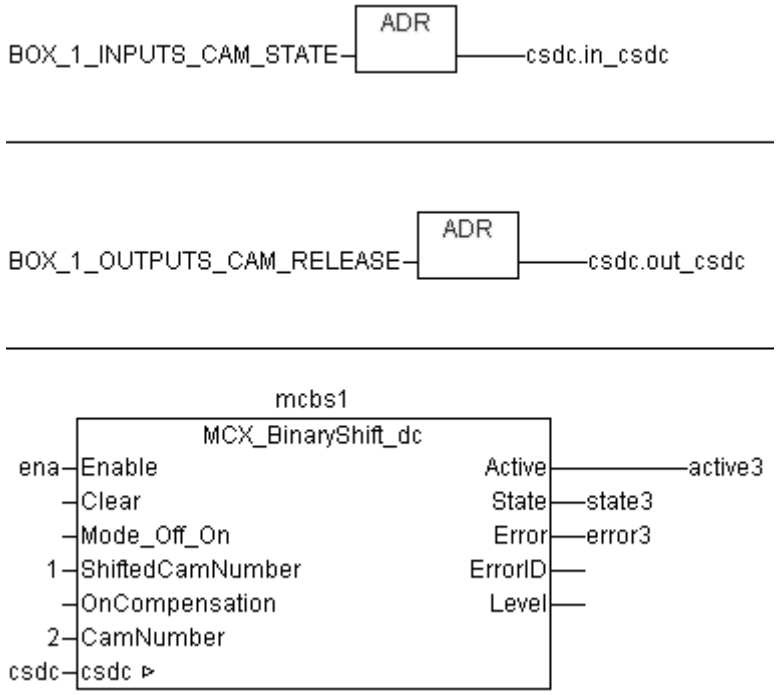
refNum returns the number of different positions which already have been captured. It counts from 0..255 and starts at 0 again. A change of refNum indicates that a new position has been captured. When the change is >1, it indicates how many positions had been captured since the last call of the function block.

refPosition

Data type	Default value	Range	Unit
DWORD	-	-	-

Output refPosition returns the captured position.

MCX_BinaryShift_DC



Create a Trigger to a Cam by a Binary Input

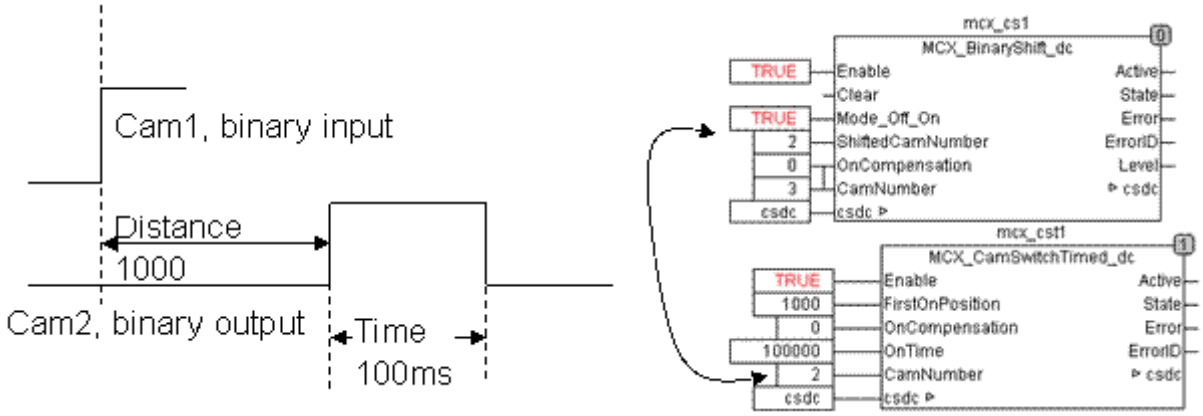
Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Group	Camswitch Extended
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

Input description

MCX_BinaryShift_dc provides the possibility to start a cam switch related to a binary input. The BinaryShift observes a binary input. When a positive (Mode_Off_On=TRUE) or negative (Mode_Off_On=FALSE) edge is received, the associated cam is started. It is then shifted by a certain distance or time. The following characteristics apply to the BinaryShift:

- Used to create a trigger to some kind of "žShiftedCam"
- Is edge triggered
- "ShiftedCam" might be
- Common, comfort, timed, multi, multi-timed
- Time-timed (just valid with shift)

The values for Mode_Off_On and OnCompensation are individually changeable online.



The example shows how a BinaryShift and a CamSwitchTimed would work together:

- Mode_Off_On=TRUE, therefore a positive edge is evaluated. The CamSwitchTimed is triggered in relation to the received edge.
- After the positive edge on a binary input was received, the connected CamSwitchTimed would be triggered. The output "level" will be increased by 1
- When the encoder moved a distance of 1000 (FirstOnPosition of CamSwitchTimed), the output of the cam will be switched on. It will stay on for 100 ms. The output "level" of the BinaryShift will be decreased by 1.
- When additional positive edges are received outside before the distance of 1000 was moved, the respective actions are queued. This is possible for up to 15 actions.

The actual state of the cam can also be monitored with the output "state". It will show the cam, not the binary input.

Enable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

Clear

Data type	Default value	Range	Unit
BOOL	-	-	-

Input Clear deletes the already triggered, but not yet executed cam switches.

Mode_Off_On

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Mode_off_on selects if a positive or negative edge will be used as trigger.

ShiftedCam-Number

Data type	Default value	Range	Unit
WORD	-	-	-

Input ShiftedCamNumber selects the number of the cam which has to be triggered, runs from 1..32.

OnCompensa-tion

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with Compensation:

- If Compensation is positive, the switch action will be delayed by the value of Compensation.
- If Compensation is negative, the switch action will be brought forward by the value of Compensation.

CamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

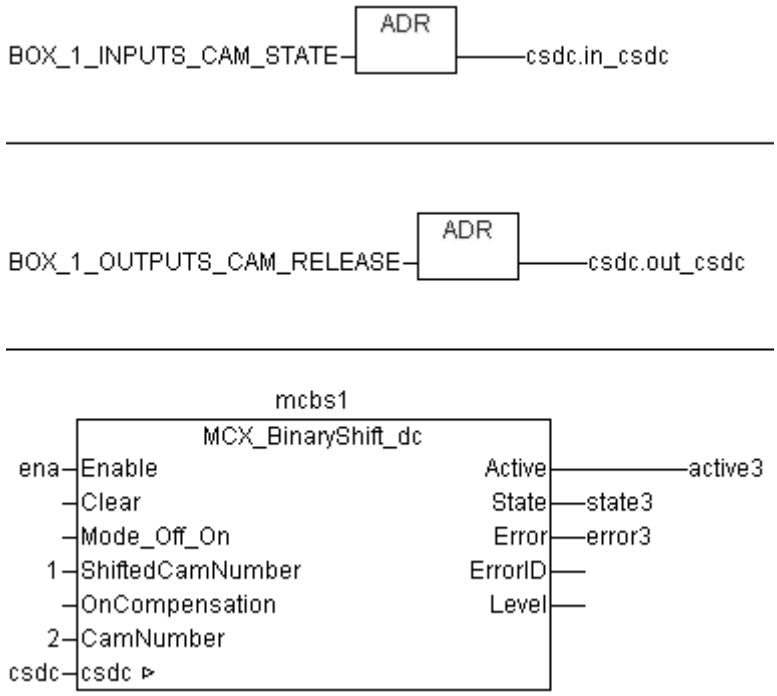
Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

csdc

Data type: CSDCX_REF_TYPE

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

Output description



active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

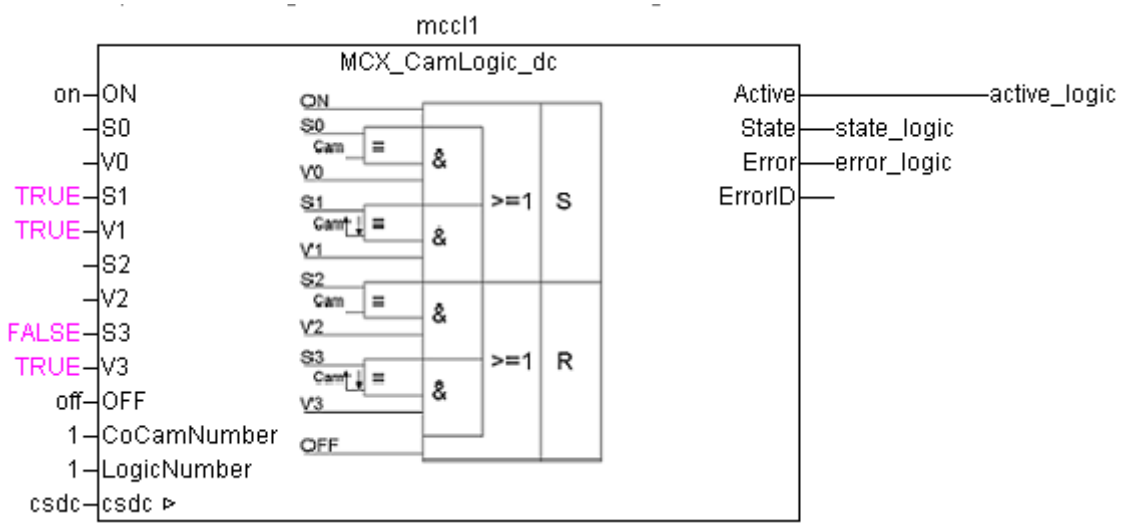
ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

Level

Data type	Default value	Range	Unit
BYTE	-	-	-

Output Level return the number of trigger actions which are queued.

MCX_CamLogic_DC



Interconnection to a Cam.

Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Group	Camswitch Extended
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

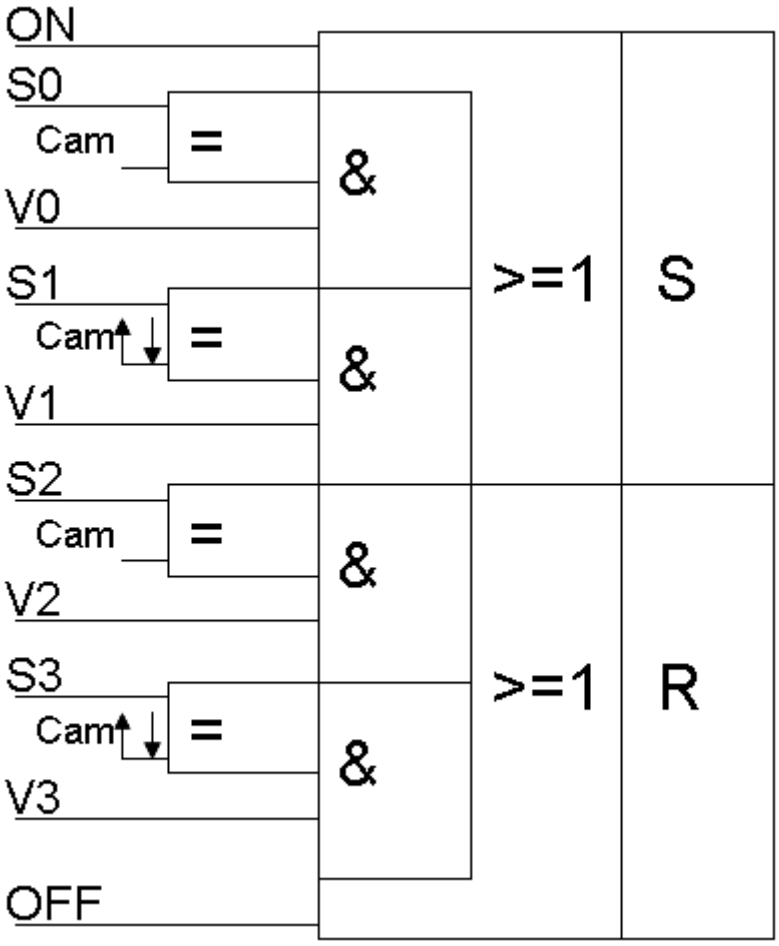
Input description

MCX_CamLogic_dc provides the possibility to add some logical (boolean) interconnection to a cam result. Usually, the binary output is switched on when the cam is switched on. Several cams could be configured to use the same binary output. This will result in an OR-connection of the cam-states to switch on the binary output. The cam state will correspond to the binary output. When other logic operations are necessary, the MCX_CamLogic_dc could be used. It will allow to:

- Switch on/off the output corresponding to the cam state
- Switch on/off the output corresponding to the inverted cam state
- Switch on/off the output corresponding to a positve/negative edge of the cam state
- Directly set or reset the logic. This will subsequently set or reset of the binary output.

Up to 16 MCX_CamLogic_dc are available. It is not necessary to have a configuration to use them, but just to use the number 1..16 to select the respective logic. The logic is connected to the cam by the input CoCamNumber.

The boolean operation which is executed matches the following diagram:



- ON=TRUE will directly set the output
- OFF=TRUE will directly reset the output
- With V0=TRUE, the cam state is enabled to set the output
- With S0=TRUE, the positive state will set the output
- With S0=FALSE, the negative state will set the output
- With V1=TRUE, the cam edge is enabled to set the output
- With S1=TRUE, the positive edge will set the output
- With S0=FALSE, the negative edge will set the output
- The reset part works accordingly
- When set and reset are active, the reset dominates

When several cams are configured to use the same output, they either all of them should have a logic block or none of them should. In case they all have a logic block, all SET-results will be connected by boolean OR and all RESET results will be connected by boolean OR. Afterwards, the operation will be executed with the OR results.

The inputs V0, V1, V2, V3, ON and OFF are transferred immediately and will be effective immediately, while the S0, S1, S2 and S3 are transferred multiplexed with other parameters (from other function block).

The actual state of the logic can also be monitored with the output "state". It will show the logics result, not the binary output.

ON

Data type	Default value	Range	Unit
BOOL	-	-	-

Input ON activates the set path of MCX_CamLogic_dc and set the binary output subsequently.

S0, S1, S2, S3 (select)

Data type	Default value	Range	Unit
BOOL	-	-	-

Inputs V0, V1, V2, V3 select the condition to enable the respective path.

V0, V1, V2, V3 (select)

Data type	Default value	Range	Unit
BOOL	-	-	-

Inputs S0, S1, S2, S3 select positive (TRUE) or negative (FALSE) signal for the respective path.

OFF

Data type	Default value	Range	Unit
BOOL	-	-	-

Input OFF activates the reset path of MCX_CamLogic_dc and reset the binary output subsequently.

CoCamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

LogicNumber

Data type	Default value	Range	Unit
WORD	-	1...16	-

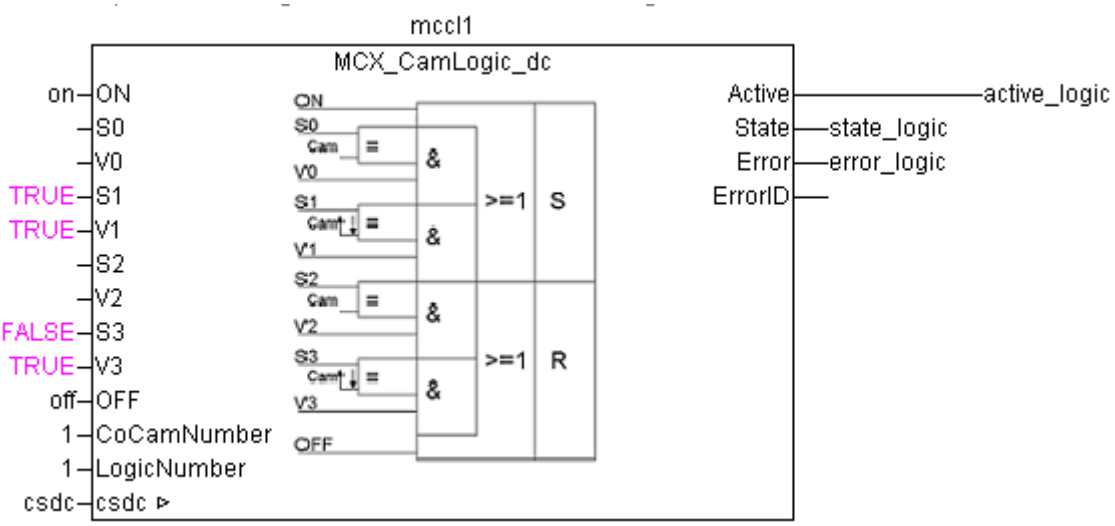
Number of the logic block: Each number should just be used once. An additional configuration is not required.

csdc

Data type: CSDCX_REF_TYPE

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

Output description



active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

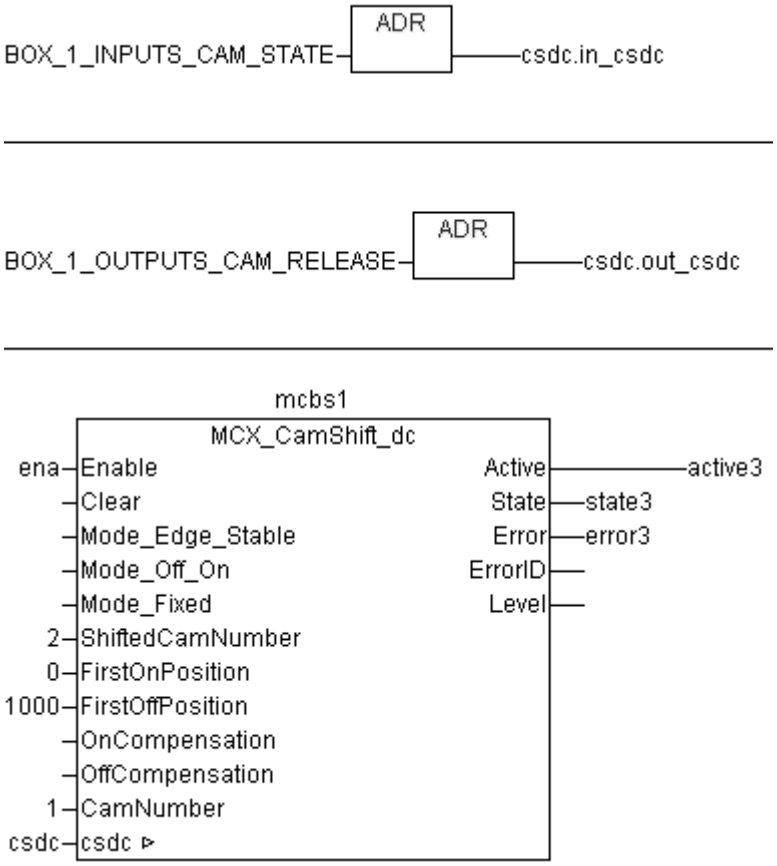
ErrorID is 2 if a wrong parameter value is applied to the function block.

ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

MCX_CamShift_DC

Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0

Parameter	Value
Type	Function block with historical values
Group	Group/Subgroup
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

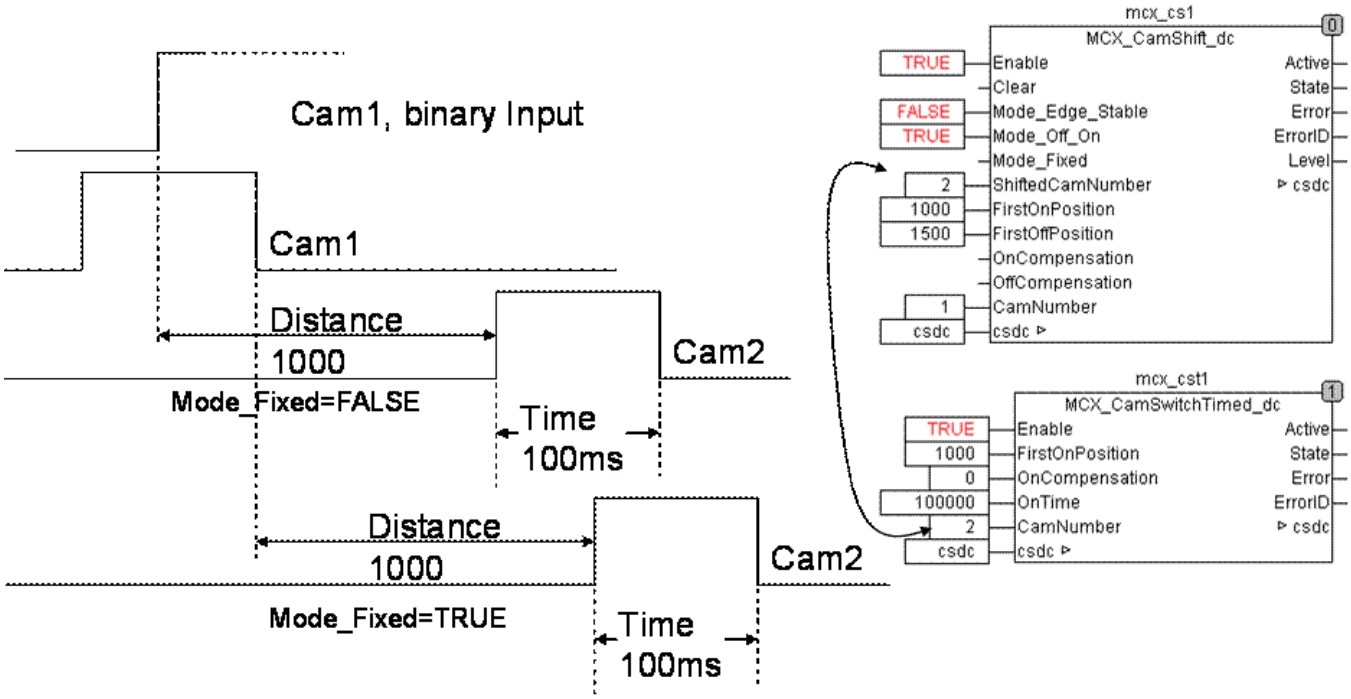


Input description

MCX_CamShift_dc provides the possibility to start a cam switch related to a "supervisor" cam in relation with a binary input. The CamShift observes a binary input during the length of the cam. Depending on the result, the associated cam is started. It is then "shifted" by a certain distance or time. The following characteristics apply to the CamShift:

- Used to create a trigger to some kind of "ShiftedCam"
- Is edge or level triggered
- "ShiftedCam" might be
- Common, comfort, timed, multi, multi-timed
- Time-timed (just valid with shift)

The values for Mode_Edge_Stable, Mode_Off_On, Mode_Fixed, FirstOnPosition, FirstOffPosition, OnCompensation and OffCompensation are individually changeable online.

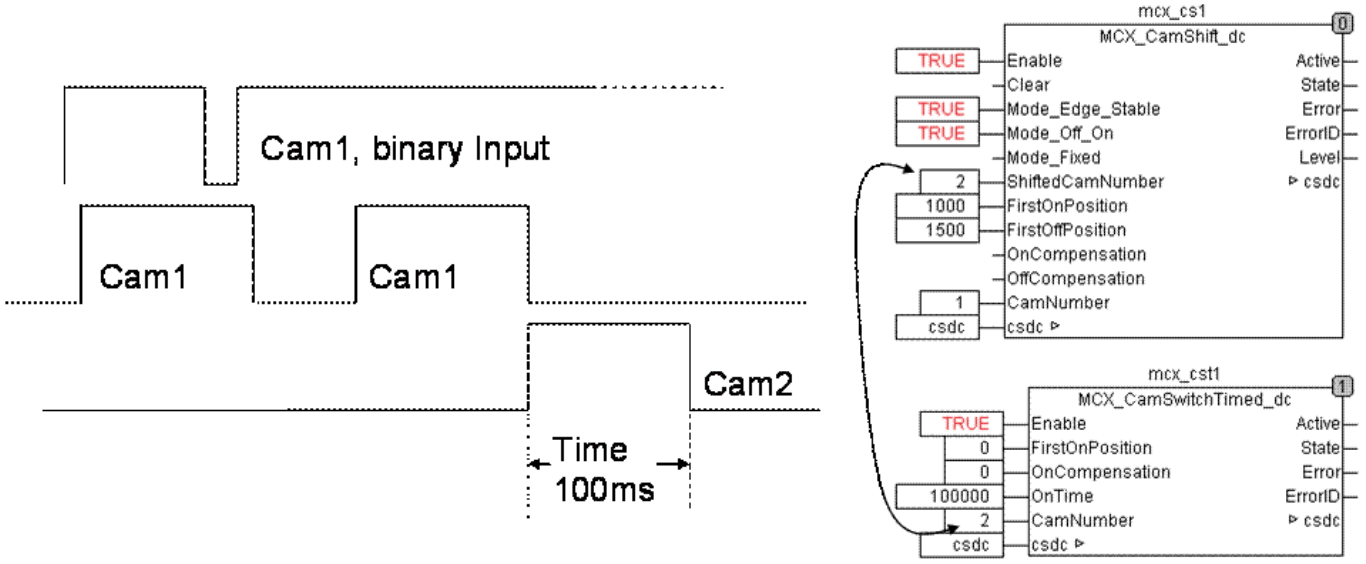


The example shows how a Cam and a CamSwitchTimed would work together:

- Mode_Edge_stable=FALSE, therefore a edge is evaluated
- Mode_Off_On=TRUE, therefore a positive signal is evaluated
- Two examples are shown, with Mode_Fixed=FALSE first: The CamswitchTimed is triggered in relation to the received edge.

With Mode_Fixed=TRUE, it is related to the end of Cam1.

- After the positive edge on a binary input was received, the connected CamSwitchTimed would be triggered. The output "level" will be increased by 1. It is not necessary to receive an edge during the length of the cam, a high signal right from the beginning would do the same.
- When the encoder moved a distance of 1000 (FirstOnPosition), the output of the cam will be switched on. It will stay on for 100 ms. The output "level" of the CamShift will be decreased by 1.
- When additional positive edges are received outside the length of Cam1, these are ignored. When Cam1 will be switched on before the distance of 1000 was moved, the respective actions are queued. This is possible for up to 15 actions.



The 2nd example shows the result when Mode_Edge_Stable=TRUE is used (Mode_Fixed in this case is "don't care"). The binary input has to be high during the length of Cam1, otherwise the ShiftedCam will not be started.

The actual state of the cam can also be monitored with the output "state". It will show the Cam, not the binary input.

Enable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

Clear

Data type	Default value	Range	Unit
BOOL	-	-	-

Input Clear deletes the already triggered, but not yet executed cam switches.

Mode_Edge_Stable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Mode_Edge_Stable selects whether an edge signal or a stable signal is to be used as trigger (FALSE= edge).

If mode_edge_stable=TRUE, the binary signal must be stable during the range of the trigger-cam, otherwise the shifted cam will not be released.

Mode_Off_On

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Mode_off_on selects if a positive or negative edge will be used as trigger.

Mode_Fixed

Data type	Default value	Range	Unit
BOOL	-	-	-

Mode_Fixed selects if an action is triggered in relation to the binary signal or to the end of the cam.

When Mode_Fixed=TRUE, the end of the cam is the reference point. When Mode_Fixed=FALSE, the binary signal is the reference point The shifted cam is started with its own FirstOnPosition as a distance from the reference point. Mode_Fixed=FALSE is only valid with Mode_Edge_Stable=FALSE.

Mode_Edge_Stable	Mode_Fixed	Reference Point
FALSE	FALSE	Binary signal
FALSE	TRUE	Cam
TRUE	Don't care	Cam

ShiftedCam-Number

Data type	Default value	Range	Unit
WORD	-	-	-

Input ShiftedCamNumber selects the number of the cam which has to be triggered, runs from 1..32.

FirstOnPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOnPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOnPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOnPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

FirstOffPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOffPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOffPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOffPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

- *If FirstOnPosition is smaller than FirstOffPosition, the cam is switched on between the values of FirstOnPosition and FirstOffPosition of the same turn.*
- *If FirstOnPosition is greater than FirstOffPosition, the cam is switched on between the values of FirstOnPosition of the actual turn and FirstOffPosition of the next turn.*
- *If FirstOnPosition is equal to FirstOffPosition, the cam is switched on for one device cycle.*

OnCompensation

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with Compensation:

- If Compensation is positive, the switch action will be delayed by the value of Compensation.
- If Compensation is negative, the switch action will be brought forward by the value of Compensation.

OffCompensation

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with OffCompensation:

- If OffCompensation is positive, the switch action will be delayed by the value of OffCompensation.
- If OffCompensation is negative, the switch action will be brought forward by the value of OffCompensation.

CamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

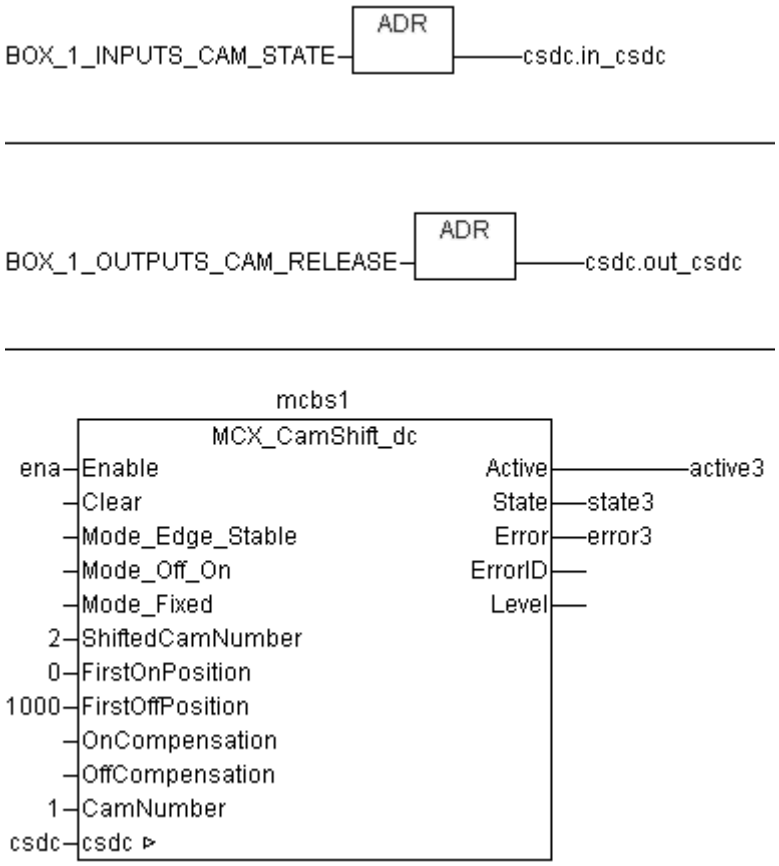
Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

csdc

Data type: CSDCX_REF_TYPE

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

Output description



active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

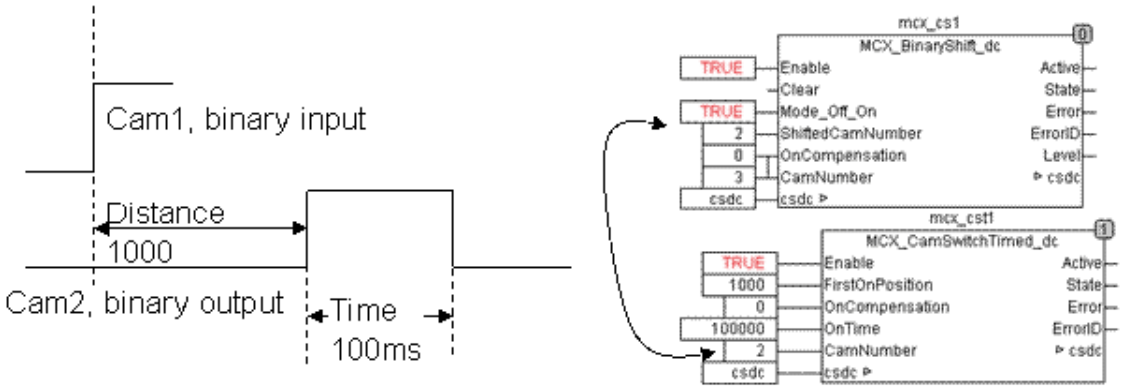
ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

Level

Data type	Default value	Range	Unit
BYTE	-	-	-

Output Level return the number of trigger actions which are queued.

MCX_CamSwitchComfort_DC

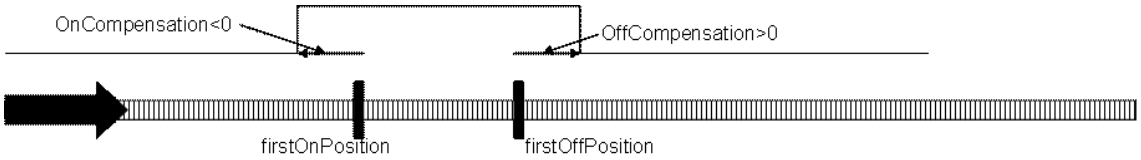


Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Group	Group/Subgroup
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

Input description

MCX_CamSwitchComfort_dc provides the possibility to switch a cam on/off at projected positions. The position is given by an encoder, which must be available, if the cam switch functionality is to be used.

The switch-on-position and the switch-off-position are individually changeable online. Further more a compensation time in both directions can be added to the switch position.



The compensation time makes the switch a "dynamic" switch. The position where to switch on and off is calculated according to the actual velocity, in a way that the output occurs a certain time before (negative compensation) or after (positive compensation) the position has been reached. The time is given at the input compensation, the distance is calculated. The accuracy of time to be reached depends on the stability of velocity, which means just on a constant velocity, the time will be correct.

```
OnDistance = velocity * OnCompensation;
OffDistance = velocity * OffCompensation;
```

The switch will be switched on at "FirstOnPosition + distance" and switched off at "FirstOffPosition + distance". While switched on, no new calculation of distance will be done.

On different times for OnCompensation and OffCompensation, the time to be switched on will be increased or decreased. For example, with a positive OnCompensation and a negative OffCompensation, the time to be switched on will be smaller. The minimum time will be a single device cycle (200 µs), the maximum will be a full revolution with a single cycle off.

The actual state of the cam can also be monitored with the output "state".

Enable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

FirstOnPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOnPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOnPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOnPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

FirstOffPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOffPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOffPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOffPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

- *If FirstOnPosition is smaller than FirstOffPosition, the cam is switched on between the values of FirstOnPosition and FirstOffPosition of the same turn.*
- *If FirstOnPosition is greater than FirstOffPosition, the cam is switched on between the values of FirstOnPosition of the actual turn and FirstOffPosition of the next turn.*
- *If FirstOnPosition is equal to FirstOffPosition, the cam is switched on for one device cycle.*

OnCompensation

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with Compensation:

- If Compensation is positive, the switch action will be delayed by the value of Compensation.
- If Compensation is negative, the switch action will be brought forward by the value of Compensation.

OffCompensation

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with OffCompensation:

- If OffCompensation is positive, the switch action will be delayed by the value of OffCompensation.
- If OffCompensation is negative, the switch action will be brought forward by the value of OffCompensation.

CamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

ErrorID

Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

CamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

Output description

active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

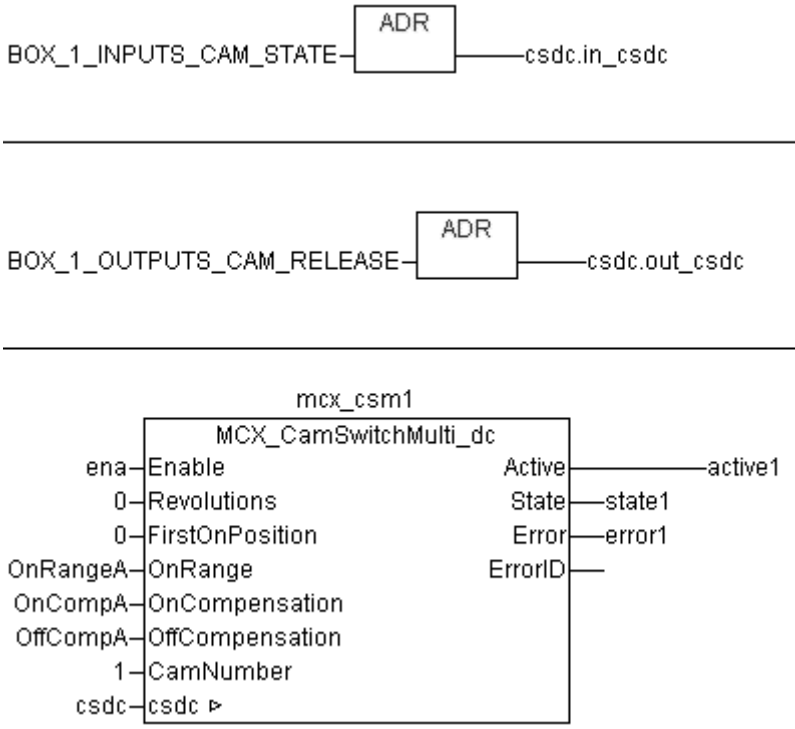
ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

csdc

Data type: CSDCX_REF_TYPE

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

MCX_CamSwitchMulti_DC



Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

Input description

MCX_CamSwitchMulti_dc provides the possibility to switch a cam on/off at projected positions. The position is given by an encoder, which must be available, if the cam switch functionality is to be used.

The switch-on-position and the on-range are individually changeable online. Further more a different compensation time in both directions can be added to the switch position.

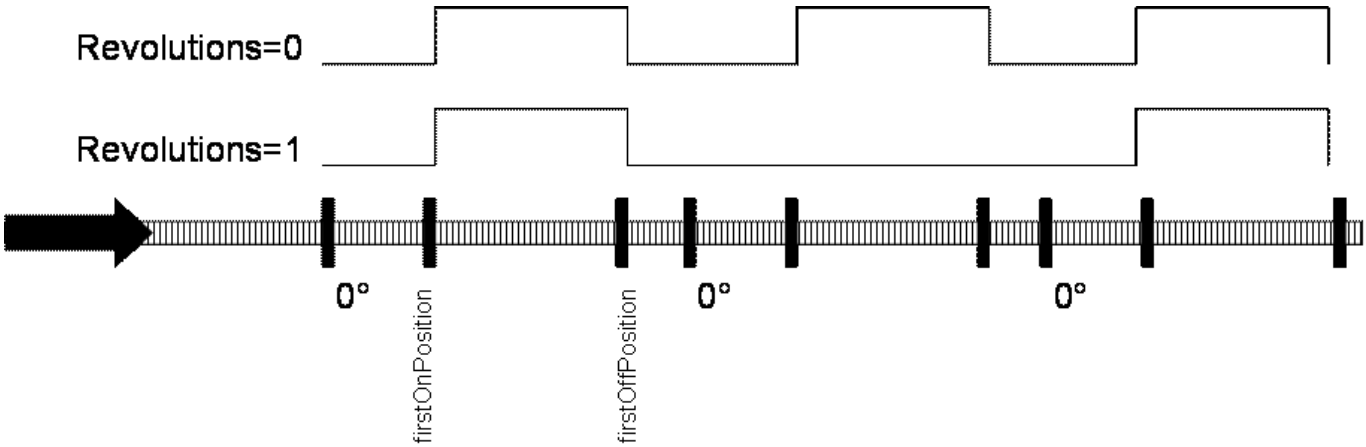
The compensation time makes the switch a "dynamic" switch. The position where to switch on and off is calculated according to the actual velocity, in a way that the output occurs a certain time before (negative compensation) or after (positive compensation) the position has been reached. The time is given at the input compensation, the distance is calculated. The accuracy of time to be reached depends on the stability of velocity, which means just on a constant velocity, the time will be correct.

OnDistance = velocity * OnCompensation;

OffDistance = velocity * OffCompensation;

The switch will be switched on at "FirstOnPosition + OnDistance" and switched off at "FirstOff-Position + OnRange + OffDistance". While switched on, no new calculation of distance will be done.

CamSwitchMulti matches the CamSwitchComfort with an additional information about revolutions. It might switch a cam a distance of several revolutions ahead. The OnDistance and OffDistance might as well cover a distance of several revolutions. OnRange must not be larger then 1 revolution. With revolutions=0, the behavior will be the same as MCX_CamSwitchComfort_dc.

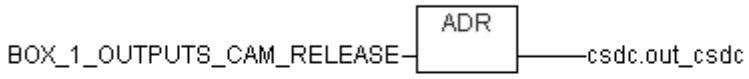


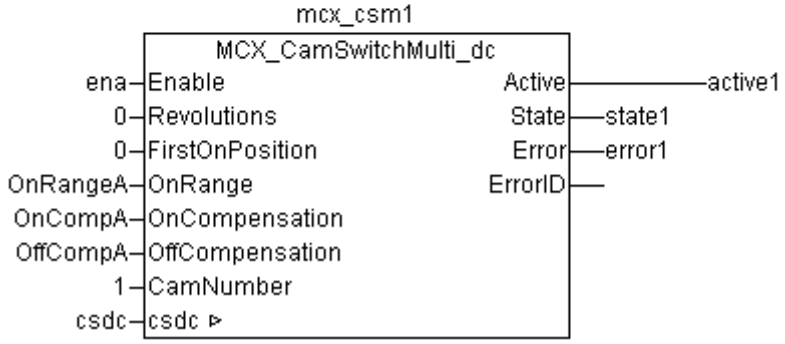
"Revolutions" inside the device start from counting up 0 at power on, therefore, even with a single-turn encoder, the "multi" could be used. The revolutions do not match the revolutions counting of a connected multi-turn encoder, it has just a relative value.

Connected with a "…shift", (BinaryShift or CamShift) it will trigger a cam several revolutions ahead.

On different values for OnCompensation and OffCompensation, the time to be switched on will be increased or decreased. For example, with OnCompensation >0 and OffCompensation <0, the Cam will be switched on later and switched off earlier, so the angle to be switched on is decreased. The minimum time will be a single device cycle (200 µs), the maximum will be a number of revolutions according to the input "revolution+1", with a single cycle off.

The actual state of the cam can also be monitored with the output "state".





Enable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

FirstOnPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOnPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOnPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOnPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

OnCompensation

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with Compensation:

- If Compensation is positive, the switch action will be delayed by the value of Compensation.
- If Compensation is negative, the switch action will be brought forward by the value of Compensation.

OnRange

Data type	Default value	Range	Unit
WORD	-	-	-

The value of OnRange is automatically truncated to the resolution of the circle without notice. For example, all OnRange greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

OnRange can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

OffCompensation

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with OffCompensation:

- If OffCompensation is positive, the switch action will be delayed by the value of OffCompensation.
- If OffCompensation is negative, the switch action will be brought forward by the value of OffCompensation.

CamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

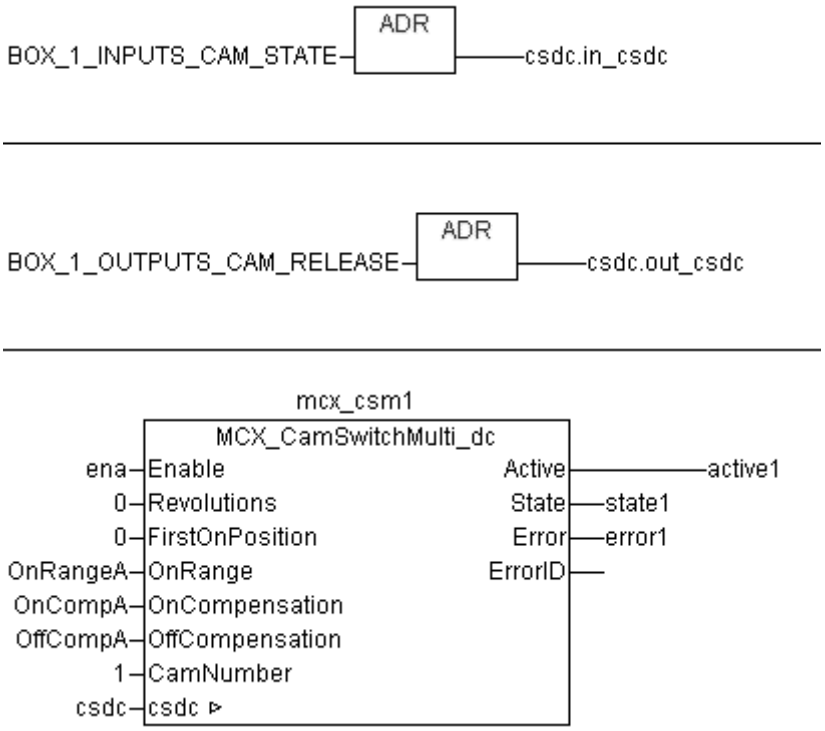
Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

csdc

Data type: CSDCX_REF_TYPE

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

Output description



active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

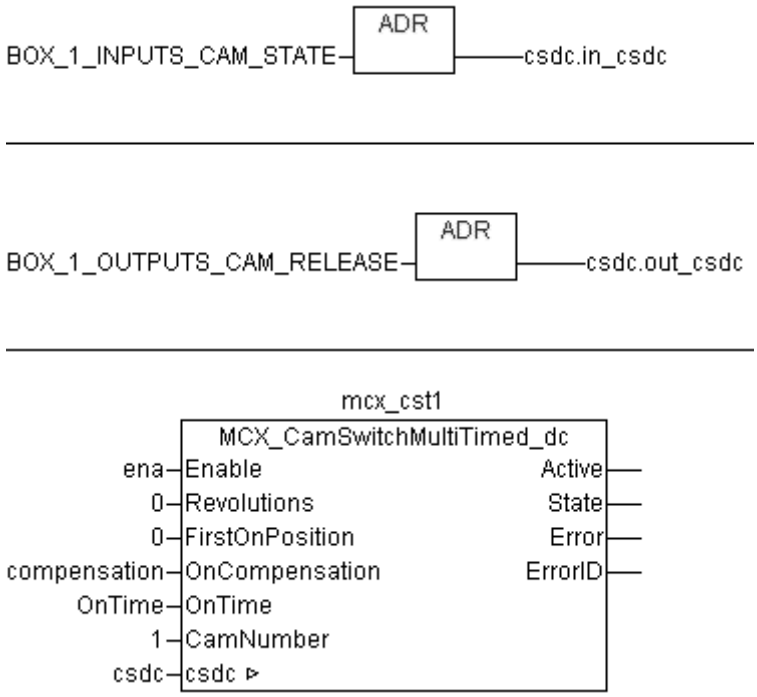
Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

MCX_CamSwitchMultiTimed_DC

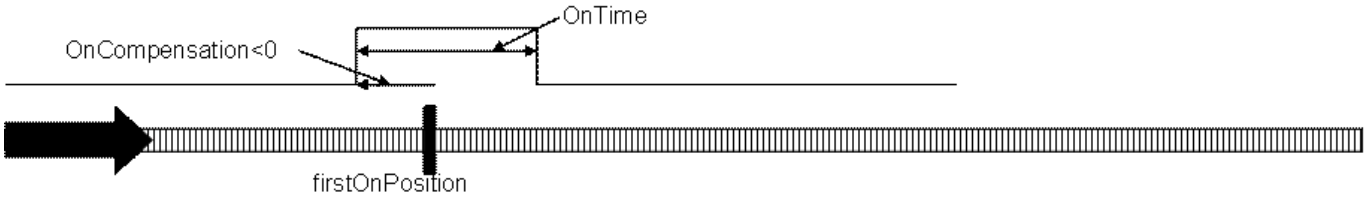


Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

Input description

MCX_CamSwitchMultiTimed_dc provides the possibility to switch a cam on a projected position and off after a projected time. The position is given by an encoder, which must be available, if the cam switch functionality is to be used.

The switch-on-position and the time are individually changeable online. Further more a compensation time in both directions can be added to the switch-on-position.



The compensation time makes the switch a "dynamic" switch. The position where to switch on and off is calculated according to the actual velocity, in a way that the output occurs a certain time before (negative compensation) or after (positive compensation) the position was reached. The time is given at the input compensation, the distance is calculated. The accuracy of time to be reached depends on the stability of velocity, which means just on a constant velocity, the time will be correct.

Distance = velocity * compensation;

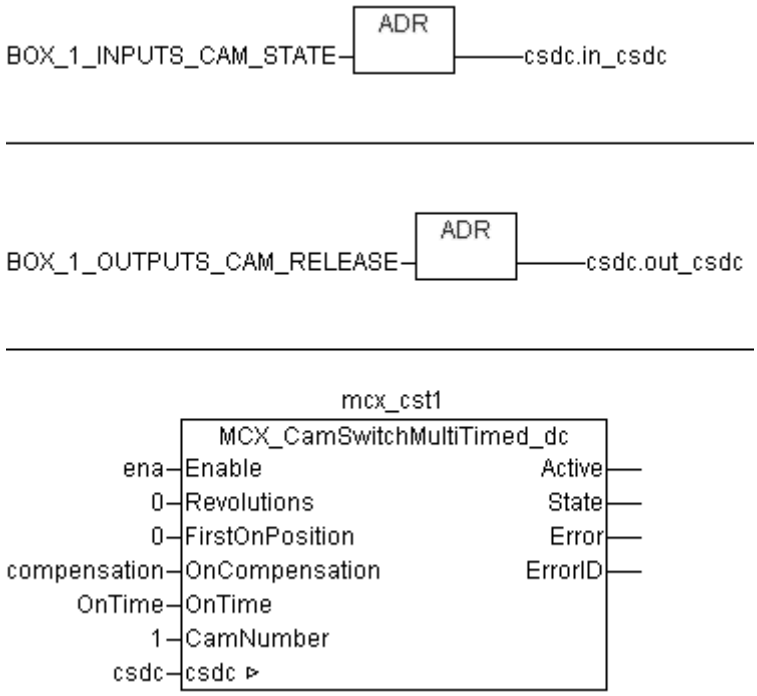
The switch will be switched on at "FirstOnPosition + distance" and switched after the time OnTime elapsed. The time is given in us. The accuracy of time is 200 µs.

CamSwitchMultiTimed matches the CamSwitchTimed with an additional information about revolutions. With revolutions=0, the behavior will be as MCX_CamSwitchTimed_dc. With revolutions > 0, the switching will leave out the respective number of revolutions.

"Revolutions" inside the device start from counting up 0 at power on, therefore, even with a single-turn encoder, the "multi" could be used. The revolutions do not match the revolutions counting of a connected multi-turn encoder, it has just a relative value.

Connected with a "…shift", (BinaryShift or CamShift) it will trigger a cam several revolutions ahead.

The actual state of the cam can also be monitored with the output "state".



Enable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

FirstOnPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOnPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOnPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOnPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

OnCompensation

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with Compensation:

- If Compensation is positive, the switch action will be delayed by the value of Compensation.
- If Compensation is negative, the switch action will be brought forward by the value of Compensation.

OnTime

Data type	Default value	Range	Unit
DWORD	-	0...10 s	µs

OnTime gives the duration to switch on the cam. Time will be evaluated with an accuracy of 200 µs (microseconds).

OnTime can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

CamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

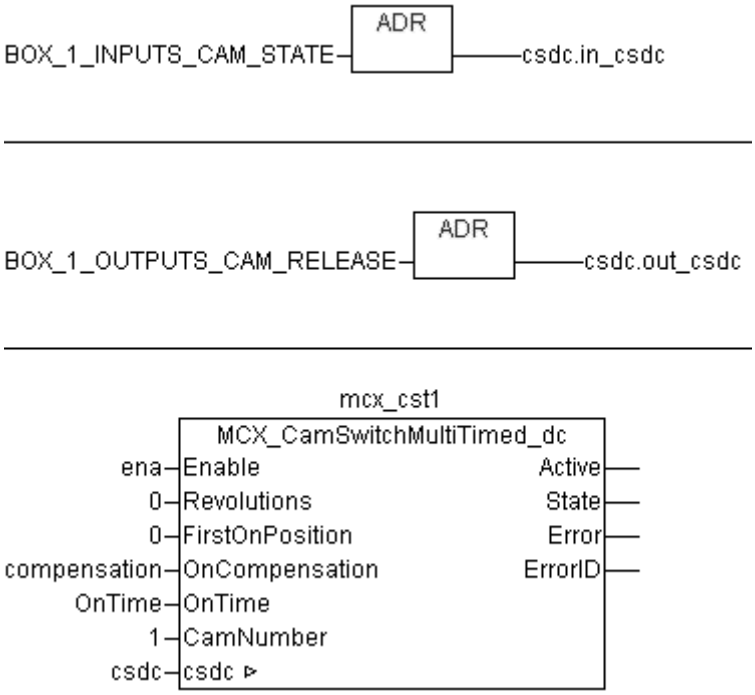
Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

csdc

Data type: CSDCX_REF_TYPE

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

Output description



active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

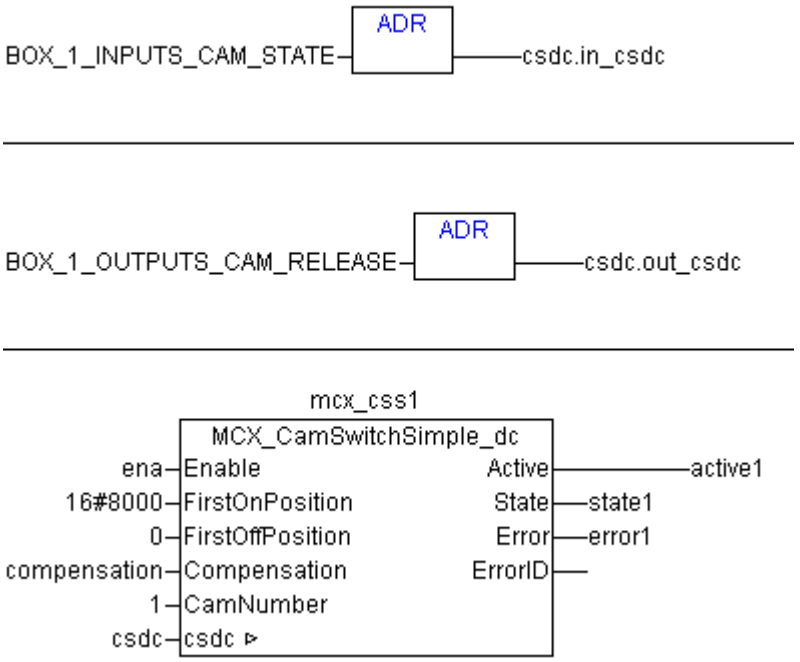
Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

MCX_CamSwitchSimple_DC

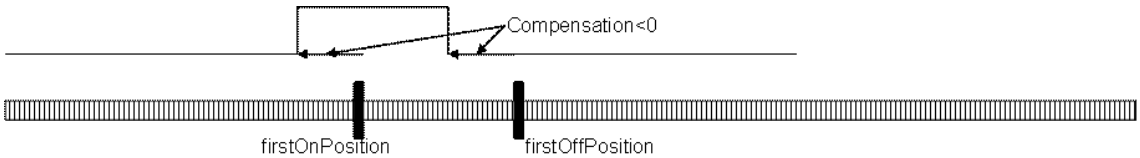


Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

Input description

MCX_CamSwitchSimple_dc provides the possibility to switch a cam on/off at projected positions. The position is given by an encoder, which must be available, if the cam switch functionality is to be used.

The switch-on-position and the switch-off-position are individually changeable online. Further more a compensation time in both directions can be added to the switch position. Compensation is applied to both switch-on-position and switch-off-position.

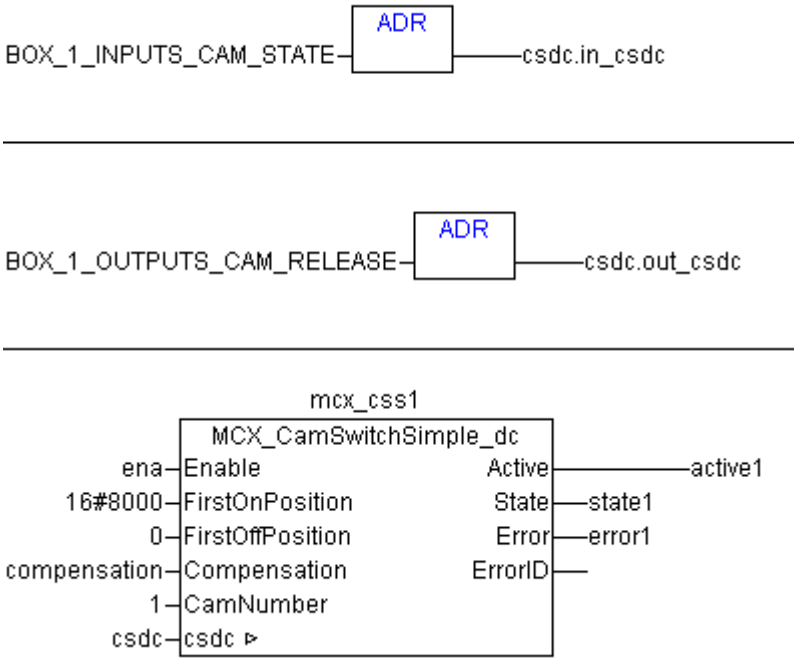


The compensation time makes the switch a "dynamic" switch. The position where to switch on and off is calculated according to the actual velocity, in a way that the output occurs a certain time before (negative compensation) or after (positive compensation) the position has been reached. The time is given at the input compensation, the distance is calculated. The accuracy of time to be reached depends on the stability of velocity, which means just on a constant velocity, the time will be correct.

```
Distance = velocity * compensation;
```

The switch will be switched on at "FirstOnPosition + distance" and switched off at "FirstOffPosition + distance". While switched on, no new calculation of distance will be done.

The actual state of the cam can also be monitored with the output "state".



Enable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

FirstOnPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOnPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOnPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOnPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

FirstOffPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOffPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOffPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOffPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

- *If FirstOnPosition is smaller than FirstOffPosition, the cam is switched on between the values of FirstOnPosition and FirstOffPosition of the same turn.*
- *If FirstOnPosition is greater than FirstOffPosition, the cam is switched on between the values of FirstOnPosition of the actual turn and FirstOffPosition of the next turn.*
- *If FirstOnPosition is equal to FirstOffPosition, the cam is switched on for one device cycle.*

Compensation

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with Compensation:

- If Compensation is positive, the switch action will be delayed by the value of Compensation.
- If Compensation is negative, the switch action will be brought forward by the value of Compensation.

CamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

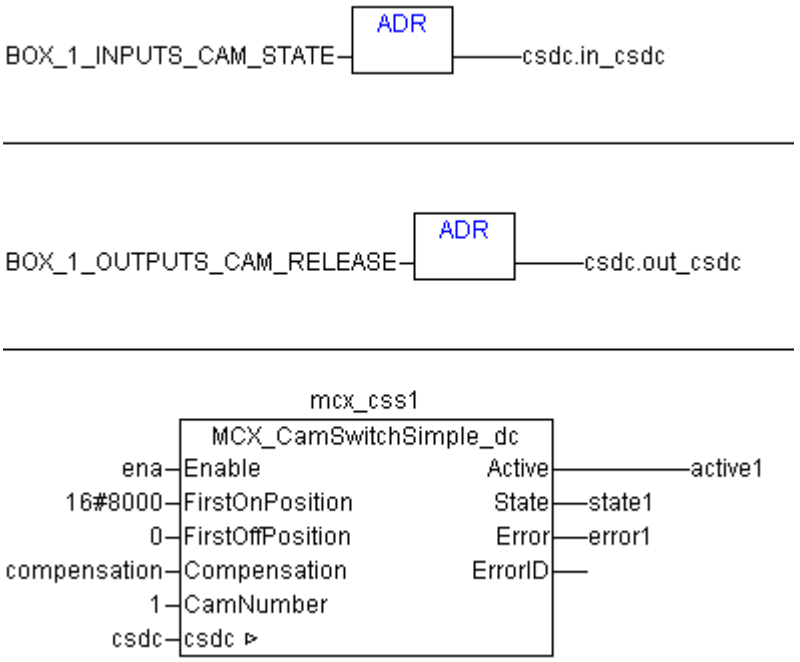
Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

csdc

Data type: CSDCX_REF_TYPE

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

Output description



active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

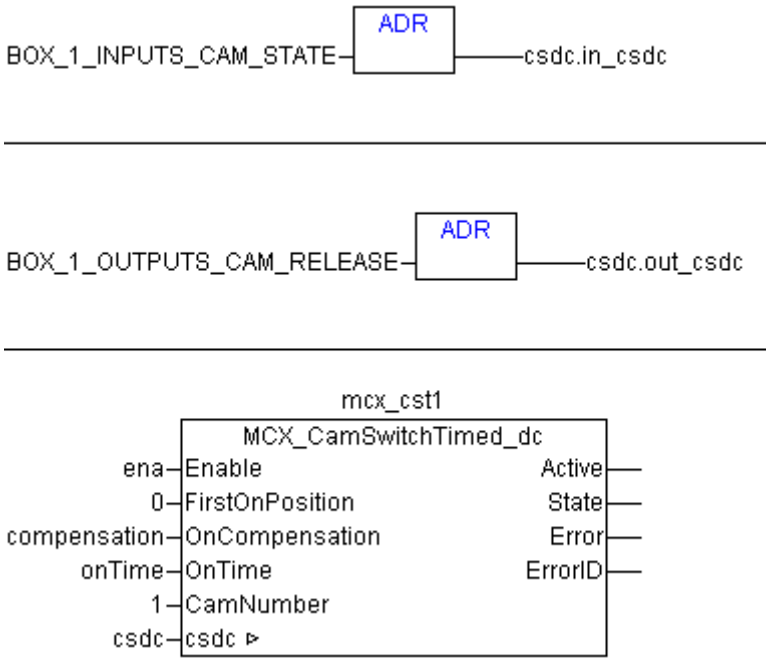
Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

MCX_CamSwitchTimed_DC

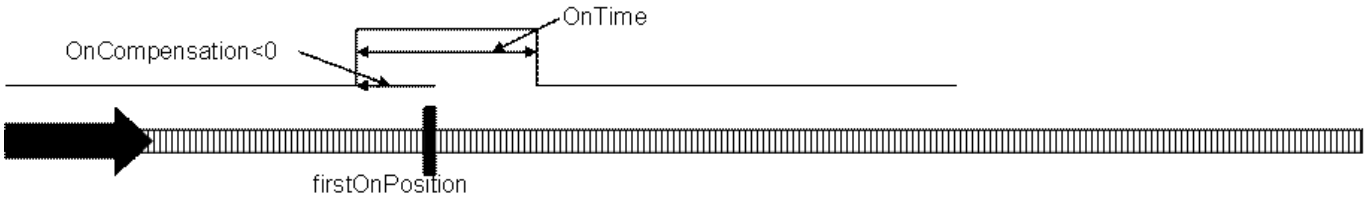


Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

Input description

MCX_CamSwitchTimed_dc provides the possibility to switch a cam on/off at projected positions. The position is given by an encoder, which must be available, if the cam switch functionality is to be used.

The switch-on-position and the switch-off-position are individually changeable online. Further more a compensation time in both directions can be added to the switch position. Compensation is applied to both switch-on-position and switch-off-position.

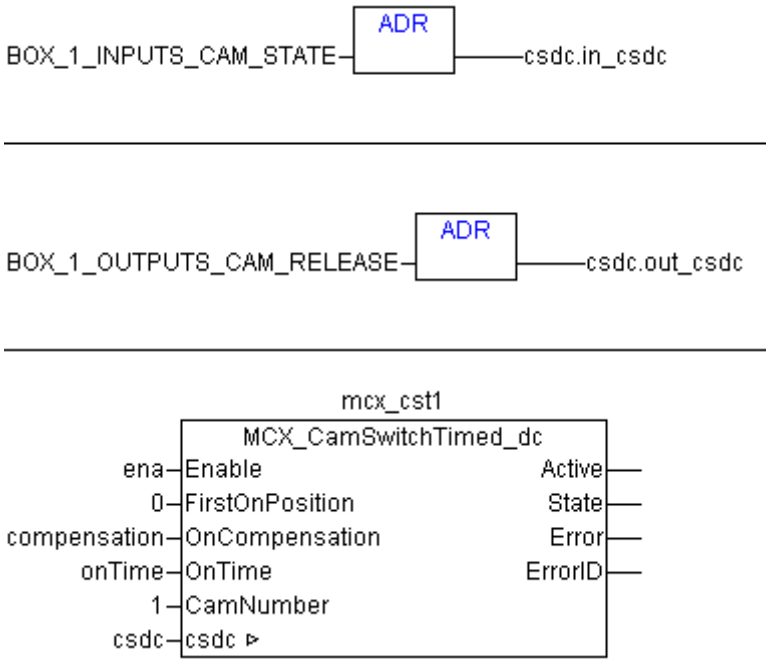


The compensation time makes the switch a "dynamic" switch. The position where to switch on and off is calculated according to the actual velocity, in a way that the output occurs a certain time before (negative compensation) or after (positive compensation) the position has been reached. The time is given at the input compensation, the distance is calculated. The accuracy of time to be reached depends on the stability of velocity, which means just on a constant velocity, the time will be correct.

Distance = velocity * compensation;

The switch will be switched on at "FirstOnPosition + distance" and switched off at "FirstOffPosition + distance". While switched on, no new calculation of distance will be done.

The actual state of the cam can also be monitored with the output "state".



Enable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

FirstOnPosition

Data type	Default value	Range	Unit
WORD	-	-	-

The value of FirstOnPosition is automatically truncated to the resolution of the circle without notice. For example, all FirstOnPosition greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

FirstOnPosition can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

OnCompensation

Data type	Default value	Range	Unit
DINT	-	-	µs

The switch action is rescheduled with Compensation:

- If Compensation is positive, the switch action will be delayed by the value of Compensation.
- If Compensation is negative, the switch action will be brought forward by the value of Compensation.

OnTime

Data type	Default value	Range	Unit
DWORD	-	0...10 s	µs

OnTime gives the duration to switch on the cam. Time will be evaluated with an accuracy of 200 µs (microseconds).

OnTime can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

CamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

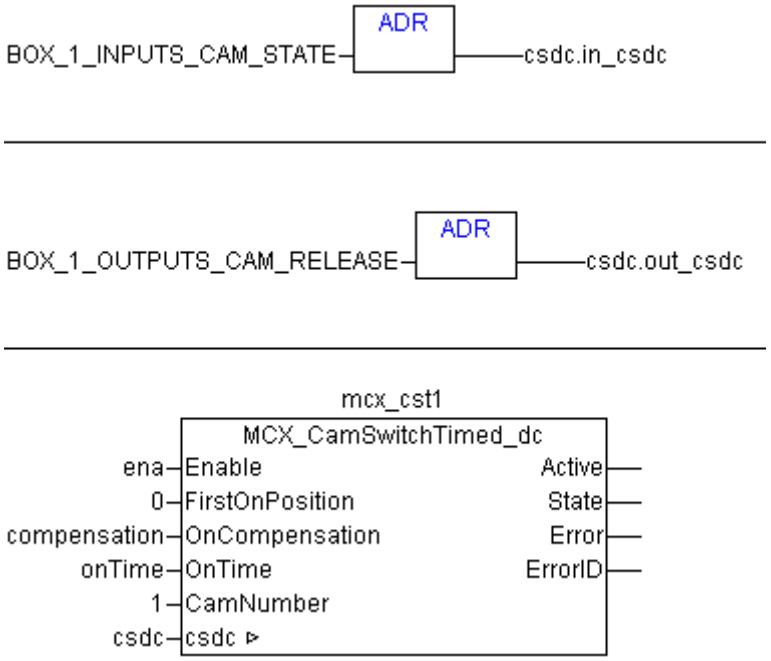
Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

csdc

Data type: CSDCX_REF_TYPE

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

Output description



active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

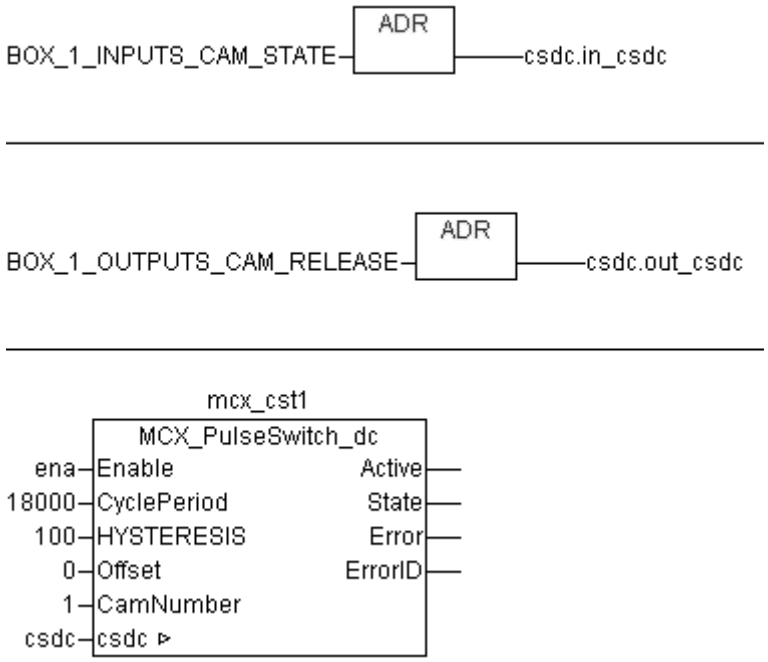
Data type	Default value	Range	Unit
WORD	-	-	-

ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

MCX_PulseSwitch_DC

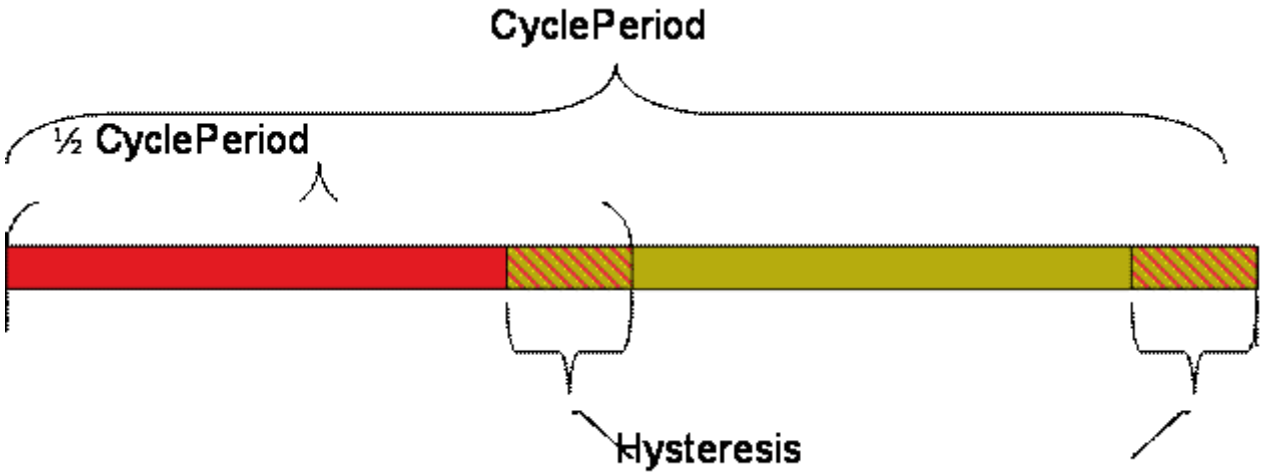


Parameter	Value
Included in library	MCX_AC500_V24.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Available for CI511-ETHCAT and CI512-ETHCAT	With device index C0 and above

Input description

MCX_PulseSwitch_dc provides the possibility to generate a pulse train according to the master position; the frequency is proportional to the velocity of the master. The master position is given by an encoder, which must be available, if the cam switch functionality is to be used.

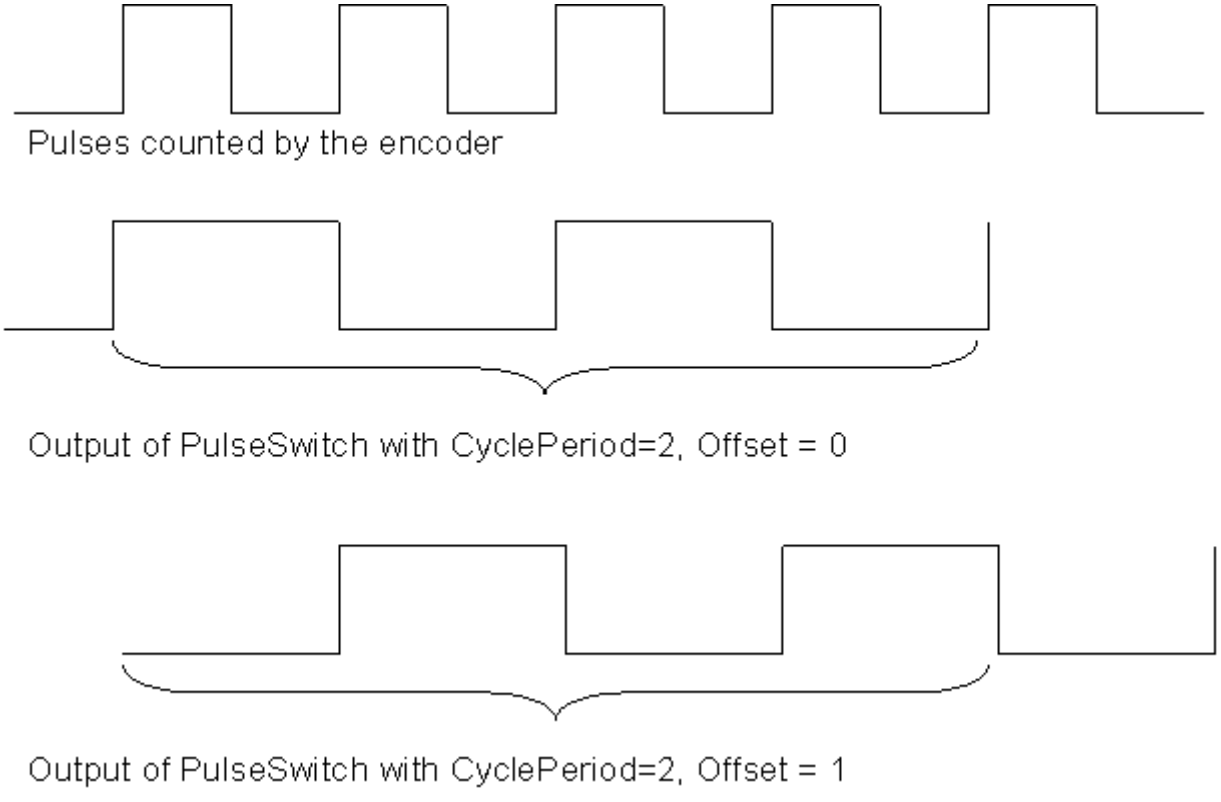
The values for CyclePeriod, Hysteresis and Offset are angle-values. They are individually changeable online.



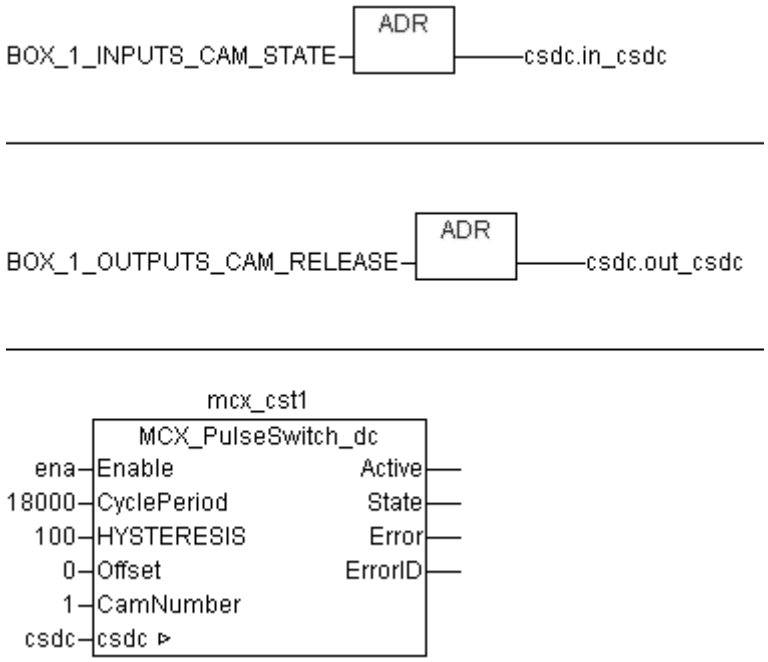
CyclePeriod is a fraction of 1 revolution (at maximum 1 revolution).The PulseSwitch will be switched on when the position is between CyclePeriod/2 and CyclePeriod " Hysteresis (shown green). The PulseSwitch will be switched off when the position is between 0 and CyclePeriod/2 " Hysteresis (shown red). It will not be changed otherwise, this prevents a toggling of the output in case the encoder stopped close to the switching position.

For example, when 1 revolution is 360° and CyclePeriod is 10°, it will be switched on for 5° and switched off for 5°, in total 36 pulses will be generated per revolution.

Several MCX_PulseSwitche_dc may be used to generate coordinated outputs, delayed by offset to each other.



The actual state of the cam can also be monitored with the output "state".



Enable

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The function block is activated with Enable TRUE. With Enable=FALSE, the respective cam will be switched off immediately.

CyclePeriod

Data type	Default value	Range	Unit
WORD	-	-	-

Number of encoder pulses for one pulsewith-period. The value of CyclePeriod is automatically truncated to the resolution of the circle without notice. For example, all CyclePeriod greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

CyclePeriod can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

Hysteresis

Data type	Default value	Range	Unit
WORD	-	-	-

The value of Hysteresis is automatically truncated to the resolution of the circle without notice. For example, all Hysteresis greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

Hysteresis can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

Offset

Data type	Default value	Range	Unit
WORD	-	-	-

The value of Offset is automatically truncated to the resolution of the circle without notice. For example, all Offset greater than 36000 will be limited to 36000 (given if the default resolution of CI51x-ETHCAT cam is used).

Offset can be changed at any time. It will be immediately valid after sending to the CI51x-ETHCAT via the POU.

CamNumber

Data type	Default value	Range	Unit
WORD	-	1...32	-

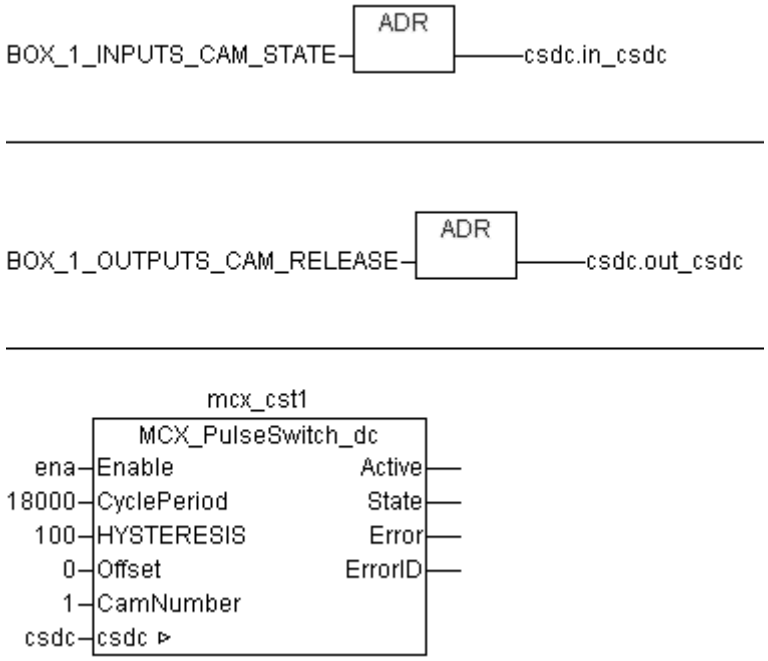
Number of the cam: this number runs from 1..32. The parameter cam_To_Track[0..31] must be used to map the cam to the available digital outputs. A configuration tool must be used for setting the cam_To_Track.

csdc

Data type: CSDCX_REF_TYPE

The 2 elements in_csdc and out_csdc of csdc must be initialized with the beginning address of the input data area and the output data area to facilitate proper function of the cam.

Output description



active

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

Parameters (getBinary, Mode_On_Off) are transferred during active is TRUE.

state

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The parameter State shows the actual cam state. If State is TRUE, the cam is on. If State is FALSE, the cam is off.

Error

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

The output ERR signals any fault detected during the processing of the function block. This output always has to be checked in conjunction with the DONE output. If DONE is TRUE and ERR is TRUE, a processing fault was detected. The value of the ERNO output provides the according error number.

ErrorID

Data type	Default value	Range	Unit
WORD	-	-	-

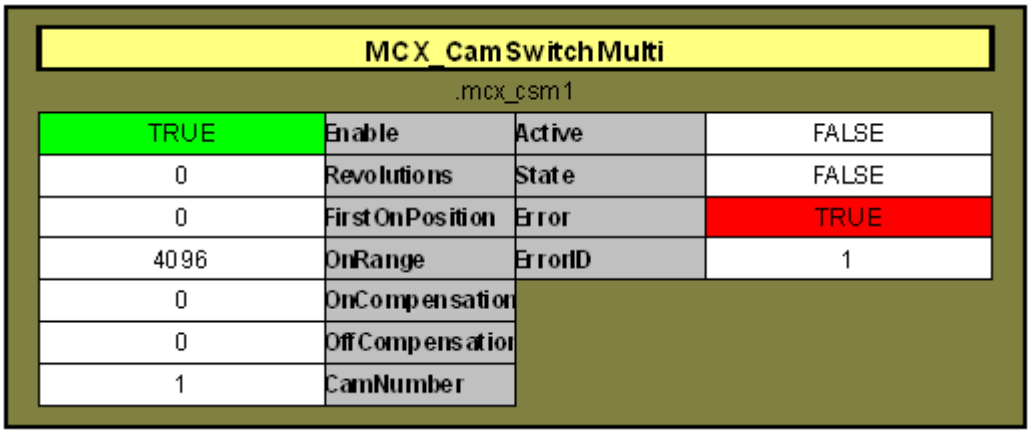
ErrorID is 1 if communication an error occurred.

ErrorID is 2 if a wrong parameter value is applied to the function block.

ErrorID is 3 if a wrong cam type is configured in the device CI51x-ETHCAT.

1.5.4.6.8 Visualization

For each of the MCX… function block, the library provides an integrated visualization element. In the configuration of these visualization elements, the placeholder has to be configured with the name of the function block's instance. The visualization looks for example as follows:



The values for all inputs and outputs and as well the name of the instance are shown.

1.5.4.7 CANopen library

Library file name: **CANopen_AC500_Vx.lib**

The library CANopen_AC500_Vx.lib is intended to be used with the CANopen master communication module.

Beside the cyclic IO communication, which is configured in the CANopen master configuration and controlled by the runtime system, additional features are implemented in the CANopen master. This library provides the possibility to use these features within a PLC application. With the contained function blocks the following functionality can be realized:

- sending and receiving of raw CAN telegrams (11bit and 29bit identifiers)
- reading of diagnosis information
- controlling of the NMT state machine of a CANopen node
- reading and writing of service data objects (SDOs)
- resetting of internal error counters
- reading of handshake error counters of synchronous IO update
- deactivating or activating of a CANopen node.

Additional system libraries are required by this library:

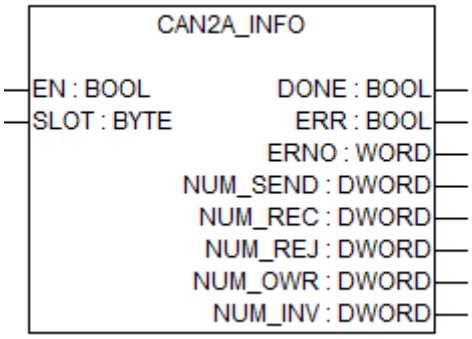
- CANopen_CME_AC500_V25.lib
- CANopen_CMN_AC500_V25.lib
- CMN_AC500_V24.lib
- SysExt_AC500_V10.lib

The CANopen library and the required system libraries will be automatically added to the PLC application when a CANopen master communication module is configured in the PLC configuration.

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

1.5.4.7.1 Function blocks

CAN2A_INFO

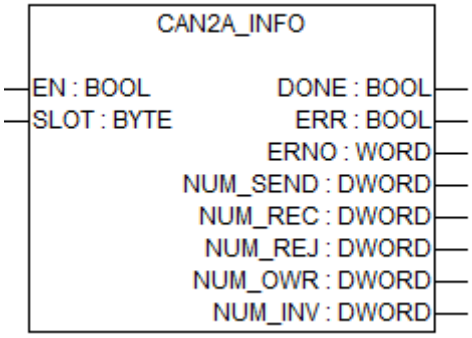


Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

The function block CAN2A_INFO outputs information concerning the status of the CAN 2.0A communication.

Input description

Using the function block CAN2A_INFO, various status information about the CAN 2.0A communication can be read.



The function block CAN2A_INFO outputs information concerning the status of the CAN 2.0A communication.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

EN

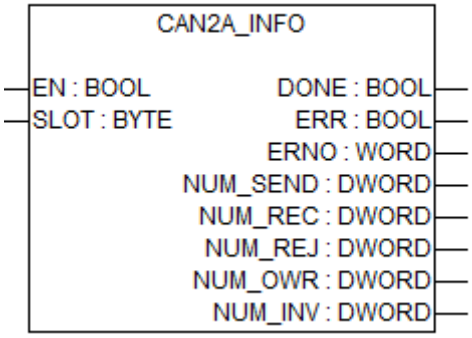
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



The function block CAN2A_INFO outputs information concerning the status of the CAN 2.0A communication.

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_SEND

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_SEND displays the number of transmitted CAN 2.0B telegrams. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept.

NUM_REC

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REC displays the number of received CAN 2.0B telegrams, regardless of whether a corresponding buffer has been set via the PLC configuration or not. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept.

NUM_REJ

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REJ displays the number of CAN 2.0B telegrams rejected due to a full receive buffer. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept. Whether incoming telegrams are generally discarded in case of a full receive buffer or the oldest entry stored in the buffer is always overwritten by a new telegram can be set using the controller configuration.

NUM_OWR

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_OWR displays the number of CAN 2.0B telegrams overwritten by a new incoming telegram due to a full receive buffer. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept. Whether incoming telegrams are generally discarded in case of a full receive buffer or the oldest entry stored in the buffer is always overwritten by a new telegram can be set using the controller configuration.

NUM_INV

Data type	Default value	Range	Unit
DWORD	-	-	-

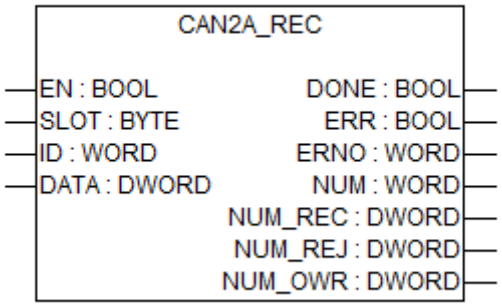
Output NUM_INV displays the number of received CAN 2.0B telegrams that could not be assigned to any buffer defined in the controller configuration. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept.

Function call in ST

```
Info2a (EN      := Info2a_EN,
        SLOT    := Info2a_SLOT);

Info2a_DONE     := Info2a.DONE;
Info2a_ERR      := Info2a.ERR;
Info2a_ERNO     := Info2a.ERNO;
Info2a_NUM_SEND := Info2a.NUM_SEND;
Info2a_NUM_REC  := Info2a.NUM_REC;
Info2a_NUM_REJ  := Info2a.NUM_REJ;
Info2a_NUM_OWR  := Info2a.NUM_OWR;
Info2a_NUM_INV  := Info2a.NUM_INV;
```

CAN2A_REC



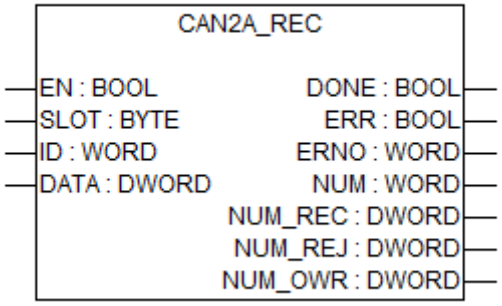
Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

With CAN2A_REC, CAN telegrams with 11 bit identifiers (base frame format or CAN2.0A) can be received.

Each identifier to be received needs a configured receive buffer.

Identifiers without configured receive buffer won´t be considered.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

ID

Data type	Default value	Range	Unit
WORD	-	-	-

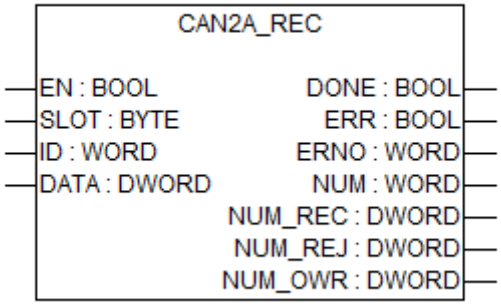
Input ID is used to specify the identifier of the CAN 2.0B telegrams to be read from the buffer. If no buffer has been specified for the selected identifier using the controller configuration, this is indicated accordingly at the function block outputs.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

The input DATA is used to provide the pointer to data structure of the object which is to be written.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM

Data type	Default value	Range	Unit
WORD	-	-	-

Output NUM displays the number of CAN 2.0A telegrams not yet read from the buffer of the selected identifier. Stopping the PLC using the keypad or the online functions "STOP", "Reset" or "Reset (cold)" does not influence the output value.

NUM_REC

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REC displays the number of received CAN 2.0B telegrams, regardless of whether a corresponding buffer has been set via the PLC configuration or not. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept.

NUM_REJ

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REJ displays the number of CAN 2.0B telegrams rejected due to a full receive buffer. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept. Whether incoming telegrams are generally discarded in case of a full receive buffer or the oldest entry stored in the buffer is always overwritten by a new telegram can be set using the controller configuration.

NUM_OWR

Data type	Default value	Range	Unit
DWORD	-	-	-

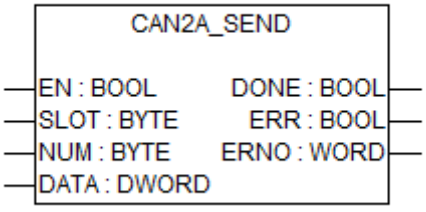
Output NUM_OWR displays the number of CAN 2.0B telegrams overwritten by a new incoming telegram due to a full receive buffer. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept. Whether incoming telegrams are generally discarded in case of a full receive buffer or the oldest entry stored in the buffer is always overwritten by a new telegram can be set using the controller configuration.

Function call in ST

```
Rec2a (EN   := Rec2a_EN,
       SLOT := Rec2a_SLOT,
       ID   := Rec2a_ID,
       DATA := ADR(Rec2a_DATA));

Rec2a_DONE     := Rec2a.DONE;
Rec2a_ERR      := Rec2a.ERR;
Rec2a_ERNO     := Rec2a.ERNO;
Rec2a_NUM      := Rec2a.NUM;
Rec2a_NUM_REC  := Rec2a.NUM_REC;
Rec2a_NUM_REJ  := Rec2a.NUM_REJ;
Rec2a_NUM_OWR  := Rec2a.NUM_OWR;
```

CAN2A_SEND



Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

Using CAN2A_SEND, CAN telegrams with 11 bit identifiers according to CAN 2.0A can be transmitted.

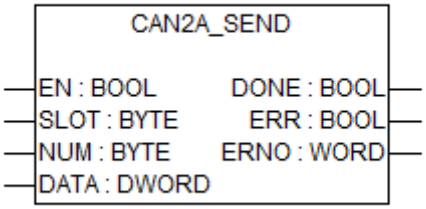
Every time a FALSE->TRUE edge is applied to input EN, CAN2A_SEND reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE->TRUE edges at input EN are ignored until the processing of the active requests is completed. The completion of the request processing is indicated by DONE = TRUE and ERR = FALSE. A possibly occurring error is indicated by output ERR = TRUE.

The function block is able to transmit several telegrams to the Communication Module within one event. The Communication Module in turn transmits these telegrams sequentially via the bus.

When the function block is used with the Communication Module CM578-CAN the total length is 254 bytes. Thus, the maximum number of simultaneously transmitted telegrams depends on the sum of the individual telegram lengths. If all telegrams to be transmitted do not contain any other data than the 2 header bytes (identifier, RTR and DLC; Data Length Code DLC = 0), up to 127 telegrams can be transmitted at the same time (2 x 127 = 254). However, if all telegrams contain the maximum 8 bytes of data, only up to 25 telegrams can be transmitted to the Communication Module simultaneously ((2 + 8) x 25 = 250).

When the function block is used with the Communication Module CM598-CN the number of frames which can be sent at once is limited to 16.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NUM

Data type	Default value	Range	Unit
BYTE	-	-	-

Input NUM is used to specify the number of valid telegrams to be transmitted and stored starting at address DATA.

When the function block is used with the Communication Module CM578-CN, the upper limit of input NUM depends on the total length of all telegrams. The total length is calculated by the function block from the data length codes (DLC) of the individual telegrams and must not exceed 254 bytes. Otherwise an error message is generated. In such cases, the number of telegrams to be transmitted has to be chosen correspondingly that the total length does not exceed 254.

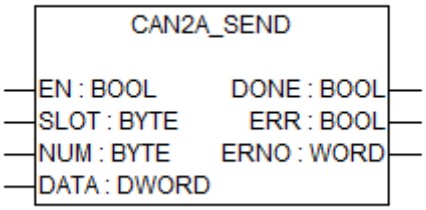
When the function block is used with the Communication Module CM598-CN the upper limit of input NUM is 16.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

The input DATA is used to provide the pointer to data structure of the object which is to be written.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

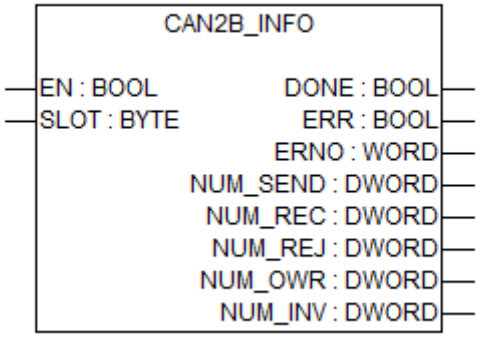
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
Send2a (  EN   := Send2a_EN,
          SLOT := Send2a_SLOT,
          NUM  := Send2a_NUM,
          DATA := ADR(Send2a_DATA));

Send2a_DONE    := Send2a.DONE;
Send2a_ERR     := Send2a.ERR;
Send2a_ERNO    := Send2a.ERNO;
```

CAN2B_INFO

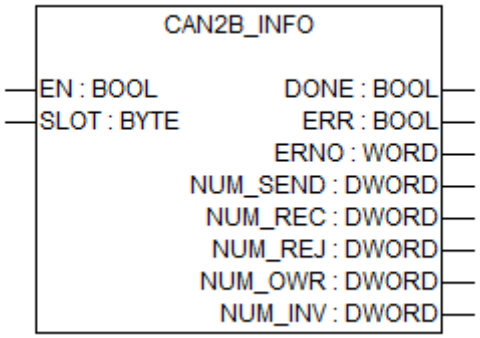


Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

The function block CAN2B_INFO outputs information concerning the status of the CAN 2.0B communication.

Input description

Using CAN2B_INFO, various status information about the CAN 2.0B communication can be read.



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

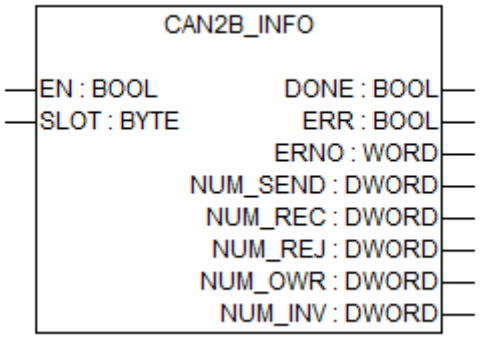
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_SEND

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_SEND displays the number of transmitted CAN 2.0B telegrams. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept.

NUM_REC

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REC displays the number of received CAN 2.0B telegrams, regardless of whether a corresponding buffer has been set via the PLC configuration or not. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept.

NUM_REJ

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REJ displays the number of CAN 2.0B telegrams rejected due to a full receive buffer. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept. Whether incoming telegrams are generally discarded in case of a full receive buffer or the oldest entry stored in the buffer is always overwritten by a new telegram can be set using the controller configuration.

NUM_OWR

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_OWR displays the number of CAN 2.0B telegrams overwritten by a new incoming telegram due to a full receive buffer. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept. Whether incoming telegrams are generally discarded in case of a full receive buffer or the oldest entry stored in the buffer is always overwritten by a new telegram can be set using the controller configuration.

NUM_INV

Data type	Default value	Range	Unit
DWORD	-	-	-

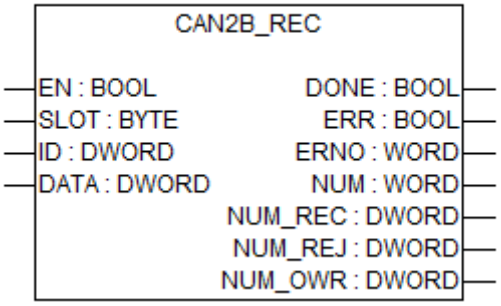
Output NUM_INV displays the number of received CAN 2.0B telegrams that could not be assigned to any buffer defined in the controller configuration. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept.

Function call in ST

```
Info2b ( EN      := Info2b_EN,
         SLOT    := Info2b_SLOT);

Info2b_DONE     := Info2b.DONE;
Info2b_ERR      := Info2b.ERR;
Info2b_ERNO     := Info2b.ERNO;
Info2b_NUM_SEND := Info2b.NUM_SEND;
Info2b_NUM_REC  := Info2b.NUM_REC;
Info2b_NUM_REJ  := Info2b.NUM_REJ;
Info2b_NUM_OWR  := Info2b.NUM_OWR;
Info2b_NUM_INV  := Info2b.NUM_INV;
```

CAN2B_REC



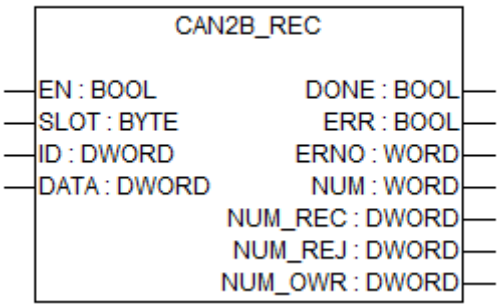
Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

With CAN2B_REC, CAN telegrams with 29 bit identifiers (extended frame format or CAN2.0B) can be received.

In the configuration the "extended" format" must be activated and the ID filter has to be parameterized accordingly. In addition each identifier to be received needs a configured receive buffer.

Identifiers without configured receive buffer won´t be considered.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

ID

Data type	Default value	Range	Unit
WORD	-	-	-

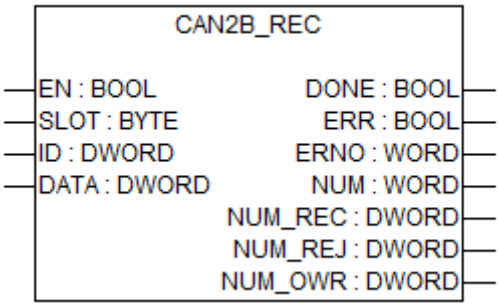
Input ID is used to specify the identifier of the CAN 2.0B telegrams to be read from the buffer. If no buffer has been specified for the selected identifier using the controller configuration, this is indicated accordingly at the function block outputs.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

The input DATA is used to provide the pointer to data structure of the object which is to be written.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM

Data type	Default value	Range	Unit
WORD	-	-	-

Output NUM displays the number of CAN 2.0A telegrams not yet read from the buffer of the selected identifier. Stopping the PLC using the keypad or the online functions "STOP", "Reset" or "Reset (cold)" does not influence the output value.

NUM_REC

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REC displays the number of received CAN 2.0B telegrams, regardless of whether a corresponding buffer has been set via the PLC configuration or not. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept.

NUM_REJ

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REJ displays the number of CAN 2.0B telegrams rejected due to a full receive buffer. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept. Whether incoming telegrams are generally discarded in case of a full receive buffer or the oldest entry stored in the buffer is always overwritten by a new telegram can be set using the controller configuration.

NUM_OWR

Data type	Default value	Range	Unit
DWORD	-	-	-

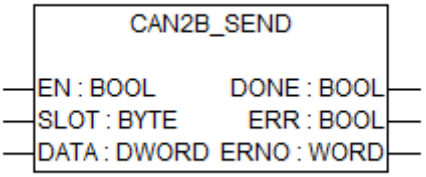
Output NUM_OWR displays the number of CAN 2.0B telegrams overwritten by a new incoming telegram due to a full receive buffer. The value can be reset to 0 using the online functions "Reset" or "Reset (cold)". Stopping the PLC via the keypad or the online function "STOP" does not influence the output. In this case, the values are kept. Whether incoming telegrams are generally discarded in case of a full receive buffer or the oldest entry stored in the buffer is always overwritten by a new telegram can be set using the controller configuration.

Function call in ST

```
Rec2b (   EN   := Rec2b_EN,
          SLOT := Rec2b_SLOT,
          ID   := Rec2b_ID,
          DATA := ADR(Rec2b_DATA));

Rec2b_DONE     := Rec2b.DONE;
Rec2b_ERR      := Rec2b.ERR;
Rec2b_ERNO     := Rec2b.ERNO;
Rec2b_NUM      := Rec2b.NUM;
Rec2b_NUM_REC  := Rec2b.NUM_REC;
Rec2b_NUM_REJ  := Rec2b.NUM_REJ;
Rec2b_NUM_OWR  := Rec2b.NUM_OWR;
```

CAN2B_SEND



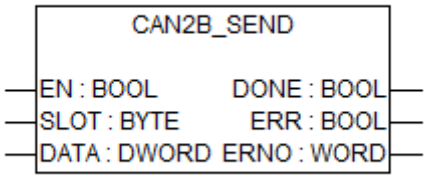
Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5:3
Type	Function block with historical values

Using CAN2B_SEND, CAN telegrams with 29 bit identifiers according to CAN 2.0B can be transmitted.

Every time a FALSE->TRUE edge is applied to input EN, CAN2B_SEND reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE->TRUE edges at input EN are ignored until the processing of the active requests is completed. The completion of the request processing is indicated by DONE = TRUE and ERR = FALSE. A possibly occurring error is indicated by output ERR = TRUE.

Only one CAN 2.0B can be sent with each transmission.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

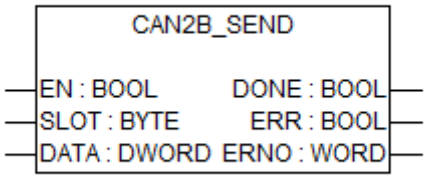
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

The input DATA is used to provide the pointer to data structure of the object which is to be written.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

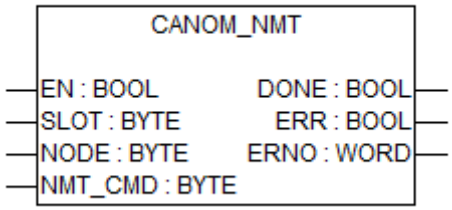
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
Send2b (  EN   := Send2b_EN,
          SLOT := Send2b_SLOT,
          DATA := ADR(Send2b_DATA));

Send2b_DONE    := Send2b.DONE;
Send2b_ERR     := Send2b.ERR;
Send2b_ERNO    := Send2b.ERNO;
```

CANOM_NMT



Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

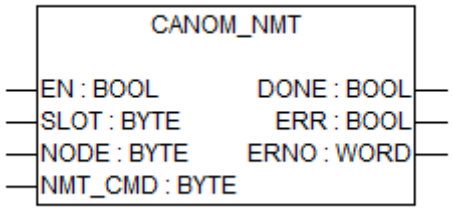
CANOM_NMT can be used to control the NMT state machine of one specific or all slaves.

Input description

CANOM_NMT can be used to control the NMT state machine of one specific or all slaves.

Every time a FALSE->TRUE edge is applied to input EN, CANOM_NMT reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE->TRUE edges at input EN are ignored until the processing of the active requests is completed. The completion of the request processing is indicated by DONE = TRUE.

Normally, control of the slave operating states is performed by the automatic control of the CANopen Communication Module used as NMT master. However, for special applications it can be required to change the state of a specific slave 'manually'. This functionality can be achieved using CANOM_NMT.



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
BYTE	-	1...127	-

The Input NODE specifies the node ID of the slave.

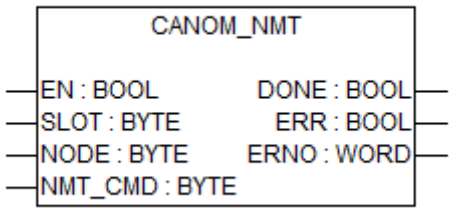
NMT_CMD

Data type	Default value	Range	Unit
BYTE	-	-	-

At input NMT_CMD, the NMT command to be sent is specified. The following NMT commands are defined:

NMT command	Constant	Meaning
1	CANOM_NMT_CMD_START	Start remote node (slave)
2	CANOM_NMT_CMD_STOP	Stop remote node (slave)
128	CANOM_NMT_CMD_ENTER_PREOP	Enter pre-operational: Set slave to pre-operational mode
129	CANOM_NMT_CMD_RESET_NODE	Reset node (slave)
130	CANOM_NMT_CMD__RESET_COM	Reset communication

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

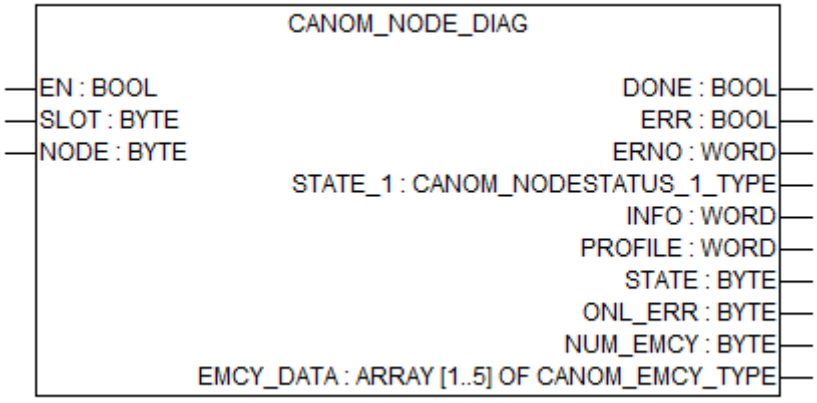
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
Nmt( EN       := Nmt_EN,
     SLOT     := Nmt_SLOT,
     NODE     := Nmt_NODE,
     NMT_CMD := Nmt_NMT_CMD);

Nmt_DONE      := Nmt.DONE;
Nmt_ERR       := Nmt.ERR;
Nmt_ERNO      := Nmt.ERNO;
```

CANOM_NODE_DIAG



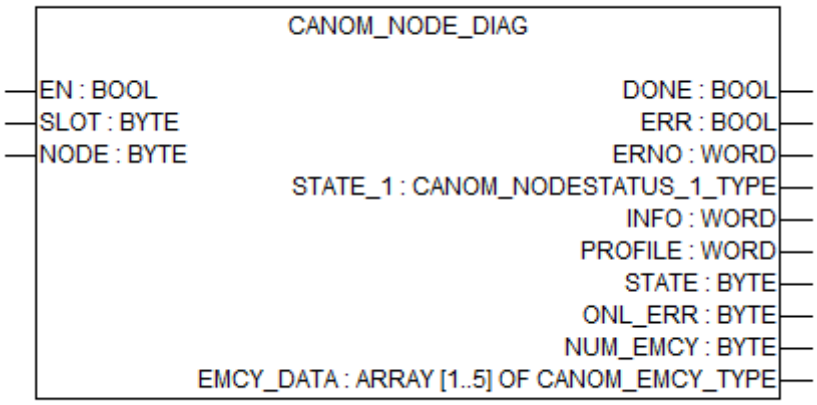
Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

Using the function block CANOM_NODE_DIAG, diagnosis data of the individual slaves can be requested.

Every time a FALSE->TRUE edge is applied at input EN, CANOM_NODE_DIAG reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE->TRUE edges at input EN are ignored until the processing of the active requests is completed. The completion of the request processing is indicated by DONE = TRUE.

The function block CANOM_NODE_DIAG is not supported by the Communication Module CM598-CAN. For the Communication Module CM598-CAN should be used the function block CANOM_NODE_DIAG_EXT.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

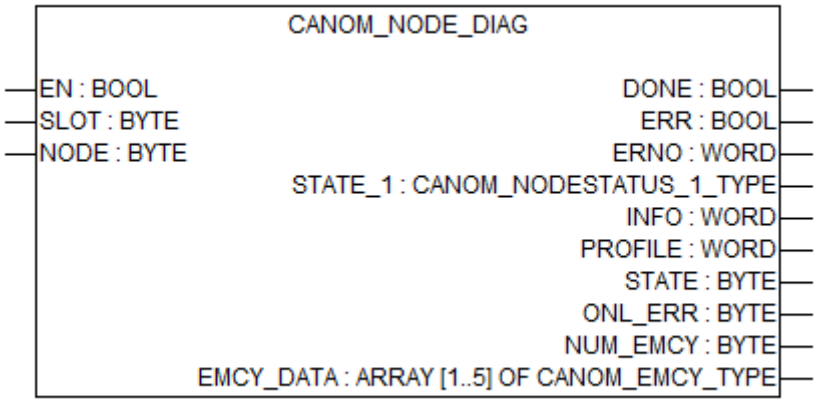
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
BYTE	-	1...127	-

The Input NODE specifies the node ID of the slave.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE_1

Data type	Default value	Range	Unit
CANOM_NODES-TATUS_1_TYPE	-	-	-

The output STATE_1 provides diagnosis flags of the specified device.

INFO

Data type	Default value	Range	Unit
WORD	-	-	-

Output INFO provides additional information according to the CiA specification from the object 16#1000.

PROFILE

Data type	Default value	Range	Unit
WORD	-	-	-

Output PROFILE provides the profile number according to the CiA specification from the object 16#1000.

STATE

Data type	Default value	Range	Unit
BYTE	-	-	-

Output STATE provides the current operating condition of the relevant slave. STATE is only valid if DONE = TRUE and ERR = FALSE.

The following table describes the possible values of STATE and their meanings as specified in the CANopen specification.

STATE	Description
1	Disconnected
2	Connecting
3	Preparing
4	Prepared
5	Operational
127	Pre-Operational

ONL_ERR

Data type	Default value	Range	Unit
BYTE	-	-	-

ONL_ERR outputs a value describing possibly existing communication errors between the master Communication Module and the slave. ONL_ERR is only valid if DONE = TRUE and ERR = FALSE.

The error identifiers of ONL_ERR correspond to the IDs of output CANOM_ERR.EVENT of the function block CANOM_STATE. They are described in the table provided in the CANOM_STATE Function Block description.

NUM_EMCY

Data type	Default value	Range	Unit
BYTE	0	0 ... 5	-

NUM_EMCY provides the number of emergency messages contained in EMCY_DATA.

EMCY_DATA

Data type	Default value	Range	Unit
ARRAY OF CANOM_EMCY_TYPE	-	1 ... 5	-

EMCY_DATA outputs the up to 5 buffered emergency messages of the slave. The number of valid messages is output by NUM_EMCY.

EMCY_DATA is only valid if DONE = TRUE and ERR = FALSE.

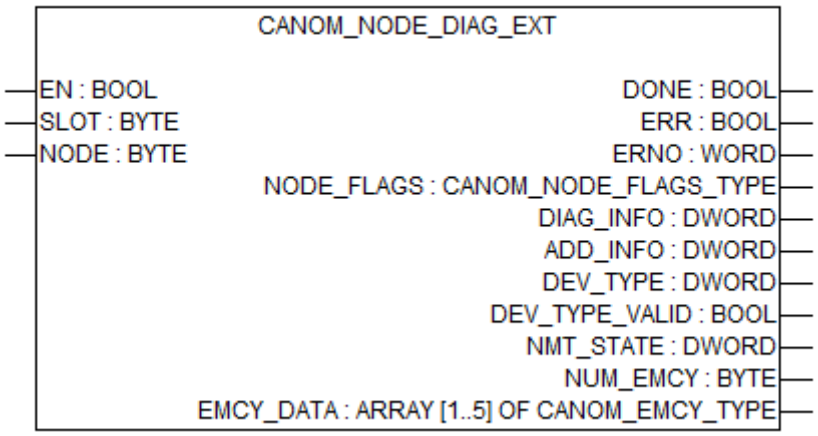
The structure of the type CANOM_EMCY_TYPE is defined in the CANopen library.

Function call in ST

```
NodeDiag(  EN       := NodeDiag_EN,
           SLOT     := NodeDiag_SLOT,
           NODE     := NodeDiag_NODE;

NodeDiag_DONE       := NodeDiag.DONE;
NodeDiag_ERR        := NodeDiag.ERR;
NodeDiag_ERNO       := NodeDiag.ERNO;
NodeDiag_STATE_1    := NodeDiag.STATE_1;
NodeDiag_INFO       := NodeDiag.INFO;
NodeDiag_PROFILE    := NodeDiag.PROFILE;
NodeDiag_STATE      := NodeDiag.STATE;
NodeDiag_ONL_ERR    := NodeDiag.ONL_ERR;
NodeDiag_NUM_EMCY   := NodeDiag.NUM_EMCY;
NodeDiag_EMCY_DATA  := NodeDiag.EMCY_DATA;
```

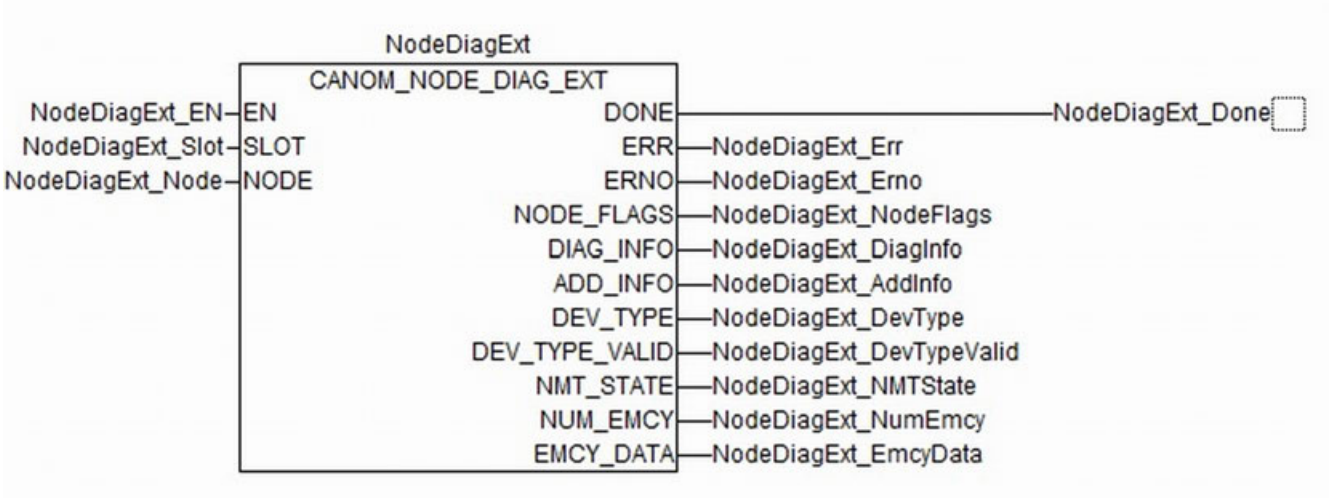
CANOM_NODE_DIAG_EXT



The function block CANOM_NODE_DIAG_EXT reads the diagnosis data of a slave.

Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

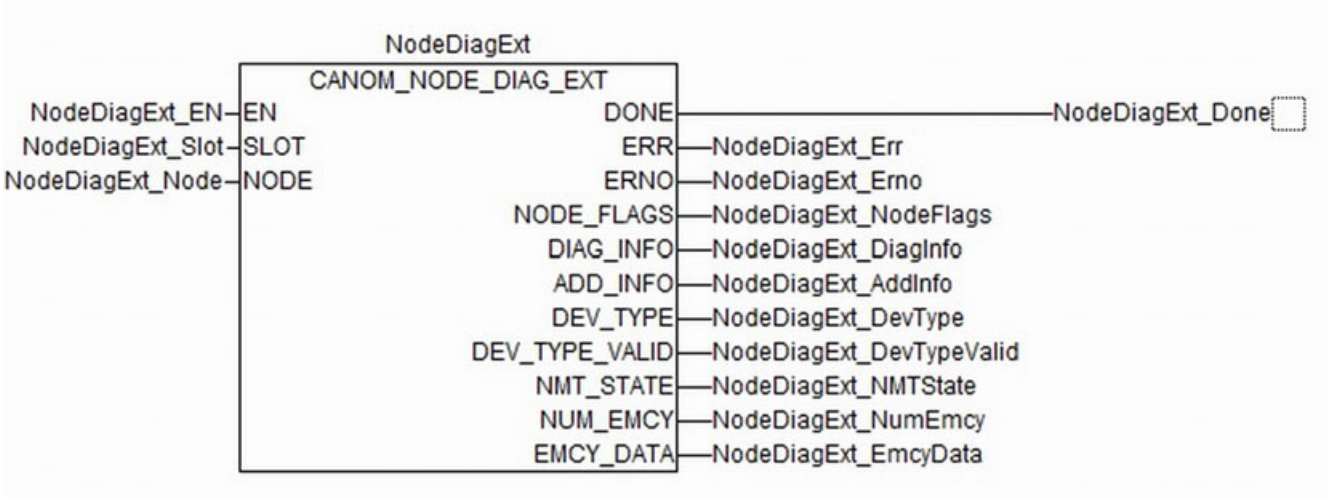
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
BYTE	-	1...127	-

The Input NODE specifies the node ID of the slave.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NODE_FLAGS

Data type	Default value	Range	Unit
CANOM_NODE_FLAGS_TYPE	-	-	-

Output NODE_FLAGS provides diagnosis flags of the specified device.

DIAG_INFO

Data type	Default value	Range	Unit
DWORD	0	-	-

Output DIAG_INFO provides the last diagnosis info of the specific device.

The output can have the following values:

Value	Description
16#40420053	State of Node was not handled
16#C042004B	Connection to Node is lost
16#C042004D	Error of heartbeat protocol
16#C042004C	Error of guarding protocol
16#C042004A	Node is in an unexpected state
16#4042004E	Heartbeat protocol was started for the node
16#C0420027	Timeout exceeded during SDO transfer
16#C0420028	Error occurred during SDO transfer
16#C0420054	The device type of node is not equal to configured value
16#C042004F	Unexpected bootup message from the node was received
16#40420055	Emergency message from node was received

ADD_INFO

Data type	Default value	Range	Unit
DWORD	0	-	-

Output ADD_INFO provides additional information.

DEV_TYPE

Data type	Default value	Range	Unit
DWORD	0	-	-

Output DEV_TYPE provides the device type according to the CiA specification from the object 16#1000.

NMT_STATE

Data type	Default value	Range	Unit
DWORD	0	-	-

Output NMT_STATE provides the current NMT state of the specified CANopen device. The output can have the following values:

Value	Constant	Description
16#00000000	CANOM_NODE_NMT_STATE_UNKNOWN	Node NMT State is unknown
16#00000001	CANOM_NODE_NMT_STATE_INITIALISING	Node NMT State INITIALISING
16#00000002	CANOM_NODE_NMT_STATE_STOPPED	Node NMT State STOPPED
16#00000003	CANOM_NODE_NMT_STATE_OPERATIONAL	Node NMT State OPERATIONAL
16#00000004	CANOM_NODE_NMT_STATE_PRE_OPERATIONAL	Node NMT State PRE_OPERATIONAL
16#00000005	CANOM_NODE_NMT_STATE_RESET_APPLICATION	Node NMT State RESET_APPLICATION
16#00000006	CANOM_NODE_NMT_STATE_RESET_COMM	Node NMT State RESET_COMM

NUM_EMCY

Data type	Default value	Range	Unit
BYTE	0	0 ... 5	-

NUM_EMCY provides the number of emergency messages contained in EMCY_DATA.

EMCY_DATA

Data type	Default value	Range	Unit
ARRAY OF CANOM_EMCY_TYPE	-	1 ... 5	-

EMCY_DATA outputs the up to 5 buffered emergency messages of the slave. The number of valid messages is output by NUM_EMCY.

EMCY_DATA is only valid if DONE = TRUE and ERR = FALSE.

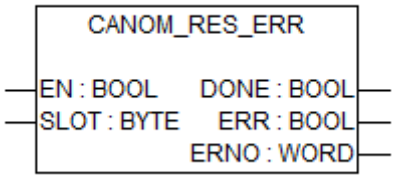
The structure of the type CANOM_EMCY_TYPE is defined in the CANopen library.

Function call in ST

```
NodeDiagExt(  EN       := NodeDiagExt_EN,
              SLOT     := NodeDiagExt_SLOT,
              NODE     := NodeDiagExt_NODE;

NodeDiagExt_DONE      := NodeDiagExt.DONE;
NodeDiagExt_ERR       := NodeDiagExt.ERR;
NodeDiagExt_ERNO      := NodeDiagExt.ERNO;
NodeDiagExt_NodeFlags := NodeDiagExt.NodeFlags;
NodeDiagExt_DiagInfo  := NodeDiagExt.DIAG_INFO;
NodeDiagExt_AddInfo   := NodeDiagExt.ADD_INFO;
NodeDiagExt_DevType   := NodeDiagExt.DEV_TYPE;
NodeDiagExt_ONL_ERR   := NodeDiagExt.DEV_TYPE_VALID;
NodeDiagExt_NMTState  := NodeDiagExt.NMT_STATE;
NodeDiagExt_NUM_EMCY  := NodeDiagExt.NUM_EMCY;
NodeDiagExt_EMCY_DATA := NodeDiagExt.EMCY_DATA;
```

CANOM_RES_ERR



Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

The function block CANOM_RES_ERR can be used to reset various internal error indications and counters of the Communication Module.

> *The function block CANOM_RES_ERR is not supported by the Communication Module CM598-CAN.*

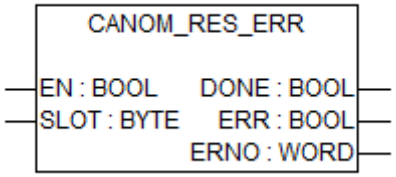
Input description

Using the function block CANOM_RES_ERR it is possible to reset the following Communication Module internal error indications and error counters output via the function block CANOM_STAT:

- STATE_BITS.EVENT
- STATE_BITS.TIMEOUT
- BUS_ERR
- BUS_OFF
- TOUT_ERR
- LOST_REC

For explanations of the error indications please refer to the description of the function block CANOM_STATE *Chapter 1.5.4.7.1.14 “CANOM_STATE ” on page 952*.

The reset is initiated by a FALSE->TRUE edge at input EN.



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

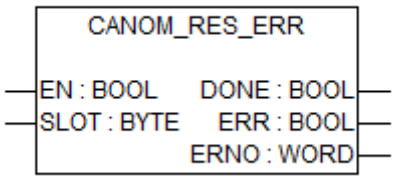
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

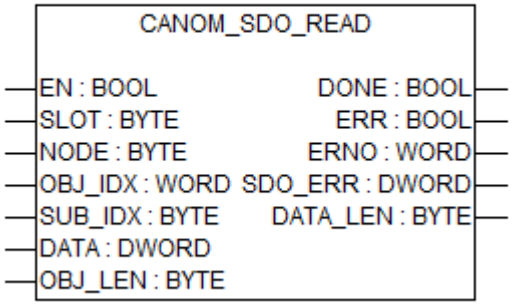
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
ResErr( EN    := ResErr_EN,
        SLOT  := ResErr_SLOT);

ResErr_DONE   := ResErr.DONE;
ResErr_ERR    := ResErr.ERR;
ResErr_ERNO   := ResErr.ERNO;
```

CANOM_SDO_READ



The function block CANOM_SDO_READ can be used to read individual service data objects (SDOs) from a slave.

In the library CANopen_AC500_V25.lib the function block CANOM_SDO_READ was extended with the input OBJ_LEN.

Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

Using the function block CANOM_SDO_READ it is possible to read service data objects (SDOs) from a slave.

Every time a FALSE->TRUE edge is applied to input EN, CANOM_SDO_READ reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE->TRUE edges at input EN are ignored until the processing of the active requests is completed. The completion of the request processing is indicated by DONE = TRUE.

The CANopen object model is defined in the communication profile and device profile specifications (see also System Technology of the CANopen Communication Modules). Furthermore, the device-specific objects are explained in the corresponding device description of the slave.

Input description

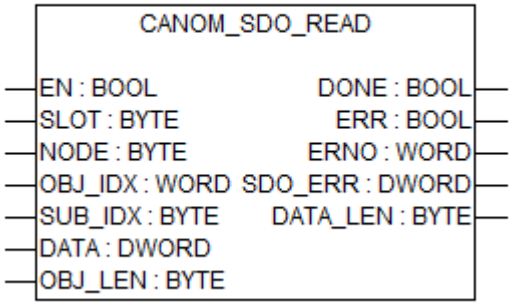


Fig. 15: CANOM_SDO_READ

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
BYTE	-	1...127	-

The Input NODE specifies the node ID of the slave.

OBJ_IDX

Data type	Default value	Range	Unit
WORD	-	-	-

Input OBJ_IDX is used to specify the object index of the object which is to be written.

SUB_IDX

Data type	Default value	Range	Unit
BYTE	-	-	-

Input SUB_IDX is used to specify the sub index of the object which is to be written.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

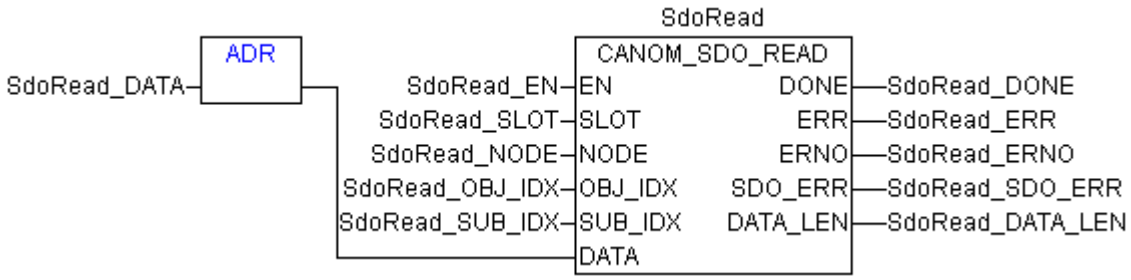
The input DATA is used to provide the pointer to data structure of the object which is to be written.

OBJ_LEN

Data type	Default value	Range	Unit
BYTE	0	0 ... 247	Number of Bytes

Input OBJ_LEN is used to specify the length of the object to be read from the CANopen slave.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

SDO_ERR

Data type	Default value	Range	Unit
DWORD	-	-	-

If the slave answered the SDO message with an abort message, the transmitted error code is output at SDO_ERR. The value output at SDO_ERR is only valid if DONE = TRUE, ERR = TRUE and ERNO = 6003hex (24579dec).

DATA_LEN

Data type	Default value	Range	Unit
BYTE	-	-	-

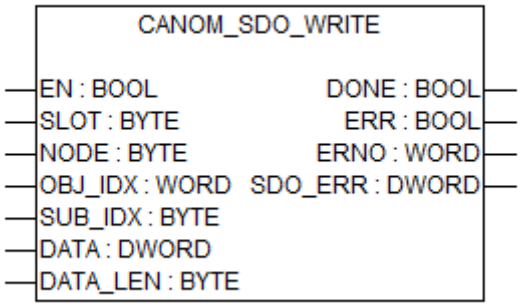
Input DATA_LEN is used to specify the size of the data structure which is provided at Input DATA.

Function call in ST

```
SdoRead ( EN       := SdoRead_EN,
          SLOT     := SdoRead_SLOT,
          NODE     := SdoRead_NODE,
          OBJ_IDX  := SdoRead_OBJ_IDX
          SUB_IDX  := SdoRead_SUB_IDX
          DATA     := ADR(SdoRead_DATA);

SdoRead_DONE       := SdoRead.DONE;
SdoRead_ERR        := SdoRead.ERR;
SdoRead_ERNO       := SdoRead.ERNO;
SdoRead_SDO_ERR    := SdoRead.SDO_ERR;
SdoRead_DATA_LEN   := SdoRead.DATA_LEN;
```

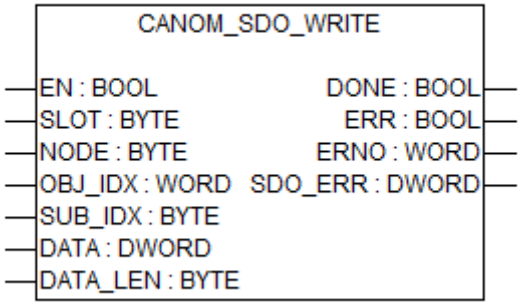
CANOM_SDO_WRITE



Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

The function block CANOM_SDO_WRITE provides write access to the Object Directory of a CANopen slave using the SDO protocol.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
BYTE	-	1...127	-

The Input NODE specifies the node ID of the slave.

OBJ_IDX

Data type	Default value	Range	Unit
WORD	-	-	-

Input OBJ_IDX is used to specify the object index of the object which is to be written.

SUB_IDX

Data type	Default value	Range	Unit
BYTE	-	-	-

Input SUB_IDX is used to specify the sub index of the object which is to be written.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

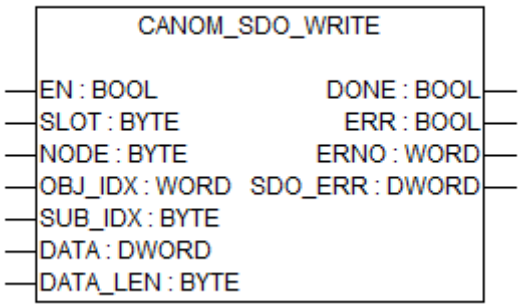
The input DATA is used to provide the pointer to data structure of the object which is to be written.

DATA_LEN

Data type	Default value	Range	Unit
BYTE	-	-	-

Input DATA_LEN is used to specify the size of the data structure which is provided at Input DATA.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

SDO_ERR

Data type	Default value	Range	Unit
DWORD	-	-	-

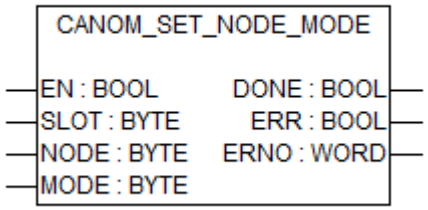
If the slave answered the SDO message with an abort message, the transmitted error code is output at SDO_ERR. The value output at SDO_ERR is only valid if DONE = TRUE, ERR = TRUE and ERNO = 6003hex (24579dec).

Function call in ST

```
SdoWrite (EN       := SdoWrite_EN,
          SLOT     := SdoWrite_SLOT,
          NODE     := SdoWrite_NODE,
          OBJ_IDX  := SdoWrite_OBJ_IDX,
          SUB_IDX  := SdoWrite_SUB_IDX,
          DATA     := ADR(SdoWrite_DATA,
          DATA_LEN := ADR(SdoWrite_DATA_LEN);

SdoWrite_DONE       := SdoWrite.DONE;
SdoWrite_ERR        := SdoWrite.ERR;
SdoWrite_ERNO       := SdoWrite.ERNO;
SdoWrite_SDO_ERR    := SdoWrite.SDO_ERR;
```

CANOM_SET_NODE_MODE



Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

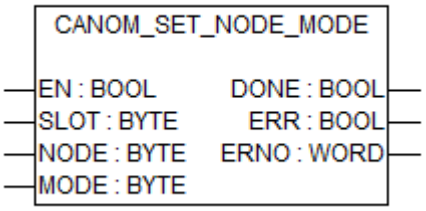
Using the function block CANOM_SET_NODE_MODE, one specific CANopen node can be deactivated or activated.

Every time a FALSE -> TRUE edge is applied to input EN, CANOM_SET_NODE_MODE reads the data at its inputs and sends a corresponding request message to the Communication Module.

Further FALSE -> TRUE edges at input EN are ignored until the processing of the active requests is completed. The completion of the request processing is indicated by DONE = TRUE.

All configured CANopen nodes are activated by default and are controlled by the CANopen Communication Module used as NMT master. However, for special applications it can be required to deactivate or activate one specific CANopen node 'manually'. This functionality can be achieved using CANOM_SET_NODE_MODE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

NODE

Data type	Default value	Range	Unit
BYTE	-	1...127	-

The Input NODE specifies the node ID of the slave.

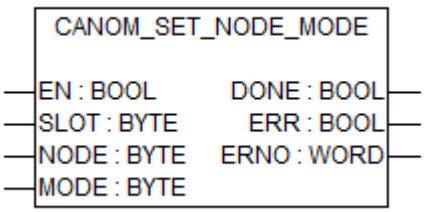
MODE

Data type	Default value	Range	Unit
BYTE	-	-	-

At input MODE, the mode of the CANopen node is specified. The following modes are defined:

NMT com-mand	Constant	Meaning
1	CANOM_NODE_MODE_ACTIVATE	Activate remote node (slave)
2	CANOM_NODE_MODE_DEACTIVATE	Deactivate remote node (slave)

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

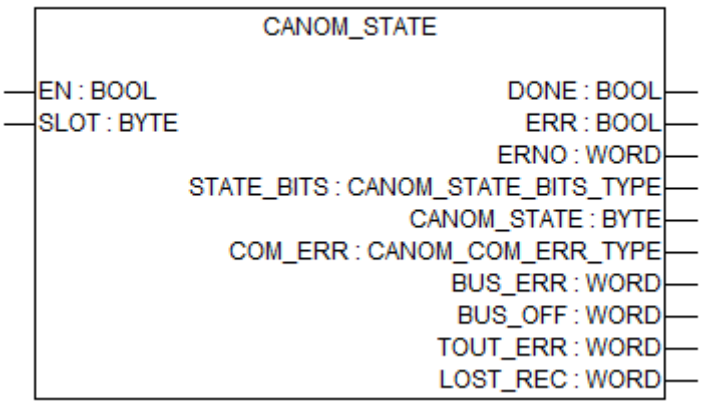
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
SetNodeMode(     EN    := SetNodeMode_EN,
                          SLOT    := SetNodeMode_SLOT,
                          NODE    := SetNodeMode_NODE,
                          MODE    := SetNodeMode_MODE);

SetNodeMode_DONE    := SetNodeMode.DONE;
SetNodeMode_ERR     := SetNodeMode.ERR;
SetNodeMode_ERNO    := SetNodeMode.ERNO;
```

CANOM_STATE

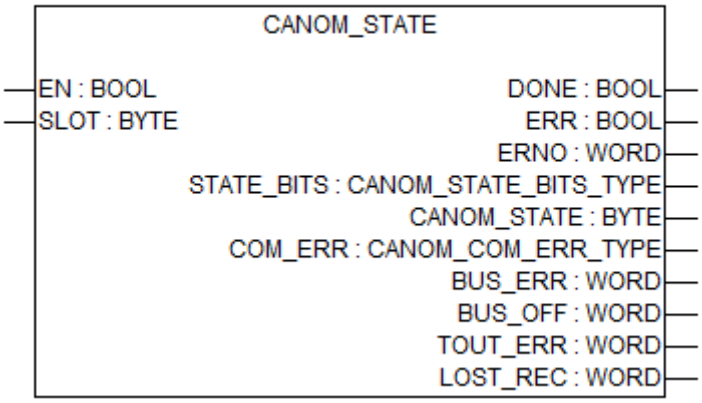


Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

The function block CANOM_STATE outputs the status of a CANopen Communication Module. The outputs provide information about the communication status and error events.

CANOM_STATE is active if input EN = TRUE. If the function block is active and if no errors occurred during Function Block processing, the current values are permanently displayed at the outputs.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

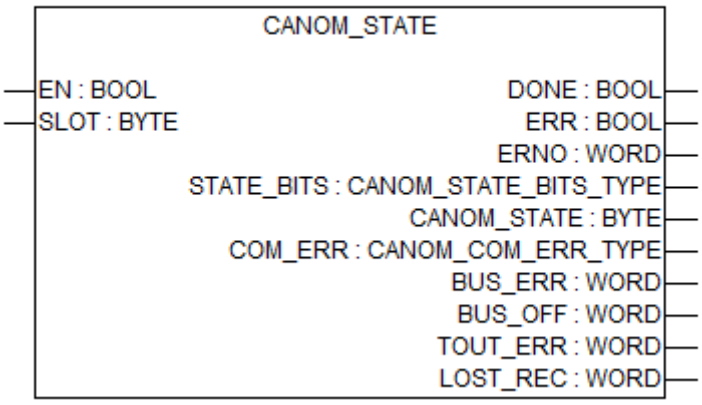
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE_BITS

Data type	Default value	Range	Unit
CANOM_STATE_BITS_TYPE	-	-	-

The Output STATE_BITS provides error or diagnosis flags of the CANopen Communication Module.

Some of them can be reset using the function block CANOM_RES_ERR *Chapter 1.5.4.7.1.10 “CANOM_RES_ERR” on page 941*.

CANOM_STATE

Data type	Default value	Range	Unit
BYTE	-	-	-

CANOM_STATE outputs the general communication state of the CANopen master. The following states are defined:

State		Meaning
Dec	**Hex**	
0	00	OFFLINE
64	40	STOP
128	80	CLEAR
192	C0	OPERATE

CANOM_STATE = OFFLINE

If CANOM_STATE is set to OFFLINE, the CANopen Communication Module performs an initialization. After the initialization phase is completed, the Communication Module changes to STOP state.

CANOM_STATE = STOP

If CANOM_STATE has the value STOP, the Communication Module is completely initialized. In this state the Communication Module is ready to receive configuration data. There is no data exchange with the slaves. The Communication Module has this state if no user program is running.

CANOM_STATE = CLEAR

If the user program is started, the Communication Module changes from STOP to CLEAR and starts to establish the connections defined during configuration. When the setup has been completed successfully, the Communication Module moves to OPERATE state. If an error occurs during parameterization, the Communication Module changes back to STOP state.

CANOM_STATE = OPERATE

Normally, the Communication Module is in OPERATE state while a user program is running. In this state the master exchanges I/O data with the slaves. If an error occurs during this process and if ‘Auto Clear Mode’ has been selected during configuration, the Communication Module changes back to CLEAR state and tries to establish the connections again. If ‘Auto Clear Mode’ has not been selected during configuration, the Communication Module remains in OPERATE state in case of an error. If the user program is stopped, the Communication Module also changes back to STOP state.

CANOM_STATE is only valid, if EN = TRUE and ERR = FALSE.

COM_ERR

Data type	Default value	Range	Unit
CANOM_COM_ERR_TYPE	-	-	-

The Output COM_ERR provides detailed information to the corresponding output STATE_BITS.

The element Address contains the node address of the faulty device and the element Event the error code.

If several errors occur simultaneously, the output contains the error of the device with the lowest address.

COM_ERR can be reset using the function block CANOM_RES_ERR *Chapter 1.5.4.7.1.10 “CANOM_RES_ERR” on page 941*.

BUS_ERR

Data type	Default value	Range	Unit
WORD	-	-	-

BUS_ERR outputs the number of occurred bus errors. A bus error occurs if the internal error frame counter exceeds a specific value. BUS_ERR is only valid if EN = TRUE and ERR = FALSE.

BUS_ERR can be reset using the function block CANOM_RES_ERR *Chapter 1.5.4.7.1.10 “CANOM_RES_ERR” on page 941*.

BUS_OFF

Data type	Default value	Range	Unit
WORD	-	-	-

BUS_OFF outputs how often the Communication Module has been excluded from bus activities. An exclusion from the bus activities is performed, if an overflow of the internal error frame counter occurs. The Communication Module is automatically re-initialized after each overflow. BUS_OFF is only valid, if EN = TRUE and ERR = FALSE.

BUS_OFF can be reset using the function block CANOM_RES_ERR *Chapter 1.5.4.7.1.10 “CANOM_RES_ERR” on page 941*.

TOUT_ERR

Data type	Default value	Range	Unit
WORD	-	-	-

TOUT_ERR outputs the number of telegrams that could not be transmitted successfully. The transmission of a telegram is considered as failed, if it could not be transmitted within 20 ms, for instance because the communication partner could not be contacted via the bus. TOUT_ERR is only valid, if EN = TRUE and ERR = FALSE.

TOUT_ERR can be reset using the function block CANOM_RES_ERR.

LOST_REC

Data type	Default value	Range	Unit
WORD	-	-	-

LOST_REC outputs the number of received telegrams that were rejected because they could not be processed successfully due to a CAN chip overload. LOST_REC is only valid, if EN = TRUE and ERR = FALSE.

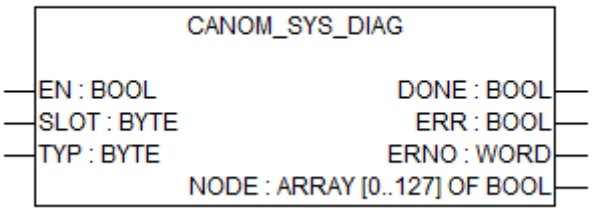
LOST_REC can be reset using the function block CANOM_RES_ERR *Chapter 1.5.4.7.1.10 “CANOM_RES_ERR” on page 941*.

Function call in ST

```
State ( EN         := State_EN,
        SLOT       := State_SLOT);

State_DONE         := State.DONE;
State_ERR          := State.ERR;
State_ERNO         := State.ERNO;
State_STATE_BITS   := State.STATE_BITS;
State_CANOM_STATE  := State.CANOM_STATE;
State_CANOM_ERR    := State.CANOM_ERR;
State_BUS_ERR      := State.BUS_ERR;
State_BUS_OFF      := State.BUS_OFF;
State_TOUT_ERR     := State.TOUT_ERR;
State_LOST_ERR     := State.LOST_ERR;
```

CANOM_SYS_DIAG



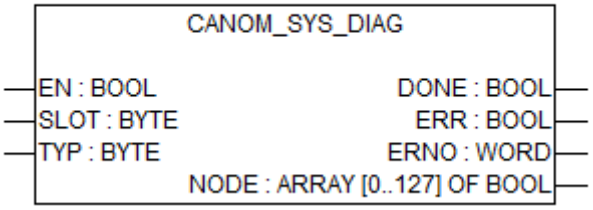
Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

The function block CANOM_SYS_DIAG outputs a bitfield as a state survey of all slaves (nodes) at output NODE. Three different survey types can be selected via input TYP.

The function block CANOM_SYS_DIAG outputs different status surveys of all slaves. Three survey types can be selected:

- configuration survey
- operational survey
- diagnosis survey

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

TYP

Data type	Default value	Range	Unit
BYTE	-	-	-

The input TYP is used to select the type of status survey displayed at output NODE.

TYP = 1 Configuration survey

Output NODE displays which slaves are successfully connected to the master (TRUE). Please note that the master only establishes connections to slaves that have been announced to the master during the definition of the configuration data.

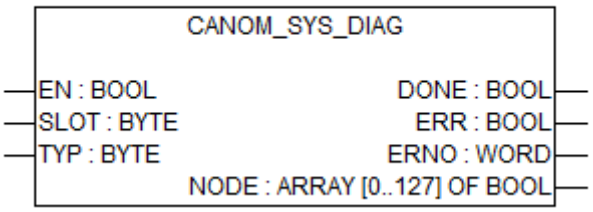
TYP = 2 Operational survey

Output NODE displays which slaves are error-free and in operation. A slave can only be announced as operational if it has been configured in the master. The operational survey can only be requested if the Communication Module is in OPERATE state.

TYP = 3 Diagnosis survey

Output NODE indicates which slaves report a diagnosis. The diagnosis survey can only be requested if the Communication Module is in OPERATE state.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NODE

Data type	Default value	Range	Unit
ARRAY OF BOOL	-	0 ... 127	-

NODE outputs the status survey as a bitfield. Each individual bit within this field represents one slave. The index number corresponds to the slave's node address. If a bit is set to TRUE, the state selected using TYP applies to the corresponding slave.

If e.g. TYP = 1 is selected and NODE[2] = TRUE, the slave with this node address was successfully configured by the master and is currently in operation. If NODE[2] = FALSE, the configuration of the specific slave has not yet been completed or the slave is not part of the master's configuration data.

If TYP = 3, NODE[2] = TRUE for example means that the slave with the node address 2 has received an emergency message or that the diagnosis indication of the slave has changed. In this case, a diagnosis description can be requested using the function block CANOM_NODE_DIAG *Chapter 1.5.4.7.1.8 “CANOM_NODE_DIAG” on page 933*.

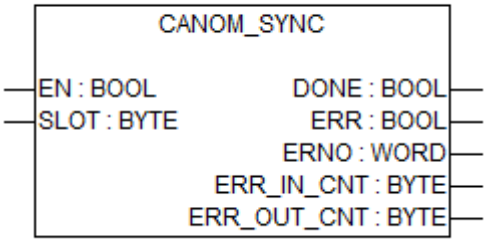
The at "NODE" output bitfield is only valid, if DONE = TRUE and ERR = FALSE.

Function call in ST

```
SysDiag( EN    := SysDiag_EN,
         SLOT  := SysDiag_SLOT,
         TYP   := SysDiag_TYP);

SysDiag_DONE   := SysDiag.DONE;
SysDiag_ERR    := SysDiag.ERR;
SysDiag_ERNO   := SysDiag.ERNO;
SysDiag_NODE   := SysDiag.NODE;
```

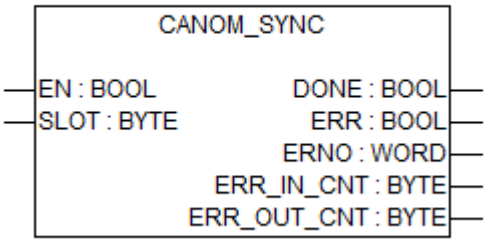
CANOM_SYNC



Parameter	Value
Included in library	CANopen_AC500_V25.lib
Available as of firmware	V2.5.3
Type	Function block with historical values

CANOM_SYNC is used to read the handshakes error counters of synchronous IO update mode. The counter ERR_IN_CNT will be set by the CANopen Master, when the IEC task was not started within the current bus cycle. And when the IEC task was not finished within the current bus cycle it will set the counter ERR_OUT_CNT.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

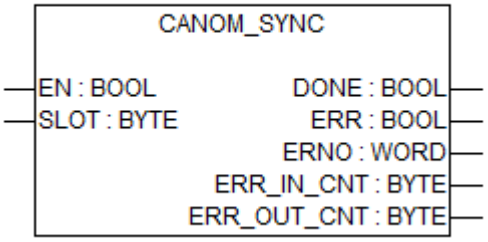
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ERR_IN_CNT

Data type	Default value	Range	Unit
BYTE	-	0 ... 255	-

At Output ERR_IN_CNT the number of input handshake errors are provided.

ERR_OUT_CNT

Data type	Default value	Range	Unit
BYTE	-	0 ... 255	-

At Output ERR_OUT_CNT the number of output handshake errors are provided.

Function call in ST

```
CANSync (EN  :=xCANSync_EN,
         SLOT  :=byCANSync_SLOT);

xCANSync_DONE          := CANSync.DONE;
xCANSync_ERR           := CANSync.ERR;
byCANSync_ERNO         := CANSync.ERNO;
byCANSync_ERR_IN_CNT   := CANSync.ERR_IN_CNT;
byCANSync_ERR_OUT_CNT  := CANSync.ERR_OUT_CNT;
```

1.5.4.7.2 Structures group CAN

Group: CAN	
CAN2A_MESSAGE_TYPE	Telegram structure according to CAN 2.0A
CAN2B_MESSAGE_TYPE	Telegram structure according to CAN 2.0B

CAN2A_MESSAGE_TYPE

The library contains one general data type CAN2A_MESSAGE_TYPE to describe a CAN 2.0 A telegram with an 11 bit identifier. This data type is declared as follows:

```
TYPE CAN2A_MESSAGE_TYPE:
STRUCT
    ID: WORD;
    RTR: BOOL;
    DLC: BYTE;
    DATA: ARRAY [1 ... 8] OF BYTE;
END_STRUCT
END_TYPE
```

ID

Data type	Default value	Range	Unit
WORD	-	0 ... 2047	-

ID contains the general 11 bit identifier.

RTR

Data type	Default value	Range	Unit
BOOL	-	-	-

RTR (remote transmission request) contains the RTR bit in the telegram header.

DLC

Data type	Default value	Range	Unit
BYTE	-	-	-

DLC (data length code) contains the data length code in the telegram header and specifies the valid length in bytes for the user data following in DATA. Valid values for DLC are 0 to 8.

DATA

DATA (ARRAY[1..8] OF BYTE) contains the telegram data (if available). A CAN telegram can contain 0 to 8 bytes of data. The actual data length of a telegram is described by the data length code (DLC) contained in the telegram header. In DATA, only the first bytes are valid as specified by the DLC.

CAN2B_MESSAGE_TYPE

The library contains one general data type CAN2B_MESSAGE_TYPE to describe a CAN 2.0 B telegram with a 29 bit identifier. This data type is declared as follows:

```
TYPE CAN2B_MESSAGE_TYPE:
STRUCT
    ID: DWORD;
    RTR: BOOL;
    DLC: BYTE;
    DATA: ARRAY [1..8] OF BYTE;
END_STRUCT
END_TYPE
```

ID

Data type	Default value	Range	Unit
DWORD	-	-	-

ID contains the general 29 bit identifier, its range of values reaches from 0 to 536870911 (16#0 to 16# 1FFFFFFF).

RTR

Data type	Default value	Range	Unit
BOOL	-	-	-

RTR (remote transmission request) contains the RTR bit in the telegram header.

DLC

Data type	Default value	Range	Unit
BYTE	-	-	-

DLC (data length code) contains the data length code in the telegram header and specifies the valid length in bytes for the user data following in DATA. Valid values for DLC are 0 to 8.

DATA

DATA (ARRAY[1..8] OF BYTE) contains the telegram data (if available). A CAN telegram can contain 0 to 8 bytes of data. The actual data length of a telegram is described by the data length code (DLC) contained in the telegram header. In DATA, only the first bytes are valid as specified by the DLC.

1.5.4.7.3 Structures Group CANopen

Group: CANopen	
CANOM_COM_ERR_TYPE	Communication error
CANOM_EMCY_TYPE	Emergency telegram
CANOM_NODESTATUS_1_TYPE	Node diagnosis
CANOM_STATE_BITS_TYPE	Bits for Communication Module state description
CANOM_NODE_FLAGS_TYPE	Diagnosis flags of a CANopen Device

CANOM_COM_ERR_TYPE

Using CANOM_ERR, it is possible to locate communication errors more precisely. The output CANOM_ERR is represented as a structure of the type CANOM_COM_ERR_TYPE. In the CANopen library this data type is declared as follows:

```
TYPE CANOM_COM_ERR_TYPE:
STRUCT
   ADDRESS: BYTE;
   EVENT:   BYTE;
END_STRUCT
END_TYPE
```

The output CANOM_ERR is not supported by the Communication Module CM598-CAN.

ADDRESS

In case of an error, ADDRESS contains the node address of the faulty device. If ADDRESS has the value 255, the error is located in the Communication Module itself.

Data type	Default value	Range	Unit
BYTE	-	-	-

EVENT

In case of an error, EVENT contains the error causing event. The event refers to a single node address (ADDRESS <> 255) or the Communication Module itself (ADDRESS = 255).

ADDRESS <> 255 Error at subscribers with node address ADDRESS

Event	Description	Error source	Cause / Remedy
30	Slave monitoring timeout	Slave	Check connection and node address of the slave
31	Slave aborted operational mode	Slave	Reset slave
32	Sequence error in node guarding protocol	Slave	Reset slave
33	No response to configured remote frame PDO	Slave	Check whether slave remote frames are supported
34	No slave response during configuration	Slave	Check whether the slave is connected and ready for operation
35	Actual device profile of the slave differs from the configured device profile	Configuration	Check the profile supported by the slave
36	Actual device type of the slave differs from the configured device type	Configuration	Check the services supported by the slave
37	Unknown SDO response received	Slave	Slave does not meet the CiA protocol specifications
38	Length indicator of a received SDO response is not equal to 8	Slave	Slave does not meet the CiA protocol specifications
39	Slave is not processed. It is in the STOP state.	Configuration/ Communication Module	Deactivate the 'Auto Clear Mode'

ADDRESS = 255 Communication Module error

Event	Description	Error source	Cause / Remedy
52	Unknown process data handshake mode	Configuration	Contact customer support
56	Invalid data transfer rate	Configuration	Contact customer support
60	Node address configured twice	Configuration / other device	Check node addresses of all devices specified in configuration data
210	No configuration data	Configuration / Communication Module	Load configuration data into Communication Module

Event	Description	Error source	Cause / Remedy
212	Error while reading database	Configuration / Communication Module	Load configuration data into Communication Module again, contact customer support
220	Watchdog error	Controller	Contact customer support

Data type	Default value	Range	Unit
BYTE	-	-	-

CANOM_EMCY_TYPE

The data type CANOM_EMCY_TYPE corresponds to the format of the emergency telegram described in the CANopen communication profile and is defined as follows:

```
TYPE CANOM_EMCY_TYPE:
STRUCT
    ERROR_CODE: WORD;
    ERROR_REG:  BYTE;
    ERROR_DATA: ARRAY[1...5] OF BYTE;
END_STRUCT
END_TYPE
```

ERROR_CODE

Data type	Default value	Range	Unit
WORD	-	-	-

For the emergency object the emergency error codes described in the following table are defined in the CANopen communication profile.

Emergency error code		Description / Error cause
Decimal	Hexadecimal	
00000...00255	0000...00FF	Error on reset or no error
04096...04351	1000...10FF	General error
08192...08447	2000...20FF	Current error
08448...08703	2100...21FF	- error on the device input side
08704...08959	2200...22FF	- error inside the device
08960...09215	2300...23FF	- error on the device output side
12288...12543	3000...30FF	Voltage error
12544...12799	3100...31FF	- supply voltage error
12800...13055	3200...32FF	- error inside the device
13056...13311	3300...33FF	- error on the device output side
16384...16639	4000...40FF	Temperature error

Emergency error code		Description / Error cause
Decimal	**Hexadecimal**	
16640...16895	4100...41FF	- ambient temperature
16896...17151	4200...42FF	- temperature inside the device
20480...20735	5000...50FF	Hardware error in the device
24576...24831	6000...60FF	Software error in the device
24832...25087	6100...61FF	- device-internal software
25088...25343	6200...62FF	- application software
25344...25599	6300...63FF	Data
28672...28927	7000...70FF	Error in additional modules
32768...33023	8000...80FF	- monitoring
33024...33279	8100...81FF	- communication
36864...37119	9000...90FF	External error
61440...61695	F000...F0FF	Error of additional functions
65280...65535	FF00...FFFF	Device-specific errors

ERROR_REG

Data type	Default value	Range	Unit
BYTE	-	-	-

The variable ERROR_REG displays the error register value (object 1001 hex) of the slave. This value is transmitted by the slave as a part of the emergency message.

ERROR_DATA

Data type	Default value	Range	Unit
ARRAY OF BYTE	-	1 ... 5	-

If applicable, ERROR_DATA is used to output manufacturer-specific error information transmitted by the slave as part of the emergency message. For detailed information about the meaning of these data please refer to the particular device documentation.

CANOM_NODESTATUS_1_TYPE

The structure CANOM_NODESTATUS_1_TYPE is declared as follows in the CANopen library:

```
TYPE CANOM_NODESTATUS_1_TYPE:
STRUCT
    NO_RESPONSE: BOOL;
    EMCY_OVF:    BOOL;
    PRM_FAULT:   BOOL;
    GUARD_ACT:   BOOL;
    reserved1:   BOOL;
    reserved2:   BOOL;
    reserved3:   BOOL;
    DEACTIVATED: BOOL;
END_STRUCT
END_TYPE
```

NO_RESPONSE

Data type	Default value	Range	Unit
BOOL	-	-	-

If this bit is set, the slave with the node number specified at function block input NODE does not respond to the master requests. Normally NO_RESPONSE should be set to FALSE.

EMCY_OVF

Data type	Default value	Range	Unit
BOOL	-	-	-

This bit is set by the Communication Module, if more emergency messages were received from the called slave than the buffer can store (refer to function block outputs NUM_EMCY and EMCY_DATA).

PRM_FAULT

Data type	Default value	Range	Unit
BOOL	-	-	-

This bit is set, if the nominal slave configuration defined in the master differs from the actual slave configuration.

GUARD_ACT

Data type	Default value	Range	Unit
BOOL	-	-	-

This bit is set by the Communication Module, if the node guarding protocol for this slave is active. This is only a status indication. The active node guarding protocol between the master and the slave is not synonymous with a node guarding error.

reserved1

Data type	Default value	Range	Unit
BOOL	-	-	-

reserved2

Data type	Default value	Range	Unit
BOOL	-	-	-

reserved3

Data type	Default value	Range	Unit
BOOL	-	-	-

DEACTIVATED

Data type	Default value	Range	Unit
BOOL	-	-	-

This bit is set to TRUE, if the slave defined in the configuration data of the master is deactivated and not processed.

CANOM_STATE_BITS_TYPE

The structure STATE_BITS consists of six boolean variables displaying different communication states. In the CANopen library, the data type CANOM_STATE_BITS_TYPE is defined as follows:

```
TYPE CANOM_STATE_BITS_TYPE:
STRUCT
   CTRL:      BOOL;
   AUTO_CLR:  BOOL;
   NO_EXCH:   BOOL;
   FATAL:     BOOL;
   EVENT:     BOOL;
   reserved1: BOOL;
   TIMEOUT:   BOOL;
   reserved2: BOOL;
END_STRUCT
END_TYPE
```

CTRL

Data type	Default value	Range	Unit
BOOL	-	-	-

If this bit is TRUE, a parameter setting error occurred. During normal operation, CTRL should be FALSE. If this is not the case, the parameter and configuration data have to be checked.

AUTO_CLR

If AUTO_CLR is set to TRUE, the Communication Module stopped data exchange with all slaves due to communication errors and changed back to CLEAR state (see also CANOM_STATE).

Data type	Default value	Range	Unit
BOOL	-	-	-

NO_EXCH

This bit is set to TRUE, if no exchange of process data can be performed with one or several slaves. The error can be caused by the configuration data or the slaves themselves.

Data type	Default value	Range	Unit
BOOL	-	-	-

FATAL

If FATAL is set to TRUE, no communication via CANopen is possible due to a fatal internal error.

Data type	Default value	Range	Unit
BOOL	-	-	-

EVENT

EVENT is set to TRUE, if the Communication Module detects transmission errors. The number of occurring transmission errors is displayed at the corresponding outputs BUS_ERR and BUS_OFF. If the EVENT bit is set to TRUE, reset is only possible via the function block CANOM_RES_ERR ↳ *Chapter 1.5.4.7.1.10 “CANOM_RES_ERR” on page 941*.

Data type	Default value	Range	Unit
BOOL	-	-	-

reserved1

This bit is reserved and currently not in use.

Data type	Default value	Range	Unit
BOOL	-	-	-

TIMEOUT

If TIMEOUT is set to TRUE, transmission of at least one telegram failed. The transmission of this telegram was aborted and its content is lost. TIMEOUT = TRUE is an indication that the communication partner could not be contacted via the bus. The number of failed transmissions is displayed at output TOUT_ERR. If the TIMEOUT bit is set to TRUE, reset is only possible using the function block CANOM_RES_ERR ↳ *Chapter 1.5.4.7.1.10 “CANOM_RES_ERR” on page 941*.

Data type	Default value	Range	Unit
BOOL	-	-	-

reserved2

This bit is reserved and currently not in use.

Data type	Default value	Range	Unit
BOOL	-	-	-

CANOM_NODE_FLAGS_TYPE

The data type CANOM_NODE_FLAGS_TYPE has the following structure:

```
TYPE CANOM_NODE_FLAGS_TYPE :
STRUCT
    xSDO_TIMEOUT:       BOOL:=False;
    xSDO_ERROR:         BOOL:=False;
    CFG_DEFAULT:        BOOL:=False;
    xHARTBEAT_STARTED:  BOOL:=False;
    xGUARD_ERROR:       BOOL:=False;
    xCON_LOST:          BOOL:=False;
    xHARTBEAT_ERROR:    BOOL:=False;
    xUNEXPECTED_STATE:  BOOL:=False;
    xEMCY_RECEIVED:     BOOL:=False;
    xEMCY_BUFF_OVER:    BOOL:=False;
    xBOOTUP:            BOOL:=False;
    xUNEXPECTED_BOOTUP: BOOL:=False;
```

```
    xINVALID_PARAMETER: BOOL:=False;
    xSTATE_NOT_HANDLED: BOOL:=False;
    xDEACTIVATED:       BOOL:=False;
END STRUCT
END TYPE
```

xSDO_TIMEOUT Timeout during SDO transfer occured.

Data type	Default value	Range	Unit
BOOL	-	-	-

xSDO_ERROR: Error during SDO transfer occured.

Data type	Default value	Range	Unit
BOOL	-	-	-

CFG_DEFAULT Configuration default occured.

Data type	Default value	Range	Unit
BOOL	-	-	-

xHART-BEAT_STARTED Hartbeat protocol is started.

Data type	Default value	Range	Unit
BOOL	-	-	-

xGUARD_ERRO R A guarding message has been lost

Data type	Default value	Range	Unit
BOOL	-	-	-

xCON_LOST Node guarding has been lost.

Data type	Default value	Range	Unit
BOOL	-	-	-

xHART-BEAT_ERROR Error in hartbeat protocol recognized.

Data type	Default value	Range	Unit
BOOL	-	-	-

xUNEX-PECTED_STATE Node is in unexpected NMT state

Data type	Default value	Range	Unit
BOOL	-	-	-

xEMCY_RECEIVED Emergency telegram received.

Data type	Default value	Range	Unit
BOOL	-	-	-

xEMCY_BUFF_OVER Emergency buffer overflow occured.

Data type	Default value	Range	Unit
BOOL	-	-	-

xBOOTUP Expected boot-up message from node received.

Data type	Default value	Range	Unit
BOOL	-	-	-

xUNEX-PECTED_BOOTUP Unexpected boot-up message from node received.

Data type	Default value	Range	Unit
BOOL	-	-	-

xIN-VALID_PARAM-ETER Parameter set of node is invalid.

Data type	Default value	Range	Unit
BOOL	-	-	-

xSTATE_NOT_HANDLED At least one state has been omitted during the initialization sequence of the node.

Data type	Default value	Range	Unit
BOOL	-	-	-

xDEACTIVATED Node is deactivated and not handled by the master.

Data type	Default value	Range	Unit
BOOL	-	-	-

1.5.4.8 CD522 library

Library file name: **CD522_AC500_Vx.lib**

The CD522 library contains all function blocks necessary for using the function module CD522.

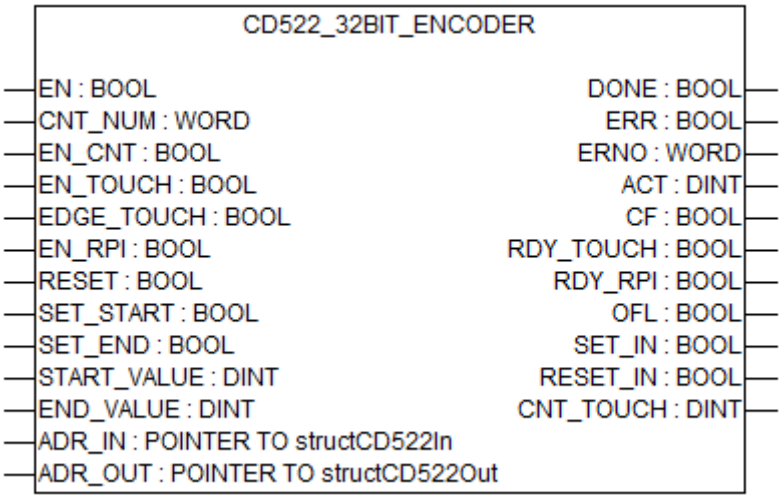
Once a CD522 has been added to the configuration, the library is automatically included with the next compilation of the project.

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

The function blocks are available in AC500 control systems with a runtime system of version V1.0.2 or higher and S500 I/O modules (DC551) with firmware version V1.11 or higher.

1.5.4.8.1 Function blocks

CD522_32BIT_ENCODER



Parameter	Value
Included in library	CD522_AC500_V13.lib
Available from CD522 firmware	V2.1
Available from runtime system:	V1.0.2
Available from S500 I/O modules (DC551) firmware	V1.11
Type	Function block with historical values

The module CD522 can be used in 12 different configurable operating modes. The operating mode is configured in PLC Configuration using module parameters. After that, it is activated during the initialization phase (power-on, cold start, warm start).

The data exchange from and to the user program is performed using input and output operands. These necessary operands are created and reserved automatically, when one module CD522 is added into the I/O bus configuration.

In order to configure and use the function encoder of module CD522, different operating modes are available. The function block CD522_32BIT_ENCODER should be used with one of these operating modes:

Operating Mode 11	"Incremental encoder"
Should be specified in PLC Configuration; parameter "mode counter" in order to use one bidirectional counter for position sensor x1 count, with possibility of touch/catch value, RPI function, set and reset actions.	
Operating Mode 12	"Incremental encoder X2"
Should be specified in PLC Configuration; parameter "mode counter" in order to use one bidirectional counter for position sensor x2 count, with possibility of touch/catch value, RPI function, set and reset actions.	
Operating Mode 13	"Incremental encoder X4"
Should be specified in PLC Configuration; parameter "mode counter" in order to use one bidirectional counter for position sensor x4 count, with possibility of touch/catch value, RPI function, set and reset actions.	

The module CD522 provides 2 encoder functions for relative positioning with 3 signals. 2 signals are used for rotation discrimination and pulse count, identified by A0 and B0 for counter0 and A1 and B1 for counter1. The third one is used in multi-turn encoder to count the number of rotation (mechanical zero), identified by Z0 for counter0 and Z1 for counter1.

The rotation is identified with a shift angle (90°) between A and B signal. In the module CD522, the clockwise rotation is identified with A signal in advance to B (see figure below).

Clockwise rotation - A signal ahead from B signal	**Counter-clockwise rotation - A signal late from B signal**
	Clockwise rotation in CD522 module	Counter-clockwise rotation in CD522 module

Depending on which kind of operating mode is specified, the counting procedure will be x1, x2 or x4 count. Basically the x1 counting mode is used (mode 11). The encoder module discriminates the rotating way and count one pulse for each rising edge of the A signal.

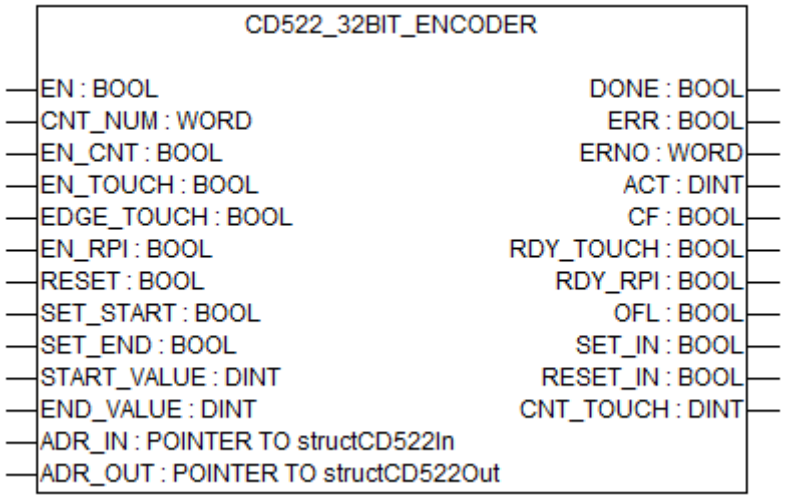
With clockwise rotation, function block CD522_32BIT_ENCODER counts downwards.

With counter-clockwise rotation, function block CD522_32BIT_ENCODER counts upwards.

In order to increase resolution, the x2 counting mode can be specified (mode 12). The encoder module counts one pulse on each rising edge of A signal and one pulse on each rising edge of B signal.

The resolution could be multiplied by 4, using the x4 counting mode (mode 13). The encoder module counts a pulse on both rising and falling edge of A signal and B signal.

Input description



EN_TOUCH The touch/catch operation is the way to acquire the counting position synchronously with hardware external signal removing all the latency time of I/O bus and network. This operation allows synchronization between 2 different encoder devices if the same hardware signal is used for touch/catch input.

On edge of the physical external signal, the current counter value (ACT) is stored in a dedicated integer (CNT_TOUCH). The touch/catch operation could be settled on rising or falling edge depending on parameter EDGE_TOUCH (see figure below).

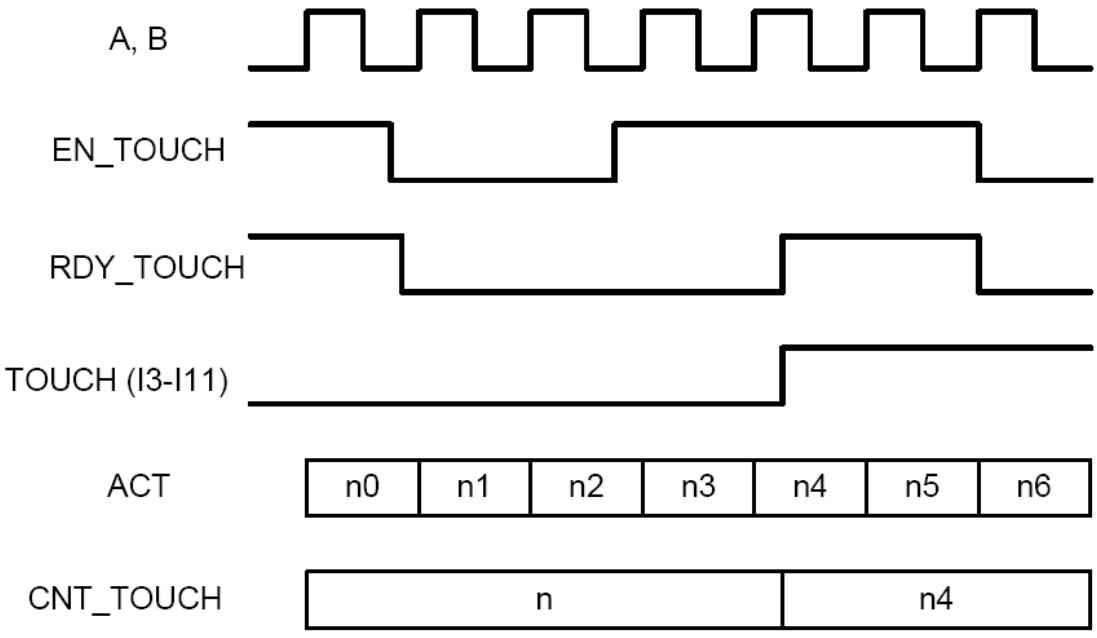


Fig. 16: Procedure and associated counting value with A signal

Touch/catch operation is enabled through control bit (EN_TOUCH). This resets the status flag (NTOUCH), when the pre-determined edge occurs; the current counter value is stored in the touch value double word. In the same time, the status NTOUCH is set to TRUE.

RPI procedure The RPI (Reference Point Initialization) is used to synchronize the counter value with the mechanical zero reference based on signal Z.

RPI procedure is enabled with control bit (EN_RPI). If this control bit is set, the module checks for the Z signal. When the signal appears, the set value is copied in the current counter value and RDY_RPI is set (see figure below).

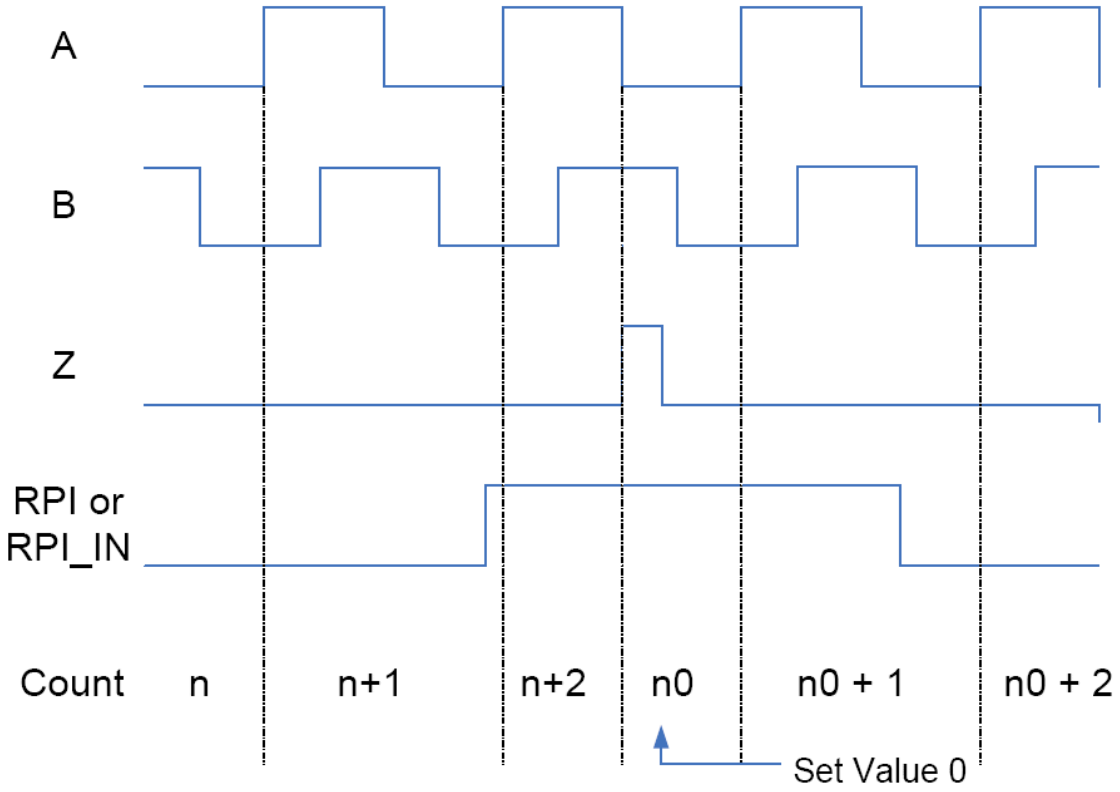

Fig. 17: RPI operation

EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

CNT_NUM

Data type	Default value	Range	Unit
WORD	-	-	-

CNT_NUM contains the counter number in the module:

- CNT_NUM = 0 is related to input A0, B0, Z0
- CNT_NUM = 1 is related to input A1, B1, Z1

EN_CNT

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_CNT = TRUE, pulse counting of counter is enabled. If EN_CNT = FALSE, no pulse counting is performed and the pulses are lost.

If counting has already started and if EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

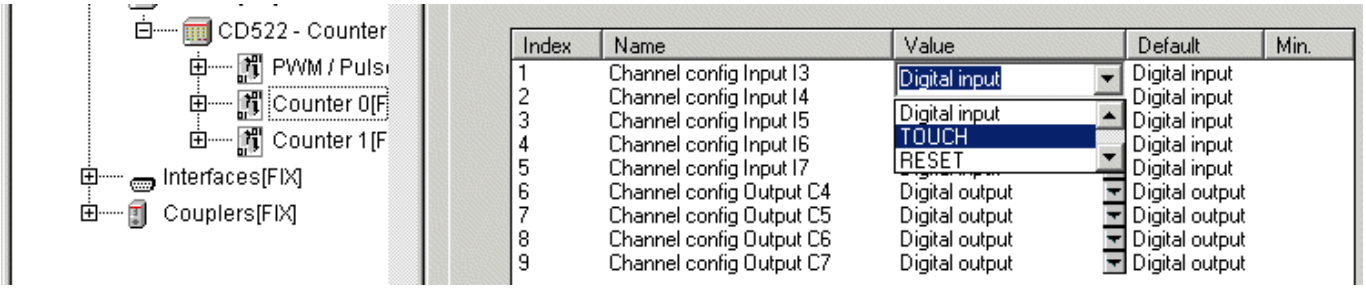
Input EN_CNT corresponds to bit 0 in "control byte".

EN_TOUCH

Data type	Default value	Range	Unit
BOOL	-	-	-

Touch/catch operation is enabled through control bit (EN_TOUCH). This resets the status flag (NTOUCH), when the pre-determined edge occurs; the current counter value is stored in the touch value double word. In the same time, the status NTOUCH is set to TRUE.

A rising edge at input EN_TOUCH enables a catch/touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at input I3 (for counters 0-A and 0-B)) or I11 (for counters 1-A and 1-B) causes the function block to store the actual counter value ACT1 and ACT2 and to display this value at output CNT_TOUCH1 and CNT_TOUCH2.



The next measurement is again initiated by a rising edge at input EN_TOUCH.

If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

Input EN_TOUCH corresponds to bit 6 in "control byte".

Only one function may be enabled at a time, either the RPI (reference point indicator) or TOUCH (touch trigger measurement). If both functions are enabled simultaneously or if the execution of one function is not yet completed when enabling the other function, a RPI function will have a higher priority than TOUCH.

EDGE_TOUCH

Data type	Default value	Range	Unit
BOOL	-	-	-

If EDGE_TOUCH = FALSE, a catch/touch value will be operate on falling edge of input I3 (for counter 0) or I11 (for counter 1).

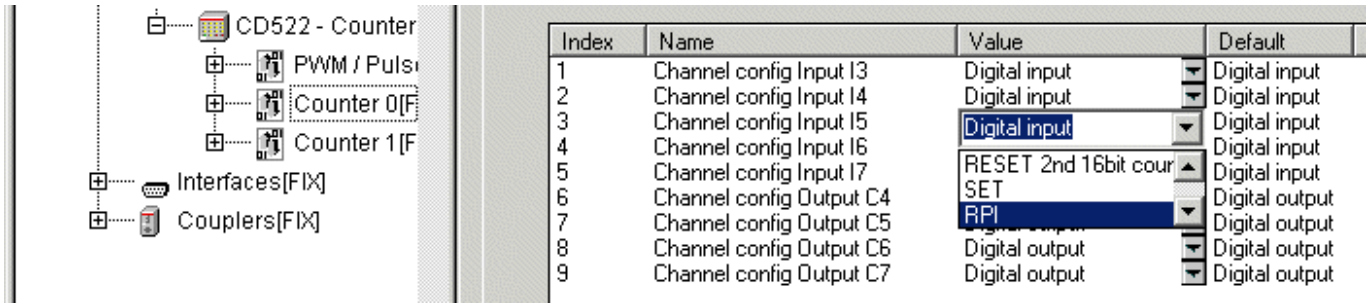
If EDGE_TOUCH = TRUE, a catch/touch value will be operate on rising edge of input I3 (for counter 0) or I11 (for counter 1).

Input EDGE_TOUCH corresponds to bit 7 in "control byte".

EN_RPI

Data type	Default value	Range	Unit
BOOL	-	-	-

A rising edge at input EN_RPI enables a reference point initiator measurement. If input EN_RPI = TRUE, a rising edge at inputs I3, I4, I5, I6 or I7 (for counter 0) or I11, I12, I13 (for counter 1) validates the counter value capture and the counter reset during the capture.



Input EN_RPI corresponds to bit 4 in "control byte".

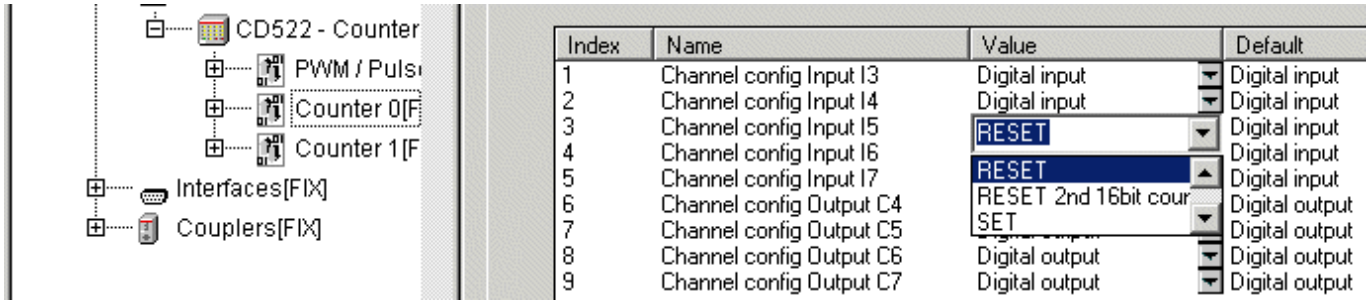
Only one function may be enabled at a time, either the RPI (reference point indicator) or TOUCH (touch trigger measurement). If both functions are enabled simultaneously or if the execution of one function is not yet completed when enabling the other function, a RPI function will have a higher priority than TOUCH.

RESET

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input RESET=TRUE, the counter takes the values 0 to transfer it to output ACT. As long as input RESET=TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at input I3, I4, I5, I6 or I7 (for counter 0) or I11, I12, I13, I14 or I15 (for counter 1) causes the function block to reset the value at output ACT.



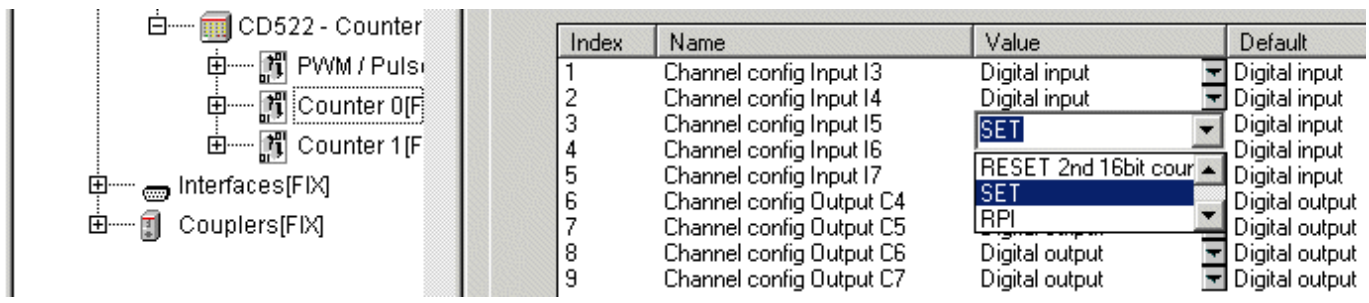
Input EN_RESET corresponds to bit 2 in "control byte".

SET_START

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET=TRUE, the counter takes the values from input START_VALUE to transfer it to output ACT. As long as input SET=TRUE, no pulses are counted because the counter is always overwritten by the input START_VALUE.

A rising edge at input I3, I4, I5,I6 or I7 (for counter 0) or I11, I12, I13,I14 or I15 (for counter 1) causes the function block to store the START_VALUE value and to display this value at output ACT.



Input EN_SET corresponds to bit 1 in "control byte".

SET_END

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET_END=TRUE, the counter is set to the value specified at input END_VALUE.

START_VALUE

Data type	Default value	Range	Unit
DINT	-	-	-

The counter can be set to a start value. This value must be applied to the input START_VALUE.

If input SET=TRUE, counter takes this value.

Input START_VALUE corresponds to counter settings (DWORD) of CD522.

END_VALUE

Data type	Default value	Range	Unit
DINT	-	-	-

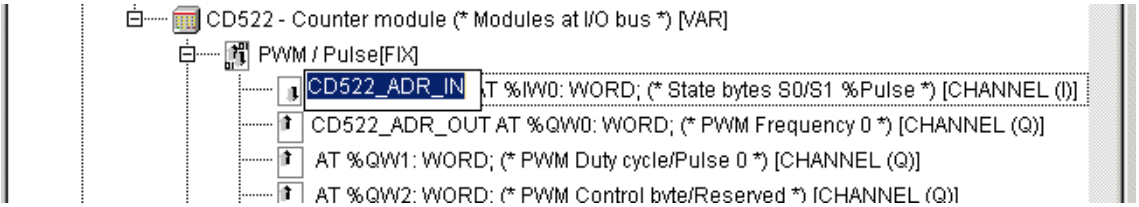
If the counter reaches the planned input END_VALUE, the binary output CF is set to TRUE and the value is stored.

Input END_VALUE corresponds to counter settings (DWORD) of CD522.

ADR_IN

At ADR_IN input (POINTER TO structCD522counterin), the address of the first input data from the structure of counter input of CD522 should be connected. The use of an ADR operator is needed. If input ADR_IN is not connected, then the outputs DONE=FALSE and ERR= TRUE.

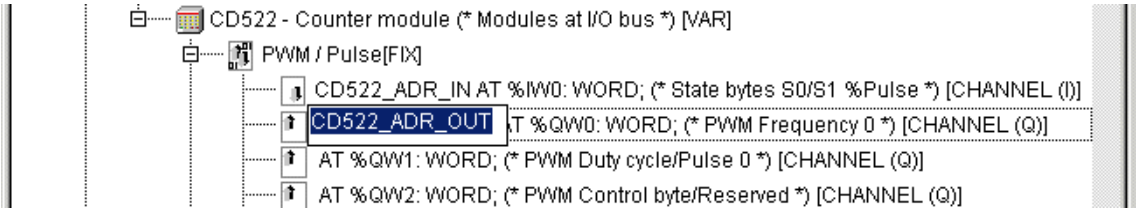
Example (for counter 0):



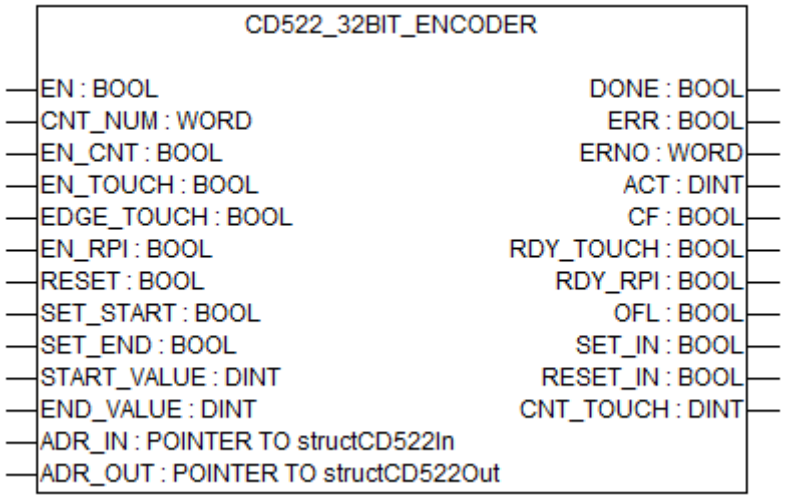
ADR_OUT

At ADR_OUT input (POINTER TO structCD522counterout), the address of the first output data from the structure of counter output of CD522 should be connected. The use of an ADR operator is needed. If input ADR_OUT is not connected, then the outputs DONE=FALSE and ERR= TRUE.

Example (for counter 0):



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ACT

Data type	Default value	Range	Unit
DINT	-	-	-

The current counter value (actual value) can be retrieved at any time using the output ACT of the function block.

Output ACT corresponds to input DWORD in "32bit counter".

CF

Data type	Default value	Range	Unit
BOOL	-	-	-

If the zero crossover indicator CF=TRUE, this output indicates the sign of the actual counter value ACT. It is set to FALSE when counter value ACT is less than or equal to zero. It is set to TRUE otherwise.

This information is validated when input B is set to TRUE.

RDY_TOUCH

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The output RDY_TOUCH is set to TRUE when a new catch/touch value is available. If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

Output RDY_TOUCH corresponds to input bit 2 in "state byte".

RDY_RPI

Data type	Default value	Range	Unit
BOOL	-	-	-

The output RDY_RPI is set to TRUE when the RPI operation is done. If input EN_RPI is set to FALSE, the output RDY_RPI is set to FALSE.

Output RDY_RPI corresponds to input bit 6 in state byte.

OFL

Data type	Default value	Range	Unit
BOOL	-	-	-

The overflow is specified at the output OFL.

The counter operates as infinite counter. An overflow occurs corresponding to the 32-bit value at 16#80000000 = 2147483648. Any exceeding or falling below of this value (depending to up and down use) will set OFL to TRUE.

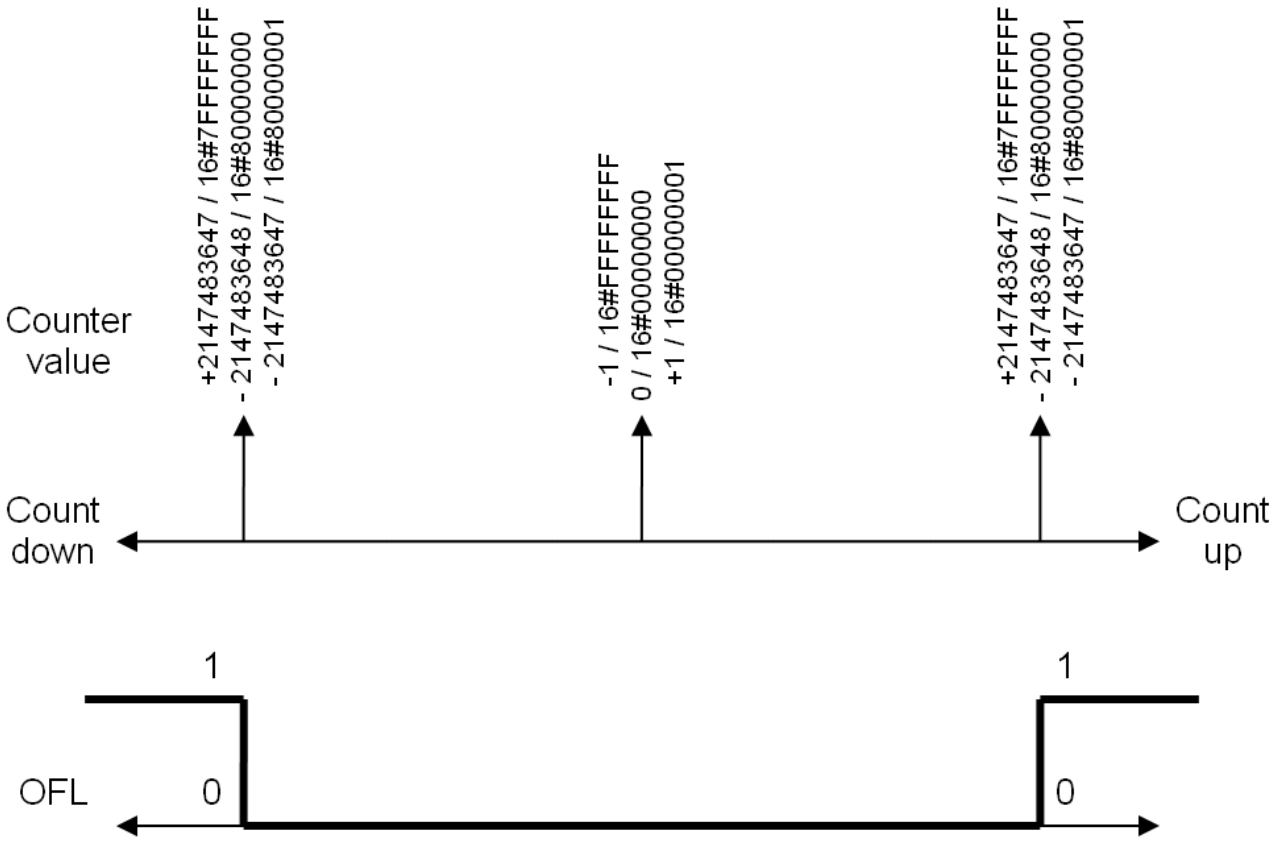


Fig. 18: Detection for output OFL

Output OFL corresponds to input bit 3 in state byte.

SET_IN

Data type	Default value	Range	Unit
BOOL	-	-	-

The output SET_IN is set to TRUE if one of the inputs is configured as SET input.

Output SET_IN corresponds to input bit 4 in "state byte".

RESET_IN

Data type	Default value	Range	Unit
BOOL	-	-	-

The output RESET_IN is set to TRUE if one of the inputs is configured as RESET input.

Output RESET_IN corresponds to input bit 5 in "state byte".

CNT_TOUCH

Data type	Default value	Range	Unit
DINT	0	-	-

The output CNT_TOUCH displays the result of the catch/touch trigger measurement.

Output CNT_TOUCH corresponds to input DWORD in "TOUCH counter value".

Function call in ST

```

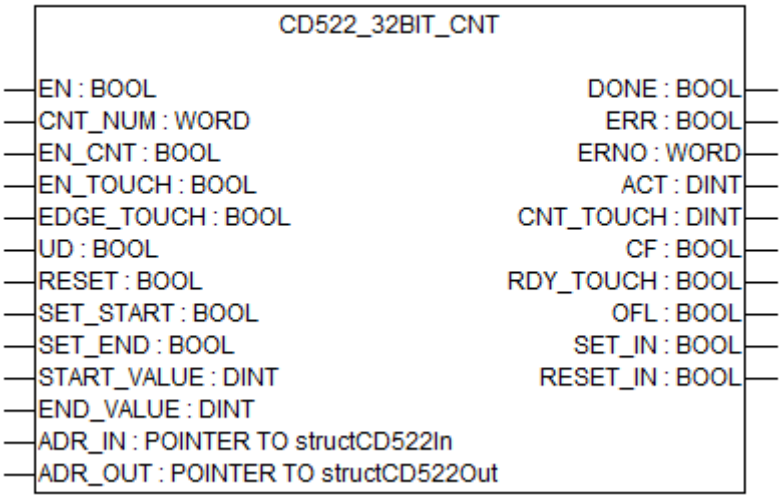
CD522_32BITENCODER_ACT       :=CD522_32BITENCODER.ACT;
CD522_32BITENCODER_CF        :=CD522_32BITENCODER.CF
CD522_32BITENCODER_RDY_TOUCH := CD522_32BITENCODER.RDY_TOUCH;
CD522_32BITENCODER_RDY_RPI   := CD522_32BITENCODER.RDY_RPI;
CD522_32BITENCODER_OFL       :=CD522_32BITENCODER.OFL;
CD522_32BITENCODER_SET_IN    :=CD522_32BITENCODER.SET_IN;
CD522_32BITENCODER_RESET_IN  :=CD522_32BITENCODER.RESET_IN;
CD522_32BITENCODER_CNT_TOUCH :=CD522_32BITENCODER.CNT_TOUCH;
```

CD522_32BIT_CNT



Parameter	Value
Included in library	CD522_AC500_V13.lib
Available from CD522 firmware	V2.1
Available from runtime system:	V1.0.2

Parameter	Value
Available from S500 I/O modules (DC551) firmware	V1.11
Type	Function block with historical values

The module CD522 can be used in 12 different configurable operating modes. The operating mode is configured in PLC Configuration using module parameters. After that, it is activated during the initialization phase (power-on, cold start, warm start).

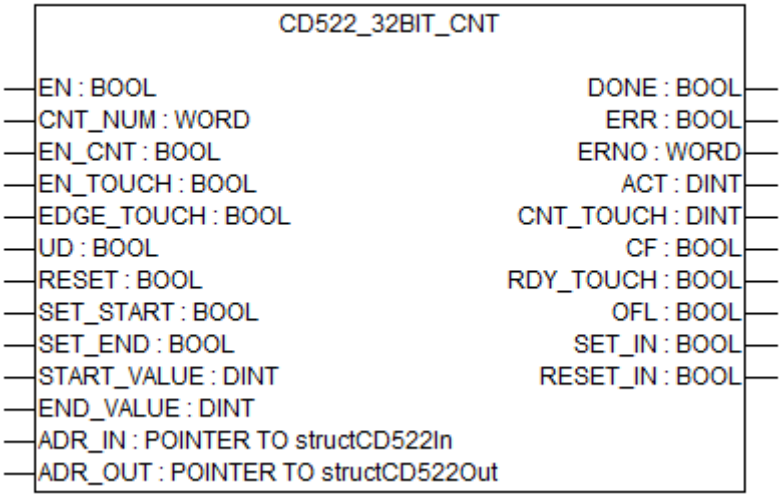
The data exchange from and to the user program is performed using input and output operands. These necessary operands are created and reserved automatically, when one module CD522 is added into the I/O bus configuration.

In order to configure and use the function counter of module CD522, different operating modes are available. The function block CD522_32BIT_CNT should be used with one of these operating modes:

Operating Mode 1	"Up/Down counter (A)"
Should be specified in PLC Configuration, parameter "mode counter" in order to use one up/down 32-bit counter on input A (dynamic changes) with set and reset input operation, end value reached indicator, touch/catch value and overflow flag.	
Operating Mode 2	"Up/Down counter with release input (B)"
Should be specified in PLC Configuration; parameter "mode counter" in order to use one up/down 32-bit counter with enable input. Counting is valid when input B is TRUE. Dynamic up/down count possibility, with set and reset input operation, end value reached indicator, touch/catch value and overflow flag.	
Operating Mode 5	"Up/Down dynamic set (B)/rising edge"
Should be specified in PLC Configuration; parameter "mode counter" in order to use one up/down 32-bit counter with set and reset input, end value reached indicator, touch/catch value and overflow flag. Additional function to mode 1 is the dynamic set input (B) on rising edge of physical.	
Operating Mode 6	"Up/Down dynamic set (B)/falling edge"
Should be specified in PLC Configuration; parameter "mode counter" in order to use one up/down 32-bit counter with set and reset input, end value reached indicator, touch/catch value and overflow flag. Additional function to mode 1 is the dynamic set input (B) on falling edge of physical.	

The module CD522 provides 2 Up/Down 32-bit counter functions. A signal used for pulse count is identified by A0 for counter 0 and A1 for counter 1. Another signal used for enable or dynamic set is identified by B0 for counter 0 and B1 for counter 1.

Input description



EN_TOUCH

The touch/catch operation is the way to acquire the counting position synchronously with hardware external signal removing all the latency time of I/O bus and network. This operation allows synchronization between 2 different encoder devices if the same hardware signal is used for touch/catch input.

On edge of the physical external signal, the current counter value (ACT) is stored in a dedicated integer (CNT_TOUCH). The touch/catch operation could be settled on rising or falling edge depending on parameter EDGE_TOUCH (see figure below).

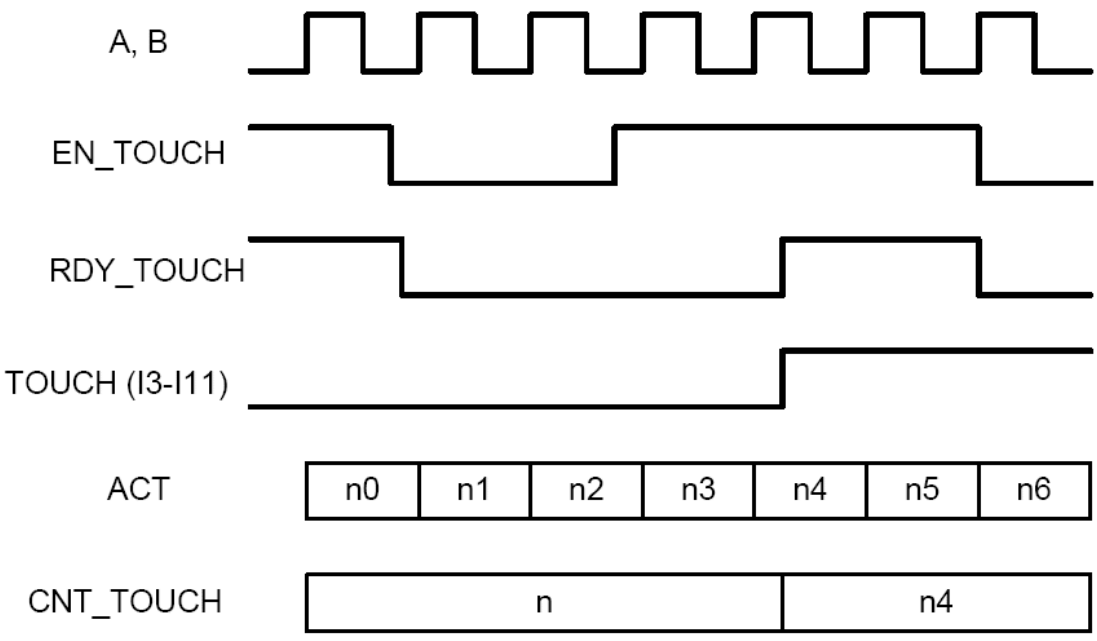


Fig. 19: Procedure and associated counting value with A signal

Touch/catch operation is enabled through control bit (EN_TOUCH). This resets the status flag (NTOUCH), when the pre-determined edge occurs; the current counter value is stored in the touch value double word. In the same time, the status NTOUCH is set to TRUE.

EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

CNT_NUM

Data type	Default value	Range	Unit
WORD	-	-	-

CNT_NUM contains the counter number in the module:

- CNT_NUM = 0 is related to input A0, B0, Z0
- CNT_NUM = 1 is related to input A1, B1, Z1

EN_COUNT

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_CNT = TRUE, pulse counting of counter is enabled. If EN_CNT = FALSE, no pulse counting is performed and the pulses are lost.

If counting has already started and if EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

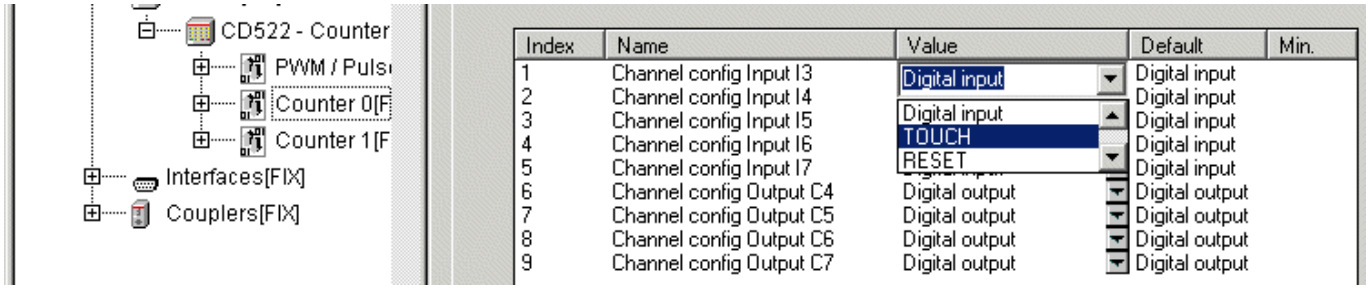
Input EN_CNT corresponds to bit 0 in "control byte".

EN_TOUCH

Data type	Default value	Range	Unit
BOOL	-	-	-

Touch/catch operation is enabled through control bit (EN_TOUCH). This resets the status flag (NTOUCH), when the pre-determined edge occurs; the current counter value is stored in the touch value double word. In the same time, the status NTOUCH is set to TRUE.

A rising edge at input EN_TOUCH enables a catch/touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at input I3 (for counters 0-A and 0-B)) or I11 (for counters 1-A and 1-B) causes the function block to store the actual counter value ACT1 and ACT2 and to display this value at output CNT_TOUCH1 and CNT_TOUCH2.



The next measurement is again initiated by a rising edge at input EN_TOUCH.

If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

Input EN_TOUCH corresponds to bit 6 in "control byte".

EDGE_TOUCH

Data type	Default value	Range	Unit
BOOL	-	-	-

If EDGE_TOUCH = FALSE, a catch/touch value will be operate on falling edge of input I3 (for counters 0-A and 0-B) or I11 (for counters 1-A and 1-B).

If EDGE_TOUCH = TRUE, a catch/touch value will be operate on rising edge of input I3 (for counters 0-A and 0-B) or I11 (for counters 1-A and 1-B).

Input EDGE_TOUCH corresponds to bit 7 in "control byte".

UD

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD, the counting selection is set for up/down counting mode:

UD=FALSE: count up

UD=TRUE: count down

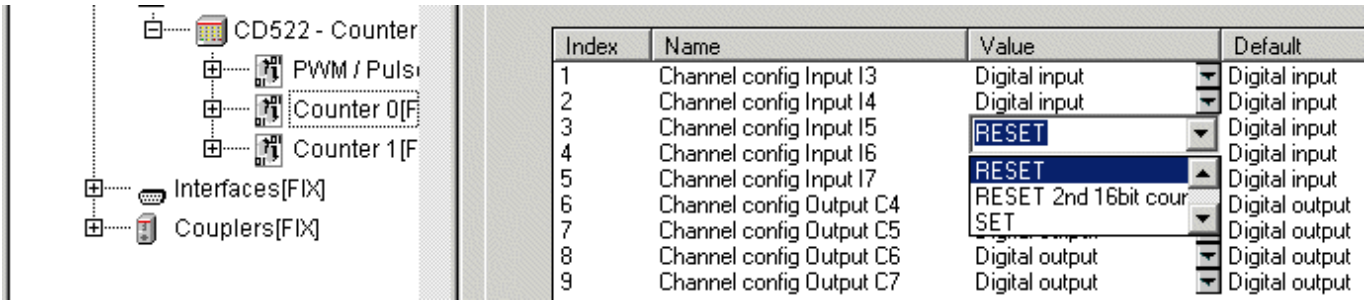
Input UD corresponds to output bit 5 in "control byte".

RESET

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input RESET=TRUE, the counter takes the values 0 to transfer it to output ACT. As long as input RESET=TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at input I3, I4, I5, I6 or I7 (for counter 0) or I11, I12, I13, I14 or I15 (for counter 1) causes the function block to reset the value at output ACT.



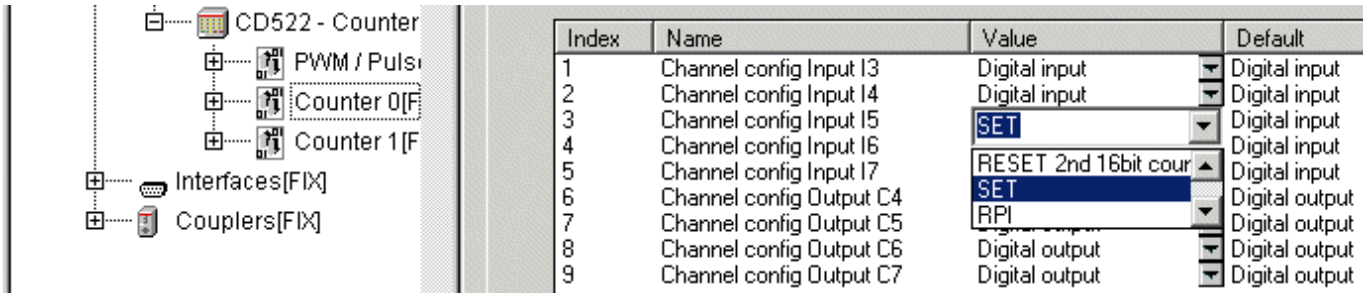
Input EN_RESET corresponds to bit 2 in "control byte".

SET_START

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET=TRUE, the counter takes the values from input START_VALUE to transfer it to output ACT. As long as input SET=TRUE, no pulses are counted because the counter is always overwritten by the input START_VALUE.

A rising edge at input I3, I4, I5,I6 or I7 (for counter 0) or I11, I12, I13,I14 or I15 (for counter 1) causes the function block to store the START_VALUE value and to display this value at output ACT.



Input EN_SET corresponds to bit 1 in "control byte".

SET_END

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET_END=TRUE, the counter is set to the value specified at input END_VALUE.

START_VALUE

Data type	Default value	Range	Unit
DINT	-	-	-

The counter can be set to a start value. This value must be applied to the input START_VALUE.

If input SET=TRUE, counter takes this value.

Input START_VALUE corresponds to counter settings (DWORD) of CD522.

END_VALUE

Data type	Default value	Range	Unit
DINT	-	-	-

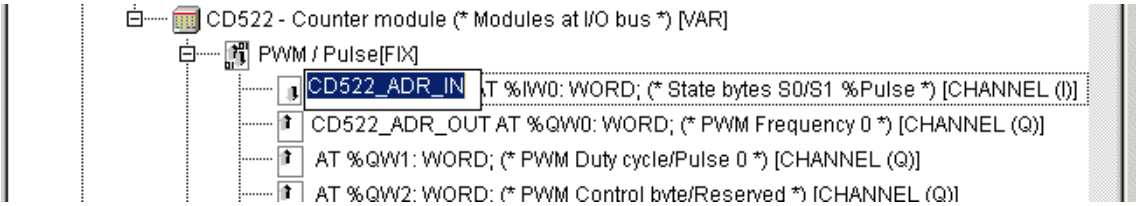
If the counter reaches the planned input END_VALUE, the binary output CF is set to TRUE and the value is stored.

Input END_VALUE corresponds to counter settings (DWORD) of CD522.

ADR_IN

At ADR_IN input (POINTER TO structCD522counterin), the address of the first input data from the structure of counter input of CD522 should be connected. The use of an ADR operator is needed. If input ADR_IN is not connected, then the outputs DONE=FALSE and ERR= TRUE.

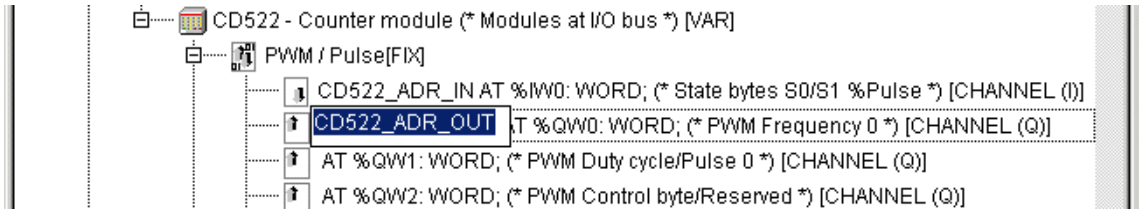
Example (for counter 0):



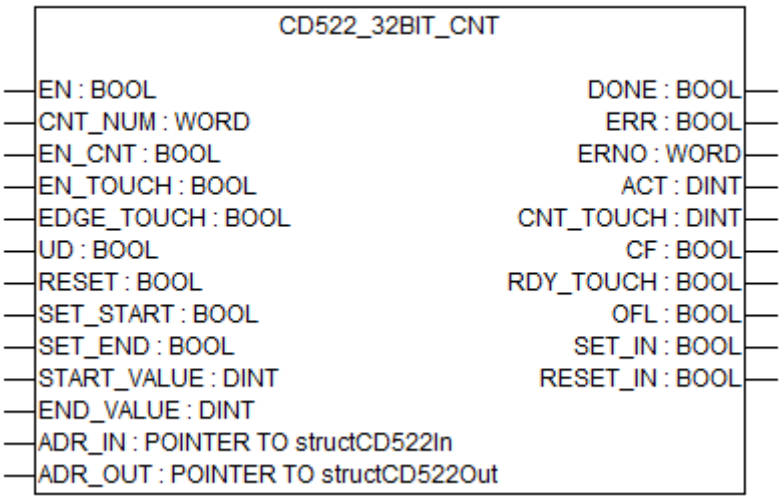
ADR_OUT

At ADR_OUT input (POINTER TO structCD522counterout), the address of the first output data from the structure of counter output of CD522 should be connected. The use of an ADR operator is needed. If input ADR_OUT is not connected, then the outputs DONE=FALSE and ERR= TRUE.

Example (for counter 0):



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ACT

Data type	Default value	Range	Unit
INT	0	-	-

The current counter value (actual value) can be retrieved at any time using the output ACT of the function block.

Output ACT corresponds to input low word in "32bit counter".

CNT_TOUCH

Data type	Default value	Range	Unit
DINT	0	-	-

The output CNT_TOUCH displays the result of the catch/touch trigger measurement.

Output CNT_TOUCH corresponds to input DWORD in "TOUCH counter value".

CF

Data type	Default value	Range	Unit
BOOL	-	-	-

If the zero crossover indicator CF=TRUE, this output indicates the sign of the actual counter value ACT. It is set to FALSE when counter value ACT is less than or equal to zero. It is set to TRUE otherwise.

This information is validated when input B is set to TRUE.

RDY_TOUCH

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The output RDY_TOUCH is set to TRUE when a new catch/touch value is available. If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

Output RDY_TOUCH corresponds to input bit 2 in "state byte".

OFL

Data type	Default value	Range	Unit
BOOL	-	-	-

The overflow is specified at the output OFL.

The counter operates as infinite counter. An overflow occurs corresponding to the 32-bit value at 16#80000000 = 2147483648. Any exceeding or falling below of this value (depending to up and down use) will set OFL to TRUE.

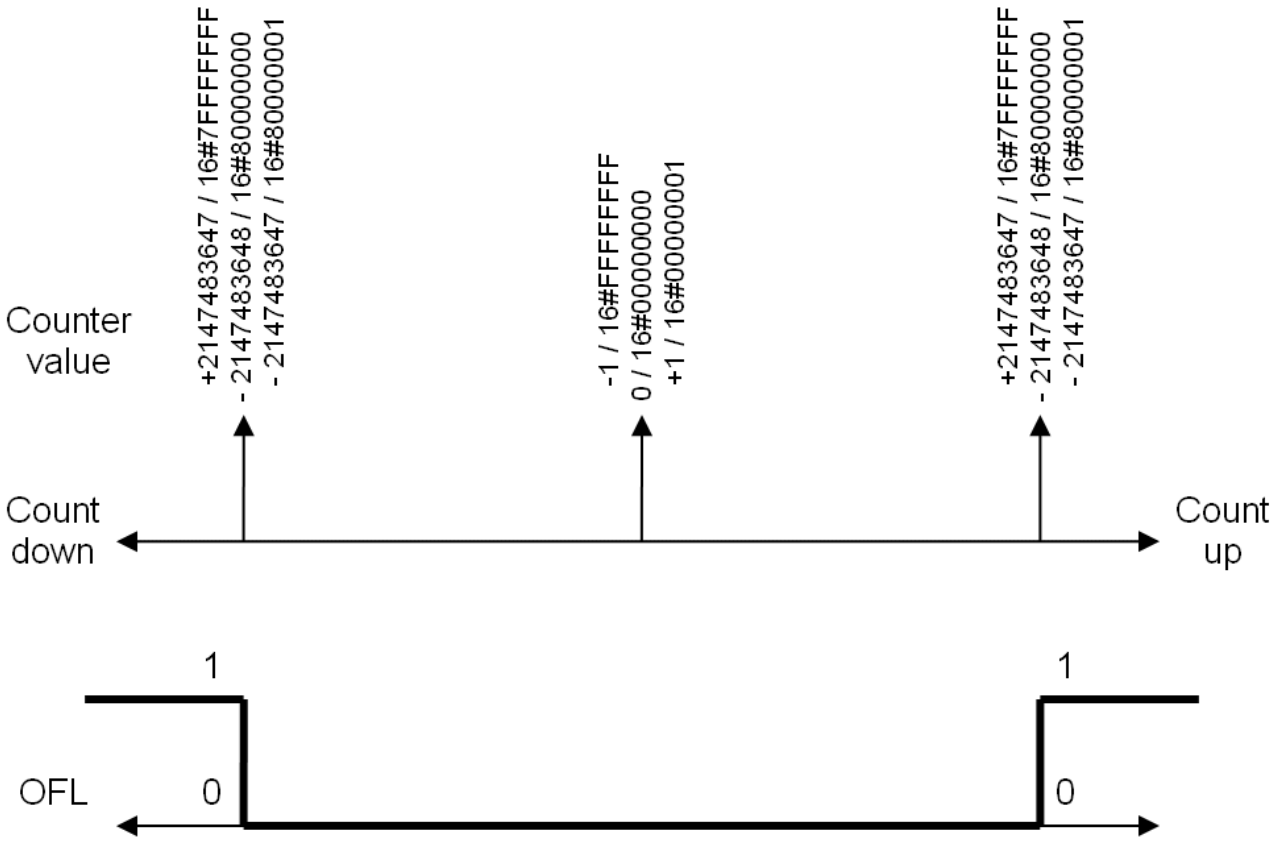


Fig. 20: Detection for output OFL

Output OFL corresponds to input bit 3 in state byte.

SET_IN

Data type	Default value	Range	Unit
BOOL	-	-	-

The output SET_IN is set to TRUE if one of the inputs is configured as SET input.

Output SET_IN corresponds to input bit 4 in "state byte".

RESET_IN

Data type	Default value	Range	Unit
BOOL	-	-	-

The output RESET_IN is set to TRUE if one of the inputs is configured as RESET input.

Output RESET_IN corresponds to input bit 5 in "state byte".

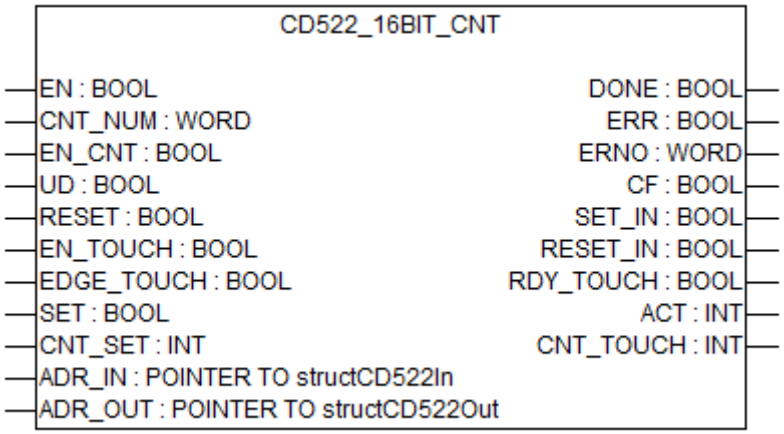
CD522_32BITCNT_RESET_IN  :=CD522_32BITCNT.RESET_IN;
```

CD522_16BIT_CNT



The module CD522 can be used in 12 different configurable operating modes. The operating mode is configured in PLC Configuration using module parameters. After that, it is activated during the initialization phase (power-on, cold start, warm start).

The data exchange from and to the user program is performed using input and output operands. These necessary operands are created and reserved automatically, when one module CD522 is added into the I/O bus configuration.

In order to configure and use the function counter of module CD522, different operating modes are available. The function block CD522_16BIT_CNT should be used with one of these operating modes:

Operating Mode 8	**"Up/Down with release (B), 0 cross detection"**
Should be specified in PLC Configuration; parameter "mode counter" in order to use one up/down 16 bit counter (in range of -32768 to 32767) with enable input and zero crossover detection (CF). Counting is valid when input B is TRUE. With set and reset input operation and touch/catch value.	

The module CD522 provides 2 Up/Down 16 bit counter functions. A signal used for pulse count is identified by A0 for counter 0 and A1 for counter 1. Another signal used for enable or dynamic set is identified by B0 for counter 0 and B1 for counter 1.

Parameter	Value

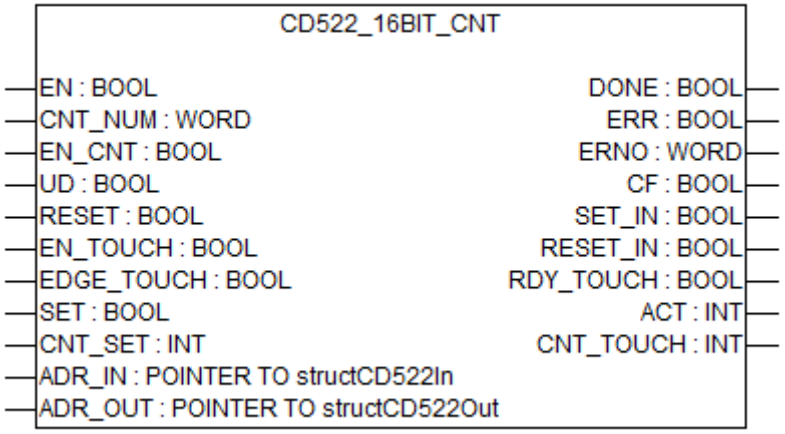
Input description



EN_TOUCH

The touch/catch operation is the way to acquire the counting position synchronously with hardware external signal removing all the latency time of I/O bus and network. This operation allows synchronization between 2 different encoder devices if the same hardware signal is used for touch/catch input.

On edge of the physical external signal, the current counter value (ACT) is stored in a dedicated integer (CNT_TOUCH). The touch/catch operation could be settled on rising or falling edge depending on parameter EDGE_TOUCH (see figure below).

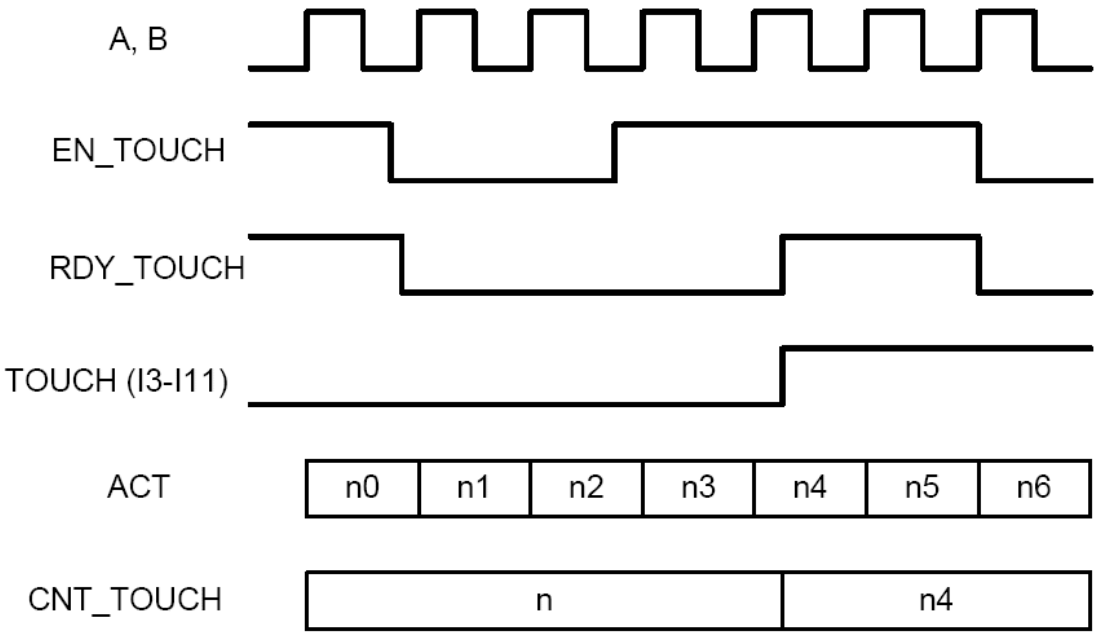


Fig. 21: Procedure and associated counting value with A signal

Touch/catch operation is enabled through control bit (EN_TOUCH). This resets the status flag (NTOUCH), when the pre-determined edge occurs; the current counter value is stored in the touch value double word. In the same time, the status NTOUCH is set to TRUE.

EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

CNT_NUM

Data type	Default value	Range	Unit
WORD	-	-	-

CNT_NUM contains the counter number in the module:

- CNT_NUM = 0 is related to input A0, B0, Z0
- CNT_NUM = 1 is related to input A1, B1, Z1

EN_COUNT

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_CNT = TRUE, pulse counting of counter is enabled. If EN_CNT = FALSE, no pulse counting is performed and the pulses are lost.

If counting has already started and if EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

Input EN_CNT corresponds to bit 0 in "control byte".

UD

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD, the counting selection is set for up/down counting mode:

UD=FALSE: count up

UD=TRUE: count down

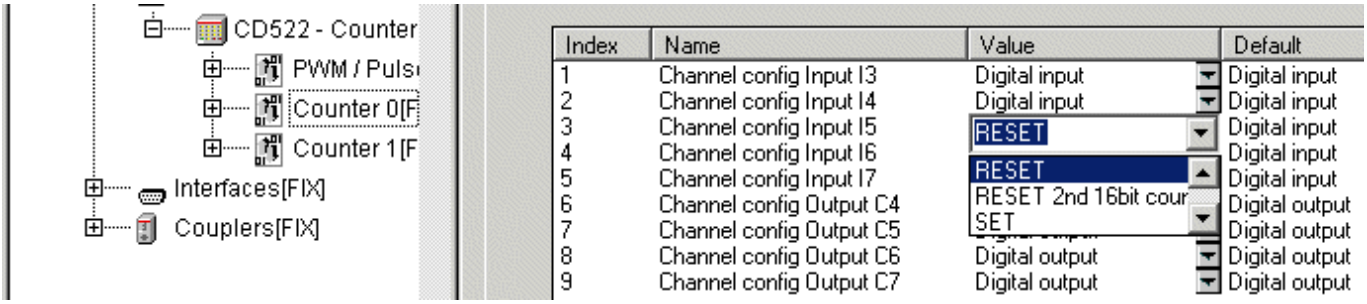
Input UD corresponds to output bit 5 in "control byte".

RESET

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input RESET=TRUE, the counter takes the values 0 to transfer it to output ACT. As long as input RESET=TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at input I3, I4, I5, I6 or I7 (for counter 0) or I11, I12, I13, I14 or I15 (for counter 1) causes the function block to reset the value at output ACT.



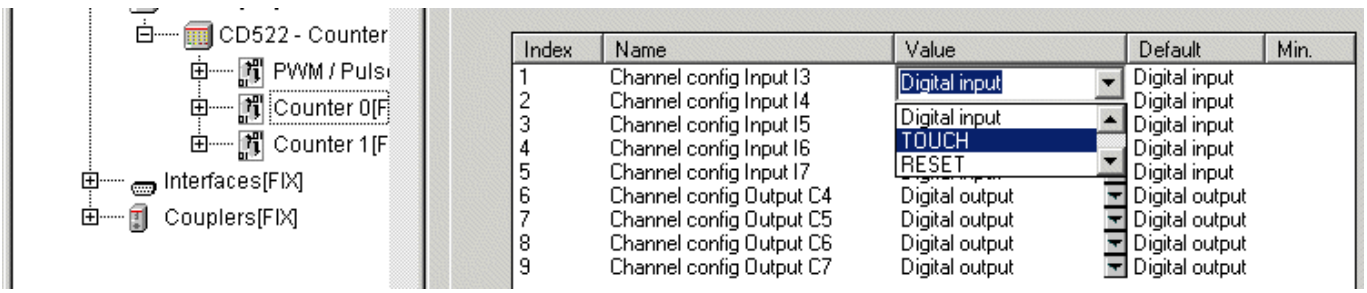
Input EN_RESET corresponds to bit 2 in "control byte".

EN_TOUCH

Data type	Default value	Range	Unit
BOOL	-	-	-

Touch/catch operation is enabled through control bit (EN_TOUCH). This resets the status flag (NTOUCH), when the pre-determined edge occurs; the current counter value is stored in the touch value double word. In the same time, the status NTOUCH is set to TRUE.

A rising edge at input EN_TOUCH enables a catch/touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at input I3 (for counters 0-A and 0-B)) or I11 (for counters 1-A and 1-B) causes the function block to store the actual counter value ACT1 and ACT2 and to display this value at output CNT_TOUCH1 and CNT_TOUCH2.



The next measurement is again initiated by a rising edge at input EN_TOUCH.

If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

Input EN_TOUCH corresponds to bit 6 in "control byte".

EDGE_TOUCH

Data type	Default value	Range	Unit
BOOL	-	-	-

If EDGE_TOUCH = FALSE, a catch/touch value will be operate on falling edge of input I3 (for counters 0-A and 0-B) or I11 (for counters 1-A and 1-B).

If EDGE_TOUCH = TRUE, a catch/touch value will be operate on rising edge of input I3 (for counters 0-A and 0-B) or I11 (for counters 1-A and 1-B).

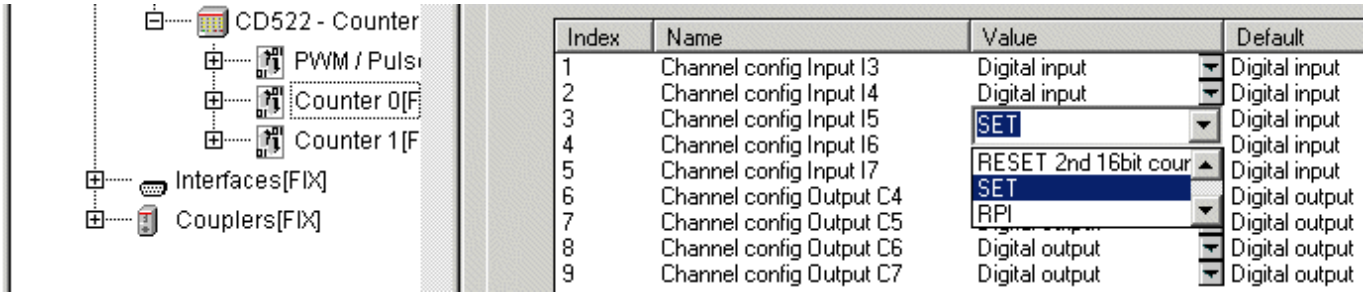
Input EDGE_TOUCH corresponds to bit 7 in "control byte".

SET

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET=TRUE, the counter takes the values from input START_VALUE to transfer it to output ACT. As long as input SET=TRUE, no pulses are counted because the counter is always overwritten by the input START_VALUE.

A rising edge at input I3, I4, I5,I6 or I7 (for counter 0) or I11, I12, I13,I14 or I15 (for counter 1) causes the function block to store the START_VALUE value and to display this value at output ACT.



Input EN_SET corresponds to bit 1 in "control byte".

CNT_SET

Data type	Default value	Range	Unit
INT	-	-	-

The counter can be set to a start value. This value must be applied to the input CNT_SET.

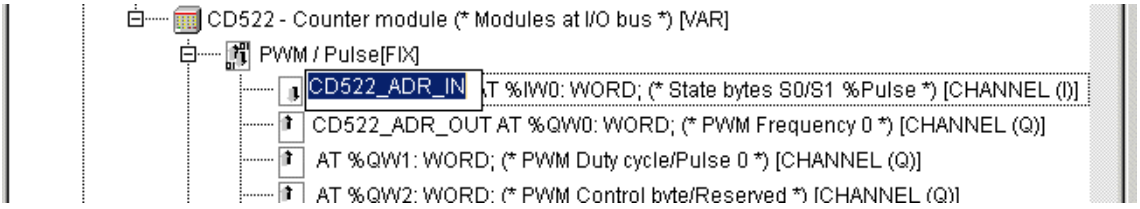
If input SET=TRUE, counter takes this value.

Input START_VALUE corresponds to output low word in "counter settings".

ADR_IN

At ADR_IN input (POINTER TO structCD522counterin), the address of the first input data from the structure of counter input of CD522 should be connected. The use of an ADR operator is needed. If input ADR_IN is not connected, then the outputs DONE=FALSE and ERR= TRUE.

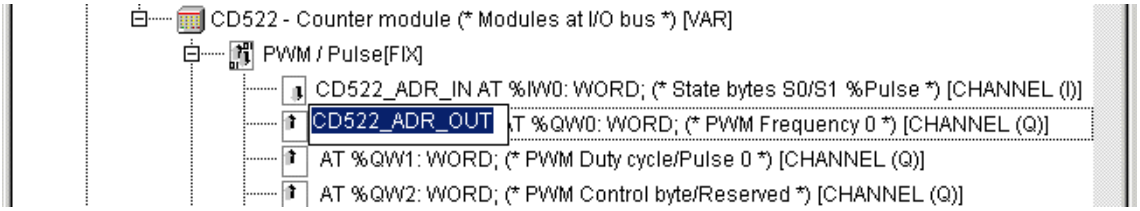
Example (for counter 0):



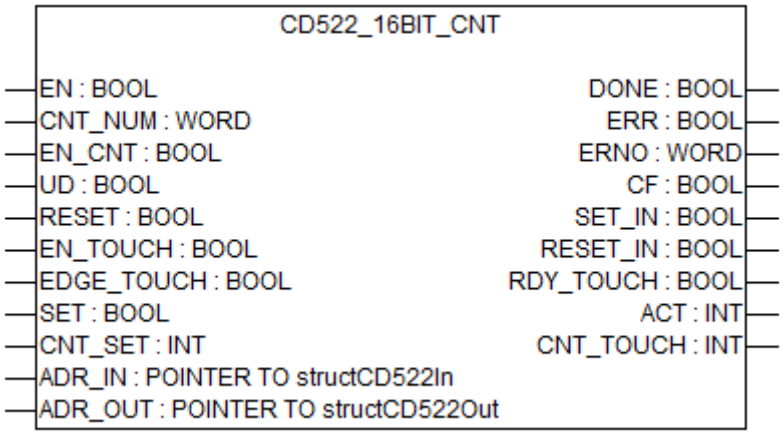
ADR_OUT

At ADR_OUT input (POINTER TO structCD522counterout), the address of the first output data from the structure of counter output of CD522 should be connected. The use of an ADR operator is needed. If input ADR_OUT is not connected, then the outputs DONE=FALSE and ERR= TRUE.

Example (for counter 0):



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

CF

Data type	Default value	Range	Unit
BOOL	-	-	-

If the zero crossover indicator CF=TRUE, this output indicates the sign of the actual counter value ACT. It is set to FALSE when counter value ACT is less than or equal to zero. It is set to TRUE otherwise.

This information is validated when input B is set to TRUE.

SET_IN

Data type	Default value	Range	Unit
BOOL	-	-	-

The output SET_IN is set to TRUE if one of the inputs is configured as SET input.

Output SET_IN corresponds to input bit 4 in "state byte".

RESET_IN

Data type	Default value	Range	Unit
BOOL	-	-	-

The output RESET_IN is set to TRUE if one of the inputs is configured as RESET input.

Output RESET_IN corresponds to input bit 5 in "state byte".

RDY_TOUCH

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The output RDY_TOUCH is set to TRUE when a new catch/touch value is available. If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

Output RDY_TOUCH corresponds to input bit 2 in "state byte".

ACT

Data type	Default value	Range	Unit
INT	0	-	-

The current counter value (actual value) can be retrieved at any time using the output ACT of the function block.

Output ACT corresponds to input low word in "32bit counter".

CNT_TOUCH

Data type	Default value	Range	Unit
INT	-	-	-

The output CNT_TOUCH displays the result of the catch/touch trigger measurement.

Output CNT_TOUCH corresponds to input low word in "TOUCH counter value".

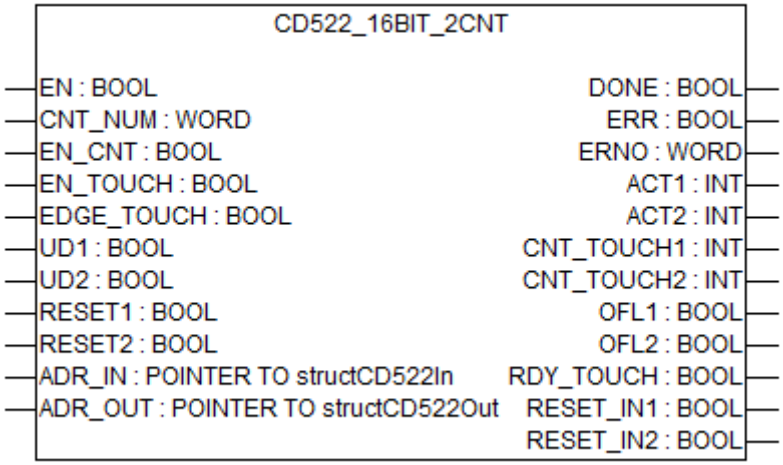
CD522_16BIT_2CNT



The module CD522 can be used in 12 different configurable operating modes. The operating mode is configured in PLC Configuration using module parameters. After that, it is activated during the initialization phase (power-on, cold start, warm start).

The data exchange from and to the user program is performed using input and output operands. These necessary operands are created and reserved automatically, when one module CD522 is added into the I/O bus configuration.

In order to configure and use the function counter of module CD522, different operating modes are available. The function block CD522_16BIT_2CNT should be used with one of these operating modes:

Operating Mode 3	"Up/Down counters (A,B)"
Should be specified in PLC Configuration, parameter "mode counter" in order to use 2 Up/Down 16 bit counter (on rising edge count) functions, with separate up/down, reset operation and overflow flag.	
Operating Mode 4	"Up/Down (A, B on falling edges)"
Should be specified in PLC Configuration, parameter mode counter in order to use two Up/Down 16 bit counter functions (with A on rising edge count and B on falling edge count), With separate up/down, reset operation and overflow flag.	

The module CD522 provides 4 Up/Down 16 bit counter functions. A signal used for pulse count is identified by A0 and B0 for counter A and A1 and B1 for counter B.

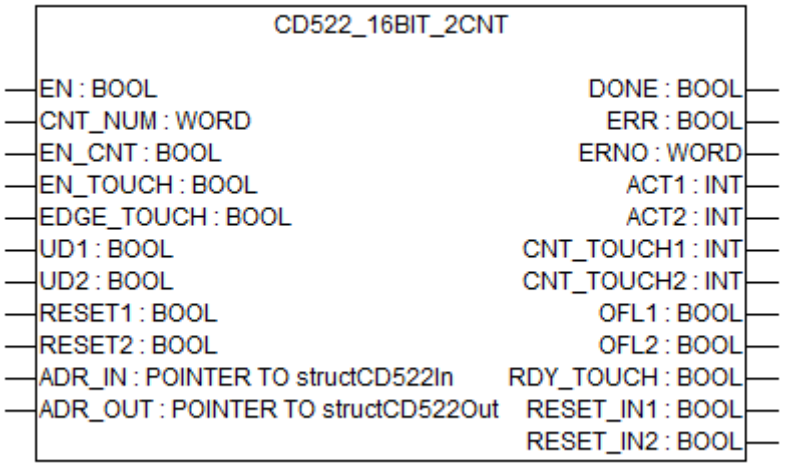
Input description



EN_TOUCH

The touch/catch operation is the way to acquire the counting position synchronously with hardware external signal removing all the latency time of I/O bus and network. This operation allows synchronization between 2 different encoder devices if the same hardware signal is used for touch/catch input.

On edge of the physical external signal, the current counter value (ACT) is stored in a dedicated integer (CNT_TOUCH). The touch/catch operation could be settled on rising or falling edge depending on parameter EDGE_TOUCH (see figure below).

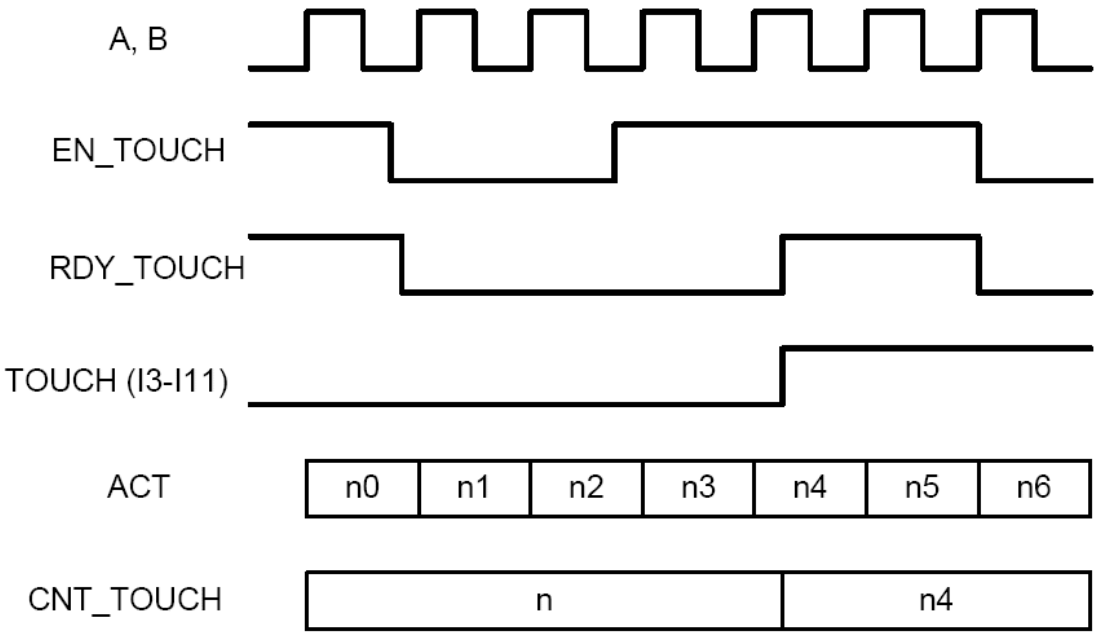


Fig. 22: Procedure and associated counting value with A signal

Touch/catch operation is enabled through control bit (EN_TOUCH). This resets the status flag (NTOUCH), when the pre-determined edge occurs; the current counter value is stored in the touch value double word. In the same time, the status NTOUCH is set to TRUE.

EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

CNT_NUM

Data type	Default value	Range	Unit
WORD	-	-	-

CNT_NUM contains the counter number in the module:

- CNT_NUM = 0 is related to input A0, B0, Z0
- CNT_NUM = 1 is related to input A1, B1, Z1

EN_CNT

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_CNT = TRUE, pulse counting of counter is enabled. If EN_CNT = FALSE, no pulse counting is performed and the pulses are lost.

If counting has already started and if EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

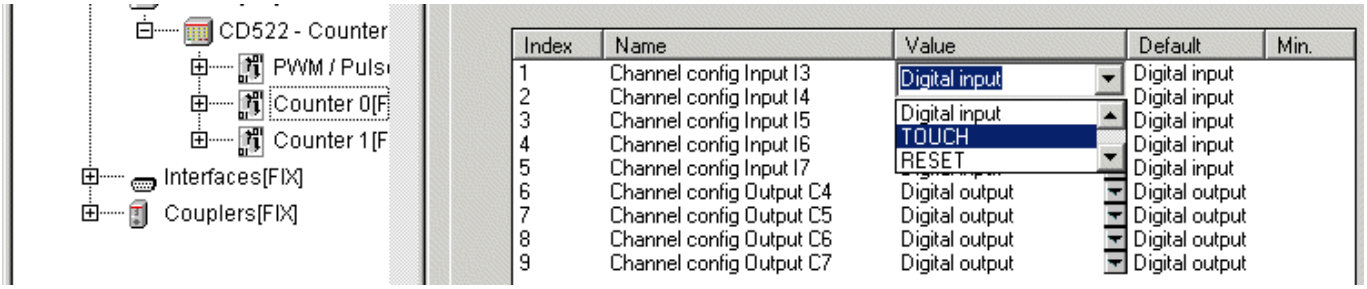
Input EN_CNT corresponds to bit 0 in "control byte".

EN_TOUCH

Data type	Default value	Range	Unit
BOOL	-	-	-

Touch/catch operation is enabled through control bit (EN_TOUCH). This resets the status flag (NTOUCH), when the pre-determined edge occurs; the current counter value is stored in the touch value double word. In the same time, the status NTOUCH is set to TRUE.

A rising edge at input EN_TOUCH enables a catch/touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at input I3 (for counters 0-A and 0-B)) or I11 (for counters 1-A and 1-B) causes the function block to store the actual counter value ACT1 and ACT2 and to display this value at output CNT_TOUCH1 and CNT_TOUCH2.



The next measurement is again initiated by a rising edge at input EN_TOUCH.

If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

Input EN_TOUCH corresponds to bit 6 in "control byte".

EDGE_TOUCH

Data type	Default value	Range	Unit
BOOL	-	-	-

If EDGE_TOUCH = FALSE, a catch/touch value will be operate on falling edge of input I3 (for counters 0-A and 0-B) or I11 (for counters 1-A and 1-B).

If EDGE_TOUCH = TRUE, a catch/touch value will be operate on rising edge of input I3 (for counters 0-A and 0-B) or I11 (for counters 1-A and 1-B).

Input EDGE_TOUCH corresponds to bit 7 in "control byte".

UD1

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD1, the counting selection is set for up/down counting mode for counter A:

UD1=FALSE: count up

UD1=TRUE: count down

Input UD1 corresponds to output bit 3 in control byte.

UD2

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD2, the counting selection is set for up/down counting mode for counter B:

UD2=FALSE: count up

UD2=TRUE: count down

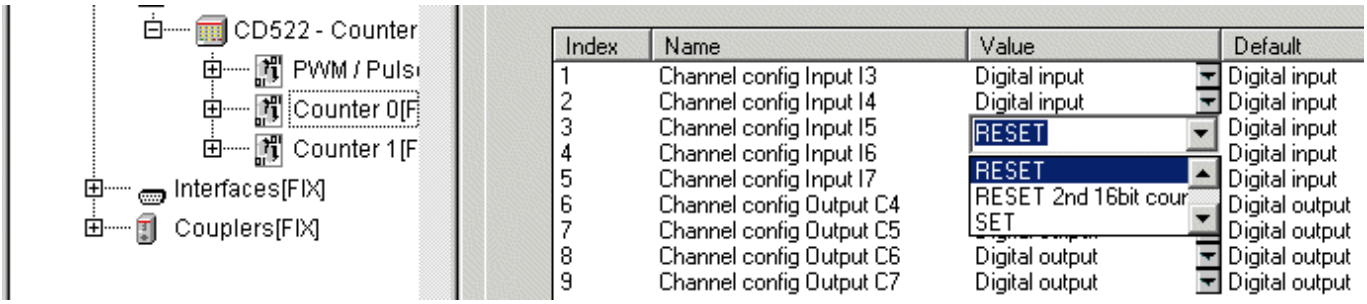
Input UD2 corresponds to output bit 5 in control byte.

RESET1

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input RESET1=TRUE, the counter A takes the values 0 to transfer it to output ACT1. As long as input RESET1=TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at input I3, I4, I5, I6 or I7 (for counter 0-A) or I11, I12, I13, I14 or I15 (for counter 1-A) causes the function block to reset the value at output ACT1.



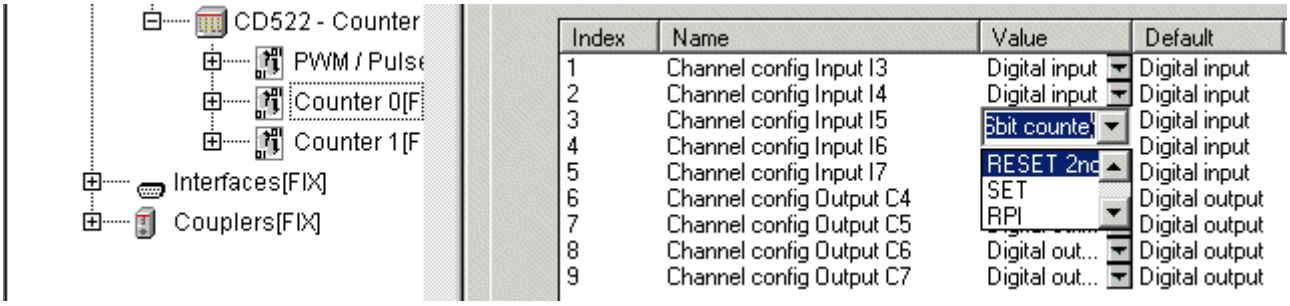
Input EN_RESET1 corresponds to bit 2 in "control byte".

RESET2

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input RESET2=TRUE, the counter takes B the values 0 to transfer it to output ACT2. As long as input RESET2=TRUE, no pulses are counted because the counter is always overwritten by the value 0.

A rising edge at input I3, I4, I5, I6 or I7 (for counter 0-B) or I11, I12, I13, I14 or I15 (for counter 1-B) causes the function block to reset the value at output ACT2.

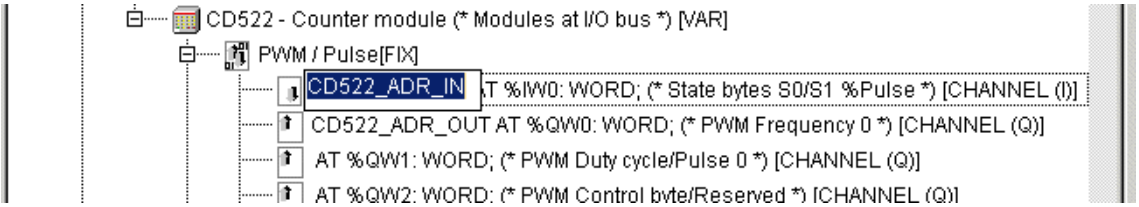


Input EN_RESET2 corresponds to bit 3 in "control byte".

ADR_IN

At ADR_IN input (POINTER TO structCD522counterin), the address of the first input data from the structure of counter input of CD522 should be connected. The use of an ADR operator is needed. If input ADR_IN is not connected, then the outputs DONE=FALSE and ERR= TRUE.

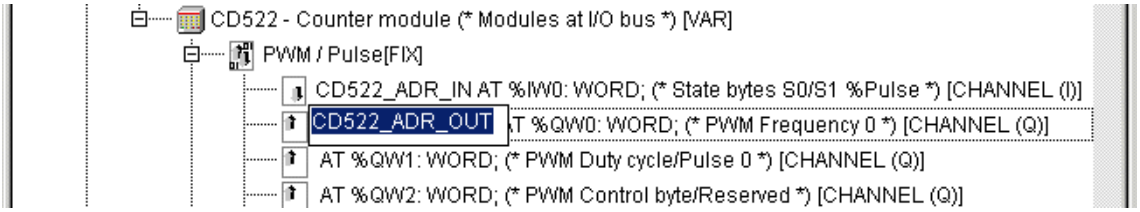
Example (for counter 0):



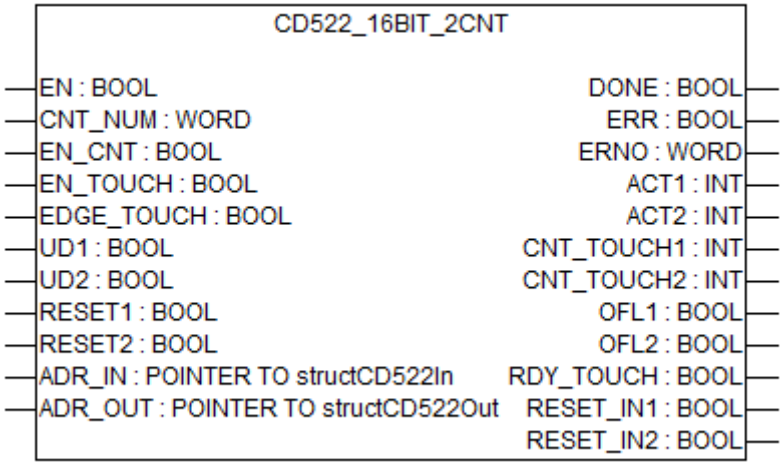
ADR_OUT

At ADR_OUT input (POINTER TO structCD522counterout), the address of the first output data from the structure of counter output of CD522 should be connected. The use of an ADR operator is needed. If input ADR_OUT is not connected, then the outputs DONE=FALSE and ERR= TRUE.

Example (for counter 0):



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ACT1

Data type	Default value	Range	Unit
INT	-	-	-

The current counter value (actual value) from counter A can be retrieved at any time using the output ACT1 of the function block.

Output ACT1 corresponds to input high word in 32bit counter.

ACT2

Data type	Default value	Range	Unit
INT	-	-	-

The current counter value (actual value) from counter B can be retrieved at any time using the output ACT2 of the function block.

Output ACT2 corresponds to input low word in 32bit counter.

CNT_TOUCH1

Data type	Default value	Range	Unit
INT	-	-	-

The output CNT_TOUCH1 displays the result of the catch/touch trigger measurement for counter A.

Output CNT_TOUCH1 corresponds to input high word in TOUCH counter value.

CNT_TOUCH2

Data type	Default value	Range	Unit
INT	-	-	-

The output CNT_TOUCH2 displays the result of the catch/touch trigger measurement for counter B.

Output CNT_TOUCH2 corresponds to input low word in TOUCH counter value.

OFL2

Data type	Default value	Range	Unit
BOOL	-	-	-

The overflow from counter A is specified at the output OFL1.

The counter operates as infinite counter. It is set to TRUE when an overflow occurs, i. e. the counter value ACT1 goes up to value 16#FFFF= -1. Any exceeding or falling below of this value (depending to up use and down use) will set OFL1=TRUE. The output OFL1 is reset when the configuration is changed and if counter value ACT1 is set or reset.

Output OFL1 corresponds to input bit 3 in state byte.

OFL2

Data type	Default value	Range	Unit
BOOL	-	-	-

The overflow from counter B is specified at the output OFL2.

The counter operates as infinite counter. It is set to TRUE when an overflow occurs, i. e. the counter value ACT2 goes up to value 16#FFFF= -1. Any exceeding or falling below of this value (depending to up use and down use) will set OFL2=TRUE. The output OFL2 is reset when the configuration is changed and if counter value ACT2 is set or reset.

Output OFL2 corresponds to input bit 4 in state byte.

RDY_TOUCH

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The output RDY_TOUCH is set to TRUE when a new catch/touch value is available. If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

Output RDY_TOUCH corresponds to input bit 2 in "state byte".

RESET_IN1

Data type	Default value	Range	Unit
BOOL	-	-	-

The output RESET_IN1 is set to TRUE if one of the inputs is configured as RESET input for counter A.

Output RESET_IN1 corresponds to input bit 5 in "state byte".

RESET_IN2

Data type	Default value	Range	Unit
BOOL	-	-	-

The output RESET_IN2 is set to TRUE if one of the inputs is configured as RESET input for counter B.

Output RESET_IN2 corresponds to input bit 7 in "state byte".

```

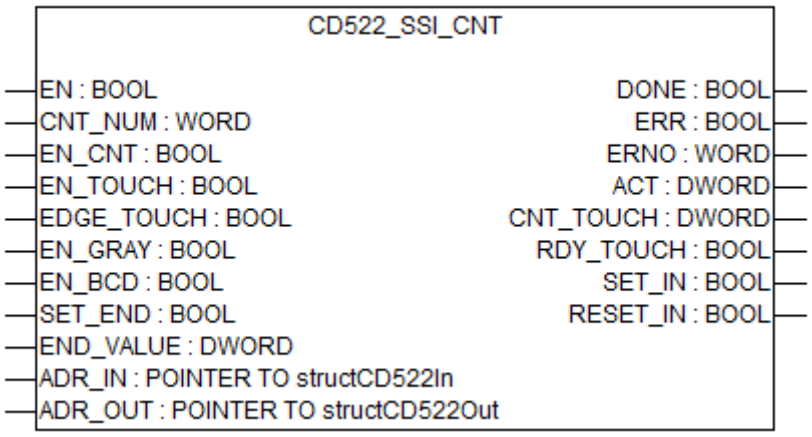
CD522_SSI_CNT



Parameter	Value
Included in library	CD522_AC500_V13.lib
Available from runtime system:	V1.0.2
Available from S500 I/O modules (DC551) firmware	V1.11
Available from CD522 firmware	V2.1
Type	Function block with historical values

The module CD522 can be used in 12 different configurable operating modes. The operating mode is configured in PLC Configuration using module parameters. After that, it is activated during the initialization phase (power-on, cold start, warm start).

The data exchange from and to the user program is performed using input and output operands. These necessary operands are created and reserved automatically, when one module CD522 is added into the I/O bus configuration.

In order to configure and use the function counter of module CD522, different operating modes are available. The function block CD522_SSI_CNT should be used with one of these operating modes:

Operating Mode 14	"SSI, absolute encoder"
Should be specified in PLC Configuration; parameter mode counter in order to use absolute encoder with SSI interface.	

The module CD522 provides 2 SSI absolute encoder functions. There is an interface for absolute angle and linear encoders (displacement measurement systems).

It allows the transmission of absolute position information through a serial data transfer.

The transmission is based on synchronous serial communication. The device sends a clock signal to the encoder and synchronously,the encoder returns the positioning data from the most significant to the less significant bit.

The synchronization for a new data stream is based on time without clock pulse. This quiet time depends on the encoder.

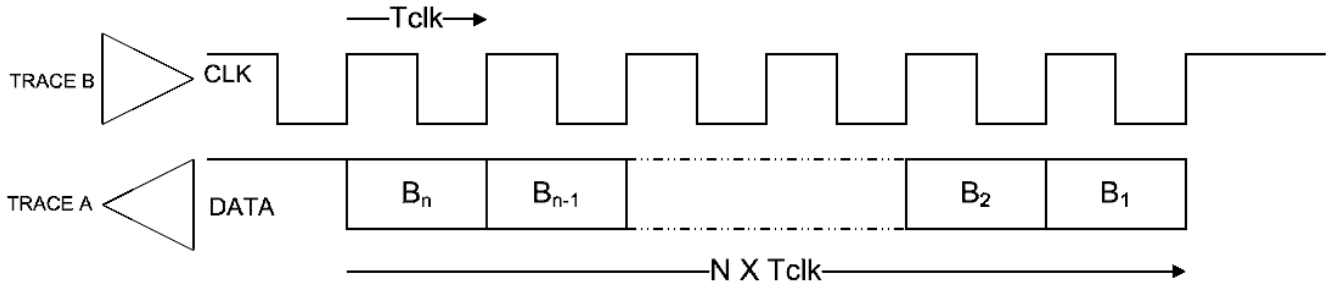


Fig. 23: Chronogram with data organization with the clock pulse

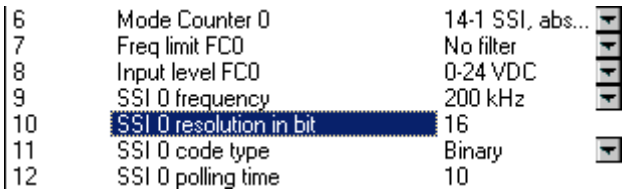
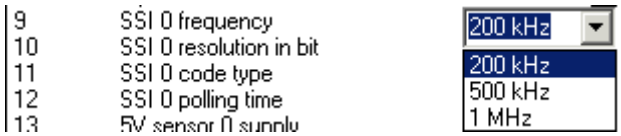
The resolution of the encoder device (see technical data from manufacturer) can be set with configuration, number of bits, etc. in PLC configuration, parameter SSI resolution in bit:



The trace B of module CD522 is switched as output signal (differential). On the rising edge of the signal, the sensor shifts a new value, starting from the most significant bit.

The clock frequency can be set to 200 kHz, 500 kHz, and 1 MHz Should be specified in PLC Configuration, parameter SSI frequency:



NOTICE!

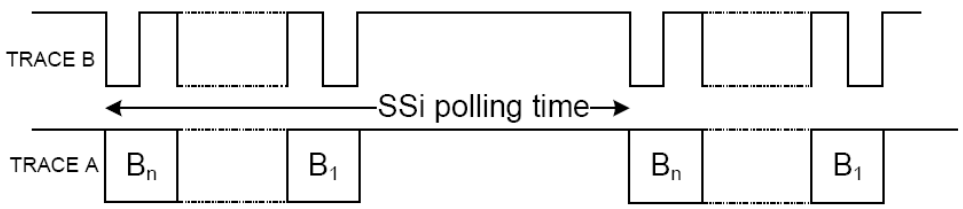
Risk of malfunctions!

The clock frequency is only an approximately value.

Do not use the clock frequency for any other purposes, e.g. time measurements.

SSI polling time definition

The complete read sequence is launched regularly by the module CD522. The interval between each sequence can be set from 1 ms to 255 ms in PLC Configuration, parameter SSI polling time:

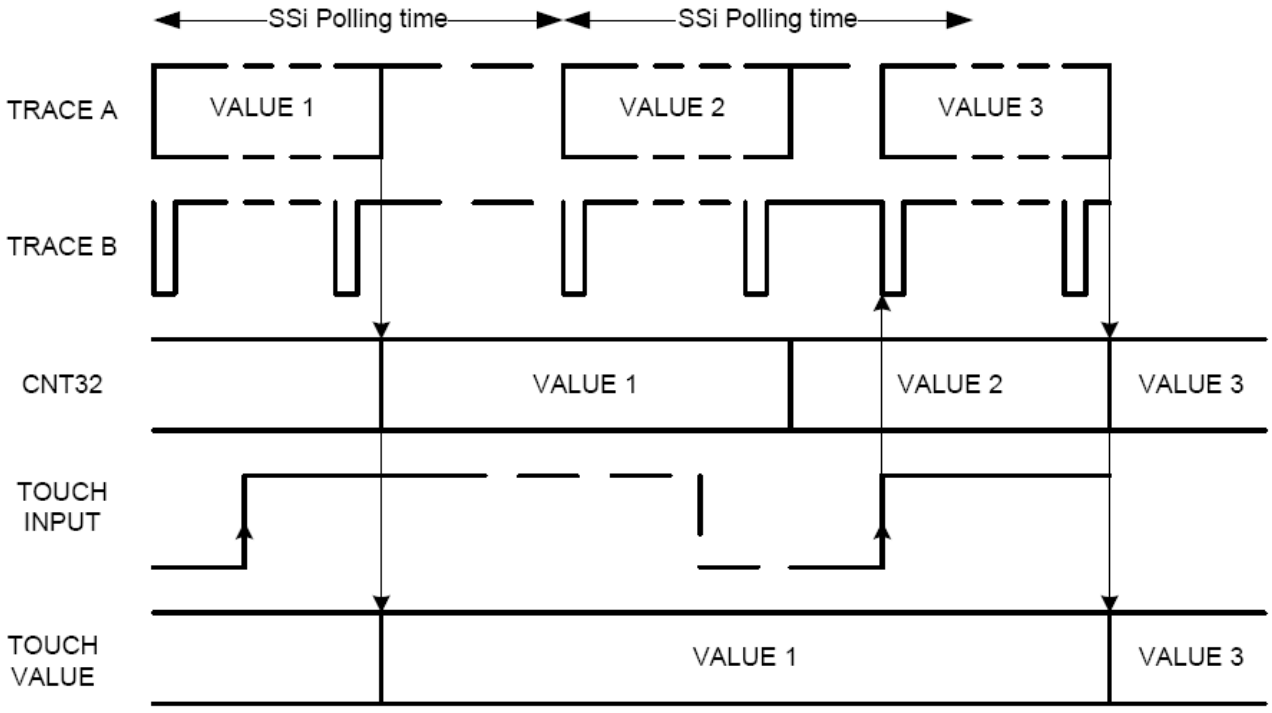


SSI and touch/ catch operation

Touch operation is valid with SSI sensor. The goal of touch operation is to synchronize sensors with the same hardware signal. In the SSI mode the management is different depending on the reading procedure is running or not.

If the reading procedure has already started while the touch signal becomes active, the reading procedure finishes normally and the last read value is stored in the touch register.

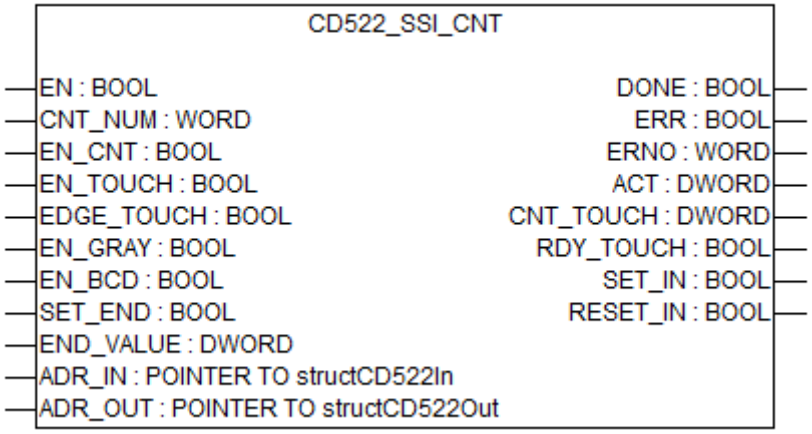
If the reading procedure has not started, the encoder is in the interval between 2 measurements. The reading procedure is started one time more and the result of the last reading is stored in the touch register.



SSI and Touch/Catch Operation: see EN_TOUCH *"EN_TOUCH" on page 1009*.

Overflow Operation: see OFL *"OFL" on page 989*.

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

CNT_NUM

Data type	Default value	Range	Unit
WORD	-	-	-

CNT_NUM contains the counter number in the module:

- CNT_NUM = 0 is related to input A0, B0, Z0
- CNT_NUM = 1 is related to input A1, B1, Z1

EN_CNT

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_CNT = TRUE, pulse counting of counter is enabled. If EN_CNT = FALSE, no pulse counting is performed and the pulses are lost.

If counting has already started and if EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

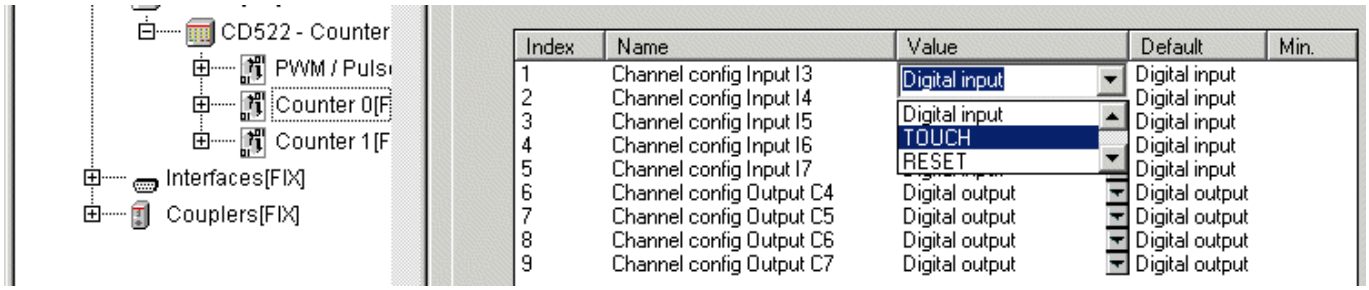
Input EN_CNT corresponds to bit 0 in "control byte".

EN_TOUCH

Data type	Default value	Range	Unit
BOOL	-	-	-

Touch/catch operation is enabled through control bit (EN_TOUCH). This resets the status flag (NTOUCH), when the pre-determined edge occurs; the current counter value is stored in the touch value double word. In the same time, the status NTOUCH is set to TRUE.

A rising edge at input EN_TOUCH enables a catch/touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at input I3 (for counters 0-A and 0-B)) or I11 (for counters 1-A and 1-B) causes the function block to store the actual counter value ACT1 and ACT2 and to display this value at output CNT_TOUCH1 and CNT_TOUCH2.



The next measurement is again initiated by a rising edge at input EN_TOUCH.

If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

Input EN_TOUCH corresponds to bit 6 in "control byte".

EDGE_TOUCH

Data type	Default value	Range	Unit
BOOL	-	-	-

If EDGE_TOUCH = FALSE, a catch/touch value will be operate on falling edge of input I3 (for counter 0) or I11 (for counter 1).

If EDGE_TOUCH = TRUE, a catch/touch value will be operate on rising edge of input I3 (for counter 0) or I11 (for counter 1).

Input EDGE_TOUCH corresponds to bit 7 in "control byte".

EN_GRAY

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_GRAY=TRUE, the actual value will be calculated from GRAY code.

EN_BCD

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_BCD=TRUE, the actual value will be calculated from BCD code.

SET_END

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET_END=TRUE, the counter is set to the value specified at input END_VALUE.

END_VALUE

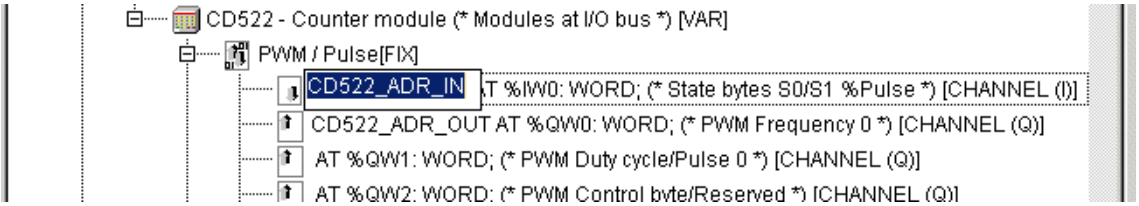
Data type	Default value	Range	Unit
DWORD	-	-	-

If the counter reaches the planned input END_VALUE (read while SET_END is set to TRUE), the outputs configured as ENDV is set to TRUE.

ADR_IN

At ADR_IN input (POINTER TO structCD522counterin), the address of the first input data from the structure of counter input of CD522 should be connected. The use of an ADR operator is needed. If input ADR_IN is not connected, then the outputs DONE=FALSE and ERR= TRUE.

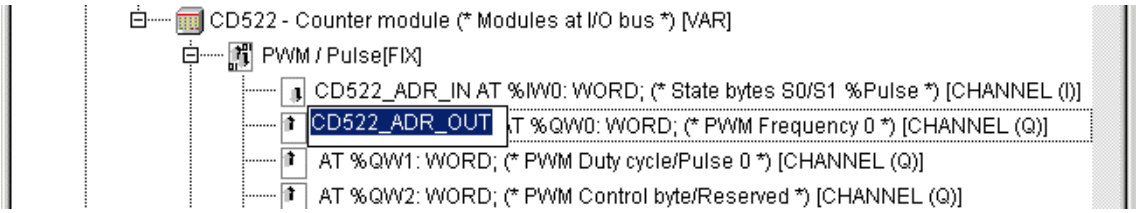
Example (for counter 0):



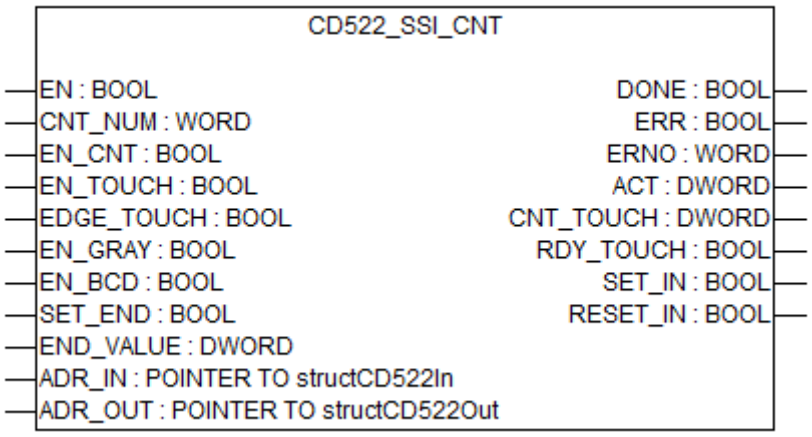
ADR_OUT

At ADR_OUT input (POINTER TO structCD522counterout), the address of the first output data from the structure of counter output of CD522 should be connected. The use of an ADR operator is needed. If input ADR_OUT is not connected, then the outputs DONE=FALSE and ERR= TRUE.

Example (for counter 0):



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ACT

Data type	Default value	Range	Unit
INT	0	-	-

The current counter value (actual value) can be retrieved at any time using the output ACT of the function block.

Output ACT corresponds to input low word in "32bit counter".

CNT_TOUCH

Data type	Default value	Range	Unit
DWORD	-	-	-

The output CNT_TOUCH displays the result of the catch/touch trigger measurement.

Output CNT_TOUCH corresponds to input DWORD in "TOUCH counter value".

RDY_TOUCH

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The output RDY_TOUCH is set to TRUE when a new catch/touch value is available. If input EN_TOUCH is set to FALSE, the output RDY_TOUCH is set to FALSE.

Output RDY_TOUCH corresponds to input bit 2 in "state byte".

SET_IN

Data type	Default value	Range	Unit
BOOL	-	-	-

The output SET_IN is set to TRUE if one of the inputs is configured as SET input.

Output SET_IN corresponds to input bit 4 in "state byte".

RESET_IN

Data type	Default value	Range	Unit
BOOL	-	-	-

The output RESET_IN is set to TRUE if one of the inputs is configured as RESET input.

Output RESET_IN corresponds to input bit 5 in "state byte".

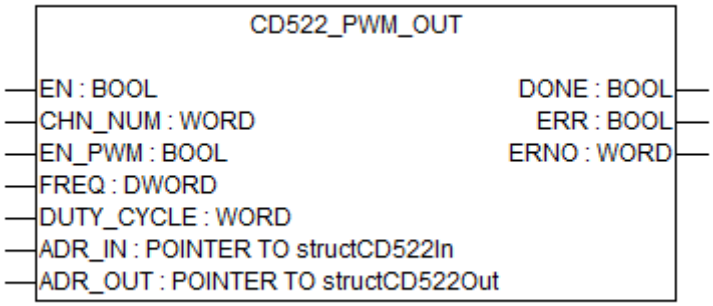
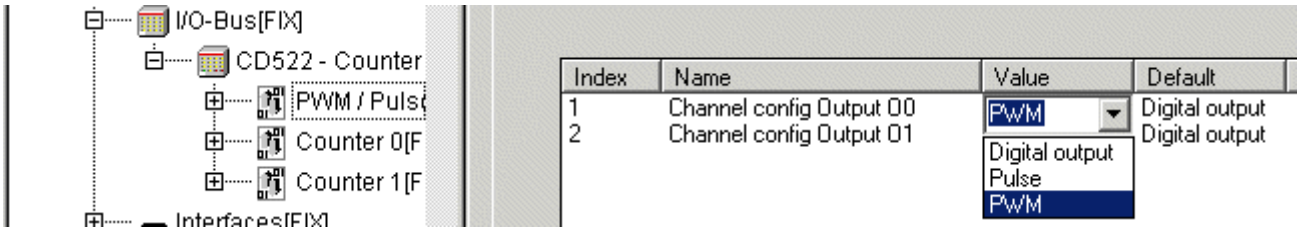
CD522SSICNT_RDY_TOUCH    := CD522SSICNT.RDY_TOUCH;
CD522SSICNT_SET_IN       := CD522SSICNT.SET_IN;
CD522SSICNT_RESET_IN     := CD522SSICNT.RESET_IN;
```

CD522_PWM_OUT



Parameter	Value
Included in library	CD522_AC500_V13.lib
Available from runtime system:	V1.0.2
Available from S500 I/O modules (DC551) firmware	V1.11
Available from CD522 firmware	V2.1
Type	Function block with historical values

The module CD522 can be used to control one output pulsing signal (Max= 100 KHz) with an adjustable duty cycle (ON/OFF ratio, max=100%). The PWM operating mode is configured in Automation Builder.



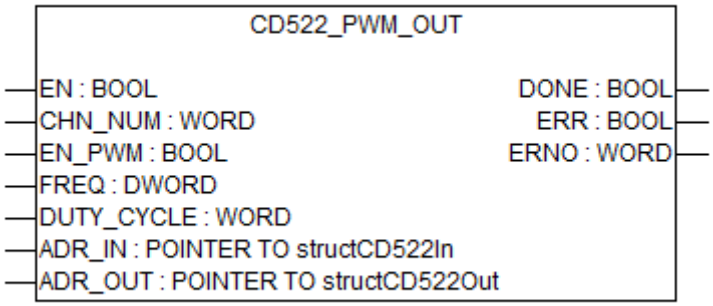
After that, it is activated during the initialization phase (power-on, cold start, warm start).

The data exchange to and from the user program is performed using input and output operands. These necessary operands are created and reserved automatically, when one module CD522 is added in I/O bus configuration.

The module CD522 provides two independent outputs which can be used in PWM mode (O0 and O1). Both have the same specification and can work separately.

The function block CD522_PWM_OUT should be used to control with input EN_PWM, configure the frequency with input FREQ and the input duty cycle DUTY_CYCLE of PWM outputs (pulse-width modulator).

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

CHN_NUM

Data type	Default value	Range	Unit
WORD	-	-	-

CHN_NUM contains the channel number managed by the function block:

- CHN_NUM = 0: the output O0 is managed
- CHN_NUM = 1: the output O1 is managed

EN_PWM

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_PWM = TRUE, the pulse-width modulator is enabled. If EN_PWM = FALSE, no pulse-width modulation is performed.

Input EN_PWM corresponds to output bit 7 in "control byte".

FREQ

Data type	Default value	Range	Unit
DWORD	-	1 ... 100	KHz

Input FREQ is used to specify the frequency of output. The frequency can be set from 1 to 100 KHz.

The duty cycle is fixed (50 %).

The frequency value is defined with a double word (DWORD), but the internal communication with CD522 is realized with WORD type. For frequencies greater than 65535 Hz (word limitation) an additional bit is internally used as multiplier. Thus, for such frequencies the resolution becomes 10 Hz.

The additional multiplier bit is the bit 0 of "control byte". If bit 0 of "control byte"=TRUE, the frequency multiplier x10 is enabled.

DUTY_CYCLE

Data type	Default value	Range	Unit
WORD	-	1 ... 100	KHz

The input DUTY_CYCLE is used to specify the percentage of time set to TRUE. The duty cycle is from 0.0 to 100.0 (0 % to 100 %); the value is written without dot. That means, for example, for 75.8 % the value written will be 758. The max. value authorized will be 1000 to specify a duty cycle = 100 %.

On fast outputs O0 and O1, the brightness of the yellow LED depends on the value of duty cycle specified (from 0 to 100 %).

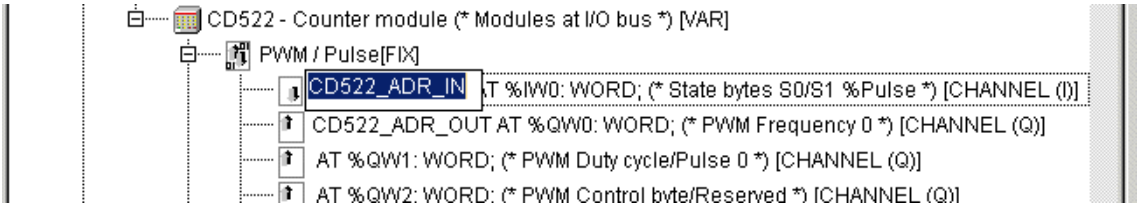
If the written value is greater than 1000 or less than 0, an error code will be displayed in ERR and ERNO outputs and the red error LED CH-ERR1 will flash. The last entered valid value will be used or the value '0' if no value has been entered before.

Input DUTY_CYCLE corresponds to output word "PWM Duty cycle/pulse".

ADR_IN

At ADR_IN input (POINTER TO structCD522counterin), the address of the first input data from the structure of counter input of CD522 should be connected. The use of an ADR operator is needed. If input ADR_IN is not connected, then the outputs DONE=FALSE and ERR= TRUE.

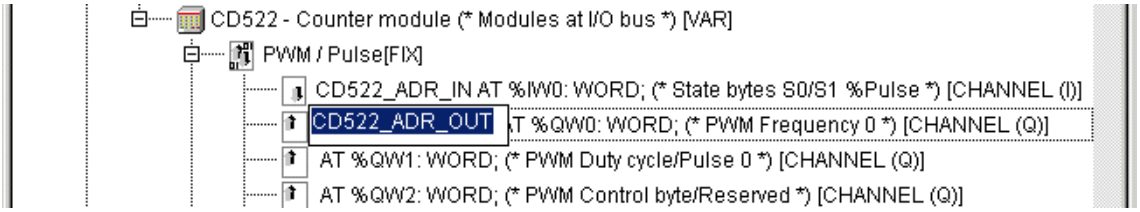
Example (for counter 0):



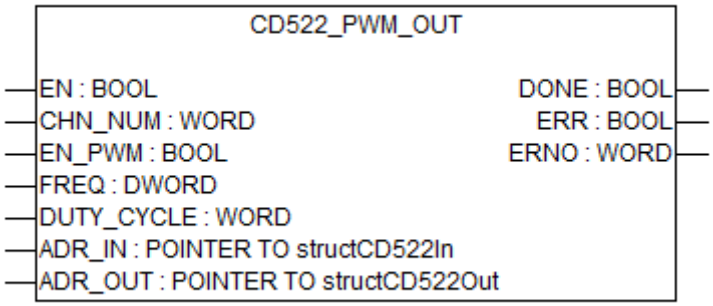
ADR_OUT

At ADR_OUT input (POINTER TO structCD522counterout), the address of the first output data from the structure of counter output of CD522 should be connected. The use of an ADR operator is needed. If input ADR_OUT is not connected, then the outputs DONE=FALSE and ERR= TRUE.

Example (for counter 0):



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

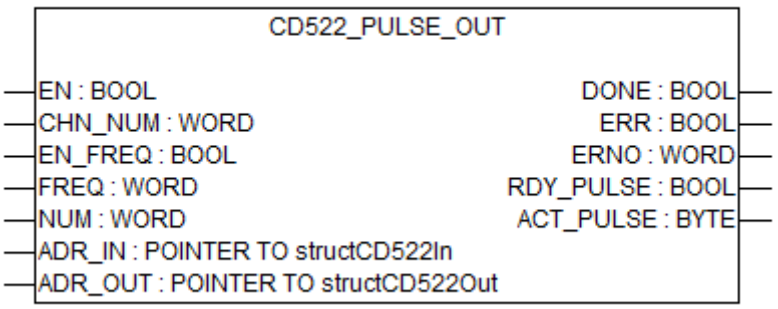
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
CD522PWMOUT    (EN          := CD522PWMOUT_EN,
                CHN_NUM     := CD522PWMOUT_CHN_NUM,
                FREQ        := CD522PWMOUT_FREQ,
                DUTY_CYCLE  := CD522PWMOUT_DUTY_CYCLE,
                ADR_IN      := ADR(CD522PWMOUT_ADR_IN),
                ADR_OUT     := ADR(CD522PWMOUT_ADR_OUT));

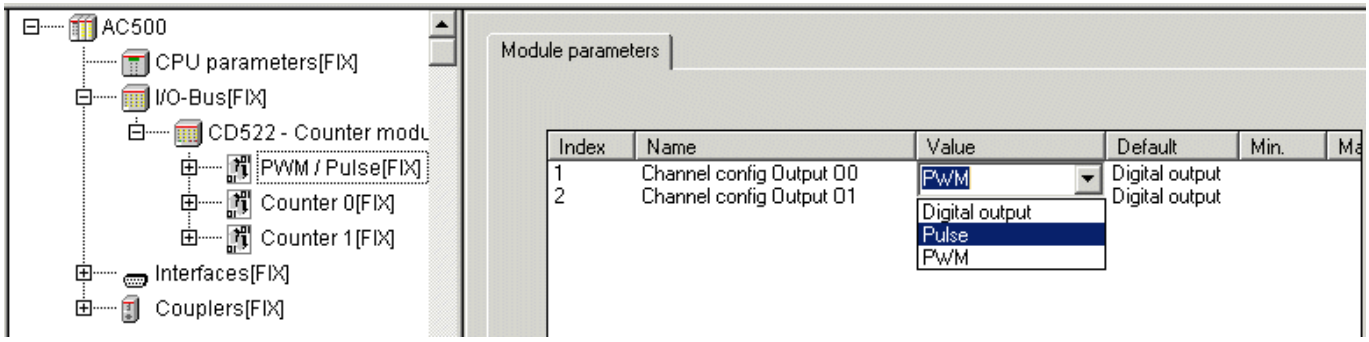
CD522PWMOUT_DONE := CD522PWMOUT.DONE;
CD522PWMOUT_ERR  := CD522PWMOUT.ERR;
CD522PWMOUT_ERNO := CD522PWMOUT.ERNO;
```

CD522_PULSE_OUT



Parameter	Value
Included in library	CD522_AC500_V13.lib
Available from runtime system:	V1.0.2
Available from S500 I/O modules (DC551) firmware	V1.11
Available from CD522 firmware	V2.1
Type	Function block with historical values

The module CD522 can be used to control one output pulses signals with a fixed duty cycle (ON/OFF ratio 50 %) and number of pulses sent with a fixed frequency (can be modified) .The PULSE operating mode is configured in PLC Configuration using module parameters:



After that, it is activated during the initialization phase (power-on, cold start, warm start).

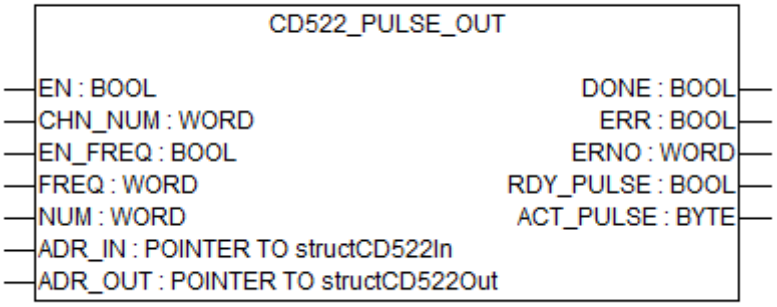
The data exchange from and to the user program is performed by using input and output operands. These necessary operands are created and reserved automatically, when one CD522 module is added into the I/O bus configuration.

The module CD522 provides two independents outputs used in PULSE mode (O0 and O1). Both have the same specification and can work separately.

The function block CD522_PULSE_OUT should be used to control the pulse output, with input EN_FREQ, configure the frequency with input FREQ and the number of pulses with input NUM. The number of pulses sent can be displayed in percentage (from 0 % to 100%).

On the fast outputs O0 or O1, the brightness of yellow LED depends on the number of pulse emitted (from 0 and 100%), When the value 100% is obtained, the yellow LED status is off.

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

CHN_NUM

Data type	Default value	Range	Unit
WORD	-	-	-

CHN_NUM contains the channel number managed by the function block:

- CHN_NUM = 0: the output O0 is managed
- CHN_NUM = 1: the output O1 is managed

EN_FREQ

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_FREQ=TRUE, the frequency output is enabled. If EN_FREQ = FALSE, no frequency output is performed.

Input EN_FREQ corresponds to output bit 7 in "control byte".

FREQ

Data type	Default value	Range	Unit
WORD	-	0 ... 15	Khz

The input FREQ is used to specify the frequency of output pulse.

The input FREQ corresponds to output word "PWM Frequency".

NUM

Data type	Default value	Range	Unit
WORD	-	-	-

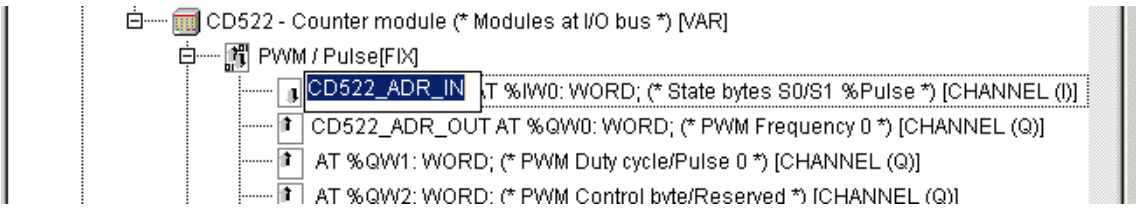
The input NUM is used to specify the number of pulses to be sent. The number is from 1 to 65535 pulses.

The input NUM corresponds to output word "PWM Frequency".

ADR_IN

At ADR_IN input (POINTER TO structCD522counterin), the address of the first input data from the structure of counter input of CD522 should be connected. The use of an ADR operator is needed. If input ADR_IN is not connected, then the outputs DONE=FALSE and ERR= TRUE.

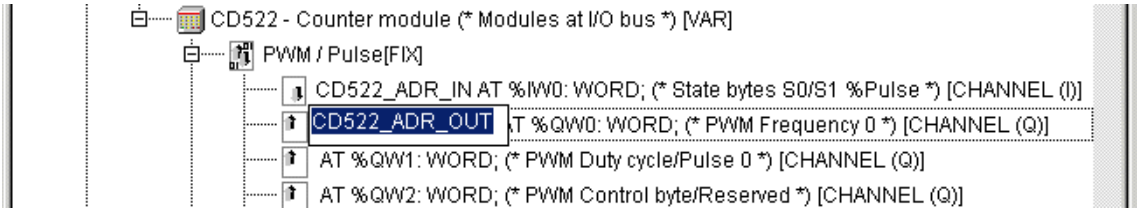
Example (for counter 0):



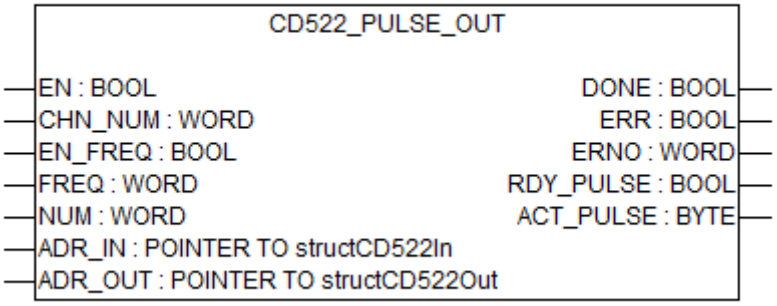
ADR_OUT

At ADR_OUT input (POINTER TO structCD522counterout), the address of the first output data from the structure of counter output of CD522 should be connected. The use of an ADR operator is needed. If input ADR_OUT is not connected, then the outputs DONE=FALSE and ERR= TRUE.

Example (for counter 0):



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY_PULSE

Data type	Default value	Range	Unit
BOOL	-	-	-

The output RDY_PULSE is set to TRUE when all pulses have been sent.

ACT_PULSE

Data type	Default value	Range	Unit
BYTE	-	-	%

The output ACT_PULSE return the percentage of pulses sent, from 0 to 100 %.

100 % is obtained only when the totality of pulses has been sent.

On the fast outputs O0 or O1, the brightness of the yellow LED depends on the number of pulse emitted (from 0 to 100 %), When the value 100 % is obtained, the yellow LED status is off.

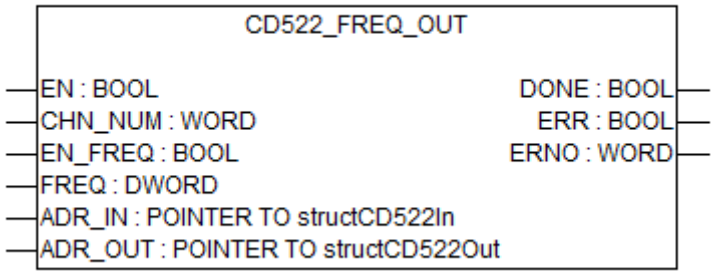
Output ACT_PULSE corresponds to input byte in "state byte Sx %pulse".

Function call in ST

```
CD522PULSEOUT     (EN      := CD522PULSEOUT_EN,
                   CHN_NUM := CD522PULSEOUT_CHN_NUM,
                   EN_FREQ := CD522PULSEOUT_EN_FREQ,
                   FREQ    := CD522PULSEOUT_FREQ,
                   NUM     := CD522PULSEOUT_NUM,
                   ADR_IN  := ADR(CD522PULSEOUT_ADR_IN),
                   ADR_OUT := ADR(CD522PULSEOUT_ADR_OUT));

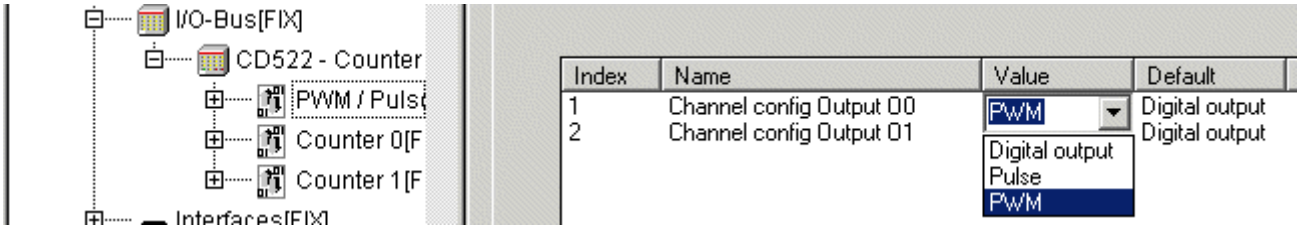
CD522PULSEOUT_DONE      := CD522PULSEOUT.DONE;
CD522PULSEOUT_ERR       := CD522PULSEOUT.ERR;
CD522PULSEOUT_ERNO      := CD522PULSEOUT.ERNO;
CD522PULSEOUT_RDY_PULSE := CD522PULSEOUT.RDY_PULSE;
CD522PULSEOUT_ACT_PULSE := CD522PULSEOUT.ACT_PULSE;
```

CD522_FREQ_OUT



Parameter	Value
Included in library	CD522_AC500_V13.lib
Available from CD522 firmware	V2.1
Available from runtime system:	V1.0.2
Available from S500 I/O modules (DC551) firmware	V1.11
Type	Function block with historical values

The module CD522 can be used to control one output pulses signals with an fixed duty cycle (ON/OFF ratio 50 %).The PWM operating mode is configured in PLC Configuration using module parameters:



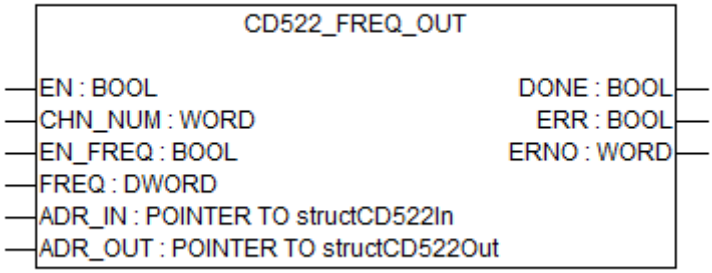
After that, it is activated during the initialization phase (power-on, cold start, warm start).

The data exchange to and from the user program is performed using input and output operands. These necessary operands are created and reserved automatically, when one module CD522 is added in I/O bus configuration.

The module CD522 provides two independent outputs which can be used in PWM mode (O0 and O1). Both have the same specification and can work separately.

The function block CD522_FREQ_OUT should be used to control with input EN_FREQ and configure the frequency with input FREQ of frequency outputs (1 kHz to 100 kHz).

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

CHN_NUM

Data type	Default value	Range	Unit
WORD	-	-	-

CHN_NUM contains the channel number managed by the function block:

- CHN_NUM = 0: the output O0 is managed
- CHN_NUM = 1: the output O1 is managed

EN_FREQ

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_FREQ=TRUE, the frequency output is enabled. If EN_FREQ = FALSE, no frequency output is performed.

Input EN_FREQ corresponds to output bit 7 in "control byte".

FREQ

Data type	Default value	Range	Unit
DWORD	-	1 ... 100	KHz

Input FREQ is used to specify the frequency of output. The frequency can be set from 1 to 100 KHz.

The duty cycle is fixed (50 %).

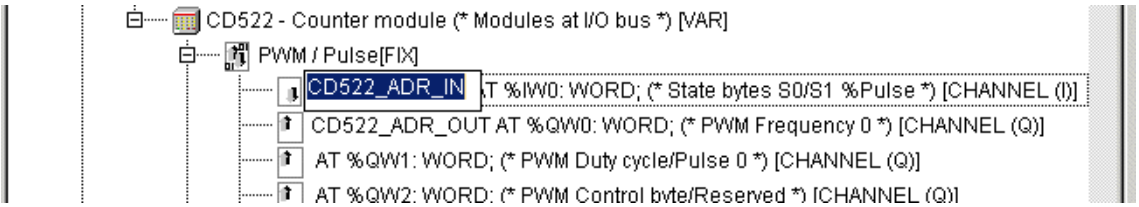
The frequency value is defined with a double word (DWORD), but the internal communication with CD522 is realized with WORD type. For frequencies greater than 65535 Hz (word limitation) an additional bit is internally used as multiplier. Thus, for such frequencies the resolution becomes 10 Hz.

The additional multiplier bit is the bit 0 of "control byte". If bit 0 of "control byte"=TRUE, the frequency multiplier x10 is enabled.

ADR_IN

At ADR_IN input (POINTER TO structCD522counterin), the address of the first input data from the structure of counter input of CD522 should be connected. The use of an ADR operator is needed. If input ADR_IN is not connected, then the outputs DONE=FALSE and ERR= TRUE.

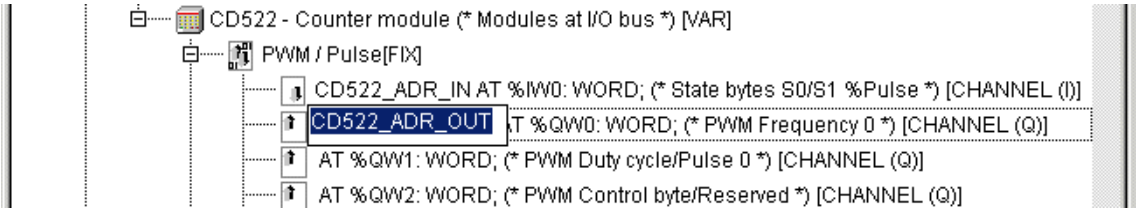
Example (for counter 0):



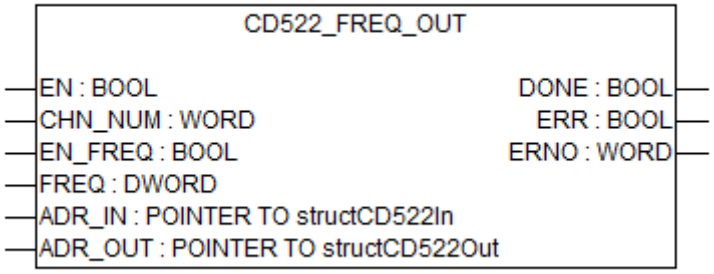
ADR_OUT

At ADR_OUT input (POINTER TO structCD522counterout), the address of the first output data from the structure of counter output of CD522 should be connected. The use of an ADR operator is needed. If input ADR_OUT is not connected, then the outputs DONE=FALSE and ERR= TRUE.

Example (for counter 0):



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

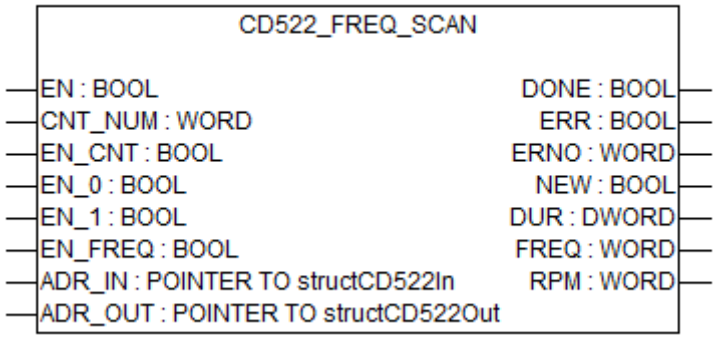
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
CD522FREQOUT        (EN:= CD522FREQOUT_EN,
     CHN_NUM:= CD522FREQOUT_CHN_NUM,
     EN_FREQ:= CD522FREQOUT_EN_FREQ,
     FREQ:= CD522FREQOUT_FREQ,
     ADR_IN:= ADR(CD522FREQOUT_ADR_IN),
     ADR_OUT:= ADR(CD522FREQOUT_ADR_OUT));

CD522FREQOUT_DONE := CD522FREQOUT.DONE;
CD522FREQOUT_ERR := CD522FREQOUT.ERR;
CD522FREQOUT_ERNO := CD522FREQOUT.ERNO;
```

CD522_FREQ_SCAN



Parameter	Value
Included in library	CD522_AC500_V13.lib
Available from runtime system:	V1.0.2
Available from S500 I/O modules (DC551) firmware	V1.11
Available from CD522 firmware	V2.1
Type	Function block with historical values

The module CD522 can be used in 12 different configurable operating modes. The operating mode is configured in PLC Configuration using module parameters. After that, it is activated during the initialization phase (power-on, cold start, warm start).

The data exchange from and to the user program is performed using input and output operands. These necessary operands are created and reserved automatically, when one module CD522 is added into the I/O bus configuration.

In order to configure and use the function counter of module CD522, different operating modes are available. The function block CD522_FREQ_SCAN should be used with one of these operating modes:

Operating Mode 15	"Time frequency meter (Z)"
Should be specified in PLC Configuration with the parameter mode counter.	

The module CD522 provides 2 channels (Z0 and Z1) which can be used to measure times, frequencies and rotational speeds with a resolution of 1 µs. Both have the same specification and can work separately.

The function block CD522_FREQ_SCAN should be used to control with input EN_CNT, configure the capture on falling edge with input EN_0 or rising edge with input EN_1 of signal, and the specification of the mode of the measurement (time, frequency and Rpm) with input EN_FREQ.

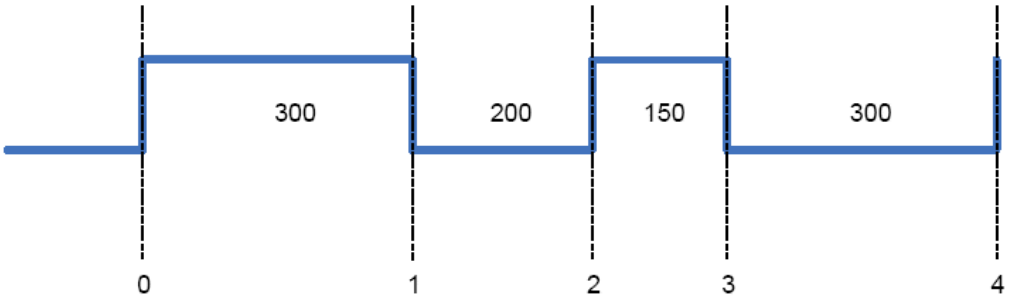
The table shows values measured according to configuration input parameters and this example of timing.

NOTICE!

Risk of malfunctions!

Never use the time measurement (bit EN_FREQ=FALSE) mode if the CD522 is connected to a CS31 communication interface module, e. g. CI592.

Depending on the input parameters of function block, the result of time measurement can be measured in time in µs, frequency in Hz or speed of rotation in rotation per minute.



EN_0	EN_1	EN_FREQ	Type	1	2	3	4
FALSE	FALSE	TRUE	No measurement	0	0	0	0
FALSE	TRUE	TRUE	Between 2 falling edges			350	
TRUE	FALSE	TRUE	Between 2 rising edges		500		450
TRUE	TRUE	TRUE	Between any 2 edges	300	200	150	300
FALSE	FALSE	FALSE	No measurement	0	0	0	0
FALSE	TRUE	FALSE	Between the rising edge and the subsequent falling edge	300		150	

EN_0	EN_1	EN_FREQ	Type	1	2	3	4
TRUE	FALSE	FALSE	Between the falling edge and the subsequent rising edge		200		300
TRUE	TRUE	FALSE	Between any 2 edges	300	200	150	300

Input description

EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

CNT_NUM

Data type	Default value	Range	Unit
WORD	-	-	-

CNT_NUM contains the counter number in the module:

- CNT_NUM = 0 is related to input A0, B0, Z0
- CNT_NUM = 1 is related to input A1, B1, Z1

EN_CNT

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_CNT = TRUE, pulse counting of counter is enabled. If EN_CNT = FALSE, no pulse counting is performed and the pulses are lost.

If counting has already started and if EN_CNT = FALSE, the pulse counting stops and counter value ACT is stored. If EN_CNT = TRUE again, the pulse counting will start again and counter value ACT will continue since previous value.

Input EN_CNT corresponds to bit 0 in "control byte".

EN_0

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_0=TRUE, the time frequency measurement will be captured on the falling edge of signal.

Input EN_0 corresponds to output bit 1 in control byte.

EN_1

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

If EN_1=TRUE, the time frequency measurement will be capture on rising edge of signal.

Input EN_1 corresponds to output bit 2 in control byte.

EN_FREQ

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

If EN_FREQ=FALSE, the time frequency measurement will be specified in time mode and displayed on output DUR (in µs).

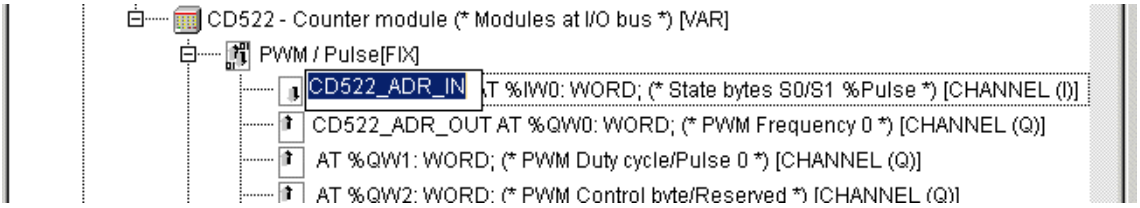
If EN_FREQ= TRUE, the time frequency measurement will be specified in frequency and rpm modes and displayed on output FREQ (in Hz) and RPM (in rotation per minute).

Input EN_FREQ corresponds to output bit 3 in control byte.

ADR_IN

At ADR_IN input (POINTER TO structCD522counterin), the address of the first input data from the structure of counter input of CD522 should be connected. The use of an ADR operator is needed. If input ADR_IN is not connected, then the outputs DONE=FALSE and ERR= TRUE.

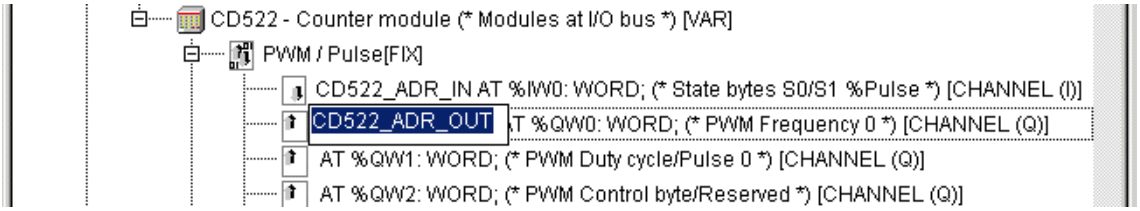
Example (for counter 0):



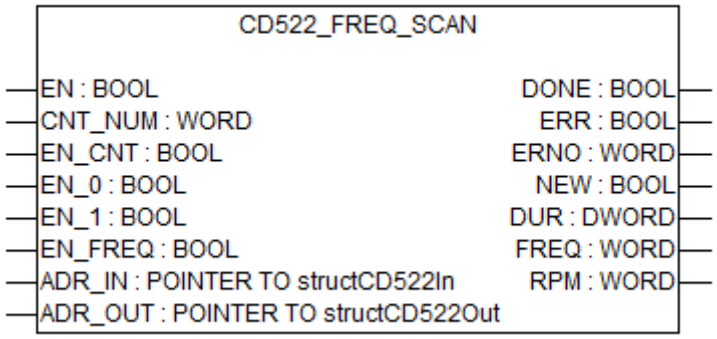
ADR_OUT

At ADR_OUT input (POINTER TO structCD522counterout), the address of the first output data from the structure of counter output of CD522 should be connected. The use of an ADR operator is needed. If input ADR_OUT is not connected, then the outputs DONE=FALSE and ERR= TRUE.

Example (for counter 0):



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NEW

Data type	Default value	Range	Unit
BOOL	-	-	-

If output NEW=TRUE, a new timing value is available.

Output NEW corresponds to input bit 6 in state byte.

DUR

Data type	Default value	Range	Unit
DWORD	-	-	-

The output DUR is used for display the result of timing measurement. If the input EN_FREQ=FALSE, measured time is in µs.

Output DUR corresponds to input word Counter low word.

FREQ

Data type	Default value	Range	Unit
WORD	-	-	-

The output FREQ is used for display the result of time measurement. If the input EN_FREQ=TRUE, measured frequency is in Hz.

Output FREQ corresponds to input word Counter high word.

RPM

Data type	Default value	Range	Unit
WORD	-	-	-

The output RPM is used for display the result of timing measurement. If the input EN_FREQ= TRUE, measured speed of rotation is in rpm (rotations per minute).

Output RPM corresponds to input word Counter low word.

Function call in ST

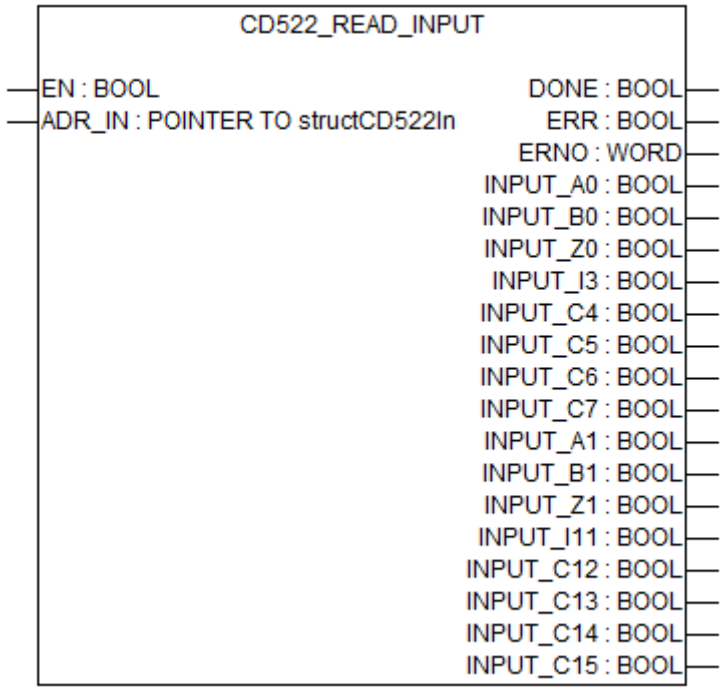
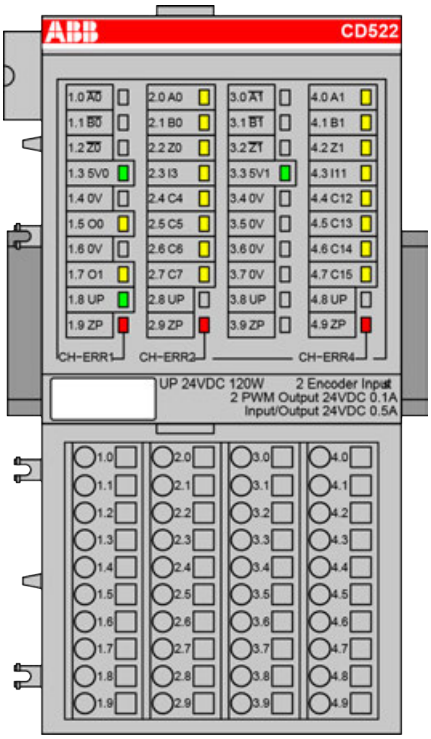
CD522FREQSCAN_RPM      := CD522FREQSCAN.RPM;
```

CD522_READ_INPUT

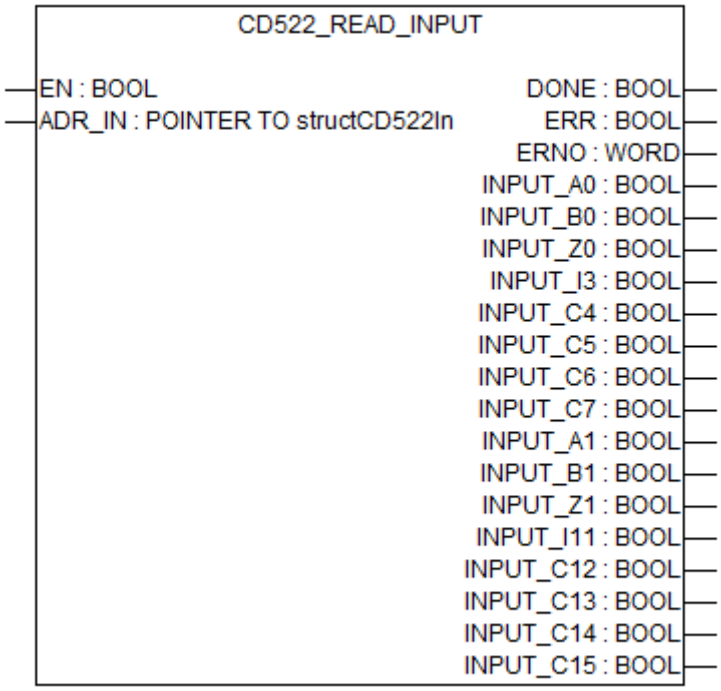


Parameter	Value
Included in library	CD522_AC500_V13.lib
Available from CD522 firmware	V2.1
Available from runtime system:	V1.0.2
Available from S500 I/O modules (DC551) firmware	V1.11
Type	Function block with historical values

The function block is used to read binary inputs from CD522. The output parameter INPUT_xx of the function block refers to the respective input channel xx on CD522.



Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

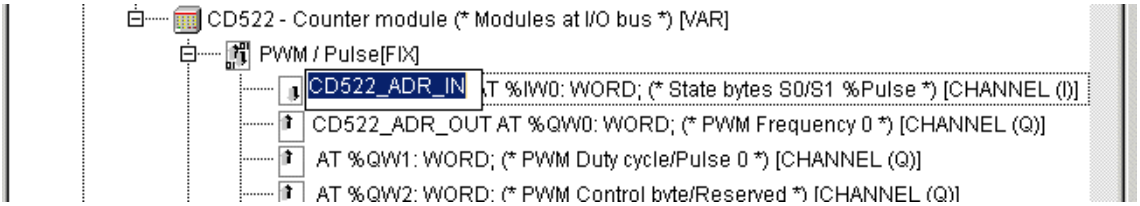
In order to enable the Function Block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and corresponding error is displayed at output ERR/ERNO.

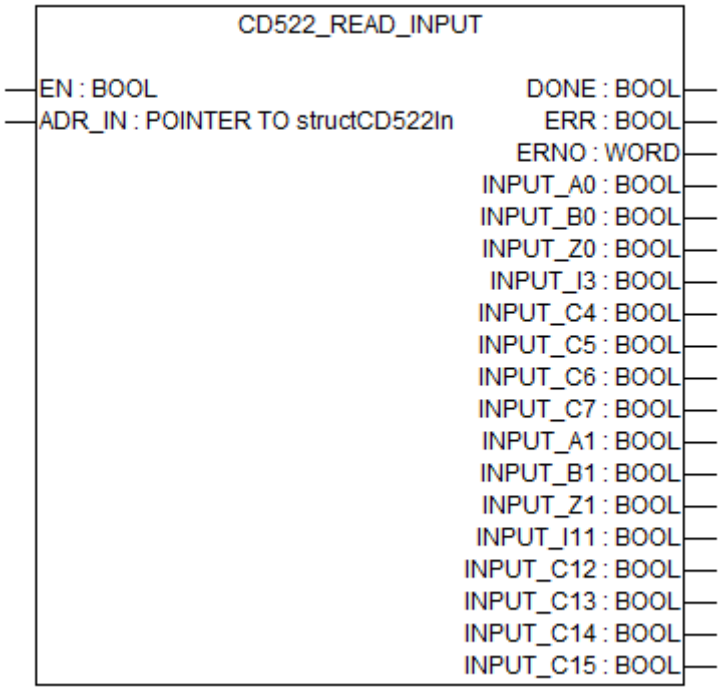
ADR_IN

At ADR_IN input (POINTER TO structCD522counterin), the address of the first input data from the structure of counter input of CD522 should be connected. The use of an ADR operator is needed. If input ADR_IN is not connected, then the outputs DONE=FALSE and ERR= TRUE.

Example (for counter 0):



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

```

1.5.4.9 Counter library

Library file name: **Counter_AC500_Vx.lib**

The Counter Library contains function blocks that simplify the use of the fast counters of the S500 I/O modules on the I/O bus of the CPU and the fast counters inside CS31 communication interface modules respectively.

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

The function blocks are available in AC500 control systems with runtime system version V2.0.0 or higher and S500 I/O modules with firmware version V1.3 or higher.

1.5.4.9.1 Function blocks

CNT_DC551

Parameter	Value
Included in library	Counter_AC500_V20.lib
Available as of runtime system	V2.0.0
Available as of CS31 com-munucation interface module firmware	V1.3, V2.0
Remark	V1.3 at DC551-CS31, V2.0 at CI590-CS31-HA and CI592-CS31
Type	Function block with historical values

Function block CNT_DC551 is used to control the fast counter of the CS31 communucation interface modules (e. g. DC551-CS31, CI590-CS31-HA and CI592-CS31).

The operating modes of the fast counters are described in *Chapter 1.6.2.6.1.2.10 “Fast counter” on page 4351*.

To activate the fast counter in CS31 communucation interface modules, the address switch of the CS31 communucation interface modules must be set to a value in the range between 70 and 99. Then, the actual module address is the set address minus 70, i.e. it is in a range between 0 and 29.

Data exchange between CPU and high-speed counter is done using input/output data. The following is required for the counter:

- 2 bytes digital inputs for status bytes 0 and 1

- 4 words analog inputs for 2 actual value double words of counters 1 and 2

- 2 bytes digital outputs for control bytes of counters 1 and 2

- 8 words analog outputs for 4 start/end value double words of counters 1 and 2

Thus, 1 CS31 communucation interface module with activated fast counter (without S500 expansion modules) occupies 2 CS31 software modules:

Module 1: digital module with digital inputs (3 bytes) and digital outputs (4 bytes)

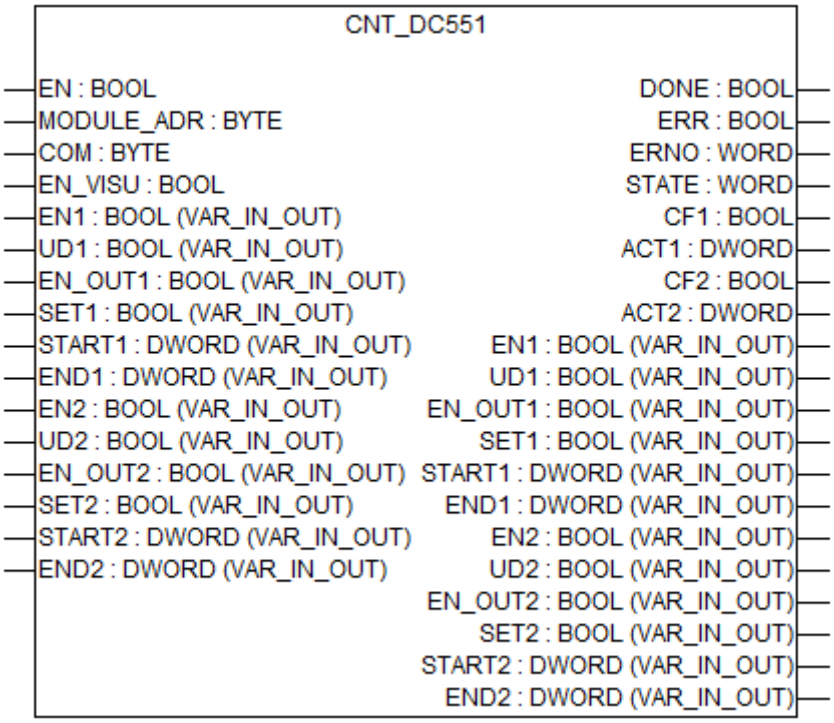
Module 2: analog module with analog inputs (8 words) and analog outputs (4 words)

The address of the modules corresponds to the address set at the DC551 minus 70.

CAUTION!
The high-speed counters of the S500 communication interface modules are not available if they are connected to CS31 communication interface modules. They are only available after connecting the modules to the I/O Bus of the AC500 CPU.

The function block CNT_DC551 has an integrated visualization visuCNT_DC551 that can be used to control all function block functions in parallel to the user program, if input EN_VISU = TRUE *Chapter 1.5.4.9.2 “Visualization” on page 1064*.

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable pulse counting for input CH, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and a corresponding error is displayed at output ERR/ERNO.

MODULE_ADR

Data type	Default value	Range	Unit
BYTE	-	0 ... 29	-

At input MODULE_ADR, the address set at the CS31 communucation interface module is entered.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

At input COM, the number of the serial interface is specified to which the CS31 communucation interface module is connected.

Valid values are 0 and 1 for COM1 and 2 for COM2 (only CM574-RS).

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

If input EN_VISU = TRUE, it is also possible to control the function block inputs (except SLOT, COM, MODULE_ADR, EN and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed ↳ *Chapter 1.5.4.9.2 “Visualization” on page 1064*.

EN1

Data type	Default value	Range	Unit
BOOL	-	-	-

If input EN1 = TRUE, pulse counting of counter 1 is enabled. If EN1 = FALSE, no pulse counting is performed and the pulses are lost.

Input EN1 corresponds to bit 1 in control byte 0.

UD1

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD1, the counting direction is set for operating modes with up/down counters (modes 3...6).

The following applies:

UD1 = FALSE → counter 1 counts up

UD1 = TRUE → counter 1 counts down

If input SET1 = TRUE, the counter takes this value.

Input UD1 corresponds to bit 0 in control byte 0.

EN_OUT1

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN_OUT1 is used to select the output control mode for the operating modes with direct output activation (modes 1 and 2).

Only for fast counter operating modes 1 and 2:

If EN_OUT1 = FALSE, the related digital output DO acts as an output indicating "end value reached" of the fast counter.

If EN_OUT1 = TRUE, the related digital output DO can be used as normal digital output.

The value change of EN_OUT1 is only effective when EN = TRUE.

Input EN_OUT1 corresponds to bit 3 in control byte 0.

SET1

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET1 = TRUE, the counter takes the values from the inputs UD1, START1 and END1.

As long as input SET1 = TRUE, no pulses are counted because the counter is always over-written by the start value START1.

Input SET1 corresponds to bit 2 in control byte 0.

START1

Data type	Default value	Range	Unit
DWORD	-	-	-

At input START1, the start value of counter 1 is entered.

If input SET1 = TRUE, counter 1 takes this value.

Input START1 corresponds to the analog outputs 0 (bit 16..31) and 1 (bit 0..15) of the CS31 communucation interface module.

END1

Data type	Default value	Range	Unit
DWORD	-	-	-

At input END1, the end value of counter 1 is entered.

If input SET1 = TRUE, counter 1 takes this value.

Input END1 corresponds to the analog outputs 2 (bit 16..31) and 3 (bit 0..15) of the CS31 communucation interface module.

UD2

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD2, the counting direction is set for operating modes with up/down counters (modes 3...6).

The following applies:

UD2 = FALSE → counter 2 counts up

UD2 = TRUE → counter 2 counts down

If input SET2 = TRUE, the counter takes this value.

Input UD2 corresponds to bit 0 in control byte 1.

EN_OUT2

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN_OUT2 is reserved. A variable with the value FALSE has to be applied.

Input EN_OUT2 corresponds to bit 3 in control byte 1.

SET2

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET2 = TRUE, the counter takes the values from the inputs UD2, START2 and END2.

As long as input SET2 = TRUE, no pulses are counted because the counter is always over-written by the start value START2.

Input SET2 corresponds to bit 2 in control byte 1.

START2

Data type	Default value	Range	Unit
DWORD	-	-	-

At input START2, the start value of counter 2 is entered.

If input SET2 = TRUE, counter 2 takes this value.

Input START2 corresponds to the analog outputs 4 (bit 16..31) and 5 (bit 0..15) of the CS31 communucation interface module.

END2

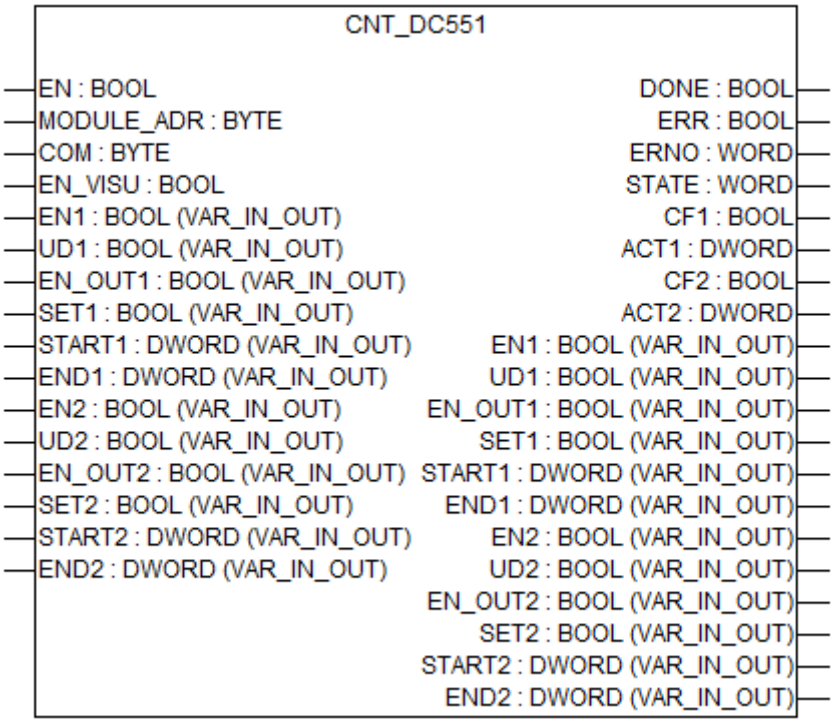
Data type	Default value	Range	Unit
DWORD	-	-	-

At input END2, the end value of counter 2 is entered.

If input SET2 = TRUE, counter 2 takes this value.

Input END2 corresponds to the analog outputs 6 (bit 16..31) and 7 (bit 0..15) of the CS31 communucation interface module.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE

Data type	Default value	Range	Unit
WORD	-	-	-

Output STATE indicates the current mode of fast counter. The mode of fast counter (0-10) can be configured in the channel parameter of the PLC configuration (please refer to fast counter mode in system technology chapter 9.3).

CF1

Data type	Default value	Range	Unit
BOOL	-	-	-

If counter 1 has reached the programmed end value (input END1), output CF1 (end value reached) is set to TRUE and stored. When setting the counter (via input SET1), CF1 is set to FALSE.

Output CF1 corresponds to bit 0 in status byte 0.

ACT1

Data type	Default value	Range	Unit
DWORD	-	-	-

At output ACT1, the actual value = counter reading of counter 1 is output as double word.

Output ACT1 corresponds to the analog inputs 0 (bit 16..31) and 1 (bit 0..15).

CF2

Data type	Default value	Range	Unit
BOOL	-	-	-

If counter 2 has reached the programmed end value (input END2), output CF2 (end value reached) is set to TRUE and stored. When setting the counter (via input SET2), CF2 is set to FALSE.

Output CF2 corresponds to bit 0 in status byte 1.

ACT2

Data type	Default value	Range	Unit
DWORD	-	-	-

At output ACT2, the actual value = counter reading of counter 2 is output as double word.

Output ACT2 corresponds to the analog inputs 2 (bit 16..31) and 3 (bit 0..15).

```

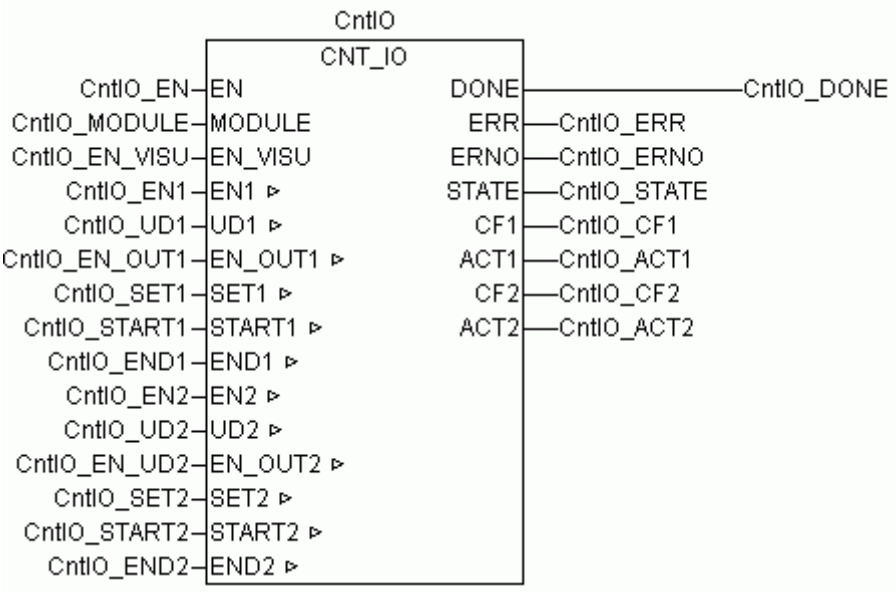
CNT_IO



Function block CNT_IO is used to control the fast counter of the digital S500 I/O Devices.

The fast counter which is integrated in CPUs PM55x and PM56x (onboard I/Os) can only be managed by function block ONB_IO_CNT ↳ Chapter 1.5.4.25.1.1 “ONB_IO_CNT” on page 1734 (and not by CNT_IO).

Parameter	Value
Included in library	Counter_AC500_V20.lib
Available as of runtime system	V2.0
Available as of S500 I/O module firmware:	V1.3
Type	Function block with historical values

Function block CNT_IO is used to control the fast counter of the digital S500 I/O Modules.

The operating modes of the fast counters are described in ↳ *Chapter 1.6.2.6.1.2.10 “Fast counter” on page 4351*.

To activate the fast counter of a digital S500 I/O module, the parameter "High-speed counter" of the I/O module must be set to the desired counting mode in the control system configuration.

Data exchange between CPU and high-speed counter is done using input/output data. The following is required for the counter:

- 2 bytes digital inputs for status bytes 0 and 1

- 4 words analog inputs for 2 actual value double words of counters 1 and 2

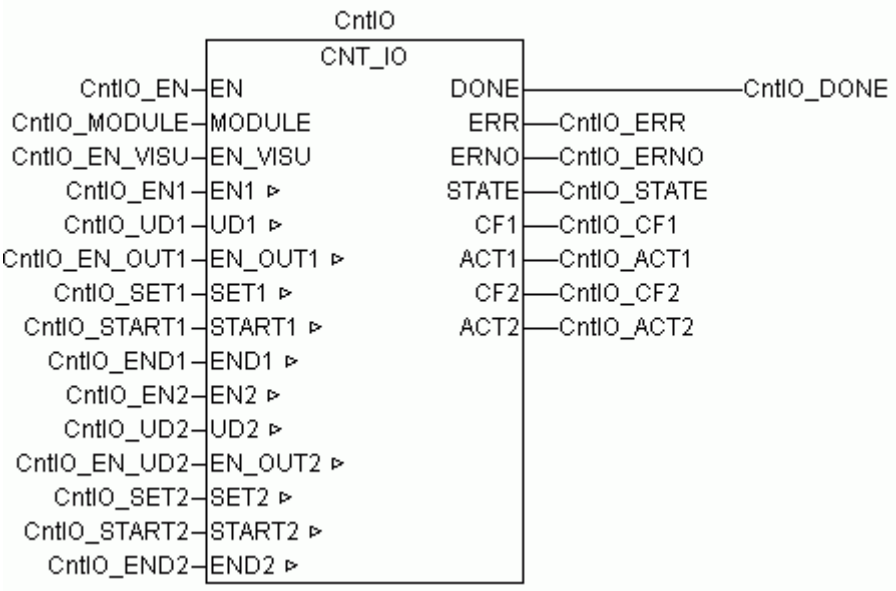
- 2 bytes digital outputs for control bytes of counters 1 and 2

- 8 words analog outputs for 4 start/end value double words of counters 1 and 2

CAUTION!
The high-speed counters of the digital S500 I/O devices are only available when connected to the I/O bus of the AC500 CPUs. If connected to the CS31 bus (e. g. with DC551-CS31 or CI590-CS31-HA) no fast counters are available.

The function block CNT_IO has an integrated visualization visuCNT_IO that can be used to control all function block functions in parallel to the user program, if input EN_VISU = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable pulse counting for input CH, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and a corresponding error is displayed at output ERR/ERNO.

Module

Data type	Default value	Range	Unit
BYTE	-	1 ... 10	-

At input MODULE, the module number of the digital S500 I/O module on the I/O bus of the AC500 CPU is specified. The first module with number 1 is the module directly right to the CPU.

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

If input EN_VISU = TRUE, it is also possible to control the function block inputs (except SLOT, COM, MODULE_ADR, EN and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed *Chapter 1.5.4.9.2 “Visualization” on page 1064*.

EN1

Data type	Default value	Range	Unit
BOOL	-	-	-

If input EN1 = TRUE, pulse counting of counter 1 is enabled. If EN1 = FALSE, no pulse counting is performed and the pulses are lost.

Input EN1 corresponds to bit 1 in control byte 0.

UD1

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD1, the counting direction is set for operating modes with up/down counters (modes 3...6).

The following applies:

UD1 = FALSE → counter 1 counts up

UD1 = TRUE → counter 1 counts down

If input SET1 = TRUE, the counter takes this value.

Input UD1 corresponds to bit 0 in control byte 0.

EN_OUT1

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN_OUT1 is used to select the output control mode for the operating modes with direct output activation (modes 1 and 2).

Only for fast counter operating modes 1 and 2:

If EN_OUT1 = FALSE, the related digital output DO acts as an output indicating "end value reached" of the fast counter.

If EN_OUT1 = TRUE, the related digital output DO can be used as normal digital output.

The value change of EN_OUT1 is only effective when EN = TRUE.

Input EN_OUT1 corresponds to bit 3 in control byte 0.

SET1

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET1 = TRUE, the counter takes the values from the inputs UD1, START1 and END1.

As long as input SET1 = TRUE, no pulses are counted because the counter is always over-written by the start value START1.

Input SET1 corresponds to bit 2 in control byte 0.

START1

Data type	Default value	Range	Unit
DWORD	-	-	-

At input START1, the start value of counter 1 is entered.

If input SET1 = TRUE, counter 1 takes this value.

Input START1 corresponds to the analog outputs 0 (bit 16..31) and 1 (bit 0..15) of the CS31 communucation interface module.

END1

Data type	Default value	Range	Unit
DWORD	-	-	-

At input END1, the end value of counter 1 is entered.

If input SET1 = TRUE, counter 1 takes this value.

Input END1 corresponds to the analog outputs 2 (bit 16..31) and 3 (bit 0..15) of the CS31 communucation interface module.

UD2

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD2, the counting direction is set for operating modes with up/down counters (modes 3...6).

The following applies:

UD2 = FALSE → counter 2 counts up

UD2 = TRUE → counter 2 counts down

If input SET2 = TRUE, the counter takes this value.

Input UD2 corresponds to bit 0 in control byte 1.

EN_OUT2

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN_OUT2 is reserved. A variable with the value FALSE has to be applied.

Input EN_OUT2 corresponds to bit 3 in control byte 1.

SET2

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET2 = TRUE, the counter takes the values from the inputs UD2, START2 and END2.

As long as input SET2 = TRUE, no pulses are counted because the counter is always overwritten by the start value START2.

Input SET2 corresponds to bit 2 in control byte 1.

START2

Data type	Default value	Range	Unit
DWORD	-	-	-

At input START2, the start value of counter 2 is entered.

If input SET2 = TRUE, counter 2 takes this value.

Input START2 corresponds to the analog outputs 4 (bit 16..31) and 5 (bit 0..15) of the CS31 communucation interface module.

END2

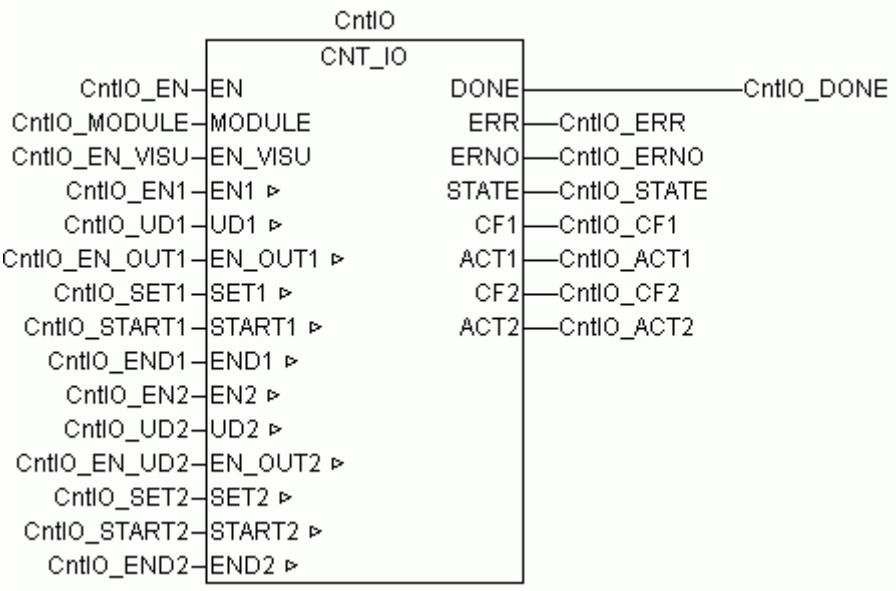
Data type	Default value	Range	Unit
DWORD	-	-	-

At input END2, the end value of counter 2 is entered.

If input SET2 = TRUE, counter 2 takes this value.

Input END2 corresponds to the analog outputs 6 (bit 16..31) and 7 (bit 0..15) of the CS31 communucation interface module.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE

Data type	Default value	Range	Unit
WORD	-	-	-

Output STATE indicates the current mode of fast counter. The mode of fast counter (0-10) can be configured in the channel parameter of the PLC configuration (please refer to fast counter mode in system technology chapter 9.3).

CF1

Data type	Default value	Range	Unit
BOOL	-	-	-

If counter 1 has reached the programmed end value (input END1), output CF1 (end value reached) is set to TRUE and stored. When setting the counter (via input SET1), CF1 is set to FALSE.

Output CF1 corresponds to bit 0 in status byte 0.

ACT1

Data type	Default value	Range	Unit
DWORD	-	-	-

At output ACT1, the actual value = counter reading of counter 1 is output as double word.

Output ACT1 corresponds to the analog inputs 0 (bit 16..31) and 1 (bit 0..15).

CF2

Data type	Default value	Range	Unit
BOOL	-	-	-

If counter 2 has reached the programmed end value (input END2), output CF2 (end value reached) is set to TRUE and stored. When setting the counter (via input SET2), CF2 is set to FALSE.

Output CF2 corresponds to bit 0 in status byte 1.

ACT2

Data type	Default value	Range	Unit
DWORD	-	-	-

At output ACT2, the actual value = counter reading of counter 2 is output as double word.

Output ACT2 corresponds to the analog inputs 2 (bit 16..31) and 3 (bit 0..15).

```

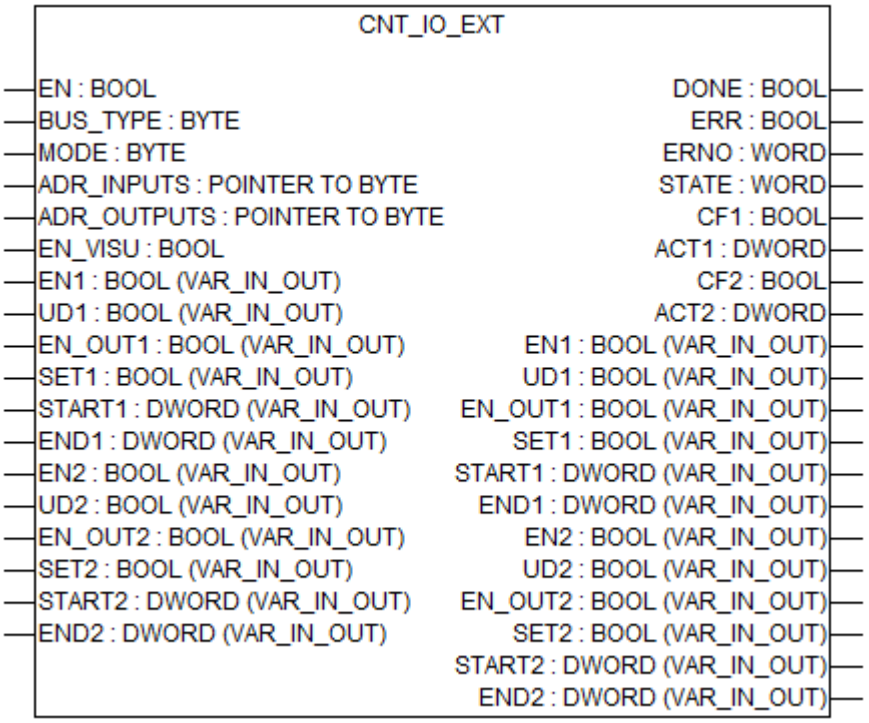
CNT_IO_EXT



The fast counter which is integrated in CPUs PM55x and PM56x (onboard I/Os) can only be managed by function block ONB_IO_CNT ↯ Chapter 1.5.4.25.1.1 “ONB_IO_CNT” on page 1734 (and not by CNT_IO_EXT).

Parameter	Value
Included in library	Counter_AC500_V20.lib
Available as of runtime system	V2.0
Available as of S500 I/O module firmware:	V1.3
Type	Function block with historical values

Function block CNT_IO_EXT is used to control the fast counter of the digital S500 I/O Modules.

The operating modes of the fast counters are described in ↯ *Chapter 1.6.2.6.1.2.10 “Fast counter” on page 4351*.

To activate the fast counter of a digital S500 I/O module, the parameter "fast counter" of the I/O module must be set to the desired counting mode in the control system configuration.

Data exchange between CPU and fast counter is done using input/output data. The following is required for the counter:

- 2 bytes digital inputs for status bytes 0 and 1

- 4 words analog inputs for 2 actual value double words of counters 1 and 2

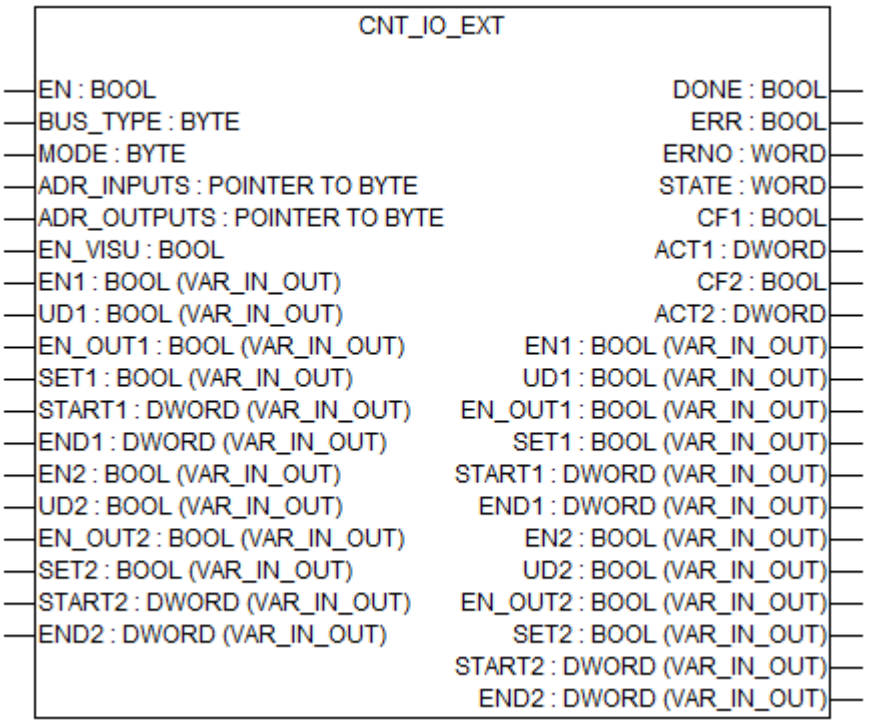
- 2 bytes digital outputs for control bytes of counters 1 and 2

- 8 words analog outputs for 4 start/end value double words of counters 1 and 2

CAUTION!
The high-speed counters of the digital S500 I/O devices are only available when connected to the I/O bus of the AC500 CPUs. If connected to the CS31 bus (e. g. with DC551-CS31 or CI590-CS31-HA) no fast counters are available.

The function block CNT_IO_EXT has an integrated visualization visuCNT_IO_EXT that can be used to control all function block functions in parallel to the user program, if input EN_VISU = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable pulse counting for input CH, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and a corresponding error is displayed at output ERR/ERNO.

BUS_TYPE

Data type	Default value	Range	Unit
BYTE	-	1 ... 10	-

At input BUS_TYPE, the user can selected between counters on I/O bus and CAN bus. The value 0 is default and means I/O bus. The value 1 means CAN bus.

MODE

Data type	Default value	Range	Unit
BYTE	0	0 ... 10	-

At input MODE the operating mode of the fast counter must be assigned. Value 0: no counter active. Value 1…10 specifies special counter modes. The operating modes of the fast counters are described in detail in a separate chapter *Chapter 1.5.4.9.2 “Visualization” on page 1064*.

ADR_INPUTS

Data type	Default value	Range	Unit
POINTER_TO_BYTE	0	0 … 4294967295	-

Pointer to inputs of the fast counter. Use the ADR operator and the symbolic name of the counters input data in the module I/O-mapping. Example: ADR(CntInData)

ADR_OUTPUTS

Data type	Default value	Range	Unit
POINTER_TO_BYTE	0	0 … 4294967295	-

Pointer to outputs of the fast counter. Use the ADR operator and the symbolic name of the counters output data in the module I/O-mapping. Example: ADR(CntOutData)

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

If input EN_VISU = TRUE, it is also possible to control the function block inputs (except SLOT, COM, MODULE_ADR, EN and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed *Chapter 1.5.4.9.2 “Visualization” on page 1064*.

EN1

Data type	Default value	Range	Unit
BOOL	-	-	-

If input EN1 = TRUE, pulse counting of counter 1 is enabled. If EN1 = FALSE, no pulse counting is performed and the pulses are lost.

Input EN1 corresponds to bit 1 in control byte 0.

UD1

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD1, the counting direction is set for operating modes with up/down counters (modes 3...6).

The following applies:

UD1 = FALSE → counter 1 counts up

UD1 = TRUE → counter 1 counts down

If input SET1 = TRUE, the counter takes this value.

Input UD1 corresponds to bit 0 in control byte 0.

EN_OUT1

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN_OUT1 is used to select the output control mode for the operating modes with direct output activation (modes 1 and 2).

Only for fast counter operating modes 1 and 2:

If EN_OUT1 = FALSE, the related digital output DO acts as an output indicating "end value reached" of the fast counter.

If EN_OUT1 = TRUE, the related digital output DO can be used as normal digital output.

The value change of EN_OUT1 is only effective when EN = TRUE.

Input EN_OUT1 corresponds to bit 3 in control byte 0.

SET1

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET1 = TRUE, the counter takes the values from the inputs UD1, START1 and END1.

As long as input SET1 = TRUE, no pulses are counted because the counter is always overwritten by the start value START1.

Input SET1 corresponds to bit 2 in control byte 0.

START1

Data type	Default value	Range	Unit
DWORD	-	-	-

At input START1, the start value of counter 1 is entered.

If input SET1 = TRUE, counter 1 takes this value.

Input START1 corresponds to the analog outputs 0 (bit 16..31) and 1 (bit 0..15) of the CS31 communucation interface module.

END1

Data type	Default value	Range	Unit
DWORD	-	-	-

At input END1, the end value of counter 1 is entered.

If input SET1 = TRUE, counter 1 takes this value.

Input END1 corresponds to the analog outputs 2 (bit 16..31) and 3 (bit 0..15) of the CS31 communucation interface module.

EN2

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

If input EN2 = TRUE, pulse counting of counter 2 is enabled. No pulse counting, if EN2 = FALSE.

Input EN2 corresponds to bit 1 in control byte 1

UD2

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD2, the counting direction is set for operating modes with up/down counters (modes 3...6).

The following applies:

UD2 = FALSE → counter 2 counts up

UD2 = TRUE → counter 2 counts down

If input SET2 = TRUE, the counter takes this value.

Input UD2 corresponds to bit 0 in control byte 1.

EN_OUT2

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN_OUT2 is reserved. A variable with the value FALSE has to be applied.

Input EN_OUT2 corresponds to bit 3 in control byte 1.

SET2

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET2 = TRUE, the counter takes the values from the inputs UD2, START2 and END2.

As long as input SET2 = TRUE, no pulses are counted because the counter is always over-written by the start value START2.

Input SET2 corresponds to bit 2 in control byte 1.

START2

Data type	Default value	Range	Unit
DWORD	-	-	-

At input START2, the start value of counter 2 is entered.

If input SET2 = TRUE, counter 2 takes this value.

Input START2 corresponds to the analog outputs 4 (bit 16..31) and 5 (bit 0..15) of the CS31 communucation interface module.

END2

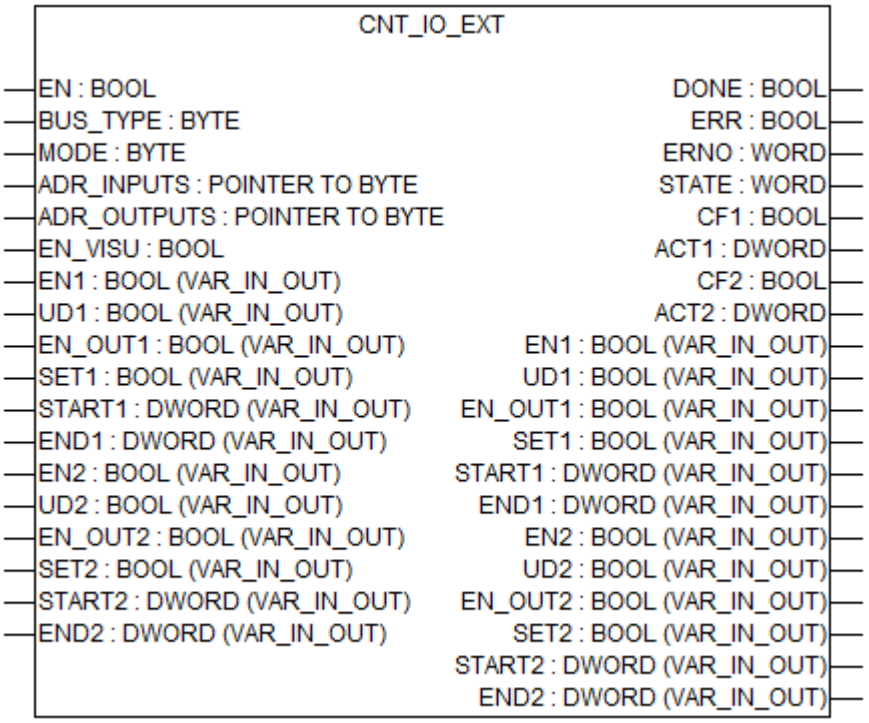
Data type	Default value	Range	Unit
DWORD	-	-	-

At input END2, the end value of counter 2 is entered.

If input SET2 = TRUE, counter 2 takes this value.

Input END2 corresponds to the analog outputs 6 (bit 16..31) and 7 (bit 0..15) of the CS31 communucation interface module.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE

Data type	Default value	Range	Unit
WORD	-	-	-

Output STATE indicates the current mode of fast counter. The mode of fast counter (0-10) can be configured in the channel parameter of the PLC configuration (please refer to fast counter mode in system technology chapter 9.3).

CF1

Data type	Default value	Range	Unit
BOOL	-	-	-

If counter 1 has reached the programmed end value (input END1), output CF1 (end value reached) is set to TRUE and stored. When setting the counter (via input SET1), CF1 is set to FALSE.

Output CF1 corresponds to bit 0 in status byte 0.

ACT1

Data type	Default value	Range	Unit
DWORD	-	-	-

At output ACT1, the actual value = counter reading of counter 1 is output as double word.

Output ACT1 corresponds to the analog inputs 0 (bit 16..31) and 1 (bit 0..15).

CF2

Data type	Default value	Range	Unit
BOOL	-	-	-

If counter 2 has reached the programmed end value (input END2), output CF2 (end value reached) is set to TRUE and stored. When setting the counter (via input SET2), CF2 is set to FALSE.

Output CF2 corresponds to bit 0 in status byte 1.

ACT2

Data type	Default value	Range	Unit
DWORD	-	-	-

At output ACT2, the actual value = counter reading of counter 2 is output as double word.

Output ACT2 corresponds to the analog inputs 2 (bit 16..31) and 3 (bit 0..15).

```

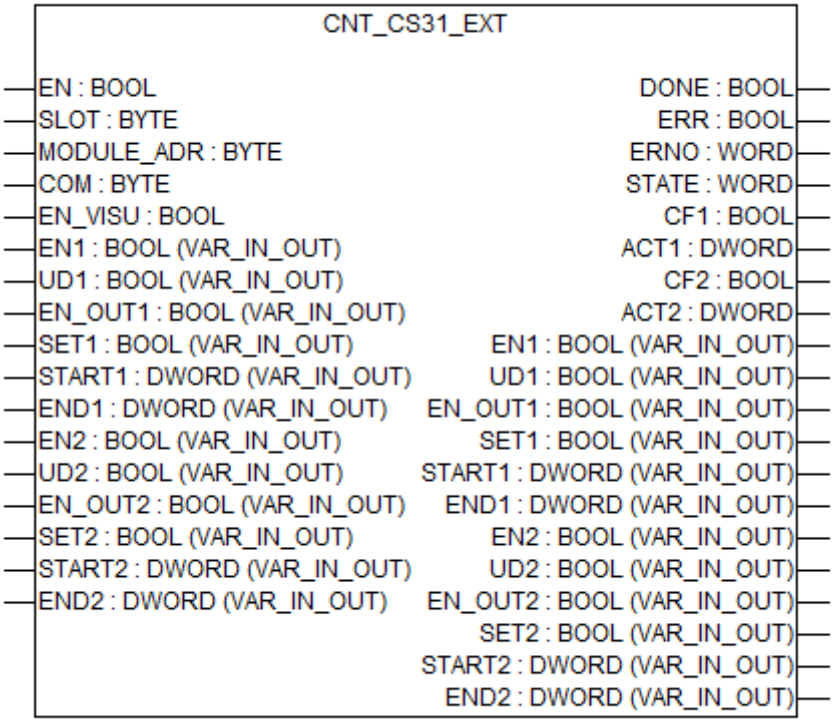
CNT_CS31_EXT



Parameter	Value
Included in library	Counter_AC500_V20.lib
Available as of runtime system	V2.0.0
Available as of CS31 com-munucation interface module firmware	V1.3, V2.0
Remark	V1.3 at DC551-CS31, V2.0 at CI590-CS31-HA and CI592-CS31
Type	Function block with historical values

Function block CNT_CS31_EXT is used to control the fast counter in CS31 communication interface modules (e. g. DC551-CS31, CI590-CS31-HA and CI592-CS31).

Function block CNT_CS31_EXT is derived from CNT_DC551 and works very similar to it.

As of firmware version 2.0 it is possible to configure and access the serial ports of a CM574-RS through the configuration of the AC500 CPU. Because CM574-RS can be installed into 1 of the 4 possible Communication Module slots, this function block has an additional input (SLOT) to give the position where the CM574 is installed. If COM1 of an AC500 CPU should be used, or if the user program which is using this function block is located in the CM574-RS, this input must have the value 0.

All other functions are the same as in CNT_DC551.

This function block can be used only with a configuration done by ABB Control Builder Plus.

The operating modes of the fast counters are described in *Chapter 1.6.2.6.1.2.10 “Fast counter” on page 4351*.

To activate the fast counter in CS31 communication interface modules, the address switch of the CS31 communication interface modules must be set to a value in the range between 70 and 99. Then, the actual module address is the set address minus 70, i.e. it is in a range between 0 and 29.

Data exchange between CPU and high-speed counter is done using input/output data. The following is required for the counter:

- 2 bytes digital inputs for status bytes 0 and 1

- 4 words analog inputs for 2 actual value double words of counters 1 and 2

- 2 bytes digital outputs for control bytes of counters 1 and 2

- 8 words analog outputs for 4 start/end value double words of counters 1 and 2

Thus, 1 CS31 communication interface module with activated fast counter (without S500 communication interface modules) occupies 2 CS31 software modules:

Module 1: digital module with digital inputs (3 bytes) and digital outputs (4 bytes)

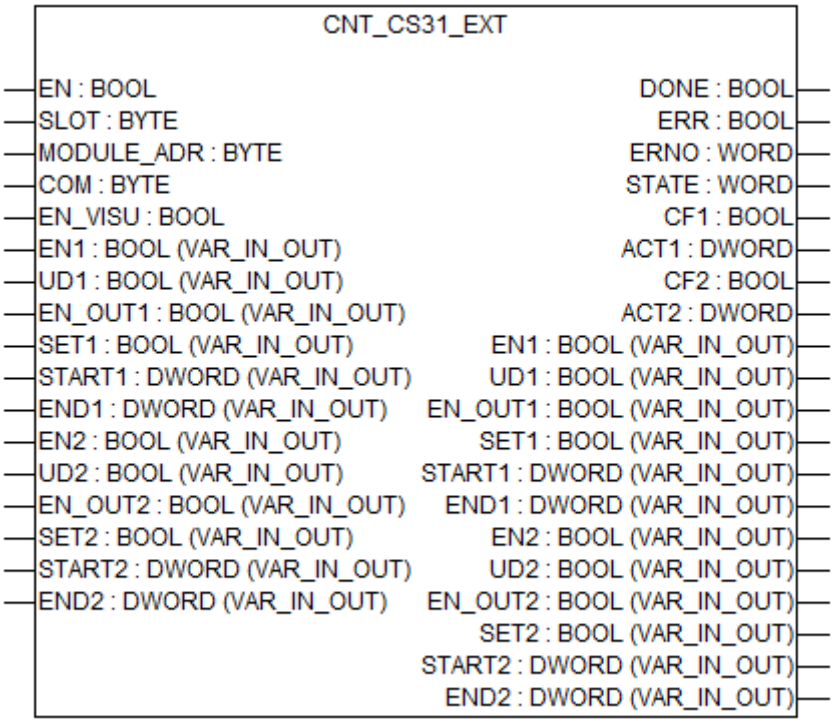
Module 2: analog module with analog inputs (8 words) and analog outputs (4 words)

The address of the modules corresponds to the address set at the DC551 minus 70.

CAUTION!
The high-speed counters of the S500 communication interface modules are not available if they are connected to CS31 communication interface modules. They are only available after connecting the modules to the I/O Bus of the AC500 CPU.

The function block CNT_DC551 has an integrated visualization visuCNT_CS31 that can be used to control all function block functions in parallel to the user program, if input EN_VISU = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable pulse counting for input CH, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE.

When calling the function block the first time, the inputs are checked for validity and plausibility. If this is not the case, processing is aborted and a corresponding error is displayed at output ERR/ERNO.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

MODULE_ADR

Data type	Default value	Range	Unit
BYTE	-	0 ... 29	-

At input MODULE_ADR, the address set at the CS31 communucation interface module is entered.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

At input COM, the number of the serial interface is specified to which the CS31 communucation interface module is connected.

Valid values are 0 and 1 for COM1 and 2 for COM2 (only CM574-RS).

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

If input EN_VISU = TRUE, it is also possible to control the function block inputs (except SLOT, COM, MODULE_ADR, EN and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed ↳ *Chapter 1.5.4.9.2 “Visualization” on page 1064*.

EN1

Data type	Default value	Range	Unit
BOOL	-	-	-

If input EN1 = TRUE, pulse counting of counter 1 is enabled. If EN1 = FALSE, no pulse counting is performed and the pulses are lost.

Input EN1 corresponds to bit 1 in control byte 0.

UD1

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD1, the counting direction is set for operating modes with up/down counters (modes 3...6).

The following applies:

UD1 = FALSE → counter 1 counts up

UD1 = TRUE → counter 1 counts down

If input SET1 = TRUE, the counter takes this value.

Input UD1 corresponds to bit 0 in control byte 0.

EN_OUT1

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN_OUT1 is used to select the output control mode for the operating modes with direct output activation (modes 1 and 2).

Only for fast counter operating modes 1 and 2:

If EN_OUT1 = FALSE, the related digital output DO acts as an output indicating "end value reached" of the fast counter.

If EN_OUT1 = TRUE, the related digital output DO can be used as normal digital output.

The value change of EN_OUT1 is only effective when EN = TRUE.

Input EN_OUT1 corresponds to bit 3 in control byte 0.

SET1

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET1 = TRUE, the counter takes the values from the inputs UD1, START1 and END1.

As long as input SET1 = TRUE, no pulses are counted because the counter is always overwritten by the start value START1.

Input SET1 corresponds to bit 2 in control byte 0.

START1

Data type	Default value	Range	Unit
DWORD	-	-	-

At input START1, the start value of counter 1 is entered.

If input SET1 = TRUE, counter 1 takes this value.

Input START1 corresponds to the analog outputs 0 (bit 16..31) and 1 (bit 0..15) of the CS31 communucation interface module.

END1

Data type	Default value	Range	Unit
DWORD	-	-	-

At input END1, the end value of counter 1 is entered.

If input SET1 = TRUE, counter 1 takes this value.

Input END1 corresponds to the analog outputs 2 (bit 16..31) and 3 (bit 0..15) of the CS31 communucation interface module.

UD2

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD2, the counting direction is set for operating modes with up/down counters (modes 3...6).

The following applies:

UD2 = FALSE → counter 2 counts up

UD2 = TRUE → counter 2 counts down

If input SET2 = TRUE, the counter takes this value.

Input UD2 corresponds to bit 0 in control byte 1.

EN_OUT2

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN_OUT2 is reserved. A variable with the value FALSE has to be applied.

Input EN_OUT2 corresponds to bit 3 in control byte 1.

SET2

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET2 = TRUE, the counter takes the values from the inputs UD2, START2 and END2.

As long as input SET2 = TRUE, no pulses are counted because the counter is always overwritten by the start value START2.

Input SET2 corresponds to bit 2 in control byte 1.

START2

Data type	Default value	Range	Unit
DWORD	-	-	-

At input START2, the start value of counter 2 is entered.

If input SET2 = TRUE, counter 2 takes this value.

Input START2 corresponds to the analog outputs 4 (bit 16..31) and 5 (bit 0..15) of the CS31 communucation interface module.

END2

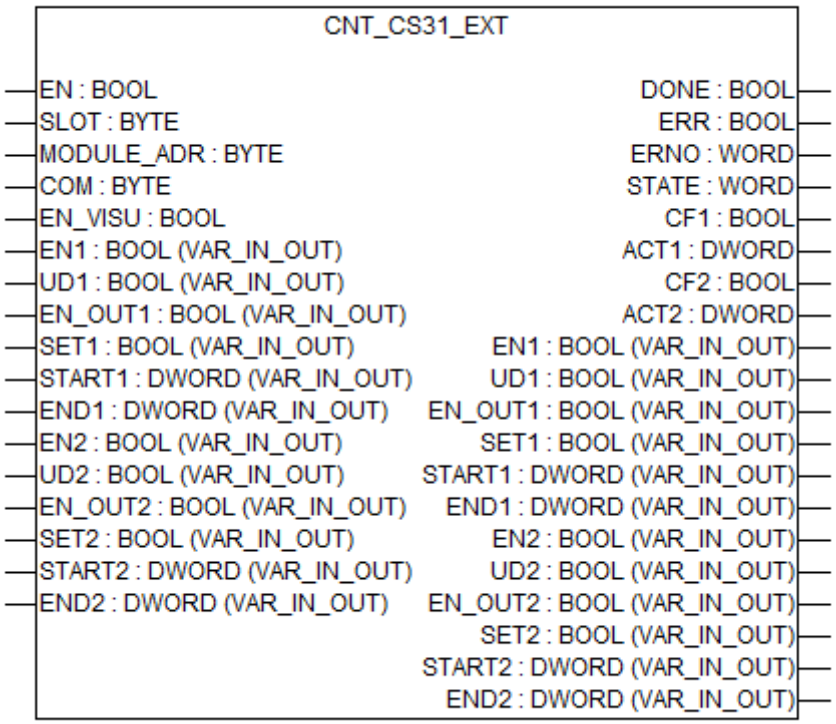
Data type	Default value	Range	Unit
DWORD	-	-	-

At input END2, the end value of counter 2 is entered.

If input SET2 = TRUE, counter 2 takes this value.

Input END2 corresponds to the analog outputs 6 (bit 16..31) and 7 (bit 0..15) of the CS31 communucation interface module.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE

Data type	Default value	Range	Unit
WORD	-	-	-

Output STATE indicates the current mode of fast counter. The mode of fast counter (0-10) can be configured in the channel parameter of the PLC configuration (please refer to fast counter mode in system technology chapter 9.3).

CF1

Data type	Default value	Range	Unit
BOOL	-	-	-

If counter 1 has reached the programmed end value (input END1), output CF1 (end value reached) is set to TRUE and stored. When setting the counter (via input SET1), CF1 is set to FALSE.

Output CF1 corresponds to bit 0 in status byte 0.

ACT1

Data type	Default value	Range	Unit
DWORD	-	-	-

At output ACT1, the actual value = counter reading of counter 1 is output as double word.

Output ACT1 corresponds to the analog inputs 0 (bit 16..31) and 1 (bit 0..15).

CF2

Data type	Default value	Range	Unit
BOOL	-	-	-

If counter 2 has reached the programmed end value (input END2), output CF2 (end value reached) is set to TRUE and stored. When setting the counter (via input SET2), CF2 is set to FALSE.

Output CF2 corresponds to bit 0 in status byte 1.

ACT2

Data type	Default value	Range	Unit
DWORD	-	-	-

At output ACT2, the actual value = counter reading of counter 2 is output as double word.

Output ACT2 corresponds to the analog inputs 2 (bit 16..31) and 3 (bit 0..15).

Function call in ST

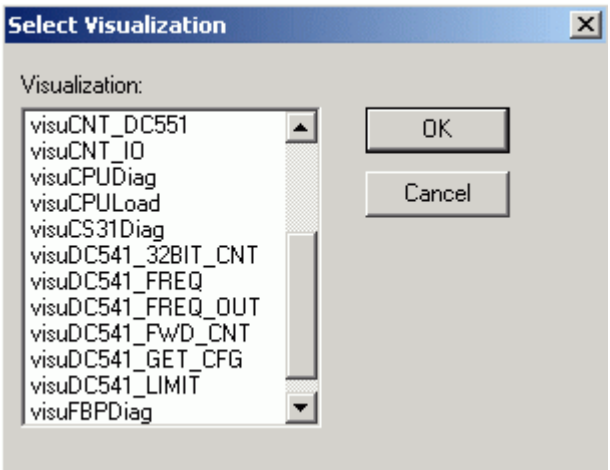
CntCS31ext_CF2       := CntCS31ext.CF2;
CntCS31ext_Act2      := CntCS31ext.ACT2;
```

1.5.4.9.2 Visualization

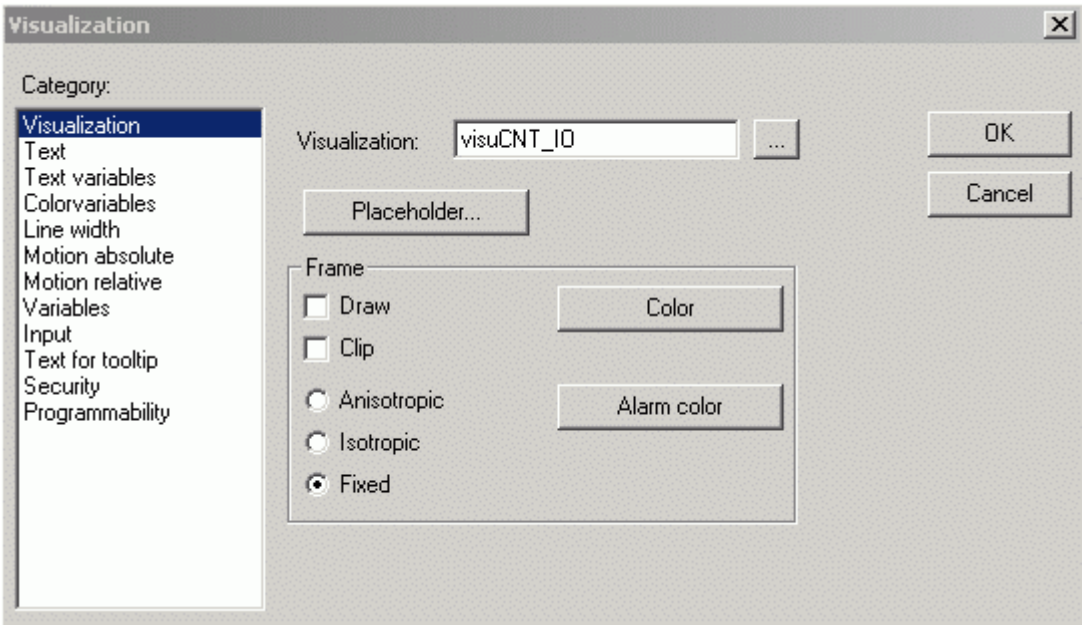
The visualization can be used to display the function block outputs. If the input EN_VISU of a function block is TRUE, it is also possible to control the inputs from the visualization. In order to allow the control of function block inputs from the program as well as from the visualization, these inputs are declared as VAR_IN_OUT and therefore have to be provided with variables accordingly. These inputs must not be provided with direct constants.

Proceed as follows to integrate the visualization into a project:

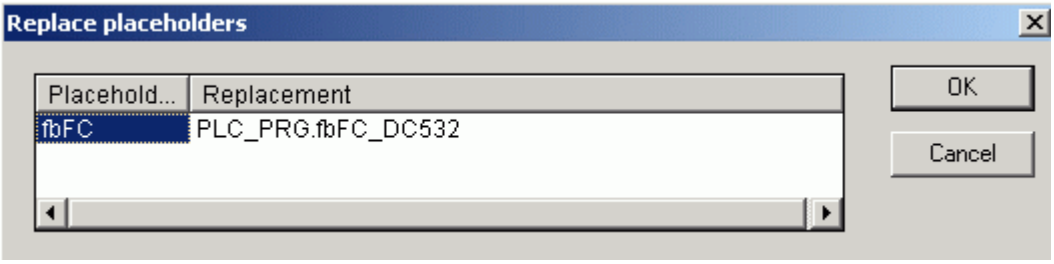
- Create a new visualization using Visualizations / Insert Object (e.g. visuTestCntIO).
- Insert a visualization using 
- In the appearing dialog, select the corresponding visualization for the function block:



- Then, the visualization integrated just now has to be configured. Highlight the visualization with a left mouse click. Then click the right mouse button and select the function "Configure..." from the context menu.
- The configuration of the visualization is done in the appearing dialog. It is recommended to set the frame to "Fixed". This way, the original width-to-height ratio and font size are kept.



- Now the visualization has to be linked to the function block instance. This is done in a dialog, opened after clicking the button "Placeholder".
- In the "Replacement" column of this dialog, the function block instance can either be entered directly or selected by pressing <F2>.



- By clicking <OK> the dialogs are closed. After this, the inserted visualization has to be adapted to the correct size.

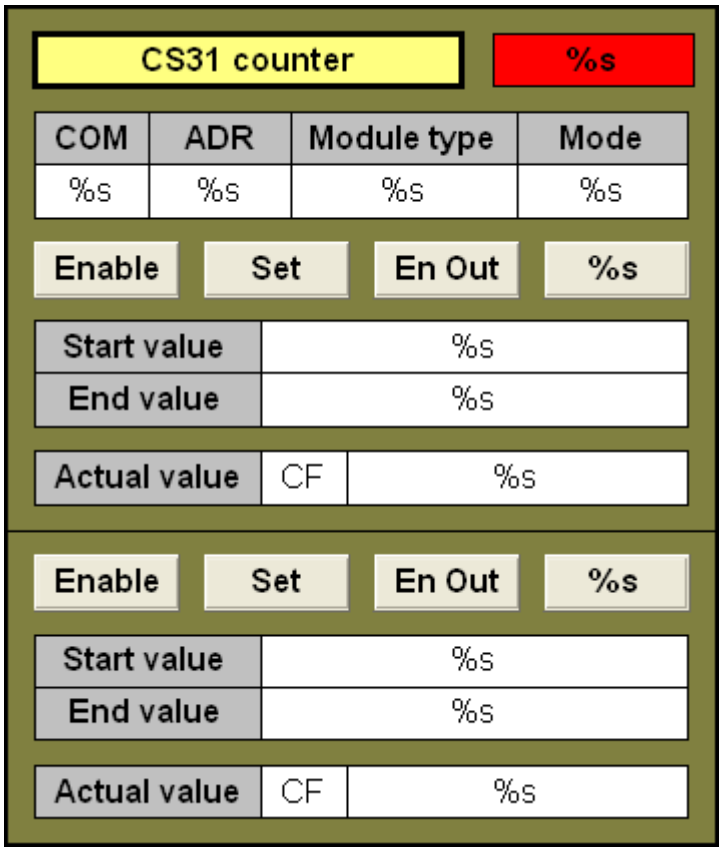


Fig. 24: Offline mode.

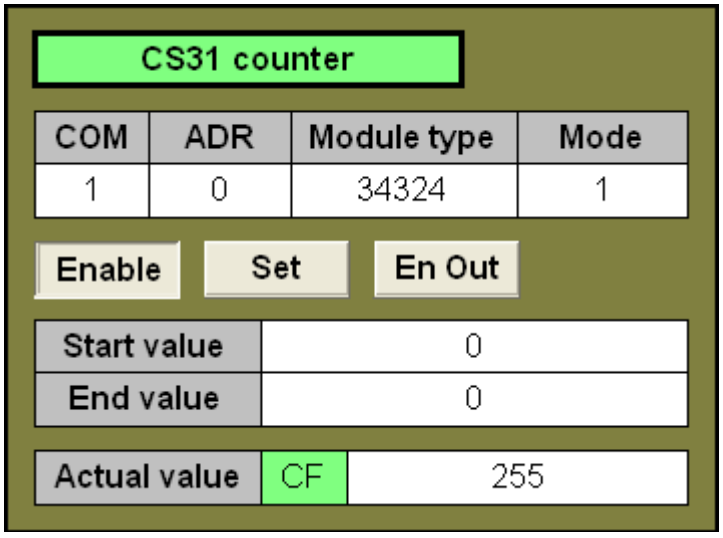

Fig. 25: Online mode, example for operating mode 1.

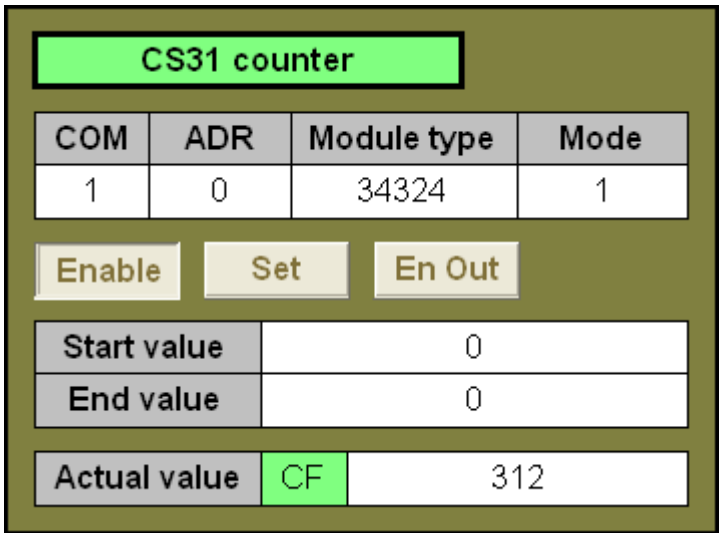
If an error occurred during function block processing, the error number is displayed in the top right until EN becomes FALSE.

If input EN_VISU = FALSE, the inputs cannot be modified using the visualization. The corresponding control elements are then displayed in gray:



1.5.4.10 CS31 library

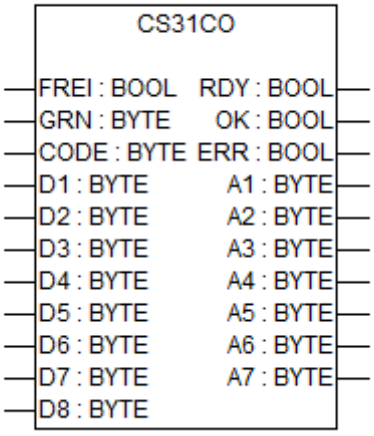
Library file name: **CS31_AC500_Vx.lib**

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

> *The function blocks of the CS31 library can only be called, if the serial interface COM1 is configured as "CS31 bus master".*

1.5.4.10.1 Function blocks

CS31CO



The function block is used to configure the AC31 remote modules. The function block can both send configuration parameters to the remote modules and also scan their currently set configuration.

Parameter	Value
Included in library	CS31_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values
Group	Group/Subgroup

The function block is used to configure the AC31 remote modules. The function block can both send configuration parameters to the remote modules and also scan their currently set configuration.

Apart from configuration of the AC31 remote modules, the function block can also process further jobs *“A1...A7” on page 1070*.

Enable for processing a job once is triggered by a FALSE/TRUE edge at input FREI.

The required job identification is specified at input CODE.

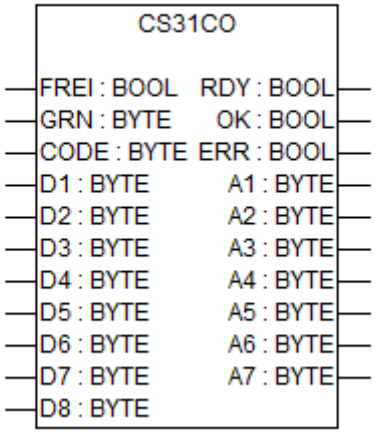
The parameters required for the job are planned at the inputs D1 ... D8.

Status messages are signalized at the outputs RDY, OK and ERR.

The response data of the job are available at the outputs A1 ... A7.

It may take several PLC cycles to process the job.

Input description



FREI

Data type	Default value	Range	Unit
BOOL	-	-	-

Processing of the function block is controlled via input FREI.

FREI = FALSE:

All function block outputs are set to the value "FALSE". However, this is not valid, if a job is currently being processed, i. e. processing of a job which is currently being processed, is not affected by FREI = FALSE.

FREI = FALSE/TRUE edge:

Processing of the job is enabled. Input FREI is no longer evaluated during processing of the job.

FREI = TRUE:

The function block is not processed, i. e. it no longer changes its outputs. However, this is not valid, if a job is currently being processed.

GRN

Data type	Default value	Range	Unit
BYTE	-	0 ... 63	-

Group number with which the remote module is addressed by the PLC program.

Example:

On binary input E 12,08, "12" is the group number and "08" is the channel number.

CODE

Data type	Default value	Range	Unit
BYTE	-	-	-

The identification of the job to be executed is specified at input CODE ↳ *"A1...A7" on page 1070*.

D1...D8

Data type	Default value	Range	Unit
BYTE	-	-	-

The parameters required for the job are preset at the inputs D1 ... D8. The number of parameters depends on the job to be executed. There are also jobs requiring no parameters ↳ *"A1...A7" on page 1070*.

RDY

Data type	Default value	Range	Unit
BOOL	-	-	-

The output RDY indicates that processing of the job currently being processed is completed. This output does not indicate whether processing of the job was successful or not. The output RDY has therefore always to be considered together with the output OK.

RDY = TRUE and OK = TRUE:

Processing of the job is completed without errors. A new job can be started with a FALSE/TRUE edge at input FREI.

RDY = TRUE and OK = FALSE:

During processing of the job an error has been detected. ERR is set to TRUE. A new job can be started with a FALSE/TRUE edge at input FREI.

RDY = FALSE

Processing of an enabled job has not yet been completed (job is still running) or output RDY has been reset with FREI = FALSE.

OK

Data type	Default value	Range	Unit
BOOL	-	-	-

Output OK indicates whether the job has been handled successfully or whether an error has been detected during processing. In case of an error, OK ist set to FALSE and ERR is set to TRUE. The output OK is not valid until the job has been completed, i. e. if RDY = TRUE.

The following applies:

If RDY = TRUE and

OK = TRUE: The job has been processed successfully.

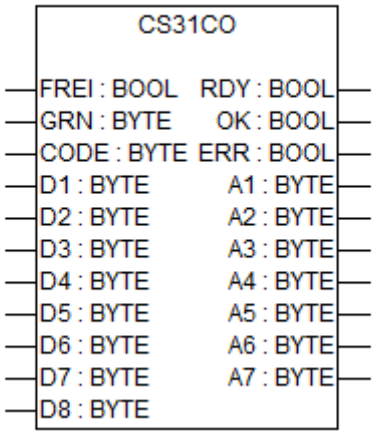
OK = FALSE: During processing of the job an error has been detected.

ERR

Data type	Default value	Range	Unit
BOOL	-	-	-

Output ERR indicates whether an error has occurred during processing of the function block. This output always has to be considered together with the outputs RDY and OK. If RDY is TRUE, OK is FALSE and ERR is TRUE, an error occurred.

Output description



A1...A7

Data type	Default value	Range	Unit
BOOL	-	-	-

After completion of job processing, the response is available at the outputs A1 ... A7. The number of response parameters depends on the job performed is described below.

List of jobs

Processing a job consists of:

- transferring the job
- supplying the OK response or not-OK response

The OK response is described in connection with the corresponding job.

The not-OK response of the individual jobs always looks as follows:

The following basically applies for the not-OK response:

RDY: TRUE

OK: FALSE

ERR:TRUE

A1...A7: 0

Updating of the maximum number of remote modules detected

The input word EW 07,15 contains, amongst other things, the maximum number of remote modules detected in the past. The actual number of remote modules which exist at the moment may be less. This command is used to update this value. The modules which exist are counted and the value is stored. The user can inquire this value in the PLC program (EW 07,15, bit 8...15).

-	Job GRN: CODE: D1...D8:	255 (Master PLC with bus) 132 Not used
-	OK response RDY: OK: A1...A7:	TRUE TRUE 0

Inquiring the open-circuit monitoring of an input to determine whether it is activated or deactivated

-	Job GRN: CODE: D1: D2...D8:	Group number 0...63 32 Channel number Not used
-	OK response RDY: OK: A1: A2...A7:	TRUE TRUE 47. Open-circuit monitoring ON 32. Open-circuit monitoring OFF 0

Inquiring the open-circuit monitoring of an output to determine whether it is activated or deactivated

-	Job GRN: CODE: D1: D2...D8:	Group number 0...63 33 Channel number Not used
-	OK response RDY: OK: A1: A2...A7:	TRUE TRUE 47. Open-circuit monitoring ON 32. Open-circuit monitoring OFF 0

Deactivating or activating the open-circuit monitoring of an input

-	Job GRN: CODE: D1: D2...D8:	Group number 0...63 224. Open-circuit monitoring ON 160. Open-circuit monitoring OFF Channel number Not used
-	OK response RDY: OK: A1...A7:	TRUE TRUE 0

Deactivating or activating the open-circuit monitoring of an output

-	Job GRN: CODE: D1: D2...D8:	Group number 0...63 225. Open-circuit monitoring ON 161. Open-circuit monitoring OFF Channel number Not used
-	OK response RDY: OK: A1...A7:	TRUE TRUE 0

Inquiring a channel to determine whether it is configured as input or input/output

-	Job GRN: CODE: D1: D2...D8:	Group number 0...63 34 Channel number Not used
-	OK response RDY: OK: A1: A2...A7:	TRUE TRUE 34. Input 35. Input/output 0

Configuration of a channel as input or input/output

-	Job GRN: CODE: D1: D2...D8:	Group number 0...63 162. Input 163. Input/output Channel number Not used
-	OK response RDY: OK: A1...A7:	TRUE TRUE 0

Inquiring the input delay of a channel

-	Job GRN: CODE: D1: D2...D8:	Group number 0...63 38 Channel number Not used
-	OK response RDY: OK: A1: A2...A7:	TRUE TRUE Input delay 2. 2 ms 4. 4 ms : : 30. 30 ms 32. 32 ms 0

Setting the input delay of a channel

-	Job GRN: CODE: D1: D2:	Group number 0...63 166 Channel number Input delay 2. 2 ms 4. 4 ms : : 30. 30 ms 32. 32 ms
-	OK response RDY: OK: A1...A7:	TRUE TRUE 0

Acknowledging errors on remote module

This command can be used to reset the error messages registered on the selected remote module. A reset is possible only if the cause of the error is no longer operative.

-	Job GRN: CODE: D1: D2: D3...D8:	Group number 0...63 232 Lowest channel number on the module: 0. Lowest channel number on the module is 0 (<7) 8. Lowest channel number on the module is 8 (>7) Module type: 0. Binary input 1. Analog input 2. Binary output 3. Analog output 4. Binary input/output 5. Analog input/output Note: Bit: even number (0, 2, 4) Wort: odd number (1, 3, 5) Not used
-	OK response RDY: OK: A1...A7:	TRUE TRUE 0

Acknowledging errors on remote module and resetting configuration values to default setting

In addition to the job "Acknowledging errors on remote module", all configurable settings are reset to the default setting.

-	Job GRN: CODE: D1: D2: D3...D8:	Group number 0...63 233 First channel number on the module: 0. First channel number on the module is 0 (<7) 8. First channel number on the module is 8 (>7) Module type: 0. Binary input 1. Analog input 2. Binary output 3. Analog output 4. Binary input/output 5. Analog input/output Note: Bit: even number (0, 2, 4) Wort: odd number (1, 3, 5) Not used
-	OK response RDY: OK: A1...A7:	TRUE TRUE 0

Inquiring the configuration of an analog input

Inquiring the bus configuration

The bus interface of the Master PLC has a list which stores specific data of the remote modules. The remote modules are numbered in this list in the order in which they can be found on the CS31 bus. The internal number of the modules must be specified with this command. The response to this command is the group number stored under this number and status information on the corresponding module.

-	Job GRN: CODE: D1: D2...D8:	Not evaluated 80 Number from the module list (1...31) Not used
-	OK response RDY: OK: A1: A2: A3: A4...A7:	TRUE TRUE Status of the remote module: Bits 0...3: Number of process data bytes (binary module) or words (word module), which the module sends to the master. Bits 4...7: Number of process data bytes (binary module) or words (word module), which the master sends to the module Group number Bit 0: 0. Lowest channel number <7 1. CS31CO_EXT

Function block CS31CO_EXT is used to configure the AC31 Modules. The function block can send configuration parameters to the AC31 Modules and scan their currently set configuration.

Parameter	Value
Included in library	CS31_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Group/Subgroup

Function block CS31CO_EXT is used to configure the AC31 Modules. The function block can send configuration parameters to the AC31 Modules and scan their currently set configuration.

Apart from configuration of the AC31 remote modules, the function block can also process further jobs *“A1...A7” on page 1070*.

Enable for processing a job once is triggered by a FALSE/TRUE edge at input FREI.

The communication port the CS31 Master is connected to is specified at input COM.

The required job identification is specified at input CODE.

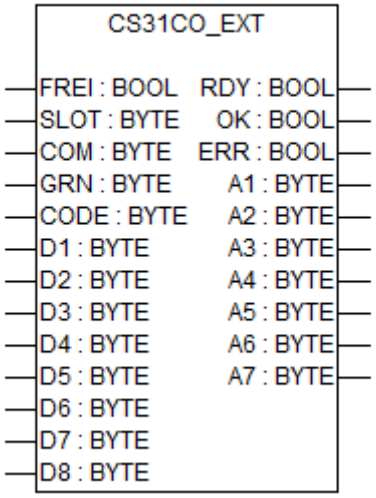
The parameters required for the job are planned at the inputs D1 ... D8.

Status messages are signalized at the outputs RDY, OK and ERR.

The response data of the job are available at the outputs A1 ... A7.

It may take several PLC cycles to process the job.

Input description



FREI

Data type	Default value	Range	Unit
BOOL	-	-	-

Processing of the function block is controlled via input FREI.

FREI = FALSE:

All function block outputs are set to the value "FALSE". However, this is not valid, if a job is currently being processed, i. e. processing of a job which is currently being processed, is not affected by FREI = FALSE.

FREI = FALSE/TRUE edge:

Processing of the job is enabled. Input FREI is no longer evaluated during processing of the job.

FREI = TRUE:

The function block is not processed, i. e. it no longer changes its outputs. However, this is not valid, if a job is currently being processed.

SLOT

Data type	Default value	Range	Unit
BYTE	-	-	-

Reserved for future extensions.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

Communication Port to which the CS31 Bus Module is connected.

GRN

Data type	Default value	Range	Unit
BYTE	-	0 ... 63	-

Group number with which the remote module is addressed by the PLC program.

Example:

On binary input E 12,08, "12" is the group number and "08" is the channel number.

CODE

Data type	Default value	Range	Unit
BYTE	-	-	-

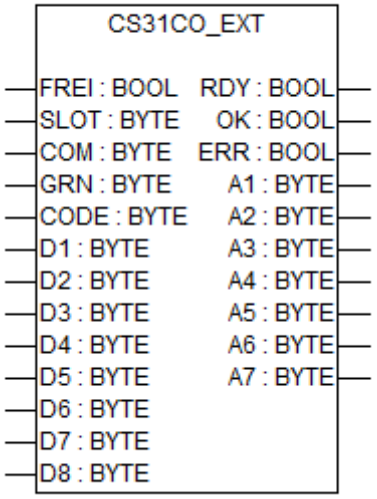
The identification of the job to be executed is specified at input CODE ↳ *"A1...A7" on page 1085*.

D1...D8

Data type	Default value	Range	Unit
BYTE	-	-	-

The parameters required for the job are preset at the inputs D1 ... D8. The number of parameters depends on the job to be executed. There are also jobs requiring no parameters ↳ *"A1...A7" on page 1085*.

Output description



RDY

Data type	Default value	Range	Unit
BOOL	-	-	-

The output RDY indicates that processing of the job currently being processed is completed. This output does not indicate whether processing of the job was successful or not. The output RDY has therefore always to be considered together with the output OK.

RDY = TRUE and OK = TRUE:

Processing of the job is completed without errors. A new job can be started with a FALSE/TRUE edge at input FREI.

RDY = TRUE and OK = FALSE:

During processing of the job an error has been detected. ERR is set to TRUE. A new job can be started with a FALSE/TRUE edge at input FREI.

RDY = FALSE

Processing of an enabled job has not yet been completed (job is still running) or output RDY has been reset with FREI = FALSE.

OK

Data type	Default value	Range	Unit
BOOL	-	-	-

Output OK indicates whether the job has been handled successfully or whether an error has been detected during processing. In case of an error, OK ist set to FALSE and ERR is set to TRUE. The output OK is not valid until the job has been completed, i. e. if RDY = TRUE.

The following applies:

If RDY = TRUE and

OK = TRUE: The job has been processed successfully.

OK = FALSE: During processing of the job an error has been detected.

ERR

Data type	Default value	Range	Unit
BOOL	-	-	-

Output ERR indicates whether an error has occurred during processing of the function block. This output always has to be considered together with the outputs RDY and OK. If RDY is TRUE, OK is FALSE and ERR is TRUE, an error occurred.

A1...A7

Data type	Default value	Range	Unit
BOOL	-	-	-

After completion of job processing, the response is available at the outputs A1 ... A7. The number of response parameters depends on the job performed is described below.

List of jobs

Processing a job consists of:

- transferring the job
- supplying the OK response or not-OK response

The OK response is described in connection with the corresponding job.

The not-OK response of the individual jobs always looks as follows:

The following basically applies for the not-OK response:

RDY: TRUE

OK: FALSE

ERR:TRUE

A1...A7: 0

Updating of the maximum number of remote modules detected

The input word EW 07,15 contains, amongst other things, the maximum number of remote modules detected in the past. The actual number of remote modules which exist at the moment may be less. This command is used to update this value. The modules which exist are counted and the value is stored. The user can inquire this value in the PLC program (EW 07,15, bit 8...15).

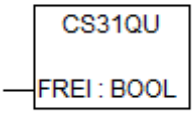
CS31QU



This function block allows to acknowledge automatically error messages of AC31 remote modules. Error messages are stored on the AC31 remote modules until they are acknowledged. Even if the error has been removed, the error message is still pending on the module until acknowledgement and is also signalized to the PLC until the message is acknowledged.

Processing of the function block is enabled with a TRUE signal at input FREI, and the function block then acknowledges AC31 errors continuously.

It may take several PLC cycles to acknowledge an error on an AC31 module.

If the function block is enabled, it constantly checks whether an AC31 error of class 3 or 4 has occurred and acknowledges this error.

An AC31 error of class 3 has occurred:

The function block acknowledges the error on the AC31 remote module which signalizes the error and also clears the error message on the PLC, i.e. the error flag M 255,13 is reset and LED FK3 is deactivated.

Example of a FK3 error:

A remote module is disconnected from the CS31 bus.

An AC31 error of class 4 has occurred:

The function block acknowledges the error on the AC31 remote module which signalizes the error and also clears the error message on the PLC, i.e. the error flag M 255,14 is reset.

Example of a FK4 error:

A remote module signalizes an open circuit.

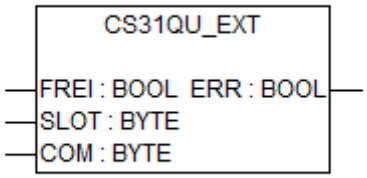
Processing of the function block is enabled with a TRUE signal at input FREI, and the function block then acknowledges AC31 errors continuously.

It may take several PLC cycles to acknowledge an error on an AC31 module.

If the function block is enabled, it constantly checks whether an AC31 error of class 3 or 4 has occurred and acknowledges this error.

Input description



FREI

Data type	Default value	Range	Unit
BOOL	-	-	-

Processing of the function block is controlled via input FREI.

FREI = FALSE:

All function block outputs are set to the value "FALSE". However, this is not valid, if a job is currently being processed, i. e. processing of a job which is currently being processed, is not affected by FREI = FALSE.

FREI = FALSE/TRUE edge:

Processing of the job is enabled. Input FREI is no longer evaluated during processing of the job.

FREI = TRUE:

The function block is not processed, i. e. it no longer changes its outputs. However, this is not valid, if a job is currently being processed.

SLOT

Data type	Default value	Range	Unit
BYTE	-	-	-

Reserved for future extensions.

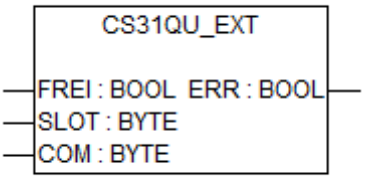
COM

Data type	Default value	Range	Unit
BYTE	-	-	-

At input COM, the number of the serial interface of the CS31 Master (AC500 or CM574) is specified.

Valid values: 0 and 1 for COM1, 2 for COM2 (CM574-RS only)

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	-	-

Output ERR indicates whether an error occurred during Function Block processing.

An AC31 error of class 3 has occurred:

The function block acknowledges the error on the AC31 remote module which signalizes the error and also clears the error message on the PLC, i.e. the error flag M 255,13 is reset and LED FK3 is deactivated.

Example of a FK3 error:

A remote module is disconnected from the CS31 bus.

An AC31 error of class 4 has occurred:

The function block acknowledges the error on the AC31 remote module which signalizes the error and also clears the error message on the PLC, i.e. the error flag M 255,14 is reset.

Example of a FK4 error:

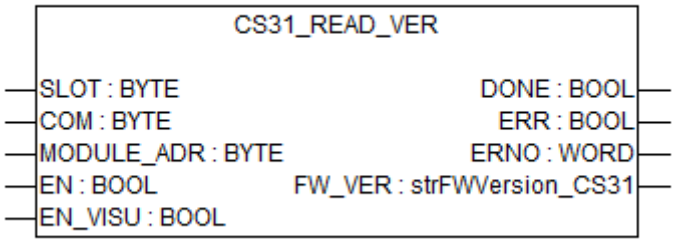
A remote module signalizes an open circuit.

Function call in ST

```
CS31QUEXT      (FREI := CS31QUEXT_FREI,
                SLOT := CS31QUEXT_SLOT,
                COM  := CS31QUEXT_COM);

CS31QUEXT_ERR        := CS31QUEXT.ERR;
```

CS31_READ_VER



Function block CS31_READ_VER is used to read out the firmware version of CS31 Bus Modules.

Parameter	Value
Included in library	CS31_AC500_V20.lib
Available as of firmware	V2.0.0
Type	Function block with historical values
Group	Group/Subgroup

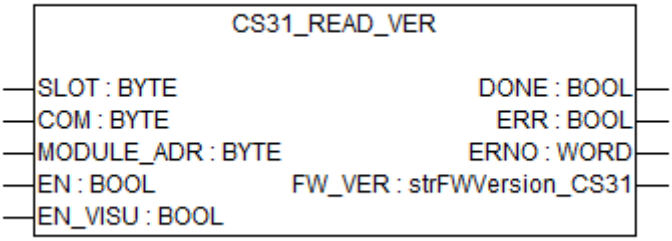
Function block CS31_READ_VER is used to readout the firmware version of CS31 communication interface module and of the Expansion Modules connected to them. The result is returned in a structure of the type strFWVersion_CS31.

The structure strFWVersion_CS31 is composed as follows:

TYPE strFWVersion_CS31 : STRUCT			
	abyFW_BM:	ARRAY[0..4] OF BYTE;	(* 5 bytes: FW version of CS31 Bus Module*)
	abyFW_Ext_1:	ARRAY[0..3] OF BYTE;	(* 4 bytes: FW version of Expansion Module 1*)
	abyFW_Ext_2:	ARRAY[0..3] OF BYTE;	(* 4 bytes: FW version of Expansion Module 2*)
	abyFW_Ext_3:	ARRAY[0..3] OF BYTE;	(* 4 bytes: FW version of Expansion Module 3*)
	abyFW_Ext_4:	ARRAY[0..3] OF BYTE;	(* 4 bytes: FW version of Expansion Module 4*)
	abyFW_Ext_5:	ARRAY[0..3] OF BYTE;	(* 4 bytes: FW version of Expansion Module 5*)

	abyFW_Ext_6:	ARRAY[0..3] OF BYTE;	(* 4 bytes: FW version of Expansion Module 6*)
	abyFW_Ext_7:	ARRAY[0..3] OF BYTE;	(* 4 bytes: FW version of Expansion Module 7*)
END_STRUCT END_TYPE			

Input description



SLOT

Data type	Default value	Range	Unit
BYTE	-	-	-

Reserved for future extensions.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

Communication Port to which the CS31 Bus Module is connected.

MODULE_ADR

Data type	Default value	Range	Unit
BYTE	-	0 ... 99	-

Address of the CS31 Bus Module from which the firmware versions should be readout.

EN

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated with a value transition from FALSE->TRUE at the variable EN. Otherwise it remains disabled.

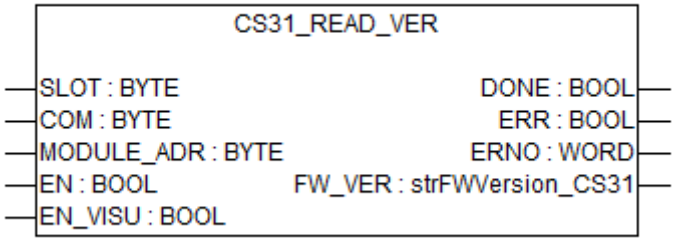
If the function block is activated the specified input values are used and the output values are available at the function block outputs.

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	-	-

If input EN_VISU = TRUE, it is also possible to control the function block inputs (except EN and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled. The actual values are always displayed.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

FW_VER

Data type	Default value	Range	Unit
strFWVersion_CS31	-	-	-

In the structure of this output value the firmware versions of the CS31 communication interface module and its expansion modules is stored.

Function call in ST

```
CS31ReadVer (SLOT       := CS31ReadVer_SLOT,
             COM        := CS31ReadVer_COM,
             MODULE_ADR := CS31ReadVer_MODULE_ADR,
             EN         := CS31ReadVer_EN,
             EN_VISU    := CS31ReadVer_EN_VISU);

CS31ReadVer_DONE   := CS31ReadVer.DONE;
CS31ReadVer_ERR    := CS31ReadVer.ERR;
CS31ReadVer_ERNO   := CS31ReadVer.ERNO;
CS31ReadVer_FW_VER := CS31ReadVer.FW_VER;
```

1.5.4.11 DC541 library

1.5.4.11.1 DC541

Library file name: **DC541_AC500_Vx.lib**

This library contains all function blocks necessary for using DC541. The configuration of DC541 is done in PLC configuration.

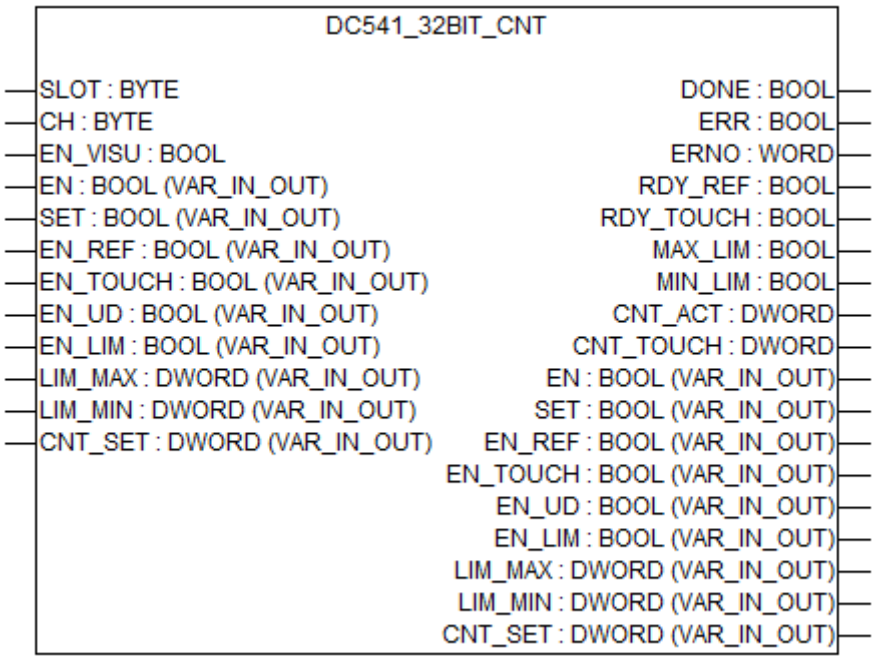
Once DC541 has been added to the PLC configuration, the library is automatically included with the next compilation of the project.

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

The function blocks are available in AC500 control systems with a runtime system of version V1.1.2 or later.

Function blocks

DC541_32BIT_CNT



Parameter	Value
Included in library	DC541_AC500_V11.lib
Available as of firmware	V1.1.3
Available as of firmware DC541	V1.1

Parameter	Value
Type	Function block with historical values
Group	Counters

The 32-bit counter is a count up/count down counter with a directional discriminator. The counter can be used in two counting modes:

- EN_UD = FALSE: Encoder mode
  Connection of an incremental transmitter (track A / track B, offset by 90°)
  It is possible to count signals up to approx. 60 kHz. This corresponds to a motor with a rotational speed of 3.600 rpm and a transmitter with 1.000 pulses per rotation. Pulse multiplication (x2 or x4) is not used.
- EN_UD = TRUE: Up / down mode
  Up-/down counter
  It is possible to count signals up to approx. 60 kHz. Count-up for signals on channel C1, count-down for signals on channel C0.

The counter always uses the channels C0...C3 of the DC541:

- C0: Track A of the incremental transmitter.
- C1: Track B of the incremental transmitter.
- C2 and C3: Reference cam or touch trigger.

The counter can be used in two operating modes:

- Infinite counter (endless mode)
- Limiting counter (limit mode)

The operating mode is selected using input EN_LIM.

If EN_LIM = FALSE, the counter operates as an infinite counter (endless mode). An overflow occurs corresponding to the 32 bit value at 16#FFFFFFFF = 4 294 967 295. In this mode, any exceeding of the limit value LIM_MAX or falling below the limit value LIM_MIN is displayed at the outputs MAX_LIM or MIN_LIM.

If EN_LIM = TRUE (limit mode), the counting range is between the limit values LIM_MIN and LIM_MAX. In case of an overflow, i.e. if LIM_MAX is reached, the counter restarts again at LIM_MIN.

The upper limit value LIM_MAX has to be higher than the lower limit value LIM_MIN. If the lower limit value LIM_MIN is higher than the upper limit value LIM_MAX, a corresponding error message is displayed at the outputs ERR/ERNO. In this case, the values for LIM_MIN and LIM_MAX are not forwarded to the DC541. The difference between LIM_MAX and LIM_MIN has to be at least twice the number (frequency) of counting pulses per DC541 cycle.

Example

Number of counting pulses (frequency) = 40 kHz = 40000 increments/s = 40 increments/ms

Cycle time of the DC541 = 100 µs

LIM_MIN = 0

Number of counting pulses per DC541 cycle: 40 increments/ms = 4 increments/100 µs

LIM_MAX > 8

Using input SET, the counter is set to the value CNT_SET. This value is kept as long as input SET = TRUE.

If the reference point approach is enabled at input EN_REF, the counter is set to the value of input CNT_SET when a rising edge occurs on channel C2 or C3.

Using input EN_TOUCH, a touch trigger measurement is enabled. This means: With the rising edge on channel C2 or C3, the counting value is stored and displayed at output CNT_TOUCH. The validity of CNT_TOUCH is indicated by output RDY_TOUCH. This functionality can be used to determine the counter value with regard to an external event. The results are increment accurate.

Only one function may be enabled at a time, either the reference point approach or the touch trigger measurement. If both functions are enabled simultaneously or if the execution of one function is not yet completed when enabling the other function, a corresponding error message is displayed at the outputs ERR/ERNO.

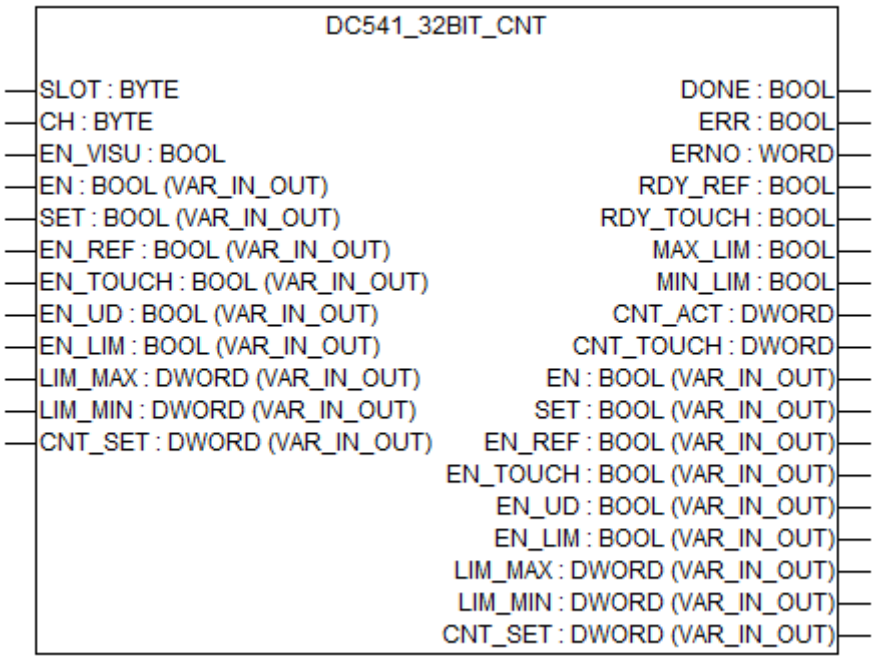
To initiate a new reference point approach or touch trigger measurement, a positive edge at the corresponding enabling input is necessary.

If the zero track of an incremental transmitter is wired to channel C2 or C3, no touch trigger measurement may be performed in the region of the reference cam!

The device DC541 must be configured as counting device (counter mode).

This function block has an integrated visualization which can be used to control all function block functions in parallel to the user program, if input EN_VISU = TRUE ↳ *Chapter 1.5.4.11.1.2 “Visualizations” on page 1154*.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type	Default value	Range	Unit
BYTE	-	0 for input C0 only	-

This input is used to select the input for the counter. The device occupies the inputs C0...C3. If an invalid value is entered at input CH or if the selected channel is not configured as a 32-bit counter (32BIT_CNT), the function block is aborted.

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

If EN_VISU input (enable input in visualization) is TRUE, it is possible to control the function block inputs (except SLOT, CH and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed.

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

In order to enable pulse counting for input CH, input EN has to be continuously TRUE. The function block is not processed if input EN = FALSE.

When the function block is called for the first time, the inputs are checked for validity and plausibility and the corresponding device is checked for correct configuration in the operating mode "counting mode". If this is not the case, processing is aborted.

SET

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

At a rising edge at this input, the counter is set to the value of input CNT_SET. Counting is enabled after reset process to SET = TRUE.

EN_REF

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

A rising edge at EN_REF input (enable reference) enables the reference point approach. If EN_REF = TRUE, a rising edge at input C2 or C3 causes the actual value of the counter CNT_ACT to be set to the value of input CNT_SET.

The next measurement is again initiated by a rising edge at input EN_REF.

Only one function may be enabled at a time, either the reference point approach or the touch trigger measurement. If both functions are enabled simultaneously or if the execution of one function is not yet completed when enabling the other function, the function block is aborted.

EN_TOUCH

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

A rising edge at EN_TOUCH input (enable touch trigger) enables a touch trigger measurement. If input EN_TOUCH = TRUE, a rising edge at input C2 or C3 causes the function block to store the actual counter value and to display this value at output CNT_TOUCH.

The next measurement is again initiated by a rising edge at input EN_TOUCH.

Only one function may be enabled at a time, either the reference point approach or the touch trigger measurement. If both functions are enabled simultaneously or if the execution of one function is not yet completed when enabling the other function, the function block is aborted.

EN_UD

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The input EN_UD (enable up/down) is used to select the counting mode of the 32-bit counter.

EN_UD = FALSE: Connection of an incremental transmitter. Track A/B offset by 90°.

EN_UD = TRUE: Up/down counter. C1: count up, C0: count down.

EN_LIM

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Input EN_LIM (enable limit) is used to set the operating mode for the counter:

EN_LIM = FALSE: Infinite counter (endless mode).

EN_LIM = TRUE: Limiting counter (limit mode).

Switching between the operating modes can be done during running operation. And it is possible to change the upper limit value LIM_MAX and the lower limit value LIM_MIN during running operation. LIM_MAX has to be higher than LIM_MIN. If LIM_MIN is higher than LIM_MAX, an error is displayed.

In case of a rising edge at input EN_LIM (transition from endless mode to limit mode), the present counter value can change depending on the values of LIM_MIN and LIM_MAX.

Present counter value	Changed counter value
ACT_CNT < LIM_MIN	ACT_CNT := LIM_MIN
LIM_MIN ≤ ACT_CNT ≤ LIM_MAX	ACT_CNT := ACT_CNT (no change)
ACT_CNT > LIM_MAX	ACT_CNT := LIM_MIN

LIM_MAX

Data type	Default value	Range	Unit
DWORD	-	-	-

LIM_MAX (limit maximum) is used to set the upper limit value for the counter. LIM_MAX has to be higher than the lower limit value LIM_MIN. If LIM_MIN is higher than LIM_MAX, an error is displayed.

LIM_MIN

Data type	Default value	Range	Unit
DWORD	-	-	-

LIM_MIN (limit minimum) is used to set the lower limit value for the counter. The upper limit value LIM_MAX has to be higher than LIM_MIN. If LIM_MIN is higher than LIM_MAX, an error is displayed.

CNT_SET

Data type	Default value	Range	Unit
DWORD	-	-	-

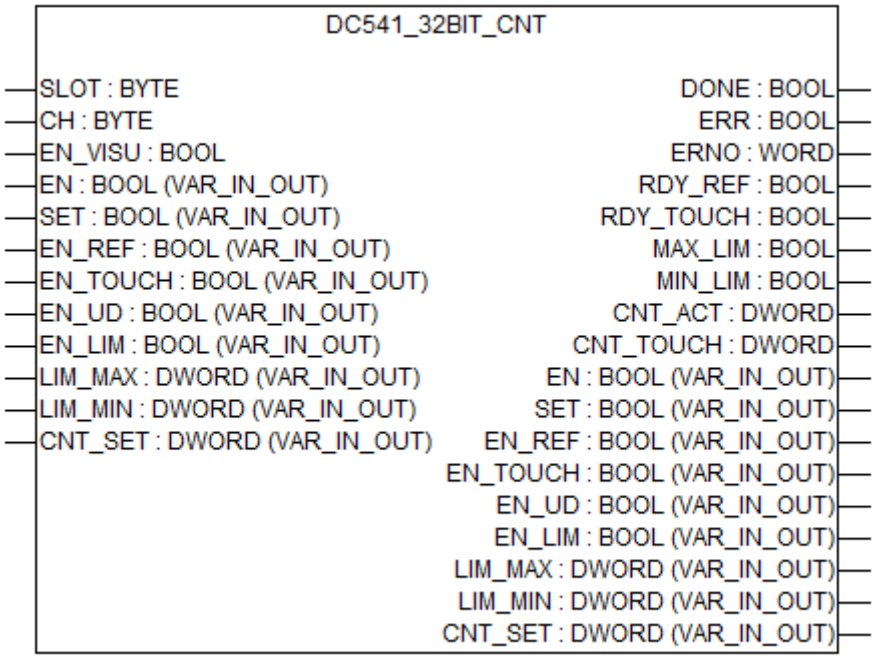
CNT_SET (counter set) is used to adjust the counter set value.

If input SET = TRUE, the counter is set to the value of input CNT_SET and remains at this value as long as input SET = TRUE. Counting is enabled again with the occurrence of the falling edge at input SET.

In case of a reference point approch (EN_REF = TRUE), the rising edge on channel C2 causes the actual value of the counter (ACT_CNT) to be adjusted to the set value CNT_SET.

A FALSE -> TRUE edge at input EN activates the status polling. If the value at input SLOT is not valid, processing is aborted and an error is displayed. The function block outputs are updated as long as input EN = TRUE. The function block processing has been completed successfully, if output DONE changes to TRUE. During the processing of a request, state changes at input EN are recognized but not evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 58: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F
24586	600A	Lifesign error from DC541

RDY_REF

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

RDY_REF (ready reference) displays the ready message of the reference point approach.

RDY_TOUCH

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

RDY_TOUCH (ready message touch trigger) displays the ready message of the touch trigger measurement.

MAX_LIM

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

In the infinite counter operating mode (endless mode), MAX_LIM indicates whether the actual counter value is higher than the value set at input LIM_MAX.

In the limiting counter operating mode (limit mode), output MAX_LIM is FALSE.

MIN_LIM

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

In the infinite counter operating mode (endless mode), output MIN_LIM indicates whether the actual counter value is lower than the value set at input LIM_MIN.

In the limiting counter operating mode (limit mode), output MIN_LIM is FALSE.

CNT_ACT

Data type	Default value	Range	Unit
DWORD	-	-	-

CNT_ACT (counter actual) displays the actual counter value of the count up counter.

CNT_TOUCH

Data type	Default value	Range	Unit
DWORD	-	-	-

Output CNT_TOUCH (counter touch trigger) displays the result of the touch trigger measurement, i.e. the actual counter value at the moment of the occurrence of the rising edge at input C2 after initiation of a touch trigger measurement by a rising edge at input EN_TOUCH.

Function call in ST

```
DC541Cnt32Bit (SLOT := DC541Cnt32Bit_SLOT,

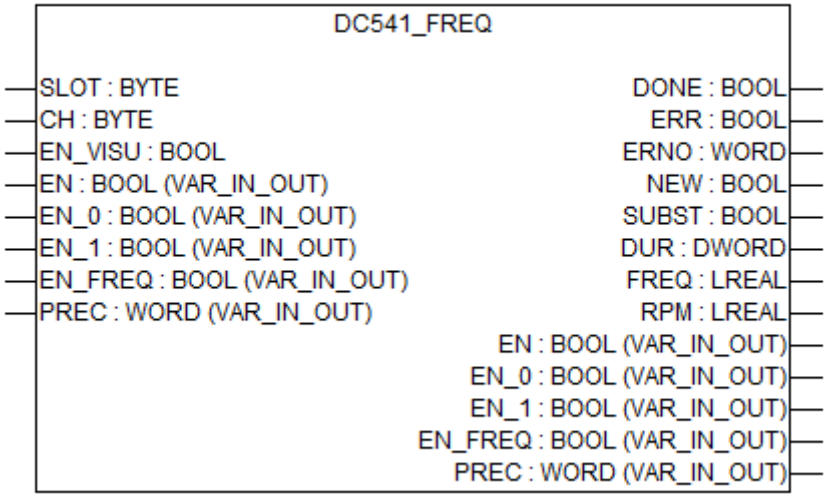
DC541Cnt32Bit_CNT_TOUCH := DC541Cnt32Bit.CNT_TOUCH;
```

DC541_FREQ



Parameter	Value
Included in library	DC541_AC500_V11.lib
Available as of firmware	V1.1.3, DC541 firmware: V1.2
Type	Function block with historical values
Group	Counters

The function block DC541_FREQ is used to measure times, frequencies and rotational speeds with a resolution of 100 µs.

It is able to measure frequencies from 0 to 2000 Hz (2 kHz). In order to obtain a precise measurement of frequencies > 50 Hz, a correspondingly high accuracy setting has to be chosen. It is recommended to use an accuracy of PREC = 1000, i.e. 0.001.

This function block has to be called cyclically, one time per second at least.

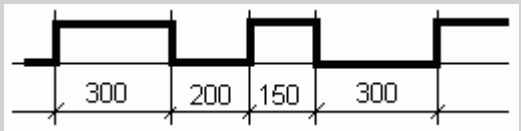
The inputs EN_0, EN_1 and EN_FREQ are used to determine the edges to be measured. If input EN_FREQ = TRUE, the frequency and the rotational speed are calculated in addition to the time measurement.

EN_0	EN_1	EN_FREQ	Edges measured	FREQ/RPM
FALSE	FALSE	TRUE	No measurement is performed.	yes
FALSE	TRUE	TRUE	Measurement of time between two rising edges. 	yes
TRUE	FALSE	TRUE	Measurement of time between two falling edges. 	yes

EN_0	EN_1	EN_FREQ	Edges measured	FREQ/RPM
TRUE	TRUE	TRUE	Measurement of time between any two edges. 	yes
FALSE	FALSE	FALSE	No measurement is performed.	no
FALSE	TRUE	FALSE	Measurement of time between the falling edge and the subsequent rising edge. 	no
TRUE	FALSE	FALSE	Measurement of time between the rising edge and the subsequent falling edge. 	no
TRUE	TRUE	FALSE	Measurement of time between any two edges. 	no

Example

Different time measurement results depending on the values applied to the inputs EN_0, EN_1 and EN_FREQ.



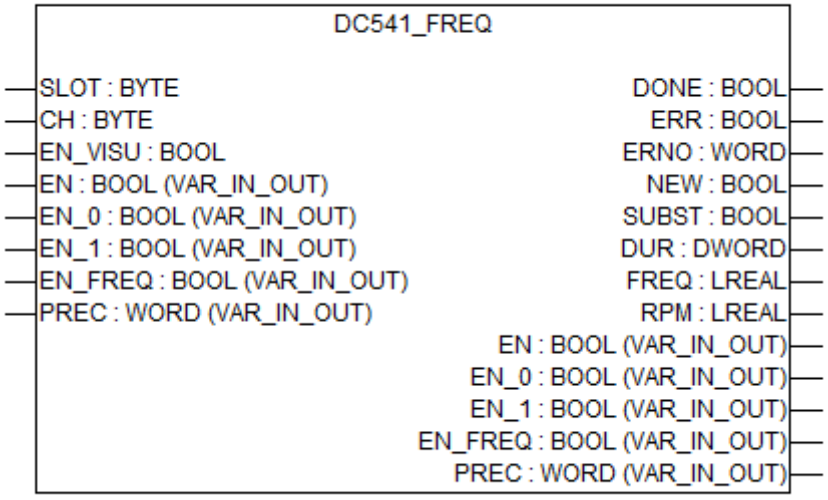
EN_0	EN_1	EN_FREQ	Time measurement (duration DUR) [µs]			
			1	2	3	4
FALSE	FALSE	TRUE	0	0	0	0
FALSE	TRUE	TRUE	-	500	-	450
TRUE	FALSE	TRUE	-	-	350	-
TRUE	TRUE	TRUE	300	200	150	300
FALSE	FALSE	FALSE	0	0	0	0
FALSE	TRUE	FALSE	300	-	150	-
TRUE	FALSE	FALSE	-	200	-	300
TRUE	TRUE	FALSE	300	200	150	300

The output NEW indicates that new measurement results are available.

The device DC541 must be configured as counting device (counter mode). Channel CH must be configured for frequency measurement.

This function block has an integrated visualization which can be used to control all function block functions in parallel to the user program, if input EN_VISU = TRUE *Chapter 1.5.4.11.1.2 “Visualizations” on page 1154*.

Input description



SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type	Default value	Range	Unit
BYTE	-	0-7 for the inputs C0-C7	-

CH is used to select the channel for time and frequency measurement. If an invalid value is specified at input CH or if the selected channel is not configured as frequency measurement, the function flock is aborted with DONE = ERR = TRUE and an error is displayed.

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

If EN_VISU input (enable input in visualization) is TRUE, it is possible to control the function block inputs (except SLOT, CH and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed.

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

In order to enable pulse counting for input CH, input EN has to be continuously TRUE. The function block is not processed if input EN = FALSE.

When the function block is called for the first time, the inputs are checked for validity and plausibility and the corresponding device is checked for correct configuration in the operating mode "counting mode". If this is not the case, processing is aborted.

EN_0 (enable 0)

Data type	Default value	Range	Unit
BOOL	-	-	-

This input is used to determine whether falling edges are considered for measurement:

EN_0 = TRUE: Measurement considers falling edges.

EN_0 = FALSE: Measurement does not consider falling edges.

EN_1

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

If EN_1=TRUE, the time frequency measurement will be capture on rising edge of signal.

Input EN_1 corresponds to output bit 2 in control byte.

EN_FREQ

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

EN_FREQ = FALSE: Measurement of time between positive or negative edges

EN_FREQ = TRUE: Measurement of time between edges and calculation of frequency and speed of rotation

PREC

Data type	Default value	Range	Unit
WORD	-	-	-

PREC (precision) input is used to specify the demanded accuracy of the measurement.

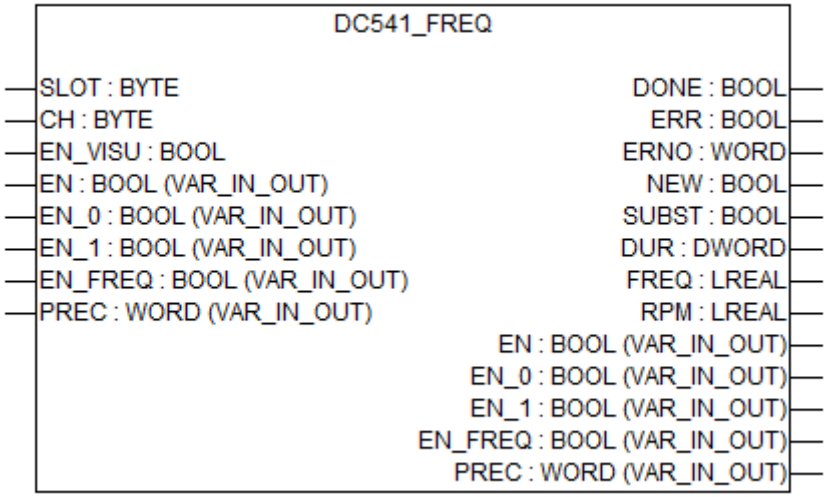
PREC = 10 corresponds to an accuracy of 0.1 (one tenth)

PREC = 100 corresponds to an accuracy of 0.01 (one hundredth)

PREC = 1000 corresponds to an accuracy of 0.001 (one thousandth)

Depending on the cycle time and the demanded accuracy, the DC541 extends its measuring time and counts multiple pulses. This setting is only used in the frequency measurement operating mode (EN_FREQ = TRUE). Then, the displayed measurement values correspond to the measured average value. This reduces jitter and latency effects resulting in improved accuracy.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 59: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F
24586	600A	Lifesign error from DC541

NEW

Data type	Default value	Range	Unit
BOOL	-	-	-

Output indicates that new measurement results are available.

NEW = TRUE: New measurement results are available.

NEW = FALSE: No new measurement results are available.

SUBST

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

SUBST (substitute) output indicates whether the output values are based on new measurement values or calculated using substitute values. Without the substitute value, the function block would still display a short time and a high speed of rotation in case of a decrease of the frequency, since no new measurement is initiated without a new signal edge. If SUBST = TRUE, the extended distance between the edges is extrapolated. PREC > 0 is an assumption for the calculation using a substitute value.

SUBST = FALSE: New measurement values.

SUBST = TRUE: Calculation using substitute values.

DUR

Data type	Default value	Range	Unit
DWORD	-	-	µs

DUR (duration) output displays the measured time.

FREQ (frequency)

Data type	Default value	Range	Unit
LREAL	-	-	Hz

If input EN_FREQ = TRUE, output FREQ displays the frequency calculated from the measured time.

If input EN_FREQ = FALSE, output FREQ = 0.

RPM

Data type	Default value	Range	Unit
LREAL	-	-	rpm

If input EN_FREQ = TRUE, output RPM (revolutions per minute) displays the speed of rotation calculated from the measured time.

If input EN_FREQ = FALSE, output RPM =0.

Function call in ST

```
DC541Freq(SLOT      := DC541Freq_SLOT,

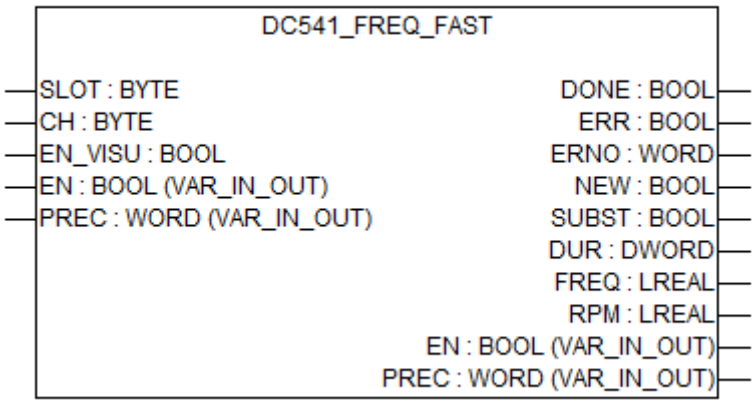
DC541_FREQ_FAST



Parameter	Value
Included in library	DC541_AC500_V12.lib
Available as of firmware	V1.2, DC541 firmware: V1.3
Type	Function block with historical values
Group	Counters

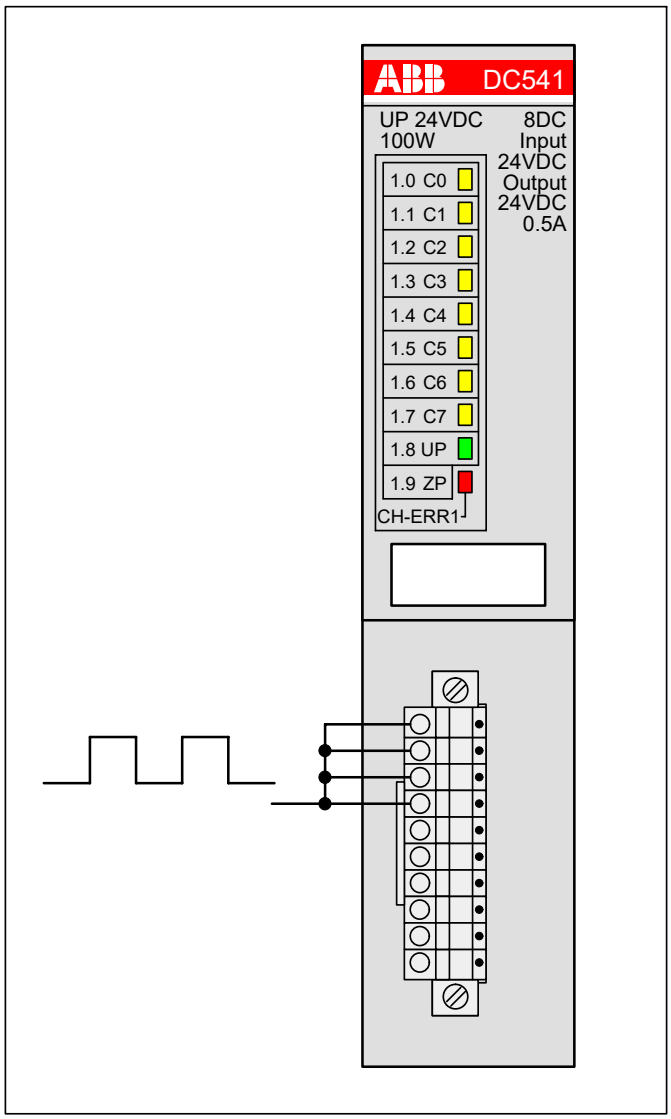
The function block DC541_FREQ_FAST is used to measure times, frequencies and rotational speeds with a resolution of 1 µs.

It is able to measure frequencies from 0-50000 Hz (50 kHz).

The function block works like DC541_FREQ, but it reaches a resolution of 1us ↳ *Chapter 1.5.4.11.1.1.2 “DC541_FREQ” on page 1111*.

Restrictions:

- The function block is only allowed once per DC541 and only for channel 0.
- It occupies the resources of the first 4 inputs, which cannot be used for other purposes.
- The inputs C0..C3 must be connected in parallel.



This function block has to be called cyclically, one time per second at least.

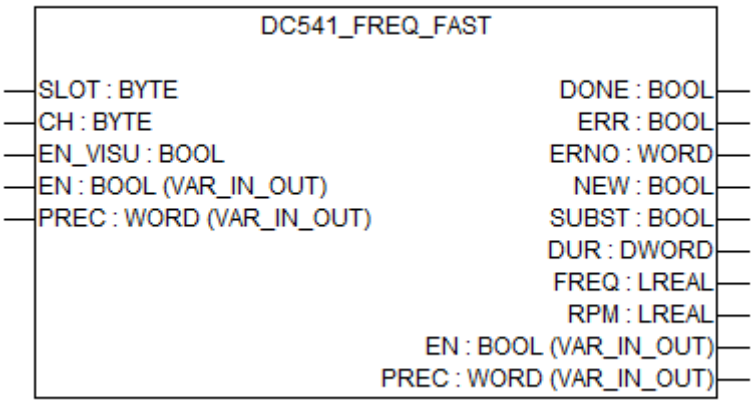
It always measures the time and frequency from one positive edge to the next positive edge.

The output NEW indicates that new measurement results are available.

The device DC541 must be configured as counting device (counter mode). Channel CH must be configured for frequency measurement.

The function block has an integrated visualization which can be used to control all function block functions in parallel to the user program, if input EN_VISU = TRUE ↳ *Chapter 1.5.4.11.1.2 “Visualizations” on page 1154*.

Input description



SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type	Default value	Range	Unit
BYTE	-	0-7 for the inputs C0-C7	-

CH is used to select the channel for time and frequency measurement. If an invalid value is specified at input CH or if the selected channel is not configured as frequency measurement, the function flock is aborted with DONE = ERR = TRUE and an error is displayed.

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

If EN_VISU input (enable input in visualization) is TRUE, it is possible to control the function block inputs (except SLOT, CH and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed.

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

In order to enable pulse counting for input CH, input EN has to be continuously TRUE. The function block is not processed if input EN = FALSE.

When the function block is called for the first time, the inputs are checked for validity and plausibility and the corresponding device is checked for correct configuration in the operating mode "counting mode". If this is not the case, processing is aborted.

PREC

Data type	Default value	Range	Unit
WORD	-	-	-

PREC (precision) input is used to specify the demanded accuracy of the measurement.

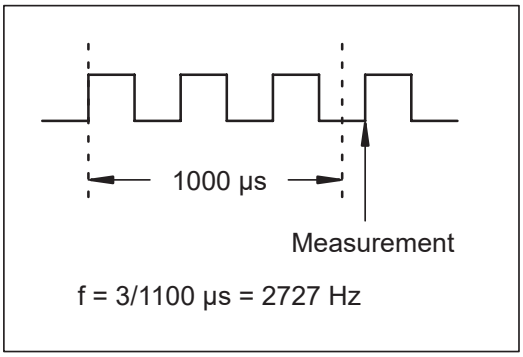
PREC = 10 corresponds to an accuracy of 0.1 (one tenth)

PREC = 100 corresponds to an accuracy of 0.01 (one hundredth)

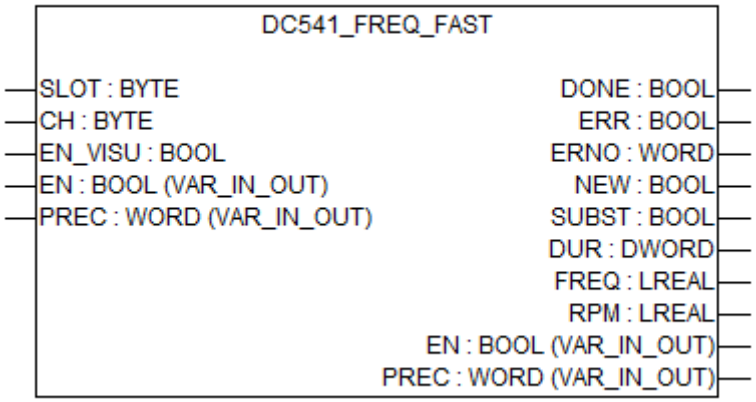
PREC = 1000 corresponds to an accuracy of 0.001 (one thousandth)

Depending on the cycle time and the demanded accuracy, the DC541 extends its measuring time and counts multiple pulses. This setting is only used in the frequency measurement operating mode (EN_FREQ = TRUE). Then, the displayed measurement values correspond to the measured average value. This reduces jitter and latency effects resulting in improved accuracy.

As the resolution for measuring is 1 µs, the precision corresponds directly to the measuring time in µs. For times < 100 µs, the device will just calculate the values as fast as possible, which will be the cycle time of the device, around 100 µs. For higher precision, the device will use the pulses per measuring time. It will measure the pulses and the time, with the time on a 1µs resolution.



Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 60: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F
24586	600A	Lifesign error from DC541

NEW

Data type	Default value	Range	Unit
BOOL	-	-	-

Output indicates that new measurement results are available.

NEW = TRUE: New measurement results are available.

NEW = FALSE: No new measurement results are available.

SUBST

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

SUBST (substitute) output indicates whether the output values are based on new measurement values or calculated using substitute values. Without the substitute value, the function block would still display a short time and a high speed of rotation in case of a decrease of the frequency, since no new measurement is initiated without a new signal edge. If SUBST = TRUE, the extended distance between the edges is extrapolated. PREC > 0 is an assumption for the calculation using a substitute value.

SUBST = FALSE: New measurement values.

SUBST = TRUE: Calculation using substitute values.

DUR

Data type	Default value	Range	Unit
DWORD	-	-	µs

DUR (duration) output displays the measured time.

FREQ (frequency)

Data type	Default value	Range	Unit
LREAL	-	-	Hz

If input EN_FREQ = TRUE, output FREQ displays the frequency calculated from the measured time.

If input EN_FREQ = FALSE, output FREQ = 0.

RPM

Data type	Default value	Range	Unit
LREAL	-	-	rpm

If input EN_FREQ = TRUE, output RPM (revolutions per minute) displays the speed of rotation calculated from the measured time.

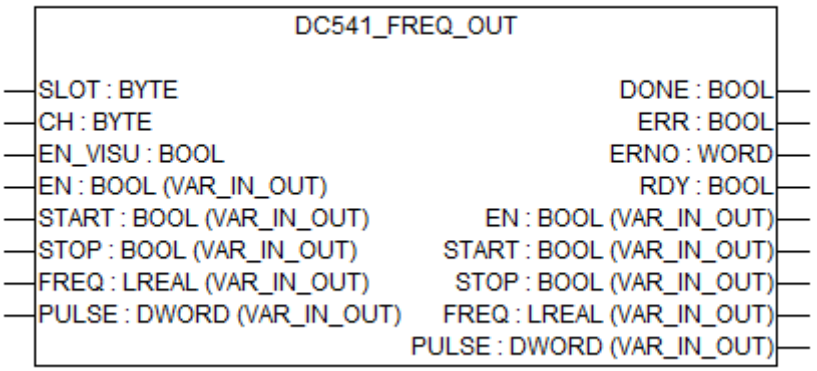
If input EN_FREQ = FALSE, output RPM =0.

Function call in ST

```
DC541FreqFast(SLOT      := DC541FreqFast_SLOT,
              CH        := DC541FreqFast_CH,
              EN_VISU   := DC541FreqFast_EN_VISU,
              EN        := DC541FreqFast_EN,
              EN_0      := DC541FreqFast_EN_0,
              EN_1      := DC541FreqFast_EN_1,
              EN_FREQ   := DC541FreqFast_EN_FREQ,
              PREC      := DC541FreqFast_PREC);

DC541FreqFast_DONE      := DC541FreqFast.DONE;
DC541FreqFast_ERR       := DC541FreqFast.ERR;
DC541FreqFast_ERNO      := DC541FreqFast.ERNO;
DC541FreqFast_NEW       := DC541FreqFast.NEW;
DC541FreqFast_SUBST     := DC541FreqFast.SUBST;
DC541FreqFast_DUR       := DC541FreqFast.DUR;
DC541FreqFast_FREQ      := DC541FreqFast.FREQ;
DC541FreqFast_RPM       := DC541FreqFast.RPM;
```

DC541_FREQ_OUT



Parameter	Value
Included in library	DC541_AC500_V11.lib
Available as of firmware	V1.1.3, DC541 firmware: V1.2
Type	Function block with historical values
Group	Counters

The function block DC541_FREQ_OUT is used to output pulses with a fixed frequency on one channel of the device DC541. It is able to output pulses with a frequency between 0.2 and 2.5 kHz. The pulse jitter depends on the cycle time of the DC541. The pulse length is always a multiple of the cycle time of the DC541.

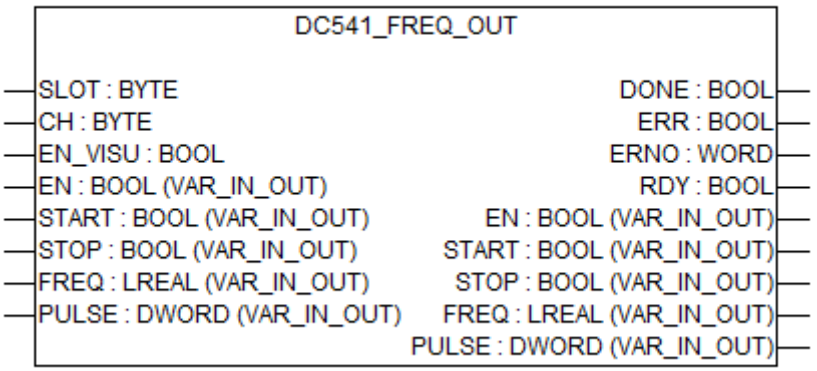
In case of a presetting of PULSE = 0, the output of pulses is infinite. The pulse output is started with a positive edge at input START. The output is aborted if START = FALSE. A positive edge at input STOP interrupts the pulse output. The output is continued if STOP = FALSE.

If input PULSE > 0, the function block outputs the number of pulses specified at input PULSE with the frequency specified at input FREQ on the channel specified at input CH. After the function block has output the number of pulses specified at PULSE, the output RDY becomes TRUE.

The device DC541 must be configured as counting device (counter mode). Channel CH must be configured for frequency output.

The function block has an integrated visualization which can be used to control all function block functions in parallel to the user program, if input EN_VISU = TRUE.

Input description



SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type	Default value	Range	Unit
BYTE	-	0-7 for the inputs C0-C7	-

CH is used to select the channel for time and frequency measurement. If an invalid value is specified at input CH or if the selected channel is not configured as frequency measurement, the function flock is aborted with DONE = ERR = TRUE and an error is displayed.

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

If EN_VISU input (enable input in visualization) is TRUE, it is possible to control the function block inputs (except SLOT, CH and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed.

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

In order to enable pulse counting for input CH, input EN has to be continuously TRUE. The function block is not processed if input EN = FALSE.

When the function block is called for the first time, the inputs are checked for validity and plausibility and the corresponding device is checked for correct configuration in the operating mode "counting mode". If this is not the case, processing is aborted.

START

Data type	Default value	Range	Unit
BOOL	-	-	-

A positive edge at input START starts the frequency output. The frequency output is aborted if START = FALSE.

STOP

Data type	Default value	Range	Unit
BOOL	-	-	-

A positive edge at input STOP interrupts the frequency output. If a given number of pulses has to be output, the counter continues counting if STOP = FALSE. The STOP is not synchronized with the frequency.

FREQ

Data type	Default value	Range	Unit
LREAL	-	0.2-2500.0	Hz

FREQ (frequency) input is used to preset the frequency to be output.

PULSE

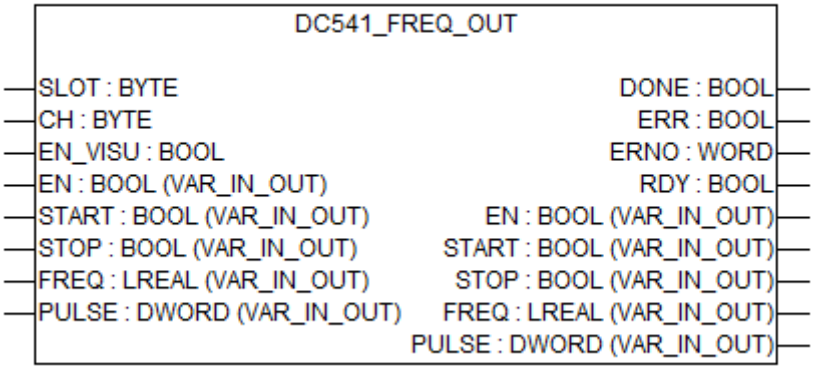
Data type	Default value	Range	Unit
DWORD	-	-	-

Input PULSE is used to determine whether frequency output shall be performed endless or only for the specified number of pulses.

PULSE = 0: Endless output.

PULSE > 0: Output of the specified number of pulses.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 61: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F
24586	600A	Lifesign error from DC541

RDY (ready)

Data type	Default value	Range	Unit
BOOL	-	-	-

If PULSE > 0, output RDY becomes TRUE after the specified number of pulses has been output.
