The function block DC541_FWD_CNT provides a 32-bit count up counter which is able to count a maximum frequency of 50 kHz at the inputs C0 and C1 or 5 kHz at the inputs C2-C7. In the DC541, the counter is implemented as a 16 bit counter. The actual counter value ACT_CNT is bulit inside the function block by adding the counter differences that occur within the individual cycles. In order not to loose any counting pulses, the function block has to be called cyclically.

- Channel 0-1: 50 kHz max. -> 32767 / 50 = 655 ms
- Channel 2-7: 5 kHz max. -> 32767 / 5 = 6550 ms

Using the counter e.g. in a 100 ms task will prevent any loss of counting pulses.

Operating modes

- Infinite counter (endless mode)
- Limiting counter (limit mode)

The operating mode is selected at input EN_LIM.

If EN_LIM = FALSE, the counter operates as an infinite counter (endless mode). An overflow occurs corresponding to the 32-bit value at 16#FFFFFFFF = 4 294 967 295. In this mode, any exceeding of the limit value LIM_MAX or falling below the limit value LIM_MIN is displayed at the outputs MAX_LIM or MIN_LIM.

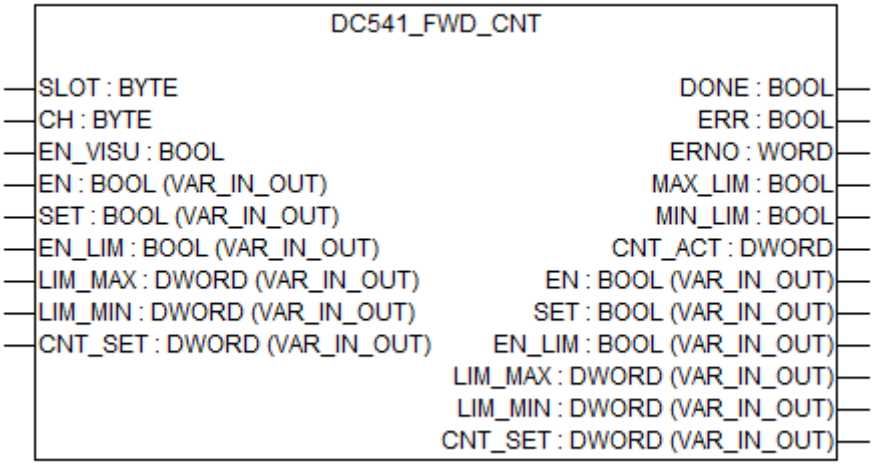
If EN_LIM = TRUE (limit mode), the counting range is between the limit values LIM_MIN and LIM_MAX. In case of an overflow, i.e. if LIM_MAX is reached, the counter restarts again at LIM_MIN.

The upper limit value LIM_MAX has to be higher than the lower limit value LIM_MIN. If LIM_MIN is higher than LIM_MAX, an error is displayed.

The device DC541 must be configured as counting device (counter mode).

The function block has an integrated visualization which can be used to control all function block functions in parallel to the user program, if input EN_VISU = TRUE.

Input description



SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type	Default value	Range	Unit
BYTE	-	0-7 for the inputs C0-C7	-

CH is used to select the channel for time and frequency measurement. If an invalid value is entered at input CH or if the selected channel is not configured as 32-bit count up counter (FWD_CNT), the function flock is aborted with DONE = ERR = TRUE and an error is displayed.

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

If EN_VISU input (enable input in visualization) is TRUE, it is possible to control the function block inputs (except SLOT, CH and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed.

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

In order to enable pulse counting for input CH, input EN has to be continuously TRUE. The function block is not processed if input EN = FALSE.

When the function block is called for the first time, the inputs are checked for validity and plausibility and the corresponding device is checked for correct configuration in the operating mode "counting mode". If this is not the case, processing is aborted.

SET

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

At a rising edge at this input, the counter is set to the value of input CNT_SET. Counting is enabled after reset process to SET = TRUE.

EN_LIM

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Input EN_LIM (enable limit) is used to set the operating mode for the counter:

EN_LIM = FALSE: Infinite counter (endless mode).

EN_LIM = TRUE: Limiting counter (limit mode).

Switching between the operating modes can be done during running operation. And it is possible to change the upper limit value LIM_MAX and the lower limit value LIM_MIN during running operation. LIM_MAX has to be higher than LIM_MIN. If LIM_MIN is higher than LIM_MAX, an error is displayed.

In case of a rising edge at input EN_LIM (transition from endless mode to limit mode), the present counter value can change depending on the values of LIM_MIN and LIM_MAX.

Present counter value	Changed counter value
ACT_CNT < LIM_MIN	ACT_CNT := LIM_MIN
LIM_MIN ≤ ACT_CNT ≤ LIM_MAX	ACT_CNT := ACT_CNT (no change)
ACT_CNT > LIM_MAX	ACT_CNT := LIM_MIN

LIM_MAX

Data type	Default value	Range	Unit
DWORD	-	-	-

LIM_MAX (limit maximum) is used to set the upper limit value for the counter. LIM_MAX has to be higher than the lower limit value LIM_MIN. If LIM_MIN is higher than LIM_MAX, an error is displayed.

LIM_MIN

Data type	Default value	Range	Unit
DWORD	-	-	-

LIM_MIN (limit minimum) is used to set the lower limit value for the counter. The upper limit value LIM_MAX has to be higher than LIM_MIN. If LIM_MIN is higher than LIM_MAX, an error is displayed.

CNT_SET

Data type	Default value	Range	Unit
DWORD	-	-	-

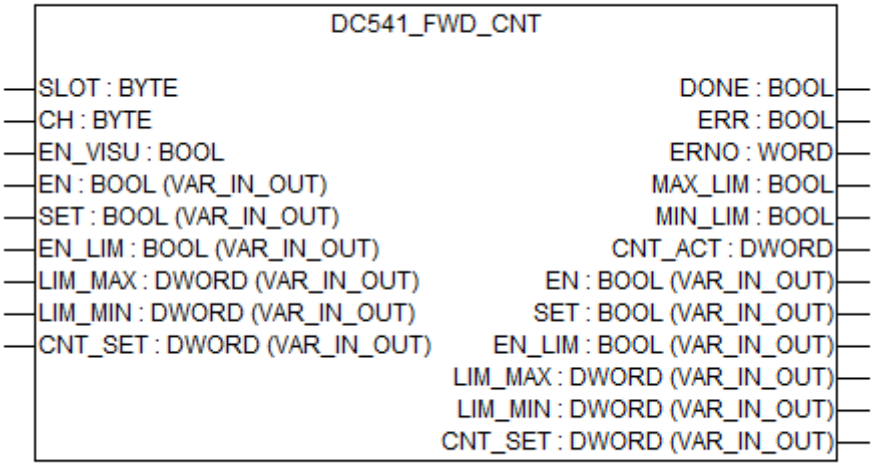
CNT_SET (counter set) is used to adjust the counter set value.

If input SET = TRUE, the counter is set to the value of input CNT_SET and remains at this value as long as input SET = TRUE. Counting is enabled again with the occurrence of the falling edge at input SET.

In case of a reference point approch (EN_REF = TRUE), the rising edge on channel C2 causes the actual value of the counter (ACT_CNT) to be adjusted to the set value CNT_SET.

A FALSE -> TRUE edge at input EN activates the status polling. If the value at input SLOT is not valid, processing is aborted and an error is displayed. The function block outputs are updated as long as input EN = TRUE. The function block processing has been completed successfully, if output DONE changes to TRUE. During the processing of a request, state changes at input EN are recognized but not evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 62: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it

DEC	HEX	Error description
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F
24586	600A	Lifesign error from DC541

MAX_LIM

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

In the infinite counter operating mode (endless mode), MAX_LIM indicates whether the actual counter value is higher than the value set at input LIM_MAX.

In the limiting counter operating mode (limit mode), output MAX_LIM is FALSE.

MIN_LIM

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

In the infinite counter operating mode (endless mode), output MIN_LIM indicates whether the actual counter value is lower than the value set at input LIM_MIN.

In the limiting counter operating mode (limit mode), output MIN_LIM is FALSE.

CNT_ACT

Data type	Default value	Range	Unit
DWORD	-	-	-

CNT_ACT (counter actual) displays the actual counter value of the count up counter.

```

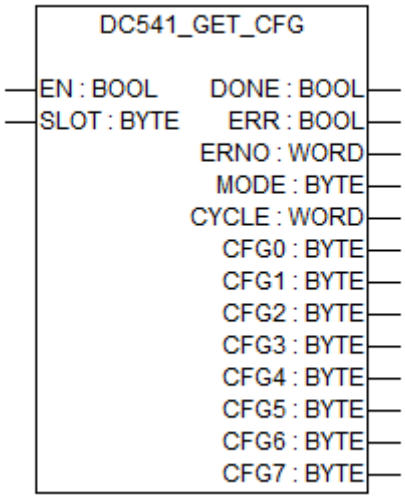
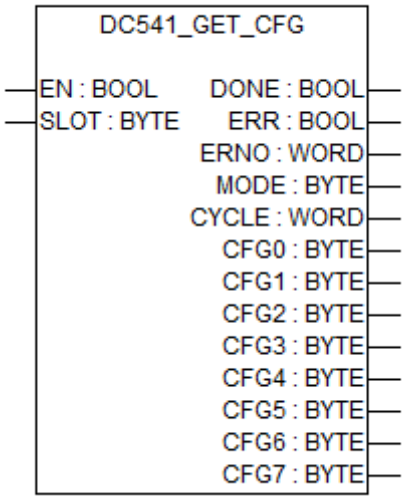
DC541_GET_CFG



Parameter	Value
Included in library	DC541_AC500_V11.lib
Available as of firmware	V1.1.3, DC541 firmware: V1.1
Type	Function block with historical values
Group	Diagnosis

The function block DC541_GET_CFG is used to poll the actual configuration of the device DC541. The information is displayed as long as input EN is TRUE. The displayed information includes the operating mode and the cycle time of the device as well as the configuration of the channels C0...C7.

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

A FALSE -> TRUE edge at input EN activates the status polling. If the value at input SLOT is not valid, processing is aborted and an error is displayed. The function block outputs are updated as long as input EN = TRUE. The function block processing has been completed successfully, if output DONE changes to TRUE. During the processing of a request, state changes at input EN are recognized but not evaluated.

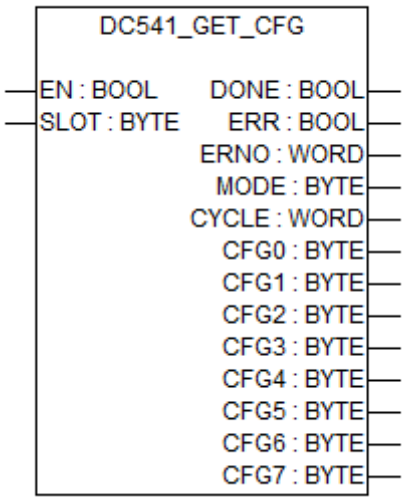
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 63: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F
24586	600A	Lifesign error from DC541

MODE

Data type	Default value	Range	Unit
BYTE	-	-	-

Output displays the actual operating mode of the device.

Parameter	Value	Operating mode
DC541_MODE_IO	= 16#11 = 17	IO device (IO mode)
DC541_MODE_COUNT	= 16#22 = 34	Counting device (counter mode)

CYCLE

Data type	Default value	Range	Unit
WORD	-	-	µs

CYCLE (cycle time) output displays the cycle time of the device. The cycle time is set during the device configuration and can have the following values depending on the channel configuration:

Parameter		Description	Value
IO device			50 µs
Counting device		1-2 functions	50 µs
		3-4 functions	100 µs
		5-8 functions	200 µs
"Functions"			
	PWM	Pulse-width modulator	
	FREQ	Time and frequency measurement	
	FREQ_OUT	Frequency output	
	32BIT_CNT	32-bit counter	

Parameter		Description	Value
	FWD_CNT	32-bit count up counter	
	LIMIT	Limit value monitoring for the 32-bit counter	

CFG0...CFG7

Data type	Default value	Range	Unit
BYTE	-	-	-

The outputs display the current channel configuration of the channels C0...C7.

Table 64: MODE = DC541_MODE_IO = 16#11 = 17

CFGx	Channel	Function
0	0...7	Normal input
1	0...7	Normal output
255	0...7	Interrupt input

Table 65: MODE = DC541_MODE_COUNT = 16#22 = 34

CFGx	Channel	Function
0	0...7	Normal input
1	0...7	Normal output
2	0...7	Pulse-width modulator (PWM)
3	0...1	50 kHz count up counter (FWD_CNT)
3	2...7	5 kHz count up counter (FWD_CNT)
4	0...7	Time and frequency measurement (FREQ)
5	4...7	Limit values for 32-bit counter (LIMIT)
6	0	Up/down 32-bit counter (uses channels 0...3). The channels CFG1...CFG3 can be set as desired.
7	0...7	Frequency output

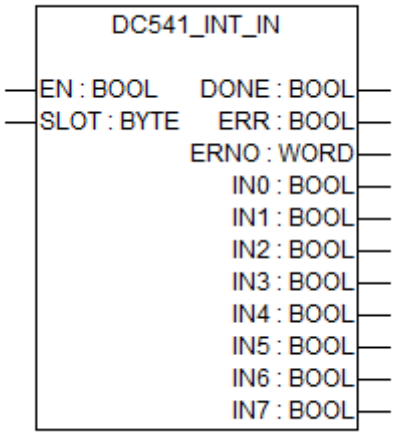
DC541_INT_IN

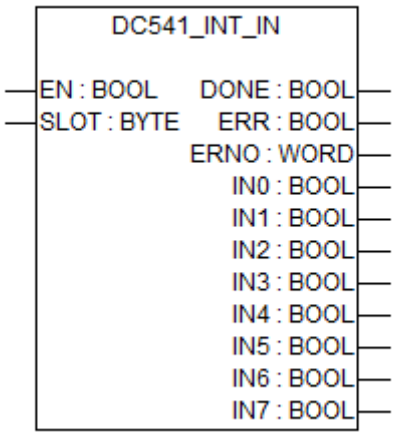


Parameter	Value
Included in library	DC541_AC500_V11.lib
Available as of firmware	V1.1.2, DC541 firmware: V1.0
Type	Function block with historical values
Group	IO

Using the function block DC541_INT_IN, the interrupt program can be polled which inputs (C0...C7) triggered interrupts since the last function block calling. The corresponding outputs IN0...IN1 are set to TRUE.

The function block DC541_INT_IN can only be used if the module is configured as I/O module.

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN has to be continuously set to TRUE.

When the function block is called for the first time, input SLOT is checked for validity and the corresponding device is checked for correct configuration in the operating mode "IO mode". If this is not the case, processing is aborted and an error is displayed. The function block outputs are updated as long as input EN = TRUE.

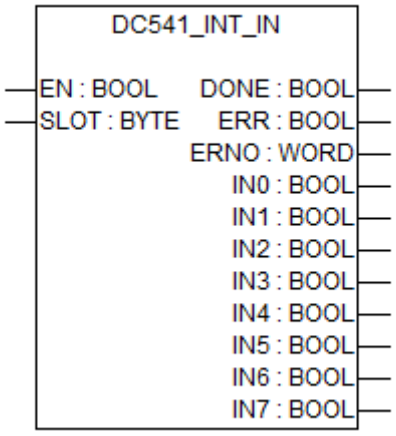
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 66: DC541 error numbers

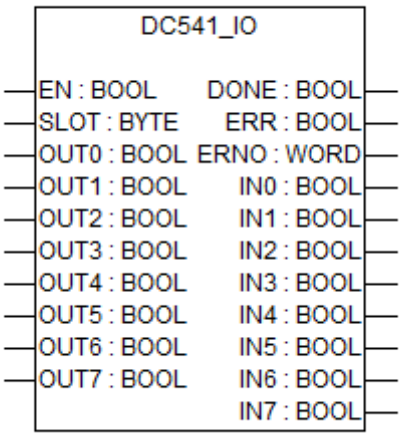
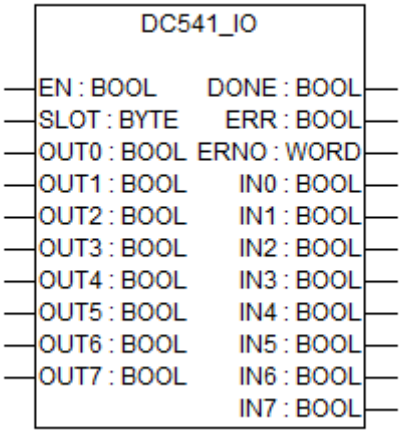
DC541_IO



Parameter	Value
Included in library	DC541_AC500_V11.lib
Available as of firmware	V1.1.2, DC541 firmware: V1.0
Type	Function block with historical values
Group	IO

The function block DC541_IO is used to read the "normal" inputs and to write the outputs of the DC541. Reading and writing the inputs and outputs is performed as long as input EN is TRUE. This function block can be used for both operating modes, i.e. when the device is configured as I/O module and when it is configured as counting device (counter mode).

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

A FALSE -> TRUE edge at input EN activates the status polling. If the value at input SLOT is not valid, processing is aborted and an error is displayed. The function block outputs are updated as long as input EN = TRUE. The function block processing has been completed successfully, if output DONE changes to TRUE. During the processing of a request, state changes at input EN are recognized but not evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

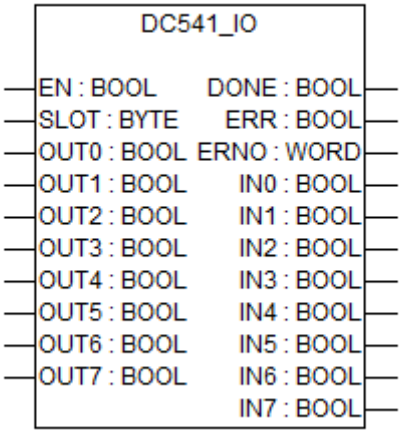
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

OUT0...OUT7

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The inputs are used to specify the set status of the outputs C0...C7. Only channels that are configured as outputs are currently written.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 67: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F
24586	600A	Lifesign error from DC541

IN0...IN7 (input C0...C7)

Data type	Default value	Range	Unit
BOOL	-	-	-

The outputs display the current status of the channels C0...C7.

Function call in ST

```

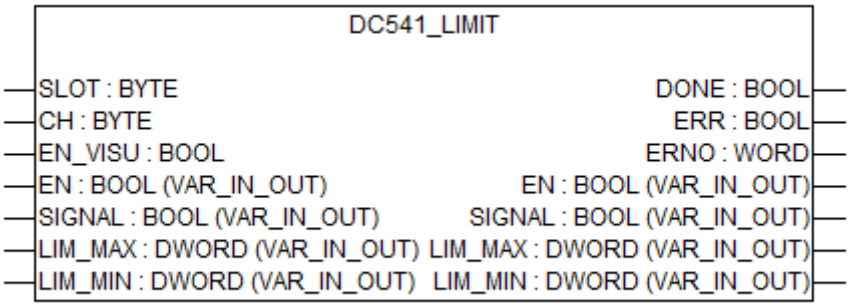
DC541Io_IN7  := DC541Io.IN7;
```

DC541_LIMIT



Parameter	Value
Included in library	DC541_AC500_V11.lib
Available as of firmware	V1.1.3, DC541 firmware: V1.1
Type	Function block with historical values
Group	Counters

The function block DC541_LIMIT is used for limit value monitoring of the 32-bit counter. The function block can be used to directly display various counting values of the 32-bit counter (DC541_32BIT_CNT) via binary outputs. Using the input SIGNAL you can determine whether the corresponding output is switched to FALSE or TRUE.

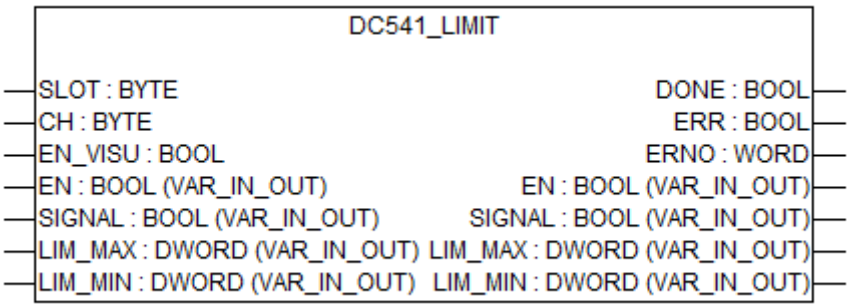
The time resolution of the function block is < 100 µs, i.e. the result is increment accurate up to a frequency of 10 kHz.

The upper limit value LIM_MAX has to be higher than the lower limit value LIM_MIN. If the lower limit value LIM_MIN is higher than the upper limit value LIM_MAX, an error message is displayed.

The device DC541 must be configured as counting device (counter mode) and channel C0 as 32-bit counter.

The function block has an integrated visualization which can be used to control all function block functions in parallel to the user program, if input EN_VISU is TRUE ↬ *Chapter 1.5.4.11.1.2 “Visualizations” on page 1154*.

Input description



SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type	Default value	Range	Unit
BYTE	-	4-7 for the outputs C4-C7	-

Input CH is used to select the channel for the limit value monitoring. If an invalid value is specified at input CH or if the selected channel is not configured as Limit Channel 0 or if channel C0 is not configured as 32-bit counter, the function block is aborted with DONE = ERR = TRUE and an error is displayed.

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

If EN_VISU input (enable input in visualization) is TRUE, it is possible to control the function block inputs (except SLOT, CH and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed.

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	TRUE / FALSE	-

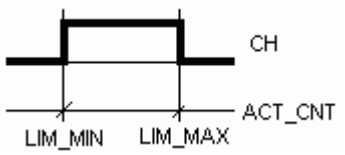
In order to enable pulse counting for input CH, input EN has to be continuously TRUE. The function block is not processed if input EN = FALSE.

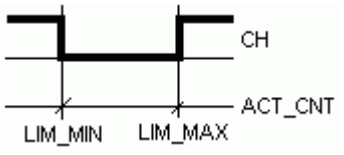
When the function block is called for the first time, the inputs are checked for validity and plausibility and the corresponding device is checked for correct configuration in the operating mode "counting mode". If this is not the case, processing is aborted.

SIGNAL

Data type	Default value	Range	Unit
BOOL	-	-	-

Using the input SIGNAL you can determine whether the corresponding output CH is switched to TRUE or FALSE.

Counter value of the 32-bit counter DC541_32BIT_CNT / ACT_CNT	Output CH when SIGNAL = TRUE	Output CH when SIGNAL = FALSE
ACT_CNT < LIM_MIN	FALSE	TRUE
LIM_MIN ≤ ACT_CNT ≤ LIM_MAX	TRUE	FALSE
ACT_CNT > LIM_MAX	FALSE	TRUE
		




If SIGNAL is TRUE, the output CH is TRUE, if the counter value of the 32-bit counter is within the range given by the limit values LIM_MIN and LIM_MAX. If the counter value is out of this range, output CH is FALSE.

If SIGNAL is FALSE, the output CH is FALSE, if the counter value of the 32-bit counter is within the range given by the limit values LIM_MIN and LIM_MAX. If the counter value is out of this range, output CH is TRUE.

LIM_MAX

Data type	Default value	Range	Unit
DWORD	-	-	-

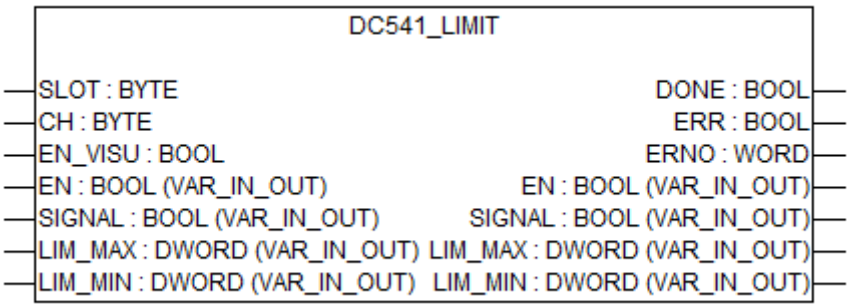
LIM_MAX (limit maximum) is used to set the upper limit value for the counter. LIM_MAX has to be higher than the lower limit value LIM_MIN. If LIM_MIN is higher than LIM_MAX, an error is displayed.

LIM_MIN

Data type	Default value	Range	Unit
DWORD	-	-	-

LIM_MIN (limit minimum) is used to set the lower limit value for the counter. The upper limit value LIM_MAX has to be higher than LIM_MIN. If LIM_MIN is higher than LIM_MAX, an error is displayed.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 68: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F

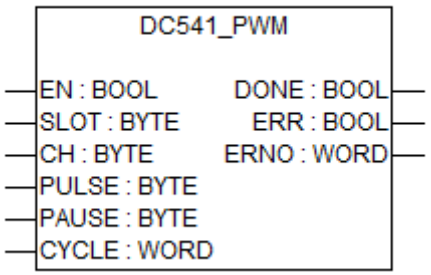
DC541Limit_ERNO  := DC541Limit.ERNO;
```

DC541_PWM



Parameter	Value
Included in library	DC541_AC500_V11.lib
Available as of firmware	V1.1.3, DC541 firmware: V1.1
Type	Function block with historical values
Group	Counters

The function block DC541_PWM outputs a pulsed signal with an adjustable on-off ratio. The on and off times are adjusted as 8 bit numbers.

The minimum switching time is specified at input CYCLE, i.e. if an output has been switched to FALSE or TRUE by the PWM, this output remains in this state for at least this time (CYCLE µs).

The minimum time specified at input CYCLE must not be smaller than the cycle time of the device DC541. Depending on its configuration, the cycle time of the DC541 can be 50, 100 or 200 µs. The cycle time can be polled using the function block ↯ *Chapter 1.5.4.11.1.1.6 “DC541_GET_CFG” on page 1132* (output CYCLE).

Examples

Table 69: Cycle time of DC541 = 50 µs

PULSE	PAUSE	CYCLE	Result (x = number of cycles of the DC541)
1	2	500	10 x TRUE / 20 x FALSE / 10 x TRUE / 20 x FALSE / … i.e. 500 µs = TRUE and 1000 µs = FALSE
4	8	500	10 x TRUE / 20 x FALSE / 10 x TRUE / 20 x FALSE / … i.e. 500 µs = TRUE and 1000 µs = FALSE (as in example 1, i.e. ratio 1 : 2)
3	2	3000	90 x TRUE / 60 x FALSE / 90 x TRUE / 60 x FALSE / … i.e. 4500 µs = TRUE and 3000 µs = FALSE

Table 70: Cycle time of DC541 = 100 µs

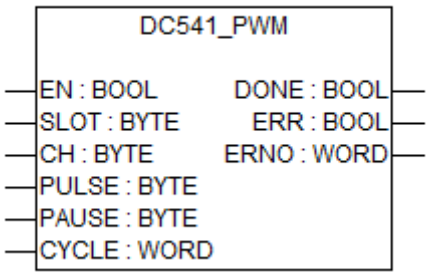
PULSE	PAUSE	CYCLE	Result (x = number of cycles of the DC541)
1	2	500	5 x TRUE / 10 x FALSE / 5 x TRUE / 10 x FALSE / … i.e. 500 µs = TRUE and 1000 µs = FALSE
4	8	500	5 x TRUE / 10 x FALSE / 5 x TRUE / 10 x FALSE / … i.e. 500 µs = TRUE and 1000 µs = FALSE (as in example 1, i.e. ratio 1 : 2)
3	2	3000	45 x TRUE / 30 x FALSE / 45 x TRUE / 30 x FALSE / … i.e. 4500 µs = TRUE and 3000 µs = FALSE

Table 71: Cycle time of DC541 = 200 µs

PULSE	PAUSE	CYCLE	Result (x = number of cycles of the DC541)
1	2	500	3 x TRUE / 6 x FALSE / 3 x TRUE / 6 x FALSE /... i.e. 600 µs = TRUE, 1200 µs = FALSE
4	8	500	3 x TRUE / 6 x FALSE / 3 x TRUE / 6 x FALSE / ... i.e. 600 µs = TRUE, 1200 µs = FALSE (as in example 1, i.e. ratio 1 : 2)
3	2	3000	22 x TRUE / 15 x FALSE / 23 x TRUE / 15 x FALSE / … i.e. first 4400 µs = TRUE and 3000 µs = FALSE and then 4600 µs = TRUE and 3000 µs = FALSE

The device DC541 must be configured as counting device (counter mode).

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN has to be continuously set to TRUE.

When the function block is called for the first time, input SLOT is checked for validity and the corresponding device is checked for correct configuration in the operating mode "IO mode". If this is not the case, processing is aborted and an error is displayed. The function block outputs are updated as long as input EN = TRUE.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type	Default value	Range	Unit
BYTE	-	-	-

Input is used to select the output to be pulsed.

PULSE

Data type	Default value	Range	Unit
BYTE	-	-	-

Input is used to specify the ratio for the TRUE signal (on time ratio).

PAUSE

Data type	Default value	Range	Unit
BYTE	-	-	-

Input is used to specify the ratio for the FALSE signal (off time ratio).

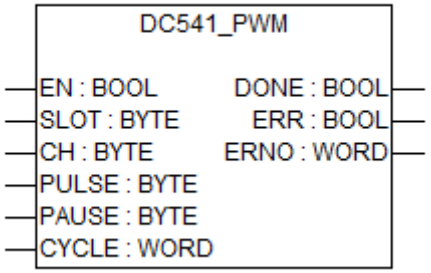
CYCLE

Data type	Default value	Range	Unit
WORD	-	-	µs

Input CYCLE is used to specify the minimum switching time of the output. The output remains in the TRUE or FALSE state for at least the time specified at CYCLE.

The minimum time specified at input CYCLE must not be smaller than the cycle time of the device DC541. Depending on its configuration, the cycle time of the DC541 can be 50, 100 or 200 µs. The cycle time can be polled using the function block DC541_GET_CFG, output CYCLE *Chapter 1.5.4.11.1.1.6 “DC541_GET_CFG” on page 1132*.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 72: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it

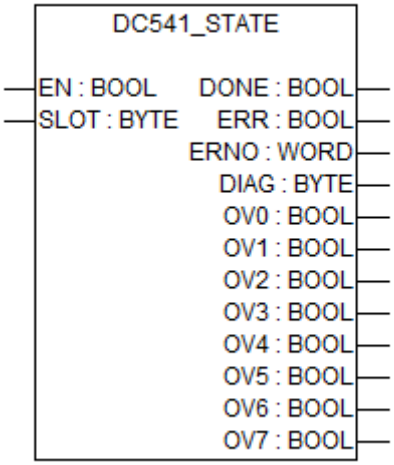
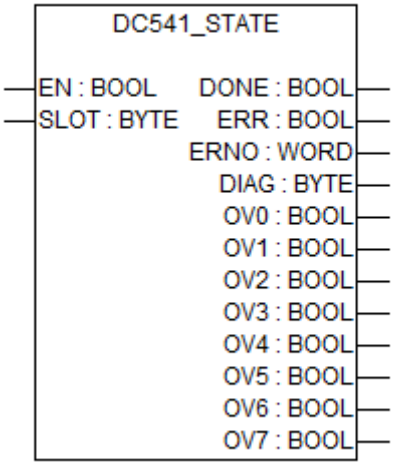
DC541_STATE



Parameter	Value
Included in library	DC541_AC500_V11.lib
Available as of firmware	V1.1.3, DC541 firmware: V1.1
Type	Function block with historical values
Group	Diagnosis

The function block DC541_STATE is used to poll the status of the device DC541. The information is displayed as long as input EN is TRUE. The displayed information includes the device diagnosis and the output status of the channels C0...C7.

Input description



EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

A FALSE -> TRUE edge at input EN activates the status polling. If the value at input SLOT is not valid, processing is aborted and an error is displayed. The function block outputs are updated as long as input EN = TRUE. The function block processing has been completed successfully, if output DONE changes to TRUE. During the processing of a request, state changes at input EN are recognized but not evaluated.

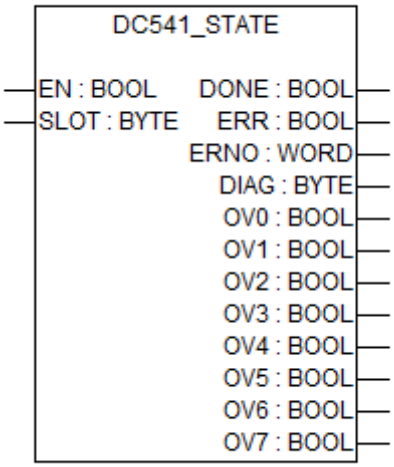
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 73: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F
24586	600A	Lifesign error from DC541

DIAG

Data type	Default value	Range	Unit
BYTE	-	0 16#01 = 1 -> Watchdog error	-

DIAG (diagnosis) output displays the diagnosis message of the DC541. If DIAG is 0, no diagnosis message is available. The following messages are possible:

OV0...OV7

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

The outputs OV0...OV7 (overload C0...C7) display the current output status of the channels C0...C7. If the respective bit is TRUE, the corresponding output cannot be switched e.g. due to an overload or a short circuit.

Function call in ST

```
DC541State(EN   := DC541State_EN,
           SLOT := DC541State_SLOT);

DC541State_DONE := DC541State.DONE;
DC541State_ERR  := DC541State.ERR;
DC541State_ERNO := DC541State.ERNO;
DC541State_DIAG := DC541State.DIAG;
DC541State_OV0  := DC541State.OV0;
DC541State_OV1  := DC541State.OV1;
DC541State_OV2  := DC541State.OV2;
DC541State_OV3  := DC541State.OV3;

DC541State_OV5  := DC541State.OV5;
DC541State_OV6  := DC541State.OV6;
DC541State_OV7  := DC541State.OV7;
```

Visualizations

The visualization can be used to display the function block outputs. If the input EN_VISU of a function block is TRUE, it is also possible to control the inputs from the visualization. In order to allow the control of function block inputs from the program as well as from the visualization, these inputs are declared as VAR_IN_OUT and consequently have to be provided with variables. These inputs must not be provided with direct constants.

Example visualization visuDC541_32BIT_CNT

Integrated visualization of function block DC541_32BIT_CNT

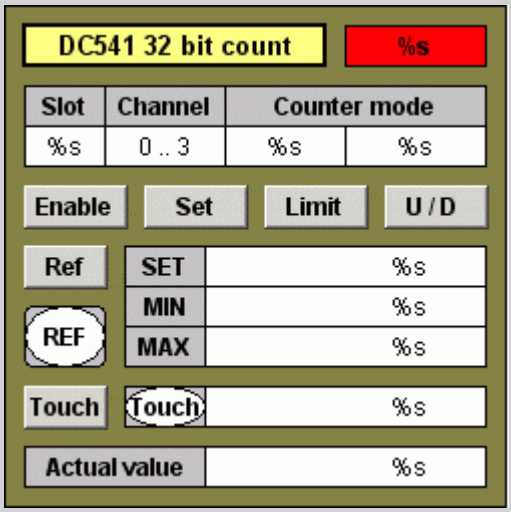

Fig. 26: Offline mode

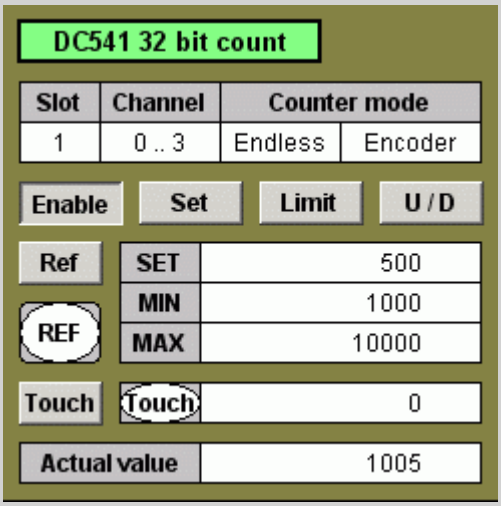

Fig. 27: Online mode, EN_VISU = TRUE

If an error occurred during function block processing, the error number is displayed in the top right until EN = FALSE.

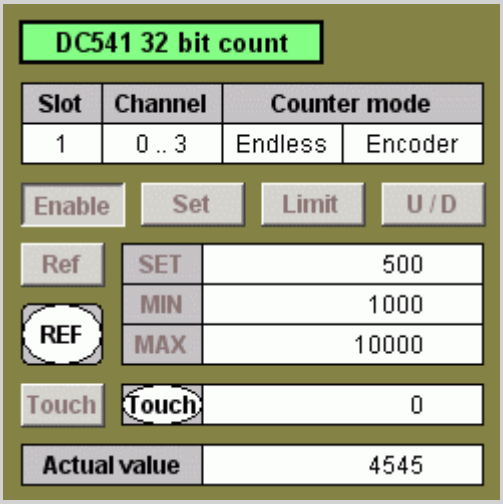

Fig. 28: Online mode, EN_VISU = FALSE. The inputs cannot be modified using the visualization.

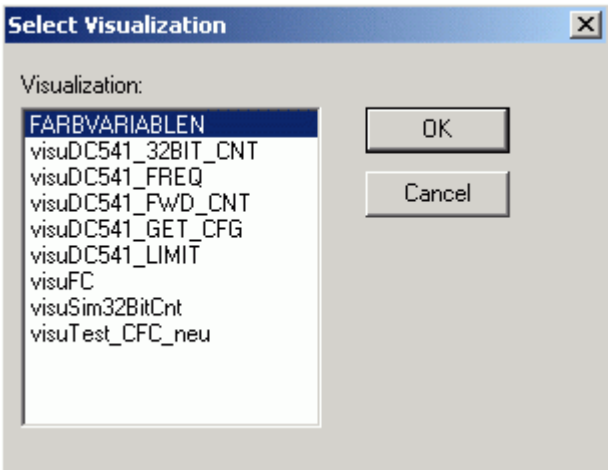
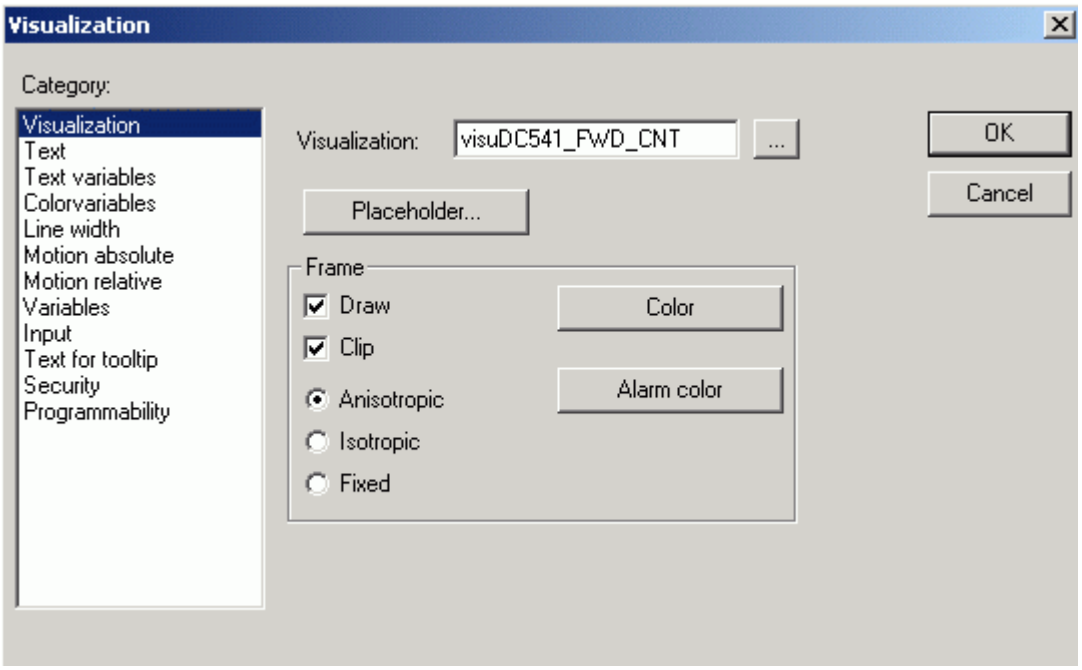
Integrate a visualization into a project

1. In the **Visualizations** tab, add an object.
2. Click on .
3. Select the corresponding visualization for the function block.



Configure the visualization

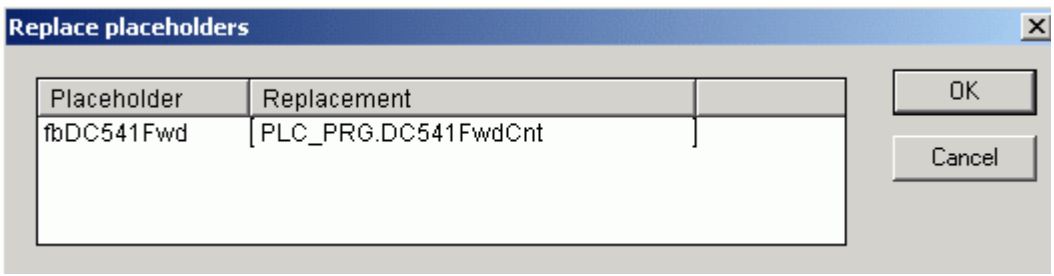
1. Right-click on the visualization and select **Configure**.



2. Under **Frame**, we recommend to select *Fixed* to maintain the original width-to-height ratio and font size.

Link the visualization to the function block instance

3. Click the **Placeholder** button.
4. In column **Replacement**, enter the function block instance directly or press F2 to open the input assistant.



5. Click **OK** to close all dialogs.
6. Adapt the visualization to the correct size.

1.5.4.11.2 DC541 dampener library

Library file name: **DC541_DAMPENER_AC500_V13.lib**

This library contains all function blocks necessary for using DC541 in DAMPENER-mode.

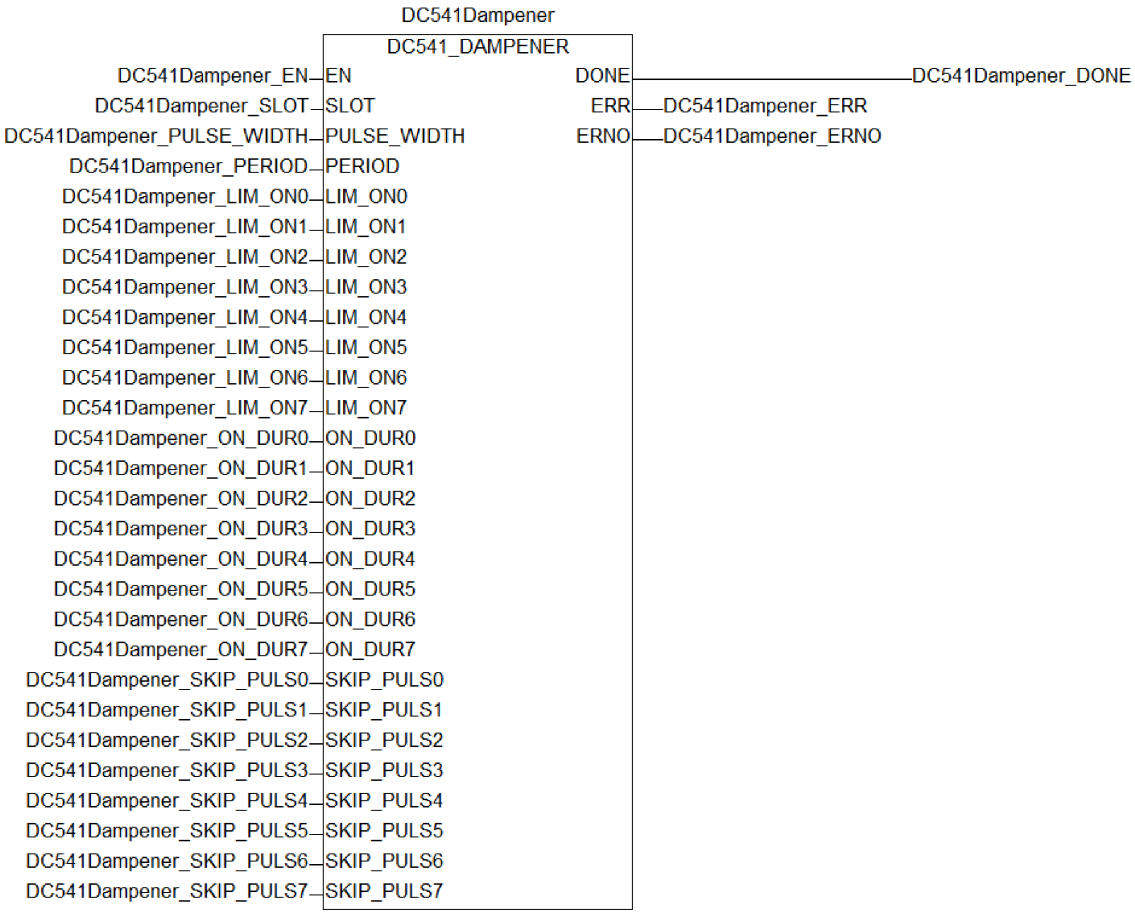
The configuration of DC541 is done in PLC configuration.

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

The function blocks are available in AC500 control systems with a runtime system of version V1.3 or later.

Function blocks

DC541_DAMPENER



Parameter	Value
Included in library	DC541_DAMPENER_AC500_V13.lib
Available as of firmware	V1.12
Type	Function block with historical values
Available as of PLC runtime system	V1.3

The function block DC541_DAMPENER transfers all values to control the DAMPENER functionality for DC541 device.

The Dampener-Mode is a modified PWM-Mode. If the device is configured as DAMPENER, all 8 outputs are controlled by the DAMPENER functionality.

All 8 outputs are switched on/off with the same frequency, but use a different time to switch on a a different duration for being on. These values are specified by function block DC541_DAMPENER with input parameters LIM_MINx and ON_DURx.

The following rule has to be applied:

- LIM_MINx < PERIOD
- ON_DURx < PERIOD

All input parameters can be continuously modified, the values are accepted immediately. The following values are specified:

- Length for a single pulse PULSE_WIDTH in microseconds from 100 to 65535
- Number of pulses for a complete period: PERIOD 100 to 65535, every pulse as a PULSE_WITDH length

The resulting frequency is then calculated as:

f = 1/ (PULSE_WIDTH*PERIOD) with a range from 1/ (100*100µs) = 100 Hz to 1/ (65535*65535µs) = 0.00023 Hz

The device uses an internal counter with a clock PULSE_WIDTH µs which counts from 0 to PERIOD.

When the condition LIM_MINx = counter is reached, the output is switched on for ON_DURx pulses.

In addition, it is possible to leave out up to 255 periods for a certain output by using SKIP_PULSx input parameter.

The following example shows the different result with SKIP_PULS=0 and SKIP_PULS=1 and otherwise identical values.

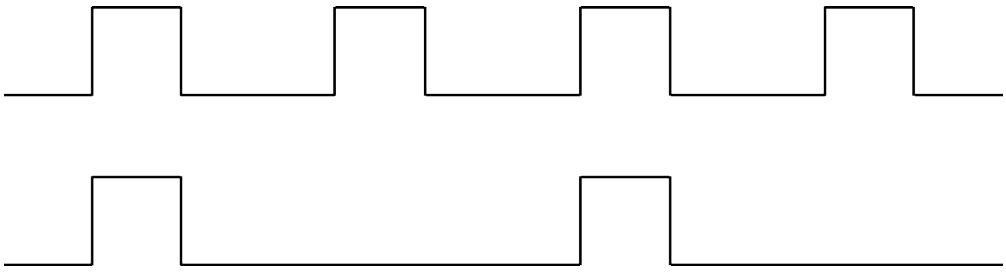


Fig. 29: SKIP_PULSE

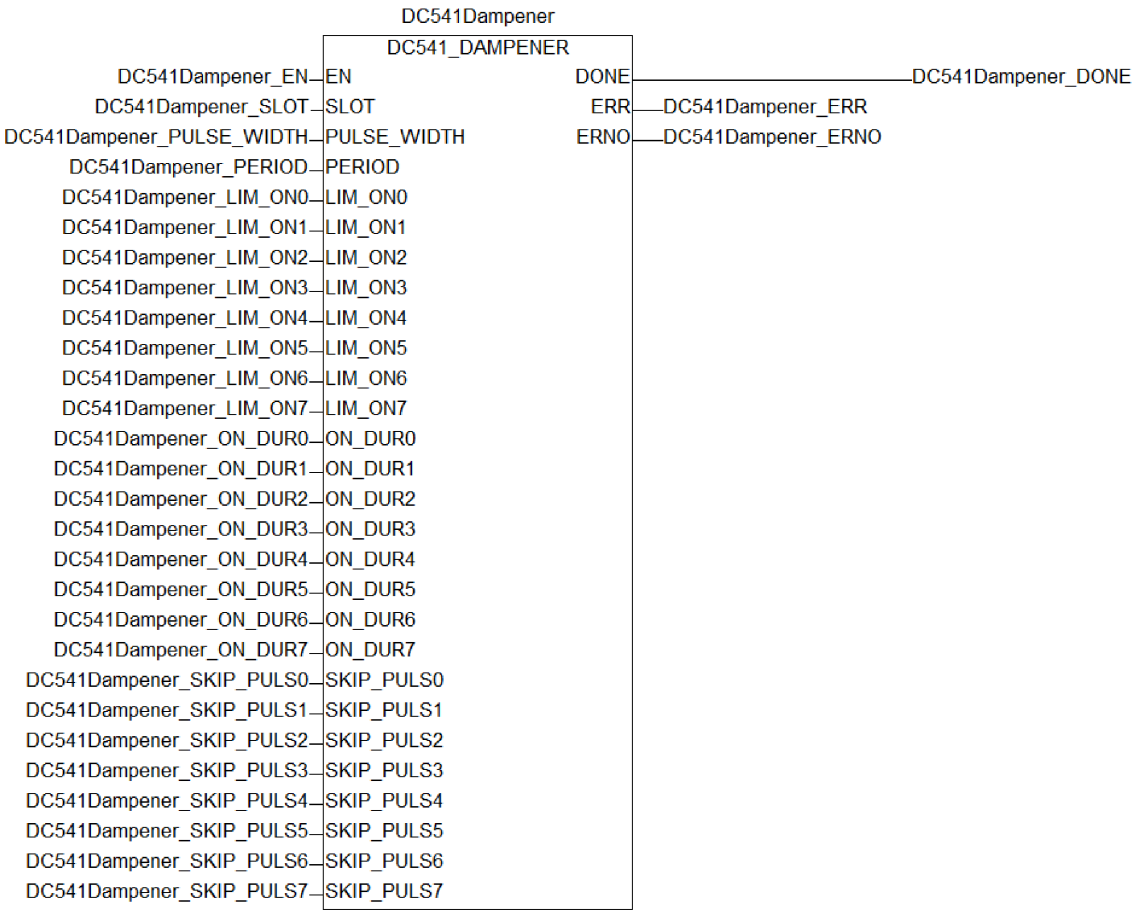
Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	-	-	-

This input is used to select the slot (module number) of the DC541.

The slots are numbered consecutively from right to left. Slot 1 is the first slot on the left of the CPU.

PULSE_WIDTH

Data type	Default value	Range	Unit
WORD	-	100 ... 65535	µs

The input PULSE_WIDTH gives the time in microseconds which is used to increase the internal counter by 1. Also, this gives the minimal time available for switching on a binary output. All other times are a multiple of this time

PERIOD

Data type	Default value	Range	Unit
WORD	-	100 to 65535	PULSE_WITDH length

Period duration [in number of pulses], i.e. internal counter value is being set to 0 when this value is reached.

LIM_MIN

Data type	Default value	Range	Unit
WORD	-	-	-

Lower limit for switching on, the respective binary output is switched on when internal counter reaches this value.

ON_DUR

Data type	Default value	Range	Unit
WORD	-	-	-

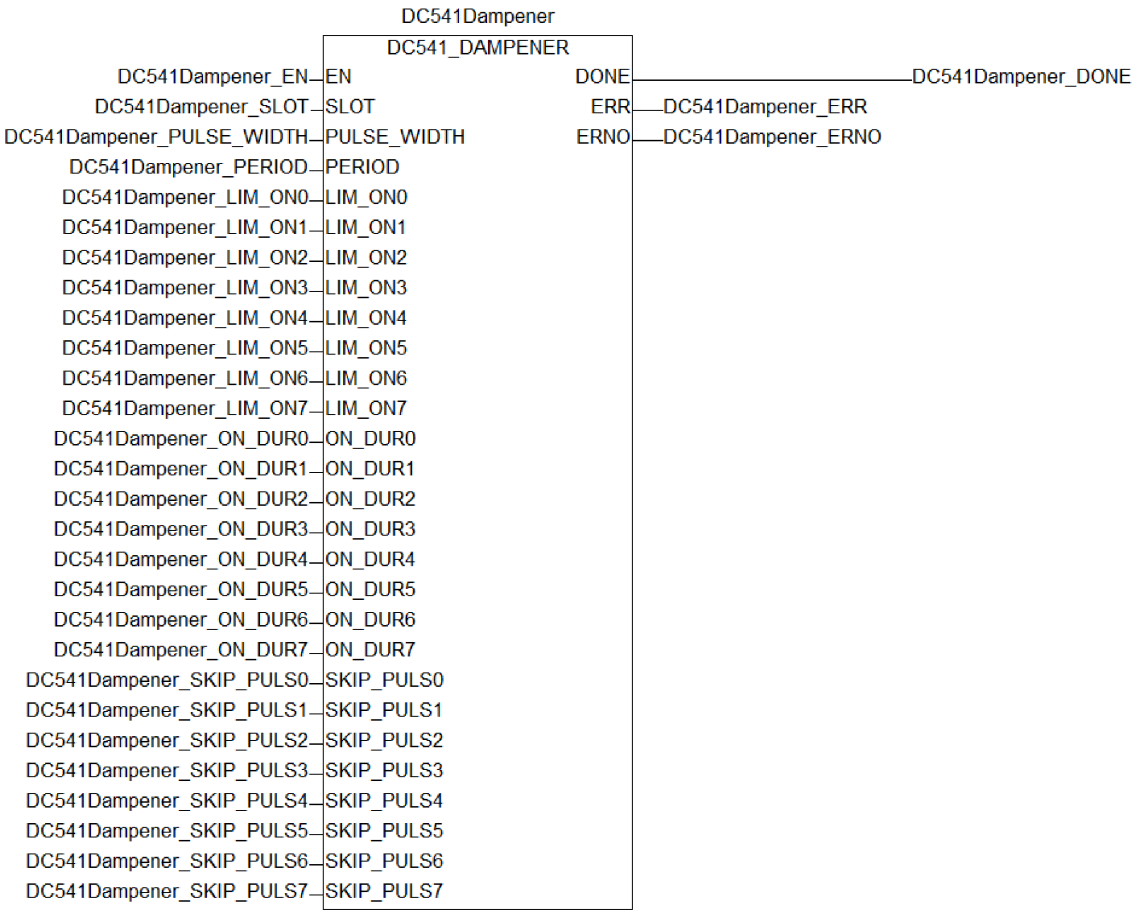
Duration [in number of pulses] for switching on the respective binary output.

SKIP_PULSE

Data type	Default value	Range	Unit
WORD	-	-	-

An optional number of periods to skip switching on the respective binary output

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO (error number)

Data type	Default value	Range	Unit
WORD	0	≥ 0	-

Output provides an error identifier if an invalid value was applied to an input. ERNO always has to be considered together with the output ERR. The value output at ERNO is only valid if ERR is TRUE.

Table 74: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F
24586	600A	Lifesign error from DC541

1.5.4.11.3 DC541 PWM library

Library file name: **DC541_PWM_AC500_V22.lib**

This library contains all function blocks necessary for using DC541 in PWM-mode.

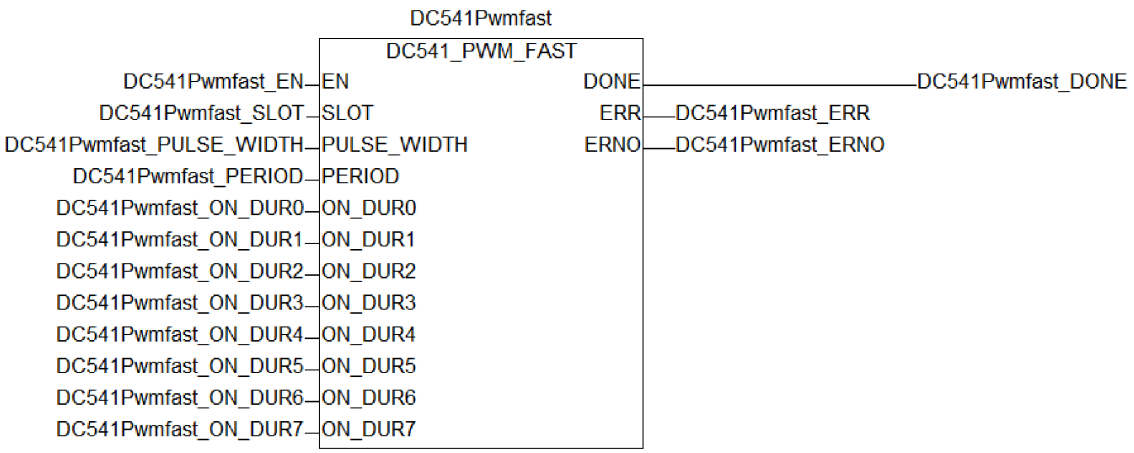
The configuration of DC541 is done in PLC configuration.

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

The function blocks are available in AC500 control systems with a runtime system of version V2.2 or later.

Function blocks

DC541_PWM_FAST



Parameter	Value
Included in library	DC541_PWM_AC500_V22.lib
Available as of firmware	V1.12
Type	Function block with historical values
Available as of runtime system	V2.2

The block DC541_DAMPENER transfers all values to control the PWM functionality for DC541 device.

If the device is configured in PWM-mode, all 8 outputs are controlled by PWM functionality (Pulse-width Modulation).

All 8 outputs are switched on with the same frequency, at the same start time, but with different duration.

The duration is adjusted with the block DC541_PWM_FAST with values for ON_DURx.

The following rule has to be applied:

- ON_DURx < PERIOD

All input parameters can be continuously modified, the values are accepted immediately.

The following values are specified:

- Minimal length for a single pulse PULSE_WIDTH in microseconds from 40 to 32767
- Number of pulses for a complete period: PERIOD 2 to 255

The resulting frequency is then calculated as:

f = 1/ (PULSE_WIDTH*PERIOD) with a range from 1/ /(2*4040 to 32767µs) = 12.5 kHz to 1/(255*32767µs) = 0.12 Hz

The device uses an internal counter with a clock PULSE_WIDTH µs which counts from 0 to PERIOD.

When the condition ON_DURx = counter is reached, the respective output is switched on, off otherwise.

All outputs with ON_DURx>0 are switched on at the same.

The following sequence would be achieved with:

- PULSE_WIDTH= 50, PERIOD=10, ON_DUR0=6 (SIGNAL0) and ON_DUR1=4 (SIGNAL1) or
- PULSE_WIDTH= 100, PERIOD=5, ON_DUR0=3 and ON_DUR1=2

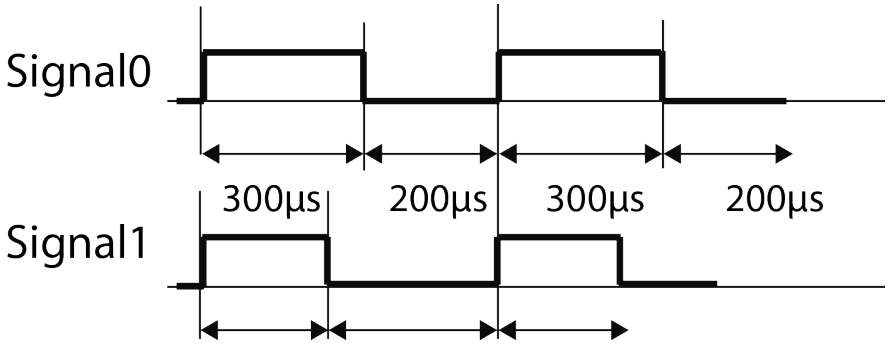


Fig. 30: SIGNAL_PWM

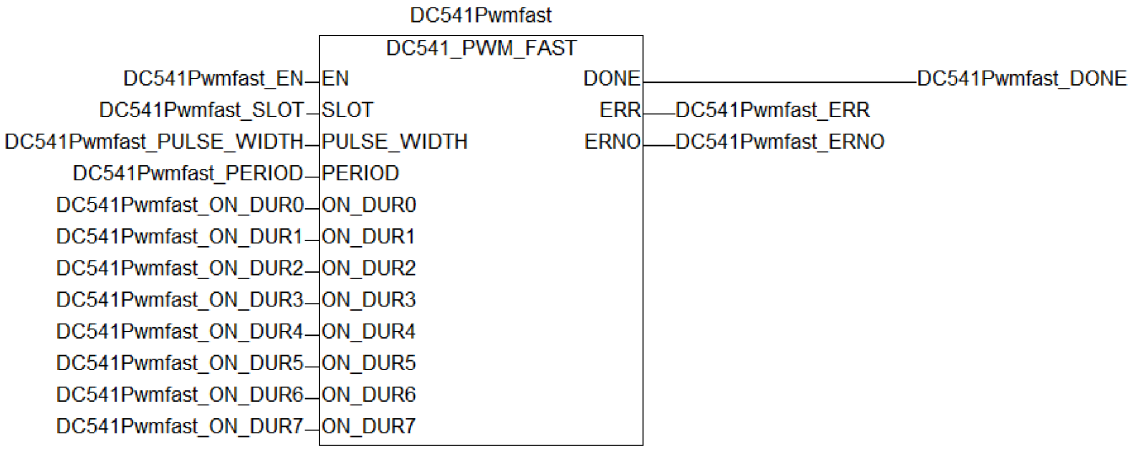
Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	-	-	-

This input is used to select the slot (module number) of the DC541.

The slots are numbered consecutively from right to left. Slot 1 is the first slot on the left of the CPU.

PULSE_WIDTH

Data type	Default value	Range	Unit
WORD	-	100 ... 65535	µs

The input PULSE_WIDTH gives the time in microseconds which is used to increase the internal counter by 1. Also, this gives the minimal time available for switching on a binary output. All other times are a multiple of this time

PERIOD

Data type	Default value	Range	Unit
WORD	-	100 to 65535	PULSE_WITDH length

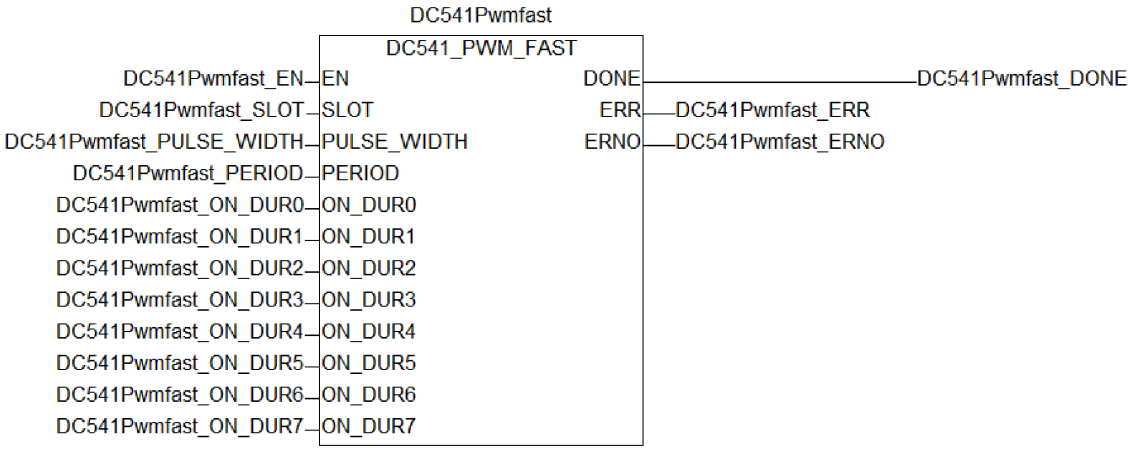
Period duration [in number of pulses], i.e. internal counter value is being set to 0 when this value is reached.

ON_DUR

Data type	Default value	Range	Unit
WORD	-	-	-

Duration [in number of pulses] for switching on the respective binary output.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE.

Table 75: DC541 error numbers

DEC	HEX	Error description
8195	2003	Unknown/wrong communication module at communication module slot
12315	301B	No access to channel, other function block might be using it
12316	301C	Illegal channel number
12329	3029	Device is not configured
16385...16399	400x 4001...400F	Wrong value at function block input number x x = 1...F
24586	600A	Lifesign error from DC541

1.5.4.12 Diagnosis library

Library file name: **Diag_AC500_V20.lib**

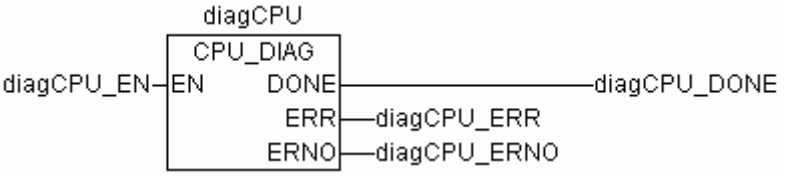
The function blocks of the diagnosis library enable the direct access on the data of the AC500 diagnosis system.

The library is not loaded automatically into an AC500 project.

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

1.5.4.12.1 Function blocks

CPU_DIAG



Parameter	Value
Included in library	Diag_AC500_V10.lib
Available as of firmware	V1.0.2
Type	Function block with historical values
Group	-

Using the function block CPU_DIAG, the entries of the AC500 diagnosis system can be read and displayed using the integrated visualization as plain text.

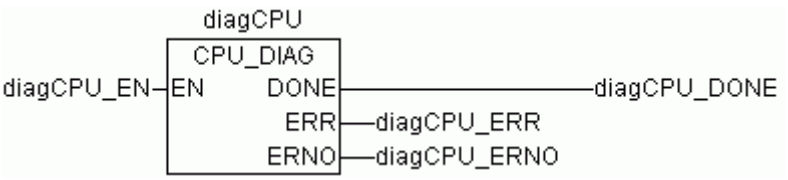
The instance diagCPU of the function block CPU_DIAG is declared in the global variables list GL_AC500_Diagnosis. The integrated visualization of the function block accesses the variables of this instance.

In order to include the function block into an AC500 project, it is only necessary to call the function block instance. Example in ST:

diagCPU(EN := TRUE);

By means of the visualization Visu_CPU_Diag, navigation within the diagnosis buffer is possible and upcoming diagnosis entries can be acknowledged.

Input description

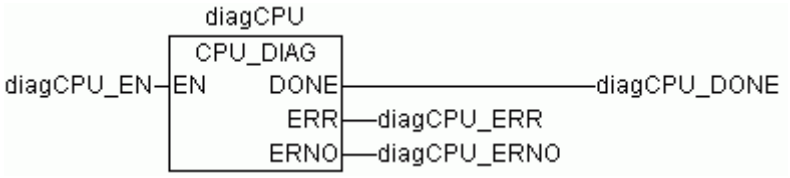


EN

Data type	Default value	Range	Unit
BOOL			

EN = TRUE enables the processing of the function block. With a FALSE -> TRUE edge at input EN, the last five entries are read from the diagnosis buffer of the CPU.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

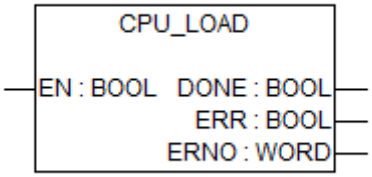
```
diagCPU(EN := diagCPU_EN);

diagCPU_DONE := diagCPU.DONE;
diagCPU_ERR  := diagCPU.ERR;
diagCPU_ERNO := diagCPU.ERNO;

or:

diagCPU(EN := TRUE);
```

CPU_LOAD



Parameter	Value
Included in library	Diag_AC500_V10.lib
Available as of firmware	V1.0.2
Type	Function block with historical values
Group	-

The function block CPU_LOAD outputs the CPU capacitiy utilization in [%].

The following is displayed:

current load

minimum load

maximum load

average (avg) load

The instance CPU of the function block CPU_LOAD is declared in the global variables list GL_AC500_Diagnosis. The integrated visualization of the function block accesses the variables of this instance.

In order to include the function block into an AC500 project, it is only necessary to call the function block instance. Example in ST:

CPU(EN := TRUE);

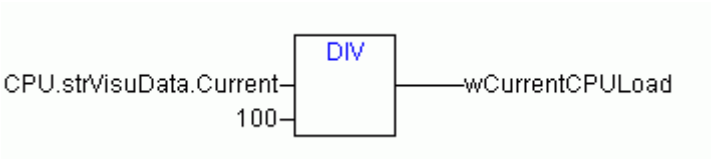
The values are entered as 0.01% values into the internal structure strVisuData of the type strCPU_LOAD in the instance CPU of the function block CPU_LOAD. To obtain the values in [%], they have to be divided by 100. The structure is composed as follows:

TYPE strCPU_LOAD :			
STRUCT			
	Current	: WORD;	(* current value *)
	Avg	: WORD;	(* average value *)
	Minimum	: WORD;	(* minimum value *)
	Maximum	: WORD;	(* maximum value *)
	Counter	: DWORD;	(* counter *)
	Conf	: WORD;	(* bit 0 = 1 (1) --> Update CPU_load *)
			(* bit 1 = 1 (2) --> Heap check *)
END_STRUCT			
END_TYPE			

If the user program should have access to these values, this is done as follows:

CPU.strVisuData.Variable.

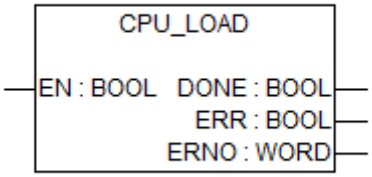
In the following example, the value of the current CPU load is read and assigned to the variable wCurrentCPULoad:



Using the visualization Visu_CPU_Load, the values are represented graphically *Chapter 1.5.4.12.2 “Visualizations” on page 1182*.

The same values can also be polled using the PLC browser command "cpuload".

Input description

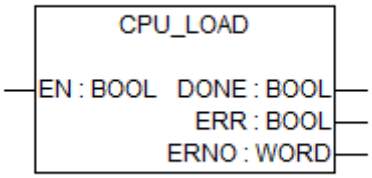


EN

Data type	Default value	Range	Unit
BOOL			

EN = TRUE enables the processing of the function block. With a FALSE -> TRUE edge at input EN, the last five entries are read from the diagnosis buffer of the CPU.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

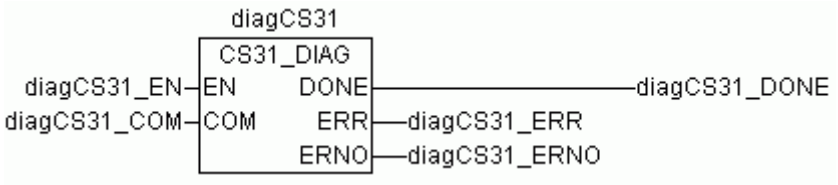
```
CPU(EN := CPU_EN);

CPU_DONE := CPU.DONE;
CPU_ERR  := CPU.ERR;
CPU_ERNO := CPU.ERNO;

or:

CPU(EN := TRUE);
```

CS31_DIAG



Parameter	Value
Included in library	Diag_AC500_V10.lib
Available as of firmware	V1.0.2
Type	Function block with historical values
Group	-

The function block CS31_DIAG provides the diagnosis data of the CS31 bus to the user.

The instance diagCS31 of the function block CS31_DIAG is declared in the global variables list GL_AC500_Diagnosis. The integrated visualization of the function block accesses the variables of this instance.

In order to include the function block into an AC500 project, it is only necessary to call the function block instance. Example in ST:

diagCS31(EN := TRUE, COM := 1);

The read values are written into internal structures of the instance diagCS31.

Structure	TYPE	Assignment
strVisuData1	strCS31_DiagBus	Diagnosis data of the CS31 master
strVisuData	strCS31_DiagModule	Diagnosis data of all 31 CS31 software modules ARRAY[0..31] OF strCS31_DiagOneModule
CS31Mod	strCS31_DiagOneModule	Diagnosis data of one CS31 software module

The structure strCS31_DiagBus is composed as follows:

```
TYPE strCS31_DiagBus :
(* STRUCT info about CS31 bus *)
STRUCT
    iCS31BusState :     DINT;   (* Bit 0=1 waiting for slave
                                   Bit 1=1 initialization
                                   Bit 4=1 I/O data exchange
                                   := 19 all modules at bus *)
    iNumberModule :     DINT;   (* current no. of CS31 software modules on the CS31 bus *)
    iMaxNumberModule :  DINT;   (* max. number of modules at CS31 bus since power ON *)
    iErrorSum :         DINT;   (* sum error counter *)
    ulCycleCount :      DWORD;  (* counter of CS31 bus cycles *)
    byStateDiag :       BYTE;   (* general bus diagnosis: 0=ok, 1=no module on the bus *)
END_STRUCT
END_TYPE
```

The structure strCS31_DiagOneModule is composed as follows:

```
TYPE strCS31_DiagOneModule :
STRUCT
    dwScheduleCycle :   DWORD;  (* internal time *)
    byPhysicalAdress :  BYTE;   (* module address x 2 *)
    byCommState :       BYTE;   (* internal communication status:
    bySlaveType :       BYTE;   (* Slave type:
                                   00 = digital input
                                   01 = analog input
                                   02 = digital output
                                   03 = analog output
                                   04 = digital input/output
                                   05 = analog input/output
                                   06 = special module
```

	byInputBytes :	BYTE;	(* reported number of input bytes *)
	byOutputBytes :	BYTE;	(* reported number of output bytes *)
	byInputBytesConf :	BYTE;	(* configured number of input bytes *)
	byOutputBytesConf :	BYTE;	(* configured number of output bytes *)
	byModuleConf :	BYTE;	(* 1-PLC config, 3- ignore module *)
	byStateDiag :	BYTE;	(* Diagnostic Condition: each bit indicates a diagnosis type)
			byStateDiag = 0 : no diagnosis Bit 0 (0x01, 1) : a device that was present on the bus has been disconnected from the bus. Bit 1 (0x02, 2) : A configured device or module could not be found on the bus Bit 2 (0x04, 4) : A device or module that is not configured, was found on the bus Bit 3 (0x08, 8) : It was noted a difference between a configured and reported I / O peripheral. Bit 4 (0x10, 16) : A CS31 device (no device of the S500 series) has a new error message reported (short circuit or internal fault) Bit 5 (0x20, 32) : A CS31 device (no device of the S500 series) has reported a new error message Bit 6 (0x40, 64) : A CS31 device of the S500 series has reported a new error message. Bit 7 (0x80, 128) : <not used>
	byd1 :	BYTE;	(* internal variable *)
	usErrorCounter :	WORD;	(* Error counter for the module *)
	byDiagErr :	BYTE;	(* internal error number *)
	byDiagChannnel :	BYTE;	(* Channel in which the error has been has occurred *)
	byd2 :	BYTE;	(* internal variable *)
	byd3 :	BYTE;	(* internal variable *)

	pConfig :	DWORD;	(* internal variable *)
	END_STRUCT END_TYPE		

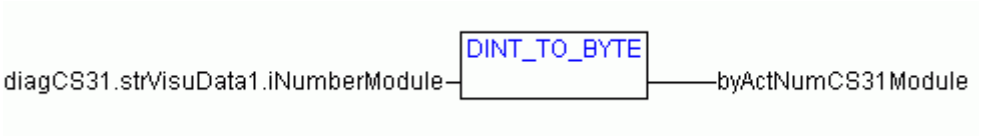
The structure strCS31_DiagModule contains an ARRAY[0..31], i.e. with 32 entries of the structure strCS31_DiagOneModule.

This way, the structures strVisuData1 and strVisuData provide access to all diagnosis data of the CS31 bus.

If the user program should have access to these values, this is done as follows:

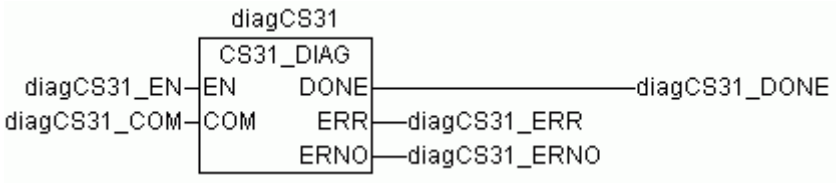
diagCS31.strVisuData1.Variable.

In the following example, the current number of CS31 modules is read and assigned to the variable byActNumCS31Module:



The most important data are available in the visualization Visu_CS31_Diag of the function block ↳ *Chapter 1.5.4.12.2 “Visualizations” on page 1182*.

Input description



EN

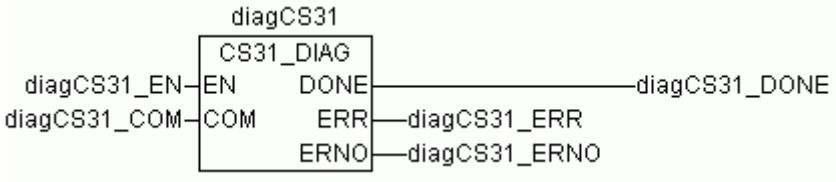
Data type	Default value	Range	Unit
BOOL			

EN = TRUE enables the processing of the function block. With a FALSE -> TRUE edge at input EN, the last five entries are read from the diagnosis buffer of the CPU.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

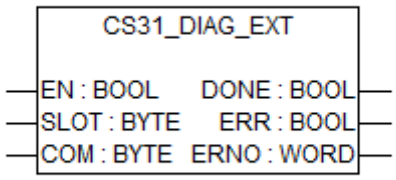
```
diagCS31(EN := diagCS31_EN, COM := diagCS31_COM);

diagCS31_DONE := diagCS31.DONE;
diagCS31_ERR  := diagCS31.ERR;
diagCS31_ERNO := diagCS31.ERNO;

or:

diagCS31(EN := TRUE, COM := 1);
```

CS31_DIAG_EXT



Parameter	Value
Included in library	Diag_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	-

Function block CS31_DIAG provides the diagnosis data of the CS31 Bus to the user.

The read values are written into internal structures of the instance.

Structure	TYPE	Assignment
strVisuData1	strCS31_DiagBus	Diagnosis data of the CS31 master
strVisuData	strCS31_DiagModule	Diagnosis data of all 31 CS31 software modules ARRAY[0..31] OF strCS31_DiagOneModule
CS31Mod	strCS31_DiagOneModule	Diagnosis data of one CS31 software module

The structure strCS31_DiagBus is composed as follows:

TYPE strCS31_DiagBus : (* STRUCT info about CS31 bus *) STRUCT			
	iCS31BusState :	DINT;	(* Bit 0=1 waiting for slave Bit 1=1 initialization Bit 4=1 I/O data exchange := 19 all modules at bus *)
	iNumberModule :	DINT;	(* current no. of CS31 software modules on the CS31 bus *)
	iMaxNumberModule :	DINT;	(* max. number of modules at CS31 bus since power ON *)
	iErrorSum :	DINT;	(* sum error counter *)
	ulCycleCount :	DWORD;	(* counter of CS31 bus cycles *)
	byStateDiag :	BYTE;	(* general bus diagnosis: 0=ok, 1=no module on the bus *)
END_STRUCT END_TYPE			

The structure strCS31_DiagOneModule is composed as follows:

TYPE strCS31_DiagOneModule : STRUCT			
	dwScheduleCycle :	DWORD;	(* internal time *)
	byPhysicalAdress :	BYTE;	(* module address x 2 *)
	byStateDiag :	BYTE;	(* communication status:

				00 = OK Bit 0=1 (1) module disconnected again Bit 1=1 (2) module not available on bus Bit 2=1 (4) unconfigured module on bus Bit 3=1 (8) difference in I/O range Bit 4=1 (16) E4 – error message Bit 5=1 (32) Bit 6=1 (64) *)
	bySlaveType :	BYTE;	(* Slave type:	
				00 = digital input 01 = analog input 02 = digital output 03 = analog output 04 = digital input/output 05 = analog input/output 06 = special module
	byInputBytes :	BYTE;	(* number of reported input bytes *)	
	byOutputBytes :	BYTE;	(* number of reported output bytes *)	
	byInputBytesConf :	BYTE;	(* number of input bytes in configuration *)	
	byOutputBytesConf :	BYTE;	(* number of output bytes in configuration *)	
	byModuleConf :	BYTE;	(* 1-PLC config, 3- ignore module *)	
	byStateDiag :	BYTE;	(* internal flag *)	
	byd1 :	BYTE;	(* internal flag *)	
	usErrorCounter :	WORD;	(* single-error counter *)	
	byDiagErr :	BYTE;	(* internal error number *)	
	byDiagChannnel :	BYTE;	(* internal error channel *)	
	byd2 :	BYTE;	(* internal flag *)	
	byd3 :	BYTE;	(* internal flag *)	
	pConfig :	DWORD;	(* internal flag *)	
	END_STRUCT END_TYPE			

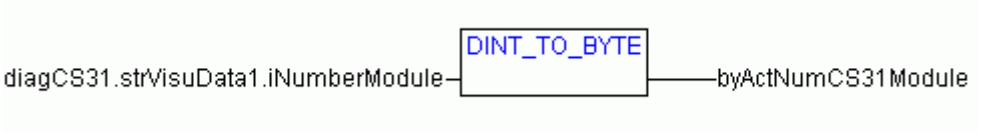
The structure strCS31_DiagModule contains an ARRAY[0..31], i.e. with 32 entries of the structure strCS31_DiagOneModule.

This way, the structures strVisuData1 and strVisuData provide access to all diagnosis data of the CS31 bus.

If the user program should have access to these values, this is done as follows:

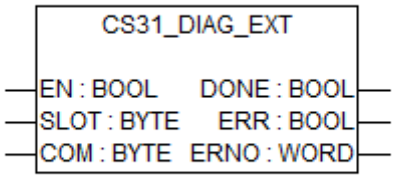
diagCS31ext.strVisuData1.Variable.

In the following example, the current number of CS31 modules is read and assigned to the variable byActNumCS31Module:



The most important data are available in the visualization Visu_CS31_Diag_EXT of the function block *Chapter 1.5.4.12.2 “Visualizations” on page 1182*.

Input description



EN

Data type	Default value	Range	Unit
BOOL			

EN = TRUE enables the processing of the function block. With a FALSE -> TRUE edge at input EN, the last five entries are read from the diagnosis buffer of the CPU.

SLOT

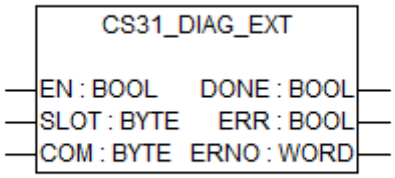
Data type	Default value	Range	Unit
BYTE	-	-	-

Reserved for future extensions.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

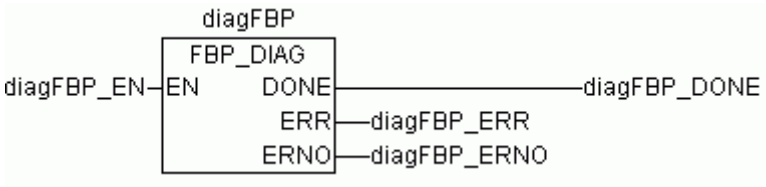
```
diagCS31EXT  (EN   := diagCS31EXT_EN,
              SLOT := diagCS31EXT_SLOT,
              COM  :=diagCS31EXT_COM);

diagCS31EXT_DONE   := diagCS31EXT.DONE;
diagCS31EXT_ERR    := diagCS31EXT.ERR;
diagCS31EXT_ERNO   := diagCS31EXT.ERNO;

or:

diagCS31EXT (EN   := TRUE,
             SLOT := 0,
             COM  := 1);
```

FBP_DIAG



Parameter	Value
Included in library	Diag_AC500_V10.lib
Available as of firmware	V1.0.2
Type	Function block with historical values
Group	-

The function block FBP_DIAG is used to output the diagnosis data of the FBP slave interface.

The instance diagFBP of the function block DIAG_FBP is declared in the global variables list GL_AC500_Diagnosis. The integrated visualization of the function block accesses the variables of this instance.

In order to include the function block into an AC500 project, it is only necessary to call the function block instance. Example in ST:

diagFBP(EN := TRUE);

The read values are written into internal structures of the instance diagFBP.

Structure	**TYPE**	**Assignment**
strVisuData	strFBP_Info	Diagnosis data of the FBP slave interface
strVisuData1	strFBP_Statistics	Statistic data of the FBP slave interface

The structure strFBP_Info is composed as follows:

TYPE strFBP_Info : STRUCT			
	pbyBinInputs :	POINTER TO BYTE;	(* internal variable *)
	pbyBinOutputs :	POINTER TO BYTE;	(* internal variable *)
	pbyAnaInputs :	POINTER TO BYTE;	(* internal variable *)
	pbyAnaOutputs :	POINTER TO BYTE;	(* internal variable *)
	pParameter :	POINTER TO BYTE;	(* internal variable *)
	apsModule :	ARRAY[1..8] OF POINTER TO strFBP_ModuleInfo;	(* submodule info *)
	usNumModules :	WORD;	(* number of modules *)
	usSizeParameters :	WORD;	(* parameter length in bytes *)
	usNumParameters :	WORD;	(* number of parameters *)
	usNumBinaryInputs :	WORD;	(* number of digital input bytes *)
	usSizeBinaryInputs :	WORD;	(* length of digital input bytes *)
	usNumBinaryOutputs :	WORD;	(* number of digital output bytes *)
	usSizeBinaryOutputs :	WORD;	(* length of digital output bytes *)
	usNumAnalogueInputs :	WORD;	(* number of analog input words *)
	usSizeAnalogueInputs :	WORD;	(* length of analog inputs in bytes *)
	usNumAnalogueOutputs :	WORD;	(* number of analog output words *)
	usSizeAnalogueOutputs :	WORD;	(* length of analog outputs in bytes *)
	ulBaudRate :	DWORD;	(* current baud rate *)

	byBusAddress :	BYTE;	(* bus address reported to FBP *)
	bySelectedTelegramType :	BYTE;	(* telegram type (acc. to FBP spec) *)
	bySelectedBaudRate :	BYTE;	(* set baud rate (acc. to FBP spec) *)
	byPrmFormat :	BYTE;	(* parameter format (acc. to FBP spec) *)
END_STRUCT END_TYPE			

The structure strFBP_Statistics is composed as follows:

TYPE strFBP_Statistics : STRUCT			
	ulNumInitRequestsSent :	DWORD;	(* no. of Inits sent to FBP since configuration *)
	ulNumRec :	DWORD;	(* no. of telegrams received from FBP since config *)
	ulNumSend :	DWORD;	(* no. of telegrams sent to FBP since config *)
	ulNumRecErrors :	DWORD;	(* number of faulty telegrams since config *)
	ulNumTimeouts :	DWORD;	(* number of timeouts since configuration *)
	ulNumChecksumErrors :	DWORD;	(* number of telegrams with checksum error *)
	ulNumInvalidRecs :	DWORD;	(* number of wrong/unknown telegrams *)
END_STRUCT END_TYPE			

If the user program should have access to these values, this is done as follows:

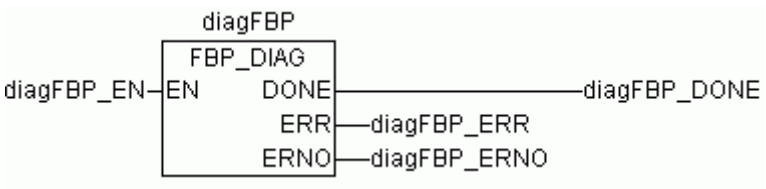
diagFBP.strVisuData.Variable.

In the following example, the FPB slave address is read and assigned to the variable byFBPAddress:

diagFBP.strVisuData.byBusAddress----------byFBPAddress

Using the visualization Visu_FBP_Diag, the values are represented graphically ↳ *Chapter 1.5.4.12.2 “Visualizations” on page 1182*.

Input description

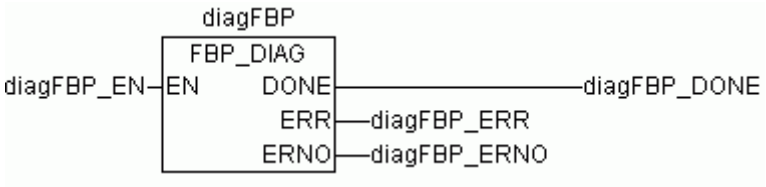


EN

Data type	Default value	Range	Unit
BOOL			

EN = TRUE enables the processing of the function block. With a FALSE -> TRUE edge at input EN, the last five entries are read from the diagnosis buffer of the CPU.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
diagFBP(EN := diagFBP_EN);

diagFBP_DONE := diagFBP.DONE;
diagFBP_ERR  := diagFBP.ERR;
diagFBP_ERNO := diagFBP.ERNO;

or:

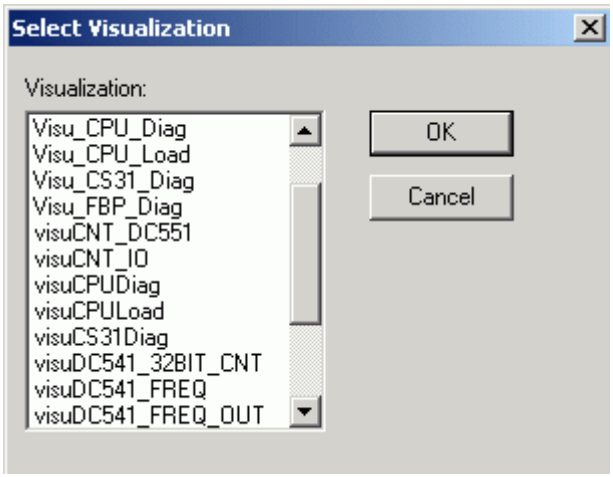
diagFBP(EN := TRUE);
```

1.5.4.12.2 Visualizations

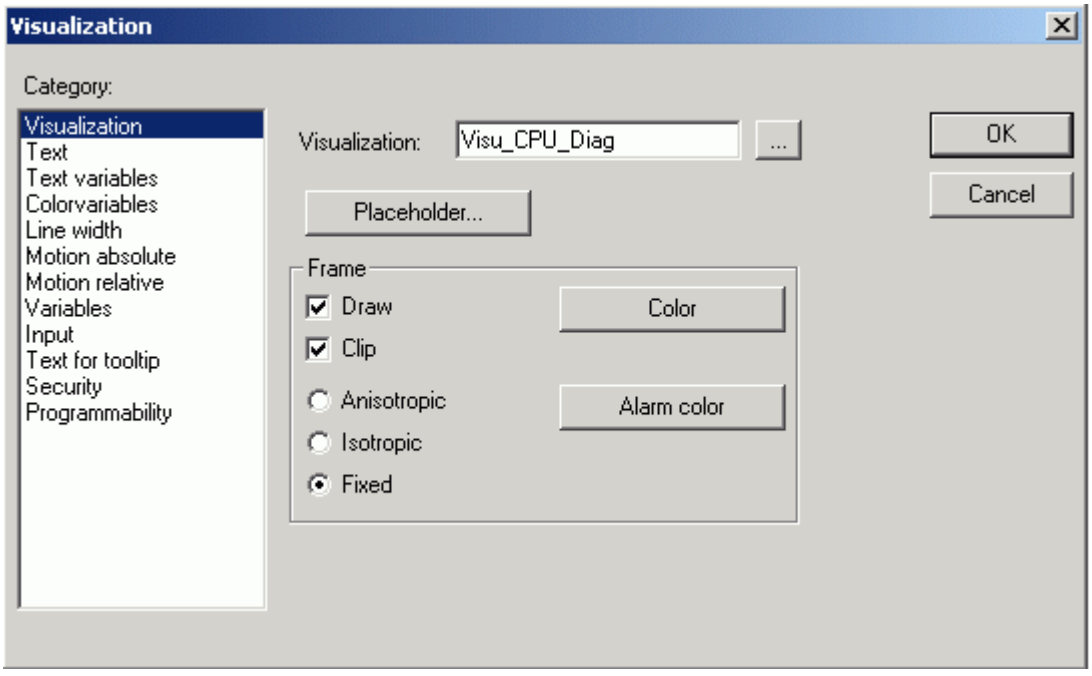
Group:	
Visu_CPU_Diag	Visualization of the CPU diagnosis
Visu_CPU_Load	Visualization of the CPU load
Visu_CS31_Diag	Visualization of the CS31 diagnosis
Visu_FBP_Diag	Visualization of the FBP slave interface diagnosis

Proceed as follows to integrate the visualization into a project:

- Create a new visualization using Visualizations / Insert Object (e.g. visuCPUDiag).
- Insert a visualization using 
- In the appearing dialog, select the corresponding visualization for the function block: e. g. Visu_CPU_Diag



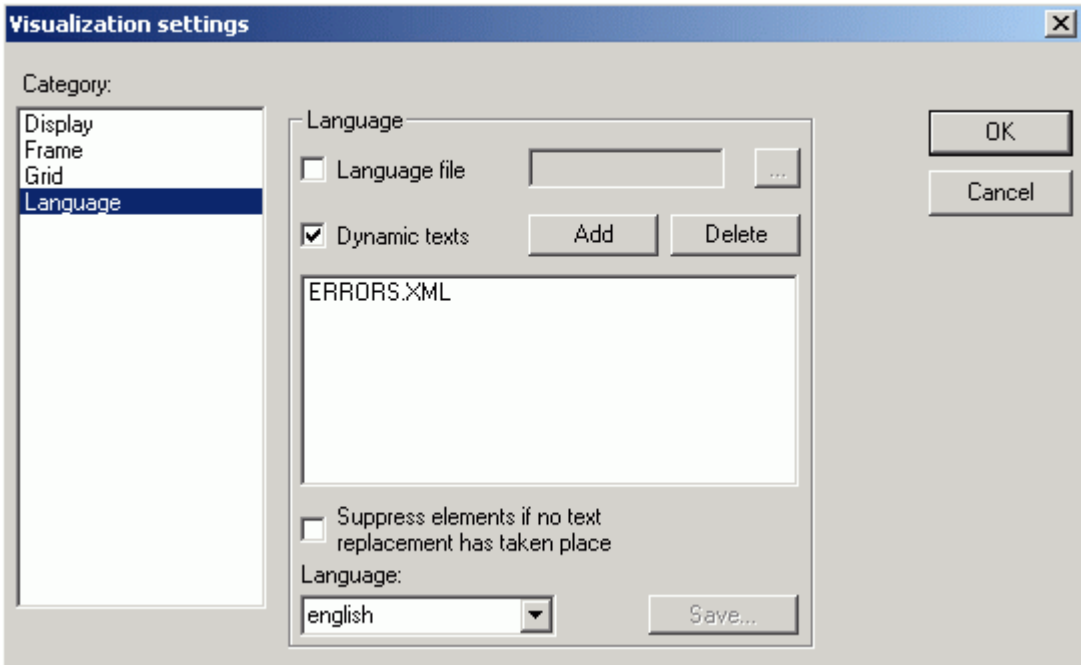
- Then, the visualization integrated just now has to be configured. Highlight the visualization with a left mouse click. Then click the right mouse button and select the function "Configure..." from the context menu.
- The configuration of the visualization is done in the appearing dialog. It is recommended to set the frame to "Fixed". This way, the original width-to-height ratio and font size are kept.



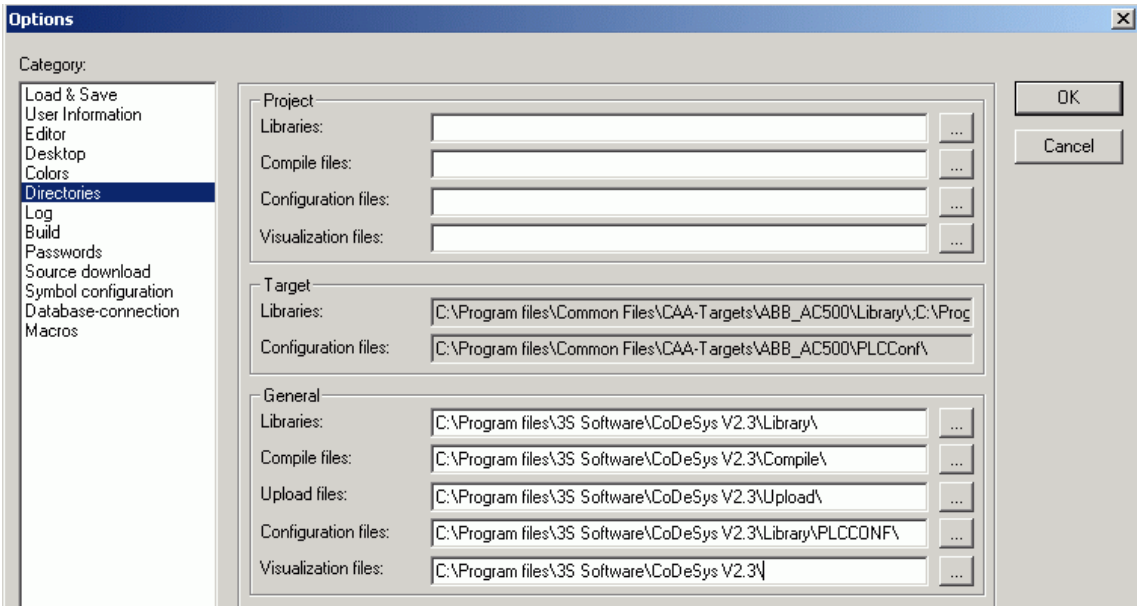
- By clicking on <OK> the dialogs are closed. After this, the inserted visualization has to be adapted to the correct size.

In the visualization of the function block CPU_DIAG, the diagnosis messages shall be output as language-dependent plain text. Proceed as follows to include the corresponding text file "Errors.xml":

- Switch to the visualization editor.
- Select the menu item "Extras"/"Settings". In the appearing dialog, select the category "Language", check "Dynamic texts" and enter "ERRORS.XML" as file name. Now, the desired language can be selected in the field "Language".



- Then, the path has to be entered in order to find the language file "ERRORS.XML". Select "Project"/"Options"/"Directories", go to "General"/"Visualization files" and enter the path CoDeSys.exe. In case of a default installation, this is:
  C:\Program Files\3S Software\CoDeSys V2.3 or C:\Programme\3S Software\CoDeSys V2.3.
  During installation of Automation Builder, the file ERRORS.XML is copied to this directory.



The following little example illustrates how to integrate diagnosis function blocks into a project and how to operate them via a central visualization.

In the same way as described for the function block CPU_DIAG, the visualizations for the function block CPU_LOAD (visuCPULoad), CS31_DIAG (visuCS31Diag) and FBP_DIAG (visuFBP-Diag) have to be created.

By means of the visualization PLC_VISU, the individual visualizations can be launched and enabled or disabled. For that purpose, the program "PLC_Diagnosis()" is included into the AC500 project:

The program contains the following declarations and calls:

```
PROGRAM PLC_Diagnosis

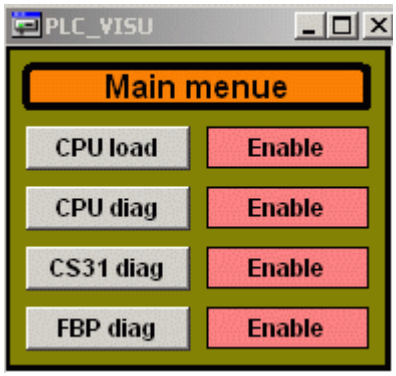
VAR

bCPUEnable : BOOL := TRUE;
bCS31Enable : BOOL := FALSE;
bFBPEnable : BOOL := FALSE;
bCPUDiagEnable : BOOL := TRUE;

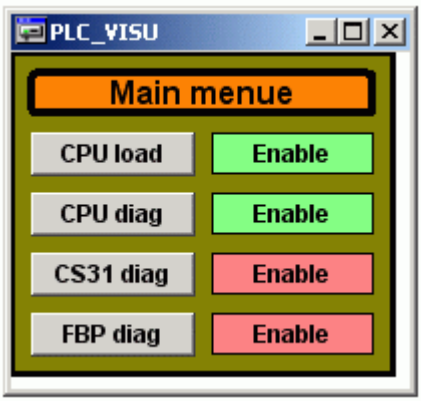
END_VAR

(* Call AC500 diagnosis *)
CPU(EN := bCPUEnable);
diagCPU(EN := bCPUDiagEnable);
diagCS31(EN := bCS31Enable, COM := 1);
diagFBP(EN := bFBPEnable);
```

In offline mode, the related visualization PLC_VISU looks as follows:



After enabling the CPU diagnosis and CPU load, PLC_VISU is displayed as follows in online mode:

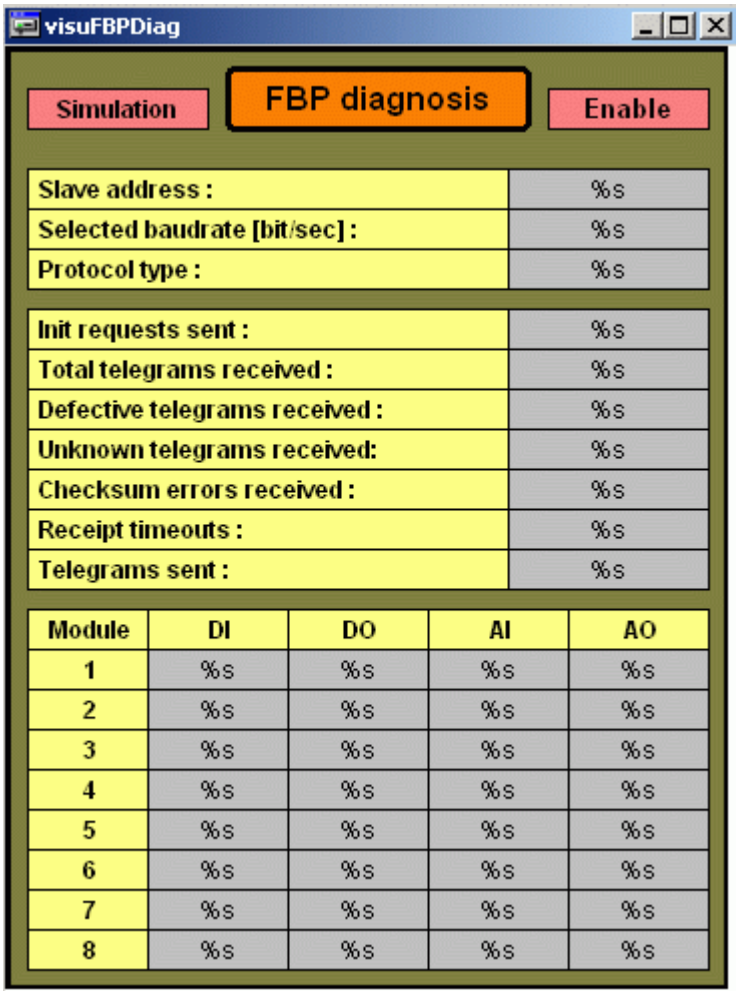


Using the buttons on the left side, the corresponding visualization is called. Clicking the "Enable" buttons enables the processing of the related function blocks.

The program "PLC_Diagnosis()" and the visualization PLC_VISU are contained in the export file AC500_PLC_Diagnosis.exp and can be inserted into an AC500 project via Project/Import.

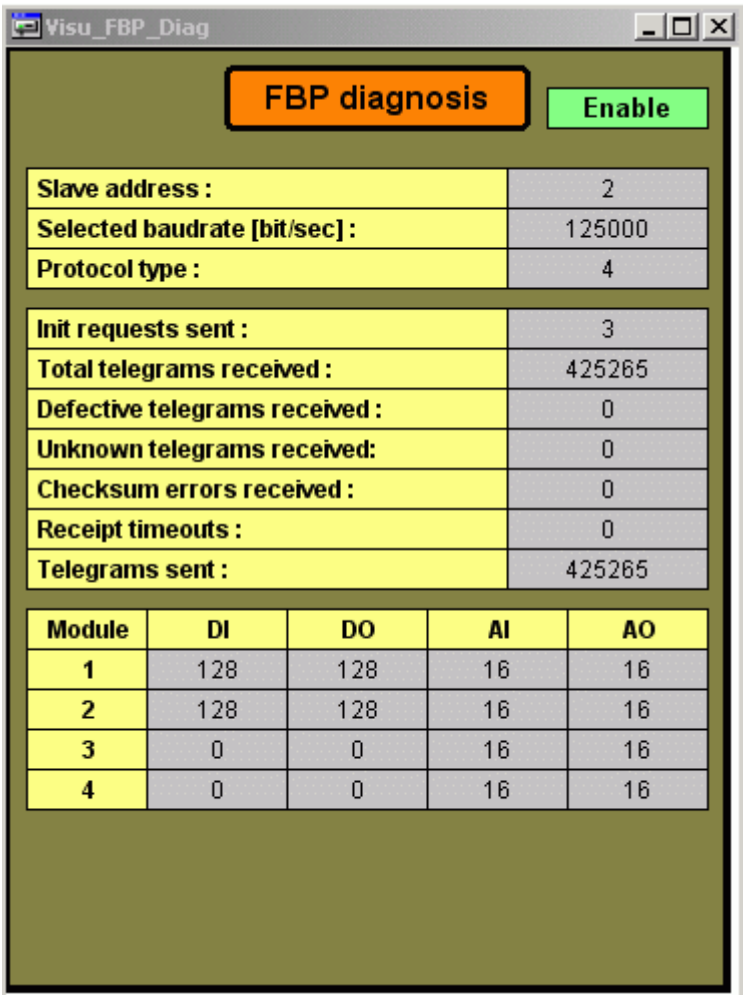
Integrated visualization of function block FBP_DIAG

The visualization Visu_FBP_Diag is part of the function block FBP_DIAG:



If input EN = TRUE, the values for the FBP diagnosis are read cyclically and entered into the structures.

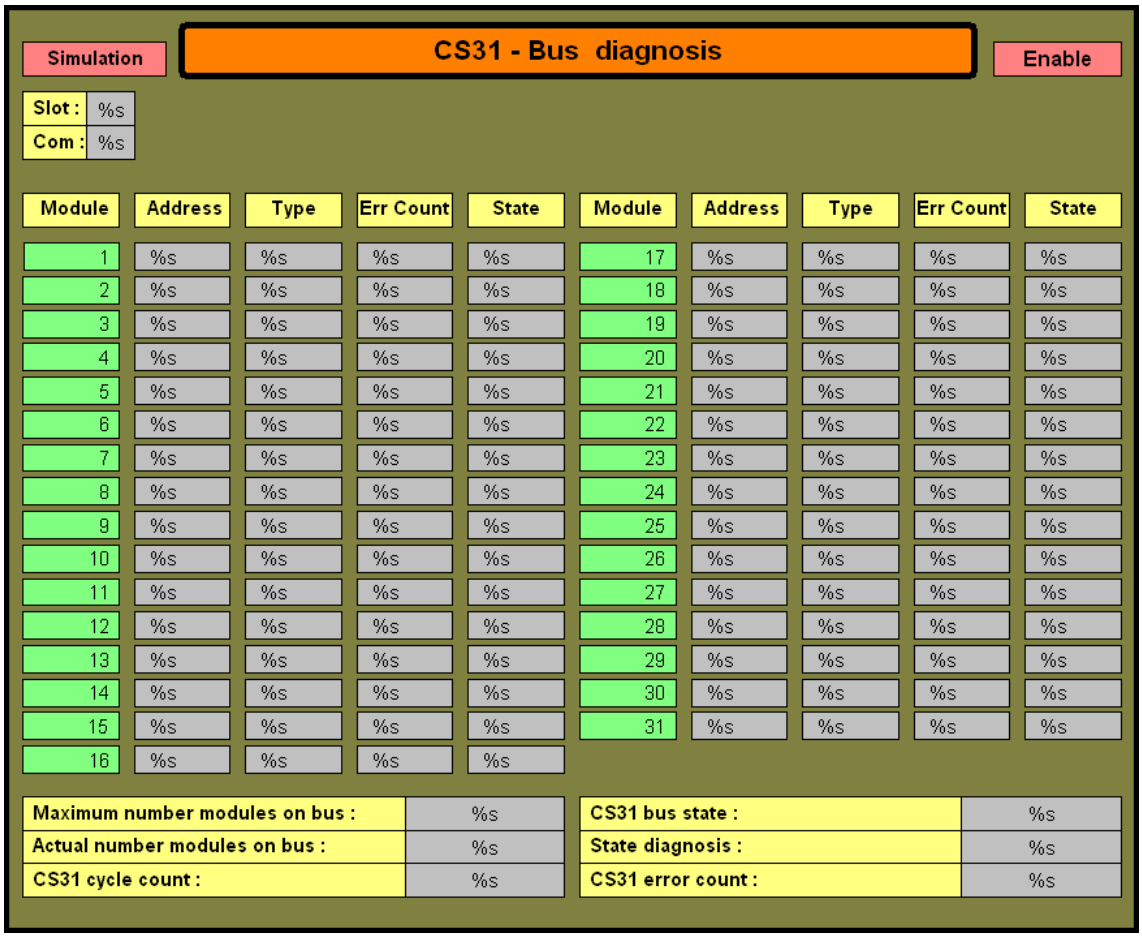
In online mode, the visualization appears, for example, as follows:



The visualization displays the number of modules that are connected to the FBP slave interface in the PLC configuration.

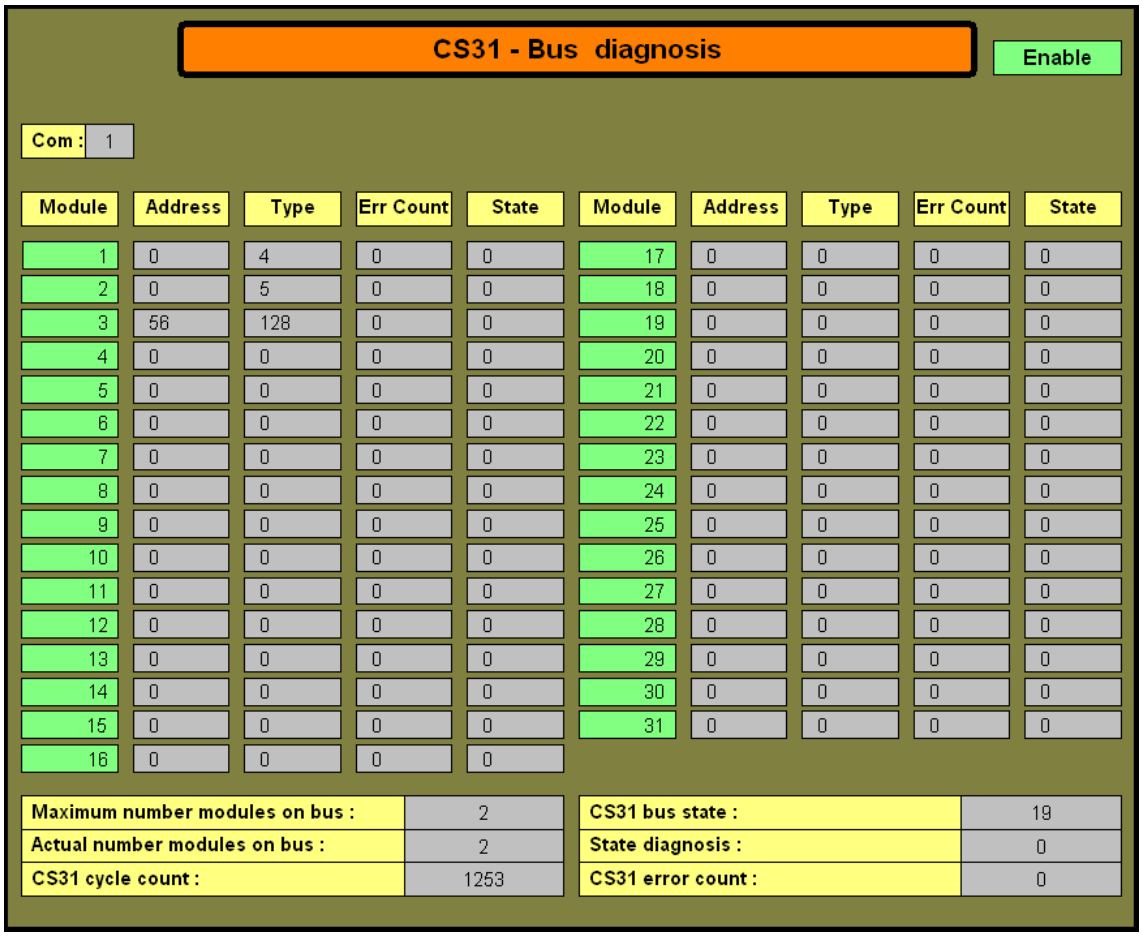
Integrated visualization of function block CS31_DIAG_EXT

The visualization Visu_CS31_Diag_EXT is part of the function block CS31_DIAG_EXT:



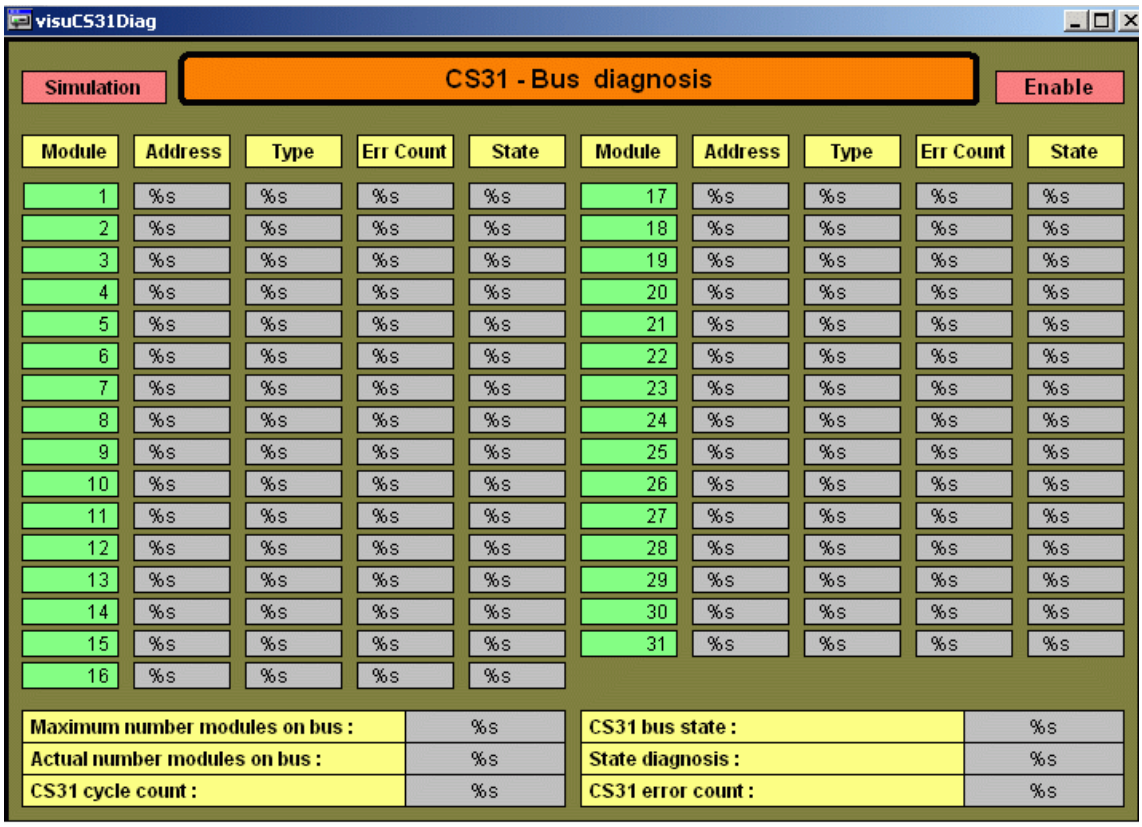
If input EN = TRUE, the values for the CS31 diagnosis are read cyclically and entered into the structures.

In online mode, the visualization appears, for example, as follows:



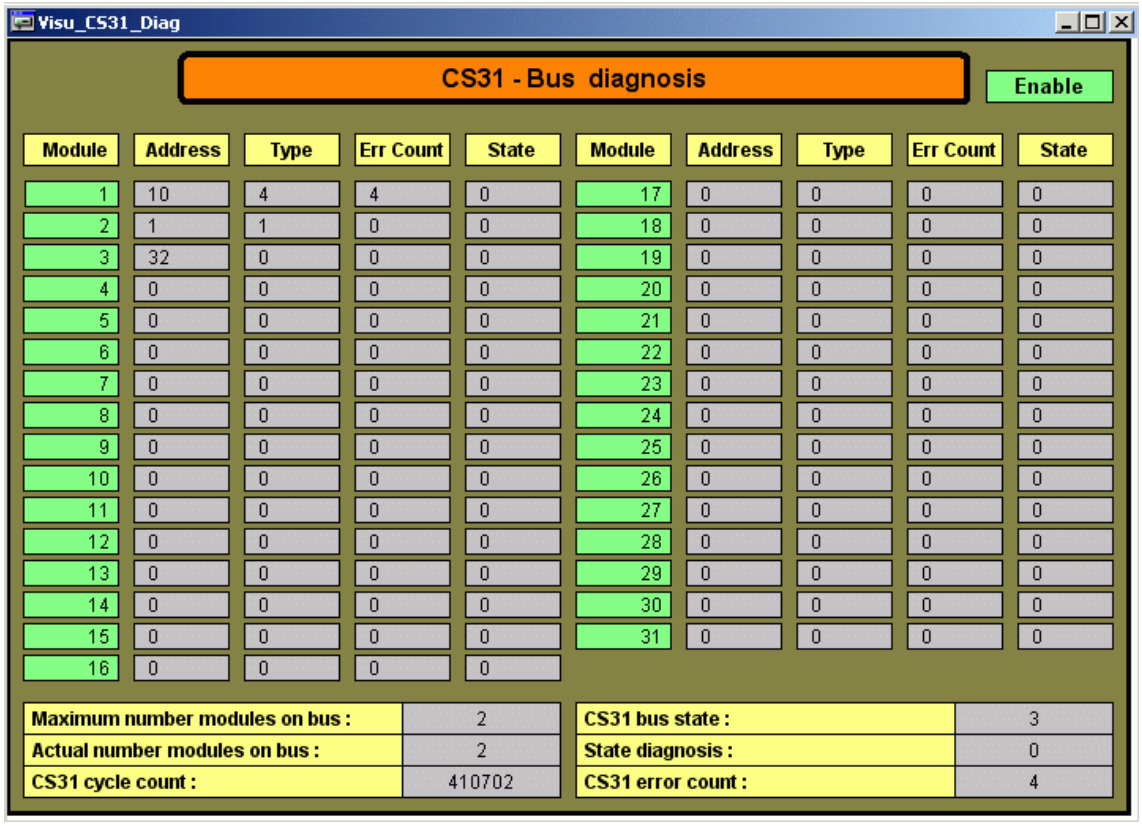
Integrated visualization of function block CS31_DIAG

The visualization Visu_CS31_Diag is part of the function block CS31_DIAG:



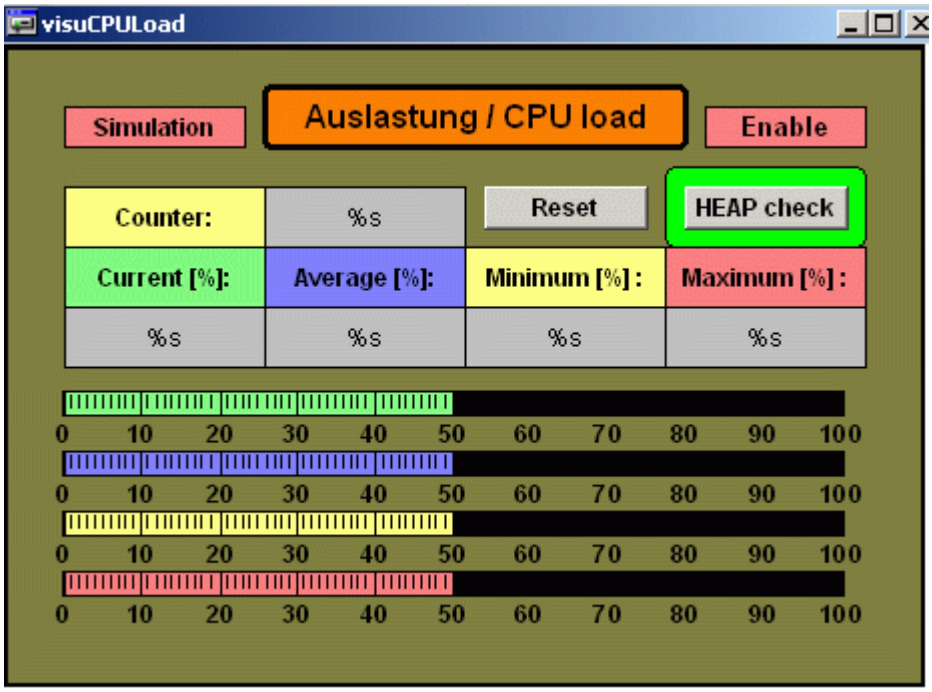
If input EN = TRUE, the values for the CS31 diagnosis are read cyclically and entered into the structures.

In online mode, the visualization appears, for example, as follows:



Integrated visualization of function block CPU_LOAD

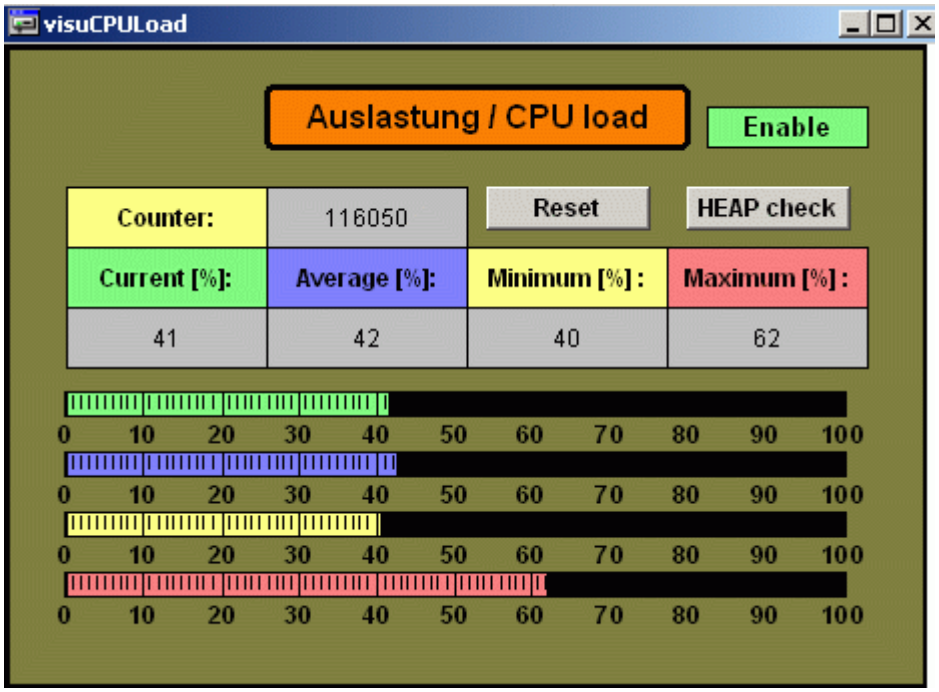
The visualization Visu_CPU_Load is part of the function block CPU_LOAD:



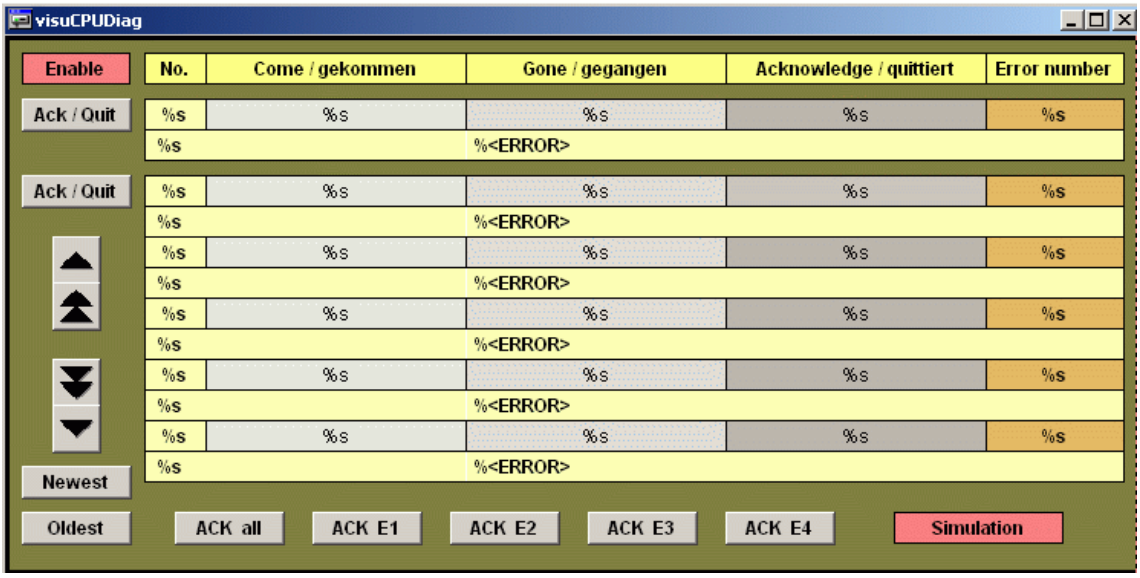
If input EN = TRUE, the CPU load values in [%] are cyclically output in a numerical and graphical (bar display) representation. Pressing the button <Reset> resets the values.

The button <HEAP check> checks the internal HEAP memory of the CPU. While the HEAP check is activated, no load values are calculated and output.

In online mode, the visualization appears, for example, as follows:



Integrated visualization of function block CPU_DIAG



This section describes how to operate the visualization.

The following is output for each diagnosis entry:

- current error number "No."
- time stamps for errror Come / Gone / Acknowledge
- "Error number"
- short text and error text taken from "ERRORS.XML"

In the upper area, the last diagnosis entry is displayed. This entry can be acknowledged by pressing the button <Ack / Quit>.

In the middle, the last 5 diagnosis entries are displayed after a FALSE/TRUE edge. The buttons on the left allow to navigate within the diagnosis buffer:

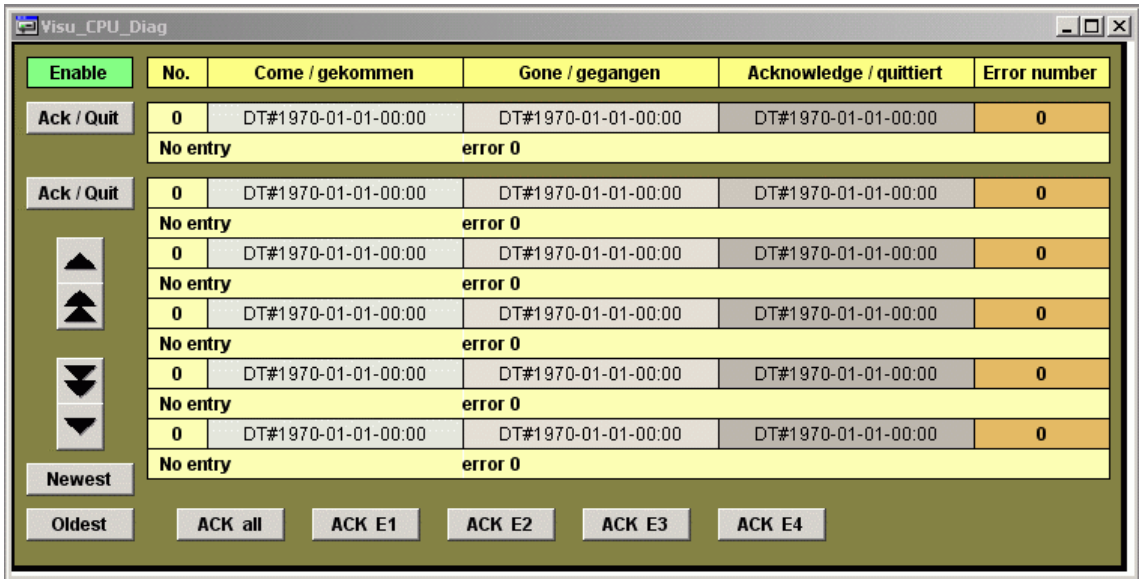
- <Ack / Quit>	- acknowledges the diagnosis entry displayed next to the button
- arrow up	- next entry
- arrow down	- previous entry
- double arrow up	- 5 entries forward
- double arrow down	- 5 entries back
- Newest	- 5 entries back starting with the latest entry
- Oldest	- 5 entries forward starting with the oldest entry

Using the buttons below the diagnosis entries, errors can be acknowledged:

- <ACK all>	- acknowledges all errors
- <ACK E1>	- acknowledges E1 errors (fatal errors)
- <ACK E2>	- acknowledges E2 errors (severe errors)
- <ACK E3>	- acknowledges E3 errors (minor error)
- <ACK E4>	- acknowledges E4 errors (warnings)

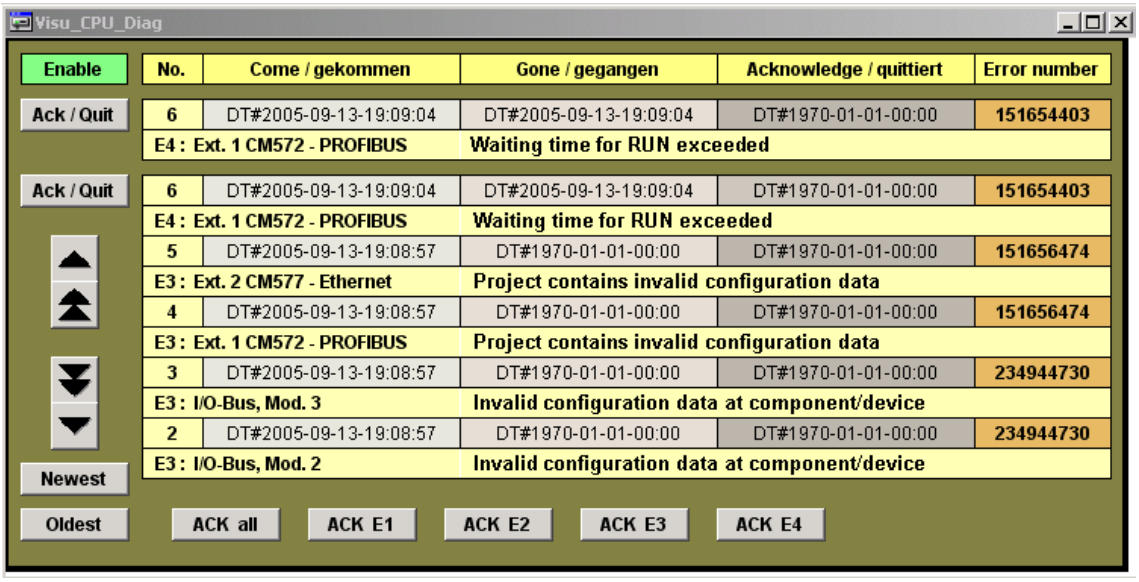
When acknowlegding errors, the function blocks DIAG_ACK and DIAG_ACK_ALL of the library SysInt_AC500_V10.lib are called.

If no diagnosis entries exist, the visualization in online mode looks as follows:



Remark: The PLC real-time clock (RTC) is not set in the example.

If errors exist, the visualization could, for example, appear as follows:



1.5.4.12.3 Structures

Group: Type_CPU_Diagnosis	
AC500_Diag_Entry	Structure of an AC500 diagnosis entry
strCPU_LOAD	Structure of the CPU load

Group: Type_CS31_Diagnosis	
strCS31_DiagBus	Diagnosis structure of CS31 master
strCS31_DiagModule	Diagnosis structure of all modules
strCS31_DiagOneModule	Diagnosis structure of a slave at the CS31 bus

Group: Type_FBP_Diagnosis	
strFBP_Info	Diagnosis structure of the FBP slave interface
strFBP_ModuleInfo	Diagnosis structure of a module of the FBP slave interface
strFBP_Statistics	Diagnosis structure with statistic values of the FBP slave interface

1.5.4.12.4 Global variables lists

Variables list: GL_AC500_Diagnosis		
Variable	**Type**	**Description**
CPU	CPU_LOAD	Instance of the function block CPU load
diagCPU	CPU_DIAG	Instance of the function block CPU diagnosis
diagCS31	CS31_DIAG	Instance of the function block CS31 diagnosis
diagFBP	FBP_DIAG	Instance of the function block FBP slave diagnosis

Variables list: GL_Diag_Constant		
Variable	**Type**	**Description**
wERNO_SIMULA-TION_MODE	WORD	16#50FF = 20735 dec, error number for simulation mode

1.5.4.13 Ethernet library

Library file name: **Ethernet_AC500_Vx.lib**

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

Operating the controller as open Modbus on TCP/IP subscriber can be performed simultaneously with other protocols. When operated in this mode, the Ethernet Communication Module is able to execute the functionality of several servers or several clients at the same time. Mixed operation is also possible.

In order to operate the controller as open Modbus on TCP/IP server (slave), only the Communication Module has to be configured. An additional use of the open Modbus on TCP/IP function blocks in the user program is not necessary.

To operate the controller as open Modbus on TCP/IP client (master), the Communication Module also has to be configured. In this case, one or more ETH_MODMAST function blocks have to be configured in the user program additionally.

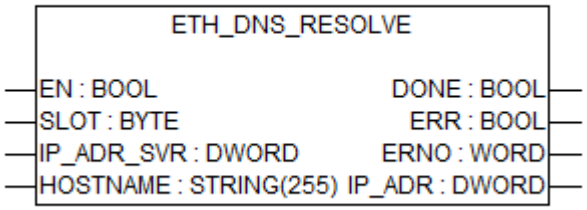
The ETH_MODMAST function block can be optionally operated in server mode as well as in client mode or in mixed operation.

Table 76: Reserved ports

Port		Reserved for
DEC	**HEX**	
32768	8000	Ethernet UDP/IP data exchange with AC31 header (ETH_UDP_xxx function blocks)
1200	04B0	TCP/IP gateway access
502	01F6	Open Modbus on TCP/IP

1.5.4.13.1 Function blocks

ETH_DNS_RESOLVE

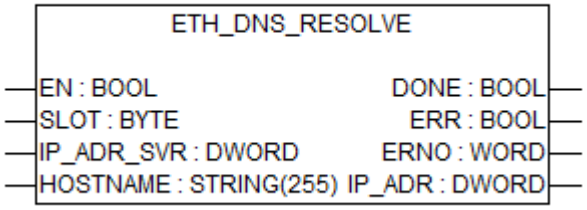


The function block ETH_DNS_RESOLVE returns an IP address of a user-specified hostname via a given DNS server.

The input SLOT is not considered by this function block.

Available as of runtime system:	V2.1	Remark:
Included in library:	Ethernet_AC500_V10.lib	Only supported with onboard Ethernet
Type	Function block with historical values	

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

IP_ADR_SVR

Data type	Default value	Range	Unit
DWORD	-	-	-

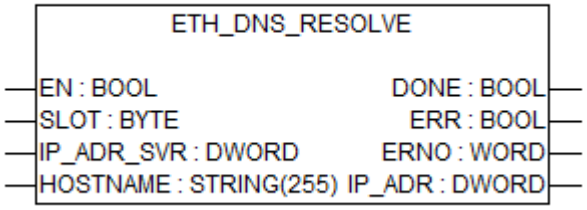
At input IP_ADR_SVR, the IP address of the DNS server to be used for resolving the hostname is specified.

HOSTNAME

Data type	Default value	Range	Unit
STRING	Empty string	-	-

At input HOSTNAME, the domain of the host to be resolved to an IP address is specified. This name is sent ot the DNS server, which answers with an IP address.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IP_ADR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

Output IP_ADR displays the resolved IP address of the hostname provided by the input HOST-NAME. Each byte in IP_ADR represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

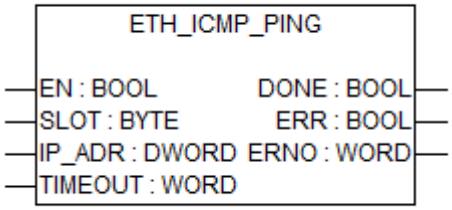
IP_ADR (dec) 3222214658

Function call in ST

```
DnsResolve    (EN         := DnsResolve_EN,
               SLOT       := DnsResolve_SLOT,
               IP_ADR_SVR := DnsResolve_IP_ADR_SVR,
               HOSTNAME   := DnsResolve_HOSTNAME);
```

```
DnsResolve_DONE   := DnsResolve.DONE;
DnsResolve_ERR    := DnsResolve.ERR;
DnsResolve_ERNO   := DnsResolve.ERNO;
DnsResolve_IP_ADR := DnsResolve.IP_ADR;
```

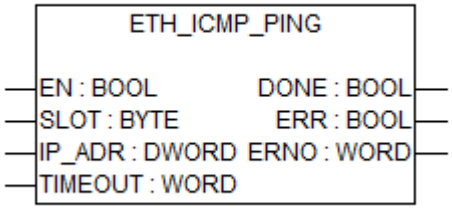
ETH_ICMP_PING



This function block only works on configured onboard Ethernet Modules, starting from CPU firmware V2.1. If no onboard Ethernet Communication Module is installed at SLOT, the corresponding error is generated and output at ERR and ERNO.

Available as of runtime system:	V2.1	Remark:
Included in library:	Ethernet_AC500_V10.lib	Only supported on onboard Ethernet communication modules
Type	Function block with historical values	

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

IP_ADR

Data type	Default value	Range	Unit
DWORD	-	-	-

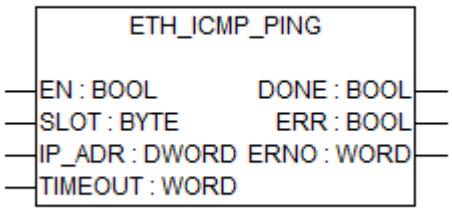
At input IP_ADR, the IP address of the host to be pinged is specified.

TIMEOUT

Data type	Default value	Range	Unit
WORD	5.000	-	ms

At input TIMEOUT, the time to wait for an ICMP echo reply from the host is specified. After this time has run out, an error will be set as output.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

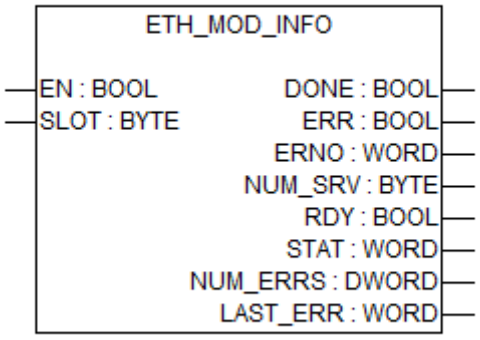
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
Ping
 (EN        := Ping_EN,
 SLOT       := Ping_SLOT,
 IP_ADR     := Ping_IP_ADR
 TIMEOUT   := Ping_TIMEOUT)

Ping_DONE  := Ping.DONE;
Ping_ERR   := Ping.ERR;
Ping_ERNO  := Ping.ERNO;
```

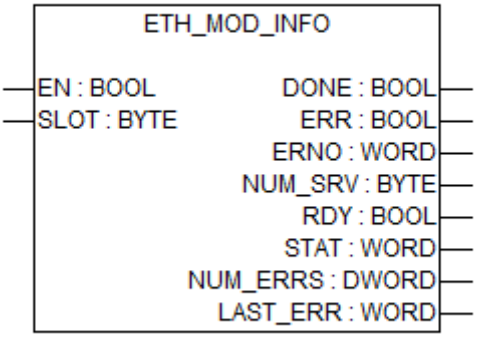
ETH_MOD_INFO



The function block ETH_MOD_INFO reads the status information of the open Modbus on TCP/IP processing. It can be used for pure server (slave) or client (master) operation of the controller as well as for mixed operation.

Available as of runtime system:	V1.0
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

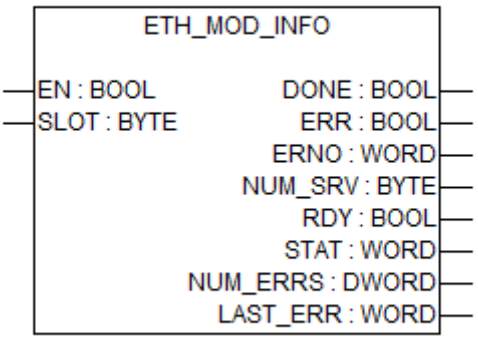
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_SRV

Data type	Default value	Range	Unit
BYTE	-	-	-

NUM_SRV (number of servers) output indicates the number of parallel server channels configured with Automation Builder software. NUM_SRV is only valid if DONE = TRUE and ERR = FALSE.

RDY

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

RDY (ready) output indicates the readiness for operation of the open Modbus on TCP/IP processing. If RDY = TRUE, the server processing as well as the client processing are ready for operation. RDY is only valid if DONE = TRUE and ERR = FALSE.

STAT

Output STAT displays the current operating state of the open Modbus on TCP/IP processing. STAT is only valid if DONE = TRUE and ERR = FALSE.

STAT		Description
Decimal	Hexadecimal	
0	00	Processing not initialized
1	01	Processing initialized and running
2	02	Processing initialization in progress
3	03	Initialization error
4	04	Processing initialized and waiting for TCP task

NUM_ERRS

Data type	Default value	Range	Unit
DWORD	-	-	-

The total number of errors detected by the Communication Module since last power up or reset.

LAST_ERR

Data type	Default value	Range	Unit
WORD	-	-	-

LAST_ERR outputs the last error occurred on the Communication Module. The error message encoding at output LAST_ERR applies to all Ethernet function blocks and is explained at the beginning of the library descriptions.

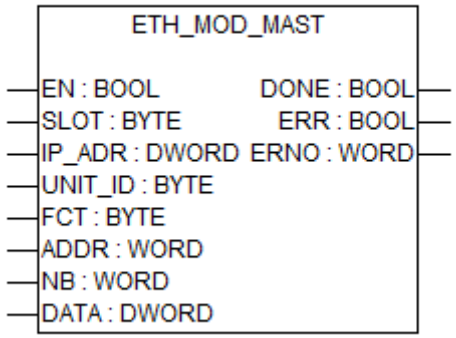
The outputs gives the value which has been received directly from the Communication Module. To find this error code inside the list of error messages, the value 0x6000 has to be added to the error value.

Function call in ST

```
ModInfo (EN := ModInfo_EN,
     SLOT := ModInfo_SLOT);

ModInfo_DONE := ModInfo.DONE;
ModInfo_ERR := ModInfo.ERR;
ModInfo_ERNO := ModInfo.ERNO;
ModInfo_NUM_SRV := ModInfo.NUM_SRV;
ModInfo_RDY := ModInfo.RDY;
ModInfo_STAT := ModInfo.STAT;
ModInfo_NUM_ERRS := ModInfo.NUM_ERRS;
ModInfo_LAST_ERR := ModInfo.LAST_ERR;
```

ETH_MOD_MAST



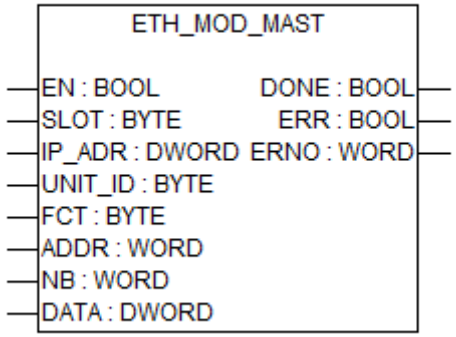
The ETH_MOD_MAST function block implements the open Modbus on TCP/IP client functionality for the Ethernet Communication Module specified at input SLOT. Depending on the configuration of the Communication Module, several ETH_MOD_MAST function blocks can be used in parallel. Prior to the use of ETH_MOD_MAST the Communication Module has to be configured.

With each FALSE > TRUE edge at input EN, the function block ETH_MOD_MAST reads the values at the inputs, generates a telegram according to the inputs and then sends this telegram to the slave.

> *Only a single instance per slave can be used with this function block.*

Available as of runtime system:	V1.0
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

IP_ADR

Data type	Default value	Range	Unit
DWORD	-	-	-

At IP_ADR, the IP address of the server has to be specified to which the telegram should be sent. Each byte in IP_ADR represents one octet of the address.

Example	IP address 192.15.24.2 IP_ADR (hex) 16#C00F1802 IP_ADR (dec) 3222214658

UNIT_ID

Data type	Default value	Range	Unit
BYTE	-	-	-

At input UNIT_ID, the address of the Modbus slave must be specified which is connected serially to the Modbus server defined by IP_ADR. If no further slaves are connected, this input is not used.

FCT

Data type	Default value	Range	Unit
BYTE	-	-	-

The function code of the request telegram is specified at input FCT.

01 or 02	Read n bits
03 or 04	Read n words
05	Write one bit (encoded in one word)
06	Write one word
07	Read 8 bit
15	Write n bits (encoded in one byte)
16	Write n words
22	Mask write
23	Read/write multiple words in one telegram

The max. telegram length for onboard Ethernet CPUs with function code 3/4 is 96 words.

The max. telegram length for onboard Ethernet CPUs with function code 15 is 1536 bits.

ADDR

Data type	Default value	Range	Unit
WORD	-	-	-

The operand/register address in the slave from which data should be read or written is specified at input ADDR.

The access to operands of AC500 devices in Modbus slave mode is defined via the Modbus cross-reference list. Only operands that are listed in the cross-reference list may be used (↯ *Chapter 1.6.4.1.8 “Communication with Modbus RTU” on page 5467*).

Only operands that are listed in the Modbus address list may be used. When accessing other devices, ADDR is freely selectable. The valid ranges have to be gathered from the corresponding device description.

NB

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At input NB (number), the number of data to be written or read is specified. The unit of NB depends on the selected function. For bit accesses the number of bits, for word and double word accesses the number of words is specified at NB. The following restrictions apply to the length:

FCT		NBmax	
Dec	**Hex**	**Serial**	**Modbus on TCP/IP**
01 or 02	01 or 02	2000 bits	255 bits (up to firmware version V01.33) 1800 bits (from firmware version V01.41) 1536 bits (PM573/PM583 only)
03 or 04	03 or 04	125 words / 62 double words	125 words / 62 double words
05	05	1 bit	1 bit
06	06	1 word	1 word
07	07	8 bits	8 bits
15	0F	1968 bits	255 bits (up to firmware version V01.33) 1800 bits (from firmware version V01.41) 1536 bits (PM573/PM583 only)
16	10	123 words / 61 double words	123 words / 61 double words
22	16	Write: 1 word	Write: 1 word
23	17	Read: 125 words / 62 double words Write: 123 words / 61 double words	Read: 125 words / 62 double words Write: 123 words / 61 double words

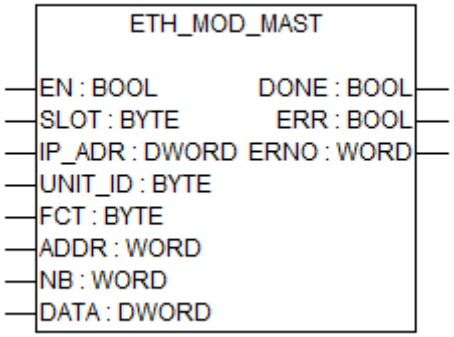
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

At input DATA, the address of the first operand in the master is specified, from which data are copied/written to the slave or to which the data read by the slave should be stored. For this purpose it is necessary that the operand type (e.g. bit) matches the selected function (e.g. FCT 1, read n bits).

If using Modbus function codes 22 or 23, the according data structures COM_MOD_FCT22_TYPE ↳ *Chapter 1.5.4.22.2.1 “COM_MOD_FCT22_TYPE” on page 1702* or COM_MOD_FCT23_TYPE ↳ *Chapter 1.5.4.22.2.2 “COM_MOD_FCT23_TYPE” on page 1703* must be defined and applied to DATA.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	-	-

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR

Data type	Default value	Range	Unit
BOOL	-	-	-

Output ERR indicates whether an error occurred during Function Block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

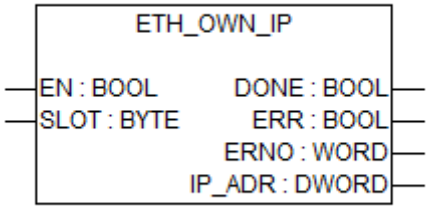
Function call in ST

```
ModMast (EN := ModMast_EN,
         SLOT := ModMast_SLOT,
         IP_ADR := ModMast_IP_ADR,
         UNIT_ID := ModMast_UNIT_ID,
         FCT := ModMast_FCT,
         ADDR := ModMast_ADDR,
         NB := ModMast_NB,
         DATA := ADR(ModMast_DATA));

ModMast_DONE := ModMast.DONE;
ModMast_ERR := ModMast.ERR;

ModMast_ERNO := ModMast.ERNO;
```

ETH_OWN_IP

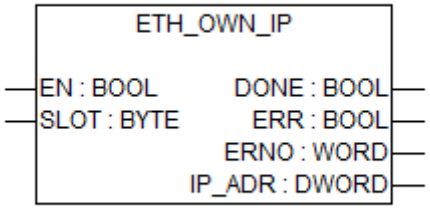


The function block ETH_OWN_IP outputs the IP address of the Communication Module installed at slot SLOT. If no Ethernet Communication Module is installed at SLOT, the corresponding error is generated and output at ERR and ERNO.

> *If using this function block in a loop (e.g. while), a sleep command must be inserted.*

Available as of runtime system:	V1.0
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

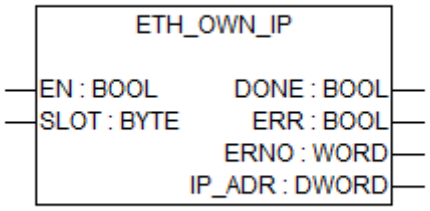
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IP_ADR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

IP_ADR displays the IP address which should be set at the CPU / Communication Module. Each byte in IP_ADR represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

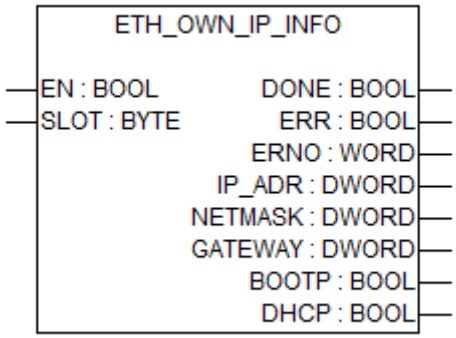
IP_ADR (dec) 3222214658

Function call in ST

```
OwnIp(EN := OwnIp_EN,
      SLOT := OwnIp_SLOT);

OwnIp_DONE := OwnIp.DONE;
OwnIp_ERR := OwnIp.ERR;
OwnIp_ERNO := OwnIp.ERNO;
OwnIp_IP_ADR := OwnIp.IP_ADR;
```

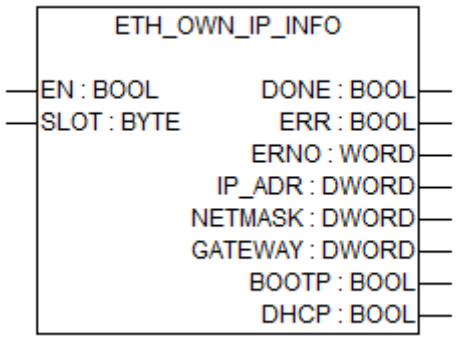
ETH_OWN_IP_INFO



The function block ETH_OWN_IP_INFO outputs the IP setup of the communication module installed at slot SLOT.If no Ethernet communication module is installed at SLOT, the corresponding error is generated and output at ERR and ERNO.

Available as of runtime system:	V1.3
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

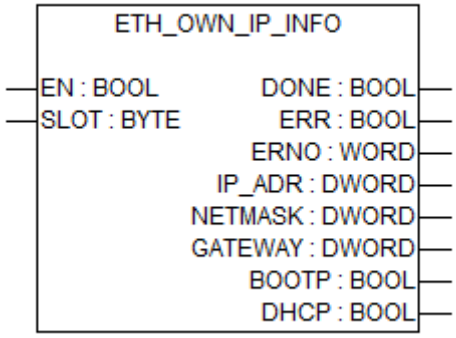
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IP_ADR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

IP_ADR displays the IP address which should be set at the CPU / Communication Module. Each byte in IP_ADR represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

IP_ADR (dec) 3222214658

NETMASK

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

Output NETMASK displays the own netmask. Each byte in NETMASK represents one octet of the address.

Example

Netmask 255.255.255.0

NETMASK (hex) 16#FFFFFF00

NETMASK (dec) 4294967040

GATEWAY

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

Output GATEWAY displays the IP address of the gateway. Each byte in GATEWAY represents one octet of the address.

Example

IP address 192.168.0.1

IP_ADR (hex) 16#C0A80001

IP_ADR (dec) 3232235521

BOOTP

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output BOOTP indicates whether the BOOTP service is activated for the Communication Module.

DHCP

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

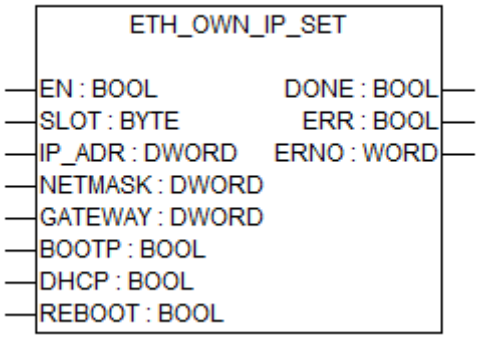
Output DHCP indicates whether the DHCP service is activated for the Communication Module.

Function call in ST

```
IpInfo(EN := IpInfo_EN,
       SLOT := IpInfo_SLOT);

IpInfo_DONE := IpInfo.DONE;
IpInfo_ERR := IpInfo.ERR;
IpInfo_ERNO := IpInfo.ERNO;
IpInfo_IP_ADR := IpInfo.IP_ADR;
IpInfo_NETMASK := IpInfo.NETMASK;
IpInfo_GATEWAY := IpInfo.GATEWAY;
IpInfo_BOOTP := IpInfo.BOOTP;
IpInfo_DHCP := IpInfo.DHCP;
```

ETH_OWN_IP_SET



Function block ETH_OWN_IP_SET is used to set

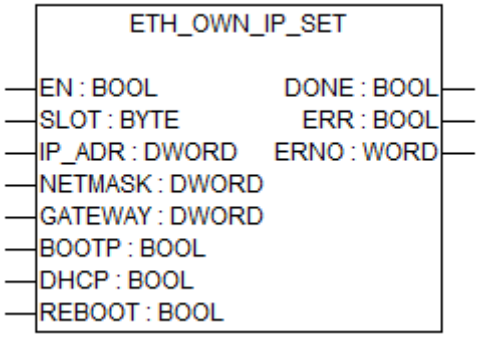
- IP address
- Subnet mask
- Gateway and
- some other parameters

at the CPU / Communication Module installed at slot SLOT.

> *The new IP configuration data will be available after the next reboot of the CPU / Communication module. Use input REBOOT=TRUE to restart the CPU / Communication Module immediately after changing the IP configuration data.*

Available as of runtime system:	V2.0
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

IP_ADR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

IP_ADR displays the IP address which should be set at the CPU / Communication Module. Each byte in IP_ADR represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

IP_ADR (dec) 3222214658

NETMASK

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At input NETMASK, the subnet mask which should be set at the CPU / Communication Module is specified. Each byte in NETMASK represents one octet of the address.

Example	Netmask 255.255.255.0 NETMASK (hex) 16#FFFFFF00 NETMASK (dec) 4294967040

GATEWAY

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At input GATEWAY, the default gateway which should be set at the CPU / Communication Module is specified. Each byte in GATEWAY represents one octet of the address.

Example	IP address 192.168.0.1 IP_ADR (hex) 16#C0A80001 IP_ADR (dec) 3232235521

BOOTP

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output BOOTP indicates whether the BOOTP service is activated for the Communication Module.

DHCP

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

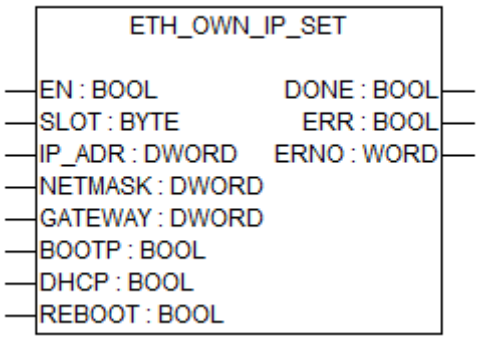
Output DHCP indicates whether the DHCP service is activated for the Communication Module.

REBOOT

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

A TRUE signal at input REBOOT restarts the CPU / Communication Module after changing the IP settings.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

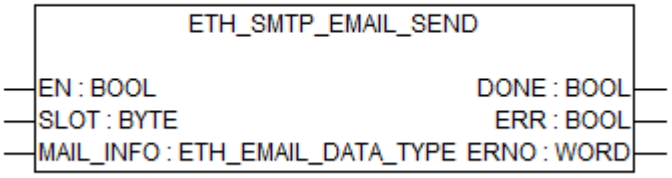
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
IPSet      (EN        := IPSet_EN,
            SLOT      := IPSet_SLOT,
            IP_ADR    := IPSet_IP_ADR,
            NETMASK   := IPSet_NETMASK,
            GATEWAY   := IPSet_GATEWAY,
            BOOTP     := IPSet_BOOTP,
            DHCP      := IPSet_DHCP,
            REBOOT    := IPSet_REBOOT);

IPSet_DONE := IPSet.DONE;
IPSet_ERR  := IPSet.ERR;
IPSet_ERNO := IPSet.ERNO;
```

ETH_SMTP_EMAIL_SEND

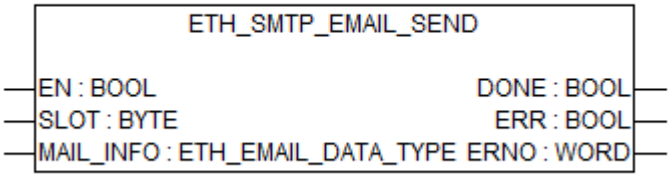


The function block ETH_SMTP_EMAIL_SEND uses a user-specified SMTP server to deliver an email to given mailboxes.

This function block only works on configured onboard Ethernet Modules. If no onboard Ethernet Communication Module is installed at SLOT, the corresponding error is generated and output at ERR and ERNO.

Available as of runtime system:	V2.1	Remark:
Included in library:	Ethernet_AC500_V10.lib	Only supported with onboard Ethernet
Type	Function block with historical values	

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

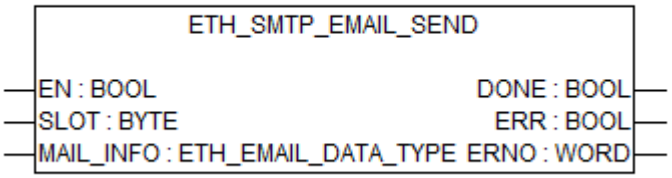
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

MAIL_INFO

Data type: ETH_EMAIL_DATA_TYPE (slot)

Input MAIL_INFO provides all necessary data to send an email via the data structure ETH_EMAIL_DATA_TYPE.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

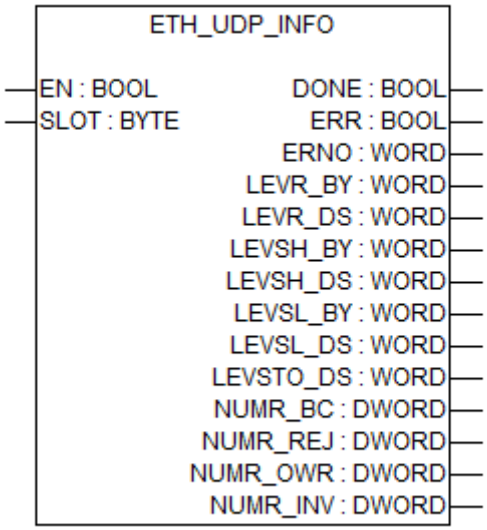
It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

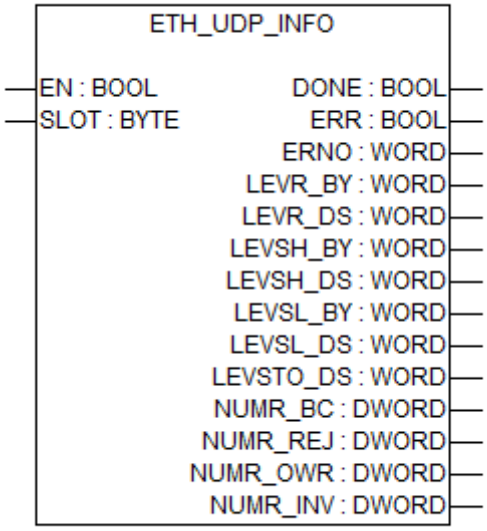
ETH_UDP_INFO



The function block ETH_UDP_INFO reads the status information of the UDP/IP processing.

Available as of runtime system:	V1.0
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

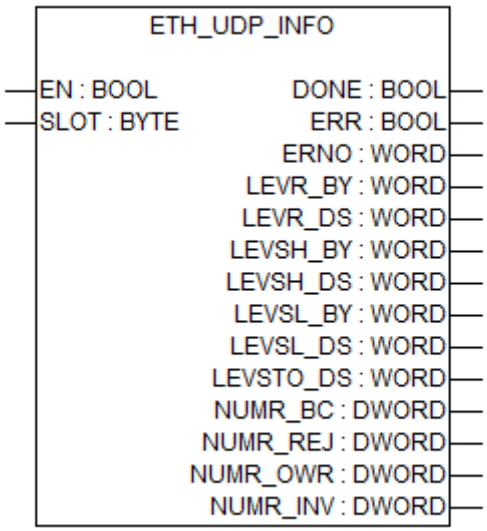
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEVR_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVR_BY displays the filling level of the receive buffer in bytes.

LEVR_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVR_DS displays the filling level of the receive buffer in data sets.

LEVSH_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSH_BY displays the filling level of the high priority send buffer in bytes.

LEVSH_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSH_DS displays the filling level of the high priority send buffer in data sets.

LEVSL_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSL_BY displays the filling level of the low priority send buffer in bytes.

LEVSL_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSL_DS displays the filling level of the low priority send buffer in data sets.

LEVSTO_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSTO_DS displays the filling level of the timeout buffer in data sets.

NUMR_BC

Data type	Default value	Range	Unit
DWORD	-	-	-

NUMR_BC outputs the number of broadcasts (data packets to all stations) which were received by this station.

NUMR_REJ

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At output NUMR_REJ (number of receipts rejected), the number of data sets is displayed which were discarded during reception due to a full receive buffer. Data sets are only discarded if this is set accordingly within the configuration of the UDP/IP processing.

NUMR_OWR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At output NUMR_OWR (number of receipts overwritten), the number of data sets is displayed which were overwritten during reception due to a full receive buffer. Data sets are only overwritten in the receive buffer, if this is set accordingly within the configuration of the UDP/IP processing.

NUMR_INV

Data type	Default value	Range	Unit
DWORD	-	-	-

NUMR_INV outputs the number of telegrams which were received faulty by this station.

Function call in ST

```
Info  (EN := Info_EN,
       SLOT := Info_SLOT)

Info_DONE := Info.DONE;
Info_ERR := Info.ERR;
Info_ERNO := Info.ERNO;
Info_LEVR_BY := Info.LEVR_BY;
Info_LEVR_DS := Info.LEVR_DS;
Info_LEVSH_BY := Info.LEVSH_BY;
Info_LEVSH_DS := Info.LEVSH_DS;
Info_LEVSL_BY := Info.LEVSL_BY;
Info_LEVSL_DS := Info.LEVSL_DS;

Info_LEVSTO_DS := Info.LEVSTO_DS;

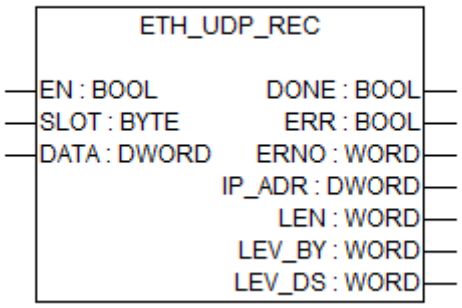
Info_NUMR_REJ := Info.NUMR_REJ;
Info_NUMR_OWR := Info.NUMR_OWR;
Info_NUMR_INV := Info.NUMR_INV;
```

ETH_UDP_REC

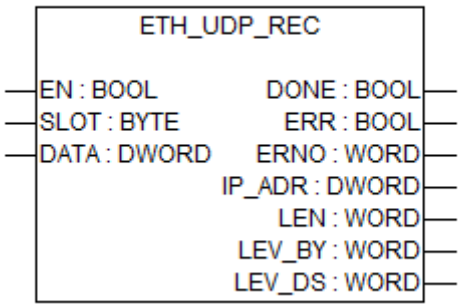


The operating system reads the received UDP/IP data packets from the Ethernet Communication Module and stores them in the receive buffer. The buffer size is determined using the PLC configuration. The data packets are stored with variable lengths. For example, a data packet consisting of 16 bytes of user data occupies exactly 22 bytes in the receive buffer (4 bytes for the IP address of the sending device, 2 bytes for the packet length and 16 bytes of user data).

Using the ETH_UDP_REC function block, exactly one data packet is read. The user data are stored in the configured memory area (DATA). The address of the sending device and the data packet length are supplied at the outputs IP_ADR and LEN. DONE = TRUE and ERR = FALSE indicate that the reading process was successful. If an error was detected during Function Block processing, the error is additionally indicated at the outputs ERR and ERNO. Furthermore, the function block provides information about the receive buffer filling level displayed in bytes (LEVR_BY) and data records (LEVR_DS).

Available as of runtime system:	V1.0
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

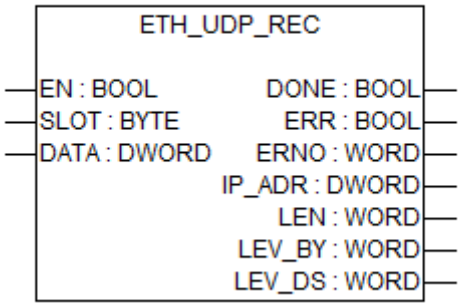
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. The address specified at DATA has to belong to a variable of the type ARRAY or STRUCT.

Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IP_ADR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

Output IP_ADR displays the IP address of the sending device which transmitted the received data package. Each byte in IP_ADR represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

IP_ADR (dec) 3222214658

LEN

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEN (length) displays the length of the received data package in bytes.

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY displays the filling level of the receive buffer in bytes. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 6 bytes in the receive buffer (4 bytes for the NODE ID of the sending device, 2 bytes for the specification of the length).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

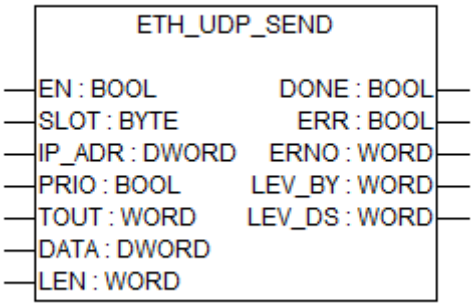
Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
REC  (EN := Rec_EN,
     SLOT := Rec_SLOT,
     DATA := ADR(Rec_DATA));

REC_DONE := Rec.DONE;
REC_ERR := Rec.ERR;
REC_ERNO := Rec.ERNO;
REC_IP_ADR := Rec.IP_ADR;
REC_LEN := Rec.LEN;
REC_LEVR_BY := Rec.LEV_BY;
REC_LEVR_DS := Rec.LEV_DS;
```

ETH_UDP_SEND

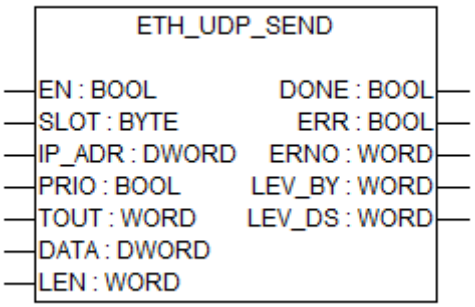


The function block ETH_UDP_SEND is used to transmit data packets via the UDP/IP protocol of the Ethernet Communication Module. The specified packages are stored in the transmit buffer selected by input PRIO. From there, the operating system hands over the data packets to the Ethernet Communication Module in order to transmit them to the target address specified at input IP_ADR. The transmit buffer size is defined by the PLC configuration. Using input TOUT, the timeout period can be specified. If TOUT <> 0, the UDP/IP data exchange is automatically performed with receive acknowledgement. If TOUT = 0, no acknowledgement is expected. Output DONE indicates that the specified data packet has been stored in the transmit buffer or that an error occurred during Function Block processing. If an error was detected during Function Block processing, the error is additionally indicated at the outputs ERR and ERNO. In case of an error, the data packet has to be transmitted again.

The function block ETH_UDP_SEND cannot store data packets to the transmit buffer until the Ethernet UDP/IP processing is set in the controller configuration (link to Controller configuration of UDP/IP processing).

Available as of runtime system:	V1.0
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

IP_ADR

Data type	Default value	Range	Unit
DWORD	-	-	-

At this input, the IP address of the recipient is specified. Each byte in IP_ADR represents one octet of the address.

Example: IP address 192.15.24.2,

IP_ADR (hex) 16#C00F1802,

IP_ADR (dec) 3222214658

PRIO

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Input PRIO (priority) is used to specify the transmit priority of the data packet.

The following applies:

If PRIO = FALSE the specified data packet has low priority. Thus, it is stored in the low priority transmit buffer. All outputs refer to this buffer.

If PRIO = TRUE the specified data packet has high priority. Thus, it is stored in the high priority transmit buffer. All outputs refer to this buffer.

TOUT

Data type	Default value	Range	Unit
WORD	-	-	-

Using input TOUT (timeout), the timeout period can be specified. If TOUT <> 0, the UDP/IP data exchange is automatically performed with receive acknowledgement. If a data packet cannot be transmitted within this period (no acknowledge telegram is received), transmission is aborted and the package is lost.

In this case, some distinctive bytes of the data packet (see *Chapter 1.6.5.3.7.1 “Contents of the UDP protocol configuration” on page 6185*) are stored to the timeout buffer and can then be read using the function block ETH_UDP_STO.

If TOUT = 0, no acknowledgement is expected.

The following applies:

TOUT = 0:

Data exchange without receive acknowledgement. No data are written to the timeout buffer.

TOUT <> 0:

Data exchange with receive acknowledgement. Each transmitted data record is acknowledged by the recipient. If no acknowledge telegram is received within the set timeout period (in ms), the data are written to the timeout buffer.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

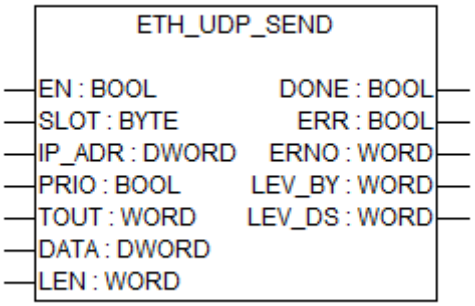
At input DATA, the address of the variable is specified the data of which are transmitted as user data in this package. The address specified at DATA has to belong to a variable of the type ARRAY or STRUCT.

LEN

Data type	Default value	Range	Unit
WORD	-	1...1464	-

At input LEN (length), the number of user data bytes is specified for the specified package.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY (level in bytes) displays the filling level (in bytes) of the transmit buffer. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 8 bytes in the transmit buffer (4 bytes for the IP address of the recipient, 2 bytes for the specification of the length and 2 bytes for the timeout period).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

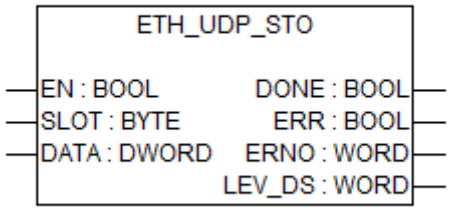
Output LEV_DS (level in data sets) displays the filling level (in data records) of the transmit buffer. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
Send (EN := Send_EN,
     SLOT := Send_SLOT,
     IP_ADR := Send_IP_ADR,
     PRIO := Send_PRIO,
     TOUT := Send_TOUT,
     DATA := ADR(Send_DATA),
     LEN := Send_LEN);

Send_DONE := Send.DONE;
Send_ERR := Send.ERR;
Send_ERNO := Send.ERNO;
Send_LEV_BY := Send.LEV_BY;
Send_LEV_DS := Send.LEV_DS;
```

ETH_UDP_STO



The ETH_UDP_STO function block reads lost data packets from the timeout data buffer and stores the user data to the specified memory area.

During the transmission of a data packet, the success of the transmission is monitored by an adjustable timeout period. When this time is exceeded, distinctive information of the data packet are stored in the timeout buffer.

These are:

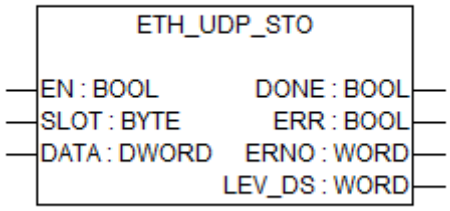
- the IP address of the receiver (4 bytes)
- header data of the data set (the number is specified with the controller configuration of the UDP/IP processing).

The buffer length can as well be set using the controller configuration of the UDP/IP processing. The buffer is constructed as a circular buffer (FIFO). If the buffer is full, the oldest entry in the buffer is overwritten. When a rising edge occurs at input EN, the ETH_UDP_STO function block verifies whether a data packet is stored in the buffer and makes the information mentioned above available for the user (starting at the variable specified at input DATA).

The function block ETH_UDP_STO cannot be used until the Ethernet UDP/IP processing is set in the controller configuration (link to Controller configuration of UDP/IP processing) Additionally, input TOUT of the transmit function block ETH_UDP_SEND must be <> 0.

Available as of runtime system:	V1.0
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

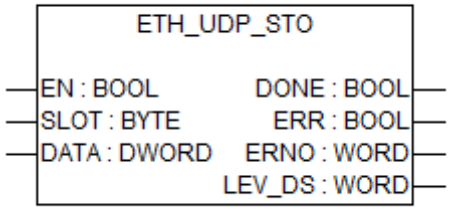
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. The address specified at DATA has to belong to a variable of the type ARRAY or STRUCT.

Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

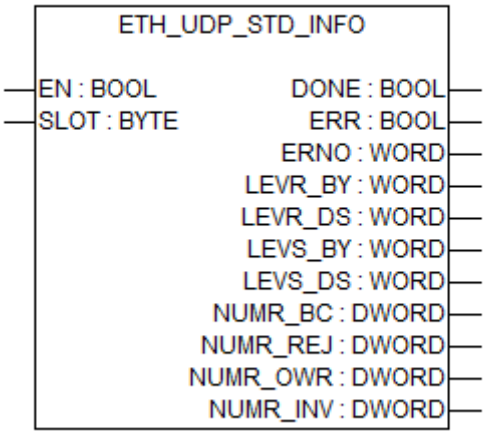
Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
Sto  (EN := Sto_EN,
     SLOT := Sto_SLOT,
     DATA := ADR(Sto_DATA));

Sto_DONE := Sto.DONE;
Sto_ERR := Sto.ERR;
Sto_ERNO := Sto.ERNO;
Sto_LEV_DS := Sto.LEV_DS;
```

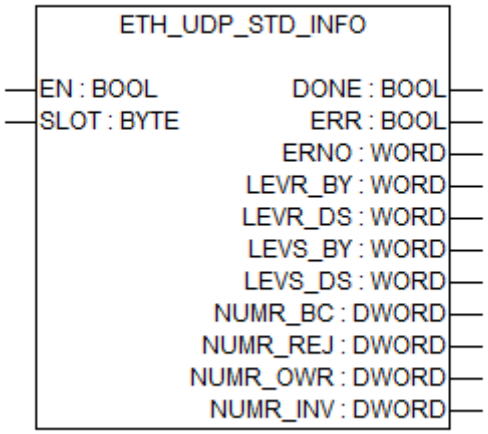
ETH_UDP_STD_INFO



The function block ETH_UDP_STD_INFO reads the status information of the UDP/IP processing.

Available as of runtime system:	V1.3
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

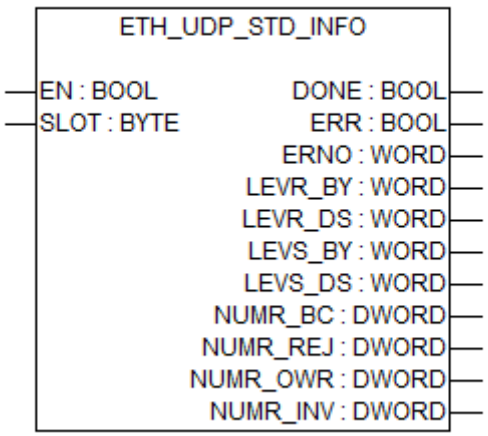
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEVR_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVR_BY displays the filling level of the receive buffer in bytes.

LEVR_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVR_DS displays the filling level of the receive buffer in data sets.

LEVS_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVS_BY (level of all send buffers in bytes) displays the filling level of all send buffers in bytes.

LEVS_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVS_DS (level of all send buffers in data sets) displays the filling level of all send buffers in data sets.

NUMR_BC

Data type	Default value	Range	Unit
DWORD	-	-	-

NUMR_BC outputs the number of broadcasts (data packets to all stations) which were received by this station.

NUMR_REJ

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At output NUMR_REJ (number of receipts rejected), the number of data sets is displayed which were discarded during reception due to a full receive buffer. Data sets are only discarded if this is set accordingly within the configuration of the UDP/IP processing.

NUMR_OWR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At output NUMR_OWR (number of receipts overwritten), the number of data sets is displayed which were overwritten during reception due to a full receive buffer. Data sets are only overwritten in the receive buffer, if this is set accordingly within the configuration of the UDP/IP processing.

NUMR_INV

Data type	Default value	Range	Unit
DWORD	-	-	-

NUMR_INV outputs the number of telegrams which were received faulty by this station.

Function call in ST

```
Info  (EN := Info_EN,
       SLOT := Info_SLOT)

Info_DONE := Info.DONE;
Info_ERR := Info.ERR;
Info_ERNO := Info.ERNO;
Info_LEVR_BY := Info.LEVR_BY;
Info_LEVR_DS := Info.LEVR_DS;
Info_LEVSH_BY := Info.LEVSH_BY;
Info_LEVSH_DS := Info.LEVSH_DS;
Info_LEVSL_BY := Info.LEVSL_BY;
Info_LEVSL_DS := Info.LEVSL_DS;

Info_LEVSTO_DS := Info.LEVSTO_DS;

Info_NUMR_BC := Info.NUMR_BC;

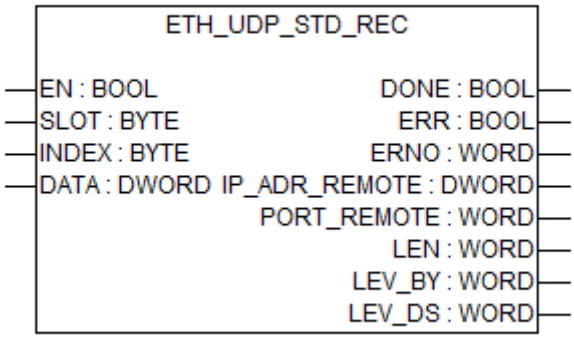
Info_NUMR_OWR := Info.NUMR_OWR;
Info_NUMR_INV := Info.NUMR_INV;
```

ETH_UDP_STD_REC



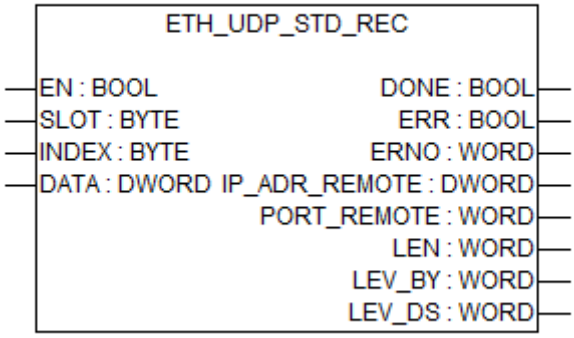
The ETH_UDP_STD_REC function block reads the next data record from the UDP/IP receive buffer and stores the user data to the configured memory area.

The operating system reads the received UDP/IP data packets from the Ethernet Communication Module and stores them in the receive buffer. The buffer size is determined using the PLC configuration. The data packets are stored with variable lengths. For example, a data packet consisting of 16 bytes of user data occupies exactly 22 bytes in the receive buffer (4 bytes for the IP address of the sending device, 2 bytes for the packet length and 16 bytes of user data).

Using the ETH_UDP_STD_REC function block, exactly one data packet is read. The user data are stored in the configured memory area (DATA). The address of the sending device and the data packet length are supplied at the outputs IP_ADR_REMOTE, PORT_REMOTE and LEN. DONE = TRUE and ERR = FALSE indicate that the reading process was successful. If an error was detected during function block processing, the error is indicated at the outputs ERR and ERNO. Furthermore, the function block provides information about the receive buffer filling level displayed in bytes (LEV_BY) and data records (LEV_DS).

Available as of runtime system:	V1.3
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

INDEX

Data type	Default value	Range	Unit
BYTE	-	-	-

Index of the standard UDP/IP connection corresponding to the PLC configuration, starting with 0. The function block only works on the connection that was selected by this input, and with the parameters set in the PLC configuration, e.g. port, buffer size, behavior in case of buffer overflow etc.

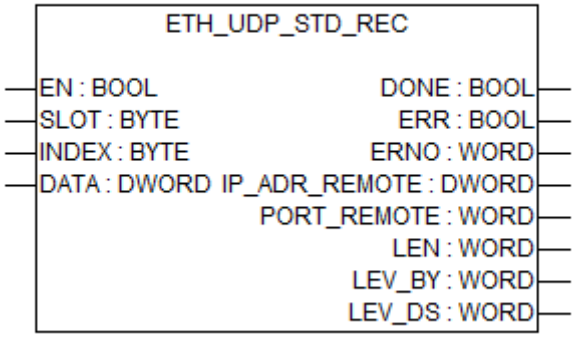
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. The address specified at DATA has to belong to a variable of the type ARRAY or STRUCT.

Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IP_ADR_REM

Data type	Default value	Range	Unit
DWORD	-	-	-

Output IP_ADR_REM (IP address remote) displays the IP address of the sending device which transmitted the received data package. Each byte in IP_ADR_REM represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

IP_ADR (dec) 3222214658

PORT_ ADR_REM

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PORT_ADR_REM (remote port address) displays the UDP remote port address of the sending device which transmitted the received data package.

LEN

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEN (length) displays the length of the received data package in bytes.

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY displays the filling level of the receive buffer in bytes. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 6 bytes in the receive buffer (4 bytes for the NODE ID of the sending device, 2 bytes for the specification of the length).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

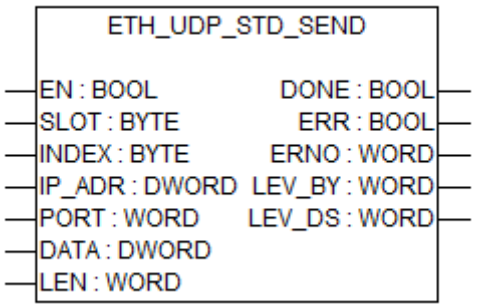
Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
REC  (EN := Rec_EN,
     SLOT := Rec_SLOT,
     INDEX := Rec_INDEX,
     DATA := ADR(Rec_DATA));

REC_DONE := Rec.DONE;
REC_ERR := Rec.ERR;
REC_ERNO := Rec.ERNO;
REC_IP_ADR_REMOTE := Rec.IP_ADR_REMOTE;
REC_PORT_REMOTE := Rec.PORT_REMOTE;
REC_LEN := Rec.LEN;
REC_LEVR_BY := Rec.LEV_BY;
REC_LEVR_DS := Rec.LEV_DS;
```

ETH_UDP_STD_SEND

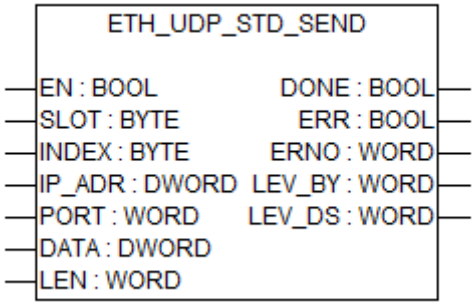


The function block ETH_UDP_STD_SEND is used to transmit data packets via the standard UDP/IP protocol of the Ethernet Communication Module. The specified packages are stored in the transmit buffer. From there, the operating system hands over the data packets to the Ethernet Communication Module in order to transmit them to the target address specified at input IP_ADR. The transmit buffer size is defined by the PLC configuration. Output DONE indicates that the specified data packet has been stored in the transmit buffer or that an error occurred during Function Block processing. If an error was detected during Function Block processing, the error is additionally indicated at the outputs ERR and ERNO. In case of an error, the data packet has to be transmitted again.

The function block ETH_UDP_STD_SEND cannot store data packets to the transmit buffer until the Ethernet UDP/IP processing is set in the controller configuration (see also the PLC configuration of the standard UDP/IP processing).

Available as of runtime system:	V1.3
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

INDEX

Data type	Default value	Range	Unit
BYTE	-	-	-

Index of the standard UDP/IP connection corresponding to the PLC configuration, starting with 0. The function block only works on the connection that was selected by this input, and with the parameters set in the PLC configuration, e.g. port, buffer size, behavior in case of buffer overflow etc.

IP_ADR

Data type	Default value	Range	Unit
DWORD	-	-	-

At this input, the IP address of the recipient is specified. Each byte in IP_ADR represents one octet of the address.

Example: IP address 192.15.24.2,

IP_ADR (hex) 16#C00F1802,

IP_ADR (dec) 3222214658

PORT

Data type	Default value	Range	Unit
WORD	-	-	-

The target port of the receiver is specified here (port to send to).

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

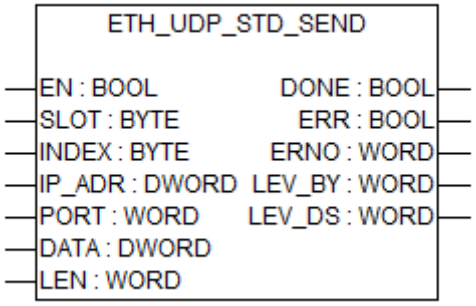
At input DATA, the address of the variable is specified the data of which are transmitted as user data in this package. The address specified at DATA has to belong to a variable of the type ARRAY or STRUCT.

LEN

Data type	Default value	Range	Unit
WORD	-	1...1464	-

At input LEN (length), the number of user data bytes is specified for the specified package.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY (level in bytes) displays the filling level (in bytes) of the transmit buffer. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 8 bytes in the transmit buffer (4 bytes for the IP address of the recipient, 2 bytes for the specification of the length and 2 bytes for the timeout period).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

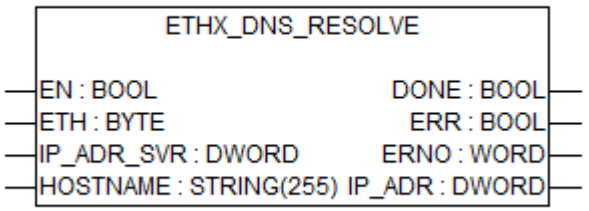
Output LEV_DS (level in data sets) displays the filling level (in data records) of the transmit buffer. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
Send (EN := Send_EN,
     SLOT := Send_SLOT,
    INDEX := Send_INDEX,
     IP_ADR := Send_IP_ADR,
     PORT := Send_PORT,
     DATA := ADR(Send_DATA),
     LEN := Send_LEN);

Send_DONE := Send.DONE;
Send_ERR := Send.ERR;
Send_ERNO := Send.ERNO;
Send_LEV_BY := Send.LEV_BY;
Send_LEV_DS := Send.LEV_DS;
```

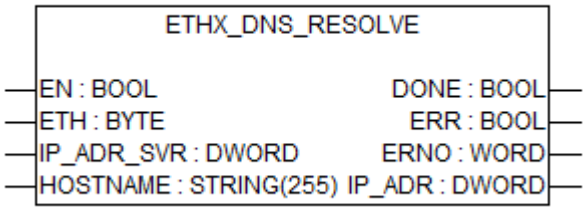
ETHx_DNS_RESOLVE



The function block ETHx_DNS_RESOLVE returns an IP address of a user-specified hostname via a given DNS server. If no Ethernet device is installed at ETH, the corresponding error is generated and output at ERR and ERNO.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

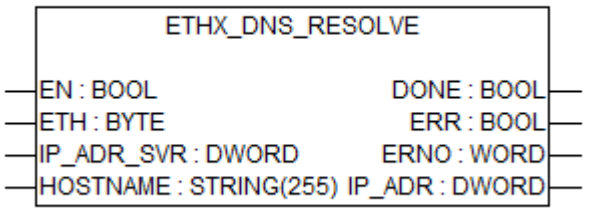
*) The Communication Modules are serially numbered from right to left, starting with module number 1.

HOSTNAME

Data type	Default value	Range	Unit
STRING	Empty string	-	-

At input HOSTNAME, the domain of the host to be resolved to an IP address is specified. This name is sent ot the DNS server, which answers with an IP address.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IP_ADR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

Output IP_ADR displays the resolved IP address of the hostname provided by the input HOST-NAME. Each byte in IP_ADR represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

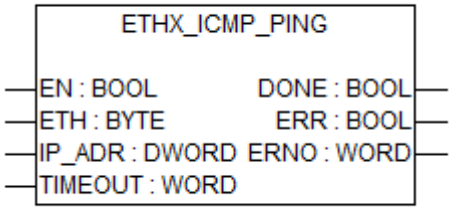
IP_ADR (dec) 3222214658

Function call in ST

```
DNSResolve    (EN          := DNSResolve_EN,
               ETH         := DNSResolve_ETH,
               IP_ADR_SVR  := DNSResolve_IP_ADR_SVR,
               HOSTNAME    := DNSResolve_HOSTNAME);
```

```
DNSResolve_DONE   := DnsResolve.DONE;
DNSResolve_ERR    := DnsResolve.ERR;
DNSResolve_ERNO   := DnsResolve.ERNO;
DNSResolve_IP_ADR := DnsResolve.IP_ADR;
```

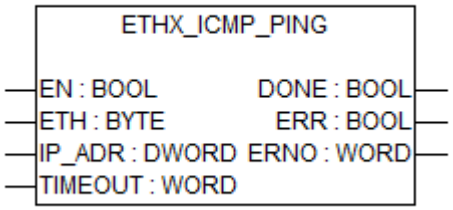
ETHx_ICMP_PING



The function block ETHx_ICMP_PING returns whether a given host in the network answers to a ping. If no Ethernet device is installed at ETH, the corresponding error is generated and output at ERR and ERNO.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

IP_ADR

Data type	Default value	Range	Unit
DWORD	-	-	-

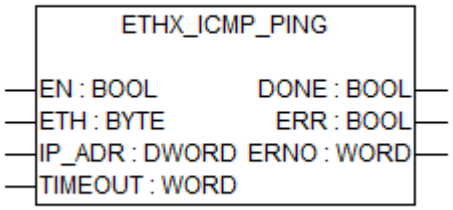
At input IP_ADR, the IP address of the host to be pinged is specified.

TIMEOUT

Data type	Default value	Range	Unit
WORD	5.000	-	ms

At input TIMEOUT, the time to wait for an ICMP echo reply from the host is specified. After this time has run out, an error will be set as output.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

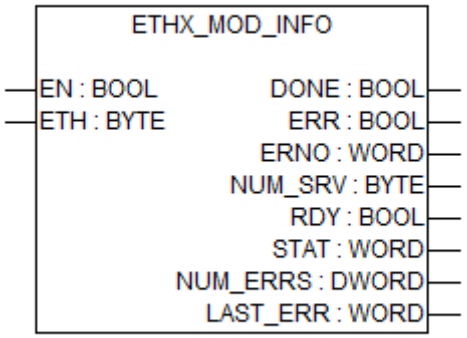
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
ICMPPing (EN         := ICMPPing_EN,
          ETH        := ICMPPing_ETH,
          IP_ADR     := ICMPPing_IP_ADR
          TIMEOUT    := ICMPPing_TIMEOUT)

ICMPPing_DONE  := ICMPPing.DONE;
ICMPPing_ERR   := ICMPPing.ERR;
ICMPPing_ERNO  := ICMPPing.ERNO;
```

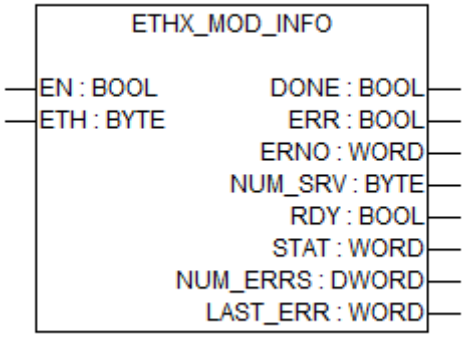
ETHx_MOD_INFO



The function block ETHx_MOD_INFO reads the status information of the open Modbus on TCP/IP processing. It can be used for pure server (slave) or client (master) operation of the controller as well as for mixed operation.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

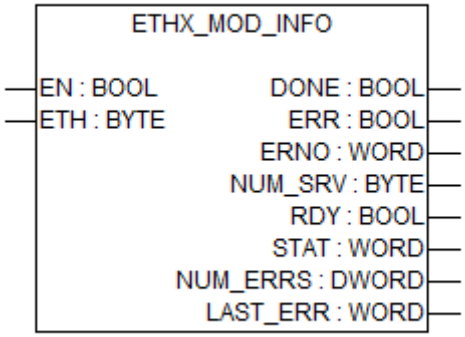
ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_SRV

Data type	Default value	Range	Unit
BYTE	-	-	-

NUM_SRV (number of servers) output indicates the number of parallel server channels configured with Automation Builder software. NUM_SRV is only valid if DONE = TRUE and ERR = FALSE.

RDY

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

RDY (ready) output indicates the readiness for operation of the open Modbus on TCP/IP processing. If RDY = TRUE, the server processing as well as the client processing are ready for operation. RDY is only valid if DONE = TRUE and ERR = FALSE.

STAT

Output STAT displays the current operating state of the open Modbus on TCP/IP processing. STAT is only valid if DONE = TRUE and ERR = FALSE.

STAT		Description
Decimal	**Hexadecimal**	
0	00	Processing not initialized
1	01	Processing initialized and running
2	02	Processing initialization in progress
3	03	Initialization error
4	04	Processing initialized and waiting for TCP task

NUM_ERRS

Data type	Default value	Range	Unit
DWORD	-	-	-

The total number of errors detected by the Communication Module since last power up or reset.

LAST_ERR

Data type	Default value	Range	Unit
WORD	-	-	-

LAST_ERR outputs the last error occurred on the Communication Module. The error message encoding at output LAST_ERR applies to all Ethernet function blocks and is explained at the beginning of the library descriptions.

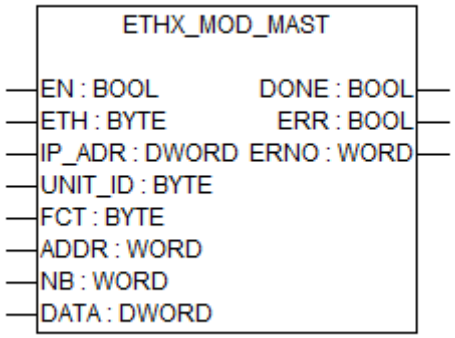
The outputs gives the value which has been received directly from the Communication Module. To find this error code inside the list of error messages, the value 0x6000 has to be added to the error value.

Function call in ST

```
MODInfo (EN  := MODInfo_EN,
         ETH := MODInfo_ETH);

MODInfo_DONE     := MODInfo.DONE;
MODInfo_ERR      := MODInfo.ERR;
MODInfo_ERNO     := MODInfo.ERNO;
MODInfo_NUM_SRV  := MODInfo.NUM_SRV;
MODInfo_RDY      := MODInfo.RDY;
MODInfo_STAT     := MODInfo.STAT;
MODInfo_NUM_ERRS := MODInfo.NUM_ERRS;
MODInfo_LAST_ERR := MODInfo.LAST_ERR;
```

ETHx_MOD_MAST



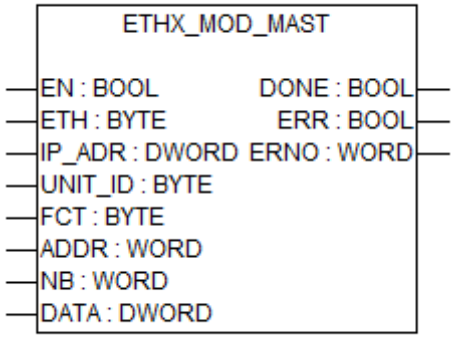
The ETHx_MOD_MAST function block implements the open Modbus on TCP/IP client functionality for the Ethernet interface specified at input ETH. Depending on the configuration of the Communication Module, several ETHx_MOD_MAST function blocks can be used in parallel. Prior to the use of ETHx_MOD_MAST for an Ethernet interface it has to be configured accordingly using Automation Builder.

With each FALSE > TRUE edge at input EN, the function block ETHx_MOD_MAST reads the values at the inputs, generates a telegram according to the inputs and then sends this telegram to the slave.

Only a single instance per slave can be used with this function block!

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

IP_ADR

Data type	Default value	Range	Unit
DWORD	-	-	-

At IP_ADR, the IP address of the server has to be specified to which the telegram should be sent. Each byte in IP_ADR represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

IP_ADR (dec) 3222214658

UNIT_ID

Data type	Default value	Range	Unit
BYTE	-	-	-

At input UNIT_ID, the address of the Modbus slave must be specified which is connected serially to the Modbus server defined by IP_ADR. If no further slaves are connected, this input is not used.

FCT

Data type	Default value	Range	Unit
BYTE	-	-	-

The function code of the request telegram is specified at input FCT.

01 or 02	Read n bits
03 or 04	Read n words
05	Write one bit (encoded in one word)
06	Write one word

07	Read 8 bit
15	Write n bits (encoded in one byte)
16	Write n words
22	Mask write
23	Read/write multiple words in one telegram

The max. telegram length for onboard Ethernet CPUs with function code 3/4 is 96 words.

The max. telegram length for onboard Ethernet CPUs with function code 15 is 1536 bits.

ADDR

Data type	Default value	Range	Unit
WORD	-	-	-

The operand/register address in the slave from which data should be read or written is specified at input ADDR.

The access to operands of AC500 devices in Modbus slave mode is defined via the Modbus cross-reference list. Only operands that are listed in the cross-reference list may be used (↳ *Chapter 1.6.4.1.8 “Communication with Modbus RTU” on page 5467*).

Only operands that are listed in the Modbus address list may be used. When accessing other devices, ADDR is freely selectable. The valid ranges have to be gathered from the corresponding device description.

NB

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At input NB (number), the number of data to be written or read is specified. The unit of NB depends on the selected function. For bit accesses the number of bits, for word and double word accesses the number of words is specified at NB. The following restrictions apply to the length:

FCT		NBmax	
Dec	**Hex**	**Serial**	**Modbus on TCP/IP**
01 or 02	01 or 02	2000 bits	255 bits (up to firmware version V01.33) 1800 bits (from firmware version V01.41) 1536 bits (PM573/PM583 only)
03 or 04	03 or 04	125 words / 62 double words	125 words / 62 double words
05	05	1 bit	1 bit
06	06	1 word	1 word
07	07	8 bits	8 bits

FCT		NBmax	
Dec	**Hex**	**Serial**	**Modbus on TCP/IP**
15	0F	1968 bits	255 bits (up to firmware version V01.33) 1800 bits (from firmware version V01.41) 1536 bits (PM573/PM583 only)
16	10	123 words / 61 double words	123 words / 61 double words
22	16	Write: 1 word	Write: 1 word
23	17	Read: 125 words / 62 double words Write: 123 words / 61 double words	Read: 125 words / 62 double words Write: 123 words / 61 double words

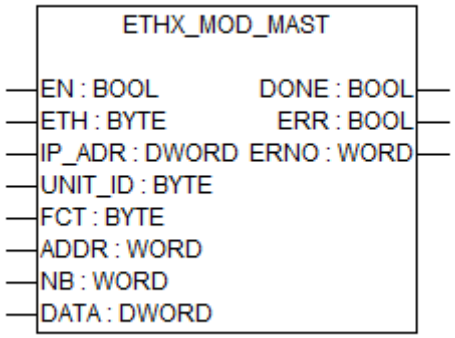
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

At input DATA, the address of the first operand in the master is specified, from which data are copied/written to the slave or to which the data read by the slave should be stored. For this purpose it is necessary that the operand type (e.g. bit) matches the selected function (e.g. FCT 1, read n bits).

If using Modbus function codes 22 or 23, the according data structures COM_MOD_FCT22_TYPE *Chapter 1.5.4.22.2.1 “COM_MOD_FCT22_TYPE” on page 1702* or COM_MOD_FCT23_TYPE *Chapter 1.5.4.22.2.2 “COM_MOD_FCT23_TYPE” on page 1703* must be defined and applied to DATA.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	-	-

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR

Data type	Default value	Range	Unit
BOOL	-	-	-

Output ERR indicates whether an error occurred during Function Block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

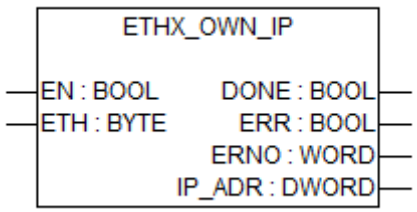
Function call in ST

```
MODMast (EN       := MODMast_EN,
         ETH      := MODMast_ETH,
         IP_ADR   := MODMast_IP_ADR,
         UNIT_ID  := MODMast_UNIT_ID,
         FCT      := MODMast_FCT,
         ADDR     := MODMast_ADDR,
         NB       := MODMast_NB,
         DATA     := ADR(ModMast_DATA));

MODMast_DONE := MODMast.DONE;
MODMast_ERR  := MODMast.ERR;

MODMast_ERNO := MODMast.ERNO;
```

ETHx_OWN_IP

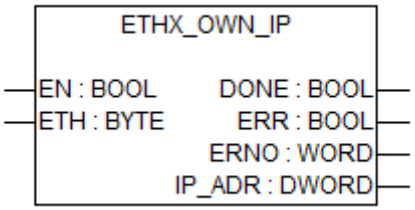


The function block ETHx_OWN_IP outputs the IP address of the Communication Module installed at input ETH.

Prior to commissioning an Ethernet interface, it has to be configured using Automation Builder software. The IP address is one of the parameters of an Ethernet interface. Using the function block ETHx_OWN_IP, the configured IP address of the device at input ETH can be read. If no Ethernet device is installed at ETH, the corresponding error is generated and output at ERR and ERNO.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

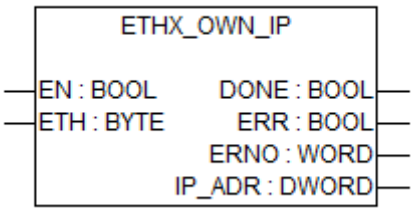
ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IP_ADR

Data type	Default value	Range	Unit
DWORD	-	-	-

Output IP_ADR displays the own IP address of the Communication Module. Each byte in IP_ADR represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

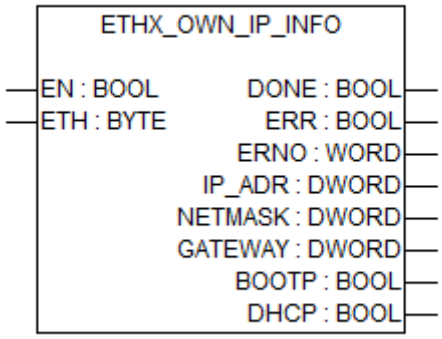
IP_ADR (dec) 3222214658

Function call in ST

```
OwnIp(EN  := OwnIp_EN,
      ETH := OwnIp_ETH);

OwnIp_DONE   := OwnIp.DONE;
OwnIp_ERR    := OwnIp.ERR;
OwnIp_ERNO   := OwnIp.ERNO;
OwnIp_IP_ADR := OwnIp.IP_ADR;
```

ETHx_OWN_IP_INFO

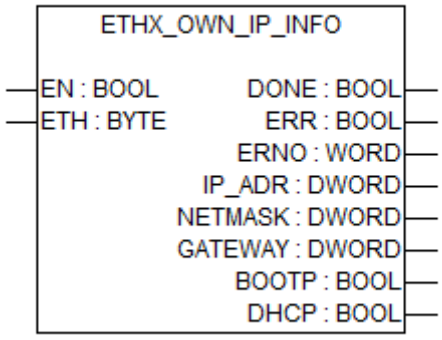


The function block ETHx_OWN_IP_INFO outputs the IP setup of the Communication Module installed at interface specified by input ETH.

Prior to commissioning an Ethernet interface, it has to be configured using Automation Builder software. Using the function block ETHx_OWN_IP_INFO, information about the IP setup of the device at ETH can be read. If no Ethernet interface is installed at input ETH, the corresponding error is generated and output at ERR and ERNO.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

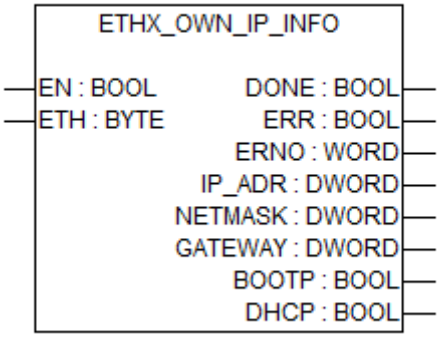
ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IP_ADR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

IP_ADR displays the IP address which should be set at the CPU / Communication Module. Each byte in IP_ADR represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

IP_ADR (dec) 3222214658

NETMASK

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

Output NETMASK displays the own netmask. Each byte in NETMASK represents one octet of the address.

Example

Netmask 255.255.255.0

NETMASK (hex) 16#FFFFFF00

NETMASK (dec) 4294967040

GATEWAY

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

Output GATEWAY displays the IP address of the gateway. Each byte in GATEWAY represents one octet of the address.

Example

IP address 192.168.0.1

IP_ADR (hex) 16#C0A80001

IP_ADR (dec) 3232235521

BOOTP

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output BOOTP indicates whether the BOOTP service is activated for the Communication Module.

DHCP

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

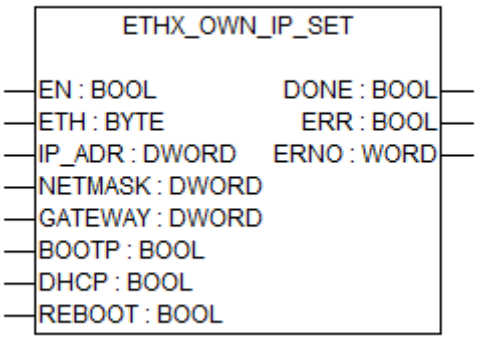
Output DHCP indicates whether the DHCP service is activated for the Communication Module.

Function call in ST

```
OwnIPInfo(EN  := OwnIPInfo_EN,
          ETH := OwnIPInfo_ETH);

OwnIPInfo_DONE    := OwnIPInfo.DONE;
OwnIPInfo_ERR     := OwnIPInfo.ERR;
OwnIPInfo_ERNO    := OwnIPInfo.ERNO;
OwnIPInfo_IP_ADR  := OwnIPInfo.IP_ADR;
OwnIPInfo_NETMASK := OwnIPInfo.NETMASK;
OwnIPInfo_GATEWAY := OwnIPInfo.GATEWAY;
OwnIPInfo_BOOTP   := OwnIPInfo.BOOTP;
OwnIPInfo_DHCP    := OwnIPInfo.DHCP;
```

ETHx_OWN_IP_SET



Function block ETH_OWN_IP_SET is used to set

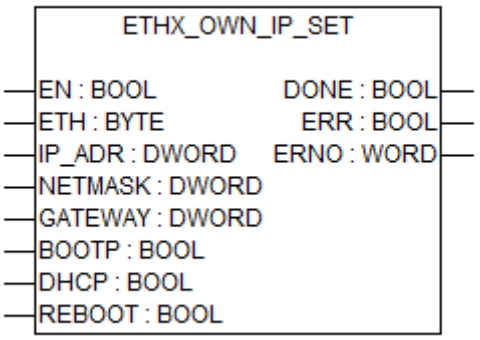
- IP address
- Subnet mask
- Gateway and
- some other parameters

at the Ethernet interface installed at input ETH.

The new IP configuration data will be available after the next reboot of the CPU / Communication module. Use input REBOOT=TRUE to restart the CPU / Communication Module immediately after changing the IP configuration data.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

IP_ADR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

IP_ADR displays the IP address which should be set at the CPU / Communication Module. Each byte in IP_ADR represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

IP_ADR (dec) 3222214658

NETMASK

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At input NETMASK, the subnet mask which should be set at the CPU / Communication Module is specified. Each byte in NETMASK represents one octet of the address.

Example

Netmask 255.255.255.0

NETMASK (hex) 16#FFFFFF00

NETMASK (dec) 4294967040

GATEWAY

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At input GATEWAY, the default gateway which should be set at the CPU / Communication Module is specified. Each byte in GATEWAY represents one octet of the address.

Example

IP address 192.168.0.1

IP_ADR (hex) 16#C0A80001

IP_ADR (dec) 3232235521

GATEWAY

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

Output GATEWAY displays the IP address of the gateway. Each byte in GATEWAY represents one octet of the address.

Example

IP address 192.168.0.1

IP_ADR (hex) 16#C0A80001

IP_ADR (dec) 3232235521

BOOTP

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output BOOTP indicates whether the BOOTP service is activated for the Communication Module.

DHCP

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

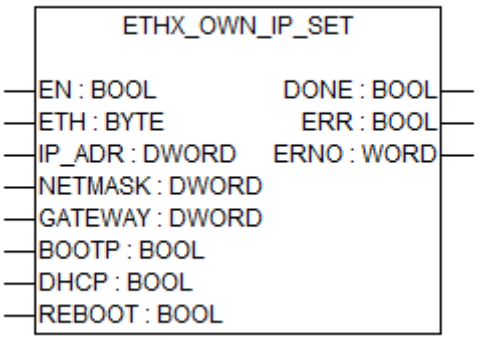
Output DHCP indicates whether the DHCP service is activated for the Communication Module.

REBOOT

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

A TRUE signal at input REBOOT restarts the CPU / Communication Module after changing the IP settings.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

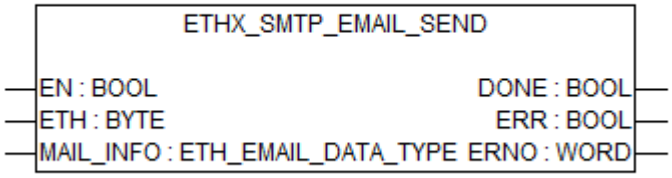
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
OwnIPSet (EN      := OwnIPSet_EN,
          ETH     := OwnIPSet_ETH,
          IP_ADR  := OwnIPSet_IP_ADR,
          NETMASK := OwnIPSet_NETMASK,
          GATEWAY := OwnIPSet_GATEWAY,
          BOOTP   := OwnIPSet_BOOTP,
          DHCP    := OwnIPSet_DHCP,
          REBOOT  := OwnIPSet_REBOOT);

OwnIPSet_DONE := OwnIPSet.DONE;
OwnIPSet_ERR  := OwnIPSet.ERR;
OwnIPSet_ERNO := OwnIPSet.ERNO;
```

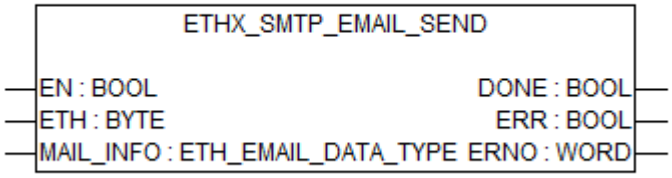
ETHx_SMTP_EMAIL_SEND



The function block ETHx_SMTP_EMAIL_SEND uses a user-specified SMTP server to deliver an email to given mailboxes.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

MAIL_INFO

Data type: ETH_EMAIL_DATA_TYPE (slot)

Input MAIL_INFO provides all necessary data to send an email via the data structure ETH_EMAIL_DATA_TYPE.

ETH BYTE (Ethernet index number)

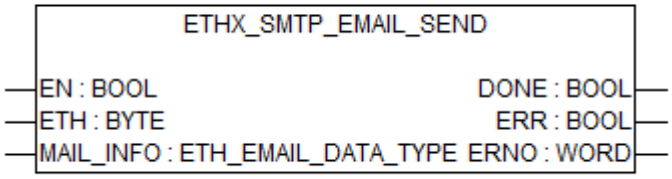
At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)

21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

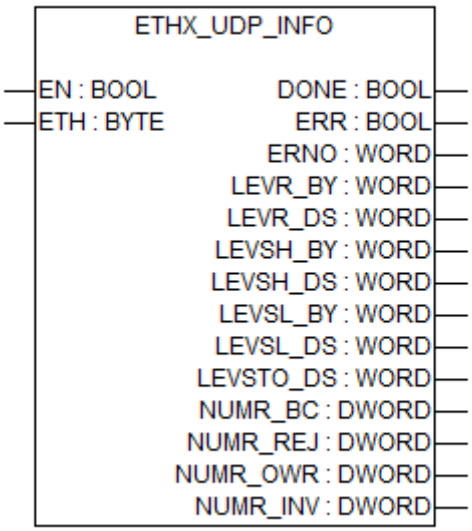
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
SMTPEmailSend (EN        := SMTPEmailSend_EN,
               ETH       := SMTPEmailSend_ETH,
               MAIL_INFO := SMTPEmailSend_MAIL_INFO)

SMTPEmailSend_DONE  := SMTPEmailSend.DONE;
SMTPEmailSend_ERR   := SMTPEmailSend.ERR;
SMTPEmailSend_ERNO  := SMTPEmailSend.ERNO;
```

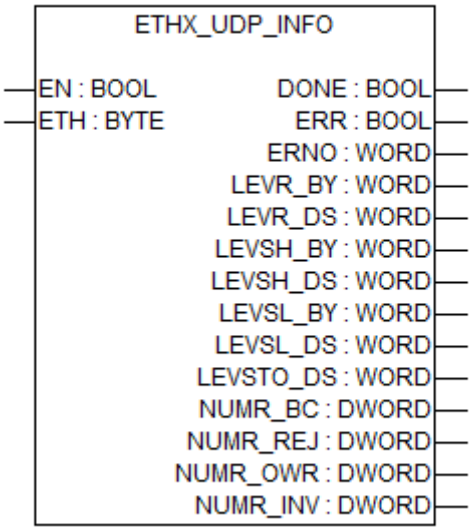
ETHx_UDP_INFO



The function block ETHx_UDP_INFO reads the status information of the UDP/IP processing.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

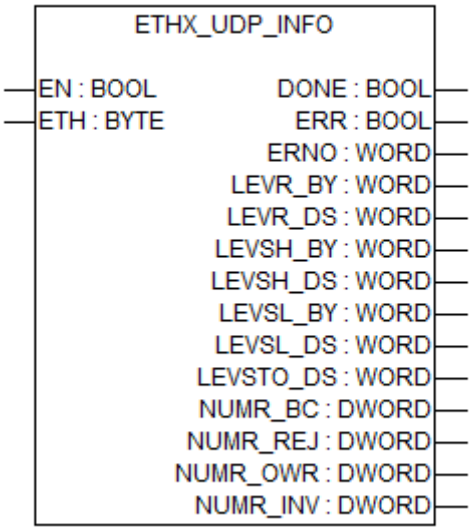
ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEVR_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVR_BY displays the filling level of the receive buffer in bytes.

LEVR_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVR_DS displays the filling level of the receive buffer in data sets.

LEVSH_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSH_BY displays the filling level of the high priority send buffer in bytes.

LEVSH_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSH_DS displays the filling level of the high priority send buffer in data sets.

LEVSL_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSL_BY displays the filling level of the low priority send buffer in bytes.

LEVSL_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSL_DS displays the filling level of the low priority send buffer in data sets.

LEVSTO_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVSTO_DS displays the filling level of the timeout buffer in data sets.

NUMR_BC

Data type	Default value	Range	Unit
DWORD	-	-	-

NUMR_BC outputs the number of broadcasts (data packets to all stations) which were received by this station.

NUMR_REJ

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At output NUMR_REJ (number of receipts rejected), the number of data sets is displayed which were discarded during reception due to a full receive buffer. Data sets are only discarded if this is set accordingly within the configuration of the UDP/IP processing.

NUMR_INV

Data type	Default value	Range	Unit
DWORD	-	-	-

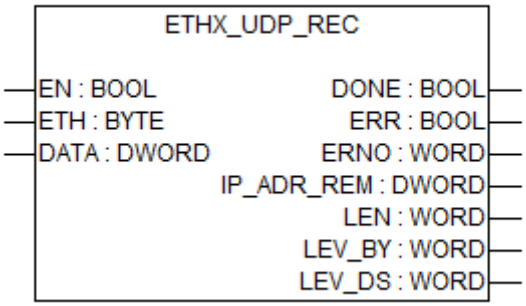
NUMR_INV outputs the number of telegrams which were received faulty by this station.

Function call in ST

```
UDPInfo (EN  := UDPInfo_EN,
         ETH := UDPInfo_ETH)

UDPInfo_DONE      := UDPInfo.DONE;
UDPInfo_ERR       := UDPInfo.ERR;
UDPInfo_ERNO      := UDPInfo.ERNO;
UDPInfo_LEVR_BY   := UDPInfo.LEVR_BY;
UDPInfo_LEVR_DS   := UDPInfo.LEVR_DS;
UDPInfo_LEVSH_BY  := UDPInfo.LEVSH_BY;
UDPInfo_LEVSH_DS  := UDPInfo.LEVSH_DS;
UDPInfo_LEVSL_BY  := UDPInfo.LEVSL_BY;
UDPInfo_LEVSL_DS  := UDPInfo.LEVSL_DS;
UDPInfo_LEVSTO_DS := UDPInfo.LEVSTO_DS;
UDPInfo_NUMR_BC   := UDPInfo.NUMR_BC;
UDPInfo_NUMR_REJ  := UDPInfo.NUMR_REJ;
UDPInfo_NUMR_OWR  := UDPInfo.NUMR_OWR;
UDPInfo_NUMR_INV  := UDPInfo.NUMR_INV;
```

ETHx_UDP_REC



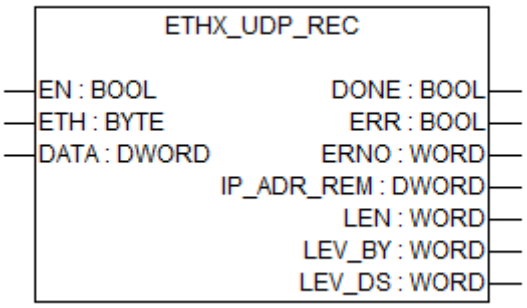
The ETHx_UDP_REC function block reads the next data record from the UDP/IP receive buffer and stores the user data to the configured memory area.

The operating system reads the received UDP/IP data packets from the Ethernet interface and stores them in the receive buffer. The buffer size is determined using the PLC configuration. The data packets are stored with variable lengths. For example, a data packet consisting of 16 bytes of user data occupies exactly 22 bytes in the receive buffer (4 bytes for the IP address of the sending device, 2 bytes for the packet length and 16 bytes of user data).

Using the ETHx_UDP_REC function block, exactly one data packet is read. The user data are stored in the configured memory area (DATA). The address of the sending device and the data packet length are supplied at the outputs IP_ADR_REM and LEN. DONE = TRUE and ERR = FALSE indicate that the reading process was successful. If an error was detected during Function Block processing, the error is additionally indicated at the outputs ERR and ERNO. Furthermore, the function block provides information about the receive buffer filling level displayed in bytes (LEVR_BY) and data records (LEVR_DS).

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

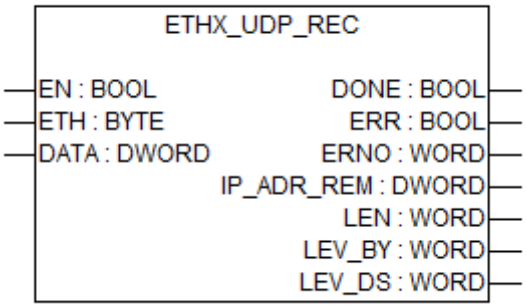
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. The address specified at DATA has to belong to a variable of the type ARRAY or STRUCT.

Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IP_ADR_REM

Data type	Default value	Range	Unit
DWORD	-	-	-

Output IP_ADR_REM (IP address remote) displays the IP address of the sending device which transmitted the received data package. Each byte in IP_ADR_REM represents one octet of the address.

Example	IP address 192.15.24.2 IP_ADR (hex) 16#C00F1802 IP_ADR (dec) 3222214658

LEN

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEN (length) displays the length of the received data package in bytes.

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY displays the filling level of the receive buffer in bytes. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 6 bytes in the receive buffer (4 bytes for the NODE ID of the sending device, 2 bytes for the specification of the length).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

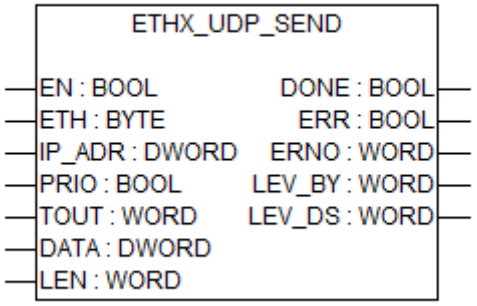
Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
UDPRec (EN   := UDPRec_EN,
        ETH  := UDPRec_ETH,
        DATA := ADR(UDPRec_DATA));

UDPRec_DONE       := UDPRec.DONE;
UDPRec_ERR        := UDPRec.ERR;
UDPRec_ERNO       := UDPRec.ERNO;
UDPRec_IP_ADR_REM := UDPRec.IP_ADR_REM;
UDPRec_LEN        := UDPRec.LEN;
UDPRec_LEVR_BY    := UDPRec.LEV_BY;
UDPRec_LEVR_DS    := UDPRec.LEV_DS;
```

ETHx_UDP_SEND

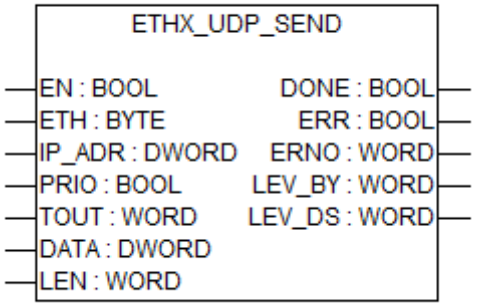


The function block ETHx_UDP_SEND is used to transmit data packets via the UDP/IP protocol of the Ethernet interface. The specified packages are stored in the transmit buffer selected by input PRIO. From there, the operating system hands over the data packets to the Ethernet interface in order to transmit them to the target address specified at input IP_ADR. The transmit buffer size is defined by the PLC configuration. Using input TOUT, the timeout period can be specified. If TOUT <> 0, the UDP/IP data exchange is automatically performed with receive acknowledgement. If TOUT = 0, no acknowledgement is expected. Output DONE indicates that the specified data packet has been stored in the transmit buffer or that an error occurred during Function Block processing. If an error was detected during Function Block processing, the error is additionally indicated at the outputs ERR and ERNO. In case of an error, the data packet has to be transmitted again.

The function block ETHx_UDP_SEND cannot store data packets to the transmit buffer until the Ethernet UDP/IP processing is set in the controller configuration.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

PRIO

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

Input PRIO (priority) is used to specify the transmit priority of the data packet.

The following applies:

If PRIO = FALSE the specified data packet has low priority. Thus, it is stored in the low priority transmit buffer. All outputs refer to this buffer.

If PRIO = TRUE the specified data packet has high priority. Thus, it is stored in the high priority transmit buffer. All outputs refer to this buffer.

TOUT

Data type	Default value	Range	Unit
WORD	-	-	-

Using input TOUT (timeout), the timeout period can be specified. If TOUT <> 0, the UDP/IP data exchange is automatically performed with receive acknowledgement. If a data packet cannot be transmitted within this period (no acknowledge telegram is received), transmission is aborted and the package is lost.

In this case, some distinctive bytes of the data packet (see *Chapter 1.6.5.3.7.1 “Contents of the UDP protocol configuration” on page 6185*) are stored to the timeout buffer and can then be read using the function block ETH_UDP_STO.

If TOUT = 0, no acknowledgement is expected.

The following applies:

TOUT = 0:

Data exchange without receive acknowledgement. No data are written to the timeout buffer.

TOUT <> 0:

Data exchange with receive acknowledgement. Each transmitted data record is acknowledged by the recipient. If no acknowledge telegram is received within the set timeout period (in ms), the data are written to the timeout buffer.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. The address specified at DATA has to belong to a variable of the type ARRAY or STRUCT.

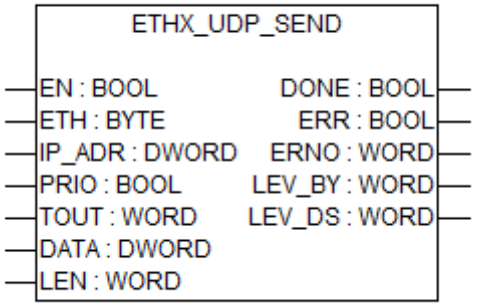
Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

LEN

Data type	Default value	Range	Unit
WORD	-	1...1464	-

At input LEN (length), the number of user data bytes is specified for the specified package.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY (level in bytes) displays the filling level (in bytes) of the transmit buffer. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 8 bytes in the transmit buffer (4 bytes for the IP address of the recipient, 2 bytes for the specification of the length and 2 bytes for the timeout period).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

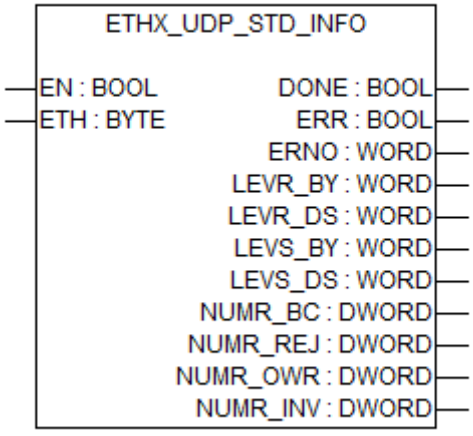
Output LEV_DS (level in data sets) displays the filling level (in data records) of the transmit buffer. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
UDPSend (EN     := UDPSend_EN,
         ETH    := UDPSend_ETH,
         IP_ADR := UDPSend_IP_ADR,
         PRIO   := UDPSend_PRIO,
         TOUT   := UDPSend_TOUT,
         DATA   := ADR(UDPSend_DATA),
         LEN    := UDPSend_LEN);

UDPSend_DONE   := UDPSend.DONE;
UDPSend_ERR    := UDPSend.ERR;
UDPSend_ERNO   := UDPSend.ERNO;
UDPSend_LEV_BY := UDPSend.LEV_BY;
UDPSend_LEV_DS := UDPSend.LEV_DS;
```

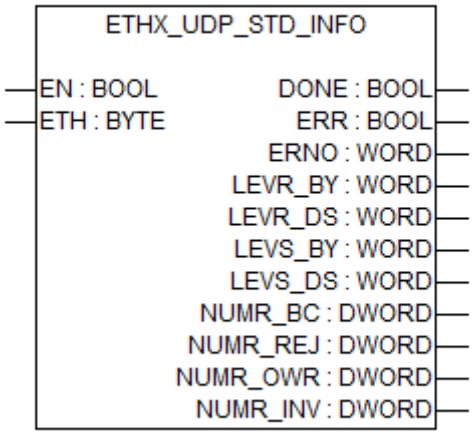
ETHx_UDP_STD_INFO



The function block ETHx_UDP_STD_INFO reads the status information of the UDP/IP processing.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

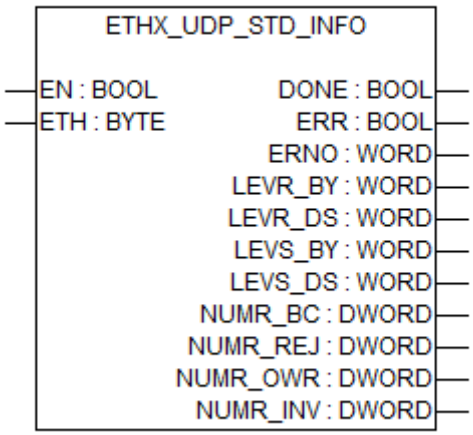
ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEVR_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVR_BY displays the filling level of the receive buffer in bytes.

LEVR_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVR_DS displays the filling level of the receive buffer in data sets.

LEVS_BY

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVS_BY (level of all send buffers in bytes) displays the filling level of all send buffers in bytes.

LEVS_DS

Data type	Default value	Range	Unit
WORD	-	-	-

As long as EN = TRUE, output LEVS_DS (level of all send buffers in data sets) displays the filling level of all send buffers in data sets.

NUMR_BC

Data type	Default value	Range	Unit
DWORD	-	-	-

NUMR_BC outputs the number of broadcasts (data packets to all stations) which were received by this station.

NUMR_REJ

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At output NUMR_REJ (number of receipts rejected), the number of data sets is displayed which were discarded during reception due to a full receive buffer. Data sets are only discarded if this is set accordingly within the configuration of the UDP/IP processing.

NUMR_OWR

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At output NUMR_OWR (number of receipts overwritten), the number of data sets is displayed which were overwritten during reception due to a full receive buffer. Data sets are only overwritten in the receive buffer, if this is set accordingly within the configuration of the UDP/IP processing.

NUMR_INV

Data type	Default value	Range	Unit
DWORD	-	-	-

NUMR_INV outputs the number of telegrams which were received faulty by this station.

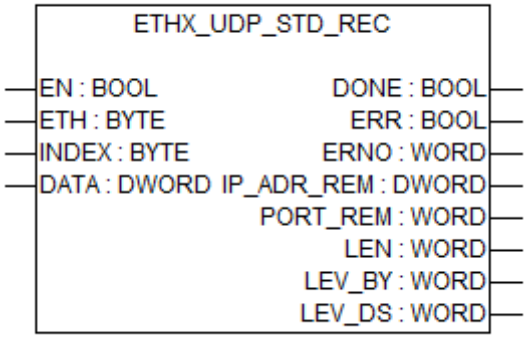
Function call in ST

```
UDPStd Info (EN  := UDPStdInfo_EN,
             ETH := UDPStdInfo_ETH);

UDPStdInfo_DONE     := UDPStdInfo.DONE;
UDPStdInfo_ERR      := UDPStdInfo.ERR;
UDPStdInfo_ERNO     := UDPStdInfo.ERNO;
UDPStdInfo_LEVR_BY  := UDPStdInfo.LEVR_BY;
UDPStdInfo_LEVR_DS  := UDPStdInfo.LEVR_DS;
UDPStdInfo_LEVS_BY  := UDPStdInfo.LEVS_BY;
```

```
UDPStdInfo_LEVS_DS  := UDPStdInfo.LEVS_DS;
UDPStdInfo_NUMR_BC  := UDPStdInfo.NUMR_BC;
UDPStdInfo_NUMR_REJ := UDPStdInfo.NUMR_REJ;
UDPStdInfo_NUMR_OWR := UDPStdInfo.NUMR_OWR;
UDPStdInfo_NUMR_INV := UDPStdInfo.NUMR_INV;
```

ETHx_UDP_STD_REC



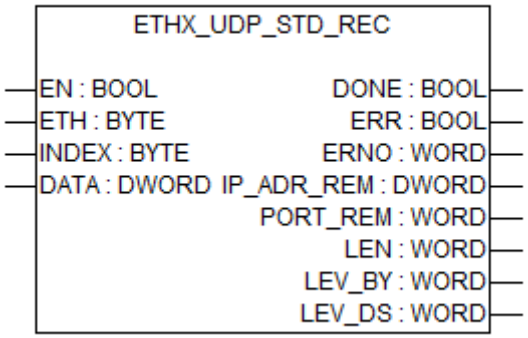
The ETHx_UDP_STD_REC function block reads the next data record from the UDP/IP receive buffer and stores the user data to the configured memory area.

The operating system reads the received UDP/IP data packets from the Ethernet Communication Module and stores them in the receive buffer. The buffer size is determined using the PLC configuration. The data packets are stored with variable lengths. For example, a data packet consisting of 16 bytes of user data occupies exactly 22 bytes in the receive buffer (4 bytes for the IP address of the sending device, 2 bytes for the packet length and 16 bytes of user data).

Using the ETHx_UDP_STD_REC function block, exactly one data packet is read. The user data are stored in the configured memory area (DATA). The address of the sending device and the data packet length are supplied at the outputs IP_ADR_REM, PORT_REM and LEN. DONE = TRUE and ERR = FALSE indicate that the reading process was successful. If an error was detected during Function Block processing, the error is indicated at the outputs ERR and ERNO. Furthermore, the function block provides information about the receive buffer filling level displayed in bytes (LEV_BY) and data records (LEV_DS).

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

INDEX

Data type	Default value	Range	Unit
BYTE	-	-	-

Index of the standard UDP/IP connection corresponding to the PLC configuration, starting with 0. The function block only works on the connection that was selected by this input, and with the parameters set in the PLC configuration, e.g. port, buffer size, behavior in case of buffer overflow etc.

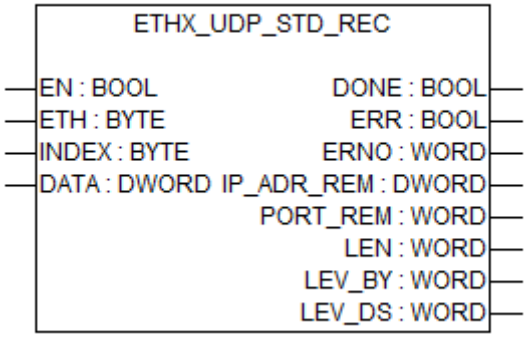
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. The address specified at DATA has to belong to a variable of the type ARRAY or STRUCT.

> *Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.*

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IP_ADR_REM

Data type	Default value	Range	Unit
DWORD	-	-	-

Output IP_ADR_REM (IP address remote) displays the IP address of the sending device which transmitted the received data package. Each byte in IP_ADR_REM represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

IP_ADR (dec) 3222214658

PORT_ADR_REM

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PORT_ADR_REM (remote port address) displays the UDP remote port address of the sending device which transmitted the received data package.

LEN

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEN (length) displays the length of the received data package in bytes.

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY displays the filling level of the receive buffer in bytes. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 6 bytes in the receive buffer (4 bytes for the NODE ID of the sending device, 2 bytes for the specification of the length).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

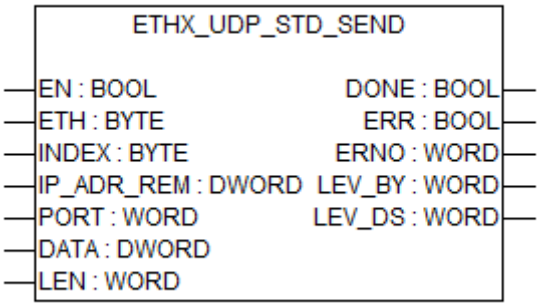
Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
UDPStdRec (EN    := UDPStdRec_EN,
           ETH   := UDPStdRec_ETH,
           INDEX := UDPStdRec_INDEX,
           DATA  := ADR(UDPStdRec_DATA));

UDPStdRec_DONE       := UDPStdRec.DONE;
UDPStdRec_ERR        := UDPStdRec.ERR;
UDPStdRec_ERNO       := UDPStdRec.ERNO;
UDPStdRec_IP_ADR_REM := UDPStdRec.IP_ADR_REM;
UDPStdRec_PORT_REM   := UDPStdRec.PORT_REM;
UDPStdRec_LEN        := UDPStdRec.LEN;
UDPStdRec_LEVR_BY    := UDPStdRec.LEV_BY;
UDPStdRec_LEVR_DS    := UDPStdRec.LEV_DS;
```

ETHx_UDP_STD_SEND

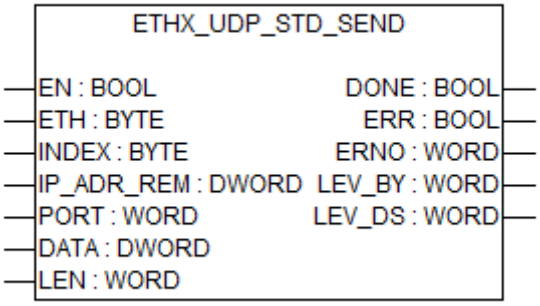


The function block ETHx_UDP_STD_SEND is used to transmit data packets via the standard UDP/IP protocol of the Ethernet interface. The specified packages are stored in the transmit buffer. From there, the operating system hands over the data packets to the Ethernet interface in order to transmit them to the target address specified at input IP_ADR_REM. The transmit buffer size is defined by the PLC configuration. Output DONE indicates that the specified data packet has been stored in the transmit buffer or that an error occurred during function block processing. If an error was detected during function block processing, the error is additionally indicated at the outputs ERR and ERNO. In case of an error, the data packet has to be transmitted again.

The function block ETHx_UDP_STD_SEND cannot store data packets to the transmit buffer until the Ethernet UDP/IP processing is set in the controller configuration (see also the PLC configuration of the standard UDP/IP processing).

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

INDEX

Data type	Default value	Range	Unit
BYTE	-	-	-

Index of the standard UDP/IP connection corresponding to the PLC configuration, starting with 0. The function block only works on the connection that was selected by this input, and with the parameters set in the PLC configuration, e.g. port, buffer size, behavior in case of buffer overflow etc.

IP_ADR_REM

Data type	Default value	Range	Unit
DWORD	-	-	-

At this input, the IP address of the recipient is specified. Each byte in IP_ADR_REM (IP address remote) represents one octet of the address.

Example

IP address 192.15.24.2

IP_ADR (hex) 16#C00F1802

IP_ADR (dec) 3222214658

PORT

Data type	Default value	Range	Unit
WORD	-	-	-

The target port of the receiver is specified here (port to send to).

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. The address specified at DATA has to belong to a variable of the type ARRAY or STRUCT.

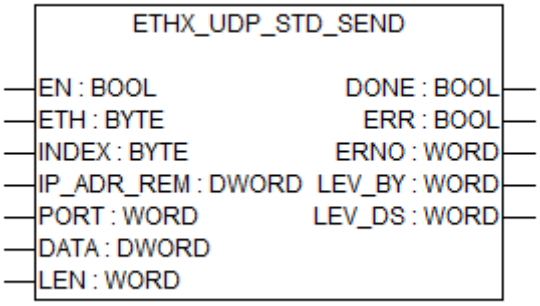
> *Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.*

LEN

Data type	Default value	Range	Unit
WORD	-	1...1464	-

At input LEN (length), the number of user data bytes is specified for the specified package.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEV_BY

Data type	Default value	Range	Unit
WORD	-	-	-

Output LEV_BY (level in bytes) displays the filling level (in bytes) of the transmit buffer. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

One data packet occupies output LEN + 8 bytes in the transmit buffer (4 bytes for the IP address of the recipient, 2 bytes for the specification of the length and 2 bytes for the timeout period).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

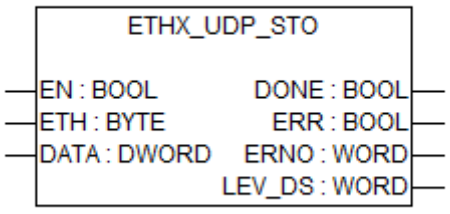
Output LEV_DS (level in data sets) displays the filling level (in data records) of the transmit buffer. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
UDPStdSend (EN     := UDPStdSend_EN,
            ETH    := UDPStdSend_ETH,
            INDEX  := UDPStdSend_INDEX,
            IP_ADR := UDPStdSend_IP_ADR,
         PORT   := UDPStdSend_PORT,
            DATA   := ADR(UDPStdSend_DATA),
            LEN    := UDPStdSend_LEN);

UDPStdSend_DONE   := UDPStdSend.DONE;
UDPStdSend_ERR    := UDPStdSend.ERR;
UDPStdSend_ERNO   := UDPStdSend.ERNO;
UDPStdSend_LEV_BY := UDPStdSend.LEV_BY;
```

ETHx_UDP_STO



The ETHx_UDP_STO function block reads lost data packets from the timeout data buffer and stores the user data to the specified memory area.

During the transmission of a data packet, the success of the transmission is monitored by an adjustable timeout period. When this time is exceeded, distinctive information of the data packet are stored in the timeout buffer.

These are:

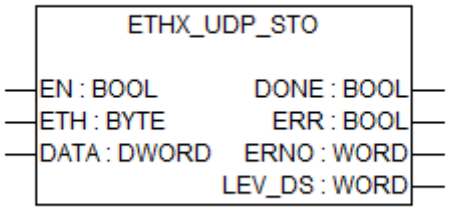
- the IP address of the receiver (4 bytes)
- header data of the data set (the number is specified with the controller configuration of the UDP/IP processing).

The buffer length can as well be set using the controller configuration of the UDP/IP processing. The buffer is constructed as a circular buffer (FIFO). If the buffer is full, the oldest entry in the buffer is overwritten. When a rising edge occurs at input EN, the ETHx_UDP_STO function block verifies whether a data packet is stored in the buffer and makes the information mentioned above available for the user (starting at the variable specified at input DATA).

The function block ETHx_UDP_STO cannot be used until the Ethernet UDP/IP processing is set in the controller configuration. Additionally, input TOUT of the transmit function block ETHx_UDP_SEND must be <> 0.

Available as of runtime system:	V2.4
Included in library:	Ethernet_AC500_V10.lib
Type	Function block with historical values

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

ETH BYTE (Ethernet index number)

At input ETH, the Ethernet index number is specified. The assignment is as follows:

1	Ethernet interface at onboard Ethernet 1
2	Ethernet interface at onboard Ethernet 2
11	Ethernet interface at Communication Module slot 1 *)
21	Ethernet interface at Communication Module slot 2 *)
31	Ethernet interface at Communication Module slot 3 *)
41	Ethernet interface at Communication Module slot 4 *)
51	Ethernet interface at Communication Module slot 5 *)
61	Ethernet interface at Communication Module slot 6 *)

*) The Communication Modules are serially numbered from right to left, starting with module number 1.

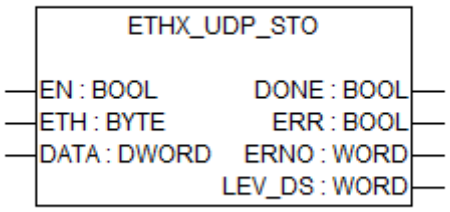
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable to which the user data shall be copied. The address specified at DATA has to belong to a variable of the type ARRAY or STRUCT.

Set the variable size to the maximum expected amount of data in order to avoid overlapping of memory areas.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

LEV_DS

Data type	Default value	Range	Unit
WORD	-	-	-

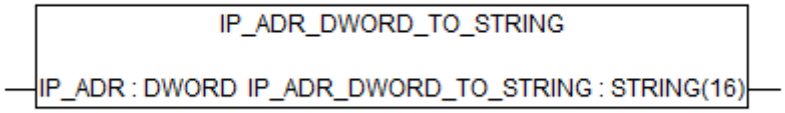
Output LEV_DS (level in data sets) displays the filling level of the receive buffer in data records. The displayed value is updated as long as EN is TRUE and applies to the input values read with the rising edge at input EN.

Function call in ST

```
UDPStdSto (EN   := UDPStdSto_EN,
           ETH  := UDPStdSto_ETH,
           DATA := ADR(UDPStdSto_DATA));

UDPStdSto_DONE   := UDPStdSto.DONE;
UDPStdSto_ERR    := UDPStdSto.ERR;
UDPStdSto_ERNO   := UDPStdSto.ERNO;
UDPStdSto_LEV_DS := UDPStdSto.LEV_DS;
```

IP_ADR_DWORD_TO_STRING



The function block IP_ADR_DWORD_TO_STRING converts an IP address given in the DWORD format into an IP address in the STRING format.

The IP address of an Ethernet device can be represented in different ways. One of the best known formats of an IP address is the STRING format, composed of four numbers between 0 and 255, separated by dots (e.g. 192.15.24.2). The function block IP_ADR_DWORD_TO_STRING converts an IP address given in the DWORD format into an IP address in the STRING format.

Available as of runtime system:	V1.0
Included in library:	Ethernet_AC500_V10.lib
Type	Function

Input description

IP_ADR

Data type	Default value	Range	Unit
DWORD	-	-	-

At input IP_ADR, the IP address of the host to be pinged is specified.

Output description

STRING(16) The output of the function block IP_ADR_DWORD_TO_STRING outputs the converted IP address in STRING(16) format.

Example: The following value is applied at function block input IP_ADR:

IP_ADR_WORD: (hex) 16#C00F1802 or

The converted value is displayed at the function block output:

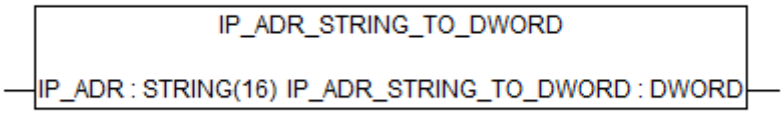
IP_ADR_WORD: (dec) 3222214658

IP_ADR_STRING: '192.15.24.2'

Function call in ST

```
IP_ADR_STRING := IP_ADR_DWORD_TO_STRING(IP_ADR_DWORD);
```

IP_ADR_STRING_TO_DWORD



The function block IP_ADR_STRING_TO_DWORD converts an IP address given in the STRING format into an IP address in the DWORD format.

The IP address of an Ethernet device can be represented in different ways. One of the best known formats of an IP address is the STRING format, composed of four numbers between 0 and 255, separated by dots (e.g. 192.15.24.2). The function block IP_ADR_STRING_TO_DWORD converts an IP address given in the STRING format into an IP address in the DWORD format.

Available as of runtime system:	V1.0
Included in library:	Ethernet_AC500_V10.lib
Type	Function

Input description

IP_ADR At input IP_ADR, the IP address in STRING(16) format is specified.

Output description

(Output) The output of the function block IP_ADR_STRING_TO_DWORD outputs the converted IP address in DWORD format.

Example: The following value is applied at function block input IP_ADR:

IP_ADR_STRING: '192.15.24.2'

The converted value is displayed at the function block output:

IP_ADR_WORD: (hex) 16#C00F1802 or

IP_ADR_WORD: (dec) 3222214658

Function call in ST

```
IP_ADR_DWORD := IP_ADR_STRING_TO_DWORD(IP_ADR_STRING);
```

1.5.4.13.2 Structures

ETH_EMAIL_DATA_TYPE

This structure is used to supply the function block ETH_SMTP_EMAIL_SEND with all necessary data to send an email via the SMTP server configured in the PLC.

The addresses and textual content of the email need to be created and defined by the user. Only references (POINTER TO STRING) are used in the structure. The contents of this structure and the memory pointed to may not be changed during operation of the function block ETH_SMTP_EMAIL_SEND.

At least one valid TO address is required for the function block ETH_SMTP_EMAIL_SEND to work. Even if using CC and/or BCC at last one TO address must be defined.

Type and the content need to be created and defined by the user.

Available as of runtime system:	V2.1	Remark:
Included in library:	Ethernet_AC500_V10.lib	

Visible variable	Type	Default value	Description
psTOAddr	POINTER TO STRING(255)	0	Pointer to a string containing TO address(es) separated by semicolon
psCCAddr	POINTER TO STRING(255)	0	Pointer to a string containing CC address(es) separated by semicolon
psBCCAddr	POINTER TO STRING(255)	0	Pointer to a string containing BCC address(es) separated by semicolon
apsBody	ARRAY[0..19] OF POINTER TO STRING(255)	0	Up to 20 pointers containing text lines for the email body
atsFiles	ARRAY[0..9] OF ETH_EMAIL_FILE_REF_TYPE	0	Up to 10 file attachments to the email via the ETH_EMAIL_FILE_REF_TYPE structure
byPrio	BYTE	0	Priority 0=normal, 1=very high, 2=high, 3=normal, 4=low, 5=very low
sSubject	STRING(255)	’’	The subject of the email

ETH_EMAIL_FILE_REF_TYPE

This structure is used to supply the function block ETH_SMTP_EMAIL_SEND with a file attachment. The ETH_EMAIL_DATA_TYPE structure holds an array of 10 ETH_EMAIL_FILE_REF_TYPE structures, so up to 10 files can be attached to each email.

The file name of an attachment can be different from the file name in the PLC's filesystem. The variable psNameInMail only defines the name of the file inside the email, while psFilePath must contain the full path including name of the file to be attached.

Type and the content need to be created and defined by the user.

Available as of runtime system:	V2.1	Remark:
Included in library:	Ethernet_AC500_V10.lib	

Visible variable	Type	Default value	Description
psNameInMail	POINTER TO STRING(255)	0	Pointer to a string containing a name to be used for the file in the email. (Can differ from the actual file name in the PLC.)
psFilePath	POINTER TO STRING(255)	0	Pointer to a string containing the full path to the file to be attached including the file name

ETH_MOD_FCT22_TYPE

This structure is used to handle the Modbus function 22 with the function block ETH_MOD_MAST ↳ *Chapter 1.5.4.13.1.4 “ETH_MOD_MAST” on page 1202*. The structure has to be used at the DATA input with an ADR(instance_of_struct) operator.

Modbus function 22 could only be used with CPUs with onboard Ethernet.

Type and the content need to be created and defined by the user.

Available as of runtime system:	V2.2	Remark:
Included in library:	Ethernet_AC500_V10.lib	

Visible variable	Type	Default value	Description
wAND_Mask	WORD	0	AND mask
wOR_Mask	WORD	0	OR mask

ETH_MOD_FCT23_TYPE

This structure is used to handle the Modbus function 23 with the function block ETH_MOD_MAST *Chapter 1.5.4.13.1.4 “ETH_MOD_MAST” on page 1202*. The structure has to be used at the DATA input with an ADR(instance_of_struct) operator.

Modbus function 23 could only be used with CPUs with onboard Ethernet.

Type and the content need to be created and defined by the user.

Available as of runtime system:	V2.2	Remark:
Included in library:	Ethernet_AC500_V10.lib	

Visible variable	Type	Default value	Description
pByDataWrite	POINTER TO BYTE	0	Pointer to buffer containing data to write. see FCT 16 input DATA
pByDataRead	POINTER TO BYTE	0	Pointer to buffer to store data to read. see FCT 03 input DATA
wDataAddressRead	WORD	0	Address of the data to be read. see FCT 16 input ADDR
wNumDataUnitsRead	WORD	0	Number of data units to be read. see FCT 16 input NB

1.5.4.14 EtherCAT library

Library file name: **EtherCAT_AC500_V13.lib**

The library EtherCAT_AC500_V13.lib is intended to be used with the EtherCAT master communication module. Beside the cyclic IO communication, which is configured in the EtherCAT master configuration and controlled by the runtime system, additional features are implemented in the EtherCAT master. This library provides the possibility to use these features within a PLC application. With the contained function blocks the following functionality can be realized:

- reading of diagnosis information
- reading and writing of service data objects (SDOs)
- reading of handshake error counters of synchronous IO update

Additional system libraries are required by this library:

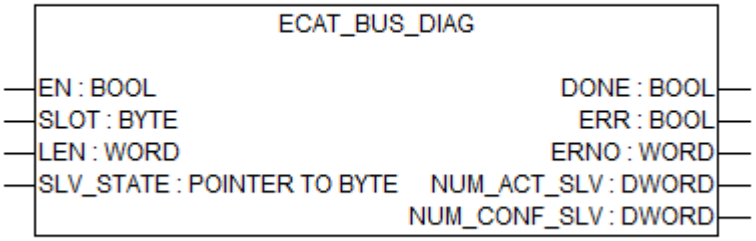
- SysExt_AC500_V10.lib
- SysLibTime.lib

The EtherCAT library and the required system libraries will be automatically added to the PLC application when an EtherCAT master communication module is configured in the PLC configuration.

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

1.5.4.14.1 Function blocks

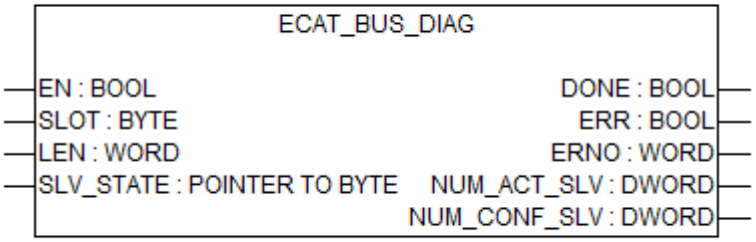
ECAT_BUS_DIAG



Parameter	Value
Included in library	EtherCAT_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	DIAG

The function block ECAT_BUS_DIAG is used to read the status and to return status information for each slave as well as the number of configured slaves and the number of active slaves of an EtherCAT Master.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

LEN

Data type	Default value	Range	Unit
UINT	0	1 ... 65535	byte

LEN (length) tells the function block how large the buffer in SLV_STATE is. For each slave 4 bytes are needed.

SLV_STATE

Data type	Default value	Range	Unit
POINTER TO ARRAY OF BYTE	0	-	-

The address of the buffer is required in order to write the state of each slave ↳ *"STATE" on page 1310*. The size of the buffer is directly related to the number of slaves. A byte for each slave is needed. In case the buffer is too small, an error will be returned. If the value of LEN does not reflect correctly the size of the buffer, this might be overrun with unpredictable consequences.

Example

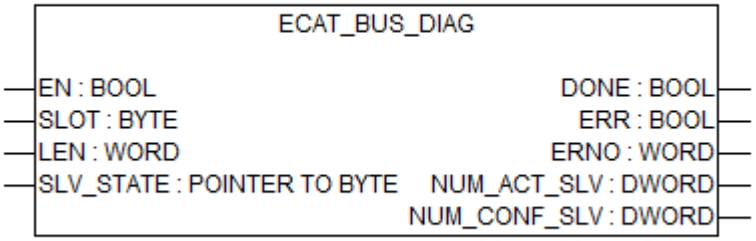
A master is configured with 20 slaves.

LEN and SLV_STATE should be configured as follows.

ECATBusDiag_LEN := 20;

ECATBusDiag_SLV_STATE: ARRAY [1..20] of BYTE;

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	-	-

Output indicates the processing state of the function block. After completion or abortion of processing (due to an error), DONE is set to TRUE for one cycle. This output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_ACT_SLV

Data type	Default value	Range	Unit
DWORD	0	0-256	-

The variable NUM_ACT_SLV (number of active slaves) contains the number of active slaves. Active slaves exchange cyclic data with the master.

NUM_CONF_SLV

Data type	Default value	Range	Unit
DWORD	0	0-256	-

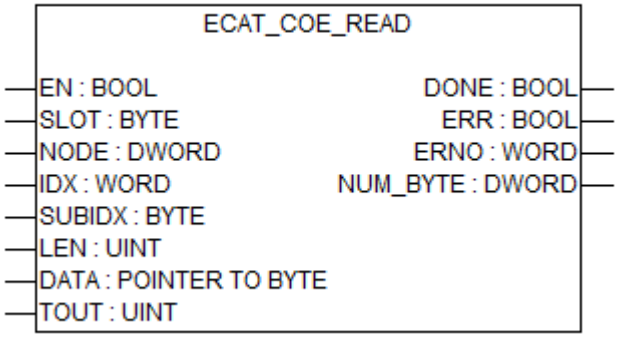
NUM_CONF_SLV (number of configured slaves) contains the number of configured slaves evaluated in the configuration file.

Function call in ST

```
ECAT_BUS_DIAG(
EN       := ECATBusDiag_EN,
SLOT     := ECATBusDiag_SLOT,
LEN      := ECATBusDiag_LEN,
SLV_STATE:=ADR(ECATBusDiag_SLV_STATE);

ECATBusDiag_DONE        := ECAT_BUS_DIAG.DONE;
ECATBusDiag_ERR         := ECAT_BUS_DIAG.ERR;
ECATBusDiag_ERNO        := ECAT_BUS_DIAG.ERNO;
ECATBusDiag_NUM_ACT_SLV := ECAT_BUS_DIAG.NUM_ACT_SLV;
ECATBusDiag_NUM_CONF_SLV:= ECAT_BUS_DIAG.NUM_CONF_SLV;
```

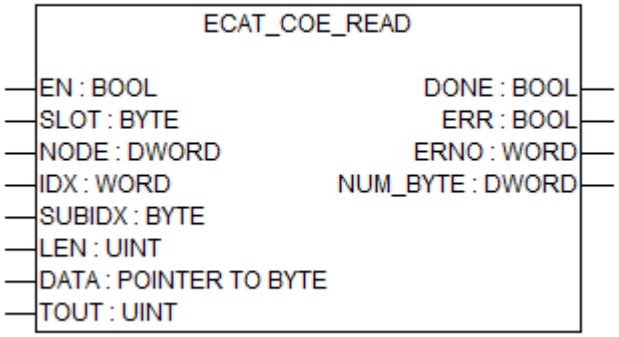
ECAT_COE_READ



Parameter	Value
Included in library	EtherCAT_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	CoE

The function block ECAT_COE_READ is used to read SD objects (SDOs) from a slave.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
DWORD	0	1 ... 4294967295	-

NODE represents the EtherCAT address of the slave.

IDX (index)

Data type	Default value	Range	Unit
WORD	0	1 ... 65535 (depending on the EtherCAT slave)	-

Index of the object which should be read/written.

SUBIDX

Data type	Default value	Range	Unit
BYTE	0	1 ... 255 (depending on the EtherCAT slave)	-

Subindex of the object, which should be read/written.

LEN

Data type	Default value	Range	Unit
UINT	0	1 ... 65535	byte

LEN (length) tells the function block how large the buffer in SLV_STATE is. For each slave 4 bytes are needed.

DATA

Data type	Default value	Range	Unit
POINTER TO ARRAY OF BYTE	0	-	-

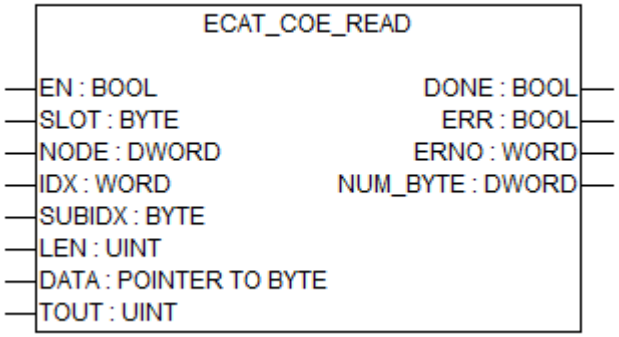
Address of the data buffer where the value of the object (Index: subindex) should be read. The needed buffer depends on the queried object.

TOUT

Data type	Default value	Range	Unit
UINT	0	0-65535	ms

Timeout constraint for the function block. If this is exceeded, the function block returns with ERR set to TRUE.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_BYTE

Data type	Default value	Range	Unit
DWORD	0	depending on the EtherCAT slave	-

Output returns how many bytes were written into the buffer.

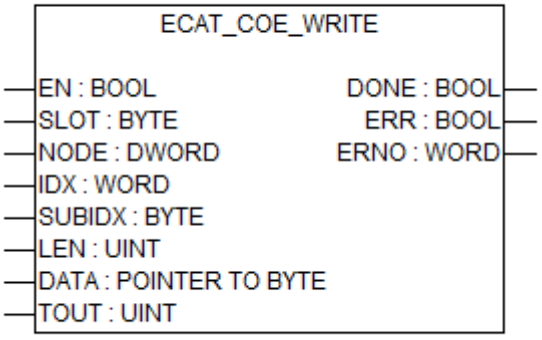
Function call in ST

```
ECAT_COE_READ(
EN    := ECATCoeRead_EN,
SLOT  := ECATCoeRead_SLOT,
LEN   := ECATCoeRead_LEN,
NODE  :=ECATCoeRead_NODE,
IDX   :=ECATCoeRead_IDX,
SUBIDX:=ECATCoeRead_SUBIDX,
LEN   :=ECATCoeRead_LEN,
```

```
DATA   :=ADR(ECATCoeRead_DATA),
TOUT   :=ECATCoeRead_TOUT);

ECATCoeRead_DONE     := ECAT_COE_READ.DONE;
ECATCoeRead_ERR      := ECAT_COE_READ.ERR;
ECATCoeRead_ERNO     := ECAT_COE_READ.ERNO;
ECATCoeRead_NUM_BYTE:= ECAT_COE_READ.NUM_BYTE;
```

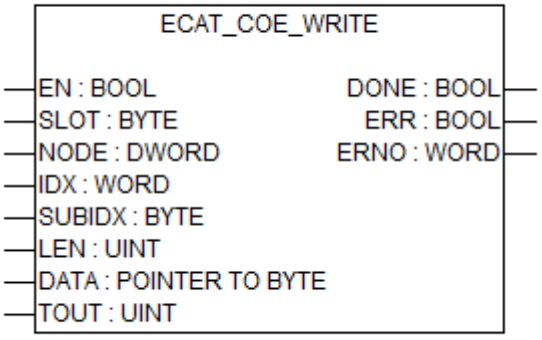
ECAT_COE_WRITE



Parameter	Value
Included in library	EtherCAT_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	CoE

ECAT_COE_WRITE writes a value to an SD Object in a slave. This object is identified with the pair Index:Subindex.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
DWORD	0	1 ... 4294967295	-

NODE represents the EtherCAT address of the slave.

IDX (index)

Data type	Default value	Range	Unit
WORD	0	1 ... 65535 (depending on the EtherCAT slave)	-

Index of the object which should be read/written.

SUBIDX

Data type	Default value	Range	Unit
BYTE	0	1 ... 255 (depending on the EtherCAT slave)	-

Subindex of the object, which should be read/written.

LEN

Data type	Default value	Range	Unit
UINT	0	1 ... 65535	byte

LEN (length) tells the function block how large the buffer in SLV_STATE is. For each slave 4 bytes are needed.

DATA

Data type	Default value	Range	Unit
POINTER TO ARRAY OF BYTE	0	-	-

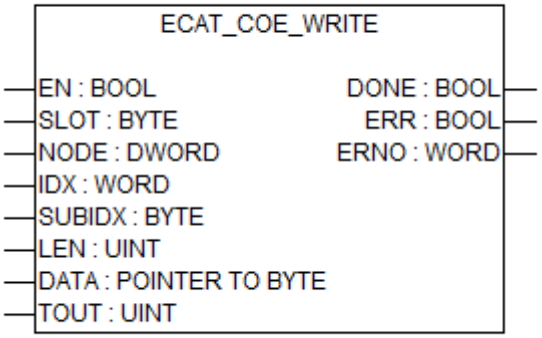
Address of the data buffer where the value of the object (Index: subindex) should be written. The needed buffer depends on the queried object.

TOUT

Data type	Default value	Range	Unit
UINT	0	0-65535	ms

Timeout constraint for the function block. If this is exceeded, the function block returns with ERR set to TRUE.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

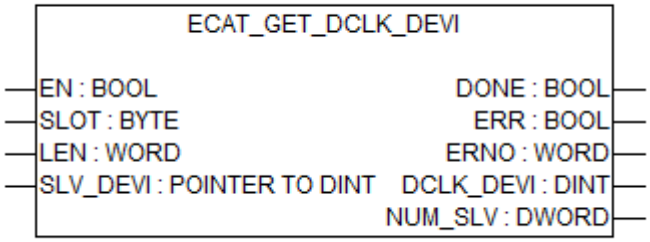
Function call in ST

```
ECAT_COE_WRITE(
EN              := ECATCoeWrite_EN,
SLOT            := ECATCoeWrite_SLOT,
NODE            := ECATCoeWrite_NODE,
IDX             := ECATCoeWrite_IDX,
SUBIDX          := ECATCoeWrite_SUBIDX,
```

```
LEN             := ECATCoeWrite_LEN,
DATA            := ADR(ECATCoeWrite_DATA),
TOUT            := ECATCoeWrite_TOUT);

ECATCoeWrite_DONE     := ECAT_COE_WRITE.DONE;
ECATCoeWrite_ERR      := ECAT_COE_WRITE.ERR;
ECATCoeWrite_ERNO     := ECAT_COE_WRITE.ERNO;
```

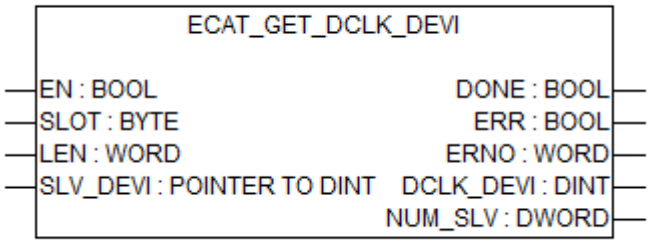
ECAT_GET_DCLK_DEVI



Parameter	Value
Included in library	EtherCAT_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	DIAG

ECAT_GET_DCLK_DEVI returns the distributed clock deviation for the EtherCAT master and for each slave individually.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

LEN

Data type	Default value	Range	Unit
UINT	0	1 ... 65535	byte

LEN (length) tells the function block how large the buffer in SLV_STATE is. For each slave 4 bytes are needed.

SLV_DEVI

Data type	Default value	Range	Unit
POINTER TO ARRAY OF DINT	0	-	-

The Input SLV_DEVI (slave deviation) provides the address of an Arrary of DINT where the distributed clock deviation of each slave is written to.

Each Element of the array has the range -2147483647... 2147483647 in unit ns.

The required size of the array is calculated as number of configured EtherCAT slaves multiplied with the size of DINT (4 bytes).

The size of the assigned array is provided at the Input LEN. If Input LEN is too small, an error will be returned.

If the value of LEN does not match with the assigned array, it can be overwritten. This will cause unexpected behavior.

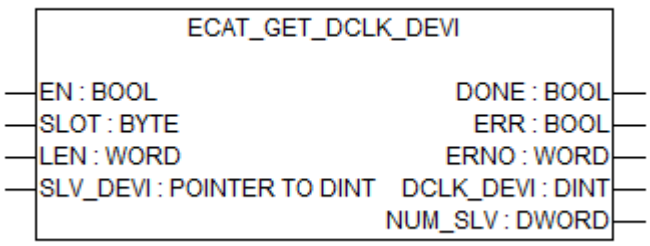
Example

A system with a master and 5 slaves is configured.

ECAT_DCLK_DEVI_LEN := 20;

ECAT_DCLK_DEVI_SLV_DEVI: ARRAY [1..5] of DINT;

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

DCLK_DEVI

Data type	Default value	Range	Unit
DINT	0	-2147483647...2147483647	ns

DCLK_DEVI (distributed clock deviation) shows the broadcast system time difference.

NUM_SLV

Data type	Default value	Range	Unit
DWORD	0	1-255	-

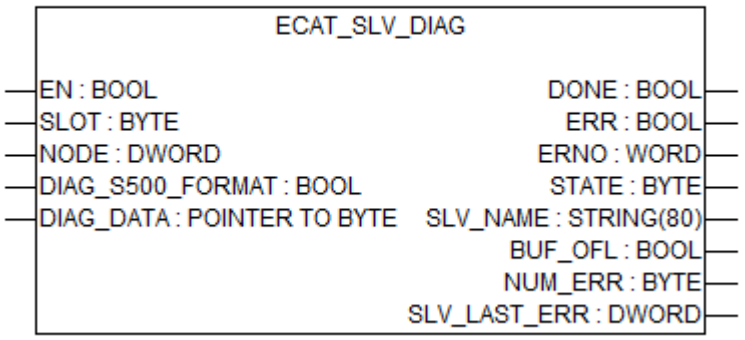
NUM_SLV shows the number of slaves for which the master has an deviation. In case the function block reports an insufficient buffer, the value of NUM_SLV has to be compared with the provided LEN value.

Function call in ST

```
ECAT_GET_DCLK_DEVI(
EN       := ECATGetDclkDevi_EN,
SLOT     := ECATGetDclkDevi_SLOT,
LEN      := ECATGetDclkDevi_LEN,
SLV_DEVI:=ADR(ECATGetDclkDevi_SLV_DEVI);

ECATGetDclkDevi_DONE     := ECAT_GET_DCLK_DEVI.DONE;
ECATGetDclkDevi_ERR      := ECAT_GET_DCLK_DEVI.ERR;
ECATGetDclkDevi_ERNO     := ECAT_GET_DCLK_DEVI.ERNO;
ECATGetDclkDevi_DCLK_DEVI:= ECAT_GET_DCLK_DEVI.DCLK_DEVI;
ECATGetDclkDevi_NUM_SLV  := ECAT_GET_DCLK_DEVI.NUM_SLV;
```

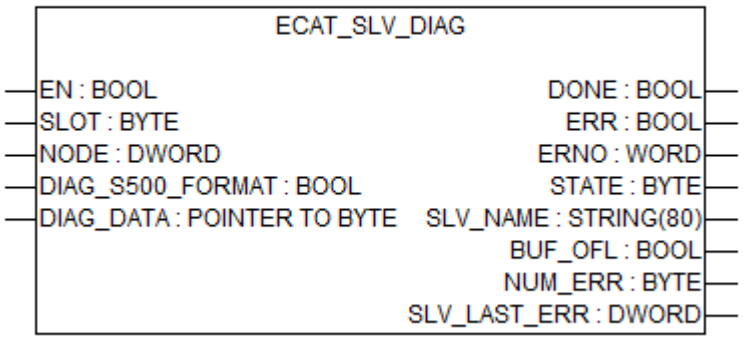
ECAT_SLV_DIAG



Available as of runtime system	V1.3.0
Included in library	EtherCAT_AC500_V13.lib
Function block Type	Function block with historical values

With the function block ECAT_SLV_DIAG status and diagnosis information of an EtherCAT slave can be read.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
DWORD	0	1 ... 4294967295	-

NODE represents the EtherCAT address of the slave.

DIAG_S500_FORMAT

Data type	Default value	Range	Unit
BOOL	FALSE	FALSE, TRUE	-

The Input DIAG_S500_FORMAT specifies the format of the diagnosis data which is provided in the buffer DIAG_DATA.

When DIAG_S500_FORMAT is TRUE the diagnosis data is in S500 Format. Otherwise it is in emergency data structure.

DIAG_DATA

Data type	Default value	Range	Unit
POINTER TO BYTE	0	-	-

The Input DIAG_DATA provides the pointer to buffer where the received diagnosis data is copied to.

The size of the provided buffer depends on the data structure of the diagnosis data which is specified with the Input DIAG_S500_FORMAT.

When the Input DIAG_S500_FORMAT is TRUE the buffer must have a size of at least 25 bytes.

The diagnosis data has the data type Array [1 ... 5] OF DIAGDATA.

```
TYPE DIAG_DATA :(*Error format for S500 slaves*) STRUCT
ERR_CLASS     : BYTE        :=0;   (*error class*)
SLAVE_NR      : BYTE        :=0;   (*slave number*)
MODULE_NR     : BYTE        :=0;   (*module number*)
CHANNEL_NR    : BYTE        :=0;   (*channel number*)
ERROR_NR      : BYTE        :=0;   (*error number*)
END_STRUCT
END_TYPE
```

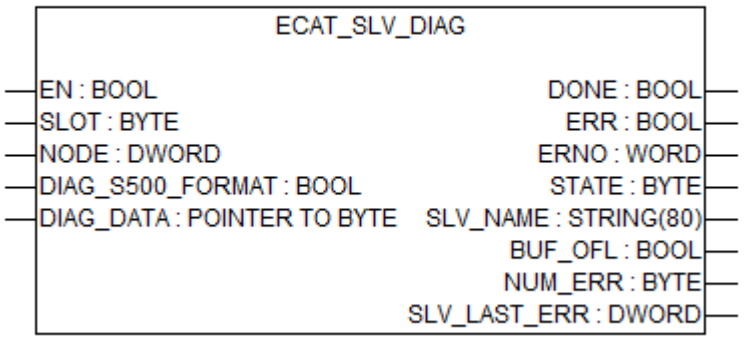
When the Input DIAG_S500_FORMAT is FALSE the buffer must have a size of at least 40 bytes.

The diagnosis data has the data type Array [1..5] OF ETHERCAT_MASTER_SLV_EMERGENCY_T.

```
TYPE ETHERCAT_MASTER_SLV_EMERGENCY_T: STRUCT
usErrorCode:    WORD               :=0;(*error code*)
bErrorRegister: BYTE               :=0;(*error register*)
abErrorData   : ARRAY [0..4]of BYTE :=5(0);(*error data*)
END_STRUCT
END_TYPE
```

The buffer should not be smaller than the sizes given for each format. Otherwise it will be overwritten and causes unexpected behavior.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE

Table 77: Current slave state

Data type	Default value	Range	Unit
BYTE	16#FF	01: INIT 02: PREOP 04: SAFEOP 08: OPERATIONAL 254: unknown 255: no response	-

SLV_NAME

Data type	Default value	Range	Unit
STRING	empty string	-	-

Output SLV_NAME provides the current slave name.

BUF_OFL

Data type	Default value	Range	Unit
BOOL	FALSE	FALSE, TRUE	-

Output BUF_OFL (buffer overflow) indicated whether there was overflow of the internal diagnosis buffer. In this case emergency messages were lost.

NUM_ERR

Data type	Default value	Range	Unit
BYTE	0	0 ... 5	-

Output NUM_ERR provides the number of elements (Diagnosis messages) contained within the buffer DIAG_DATA.

Example 1 NUM_ERR returns the value of 3 and DIAG_S500_FORMAT was TRUE. This means that the first 3 elements of DIAG_DATA contain relevant information.

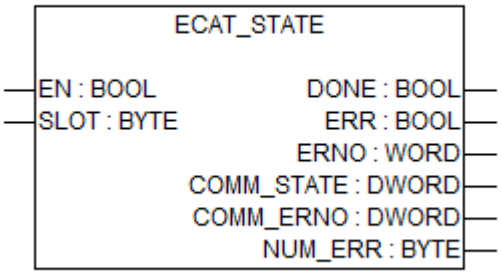
Example 2 A NUM_ERR of 4 and DIAG_S500_FORMAT was FALSE means that DIAG_DATA has 32 relevant bytes (8 per error).

Function call in ST

```
ECAT_SLV_DIAG(
EN                  := ECATSlvDiag_EN,
SLOT                := ECATSlvDiag_SLOT,
SLV                 := ECATSlvDiag_SLV,
DIAG_S500_FORMAT    := ECATSlvDiag_DIAG_S500_FORMAT,
DIAG_DATA           :=ADR(ECATSlvDiag_DIAG_DATA));

ECATSlvDiag_DONE        := ECAT_SLV_DIAG.DONE;
ECATSlvDiag_ERR         := ECAT_SLV_DIAG.ERR;
ECATSlvDiag_ERNO        := ECAT_SLV_DIAG.ERNO;
ECATSlvDiag_SLV_NAME    := ECAT_SLV_DIAG.SLV_NAME;
ECATSlvDiag_BUF_OFL     := ECAT_SLV_DIAG.BUF_OFL;
ECATSlvDiag_NUM_ERR     := ECAT_SLV_DIAG.NUM_ERR;
```

ECAT_STATE

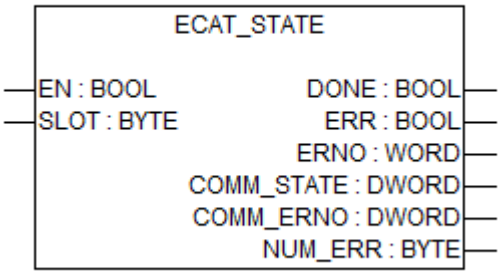


Available as of runtime system	V1.3.0
Included in library	EtherCAT_AC500_V13.lib
Function block Type	Function block with historical values

The function block ECAT_STATE is used to read the state and possible errors of an EtherCAT fieldbus.

The function block ECAT_STATE returns the status of an EtherCAT Communication Module. The function block also delivers - when present - a communication error and the number of errors since power-up.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

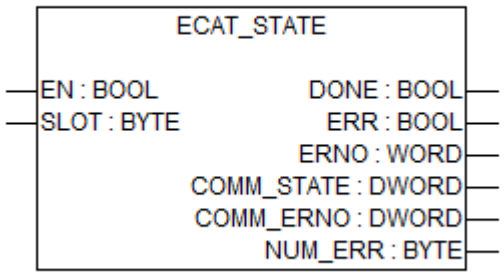
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

COMM_STATE

Data type	Default value	Range	Unit
DWORD	0	0...4	-

COMM_STATE returns the state of the field bus related to chosen master. The possible codes for COMM_STATE are:

```
UNKNOWN     0x00000000
OFFLINE     0x00000001
STOP        0x00000002
IDLE        0x00000003
OPERATE     0x00000004
```

COMM_ERNO

Data type	Default value	Range	Unit
DWORD	0	-	-

COMM_ERNO returns an error, if present, related to the communication channel. The possible codes for COMM_ERNO are following:

```
SUCCESS                                    0x00000000
WATCHDOG TIMEOUT                                      0xC000000C
INITIALIZATION FAULT                                  0xC0000100
DATABASE ACCESS FAILED                                0xC0000101
(General) CONFIGURATION FAULT                         0xC0000120

```

NUM_ERRS

Data type	Default value	Range	Unit
BYTE	0	0 ... 255	-

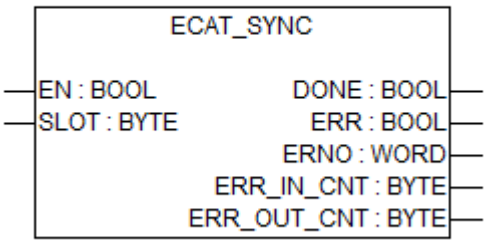
NUM_ERRS contains the number of errors since the power-up of the Communication Module.

Function call in ST

```
ECAT_STATE(
EN   := ECATState_EN,
SLOT := ECATState_SLOT);

ECATState_DONE           := ECAT_STATE.DONE;
ECATState_ERR            := ECAT_STATE.ERR;
ECATState_ERNO           := ECAT_STATE.ERNO;
ECATState_COMM_STATE     := ECAT_STATE.COMM_STATE;
ECATState_COMM_ERNO      := ECAT_STATE.COMM_ERNO;
ECATState_NUM_ERR     := ECAT_STATE.NUM_ERR;
```

ECAT_SYNC



The function block ECAT_SYNC is used to synchronize an IEC task with the EtherCAT bus cycle.

With the function block ECAT_SYNC the error counters ERR_IN_CNT and ERR_OUT_CNT can be read.

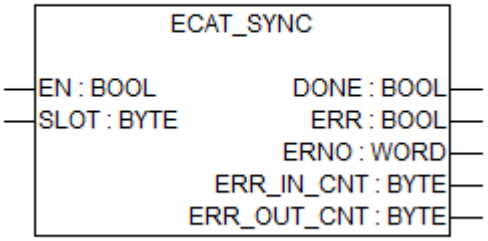
The error counter ERR_IN_CNT is set, if the IEC task was not started within the current bus cycle.

The error counter ERR_OUT_CNT is set, If the task was not finished within the current bus cycle.

The function block ECAT_SYNC requires Communication Module firmware version 2.4.11 or higher.

The function block ECAT_SYNC requires CPU firmware version 2.1.x or higher.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

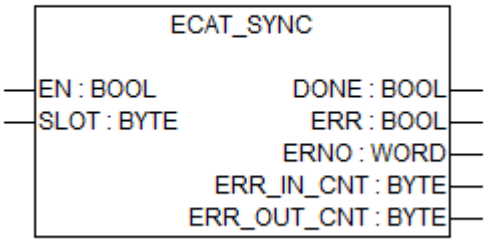
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ERR_IN_CNT

Data type	Default value	Range	Unit
BYTE	0	0 ... 255	-

The variable ERR_IN_CNT (error input counter) contains the number of input errors.

The error counter ERR_IN_CNT will be incremented, if the synchronized IEC task was not started within the current bus cycle.

ERR_OUT_CNT

Data type	Default value	Range	Unit
BYTE	0	0 ... 255	-

The variable ERR_OUT_CNT (error output counter) contains the number of output errors.

The error counter ERR_OUT_CNT will be incremented, if the started task was not finished within the current bus cycle.

Function call in ST

```
ECAT_SYNC(
EN   := ECATSYNC_EN,
SLOT := ECATSYNC_SLOT);

ECATSYNC_DONE           := ECAT_SYNC.DONE;
ECATSYNC_ERR            := ECAT_SYNC.ERR;
ECATSYNC_ERNO           := ECAT_SYNC.ERNO;
ECATSYNC_ERR_IN_CNT     := ECAT_SYNC.ERR_IN_CNT;
ECATSYNC_ERR_OUT_CNT    := ECAT_SYNC.ERR_OUT_CNT;
```

1.5.4.15 Extended EtherCAT library

Library file name: **Ethercat_ext_AC500_Vx.lib**

This library is used to control the EtherCAT network and the connected slave devices. It is also used for diagnostics of the EtherCAT network and the connected slave devices.

Preconditions

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

The following libraries are required to use the function blocks of the EtherCAT library:

- *CMN_AC500_V24.lib (V 1.0.0)*
- *SysInt_AC500_V10.lib (V 1.4.3)*

1.5.4.15.1 Function blocks

ECAT_SLV_SET_STATE

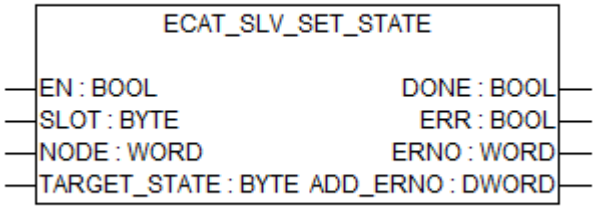


Table 78: General information

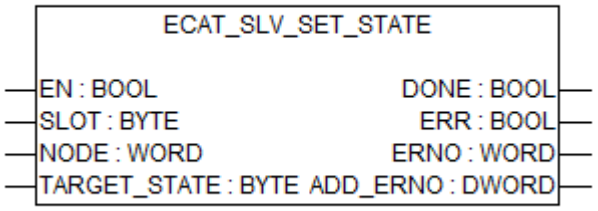
Available as of runtime system	V2.4.3 and above
Available as of AB version	V1.2 and above
Available as of CM579-EthCAT version	V4.0.0 and above
Included in library	EtherCAT_EXT_AC500_V25.lib
Type	Function block with historical values.

ECAT_SLV_SET_STATE can be used to change state of the “EtherCAT State Machine” of an EtherCAT slave. The direct state transitions are:

- INIT -> PREOP
- PREOP -> SAFEOP
- SAFEOP -> OP
- OP -> SAFEOP
- OP -> PREOP
- OP -> INIT
- SAFEOP -> PREOP
- SAFEOP -> INIT
- PREOP -> INIT

This POU allows direct state changes and state changes over intermediate states, e.g. for a change from “init” to “Operational”.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
DWORD	0	1 ... 4294967295	-

NODE represents the EtherCAT address of the slave.

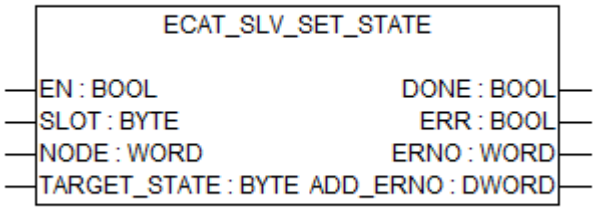
TARGET_STATE

Data type	Default value	Range	Unit
BYTE	0	1, 2, 4, 8	-

Possible target states of the slave:

- 1: INIT
- 2: PREOPERATIONAL
- 4: SAFEOPERATIONAL
- 8: OPERATIONAL

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADD_ERNO

Data type	Default value	Range	Unit
DWORD	-	$0…2^{32-1}$	-

At output ADD_ERNO an additional error code is provided when output ERNO is 0 x 0031.

ECAT_SLV_GET_STATE

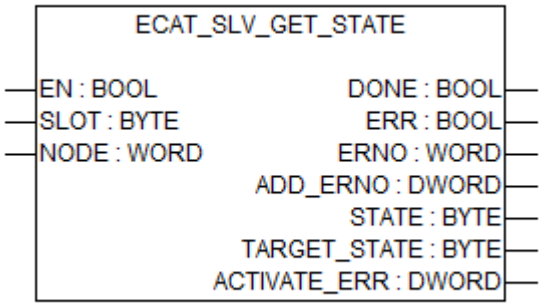


Table 79: General information

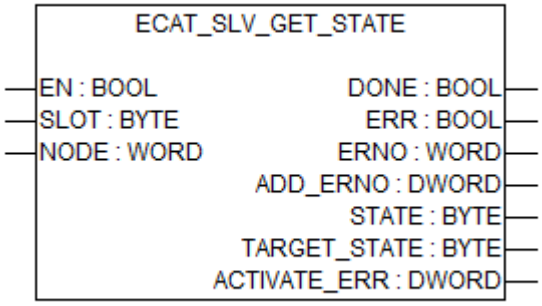
Available as of runtime system	V2.4.3 and above
Available as of AB version	V1.2 and above
Available as of CM579-EthCAT version	V4.0.0 and above
Included in library	EtherCAT_EXT_AC500_V25.lib
Type	Function block with historical values.

The function block ECAT_SLV_GET_STATE can be used to change state of the “EtherCAT State Machine” of an EtherCAT slave. If exists, the error of the last state change is also read with this function block.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

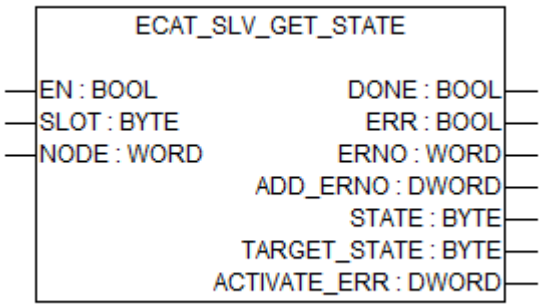
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
DWORD	0	1 ... 4294967295	-

NODE represents the EtherCAT address of the slave.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADD_ERNO

Data type	Default value	Range	Unit
DWORD	-	$0…2^{32-1}$	-

At output ADD_ERNO an additional error code is provided when output ERNO is 0 x 0031.

STATE

Data type	Default value	Range	Unit
BYTE	0	1, 2, 4, 8	-

Output STATE provides the current state of the selected slave. The following values are possible:

- 1: INIT
- 2: PREOPERATIONAL
- 4: SAFEOPERATIONAL
- 8: OPERATIONAL

TARGET_STATE

Data type	Default value	Range	Unit
BYTE	0	1, 2, 4, 8	-

Output TARGET_STATE provides the target_value of the last target in ECAT_SLV_SET_STATE. The following target values are possible:

- 1: INIT
- 2: PREOPERATIONAL
- 4: SAFEOPERATIONAL
- 8: OPERATIONAL

ACTIVATE_ERR

Data type	Default value	Range	Unit
DWORD	0	-	-

ACTIVATE_ERR shows the activation error reported by the slave.

ECAT_BUS_SET_STATE

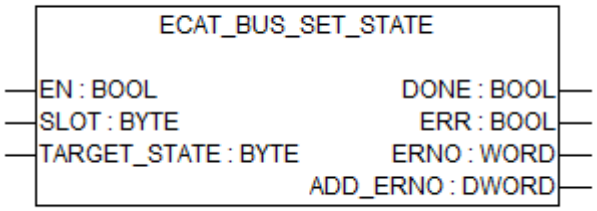


Table 80: General information

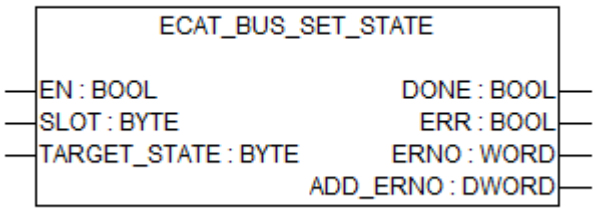
Available as of runtime system	V2.4.3 and above
Available as of AB version	V1.2 and above
Available as of CM579-EthCAT version	V4.0.0 and above
Included in library	EtherCAT_EXT_AC500_V25.lib
Type	Function block with historical values.

ECAT_BUS_SET_STATE can be used to change the state of all connected and configured EtherCAT slaves. All transition between the four states “Init”, “Pre-Operational”, “Safe Operational” and “Operational” are possible.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

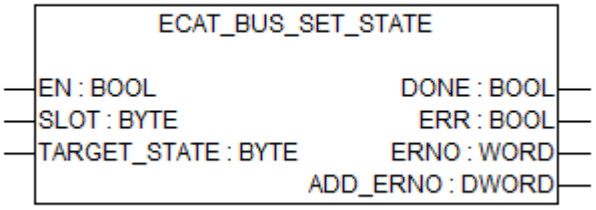
TARGET_STATE (target state)

Data type: BYTE, default value: 0, range: 1, 2, 4, 8

Target State of the bus. The following target states are possible:

- 1: INIT
- 2: PREOPERATIONAL
- 4: SAFEOPERATIONAL
- 8: OPERATIONAL

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADD_ERNO

Data type	Default value	Range	Unit
DWORD	-	$0…2^{32-1}$	-

At output ADD_ERNO an additional error code is provided when output ERNO is 0 x 0031.

ECAT_START_COM

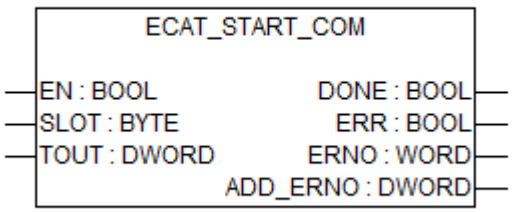


Table 81: General information

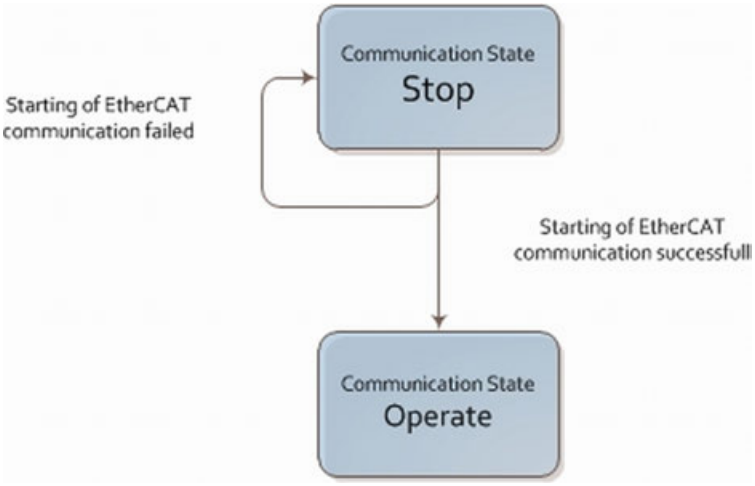
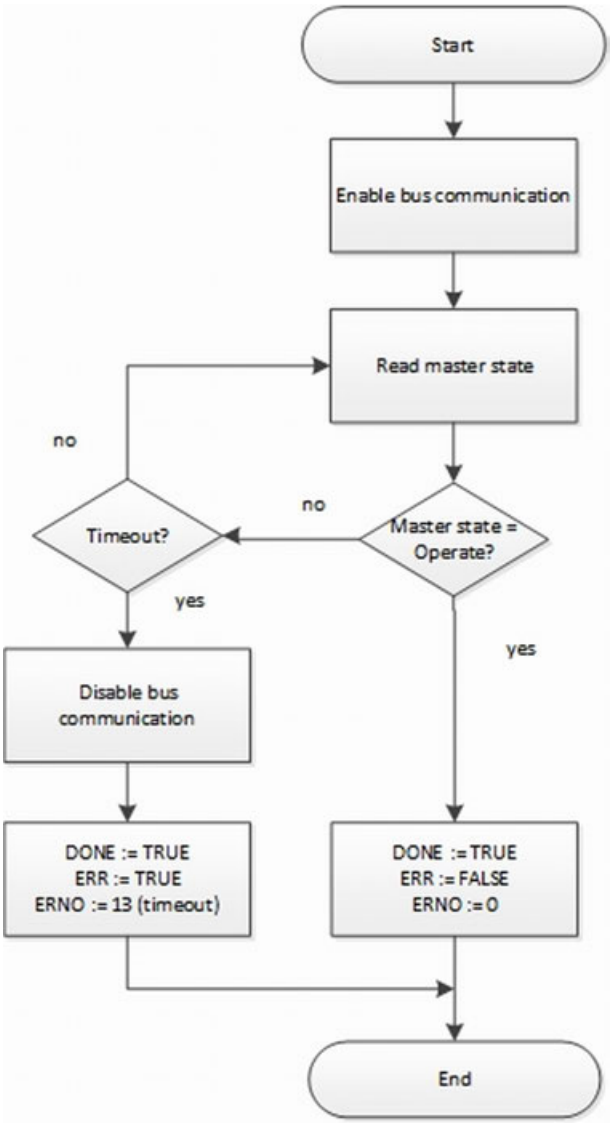
Available as of runtime system	V2.4.3 and above
Available as of AB version	V1.2 and above
Available as of CM579-EthCAT version	V4.0.0 and above
Included in library	EtherCAT_EXT_AC500_V25.lib
Type	Function block with historical values.

ECAT_START_COM can be used to start communication of the EtherCAT master. That means the communication state of the master is changed from Stop to Operate. If execution of the function block fails the master stays in the communication state Stop.



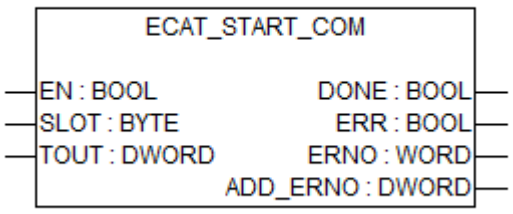
The following figure demonstrates execution of ECAT_START_COM:



With execution start the bus communication is enabled. Communication state of the Master is checked and it’s waited until the communication state is 'Operate'.

Execution of the function block was successful if the master was changed to the communication state 'Operate'. If the master is not in this state within the specified timeout, execution of the function block is failed and the bus communication is disabled again.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

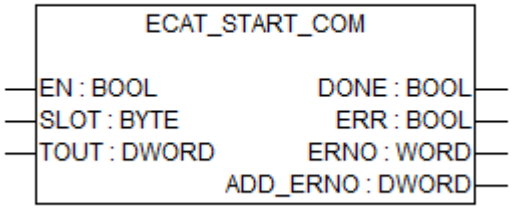
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

TOUT

Data type	Default value	Range	Unit
DWORD	0	0 … 4294967295	ms

Value of timeout in ms.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADD_ERNO

Data type	Default value	Range	Unit
DWORD	-	$0…2^{32-1}$	-

At output ADD_ERNO an additional error code is provided when output ERNO is 0 x 0031.

ECAT_STOP_COM

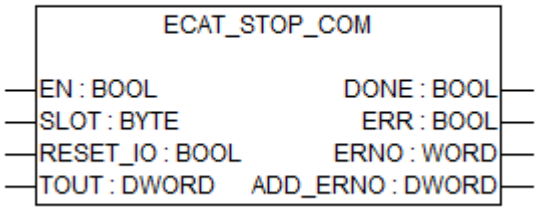


Table 82: General information

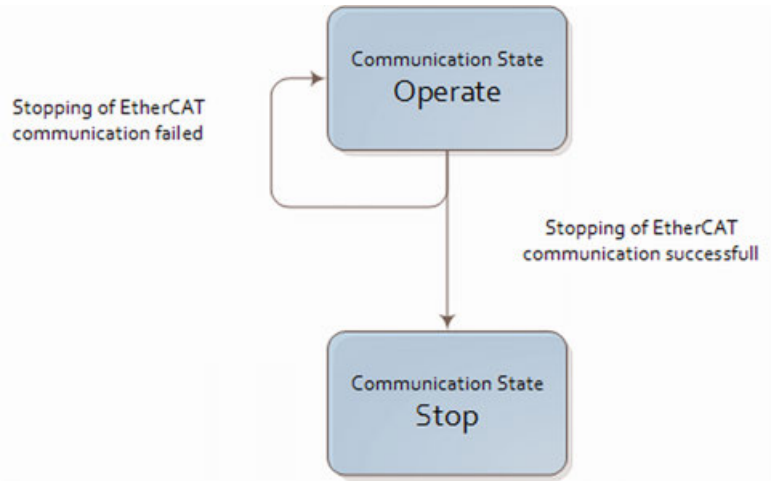
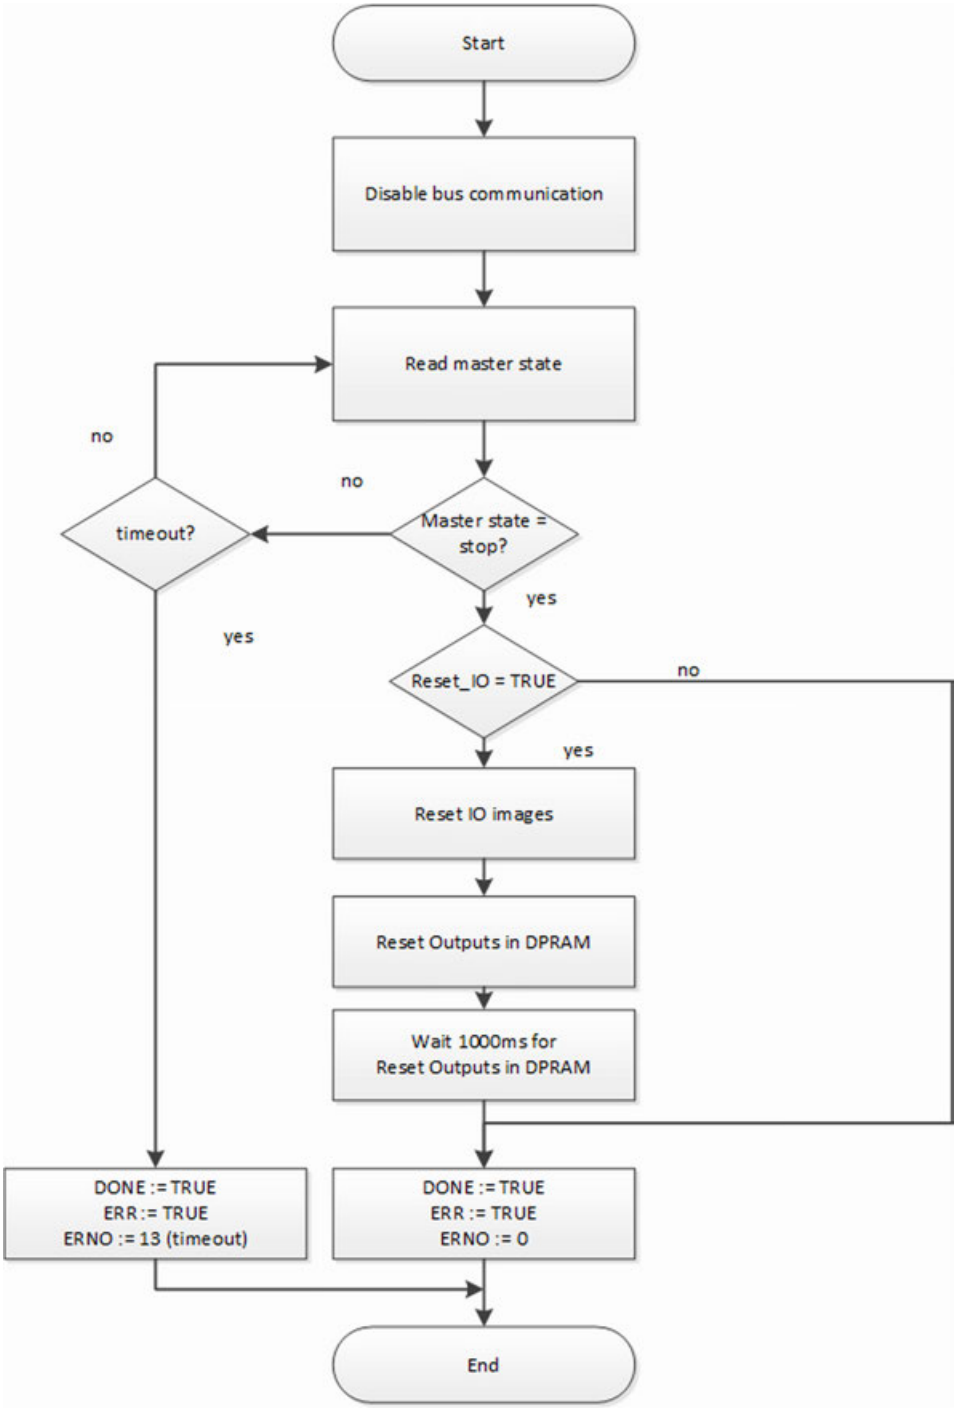
Available as of runtime system	V2.4.3 and above
Available as of AB version	V1.2 and above
Available as of CM579-EthCAT version	V4.0.0 and above
Included in library	EtherCAT_EXT_AC500_V25.lib
Type	Function block with historical values.

ECAT_STOP_COM can be used to start communication of the EtherCAT master. That means the communication state of the master is changed from 'Operate' to 'Stop'. If execution of the function block fails the master stays in the communication state 'Operate'.



The user is responsible for resetting EtherCAT related part of the PLC application when the bus communication is restarted. At least the internal variables of the sync task have to be reset.

The following figure demonstrates execution of ECAT_STOP_COM:

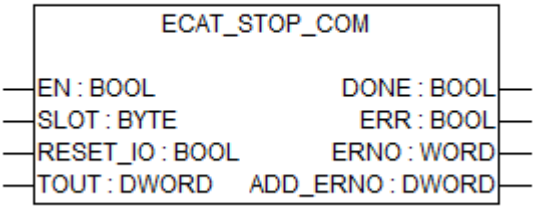


With execution start the bus communication is disabled. Communication state of the Master is checked and it's waited until the communication state is 'Stop'. If the master is in communication state 'Stop' and the input RESET_IO is TRUE the IOs will be reset.

Execution of the function block was successful if the master was changed to the communication state 'Stop' and no error occurred during IO reset. If the master is not in the communication state 'Stop' within the specified timeout, the execution of the function block is failed.

> *The IO reset function of ECAT_STOP_COM is not synchronized. That means there is no notification when the reset is finished. ECAT_STOP_COM has an internal waiting time of 1000 ms to ensure the IOs have been reset. If this time is not sufficient it has to be waited an additional time before the communication is re-started with the FB ECAT_START_COM.*

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

RESET_IO

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

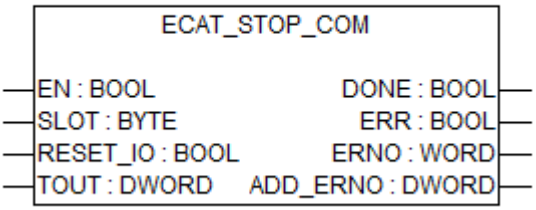
IO values will be reset if set to true.

TOUT

Data type	Default value	Range	Unit
DWORD	0	0 … 4294967295	ms

Value of timeout in ms.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADD_ERNO

Data type	Default value	Range	Unit
DWORD	-	$0…2^{32-1}$	-

At output ADD_ERNO an additional error code is provided when output ERNO is 0 x 0031.

ECAT_SOE_READ

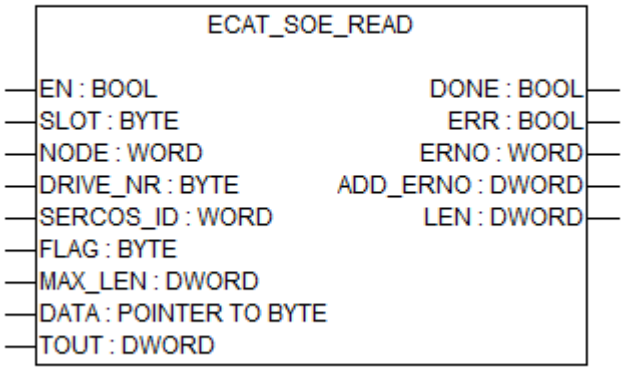


Table 83: General information

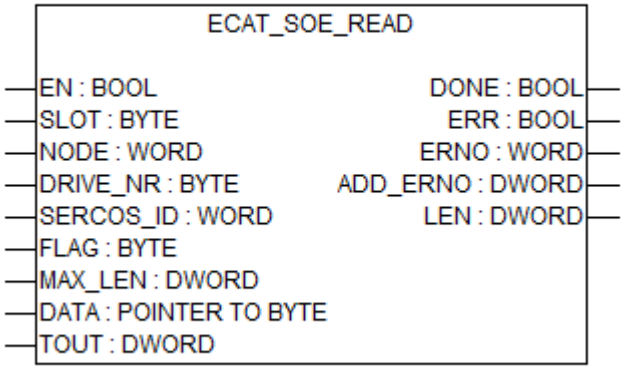
Available as of runtime system	V2.4.3 and above
Available as of AB version	V1.2 and above
Available as of CM579-EthCAT version	V4.0.0 and above
Included in library	EtherCAT_EXT_AC500_V25.lib
Type	Function block with historical values.

ECAT_SOE_READ can be used to read SERCOS II objects.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
DWORD	0	1 ... 4294967295	-

NODE represents the EtherCAT address of the slave.

DRIVE_NR

Data type	Default value	Range	Unit
BYTE	0	-	-

Drive number, starting with 0.

SERCOS_ID

Data type	Default value	Range	Unit
WORD	0	-	-

SERCOS identification number of the object to be read.

FLAG

Data type	Default value	Range	Unit
BYTE	0	-	-

The following values are allowed:

- 0x01: SOE_ELEMENT_FLAGS_DATASTATE
- 0x02: SOE_ELEMENT_FLAGS_NAME
- 0x04: SOE_ELEMENT_FLAGS_ATTRIBUTE
- 0x08: SOE_ELEMENT_FLAGS_UNIT
- 0x10: SOE_ELEMENT_FLAGS_MIN
- 0x20: SOE_ELEMENT_FLAGS_MAX
- 0x40: SOE_ELEMENT_FLAGS_VALUE

MAX_LEN

Data type	Default value	Range	Unit
DWORD	0	-	-

Maximal length of the data array.

DATA

Data type	Default value	Range	Unit
POINTER TO ARRAY OF BYTE	-	-	-

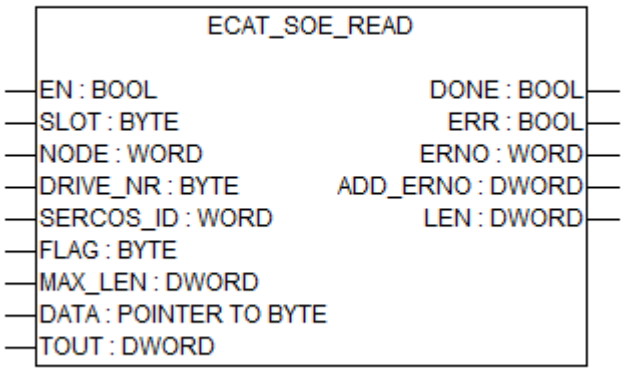
Pointer to the receive Buffer.

TOUT

Data type	Default value	Range	Unit
DWORD	0	0 … 4294967295	ms

Value of timeout in ms.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADD_ERNO

Data type	Default value	Range	Unit
DWORD	-	$0…2^{32-1}$	-

At output ADD_ERNO an additional error code is provided when output ERNO is 0 x 0031.

LEN

Data type	Default value	Range	Unit
DWORD	0	-	-

Length of the received data in bytes.

ECAT_SOE_WRITE

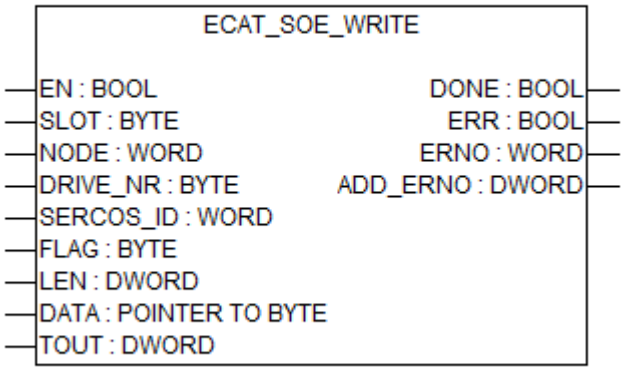


Table 84: General information

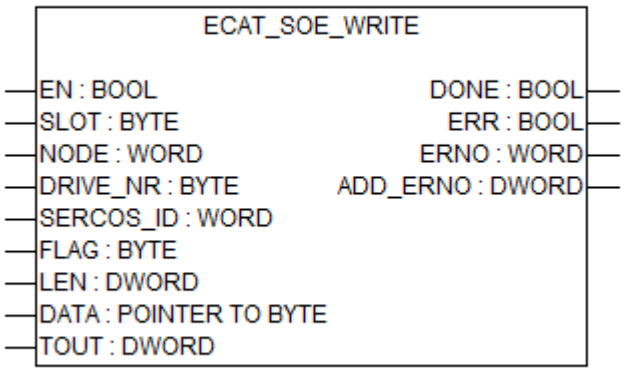
Available as of runtime system	V2.4.3 and above
Available as of AB version	V1.2 and above
Available as of CM579-EthCAT version	V4.0.0 and above
Included in library	EtherCAT_EXT_AC500_V25.lib
Type	Function block with historical values.

The function block ECAT_SOE_WRITE can be used to write SERCOS II – objects.

It depends on the specific EtherCAT device which objects or attributes of objects are writeable.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
DWORD	0	1 ... 4294967295	-

NODE represents the EtherCAT address of the slave.

DRIVE_NR

Data type	Default value	Range	Unit
BYTE	0	-	-

Drive number, starting with 0.

SERCOS_ID

Data type	Default value	Range	Unit
WORD	0	-	-

SERCOS identification number of the object to be write.

FLAG

Data type	Default value	Range	Unit
BYTE	0	-	-

The following values are allowed:

- 0x01: SOE_ELEMENT_FLAGS_DATASTATE
- 0x02: SOE_ELEMENT_FLAGS_NAME
- 0x04: SOE_ELEMENT_FLAGS_ATTRIBUTE
- 0x08: SOE_ELEMENT_FLAGS_UNIT
- 0x10: SOE_ELEMENT_FLAGS_MIN
- 0x20: SOE_ELEMENT_FLAGS_MAX
- 0x40: SOE_ELEMENT_FLAGS_VALUE

LEN

Data type	Default value	Range	Unit
DWORD	0	0…1024	-

Length of the data array.

DATA

Data type	Default value	Range	Unit
POINTER TO ARRAY OF BYTE	-	-	-

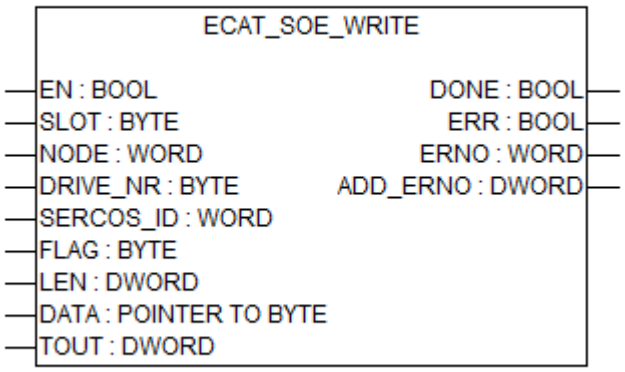
Pointer to the receive Buffer.

TOUT

Data type	Default value	Range	Unit
DWORD	0	0 … 4294967295	ms

Value of timeout in ms.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADD_ERNO

Data type	Default value	Range	Unit
DWORD	-	$0…2^{32-1}$	-

At output ADD_ERNO an additional error code is provided when output ERNO is 0 x 0031.

1.5.4.15.2 Global variables

Communication states

Table 85: Communication states of the EtherCAT master

ECAT_MASTER_COM_STATE_UNKNOWN:	DWORD:=16#00000000;	Communication State "UNKNOWN" of the EtherCAT master
ECAT_MASTER_COM_STATE_NOT_CONFIGURED:	DWORD:=16#00000001;	Communication State "NOT CONFIGURED" of the EtherCAT master
ECAT_MASTER_COM_STATE_STOP:	DWORD:=16#00000002;	Communication State "STOP" of the EtherCAT master
ECAT_MASTER_COM_STATE_IDLE:	DWORD:=16#00000003;	Communication State "IDLE" of the EtherCAT master
ECAT_MASTER_COM_STATE_OPERATE:	DWORD:=16#00000004;	Communication State "OPERATE" of the EtherCAT master

Flags for SERCOS

Table 86: Flags for the attribute selection of the SERCOS objects

ECAT_SOE_ELEMENT_FLAGS_DATASTATE:	BYTE := 16#01;	State of the selected Sercos ID
ECAT_SOE_ELEMENT_FLAGS_NAME:	BYTE := 16#02;	Name of the selected Sercos ID
ECAT_SOE_ELEMENT_FLAGS_ATTRIBUTE:	BYTE := 16#04;	Attribute of the selected Sercos ID
ECAT_SOE_ELEMENT_FLAGS_UNIT:	BYTE := 16#08;	Unit of the selected Sercos ID

ECAT_SOE_ELE-MENT_FLAGS_MIN:	BYTE := 16#10;	Minimum value of the selected Sercos ID
ECAT_SOE_ELE-MENT_FLAGS_MAX:	BYTE := 16#20;	Maximum value of the selected Sercos ID
ECAT_SOE_ELE-MENT_FLAGS_VALUE:	BYTE := 16#40;	Current value of the selected Sercos ID

EtherCAT state machine

ECAT_STATE_MACHINE_STATE_SAFEOP:	BYTE := 16#04;	SAFEOPERATIONAL state in the EtherCAT state machine
ECAT_STATE_MACHINE_STATE_OP:	BYTE := 16#08;	OPERATIONAL state in the EtherCAT state machine

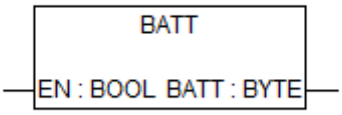
1.5.4.16 External System library

Library file name: **SysExt_AC500_Vx.lib**

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

1.5.4.16.1 Function blocks

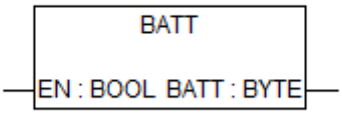
BATT



Parameter	Value
Included in library	SysExt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function
Group	Battery

Using the function block BATT the charge state of the battery can be requested.

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN. If the function block is active, the charge state of the battery is available at the function block output.

Output description

(Output)

Data type	Default value	Range	Unit
BYTE	-	-	-

The output of the function block BATT outputs the charge state of the battery. The following values are possible at present:

0: Battery empty

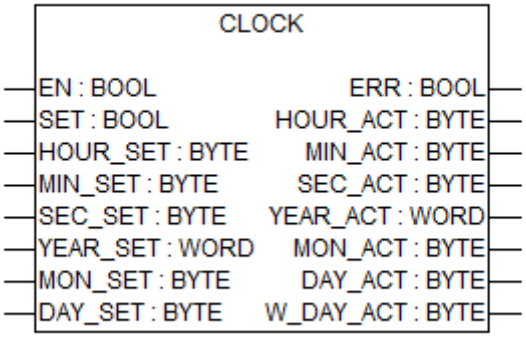
20: Remaining battery charge below 20 %

100: Battery charge OK

Function call in ST

```
BATT_LOAD := BATT(BATT_EN);
```

CLOCK

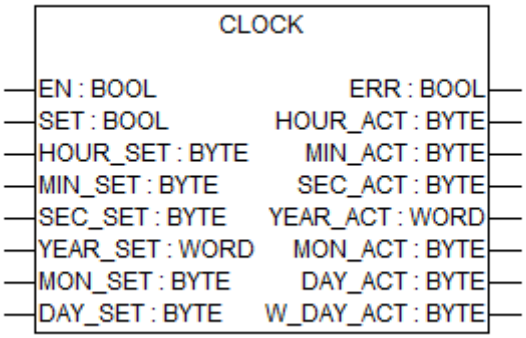


Parameter	Value
Included in library	SysExt_AC500_V10.lib
Available as of firmware	V1.0

Parameter	Value
Type	Function block with historical values
Group	Real-time clock

This function block allows to set and display the current time and date. The clock is set by means of the set inputs for the time and date. The values available at the set inputs are read in with the occurrence of a FALSE/TRUE edge at input SET. As long as a TRUE signal is present at the EN input, the current date and time are displayed at the function block outputs.

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN. If the function block is active, the current time and date are available at the outputs.

SET

Data type	Default value	Range	Unit
BOOL	-	-	-

With an occurring FALSE/TRUE edge at input SET, the clock is set to the values available at the time and date inputs.

HOUR_SET

Data type	Default value	Range	Unit
BYTE	-	-	-

Set input for the hours. The clock works in 24 hours mode, i.e. it changes from 23:59:59 h to 0:0:0 h.

Valid range of values: 0...23.

MIN_SET

Data type	Default value	Range	Unit
BYTE	-	-	-

Set input for the minutes.

Valid range of values: 0...59.

SEC_SET

Data type	Default value	Range	Unit
BYTE	-	-	-

Set input for the seconds.

Valid range of values: 0...59.

YEAR_SET

Data type	Default value	Range	Unit
WORD	-	-	-

Set input for the year. Four-digit input, e.g. 2005.

MON_SET

Data type	Default value	Range	Unit
BYTE	-	-	-

Set input for the month.

Valid range of values: 1...12.

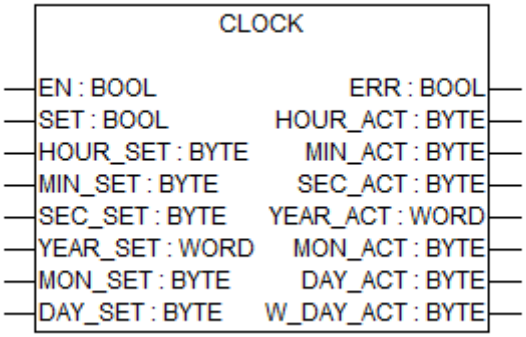
DAY_SET

Data type	Default value	Range	Unit
BYTE	-	-	-

Set input for the day (which day of the month).

Valid range of values: 1...31.

Output description



ERR

Data type	Default value	Range	Unit
BOOL	-	-	-

Output ERR indicates whether an error occurred during Function Block processing.

HOUR_ACT

Data type	Default value	Range	Unit
BYTE	-	-	-

Current value for the hours.

MIN_ACT

Data type	Default value	Range	Unit
BYTE	-	-	-

Current value for the minutes.

SEC_ACT

Data type	Default value	Range	Unit
BYTE	-	-	-

Current value for the seconds.

YEAR_ACT

Data type	Default value	Range	Unit
WORD	-	-	-

Current value for the year.

MON_ACT

Data type	Default value	Range	Unit
BYTE	-	-	-

Current value for the month.

DAY_ACT

Data type	Default value	Range	Unit
BYTE	-	-	-

Current value for the day.

W_DAY_ACT

Data type	Default value	Range	Unit
BYTE	-	-	-

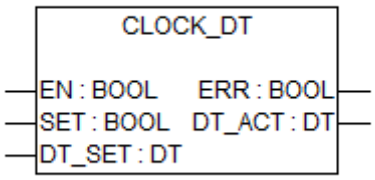
Current value for the number of the day of week. 0 = Sunday, 1 = Monday, .., 6 = Saturday.

Function call in ST

```
Clock  (EN := Clock_EN,
       SET := Clock_SET,
       HOUR_SET := Clock_HOUR_SET,
       MIN_SET := Clock_MIN_SET,
       SEC_SET := Clock_SEC_SET,
       YEAR_SET := Clock_YEAR_SET,
       MON_SET := Clock_MON_SET,
       DAY_SET := Clock_DAY_SET);

Clock_ERR := Clock.ERR;
Clock_HOUR_ACT := Clock.HOUR_ACT;
Clock_MIN_ACT := Clock.MIN_ACT;
Clock_SEC_ACT := Clock.SEC_ACT;
Clock_YEAR_ACT := Clock.YEAR_ACT;
Clock_MON_ACT := Clock.MON_ACT;
Clock_DAY_ACT := Clock.DAY_ACT;
Clock_W_DAY_ACT := Clock.W_DAY_ACT;
```

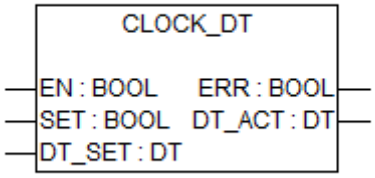
CLOCK_DT



Parameter	Value
Included in library	SysExt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values
Group	Real-time clock

This function block allows to set and display the current time and date in the standardized "DT" format. Setting of the clock is performed via set input "DT_SET". The value available at the set input is read in with the occurrence of a FALSE/TRUE edge at input SET. As long as a TRUE signal is present at the EN input, the current time and date are displayed in the standardized "DT" format at function block output "DT_ACT".

Input description



EN

Data type	Default value	Range	Unit
BOOL	-	-	-

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN. If the function block is active, the current time and date are available at the outputs.

SET

Data type	Default value	Range	Unit
BOOL	-	-	-

With an occurring FALSE/TRUE edge at input SET, the clock is set to the values available at the time and date inputs.

DT_SET

Data type	Default value	Range	Unit
BYTE	-	-	-

Set input for time and date in standardized "DT" format. The input for a "DT" value always has to start with the preceding designation "DT#", followed by the date, a hyphen and the time.

Valid range of values: DT#1970-01-01-00:00:00 to DT#2106-02-06-06:28:15

Output description

ERR

Data type	Default value	Range	Unit
BOOL	-	-	-

Output ERR indicates whether an error occurred during Function Block processing.

DT_ACT

Data type	Default value	Range	Unit
BYTE	-	-	-

Current value for date and time in standardized "DT" format.

Function call in ST

```
Clock  (EN := ClockDt_EN,
       SET := ClockDt_SET,
       DT_SET := ClockDt_DT_SET);

ClockDt_ERR := ClockDt.ERR;
ClockDt_DT_ACT := ClockDt.DT_ACT;
```

1.5.4.17 FlexConf library

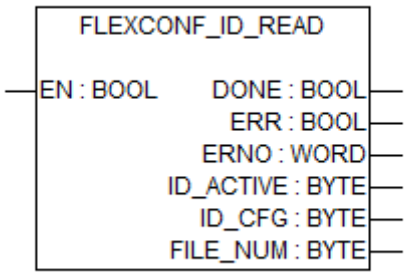
Library file name: **FlexConf_AC500_Vx.lib**

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

Only one instance of the function blocks FLEXCONF_ID_READ and FLEXCONF_ID_WRITE are allowed.

1.5.4.17.1 Function blocks

FLEXCONF_ID_READ

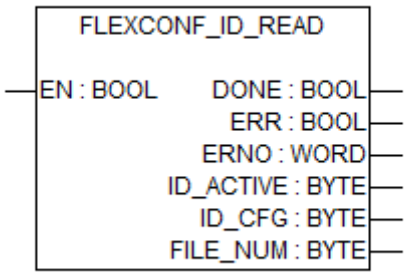


Parameter	Value
Included in library	FlexConf_AC500_V24.lib
Available as of firmware	V2.4
Type	Function block with historical values
Group	-

The function block FLEXCONF_ID_READ is used for reading the current settings of a flexible configuration. The following parameters can be read:

- Current value of the FlexConfID
- Value of the FlexConfID in the configuration data
- Numbers of alternative configuration files of the currently loaded project

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

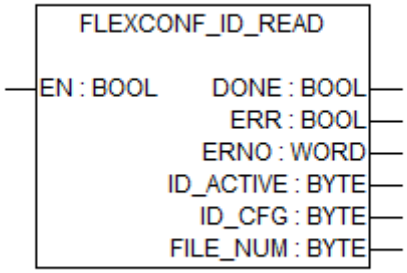
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ID_ACTIVE

Data type	Default value	Range	Unit
BYTE	-	-	-

Output ID_ACTIVE returns the current value of the FlexConfID which has been determined during booting of the PLC by reading from the configuration data file in the PLC's flash memory. This value has been used to determine the configuration file of the current executed application.

ID_CFG

Data type	Default value	Range	Unit
BYTE	-	-	-

Output ID_CFG returns the value of the FlexConfID which is stored in the configuration data file in the PLC's flash memory. This value is applied when the PLC is rebooted.

FILE_NUM

Data type	Default value	Range	Unit
BYTE	-	-	-

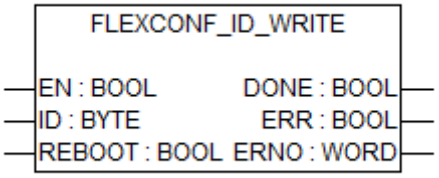
Ouput FILE_NUM returns the number of alternative configuration files of the currently executed application.

Function call in ST

```
FLEXCONF_ID_READ (EN := FLEXCONF_ID_READ_EN);

FLEXCONF_ID_READ_DONE         := FLEXCONF_ID_READ.DONE;
FLEXCONF_ID_READ_ERR          := FLEXCONF_ID_READ.ERR;
FLEXCONF_ID_READ_ERNO         := FLEXCONF_ID_READ.ERNO;
FLEXCONF_ID_READ_ID_ACTIVE    := FLEXCONF_ID_READ.ID_ACTIVE;
FLEXCONF_ID_READ_ID_CFG       := FLEXCONF_ID_READ.ID_CFG;
FLEXCONF_ID_READ_ID_FILE_NUM := FLEXCONF_ID_READ.FILE_NUM;
```

FLEXCONF_ID_WRITE

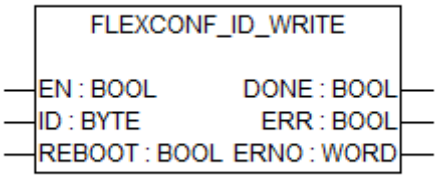


Parameter	Value
Included in library	FlexConf_AC500_V24.lib
Available as of firmware	V2.4
Type	Function block with historical values
Group	-

The function block FLEXCONF_ID_WRITE is used for writing the value of the FlexConfID to the configuration data file in the PLC's flash memory. Optionally the PLC can be rebooted after the value of the FlexConfID has been written.

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN. If the function block is active, the current values are available at the outputs.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

ID

Data type	Default value	Range	Unit
BYTE	-	-	-

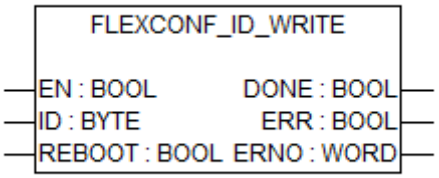
At input ID, the value of the FlexConfID which should be written to the configuration data has to be has to be specified.

REBOOT

Data type	Default value	Range	Unit
BOOL	-	-	-

If this input is set to TRUE, the PLC will be rebooted after the FlexConfID has been written. If this input is set to FALSE, the PLC will not be rebooted. In this case, the currently configuration stays active until the CPU will be rebooted manually.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
FLEXCONF_ID_WRITE (EN     := FLEXCONF_ID_WRITE_EN,
                   ID     := FLEXCONF_ID_WRITE_ID,
                   REBOOT := FLEXCONF_ID_WRITE_REBOOT);

FLEXCONF_ID_WRITE_DONE := FLEXCONF_ID_WRITE.DONE;
FLEXCONF_ID_WRITE_ERR  := FLEXCONF_ID_WRITE.ERR;
FLEXCONF_ID_WRITE_ERNO := FLEXCONF_ID_WRITE.ERNO;
```

1.5.4.18 IEC60870 library

Library file name: **IEC60870_AC500_Vx.lib**

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

The library can only be executed with CPUs with onboard Ethernet and at least CPU firmware V_2_0_0.

1.5.4.18.1 Information

The function blocks of the IEC60870 library allow link-ups to be made between AC500 CPUs with onboard Ethernet and external systems. The link-up takes place via the internal Ethernet interface of the CPU. The telecontrol protocol according to IEC60870-5 is used.

The CPU can work as both control station and substation. In control direction setpoints and commands are set. In monitoring direction the control station sends status values, real values and discrete values to the substation. Via general inquiry, the substation requests the control station to send all status values, real values and discrete values. Otherwise, these values are sent by the control station on a change-driven basis, cyclically or when triggered by an application. Status values, real values and discrete values may contain timestamps. These are filled in with the time of the process station when sent. The CPU can time-synchronize the telecontrol link.

A module accepts the configuration of the physical interface (link layer) and the general protocol parts (application layer), see PLC configuration in Control Builder Plus help.

Send and receive blocks are available for data exchange. These blocks exist for the IEC60870-5 data types

- setpoint value
- command value
- double command value
- status value
- double status value
- real value and discrete value.

The inputs/outputs of the send and receive blocks are combined with the signals to be communicated.

Data flow control

Each send or receive block can only process one data message. Ideally, new data are available at each user task run-through or new data can be sent.

If the OV output (send block only) indicates TRUE, the block computes more quickly than the data can be sent. If the receive block is not computed quickly enough and has thus not collected all the data.

Alternatively, this block sends either cyclically or when the input value is changed. Ideally, the topical data can be sent via the telecontrol link in connection with every user task run-through.

Data integrity of the IEC60870-5 protocol

With the IEC60870-5 protocol, a distinction is made between data transmission in the monitoring direction (status values, real values, discrete values) and in the control direction (commands and setpoints).

All data transmissions are acknowledged from the link communication level by the receiver. This acknowledgement is not sent to the sender of the data in every telecontrol link.

For data transmission in the control direction, additional acknowledgement (e.g. actterm) is possible. These acknowledgements are not sent by every telecontrol link either. For safe data transmission, it is necessary, in such cases, to configure data readback. The receiver then sends the data received back to the sender via the corresponding send blocks.

Information in the monitoring direction is acknowledged by the receiver on the lowest communication level (link level) when received. This acknowledgement is generated by the telecontrol head itself with some telecontrol heads. In the event of overload/overrun, a data message may be lost. For data in the control direction, so-called actterm acknowledgement can be used. This additional acknowledgement is sent back to the sender when the data have been executed in the process. If data are to be sent in the monitoring direction with guaranteed transmission, it is necessary to read back the sent value via another variable and, after observing a monitoring time, resend in the event of an error.

Data transmission function blocks

Send blocks

On the basis of the communication protocol, it is sensible to restrict the data types at one send block to one type. Therefore, there are five types of send blocks:

- send of status values
- commands
- real values
- setpoints
- discrete values.

These types are mapped to the IEC1131 data types BOOL, REAL and DINT.

Operating modes of the send blocks

The send blocks know three operating modes to send their data

- caused by request pin (SEND),
- send in connection with a change of data (AUTO), or
- cyclic send of data (CYCLE).

Send via request pin

The SEND signal is evaluated on the rising edge. The RDY signal remains applied for one computation cycle. If a rising edge is generated again at the SEND signal although no acknowledgement has yet been received from the receiver, the OV pin is set in order to indicate that an overrun has taken place. The evaluation of the receive acknowledgement is carried out before the evaluation of whether transmission is to take place. This means, assuming that there is an appropriately fast telecontrol link, that in connection with change-driven and cyclic transmission, a transmission job can be sent in connection with every computation of the block. In connection with send via the request pin it is possible to send only in connection with every second computation (send takes place only with a rising edge).

Change-driven send of data

Data are always sent when the value of the input variables changes. When changes take place, there is an internal simulation that the SEND pin changed from 0 to 1.

In order to prevent unnecessarily frequent send in the event of mild fluctuations in the input value, a threshold value can be configured for real values and setpoints. The input value is not sent until it differs positively or negatively from the value last sent by more than the threshold value.

If the input value changes again although no acknowledgement has yet been received from the receiver, the OV pin is set in exactly the same way as in connection with send via the Request pin. If an error occurs during send, the job is automatically retried until the value has been sent without error.

Cyclic send

The data are automatically sent after the expiry of a configurable cycle time (SCANDOWN). This cycle time is indicated in multiples of the task cycle time in which the block is computed. In this operating mode, an overrun error can occur if the transmission is faster than the response time of the receiver. For setpoints, it is necessary to ensure that an acknowledgement is generated by the receiver which is not sent until the setpoint is accepted. The send block is not ready for transmission again until after this acknowledgement has been received.

Timestamps

Timestamps for data types with time associated to the data are generated when a data point is being given to the underlying protocol. So for example on the rising edge of the SEND Pin. For values where an explicit timestamp different from the actual time is required, a new group of function blocks has been created all ending with the extension _ET.

All timestamps are only send at all if the correct IEC60870 data type with timestamps has been configured.

Receive blocks

In receive direction, the jobs enter the device module via the interface. The device module selects the correct receive block using the telecontrol address. To this end, during installation the receive blocks pass their parameterised telecontrol addresses to the device module, see ↳ *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

The device module stores the data received and the receive blocks make the data available at their output pins in connection with the next computation of the user task.

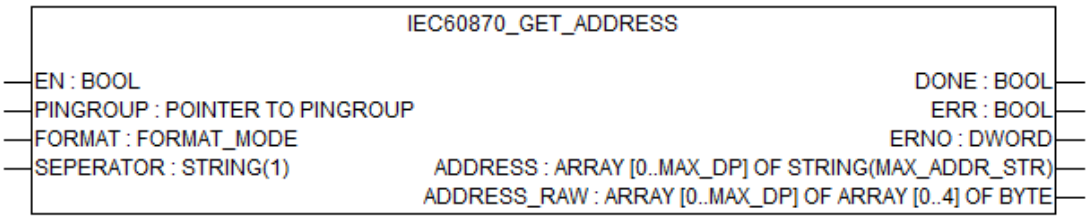
Interrogation command

The AC500 will answer interrogation command only if some general requirements are met:

For the command C_IC_NA_1 (interrogation command) the common address is either the broadcast address 255 255 or the defined station address and the qualifier of interrogation is <20> station interrogation. The answer will encode the defined station address. See ↳ *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

1.5.4.18.2 Function blocks

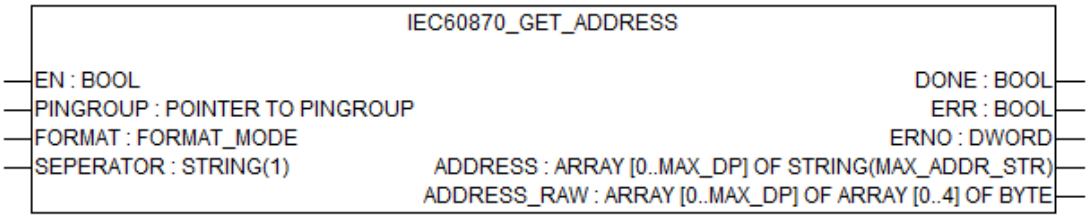
IEC60870_GET_ADDRESS



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.2.x
Type	Function block with historical values
Group	General

The function block returns the address (GADU1, GADU2, IAD1, IAD2, IAD3) of the given PINGROUP in string representation.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

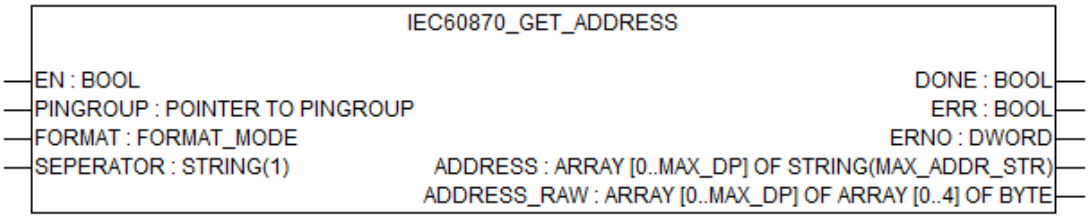
PINGROUP Pointer to a structure representing a pin group. Normally generated by the Control Builder Plus and stored under the global variable list "Command (CONSTANT)".

FORMAT Describes the desired output format of the address. The different formats can be accessed through the FORMAT_MODE (ENUM). Following values are defined:

DEC_ONE:	Decimal value of the 40 bits representing the address (default)
HEX_ASC:	Hexadecimal value of each byte in ascending order: 0xGADU1<SEP>0xGADU2<SEP>0xIAD1<SEP>0xIAD2<SEP>0xIAD3
HEX_DESC:	Hexadecimal value of each byte in descending order: 0xGADU2<SEP>0xGADU1<SEP>0xIAD3<SEP>0xIAD2<SEP>0xIAD1
DEC_ASC:	Decimal value of each byte in ascending order: GADU1<SEP>GADU2<SEP>IAD1<SEP>IAD2<SEP>IAD3
DEC_DESC:	Decimal value of each byte in descending order: GADU2<SEP>GADU1<SEP>IAD3<SEP>IAD2<SEP>IAD1

SEPARATOR One character that is used to divide the single bytes of the address from each other. See the above description of FORMAT where <SEP> represents this one character. Default is a blank.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADDRESS

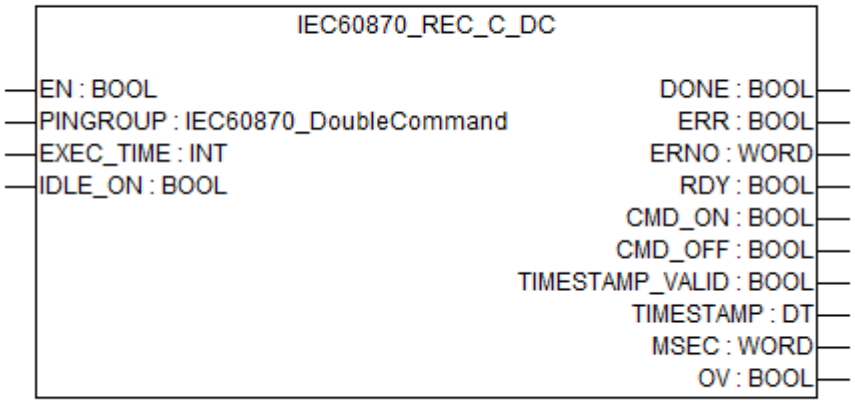
Contains the string representations of the addresses for the given PINGROUP depending on the selected FORMAT (ARRAY[0..MAX_DP] OF STRING(MAX_ADDR_STR)). Each array index belongs to one data point. If only one data point exists only the first index [0] is set and all the others contain empty strings.

Function call in ST

```
IEC60870_SEND_M_EI_NA_1
                    EN                                          := TRUE,
                    PINGROUP                 := ADR(Measured_value),
                    FORMAT                        := FORMAT_HEX_ASC,
                    SEPARATOR             := ';'
);

GET_ADDR_DONE                    := GET_ADDR.DONE;
GET_ADDR_ERR                        := GET_ADDR.ERR;
GET_ADDR_ERNO                    := GET_ADDR.ERNO;
GET_ADDR_ADDRESS        := GET_ADDR.ADDRESS;
```

IEC60870_REC_C_DC



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

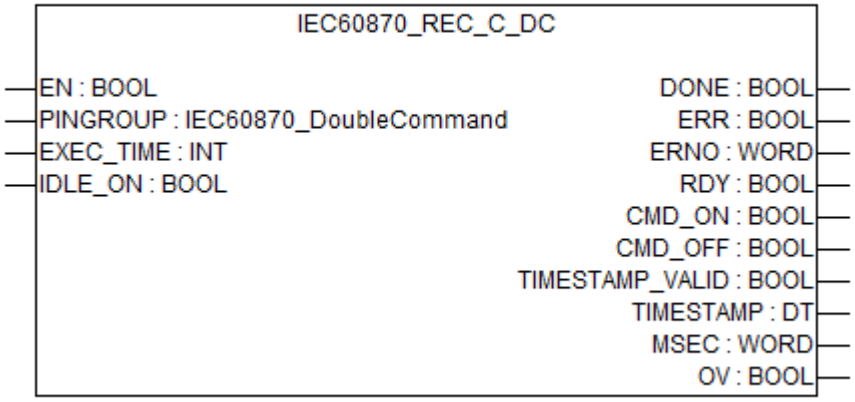
Reception of data messages of the data type according to IEC 60870-5 C_DC_xx message, sent by e.g. SEND_C_DC function block.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The data received are available at the corresponding output pins.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP

At input PINGROUP (IEC60870_IntegratedTotal) the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

EXEC_TIME INT

Data type	Default value	Range	Unit
INT	-	-	-

Input EXEC_TIME (execution time) sets the execution time in cycles for a command.

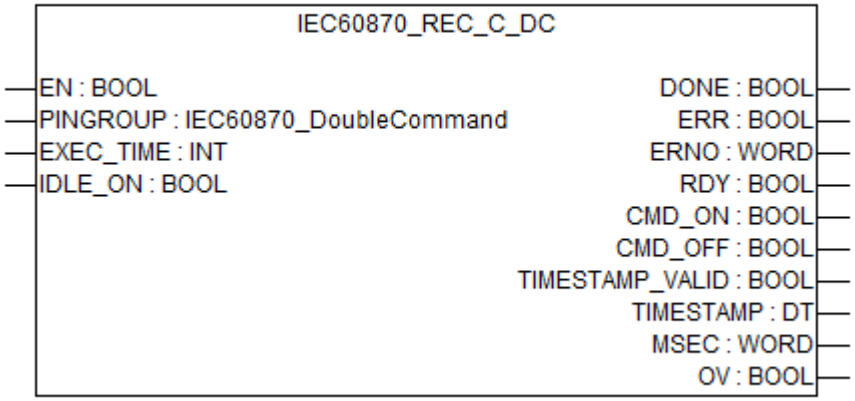
EXEC_TIME = 0: Unlimited

IDLE_ON

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Value for ON; if IDLE_ON => OFF the function block is OFF.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command was received if the output RDY = TRUE.

CMD_ON BOOL (commandon) The received command depending on input IDLE_ON.

The output always has to be considered together with output RDY.

CMD_OFF BOOL (commandoff) The received command depending on input IDLE_ON.

The output always has to be considered together with output RDY.

TIMESTAMP_VALID BOOL (timestampvalid) Valid timestamp was received when the output is TRUE.

The output always has to be considered together with output RDY.

TIMESTAMP DT (timestamp) If data with timestamp is received, the timestamp is given at this output.

The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

MSEC WORD (milliseconds) Value of the received timestamp in milliseconds. The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

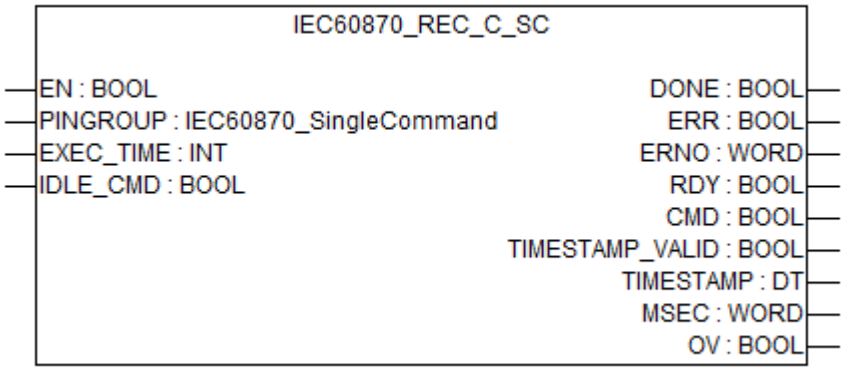
The output always has to be considered together with output RDY.

Function call in ST

```
REC   (EN := REC_EN,
PINGROUP := REC_PINGROUP,
EXEC_TIME := REC_EXEC_TIME,
IDLE_ON := REC_IDLE_ON);

REC_DONE            := REC.DONE;
REC_ERR             := REC.ERR;
REC_ERNO            := REC.ERNO;
REC_RDY             := REC.RDY;
REC_CMD_ON          := REC.CMD_ON;
REC_CMD_OFF         := REC.CMD_OFF;
REC_TIMESTAMP_VALID := REC.TIMESTAMP_VALID;
REC_TIMESTAMP       := REC.TIMESTAMP;
REC_MSEC            := REC.MSEC;
REC_OV              := REC.OV;
```

IEC60870_REC_C_SC



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Group/Subgroup

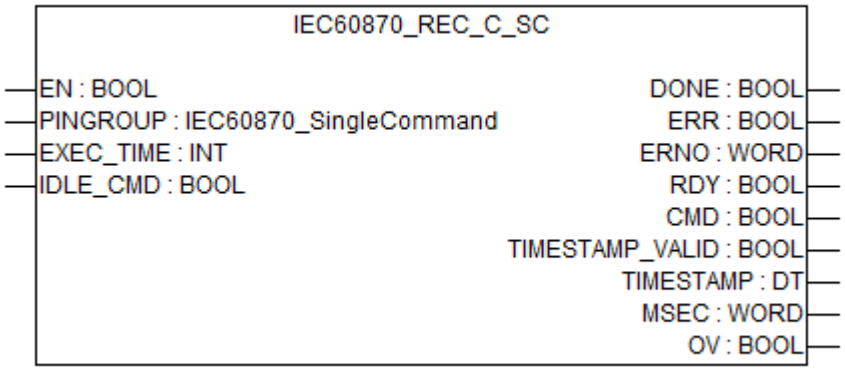
Reception of data messages of the data type according to IEC 60870-5 (C_SC_xx message).

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The data received are available at the corresponding output pins.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_SingleCommand (pingroup)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pingroup of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC 60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pingroup can only be assigned to one defined function block! It is not possible to use the pingroup twice (e.g. Send and Rec function blocks)!

EXEC_TIME INT (execution time)

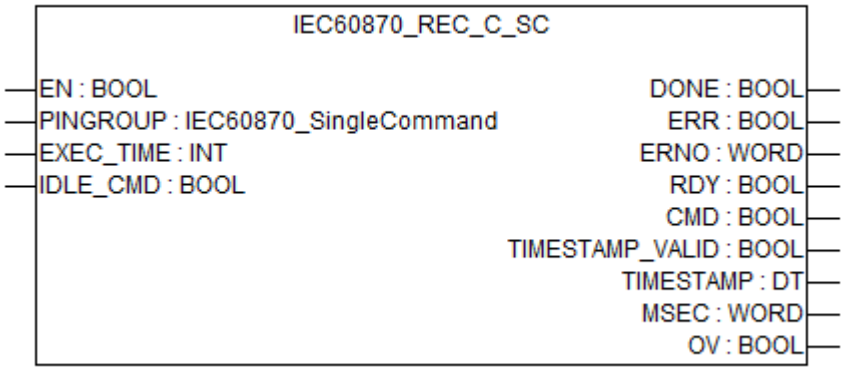
Input EXEC_TIME sets the execution time in cycles for a command.

EXEC_TIME = 0: Unlimited

IDLE_CMD BOOL (idle on)

Input for positive (IDLE_CMD = TRUE) or negative (IDLE_CMD = FALSE) logic.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command was received if the output RDY = TRUE.

CMD BOOL (command) The received command depending on input IDLE_CMD.

The output always has to be considered together with output RDY.

TIMESTAMP_VALID BOOL (timestampvalid) Valid timestamp was received when the output is TRUE.

The output always has to be considered together with output RDY.

TIMESTAMP DT (timestamp) If data with timestamp is received, the timestamp is given at this output.

The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

MSEC WORD (milliseconds) Value of the received timestamp in milliseconds. The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

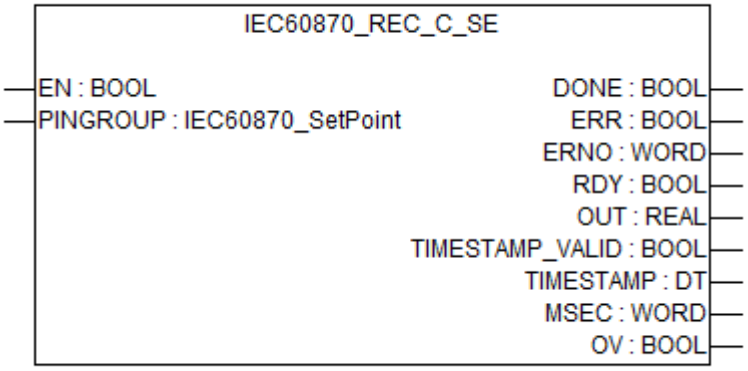
Function call in ST

```
REC   (EN       := REC_EN,
PINGROUP := REC_PINGROUP,
EXEC_TIME := REC_EXEC_TIME,
IDLE_CMD := REC_IDLE_CMD);

REC_DONE            := REC.DONE;
REC_ERR             := REC.ERR;
REC_ERNO            := REC.ERNO;
REC_RDY             := REC.RDY;
```

```
REC_CMD             := REC.CMD;
REC_TIMESTAMP_VALID := REC.TIMESTAMP_VALID;
REC_TIMESTAMP       := REC.TIMESTAMP;
REC_MSEC            := REC.MSEC;
REC_OV              := REC.OV;
```

IEC60870_REC_C_SE



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

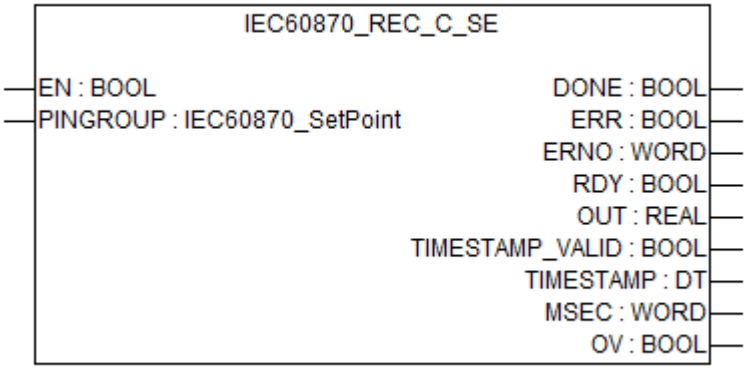
Reception of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The data received are available at the corresponding output pins.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_SetPoint (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

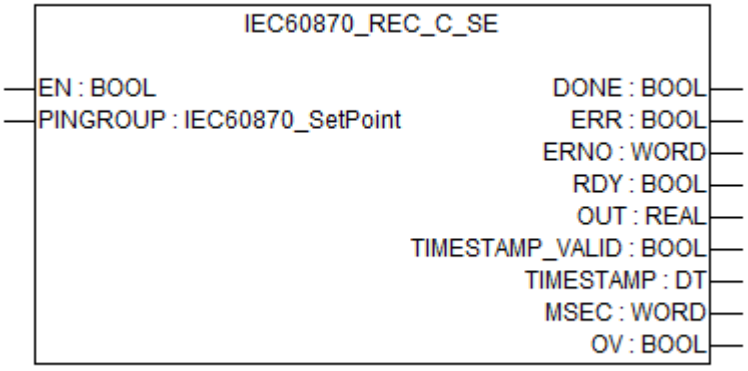
The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

OUT REAL (output)

The output OUT gives the received value as a floating point number.

The output always has to be considered together with output RDY.

TIME-STAMP_VALID BOOL (time-stampvalid)

Valid timestamp was received when the output is TRUE.

The output always has to be considered together with output RDY.

TIMESTAMP DT (time-stamp)

If data with timestamp is received, the timestamp is given at this output.

The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

MSEC WORD (milliseconds) Value of the received timestamp in milliseconds. The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

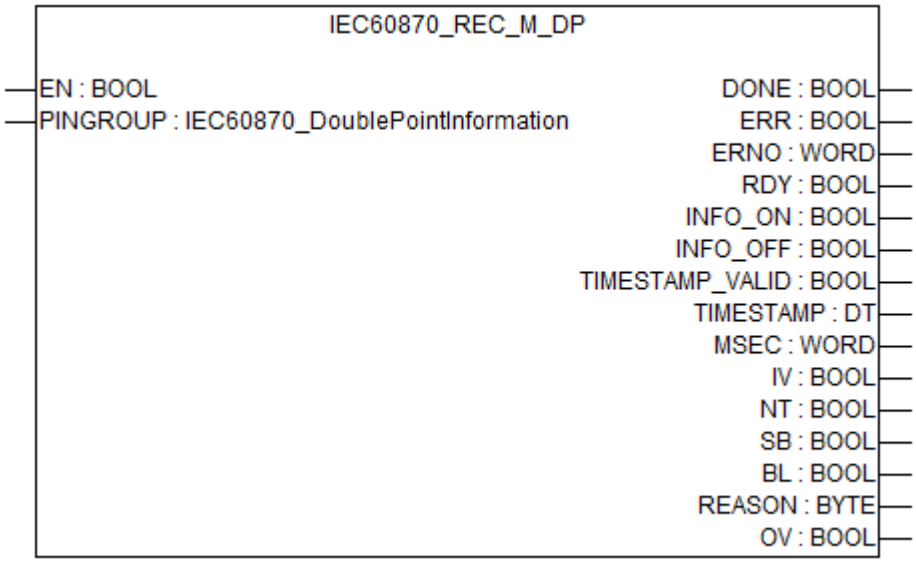
The output always has to be considered together with output RDY.

Function call in ST

```
REC    (EN       := REC_EN,
PINGROUP := REC_PINGROUP);

REC_DONE            := REC.DONE;
REC_ERR             := REC.ERR;
REC_ERNO            := REC.ERNO;
REC_RDY             := REC.RDY;
REC_OUT             := REC.OUT;
REC_TIMESTAMP_VALID := REC.TIMESTAMP_VALID;
REC_TIMESTAMP       := REC.TIMESTAMP;
REC_MSEC            := REC.MSEC;
REC_OV              := REC.OV;
```

IEC60870_REC_M_DP



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Group/Subgroup

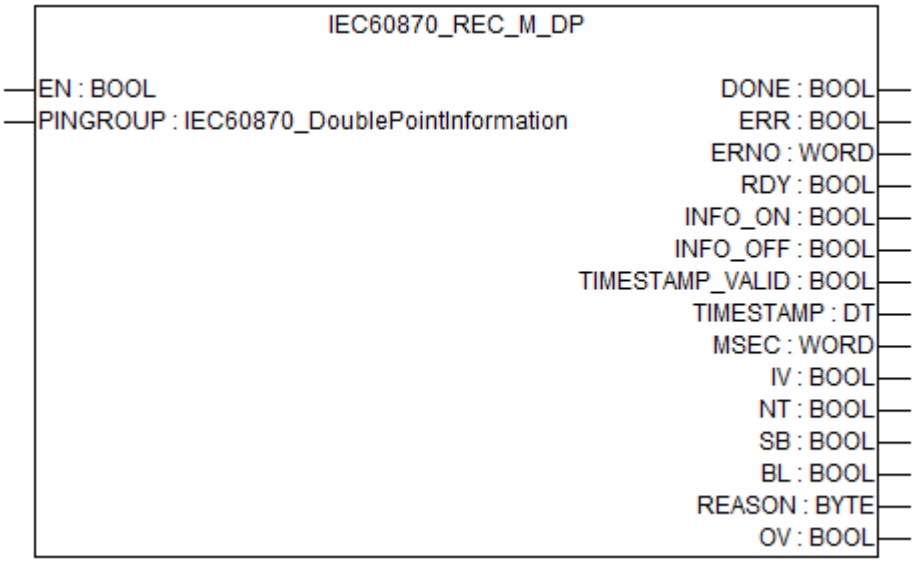
Reception of data messages of the data type according to IEC 60870-5 (M_DP_xx message).

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The data received are available at the corresponding output pins.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_DoublePointInformation (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

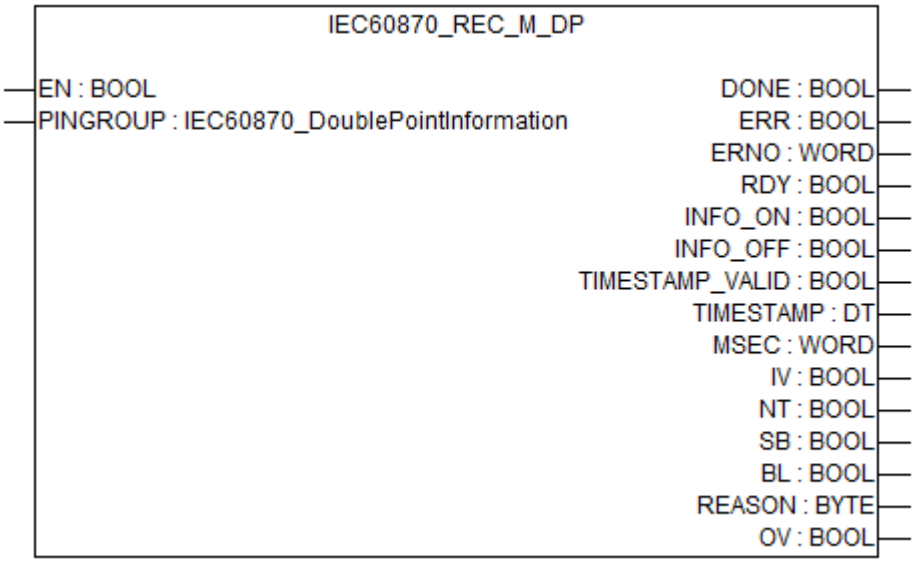
The pin group of the data type IEC 60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC 60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

> *A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!*

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

INFO_ON BOOL (infoon)

The received ON information, if output INFO_ON = TRUE.

The output always has to be considered together with output RDY.

INFO_OFF BOOL (infooff)

The received OFF information, if output INFO_OFF = TRUE.

The output always has to be considered together with output RDY.

TIME-STAMP_VALID BOOL (time-stampvalid)

Valid timestamp was received when the output is TRUE.

The output always has to be considered together with output RDY.

TIMESTAMP DT (time-stamp)

If data with timestamp is received, the timestamp is given at this output.

The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

MSEC WORD (milliseconds)

Value of the received timestamp in milliseconds. The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

IV BOOL (invalid)

Output IV displays the status/information of the data. If IV = TRUE, the data is invalid.

The output always has to be considered together with output RDY.

NT BOOL (not topical)

Output NT displays the status/information of the data. If NT = TRUE, the data is not topical/ actual.

The output always has to be considered together with output RDY.

SB BOOL (substituted)

Output SB displays the status/information of the data. If SB = TRUE, the data is substituted.

The output always has to be considered together with output RDY.

BL BOOL (blocked)

Output BL displays the status/information of the data. If BL = TRUE, the data is blocked.

The output always has to be considered together with output RDY.

REASON BYTE (reason)

Output REASON displays the cause of the transmission.

The output always has to be considered together with output RDY.

Reasons for transmission:

1	Periodic/cyclic
2	Background interrogation
3	Spontaneous
4	Initialised
5	Requested
6	Activation
7	Confirmation of activation
8	Deactivation
9	Confirmation of deactivation
10	Termination of activation
11	Return information, caused by a remote command
12	Return information, caused by a local command
20	Interrogated by general inquiry

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```
REC    (EN        := REC_EN,
PINGROUP := REC_PINGROUP);

REC_DONE             := REC.DONE;
REC_ERR              := REC.ERR;
REC_ERNO             := REC.ERNO;
REC_RDY              := REC.RDY;

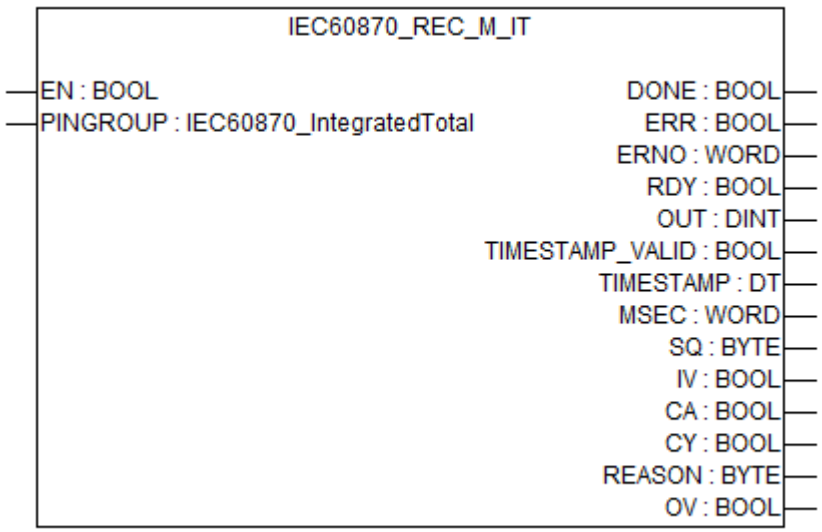
REC_OV               := REC.OV;
```

IEC60870_REC_M_IT



Parameter	Value
Included in library	library.lib IEC60870_AC500_V20.lib
Available as of firmware	Vx.x.x V2.0
Type	Function block with historical values
Group	Data

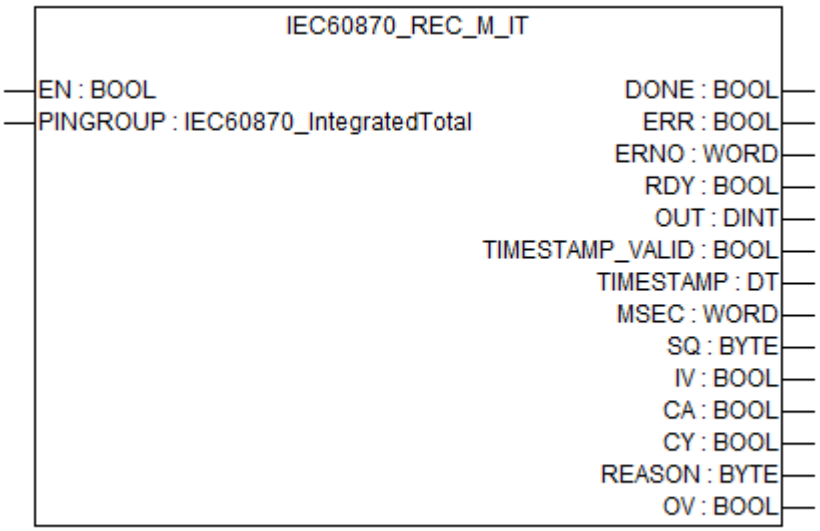
Reception of data messages of the data type according to IEC 60870-5 (M_DP_xx message).

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The data received are available at the corresponding output pins.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP

At input PINGROUP (IEC60870_IntegratedTotal) the corresponding data point is set, which gets received by this function block.

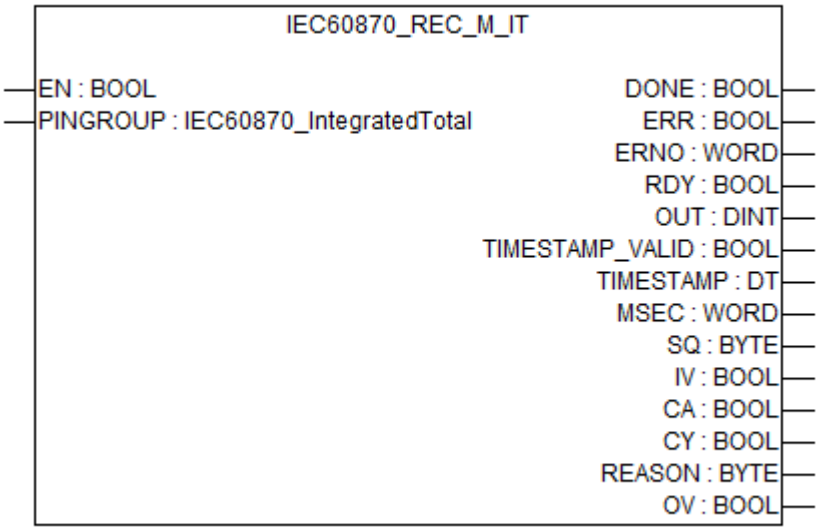
The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

> *A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!*

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OUT REAL (output)

The output OUT gives the received value as a floating point number.

The output always has to be considered together with output RDY.

TIME-STAMP_VALID BOOL (time-stampvalid)

Valid timestamp was received when the output is TRUE.

The output always has to be considered together with output RDY.

TIMESTAMP DT (time-stamp)

If data with timestamp is received, the timestamp is given at this output.

The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

MSEC WORD (milliseconds)

Value of the received timestamp in milliseconds. The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

SQ BYTE (sequence)

Output SQ displays the sequence number.

The output always has to be considered together with output RDY.

IV BOOL (invalid)

Output IV displays the status/information of the data. If IV = TRUE, the data is invalid.

The output always has to be considered together with output RDY.

CA BOOL (counter adjusted)

Output CA displays the status/information of the data. If CA = TRUE, the counter has been preset since the last reading.

The output always has to be considered together with output RDY.

CY BOOL (carry)

Output CY displays the status/informations of the data. If CY = TRUE, the transmission divided into associated measurement periods.

The output always has to be considered together with output RDY.

REASON BYTE (reason)

Output REASON displays the cause of the transmission.

The output always has to be considered together with output RDY.

Reasons for transmission:

1	Periodic/cyclic
2	Background interrogation
3	Spontaneous
4	Initialised

5	Requested
6	Activation
7	Confirmation of activation
8	Deactivation
9	Confirmation of deactivation
10	Termination of activation
11	Return information, caused by a remote command
12	Return information, caused by a local command
20	Interrogated by general inquiry

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```
REC   (EN       := REC_EN,
PINGROUP := REC_PINGROUP);

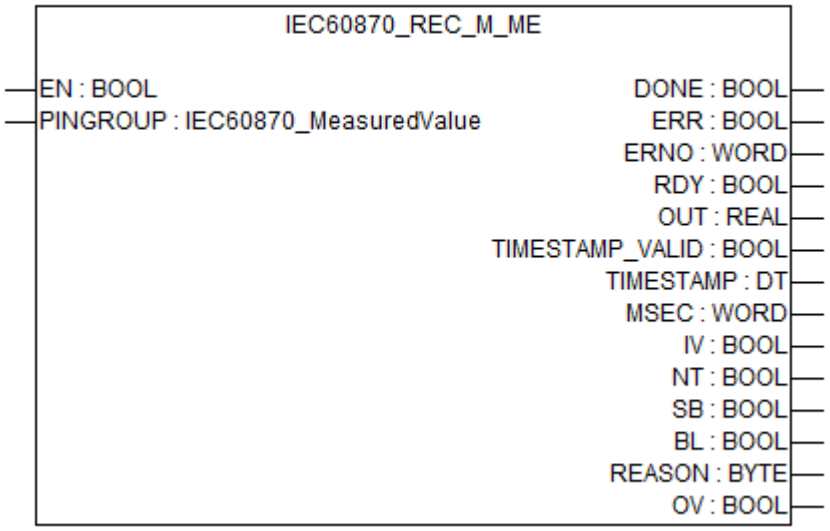
```

IEC60870_REC_M_ME



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

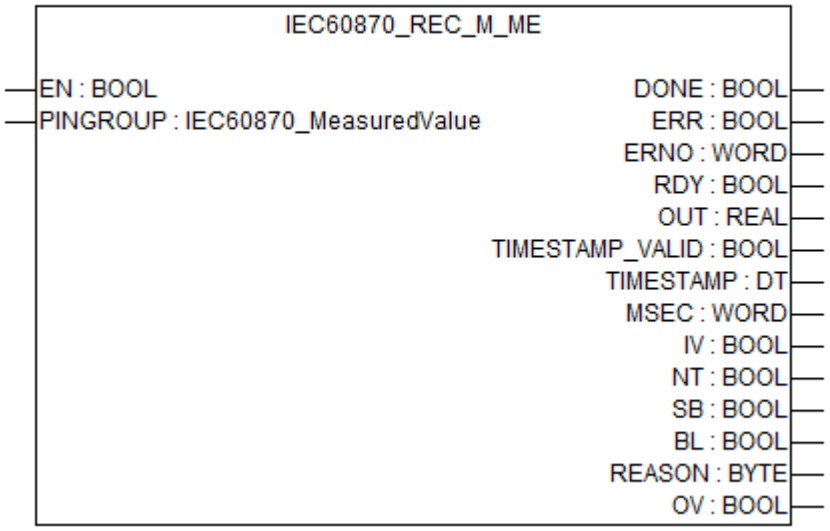
Reception of data messages of the data type according to IEC 60870-5 (M_DP_xx message).

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The data received are available at the corresponding output pins.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_MeasuredValue (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

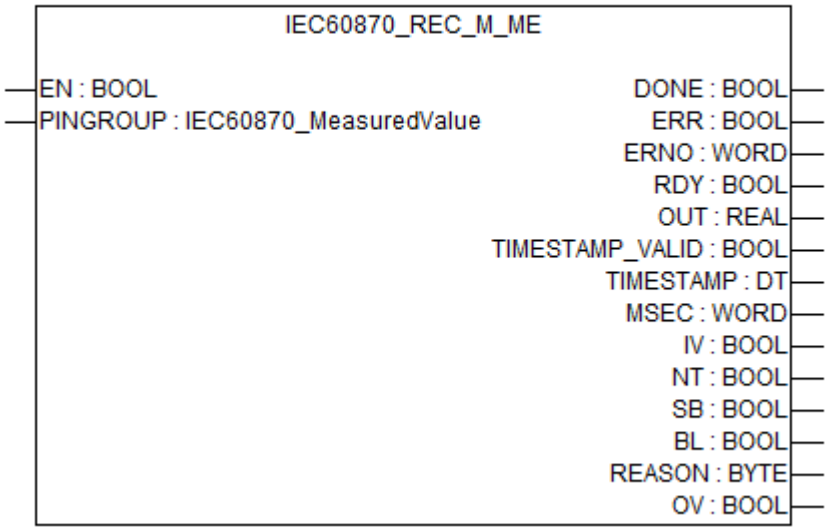
The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OUT REAL (output)

The output OUT gives the received value as a floating point number.

The output always has to be considered together with output RDY.

TIME-STAMP_VALID BOOL (time-stampvalid)

Valid timestamp was received when the output is TRUE.

The output always has to be considered together with output RDY.

TIMESTAMP DT (time-stamp)

If data with timestamp is received, the timestamp is given at this output.

The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

MSEC WORD (milliseconds)

Value of the received timestamp in milliseconds. The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

IV BOOL (invalid)

Output IV displays the status/information of the data. If IV = TRUE, the data is invalid.

The output always has to be considered together with output RDY.

NT BOOL (not topical)

Output NT displays the status/information of the data. If NT = TRUE, the data is not topical/ actual.

The output always has to be considered together with output RDY.

SB BOOL (substituted)

Output SB displays the status/information of the data. If SB = TRUE, the data is substituted.

The output always has to be considered together with output RDY.

BL BOOL (blocked)

Output BL displays the status/information of the data. If BL = TRUE, the data is blocked.

The output always has to be considered together with output RDY.

REASON BYTE (reason)

Output REASON displays the cause of the transmission.

The output always has to be considered together with output RDY.

Reasons for transmission:

1	Periodic/cyclic
2	Background interrogation
3	Spontaneous
4	Initialised
5	Requested
6	Activation
7	Confirmation of activation
8	Deactivation
9	Confirmation of deactivation
10	Termination of activation
11	Return information, caused by a remote command
12	Return information, caused by a local command
20	Interrogated by general inquiry

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

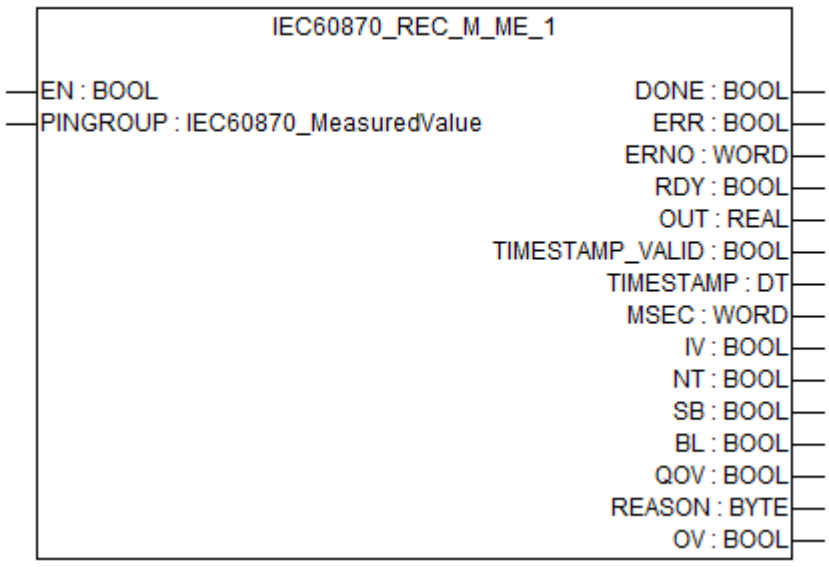
IEC60870_REC_M_ME_1



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

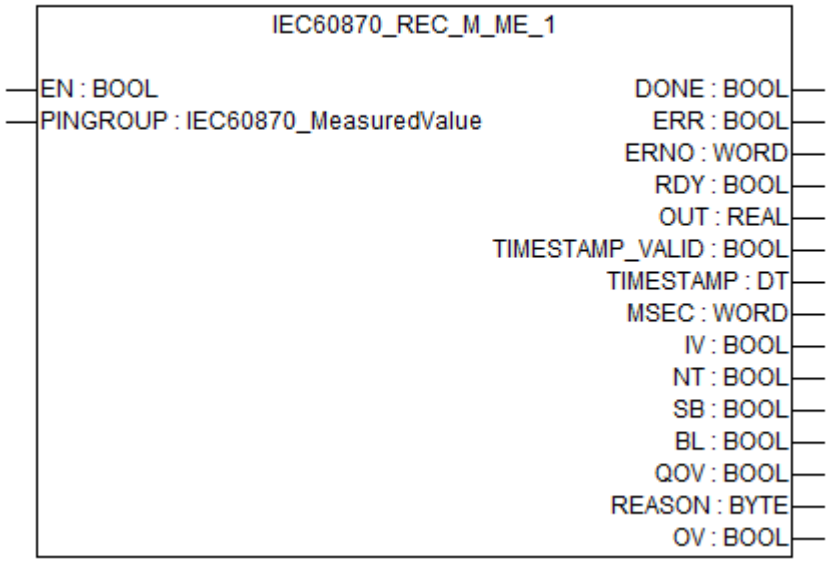
Reception of data messages of the data type according to IEC 60870-5 (M_DP_xx message).

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The data received are available at the corresponding output pins.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_MeasuredValue (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

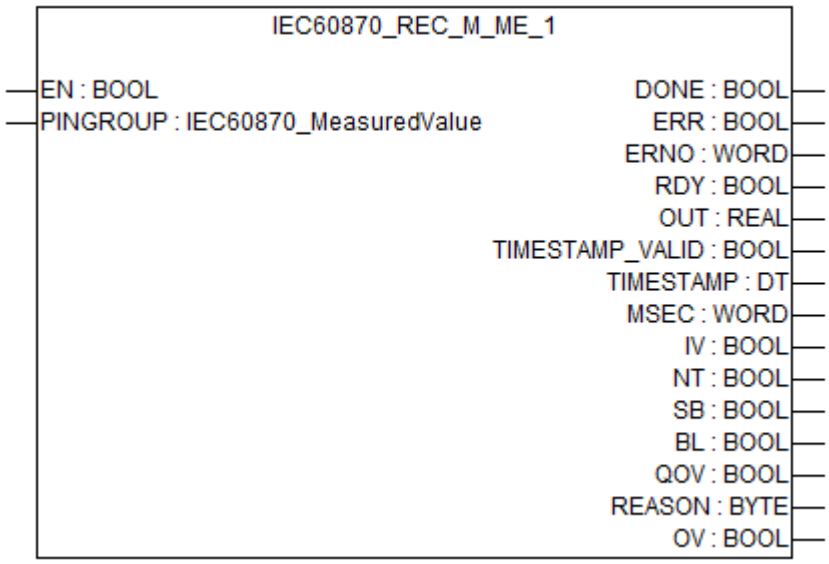
The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

> *A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!*

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OUT REAL (output)

The output OUT gives the received value as a floating point number.

The output always has to be considered together with output RDY.

TIME-STAMP_VALID BOOL (time-stampvalid)

Valid timestamp was received when the output is TRUE.

The output always has to be considered together with output RDY.

TIMESTAMP DT (time-stamp)

If data with timestamp is received, the timestamp is given at this output.

The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

MSEC WORD (milliseconds)

Value of the received timestamp in milliseconds. The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

IV BOOL (invalid)

Output IV displays the status/information of the data. If IV = TRUE, the data is invalid.

The output always has to be considered together with output RDY.

NT BOOL (not topical)

Output NT displays the status/information of the data. If NT = TRUE, the data is not topical/ actual.

The output always has to be considered together with output RDY.

SB BOOL (substituted)

Output SB displays the status/information of the data. If SB = TRUE, the data is substituted.

The output always has to be considered together with output RDY.

BL BOOL (blocked)

Output BL displays the status/information of the data. If BL = TRUE, the data is blocked.

The output always has to be considered together with output RDY.

QOV BOOL (overflow)

Output QOV displays the status/information of the data. If QOV = TRUE, the data signals an overflow.

The output always has to be considered together with output RDY.

REASON BYTE (reason)

Output REASON displays the cause of the transmission.

The output always has to be considered together with output RDY.

Reasons for transmission:

1	Periodic/cyclic
2	Background interrogation
3	Spontaneous
4	Initialised
5	Requested
6	Activation
7	Confirmation of activation
8	Deactivation
9	Confirmation of deactivation
10	Termination of activation
11	Return information, caused by a remote command

12	Return information, caused by a local command
20	Interrogated by general inquiry

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```
REC    (EN       := REC_EN,
        PINGROUP := REC_PINGROUP);

REC_DONE            := REC.DONE;
REC_ERR             := REC.ERR;
REC_ERNO            := REC.ERNO;
REC_RDY             := REC.RDY;
REC_OUT             := REC.OUT;
REC_TIMESTAMP_VALID := REC.TIMESTAMP_VALID;
REC_TIMESTAMP       := REC.TIMESTAMP;
REC_MSEC            := REC.MSEC;

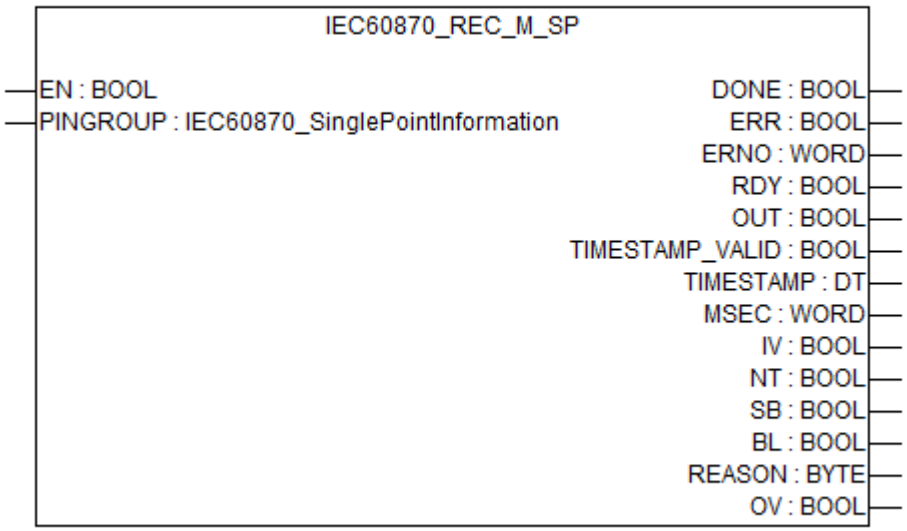
REC_QOV             := REC.QOV;
REC_REASON          := REC.REASON;
REC_OV              := REC.OV;
```

IEC60870_REC_M_SP



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

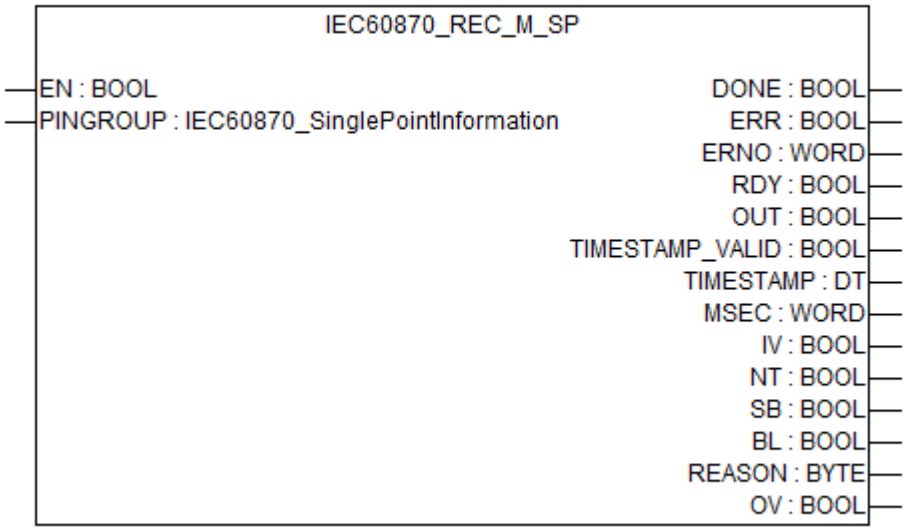
Reception of data messages of the data type according to IEC 60870-5 (M_DP_xx message).

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The data received are available at the corresponding output pins.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_SinglePointInformation (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

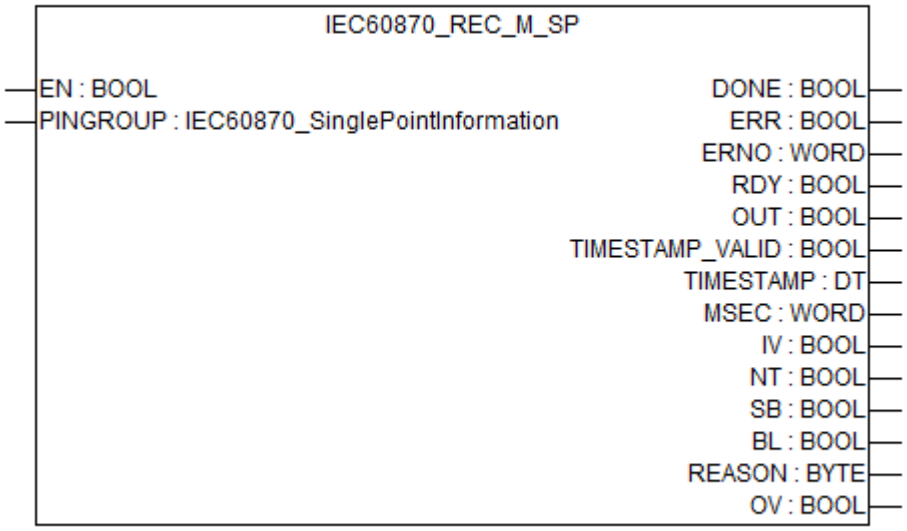
The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC 60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

> *A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!*

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command has been received if RDY = TRUE.

OUT REAL (output) The output OUT gives the received value as a floating point number.

The output always has to be considered together with output RDY.

TIME-STAMP_VALID BOOL (time-stampvalid) Valid timestamp was received when the output is TRUE.

The output always has to be considered together with output RDY.

TIMESTAMP DT (time-stamp) If data with timestamp is received, the timestamp is given at this output.

The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

MSEC WORD (milliseconds) Value of the received timestamp in milliseconds. The value is given if a valid timestamp was received and the output VALID_TIMESTAMP = TRUE.

IV BOOL (invalid) Output IV displays the status/information of the data. If IV = TRUE, the data is invalid.

The output always has to be considered together with output RDY.

NT BOOL (not topical) Output NT displays the status/information of the data. If NT = TRUE, the data is not topical/ actual.

The output always has to be considered together with output RDY.

SB BOOL (substituted) Output SB displays the status/information of the data. If SB = TRUE, the data is substituted.

The output always has to be considered together with output RDY.

BL BOOL (blocked) Output BL displays the status/information of the data. If BL = TRUE, the data is blocked.

The output always has to be considered together with output RDY.

REASON BYTE (reason) Output REASON displays the cause of the transmission.

The output always has to be considered together with output RDY.

Reasons for transmission:

1	Periodic/cyclic
2	Background interrogation
3	Spontaneous
4	Initialised
5	Requested
6	Activation
7	Confirmation of activation

8	Deactivation
9	Confirmation of deactivation
10	Termination of activation
11	Return information, caused by a remote command
12	Return information, caused by a local command
20	Interrogated by general inquiry

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```
REC    (EN        := REC_EN,
PINGROUP := REC_PINGROUP);

REC_DONE             := REC.DONE;
REC_ERR              := REC.ERR;
REC_ERNO             := REC.ERNO;
REC_RDY              := REC.RDY;

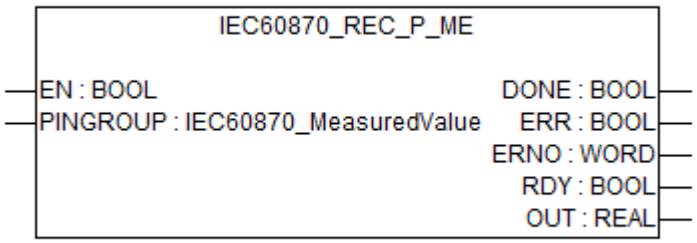
REC_OV               := REC.OV;
```

IEC60870_REC_P_ME



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0

Parameter	Value
Type	Function block with historical values
Group	Data

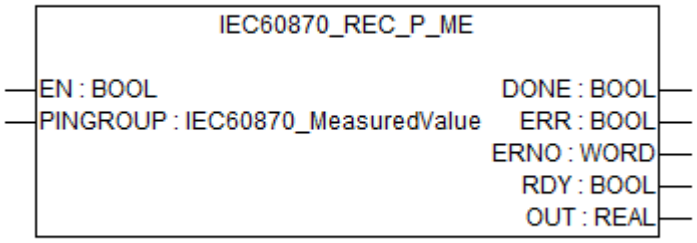
Reception of data messages of the data type according to IEC 60870-5 (M_IT_xx message).

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The data received are available at the corresponding output pins.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_MeasuredValue (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

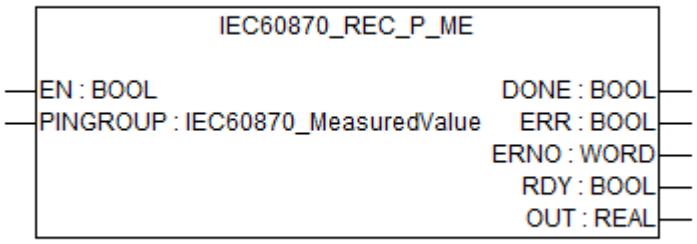
The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OUT REAL (output)

The output OUT gives the received value as a floating point number.

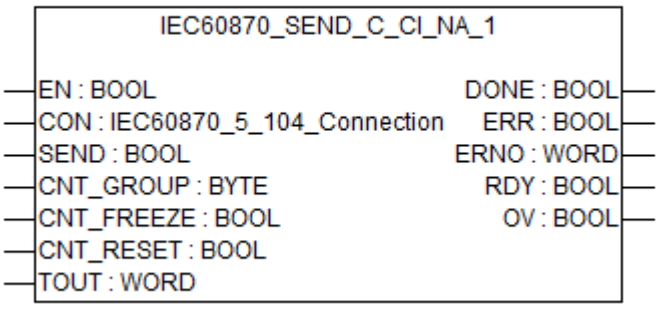
The output always has to be considered together with output RDY.

Function call in ST

```
REC    (EN        := REC_EN,
PINGROUP := REC_PINGROUP);

REC_DONE             := REC.DONE;
REC_ERR              := REC.ERR;
REC_ERNO             := REC.ERNO;
REC_RDY              := REC.RDY;
REC_OUT              := REC.OUT;
```

IEC60870_SEND_C_CI_NA_1



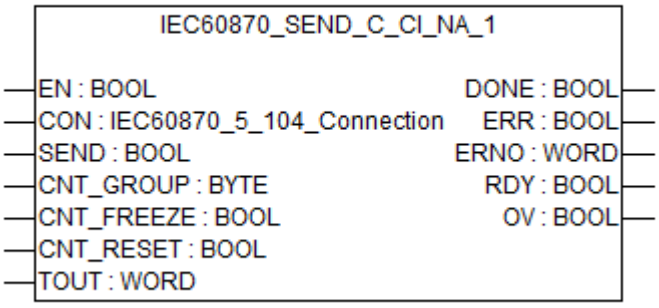
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CON IEC60870_5_104_Connection (connection)

At input CON the corresponding connection is set to gather information.

The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

SEND BOOL (send)

Start a send request on a rising edge.

CNT_GROUP BYTE (counter group)

Counter group (1...4) to poll; 5 means all groups.

CNT_FREEZE BOOL (counter freeze)

Freeze the counter.

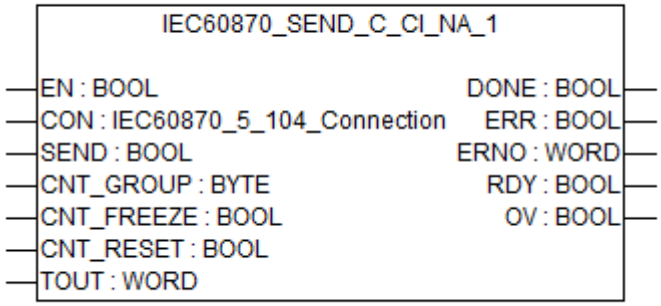
CNT_RESET BOOL (counter reset)

Reset the counter.

TOUT WORD (timeout)

Timeout in ms until ACTERM is expected; 0 = infinite.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

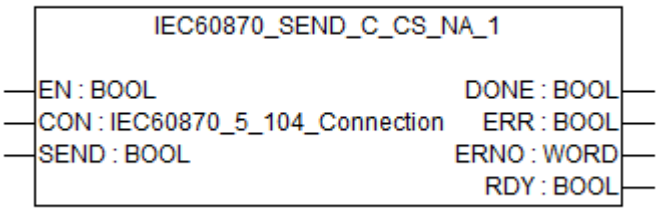
The output always has to be considered together with output RDY.

Function call in ST

```
SEND    (EN          := SEND_EN,
CON         := SEND_CON,
SEND        := SEND_SEND,
CNT_GROUP   := SEND_CNT_GROUP,
CNT_FREEZE  := SEND_SNT_FREEZE,
CNT_RESET   := SEND_CNT_RESET,
TOUT        := SEND_TOUT);

SEND_DONE             := SEND.DONE;
SEND_ERR              := SEND.ERR;
SEND_ERNO             := SEND.ERNO;
SEND_RDY              := SEND.RDY;
SEND_OV               := SEND.OV;
```

IEC60870_SEND_C_CS_NA_1



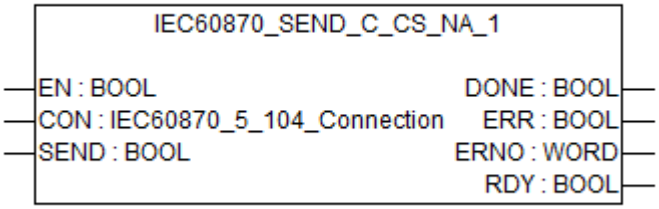
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CON IEC60870_5_104_Connection (connection)

At input CON the corresponding connection is set to gather information.

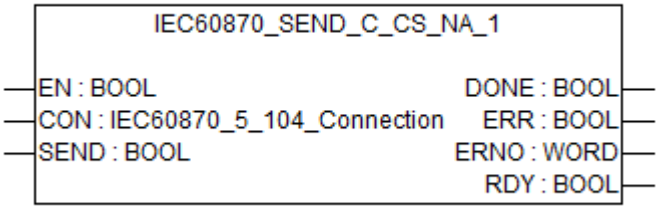
The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

SEND BOOL (send)

Start a send request on a rising edge.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

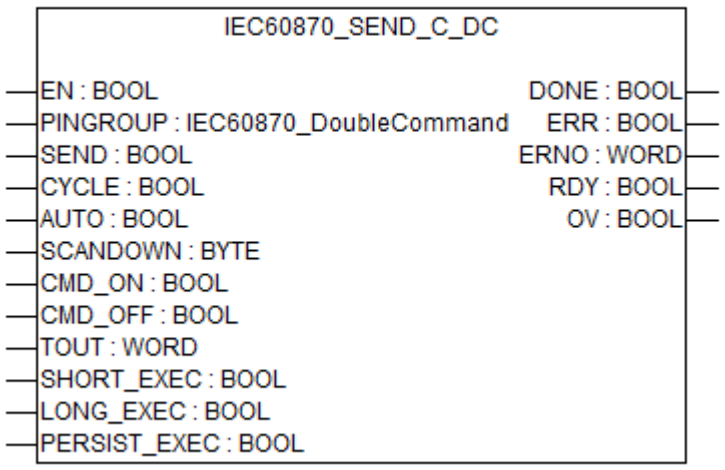
RDY BOOL (ready) A command has been received if RDY = TRUE.

Function call in ST

```
SEND    (EN          := SEND_EN,
CON         := SEND_CON,
SEND        := SEND_SEND);

SEND_DONE             := SEND.DONE;
SEND_ERR              := SEND.ERR;
SEND_ERNO             := SEND.ERNO;
SEND_RDY              := SEND.RDY;
```

IEC60870_SEND_C_DC



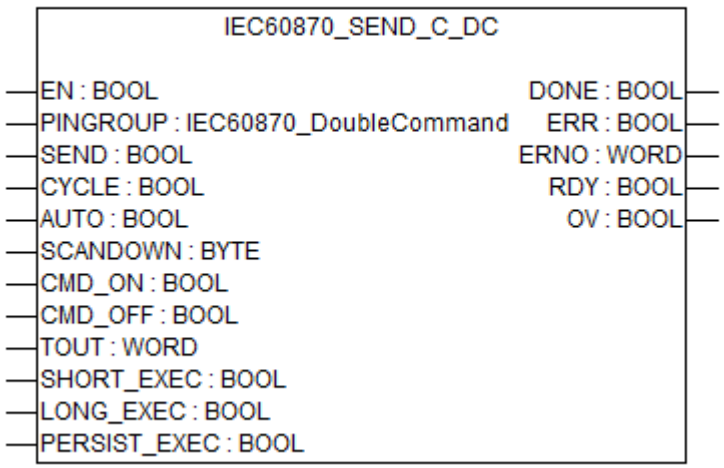
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_DoubleCommand (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec, see *Chapter 1.6.5.3.2.3.4 “Data points” on page 6131*).

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send) Start a send request on a rising edge.

CYCLE BOOL (cycle) Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.

On cyclic sending only send within each scandown cycle.

CMD_ON BOOL (commandon) Input value Bit 1.

CMD_OFF BOOL (commandoff) Input value Bit 2.

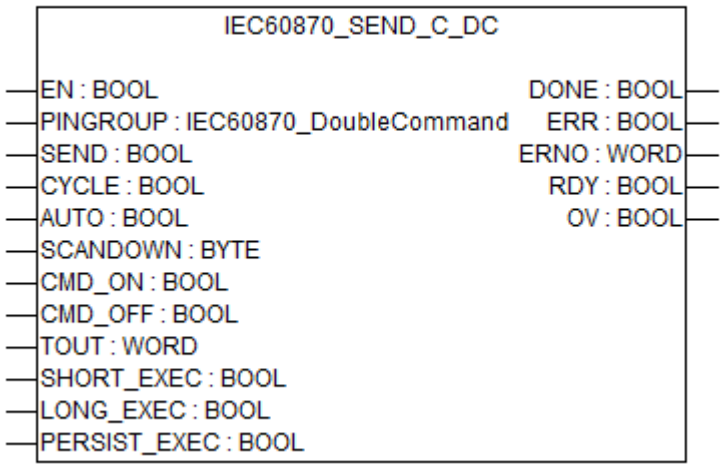
TOUT WORD (timeout) Timeout in ms until ACTERM is expected; 0 = infinite.

SHORT_EXEC BOOL (shortexecution) If input SHORT_EXEC = TRUE, short execution is enabled on controlled station.

LONG_EXEC BOOL (longexecution) If input LONG_EXEC = TRUE, long execution is enabled on controlled station.

PERSIST_EXEC BOOL (persistent execution) If input PERSISTENT_EXEC = TRUE, persistent execution is enabled on controlled station.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

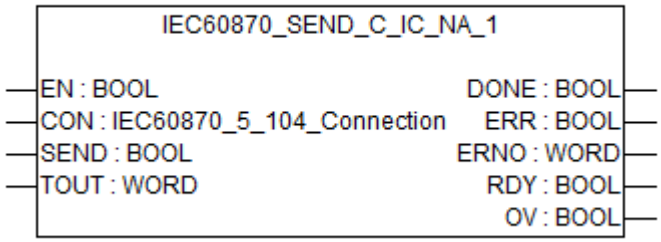
The output always has to be considered together with output RDY.

Function call in ST

```
SEND   (EN           := SEND_EN,
PINGROUP     := SEND_PINGROUP,
EXEC_TIME    := SEND_EXEC_TIME,
SEND         := SEND_SEND,
CYCLE        := SEND_CYCLE,
AUTO         := SEND_AUTO,
SCANDOWN     := SEND_SCANDOWN,
CMD_ON       := SEND_CMD_ON,
CMD_OFF      := SEND_CMD_OFF,
TOUT         := SEND_TOUT,
SHORT_EXEC   := SEND_SHORT_EXEC,
LONG_EXEC    := SEND_LONG_EXEC,
PERSIST_EXEC := SEND_PERSIST_EXEC);

SEND_DONE            := SEND.DONE;
SEND_ERR             := SEND.ERR;
SEND_ERNO            := SEND.ERNO;
SEND_RDY             := SEND.RDY;
SEND_OV              := SEND.OV;
```

IEC60870_SEND_C_IC_NA_1



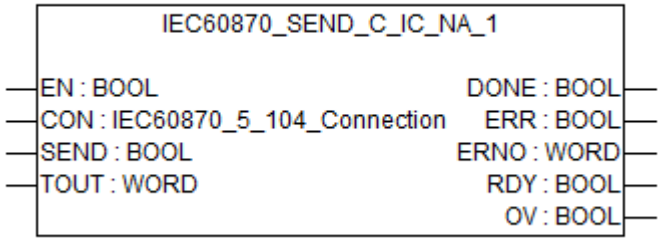
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5 protocol.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CON IEC60870_5_104_Connection (connection)

At input CON the corresponding connection is set to gather information.

The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

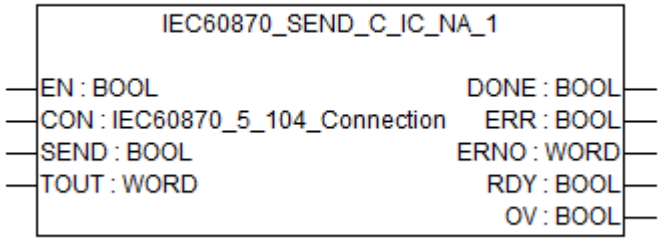
SEND BOOL (send)

Start a send request on a rising edge.

TOUT WORD (timeout)

Timeout in ms until ACTERM is expected; 0 = infinite.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

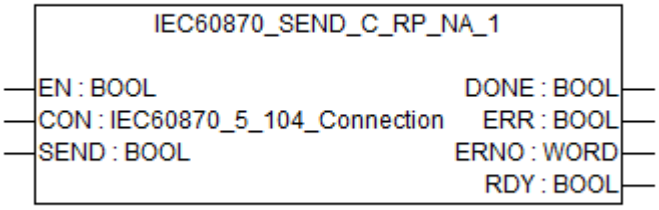
The output always has to be considered together with output RDY.

Function call in ST

```
SEND    (EN          := SEND_EN,
CON         := SEND_CON,
SEND        := SEND_SEND,
TOUT        := SEND_TOUT);

SEND_DONE             := SEND.DONE;
SEND_ERR              := SEND.ERR;
SEND_ERNO             := SEND.ERNO;
SEND_RDY              := SEND.RDY;
SEND_OV               := SEND.OV;
```

IEC60870_SEND_C_RP_NA_1



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0

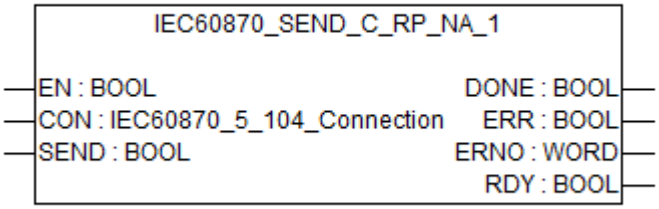
Parameter	Value
Type	Function block with historical values
Group	System_Information

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CON IEC60870_5_104_Connection (connection)

At input CON the corresponding connection is set to gather information.

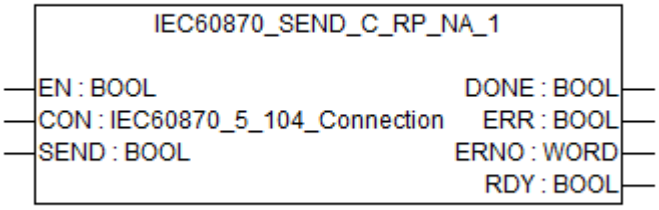
The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

SEND BOOL (send)

Start a send request on a rising edge.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY (ready) BOOL

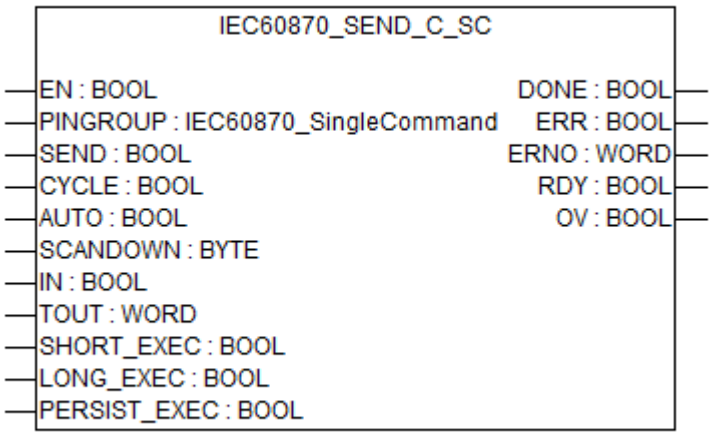
A command has been received if RDY = TRUE.

Function call in ST

```
SEND   (EN          := SEND_EN,
     CON         := SEND_CON,
SEND        := SEND_SEND);

SEND_DONE             := SEND.DONE;
SEND_ERR              := SEND.ERR;
SEND_ERNO             := SEND.ERNO;
SEND_RDY              := SEND.RDY;
```

IEC60870_SEND_C_SC



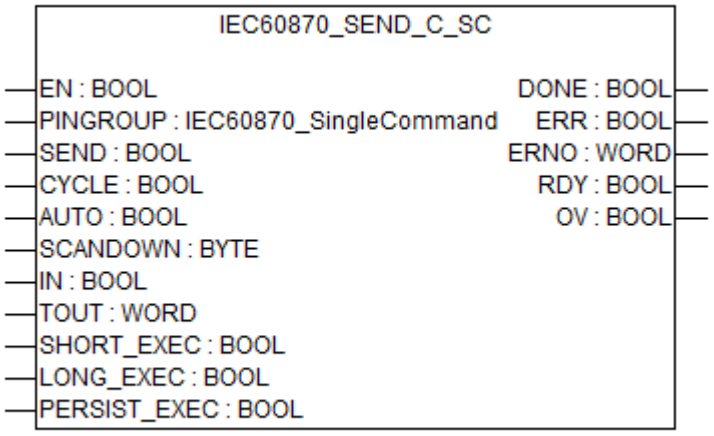
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_SingleCommand (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec, see *Chapter 1.6.5.3.2.3.4 “Data points” on page 6131*.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send)

Start a send request on a rising edge.

CYCLE BOOL (cycle)

Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto)

If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown)

Input SCANDOWN is valid when input CYCLE = TRUE.

On cyclic sending only send within each scandown cycle.

IN BOOL (input)

Input value Bit 1.

TOUT WORD (timeout)

Timeout in ms until ACTERM is expected; 0 = infinite.

SHORT_EXEC BOOL (short-execution)

If input SHORT_EXEC = TRUE, short execution is enabled on controlled station.

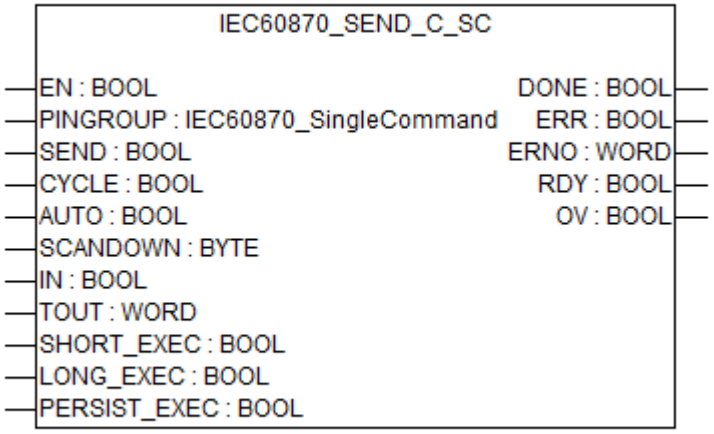
LONG_EXEC BOOL (longexecution)

If input LONG_EXEC = TRUE, long execution is enabled on controlled station.

PERSIST_EXEC BOOL (persistent execution)

If input PERSISTENT_EXEC = TRUE, persistent execution is enabled on controlled station.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

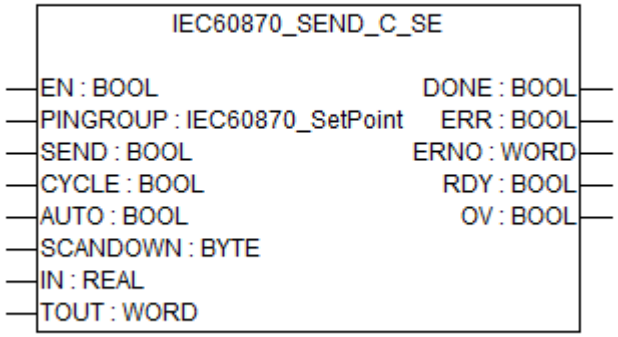
The output always has to be considered together with output RDY.

Function call in ST

```
SEND   (EN           := SEND_EN,
PINGROUP     := SEND_PINGROUP,
EXEC_TIME    := SEND_EXEC_TIME,
SEND         := SEND_SEND,
CYCLE        := SEND_CYCLE,
AUTO         := SEND_AUTO,
SCANDOWN     := SEND_SCANDOWN,
IN           := SEND_IN,
TOUT         := SEND_TOUT,
SHORT_EXEC   := SEND_SHORT_EXEC,
LONG_EXEC    := SEND_LONG_EXEC,
PERSIST_EXEC := SEND_PERSIST_EXEC);

SEND_DONE            := SEND.DONE;
SEND_ERR             := SEND.ERR;
SEND_ERNO            := SEND.ERNO;
SEND_RDY             := SEND.RDY;
SEND_OV              := SEND.OV;
```

IEC60870_SEND_C_SE



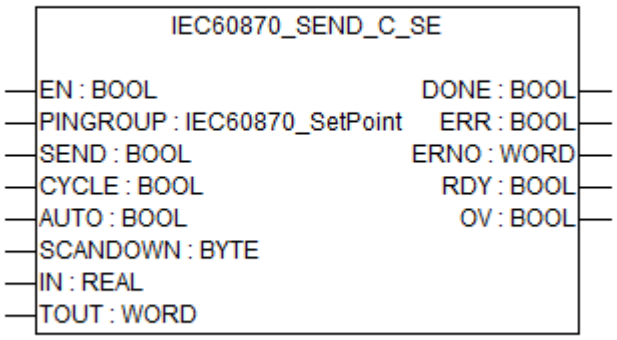
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_SetPoint (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send)

Start a send request on a rising edge.

CYCLE BOOL (cycle)

Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto)

If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown)

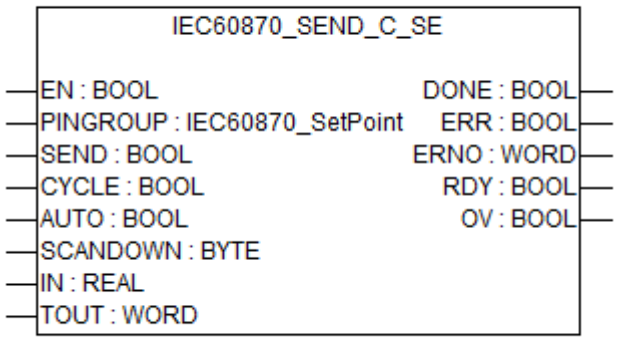
Input SCANDOWN is valid when input CYCLE = TRUE.

On cyclic sending only send within each scandown cycle.

IN BOOL (input) Input value Bit 1.

TOUT WORD (timeout) Timeout in ms until ACTERM is expected; 0 = infinite.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command has been received if RDY = TRUE.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

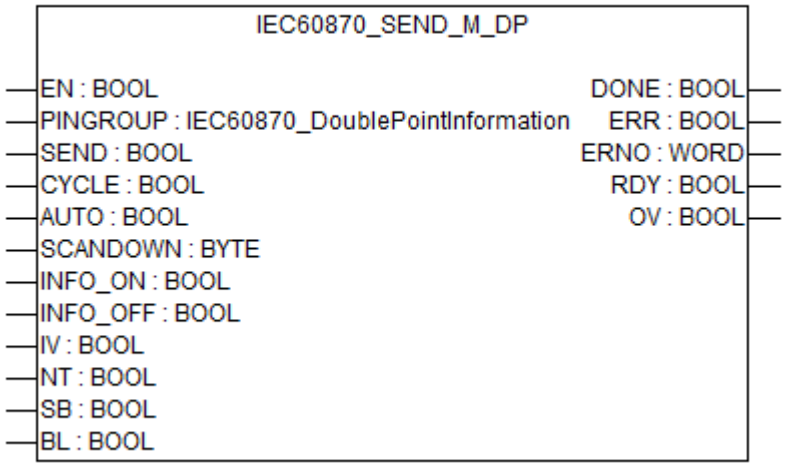
The output always has to be considered together with output RDY.

Function call in ST

```
SEND   (EN           := SEND_EN,
PINGROUP     := SEND_PINGROUP,
EXEC_TIME    := SEND_EXEC_TIME,
SEND         := SEND_SEND,
CYCLE        := SEND_CYCLE,
AUTO         := SEND_AUTO,
SCANDOWN     := SEND_SCANDOWN,
IN           := SEND_IN,
TOUT         := SEND_TOUT);

SEND_DONE            := SEND.DONE;
SEND_ERR             := SEND.ERR;
SEND_ERNO            := SEND.ERNO;
SEND_RDY             := SEND.RDY;
SEND_OV              := SEND.OV;
```

IEC60870_SEND_M_DP



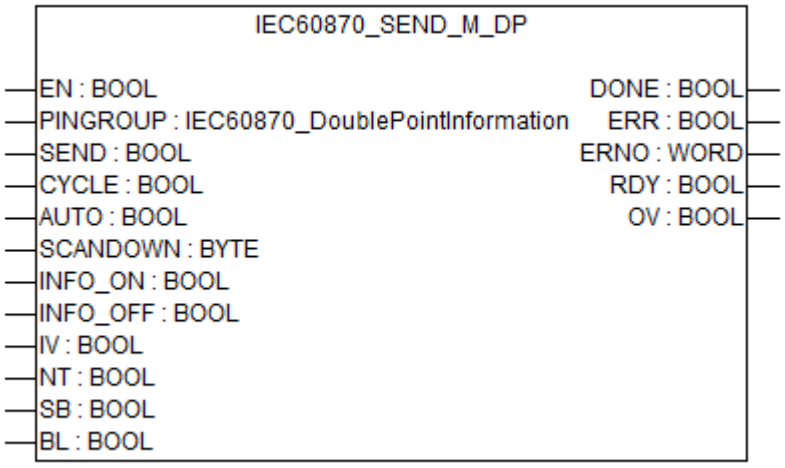
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_DoublePointInformation (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC 60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC 60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

> *A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!*

SEND BOOL (send)

Start a send request on a rising edge.

CYCLE BOOL (cycle)

Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto)

If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.

On cyclic sending only send within each scandown cycle.

INFO_ON BOOL (information on) Input value of bit 1.

INFO_OFF BOOL (information off) Input value of bit 2.

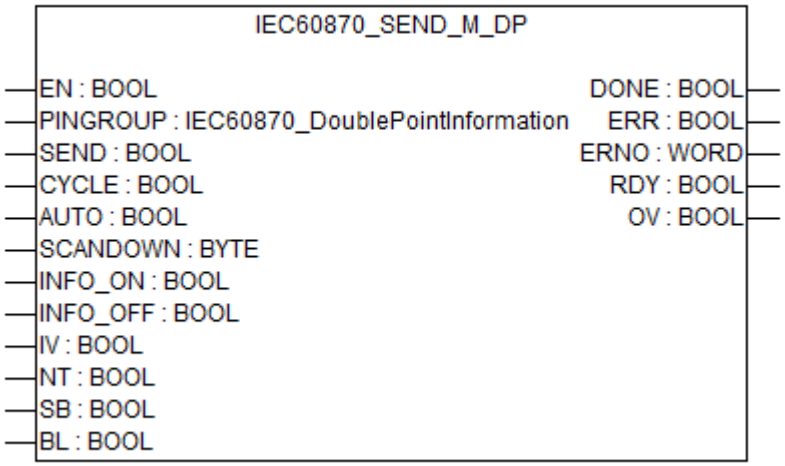
IV BOOL (invalid) Input IV sets the status/information of the data. If IV = TRUE, the data is invalid.

NT BOOL (not topical) Input NT sets the status/information of the data. If NT = TRUE, the data is not topical/actual.

SB BOOL (substituted) Input SB sets the status/information of the data. If SB = TRUE, the data is substituted.

BL BOOL (blocked) Input BL displays the status/information of the data. If BL = TRUE, the data is blocked.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

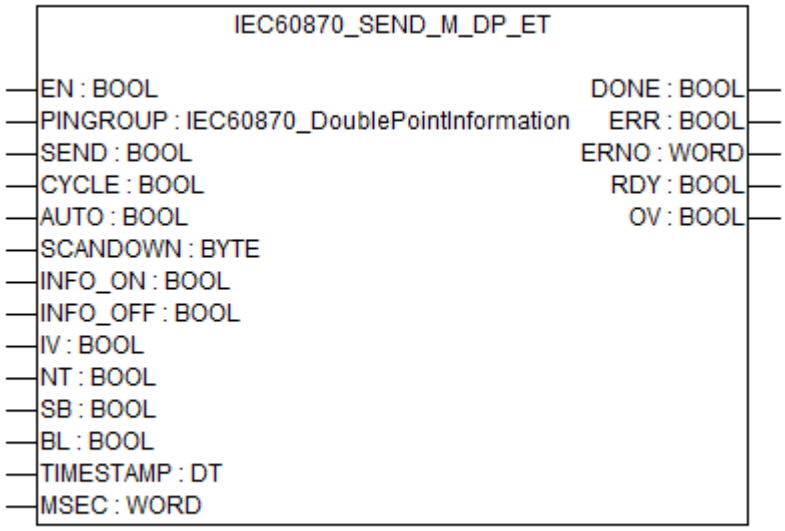
The output always has to be considered together with output RDY.

Function call in ST

```
SEND     (EN       := SEND_EN,
 PINGROUP := SEND_PINGROUP,
 SEND     := SEND_SEND,
 CYCLE    := SEND_CYCLE,
 AUTO     := SEND_AUTO,
 SCANDOWN := SEND_SCANDOWN,
 INFO_ON  := SEND_INFO_ON,
 INFO_OFF := SEND_INFO_OFF,
 IV       := SEND_IV,
 NT       := SEND_NT,
 SB       := SEND_SB,
 BL       := SEND_BL);

SEND_DONE            := SEND.DONE;
SEND_ERR             := SEND.ERR;
SEND_ERNO            := SEND.ERNO;
SEND_RDY             := SEND.RDY;
SEND_OV              := SEND.OV;
```

IEC60870_SEND_M_DP_ET



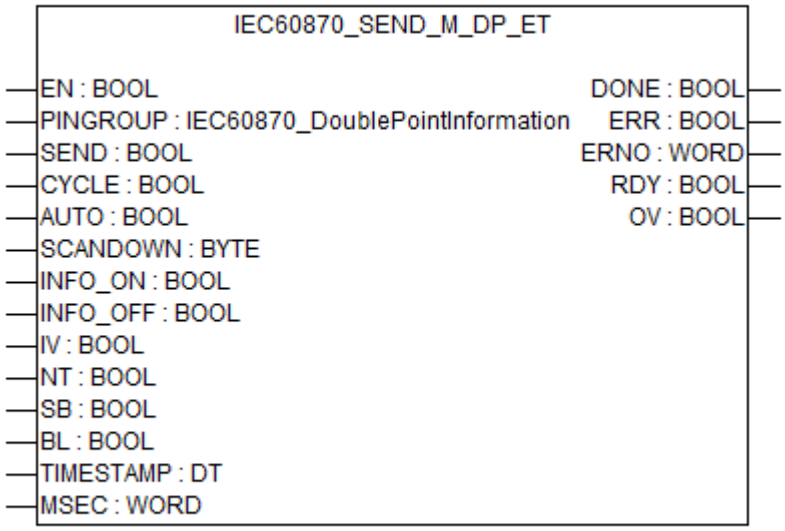
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_DoublePointInformation (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC 60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see ↳ *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC 60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

> *A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!*

SEND BOOL (send)

Start a send request on a rising edge.

CYCLE BOOL (cycle)

Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.
On cyclic sending only send within each scandown cycle.

INFO_ON BOOL (information on) Input value of bit 1.

INFO_OFF BOOL (information off) Input value of bit 2.

IV BOOL (invalid) Input IV sets the status/information of the data. If IV = TRUE, the data is invalid.

NT BOOL (not topical) Input NT sets the status/information of the data. If NT = TRUE, the data is not topical/actual.

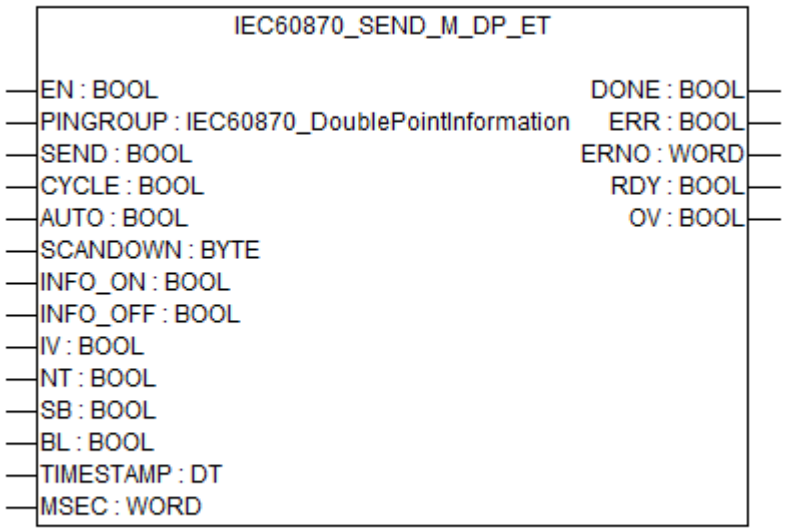
SB BOOL (substituted) Input SB sets the status/information of the data. If SB = TRUE, the data is substituted.

BL BOOL (blocked) Input BL displays the status/information of the data. If BL = TRUE, the data is blocked.

TIMESTAMP DT (timestamp) TIMESTAMP which should be sent with the data.

MSEC WORD (milliseconds) Millisecond part of TIMESTAMP which should be sent with the data.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```
SEND     (EN         := SEND_EN,
          PINGROUP   := SEND_PINGROUP,
          SEND       := SEND_SEND,
          CYCLE      := SEND_CYCLE,
          AUTO       := SEND_AUTO,
          SCANDOWN   := SEND_SCANDOWN,
          INFO_ON    := SEND_INFO_ON,
          INFO_OFF   := SEND_INFO_OFF,

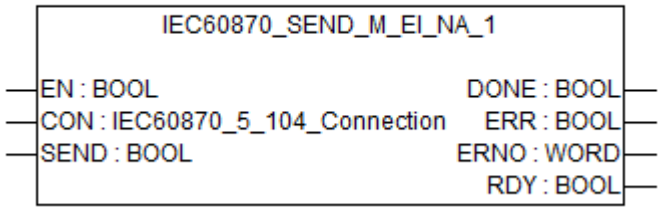
SEND_ERR            := SEND.ERR;
SEND_ERNO           := SEND.ERNO;
SEND_RDY            := SEND.RDY;
SEND_OV             := SEND.OV;
```

IEC60870_SEND_M_EI_NA_1



Sending of data messages of the data type according to IEC 60870-5 protocol.

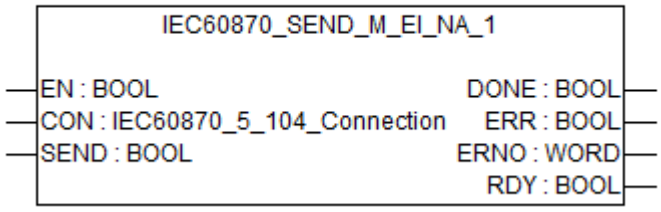
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	System_Information

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CON IEC60870_5_104_Connection (connection)

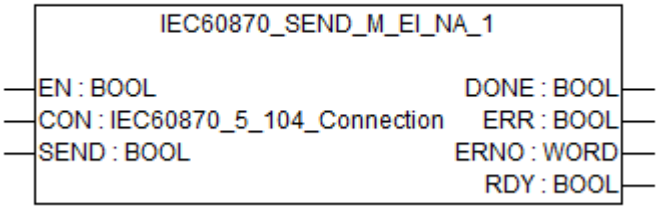
At input CON the corresponding connection is set to gather information.

The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

SEND BOOL (send) Start a send request on a rising edge.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

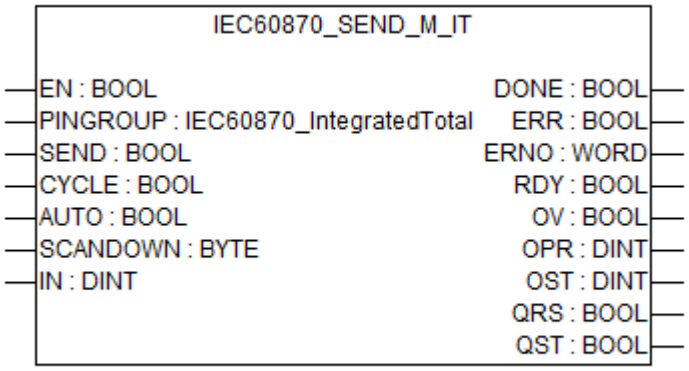
RDY BOOL (ready) A command has been received if RDY = TRUE.

Function call in ST

```
SEND    (EN          := SEND_EN,
         CON         := SEND_CON,
SEND        := SEND_SEND);

SEND_DONE             := SEND.DONE;
SEND_ERR              := SEND.ERR;
SEND_ERNO             := SEND.ERNO;
SEND_RDY              := SEND.RDY;
```

IEC60870_SEND_M_IT



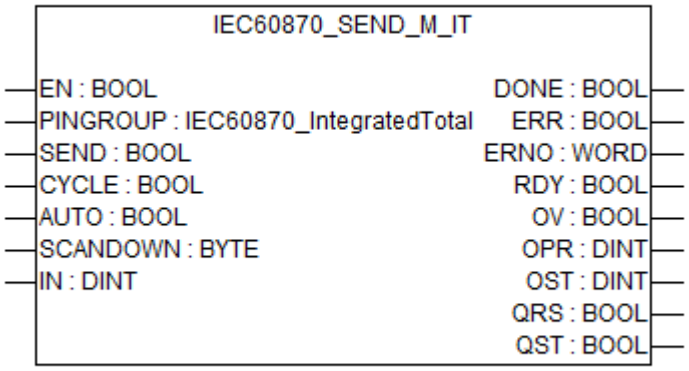
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP

At input PINGROUP (IEC60870_IntegratedTotal) the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send)

Start a send request on a rising edge.

CYCLE BOOL (cycle)

Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto)

If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown)

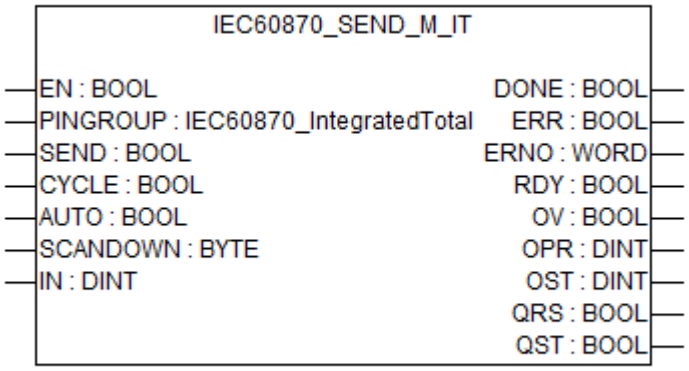
Input SCANDOWN is valid when input CYCLE = TRUE.

On cyclic sending only send within each scandown cycle.

IN BOOL (input)

The input value.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

OPR DINT (opr)

Preset of discrete value. Output OPR receives the current discrete value on reset.

The output always has to be considered together with output RDY.

OST DINT (ost) Relocated discrete value. Output OST receives the current discrete value on relocation.
The output always has to be considered together with output RDY.

QRS BOOL (qrs) The output QRS indicates a reset of the discrete value by changing from FALSE to TRUE.
The output always has to be considered together with output RDY.

QST BOOL (qst) Relocate discrete value.
The output QRS indicates a relocation of the discrete value by changing from FALSE to TRUE.
The output always has to be considered together with output RDY.

Function call in ST

```
SEND   (EN           := SEND_EN,
PINGROUP     := SEND_PINGROUP,
SEND         := SEND_SEND,
CYCLE        := SEND_CYCLE,
AUTO         := SEND_AUTO,
SCANDOWN     := SEND_SCANDOWN,
IN           := SEND_IN);

SEND_DONE            := SEND.DONE;
SEND_ERR             := SEND.ERR;

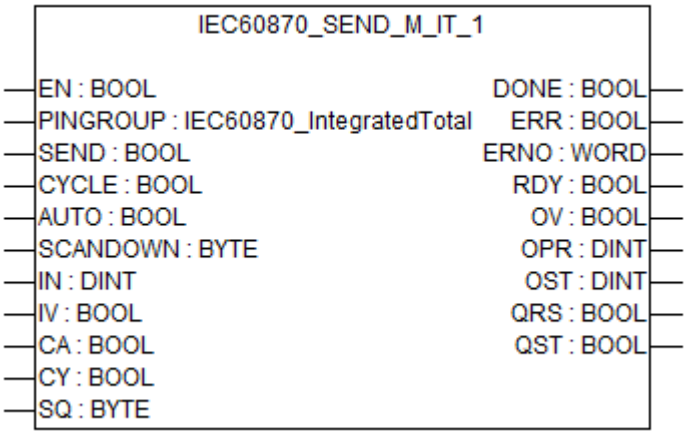
SEND_QRS             := SEND.QRS;
SEND_QST             := SEND.QST;
```

IEC60870_SEND_M_IT_1



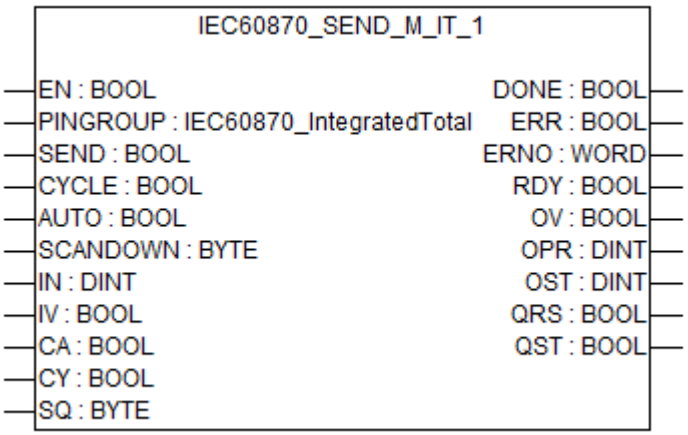
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP

At input PINGROUP (IEC60870_IntegratedTotal) the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see ↳ *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

> *A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!*

SEND BOOL (send) Start a send request on a rising edge.

CYCLE BOOL (cycle) Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.
On cyclic sending only send within each scandown cycle.

IN BOOL (input) The input value.

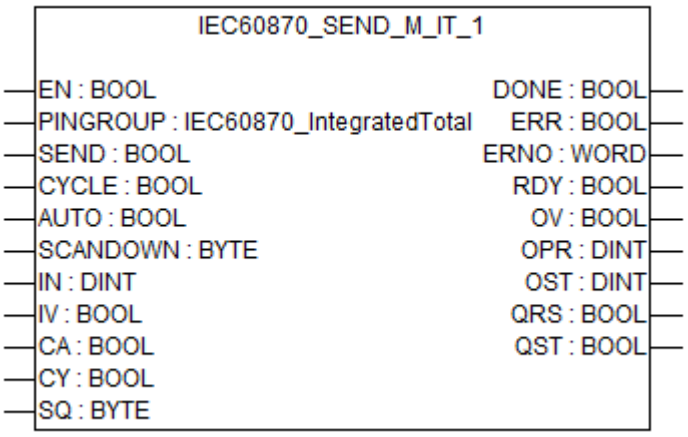
IV BOOL (invalid) Input IV is the status/information of the data. If IV = TRUE, the data is invalid.

CA BOOL (counter adjusted) Input CA is the status/information of the data. If CA = TRUE, the counter has been preset since the last reading.

CY BOOL (carry) Input CY is the status/informations of the data. If CY = TRUE, the transmission divided into associated measurement periods.

SQ BYTE (sequence) Input SQ is the sequence number.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

OPR DINT (opr)

Preset of discrete value. Output OPR receives the current discrete value on reset.

The output always has to be considered together with output RDY.

OST DINT (ost)

Relocated discrete value. Output OST receives the current discrete value on relocation.

The output always has to be considered together with output RDY.

QRS BOOL (qrs)

The output QRS indicates a reset of the discrete value by changing from FALSE to TRUE.

The output always has to be considered together with output RDY.

QST BOOL (qst)

Relocate discrete value.

The output QRS indicates a relocation of the discrete value by changing from FALSE to TRUE.

The output always has to be considered together with output RDY.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP

At input PINGROUP (IEC60870_IntegratedTotal) the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send)

Start a send request on a rising edge.

CYCLE BOOL (cycle)

Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.

On cyclic sending only send within each scandown cycle.

IN BOOL (input) The input value.

IV BOOL (invalid) Input IV is the status/information of the data. If IV = TRUE, the data is invalid.

CA BOOL (counter adjusted) Input CA is the status/information of the data. If CA = TRUE, the counter has been preset since the last reading.

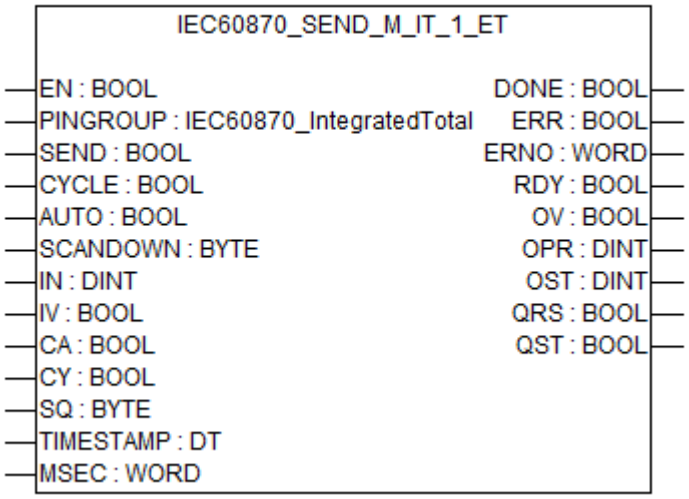
CY BOOL (carry) Input CY is the status/informations of the data. If CY = TRUE, the transmission divided into associated measurement periods.

SQ BYTE (sequence) Input SQ is the sequence number.

TIMESTAMP DT (timestamp) TIMESTAMP which should be sent with the data.

MSEC WORD (milliseconds) Millisecond part of TIMESTAMP which should be sent with the data.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command has been received if RDY = TRUE.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

OPR DINT (opr) Preset of discrete value. Output OPR receives the current discrete value on reset.

The output always has to be considered together with output RDY.

OST DINT (ost) Relocated discrete value. Output OST receives the current discrete value on relocation.

The output always has to be considered together with output RDY.

QRS BOOL (qrs) The output QRS indicates a reset of the discrete value by changing from FALSE to TRUE.

The output always has to be considered together with output RDY.

QST BOOL (qst) Relocate discrete value.

The output QRS indicates a relocation of the discrete value by changing from FALSE to TRUE.

The output always has to be considered together with output RDY.

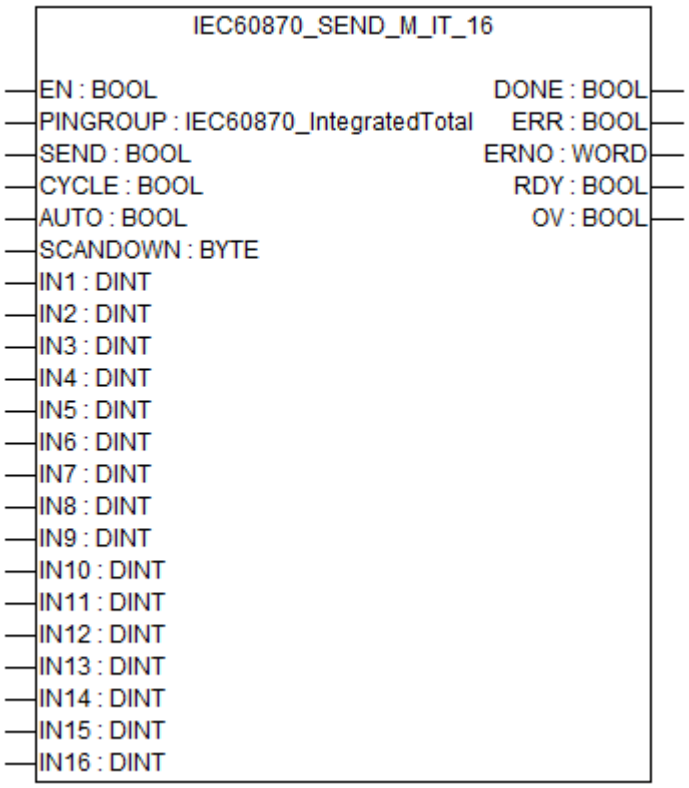
IEC60870_SEND_M_IT_16



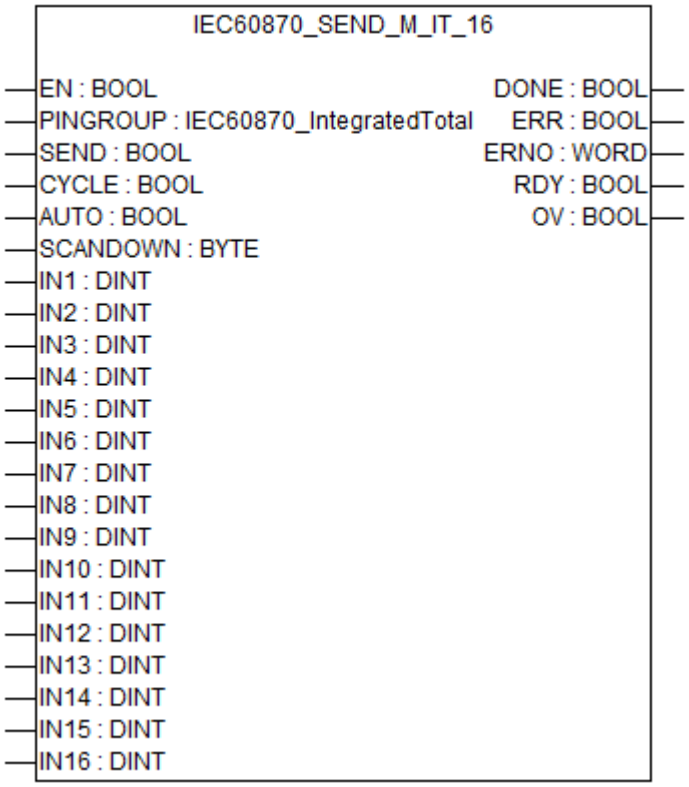
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP

At input PINGROUP (IEC60870_IntegratedTotal) the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send) Start a send request on a rising edge.

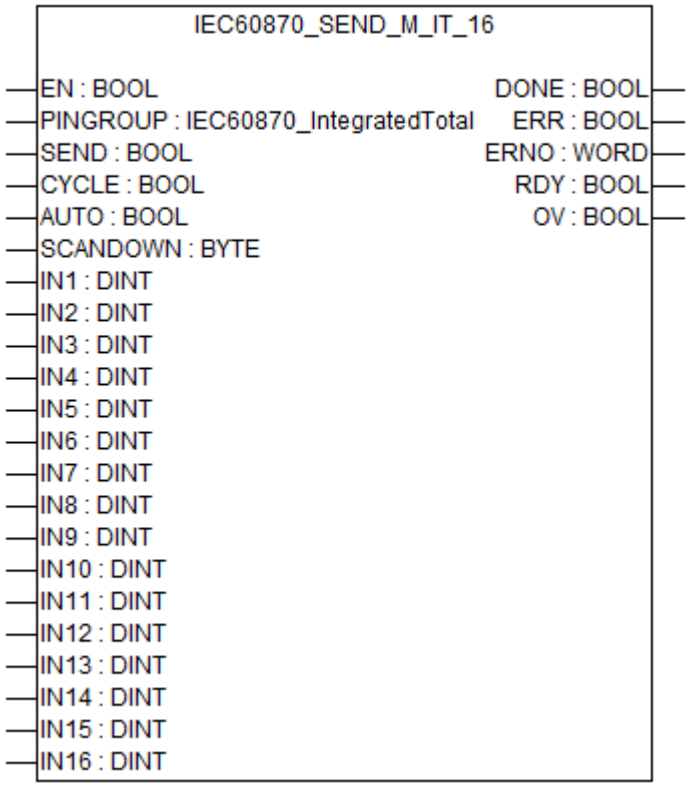
CYCLE BOOL (cycle) Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.
On cyclic sending only send within each scandown cycle.

IN1 ... IN16 DINT (input 1...16) Input value for member 1 to 16.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP

At input PINGROUP (IEC60870_IntegratedTotal) the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see ↳ *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send) Start a send request on a rising edge.

CYCLE BOOL (cycle) Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.
On cyclic sending only send within each scandown cycle.

IN1 ... IN16 DINT (input 1...16) Input value for member 1 to 16.

CA BOOL (counter adjusted) Input CA is the status/information of the data. If CA = TRUE, the counter has been preset since the last reading.

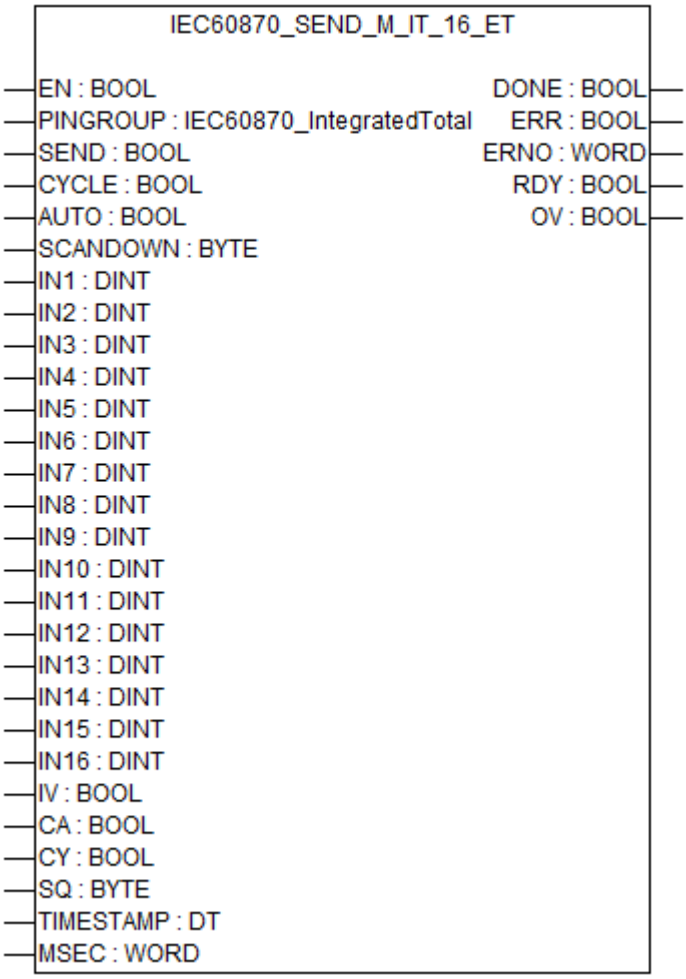
CY BOOL (carry) Input CY is the status/informations of the data. If CY = TRUE, the transmission divided into associated measurement periods.

SQ BYTE (sequence) Input SQ is the sequence number.

TIMESTAMP DT (timestamp) TIMESTAMP which should be sent with the data.

MSEC WORD (milliseconds) Millisecond part of TIMESTAMP which should be sent with the data.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command has been received if RDY = TRUE.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

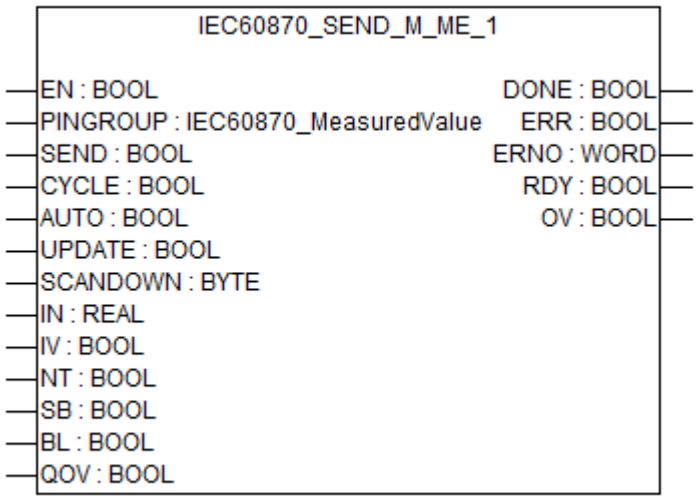
IEC60870_SEND_M_ME_1



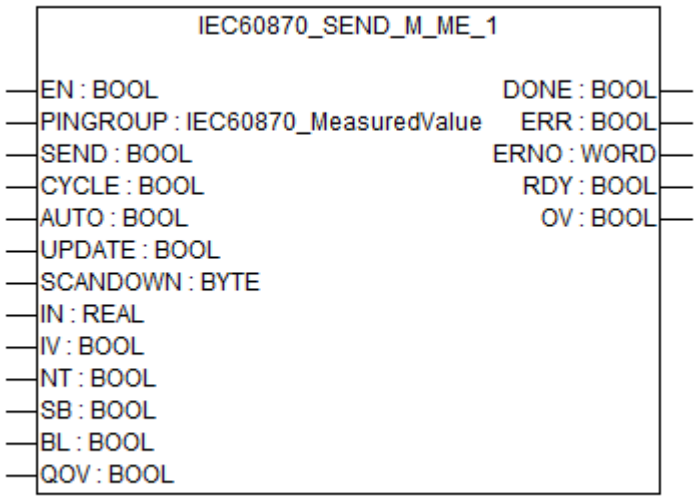
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_MeasuredValue (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send)

Start a send request on a rising edge.

CYCLE BOOL (cycle)

Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto)

If input AUTO = TRUE, each input value change might trigger a sending process.

UPDATE BOOL (update) If UPDATE = TRUE, updates of threshold via control station are allowed.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.

On cyclic sending only send within each scandown cycle.

IN REAL (input) Input value.

IV BOOL (invalid) Input IV is the status/information of the data. If IV = TRUE, the data is invalid.

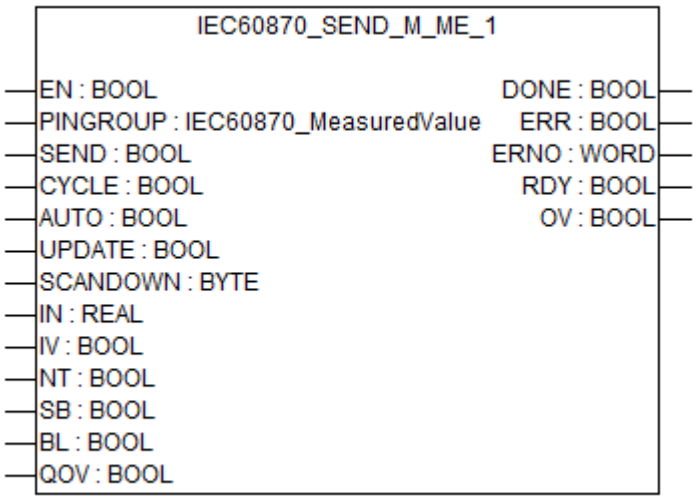
NT BOOL (not topical) Input NT is the status/information of the data. If NT = TRUE, the data is not topical/actual.

SB BYTE (substituted) Input SB is the status/information of the data. If SB = TRUE, the data is substituted.

BL BYTE (blocked) Input BL is the status/information of the data. If BL = TRUE, the data is blocked.

QOV BYTE (overflow/no overflow) Input QOV is the status/information of the data. If QOV = TRUE, the data signals an overflow.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```
SEND    (EN             := SEND_EN,
         PINGROUP       := SEND_PINGROUP,
         SEND           := SEND_SEND,
         CYCLE          := SEND_CYCLE,
         AUTO           := SEND_AUTO,
         UPDATE         := SEND_UPDATE,
         SCANDOWN       := SEND_SCANDOWN,
         IN             := SEND_IN,
         IV             := SEND_IV,

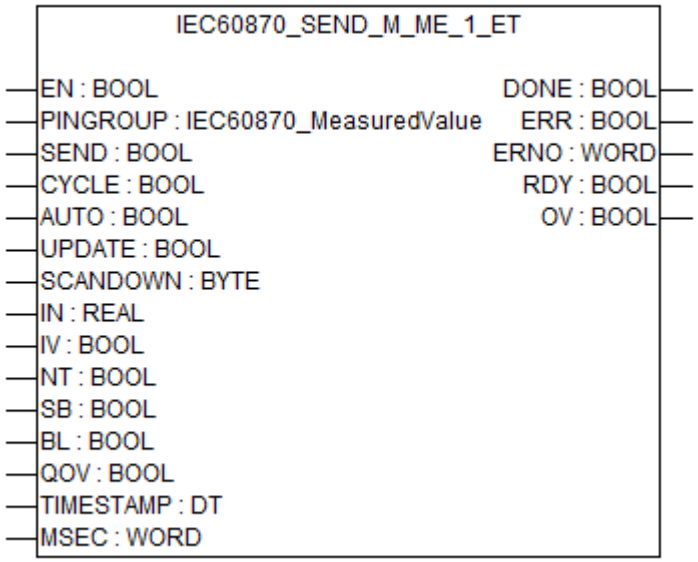
SEND_OV                 := SEND.OV;
```

IEC60870_SEND_M_ME_1_ET



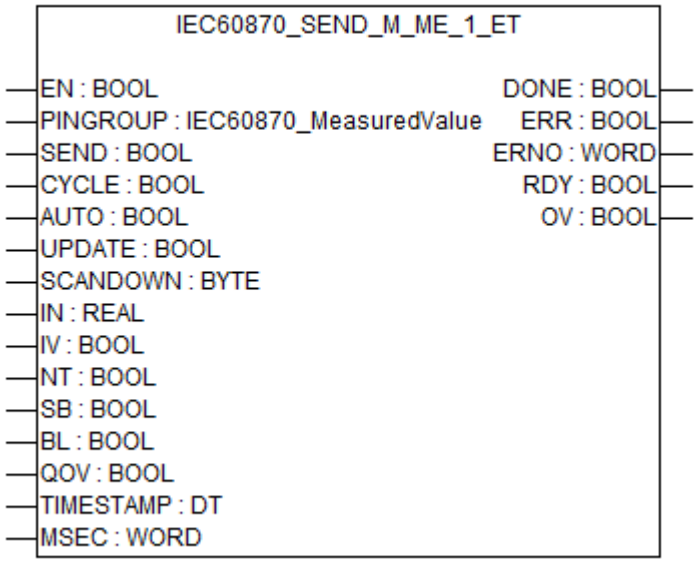
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_MeasuredValue (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send)

Start a send request on a rising edge.

CYCLE BOOL (cycle)

Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

UPDATE BOOL (update) If UPDATE = TRUE, updates of threshold via control station are allowed.

SCANDOWN BYTE (scan-down) Input SCANDOWN is valid when input CYCLE = TRUE.
On cyclic sending only send within each scandown cycle.

IN REAL (input) Input value.

IV BOOL (invalid) Input IV is the status/information of the data. If IV = TRUE, the data is invalid.

NT BOOL (not topical) Input NT is the status/information of the data. If NT = TRUE, the data is not topical/actual.

SB BYTE (substituted) Input SB is the status/information of the data. If SB = TRUE, the data is substituted.

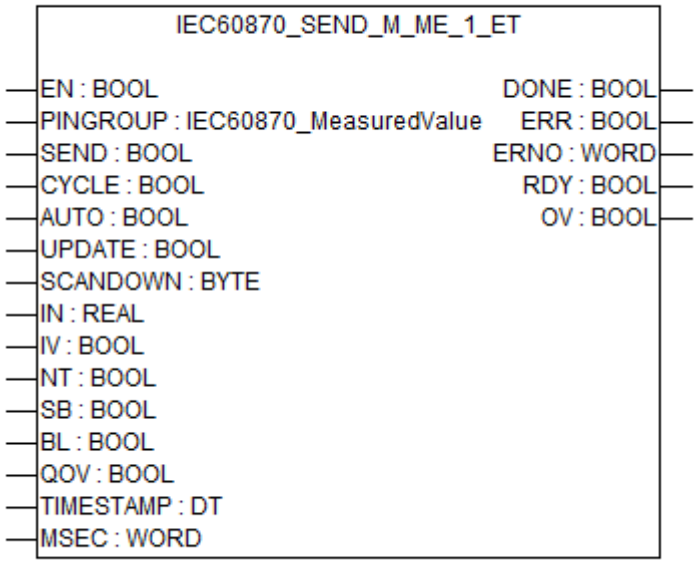
BL BYTE (blocked) Input BL is the status/information of the data. If BL = TRUE, the data is blocked.

QOV BYTE (overflow/no overflow) Input QOV is the status/information of the data. If QOV = TRUE, the data signals an overflow.

TIMESTAMP DT (time-stamp) TIMESTAMP which should be sent with the data.

MSEC WORD (milliseconds) Millisecond part of TIMESTAMP which should be sent with the data.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```
SEND    (EN             := SEND_EN,
         PINGROUP       := SEND_PINGROUP,
         SEND           := SEND_SEND,
         CYCLE          := SEND_CYCLE,
         AUTO           := SEND_AUTO,
         UPDATE         := SEND_UPDATE,
         SCANDOWN       := SEND_SCANDOWN,
         IN             := SEND_IN,
         IV             := SEND_IV,
         NT             := SEND_NT,
         SB             := SEND_SB,
         BL             := SEND_BL,
         QOV            := SEND_QOV,

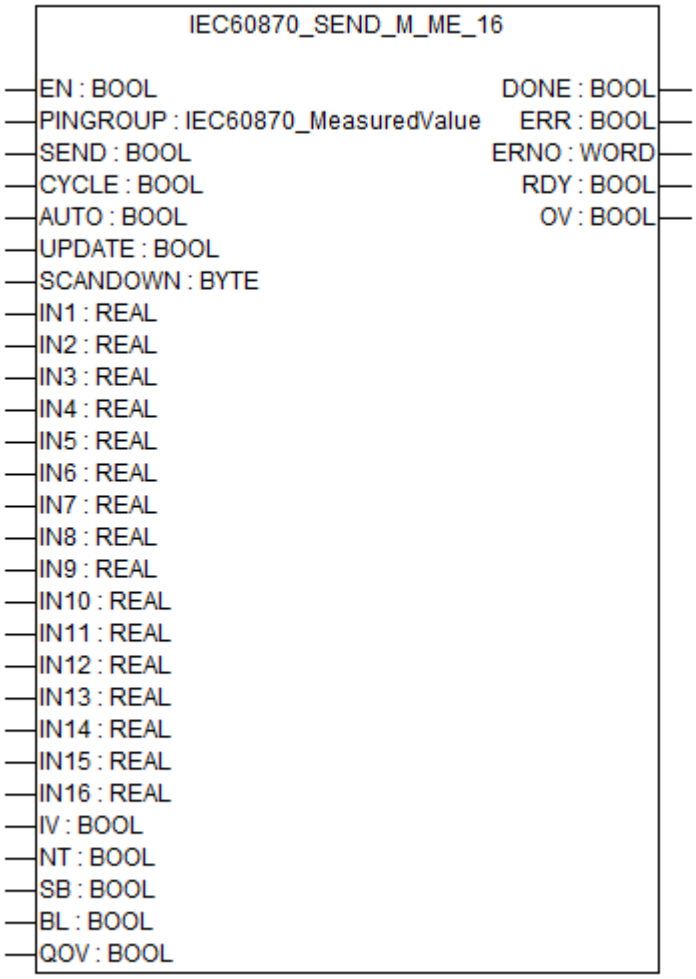
SEND_RDY                := SEND.RDY;
SEND_OV                 := SEND.OV;
```

IEC60870_SEND_M_ME_16



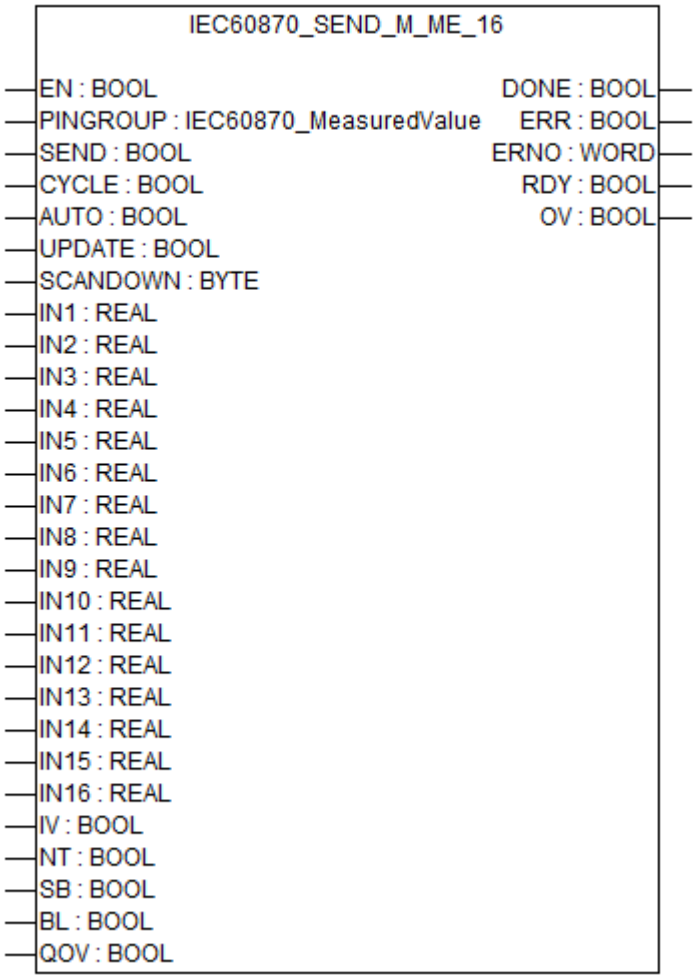
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_MeasuredValue (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send) Start a send request on a rising edge.

CYCLE BOOL (cycle) Input CYCLE performs a cyclic send each scandown cycle.

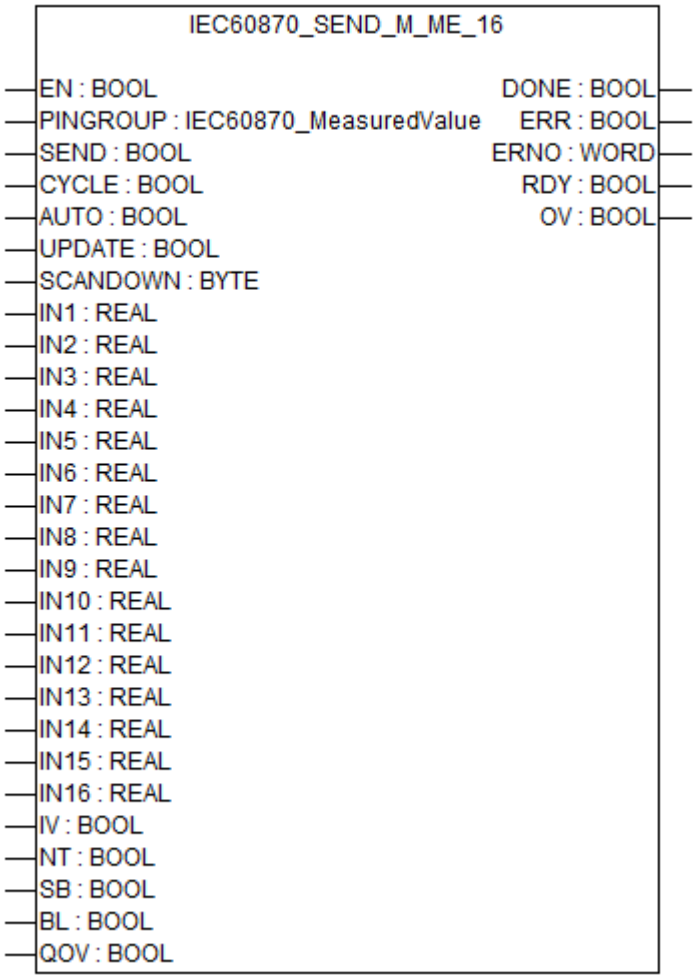
AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

UPDATE BOOL (update) If UPDATE = TRUE, updates of threshold via control station are allowed.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.
On cyclic sending only send within each scandown cycle.

IN1 ... IN16 REAL (input 1...16) Input value for member 1 to 16.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command has been received if RDY = TRUE.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```

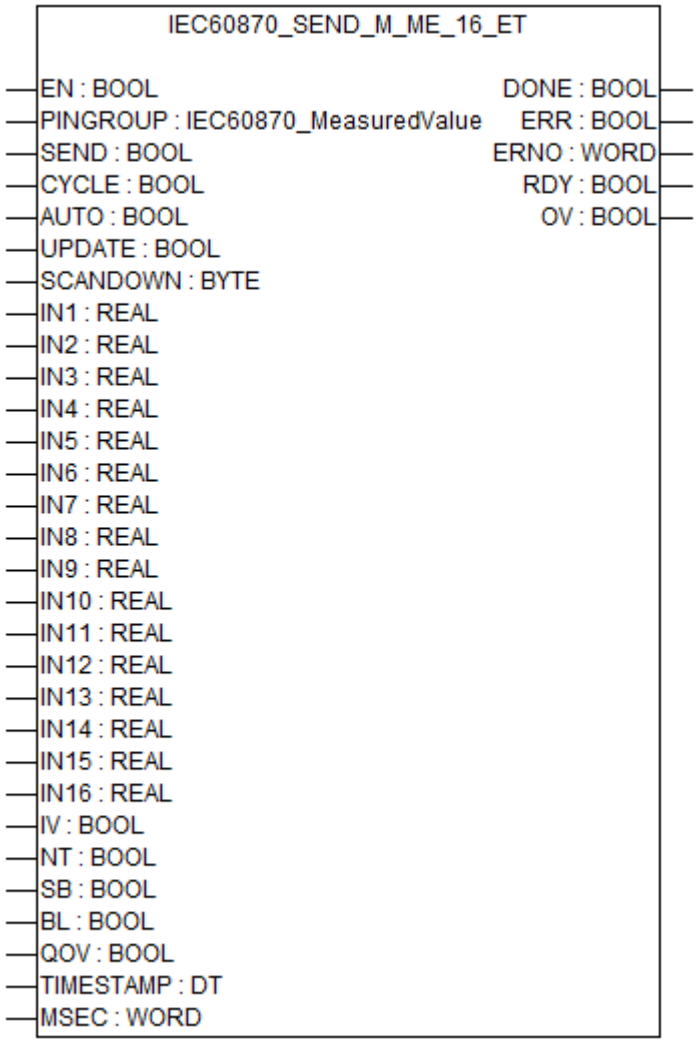
IEC60870_SEND_M_ME_16_ET



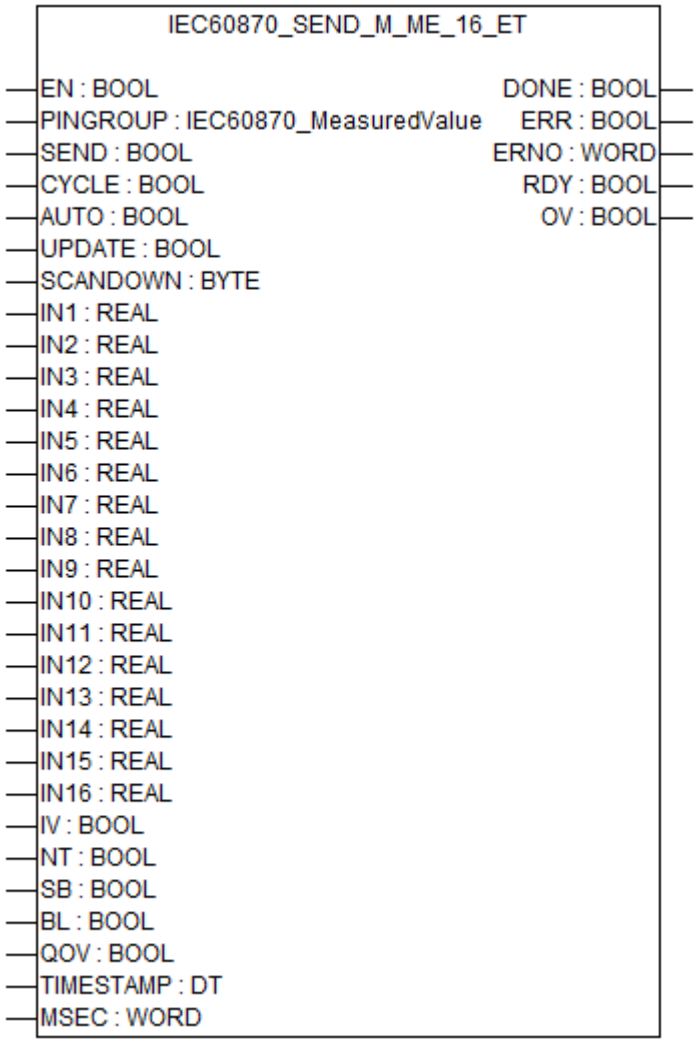
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_MeasuredValue (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send) Start a send request on a rising edge.

CYCLE BOOL (cycle) Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

UPDATE BOOL (update) If UPDATE = TRUE, updates of threshold via control station are allowed.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.
On cyclic sending only send within each scandown cycle.

IN1 ... IN16 REAL (input 1...16) Input value for member 1 to 16.

IV BOOL (invalid) Input IV is the status/information of the data. If IV = TRUE, the data is invalid.

NT BOOL (not topical) Input NT is the status/information of the data. If NT = TRUE, the data is not topical/actual.

SB BYTE (substituted) Input SB is the status/information of the data. If SB = TRUE, the data is substituted.

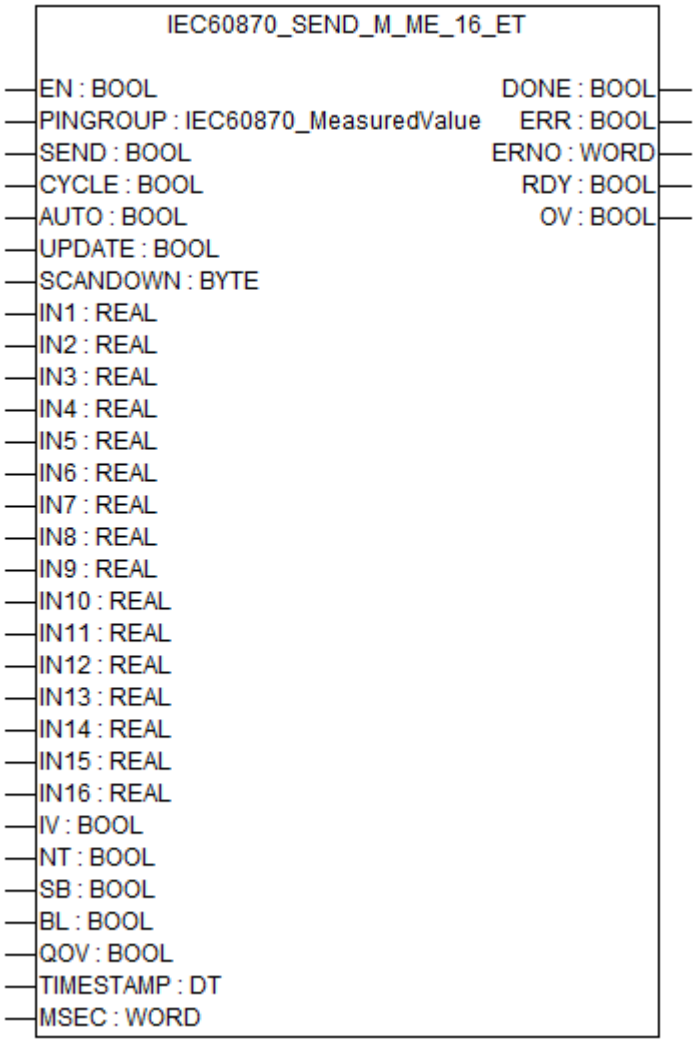
BL BYTE (blocked) Input BL is the status/information of the data. If BL = TRUE, the data is blocked.

QOV BYTE (overflow/no overflow) Input QOV is the status/information of the data. If QOV = TRUE, the data signals an overflow.

TIMESTAMP DT (timestamp) TIMESTAMP which should be sent with the data.

MSEC WORD (milliseconds) Millisecond part of TIMESTAMP which should be sent with the data.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command has been received if RDY = TRUE.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```
SEND   (EN           := SEND_EN,
        PINGROUP     := SEND_PINGROUP,
        SEND         := SEND_SEND,

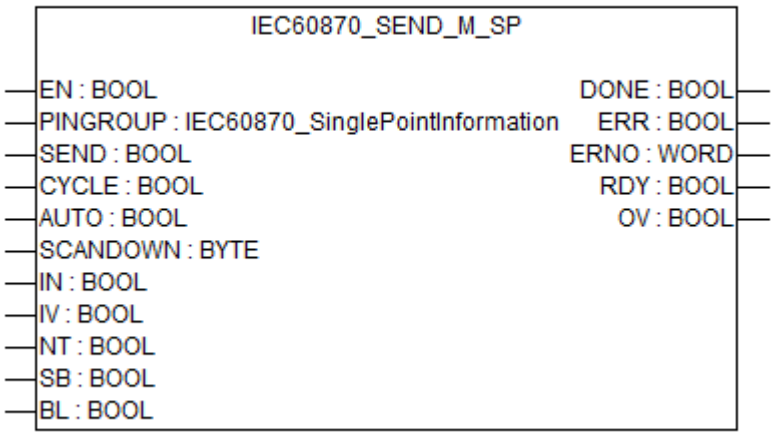
```

IEC60870_SEND_M_SP



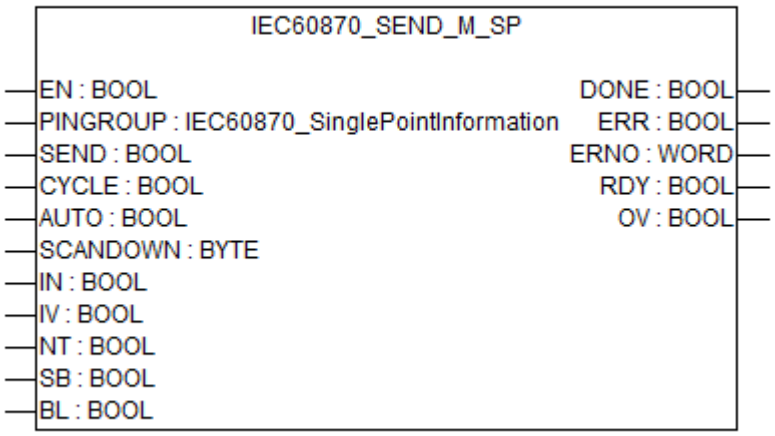
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_SinglePointInformation (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC 60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send)

Start a send request on a rising edge.

CYCLE BOOL (cycle)

Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto)

If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown)

Input SCANDOWN is valid when input CYCLE = TRUE.

On cyclic sending only send within each scandown cycle.

IN BOOL (input)

Input value.

IV BOOL (invalid)

Input IV sets the status/information of the data. If IV = TRUE, the data is invalid.

NT BOOL (not topical)

Input NT sets the status/information of the data. If NT = TRUE, the data is not topical/actual.

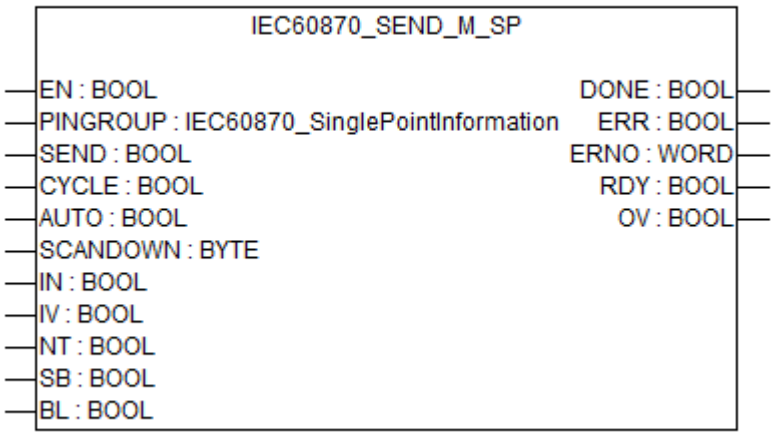
SB BOOL (substituted)

Input SB sets the status/information of the data. If SB = TRUE, the data is substituted.

BL BOOL (blocked)

Input BL displays the status/information of the data. If BL = TRUE, the data is blocked.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

DONE BOOL (done)

The output variable DONE shows the processing state of the function block. It shows TRUE when the processing ended or an error took place. This variable DONE should be checked together with the variable ERR. If DONE and ERR are set to TRUE then the output ERNO should be checked to see which error occurred.

ERR BOOL (error)

ERR shows TRUE if the function block was terminated as a consequence of an error, or FALSE if it ended normally.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

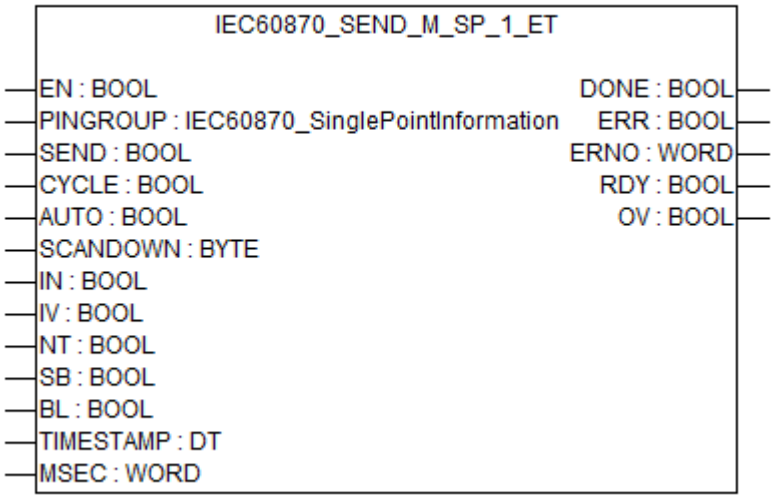
The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```
SEND_DONE           := SEND.DONE;
SEND_ERR            := SEND.ERR;
SEND_ERNO           := SEND.ERNO;
SEND_RDY            := SEND.RDY;
SEND_OV             := SEND.OV;
```

IEC60870_SEND_M_SP_1_ET



Sending of data messages of the data type according to IEC 60870-5 protocol.

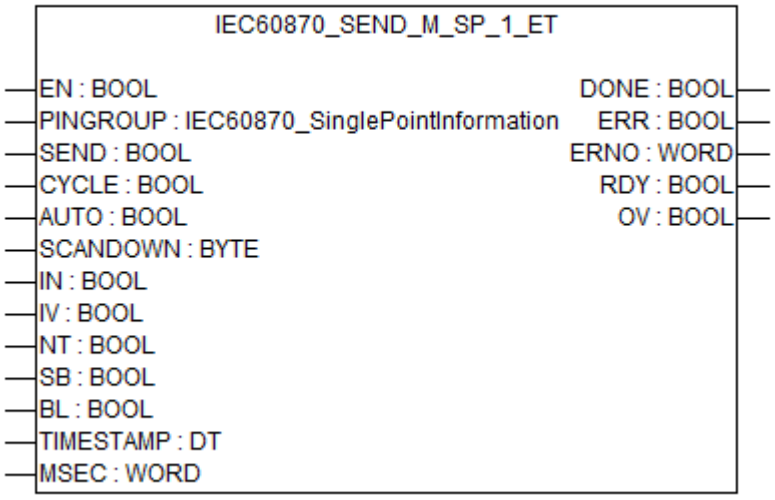
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_SinglePointInformation (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC 60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send)

Start a send request on a rising edge.

CYCLE BOOL (cycle)

Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto)

If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scan-down) Input SCANDOWN is valid when input CYCLE = TRUE.
On cyclic sending only send within each scandown cycle.

IN BOOL (input) Input value.

IV BOOL (invalid) Input IV sets the status/information of the data. If IV = TRUE, the data is invalid.

NT BOOL (not topical) Input NT sets the status/information of the data. If NT = TRUE, the data is not topical/actual.

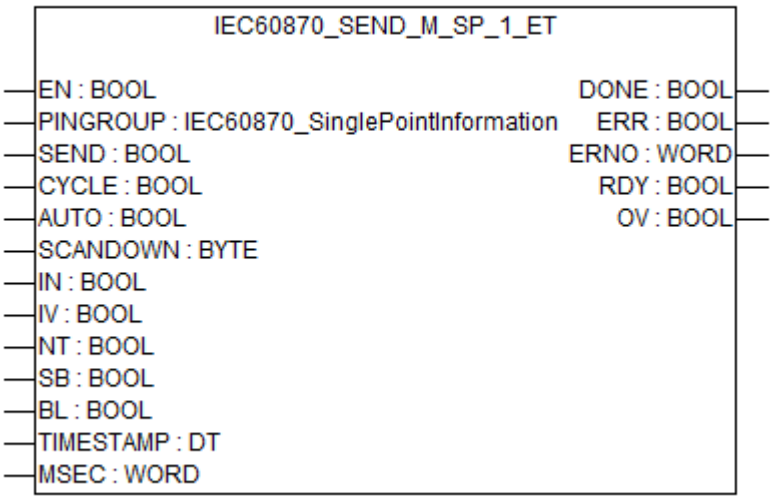
SB BOOL (substituted) Input SB sets the status/information of the data. If SB = TRUE, the data is substituted.

BL BOOL (blocked) Input BL displays the status/information of the data. If BL = TRUE, the data is blocked.

TIMESTAMP DT (time-stamp) TIMESTAMP which should be sent with the data.

MSEC WORD (milliseconds) Millisecond part of TIMESTAMP which should be sent with the data.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

```
SEND    (EN             := SEND_EN,
         PINGROUP       := SEND_PINGROUP,
         SEND           := SEND_SEND,
         CYCLE          := SEND_CYCLE,
         AUTO           := SEND_AUTO,
         SCANDOWN       := SEND_SCANDOWN,
         IN             := SEND_IN,
         IV             := SEND_IV,
         NT             := SEND_NT,

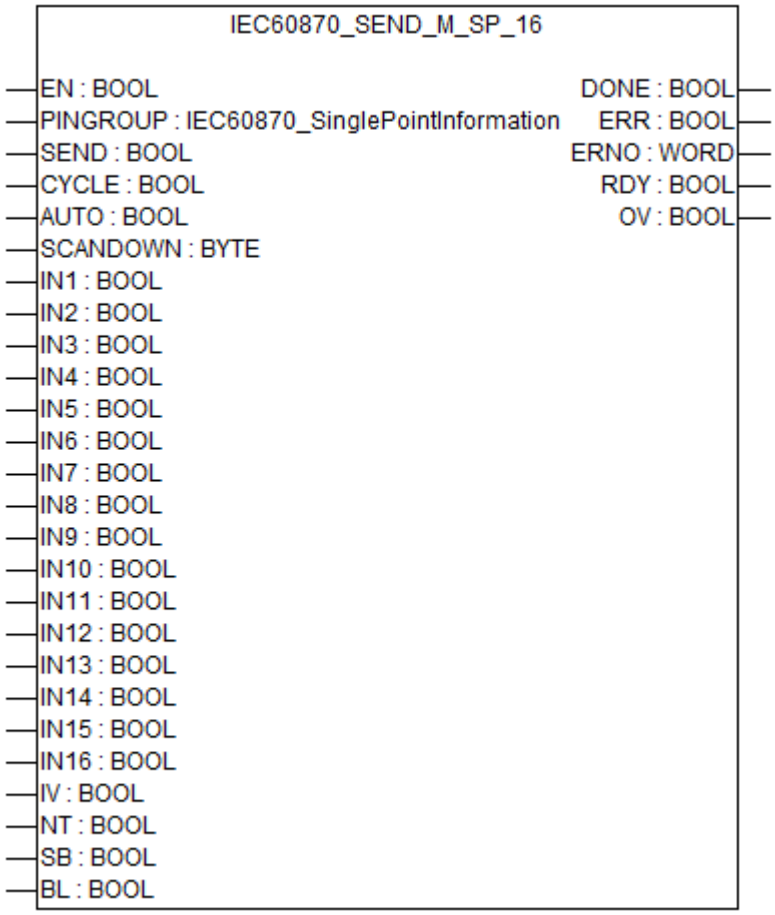
SEND_ERNO               := SEND.ERNO;
SEND_RDY                := SEND.RDY;
SEND_OV                 := SEND.OV;
```

IEC60870_SEND_M_SP_16



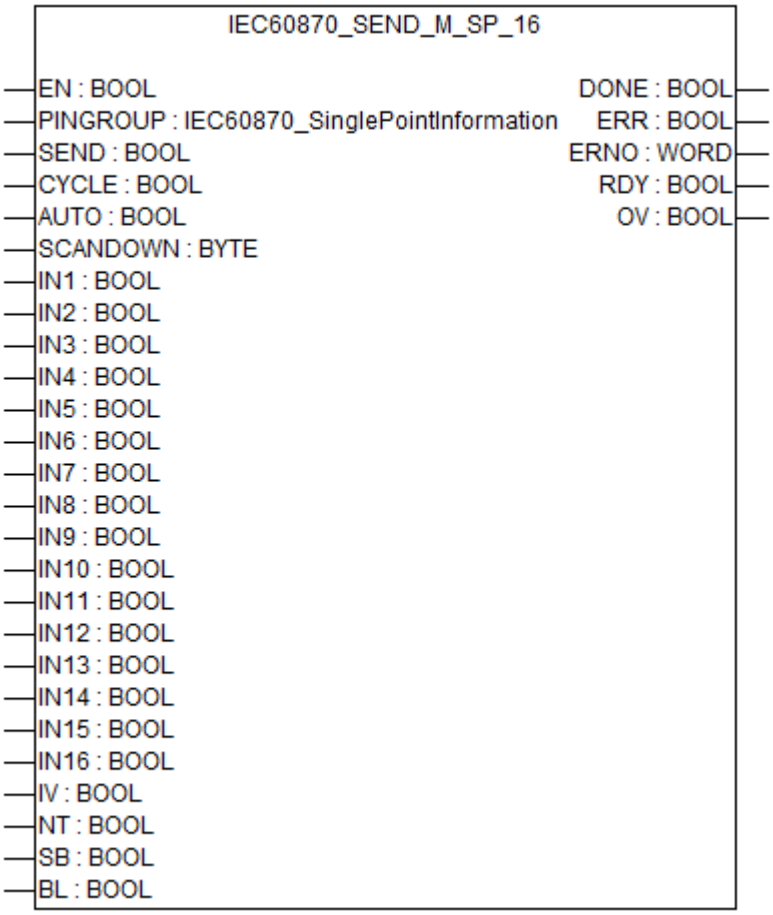
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_SinglePointInformation (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see ↳ *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC 60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send) Start a send request on a rising edge.

CYCLE BOOL (cycle) Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.
On cyclic sending only send within each scandown cycle.

IN1 ... IN16 BOOL (input 1...16) Input value for member 1 to 16.

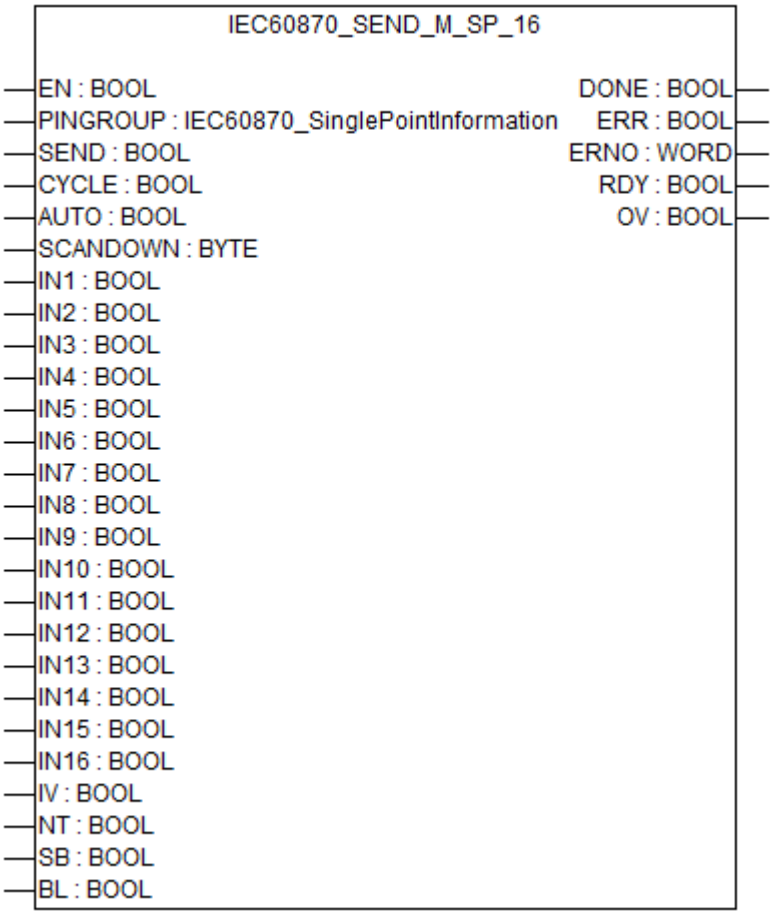
IV BOOL (invalid) Input IV sets the status/information of the data. If IV = TRUE, the data is invalid.

NT BOOL (not topical) Input NT sets the status/information of the data. If NT = TRUE, the data is not topical/actual.

SB BOOL (substituted) Input SB sets the status/information of the data. If SB = TRUE, the data is substituted.

BL BOOL (blocked) Input BL displays the status/information of the data. If BL = TRUE, the data is blocked.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command has been received if RDY = TRUE.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

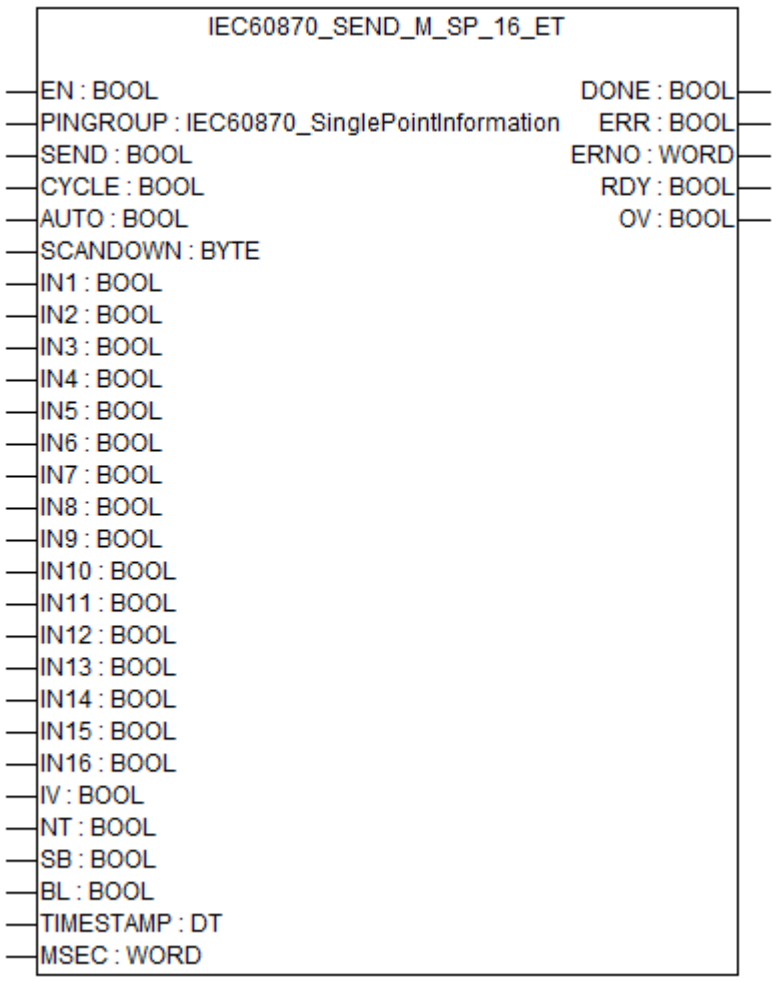
SEND_OV              := SEND.OV;
```

IEC60870_SEND_M_SP_16_ET



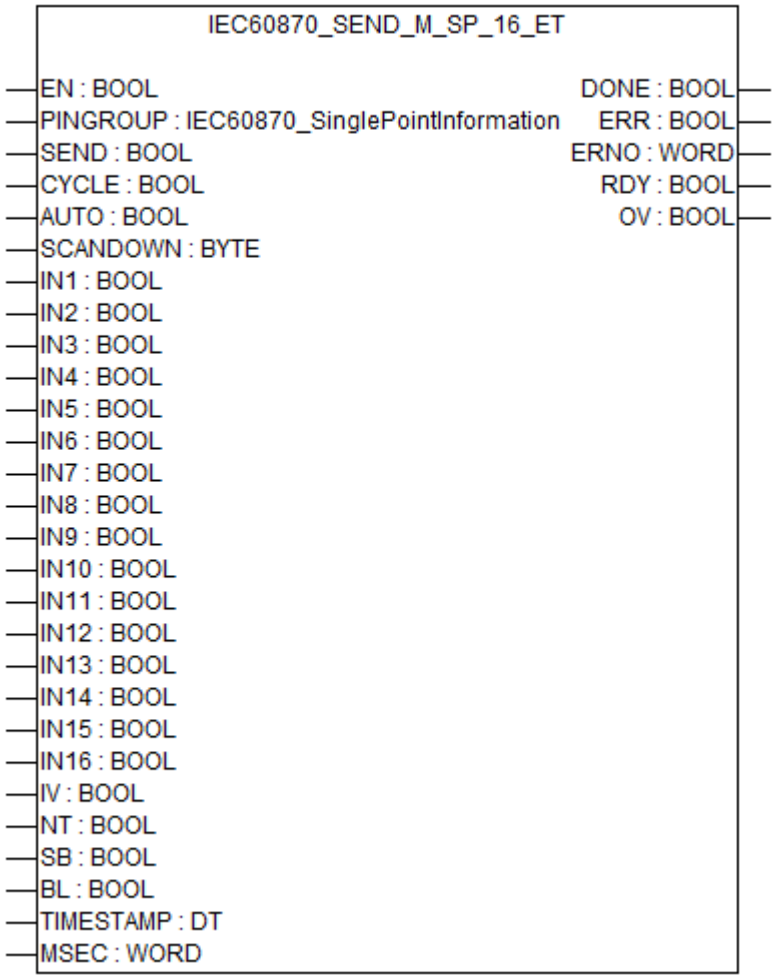
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Data

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP IEC60870_SinglePointInformation (pin group)

At input PINGROUP the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec, see *Chapter 1.6.5.3.2.3.4 “Data points” on page 6131*).

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

SEND BOOL (send) Start a send request on a rising edge.

CYCLE BOOL (cycle) Input CYCLE performs a cyclic send each scandown cycle.

AUTO BOOL (auto) If input AUTO = TRUE, each input value change might trigger a sending process.

SCANDOWN BYTE (scandown) Input SCANDOWN is valid when input CYCLE = TRUE.
On cyclic sending only send within each scandown cycle.

IN1 ... IN16 BOOL (input 1...16) Input value for member 1 to 16.

IV BOOL (invalid) Input IV sets the status/information of the data. If IV = TRUE, the data is invalid.

NT BOOL (not topical) Input NT sets the status/information of the data. If NT = TRUE, the data is not topical/actual.

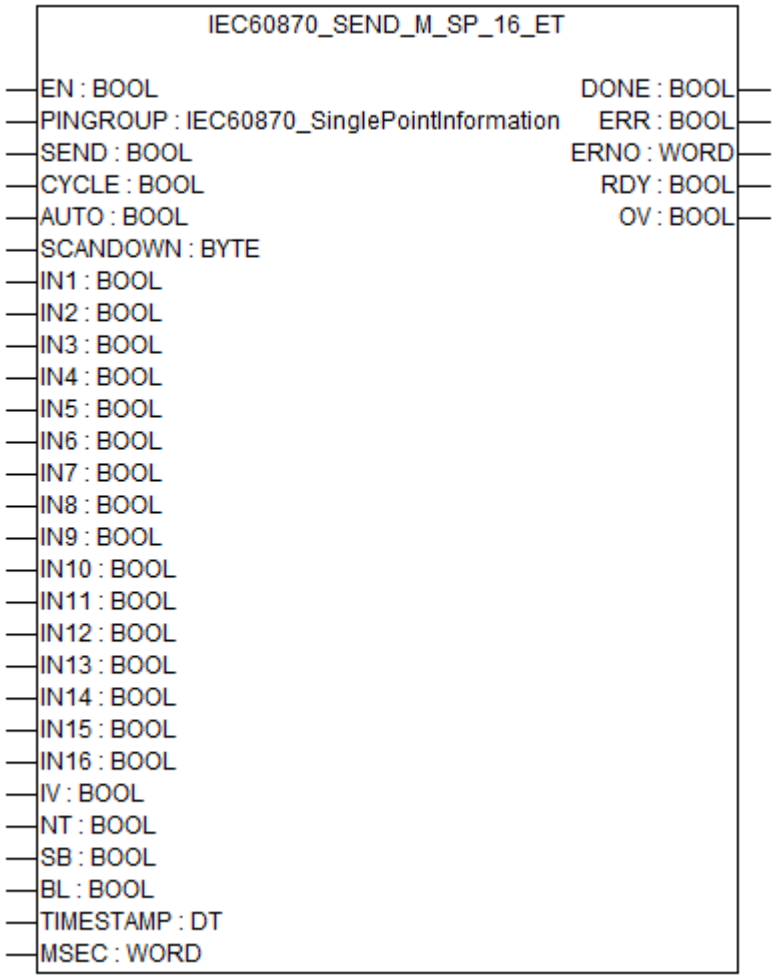
SB BOOL (substituted) Input SB sets the status/information of the data. If SB = TRUE, the data is substituted.

BL BOOL (blocked) Input BL displays the status/information of the data. If BL = TRUE, the data is blocked.

TIMESTAMP DT (timestamp) TIMESTAMP which should be sent with the data.

MSEC WORD (milliseconds) Millisecond part of TIMESTAMP which should be sent with the data.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command has been received if RDY = TRUE.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

Function call in ST

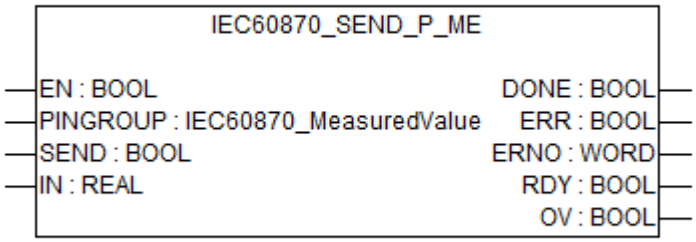
IEC60870_SEND_P_ME



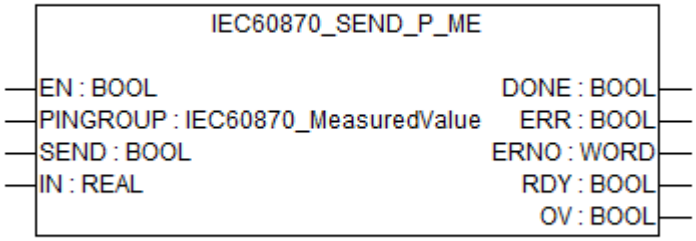
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Parameter_settings

Sending of data messages of the data type according to IEC 60870-5.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

The output RDY indicates the state of the transmission. When new data are received, this is indicated by a change from FALSE to TRUE. This signal is applied for one computation cycle.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

PINGROUP

At input PINGROUP (IEC60870_IntegratedTotal) the corresponding data point is set, which gets received by this function block.

The pin group of the data type IEC60870_DoubleCommand corresponds to the defined data type at the global address list due to the Control-/Substation in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

The IEC60870 data is sent/recorded to the associated datapoint which is defined by the address in Automation Builder (address datapoint send has to be the same as datapoint rec.

A pin group can only be assigned to one defined function block! It is not possible to use the pin group twice (e.g. Send and Rec function blocks)!

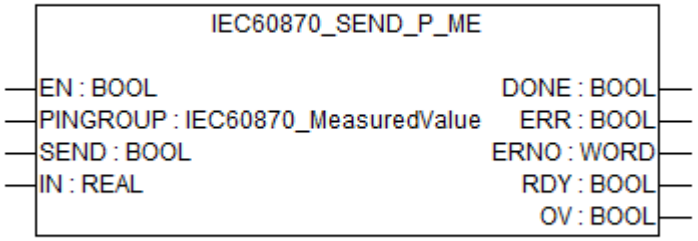
SEND BOOL (send)

Start a send request on a rising edge.

IN REAL (input)

Input value.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command has been received if RDY = TRUE.

OV BOOL (overrun)

Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

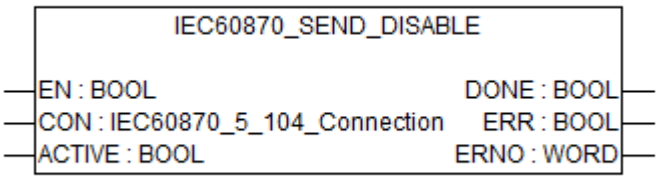
The output always has to be considered together with output RDY.

Function call in ST

```
SEND    (EN             := SEND_EN,
PINGROUP      := SEND_PINGROUP,
SEND          := SEND_SEND,
IN            := SEND_IN);

SEND_DONE             := SEND.DONE;
SEND_ERR              := SEND.ERR;
SEND_ERNO             := SEND.ERNO;
SEND_RDY              := SEND.RDY;
SEND_OV               := SEND.OV;
```

IEC60870_SEND_DISABLE



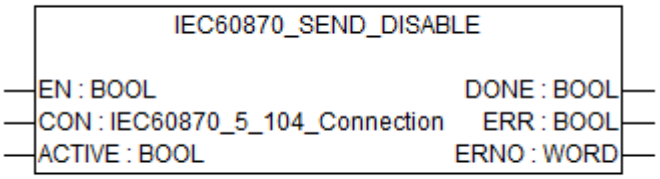
Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.6.2 and above
Type	Function block with historical values
Group	Data

IEC60870_SEND_DISABLE can be used to disable sending any data packets from a IEC 60870 station.

No data will be send in monitored direction on an active link any more if IEC60870_SEND_DISABLE has been executed with inputs EN=TRUE and ACTIVE=FALSE.

To select the IEC60870 connection on which no data will be sent any more, the connection needs to be specified on input CON. On the SEND_DISABLED connection no inquiries will be answered with data any more. The normal ACT_CON, ACT_TERM for an inquiry will be still answered to fulfill the normal command state machine. The sending of data can be enabled any time by executing the IEC60870_SEND_DISABLE function block with EN=TRUE, CON=<desired connection> and ACTIVE=TRUE any time. From that point in time data will be send again in monitored direction. This also applies for inquiries, read requests and background scan data.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CON IEC60870_5_104_Connection (connection)

At input CON the corresponding connection is set to gather information.

The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

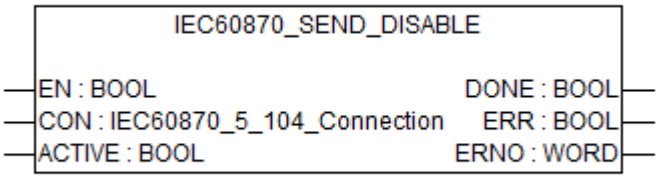
ACTIVE

Data type	Default value	Range	Unit
BOOL	TRUE	TRUE/FALSE	-

If the function block gets executed with ACTIVE=FALSE the PLC will disable all IEC60870 connections.

If the function block gets executed with ACTIVE=TRUE the PLC will enable all IEC60870 connections if they were disabled before.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

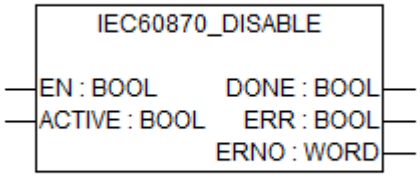
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
SEND_DISABLE (EN  := SEND_DISABLE_EN,
CON    := SEND_DISABLE_CON, ACTIVE  := SEND_DISABLE_ACTIVE;)

SEND_DISABLE_DONE            := SEND_DISABLE.DONE;
SEND_DISABLE_ERR             := SEND_DISABLE.ERR;
SEND_DISABLE_ERNO            := SEND_DISABLE.ERNO;
```

IEC60870_DISABLE



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.6.2 and above
Type	Function block with historical values
Group	Data

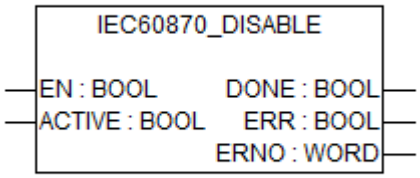
The function block IEC60870_DISABLE can be used to shut down all IEC60870 connections on a PLC.

No further connections can be established after the function block IEC60870_DISABLE has been executed with EN=TRUE and ACTIVE=FALSE.

All already established connections will be aborted. The PLC won’t answer any IEC60870-5-104 connections request any more.

When the IEC60870_DISABLE function block gets executed with EN=TRUE and ACTIVE=TRUE the PLC will listen for new IEC60870-5-104 connections again, and also try to establish connections again.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

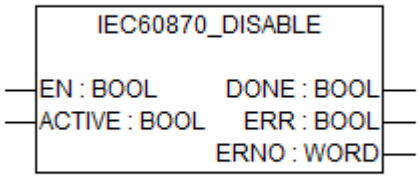
ACTIVE

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

If the function block gets executed with ACTIVE=FALSE the PLC will disable all IEC60870 connections.

If the function block gets executed with ACTIVE=TRUE the PLC will enable all IEC60870 connections if they were disabled before.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

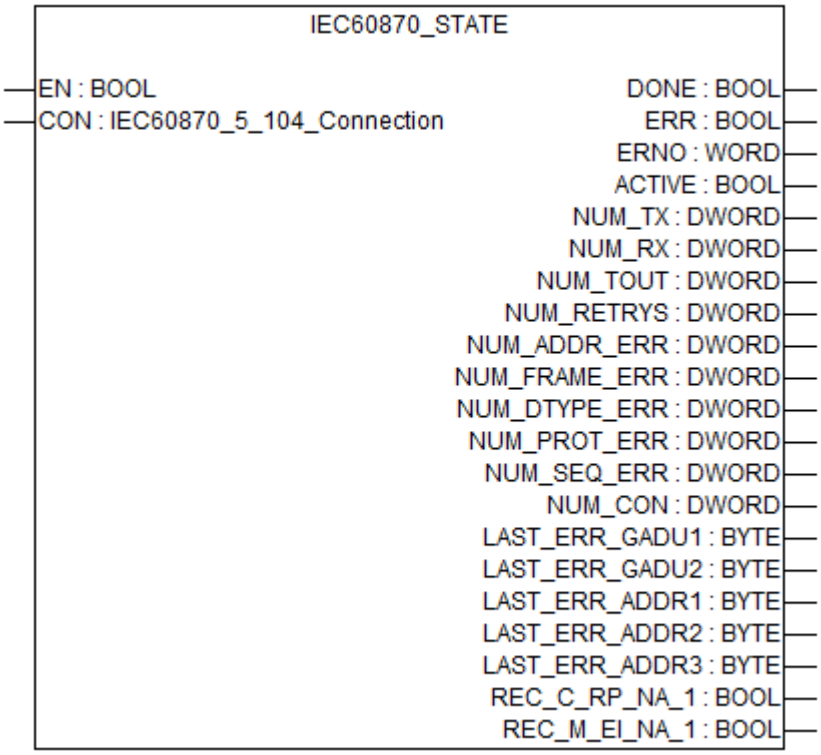
It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IEC60870_STATE



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	General

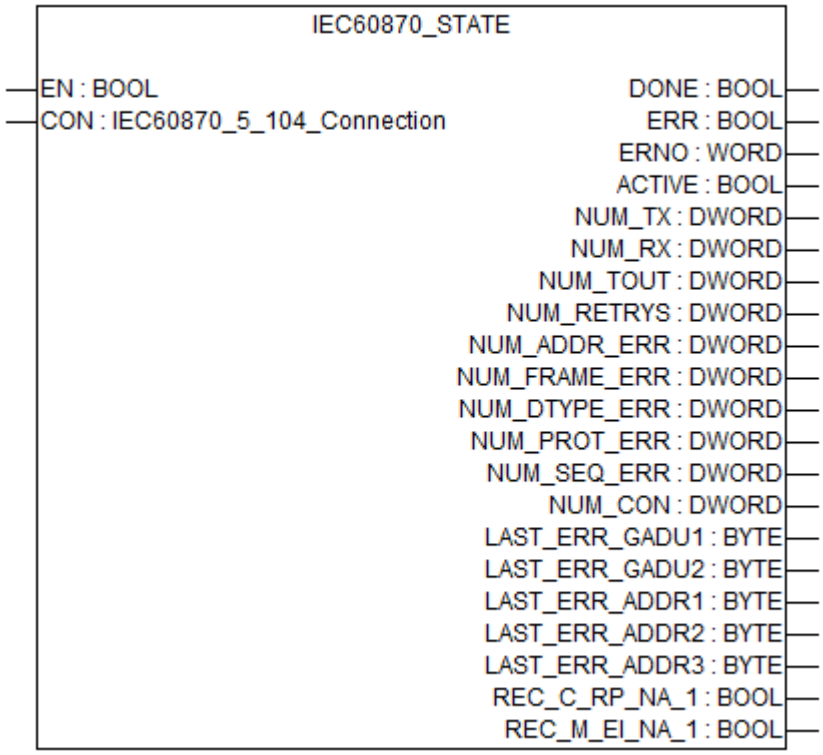
The function block IEC60870_STATE outputs statistically information from the IEC60870-5 protocol.

The function block has to enable to use it. Only if EN = TRUE the specific IEC 60870-5 functions can be activated and used.

For each cyclical processing of the module, the statistical outputs were updated. The actual telecontrol communication via the hardware interface runs in the background independently of the user task.

The data received are available at the corresponding output pins.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

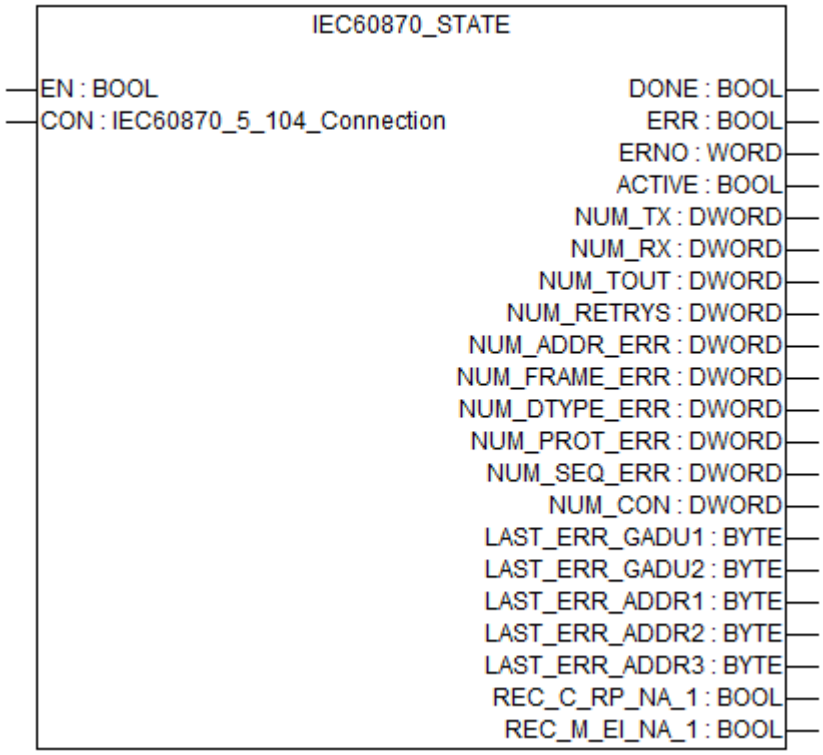
CON IEC60870_5_104_Connection (connection)

At input CON the corresponding connection is set to gather information.

The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ACTIVE (active) BOOL

If ACTIVE = TRUE, the communication is established and active.

NUM_TX DWORD (number tx)	Counter of data transmitted.
NUM_RX DWORD (number rx)	Counter of data received.
NUM_TOUT DWORD (number timeout)	Counter of transmission/reception timeouts.
NUM_RETRYS DWORD (number retries)	Counter of transmission/reception retries.
NUM_ADDR_ERR DWORD (number address error)	Counter of address errors.
NUM_FRAME_ERR DWORD (number frameerror)	Counter of frame errors.
NUM_DTYPE_ERR DWORD (number data typeerror)	Counter of data type errors.
NUM_PROT_ERR DWORD (number protocol error)	Counter of protocol errors.
NUM_SEQ_ERR DWORD (number sequence error)	Counter of sequence errors.
NUM_CON DWORD (number connection)	Amount of established connections.
LAST_ERR_GADU1 BYTE (lasterror global address unit 1)	Last Global Address 1 with error.
LAST_ERR_GADU2 BYTE (lasterror global address unit 2)	Last Global Address 2 with error.
LAST_ERR_ADDR1 BYTE (last local error address unit 1)	Last Global Address 1 with error.
LAST_ERR_ADDR2 BYTE (last local error address unit 2)	Last Global Address 2 with error.

LAST_ERR_ADDR3 BYTE (last local error address unit 3) Last Global Address 3 with error.

REC_C_RP_NA_1 BOOL (receive command reset process) If REC_C_RP_NA_1 = TRUE, a reset process command has been received.

REC_M_EI_NA_1 BOOL (receive monitored init end) If REC_M_EI_NA_1 = TRUE, an init end has been received after a connection was established.

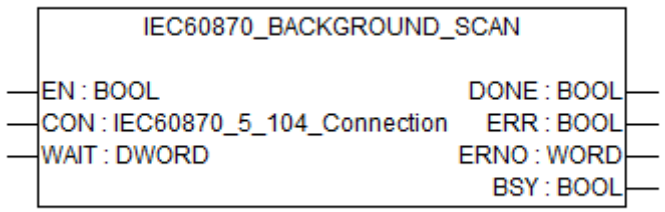
IEC60870_BACKGROUND_SCAN



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.6.x

Parameter	Value
Type	Function block with historical values
Group	General

The background scan allows a monitoring station to report all monitored data without any request.

The data will be sent with a defined delay, so also slow monitoring stations can be handled. The data the monitored station needs to send must be stored within the protocol stack by utilizing SEND_ function blocks without any active send reason.

Then on any event the monitored station may start the background scan by executing the IEC60870_BACKGROUND_SCAN function block.

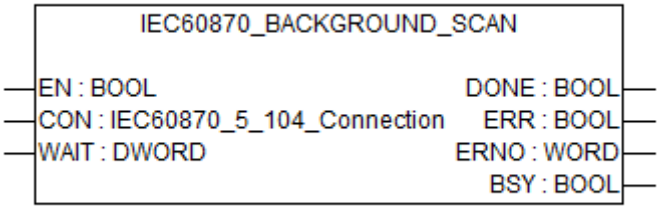
If an active connection exists, the monitored station will then send all monitored data to the monitoring station with a send reason “background scan (2)”.

The data types being used are the same as for a general interrogation.

The receiving station must be able to handle the send reason. For AC500 this send reason is supported since V2.6 and V3.0.

Also data send actively before will be resend by a background scan. If a monitored station sends actively the monitoring station can only distinguish the received data by controlling the send reason value.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CON IEC60870_5_104_Connection (connection)

At input CON the corresponding connection is set to gather information.

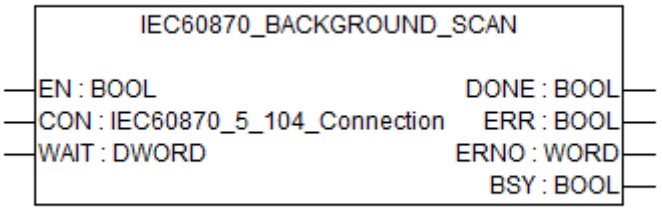
The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

WAIT

This input value denotes a wait time between sending each information object. This allows overcoming any congestion on either the link or the opposite station. The time is given in ms.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BSY (busy)

The output will be TRUE as long as a background scan is already running.

Function call in ST

```
IEC60870_BACKGROUND_SCAN

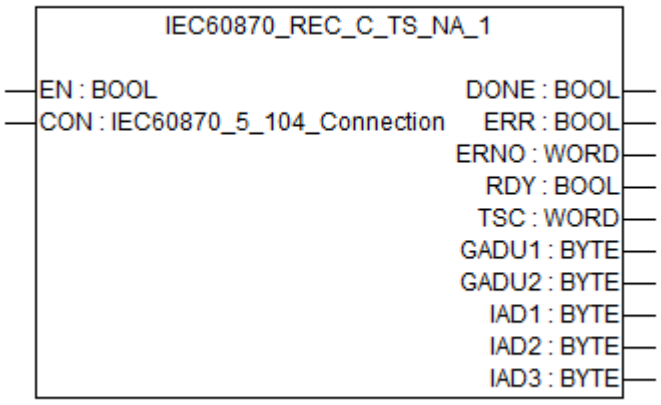
BACKGROUND_SCAN_ERNO                  := BACKGROUND_SCAN.ERNO;
BACKGROUND_SCAN_BSY                    := BACKGROUND_SCAN.BSY;
```

IEC60870_REC_C_TS_NA_1



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	System Information

The test command within IEC60870-5 is used to test the whole loop from monitoring station to the application on the monitored station.

For the AC500 this implies to have an IEC1131 action on receiving a test command in the user application. So the test request must be received by the user application and must also be answered by the user application.

The interface for this is build from 3 function blocks:

- IEC60870_SEND_C_TS_NA_1_ACT to request a test and verify if the correct response was received.

2 function blocks on the tested end.

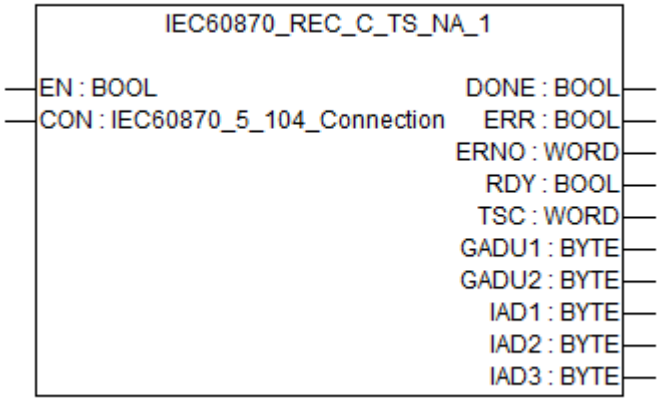
- IEC60870_REC_C_TS_NA_1 to receive an actual test request.
- IEC60870_SEND_C_TS_NA_1_ACTCON to answer an actual test request

For a successful test the testing station needs to request a test by sending a C_TS_NA_1 ACT request to the tested station.

The tested station needs to detect the test request and answer by sending a C_TS_NA_1 ACTCON confirmation with the data received.

The protocol implementation will make sure the correct time stamps are being send, but for the test sequence and address the tested station is responsible

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

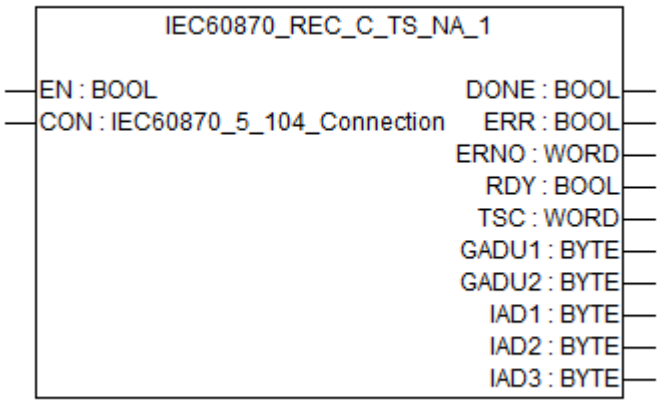
CON IEC60870_5_104_Connection (connection)

At input CON the corresponding connection is set to gather information.

The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready)

A command was received if the output RDY = TRUE.

TSC WORD (Test Sequence Counter)

The requesting station may choose any value of TSC. The TSC in the response shall match the request.

The following 5 outputs provide the address the testing station requested.

The tested station needs to answer with this address.

GADU1 (Common Address of ASDU Byte 1)

GADU2 (Common Address of ASDU Byte 2)

IAD1 (Information Object Address Byte 1)

IAD2 (Information Object Address Byte 2)

IAD3 (Information Object Address Byte 3)

Function call in ST

```

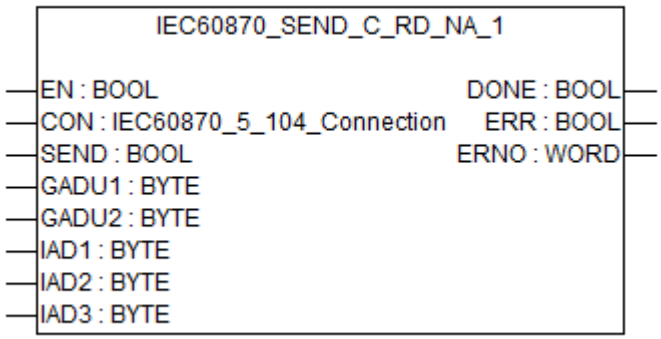
REC_C_TS_NA_1_IAD2            := REC_C_TS_NA_1.IAD2;
REC_C_TS_NA_1_IAD3            := REC_C_TS_NA_1.IAD3;
```

IEC60870_SEND_C_RD_NA_1



Parameter	Value
Included in library	IEC60870_AC500_V20.lib
Available as of firmware	V2.6
Type	Function block with historical values
Group	Sytem Information

The read command C_RD_NA_1 is used to request data from a monitoring station.

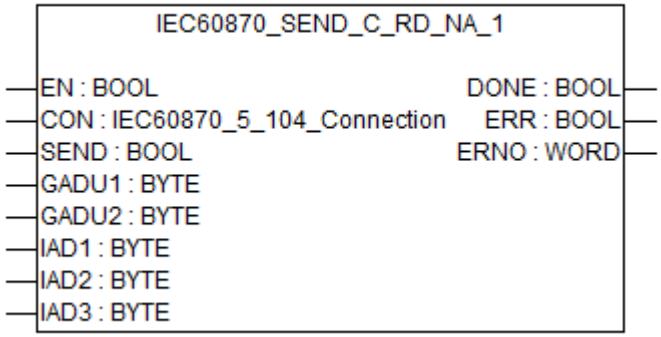
Only monitored data can be requested.

The monitored station will answer a read command with a send of a monitored data type and the send reason being “requested”.

The data that will be send is the last value provided to the protocol with either an active send request, or an inactive send (no send reason active on execution of send function block).

Any data send by normal active sends can be used on the same data point as requested. To detect the requested data, the send reason must be checked. See also background scan or interrogation.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CON IEC60870_5_104_Connection (connection)

At input CON the corresponding connection is set to gather information.

The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

SEND BOOL (send)

A true in conjunction with EN being TRUE will send a C_RD_NA_1 requesting the information object with the given address (GADU1 ,GADU2, IAD1, IAD2, IAD3)

GADU1 (Common Address of ASDU Byte 1)

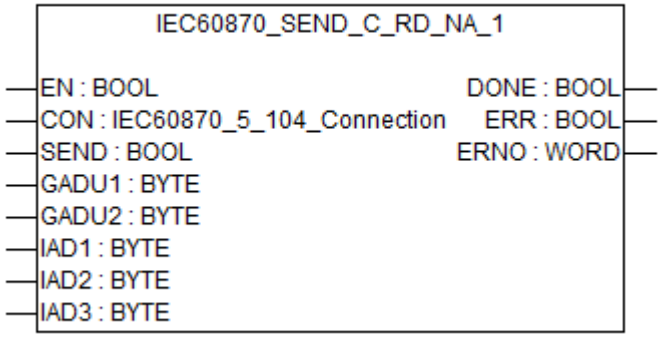
GADU2 (Common Address of ASDU Byte 2)

IAD1 (Information Object Address Byte 1)

IAD2 (Information Object Address Byte 2)

IAD3 (Information Object Address Byte 3)

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

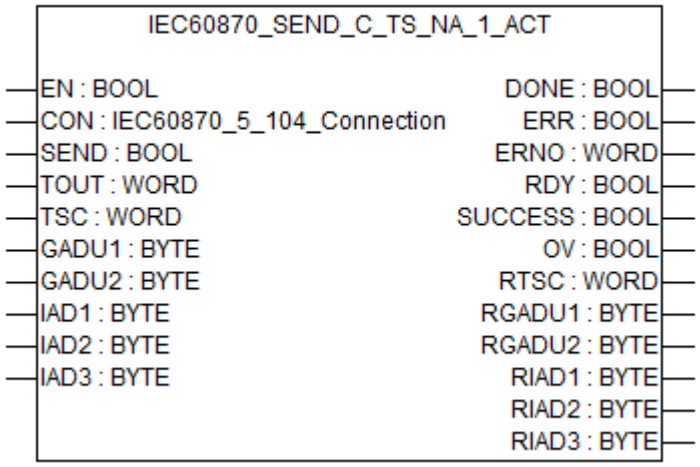
Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CON IEC60870_5_104_Connection (connection)

At input CON the corresponding connection is set to gather information.

The data type of the type IEC60870_5_104_Connection corresponds to the defined Control-/Substation name in Automation Builder, see *Chapter 1.6.5.3.2.4.2 “Control station and substation configuration” on page 6139*.

After the declaration in Automation Builder the data type is available at the global variables constants list.

SEND BOOL (send)

Start a send request on a rising edge.

TOUT WORD (timeout)

Timeout in cycles until ACTERM is expected; 0 = infinite.

TSC WORD (Test Sequence Counter)

The requesting station may choose any value of TSC. The TSC in the response shall match the request.

GADU1 (Common Address of ASDU Byte 1)

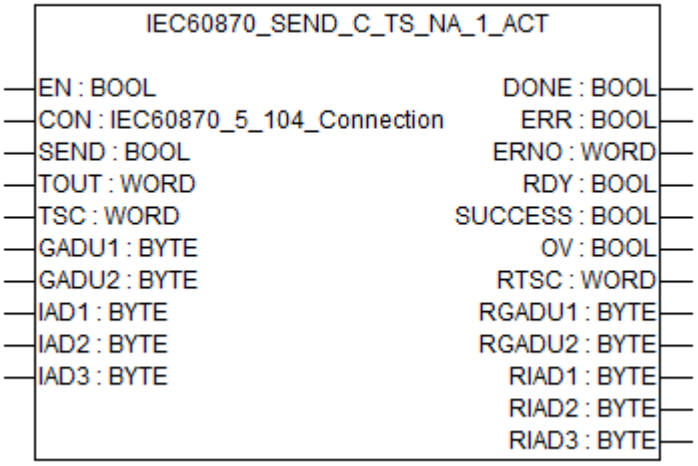
GADU2 (Common Address of ASDU Byte 2)

IAD1 (Information Object Address Byte 1)

IAD2 (Information Object Address Byte 2)

IAD3 (Information Object Address Byte 3)

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RDY BOOL (ready) A command was send if the output RDY = TRUE.

SUCCESS BOOL (receive monitored init end) The test sequence finished successful. The matching answer was received within the specified timeout.

OV BOOL (overrun) Overrun was detected if the output OV = TRUE.

The output OV indicates by changing from FALSE to TRUE, that the transmission requests are coming too fast, i.e. the task cycle time is configured as too fast.

The output always has to be considered together with output RDY.

RTSC BOOL Received test sequence counter, this must match the requested TSC (Input)

RGADU1 BYTE Received adress must match the requested adress at input.

RGADU2 BYTE Received adress must match the requested adress at input.

RIAD1 BYTE Received adress must match the requested adress at input.

RIAD2 BYTE Received adress must match the requested adress at input.

RIAD3 BYTE Received adress must match the requested adress at input.

1.5.4.19 Internal system library

Library file name: **SysInt_AC500_Vx.lib**

The internal system library contains all generally applicable function blocks for the system, i.e. function blocks for general system diagnosis functions or system information. The only exception is the "Data Storage" subgroup which contains special FLASH and memory card function blocks. Using these function blocks, data can be either stored to the Flash memory or to the memory card, as desired.

When creating a new project, the library is automatically included to the project.

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

1.5.4.19.1 Structure of the file USRDATXX.DAT on the memory card

Depending on the AC500 CPU type, the data are stored to the memory card in the following directory:

Table 88: Example

AC500 CPU	Directory	File
PM591	..\UserData\PM591\UserDat	USRDATxx.dat

An memory card must be inserted in the AC500!

A maximum of 100 files (USRDAT0.DAT...USRDAT99.DAT) can be stored in one directory. Each data file USRDATxx.dat can be divided into individual sectors, if necessary. The "sector label" enclosed in square brackets (such as [Sector_01]<CR><LF>) indicates the start of the sector. Within a sector, data are saved as data sets in ASCII format. The individual elements of a data set are automatically separated by semicolon. Each data set is terminated with <CR><LF> (0dhex, 0ahex).

This allows to directly import/export the data files from/to EXCEL. The data files can be viewed and edited using a standard ASCII editor (such as Notepad).

When saving / loading the data files, the following rules have to be observed:

- Writing on a non-existent file creates that file prior to the first write access.
- Data sets within a sector must always have the same number of values.
- Data sets in different sectors can have a different number of values.
- The values of a data set must have the same data format (BYTE, WORD, INT,..).
- A sector can have data sets with different data format. (Warning: The user must know the structure of the data when reading them.)
- The data sets are always appended to the end of the file when writing them.
- Searching for a "sector label" within a file is possible when reading it.
- Data sets can be read starting from a particular "sector label".
- A particular data set of a sector cannot be read or written.
- If you want to read each data set individually, a "sector label" must be inserted before each data set.
- Reading and writing the data with help of the user program is done with the function blocks SD_READ and SD_WRITE.
- The values of a data set must be available in variables successively arranged in the PLC (e.g. ARRAY, STRING, %M area).
- A data file can be deleted with help of the PLC program.
- Individual data sets and/or sectors cannot be deleted with the user program. This has to be done on the PC using an ASCII editor such as Notepad.

Data file example 1

Data file USRDAT5.dat without sectors:

-> 5 data sets, each with 10 DINT values:

600462;430;506;469;409;465;466;474;476;-1327203

600477;446;521;484;425;480;482;490;491;-1327187

600493;461;537;499;440;496;497;505;507;-1327172

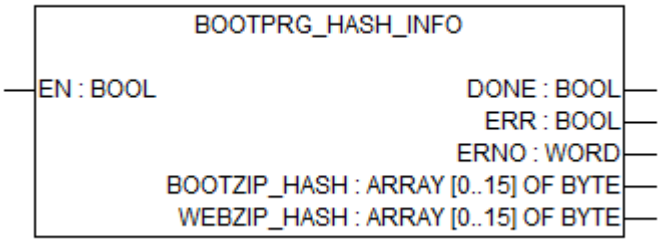
600508;477;552;515;456;511;513;521;522;-1327156

600524;492;568;530;471;527;528;536;538;-1327141

Data file example 2	Data file USRDAT7.dat with sectors: -> 3 sectors, each with 3 data sets and 10 DINT values per data set: [Sector_01] 610439;10408;10483;10446;10387;10442;10444;10452;10453;-1317225 610455;10423;10499;10462;10402;10458;10460;10467;10469;-1317209 610476;10445;10520;10483;10424;10479;10481;10489;10490;-1317188 [Sector_02] 610570;10539;10614;10577;10518;10573;10575;10583;10584;-1317094 610585;10554;10630;10592;10533;10589;10591;10598;10600;-1317078 610602;10571;10646;10609;10550;10605;10607;10615;10616;-1317062 [Sector_03] 610701;10670;10746;10708;10649;10704;10706;10714;10715;-1316963 610717;10686;10761;10724;10665;10720;10722;10730;10731;-1316947 610739;10708;10783;10746;10686;10742;10744;10751;10753;-1316926 The sector name can consist of a maximum of 32 characters (including []).

1.5.4.19.2 Function blocks

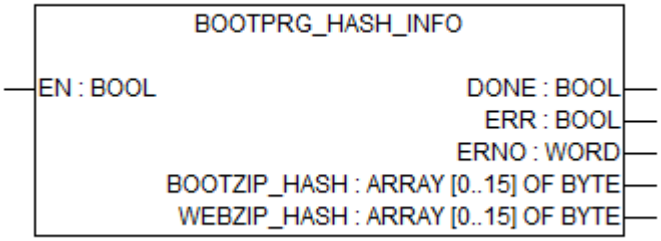
BOOTPRG_HASH_INFO



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V2.3.0
Type	Function block with historical values

The function block BOOTPRG_HASH_INFO reads the MD5 hash of the boot project.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

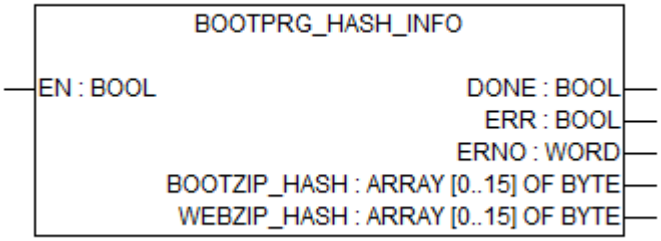
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BOOTZIP_HASH BOOTZIP_HASH (array [0..15] of byte) outputs the MD5 hash of the user program part of the boot project (BOOT.ZIP file).

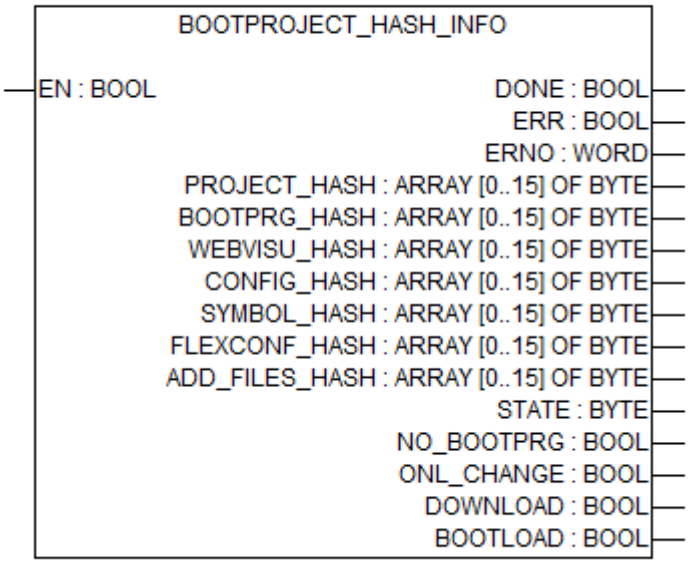
WEBZIP_HASH WEBZIP_HASH (array [0..15] of byte) outputs the MD5 hash of the webvisu part of the boot project (WEB.ZIP file).

Function call in ST

```
Hash (EN := Hash_EN);

Hash_DONE          := Hash.DONE;
Hash_ERR           := Hash.ERR;
Hash_ERNO          := Hash.ERNO;
Hash_BOOTZIP_HASH  := Hash.BOOTZIP_HASH;
Hash.WEBZIP_HASH   := Hash.WEBZIP_HASH;
```

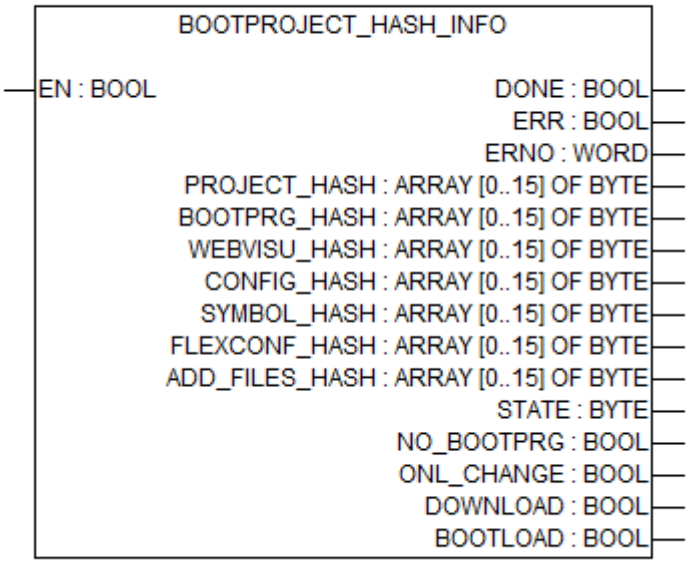
BOOTPROJECT_HASH_INFO



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V2.3.2
Type	Function block with historical values

The function block BOOTPROJECT_HASH_INFO reads the MD5 hash of different parts of the boot project.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

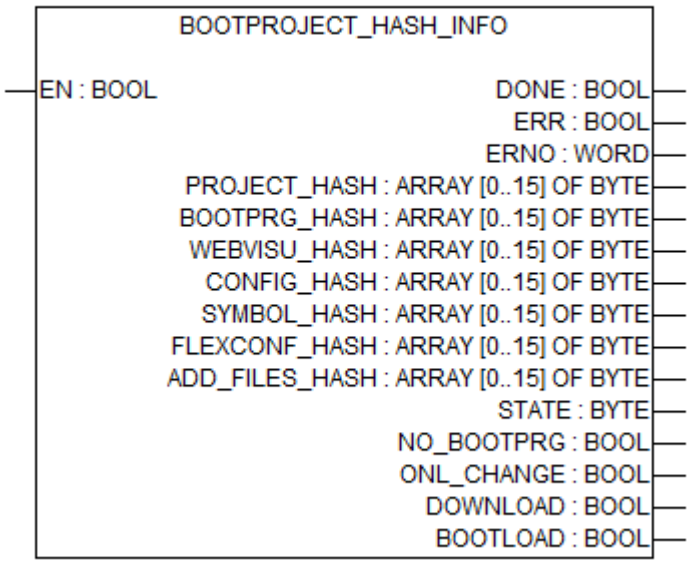
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

PROJECT_HASH

PROJECT_HASH (array [0..15] of byte) outputs the MD5 hash of the whole boot project. It is calculated from all the following MD5 sums.

BOOTPRG_HASH

BOOTZIP_HASH (array [0..15] of byte) outputs the MD5 hash of the user program code of the boot project (BOOT.ZIP file).

WEB-VISU_HASH WEBVISU_HASH (array [0..15] of byte) outputs the MD5 hash of all web visualization files in the boot project.

CONFIG_HASH CONFIG_HASH (array [0..15] of byte) outputs the MD5 hash of PLC configuration in the boot project.

SYMBOL_HASH SYMBOL_HASH (array [0..15] of byte) outputs the MD5 hash of the symbol file in the boot project.

FLEX-CONF_HASH FLEXCONF_HASH (array [0..15] of byte) outputs the MD5 hash of the flexible configuration file of the boot project.

ADD_FILES_HASH ADD_FILES_HASH (array [0..15] of byte) outputs the MD5 hash of all additional files contained in the boot project.

STATE BYTE STATE outputs the validity of the hash outputs. It contains status bits for different states the PLC can be in. These states affect whether the hashes at the outputs of this function block will be valid or not and why. All the Status Bits are also shown at the other BOOL outputs of this function block:

NO_BOOTPRG STATE.Bit0

ONL_CHANGE STATE.Bit1

DOWNLOAD STATE.Bit2

BOOTLOAD STATE.Bit3

NO_BOOTPRG

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

NO_BOOTPRG is set to TRUE if no boot project has been found that could be hashed (STATE Bit 0).

ONL_CHANGE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

ONL_CHANGE is set to TRUE if an online change has been done since booting the PLC, so the hashes are outdated (STATE Bit 1).

DOWNLOAD

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

DOWNLOAD is set to TRUE if a project download has been done since booting the PLC, so the hashes are outdated (STATE Bit 2).

BOOTLOAD

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

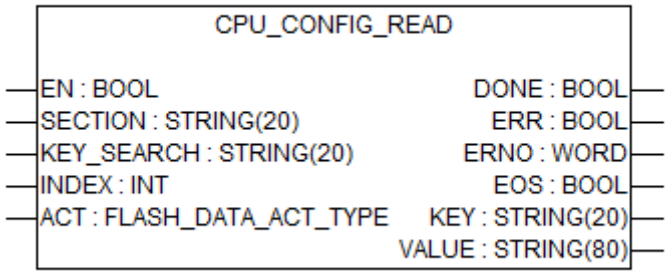
DOWNLOAD is set to TRUE if a boot project download has been flashed since booting the PLC, so the hashes are outdated (STATE Bit 3).

Function call in ST

```
BOOTPROJECT_HASH_INFO (EN := Hash_EN);

Hash_DONE := BOOTPROJECT_HASH_INFO.DONE;
Hash_ERR  := BOOTPROJECT_HASH_INFO.ERR;
Hash_ERNO := BOOTPROJECT_HASH_INFO.ERNO;
Hash_PROJECT_HASH    := BOOTPROJECT_HASH_INFO.PROJECT_HASH;
Hash_BOOTPRG_HASH    := BOOTPROJECT_HASH_INFO.BOOTPRG_HASH;
Hash_WEBVISU_HASH    := BOOTPROJECT_HASH_INFO.WEBVISU_HASH;
Hash_CONFIG_HASH     := BOOTPROJECT_HASH_INFO.CONFIG_HASH;
Hash_SYMBOL_HASH     := BOOTPROJECT_HASH_INFO.SYMBOL_HASH;
Hash_FLEXCONF_HASH   := BOOTPROJECT_HASH_INFO.FLEXCONF_HASH;
Hash_ADD_FILES_HASH  := BOOTPROJECT_HASH_INFO.ADD_FILES_HASH;
Hash_STATE           := BOOTPROJECT_HASH_INFO.STATE;
Hash_NO_BOOTPRG      := BOOTPROJECT_HASH_INFO.NO_BOOTPRG;
Hash_ONL_CHANGE      := BOOTPROJECT_HASH_INFO.ONL_CHANGE;
Hash_DOWNLOAD        := BOOTPROJECT_HASH_INFO.DOWNLOAD;
Hash_BOOTLOAD        := BOOTPROJECT_HASH_INFO.BOOTLOAD;
```

CPU_CONFIG_READ



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

The function block reads individual values of configuration data from the Flash memory. One line consists of a pair of key values and is located within the section. The configuration data stored in the Flash are like an ini file in their construction, like for example the sdcard.ini on the memory card of the AC500.

Example for a line with an IP address in the section Common:

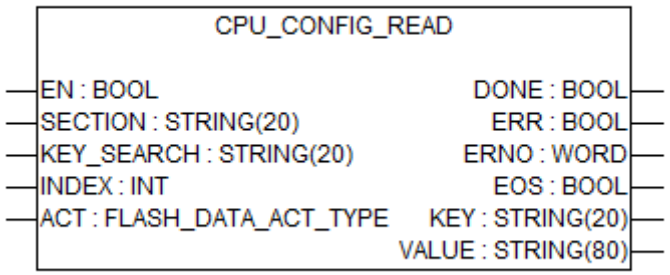
[Common]

IP_ADR=192.168.0.1

The procedure should be performed in three steps:

1. Initialization (ACT = FLASH_DATA_INIT) of the configuration data with a FALSE/TRUE edge at input EN.
2. Reading (ACT = FLASH_DATA_READ) of the individual values (SECTION, KEY_SEARCH, INDEX) with a FALSE/TRUE edge at input EN.
3. Cancel (ACT = FLASH_DATA_SKIP) the reading with a FALSE/TRUE edge at input EN.

Input Description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SECTION

Data type: STRING[20]

Section, within to search/read. A section has always to be specified, except for the initialization step.

KEY_SEARCH

Data type: STRING[20]

If it is searched for the value of a known key, this must be specified at the input KEY_SEARCH. The key is searched within the section which is specified at the input SECTION. In this case, the input INDEX is ignored.

INDEX

Data type: INT

The INDEX input is only evaluated, if the KEY_SEARCH input is 0.

With the INDEX input, a specified line of the configuration data within the section, specified at input SECTION, is output.

If INDEX is unequal to 0, exactly this line number is output, if it exists. If INDEX equals 0 and if there is no value at input KEY_SEARCH, the lines of the section (specified at input SECTION) are output sequentially.

In the latter case each time the next line is read with every FALSE/TRUE edge at input EN as long as the output EOS changes to TRUE and thus terminating the section.

ACT

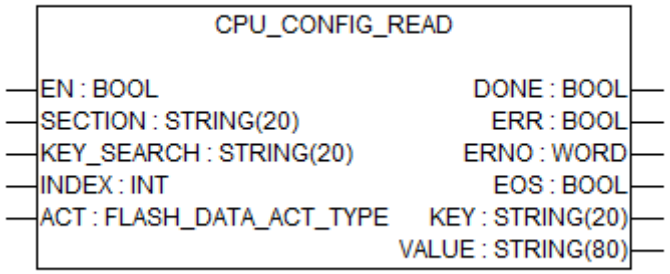
Data type: FLASH_DATA_ACT_TYPE

With the ACT input, the function block can be set to initialize, read the configuration data or to cancel the function block operation.

The input can be set to the following values:

- FLASH_DATA_INIT
  With this input, the function block is initialized for processing of configuration data. The configuration data is copied from the Flash to the RAM, where it can be processed until a re-write into the Flash is performed via the SAVE input.
  If ACT=FLASH_DATA_INIT, all the other inputs are ignored. If the initialization process is performed, all the previous changes are discarded and the original configuration data is copied from the Flash.
- FLASH_DATA_READ
  Read data from RAM disk with the ACT = FLASH_DATA_READ.
- FLASH_DATA_SKIP
  Skip current changes in RAM disk by using FLASH_DATA_SKIP at the input ACT.

Output Description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

EOS

Data type: BOOL

Output EOS (end of section) indicates whether the end of the section was reached while searching sequentially. This output only must be evaluated, if a search is carried out with INDEX=0 and KEY_SEARCH=0.

KEY Data type: STRING[20]

Output KEY indicates the found key.

VALUE Data type: STRING[80]

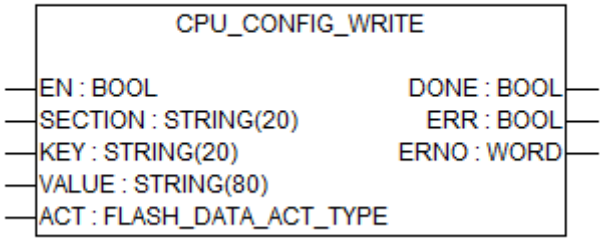
Output VALUE indicates the value of the found key.

Function Call in ST

```
ConfigRead   (EN         := ConfigRead_EN,
    SECTION    := ConfigRead_SECTION,
    KEY_SEARCH := ConfigRead_KEY_SEARCH,
    INDEX      := ConfigRead_INDEX,
    ACT        := ConfigRead_ACT);

ConfigRead_DONE      := ConfigRead.DONE;
ConfigRead_DONE_ERR  := ConfigRead.ERR;
ConfigRead_ERNO      := ConfigRead.ERNO;
ConfigRead_EOS       := ConfigRead.EOS;
ConfigRead_KEY       := ConfigRead.KEY;
ConfigRead_VALUE     := ConfigRead.VALUE;
```

CPU_CONFIG_WRITE



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

The function block writes user-defined configuration data to the Flash memory. The configuration data stored in the Flash are like an ini file in their construction, like for example the sdcard.ini on the memory card of the AC500.

Example for a line with an IP address in the section Common:

[Common]

IP_ADR=192.168.0.1

The procedure should be performed in three steps:

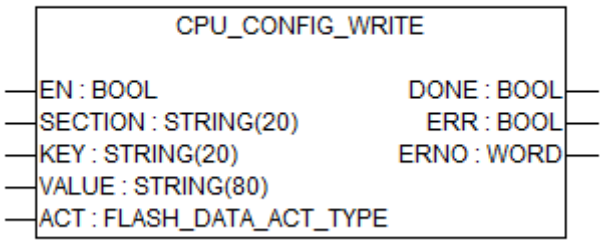
1) Initialization (ACT = FLASH_DATA_INIT) of the configuration data with a FALSE/TRUE edge at input EN.

2) Writing (ACT = FLASH_DATA_WRITE) of the individual values (SECTION, KEY, VALUE) with a FALSE/TRUE edge at input EN. This step is repeated for each entry until all the desired data has been written.

3) Transmit (ACT = FLASH_DATA_SAVE) the data into the Flash and ensuring a permanent data storage in this way.

Only after the third step has been done, the data is stored in the Flash and will be non-volatile in case of power-down.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SECTION Section to write to.

KEY Key to be written.

VALUE Value of the key to be written.

ACT Data type: FLASH_DATA_ACT_TYPE

With the ACT input, the function block can be set to initialize, write the configuration data or to save, to skip or reset the function block operation. The input can be set to following values:

FLASH_DATA_INIT:

With this input, the function block is initialized for processing of configuration data. The configuration data is copied from the Flash to the RAM, where it can be processed until a re-write into the Flash is performed via the SAVE input. If ACT = FLASH_DATA_INIT, all the other inputs are ignored. If the initialization process is performed, all the previous changes are discarded and the original configuration data is copied from the Flash.

FLASH_DATA_WRITE:

Write data to RAM disk with the ACT = FLASH_DATA_WRITE.

FLASH_DATA_SAVE: Save data from RAM disk to Flash

Using ACT = FLASH_DATA_SAVE, all changes made at the configuration data are saved to Flash. So they are stored non-volatile during power-down. If this step is not carried out, all previous changes are lost. Since writing into the Flash takes some time, the save action should be performed as the last step, after all of the desired values are written, modified or deleted.

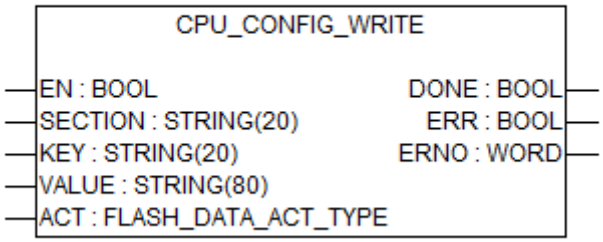
FLASH_DATA_SKIP:

Skip current changes in RAM disk by using FLASH_DATA_SKIP at the input ACT.

FLASH_DATA_RES:

With this input, a reset function is carried out, which deletes all of the configuration data completely.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

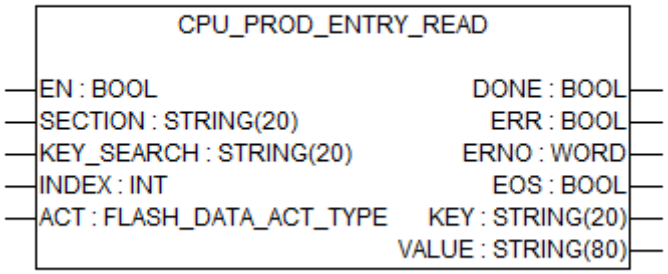
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
ConfigWrite  (EN      := ConfigWrite_EN,
     SECTION := ConfigWrite_SECTION,
     KEY     := ConfigWrite_KEY,
     VALUE   := ConfigWrite_VALUE,
     ACT     := ConfigWrite_ACT);

ConfigWrite_DONE      := ConfigWrite.DONE;
ConfigWrite_ERR       := ConfigWrite.ERR;
ConfigWrite_ERNO      := ConfigWrite.ERNO;
```

CPU_PROD_ENTRY_READ



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

The function block reads one line from the production data in the Flash memory. One line consists of a pair of key values and is located within a section.

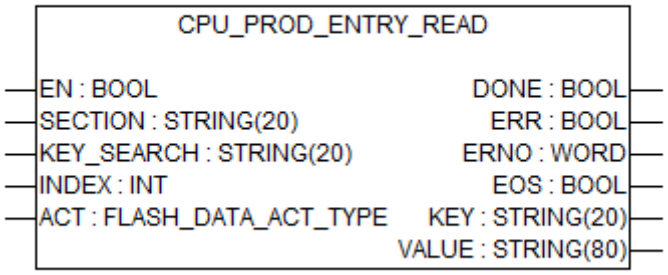
The section name of the production data is called "Common". It consists of many keys with the corresponding values, see table:

Production data		Comment
Common	Section Name	Name of the section
BA_INST	Key and value	BA number
IDENT	Key and value	SAP identnumber
INDEX	Key and value	Index of the module
MAC	Key and value	MAC address of the CPU
MANUF_DATE	Key and value	Date of manufacture
MANUF_YEAR	Key and value	Manufacturing year
MANUF_PLACE	Key and value	Place where the PLC was produced
SERIAL_NR	Key and value	Serial number of the PLC
TYPE	Key and value	CPU type

The procedure should be performed in three steps:

1. Initialization (ACT = FLASH_DATA_INIT) of the production data with a FALSE/TRUE edge at input EN.
2. Reading (ACT = FLASH_DATA_READ) of the individual values (SECTION, KEY_SEARCH, INDEX) with a FALSE/TRUE edge at input EN.
3. Cancel (ACT = FLASH_DATA_SKIP) the reading with a FALSE/TRUE edge at input EN.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SECTION

Data type: STRING[20]

Section, within to search/read. A section has always to be specified, except for the initialization step.

KEY_SEARCH

Data type: STRING[20]

If it is searched for the value of a known key, this must be specified at the input KEY_SEARCH. The key is searched within the section which is specified at the input SECTION. In this case, the input INDEX is ignored.

INDEX

Data type: INT

The INDEX input is only evaluated, if the KEY_SEARCH input is 0.

With the INDEX input, a specified line of the configuration data within the section, specified at input SECTION, is output.

If INDEX is unequal to 0, exactly this line number is output, if it exists. If INDEX equals 0 and if there is no value at input KEY_SEARCH, the lines of the section (specified at input SECTION) are output sequentially.

In the latter case each time the next line is read with every FALSE/TRUE edge at input EN as long as the output EOS changes to TRUE and thus terminating the section.

ACT

Data type: FLASH_DATA_ACT_TYPE

With the ACT input the function block can be set to initialize, read the production data or to cancel the function block operation. The input can be set to following values:

FLASH_DATA_INIT:

With this input, the function block is initialized for processing of production data. The production data is copied from the Flash to the RAM, where it can be processed until a re-write into the Flash is performed via the SAVE input. If ACT = FLASH_DATA_INIT, all the other inputs are ignored. If the initialization process is performed, all the previous changes are discarded and the original configuration data is copied from the Flash.

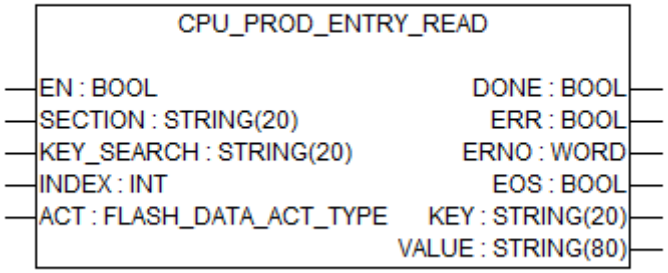
FLASH_DATA_READ:

Read data from RAM disk with the ACT = FLASH_DATA_READ.

FLASH_DATA_SKIP:

Skip current changes in RAM disk by using FLASH_DATA_SKIP at the input ACT.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

EOS Data type: BOOL

Output EOS (end of section) indicates whether the end of the section was reached while searching sequentially. This output only must be evaluated, if a search is carried out with INDEX=0 and KEY_SEARCH=0.

KEY Data type: STRING[20]

Output KEY indicates the found key.

VALUE Data type: STRING[80]

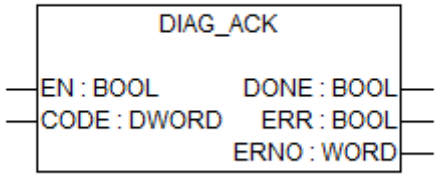
Output VALUE indicates the value of the found key.

Function call in ST

```
CPU_PROD_ENTRY_READ(EN := EN_CPU_PROD_ENTRY_READ,
 SECTION := SECTION_CPU_PROD_ENTRY_READ,
 KEY_SEARCH := KEY_SEARCH_CPU_PROD_ENTRY_READ,
 INDEX := INDEX_CPU_PROD_ENTRY_READ,
 ACT := ACT_CPU_PROD_ENTRY_READ);

DONE_CPU_PROD_ENTRY_READ := CPU_PROD_ENTRY_READ.DONE;
ERR_CPU_PROD_ENTRY_READ  := CPU_PROD_ENTRY_READ.ERR;
ERNO_CPU_PROD_ENTRY_READ := CPU_PROD_ENTRY_READ.ERNO;
EOS_CPU_PROD_ENTRY_READ  := CPU_PROD_ENTRY_READ.EOS;
KEY_CPU_PROD_ENTRY_READ  := CPU_PROD_ENTRY_READ.KEY;
VALUE_CPU_PROD_ENTRY_READ:= CPU_PROD_ENTRY_READ.VALUE;
```

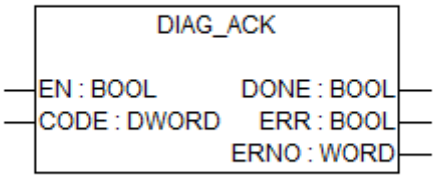
DIAG_ACK



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The function block DIAG_ACK can be used to acknowledge any error. Selection of the error to be acknowledged is performed using a 32-bit code. If the error list contains several entries with the selected error code number, acknowledgement is always performed for the oldest entry in the list.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

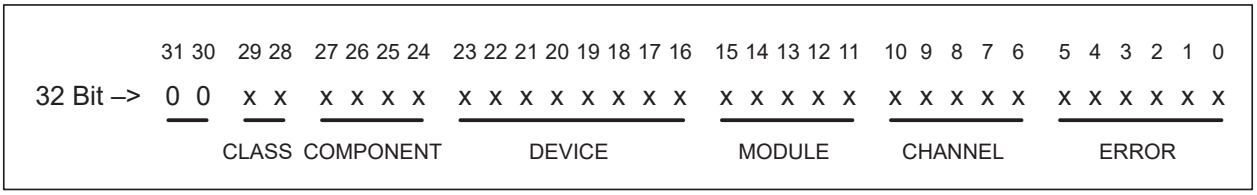
In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

CODE

Data type	Default value	Range	Unit
DWORD	-	-	-

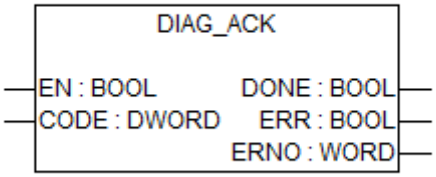
At input CODE, the code number of the error to be acknowledged is specified. The code number of an existing error can be read using the function block DIAG_GET or calculated manually. The structure of the error coding is as follows:



Bit 0 to 5	- Error number	Valid range: 0...63
Bit 6 to 10	- Channel number	Valid range: 0...31
Bit 11 to 15	- Module number	Valid range: 0...31
Bit 16 to 23	- Device number	Valid range: 0...255
Bit 24 to 27	- Component number	Valid range: 0...15
Bit 28 to 29	- Error class	Valid range: 1...4
Bit 30 to 31	- Reserved; both bits always must be zero.	

Valid range: 16#3E9...16#3FFFFFFF

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

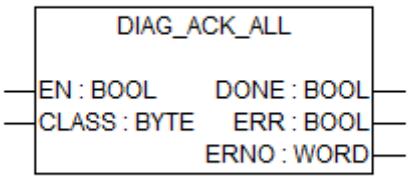
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
DiagAck(EN := DiagAck_EN,
      CODE := DiagAck_CODE);

DiagAck_DONE := DiagAck.DONE;
DiagAck_ERR  := DiagAck.ERR;
DiagAck_ERNO := DiagAck.ERNO;
```

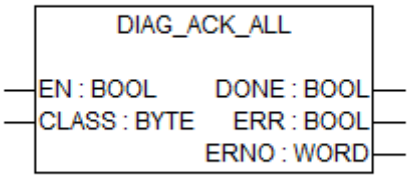
DIAG_ACK_ALL



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The function block DIAG_ACK_ALL can be used to acknowledge all errors of an error class simultaneously. Selection of the error class, the errors of which are to be acknowledged, is done using the input CLASS.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

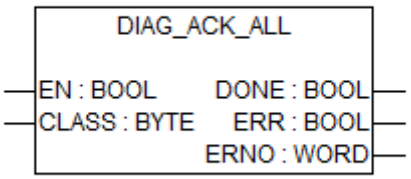
Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

CLASS

Data type	Default value	Range	Unit
BYTE	-	1...4	-

At input CLASS, the error class is specified, the errors of which are to be acknowledged.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

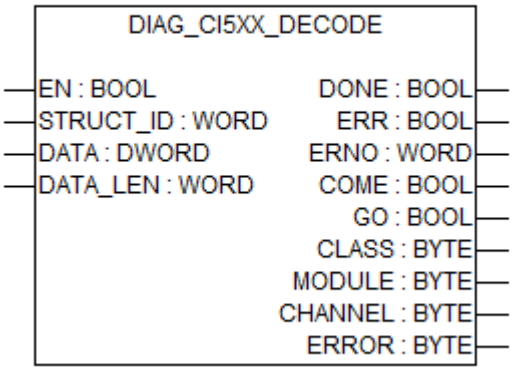
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
DiagAckAll(EN := DiagAckAll_EN,
        CLASS := DiagAckAll_CLASS);

DiagAckAll_DONE := DiagAckAll.DONE;
DiagAckAll_ERR  := DiagAckAll.ERR;
DiagAckAll_ERNO := DiagAckAll.ERNO;
```

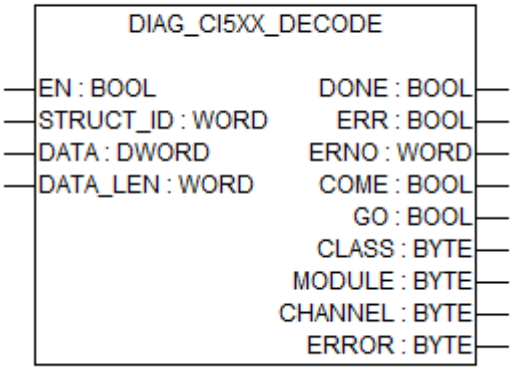
DIAG_CI5XX_DECODE



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The function block decodes CI5XX diagnosis data to AC500 diagnosis system information.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

STRUCT_ID

Data type	Default value	Range	Unit
WORD	0	-	-

Identifier of the diagnosis format to read from CI5XX.

DATA

Data type	Default value	Range	Unit
DWORD	0	-	-

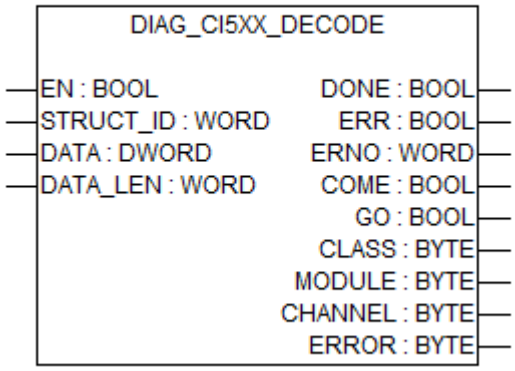
Address to the memory where the diagnosis message should be read from.

DATA_LEN

Data type	Default value	Range	Unit
WORD	0	-	-

Length of the data to read from CI5XX in bytes. Depends on the ID. For available structures see your CI5XX documentation.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

COME

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

The output COME is the flag of standard AC500 diagnosis. It indicates that a diagnosis messages has appeared. For details see *Chapter 1.7.1 “The diagnosis system” on page 6365*.

GO

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

The output GO is the flag of standard AC500 diagnosis. It indicates that a diagnosis messages has disappeared. For details see *Chapter 1.7.1 “The diagnosis system” on page 6365*.

CLASS

Data type	Default value	Range	Unit
BYTE	0	-	-

The output CLASS indicates the severity of the diagnosis message. For details see *Chapter 1.7.1 “The diagnosis system” on page 6365*.

MODULE

Data type	Default value	Range	Unit
BYTE	0	-	-

The output MODULE shows the module the read error is assigned to.

CHANNEL

Data type	Default value	Range	Unit
BYTE	0	-	-

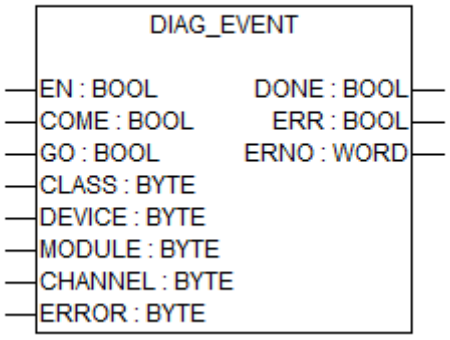
The output CHANNEL shows the channel the read error is assigned to.

ERROR

Data type	Default value	Range	Unit
BYTE	0	-	-

The outputs ERROR provides the error number of the read error.

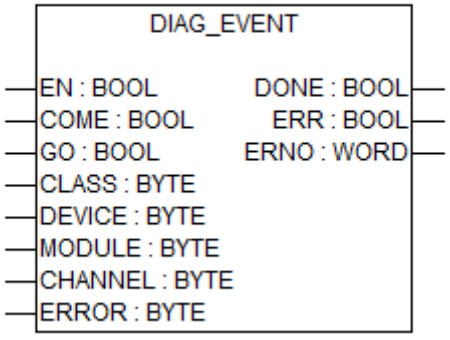
DIAG_EVENT



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The function block DIAG_EVENT can be used to generate any error of component 15 (*Chapter 1.7.1.5 "Structure of error numbers" on page 6369*). Each error can have three possible states: 1) "Error has come" (COME), 2)"Error has gone" (GO) and 3) "Error has been acknowledged". Using the function block DIAG_EVENT, errors of the states 1) and 2) can be generated. Error acknowledgement is done using the function blocks DIAG_ACK *Chapter 1.5.4.19.2.6 "DIAG_ACK" on page 1517* or DIAG_ACK_ALL *Chapter 1.5.4.19.2.7 "DIAG_ACK_ALL" on page 1520* or using the *Chapter 1.7.1.5 "Structure of error numbers" on page 6369* or directly using the display.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

COME

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Input COME is used to specify the status of the error to be generated. This input can be used in combination with input GO.

COME = TRUE = "Error has come"

GO

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Input GO is used to specify the status of the error to be generated. This input can be used in combination with input COME.

GO = TRUE = "Error has gone"

CLASS

Data type	Default value	Range	Unit
BYTE	-	1...4	-

At input CLASS, the error class is specified, the errors of which are to be acknowledged.

DEVICE

Data type	Default value	Range	Unit
BYTE	-	0...255	-

Input "DEVICE" is used to specify the device number the generated error should be assigned to.

MODULE

Data type	Default value	Range	Unit
BYTE	-	0...31	-

Input "MODULE" is used to specify the module the generated error should be assigned to.

CHANNEL

Data type	Default value	Range	Unit
BYTE	-	0...31	-

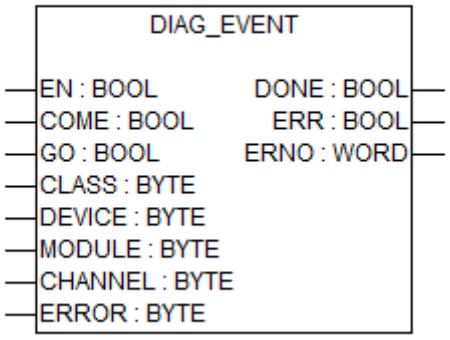
Input "CHANNEL" is used to specify the channel the generated error should be assigned to.

ERROR

Data type	Default value	Range	Unit
BYTE	-	0...63	-

At input "ERROR", the error number to be generated is specified. In order to facilitate later assignment of the errors, it is recommended to use the error numbers already defined. Please refer to the corresponding chapter for a more detailed overview of possible system errors and the used error numbers. If an error is not yet declared by an error number, it is recommended to use a free error number.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

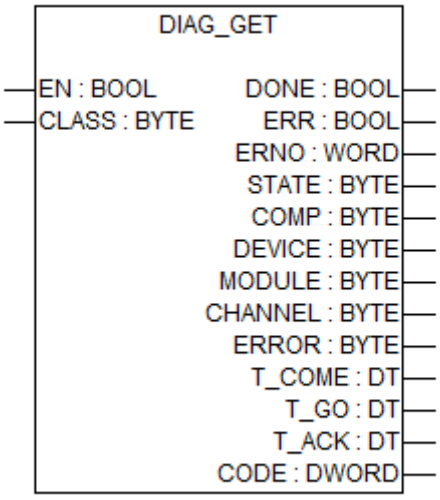
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
DiagEvent(EN := DiagEvent_EN,
        COME := DiagEvent_COME,
        GO := DiagEvent_GO,
        CLASS := DiagEvent_CLASS,
        DEVICE := DiagEvent_DEVICE,
        MODULE := DiagEvent_MODULE,
        CHANNEL := DiagEvent_CHANNEL,
        ERROR := DiagEvent_ERROR);

DiagEvent_DONE := DiagEvent.DONE;
DiagEvent_ERR  := DiagEvent.ERR;
DiagEvent_ERNO := DiagEvent.ERNO;
```

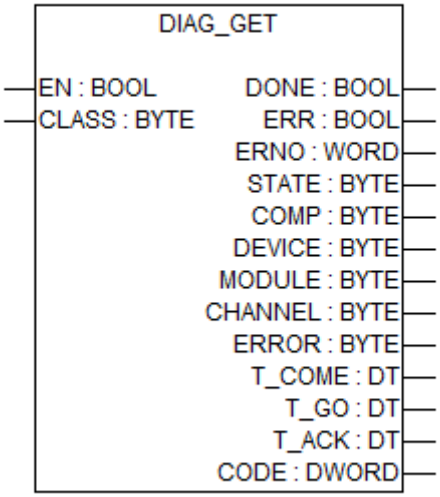
DIAG_GET



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The function block "DIAG_GET" can be used to read an error of any error class. Each error can only be read once. If this function block is used more than once for a specific error class, the next error output is the oldest error that has not been read yet. If all errors were already read or if there is no existing error available, this is accordingly indicated at output STATE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

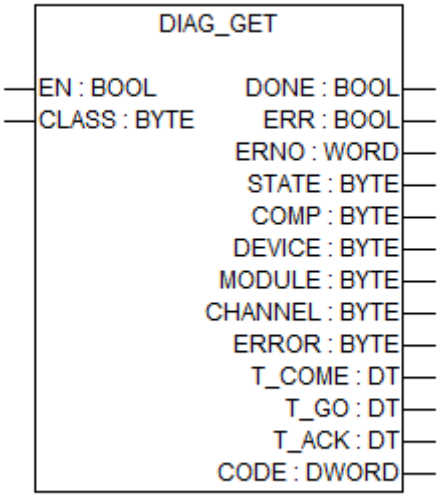
Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

CLASS

Data type	Default value	Range	Unit
BYTE	-	1...4	-

At input CLASS, the error class is specified, the errors of which are to be acknowledged.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE

Data type	Default value	Range	Unit
BYTE	-	-	-

STATE outputs the current status of the read error. The error status is a combination of the states "Error has come", "Error has gone" and "Error has been acknowledged". The following status numbers are possible:

State	Error	come	gone	acknowledged
16#02		x		
16#04			x	
16#06		x	x	
16#08				x
16#0A		x		x
16#0C			x	x
16#0E		x	x	x
16#F0	Alle errors read or no error available			

COMP

Data type	Default value	Range	Unit
BYTE	-	-	-

"COMP" outputs the component number the read error is assigned to.

DEVICE

Data type	Default value	Range	Unit
BYTE	-	-	-

"DEVICE" outputs the device number the read error is assigned to.

MODULE

Data type	Default value	Range	Unit
BYTE	-	-	-

"MODULE" outputs the module the read error is assigned to.

CHANNEL

Data type	Default value	Range	Unit
BYTE	-	-	-

"CHANNEL" outputs the channel the read error is assigned to.

ERROR

Data type	Default value	Range	Unit
BYTE	-	-	-

"ERROR" outputs the error number of the read error.

T_COME Data type: DT

T_COME (time come) outputs the time stamp, when the read error occurred ("has come"). If no time stamp is available for the error status "come" (see also the description of output STATE), no value is written to this output. In this case, the output value remains at the default value DT#1970-01-01-00:00.

T_GO Data type: DT

T_GO (time go) outputs the time stamp, when the read error "has gone". If no time stamp is available for the error status "gone" (see also the description of output STATE), no value is written to this output. In this case, the output value remains at the default value DT#1970-01-01-00:00.

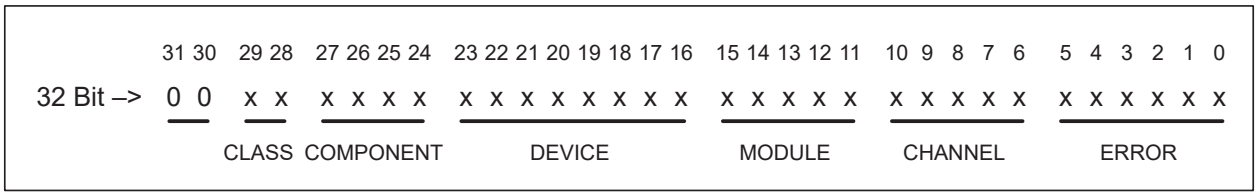
T_ACK Data type: DT

T_ACK (time acknowledge) outputs the time stamp, when the read error was "acknowledged". If no time stamp is available for the error status "acknowledged" (see also the description of output STATE), no value is written to this output. In this case, the output value remains at the default value DT#1970-01-01-00:00.

CODE

Data type	Default value	Range	Unit
DWORD	-	-	-

CODE outputs the code number of the read error. The structure of the error encoding is as follows:



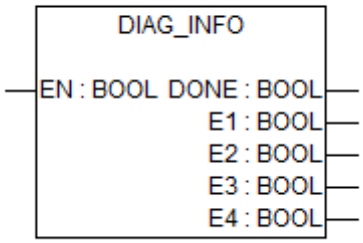
Function call in ST

```
DiagGet(EN := DiagGet_EN,
        CLASS := DiagGet_CLASS);

DiagGet_DONE := DiagGet.DONE;
DiagGet_ERR := DiagGet.ERR;
DiagGet_ERNO := DiagGet.ERNO;
DiagGet_STATE := DiagGet.STATE;
DiagGet_COMP := DiagGet.COMP;
DiagGet_DEVICE := DiagGet.DEVICE;
DiagGet_MODULE := DiagGet.MODULE;
DiagGet_CHANNEL := DiagGet.CHANNEL;
```

```
DiagGet_ERROR := DiagGet.ERROR;
DiagGet_T_COME := DiagGet.T_COME;
DiagGet_T_GO := DiagGet.T_GO;
DiagGet_T_ACK := DiagGet.T_ACK;
DiagGet_CODE := DiagGet.CODE;
```

DIAG_INFO



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The function block DIAG_INFO can be used to display an overview of all errors that were not read yet. The output is sorted according to the error classes E1 to E4. If at least one error is present in any error class and if this error has not been read yet using the function block DIAG_GET, this is displayed at the corresponding Ex output.

Input description

EN

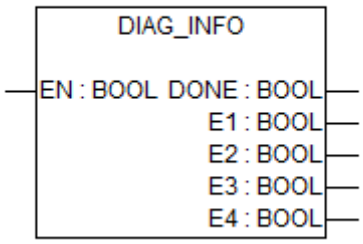
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE (done)

Data type: BOOL

Operation done = TRUE, as long as EN = TRUE

Output DONE indicates the state of job processing. If the processing is finished, DONE is set to TRUE.

E1 (error class 1)

Data type: BOOL

Output E1 is set to TRUE, if at least 1 error is present in error class 1 and if this error has not been read yet using the function block DIAG_GET.

Consequently, if E1 is FALSE, either no errors are available in this error class or, if errors are available, all errors of this class were already read.

E2 (error class 2)

Data type: BOOL

Output E2 is set to TRUE, if at least 1 error is present in error class 2 and if this error has not been read yet using the function block DIAG_GET.

Consequently, if E2 is FALSE, either no errors are available in this error class or, if errors are available, all errors of this class were already read.

E3 (error class 3)

Data type: BOOL

Output E3 is set to TRUE, if at least 1 error is present in error class 3 and if this error has not been read yet using the function block DIAG_GET.

Consequently, if E3 is FALSE, either no errors are available in this error class or, if errors are available, all errors of this class were already read.

E4 (error class 4)

Data type: BOOL

Output E4 is set to TRUE, if at least 1 error is present in error class 4 and if this error has not been read yet using the function block DIAG_GET.

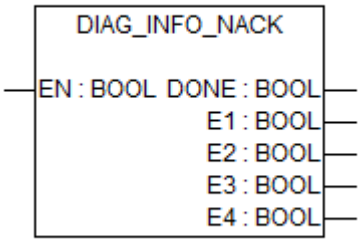
Consequently, if E4 is FALSE, either no errors are available in this error class or, if errors are available, all errors of this class were already read.

Function call in ST

```
DiagInfo(EN := DiagInfo_EN);

DiagInfo_DONE := DiagInfo.DONE;
DiagInfo_E1 := DiagInfo.E1;
DiagInfo_E2 := DiagInfo.E2;
DiagInfo_E3 := DiagInfo.E3;
DiagInfo_E4 := DiagInfo.E4;
```

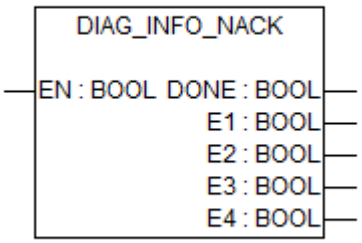
DIAG_INFO_NACK



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

The function block DIAG_INFO_NACK displays an overview of all errors that were not acknowledged yet by buttons/display or function block DIAG_EVENT. The output is sorted according to the error classes E1 to E4. If at least one error is present in any error class and if this error has not been acknowledged yet, this is displayed at the corresponding Ex output.

Input description



EN

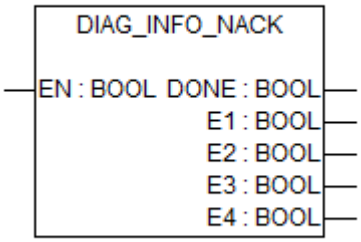
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE (done)

Data type: BOOL

Operation done = TRUE, as long as EN = TRUE

Output DONE indicates the state of job processing. If the processing is finished, DONE is set to TRUE.

E1 (error class 1)

Data type: BOOL

Output E1 is set to TRUE, if at least 1 error is present in error class 1 and if this error has not been read yet using the function block DIAG_GET.

Consequently, if E1 is FALSE, either no errors are available in this error class or, if errors are available, all errors of this class were already read.

E2 (error class 2)

Data type: BOOL

Output E2 is set to TRUE, if at least 1 error is present in error class 2 and if this error has not been read yet using the function block DIAG_GET.

Consequently, if E2 is FALSE, either no errors are available in this error class or, if errors are available, all errors of this class were already read.

E3 (error class 3)

Data type: BOOL

Output E3 is set to TRUE, if at least 1 error is present in error class 3 and if this error has not been read yet using the function block DIAG_GET.

Consequently, if E3 is FALSE, either no errors are available in this error class or, if errors are available, all errors of this class were already read.

E4 (error class 4)

Data type: BOOL

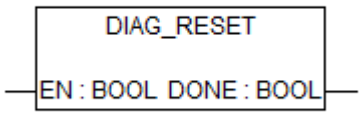
Output E4 is set to TRUE, if at least 1 error is present in error class 4 and if this error has not been read yet using the function block DIAG_GET.

Consequently, if E4 is FALSE, either no errors are available in this error class or, if errors are available, all errors of this class were already read.

Function call in ST

```
DiagInfo(EN := DiagInfo_EN);
DiagInfo_DONE := DiagInfo.DONE;
DiagInfo_E1 := DiagInfo.E1;
DiagInfo_E2 := DiagInfo.E2;
DiagInfo_E3 := DiagInfo.E3;
DiagInfo_E4 := DiagInfo.E4;
```

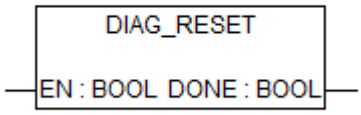
DIAG_RESET



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

Function block DIAG_RESET is used for resetting the diagnosis system of the CPU completely.

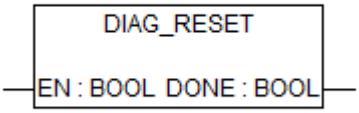
Input description



EN (enable) Data type: BOOL

The function block is activated by a TRUE at the input EN. A FALSE keeps the function block deactivated. Is the function block activated, the values being present at the inputs are processed and the output values are delivered.

Output description



DONE (done) Data type: BOOL

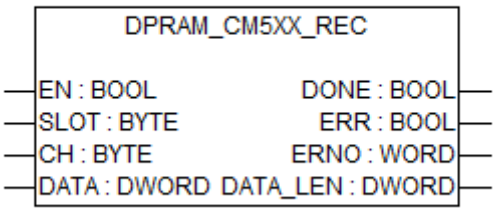
Operation done = TRUE, as long as EN = TRUE

Output DONE indicates the state of job processing. If the processing is finished, DONE is set to TRUE.

Function call in ST

```
DiagReset(EN := DiagReset_EN);
DiagReset_DONE := DiagReset.DONE;
```

DPRAM_CM5XX_REC



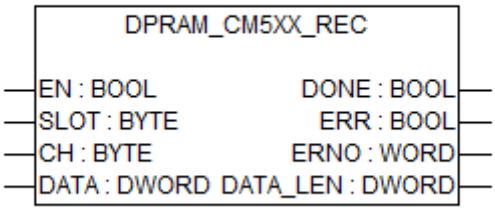
Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

The function block DPRAM_CM5XX_REC is used for receiving data from an CM5xx. This data is stored in the configured memory area (DATA), i.e. the memory address for the received data via ADR operator. The function block is triggered by a high signal at input EN. It remains active until the input EN is set to FALSE. The slot number and the channel of the CM5xx are put to the inputs SLOT and CH. The output DATA_LEN shows the length of the received data in bytes. The successful data reception is indicated by DONE=TRUE and ERR=FALSE. If during operation an error was detected, this is indicated at the outputs ERR and ERNO.

CAUTION!
The reception using the function function block DPRAM_CM5XX_REC is not edge-triggered. The input EN must therefore be at TRUE as long as data has to be received.

DPRAM message-based data exchange allows a maximum of 260 Bytes per message to be sent or received.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type: BYTE

At input CH (channel), the addressed channel is specified.

Valid values: 1 and 2.

DATA (data)

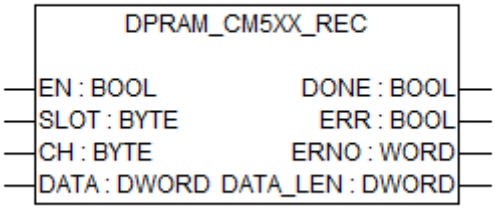
Data type: DWORD

At input DATA, the address of the variable is specified, of which the user data shall be received.

DATA must be the address of a variable of the type ARRAY or STRUCT.

CAUTION!
Memory area overlapping
Avoid memory area overlappings by specifying the size of the variable to the max. data expected.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

DATA_LEN

Data type	Default value	Range	Unit
DWORD	-	-	-

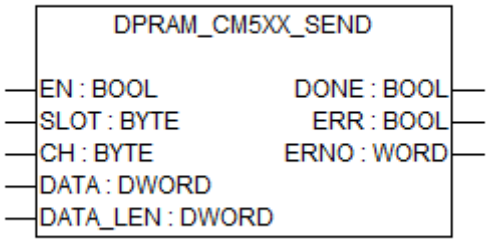
DATA_LEN (datalength) outputs the length of the received data in bytes. DATA_LEN is only valid if DONE = TRUE.

Function call in ST

```
CM5xxRec (EN := CM5xxRec_EN,
          SLOT := CM5xxRec_SLOT,
          CH := CM5xxRec_CH,
          DATA := ADR(CM5xxRec_DATA),
          DONE => CM5xxRec_DONE,
          ERR => CM5xxRec_ERR,
          ERNO => CM5xxRec_ERNO,
          DATA_LEN => CM5xxRec_DATA_LEN);

CM5xxRec_DONE := CM5xxRec.DONE;
CM5xxRec_ERR := CM5xxRec.ERR;
CM5xxRec_ERNO := CM5xxRec.ERNO;
CM5xxRec_DATA_LEN := CM5xxRec.DATA_LEN;
```

DPRAM_CM5XX_SEND



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

The function block DPRAM_CM5XX_SEND is used for sending data to the CM5xx. This data is provided in the configured memory area (DATA), i.e. the memory address for the data to be sent via ADR operator. The function block is activateded by a high signal at input EN. It remains active until the input EN is set to FALSE. The slot number and the channel of the CM5xx are put to the inputs SLOT and CH. At the input DATA_LEN the length of the data to be sent is specified in bytes. The successful data transmission is indicated by DONE=TRUE and ERR=FALSE. If during operation an error was detected, this is indicated at the outputs ERR and ERNO.

Sending data with the function block DPRAM_CM5XX_SEND is edge-triggered, i.e. that each sending process is triggered by a FALSE/TRUE edge at input EN.

DPRAM message-based data exchange allows a maximum of 260 Bytes per message to be sent or received.

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type: BYTE

At input CH (channel), the addressed channel is specified.

Valid values: 1 and 2.

DATA (data)

Data type: DWORD

At input DATA, the address of the variable is specified, of which the user data shall be received.

DATA must be the address of a variable of the type ARRAY or STRUCT.

CAUTION!
Memory area overlapping
Avoid memory area overlappings by specifying the size of the variable to the max. data expected.

DATA_LEN

Data type: DWORD

At input DATA_LEN the length of the data to be sent is specified in bytes.

Output description

DONE

Data type: BOOL

Output DONE indicates that data has been sent. The output must always be considered together with the output ERR.

The following is valid:

DONE = TRUE and ERR = FALSE:

The sending process has been completed. A data set has been sent correctly.

DONE = TRUE and ERR = TRUE:

An error occurred while sending data. The error number is indicated at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during Function Block processing. This output always has to be considered together with output DONE. If DONE is TRUE and ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

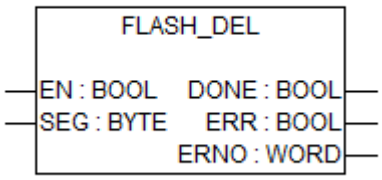
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
CM5xxSend (EN := CM5xxSend_EN,
           SLOT := CM5xxSend_SLOT,
           CH := CM5xxSend_CH,
           DATA := ADR(CM5xxSend_DATA),
           DATA_LEN := CM5xxSend_DATA_LEN,
           DONE => CM5xxSend_DONE,
           ERR => CM5xxSend_ERR,
           ERNO => CM5xxSend_ERNO);

CM5xxSend_DONE := CM5xxSend.DONE;
CM5xxSend_ERR := CM5xxSend.ERR;
CM5xxSend_ERNO := CM5xxSend.ERNO;
```

FLASH_DEL



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

This function block deletes a user data segment from the Flash. All data in this data segment are lost after deletion.

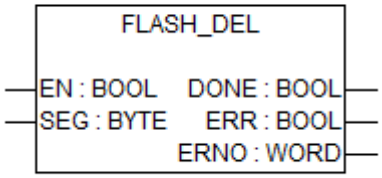
Access to the Flash is only possible using the function blocks FLASH_DEL, FLASH_WRITE and FLASH_READ.

The input SEG defines the data segment within the Flash. In the AC500, two segments with the number 1 and 2 are reserved for the user, each providing 64 kB. Deleting a data segment within the Flash may take several PLC cycles.

A FALSE/TRUE edge at input EN triggers the deletion of the data segment once. Input EN will not be evaluated again, until the delete operation is completed (DONE = TRUE).

After completion of the delete procedure, all function block outputs are updated. The deletion was successful, if DONE = TRUE and ERR = FALSE. If the outputs show DONE = TRUE and ERR = TRUE, the data segment could not be deleted.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

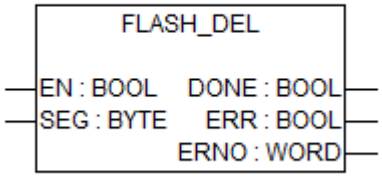
SEG

Data type: BYTE

At input SEG, the number of the data segment in the Flash is specified. In the AC500, controller two data segments are available for the user.

Valid values: 1 and 2 respectively

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO WORD (error number)

The output ERNO indicates an error number (see *Chapter 1.5.3 "Error messages of the AC500 V2 function block libraries" on page 735*). This output has always to be considered together with the outputs DONE and ERR.

The functions FLASH_DEL, FLASH_WRITE and FLASH_READ are executed in the background by the operating system. This procedures can take quite long time, since the PLC user program is processed with priority. Output ERNO then indicates that the block execution is in progress (0x0FFF).

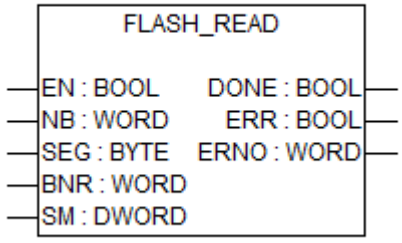
During this phase, the outputs ERR and DONE are set to FALSE.

The inputs and outputs can neither be duplicated nor inverted.

Function call in ST

```
DEL_FLASH(EN := EN_FLASH_DEL,
SEG := SEG_FLASH_DEL);
DONE_FLASH_DEL := DEL_FLASH.DONE;
ERR_FLASH_DEL := DEL_FLASH.ERR;
ERNO_FLASH_DEL := DEL_FLASH.ERNO;
```

FLASH_READ



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The function block reads a data set from a data segment of the Flash and stores the read data set beginning at the start flag defined by SM. The data of the data set have been previously stored to the Flash using the function block FLASH_WRITE.

Important note:

Access to the Flash is only possible using the function blocks FLASH_WRITE and FLASH_READ.

NB function blocks are read starting at function block BNR within segment SEG and stored starting at address SM.

Either 32 binary data or 16 word data or 8 double word data are read per function block.

One function block contains 34 bytes:

32 bytes of data

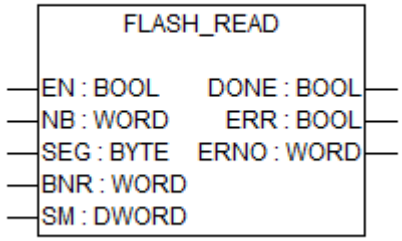
1 byte CRC checksum

1 byte "written identifier"

Reading a data set is triggered once by a FALSE/TRUE edge at input EN. If no error occurred when reading the data, DONE is set to TRUE and the outputs ERR and ERNO are set to FALSE. The data set is stored beginning at the defined start flag SM. Storing the data set can take several PLC cycles.

If an error occurs during reading, DONE and ERR are both set to TRUE. The error type is indicated at output ERNO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

NB

Data type	Default value	Range	Unit
WORD	-	1 ... 1927	-

The number of the data set blocks is specified at input NB. Either 32 binary data or 16 word data or 8 double word data are read per block.

Example:

- SM = ADR(%MW0.0) and NB = 1: Storing data from %MW0.0 to %MW0.15
(1 block = 16 word data)
- SM = ADR(%MW0.0) and NB = 2: Storing data from %MW0.0 to %MW0.31
(2 blocks = 32 word data)

SEG

Data type: BYTE

At input SEG, the number of the data segment in the Flash is specified. In the AC500, controller two data segments are available for the user.

Valid values: 1 and 2 respectively

BNR

Data type	Default value	Range	Unit
WORD	-	-	-

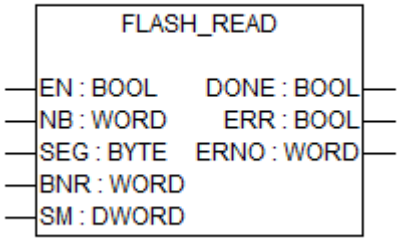
The block number in the data segment is specified at input BNR. Valid values: 0...1926

SM

Data type	Default value	Range	Unit
DWORD	-	-	-

At input SM (source memory), the address of the first variable for storing the data set is specified using an ADR operator.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO WORD The output ERNO indicates an error number(see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*). This output has always to be considered together with the outputs DONE and ERR.

The functions FLASH_DEL, FLASH_WRITE and FLASH_READ are executed in the background by the operating system. This procedures can take quite long time, since the PLC user program is processed with priority. Output ERNO then indicates that the block execution is in progress (0x0FFF).

During this phase, the outputs ERR and DONE are set to FALSE.

The inputs and outputs can neither be duplicated nor inverted.

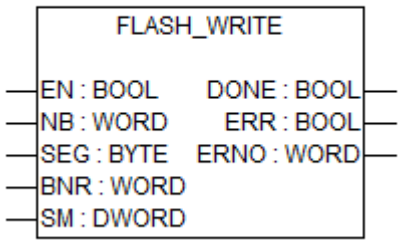
The following figure shows the structure of a Flash segment.

Byte:		**1 | 2**	**3 | 4**	**5 | 6**	**....**	**29 | 30**	**31 | 32**	**33**	**34**
Byte-Offset	**Block-No.**	**Word 1**	**Word 2**	**Word 3**	**....**	**Word 15**	**Word 16**	**CRC**	**Written Identi-fier**
0	0								
34	1								
68	2								
...	...								
65450	1925								
65484	1926								

Function call in ST

```
READ_FLASH(EN := EN_FLASH_READ,
     NB := NB_FLASH_READ,
     SEG := SEG_FLASH_READ,
     BNR := BNR_FLASH_READ,
     SM := SM_FLASH_READ)
DONE_FLASH_READ := READ_FLASH.DONE;
ERR_FLASH_READ := READ_FLASH.ERR;
ERNO_FLASH_READ := READ_FLASH.ERNO;
```

FLASH_WRITE



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The function block writes a data set to a data segment in the Flash. For that purpose, two data segments are available for the AC500. A delete operation (function block FLASH_DEL) always deletes a complete data segment. A data segment consists of 1927 blocks (0 ... 1926). Each block is composed of 34 bytes.

After a delete operation, data can be written only once to each of these 1927 data segment blocks. If a block containing data is to be overwritten with new data, the entire data segment has to be deleted first. In doing so, all data in this segment are lost.

Access to the Flash is only possible using the function blocks FLASH_DEL, FLASH_WRITE and FLASH_READ.

NB blocks are read starting at address SM and stored in the segment SEG starting at block BNR.

Either 32 binary data or 16 word data or 8 double word data are read per block.

One block contains 34 bytes:

32 bytes of data

1 byte CRC checksum

1 byte "written identifier"

(see figure at the end of this block description)

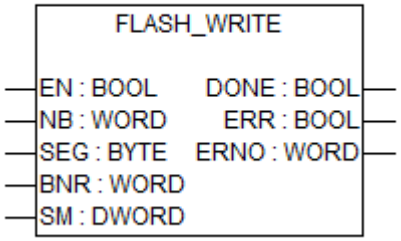
When a write operation of a data set is started (FALSE/TRUE edge at input EN), the data of the data set must not be changed until the end of the write procedure (DONE = TRUE). Storing the data set in the FLASH can take several PLC cycles.

With a FALSE/TRUE edge at input EN, the data set is written once. Until the storage procedure has not been finished (DONE = TRUE), input EN will not be evaluated again.

After the write operation is completed, the block outputs DONE, ERR and ERNO are updated. The storage was successful, if DONE = TRUE and ERR = FALSE. If DONE = TRUE and ERR = TRUE, an error occurred. The error type is signalized at output ERNO.

A new FALSE/TRUE edge at input EN starts a new write operation. Since without a previous deletion of the data segment no new data can be written to blocks which already contain data, the input BNR must point to the next free block for the next write procedure.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

NB

Data type	Default value	Range	Unit
WORD	-	1 ... 1927	-

The number of the data set blocks is specified at input NB. Either 32 binary data or 16 word data or 8 double word data are read per block.

Example:

- SM = ADR(%MW0.0) and NB = 1: Storing data from %MW0.0 to %MW0.15

(1 block = 16 word data)

- SM = ADR(%MW0.0) and NB = 2: Storing data from %MW0.0 to %MW0.31

(2 blocks = 32 word data)

SEG

Data type: BYTE

At input SEG, the number of the data segment in the Flash is specified. In the AC500, controller two data segments are available for the user.

Valid values: 1 and 2 respectively

BNR

Data type	Default value	Range	Unit
WORD	-	-	-

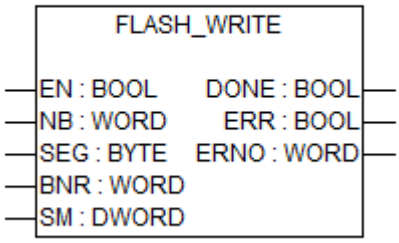
The block number in the data segment is specified at input BNR. Valid values: 0...1926

SM

Data type	Default value	Range	Unit
DWORD	-	-	-

At input SM (source memory), the address of the first variable for storing the data set is specified using an ADR operator.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO WORD

The output ERNO indicates an error number(see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*). This output has always to be considered together with the outputs DONE and ERR.

The functions FLASH_DEL, FLASH_WRITE and FLASH_READ are executed in the background by the operating system. This procedures can take quite long time, since the PLC user program is processed with priority. Output ERNO then indicates that the block execution is in progress (0x0FFF).

During this phase, the outputs ERR and DONE are set to FALSE.

The inputs and outputs can neither be duplicated nor inverted.

The following figure shows the structure of a Flash segment.

Byte:		**1 | 2**	**3 | 4**	**5 | 6**	**....**	**29 | 30**	**31 | 32**	**33**	**34**
Byte-Offset	**Block-No.**	**Word 1**	**Word 2**	**Word 3**	**....**	**Word 15**	**Word 16**	**CRC**	**Written Identifier**
0	0								
34	1								
68	2								
...	...								

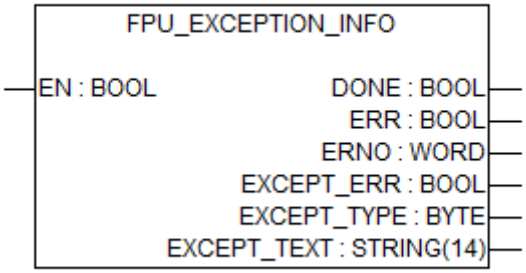
Byte:		1 | 2	3 | 4	5 | 6	....	29 | 30	31 | 32	33	34
Byte-Offset	Block-No.	Word 1	Word 2	Word 3	....	Word 15	Word 16	CRC	Written Identi-fier
65450	1925								
65484	1926								

Function call in ST

Function call in ST

```
WRITE_FLASH(EN := EN_FLASH_WRITE,
     NB := NB_FLASH_WRITE,
     SEG := SEG_FLASH_WRITE,
     BNR := BNR_FLASH_WRITE,
     SM := SM_FLASH_WRITE)
DONE_FLASH_WRITE := WRITE_FLASH.DONE;
ERR_FLASH_WRITE := WRITE_FLASH.ERR;
ERNO_FLASH_WRITE := WRITE_FLASH.ERNO;
```

FPU_EXCEPTION_INFO



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.2
Type	Function block with historical values

The function block FPU_EXCEPTION_INFO reads information which has been stored during an FPU exception. The reading operation takes 1 PLC cycle. If data are available, they are provided by setting the outputs DONE = TRUE and ERR = FALSE. If several errors have appeared up to the call of the function block, the last error is shown.

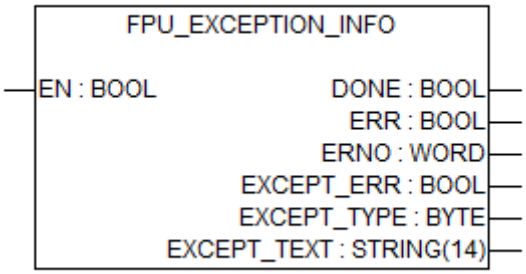
This function block only has to be used with CPUs which have an FPU. The CPU parameter "Reaction on floating point exception" has to be set to "No failure".

The following table represents an overview of the possible return values of the function block.

EXCEPT_ERR	EXCEPT_TYPE	EXCEPT_TEXT
FALSE	16#00	"No error"
TRUE	16#01	"Zero Divide"
TRUE	16#02	"Overflow"
TRUE	16#03	"Underflow"
TRUE	16#04	"Invalid"
TRUE	16#05	"Inexact"
TRUE	16#06	"Function"

The error "Function" occurs, if a result of a function (e.g. SQRT, LN or ACOS) cannot be calculated.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

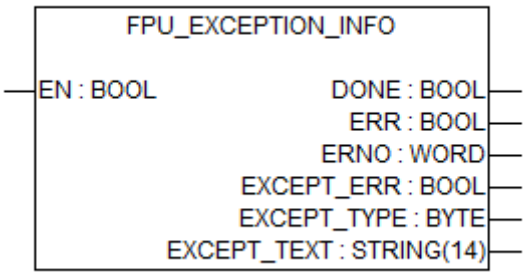
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

EXCEPT_ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output EXCEPT_ERR (exception error) indicates that an exception error has occurred in the FPU.

EXCEPT_TYPE BYTE

Data type	Default value	Range	Unit
BYTE	-	-	-

Output EXCEPT_TYPE (exception type) indicates the type of the occurred exception error.

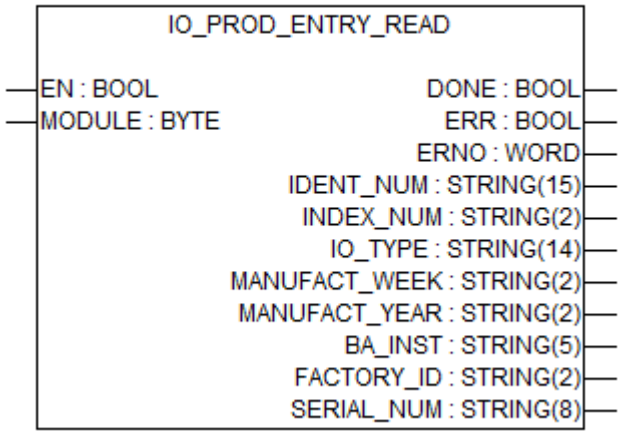
EXCEPT_TEXT Output EXCEPT_TEXT (exception text) indicates in text form which exception error has occurred.

Function call in ST

```
FpuInfo(EN := FpuInfo_EN);

FpuInfo_DONE := FpuInfo.DONE;
FpuInfo_ERR := FpuInfo.ERR;
FpuInfo_ERNO := FpuInfo.ERNO;
FpuInfo_EXCEPT_ERR := FpuInfo.EXCEPT_ERR;
FpuInfo_EXCEPT_TYPE := FpuInfo.EXCEPT_TYPE;
FpuInfo_EXCEPT_TEXT := FpuInfo.EXCEPT_TEXT;
```

IO_PROD_ENTRY_READ

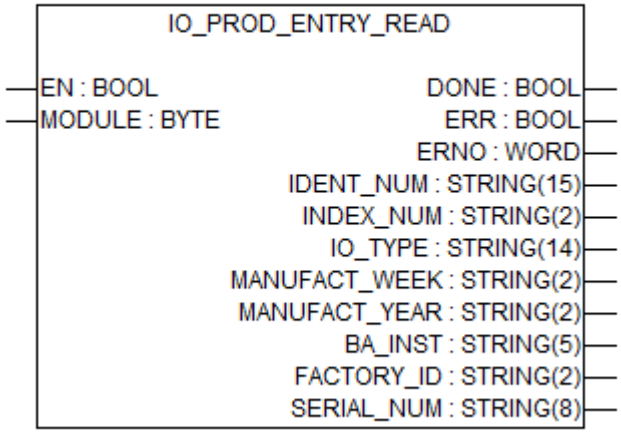


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V2.2.0
Type	Function block with historical values

The function block reads production data from I/O modules.

This function block can be used only for I/O modules which are attached to the local I/O bus master.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

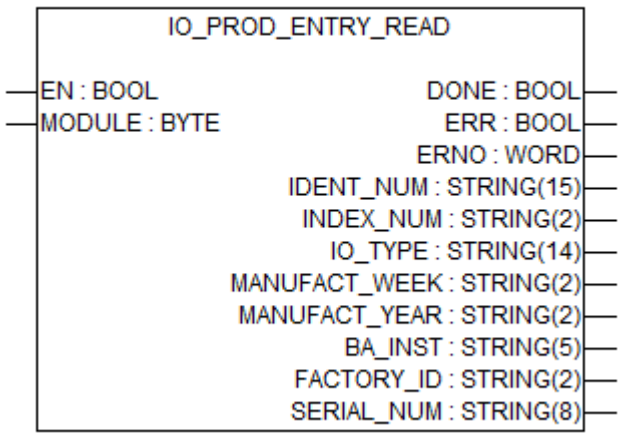
MODULE

Data type	Default value	Range	Unit
BYTE	-	1...n*	-

*) n is the max. number of I/O modules which can be attached to the local I/O bus master

Input MODULE selects the I/O module attached to the local I/O bus master. Valid values are counted from left to right, starting with 1 as the first I/O module right to the CPU.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IDENT_NUM Identification number.

INDEX_NUM Index number.

IO_TYPE Type of the I/O module in plain text.

MANU-FACT_WEEK Calendar week when the I/O module has been manufactured.

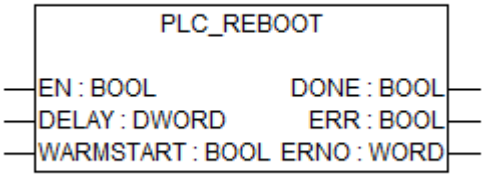
MANU-FACT_YEAR Year when the I/O module has been manufactured.

BA_INST Reserved for future extensions.

FACTORY_ID Factory, where the I/O module has been manufactured.

SERIAL_NUM Serial number of the I/O module.

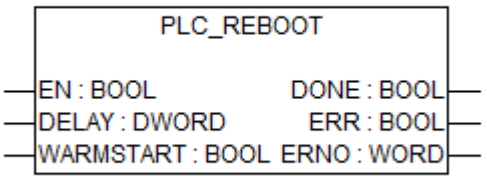
PLC_REBOOT



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

The function block reboots the PLC. Using the input DELAY, a delay can be specified how long to wait until the new start. At the input WARMSTART it can be specified, whether only the firmware shall be re-started or if a cold start shall be performed. A cold start has the same effect as power-off/on.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

DELAY

Data type	Default value	Range	Unit
DWORD	-	-	-

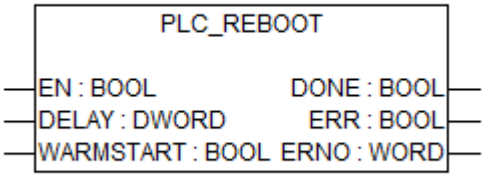
The value at the input DELAY (delay until reboot) specifies how much time will elapse until the new start after the re-boot was triggered at the input EN.

WARMSTART

Data type: BOOL

The input WARMSTART specifies how the PLC behaves in case of a new start. If WARMSTART = TRUE, only the firmware of the PLC is started anew. If WARMSTART = FALSE, the new start is equal to a cold start (like power off/on).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

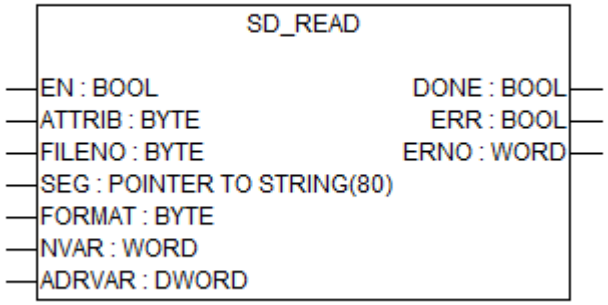
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
PLC_REBOOT(EN := EN_PLC_REBOOT,
           DELAY := DELAY_PLC_REBOOT,
           WARMSTART := WARMSTART_PLC_REBOOT);

DONE_PLC_REBOOT := PLC_REBOOT.DONE;
ERR_PLC_REBOOT  := PLC_REBOOT.ERR;
ERNO_PLC_REBOOT := PLC_REBOOT.ERNO;
```

SD_READ



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The function block SD_READ reads a data set from a file on the memory card and stores the read data set beginning at the start flag defined by ADRVAR.

In this context it has to be observed that the function blocks are mutually interlocked, i.e. it must be ensured that only one function block is active at the same time.

The function block reads a data set in the file on the memory card:

...\UserData\PM5x1\UserDat\USRDATxx.DAT ↳ *Chapter 1.5.4.19.1 “Structure of the file USRDATXX.DAT on the memory card” on page 1500*

Access to the memory card is only possible by using the function blocks SD_WRITE and SD_READ.

The inputs ATTRIB, FILENO, FORMAT, ADRVAR and NVAR determine how many values should be read from which file and in which format on the memory card as well as to which target address they should be stored. Always a complete data set must be read.

Reading a data set from the memory card can take several PLC cycles.

With a FALSE/TRUE edge at input EN, the data set reading is triggered once. Input EN is not evaluated again until the ready message DONE = TRUE is available, i.e. the state of EN is ignored during reading.

After the read operation is completed, the function block outputs DONE, ERR and ERNO are updated. Reading was successful, if DONE = TRUE and ERR = FALSE. If DONE = TRUE and ERR = TRUE, an error occurred. The error type is signalized at output ERNO.

After reading a data set from the memory card, the function block outputs are valid for one cycle. In the next cycle, the outputs DONE, ERR and ERNO are reset to zero. A new FALSE/TRUE edge at input EN starts a new read operation.

Reading example 1:

To read user data from a data file without sectors from the memory card and write them to the PLC, proceed as follows:

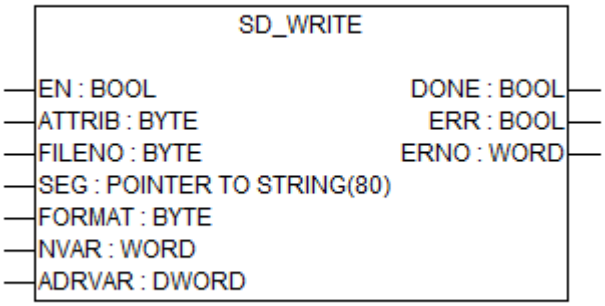
1. Insert the memory card.
2. Read a data set by calling the function block SD_READ with the following settings: EN := TRUE (* FALSE/TRUE edge triggers reading *) ATTRIB := 2 (* open / read *) FILENO := 0..99 (* number of file to be read *) SEG := address of the variable sector name FORMAT := data format NVAR := number of data in the data set ADRVAR := address of the first variable to which data are to be stored.
3. 3. Further data sets can be read with the following settings after the completion message (DONE=TRUE) is displayed. This process is started with a FALSE/TRUE edge at input EN: EN := TRUE (* FALSE/TRUE edge triggers reading*) ATTRIB := 3 (* continue read *) FILENO := 0..99 (* number of file to be read *) SEG := address of the variable sector name FORMAT := data format NVAR := number of data in the data set ADRVAR := address of the first variable to which data are to be stored If an unexpected sector name or the end of file (EOF) is detected during reading, an appropriate error message is generated.
4. To read a further data set and to close the file afterwards, call the function block SD_READ with the following settings after the completion message (output DONE=TRUE) is displayed and start the process with a FALSE/TRUE edge at input EN: EN := TRUE (* FALSE/TRUE edge triggers reading*) ATTRIB := 4 (* read / close *) FILENO := 0...99 (* number of file to be read *) SEG := address of the variable sector name FORMAT := data format NVAR := number of data in the data set ADRVAR := address of the first variable to which data are to be stored If an unexpected sector name or the end of file (EOF) is detected during reading, an appropriate error message is generated.
5. To close the file without reading it, call the function block SD_READ with the following settings after the completion message (DONE=TRUE) and start the process with a FALSE/TRUE edge at input EN: EN := TRUE (* FALSE/TRUE edge closes the file *) ATTRIB := 5 (* close *) FILENO := 0..99 (* number of file to be closed *)

Reading example 2:

To read user data from a data file with sectors from the memory card and write them to the PLC, proceed as follows:

1. Insert the memory card.
2. Seek a sector label and read a data set by calling the function block SD_READ with the following settings: EN := TRUE (* FALSE/TRUE edge triggers reading *) ATTRIB := 1 (* open / seek / read *) FILENO := 0..99 (* number of the file to be read *) SEG := address of the variable sector name FORMAT := data format NVAR := number of data in the data set ADRVAR := address of the first variable to which data should be written The read operation is finished successfully if output DONE = TRUE and output ERR = FALSE. A seek error is indicated with ERR = TRUE and ERNO <> 0.
3. Further data sets can be read with the following settings after the completion message (DONE=TRUE) is displayed. This process is started with a FALSE/TRUE edge at input EN: EN := TRUE (* FALSE/TRUE edge triggers reading*) ATTRIB := 3 (* continue read *) FILENO := 0..99 (* number of file to be read *) SEG := address of the variable sector name FORMAT := data format NVAR := number of data in the data set ADRVAR := address of the first variable to which data are to be stored If an unexpected sector name or the end of file (EOF) is detected during reading, an appropriate error message is generated.
4. If you want to read further sectors / data sets, repeat steps 2 and 3.
5. To read a further data set and to close the file afterwards, call the function block SD_READ with the following settings after the completion message (output DONE=TRUE) is displayed and start the process with a FALSE/TRUE edge at input EN: EN := TRUE (* FALSE/TRUE edge triggers reading*) ATTRIB := 4 (* read / close *) FILENO := 0..99 (* number of file to be read *) SEG := address of the variable sector name FORMAT := data format NVAR := number of data in the data set ADRVAR := address of the first variable to which data are to be written If an unexpected sector name or the end of file (EOF) is detected during reading, an appropriate error message is generated.
6. To close the file without reading it, call the function block SD_READ with the following settings after the completion message (DONE=TRUE) and start the process with a FALSE/TRUE edge at input EN: EN := TRUE (* FALSE/TRUE edge closes the file *) ATTRIB := 5 (* close *) FILENO := 0..99 (* number of file to be closed *)

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

ATTRIB

Data type	Default value	Range	Unit
BYTE	-	-	-

At input ATTRIB (attribute), the function block operation (action) is specified.

Possible values:

1 - Open file, search sector, read data set (Open, Seek, Read), additionally needed inputs:

FILENO, SEG, FORMAT, NVAR, ADRVAR

2 - Open file, read data set (Open, Read), additionally needed inputs:

FILENO, FORMAT, NVAR, ADRVAR

3 - Read next data set (Read), additionally needed inputs:

FILENO, FORMAT, NVAR, ADRVAR

4 - Read data set, close file (Read, Close), additionally needed inputs:

FILENO, FORMAT, NVAR, ADRVAR

5 - Close file (Close), additionally needed inputs:

FILENO

SEG

Data type	Default value	Range	Unit
DWORD	-	-	-

At input SEG (segment), the start address of the segment label to be searched is specified. A segment label must be enclosed in brackets "[...]".

Examples:

[Values_Tab1]

[Temperature_12]

The length is limited to 32 characters.

FILENO

Data type	Default value	Range	Unit
BYTE	-	0...99	-

At input FILENO (filenumber), the number of the file is specified from which data are to be read.

FORMAT

Data type	Default value	Range	Unit
BYTE	-	-	-

Input Format is used to define the format of the data elements. All elements of one data set must have the same format.

Valid data formats:

00 hex - 0 - BYTE

01 hex - 1 - CHAR

10 hex - 16 - WORD

11 hex - 17 - INT

20 hex - 32 - DWORD

21 hex - 33 - DINT

NVAR

Data type	Default value	Range	Unit
WORD	-	-	-

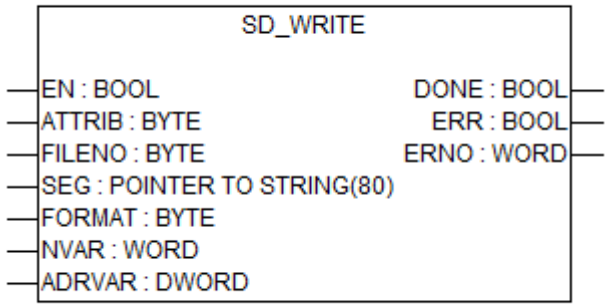
At input NVAR (number of variable), the number of elements of the data set to be read is specified.

ADRVAR

Data type	Default value	Range	Unit
DWORD	-	-	-

Input ADRVAR (address of variable) is used to specify the target start address of the data set. The values of a data set are stored in variables successively arranged in the PLC (e.g. ARRAY, STRING, %M area).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

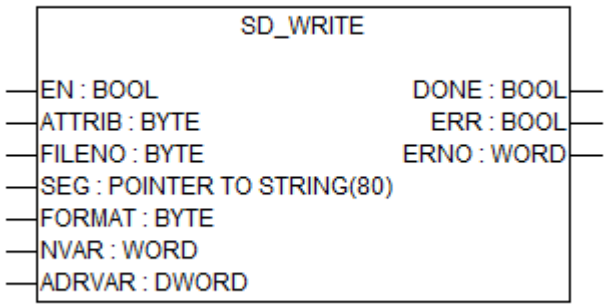
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
READ_SD(EN := EN_SD_READ,
     ATTRIB := ATTRIB_SD_READ,
     FILENO := FILENO_SD_READ,
     SEG := SEG_SD_READ,
     FORMAT := FORMAT_SD_READ,
     NVAR := NVAR_SD_READ,
     ADRVAR := ADRVAR_SD_READ);
DONE_SD_READ := READ_SD.DONE;
ERR_SD_READ := READ_SD.ERR;
ERNO_SD_READ := READ_SD.ERNO;
```

SD_WRITE



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The AC500 control system contains a memory card of the type "SD Memory Card" (in short memory card) as external storage medium which is accessed by the PLC like a floppy disk drive. The memory card is used to transfer data between a commercially available PC with memory card interface and the AC500 control system.

Read and write accesses take quite long time, since they are handled in the background by the internal file system of the operating system. When performing a write access, the current file is always copied to a backup file.

In this context it has to be observed that the function blocks are mutually interlocked, i.e. it must be ensured that only one function block is active at the same time.

The function block SD_WRITE writes a data set to a file USRDATxx.DAT on the memory card.

The function block writes a data set to a file on the memory card: ...\User-Data\PM5x1\UserDat\USRDATxx.DAT (see also Structure of the file USRDATXX.DAT on the memory card *Chapter 1.5.4.19.1 “Structure of the file USRDATXX.DAT on the memory card” on page 1500*)

Access to the memory card is only possible by using the function blocks SD_WRITE and SD_READ.

The inputs ATTRIB, FILENO, FORMAT, ADRVAR and NVAR determine how many values should be written to which file and in which format on the memory card as well as from which source address they should be read. To create a readable and EXCEL-compatible file, the individual values are stored in ASCII format, automatically separated by a semicolon. The last value is automatically terminated by a <CR><LF>.

When a write operation of a data set is started (FALSE/TRUE edge at input EN), the data of the data set must not be changed until the end of the write procedure (DONE = TRUE). Storing a data set on the memory card can take several PLC cycles.

Input EN is not evaluated again until the ready message DONE = TRUE is available, i.e. the state of EN is ignored during writing.

After the write operation is completed, the function block outputs DONE, ERR and ERNO are updated. The storage was successful, if DONE = TRUE and ERR = FALSE. If DONE = TRUE and ERR = TRUE, an error occurred. The error type is signalized at output ERNO.

After storing a data set on the memory card, the function block outputs are valid for one cycle. In the next cycle, the outputs DONE, ERR and ERNO are reset to zero. A new FALSE/TRUE edge at input EN starts a new write operation.

Note: In case of a power failure during the write access, the file USRDATxx.DAT will be corrupted. In order to backup at least the already stored data sets, the file USRDATxx.BAK has to be copied from the SC Card prior to restarting the program. The file can be renamed to USRDATxx.DAT on the PC and can then be used for further storage.

Writing example 1: To store user data to the memory card in a data file without sectors, proceed as follows:

1. Insert the memory card.
2. Write a data set by calling the function block SD_WRITE with the following settings: EN := TRUE (* FALSE/TRUE edge triggers write operation *) ATTRIB := 2 (* write append *) FILENO := 0..99 (* number of the file to be written *) SEG := address of the variable sector name (* any *) FORMAT := data format NVAR := number of data in the data set ADRVAR := address of the first variable to be written If no appropriate file can be found, it will be created. The write process is successfully completed if output DONE = TRUE and output ERR = FALSE. A write error is indicated with ERR = TRUE and ERNO <> 0.
3. Further data sets can be written with the same function block settings after the completion message (output DONE=TRUE) is displayed. This process is started with a FALSE/TRUE edge at input EN.

Writing example 2: To store user data to the memory card in a data file with sectors, proceed as follows:

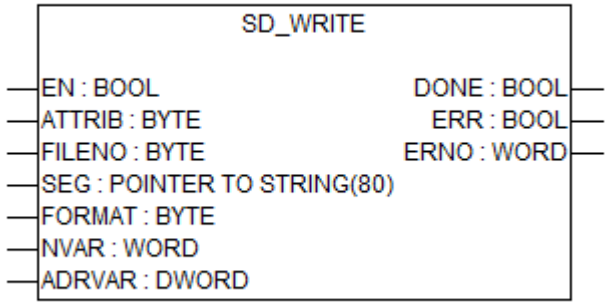
1. Insert the memory card.
2. Write the sector label by calling the function block SD_WRITE with the following settings: EN := TRUE ATTRIB := 3 (* write sector *) FILENO := 0..99 (* number of the file to be written *) SEG := address of the variable sector name If no appropriate file can be found, it will be created. The sector is successfully written when the output DONE:=TRUE and the output ERR:=FALSE. A write error is indicated with ERR = TRUE and ERNO <> 0.
3. Write a data set by calling the function block SD_WRITE with the following settings: EN := TRUE (* FALSE/TRUE edge triggers write operation *) ATTRIB := 2 (* write append *) FILENO := 0..99 (* number of the file to be written *) SEG := address of the variable sector name FORMAT := data format NVAR := number of data in the data set ADRVAR := address of the first variable to be written The write process is successfully completed if output DONE = TRUE and output ERR = FALSE. A write error is indicated with ERR = TRUE and ERNO <> 0.
4. Further data sets can be written with the same function block settings after the completion message (output DONE=TRUE) is displayed. This process is started with a FALSE/TRUE edge at input EN.
5. If you want to write further sectors and data sets, repeat steps 2...4. Note:

The file USRDATxx.DAT is saved as USRDATxx.BAK for each write process and a "Open file / Write file / Close file" procedure is performed.

Deleting a file: To delete a data file from the memory card, proceed as follows:

1. Insert the memory card.
2. Call the function block SD_WRITE with the following settings: EN := TRUE ATTRIB := 1 (* delete *) FILENO := 0..99 (* number of the file to be deleted *) SEG, FORMAT, NVAR, ADRVAR – any

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

ATTRIB

Data type	Default value	Range	Unit
BYTE	-	-	-

At input ATTRIB (attribute), the function block operation (action) is specified.

Possible values:

1 - Delete file (Delete), additionally needed inputs:

FILENO

2 - Write data set (Open(create), Write(append), Close), additionally needed inputs:

FILENO, FORMAT, NVAR, ADRVAR

3 - Write segment label (Open(create), Write(append), Close), additionally needed inputs:

FILENO, SEG

SEG

Data type	Default value	Range	Unit
DWORD	-	-	-

At input SEG (segment), the start address of the segment label to be searched is specified. A segment label must be enclosed in brackets "[...]".

Examples: [Values_Tab1]

[Temperature_12]

The length is limited to 32 characters.

FILENO

Data type	Default value	Range	Unit
BYTE	-	0...99	-

At input FILENO, the number of the file is specified to which data are to be written or which should be created or deleted respectively.

FORMAT

Data type	Default value	Range	Unit
BYTE	-	-	-

Input Format is used to define the format of the data elements. All elements of one data set must have the same format.

Valid data formats:

00 hex - 0 - BYTE

01 hex - 1 - CHAR

10 hex - 16 - WORD

11 hex - 17 - INT

20 hex - 32 - DWORD

21 hex - 33 - DINT

NVAR

Data type	Default value	Range	Unit
WORD	-	-	-

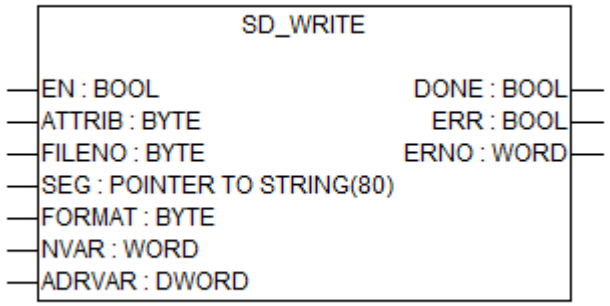
At input NVAR, the number of elements of a data set is specified.

ADRVAR

Data type	Default value	Range	Unit
DWORD	-	-	-

Input ADRVAR is used to specify the start address of the data set. The values of a data set must be available in variables successively stored in the PLC (e.g. ARRAY, STRING, %M area).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

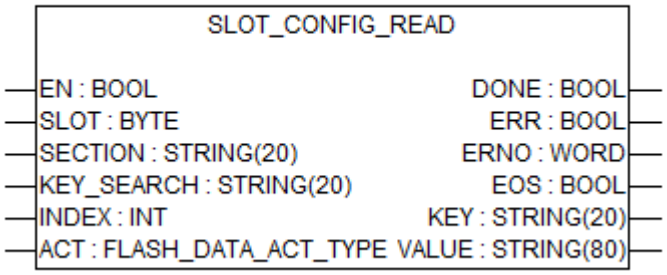
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
WRITE_SD(EN := EN_SD_WRITE,
     ATTRIB := ATTRIB_SD_WRITE,
     FILENO := FILENO_SD_WRITE,
     SEG := SEG_SD_WRITE,
     FORMAT := FORMAT_SD_WRITE,
     NVAR := NVAR_SD_WRITE,
     ADRVAR := ADRVAR_SD_WRITE);
DONE_SD_WRITE := WRITE_SD.DONE;
ERR_SD_WRITE := WRITE_SD.ERR;
ERNO_SD_WRITE := WRITE_SD.ERNO;
```

SLOT_CONFIG_READ



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

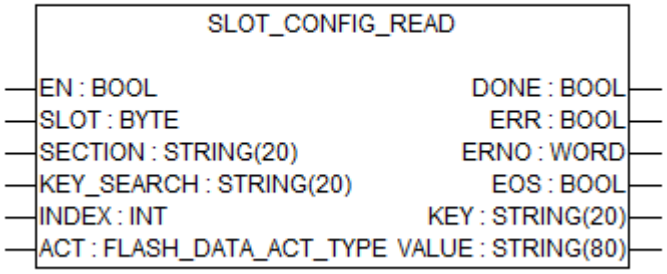
Function block SLOT_CONFIG_READ reads configuration data from flash of a Communication Module in form of KEY/VALUE pairs. One line consists of a pair of key values and is located within the section. The configuration data stored in the Flash are like an "ini" file in their construction, like for example the sdcard.ini on the memory card of the AC500. Example for a line with an IP address in the section Common:

```
[Common]
IP_ADR=192.168.0.1
```

The procedure should be performed in three steps:

1. Initialization (ACT = FLASH_DATA_INIT) of the configuration data with a FALSE/TRUE edge at input EN.
2. Reading (ACT = FLASH_DATA_READ) of the individual values (SECTION, KEY_SEARCH, INDEX) with a FALSE/TRUE edge at input EN.
3. Cancel (ACT = FLASH_DATA_SKIP) the reading with a FALSE/TRUE edge at input EN.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

SECTION Data type: STRING[20]

Section, within to search/read. A section has always to be specified, except for the initialization step.

KEY_SEARCH Data type: STRING[20]

If it is searched for the value of a known key, this must be specified at the input KEY_SEARCH. The key is searched within the section which is specified at the input SECTION. In this case, the input INDEX is ignored.

INDEX Data type: INT

The INDEX input is only evaluated, if the KEY_SEARCH input is 0.

With the INDEX input, a specified line of the configuration data within the section, specified at input SECTION, is output.

If INDEX is unequal to 0, exactly this line number is output, if it exists. If INDEX equals 0 and if there is no value at input KEY_SEARCH, the lines of the section (specified at input SECTION) are output sequentially.

In the latter case each time the next line is read with every FALSE/TRUE edge at input EN as long as the output EOS changes to TRUE and thus terminating the section.

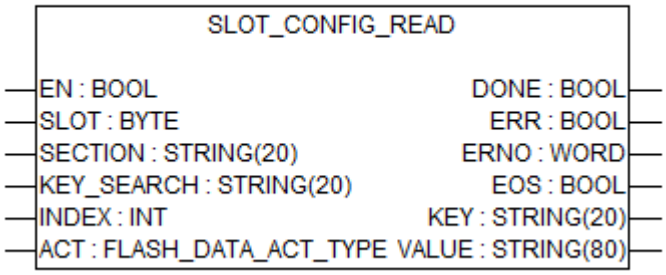
ACT Data type: FLASH_DATA_ACT_TYPE

With the ACT input, the function block can be set to initialize, read the configuration data or to cancel the function block operation.

The input can be set to the following values:

- FLASH_DATA_INIT
  With this input, the function block is initialized for processing of configuration data. The configuration data is copied from the Flash to the RAM, where it can be processed until a re-write into the Flash is performed via the SAVE input.
  If ACT=FLASH_DATA_INIT, all the other inputs are ignored. If the initialization process is performed, all the previous changes are discarded and the original configuration data is copied from the Flash.
- FLASH_DATA_READ
  Read data from RAM disk with the ACT = FLASH_DATA_READ.
- FLASH_DATA_SKIP
  Skip current changes in RAM disk by using FLASH_DATA_SKIP at the input ACT.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

The function blocks SLOT_CONFIG_READ, SLOT_CONFIG_WRITE and SLOT_PROD_ENTRY_READ are executed in the background by the operating system. This procedures can take quite a long time, since the PLC user program is processed with priority. During this phase ERR=FALSE and DONE=FALSE.

EOS

Data type: BOOL

Output EOS (end of section) indicates whether the end of the section was reached while searching sequentially. This output only must be evaluated, if a search is carried out with INDEX=0 and KEY_SEARCH=0.

KEY

Data type: STRING[20]

Output KEY indicates the found key.

VALUE

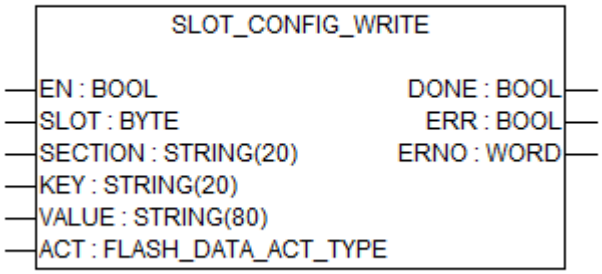
Data type: STRING[80]

Output VALUE indicates the value of the found key.

Function call in ST

```
ConfigRead   (EN         := ConfigRead_EN,
SLOT       := ConfigRead_SLOT,
SECTION    := ConfigRead_SECTION,
KEY_SEARCH := ConfigRead_KEY_SEARCH,
INDEX      := ConfigRead_INDEX,
ACT        := ConfigRead_ACT);
ConfigRead_DONE      := ConfigRead.DONE;
ConfigRead_DONE_ERR  := ConfigRead.ERR;
ConfigRead_ERNO      := ConfigRead.ERNO;
ConfigRead_EOS       := ConfigRead.EOS;
ConfigRead_KEY       := ConfigRead.KEY;
ConfigRead_VALUE     := ConfigRead.VALUE;
```

SLOT_CONFIG_WRITE



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

Function block SLOT_CONFIG_WRITE writes configuration data to the flash of a Communication Module in form of KEY/VALUE pairs. The configuration data stored in the Flash are like an "ini" file in their construction, like for example the sdcard.ini on the memory card of the AC500.

Example for a line with an IP address in the section Common:

[Common]

IP_ADR=192.168.0.1

The procedure should be performed in three steps:

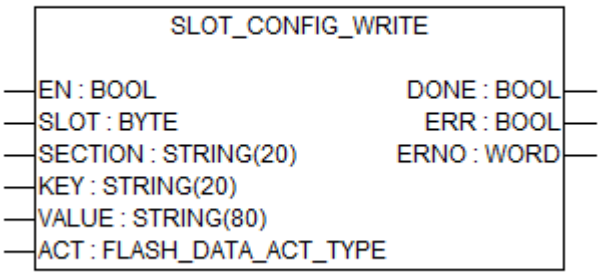
1. Initialization (ACT = FLASH_DATA_INIT) of the configuration data with a FALSE/TRUE edge at input EN
2. Writing (ACT = FLASH_DATA_WRITE) of the individual values (SECTION, KEY, VALUE) with a FALSE/TRUE edge at input EN

   This step is repeated for each entry until all the desired data has been written.

3. Transmit (ACT = FLASH_DATA_SAVE) the data into the Flash and ensuring a permanent data storage in this way.

   Only after the third step has been done, the data is stored in the Flash and will be non-volatile in case of power-down.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

SECTION

Data type: STRING[20]

Section to write to.

KEY (key to write)

Data type: STRING[20]

Key to be written.

VALUE (value to write)

Data type: STRING[80]

Value of the key to be written.

ACT

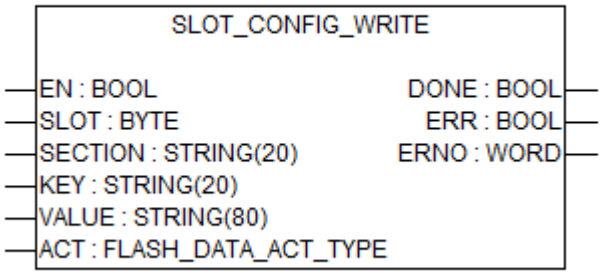
Data type: FLASH_DATA_ACT_TYPE

With the ACT (actual) input, the function block can be set to initialize, write the configuration data or to save, to skip or reset the function block operation.

The input can be set to the following values:

- FLASH_DATA_INIT
  With this input, the function block is initialized for processing of configuration data. The configuration data is copied from the Flash to the RAM, where it can be processed until a re-write into the Flash is performed via the SAVE input.
  If ACT=FLASH_DATA_INIT, all the other inputs are ignored. If the initialization process is performed, all the previous changes are discarded and the original configuration data is copied from the Flash.
- FLASH_DATA_WRITE
  Write data to a RAM disk with the ACT = FLASH_DATA_WRITE.
- FLASH_DATA_SKIP
  Skip current changes in RAM disk by using FLASH_DATA_SKIP at the input ACT.
- FLASH_DATA_RES
  With this input, a reset function is carried out, which deletes all of the configuration data completely.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

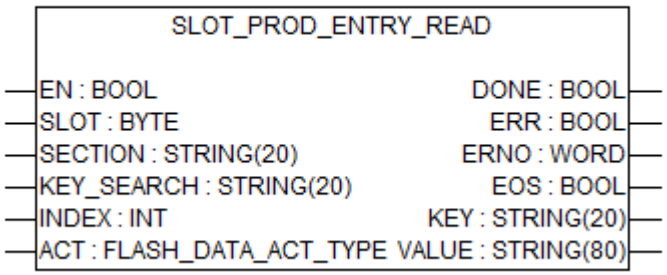
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

The functions SLOT_CONFIG_READ, SLOT_CONFIG_WRITE and SLOT_PROD_ENTRY_READ are executed in the background by the operating system. This procedures can take quite a long time, since the PLC user program is processed with priority. During this phase ERR=FALSE and DONE=FALSE.

Function call in ST

```
ConfigWrite (EN := ConfigWrite_EN,
SLOT := ConfigWrite_SLOT,
SECTION := ConfigWrite_SECTION,
KEY := ConfigWrite_KEY,
VALUE := ConfigWrite_VALUE,
ACT := ConfigWrite_ACT);
ConfigWrite_DONE := ConfigWrite.DONE;
ConfigWrite_ERR := ConfigWrite.ERR;
ConfigWrite_ERNO := ConfigWrite.ERNO;
```

SLOT_PROD_ENTRY_READ



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function block with historical values

The function block reads one line from the production data in the Flash memory of a Communication Module.

One line consists of a pair of key values and is located within a section. The section name of the production data is called "Common".

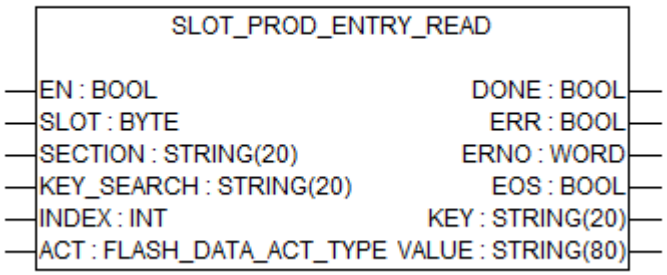
It consists of many keys with the corresponding values, see table:

Production data		Comment
Common	Section Name	Name of the section
BA_INST	Key and value	BA number
IDENT	Key and value	SAP identnumber
IDENT	Key and value	Index of the module
MAC	Key and value	MAC address of the CPU
MANUF_DATE	Key and value	Date of manufacture
MANUF_YEAR	Key and value	Manufacturing year
MANUF_PLACE	Key and value	Place where the PLC was produced
SERIAL_NR	Key and value	Serial number of the PLC
TYPE	Key and value	CPU type

The procedure should be performed in three steps:

1. Initialization (ACT = FLASH_DATA_INIT) of the production data with a FALSE/TRUE edge at input EN.
2. Reading (ACT = FLASH_DATA_READ) of the individual values (SECTION, KEY_SEARCH, INDEX) with a FALSE/TRUE edge at input EN.
3. Cancel (ACT = FLASH_DATA_SKIP) the reading with a FALSE/TRUE edge at input EN.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

SECTION Data type: STRING[20]

Section, within to search/read. A section has always to be specified, except for the initialization step.

KEY_SEARCH Data type: STRING[20]

If it is searched for the value of a known key, this must be specified at the input KEY_SEARCH. The key is searched within the section which is specified at the input SECTION. In this case, the input INDEX is ignored.

INDEX Data type: INT

The INDEX input is only evaluated, if the KEY_SEARCH input is 0.

With the INDEX input, a specified line of the configuration data within the section, specified at input SECTION, is output.

If INDEX is unequal to 0, exactly this line number is output, if it exists. If INDEX equals 0 and if there is no value at input KEY_SEARCH, the lines of the section (specified at input SECTION) are output sequentially.

In the latter case each time the next line is read with every FALSE/TRUE edge at input EN as long as the output EOS changes to TRUE and thus terminating the section.

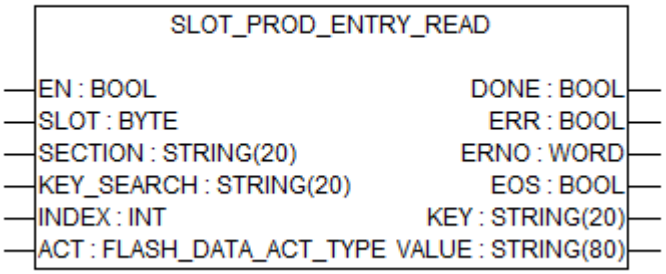
ACT Data type: FLASH_DATA_ACT_TYPE

With the ACT input, the function block can be set to initialize, read the configuration data or to cancel the function block operation.

The input can be set to the following values:

- FLASH_DATA_INIT
  With this input, the function block is initialized for processing of configuration data. The configuration data is copied from the Flash to the RAM, where it can be processed until a re-write into the Flash is performed via the SAVE input.
  If ACT=FLASH_DATA_INIT, all the other inputs are ignored. If the initialization process is performed, all the previous changes are discarded and the original configuration data is copied from the Flash.
- FLASH_DATA_READ
  Read data from RAM disk with the ACT = FLASH_DATA_READ.
- FLASH_DATA_SKIP
  Skip current changes in RAM disk by using FLASH_DATA_SKIP at the input ACT.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

The functions CPU_CONFIG_READ, CPU_CONFIG_WRITE and CPU_PROD_ENTRY_READ are executed in the background by the operating system. This procedures can take quite a long time, since the PLC user program is processed with priority. During this phase ERR=FALSE and DONE=FALSE.

EOS

Data type: BOOL

Output EOS (end of section) indicates whether the end of the section was reached while searching sequentially. This output only must be evaluated, if a search is carried out with INDEX=0 and KEY_SEARCH=0.

KEY

Data type: STRING[20]

Output KEY indicates the found key.

VALUE

Data type: STRING[80]

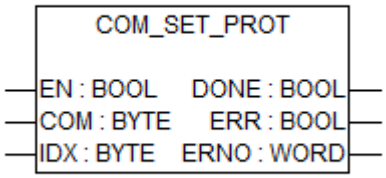
Output VALUE indicates the value of the found key.

Function call in ST

```
CPU_PROD_ENTRY_READ(EN := EN_CPU_PROD_ENTRY_READ,
SECTION := SECTION_CPU_PROD_ENTRY_READ,
KEY_SEARCH := KEY_SEARCH_CPU_PROD_ENTRY_READ,
INDEX := INDEX_CPU_PROD_ENTRY_READ,
ACT := ACT_CPU_PROD_ENTRY_READ);
DONE_CPU_PROD_ENTRY_READ := CPU_PROD_ENTRY_READ.DONE;
ERR_CPU_PROD_ENTRY_READ := CPU_PROD_ENTRY_READ.ERR;
ERNO_CPU_PROD_ENTRY_READ := CPU_PROD_ENTRY_READ.ERNO;
EOS_CPU_PROD_ENTRY_READ := CPU_PROD_ENTRY_READ.EOS;
KEY_CPU_PROD_ENTRY_READ := CPU_PROD_ENTRY_READ.KEY;
VALUE_CPU_PROD_ENTRY_READ:= CPU_PROD_ENTRY_READ.VALUE;
```

1.5.4.19.3 Programs

COM_SET_PROT



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V2.0
Type	Program

With the function block COM_SET_PROT, the serial interfaces of the CPU can actively be set on a predefined protocol or changed between several protocols from the user program.

The block COM_SET_PROT can be used for different functions:

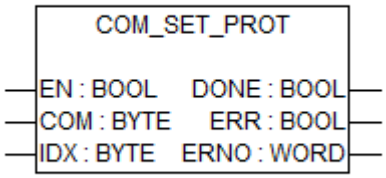
- Switching between two different protocols, for example ASCII/Modbus
- Switching the interface parameters of a protocol, for example changing the transmission rate
- Re-initialization of an interface protocol (for example, if an interface "hangs up")
- Switching between "Online access" and ASCII/Modbus/SysLibCom depending on the current PLC mode, for example STOP=Online access, RUN=Modbus (or ASCII, SysLibCom). In this case, the parameter "Enable login" does not have to be activated and the interface can use other interface parameters than required for "Online access" (see the following program example).

With the setting "COMx "“ Multi[SLOT]" in the configuration, several protocols can be predefined per COM. Using the function block COM_SET_PROT, the user can switch between these protocols from the user program. The rising edge (FALSE->TRUE) at the input EN activates the protocol which was selected over the inputs COM and IDX.

If the function block is used with a serial interface on which only one protocol was defined, the interface is initialized newly and the protocol started again.

Other applications of the function block can be e.g. a change of the transmission rate or also a RESET defined of a protocol.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

At input COM (communication), the number of the serial input is defined.

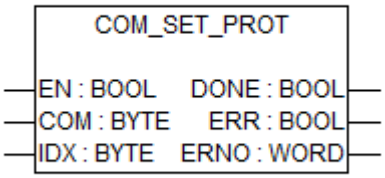
COM = 1: COM1, COM = 2: COM2

IDX

Data type	Default value	Range	Unit
BYTE	-	-	-

The index number of the protocol, which is to be activated on the serial interface COM, is indicated at the input IDX. The assignment of the index number to the individual protocols is carried out in the configuration. If several protocols are defined in the setting "COMx "“ Multi[SLOT]", the index number IDX = 0 corresponds to the protocol in the first place, and IDX = 1 corresponds to the protocol in the second place. In all other cases, if only one protocol is defined per interface, the index number IDX = 0 must be used.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

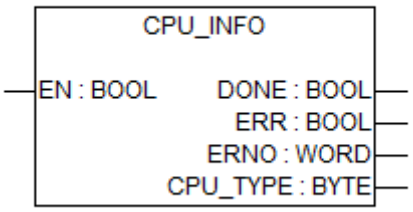
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
COM_SET_PROT (EN  := ComSetProtocol_EN,
              COM := ComSetProtocol_COM,
              IDX := ComSetProtocol_IDX);

ComSetProtocol_DONE := COM_SET_PROT.DONE;
ComSetProtocol_ERR  := COM_SET_PROT.ERR;
ComSetProtocol_ERNO := COM_SET_PROT.ERNO;
```

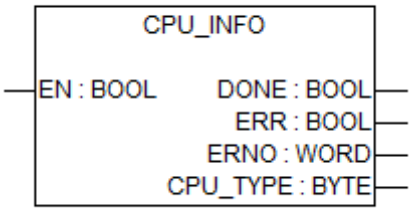
CPU_INFO



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Program

The Program CPU_INFO reads the CPU type.

Input description



EN

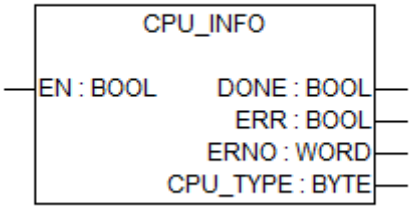
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

CPU_TYPE

Data type	Default value	Range	Unit
BYTE	-	-	-

CPU_TYPE outputs the type of the CPU.

The following values are possible:

```
Value CPU type

20   PM571
21   PM581
22   PM591
23   PM582
25   CM574
26   PM590
27   not used
28   not used
29   PM583-ETH
30   not used
31   PM554
32   PM564
33   PM554-ETH
34   PM564-ETH
35   SM560
36   PM572
37   PM573-ETH
38   PM592-ETH
39   not used
40   PM590-ETH
41   PM591-ETH
42   PM556-ETH
44   PM590-ARC
45   PM591-2ETH
46   PM595-4ETH-F (internal Communication Module via Communication
Module bus)
47   PM595-4ETH-M (internal Communication Module via Communication
```

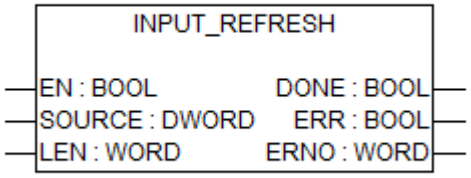
```
Module bus)
48   PM595-4ETH-F (internal Communication Module via PCIe)
49   PM595-4ETH-M (internal Communication Module via PCIe)
50   PM585-ETH
51   PM590-ARC-ETH
```

Function call in ST

```
CPU_INFO(EN := CpuInfo_EN);

CpuInfo_DONE := CPU_INFO.DONE;
CpuInfo_ERR := CPU_INFO.ERR;
CpuInfo_ERNO := CPU_INFO.ERNO;
CpuInfo_CPU_TYPE := CPU_INFO.CPU_TYPE;
```

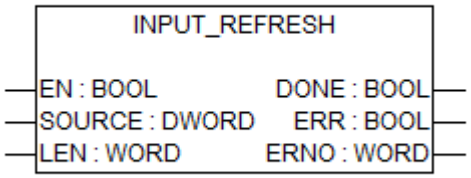
INPUT_REFRESH



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Program

Program INPUT_REFRESH copys the IO input data image into the image area consistently.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

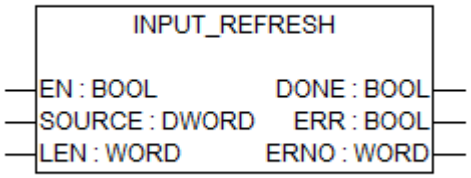
SOURCE Data type: DWORD

At input SOURCE, the address of the first data byte in the source IO area has to be specified.

LEN (length) Data type: BOOL

At input LEN, the number of bytes to be copied has to be specified.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

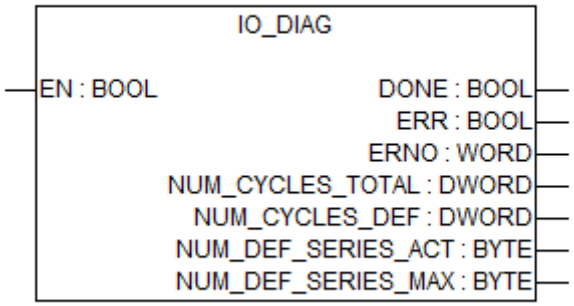
ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during Function Block processing. This output always has to be considered together with output DONE. If DONE is TRUE and ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input, or if an error occurred during job processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

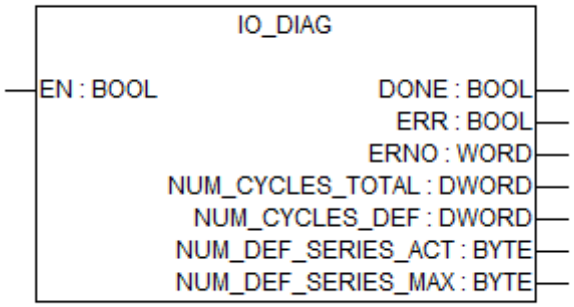
IO_DIAG



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values

The Program IO_DIAG reads the diagnosis data of the I/O bus.

Input description



EN

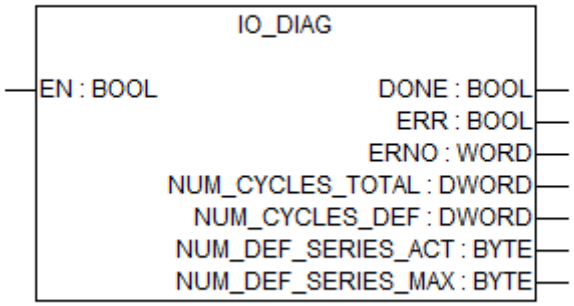
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_CYCLES_TOTAL

Data type	Default value	Range	Unit
DWORD	-	-	-

NUM_CYCLES_TOTAL displays the total number of I/O bus cycles performed since system start.

NUM_CYCLES_DEF

Data type	Default value	Range	Unit
DWORD	-	-	-

NUM_CYCLES_DEF displays the total number of defective I/O bus cycles occurred since system start.

NUM_DEF_SERIES_ACT

Data type	Default value	Range	Unit
BYTE	-	-	-

NUM_DEF_SERIES_ACT displays the actual number of successively occurred defective I/O bus cycles.

NUM_DEF_SERIES_MAX

Data type	Default value	Range	Unit
BYTE	-	-	-

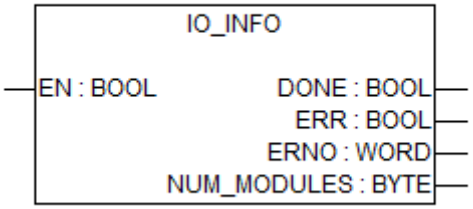
NUM_DEF_SERIES_MAX displays the maximum number of successively occurred defective I/O bus cycles captured since system start.

Function call in ST

```
IO_DIAG (EN := IoDiag_EN);

IoDiag_DONE := IO_DIAG.DONE;
IoDiag_ERR := IO_DIAG.ERR;
IoDiag_ERNO := IO_DIAG.ERNO;
IoDiag_NUM_CYCLES_TOTAL := IO_DIAG.NUM_CYCLES_TOTAL;
IoDiag_NUM_CYCLES_DEF := IO_DIAG.NUM_CYCLES_DEF;
IoDiag_NUM_DEF_SERIES_ACT := IO_DIAG. NUM_DEF_SERIES_ACT;
IoDiag_NUM_DEF_SERIES_MAX := IO_DIAG. NUM_DEF_SERIES_MAX;
```

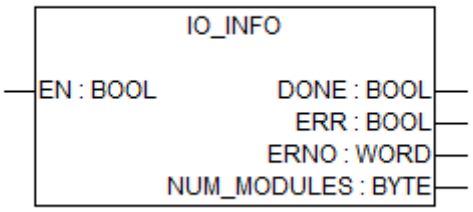
IO_INFO



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Program

The Program IO_INFO displays the number of devices connected to the I/O bus.

Input description



EN

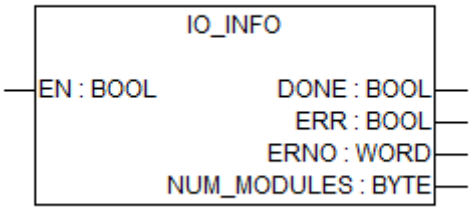
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

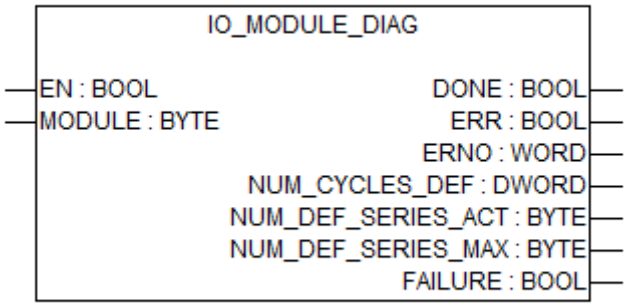
NUM_MODULES BYTE NUM_MODULES displays the number of devices connected to the I/O bus.

Function call in ST

```
IO_INFO (EN := IoInfo_EN);

IoInfo_DONE := IO_INFO.DONE;
IoInfo_ERR := IO_INFO.ERR;
IoInfo_ERNO := IO_INFO.ERNO;
IoInfo_NUM_ MODULES := IO_INFO.NUM_ MODULES;
```

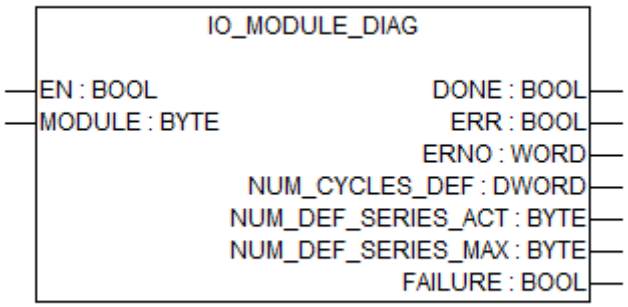
IO_MODULE_DIAG



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Program

The Program IO_MODULE_DIAG reads the module diagnosis data of the I/O Bus.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

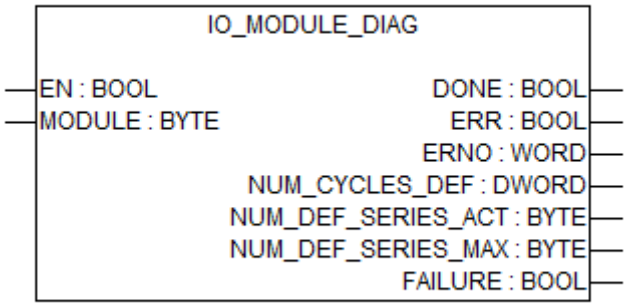
While it is executed its inputs are continuously evaluated.

MODULE

Data type	Default value	Range	Unit
BYTE	-	1..10	-

Module position on bus.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_CYCLES_DEF

Data type	Default value	Range	Unit
DWORD	-	-	-

NUM_CYCLES_DEF (number of cyclesdefective) displays the total number of defective I/O bus cycles occurred for the selected module since system start.

NUM_DEF_SERIES_ACT

Data type	Default value	Range	Unit
BYTE	-	-	-

NUM_DEF_SERIES_ACT (number of defective cycles in seriesactual) displays the actual number of successive defective I/O bus cycles occurred for the selected module.

NUM_DEF_SERIES_MAX

Data type	Default value	Range	Unit
BYTE	-	-	-

NUM_DEF_SERIES_MAX (number of defective cycles in seriesmaximal) displays the maximum number of successive defective I/O bus cycles occurred for the selected module since system start.

FAILURE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

FAILURE indicates that the maximum allowed number of successively occurring defective I/O bus cycles has been exceeded. In this case the module has to be considered as failed. A failure of one module results in a stop of the entire I/O bus.

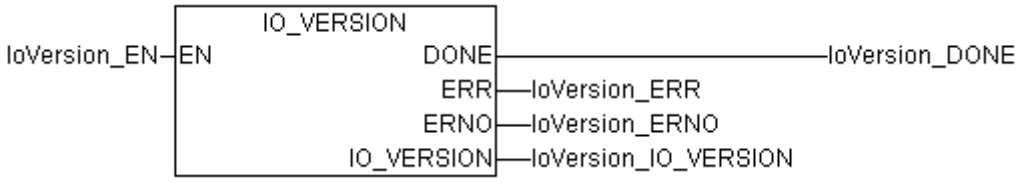
Function call in ST

```
IO_MODULE_DIAG (EN := IoModuleDiag_EN,
                MODULE := IoModuleDiag_MODULE);

IoModuleDiag_DONE := IO_ MODULE_DIAG.DONE;
IoModuleDiag_ERR := IO_ MODULE_DIAG.ERR;
IoModuleDiag_ERNO := IO_ MODULE_DIAG.ERNO;
```

```
IoModuleDiag_NUM_CYCLES_DEF := IO_ MODULE_DIAG.NUM_CYCLES_DEF;
IoModuleDiag_NUM_DEF_SERIES_ACT := IO_ MODULE_DIAG.
NUM_DEF_SERIES_ACT;
IoModuleDiag_NUM_DEF_SERIES_MAX:= IO_ MODULE_DIAG. NUM_DEF_SERIES_MAX;
IoModuleDiag_FAILURE := IO_ MODULE_DIAG.FAILURE;
```

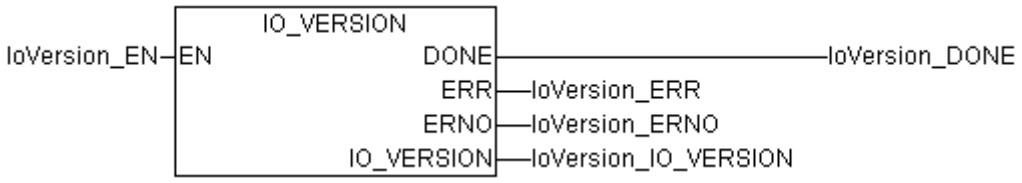
IO_DRIVER_VERSION



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Program

The Program IO_DRIVER_VERSION reads the version of the I/O bus driver.

Input description



EN

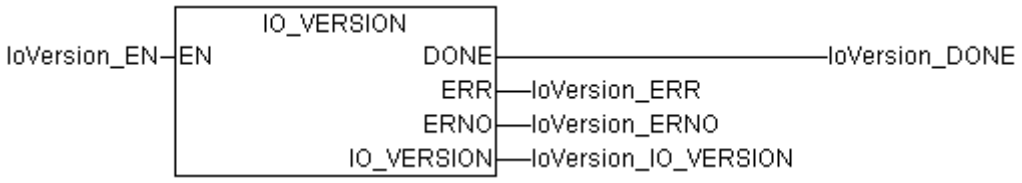
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IO_VERSION

Data type	Default value	Range	Unit
WORD	-	-	-

IO_VERSION (I/O bus driver version) outputs the version of the I/O bus driver.

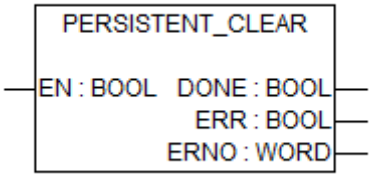
Example: IO_VERSION = 1000 -> V1.0.0.0

Function call in ST

```
IO_VERSION (EN := IoVersion_EN);

IoVersion_DONE := IO_VERSION.DONE;
IoVersion_ERR := IO_VERSION.ERR;
IoVersion_ERNO := IO_VERSION.ERNO;
IoVersion_IO_VERSION := IO_VERSION.IO_VERSION;
```

PERSISTENT_CLEAR

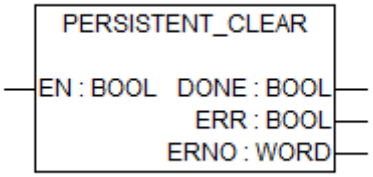


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.2
Type	Program

With a rising edge (False -> True) at input EN of the function block PERSISTENT_CLEAR, all data in the areas PERSISTENT or %R are deleted.

The use of the Program requires that a valid PERSISTENT area or %R area is set in the CPU.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

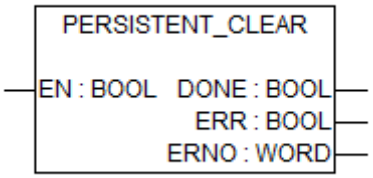
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

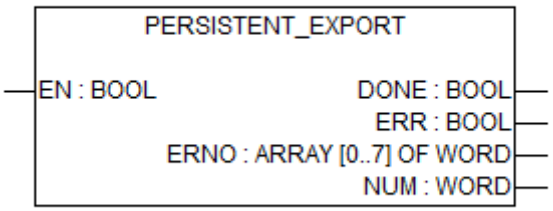
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
PERSISTENT_CLEAR (EN := PersistentClear_EN);

PersistentClear_DONE := PERSISTENT_CLEAR.DONE;
PersistentClear_ERR  := PERSISTENT_CLEAR.ERR;
PersistentClear_ERNO := PERSISTENT_CLEAR.ERNO;
```

PERSISTENT_EXPORT

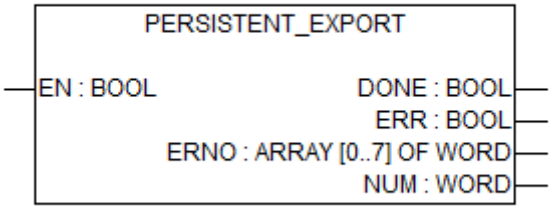


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.2
Type	Program

With a rising edge (False -> True) at input EN of the Program PERSISTENT_EXPORT, all data in the areas PERSISTENT or %R are written from the RAM-DISC to the SD Card.

The use of the Program requires that a valid PERSISTENT area or %R area is set in the CPU.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

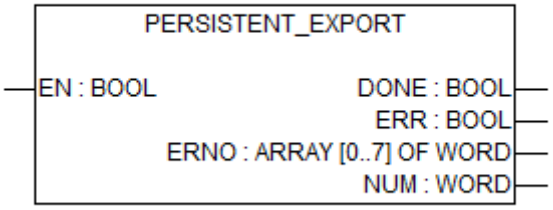
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM WORD (number of areas)

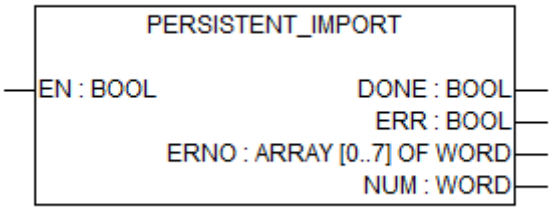
The number of written segments is available at output NUM.

Function call in ST

```
PERSISTENT_EXPORT (EN := PersistentExport_EN);

PersistentExport_DONE := PERSISTENT_EXPORT.DONE;
PersistentExport_ERR  := PERSISTENT_EXPORT.ERR;
PersistentExport_ERNO := PERSISTENT_EXPORT.ERNO;
PersistentExport_NUM  := PERSISTENT_EXPORT.NUM;
```

PERSISTENT_IMPORT

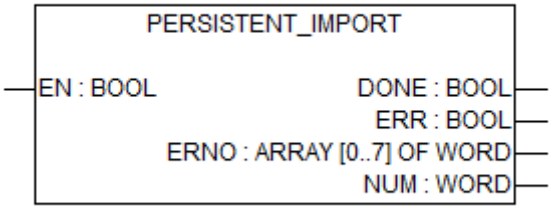


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.2
Type	Program

With a rising edge (False -> True) at input EN of the Program PERSISTENT_IMPORT, all data in the areas PERSISTENT or %R are written from the memory card to the RAM-DISC.

The use of the Program requires that a valid PERSISTENT area or %R area is set in the CPU.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

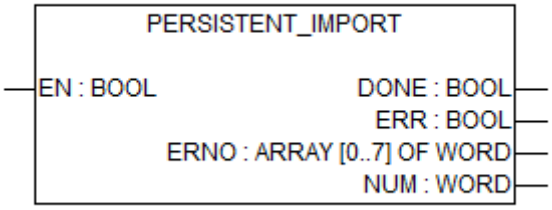
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM WORD (number of areas)

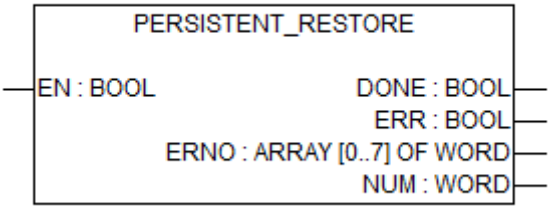
The number of written segments is available at output NUM.

Function call in ST

```
PERSISTENT_IMPORT (EN := PersistentImport_EN);

PersistentImport_DONE := PERSISTENT_IMPORT.DONE;
PersistentImport_ERR  := PERSISTENT_IMPORT.ERR;
PersistentImport_ERNO := PERSISTENT_IMPORT.ERNO;
PersistentImport_NUM  := PERSISTENT_IMPORT.NUM;
```

PERSISTENT_RESTORE

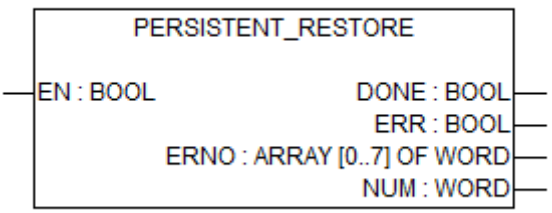


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.2
Type	Program

With a rising edge (False -> True) at input EN of the Program PERSISTENT_RESTORE, all data in the areas PERSISTENT or %R are written from the RAM-DISC to the SRAM.

The use of the Program requires that a valid PERSISTENT area or %R area is set in the CPU.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

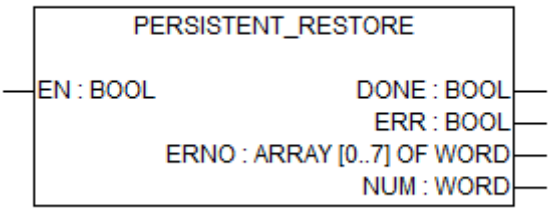
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM WORD (number of areas)

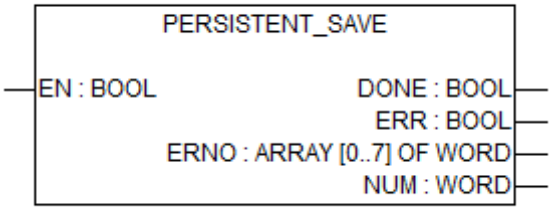
The number of written segments is available at output NUM.

Function call in ST

```
PERSISTENT_RESTORE (EN := PersistentRestore_EN);

PersistentRestore_DONE := PERSISTENT_RESTORE.DONE;
PersistentRestore_ERR  := PERSISTENT_RESTORE.ERR;
PersistentRestore_ERNO := PERSISTENT_RESTORE.ERNO;
PersistentRestore_NUM  := PERSISTENT_RESTORE.NUM;
```

PERSISTENT_SAVE

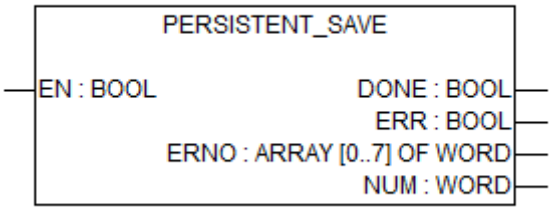


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.2
Type	Program

With a rising edge (False -> True) at input EN of the Program PERSISTENT_SAVE, all data in the areas PERSISTENT or %R are written from the SRAM to the RAM-DISC.

The use of the Program requires that a valid PERSISTENT area or %R area is set in the PLC Configuration of the CPU.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

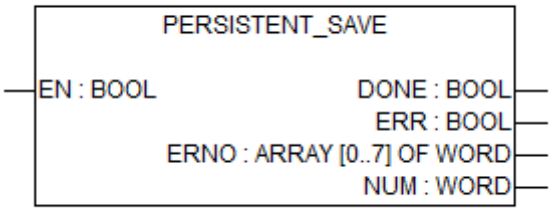
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM WORD (number of areas)

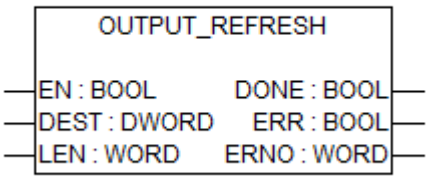
The number of written segments is available at output NUM.

Function call in ST

```
PERSISTENT_SAVE (EN := PersistentSave_EN);

PersistentSave_DONE := PERSISTENT_SAVE.DONE;
PersistentSave_ERR  := PERSISTENT_SAVE.ERR;
PersistentSave_ERNO := PERSISTENT_SAVE.ERNO;
PersistentSave_NUM  := PERSISTENT_SAVE.NUM;
```

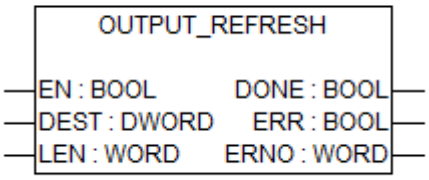
OUTPUT_REFRESH



Program OUPUT_REFRESH copys the image area into the IO image consistently.

Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Program

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

DEST (destination)

Data type: BOOL

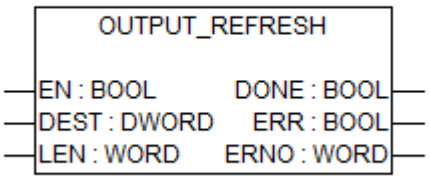
At input DEST, the address of the first data byte in the destination IO area has to be specified.

LEN (length)

Data type: BOOL

At input LEN, the number of bytes to be copied has to be specified.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR (error)

Data type: BOOL

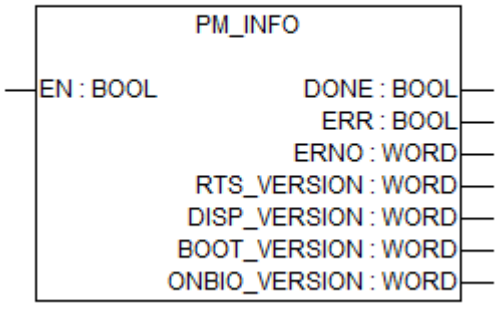
Output ERR indicates whether an error occurred during Function Block processing. This output always has to be considered together with output DONE. If DONE is TRUE and ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input, or if an error occurred during job processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

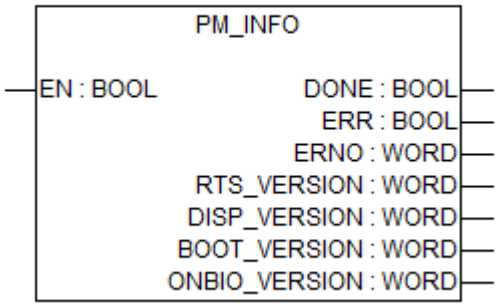
PM_INFO



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V2.2.0
Type	Program

The Program PM_INFO reads the software version information of a PLC.

Input description



EN

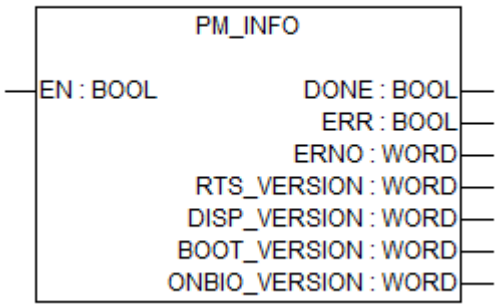
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RTS_VERSION

Data type	Default value	Range	Unit
WORD	-	-	-

Output RTS_VERSION (runtime system version) delivers the version of the runtime system in BCD code (e. g. 16#10 means version 1.0)

DISP_VERSION

Data type	Default value	Range	Unit
WORD	-	-	-

Output DISP_VERSION (display version) delivers the version of the PLC display firmware (not for AC500 eCo-CPUs) in BCD code (e. g. 16#10 means version 1.0).

BOOT_VERSION

Data type	Default value	Range	Unit
WORD	-	-	-

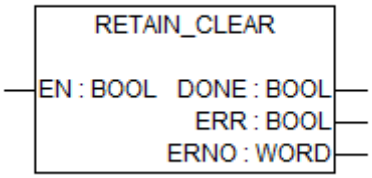
Output BOOT_VERSION (bootcode version) delivers the version of the PLC bootcode in BCD code (e. g. 16#10 means version 1.0).

ONBIO_VERSION

Data type	Default value	Range	Unit
WORD	-	-	-

Output ONBIO_VERSION (onboard IO version) delivers the version of the PLC onboard IOs (AC500 eCo-CPUs only) in BCD code (e. g. 16#10 means version 1.0).

RETAIN_CLEAR

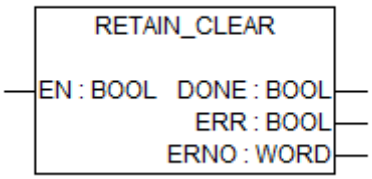


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.2
Type	Program

With a rising edge (False -> True) at input EN of the Program RETAIN_CLEAR, all data in the retain area are deleted.

Retain variables are declared with the keyword RETAIN. These variables keep their values after an uncontrolled abort as well as after a normal switch off/on of the control system (or with the command 'online' 'reset'). At a new start of the program work is continued with the stored values.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

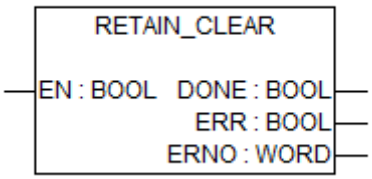
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

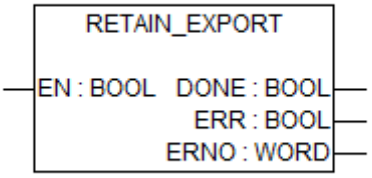
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RETAIN_CLEAR (EN := RetainClear_EN);

RetainClear_DONE := RETAIN_CLEAR.DONE;
RetainClear_ERR  := RETAIN_CLEAR.ERR;
RetainClear_ERNO := RETAIN_CLEAR.ERNO;
```

RETAIN_EXPORT

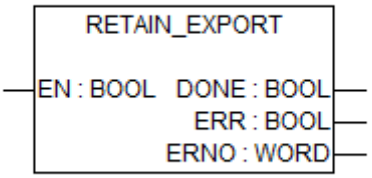


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.2
Type	Program

With a rising edge (False -> True) at input EN of the Program RETAIN_EXPORT, all data in the retain area are written from the RAM-DISC to the memory card.

Retain variables are declared with the keyword RETAIN. These variables keep their values after an uncontrolled abort as well as after a normal switch off/on of the control system (or with the command 'online' 'reset'). At a new start of the program work is continued with the stored values.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

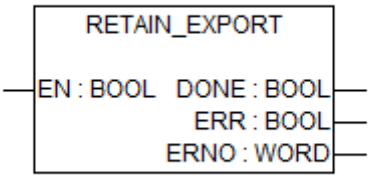
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

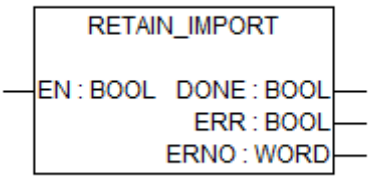
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RETAIN_EXPORT (EN := RetainExport_EN);

RetainExport_DONE := RETAIN_EXPORT.DONE;
RetainExport_ERR  := RETAIN_EXPORT.ERR;
RetainExport_ERNO := RETAIN_EXPORT.ERNO;
```

RETAIN_IMPORT

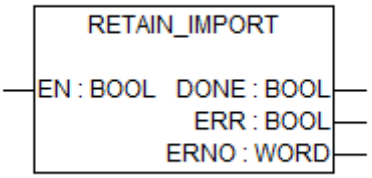


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.2
Type	Program

With a rising edge (False -> True) at input EN of the Program RETAIN_IMPORT, all data in the retain area are written from the memory card to the RAM-DISC.

Retain variables are declared with the keyword RETAIN. These variables keep their values after an uncontrolled abort as well as after a normal switch off/on of the control system (or with the command 'online' 'reset'). At a new start of the program work is continued with the stored values.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

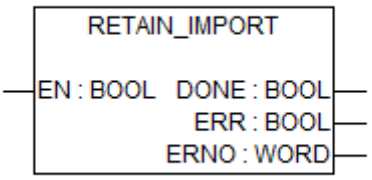
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

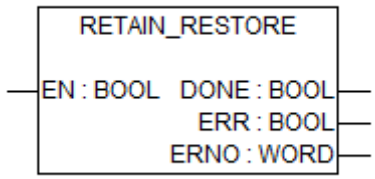
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RETAIN_IMPORT (EN := RetainImport_EN);

RetainImport_DONE := RETAIN_IMPORT.DONE;
RetainImport_ERR  := RETAIN_IMPORT.ERR;
RetainImport_ERNO := RETAIN_IMPORT.ERNO;
```

RETAIN_RESTORE

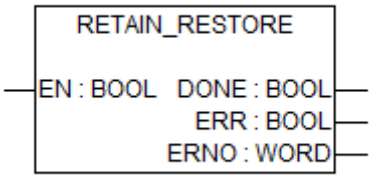


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1:2
Type	Program

With a rising edge (False -> True) at input EN of the Program RETAIN_RESTORE, all data in the retain area are written from the RAM-DISC to the SRAM.

Retain variables are declared with the keyword RETAIN. These variables keep their values after an uncontrolled abort as well as after a normal switch off/on of the control system (or with the command 'online' 'reset'). At a new start of the program work is continued with the stored values.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

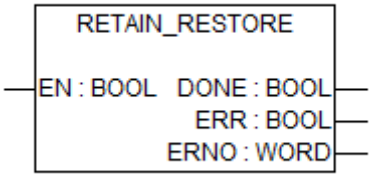
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

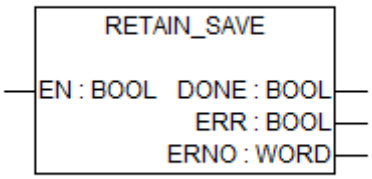
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RETAIN_RESTORE (EN := RetainRestore_EN);

RetainRestore_DONE := RETAIN_RESTORE.DONE;
RetainRestore_ERR  := RETAIN_RESTORE.ERR;
RetainRestore_ERNO := RETAIN_RESTORE.ERNO;
```

RETAIN_SAVE

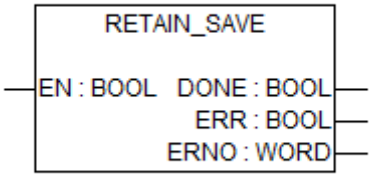


Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.2
Type	Program

With a rising edge (False -> True) at input EN of the Program RETAIN_SAVE, all data in the retain area are written from the SRAM to the RAM-DISC.

Retain variables are declared with the keyword RETAIN. These variables keep their values after an uncontrolled abort as well as after a normal switch off/on of the control system (or with the command 'online' 'reset'). At a new start of the program work is continued with the stored values.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

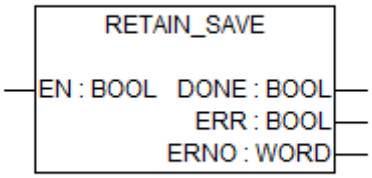
The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

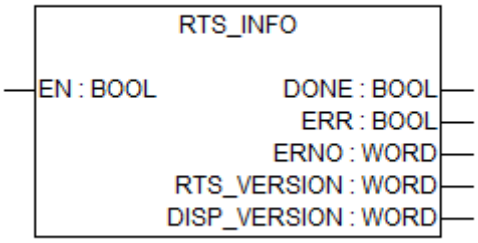
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RETAIN_SAVE (EN := RetainSave_EN);

RetainSave_DONE := RETAIN_SAVE.DONE;
RetainSave_ERR  := RETAIN_SAVE.ERR;
RetainSave_ERNO := RETAIN_SAVE.ERNO;
```

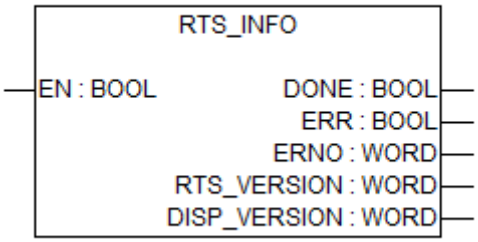
RTS_INFO



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Program

The Program RTS_INFO reads the version of the CPU runtime system.

Input description



EN

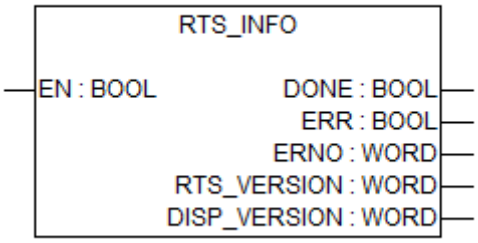
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

RTS_VERSION

Data type	Default value	Range	Unit
WORD	-	-	-

RTS_VERSION (RTSversion) outputs the version of the CPU runtime system. The upper BYTE of the entry represents the main version, the lower BYTE represents the subversion of the runtime system.

> ***Different data format display***
> *Examples:*
> *Runtime system ≤ V2.3.3 = RTS_VERSION 16#0233*
> *Runtime system ≥ V2.4.0 = RTS_VERSION 16#2400*

DISP_VERSION

Data type	Default value	Range	Unit
WORD	-	-	-

DISP_VERSION (display version) outputs the software version of the display. The upper BYTE of the entry represents the main version, the lower BYTE represents the subversion of the display software.

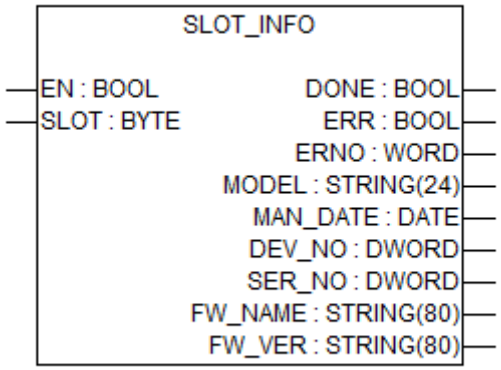
Example: DISP_VERSION = 16#0110 -> V01.16

Function call in ST

```
RTS_INFO (EN := RtsInfo_EN);

RtsInfo_DONE := RTS_INFO.DONE;
RtsInfo_ERR := RTS_INFO.ERR;
RtsInfo_ERNO := RTS_INFO.ERNO;
RtsInfo_RTS_VERSION := RTS_INFO.RTS_VERSION;
RtsInfo_DISP_VERSION := RTS_INFO.DISP_VERSION;
```

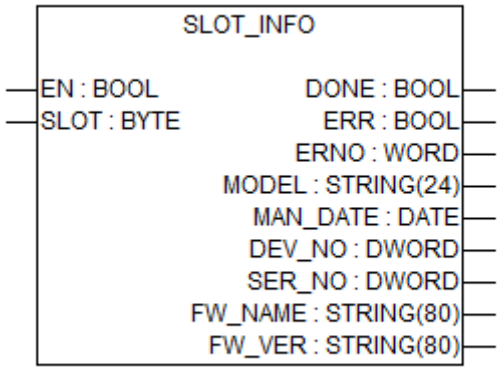
SLOT_INFO



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Program

The Program SLOT_INFO reads information from the slot from the connected device (Communication module).

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

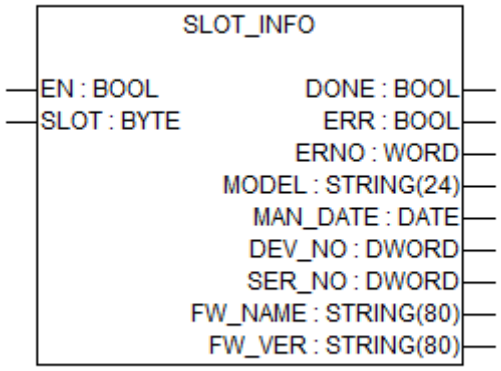
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

MODEL

Data type: STRING(24)

The output MODEL provides the type of the device which is connected to the selected slot. The output is in plain text.

MAN_DATE

Data type: DATE

The output MAN_DATE (date of manufacture)provides the date of manufacture of the device which is connected to the selected slot.

DEV_NO

Data type	Default value	Range	Unit
DWORD	-	-	-

The output DEV_NO (device number) provides the manufacturer-specific number of the device which is connected to the selected slot.

SER_NO

Data type	Default value	Range	Unit
DWORD	-	-	-

The output SER_NO (serial number) provides the serial number of the device which is connected to the selected slot.

FW_NAME

Data type: STRING(16)

The output FW_NAME (firmware name) provides the firmware name of the device which is connected to the selected slot. The output is in plain text.

FW_VER

Data type: STRING(16)

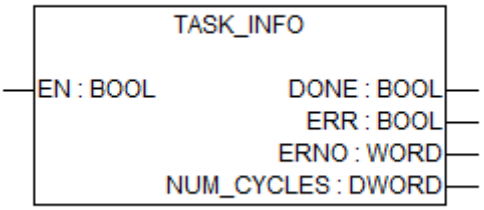
The output FW_VER (firmware version) provides the firmware version of the device which is connected to the selected slot. The output is in plain text.

Function call in ST

```
SLOT_INFO (EN := SlotInfo_EN, SLOT := SlotInfo_SLOT);

SlotInfo_DONE := SLOT_INFO.DONE;
SlotInfo_ERR := SLOT_INFO.ERR;
SlotInfo_ERNO := SLOT_INFO.ERNO;
SlotInfo_MODEL := SLOT_INFO.MODEL;
SlotInfo_MAN_DATE := SLOT_INFO.MAN_DATE;
SlotInfo_DEV_NO := SLOT_INFO.DEV_NO;
SlotInfo_SER_NO := SLOT_INFO.SER_NO;
SlotInfo_FW_NAME := SLOT_INFO.FW_NAME;
SlotInfo_FW_VER := SLOT_INFO.FW_VER;
```

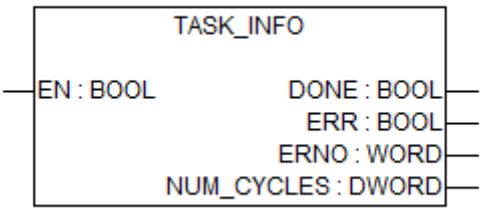
TASK_INFO read number of completed task cycles



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Program

The Program TASK_INFO outputs the number of completed cycles for the task it is called in.

Input description



EN

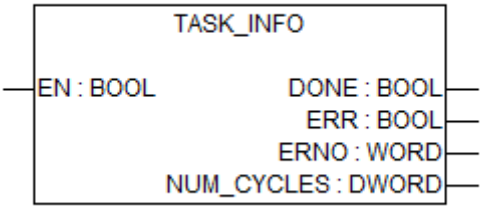
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_CYCLES DWORD (number of cycles)

Output NUM_CYCLES displays a counter of the number of times the current task has completed a cycle. The number is reset to 0 on PLC STOP, download of new user program or reset of the PLC.

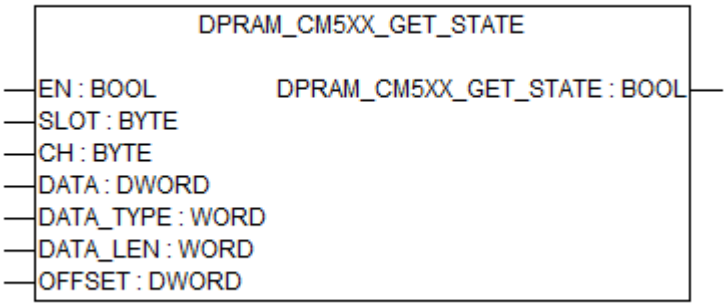
Function call in ST

```
TaskInfo (EN         := TaskInfo_EN);

TaskInfo_DONE        := TaskInfo.DONE;
TaskInfo_ERR         := TaskInfo.ERR;
TaskInfo_ERNO        := TaskInfo.ERNO;
TaskInfo_NUM_CYCLES  := TaskInfo.NUM_CYCLES;
```

1.5.4.19.4 Functions

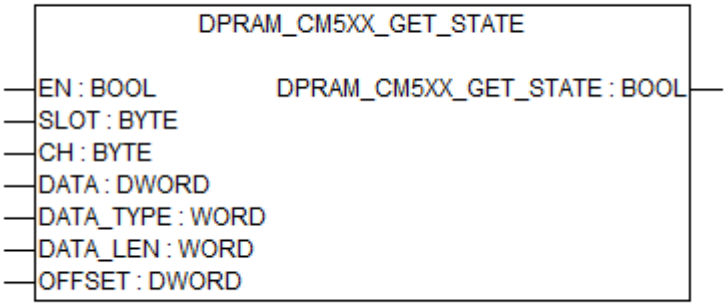
DPRAM_CM5XX_GET_STATE



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function

Function DPRAM_CM5XX_GET_STATE is used for getting value(s) in extended status from a Communication Module.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type: BYTE

At input CH (channel), the addressed channel is specified.

Valid values: 1 and 2.

DATA (data)

Data type: DWORD

At input DATA, the address of the variable is specified, of which the user data shall be received.

DATA must be the address of a variable of the type ARRAY or STRUCT.

CAUTION!

Memory area overlapping

Avoid memory area overlappings by specifying the size of the variable to the max. data expected.

DATA_TYPE (data type)

Data type: WORD

At input DATA_TYPE, the type of data has to be specified. The following allocation is used:

- 0 = Bit
- 1 = Byte
- 2 = Word
- 4 = DWord

DATA_LEN (data length)

Data type: DWORD

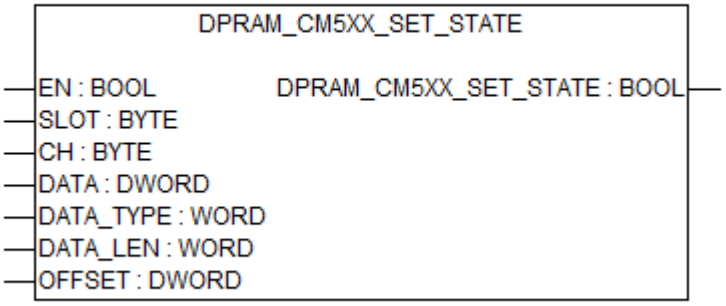
At input DATA_LEN, the length of the data which should be read has to be specified.

OFFSET (offset)

Data type: DWORD

At input OFFSET, the offset within the block in bytes has to be specified.

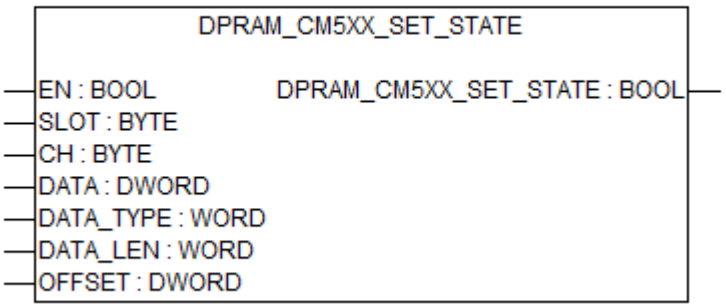
DPRAM_CM5XX_SET_STATE



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.3.0
Type	Function

Function DPRAM_CM5XX_SET_STATE is used for setting value(s) in extended status from a Communication Module.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

CH (channel)

Data type: BYTE

At input CH (channel), the addressed channel is specified.

Valid values: 1 and 2.

DATA (data)

Data type: DWORD

At input DATA, the address of the variable is specified, of which the user data shall be received.

DATA must be the address of a variable of the type ARRAY or STRUCT.

CAUTION!
Memory area overlapping
Avoid memory area overlappings by specifying the size of the variable to the max. data expected.

DATA_TYPE (data type)

Data type: WORD

At input DATA_TYPE, the type of data has to be specified. The following allocation is used:

- 0 = Bit
- 1 = Byte
- 2 = Word
- 4 = DWord

DATA_LEN (data length)

Data type: DWORD

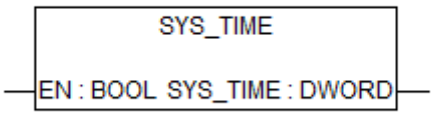
At input DATA_LEN, the length of the data which should be read has to be specified.

OFFSET (offset)

Data type: DWORD

At input OFFSET, the offset within the block in bytes has to be specified.

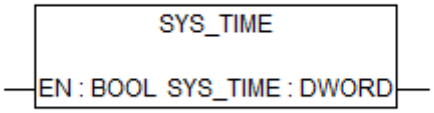
SYS_TIME



Parameter	Value
Included in library	SysInt_AC500_V10.lib
Available as of firmware	V1.0
Type	Function

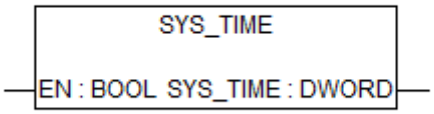
The Function SYS_TIME outputs the system tick in milliseconds as a double word. The system tick is provided with a resolution of a millisecond and also serves as a time basis for the PLC application program and all time-dependent function blocks. After a PLC reset the system tick always starts with 0. An overflow is reached after 49 days. After this, the counter restarts at 0.

Input description



EN BOOL (enable) The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

Output description



(Output) DWORD The function block output delivers the system tick in ms.

Function call in ST

```
SysTime := SYS_TIME(SysTime_EN);
```

1.5.4.20 Extended internal system library

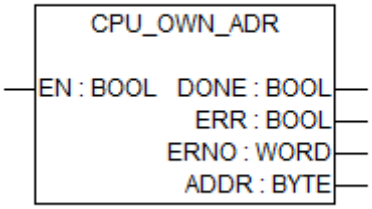
Library file name: **SysIntExt_AC500_Vx.lib**

The extended internal system library contains all function blocks that are generally applicable to the system, i.e. function blocks for general system diagnosis functions or for system information.

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

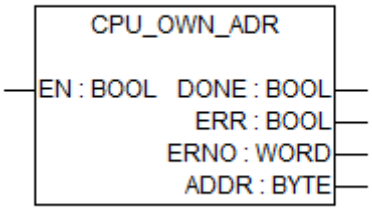
1.5.4.20.1 Function blocks

CPU_OWN_ADR



Parameter	Value
Included in library	SysIntExt_AC500_V13.lib
Available as of firmware	V1.3
Type	Function block with historical values
Group	System information

Input description



EN

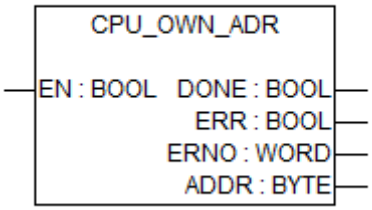
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADDR

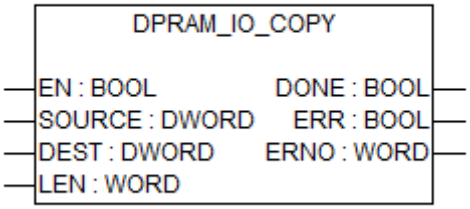
Data type	Default value	Range	Unit
BYTE	-	-	-

Output ADDR provides the current address value set with the rotary switch on the CM574-RS.

Function call in ST

```
OWN_ADR (EN := OWN_ADR_EN);
OWN_ADR_DONE := OWN_ADR.DONE;
OWN_ADR_ERR := OWN_ADR.ERR;
OWN_ADR _ERNO := OWN_ADR.ERNO;
OWN_ADR_MAP := OWN_ADR.ADDR;
```

DPRAM_IO_COPY



Parameter	Value
Included in library	SysIntExt_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	DPRAM communication

This function block is used to copy IO data areas.

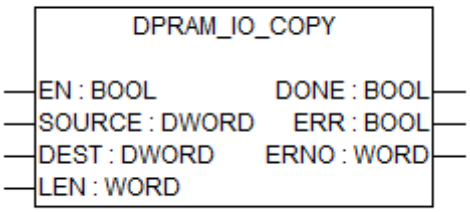
Using this function block it is possible to transfer for instance the inputs of the CS31 to the CM574-RS outputs without occupying any PLC code.

To use this function block, symbolic names have to be assigned to each first byte, e.g. "Input1" for %IB1000 = SOURCE and "Output1" for %QB0 = DEST.

If enabled, the function block first reads all IO data assigned from the I/O image into the image area. Then it copies the image area to the assigned IO data. Input LEN specifies the number of bytes to be copied. Output DONE = TRUE indicates that the operation is finished.

See also *Chapter 1.6.4.1.1 “Inputs, outputs and flags for AC500 V2 products” on page 5395* in the Multitasking System.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SOURCE

Data type	Default value	Range	Unit
DWORD	-	-	-

Input SOURCE specifies the address of the first data byte of the IO area to be read.

DEST

Data type	Default value	Range	Unit
DWORD	-	-	-

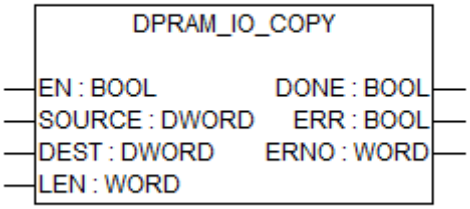
Input DEST specifies the address of the first data byte of the destination IO area the data should be copied to.

LEN

Data type	Default value	Range	Unit
WORD	-	-	-

Input LEN specifies the length (in bytes) of the data to be copied.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

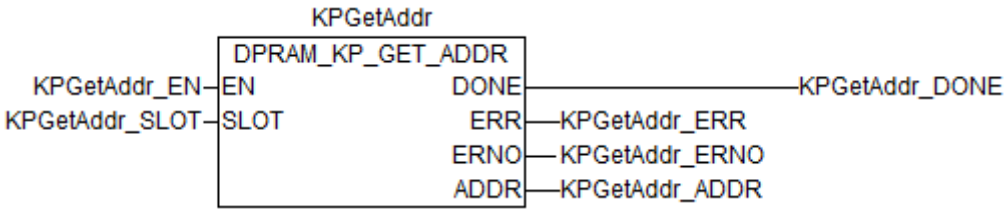
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
DPRAM_IO_COPY(EN:= IOcopy_EN,
              SOURCE:= IOcopy_SOURCE,
              DEST:= IOcopy_DEST,
              LEN:= IOcopy_LEN);
DPRAM_IO_COPY_DONE:= DPRAM_IO_COPY.DONE;
DPRAM_IO_COPY_ERR:= DPRAM_IO_COPY.ERR;
DPRAM_IO_COPY_ERNO:= DPRAM_IO_COPY.ERNO;
```

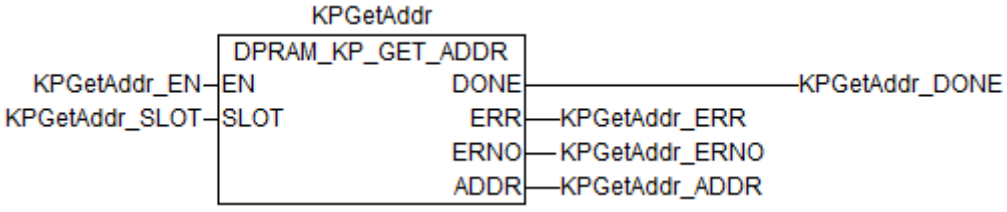
DPRAM_KP_GET_ADDR



Parameter	Value
Included in library	SysIntExt_AC500_V13.lib
Available as of firmware	V2.4.0
Type	Function block with historical values
Group	DPRAM communication

This function block is used to get the start address of DPRAM for KP-based Communication Modules.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

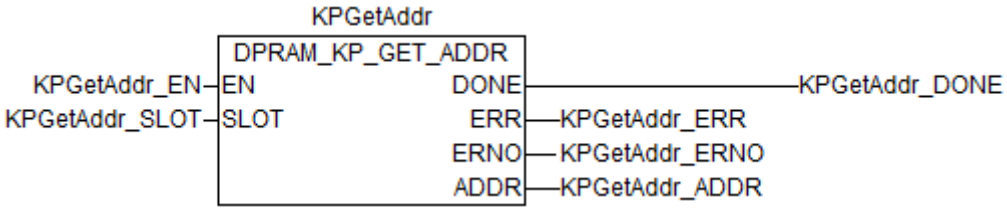
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADDR

Data type	Default value	Range	Unit
DWORD	-	-	-

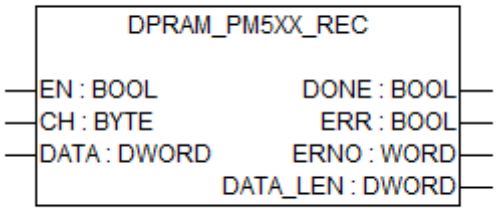
Output ADDR returns the start address of the DPRAM. If KP has not been completely detected yet, output ERNO will indicate busy state and set DONE to TRUE.

Function call in ST

```
KPGetAddr(EN:= KPGetAddr_EN,
              SLOT:= KPGetAddr_SLOT);

KPGetAddr_DONE:= KPGetAddr.DONE;
KPGetAddr_ERR := KPGetAddr.ERR;
KPGetAddr_ERNO:= KPGetAddr.ERNO;
KPGetAddr_ADDR:= KPGetAddr.ADDR;
```

DPRAM_PM5XX_REC



Parameter	Value
Included in library	SysIntExt_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	DPRAM communication

This function block is used to receive data from a AC500 CPU.

The data received are stored in the configured memory area, i.e. at the memory address specified at input DATA via the ADR operator.

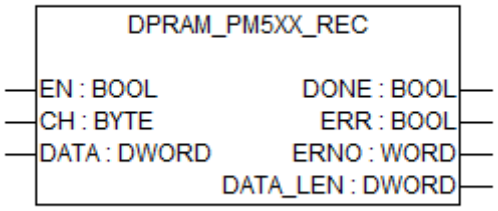
The function block is enabled by a TRUE signal at input EN. It remains active until input EN is set to FALSE. The channel of the AC500 CPU is specified at input CH.

Output DATA_LEN displays the length of the received data in bytes. Successful data reception is indicated by DONE = TRUE and ERR = FALSE. The outputs ERR and ERNO indicate whether an error occurred during Function Block processing.

Data reception using the DPRAM_PM5XX_REC function block is not edge-triggered. Therefore, input EN must be TRUE during data reception.

DPRAM message-based data exchange allows a maximum of 260 Bytes per message to be sent or received.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CH

Data type	Default value	Range	Unit
BYTE	-	-	-

Input CH (channel) is used to specify the channel of the AC500 CPUs to be addressed.

Valid values: 1 and 2.

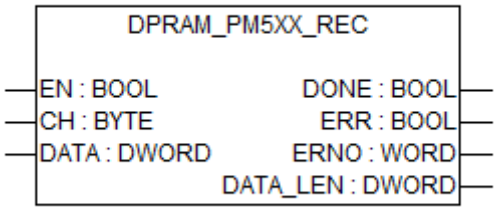
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable the user data are to be copied to. DATA must contain an address of a variable of the type ARRAY or STRUCT.

Specify the size of the variable according to the maximum amount of data expected in order to avoid memory area overlapping.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

DATA_LEN

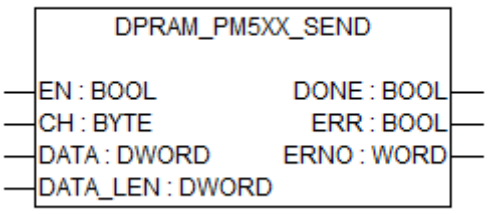
Data type	Default value	Range	Unit
WORD	-	-	Byte

Output DATA_LEN displays the length of the received data. The output value at DATA_LEN is only valid if DONE = TRUE.

Function call in ST

```
PM5xxRec (EN := PM5xxRec_EN,
CH := PM5xxRec_CH,
DATA := ADR(PM5xxRec_DATA),
DONE => PM5xxRec_DONE,
ERR => PM5xxRec_ERR,
ERNO => PM5xxRec_ERNO,
DATA_LEN => PM5xxRec_DATA_LEN);
PM5xxRec_DONE := PM5xxRec.DONE;
PM5xxRec_ERR := PM5xxRec.ERR;
PM5xxRec_ERNO := PM5xxRec.ERNO;
PM5xxRec_DATA_LEN := PM5xxRec.DATA_LEN;
```

DPRAM_PM5XX_SEND



Parameter	Value
Included in library	SysIntExt_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	DPRAM communication

This function block is used to send data to the AC500 CPU.

The data to be sent are provided in the configured memory area, i.e. at the memory address specified at input DATA via the ADR operator.

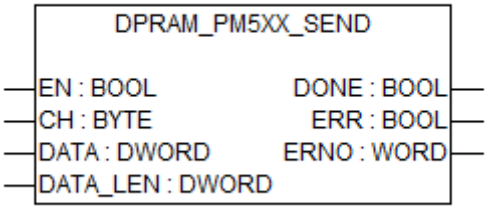
The function block is enabled by a TRUE signal at input EN. It remains active until input EN is set to FALSE. The channel of the AC500 CPU is specified at input CH. The data length (in bytes) to be sent is specified at input DATA_LEN.

Successful data transfer is indicated by DONE = TRUE and ERR = FALSE. The outputs ERR and ERNO indicate whether an error occurred during Function Block processing.

Sending data using the DPRAM_PM5XX_SEND function block is edge-triggered, i.e. each sending process is initiated by a FALSE/TRUE edge at input EN.

DPRAM message-based data exchange allows a maximum of 260 Bytes per message to be sent or received.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

CH

Data type	Default value	Range	Unit
BYTE	-	-	-

Input CH (channel) is used to specify the channel of the AC500 CPUs to be addressed.

Valid values: 1 and 2.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA is used to specify the address of the variable the user data are to be copied to. DATA must contain an address of a variable of the type ARRAY or STRUCT.

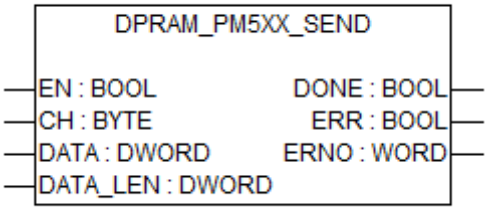
Specify the size of the variable according to the maximum amount of data expected in order to avoid memory area overlapping.

DATA_LEN

Data type	Default value	Range	Unit
WORD	-	-	Byte

Output DATA_LEN displays the length of the received data. The output value at DATA_LEN is only valid if DONE = TRUE.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

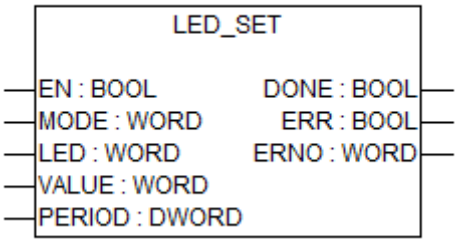
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
PM5xxSend (EN := PM5xxSend_EN,
SLOT := PM5xxSend_SLOT,
CH := PM5xxSend_CH,
DATA := ADR(PM5xxSend_DATA),
DATA_LEN := PM5xxSend_DATA_LEN,
DONE => PM5xxSend_DONE,
ERR => PM5xxSend_ERR,
ERNO => PM5xxSend_ERNO);
PM5xxSend_DONE := PM5xxSend.DONE;
PM5xxSend_ERR := PM5xxSend.ERR;
PM5xxSend_ERNO := PM5xxSend.ERNO;
```

LED_SET



Parameter	Value
Included in library	SysIntExt_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	LED

This function block is used to control the LED states of the AC500 PLCs. Using this function block it is possible to access each LED on the AC500 PLC and to change its state and blinking period.

Each LED has to be controlled individually.

The LED assignment depends on PLC type.

CM574:

1 : RUN LED

2 : ERROR LED

3 : COM1 Status LED

4 : COM2 Status LED

5 : READY LED

6 : STAT LED

PM57x, PM58x, PM59x:

1 : RUN LED

2 : ERROR LED

Eco:

1 : RUN LED

2 : ERROR LED

3 : COM1 Status LED

PM595:

1 : RUN LED (green only)

2 : ERROR LED (red only)

3 : CAN LED(green/red/orange)

8 : Batt State LED (green/red/orange)

9 : Function 1 LED (green/red/orange)

10 : Function 2 LED (green/red/orange)

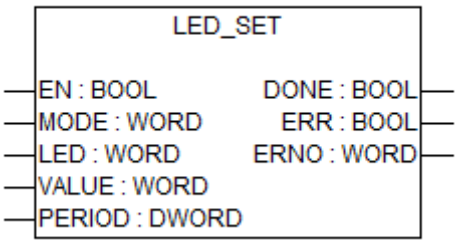
11 : Function 3 LED (green/red/orange)

12 : Function 4 LED (green/red/orange)

13 : Function 5 LED (green/red/orange)

If the LED should be controlled by the runtime system again, just switch the MODE back to 0. (MODE 0 = runtime system , MODE 1 = user program).

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Mode

Data type	Default value	Range	Unit
WORD	-	-	-

Access control for the LED:

MODE = 0 = runtime system

MODE = 1 = user program

LED

Data type	Default value	Range	Unit
WORD	-	-	-

Input LED is used to specify the LED:

CM574:

1 : RUN LED

2 : ERROR LED

3 : COM1 Status LED

4 : COM2 Status LED

5 : READY LED

6 : STAT LED

PM57x, PM58x, PM59x:

1 : RUN LED

2 : ERROR LED

Eco:

1 : RUN LED

2 : ERROR LED

3 : COM1 Status LED

PM595:

1 : RUN LED (green only)

2 : ERROR LED (red only)

3 : CAN LED (green/red/orange)

8 : Batt State LED (green/red/orange)

9 : Function 1 LED (green/red/orange)

10 : Function 2 LED (green/red/orange)

11 : Function 3 LED (green/red/orange)

12 : Function 4 LED (green/red/orange)

13 : Function 5 LED (green/red/orange)

VALUE

Data type	Default value	Range	Unit
WORD	-	-	-

Input VALUE is used to specify the static value of the LED. Only applicable if the LED is not in mode = 0.

Following values are possible:

0 = LED off

1 = LED on (Default colour used if applicable)

2 = LED on, green (only at PM595)

3 = LED on, red (only at PM595)

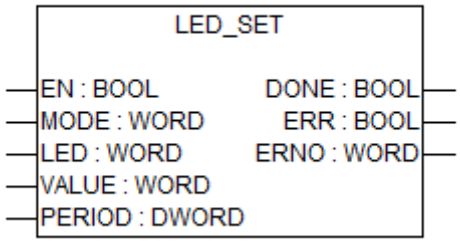
4 = LED on, orange (only at PM595)

PERIOD

Data type	Default value	Range	Unit
DWORD	-	-	ms

Input PERIOD is used to set the blinking period of the LED in ms.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
LedSet (EN := LedSet_EN,
MODE:= LedSet_MODE,
LED := LedSet_LED,
VALUE := LedSet_VALUE,
PERIOD := LedSet_PERIOD,
DONE => LedSet_DONE,
ERR => LedSet_ERR,
ERNO => LedSet_ERNO);
LedSet_DONE := LedSet.DONE;
LedSet_ERR := LedSet.ERR;
LedSet_ERNO := LedSet.ERNO;
```

1.5.4.21 JSON library

1.5.4.21.1 System technology

JSON is an acronym for *“JavaScript Object Notation”*. It is a compact data format that is often used to transfer data between clients and a server (e. g. via MQTT). JSON has arisen from JavaScript, whereby many implementations for several programming languages exist.

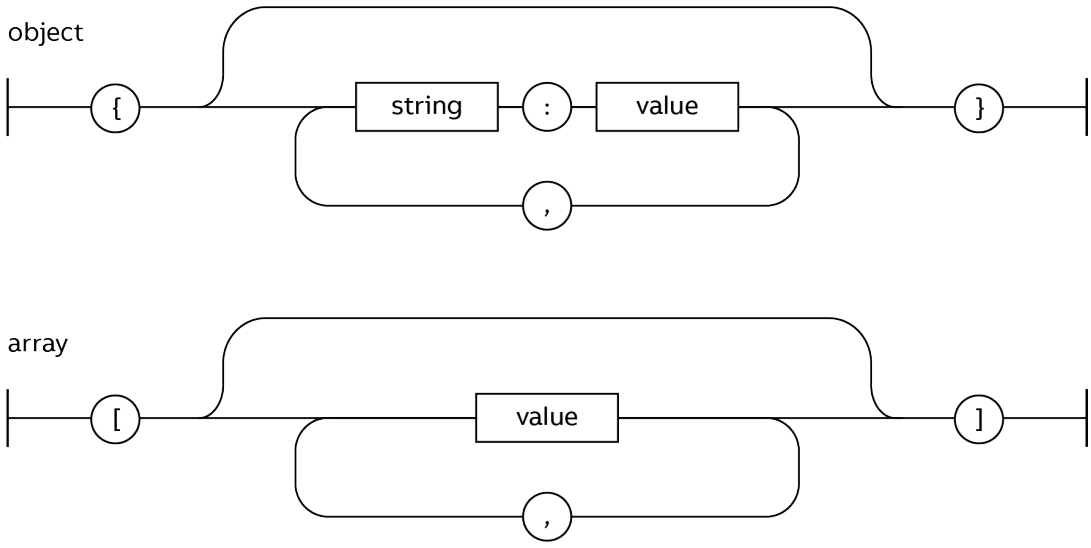
JSON embeds several data types as *“values”* into either *“JSON OBJECTS”* or *“JSON ARRAYS”*.

In objects each value is identified by a key string, while arrays make values accessible via indices.

JSON also allows the nesting of objects and arrays as values providing a recursive parent-child hierarchy.

The possible types for a value are namely: *“string”*, *“number”*, *“object”* and *“array”*. Values can also consist of the constants `true`, `false` and `null`.

The following figure displays the structure of JSON objects and arrays. Detailed information on the JSON format is given at *https://www.json.org*.



The use of the JSON library allows creating and parsing of JSON strings without manual string operations and detailed knowledge about JSON syntax. This reduces the risk of data transfer errors, as syntax of JSON strings will always be correct.

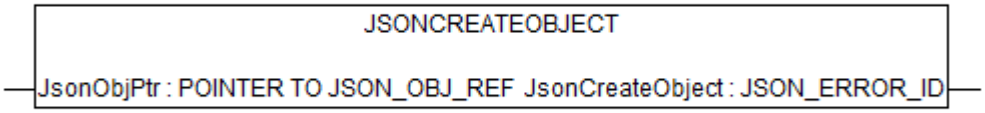
To realize those benefits, there are functions implemented in the JSON library.

A detailed description for each function is given in the section *Chapter 1.5.4.21.2 “Function block description” on page 1647*.

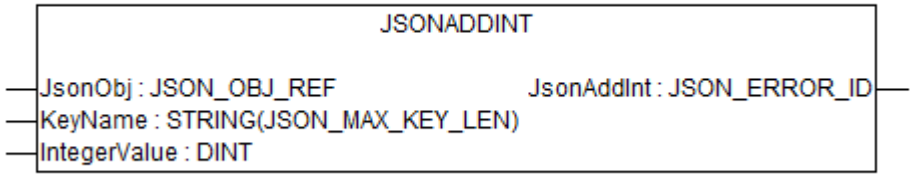
Creating and sending

One JSON create and send use case could look like this:

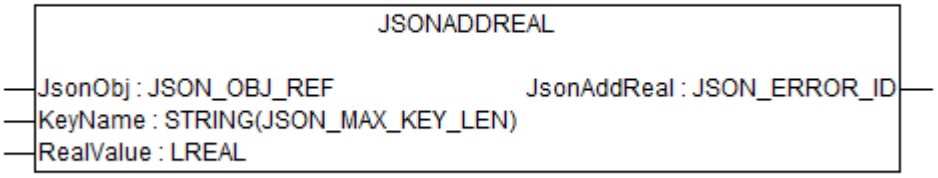
1. Create an empty JSON object with the function block *"JSONCREATEOBJECT"*.



2. Add a sender ID with the function block *"JSONADDINT"*.

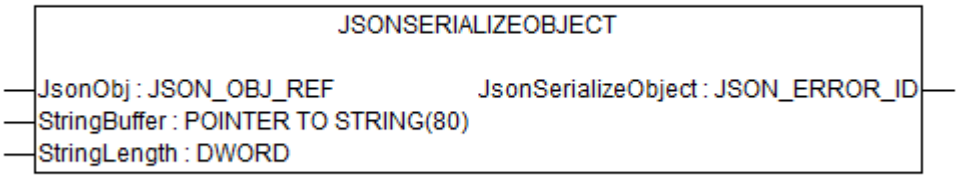


3. Add a telemetry value (i.e. "temperature":21.0) with the function block *"JSONADDREAL"*.

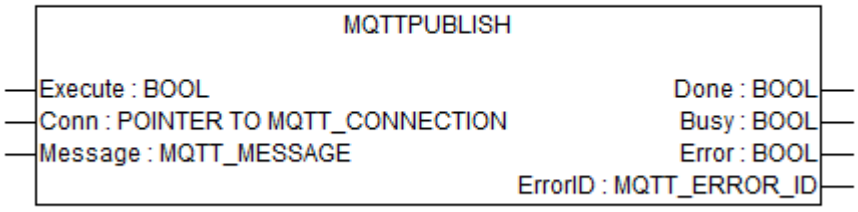


4. Serialize the created object into a string for sending with the function block *"JSONSERIALIZEOBJECT"*

.



5. Send the JSON string for instance to a MQTT broker with the function block *"MQTTPUBLISH"*.

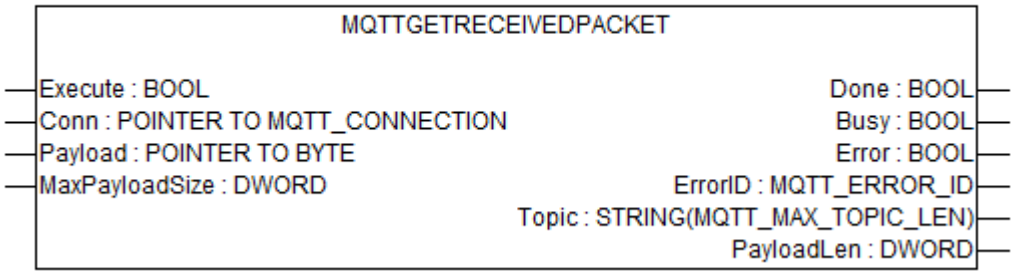


6. If no longer needed, free the created JSON object.

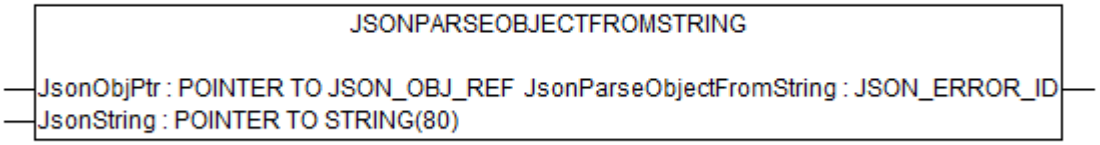
Receiving and parsing

One JSON receive and parse use case could look like this:

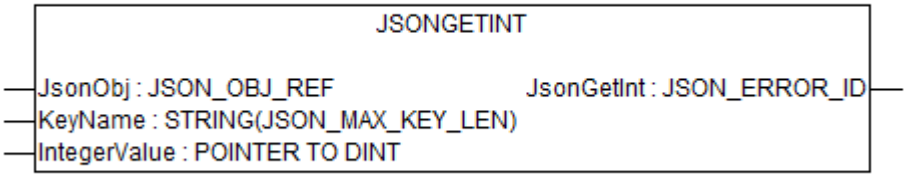
1. Receive a JSON string for instance from a MQTT broker with the function block *"MQTTGETRECEIVEDPACKET"*.



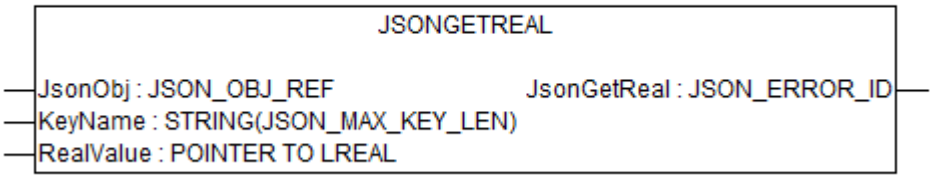
2. Parse the received string into a JSON object with the function block *"JSONPARSEOBJECTFROMSTRING"*.



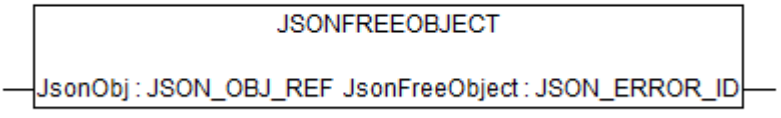
3. Get the ID of the sender with the function block *"JSONGETINT"*.



4. Get settings for the PLC (i.e. "frequency":2.7) with the function block JSONGETREAL.



5. If no longer needed, free the created JSON object.



Configuration in Automation Builder

For the JSON library no special configuration is needed.

Task configuration in CODESYS

All functions have to be called in tasks with cyclically processing.

Limitations

- Function calls are synchronous. Processing large objects might stall the execution of the task.
- The maximum length of each JSON key is limited to 100 characters (see *“JSON_MAX_KEY_LEN”* constant).
- The maximum recursion level for the nesting of JSON OBJECTS and JSON ARRAYS is limited to a depth of 64.

Functions

The functions in this library can only be executed in RUN mode of the processor module, not in simulation mode.

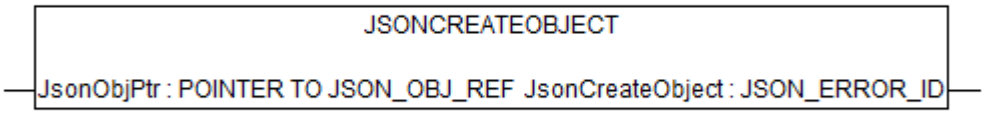
Standard

JSON library is based on *[RFC 8259]*.

1.5.4.21.2 Function block description

JSON object functions

JSONCREATEOBJECT

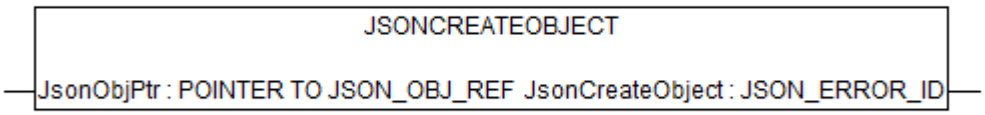


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function *"JSONCREATEOBJECT"* creates an empty JSON OBJECT. This function allocates memory for the new OBJECT. The new OBJECT reference is assigned to the given pointer.

Input description



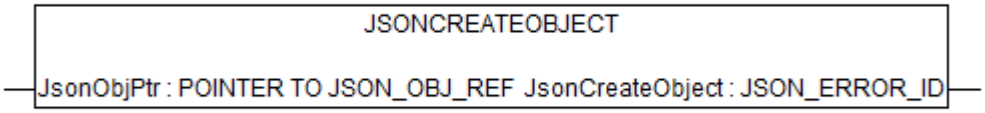
JsonObjPtr

Data type	Default value	Range	Unit
POINTER TO JSON_OBJ_REF	-	-	-

The pointer to a JSON OBJECT reference to assign the new OBJECT.

In case of any error, the data at the provided pointer stays unchanged.

Output description

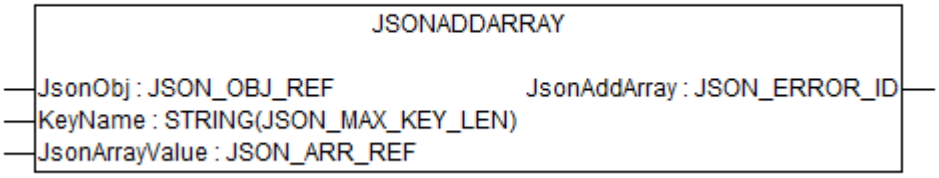


JsonCreate Object

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONADDARRAY

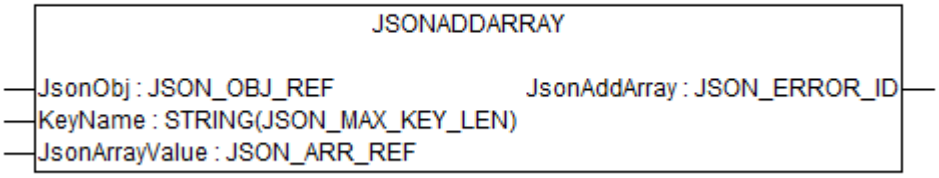


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONADDARRAY nests a JSON ARRAY reference to a JSON OBJECT. The given JSON ARRAY is not copied into the OBJECT, only meta information is added. The JSON ARRAY will be identified under the provided key name. If the key value pair already exists, the value gets replaced by the JSON ARRAY. Memory of the old value gets freed in the replacement.

Input Description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT to which the JSON ARRAY is added.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

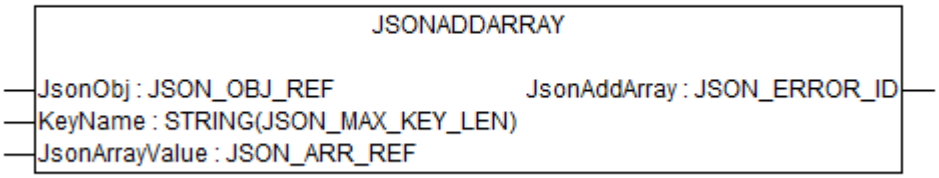
The key string by which the added JSON ARRAY is identified.

JsonArrayValue

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the JSON ARRAY which gets inserted.

Output Description

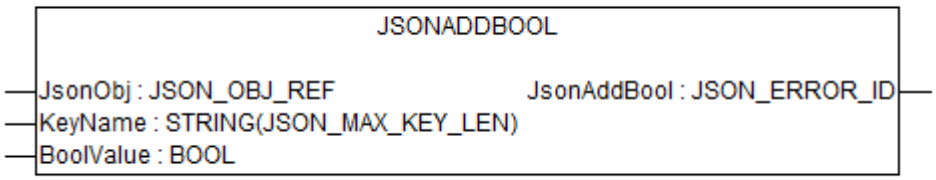


JsonAddArray

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONADDBOOL

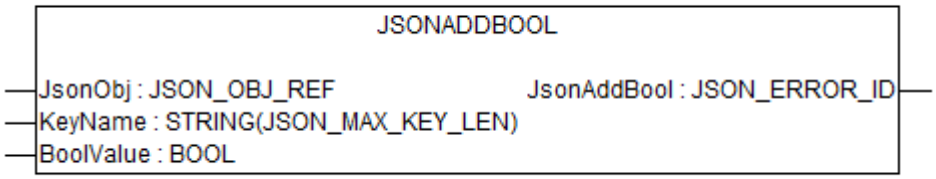


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONADDBOOL adds a BOOLEAN value to a JSON OBJECT. The given BOOLEAN is copied into the OBJECT. The BOOLEAN will be identified under the provided key name. If the key value pair already exists, the value gets replaced by the BOOLEAN. Memory of the old value gets freed in the replacement.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT to which the BOOLEAN value is added.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

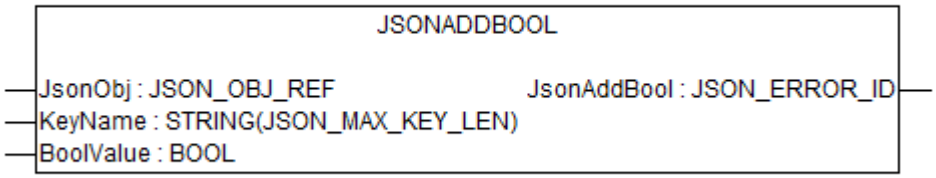
The key string by which the added BOOLEAN is identified.

BoolValue

Data type	Default value	Range	Unit
BOOL	-	-	-

The BOOLEAN value which gets added.

Output description

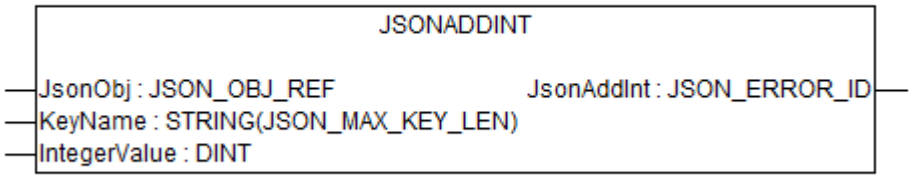


JsonAddBool

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONADDINT

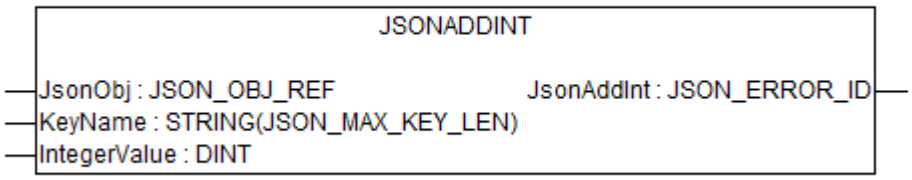


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONADDINT adds an INTEGER value to a JSON OBJECT. The given INTEGER is copied into the OBJECT. The INTEGER will be identified under the provided key name. If the key value pair already exists, the value gets replaced by the INTEGER. Memory of the old value gets freed in the replacement.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT to which the INTEGER value is added.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

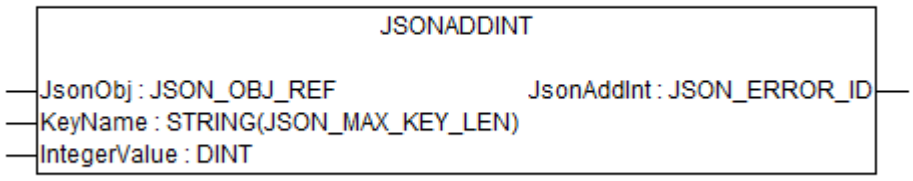
The key string by which the added INTEGER is identified.

IntegerValue

Data type	Default value	Range	Unit
DINT	-	-	-

The INTEGER value which gets added. The input is DINT. In case an INT variable in CODESYS is added the function INT_TO_DINT has to be used.

Output description

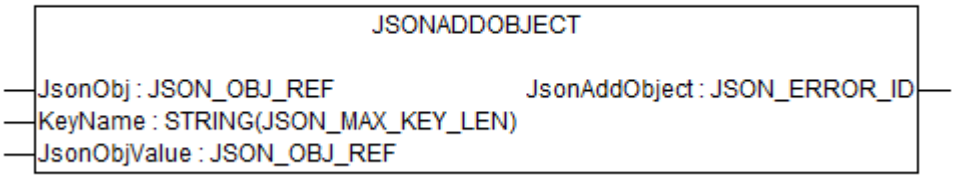


JsonAddInt

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONADDOBJECT

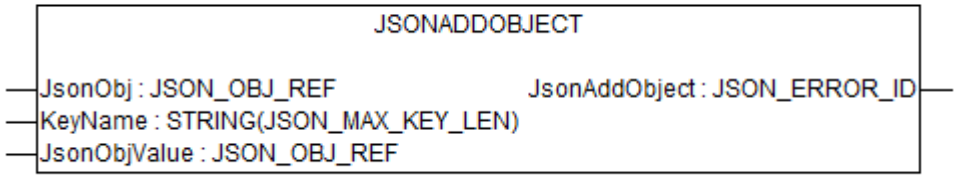


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONADDOBJECT nests a JSON OBJECT reference to another JSON OBJECT. The child JSON OBJECT is not copied into the parent JSON OBJECT, only meta information is added. The child JSON OBJECT will be identified under the provided key name. If the key value pair already exists, the value gets replaced by the new JSON OBJECT. Memory of the old value gets freed in the replacement.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the parent JSON OBJECT to which the child JSON OBJECT is added.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

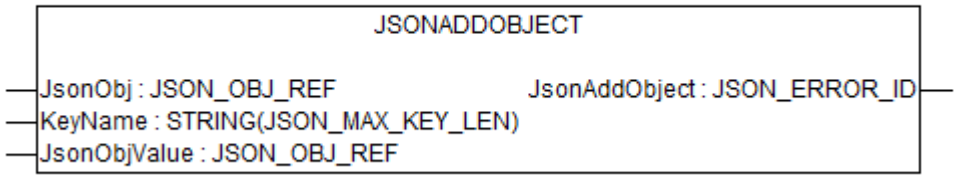
The key string by which the added child JSON OBJECT is identified.

JsonObjValue

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The child JSON OBJECT which gets added.

Output description

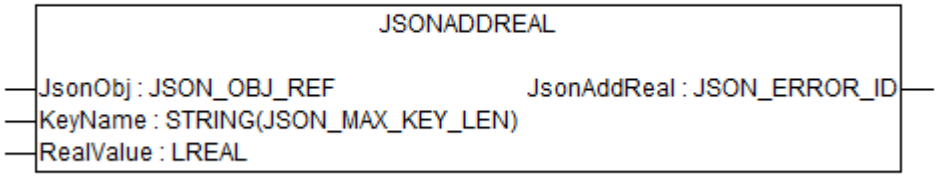


JsonAddObject

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONADDREAL

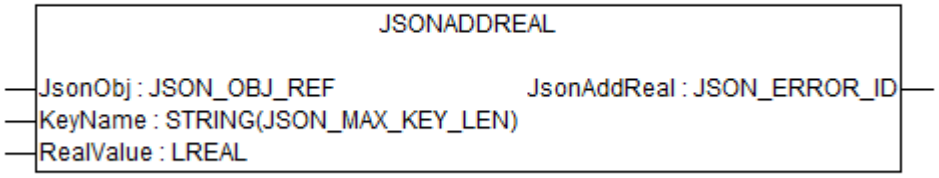


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONADDREAL adds a REAL value to a JSON OBJECT. The given REAL is copied into the OBJECT. The REAL will be identified under the provided key name. If the key value pair already exists, the value gets replaced by the REAL. Memory of the old value gets freed in the replacement.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT to which the REAL value is added.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

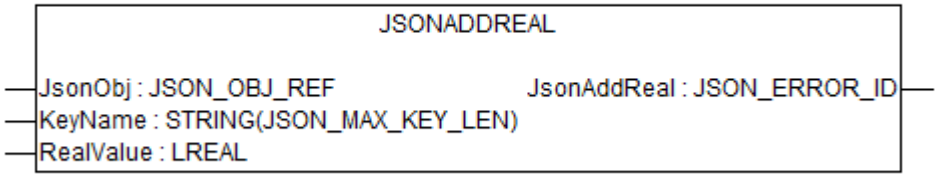
The key string by which the added REAL is identified.

RealValue

Data type	Default value	Range	Unit
LREAL	-	-	-

The REAL value which gets added. The input is LREAL. In case a REAL variable in CODESYS is added the function REAL_TO_LREAL has to be used.

Output description

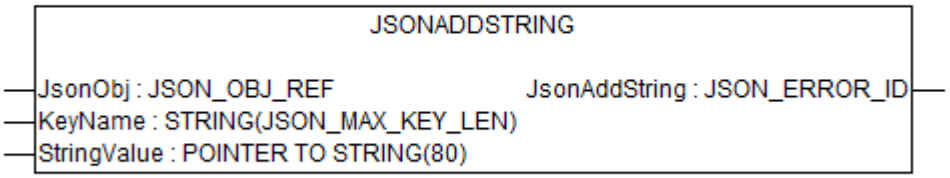


JsonAddReal

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONADDSTRING

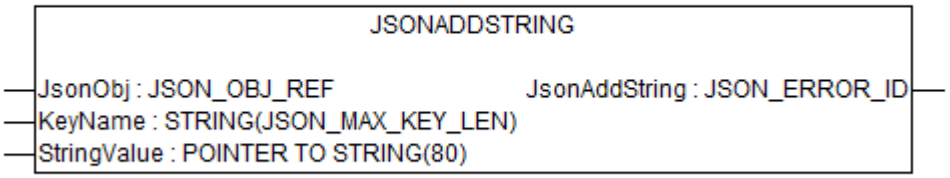


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONADDSTRING adds a STRING value to a JSON OBJECT. The given STRING is copied into an internal buffer of the OBJECT. The STRING will be identified under the provided key name. If the key value pair already exists, the value gets replaced by the STRING. Memory of the old value gets freed in the replacement. Different from the function figure, STRING values are allowed to have any viable length, including STRING that are longer than 80 characters.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT to which the STRING value is added.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

The key string by which the added STRING is identified.

StringValue

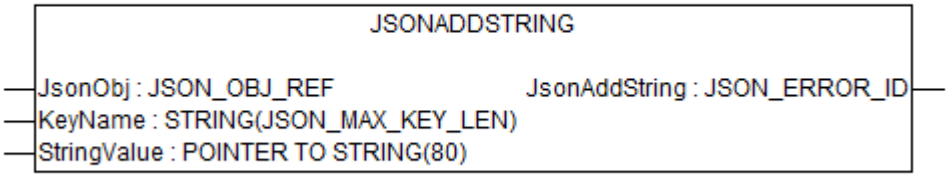
Data type	Default value	Range	Unit
POINTER TO STRING(80)	-	-	-

The pointer to a STRING value which gets added.

Contrary to the figure the STRING value is not limited to 80 characters.

Strings of any viable length can be provided.

Output description

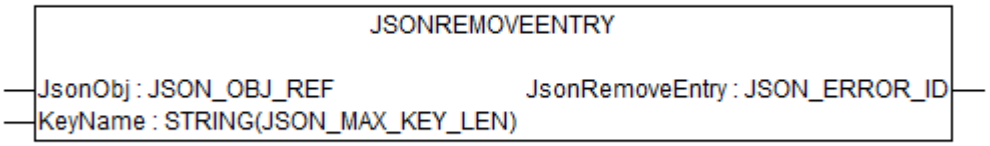


JsonAddString

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONREMOVEENTRY

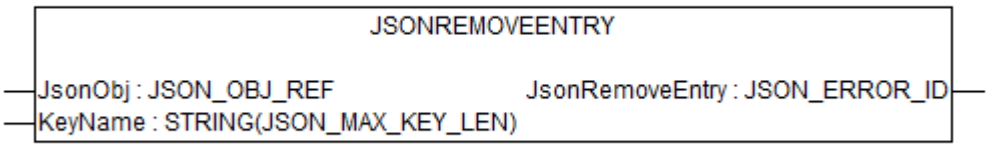


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONREMOVEENTRY removes a JSON value from a JSON OBJECT, that is identified by the given key name. All memory used by that value is freed. If the entry contains a JSON OBJECT or JSON ARRAY all contained recursive entries get freed as well.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

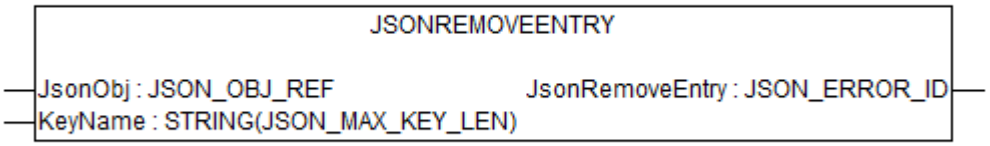
The reference to the JSON OBJECT from which the value is removed.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

The key string by which the removed JSON value is identified.

Output description

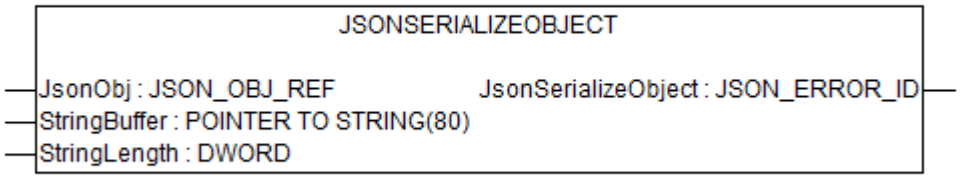


JsonRemoveEntry

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONSERIALIZEOBJECT

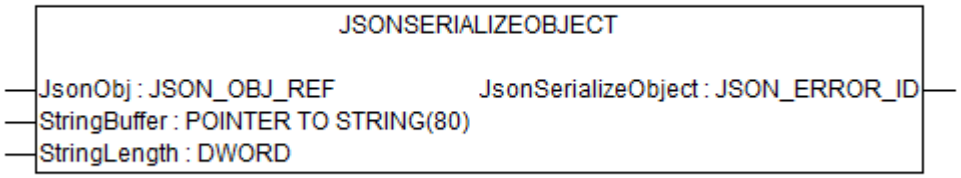


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONSERIALIZEOBJECT serializes a JSON OBJECT into a given STRING buffer. Different from the figure, the STRING buffer is allowed to have any viable length, including STRINGS that are longer than 80 characters.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT which is serialized.

StringBuffer

Data type	Default value	Range	Unit
POINTER TO STRING(80)	-	-	-

The pointer to a STRING buffer which is the target of the serialization.

> *Contrary to the figure the STRING buffer is not limited to 80 characters.*
>
> *STRING buffers of any viable length can be provided.*
>
> *No memory will be acquired so a target buffer has to be provided.*

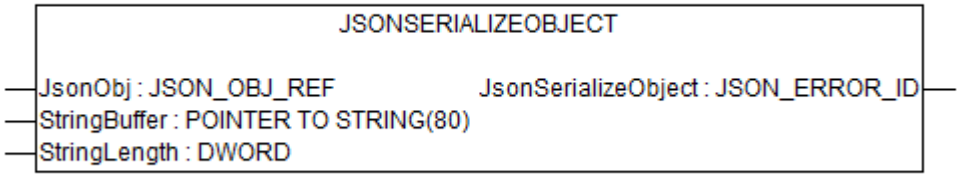
StringLength

Data type	Default value	Range	Unit
DWORD	-	-	-

The StringLength parameter specifies the limit of the provided STRING buffer.

If the size of the STRING buffer is not sufficient to contain the JSON OBJECT representation, the buffer stays unchanged.

Output description



JsonSerialize Object

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONFREEOBJECT

General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONFREEOBJECT frees all memory used by a JSON OBJECT. All recursively contained JSON OBJECTS and JSON ARRAYS are freed as well.

Input description

JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT which is freed. After the function returned without error, this reference becomes invalid.

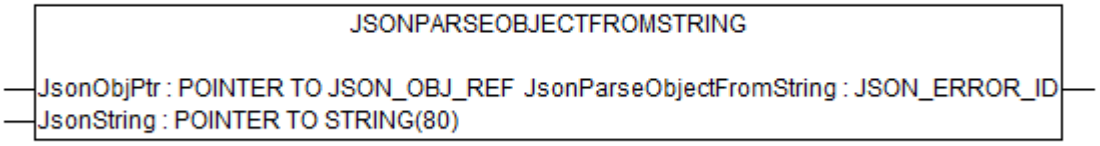
Output description

JsonFreeObject

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONPARSEOBJECTFROMSTRING

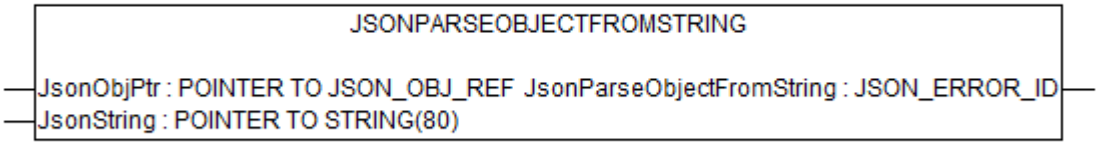


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONPARSEOBJECTFROMSTRING parses a STRING, which represents a JSON OBJECT and creates a corresponding OBJECT from it. The new OBJECT contains all values from the STRING representation. The function expects a reference to a JSON OBJECT to assign the new OBJECT.

Input description



JsonObjPtr

Data type	Default value	Range	Unit
POINTER TO JSON_OBJ_REF	-	-	-

The pointer to a JSON OBJECT reference to assign the parsed OBJECT.

In case of any error, the data at the provided pointer stays unchanged.

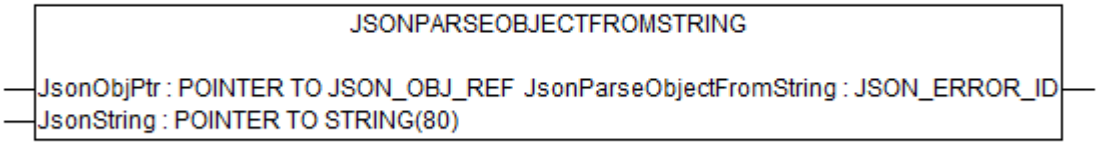
JsonString

Data type	Default value	Range	Unit
POINTER TO STRING(80)	-	-	-

JsonString is a pointer to a STRING representing a JSON OBJECT.

> *Contrary to the figure the STRING buffer is not limited to 80 characters.*
> *Strings of any viable length can be provided.*

Output description

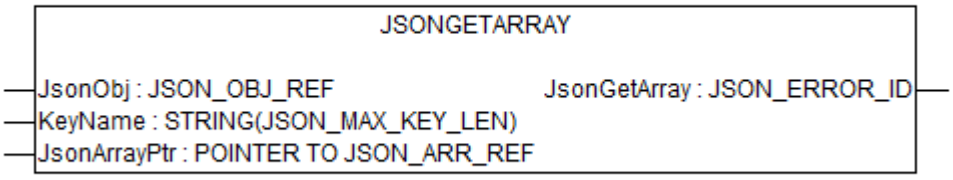


JsonParse ObjectFrom String

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONGETARRAY

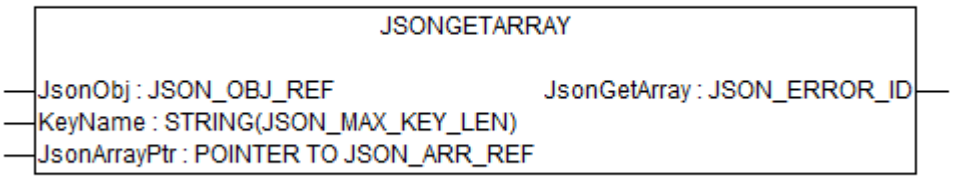


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONGETARRAY gets a JSON ARRAY identified by a key name from a JSON OBJECT. The ARRAY is not copied, only a reference is retrieved. This reference is assigned to the given pointer.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT from which the JSON ARRAY is retrieved.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

The key string which identifies the retrieved JSON ARRAY.

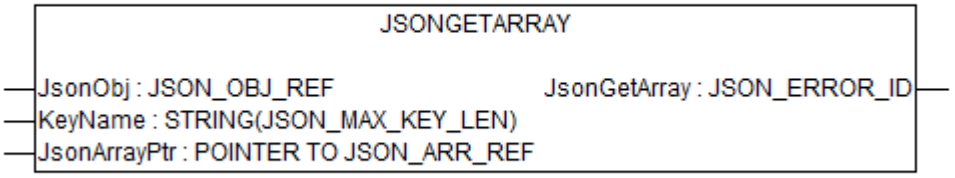
JsonArrayPtr

Data type	Default value	Range	Unit
POINTER TO JSON_ARR_REF	-	-	-

The pointer to a JSON ARRAY to assign the retrieved ARRAY reference.

In case of any error, the data at the provided pointer stays unchanged.

Output description

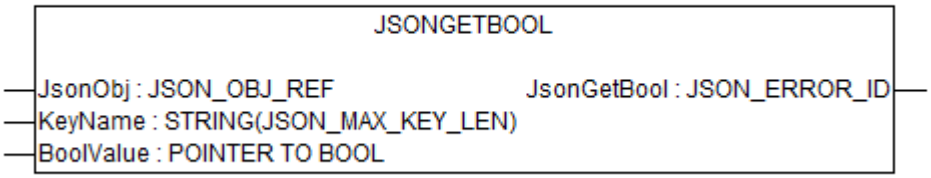


JsonGetArray

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONGETBOOL

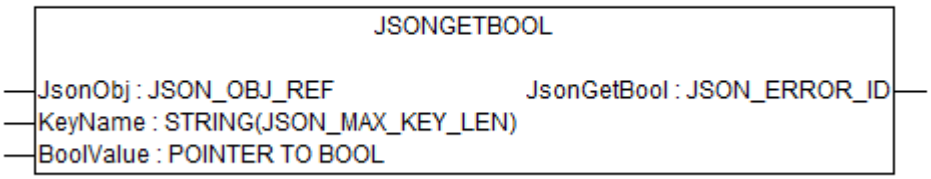


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONGETBOOL gets a BOOLEAN value identified by a key name from a JSON OBJECT. The retrieved value is assigned to the given pointer.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT from which the BOOLEAN value is retrieved.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

The key string by which identifies the retrieved BOOLEAN value.

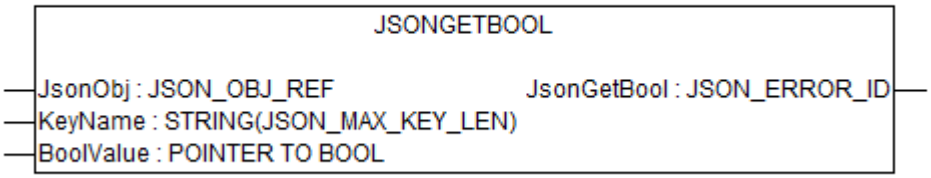
BoolValue

Data type	Default value	Range	Unit
POINTER TO BOOL	-	-	-

The pointer to a BOOLEAN variable to assign the retrieved value.

In case of any error, the data at the provided pointer stays unchanged.

Output description

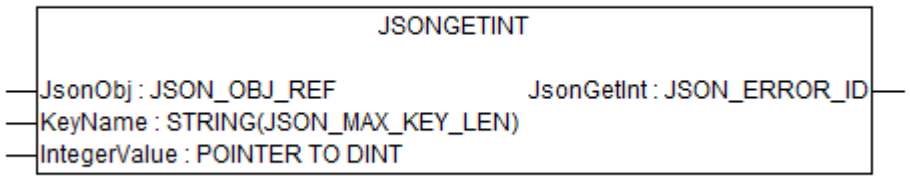


JsonGetBool

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONGETINT

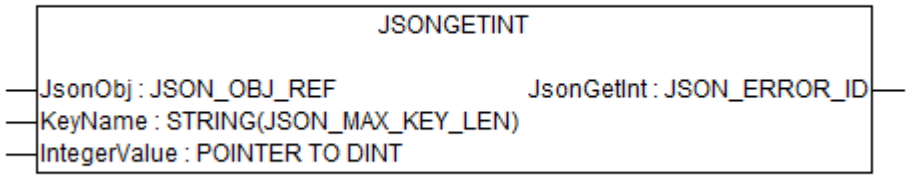


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONGETINT gets an INTEGER value identified by a key name from a JSON OBJECT. The retrieved value is assigned to the given pointer.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT from which the INTEGER value is retrieved.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

The key string which identifies the retrieved INTEGER value.

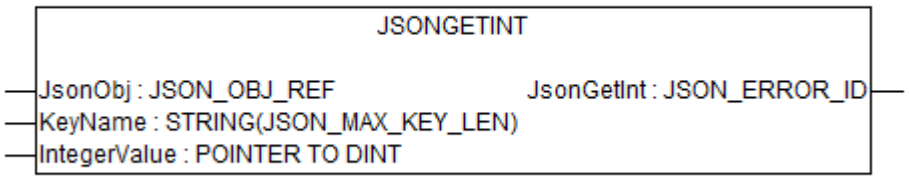
IntegerValue

Data type	Default value	Range	Unit
POINTER TO DINT	-	-	-

The pointer to an INTEGER variable to assign the retrieved value. In CODESYS a DINT variable has to be used.

In case of any error, the data at the provided pointer stays unchanged.

Output description

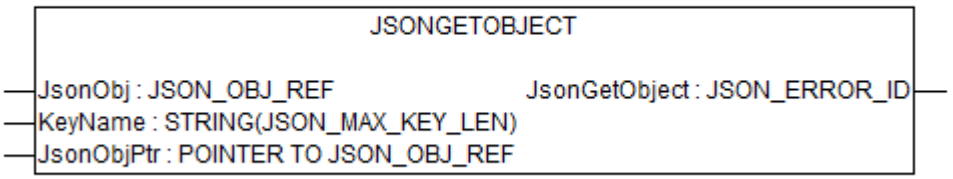


JsonGetInt

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONGETOBJECT

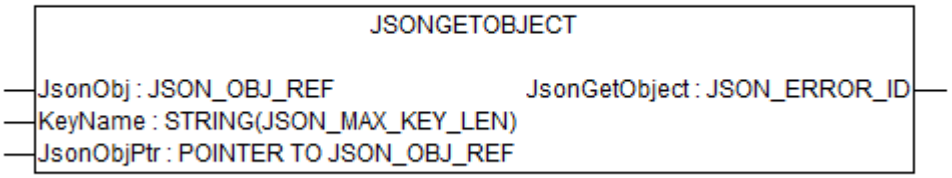


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONGETOBJECT gets a nested child JSON OBJECT identified by a key name from a parent JSON OBJECT. The OBJECT is not copied, only a reference is retrieved. This reference is assigned to the given pointer.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the parent JSON OBJECT from which the child JSON OBJECT is retrieved.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

The key string which identifies the retrieved child JSON OBJECT.

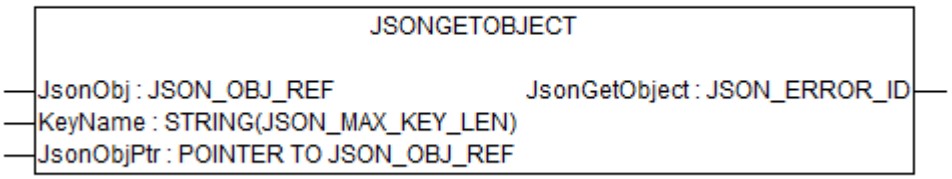
JsonObjPtr

Data type	Default value	Range	Unit
POINTER TO JSON_OBJ_REF	-	-	-

The pointer to a JSON OBJECT to assign the retrieved child OBJECT reference.

In case of any error, the data at the provided pointer stays unchanged.

Output description

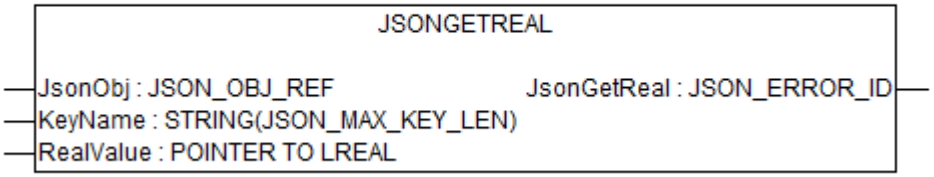


JsonGetObject

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONGETREAL

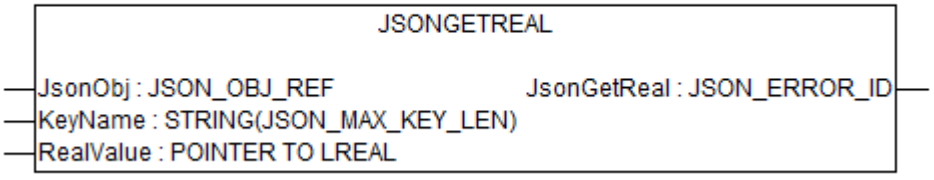


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONGETREAL gets a REAL value identified by a key name from a JSON OBJECT. The retrieved value is assigned to the given pointer.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT from which the REAL value is retrieved.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

The key string which identifies the retrieved REAL value.

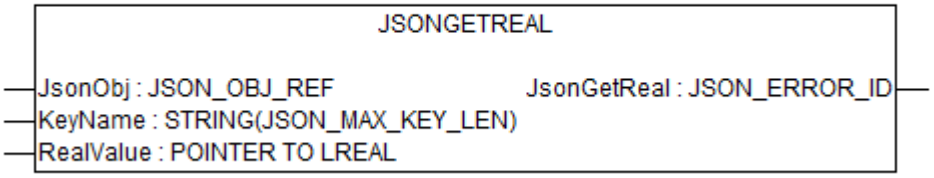
RealValue

Data type	Default value	Range	Unit
POINTER TO LREAL	-	-	-

The pointer to a REAL variable to assign the retrieved value. In CODESYS a LREAL variable has to be used.

In case of any error, the data at the provided pointer stays unchanged.

Output description

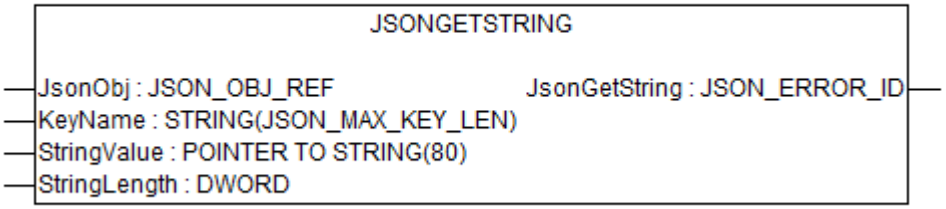


JsonGetReal

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONGETSTRING

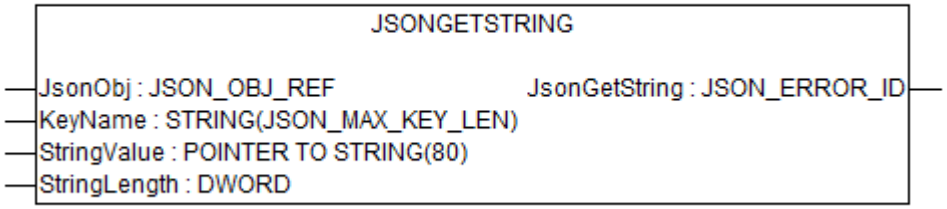


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONGETSTRING gets a STRING value identified by a key name from a JSON OBJECT. The STRING value is copied to the given pointer.

Input description



JsonObj

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The reference to the JSON OBJECT from which the STRING value is retrieved.

KeyName

Data type	Default value	Range	Unit
STRING(JSON_ MAX_KEY_LEN)	-	-	-

The key string which identifies the retrieved STRING value.

StringValue

Data type	Default value	Range	Unit
POINTER TO STRING(80)	-	-	-

The pointer to a STRING buffer to copy the retrieved value.

Contrary to the figure the STRING value is not limited to 80 characters.
STRING buffers of any viable length can be provided.

In case of any error, the data at the provided pointer stays unchanged.

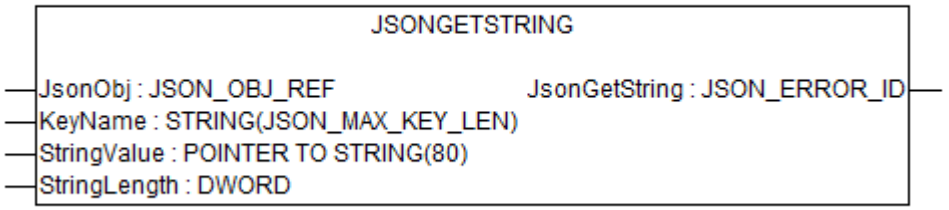
StringLength

Data type	Default value	Range	Unit
DWORD	-	-	-

The StringLength parameter specifies the limit of the provided STRING value.

If the size of the STRING value is not sufficient, it stays unchanged.

Output description



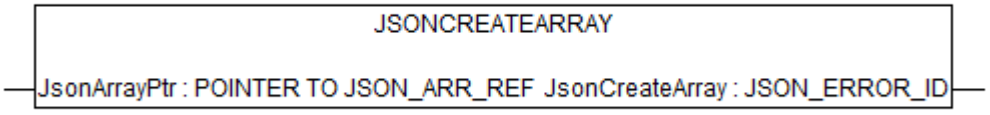
JsonGetString

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSON array functions

JSONCREATEARRAY

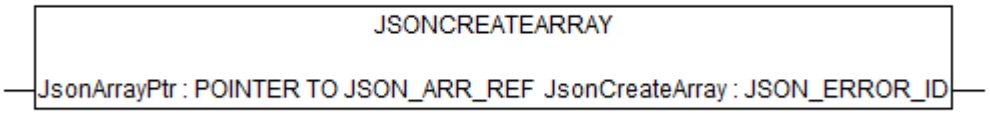


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function *"JSONCREATEARRAY"* creates an empty JSON ARRAY. This function allocates memory for the new ARRAY. The new ARRAY reference is assigned to the given pointer.

Input description



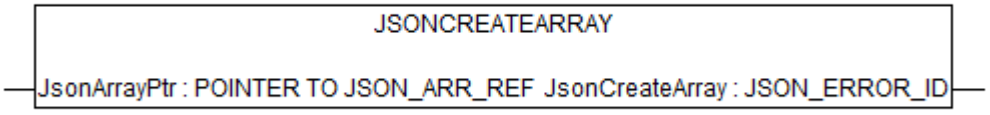
JsonArrayPtr

Data type	Default value	Range	Unit
POINTER TO JSON_ARR_REF	-	-	-

The pointer to a JSON ARRAY reference to assign the new ARRAY.

In case of any error, the data at the provided pointer stays unchanged.

Output description

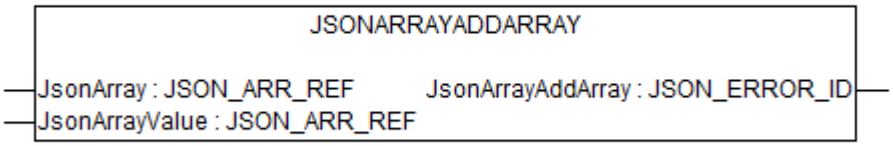


JsonCreateArray

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYADDARRAY

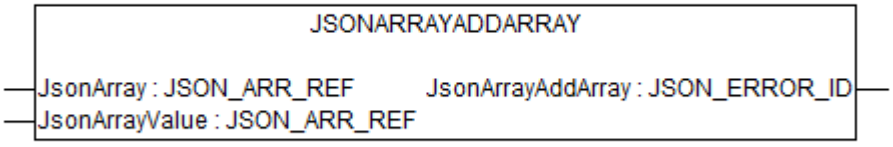


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYADDARRAY nests a JSON ARRAY reference to another JSON ARRAY. The child JSON ARRAY is not copied into the parent JSON ARRAY, only meta information is appended. The child JSON ARRAY will be identified by the last index after insertion.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

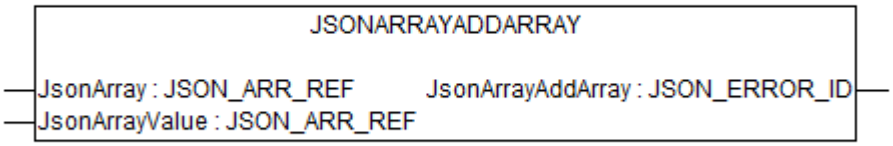
The reference to the parent JSON ARRAY to which the child JSON ARRAY is appended.

JsonArrayValue

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The child JSON ARRAY which gets appended.

Output description

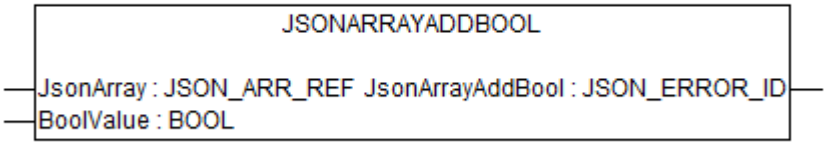


JsonArrayAddArray

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYADDBOOL

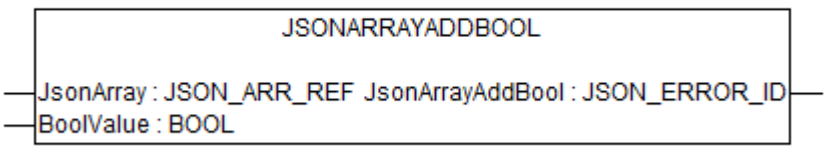


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYADDBOOL adds a BOOLEAN value to a JSON ARRAY. The given BOOLEAN is copied into the ARRAY. The BOOLEAN will be identified by the last index after insertion.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

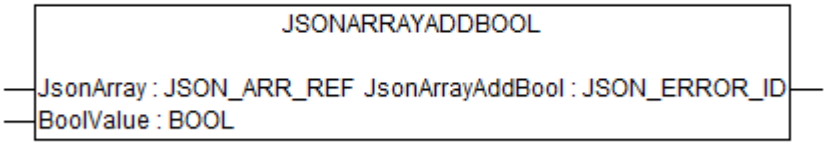
The reference to the JSON ARRAY to which the BOOLEAN is appended.

BoolValue

Data type	Default value	Range	Unit
BOOL	-	-	-

The BOOLEAN value which gets appended.

Output description

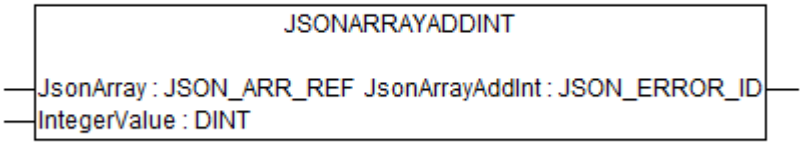


JsonArrayAdd Bool

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYADDINT

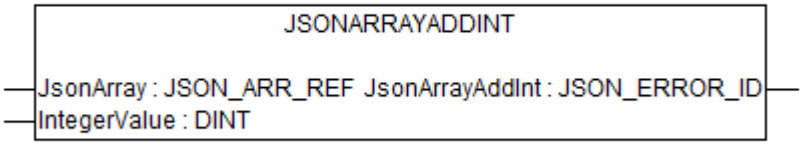


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYADDINT adds an INTEGER value to a JSON ARRAY. The given INTEGER is copied into the ARRAY. The INTEGER will be identified under the provided key name. If the key value pair already exists, the value gets replaced by the INTEGER. Memory of the old value gets freed in the replacement.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

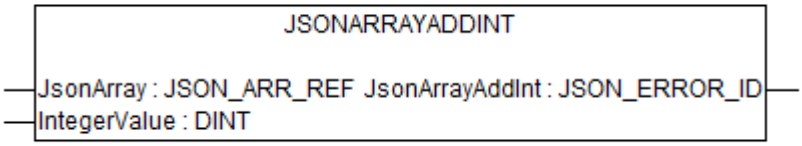
The reference to the JSON ARRAY to which the INTEGER is appended.

IntegerValue

Data type	Default value	Range	Unit
DINT	-	-	-

The INTEGER value which gets appended. The input is DINT. In case an INT variable in CODESYS is appended the function INT_TO_DINT has to be used.

Output description

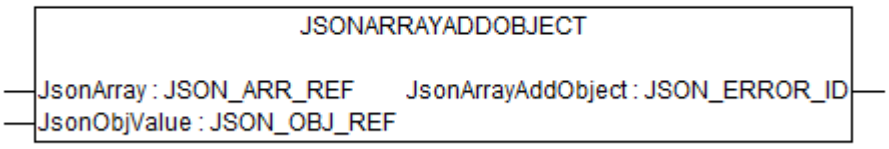


JsonArrayAddInt

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYADDOBJECT

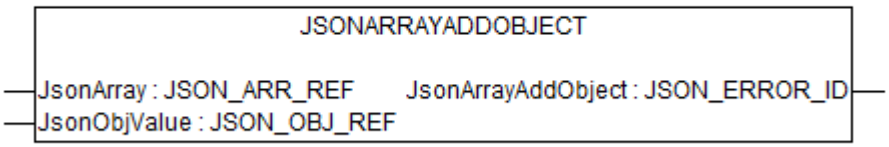


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYADDOBJECT nests a JSON OBJECT reference to a JSON ARRAY. The JSON OBJECT is not copied into the JSON ARRAY, only meta information is appended. The JSON OBJECT will be identified by the last index after insertion.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

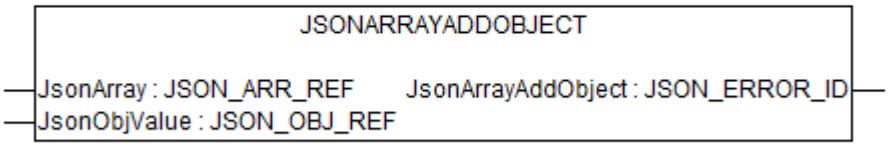
The reference to the JSON ARRAY to which the JSON OBJECT is appended.

JsonObjValue

Data type	Default value	Range	Unit
JSON_OBJ_REF	-	-	-

The JSON OBJECT reference which gets appended.

Output description

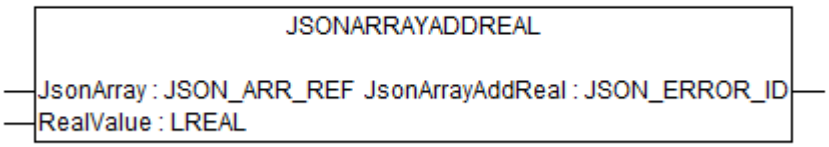


JsonArrayAdd Object

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYADDREAL

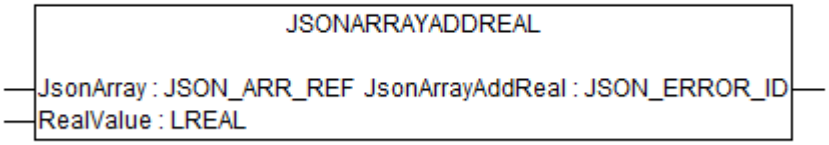


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYADDREAL adds a REAL value to a JSON ARRAY. The given REAL is copied into the ARRAY. The REAL will be identified by the last index after insertion.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

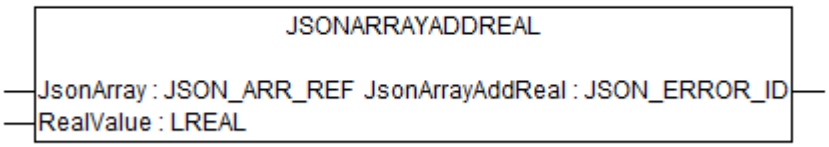
The reference to the JSON ARRAY to which the REAL is appended.

RealValue

Data type	Default value	Range	Unit
LREAL	-	-	-

The REAL value which gets appended. The input is LREAL. In case a REAL variable in CODESYS is appended the function REAL_TO_LREAL has to be used.

Output description

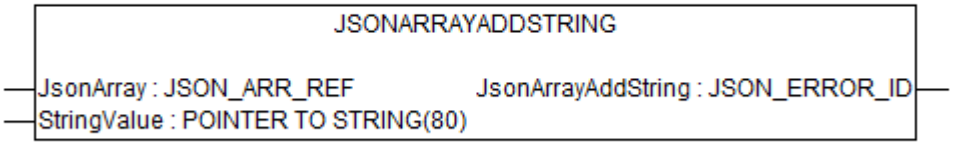


JsonArrayAddReal

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYADDSTRING

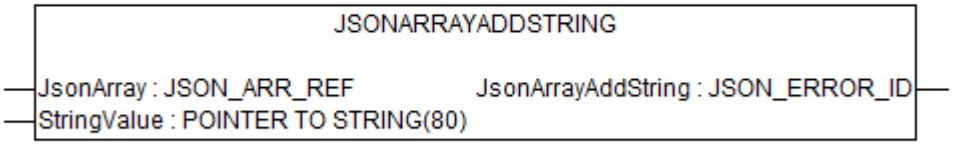


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYADDSTRING adds a STRING value to a JSON ARRAY. The given STRING is copied into an internal buffer of the ARRAY. The STRING will be identified by the last index after insertion. Different from the function figure, STRING values are allowed to have any viable length, including STRINGS that are longer than 80 characters.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the JSON ARRAY to which the STRING value is appended.

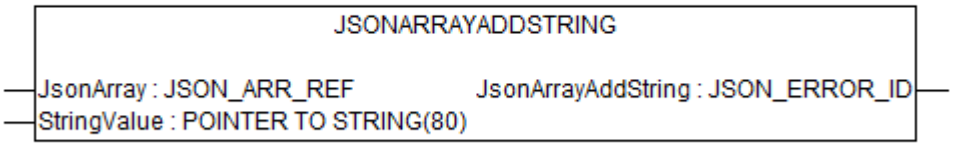
StringValue

Data type	Default value	Range	Unit
POINTER TO STRING(80)	-	-	-

The pointer to a STRING value which gets appended.

Contrary to the figure the STRING value is not limited to 80 characters.
Strings of any viable length can be provided.

Output description

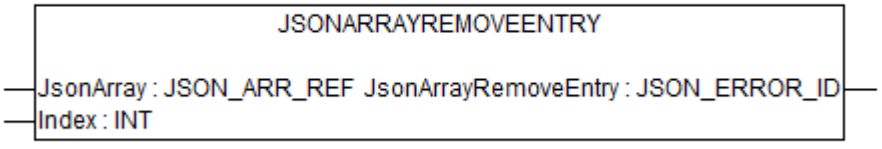


JsonArrayAdd String

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYREMOVEENTRY

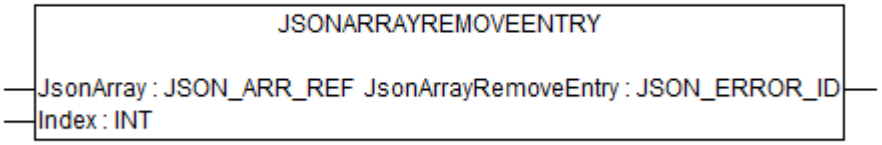


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYREMOVEENTRY removes a JSON value from a JSON ARRAY, that is identified by the given key name. All memory used by that value is freed. If the entry contains a JSON OBJECT or JSON ARRAY all contained recursive entries get freed as well.

Input description

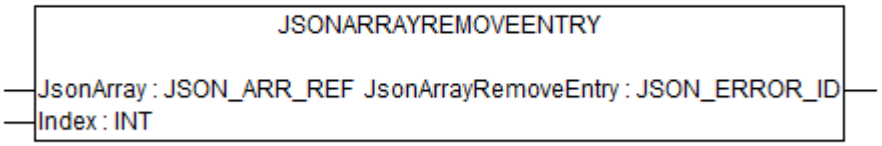


JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the JSON ARRAY from which the value is removed.

Output description

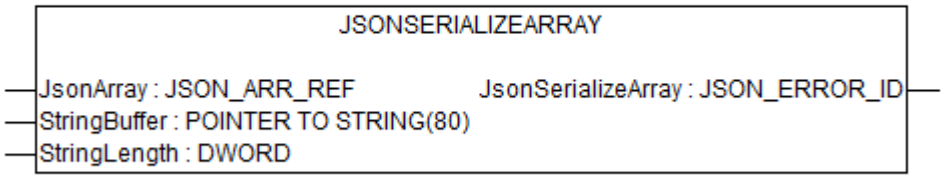


JsonArray RemoveEntry

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONSERIALIZEARRAY

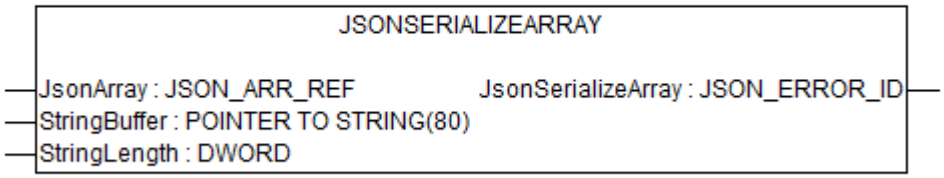


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONSERIALIZEARRAY serializes a JSON ARRAY into a given STRING buffer. Different from the figure, the STRING buffer is allowed to have any viable length, including STRINGS that are longer than 80 characters.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the JSON ARRAY which is serialized.

StringBuffer

Data type	Default value	Range	Unit
POINTER TO STRING(80)	-	-	-

The pointer to a STRING buffer which is the target of the serialization.

> *Contrary to the figure the STRING buffer is not limited to 80 characters.*
>
> *STRING buffers of any viable length can be provided.*
>
> *No memory will be acquired so a target buffer has to be provided.*

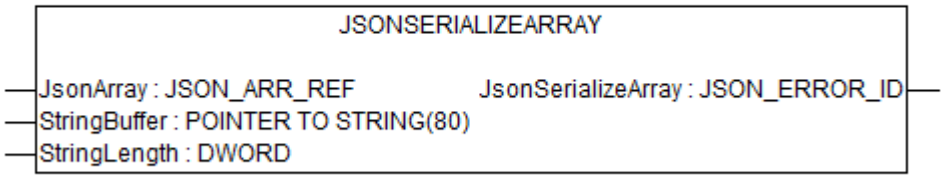
StringLength

Data type	Default value	Range	Unit
DWORD	-	-	-

The StringLength parameter specifies the limit of the provided STRING buffer.

If the size of the STRING buffer is not sufficient to contain the JSON ARRAY representation, the buffer stays unchanged.

Output description

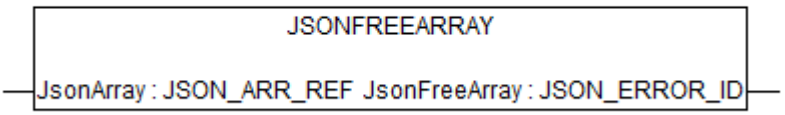


JsonSerialize Object

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONFREEARRAY

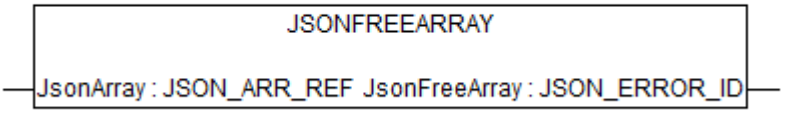


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONFREEOBJECT frees all memory used by a JSON OBJECT. All recursively contained JSON OBJECTS and JSON ARRAYS are freed as well.

Input description

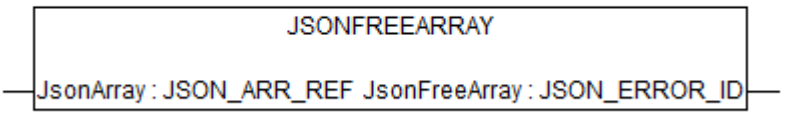


JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the JSON ARRAY which is freed. After the function returned without error, this reference becomes invalid.

Output description

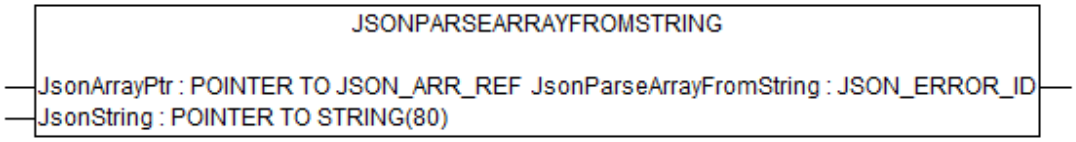


JsonFreeArray

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONPARSEARRAYFROMSTRING

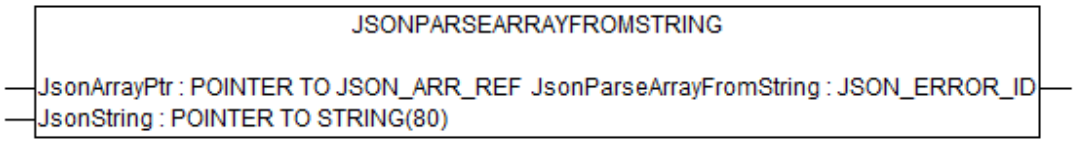


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONPARSEARRAYFROMSTRING parses a STRING, which represents a JSON ARRAY and creates a corresponding ARRAY from it. The new ARRAY contains all values from the STRING representation. The function expects a reference to a JSON ARRAY to assign the new ARRAY.

Input description



JsonArrayPtr

Data type	Default value	Range	Unit
POINTER TO JSON_ARR_REF	-	-	-

The pointer to a JSON ARRAY reference to assign the parsed ARRAY.

In case of any error, the data at the provided pointer stays unchanged.

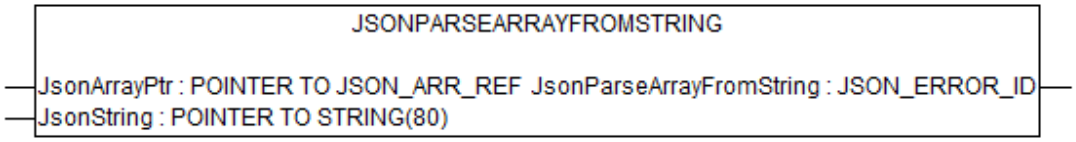
JsonString

Data type	Default value	Range	Unit
POINTER TO STRING(80)	-	-	-

JsonString is a pointer to a STRING representing a JSON ARRAY.

> *Contrary to the figure the STRING buffer is not limited to 80 characters.*
> *Strings of any viable length can be provided.*

Output description

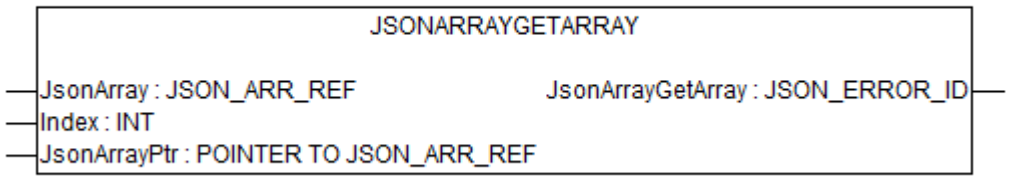


JsonParseArrayFromString

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYGETARRAY

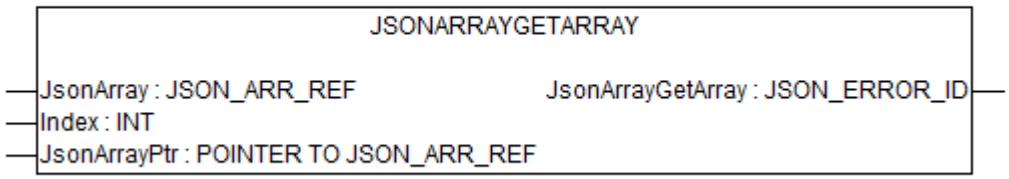


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYGETARRAY gets a nested child JSON ARRAY identified by an index from a parent JSON ARRAY. The ARRAY is not copied, only a reference is retrieved. This reference is assigned to the given pointer.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the parent JSON ARRAY from which the child JSON ARRAY is retrieved.

Index

Data type	Default value	Range	Unit
INT	-	-	-

The index which identifies the retrieved child JSON ARRAY.

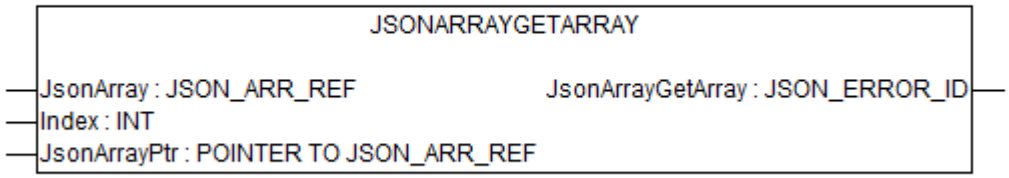
JsonArrayPtr

Data type	Default value	Range	Unit
POINTER TO JSON_ARR_REF	-	-	-

The pointer to a JSON ARRAY to assign the retrieved child ARRAY reference.

In case of any error, the data at the provided pointer stays unchanged.

Output description

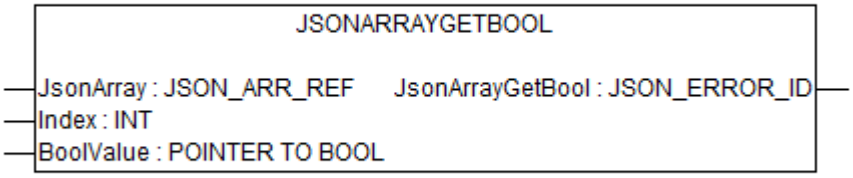


JsonArrayGetArray

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYGETBOOL

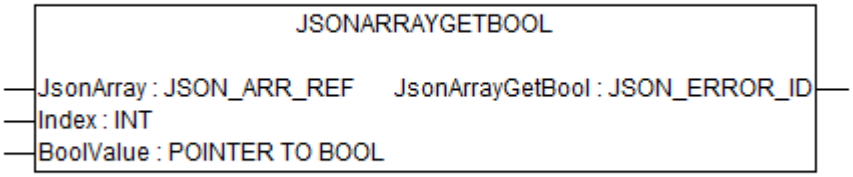


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYGETBOOL gets a BOOLEAN value identified by an index from a JSON ARRAY. The retrieved value is assigned to the given pointer.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the JSON ARRAY from which the BOOLEAN is retrieved.

Index

Data type	Default value	Range	Unit
INT	-	-	-

The index which identifies the retrieved BOOLEAN value.

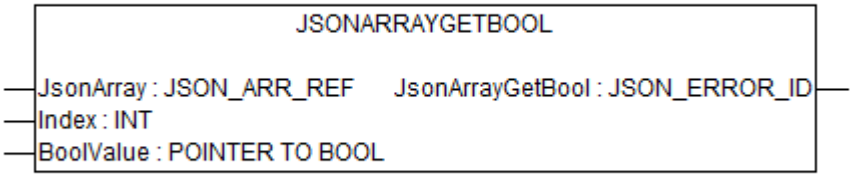
BoolValue

Data type	Default value	Range	Unit
POINTER TO BOOL	-	-	-

The pointer to a BOOLEAN variable to assign the retrieved value.

In case of any error, the data at the provided pointer stays unchanged.

Output description

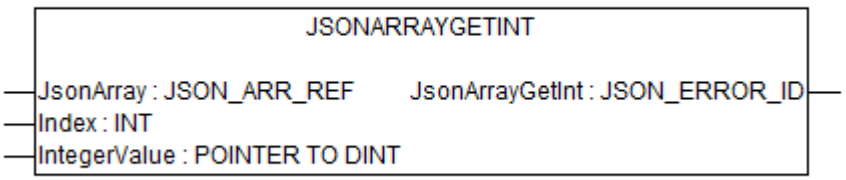


JsonArrayGetBool

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYGETINT

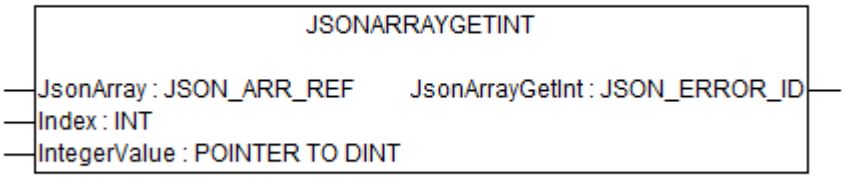


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYGETINT gets an INTEGER value identified by an index from a JSON ARRAY. The retrieved value is assigned to the given pointer.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the JSON ARRAY from which the INTEGER value is retrieved.

Index

Data type	Default value	Range	Unit
INT	-	-	-

The index which identifies the retrieved INTEGER value.

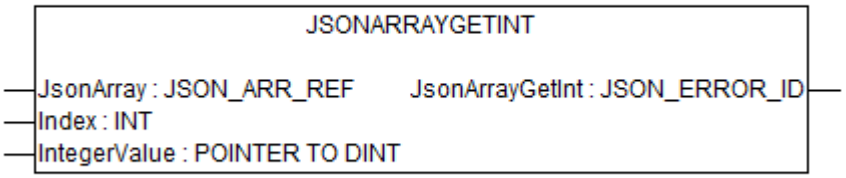
IntegerValue

Data type	Default value	Range	Unit
POINTER TO DINT	-	-	-

The pointer to an INTEGER variable to assign the retrieved value. In CODESYS a DINT variable has to be used.

In case of any error, the data at the provided pointer stays unchanged.

Output description

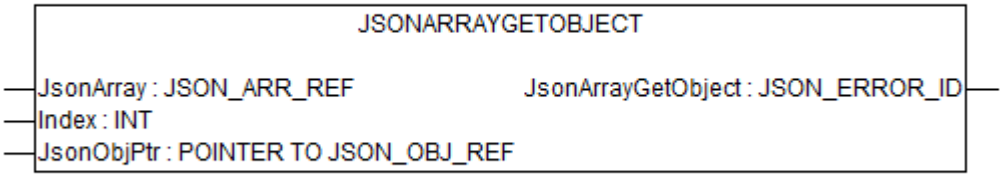


JsonArrayGetInt

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYGETOBJECT

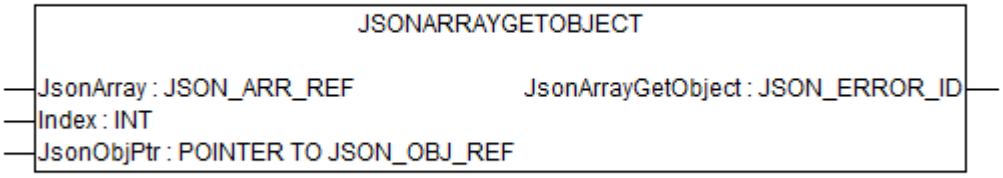


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYGETOBJECT gets a JSON OBJECT identified by an index from a JSON ARRAY. The OBJECT is not copied, only a reference is retrieved. This reference is assigned to the given pointer.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the JSON ARRAY from which the JSON OBJECT is retrieved.

Index

Data type	Default value	Range	Unit
INT	-	-	-

The index which identifies the retrieved JSON OBJECT.

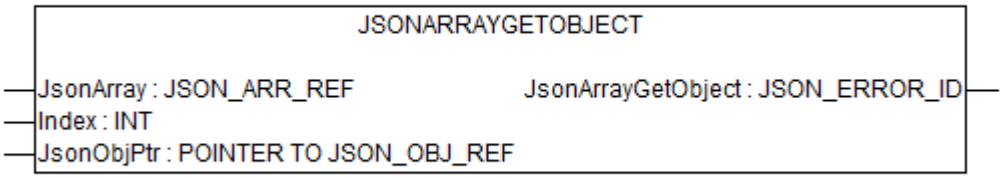
JsonObjPtr

Data type	Default value	Range	Unit
POINTER TO JSON_OBJ_REF	-	-	-

The pointer to a JSON OBJECT to assign the retrieved OBJECT reference.

In case of any error, the data at the provided pointer stays unchanged.

Output description

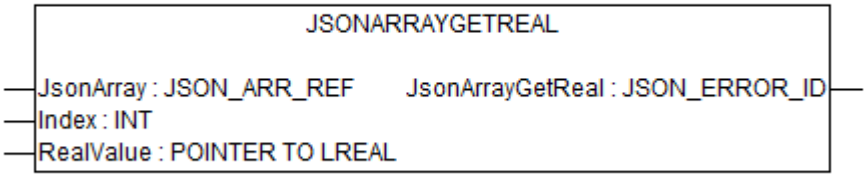


JsonArrayGetObject

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYGETREAL

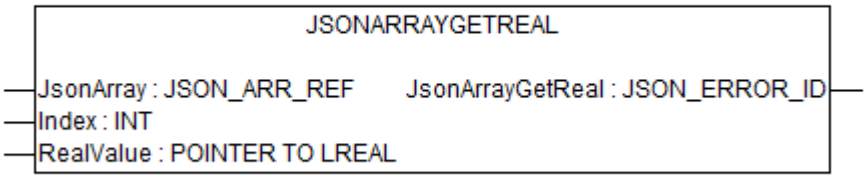


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYGETREAL gets a REAL value identified by an index from a JSON ARRAY. The retrieved value is assigned to the given pointer.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the JSON ARRAY from which the REAL is retrieved.

Index

Data type	Default value	Range	Unit
INT	-	-	-

The index which identifies the retrieved REAL value.

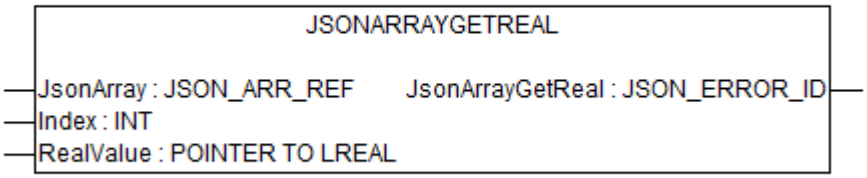
RealValue

Data type	Default value	Range	Unit
POINTER TO LREAL	-	-	-

The pointer to a REAL variable to assign the retrieved value. In CODESYS a LREAL variable has to be used.

In case of any error, the data at the provided pointer stays unchanged.

Output description

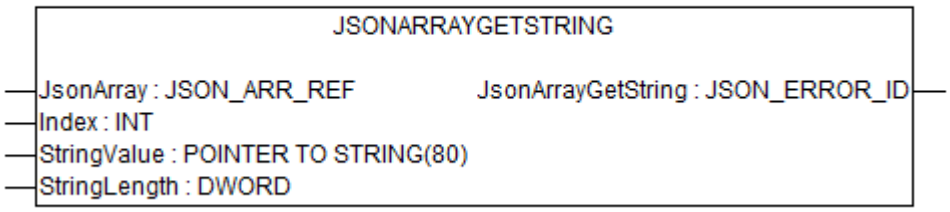


JsonArrayGetReal

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

JSONARRAYGETSTRING

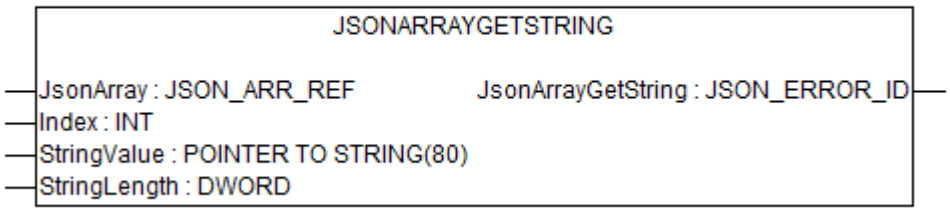


General information

Parameter	Value
Included in library	JSON_AC500_V28.lib
Available as of firmware	V2.8
Type	Function
Group	C interface

The function JSONARRAYGETSTRING gets a STRING value identified by an index from a JSON ARRAY. The STRING value is copied to the given pointer.

Input description



JsonArray

Data type	Default value	Range	Unit
JSON_ARR_REF	-	-	-

The reference to the JSON ARRAY from which the STRING value is retrieved.

Index

Data type	Default value	Range	Unit
INT	-	-	-

The index which identifies the retrieved STRING value.

StringValue

Data type	Default value	Range	Unit
POINTER TO STRING(80)	-	-	-

The pointer to a STRING buffer to copy the retrieved value.

> *Contrary to the figure the STRING value is not limited to 80 characters.*
> *STRING buffers of any viable length can be provided.*

In case of any error, the data at the provided pointer stays unchanged.

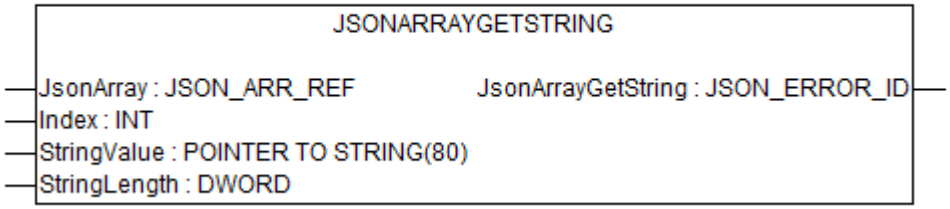
StringLength

Data type	Default value	Range	Unit
DWORD	-	-	-

The StringLength parameter specifies the limit of the provided STRING value.

If the size of the STRING value is not sufficient, it stays unchanged.

Output description



JsonArrayGetString

Data type	Default value	Range	Unit
JSON_ERROR_ID	JSON_ERR_NO_ERR	-	-

Provides an error number from enumeration JSON_ERROR_ID if an error occurred while processing the function.

Structures and enumerations

JSON_ERROR_ID

Enumeration

Parameter	Default value	Description
JSON_ERR_NO_ERR	0	No error.
JSON_ERR_PARSE_ERR	16#3015	Error on parsing given STRING. STRING does not represent a valid JSON OBJECT/ARRAY or not enough memory is available.
JSON_ERR_STRING_LEN_ERR	16#3017	Error on given STRING buffer. JSON serialization or STRING value is longer than STRING length.
JSON_ERR_KEY_NOT_EXISTING	16#301B	Error on given key. The key does not exist in the JSON OBJECT.
JSON_ERR_INDEX_NOT_EXISTING	16#301C	Error on given index. The index does not exist in the JSON ARRAY.
JSON_ERR_TYPE_ERR	16#3027	Type mismatch of value at given key in JSON OBJECT or at given index in JSON ARRAY.
JSON_ERR_MEM_ERR	16#3028	Error on allocating memory on JSON value creation or insertion.

JSON_OBJ_REF

Type

Type name	Data type	Description
JSON_OBJ_REF	DWORD	Address handle for JSON OBJECTS.

JSON_ARR_REF

Type

Type name	Data type	Description
JSON_ARR_REF	DWORD	Address handle for JSON ARRAYS.

Global variables

JSON_CONSTANTS

Parameter	Data type	Default value	Description
JSON_MAX_KEY_LEN	DWORD	100	Maximum size of a key string in a JSON OBJECT.

Hardware

The JSON Library requires an suitable processor module.

The firmware of the processor module must be minimum FW 2.8.0.

The processor module must have an Ethernet connection.

The following **processor modules** can be used:

AC500-eCo

- PM556-TP-ETH
- PM566-TP-ETH

AC500

- PM573-ETH
- PM583-ETH
- PM585-ETH
- PM590-ETH
- PM591-ETH
- PM591-2ETH
- PM592-ETH
- PM595-4ETH

Examples

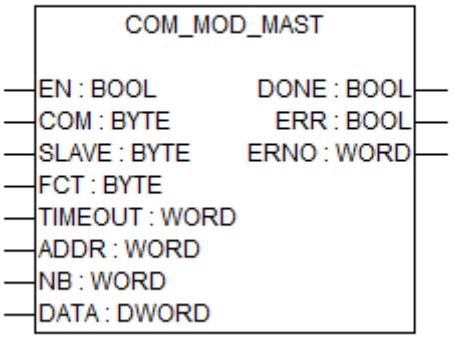
Example projects for the libraries can be found in the folder: \Users\Public\Documents\AutomationBuilder\Examples

1.5.4.22 Modbus library

Library file name: **Modbus_AC500_Vx.lib**

1.5.4.22.1 Function blocks

COM_MOD_MAST



Parameter	Value
Included in library	Modbus_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values
Group	Modbus

The function block COM_MOD_MAST realizes the Modbus master function for the Modbus interface of the controller (COM1, COM2) specified at input COM.

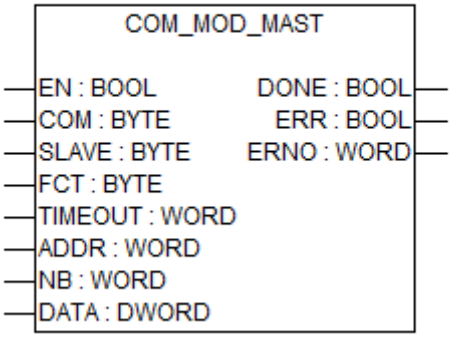
For each interface, a separate COM_MOD_MAST function block must be used.

Prior to the use of COM_MOD_MAST for an interface, the particular interface has to be configured via the controller configuration of the Control Builder (PS501) as the Modbus master interface.

With each FALSE > TRUE edge at input EN, the function block COM_MOD_MAST reads the values at the inputs, generates a telegram according to the inputs and sends this telegram to the slave.

For detailed information on Modbus RTU, see ↬ Chapter 1.6.4.1.8 “Communication with Modbus RTU” on page 5467.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

At input COM, the Modbus interface number is specified.

COM = 1: COM1

COM = 2: COM2

SLAVE

Data type	Default value	Range	Unit
BYTE	-	-	-

At input SLAVE, the address of the slave to which the telegram shall be sent is specified.

FCT

Data type	Default value	Range	Unit
BYTE	-	-	-

The function code of the request telegram is specified at input FCT.

01 or 02	Read n bits
03 or 04	Read n words
05	Write one bit (encoded in one word)
06	Write one word
07	Read 8 bit

15	Write n bits (encoded in one byte)
16	Write n words
22	Mask write
23	Read/write multiple words in one telegram

TIMEOUT

Data type	Default value	Range	Unit
WORD	-	-	ms

The telegram timeout in milliseconds (ms) is specified at input TIMEOUT.

If no response is received within the time interval specified in TIMEOUT, the procedure is aborted and an error identifier is output.

Keeping the timeout depends on the cycle time of the task in which the MODMAST function block is processed. The real time may deviate from the specification in worst case by task cycle time - 1 ms.

ADDR

Data type	Default value	Range	Unit
WORD	-	-	-

The operand/register address in the slave from which data should be read or written is specified at input ADDR.

The access to operands of AC500 devices in Modbus slave mode is defined via the Modbus cross-reference list. Only operands that are listed in the cross-reference list may be used (*Chapter 1.6.4.1.8 “Communication with Modbus RTU” on page 5467*).

Only operands that are listed in the Modbus address list may be used. When accessing other devices, ADDR is freely selectable. The valid ranges have to be gathered from the corresponding device description.

NB

Data type	Default value	Range	Unit
DWORD	Empty string	-	-

At input NB (number), the number of data to be written or read is specified. The unit of NB depends on the selected function. For bit accesses the number of bits, for word and double word accesses the number of words is specified at NB. The following restrictions apply to the length:

FCT		NBmax	
Dec	**Hex**	**Serial**	**Modbus on TCP/IP**

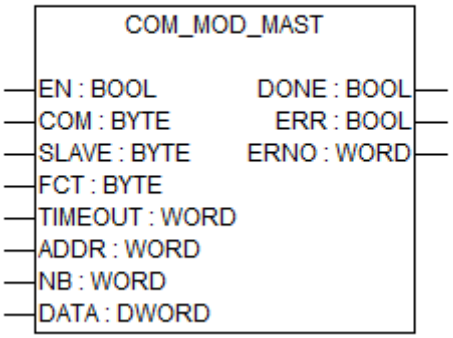
DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

At input DATA, the address of the first operand in the master is specified, from which data are copied/written to the slave or to which the data read by the slave should be stored. For this purpose it is necessary that the operand type (e.g. bit) matches the selected function (e.g. FCT 1, read n bits).

If using Modbus function codes 22 or 23, the according data structures COM_MOD_FCT22_TYPE *Chapter 1.5.4.22.2.1 “COM_MOD_FCT22_TYPE” on page 1702* or COM_MOD_FCT23_TYPE *Chapter 1.5.4.22.2.2 “COM_MOD_FCT23_TYPE” on page 1703* must be defined and applied to DATA.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
ModMast  (EN      := ModMast_EN,
          COM     := ModMast_COM,
          SLAVE   := ModMast_SLAVE,
          FCT     := ModMast_FCT,
          TIMEOUT := ModMast_TIMEOUT,
          ADDR    := ModMast_ADDR,
          NB      := ModMast_NB,
          DATA    := ADR(ModMast_DATA));

ModMast_DONE := ModMast.DONE;
ModMast_ERR := ModMast.ERR;
ModMast_ERNO:= ModMast.ERNO;
```

1.5.4.22.2 Structures

COM_MOD_FCT22_TYPE

Parameter	Value
Included in library	Modbus_AC500_V10.lib
Available as of firmware	V2.2

This structure is used to handle the Modbus function 22 with the function block COM_MOD_MAST *Chapter 1.5.4.22.1.1 “COM_MOD_MAST” on page 1698*. The structure has to be used at the DATA input with an ADR(instance_of_struct) operator.

Type and the content need to be created and defined by the user.

Visible variable	Type	Default value	Description
wAND_Mask	WORD	0	AND mask
wOR_Mask	WORD	0	OR mask

COM_MOD_FCT23_TYPE

Parameter	Value
Included in library	Modbus_AC500_V10.lib
Available as of firmware	V2.2

This structure is used to handle the Modbus function 23 with the function block COM_MOD_MAST ↬ *Chapter 1.5.4.22.1.1 “COM_MOD_MAST” on page 1698*. The structure has to be used at the DATA input with an ADR(instance_of_struct) operator.

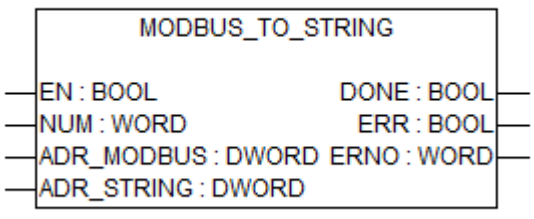
Modbus function 23 could only be used with CPUs with onboard Ethernet.

Type and the content need to be created and defined by the user.

Visible variable	Type	Default value	Description
pByDataWrite	POINTER TO BYTE	0	Pointer to buffer containing data to write. Compare FCT 16 input DATA
pByDataRead	POINTER TO BYTE	0	Pointer to buffer to store data to read. Compare FCT 03 input DATA
wDataAddress-Read	WORD	0	Address of the data to be read. Compare FCT 16 input ADDR
wNumDataUnits-Read	WORD	0	Number of data units to be read. Compare FCT 16 input NB

1.5.4.22.3 Programs

MODBUS_TO_STRING



Parameter	Value
Included in library	Modbus_AC500_V10.lib
Available as of firmware	V1.0.2
Type	Program

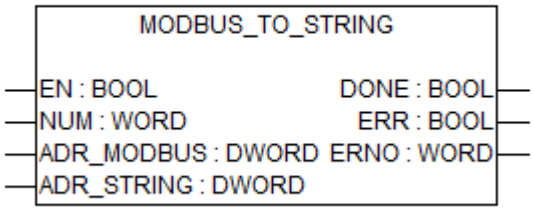
The Program MODBUS_TO_STRING converts data received or data to be send via Modbus to a String.

It does not change the value of the data but swaps and aligns data correctly. So it finally just rearranges the original data.

The output String is NULL-terminated. Any Byte in input data containing value ‘0’ is also set to ‘\0’ in output String. In this case output String is shorter than NUM or variable referenced at input ADR_STRING contains multiple strings with an overall length of NUM.

The Program MODBUS_TO_STRING can be used for Modbus Master as well as for Modbus Slave.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

NUM

Data type	Default value	Range	Unit
WORD	-	0..65536	-

The input NUM specifies the number of Bytes contained in variable referenced at input ADR_MODBUS to be converted and put to variable referenced at input ADR_STRING.

ADR_MODBUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Input ADR_MODBUS specifies the start address of the Modbus payload to be converted.

The total length of the data is assumed to be NUM Bytes long. It may contain any values. The value 0 is treated as string separator/terminator.

ADR_STRING

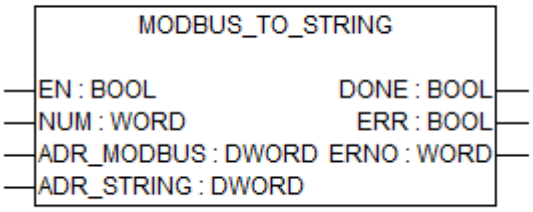
Data type	Default value	Range	Unit
DWORD	-	-	-

Input ADR_STRING specifies the start address of the String to contain the converted Modbus payload.

The total size/length of this variable is assumed to be at least NUM characters.

Since the input data may contain any values (even 0), after conversion ADR_STRING may contain one String shorter than NUM or multiple ones of NUM characters overall length.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

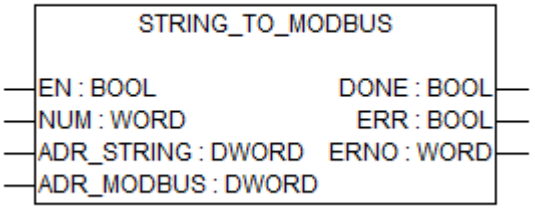
It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STRING_TO_MODBUS



Parameter	Value
Included in library	Modbus_AC500_V10.lib
Available as of firmware	V1.0.2
Type	Program

The Program STRING_TO_MODBUS converts a String to data to be send via Modbus.

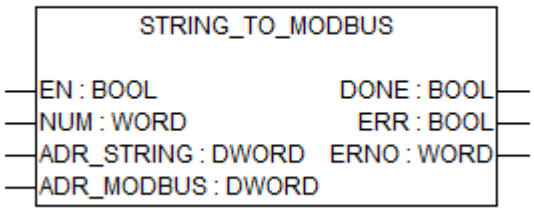
It does not change the value of the data but swaps and aligns data correctly. So it finally just re-arranges the original String.

Any terminating character (‘\0’) in input String is also set to ‘0’ in output data.

Since Program converts NUM characters in any case (independent of any terminating characters in between) input data may contain multiple Strings in this case.

The Program STRING_TO_MODBUS can be used for Modbus Master as well as for Modbus Slave.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

NUM

Data type	Default value	Range	Unit
WORD	-	0..65536	-

The input NUM specifies the number of Characters contained in variable referenced at input ADR_STRING to be converted and put to variable referenced at input ADR_MODBUS.

ADR_STRING

Data type	Default value	Range	Unit
DWORD	-	-	-

Input ADR_STRING specifies the start address of the String(s) to contain the converted to Modbus payload.

The total size/length of this variable is assumed to be NUM characters.

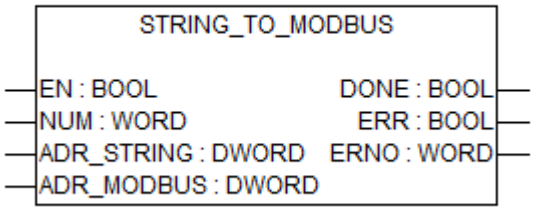
ADR_MODBUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Input ADR_MODBUS specifies the start address of the Modbus payload to contain the converted input String(s).

The total size of the data is assumed to be at least NUM Bytes.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

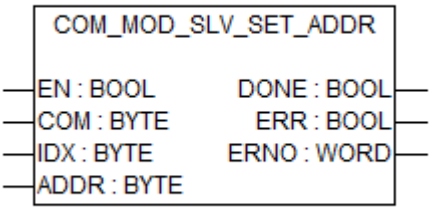
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

1.5.4.23 Extended Modbus library

Library file name: **MODBUS_Ext_AC500_Vx.lib**

1.5.4.23.1 Function blocks

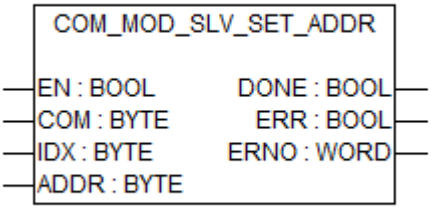
COM_MOD_SLV_SET_ADDR



Parameter	Value
Included in library	MODBUS_Ext_AC500_V10.lib MODBUS_Ext_AC500_V20.lib
Available as of firmware	V1.2.4 (MODBUS_Ext_AC500_V10.lib) V2.0.0 (MODBUS_Ext_AC500_V20.lib)
Type	Function block
Group	Modbus

The function block allows to set the address of a Modbus slave in serial mode during run time using the MULTI protocol.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

Input COM specifies the COM port where the MULTI protocol is configured.

IDX

Data type	Default value	Range	Unit
BYTE	-	-	-

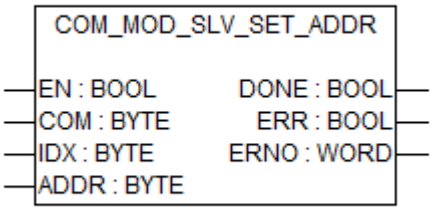
Input IDX specifies the index of the sub-module that should be used for the Modbus communication.

ADDR

Data type	Default value	Range	Unit
BYTE	-	-	-

Input ADDR specifies the address that should be set for the corresponding Modbus slave.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

1.5.4.24 MQTT client library

1.5.4.24.1 Function blocks

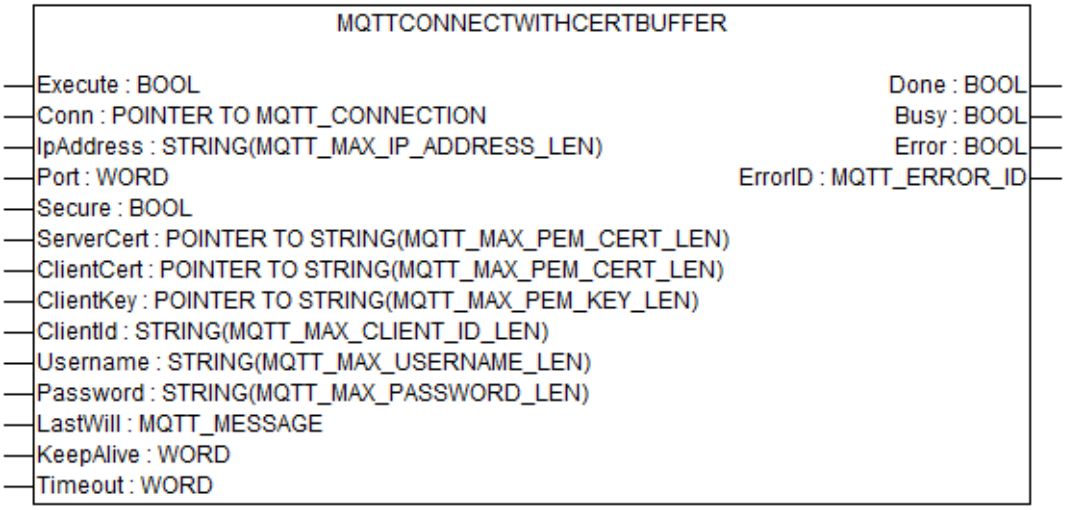
The function blocks in this library can only be executed in RUN mode of the processor module, not in simulation mode.

MQTT client library is based on OASIS MQTT specification (v3.1.1).

MQTT client protocol

For further information see *Chapter 1.6.5.3.4 “MQTT client protocol” on page 6178*

MqttConnectWithCertBuffer



Parameter	Value
Included in library	ABB_MqttClient_AC500.lib
Available as of firmware	V2.8
Type	Function block with historical values
Group	C interface

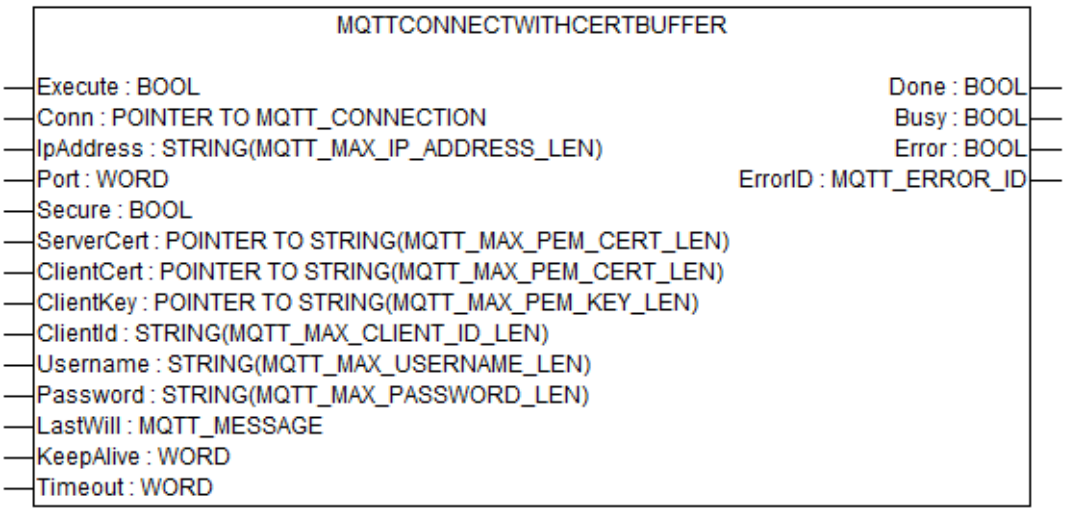
The function block MqttConnectWithCertBuffer establishes a connection to a MQTT broker. This function block only has to be called once per connection. The input parameters of the function block are used to access to the broker.

Comparing to function block MqttConnectWithCertFile it is possible to establish a TLS connection with certificates from buffer.

In this case copy the content of the certificate .pem file into a STRING variable. All line breaks from the file must be replace with the ST specific line break character ‘$n’.

Each time a TLS connection is established to a broker, the AC500 calculates some key pairs. For AC500-eCo PLCs, this calculation can take up to 7 seconds. Hence, ensure correct configuration of your watchdog.

Input description



Execute

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

A rising edge starts the operation, the output Busy goes to TRUE. In the first cycle all other inputs are read and stored, afterwards they are ignored. A falling edge does not stop the operation. After Done = TRUE or Error = TRUE and Execute = FALSE all outputs will be reset.

Conn

Data type	Default value	Range	Unit
POINTER TO MQTT_CONNECTION	0	-	-

Set a reference to the connection.

MQTT_CONNECTION is used for other function blocks to reference to the established connection.

IpAddress

Data type	Default value	Range	Unit
STRING	Empty string	-	-

Set the IP address of the MQTT Broker. The IP address needs to be a string like ‘192.168.0.1’.

Port

Data type	Default value	Range	Unit
WORD	8883	-	-

Set the port number of the MQTT broker.

Secure

Data type	Default value	Range	Unit
BOOL	TRUE	-	-

Decide if using secure channel (TLS, Secure := TRUE) for communication.

ServerCert

Data type	Default value	Range	Unit
POINTER TO STRING(MQTT_MAX_PEM_CERT_LEN)	0	-	-

Set server certificate in PEM format. Only necessary if using a TLS connection. MQTT_MAX_PEM_CERT_LEN is an internal constant which is set to 3072.

ClientCert

Data type	Default value	Range	Unit
POINTER TO STRING(MQTT_MAX_PEM_CERT_LEN)	0	-	-

Set (optional) client certificate in PEM format. Only necessary if using a TLS connection. MQTT_MAX_PEM_CERT_LEN is an internal constant which is set to 3072.

ClientKey

Data type	Default value	Range	Unit
POINTER TO STRING(MQTT_MAX_PEM_CERT_LEN)	0	-	-

Set (optional) client certificate in PEM format. Only necessary if using a TLS connection and if using a client certificate. MQTT_MAX_PEM_CERT_LEN is an internal constant which is set to 3072.

ClientId

Data type	Default value	Range	Unit
POINTER TO STRING(MQTT_MAX_PEM_CERT_LEN)	0	-	-

Set client identifier which is used to identify the client to the server. Only necessary if using a TLS connection. MQTT_MAX_CLIENT_ID_LEN is an internal constant which is set to 250.

Username

Data type	Default value	Range	Unit
STRING(MQTT_MAX_USERNAME_LEN)	Empty string	-	-

Set username for MQTT broker. MQTT_MAX_USERNAME_LEN is an internal constant which is set to 250.

Password

Data type	Default value	Range	Unit
STRING(MQTT_MAX_PASSWORD_LEN)	Empty string	-	-

Set password for MQTT broker. MQTT_MAX_PASSWORD_LEN is an internal constant which is set to 250.

LastWill

Data type	Default value	Range	Unit
MQTT_MESSAGE	-	-	-

Optional Last Will message.

KeepAlive

Data type	Default value	Range	Unit
WORD	600	-	-

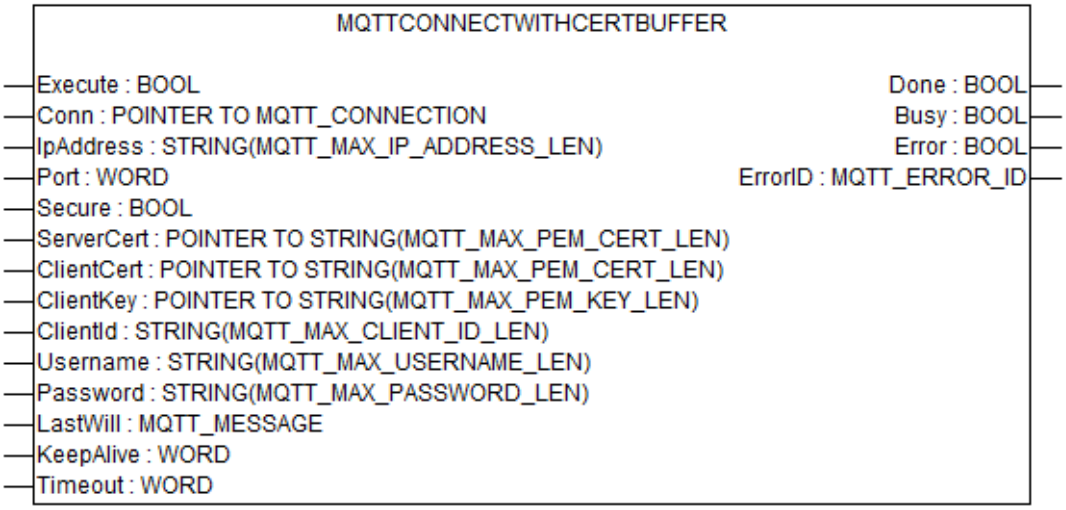
Time in seconds, which will be passed to the MQTT Broker and which is normally used by the Broker to disconnect clients if no communication was made for 1,5 * KeepAlive.

Timeout

Data type	Default value	Range	Unit
WORD	30000	-	Millisecond

Timeout for connect and all subsequent calls (ping, subscribe, unsubscribe, publish with QoS > 0).

Output description



Done

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is completed without error (while outputs Busy and Error are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

Busy

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

Error

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

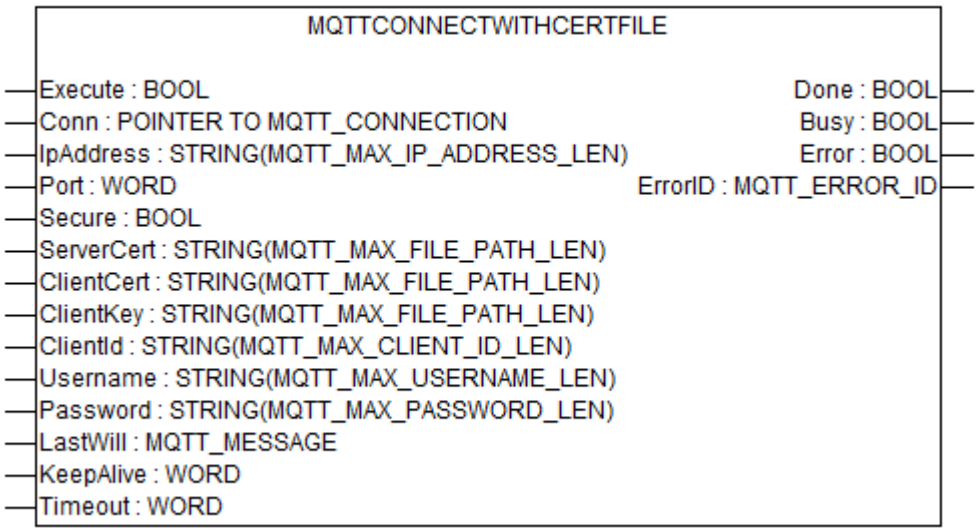
Operation is stopped with error (while outputs Busy and Done are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

ErrorID

Data type	Default value	Range	Unit
MQTT_ERROR_ID	MQTT_ERR_NO_ERROR	-	-

Provides an error number from enumeration *“MQTT_ERROR_ID (Enum) ” on page 1729* if an error occurred while processing the function block.

MqttConnectWithCertFile



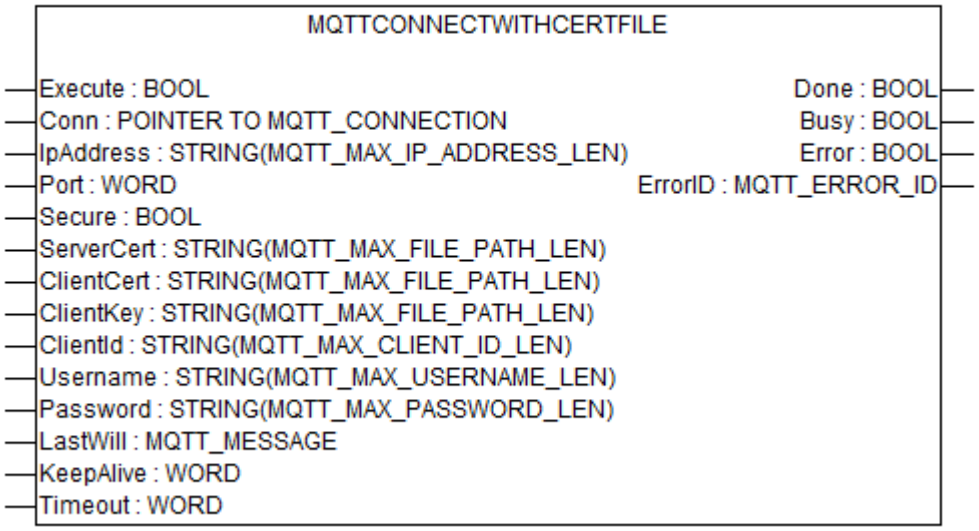
Parameter	Value
Included in library	ABB_MqttClient_AC500.lib
Available as of firmware	V2.8
Type	Function block with historical values
Group	C interface

The function block MqttConnectWithCertFile establishes a connection to a MQTT broker. This function block only has to be called once per connection. The input parameters of the function block are used to access to the broker.

Comparing to function block MqttConnectWithCertBuffer it is possible to establish a TLS connection with certificates from file.

If your PLC does not have a persistent file storage like memory card or flash disk, consider using MqttConnectWithCertBuffer.

Input description



Execute

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

A rising edge starts the operation, the output Busy goes to TRUE. In the first cycle all other inputs are read and stored, afterwards they are ignored. A falling edge does not stop the operation. After Done = TRUE or Error = TRUE and Execute = FALSE all outputs will be reset.

Conn

Data type	Default value	Range	Unit
POINTER TO MQTT_CONNEC-TION	0	-	-

Set a reference to the connection.

MQTT_CONNECTION is used for other function blocks to reference to the established connection.

IpAddress

Data type	Default value	Range	Unit
STRING	Empty string	-	-

IP address of the MQTT Broker. The IP address needs to be a string like ‘192.168.0.1’.

Port

Data type	Default value	Range	Unit
WORD	8883	-	-

Set the port number of the MQTT broker.

Secure

Data type	Default value	Range	Unit
BOOL	TRUE	-	-

Decide if using secure channel (TLS, Secure := TRUE) for communication.

ServerCert

Data type	Default value	Range	Unit
STRING(MQTT_MAX_FILE_PATH_LEN)	Empty string	-	-

File name of server certificate in PEM format. Only necessary if using a TLS connection.

ClientCert

Data type	Default value	Range	Unit
STRING(MQTT_MAX_FILE_PATH_LEN)	Empty string	-	-

File name of client certificate in PEM format. Only necessary if using a TLS connection.

ClientKey

Data type	Default value	Range	Unit
STRING(MQTT_MAX_FILE_PATH_LEN)	Empty string	-	-

File name of client private key in PEM format (optional). Only necessary if using a TLS connection and if using a client certificate.

ClientId

Data type	Default value	Range	Unit
POINTER TO STRING(MQTT_MAX_PEM_CERT_LEN)	0	-	-

Set client identifier which is used to identify the client to the server. Only necessary if using a TLS connection. MQTT_MAX_CLIENT_ID_LEN is an internal constant which is set to 250.

Username

Data type	Default value	Range	Unit
STRING(MQTT_MAX_USERNAME_LEN)	Empty string	-	-

Set username for MQTT broker. MQTT_MAX_USERNAME_LEN is an internal constant which is set to 250.

Password

Data type	Default value	Range	Unit
STRING(MQTT_MAX_PASSWORD_LEN)	Empty string	-	-

Set password for MQTT broker. MQTT_MAX_PASSWORD_LEN is an internal constant which is set to 250.

LastWill

Data type	Default value	Range	Unit
MQTT_MESSAGE	-	-	-

Optional Last Will message.

KeepAlive

Data type	Default value	Range	Unit
WORD	600	-	-

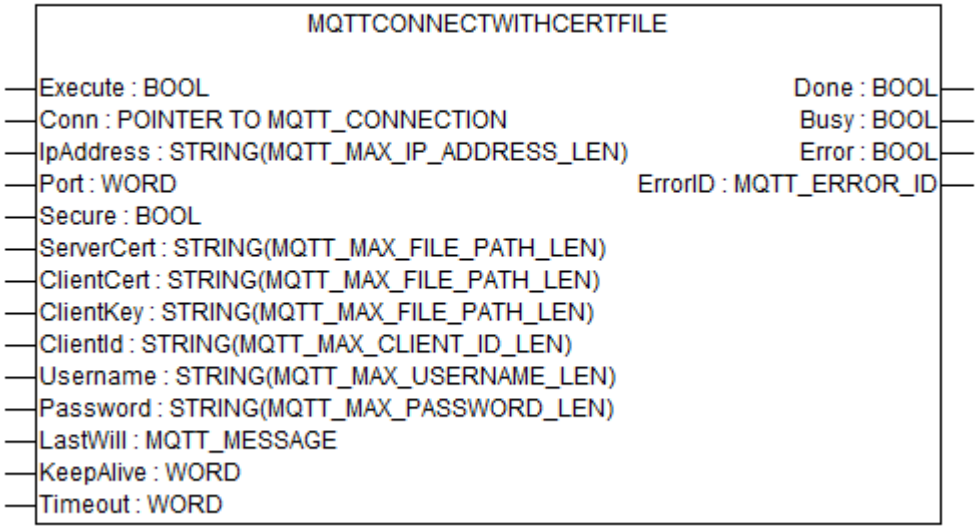
Time in seconds, which will be passed to the MQTT Broker and which is normally used by the Broker to disconnect clients if no communication was made for 1,5 * KeepAlive.

Timeout

Data type	Default value	Range	Unit
WORD	30000	-	Millisecond

Timeout for connect and all subsequent calls (ping, subscribe, unsubscribe, publish with QoS > 0).

Output description



Done

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is completed without error (while outputs Busy and Error are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

Busy

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

Error

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

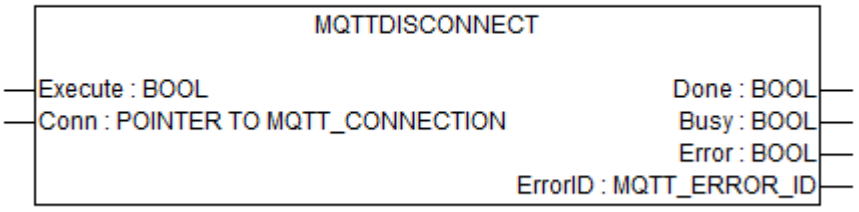
Operation is stopped with error (while outputs Busy and Done are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

ErrorID

Data type	Default value	Range	Unit
MQTT_ERROR_ID	MQTT_ERR_NO_ERROR	-	-

Provides an error number from enumeration *“MQTT_ERROR_ID (Enum) ” on page 1729* if an error occurred while processing the function block.

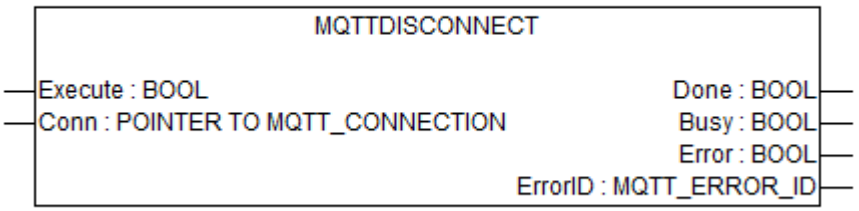
MqttDisconnect



Parameter	Value
Included in library	ABB_MqttClient_AC500.lib
Available as of firmware	V2.8
Type	Function block with historical values
Group	C interface

The function block MqttDisconnect is used to disconnect from the MQTT Broker. This function block resets the used socket. In case of an error during the connection, the used socket will be reset automatically.

Input description



Execute

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

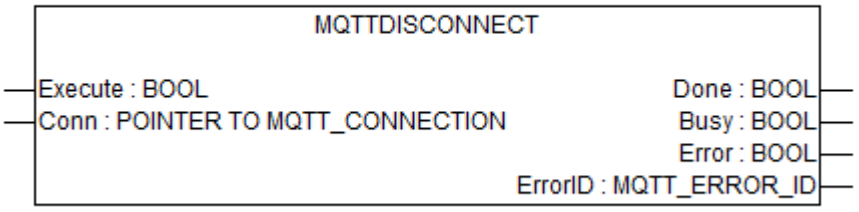
A rising edge starts the operation, the output Busy goes to TRUE. In the first cycle all other inputs are read and stored, afterwards they are ignored. A falling edge does not stop the operation. After Done = TRUE or Error = TRUE and Execute = FALSE all outputs will be reset.

Conn

Data type	Default value	Range	Unit
POINTER TO MQTT_CONNECTION	0	-	-

Pointer to a valid connection structure created by MqttConnect.

Output description



Done

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is completed without error (while outputs Busy and Error are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

Busy

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

Error

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

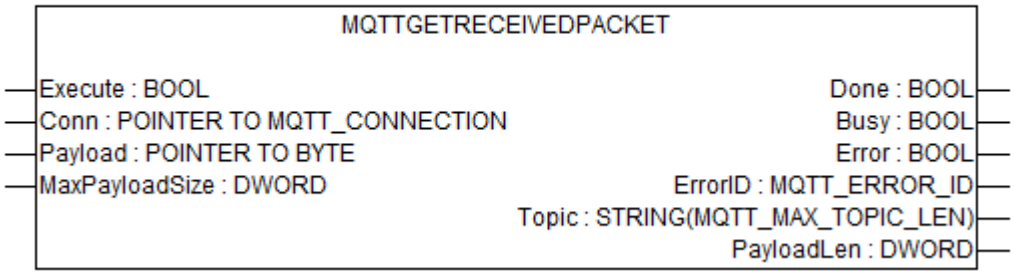
Operation is stopped with error (while outputs Busy and Done are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

ErrorID

Data type	Default value	Range	Unit
MQTT_ERROR_ID	MQTT_ERR_NO_ERROR	-	-

Provides an error number from enumeration *“MQTT_ERROR_ID (Enum) ” on page 1729* if an error occurred while processing the function block.

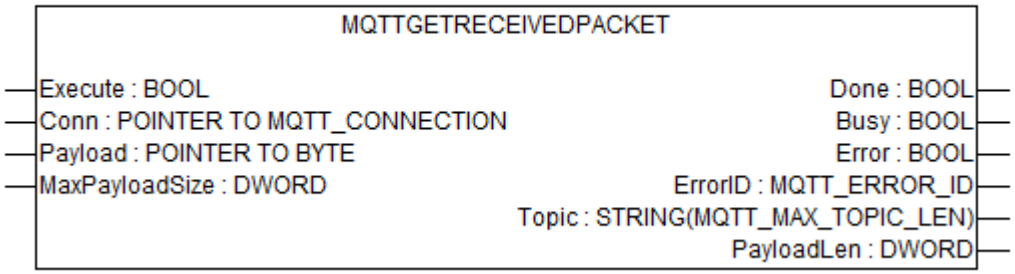
MqttGetReceivedPacket



Parameter	Value
Included in library	ABB_MqttClient_AC500.lib
Available as of firmware	V2.8
Type	Function block with historical values
Group	C interface

The function block MqttGetReceivedPacket returns the first packet received for any subscribed topic. Done = TRUE with PayloadLen = 0 indicates that nothing new has been received since the last call..

Input description



Execute

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

A rising edge starts the operation, the output Busy goes to TRUE. In the first cycle all other inputs are read and stored, afterwards they are ignored. A falling edge does not stop the operation. After Done = TRUE or Error = TRUE and Execute = FALSE all outputs will be reset.

Conn

Data type	Default value	Range	Unit
POINTER TO MQTT_CONNEC-TION	0	-	-

Pointer to a valid connection structure created by MqttConnect.

Payload

Data type	Default value	Range	Unit
POINTER TO BYTE	0	-	-

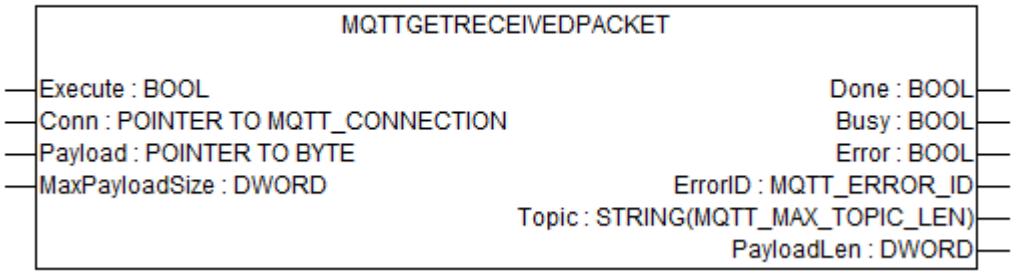
Pointer to the data area where the received packet can be stored.

MaxPayloadSize

Data type	Default value	Range	Unit
WORD	0	-	-

Size of the data area where the received packet can be stored.

Output description



Done

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is completed without error (while outputs Busy and Error are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

Busy

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

Error

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is stopped with error (while outputs Busy and Done are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

ErrorID

Data type	Default value	Range	Unit
MQTT_ERROR_ID	MQTT_ERR_NO_ERROR	-	-

Provides an error number from enumeration *"MQTT_ERROR_ID (Enum) " on page 1729* if an error occurred while processing the function block.

Topic

Data type	Default value	Range	Unit
STRING(MQTT_MAX_TOPIC_LEN)	Empty string	-	-

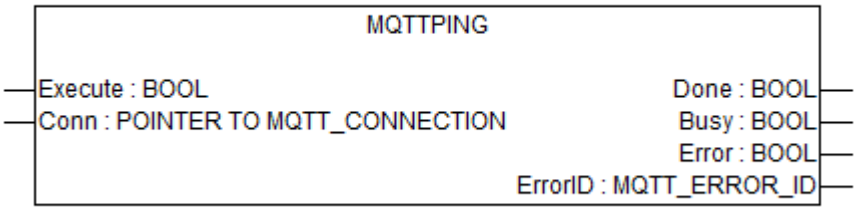
Topic where the payload data belongs to.

PayLoadLen

Data type	Default value	Range	Unit
STRING(MQTT_MAX_TOPIC_LEN)	Empty string	-	-

Actual length of the payload.

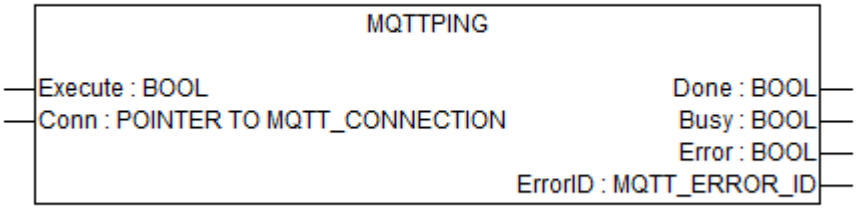
MqttPing



Parameter	Value
Included in library	ABB_MqttClient_AC500.lib
Available as of firmware	V2.8
Type	Function block with historical values
Group	C interface

MqttPing sends an MQTT Ping request to the broker and waits for the response packet. If output Done is TRUE and output Error is FALSE, the client still reaches the broker.

Input description



Execute

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

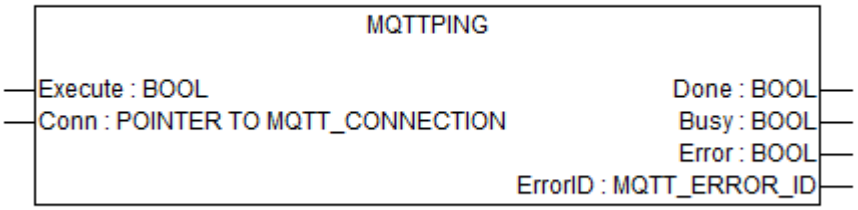
A rising edge starts the operation, the output Busy goes to TRUE. In the first cycle all other inputs are read and stored, afterwards they are ignored. A falling edge does not stop the operation. After Done = TRUE or Error = TRUE and Execute = FALSE all outputs will be reset.

Conn

Data type	Default value	Range	Unit
POINTER TO MQTT_CONNECTION	0	-	-

Pointer to a valid connection structure created by MqttConnect.

Output description



Done

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is completed without error (while outputs Busy and Error are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

Busy

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

Error

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

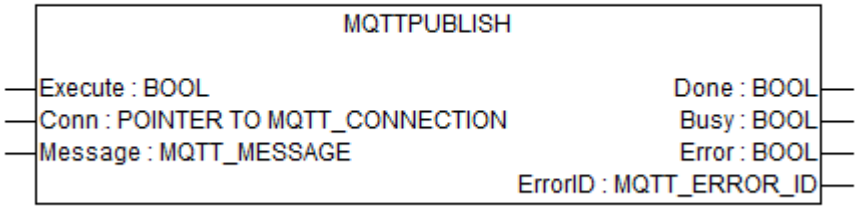
Operation is stopped with error (while outputs Busy and Done are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

ErrorID

Data type	Default value	Range	Unit
MQTT_ERROR_ID	MQTT_ERR_NO_ERROR	-	-

Provides an error number from enumeration *“MQTT_ERROR_ID (Enum) ” on page 1729* if an error occurred while processing the function block.

MqttPublish



Parameter	Value
Included in library	ABB_MqttClient_AC500.lib
Available as of firmware	V2.8
Type	Function block with historical values
Group	C interface

MqttPublish publishes a MQTT message to MQTT Broker. The properties of the message (Topic, Payload, QOS, Retain Flag) can be set with the message input.

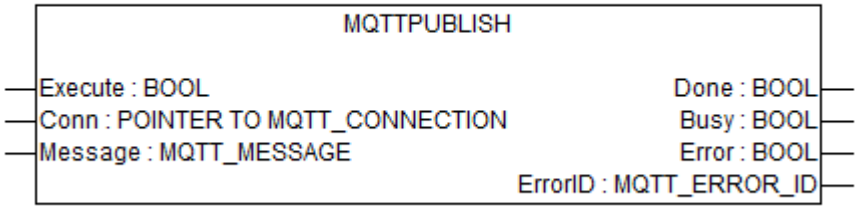
The *Timeout* that was set on the *MqttConnect POUs* is used when a QoS Level of 1 or 2 is set for a message.

This means that this POU will wait for an answer from the broker until the *Timeout* is reached when the message is either Q0s Level 1 or Level 2.

It will not wait for any answer when QoS Level is 0.

The application using this FB has to define if the message shall be re-published and how often that shall be done.

Input description



Execute

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

A rising edge starts the operation, the output Busy goes to TRUE. In the first cycle all other inputs are read and stored, afterwards they are ignored. A falling edge does not stop the operation. After Done = TRUE or Error = TRUE and Execute = FALSE all outputs will be reset.

Conn

Data type	Default value	Range	Unit
POINTER TO MQTT_CONNECTION	0	-	-

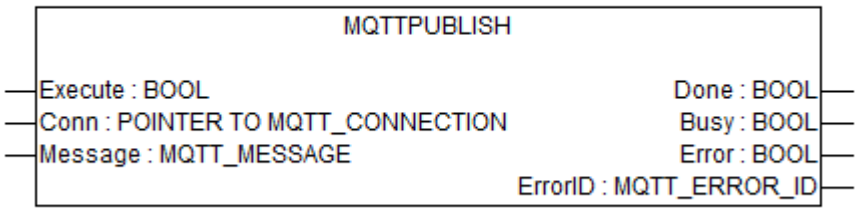
Pointer to a valid connection structure created by MqttConnect.

Message

Data type	Default value	Range	Unit
MQTT_MESSAGE	See description of MQTT_MESSAGE	-	-

Defines the Message to be published.

Output description



Done

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is completed without error (while outputs Busy and Error are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

Busy

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

Error

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

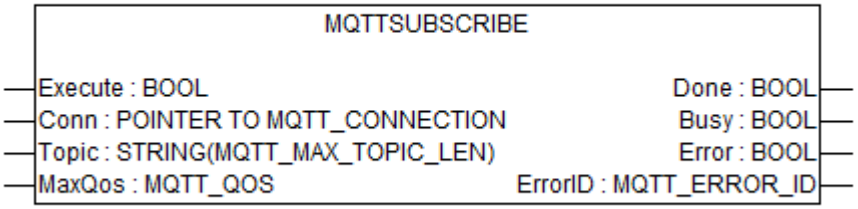
Operation is stopped with error (while outputs Busy and Done are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

ErrorID

Data type	Default value	Range	Unit
MQTT_ERROR_ID	MQTT_ERR_NO_ERROR	-	-

Provides an error number from enumeration *“MQTT_ERROR_ID (Enum) ” on page 1729* if an error occurred while processing the function block.

MqttSubscribe

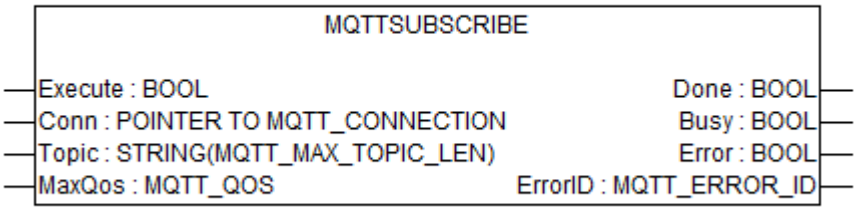


Parameter	Value
Included in library	ABB_MqttClient_AC500.lib
Available as of firmware	V2.8
Type	Function block with historical values
Group	C interface

The function block MqttSubscribe is used to subscribe to a topic name like 'topic/name'. Wildcard symbols (#/+).

It can be used for subscribing like city/# or city/+/temperature. If the connection between the client and the broker is interrupted, the client needs to subscribe again to a topic after a new connect.

Input description



Execute

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

A rising edge starts the operation, the output Busy goes to TRUE. In the first cycle all other inputs are read and stored, afterwards they are ignored. A falling edge does not stop the operation. After Done = TRUE or Error = TRUE and Execute = FALSE all outputs will be reset.

Conn

Data type	Default value	Range	Unit
POINTER TO MQTT_CONNECTION	0	-	-

Pointer to a valid connection structure created by MqttConnect.

Topic

Data type	Default value	Range	Unit
STRING(MQTT_MAX_TOPIC_LEN)	Empty string	-	-

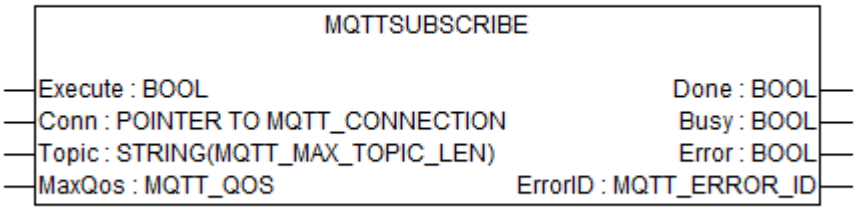
Set the Topic name as a string. The topic name must look like ‘topic/name’. Wildcard symbols can also be used for subscribing (for example: ‘city/#’ or ‘city/+/temperature’). For further information see the MQTT specification.

MaxQos

Data type	Default value	Range	Unit
MQTT_QOS	QOS_0	BASC_NORMAL, BASC_REVERSE	-

This input is used to signal the server which is the highest QoS level which can be handled. Can be reduced to relive the client from high network load.

Output description



Done

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is completed without error (while outputs Busy and Error are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

Busy

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

Error

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

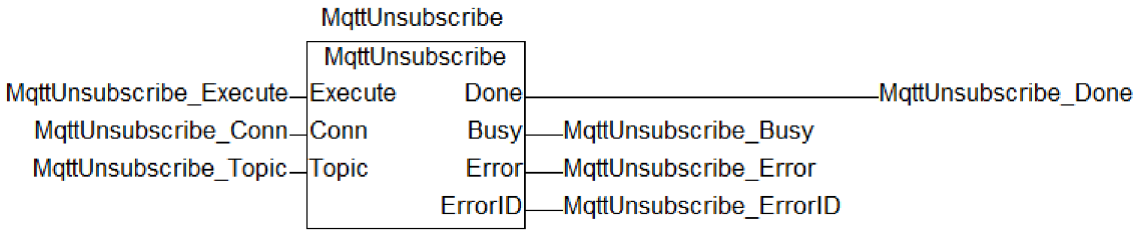
Operation is stopped with error (while outputs Busy and Done are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

ErrorID

Data type	Default value	Range	Unit
MQTT_ERROR_ID	MQTT_ERR_NO_ERROR	-	-

Provides an error number from enumeration *“MQTT_ERROR_ID (Enum) ” on page 1729* if an error occurred while processing the function block.

MqttUnsubscribe

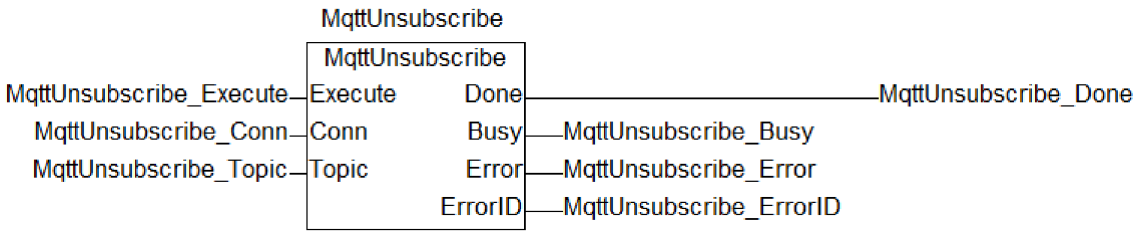


Parameter	Value
Included in library	ABB_MqttClient_AC500.lib
Available as of firmware	V2.8
Type	Function block with historical values
Group	C interface

The function block MqttUnsubscribe is used to unsubscribe from a topic name like 'topic/name'.

Wildcard symbols (#/+) can be used for subscribing like city/# or city/+/temperature

Input description



Execute

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

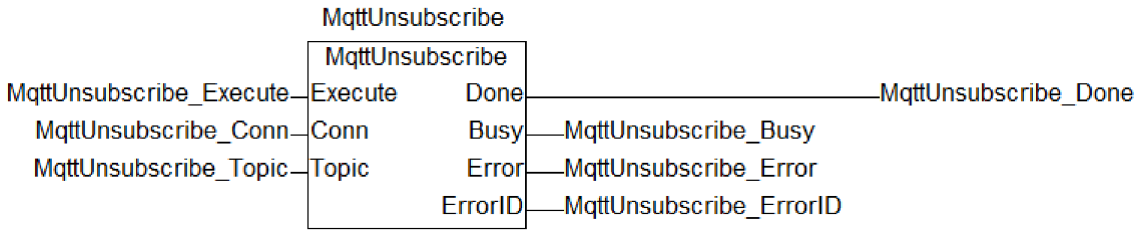
A rising edge starts the operation, the output Busy goes to TRUE. In the first cycle all other inputs are read and stored, afterwards they are ignored. A falling edge does not stop the operation. After Done = TRUE or Error = TRUE and Execute = FALSE all outputs will be reset.

Conn

Data type	Default value	Range	Unit
POINTER TO MQTT_CONNEC-TION	0	-	-

Pointer to a valid connection structure created by MqttConnect.

Output description



Done

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is completed without error (while outputs Busy and Error are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

Busy

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

Error

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is stopped with error (while outputs Busy and Done are FALSE). This output is TRUE for at least one cycle or until Execute is set to FALSE.

ErrorID

Data type	Default value	Range	Unit
MQTT_ERROR_ID	MQTT_ERR_NO_ERROR	-	-

Provides an error number from enumeration *"MQTT_ERROR_ID (Enum) " on page 1729* if an error occurred while processing the function block.

1.5.4.24.2 Structures and enumerations

MQTT_ERROR_ID (Enum)

Parameter	Value	Description
MQTT_ERR_NO_ERROR	0	No error.
MQTT_ERR_CONN_SERVICE_UNAVAIL	16#3001	The Network Connection has been made but the MQTT service is unavailable on the specified port.
MQTT_ERR_COMMUNICATION_TIMEOUT	16#3013	The timeout value for the communication has been exceeded.
MQTT_ERR_REC_PACKET_TOO_LONG	16#3017	Received topic is too long.
MQTT_ERR_PING_NO_ANSWER	16#301A	The MQTT broker did not answer the ping. MQTT client has passed the KeepAlive or MQTT broker is unreachable.
MQTT_ERR_CONN_CLIENT_ID_NOT_ALLOWED	16#301F	The Client identifier is correct UTF-8 but not allowed by the Server.

Parameter	Value	Description
MQTT_ERR_CONN_ REFUSED_PROTOCOL	16#3020	The Server does not support the level of the MQTT protocol requested by the Client.
MQTT_ERR_CONN_REFU SED_CONNECTION	16#3025	Connection refused, maybe the IP address is malformed.
MQTT_ERR_UNSPECI-FIED_ERROR	16#302B	Internal library returned an unspecified error.
MQTT_ERR_NET-WORK_ERROR	16#302D	General network error.
MQTT_ERR_CONN_AUTH _FAILED	16#3217	Authentication failed: Bad username, password OR client id.
MQTT_ERR_CONN_TLS_ HANDSHAKE_FAILED	16#3230	Error on TLS handshake.
MQTT_ERR_CONN_SERV ER_CERT_NOT_VALID	16#3231	Server certificate not valid. Check if PLC date has been set correctly.
MQTT_ERR_CONN_SERV ER_CERT_NOT_PEM	16#3232	Server certificate format is not formatted as PEM.
MQTT_ERR_CONN_SERV ER_CERT_EXPIRED	16#3233	Server certificate has expired.
MQTT_ERR_CONN_CLIE NT_CERT_NOT_VALID	16#3234	Client certificate not valid. Check if PLC date has been set correctly.
MQTT_ERR_CONN_CLIE NT_CERT_NOT_PEM	16#3235	Client certificate or client key format is not formatted as PEM.
MQTT_ERR_CONN_CLIE NT_CERT_EXPIRED	16#3236	Client certificate has expired.
MQTT_ERR_INPUT_02_0	16#4020	Function block Input 02 error (error case 0), specific error depends on used function block: ● MqttConnectWithCertBuffer (FB): Parameter Conn of function block was not set. ● MqttConnectWithCertFile (FB): Parameter Conn of function block was not set. ● MqttGetReceivedPacket (FB): Parameter Conn of function block was not set. ● MqttPublish (FB): Parameter Conn of function block was not set. ● MqttSubscribe (FB): Parameter Conn of function block was not set. ● MqttUnsubscribe (FB): Parameter Conn of function block was not set. MqttPing (FB): Parameter Conn of function block was not set.

Parameter	Value	Description
MQTT_ERR_INPUT_03_0	16#4030	Function block Input 03 error (error case 0), specific error depends on used function block: ● MqttGetReceivedPacket (FB): Pointer payload not initialized. ● MqttPublish (FB): Publish topic name must not contain wildcard characters (+ or #). ● MqttSubscribe (FB): Topic is missing. ● MqttUnsubscribe (FB): Topic is missing.
MQTT_ERR_INPUT_03_1	16#4031	Function block Input 03 error (error case 1), specific error depends on used function block: ● MqttPublish (FB): Payload is not set in MQTT_MESSAGE.
MQTT_ERR_INPUT_04_0	16#4040	Function block Input 04 error (error case 0), specific error depends on used function block: ● MqttConnectWithCertBuffer (FB): Check if Port number has been set correctly (0 is not accepted). ● MqttConnectWithCertFile (FB): Check if Port number has been set correctly (0 is not accepted).
MQTT_ERR_INPUT_06_0	16#4060	Function block Input 06 error (error case 0), specific error depends on used function block: ● MqttConnectWithCertFile (FB): Server certificate file was not found.
MQTT_ERR_INPUT_07_0	16#4070	Function block Input 07 error (error case 0), specific error depends on used function block: ● MqttConnectWithCertFile (FB): Client certificate file was not found.
MQTT_ERR_INPUT_08_0	16#4080	Function block Input 08 error (error case 0), specific error depends on used function block: ● MqttConnectWithCertFile (FB): Client key file was not found.
MQTT_ERR_INPUT_12_0	16#4120	Function block Input 12 error (error case 0), specific error depends on used function block: ● MqttConnectWithCertBuffer (FB): Couldn't initialize Last Will message because the topic is not set. ● MqttConnectWithCertFile (FB): Couldn't initialize Last Will message because the payload is not set.

Parameter	Value	Description
MQTT_ERR_INPUT_12_1	16#4121	Function block Input 12 error (error case 1), specific error depends on used function block: ● MqttConnectWithCertBuffer (FB): Couldn't initialize Last Will message because the topic is not set. ● MqttConnectWithCertFile (FB): Couldn't initialize Last Will message because the payload is not set.
MQTT_ERR_FATAL_ERROR	16#5FFFF	Fatal error state machine.

MQTT_QOS (Enum)

Parameter	Value	Description
QOS_0	-	Fire and forget (At most once delivered).
QOS_1	-	Simple acknowledgement (At least once delivered).
QOS_2	-	Complex acknowledgement (Exactly once delivered).

MQTT_MESSAGE

This structure is used for messages which can be published or used for LastWill on MqttConnect(FB).

Variable name	Data type	Default value	Description
sTopic	STRING(MQTT_MAX_TOPIC_LEN)	Empty string	Topic where this message belongs to.
pbyPayload	POINTER TO BYTE	0	Payload which should be sent.
dwLen	DWORD	0	Length of the payload.
eQos	MQTT_QOS	QOS_0	Quality of Service level.
xRetainFlag	BOOL	FALSE	True = message must be stored by the server, False = server must not store this message.

MQTT_CONNECTION

Internal data required by the library to operate. This structure allocates memory and it is used to identify the MQTT connection you want to work with

Parameter	Data type	Range
abyConn	Array	MQTT_CLIENT_STRUCT_SIZE
abyTxBuf	Array	MQTT_TX_BUF_SIZE
abyRxBuf	Array	MQTT_RX_BUF_SIZE
abyMsgBuf	Array	MQTT_MSG_BUF_SIZE

1.5.4.24.3 Global variables

MQTT_CONSTANTS

Parameter	Datatype	Value	Description
MQTT_MAX_IP_ADDRESS_LEN	Word	15	Maximum length of the IP address.
MQTT_MAX_PEM_KEY_LEN	Word	2048	Maximum length of the PEM key.
MQTT_MAX_PEM_CERT_LEN	Word	3072	Maximum length of the PEM certificate.
MQTT_MAX_FILE_PATH_LEN	Word	255	Maximum length of the file path to the certificate files.
MQTT_MAX_CLIENT_ID_LEN	Word	250	Maximum length of the client id.
MQTT_MAX_USERNAME_LEN	Word	250	Maximum length of the username.
MQTT_MAX_PASSWORD_LEN	Word	250	Maximum length of the password.
MQTT_MAX_TOPIC_LEN	Word	255	Maximum length of the topic.
MQTT_CLIENT_STRUCT_SIZE	Word	336	Size of the internal connection structure representing the connection state.
MQTT_TX_BUF_SIZE	Word	1024	Size of the internally used output buffer.
MQTT_RX_BUF_SIZE	Word	1024	Size of the internally used input buffer.
MQTT_MSG_BUF_SIZE	Word	2148	Size of the internally used message buffer.

1.5.4.25 Onboard IO library

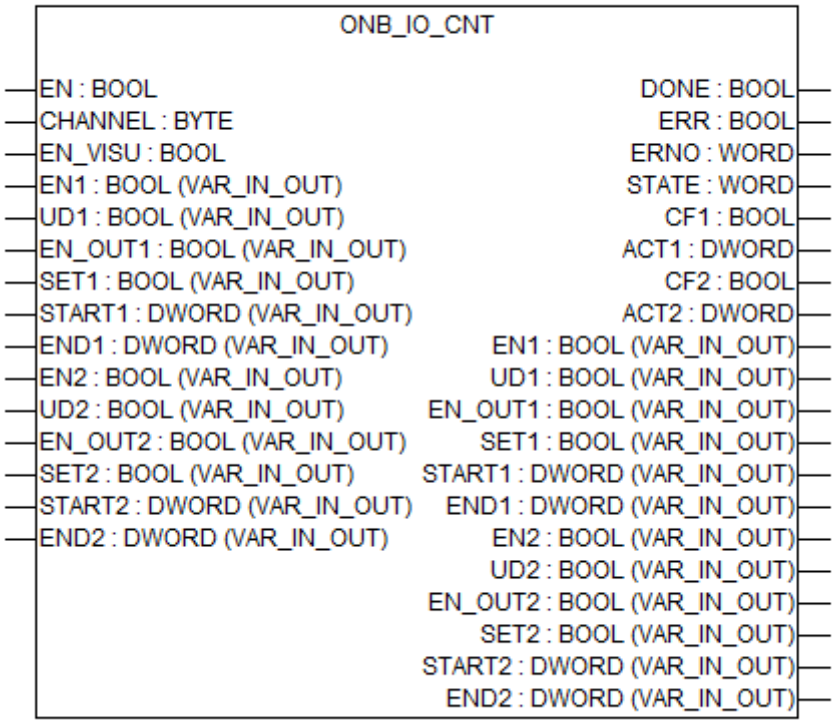
Library file name: **OnBoardIO_AC500_Vx.lib**

The Onboard I/O Library contains all function blocks necessary for using the Onboard I/Os of AC500 CPUs PM55x and PM56x.

The library is automatically included if a project has an processor module PM55x/PM56x.

1.5.4.25.1 Function blocks

ONB_IO_CNT

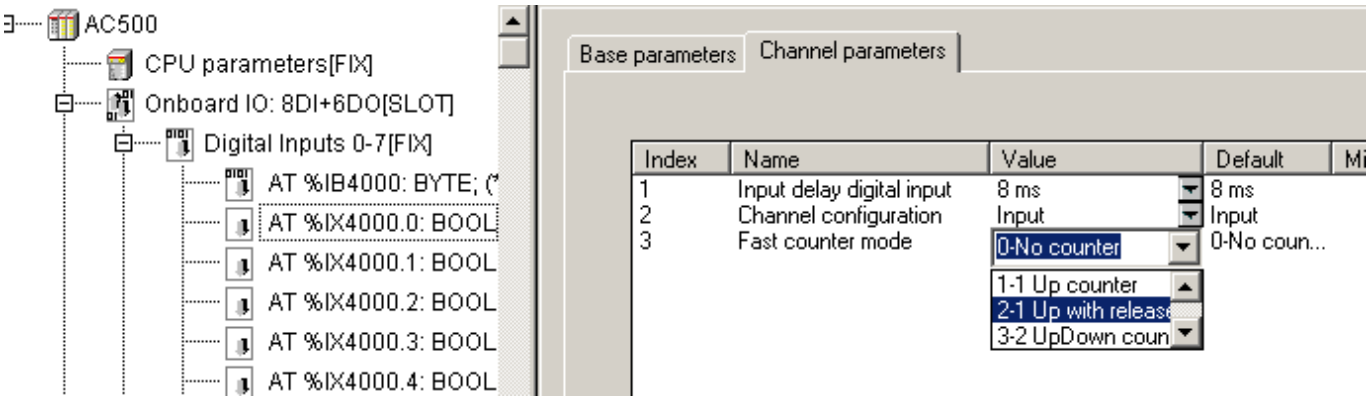


Parameter	Value
Included in library	OnBoardIO_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	Counter_OBIO

The function block ONB_IO_CNT is used to control the fast counters which are integrated in AC500 CPUs PM55x and PM56x.

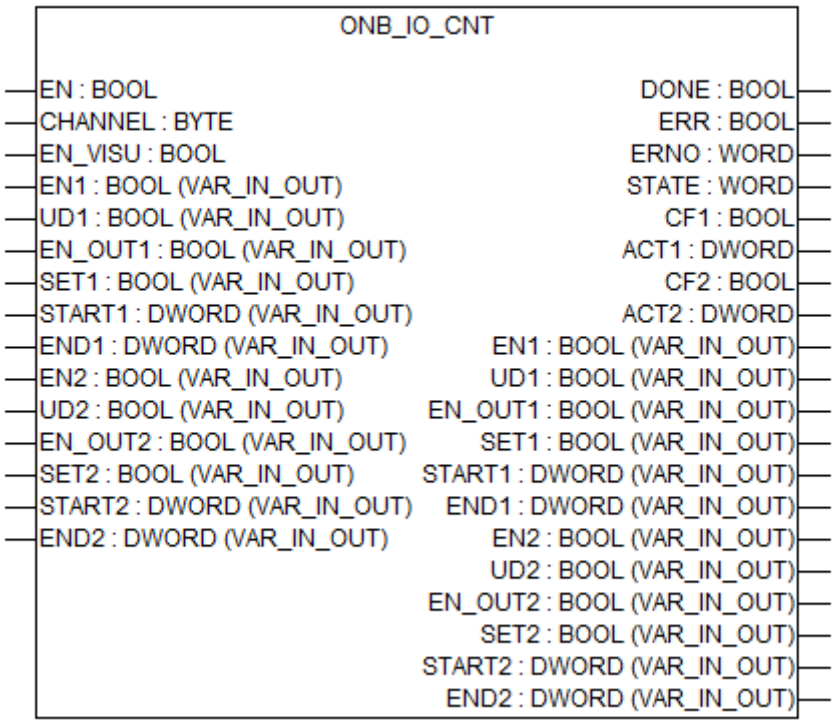
The operating modes of the fast counters are described in detail in *Chapter 1.6.2.6.1.2.10 “Fast counter” on page 4351*.

To activate the fast counters of AC500 CPUs PM55x and PM56x, the parameter "Fast Counter" of the I/O module must be set to the desired counting mode in the control system configuration.



The function block ONB_IO_CNT has an integrated visualization block that can be used to control all block functions in parallel to the user program (if input EN_VISU = TRUE). A detailed functional description of the visualization and how to integrate it can be found at the end of this Function Block description.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CHANNEL

Data type	Default value	Range	Unit
BYTE	-	-	-

Input CHANNEL is used to select the input for the counter. Currently the only valid value is 0. The device occupies the inputs I0...I1. If an invalid value is entered at input CHANNEL or if the selected channel is not configured as a counter, the function block is aborted with DONE=ERR=TRUE and a corresponding error number at ERNO.

CHANNEL contains the channel number managed by the function block:

- CHANNEL = 0: the output O2 is managed
- CHANNEL = 1: the output O3 is managed

EN_VISU

Data type	Default value	Range	Unit
BOOL	-	-	-

If input EN_VISU = TRUE, it is also possible to control the function block inputs (except CHANNEL and EN_VISU) via the integrated visualization of the function block. If input EN_VISU = FALSE, control via the visualization is disabled and the labelling of the corresponding control elements is displayed in gray. The actual values are always displayed.

EN1

Data type	Default value	Range	Unit
BOOL	-	-	-

If input EN1 = TRUE, pulse counting of counter 1 is enabled. If EN1 = FALSE, no pulse counting is performed and the pulses are lost.

Input EN1 corresponds to bit 1 in control byte 0.

UD1

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD1, the counting direction is set for operating modes with up/down counters (modes 3...6).

The following applies:

UD1 = FALSE → counter 1 counts up

UD1 = TRUE → counter 1 counts down

If input SET1 = TRUE, the counter takes this value.

Input UD1 corresponds to bit 0 in control byte 0.

EN_OUT1

Data type	Default value	Range	Unit
BOOL	-	-	-

Input EN_OUT1 is used to enable/disable the output control for the operating modes with direct output activation (modes 1 and 2).

The functionality of the input variable is not supported before Onboard I/O firmware V1.04.

Only for fast counter operating modes 1 and 2:

If EN_OUT1 = FALSE, the related digital output DO acts as an output indicating "end value reached" of the fast counter.

If EN_OUT1 = TRUE, the related digital output DO can be used as normal digital output.

The value change of EN_OUT1 is only effective when EN = TRUE.

Input EN_OUT1 corresponds to bit 3 in control byte 0.

SET1

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET1 = TRUE, the counter takes the values from the inputs UD1, START1 and END1.

As long as input SET1 = TRUE, no pulses are counted because the counter is always over-written by the start value START1.

Input SET1 corresponds to bit 2 in control byte 0.

START1

Data type	Default value	Range	Unit
DWORD			

At input START1, the start value of counter 1 is entered.

If input SET1 = TRUE, counter 1 takes this value.

END1

Data type	Default value	Range	Unit
DWORD	-	-	-

At input END1, the end value of counter 1 is entered.

If input SET1 = TRUE, counter 1 takes this value.

UD2

Data type	Default value	Range	Unit
BOOL	-	-	-

At input UD2, the counting direction is set for operating modes with up/down counters (modes 3...6).

The following applies:

UD2 = FALSE → counter 2 counts up

UD2 = TRUE → counter 2 counts down

If input SET2 = TRUE, the counter takes this value.

Input UD2 corresponds to bit 0 in control byte 1.

EN_OUT2

Data type	Default value	Range	Unit
BOOL	-	-	-

The functionality of the input variable is not supported before Onboard I/O firmware V1.04.

Input EN_OUT2 is reserved. The value FALSE has to be applied.

Input EN_OUT2 corresponds to bit 3 in control byte 1.

SET2

Data type	Default value	Range	Unit
BOOL	-	-	-

If set input SET2 = TRUE, the counter takes the values from the inputs UD2, START2 and END2.

As long as input SET2 = TRUE, no pulses are counted because the counter is always overwritten by the start value START2.

Input SET2 corresponds to bit 2 in control byte 1.

START2

Data type	Default value	Range	Unit
DWORD	-	-	-

At input START2, the start value of counter 2 is entered.

If input SET2 = TRUE, counter 2 takes this value.

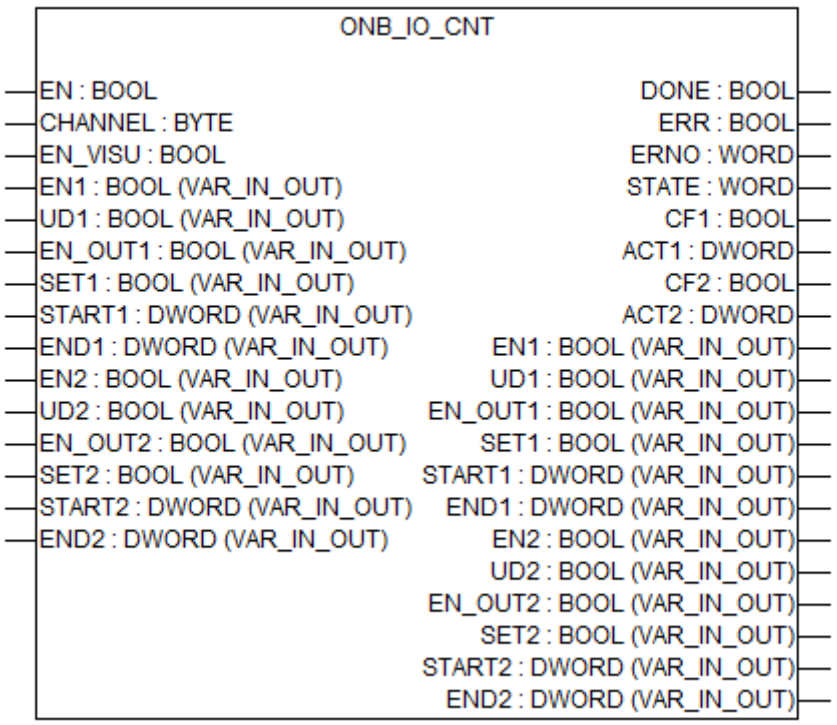
END2

Data type	Default value	Range	Unit
DWORD	-	-	-

At input END2, the end value of counter 2 is entered.

If input SET2 = TRUE, counter 2 takes this value.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE

Data type	Default value	Range	Unit
WORD	-	-	-

Output STATE indicates the current mode of fast counter. The mode of fast counter (0-10) can be configured in the channel parameter of the PLC configuration (please refer to fast counter mode in system technology chapter 9.3).

CF1

Data type	Default value	Range	Unit
BOOL	-	-	-

If counter 1 has reached the programmed end value (input END1), output CF1 (end value reached) is set to TRUE and stored. When setting the counter (via input SET1), CF1 is set to FALSE.

Output CF1 corresponds to bit 0 in status byte 0.

ACT1

Data type	Default value	Range	Unit
DWORD	-	-	-

At output ACT1, the actual value = counter reading of counter 1 is output as double word.

CF2

Data type	Default value	Range	Unit
BOOL	-	-	-

If counter 2 has reached the programmed end value (input END2), output CF2 (end value reached) is set to TRUE and stored. When setting the counter (via input SET2), CF2 is set to FALSE.

Output CF2 corresponds to bit 0 in status byte 1.

ACT2

Data type	Default value	Range	Unit
DWORD	-	-	-

At output ACT2, the actual value = counter reading of counter 2 is output as double word.

Function call in ST

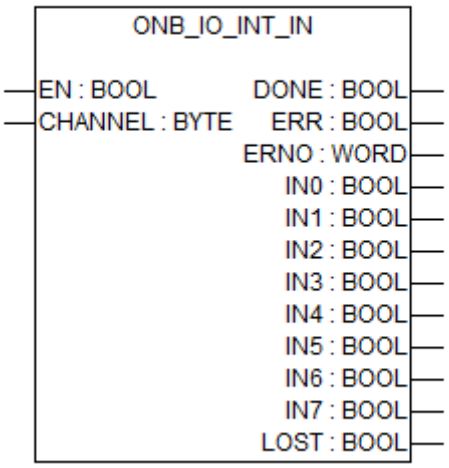
ONB_IO_CNT_CF2      := ONB_IO_CNT.CF2;
ONB_IO_CNT_ACT2     := ONB_IO_CNT.ACT2;
```

ONB_IO_INT_IN

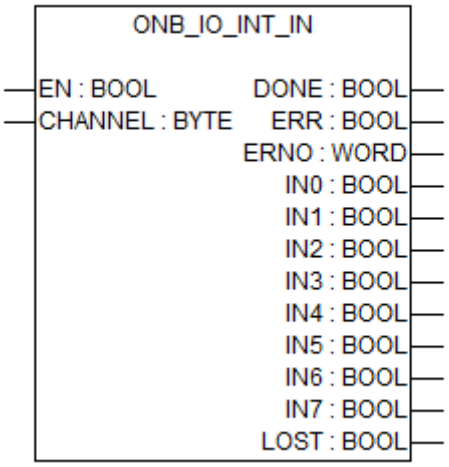


Parameter	Value
Included in library	OnBoardIO_AC500_V13.lib
Available as of firmware	V1.3.0

Parameter	Value
Type	Function block with historical values
Group	Interrupt_Input_OBIO

Using the function block ONB_IO_INT_IN, the interrupt program can be polled which inputs (IN0...IN3) triggered interrupts since the last function block calling. The corresponding outputs IN0...IN3 are set to TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CHANNEL

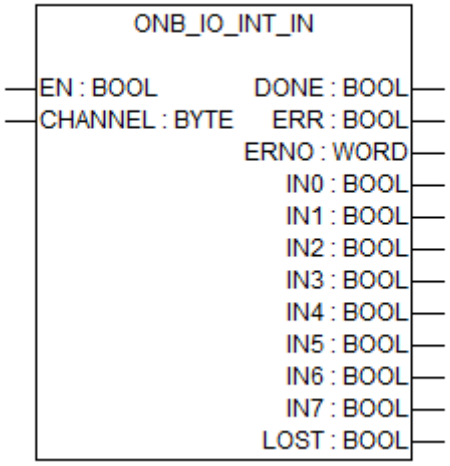
Data type	Default value	Range	Unit
BYTE	-	-	-

Input CHANNEL is used to select the input for the counter. Currently the only valid value is 0. The device occupies the inputs I0...I1. If an invalid value is entered at input CHANNEL or if the selected channel is not configured as a counter, the function block is aborted with DONE=ERR=TRUE and a corresponding error number at ERNO.

CHANNEL contains the channel number managed by the function block:

- CHANNEL = 0: the output O2 is managed
- CHANNEL = 1: the output O3 is managed

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

IN0...IN7

Data type	Default value	Range	Unit
BOOL	-	-	-

The outputs IN0...IN7 display which inputs triggered an interrupt since the last function block calling. 4 channels (I0..I3) of AC500-eCo Onboard I/O can be configured as interrupt inputs. Therefore, IN0…IN3 will be used to display the status of interrupt inputs.

LOST

Data type	Default value	Range	Unit
BOOL	-	-	-

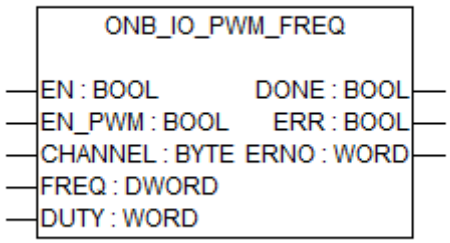
If interrupt pulse was lost, LOST=TRUE. Otherwise, LOST=FALSE.

Function call in ST

```
ONB_IO_INT_IN    (EN      := ONB_IO_INT_IN_EN,
    CHANNEL := ONB_IO_INT_IN_CHANNEL);

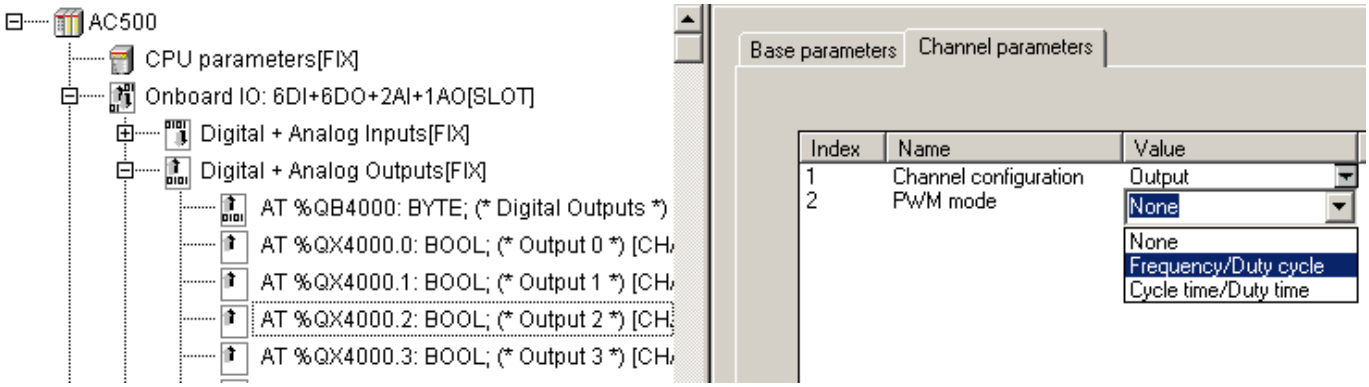
ONB_IO_INT_IN_DONE     := ONB_IO_INT_IN.DONE;
ONB_IO_INT_IN_ERR      := ONB_IO_INT_IN.ERR;
ONB_IO_INT_IN_ERNO     := ONB_IO_INT_IN.ERNO;
ONB_IO_INT_IN_IN0      := ONB_IO_INT_IN.IN0;
ONB_IO_INT_IN_IN1      := ONB_IO_INT_IN.IN1;
ONB_IO_INT_IN_IN2      := ONB_IO_INT_IN.IN2;
ONB_IO_INT_IN_IN3      := ONB_IO_INT_IN.IN3;
ONB_IO_INT_IN_IN4      := ONB_IO_INT_IN.IN4;
ONB_IO_INT_IN_IN5      := ONB_IO_INT_IN.IN5;
ONB_IO_INT_IN_IN6      := ONB_IO_INT_IN.IN6;
ONB_IO_INT_IN_IN7      := ONB_IO_INT_IN.IN7;
ONB_IO_INT_IN_LOST     := ONB_IO_INT_IN.LOST;
```

ONB_IO_PWM_FREQ



Parameter	Value
Included in library	OnBoardIO_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	PWM_OBIO

The onboard digital outputs O2…O3 can be used to control output pulses signals with an adjustable duty cycle (ON/OFF ratio).The PWM operating mode is configured in PLC Configuration using channel parameters (see figure below).



After that, it is activated during the initialization phase (power-on, cold start, warm start).

The data exchange to and from the user program is performed using input and output operands. These necessary operands are created and reserved automatically when target is set as CPU PM55x or PM56x.

The CPU PM55x or PM56x provides 2 outputs which can be used in PWM mode (O2 and O3). Both have the same specification and work with the same frequency. The duty time can be adjusted independently.

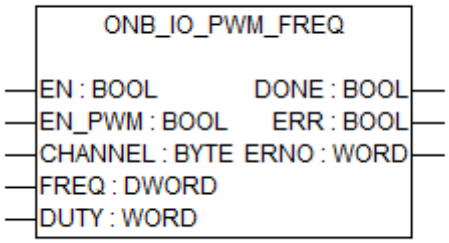
The function block ONB_IO_PWM_FREQ should be used to control with input EN_PWM, configure the frequency with input FREQ and the input duty cycle DUTY of PWM outputs (pulse-width modulator).

The PWM function can be realized by using two function blocks:

- ONB_IO_PWM_FREQ (this function block)
- ONB_IO_PWM_TIME *Chapter 1.5.4.25.1.4 “ONB_IO_PWM_TIME” on page 1746*

> *The frequency for both PWM channels must be the same. If both channels are used, the frequency of the first PWM channel (CHANNEL=0) is valid for both channels. The frequency input of the second channel (CHANNEL=1) must be set to 0.*

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

EN_PWM

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_PWM = TRUE, the pulse-width modulator is enabled. If EN_PWM = FALSE, no pulse-width modulation is performed.

Input EN_PWM corresponds to output bit 7 in "control byte PWM x ".

CHANNEL

Data type	Default value	Range	Unit
BYTE	-	-	-

Input CHANNEL is used to select the input for the counter. Currently the only valid value is 0. The device occupies the inputs I0...I1. If an invalid value is entered at input CHANNEL or if the selected channel is not configured as a counter, the function block is aborted with DONE=ERR=TRUE and a corresponding error number at ERNO.

CHANNEL contains the channel number managed by the function block:

- CHANNEL = 0: the output O2 is managed
- CHANNEL = 1: the output O3 is managed

FREQ

Data type	Default value	Range	Unit
DWORD	-	125 - 20000	Hz

The input FREQ is used to specify the frequency of PWM.

The frequency value is defined with a double word (DWORD), but the internal communication is realized with WORD type. For frequencies greater than 65535, an additional bit is used internally as a multiplier. Thus, for such frequencies the resolution becomes 10 Hz.

The additional multiplier bit is the bit 0..1 of "control byte PWM x ".

Input FREQ corresponds to output word "PWM x -Frequency/Cycle time".

DUTY

Data type	Default value	Range	Unit
WORD	-	0.0 - 100.0	%

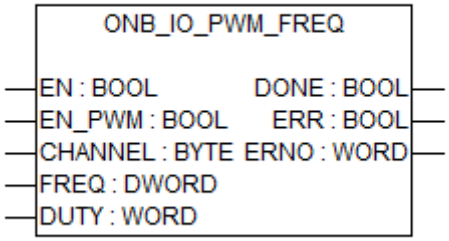
The input DUTY is used to specify the percentage of time set to TRUE. The duty cycle is from 0 to 1000 (0.0 % to 100.0 %); the value is written without dot. That means, for example, for 75.8 % the value written will be 758. The max. value authorized will be 1000 to specify a duty cycle = 100.0 %.

On fast outputs O2 and O3, the brightness of the yellow LED depends on the value of duty cycle specified (from 0 to 100 %).

If the written value is greater than 1000, the value 1000 will be read. If the written value is less than 0, the value 0 will be read. No error message will be generated in these two cases. The last entered valid value will be used or the value '0' if no value has been entered before.

Input DUTY corresponds to output word "PWM x - Duty cycle/Duty time".

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

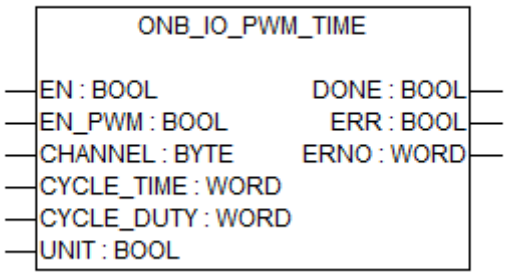
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
ONB_IO_PWM_FREQ    (EN       := ONB_IO_PWM_FREQ_EN,
EN_PWM  := ONB_IO_PWM_EN_PWM,
CHANNEL := ONB_IO_PWM_FREQ_CHANNEL,
FREQ    := ONB_IO_PWM_FREQ_FREQ,
DUTY    := ONB_IO_PWM_FREQ_DUTY);

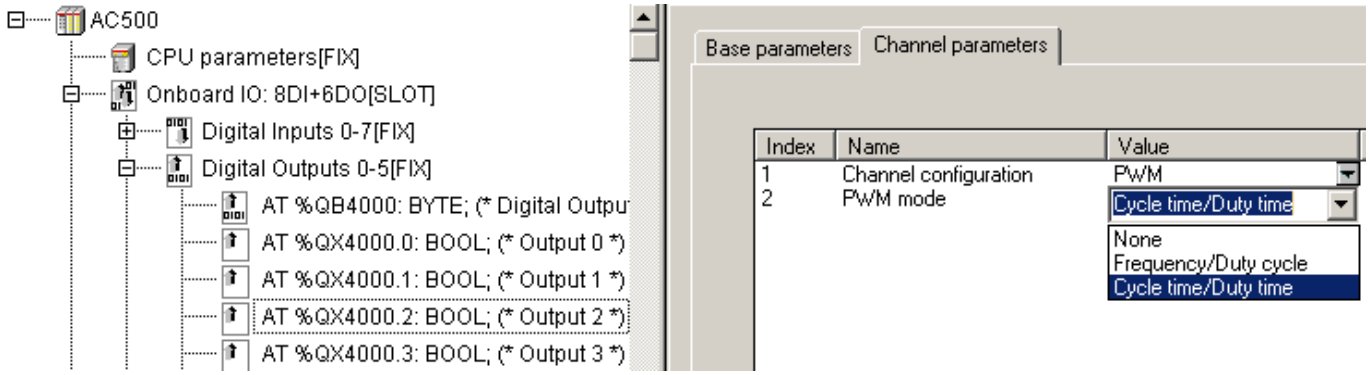
ONB_IO_PWM_FREQ_DONE      := ONB_IO_PWM_FREQ.DONE;
ONB_IO_PWM_FREQ_ERR       := ONB_IO_PWM_FREQ.ERR;
ONB_IO_PWM_FREQ_ERNO      := ONB_IO_PWM_FREQ.ERNO;
```

ONB_IO_PWM_TIME



Parameter	Value
Included in library	OnBoardIO_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	PWM_OBIO

The onboard digital outputs O2…O3 can be used to control output pulses signals with an adjustable duty cycle (ON/OFF ratio).The PWM operating mode is configured in PLC Configuration using channel parameters (see figure below).



After that, it is activated during the initialization phase (power-on, cold start, warm start).

The data exchange to and from the user program is performed using input and output operands. These necessary operands are created and reserved automatically when target is set as CPU PM55x or PM56x.

The CPU PM55x or PM56x provides two outputs which can be used in PWM mode (O2 and O3). Both have the same specification and work with the same frequency. The duty time can be adjusted independently.

The function block ONB_IO_PWM_TIME should be used to control with input EN_PWM, configure the frequency with input CYCLE_TIME and the input CYCLE_DUTY of PWM outputs (pulse-width modulator).

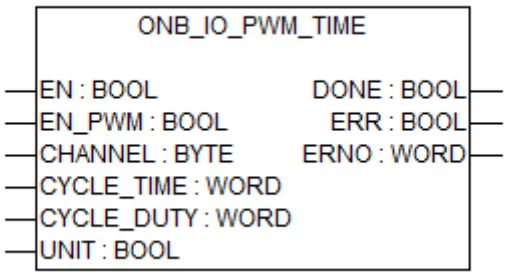
The PWM function can be realized by using two function blocks:

- ONB_IO_PWM_FREQ ↳ *Chapter 1.5.4.25.1.3 “ONB_IO_PWM_FREQ” on page 1743*
- ONB_IO_PWM_TIME (this function block)

For PWM functionality two channels share the same frequency. With this by using the second channel, frequency on its function block won't work. To resolve this, enable the function block of the first channel and set the frequency.

The cycle time for both PWM channels must be the same. If both channels are used, the cycle time of the first PWM channel (CHANNEL=0) is valid for both channels. The cycle time input of the second channel (CHANNEL=1) must be set to 0.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

EN_PWM

Data type	Default value	Range	Unit
BOOL	-	-	-

If EN_PWM = TRUE, the pulse-width modulator is enabled. If EN_PWM = FALSE, no pulse-width modulation is performed.

Input EN_PWM corresponds to output bit 7 in "control byte PWM x ".

CHANNEL

Data type	Default value	Range	Unit
BYTE	-	-	-

Input CHANNEL is used to select the input for the counter. Currently the only valid value is 0. The device occupies the inputs I0...I1. If an invalid value is entered at input CHANNEL or if the selected channel is not configured as a counter, the function block is aborted with DONE=ERR=TRUE and a corresponding error number at ERNO.

CHANNEL contains the channel number managed by the function block:

- CHANNEL = 0: the output O2 is managed
- CHANNEL = 1: the output O3 is managed

CYCLE_TIME

Data type	Default value	Range	Unit
WORD	-	50 µs (20 kHz) - 8000 µs (125 Hz)	µs (Hz)

The input CYCLE_TIME is used to specify the cycle time of PWM. The unit can be also set as "ms" by configuring the input variable UNIT=TRUE.

Input CYCLE_TIME corresponds to output word "PWM x -Frequency/Cycle time".

CYCLE_DUTY

Data type	Default value	Range	Unit
WORD	-	-	-

Input CYCLE_DUTY is used to preset the duty time for the output. The input CYCLE_DUTY is used to specify the time of TRUE signal. By normal operation mode, the value of CYCLE_DUTY should be smaller or equal to the value of CYCLE_TIME.

On fast outputs O2 and O3 the brightness of the yellow LED depends on the value of duty time specified.

The last entered valid value will be used or the value '0' if no value has been entered before.

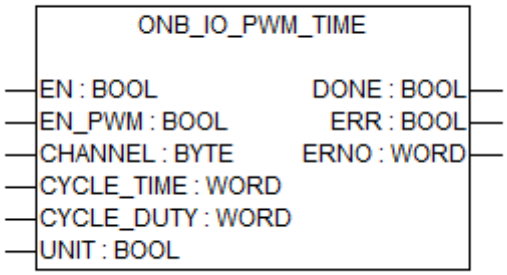
Input CYCLE_DUTY corresponds to output word "PWM x - Duty cycle/Duty time".

UNIT

Data type	Default value	Range	Unit
BOOL	-	-	-

Input UNIT is used to preset the timebase for the PWM output. FALSE sets the timebase to µs and TRUE to ms.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
ONB_IO_PWM_TIME (EN          := ONB_IO_PWM_TIME_EN,
EN_PWM      := ONB_IO_PWM_TIME_EN_PWM,
CHANNEL     := ONB_IO_PWM_TIME_CHANNEL,
CYCLE_TIME  := ONB_IO_PWM_TIME_CYCLE_TIME,
CYCLE_DUTY  := ONB_IO_PWM_TIME_CYCLE_DUTY,
UNIT        := ONB_IO_PWM_TIME_UNIT);

ONB_IO_PWM_TIME_DONE      := ONB_IO_PWM_TIME.DONE;
ONB_IO_PWM_TIME_ERR       := ONB_IO_PWM_TIME.ERR;
ONB_IO_PWM_TIME_ERNO      := ONB_IO_PWM_TIME.ERNO;
```

1.5.4.26 PROFIBUS DP library

Library file name: **PROFIBUS_AC500_Vx.lib**

The PROFIBUS DP Communication Module in the AC500 controller series can solely be operated in operating mode DP master.

The function blocks provided by PROFIBUS DP library can be used to work with Communication Module CM592-DP. Depending on the functionality runtime system or directly the Communication Module is accessed. Required definitions are provided by the libraries *SysExt_AC500_V10.lib*, *PROFIBUS_CME_AC500_V25.lib*, *PROFIBUS_CMN_AC500_V25.lib* and *CMN_AC500_V24.lib*. The library is automatically included into the user program due to Communication Module configuration.

Basically this library replaces the library *PROFIBUS_AC500_V10.lib* and provides function block types with identical type names and input and output layouts. The function blocks act in compatible behavior for both Communication Module types. Thus description of the functionality is valid regardless of the Communication Module type. Already existing user programs can be reused without changes. However, CM592-DP uses different PROFIBUS protocol stack implementations which acts different in a few details. If such differences are to be considered in using the function blocks, this is described at the certain Function Block descriptions.

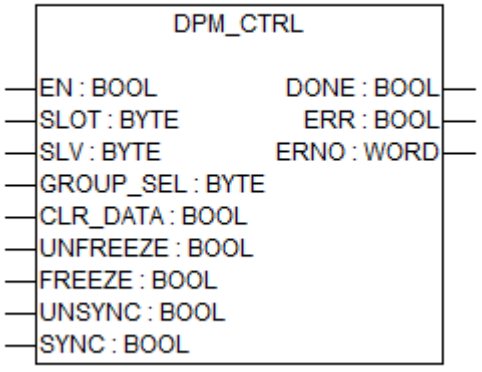
Neither the function blocks of the PROFIBUS DP library nor the PROFIBUS DP communication can be run in simulation mode. The PROFIBUS DP communication only runs in the PLC mode RUN, but not in the modes Single Cycle, Step and Breakpoint.

It is not necessary to include the library for normal cyclic data exchange via PROFIBUS DP. The library contains additional function blocks which allow an easy handling of the PROFIBUS DP Communication Module. Additionally, various data types are defined in this library. These structures enable a clear presentation of data sets.

If you update an Automation Builder project from Automation Builder Version 1.2 to a Automation Builder Version ≥ 1.2, delete the PROFIBUS_AC500_V10.lib from your CODESYS V2.3 project in advance.

1.5.4.26.1 Function blocks

DPM_CTRL



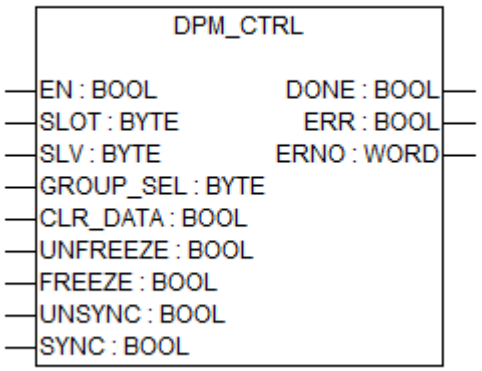
Parameter	Value
Included in library	PROFIBUS_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	Control

The function block DPM_CTRL implements thePROFIBUS DP function DDLM_Global_Control. DDLM_Global_Control is a broadcast function.

Using global control commands, the output data of one, several or all slaves can be reset and input or output data of slaves can be synchronized. The commands are selected by different combinations of the outputs CLR_DATA, FREEZE / UNFREEZE and SYNC / UNSYNC. The called slaves are selected using three parameters. First, during project planning, the slaves can be divided into logical groups. Then, during run time, the slaves can be called individually or in groups via the function block inputs SLV and GROUP_SLV.

Every time a FALSE → TRUE edge is applied to input EN, DPM_CTRL reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE → TRUE edges at input EN are ignored until the processing of the active requests is finished. The completion of the request processing is indicated by DONE = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

SLV

Data type	Default value	Range	Unit
BYTE	-	-	-

At input SLV the bus address of the DP slave is specified, to which a global control command shall be sent.

With SLV = 0..126, a particular slave with the corresponding bus address is called directly, independent of the group to which it was assigned during configuration and independent of the value applied at function block input GROUP_SEL.

If SLV = 127 and GROUP_SEL = 0, all slaves are called simultaneously. The selection of individual slave groups is done with SLV = 127 and a combination of GROUP_SEL and the group assignment made during configuration. For that reason, the function block outputs SLV and GROUP_SEL always have to be considered together with the group assignment made during configuration.

For possible combinations see *Possible combinations of global control commands*.

GROUP_SEL

Data type: BYTE

At input GROUP_SEL (slave group selection) the slave groups are selected, to which a global control command shall be sent.

With SLV = 0..126, a particular slave with the corresponding bus address is called directly, independent of the group assignment which was made during configuration and independent of the value applied at function block input GROUP_SEL. If GROUP_SEL = 0 and SLV = 127, all slaves are called simultaneously.

The selection of individual slave groups is done with SLV = 127 and a combination of GROUP_SEL and the group assignment made during configuration. For that reason, the function block outputs SLV and GROUP_SEL always have to be considered together with the group assignment made during configuration.

For possible combinations see *Possible combinations of global control commands*.

CLR_DATA

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Using input CLR_DATA (clear data), the output data of slaves can be reset on site.

The called slave resets its outputs on-site to 0 when it receives a global control command with CLR_DATA = TRUE.

If the CLR_DATA part of a command is FALSE, the outputs of the called slaves keep their current state. Slaves which are not called ignore the entire command.

For possible combinations see *Possible combinations of global control commands*.

CLR_DATA is not supported on using function block DPM_CTRL with Communication Module of type CM592-DP.

UNFREEZE Data type: BOOL

When input UNFREEZE is TRUE, the synchronization mode for input data of the called slaves is terminated, regardless of the current state of input FREEZE (TRUE or FALSE).

Then, the called slaves forward their input values directly to the master again. If the UNFREEZE part of a command is FALSE, the called slaves keep their current state. The UNFREEZE command is ignored, if the called slave is not in the FREEZE state. Slaves, which are not called, ignore the entire command.

UNFREEZE always has to be considered together with FREEZE.

For possible combinations see *Possible combinations of global control commands*.

FREEZE Data type: BOOL

When input FREEZE is TRUE and input UNFREEZE is FALSE at the same time, the called slaves change to input data synchronization mode.

This mode is activated with the first FREEZE command. As a result, the called slaves simultaneously freeze the values currently applying at their local inputs and store them temporarily. During the subsequent process data cycles, the temporarily stored input values are transmitted to the master, regardless of possible changes of the input values in the mean time.

When another FREEZE command is received, the temporarily stored input values are updated, i.e. the called slaves simultaneously store the present input values into an internal buffer once again and then transmit these values to the master during the subsequent cycles.

FREEZE always has to be considered together with UNFREEZE.

For possible combinations see *Possible combinations of global control commands*.

UNSYNC Data type: BOOL

If input UNSYNC is TRUE, the synchronization mode for the output data of the called slaves is terminated, regardless of the current state of input SYNC (TRUE or FALSE). From now on, the called slaves immediately forward the output data received from the master to their own outputs again.

If the UNSYNC part of a command is FALSE, the called slaves keep their current state. The UNSYNC command is ignored, if the called slave is not in the SYNC state. Slaves which are not called ignore the entire command.

UNSYNC always has to be considered together with SYNC.

For possible combinations see *Possible combinations of global control commands*.

SYNC Data type: BOOL

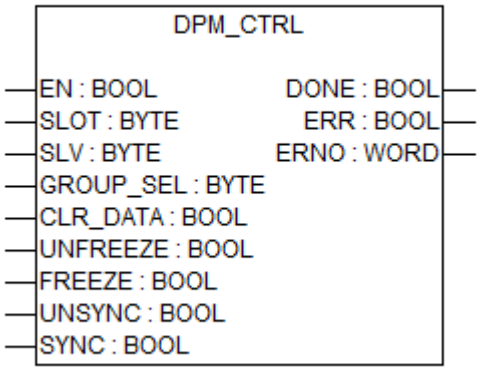
If input SYNC is TRUE and input UNSYNC is FALSE at the same time, the called slaves change to output data synchronization mode.

This mode is activated with the first SYNC command. As a result, the called slaves freeze the current states of their local outputs. The output data sent during the subsequent process data cycles are first stored only locally in these slaves.

On reception of another SYNC command, the slaves then simultaneously apply these temporarily stored values to their outputs. SYNC always has to be considered together with UNSYNC.

For possible combinations see *Possible combinations of global control commands*.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
CTRL
     (EN      := CTRL_EN,
     SLOT  := CTRL_SLOT,
     SLV      := CTRL_SLV,
     GROUP_SEL  := CTRL_GROUP_SEL,
     CLR_DATA      := CTRL_CLR_DATA,
     UNFREEZE      := CTRL_UNFREEZE,
     FREEZE  := CTRL_FREEZE,
     UNSYNC  := CTRL_UNSYNC,
     SYNC  := CTRL_SYNC);
```

```
CTRL_DONE := CTRL.DONE;
CTRL_ERR  := CTRL.ERR;

SYSDIAG_ERNO:= SYSDIAG.ERNO;
```

Selection of the called slaves

Group assignment is part of the PROFIBUS DP slave configuration procedure and will be loaded to the PROFIBUS DP master as part of the slave parameter set. As default a slave is not connected to a specific group. This has to be done manually. The group assignment parameter is coded of type byte and provides a bitfield. Each bit points to a certain group and several bits can be set in parallel. Thus a slave can be assigned to multiple groups at the same time which is limited to 8 groups in total.

G8	G7	G6	G5	G4	G3	G2	G1
7	6	5	4	3	2	1	0

For instance, if a slave is to be assigned to the groups 7 and 1, the master sends a byte with the decimal value 65 (= binary value 01000001) to this slave.

The function block inputs SLV and GROUP_SEL specify which slaves are to be called by a global control command during run time.

SLV = 0..126 calls only the slave with a bus address = SLV, independent of the group assignment and of the value applied at input GROUP_SEL. All other slaves discard this telegram. Applying SLV = 127 and GROUP_SEL = 0 calls all slaves connected to the bus, independent of their group assignment. The group assignment defined during the configuration is only considered by the slaves if they receive a global control command with SLV = 127 and GROUP_SEL unequal to 0. In this case, each slave compares the GROUP_SEL value with the group assignment byte received during parameterization. The slave accepts the command if a bitwise collation of these two values delivers a result unequal to 0 and discards the command if the collation delivers a value of 0. For instance, if a slave which is assigned to groups 1 and 7 (see above) receives a global control command with SLV = 127 and GROUP_SEL = 64 dec. (= 01000000 bin.), the command is also (among others) addressed to this slave.

Group assignment		0	1	0	0	0	0	0	1
GROUP_SEL	AND	0	1	0	0	0	0	0	0
Result of the comparison		0	1	0	0	0	0	0	0

The following table shows the possible combinations of the three parameters SLV, GROUP_SEL and group assignment and lists the slaves called with these combinations.

SLV	GROUP_SEL	Group assignment	Called slaves
0...126	X	X	Only slave with bus address = SLV
127	0	X	All slaves
127	1 - 255	1 - 255	Slaves, for which a bitwise collation of group assignment and GROUP_SEL delivers a value unequal to 0.

Group assignment does not have impact on cyclic data exchange.

Possible combinations of global control commands

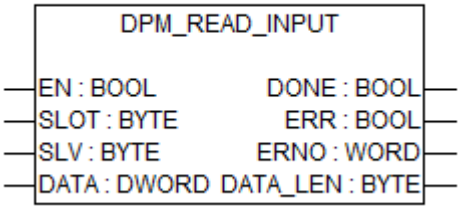
During the process data exchange, the master cyclically transmits the output data to the corresponding slave, which applies these data immediately to its outputs. In return, a slave transmits the values currently applied at its inputs to the master. During this process, the slaves are called one after the other within one bus cycle of the master. As a result, a small time difference appears between the points of time at which the individual slaves apply the received data at their local outputs. In the same way, the points of time differ at which the acquisition of values at the slave inputs and their transmission to the master takes place. A time-synchronization of the inputs or outputs is achieved with the help of global commands. While a CLR_DATA causes all called slaves to set their outputs to 0 once and at the same time, the combinations of SYNC / UNSYNC or FREEZE / UNFREEZE must be considered together.

The following table shows the possible combinations within a global control command and explains their effects.

CLR_ DATA	SYNC	UN-SYNC	FREEZE	UN-FREEZE	Effect
1	X	X	X	X	All called slaves set their outputs to 0
X	0	0	X	X	No effect to SYNC mode
X	0	1	X	X	SYNC mode for output data is terminated
X	1	0	X	X	SYNC mode; the output data received last are applied to the outputs
X	1	1	X	X	SYNC mode for output data is terminated
X	X	X	0	0	No effect to FREEZE mode
X	X	X	0	1	FREEZE mode for input data is terminated
X	X	X	1	0	
X	X	X	1	1	

CLR_DATA is not supported on using function block DPM_CTRL with Communication Module of type CM592-DP.

DPM_READ_INPUT

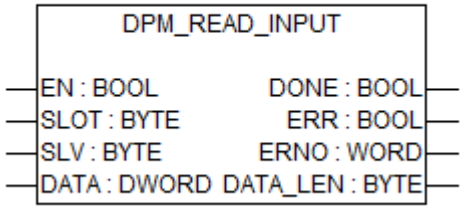


Parameter	Value
Included in library	PROFIBUS_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	Data

The function block DPM_READ_INPUT implements the acyclic PROFIBUS DP function DDLM_RD_Inp which can be used to read input data of a slave. Using this function the master can read also input data of slaves which are assigned to other masters. DPM_READ_INPUT works outside the cyclic process data exchange.

Every time a FALSE → TRUE edge is applied to input EN, DPM_READ_INPUT reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE → TRUE edges at input EN are ignored until the processing of the active requests is finished. The completion of the request processing is indicated by DONE = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

SLV (slave)

Data type: BYTE

At input SLV the bus address of the DP slave is applied, the input data of which shall be read.

DATA (data)

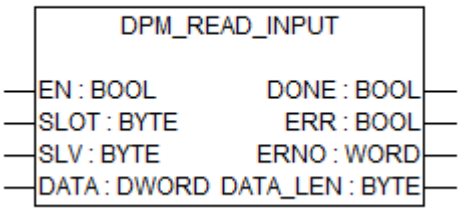
Data type: DWORD

At input DATA the address of the variable to be used to store the received input data is specified via the address operator ADR.

The size of this variable must be big enough to store all input data of the slave (e.g. BYTE array). Furthermore, the format (BYTE, WORD, etc.) of the slave inputs must be considered.

If the slave has mixed inputs of different types, it is recommended to first define a STRUCT data type which represents an image of the slave's input structure (see I/O configuration of the slave) and then to declare a variable of this type.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

DATA_LEN (data length)

Data type: BYTE

Output DATA_LEN displays the length (in bytes) of the input data read by the slave.

DATA_LEN is only valid, if DONE is TRUE and ERR is FALSE. If DATA_LEN contains a value X which is not 0, the function block has stored X bytes of input data in the variable specified at DATA.

Example

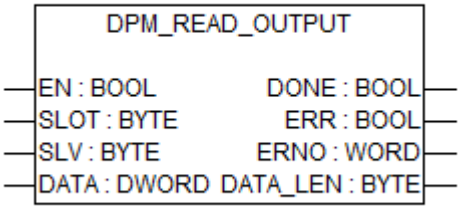
If DATA is a byte array with start index 1, the valid input data of the slave are contained in the entries DATA[1] to DATA[X].

Function call in ST

```
READ_INPUT
     (EN := RAED_INPUT_EN,
     SLOT:= RAED_INPUT_SLOT,
     SLV := RAED_INPUT_SLV,
     DATA:= ADR(RAED_INPUT_DATA));

READ_INPUT_DONE:= READ_INPUT.DONE;
READ_INPUT_ERR := READ_INPUT.ERR;
SYSDIAG_ERNO   := SYSDIAG.ERNO;
READ_INPUT_DATA_LEN:= READ_INPUT.DATA_LEN;
```

DPM_READ_OUTPUT

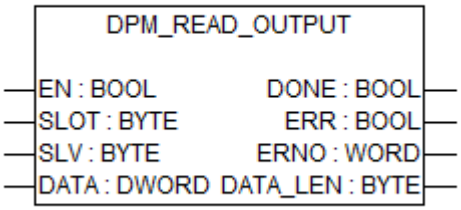


Parameter	Value
Included in library	PROFIBUS_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	Data

The function block DPM_READ_OUTPUT implements the acyclic PROFIBUS DP function DDLM_RD_Outp which can be used to read output data of a slave. Using this function the master can also read output data of slaves which are assigned to other masters. Write access to output data of these slaves is not possible. DPM_READ_OUTPUT works outside the cyclic process data exchange.

Every time a FALSE → TRUE edge is applied to input EN, DPM_READ_OUTPUT reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE → TRUE edges at input EN are ignored until the processing of the active requests is finished. The completion of the request processing is indicated by DONE = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

SLV (slave)

Data type: BYTE

At input SLV the bus address of the DP slave is applied, the output data of which shall be read.

DATA (data)

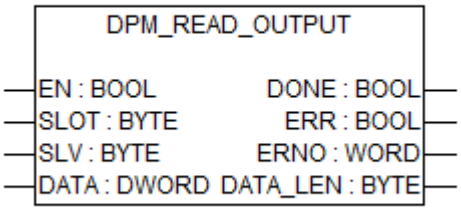
Data type: DWORD

At input DATA the address of the variable to be used to store the received output data is specified via the address operator ADR.

The size of this variable must be big enough to store all output data of the slave (e.g. BYTE array). Furthermore, the format (BYTE, WORD, etc.) of the slave outputs must be considered.

If the slave has mixed outputs of different types, it is recommended to first define a STRUCT data type which represents an image of the slave's output structure (see I/O configuration of the slave) and then to declare a variable of this type.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

DATA_LEN (data length)

Data type: BYTE

Output DATA_LEN displays the length (in bytes) of the output data read by the slave.

DATA_LEN is only valid, if DONE is TRUE and ERR is 0. If DATA_LEN contains a value X which is not 0, the function block has stored X bytes of output data in the variable specified at DATA.

Example

If DATA is a byte array with start index 1, the valid output data of the slave are contained in the entries DATA[1] to DATA[X].

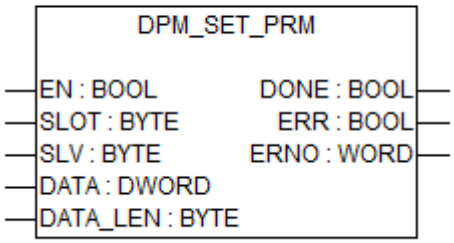
Function call in ST

```
READ_OUTPUT
     (EN   := READ_OUTPUT_EN,
     SLOT  := READ_OUTPUT_SLOT,
     SLV   := READ_OUTPUT_SLV,
     DATA  := ADR(READ_OUTPUT_DATA));

READ_OUTPUT_DONE:= READ_OUTPUT.DONE;
```

```
READ_OUTPUT_ERR := READ_OUTPUT.ERR;
SYSDIAG_ERNO:= SYSDIAG.ERNO;
READ_OUTPUT_DATA_LEN:= READ_OUTPUT.DATA_LEN;
```

DPM_SET_PRM



Parameter	Value
Included in library	PROFIBUS_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	Parameter

The function block DPM_SET_PRM implements the PROFIBUS function DDLM_Set_Prm.

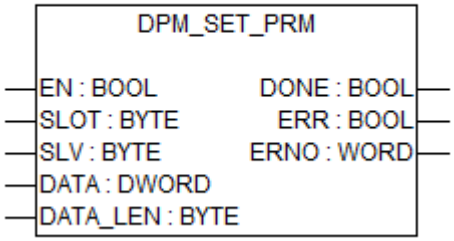
With function block DPM_SET_PRM the user parameter of a slave can be modified during run time. The parameters are immediately sent to the slave. This slave parameter set is used temporarily only. It is not taken into the corresponding slave parameter set stored in master configuration. In case of restarting the PROFIBUS DP communication for any reason the master will configure the slave using the parameter set defined in slave configuration data. The parameter set written to the slave by using DPM_SET_PRM is lost in this case.

Format and length of the user parameters are slave-specific. Due to this, the function block DPM_SET_PRM provides inputs where only the variable address and the length of the user parameters to be sent must be specified. It is in the responsibility of the user that the data comply with the requirements of the corresponding device regarding format and length (e.g. by defining a structure).

Every time a FALSE → TRUE edge is applied to input EN, DPM_SET_PRM reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE → TRUE edges at input EN are ignored until the processing of the active requests is finished. The completion of the request processing is indicated by DONE = TRUE.

Due to temporarily validity of salve parameters loaded by DPM_SET_PRM Communication Module of type CM592-DP does not support this function.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

SLV (slave)

Data type: BYTE

At input SLV the bus address of the DP slave is specified, to which the user parameters shall be sent.

Valid addresses are values between 0 and 126.

DATA (data)

Data type: DWORD

At input DATA the address of the variable from which onwards the parameters to be sent are stored, is specified via the address operator ADR.

The data format and the length of the variable must correspond to the structure of the user parameters of the slave. It is recommended to first define a STRUCT data type which represents an image of the slave's structure, and then to declare a variable of this type.

Please note that only the user parameters are to be specified at this point. The standard parameters cannot be modified during run time. The standard parameter settings specified during configuration are automatically completed by the function block.

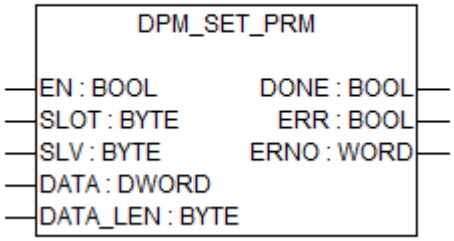
DATA_LEN (data length)

Data type: BYTE

The input DATA_LEN informs the function block about the length (number of bytes) of the user parameters to be transmitted.

The maximum length is 237 bytes.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

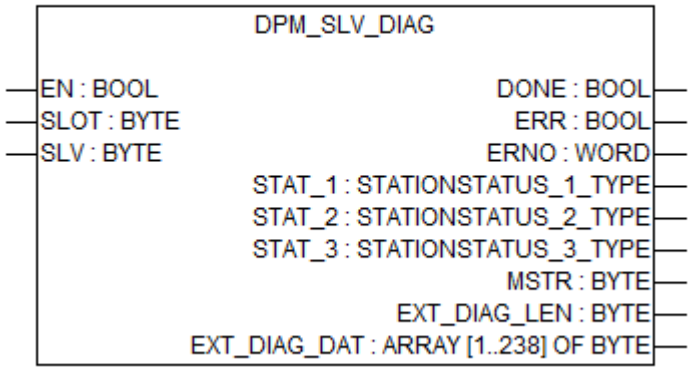
Function call in ST

```
SETPRM
      (EN  := SETPRM_EN,
      SLOT := SETPRM_SLOT,
      SLV  := SETPRM_SLV,
      DATA := SETPRM_DATA,
      DATA_LEN := SETPRM_DATA_LEN);

SETPRM_DONE :=  SETPRM.DONE;
SETPRM_ERR  :=  SETPRM.ERR;

SYSDIAG_ERNO:= SYSDIAG.ERNO;
```

DPM_SLV_DIAG



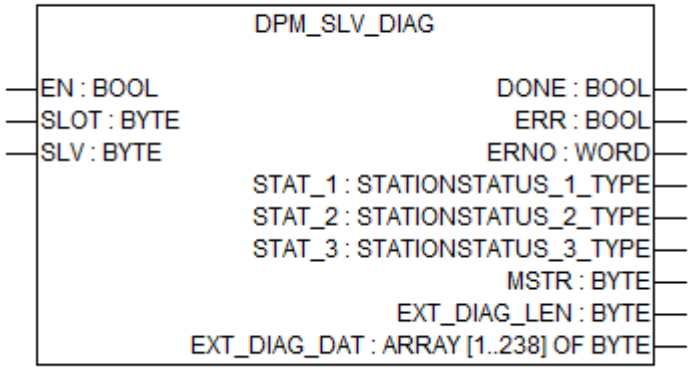
Parameter	Value
Included in library	PROFIBUS_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	Diagnosis

The function block DPM_SLV_DIAG implements the PROFIBUS DP function DDLM_Slave_Diag.

Every time a FALSE → TRUE edge is applied to input EN, DPM_SLV_DIAG reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE → TRUE edges at input EN are ignored until the processing of the active requests is finished.

The completion of the request processing is indicated by DONE = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

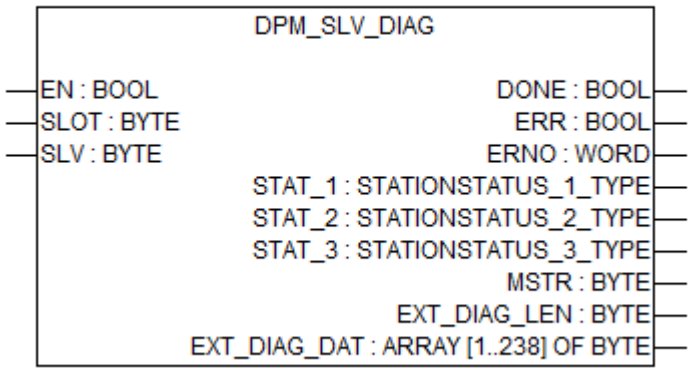
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

SLV (slave)

Data type: BYTE

At input SLV the bus address of the DP slave is specified, for which diagnosis data are requested.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STAT_1 (station status)

Data type: STATIONSTATUS_1_TYPE

STAT_1 outputs the first octet of the DP slave diagnosis data.

STAT_1 is only valid, if DONE = TRUE and ERR = FALSE. The structure of the type STATIONSTATUS_1_TYPE corresponds to the octet Stationstatus_1 defined in the standard as described below.

STAT_2 (station status)

Data type: STATIONSTATUS_2_TYPE

STAT_2 outputs the second octet of the DP slave diagnosis data.

STAT_2 is only valid, if DONE = TRUE and ERR = FALSE. The structure of the type STATIONSTATUS_2_TYPE corresponds to the octet Stationstatus_2 defined in the standard as described below.

STAT_3 (station status)

Data type: STATIONSTATUS_3_TYPE

STAT_3 outputs the third octet of the DP slave diagnosis data.

STAT_3 is only valid, if DONE = TRUE and ERR = FALSE. The structure of the type STATIONSTATUS_3_TYPE corresponds to the octet Stationstatus_3 defined in the standard as described below.

MSTR (master)

Data type: BYTE

MSTR outputs the bus address of the DP master to which has done the configuration of this slave.

MSTR is only valid, if DONE = TRUE and ERR = FALSE. Using the function block DPM_SLV_DIAG, diagnosis data for all DP slaves can be polled which are connected to the bus. If the diagnosis data are requested by a DP slave which was assigned to the PLC during configuration, the PLC bus address is output at MSTR.

In multi-master systems it is possible that diagnosis data are also requested by DP slaves which are assigned to other DP masters. In this case, MSTR outputs the bus address of the DP master to which the requesting DP slave is assigned.

EXT_DIAG_LEN

Data type	Default value	Range	Unit
BYTE	-	-	-

EXT_DIAG_LEN (extended diagnosis data length) outputs the number of valid bytes, following in EXT_DIAG_DAT.

If EXT_DIAG_LEN = 0, no extended diagnosis data are available. Otherwise, EXT_DIAG_DAT[1] to EXT_DIAG_DAT[EXT_DIAG_LEN] contain the extended diagnosis data reported by the DP slave. EXT_DIAG_LEN is only valid, if DONE = TRUE and ERR = FALSE.

EXT_DIAG_DAT

Data type: ARRAY[1..238] OF BYTE

At output EXT_DIAG_DAT (extended diagnosis data) the extended diagnosis data reported by the DP slave are applied as a byte array.

The data in EXT_DIAG_DAT are only valid, if DONE = TRUE, ERR = FALSE and EXT_DIAG_LEN > 0. The extended diagnosis data are structured according to the standard. Since the meaning of these data strongly depends on the used devices, no automatic interpretation by the function block is possible at this point.

The evaluation of the data must be performed by the user, with the aid of the particular device description and the GSD file respectively. The general structure of the extended diagnosis data (according to the standard) is described in *Structure of DP slave diagnostic data*.

Function call in ST

```
DIAG
     (EN           := DIAG_EN,
     SLOT          := DIAG_SLOT,
     SLV           := DIAG_SLV);

DIAG_DONE          := DIAG.DONE;
DIAG_ERR           := DIAG.ERR;
DIAG_ERNO          := DIAG.ERNO;
DIAG_STAT_1        := DIAG.STAT_1;
DIAG_STAT_2        := DIAG.STAT_2;
DIAG_STAT_3        := DIAG.STAT_3;
DIAG_MSTR          := DIAG.MSTR;
DIAG_EXT_DIAG_LEN := DIAG.EXT_DIAG_LEN;
DIAG_EXT_DIAG_DAT := DIAG.EXT_DIAG_DAT;
```

Structure of DP slave diagnosis data

The function block DPM_SLV_DIAG divides the diagnosis data of a DP slave into sections and applies them to the corresponding outputs. The structure of the DP slave diagnosis data is prescribed by the standard as follows:

Octet 1	Stationstatus_1 ↳ *Chapter 1.5.4.26.1.5.4.1 “Stationstatus_1” on page 1769*	STAT_1
Octet 2	Stationstatus_2 ↳ *Chapter 1.5.4.26.1.5.4.2 “Stationstatus_2” on page 1770*	STAT_2
Octet 3	Stationstatus_3 ↳ *Chapter 1.5.4.26.1.5.4.3 “Stationstatus_3” on page 1771*	STAT_3
Octet 4	Master_Add ↳ *Chapter 1.5.4.26.1.5.4.4 “Master_Add” on page 1771*	MSTR
Octet 5 to 6	Ident_Number ↳ *Chapter 1.5.4.26.1.5.4.5 “Ident_Number” on page 1771*	
Octet 7 to 244	Ext_Diag_Data ↳ *Chapter 1.5.4.26.1.5.4.6 “Ext_Diag_Data” on page 1771*	EXT_DIAG_DAT[1] to EXT_DIAG_DAT[EXT_DIAG_LEN]

Stationstatus_1

STATION-STATUS_1_TYPE

The diagnostic byte Stationstatus_1 (defined within the standard) is output at STAT_1 of the function block DPM_SLV_DIAG. It is represented as a structure of the data type STATION-STATUS_1_TYPE.

Within the PROFIBUS DP library the structure STATIONSTATUS_1_TYPE is declared as follows:

```
TYPE STATIONSTATUS_1_TYPE:
STRUCT
    NON_EXISTENT:     BOOL;
    NOT_READY:        BOOL;
    CFG_FAULT:        BOOL;
    EXT_DIAG:         BOOL;
    NOT_SUPPORTED:    BOOL;
    INVALID_RESPONSE: BOOL;
    PRM_FAULT:        BOOL;
    MASTER_LOCK:      BOOL;
END_STRUCT
END_TYPE
```

NON_EXISTENT Data type: BOOL

If this bit is set, the PROFIBUS DP Communication Module has not found a DP slave at the bus address applied at function block input SLV.

NOT_READY Data type: BOOL

This bit is set to TRUE by the DP slave if the DP slave is not ready for I/O data exchange.

CFG_FAULT Data type: BOOL

This bit is set to TRUE by the DP slave, if the configuration data (nominal configuration) received from the DP master do not match the data stored in the DP slave (actual configuration).

EXT_DIAG Data type: BOOL

If this bit is TRUE, extended diagnosis data are available in EXT_DIAG_DAT. If this bit is not set (FALSE) and EXT_DIAG_LEN > 0, possibly a status message is available in EXT_DIAG_DAT.

The meaning of such a status message is device-dependent.

NOT_SUPPORTED Data type: BOOL

This bit is set to TRUE by the DP slave, if an unsupported function was requested before.

INVALID_RESPONSE Data type: BOOL

If this bit is TRUE, the PROFIBUS Communication Module has not received a plausible response from the requested DP slave.

PRM_FAULT Data type: BOOL

The DP slave sets this bit to TRUE, if the parameter data received last were faulty.

MASTER_LOCK Data type: BOOL

This bit is set to TRUE, if the DP slave is assigned to another DP master. In this case, MSTR contains the bus address of this DP master.

Stationstatus_2

STATION-STATUS_2_TYPE

The diagnostic byte Stationstatus_2 (defined within the standard) is output at STAT_2 of the function block DPM_SLV_DIAG. It is represented as a structure of the data type STATION-STATUS_2_TYPE.

The structure STATIONSTATUS_2_TYPE is declared as follows in the PROFIBUS library:

```
TYPE STATIONSTATUS_2_TYPE:
STRUCT
     PRM_REQ:          BOOL;
     STAT_DIAG:        BOOL;
     DP_Slave:         BOOL;
     WD_ON:            BOOL;
     FREEZE_MODE:      BOOL;
     SYNC_MODE:        BOOL;
     reserved:         BOOL;
     DEACTIVATED:      BOOL;
END_STRUCT
END_TYPE
```

PRM_REQ Data type: BOOL

This bit is set to TRUE by the DP slave, if reparameterization and reconfiguration of the slave is required (e.g. when adding an additional I/O module). The bit remains set until reparameterization is done.

STAT_DIAG Data type: BOOL

This bit is set to TRUE by the DP slave, if the slave has a static diagnosis. A DP slave with static diagnosis is not ready for I/O data exchange.

DP_SLAVE Data type: BOOL

This bit is permanently set to TRUE.

WD_ON Data type: BOOL

This bit is set to TRUE by the DP slave, if the slave response monitoring is active.

FREEZE_MODE Data type: BOOL

This bit is set to TRUE by the DP slave, if the slave is currently running in Freeze mode. SYNC_MODE BOOL

SYNC_MODE Data type: BOOL

This bit is set to TRUE by the DP slave, if the slave is currently running in Sync mode.

reserved Data type: BOOL

This bit is reserved and currently not used.

DEACTIVATED Data type: BOOL

This bit is set to TRUE, if the DP slave is marked as non-active in the DP master's configuration data and has been taken out of the cyclic I/O data exchange.

Stationstatus_3

STATION-STATUS_3_TYPE

The diagnostic byte Stationstatus_3 (defined within the standard) is output at STAT_3 of the function block DPM_SLV_DIAG. It is represented as a structure of the data type STATION-STATUS_3_TYPE.

The structure STATIONSTATUS_3_TYPE is declared as follows within the PROFIBUS DP library:

```
TYPE STATIONSTATUS_3_TYPE:
STRUCT
    reserved0:          BOOL;
    reserved1:          BOOL;
    reserved2:          BOOL;
    reserved3:          BOOL;
    reserved4:          BOOL;
    reserved5:          BOOL;
    reserved6:          BOOL;
    EXT_DIAG_OVERFLOW: BOOL;
END_STRUCT
END_TYPE
```

Master_Add

MSTR

Data Type: BYTE

The DP slave enters the DP master's address into this octet by which it was parameterized (i.e. to which it is assigned). If the DP slave was not yet parameterized by any DP master, MSTR is set to 255.

Ident_Number

Here, the DP slave enters its identification number in the diagnosis telegram. The identification number is assigned by the PNO (PROFIBUS DP Nutzerorganisation e.V. = PROFIBUS DP user organization) for each device type. This number is a firm component of the GSD file. The function block DPM_SLV_DIAG does not output the device identification number, because the number is not necessary for evaluating the diagnosis data.

Ext_Diag_Data

EXT_DIAG_DAT

Data Type: ARRAY [1..238] OF BYTE

The six bytes of standard diagnosis data described above have to be supported by each DP slave. Optionally, a DP slave can additionally provide extended diagnosis data. This is the case if a value greater than 6 is assigned to the item Max_Diag_Data_Len in the GSD file of the DP slave. The format of the extended diagnosis is defined by the standard. Since the extended diagnosis data are not static on the one side and can contain manufacturer-specific entries on the other side, no automatic data evaluation can be performed by the function block DM_SLV_DIAG.

The evaluation of extended diagnosis data must be performed by the user with the aid of the GSD file for the particular DP slave and the description of the general data format given below.

The extended diagnosis data are divided into three parts (sections):

- device-related diagnosis
- module-related diagnosis
- channel-related diagnosis

Device-related diagnosis

The device-related diagnosis section contains general diagnosis information, such as overtemperature or undervoltage. This section starts with a header byte, the highest two bits of which are permanently set to 00. The lower six bits indicate the length of the following function block, including the header byte itself.

0	0	L	e	n	g	t	h
7	6	5	4	3	2	1	0

The device-related diagnosis data are defined by the manufacturer. For detailed information about their meaning please refer to the particular device documentation.

Module-related diagnosis

The module-related diagnosis section contains diagnosis information, which can be assigned directly to the particular I/O modules of the device. This section containing the module-related diagnosis starts with a header byte, the highest two bits of which are permanently set to 01. The lower six bits indicate the length of the following function block, including the header byte itself.

0	1	L	e	n	g	t	h
7	6	5	4	3	2	1	0

In the following function block, one single bit is assigned to each module. The module index is represented by the bit offset within the function block (please refer to the example). A bit which is set to TRUE means that diagnosis is required for the related I/O module.

Channel-related diagnosis

In the channel-related diagnosis section, the diagnosed channels and the cause for the diagnosis are entered in sequence. Each entry consists of three bytes and starts with a header byte, the highest two bits of which are permanently set to 10. The lower six bits contain the index of the module for which the following diagnosis was made.

1	0	M	o	d	u	l	e
7	6	5	4	3	2	1	0

The lower six bits of the following byte contain the number of the channel which reports a diagnosis. The highest two bits indicate whether the specific channel is an input channel, an output channel or an I/O channel.

I	O	C	h	a	n	n	l
7	6	5	4	3	2	1	0

The direction identifier in the bits 6 and 7 is encoded as follows:

0	0	Reserved
0	1	Input
1	0	Output
1	1	Input / Output

The third byte of each entry contains the channel type in its upper three bits and the error type in the lower five bits.

C	h	n	E	r	r	o	r
7	6	5	4	3	2	1	0

The channel type (channel width) is encoded as follows:

0	0	0	Reserved
0	0	1	Bit
0	1	0	2 bit
0	1	1	4 bit
1	0	0	Byte
1	0	1	Word
1	1	0	2 Word
1	1	1	Reserved

The encoding of the error type is as follows:

0	Reserved	0	0	0	0	0
1	Short circuit	0	0	0	0	1
2	Undervoltage	0	0	0	1	0
3	Overvoltage	0	0	0	1	1
4	Overload	0	0	1	0	0
5	Overtemperature	0	0	1	0	1
6	Cable brake	0	0	1	1	0
7	Upper limit exceeded	0	0	1	1	1
8	Lower limit exceeded	0	1	0	0	0
9	Error	0	1	0	0	1
10	Reserved	0	1	0	1	0
:	:	0	1	x	x	x
15	Reserved	0	1	1	1	1
16	Manufacturer-specific	1	0	0	0	0
:	:	1	x	x	x	x
31	Manufacturer-specific	1	1	1	1	1

The valid length of the complete extended diagnosis data is indicated at output EXT_DIAG_LEN of the function block DPM_SLV_DIAG. When evaluating the diagnosis, only data have to be considered which are contained in the range EXT_DIAG_DAT[1] to EXT_DIAG_DAT[EXT_DIAG_LEN].

Example for extended diagnosis data

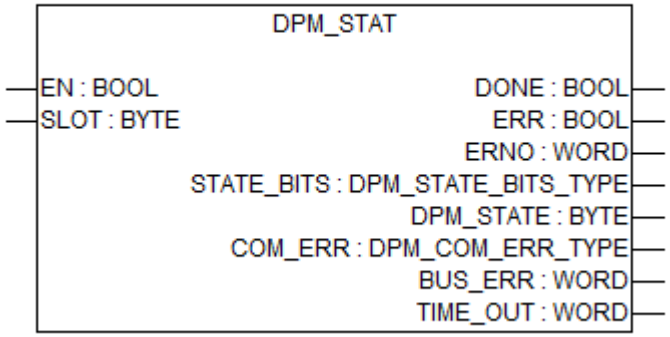
EXT_DIAG_LEN = 15

	7	6	5	4	3	2	1	0	
EXT_DIAG_DAT[1]	0	0	0	0	0	1	0	0	Device-related diagnosis; Length: 4 bytes incl. header byte
EXT_DIAG_DAT[2]	X	x	x	X	X	x	X	X	Device-related diagnosis
EXT_DIAG_DAT[3]	X	x	x	X	X	x	X	X	Length: 3 bytes
EXT_DIAG_DAT[4]	X	x	x	X	X	x	X	X	Meaning of the data is manufacturer-specific
EXT_DIAG_DAT[5]	0	1	0	0	0	1	0	1	ID-related diagnosis; Length: 5 bytes incl. header byte
EXT_DIAG_DAT[6]	0 7	0 6	0 5	0 4	0 3	0 2	0 1	1 0	Module 0 with diagnosis
EXT_DIAG_DAT[7]	015	014	013	112	011	010	0 9	0 8	Module 12 with diagnosis
EXT_DIAG_DAT[8]	023	022	021	020	019	118	017	016	Module 18 with diagnosis
EXT_DIAG_DAT[9]	031	130	029	028	027	026	025	024	Module 30 with diagnosis
EXT_DIAG_DAT[10]	1	0	0	0	0	0	0	0	Channel-related diagnosis module 0
EXT_DIAG_DAT[11]	0	1	0	0	0	0	1	0	Channel 2, Input
EXT_DIAG_DAT[12]	0	0	1	0	0	1	0	0	Overload, channel organized bitwise
EXT_DIAG_DAT[13]	1	0	0	0	1	1	0	0	Channel-related diagnosis module 12
EXT_DIAG_DAT[14]	1	0	0	0	0	1	1	0	Channel 6, Output
EXT_DIAG_DAT[15]	1	0	1	0	0	1	1	1	Upper limit exceeded, channel organized wordwise

Example program for evaluating extended diagnosis data

A detailed example program for the evaluation of extended diagnosis data can be found onABB website under *Download Application Examples*.

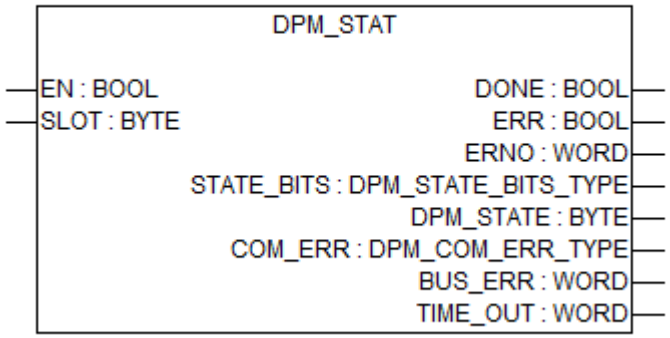
DPM_STAT



Parameter	Value
Included in library	PROFIBUS_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	Diagnosis

The function block DPM_STAT outputs the current PROFIBUS DP Communication Module status. DPM_STAT is active, if input EN = TRUE. While the function block is active, the current values are permanently displayed at the outputs. The outputs provide information about the communication state and error events.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

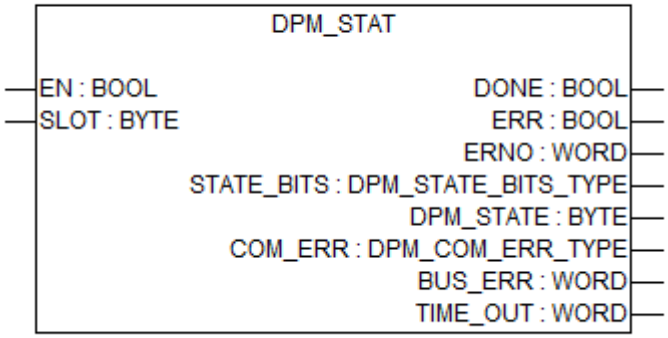
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE_BITS Data type: DPM_STATE_BITS_TYPE

The Output STATE_BITS provides error or diagnosis flags of the PROFIBUS DP Communication Module.

DPM_STATE Data type: BYTE

At output DPM_STATE, the DP master state is output according to the standard. The following states are defined:

```
OFFLINE  00HEX / 00DEC
STOP     40HEX / 64DEC
CLEAR    80HEX / 128DEC
OPERATE  C0HEX / 192DEC
DPM_STATE = OFFLINE
```

The PROFIBUS DP Communication Module is in initialization state, if DPM_STATE has the value OFFLINE. After the initialization phase is completed, the Communication Module changes to STOP state.

DPM_STATE = STOP

The Communication Module is completely initialized, if DPM_STATE has the value STOP. In this state the Communication Module is ready to receive configuration data. No data are exchanged with the DP slaves. The Communication Module has this state, if no user program is running.

DPM_STATE = CLEAR

When starting the user program, the Communication Module changes from STOP into CLEAR state and begins, via the bus, to parameterize (set into operation) the DP slaves assigned during configuration. When the setup has been completed successfully, the Communication Module moves to OPERATE state. If an error occurs during parameterization, the Communication Module changes back to STOP state.

DPM_STATE = OPERATE

Normally, the Communication Module is in OPERATE state, while a user program is running. In this state, the DP master exchanges I/O data with the DP slaves. If an error occurs during this process, and if *Auto Clear Mode* was selected during configuration, the Communication Module changes back to CLEAR state and tries to parameterize the DP slaves again.

If *Auto Clear Mode* was not selected, the Communication Module remains (in case of an error) in OPERATE state. When stopping the user program, the Communication Module also changes back to STOP state.

DPM_STATE is only valid, if EN = TRUE and ERR = FALSE.

COM_ERR Data type: DPM_COM_ERR_TYPE

The Output COM_ERR provides detailed information to the corresponding output STATE_BITS.

The element address contains the node address of the faulty device and the element event the error code. If several errors occur simultaneously, the output contains the error of the device with the lowest address.

The structure of the type DPM_COM_ERR_TYPE is defined in the PROFIBUS library and described in the following chapter together with the possible errors.

BUS_ERR Data type: WORD

BUS_ERR outputs the number of serious bus errors since system startup, such as transmission line short circuits.

BUS_ERR is only valid, if EN = TRUE and ERR = FALSE.

TIME_OUT Data type: WORD

TIME_OUT outputs the number of timeout errors since system startup. A timeout error occurs, if a DP slave does not respond to a DP master's request within the configured time.

TIME_OUT is only valid, if EN = TRUE and ERR = FALSE.

On CM592-DP BUS_ERR and TIME_OUT are incremented always at once. Due to internal handling of error events the counters are updated with steps greater one always.

Function call in ST

```
STAT
    (EN := STAT_EN,
   SLOT := STAT_SLOT);

STAT_DONE       := STAT.DONE;
STAT_ERR        := STAT.ERR;
STAT_ERNO       := STAT.ERNO;
STAT_STATE_BITS := STAT.STATE_BITS;
STAT_DPM_STATE  := STAT.DPM_STATE;
STAT_COM_ERR    := STAT.COM_ERR;
STAT_BUS_ERR    := STAT.BUS_ERR;
STAT_TIME_OUT   := STAT.TIME_OUT;
```

STATE_BITS DPM_STATE_BITS_TYPE

The structure STATE_BITS includes four Boolean variables which display different communication states. Within the PROFIBUS DP library, the data type DPM_STATE_BITS_TYPE is declared as follows:

```
TYPE DPM_STATE_BITS_TYPE:
STRUCT
    CTRL:       BOOL;
    AUTO_CLR:   BOOL;
    NO_EXCH:    BOOL;
    FATAL:      BOOL;
    EVENT:      BOOL;
    TIMEOUT:    BOOL;
END_STRUCT
END_TYPE
```

CTRL Data type: BOOL

If this bit is TRUE, a parameter setting error occurred. During normal operation, CTRL should be FALSE. If this is not the case, the parameter and configuration data have to be checked.

AUTO_CLR Data type: BOOL

This bit is only valid, if *Auto Clear Mode* was set during the configuration. If AUTO_CLR is true, an error occured during communication with at least one DP slave. As a result, the Communication Module stopped the data exchange with all DP slaves and changed back to CLEAR state (see DPM_STATE).

NO_EXCH Data type: BOOL

This bit is set to TRUE, if process data exchange with one or several DP slaves is not possible. The error can be caused by the configuration data or by the DP slaves.

If no slave devices are connected, the Communication Modules signal state the following information:

CM592-DP: the bit NO_EXCH remains not set and has FALSE value.

FATAL Data type: BOOL

If FATAL is TRUE, no communication via the PROFIBUS DP is possible due to a serious bus error (e.g. bus line short circuit). In this case, all bus lines have to be checked.

EVENT Data type: BOOL

This bit is set to TRUE, if a bus short circuit was detected. The number of detected short circuits can be read at the BUS_ERR output. After setting the bit once, its state remains TRUE.

State bit EVENT is not supported by Communication Module CM592-DP. EVENT is always set to FALSE .

TIMEOUT Data type: BOOL

This bit is set to TRUE, if a telegram timeout was detected. The number of detected timeouts can be read at the TIME_OUT output. After setting the bit once, its state remains TRUE.

COM_ERR DPM_COM_ERR_TYPE

Communication errors can be located more detailed using COM_ERR. COM_ERR outputs a structure of the type DPM_COM_ERR_TYPE. This data type is declared as follows within the PROFIBUS DP library:

```
TYPE DPM_COM_ERR_TYPE:
STRUCT
    ADDRESS:  BYTE;
    EVENT:    BYTE;
END_STRUCT
END_TYPE
```

COM ERR is not supported by Communication Module CM592-DP. ADDRESS and EVENT are always set to 0.

ADDRESS Data type: BYTE

If an error occurs, ADDRESS contains the bus address of the faulty device (0 to 125). If ADDRESS has the value 255, the error is located in the Communication Module itself.

EVENT Data type; BYTE

EVENT displays the cause of an error.

The following tables show the encoding of the various errors.

Table 89: ADDRESS = 255 / Communication module error

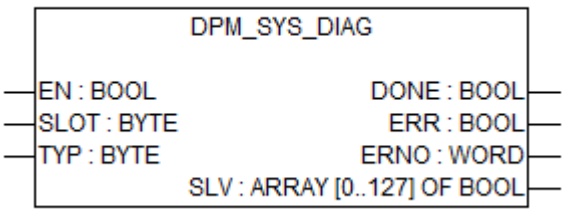
Event	Description	Error source	Remedy
50	USR_INTF task not found	Communication Module	Contact ABB
51	No global data field	Communication Module	Contact ABB
52	FDL task not found	Communication Module	Contact ABB
53	PLC task not found	Communication Module	Contact ABB
54	No master parameter record	Configuration	Generate configuration in the project and reload program to controller
55	Faulty value in master parameter record	Configuration	Check configuration data for Communication Module in the project and/or reload program to controller
56	No slave parameter records	Configuration	Add DP slaves to configuration data and reload program to controller
57	Faulty value in a slave parameter record	Configuration	Check configuration data of subordinate DP slaves in the project and/or reload program to controller
58	Doubled slave address	Configuration	Check configuration data of subordinate DP slaves in the project for doubled bus addresses and/or reload program to controller
59	Invalid offset address output data	Configuration	Check configuration data of subordinate DP slaves in the project for invalid IEC addresses and/or reload program to controller
60	Invalid offset address input data	Configuration	Check configuration data of subordinate DP slaves in the project for invalid IEC addresses and/or reload program to controller
61	Range overlapping in output data	Configuration	Check configuration data of subordinate DP slaves in the project for overlapping IEC address ranges and/or reload program to controller
62	Range overlapping in input data	Configuration	Check configuration data of subordinate DP slaves in the project for overlapping IEC address ranges and/or reload program to controller

Event	Description	Error source	Remedy
63	Unknown process data handshake	Controller	Supply voltage OFF/ON, otherwise contact ABB
64	Insufficient memory	Communication Module	Contact ABB
65	Faulty slave parameter record	Configuration	Check configuration data of subordinate DP slaves in the project and/or reload program to controller
202	No segment available	Communication Module	Contact ABB
212	Error while reading database	Configuration/ Communication Module	Reload program with configuration data to controller
213	Faulty transfer structure operating system	Communication Module	Contact ABB

Table 90: ADDRESS = 0..125 / Error at subscriber with bus address ADDRESS

Event	Description	Error source	Remedy
2	Subscriber reports overflow	DP master telegram	Check configuration data of subordinate DP slave in the project and/or reload program to controller
3	Subscriber does not support requested function	DP master telegram	Check DP slave for conformity according to PROFIBUS DP standard
9	No data in response telegram	DP slave	Compare configuration data of subordinate DP slave in the project with actual configuration and reload program to controller if necessary
17	Subscriber does not response	DP slave	Check bus line and DP slave bus address
18	DP master not in logical token ring	DP master	Check the configured DP master bus address, the highest station address (HSA) in the other system DP masters and/or bus line for short circuits
21	Faulty parameter in request telegram	DP master telegram	Contact ABB

DPM_SYS_DIAG

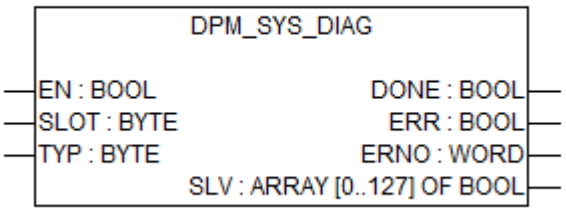


Parameter	Value
Included in library	PROFIBUS_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	Diagnosis

The function block DPM_SYS_DIAG outputs different surveys reporting the status of all DP slaves. Three survey types can be selected:

- configuration survey
- I/O data exchange survey
- diagnosis survey

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

TYP (type)

Data type: BYTE

TYP=1, configuration survey

Output SLV indicates which DP slaves have been configured successfully (i.e. set into operation) by the DP master. Please note, that the DP master only sets DP slaves into operation which were assigned to the master when generating the configuration data.

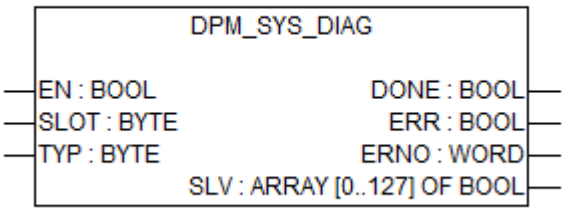
TYP=2, data exchange survey

SLV outputs all DP slaves with which the DP master exchanges data. The data exchange can only be performed with DP slaves which were configured by the DP master itself. The data exchange survey can only be requested, if the communication module is in OPERATE state.

TYP=3, diagnosis survey

Output SLV indicates all DP slaves which have signalized an available diagnosis. The diagnosis survey can only be requested, if the Communication Module is in OPERATE state.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

SLV (slave)

Data type: ARRAY[0..127] OF BOOL

SLV outputs the status survey as array of BOOL values. Every index within this array represents a DP slave. The index itself corresponds to the DP slave bus address. When a certain value is set to TRUE, corresponding slave signals information regarding selected survey type in input TYP.

If e.g. TYP = 1 is selected and SLV[2] = TRUE, the DP slave was successfully configured with bus address 2 by the DP master. If SLV[2] = FALSE, the configuration of the specific DP slave has not yet been completed or the DP slave is not part of the DP master configuration data.

If TYP = 2 was selected and SLV[2] = TRUE, the DP master exchanges I/O data with the DP slave having bus address 2. If SLV[2] = FALSE, the DP master currently does not exchange I/O data with the DP slave. The DP master is only able to exchange data with DP slaves which it has successfully set into operation before.

If TYP = 3, SLV[2] = TRUE means, that the DP slave with bus address 2 has signalized a diagnosis. The diagnosis description can then be requested using the function block DPM_SLV_DIAG.

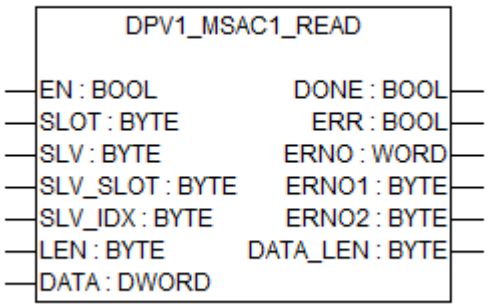
Output SLV is only valid, if EN = TRUE and ERR = FALSE.

Function call in ST

```
SYSDIAG
       (EN := SYSDIAG_EN,
       SLOT:= SYSDIAG_SLOT,
       TYP := SYSDIAG_TYP);

SYSDIAG_DONE:= SYSDIAG.DONE;
SYSDIAG_ERR := SYSDIAG.ERR;
SYSDIAG_ERNO:= SYSDIAG.ERNO;
SYSDIAG_SLV := SYSDIAG.SLV;
```

DPV1_MSAC1_READ

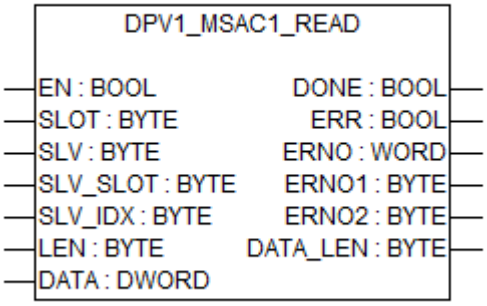


Parameter	Value
Included in library	PROFIBUS_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	Data

The function block DPV1_MSAC1_READ implements the acyclic PROFIBUS DP DPV1 service MSAC1_READ. Using this function, the master has read access to slot and index-related data of slaves supporting DPV1. DPV1_MSAC1_READ works outside the cyclic process data exchange.

Every time a FALSE → TRUE edge is applied to input EN, DPV1_MSAC1_READ reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE → TRUE edges at input EN are ignored until the processing of the active requests is finished. The completion of the request processing is indicated by DONE = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

SLV (slave)

Data type: BYTE

At input SLV the bus address of the DP slave is applied, the data of which shall be read.

Different range of values have to be considered depending on the used communication module. For CM592-DP it is 0..125.

SLV_SLOT

Data type: BYTE

At input SLV_SLOT the number of the slot within the slave is specified, the data of which shall be read.

Valid values: 0..254.

SLV_IDX

Data type: BYTE

At input SLV_IDX the number of the index within the slot is specified, the data of which shall be read.

Valid values: 0..254.

LEN (length)

Data type: BYTE

The length of the data block to be read is specified at input LEN.

Valid values: 0..240.

Function block reads a complete data block independent of input LEN.

If length of data block is unknown, set LEN = 240 (max. data LEN).

CAUTION!

Overwriting of variables to data!

If LEN is lower than length of data block the following variables to data will be overwritten!

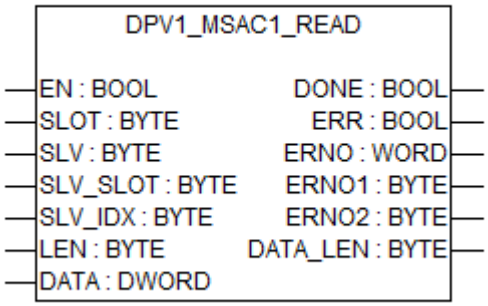
DATA (data)

Data type: DWORD

At input DATA the address of the variable where the received data block shall be stored is specified via the ADR address operator.

The size of the variable must be big enough to store the complete data block (e.g. BYTE array). Furthermore, the format (BYTE, WORD, etc.) of the data must be considered.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ERNO1 (error number 1)

Data type: BYTE

Output ERNO1 provides an additional DPV1-specific error information in case that an error occurred during processing.

ERNO1 always has to be considered together with the outputs DONE, ERR and ERNO. The value applied at ERNO1 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC).

ERNO1 of the DPV1 function blocks is encoded as follows. The upper nibble (the higher significant 4 bits) describes the error class, the lower nibble represents the error cause.

7	6	5	4	3	2	1	0
Error class				Error code			

ERNO1		Error class/Error code
DEC	HEX	
0	0	Reserved
...	...	...
159	9F	Reserved
160	A0	10 Application / 0 Read error
161	A1	10 Application / 1 Write error
162	A2	10 Application / 2 Error module
163	A3	Reserved
...	...	...
167	A7	Reserved
168	A8	10 Application / 8 Version conflict
169	A9	10 Application / 9 Function not supported
170	AA	10 Application / 10 Manufacturer-specific
...	...	...
175	AF	10 Application / 15 Manufacturer-specific
176	B0	11 Access / 0 Invalid index
177	B1	11 Access / 1 Invalid length of data to be written
178	B2	11 Access / 2 Invalid slot
179	B3	11 Access / 3 Type conflict
180	B4	11 Access / 4 Invalid range
181	B5	11 Access / 5 Status conflict
182	B6	11 Access / 6 Access denied
183	B7	11 Access / 7 Invalid value range

184	B8	11 Access / 8 Invalid parameter
185	B9	11 Access / 9 Invalid type
186	BA	11 Access / 10 Manufacturer-specific
...	...	...
191	BF	11 Access / 15 Manufacturer-specific
192	C0	12 Resources / 0 Read conflict
193	C1	12 Resources / 1 Write conflict
194	C2	12 Resources / 2 Resource used
195	C3	12 Resources / 3 Resource not available
196	C4	Reserved
...	...	...
199	C7	Reserved
200	C8	12 Resources / 10 Manufacturer-specific
...	...	...
207	CF	12 Resources / 15 Manufacturer-specific
208	D0	Reserved
...	...	...
255	FF	Reserved

ERNO2 (error number 2)

Data type: BYTE

Output ERNO2 provides an additional DPV1-specific error information, if an error occurred during processing. ERNO2 always has to be considered together with the outputs DONE, ERR and ERNO.

The value applied at ERNO2 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC).

The encoding of ERNO2 is completely manufacturer-specific.

DATA_LEN (data length)

Data type: BYTE

Output DATA_LEN displays the length (in bytes) of the input data read by the slave.

DATA_LEN is only valid, if DONE is TRUE and ERR is FALSE. If DATA_LEN contains a value X which is not 0, the function block has stored X bytes of input data in the variable specified at DATA.

Example

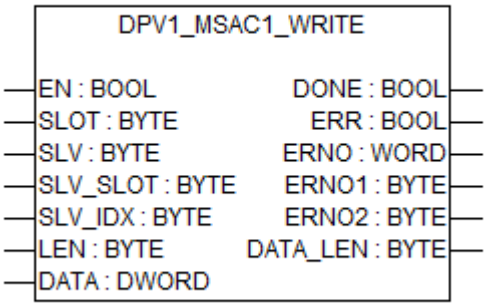
If DATA is a byte array with start index 1, the valid input data of the slave are contained in the entries DATA[1] to DATA[X].

Function call in ST

```
DPV1_READ
     (EN  := DPV1_READ_EN,
     SLOT := DPV1_READ_SLOT,
     SLV  := DPV1_READ_SLV,
     SLV_SLOT := DPV1_READ_SLV_SLOT,
     SLV_IDX  := DPV1_READ_SLV_IDX,
     LEN  := DPV1_READ_LEN,
     DATA := ADR(DPV1_READ_DATA));
```

```
DPV1_READ_DONE     := DPV1_READ.DONE;
DPV1_READ_ERR      := DPV1_READ.ERR;
DPV1_READ_ERNO     := DPV1_READ.ERNO;
DPV1_READ_ERNO1    := DPV1_READ.ERNO1;
DPV1_READ_ERNO2    := DPV1_READ.ERNO2;
DPV1_READ_DATA_LEN := DPV1_READ.DATA_LEN;
```

DPV1_MSAC1_WRITE

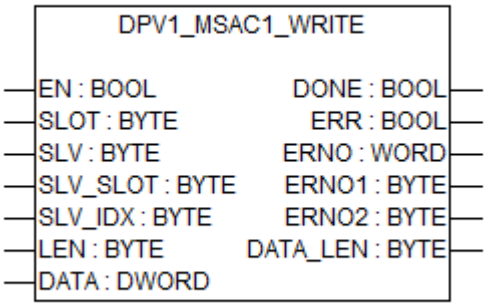


Parameter	Value
Included in library	PROFIBUS_AC500_V25.lib
Available as of firmware	V2.5
Type	Function block with historical values
Group	Data

The function block DPV1_MSAC1_WRITE implements the acyclic PROFIBUS DP DPV1 service MSAC1_WRITE. Using this function, the master has write access to slot and index-related data of slaves supporting DPV1. DPV1_MSAC1_WRITE works outside the cyclic process data exchange.

Every time a FALSE → TRUE edge is applied to input EN, DPV1_MSAC1_WRITE reads the values at its inputs and the data to be written and sends a corresponding request message to the Communication Module. Further FALSE → TRUE edges at input EN are ignored until the processing of the active requests is finished. The completion of the request processing is indicated by DONE = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

SLV (slave)

Data type: BYTE

At input SLV the bus address of the DP slave is specified to which the data shall be written.

Different range of values have to be considered depending on the used communication module. For CM592-DP it is 0..125.

SLV_SLOT

Data type: BYTE

At input SLV_SLOT the number of the slot within the slave is specified to which the data shall be written.

Valid values: 0..254.

SLV_IDX

Data type: BYTE

At input SLV_IDX the number of the index within the slot is specified to which the data shall be written.

Valid values: 0..254.

LEN (length)

Data type: BYTE

At input LEN the length of the data block to be written is specified.

Valid values: 0..240.

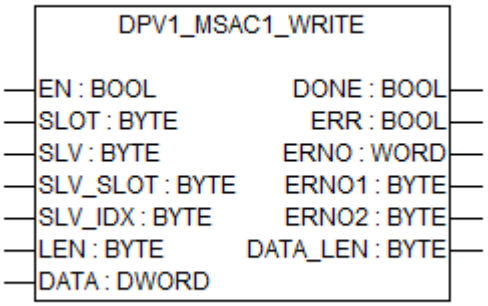
DATA (data)

Data type: DWORD

At input DATA the address of the variable containing the data block to be transmitted is specified via the ADR address operator. The size of the variable must be big enough to store the complete data block (e.g. BYTE array).

Furthermore, the format (BYTE, WORD, etc.) of the data must be considered.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ERNO1 (error number 1)

Data type: BYTE

Output ERNO1 provides an additional DPV1-specific error information in case that an error occurred during processing.

ERNO1 always has to be considered together with the outputs DONE, ERR and ERNO. The value applied at ERNO1 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC).

ERNO1 of the DPV1 function blocks is encoded as follows. The upper nibble (the higher significant 4 bits) describes the error class, the lower nibble represents the error cause.

7	6	5	4	3	2	1	0
Error class				Error code			

ERNO1		**Error class/Error code**
DEC	HEX	
0	0	Reserved
...	...	...
159	9F	Reserved
160	A0	10 Application / 0 Read error
161	A1	10 Application / 1 Write error
162	A2	10 Application / 2 Error module
163	A3	Reserved
...	...	...
167	A7	Reserved
168	A8	10 Application / 8 Version conflict
169	A9	10 Application / 9 Function not supported
170	AA	10 Application / 10 Manufacturer-specific
...	...	...
175	AF	10 Application / 15 Manufacturer-specific
176	B0	11 Access / 0 Invalid index
177	B1	11 Access / 1 Invalid length of data to be written
178	B2	11 Access / 2 Invalid slot
179	B3	11 Access / 3 Type conflict
180	B4	11 Access / 4 Invalid range
181	B5	11 Access / 5 Status conflict
182	B6	11 Access / 6 Access denied
183	B7	11 Access / 7 Invalid value range
184	B8	11 Access / 8 Invalid parameter
185	B9	11 Access / 9 Invalid type
186	BA	11 Access / 10 Manufacturer-specific
...	...	...
191	BF	11 Access / 15 Manufacturer-specific
192	C0	12 Resources / 0 Read conflict
193	C1	12 Resources / 1 Write conflict
194	C2	12 Resources / 2 Resource used
195	C3	12 Resources / 3 Resource not available

196	C4	Reserved
...	...	...
199	C7	Reserved
200	C8	12 Resources / 10 Manufacturer-specific
...	...	...
207	CF	12 Resources / 15 Manufacturer-specific
208	D0	Reserved
...	...	...
255	FF	Reserved

ERNO2 (error number 2)

Data type: BYTE

Output ERNO2 provides an additional DPV1-specific error information, if an error occurred during processing. ERNO2 always has to be considered together with the outputs DONE, ERR and ERNO.

The value applied at ERNO2 is only valid, if DONE = TRUE, ERR = TRUE and ERNO = 6036 HEX (24630 DEC).

The encoding of ERNO2 is completely manufacturer-specific.

DATA_LEN (data length)

Data type: BYTE

The output DATA_LEN displays the actual length (in bytes) of the data written to the slave.

DATA_LEN is only valid, if DONE = TRUE and ERR = 0.

Function call in ST

```
DPV1_WRITE
     (EN  := DPV1_WRITE_EN,
     SLOT := DPV1_WRITE_SLOT,
     SLV  := DPV1_WRITE_SLV,
     SLV_SLOT := DPV1_WRITE_SLV_SLOT,
     SLV_IDX  := DPV1_WRITE_SLV_IDX,
     LEN  := DPV1_WRITE_LEN,
     DATA := ADR(DPV1_WRITE_DATA));

DPV1_WRITE_DONE     := DPV1_WRITE.DONE;
DPV1_WRITE_ERR      := DPV1_WRITE.ERR;
DPV1_WRITE_ERNO     := DPV1_WRITE.ERNO;
DPV1_WRITE_ERNO1    := DPV1_WRITE.ERNO1;
DPV1_WRITE_ERNO2    := DPV1_WRITE.ERNO2;
DPV1_WRITE_DATA_LEN := DPV1_WRITE.DATA_LEN;
```

1.5.4.26.2 Data types

Data type	Description
DPM_COM_ERR_TYPE	Communication error
DPM_STATE_BITS_TYPE	Bits for Communication Module state description
STATIONSTATUS_1_TYPE	Stationstatus_1 (DP slave diagnosis according to standard)

Data type	Description
STATIONSTATUS_2_TYPE	Stationstatus_2 (DP slave diagnosis according to standard)
STATIONSTATUS_3_TYPE	Stationstatus_3 (DP slave diagnosis according to standard)

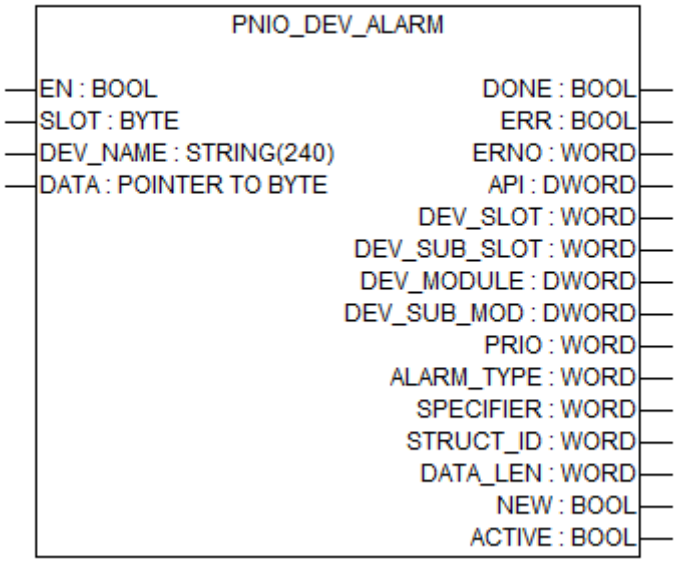
1.5.4.27 PROFINET IO library

Library file name: **PROFINET_AC500_Vx.lib.**

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

1.5.4.27.1 Function blocks

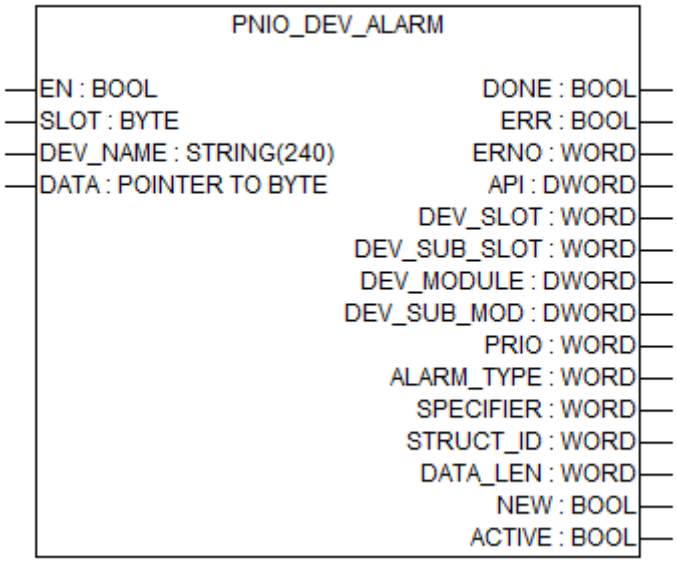
PNIO_DEV_ALARM



Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	Alarm

The function block PNIO_DEV_ALARM provides diagnostic and emergency information describing the current condition of a certain PROFINET IO device.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

The input DEV_NAME describes the PROFINET IO device to be queried. The string may have a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target IO module of this request.

Valid values are (examples for the ABB module, where the hash marks # are place holders for the address selected by the rotary switch at the front of the module):

ci501-pn-##

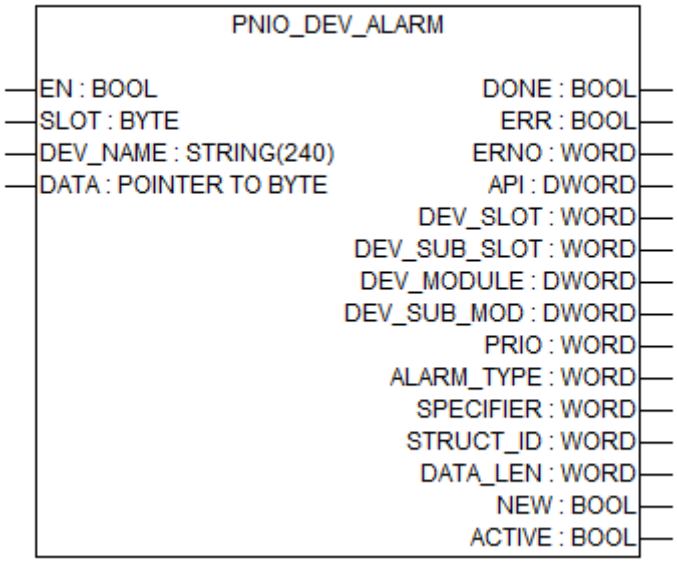
ci502-pn-##

DATA

Data type	Default value	Range	Unit
BYTE	-	-	-

Input DATA specifies via the ADR address operator the address of the variable where the received data block shall be stored. The size of the variable must be big enough to store the complete data block (e.g. BYTE array). And the format (BYTE, WORD etc.) of the data must be considered.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

API

Data type	Default value	Range	Unit
DWORD	-	-	-

The output API provides the ALARM API of the current alarm.

DEV_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SLOT provides the device slot which sent the alarm.

DEV_SUB_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SUB_SLOT provides the device sub slot which sent the alarm.

DEV_MODULE

Data type	Default value	Range	Unit
DWORD	-	-	

The output DEV_MODULE provides the ID of the module which sent the alarm.

DEV_SUB_MOD

Data type	Default value	Range	Unit
DWORD	-	-	-

The output DEV_SUB_MOD provides the ID of the sub module which sent the alarm.

PRIO

Data type	Default value	Range	Unit
WORD	-	-	-

The output PRIO provides the priority of the alarm sent by the device.

ALARM_TYPE

Data type	Default value	Range	Unit
WORD	-	-	-

The output ALARM_TYPE describes the kind of the reason for diagnosis message received. The ABB I/O modules CI501-PNIO and CI502-PNIO currently only deliver messages of the type (2): process.

Value	Diagnosis type
16#0000	reserved
16#0001	Diagnosis appears
16#0002	Process
16#0003	Pull
16#0004	Plug
16#0005	Status
16#0006	Update
16#0007	Redundancy

Value	Diagnosis type
16#0008	Controlled by supervisor
16#0009	Released
16#000A	Plug wrong submodule
16#000B	Return of submodule
16#000C	Diagnosis disappears
16#000D	Multicast communication mismatch
16#000E	Port data change notification
16#000F	Sync data change notification
16#0010	Isochronous mode notification
16#0011	Network component problem notification
16#0012	Time data changed notification
16#0013	Dynamic Frame Packing problem notification
16#0014	MRPD problem notification
16#0015	System Redundancy notification
16#0016	Multiple interface mismatch notification
16#0017 - 16#001D	Reserved
16#001E	Upload and retrieval notification
16#001F	Pull mode
16#0020 - 16#007F	Manufacturer specific
16#0080 - 16#00FF	Reserved for profiles
16#0100 - 16#FFFF	Reserved

SPECIFIER

Data type	Default value	Range	Unit
WORD	-	0-15	bit

The bits of the diagnosis specifier describe the type and specification of the current diagnosis:

Bit	Description
0 ... 10	Sequence number
11	Channel diagnosis
12	Manufacturer specific diagnosis
13	Submodule diagnosis state
14	Reserved
15	AR diagnosis state

The SPECIFIER can be displayed in plain text using the function PNIO_DEV_SPECIFIER
↳ *Chapter 1.5.4.27.1.3 “PNIO_DEV_INFO” on page 1803*.

SRUCT_ID

Data type	Default value	Range	Unit
WORD	-	-	-

The output STRUCT_ID provides the manufacture's proprietary data structure ID.

DATA_LEN

Data type	Default value	Range	Unit
WORD	-	-	-

The output DATA_LEN provides the size of / numbers of bytes which were written to DATA.

NEW

Data type	Default value	Range	Unit
BOOL	-	-	-

Signals whether new valid diagnosis information is available. If DONE and NEW are TRUE, the outputs marked with an asterisk (*) are valid and the data transferred to DATA is up to date.

ACTIVE

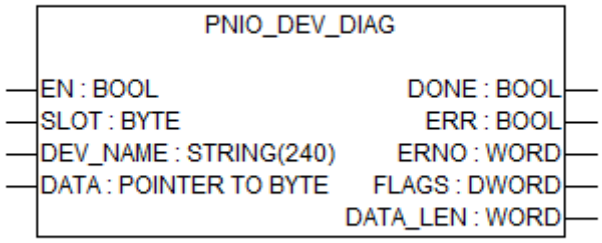
Data type	Default value	Range	Unit
BOOL	-	-	-

The inquired device is currently active. This output does not depend on the NEW output.

Function call in ST

```
PNIO_DEVICE_ALARM(
EN         := PNIO_DEVICE_ALARM_EN,
SLOT       := PNIO_DEVICE_ALARM_SLOT,
SLV_NAME   := PNIO_DEVICE_ALARM_DEV_NAME,
DATA       := ADR(PNIO_DEVICE_ALARM_DATA));
PNIO_DEVICE_ALARM_DONE                  := PNIO_DEVICE_ALARM.DONE;
PNIO_DEVICE_ALARM_ERR                   := PNIO_DEVICE_ALARM.ERR;
PNIO_DEVICE_ALARM_ERNO                  := PNIO_DEVICE_ALARM.ERNO;
PNIO_DEVICE_ALARM_API                   := PNIO_DEVICE_ALARM.API;
PNIO_DEVICE_ALARM_DEV_SLOT              := PNIO_DEVICE_ALARM.DEV_SLOT;
PNIO_DEVICE_ALARM_DEV_SUB_SLOT          :=
PNIO_DEVICE_ALARM.DEV_SUBSLOT;
PNIO_DEVICE_ALARM_DEV_MODULE            :=
PNIO_DEVICE_ALARM.DEV_MODULE;
PNIO_DEVICE_ALARM_DEV_SUB_MOD           :=
PNIO_DEVICE_ALARM.DEV_SUB_MOD;
PNIO_DEVICE_ALARM_PRIO                  := PNIO_DEVICE_ALARM.PRIO;
PNIO_DEVICE_ALARM_ALARM_TYPE            :=
PNIO_DEVICE_ALARM.ALARM_TYPE;
PNIO_DEVICE_ALARM_SPECIFIER             :=
PNIO_DEVICE_ALARM.SPECIFIER;
PNIO_DEVICE_ALARM_STRUCT_ID             :=
PNIO_DEVICE_ALARM.STRUCT_ID;
PNIO_DEVICE_ALARM_DATA_LEN              := PNIO_DEVICE_ALARM.DATA_LEN;
PNIO_DEVICE_ALARM_NEW                   := PNIO_DEVICE_ALARM.NEW;
PNIO_DEVICE_ALARM_ACTIVE                := PNIO_DEVICE_ALARM.ACTIVE;
```

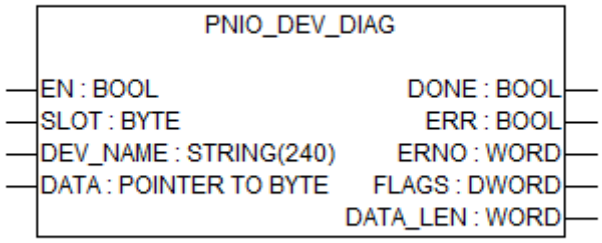
PNIO_DEV_DIAG



Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Simple function block with cycle persistent data.
Group	Diagnosis

The function block PNIO_DEV_DIAG provides diagnostic information of a certain PROFINET IO device.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

The input DEV_NAME describes the PROFINET IO device to be queried. The string may have a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target IO module of this request.

Valid values are (examples for the ABB module, where the hash marks # are place holders for the address selected by the rotary switch at the front of the module):

ci501-pn-##

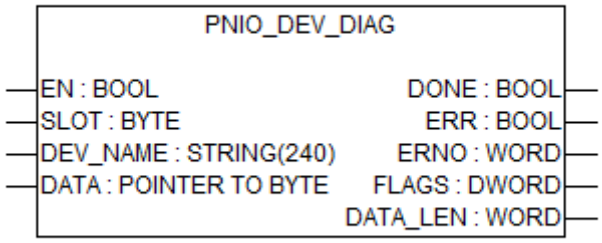
ci502-pn-##

DATA

Data type	Default value	Range	Unit
BYTE	-	-	-

Input DATA specifies via the ADR address operator the address of the variable where the received data block shall be stored. The size of the variable must be big enough to store the complete data block (e.g. BYTE array). And the format (BYTE, WORD etc.) of the data must be considered.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

FLAGS

Data type	Default value	Range	Unit
DWORD	-	0-11	Bit

The output FLAGS provides the status flags of the PROFINET IO device chosen by DEV_NAME.

The individual bits have the following meaning:

Bit	Description
0	The I/O module does not exist / The I/O module does not respond to DCP Ident requests
1	The I/O module is not ready
2	A configuration fault exists for this I/O module (e. g. NameOf-Station or IP is used more than once in one network)
3	The I/O module transmits an invalid response (e. g. DCP Set IP was not successful)
4	A parameter fault exists for this I/O module (e. g. wrong Module ID)
5	This I/O module is deactivated
6	Diagnosis data exists for this I/O module
7	The I/O module sends a "Diagnosis disappeared" alert
8	The diagnosis buffer of the Communication Module was too small for the diagnosis data sent by the I/O module
9	The diagnosis buffer of the Communication Module was over-written by new diagnosis data of the I/O module before the old data was read out
10	The packet requesting diagnosis data is too small to carry the diagnosis data for this I/O module
11	The I/O module reported a ModuleDiffBlock during connection establishment

DATA_LEN

Data type	Default value	Range	Unit
DWORD	-	-	-

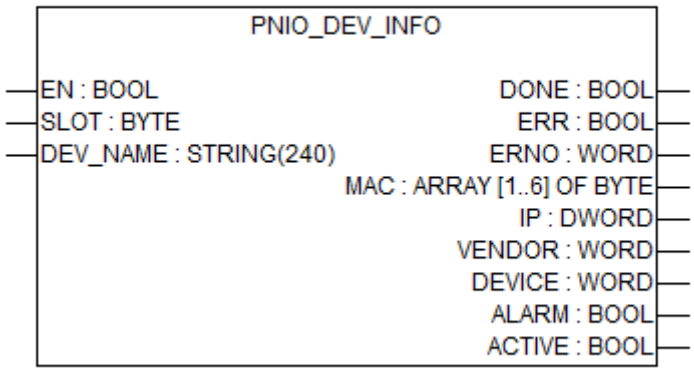
The output DATA_LEN provides the size of numbers / of bytes which were written to DATA.

Function call in ST

```
PNIO_DEVICE_DIAG(EN := PNIO_DEVICE_DIAG_EN,
```

```
    SLOT := PNIO_DEVICE_DIAG_SLOT,
    DATA:= ADR(PNIO_DEVICE_DIAG_DATA));
PNIO_DEVICE_DIAG_DONE            := PNIO_DEVICE_DIAG.DONE;
PNIO_DEVICE_DIAG_ERR             := PNIO_DEVICE_DIAG.ERR;
PNIO_DEVICE_DIAG_ERNO            := PNIO_DEVICE_DIAG.ERNO;
PNIO_DEVICE_DIAG_FLAGS           := PNIO_DEVICE_DIAG.FLAGS;
PNIO_DEVICE_DIAG_DATA_LEN        := PNIO_DEVICE_DIAG.DATA_LEN;
```

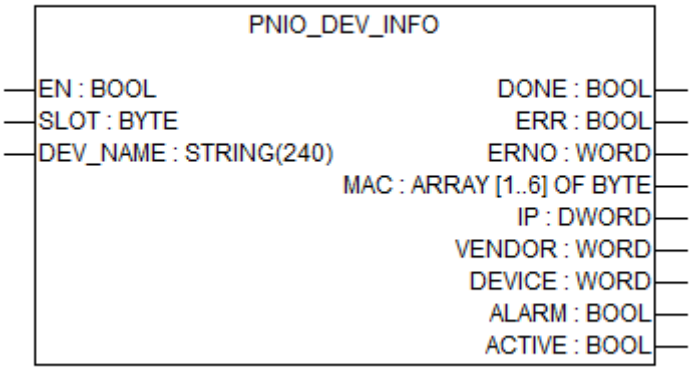
PNIO_DEV_INFO



Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Simple function block with cycle persistent data.
Group	Info

The function block PNIO_DEV_INFO provides general information of a certain PROFINET device.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

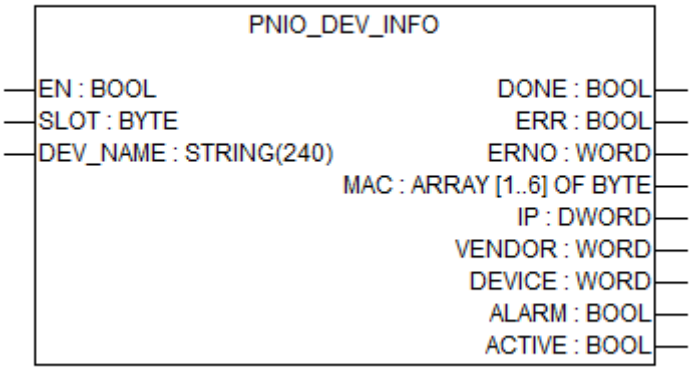
The input DEV_NAME describes the PROFINET IO device to be queried. The string may have a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target IO module of this request.

Valid values are (examples for the ABB module, where the hash marks # are place holders for the address selected by the rotary switch at the front of the module):

ci501-pn-##

ci502-pn-##

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

MAC

Data type	Default value	Range	Unit
ARRAY	-	-	-

The output MAC provides the MAC address of the device chosen by DEV_NAME.

IP

Data type	Default value	Range	Unit
DWORD	-	-	-

The output IP provides the IP address of the device chosen by DEV_NAME.

VENDOR

Data type	Default value	Range	Unit
WORD	-	-	-

The output VENDOR provides the manufacturers VENDOR ID of the device chosen by DEV_NAME.

DEVICE

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEVICE provides the Device ID of the device chosen by DEV_NAME.

ALARM

Data type	Default value	Range	Unit
BOOL	-	-	-

If this output is TRUE an alarm is pending on the device chosen by DEV_NAME.

ACTIVE

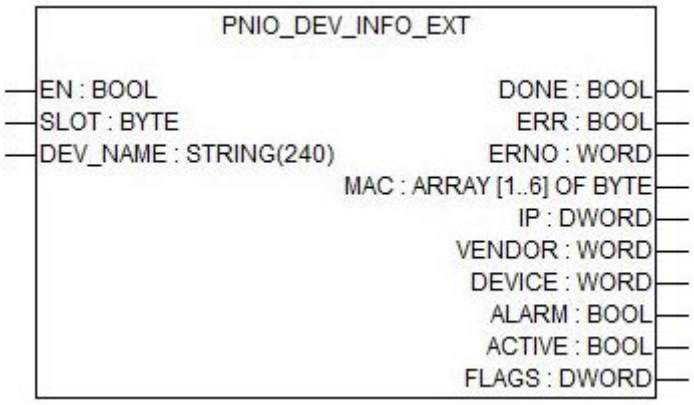
Data type	Default value	Range	Unit
BOOL	-	-	-

The inquired device is currently active. This output does not depend on the NEW output.

Function call in ST

```
PNIO_DEVICE_INFO(EN := PNIO_DEVICE_INFO_EN,
    SLOT := PNIO_DEVICE_INFO_SLOT,
DEV_NAME := PNIO_DEVICE_INFO_DEV_NAME);
PNIO_DEVICE_INFO_DONE             := PNIO_DEVICE_INFO.DONE;
PNIO_DEVICE_INFO_ERR              := PNIO_DEVICE_INFO.ERR;
PNIO_DEVICE_INFO_ERNO             := PNIO_DEVICE_INFO.ERNO;
PNIO_DEVICE_INFO_MAC              := PNIO_DEVICE_INFO.MAC;
PNIO_DEVICE_INFO_IP               := PNIO_DEVICE_INFO.IP;
PNIO_DEVICE_INFO_VENDOR           := PNIO_DEVICE_INFO.VENDOR;
PNIO_DEVICE_INFO_DEVICE           := PNIO_DEVICE_INFO.DEVICE;
PNIO_DEVICE_INFO_ALARM            := PNIO_DEVICE_INFO.ALARM;
PNIO_DEVICE_INFO_ACTIVE           := PNIO_DEVICE_INFO.ACTIVE;
```

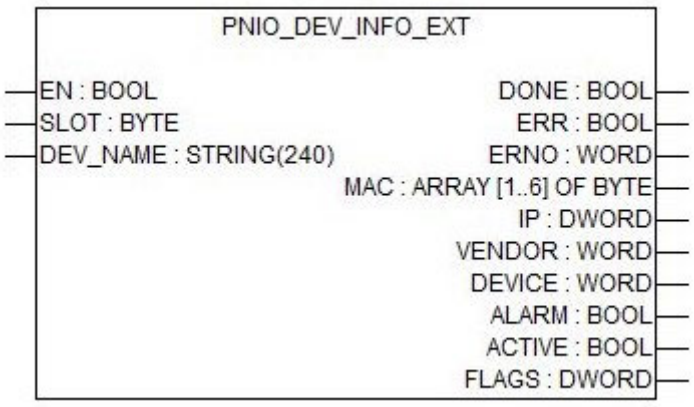
PNIO_DEV_INFO_EXT



Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Simple function block with cycle persistent data.
Group	Info

The function block PNIO_DEV_INFO_EXT provides general information of a certain PROFINET IO device.

Input Description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

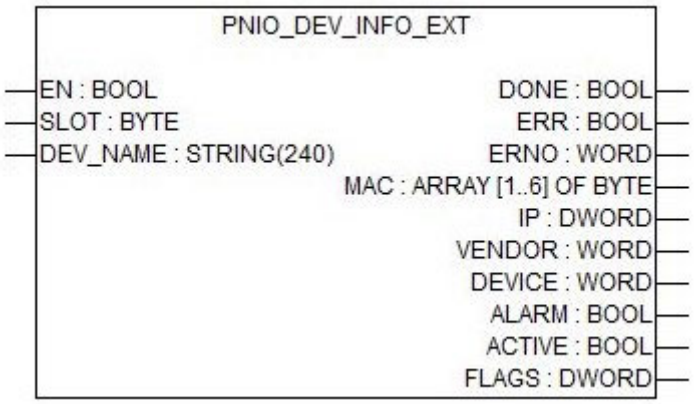
The input DEV_NAME describes the PROFINET IO device to be queried. The string may have a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target IO module of this request.

Valid values are (examples for the ABB module, where the hash marks # are place holders for the address selected by the rotary switch at the front of the module):

ci501-pn-##

ci502-pn-##

Output Description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

MAC

Data type	Default value	Range	Unit
ARRAY	-	-	-

The output MAC provides the MAC address of the device chosen by DEV_NAME.

IP

Data type	Default value	Range	Unit
DWORD	-	-	-

The output IP provides the IP address of the device chosen by DEV_NAME.

VENDOR

Data type	Default value	Range	Unit
WORD	-	-	-

The output VENDOR provides the manufacturers VENDOR ID of the device chosen by DEV_NAME.

DEVICE

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEVICE provides the Device ID of the device chosen by DEV_NAME.

ALARM

Data type	Default value	Range	Unit
BOOL	-	-	-

If this output is TRUE an alarm is pending on the device chosen by DEV_NAME.

ACTIVE

Data type	Default value	Range	Unit
BOOL	-	-	-

The inquired device is currently active. This output does not depend on the NEW output.

FLAGS

Data type	Default value	Range	Unit
DWORD	-	0-11	Bit

The output FLAGS provides the status flags of the PROFINET IO device chosen by DEV_NAME.

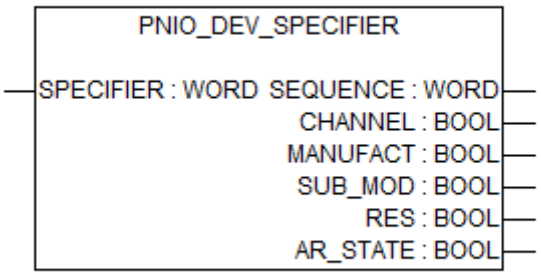
The individual bits have the following meaning:

Bit	Description
0	The I/O module does not exist / The I/O module does not respond to DCP Ident requests
1	The I/O module is not ready
2	A configuration fault exists for this I/O module (e. g. NameOf-Station or IP is used more than once in one network)
3	The I/O module transmits an invalid response (e. g. DCP Set IP was not successful)
4	A parameter fault exists for this I/O module (e. g. wrong Module ID)
5	This I/O module is deactivated
6	Diagnosis data exists for this I/O module
7	The I/O module sends a "Diagnosis disappeared" alert
8	The diagnosis buffer of the Communication Module was too small for the diagnosis data sent by the I/O module
9	The diagnosis buffer of the Communication Module was over-written by new diagnosis data of the I/O module before the old data was read out
10	The packet requesting diagnosis data is too small to carry the diagnosis data for this I/O module
11	The I/O module reported a ModuleDiffBlock during connection establishment

Function call in ST

```
PNIO_DEVICE_INFO_EXT(EN   := PNIO_DEVICE_INFO_EXT_EN,
                     SLOT := PNIO_DEVICE_INFO_EXT_SLOT);
PNIO_DEVICE_INFO_EXT_DONE             := PNIO_DEVICE_INFO_EXT.DONE;
PNIO_DEVICE_INFO_EXT_ERR              := PNIO_DEVICE_INFO_EXT.ERR;
PNIO_DEVICE_INFO_EXT_ERNO             := PNIO_DEVICE_INFO_EXT.ERNO;
PNIO_DEVICE_INFO_EXT_MAC              := PNIO_DEVICE_INFO_EXT.MAC;
PNIO_DEVICE_INFO_EXT_IP               := PNIO_DEVICE_INFO_EXT.IP;
PNIO_DEVICE_INFO_EXT_VENDOR           := PNIO_DEVICE_INFO_EXT.VENDOR;
PNIO_DEVICE_INFO_EXT_DEVICE           := PNIO_DEVICE_INFO_EXT.DEVICE;
PNIO_DEVICE_INFO_EXT_ALARM            := PNIO_DEVICE_INFO_EXT.ALARM;
PNIO_DEVICE_INFO_EXT_ACTIVE           := PNIO_DEVICE_INFO_EXT.ACTIVE;
PNIO_DEVICE_INFO_EXT_FLAGS            := PNIO_DEVICE_INFO_EXT.FLAGS;
```

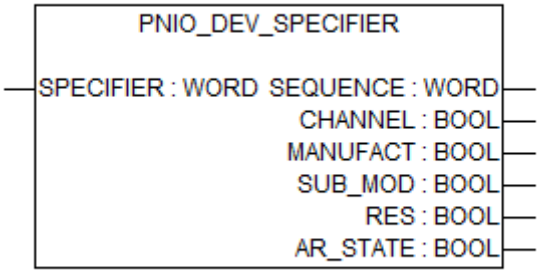
PNIO_DEV_SPECIFIER



Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block without historical values
Group	Alarm

The function PNIO_DEV_SPECIFIER displays the PNIO_DEV_ALARM SPECIFIER in plain text.

Input description



SPECIFIER

Data type	Default value	Range	Unit
WORD	-	0-15	bit

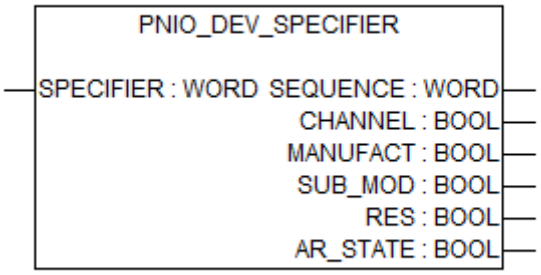
The bits of the diagnosis specifier describe the type and specification of the current diagnosis:

Bit	Description
0 ... 10	Sequence number
11	Channel diagnosis
12	Manufacturer specific diagnosis
13	Submodule diagnosis state

Bit	Description
14	Reserved
15	AR diagnosis state

The SPECIFIER can be displayed in plain text using the function PNIO_DEV_SPECIFIER
↳ *Chapter 1.5.4.27.1.3 “PNIO_DEV_INFO” on page 1803*.

Output description



SEQUENCE

Data type	Default value	Range	Unit
WORD	-	-	-

The output SEQUENCE provides the alarm sequence number.

CHANNEL

Data type	Default value	Range	Unit
BOOL	-	-	-

The output CHANNEL shows if the current alarm is a channel diagnosis. If CHANNEL=TRUE, the current alarm is a channel diagnosis.

MANUFACT

Data type	Default value	Range	Unit
BOOL	-	-	-

The output MANUFACT shows if the current alarm is a manufacturer-specific diagnosis. If MANUFACT=TRUE, the current alarm is a manufacturer-specific diagnosis.

SUB_MOD

Data type	Default value	Range	Unit
BOOL	-	-	-

The output SUB_MOD shows if the current alarm is a sub module diagnosis. If SUB_MOD=TRUE, the current alarm is a sub module diagnosis.

RES

Data type	Default value	Range	Unit
BOOL	-	-	-

The output res in not used. It is reserved for future use.

AR_STATE

Data type	Default value	Range	Unit
BOOL	-	-	-

The output AR_STATE displays the AR diagnosis state.

Function call in ST

```
PNIO_DEV_SPECIFIER                  ( EN :=
PNIO_DEV_SPECIFIER_SPECIFIER);

PNIO_DEV_SPECIFIER_SEQUENCE             :=
PNIO_DEV_SPECIFIER.SEQUENCE;

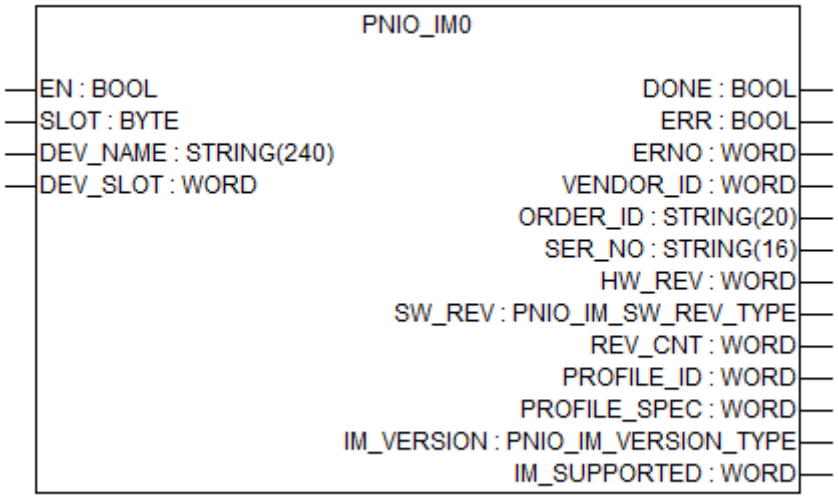
PNIO_DEV_SPECIFIER_CHANNEL              := PNIO_DEV_SPECIFIER.CHANNEL;

PNIO_DEV_SPECIFIER_MANUFACT             :=
PNIO_DEV_SPECIFIER.MANUFACT;

PNIO_DEV_SPECIFIER_SUB_MOD              := PNIO_DEV_SPECIFIER.SUB_MOD;

PNIO_DEV_SPECIFIER_AR_STATE             :=
PNIO_DEV_SPECIFIER.AR_STATE;
```

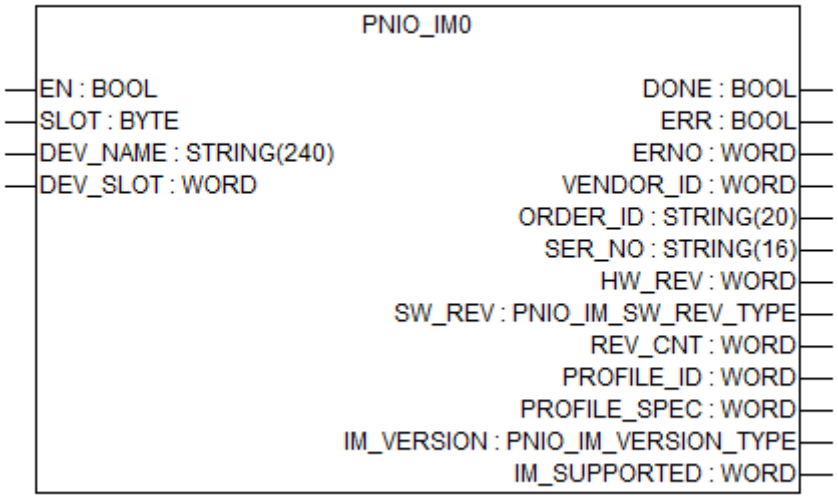
PNIO_IM0



Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Simple function block with cycle persistent data.
Group	Info

The function block PNIO_IM0 provides Identification & Maintenance information, describing the manufacturer and the current version and revision of a certain PROFINET IO device.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SLOT provides the device slot which sent the alarm.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

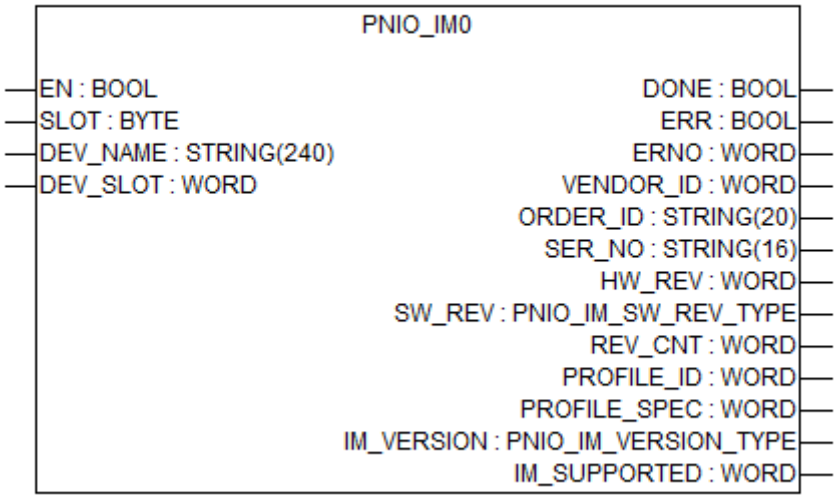
The input DEV_NAME describes the PROFINET IO device to be queried. The string may have a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target IO module of this request.

Valid values are (examples for the ABB module, where the hash marks # are place holders for the address selected by the rotary switch at the front of the module):

ci501-pn-##

ci502-pn-##

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

VENDOR_ID

Data type	Default value	Range	Unit
WORD	0000h	-	-

The output parameter VENDOR_ID (or MANUFACTURER_ID) returns the ID of a specific manufacturer that had been assigned by the PROFIBUS/PROFINET business office. Default value is 0000h in case a manufacturer does not want to handle an ID. With this ID the manufacturer of a device can be identified from a list, hosted at and available from the PROFIBUS community. See *http://www.profibus.com* for further details.

ORDER_ID

Data type	Default value	Range	Unit
STRING	-	-	

The ORDER_ID output contains the complete order number or at least a relevant part that allows unambiguous identification of the device/module within the manufacturer's web site. It consists of a string of 20 octets, whereas unused octets are set to "20h" (blank).

SER_NO

Data type	Default value	Range	Unit
STRING	-	-	-

The SER_NO output contains an unique production number assigned by the manufacturer to this device during production. It consists of a string of 16 octets, whereas unused octets are set to "20h" (blank).

HW_REV

Data type	Default value	Range	Unit
WORD	-	-	-

The content of this parameter characterizes the edition of the hardware only. Default value is 0000h. FFFFh indicates availability of profile specific information.

SW_REV

Data type	Default value	Range	Unit
STRUCT PNIO_IM_SW_REV_TYPE	-	-	-

The content of this structure characterizes the edition of the software or firmware of a device or module. The structure supports coarse and detailed differentiation that may be defined by the manufacturer: Vx.y.z.

Any component that carries software shall present its software version even if the user may not be aware of it. V255.255.255 indicates the availability of profile specific information.

Valid values for SW_REV.REV_TYPE are:

V = officially released version

R = Revision (of a virtual or physically modular product)

P = Prototype

U = Under Test (field test)

T = Test Device

SW_REV.FUNCTIONAL (0..255) reflects the functional enhancement level

SW_REV.BUG_FIX (0..255) reflects the bug fix release level SW_REV.INTERNAL (0..255) reflects a certain internal change level

REV_CNT

Data type	Default value	Range	Unit
WORD	-	-	-

The output value of the REV_CNT parameter of a given module reflects the number of changes of the hardware or of its parameters. At production time the counter is set to 0. This value is reserved for the first installation and the first increment. Thus, the counter increments from

1... 65535, wrapping over back to 1 at the end.

PROFILE_ID

Data type	Default value	Range	Unit
WORD	-	-	-

A module following a special profile may offer extended information (PROFILE_SPEC) about its function and/or sub devices, e. g. HART. Devices not following any PROFINET application profile shall use F600h. In this case, the device is generic and may indicate its type via the parameter PROFILE_SPEC.

PROFILE_SPEC

Data type	Default value	Range	Unit
WORD	-	-	-

In case a module follows a special profile, this output parameter offers information about the usage of its channels and/or sub devices. The module/channel information is according to the respective definitions of the application profile. Devices/modules not following any PROFINET application profile are generic and are using F600h "“ F6FFh.

IM_SUPPORTED

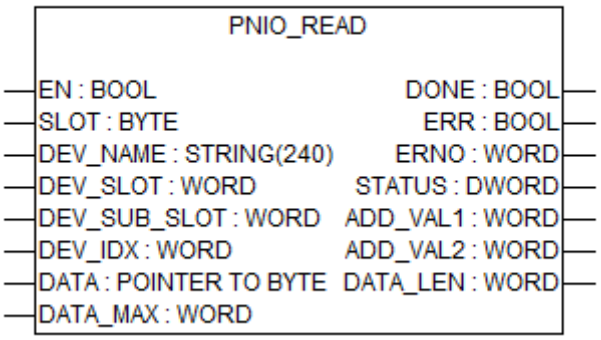
Data type	Default value	Range	Unit
DWORD	-	-	Bit

The output value of IM_SUPPORTED reflects the availability of I&M records. Each of the 16 bits of this value represents an I&M record. Starting with Bit 0, which represents the availability of a profile specific I&M information, the Bits 1...15 are counted upwards: Bit 1 equals to I&M1, Bit 2 equals to I&M2 etc. A bit set to 1 identifies an I&M being available.

Function call in ST

```
PNIO_IM(
          EN       := PNIO_IM_EN,
          SLOT     := PNIO_IM_SLOT,
          DEV_SLOT := PNIO_IM_DEV_SLOT,
          DEV_NAME := PNIO_IM_DEV_NAME);
PNIO_IM_DONE               := PNIO_IM.DONE;
PNIO_IM_ERR                := PNIO_IM.ERR;
PNIO_IM_ERNO               := PNIO_IM.ERNO;
PNIO_IM_VENDOR_ID          := PNIO_IM.VENDOR_ID;
PNIO_IM_ORDER_ID           := PNIO_IM.ORDER_ID;
PNIO_IM_SER_NO             := PNIO_IM.SER_NO;
PNIO_IM_HW_REV             := PNIO_IM.HW_REV; PNIO_IM_SW_REV
:= PNIO_IM.SW_REV; PNIO_IM_REV_CNT            := PNIO_IM.REV_CNT;
PNIO_IM_PROFILE_ID         := PNIO_IM.PROFILE_ID;
PNIO_IM_PROFILE_SPEC       := PNIO_IM.PROFILE_SPEC;
PNIO_IM_IM_VERSION         := PNIO_IM.IM_VERSION;
PNIO_IM_IM_SUPPORTED       := PNIO_IM.IM_SUPPORTED;
```

PNIO_READ

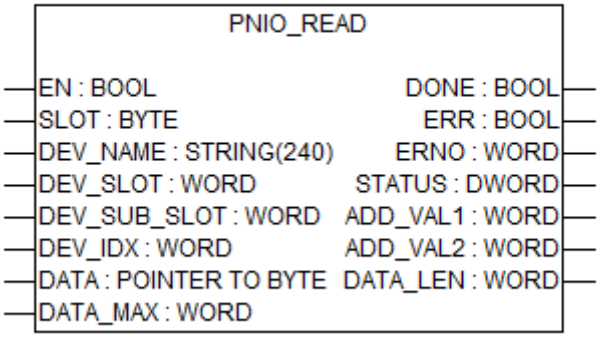


Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	Data

The function block PNIO_READ implements the acyclic PROFINET READ service. Using this function, the controller has read access to slot, sub slot and index-related data of PROFINET IO devices. PNIO_READ works outside the cyclic process data exchange.

Every time a FALSE->TRUE edge is applied to input EN, PNIO _READ reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE->TRUE edges at input EN are ignored until the processing of the active requests is finished. The completion of the request processing is indicated by DONE = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

The input DEV_NAME describes the PROFINET IO device to be queried. The string may have a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target IO module of this request.

Valid values are (examples for the ABB module, where the hash marks # are place holders for the address selected by the rotary switch at the front of the module):

ci501-pn-##

ci502-pn-##

DEV_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SLOT provides the device slot which sent the alarm.

DEV_SUB_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SUB_SLOT provides the device sub slot which sent the alarm.

DEV_IDX

Data type	Default value	Range	Unit
WORD	-	-	-

Input DEV_IDX specifies the number of the index within the sub slot, the data of which shall be read.

DATA

Data type	Default value	Range	Unit
BYTE	-	-	-

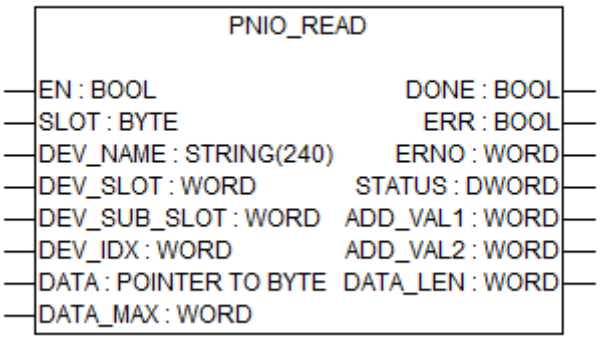
Input DATA specifies via the ADR address operator the address of the variable where the received data block shall be stored. The size of the variable must be big enough to store the complete data block (e.g. BYTE array). And the format (BYTE, WORD etc.) of the data must be considered.

DATA_MAX

Data type	Default value	Range	Unit
WORD	-	1-1024	-

Input DATA_MAX specifies the length of the data block to be read. Valid values are 1..1024.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

PNIO_STATUS contains the PNIO error code and error decode (see, *Chapter 1.5.4.27.1.13 “PROFINET status*” on page 1839*).

ADD_VAL1

Data type	Default value	Range	Unit
WORD	1	-	-

PNIO_ADD_VAL1 contains the PNIO error code 1.

ADD_VAL2

Data type	Default value	Range	Unit
WORD	2	-	-

PNIO_ADD_VAL2 contains the PNIO error code 2.

DATA_LEN

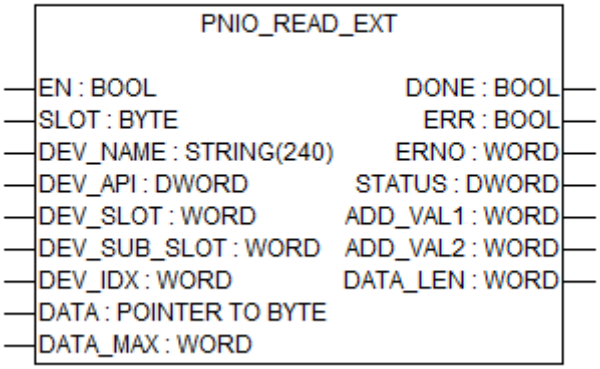
Data type	Default value	Range	Unit
DWORD	-	-	-

The output DATA_LEN provides the size of numbers / of bytes which were written to DATA.

Function call in ST

```
PNIO_READ (EN           := PNIO_READ_EN,
           SLOT         := PNIO_READ_SLOT,
           DEV_NAME     := PNIO_READ_DEV_NAME,
           DEV_SLOT     := PNIO_READ_DEV_SLOT,
           DEV_SUB_SLOT := PNIO_READ_DEV_SUB_SLOT,
           DEV_IDX      := PNIO_READ_DEV_IDX,
           DATA         := ADR(PNIO_READ_DATA),
           DATA_MAX     := PNIO_READ_DATA_MAX);
PNIO_READ_DONE     := PNIO_READ.DONE;
PNIO_READ_ERR      := PNIO_READ.ERR;
PNIO_READ_ERNO     := PNIO_READ.ERNO;
PNIO_READ_STATUS   := PNIO_READ.STATUS;
PNIO_READ_ADD_VAL1 := PNIO_READ.ADD_VAL1;
PNIO_READ_ADD_VAL2 := PNIO_READ.ADD_VAL2;
PNIO_READ_DATA_LEN := PNIO_READ.DATA_LEN;
```

PNIO_READ_EXT

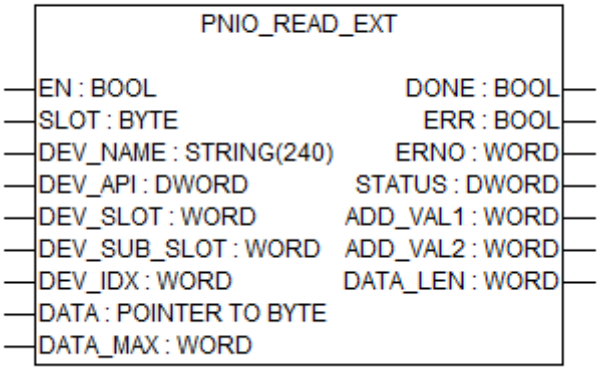


Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V2.2.0
Type	Function block with historical values
Group	Data

The function block PNIO_READ_EXT implements the acyclic PROFINET READ service. Using this function, the controller has read access to API, slot, sub slot and index-related data of PROFINET IO devices. PNIO_READ_EXT works outside the cyclic process data exchange.

Every time a FALSE->TRUE edge is applied to input EN, PNIO_READ_EXT reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE->TRUE edges at input EN are ignored until the processing of the active requests is finished. The completion of the request processing is indicated by DONE = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

The input DEV_NAME describes the PROFINET IO device to be queried. The string may have a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target IO module of this request.

Valid values are (examples for the ABB module, where the hash marks # are place holders for the address selected by the rotary switch at the front of the module):

ci501-pn-##

ci502-pn-##

DEV_API

Data type	Default value	Range	Unit
WORD	-	-	-

Input DEV_API specifies the Application Process Identifier of the AP to which the data block belongs.

DEV_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SLOT provides the device slot which sent the alarm.

DEV_SUB_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SUB_SLOT provides the device sub slot which sent the alarm.

DEV_IDX

Data type	Default value	Range	Unit
WORD	-	-	-

Input DEV_IDX specifies the number of the index within the sub slot, the data of which shall be read.

DATA

Data type	Default value	Range	Unit
BYTE	-	-	-

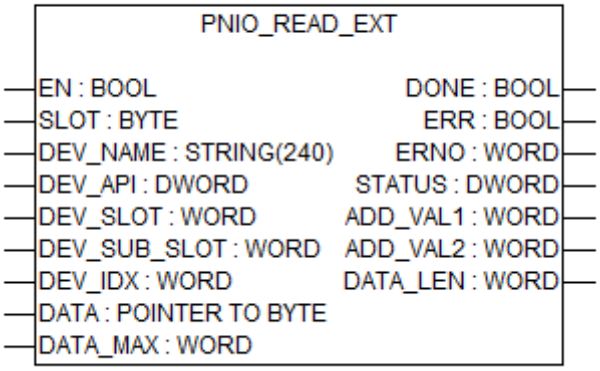
Input DATA specifies via the ADR address operator the address of the variable where the received data block shall be stored. The size of the variable must be big enough to store the complete data block (e.g. BYTE array). And the format (BYTE, WORD etc.) of the data must be considered.

DATA_MAX

Data type	Default value	Range	Unit
WORD	-	1-1024	-

Input DATA_MAX specifies the length of the data block to be read. Valid values are 1..1024.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

PNIO_STATUS contains the PNIO error code and error decode (see, *Chapter 1.5.4.27.1.13 “PROFINET status*” on page 1839*).

ADD_VAL1

Data type	Default value	Range	Unit
WORD	1	-	-

PNIO_ADD_VAL1 contains the PNIO error code 1.

ADD_VAL2

Data type	Default value	Range	Unit
WORD	2	-	-

PNIO_ADD_VAL2 contains the PNIO error code 2.

DATA_LEN

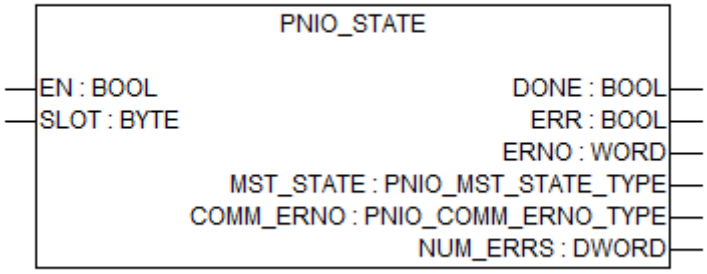
Data type	Default value	Range	Unit
DWORD	-	-	-

The output DATA_LEN provides the size of numbers / of bytes which were written to DATA.

Function call in ST

```
PNIO_READ_EXT (EN           := PNIO_READ_EXT_EN,
               SLOT         := PNIO_READ_EXT_SLOT,
               DEV_NAME     := PNIO_READ_EXT_DEV_NAME,
               DEV_API      := PNIO_READ_EXT_DEV_API,
               DEV_SLOT     := PNIO_READ_EXT_DEV_SLOT,
               DEV_SUB_SLOT := PNIO_READ_EXT_DEV_SUB_SLOT,
               DEV_IDX      := PNIO_READ_EXT_DEV_IDX,
               DATA         := ADR(PNIO_READ_EXT_DATA),
               DATA_MAX     := PNIO_READ_EXT_DATA_MAX);
PNIO_READ_EXT_DONE     := PNIO_READ_EXT.DONE;
PNIO_READ_EXT_ERR      := PNIO_READ_EXT.ERR;
PNIO_READ_EXT_ERNO     := PNIO_READ_EXT.ERNO;
PNIO_READ_EXT_STATUS   := PNIO_READ_EXT.STATUS;
PNIO_READ_EXT_ADD_VAL1 := PNIO_READ_EXT.ADD_VAL1;
PNIO_READ_EXT_ADD_VAL2 := PNIO_READ_EXT.ADD_VAL2;
PNIO_READ_EXT_DATA_LEN := PNIO_READ_EXT.DATA_LEN;
```

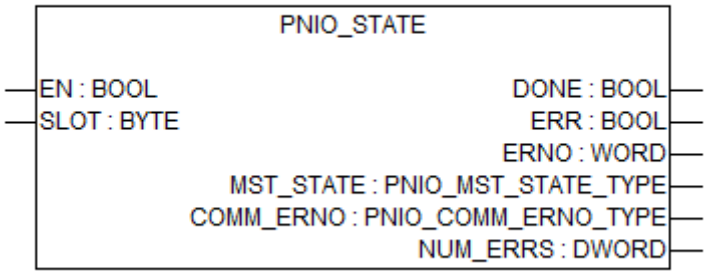
PNIO_STATE



Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Simple function block with cycle persistent data.
Group	Info

The function block PNIO_STATE provides diagnostic and emergency information describing the current condition of a PROFINET I/O bus.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

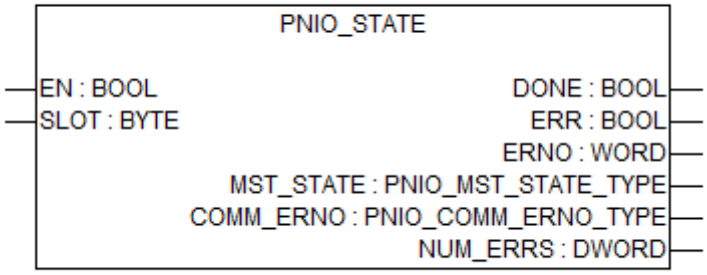
SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

MST_STATE

Data type	Default value	Range	Unit
PNIO_MST_STATE_TYPE	-	-	-

The MST_STATE output reflects the major state of the PROFINET Communication Module. This value is valid with DONE=TRUE and ERR=FALSE.

The MST_STATE is displayed in plain text with aid of the enumeration PNIO_MST_STATE_TYPE.

PNIO_MST_STATE_UNKOWN	Unknown state
PNIO_MST_STATE_NOT_CONFIGURED	Pre-configuration
PNIO_MST_STATE_STOP	Configured but not running
PNIO_MST_STATE_IDLE	Idle
PNIO_MST_STATE_OPERATE	All up, normal operational state

COMM_ERNO

Data type	Default value	Range	Unit
PNIO_COMM_ERNO_TYPE	-	-	-

The COMM_ERNO output value represents the current PROFINET bus condition. A transition of this output with DONE=TRUE to a non-zero-value signals a communication error caused by one of the reasons listed in the table below.

The COMM_ERNO is displayed in plain text with aid of the enumeration PNIO_COMM_ERNO_TYPE.

PNIO_COMM_ERNO_NONE	No error
PNIO_CONIFGURATION_FAULT	Configuration fault
PNIO_PARAMETER_ERROR	Parameter error
PNIO_INV_NETWORK_ERROR	Invalid network address
PNIO_NETWORK_FAULT	Network fault
PNIO_CONNECTION_CLOSED	Connection closed
PNIO_CONNECTION_TIMEOUT	Connection timeout
PNIO_LONELY_NETWORK	Lonely network
PNIO_DUBLICATE_NODE	Duplicate node
PNIO_CABLE_DISCONNECTED	Cable disconnected
PNIO_COMM_ERNO_UNKNOWN	Unknown communication error

NUM_ERRS

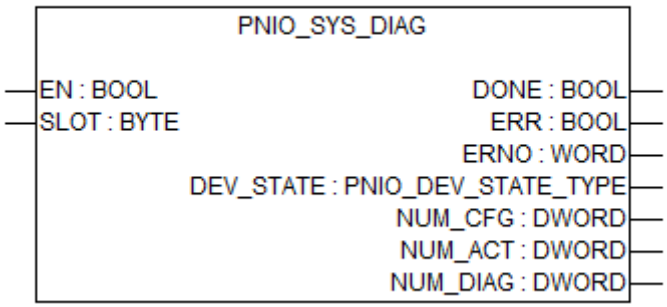
Data type	Default value	Range	Unit
DWORD	-	-	-

The total number of errors detected by the Communication Module since last power up or reset.

Function call in ST

```
PNIO_GENERAL_STATE( EN   := PNIO_GENERAL_STATE_EN,
SLOT := PNIO_GENERAL_STATE_SLOT);
PNIO_GENERAL_STATE_DONE := PNIO_GENERAL_STATE.DONE;
PNIO_GENERAL_STATE_ERR := PNIO_GENERAL_STATE.ERR;
PNIO_GENERAL_STATE_ERNO := PNIO_GENERAL_STATE.ERNO;
PNIO_GENERAL_STATE_MST_STATE := PNIO_GENERAL_STATE.MST_STATE;
PNIO_GENERAL_STATE_COMM_ERNO := PNIO_GENERAL_STATE.COMM_ERNO;
PNIO_GENERAL_STATE_NUM_ERRS := PNIO_GENERAL_STATE.NUM_ERRS;
```

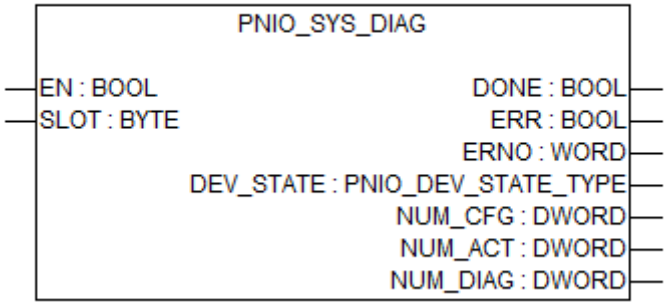
PNIO_SYS_DIAG



Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Simple function block with cycle persistent data.
Group	Info

The function block PNIO_SYS_DIAG provides diagnostic and emergency information describing the current condition of all of the PROFINET IO devices, connected to a certain PROFINET communication module.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

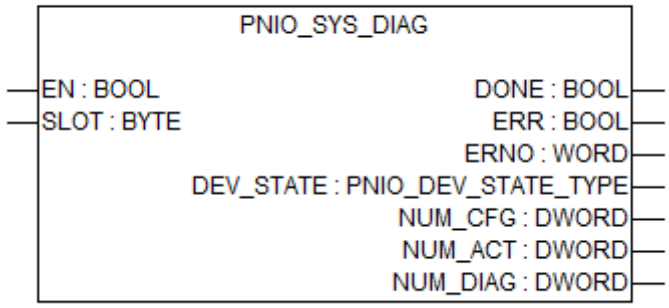
SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

DEV_STATE

Data type	Default value	Range	Unit
PNIO_DEV_STATE_TYPE	-	-	-

The output DEV_STATE indicates whether the cyclic process data exchange with all configured I/O modules is working, and no module has any diagnosis issue to be solved. On any I/O module missing or having a diagnosis issue pending, this output will change to FAILED.

After all slaves are back to normal operation, DEV_STATE will change back to OK

The DEV_STATE is displayed in plain text with aid of the enumeration PNIO_DEV_STATE_TYPE.

Value	Description
PNIO_DEV_STATE_UNDEFINED	Undefined
PNIO_DEV_STATE_OK	OK
PNIO_DEV_STATE_FAILED	Failed (at least one I/O module) or Warning (at least one I/O module)

NUM_CFG

Data type	Default value	Range	Unit
DWORD	-	-	-

The output NUM_CFG indicates the number of configured I/O modules, known by the communication module.

NUM_ACT

Data type	Default value	Range	Unit
DWORD	-	-	-

The output NUM_ACT indicates the number of currently active I/O modules, known by the communication module.

NUM_DIAG

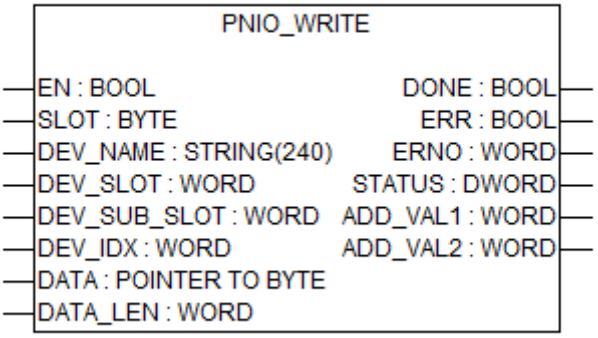
Data type	Default value	Range	Unit
DWORD	-	-	-

The output NUM_DIAG indicates the number I/O modules which have current alarms and current diagnosis information to be proceeded.

Function call in ST

```
PNIO_SYSTEM_DIAG( EN := PNIO_SYSTEM_DIAG_EN,
SLOT := PNIO_SYSTEM_DIAG_SLOT);
PNIO_SYSTEM_DIAG_DONE             := PNIO_SYSTEM_DIAG.DONE;
PNIO_SYSTEM_DIAG_ERR              := PNIO_SYSTEM_DIAG.ERR;
PNIO_SYSTEM_DIAG_ERNO             := PNIO_SYSTEM_DIAG.ERNO;
PNIO_SYSTEM_DIAG_DEV_STATE        := PNIO_SYSTEM_DIAG.DEV_STATE;
PNIO_SYSTEM_DIAG_NUM_CFG          := PNIO_SYSTEM_DIAG.NUM_CFG;
PNIO_SYSTEM_DIAG_NUM_ACT          := PNIO_SYSTEM_DIAG.NUM_ACT;
PNIO_SYSTEM_DIAG_NUM_DIAG         := PNIO_SYSTEM_DIAG.NUM_DIAG;
```

PNIO_WRITE

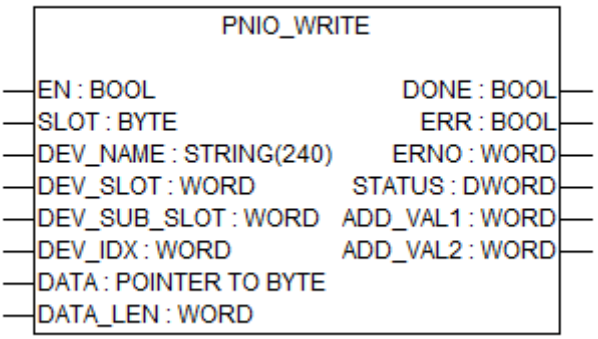


Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V1.3.0
Type	Function block with historical values
Group	Data

The function block PNIO_WRITE implements the acyclic PROFINET WRITE service. Using this function, the controller has write access to slot, sub slot and index-related data of PROFINET IO devices. PNIO_WRITE works outside the cyclic process data exchange.

Every time a FALSE->TRUE edge is applied to input EN, PNIO_WRITE reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE->TRUE edges at input EN are ignored until the processing of the active requests is finished. The completion of the request processing is indicated by DONE = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

The input DEV_NAME describes the PROFINET IO device to be queried. The string may have a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target IO module of this request.

Valid values are (examples for the ABB module, where the hash marks # are place holders for the address selected by the rotary switch at the front of the module):

ci501-pn-##

ci502-pn-##

DEV_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SLOT provides the device slot which sent the alarm.

DEV_SUB_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SUB_SLOT provides the device sub slot which sent the alarm.

DEV_IDX

Data type	Default value	Range	Unit
WORD	-	-	-

Input DEV_IDX specifies the number of the index within the sub slot, the data of which shall be read.

DATA

Data type	Default value	Range	Unit
BYTE	-	-	-

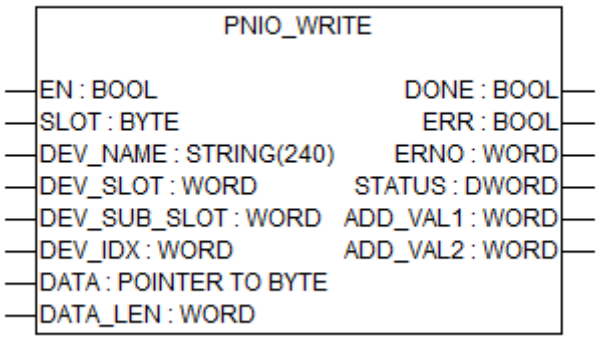
Input DATA specifies via the ADR address operator the address of the variable where the received data block shall be stored. The size of the variable must be big enough to store the complete data block (e.g. BYTE array). And the format (BYTE, WORD etc.) of the data must be considered.

DATA_LEN

Data type	Default value	Range	Unit
DWORD	-	-	-

The output DATA_LEN provides the size of numbers / of bytes which were written to DATA.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

PNIO_STATUS contains the PNIO error code and error decode (see, *Chapter 1.5.4.27.1.13 “PROFINET status*” on page 1839*).

ADD_VAL1

Data type	Default value	Range	Unit
WORD	1	-	-

PNIO_ADD_VAL1 contains the PNIO error code 1.

ADD_VAL2

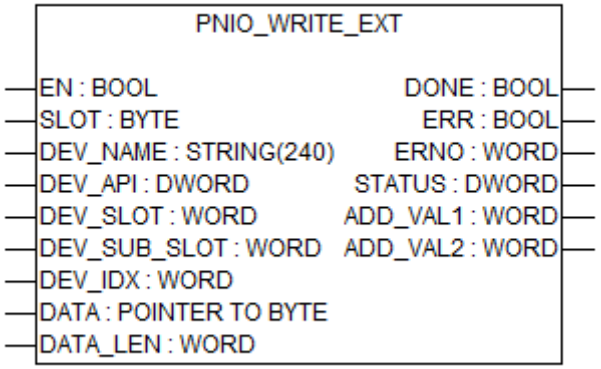
Data type	Default value	Range	Unit
WORD	2	-	-

PNIO_ADD_VAL2 contains the PNIO error code 2.

Function call in ST

```
PNIO_WRITE (EN           := PNIO_WRITE _EN,
            SLOT         := PNIO_WRITE_SLOT,
            DEV_NAME     := PNIO_WRITE_DEV_NAME,
            DEV_SLOT     := PNIO_WRITE_DEV_SLOT,
            DEV_SUB_SLOT := PNIO_WRITE_DEV_SUB_SLOT,
            DEV_IDX      := PNIO_WRITE_DEV_IDX,
            DATA         := ADR(PNIO_WRITE_DATA),
            DATA_LEN     := PNIO_WRITE_DATA_LEN);
PNIO_WRITE_DONE     := PNIO_WRITE.DONE;
PNIO_WRITE_ERR      := PNIO_WRITE.ERR;
PNIO_WRITE_ERNO     := PNIO_WRITE.ERNO;
PNIO_WRITE_STATUS   := PNIO_WRITE.STATUS;
PNIO_WRITE_ADD_VAL1 := PNIO_WRITE.ADD_VAL1;
PNIO_WRITE_ADD_VAL2 := PNIO_WRITE.ADD_VAL2;
```

PNIO_WRITE_EXT

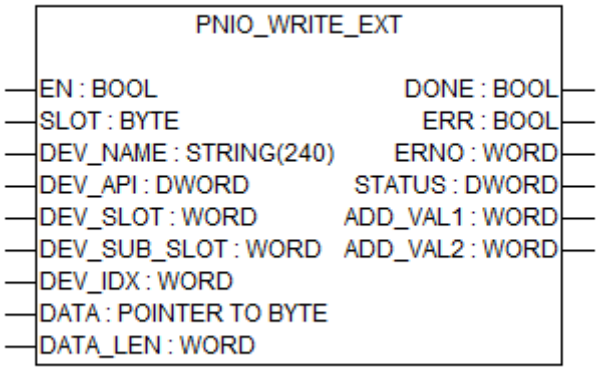


Parameter	Value
Included in library	PROFINET_AC500_V13.lib
Available as of firmware	V2.2.0
Type	Function block with historical values
Group	Data

The function block PNIO_WRITE_EXT implements the acyclic PROFINET WRITE service. Using this function, the controller has write access to API, slot, sub slot and index-related data of PROFINET IO devices. PNIO_WRITE_EXT works outside the cyclic process data exchange.

Every time a FALSE->TRUE edge is applied to input EN, PNIO_WRITE_EXT reads the data at its inputs and sends a corresponding request message to the Communication Module. Further FALSE->TRUE edges at input EN are ignored until the processing of the active requests is finished. The completion of the request processing is indicated by DONE = TRUE.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	-	1 ... 6	-

The SLOT input selects the communication module serving the PROFINET IO device described by DEV_NAME. Valid values are 1...6, counting from right to left, starting with 1 as the first communication module left to the CPU.

For PM595 processor modules, internal PROFINET communication module with connector ETH3 is slot 5, ETH4 is slot 6.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

The input DEV_NAME describes the PROFINET IO device to be queried. The string may have a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target IO module of this request.

Valid values are (examples for the ABB module, where the hash marks # are place holders for the address selected by the rotary switch at the front of the module):

ci501-pn-##

ci502-pn-##

DEV_API

Data type	Default value	Range	Unit
WORD	-	-	-

Input DEV_API specifies the Application Process Identifier of the AP to which the data block belongs.

DEV_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SLOT provides the device slot which sent the alarm.

DEV_SUB_SLOT

Data type	Default value	Range	Unit
WORD	-	-	-

The output DEV_SUB_SLOT provides the device sub slot which sent the alarm.

DEV_IDX

Data type	Default value	Range	Unit
WORD	-	-	-

Input DEV_IDX specifies the number of the index within the sub slot, the data of which shall be read.

DATA

Data type	Default value	Range	Unit
BYTE	-	-	-

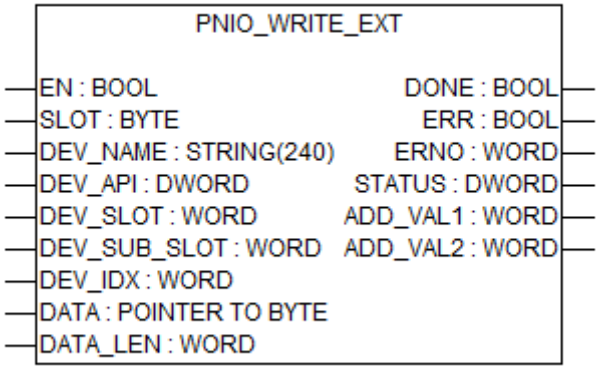
Input DATA specifies via the ADR address operator the address of the variable where the received data block shall be stored. The size of the variable must be big enough to store the complete data block (e.g. BYTE array). And the format (BYTE, WORD etc.) of the data must be considered.

DATA_LEN

Data type	Default value	Range	Unit
DWORD	-	-	-

The output DATA_LEN provides the size of numbers / of bytes which were written to DATA.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

PNIO_STATUS contains the PNIO error code and error decode (see, *Chapter 1.5.4.27.1.13 “PROFINET status*” on page 1839*).

ADD_VAL1

Data type	Default value	Range	Unit
WORD	1	-	-

PNIO_ADD_VAL1 contains the PNIO error code 1.

ADD_VAL2

Data type	Default value	Range	Unit
WORD	2	-	-

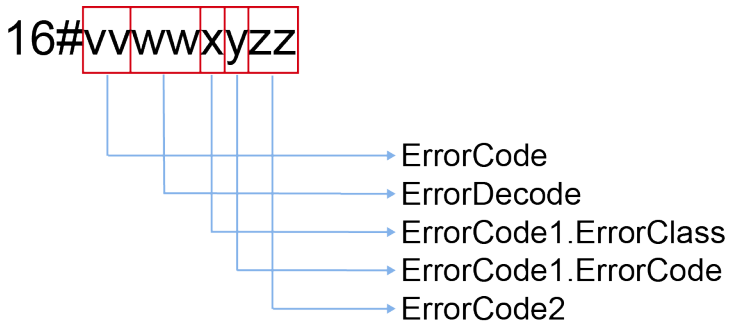
PNIO_ADD_VAL2 contains the PNIO error code 2.

Function call in ST

```
PNIO_WRITE_EXT (EN           := PNIO_WRITE_EXT_EN,
                SLOT         := PNIO_WRITE_EXT_SLOT,
                DEV_NAME     := PNIO_WRITE_EXT_DEV_NAME,
                DEV_API      := PNIO_WRITE_EXT_DEV_API,
                DEV_SLOT     := PNIO_WRITE_EXT_DEV_SLOT,
                DEV_SUB_SLOT := PNIO_WRITE_EXT_DEV_SUB_SLOT,
                DEV_IDX      := PNIO_WRITE_EXT_DEV_IDX,
                DATA         := ADR(PNIO_WRITE_EXT_DATA),
                DATA_LEN     := PNIO_WRITE_EXT_DATA_LEN);
PNIO_WRITE_EXT_DONE     := PNIO_WRITE_EXT.DONE;
PNIO_WRITE_EXT_ERR      := PNIO_WRITE_EXT.ERR; PNIO_WRITE_EXT_ERNO
:= PNIO_WRITE_EXT.ERNO;
PNIO_WRITE_EXT_STATUS   := PNIO_WRITE_EXT.STATUS;
PNIO_WRITE_EXT_ADD_VAL1 := PNIO_WRITE_EXT.ADD_VAL1;
PNIO_WRITE_EXT_ADD_VAL2 := PNIO_WRITE_EXT.ADD_VAL2;
```

PROFINET status*

The PROFINET status of read / write service is described in the following structures:



ErrorCode	
16#DE	PNIO READ Response
16#DF	PNIO WRITE Respone

ErrorDecode	
16#80	PNIO READ / WRITE Service

ErrorClass	
16#0 - 16#9	Not Specified / Reserved
16#A	Application
16#B	Access
16#C	Resource
16#D - 16#F	User / Module specific

ErrorCode inside ErrorCode1 for ErrorClass 16#A (Application)	
16#0	Read error
16#1	Write error
16#2	Module failure
16#3 - 16#6	Not specific / Reserved
16#7	Module busy
16#8	Version conflict
16#9	Feature not supported
16#A - 16#F	User / Module specific

ErrorCode inside ErrorCode1 for ErrorClass 16#B (Access)	
16#0	Invalid Index
16#1	Write lenhth error
16#2	Invalid slot / subslot
16#3	Type conflict
16#4	Invalid area / API
16#5	State conflict
16#6	Access denied
16#7	Invalid range
16#8	Invalid parameter
16#9	Invalid type
16#A	Backup
16#B - 16#F	User / Module specific

ErrorCode inside ErrorCode1 for ErrorClass 16#C (Resource)	
16#0	Read constrain confict
16#1	Write constrain confict
16#2	Resource busy
16#3	Resource unavailable
16#4 - 16#7	Not specific / Reserved
16#8 - 16#16	User / Module specific

ErrorCode2	
16#00 - 16#FF	User / Module specific

*)This chapter corresponds in substance to the standard PN-AL-protocol_2722.

1.5.4.28 Extended PROFINET IO library

Library file name: **PROFINET_Ext_AC500_Vx.lib**

The function blocks of this library provide access to the Communication Modules CI504-PNIO and CI506-PNIO and the beneath connected devices.

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

1.5.4.28.1 Function blocks

Error messages of the CI506-PNIO CANopen master

The following table defines error messages of the CI506-PNIO CANopen Master. They will be set as last error code if communication to a CANopen slave fails. The function block CI506_CANOM_NODE_DIAG provides this as last error code. This last error is also displayed in the Control Builder Plus online diagnosis.

Hexadecimal Value	Definition	Description
0x00000000	TLR_S_OK	Status ok.
0xC0000001	TLR_E_FAIL	Common error, detailed error information optionally present in the data area of packet.
0xC0420003	TLR_E_CANOPEN_MASTER_DATA_COUNT	Invalid data count.
0xC0420004	TLR_E_CANOPEN_MASTER_DATA_OFFSET	Invalid data offset.
0xC0420005	TLR_E_CANOPEN_MASTER_DATA_COUNT_WITH_OFFSET	Invalid data count in combination with offset.
0xC0420006	TLR_E_CANOPEN_MASTER_MODE	Invalid mode in command.
0xC0420007	TLR_E_CANOPEN_MASTER_STATE	Command is not allowed in current state.
0xC0420008	TLR_E_CANOPEN_MASTER_NO_VALID_BUS_PARAM	No valid bus configuration parameterized.
0xC042000A	TLR_E_CANOPEN_MASTER_BUS_RUNNING	Command is not allowed because CANopen is running.
0xC042000B	TLR_E_CANOPEN_MASTER_BUS_PARAM_ALREADY_SET	Bus parameters are already configured.
0xC042000C	TLR_E_CANOPEN_MASTER_LOCAL_NODE_ID	Invalid Node ID for CANopen Master
xC042000D	TLR_E_CANOPEN_MASTER_BAUDRATE	Invalid Baud rate.

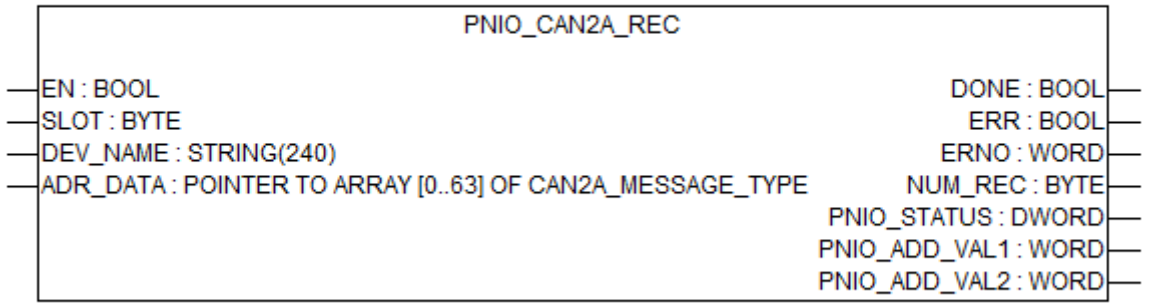
Hexadecimal Value	Definition	Description
0xC042000B	TLR_E_CANOPEN_MASTER_BUS_PARAM_ALREADY_SET	Bus parameters are already configured.
0xC042000C	TLR_E_CANOPEN_MASTER_LOCAL_NODE_ID	Invalid Node ID for CANopen Master.
xC042000D	TLR_E_CANOPEN_MASTER_BAUDRATE	Invalid Baud rate.
0xC042000E	TLR_E_CANOPEN_MASTER_29BIT_SELECTOR	Invalid parameter for 29 bit selector.
0xC042000F	TLR_E_CANOPEN_MASTER_SYNC_TIMER_VALUE	Invalid parameter for SYNC timer
0xC0420010L	TLR_E_CANOPEN_MASTER_COB_ID_SYNC	Invalid parameter for COB-ID SYNC.
0xC0420011	TLR_E_CANOPEN_MASTER_PROD_HEARTBEAT_TIME	Invalid parameter for Producer Heartbeat time.
0xC0420013	TLR_E_CANOPEN_MASTER_NODE_PARAM_SET_SIZE	Invalid size of Node parameter set.
0xC0420014	TLR_E_CANOPEN_MASTER_NODE_PARAM_HEADER_SIZE	Invalid size of Node parameter header.
0xC0420015	TLR_E_CANOPEN_MASTER_NODE_ALREADY_CONFIGURED	Node is already configured.
0xC0420016	TLR_E_CANOPEN_MASTER_SLAVE_NODE_ID	Invalid Node ID for Slave.
0xC0420017	TLR_E_CANOPEN_MASTER_NODE_ID_EQUAL	Node ID of Slave is equal to Master Node ID.
0xC0420018	TLR_E_CANOPEN_MASTER_PARAMETER_SET_LENGTH	Length of parameter set is different from length in parameter header.
0xC0420019	TLR_E_CANOPEN_MASTER_SDO_PARAMETER_SET_LENGTH	Invalid size of SDO parameter set:
0xC042001A	TLR_E_CANOPEN_MASTER_PDO_PARAMETER_SET_LENGTH	Invalid size of PDO parameter set:
0xC042001B	TLR_E_CANOPEN_MASTER_ADDR_TABLE_SET_LENGTH	Invalid size of address table
0xC042001C	TLR_E_CANOPEN_MASTER_ADDR_TABLE_LENGTH_INCONSISTENT	Address table size is inconsistent.
0xC042001E	TLR_E_CANOPEN_MASTER_TPDO_CNT	Invalid number of transmitted PDOs.
0xC042001F	TLR_E_CANOPEN_MASTER_RPDO_CNT	Invalid number of received PDOs.
0xC0420020	TLR_E_CANOPEN_MASTER_COB_ID_EMCY	Invalid value for COB-ID Emergency.
0xC0420021	TLR_E_CANOPEN_MASTER_COB_ID_GUARD	Invalid value for COB-ID Guard.
0xC0420022	TLR_E_CANOPEN_MEMORY_ALLOCATION	No memory for parameter set.
0xC0420023	TLR_E_CANOPEN_SDO_DATA_CNT	Invalid value for SDO data count.
0xC0420024	TLR_E_CANOPEN_PDO_DATA_CNT	Invalid value for PDO data count.

Hexadecimal Value	Definition	Description
0xC0420025	TLR_E_CANOPEN_ADDR_TAB_DATA_CNT	Invalid value for address table data count.
0xC0420026	TLR_E_CANOPEN_ADDR_TAB_PDO_CNT	Invalid value for address table PDO count.
0xC0420027	TLR_E_CANOPEN_MASTER_NODE_SDO_TIMEOUT	Timeout during SDO transfer.
0xC0420028	TLR_E_CANOPEN_MASTER_NODE_SDO_ERROR	Error during SDO transfer.
0xC0420029	TLR_E_CANOPEN_MASTER_NO_PDO_AVAILABLE	No further PDO available.
0xC042002A	TLR_E_CANOPEN_MASTER_AUTO_CLEAR_ACTIVE	Master is in auto clear state.
0xC042002B	TLR_E_CANOPEN_MASTER_WATCHDOG_FAIL	Watchdog failure detected.
0xC042002C	TLR_E_CANOPEN_MASTER_INVALID_INDEX	Invalid index for request.
0xC042002D	TLR_E_CANOPEN_MASTER_NODE_STATE	Request not possible in current Node state.
0xC042002F	TLR_E_CANOPEN_MASTER_SDO_REQUEST_FAILED	SDO request failed.
0x40420030	TLR_I_CANOPEN_MASTER_ALREADY_IN_STATE	Master is already in requested state.
0xC0420031	TLR_E_CANOPEN_MASTER_COB_ID_PDO	Invalid value for PDO COB-ID.
0xC0420032	TLR_E_CANOPEN_MASTER_SEND_EMCY	Send emergency-telegram failed.
0xC0420033	TLR_E_CANOPEN_MASTER_INIT_SDO_REQUEST	Failed to initialize SDO request.
0xC0420034	TLR_E_CANOPEN_MASTER_SET_NMT_STATE	Set NMT state failed.
0xC0420035	TLR_E_CANOPEN_MASTER_ERROR_PASSIVE	CANopen is in error-passive state.
0xC0420036	TLR_E_CANOPEN_MASTER_BUS_OFF	CANopen is in bus-off state.
0x40420037	TLR_I_CANOPEN_MASTER_NODE_DEACTIVATED	Node is deactivated in configuration.
0xC0420038	TLR_E_CANOPEN_MASTER_DL_REQ_FAILED	CAN-DL request failed.
0xC0420039	TLR_E_CANOPEN_MASTER_PUT_OBJECT_DATA	Failed to write object data.
0xC042003A	TLR_E_CANOPEN_MASTER_SET_OBJECT_DATA_VALID	Failed to set object data valid.
0xC042003B	TLR_E_CANOPEN_MASTER_INIT_lib	Failed to initialize CANopen library.
0xC042003C	TLR_E_CANOPEN_MASTER_SET_COB_ID_FAILED	COB-ID could not be set.
0xC042003D	TLR_E_CANOPEN_MASTER_ADD_REMOTE_NODE_REQUEST	Failed to add remote Node.

Hexadecimal Value	Definition	Description
0xC042003E	TLR_E_CANOPEN_MASTER_SET_HEARTBEAT_TIME	Heartbeat time could not be set.
0xC042003F	TLR_E_CANOPEN_MASTER_DD_GUARDING_SLAVE	Node could not be added to Node guarding list.
0xC0420040	TLR_E_CANOPEN_MASTER_SET_GUARDING_TIME	Node guard time could not be set.
0xC0420041	TLR_E_CANOPEN_MASTER_START_NODE_GUARD	Node guarding could not be started.
0xC0420042	TLR_E_CANOPEN_MASTER_RESET_NODE	Reset Node failed.
0xC0420043	TLR_E_CANOPEN_MASTER_RESET_COMMUNICATION	Failed to reset communication of Node.
0xC0420044	TLR_E_CANOPEN_MASTER_SET_NODE_PREOPERATIONAL	Failed to set Node to preoperational state.
0xC0420045	TLR_E_CANOPEN_MASTER_STOP_NODE	Failed to set Node to stop state.
0xC0420046	TLR_E_CANOPEN_MASTER_START_NODE	Failed to set Node to operational state.
0xC0420047	TLR_E_CANOPEN_MASTER_SET_EMCY_COB_ID	Failed to set Emergency COB-ID.
0xC0420048	TLR_E_CANOPEN_MASTER_START_SYNC	Failed to start SYNC-telegram.
0xC0420049	TLR_E_CANOPEN_MASTER_STOP_SYNC	Failed to stop SYNC-telegram.
0xC042004A	TLR_E_CANOPEN_MASTER_NODE_UNEXPECTED_STATE	Node is not in expected state.
0xC042004B	TLR_E_CANOPEN_MASTER_NODE_LOST_CONNECTION	Connection to Node lost.
0xC042004C	TLR_E_CANOPEN_MASTER_NODE_GUARDING_ERROR	Node guarding error.
0xC042004D	TLR_E_CANOPEN_MASTER_NODE_HEARTBEAT_ERROR	Heartbeat error.
0x4042004E	TLR_I_CANOPEN_MASTER_NODE_HEARTBEAT_STARTED	Heartbeat supervision of Node started
0xC042004F	TLR_E_CANOPEN_MASTER_NODE_UNEXPECTED_BOOTUP	Unexpected Boot up message from Node received.
0xC0420050	TLR_E_CANOPEN_MASTER_WRITE_PDO_REQ	Failed to transmit PDO.
0xC0420051	TLR_E_CANOPEN_MASTER_READ_PDO_REQ	Failed to request PDO.
0xC0420052	TLR_E_CANOPEN_MASTER_INIT_BUFFER	Initialization of buffer failed.
0x40420053	TLR_I_CANOPEN_MASTER_NODE_STATE_NOT_HANDLED	State of Node not handled.
0xC0420054	TLR_E_CANOPEN_MASTER_NODE_DEVICE_TYPE	Node Device Type unequal to configured Device Type.
0x40420055	TLR_I_CANOPEN_MASTER_NODE_EMERGENCY_RECEIVED	Emergency message received from Node

Hexadecimal Value	Definition	Description
0x40420056	TLR_I_CANOPEN_MASTER_INITIALIZE	Master is initializing.
0x40420057	TLR_I_CANOPEN_MASTER_NODE_BOOTUP	Boot up message from Node received.

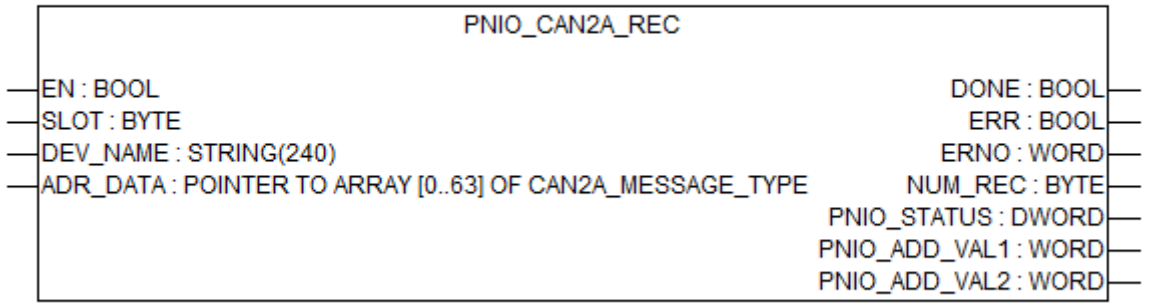
PNIO_CAN2A_REC



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CAN2A

The function block PNIO_CAN2A_REC provides all CAN2A messages received on the addressed CI506- PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

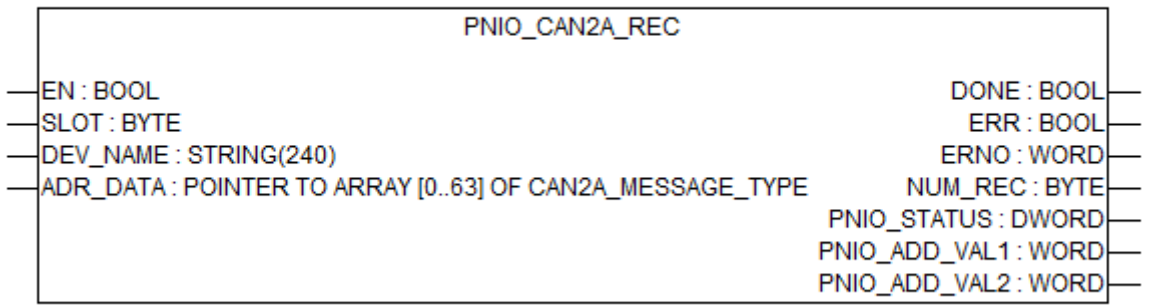
ci506-pn-##

ADR_DATA

Data type	Default value	Range	Unit
ARRAY	-	-	-

Input ADR_DATA specifies the address starting from which the received CAN 2.0A telegrams should be written. Usually, this specification is done via the ADR operator and should point to an array with 64 entries of the type CAN2A_MESSAGE_TYPE.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_REC

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REC displays the total number of CAN 2.0A telegrams received.

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

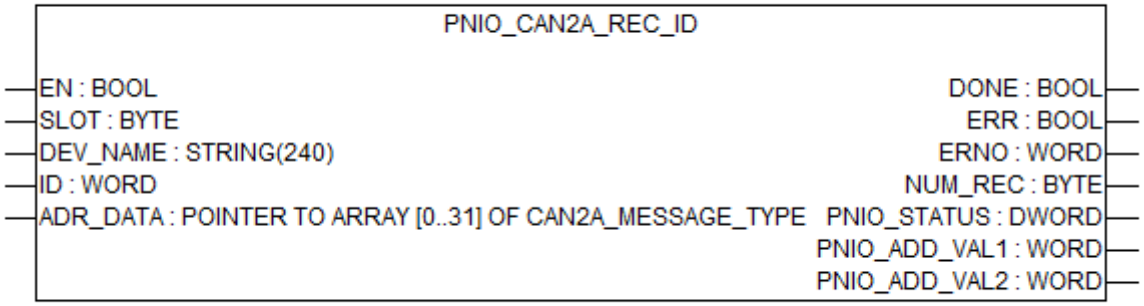
Function call in ST

```
REC (EN       := REC_EN,
     SLOT     := REC_SLOT,
     DEV_NAME := REC_DEV_NAME,
     ADR_DATA := REC_ADR_DATA);

REC_ERR           := REC.ERR;
REC_ERNO          := REC.ERNO;
```

```
REC_NUM_REC        := REC.NUM_REC;
REC_PNIO_STATUS    := REC.PNIO_STATUS;
REC_PNIO_ADD_VAL1  := REC.PNIO_ADD_VAL1;
REC_PNIO_ADD_VAL2  := REC.PNIO_ADD_VAL2;
REC_DONE           := REC.DONE;
```

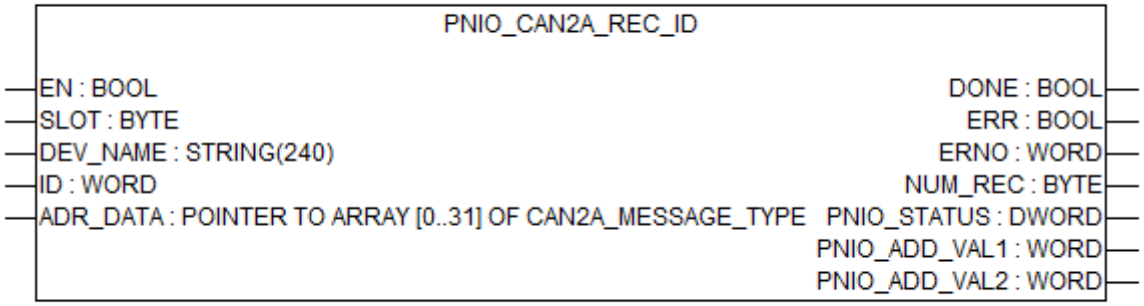
PNIO_CAN2A_REC_ID



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CAN2A

The function block PNIO_CAN2A_REC_ID provides one CAN2A message of the defined CAN identifier received on the addressed CI506-PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

ID

Data type	Default value	Range	Unit
WORD	-	-	-

Input ID specifies the identifier of the CAN 2.0A telegrams to be read from the buffer. If no buffer has been specified for the selected identifier using the controller configuration, this is indicated accordingly at the function block outputs.

ADR_DATA

Data type	Default value	Range	Unit
ARRAY	-	-	-

Input ADR_DATA specifies the address starting from which the received CAN 2.0A telegrams should be written. Usually, this specification is done via the ADR operator and should point to an array with 64 entries of the type CAN2A_MESSAGE_TYPE.

Output description

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_REC

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REC displays the total number of CAN 2.0A telegrams received.

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

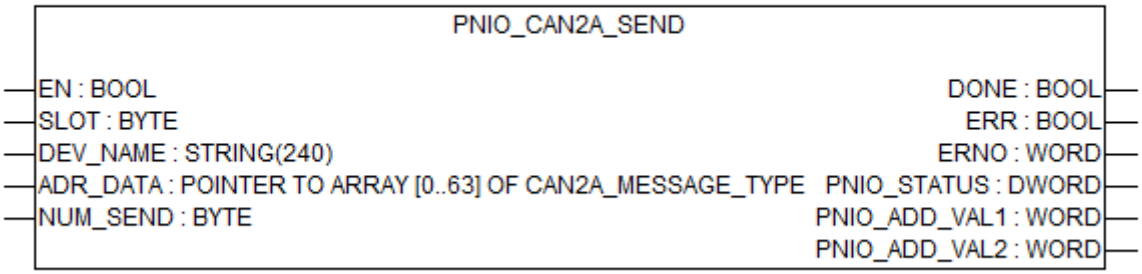
PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

Function call in ST

```
REC_ID(EN       := REC_ID_EN,
       SLOT     := REC_ID_SLOT,
       DEV_NAME := REC_ID_DEV_NAME,
       ID       := REC_ID_ID,
       ADR_DATA := REC_ID_ADR_DATA);

REC_ID_ERR           := REC_ID.ERR;
REC_ID_ERNO          := REC_ID.ERNO;
REC_ID_NUM_REC       := REC_ID.NUM_REC;
REC_ID_PNIO_STATUS   := REC_ID.PNIO_STATUS;
REC_ID_PNIO_ADD_VAL1 := REC_ID.PNIO_ADD_VAL1;
REC_ID_PNIO_ADD_VAL2 := REC_ID.PNIO_ADD_VAL2;
REC_ID_DONE          := REC_ID.DONE;
```

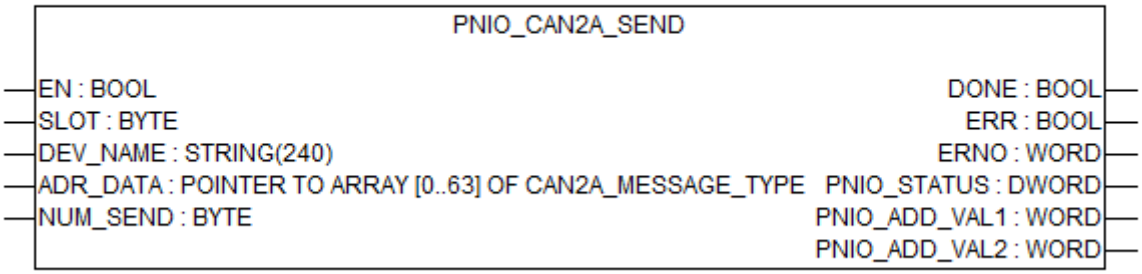
PNIO_CAN2A_SEND



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CAN2A

The function block PNIO_CAN2A_SEND sends CAN2A messages via the addressed CI506-PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

ADR_DATA

Data type	Default value	Range	Unit
ARRAY	-	-	-

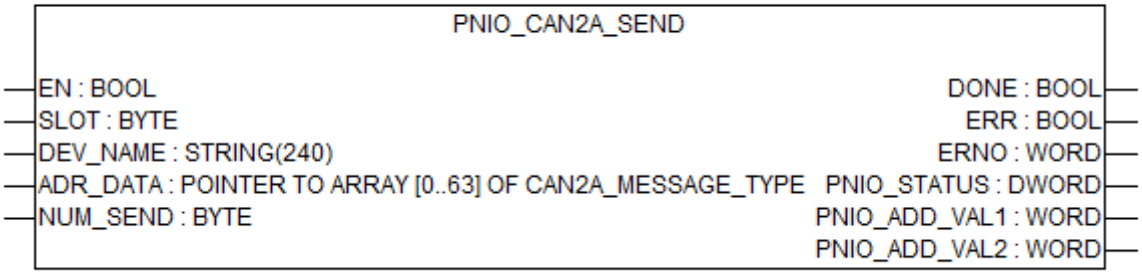
Input ADR_DATA specifies the address starting from which the received CAN 2.0A telegrams should be written. Usually, this specification is done via the ADR operator and should point to an array with 64 entries of the type CAN2A_MESSAGE_TYPE.

NUM_SEND

Data type	Default value	Range	Unit
BYTE	-	1 - 64	-

Input NUM_SEND specifies the number of valid telegrams to be transmitted and stored starting at address ADR_DATA. The valid values for NUM_SEND are 1 to 64.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

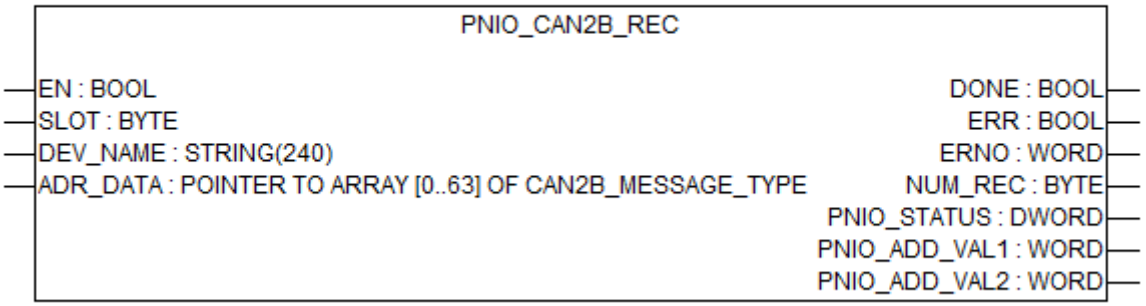
PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

Function call in ST

```
SEND (EN       := SEND_EN,
      SLOT     := SEND_SLOT,
      DEV_NAME := SEND_DEV_NAME,
      ADR_DATA := SEND_DEV_ADR_DATA,
      NUM_SEND := SEND_NUM_SEND);

SEND_ERR           := SEND.ERR;
SEND_ERNO          := SEND.ERNO;
SEND_STATUS        := SEND.PNIO_STATUS;
SEND_PNIO_ADD_VAL1 := SEND.PNIO_ADD_VAL1;
SEND_PNIO_ADD_VAL2 := SEND.PNIO_ADD_VAL2;
SEND_DONE          := SEND.DONE;
```

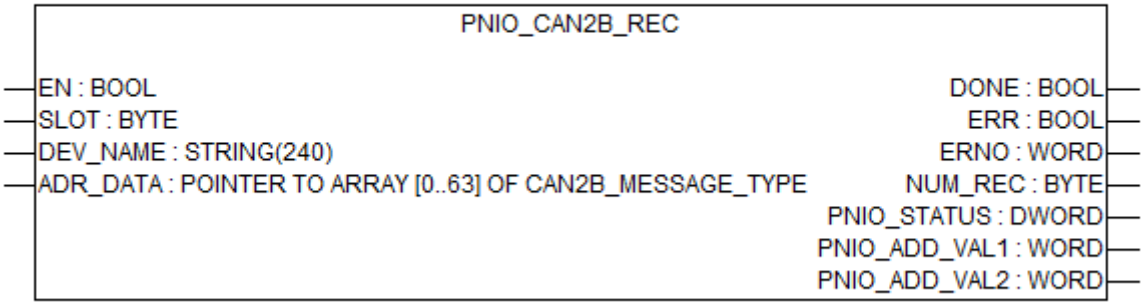
PNIO_CAN2B_REC



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	Group/Subgroup

The function block PNIO_CAN2B_REC provides all CAN2B messages received on the addressed CI506-PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

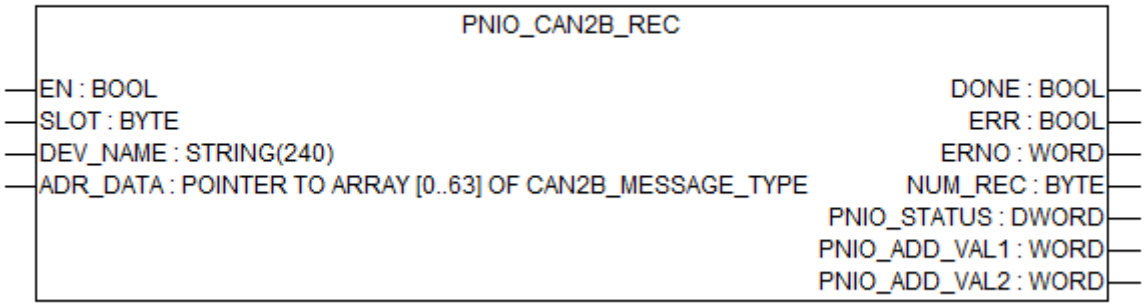
ci506-pn-##

ADR_DATA

Data type	Default value	Range	Unit
ARRAY	-	-	-

Input ADR_DATA specifies the address starting from which the received CAN 2.0A telegrams should be written. Usually, this specification is done via the ADR operator and should point to an array with 64 entries of the type CAN2A_MESSAGE_TYPE.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_REC

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REC displays the total number of CAN 2.0A telegrams received.

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

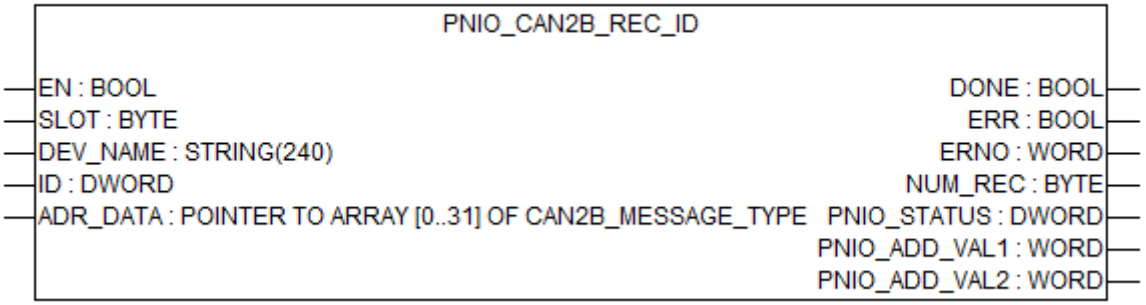
PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

Function call in ST

```
REC (EN       := REC_EN,
     SLOT     := REC_SLOT,
     DEV_NAME := REC_DEV_NAME,
     ADR_DATA := REC_ADR_DATA);

REC_ERR           := REC.ERR;
REC_ERNO          := REC.ERNO;
REC_NUM_REC       := REC.NUM_REC;
REC_PNIO_STATUS   := REC.PNIO_STATUS;
REC_PNIO_ADD_VAL1 := REC.PNIO_ADD_VAL1;
REC_PNIO_ADD_VAL2 := REC.PNIO_ADD_VAL2;
REC_DONE          := REC.DONE;
```

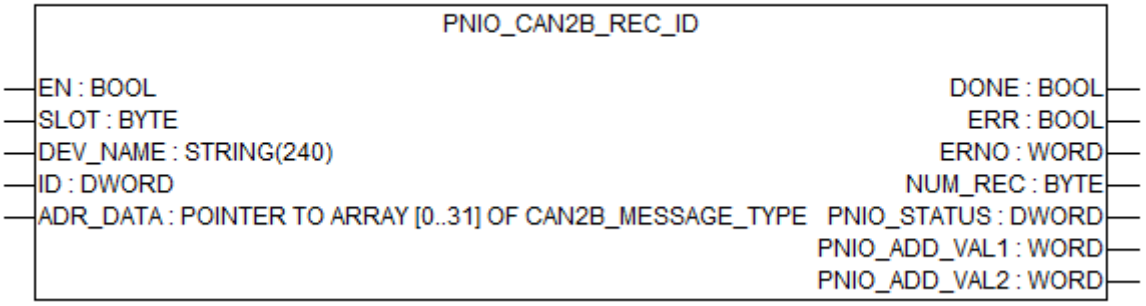
PNIO_CAN2B_REC_ID



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CAN2B

The function block PNIO_CAN2B_REC_ID provides one CAN2B message of the defined CAN identifier received on the addressed CI506-PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

ID

Data type	Default value	Range	Unit
WORD	-	-	-

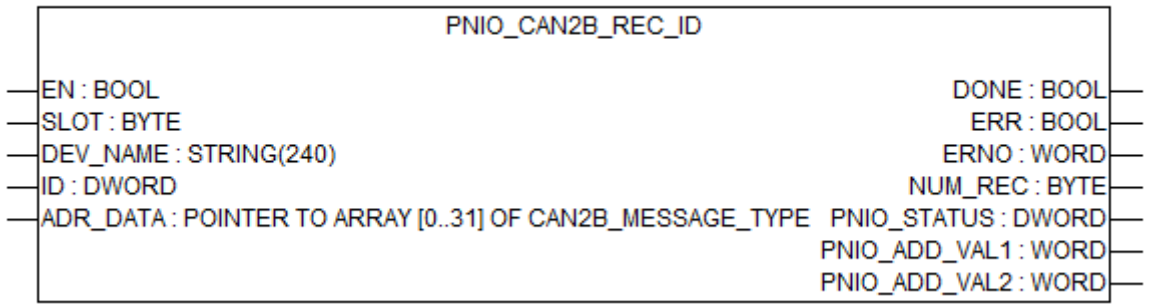
Input ID specifies the identifier of the CAN 2.0A telegrams to be read from the buffer. If no buffer has been specified for the selected identifier using the controller configuration, this is indicated accordingly at the function block outputs.

ADR_DATA

Data type	Default value	Range	Unit
ARRAY	-	-	-

Input ADR_DATA specifies the address starting from which the received CAN 2.0A telegrams should be written. Usually, this specification is done via the ADR operator and should point to an array with 64 entries of the type CAN2A_MESSAGE_TYPE.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_REC

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REC displays the total number of CAN 2.0A telegrams received.

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

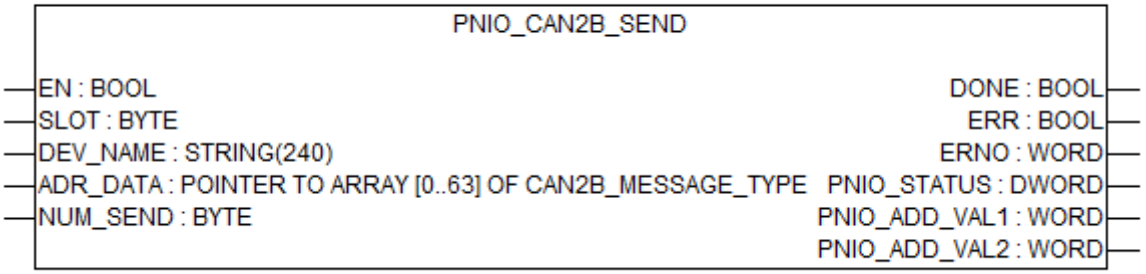
Function call in ST

```
REC_ID(EN       := REC_ID_EN,
       SLOT     := REC_ID_SLOT,
       DEV_NAME := REC_ID_DEV_NAME,
       ID       := REC_ID_ID,
       ADR_DATA := REC_ID_ADR_DATA);

REC_ID_ERR           := REC_ID.ERR;
REC_ID_ERNO          := REC_ID.ERNO;
```

```
REC_ID_NUM_REC        := REC_ID.NUM_REC;
REC_ID_PNIO_STATUS    := REC_ID.PNIO_STATUS;
REC_ID_PNIO_ADD_VAL1  := REC_ID.PNIO_ADD_VAL1;
REC_ID_PNIO_ADD_VAL2  := REC_ID.PNIO_ADD_VAL2;
REC_ID_DONE           := REC_ID.DONE;
```

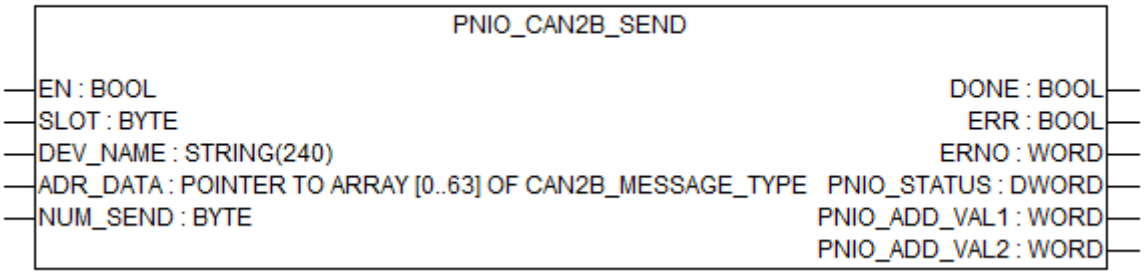
PNIO_CAN2B_SEND



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CAN2B

The function block PNIO_CAN2B_SEND sends CAN2B messages via the addressed CI506-PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

ADR_DATA

Data type	Default value	Range	Unit
ARRAY	-	-	-

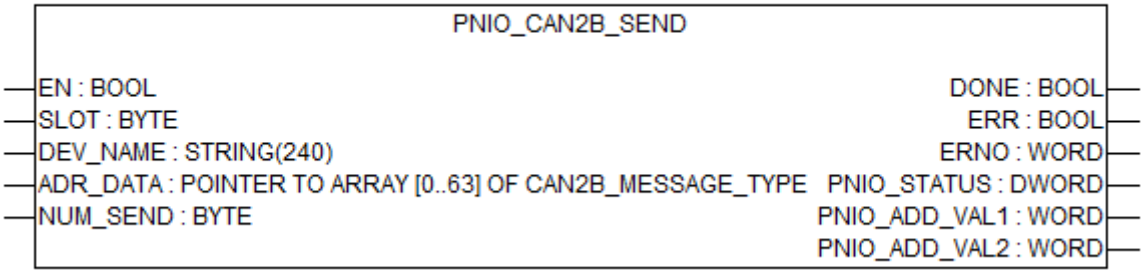
Input ADR_DATA specifies the address starting from which the received CAN 2.0A telegrams should be written. Usually, this specification is done via the ADR operator and should point to an array with 64 entries of the type CAN2A_MESSAGE_TYPE.

NUM_SEND

Data type	Default value	Range	Unit
BYTE	-	1 - 64	-

Input NUM_SEND specifies the number of valid telegrams to be transmitted and stored starting at address ADR_DATA. The valid values for NUM_SEND are 1 to 64.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

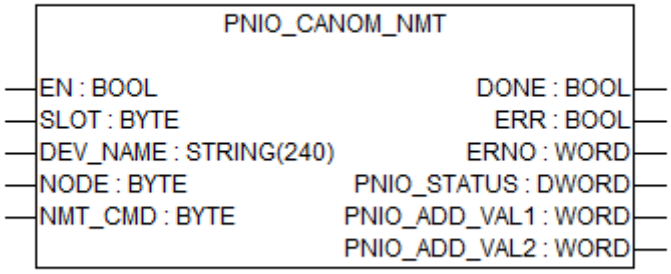
PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

Function call in ST

```
SEND (EN       := SEND_EN,
      SLOT     := SEND_SLOT,
      DEV_NAME := SEND_DEV_NAME,
      ADR_DATA := SEND_DEV_ADR_DATA,
      NUM_SEND := SEND_NUM_SEND);

SEND_ERR           := SEND.ERR;
SEND_ERNO          := SEND.ERNO;
SEND_STATUS        := SEND.PNIO_STATUS;
SEND_PNIO_ADD_VAL1 := SEND.PNIO_ADD_VAL1;
SEND_PNIO_ADD_VAL2 := SEND.PNIO_ADD_VAL2;
SEND_DONE          := SEND.DONE;
```

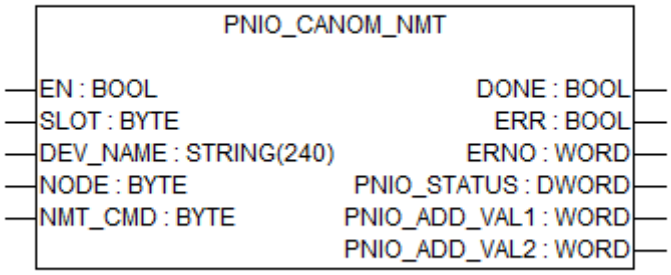
PNIO_CANOM_NMT



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CANopen

The function block PNIO_CANOM_NMT sends a CANopen Network Management (NMT) command to a CANopen slave that is connected to the CI506-PNIO CANopen master interface.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

NODE

Data type	Default value	Range	Unit
BYTE	-	1 - 127	-

Input NODE describes the target CANopen slave node ID for which the NMT command is intended.

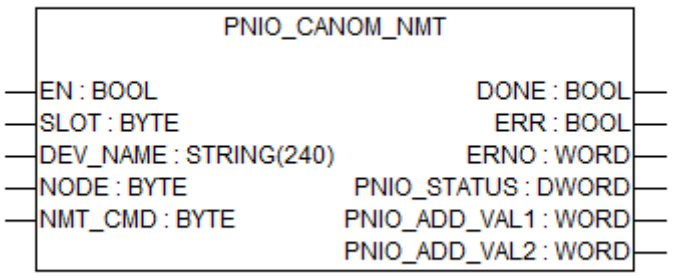
NMT_CMD

Data type	Default value	Range	Unit
BYTE	-	-	-

Input NMT_CMD describes the type of the NMT command to be transmitted to the CANopen slave. The range of values of node ID is as follows:

NMT Command	NMT_CMD value in hex	NMT_CMD value in decimal
Start remote node	16#01	1
Stop remote node	16#02	2
Enter pre-operational	16#80	128
Reset remote node	16#81	129

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

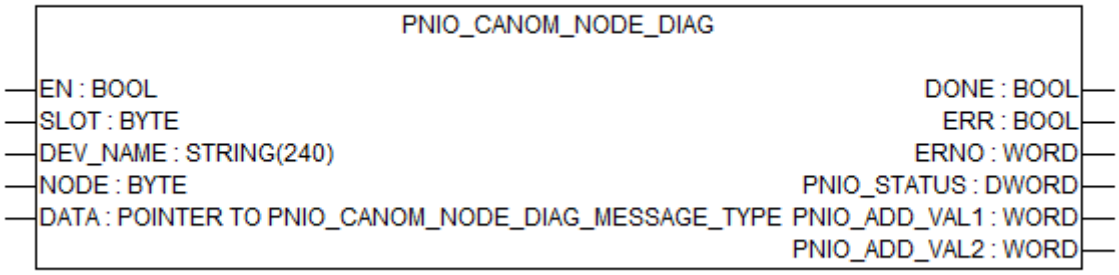
PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

Function call in ST

```
PNIO_CANOM_NMT(EN        := NMT_EN,
               SLOT      := NMT_SLOT,
               DEV_NAME  := NMT_DEV_NAME,
               NODE      := NMT_NODE,
               NMT_CMD   := NMT_CMD);

NMT_ERR          := PNIO_CANOM_NMT.ERR;
NMT_ERNO         := PNIO_CANOM_NMT.ERNO;
NMT_PNIO_STATUS  := PNIO_CANOM_NMT.PNIO_STATUS;
NMT_ADD_VAL1     := PNIO_CANOM_NMT.PNIO_ADD_VAL1;
NMT_ADD_VAL2     := PNIO_CANOM_NMT.PNIO_ADD_VAL2;
NMT_DONE         := PNIO_CANOM_NMT.DONE;
```

PNIO_CANOM_NODE_DIAG



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CANopen

The function block PNIO_CANOM_NODE_DIAG reads the diagnosis data from a CANopen slave that is connected to the CANopen master of the addressed CI506-PNIO.

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

NODE

Data type	Default value	Range	Unit
BYTE	-	1 - 127	-

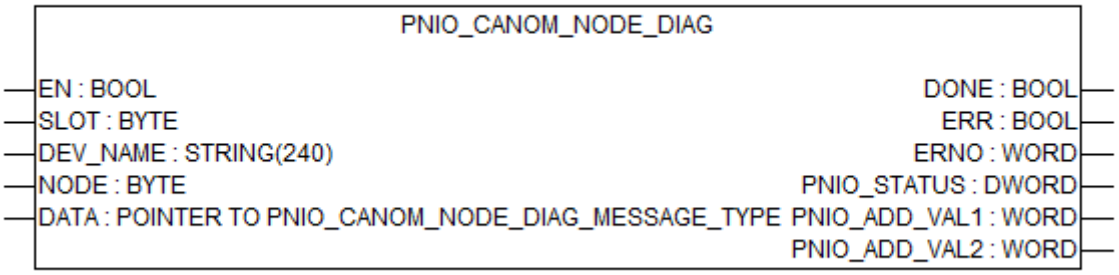
Input NODE describes the target CANopen slave node ID for which the NMT command is intended.

DATA

Data type	Default value	Range	Unit
DWORD POINTER	-	-	-

Input DATA specifies the address of the variable containing the telegrams to be transmitted. This specification is usually done via the ADR operator. The node diagnostic data have to be of the data type PNIO_CANOM_NODE_DIAG_MESSAGE_TYPE defined in the library.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

PNIO_CANOM_ NODE_DIAG_M ESSAGE_TYPE

Data type	Default value	Range	Unit
-	-	-	-

The CANopen slave node diagnostic can be displayed properly by using the structure PNIO_CANOM_NODE_DIAG_MESSAGE_TYPE which is declared as follows.

TYPE PNIO_CANOM_NODE_DIAG_MESSAGE_TYPE:

STRUCT

NODE_FLAG: DWORD;

LAST_DIAG: DWORD;

DEV_TYPE_VALID: DWORD;

DEV_TYPE: DWORD;

NMT_STATE: DWORD;

EMCY_CNT: DWORD;

EMCY_DATA: ARRAY [1..5] OF CANOM_EMCY_TYPE;

ADD_INFO: DWORD;

RESERVED : ARRAY [1..4] OF DWORD;

END_STRUCT

END_TYPE

NODE_FLAG

Data type	Default value	Range	Unit
DWORD	-	0 - 31	-

Each bit in this variable describes an occurrence of a certain event for the node. The bit organization is displayed in the following table:

Bit	Name	Description
31	FLAG_DEACTIVATED	Node is deactivated and not handled by the master. This bit does not generate an entry in the diagnostic list.
30	FLAG_STATE_NOT_HANDLED	At least one state has been omitted during the initialization sequence of the node. This bit does not generate an entry in the diagnostic list.
13..29	Reserved	Reserved
12	FLAG_INVALID_PARAMETER	Parameter set of node is invalid.
11	FLAG_UNEXPECTED_BOOTUP	Unexpected boot-up message from node received.
10	FLAG_BOOTUP	Expected boot-up message from node received.
9	FLAG_EMCY_BUFF_OVER	Emergency buffer overflow
8	FLAG_EMCY_RECEIVED	Emergency telegram received
7	FLAG_UNEXPECTED_STATE	Node is in unexpected NMT state
6	FLAG_HEARTBEAT_ERROR	Error in heartbeat protocol
5	FLAG_CON_LOST	Node guarding has been lost
4	FLAG_GUARD_ERROR	A guarding message has been lost. This bit does not generate an entry in the diagnostic list.
3	FLAG_HEARTBEAT_STARTED	Heartbeat protocol started. This bit does not generate an entry in the diagnostic list.
2	FLAG_CFG_FAULT	Configuration fault
1	FLAG_SDO_ERROR	Error during SDO transfer
0	FLAG_SDO_TIMEOUT	Timeout during SDO transfer

LAST_DIAG

Data type	Default value	Range	Unit
DWORD	-	-	-

Last error code recorded by the CANopen master for the slave. See 'Error Messages of the CI506 CANopen Master' *Chapter 1.5.4.28.1.1 “Error messages of the CI506-PNIO CANopen master” on page 1841*.

DEV_TYPE_VALID

Data type	Default value	Range	Unit
DWORD	-	-	-

DEV_TYPE_VALID describes the validity of the device type displayed in the variable DEV_TYPE.

If DEV_TYPE_VALID = 1, the device type is valid.

If DEV_TYPE_VALID = 0, the device type is invalid.

DEV_TYPE

Data type	Default value	Range	Unit
DWORD	-	-	-

DEV_TYPE describes the device type read from the CANopen slaves upon node start-up. The values are predefined in the CANopen specification. Example for device type values are:

Device Profile for I/O modules: 401 decimal

Device Profile for Drives: 402 decimal

Device Profile Encoder modules: 406 decimal

NMT_STATE

Data type	Default value	Range	Unit
DWORD	-	0 - 6	-

NMT_STATE describes the current CANopen slave NMT state. The following table describes the possible value of the NMT_STATE.

NMT State	Value
Unknown	0
Initializing	1
Stopped	2
Operational	3
Pre-operational	4
Reset application	5
Reset communication	6

EMCY_CNT

Data type	Default value	Range	Unit
DWORD	-	-	-

EMCY_CNT outputs the number of valid emergency messages of the slave output at EMCY_DATA according to the CANopen specification. Up to 5 emergency messages per slave can be buffered in the CANopen master.

EMCY_DATA

Data type	Default value	Range	Unit
ARRAY	-	-	-

EMCY_DATA outputs up to 5 buffered emergency messages of the slave. The number of valid messages is output by NUM_EMCY. The structure of the type CANOM_EMCY_TYPE is defined in the AC500 CANopen library.

ADD_INFO

Data type	Default value	Range	Unit
DWORD	-	-	-

Not used.

RESERVED

Data type	Default value	Range	Unit
DWORD	-	-	-

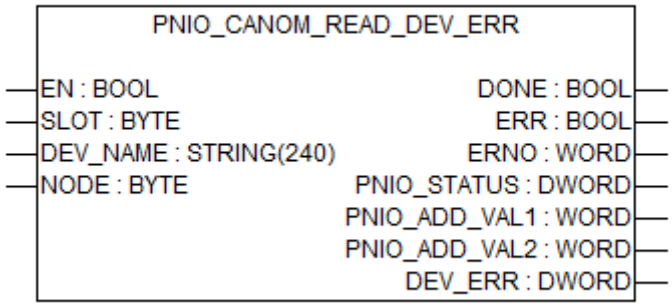
Reserved and not used.

Function call in ST

```
PNIO_CANOM_NODE_DIAG(EN       := DIAG_EN,
                     SLOT     := DIAG_SLOT,
                     DEV_NAME := DIAG_DEV_NAME,
                     NODE     := DIAG_NODE,
                     DATA     := DIAG_DATA);

DIAG_ERR           := PNIO_CANOM_NODE_DIAG.ERR;
DIAG_ERRNO         := PNIO_CANOM_NODE_DIAG.ERNO;
DIAG_STATUS        := PNIO_CANOM_NODE_DIAG.PNIO_STATUS;
DIAG_PNIO_ADD_VAL1 := PNIO_CANOM_NODE_DIAG.PNIO_ADD_VAL1;
DIAG_PNIO_ADD_VAL2 := PNIO_CANOM_NODE_DIAG.PNIO_ADD_VAL2;
DIAG_DONE          := PNIO_CANOM_NODE_DIAG.DONE;
```

PNIO_CANOM_READ_DEV_ERR



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CANopen

The function block PNIO_CANOM_READ_DEV_ERR reads the CANopen slave device error object (index 16#1001) of a CANopen slave connected to the CANopen master of the addressed CI506-PNIO.

Input description

EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

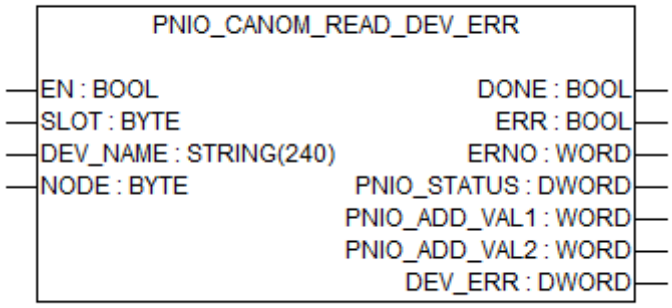
ci506-pn-##

NODE

Data type	Default value	Range	Unit
BYTE	-	1 - 127	-

Input NODE describes the target CANopen slave node ID for which the NMT command is intended.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

DEV_ERR

Data type	Default value	Range	Unit
DWORD	-	-	-

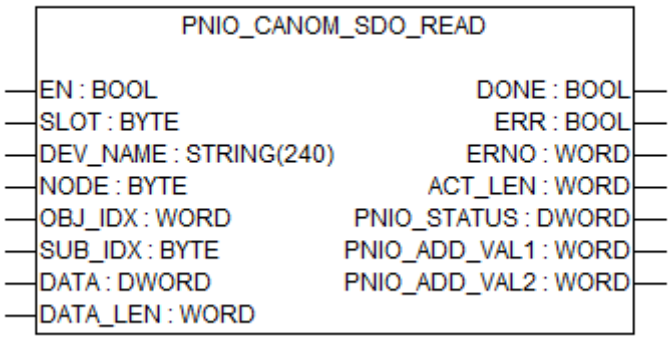
Value of the CANopen slave device error object (index 16#1001).

Function call in ST

```
PNIO_CANOM_READ_DEV_ERR(EN       := DEV_ERR_EN,
                        SLOT     := DEV_ERR_SLOT,
                        DEV_NAME := DEV_ERR_DEV_NAME,
                        NODE     := DEV_ERR_NODE);

DEV_ERR_ERR           := PNIO_CANOM_READ_DEV_ERR.ERR;
DEV_ERR_ERNO          := PNIO_CANOM_READ_DEV_ERR.ERNO;
DEV_ERR_PNIO_STATUS   := PNIO_CANOM_READ_DEV_ERR.PNIO_STATUS;
DEV_ERR_PNIO_ADD_VAL1 := PNIO_CANOM_READ_DEV_ERR.PNIO_ADD_VAL1;
DEV_ERR_PNIO_ADD_VAL2 := PNIO_CANOM_READ_DEV_ERR.PNIO_ADD_VAL2;
DEV_ERR_DEV_ERR       := PNIO_CANOM_READ_DEV_ERR.DEV_ERR;
DEV_ERR_DONE          := PNIO_CANOM_READ_DEV_ERR.DONE;
```

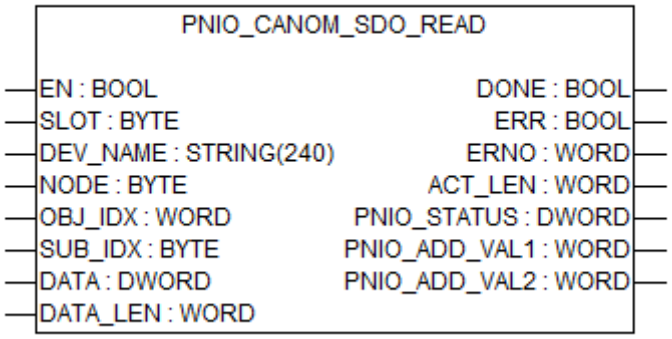
PNIO_CANOM_SDO_READ



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CANopen

The function block PNIO_CANOM_SDO_READ reads "service data object" (SDO) of a CANopen slave connected to the CANopen master of the addressed CI506-PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

NODE

Data type	Default value	Range	Unit
BYTE	-	1 - 127	-

Input NODE describes the target CANopen slave node ID for which the NMT command is intended.

OBJ_IDX

Data type	Default value	Range	Unit
WORD	-	-	-

Input OBJ_IDX describes the index of the CANopen object in the slave dictionary (refer to the CANopen slave EDS file) to be read.

SUB_IDX

Data type	Default value	Range	Unit
BYTE	-	-	-

Input OBJ_IDX describes the sub-index of the CANopen object in the slave dictionary (refer to the CANopen slave EDS file) to be read.

DATA

Data type	Default value	Range	Unit
DWORD POINTER	-	-	-

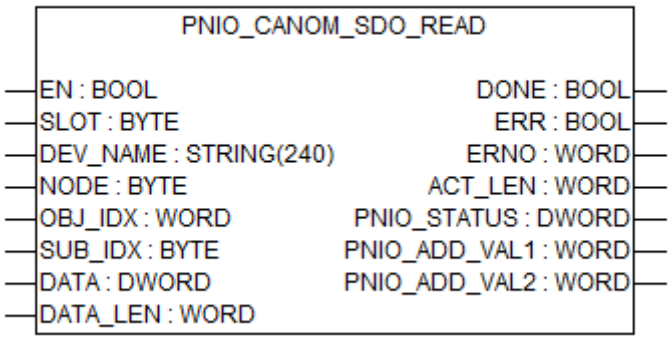
Input DATA specifies the address of the variable containing the telegrams to be transmitted. This specification is usually done via the ADR operator. The node diagnostic data have to be of the data type PNIO_CANOM_NODE_DIAG_MESSAGE_TYPE defined in the library.

DATA_LEN

Data type	Default value	Range	Unit
WORD	-	-	-

Input DATA_LEN describes the maximum length of the SDO data to be uploaded in bytes.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ACT_LEN

Data type	Default value	Range	Unit
WORD	-	-	-

ACT_LEN outputs the length of the received object data (in bytes), after the procedure has been completed successfully. Since function block execution requires bus access, the data are available in the next cycle after activating the function block at the earliest. The output value is only valid, if DONE = TRUE and ERR = FALSE.

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

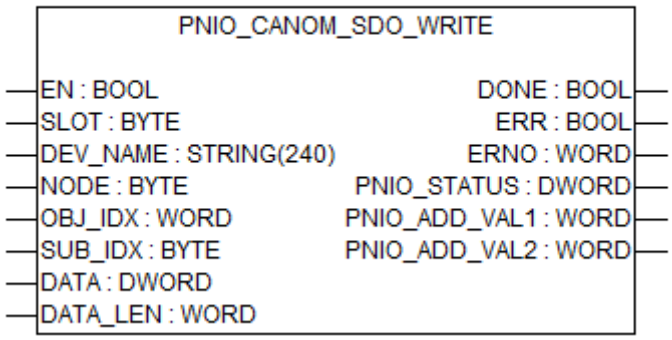
PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

Function call in ST

```
PNIO_CANCOM_SDO_READ(EN       := SDO_READ_EN,
                     SLOT     := SDO_READ_SLOT,
                     DEV_NAME := SDO_READ_DEV_NAME,
                     NODE     := SDO_READ_NODE,
                     OBJ_IDX  := SDO_READ_OBJ_IDX,
                     SUB_IDX  := SDO_READ_SUB_IDX,
                     DATA     := SDO_READ_DATA,
                     DATA_LEN := SDO_READ_DATA_LEN);

SDO_RED_ERR             := PNIO_CANCOM_SDO_READ.ERR;
SDO_READ_ERNO           := PNIO_CANCOM_SDO_READ.ERNO;
SDO_READ_ACT_LEN        := PNIO_CANCOM_SDO_READ.ACT_LEN;
SDO_READ_PNIO_STATUS    := PNIO_CANCOM_SDO_READ.PNIO_STATUS;
SDO_READ_PNIO_ADD_VAL1  := PNIO_CANCOM_SDO_READ.PNIO_ADD_VAL1;
SDO_READ_PNIO_ADD_VAL2  := PNIO_CANCOM_SDO_READ.PNIO_ADD_VAL2;
SDO_READ_DONE           := PNIO_CANCOM_SDO_READ.DONE;
```

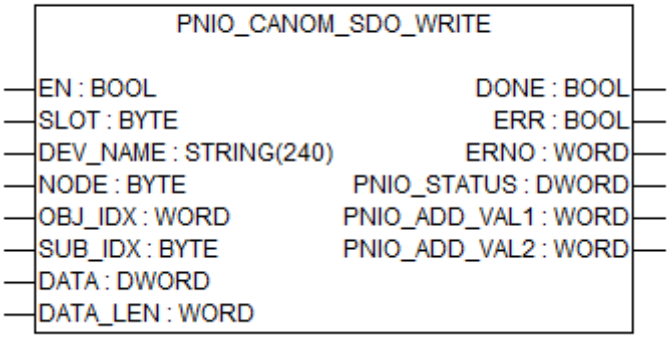
PNIO_CANOM_SDO_WRITE



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CANopen

The function block PNIO_CANOM_SDO_WRITE writes a "service data object" (SDO) of a CANopen slave connected to the CANopen master of the addressed CI506-PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

NODE

Data type	Default value	Range	Unit
BYTE	-	1 - 127	-

Input NODE describes the target CANopen slave node ID for which the NMT command is intended.

OBJ_IDX

Data type	Default value	Range	Unit
WORD	-	-	-

Input OBJ_IDX describes the index of the CANopen object in the slave dictionary (refer to the CANopen slave EDS file) to be read.

SUB_IDX

Data type	Default value	Range	Unit
BYTE	-	-	-

Input OBJ_IDX describes the sub-index of the CANopen object in the slave dictionary (refer to the CANopen slave EDS file) to be read.

DATA

Data type	Default value	Range	Unit
DWORD POINTER	-	-	-

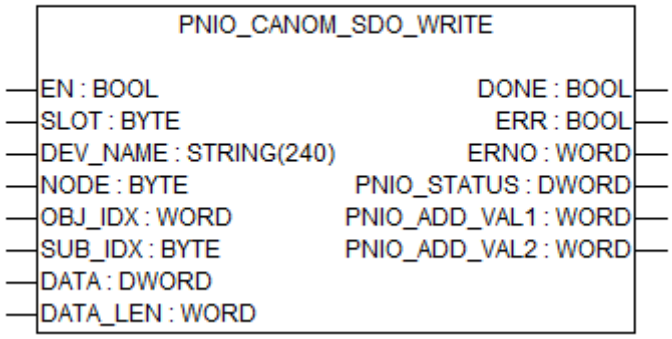
Input DATA specifies the address of the variable containing the telegrams to be transmitted. This specification is usually done via the ADR operator. The node diagnostic data have to be of the data type PNIO_CANOM_NODE_DIAG_MESSAGE_TYPE defined in the library.

DATA_LEN

Data type	Default value	Range	Unit
WORD	-	-	-

Input DATA_LEN describes the maximum length of the SDO data to be uploaded in bytes.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

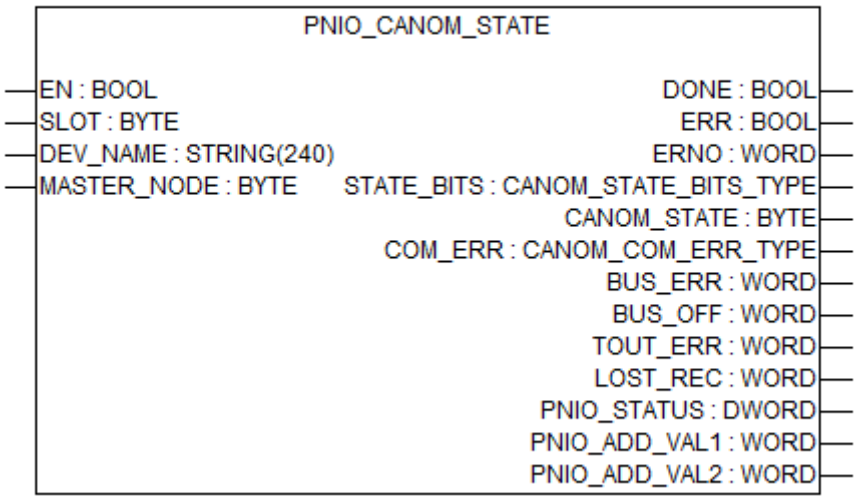
PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

Function call in ST

```
PNIO_CANCOM_SDO_WRITE(EN       := SDO_WRITE_EN,
                      SLOT     := SDO_WRITE_SLOT,
                      DEV_NAME := SDO_WRITE_DEV_NAME,
                      NODE     := SDO_WRITE_NODE,
                      OBJ_IDX  := SDO_WRITE_OBJ_IDX,
                      SUB_IDX  := SDO_WRITE_SUB_IDX,
                      DATA     := SDO_WRITE_DATA,
                      DATA_LEN := SDO_WRITE_DATA_LEN);

SDO_WRITE_ERR           := PNIO_CANCOM_SDO_WRITE.ERR;
SDO_WRITE_ERNO          := PNIO_CANCOM_SDO_WRITE.ERNO;
SDO_WRITE_PNIO_STATUS   := PNIO_CANCOM_SDO_WRITE.PNIO_STATUS;
SDO_WRITE_PNIO_ADD_VAL1 := PNIO_CANCOM_SDO_WRITE.PNIO_ADD_VAL1;
SDO_WRITE_PNIO_ADD_VAL2 := PNIO_CANCOM_SDO_WRITE.PNIO_ADD_VAL2;
SDO_WRITE_DONE          := PNIO_CANCOM_SDO_WRITE.DONE;
```

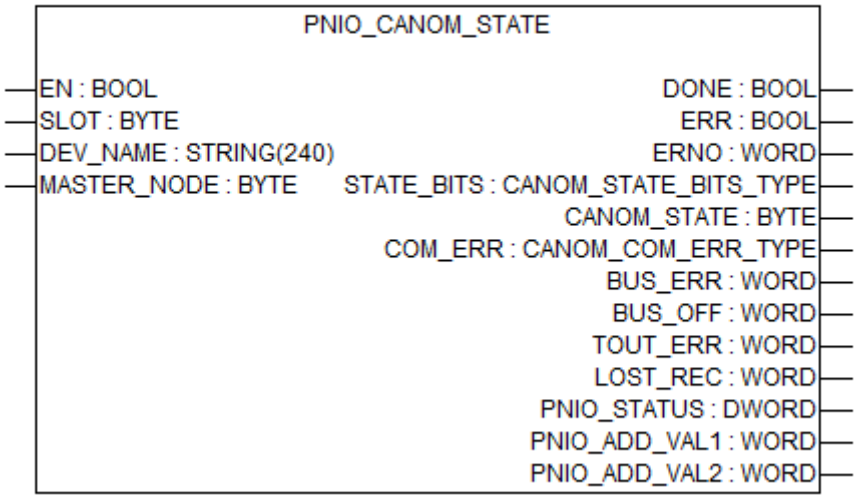
PNIO_CANOM_STATE



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CANopen

The function block PNIO_CANOM_STATE provides state information of the CANopen master of the addressed CI506-PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

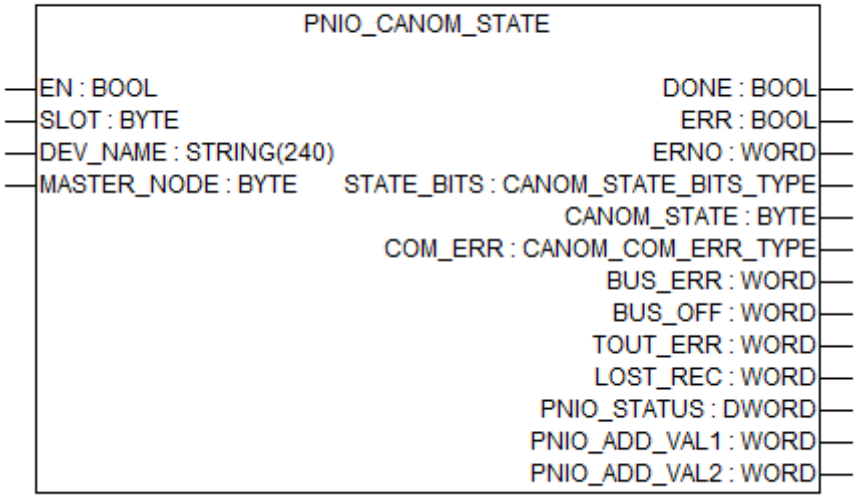
ci506-pn-##

MASTER_NODE

Data type	Default value	Range	Unit
BYTE	-	1 - 127	-

Input MASTER_NODE describes the CANopen master node ID in CI506.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

STATE_BITS

Data type	Default value	Range	Unit
CANOM_STATE_BITS_TYPE	-	-	-

Output STATE_BITS indicates a typical communication states of the CANopen master. STATE_BITS is only valid if EN = TRUE and ERR = FALSE.

CANOM_STATE

Data type	Default value	Range	Unit
BYTE	-	-	-

CANOM_STATE outputs the general communication state of the CANopen master in CI506. CANOM_STATE is only valid, if EN = TRUE and ERR = FALSE. The following states are defined:

State		Meaning
Dec	Hex	
0	00	OFFLINE
64	40	STOP
128	80	CLEAR
192	C0	OPERATE

CANOM_STATE = OFFLINE

If CANOM_STATE is set to OFFLINE, the CANopen master performs an initialization. After the initialization phase is completed, the CANopen master changes to STOP state.

CANOM_STATE = STOP

If CANOM_STATE has the value STOP, the CANopen master is completely initialized. In this state the CANopen master is ready to receive configuration data. There is no data exchange with the slaves. CANOM_STATE = CLEAR

If a CANopen network configuration is received the CANopen master changes from STOP to CLEAR and starts to establish the connections defined during configuration. When the setup has been completed successfully, the CANopen master moves to OPERATE state. If an error occurs during parameterization, the CANopen master changes back to STOP state.

CANOM_STATE = OPERATE

If CANOM_STATE has the value OPERATE, the master exchanges I/O data with the slaves.

COM_ERR

Data type	Default value	Range	Unit
CANOM_COM_ERR_TYPE	-	-	-

Not used in CI506.

BUS_ERR

Data type	Default value	Range	Unit
WORD	-	-	-

BUS_ERR outputs the number of occurred bus errors. A bus error occurs if the internal error frame counter exceeds a specific value. BUS_ERR is only valid if EN = TRUE and ERR = FALSE.

BUS_OFF

Data type	Default value	Range	Unit
WORD	-	-	-

BUS_OFF is incremented if the CAN interface reports that it detaches itself from CAN bus due to exceeded internal bus error counters and must be reinitialized. BUS_OFF is only valid if EN = TRUE and ERR = FALSE.

LOST_REC

Data type	Default value	Range	Unit
WORD	-	-	-

LOST_REC outputs the number of received telegrams that were rejected because they could not be processed successfully due to a CAN chip overload. LOST_REC is only valid, if EN = TRUE and ERR = FALSE.

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

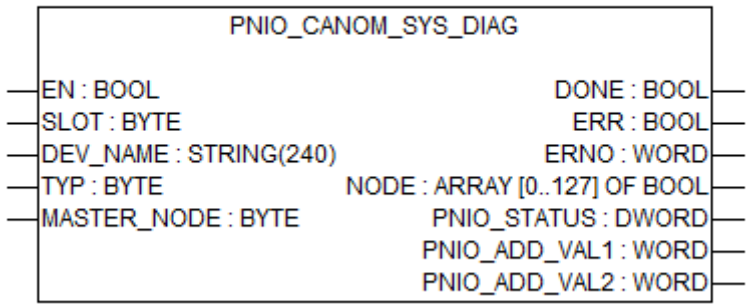
PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

Function call in ST

```
PNIO_CANOM_STATE(EN          := STATE_EN,
                 SLOT         := STATE_SLOT,
                 DEV_NAME     := STATE_DEV_NAME,
                 MASTER_NODE  := STATE_MASTER_NODE);

STATE_ERR           := PNIO_CANOM_STATE.ERR;
STATE_ERNO          := PNIO_CANOM_STATE.ERNO;
STATE_BITS          := PNIO_CANOM_STATE.STATE_BITS;
STATE_CANCOM_STATE  := PNIO_CANOM_STATE.CANOM_STATE;
STATE_CANCOM_ERR    := PNIO_CANOM_STATE.COM_ERR;
STATE_BUS_ERR       := PNIO_CANOM_STATE.BUS_ERR;
STATE_BUS_OFF       := PNIO_CANOM_STATE.BUS_OFF;
STATE_TOUT_ERR      := PNIO_CANOM_STATE.TOUT_ERR;
STATE_LOST_REC      := PNIO_CANOM_STATE.LOST_REC;
STATE_PNIO_STATUS   := PNIO_CANOM_STATE.PNIO_STATUS;
STATE_PNIO_ADD_VAL1 := PNIO_CANOM_STATE.PNIO_ADD_VAL1;
STATE_PNIO_ADD_VAL2 := PNIO_CANOM_STATE.PNIO_ADD_VAL2;
STATE_DONE          := PNIO_CANOM_STATE.DONE;
```

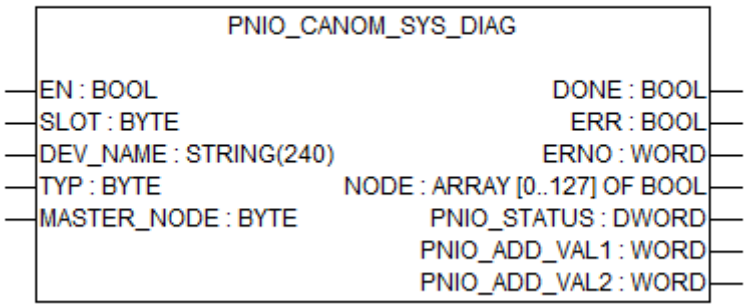
PNIO_CANOM_SYS_DIAG



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	CANopen

The function block PNIO_CANOM_SYS_DIAG gets the states of all slaves connected to the CI506-PNIO CANopen master.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

TYP

Data type	Default value	Range	Unit
BYTE	-	-	-

Input TYP selects the type of CANopen system diagnosis displayed at output NODE.

TYP = 1 Configured slaves

Output NODE displays which slaves are configured for the CANopen master in CI506 (TRUE).

TYP = 2 Operational slaves

Output NODE displays which slaves are error-free and in operation. A slave can only be operational if it has been configured in the master. The type of system diagnosis can only be requested if the CANopen master is in OPERATE state.

TYP = 3 Slaves with diagnosis

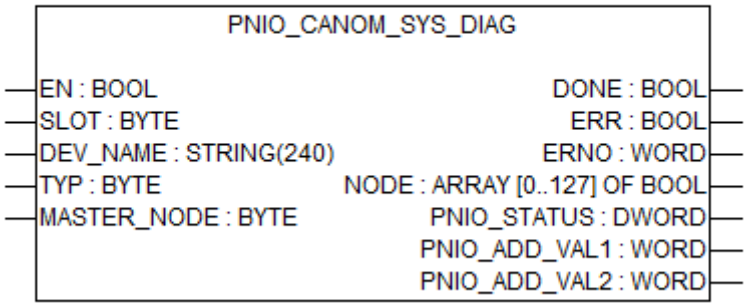
Output NODE indicates which slaves report a diagnosis. The diagnosis survey can only be requested if the CANopen master is in OPERATE state.

MASTER_NODE

Data type	Default value	Range	Unit
BYTE	-	1 - 127	-

Input MASTER_NODE describes the CANopen master node ID in CI506.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NODE

Data type	Default value	Range	Unit
ARRAY ARRAY	-	-	-

Output NODE outputs the status of each slave as a bitfield. Each individual bit within this field represents one slave. The index number corresponds to the slave's node address. If a bit is set to TRUE, the state selected using TYP applies for the slave. If e.g. TYP = 1 is selected and NODE[2] = TRUE, the slave with a configuration for this node was received and stored in master. If NODE[2] = FALSE, the slave is not part of the master's configuration data. If TYP = 3, NODE[2] = TRUE means that the slave with the node address 2 has received an emergency message or that the diagnosis indication of the slave has changed. In this case, a diagnosis description can be requested using the function block PNIO_CANOM_NODE_DIAG ↳ *Chapter 1.5.4.28.1.9 “PNIO_CANOM_NODE_DIAG” on page 1866*.

The bitfield output at NODE is only valid, if EN = TRUE and ERR = FALSE.

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

Function call in ST

```
PNIO_CANOM_SYS_DIAG(EN          := SYS_DIAG_EN,
                    SLOT         := SYS_DIAG_SLOT,
                    DEV_NAME     := SYS_DIAG_DEV_NAME,
                    TYP          := SYS_DIAG_TYP,
                    MASTER_NODE := SYS_DIAG_MASTER_NODE);

SYS_DIAG_ERR           := PNIO_CANOM_SYS_DIAG.ERR;

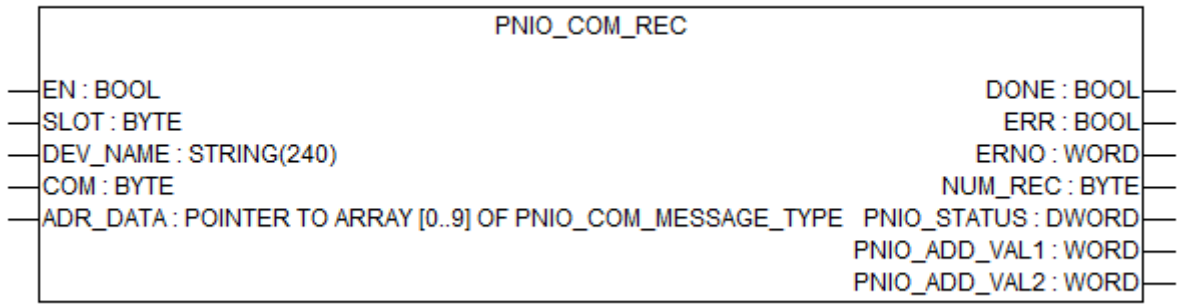
SYS_DIAG_PNIO_ADD_VAL1 := PNIO_CANOM_SYS_DIAG.PNIO_ADD_VAL1;
SYS_DIAG_PNIO_ADD_VAL2 := PNIO_CANOM_SYS_DIAG.PNIO_ADD_VAL2;
SYS_DIAG_DONE          := PNIO_CANOM_SYS_DIAG.DONE;
```

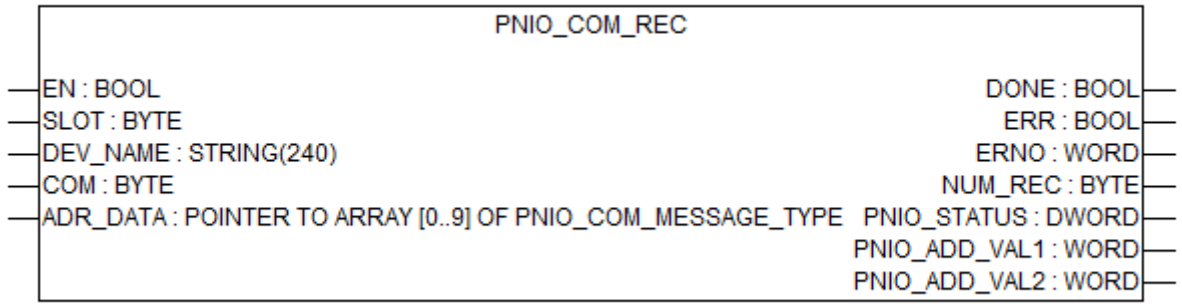
PNIO_COM_REC



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	COM

The function block PNIO_COM_REC provides all serial messages received on the addressed CI504-PNIO or CI506-PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

At the COM input, the number of the serial interface is specified.

COM = 1: COM1

COM = 2: COM2

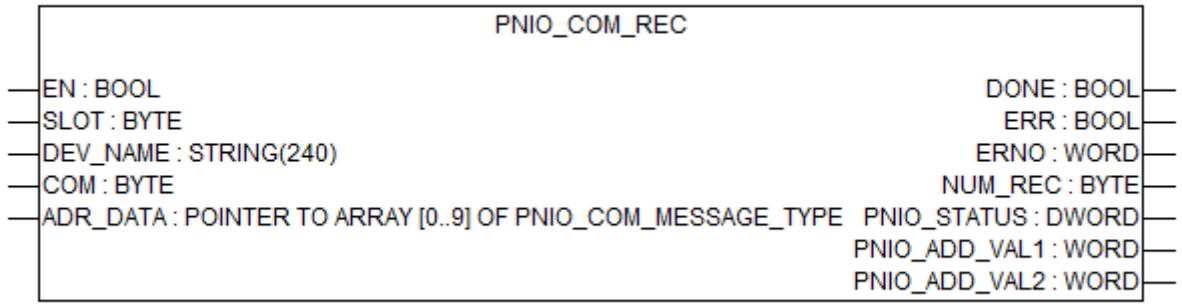
COM = 3: COM3 (CI504 only)

ADR_DATA

Data type	Default value	Range	Unit
ARRAY	-	-	-

Input ADR_DATA specifies the address starting from which the received CAN 2.0A telegrams should be written. Usually, this specification is done via the ADR operator and should point to an array with 64 entries of the type CAN2A_MESSAGE_TYPE.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_REC

Data type	Default value	Range	Unit
DWORD	-	-	-

Output NUM_REC displays the total number of CAN 2.0A telegrams received.

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

PNIO_COM_MESSAGE_TYPE

This data type is declared as follows:

```
TYPE PNIO_COM_MESSAGE_TYPE:
STRUCT
    HEADER: PNIO_COM_MESSAGE_HEADER_TYPE; (*HEADER*)
    DATA: ARRAY [1..256] OF BYTE; (*data if any, depends on LENGTH in
HEADER*)
END_STRUCT
END_TYPE
```

PNIO_COM_MESSAGE_HEADER_TYPE

This data type is declared as follows:

```
TYPE PNIO_COM_MESSAGE_HEADER_TYPE:
STRUCT
    STATUS: WORD; (*STATUS*)
    LENGTH: WORD; (*LENGTH*)
END_STRUCT
END_TYPE
```

Possible values for STATUS are:

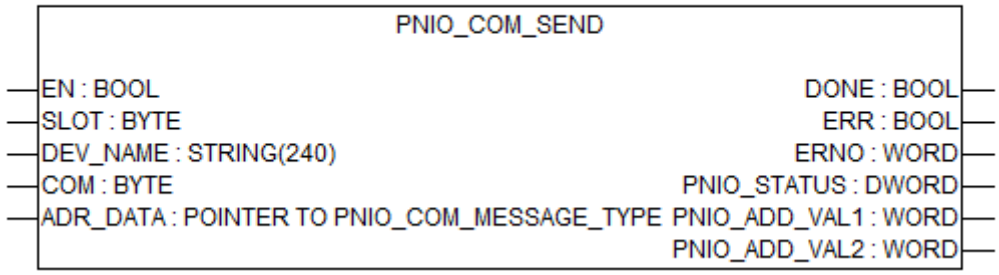
```
CDRV_FRAME_BUFFER_FULL = 0x101,
CDRV_FRAME_END_CHAR = 0x102,
CDRV_FRAME_TIMEOUT = 0x103,
CDRV_FRAME_BREAK = 0x104,
CDRV_FRAME_FRAMING = 0x105,
CDRV_FRAME_PARITY = 0x106,
CDRV_FRAME_CANCELED = 0x107,
CDRV_FRAME_ERROR = 0x108,
CDRV_FRAME_CHKSUM = 0x109,
CDRV_FRAME_LEN = 0x10A
```

Function call in ST

```
PNIO_COM_REC(EN       := REC_EN,
                      SLOT     := REC_SLOT,
                      DEV_NAME := REC_DEV_NAME,
                      COM      := REC_COM,
                      ADR_DATA := REC_ADR);

REC_ERR           := PNIO_COM_REC.ERR;
REC_ERNO          := PNIO_COM_REC.ERNO;
REC_NUM_REC       := PNIO_COM_REC.NUM_REC;
REC_PNIO_STATUS   := PNIO_COM_REC.PNIO_STATUS;
REC_PNIO_ADD_VAL1 := PNIO_COM_REC.PNIO_ADD_VAL1;
REC_PNIO_ADD_VAL2 := PNIO_COM_REC.PNIO_ADD_VAL2;
REC_DONE          := PNIO_COM_REC.DONE;
```

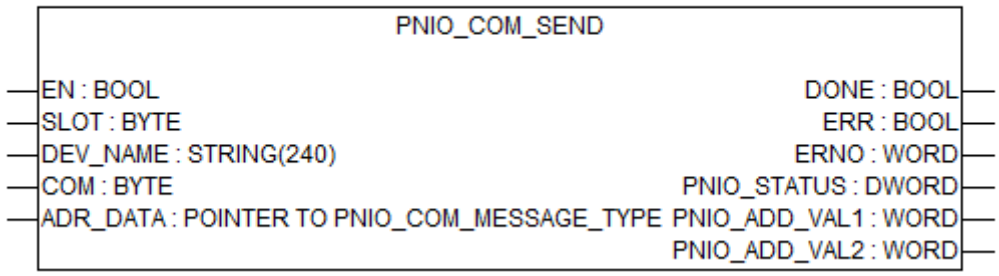
PNIO_COM_SEND



Parameter	Value
Included in library	PROFINET_Ext_AC500_V20.lib
Available as of firmware	V2.1.x
Type	Function block with historical values
Group	COM

The function block PNIO_COM_SEND provides all serial messages via the addressed CI504-PNIO or CI506-PNIO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

DEV_NAME

Data type	Default value	Range	Unit
STRING	-	-	-

Input DEV_NAME describes the PROFINET IO device to be queried. The string has a maximum length of 240 characters, including the zero terminating char. In conjunction with the SLOT value this string selects the target I/O module of this request.

Valid values are (examples for the ABB modules, the hash marks # are place holders for the address selected by the rotary switch at the front of the device):

ci506-pn-##

COM

Data type	Default value	Range	Unit
BYTE	-	-	-

At the COM input, the number of the serial interface is specified.

COM = 1: COM1

COM = 2: COM2

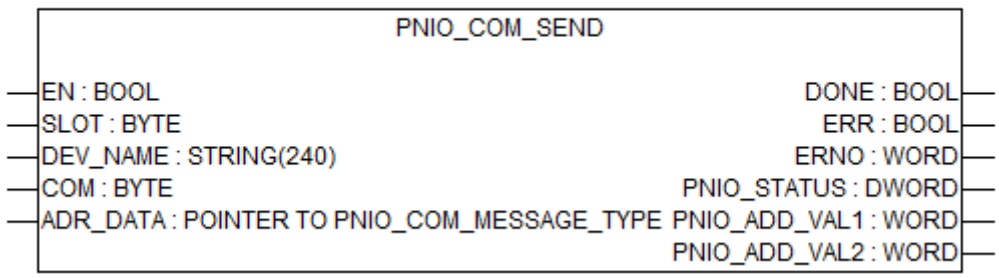
COM = 3: COM3 (CI504 only)

ADR_DATA

Data type	Default value	Range	Unit
ARRAY	-	-	-

Input ADR_DATA specifies the address starting from which the received CAN 2.0A telegrams should be written. Usually, this specification is done via the ADR operator and should point to an array with 64 entries of the type CAN2A_MESSAGE_TYPE.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE. (see *Chapter 1.5.3 "Error messages of the AC500 V2 function block libraries" on page 735*).

PNIO_STATUS

Data type	Default value	Range	Unit
DWORD	-	-	-

Output PNIO_STATUS contains the PNIO ErrorCode and ErrorDecode.

PNIO_ADD_VAL 1

Data type	Default value	Range	Unit
WORD	1	-	-

Output PNIO_ADD_VAL1 contains the PNIO ErrorCode1.

PNIO_ADD_VAL 2

Data type	Default value	Range	Unit
WORD	2	-	-

PNIO_ADD_VAL2 contains the PNIO ErrorCode2.

Function call in ST

```
PNIO_COM_SEND(EN       := SEND_EN,
                      SLOT     := SEND_SLOT,
                      DEV_NAME := SEND_DEV_NAME,
                      COM      := SEND_COM,
                      ADR_DATA := SEND_ADR_DATA);

SEND_ERR           := PNIO_COM_SEND.ERR;
SEND_ERNO          := PNIO_COM_SEND.ERNO;
SEND_PNIO_STATUS   := PNIO_COM_SEND.PNIO_STATUS;
SEND_PNIO_ADD_VAL1 := PNIO_COM_SEND.PNIO_ADD_VAL1;
SEND_PNIO_ADD_VAL2 := PNIO_COM_SEND.PNIO_ADD_VAL2;
SEND_DONE          := PNIO_COM_SEND.DONE;
```

1.5.4.29 Profinet_Ext2 library

Library file name: **Profinet_Ext2_AC500_Vx.lib**

This library contains function blocks which are used to control the PROFINET IO network and the connected devices.

Preconditions

All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.

The following libraries are required to use the function blocks of the Profinet_Ext2 library:

- *CMN_AC500_V24.lib (V 1.0.0)*
- *SysInt_AC500_V10.lib (V 1.4.3)*
- *Profinet_AC500_V13.lib (V1.2.1)*

These libraries are part of the Automation Builder.

1.5.4.29.1 Function blocks

PNIO_CNTL_START_COM

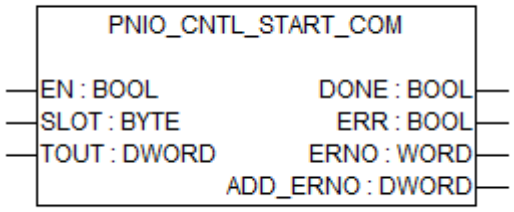


Table 91: General information

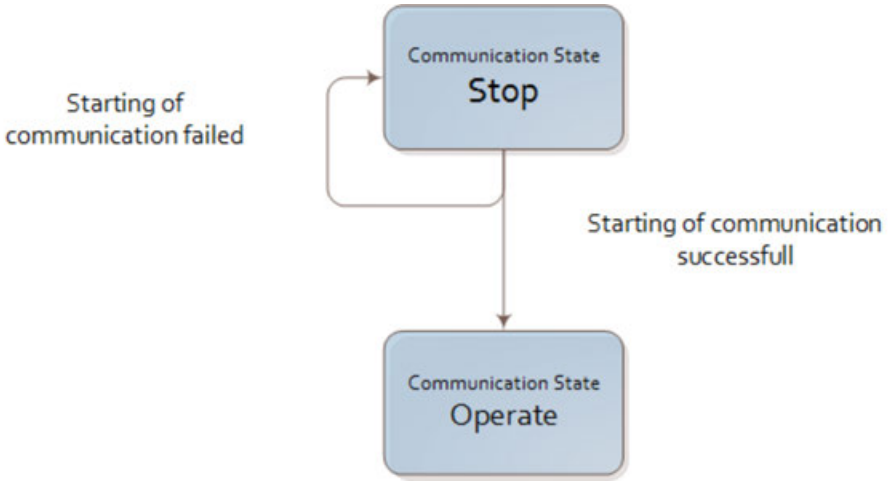
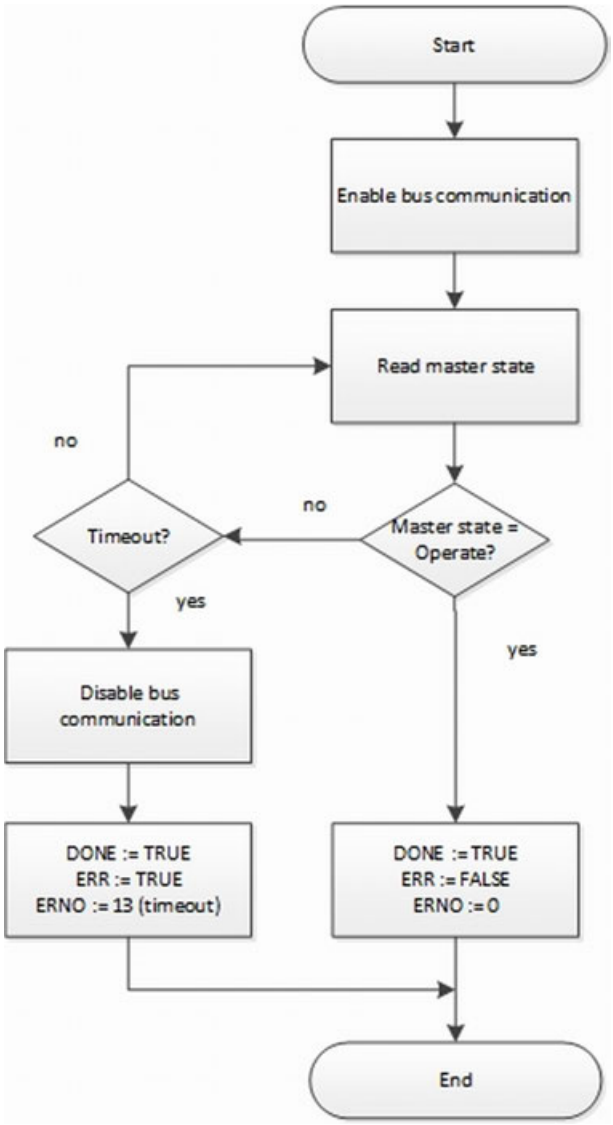
Available as of runtime system	V2.6.2 and above
Available as of AB version	V2.1 and above
Available as of CM579-PNIO version	V2.8.4.20 and above
Included in library	Profinet_Ext2_AC500_V26.lib
Type	Function block with historical values.

The function block PNIO_CNTL_START_COM can be used to start the communication of the PROFINET IO Controller. That means the communication state is changed from Stop to Operate.



The next figure shows the flowchart of the execution of the function block PNIO_CNTL_START_COM.:

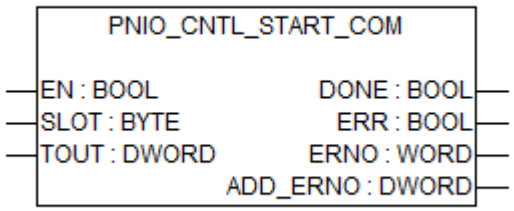


When the execution is started the bus communication will be enabled. After that the communication state of the PROFINET IO Controller is checked and it's waited until the communication state is Operate.

The execution of the FB was successful if the PROFINET IO Controller was changed to the communication state Operate.

If the PROFINET IO Controller is not in the communication state Operate within the specified timeout the execution of the FB is failed and the bus communication is disabled again.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

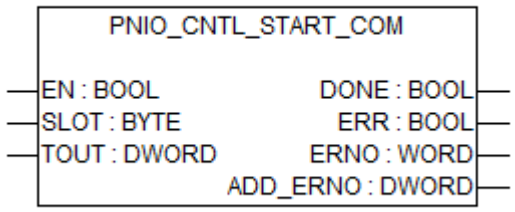
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

TOUT

Data type	Default value	Range	Unit
DWORD	0	0 … 4294967295	ms

Value of timeout in ms.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADD_ERNO

Data type	Default value	Range	Unit
DWORD	-	$0…2^{32-1}$	-

At output ADD_ERNO an additional error code is provided when output ERNO is 0 x 0031.

PNIO_CNTL_STOP_COM

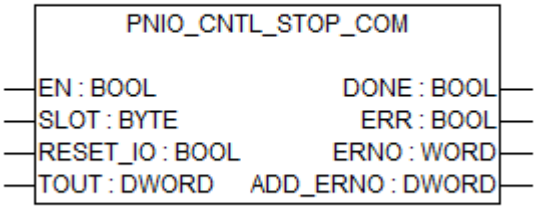


Table 92: General information

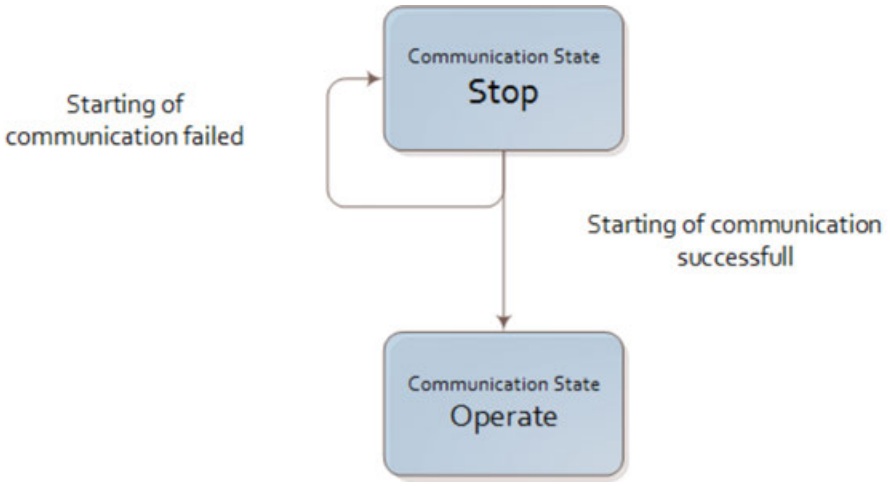
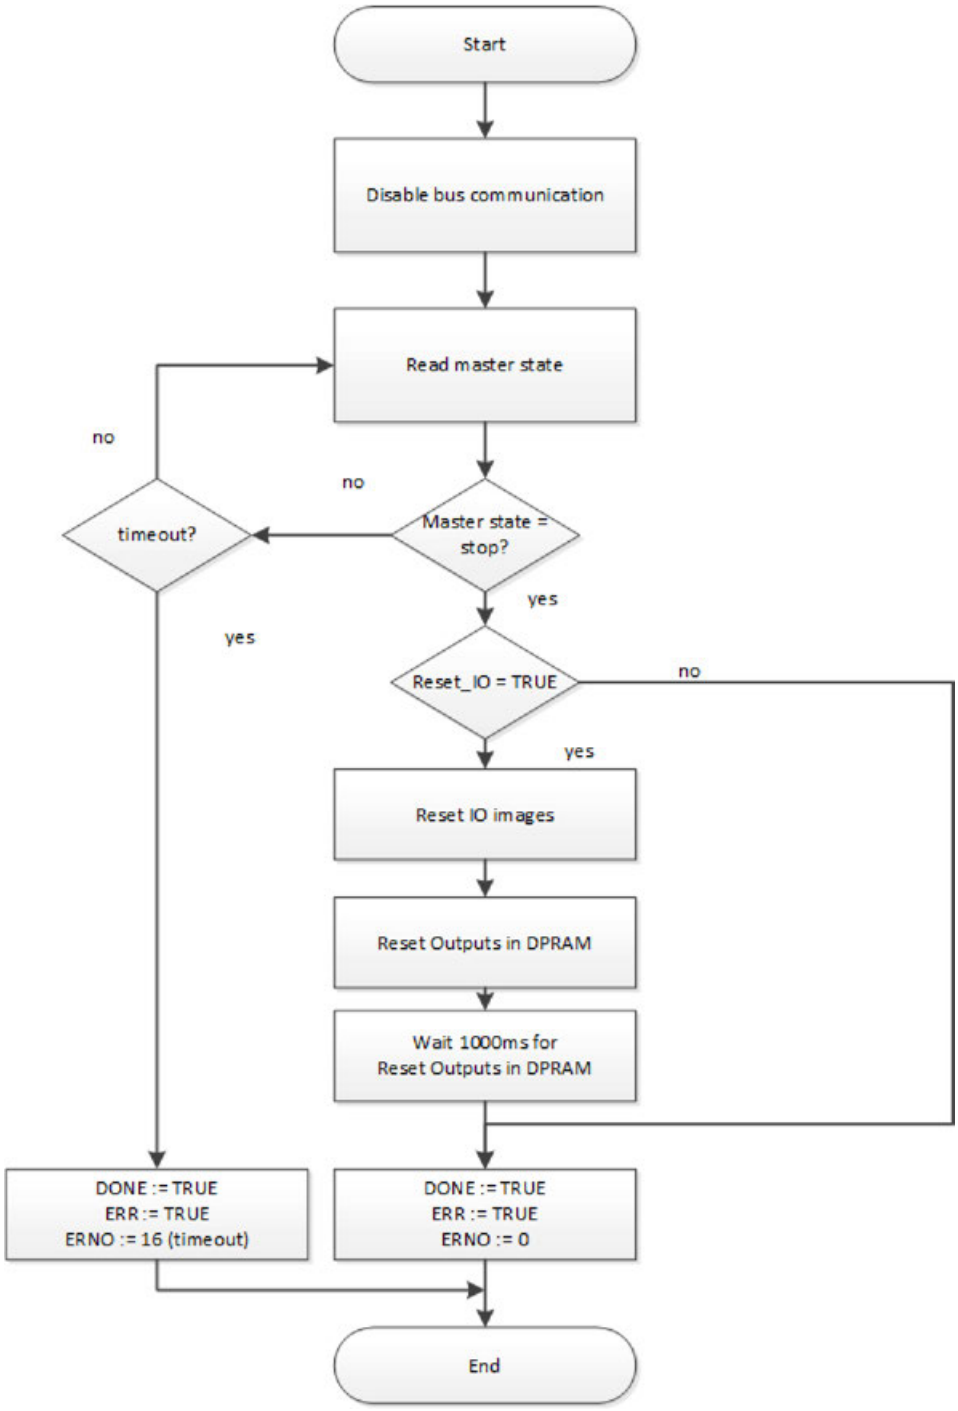
Available as of runtime system	V2.6.2 and above
Available as of AB version	V2.1 and above
Available as of CM579-PNIO version	V2.8.4.20 and above
Included in library	Profinet_Ext2_AC500_V26.lib
Type	Function block with historical values.

The function block PNIO_CNTL_STOP_COM can be used to stop the communication of the PROFINET IO Controller. That means the communication state is changed from Operate to Stop.



The user is responsible for resetting of the PROFINET IO related part of the PLC application when the bus communication is re-started

The next figure shows the flowchart of the execution of the function block PNIO_CNTL_STOP_COM.:



When the execution is started the bus communication will be disabled. After that the communication state is checked and it's waited until the communication state is Stop.

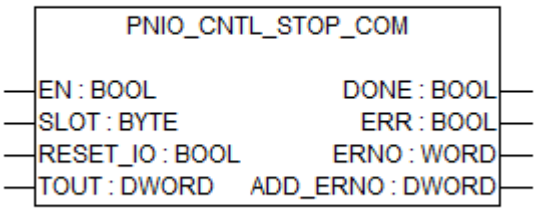
If the PROFINET IO Controller is in communication Stop and the input RESET_IO is TRUE the IOs will be reset.

The execution of the FB was successful if the communication state was changed to Stop and no error is occurred during resetting the IOs. If the PROFINET IO Controller is not in the communication state Stop within the specified timeout the execution of the FB is failed.

The IO reset functionality of the FB PNIO_CNTL_STOP_COM is not synchronized. That means there is no notification when the reset is finished.

The FB PNIO_CNTL_STOP_COM has an internal waiting time of 1000ms to be sure the IOs were reset. If this time is not sufficient it has to be waited an additional time before the communication is re-started with the FB PNIO_CNTL_START_COM.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

RESET_IO

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

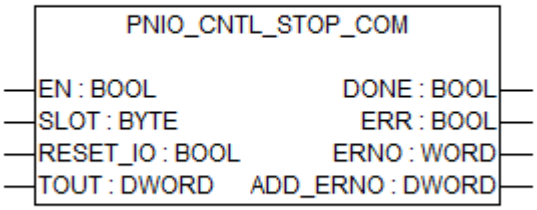
IO values will be reset if set to true.

TOUT

Data type	Default value	Range	Unit
DWORD	0	0 … 4294967295	ms

Value of timeout in ms.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

ADD_ERNO

Data type	Default value	Range	Unit
DWORD	-	$0…2^{32-1}$	-

At output ADD_ERNO an additional error code is provided when output ERNO is 0 x 0031.

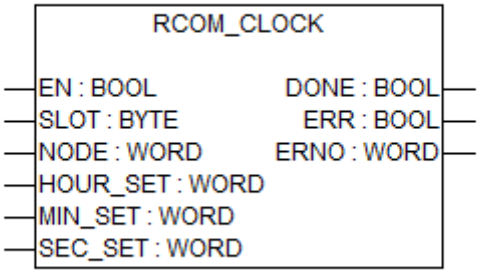
1.5.4.30 RCOM/RCOM+ library

Library file name: **RCOM_AC500_Vx.lib**

> *All function blocks of this library can only be executed in RUN mode of the processor module, not in simulation mode.*

1.5.4.30.1 Function blocks

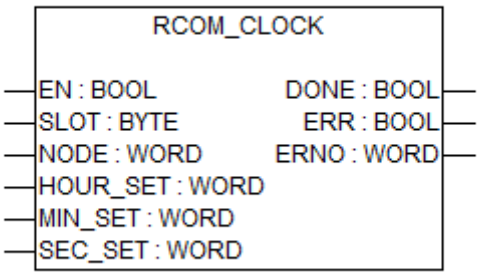
RCOM_CLOCK



Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

This function block transmits a telegram that sets the clock of the called slave(s) to the time specified at the function block inputs. The master clock is set to the same value.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

HOUR_SET

Data type	Default value	Range	Unit
WORD	-	-	-

Input HOUR_SET specifies the value of the hour component of the time.

MIN_SET

Data type	Default value	Range	Unit
WORD	-	-	-

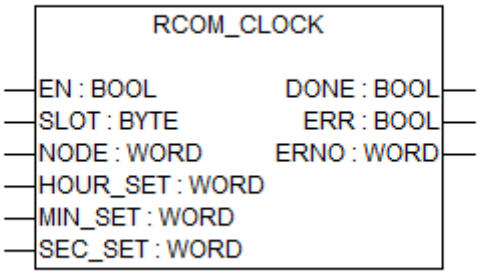
Input MIN_SET specifies the value of the minutes component of the time.

SEC_SET

Data type	Default value	Range	Unit
WORD	-	-	-

Input SEC_SET specifies the value of the seconds component of the time.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

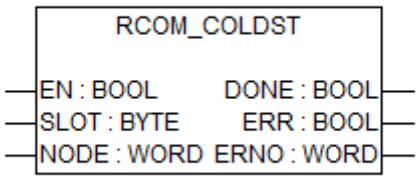
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RCOMClock(
     EN := RCOMClock_EN,
     SLOT := RCOMClock_SLOT,
     NODE := RCOMClock_NODE,
     HOUR_SET := RCOMClock_HOUR_SET,
     MIN_SET := RCOMClock_MIN_SET,
     SEC_SET := RCOMClock_SEC_SET);
RCOMClock_DONE := RCOMClock.DONE;
RCOMClockart_ERR   := RCOMClock.ERR;
RCOMClock_ERNO := RCOMClock.ERNO;
```

RCOM_COLDST



Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

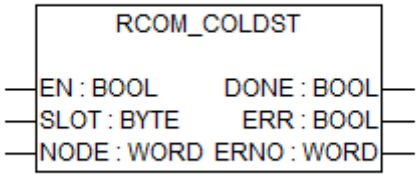
This function block performs a cold start of the called slave(s). After the cold start, the slave(s) are partially reinitialized.

At the called slave(s) the sequence marks (RCOM-specific protocol parameter) are reset and the transmission of data records is disabled. All entries in the event queue are deleted, and, after this, a cold start event is generated.

After a cold start, always a normalization is required.

This function block has to be used for the initialization of the RCOM network, e.g. after the initialization of the master's CM574-RCOM device.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

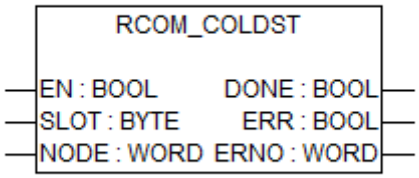
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

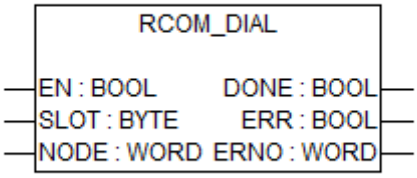
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RCOMColdstart(
     EN := RCOMColdstart_EN,
     SLOT := RCOMColdstart_SLOT,
     NODE := RCOMColdstart_NODE);
RCOMColdstart_DONE := RCOMColdstart.DONE;
RCOMColdstart_ERR  := RCOMColdstart.ERR;
RCOMColdstart_ERNO := RCOMColdstart.ERNO;
```

RCOM_DIAL



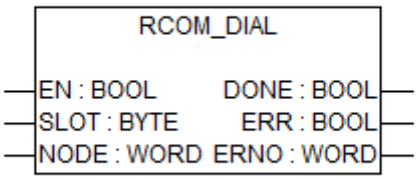
Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

This function block calls a specified subscriber in a network realized with dial lines. If used in the RCOM master, the function block has to be processed before transmitting system services or data records to a slave.

If used in a slave, the function block can be used to call the master in order to request event polling.

The dial line has to be terminated using the RCOM_HANGUP function block after transmission is completed.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

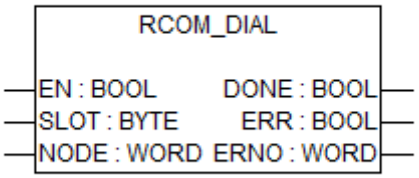
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

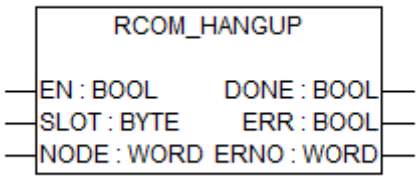
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RCOMDial(
```

```
      EN := RCOMDial_EN,
      SLOT := RCOMDial_SLOT,
      NODE := RCOMDial_NODE);
RCOMDial_DONE := RCOMDial.DONE;
RCOMDial_ERR  := RCOMDial.ERR;
RCOMDial_ERNO := RCOMDial.ERNO;
```

RCOM_HANGUP



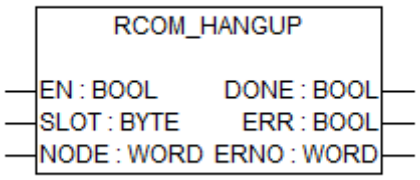
Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

This function block hangs up the connection in networks realized with dial lines.

The function block has to be used to terminate the connection after transmitting data records to or from a slave.

The function block cannot be used until all jobs for a slave are processed completely. Furthermore, the function block can only be used, if the RCOM network is realized by dial lines ("Hayes compatible dial modem"; has to be selected as modem type in PLC configuration).

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

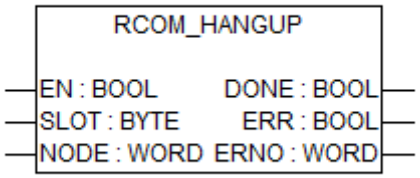
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

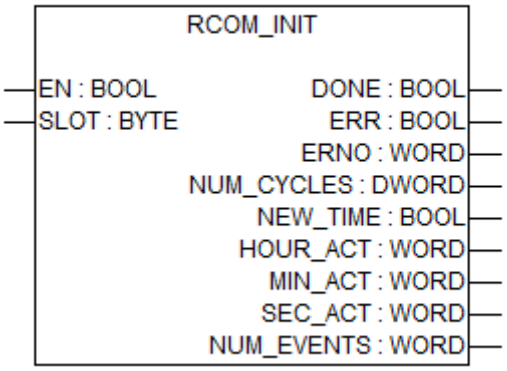
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RCOMHangup(
     EN := RCOMHangup_EN,
     SLOT := RCOMHangup_SLOT,
     NODE := RCOMHangup_NODE);
RCOMHangup_DONE := RCOMHangup.DONE;
RCOMHangup_ERR  := RCOMHangup.ERR;
RCOMHangup_ERNO := RCOMHangup.ERNO;
```

RCOM_INIT



Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

This function block is used to initialize the CM574-RCOM. It sets all necessary network parameters and starts initialization.

Once the function block is started, the input parameters must not be changed anymore. Due to this, the parameters should be preset by assigning constants.

A rising edge at input EN initiates the function block. The signal TRUE must be applied until the function block is processed completely.

If DONE = TRUE and ERR = FALSE, the initialization process was successful. If DONE = TRUE and ERR = TRUE, an error occurred and the error number is indicated at output ERNO.

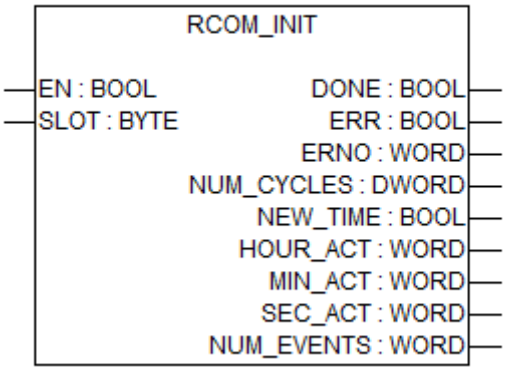
After initialization, the outputs ERR, ERNO, NUM_CYCLES, NEW_TIME, HOUR_ACT, MIN_ACT, SEC_ACT and NUM_EVENTS are updated with each PLC cycle as long as EN = TRUE. This way, the PLC permanently receives the cycle counter value and error messages from the CM574-RCOM. Therefore, input EN should constantly remain TRUE, except when the Communication Module has to be reinitialized with new parameters.

A falling edge at input EN resets the outputs ERR and ERNO.

Output NUM_CYCLES indicates the current cycle counter value of the CM574-RCOM. The outputs NEW_TIME, HOUR_ACT, MIN_ACT and SEC_ACT indicate the current RCOM system time which can also be used in the PLC program. Time starts at switching on with 00:00.00. If a ‘set clock’ command is received, the time is set to the new value and output NEW_TIME is set for approx. 5 seconds (e.g. for setting a real-time clock).

For RCOM slaves, output NUM_EVENTS indicates the number of events stored in the event queue. For the RCOM master, NUM_EVENTS is always zero.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

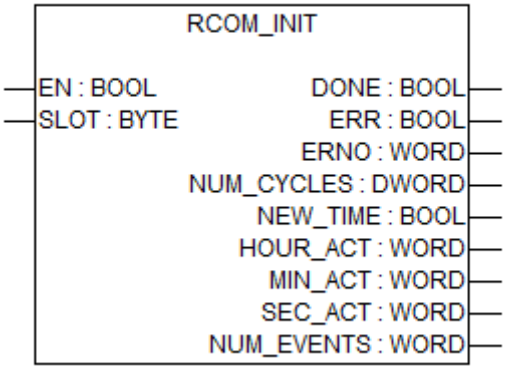
SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_CYCLES

Data type	Default value	Range	Unit
WORD	-	-	-

Output NUM_CYCLES provides the current value of the CM574-RCOM cycle counter. This value is permanently updated as long as EN = TRUE. The cycle counter should be used to monitor the CM574-RCOM (life identifier).

NEW_TIME

Data type	Default value	Range	Unit
BOOL	-	-	-

Output NEW_TIME is set to TRUE for approx. 5 seconds, if a new RCOM time has been set using the RCOM_CLOCK function block. This output can be used to adjust a real-time clock to the time applied at HOUR_ACT, MIN_ACT and SEC_ACT.

HOUR_ACT

Data type	Default value	Range	Unit
WORD	-	-	-

Output HOUR_ACT indicates the hours component of the RCOM system time. The master can adjust the time using the RCOM_CLOCK function block.

MIN_ACT

Data type	Default value	Range	Unit
WORD	-	-	-

Output MIN_ACT indicates the minutes component of the RCOM system time. The master can adjust the time using the RCOM_CLOCK function block.

SEC_ACT

Data type	Default value	Range	Unit
WORD	-	-	-

Output SEC_ACT indicates the seconds component of the RCOM system time. The master can adjust the time using the RCOM_CLOCK function block.

NUM_EVENTS

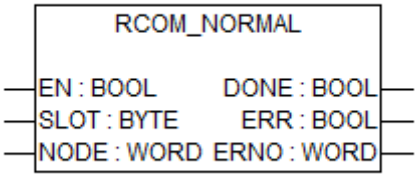
Data type	Default value	Range	Unit
WORD	-	-	-

For RCOM slaves, output NUM_EVENTS indicates the number of events stored in the event queue. For the RCOM master, NUM_EVENTS is always zero.

Function call in ST

```
RCOMInit(
EN := RCOMInit_EN,
SLOT := RCOMInit_SLOT);
RCOMInit_DONE := RCOMInit.DONE;
RCOMInit_ERR := RCOMInit.ERR;
RCOMInit_ERNO := RCOMInit.ERNO;
RCOMInit_NUM_CYCLES := RCOMInit.NUM_CYCLES;
RCOMInit_NEWTIME := RCOMInit.NEWTIME;
RCOMInit_HOUR_ACT := RCOMInit.HOUR_ACT;
RCOMInit_MIN_ACT := RCOMInit.MIN_ACT;
RCOMInit_SEC_ACT := RCOMInit.SEC_ACT;
RCOMInit_NUM_EVENTS := RCOMInit.NUM_EVENTS;
```

RCOM_NORMAL

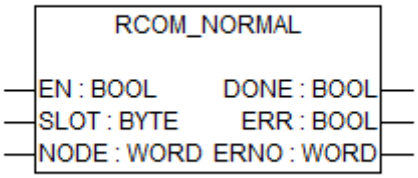


Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

This function block performs a normalization at the called slave and thus enables the transmission of data records.

This function block has to be processed each time after switching on and after a cold start or a warm start.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

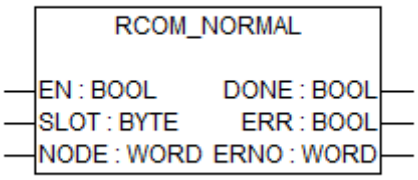
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

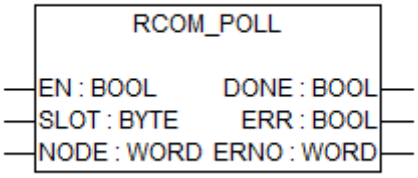
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RCOMNormal(
     EN := RCOMNormal_EN,
     SLOT := RCOMNormal_SLOT,
     NODE := RCOMNormal_NODE);
RCOMNormal_DONE := RCOMNormal.DONE;
RCOMNormal_ERR  := RCOMNormal.ERR;
RCOMNormal_ERNO := RCOMNormal.ERNO;
```

RCOM_POLL

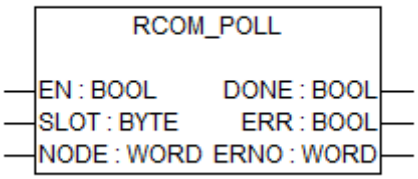


Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

This function block performs event polling on the called slave, i.e. the slave is asked whether it wants to transfer data records to the master.

The data records returned by the slave appear in the master in a correspondingly configured here *Chapter 1.5.4.30.1.10 “RCOM_REC” on page 1927* function block.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

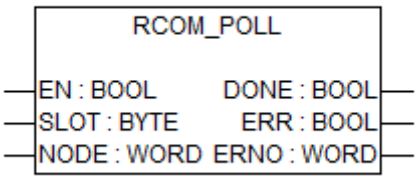
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

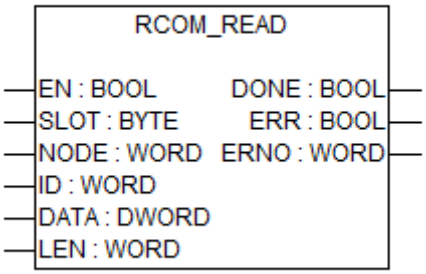
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RCOMPoll(
     EN := RCOMPoll_EN,
     SLOT := RCOMPoll_SLOT,
     NODE := RCOMPoll_NODE);
RCOMPoll_DONE := RCOMPoll.DONE;
RCOMPoll_ERR  := RCOMPoll.ERR;
RCOMPoll_ERNO := RCOMPoll.ERNO;
```

RCOM_READ



Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

The function block reads data from an RCOM slave. For this, a READ job is sent to the communication partner via the CM574-RCOM communication module. As a result, the communication partner returns an acknowledgement including the data.

The data received from the slave are stored in a flag area specified at input DATA.

Data transmission (i.e. reading data) using the RCOM_READ function block is only possible, if the CM574-RCOM communication module has been initialized (RCOM function block) and if normalization has been performed previously.

Once a job is started (FALSE/TRUE edge at input EN), the data at the inputs NODE, ID, DATA and LEN must not be changed until the job is completed (i.e. until DONE = TRUE).

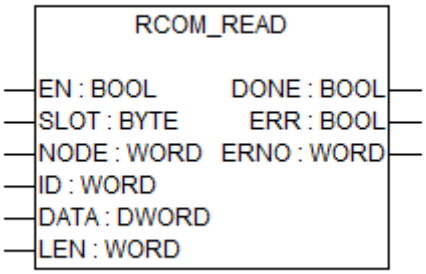
With each FALSE/TRUE edge at input EN the reading operation is performed once.

Further FALSE/TRUE edges at input EN are ignored until the reading operation is completed. The outputs DONE, ERR and ERNO are set when reading is completed.

Input NODE specifies the RCOM subscriber providing the data to be read. Input ID specifies the data record number within this subscriber and input LEN specifies the number of words to be transmitted.

If DONE = TRUE and ERR = FALSE, the reading operation could be completed successfully. If DONE = TRUE and ERR = TRUE, an error occurred and the error number is indicated at output ERNO. The outputs DONE, ERR and ERNO are reset with each falling edge at input EN.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

ID

Data type	Default value	Range	Unit
WORD	-	-	-

Input ID specifies the number of the data record to be read.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

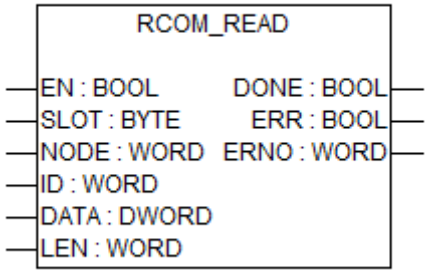
Input DATA specifies the first flag of the flag area where the data should be stored.

LEN

Data type	Default value	Range	Unit
WORD	-	-	-

Input LEN specifies the number of words to be read (has to be even-numbered).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

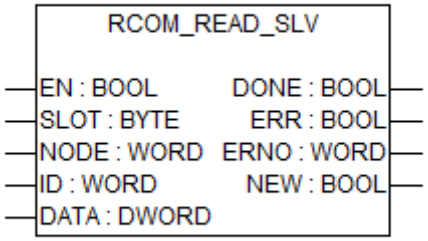
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RCOMRead(
EN := RCOMRead_EN,
SLOT := RCOMRead_SLOT,
NODE := RCOMRead_NODE,
IDT := RCOMRead_IDT,
DATA := ADR(RCOMRead_DATA),
LEN := RCOMRead_LEN);
RCOMRead_DONE := RCOMRead.DONE;
RCOMRead_ERR  := RCOMRead.ERR;
```

```
RCOMRead_ERNO := RCOMRead.ERNO;
```

RCOM_READ_SLV



Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

This function block provides the data to be read by the master using an RCOM_READ function block.

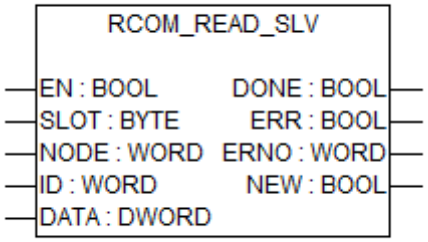
The data are provided to the Communication Module with an incoming READ job for the specified flag area.

If EN = FALSE or if the slave has not been normalized before, the function block rejects reading jobs (answer: ‘application part not ready’).

The data record number must match the number in the RCOM_READ function block.

The sender of the reading job is specified at input NODE. Because only the master of an RCOM network can send reading jobs, input NODE always has to be zero.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

ID

Data type	Default value	Range	Unit
WORD	-	-	-

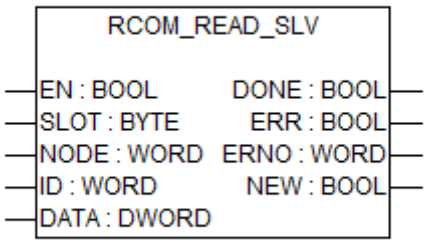
Input ID specifies the number of the data record to be read.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA specifies the first flag of the flag area where the data should be stored.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NEW

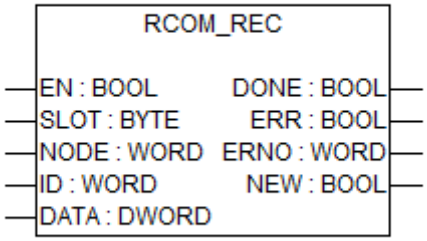
Data type	Default value	Range	Unit
BOOL	-	-	-

Output NEW is set to TRUE, if the master has read the requested data record. This way, the PLC is able to detect the reception of data by the master. Output NEW is reset during the next PLC cycle.

Function call in ST

```
RCOMReadSlv(
     EN := RCOMReadSlv_EN,
     SLOT := RCOMReadSlv_SLOT,
     NODE := RCOMReadSlv_NODE,
     IDT := RCOMReadSlv_IDT,
     DATA := ADR(RCOMReadSlv_DATA));
RCOMReadSlv_DONE := RCOMReadSlv.DONE;
RCOMReadSlv_ERR  := RCOMReadSlv.ERR;
RCOMReadSlv_ERNO := RCOMReadSlv.ERNO;
RCOMReadSlv_NEW  := RCOMReadSlv.NEW;
```

RCOM_REC



Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

This function block is used to receive the data records transmitted using the RCOM_TRANSMIT function block.

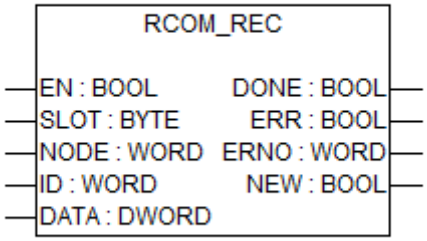
Output NEW is TRUE for one PLC cycle, if new data are available for the called data record. After this, the new data are stored to the specified flag area.

The data record number (ID) must match the number in the RCOM_TRANSMIT function block.

If EN = FALSE or if the slave has not been normalized before, the function block rejects writing requests (answer ‘application part not ready’).

The sender of the writing job is specified at input NODE. Data records for a slave are always sent by the master, therefore input NODE hast to be zero. Data records for the master (events) can be sent by different slaves, therefore input NODE has to be specified here. This enables the CM574-RCOM in the master to distribute data records correctly.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

ID

Data type	Default value	Range	Unit
WORD	-	-	-

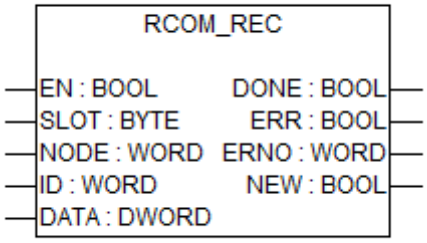
Input ID specifies the number of the data record to be read.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

Input DATA specifies the first flag of the flag area where the data should be stored.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NEW

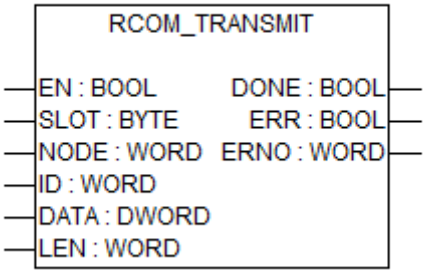
Data type	Default value	Range	Unit
BOOL	-	-	-

Output NEW is set to TRUE, if the master has read the requested data record. This way, the PLC is able to detect the reception of data by the master. Output NEW is reset during the next PLC cycle.

Function call in ST

```
RCOMRec(
     EN := RCOMRec_EN,
     SLOT := RCOMRec_SLOT,
     NODE := RCOMRec_NODE,
     ID := RCOMRec_ID,
     DATA := ADR(RCOMRec_DATA));
RCOMRec_DONE := RCOMRec.DONE;
RCOMRec_ERR  := RCOMRec.ERR;
RCOMRec_ERNO := RCOMRec.ERNO;
RCOMRec_NEW  := RCOMRec.NEW;
```

RCOM_TRANSMIT



Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

This function block transmits a data record to an RCOM communication partner.

If used in an RCOM master, a send job including the user data is sent to the called slave. As a result, the slave sends an acknowledgement.

If the function block is used in a slave, the data record is transferred to the event queue and transmitted to the master with the next event poll.

At the receiver, the transmitted data appear at an accordingly programmed RCOM_REC function block.

Once a job has been started (FALSE/TRUE edge at input EN), the data at the inputs NODE, ID, LEN and DATA must not be changed until the job is completed (DONE = TRUE).

Data transmission using the RCOM_TRANSMIT function block is only possible, if the CM574-RCOM has been initialized (RCOM function block) and if normalization has been performed previously.

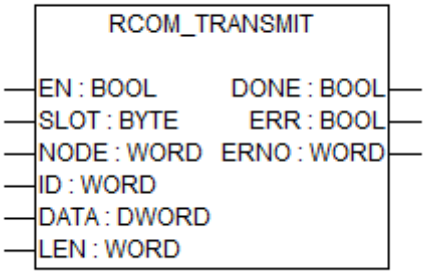
With each FALSE/TRUE edge at input EN, transmission is performed once. With this edge, the outputs DONE, ERR and ERNO are also set to zero.

Further FALSE/TRUE edges at input EN are ignored until transmission is completed (i.e. until DONE = TRUE). When transmission is completed, the outputs DONE, ERR and ERNO are set. DONE, ERR and ERNO are reset with a falling edge at input EN.

Input NODE specifies the RCOM subscriber that should receive the data. ID specifies the data record number within this subscriber, LEN has to be even-numbered and specifies the number of transmitted words. If the function block is used in a slave (event transmission), NODE has to be set to zero. LEN can be max. 14, because the timing mark is stored in addition to the user data.

Transmission was successful, if DONE = TRUE and ERR = FALSE. If DONE = TRUE and ERR = TRUE, an error occurred and the error type is indicated at output ERNO.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

ID

Data type	Default value	Range	Unit
WORD	-	-	-

Input ID specifies the number of the data record to be read.

DATA

Data type	Default value	Range	Unit
DWORD	-	-	-

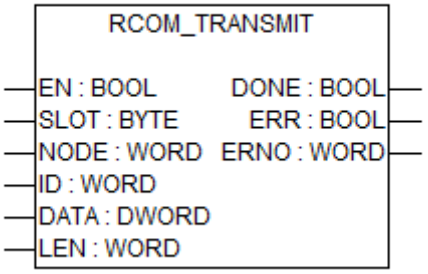
Input DATA specifies the first flag of the flag area where the data should be stored.

LEN

Data type	Default value	Range	Unit
WORD	-	-	-

Input LEN specifies the number of words to be read (has to be even-numbered).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

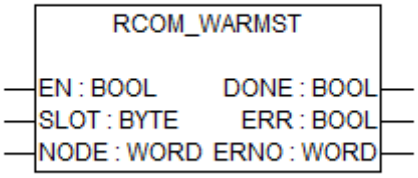
Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RCOMTransmit(
EN := RCOMTransmit_EN,
SLOT := RCOMTransmit_SLOT,
NODE := RCOMTransmit_NODE,
ID := RCOMTransmit_ID,
DATA := ADR(RCOMTransmit_DATA),
LEN := RCOMTransmit_LEN);
RCOMTransmit_DONE := RCOMTransmit.DONE;
RCOMTransmit_ERR := RCOMTransmit.ERR;
RCOMTransmit_ERNO := RCOMTransmit.ERNO;
```

RCOM_WARMST



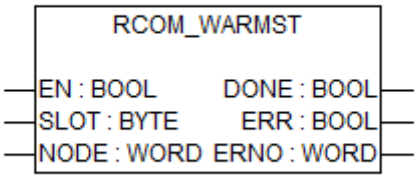
Parameter	Value
Included in library	RCOM_AC500_V13.lib
Available as of firmware	V1.3.1
Type	Function block with historical values
Group	RCOM/RCOM+ communication

This function block performs a warm start of the called slave. This deletes the event queue and disables the transmission of data records.

The function block can be used to resume communication, e.g. after a transmission error.

After a warm start, always a normalization has to be performed.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in edge triggered mode.

The execution of the function block is started with a positive edge on the input EN.

In the first call it evaluates its inputs and creates a local copy of them. Afterwards it starts its internal algorithm. It may take several PLC task cycles until it is executed.

Once the execution is completed DONE and its other outputs are set. To start the function block again a new positive edge on the input EN has to be applied.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

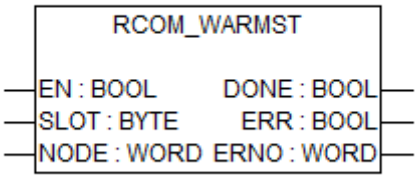
The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

NODE

Data type	Default value	Range	Unit
WORD	-	-	-

Input NODE specifies the number of the slave. The value 255 sets all slaves to the same time (all slaves are called).

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

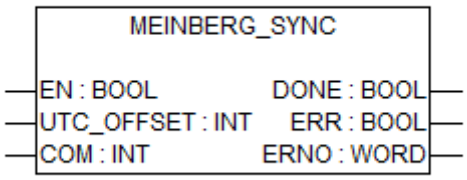
```
RCOMWarmst(
     EN := RCOMWarmst_EN,
     SLOT := RCOMWarmst_SLOT,
     NODE := RCOMWarmst_NODE);
RCOMWarmst_DONE := RCOMWarmst.DONE;
RCOMWarmst_ERR  := RCOMWarmst.ERR;
RCOMWarmst_ERNO := RCOMWarmst.ERNO;
```

1.5.4.31 RTC library

Library file name: **RTC_AC500_Vx.lib**

1.5.4.31.1 Function blocks

MEINBERG_SYNC



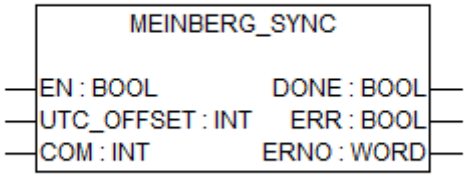
Parameter	Value
Included in library	RTC_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Radio clock

The function block MEINBERG_SYNC reads a telegram out off the Meinberg Radio Clock. The connection of Meinberg Radio Clock to an AC500 PLC is done via RS-232 interface (COM 1 or COM 2) and ASCII Protocol. The AC500 time management receives this telegram and disassembles the telegram.

The function block MEINBERG_SYNC will adjust the current time to the time received from the Meinberg Radio Clock.

MEINBERG_SYNC is called cyclic in users application.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

UTC_OFFSET

Data type	Default value	Range	Unit
INT	-	-	-

If time format of Radio Clock is UTC, with UTC_OFFSET you can calculate the time in MEZ / MESZ.

The offset UTC_OFFSET is in minutes.

COM

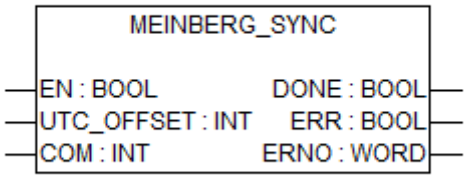
Data type	Default value	Range	Unit
INT	-	-	-

Specifies the COM-Port the real time Radio Clock is connected to:

COM:= 1 à COM-Port 1

COM:= 2 à COM-Port 2

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

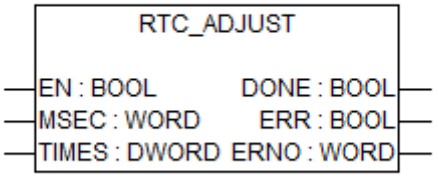
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
MEINBERG_SYNC(
EN:= Meinberg_Sync_EN,
   UTC_OFFSET:= Meinberg_Sync_UTC,
   COM:= Meinberg_Sync_COM);

Meinberg_Sync_DONE:= Meinberg_Sync.DONE;
Meinberg_Sync_ERR:= Meinberg_Sync.ERR;
Meinberg_Sync_ERNO:= Meinberg_Sync.ERNO;
```

RTC_ADJUST

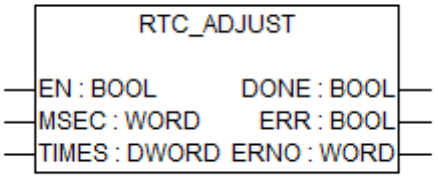


Parameter	Value
Included in library	RTC_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Real-time clock

The function block RTC_ADJUST is used to adjust the current time with the supplied time. It also evaluates the correction values for the time tick adjustment.

Adjustment will be done smoothly during the interval set by RTC_SET_ADJUST_INTERVAL. Should be called on each readout of the external time source.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

MSEC

Data type	Default value	Range	Unit
WORD	-	-	-

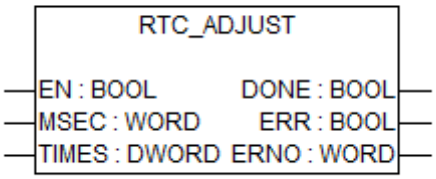
Contains the actual milliseconds within this second.

TIMES

Data type	Default value	Range	Unit
DWORD	-	-	-

Contains the actual time in seconds since 01.01.1970.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

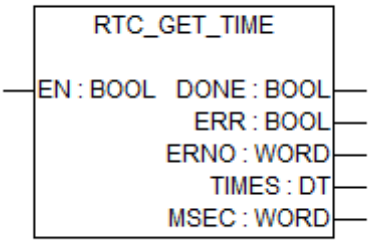
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RTC_ADJUST(EN:= RTC_Adjust_EN,
  MSEC:= RTC_Adjust_MSEC,
        TIMES:= RTC_Adjust_TIMES);

RTC_Adjust_DONE:= RTC_Adjust.DONE;
RTC_Adjust_ERR:= RTC_Adjust.ERR;
RTC_Adjust_ERNO:= RTC_Adjust.ERNO;
```

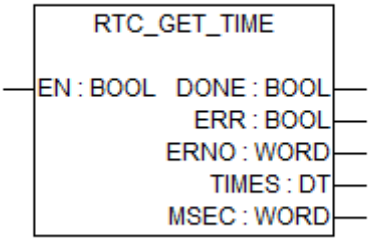
RTC_GET_TIME



Parameter	Value
Included in library	RTC_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Real-time clock

With this function block the user is able to read the actual time out of AC500. The format of time is in seconds since 01.01.1970 and a word containing the milliseconds within the current second.

Input description



EN

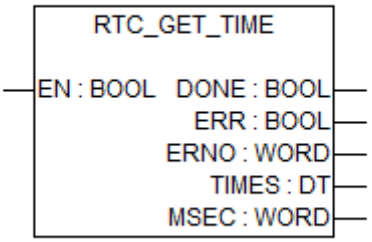
Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

TIMES

Data type	Default value	Range	Unit
DWORD	-	-	-

Contains the actual time in seconds since 01.01.1970.

MSEC

Data type	Default value	Range	Unit
WORD	-	-	-

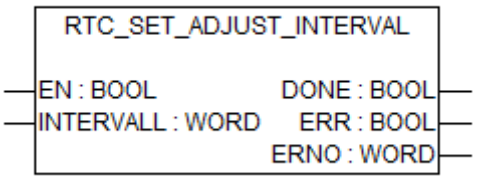
Contains the actual milliseconds within this second.

Function call in ST

```
RTC_GET_TIME(
EN:= RTC_Get_Time_EN);

RTC_Get_Time_DONE:= RTC_Get_Time.DONE;
RTC_Get_Time_ERR:= RTC_Get_Time.ERR;
RTC_Get_Time_ERNO:= RTC_Get_Time.ERNO;
RTC_Get_Time_TIMES:= RTC_Get_Time.TIMES;
RTC_Get_Time_MSEC:= RTC_Get_Time.MSEC;
```

RTC_SET_ADJUST_INTERVAL

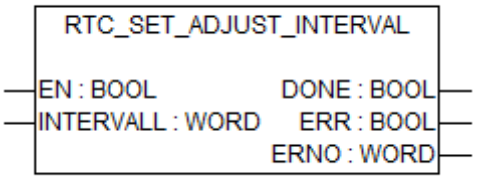


Parameter	Value
Included in library	RTC_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Real-time clock

The function block RTC_SET_ADJUST_INTERVAL is used to set the adjustment interval and calculate the maximum correction possible in that interval.

Smallest value is 2 sec. For the Meinberg real-time clock as time source a value of 60 sec is chosen.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

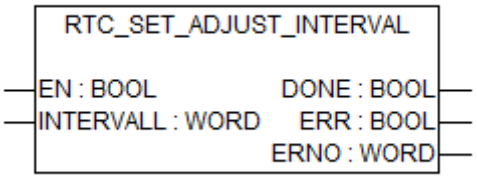
While it is executed its inputs are continuously evaluated.

INTERVALL

Data type	Default value	Range	Unit
WORD	-	-	-

Adjustment interval time in seconds.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

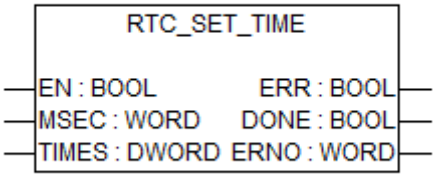
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RTC_SET_ADJUST_INTERVAL(
      EN:= RTC_Set_Adjust_Interval_EN,
      INTERVALL:= RTC_Set_Adjust_Interval_INTERVALL);

RTC_Set_Adjust_Interval_DONE:= RTC_Set_Adjust_Interval.DONE;
RTC_Set_Adjust_Interval_ERR:= RTC_Set_Adjust_Interval.ERR;
RTC_Set_Adjust_Interval_ERNO:= RTC_Set_Adjust_Interval.ERNO;
```

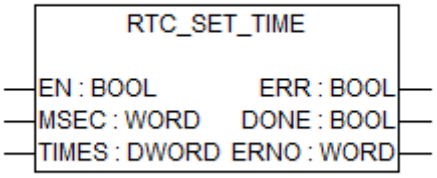
RTC_SET_TIME



Parameter	Value
Included in library	RTC_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Group/Subgroup

The function block RTC_SET_TIME is used to set the current time in AC500. The time must be supplied in seconds since 01.01.1970 and milliseconds of current second.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

MSEC

Data type	Default value	Range	Unit
WORD	-	-	-

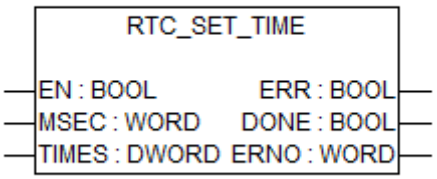
Contains the actual milliseconds within this second.

TIMES

Data type	Default value	Range	Unit
DWORD	-	-	-

Contains the actual time in seconds since 01.01.1970.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

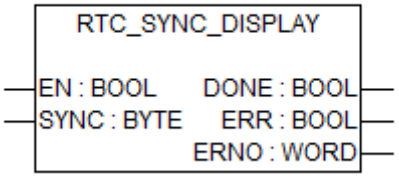
At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RTC_SET_TIME(
EN:= RTC_Set_Time_EN,
MSEC:= RTC_Set_Time_MSEC,
TIMES:= RTC_Set_Time_Times);

RTC_Set_Time_DONE:= RTC_Set_Time.DONE;
RTC_Set_Time_ERR:= RTC_Set_Time.ERR;
RTC_Set_Time_ERNO:= RTC_Set_Time.ERNO;
```

RTC_SYNC_DISPLAY

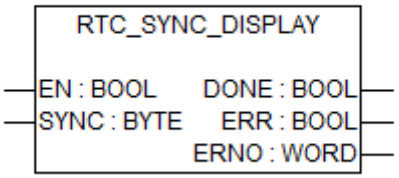


Parameter	Value
Included in library	RTC_AC500_V20.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	Real-time clock

This Funktion Block is used to inform the time management of AC500, if the source of its current time shall be the RTC of the display unit or if an external time source is used.

When using an external time source, this function block is called in the user program if the time of the external source is valid.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

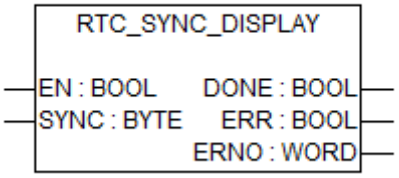
SYNC

Data type	Default value	Range	Unit
BYTE	-	-	-

0: External time source (e.g. Meinberg real-time clock) will be master.

1: RTC on the display will be master.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function call in ST

```
RTC_SYNC_DISPLAY(
 EN:= RTC_Sync_Display_EN,
 SYNC:= RTC_Sync_Display_SYNC);

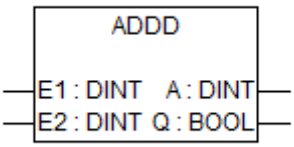
RTC_Sync_Display_DONE:= RTC_Sync_Display.DONE;
RTC_Sync_Display_ERR:= RTC_Sync_Display.ERR;
RTC_Sync_Display_ERNO:= RTC_Sync_Display.ERNO;
```

1.5.4.32 Series90 AC500 library

Library file name: **Serie90_AC500_Vx.lib**

1.5.4.32.1 Function blocks

ADDD

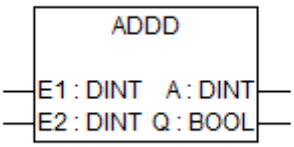


Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function block without historical values
Group	-

The value of the operand at input E1 is added to the value of the operand at input E2 and the result is assigned to the operand at output A.

The result is limited to the maximum or minimum value of the number range (-2147483647 … 2147483647). If limiting occurred, a TRUE signal is assigned to the binary operand at output Q. If no limiting occurred, a FALSE signal is assigned to the binary operand at output Q. The inputs and outputs can neither be duplicated nor negated.

Input and output description

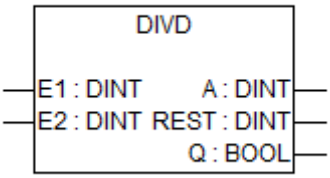


Parameter	Type	Data type	Description
E1	Input	DINT	Summand 1
E2	Input	DINT	Summand 2
A	Output	DINT	Total
Q	Output	BOOL	Total, limited

Function call in ST

```
ADDD1(E1 := ADDD_E1, E2 := ADDD_E2);
ADDD_Q:=ADDD1.Q;
ADDD_A:=ADDD1.A;
```

DIVD



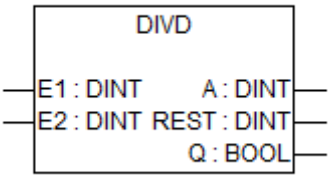
Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function block without historical values
Group	-

The value of the operand at input E1 is divided by the value of the operand at input E2 and the result is assigned to the operand at output A. The remainder is assigned to the operand at output REST. If a remainder is produced, the result will always be rounded down. If the result lies outside of the permissible number range, it will be limited to the maximum or minimum value of the number range: -2147483647 (8000 0001H) … 2147483647 (7FFF FFFFH). If a limiting has been performed, a TRUE signal is assigned to the binary operand at output Q and the value 0 is assigned to output REST. If no limiting occurred, a FALSE signal is assigned to the binary operand at output Q.

Division by »zero« is therefore also signalized at the binary output Q.

The inputs and outputs can neither be duplicated nor negated.

Input and output Description



Instance		DIVD	Instance name
E1	Input	DINT	Dividend
E2	Input	DINT	Divisor
A	Output	DINT	Result (quotient)
REST	Output	DINT	Remainder
Q	Output	BOOL	Result limited

Remainder handling

If the division results in a remainder, this is available at the double word output REST. The result of the division is always rounded down if a remainder occurs.

Example:

3 : 3 = 1 Remainder 0

4 : 3 = 1 Remainder 1

5 : 3 = 1 Remainder 2

6 : 3 = 2 Remainder 0

As the remainder is available at the output REST, the user can compare this to the divisor and can round the result at output A according to his own requirements.

Example:

Remainder > divisor/2 → round up the result at output A.

Division by »zero«

If the divisor has the value »zero«, the positive or negative limit of the number range is assigned to output A.

For the division by »zero« the following applies:

A = -2147483647 (8000 0001H) if dividend is negative

A = +2147483647 (7FFF FFFFH) if dividend is positive

REST = 0 Output for the remainder

Q = TRUE Output to signalize that the value at output A has been limited

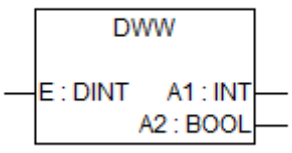
Invalid result value

If the invalid value 8000 0000H is the result of the division, this will be corrected to the permissible limit 8000 0001H (-2 147 483 647), the binary output Q will be set to the value TRUE and the output REST will be set to the value 0.

Function call in ST

```
DIVD1(E1 := DIVD_E1,E2 := DIVD_E2);
DIVD_REST:=DIVD1.REST;
DIVD_Q:=DIVD1.Q;
DIVD_A:=DIVD1.A;
```

DWW



Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function block without historical values
Group	-

The value of the double word operand at input E1 is converted to a word variable and the result is assigned to the word operand at output A1.

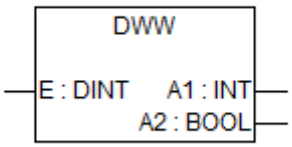
The result is limited to the maximum or minimum number range.

- max. number range: +32767 (7FFFH)
- min. number range: -32767 (8001H)

If limiting occurred, a TRUE signal is assigned to the binary operand at output A2. If no limiting occurred, a FALSE signal is assigned to the binary operand at output A2.

The input and the outputs can neither be duplicated nor negated.

Input and output description

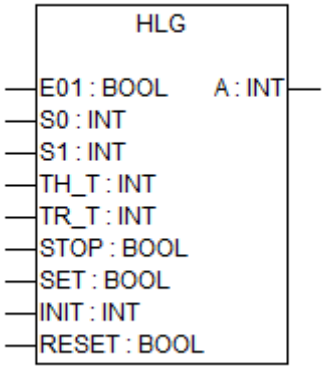


Instance		DWW	Instance name
E1	Input	DINT	Double word variable to be converted
A1	Output	INT	Result of conversion, word variable
A2	Output	BOOL	Result limited

Function call in ST

```
DWW1(E := DWW_E);
DWW_A2:=DWW1.A2;
DWW_A1:=DWW1.A1;
```

HLG



Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	-

The ramp function generator is used for the rampshaped adaption of the current actual value at the output to a specified set point.

The value at the HLG output is adapted linearly from the current actual value to the specified set point with the slope y'.

In doing so, the value at the output precisely runs through the amount of the set point during the time TH or TR. If the value at the HLG output has reached the set point, it no longer changes unless a new set point is specified.

The inputs and the output can neither be duplicated nor negated/inverted.

The slope y' of the ramp results from the specified time TH (start up time) or TR (return time) and the amount of the set point:

Slope y' =	Set point amount
	TH or TR

The slope is

- positive, if set point > actual value
- negative, if set point < actual value
- 0, if set point = 0

Therefore, the specified set point has two functions

- its amount defines the slope of the ramp in conjunction with the specified time TH or TR;
- it represents the value to which the current actual value must be adapted in a ramp shape.

The user can specify the start up time TH and the return time TR separately. The direction of the slope is defined on the basis of the set point. The direction of the slope then defines whether or not the running time TH or TR is used.

Slope y' positive → TH, i.e. the ramp runs upwards.

Slope y' negative → TR, i.e. the ramp runs downwards.

The start up time TH and the return time TR must be scaled to the program cycle time TZ, i.e. the following must be specified at the corresponding function block inputs:

- Start up time: TH/TZ
- Return time: TR/TZ

The times are specified in milliseconds. The following applies to the time constants TH or TR:

0 ≤ TH ≤ 32767

0 ≤ TR ≤ 32767

Two set points can be planned (S0 and S1), whereby one of these set points is selected by the binary input E01 (set point selection).

The set points can assume the following values:

-32767 ≤ set point ≤ +32767

At any time, the output of the ramp function generator can be

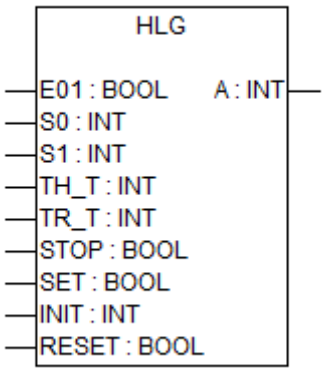
- stopped at the current value
- set to an initial value
- reset (output = 0)

The STOP input has the highest priority and the R input has the lowest.

The values at the HLG inputs can be changed at any time in the user program. In this way, any (non-linear) adaption to the set point can be realized on the basis of the linear adaption of the actual value.

> *Set point = 0 means that the slope of the ramp is also 0, i. e. the current actual value does not change. If it is intended to switch from an actual value unequal to 0 to an actual value of 0, a set point unequal to 0 must be specified and the output of the ramp function generator must be limited to 0 by a subsequent limiter. (On interpolation, the rounding transitions are based on calculation of integral numbers only).*

Input description



E01

Data type	Default value	Range	Unit
BOOL	-	-	-

One of the two set points is selected with input E01.

E01 = FALSE → set point S0

E01 = TRUE → set point S1

S0

Data type	Default value	Range	Unit
INT	-	-	-

The set point 0 is specified at input S0.

S1

Data type	Default value	Range	Unit
INT	-	-	-

The set point 1 is specified at input S1.

TH_T

Data type	Default value	Range	Unit
INT	-	-	-

The start up time is specified at input TH_T. At the same time, the start up time TH must be scaled to the cycle time T.

TR_T

Data type	Default value	Range	Unit
INT	-	-	-

STOP

Data type	Default value	Range	Unit
BOOL	-	-	-

The output can be latched to the current value by means of the STOP input.

STOP = FALSE → Output not latched

STOP = TRUE → Output is latched

The STOP input has higher priority than the inputs S and R.

S

Data type	Default value	Range	Unit
BOOL	-	-	-

INIT

Data type	Default value	Range	Unit
INT	-	-	-

The initial value to which the output is to be set if required is specified at input INIT.

R

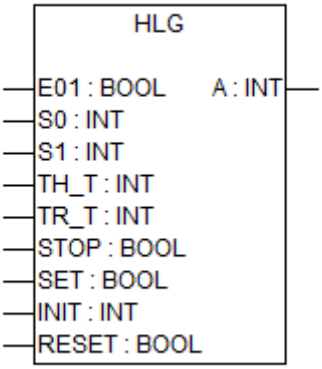
Data type	Default value	Range	Unit
BOOL	-	-	-

The output can be set to the value 0 with the input R.

R = FALSE → Output is not reset

R = TRUE → Output is reset to value 0.

Output description



A

Data type	Default value	Range	Unit
BOOL	-	-	-

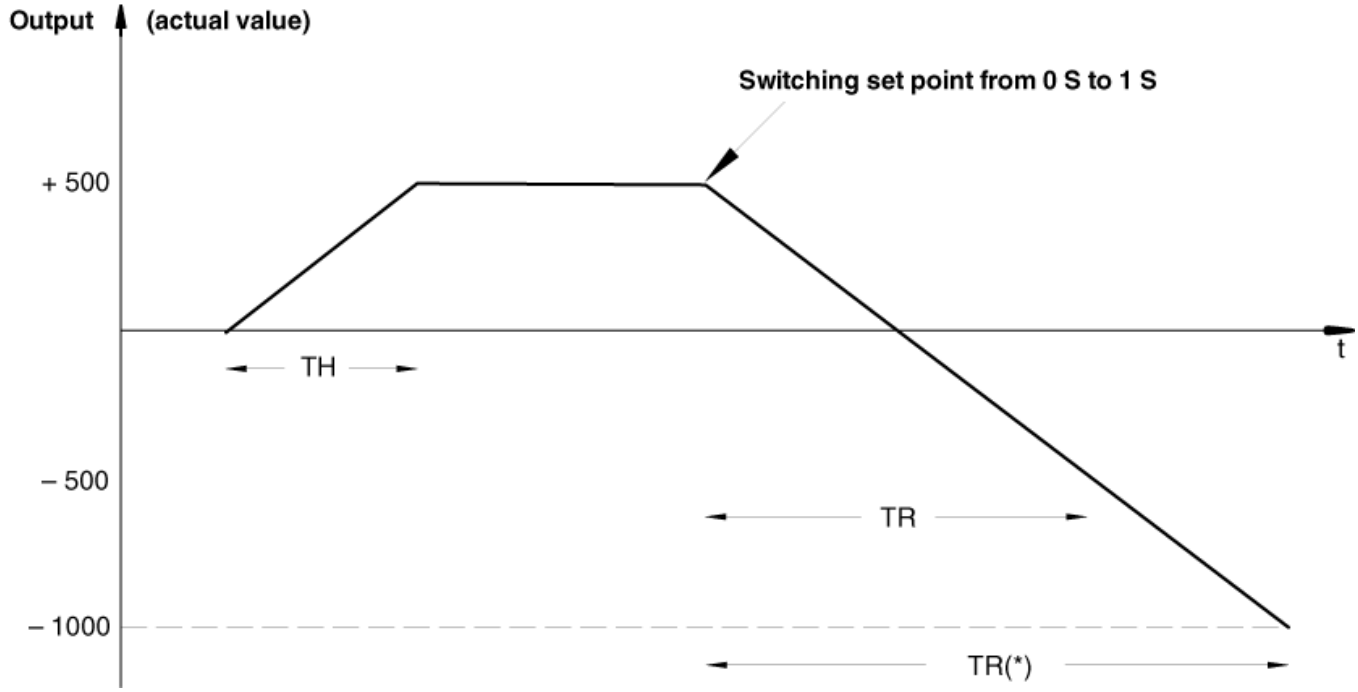
Output of the function block.

Example 1

The actual value is to be changed from 0 to the set point +500 (set point amount 500) and then from +500 to the set point -1000 (set point amount 1000).

The start up time is TH and the return time TR.

0 S: 500 1 S: -1000



TR(*) is the actual time until the actual value has reached -1000. During the time TH or TR, the actual value changes by the amount of the applied set point.

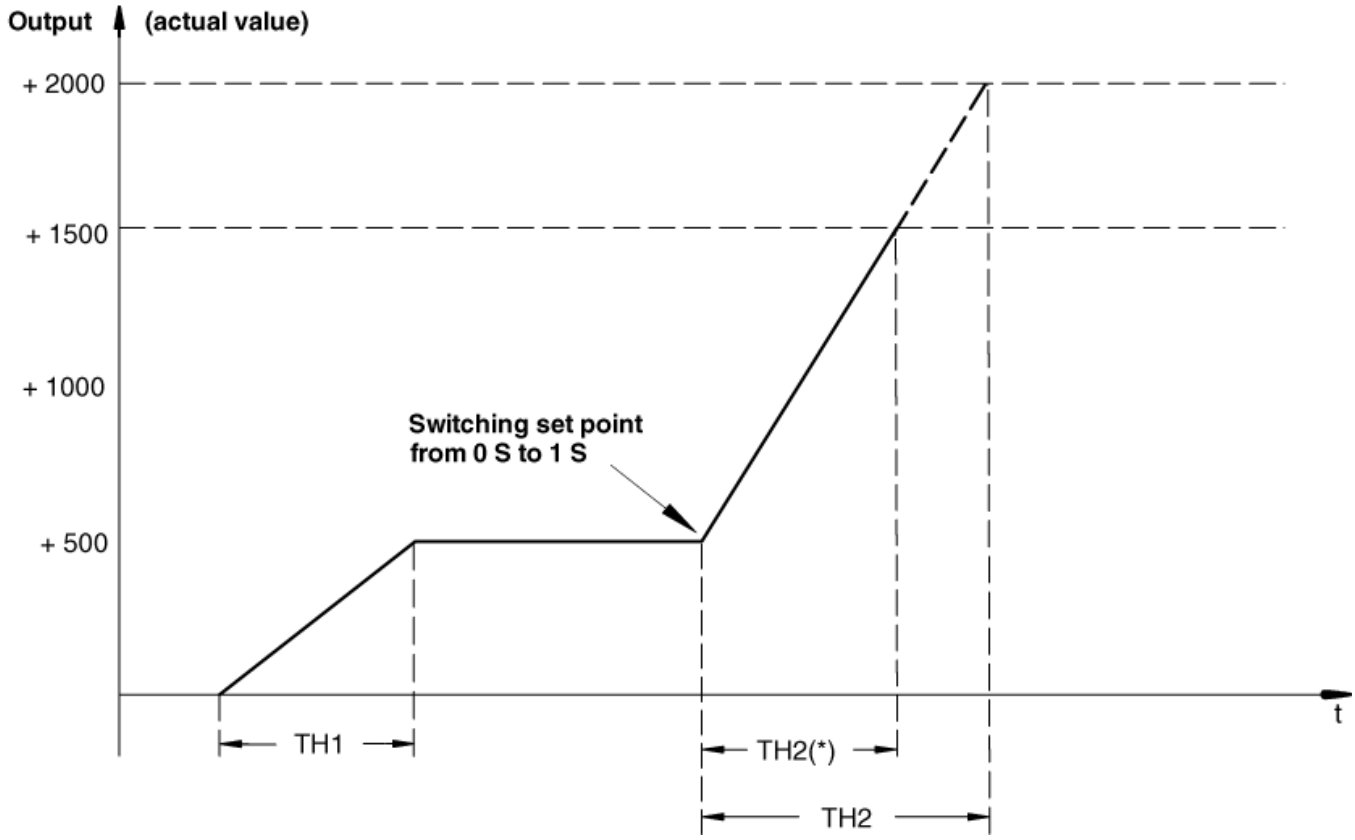
Example 2

The actual value is to be changed from 0 to the set point +500 (set point amount 500) and then from +500 to the set point 1500 (set point amount 1500).

The start up time is TH and the return time TR.

0 S: 500

1 S: 1500

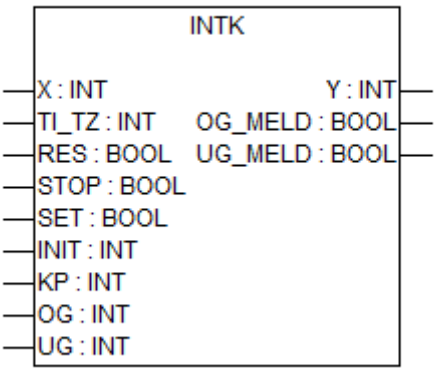


TR(*) is the actual time until the actual value has reached 1500. During the time TH or TR, the actual value changes by the amount of the applied set point.

Function call in ST

```
HLG1(E01   := HLG_E01,
S1    := HLG_S1,S0    := HLG_S0,
TH_T  := HLG_THT,
TR_T  := HLG_TRT,
STOP  := HLG_STOP,
SET   := HLG_SET,
INIT  := HLG_INIT,
RESET := HLG_RES);
HLG_A    :=    HLG1.A;
```

INTK



Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values
Group	-

The function block generates the integral of the controlled variable X multiplied by the coefficient of proportionality KP. The integrator output Y can be manipulated as follows:

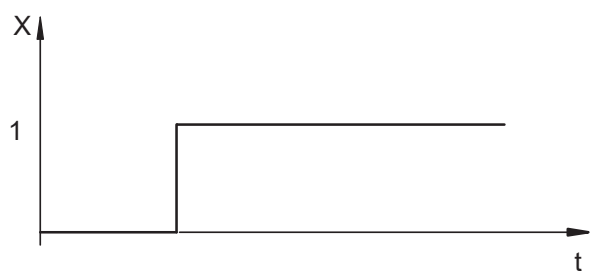
- It can be set to the value 0 by a 1 signal at input RES (reset).
- It can be latched to a current value by a TRUE signal at input STOP.
- It can be set to the initial value at input INIT by a TRUE signal at input SET.
- It can be limited to a maximum value specified at input OG (high limit).
- It can be limited to a minimum value specified at input UG (low limit).

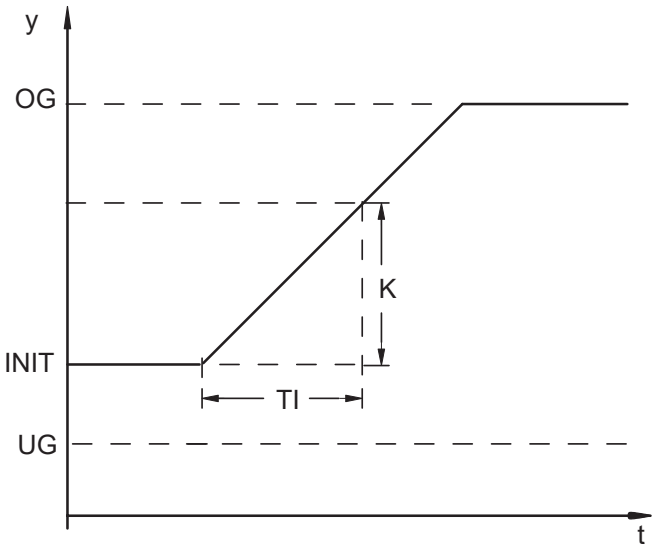
The inputs and outputs can neither be duplicated nor negated/inverted.

Transfer function

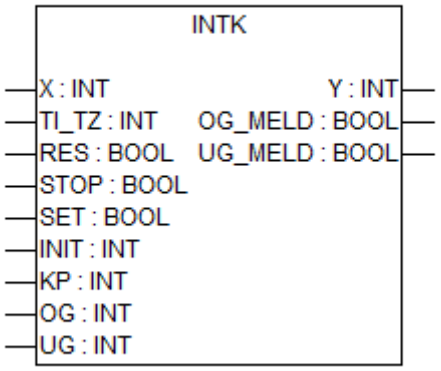
$$F(s) = \frac{KP}{s * T}$$

Transient function:





Input description



X

Data type	Default value	Range	Unit
INT	-	-	-

The operand for the controlled variable is specified at input X.

T1_TZ

Data type	Default value	Range	Unit
INT	-	-	-

The integration time is specified at input T1_TZ. In this case, it must be scaled to the cycle time. During the time T1, the output Y of the integrator changes by the value KP * X.

Range of values: 0 ≤ T1_TZ ≤ 328

- If values are specified which are beyond the admissible range of values, the PLC generally uses the value 328.
- A large integration time (T1) can be achieved by choosing a large cycle time, too. If the function block is used within a run number block, the cycle time of the run number block is valid for INTK and not the cycle time of the PLC program.

RES

Data type	Default value	Range	Unit
BOOL	-	-	-

The output Y can be reset to the value 0 with the input RES. Integration then begins as from the value 0.

STOP

Data type	Default value	Range	Unit
BOOL	-	-	-

The output can be latched to the current value by means of the STOP input.

STOP = FALSE → Output not latched

STOP = TRUE → Output is latched

The STOP input has higher priority than the inputs S and R.

SET

Data type	Default value	Range	Unit
BOOL	-	-	-

With the input SET, the manipulated value Y can be set to the initial value at input INIT. Integration then begins as from the initial value.

SET = FALSE

→ No setting

SET = TRUE

→ Output Y is set to the specified initial value.

*) Priority sequence for the inputs STOP, SET and RES:

RES highest priority

STOP

SET lowest priority

INIT

Data type	Default value	Range	Unit
INT	-	-	-

The initial value to which the output is to be set if required is specified at input INIT.

KP

Data type	Default value	Range	Unit
INT	-	-	-

The coefficient of proportionality is specified at input KP. It serves to weight the controlled variable at input X. Weighting is achieved by multiplying the controlled variable by the coefficient of proportionality. The coefficient of proportionality is specified as a percentage.

Example:

KP	is equal to	Description
1	1 percent	The function block multiplies the value at input X by the factor 0.01
55	55 percent	The function block multiplies the value at input X by the factor 0.55
100	100 percent	The function block multiplies the value at input X by the factor 1
1000	1000 percent	The function block multiplies the value at input X by the factor 10
-100	-100 percent	The function block multiplies the value at input X by the factor -1

OG

Data type	Default value	Range	Unit
INT			

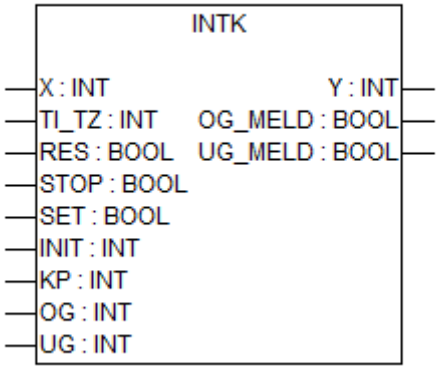
The manipulated variable Y can be limited to a range of values. The high limit for the manipulated variable Y is specified at input OG.

UG

Data type	Default value	Range	Unit
INT	-	-	-

The manipulated variable Y can be limited to a range of values. The low limit for the manipulated variable Y is specified at input UG.

Output description



OG_MELD

Data type	Default value	Range	Unit
BOOL	-	-	-

Whether the value at output Y has reached the specified high limit is signalized at output OG_MELD. Integration is stopped automatically when the limit is reached.

OG_MELD = FALSE

→ Output Y has not reached the limit (yet).

OG_MELD = TRUE

→ Output Y has reached the limit.

UG_MELD

Data type	Default value	Range	Unit
BOOL	-	-	-

Whether the value at output Y has reached the specified low limit is signalized at output UG_MELD. Integration is stopped automatically when the limit is reached.

UG_MELD = FALSE

→ Output Y has not reached the limit (yet).

UG_MELD = TRUE

→ Output Y has reached the limit.

Y

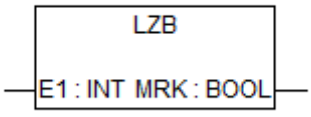
Data type	Default value	Range	Unit
INT	-	-	-

The manipulated variable (output value of the integrator) is provided at the output Y.

Function call in ST

```
INTK1(X := INTK_X, T1_TZ := INTK_T1TZ,
  RES := INTK_RES, STOP := INTK_STOP,
SET := INTK_SET, INIT := INTK_INIT,
KP := INTK_KP, OG := INTK_OG, UG := INTK_UG);
INTK_MOG := INTK1.OG_MELD;
INTK_MUG := INTK1.UG_MELD;
INTK_Y := INTK1.Y;
```

LZB

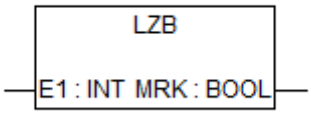


Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block with historical values
Group	-

The function block controls processing of a program part. This program part is called run number function block and begins with the function block LZB and ends with the appropriate target label specified at the function block output MRK. This program part is processed as follows depending on the value of the operand at input E1:

E1 = 0:	Program part is not processed.
E1 = 1:	Program part is processed during every cycle.
E1 = 2:	Program part is processed during every second cycle.
:	:
E1 = n:	Program part is processed during every nth cycle.

Input description



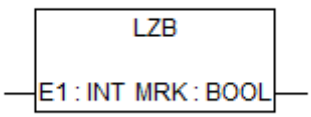
E1

Data type	Default value	Range	Unit
INT	-	-	-

This program part is processed as follows depending on the value of the operand at input E1:

E1 = 0:	Program part is not processed.
E1 = 1:	Program part is processed during every cycle.
E1 = 2:	Program part is processed during every second cycle.
:	:
E1 = n:	Program part is processed during every nth cycle.

Output description



MRK

Data type	Default value	Range	Unit
BOOL	-	-	-

At this output, a jump instruction with a corresponding jump destination must be specified. Output MRK only signalizes, whether the subsequent program part is processed or not.

The following applies:

MRK = FALSE

→ Processing of program part

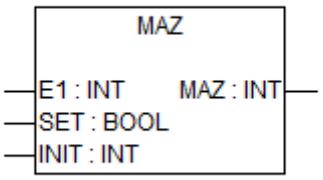
MRK = TRUE

→ No processing of program part

Function call in ST

```
LZB(E1 := LZB_E1);
IF (LZB1.MRK)
       THEN .....;
END_IF
```

MAZ



Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function block without historical values
Group	-

This function block determines the maximum value of a signal up to the current point of time by evaluating the time behavior of the signal.

The value of the operand at input E1 is compared to the previously occurred maximum value. If the input value E1 is higher than the previously occurred maximum, the input value is the new maximum value and is assigned to the operand at output MAZ.

If the input value E1 is less than the previously occurred maximum value, the previous maximum value is assigned to the output.

Output MAZ is set to the value of the operand at input INIT (initial value) with the FALSE → TRUE edge at binary input SET.

The following applies:

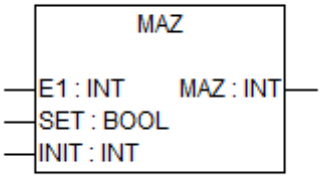
E1 < MAZ → MAZ = MAZ

E1 > MAZ → MAZ = E1

SET = FALSE→TRUE edge → MAZ = INIT

The inputs and the output can not be negated/inverted.

Input and output description



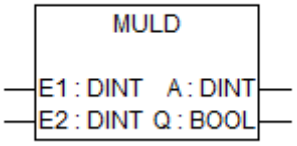
Instance		MAZ	Instance name
E1	Input	INT	Input value whose time maximum has to be determined
SET	Input	BOOL	Set input
INIT	Input	INT	Initial value
MAZ	Output	INT	Result of conversion, word variable

Function call in ST

```
IF E1 > MAZ THEN
 MAZ
   := E1; (* new max value *)
END_IF;

   IF SET
   AND NOT SET_old THEN
(* rising
   edge of input SET *)
MAZ
   := INIT; (* set INIT value *)
END_IF;
SET_old
   := SET; (* for edge detection *)
MAZ1(E1 := MAZ_E1, SET := MAZ_SET,INIT := MAZ_INIT);
MAZ_MAZ:=MAZ1.MAZ;
```

MULD



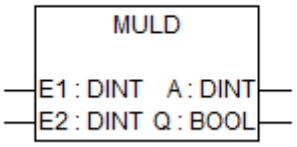
Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function block without historical values
Group	Group/Subgroup

The value of the operand at input E1 is multiplied by the value of the operand at input E2 and the result is assigned to the operand at output A.

The result is limited to the maximum or minimum value of the number range (Number range: -2147483647 … 2147483647). If limiting occurred, a TRUE signal is assigned to the binary operand at output Q. If no limiting occurred, a FALSE signal is assigned to the binary operand at output Q.

The inputs and outputs can neither be duplicated nor negated.

Input and output description

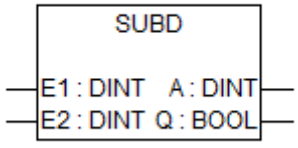


Instance		MULD	Instance name
E1	Input	DINT	Multiplicand
E2	Input	DINT	Multiplier
A	Output	DINT	Result (product)
Q	Output	BOOL	Result limited

Function call in ST

```
MULD1(E1 := MULD_E1, E2 := MULD_E2);
  MULD_Q:=MULD1.Q;
MULD_A:=MULD1.A;
```

SUBD



The value of the operand at input E2 is subtracted from the value of the operand at input E1 and the result is assigned to the operand at output A.

The result is limited to the maximum or minimum value of the number range (Number range: -2147483647 … 2147483647). If limiting occurred, a TRUE signal is assigned to the binary operand at output Q. If no limiting occurred, a FALSE signal is assigned to the binary operand at output Q.

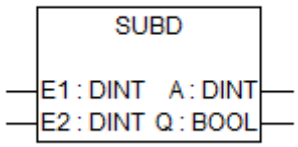
Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function block without historical values
Group	-

The value of the operand at input E2 is subtracted from the value of the operand at input E1 and the result is assigned to the operand at output A.

The result is limited to the maximum or minimum value of the number range (Number range: -2147483647 … 2147483647). If limiting occurred, a TRUE signal is assigned to the binary operand at output Q. If no limiting occurred, a FALSE signal is assigned to the binary operand at output Q.

The inputs and outputs can neither be duplicated nor negated.

Input and output description

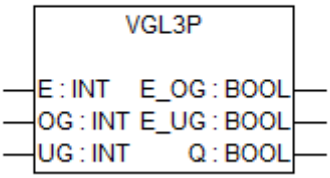


Instance		SUBD	Instance name
E1	Input	DINT	Minuend
E2	Input	DINT	Subtrahend
A	Output	DINT	Result (difference)
Q	Output	BOOL	Result limited

Function call in ST

```
SUBD1(E1 := SUBD_E1, E2 := SUBD_E2);
  SUBD_Q:=SUBD1.Q;
  SUBD_A:=SUBD1.A;
```

VGL3P



Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V1.0
Type	Function block without historical values
Group	-

The value of the operand at input E is compared to the values of the operands at the inputs OG and UG.

The possible results are signalled at the outputs E_OG, E_UG and Q.

The following applies:

E < UG

→ E_OG = FALSE, E_UG = TRUE, Q = FALSE

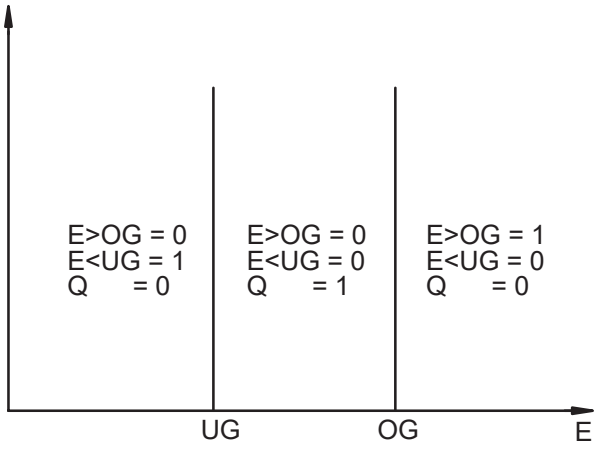
UG ≤ E ≤ OG

→ E_OG = FALSE, E_UG = FALSE, Q = TRUE

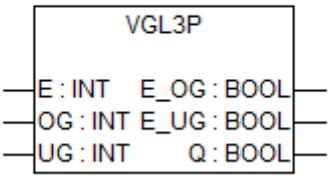
E > OG

→ E_OG = TRUE, E_UG = FALSE, Q = FALSE

The inputs and outputs can neither be duplicated nor negated/inverted.



Input and output description

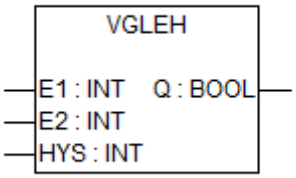


Instance		VGL3P	Instance name
E	Input	INT	Input value
OG	Input	INT	High limit
UG	Input	INT	Low limit
E_OG	Output	BOOL	Value > high limit
E_UG	Output	BOOL	Value < low limit
Q	Output	BOOL	Low limit ≤ input value ≤ high limit

Function call in ST

```
VGL3P1(E := V3P_E, OG := V3P_OG,
  UG := V3P_UG);
  V3P_EUG := VGL3P1.E_UG;
V3P_Q := VGL3P1.Q
V3P_EOG := VGL3P1.E_OG;
```

VGLEH



Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function block with historical values
Group	-

The values of the operands at the inputs E1 and E2 are compared to each other. Taking the hysteresis at input HSY into account, the result is signaled at output Q.

The following applies:

E1 ≥ E2

→ Q = 1

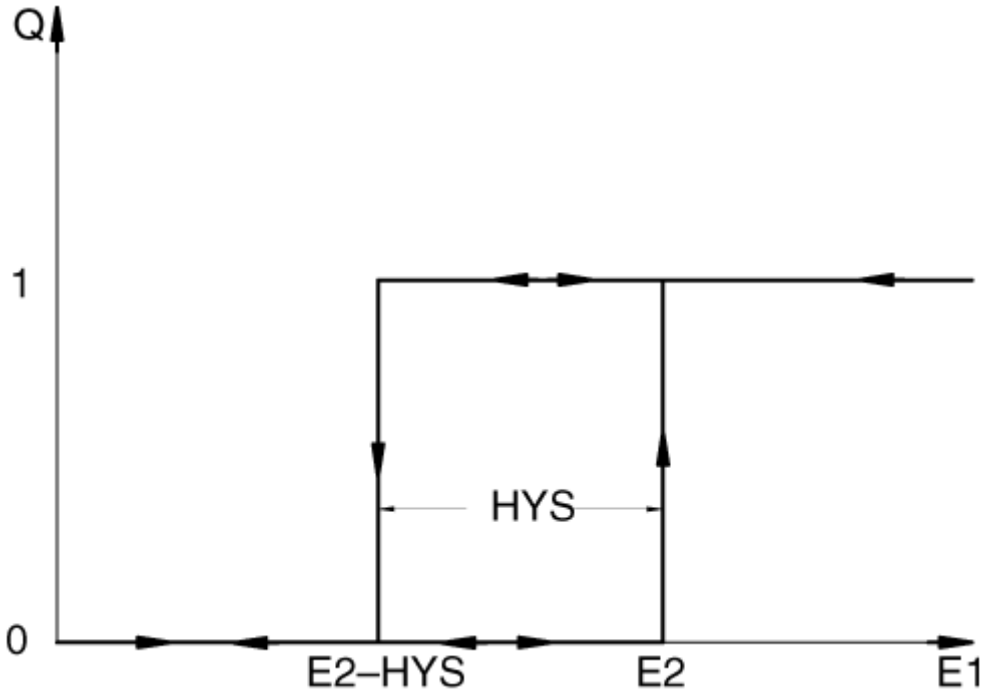
E1 < E2 "“ HYS

→ Q = FALSE

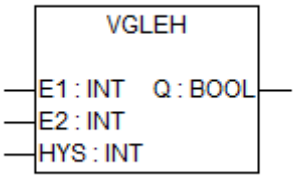
E2 - HYS ≤ E1 < E2

→ Q as in the previous cycle

The inputs can neither be duplicated nor inverted. The output can neither be duplicated nor inverted.



Input and output description



Instance		VGLEH	Instance name
E1	Input	INT	Input value 1
E2	Input	INT	Input value 2
HYS	Input	INT	Hysteresis
Q	Output	BOOL	Result of the comparison

Number range

Integer word (16 bits)

Low limit	8001H	-32767
High limit	7FFFH	+32767
Inadmissible value	8000H	---

The following especially applies here to the specification for the left edge of the hysteresis:

E2 - HYS ≥ -32767 (8001H)

In the two's complement arithmetic, the value 8000H (-32768) lies outside of the number range and is neither generated nor processed correctly by the PLC. If this forbidden value reaches the PLC

- by bit manipulations of the user or
- by reading from outside the PLC or
- by an indirect word constant

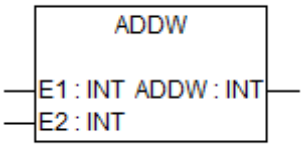
it is absolutely not allowed to carry out a negation or subtraction on this value.

Function call in ST

```
VGLEH1(E1 := VEH_E1, E2 := VEH_E2,HYS := VEH_HYS);
VEH_Q:=VGLEH1.Q;
```

1.5.4.32.2 Functions

ADDW



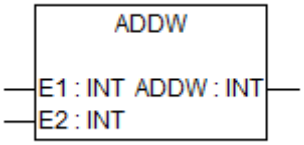
Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function
Group	-

The values of the operands at the inputs of the function are added and the result is assigned to the operand at the output.

The result is limited to the maximum value 32767 and the minimum value ""32767.

The inputs and the output can neither be duplicated nor negated.

Input and output description

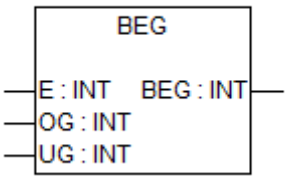


E1	Input	INT	Summand 1
E2	Input	INT	Summand 2
	Output	INT	Total

Function call in ST

```
ADDW_A:=ADDW(ADDW_E1,ADDW_E2);
```

BEG



Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function
Group	Group/Subgroup

The value of the operand at input E is limited to the range between the upper and lower limits.

The upper limit is specified by the operand at the OG input and the lower limit is specified by the one at the UG input.

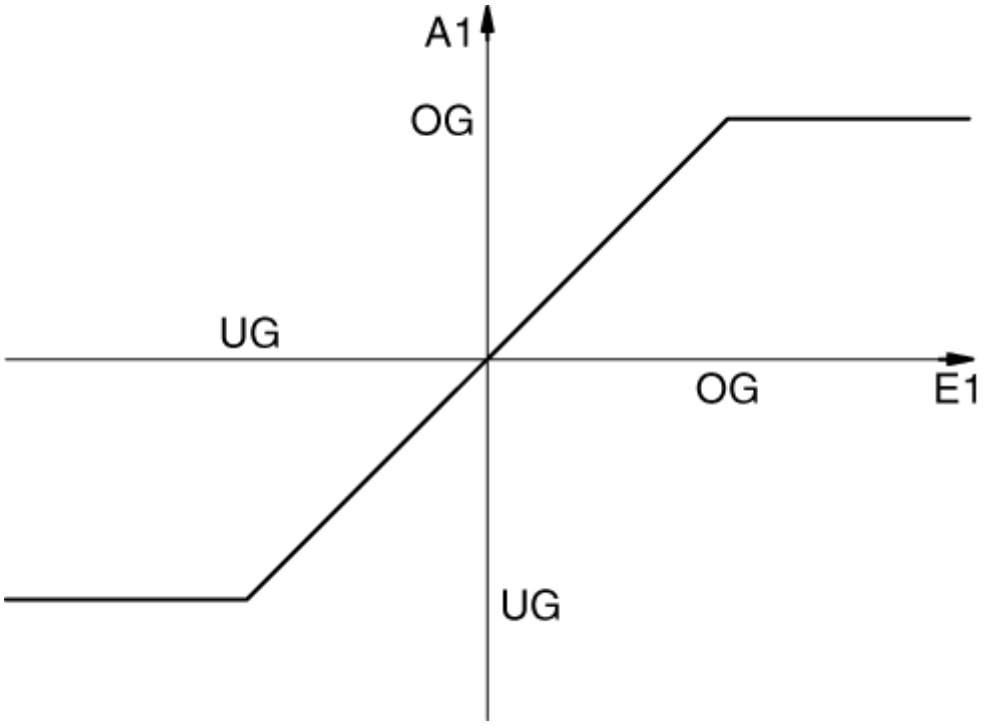
The following applies:

A = UG for E < UG

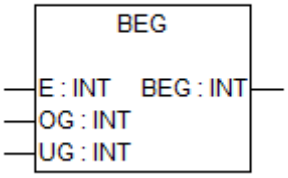
A = E for UG ≤ E ≤ OG

A = OG for E > OG

The inputs and the output can neither be duplicated nor negated.



Input and output description

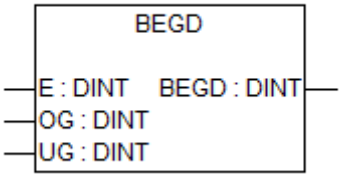


E	Input	INT	Input value
OG	Input	INT	Upper limit
UG	Input	INT	Lower limit
	Output	INT	Limited value

Function call in ST

```
BEG_A:=BEG(BEG_E, BEG_OG,BEG_UG);
```

BEGD



Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function
Group	-

The value of the operand at input E is limited to the range between the upper and lower limits.

The upper limit is specified by the operand at the OG input and the lower limit is specified by the one at the UG input.

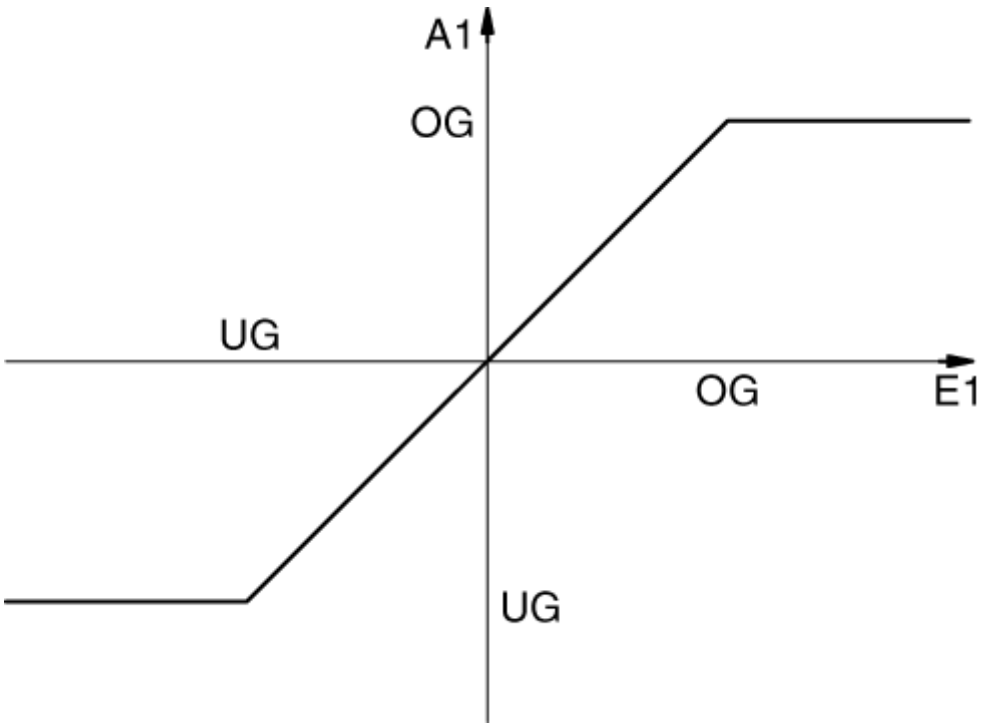
The following applies:

A = UG for E < UG

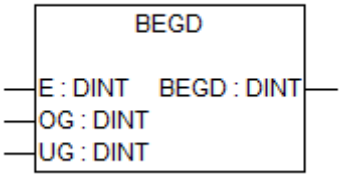
A = E for UG ≤ E ≤ OG

A = OG for E > OG

The inputs and the output can neither be duplicated nor negated.



Input and output description

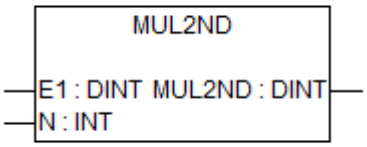


E	Input	DINT	Input value
OG	Input	DINT	Upper limit
UG	Input	DINT	Lower limit
	Output	DINT	Limited value

Function call in ST

```
BEGD_A:=BEGD(BEGD_E, BEGD_OG,BEGD_UG);
```

MUL2ND



The value of the operand at input E1 is shifted bitwise N times.

If the value at input N is positive, the value is shifted to the left. Each shift by 1 bit position corresponds to a multiplication of the current value by 2.

If the value at input N is negative, the value is shifted to the right. Each shift by 1 bit position corresponds to a division of the current value by 2.

The result is assigned to the operand at output A1.

Parameter	**Value**
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function
Group	-

The value of the operand at input E1 is shifted bitwise N times.

If the value at input N is positive, the value is shifted to the left. Each shift by 1 bit position corresponds to a multiplication of the current value by 2.

If the value at input N is negative, the value is shifted to the right. Each shift by 1 bit position corresponds to a division of the current value by 2.

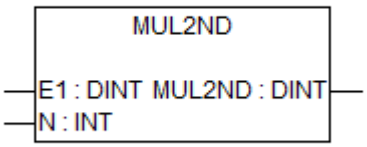
The result is assigned to the operand at output A1.

The inputs and the output can neither be duplicated nor negated.

Reasonable range for N: -30 ≤ N ≤ +30

If N = 0, the value at input E1 is passed directly to output A1.

Input and output description



E1	Input	DINT	Input operand
N	Input	INT	Quantity
	Output	DINT	Result

Sign of the value at input E1

The sign of value E1 is not influenced by the shift operation. I.e. the sign of the output value is always identical with the sign of the input value.

Shift to the left (Multiplication)

When the value at the input is shifted to the left, the released bit 0 is filled with 0. The sign bit (bit 31) is not changed because a limiting to the limit of the number range is performed before.

Limiting the value at output A1 when shifting to the left:

- The following applies to positive values at input E1: If bit 30 has a »1« and if shift operations still have to be carried out on the basis of the value at input N, these are no longer executed. Instead, the output is set to the limit of the positive number range. I.e. the limit has been reached in any case at the latest after 30 shifts.
  Limit value: Output A1 = +2147483647 (7FFFFFFFH).
- The following applies to negative values at input E1: If bit 30 has a »0« and if shift operations still have to be carried out on the basis of the value at input N, these are no longer executed. Instead, the output is set to the limit of the negative number range. I.e. the limit has been reached in any case at the latest after 30 shifts.
  Limit value: Output A1 = -2147483647 (80000001H).

Shift to the right (Division)

When shifting to the right, every bit moves to the right by one position. At the same time, the sign bit (bit 31) always retains its value. The released bit (bit 30) is filled in each case with the value of the sign bit.

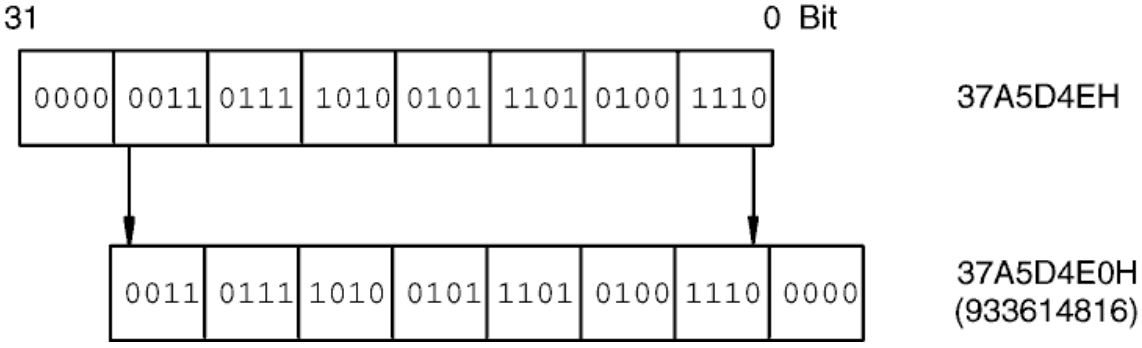
Limiting the value at the output when shifting to the right:

- The following applies to positive values at input E1: If now only bit 0 has a »1« and shift operations still have to be carried out because of the value at input N, the output will be set to the value 0. I.e. value 0 has been reached in any case at the latest after 30 shifts.
  Output A1 = 0.
- The following applies to negative values at input E1: If bit 0 ... bit 31 has a »1« as the result of the shift, the limit value (-1) has been reached. Further shifts have no effect. I.e. the value -1 has been reached at the latest at 31 shifts.
  Output A1 = -1 (FFFFFFFFH).

The inputs and the output can neither be duplicated nor negated.

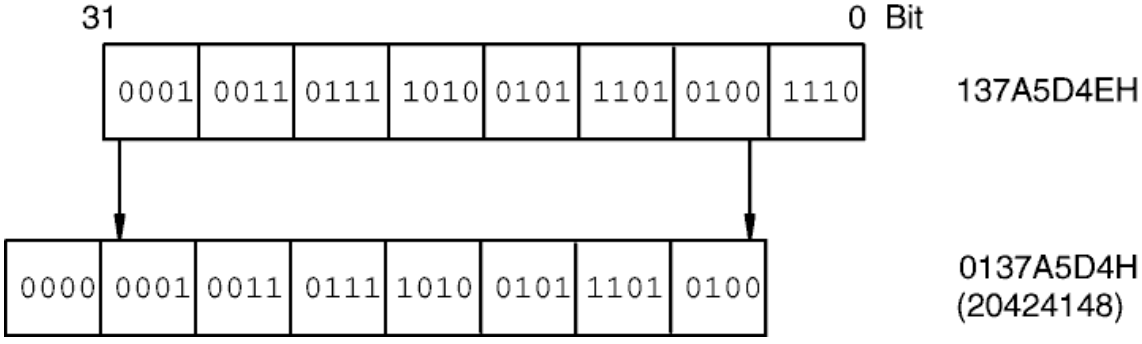
Examples

1. Input value E1 = 58350926 (37A5D4EH) Exponent N = 4 4 * Left shift



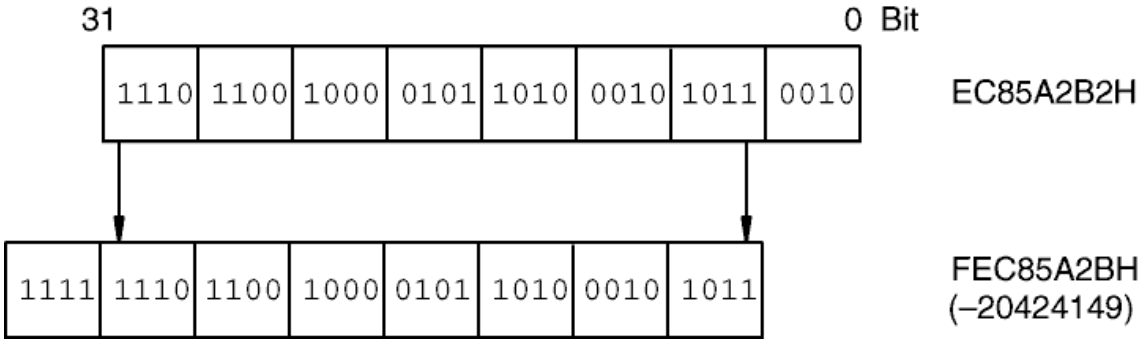
2. Input value E1 = 326786382 (137A5D4EH)

Exponent N = -4 4 * Right shift



3. Input value E1 = -326786382 (EC85A2B2H)

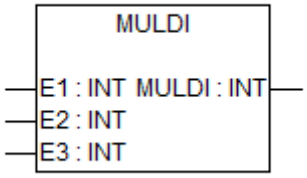
Exponent N = -4 4 * Right shift



Function call in ST

```
MUL2ND_A:=MUL2ND(MUL2ND_E1, MUL2ND_N);
```

MULDI



The operand value at input E1 is multiplied by the operand value at input E2, the intermediate result is divided by the operand value at E3 and then the result is assigned to output A.

The result is limited to the maximum or minimum value of the number range.

Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function
Group	-

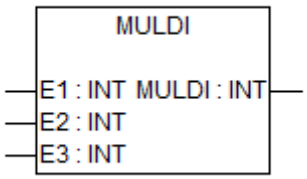
The operand value at input E1 is multiplied by the operand value at input E2, the intermediate result is divided by the operand value at E3 and then the result is assigned to output A.

Internal, the function block performs the multiplication and division with the accuracy of a double word (32 bit). Only when assigning the result to output A, the limiting to the accuracy of a word (16 bit) is carried out. If the remainder of the division is > 0,5, the result is rounded up. If a numerical overflow occurs during the division (e.g. division by zero), the correct signed limit of the number range is applied at output A.

The result is limited to the maximum value 32767 and the minimum value -32767.

The inputs and the output can neither be duplicated nor negated.

Input and output description

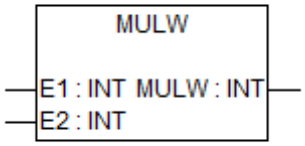


E1	Input	INT	Multiplicand
E2	Input	INT	Multiplier
E3	Input	INT	Divisor
	Output	INT	Result

Function call in ST

```
MULDI_A := MULDI(MULDI_E1, MULDI_E2,MULDI_E3);
```

MULW



The values of the operands at the inputs of the function are multiplied and the result is assigned to the operand at the output.

The result is limited to the maximum or minimum value of the number range.

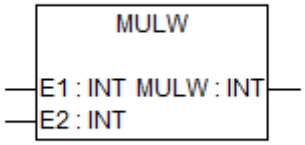
Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function
Group	-

The values of the operands at the inputs of the function are multiplied and the result is assigned to the operand at the output.

The result is limited to the maximum value 32767 and the minimum value -32767.

The inputs and the output can neither be duplicated nor negated.

Input and output description

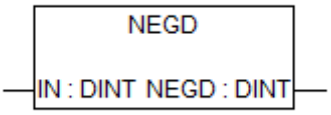


E1	Input	INT	Multiplicand
E2	Input	INT	Multiplier
	Output	INT	Result (product)

Function call in ST

```
MULW_A := MULW(MULW_E1, MULW_E2);
```

NEGD



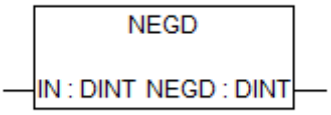
Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function
Group	-

The value of the operand at input IN is negated and the result is assigned to the operand at output A.

The result is limited to the maximum or minimum value of the number range. (Number range: -2147483647 … 2147483647).

The input and the output can neither be duplicated nor negated.

Input and output description

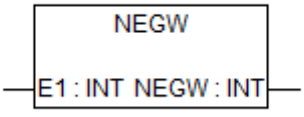


IN	Input	DINT	Input value
	Output	DINT	Negated value

Function call in ST

```
NEGD_A:=NEGD(NEGD_E1);
```

NEGW



The value of the operand at input E1 is negated and the result is assigned to the operand at output A.

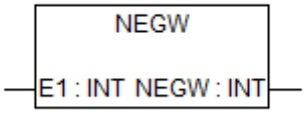
Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0
Type	Function
Group	Group/Subgroup

The value of the operand at input E1 is negated and the result is assigned to the operand at output A.

The result is limited to the maximum or minimum value of the number range. (Number range: -2147483647 … 2147483647).

The input and the output can neither be duplicated nor negated.

Input and output description

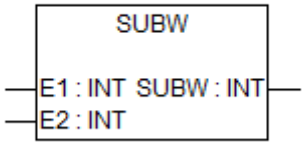


E1	Input	INT	Input value
	Output	INT	Negated value

Function call in ST

```
NEGW_A:=NEGW(NEGW_E1);
```

SUBW



The value of the operand at input E2 is subtracted from the value of the operand at input E1 and the result is assigned to the operand at output A.

Parameter	Value
Included in library	Serie90_AC500_V10.lib
Available as of firmware	V2.0

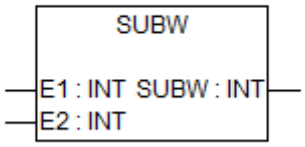
Parameter	Value
Type	Function
Group	-

The value of the operand at input E2 is subtracted from the value of the operand at input E1 and the result is assigned to the operand at output A.

The result is limited to the maximum value 32767 and the minimum value -32767.

The inputs and the output can neither be duplicated nor negated.

Input and output description



E1	Input	INT	Minuend
E2	Input	INT	Subtrahend; input can be dublicated
	Output	INT	Result (difference)

Function call in ST

```
SUBW_A:=SUBW(SUBW_E1, SUBW_E2);
```

1.5.4.33 Glossary

BOOL Variables of the type BOOL can have the values TRUE and FALSE. For this, 8 bit of memory space are reserved.

BYTE BYTE belongs to the integer data types. The different numerical types are responsible for a different numerical range.

Table 93: For integer data types the following range limits are valid:

TYPE	BYTE
Lower limit	0
Upper limit	255
Memory space	8 bits

Due to this, it is possible that information are lost when converting greater data types to smaller data types.

DINT

DINT belongs to the integer data types. The different numerical types are responsible for a different numerical range.

Table 94: For integer data types the following range limits are valid:

TYPE	DINT
Lower limit	-2147483648
Upper limit	2147483647
Memory space	32 bits

Due to this, it is possible that information are lost when converting greater data types to smaller data types.

DWORD

DWORD belongs to the integer data types. The different numerical types are responsible for a different numerical range.

Table 95: For integer data types the following range limits are valid:

TYPE	DWORD
Lower limit	0
Upper limit	4294967295
Memory space	32 bits

Due to this, it is possible that information are lost when converting greater data types to smaller data types.

Functions

Functions are subroutines which have multiple input parameters and return exactly one result element. The returned result can be of an elementary or a derived data type. Due to this, a function may also return an array, a structure, an array of structures and so on. For the same input parameters, functions always return the same result (they do not have an internal memory).

Therefore, the following rules can be derived:

- Within functions, global variables can neither be read nor written.
- Within functions, absolute operands can neither be read nor written.
- Within functions, function 'Function Blocks' must not be called.

Function blocks

Function blocks are subroutines which can have as many inputs, outputs and internal variables as required. They are called from a program or from another function block. As they can be used several times (with different data records), function blocks (code and interface) can be considered as type. When assigning an individual data record (declaration) to the function block, a function block instance is generated. In contrast to functions, function blocks can contain statically local data which are saved from one call to the next. Therefore e.g. counters can be realized which may not forget their counter value. I.e. function blockscan have an internal memory.

Functions and function blocks differ in two essential points:

- A function block has multiple output parameters, a function only one. The output parameters of functions and function blocks differ syntactically.
- In contrast to a function, a function block can have an internal memory.

INT

INT belongs to the integer data types. The different numerical types are responsible for a different numerical range.

Table 96: For integer data types the following range limits are valid:

TYPE	INT
Lower limit	-32768
Upper limit	32767
Memory space	16 bits

Due to this, it is possible that information are lost when converting greater data types to smaller data types.

WORD

WORD belongs to the integer data types. The different numerical types are responsible for a different numerical range.

Table 97: For integer data types the following range limits are valid:

TYPE	WORD
Lower limit	0
Upper limit	65535
Memory space	16 bits

Due to this, it is possible that information are lost when converting greater data types to smaller data types.

1.5.5 AC500 HA High Availability System

1.5.5.1 AC500 HA-CS31 based on serial communication

For the AC500 HA-CS31 high availability based on ABBs CS-31 Bus with serial communication (2 parallel lines) see High Availability System Technology Chapter in Automation Builder online documentation.

1.5.5.1.1 Introduction

Safety instructions

Consider the following before using the libraries:

- All pertinent state, regional, and local safety regulations must be observed when installing and using this product. When functions or devices are used for applications with technical safety requirements, the relevant instructions must be followed.
- Read the complete safety instructions of the user's manuals for the drives you are using, before installation and commissioning.
- Read all *Chapter 1.6.1.1 “Safety instructions” on page 3697* for the AC500 PLC.
- Read the user information of the devices and functions you are using, see Automation Builder online help.

Preconditions: HA-CS31 library

The library package has been released for the software and firmware versions listed in the readme file of Automation Builder only (see *“Help ➔ Automation Builder Release Notes”*) .

In no event will ABB or its representatives be liable for loss of data, profits, revenue or consequential, incidental or other damage that may result from the use of other versions of product, software or firmware versions. The error-free operation of the HA library with other devices, software or firmware versions should be possible but cannot be guaranteed and may need adaptations e.g. of example programs.

CAUTION!
Generally, the user in all applications is fully and alone responsible for checking all functions carefully, especially for safe and reliable operation.

The function blocks contained in the library can be executed only in RUN mode of the PLC, but not in simulation mode.

1.5.5.1.2 AC500 High Availability CS31 system technology

Introduction

What is the AC500 High Availability CS31 system?

The AC500 High Availability CS31 system is designed for the demand of automation systems that require a higher availability, which is realized by redundant devices and communications. The redundancy concept reduces the risk of losing production due to failure of parts of the automation system and thereby minimizes scheduled idle times. For instance, control can be taken over by the secondary station if the primary station fails.

AC500 High Availability CS31 system helps to implement redundancy based on standard AC500 PLCs:

- CPU
- Field communication
- SCADA communication

HA-CS31 system

Greater availability to the field connection is provided by redundant fieldbus (CS31) connection to CI590-CS31-HA, a redundant CS31 slave as S500 I/O module. The CI590-CS31-HA includes two CS31 slave interfaces: One is connected to the CS31 master system on station A, the other is connected to the CS31 master system on station B. Further information on the device is provided in the device description for ↬ *Chapter 1.6.2.8.3.1 “CI590-CS31-HA” on page 4745*.

Both automation systems require activated HA-CS31 function blocks to achieve that the control sequences can be switched over bumplessly, meaning they continue in the event of failures. The total application program has to be made considering high availability.

The HA-CS31 system has hot-standby redundancy as a quality level:

- Both CPUs are running in parallel
- Both CPUs are continuously synchronized
- The fieldbus is redundant and continuously running (updated by both CPUs)
- The CI590 remote I/O decides itself which CPU and route to trust (voter) which ensures very fast switch over times while keeping the process running.

When to use AC500 High Availability CS31 system?

Centralized and particularly important system components require greater levels of availability. To keep the control sequences operational in the event of a failure, the mechanism of HA-CS31 system automatically switches over to the redundant backup system.

HA-CS31 system can be used in any situation in which system components require greater levels of availability by redundancy and automatic switch over, where a brief freeze of the system can be tolerated by the process while switching from one station to another. See ↬ *Chapter 1.5.5.1.2.4.1 “Use case and reaction time” on page 2004*.

AC500 HA system can be used to manage the following types of failure:

- Failure of CPU components:
  - Failure of the power supply unit
  - Failure of the terminal base of the CPU
  - Failure of the CS31 master
  - CPU failure due to hardware or software faults
- Failure of field device connection:
  - Breaks/short circuit in the bus cable for the data link or CS31 slave interface faults on CI590-CS31-HA module
- Failure of HMI connection (if using HMI and switches):
  - Switch
  - Connection between CPU and switch
  - Connection between switch and HMI

Requirements

Hardware

The communication interface module *Chapter 1.6.2.8.3.1 “CI590-CS31-HA” on page 4745* is required.

Two AC500 CPUs are required as central hardware components. Each CPU must be equipped with an integrated Ethernet port (or Ethernet communication module) and a connection for a CS31 master system. These two CPUs, called station A and station B, are linked by means of an Ethernet bus system through which they can exchange information. Connection to the peripheral devices is performed via two CS31 master systems - one on station A and another on station B.

AC500 I/O modules on CI590-CS31-HA are connected to both CS31 master systems. The CS31 slave interface enables switching from the first to the second interface in the event of a fault, thereby enabling process status data to be passed to the peripherals by the second CS31 master.

Until version V2.3.0 (HA_CS31_AC500_V23.lib) the library supported high availability only for I/O modules connected on CPU COM1 of the CS31 bus.

Only one PLC COM CS31 bus

The following diagram represents HA-CS31 system recommendation for applications using one CPU COM CS31 Bus only.

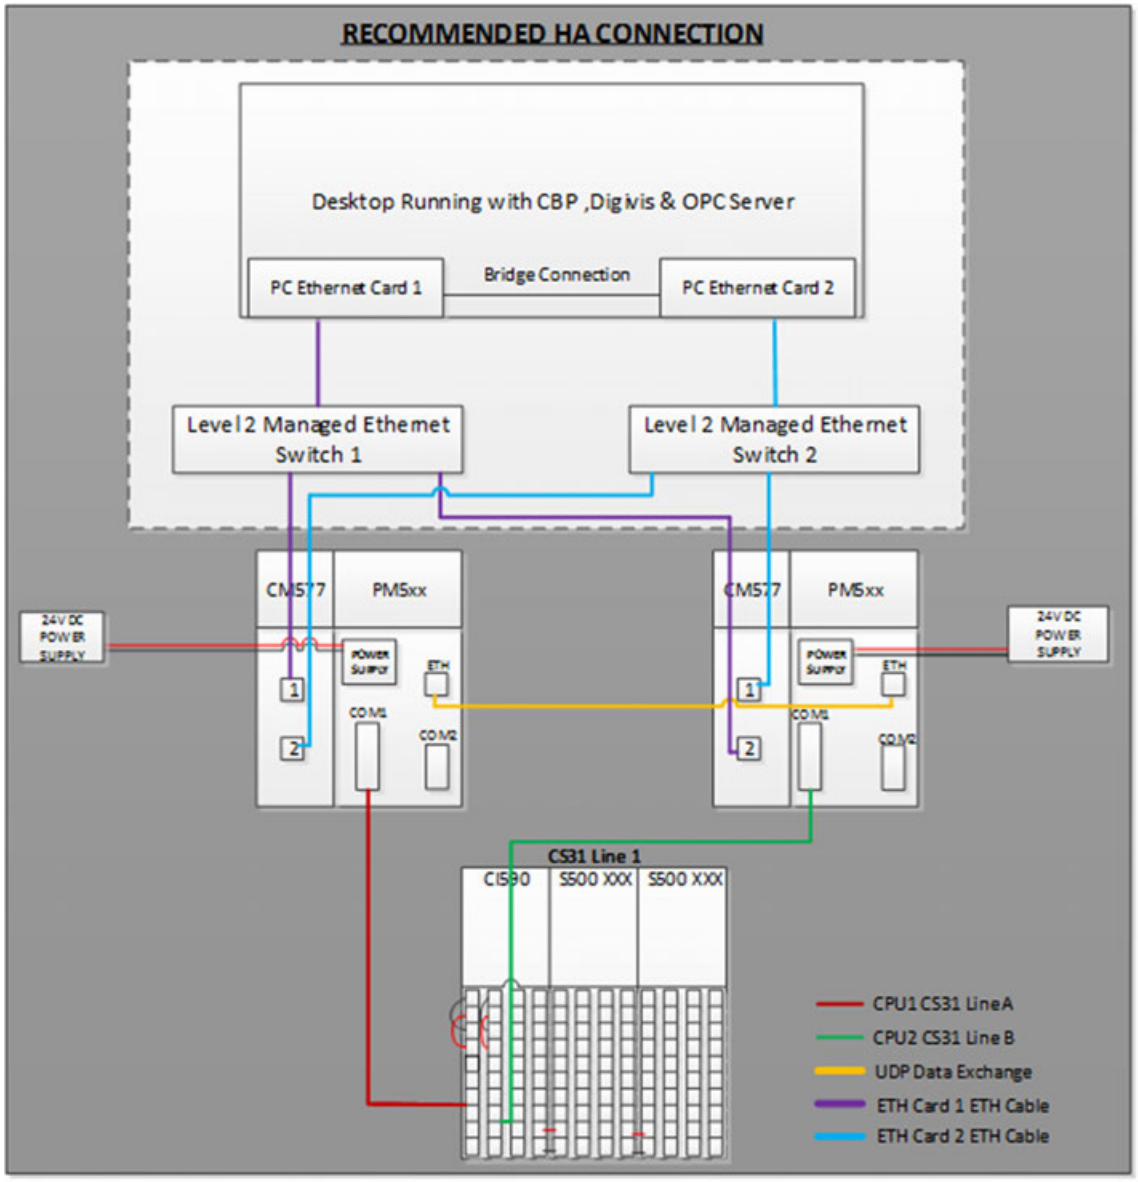


Fig. 31: Recommended high availability connection.

> *Blocks inside the doted box are not mandatory. However, if users require Ethernet redundancy with a control system/SCADA/ DigiVis 500, the customer has to use Level 2 Managed Ethernet switch.*

PLC COM CS31 bus and CM574-RS COM CS31 bus

As of HA-CS31 library version V2.4.0 (HA_CS31_AC500_V23.lib) and higher, high availability also supports the I/O modules connected on both CPU COM ports and CM574-RS COM ports.

The HA-CS31 library supports up to three CM574-RS modules and each CM574-RS supports two CS31 lines. So it supports a maximum of seven CS31 lines including CPU COM1 CS31 line.

> *PM595 supports maximum 2 CM574-RS modules. So it supports a maximum of 5 CS31 lines including CPU COM1 CS31 line.*

PM591-2 ETH and PM595 PLCs must use onboard ETH1 for UDP data communication.

The following diagram represents one CPU COM CS31 Bus and only one CM574-RS COM CS31 bus. Users can add up to three CM574-RS as per the requirements:

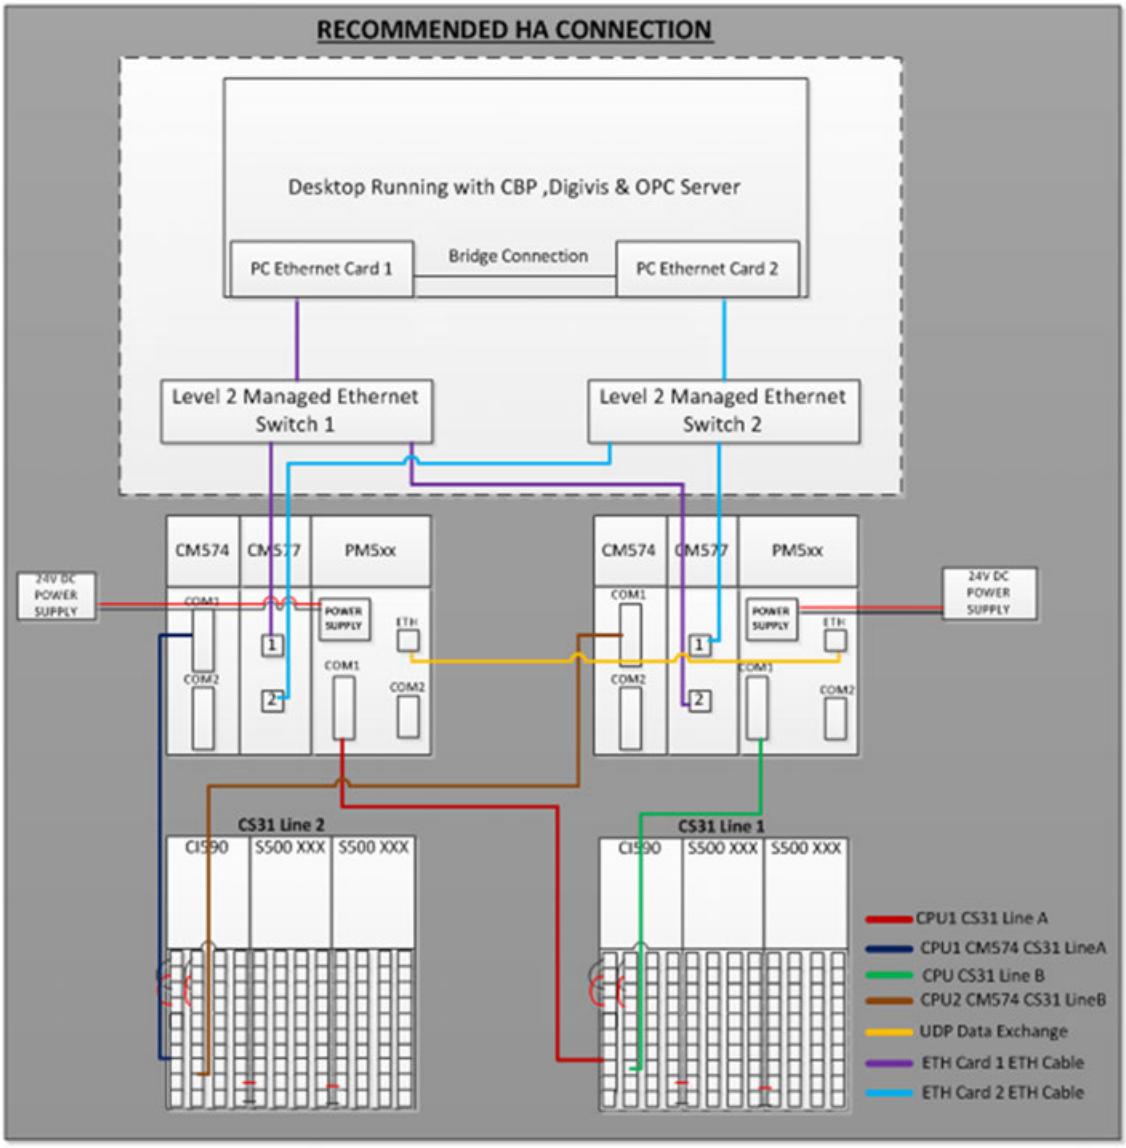

Fig. 32: Recommended high availability connection. Option 2.

Blocks inside the doted box are not mandatory. However, if the application requires Ethernet redundancy with DigiVis 500, the user has to use Level 2 Managed Ethernet switch.

Recommended connections for a HA-CS31 system

CPU redundancy is ensured by using two CPUs in combination with the HA-CS31 library. Redundancy of the Ethernet connection between CPUs and HMI can be achieved depending on the type of HMI and use of managed switches:

Sl no.	HMI (DigiVis 500/ CP6xx)	CPU Redundancy	Ethernet Redundancy	Recommendation
1	DigiVis 500 with two Ethernet ports on PC and Layer 2 managed switch. Refer to *Chapter 1.5.5.1.2.2.1.1.1 "DigiVis 500 with two Ethernet ports" on page 1987*.	Yes (with the HA-CS31 library)	Yes (complete Ethernet network is redundant with Layer 2 managed switches).	Recommended for users who require CPU and Ethernet network redundancy.
2	HMI CP6xx with two Ethernet ports on HMI with same IP and Layer 2 managed switch. Refer to *Chapter 1.5.5.1.2.2.1.1.2 "HMI CP6xx with two Ethernet ports" on page 1988*.	Yes (with the HA-CS31 library)	Yes (complete Ethernet network is redundant with Layer 2 managed switches, HMI IP switching functionality is achieved by 'Node Override IP' functionality within the script programming. Refer to Example_AC500_HA_CS31_V242.project, HA_CS31_Example_OnlyCPU_HMI)	Recommended for users who require CPU and Ethernet network redundancy.
3	DigiVis 500 with standard Ethernet switch (unmanaged switch). Refer to *Chapter 1.5.5.1.2.2.1.1.3 "DigiVis 500 with standard Ethernet switch" on page 1989*.	Yes (with the HA-CS31 library)	No	Recommended for users who require CPU redundancy but no Ethernet network redundancy.
4	HMI CP6xx with one Ethernet port on HMI with standard Ethernet switch (unmanaged switch). Refer to *Chapter 1.5.5.1.2.2.1.1.4 "HMI CP6xx with one/two Ethernet ports" on page 1990*.	Yes (with the HA-CS31 library)	No	Recommended for users who require CPU redundancy but no Ethernet network redundancy.

DigiVis 500 with two Ethernet ports

DigiVis 500 with two Ethernet ports on PC and Layer 2 managed switch.

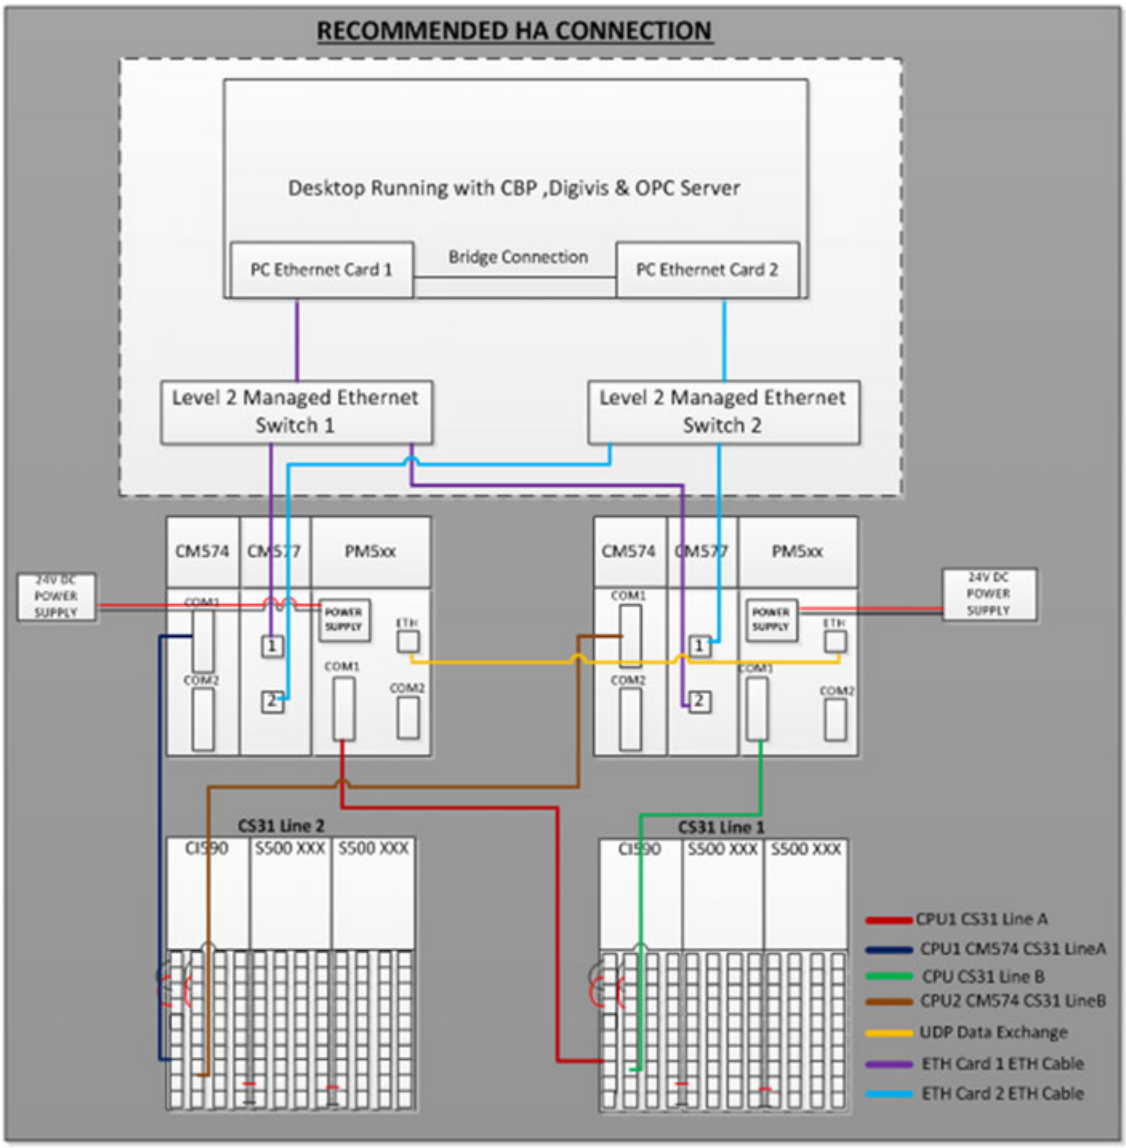

Fig. 33: Recommended high availability connection. Option 1.

HMI CP6xx with two Ethernet ports

HMI CP6xx with two Ethernet ports on HMI with same IP and Layer 2 managed switch:

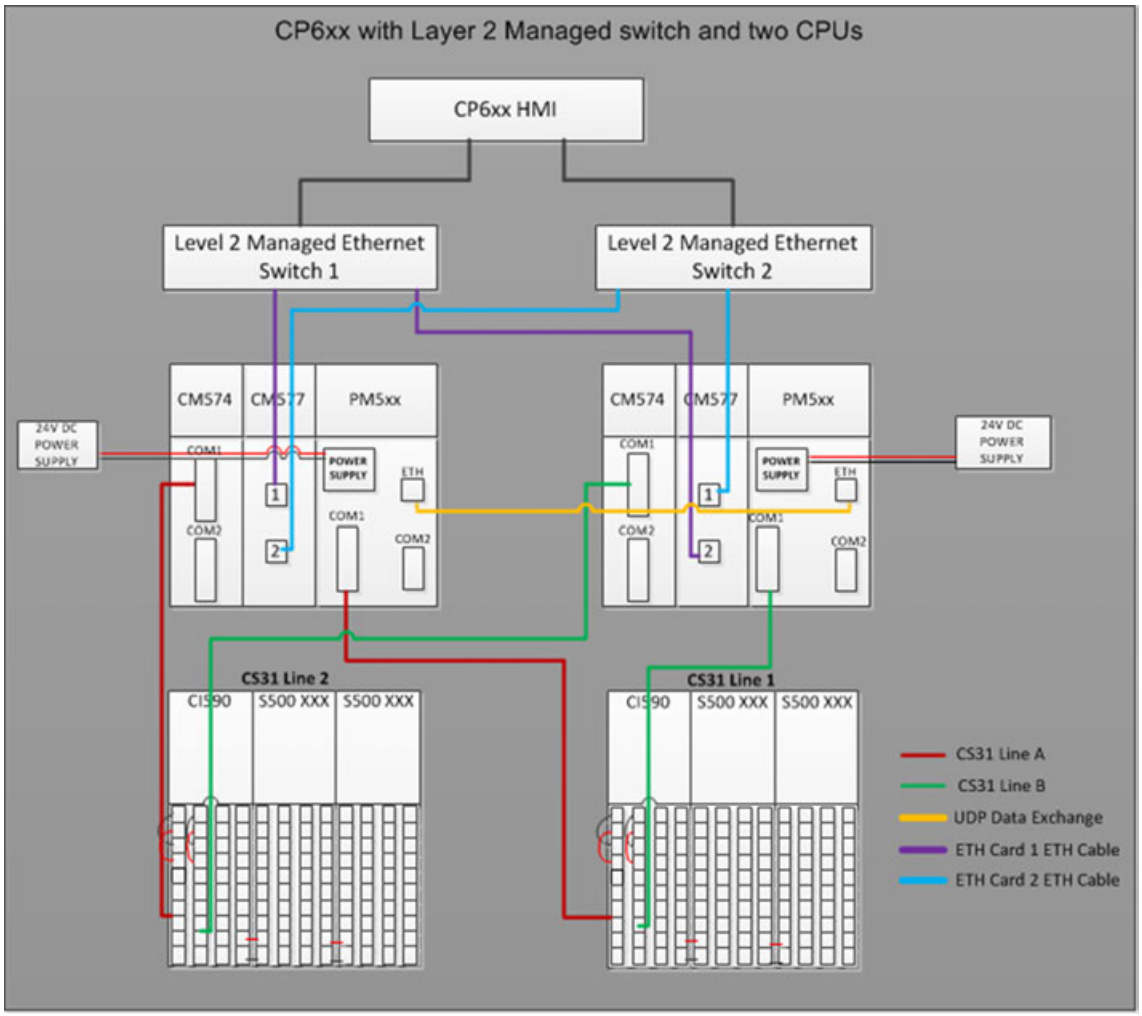

Fig. 34: Recommended high availability connection. Option 2.

Ethernet redundancy must be done by the application and Layer 2 managed switches.

HA example application program (Example_AC500_HA_CS31_V242.project) provides a sample application program for CP620 HMI. It has the required scripts to read data from the primary PLC. Also it provides an option for the user to select one of the two PLCs to read data. This is done using the IP override functionality. With minor modifications the HMI application program can be made application specific.

Data writing from HMI to PLC is not recommended as it will write data only to the primary CPU.

DigiVis 500 with standard Ethernet switch

DigiVis 500 with standard Ethernet switch (unmanaged switch):

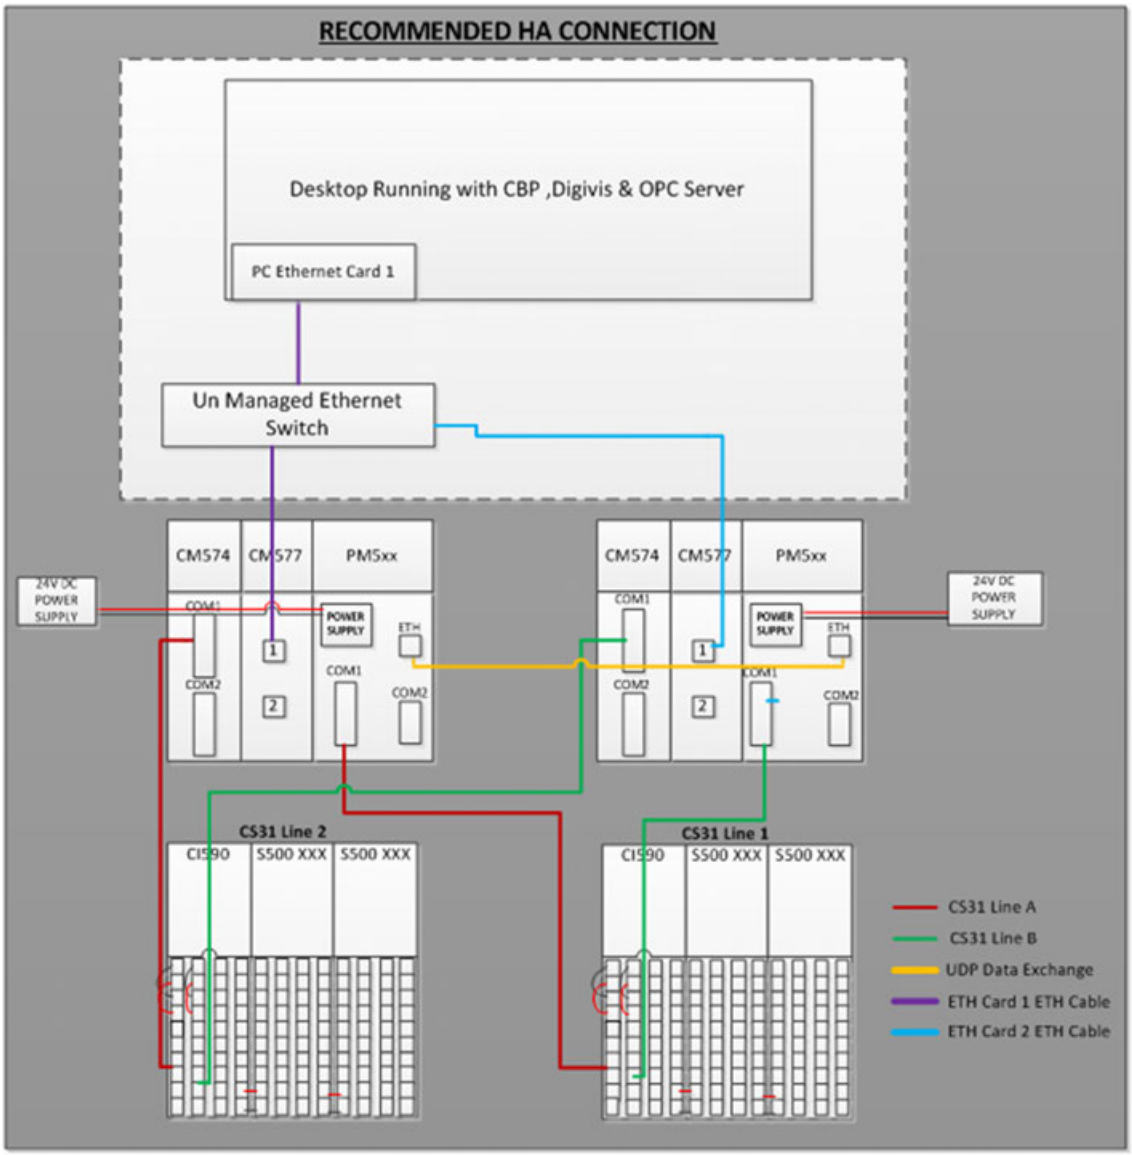

Fig. 35: Recommended high availability connection. Option 3.

If HA application requires CPU redundancy but no Ethernet redundancy, users can use a standard Ethernet switch (unmanged switch) with Digivis 500.

HMI CP6xx with one/two Ethernet ports

HMI CP6xx with One/Two Ethernet ports on HMI with standard Ethernet switch (unmanaged switch):

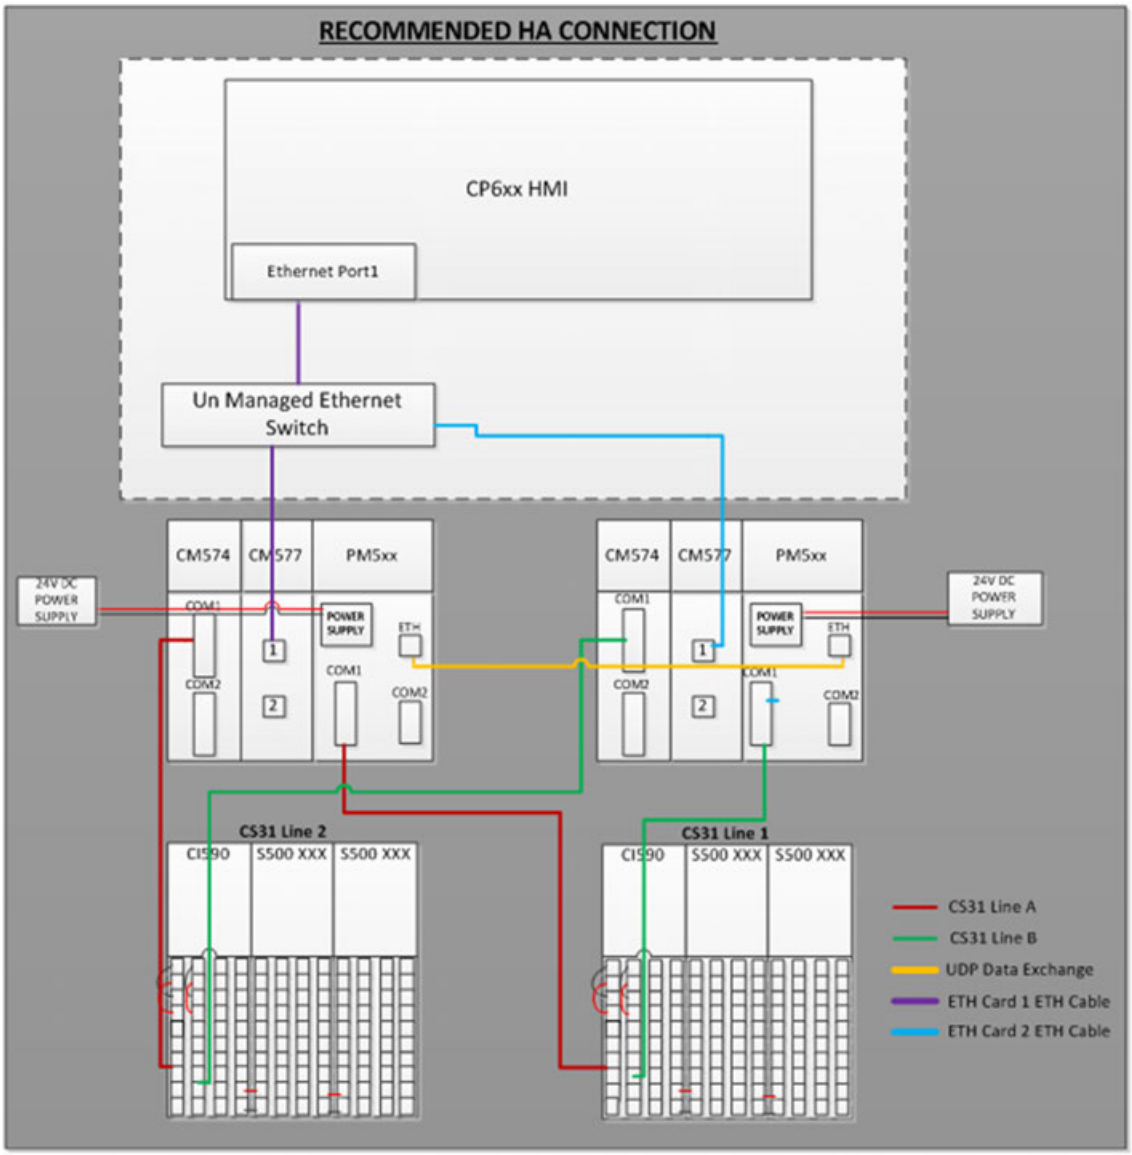

Fig. 36: Recommended high availability connection. Option 4.

If application requires only CPU redundancy and no Ethernet redundancy, the users can use standard Ethernet switch (unmanaged switch) with CP6xx HMI.

HA example application program (Example_AC500_HA_CS31_V242.project) provides a sample application program for CP620 HMI. It has the required scripts to read the data from the primary PLC. Also it provides an option for the user to select one of the two PLCs to read data. This is done using the IP override functionality. With minor modifications the HMI application program can be made application specific.

Data writing from HMI to PLC is not recommended as it will write data only to the primary CPU.

Recommended use of Ethernet connections

The following types of Ethernet communication is required:

- UDP: Communication between the two CPUs for HA synchronization.
- AB: Communication between CPUs and Engineering PC for program download.
- OPC: Communication between CPUs and HMI (optionally).
- WEB: Web server communication between CPUs and HMI (optionally).

Ethernet ports are available on the CPU (onboard) and on the CM597-ETH communication module. For an optimal load balance the following connections are recommended:

CPU Type	Web server required	Onboard ETH1	Onboard ETH2	CM597-ETH
PM57x, PM58x, PM591, PM592	No	UDP	n/a	AB, OPC
PM57x, PM58x, PM591, PM592	Yes	AB, OPC, WEB	n/a	UPD
PM592-2ETH, PM595	No	UDP	AB, OPC	-
PM592-2ETH, PM595	Yes	UDP	AB, OPC, WEB	-

PM591-2 ETH and PM595 PLCs must use onboard ETH1 for UDP data communication.

Software

The HA-CS31 library V2.4.2 (HA_CS31_AC500_V23.lib) has been tested with the following versions:

- Automation Builder: 1.1
- CODESYS: 2.3.9.46
- CPU and CM574 Firmware: 2.4.2
- CI590 Firmware: 3.0.15

Guidelines for usage

Introduction

The following sections give an overview of the engineering steps (hardware configuration, programming, task configuration and program download) and the operation.

If only one CS31 line is required, please consider the information provided in the chapters “Single CS31 Bus on CPU COM Port”. If more than one CS31 line is required (with CM574 extension), please consider the information provided in the chapters “CS31 Bus Extension with CM574-RS communication module”.

For further information on HA-CS31 library preconditions, please refer to Chapter 1.5.5.1.3.2 “Prerequisites for the use of HA-CS31 library” on page 2020.

For further information on HA configuration, please refer to the provided HA examples - typically located in: C:\Users\Public\Documents\Automation-Builder\Examples.

Hardware configuration in Automation Builder

Single CS31 bus on CPU COM port

In order to configure a single CS31 Bus on a CPU COM port, build-up the hardware configuration in Automation Builder. The following figure demonstrates necessary configuration:

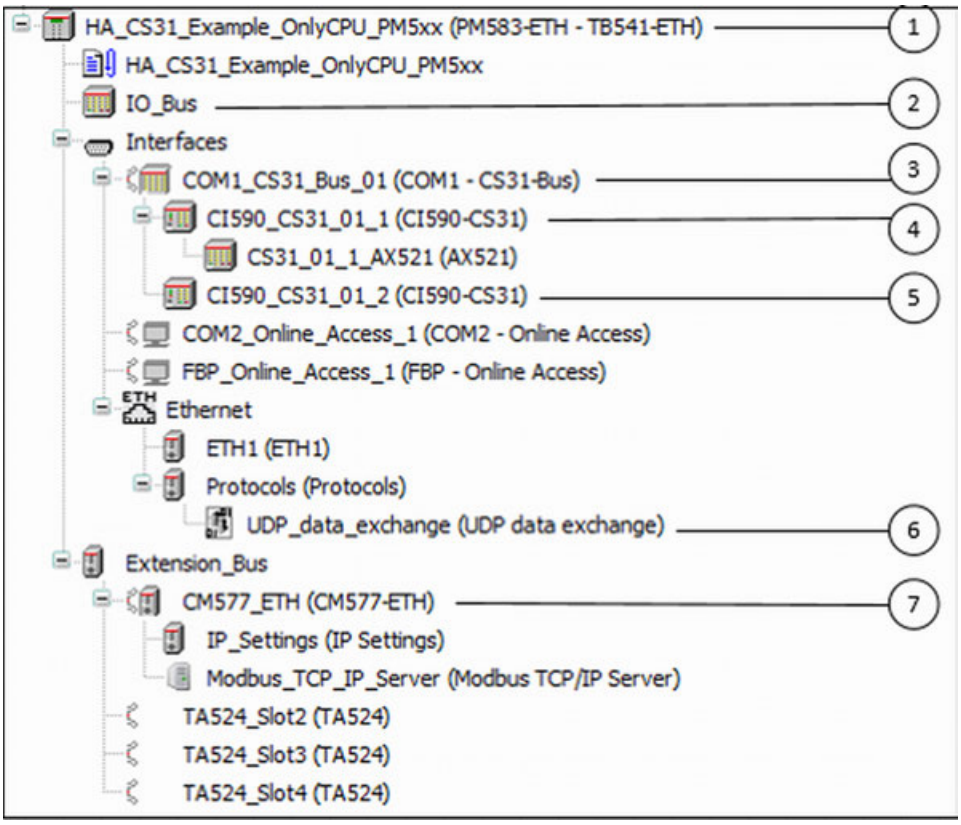

Fig. 37: Hardware Configuration Tree. Option 1.

1. Shows the configured PLC type.
2. Addition of local I/O Bus modules is possible but the I/O modules will not be redundant.
3. CS31 Bus module below CPU COM1 interface.
4. CI590-CS31-HA module and I/O modules below CS31 Bus.
5. Maximum limit is 31 CI590-CS31-HA modules in one CS31 line.
6. UDP data exchange below the Ethernet interface. This is mandatory for a HA-CS31 system to run since it is responsible for synchronization of CPU A and CPU B.

7. CM597-ETH module below the communication module slot for OPC server and Automation Builder communication etc. If the PLC has more than one onboard ETH port (Example: PM595, PM591-2ETH) the user can use ETH2 port instead of CM597-ETH. Refer to *Chapter 1.5.5.1.2.2.1.2 “Recommended use of Ethernet connections” on page 1991*.

PM591-2 ETH and PM595 PLCs must use onboard ETH1 for UDP data communication.

We recommend you, to use separate Ethernet slots for UDP data exchange and PC connectivity. Refer to Chapter 1.5.5.1.2.2.1.2 “Recommended use of Ethernet connections” on page 1991.

For using CI590 2FC (fast counter) users have to add CI590 2FC under CS31 network. Then, the “Fast Counter” selection must be updated with the appropriate counter type. With the default setting “No Counter” the system will become unstable.

CS31 bus extension with CM574-RS module

If more than one CS31 line is needed, CM574 can be used for extension. The following figure demonstrates an example of CPU and CM574 hardware configuration tree:

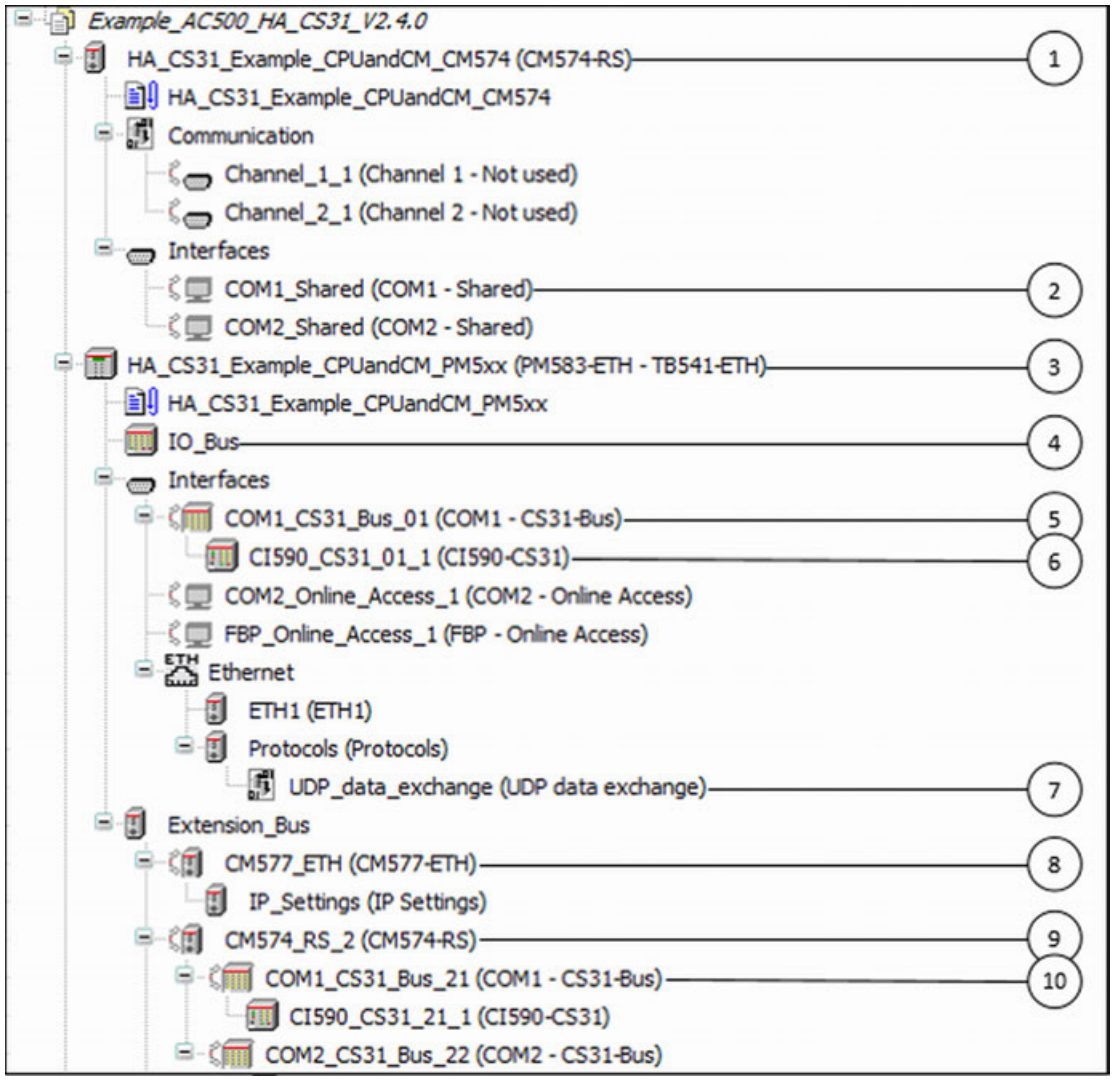

Fig. 38: Hardware Configuration Tree. Option 2.

1. Shows the configured device type: CM574-RS.
2. Configure Interfaces as “shared” com ports. Engineering of underlying CS31 lines and CI590-CS31-HA is done in the CPU hardware tree.
3. Shows the configured PLC type.
4. Addition of local I/O Bus modules is possible but the I/O modules will not be redundant.
5. CS31 Bus module below CPU COM1 interface.
6. CI590-CS31-HA module and I/O modules below CS31 Bus.
7. UDP data exchange below the Ethernet interface. This is mandatory for a HA-CS31 system to RUN, it does the synchronization between CPU A and CPU B.
8. CM597-ETH module below the communication module slot for program download, OPC server communication etc. We recommend you, to have separate Ethernet slot for UDP data exchange and PC connectivity. In another case if a user has a PLC with more than one onboard ETH port (Example: PM595, PM591-2ETH) the user can use ETH2 port for downloading e.g. the program, web server, OPC server communication etc. Refer to ↬ *Chapter 1.5.5.1.2.2.1.2 “Recommended use of Ethernet connections” on page 1991*.
9. CM574-RS for CS31 extension.
10. CS31 Bus module below CM574-RS COM1 interface and CI590-CS31-HA module and additional I/O modules.

PM591-2 ETH and PM595 PLCs must use onboard ETH1 for UDP data communication.

The following hardware configuration (CS31 lines below CM574-RS) is not supported for a HA-CS31 system even though it is supported by Automation Builder:

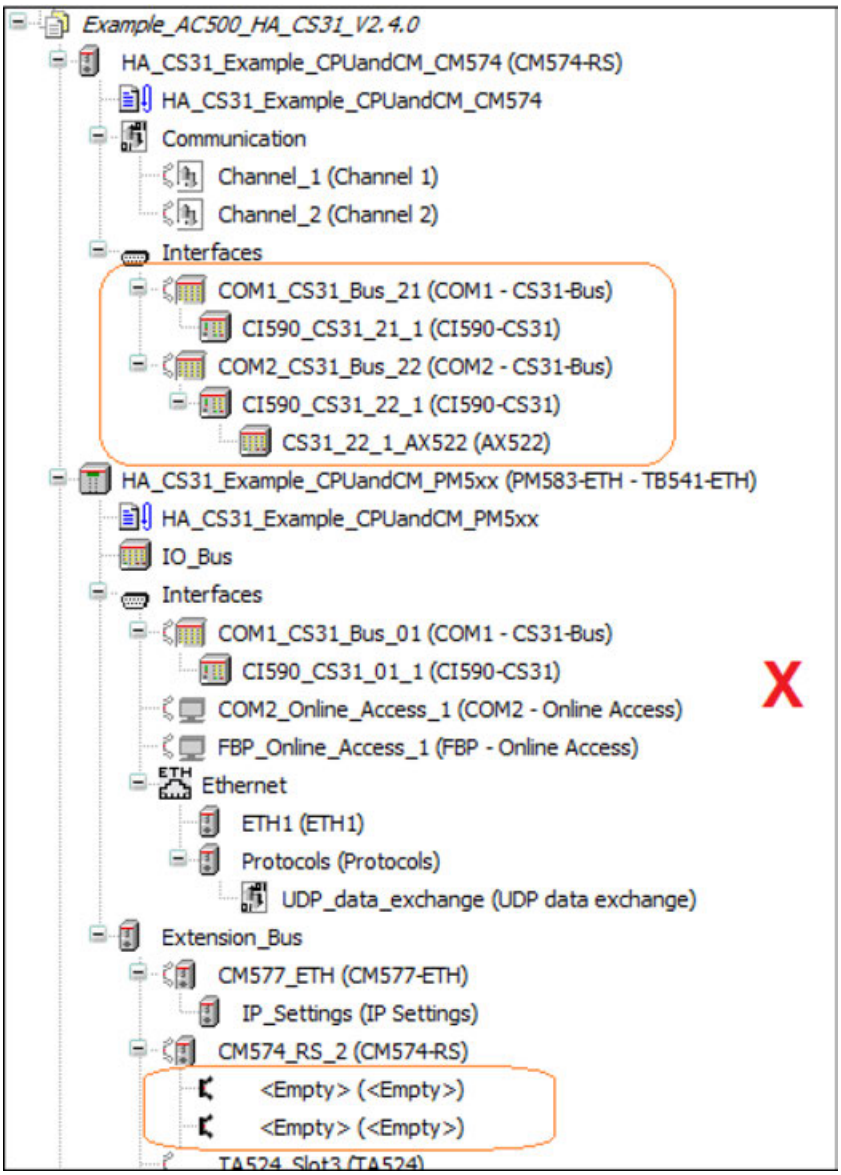

Fig. 39: Not supported/ not recommended hardware configuration.

For more details about the configuration please refer to the Example_AC500_HA_CS31_V242_3ADR023070M0201.pdf.

Programming

Single CS31 bus on CPU COM port

The CPU program contains different types of HA-CS31 function blocks.

The following figure describes function blocks and functions for a HA-CS31 system to work with a CPU COM1 CS31 Bus connected with I/O modules. The function blocks indicated with dotted lines are not mandatory for a HA-CS31 system to run.

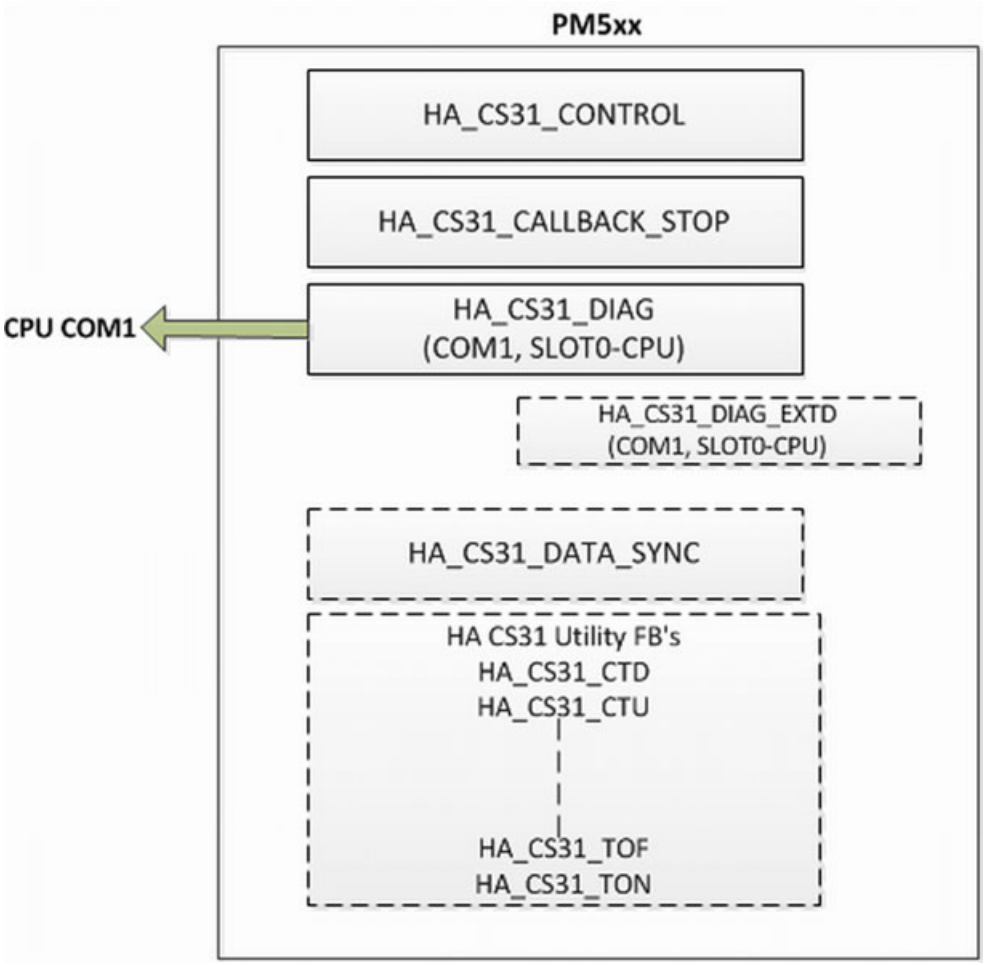

Fig. 40: Function blocks in CPU

The following function blocks and functions are required to be called and downloaded to the PLC:

- HA_CS31_CONTROL
- HA_CS31_DIAG
- HA_CS31_CALLBACK_STOP

CS31 bus extension with CM574-RS module

If configuration requires more than one CS31 network, then the CM574-RS is used to extend the CS31 lines. In this case, users have to create two separate programs: one for the AC500 CPU and one for the CM574-RS including the respective function blocks called from the library.

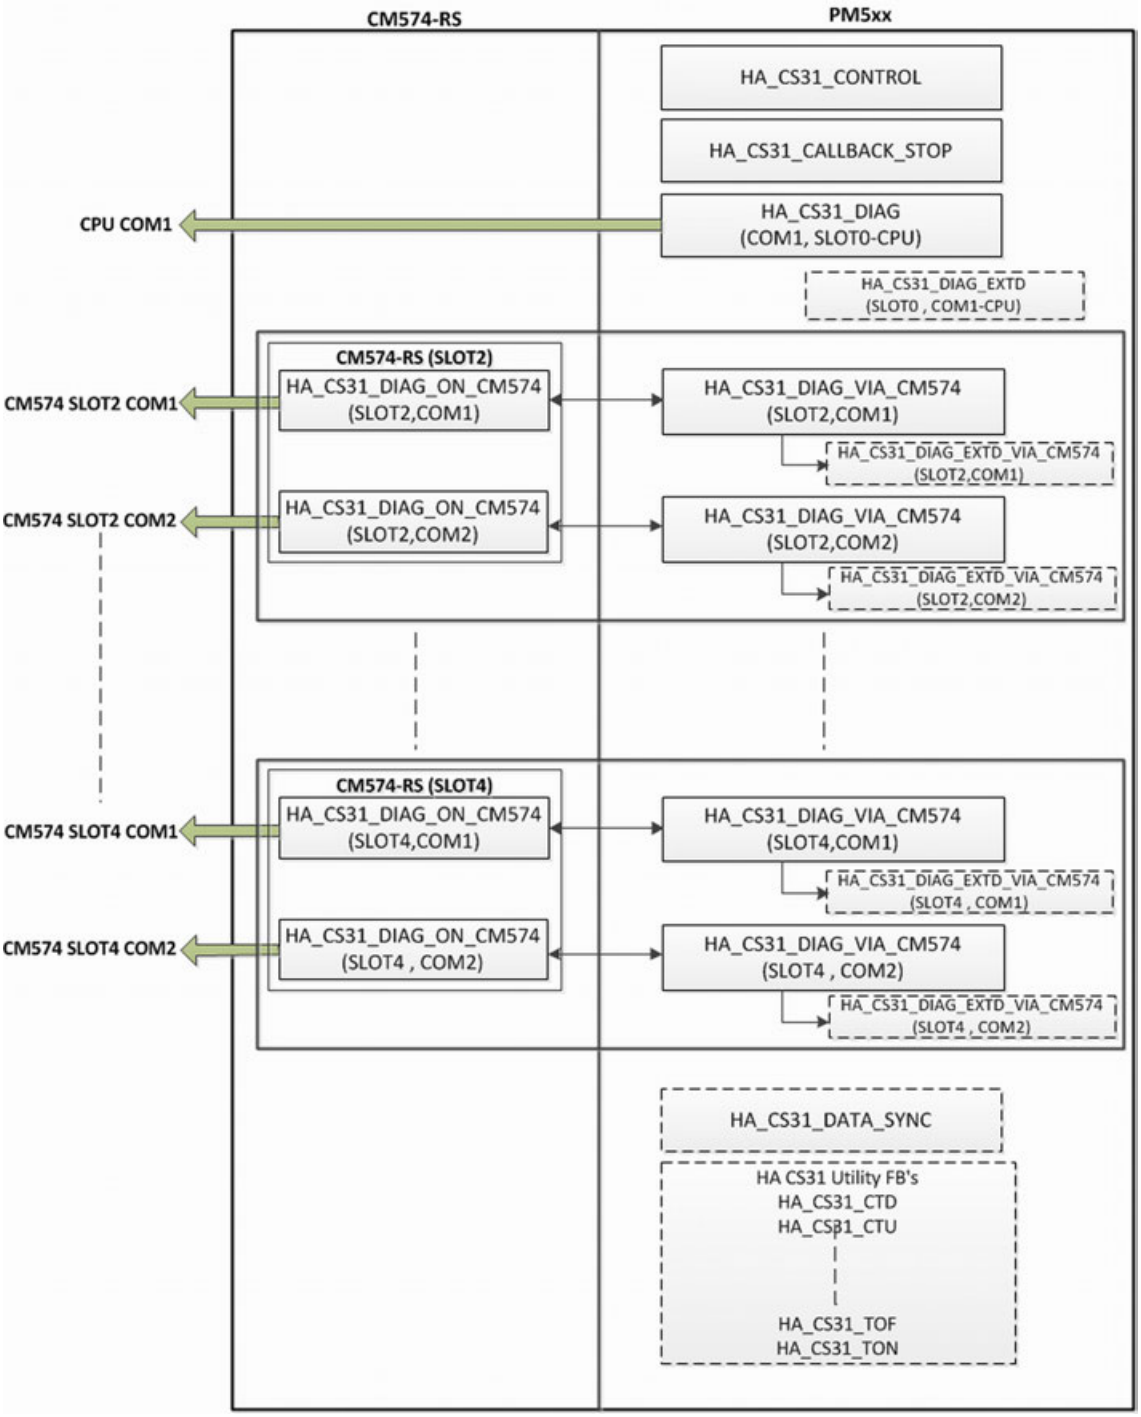

Fig. 41: Function blocks in CPU and CM574-RS

The following sections explain mandatory steps required while programming such a set-up.

CPU program

The right part of the figure above describes function blocks for the CPU. The function blocks indicated with dotted lines are not mandatory for a HA-CS31 system to run.

The following function blocks and functions are required to be downloaded to the CPU:

- HA_CS31_CONTROL
- HA_CS31_DIAG
- HA_CS31_DIAG_VIA_CM574
- HA_CS31_CALLBACK_STOP

> *For HA programming using SFC language (Sequential Function Chart) is not recommended as too much and too spread data is to be synchronized. For further information about programming, please refer to Example_AC500_HA_CS31_V242_3ADR023070M0201.pdf.*

- Application will start on CPU A connected to CS31 Bus A if both CPUs start together or on CPU CS31 B and Bus B if only CPU B is connected.
- If CPU A stops / turns off or crashes -> application will run on CPU B and Bus B.
- If CS31 Bus A is open or in short circuit -> application will run on CPU B and Bus B.

CM574-RS program

The left part of the figure above describes the function blocks for CM574-RS.

Function block HA_CS31_DIAG_ON_CM574 must be downloaded to CM574 module. This function block sends CS31 Bus diagnosis information to host CPU.

The CM574-RS program is common and can be used for each CM574-RS module without any specific changes (please refer to Example_AC500_HA_CS31_V242_3ADR023070M0201.pdf).

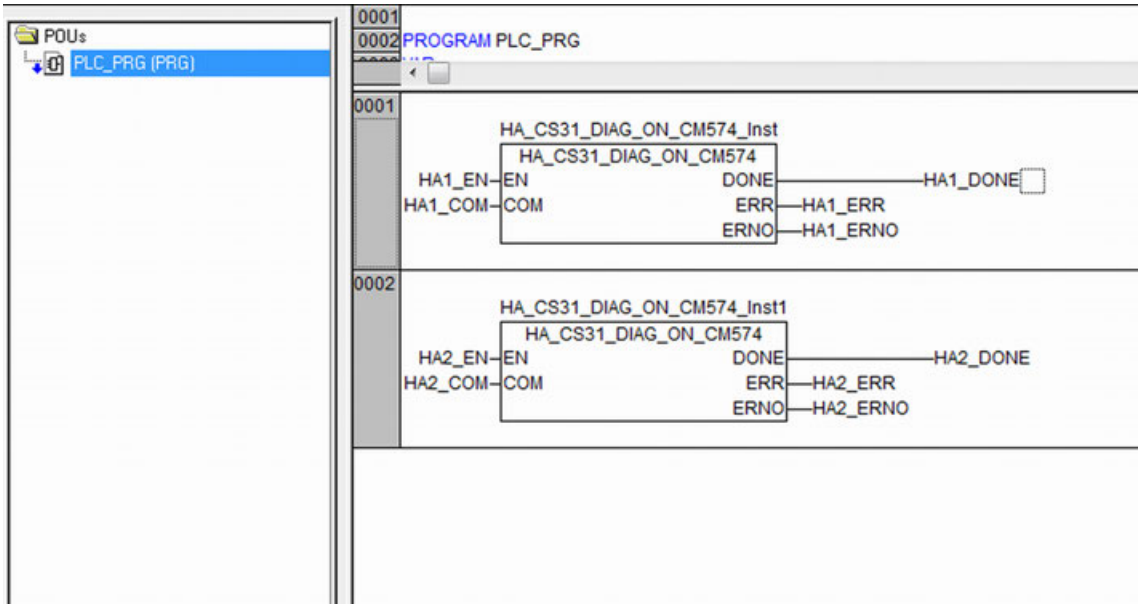

Fig. 42: Common program for CM574-RS

Task configuration

Single CS31 bus on CPU COM port

Task configuration for the CPU program

At least, two tasks must be defined:

- HA_Task for the mandatory HA-CS31 function blocks HA_CS31_CONTROL, HA_CS31_DIAG, HA_CS31_DIAG_VIA_CM574. Recommended HA task cycle time is equal to CS31 cycle time (as indicated in Automation Builder), but at least 30 ms. Priority must be higher than priority of the other tasks in the project.
- Main task for the application itself: lower priority than the HA_Task. Cycle time to be decided based on CPU loading, but not less than HA cycle time.

HA_Task priority must be higher than the main task priority.

CS31 bus extension with CM574-RS module

Task configuration for the CPU program

At least, two tasks must be defined:

- HA_Task for the mandatory HA-CS31 function blocks HA_CS31_CONTROL, HA_CS31_DIAG, HA_CS31_DIAG_VIA_CM574. Recommended HA task cycle time is equal to CS31 cycle time (as indicated in Automation Builder), but at least 30 ms. Priority must be higher than priority of the other tasks in the project.
- Main task for the application itself: lower priority than the HA_Task. Cycle time to be decided based on CPU loading, but not less than HA cycle time.

HA_Task priority must be higher than the main task priority.

Task configuration for the CM574 program

The program which calls function block HA_C31_DIAG_ON_CM574 must be called and assigned to a cyclic task.

The cycle time of this task must not be more than the cycle time of the HA_Task above.

For further information, please refer to Example_AC500_HA_CS31_V242_3ADR023070M0201.pdf.

Program download

To avoid any difference in configuration, we recommend you to create a single Automation Builder project for high availability. Download this project to both CPUs.

Single CS31 bus on CPU COM port

Download for CPU program

The CPU program can be downloaded to the PLC using normal TCP/IP gateway. We recommend you, to use a dedicated CM597-ETH slot for downloading the program to both PLCs. If no CM597-ETH is available, onboard Ethernet slot can be used. In another case if user has a PLC with more than one onboard ETH port (Example: PM595, PM591-2ETH) the user can use ETH2 port for downloading e.g. the program, webserver, OPC server communication etc. After the download, create a boot project.

For further information, please refer to Example_AC500_HA_CS31_V242_3ADR023070M0201.pdf.

CS31 bus extension with CM574-RS module

Download for CPU program

The CPU program can be downloaded to the PLC using normal TCP/IP gateway. We recommend you, to use a dedicated CM597-ETH slot for downloading the program to both PLCs. If no CM597-ETH is available, onboard Ethernet slot can be used. In another case if user has a PLC with more than one onboard ETH port (Example: PM595, PM591-2ETH) the user can use ETH2 port for downloading e.g. the program, webserver, OPC server communication etc. After the download, create a boot project.

For further information, please refer to Example_AC500_HA_CS31_V242_3ADR023070M0201.pdf.

Download for CM574 program

Download the configuration and program to CM574 via Ethernet level 2 root driver. The following figure describes the settings of a gateway channel for connection via AC500 CPU. The Ethernet port uses the IP address 192.168.3.10 with routing to CM574-RS plugged into slot 2 (line 2).

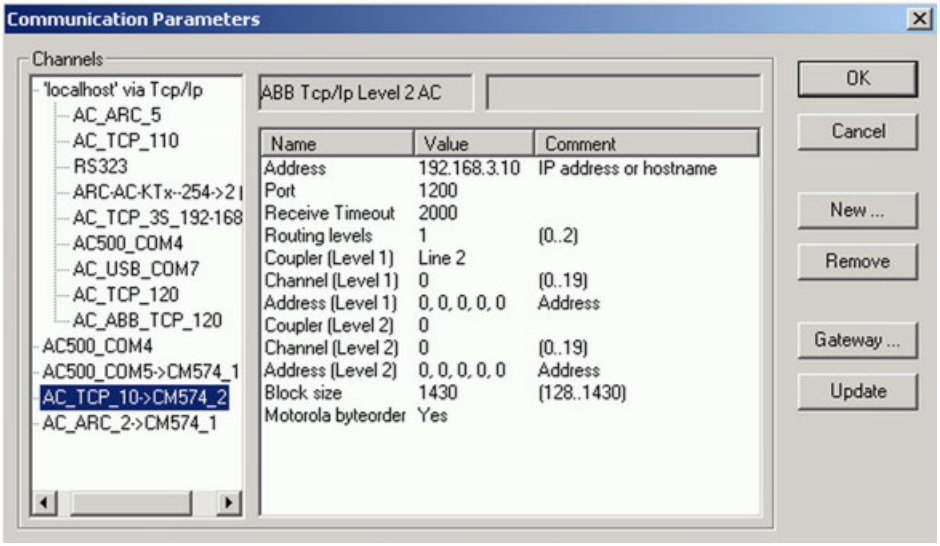

Fig. 43: Communication Parameters

Table 98: The following settings have to be specified:

Address	IP address of the AC500 CPU, in the example: 192.168.3.10
Routing levels	1
Communication module (level 1)	Line 2
Motorola byte order	Yes

After downloading the program, create a boot project. For further information on providing access to CM574, please refer to *Chapter 1.6.4.2.6.5 “Programming access to the CM574-RS” on page 5610*

Operation

Single CS31 bus on CPU COM port

HA_CS31_CONTROL function block handles HA-CS31 operation such as change over from primary to secondary CPU in case of fault with related diagnostics and also data transfer between HA-CS31 CPUs. This is a mandatory function block for High Availability to run. For further information on this function block, please refer to *Chapter 1.5.5.1.3.3.2 “HA_CS31_CONTROL - HA control FB” on page 2026*.

HA_CS31_DIAG function block will be used to get diagnosis information only from CPU COM1 CS31 line. For further information on this function block, please refer to *Chapter 1.5.5.1.3.3.4 “HA_CS31_DIAG - Reading HA diagnosis” on page 2035*.

HA_CS31_DATA_SYNC function block is used for synchronizing non High Availability function blocks or any other data. For further information on this function block, please refer to ↳ *Chapter 1.5.5.1.3.3.3 “HA_CS31_DATA_SYNC - HA data synchronization FB” on page 2028*.

High Availability Utility function blocks outputs are internally synchronized and can be used directly without using HA_CS31_SYNC function block. For further information on these function blocks, please refer to ↳ *Chapter 1.5.5.1.3.4 “Utility function blocks” on page 2047*.

Visualization

High Availability overview visualization can be used for monitoring purpose but it will show data only for the CPU on which we are logged into.

The following figure describes the visualization screen of a running HA-CS31 system with the CS31 lines only on the PLC COM port:

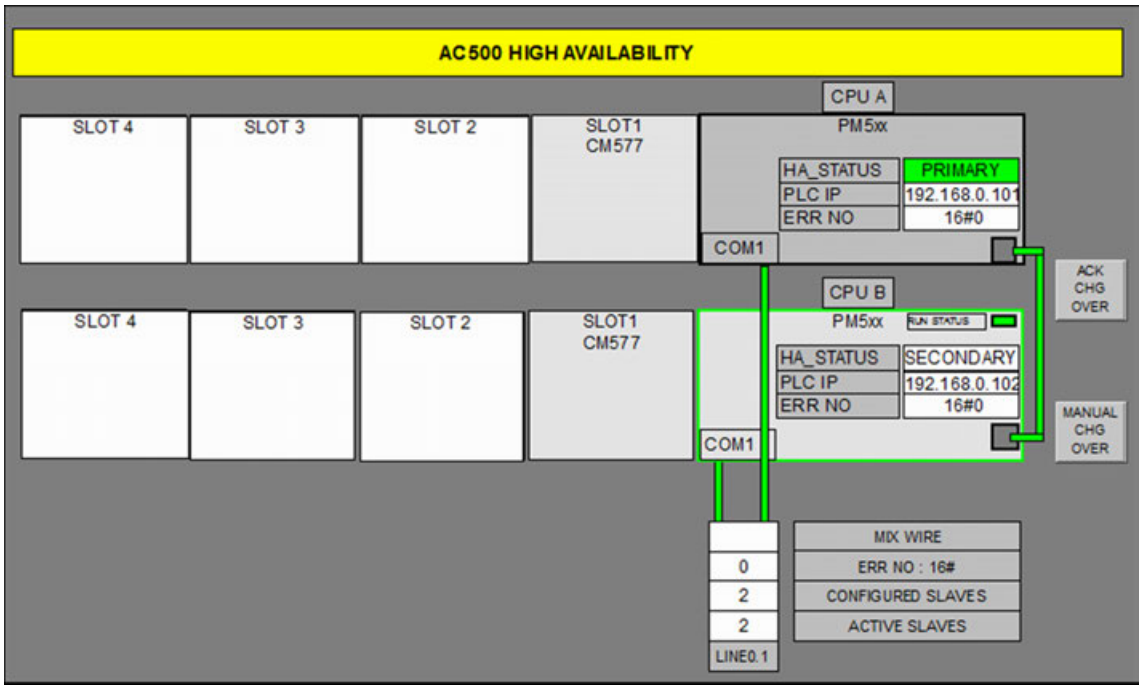

Fig. 44: Visualization of AC500 High Availability System. Option 1.

DigiVis and OPC server can be used to write data as it will allow the user to write data to both PLCs at the same time. Data is read out from the primary PLC only. We recommend you, not to use HMI for writing data as it is not written to both PLCs.

> *If during the startup of the HA-CS31 system none CI590-CS31-HA module is powered on, or if all CI590-CS31-HA modules have a wrong module address, the system does not become stable.*
>
> *If any CI590-CS31-HA module address has been changed after startup of the HA-CS31 system the system will continue to run as it is. In order to activate the new address the complete system must be restarted.*
>
> *If any CI590-CS31-HA module is powered off and on, there is no need to power restart the complete system from library version V2.4.2 onwards. Sync LED of failed CI590 line will blink and has to be acknowledged by the user.*

For further information, please refer to both, the online help for HA-CS31 function blocks (↳ *Chapter 1.5.5.1.3 “AC500 High Availability CS31 library” on page 2017*) and the Example_AC500_HA_CS31_V242_3ADR023070M0201.pdf.

CS31 bus extension with CM574-RS communication module

Apart from all functions explained in chapter *Chapter 1.5.5.1.2.3.6.1 "Single CS31 bus on CPU COM port" on page 2001* there are CM574 related function blocks which are called in the programs of this configuration.

CPU program Function block HA_CS31_DIAG_VIA_CM574 reads the extended diagnostics of CM574-RS CS31 Bus in high availability operation.

CM574 program Function block HA_CS31_DIAG_ON_CM574 sends CS31 Bus diagnosis information to host CPU and receives CS31 configuration information from host CPU.

Visualization The following figure describes visualization of a running HA-CS31 system with the CS31 lines both on the PLC COM port and the CM574 COM ports.

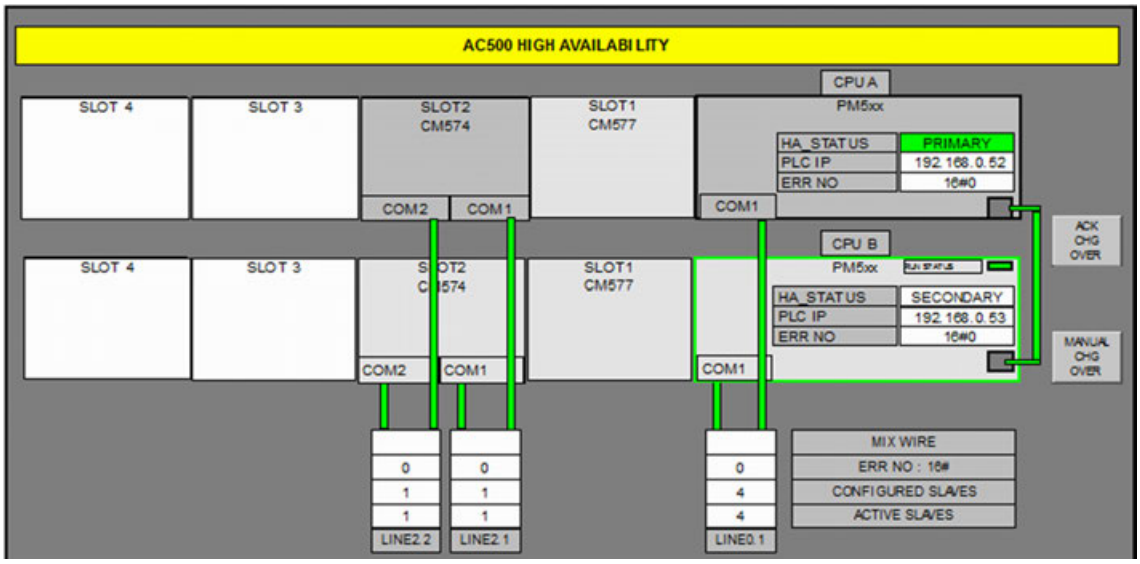

Fig. 45: Visualization of AC500 High Availability System. Option 2.

Example of a utility function block - Switch over

Consider the on-delay timer HA_CS31_TON (refer to *Chapter 1.5.5.1.3.4.12 "HA_CS31_TON - HA turn-on delay timer" on page 2071*).

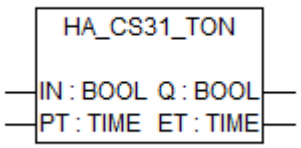

Fig. 46: HA_CS31_TON

Both CPUs require the same function block called in the program. Under normal operating conditions the elapsed time ET and output, Q of the timer is synchronized internally for both CPUs. ET and Q data are available and can be attached to local or global variables in the program as per application requirements. If CPU A shuts down due to a fault, the primary status switches over to CPU B.

In the event of a switch over, the moment the CPU B becomes the primary, the timer on this PLC will keep running. Since till the time of CPU A failure the timer on the CPU B was synchronized, the actual process remains unaffected by the switch over.

All possible use cases for switch over are described under *Chapter 1.5.5.1.2.4.1 “Use case and reaction time” on page 2004*.

Fault on primary and secondary PLC

HA-CS31 system only takes care of the first fault. In case of a second fault the primary CPU remains primary CPU until the second fault occurs. This results in no further switch overs (manual switch overs included).

Example: If an error occurs on PLC A (primary) due to CS31 cable disconnection, the HA-CS31 system will switch over to PLC B (primary). If there is any cable disconnection happened in either PLC A (secondary) or PLC B (primary) the HA-CS31 system will remain in PLC B as primary.

In case of a second error generated in the HA-CS31 system, function block HA_CS31_CONTROL will generate an error with error code 16#2006.

If one fault occurs in both, CPU A and CPU B, error code 16#2006 occurs. This error code does not consider two faults on the same PLC. In the following the most common scenarios that trigger error code 16#2006 (named as wHA_ER_LOCAL_AND_REMOTE_FAULT) are listed:

- CS31 cable is removed from PLC A and PLC B (from same corresponding ports).
- CS31 cable is removed from PLC A and PLC B (from different ports).
- Cable of CS31 network is removed from any CI590-CS31-HA related to PLC A and afterwards it is removed from PLC B (coming from the same corresponding ports).
- Cable of CS31 network is removed from any CI590-CS31-HA related to PLC A and afterwards it is removed from PLC B (coming from different ports).
- PLC A is stopped and PLC B CS31 line is removed.
- PLC A CS31 line is removed and PLC B is stopped.
- PLC A is powered off and PLC B CS31 line is removed.
- PLC A CS31 line is removed and PLC B is powered off.
- PLC A CS31 line is removed and PLC B CI-590 is powered off.

All outputs on the remote modules keep on working properly as long as at least one CS31 line is active - regardless of CPU primary or secondary status. This is because of the self-primary action in CI590-CS31-HA module.

Functionality

Use case and reaction time

The HA-CS31 system performs a switch over when the primary CPU is powered off, crashed or stopped or if the primary CS31 bus is disconnected. The total switch over time depends on the use case. The following table gives an overview of the switch over times assuming that HA cycle = CS31 cycle time (as indicated in Automation Builder) or at least 30 ms according to the recommendation. After CI590 switchover period the outputs will be written from the new CPU. CI590 LED will be steadily green after CPU switch over period.

	Capacitor discharge period	**CI590 switch over period**	**CPU switch over period, afterwards remaining CI590 are switched over**
Primary CPU powered off	Depending on system size	≤ 4 CS31 cycles	Not relevant, all CI590 already switched over
Primary CPU stopped	0	≤ 2 CS31 cycles	Not relevant, all CI590 already switched over

	Capacitor discharge period	CI590 switch over period	CPU switch over period, afterwards remaining CI590 are switched over
Primary CS31 bus cut near CPU	0	≤ 4 CS31 cycles	35 HA cycles
Primary CS31 bus cut at local CI590	0	≤ 4 CS31 cycles	35 HA cycles

Details are described in the following sections:

Primary CPU off or primary CPU crash

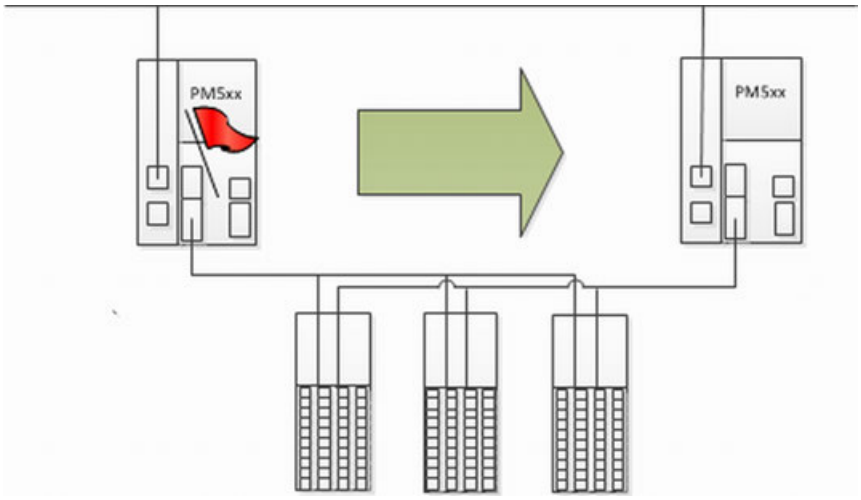

Fig. 47: Use case 1

Reaction	Switch over to secondary CPU. All CI590 are immediately switched over.
Total switch over time	CI590 switch over period (≤ 4 CS31 cycles).
Comment	In case of power off there is a capacitor discharge period before CI590 switch over period. Duration depends on the system size. Outputs are frozen during CI590 switch over period. It takes some more HA cycles until the other CPU takes over primary status. However, this is not relevant for the process, because all CI590 were already switched over individually in the first CI590 switch over period.
Diagnosis message on function block	• Primary CPU: Power OFF • Secondary CPU: HA_CS31_CONTROL: 16#101B (remote CPU failure: other CPU is OFF or out of order.)
Diagnosis message on CI590-CS31 LEDs	“CS31 A” OFF, “CB” ON, "RUN A" OFF, "RB" ON, "SYNC-ERR" RED (Blinking), "S-ERR" RED (Blinking).

Primary CPU stop

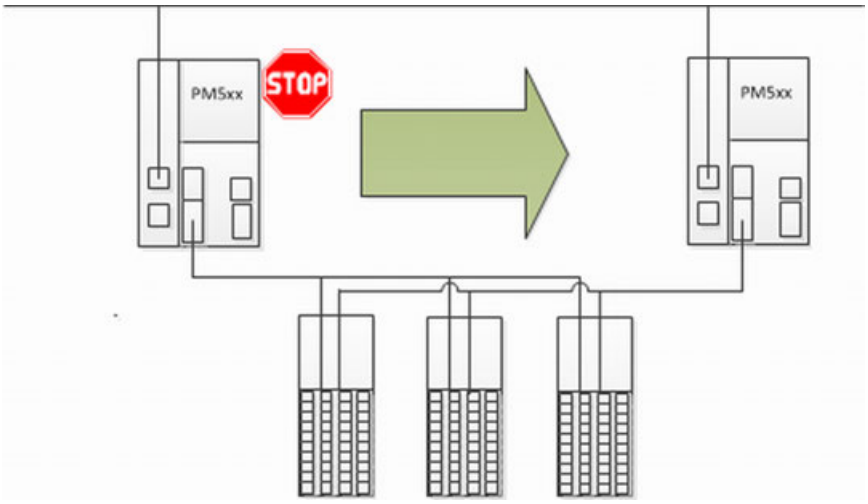

Fig. 48: Use case 2

Reaction	Switch over to secondary CPU. All CI590 are immediately switched over.
Total switch over time	CI590 switch over period (≤ 2 CS31 cycles).
Comment	Outputs are frozen during CI590 switch over period. It takes some more High Availability cycles until the other CPU takes over primary status. However, this is not relevant for the process, because all CI590 were already switched over individually in the first CI590 switch over period.
Diagnosis message on function block	• Primary CPU: STOP • Secondary CPU: HA_CS31_CONTROL: 16#101B (remote CPU failure: other CPU is OFF or out of order.)
Diagnosis message on CI590-CS31 LEDs	“CS31 A” ON (Blinking), “CB” ON, "RUN A" OFF, "RB" ON, "SYNC-ERR" RED (Blinking), "S-ERR" OFF.

Secondary CPU off or secondary CPU crash

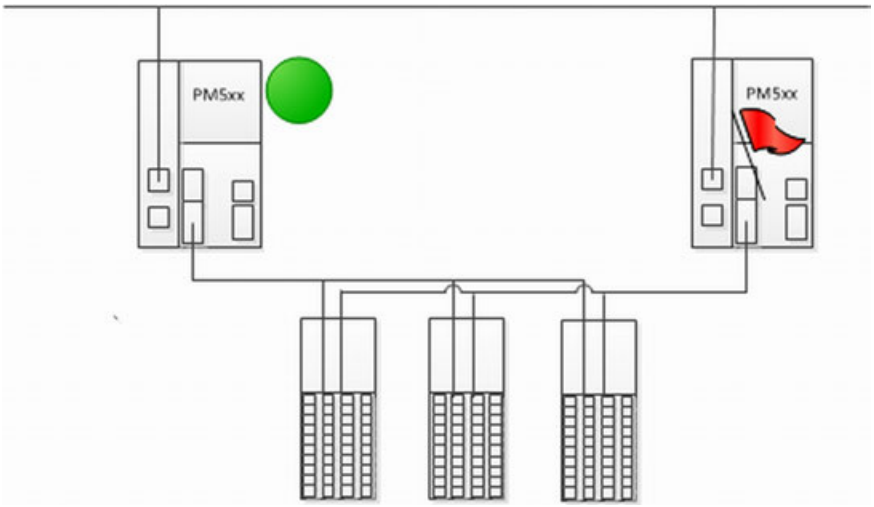

Fig. 49: Use case 3

Reaction	No switch over
Total switch over time	N.A.
Comment	Process continues
Diagnosis message on function block	• Primary CPU: HA_CS31_CONTROL: 16#101B (remote CPU failure: other CPU is OFF or out of order.) • Secondary CPU: Power OFF
Diagnosis message on CI590-CS31 LEDs	“CS31 A” ON, “CB” OFF, "RUN A" ON, "RB" OFF, "SYNC-ERR" OFF, "S-ERR" ON (Blinking).

Secondary CPU stop

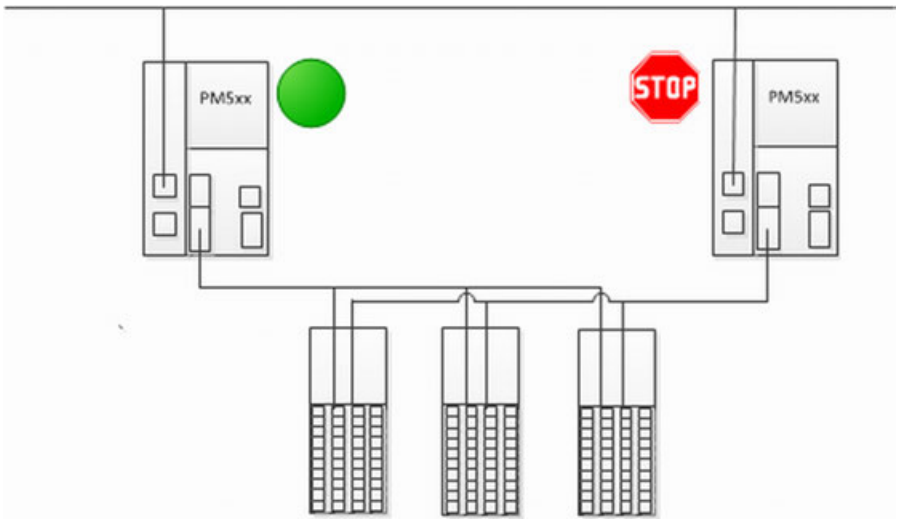

Fig. 50: Use case 4

Reaction	No switch over
Total switch over time	N.A.
Comment	Process continues
Diagnosis message on function block	• Primary CPU: HA_CS31_CONTROL: 16#101B (remote CPU failure: other CPU is OFF or out of order.) • Secondary CPU: STOP
Diagnosis message on CI590-CS31 LEDs	“CS31 A” ON, “CB” ON (Blinking), "RUN A" ON, "RB" OFF, "SYNC-ERR" OFF, "S-ERR" OFF.

Primary CS31 bus off / Disconnected / Short circuit near CPU / No module connected

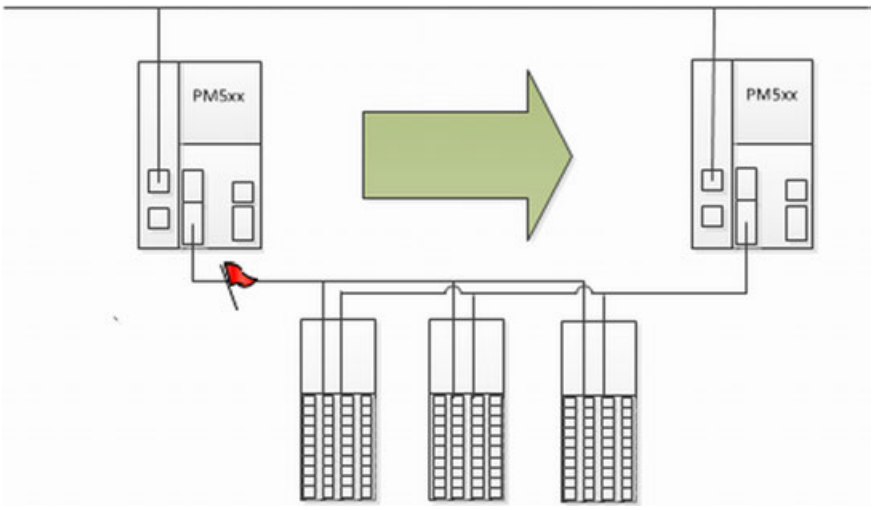

Fig. 51: Use case 5

Reaction	Switch over to secondary CPU. All CI590 from the broken CS31 bus are immediately switched over. After the CPU switch over period all CI590 from the other CS31 lines are switched over.
Total switch over time	CI590 switch over period (≤ 4 CS31 cycles) + CPU switch over period (~ 35 HA cycles)
Comment	Outputs are frozen during CI590 switch over period. It takes ~ 35 HA cycles until the other CPU takes over primary status. Thus short disturbances of the CS31 bus cannot cause an unintended switch over.
Diagnosis message on function block	● Primary CPU: HA_CS31_CONTROL: 16#2005 (CS31 Bus failure), HA_CS31_DIAG / HA_CS31_DIAG_VIA_CM574: 16#1021 (one or more CI590-CS31-HA slave(s) is inactive) ● Secondary CPU: STOP
Diagnosis message on CI590-CS31 LEDs	“CS31 A” ON, “CB” ON (Blinking), "RUN A" ON, "RB" OFF, "SYNC-ERR" OFF, "S-ERR" OFF.

Primary CS31 bus off / Disconnected / Short circuit at local CI590/ Some Modules still connected

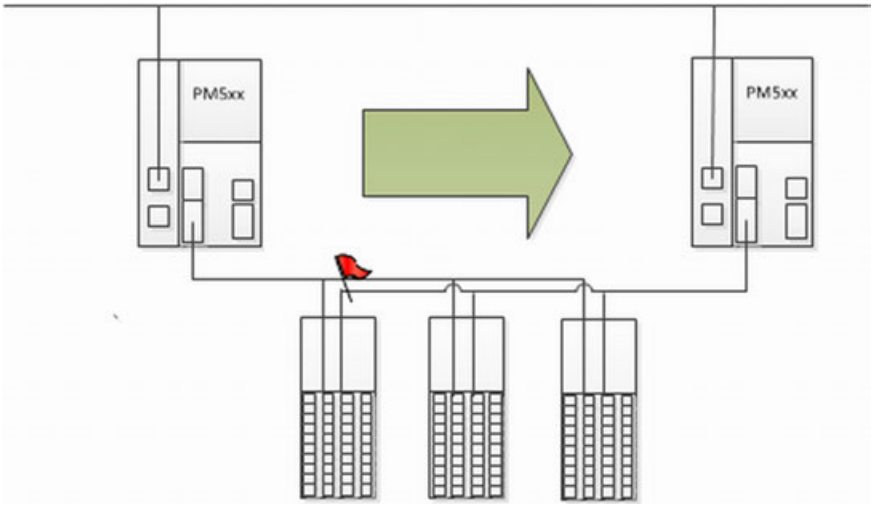

Fig. 52: Use case 6

Reaction	Switch over to secondary CPU. All disconnected CI590 are immediately switched over. After the CPU switch over period all remaining CI590 of the same CS31 line and all CI590 from the other CS31 lines are switched over.
Total switch over time	CI590 switch over period (≤ 4 CS31 cycles) + CPU switch over period (~ 35 HA cycles)
Comment	Outputs are frozen during CI590 switch over period. It takes ~ 35 HA cycles until the other CPU takes over primary status. Thus short disturbances of the CS31 bus cannot cause an unintended switch over.
Diagnosis message on function block	● Primary CPU: HA_CS31_CONTROL: 16#1021 (own CI590-CS31-HA slave failure (missing module), HA_CS31_DIAG / HA_CS31_DIAG_VIA_CM574: 16#1021 (one or more CI590-CS31-HA slave(s) is inactive) ● Secondary CPU: HA_CS31_CONTROL: 16#201B (remote CS31 Bus failure: other CPUs' CS31 Bus is out of order)
Diagnosis message on CI590-CS31 LEDs	“CS31 A” OFF, “CB” ON, "RUN A" OFF, "RB" ON, "SYNC-ERR" ON, "S-ERR" ON (Blinking).

Secondary CPU CS31 bus disconnected / Short Circuit / At least one Module is disconnected

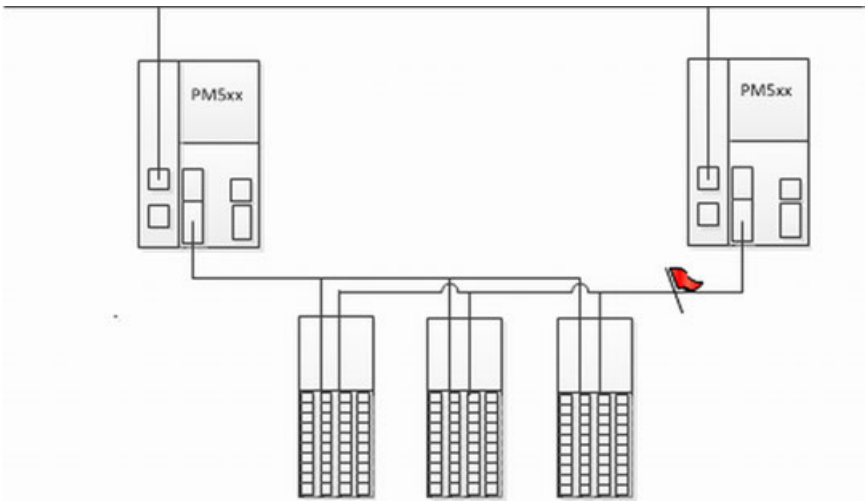

Fig. 53: Use case 7

Reaction	No switch over
Total switch over time	N.A.
Comment	Process continues
Diagnosis message on function block	● Primary CPU: HA_CS31_CONTROL: 16#201B (remote CS31 Bus failure: other CPUs' CS31 Bus is out of order) ● Secondary CPU: HA_CS31_CONTROL: 16#1021 (own CI590-CS31-HA slave failure (missing module), HA_CS31_DIAG / HA_CS31_DIAG_VIA_CM574: 16#1021 (one or more CI590-CS31-HA slave(s) is inactive.)
Diagnosis message on CI590-CS31 LEDs	“CS31 A” ON, “CB” OFF, "RUN A" ON, "RB" OFF, "SYNC-ERR" OFF, "S-ERR" ON (Blinking).

Ethernet cable disconnected or no Ethernet communication

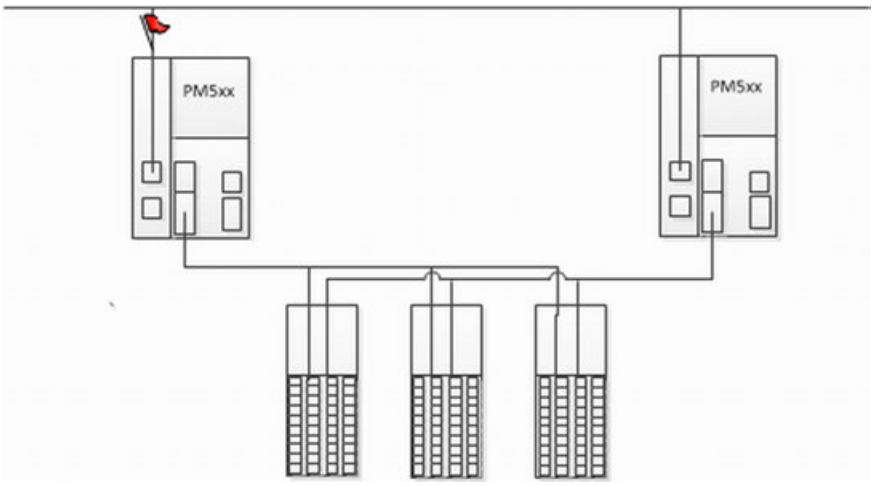

Fig. 54: Use case 8

Reaction	No switch over
Total switch over time	N.A.
Comment	Process continues
Diagnosis message on function block	• Primary CPU: HA_CS31_CONTROL: 16#2013 (no Ethernet Link) • Secondary CPU: HA_CS31_CONTROL: 16#2013 (No Ethernet Link)
Diagnosis message on CI590-CS31 LEDs	CI590-CS31 LEDs status: “CS31 A” ON, “CB” ON, "RUN A" ON, "RB" OFF, "SYNC-ERR" OFF, "S-ERR" OFF (considering PM1 is Primary).

One or more CI590-CS31-HA are off or not connected to both CPUs

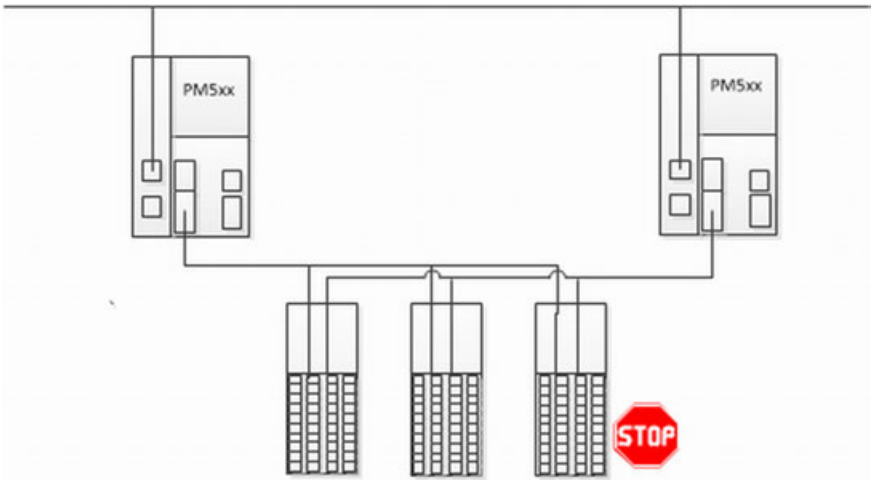

Fig. 55: Use case 9

Reaction	No switch over
Total switch over time	N.A.
Comment	Process continues on existing module according user's choice

Diagnosis message on function block	• Primary CPU: HA_CS31_CONTROL: 16#2006 (fault on both local and remote CPU), HA_CS31_DIAG / HA_CS31_DIAG_VIA_CM574: 16#1021(one or more CI590-CS31-HA slave(s) is inactive),HA_CS31_DIAG_VIA_CM574: 16#1021(one or more CI590 are inactive) • Secondary CPU: HA_CS31_CONTROL: 16#2006 (fault on both local and remote CPU), HA_CS31_DIAG / HA_CS31_DIAG_VIA_CM574: 16#1021(one or more CI590-CS31-HA slave(s) is inactive), HA_CS31_DIAG_VIA_CM574: 16#1021 (one or more CI590 are inactive)
Diagnosis message on CI590-CS31 LEDs	“CS31 A” ON, “CB” ON, "RUN A" ON, "RB" OFF, "SYNC-ERR" OFF, "S-ERR" OFF.

CM574-RS is not in RUN mode in primary

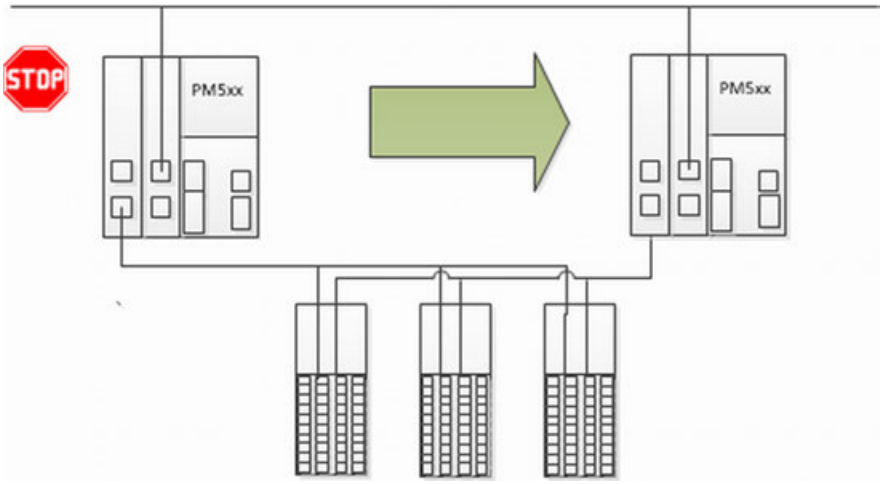

Fig. 56: Use case 10

Reaction	Switch over to secondary PLC
Total switch over time	5 ms
Comment	Outputs freeze to last state during switch over time. Then process continues on secondary CPU.
Diagnosis message on function block	• Primary CPU: HA_CS31_CONTROL: 16#2005 (CS31 Bus failure), HA_CS31_DIAG_VIA_CM574: 16#2013 (error in DPRAM communication between CM574-RS and AC500 CPU) • Secondary CPU: HA_CS31_CONTROL: 16#201B (remote CS31 Bus failure: other CPUs' CS31 Bus is out of order)
Diagnosis message on CI590-CS31 LEDs	“CS31 A” ON (Blinking), “CB” ON, "RUN A" OFF, "RB" ON, "SYNC-ERR" ON (Blinking), "S-ERR" OFF.

CM574-RS not in RUN mode in secondary

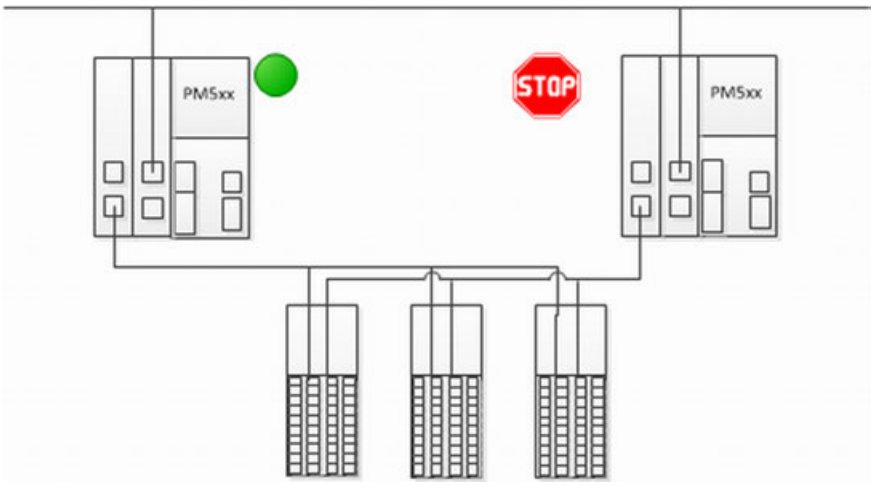

Fig. 57: Use case 11

Reaction	No switch over
Total switch over time	N.A.
Comment	Process continues
Diagnosis message on function block	• Primary CPU: HA_CS31_CONTROL: 16#201B (remote CS31 Bus failure: other CPUs' CS31 Bus is out of order) • Secondary CPU: HA_CS31_CONTROL: 16#2005 (CS31 Bus failure), HA_CS31_DIAG_VIA_CM574: 16#2013 (error in DPRAM communication between CM574-RS and AC500 CPU)
Diagnosis message on CI590-CS31 LEDs	“CS31 A” ON, “CB” ON (Blinking), "RUN A" ON, "RB" OFF, "SYNC-ERR" OFF, "S-ERR" OFF.

CM574-RS not in RUN mode in both systems

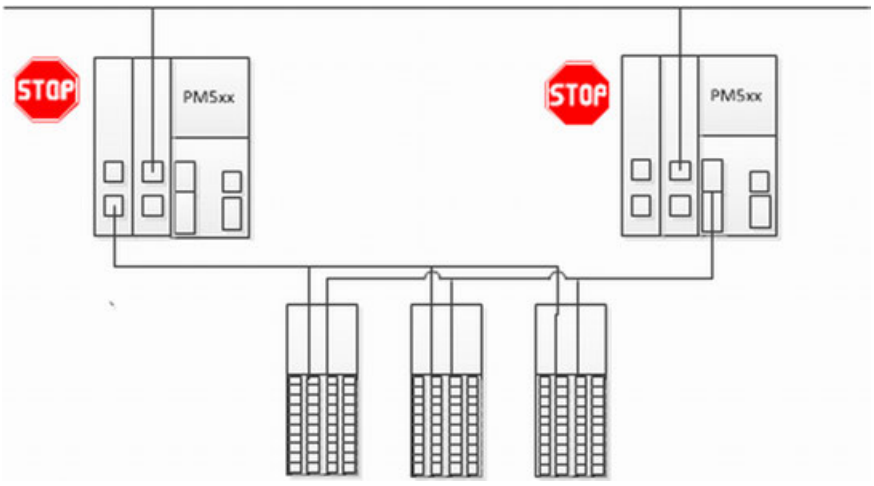

Fig. 58: Use case 12

Reaction	No switch over as fault is in both system
Total switch over time	N.A.
Comment	-

Diagnosis message on function block	● Primary CPU: HA_CS31_CONTROL: 16#2006 (fault on both local and remote CPU), HA_CS31_DIAG_VIA_CM574: 16#2013 (error in DPRAM communication between CM574-RS and AC500 CPU) ● Secondary CPU: HA_CS31_CONTROL: 16#2006 (fault on both local and remote CPU), HA_CS31_DIAG_VIA_CM574: 16#2013 (error in DPRAM communication between CM574-RS and AC500 CPU)
Diagnosis message on CI590-CS31 LEDs	“CS31 A” ON (Blinking), “CB” ON (Blinking), "RUN A" ON (Blinking), "RB" OFF, "SYNC-ERR" OFF, "S-ERR" ON (Blinking).

Manual switch over by users

Reaction	Switch over to secondary CPU at user's request
Total switch over time	N.A.
Comment	Process continues, primary and secondary CPUs are swapped
Diagnosis message on function block	● Primary CPU: No Error ● Secondary CPU: No Error
Diagnosis message on CI590-CS31 LEDs	“CS31 A” ON, “CB” ON, "RUN A" OFF, "RB" ON, "SYNC-ERR" ON, "S-ERR" OFF (Considering Manual switch over request to PM1).

Procedure for modifying hardware and application program

In order to modify hardware configuration or application program while HA-CS31 system is running, proceed as follows:

1. Execute all necessary changes.
2. Compile the project.
3. Make sure that there is no error in the program.
4. We recommend you, to carry out a 'Clean All' and 'Rebuild All'.
5. Select the communication channel of the primary CPU.
6. Download the modified program.
   ⇨ Now the CPU goes to STOP mode and there will be a changeover to secondary CPU.
7. After a successful download, set the primary CPU to RUN mode and create a boot project.
   ⇨ Now, the primary CPU is updated with the new program.
8. Select the communication channel of the second CPU which is now the primary. Download the modified program.
   ⇨ The CPU switches to STOP mode which results in a change over to the original CPU. The original CPU will start working as Primary.
9. After a successful download, set the CPU to RUN mode and create a boot project.
   ⇨ The complete system works in the same status as before modification.

After adding or deleting the HA_CS31_DATA_SYNC function block or any HA-CS31 utility function block, restart the complete system.

It is absolutely necessary that both CPUs have identically user programs.

The replacement of CI590 is possible with a normal HA-CS31 system, which otherwise has no error: PLC A has to be the primary.

For replacement of CI590 when PLC B is the primary, the following pins of TU522-CS31 must be bridged before:

- *2.2 to 2.5*
- *2.3 to 2.6*
- *2.4 to 2.7*

System structure

A HA-CS31 system is characterized by two AC500 CPUs with the following features:

- Synchronized by means of UDP Ethernet Bus system.
- Identical application program that is loaded in both CPUs.
- Two CS31 master systems with redundant CI590-CS31-HA slave(s) and additionally connected I/O devices.

Single CS31 bus on CPU COM port

The following picture describes basic operation of HA-CS31 system - a typical scan cycle of an AC500 CPU with redundant CS31 slave (CI590-CS31-HA).

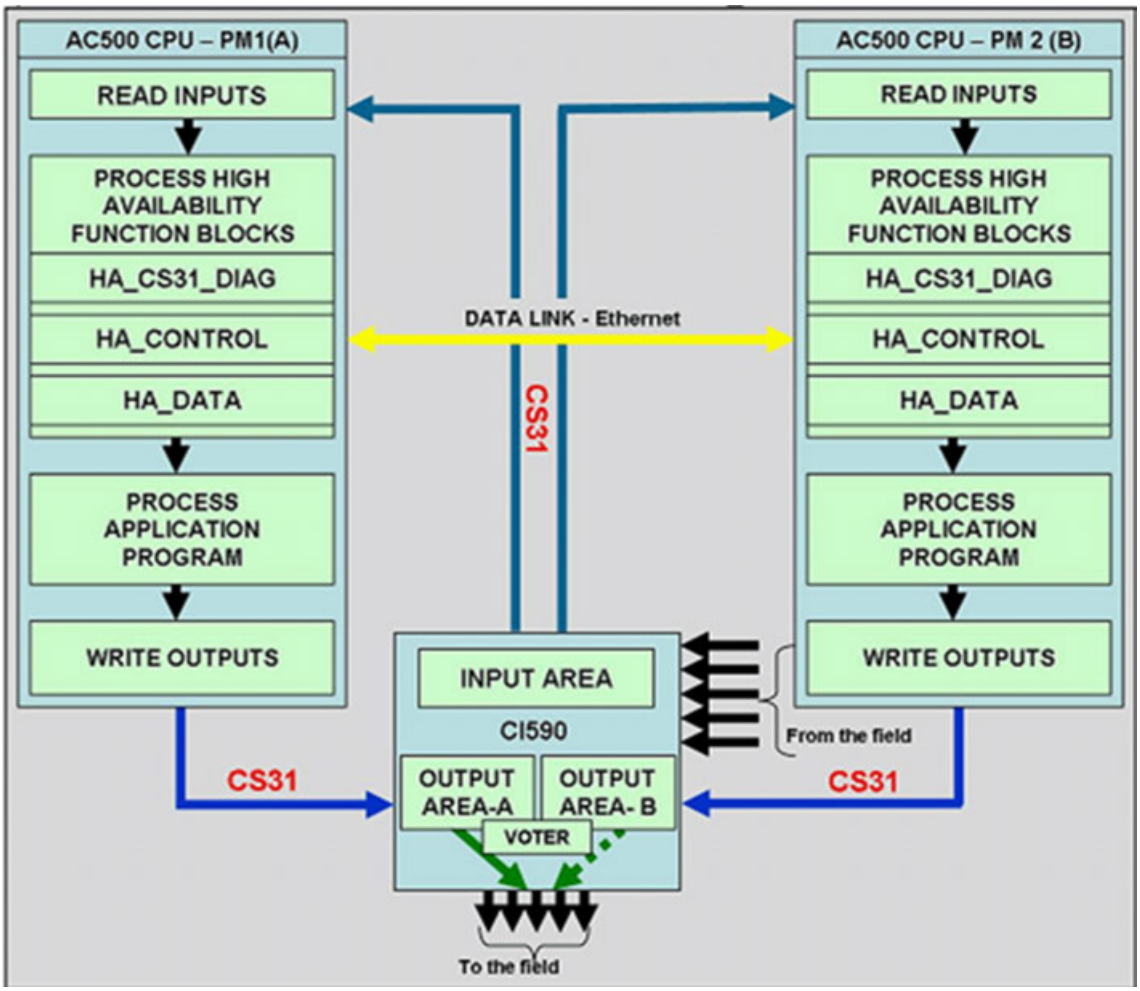

Fig. 59: System Structure AC500 CPU

Status of the inputs connected to CI590-CS31-HA is transferred to both CPUs simultaneously in every CS31 cycle. The CPUs process HA-CS31 function blocks along with the application program. At the end of the program, the generated outputs are transferred to respective buffers in the CI590-CS31-HA via CS31 Bus. Depending on the control byte and on diagnosis events, the CI590-CS31-HA selects one of the output buffers. Then, the buffer content is transferred to physical outputs through the I/O Bus.

Data transfer between the CPUs is watched by HA_CS31_CONTROL function block. HA_CS31_DATA_SYNC function block collects data from the primary CPU and creates a data table which is transferred to the secondary CPU via Ethernet link. Depending on data size, data transfer may take more than one cycle.

CS31 bus extension with CM574-RS module

As of HA-CS31 library version V2.4.0 (HA_CS31_AC500_V23.lib) the library supports CM574-RS CS31 Bus. Data transfer between CPU and CM574-RS is done with the help of the HA-CS31 library function blocks HA_CS31_DIAG_VIA_CM574 and HA_CS31_DIAG_ON_CM574.

The following picture describes the basic operation for this type of configuration:

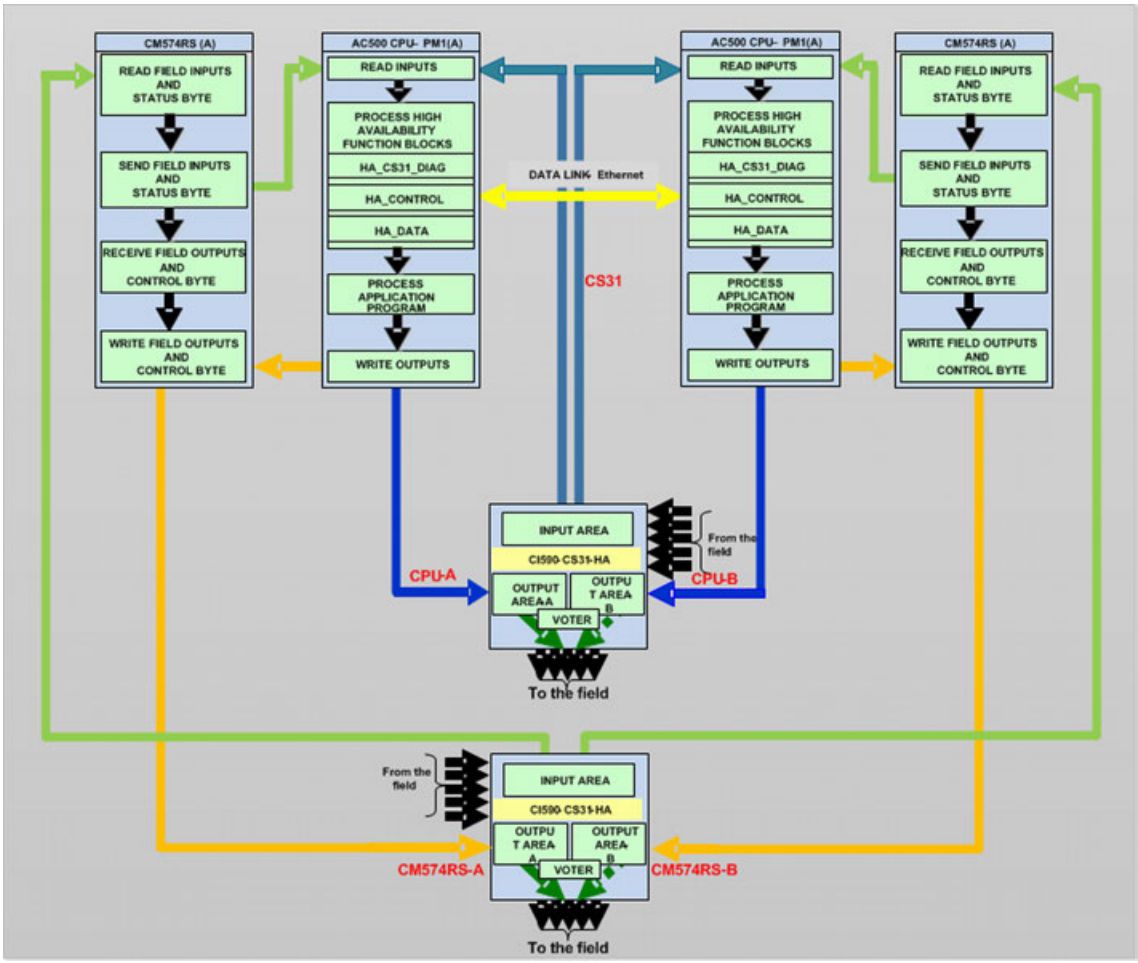

Fig. 60: Operation Process for CS31 and CM574-RS

For further information on function block operations, please refer to the online help for HA-CS31 function blocks (*Chapter 1.5.5.1.2 “AC500 High Availability CS31 system technology” on page 1983*).

Details of control and state byte

These bytes are managed by HA_CS31_CONTROL function block.

Table 99: Structure of the control byte

Bit 0	Bit 1	Bit 2	Bit 3	Bit 4	Bit5	Bit6	Bit 7
CPU status: 0: CPU in STOP mode 1: CPU in RUN mode	Not used	Manual change over request: 0: No request 1: Request	Switch over acknowl-edge-ment: 0: No request 1: Request	Primary request 0: No pri-mary request 1: Primary request	Not used	Not used	Life status: Toggles when CS31 Bus is active

Table 100: Structure of status byte

Bit 0	Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6	Bit 7
Line information: 0: Line B 1: Line A	Other Bus Active: 0: Not Active 1: Active	Manual change over request: 0: No Request 1: Request	Digital O/P buffer different 0: Identical 1: Different	Other Bus Primary 0: Not primary 1: Primary	Analog O/P buffer different 0: Identical 1: Different	CI590-CS31-HA Initialization 0: Not done 1: Done	Life status: Toggles when CS31 Bus is active

HA-CS31 limitations

- The HA-CS31 library does not recommend more than three CM574-RS modules for HA-CS31 Bus. For PM57x CPU only one CM574-RS is recommended.
- The HA-CS31 library will not support more than 1024 HA_CS31_DATA_SYNC function blocks in one POU.
- AC500-eCo PLCs are not supported for HA-CS31 library.
- The HA-CS31 system takes care of the first fault only. If more than one error occurs in the same PLC, the user must restart the system to reset the error.
- To avoid compatibility issues with HA-CS31 library, users must have recommended hardware with runtime system and software *Chapter 1.5.5.1.2.2 “Requirements” on page 1984*.
  For further information on CS31 limitations please refer to *Chapter 1.6.2.8.3.1 “CI590-CS31-HA” on page 4745*.

1.5.5.1.3 AC500 High Availability CS31 library

Components of HA-CS31 library

The HA-CS31 library contains the following function blocks, structures, visualizations, constants and variables.

HA-CS31 library - Overview diagram

The following table gives an overview which function blocks and functions run on CPU and on CM574 (slot 2 to 4). In the example slot 1 is used for CM597-ETH for program download. Function blocks marked in italic font are only available from HA-CS31 library version V2.4.0. In another case if a user has a PLC with more than one onboard ETH (Example: PM595, PM591-2ETH) the user can use ETH2 port for downloading e.g. the program, web server, OPC server communication etc.

Function blocks

POU Name	Function
Group: Control	
HA_CS31_CONTROL	High Availability control block
HA_CS31_DATA_SYNC	High Availability data synchronization block
Group: Diagnosis_PM5xx	
HA_CS31_DIAG	High Availability diagnosis block for CPU COM1 CS31 Line
HA_CS31_DIAG_EXTD	High Availability extended diagnosis block for CPU COM1 CS31 Line
HA_CS31_DIAG_VIA_CM574	High Availability diagnosis block used in CPU for CM574-RS CS31 Line
HA_CS31_DIAG_EXTD_VIA_CM574	High Availability extended diagnosis block for CM574 CS31 Line
Group: Diagnosis_CM574-RS	

POU Name	Function
HA_CS31_DIAG_ON_CM574	High Availability diagnosis block used in CM574 for CM574-RS CS31 Line
Group: Utility	
HA_CS31_CTD	High Availability count down counter
HA_CS31_CTU	High Availability count up counter
HA_CS31_CTUD	High Availability Up/down counter
HA_CS31_INTEGRAL	High Availability integral function
HA_CS31_PID	High Availability PID controller
HA_CS31_PID_DV500	High Availability PID controller for DigiVis 500 face-plates
HA_CS31_PID_FIXCYCLE	High Availability PID controller with fix cycle
HA_CS31_PID_FIXCYCLE_DV500	High Availability PID controller for DigiVis 500 face-plates
HA_CS31_RAMP_INT	High Availability ramp with integer
HA_CS31_RAMP_REAL	High Availability ramp with real
HA_CS31_TOF	High Availability off delay timer
HA_CS31_TON	High Availability on delay timer

Function

Group: Callback	
HA_CS31_CALLBACK_STOP	High Availability CPU STOP event function

Visualizations

HA_CS31_DIAG_VISU_PH	Faceplate for function block HA_CS31_DIAG
HA_CS31_OVERVIEW_VISU	Visualization for HA-CS31 library overview. This is available as of HA-CS31 library version 2.4.0 (HA_CS31_AC500_V23.lib)
Group: Control	
HA_CS31_CONTROL_VISU_PH	Faceplate for function block HA_CS31_CON-TROL
HA_CS31_DATA_SYNC_VISU_PH	Faceplate for function block HA_CS31_DATA_SYNC
Group: Diagnosis_PM5xx	
HA_CS31_DIAG_EXTD_VIA_CM574_VISU_PH	Faceplate for function block HA_CS31_DIAG_EXTD_VIA_CM574
HA_CS31_DIAG_EXTD_VISU_PH	Faceplate for function block HA_CS31_DIAG_EXTD
HA_CS31_DIAG_VIA_CM574_VISU_PH	Faceplate for function block HA_CS31_DIAG_VIA_CM574

Structures

stTON_TOFFSyncData	Structure for synchronized TON and TOFF data
zHA_CS31_PID_DV500_DATA_TYPE	Structure for synchronization data for HA_CS31_PID_DV500
zHA_CS31_PID_FIX-CYCLE_DV500_DATA_TYPE	Structure for synchronization data for HA_CS31_PID_FIXCYCLE_DV500

Global variables

Group: HA_Global_Variables	
fG_HA_PRIMARY	State of the AC500 CPU (FALSE -> PM acts as secondary, TRUE -> PM acts as primary)
fG_HA_PM1_PRIMARY	Indication of primary PM (FALSE -> PM1 / IP1 is not primary, TRUE -> PM1 / IP1 acts as primary
fG_HA_CPU_STOP	Indication of PLC STOP status (FALSE -> indicates the CPU in RUN mode. If TRUE -> indicates the CPU in STOP MODE)
fG_HA_Err	High Availability error state
wG_HA_ErNo	High Availability error code
bitG_Data_ERR	High Availability error state for data synchronization
wG_DATA ERNO	High Availability error code for data synchronization
dwG_HA_OwnIP	Own IP address on sync link connection
dwG_HA_OtherIP	Other PMs IP address on sync link connection
bG_HA_Slot	Slot of interface to sync link connection
dwG_HA_ServerAlive	Life counter incremented by OPC server
byLastDataDelay	Variable to store last delay in data exchange
bitRefreshDataDelay	Bit to refresh data delay
byCntDataDelay	Data delay counts
wETH_Life	Ethernet Life Count
dwHATimersBaseTime	High Availability base timer
Group: HA_VISU_COLOR_INFO	
dwHaVisuBackgroundColor	Visualization elements background color 16#00<B><G><R>
dwHaVisuTitleColor	Visualization elements title background color 16#00<B><G><R>

Prerequisites for the use of HA-CS31 library

Introduction

This library is intended to be used for a HA-CS31 project along with two AC500 CPUs with Ethernet port (or with a Ethernet Communication Module) and CI590-CS31-HA communication interface modules. For general information on how to use CI590-CS31-HA please refer to ↳ *Chapter 1.5.5.1.2.3.4 “Task configuration” on page 1999*.

The following table specifies the mandatory function blocks to be used for HA-CS31 library in order to work with different configurations:

Serial No.	Hardware Configuration Type	Mandatory functions and function blocks	
		To be Downloaded on CPU	To be Downloaded on CM574-RS
1	Only CPU	HA_CALLBACK_STOP HA_CS31_CONTROL HA_CS31_DIAG	Not applicable
2	CPU + CM574-RS	HA_CALLBACK_STOP HA_CS31_CONTROL HA_CS31_DIAG HA_CS31_DIAG_VIA_CM574	HA_CS31_DIAG_ON_CM574

Only the I/O channels of the CI590-CS31-HA and those of connected I/O modules are covered under high availability. It is possible to use local I/O modules, but only with standard functionality and not with high availability feature.

The limitations of the HA-CS31 Bus are the same as of the standard CS31 Bus.

It is not possible to use or mix any other CS31 slave (e.g. DC551-CS31) with a CI590-CS31-HA slave.

The HA-CS31 system only takes care of the first occurring error. If both PLCs are erroneous, then the CPU which generates the second error will remain primary CPU - independent of further errors or manual switch over command.

Hardware configuration

General preconditions

The AC500 I/O configuration on redundant CS31 slave interface (CI590-CS31-HA) must be identical in both CPUs. To avoid any differences in configurations we recommend you, to create a single Automation Builder project for high availability. Then import this project into both CPUs.

CS31 Bus wiring: The CPU connected to CI590-CS31-HA Bus A will be CPU A and will be the primary CPU in usual operation mode. The CPU connected to CI590-CS31-HA Bus B will be CPU B and will be the secondary CPU.

We recommend you, to use separate CM597-ETH modules for larger systems, refer to
↳ *Chapter 1.5.5.1.2.2.1.2 “Recommended use of Ethernet connections” on page 1991*.

In order to use CI590-CS31-2FC (Fast counter) the users have to perform the following:

- CI590-CS31-2FC must be added to their CS31 network.
- Section “Fast Counter” must be updated with the appropriate counter type. The default setting "No Counter” leads the system to become unstable.

For further information please refer to
Example_AC500_HA_CS31_V242_3ADR023070M0201.pdf.

Preconditions when using more than one CS31 line (AC500 CPU configuration + CM574-RS)

- Download the CPU configuration before downloading configuration and program to CM574-RS.
- CM574-RS is a programmable co–processor module with two serial communication ports. Configuration and programming of the CM574-RS module is done by creating a separate node in Automation Builder project. In case of problems, please check configuration of CM574-RS below AC500 CPU node: “Enable debug” must be set to “On”.
- The AC500 CPU node in Automation Builder project must be downloaded to AC500 CPU before downloading CM574-RS configuration and the program to CM574-RS.
- If more than one CS31 line is configured, the users have to set the “Max Wait Run” under each CS31 Bus line based on the actual time taken for all CS31 lines to come online. This will ensure that all outputs of the I/O modules get activated at the same time.
- If the CS31 lines have different sizes their startup time will be different. In order to avoid an unsynchronized I/O module startup, users have to set the “Max Wait Run” under each CS31 Bus line and it must be greater than the actual time taken for all CS31 lines to come online. This will ensure that all I/O module outputs will get activated at the same time.

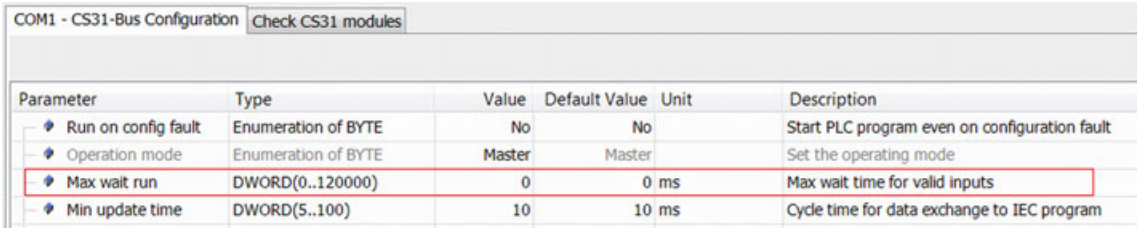

Fig. 61: Configuration in Automation Builder

Program

We recommend you, to use an AC500 PLC node (Automation Builder configuration + program) download to both PLCs, create boot project in both and restart the complete system.

We recommend you, to use the IP address of CPU A as IP1 in HA_CS31_CONTROL function block.

HA-CS31 utility function blocks are synchronized internally. Any other synchronization requirement is to be done through HA_CS31_DATA_SYNC function block.

Restart the complete system if any of the HA-CS31 library function blocks changed. Else the system may become unstable as HA library function blocks are not supporting online changes.

If online program modification is required on a running high availability application (e.g. additional variable, number or type of the variable in HA_CS31_DATA_SYNC), it is necessary to restart the whole system to recreate synchronization.

SFC language (Sequential Function Chart) is not recommended for HA programming as too much and too spread data is to synchronize.

If web visualization is required, the following setup is recommended: Onboard Ethernet for web server and OPC & Automation Builder communication, CM597-ETH for HA data synchronization, refer to *Chapter 1.5.5.1.2.2.1.2 “Recommended use of Ethernet connections” on page 1991*.

For web visualization users have to use onboard Ethernet slot. If a user has a PLC with more than one onboard ETH port (Example: PM595, PM591-2ETH) the user can use ETH1 port for UDP data exchange and ETH2 for web server.

If a user is using a PLC with one onboard ETH port and requires web visualization, then use onboard ETH for web visualization (CM597-ETH does not support web server) and CM597-ETH for UDP data exchange. This change may be able to make some impact on UDP data exchange performance as CM597-ETH port has a lower priority than the PLC on board port.

Use DigiVis and OPC server for writing data as it will be written to both PLCs at the same time. We recommend you, not to use HMI for writing data as it is not written to both PLCs.

PM591-2 ETH and PM595 PLCs must use onboard ETH1 for UDP data communication.

Task configuration

The default task in the CPU can be used for the application program, containing the utility blocks. Beyond this the following tasks have to be created:

- HA_Task on CPU, containing the CONTROL and DIAG function blocks.
- HA_Task on CM574, containing DIAG_ON_CM574 function blocks.

The cycle times are dependent on the CS31 cycle time which is calculated by the Automation Builder and indicated in the CS31 Bus node (tab “Check CS31 modules”). Minimum HA CPU cycle time must be either 30 ms or (CS31 cycle time) whichever value is higher. HA-CM574-RS cycle time must be always lesser than the CPU cycle time.

HA_CS31_CALLBACK_STOP function must be called in CPU program as a Stop Event under SYSTEM EVENTS with the name starting with "callback" (e.g. "callback_stop").

Proceed as follows:

- Select: *Task configuration -> system event*.
- Enable the system event **Stop**.
- In the ‘Called POU’ column type in the POU name, starting with CALLBACK (e.g. CALLBACK_STOP).
- Click the ‘Create POU <individual POU name>’ button to create the CALLBACK_STOP (FUN) function in the POU project.
- Switch to CALLBACK_STOP POU and insert HA_CS31_CALLBACK_STOP function.

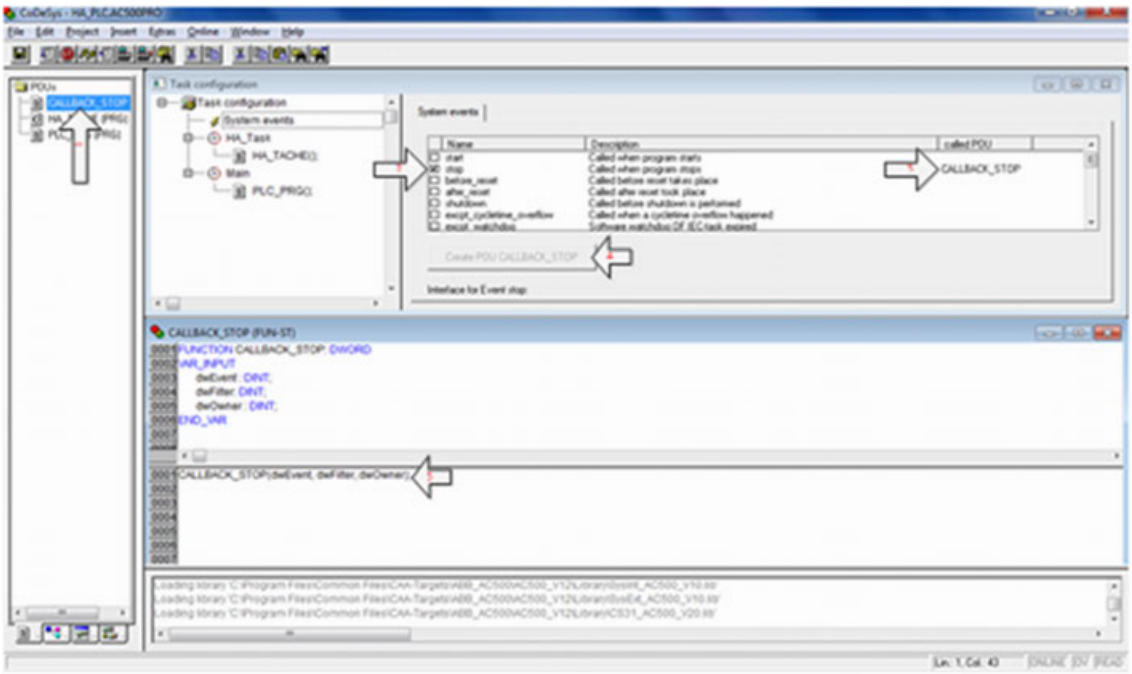

Fig. 62: Callback stop event

If a customer has downloaded the program to the PLC with a wrong callback stop event name then the CPU freezes and is unable to log in/on to the PLC using Ethernet cable. Users have to download a blank project to the PLC using RS-232 communication cable (TK501) in order to return the PLC into healthy stage. After this, the users have to correct the callback stop event name as recommended and restart the download.

The callback stop event should follow the name pattern “CALLBACK_xxx”.

The blocks contained in the library can only be executed in RUN mode of the PLC, but not in 'simulation' mode.

Control and diagnosis - Function blocks and functions

HA_CS31_CALLBACK_STOP - HA CPU STOP event function

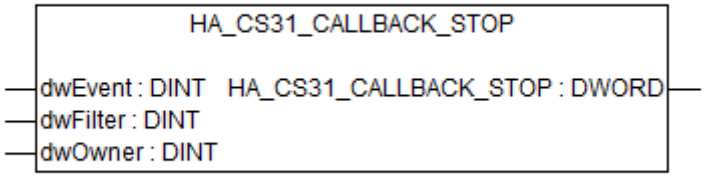

Fig. 63: Function HA_CS31_CALLBACK_STOP

Table 101: General information

Available as of runtime system	V2.3 and above
Included in library	HA_CS31_AC500_V23.lib (V2.4). In previous library versions this component was a program (not a function).
Type	DWORD (previously this function was a program)

This mandatory function is intended to detect the CPU stop event and process logic related to HA-CS31 project. For further information please refer to *Chapter 1.5.5.1.3.2.4 “Task configuration” on page 2023*.

HA_CS31_CALLBACK_STOP function is programmed to process logic related to HA-CS31 project in case of CPU switching into stop mode.

If there is a STOP event initiated in the PLC, HA_CS31_CALLBACK_STOP function is processed before the CPU switches to STOP state. This function sets/resets some HA-CS31 library global variables, to provide the one CPU’s STOP information to the other CPU.

Input description

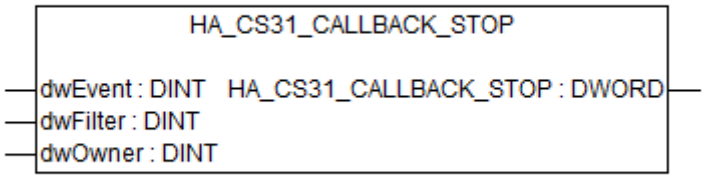

Fig. 64: Function HA_CS31_CALLBACK_STOP

dwEvent Data type: DINT.
Runtime system event in which the function block is to be called.

dwFilter Data type: DINT.
Runtime system event filter.

dwOwner Data type: DINT.
Runtime event system source.

Output description

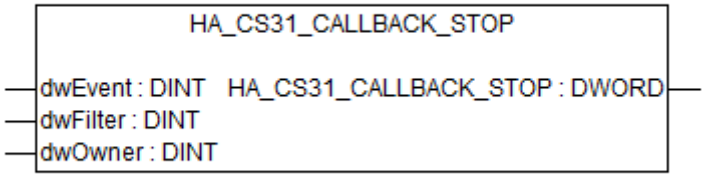

Fig. 65: Function HA_CS31_CALLBACK_STOP

dwHACS31Call-backStop Data type: DWORD.

Function call in ST

```
HA_CS31_CALLBACK_STOP(dwEvent, dwFilter, dwOwner);
```

HA_CS31_CONTROL - HA control FB

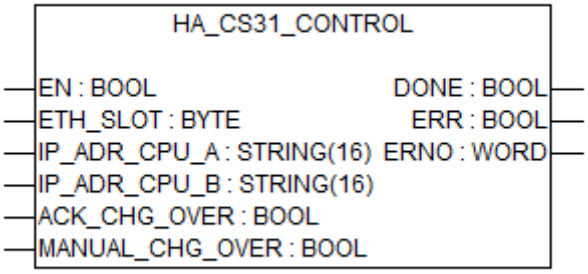

Fig. 66: Function Block HA_CS31_CONTROL

Table 102: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block handles HA-CS31 operation such as change over from primary to secondary CPU in case of an error with related diagnosis. Further it is used for data transfer between high availability CPUs. This is a mandatory function block for high availability application. HA_CS31_CONTROL receives the status data from all seven CS31 lines and sends back the control data.

This function block works with the respective diagnosis function blocks for sending and receiving diagnosis information.

Input description

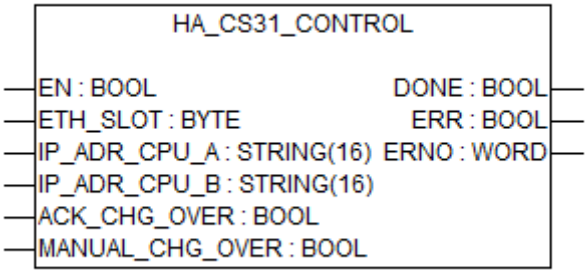

Fig. 67: Function Block HA_CS31_CONTROL

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and an error is displayed.

ETH_SLOT Data type: BYTE, default value: 0, range: 0 to 4.

Ethernet slot number. At input ETH_SLOT the communication module slot (module number) is selected which shall be used by the block.

The internal communication module always has the module number 0. All external communication modules are serially numbered from right to left, starting with module number 1.

> *PM591-2 ETH and PM595 PLCs must use onboard ETH1 for UDP data communication.*

IP_ADR_CPU_A Data type: STRING, default value: 0.0.0.0, range: 000.000.000.000 to 255.255.255.255.

IP address of the AC500 CPU connected to line A.

IP_ADR_CPU_B Data type: STRING, default value: 0.0.0.0, range: 000.000.000.000 to 255.255.255.255

IP address of the AC500 CPU connected to line B.

ACK_CHG_OVER Data type: BOOL, default value: FALSE, range: TRUE/FALSE

The user can acknowledge the changeover event.

MANUAL_CHG_OVER Data type: BOOL, default value: FALSE, range: TRUE/FALSE

A manual change in the primary CPU to value TRUE forces a changeover from the primary CPU to the secondary CPU.

Output description

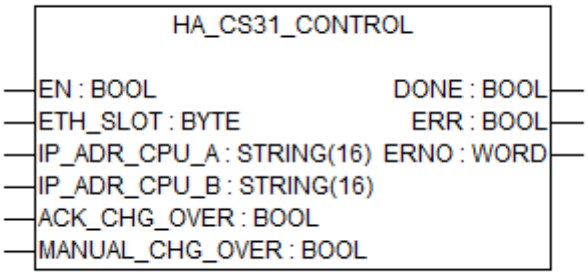

Fig. 68: Function Block HA_CS31_CONTROL

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function block call in ST

```
HACS31control(
EN                      := hacs31_EN,
ETH_SLOT                := hacontrol_ethslot,
IP_ADR_CPU_A            := hacontrol_ipadr_a,
IP_ADR_CPU_B            := hacontrol_ipadr_b,
ACK_CHG_OVER            := hacontrol_ackn,
MANUAL_CHG_OVER         := hacontrol_man_chnge_ovr);
hacontrol_done          := HACS31control.DONE;
hacontrol_err           := HACS31control.ERR;
hacontrol_erno          := HACS31control.ERNO;
```

HA_CS31_DATA_SYNC - HA data synchronization FB

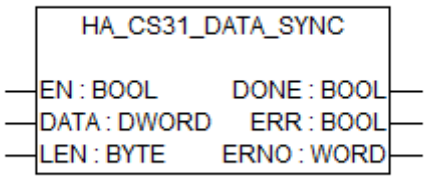

Fig. 69: Function block HA_CS31_DATA_SYNC

Table 103: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

The function block HA_CS31_DATA_SYNC is intended to be used for synchronizing different instances of function blocks in the HA-CS31 project. It is needed only if the user is not using HA-CS31 utility function blocks.

HA_CS31_DATA_SYNC is part of the HA-CS31 library and is used for synchronization. It collects data and size information of the connected function block instance and delivers those details to the HA_CS31_CONTROL function block for data synchronization. Users can use up to 1024 instances of HA_CS31_DATA_SYNC in one program. The maximum of 1024 bytes (user data) can be synchronized in one cycle. In previous library versions (< 2.4.0) the users can use only up to 256 instances of HA_CS31_DATA_SYNC.

To start synchronization HA_CS31_DATA_SYNC should be enabled in both CPUs at least once. Once the function block is enabled, it runs till the system is powered off (regardless of an enabled input status). We recommend you, always to keep ENABLE input as TRUE instead of connecting a variable.

Functionality

The following figure describes the function blocks which are mandatory for data synchronization in all switchover conditions and which are necessary for a complete redundant system.

HA_CS31_SYNC will help users to synchronize different function block instances, variables, arrays etc. HA_CS31_TON is a utility function block available in HA-CS31 library and the outputs of this function block are internally synchronized. All utility function blocks which are available in HA-CS31 library are internally synchronized.

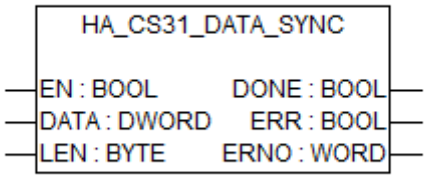

Fig. 70: Function block PUMP_LEVEL_CTRL

Data synchronization is used for writing the values of the defined variables or internal historical values of function blocks from the primary CPU to the secondary CPU. Users need this in case of external change or after repair. Please note that the data is always written from primary to secondary CPU.

Rules for data synchronization

- All instances on HA_CS31_DATA_SYNC must be executed at least once to have a correct data synchronization table.
- We recommend you, to have all instances of HA_CS31_DATA_SYNC and HA-CS31 function blocks to be called in one separate POU. This POU should be called in PLC_PRG.
- During commissioning the users have to use OPC client to tune the parameters of HA-CS31 utility function blocks to make sure that both PLCs are sending/receiving data at the same time without any time delay.

Synchronization of function blocks

The following figure describes how function blocks are provided by HA_CS31_AC500_V23 library. Internal historical values are placed in an exchange table and copied from the primary to the secondary CPU. Then, the secondary CPU is synchronized with the primary and the process outputs are identically on both CPUs.

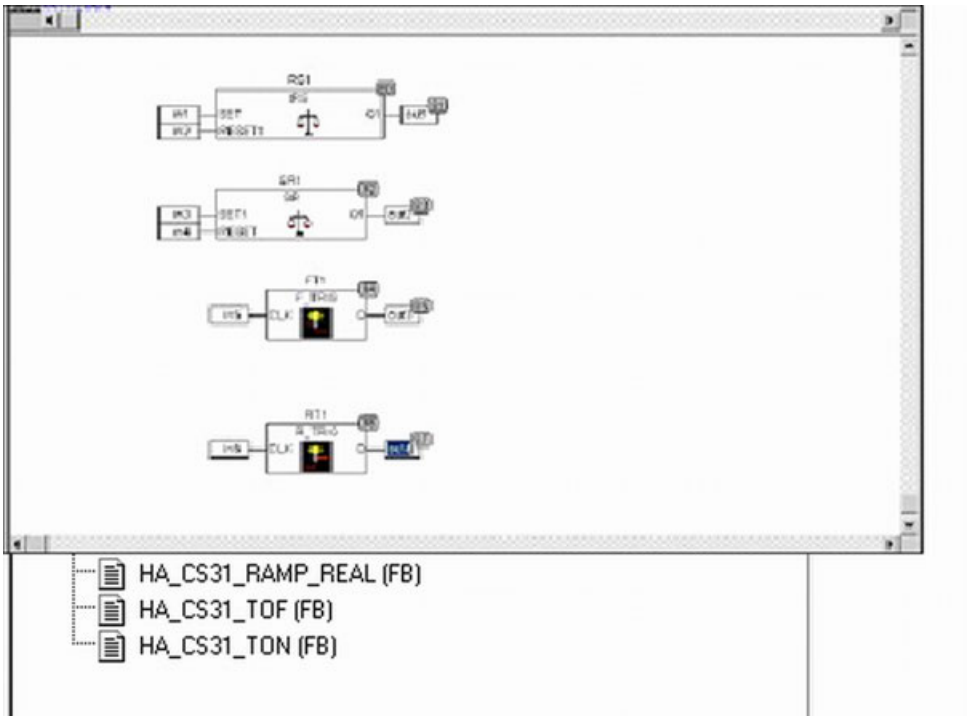

Fig. 71: Function block PUMP_LEVEL_CTRL

The following function blocks with historical values are not included in the HA_CS31_AC500_V23 library:

- Set Reset (SR)
- Reset Set (RS)
- Rising edge trigger (R_TRIG)
- Falling edge trigger (F_TRIG)
- etc.

To be able to resynchronize these values after an error or a PLC stop, these internal values can be added in a synchronization table.

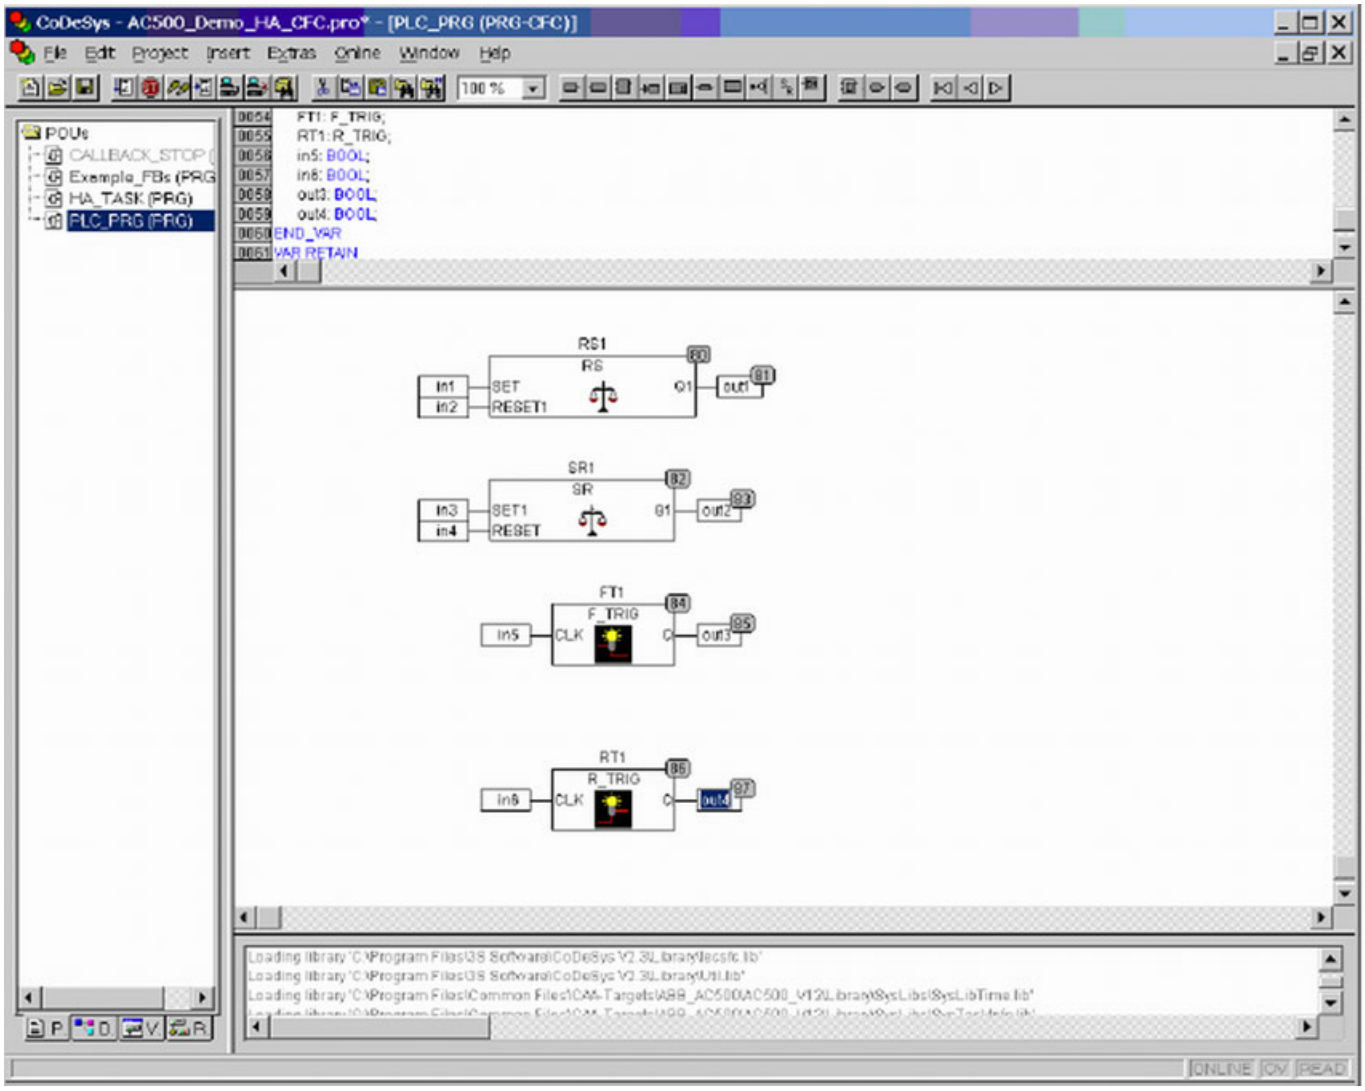

Fig. 72: Function block PUMP_LEVEL_CTRL

Internal values to synchronize are:

- RS1.Q1 (internal value of RS1)
- SR1.Q1 (internal value of SR1)
- FT1.Q (internal value of FT1)
- RT1.Q (internal value of RT1)

User data synchronization

The variables which are changed by a SCADA/ HMI on the primary CPU should be synchronized, e.g:

- Set points, limits, on/off command, etc.
- Variables used to manage program sequences.
- Sequence number, condition with historical values, etc.

Tips for data synchronization:

To optimize data exchange and synchronization in a High Availability program data can be grouped in a structure as shown in the following figure to avoid multiple entries in synchronization table.

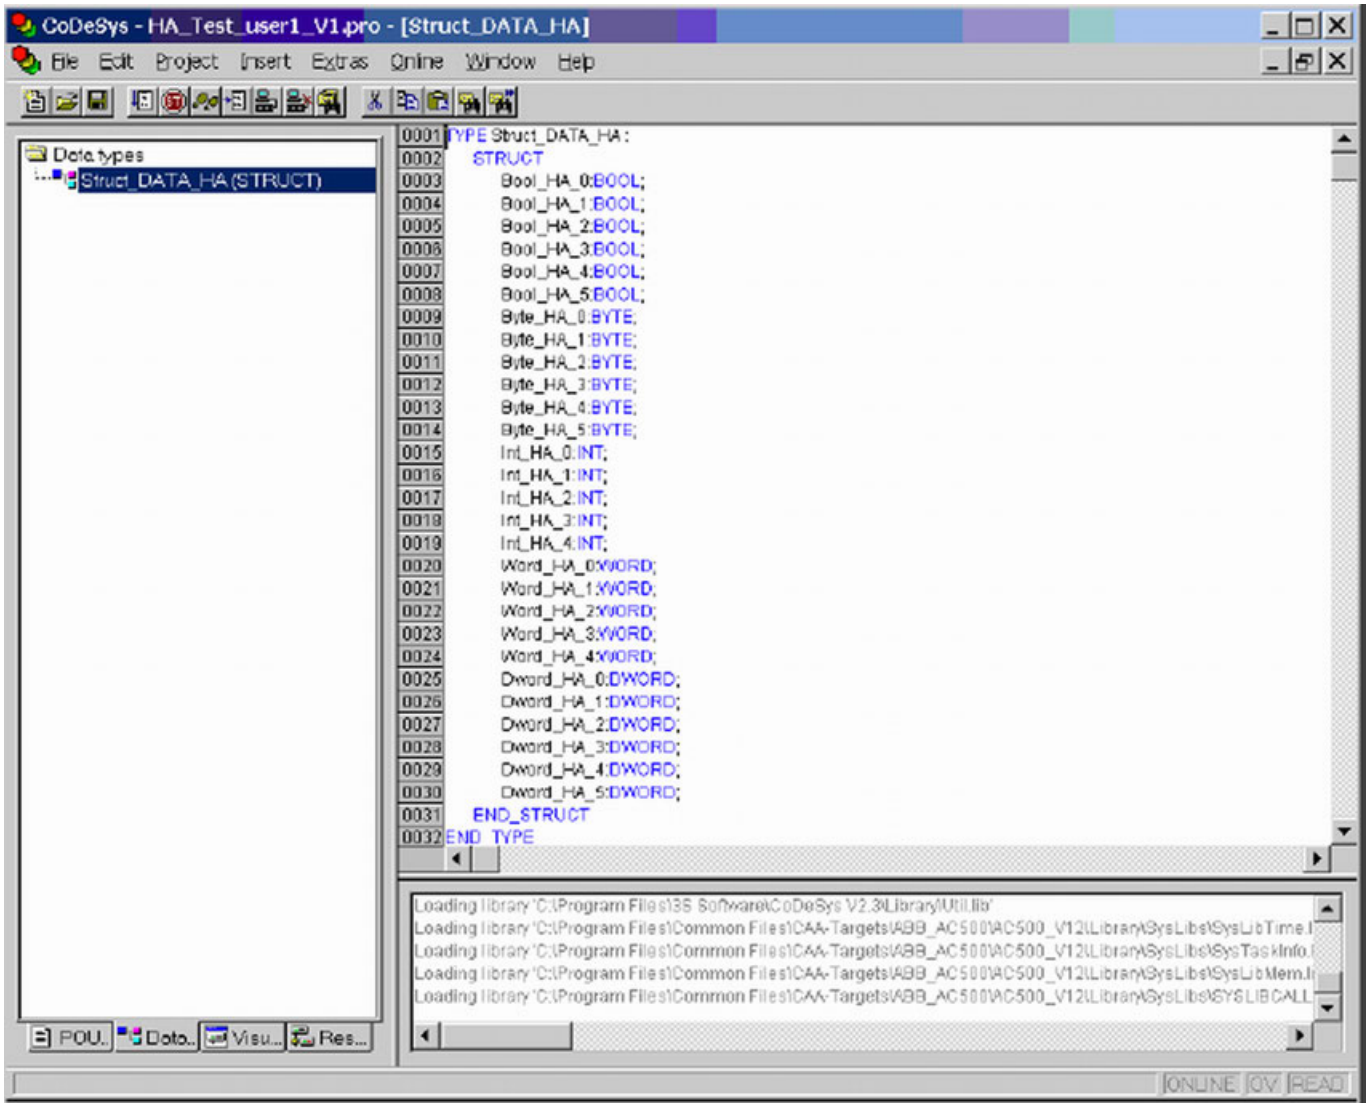

Fig. 73: Function block PUMP_LEVEL_CTRL

Then, one complete structure can be placed in a synchronization table. In the example all variables of the structure data will be synchronized using only one instance of HA_CS31_DATA_SYNC.

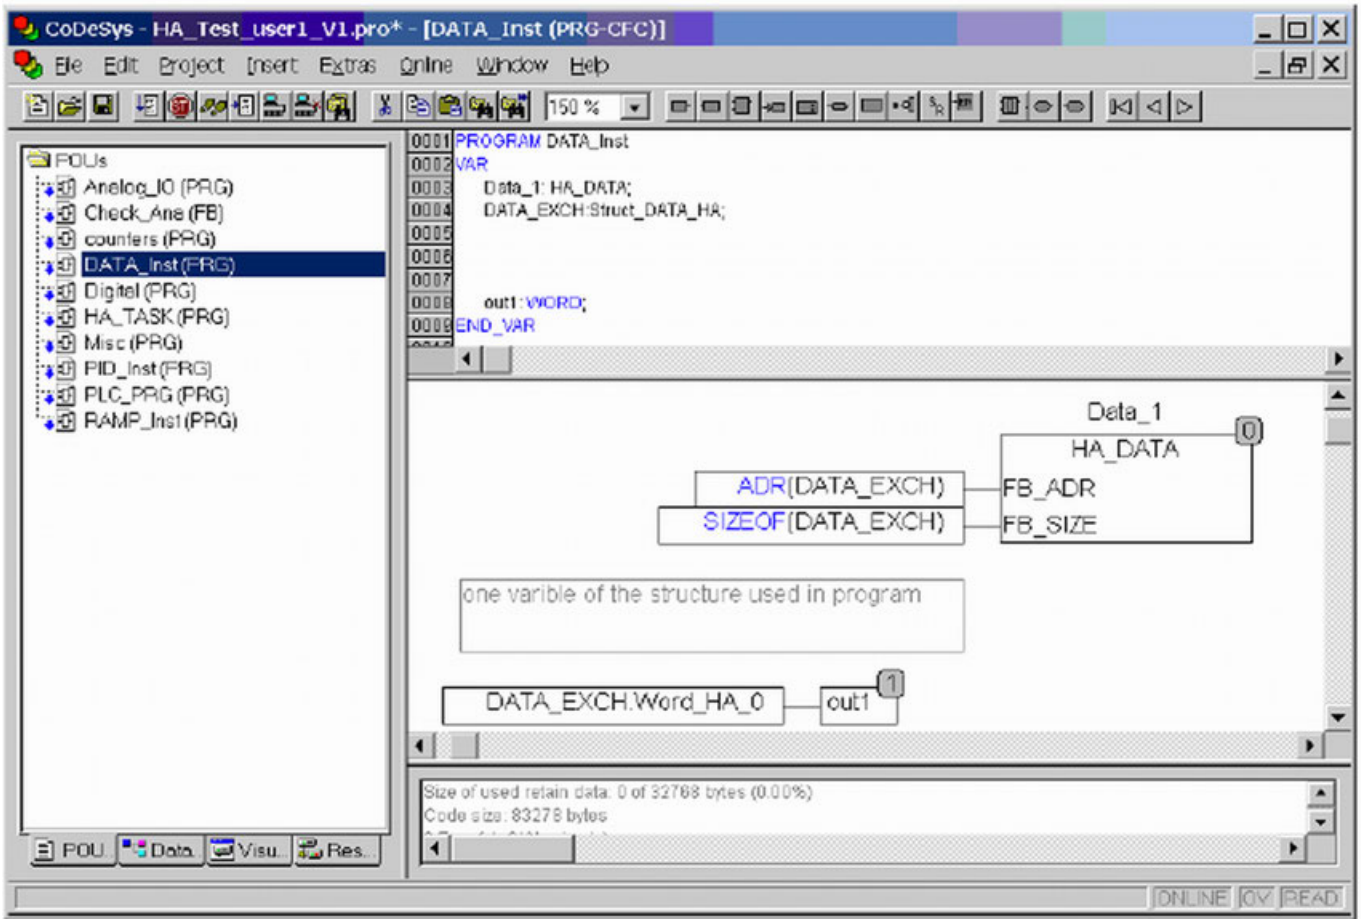

Fig. 74: Function block PUMP_LEVEL_CTRL

Input description

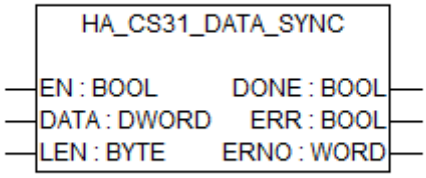

Fig. 75: Function block HA_CS31_DATA_SYNC

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and an error is displayed.

DATA

Data type: DWORD, default value: 0, range: 0-255.

Start address of the parameters/ variables to be synchronized (via ADR-operator).

LEN (length) Data type: BYTE, default value: 0, range: 0-255.

Length of the parameters/variables to be synchronized (via SIZEOF-operator).

Output description

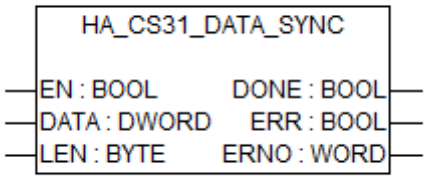

Fig. 76: Function block HA_CS31_DATA_SYNC

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function block call in ST

```
HACS31_datasync(
EN       := hacs31_sync_EN,
DATA     := ADR(VAR1),
LEN      := SIZEOF(VAR1),
DONE     := hacs31_data_done,
ERR      := hacs31_data_err,
ERNO     := hacs31_data_erno);
```

HA_CS31_DIAG - Reading HA diagnosis

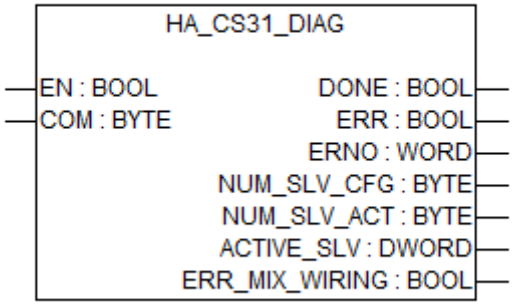

Fig. 77: Function block HA_CS31_DIAG

Table 104: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block handles the control and status bytes of each CI590-CS31-HA module on the CPU COM1 CS31 Bus and related diagnostics. It is a mandatory function block for CPU COM CS31 Bus to work.

HA_CS31_DIAG will be used to get diagnosis information from CPU COM1 CS31 line only. It handles the control and status bytes of each CI590-CS31-HA module on the CS31 Bus. It is also possible to find information such as configured and active CI590-CS31-HA slaves available on CPU COM1 CS31 Bus and related diagnosis.

Input description

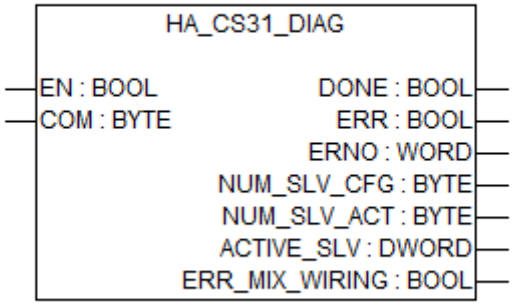

Fig. 78: Function block HA_CS31_DIAG

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and an error is displayed.

COM (communication port)

Data type: BYTE, default value: 1, range: 1.

CS31 communication port number. At input COM, the port number of the serial interface on AC500 CPU for CS31 protocol is selected.

Output description

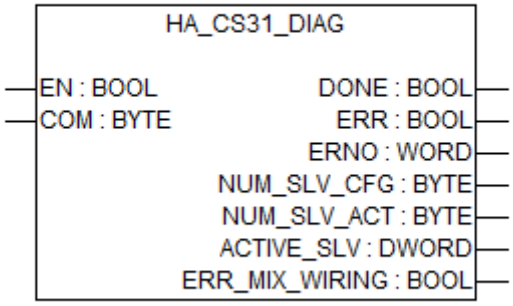

Fig. 79: Function block HA_CS31_DIAG

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_SLV_CFG (number of slaves configured) Number of CI590-CS31-HA slaves configured in the PLC configuration. The output NUM_SLV_CFG indicates the number of CI590-CS31-HA slaves configured in the PLC configuration.

NUM_SLV_ACT (number of active slaves) Number of active CI590-CS31-HA slaves in the CS31 Bus. The output NUM_SLV_ACT indicates the number of active CI590-CS31-HA slaves available in the CS31 Bus.

ACTIVE_SLV (active slaves) Each bit of this DWORD represents an active CI590-CS31-HA device on the CS31 Bus. Each bit of the output ACTIVE_SLV indicates an active CI590-CS31-HA in the CS31 Bus.

ERR_MIX_WIRING (error of mix-wiring) Error in case of mix-wiring between Bus line A and Bus line B of CS31 slaves. Output ERR_MIX_WIRING indicates a mix-wiring (cross-wiring) between line A and line B of CI590-CS31-HA slaves.

Function block call in ST

```
HACS31diag(
EN                  := hacs31_EN,
COM                 := hacs31_COM);
hacs31_done         := HACS31diag.DONE;
hacs31_err          := HACS31diag.ERR;
hacs31_erno         := HACS31diag.ERNO;
hacs31_num_cfg_slv  := HACS31diag.NUM_SLV_CFG;
hacs31_num_act_slv  := HACS31diag.NUM_SLV_ACT;
hacs31_act_slv      := HACS31diag.ACTIVE_SLV;
hacs31_err_mix_wire := HACS31diag.ERR_MIX_WIRING;
```

HA_CS31_DIAG_EXTD - HA Extended Diagnosis FB

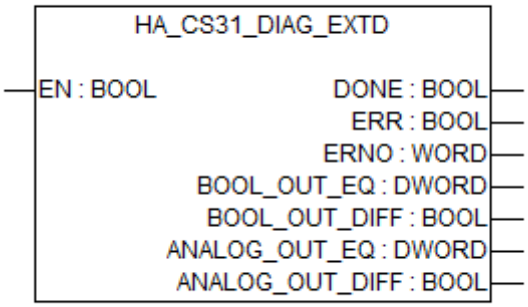

Fig. 80: Function block HA_CS31_DIAG_EXTD

Table 105: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block reads the extended diagnosis from CPU COM1 CS31 Bus. It works only if HA_CS31_DIAG is enabled in the CPU program.

HA_CS31_DIAG_EXTD is an optional function block which can be used to read the extended diagnosis from CI590-CS31-HA slave module. It is used in order to get extended diagnosis information from CPU COM1 CS31 line only.

Input description

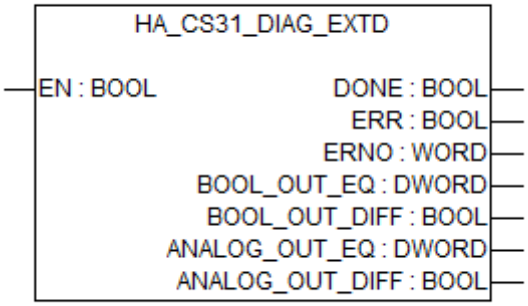

Fig. 81: Function block HA_CS31_DIAG_EXTD

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and an error is displayed.

Output description

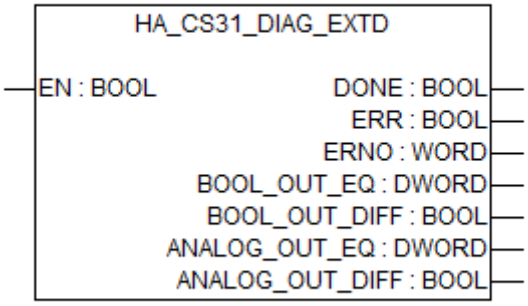

Fig. 82: Function block HA_CS31_DIAG_EXTD

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BOOL_OUT_EQ (bool out equality)

Data type: DWORD.

Each bit of this DWORD represents a CI590-CS31-HA with identical buffer for digital type.

BOOL_OUT_DIFF (bool out difference)

Data type: BOOL.

Error bit to indicate that the output buffer for digital type data is different in one or more CI590-CS31-HA which are active on the Bus.

ANALOG_OUT_EQ (analog out equality)

Data type: DWORD.

Each bit of this DWORD represents a CI590-CS31-HA with identical buffer for analog type.

ANALOG_OUT_DIFF (analog out difference)

Data type: BOOL.

Error bit to indicate that the output buffer for analog type data is different in one or more CI590-CS31-HA which are active on the Bus.

Function block call in ST

```
HACS31_extdiag(
EN                    :=    hacs31_ext_EN);
hacs31_ext_done       :=    HACS31_extdiag.DONE;
hacs31_ext_err        :=    HACS31_extdiag.ERR;
hacs31_ext_erno       :=    HACS31_extdiag.ERNO;
hacs31_ext_out_eq     :=    HACS31_extdiag.BOOL_OUT_EQ;
hacs31_ext_out_diff   :=    HACS31_extdiag.BOOL_OUT_DIFF;
hacs31_ext_ana_out_eq :=    HACS31_extdiag.ANALOG_OUT_EQ;
hacs31_ext_ana_out_diff :=  HACS31_extdiag.ANALOG_OUT_DIFF;
```

HA_CS31_DIAG_EXTD_VIA_CM574 - HA extended diagnosis FB

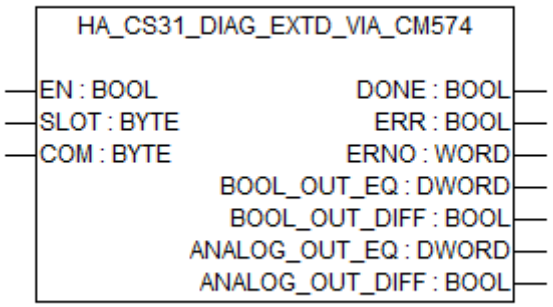

Fig. 83: Function block HA_CS31_DIAG_EXTD_VIA_CM574

Table 106: General Information

Available as of runtime system	V2.3 and above
Included in library	HA_CS31_AC500_V23.lib (V2.4) and above
Type	Function block with historical values.

This function block reads the extended diagnosis of CM574-RS CS31 Bus in High Availability operation. HA_CS31_DIAG_EXTD_VIA_CM574 works only if HA_CS31_DIAG_VIA_CM574 is enabled in the CPU program.

Input description

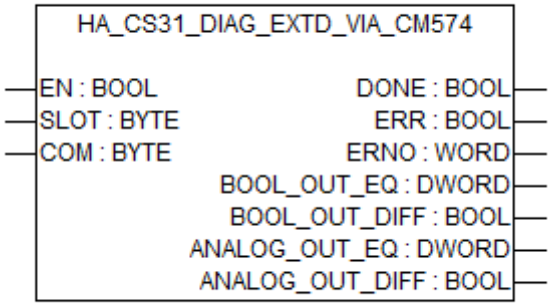

Fig. 84: Function block HA_CS31_DIAG_EXTD_VIA_CM574

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and an error is displayed.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

COM

Data type: BYTE, default value: 1, range: 1 to 2.

CS31 communication port number of the CS31 master.

Output description

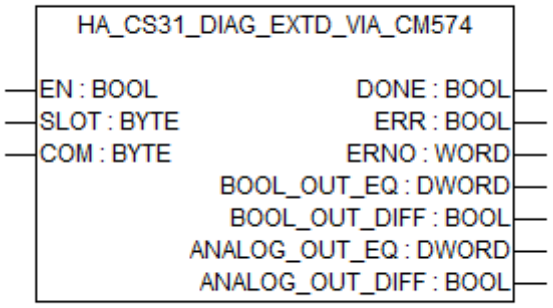

Fig. 85: Function block HA_CS31_DIAG_EXTD_VIA_CM574

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

BOOL_OUT_EQ (BOOL out equal) Data type: DWORD.
Each bit of the DWORD represents identical output buffer for BOOL data in each CS31 slave.

BOOL_OUT_DIFF (BOOL out difference) Data type: DWORD.
If PLC A and PLC B bool output buffer is different, then this bit will turn on to TRUE.

ANALOG_OUT_EQ (analog out equal) Data type: DWORD.
Each bit of the DWORD represents identical output buffer for analog data in each CS31 slave.

ANALOG_OUT_DIFF (analog out different) Data type: DWORD.
If PLC A and PLC B analog output buffer is different, then this bit will turn on to TRUE.

Function block call in ST

```
HACS31_extdiagviaCM574-RS(
EN                                  :=    hacs31_extdiagviaCM574_EN;
SLOT                                :=    hacs31_extdiagviaCM574_EN;
COM                                 :=    hacs31_extdiagviaCM574_EN);
hacs31_extdiagviaCM574_done         :=    HACS31_extdiagviaCM574.DONE;
hacs31_extdiagviaCM574_err          :=    HACS31_extdiagviaCM574.ERR;
hacs31_extdiagviaCM574_erno         :=    HACS31_extdiagviaCM574.ERNO;

```

HA_CS31_DIAG_ON_CM574 - HA diagnosis FB on CM574-RS

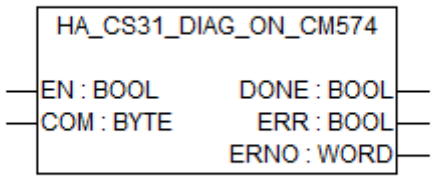

Fig. 86: Function block HA_CS31_DIAG_ON_CM574

Table 107: General Information

Available as of runtime system	V2.3 and above
Included in library	HA_CS31_AC500_V23.lib (V2.4) and above
Type	Function block with historical values.

This function block will work only on CM574-RS and in combination with enabled HA_CS31_DIAG_VIA_CM574 on the CPU. It is a mandatory function block for CM574-RS CS31 Bus to work. HA_CS31_DIAG_ON_CM574-RS sends CS31 Bus diagnosis information to host CPU and receives CS31 configuration information from host CPU.

This function block has to be called separately for each CM574-RS CS31 line (number of CM574-RS CS31 = number of HA_CS31_DIAG_ON_CM574).

Input description

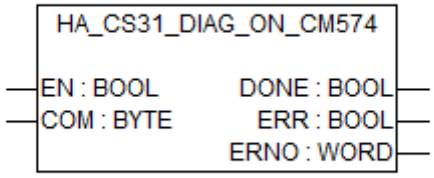

Fig. 87: Function block HA_CS31_DIAG_ON_CM574

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and an error is displayed.

COM

Data type: BYTE, default value: 1, range: 1 to 2.

CS31 communication port number of the CS31 master.

Output description

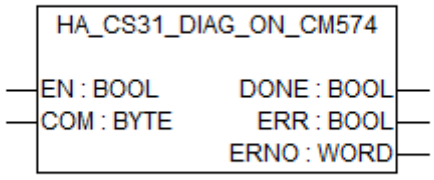

Fig. 88: Function block HA_CS31_DIAG_ON_CM574

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

Function block call in ST

```
HACS31diagonCM574(
EN                      :=    hacs31diagonCM574_EN,
COM                     :=    hacs31diagonCM574_COM);
hacs31diagonCM574_done  :=    HACS31diagonCM574.DONE;
hacs31diagonCM574_err   :=    HACS31diagonCM574.ERR;
hacs31diagonCM574_erno  :=    HACS31diagonCM574.ERNO;
```

HA_CS31_DIAG_VIA_CM574 - HA diagnosis FB for CM574-RS

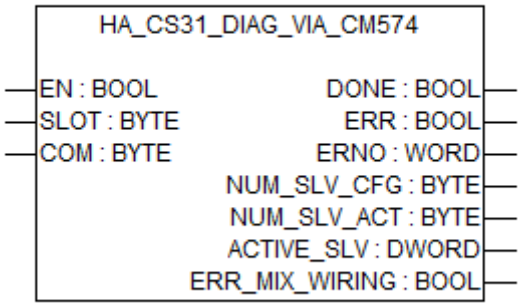

Fig. 89: Function block HA_CS31_DIAG_VIA_CM574

Table 108: General Information

Available as of runtime system	V2.3 and above
Included in library	HA_CS31_AC500_V23.lib (V2.4) and above
Type	Function block with historical values.

This function block will work only on the CPU and in combination with an enabled HA_CS31_DIAG_ON_CM574 in CM574-RS program. HA_CS31_DIAG_VIA_CM574 reads the status byte and writes the control byte of all CI590-CS31-HA connected on CM574-RS COM with relevant diagnosis. This is a mandatory function block for CM574-RS CS31 Bus to work.

This function block has to be called separately for each CM574-RS CS31 line (number of CM574-RS CS31 = number of HA_CS31_DIAG_ON_CM574).

Input description

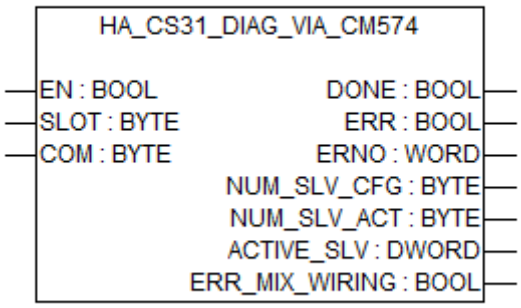

Fig. 90: Function block HA_CS31_DIAG_VIA-CM574

EN (enable)

Data type	Default value	Range	Unit
BOOL	-	-	-

In order to enable the function block processing, input EN has to be continuously set to TRUE. The function block is not processed if input EN = FALSE. While input is set to TRUE, the inputs are continuously checked for validity and plausibility. If this is not the case, processing is aborted and an error is displayed.

SLOT

Data type	Default value	Range	Unit
BYTE	0	0 ... 4 (6)	-

At input SLOT, the device slot is specified which should be used by the function block.

The internal device always has the index 0. All external devices are serially numbered from right to left, starting with 1.

COM

Data type: BYTE, default value: 1, range: 1 to 2.

Communication port number of the CS31 master.

Output description

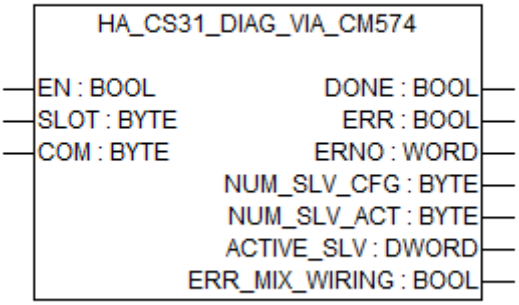

Fig. 91: Function block HA_CS31_DIAG_VIA-CM574

DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

NUM_SLV_CFG (number of slave configured)

Data type: BYTE.

This output indicates the number of CI590-CS31-HA slaves configured in the PLC configuration.

NUM_SLV_ACT (number of slave active)

Data type: BYTE

This output indicates the number of active CI590-CS31-HA slaves available in CS31 Bus.

ACTIVE_SLV (active slaves)

Data type: DWORD

Each bit of this output indicates an active CI590-CS31-HA slave in the CS31 Bus.

ERR_MIX_WIRING (Error Mix Wiring)

Data type: BOOL

This output indicates a mix-wiring (cross-wiring) between line A and line B of CI590-CS31-HA slaves.

Function block call in ST

```
HACS31diagviaCM574(
EN                          :=    hacs31diagviaCM574_EN,
COM                         :=    hacs31diagviaCM574_COM);
hacs31_viaCM574_done        :=    HACS31diagviaCM574.DONE;
hacs31_viaCM574_err         :=    HACS31diagviaCM574.ERR;
hacs31_viaCM574_erno        :=    HACS31diagviaCM574.ERNO;
hacs31_viaCM574_num_cfg_slv :=    HACS31diagviaCM574.NUM_SLV_CFG;
hacs31_viaCM574_num_act_slv :=    HACS31diagviaCM574.NUM_SLV_ACT;
hacs31_viaCM574_act_slv     :=    HACS31diagviaCM574.ACTIVE_SLV;
hacs31_viaCM574_err_mix_wire :=   HACS31diagviaCM574.ERR_MIX_WIRING;
```

Utility function blocks

HA_CS31_CTD - HA count down counter

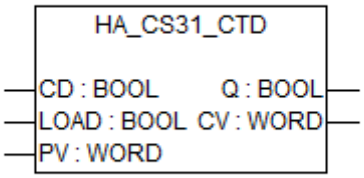

Fig. 92: Function block HA_CS31_CTD

Table 109: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block is a standard count down counter with automatic data synchronization in a high availability application.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_CS31_DATA_SYNC to achieve the same.*

If parameter LOAD=TRUE, parameter CV (**C**ounter **V**ariable) will be initialized with the upper limit of PV (**P**reset **V**alue). If parameter CD (**C**ount **D**own) has a rising edge from FALSE to TRUE, CV will be lowered by 1, provided that CV > 0 (i.e., it does not cause the value to fall below 0).

Input description

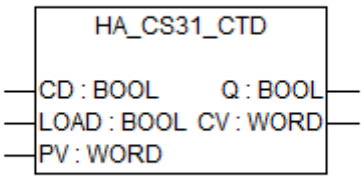

Fig. 93: Function block HA_CS31_CTD

CD Data type: BOOL, default value: FALSE, range: TRUE/FALSE.

Count down with rising edge.

LOAD Data type: BOOL, default value: FALSE, range: TRUE/FALSE.

This parameter loads the parameter PV (preset value) into the parameter CV (counter value) with rising edge at LOAD.

PV Data type: WORD, default value: 0, range: 0 to 65535.

Preset value.

Output description

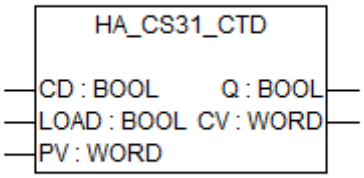

Fig. 94: Function block HA_CS31_CTD

Q Data type: BOOL.

This parameter returns TRUE if parameter CV is 0.

CV Data type: WORD.

Actual counter value.

Function block call in ST

```
HACS31CTD (
CD              := hactd_cd,
LOAD            := hactd_load,
PV              := hactd_pv);
hactd_q         := HACS31CTD.Q;
hactd_cv        := HACS31CTD.CV;
```

HA_CS31_CTU - HA count up counter

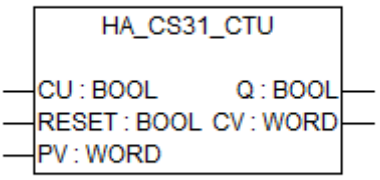

Fig. 95: Function block HA_CS31_CTU

Table 110: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block is a standard count up counter with automatic data synchronization in a high availability application.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_CS31_DATA_SYNC to achieve the same.*

Parameter CV (**C**ounter **V**ariable) will be initialized with 0 if RESET=TRUE. If parameter CU (**C**ount **U**p) has a rising edge from FALSE to TRUE, parameter CV will be raised by 1. Parameter Q will return TRUE when CV is greater or equal to the upper limit PV (**P**reset **V**alue).

Input description

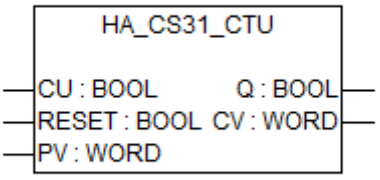

Fig. 96: Function block HA_CS31_CTU

CU Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
Count up with rising edge.

RESET Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
Loads value '0' into CV with a rising edge at RESET.

PV Data type: WORD, default value: 0, range: 0 - 65535.
Preset value.

Output description

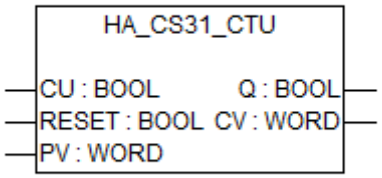

Fig. 97: Function block HA_CS31_CTU

Q Data type: BOOL, range: TRUE/FALSE.
Parameter Q returns TRUE when parameter CV (counter value) is greater than or equal to parameter PV (preset value).

CV Data type: WORD.
Actual counter value.

Function block call in ST

```
HACS31CTU (
CU              := hactu_cu,
RESET           := hactu_reset,
PV              := hactu_pv);
hactu_q         := HACS31CTU.Q;
hactu_cv        := HACS31CTU.CV;
```

HA_CS31_CTUD - HA up/down counter

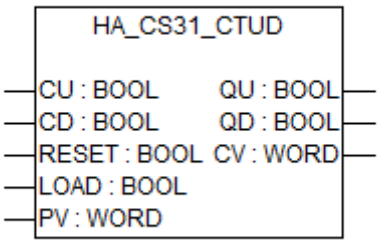

Fig. 98: Function block HA_CS31_CTUD

Table 111: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block is standard bidirectional counter with automatic data synchronization in a high availability application (high availability bidirectional counter).

> *Only internal variables and outputs are synchronized. Input variables or parameters are not synchronized. If necessary, use HA_CS31_DATA_SYNC function block to synchronize the input variables.*

If the CU (Count Up) parameter has a rising edge from FALSE to TRUE, parameter CV (Counter Variable) will be increased by 1. If parameter CD (Count Down) has a rising edge from FALSE to TRUE, parameter CV will be decreased by 1, provided that this does not cause the value to fall below 0.

If RESET=TRUE, CV will be initialized with 0. If LOAD=TRUE, parameter CV will be initialized with PV (Preset Value). QU returns TRUE when CV has become greater or equal PV. QD returns TRUE when CV has become equal 0.

Input description

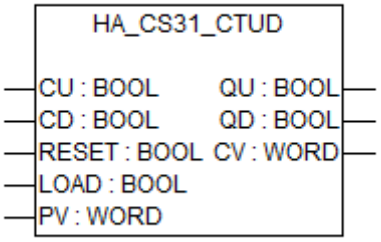

Fig. 99: Function block HA_CS31_CTUD

CU Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
Count up with rising edge.

CD Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
Count down with rising edge.

RESET Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
Loads value 0 into parameter CV with a rising edge at RESET.

LOAD Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
Loads parameter PV into parameter CV with rising edge at LOAD.

PV Data type: WORD, default value: 0, range: 0-65535.
Preset value.

Output description

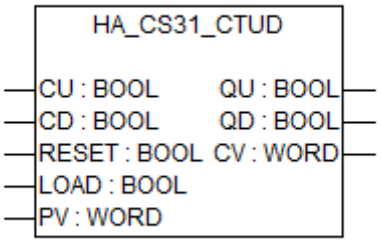

Fig. 100: Function block HA_CS31_CTUD

QU Data type: BOOL
QU is TRUE when parameter CV is greater than or equal to parameter PV.

QD Data type: BOOL
QD is TRUE when parameter CV is 0.

CV Data type: WORD, default value: , range:
Actual counter value.

Function call in ST

```
HACS31CTUD(
CU          := hactud_cu,
CD          := hactud_cd,
RESET       := hactud_reset,
LOAD        := hactud_load,
PV          := hactud_pv);
hactud_qu   := HACS31CTUD.QU;
hactud_qd   := HACS31CTUD.QD;
hactud_cv   := HACS31CTUD.CV;
```

HA_CS31_INTEGRAL - HA integral function block

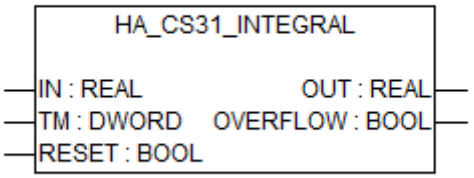

Fig. 101: Function block HA_CS31_INTEGRAL

Table 112: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block approximately determines the integral of the function with automatic data synchronization in a High Availability application.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_CS31_DATA_SYNC to achieve the same.*

In an analogous fashion to DERIVATIVE, the function value is delivered as a REAL variable by using IN. TM contains the time which has passed in a DWORD (in ms). The input of RESET of the bool type allows the function block to start anew with value TRUE. The integral is approximated by two step functions. The average of these is delivered as the approximated integral.

Input description

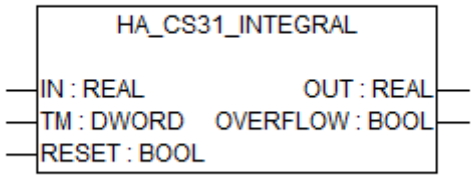

Fig. 102: Function block HA_CS31_INTEGRAL

IN Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Input function value.

TM Data type: REAL, default value: 0, range: 0 to 4294967295.
Time in ms.

RESET Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
Rising edge starts with a new value.

Output description

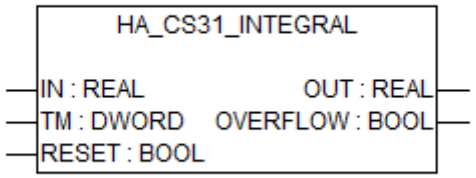

Fig. 103: Function block HA_CS31_INTEGRAL

OUT Data type: REAL.
Integral output.

OVERFLOW Data type: BOOL.
Overflow in the integral part.

Function block call in ST

```
HACS31INTEGRAL(
IN                      := haintegral_in,
TM                      := haintegral_tm,
RESET                   := haintegral_reset);
haintegral_out          := HACS31INTEGRAL.OUT;
haintegral_overflow     := HACS31INTEGRAL.OVERFLOW;
```

HA_CS31_PID - HA PID controller

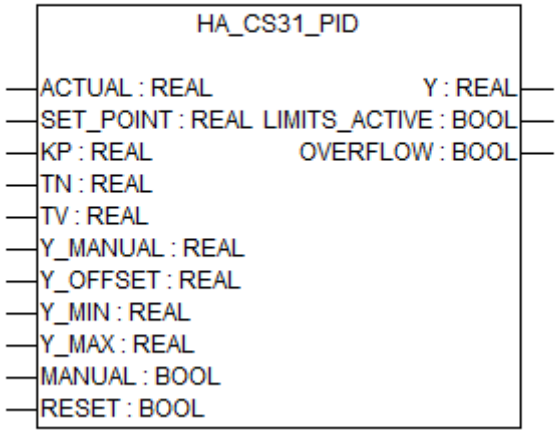

Fig. 104: Function block HA_CS31_PID

Table 113: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block is a standard PID controller with automatic data synchronization in a High Availability application.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_CS31_DATA_SYNC to achieve the same.*

Parameter description

- The parameters Y_OFFSET, Y_MIN and Y_MAX serve for transformation of the manipulated variable within a prescribed range.
- MANUAL parameter can be used to switch to manual operation.
- RESET parameter can be used to re-initialize the controller.
- In normal operation (MANUAL = RESET = LIMITS_ACTIVE = FALSE) the controller calculates the controller error as difference from SET_POINT parameter – ACTUAL parameter, generates the derivation with respect to time de/dt and stores these values internally.
- The output, i.e. the manipulated variable Y unlike the PD controller contains an additional integral part and is calculated as follows: $Y = KP \times (D + 1/TN \int edt + TV\ dD/dt) + Y\_OFFSET$. So besides the P-part also the current change of the controller error (D-part) and the history of the controller error (I-part) influence the manipulated variable. The PID controller can be easily converted to a PI controller by setting TV=0. Because of the additional integral part, an overflow can come about by incorrect parameterization of the controller if the integral of error D becomes too great. Therefore for the sake of security a BOOLEAN output called OVERFLOW is present, which in this case would have the value TRUE. This only will happen if the control system is instable due to incorrect parameterization. At the same time, the controller will be suspended and will only be activated again by re-initialization.

Input description

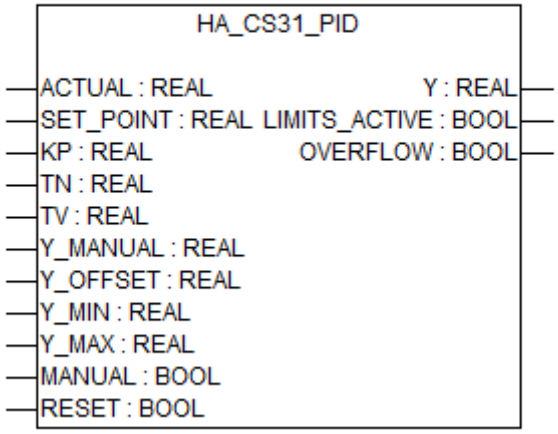

Fig. 105: Function block HA_CS31_PID

ACTUAL Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Current value of the controlled variable.

SET_POINT Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Desired value, command variable.

KP Data type: REAL, default value: 0, range; 0 to 3.402823466e+38.
Coefficient of proportionality, unity gain of the P-part.

TN Data type: REAL, default value: 0, range: 0 to 3.402823466e+38.
Reset time, reciprocal unity gain of the I-part; given in seconds, e.g. "0.5" for 500 ms.

TV Data type: REAL, default value: 0, range: 0 to 3.402823466e+38.
Derivative action time, unity gain of the D-part in seconds, e.g. "0.5" for 500 ms.

Y_MANUAL Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Defines output value Y in case of MANUAL=TRUE.

Y_OFFSET Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Offset for the manipulated variable Y.

Y_MIN Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Lower limit for the manipulated variable Y. If Y exceeds these limits, output LIMITS_ACTIVE will be set to TRUE and Y will be kept within the prescribed range. This control will only work if Y_MIN < Y_MAX.

Y_MAX Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.

Upper limit for the manipulated variable Y. If Y exceeds these limits, output LIMITS_ACTIVE will be set to TRUE and Y will be kept within the prescribed range. This control will only work if Y_MIN < Y_MAX.

MANUAL Data type: BOOL, default value: FALSE, range: TRUE/FALSE.

If TRUE, manual operation will be active, i.e. the manipulated value will be defined by Y_MANUAL.

RESET Data type: BOOL, default value: FALSE, range: TRUE/FALSE.

TRUE resets the controller; during re-initialization Y = Y_OFFSET.

Output description

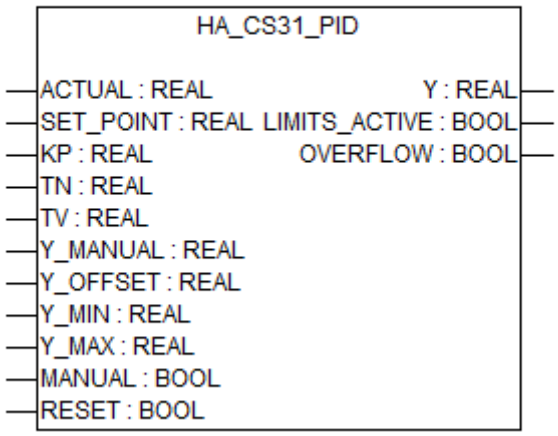

Fig. 106: Function block HA_CS31_PID

Y Data type: REAL.

Manipulated value, calculated by the function block.

LIMITS_ACTIVE Data type: BOOL.

TRUE indicates that Y has exceeded the given limits (Y_MIN, Y_MAX).

OVERFLOW Data type: BOOL.

TRUE indicates an overflow in the integral part.

Function block call in ST

```
HACS31PID(
ACTUAL                  := hapid_actual,
SET_POINT               := hapid_set_point,
KP                      := hapid_kp,
TN                      := hapid_tn,
```

```
TV                      := hapid_tv,
Y_MANUAL                := hapid_y_manual,
Y_OFFSET                := hapid_y_offset,
Y_MIN                   := hapid_y_min,
Y_MAX                   := hapid_y_max,
MANUAL                  := hapid_manual,
RESET                   := hapid_reset);
hapid_y                 := HACS31PID.A;
hapid_limits_active     := HACS31PID.LIMITS_ACTIVE;
hapid_overflow          := HACS31PID.OVERFLOW;
```

HA_CS31_PID_DV500 - HA PID controller for DigiVis

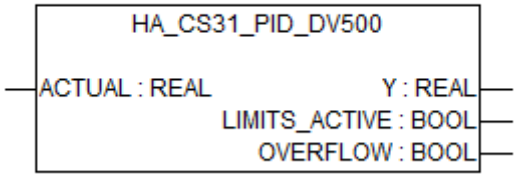

Fig. 107: Function block HA_CS31_PID_DV500

Table 114: General Information

Available as of runtime system	V2.3 and above
Included in library	HA_CS31_AC500_V23.lib (V2.4) and above
Type	Function block with historical values.

This function block is a standard PID controller with automatic data synchronization in a High Availability application.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_CS31_DATA_SYNC to achieve the same.*

In terms of functionality this function block is similar to HA_CS31_PID, though, users can only access the ACTUAL parameter. Users get the complete configuration faceplate on the DigiVis, which is identical to the faceplate of HA_CS31_PID.

Parameter description

- The parameters Y_OFFSET, Y_MIN and Y_MAX serve for transformation of the manipulated variable within a prescribed range.
- MANUAL parameter can be used to switch to manual operation.
- RESET parameter can be used to re-initialize the controller.

- In normal operation (MANUAL = RESET = LIMITS_ACTIVE = FALSE) the controller calculates the controller error as difference from SET_POINT parameter – ACTUAL parameter, generates the derivation with respect to time de/dt and stores these values internally.
- The output, i.e. the manipulated variable Y unlike the PD controller contains an additional integral part and is calculated as follows: Y = KP × (D + 1/TN ∫edt + TV dD/dt) + Y_OFFSET. So besides the P-part also the current change of the controller error (D-part) and the history of the controller error (I-part) influence the manipulated variable. The PID controller can be easily converted to a PI controller by setting TV=0. Because of the additional integral part, an overflow can come about by incorrect parameterization of the controller if the integral of error D becomes too great. Therefore for the sake of security a BOOLEAN output called OVERFLOW is present, which in this case would have the value TRUE. This only will happen if the control system is instable due to incorrect parameterization. At the same time, the controller will be suspended and will only be activated again by re-initialization.

Input description

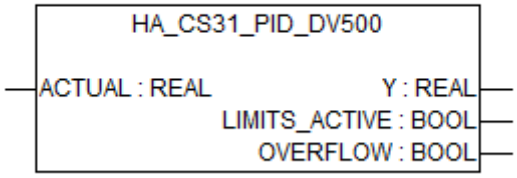

Fig. 108: Function block HA_CS31_PID_DV500

ACTUAL Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Current value of the controlled variable.

Output description

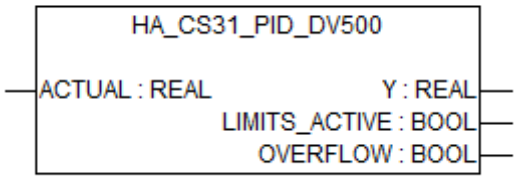

Fig. 109: Function block HA_CS31_PID_DV500

Y Data type: REAL.
Manipulated value, calculated by the function block.

LIMITS_ACTIVE Data type: BOOL.
TRUE indicates that Y has exceeded the given limits (Y_MIN, Y_MAX).

OVERFLOW Data type: BOOL.
TRUE indicates an overflow in the integral part.

Function block call in ST

```
HACS31PIDDV500(
ACTUAL                  := haPID_actual,
hapid_y                 := HACS31PID.A;
hapid_limits_active     := HACS31PID.LIMITS_ACTIVE;
hapid_overflow          := HACS31PID.OVERFLOW;
```

HA_CS31_PID_FIXCYCLE - HA PID controller with fix cycle

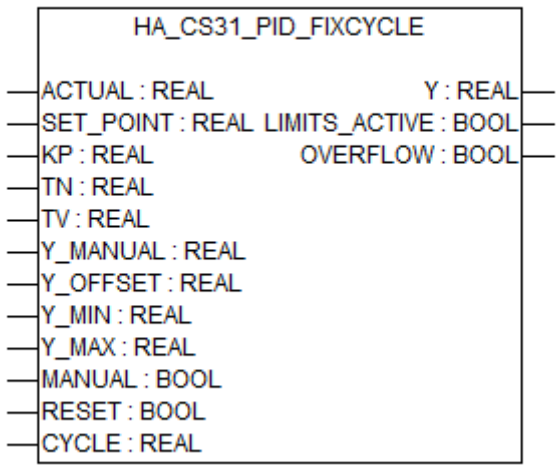

Fig. 110: Function block HA_CS31_PID_FIXCYCLE

Table 115: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block is a standard PID controller with automatic data synchronization in a High Availability application.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_CS31_DATA_SYNC to achieve the same.*

Parameter description

- The parameters Y_OFFSET, Y_MIN and Y_MAX serve for transformation of the manipulated variable within a prescribed range.
- MANUAL parameter can be used to switch to manual operation.
- CYCLE ia an input to to the function block and is to be set by the user (in ms).
- RESET parameter can be used to re-initialize the controller.
  The cycle time is not measured automatically. It is set by the input CYCLE (in seconds).

- In normal operation (MANUAL = RESET = LIMITS_ACTIVE = FALSE) the controller calculates the controller error as difference from SET_POINT parameter – ACTUAL parameter, generates the derivation with respect to time de/dt and stores these values internally.
- The output, i.e. the manipulated variable Y unlike the PD controller contains an additional integral part and is calculated as follows: Y = KP × (D + 1/TN ∫edt + TV dD/dt) + Y_OFFSET. So besides the P-part also the current change of the controller error (D-part) and the history of the controller error (I-part) influence the manipulated variable. The PID controller can be easily converted to a PI controller by setting TV=0. Because of the additional integral part, an overflow can come about by incorrect parameterization of the controller if the integral of error D becomes too great. Therefore for the sake of security a boolean output called OVERFLOW is present, which in this case would have the value TRUE. This only will happen if the control system is instable due to incorrect parameterization. At the same time, the controller will be suspended and will only be activated again by re-initialization.

Input description

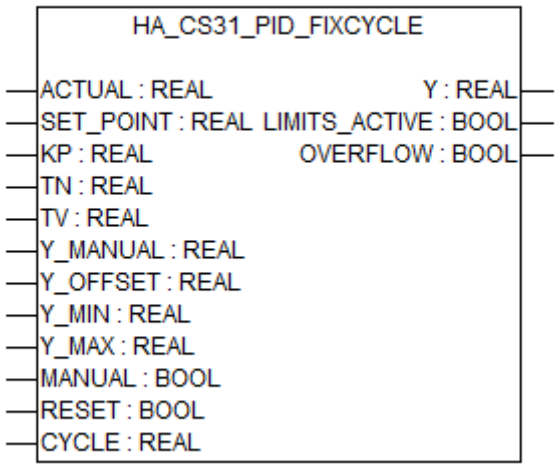

Fig. 111: Function block HA_CS31_PID_FIXCYCLE

ACTUAL Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Current value of the controlled variable.

SET_POINT Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Desired value, command variable.

KP Data type: REAL, default value: 0, range: 0 to 3.402823466e+38.
Coefficient of proportionality, unity gain of the P-part.

TN Data type: REAL, default value: 0, range: 0 to 3.402823466e+38.
Reset time, reciprocal unity gain of the I-part; given in seconds, e.g. "0.5" for 500 ms.

TV Data type: REAL, default value: 0, range: 0 to 3.402823466e+38.
Derivative action time, unity gain of the D-part in seconds, e.g. "0.5" for 500 ms.

Y_MANUAL Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.

Defines output value Y in case of MANUAL = TRUE.

Y_OFFSET Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.

Offset for the manipulated variable Y.

Y_MIN Data type: REAL, default value: 0.

Lower limit for the manipulated variable Y. If Y exceeds these limits, output LIMITS_ACTIVE will be set to TRUE and Y will be kept within the prescribed range. This control will only work if Y_MIN < Y_MAX.

Y_MAX Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.

Upper limit for the manipulated variable Y. If Y exceeds these limits, output LIMITS_ACTIVE will be set to TRUE and Y will be kept within the prescribed range. This control will only work if Y_MIN < Y_MAX.

MANUAL Data type: BOOL, default value: FALSE, range: TRUE/FALSE.

If TRUE, manual operation will be active, i.e. the manipulated value will be defined by Y_MANUAL.

RESET Data type: BOOL, default value: FALSE, range: TRUE/FALSE.

TRUE resets the controller; during re-initialization Y = Y_OFFSET.

CYCLE Data type: REAL, default value: 0, range: 0 to 3.402823466e+38.

Number of cycles.

Output description

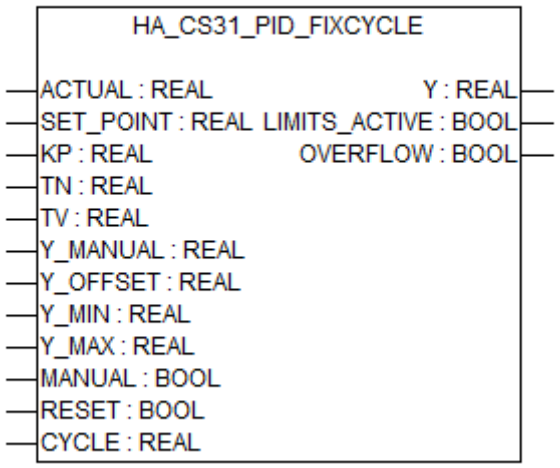

Fig. 112: Function block HA_CS31_PID_FIXCYCLE

Y Data type: REAL

Manipulated value, calculated by the function block.

LIMITS_ACTIVE Data type: BOOL

TRUE indicates that Y has exceeded the given limits (Y_MIN, Y_MAX).

OVERFLOW Data type: BOOL

TRUE indicates an overflow in the integral part.

Function block call in ST

```
HACS31PIDFIXCYCLE(
ACTUAL          := hapid_actual,

- RESET parameter can be used to re-initialize the controller.
- In normal operation (MANUAL = RESET = LIMITS_ACTIVE = FALSE) the controller calculates the controller error as difference from SET_POINT parameter – ACTUAL parameter, generates the derivation with respect to time de/dt and stores these values internally.
- The output, i.e. the manipulated variable Y unlike the PD controller contains an additional integral part and is calculated as follows: Y = KP × (D + 1/TN ∫edt + TV dD/dt) + Y_OFFSET. So besides the P-part also the current change of the controller error (D-part) and the history of the controller error (I-part) influence the manipulated variable. The PID controller can be easily converted to a PI controller by setting TV=0. Because of the additional integral part, an overflow can come about by incorrect parameterization of the controller if the integral of error D becomes too great. Therefore for the sake of security a BOOLEAN output called OVERFLOW is present, which in this case would have the value TRUE. This only will happen if the control system is instable due to incorrect parameterization. At the same time, the controller will be suspended and will only be activated again by re-initialization.

Input description

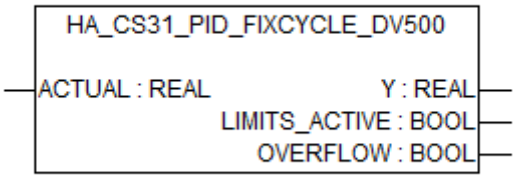

Fig. 114: Function block HA_CS31_PID_FIXCYCLE_DV500

ACTUAL Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.

Current value of the controlled variable.

Output description

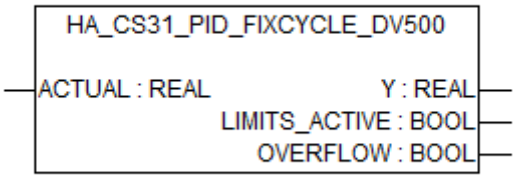

Fig. 115: Function block HA_CS31_PID_FIXCYCLE_DV500

Y Data type: REAL

Manipulated value, calculated by the function block.

LIMITS_ACTIVE Data type: BOOL

TRUE indicates that Y has exceeded the given limits (Y_MIN, Y_MAX).

OVERFLOW Data type: BOOL

TRUE indicates an overflow.

Function block call in ST

```
HACS31PIDFIXCYCLEDV500(
ACTUAL                      := hapid_actual,
hapid_y                     := HACS31PID.A;
hapid_limits_active         := HACS31PID.LIMITS_ACTIVE;
hapid_overflow              := HACS31PID.OVERFLOW;
```

HA_CS31_RAMP_INT - HA ramp with integer

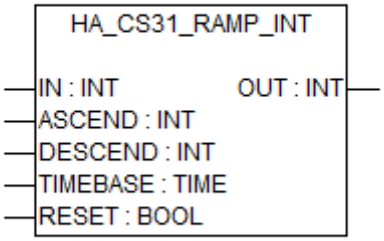

Fig. 116: Function block HA_CS31_RAMP_INT

Table 117: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block is an integer ramp generator with automatic data synchronization in a High Availability application.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_CS31_DATA_SYNC to achieve the same.*

This function block serves to limit ascending or descending of a function:

The input consists of three INT values: IN (function input), and ASCEND and DESCEND, the maximum increase or decrease for a given time interval, which is defined by the TIMEBASE parameter. Setting RESET parameter to TRUE causes the function block to be initialized anew.

The output OUT of the type INT contains ascends and descends limited function value. If the TIMEBASE parameter is set to t#0s, ASCEND and DESCEND are not related to the time interval, but remain the same.

Input description

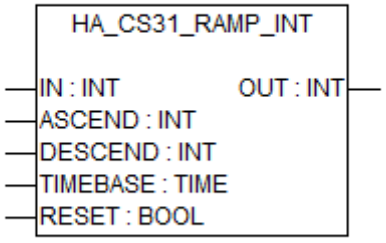

Fig. 117: Function block HA_CS31_RAMP_INT

IN Data type: INT, default value: 0, range: -32767 to 32767.
Function input.

ASCEND Data type: INT, default value: 0, range: -32767 to 32767.
Max. ascension per time interval.

DESCEND Data type: INT, default value: 0, range: -32767 to 32767.
Max. descend per time interval.

TIMEBASE Data type: TIME, default value: 0, range: 0 to 4194967295 ms.
Time interval for the maximum increase/decrease.

RESET Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
Reset input to reinitialize the function block.

Output description

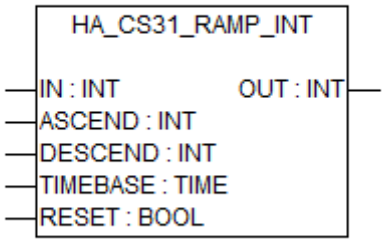

Fig. 118: Function block HA_CS31_RAMP_INT

OUT Data type: INT.

Output with ascended or descended function value.

Function block call in ST

```
HACS31RAMPINT(
IN                  := harampint_in,
ASCEND              := harampint_ascend,
DESCEND             := harampint_descend,
TIMEBASE            := harampint_timebase,
RESET               := harampint_reset);
harampint_out       := HACS31RAMPINT.OUT;
```

HA_CS31_RAMP_REAL - HA Ramp with Real

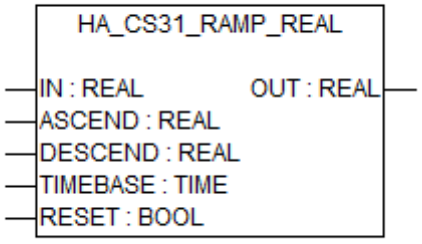

Fig. 119: Function block HA_CS31_RAMP_REAL

Table 118: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block is a real ramp generator with automatic data synchronization in a High Availability application.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_CS31_DATA_SYNC to achieve the same.*

This function block serves to limit ascending or descending of a function:

The input consists of three REAL values: IN (function input), and ASCEND and DESCEND, the maximum increase or decrease for a given time interval, which is defined by the TIMEBASE parameter. Setting RESET parameter to TRUE causes the function block to be initialized anew.

The output OUT of the type REAL contains ascends and descends limited function value. When the TIMEBASE parameter is set to t#0s, ASCEND and DESCEND are not related to the time interval, but remain the same.

Input description

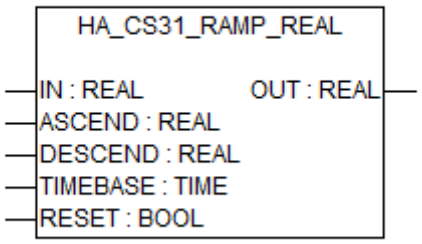

Fig. 120: Function block HA_CS31_RAMP_REAL

IN Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Function input.

ASCEND Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Max. ascension per time interval.

DESCEND Data type: REAL, default value: 0, range: 1.175494351e-38 to 3.402823466e+38.
Max. descend per time interval.

TIMEBASE Data type: TIME, default value: 0, range: 0 to 4194967295 ms.
Time interval for the maximum increase/decrease.

RESET Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
Reset input to re-initialize the function block.

Output description

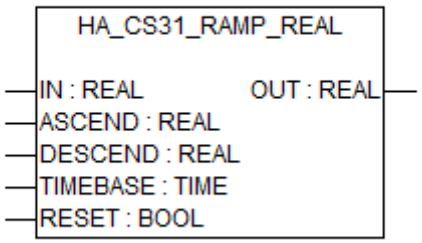

Fig. 121: Function block HA_CS31_RAMP_REAL

OUT Data type: REAL.

Output with ascended or descended function value.

Function block call in ST

```
HACS31RAMPREAL(
IN                  := harampreal_in,
SCEND               := harampreal_ascend,
DESCEND             := harampreal_descend,
TIMEBASE            := harampreal_timebase,
RESET               := harampreal_reset);
harampreal_out      := HACS31RAMPREAL.OUT;
```

HA_CS31_TOF - HA Turn-Off delay timer

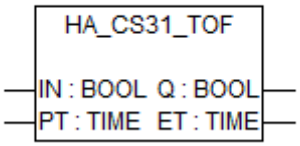

Fig. 122: Function block HA_CS31_TOF

Table 119: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block is standard turn-off delay with automatic data synchronization in a High Availability application.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_CS31_DATA_SYNC to achieve the same.*

This function block implements a turn-off delay timer. As soon as the IN parameter becomes FALSE, time counting in ET will start (unit: ms). Counting will proceed until the value in ET is equal to PT value. Then, it will remain constant. Q is FALSE if IN is FALSE and ET is equal to PT. Otherwise it is TRUE. Thus, the Q parameter has a falling edge as soon as time indicated in PT has run out (unit: ms).

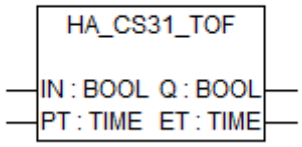

Fig. 123: A_CS31_TOF behavior over time

Input description

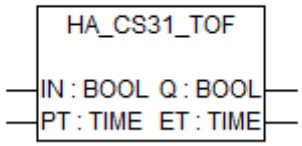

Fig. 124: Function block HA_CS31_TOF

IN Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
If IN=FALSE, the turn-off delay starts.

PT Data type: TIME, default value: 0, range: 0 to 4194967295 ms.
Preset time for turn-off delay.

Output description

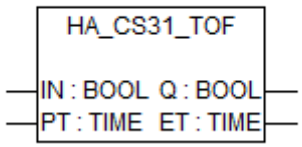

Fig. 125: Function block HA_CS31_TOF

Q Data type: BOOL, range: TRUE/FALSE.
Q=FALSE if IN=FALSE and ET=PT.

ET Data type: TIME.
Actual time of turn-off delay.

Function block call in ST

```
HACS31TOF(
IN              := hatof_in,
PT              := hatof_pt);
hatof_q         := HACS31TOF.Q;
hatof_et        := HACS31TOF.ET;
```

HA_CS31_TON - HA turn-on delay timer

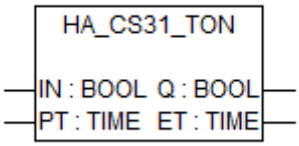

Fig. 126: Function block HA_CS31_TON

Table 120: General information

Available as of runtime system	V1.3 and above
Included in library	HA_CS31_AC500_V13.lib (V1.3) and above
Type	Function block with historical values.

This function block is a standard turn-on delay with automatic data synchronization in a High Availability application.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_CS31_DATA_SYNC to achieve the same.*

This function block implements a turn-on delay timer. As soon as the IN parameter becomes TRUE, time counting in ET will start (unit: ms). Counting will proceed until the value in ET is equal to PT value. Then, it will remain constant. Q is TRUE when IN is TRUE and ET is equal to PT. Otherwise it is FALSE. Thus, the Q parameter has a rising edge as soon as time indicated in PT has run out (unit: ms).

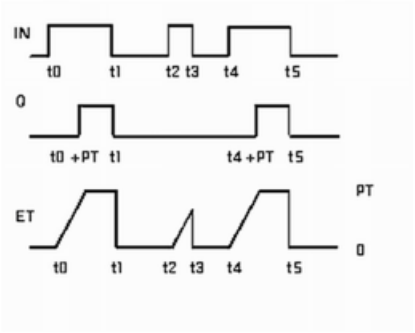

Fig. 127: HA_CS31_TON behavior over time.

Input description

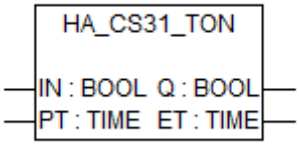

Fig. 128: Function block HA_CS31_TON

IN Data type: BOOL, default value: FALSE, range: TRUE/FALSE.
If IN=TRUE, the turn-on delay starts.

PT Data type: TIME, default value: 0, range: 0 to 4194967295 ms.
Preset time for turn-on delay.

Output description

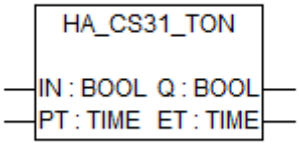

Fig. 129: Function block HA_CS31_TON

Q Data type: BOOL.
Q=TRUE if IN=TRUE and ET=PT.

ET Data type: TIME.
Actual time of turn-on delay.

Function block call in ST

```
HACS31TON(
IN              := haton_in,
PT              := haton_pt);
haton_q         := HACS31TON.Q;
haton_et        := HACS31TON.ET;
```

Visualizations

In the application program, the user can add the visualization object in his project. The following figure describes how to add the faceplate of the required function block to the visualization object:

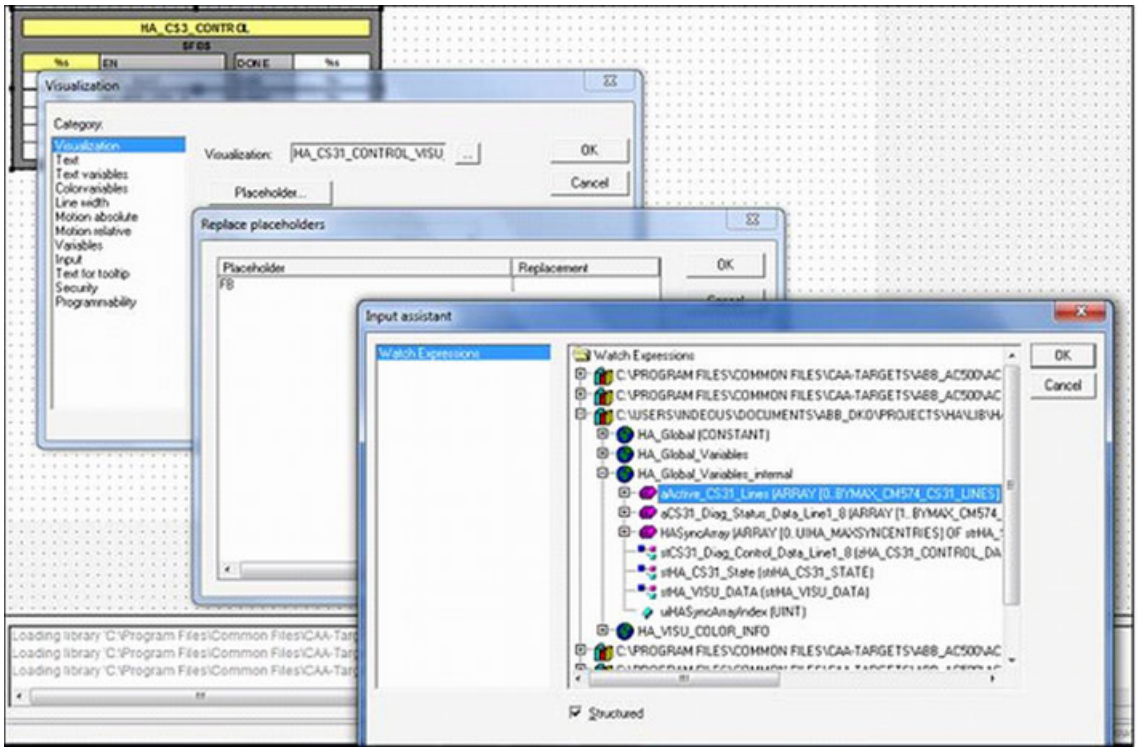

Fig. 130: HA_CS31_Visualization

In the following chapter, overall visualization and visualization for each individual function block are discussed in detail.

HA_CS31_OVERVIEW_VISU - Visualization

This overview visualization for a AC500 High Availability CS31 system provides information for easy diagnosis in case of an error. It contains information about Ethernet cable status, PLC primary and secondary status, status for each CS31 line and diagnosis information, the HA _CS31_CONTROL status etc.

The following figure describes the visualization in offline and online mode:

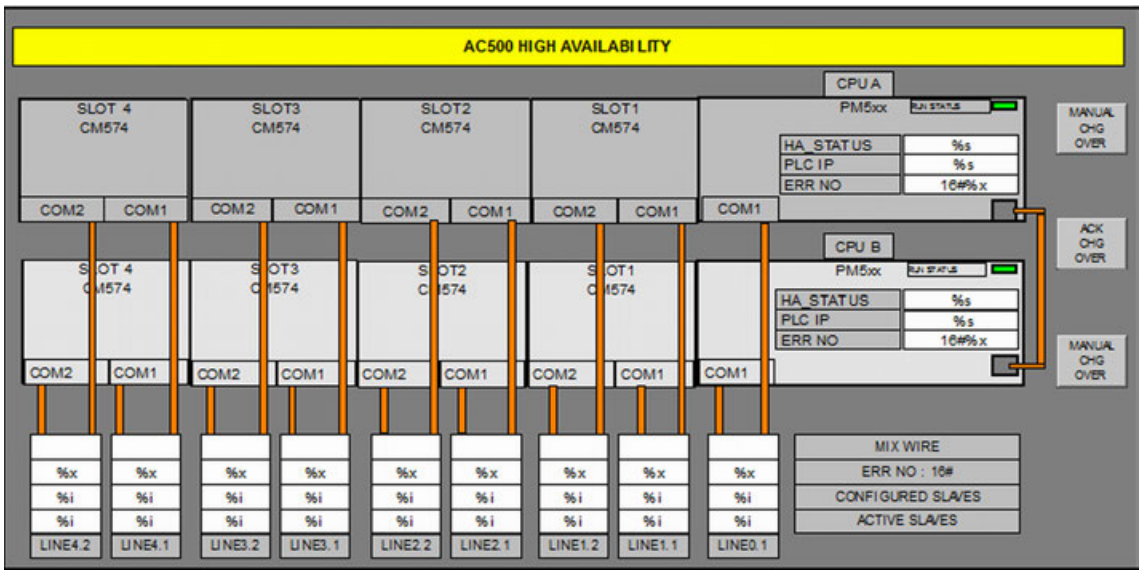

Fig. 131: HA_CS31_Visualization_offline

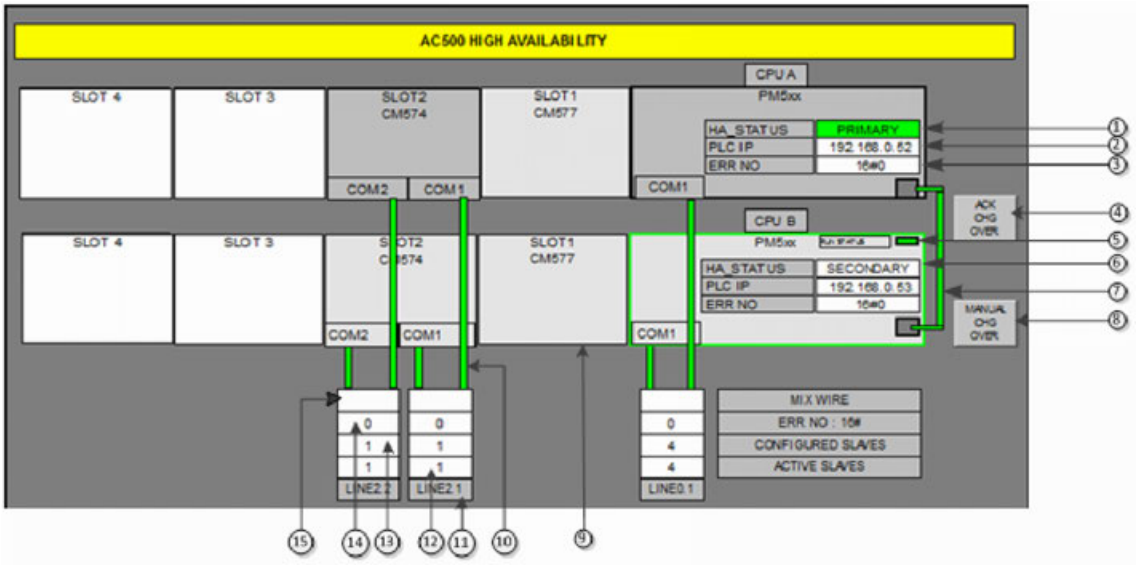

Fig. 132: HA_CS31_Visualization_online

No.	Description
1	Shows the PLC status as PRIMARY or SECONDARY.
2	Shows PLC IP address.
3	Shows HA_CS31_CONTROL error code.
4	Acknowledge button for change over.
5	Shows PLC RUN status (green: running, red: stopped).
6	A green frame surrounding a PLC indicates the PLC that is connected to the programming software.
7	Shows UDP data exchange Ethernet status (green: no error, red: error).
8	Changeover button (only available in primary PLC).
9	Shows CM597-ETH if configured.
10	Shows CS31 line status (green: active, red: not active).
11	Shows CS31 line number.
12	Shows active salves in that particular CS31 line.
13	Shows configured slaves in that particular CS31 line.
14	Shows errors related to that particular CS31 line.
15	A red box indicates mix wire errors (white box = no error).

HA-CS31 visualization can be used only for monitoring purpose. Users can only view the logged PLC information using visualization. The only possible action is a manual changeover and the acknowledgment. Users can use DigiVis and OPC server to read out data from or to write data to the HA-CS31 system. Writing data through OPC server will affect both PLCs. Reading out data is done from primary PLC.

HA_CS31_CONTROL_VISU_PH - Visualization

Visualization element HA_CS31_CONTROL_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of the HA_CS31_CONTROL function block. The visualization could also be used to control the function block by those inputs which are not connected inside the program.

The following figures demonstrate visualization in the offline and online mode.

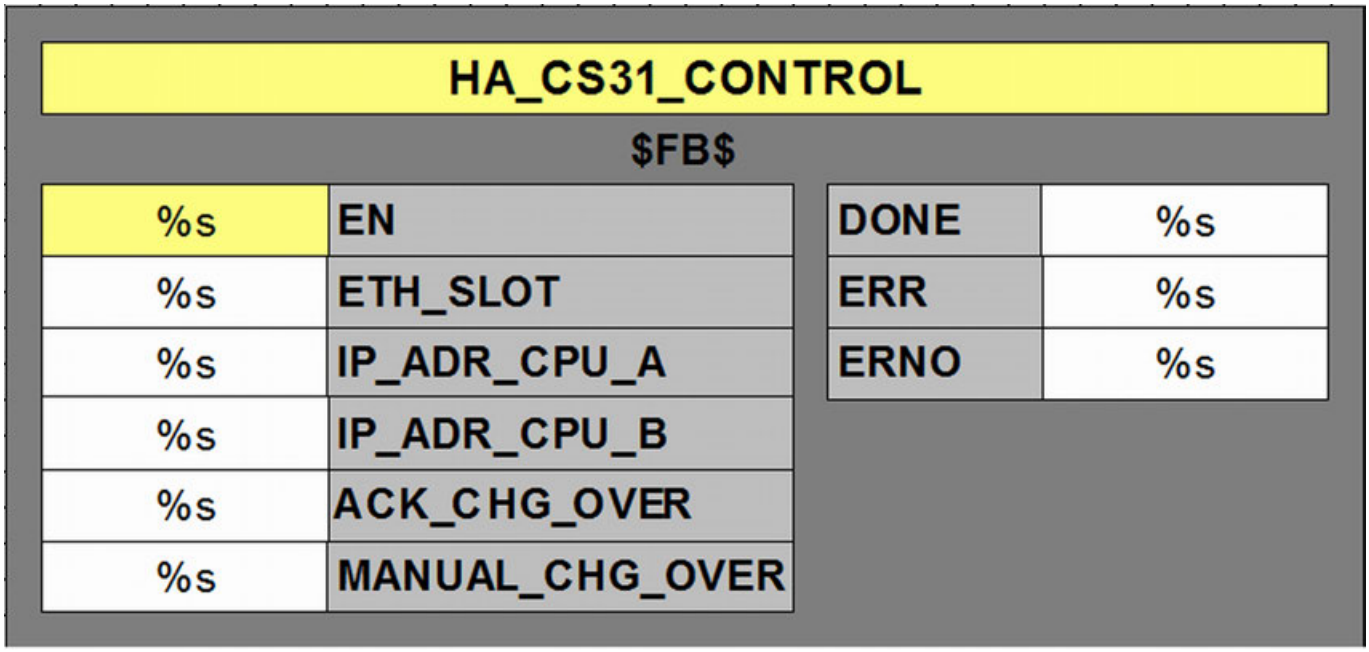

Fig. 133: Faceplate HA_CS31_CONTROL_VISU_PH offline mode

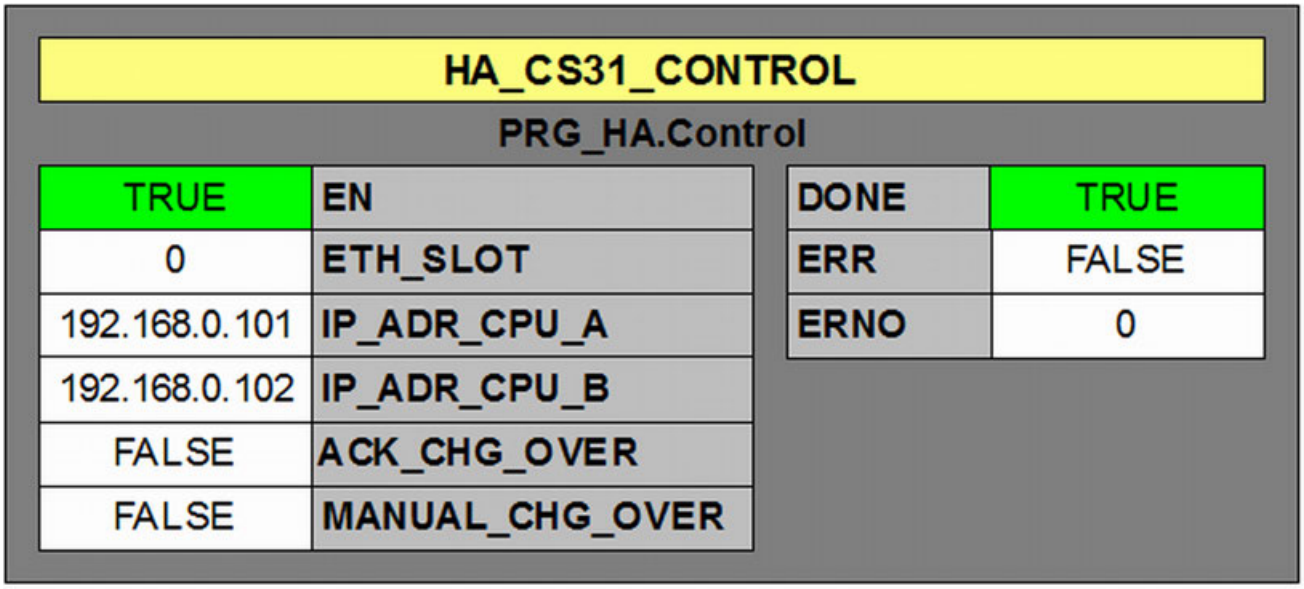

Fig. 134: Faceplate HA_CS31_CONTROL_VISU_PH online mode

Colors

The color of the variables has the following meaning:

- White: Actual FALSE and should be FALSE in normal operation.
- Green: Actual TRUE and should be TRUE in normal operation.
- Yellow: Actual FALSE but should be TRUE in normal operation.
- Red: Actual TRUE but should be FALSE in normal operation

Visualization parameters

Variable	Access	Way of Access	Description *)
EN	R		To enable the function block with value TRUE.
ETH_SLOT	R		Slot number for UDP data exchange.
IP_ADR_CPU_A	R		IP address of CPU A.
IP_ADR_CPU_B	R		IP address of CPU B.
ACK_CHG_OVER	R/W	Toggle	Acknowledgement for switch over.
MANUAL_CHG_OVER	R/W	Toggle	Manual change over
DONE	R		Execution finished when output DONE=TRUE.
ERR	R		Error occurred during execution when output ERR=TRUE.
ERNO	R		Error code.

*) all elements refer to the function block instance replaced for the placeholder FB.

All inputs of the HA_CS31_DATA_SYNC function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The color of the background can be changed by writing a value to the global variable *dwAcsVisuBackgroundColor*. The color of the title can be changed by writing a value to the global variable *dwAcsVisuTitleColor*.

All inputs of the HA_CS31_ DIAG_EXTD_VIA_CM574-RS function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The color of the background can be changed by writing a value to the global variable *dwAcsVisuBackgroundColor*. The color of the title can be changed by writing a value to the global variable *dwAcsVisuTitleColor*.

HA_CS31_DATA_SYNC_VISU_PH - Visualization

Description

Visualization element HA_CS31_DATA_SYNC_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of the HA_CS31_DATA_SYNC function block. Visualization can also be used to control the function block by those inputs which are not connected inside the program.

The following figures demonstrate visualization in the offline and online mode:

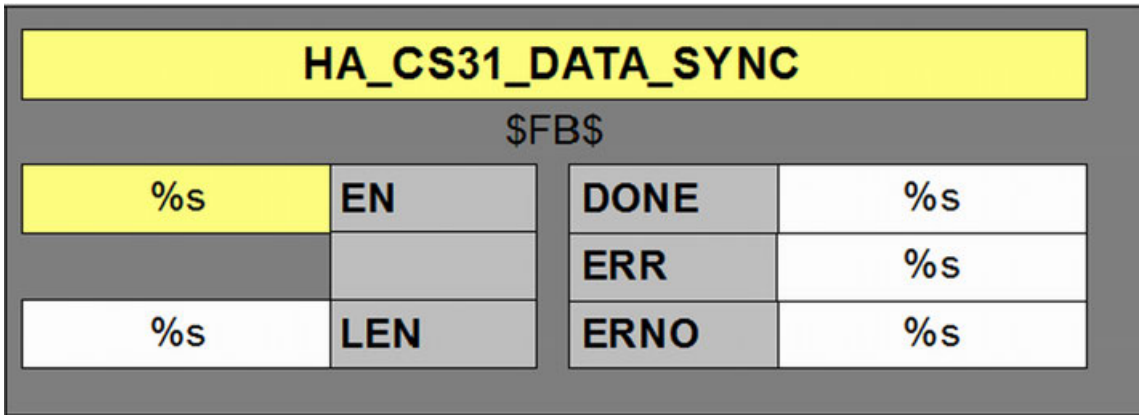

Fig. 135: HA_CS31_Visualization_SYNC_offline

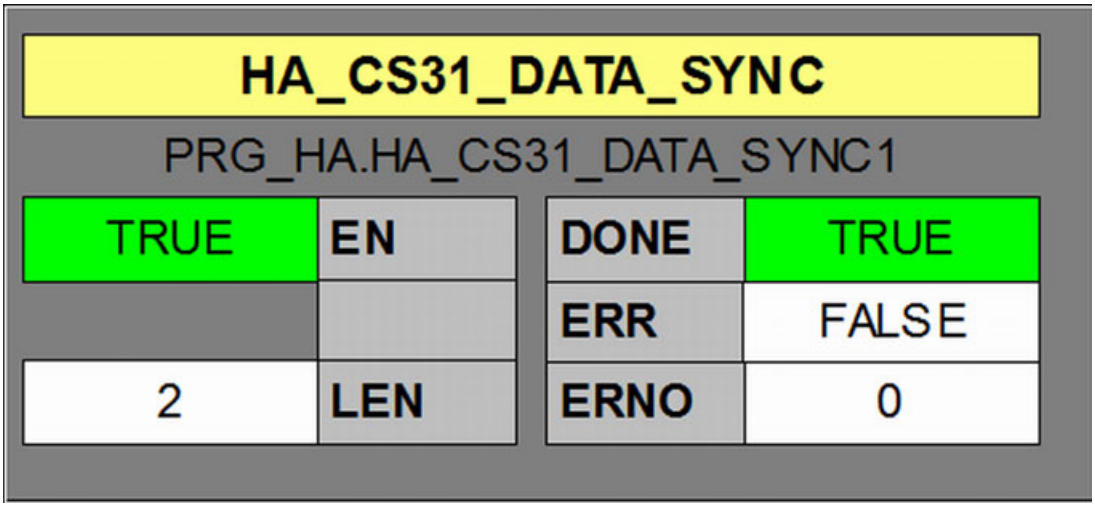

Fig. 136: HA_CS31_Visualization_SYNC_online

Colors

The color of the variables has the following meaning:

- White: Actual FALSE and should be FALSE in normal operation.
- Green: Actual TRUE and should be TRUE in normal operation.
- Yellow: Actual FALSE but should be TRUE in normal operation.
- Red: Actual TRUE but should be FALSE in normal operation

Visualization parameters

Variable	Access	Description *)
EN	R	To enable the function block with value TRUE.
LEN	R	Function block instance input (via SIZEOF-operator) for size.
DONE	R	Execution finished when output DONE=TRUE.
ERR	R	Error occurred during execution when output ERR=TRUE.
ERNO	R	Error code.

*) all elements refer to the function block instance replaced for the placeholder FB.

All inputs of the HA_CS31_DATA_SYNC function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. Background color can be changed by writing a value to the global variable *dwAcsVisuBackgroundColor*. Title color can be changed by writing a value to the global variable *dwAcsVisuTitleColor*.

HA_CS31_DIAG_EXTD_VIA_CM574_VISU_PH - Visualization

Description

Visualization element HA_CS31_DIAG_EXTD_VIA_CM574_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of the HA_CS31_DIAG_EXTD_VIA_CM574 function block. The visualization could also be used to control the function block by those inputs which are not connected inside the program.

The following figure describes visualization in the offline and online mode:

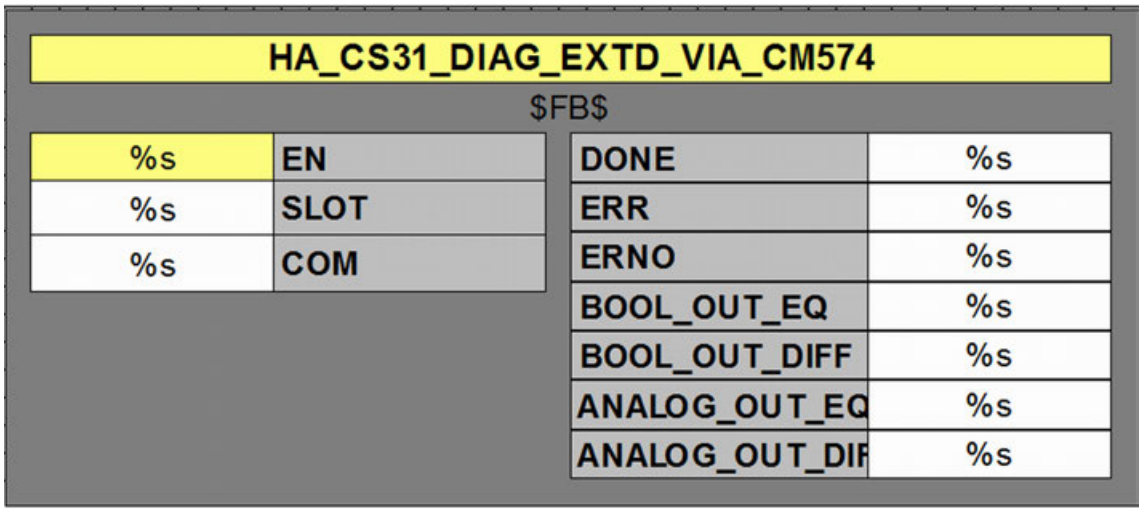

Fig. 137: HA_CS31_DIAG_EXTD_VIA_CM574_offline

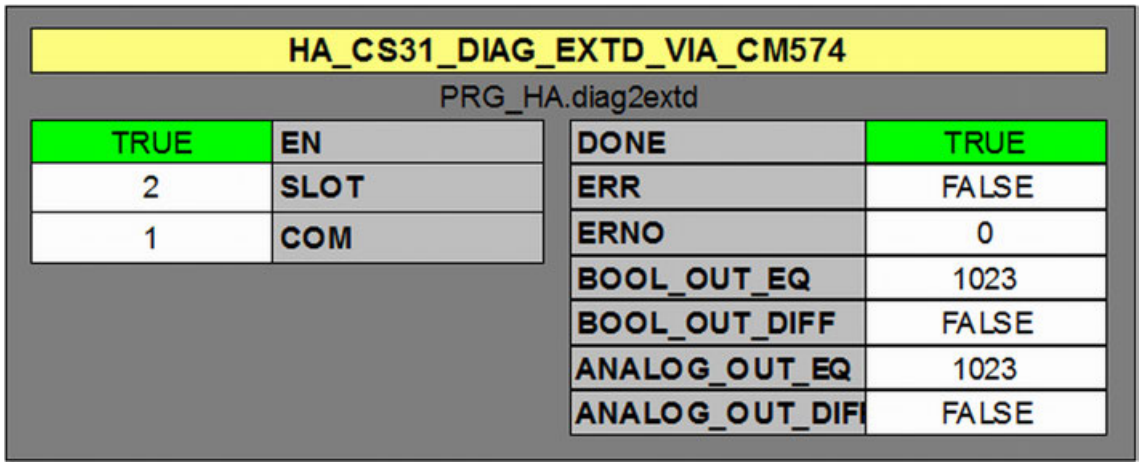

Fig. 138: HA_CS31_DIAG_EXTD_VIA_CM574_online

Colors

The color of the variables has the following meaning:

- White: Actual FALSE and should be FALSE in normal operation.
- Green: Actual TRUE and should be TRUE in normal operation.
- Yellow: Actual FALSE but should be TRUE in normal operation.
- Red: Actual TRUE but should be FALSE in normal operation

Visualization Parameters

Variable	Access	Description *)
EN	R	To enable the function block with value TRUE.
SLOT	R	Slot number of the CS31 master.
COM	R	COM port number of the CS31 master.
DONE	R	Execution finished when output DONE=TRUE.
ERR	R	Error occurred during execution when output ERR=TRUE.
ERNO	R	Error code.
BOOL_OUT_EQ	R	Each bit of the DWORD represents identical output buffer for BOOL data.
BOOL_OUT_DIFF	R	Output buffer with different BOOL data.
ANALOG_OUT_EQ	R	Each bit of the DWORD represents identical output buffer for analog data.
ANALOG_OUT_DIFF	R	Output buffer with different analog data.

*) all elements refer to the function block instance replaced for the placeholder FB.

All inputs of the HA_CS31_ DIAG_EXTD_VIA_CM574 function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. Background color can be changed by writing a value to the global variable *dwAcsVisuBackgroundColor*. Title color can be changed by writing a value to the global variable *dwAcsVisuTitleColor*.

HA_CS31_DIAG_EXTD_VISU_PH - Visualization

Description

Visualization element HA_CS31_DIAG_EXTD_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of the HA_CS31_DIAG_EXTD function block. The visualization could also be used to control the function block by those inputs which are not connected inside the program.

The following figure describes the visualization in the offline and online mode:

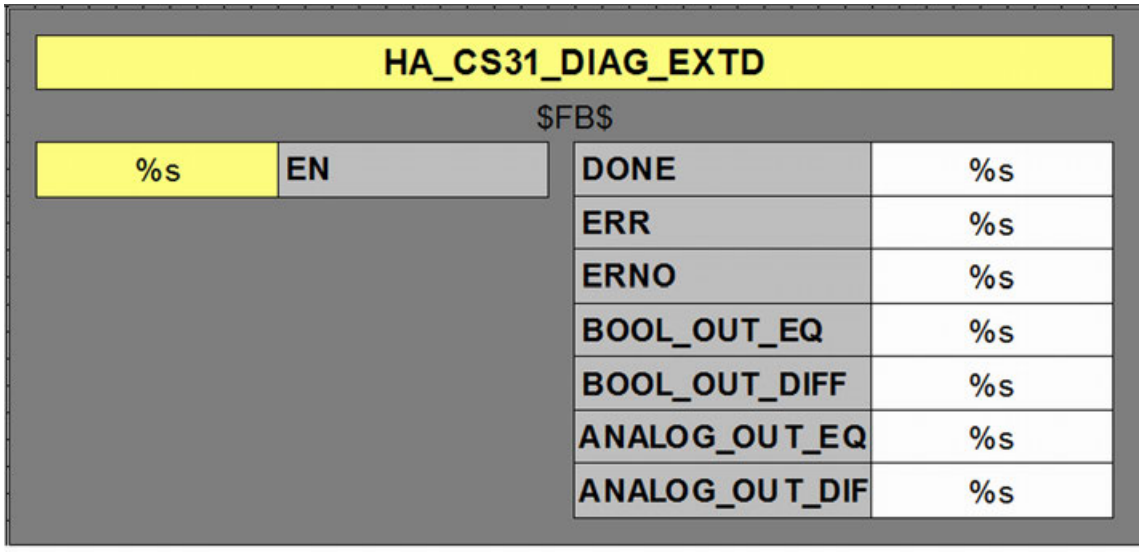

Fig. 139: HA_CS31_DIAG_EXTD_VISU_PH_offline

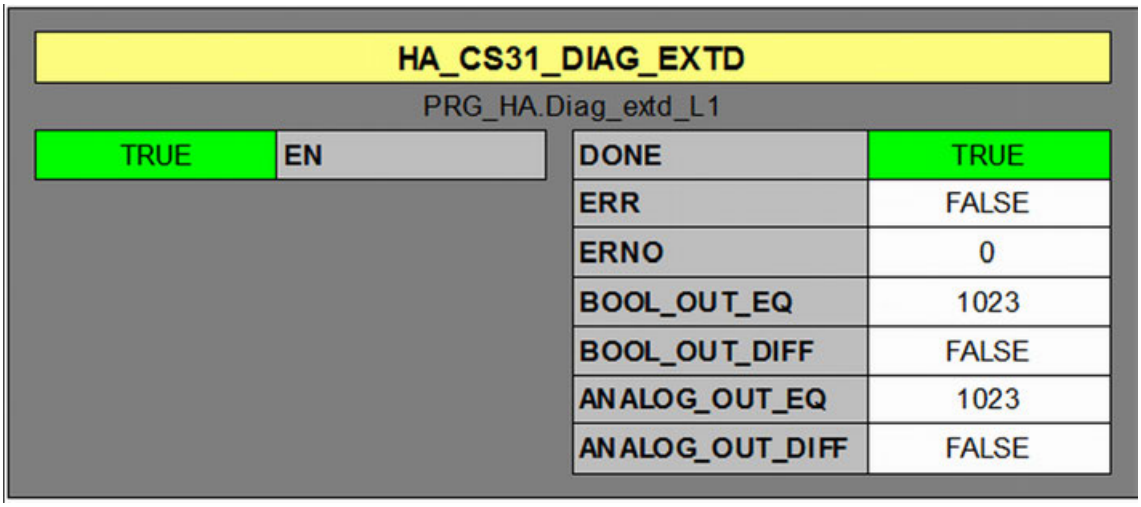

Fig. 140: HA_CS31_DIAG_EXTD_VISU_PH_online

Colors

The color of the variables has the following meaning:

- White: Actual FALSE and should be FALSE in normal operation.
- Green: Actual TRUE and should be TRUE in normal operation.
- Yellow: Actual FALSE but should be TRUE in normal operation.
- Red: Actual TRUE but should be FALSE in normal operation

Visualization parameters

Variable	Access	Description *)
EN	R	To enable the function block with value TRUE.
DONE	R	Execution finished when output DONE=TRUE.
ERR	R	Error occurred during execution when output ERR=TRUE.
ERNO	R	Error code.
BOOL_OUT_EQ	R	Each bit of the DWORD represents identical output buffer for BOOL data.
BOOL_OUT_DIFF	R	Output buffer with different BOOL data.
ANALOG_OUT_EQ	R	Each bit of the DWORD represents identical output buffer for analog data.
ANALOG_OUT_DIFF	R	Output buffer with different analog data.

*) all elements refer to the function block instance replaced for the placeholder FB.

All inputs of the HA_CS31_ DIAG_EXTD function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. Background color can be changed by writing a value to the global variable *dwAcsVisuBackgroundColor*. Title color can be changed by writing a value to the global variable *dwAcsVisuTitleColor*.

HA_CS31_DIAG_VIA_CM574_VISU_PH - Visualization

Description

Visualization element HA_CS31_DIAG_VIA_CM574_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of the HA_CS31_DIAG_VIA_CM574 function block. The visualization could also be used to control the function block by those inputs which are not connected inside the program.

The following figures describe visualization in the offline and online mode:

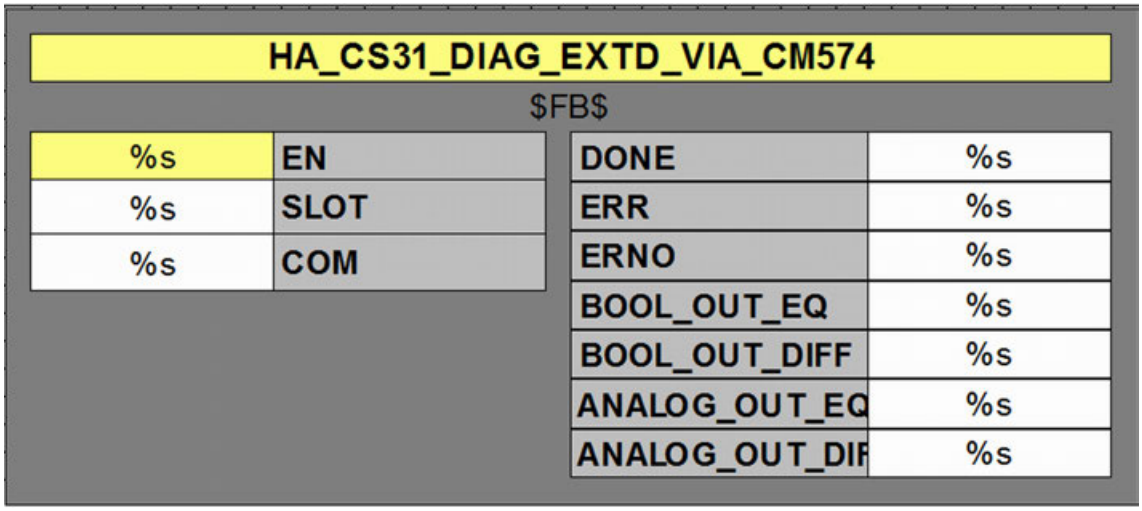

Fig. 141: HA_CS31_DIAG_VIA_CM574_VISU_PH_offline

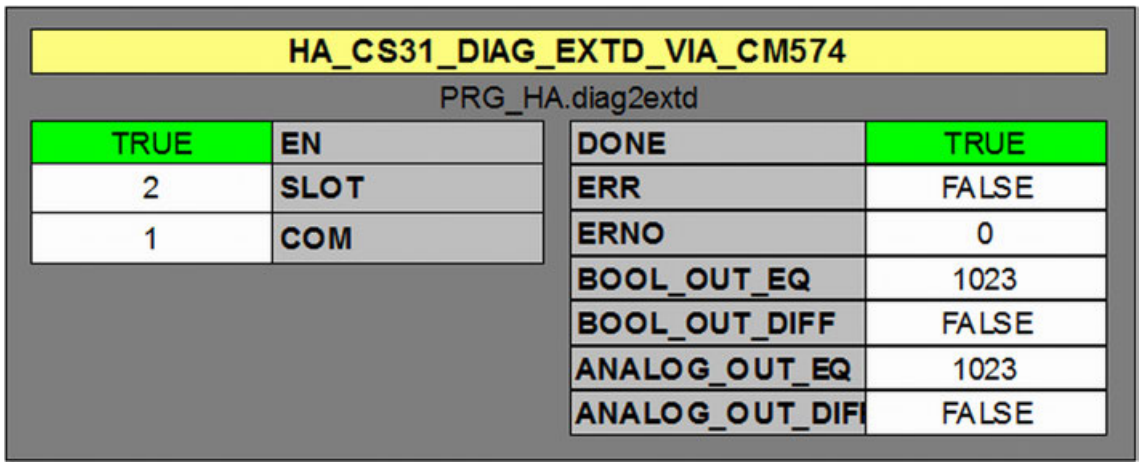

Fig. 142: HA_CS31_DIAG_VIA_CM574-RS_VISU_PH_online

Colors

The color of the variables has the following meaning:

- White: Actual FALSE and should be FALSE in normal operation.
- Green: Actual TRUE and should be TRUE in normal operation.
- Yellow: Actual FALSE but should be TRUE in normal operation.
- Red: Actual TRUE but should be FALSE in normal operation

Visualization parameters

Variable	Access	Description *)
EN	R	To enable the function block with value TRUE.
SLOT	R	Slot number of the CS31 master.
COM	R	COM port number of the CS31 master.
DONE	R	Execution finished when output DONE=TRUE.

Variable	Access	Description *)
ERR	R	Error occurred during execution when output ERR=TRUE.
ERNO	R	Error code.
NUM_SLV_CFG	R	Number of configured CI590-CS31-HA slave modules on COM.
NUM_SLV_ACT	R	Number of CI590-CS31-HA slave modules active on CS31 Bus.
ACTIVE_SLV	R	Each bit of the DWORD indicates the active slave modules CI590-CS31-HA.
ERR_MIX_WIRING	R	Error bit indicating mix wiring between Bus 1 and Bus 2.

*) all elements refer to the function block instance replaced for the placeholder FB.

All inputs of the HA_CS31_ DIAG_VIA_CM574 function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. Background color can be changed by writing a value to the global variable *dwAcsVisuBackgroundColor*. Title color can be changed by writing a value to the global variable *dwAcsVisuTitleColor*.

HA_CS31_DIAG_VISU_PH - Visualization

Description

Visualization element HA_CS31_DIAG_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of HA_CS31_DIAG function block. The visualization can also be used to control the function block by those inputs which are not connected inside the program.

The following figure describes visualization in offline and online mode:

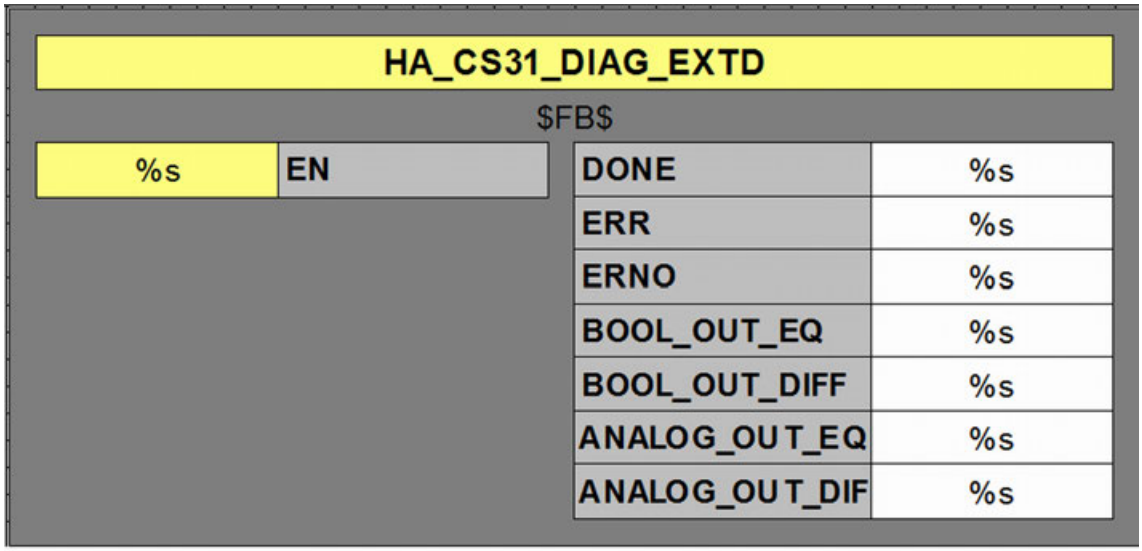

Fig. 143: HA_CS31_DIAG_VISU_PH_offline

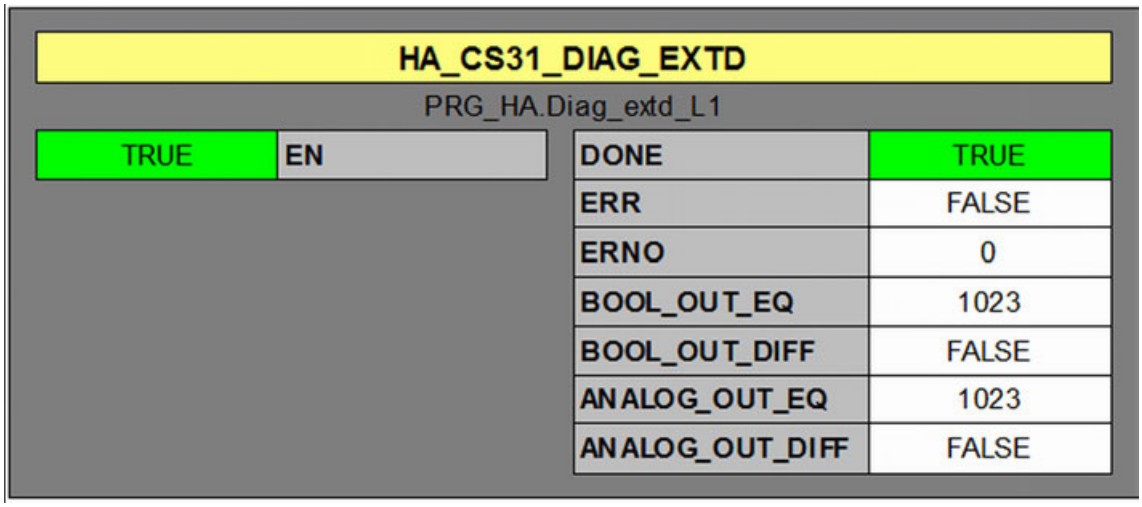

Fig. 144: HA_CS31_DIAG_VISU_PH_online

Colors

The color of the variables has the following meaning:

- White: Actual FALSE and should be FALSE in normal operation.
- Green: Actual TRUE and should be TRUE in normal operation.
- Yellow: Actual FALSE but should be TRUE in normal operation.
- Red: Actual TRUE but should be FALSE in normal operation

Visualization parameters

Variable	Access	Description *)
EN	R	To enable the function block with value TRUE.
COM	R	COM port number of CS31 master.
DONE	R	Execution finished when output DONE=TRUE.
ERR	R	Error occurred during execution when output ERR=TRUE.
ERNO	R	Error code.
NUM_SLV_CFG	R	Number of configured CI590-CS31-HA slave modules on COM.
NUM_SLV_ACT	R	Number of CI590-CS31-HA active slave modules on CS31 Bus.
ACTIVE_SLV	R	Each bit of the DWORD indicates the active CI590-CS31-HA slave modules.
ERR_MIX_WIRING	R	Error bit indicating mix wiring between Bus 1 and Bus 2.

*) all elements refer to the function block instance replaced for the placeholder FB.

All inputs of the HA_CS31_ DIAG function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. Background color can be changed by writing a value to the global variable *dwAcsVisuBackgroundColor*. Title color can be changed by writing a value to the global variable *dwAcsVisuTitleColor*.

Structures

stTON_TOFFSyncData	Structure for synchronized TON and TOFF data.
zHA_CS31_PID_DV500_DATA_TYPE	Structure for synchronization data for HA_CS31_PID_DV500.
zHA_CS31_PID_FIX-CYCLE_DV500_DATA_TYPE	Structure for synchronization data for HA_CS31_PID_FIXCYCLE_DV500.

Global variables

Group: HA_Global_Variables	**Description**
fG_HA_PRIMARY	State of the AC500 CPU: FALSE: PM acts as secondary. TRUE: PM acts as primary.
fG_HA_PM1_PRIMARY	Indication of primary PM. FALSE: PM1/ IP1 is not primary. TRUE: PM1/ IP1 acts as primary.
fG_HA_CPU_STOP	Indication of PLC Stop status. FALSE: Indicates the CPU in Run mode. TRUE: Indicates the CPU in Stop mode.
fG_HA_Err	High Availability error state.
wG_HA_ErNo	High Availability error code.
bitG_Data_ERR	High Availability error state for data synchronization.
wG_Data_ERNO	High Availability error code for data synchronization.
dwG_HA_OwnIP	Own IP address on synchronization link connection.
dwG_HA_OtherIP	Other PMs IP address on synchronization link connection.
bG_HA_Slot	Slot of interface to synchronization link connection.
dwG_HA_ServerAlive	Life counter incremented by OPC server.
byLastDataDelay	Variable to store last delay in data exchange.
bitRefreshDataDelay	Bit to refresh data delay.
byCntDataDelay	Data delay counts.
wETH_Life	Ethernet life count.
dwHATimersBaseTime	High Availability base timer.

Group: HA_VISU_COLOR_INFO	**Description**
dwHaVisuBackgroundColor	Visualization elements background color 16#00<B><G><R>.
dwHaVisuTitleColor	Visualization elements title background color 16#00<B><G><R>.

Appendix

Table: Call names of HA function blocks

Used abbreviations:

- FBhv: Function block with historical values
- FBnohv: Function block without historical values
- F: Function

POU Name	Type	Function
HA_CS31_CALLBACK_STOP	F	High Availability CPU STOP event function
HA_CS31_CONTROL	FBhV	High Availability control function block
HA_CS31_CTD	FBhV	High Availability count down counter function block
HA_CS31_CTU	FBhV	High Availability count up counter function block
HA_CS31_CTUD	FBhV	High Availability Up/down counter function block
HA_CS31_DATA_SYNC	FBhV	High Availability data synchronization function block
HA_CS31_DIAG_ON_CM574	FBhV	High Availability diagnosis function block for CM574-RS CS31 line used in CM574-RS
HA_CS31_DIAG	FBhV	High Availability diagnosis function block for CPU COM1 CS31 line
HA_CS31_DIAG_EXTD	FBhV	High Availability extended diagnosis function block for CPU COM1 CS31 line
HA_CS31_DIAG_EXTD_VIA_CM574	FBhV	High Availability extended diagnosis function block for CM574-RS CS31 line used in CPU
HA_CS31_DIAG_VIA_CM574	FBhV	High Availability diagnosis function block for CM574-RS CS31 line used in CPU
HA_CS31_INTEGRAL	FBhV	High Availability integral function block
HA_CS31_PID	FBhV	High Availability PID controller function block
HA_CS31_PID_FIXCYCLE	FBhV	High Availability PID controller with fix cycle function block
HA_CS31_RAMP_INT	FBhV	High Availability ramp function block with integer
HA_CS31_RAMP_REAL	FBhV	High Availability ramp function block with real
HA_CS31_TOF	FBhV	High Availability off delay timer function block
HA_CS31_TON	FBhV	High Availability on delay timer function block

Table: HA library versions and runtime system details

High Availability Library				
Library name	HA_CS31_AC500__V.V13.lib (V1.3.0)	HA_CS31_AC500_V20.lib (V2.0.0)	HA_CS31_AC500_V23.lib (V2.3.0)	HA_CS31_AC500_V23.lib (V2.4)
Tested with firmware version	V13	V20	V23	V24

Glossary

BOOL Variables of the type BOOL can have the values TRUE and FALSE. For this, 8 bit of memory space are reserved.

BYTE BYTE belongs to the integer data types. The different numerical types are responsible for a different numerical range.

Table 121: For integer data types the following range limits are valid:

TYPE	BYTE
Lower limit	0
Upper limit	255
Memory space	8 bits

Due to this, it is possible that information are lost when converting greater data types to smaller data types.

DINT

DINT belongs to the integer data types. The different numerical types are responsible for a different numerical range.

Table 122: For integer data types the following range limits are valid:

TYPE	DINT
Lower limit	-2147483648
Upper limit	2147483647
Memory space	32 bits

Due to this, it is possible that information are lost when converting greater data types to smaller data types.

DWORD

DWORD belongs to the integer data types. The different numerical types are responsible for a different numerical range.

Table 123: For integer data types the following range limits are valid:

TYPE	DWORD
Lower limit	0
Upper limit	4294967295
Memory space	32 bits

Due to this, it is possible that information are lost when converting greater data types to smaller data types.

INT

INT belongs to the integer data types. The different numerical types are responsible for a different numerical range.

Table 124: For integer data types the following range limits are valid:

TYPE	INT
Lower limit	-32768
Upper limit	32767
Memory space	16 bits

Due to this, it is possible that information are lost when converting greater data types to smaller data types.

WORD

WORD belongs to the integer data types. The different numerical types are responsible for a different numerical range.

Table 125: For integer data types the following range limits are valid:

TYPE	WORD
Lower limit	0
Upper limit	65535
Memory space	16 bits

Due to this, it is possible that information are lost when converting greater data types to smaller data types.

Functions

Functions are subroutines which have multiple input parameters and return exactly one result element. The returned result can be of an elementary or a derived data type. Due to this, a function may also return an array, a structure, an array of structures and so on. For the same input parameters, functions always return the same result (they do not have an internal memory).

Therefore, the following rules can be derived:

- Within functions, global variables can neither be read nor written.
- Within functions, absolute operands can neither be read nor written.
- Within functions, function 'Function Blocks' must not be called.

Function blocks

Function blocks are subroutines which can have as many inputs, outputs and internal variables as required. They are called from a program or from another function block. As they can be used several times (with different data records), function blocks (code and interface) can be considered as type. When assigning an individual data record (declaration) to the function block, a function block instance is generated. In contrast to functions, function blocks can contain statically local data which are saved from one call to the next. Therefore e.g. counters can be realized which may not forget their counter value. I.e. function blockscan have an internal memory.

Functions and function blocks differ in two essential points:

- A function block has multiple output parameters, a function only one. The output parameters of functions and function blocks differ syntactically.
- In contrast to a function, a function block can have an internal memory.

Function blocks with historical values (memory)

For function blocks with historical values it has to be observed that instance names may not be defined several times if different data sets should be called.

Function blocks without historical values (memory)

For function blocks without historical values only one instance has to be defined for the function block type. This instance can be used for several calls of the function block (also with different I/O values).

1.5.5.2 AC500 HA-Modbus TCP

1.5.5.2.1 Safety instructions and preconditions to use HA-Modbus TCP library

Safety instructions

Consider the following before using the libraries:

- All pertinent state, regional, and local safety regulations must be observed when installing and using this product. When functions or devices are used for applications with technical safety requirements, the relevant instructions must be followed.
- Read the complete safety instructions of the user's manuals for the drives you are using, before installation and commissioning.
- Read all *Chapter 1.6.1.1 “Safety instructions” on page 3697* for the AC500 PLC.
- Read the user information of the devices and functions you are using, see Automation Builder online help.

Preconditions of HA-Modbus TCP library

The library package has been released for the software and firmware versions listed in the readme file of Automation Builder only (see *“Help ➔ Automation Builder Release Notes”*) .

In no event will ABB or its representatives be liable for loss of data, profits, revenue or consequential, incidental or other damage that may result from the use of other versions of product, software or firmware versions. The error-free operation of the HA library with other devices, software or firmware versions should be possible but cannot be guaranteed and may need adaptations e.g. of example programs.

CAUTION!
Generally, the user in all applications is fully and alone responsible for checking all functions carefully, especially for safe and reliable operation.

The function blocks contained in the library can be executed only in RUN mode of the PLC, but not in simulation mode.

1.5.5.2.2 HA-Modbus TCP - System technology

The AC500 High Availability system

The AC500 High Availability system is designed for the demand of automation systems that require a higher availability, which is realized by redundant devices and communications. The redundancy concept reduces the risk of losing production due to failure of parts of the automation system and thereby minimizes scheduled idle times.

For instance, control can be taken over by the secondary station automatically if the primary station fails.

AC500 High Availability system implements redundancy based on standard AC500 PLCs:

- PLC
- Field communication
- SCADA communication

General differences in high availability / redundancy systems are in which way and how fast the switchover between redundancies happens.

- Cold standby: A replacement system is there but not up and running - Process has (to allow) to completely stop for switchover – e.g. outputs may go to zero.
- Warm standby: Both CPU may be running (= warm) but e.g. communication need to be started/stopped for switch-over - Process needs to tolerate longer freeze times e.g. on outputs - e.g. several seconds.
- AC500 High Availability systems are "hot-standby":
  - Redundant CPUs and all communications are always up and running (hot)
  - Continuous failure detection in both CPU´s and mutual exchange of status
  - Continuous synchronization of critical/historical data from primary to secondary
  - Automatic switch-over in very short time in case of any failure in primary CPU

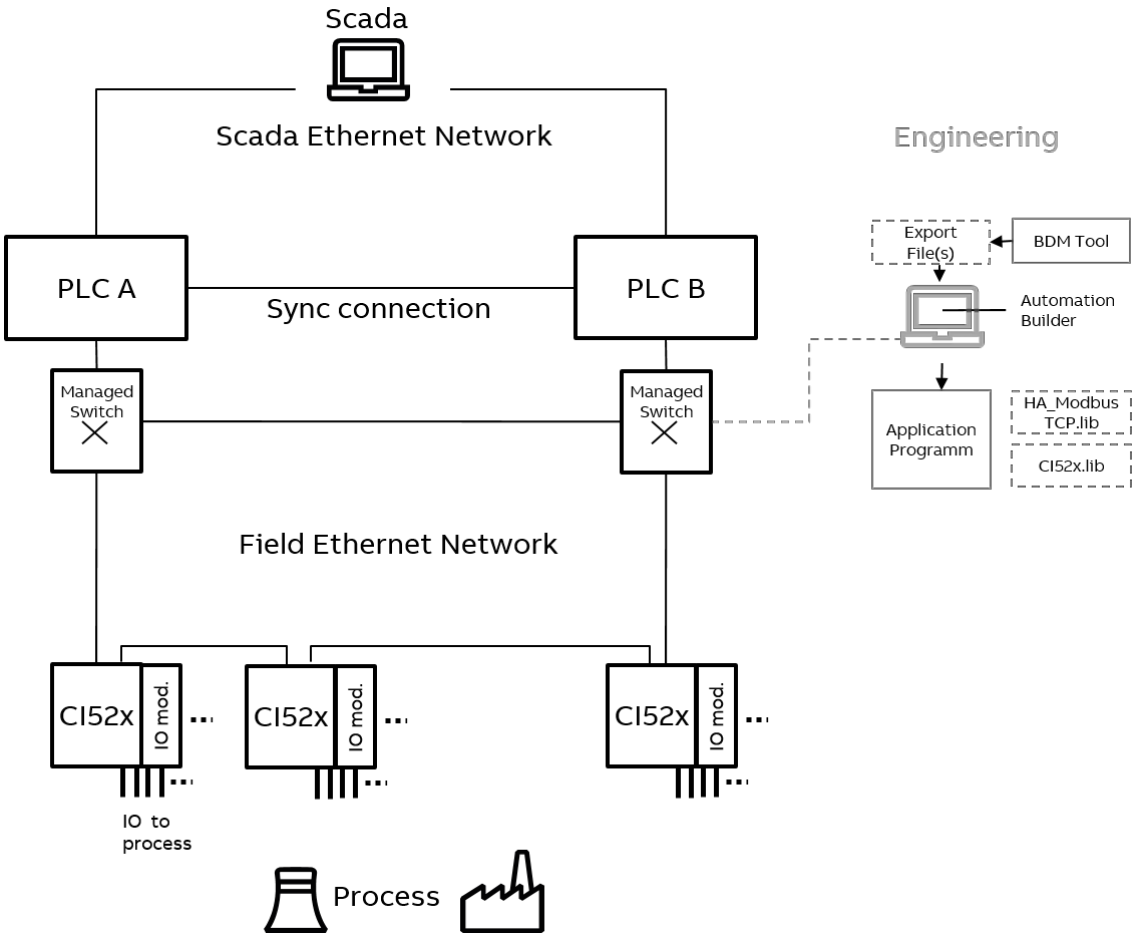

Fig. 145: Principle AC500 HA-Modbus TCP architecture example based on Ethernet redundancy

Details of AC500 HA operation along the figure above:

- PLC redundancy: The two PLCs (A and B) are running in parallel and calculating and reading.
  One is *"primary"* = active, which means also writing data to field devices.
  The other one is *"secondary"* (= stand-by), also calculating but only reading data from field and receiving synchronization (or short = sync) data from the primary.
- Synchronisation data are critical internal variables with e.g. historical content, which will be transmitted from primary to secondary CPU over the sync connection, so that secondary always has the latest data and can take over immediately. Automatically synced are the historic data of the special HA library function blocks (like counters, timers, integral controllers, …), additional Data e.g. of events and diagnosis can be synced by the user with sync blocks. The sync connection also transmits a *"lifecom1"* signal (back and forth) containing diagnosis data of each CPU, so that both CPU know the status of the other CPU. If secondary CPU receives no *"lifecom1"* anymore it assumes that primary CPU has a failure and takes over primary status. If the sync connection is broken both CPUs would try to adopt primary status, therefore, a separate connection *"lifecom2"* is used to differential a "sync link" failure from an "other PLC" failure. The *"lifecom2"* should be routed via a different physical communication path than the data sync/lifecom1, e.g. the Field or SCADA network.
- The field I/O connection is performed via the Ethernet protocol *ModbusTCP* - connecting the CI52x devices (↳ *Chapter 1.6.2.8.5.1 "CI521-MODTCP" on page 4864* or ↳ *Chapter 1.6.2.8.5.2 "CI522-MODTCP" on page 4904*).

For high availability/redundancy of the field or SCADA network, proven Ethernet network redundancy mechanisms are used. (In AC500 this is assumed to be realized by at least 2 (to avoid a single point of failure) external, managed switches), which has the advantage to be able to use AC500 HA with any faster redundancy mechanism / protocol.

- For the I/O communication with CI52x modules two variants exist (see online help: PLC Automation with V2 CPUs ➔ PLC integration ➔ Device specifications ➔ Communication interface modules (S500) ➔ Modbus XY)
  For smaller systems, the CI52x modules can be directly daisy chained (as in previous figure above) if MRP (Media Redundancy Protocol) or DLR (Device Level Ring) is used. Ci52x are not actively participating in ring recovery however, a special FW allows fast ring detection and very short freeze times. Larger systems with e.g. many IO and clusters typically anyway connect to the network via a dedicated managed switch.
- SCADA connection is redundant by nature of the two Ethernet ports and can be extended with further redundancy level as well by managed switches. SCADA itself can also switch the primary PLC to ensure communication to the active PLC in case of a simple connection and a connection failure. If the redundancy mechanism of the OPC DA server is not used, SCADA level itself must be able to handle and differentiate primary and secondary PLC and IP addresses based on the HA-status bits. For CP600 a script exists to do the same for Modbus or AC500 communication protocol.

In most PLC applications the critical components to fail are, beneath PLC, typically the power supply or communication components such as wires or switches. Therefore a *SPOF (Single Point Of Failure)* has to be avoided by adding redundant devices or redundancy functions wherever a failure likelihood is high and failures are not tolerable.

HA core functionality typically can tolerate only a single failure in the different levels. Then, a repair of the failed part is highly advised to achieve and ensure redundancy again. As shown in the above figure, the I/O-network cabling already provides a second independent redundancy layer e.g. for cable failure by its redundancy mechanism (e.g. ring), which can keep up communication without switching the PLCs: There a second failure in the PLC level could be tolerated as long as both connecting, managed switched still work, but it is highly advised to repair immediately anyway.

The AC500 High Availability system itself only takes care of the first fault. For example, in case of a second fault the primary PLC remains primary PLC until the second fault occurs. This results in no further switchovers (manual switchovers included).

Due to the efficient data sync mechanism, which allows data sync over normal and shared ethernet networks, with a well-planned communication network, the PLCs can operate geographically separated (by many 10^{th} of kilometers). So even in catastrophic events with full mechanical destruction still one PLC will be available to control the process or infrastructure.

The secondary PLC or single CI52x modules can be exchanged in a running system without interruption of the primary PLC or the process. (Check document in “Examples” directory of Automation Builder if HA package was installed.)

Libraries

In order to achieve high availability, the CODESYS application must be enhanced with HA function blocks, from the HA-Modbus TCP library and the CI52x library. If the bulk data manager tool (BDM) is used for configuring the System and I/O modules - this is done automatically for the basic initial configuration step by code creation resulting in a prepared user specific “template” application (see below).

- HA-Modbus TCP library contains *HA control* and *HA utility* function blocks
  - *HA control* function blocks manage the core HA functionality by collecting diagnosis and switching if necessary.
  - *HA utility* function blocks provide standard functions in the application program with internal *sync* for integral data e.g. timers, counters, PI control.
- *CI52x library* contains a function block to configure and communicate to the communication interface modules and ensures that only the primary PLC writes to the outputs. The inputs are read by both PLCs.
- For both PLCs the same application must be used/downloaded.

Bulk data manager tool (BDM)

For configuration of the CI52x Modbus TCPs, a separate Bulk Data Manager tool (BDM) is provided. Especially in larger systems usage of BDM is recommended to comfortably engineer HA and create CI52x related configuration and variable data in one place:

- Configuration and parameters of the used I/O modules
- Program code creationfor variable naming, configuration, communication and all basic HA functionality

The BDM tool can serve SCADA programming and documentation as well in an efficient manner.

Hardware, requirements and options overview

Two same type AC500 PLCs are required as central hardware components. Each PLC is equipped with at least two Ethernet ports at a processor module or at a communication module. The two PLCs, called PLC A and PLC B, are linked by Ethernet to exchange and synchronize information (*Sync*). Connections to the AC500 peripheral field devices (I/O) are performed via Ethernet as well.

For further information on which CPU type and library to be used refer to *Table 126 “Overview of AC500 HA systems and options” on page 2093*.

The following table gives an overview of the different High Availability variants possible with AC500.

The figures are indicative, depend on chosen architectures, system size, network and CPU/CM modules used.

Table 126: Overview of AC500 HA systems and options

Library version		HA-CS31	HA-Modbus TCP					
CPU version		V2 CPUs	V2 CPUs			V3 CPUs		
I/O communication		Parallel serial	Ethernet			Ethernet		
CPUs		PM573 - 595	PM573	PM591	PM595	PM5630	PM5650	PM5670
		Parallel serial	I/O network based on Ethernet and ext.edundancy mechanism					
Max. system size CI52x [1, 6]		3 - 50 [2]	3	< 25 / 50	< 60 / 92	< 30	< 50	< 120
I/O modules		CI590: S500	CI52x: S500 and S500-eCo usable [4]					
Switch-over times	CPU	25 -120 ms [3]	Typically < 50 ms ~[6]					
	Field	15 - 120 ms [3]	Depends mainly on network size, redundancy mechanism of external switches [7]					
SCADA connectivity		OPC DA, IEC60870, …	OPC DA, IEC60870, …			OPC DA, OPC UA, IEC60870, …		
Interfaces		Several CS31 and Ethernet	Several ETH ports, via CM597			2 ETH ports [5] + 1 CAN Interface		
Sync		UDP	UDP			UDP		
Lifecom1		-	UDP			UDP		
Lifecom2		-	Modbus TCP			Modbus TCP / CAN		
Overview of AC500 HA system								

[1] Number of CI52x recommendation based on performance or max. number of sockets (CPU and CM modules).

For more details of sockets supported in AC500 V2 PLCs refer to *Chapter 1.6.4.1.6.1.1.2 “Numbers and usage of Ethernet sockets” on page 5448*.

[2] Limited by CPU performance, number of CM574 modules number of CS31 clients and process data limits.

[3] Depends on system size and CPU type.

[4] For details on certain S500-eCo modules not supported, see the Automation Builder release notes, Appendix 1.

[5] CM597 not available for V3 CPUs.

[6] Based on HA bits switchover, depending on failure case *Chapter 1.5.5.2.2.3.2 “Use case descriptions” on page 2100* *Chapter 1.5.5.2.2.5.2 “Task configuration recommendations for HA system” on page 2113*.

[7] Field network: If CI52x are used with their 2 ports as part of a ring: In the moment of a network switchover single telegrams may be destroyed: - for V2 ETH onboard: Standard TCP delays repeats by 500 ms - for V3 CPUs onboard or V2 CPU using CM597: A special HA-FW ensures fast repeats of typ. ~50ms (settable).

CPU choice, system size and performance indications

The diagrams below indicate the example choices of AC500 CPU's (horizontal axes) based on the number of communication interface CI-remote I/O clusters (Communication Interface modules; numbers see legend) used in a system and resulting application cycle times (vertical axes).

Further details can be found in *Chapter 1.5.5.2.2.5.2 “Task configuration recommendations for HA system” on page 2113*. The values in below graphs base on the assumption to use max. 50-60% as CPU loading by the bare fast IO communication and HA functionality. So the application load would come on top and cycle times (especially HA, Modbus) need to be relaxed (made higher) compared to below indication.

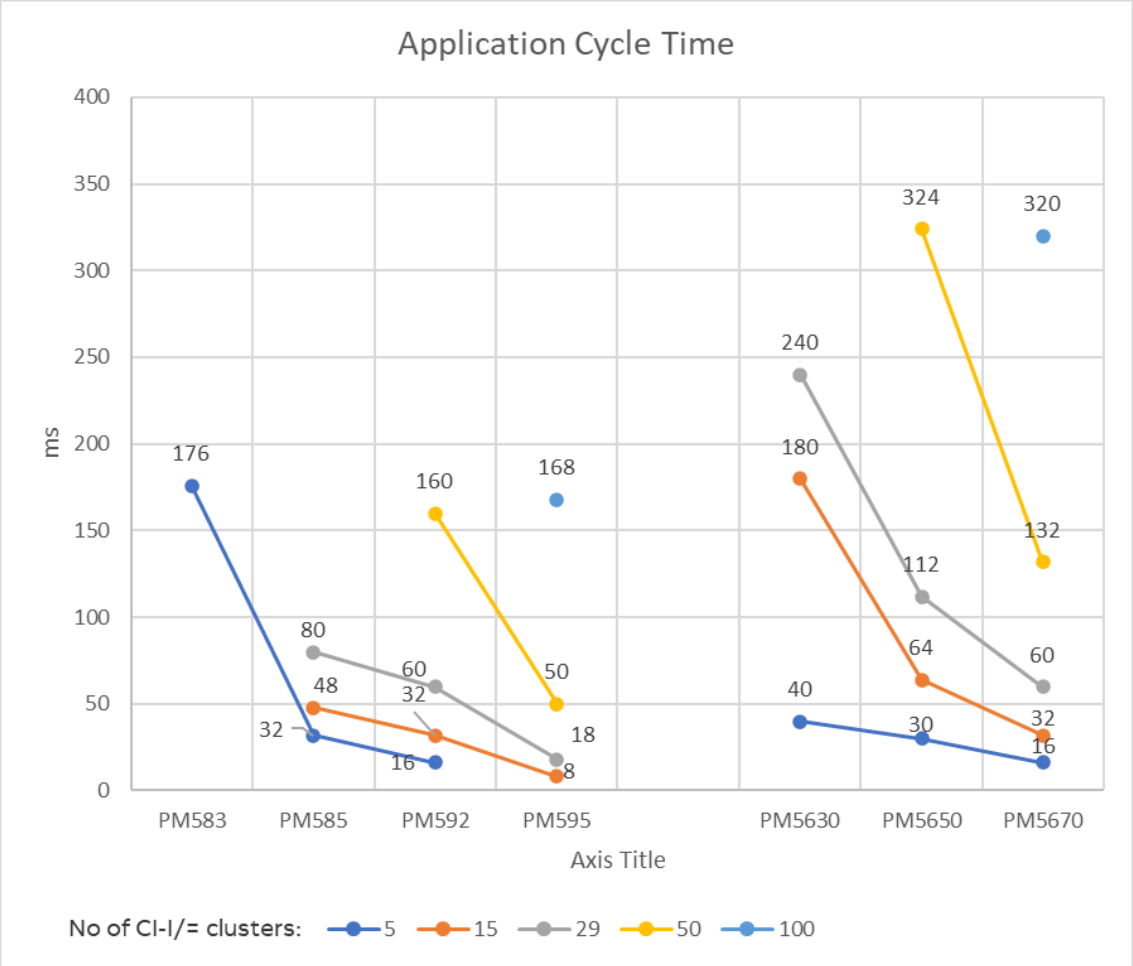

Fig. 146: Indication of AC500 CPU's performance (horizontal axes) based on the number of communication interface CI-remote I/O clusters (Communication Interface modules; numbers see legend) used in a system and resulting application cycle times (vertical axes).

Example: If you need a system supporting min. 25 CI at application cycle time around 120 ms, suitable options based on above graph would be V2 PLCs - PM592 or PM595 and V3 PLCs – PM5650 or PM5670. The main parameter in the application cycle determination is the amount of overall Sync data, which is assumed 160 bytes per CI for the smaller systems, up to 250 bytes per CI for the larger ones. Sync data of the project of in total more than ~1200 byte necessitates several HA cycles to transfer within one application cycle.

The V2 or V3 PLCs types, also differ in available interfaces, protocols supported and memory size.

CI521-MODTCP or CI522-MODTCP can be used as peripheral devices which communicate via the Modbus TCP protocol with the PLCs. The HA-Modbus TCP library supports currently up to 120 CI52x, depending on the CPU type as listed in ↳ *Further information on page 2093*. Each CI52x supports up to a maximum of 10 S500-I/O modules. Nevertheless the standard Modbus TCP communication of the HA library transfers only 120 words per cycle: Therefore please check if for your module configuration matches: In case of many analog IO modules with high-density - like 16 channel AI523/AO523 or modules with fast counters - this limit might be surpassed by roughly 5-6 such modules (to help calculate exactly, there is an Excel sheet provided in the HA “Examples” subfolder of Automation Builder once installed).

For more details of sockets supported in AC500 V2 PLCs refer to ↳ *Chapter 1.6.4.1.6.1.1.2 “Numbers and usage of Ethernet sockets” on page 5448*.

Local I/O on a CPU can signal / interact for diagnosis or service with / from this CPU. This local I/O is not redundant and won't be available to communicate to in case of a CPU failure.

Hardware connections

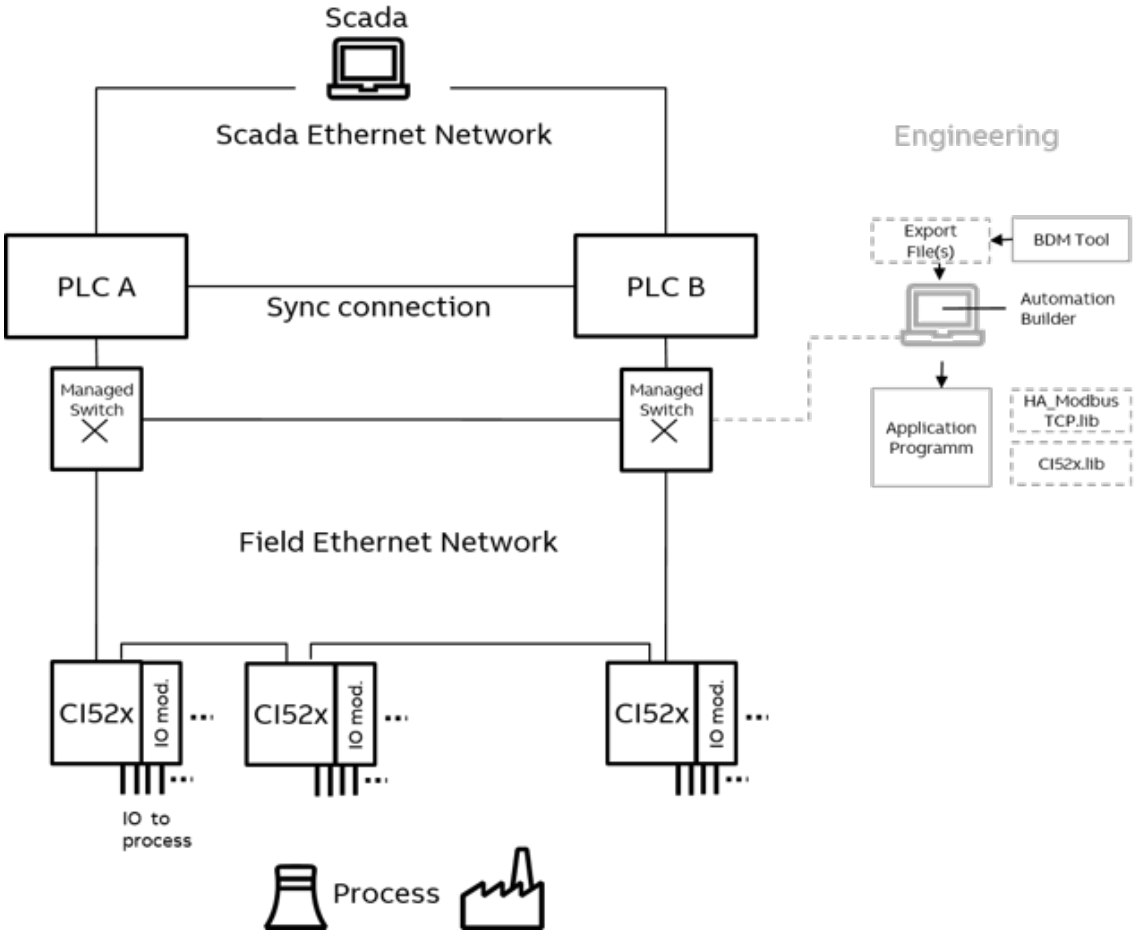

Fig. 147: AC500 HA and SCADA connection

SCADA/ Engineering connection is done using ETH ports of both PLCs and one or several managed Ethernet switches depending on the redundancy requirements in the Ethernet levels.

- HA communication between PLC A and PLC B must be done via two physical connections between PLC A and PLC B in order to distinguish a “sync link” failure from another PLC failure:
  - Sync (including *“lifecom1”*) over Ethernet
  - *“Lifecom2”*
    over Ethernet (Modbus TCP): Can be combined with Field or SCADA network or a separate Ethernet network
    over CAN (only possible with AC500 V3 CPU)
- Field devices (CI52x modules) will be connected via Ethernet switches, forming a redundant network (if requested). For details on network configuration see ↳ *Chapter 1.5.5.2.2.5.3 “Field I/O network topologies” on page 2115*.

The following table shows possible combinations of connections for different CPU types. There must be at least two physical connections. The availability can be increased with a third physical connection, e.g. CM597 for AC500 V2 CPUs or CAN for AC500 V3 CPUs.

	V2 CPU with 1 ETH onboard + CM597		V2 CPU with 2 ETH onboard (+CM597)			V3 CPU with 2 ETH onboard (+ CAN)			
Scada / Engineering	1	1	1	1	1	1	1	1	1
Sync / lifecom1	1	11	1	2	2	1	2	1	2
lifecom2	11	1	2	1	11	2	1	3	3
Field (Modbus TCP)	11	11	2	2	2	2	2	2	2
# of physical connections	2	2	2	2	3	2	2	3	3

1 ETH1 (orange)
2 ETH2 (green)
3 CAN (blue, applicable only in V3)
11 CM597 communication module at slot1 (grey)
The blue box indicates the example which is used in the next chapters.

The numbers in the figure above define the slot on which the connection is made. Last line # of physical connections define how many physical interfaces are used or connected between the PLCs.

It is also possible to realize an HA system without a communication interface CI module see chapter ↳ *Chapter 1.5.5.2.2.6.1.1 "Configuration without communication interface modules to establish redundancy" on page 2119*.

Hardware Example

HA hardware configuration based on V3 PLC to explain the minimal recommended Ethernet port configuration.

- The *Sync* connection is performed via SCADA network, the
- *"lifecom2"* is performed via field network (or the other way around).

The following figure represents the connection example with the details from the highlighted box (see previous figure).

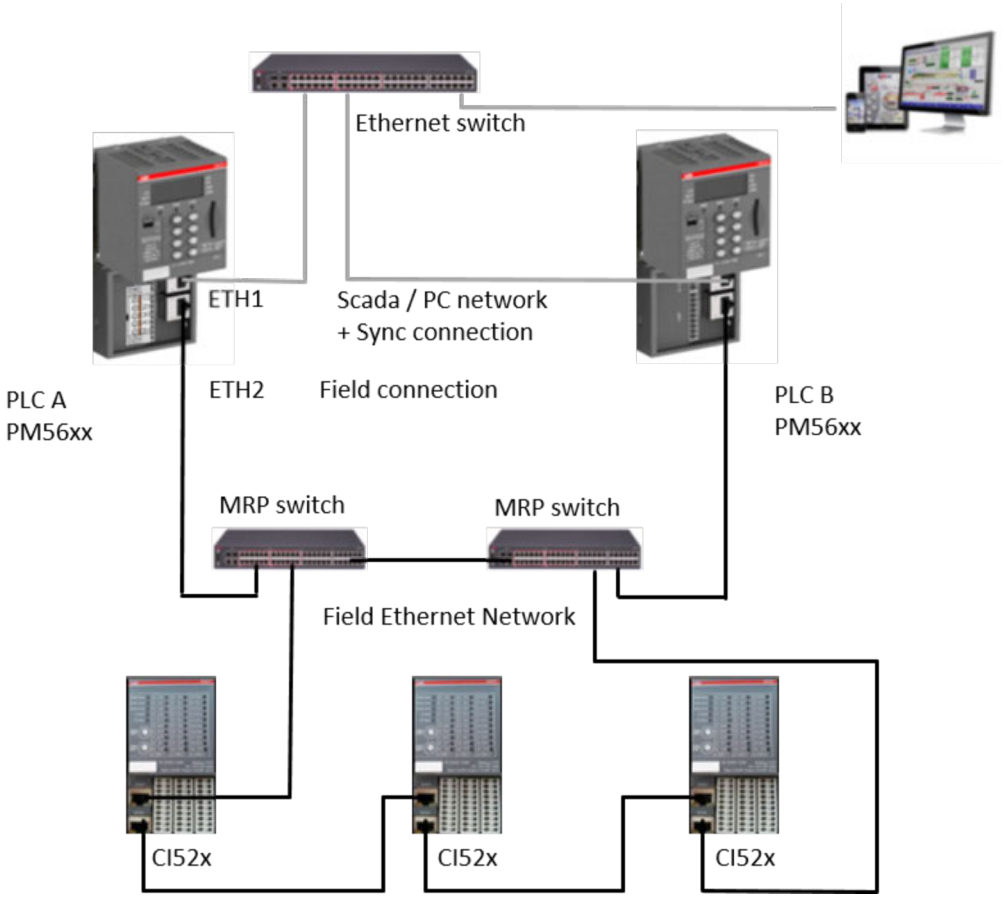

Fig. 148: Physical connection example: 2 ETH CPUs combining sync data / "lifefcom2" with SCADA / Field I/O network

Support of I/O modules (S500/S500-eCo) depends on the version of the library package. See the version details of the library in the Automation Builder release notes.

Functionality

Failures and use cases

The AC500 High Availability system performs a switch-over whenever the primary PLC is powered off, crashed or stopped or if the primary PLC loses fieldbus communication (cut of ETH or defect MRP switch) while the secondary PLC still has connection.

In the following the different use cases and reaction times are outlined.

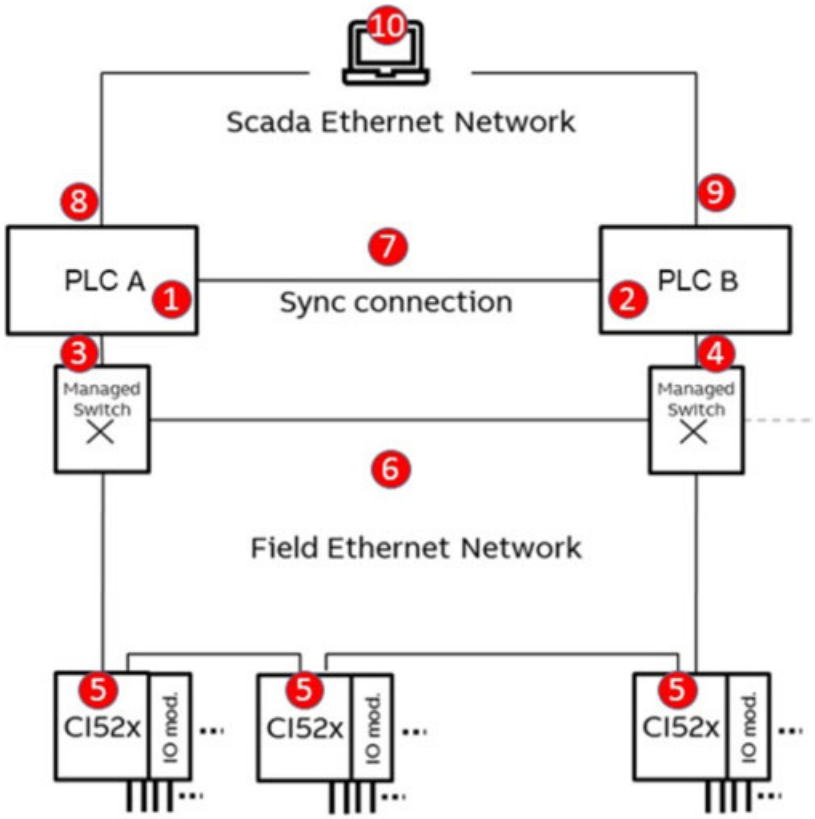

Fig. 149: HA use cases – failures, assuming PLC A is primary and "lifecom2" over field network

The below use case table with reaction and diagnosis messages are based on the setup where Sync is via SCADA network, *"lifecom2"* over field network and PLC A is primary.

Case	Use case	Reaction	Diagnosis message on *)
1	Primary PLC is powered off, crashed or stopped.	Switchover to secondary PLC. CI52x outputs are frozen during switchover period.	Secondary
2	Secondary PLC is powered off, crashed or stopped.	No switchover, process continues.	Primary
3	Primary PLC loses connection to fieldbus CI52x modules while secondary PLC still has a connection.	Switchover to the secondary PLC. CI52x outputs are frozen during switchover period.	Primary
4	Secondary PLC loses connection to one or more CI52x modules.	No switchover, process continues.	Secondary
5	CI52x module is stopped/ powered off.	No switchover, process continues.	Primary and secondary
6	Connection lost in Field Ethernet network.	Depending on Ethernet network structure, and redundancy mechanisms used a reconfiguration time exists.	Lifecom2 lost and CI module lost errors will be generated in primary and secondary.
7	*Sync* and/ or *"lifecom2"* are broken.	No switchover, process continues.	Primary and secondary

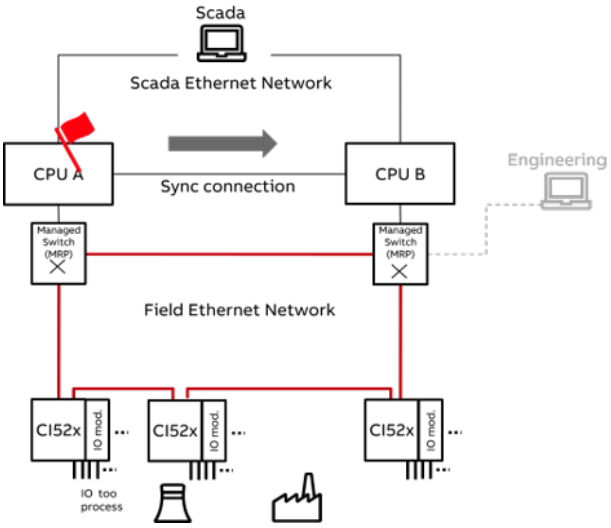
Case	Use case	Reaction	Diagnosis message on *)
8	Primary PLC loses connection to SCADA.	SCADA is responsible to detect and to switch over.	-
9	Secondary PLC loses connection to SCADA.	SCADA is responsible to detect and to switch over.	-
10	SCADA is broken	SCADA is responsible to detect and to switch over.	-
11	Manual switchover by the user.	Switchover to the secondary PLC. CI52x outputs are frozen during switchover period.	-
*) Diagnosis description, see function block description.			

Use case descriptions

The below cases explain the behavior of the system during different use cases.

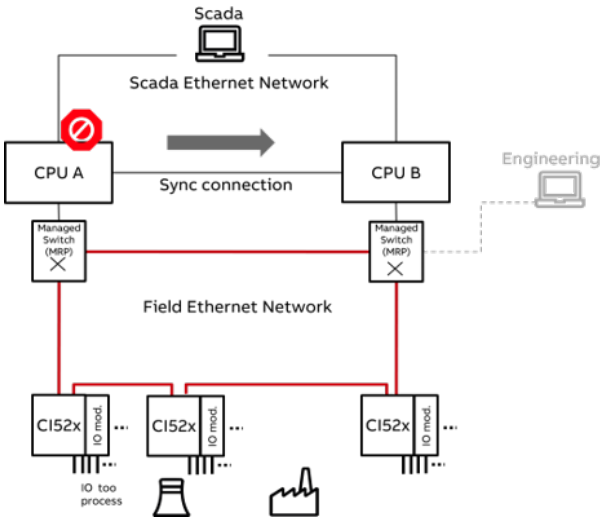
Basic diagnosis information is provided for each case. For diagnosis description refer to *Chapter 1.5.5.2.2.8 “Diagnosis” on page 2124*.

Case 1 a): Primary PLC is powered off or crashes



Reaction	Switchover to secondary PLC. The communication interface modules are updated by the new primary PLC.
Comment	CI52x outputs are frozen during switchover period.
Diagnosis message on function block	Primary PLC is powered off. Secondary PLC: control block output Runtime Error = 16#001E and xHaModPrimary = TRUE

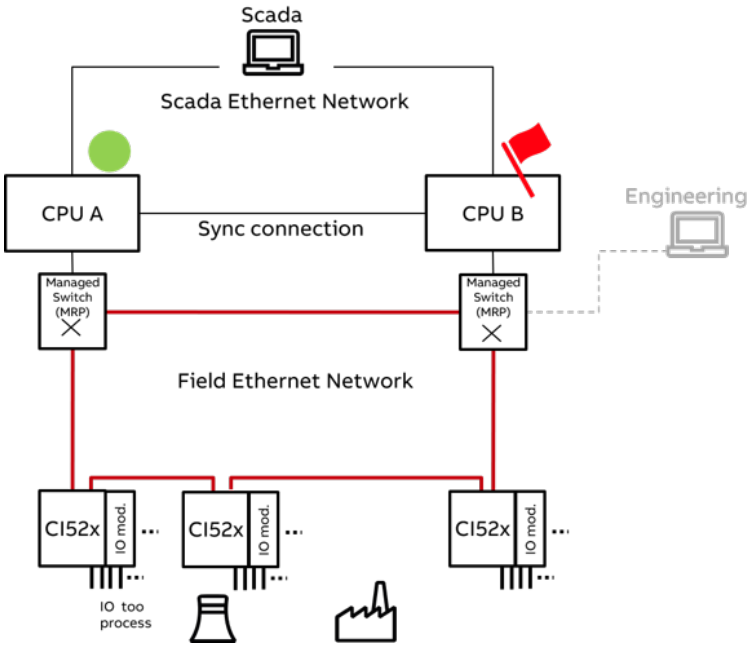
Case 1 b): Primary PLC is stopped



Reaction	Switchover to secondary PLC. The communication interface modules are updated by the new primary PLC.
Comment	CI52x outputs are frozen during switchover period.
Diagnosis message on function block	Primary PLC is stopped. Secondary PLC: control block output Runtime Error = 16#0016 and xHaModPrimary = TRUE

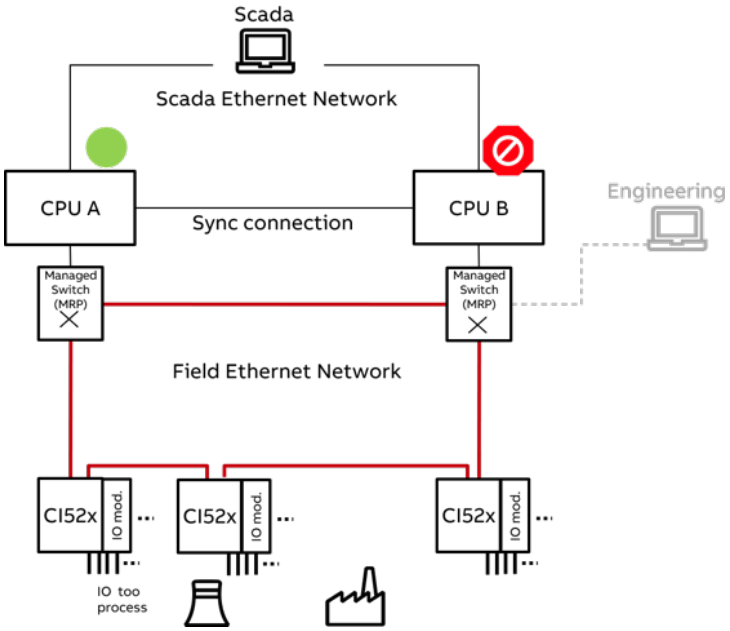
If “lifecom2” is lost and the PLC is in STOP mode RUNTIME ERROR will not be TRUE. This is because Modbus is still responding even if PLC is in STOP mode.

Case 2 a): Secondary PLC is powered off or crashes



Reaction	No switchover
Comment	Process continues
Diagnosis message on function block	Primary PLC: control block output Runtime Error = 16#001E and xHaModPrimary = TRUE Secondary PLC is stopped.

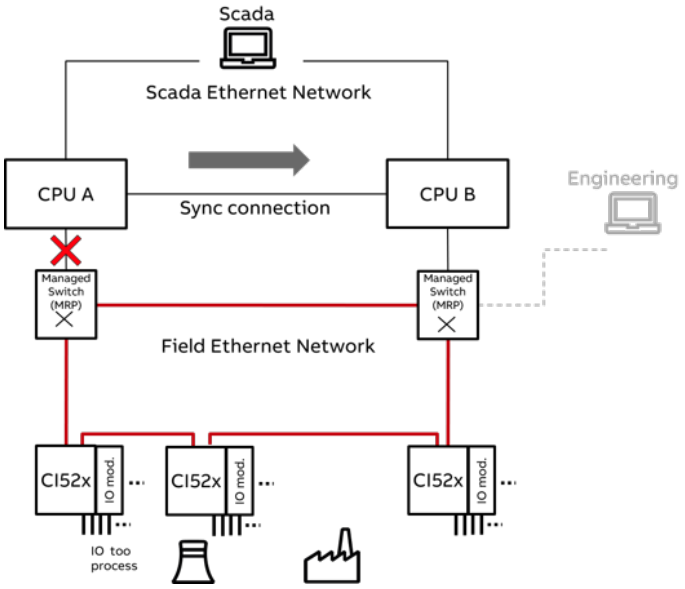
Case 2 b): Secondary PLC stop



Reaction	No switchover
Comment	Process continues
Diagnosis message on function block	Primary PLC: control block output Runtime Error = 16#0016 and xHaModPrimary = TRUE Secondary PLC is stopped.

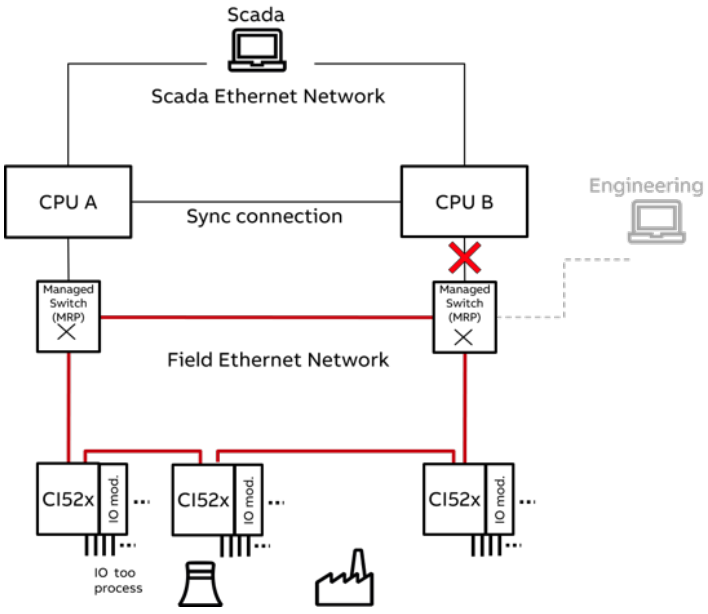
If “lifecom2” is lost and the PLC is in STOP mode RUNTIME ERROR will not be TRUE. This is because Modbus is still responding even if PLC is in STOP mode.

Case 3: Primary PLC loses connection to fieldbus CI52x modules



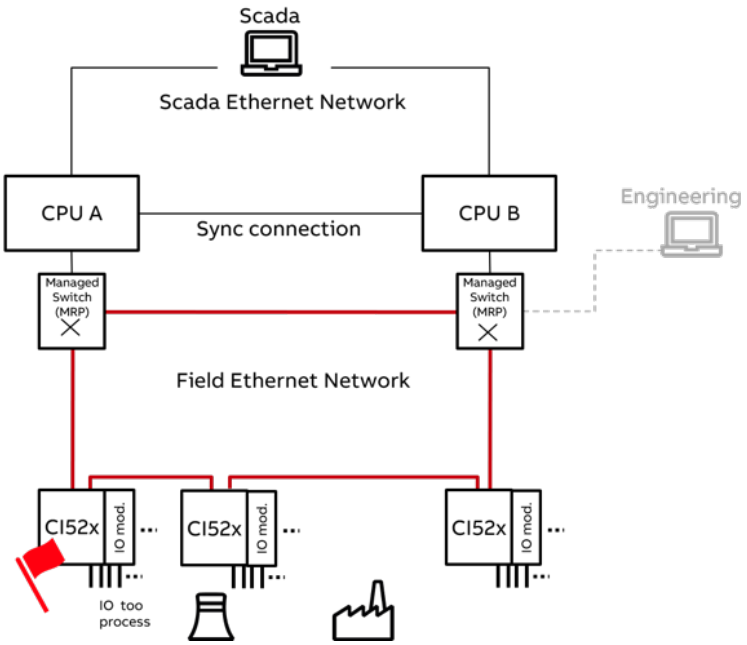
Reaction	Switchover to secondary PLC. The communication interface modules are updated by the new primary.
Comment	CI52x outputs are frozen during the switchover period.
Diagnosis message on function block	Primary PLC: control block output Runtime Error = 16#0094 and xHaModPrimary = FALSE Secondary PLC: control block output Runtime Error = 16#0015 and xHaModPrimary = TRUE

Case 4: Secondary PLC loses connection to fieldbus CI52x modules



Reaction	No switchover
Comment	Process continues
Diagnosis message on function block	Primary PLC: control block output Runtime Error = 16#0015 and xHaModPrimary = TRUE Secondary PLC: control block output Runtime Error = 16#0094 and xHaModPrimary = FALSE

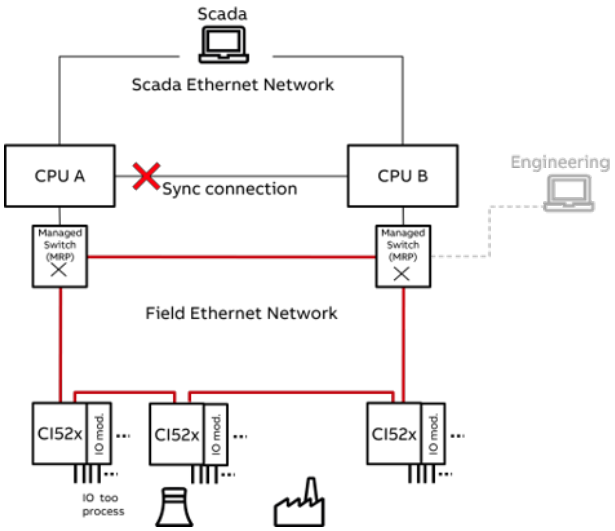
Case 5: CI52x is powered off or stopped



Reaction	No switchover
Comment	Process continues
Diagnosis message on function block	Primary PLC: control block output Runtime Error = 16#0081 and xHaModPrimary = TRUE Secondary PLC: control block output Runtime Error = 16#0081 and xHaModPrimary = FALSE

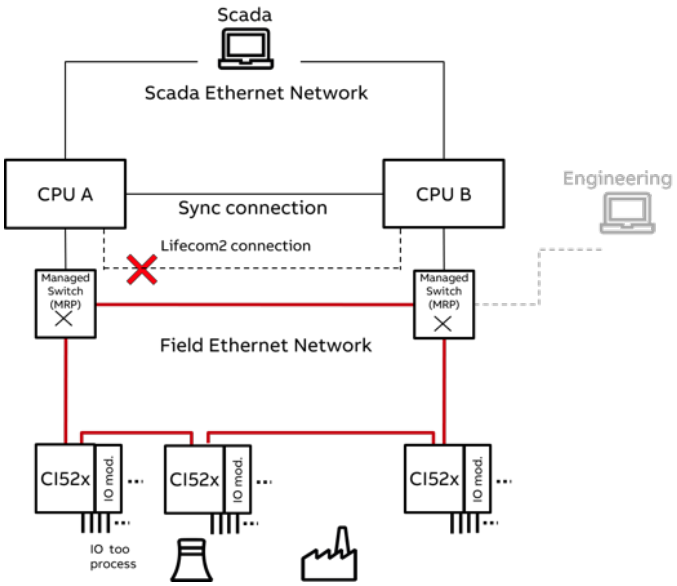
If any CI52x-MODTCP module is powered off and on, there is no need to power restart the complete system. The module will be recognized once the communication is reestablished.

Case 7 a): Sync connection is broken between the PLCs



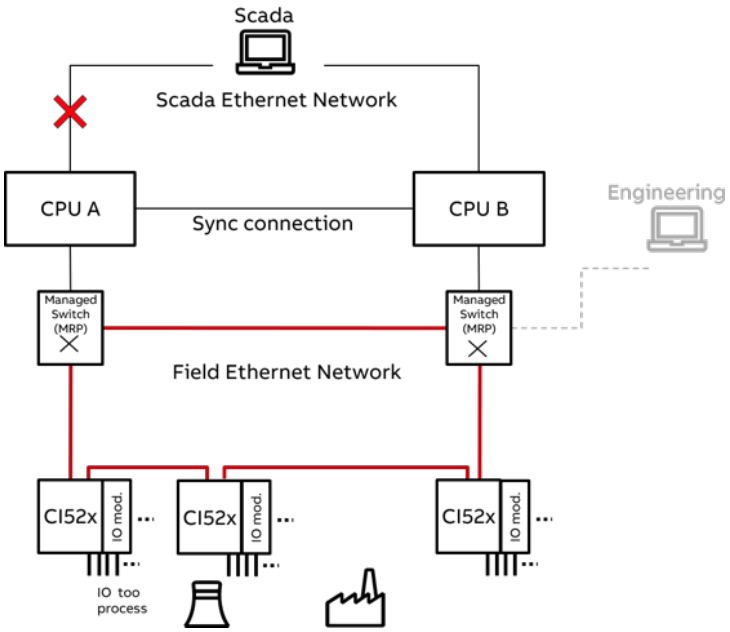
Reaction	No switchover
Comment	Process continues
Diagnosis message on function block	Primary PLC: control block output Runtime Error = 16#0014 / 16#0094 and xHaModPrimary = TRUE Secondary PLC: control block output Runtime Error = 16#0014 / 16#0094 and xHaModPrimary = FALSE

Case 7 b): Lifecom2 connection is lost between the PLCs



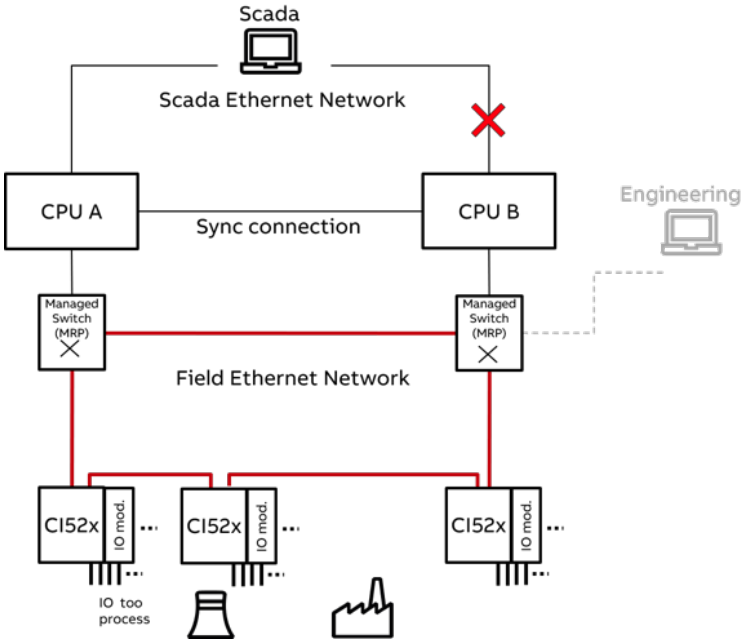
Reaction	No switchover
Comment	Process continues
Diagnosis message on function block	Primary PLC: control block output Runtime Error = 16#0008 and xHaModPrimary = TRUE Secondary PLC: control block output Runtime Error = 16#0008 and xHaModPrimary = FALSE

Case 8: Primary PLC loses SCADA connection



Reaction	No switchover
Comment	Process continues, SCADA is responsible to detect and switchover
Diagnosis message on function block	Primary PLC: control block output Runtime Error = 16#0000 and xHaModPrimary = TRUE Secondary PLC: control block output Runtime Error = 16#0000 and xHaModPrimary = FALSE

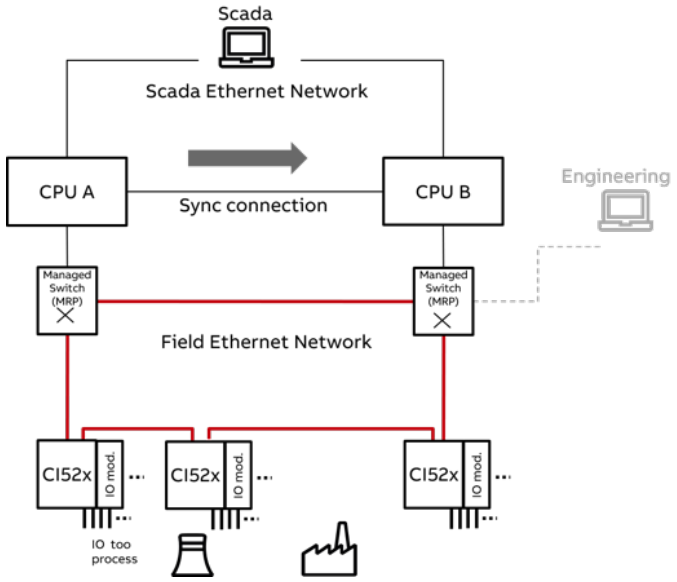
Case 9: Secondary PLC loses SCADA connection



Reaction	No switchover
Comment	Process continues, SCADA is responsible to detect and switchover
Diagnosis message on function block	Primary PLC: control block output Runtime Error = 16#0000 and xHaModPrimary = TRUE Secondary PLC: control block output Run-time Error = 16#0000 and xHaModPrimary = FALSE

SCADA link may be combined with sync connection or “lifecom2” connection. In that case runtime error and system behavior will be as described in the cases above (Sync connection lost / “lifecom2” connection broken).

Case 11: Manual changeover by user



Reaction	Changeover from primary PLC to secondary PLC.
Comment	CI52x outputs will be frozen during switchover
Diagnosis message on function block	Primary PLC: control block output Runtime Error = 16#0000 and xHaModPrimary = FALSE Secondary PLC: control block output Runtime Error = 16#0000 and xHaModPrimary = TRUE

A manual switchover can be triggered from both PLCs. For each trigger a switchover from primary PLC to secondary PLC will take place.

How to get and install the AC500 High Availability system package

The PS5601- High Availability Modbus library package can be installed from the *Automation Builder Installation Manager* by selecting the component.

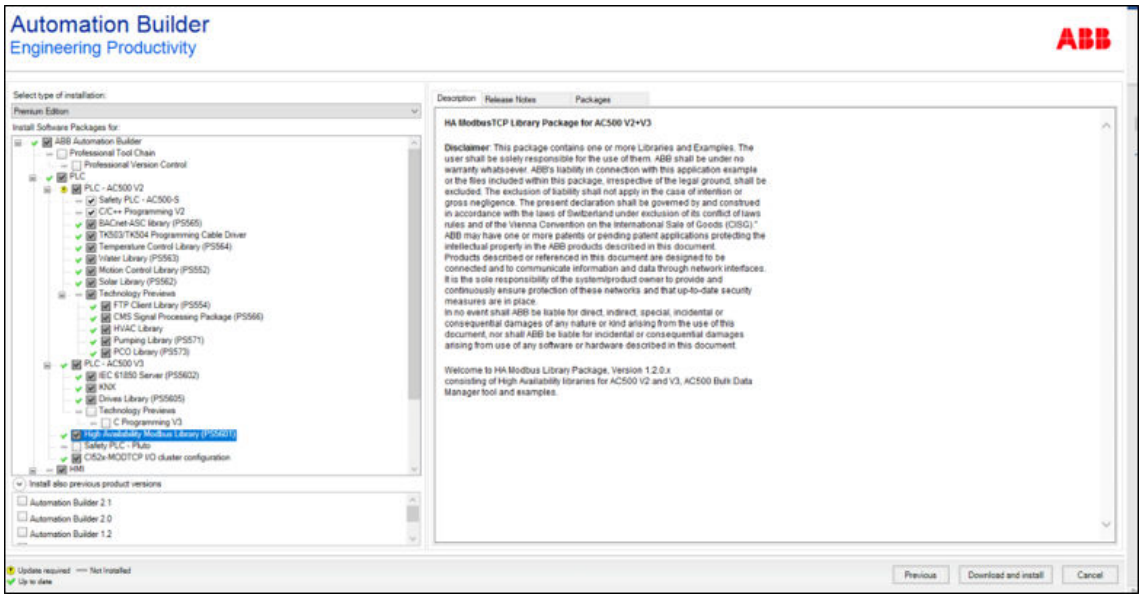


Fig. 150: Automation Builder Installation Manager

The following components are installed:

- Libraries
  - AC500 V2 libraries: *C:\Program Files (x86)\Common Files\CAA-Targets\ABB_AC500\AC500_V12\library\PS5601-HA-MTCP*
    CI52x_AC500_Vxx.lib, HAModbus_AC500_Vxx.lib.
  - AC500 V3 libraries available in library repository:
    ABB_CI52x_AC500.compiled-library, ABB_HaModbus_AC500.compiled-library
- Online help: HA-CS31, HA Modbus V2 function block description
- Automation Builder Example folder: *C:\Users\Public\Documents\AutomationBuilder\Examples\PS5601-HA-MTCP*
  - AC500_V2: Examples for AC500 V2 including documentation
  - AC500_V3: Examples for AC500 V3 including documentation
  - BulkDataManager: Bulk Data Manager (BDM) tool which helps efficient engineering in larger projects. This requires a separate installation. Further information can be found in the document: *C:\Users\Public\Documents\AutomationBuilder\Examples\PS5601-HA-MTCP\BulkDataManager\Documentation*.
  - HA-Modbus TCP System Technology.pdf (this document)

System structure

This chapter explains the detailed structure of the HA system in CODESYS. A HA-Modbus TCP system is characterized by two AC500 PLCs with the following features:

- Identical programs (application with additional HA and Modbus function blocks) that are loaded to both PLCs.
- Communication interface modules CI52x-MODTCP that are connected via Modbus TCP.
- Synchronization of both PLCs (*sync/lifecom1* and *lifecom2* logical connections).

Programming

Each PLC contains at least three main tasks/ programs:

- HA program
- Application program
- Modbus program

The programs in one PLC communicate via internal structures of the libraries and dedicated internal memory areas for HA-Sync array and the Modbus CI52x memory(ies) CiModDataxx.

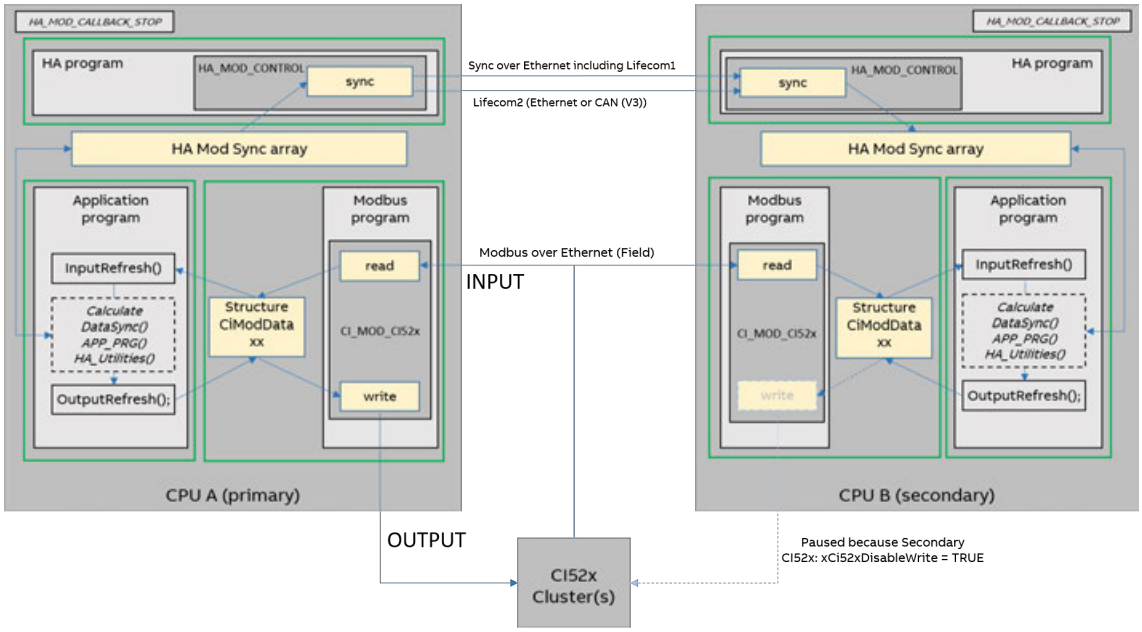

Fig. 151: Principle structure of the HA system and recommended tasks: HA, Modbus, Application

Table 127: Image description

Layout element	Meaning
Dotted outline box	Indicates optional function block or programs.
Solid outline box	Indicates the mandatory function blocks or programs. All mandatory blocks are called when an export is created from Bulk data manager.
Italic font	Indicates the program or functions user should call in his project and not created by Bulk data manager.
Light yellow background block / blue arrow	Indicates the operations which are handled internally in the library.
Green solid box	Indicates the three different tasks which user has to configure.

Modbus program

The function block CIModCI52x (V3) / CI_MOD_CI52x (V2) reads the input values from the CI52x modules and stores them in the structure CiModDataxx. If the CPU is primary it also writes the outputs to the CI52x modules. The Function block also parametrizes the CI Module as configured in e.g. Bulk data manager tool during the first startup or when a CI module is exchanged.

Normally the HA-Modbus TCP library takes care of communication monitoring. Nevertheless if com- munication is cut completely, the CI52x communication interfaces and its I/O modules have to react on their own to achieve a bumpless or desired behavior: The following parameters for the CI52x com- munication interfaces and I/O modules need to be considered:

- *– CI52x: parameter "Timeout" for Bus supervision: [2)]*
  Allows to detect errors from communication interface side as well and take action to ensure a fail- safe behavior if communication is cut. It can be set in 10 ms steps. If set to 0 no bus supervision is active. Proposed value: 50 = 500 ms = default in Bulk data manager; this value should be increased, e.g. to value 65 if AC500 V2 CPU ports are used for field communication to take care of the larger TCP retransmit time.
- *"Behaviour Outputs" at "Timeout for Bus supervision" [1), 2)]. This fail-safe parameter has to be con- sciously set: separate settings are possible for each module (and communication interface): "off"; "last" or "substitute": 5 s, 10 s, ∞ s [1)].*

Remarks:

[1)] The parameters "Behaviour Outputs at comm. Error" is only analyzed if the Failsafe-mode is [ON].

[2)] Both are CI52x parameters set e.g. via Bulk data manager tool in the program.

Application program

- At the start of the application task the InputRefresh program has to be called. It copies data from Modbus via the structure CiModDataxx to the user variables, which were defined in BDM as signals. For further information refer to BDM documentation, chapter 7 which is available in the path: *C:\Users\Public\Documents\AutomationBuilder\Examples\PS5601-HA-MTCP\BulkDataManager\Documentation*.
- Only the main application programs should be in this task and use these variables for the user defined functions. E.g here the user programs and logic should be called and use the HA libraries utility blocks (which *sync* their historic data automatically) and HA_MOD_DATA_SYNC blocks for further user data which should be synchronized.
- Data of utility blocks and HA_MOD_DATA_SYNC blocks are copied to the HA Sync array of the primary CPU (which is sent to the secondary CPU by the HA program).
- OutputRefresh program is called as a last step. It copies data from the user variables via structure CiModDataxx to Modbus.

Example of a utility function block (with integrated sync data)

Consider the on-delay timer HA_MOD_TON (V2)/ HaModTon (V3).

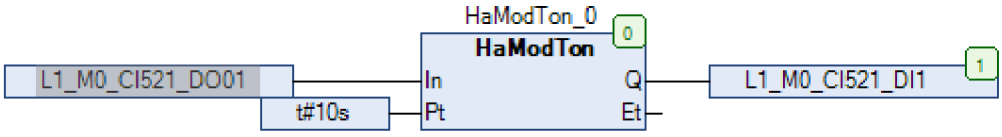

Fig. 152: HaModTon utility function block with internal synchronization

Both PLCs require the same function block called in the program. Under normal operating conditions the elapsed time ET and output Q of the timer is synchronized internally from primary to the secondary CPU. ET and Q data are available and can be attached to local or global variables in the program as per application requirements. If PLC A shuts down due to a fault, the primary status switches over to PLC B.

In the event of a switchover, the moment PLC B becomes the primary, the timer on this PLC will keep running. Until the time of PLC A failure, the timer on PLC B was synchronized. This is most important in cases when one CPU was not in run or off and needs to “catch up” such integral or historic system values (timers, counters, operator settings, …). The actual process remains then unaffected by the switchover.

HA program

HA_MOD_CONTROL has two functions:

- Exchange status data (lifecom1 and lifecom2) and switch from secondary to primary PLC (or vice versa) based on the status according to the use cases described in *Chapter 1.5.5.2.2.3.1 “Failures and use cases” on page 2098*.
- Send sync “HA SYNC” array from primary to secondary PLC to ensure that the secondary PLC is always in hot-stand-by and can take over immediately. UDP protocol is used for data synchronization between the CPUs.

Data synchronization via UDP

This chapter explains how the data synchronization happens between primary and secondary PLC via UDP.

All prepared sync data is synchronized with the secondary PLC. Typically only integral values (timers, counters, PID, …) or settings which might have been received have to be synchronized. For example for fast start-up cases when a secondary CPU was restarted, as both PLCs are running and calculating closely in parallel and based on the same input values, synchronization will make the secondary start with current value instead of default value. For details on how to configure or use the data sync function block refer example projects.

Following steps are performed:

- HA SYNC array is transferred via UDP to the secondary CPU. This includes the exchange of lifecom1 status between primary and secondary CPU.
- In the HA program the HA_MOD_CONTROL function block collects all diagnosis, sync and lifecom2 data from the field and/ or the other PLC. Whether a switchover is necessary is decided based on a simple decision matrix.
- Lifecom2 is exchanged between CPUs over Modbus TCP every cycle.
- One task per program, see figure above.
- Status of the inputs connected to CI52x decentralized I/O stations is transferred to both PLCs simultaneously in every PLC cycle. They are received by the CI52x function block.
- At the end of the program, the generated output values are sent, by transferring from the primary PLC respective buffers to the CI52x-MODTCP module(s) via CI52x function block and Modbus TCP. The secondary PLC is prepared to send but stays “silent” (not sending output values).

PLC needs one HA cycle to send one ETH frame data from primary to secondary CPU and receive acknowledge from secondary CPU. Similarly V3 PLC needs two HA cycles.

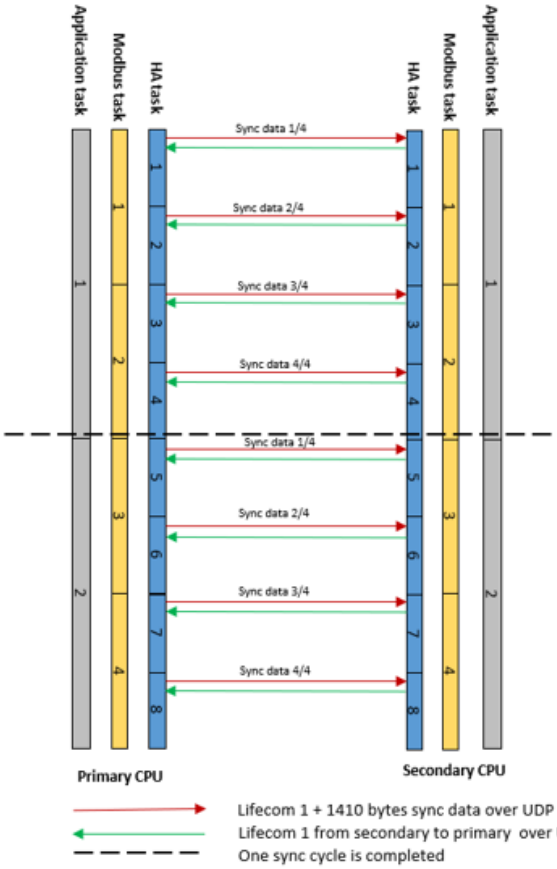
One ETH frame copies approx. 1412 data bytes. The number of ETH frames needed to synchronize HA Sync Array completely depends on the number of data sync bytes. Global variable *iNoOfEthFrames* gives the user this information, which should be used to calculate the cycle time for the application task.

Chapter 1.5.5.2.2.5.2 “Task configuration recommendations for HA system” on page 2113

Up to max. 60 kB of Sync data can be synchronized.

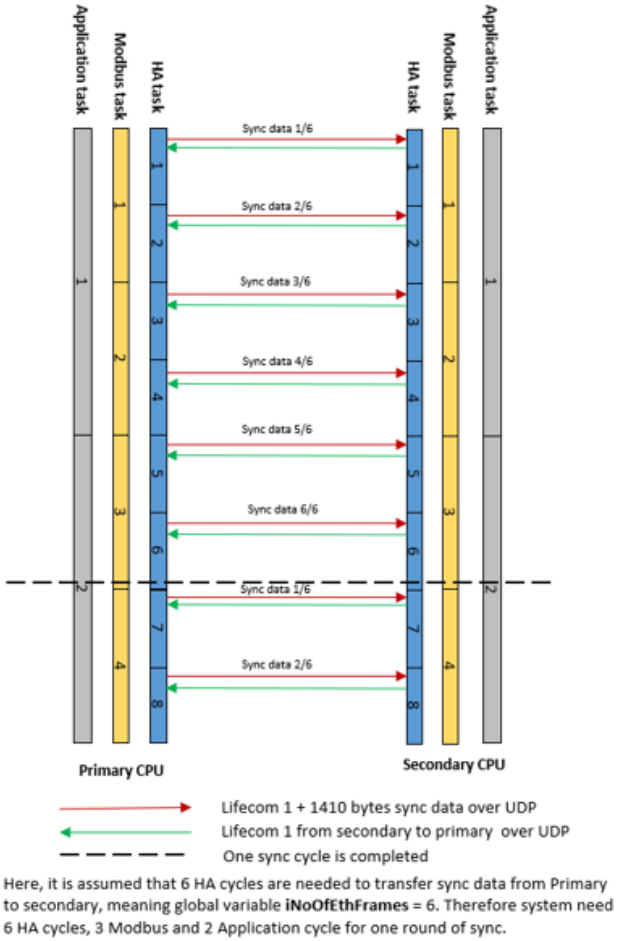
Synchronization between the primary and the secondary PLC happens over a few cycles of HA task time depending on the total sync data bytes configured in the system. Lifecom1 is also exchanged between the primary and the secondary PLC. The primary PLC sends lifecom1 to the secondary PLC along with sync data. Backwards the secondary PLC sends lifecom1 to the primary PLC every cycle.

The following figures shows an example for V2 PLC. When in the project the sync data is equal to 4 *iNoOfEthFrames* then it takes 4 HA cycles to synchronize the data between the PLCs.



Here, it is assumed that 4 HA cycles are needed to transfer sync data from Primary to secondary, meaning global variable **iNoOfEthFrames** = 4. Therefore system need 4 HA cycles, 2 Modbus and 1 Application cycle for one round of sync.

When sync data in the project is equal to 6 *iNoOfEthFrames* then it takes 6 HA cycles to synchronize the data between the PLCs.



Here, it is assumed that 6 HA cycles are needed to transfer sync data from Primary to secondary, meaning global variable **iNoOfEthFrames** = 6. Therefore system need 6 HA cycles, 3 Modbus and 2 Application cycle for one round of sync.

Task configuration recommendations for HA system

For a balanced performance of the HA system consider the following recommendations in your project task configuration:

General

- Use the real time priorities for all HA related tasks. The HA program/ task should be called at highest priority as it is responsible for the core HA functionality and should be the fastest task.
- The Modbus task contains the Modbus communication function blocks at lower priority and (depending on CPU performance) also a faster cycle time to ensure sufficient update rates on Modbus without over- loading the CPU with communication.
- The application program parts should be called in the application task with even lower priority and a larger cycle time than above tasks.
- Configuration to improve standard Modbus TCP for a fast switch over between PLCs.
- AC500 V2
  - CM597ETH_SET_TCP_RTO function block from CM597_ETH_AC500_V28.lib needs to be called inside HA task. User needs to call this function block for each CM597 module connected. For recommended values see example description.
- AC500 V3
  - RTO retransmission time function block “EthSetRtoMin” for the ETH port where fieldbus communication is configured. By default, minimum retransmission time configured is 15 ms.

Task	Priority	PM57x, PM58x, PM59x	PM595-4ETH	V3 PLCs
HA	10 (high)	4 ms or higher	2 ms or higher	4 ms or higher
Modbus	11 (medium)	Maximum of (HA cycle time *2), (3 ms + roundup (#CI/2))	Maximum of (HA cycle time *2), (3 ms + roundup (#CI/2))	Maximum of (HA cycle time *2), (3 ms + roundup (#CI/2))
Application	12 (low)	Maximum of (Modbus cycle time *2), (iNoOfEthFrames * HA cycle time)	(iNoOfEthFrames * HA cycle time)	Maximum of (Modbus cycle time *2), (iNoOfEthFrames * HA cycle time *2)

Procedure for task configuration

1. Choose suitable CPU type according to chapter CPU choice, system size, performance indications
2. Configure task priorities according to the table
3. Set HA task to minimum according to above table
4. Calculate Modbus cycle time according formulas in the table, based on HA cycle and number of CI modules “#CI”
5. Calculate Application cycle time according to formulas in the table, based on Modbus cycle time and variable iNoOfEthFrames, which is defined in the global variables of HA-Modbus TCP library.
6. Measure PLC and CPU load during trial operation.

   V2: CPU load : *Chapter 1.5.4.12.1.2 “CPU_LOAD” on page 1168*

   If the PLC load is higher than 40 % or CPU load higher than 60 % then increase HA cycle time (e.g. to 8 ms / 12 ms / 24 ms, …) and go to step 4, repeat the steps until loading is within defined range.

   *A new **V3 CPU configuration option** is introduced from Automation Builder 2.4.1 and onwards which allows to change the priority for Ethernet communication in PLCs.*

   Set this configuration in the device tree of the CPU in Automation Builder double click on PLC “CPU_Parameters Parameters ➔ Communication Schema ➔ Select “Onboard Ethernet””.

   The above parameter should be set to “Onboard” Ethernet for HA systems and it will consequently increase the loading due to the higher priority. PLC Load < 50 % and CPU load < 70 % should be considered as guidelines here instead, while setting the task times while setting the task times.

7. Following timeout values has to be defined in the user project according to the relation defined.

Timeout variables (see definitions in box below table)	HA in V2	HA in V3
timCI52xTimeOut	1 * Modbus Task time	50 ms or Modbus Task time, whichever is higher
timHaModSyncTimeOut	1* HA Task time	2 * HA Task time
timResponseTimeout	Not applicable	50ms or (2 * Modbus Task time), whichever is higher
timCanTimeOut	Not applicable	100 ms or (2 * Application Task time) whichever is higher

8. Add additional applications and SCADA communication: Check PLC and CPU load again vs. your requirements.

In the HA Modbus system different timeouts must be configured for the fine operation of the system as described above in the task configuration for V2 and V3 PLCs. These different timeouts meaning, and relation is explained below:

timHaModSyncTimeOut:

Time limit to check if the new sync data is received or not in the secondary PLC. If this timeout is not defined properly, Sync lost error/ “lifecom1” lost error will be generated.

timCanTimeOut:

Time used for the check whether “lifecom2” is received when configured via CAN. This value is applicable only in AC500 V3. Lifecom2 via CAN won’t be stable between the PLCs and runtime error "lifecom2 lost" will be flickering if not the right value is configured.

timCI52xTimeOut:

Time limit to check whether new data is received in the Modbus field modules. It is also used to check whether “lifecom2” is received when configured via Modbus TCP. If 'timCI52xTimeOut' is not defined as described, “lifecom2” error / communication interface diagnosis error will not be generated as expected.

timResponseTimeOut:

Timeout value to check whether CPU has lost the communication interface modules connected in the network. If this value is not defined as described, communication interface module lost detection will not be indicated properly.

Field I/O network topologies

Modbus TCP communication between PLC and communication interface modules CI521-MODTCP or CI522-MODTCP can be done using different network topologies. In the following subchapters different simple combinations with their pros and cons are explained.

If a CI52x module of a daisy chain is powered off, next following modules will lose connection/ data provided there is no redundancy in the Ethernet network (e.g. ring and managed switch).

Simple ring topology (smaller systems)

In a simple configuration, CI52x modules can be part of a ring if MRP (or DLR) protocol is used in the managed switches. Then the CI52x are connected from one to another device (“daisy chained") through e.g. two network switches. The redundancy protocol detects a closed ring and opens one port of a managed switch to avoid the ring. The user has to configure the necessary ring configurations and enable the ring manager for the used ring ports in one switch.

It is recommended that time interval between ETH cable disconnection and re-connection should be greater than 2-3 seconds.

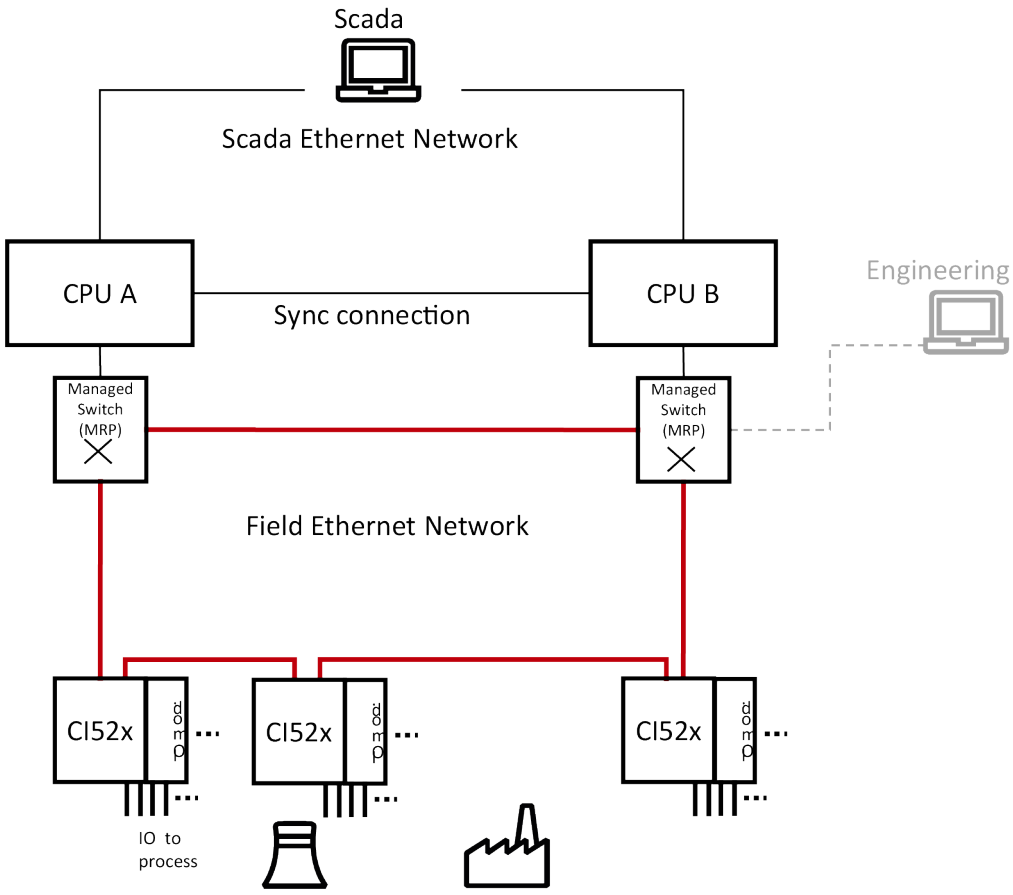


Fig. 153: Redundant ring topology with 2 MRP switches (avoids a SPOF (Single Point Of Failure))

Standard network topology (large systems)

In the standard redundant network, which is often done by third party dedicated telecommunication companies, managed switches are used for every connection point to this network. It’s the network's (and operator's) responsibility to repair any failure fast enough so that no influence on the HA system or its outputs occur.

The network can use other fast redundancy algorithms, also having other than ring structures, if redundancy links are activated fast enough.

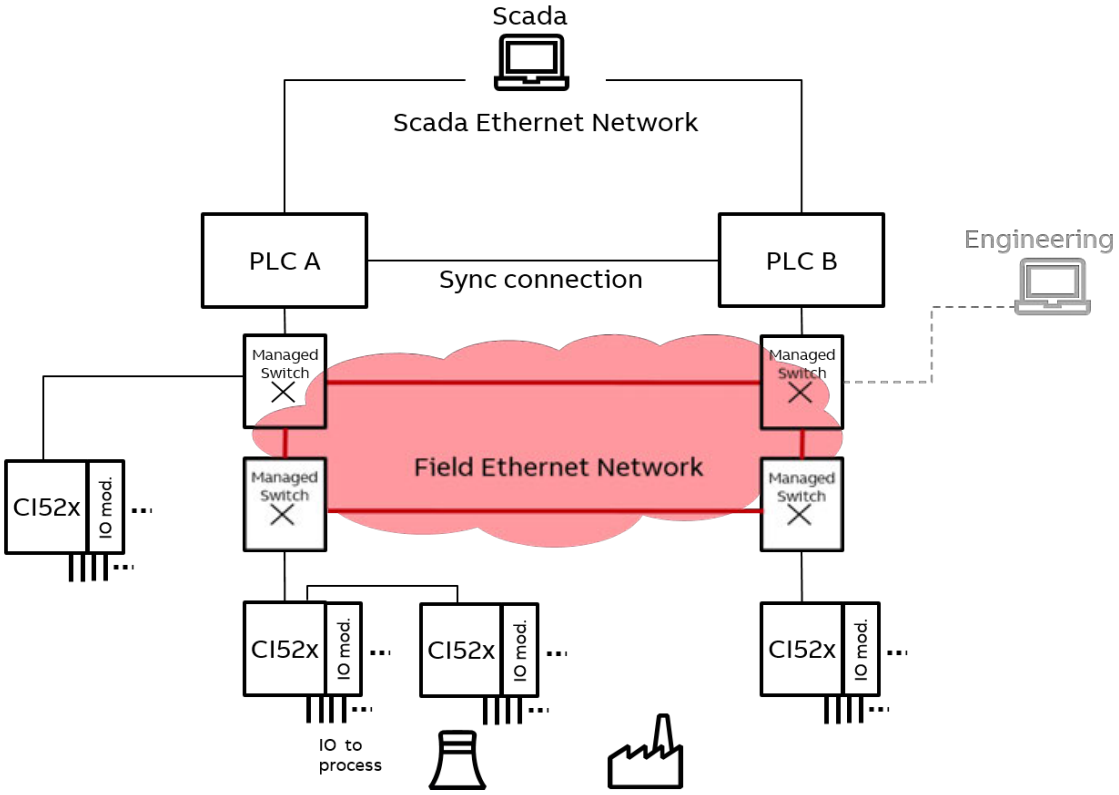

Fig. 154: Redundant ring topology with independent network (using any fast redundancy mechanism internally in a ring or meshed network)

Parallel network topology (using PRP)

Each CI52x module and PLCs as single ended devices are connected by PRP switches to both networks. Here the failure of the switch which connects the primary CPU will also lead to a switchover.

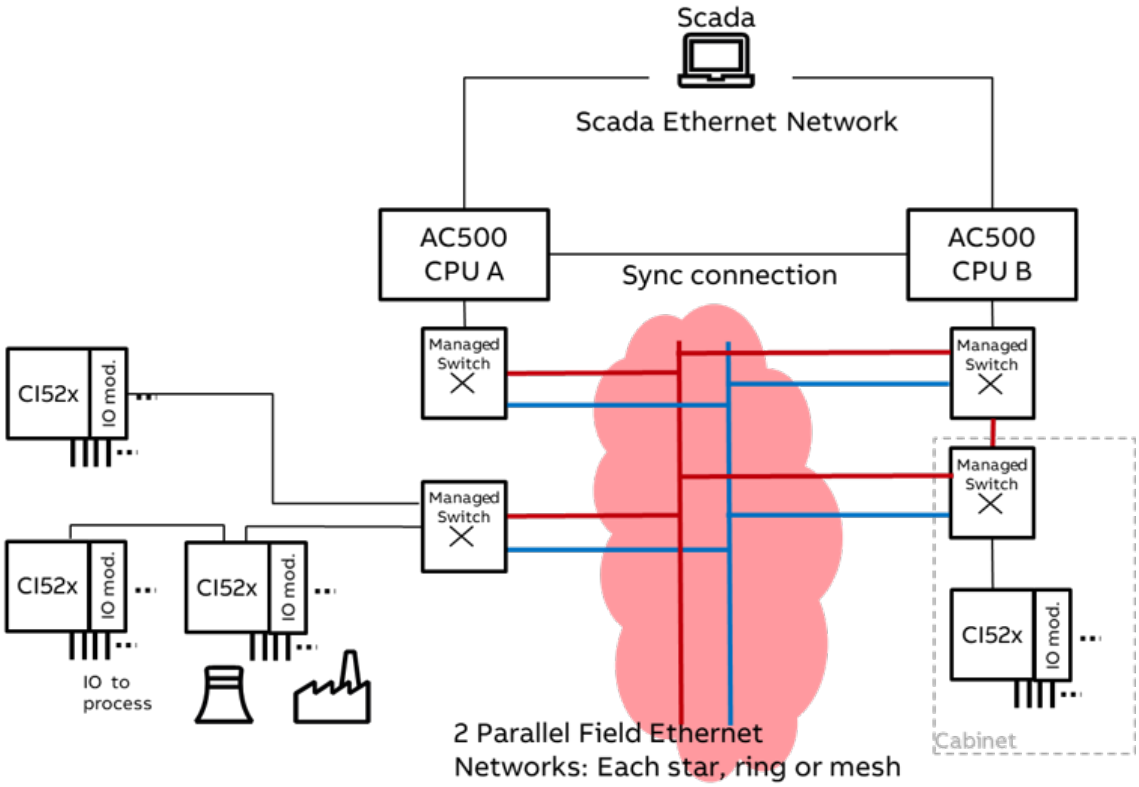

Fig. 155: Parallel-redundant network, PRP switches to connect each device, CPU and communication inter- face modules

Redundancy switchover timing should match the settings in the program and communication interface modules for time-out and freeze periods. The networks for larger systems are often seen as a separate entity and done by a separate company. Make sure to have the redundancy status information of the network at least in SCADA, to repair in time. If the I/O field network responsibility is with the automation/ PLC part, the redundancy status should be also monitored by the PLC. A warning to initiate repair may be created from the managed switches in the I/O field network.

Examples

- Alarm output(s) wired (e.g. to a CI52x input and related settings of the switch(es)).
- Settings of the switch(es) to send (e.g. SNMP traps, which can be received in PLC (AC500 SNMP library)).
- Use of “automation switches” which can also communicate their status directly via Modbus.

It is also possible to connect switches in ring combination with CI modules connected to them in daisy chain. User needs to do the relevant setting based on type of switch and protocol (Ex: MRP, RSTP).

If RSTP ring configuration is used in the system, ring reconfiguration time is slower than other ring protocols. During this reconfiguration, connection to the CI modules will be lost.

HA Modbus system without communication interface modules in the network

It is also possible to have a HA Modbus system without connecting any field devices, CI521-MODTCP / CI522-MODTCP in the network. This system can be used for establishing a redundant PLC system with data synchronization between two AC500 controllers, either without field IO or with user integration of other protocols to field-IO or “intelligent” IO: CPUs as field devices.

Secondary will be on hot standby with primary PLC, during a power off/ stop of the primary PLC. Secondary will take over the control and continue the process. Any user integrated field-IO or CPUs can establish communication mapped with the primary bit: parallel reading but prevent parallel writing.

HA without CI modules can be also used during commissioning to check the data sync, OPC and SCADA related communications without any field devices configured. The user has to set the global variable 'xNoCiBus' to TRUE defined in the HA_GLOBAL_VARIABLES. This variable has to be set to TRUE in both PLCs. Note: It is not advised to update this variable during run time.

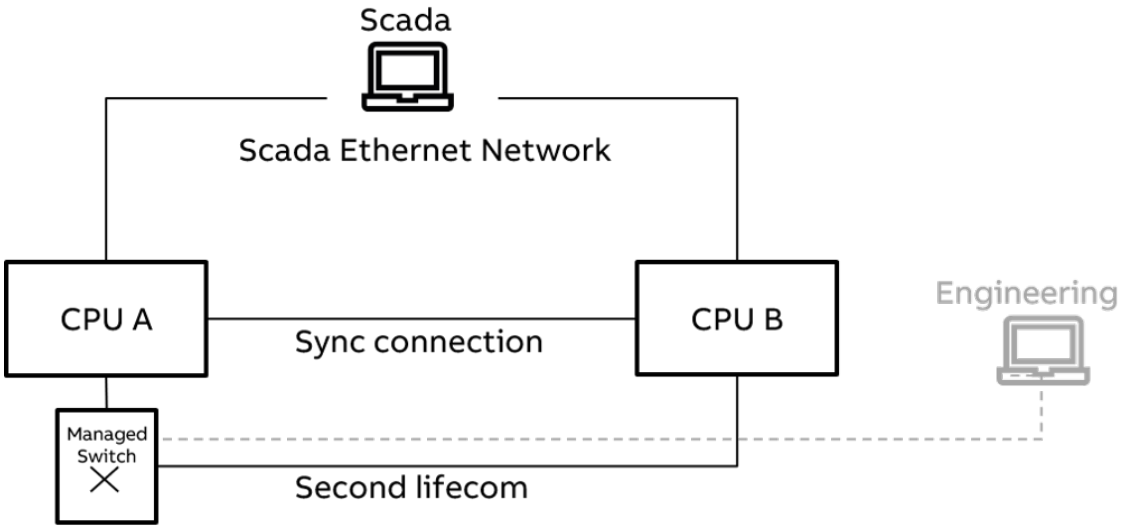

Fig. 156: Simple SCADA connection

Getting started

Quick start list and guidelines

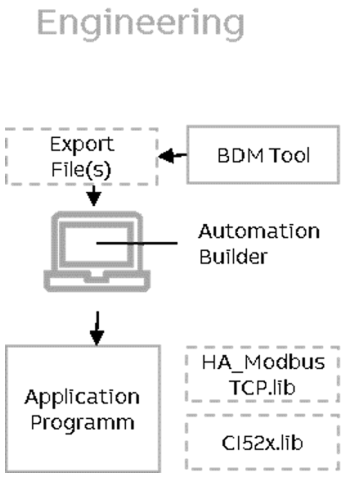

Fig. 157: Engineering workflow using Automation Builder

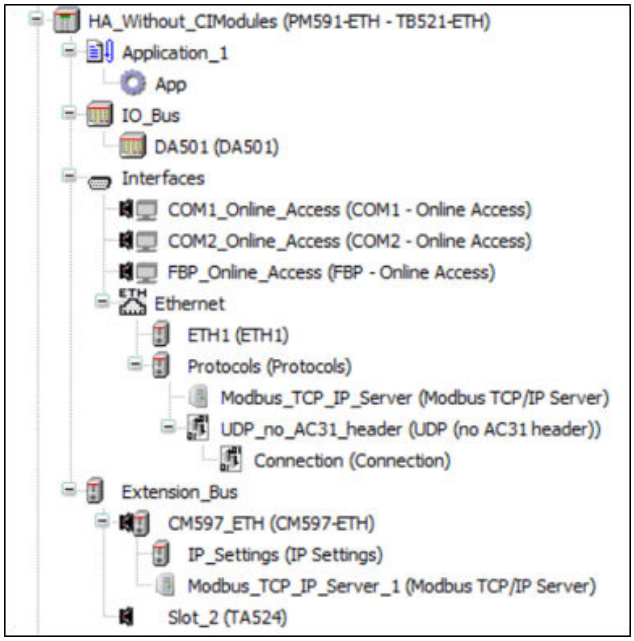
Simple steps to engineer the HA Modbus system is explained in the following chapters.

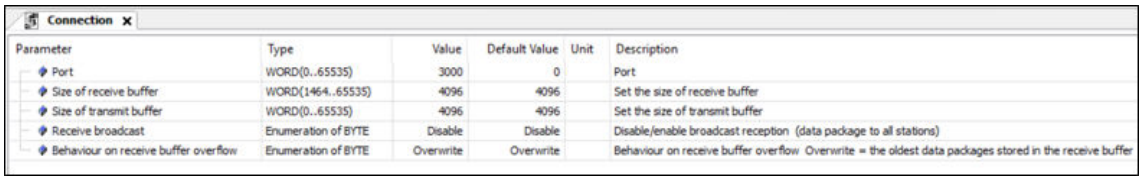
Configuration without communication interface modules to establish redundancy

Configuration of the HA system without communication interface modules to establish redundancy is done by the following steps (for details see the example documentations):

1. Install the hardware ↳ *Chapter 1.5.5.2.2.2 “Hardware, requirements and options overview” on page 2092*.
2. Select the CPUs based on the requirements ↳ *Chapter 1.5.5.2.2.2.1 “CPU choice, system size and performance indications” on page 2094*.
3. Install Automation Builder including the latest libraries ↳ *Chapter 1.5.5.2.2.4 “How to get and install the AC500 High Availability system package” on page 2107*.
4. Create a new project in Automation Builder for the chosen CPUs.
5. Configure the required Modbus and UDP configuration in the Automation Builder device tree of the CPU.



6. For UDP in AC500 V2 PLC, configure *“UDP_no_AC31_header”* and set the port number to value '3000'.

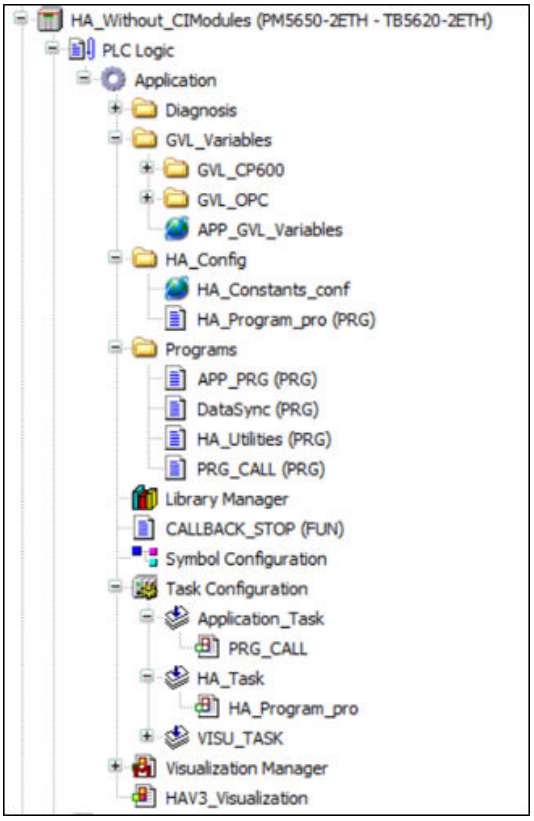


Connection

Parameter	Type	Value	Default Value	Unit	Description
Port	WORD(0..65535)	3000	0		Port
Size of receive buffer	WORD(1464..65535)	4096	4096		Set the size of receive buffer
Size of transmit buffer	WORD(0..65535)	4096	4096		Set the size of transmit buffer
Receive broadcast	Enumeration of BYTE	Disable	Disable		Disable/enable broadcast reception (data package to all stations)
Behaviour on receive buffer overflow	Enumeration of BYTE	Overwrite	Overwrite		Behaviour on receive buffer overflow Overwrite = the oldest data packages stored in the receive buffer

7. Assign the IP addresses in ≥ 2 different Ethernet networks:
   - SCADA network: SCADA, connected PLC A and PLC B
   - Field network: connected CI52x module(s)
8. Configure the mandatory HA_MOD_CONTROL function block for the HA task ↳ *“HA program” on page 2111*.
9. Add Callback stop function HA_MOD_CALLBACK_STOP and call it in the system event “stop”.
10. Add optional HA utility function blocks or function block HA_MOD_DATASYNC.

11. Make the global variable xNoCiBus = TRUE to run the system without communication interface module configured in the system. Refer to *Chapter 1.5.5.2.2.5.3.4 “HA Modbus system without communication interface modules in the network” on page 2118*.



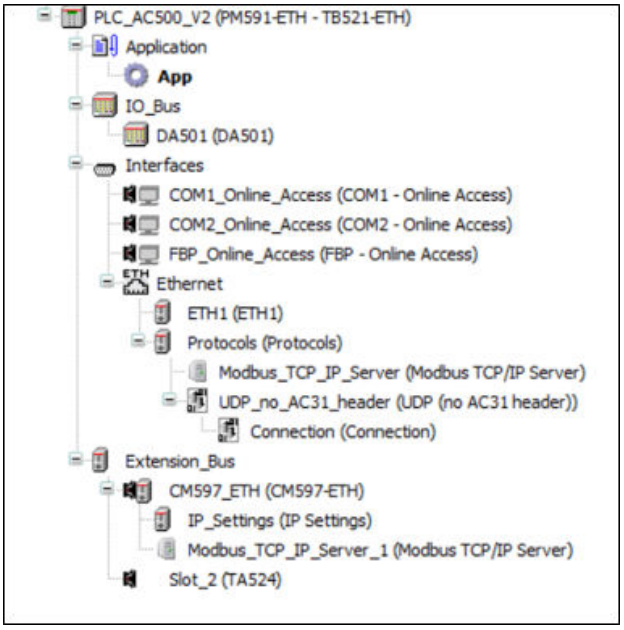
12. Add the task configuration *Chapter 1.5.5.2.2.5.2 “Task configuration recommendations for HA system” on page 2113*.
13. Compile and download to both PLCs (simplified in V3 via integrated download manager).
14. Create a boot project, restart the complete system and RUN.
15. Operation: Test use cases (e.g. by putting the primary PLC to STOP mode and observe the switchover). For different use cases and behavior refer to .
16. Runtime error and diagnosis function block can be used to monitor the system . For details refer to chapter Diagnosis *Chapter 1.5.5.2.2.8 “Diagnosis” on page 2124*.

Configuration with communication interface modules and redundancy

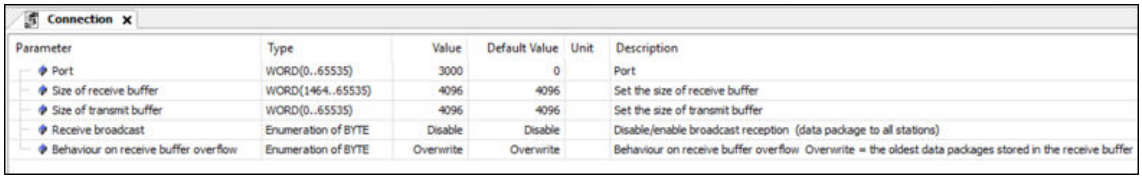
For medium or large HA systems the configuration with communication interface modules and redundancy is done by the following steps. For details see the example documentations:

1. Install the hardware *Chapter 1.5.5.2.2.2 “Hardware, requirements and options overview” on page 2092*.
2. Select the CPUs based on the requirements *Chapter 1.5.5.2.2.2.1 “CPU choice, system size and performance indications” on page 2094*.
3. Install Automation Builder including the latest libraries *Chapter 1.5.5.2.2.2 “Hardware, requirements and options overview” on page 2092*.
4. Install the Bulk Data Manager tool (BDM) *Chapter 1.5.5.2.2.4 “How to get and install the AC500 High Availability system package” on page 2107*.
5. Create a new project in Automation Builder for the chosen CPUs.

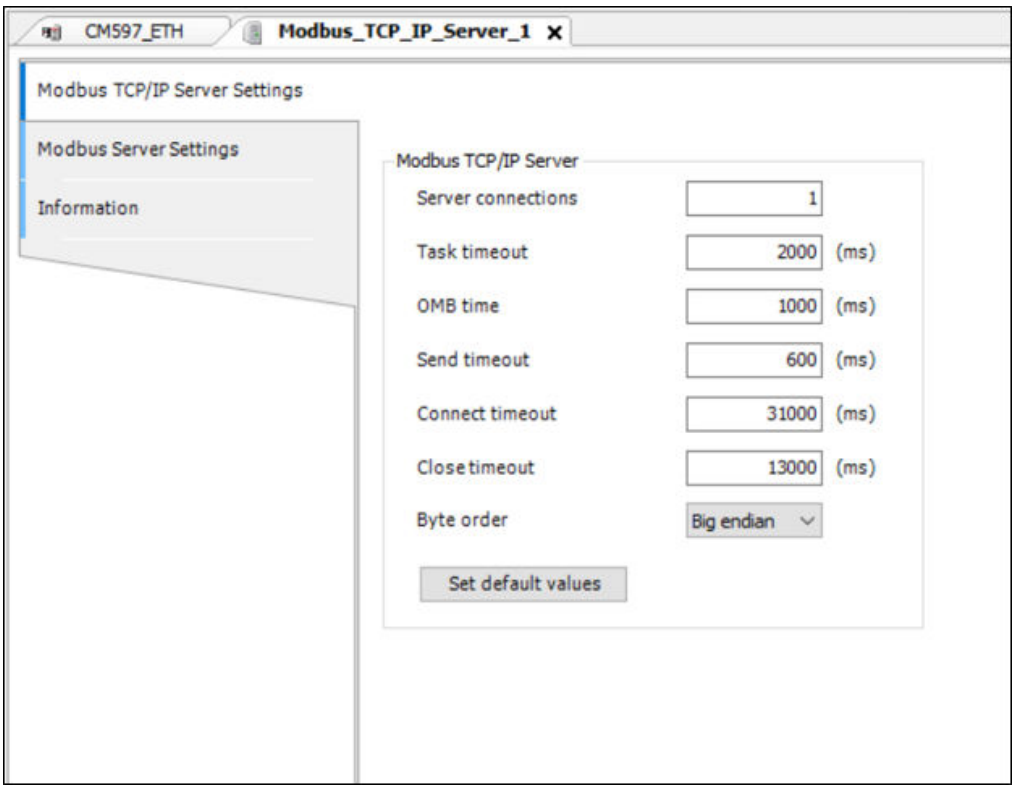
6. Configure the required Modbus and UDP configuration in the Automation Builderdevice tree of the CPU. UDP settings are only required in AC500 V2 PLCs.



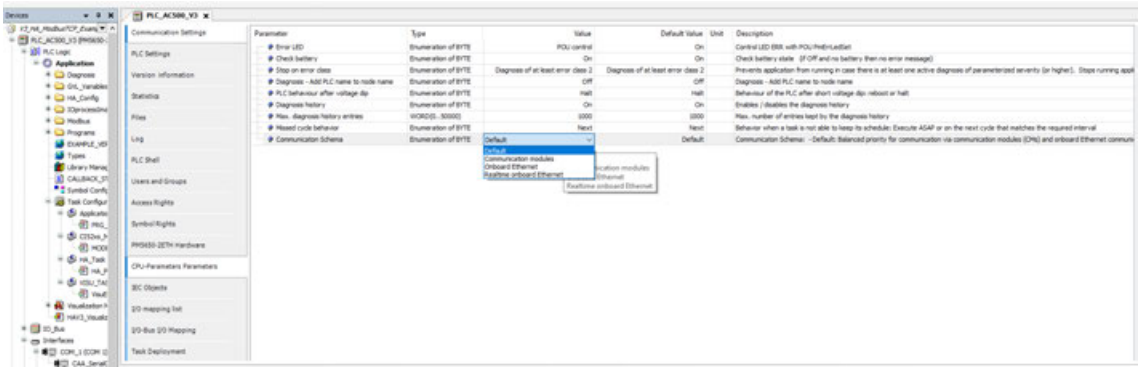
7. For UDP in AC500 V2 PLC, configure *"UDP_no_AC31_header"* and define the port number as '3000'.



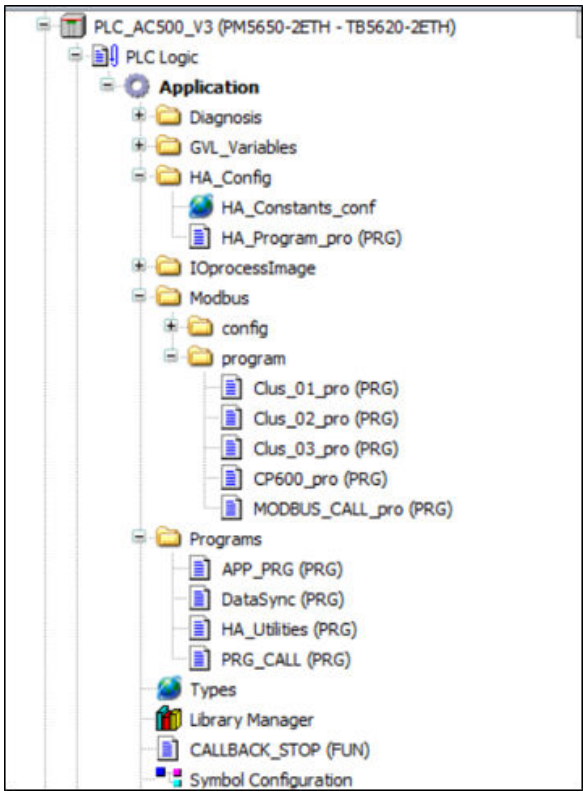
8. In AC500 V2 PLCs for each CM597-ETH communication module added the *"Send timeout"* value has to be changed to 600 ms for the Modbus TCP server.



9. Assign the IP addresses in ≥ 2 different Ethernet networks:
   - SCADA network: SCADA, connected PLC A and PLC B.
   - Field network: connected CI52x module(s).
10. Configure a network switch in the field network (if managed /redundant) based on network redundancy required ↳ *Chapter 1.5.5.2.2.5.3 “Field I/O network topologies” on page 2115*.
11. Run BDM tool to configure CI52x network.
12. Export the files. Refer for details in the document: *C:\Users\Public\Documents\AutomationBuilder\Examples\PS5601-HA-MTCP\BulkDataManager\Documentation*.
13. Import the Bulk data export files to the Automation Builder project.
14. Add Modbus TCP configuration for the ETH ports.
15. For the system with V3 PLCs, set the Communication Schema to “Onboard Ethernet” *“CPU-Parameters Parameters”* for better performance.



16. Add Callback stop function HA_MOD_CALLBACK_STOP and call it in the system event *“stop”*.
17. Add optional HA utility function blocks or function block HA_MOD_DATASYNC.



18. Add the task configuration ↳ *Chapter 1.5.5.2.2.5.2 “Task configuration recommendations for HA system” on page 2113*.
19. Compile and download to both PLCs (simplified in V3 via integrated download manager).

20. Create a boot project, restart the complete system and RUN.
21. Operation: Test use cases (e.g. by putting the primary PLC to STOP mode and observe the switchover).
22. For different use cases and behavior refer to *Chapter 1.5.5.2.2.3.1 “Failures and use cases” on page 2098*.
23. Runtime error and diagnosis function block can be used to monitor the system. For details refer to *Chapter 1.5.5.2.2.8 “Diagnosis” on page 2124*.

HA-Modbus TCP Limits

HA-Modbus TCP is supported as of Automation Builder 2.0 or higher and the corresponding AC500 CPUs mentioned previously. AC500 V3 PLC is currently not supporting external ETH communication modules. Therefore, onboard ETH1, ETH2 (and eventually CAN) ports are to be used for communication.

3000 sync instances can be used: Either 3000 HA_MOD_DATA_SYNC function block instances alone or together 3000 instances of HA_MOD_DATA_SYNC inclouding + HA utility function block can be used. If more than 3000 instances are configured user can see the error at xHaModDataErr = True and wHaModDataErNo = 16#2022 in HA_GLOBAL_VARIABLES.

The maximum length of sync data at an instance of HA_MOD_DATA_SYNC function block would be 1412 bytes. The maximum size of sync data which can be synced between PLCA and PLCB in total can be max. 60 000 bytes.

The HA-Modbus TCP system takes care of the first fault only. This fault must be visualized by the programmer and overall system (e.g. HMI, SCADA) to the operator, to plan and repair as soon as possible as redundancy might be lost. If more than one error occurs, system may not react to second or following faults.

SCADA/ HMI has to be configured/programmed to:

- Only read data from the primary PLC.
- Parameters and control data should be always written to both PLCs or has to be synchronized via the function block.

This is given automatically when using OPC DA, where the CODESYS OPC Server does this switching for the connected clients according to the primary status. For CP600 HMI a script is available to switch likewise (connected via the internal AC500 protocol or Modbus). Zenon as a SCADA also uses the AC500 protocol to automatically switchover.

Diagnosis

This chapter explains the diagnosis information available to the user in the HA Modbus library and CI52x library. Diagnosis information is available at the outputs of HA control function block, HA Diagnosis function block and at the CI52x function block.

Depending on the use case defined in *Chapter 1.5.5.2.2.3 “Functionality” on page 2098* different diagnosis information can be accessed.

Primary CPU currently can read-out the diagnosis information (CI52x function block outputs) from communication interface module only once, hence secondary PLC will not be able to read the diagnosis information from the CI52x module.

So if any change happens in CI52x diagnosis it is not reflected in the secondary CPU.

This can lead to different diagnosis information of CI52x module in the primary and the secondary CPU. Hence it is recommended to customers that diagnosis information should be handled in the application (e.g. SCADA).

Diagnosis in HA-Modbus TCP library

In the HA Modbus library diagnosis information is available at the control block and diagnosis block.

Output System Configuration

This output at the HA control block gives the information of system configuration. Each bit of the word represents a different configuration.

Bit	Description
0	Sync is configured via CAN
1	Sync is configured via UDP
2	Lifecom2 is configured via CAN
3	Lifecom2 is configured via UDP
4	Lifecom2 is configured via Modbus TCP
5	Initialization for Ethernet configuration

Output System Configuration error

This output at the HA control block gives the details of error in the configuration. Each bit of the word represents different configuration errors. It is valid only when Error = TRUE.

Bit	Description
0	Communication interface module is not configured properly
1	1< SyncSlot >3. Invalid value at input sync slot
2	1<SecSlot>3. Invalid value at input second slot
3	Value at IpAdrCpuASync is invalid
4	Value at IpAdrCpuBSync is invalid
5	Value at IpAdrCpuALifecom2 is invalid
6	Value at IpAdrCpuBLifecom2 is invalid
7	IpAdrCpuASync = IpAdrCpuBSync or IpAdrCpuALifecom2 = IpAdrCpuBLifecom2 The IP addresses assigned at sync or lifecom2 inputs are wrong

Output Runtime error

This output at the HA control block gives the details of the error during run time of the system. Each bit of the word represents different runtime errors. It will not set Error = FALSE.

Bit	Description
0	Communication interface modules are lost
1	Other CPU is not active
2	Lifecom1 is lost (part of sync)
3	Lifecom2 is lost. This error will not be TRUE if the PLC is in STOP status. This is because Modbus is still responding even when PLC is in STOP
4	Synchronization is lost
5	Error in synchronization
6	Ethernet status error

Bit	Description
7	Other PLC lost communication to CI52x modules
8	CAN_HEADER function block has error
9	CAN_DATA function block has error
10	fbGetOwnIP function block has error

Diagnosis function block

Outputs at the HA Diagnosis function block, HaModDiag (V3) / HA_MOD_DIAG (V2) provides the following diagnosis information of the HA system.

Output	Description
CpuAPrimary / CPUA_PRIMARY	TRUE indicates CPU A is primary
CpuBPrimary / CPUB_PRIMARY	TRUE indicates CPU B is primary
CpuARun / CPUA_RUN	TRUE means CPU A is in RUN mode
CpuBRun / CPUB_RUN	TRUE means CPU B is in RUN mode
CpuACI52xBusActive / CPUA_CI52x_BUS_ACTIVE	Modbus TCP CI52x bus active on CPU A
CpuBCI52xBusActive / CPUB_CI52x_BUS_ACTIVE	Modbus TCP CI52x bus active on CPU B
CpuACi52xCfg / CPUA_CI52x_CFG	Total number of CI52x configured on CPU A
CpuBCi52xCfg / CPUB_CI52x_CFG	Total number of CI52x configured on CPU B
CpuACi52xAct / CPUA_CI52x_ACT	Total number of CI52x active on CPU A line
CpuBCi52xAct / CPUB_CI52x_ACT	Total number of CI2x active on CPU B line
SyncInstances / SYNC_INSTANCES	Number of data sync and utility blocks initialized in the system
SyncDataCheckSum / SYNC_DATA_SUM	Checksum of all address pointer blocks in bytes, indicates total number of bytes getting synchronized.

Output	Description
StHACpuStatus / stHA_CPU_STATUS	HA own CPU status. It will show the status details of logged in CPU for the following parameters: ● HA1: CPU A is primary ● HA2: CPU B is primary ● bit_CI52x_BUS_active: CI52x bus with one or more communication interface modules active ● bit_CI52x_BUS_err: CI52x bus one or more communication interface modules powered off / connection lost ● RUN: Run status of CI52x ● cnt: Count of data sync communication, indicates data sync between CPUs is okay.
StHAotherCpuStatus / stHA_OTHER_CPU_STATUS	HA other CPU status. It will show the status details of other CPU for the following parameters: ● HA1: CPU A is primary ● HA2: CPU B is primary ● bit_CI52x_BUS_active: CI52x bus with one or more communication interface modules active ● bit_CI52x_BUS_err: CI52x bus one or more communication interface modules powered off / connection lost ● RUN: Run status of CI52x ● byETH_ACT_CI52x_Count: CI52x alive identification count.

Other diagnosis variables

Apart from the errors / diagnosis information available in the control and diagnosis block, few other variables can be monitored too.

Variable	Value	Description
wHA_ER_NO_SYNC_LINK	16#7487	No sync link between the PLCs
HA_MOD_INVALID_LENGTH	16#2017	Invalid length at the input of the data sync block
HA_MOD_ERNO_TBL_OVERFLOW	16#2022	HA data reference table is full
xHaModDataErr	TRUE	IF TRUE – HA data sync is in error state
wHaModDataErNo		HA data sync error code
xHaModErr	TRUE	HA system is in error state
dwHaModServerAlive		Life counter incremented by OPC DA server

Diagnosis in CI52x library

In addition to the diagnosis information in the HA Modbus library, additional diagnosis information for each communication interface module can be obtained from the CI52x library.

System Configuration error

This output at the CI52x function block gives the details of the configuration error in the CI52x module. Each bit of the byte represents different configuration errors:

Bit	Description
0	Reserved
1	Wrong ETH port is configured at input Config ETH
2	Wrong IP address is configured for communication interface module

Runtime error

RuntimeError (v3) / RUNTIME_ERROR (v2) of the function block CiModCi52x (v3) / CI_MOD_CI52x (v2). Runtime error is a combination of error bits that are described in the following:

Runtime Error	Description
Bit 0	Indicates communication error i.e., when CPU is not able to get any response from CI52x module. This error will get reset when communication is reestablished.
Bit 1	Indicates parameter state is not equal to 2 (PARA_STATE_PARA_DONE). If not true, then system gives I/O bus error. System resets this error when parameter state is equal to 2.
Bit 2	Indicates the cluster error [1]) in the system, if there is an error in the diagnosis buffer. ACK input is needed to reset this error.
Bit 3	Indicates the hardware configuration error, mismatch between configuration and actual hardware detected. System automatically resets this error when the hardware matches.
S-ERR (LED on communication interface module)	Indicates that there is some issue with channel configuration in the cluster [1]). It is not linked with Runtime Error. User can read DiagBuffer (v3) / DIAG_BUFFER (v2) from CiModDiag (v3)/ CI_MOD_DIAG (v2) function block to get more information. This error does not get reset using ACK. It will only reset when all channel errors are removed.
[1]) "Cluster" means a combination of one communication interface module and several I/O modules attached to it.	

Runtime error in different scenarios:

Error	Run-time error	PLC A: Primary				PLC B: Secondary			
		Bit0 - comm error	Bit1 - I/O bus error	Bit2 - cluster error	Bit3 - HW config error	Bit0 - comm error	Bit1 - I/O bus error	Bit2 - cluster error	Bit3 - HW config error
Wrong IP address configured	16#1	TRUE	FALSE	FALSE	FALSE	TRUE	FALSE	FALSE	FALSE
Wrong slot address configured [1])	16#0	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE
Communi-cation cable dis-connected	16#2	TRUE	TRUE	FALSE	FALSE	TRUE	TRUE	FALSE	FALSE
Wrong I/O module plugged in the CI module	16#B	BLINK	TRUE	FALSE	TRUE	BLINK	TRUE	FALSE	TRUE
Wrong hotswap I/O module plugged at the start	16#B	BLINK	TRUE	FALSE	TRUE	BLINK	TRUE	FALSE	TRUE
Wrong hotswap I/O module swapped online	16#4	FALSE	FALSE	TRUE	FALSE	FALSE	FALSE	FALSE	FALSE
Configured I/O module not con-nected at start [2])	16#B	BLINK	TRUE	FALSE	TRUE	BLINK	TRUE	FALSE	TRUE
Configured hotswap I/O module not con-nected at start [2])	16#B	BLINK	TRUE	FALSE	TRUE	BLINK	TRUE	FALSE	TRUE
I/O module powered off in CI module [2])	16#4	FALSE	FALSE	TRUE	FALSE	FALSE	FALSE	FALSE	FALSE
Hotswap I/O module powered off in CI module [2])	16#4	FALSE	FALSE	TRUE	FALSE	FALSE	FALSE	FALSE	FALSE
Remove hotswap I/O module when online [2])	16#4	FALSE	FALSE	TRUE	FALSE	FALSE	FALSE	FALSE	FALSE

Error	Run-time error	PLC A: Primary				PLC B: Secondary			
		Bit0 - comm error	Bit1 - I/O bus error	Bit2 - cluster error	Bit3 - HW config error	Bit0 - comm error	Bit1 - I/O bus error	Bit2 - cluster error	Bit3 - HW config error
CI module is powered off	16#2	TRUE	TRUE	FALSE	FALSE	TRUE	TRUE	FALSE	FALSE
Mismatch in Channel configura-tion and wiring [3])	16#0	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE
Regular I/O module mounted on hotswap terminal unit [4])	16#0	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE
During an error stage if HA system changeover is initiated [5])	16#0	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE	FALSE

[1]) Slot input in the block can be ignored. Similar to ETH input of the ModMast blocks.

[2]) Error generated only in the primary PLC, to reset ACK input to be used.

[3]) No runtime error in function block. Module generates S-Err and ZP Blinks.

[4]) No runtime error in function block. Module generates S-Err.

[5]) Runtimer Error bit2 gets reset when the PLC is switched over and error won’t be available in any of the PLC regardless of its Primary status.

Communication interface diagnosis

Table 128: Function block CiModDiag (V3) and CI_MOD_DIAG (V2)

Output	Description
DevState / DEV_STATE	CI521 or CI522 device current status is displayed. ● STATE_PREOP: Device is booting ● STATE_OPERATION: Device is operational, no bus supervision is active ● STATE_ERROR: Device detected a bus error, bus supervision is active ● STATE_IP_ERROR: Device has an IP address error ● STATE_CYLIC_OPERATION: Device is operational, bus supervision is active ● STATE_NA: Not available
ParaState / PARA_STATE	CI521 or CI522 device parameter status. ● PARA_STATE_NO_PARA: Device has no parameters ● PARA_STATE_PARA_ACTIVE: Parameterization process is running ● PARA_STATE_PARA_DONE: Device used valid parameters and parameterization is done ● PARA_STATE_ERROR: Device has invalid parameters ● PARA_STATE_NA: Not available
DeviceInfo / DEVICE_INFO	CI521 or CI522 type and extended module types. This will give the details of the module configured in the communication interface module including the I/O modules. If module is with suffix F, then fast counter is enabled for that module.
DiagBuffer / DIAG_BUFFER	CI521 or CI522 module diagnosis buffer. Refer to *Chapter 1.6.4.3.1.2.3.2 “Diagnosis data” on page 5659*.
ErClass / ERR_CLASS	Communication interface error class. Refer to *Chapter 1.7.3 “Diagnosis messages” on page 6429*
ErNo / ERR_NO	Communication interface error number. Refer to *Chapter 1.7.3 “Diagnosis messages” on page 6429*
ModMastErr / MODMAST_ERR	Latest 22 Modbus TCP error message status of the ModMastTcp (V2) / COM_MOD_MAST (V2) function block.
ModMastErNo / MODMAST_ERR_NO	Latest 22 Modbus TCP error numbers. Refer to the error details in Modbus library *Chapter 1.5.5.2.2.8.1 “Diagnosis in HA-Modbus TCP library” on page 2125*. V2: Refer to the error messages related to *Chapter 1.5.4.22.1.1 “COM_MOD_MAST” on page 1698*

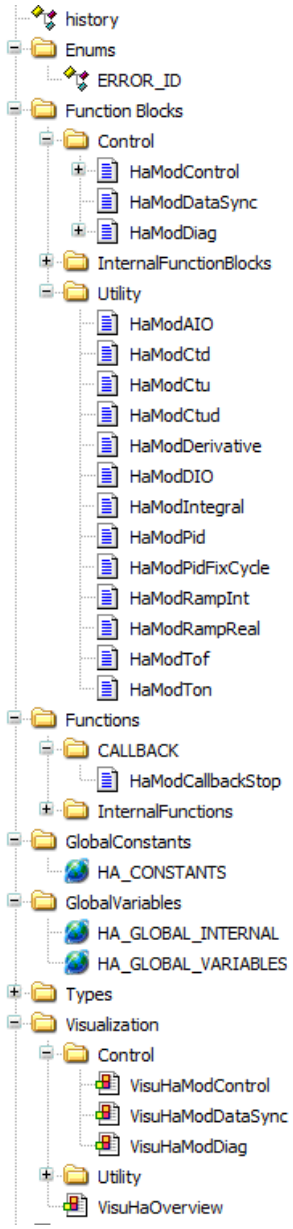
Library overview

Documentation

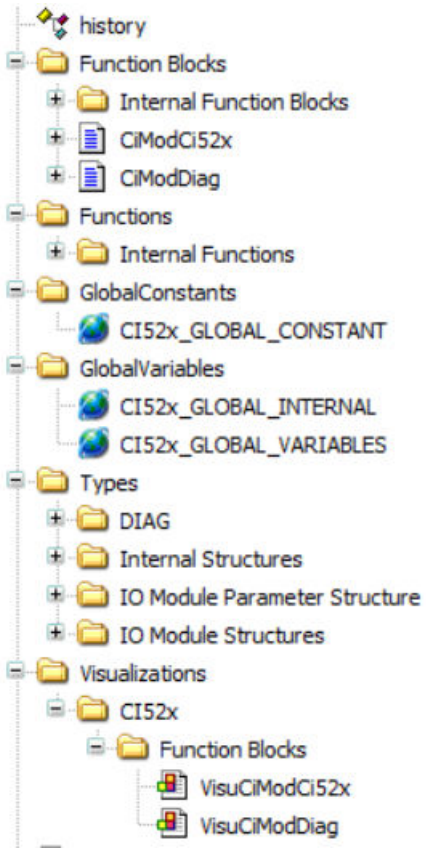
CODESYS V2 libraries are described in a separate library documentation: *Chapter 1.5.5.2.3 “HA-Modbus TCP V2 library function block description” on page 2133*.

The following function blocks are contained in the libraries:

HA-Modbus TCP library



HA_CI52x library



1.5.5.2.3 HA-Modbus TCP V2 library function block description

Scope and structure of this document

The purpose of this libraries description is to explain different components of HA-Modbus TCP and CI52x library.

The libraries description is valid for AC500 V2 products (using CODESYS V2 libraries).

For AC500 V3 products (using CODESYS V3 libraries) the library description is integrated in the Library Manager of Automation Builder.

HA-Modbus TCP library

Components of HA-Modbus TCP library

The HA-Modbus TCP library contains the following function, function blocks, structures, visualizations, constants and variables.

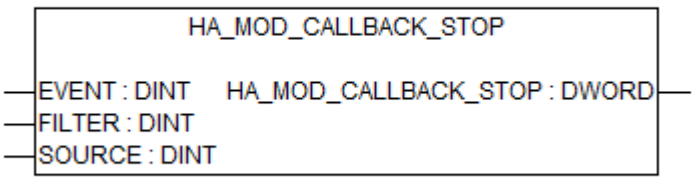
- Function
  - HA_MOD_CALLBACK_STOP
- Function blocks

  Main:
  - HA_MOD_DATA_SYNC
  - HA_MOD_CONTROL
  - HA_MOD_DIAG

- Function blocks
  Utility:
  – HA_MOD_AIO
  – HA_MOD_CTD
  – HA_MOD_CTU
  – HA_MOD_CTUD
  – HA_MOD_DERIVATIVE
  – HA_MOD_DIO
  – HA_MOD_INTEGRAL
  – HA_MOD_PID
  – HA_MOD_PID_FIXCYCLE
  – HA_MOD_RAMP_INT
  – HA_MOD_RAMP_REAL
  – HA_MOD_TOF
  – HA_MOD_TON
- Visualizations
  – HA_MOD_DATA_SYNC_VISU_PH
  – HA_MOD_CONTROL_VISU_PH
  – HA_MOD_DIAG_VISU_PH
  – HA_MOD_AIO_VISU_PH
  – HA_MOD_CTD_VISU_PH
  – HA_MOD_CTU_VISU_PH
  – HA_MOD_CTUD_VISU_PH
  – HA_MOD_DERIVATIVE_VISU_PH
  – HA_MOD_DIO_VISU_PH
  – HA_MOD_INTEGRAL_VISU_PH
  – HA_MOD_PID_VISU_PH
  – HA_MOD_PID_FIXCYCLE_VISU_PH
  – HA_MOD_RAMP_INT_VISU_PH
  – HA_MOD_RAMP_REAL_VISU_PH
  – HA_MOD_TOF_VISU_PH
  – HA_MOD_TON_VISU_PH
  – HA_OVERVIEW_VISU
- Global variables
  – HA_GLOBAL (constant)
  – HA_GLOBAL_VARIABLES
- Structures

Function

HA_MOD_CALLBACK_STOP



Parameter	Value
Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Event Function, Return DWORD

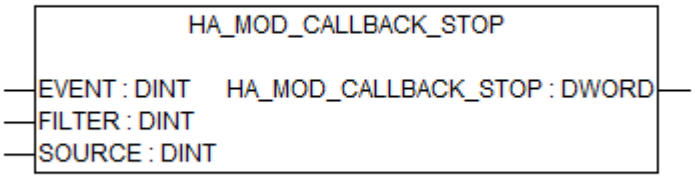
HA_MOD_CALLBACK_STOP function is programmed to process logic related to AC500 High Availability project in case of CPU switching into stop mode.

If there is a STOP event initiated in the PLC, HA_MOD_CALLBACK_STOP function is processed before the CPU switches to STOP state. This function sets/resets some HA library global variables, to provide the CPU's STOP information to the other CPU.

This function needs to be called under runtime system event. For further information on how to call the call back stop function in system events please refer to example project and documentation of the library.

- *The Callback stop event should follow the name pattern "CALLBACK_xxx".*
  - *If a user has downloaded the program to the PLC with a wrong callback stop event name then the CPU freezes and is unable to log in/on to the PLC using Ethernet cable.*
  - *User has to download a blank project using RS232 communication cable (TK501/TK502/TK503) in order to return the PLC into healthy stage.*
  - *After this, the user has to correct the callback stop event name as recommended and restart the download*
- *When a PLC type is changed in Automation Builder project, assigning of callback stop to "Stop event" in the System events, checkbox stop gets unchecked.*
  The user has to select the stop event again manually.

Input description



EVENT

Data type	Default value	Range	Unit
DINT	-	-	-

Runtime system event in which the function block is to be called.

FILTER

Data type	Default value	Range	Unit
DINT	-	-	-

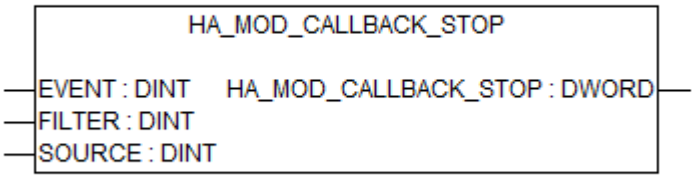
Runtime system event filter.

OWNER

Data type	Default value	Range	Unit
DINT	-	-	-

Runtime event system source.

Output description

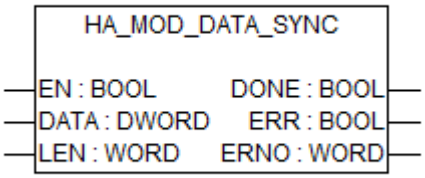


HA_MOD_CALL-BACK_STOP

Data type	Default value	Range	Unit
DWORD	-	-	-

Function blocks

HA_MOD_DATA_SYNC



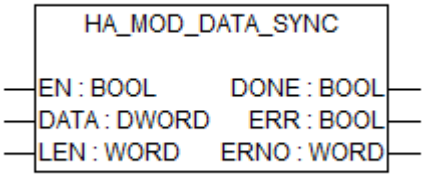
Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_DATA_SYNC is used for synchronizing different instances of function blocks, or any other data that need to be synchronized, in the HA application.

It collects data and size information from the connected function block and delivers details to the HA_MOD_CONTROL function block.

User can use up to 1024 instances of HA_MOD_DATA_SYNC function block in one program. This number depends on the number of High Availability utility function blocks used. The utility function blocks are synchronizing relevant data automatically.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

DATA

Data type	Default value	Range	Unit
DWORD	0	0 ... 255	-

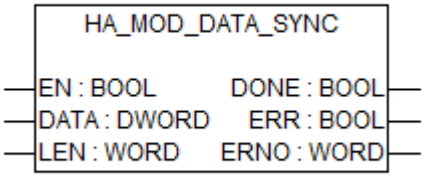
Function block instance input (via ADR-operator) for pointer data.

LEN (length)

Data type	Default value	Range	Unit
WORD	0	0 ... 255	-

Function block instance input (via SIZEOF-operator) for size, maximum 1412 bytes.

Output description



DONE

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output DONE indicates the state of execution.

It has the value TRUE when the execution is finished and the outputs are valid. When DONE becomes FALSE other outputs are not valid any more.

ERR

Data type	Default value	Range	Unit
BOOL	-	TRUE/FALSE	-

Output ERR indicates whether an error occurred during function block execution.

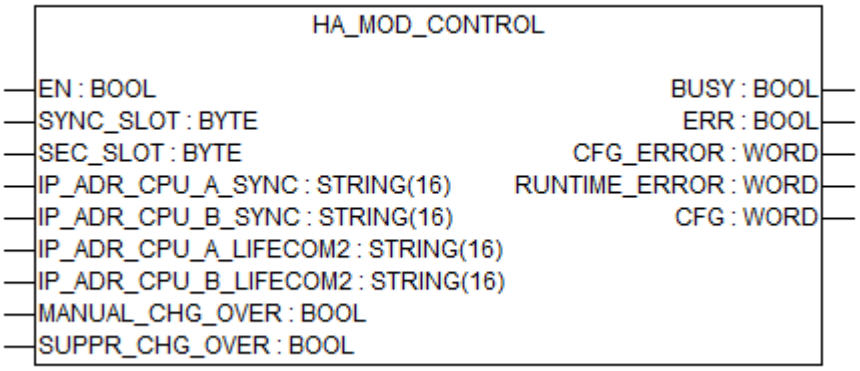
It is only valid when DONE is TRUE. The kind of occurred error is specified by the error identifier at output ERNO.

ERNO

Data type	Default value	Range	Unit
WORD	-	0 ... 65535	-

At output ERNO the identifier of an occurred error is provided. It is only valid when DONE and ERR is TRUE (see *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*).

HA_MOD_CONTROL

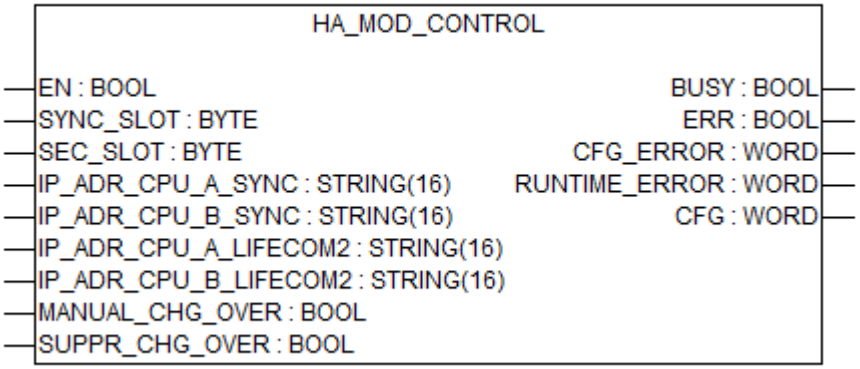


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

HA_MOD_CONTROL function block handles the AC500 High Availability operation such as change over from primary to secondary CPU in case of an error with related diagnostics.

Further it is used to data transfer between high availability CPUs. This is a mandatory function block for HA application.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

SYNC_SLOT

Data type	Default value	Range	Unit
BYTE	0	1 ... 61	-

Slot number on which Sync Communication is configured. Possible 1, 2, 3, 4, 11, 21, 31, 41, 51, 61 dependent on CPU type and communication module position of ETH port.

SEC_SLOT

Data type	Default value	Range	Unit
BYTE	0	1 ... 61	-

Slot number on which second communication LifeCom2 is configured. Possible 1, 2, 3, 4, 11, 21, 31, 41, 51, 61 dependent on CPU type and communication module position of ETH port.

IP_ADR_CPU_A_SYNC

Data type	Default value	Range	Unit
STRING(16)	‘0.0.0.0’	-	-

IP Address (on which SYNC communication is configured) of AC500 CPU connected to PLC A.

IP_ADR_CPU_B_SYNC

Data type	Default value	Range	Unit
STRING(16)	‘0.0.0.0’	-	-

IP Address (on which SYNC Communication is configured) of AC500 CPU connected to PLC B.

IP_ADR_CPU_A_LIFECOM2

Data type	Default value	Range	Unit
STRING(16)	‘0.0.0.0’	-	-

IP Address (on which LifeCom2 Communication is configured) of AC500 CPU connected to PLC A.

IP_ADR_CPU_B_LIFECOM2

Data type	Default value	Range	Unit
STRING(16)	'0.0.0.0'	-	-

IP Address (on which LifeCom2 Communication is configured) of AC500 CPU connected to PLC B.

MANUAL_CHG_OVER

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

TRUE- Manual changeover from primary to secondary PLC.

SUPPR_CHG_OVER

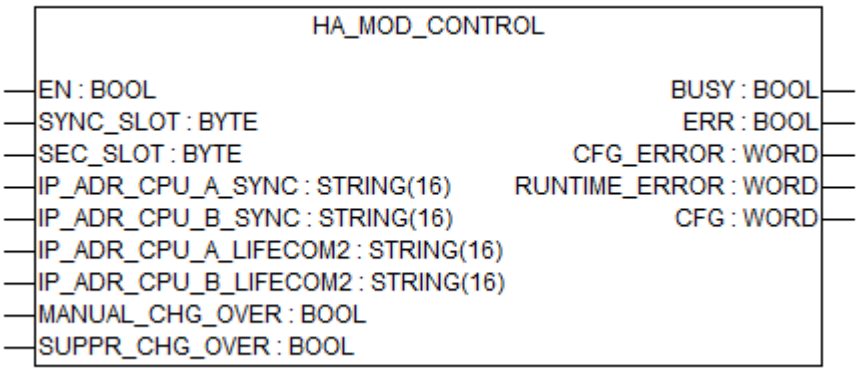
Data type	Default value	Range	Unit
BOOL	FALSE	-	-

TRUE- Suppress changeover (from primary to secondary PLC)

If used this input should be activated in both the CPU at the same time else system may behave randomly.

> *Suppress changeover feature is recommended to use only during network reconfiguration and not during any other switchover scenarios for example PLC STOP.*

Output description



BUSY

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Error occurred during execution when output ERR = TRUE.

CFG_ERROR

Data type	Default value	Range	Unit
WORD	0	-	-

Each bit of the WORD represents different configuration errors:

Bit0 - *CI module* configuration mismatch,

Bit1 - *SYNC_SLOT* invalid,

Bit2 - *SEC_SLOT* invalid,

Bit3 - *IP_ADR_CPU_A_SYNC* invalid,

Bit4 - *IP_ADR_CPU_B_SYNC* invalid,

Bit5 - *IP_ADR_CPU_A_LIFECOM2* invalid,

Bit6 - *IP_ADR_CPU_B_LIFECOM2* invalid,

Bit7 - *IP_ADR_CPU_A_SYNC* = *IP_ADR_CPU_B_SYNC* or *IP_ADR_CPU_A_LIFECOM2*= *IP_ADR_CPU_B_LIFECOM2*.

CFG_ERROR is valid only when ERR = TRUE

RUN-TIME_ERROR

Data type	Default value	Range	Unit
WORD	0	-	-

Each bit of the WORD represents different Runtime errors:

Bit0 - CI module lost,

Bit1 - Other CPU not active,

Bit2 - Lifecom1 is lost (part of Sync),

Bit3 - Lifecom2 is lost,

Bit4 - Sync lost,

Bit5 - Error in Sync,

Bit6 - Ethernet status,

Bit7- Other PLC Lost communication to CI52x,

Bit8- Not used,

Bit9- Not used,

Bit10- Error reading own IP address.

RUNTIME Errors may occur during operation, but they will not generate ERR output = TRUE. This allows the system to run and revert to an error free state.

Bit3 - Lifecom2 is lost in RUNTIME ERROR will not be TRUE if the PLC is in STOP status. This is because Modbus is still responding even when PLC is in STOP.

CFG

Data type	Default value	Range	Unit
WORD	0	-	-

Bit0 - Not used,

Bit1 - Sync via UDP enabled,

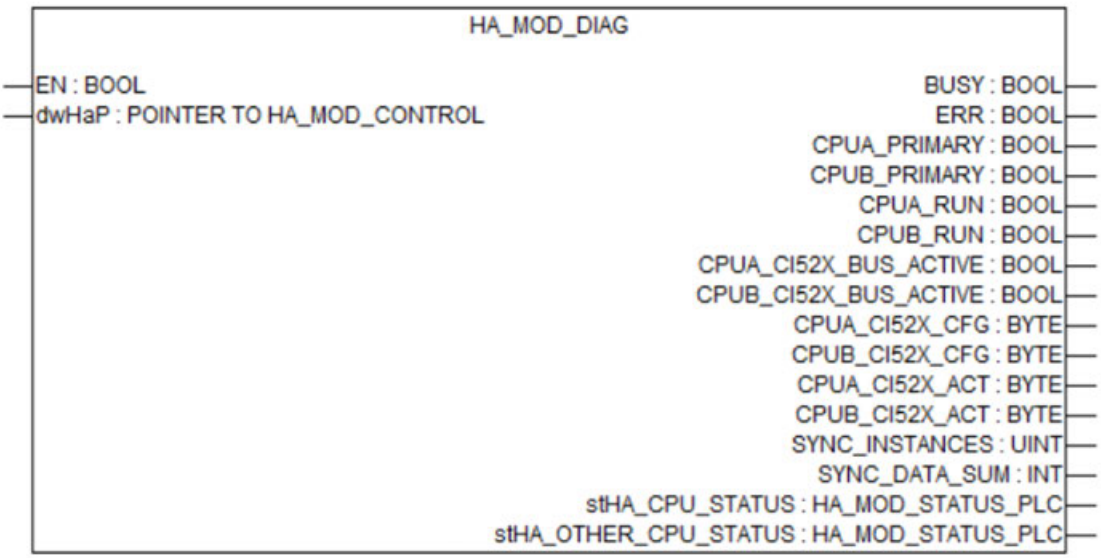
Bit2 - Not used,

Bit3 - Not used,

Bit4 - LifeCom2 via Modbus TCP is enabled,

Bit5 - Initialization for Ethernet configuration.

HA_MOD_DIAG

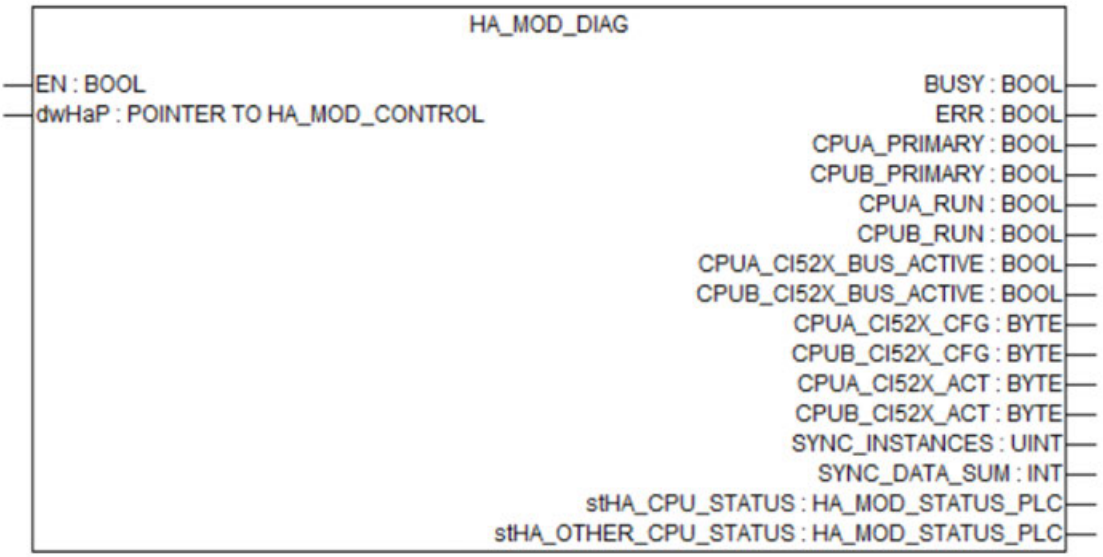


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

HA_MOD_DIAG function block provides the diagnosis information other than the configuration and runtime errors displayed in the HA_MOD_CONTROL function block. Using this function block, user will be able to get the diagnosis information such as primary status, active and configured CI modules, CI communication status, sync instances and number of sync bytes configured.

This function block must be connected to HA_MOD_CONTROL function block instance called for the system using ADR operator to populate the diagnosis information.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

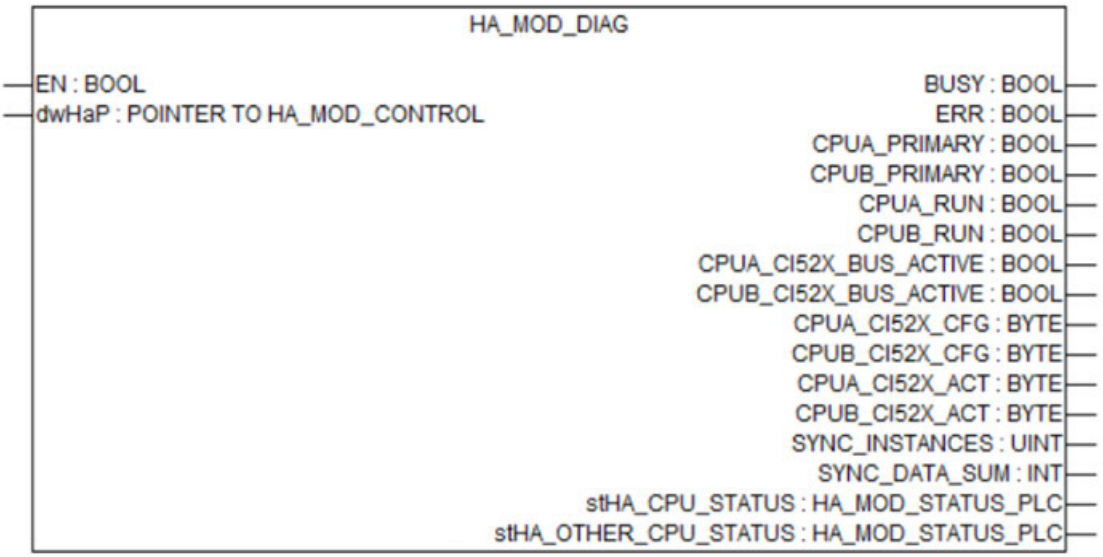
While it is executed its inputs are continuously evaluated.

dwHaP

Data type	Default value	Range	Unit
POINTER TO HA_MOD_CONTROL	-	-	-

This input points to the address of the control block instance from which the diagnosis information has to be read. Use the ADR operator and connect the instance of HA_MOD_CONTROL function block.

Output description



BUSY

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Error occurred during execution when output ERR = TRUE.

CPUA_ PRIMARY

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

CPU A primary status.

CPUB_ PRIMARY

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

CPU B primary status.

CPUA_RUN

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

CPU A RUN status.

CPUB_RUN

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

CPU B RUN status.

CPUA_CI52X_BUS_ACTIVE

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Modbus TCP CI52x – Bus active on CPU A.

CPUB_CI52X_BUS_ACTIVE

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Modbus TCP CI52x – Bus active on CPU B.

CPUA_CI52X_CFG

Data type	Default value	Range	Unit
BYTE	0	-	-

Number of CI52x configured on CPU A.

CPUB_CI52X_CFG

Data type	Default value	Range	Unit
BYTE	0	-	-

Number of CI52x configured on CPU B.

CPUA_CI52X_ACT

Data type	Default value	Range	Unit
BYTE	0	-	-

Number of CI52x active on CPU A.

CPUB_CI52X_ACT

Data type	Default value	Range	Unit
BYTE	0	-	-

Number of CI52x active on CPU B.

SYNC_INSTANCES

Data type	Default value	Range	Unit
UINT	0	-	-

Number of data sync and utility blocks initialized in project.

SYNC_DATA_SUM

Data type	Default value	Range	Unit
INT	0	-	-

Total number of sync data in bytes.

stHA_CPU_STATUS

Data type	Default value	Range	Unit
HA_MOD_STATUS_PLC	-	-	-

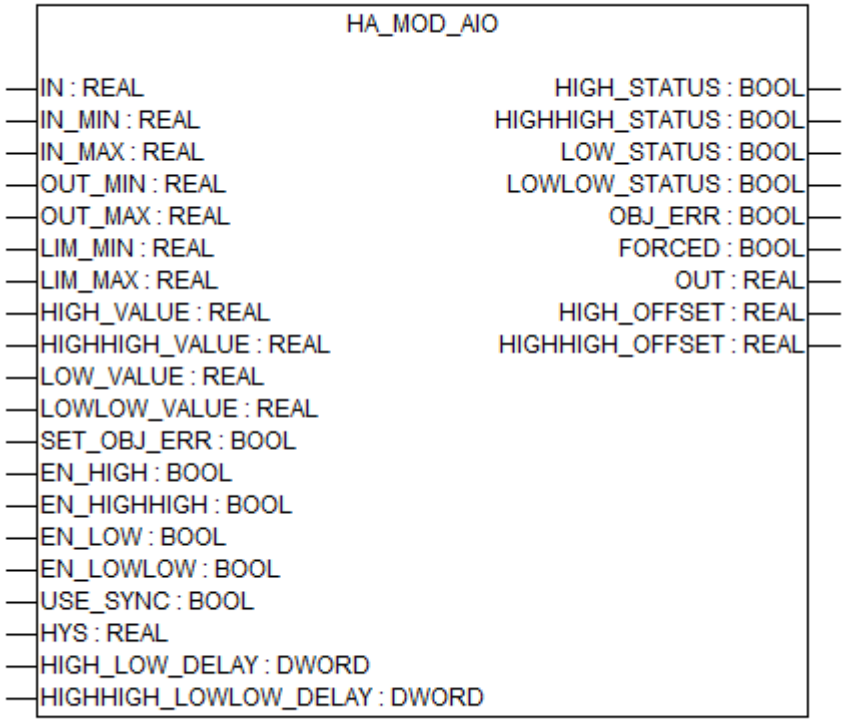
HA own CPU status. It will show the status details of logged in CPU.

stHA_OTHER_CPU_STATUS

Data type	Default value	Range	Unit
HA_MOD_STATUS_PLC	-	-	-

HA other CPU status. It will show the status of another CPU.

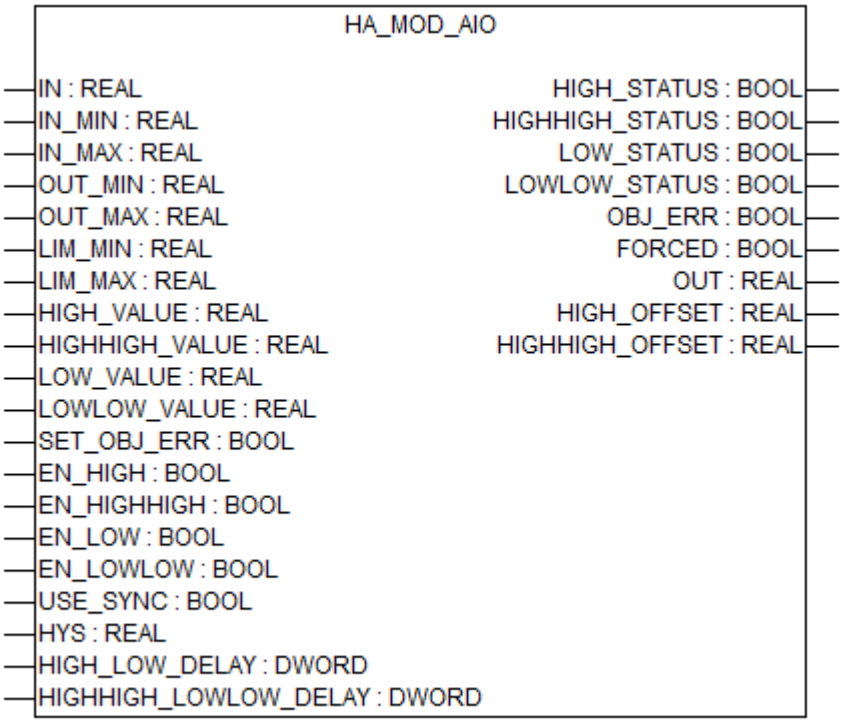
HA_MOD_AIO



Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

This function block can add in a standardized way scaling, limiting, alarming and other functions as often available in DCS type environment for analog inputs and outputs.

Input description



IN

Data type	Default value	Range	Unit
REAL	0	-	-

Signal input.

IN_MIN

Data type	Default value	Range	Unit
REAL	0	-	-

Lower limit of input range of values.

IN_MAX

Data type	Default value	Range	Unit
REAL	0	-	-

Upper limit of input range of values.

OUT_MIN

Data type	Default value	Range	Unit
REAL	0	-	-

Lower limit of output value range.

OUT_MAX

Data type	Default value	Range	Unit
REAL	0	-	-

Upper limit of output value range.

LIM_MIN

Data type	Default value	Range	Unit
REAL	0	-	-

Signal minimum range.

LIM_MAX

Data type	Default value	Range	Unit
REAL	0	-	-

Signal maximum range.

HIGH_VALUE

Data type	Default value	Range	Unit
REAL	0	-	-

Value for High alarm event.

HIGH_HIGH_VALUE

Data type	Default value	Range	Unit
REAL	0	-	-

Value for High high alarm event.

LOW_VALUE

Data type	Default value	Range	Unit
REAL	0	-	-

Value for Low alarm event.

LOW_LOW_VALUE

Data type	Default value	Range	Unit
REAL	0	-	-

Value for Low low alarm event.

SET_OBJ_ERROR

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Set object error

EN_HIGH

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Enable High alarm event.

EN_HIGHHIGH

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Enable High high alarm event.

EN_LOW

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Enable Low alarm event.

EN_LOWLOW

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Enable Low low alarm event.

USE_SYNC

Data type	Default value	Range	Unit
BOOL	TRUE	-	-

Use HA sync.

HYS

Data type	Default value	Range	Unit
REAL	0	-	-

Hysteresis alarm event.

HIGH_LOW_ DELAY

Data type	Default value	Range	Unit
DWORD	-	-	-

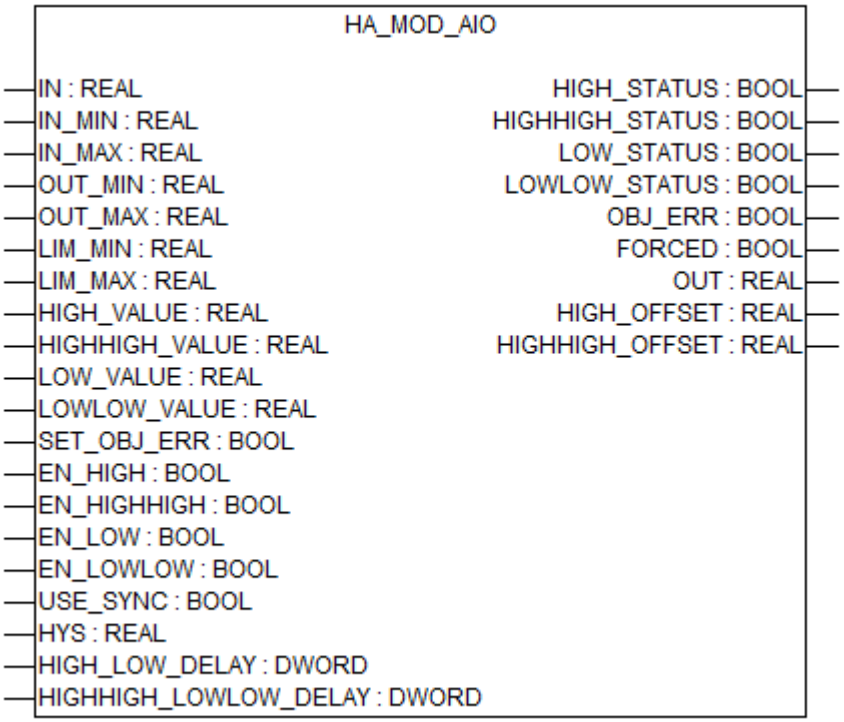
High & Low On delay [ms].

HIGHHIGH_ LOWLOW_ DELAY

Data type	Default value	Range	Unit
DWORD	0	-	-

High High & Low Low On delay [ms].

Output description



HIGH_STATUS

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

High alarm active.

HIGH-HIGH_STATUS

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

High high alarm active.

LOW_STATUS

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Low alarm active.

LOWLOW_STATUS

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Low low alarm active.

OBJ_ERR

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Signal object error.

FORCED

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Simulation ON.

OUT

Data type	Default value	Range	Unit
REAL	0	-	-

Signal out.

HIGH_OFFSET

Data type	Default value	Range	Unit

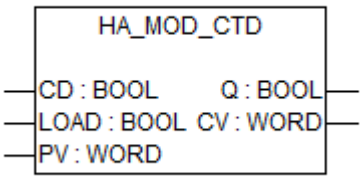
High offset.

HIGH-HIGH_OFFSET

Data type	Default value	Range	Unit
REAL	0	-	-

High high offset.

HA_MOD_CTD

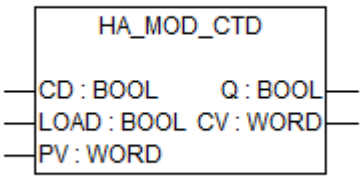


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_CTD is a standard count down counter with automatic data synchronization in a high availability system.

Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.

Input description



CD

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Count down on rising edge.

LOAD

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

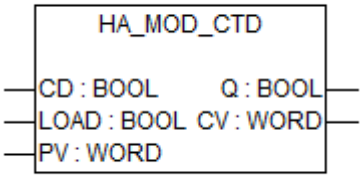
Load start value.

PV

Data type	Default value	Range	Unit
WORD	0	-	-

Start value

Output description



Q

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

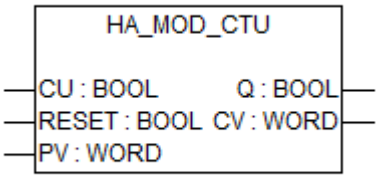
Counter reached 0.

CV

Data type	Default value	Range	Unit
WORD	0	-	-

Current counter value.

HA_MOD_CTU

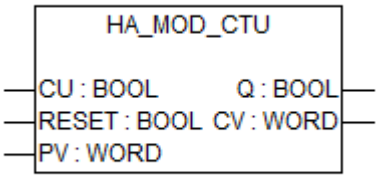


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_CTU is a standard count up counter with automatic data synchronization in a high availability system.

Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.

Input description



CU

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Count up.

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

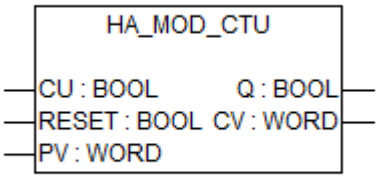
Reset counter to 0.

PV

Data type	Default value	Range	Unit
WORD	0	-	-

Counter limit

Output description



Q

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

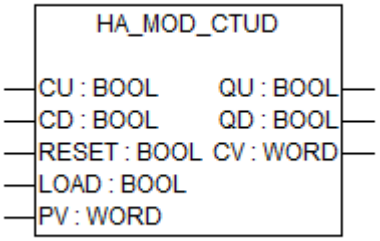
Counter reached the limit.

CV

Data type	Default value	Range	Unit
WORD	0	-	-

Current counter value.

HA_MOD_CTUD



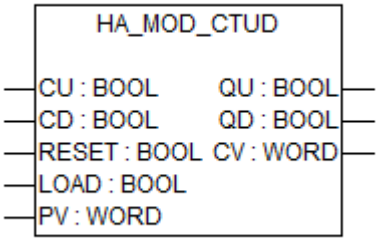
Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_CTUD is a standard count up and count down counter with automatic data synchronization in a high availability system.

QD is TRUE, if counter is 0. QU is TRUE, if counter is PV.

Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.

Input description



CU

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Count up.

CD

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Count down.

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Reset counter to 0.

LOAD

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

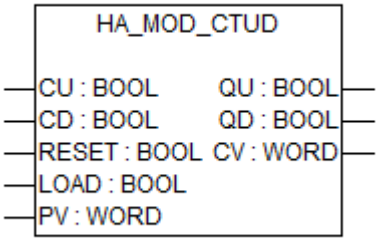
Load start value.

PV

Data type	Default value	Range	Unit
WORD	0	-	-

Start value / counter limit.

Output description



QU

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Counter reached limit.

QD

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

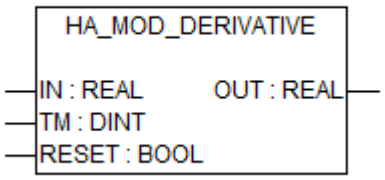
Counter reached 0.

CV

Data type	Default value	Range	Unit
WORD	0	-	-

Current counter value.

HA_MOD_DERIVATIVE

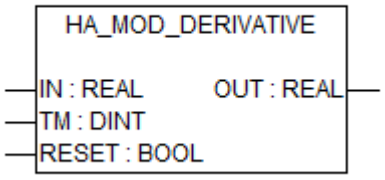


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_DERIVATIVE is a standard derivative with automatic data synchronization in a high availability system.

Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.

Input description



IN

Data type	Default value	Range	Unit
REAL	0	-	-

Input variable.

TM

Data type	Default value	Range	Unit
DINT	0	-	-

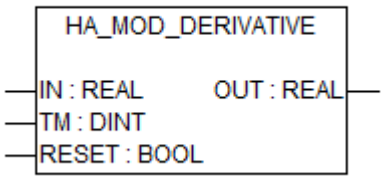
Time since last call [ms].

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

OUT is set to zero.

Output description

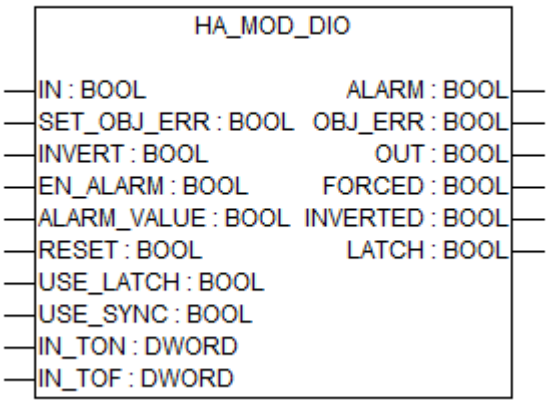


OUT

Data type	Default value	Range	Unit
REAL	0	-	-

Value of the derivative.

HA_MOD_DIO

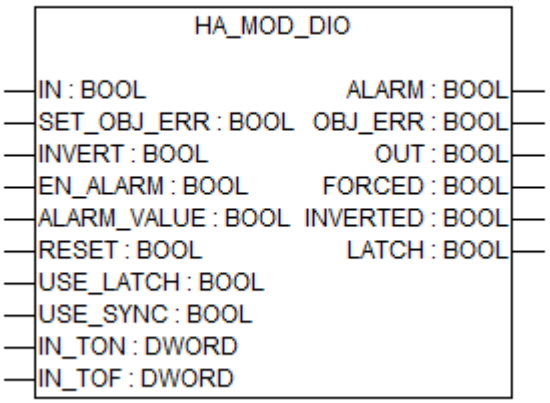


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

This function block can add in a standardized way event handling, alarming and other functions as often available in DCS type environment for digital in- and outputs.

Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.

Input description



IN

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Signal input.

SET_OBJ_ERR

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Set object error.

INVERT

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Signal inversion.

EN_ALARM

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Signal alarm configuration enabled.

ALARM_VALUE

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Signal alarm configuration, alarm value 0 / 1 active.

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Reset latched state.

USE_LATCH

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Automatically reset latched state.

USE_SYNC

Data type	Default value	Range	Unit
BOOL	TRUE	-	-

HA sync is used.

IN_TON

Data type	Default value	Range	Unit
DWORD	0	-	-

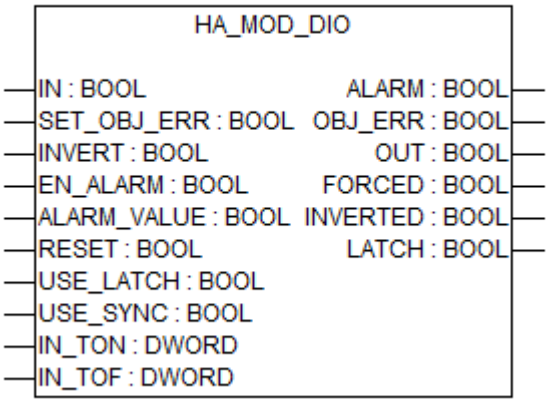
Signal input switch ON delay [ms].

IN_TOF

Data type	Default value	Range	Unit
DWORD	0	-	-

Signal input switch OFF delay [ms].

Output description



ALARM

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Signal alarm.

OBJ_ERR

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Signal object error.

OUT

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Signal out.

FORCED

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Simulation ON.

INVERTED

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

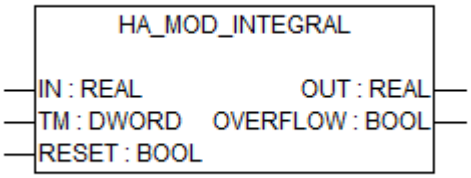
Signal inversion.

LATCH

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Latched output.

HA_MOD_INTEGRAL

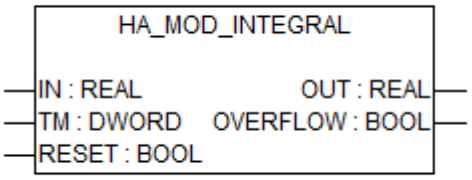


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_INTEGRAL is a standard integral with automatic data synchronization in a high availability system.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.*

Input description



IN

Data type	Default value	Range	Unit
REAL	0	-	-

Input variable.

TM

Data type	Default value	Range	Unit
DINT	0	-	-

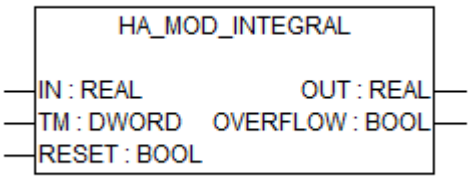
Time since last call [ms].

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

OUT is set to zero and OVERFLOW to false.

Output description



OUT

Data type	Default value	Range	Unit
REAL	0	-	-

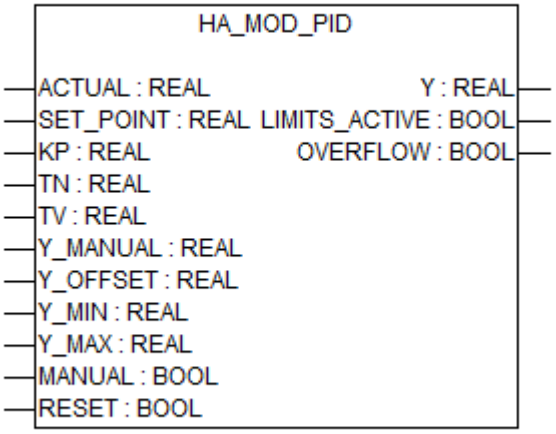
Value of the integral.

OVERFLOW

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Overflow.

HA_MOD_PID

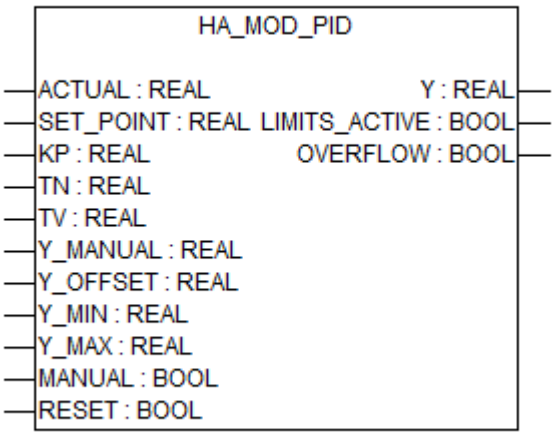


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_PID is a standard PID with automatic data synchronization in a high availability system.

Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.

Input description



ACTUAL

Data type	Default value	Range	Unit
REAL	0	-	-

Actual value, process variable.

SET_POINT

Data type	Default value	Range	Unit
REAL	0	-	-

Desired value, set point.

KP

Data type	Default value	Range	Unit
REAL	0	-	-

Coefficient of proportionality, unity gain of the P-part (P).

TN

Data type	Default value	Range	Unit
REAL	0	-	-

Reset time (I) [s].

TV

Data type	Default value	Range	Unit
REAL	0	-	-

Rate time, derivative time (D) [s].

Y_MANUAL

Data type	Default value	Range	Unit
REAL	0	-	-

Y is set to this value as long as MANUAL=TRUE.

Y_OFFSET

Data type	Default value	Range	Unit
REAL	0	-	-

Offset for manipulated variable.

Y_MIN

Data type	Default value	Range	Unit
REAL	0	-	-

Minimum value for manipulated variable.

Y_MAX

Data type	Default value	Range	Unit
REAL	0	-	-

Maximum value for manipulated variable.

MANUAL

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

TRUE: Y is not influenced by controller.

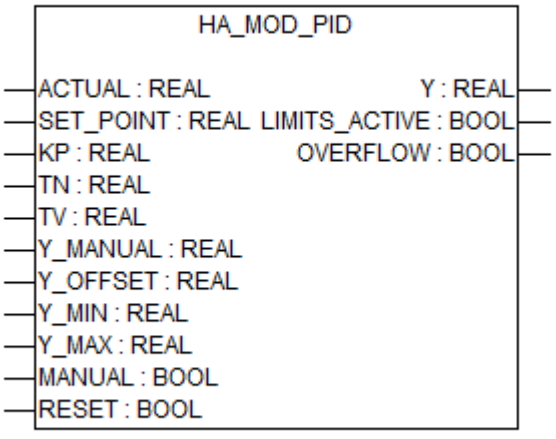
FALSE: controller determines Y.

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Set Y output to Y_OFFSET, reset integral part.

Output description



Y

Data type	Default value	Range	Unit
REAL	0	-	-

Manipulated variable, set value.

LIMITS_ACTIVE

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

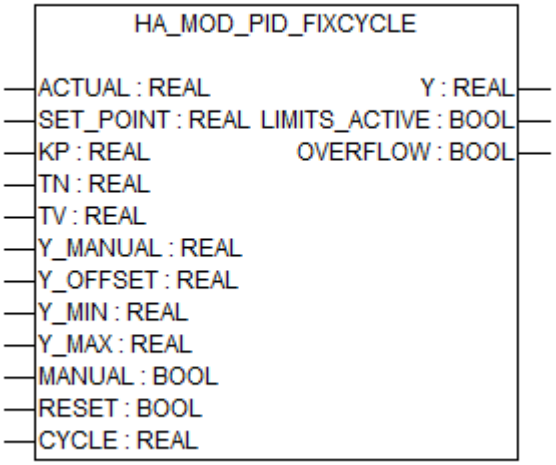
TRUE set value would exceed limits Y_MIN, Y_MAX.

OVERFLOW

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Overflow in integral part.

HA_MOD_PID_FIXCYCLE

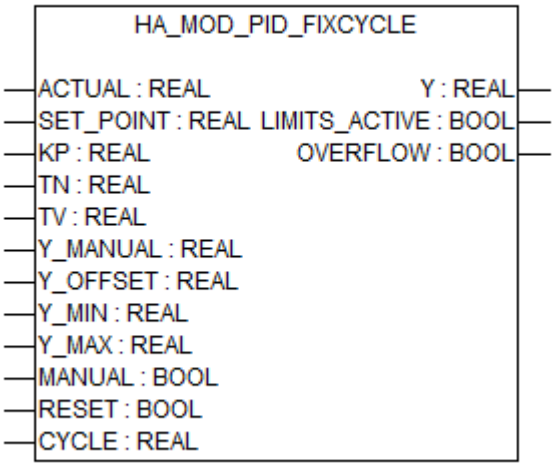


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_PID_FIXCYCLE is a standard PID in fix cycle with automatic data synchronization in a high availability system.

Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.

Input description



ACTUAL

Data type	Default value	Range	Unit
REAL	0	-	-

Actual value, process variable.

SET_POINT

Data type	Default value	Range	Unit
REAL	0	-	-

Desired value, set point.

KP

Data type	Default value	Range	Unit
REAL	0	-	-

Coefficient of proportionality, unity gain of the P-part (P).

TN

Data type	Default value	Range	Unit
REAL	0	-	-

Reset time (I) [s].

TV

Data type	Default value	Range	Unit
REAL	0	-	-

Rate time, derivative time (D) [s].

Y_MANUAL

Data type	Default value	Range	Unit
REAL	0	-	-

Y is set to this value as long as MANUAL=TRUE.

Y_OFFSET

Data type	Default value	Range	Unit
REAL	0	-	-

Offset for manipulated variable.

Y_MIN

Data type	Default value	Range	Unit
REAL	0	-	-

Minimum value for manipulated variable.

Y_MAX

Data type	Default value	Range	Unit
REAL	0	-	-

Maximum value for manipulated variable.

MANUAL

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

TRUE: Y is not influenced by controller.

FALSE: controller determines Y.

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

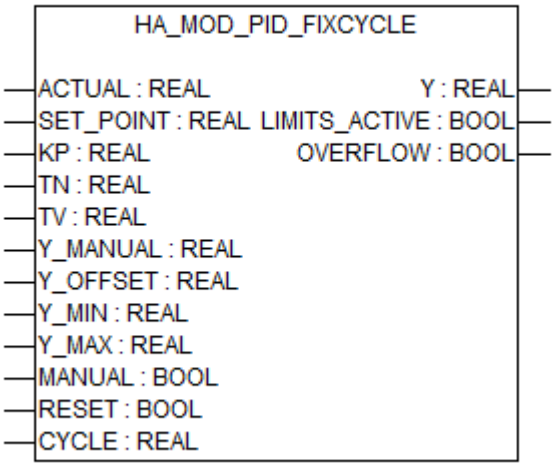
Set Y output to Y_OFFSET, reset integral part.

CYCLE

Data type	Default value	Range	Unit
REAL	0	-	-

Time in [s] between two calls.

Output description



Y

Data type	Default value	Range	Unit
REAL	0	-	-

Manipulated variable, set value.

LIMITS_ACTIVE

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

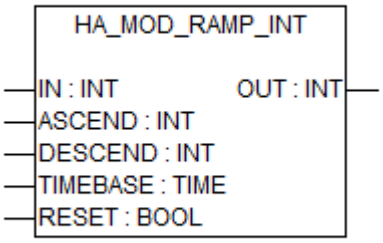
TRUE set value would exceed limits Y_MIN, Y_MAX.

OVERFLOW

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Overflow in integral part.

HA_MOD_RAMP_INT

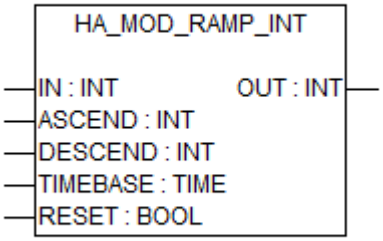


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_RAMP_INT is a standard integer ramp generator with automatic data synchronization in a high availability system.

Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.

Input description



IN

Data type	Default value	Range	Unit
INT	0	-	-

Input variable.

ASCEND

Data type	Default value	Range	Unit
INT	0	-	-

Maximum positive slope.

DESCEND

Data type	Default value	Range	Unit
INT	0	-	-

Maximum negative slope (non-negative!).

TIMEBASE

Data type	Default value	Range	Unit
TIME	TIME#0ms	-	-

Reference for ASCEND / DESCEND : t#0s : ASCEND / DESCEND defined per call

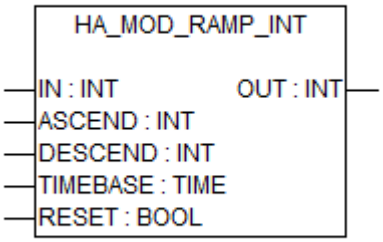
else : ASCEND / DESCEND defined per specified time.

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Resets the OUT value.

Output description

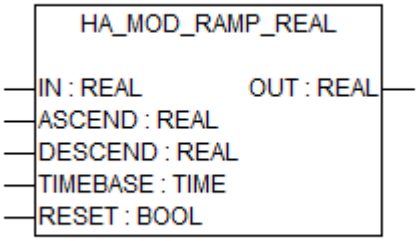


OUT

Data type	Default value	Range	Unit
INT	0	-	-

Value of function with limited slope.

HA_MOD_RAMP_REAL

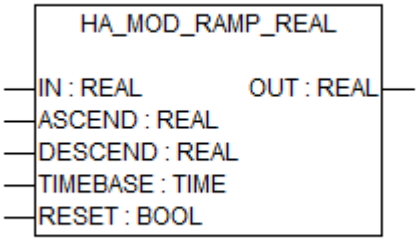


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_RAMP_REAL is a standard real ramp generator with automatic data synchronization in a high availability system.

Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.

Input description



IN

Data type	Default value	Range	Unit
REAL	0	-	-

Input variable.

ASCEND

Data type	Default value	Range	Unit
REAL	0	-	-

Maximum positive slope.

DESCEND

Data type	Default value	Range	Unit
REAL	0	-	-

Maximum negative slope (non-negative!).

TIMEBASE

Data type	Default value	Range	Unit
TIME	TIME#0ms	-	-

Reference for ASCEND / DESCEND : t#0s : ASCEND / DESCEND defined per call

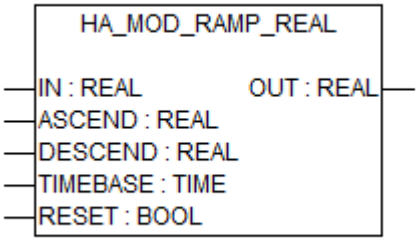
else : ASCEND / DESCEND defined per specified time.

RESET

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Resets the OUT value.

Output description

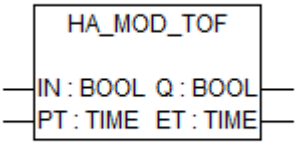


OUT

Data type	Default value	Range	Unit
REAL	0	-	-

Value of function with limited slope.

HA_MOD_TOF

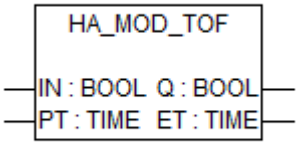


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_TOF is a standard off delay timer with automatic data synchronization in a high availability system.

> *Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.*

Input description



IN

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Starts timer with falling edge.

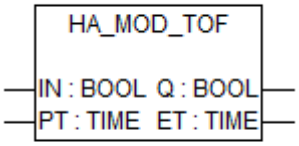
Resets timer with rising edge.

PT

Data type	Default value	Range	Unit
TIME	TIME#0ms	-	-

Time to pass, before Q is set.

Output description



Q

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

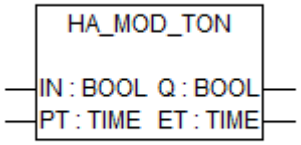
Is FALSE, PT seconds after IN had a falling edge.

ET

Data type	Default value	Range	Unit
TIME	TIME#0ms	-	-

Elapsed time.

HA_MOD_TON

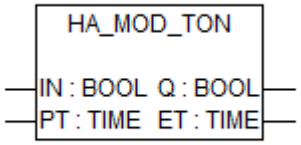


Available as of firmware	V2.6
Included in library	HaModbus_AC500_V26.lib
Type	Function block with historical values

Function block HA_MOD_TON is a standard on delay timer with automatic data synchronization in a high availability system.

Only internal variables and outputs are synchronized. Input variables and parameters are not synchronized. If needed, use HA_MOD_DATA_SYNC.

Input description



IN

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Starts timer with rising edge.

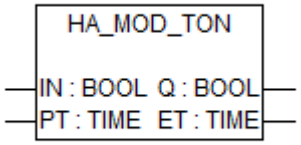
Resets timer with falling edge.

PT

Data type	Default value	Range	Unit
TIME	TIME#0ms	-	-

Time to pass, before Q is set.

Output description



Q

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Is TRUE, PT seconds after IN had a rising edge.

ET

Data type	Default value	Range	Unit
TIME	TIME#0ms	-	-

Elapsed time.

Visualization

In the application program, the user can add visualization objects in his project. In the following chapter, overall visualization and visualization for each individual function block are discussed in detail.

HA_OVERVIEW_VISU

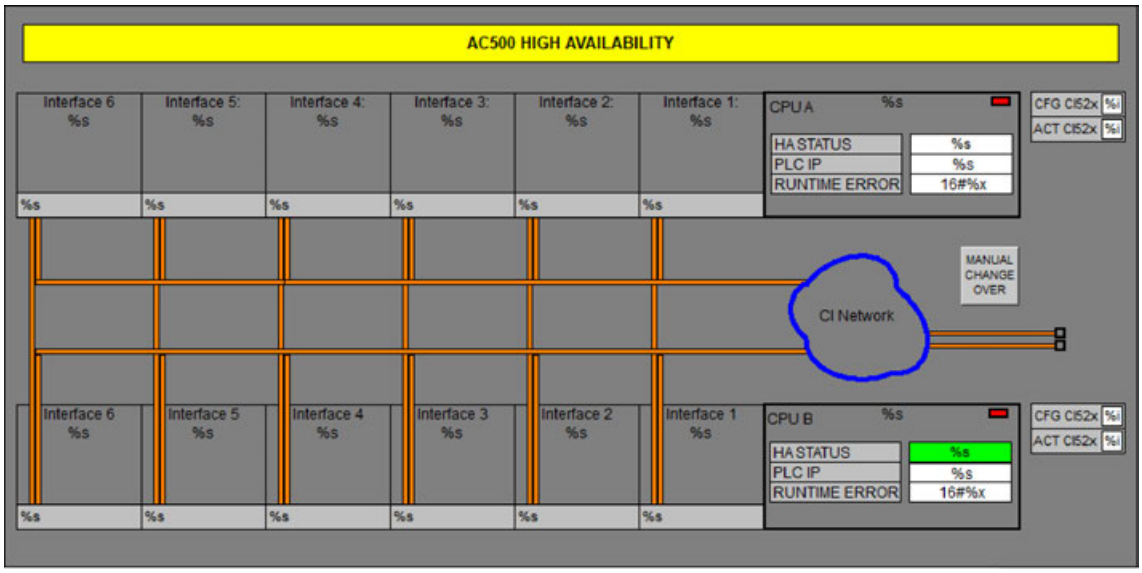
Visualization element HA_OVERVIEW_VISU gives an overview of the HA system state.

Based on the configuration, the state of the interfaces which are used is indicated.

Run state, PLC type, Primary or Secondary state, IP Address, Runtime Error, configured and actual count of CI52x modules are represented for both CPUs.

The button *[MANUAL CHANGE OVER]* may be used to perform a manual switch over.

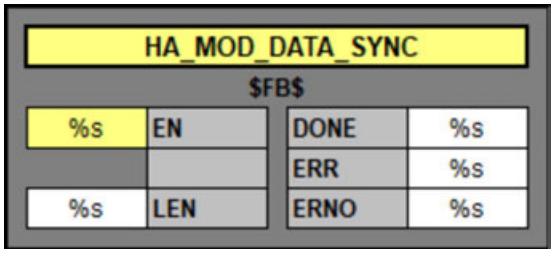
The following figure demonstrates visualization in the offline mode:



HA_MOD_DATA_SYNC_VISU_PH

Visualization element HA_MOD_DATA_SYNC_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of the HA_MOD_DATA_SYNC function block. Visualization can also be used to control the function block by those inputs which are not connected inside the program.

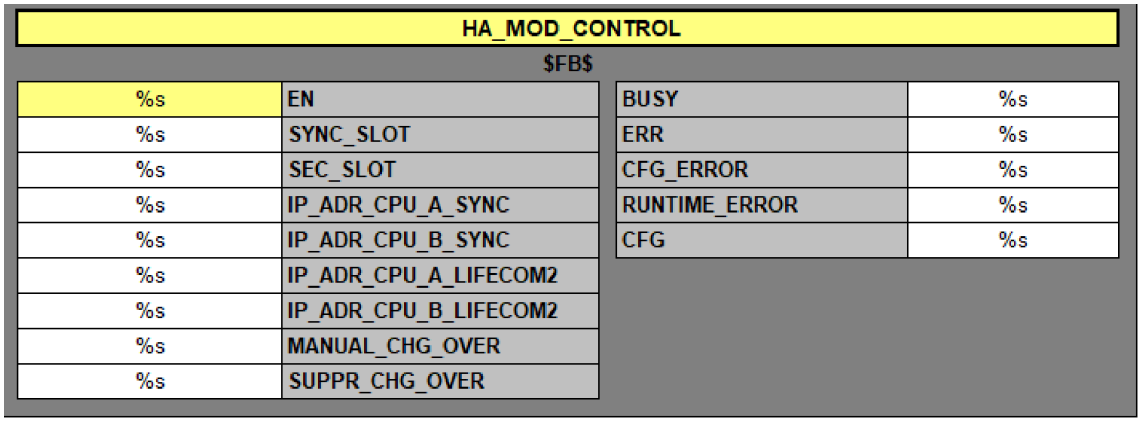
The following figure demonstrates visualization in the offline mode:



HA_MOD_CONTROL_VISU_PH

Visualization element HA_MOD_CONTROL_VISU_PH can be used to show the actual values of all inputs and outputs of the HA_MOD_CONTROL function block. The visualization could also be used to control the function block by those inputs which are not connected inside the program.

The following figure demonstrates visualization in the offline mode:



For all the utility and diagnosis function blocks visualizations are available in the library. All these visualization works same like the main function block visualizations defined above.

Global variables

HA_GLOBAL - errors/constants

List of all error numbers generated by HA-Modbus TCP library and specific constants declared in the library.

scope	Name	Type	Initial	Comment
Error Numbers	HA_MOD_INVALID_LENGTH	WORD	16#2017	Invalid length at the input of data sync block.
	HA_MOD_ERNO_TBL_OVERFLOW	WORD	16#2022	HA data reference table is full.
	HA_MOD_FRAME_TYPE_STATUS	BYTE	16#42	HA status frame.
Constants	HA_MOD_FRAME_TYPE_STATUS_DATA	BYTE	16#42	HA status and data frame 16#DD.
	HA_MOD_MAX_BUFFER_SIZE	UINT	1464	HA sync max. frame size (1400 original).
	HA_MOD_DELAY_CI52x_ERR	UINT	0	Number of cycle delay before declaring the CI52x failure error.
	HA_MOD_FILTER_TIME_HA_SYNC_ARRAY_INIT	UINT	200	Number of cycles to wait before calculating HA_SyncArray ptrData CS.
	HA_MOD_MAX_SYNC_ENTRIES	UINT	3000	Total size of the sync entry array (NoSyncFB-Pins* MaxSyncFBs.) in bytes.
	HA_MOD_MAX_DATA_IN_ETH_FRAME	UINT	1416	Ethernet Frame Length - Size of Header (1416 UDP) in bytes.

HA_GLOBAL_VARIABLES

Global variables for the status of high availability and Ethernet data exchange.

Name	Type	Initial	Comment
xHaModPrimary	BOOL	FALSE	State of the AC500 CPU. TRUE = PM acts as Primary. FALSE = PM acts as Secondary
xHaModCpuStop	BOOL	FALSE	If TRUE -> Indicates the CPU in STOP Mode
xHaModDataErr	BOOL	FALSE	If TRUE -> HA data sync is in error state.
wHaModDataErNo	WORD	0	HA data sync error code.
dwHaModTimersBaseTime	DINT	0	HA base time value for the HA timers
xHaModErr	BOOL	FALSE	If TRUE -> HA error state.
dwHaModOwnIP	DWORD	0	Own IP address configured for sync link connection.
dwHaModOtherIP	DWORD	0	Other PMs IP address configured for sync link connection.
dwHaModServerAlive	DWORD	0	Life counter incremented by OPC server.
wHaModEthLife	WORD	0	Ethernet Life Count.
timHaModSyncTimeOut	TIME	T#10MS	LifeCom1 UDP synchronization time out. May be changed by the user based on Cycle Time of the HA Task.
uiHaModSyncArrayIndex:	UINT	0	Synchronization ARRAY index
stHAEthRecData: HA_MOD_ETH_FRAME_HEADER;			Received Ethernet header
iTotalSyncData	UINT	0	Total sync data for the HA system
iNoOfEthFrames	INT	0	Number of packages sent for all Sync data.
xNoCiBus	BOOL	FALSE	No CI Bus configured. HA standalone system.

CI52x library

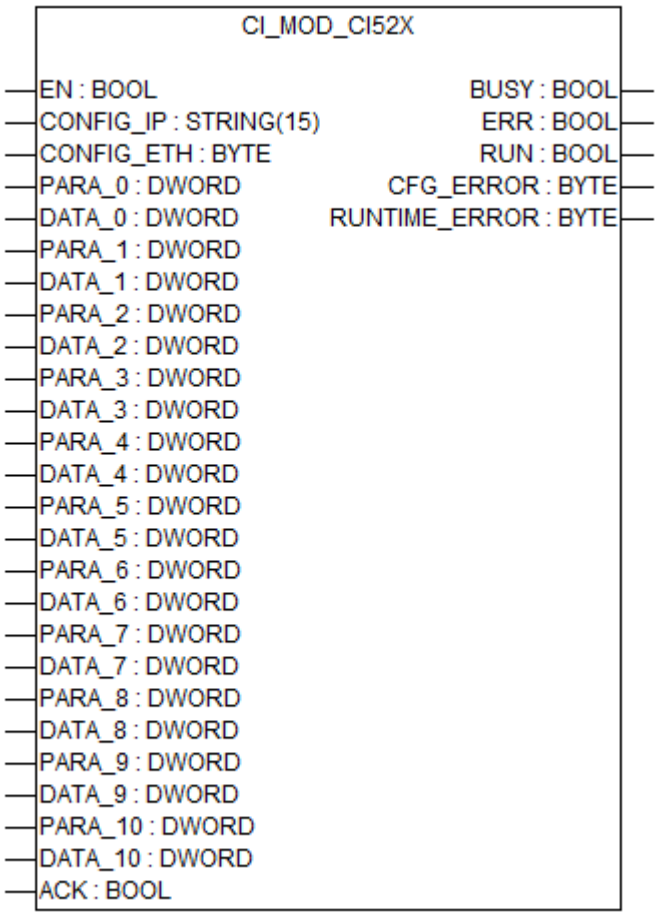
CI52x library is a part of HA-Modbus TCP library package.

Components of CI52x library:

- Function block:
  - CI_MOD_CI52x
  - CI_MOD_DIAG
- Visualization:
  - CI_MOD_CI52x_VISU_PH
  - CI_MOD_DIAG_VISU_PH
  - AI523, AI531, AI561, AI562, AI563
  - AO523, AO561
  - AX521, AX522, AX561
  - CI521, CI522
  - DA501, DA502
  - DC522, DC523, DC532, DC561
  - DI524, DI561, DI562, DI571, DI572
  - DO524, DO526, DO561, DO571, DO572, DO573
  - DX522, DX531, DX561, DX571
- Global variables *Chapter 1.5.5.2.3.3.3 “Global variable list (GVL)” on page 2191*
  - CI52x_GLOBAL_CONSTANT
  - CI52x_GLOBAL_VARIABLES

Function blocks

CI_MOD_CI52x



Available as of firmware	V2.6
Included in library	CI52x_AC500_V26.lib
Type	Function block with historical values

CI_MOD_CI52x function block is to establish the communication between AC500 PLC and communication interface module CI521 or CI522. Using this function block, status of the CI52x module configured in the network can be known.

The diagnosis info (CI_MOD_CI52x function block outputs) from CI52x communication interface module can be read out only once, so e.g. the secondary CPU once it was read.

So if change happens in CI52x diagnosis, it is not reflected in secondary CPU, leading to different diagnosis information in Primary and Secondary CPU.

Hence it is recommended to the user that the diagnosis info handled in application program e.g. should be synchronized in a separate structure OR handled e.g. on SCADA side

NOTICE!

For updating the state of inputs and outputs actions of the CI_MOD_CI52x function block must be called:

- Action “ACTION_INPUT_REFRESH” for refreshing the inputs,
- Action “ACTION_OUTPUT_REFRESH” for refreshing the outputs.

Input refresh should be done at the beginning of the task, output refresh at the end.

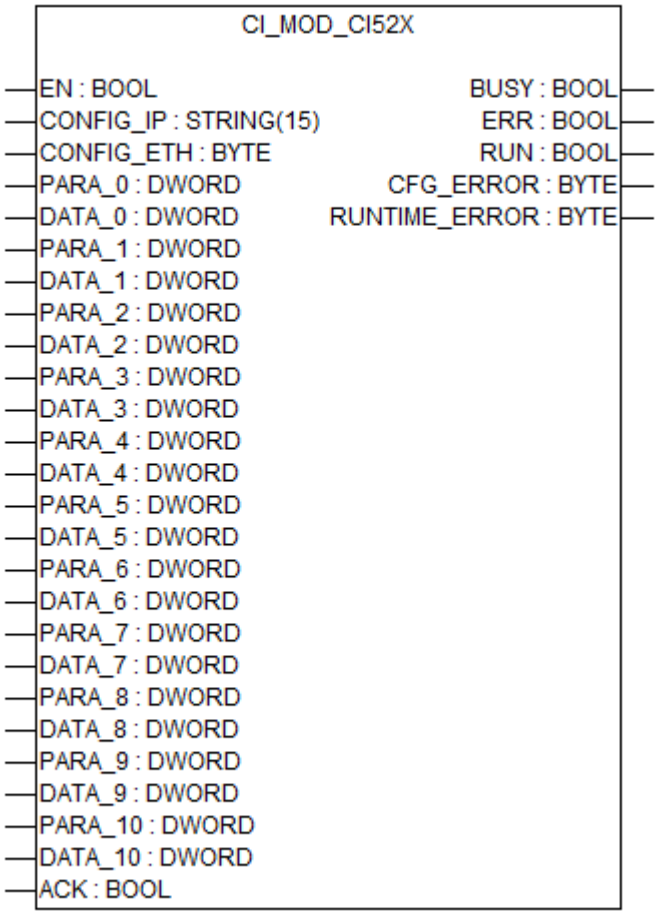
When there is a different task for the application logic, where the inputs and outputs are read/written it is mandatory that these actions are called from the task which is reading/writing the IO data.

For example, two Tasks: Modbus task and application task. In the Modbus Task the CI_MOD_CI52x function block is called.

The action “ACTION_INPUT_REFRESH” of the function block is called in beginning of the application task. Then all necessary calls for the application logic are done.

At the end of the application task the action “ACTION_OUTPUT_REFRESH” of the function block is called.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

While it is executed its inputs are continuously evaluated.

CI_MOD_CI52x function block disabling (EN = FALSE) will not set output RUN-TIME_ERROR Bit 0 (Bit 0 - CI module lost error) on HA_MOD_CONTROL function block.

CONFIG_IP

Data type	Default value	Range	Unit
STRING(15)	-	-	-

IP Address of the I/O module.

CONFIG_ETH

Data type	Default value	Range	Unit
BYTE	0	-	-

Ethernet slot used for communication on the PLC (see *Chapter 1.5.4.13.1.19 “ETHx_MOD_MAST” on page 1250*).

PARA_0

Data type	Default value	Range	Unit
DWORD	0	-	-

Communication interface module configuration address

DATA_0

Data type	Default value	Range	Unit
DWORD	0	-	-

Communication interface module IO structure address

PARA_1

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 1 configuration address.

DATA_1

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 1 IO structure address

PARA_2

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 2 configuration address.

DATA_2

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 2 IO structure address

PARA_3

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 3 configuration address.

DATA_3

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 3 IO structure address

PARA_4

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 4 configuration address.

DATA_4

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 4 IO structure address

PARA_5

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 5 configuration address.

DATA_5

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 5 IO structure address

PARA_6

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 6 configuration address.

DATA_6

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 6 IO structure address

PARA_7

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 7 configuration address.

DATA_7

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 7 IO structure address

PARA_8

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 8 configuration address.

DATA_8

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 8 IO structure address

PARA_9

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 9 configuration address.

DATA_9

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 9 IO structure address

PARA_10

Data type	Default value	Range	Unit
DWORD	0	-	-

I/O module 10 configuration address.

DATA_10

Data type	Default value	Range	Unit
DWORD	0	-	-

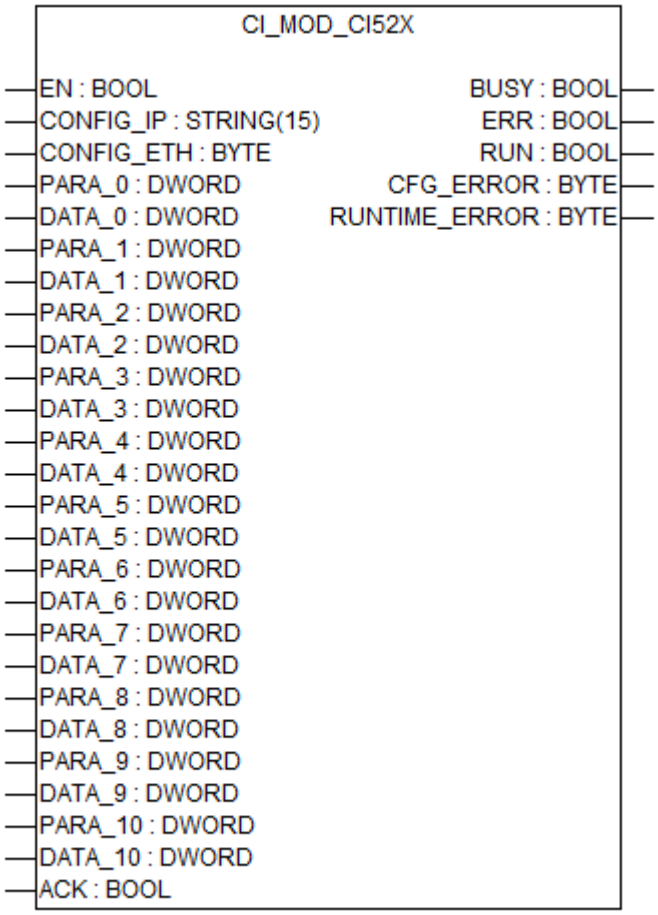
I/O module 10 IO structure address

ACK

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

To acknowledge errors.

Output description



BUSY

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

If TRUE - Error condition reached, mismatch between configuration and actual hardware detected.

RUN

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

If TRUE - CI52x module is running.

CFG_ERROR

Data type	Default value	Range	Unit
BYTE	0	-	-

Each bit of the byte represents different configuration errors:

- Bit 0: CPU_INFO error
- Bit 1: CONFIG_ETH invalid
- Bit 2: CONFIG_IP invalid

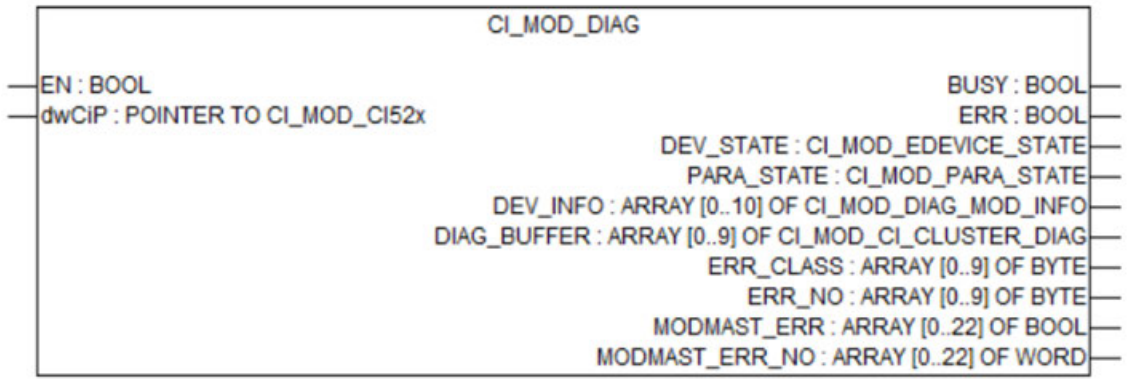
RUNTIME_ERROR

Data type	Default value	Range	Unit
BYTE	0	-	-

Each bit of the byte represents different runtime errors:

- Bit 0: Communication error
- Bit 1: I/O bus error
- Bit 2: Cluster error
- Bit 3: Hardware configuration error, mismatch between configuration and actual hardware detected

CI_MOD_DIAG

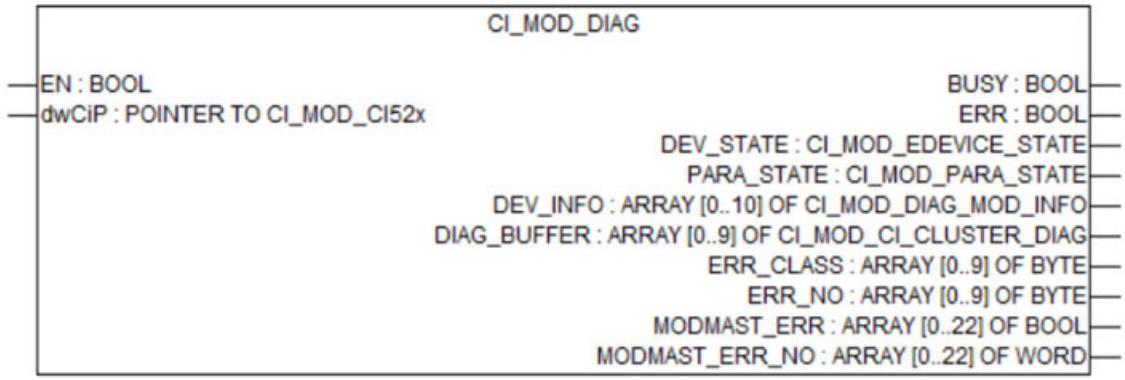


Available as of firmware	V2.6
Included in library	CI52x_AC500_V26.lib
Type	Function block with historical values

CI_MOD_DIAG function block can be used to get the additional diagnosis information related to the CI521 / CI522 communication module. This block provides addition information like device state, parameter state, device information, CI module diagnosis buffer, CI module related errors and details of error generated in the COM_MOD_MAST core block.

This function block must be connected to CI_MOD_CI52x function block instance using ADR operator to read the diagnosis of particular communication interface module.

Input description



EN

Data type	Default value	Range	Unit
BOOL	FALSE	TRUE/FALSE	-

The input EN has to be driven in level triggered mode.

In order to enable the execution of the function block the input EN has to be set to value TRUE. It keeps on executing until the input EN is set back to value FALSE.

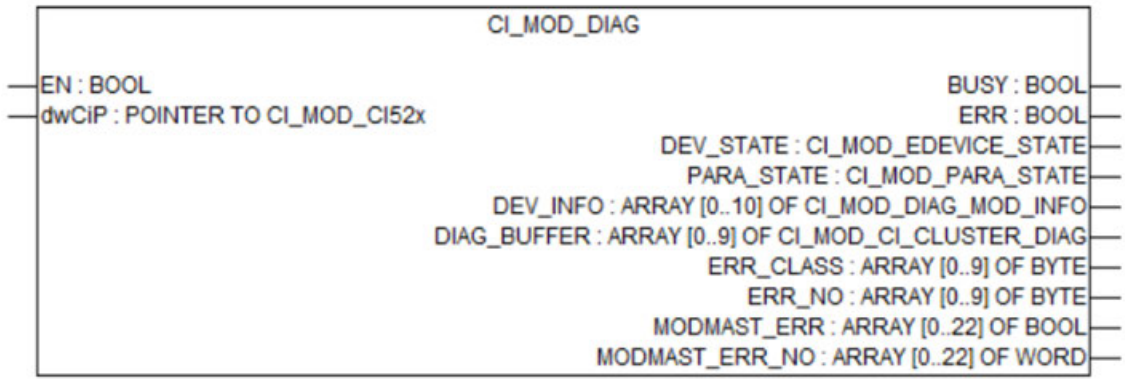
While it is executed its inputs are continuously evaluated.

dwCiP

Data type	Default value	Range	Unit
POINTER TO CI_MOD_CI52x	-	-	-

This input points to the address of the CI communication block instance from which the diagnosis information has to be read. Use the ADR operator and connect the instance of CI_MOD_CI52x function block.

Output description



BUSY

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Operation is running.

ERR

Data type	Default value	Range	Unit
BOOL	FALSE	-	-

Error occurred during execution when output ERR = TRUE.

DEV_STATE

Data type	Default value	Range	Unit
CI_MOD_DEVICE_STATE	-	-	-

CI521 or CI522 device current status is displayed.

- STATE_PREOP – Device is booting
- STATE_OPERATION – Device is operational, no bus monitoring is active
- STATE_ERROR – Device detected a bus error, bus monitoring is active
- STATE_IP_ERROR – Device has an IP address error
- STATE_CYCLIC_OPERATION – Device is operational, bus monitoring is active
- STATE_NA – Not available

PARA_STATE

Data type	Default value	Range	Unit
CI_MOD_PARA_STATE	-	-	-

CI521 or CI522 device current status is displayed.

- PARA_STATE_NO_PARA – Device has no parameters
- PARA_STATE_PARA_ACTIVE – Parameterization process is running
- PARA_STATE_PARA_DONE– Device used valid parameters and parameterization is done
- PARA_STATE_ERROR– Device has invalid parameters
- PARA_STATE_NA – Not available

DEV_INFO

Data type	Default value	Range	Unit
ARRAY[0..10] OF CI_MOD_DIAG_MOD_INFO	-	-	-

CI521 or CI522 type and extended module types. This will give the details of the module configured in the communication interface module including the I/O modules.

If module is with suffix F, then fast counter is enabled for that module.

DIAG_BUFFER

Data type	Default value	Range	Unit
ARRAY[0..9] OF CI_MOD_CI_CLUSTER_DIAG	-	-	-

CI521 or CI522 module diagnosis buffer. More details on this are provided in ↳ *Chapter 1.6.4.3.1.2.3.2 “Diagnosis data” on page 5659*

ERR_CLASS

Data type	Default value	Range	Unit
ARRAY[0..9] OF BYTE	-	-	-

CI error class. Refer to the diagnostics ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

ERR_NO

Data type	Default value	Range	Unit
ARRAY[0..9] OF BYTE	-	-	-

CI error number. Refer to the diagnostics *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

MODMAST_ERR

Data type	Default value	Range	Unit
ARRAY[0..22] OF BOOL	-	-	-

Latest 22 Modbus TCP error messages of the block.

MODMAST_ERR_NO

Data type	Default value	Range	Unit
ARRAY[0..22] OF WORD	-	-	-

Latest 22 Modbus TCP error numbers. Refer to the error details in Modbus *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

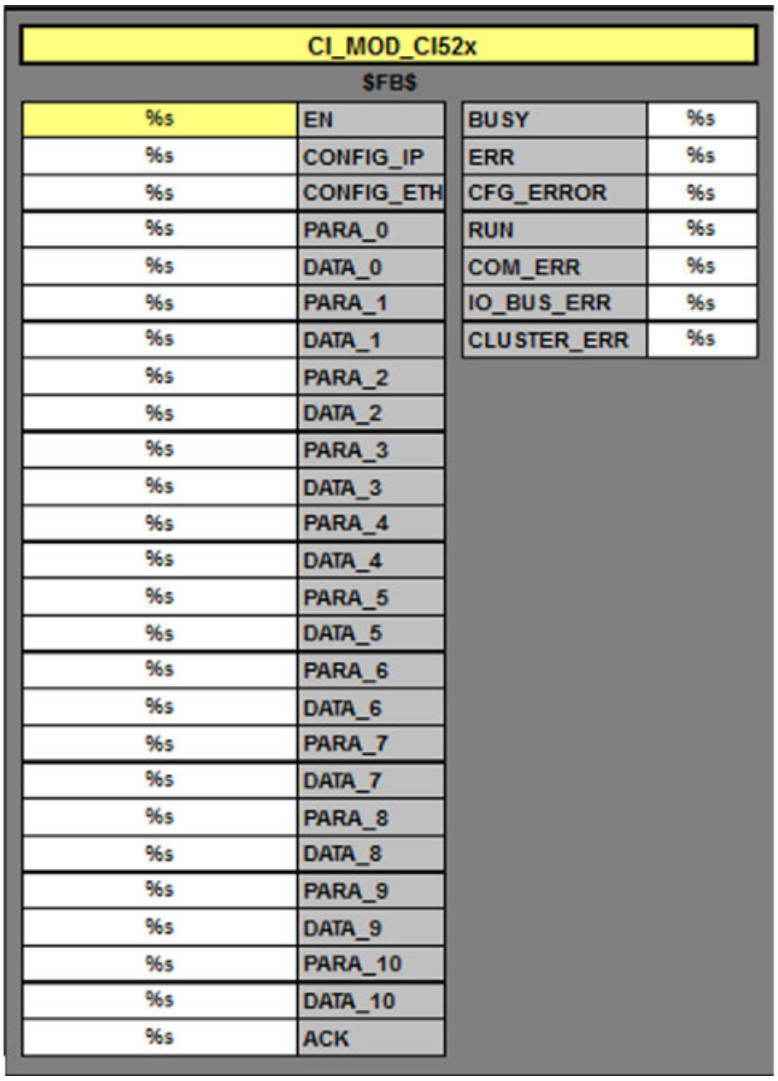
Visualization

In the application program, the user can add the visualization object in his project. In the following chapter, overall visualization and visualization for each individual function block are discussed in detail.

CI_MOD_CI52x_VISU_PH

The visualization element CI_MOD_CI52x_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of the CI52x function block. Visualization can also be used to control the function block by those inputs which are not connected inside the program.

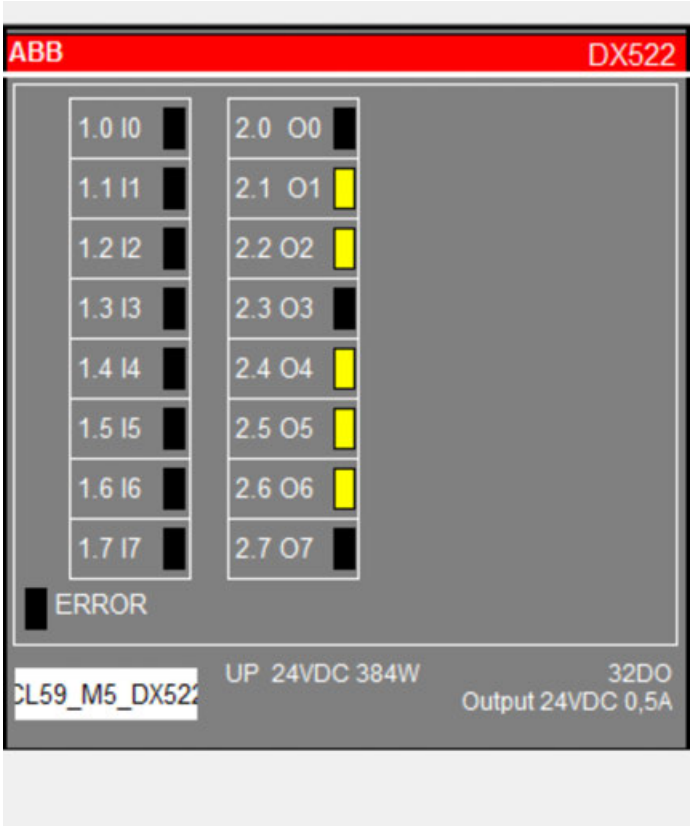
The following picture demonstrates visualization in offline mode:



IO visualization

Visualization elements can be used to show the actual values of all inputs and outputs on the hardware module. Values will be updated only on the primary PLC.

The following example figure demonstrates visualization in the online mode:



In the similar way for all the IO modules visualizations are available in the library which can be used to view the state of the LEDs on hardware module.

Values will be updated only on the Primary PLC.

Global variable list (GVL)

List of all global variables declared in the library.

CI52x_GLOBAL_CONSTANT

List of all the global constants declared in the library.

Scope	Name	Type	Initial	Comment
Constants	CI52x_MOD_SEND	BYTE	16	Write the values to the CI modules selected
	CI52x_MOD_REC	BYTE	3	Read the values from the CI modules selected
	CI52x_MOD_FC23	BYTE	23	Read or write the values to the CI modules selected
	CI52x_MOD_NOT_VALID	BYTE	16#0	Status to indicate that module is not available.

CI52x_GLOBAL_VARIABLES

List of all global variables declared in the library which are intended for the user

Name	Type	Initial	Comment
byCI52xActive-CICluster	BYTE	0	Number of active CI52x clusters in the network.
aCI52xActiveCIClus-terStatus	ARRAY [1..100] OF POINTER TO CI_MOD_CLUSTER_STATUS		Status of the clusters configured.
timCI52xTimeOut	TIME	T#10ms	Modbuscommunica-tion time out.

1.5.5.3 Examples

Example projects for the libraries can be found in the folder: \Users\Public\Documents\AutomationBuilder\Examples

1.5.6 ACS / DCS drives libraries

1.5.6.1 System technology

In the following chapter a guide is given how to select the appropriate function blocks to set up a working system of AC500 together with ACS drives. This guide is given in form of questions which answers will lead step by step to the selection of correct components and function blocks.

Additional information on preconditions of the configuration of the drives can then be found at the documentation of the selected function blocks.

1.5.6.1.1 Application selection

Question: What kind of application should be realized?

- Motion control application using PLC open motion control function blocks --> Use the PS552-MC motion control library
- Speed and/or torque applications using ABB Drives Profile in the ACS drive --> Go to chapter Connection Selection ↳ *Chapter 1.5.6.1.2 “Connection selection” on page 2192*

1.5.6.1.2 Connection selection

Question: What kind of connection between AC500 and ACS drive should be used?

- discrete or analog wiring to start/stop and give reference values --> no special function blocks needed. Please see drive manuals how to connect.
  PROFIBUS ↳ *Chapter 1.5.6.1.3 “PROFIBUS” on page 2192*
  PROFINET ↳ *Chapter 1.5.6.1.4 “PROFINET” on page 2194*
  CANopen ↳ *Chapter 1.5.6.1.5 “CANopen” on page 2194*
  EtherCAT ↳ *Chapter 1.5.6.1.6 “EtherCAT” on page 2195*
  Modbus TCP ↳ *Chapter 1.5.6.1.7 “Modbus TCP” on page 2195*
  Modbus RTU ↳ *Chapter 1.5.6.1.8 “Modbus RTU” on page 2200*

1.5.6.1.3 PROFIBUS

The following hardware components must be available:

- AC500 with a PROFIBUS master Communication Module
- ACSxxx / DCSxxx drive with FPBA-01 or RPBA-01 PROFIBUS Communication Module
- PROFIBUS cable with DSUB9 for the PROFIBUS master Communication Module and DSUB9 for drive Communication Modules

The following values should be mapped in the fieldbus configuration of the drive and the configuration of AC500.

- Drive --> AC500: Status word and actual value 1 (speed) and optional actual value 2 (torque).
- AC500 --> drive: Control word and reference value 1 (speed) and optional reference value 2 (torque)

The following libraries have to be loaded into the project:

- ACSDrivesBase_AC500_V20.lib *Chapter 1.5.6.2 “ACS drives base library” on page 2204*
- Optional ACSDrivesComPB_AC500_V24.lib *Chapter 1.5.6.6 “ACS / DCS Drives communication via PROFIBUS” on page 2410*
- DCS Drives Library *Chapter 1.5.6.8 “DCS drives library” on page 2467* (if DCS drives are used)

The following communication profile should be used:

- ABB Drives profile

The following function blocks can be used in AC500 program

- Control function blocks:
  - Generic control blocks – only ACSDrivesBase_AC500_V20.lib “ACS Drives Base Library” and DCSDrivesBase_AC500_V24.lib is needed.
  - ACS_DRIVES_CTRL_STANDARD_GEN *Chapter 1.5.6.2.4.7 “ACS_DRIVES_CTRL_STANDARD_GEN” on page 2241*
  - DCS_DRIVES_CTRL_GEN *Chapter 1.5.6.8.4.2 “DCS_DRIVES_CTRL_GEN control of DCS drives with ABB-Drives profile via generic fieldbus” on page 2477*(if DCS drives are used)
  - Standard control blocks toghether with communication blocks
    ACS_DRIVES_CTRL_STANDARD
    DCS_DRIVES_CTRL_STANDARD
- scaling: ACS_REF_SCALING (optional) *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- Communication function blocks:
  - ACS_COM_PB *Chapter 1.5.6.6.3.1 “ACS_COM_PB communication block via PROFIBUS” on page 2412* Communication for ACS drives via PROFIBUS DP for PZD1..3
  - ACS_COM_PB_PZD *Chapter 1.5.6.6.3.2 “ACS_COM_PB_PZD communication block for direct access to PZD4..12” on page 2415* (Communication for ACS drives via PROFIBUS DP for Process Data PZD4..12)
- Parameter READ / WRITE function blocks:
  PPO-Types 3, 4, 6 or 8 (DPV1)
  - ACS_PB_READ_N_PRM_DPV1 *Chapter 1.5.6.6.3.5 “ACS_PB_N_READ_PRM_DPV1 read parameters from ABB drives via PROFIBUS DPV1” on page 2425*
  - ACS_PB_WRITE_N_PRM_DPV1 *Chapter 1.5.6.6.3.6 “ACS_PB_N_WRITE_PRM_DPV1 write parameters from ABB drives via PROFIBUS DPV1” on page 2431*
    These function blocks can be used stand-alone without any communication block.
  - ACS_PB_READ_PRM_DPV0 *Chapter 1.5.6.6.3.3 “ACS_PB_READ_PRM_DPV0 read parameters from ABB drives via PROFIBUS DPV0” on page 2420*
  - ACS_PB_WRITE_PRM_DPV0 *Chapter 1.5.6.6.3.4 “ACS_PB_WRITE_PRM_DPV0” on page 2423*
    These function blocks must be used together with FB ACS_COM_PB “ACS_COM_PB”

1.5.6.1.4 PROFINET

The following hardware components must be available:

- AC500 with CM579-PNIO (PROFINET master Communication Module)
- ACSxxx drive with FENA-01, FENA-11, FENA-21 or RETA-02 realtime Ethernet communication module
- Ethernet cable with RJ45 plugs

The following values should be mapped in the fieldbus configuration of the drive and the configuration of AC500.

- Drive --> AC500: Status word and actual value 1 (speed) and optional actual value 2 (torque).
- AC500 --> drive: Control word and reference value 1 (speed) and optional reference value 2 (torque)

The following libraries have to be loaded into the project:

- ACSDrivesBase_AC500_V20.lib *Chapter 1.5.6.2 “ACS drives base library” on page 2204*
- DCS Drives Library *Chapter 1.5.6.8 “DCS drives library” on page 2467*(if DCS drives are used)
- Optional: ACSDrivesComPN_AC500_V24.lib *Chapter 1.5.6.7 “ACS / DCS Drives read / write parameter via PROFINET library” on page 2451*

The following function blocks can be used in AC500 program:

- Control function block:

The following communication profile should be used:

ABB Drives profile

- ACS_DRIVES_CTRL_STANDARD_GEN *Chapter 1.5.6.2.4.7 “ACS_DRIVES_CTRL_STANDARD_GEN” on page 2241*
- DCS_DRIVES_CTRL_GEN (if DCS drives are used) *Chapter 1.5.6.8.4.2 “DCS_DRIVES_CTRL_GEN control of DCS drives with ABB-Drives profile via generic fieldbus” on page 2477*
- scaling: ACS_REF_SCALING (optional) *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- Parameter READ / WRITE function blocks:
  - ACS_PN_READ_N_PRM_DPV1 *Chapter 1.5.6.7.4.1 “ACS_PN_READ_N_PRM_DPV1 read parameters from ABB drives via PROFINET DPV1” on page 2453*
  - ACS_PN_WRITE_N_PRM_DPV1 *Chapter 1.5.6.7.4.2 “ACS_PN_WRITE_N_PRM_DPV1 write parameters from ABB drives via PROFINET DPV1” on page 2457*

1.5.6.1.5 CANopen

The following hardware components must be available:

- AC500 with CM598-CN (CANopen master Communication Module)
- ACSxxx drive with FCAN-01 or RCAN-01 CANopen slave Communication Module
- CANopen cable

The following values should be mapped in the fieldbus configuration of the drive and the Automation Builder configuration of AC500.

- Drive --> AC500: Status word and actual value 1 (speed) and optional actual value 2 (torque).
- AC500 --> drive: Control word and reference value 1 (speed) and optional reference value 2 (torque)

The following libraries have to be loaded into the project:

- ACSDrivesBase_AC500_V20.lib *Chapter 1.5.6.2 “ACS drives base library” on page 2204*
- DCS Drives Library (if DCS drives are used) *Chapter 1.5.6.8 “DCS drives library” on page 2467*

The following communication profile should be used:

- ABB Drives profile

The following function blocks can be used in AC500 program:

- Control function blocks:
  - ACS_DRIVES_CTRL_STANDARD_GEN *Chapter 1.5.6.2.4.7 “ACS_DRIVES_CTRL_STANDARD_GEN” on page 2241*
  - DCS_DRIVES_CTRL_GEN (if DCS drives are used) *Chapter 1.5.6.8.4.2 “DCS_DRIVES_CTRL_GEN control of DCS drives with ABB-Drives profile via generic fieldbus” on page 2477*
- scaling: ACS_REF_SCALING *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*(optional)

1.5.6.1.6 EtherCAT

The following hardware components must be available:

- AC500 with CM579-ETHCAT (EtherCAT master Communication Module)
- ACSxxx drive with FECA01 or RECA-01 EtherCAT slave Communication Module
- Ethernet cable with RJ45 plugs

The following values should be mapped in the fieldbus configuration of the drive and the Automation Builder configuration of AC500.

- Drive --> AC500: Status word and actual value 1 (speed) and optional actual value 2 (torque).
- AC500 --> drive: Control word and reference value 1 (speed) and optional reference value 2 (torque)

The following libraries have to be loaded into the project:

- ACSDrivesBase_AC500_V20.lib *Chapter 1.5.6.2 “ACS drives base library” on page 2204*
- DCS Drives Library (if DCS drives are used) *Chapter 1.5.6.8 “DCS drives library” on page 2467*

The following communication profile should be used:

- ABB Drives profile

The following function blocks can be used in AC500 program

- Control function blocks:
  - ACS_DRIVES_CTRL_STANDARD_GEN *Chapter 1.5.6.2.4.7 “ACS_DRIVES_CTRL_STANDARD_GEN” on page 2241*
  - DCS_DRIVES_CTRL_GEN (if DCS drives are used) *Chapter 1.5.6.8.4.2 “DCS_DRIVES_CTRL_GEN control of DCS drives with ABB-Drives profile via generic fieldbus” on page 2477*
- scaling: ACS_REF_SCALING (optional) *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*

1.5.6.1.7 Modbus TCP

The following hardware components must be available:

- AC500 or AC500-eCo with Ethernet option
- Drive with FENA-01 or FENA-11 or RETA-01 or RETA-02 realtime Ethernet communication module
- Ethernet cable with RJ45 plugs

The following libraries have to be loaded into the project:

- ACSDrivesBase_AC500_V20.lib ↳ *Chapter 1.5.6.2 “ACS drives base library” on page 2204*
- In case the Firmware is less then V2.4 and CPU has only one Ethernet Interface: ACSDrivesComModTCP_AC500_V22.lib ↳ *Chapter 1.5.6.4 “ACS / DCS drives communication via Modbus TCP library” on page 2359*
- In case the CPU has two Ethernet Interfaces e.g. PM595 or PM591-2ETH and at least with Firmware V2.4. ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*

Question:Which ACSxxx drive should be used?

- ACS355 ↳ *Chapter 1.5.6.1.7.1 “ACS355 with Modbus TCP” on page 2196*
- ACS550 or ACH550 ↳ *Chapter 1.5.6.1.7.2 “ACS550 or ACH550 with Modbus TCP” on page 2197*
- ACS580 ↳ *Chapter 1.5.6.1.7.3 “ACS580 with Modbus TCP” on page 2197*
- ACS800 ↳ *Chapter 1.5.6.1.7.4 “ACS800 with Modbus TCP” on page 2198*
- ACS850, ACQ810 or ACSM1 ↳ *Chapter 1.5.6.1.7.5 “ACS850, ACQ810 or ACSM1 with Modbus TCP ” on page 2199*
- ACS880 ↳ *Chapter 1.5.6.1.7.6 “ACS880 with Modbus TCP” on page 2200*
- DCS800 or DCS550 ↳ *Chapter 1.5.6.1.7.7 “DCS800 or DCS550 with Modbus TCP” on page 2200*

ACS355 with Modbus TCP

Used drive Communication Module: FENA-x1:

Question: How many values should be exchanged?

- only status word, actual speed, control word and speed reference:
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx ↳ *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385*
  - control function block in AC500 program: ACS3XX_DRIVES_CTRL_BASIC ↳ *Chapter 1.5.6.2.4.4 “ACS3XX_DRIVES_CTRL_BASIC” on page 2220*
  - scaling: the scaling is included in the ACS3XX_DRIVES_CTRL_BASIC ↳ *Chapter 1.5.6.2.4.4 “ACS3XX_DRIVES_CTRL_BASIC” on page 2220* function block
- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed) and reference value2 (torque):
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx ↳ *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*(optional)

- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed), reference value2 (torque) and up to 10 more values read from drive and up to 10 more values write to the drive
  - communication profile in drive parameters: ABB Drives enhanced
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP_ENHANCED ↳ *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx_ENHANCED ↳ *Chapter 1.5.6.5.3.2 “ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2392*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- to exchange more than above mentioned values use additionally the following blocks:
  - ACS_MOD_READ_N_PRM ↳ *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212*
  - ACS_MOD_WRITE_N_PRM ↳ *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*

ACS550 or ACH550 with Modbus TCP

Used drive Communication Module: RETA-01

Question: How many values should be exchanged?

- only status word, actual speed, control word and speed reference:
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx ↳ *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385*
  - control function block in AC500 program: ACS3XX_DRIVES_CTRL_BASIC ↳ *Chapter 1.5.6.2.4.4 “ACS3XX_DRIVES_CTRL_BASIC” on page 2220*
  - scaling: the scaling is included in the ACS3XX_DRIVES_CTRL_BASIC function block
- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed) and reference value2 (torque):
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx ↳ *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- to exchange more than above mentioned values use additionally the following blocks:
  - ACS_MOD_READ_N_PRM ↳ *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212*
  - ACS_MOD_WRITE_N_PRM ↳ *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*

ACS580 with Modbus TCP

Used drive Communication Module: FENA-x1

Question: How many values should be exchanged?

- only status word, actual speed, control word and speed reference:
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx ↳ *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385*
  - control function block in AC500 program: ACS_DRIVES_CTRL ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed), reference value2 (torque) and up to 12 more values read from drive and up to 12 more values write to the drive
  - communication profile in drive parameters: ABB Drives enhanced
  - communication function block in AC500 program:
    Use ACS_COM_MOD_TCP_ENHANCED ↳ *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367*

    “ACS_COM_MOD_TCP_ENHANCED Communication for ACS Drives via Modbus TCP”, if PLC firmware is less than V2.4, else use

    ACS_COM_MOD_TCPx_ENHANCED ↳ *Chapter 1.5.6.5.3.2 “ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2392*

    “ACS_COM_MOD_TCPx_ENHANCED Communication for ACS Drives via Modbus TCP”
  - control function block in AC500 program:
    ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*

    “ACS_DRIVES_CTRL_STANDARD Control of ACS Drives with ABB-Drives Profile”
  - scaling: ACS_REF_SCALING (optional)
    “ACS_REF_SCALING ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246* Scaling for ACS Reference and Actual Values”
- to exchange more than above mentioned values use additionally the following blocks:
  - ACS_MOD_READ_N_PRM ↳ *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212*
  - ACS_MOD_WRITE_N_PRM ↳ *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*

ACS800 with Modbus TCP

Used drive Communication Module: RETA-01

Question: How many values should be exchanged?

- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed) and reference value2 (torque):
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx ↳ *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- to exchange more than above mentioned values use additionally the following blocks:
  - ACS_MOD_READ_N_PRM ↳ *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212*
  - ACS_MOD_WRITE_N_PRM ↳ *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*
-

ACS850, ACQ810 or ACSM1 with Modbus TCP

Used drive Communication Module: FENA-x1

Question: How many values should be exchanged?

- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed) and reference value2 (torque):
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx ↳ *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385*.
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246* (optional)
- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed), reference value2 (torque) and up to 12 more values read from drive and up to 12 more values write to the drive
  - communication profile in drive parameters: ABB Drives enhanced
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP_ENHANCED ↳ *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx_ENHANCED ↳ *Chapter 1.5.6.5.3.2 “ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2392*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- to exchange more than above mentioned values use additionally the following blocks:
  - ACS_MOD_READ_N_PRM ↳ *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212*
  - ACS_MOD_WRITE_N_PRM ↳ *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*
-

ACS880 with Modbus TCP

Used drive Communication Module: FENA-11

Question: How many values should be exchanged?

- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed), reference value2 (torque) and up to 12 more values read from drive and up to 12 more values write to the drive
  - communication profile in drive parameters: ABB Drives enhanced
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP_ENHANCED *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx_ENHANCED *Chapter 1.5.6.5.3.2 “ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2392*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed), reference value2 (torque) and up to 12 more values read from drive and up to 12 more values write to the drive
  - communication profile in drive parameters: ABB Drives enhanced
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP_ENHANCED *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367* “ACS_COM_MOD_TCP_ENHANCED, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx_ENHANCED *Chapter 1.5.6.5.3.2 “ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2392*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*

DCS800 or DCS550 with Modbus TCP

Used drive Communication Module: RETA-01

Question: How many values should be exchanged?

- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed) and reference value2 (torque):
  - communication function block in AC500 program: Use ACS_COM_MOD_TCP *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*, if PLC firmware is less than V2.4, else use ACS_COM_MOD_TCPx *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385*
  - control function block in AC500 program: DCS_DRIVES_CTRL_STANDARD *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - to exchange more than above mentioned values use additionally the following blocks: ACS_MOD_READ_N_PRM *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212* ACS_MOD_WRITE_N_PRM *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*

1.5.6.1.8 Modbus RTU

The following hardware components must be available:

- AC500 or AC500-eCo
- Drive with embedded Modbus RTU or FMBA-01 or FSCA-01 or RMBA-01 RS-485 Communication Module
- Twisted pair serial cable

The following libraries have to be loaded into the project:

- ACSDrivesBase_AC500_V20.lib *Chapter 1.5.6.2 “ACS drives base library” on page 2204*
- ACSDrivesComModRTU_AC500_V22.lib *Chapter 1.5.6.3 “ACS / DCS Drives communication via Modbus RTU library” on page 2288*
- DCS Drives Library *Chapter 1.5.6.8 “DCS drives library” on page 2467* (if DCS drives are used)

Question:Which Drive should be used?

- ACS310, ACS350, ACS355, ACS550 or ACH550 *Chapter 1.5.6.1.8.1 “ACS310, ACS350, ACS355, ACS550 or ACH550 with Modbus RTU” on page 2201*
- ACS800 *Chapter 1.5.6.1.8.2 “ACS800 with Modbus RTU” on page 2202*
- ACS850 or ACQ810 *Chapter 1.5.6.1.8.3 “ACS850, ACQ810 with Modbus RTU” on page 2202*
- ACS880 or ACSM1 or ACS580 *Chapter 1.5.6.1.8.4 “ACS880 or ACSM1 or ACS580 with Modbus RTU” on page 2203*
- DCS800 *Chapter 1.5.6.1.8.5 “DCS800 with Modbus RTU” on page 2203* or DCS550

ACS310, ACS350, ACS355, ACS550 or ACH550 with Modbus RTU

Used drive Communication Module: embedded, only ACS350 or ACS355 with FMBA-01:

Question: Are the Emergency stops needed and is the change to Ext1/2 control location needed?

- Emergency stops or change to external control location is NOT needed
  - READ / WRITE variables: status word, actual speed, control word and speed reference and up to 7 more values read from the drive
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: ACS3XX_COM_MOD_RTU *Chapter 1.5.6.3.5.1 “ACS3XX_COM_MOD_RTU communication for ACS3XXwrite one bit/ACX550 drives via Modbus RTU” on page 2293*
  - control function block in AC500 program: ACS3XX_DRIVES_CTRL_BASIC *Chapter 1.5.6.2.4.4 “ACS3XX_DRIVES_CTRL_BASIC” on page 2220*
  - scaling:the scaling is included in the ACS3XX_DRIVES_CTRL_BASIC function block
- Emergency stops or change to external control location is needed
  - read/write variables: status word, actual speed, control word and speed reference and up to 7 more values read from the drive:
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: ACS3XX_COM_MOD_RTU *Chapter 1.5.6.3.5.1 “ACS3XX_COM_MOD_RTU communication for ACS3XXwrite one bit/ACX550 drives via Modbus RTU” on page 2293*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- to exchange more than above mentioned values use additionally the following blocks:
  - ACS_MOD_READ_N_PRM *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212*
  - ACS_MOD_WRITE_N_PRM *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*

ACS800 with Modbus RTU

Used drive Communication Module: RMBA-01

Question: How many values should be exchanged?

- READ / WRITE variables: status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed), reference value2 (torque)
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: ACS_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.2 “ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU” on page 2301*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- to exchange more than above mentioned values use additionally the following blocks:
  - ACS_MOD_READ_N_PRM ↳ *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212*
  - ACS_MOD_WRITE_N_PRM ↳ *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*

ACS850, ACQ810 with Modbus RTU

Question: How many values should be exchanged?

- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed) and reference value2 (torque) and up to 24 more values read from the drive
  - used drive Communication Module: embedded Modbus using the D2D plug
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: ACS_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.2 “ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU” on page 2301*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed) and reference value2 (torque)
  - used drive Communication Module: embedded Modbus using the D2D plug or FSCA-01
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: ACS_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.2 “ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU” on page 2301*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*

- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed), reference value2 (torque) and up to 12 more values read from drive and up to 12 more values write to the drive
  - used drive Communication Module: FSCA-01
  - communication profile in drive parameters: ABB Drives enhanced
  - communication function block in AC500 program: ACS_COM_MOD_RTU_ENHANCED *Chapter 1.5.6.3.5.3 “ACS_COM_MOD_RTU_ENHANCED communication for ACS drives via Modbus RTU using ABB drives profile enhanced” on page 2312*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- to exchange more than above mentioned values use additionally the following blocks:
  - ACS_MOD_READ_N_PRM *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212*
  - ACS_MOD_WRITE_N_PRM *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*

ACS880 or ACSM1 or ACS580 with Modbus RTU

Used drive Communication Module: FSCA-01:

Question: How many values should be exchanged?

- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed) and reference value2 (torque)
  - communication profile in drive parameters: ABB Drives classic
  - communication function block in AC500 program: ACS_COM_MOD_RTU *Chapter 1.5.6.3.5.2 “ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU” on page 2301*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed), reference value2 (torque) and up to 12 more values read from drive and up to 12 more values write to the drive
  - communication profile in drive parameters: ABB Drives enhanced
  - communication function block in AC500 program: ACS_COM_MOD_RTU_ENHANCED *Chapter 1.5.6.3.5.3 “ACS_COM_MOD_RTU_ENHANCED communication for ACS drives via Modbus RTU using ABB drives profile enhanced” on page 2312*
  - control function block in AC500 program: ACS_DRIVES_CTRL_STANDARD *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234*
  - scaling: ACS_REF_SCALING (optional) *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- to exchange more than above mentioned values use additionally the following blocks:
  - ACS_MOD_READ_N_PRM *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212*
  - ACS_MOD_WRITE_N_PRM *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*

DCS800 with Modbus RTU

Used drive Communication Module: RMBA-01

Question: How many values should be exchanged?

- status word, actual value1 (speed), actual value2 (torque), control word, reference1 (speed) and reference value2 (torque):
  - communication function block in AC500 program: Use ACS_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.2 “ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU” on page 2301*
  - control function block in AC500 program: DCS_DRIVES_CTRL ↳ *Chapter 1.5.6.8.4.1 “DCS_DRIVES_CTRL Control of DCS Drives with ABB-Drives profile using a communication block” on page 2470*
  - scaling: ACS_REF_SCALING (optional) ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*
- to exchange more than above mentioned values use additionally the following blocks:
  - ACS_MOD_READ_N_PRM ↳ *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212*
  - ACS_MOD_WRITE_N_PRM ↳ *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*

1.5.6.2 ACS drives base library

1.5.6.2.1 Preconditions for the use of the ACS drives base library

The function blocks contained in the library can only be executed in RUN mode of the PLC, but not in simulation mode.

Some of the function blocks can only be used in combination with one of the ACSDrivesComXXX_AC500_V20 libraries, e.g. the ACSDrivesComModRTU_AC500_V20.lib.

The library is released for the following products:

CPUs: AC500, AC500-eCo

Modbus communication is tested for connection of 7 drives in total. Connection of more drives depends on performance of used CPU, communication type and settings.

Fieldbuses: Modbus RTU (Serial Modbus)

Modbus TCP

CANopen: For CANopen communication we have to use FCAN-01 module firmware version 1050 or above has to be used.

PROFIBUS

PROFINET

EtherCAT

General blocks Following blocks can be used independent of used fieldbus:

- ACS_DRIVES_CTRL_STANDARD_GEN ↳ *Chapter 1.5.6.2.4.7 “ACS_DRIVES_CTRL_STANDARD_GEN” on page 2241*
- ACS_REF_SCALING ↳ *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246*

Compatibility

To check the compatiblity of drives and their communication modules please refer to the following table, that shows the tested combinations:

Communication	PLC communication modules		PLC Fieldbus Adapter			Drive		
	PLC communication module	Firmware Version	Fieldbus Adapter (FBA)	FBA comm sw ver	FBA appl sw ver	Drive	Firmware Version	Drive Rating ID

1.5.6.2.2 Special characteristics of the ACS drives base library

The types and constants defined in this library are base types and can be used in other ACSDrivesXXX libraries, e.g. ACSDrivesComModRTU_AC500_V20.lib.

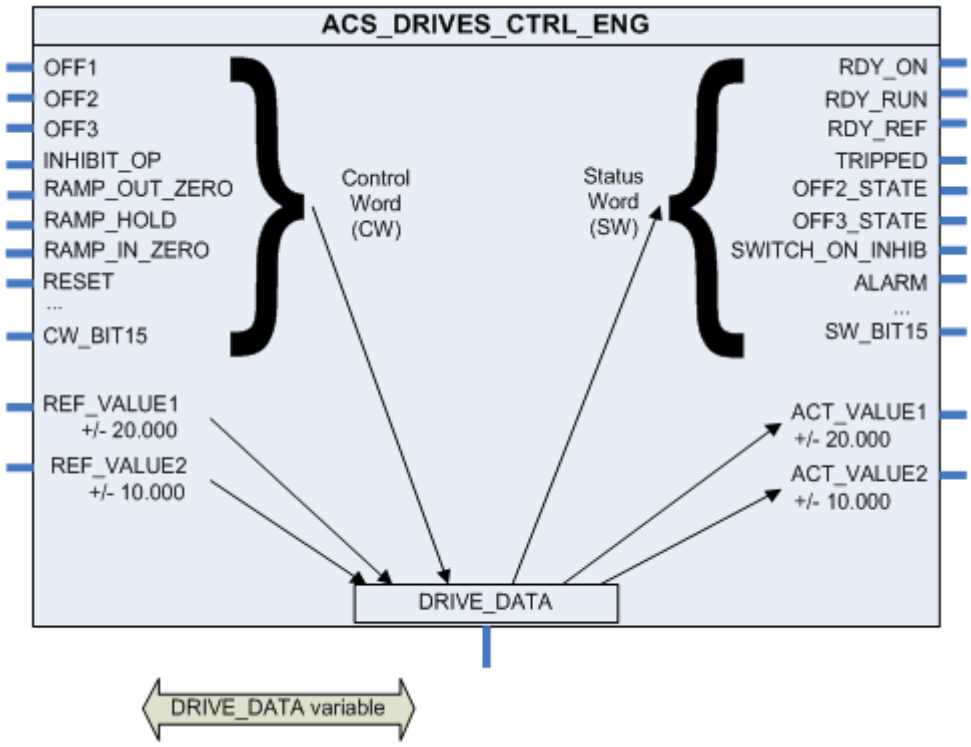
The ACSDrivesBase_AC500_V20 Library includes 3 different control function blocks to be used with ACS drives configured for ABB Drives Profile.

For three of these blocks the communication to the drive is made via the DRIVE_DATA variable which must be connected to an communication function block. The communication function blocks for different fieldbuses can be found in separate libraries, e.g. ACSCom-ModRTU_AC500_V20.lib for Modbus RTU connection.

One control function block (ACS_DRIVES_CTRL_STANDARD_GEN) is a generic block which doesn´t need a communication block. The input of Status Word and output of Control Word must be mapped somehow to any fieldbus.

The control function blocks work independent of the used fieldbus connection. The principle and differences of the 4 control blocks is shortly described below:

ACS_DRIVES_CTRL_ENG

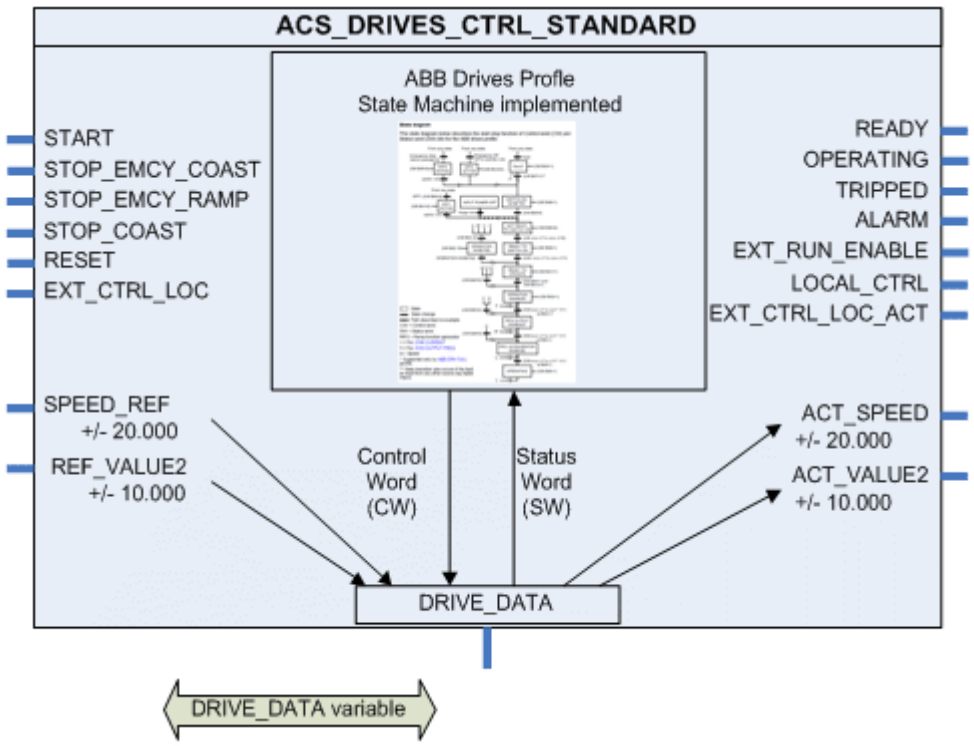


The ACS_DRIVES_CTRL_ENG function block is designed for user specific control of the drive setting the Control Word (CW) by the user in the program.

Therefore the user should have a detailed knowledge of the ABB Drives Profile handling.

The reference and actual values must be given in fieldbus equivalent, e.g. +/- 20000 for the reference value 1.

ACS_DRIVES_CTRL_STANDARD

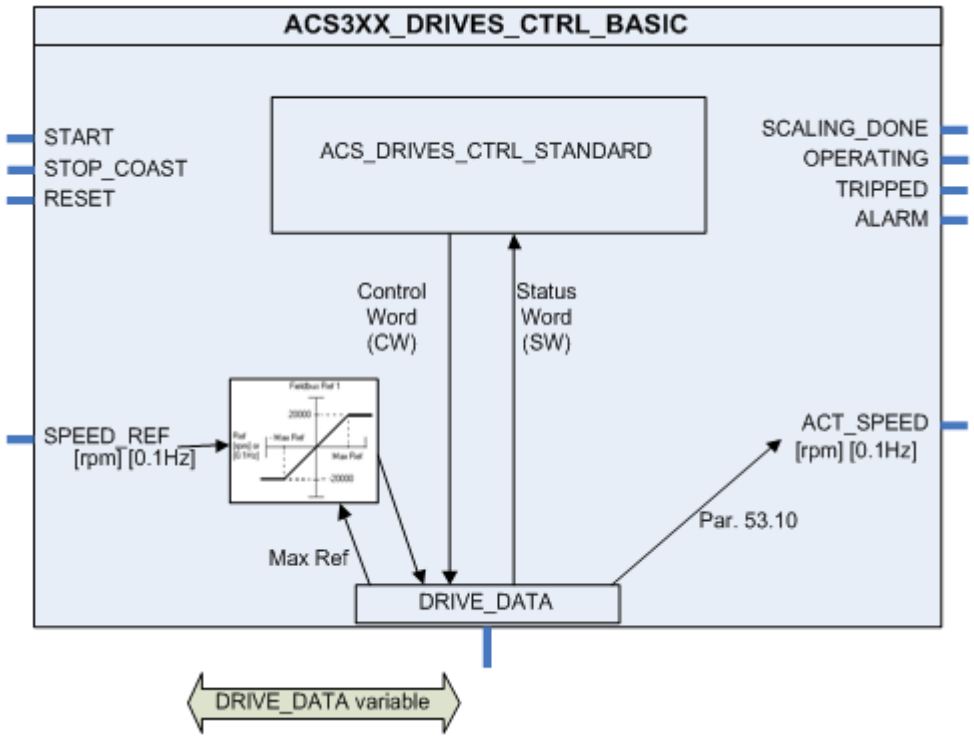


The ACS_DRIVES_CTRL_STANDARD function block can be used for standard control functions.

The handling of the ABB Drives Profile State Machine is done inside the block. The Control Word is built according to ABB Drives Profile State Machine, the Status Word (SW) and the inputs of the function block.

The reference and actual values must be given in fieldbus equivalent, e.g. +/- 20000 for the reference value 1.

ACS3XX_DRIVES_CTRL_BASIC



The ACS3XX_DRIVES_CTRL_BASIC function block is designed especially for ACS3XX and ACX550 drives and provides additionally scaling functions for the speed reference.

The handling of the ABB Drives Profile State Machine is done inside the block. The Control Word is built according to ABB Drives Profile State Machine, the Status Word (SW) and the inputs of the function block.

The speed reference input can be given in rpm or in 0.1 Hz. The act speed output is also in rpm or 0.1 Hz.

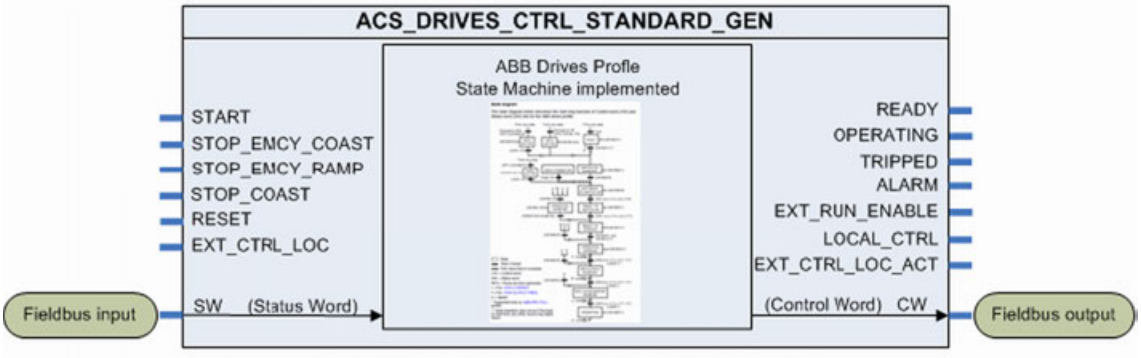
ACS_DRIVES_CTRL_STANDARD_GEN

The ACS_DRIVES_CTRL_STANDARD_GEN function block can be used for standard control functions, using any generic fieldbus.

The handling of the ABB Drives Profile State Machine is done inside the block. The Control Word is built according to ABB Drives Profile State Machine, the Status Word (SW) and the inputs of the function block.

The block does not have a DRIVE_DATA input. The SW and CW can be retrieved from any where. So any generic fieldbus can be used to get the SW and send the CW to the drive.

The block does not have any input or output for actual- or reference speed values. These can be send directly via the fieldbus to the drive.

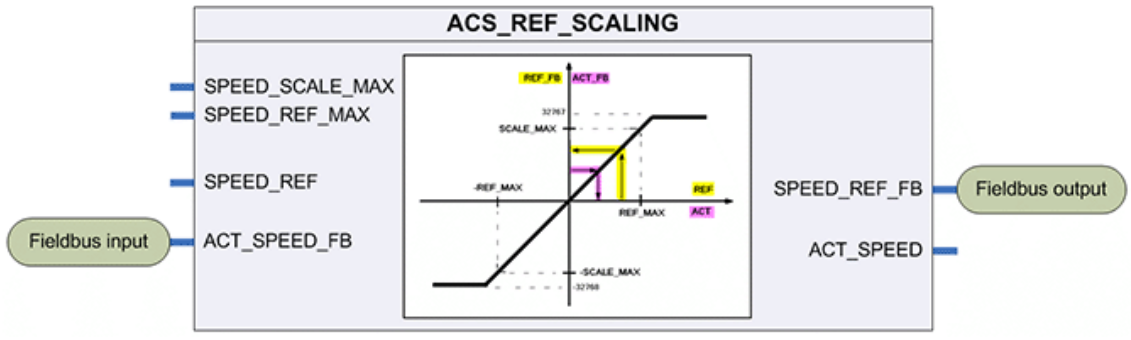


ACS_REF_SCALING

This block can be used to scale the actual and reference values from fieldbus equivalent (+/- 20000 or +/- 10000) to the physical value ("rpm" or "Hz").

Figure bellow shows an overview for the speed values. Same functionality is also provided in the same block for the torque values.

This block can also be used together with other ACS or DCS blocks, e.g. ACS_DRIVES_CTRL_STANDARD or DCS_DRIVES_CTRL to scale the fieldbus values to physical values used in the PLC program.



1.5.6.2.3 Overview of the ACS drives base components according to their call names

Used abbreviations:

FBhv	Function block with historical values
FBnohv	Function block without historical values
F:	Function
Enum:	Enumeration
Struct:	Structure
Visu:	Visualization

VE name	Type	Function
ACS_CW_VISU_PH ↳ *Chapter 1.5.6.2.8.9 “ACS_CW_VISU_PH visualization for the ABB drives profile control word” on page 2286*	Visu	Visualization for the ABB Drives Profile Control Word
ACS_DRIVE_CONFIG_TYPE ↳ *Chapter 1.5.6.2.6.1 “ACS_DRIVE_CONFIG_TYPE structure including configurations parameters of the ACS3XX drive” on page 2252*	Struct	Structure Including Configurations Parameters of the ACS3XX Drive
ACS_DRIVE_DATA_TYPE ↳ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*	Struct	Structure to Exchange Data between function blocks for 1 drive

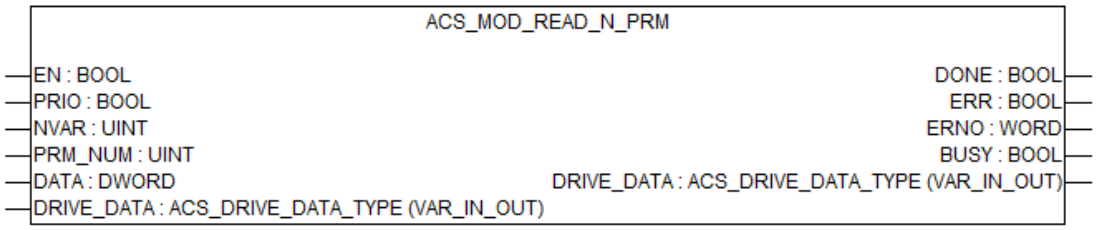
1.5.6.2.4 Function blocks

ACS_MOD_READ_N_PRM



Function block ACS_MOD_READ_N_PRM is used for reading n parameters from a drive via Modbus.

Function block information

Available in runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_MOD_READ_N_PRM reads n parameters of the drive. The number of parameters to be read is specified at the input NVAR. The first parameter number is specified at the input PRM_NUM. All parameters must be accessible from consecutive Modbus registers in the drive. The values of the parameters are stored in the PLC memory area, defined at the input DATA. The values in the PLC memory area are updated when the read job was performed without error. This is indicated by DONE=TRUE and ERR=FALSE.

As long as the EN = TRUE a new read job is requested each time the further read job is terminated.

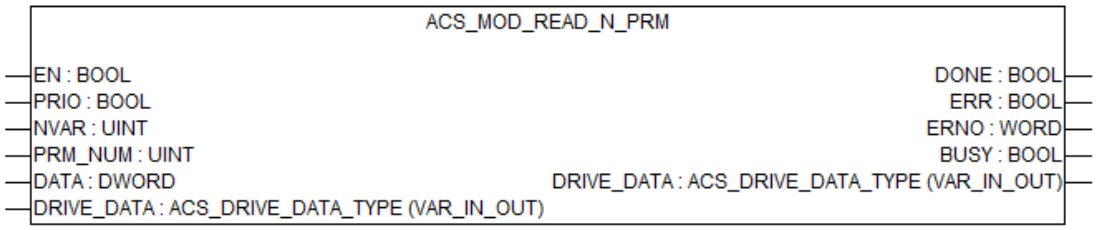
The Modbus job is started from the communication block which is connected to the same DRIVE_DATA variable. It uses the Modbus function code 03 (Read n words).

The drive (Modbus slave) from which the parameter is read is specified at this communication block.

The communication blocks are available from other ACSDrivesComXXX libraries e.g. ACS_3XX_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.1 “ACS3XX_COM_MOD_RTU communication for ACS3XXwrite one bit/ACX550 drives via Modbus RTU” on page 2293* in ACSDrivesComModRTU_AC500_V20.lib. ↳ *Chapter 1.5.6.3 “ACS / DCS Drives communication via Modbus RTU library” on page 2288* or ACS_COM_MOD_TCP_ENHANCED ↳ *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367* in ACSDrivesComModTCP_V22.lib ↳ *Chapter 1.5.6.4 “ACS / DCS drives communication via Modbus TCP library” on page 2359*ACS_COM_MOD_TCPx_ENHANCED ↳ *Chapter 1.5.6.5.3.2 “ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2392* in ACSDrivesComModTCP_Ext_AC500_V24.lib.

If the connected communication block (via DRIVE_DATA variable) is disabled or not parametrized correctly and EN = TRUE, the variables or arrays that are attached via DATA input are reset to zero. This can be checked by the ERNO output.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type: BOOL

If a TRUE state is applied to the input EN, a request to perform a Modbus read job is set to the DRIVE_DATA variable.

All further inputs are read in.

If the input values are valid, a request to perform a Modbus job is send to the communication block via the DRIVE_DATA variable.

If at least 1 input is invalid, no job is generated and the error is displayed at the outputs ERR and ERNO instead.

If the state of EN stays TRUE a new read job is requested each time the previous job is terminated, indicated by the DONE = TRUE flag.

PRIO (priority)

Data type: BOOL

Input PRIO is reserved for future usage. It can be left open.

NVAR (number of variables)

Data type: UINT, Default value: 1, Range: 1 to 125

Input NVAR defines the number of variables to be read by the function block.

If the read job was finished successfully the first 15 parameter values are written to the internal array VALUE, which can be made visible in the visualization element ACS_MOD_READ_N_PRM_VISU_PH *Chapter 1.5.6.2.8.1 “ACS_MOD_READ_N_PRM_VISU_PH faceplate for the function block ACS_MOD_READ_N_PRM” on page 2256*or used via <instance of the function block>.VALUE[1..15].

PRM_NUM (parameter number)

Data type: UINT, Range 0 to 65535

For 16bit Parameters it is set in the format 100 * GG + ii as decimal integer value. (GG = parameter group, ii = parameter index of the drive, e.g. for parameter 12.02, 100 * GG + ii = 1202.)

(GG = parameter group, ii = parameter index of the drive)

For 32bit Parameters it must be set according to the formula 20000 + 200 x GG + 2 x ii.(see description of related drive fieldbus module), e.g. for parameter 14.54 = 22908.

This calculation is provided in the function ACS_MOD_PRM_NUM_32BIT *Chapter 1.5.6.2.4.3 “ACS_MOD_PRM_NUM_32BIT” on page 2219*, which output can then be connected to the PRM_NUM input. The Modbus address which is used at the Communication Block is PRM_NUM - 1.

> *The parameter number must be set prior or at the same cycle when input EN is set to TRUE.*

The Modbus address which is used at the communication block is PRM_NUM - 1.

DATA (data)

Data type: DWORD

At input DATA, the address of the first operand in the PLC is specified to which the data read by the slave should be stored.

For this purpose it is necessary that all PLC variables, which are written to the drive, have consecutive addresses. This can be obtained by declaration of each variable within the %MW0.xxx area or declaration of an array containing all variables.

Declaration of each variable has the advantage, that the types (integer or word) can be selected individually.

DRIVE_DATA (drive data)

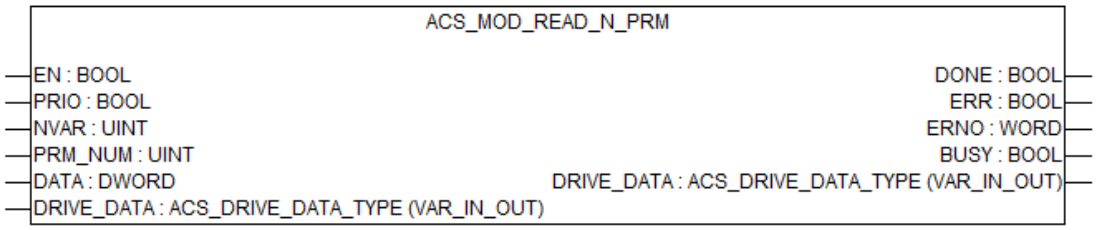
Data type: ACS_DRIVE_DATA_TYPE *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_RTU_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy)

Data type: BOOL

Output BUSY indicates whenever there is a communication action performed.

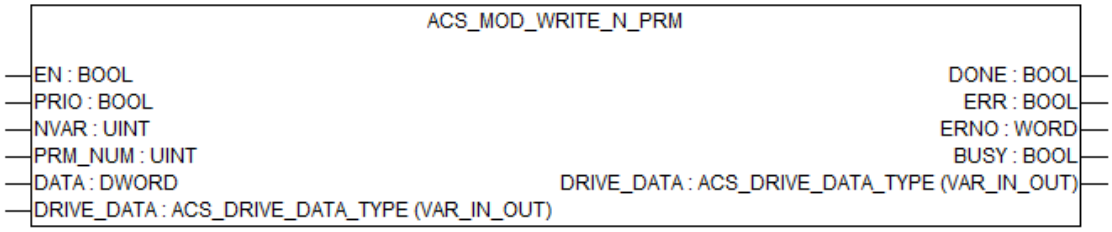
Function call in ST:

```
dwAcsModReadNPrm_DATA              := ADR(aiAcsModReadNPrm_VALUE[1]);

aiAcsModReadNPrm_DATA (EN          := xAcsModReadPrm_EN,
                       PRM_NUM     := uiAcsModReadPrm_PRM_NUM,
                       DATA        := dwAcsModReadNPrm_DATA,
                       DRIVE_DATA := tsDriveData);

xAcsModReadNPrm_DONE := AcsModReadNPrm.DONE;
xAcsModReadNPrm_ERR  := AcsModReadNPrm.ERR;
wAcsModReadNPrm_ERNO := AcsModReadNPrm.ERNO;
xAcsModReadNPrm_BUSY := AcsModReadNPrm.BUSY;
```

ACS_MOD_WRITE_N_PRM



Function block ACS_MOD_WRITE_N_PRM is used for writing n parameters to a drive via Modbus.

Function block information

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_MOD_WRITE_PRM writes n parameter to the drive. The number of parameters to be written is specified must be available in the PLC memory area, defined at the input DATA. The write job has been performed without error if DONE=TRUE and ERR=FALSE.

To start a new write job the input EN has to be set from FALSE to TRUE (edge sensitive).

The Modbus job is started from the Communication Block which is connected to the same DRIVE_DATA variable. It uses the Modbus function code 16 (Write n words).

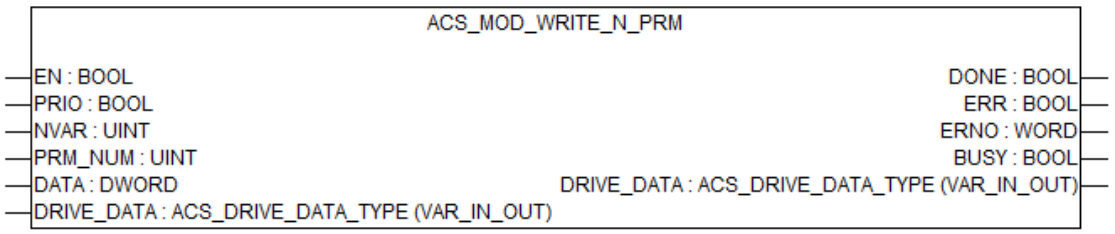
The drive (Modbus Slave) to which the parameter is written is specified at this communication block.

The communication blocks are available from other ACSDrivesComXXX libraries e.g. ACS3XX_COM_MOD_RTU *Chapter 1.5.6.3.5.1 “ACS3XX_COM_MOD_RTU communication for ACS3XXwrite one bit/ACX550 drives via Modbus RTU” on page 2293* in ACSDrivesComModRTU_AC500_V20.lib *Chapter 1.5.6.3 “ACS / DCS Drives communication via Modbus RTU library” on page 2288*. or ACS_COM_MOD_TCP_ENHANCED *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367* in ACSDrivesComModTCP_V22.lib *Chapter 1.5.6.4 “ACS / DCS drives communication via Modbus TCP library” on page 2359*. See description of these blocks for further information.

> *ACS drive parameters are only saved temporarily, if changed via fieldbus. To make these changes permanent in the drive the special parameter "PARAMETER SAVE" has to be set. Please see drive manuals and following table which parameter has to be set.*

Save valid parameters to permanent memory in drive	**ACS3XX, ACX550, ACQ810, ACS850, ACSM1, ACS800**	**ACS880**
1 = Saves the valid parameter values to permanent memory. 0 = Save completed.	Par 16.07 = 1	Par 96.07 = 1

Input description



EN (enable) Data type: BOOL

If a FALSE->TRUE edge is applied to input EN, all further inputs are read in (edge sensitive).

If the input values are valid, a request telegram is sent to the communication block via the DRIVE_DATA variable.

If at least 1 input is invalid, no telegram is generated and the error is displayed at the outputs ERR and ERNO instead.

While the request is processed, state changes at input EN are recognized but not evaluated.

PRIO (priority) Data type: BOOL

Input PRIO is reserved for future usage. It can be left open.

NVAR (number of variables)

Data type: UINT, Default value: 1, Range: 1 to 125

Input NVAR defines the number of variables to be read by the function block.

If the read job was finished successfully the first 15 parameter values are written to the internal array VALUE, which can be made visible in the visualization element ACS_MOD_READ_N_PRM_VISU_PH *Chapter 1.5.6.2.8.1 “ACS_MOD_READ_N_PRM_VISU_PH faceplate for the function block ACS_MOD_READ_N_PRM” on page 2256*or used via <instance of the function block>.VALUE[1..15].

PRM_NUM (parameter number)

Data type: UINT, Range 0 to 65535

For 16bit Parameters it is set in the format 100 * GG + ii as decimal integer value. (GG = parameter group, ii = parameter index of the drive, e.g. for parameter 12.02, 100 * GG + ii = 1202.)

(GG = parameter group, ii = parameter index of the drive)

For 32bit Parameters it must be set according to the formula 20000 + 200 x GG + 2 x ii.(see description of related drive fieldbus module), e.g. for parameter 14.54 = 22908.

This calculation is provided in the function ACS_MOD_PRM_NUM_32BIT *Chapter 1.5.6.2.4.3 “ACS_MOD_PRM_NUM_32BIT” on page 2219*, which output can then be connected to the PRM_NUM input. The Modbus address which is used at the Communication Block is PRM_NUM - 1.

The parameter number must be set prior or at the same cycle when input EN is set to TRUE.

The Modbus address which is used at the communication block is PRM_NUM - 1.

DATA (data)

Data type: DWORD

At input DATA, the address of the first operand in the PLC is specified to which the data read by the slave should be stored.

For this purpose it is necessary that all PLC variables, which are written to the drive, have consecutive addresses. This can be obtained by declaration of each variable within the %MW0.xxx area or declaration of an array containing all variables.

Declaration of each variable has the advantage, that the types (integer or word) can be selected individually.

DRIVE_DATA (drive data)

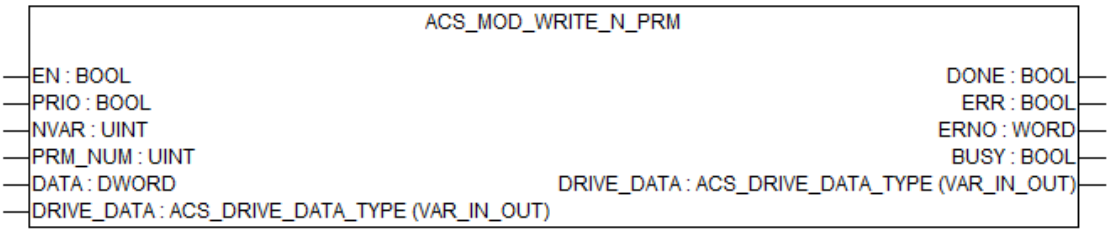
Data type: ACS_DRIVE_DATA_TYPE *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_RTU_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output description



DONE (done) Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy) Data type: BOOL

Output BUSY indicates whenever there is a communication action performed.

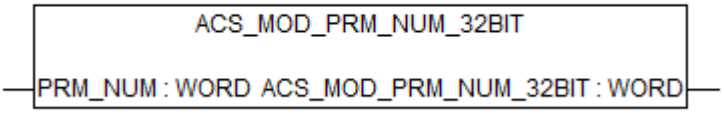
Function call in ST:

```
dwAcsModWriteNPrm_DATA := ADR(aiAcsModWriteNPrm_VALUE[1]);

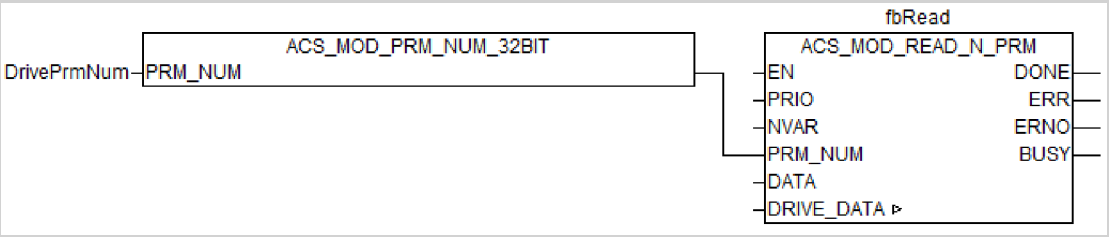
AcsModWriteNPrm (EN         := xAcsModWritePrm_EN,
                 PRM_NUM    := uiAcsModWritePrm_PRM_NUM,
                 DATA       := dwAcsModWriteNPrm_DATA,
                 DRIVE_DATA := tsDriveData);

xAcsModWritePrm_DONE := AcsModWritePrm.DONE;
xAcsModWritePrm_ERR  := AcsModWritePrm.ERR;
xAcsModWritePrm_ERNO := AcsModWritePrm.ERNO;
xAcsModWritePrm_BUSY := AcsModWritePrm.BUSY;
```

ACS_MOD_PRM_NUM_32BIT



Example



Function to create the Modbus address for a 32-bit parameter of ACSxxx drives.

Function information

Available as of runtime system:	V1.3.2 and above
Included in library:	ACSDrivesBase_AC500_V20.lib
Function type:	Function block with historical values.

Function description

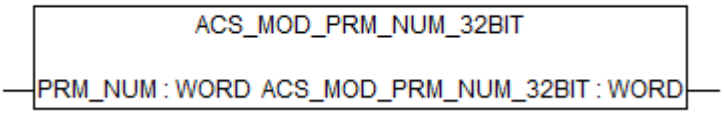
This function will create the Modbus address for 32-bit parameters of the ACSXXX / ACx550 drives using the format for 16 bit parameter as input.

Output is the calculated address for 32-bit parameters according the following rule:

ACS_MOD_PRM_NUM_32BIT = 20000 + (200 * GG) + (2 * ii)

Where GG = parameter group and ii = the index of input PRM_NUM in format of 4 digits: GGii.

Input description



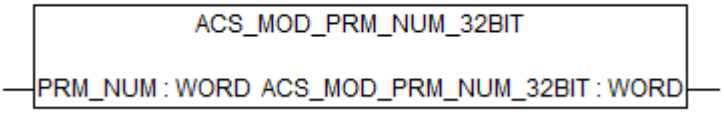
PRM_NUM (parameter number)

Data type: WORD

Input for function. Parameter number in format: 100 * GG + ii

(GG = parameter group, ii = parameter index of the drive, e.g. for parameter 12.02, 100 * GG + ii = 1202.)

Output description



ACS_MOD_PRM_NUM_32BIT (acs mod prm num 32 bit)

Data type: WORD

Output of function. Modbus address for 32-bit parameter access, which can be used at input PRM_NUM of ACS_MOD_READ_N_PRM *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212* or ACS_MOD_WRITE_N_PRM *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215*.

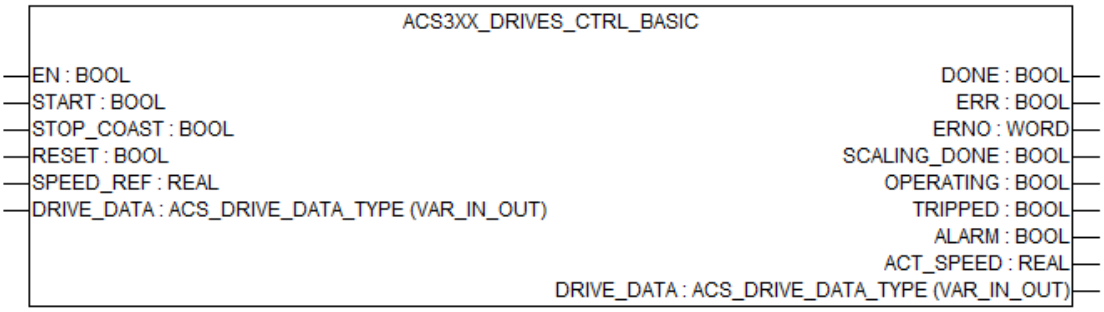
E.g. ACQ810 Par.14.54 (32-bit parameter) Modbus Address is 22908. This is the output of the function if PRM_NUM input is set to 1454.

Function call in ST

```
uiAcsModReadNPrm_PRM_NUM  := ACS_MOD_PRM_NUM_32BIT (

          PAR_NUM         := wAcsModPrmNum32Bit_PAR_NUM);
```

ACS3XX_DRIVES_CTRL_BASIC

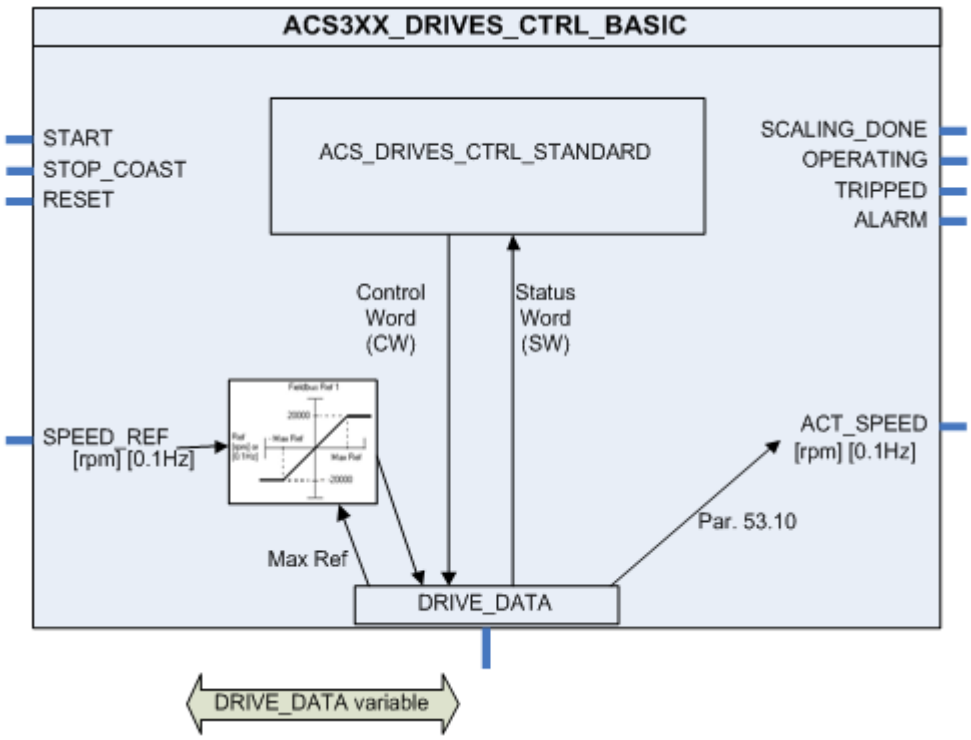


Function block ACS3XX_DRIVES_CTRL_BASIC is used for the control of ACS3XX and ACX550 drives with ABB Drives profile.

Function block information

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib
Function block type:	Function block with historical values

Block description



Function block ACS_DRIVES_CTRL_BASIC is used for controlling ACS3XX and ACX550 drives with ABB Drives profile.

The Function block provides basic start/stop signals, basic diagnosis signals and scaling of the SPEED_REF input and ACT_SPEED to the ACS fieldbus scaling range -20000 to +20000.

The scaling is done according to the drive parameter 11.05 (Ref1 Max) which is read automatically at the first start of the function block form the drive. A successful reading of this and some other configuration parameters is indicated by the output SCALING_DONE. These parameter values are available at the DRIVE_DATA variable element “config” e.g. tsDriveData.config. iRefScaleMax.

The function block internally calls the function block ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234* which is included in the same library.

If the connected communication block (via DRIVE_DATA variable) is disabled or not parametrized correctly all outputs except DONE, ERR and ERNO are reset to zero. This can be checked by the ERNO output.

PRECONDITIONS

The function block is only working for ACS3XX (ACS310, ACS350 and ACS355) and ACX550 (ACS550 and ACH550) drives via Modbus RTU communication.

> *This function block cannot be used with ACS380 drive.*
>
> *Instead for ACS380 drive use ACS_DRIVES_CTRL_STANDARD function block.*

The data transfer to the ACS3XX / ACX550 drive is realized via the IN_OUT variable DRIVE_DATA, which must be connected to a communication block such as ACS3XX_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.1 “ACS3XX_COM_MOD_RTU communication for ACS3XXwrite one bit/ACX550 drives via Modbus RTU” on page 2293* or an ACS_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.2 “ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU” on page 2301*, ACS_COM_MOD_RTU_ENHANCED ↳ *Chapter 1.5.6.3.5.3 “ACS_COM_MOD_RTU_ENHANCED communication for ACS drives*

via Modbus RTU using ABB drives profile enhanced" on page 2312, ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 "ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP" on page 2360*or ACS_COM_MOD_TCP_ENHANCED ↳ *Chapter 1.5.6.4.3.2 "ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP" on page 2367*.

The drive parameters to select the source of the Control Word must be set to fieldbus control. Also the source for reference 1 and the RESET signal must be set to fieldbus.

For an ACS3XX / ACX550 drive the setting must be as follows:

```
10.01 = 10          (EXT1 COMMANDS = COMM)

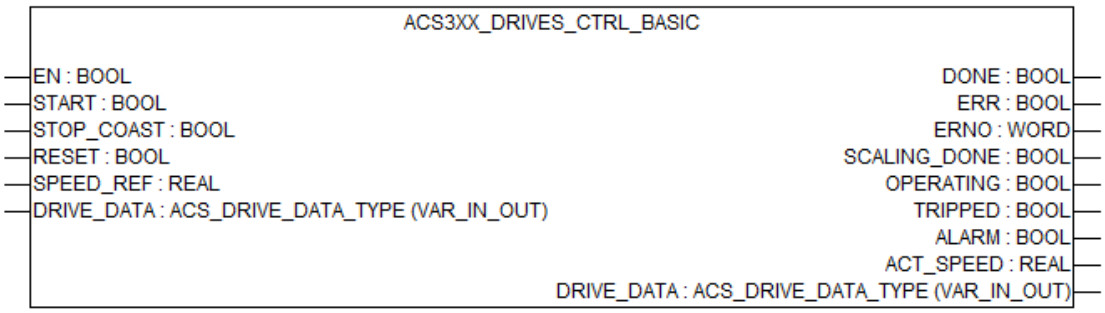
11.02 = 8           (EXT1/EXT2 SEL = COMM)

11.03 = 8           (REF1 SEL = COMM)

16.04 = 8           (FAULT RESET SEL = COMM)

53.05 = 2           (ABB drives profile)
```

Input description



EN (enable) Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the function block is active, the current values are available at the outputs.

If the function block has been deactivated, all outputs are set to 0.

After a rising edge (FALSE -> TRUE) of input EN some parameters are read from the ACS3XX / ACX550 drive. Included is parameter 11.05 which reflects the maximum speed reference value of the drive. After successful reading of the ACS3XX / ACX550 parameters output SCALING_DONE is set to TRUE.

START (start) Data type: BOOL

With a rising edge at input START (FALSE -> TRUE) the ACS Drive is started. If START = FALSE the drive is stopped along the normal stop ramp, defined in the drive (e.g. Par. 22.03 for ACS355).

> *According to the ABB Drives Profile a new rising edge of START input will be ignored by the drive until zero speed was reached.*

After an emergency stop of the drive a new rising edge of the START input is required to restart the drive.

STOP_COAST (stop coast)

Data type: BOOL

Input STOP_COAST = TRUE will coast the drive immediately (STOP_COAST = inverted Bit 3 of the Control Word – INHIBIT_OP). Setting STOP_COAST=FALSE will restart the drive immediately without need of an rising edge at input START.

RESET (reset)

Data type: BOOL

Input RESET is packed to bit 7 of the Control Word as long as input USE_CW=FALSE. RESET = TRUE resets faults and warnings in the drive. It does not reset the function block itself.

SPEED_REF (speed reference)

Data type: REAL

Input SPEED_REF must be given according to ACS3XX / ACX550 drive motor control mode. The motor control mode is set in the drive (e.g. Par. 99.04 for ACS355). In case of a scalar motor control mode (99.04 = 3 for ACS355) the input SPEED_REF reflects the frequency reference in 0.1 Hz (10 = 1Hz). In case of vector speed control mode (99.04 = 2 for ACS35) the input SPEED_REF reflects the speed reference in rpm.

The function block includes a linear scaling of input SPEED_REF to the fieldbus equivalent value between -20000 to +20000. 20000 = the value defined in the drive parameter 11.05 (Ref1 Max). This parameter 11.05 is automatically read by the function block after a rising edge is given at the input START.

The input range is from negative to positive value of maximum speed (Par.11.05 “Ref1 Max”), e.g. –1500 .. +1500 rpm.

If the input value exceeds the input range, the speed reference value is limited to maximum value. ERR is set to TRUE, ERNO is set to the message that the input of SPEED_REF is out of range. Nevertheless, the function block is processed normally.

DRIVE_DATA (drive data)

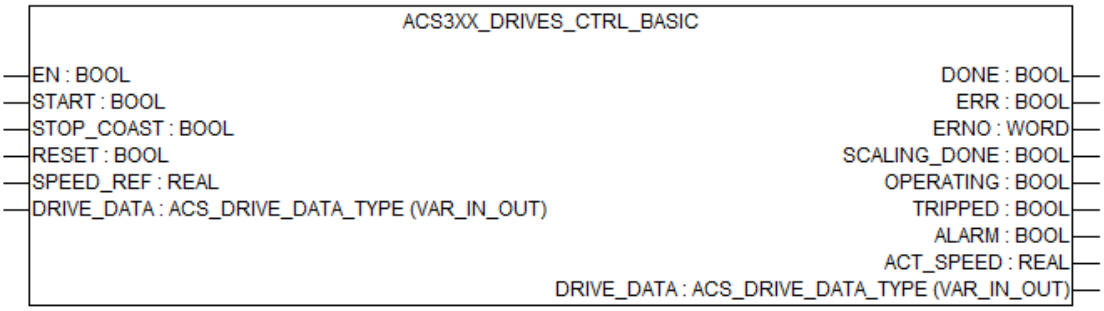
Data type: ACS_DRIVE_DATA_TYPE ↳ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_RTU_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

SCALING_DONE (scaling done)

Data type: BOOL

Output SCALING_DONE is set to TRUE when the reading of the scaling parameters from the ACS3XX / ACX550 drive has been finished. SCALING_DONE will be reset to FALSE if EN = FALSE. With a rising edge of EN the reading of the scaling parameters will be started. If the reading of a scaling parameter is not successful the ERR output is set to TRUE and the ERNO indicates that the reading of the scaling parameters was erroneous.

Scaling parameters for ACS3XX / ACX550 are written to the DRIVE_DATA variable structure under DRIVE_DATA.config (see description of DRIVE_DATA). They are only valid if SCALING_DONE = TRUE.

The parameters can be accessed via the DRIVE_DATA variable using the Point-Operator. Scaling parameters are Par.11.05 (Ref1 Max); Par 99.04 (Motor Ctrl Mode), Par 99.07 (Motor Nom Freq), Par. 99.08 (Motor Nom Speed).

OPERATING (operating)

Data type: BOOL

Output OPERATING=TRUE indicates that the drive is controlled by this function block. The drive is enabled and running (Status Word of drive bits: RDY_ON = TRUE, RDY_RUN = TRUE, RDY_REF = TRUE).

If the drive is controlled from another control place, e.g. local panel, output OPERATING is reset to FALSE, even if the drive might be enabled and running.

To get a control place independent indication, evaluate if the following bits of input SW are set: SW.0 AND SW.1 AND SW.2

TRIPPED (tripped)

Data type: BOOL

Output TRIPPED=TRUE indicates that the drive is tripped (Bit 3 in the Status Word from the drive).

ALARM (alarm)

Data type: BOOL

Output ALARM=TRUE indicates that the drive has an alarm (Bit 7 in the Status Word from the drive).

ACT_SPEED (actual speed)

Data type: REAL

Output ACT_SPEED returns the actual speed value from the drive. The scaling depends on the drive settings.

Drive	Fieldbus	Parameter Settings	Scaling
ACS3XX / ACX550	Modbus RTU	53.10=101	Actual speed [rpm] 1 = 1 rpm
ACS3XX / ACX550	Modbus RTU	53.10=103	Absolute frequency 10 = 1 Hz

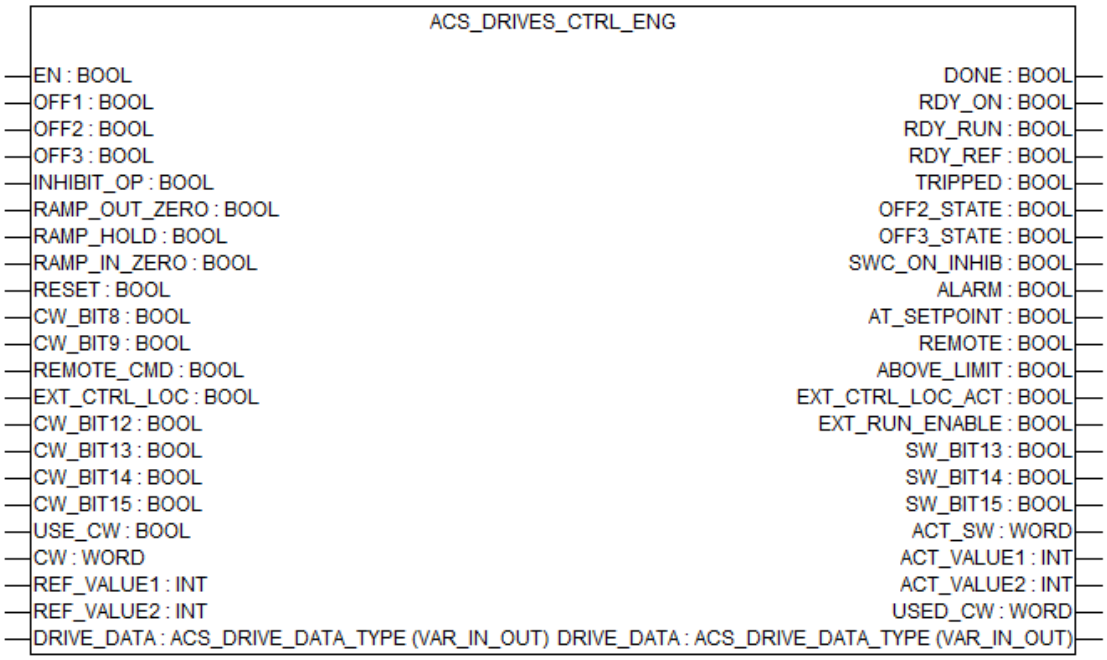
ACS_DRIVES_CTRL_ENG



Function block ACS_DRIVES_CTRL_ENG is used as an engineering interface for ACS Drives with ABB Drives profile.

Function block information

Available as of runtime system:	V1.3.2
Available as of runtime system:	ACSDrivesBase_AC500_V20.lib
Function block type	Function block with historical values

Block description

Function block ACS_DRIVES_CTRL_ENG is used as an engineering interface for ACS Drives with ABB Drives profile.

Inputs REF_VALUE1 and REF_VALUE2 and the generated Control Word are written to the DRIVE_DATA variable which transfers these values to a communication function block, e.g. ACS3XX_MOD-MAST_RTU. That communication function block writes them to the drive. In the same way ACT_VALUE1, ACT_VALUE2 and the Status Word are transferred from the communication function block to the ACS_DRIVES_CTRL_ENG block where they are written to the outputs.

As long as EN=FALSE no values are read nor written to the DRIVE_DATA variable.

The Control Word can be generated in 2 ways. First way is to set the single bits of the Control Word separately at the inputs OFF1 ... CW_BIT15 while the input USE_CW=FALSE. Second way is to set the input USE_CW=TRUE and write the Control Word as a whole word directly to the input CW. The generated Control Word is written to the DRIVE_DATA variable and for diagnosis purpose also available at output USED_CW.

PRECONDITIONS

The data transfer to the ACS drive is realized via the IN_OUT variable DRIVE_DATA, which must be connected to an ACS3XX_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.1 “ACS3XX_COM_MOD_RTU communication for ACS3XXwrite one bit/ACX550 drives via Modbus RTU” on page 2293*, ACS_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.2 “ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU” on page 2301*, ACS_COM_MOD_RTU_ENHANCED ↳ *Chapter 1.5.6.3.5.3 “ACS_COM_MOD_RTU_ENHANCED communication for ACS drives via Modbus RTU using ABB drives profile enhanced” on page 2312*, ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360* or ACS_COM_MOD_TCP_ENHANCED ↳ *Chapter*

1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367, ACS_COM_MOD_TCPx ↳ *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385* or ACS_COM_MOD_TCPx_ENHANCED ↳ *Chapter 1.5.6.5.3.2 “ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2392*.

Table 129: Necessary configuration of parameters in the drive

Drive Parameter	ACS3XX, ACX550	ACS850, ACQ810 embedded	ACS850, ACQ810	ACSM1	ACS580, ACS880	ACS800	Comment
EXT1 COMMANDS	10.01 = COMM	10.01 = FBA	10.01 = FB	10.01 = FBA	20.01 = Fieldbus A	10.01 = COMM.CW	Fieldbus interface as source for start and stop.

PROFILE	53.05 = ABB DRV FULL	58.06 = ABB Drives classic/ enhanced	51.02 = ABB Drives classic/ enhanced	51.02 = ABB Drives classic/ enhanced	51.02 = ABB Drives classic/ enhanced	98.07 = ABB DRIVES	Control Profile to ABB Drives Profile classic or enhanced.

Only one of the function blocks ACS3XX_DRIVES_CTRL_BASIC, ACS_DRIVES_CTRL_STANDARD or ACS_DRIVES_CTRL_ENG must be enabled (EN=TRUE) at the same time.

The data transfer to the ACS drive is realized via the IN_OUT variable DRIVE_DATA, which must be connected to an ACS3XX_COM_MOD_RTU or an ACS_COM_xxx function block.

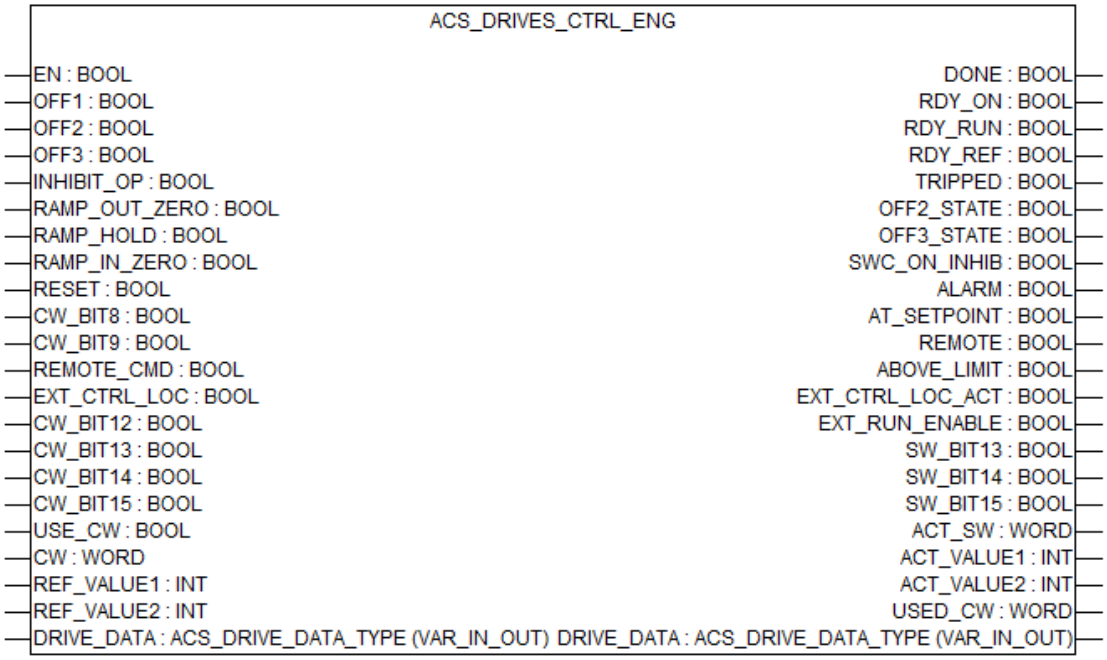
The input and output names of the bits of the Control Word and Status Word reflect the functions used with ABB Drive profile. So the block should be used with ABB Drives profile setting in the drive.

The function block does not execute any functionality expect data transfer to and from the DRIVE_DATA variable. So there is no special drive parameter setting necessary to use this block.

The programmer using this block should have a detailed understanding of how to set the Control Word according to the Status Word and the description of the used drive.

For standard speed & torque control application it is recommended to the use the ACS_DRIVES_CTRL_STANDARD instead.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable) Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the function block is active, the current values are available at the outputs.

If the function block has been deactivated, all outputs are set to 0, with the exception of the USED_CW output and the DRIVE_DATA.cw, which are set to 1024 (hex 0400 - only remote bit).

OFF1 (off1) Data type: BOOL

Input OFF1 is packed to bit 0 of the Control Word as long as input USE_CW=FALSE.

OFF2 (off2) Data type: BOOL

Input OFF2 is packed to bit 1 of the Control Word as long as input USE_CW=FALSE.

OFF3 (off3) Data type: BOOL

Input OFF3 is packed to bit 2 of the Control Word as long as input USE_CW=FALSE.

INHIBIT_OP (inhibit operation)
Data type: BOOL
Input INHIBIT_OP is packed to bit 3 of the Control Word as long as input USE_CW=FALSE.

RAMP_OUT_ZERO (ramp out zero)
Data type: BOOL
Input RAMP_OUT_ZERO is packed to bit 4 of the Control Word as long as input USE_CW=FALSE.

RAMP_HOLD (ramp hold)
Data type: BOOL
Input RAMP_HOLD is packed to bit 5 of the Control Word as long as input USE_CW=FALSE.

RAMP_IN_ZERO (ramp in zero)
Data type: BOOL
Input RAMP_IN_ZERO is packed to bit 6 of the Control Word as long as input USE_CW=FALSE.

RESET (reset)
Data type: BOOL
Input RESET is packed to bit 7 of the Control Word as long as input USE_CW=FALSE. RESET = TRUE resets faults and warnings in the drive. It does not reset the function block itself.

CW_BIT8 (control word bit 8)
Data type: BOOL
Input CW_BIT8 is packed to bit 8 of the Control Word as long as input USE_CW=FALSE.

CW_BIT9 (control word bit 9)
Data type: BOOL
Input CW_BIT9 is packed to bit 9 of the Control Word as long as input USE_CW=FALSE.

REMOTE (remote command)
Data type: BOOL
Input REMOTE_CMD is packed to bit 10 of the Control Word as long as input USE_CW=FALSE.

EXT_CTRL_LOC (external control location)
Data type: BOOL
Input EXT_CTRL_LOC is packed to bit 11 of the Control Word as long as input USE_CW=FALSE.

Input EXT_CTRL_LOC=TRUE sets the control place for the drive to EXT2 (Bit 11 in the Control Word to the drive). For normal control of the drive from the PLC EXT_CTRL_LOC should be set to FALSE.

CW_BIT12 (control word bit 12)
Data type: BOOL
Input CW_BIT12 is packed to bit 12 of the Control Word as long as input USE_CW=FALSE.

CW_BIT13 (control word bit 13)
Data type: BOOL
Input CW_BIT13 is packed to bit 13 of the Control Word as long as input USE_CW=FALSE.

CW_BIT14 (control word bit 14)
Data type: BOOL
Input CW_BIT14 is packed to bit 14 of the Control Word as long as input USE_CW=FALSE.

CW_BIT15 (control word bit 15)

Data type: BOOL

Input CW_BIT15 is packed to bit 15 of the Control Word as long as input USE_CW=FALSE.

USE_CW (use control word)

Data type: WORD

Output USED_CW shows the used Control Word which is written to the DRIVE_DATA variable.

E.g. the packed word from the input bits OFF1 .. CW_BIT15 if USE_CW=FALSE.

CW (control word)

Data type: WORD

Input CW is written to the DRIVE_DATA variable as Control Word as long as USE_CW=TRUE.

REF_VALUE1 (reference value 1)

Data type: INT

Input REF_VALUE1 is written to the DRIVE_DATA variable as Reference Value 1 (SPEED_REF).

REF_VALUE2 (reference value 2)

Data type: INT

Input REF_VALUE2 is written to the DRIVE_DATA variable as Reference Value 2. Input REF_VALUE2 must be given in fieldbus equivalent value between -10000 .. +10000. 10000 = the value defined in the drive as Ref2 Max (e.g. Par.11.08 Ref2 Max for ACS3XX or Par Gr. 32.for ACSM1).

DRIVE_DATA (drive data)

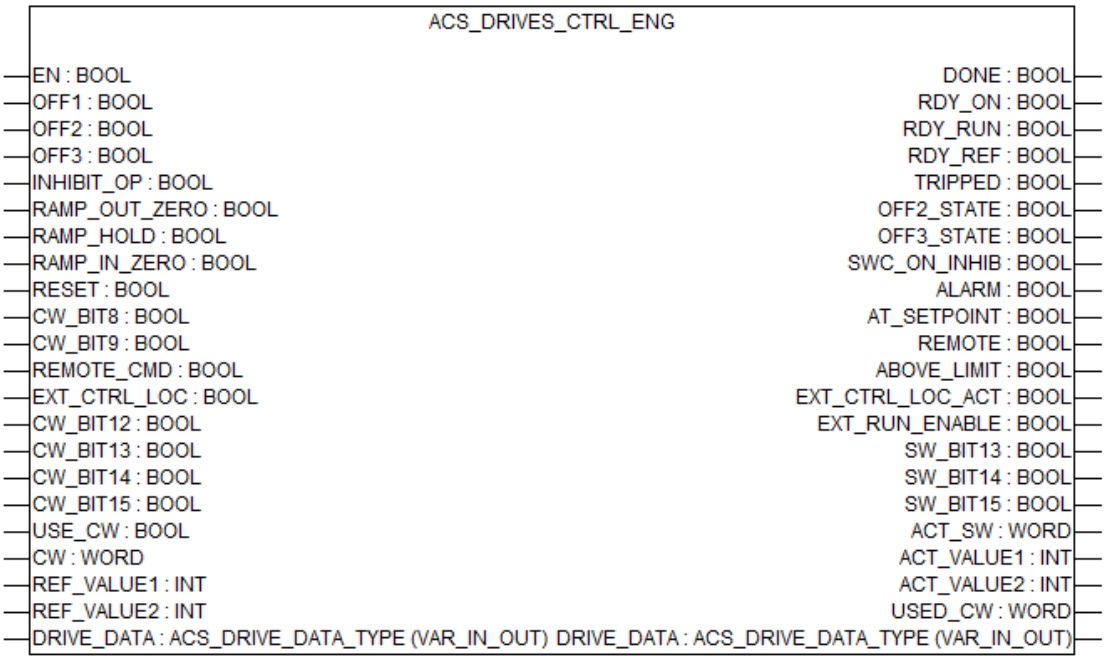
Data type: ACS_DRIVE_DATA_TYPE ↯ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_RTU_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

RDY_ON (ready on)

Data type: BOOL

Output RDY_ON is bit 0 of actual Status Word from the drive.

RDY_RUN (ready run)

Data type: BOOL

Output RDY_RUN is bit 1 of actual Status Word from the drive.

RDY_REF

Data type: BOOL

Output RDY_REF (ready reference) is bit 2 of actual Status Word from the drive.

TRIPPED (tripped)

Data type: BOOL

Output TRIPPED=TRUE indicates that the drive is tripped (Bit 3 in the Status Word from the drive).

OFF2_STATE (off state 2)

Data type: BOOL

Output OFF_STATE2 is bit 4 of actual Status Word from the drive.

OFF3_STATE (off state 3)

Data type: BOOL

Output OFF_STATE3 is bit 5 of actual Status Word from the drive.

SWC_ON_INHIB (switch on inhibit) Data type: Bool

Output SWC_ON_INHIB is bit 6 of actual Status Word from the drive.

ALARM (alarm) Data type: BOOL

Output ALARM=TRUE indicates that the drive has an alarm (Bit 7 in the Status Word from the drive).

AT_SETPOINT (actual tolerance setpoint) Data type: BOOL

Output AT_SETPOINT is bit 8 of actual Status Word from the drive.

REMOTE (remote) Data type: BOOL

Output REMOTE is bit 9 of actual Status Word from the drive.

ABOVE_LIMIT (above limit) Data type: BOOL

Output ABOVE_LIMIT is bit 10 of actual Status Word from the drive.

EXT_CTRL_LOC_ACT (external control location active) Data type: BOOL

Output EXT_CTRL_LOC_ACT is bit 11 of actual Status Word from the drive. Output EXT_CTRL_LOC_ACT = TRUE indicates that the drive is controlled from the control place EXT2 (Bit 11 in Status Word from the drive). EXT_CTRL_LOC_ACT might be set to TRUE due to the input EXT_CTRL_LOC = TRUE.

EXT_RUN_ENABLE (external run enable) Data type: BOOL

Output EXT_RUN_ENABLE is bit 12 of actual Status Word from the drive. Output EXT_RUN_ENABLE=TRUE indicates that the drive received External Run Enable signal. For normal control of the drive from the PLC EXT_RUN_ENABLE must be set to TRUE.

SW_BIT13 (status word bit 13) Data type: BOOL

Output SW_BIT13 is bit 13 of actual Status Word from the drive.

SW_BIT14 (status word bit 14) Data type: BOOL

Output SW_BIT14 is bit 14 of actual Status Word from the drive.

SW_BIT15 (status word bit 15) Data type: BOOL

Output SW_BIT15 is bit 15 of actual Status Word from the drive.

ACT_SW (actual status word) Data type: WORD

Output ACT_SW is the actual Status Word from the drive.

ACT_VALUE1 (actual value 1) Data type: INT

Output ACT_VALUE1 is the Actual Value 1 (actual speed value) from the drive.

ACT_VALUE2 (actual value 2)

Data type: INT

Output ACT_VALUE2 is the Actual Value 2 from the drive.

USED_CW (used control word)

Data type: WORD

Output USED_CW shows the used Control Word which is written to the DRIVE_DATA variable.

E.g. the packed word from the input bits OFF1 .. CW_BIT15 if USE_CW=FALSE.

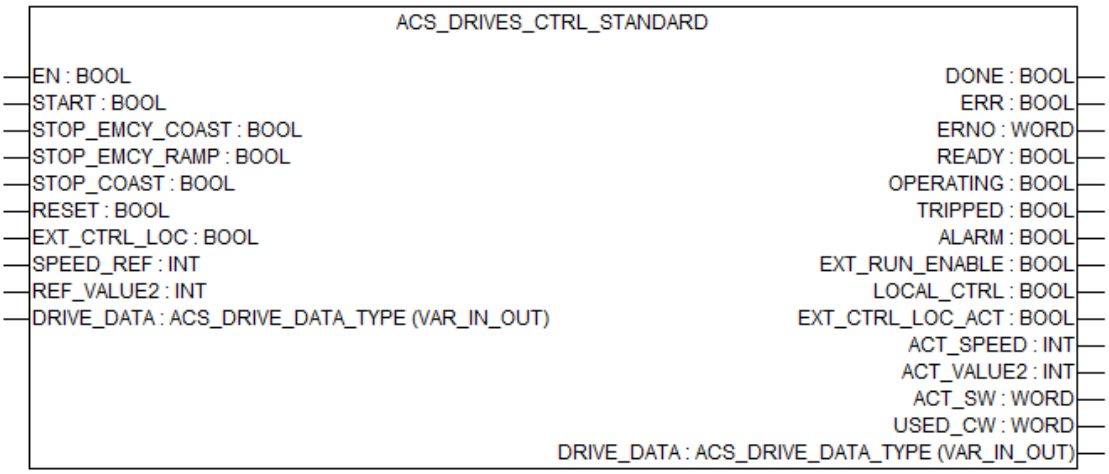
ACS_DRIVES_CTRL_STANDARD

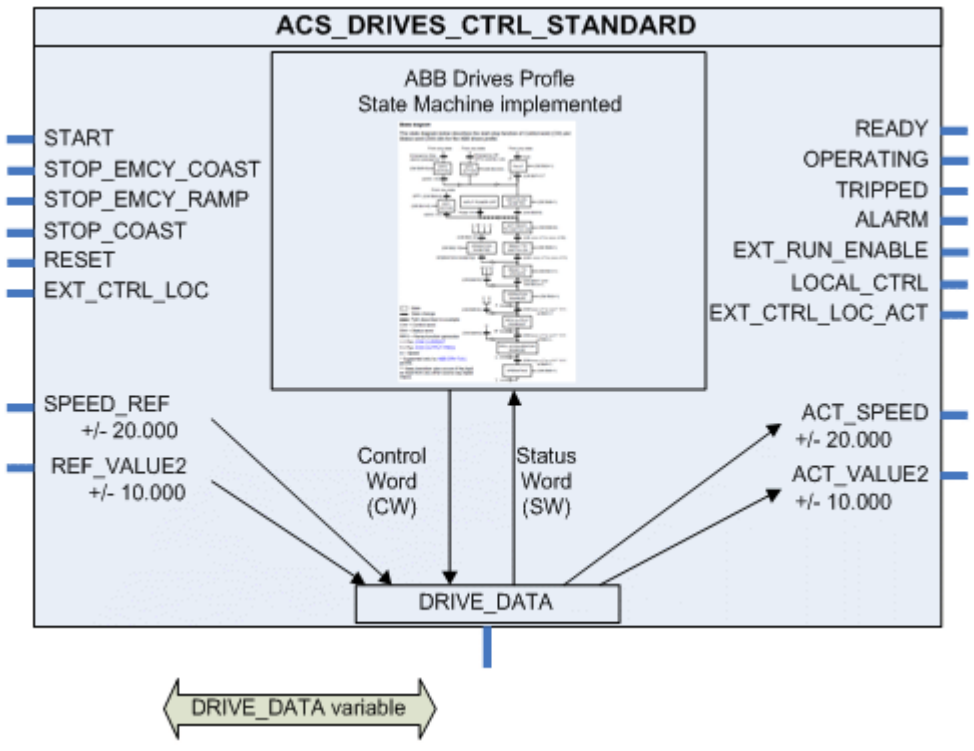


Function block ACS_DRIVES_CTRL_STANDARD is used for controlling ACS Drives with ABB Drives profile.

Function block information

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib
Function block type	Function block with historical values

Block description



Function block ACS_DRIVES_CTRL_STANDARD is used for controlling ACS Drives with ABB Drives profile.

The function block provides standard start/stop signals to control the drive and standard diagnosis signals read from the drive.

According to the start/stop input signals and the actual Status Word (SW), read from the DRIVE_DATA variable, the ABB Drives profile state machine is executed. The Control Word (CW) is built and written to the DRIVE_DATA variable. For diagnosis purpose the CW is also written to the output USED_CW.

SPEED_REF input has to be given in the ACS fieldbus range.of -20000 .. +20000, according to the scaling parameter in the drive (e.g. Par. 11.05 of ACS355)

ACT_SPEED provides the actual speed in the ACS fieldbus range of -20000 .. +20000, according to the scaling parameter in the drive (e.g. Par. 11.05 of ACS355).

ACS_REF_SCALING *Chapter 1.5.6.2.4.8 “ACS_REF_SCALING” on page 2246* function block could be used to scale the fieldbus range to a physical value.

If the connected communication block (via DVIVE_DATA variable) is disabled or not parameterized correctly all outputs except DONE, ERR and ERNO are reset to zero. This can be checked by the ERNO output.

PRECONDITIONS

The function block is only working for ACS drives using ABB Drive profile.

The data transfer to the ACS drive is realized via the IN_OUT variable DRIVE_DATA, which must be connected to an ACS3XX_COM_MOD_RTU *Chapter 1.5.6.3.5.1 “ACS3XX_COM_MOD_RTU communication for ACS3XXwrite one bit/ACX550 drives via Modbus RTU” on page 2293*, ACS_COM_MOD_RTU *Chapter 1.5.6.3.5.2 “ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU” on page 2301*, ACS_COM_MOD_RTU_ENHANCED *Chapter 1.5.6.3.5.3 “ACS_COM_MOD_RTU_ENHANCED communication for ACS drives via Modbus RTU using ABB drives profile enhanced” on page 2312*, ACS_COM_MOD_TCP *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*, ACS_COM_MOD_TCP_ENHANCED *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367*, ACS_COM_MOD_TCPx *Chapter 1.5.6.5.3.1 “ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP” on page 2385* or ACS_COM_MOD_TCPx_ENHANCED *Chapter 1.5.6.5.3.2 “ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2392*.

Please refer the respective drives manual for parameter setting if the drive is not mentioned in below table.

Table 130: Necessary configuration of parameters in the drive

Drive Parameter	ACS3XX, ACX550	ACS850, ACQ810 embedded	ACS850, ACQ810	ACSM1	ACS580, ACS880	ACS800	Comment

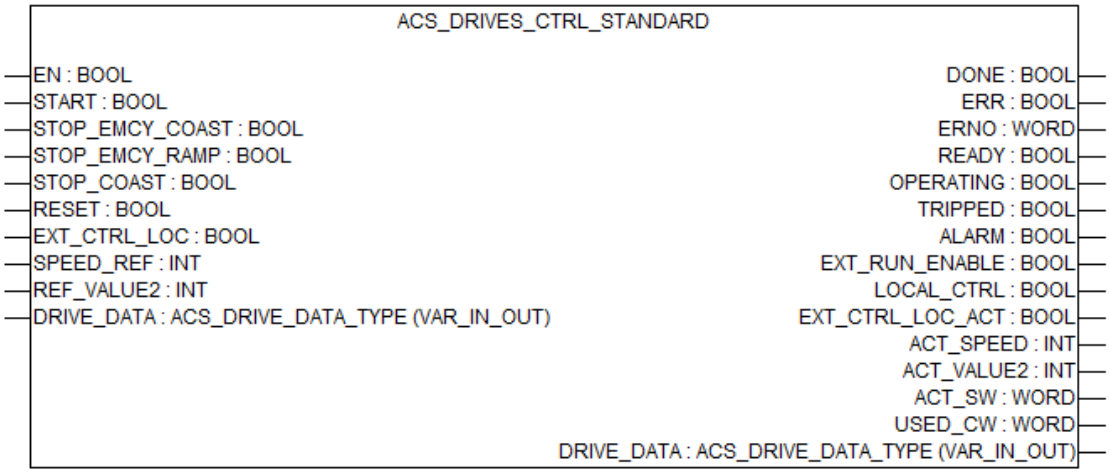
REF1 SELECT	11.03 = COMM	21.01 = EFB REF1	21.01 = FBA REF1	24.01 = FBA Ref1	22.11 = FBA ref1	11.03 = COMM.REF	Fieldbus interface as source for speed reference

Drive Parameter	ACS3XX, ACX550	ACS850, ACQ810 embedded	ACS850, ACQ810	ACSM1	ACS580, ACS880	ACS800	Comment
FAULT RESET SEL	16.04 = COMM	10.10 = P.02.36 bit 8	10.10 = P.02.22 bit 8	10.08 = P.02.12 bit 8	31.11 = P.06.01 bit 7	16.04 = COMM.CW	Fieldbus interface as source for fault reset
PROFILE	53.05 = ABB DRV FULL	58.06 = ABB Drives classic/ enhanced	51.02 = ABB Drives classic/ enhanced	51.02 = ABB Drives classic/ enhanced	51.02 = ABB Drives classic/ enhanced	98.07 = ABB DRIVES	Control Profile to ABB Drives Profile classic or enhanced.

Only one of the function blocks ACS3XX_DRIVES_CTRL_BASIC, ACS_DRIVES_CTRL_STANDARD or ACS_DRIVES_CTRL_ENG must be enabled (EN=TRUE) at the same time.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable) Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the function block is active, the current values are available at the outputs.

If the function block has been deactivated, all outputs are set to 0, with the exception of the USED_CW output and the DRIVE_DATA.cw, which are set to 1024 (hex 0400 - only remote bit).

START (start) Data type: BOOL

With a rising edge at input START (FALSE -> TRUE) the ACS Drive is started. If START = FALSE the drive is stopped along the normal stop ramp, defined in the drive (e.g. Par. 22.03 for ACS355).

According to the ABB Drives Profile a new rising edge of START input will be ignored by the drive until zero speed was reached.

After an emergency stop of the drive a new rising edge of the START input is required to restart the drive.

STOP_EMCY_COAST (stop emergency coast)

Data type: BOOL

Input STOP_EMCY_COAST=FALSE will coast the drive (bit 1 of the Control Word OFF2). A new rising edge of the START input is needed to start the drive again.

STOP_EMCY_COAST=TRUE enables normal operation of the drive.

Default value = TRUE.

STOP_EMCY_RAMP (stop emergency ramp)

Data type: BOOL

Input STOP_EMCY_RAMP = FALSE will stop the drive along the emergency ramp, defined in the drive (bit 2 of the Control Word OFF3). A new rising edge of the START input is needed to start the drive again.

STOP_EMCY_RAMP = TRUE enables normal operation of the drive.

Default value = TRUE.

STOP_COAST (stop coast)

Data type: BOOL

Input STOP_COAST = TRUE will coast the drive immediately (STOP_COAST = inverted Bit 3 of the Control Word – INHIBIT_OP). Setting STOP_COAST=FALSE will restart the drive immediately without need of an rising edge at input START.

RESET (reset)

Data type: BOOL

Input RESET is packed to bit 7 of the Control Word as long as input USE_CW=FALSE. RESET = TRUE resets faults and warnings in the drive. It does not reset the function block itself.

EXT_CTRL_LOC (external control location)

Data type: BOOL

Input EXT_CTRL_LOC is packed to bit 11 of the Control Word as long as input USE_CW=FALSE.

Input EXT_CTRL_LOC=TRUE sets the control place for the drive to EXT2 (Bit 11 in the Control Word to the drive). For normal control of the drive from the PLC EXT_CTRL_LOC should be set to FALSE.

SPEED_REF (speed reference)

Data type: REAL

Input SPEED_REF must be given according to ACS3XX / ACX550 drive motor control mode. The motor control mode is set in the drive (e.g. Par. 99.04 for ACS355). In case of a scalar motor control mode (99.04 = 3 for ACS355) the input SPEED_REF reflects the frequency reference in 0.1 Hz (10 = 1Hz). In case of vector speed control mode (99.04 = 2 for ACS35) the input SPEED_REF reflects the speed reference in rpm.

The function block includes a linear scaling of input SPEED_REF to the fieldbus equivalent value between -20000 to +20000. 20000 = the value defined in the drive parameter 11.05 (Ref1 Max). This parameter 11.05 is automatically read by the function block after a rising edge is given at the input START.

The input range is from negative to positive value of maximum speed (Par.11.05 “Ref1 Max”), e.g. –1500 .. +1500 rpm.

If the input value exceeds the input range, the speed reference value is limited to maximum value. ERR is set to TRUE, ERNO is set to the message that the input of SPEED_REF is out of range. Nevertheless, the function block is processed normally.

REF_VALUE2 (reference value 2)

Data type: INT

Input REF_VALUE2 is written to the DRIVE_DATA variable as Reference Value 2. Input REF_VALUE2 must be given in fieldbus equivalent value between -10000 .. +10000. 10000 = the value defined in the drive as Ref2 Max (e.g. Par.11.08 Ref2 Max for ACS3XX or Par Gr. 32.for ACSM1).

DRIVE_DATA (drive data)

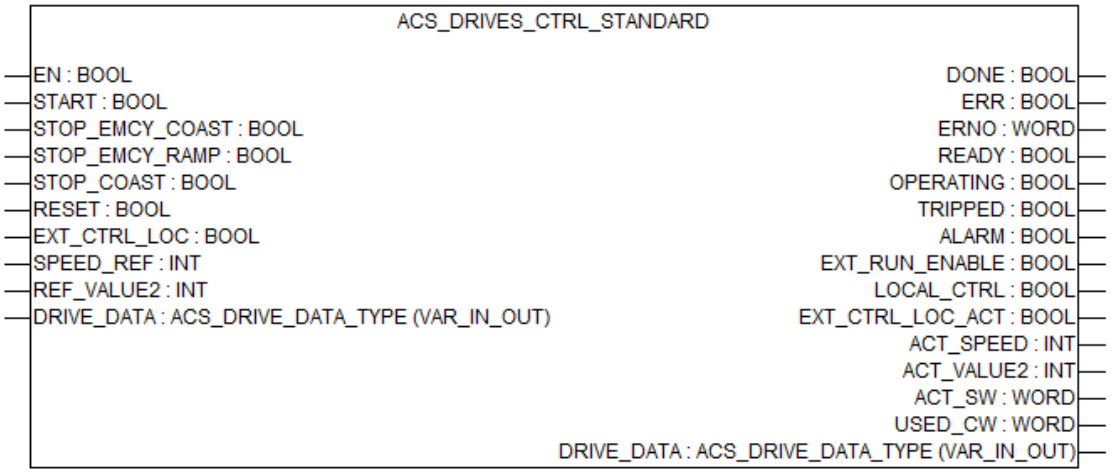
Data type: ACS_DRIVE_DATA_TYPE *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_RTU_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

READY (ready)

Data type: BOOL

Output READY=TRUE indicates that the drive is ready to switch on (Bit 0 in the status word from the drive).

OPERATING (operating)

Data type: BOOL

Output OPERATING=TRUE indicates that the drive is controlled by this function block. The drive is enabled and running (Status Word of drive bits: RDY_ON = TRUE, RDY_RUN = TRUE, RDY_REF = TRUE).

If the drive is controlled from another control place, e.g. local panel, output OPERATING is reset to FALSE, even if the drive might be enabled and running.

To get a control place independent indication, evaluate if the following bits of input SW are set: SW.0 AND SW.1 AND SW.2

TRIPPED (tripped)

Data type: BOOL

Output TRIPPED=TRUE indicates that the drive is tripped (Bit 3 in the Status Word from the drive).

ALARM (alarm)

Data type: BOOL

Output ALARM=TRUE indicates that the drive has an alarm (Bit 7 in the Status Word from the drive).

EXT_RUN_ENABLE (external run enable)

Data type: BOOL

Output EXT_RUN_ENABLE is bit 12 of actual Status Word from the drive. Output EXT_RUN_ENABLE=TRUE indicates that the drive received External Run Enable signal. For normal control of the drive from the PLC EXT_RUN_ENABLE must be set to TRUE.

LOCAL_CTRL (local control)

Data type: BOOL

Output LOCAL_CTRL = TRUE indicates that the drive is not controlled from remote control e.g. PLC (LOCAL_CTRL = inverted bit 9 in the Status Word from the drive - REMOTE). LOCAL_CTRL might be set to TRUE due to no connection to the drive or the drive was set to local control via the drive panel or a drive configuration tool from PC.

EXT_CTRL_LOC_ACT (external control location active)

Data type: BOOL

Output EXT_CTRL_LOC_ACT is bit 11 of actual Status Word from the drive. Output EXT_CTRL_LOC_ACT = TRUE indicates that the drive is controlled from the control place EXT2 (Bit 11 in Status Word from the drive). EXT_CTRL_LOC_ACT might be set to TRUE due to the input EXT_CTRL_LOC = TRUE.

ACT_SPEED (actual speed)

Data type: INT, Range: -20000 .. +20000

Output ACT_SPEED returns the actual speed value from the drive. The scaling depends on the drive settings.

Drive	Fieldbus	Parameter Settings	Scaling
ACS3XX / ACX550	Modbus RTU	53.10=101	Actual speed [rpm] 1 = 1 rpm
ACS3XX / ACX550	Modbus RTU	53.10=103	Absolute frequency 10 = 1 Hz

ACT_VALUE2 (actual value 2)

Data type: INT

Output ACT_VALUE2 is the Actual Value 2 from the drive.

ACT_SW (actual status word)

Data type: WORD

Output ACT_SW is the actual Status Word from the drive.

USED_CW (used control word)

Data type: WORD

Output USED_CW shows the used Control Word which is written to the DRIVE_DATA variable.

E.g. the packed word from the input bits OFF1 .. CW_BIT15 if USE_CW=FALSE.

```

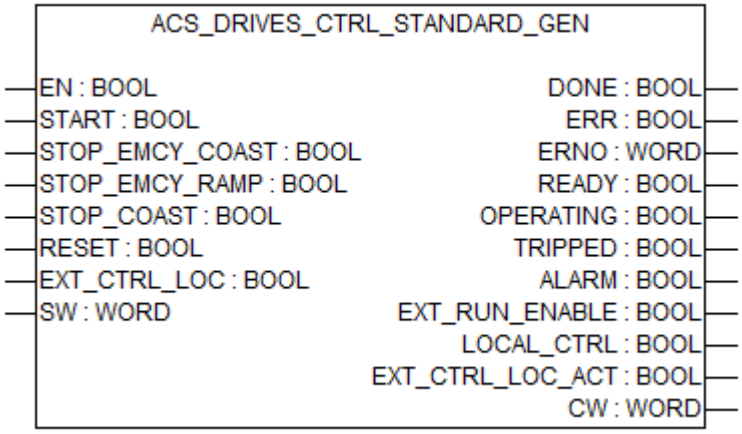
ACS_DRIVES_CTRL_STANDARD_GEN

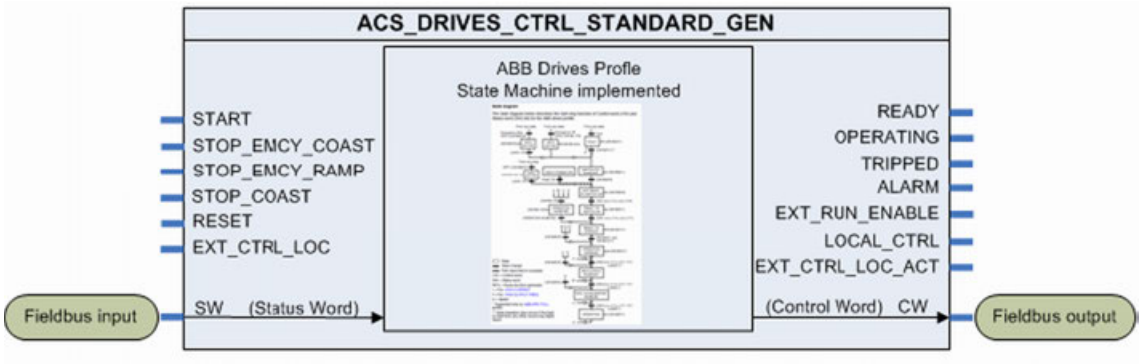


Function block ACS_DRIVES_CTRL_STANDARD_GEN is used for controlling ACS Drives with ABB Drives profile. The Status Word (SW) and Control Word (CW) can be transferred via any generic fieldbus.

Function block information

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib
Function block type	Function block with historical values

Block description



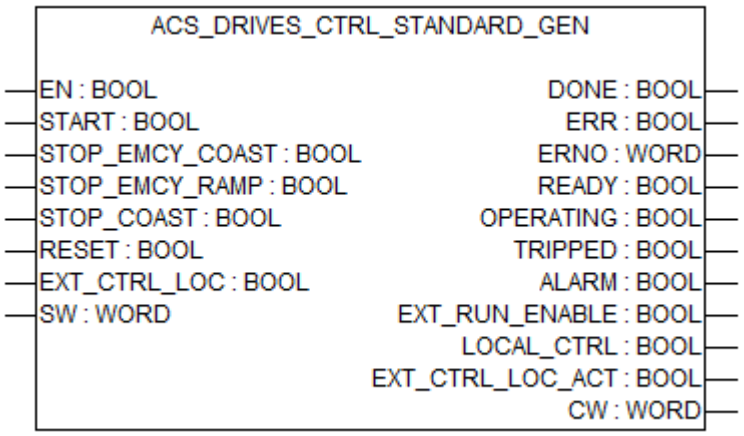
Function block ACS_DRIVES_CTRL_STANDARD_GEN is used for controlling ACS Drives with ABB Drives profile. User has to connect Status Word from the fieldbus to this function block input. Function block generates Control Word, which has to be connected to the fieldbus.

Please refer the respective drives manual for parameter setting, if the drive is not mentioned in below table.

Table 131: Necessary configuration of parameters in the drive

Drive Parameter	ACS3XX, ACX550	ACS850, ACQ810	ACSM1	ACS580, ACS880	ACS800	Comment
EXT1 COM-MANDS	10.01 = COMM	10.01 = FB	10.01 = FBA	20.01 = Fieldbus A	10.01 = COMM.CW	Fieldbus interface as source for start and stop
EXT1/EXT2 SEL	11.02 = COMM	12.01 = P.02.22 bit 15	34.01 = P.02.12 bit 15	19.11 = MCW Bit11 (06.01)	11.02 = COMM.CW	Fieldbus interface as source to switch to EXT2 con-trol place
REF1 SELECT	11.03 = COMM	21.01 = FBA REF1	24.01 = FBA Ref1	22.11 = FBA ref1	11.03 = COMM.REF	Fieldbus interface as source for speed refer-ence
FAULT RESET SEL	16.04 = COMM	10.10 = P.02.22 bit 8	10.08 = P.02.12 bit 8	31.11 = P.06.01 bit 7	16.04 = COMM.CW	Fieldbus interface as source for fault reset
PROFILE	53.05 = ABB DRV FULL	51.02 = ABB Drives classic/ enhanced	51.02 = ABB Drives classic/ enhanced	51.02 = ABB Drives classic/ enhanced	98.07 = ABB DRIVES	Control Pro-file to ABB Drives Pro-file classic or enhanced.

Input description



EN (enable)

Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the function block is active, the current values are available at the outputs.

If the function block has been deactivated, all outputs are set to 0, with the exception of the CW output to 1024 (hex 0400 - only remote bit).

START (start)

Data type: BOOL

With a rising edge at input START (FALSE -> TRUE) the ACS Drive is started. If START = FALSE the drive is stopped along the normal stop ramp, defined in the drive (e.g. Par. 22.03 for ACS355).

According to the ABB Drives Profile a new rising edge of START input will be ignored by the drive until zero speed was reached.

After an emergency stop of the drive a new rising edge of the START input is required to restart the drive.

STOP_EMCY_COAST (stop emergency coast)

Data type: BOOL

Input STOP_EMCY_COAST=FALSE will coast the drive (bit 1 of the Control Word OFF2). A new rising edge of the START input is needed to start the drive again.

STOP_EMCY_COAST=TRUE enables normal operation of the drive.

Default value = TRUE.

STOP_EMCY_RAMP (stop emergency ramp)

Data type: BOOL

Input STOP_EMCY_RAMP = FALSE will stop the drive along the emergency ramp, defined in the drive (bit 2 of the Control Word OFF3). A new rising edge of the START input is needed to start the drive again.

STOP_EMCY_RAMP = TRUE enables normal operation of the drive.

Default value = TRUE.

STOP_COAST (stop coast)

Data type: BOOL

Input STOP_COAST = TRUE will coast the drive immediately (STOP_COAST = inverted Bit 3 of the Control Word – INHIBIT_OP). Setting STOP_COAST=FALSE will restart the drive immediately without need of an rising edge at input START.

RESET (reset)

Data type: BOOL

Input RESET is packed to bit 7 of the Control Word as long as input USE_CW=FALSE. RESET = TRUE resets faults and warnings in the drive. It does not reset the function block itself.

EXT_CTRL_LOC (external control location)

Data type: BOOL

Input EXT_CTRL_LOC is packed to bit 11 of the Control Word as long as input USE_CW=FALSE.

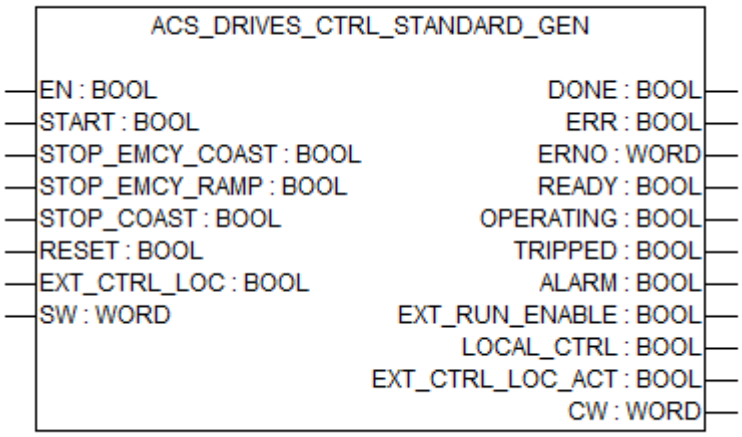
Input EXT_CTRL_LOC=TRUE sets the control place for the drive to EXT2 (Bit 11 in the Control Word to the drive). For normal control of the drive from the PLC EXT_CTRL_LOC should be set to FALSE.

SW (status word)

Data type: WORD

Status Word from drive. Connect Status Word from fieldbus to this input.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

READY (ready)

Data type: BOOL

Output READY=TRUE indicates that the drive is ready to switch on (Bit 0 in the status word from the drive).

OPERATING (operating)

Data type: BOOL

Output OPERATING=TRUE indicates that the drive is controlled by this function block. The drive is enabled and running (Status Word of drive bits: RDY_ON = TRUE, RDY_RUN = TRUE, RDY_REF = TRUE).

If the drive is controlled from another control place, e.g. local panel, output OPERATING is reset to FALSE, even if the drive might be enabled and running.

To get a control place independent indication, evaluate if the following bits of input SW are set: SW.0 AND SW.1 AND SW.2

TRIPPED (tripped)

Data type: BOOL

Output TRIPPED=TRUE indicates that the drive is tripped (Bit 3 in the Status Word from the drive).

ALARM (alarm)

Data type: BOOL

Output ALARM=TRUE indicates that the drive has an alarm (Bit 7 in the Status Word from the drive).

EXT_RUN_ENABLE (external run enable)

Data type: BOOL

Output EXT_RUN_ENABLE is bit 12 of actual Status Word from the drive. Output EXT_RUN_ENABLE=TRUE indicates that the drive received External Run Enable signal. For normal control of the drive from the PLC EXT_RUN_ENABLE must be set to TRUE.

LOCAL_CTRL (local control)

Data type: BOOL

Output LOCAL_CTRL = TRUE indicates that the drive is not controlled from remote control e.g. PLC (LOCAL_CTRL = inverted bit 9 in the Status Word from the drive - REMOTE). LOCAL_CTRL might be set to TRUE due to no connection to the drive or the drive was set to local control via the drive panel or a drive configuration tool from PC.

EXT_CTRL_LOC_ACT (external control location active)

Data type: BOOL

Output EXT_CTRL_LOC_ACT is bit 11 of actual Status Word from the drive. Output EXT_CTRL_LOC_ACT = TRUE indicates that the drive is controlled from the control place EXT2 (Bit 11 in Status Word from the drive). EXT_CTRL_LOC_ACT might be set to TRUE due to the input EXT_CTRL_LOC = TRUE.

CW (control word)

Data type: WORD

Input CW is written to the DRIVE_DATA variable as Control Word as long as USE_CW=TRUE.

```

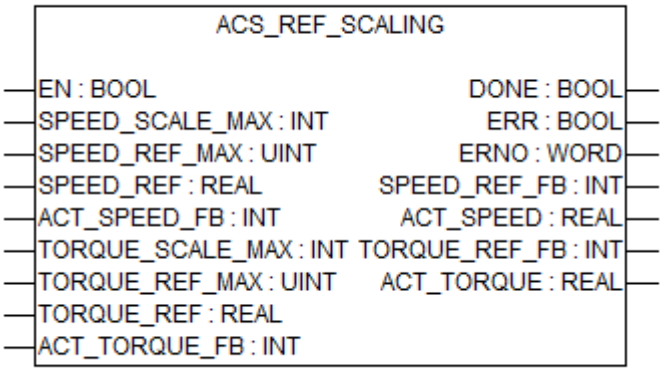
ACS_REF_SCALING

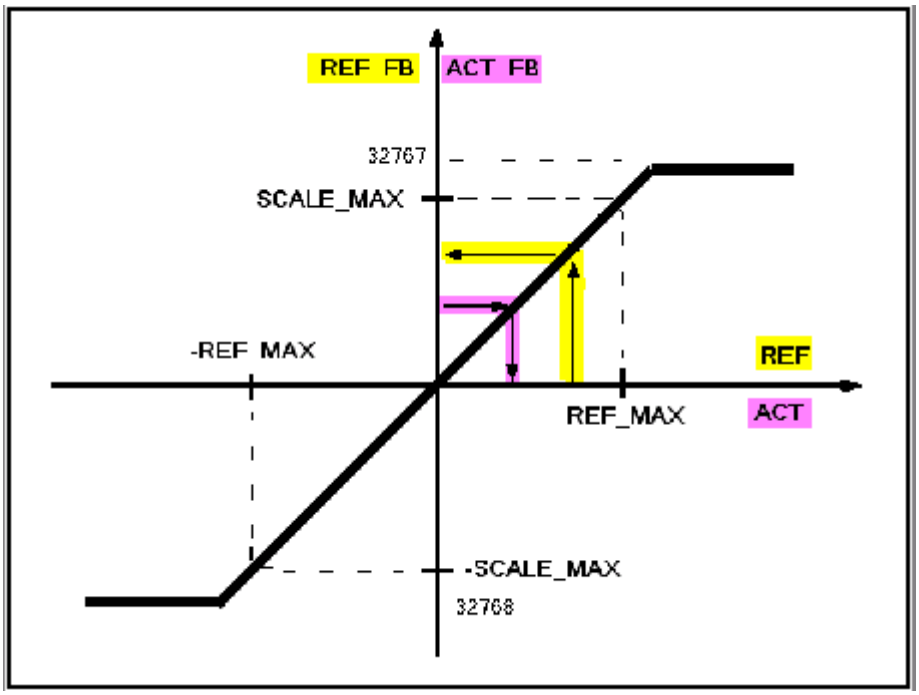


Function block ACS_REF_SCALING is used for scaling of fieldbus integer reference and actual values to real values.

Function block information

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib
Function block type:	Function block with historical values

Block description



Function block ACS_REF_SCALING can be used to scale the variables from fieldbus equivalent values to values used in the program. With the scaling also a conversion from INT to REAL is performed.

Fieldbus variables are mostly given in fieldbus equivalent values as INT values.

Reference1 and Actual Value1 (speed) are mostly given in the range of -20000 .. + 20000.

Reference2 and Actual Value2 (torque) are mostly given in the range of -10000 .. + 10000.

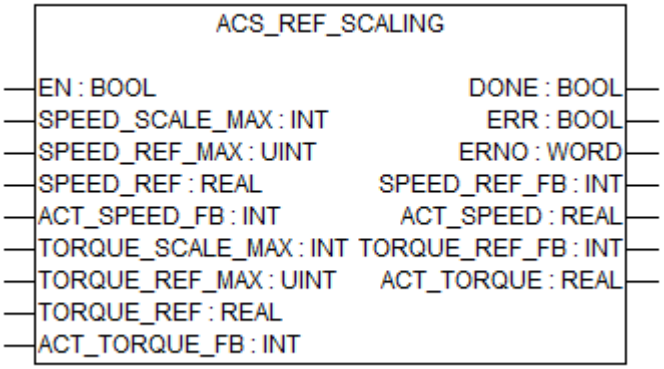
In the program it´s often useful to work with real physical values such as "rpm", "Hz", "%" or "Nm" as REAL values.

The function block provides scaling for two scaling settings: Speed (Reference1 and Actual Value1) and Torque (Reference2 and Actual Value2).

The Scaling maximum and the according reference maximum can be set at the inputs of the function block. This is independent of the drives profile used and could also be utilized for transparent mode or any drive independent linear scaling.

The linear calculation limits the outputs only at the maximum of the INT range at -32768 and +32767. If the scaling would result in a higher value the ERR and ERNO output are indicating the overflow.

Input description



EN (enable)

Data type: BOOL

Enabling of the function block processing.

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the function block is deactivated all outputs are set to zero.

SPEED_SCALE_MAX

Data type: UINT, Default value: 20000; Range: Minimum=1

Scaling maximum for speed. With ABB Drives Profile mostly maximum fieldbus equivalent for maximum of Reference1 and Actual Value1 = +20000.

This value (speed reference maximum) can be adapted at this input by setting a different value, e.g. if transparent mode is used, or speed is used as the Reference2 and Actual Value2.

SPEED_REF_MAX (speed reference maximum)

Data type: INT, Default value: 20000, Range: Minimum=1

Value which corresponds to 100% of the SPEED_REF range.

Should be the speed scaling parameter from the drive. ACS850 = Par.19.01, ACSM1 = Par25.02, ACS355 = Par11.05. e.g. 1500[rpm] or 500 [(0.1)Hz].

SPEED_REF

Data type: REAL

Input SPEED_REF (speed reference) is a REAL value, in rpm or 0.1 Hz or %.

Output SPEED_REF_FB will be calculated according to this input and scaled to +/- SPEED_SCALE_MAX. The scaled value is available at ouput SPEED_REF_FB.

If SPEED_REF exeeds 32767, an error (16#4042) will be indicated and SPEED_REF is set to 32767.

ACT_SPEED_FB (actual speed in fieldbus equivalent)

Data type: INT

Actual speed input from fieldbus in fieldbus equivalent. 100% = +SPEED_SCALE_MAX.

TORQUE_SCALE_MAX (torque reference maximum)

Data type: INT

Scaling maximum for torque. With ABB Drives Profile mostly maximum fieldbus equivalent for maximum of Reference2 and Actual Value2 = +10000.

This value can be adapted at this input by setting a different value, e.g. if transparent mode is used, or torque is used as the Reference1 and Actual Value1.

Default: 10000. Minimum = 1.

TORQUE_REF_MAX (torque reference maximum)

Data type: INT

Value which corresponds to 100% of the TORQUE_REF range.

Working with [Nm] instead of [%] the scaling parameter from the drive should be connected here: e.g. ACS850 = Par.1.29, ACSM1= Par98.1.

Default: 100. Minimum = 1.

TORQUE_REF (torque reference)

Data type: UINT

Torque reference input as real value which is used in the program. Can be in [%] or [Nm].

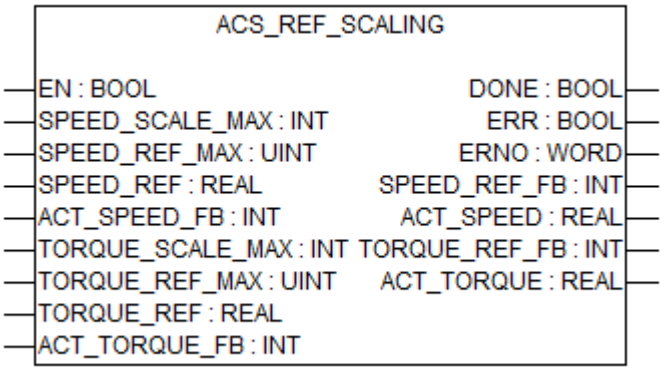
Will be scaled to +/-TORQUE_SCALE_MAX and be available at ouput TORQUE_REF. If TORQUE_REF would be more than 32767 an error 16#4042 will be indicated. TORQUE_REF is set to 32767.

ACT_TORQUE_FB (actual torque in fieldbus equivalent)

Data type: INT

Actual torque input form fieldbus in fieldbus equivalent (+/- TORQUE_SCALE_MAX). TORQUE_SCALE_MAX will be scaled to TORQUE_REF_MAX input and be available at output ACT_TORQUE.

Output description



DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

SPEED_REF_FB (speed reference in fieldbus equivalent)

Data type: INT

Speed reference for fieldbus = SPEED_REF input scaled to (SPEED_SCALE_MAX / SPEED_REF_MAX).

This reference should be connected directly to the fieldbus.

If the result would be higher than 32767 or less than -32768, the output is limit at these values and ERR and ERNO indicating the overflow.

ACT_SPEED (actual speed)

Data type: REAL

Output ACT_SPEED returns the actual speed value from the drive. The scaling depends on the drive settings.

Drive	Fieldbus	Parameter Settings	Scaling
ACS3XX / ACX550	Modbus RTU	53.10=101	Actual speed [rpm] 1 = 1 rpm
ACS3XX / ACX550	Modbus RTU	53.10=103	Absolute frequency 10 = 1 Hz

TORQU_REF_FB (torque reference in fieldbus equivalent)

Data type: INT

Torque reference for fieldbus = TORQUE_REF input scaled to (TORQUE_SCALE_MAX / TORQUE_REF_MAX).

This reference should be connected directly to the fieldbus.

If the result would be higher than 32767 or less than -32768, the output is limit at these values and ERR and ERNO indicating the overflow.

ACT_TORQUE (actual torque)

Data type: REAL

Actual torque = ACT_TORQUE_FB input scaled to (TORQUE_REF_MAX / TORQUE_SCALE_MAX) and converted to REAL.

Function call in ST

```
AcsRefScaling    (EN    := xAcsRefScaling_EN,

           SPEED_SCALE_MAX        := iAcsRefScaling_SPEED_SCALE_MAX,

           SPEED_REF_MAX                :=
uiAcsRefScaling_SPEED_REF_MAX,

1.5.6.2.5 Enumerations

ACS_DRIVE_ENUM enumerations to select the type of drive used

Enumeration information

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

Enumeration	Value	Description
ACS_DRIVE_ACS800	1	ACS800
ACS_DRIVE_ACSM1	2	ACSM1
ACS_DRIVE_ACS350	3	ACS350
ACS_DRIVE_ACS355	4	ACS355
ACS_DRIVE_ACS310	5	ACS310
ACS_DRIVE_ACS550	6	ACS550
ACS_DRIVE_ACH550	7	ACH550
ACS_DRIVE_ACQ810	8	ACQ810
ACS_DRIVE_ACS850	9	ACS850
ACS_DRIVE_ACS880	10	ACS880
ACS_DRIVE_ACS580	11	ACS580
ACS_DRIVE_DCS800	12	DCS800
ACS_DRIVE_DCS550	13	DCS550
ACS_DRIVE_ACH580	14	ACH580
ACS_DRIVE_ACS380	15	ACS380
ACS_DRIVE_ACS480	16	ACS480
ACS_DRIVE_ACQ580	17	ACQ580

ACS_PB_PN_PRM_TYPE_ENUM

Enumeration information

Available as of runtime system:	V2.4
Included in library:	ACSDrivesBase_AC500_V20.lib

Enumeration	Value		Description
	Hex	DEC	
ACS_INT16_PRM	16#03	3	Integer of 16 bits
ACS_INT32_PRM	16#04	4	Integer of 32 bits
ACS_UINT16_PRM	16#06	6	Unsigned 16 bits
ACS_UINT32_PRM	16#07	7	Unsigned 32 bits
ACS_ZERO_VALUE	16#40	64	Zero value returned, Ex.Parameter is not availabe inside the Drive

Enumeration	Value		Description
ACS_BYTE_PRM	16#41	65	Byte
ACS_WORD_PRM	16#42	66	Word
ACS_DWORD_PRM	16#43	67	Double Word
ACS_ERROR_VALUE	16#44	68	Error returned, Ex.Not able to read / write because of communication fault or read or write protected parameter etc

Description

For writing any parameter using PROFIBUS/PROFINET DPV1 function blocks, user need to speficy the data type in function block input. For example, if user is writing one parameter to drive which is double word then user need to specify 16#43 in DATA input abyPrmType.

1.5.6.2.6 Structures

ACS_DRIVE_CONFIG_TYPE structure including configurations parameters of the ACS3XX drive

Structure ACS_DRIVE_CONFIG_TYPE is used in the ACS_DRIVE_DATA_TYPE as subelement and contains configuration parameters of the drive.

Structure information

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

Visible Variable	Type	Default Value	Description
iMotorCtrlMode	INT	0	0=no information, 1=scalar control, 2=vector control or DTC
iRefScaleMax	INT	0	Reference scaling = +20000
iRefScaleMin	INT	0	Reference scaling = -20000
iActScaleMax	INT	0	Actual value scaling = +20000
iActScaleMin	INT	0	Actual value scaling = -20000
iMotorNomFrqHz	INT	0	Nominal motor frequency [0.1 Hz]
iMotorNomSpeedRpm	INT	0	Nominal motor speed [rpm]

Structure description

Structure ACS_DRIVE_CONFIG_TYPE is used in the ACS_DRIVE_DATA_TYPE as subelement and contains configuration parameters of the drive.

The ACS3XX_DRIVES_CTRL_BASIC function block reads scaling and other configuration parameters from the drive. These values are written to subelement CONFIG of the DRIVE_DATA variable.

These values are only valid if output SCALING_DONE at the ACS3XX_DRIVES_CTRL_BASIC is set to TRUE.

The user can read these values via the DRIVE_DATA variable but he must not change these values.

ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive

Structure ACS_DRIVE_DATA_TYPE is used for the DRIVE_DATA variable to exchange the data for one drive.

Structure information

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

Visible Variable	Type	Default value	User Access *)	Description
sw	WORD	0	R	Actual Status Word from drive
actValue1	INT	0	R	Actual value 1 from drive - mostly actual speed
actValue2	INT	0	R	Actual value 2 from drive - mapping is made in drive configuration
cw	WORD	0	R	Control Word to drive
refValue1	INT	0	R	Reference Value 1 to drive - mostly speed reference
refValue2	INT	0	R	Reference Value 2 to drive - mapping is made in drive configuration
driveType	INT	0	R	Selected drive type – input of communication function block
adapterType	INT	0	R	Seleceted fieldbus adapter type – built in communication function block according to chosen drive type and communication block for specific fieldbus type
name	STRING[20]	"Default Drive Name"	R/W	Name for drive which can be set by user directly to DRIVE_DATA variable
online	BOOL		R	Connection established – set in Modbus communication function block after successful reading and writing one Modbus job
config	ACS_DRIVE_CONFIG_TYPE		R	Some configuration and scaling parameters of the drive – read by the ACS3XX_DRIVES_CTRL_BASIC function block

*) R = read only, R/W = read and write access

Structure description

Structure ACS_DRIVE_DATA_TYPE is used for the DRIVE_DATA variable which must be connected to all function blocks related to the same drive.

Besides the variable “name” all variables should not be written by the user directly. They are read and written within the function blocks.

The ACS_DRIVE_DATA_TYPE contains some more internal, invisible variables which are used for interlocks and data transfer and not meant for user access.

ACS_MOD_TOKEN_TYPE structure to exchange the internal Modbus token for Modbus RTU communication with more than 1 Drive

Structure ACS_MOD_TOKEN_TYPE is used to exchange the internal Modbus token between the ACS3XX_COM_MOD_RTU or ACS_COM_MOD_RTU function blocks.

Structure information

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

Structure description

Structure ACS_MOD_TOKEN_TYPE is used for the LINE_TOKEN variable which must be connected to all Modbus communication function blocks of the same physical Modbus line, e.g. COM1. As on the same Modbus line, only one job at a time can be processed, this variable is used to transfer the internal Modbus token to handle this.

ACS_PB_PN_PRM_DPV1_DATA_TYPE

Structure information

Available as of runtime system:	V2.4	Remark:
Included in library:	ACSDrives-Base_AC500_V20.lib	

Visible Variable	Type	Default Value	Description
abyPrmGroup	ARRAY[1..37] OF BYTE	0	Drive parameter Group Number. For example: Parameter 20.12 , Group number is 20.
abyPrmIndex	ARRAY[1..37] OF BYTE	0	Drive parameter Index Number. For example: Parameter 20.12 , Index number is 12.
abyPrmType	ARRAY[1..37] OF BYTE	0	While using READ block, it will act as an output and for WRITE block, it will act as an input. For writing, user need to speficy the Drive Parameter Type here. Refer ACS_PB_PN_PRM_TYPE_ENUM for ENUM for each data type ↬ *Chapter 1.5.6.2.5.2 “ACS_PB_PN_PRM_TYPE_ENUM” on page 2251*.
adwPrmValue	ARRAY[1..37] OF DWORD	0	While using READ block, it will act as an output and for WRITE block, it will act as an input. For writing the value to drive, user need to specify the value here. While reading, user will receive the value here.

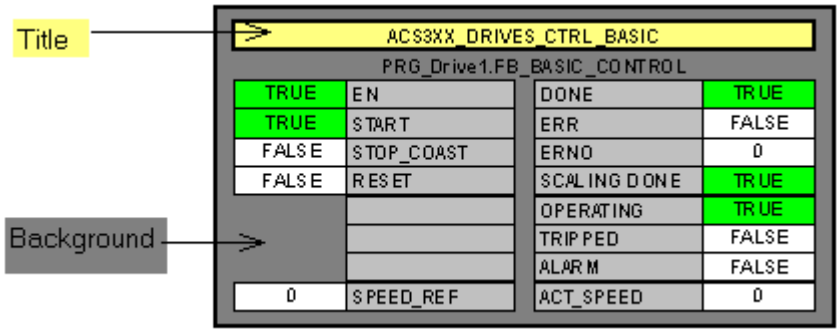
Description

Structure ACS_PB_PN_PRM_DPV1_DATA_TYPE is used to assign assigning Group, Index, Type and Value in input DATA for ACS_PB_WRITE_N_PRM_DPV1 and ACS_PN_WRITE_N_PRM_DPV1.

Same structure is used in ACS_PB_READ_N_PRM_DPV1 and ACS_PN_READ_N_PRM_DPV1 for assigning Group and Index in Input DATA . READ function block reads the values and stores it in type and Value array available in the same structure.

1.5.6.2.7 Global variables

dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements



The background color and the color of the title in the visualization elements of the ACS Drives Libraries can be changed with the two global variables dwAcsVisuBackgroundColor and dwAcs-VisuTitleColor.

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

Parameters

The color variables are given in hex format and represent the following colors:

```
variable := 16#00BBGGRR          (where RR = red, GG = green, BB = blue)
```

The color variables can be changed to another value in any part of the users program.

Examples

	dwAcsVisuBack-groundColor	dwAcsVisuTitleColor	Example
Example 1	16#00808080	16#0080FFFF	Example 2	16#00000000 (black)	16#00FFFFFF (white)	Example 3	16#00000080	16#00008000	
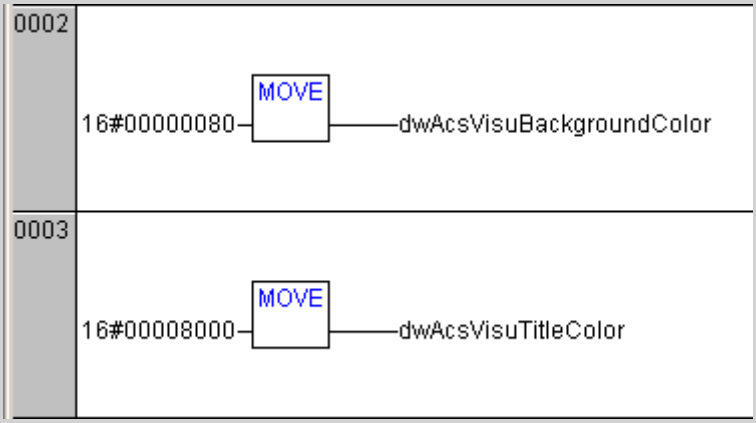
Change Color Variables in ST

Example 3:

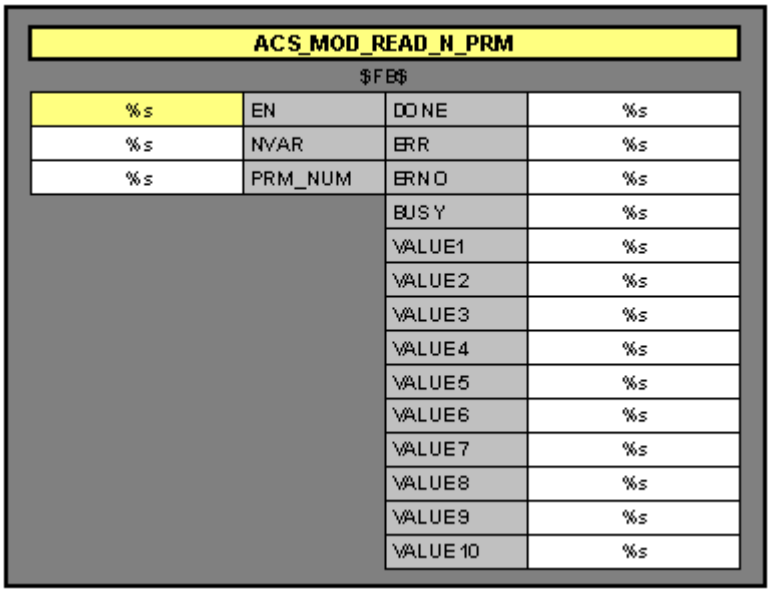
```
dwAcsVisuBackgroundColo := 16#00000080;
dwAcsVisuTitleColor := 16#00008000;
```

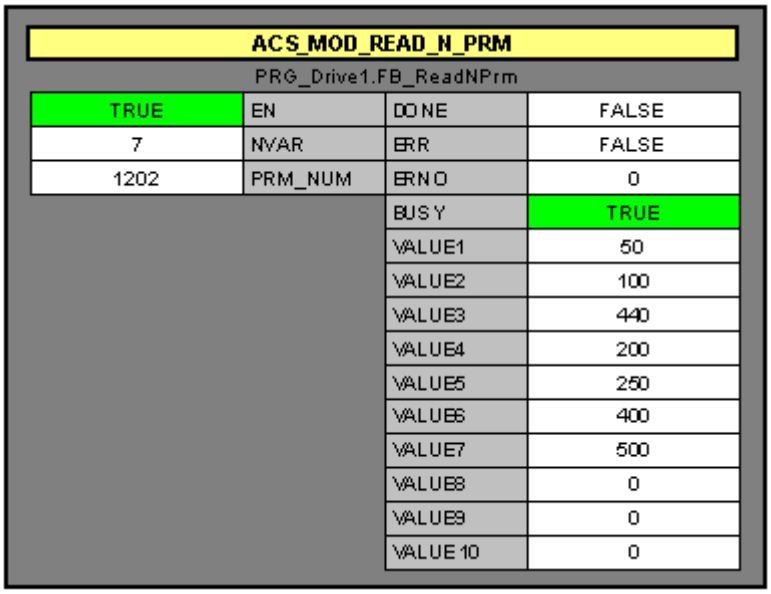
Change Color Variables in FUP



1.5.6.2.8 Visualizations

ACS_MOD_READ_N_PRM_VISU_PH faceplate for the function block ACS_MOD_READ_N_PRM





Visualization element ACS_MOD_READ_N_PRM_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_MOD_READ_N_PRM function block which instance was used to replace the placeholder FB.

The visualization can also be used to control the function block by those inputs which are not connected inside the program.

Additionally the first 10 values of the read block are shown.

Visualization information

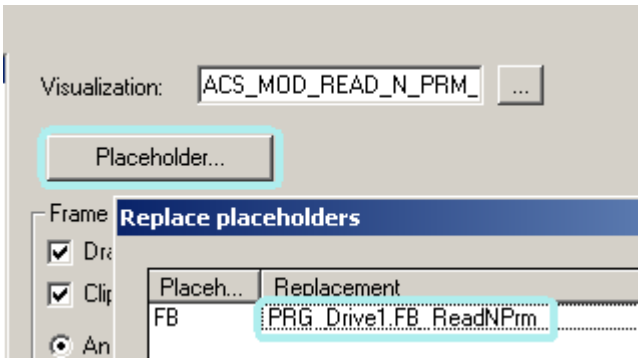
Available in runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

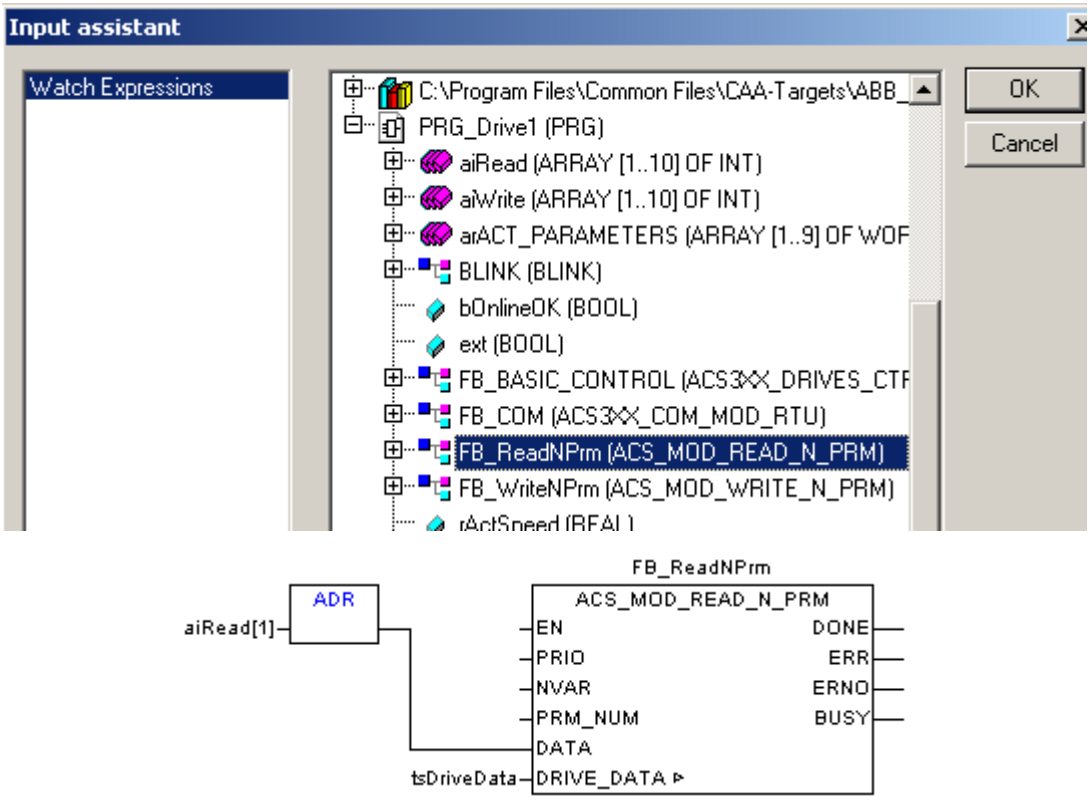
Visualization description

Visualization element ACS_MOD_READ_N_PRM_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_MOD_READ_N_PRM function block which instance was used to replace the placeholder FB.

All inputs of that ACS_MOD_READ_N_PRM ↳ *Chapter 1.5.6.2.4.1 "ACS_MOD_READ_N_PRM" on page 2212* function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.

The values to be written can not be displayed with this faceplate, because they have to be accessed by the ADR operator outside the function block ACS_MOD_READ_N_PRM.





Parameters

Access R/W

EN Access via: Toggle

Description: EN input

NVAR Access via: Numpad 1...125

Description: NVAR input

PRM_NUM Access via:

Description: PRM_NUM input

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Drive1.FB_ReadNPrm

Access R

DONE Description: DONE output.

ERR Description: ERR output.

ERNO Description: ERNO output.

BUSY Description: BUSY output.

VALUE1 Description: Value of 1st read parameter, written if read job was successfully.

VALUE2 Description: Value of 2nd read parameter, written if read job was successfully.

VALUE3 Description: Value of 3rd read parameter, written if read job was successfully.

VALUE4 Description: Value of 4th read parameter, written if read job was successfully.

VALUE5 Description: Value of 5th read parameter, written if read job was successfully.

VALUE6 Description: Value of 6th read parameter, written if read job was successfully.

VALUE7 Description: Value of 7th read parameter, written if read job was successfully.

VALUE8 Description: Value of 8th read parameter, written if read job was successfully

VALUE9 Description: Value of 9th read parameter, written if read job was successfully.

VALUE10 Description: Value of 10th read parameter, written if read job was successfully.

Colors

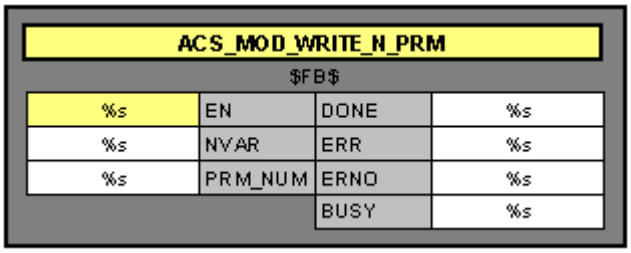
The color of the variables have the following meaning:

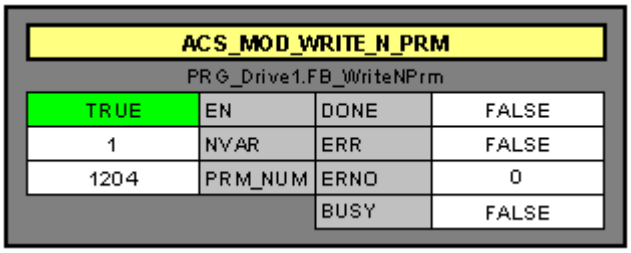
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" ↳ *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" ↳ *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_MOD_WRITE_N_PRM_VISU_PH faceplate for the function block ACS_MOD_WRITE_N_PRM





Visualization element ACS_MOD_WRITE_N_PRM_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_MOD_WRITE_N_PRM function block which instance was used to replace the placeholder FB.

The visualization can also be used to control the function block by those inputs which are not connected inside the program.

Visualization information

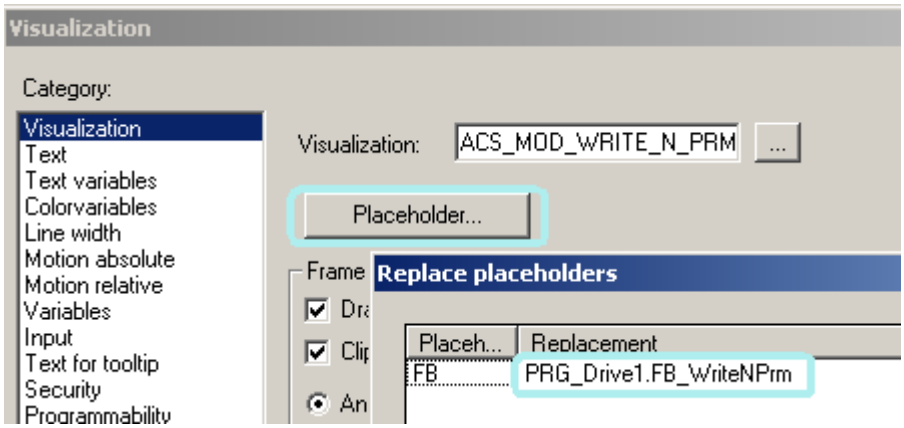
Available in runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

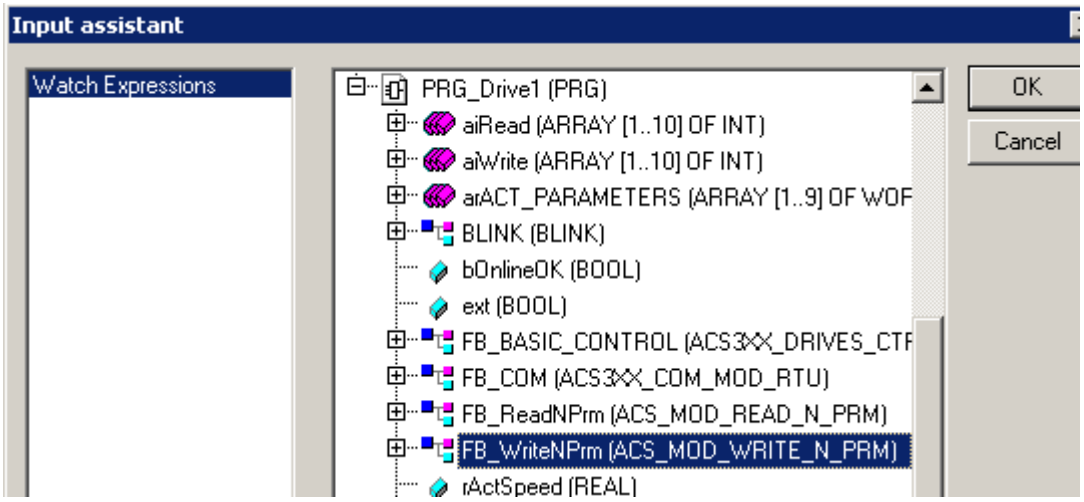
Visualization description

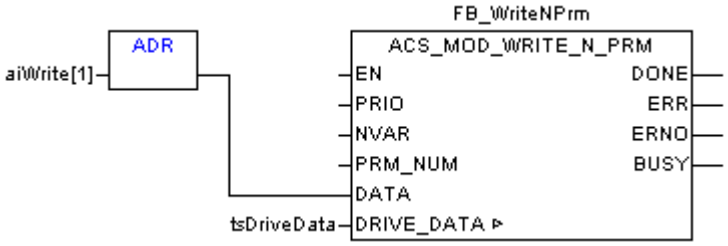
Visualization element ACS_MOD_WRITE_N_PRM_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_MOD_WRITE_N_PRM function block which instance was used to replace the placeholder FB.

All inputs of that ACS_MOD_WRITE_N_PRM_MOD ↬ *Chapter 1.5.6.2.4.2 "ACS_MOD_WRITE_N_PRM" on page 2215* function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.

The values to be written can not be displayed with this faceplate, because they have to be accessed by the ADR operator outside the function block ACS_MOD_WRITE_N_PRM.







Parameters

Access R/W

EN Access via: Toggle
Description: EN input

NVAR Access via: Numpad 1...125
Description: NVAR input

PRM_NUM Access via:
Description: PRM_NUM input

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Drive1.FB_WriteNPrm

Access R

DONE Description: DONE output.

ERR Description: ERR output.

ERNO Description: ERNO output.

BUSY Description: BUSY output.

Colors

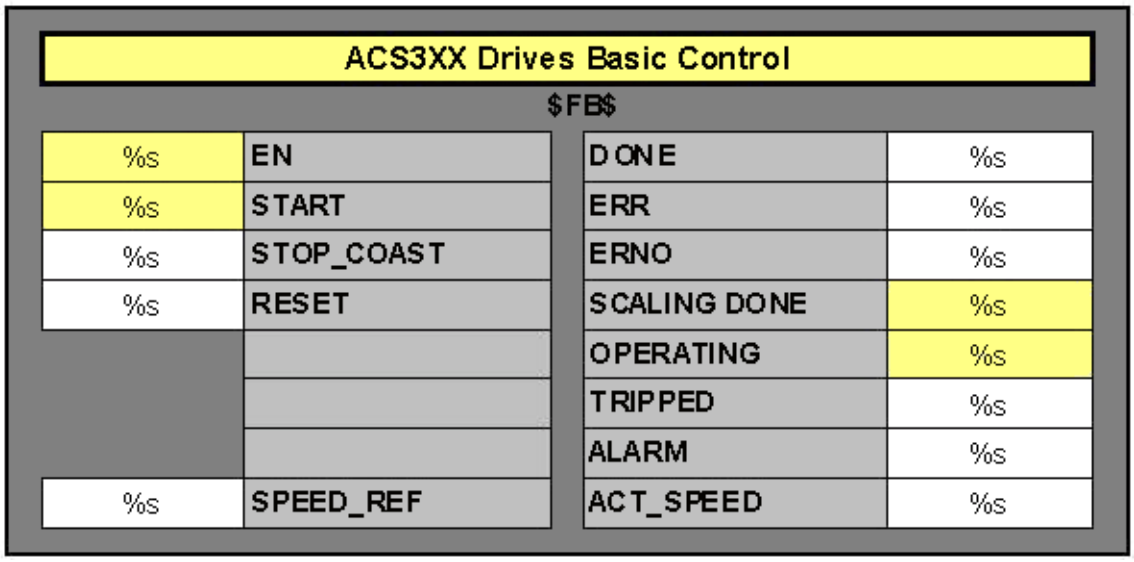
The color of the variables have the following meaning:

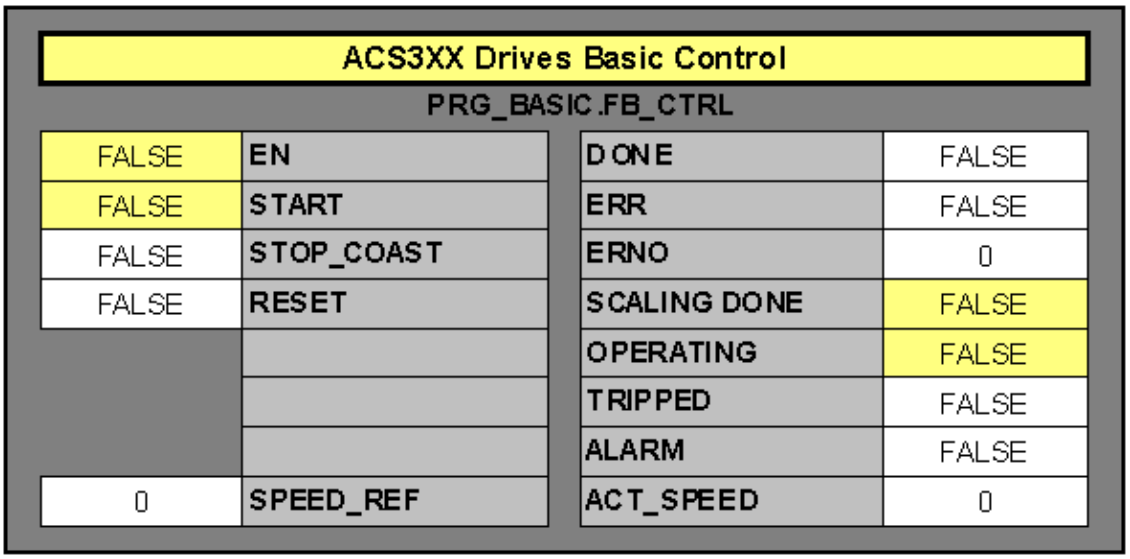
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS3XX_DRIVES_CTRL_BASIC_VISU_PH faceplate of function block ACS3XX_DRIVES_CTRL_BASIC





Visualization element ACS3XX_DRIVES_CTRL_BASIC_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS3XX_DRIVES_CTRL_BASIC function block which instance was used to replace the placeholder FB.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

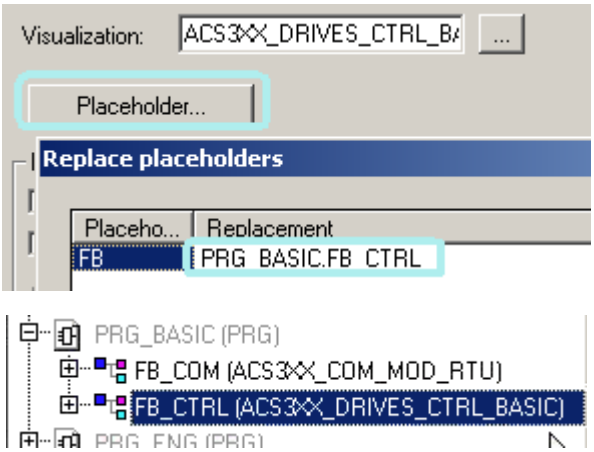
Visualization information

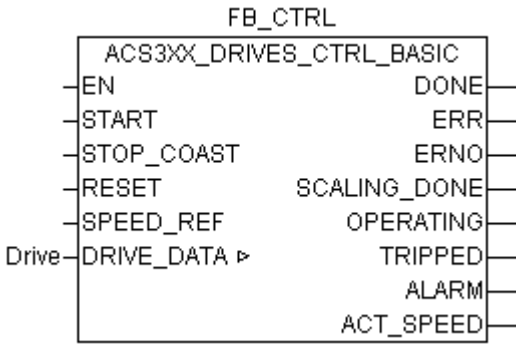
Available in runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

Visualization description

Visualization element ACS3XX_DRIVES_CTRL_BASIC_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS3XX_DRIVES_CTRL_BASIC *Chapter 1.5.6.2.4.4 "ACS3XX_DRIVES_CTRL_BASIC" on page 2220* function block which instance was used to replace the placeholder FB.

All inputs of that ACS3XX_DRIVES_CTRL_BASIC function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.





Parameters

Access R/W

EN Access via: Toggle
Description: EN input

START Access via: Toggle
Description: START input

STOP_COAST Access via: Toggle
Description: STOP_COAST input

RESET Access via: Toggle
Description: RESET input

SPEED_REF Access via: Numpad, no limits
Description: SPEED_REF input

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Drive1.FB_BASIC_CTRL

Access R

DONE Description: DONE output.

ERR Description: ERR output.

ERNO Description: ERNO output.

SCALING_DONE Description: SCALING_DONE output

OPERATING Description: OPERATING output

TRIPPED Description: TRIPPED output

ALARM Description: ALARM output

ACT_SPEED Description: ACT_SPEED output

Colors

The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

Colors

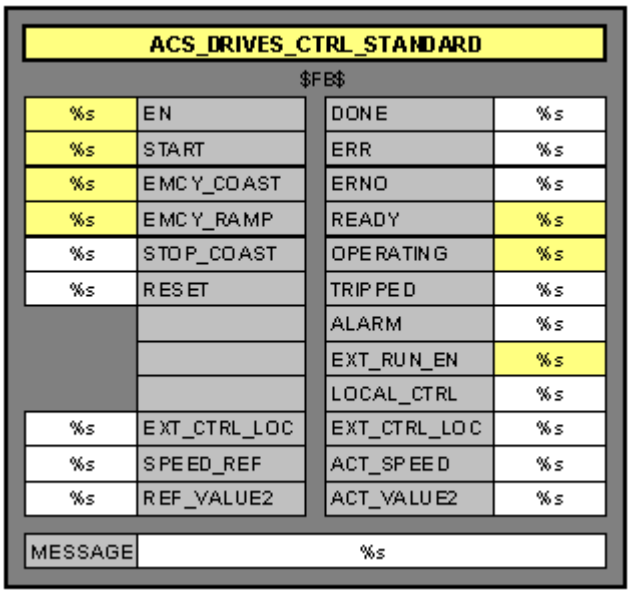
The color of the variables have the following meaning:

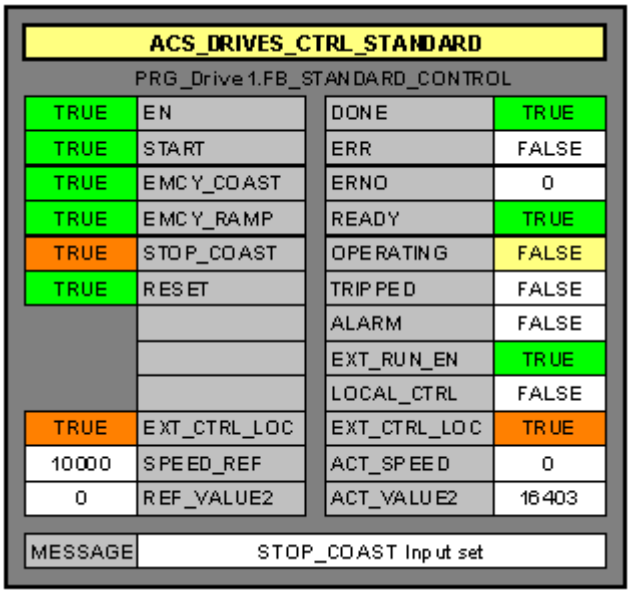
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_DRIVES_CTRL_STANDARD_VISU_PH faceplate of function block ACS_DRIVES_CTRL_STANDARD





Visualization element ACS_DRIVES_CTRL_STANDARD_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_DRIVES_CTRL_STANDARD function block which instance was used to replace the placeholder FB.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

Visualization information

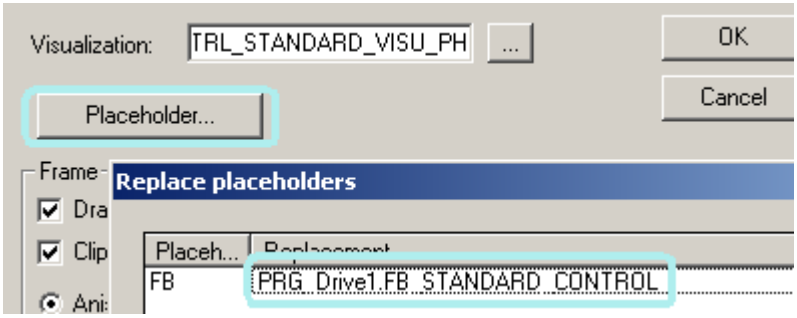
Available in runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

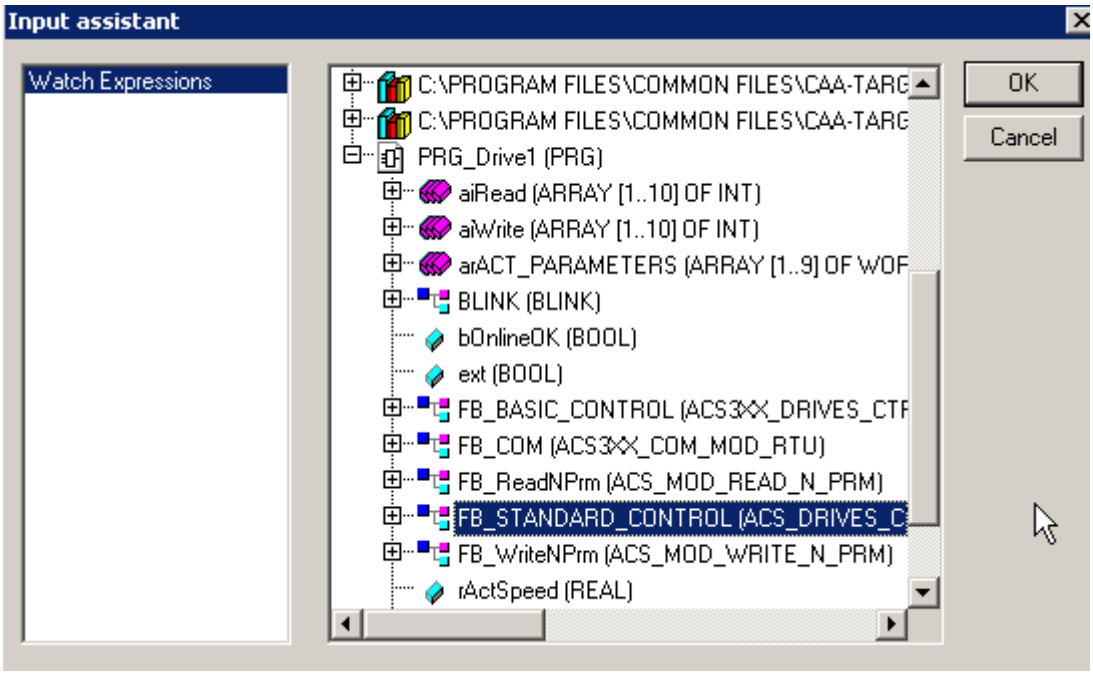
Visualization description

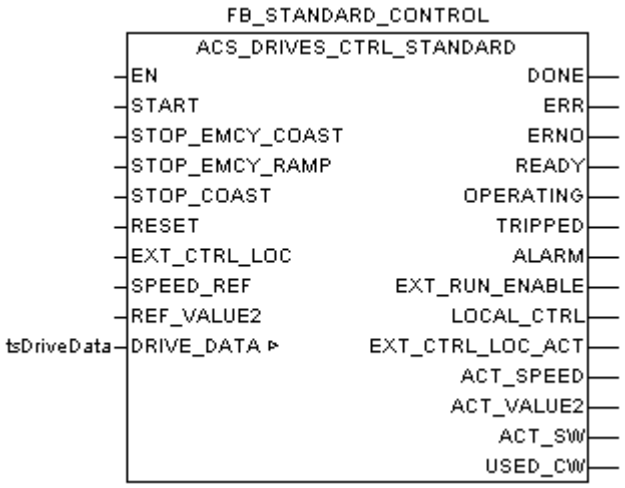
Visualization element ACS_DRIVES_CTRL_STANDARD_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_DRIVES_CTRL_STANDARD ↳ *Chapter 1.5.6.2.4.6 “ACS_DRIVES_CTRL_STANDARD ” on page 2234* function block which instance was used to replace the placeholder FB.

All inputs of that ACS_DRIVES_CTRL_STANDARD function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.

Additionally, a text message of the actual state, e.g. missing input or missing feedback from drive, is given by the variable MESSAGE, shown next to label MESSAGE.







Parameters

Access R/W

EN Access via: Toggle
Description: EN input

START Access via: Toggle
Description: START input

EMCY_COAST Access via: Toggle
Description: EMCY_COAST input

EMCY_RAMP Access via: Toggle
Description: EMCY_RAMP input

STOP_COAST Access via: Toggle
Description: STOP_COAST input

RESET Access via: Toggle
Description: RESET input

EXT_CTRL_LOC Access via: Toggle
Description: EXT_CTRL_LOC input

SPEED_REF Access via: Numpad, no limits
Description: SPEED_REF input

REF_VALUE2 Access via: Text input -32768...+32768
Description: REF_VALUE2 input

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Drive1.FB_BASIC_CTRL

Access R

DONE Description: DONE output.

ERR Description: ERR output.

ERNO Description: ERNO output.

READY Description: READY output

OPERATING Description: OPERATING output

TRIPPED Description: TRIPPED output

ALARM Description: ALARM output

EXT_RUN_EN Description: EXT_RUN_EN output

LOC_CTRL Description: LOC_CTRL output

EXT_CTRL_LOC Description: EXT_CTRL_LOC output

ACT_SPEED Description: ACT_SPEED output

ACT_VALUE2 Description: ACT_VALUE2 output

MESSAGE Description: MESSAGE output

Colors

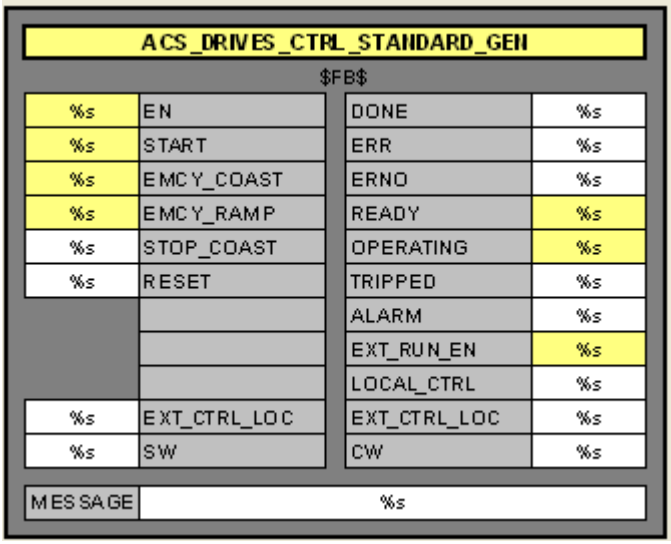
The color of the variables have the following meaning:

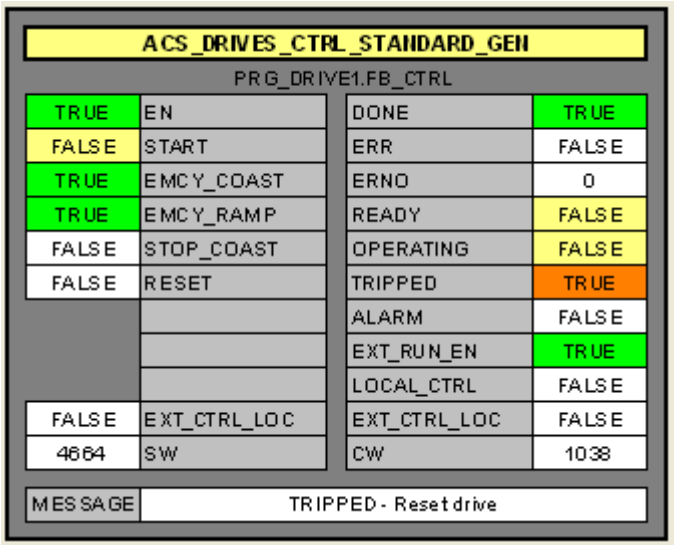
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" ↳ *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" ↳ *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_DRIVES_CTRL_STANDARD_GEN_VISU_PH faceplate for the function block





Visualization element ACS_DRIVES_CTRL_STANDARD_GEN_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_DRIVES_CTRL_STANDARD_GEN ↳ *Chapter 1.5.6.2.4.7 "ACS_DRIVES_CTRL_STANDARD_GEN" on page 2241* function block which instance is used to replace the placeholder FB.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

Visualization information

Available in runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

Visualization description

Visualization element ACS_DRIVES_CTRL_STANDARD_GEN_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_DRIVES_CTRL_STANDARD_GEN ↳ *Chapter 1.5.6.2.4.7 "ACS_DRIVES_CTRL_STANDARD_GEN" on page 2241*function block which instance was used to replace the placeholder FB.

ACT_SPEED Description: ACT_SPEED output

TORQUE_REF_FB Description: TORQUE_REF_FB output – should be connected to the fieldbus.

ACT_TORQUE Description: ACT_TORQUE output

Colors

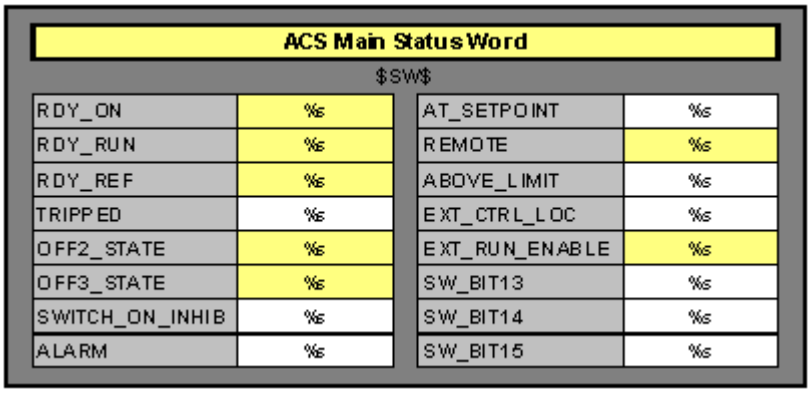
The color of the variables have the following meaning:

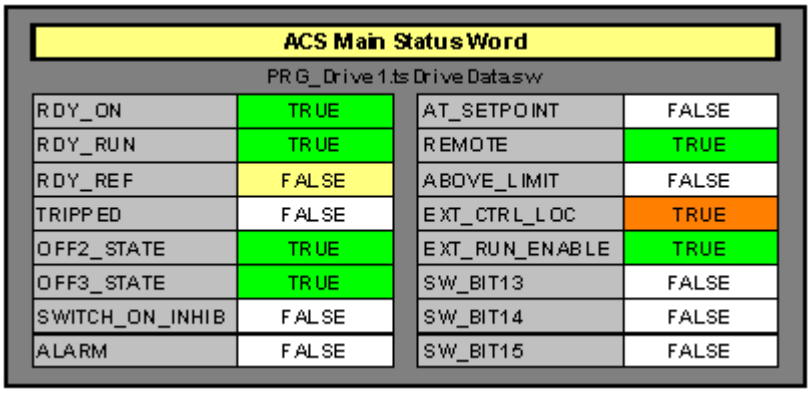
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_SW_VISU_PH visualization for the ABB drives profile status word





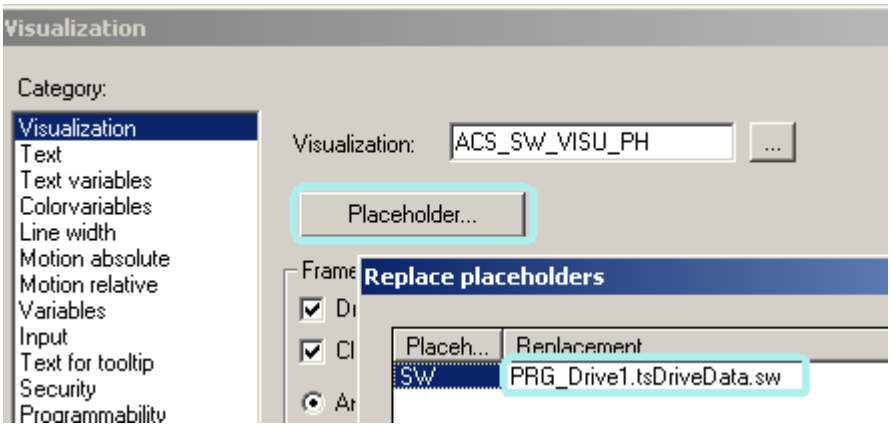
Visualization element ACS_SW_VISU_PH can be used to show the actual values of all bits of the Status Word.

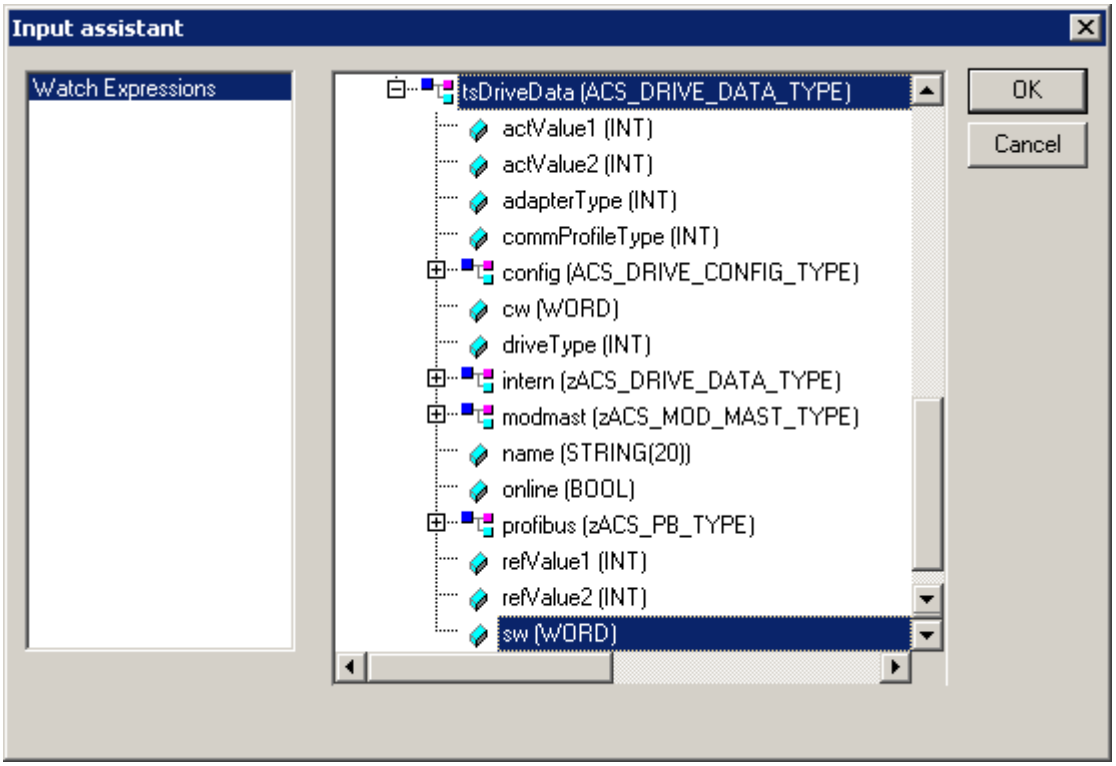
Visualization information

Available in runtime system:	V1.3.2
Included in library:	ACSDrivesBase_AC500_V20.lib

Visualization description

Visualization element ACS_SW_VISU_PH can be used to show the actual values of all bits of the Status Word. The placeholder SW must be replaced by the “sw” element of the DRIVE_DATA variable.





```
PROGRAM PRG_Drive1
VAR
    FB_COM:             ACS3XX_COM_MOD_RTU;
    tsDriveData:        ACS_DRIVE_DATA_TYPE;
    FB_BASIC_CONTROL:   ACS3XX_DRIVES_CTRL_BASIC;
```

Parameters

Access R

RDY_ON	Description: RDY_RUN output
RDY_RUN	Description: RDY_RUN output
RDY_REF	Description: RDY_REF output
TRIPPED	Description: TRIPPED output
OFF2_STATE	Description: OFF2_STATE output
OFF3_STATE	Description: OFF3_STATE output
SWITCH_ON_INHIB	Description: SWITCH_ON_INHIB output
ALARM	Description: ALARM output

AT_SETPOINT Description: AT_SETPOINT output

REMOTE Description: REMOTE output

ABOVE_LIMIT Description: ABOVE_LIMIT output

EXT_CTRL_LOC Description: EXT_CTRL_LOC output

EXT_RUN_EN Description: EXT_RUN_EN output

SW_BIT13 Description: SW_BIT13 output

SW_BIT14 Description: SW_BIT14 output

SW_BIT15 Description: SW_BIT15 output

Placeholder	Replacement	Example
SW	SW element of DRIVE_DATA variable	PRG_Drive1.tsDriveData.sw

Colors

The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

Placeholder	Replacement	Example
CW	CW element of DRIVE_DATA variable	PRG_Drive1.tsDriveData.cw

Colors

The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

1.5.6.3 ACS / DCS Drives communication via Modbus RTU library

1.5.6.3.1 Preconditions for the use of the ACS / DCS drives communication via Modbus RTU library

The library is released for the following products:

CPUs:	AC500 and AC500-eCo
Fieldbus:	Modbus RTU (Serial Modbus)
Drives:	ACS800, ACSM1, ACS350, ACS355, ACS310, ACS550, ACH550, ACQ810, ACS850, ACS880, ACS800, DCS800, DCS550

Generic Devices:	No specific limit except that they can work with the Modbus function codes defined in function block *Chapter 1.5.4.22.1.1 “COM_MOD_MAST” on page 1698*.
Modbus RTU configuration:	Prior to the use of the function blocks a Communication Module "COMx_Modbus" has to be configured accordingly using Automation Builder, either at "Interfaces" or at "CM574-RS" module.
ACS3XX_COM_MOD_RTU, ACS_COM_MOD_RTU, ACS_COM_MOD_RTU_ENHANCED:	Modbus communication tested for connection of 7 drives in total. Connection of more drives depends on the performance of used CPU and communication settings. The communication function blocks are designed to be used for one specific drive at run time. So it´s not recommanded to change the COM or SLAVE inputs of the blocks while the program is running.
ACS_COM_MOD_RTU_GEN:	Modbus communication for generic devices. The communication performance depends on performance of used CPU and communication settings. The communication function block is designed to be used for one specific slave device at run time. So it´s not recommanded to change the COM or SLAVE inputs of the block while the program is running.

The function blocks contained in the library can only be executed in RUN mode of the PLC, but not in simulation mode.

The blocks can only be used in combination with the ACSDrives-Base_AC500_V20 Library.

1.5.6.3.2 Special characteristics of the ACS / DCS drives communication via Modbus RTU library

The function blocks in the ACSDrivesComModRTU_AC500_V20 Library are designed to handle the Modbus RTU communication to 1 or more drives.

The function blocks ACSxxxx_COM_MOD_RTU perform all the actions that are needed to read and write Modbus RTU jobs from / to different slaves.

The data handling is automatically done in the ACSxxxx_COM_MOD_RTU function blocks using the COM_MOD_MAST and ACS_COM_READ_N_PRM and ACS_COM_WRITE_N_PRM function blocks internally.

The user just has to connect the communication function blocks together via the common LINE_TOKEN variable of type ACS_MOD_TOKEN_TYPE.

The following block diagram shows the general connection of the function blocks for 3 drives:

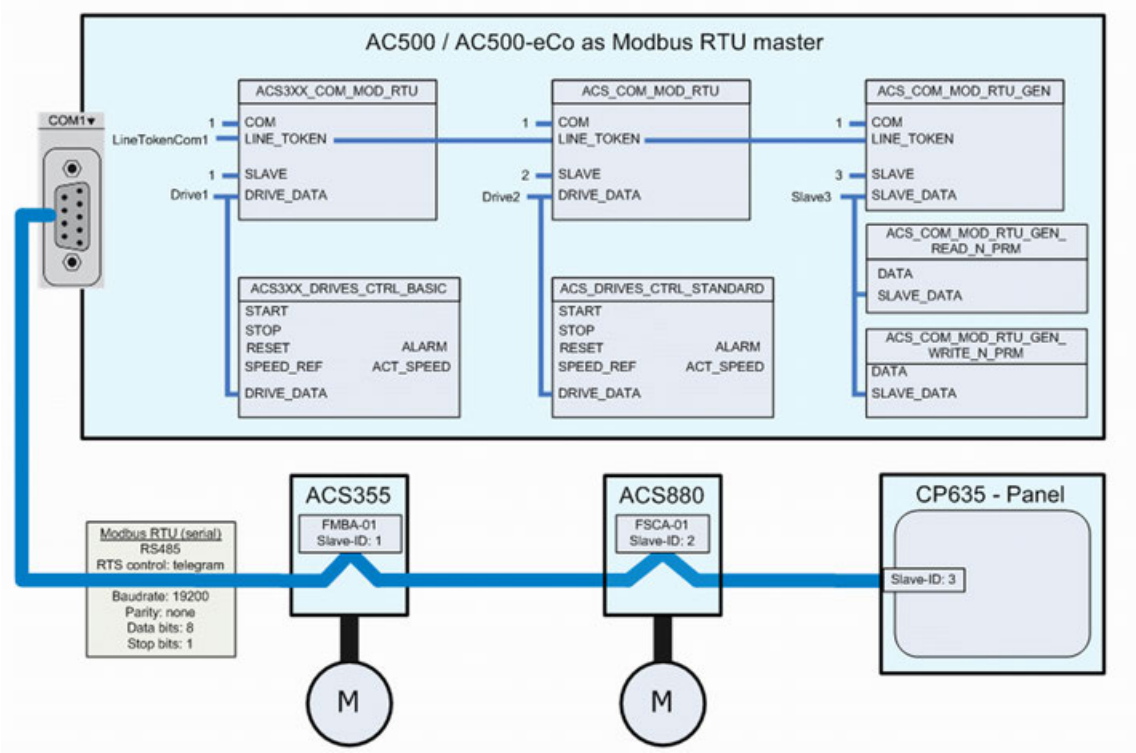

Fig. 158: Function Block Diagram PS553-DRIVES library Modbus RTU connection for three ACS drives

The communication function blocks are connected together via the LineToken variable. All function blocks regarding 1 drive are connected together via the DRIVE_DATA variable of type ACS_DRIVE_DATA_TYPE.

For the Modbus settings in the AC500 see tab PLC configuration \ Interfaces \ COMx – Modbus \ Module parameters – or in ABB Automation Builder: Setting_COMx_Modbus

For the Modbus settings in the ACS drives see Parameter group "EFB Protocoll", e.g. Par. 53.02 .. 53.04 for ACS355.

Performance

The following timing performance has been measured:

Test was done with no change of commands nor reference values. So just a continuous reading of status values from each drive were performed.

Test conditions general: PM554-T, timeout at ACS3XX_COM_MOD_RTU: 1000 ms

Transmission rate	**Number of drives**	**Update time for 1 drive**		
-	-	PLC scan time: 10ms PLC load: 50%	PLC scan time: 5ms PLC load: 74%	PLC scan time: 3ms PLC load: 75%
19,2 kBd	7	450 ms	360 ms	-
19,2 kBd	3	190 ms	-	147 ms
115,2 kBd	7	370 ms	280 ms	-
115,2 kBd	3	160 ms	-	100 ms

Reconnection pause:

When one or more drives in the Modbus RTU lines are offline, all the other drives have to wait for the TIMEOUT to elapse until a line token is assigned to next drive.

Reconnection pause input helps in skipping the drives which are offline from the next Modbus job and execute Modbus job operations only for the drives which are online.

“reconnectPause” is time in seconds before next retry to connect after a timeout was detected. Timeout is detected with ERNO = 8211.

This feature can be used with the ACS_COM_MOD_RTU or ACS_COM_MOD_RTU_ENHANCED function block when Modbus RTU communication is used.

User must configure the reconnect pause input value using the input/output variable “DRIVE_DATA.reconnectPause”.

For the generic RTU function block ACS_COM_MOD_RTU_GEN, value for the reconnect pause must be configured at the input/output variable “SLAVE_DATA.reconnectPause”.

1.5.6.3.3 Components of the ACS / DCS drives communication via Modbus RTU library

The library ACSDrivesComModRTU_AC500_V20.lib contains the following function blocks, structures and visualizations:

Table 132: Function blocks

Group: Modbus RTU -> ACS Drives	
ACS3XX_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.1 “ACS3XX_COM_MOD_RTU communication for ACS3XXwrite one bit/ACX550 drives via Modbus RTU” on page 2293*	Communication for ACS 3xx or ACX550 Drives via Modbus RTU

1.5.6.3.4 Overview of the ACS / DCS drives communication via Modbus RTU function blocks according to their call names

Used abbreviations:

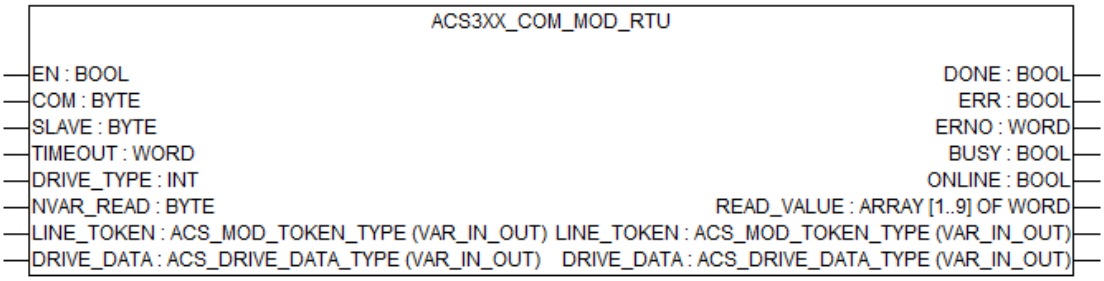
FBhv	Function block with historical values
FBnohv	Function block without historical values
F:	Function
Enum:	Enumeration

Struct:	Structure
Visu:	Visualization

VE Name	Type	Function
ACS3XX_COM_MOD_RTU	FBhv	Communication for ACS3xx and ACX550 Drives via Modbus RTU
ACS_COM_MOD_RTU	FBhv	Communication for ACS / DCS Drives via Modbus RTU
ACS_COM_MOD_RTU_ENHANCED	FBhv	Communication for ACS DCS Drives via Modbus RTU
ACS_COM_MOD_RTU_GEN	FBhv	Communication for Generic Devices via Modbus RTU
ACS_COM_MOD_RTU_GEN_READ_N_PRM	FBhv	Read N Parameters from a Generic Modbus RTU device
ACS_COM_MOD_RTU_GEN_WRITE_N_PRM	FBhv	Write N Parameters to a Generic Modbus RTU Device

1.5.6.3.5 Function blocks

ACS3XX_COM_MOD_RTU communication for ACS3XXwrite one bit/ACX550 drives via Modbus RTU



Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesComModRTU_AC500_V20.lib
Function block	with historical values

Function block ACS3XX_COM_MOD_RTU controls the Modbus RTU communication to an ACS3XX / ACX550 drive (except ACS380) and is used for the basic control of ACS3XX / ACX550 drives (except ACS380) with ABB Drives profile.

The function block continuously reads data from the drive starting at Modbus register 40004. So at least the Status Word (SW), Actual Value 1 (SPEED_REF), Actual Value 2 (ACT_VALUE2) are continuously read from the drive and written to the DRIVE_DATA variable.

With input NVAR_READ the function block can be configured to read between 3 and 9 signals from the drive. All read data is also written to the array at the READ_VALUE output. The first signal is the Status Word. The following signals are configured in the ACS3XX / ACX550 drive with Par. 53.10 .. 53.17. The array READ_VALUE contains the data as follows:

The following table shows the performed Modbus read job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Modbus register address in drive	**Mapping configuration in drive**		**Written to in AC500**	**Condition at function block**	
	ACS3XX, ACX550	**ACS355 default values using the Macro "AC500 Modbus" in Par. 99.02**			
Communication module	**embedded fieldbus or FMBA-01**				
40004	Status Word (SW)	Fix	DRIVE_DATA .sw READ_VALUE[1]	EN = TRUE NVAR_READ >= 3	
40005	Par. 53.10 (e.g.101)	Speed & direction (101)	DRIVE_DATA .actValue1 READ_VALUE[2]	EN = TRUE NVAR_READ >= 3	
40006	Par. 53.11 (e.g.105)	FB STS WORD 1 (303)	DRIVE_DATA .actValue2 READ_VALUE[3]	EN = TRUE NVAR_READ >= 3	
40007	Par. 53.12	FAULT WORD 1 (305)	READ_VALUE[4]		EN = TRUE and NVAR_READ >= 4
40008	Par. 53.13	0	READ_VALUE[5]		EN = TRUE and NVAR_READ >= 5
40012	Par. 53.17	0	READ_VALUE[9]		EN = TRUE and NVAR_READ = 9

If a Modbus job tries to access a register in the drive which has no valid mapping information the job is aborted with an error. Therefore in ACS3XX/ACX550 at least the Par. 53.10 and 53.11 have to be configured to the Actual Value1 and Actual Value2 e.g. 101 and 105.

If e.g. NVAR_READ = 5 the values from READ_VALUE[1 .. 5] are updated. Then none of the configured parameters Par. 53.10 .. 53.13 in the ACS3XX drive must be zero.

The READ_VALUE array is reset to zero in the following cases:

- EN = FALSE
- COM, SLAVE or TIMEOUT are out of range
- Communication error occurs

Writing Control Word and Reference Values to Drive

The function block checks, if there are changes of the Control Word (CW), Reference Value 1 (SPEED_REF) or Reference Value 2 (REF_VALUE2) on the DRIVE_DATA variable. If there is a change a write job is requested to send these 3 values to the ACS3XX / ACX550 drive starting at Modbus register 40001.

The following table shows the performed Modbus write job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Modbus register address in drive	Mapping configuration in drive	Taken form AC500
	For ACS3XX / ACX550 drives	
40001	Control Word (CW)	DRIVE_DATA.cw
40002	Reference Value1	DRIVE_DATA.refValue1
40003	Reference Value2	DRIVE_DATA.refValue2

Read/Write Jobs Coming from Other function blocks

The requests to process other read or write Modbus jobs is transferred via the DRIVE_DATA variable at the IN_OUT variable DRIVE_DATA which can be connected to several other read/ write function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM of this drive.

Communication with Several ACS3XX Drives

If several drives are used, for each drive an communication function block such as ACS3XX_COM_MOD_RTU must be programmed. Also every other generic slave device on the same Modbus RTU line must be programmed with it´s own ACS_COM_MOD_RTU_GEN function block. All those communication function blocks of one Modbus RTU line must be linked together via one variable of type ACS_MOD_TOKEN_TYPE, connected to the IN_OUTPUTs LINE_TOKEN. Via this variable the Modbus token is passed to the next drive / device, so only one drive / device at a time is communicating with the PLC.

Preconditions

The function block is only working with ACS3XX / ACX550 drives (ACS310, ACS350, ACS355, ACS500, ACH550) via Modbus RTU communication.

This function block cannot be used with ACS380 drive.

Instead for ACS380 drive use ACS_COM_MOD_RTU function block or ACS_COM_MOD_RTU_ENHANCED function block based on the drive configuration.

The data transfer to other function blocks for this drive communication to the ACS3XX/ACX550 drive is realized via the IN_OUTPUT variable DRIVE_DATA, which must be connected to then ACS3XX_COM_MOD_RTU even if no other function block is connected.

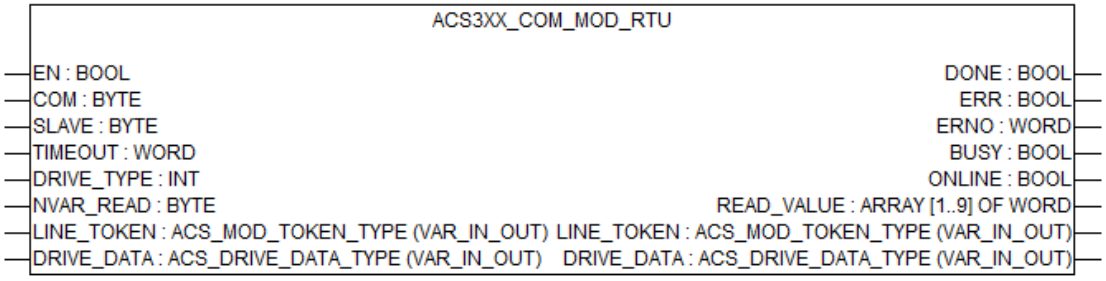
The Modbus token is passed to other Modbus communication blocks such as ACS3XX_COM_MOD_RTU via the IN_OUTPUT variable LINE_TOKEN which must be connected even if no other ACS3XX_COM_MOD_RTU function block is used.

The ACS3XX / ACX550 parameters must be set as follows:

Setting according to AC500 configuration or function block input Communication module:	ACS3XX, ACX550	ACS355 default values using the Macro "AC500 Modbus" in Par. 99.02	Condition at function block
	Embedded fieldbus or FMBA-01		
Fieldbus activation = STD Modbus or Modbus RS-232	98.02	STD Modbus	EN = TRUE and NVAR_READ >= 3
SLAVE number	53.02	2	EN = TRUE and NVAR_READ >= 3

Setting according to AC500 configuration or function block input **Communication module:**	**ACS3XX, ACX550** **Embedded fieldbus or FMBA-01**	**ACS355 default values using the Macro "AC500 Modbus" in Par. 99.02**	**Condition at function block**
Transmission rate = AC500 Modbus configuration	53.03	19.2 kbit/s (192)	EN = TRUE and NVAR_READ >= 3
Parity, Data- and Stopbits = AC500 Modbus configuration	53.04	8 NONE 1 (1)	EN = TRUE and NVAR_READ >= 3
Control profile = ABB Drives (lim or full) but not ABB drives enhanced nor DCU profile	53.05	ABB DRV FULL (2)	EN = TRUE and NVAR_READ >= 3
Mapping of Actual Value1 Modbus register 40005	53.10 e.g. 101	Speed & direction (101)	EN = TRUE and NVAR_READ >= 3
Mapping of Actual Value2 Modbus register 40006	53.11 e.g. 105	FB STS WORD 1 (303)	EN = TRUE and NVAR_READ >= 3
Optional Modbus register 40007	53.12 e.g. 305	FAULT WORD 1 (305)	EN = TRUE and NVAR_READ >= 4
Optional Modbus register 40012	53.17		EN = TRUE and NVAR_READ = 9

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable) Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the block is active, the current values are available at the outputs.

After a rising edge (FALSE -> TRUE) of input EN output ONLINE is set to FALSE and parameters are read from the ACS3XX / ACX550 drive.

After first successful reading and writing parameters, output ONLINE is set to TRUE.

The processing of continuously read of status information from the drive (SW, ACT_VALUE1 and ACT_VALUE2) and writing of Control Word and Reference Values (CW, SPEED_REF, REF_VALUE2) to the drive is started.

If EN is reset to FALSE while a Modbus job is performed (BUSY = TRUE), the function block will be processed until the Modbus job is terminated (DONE = TRUE for 1 cycle).

If EN is reset to FALSE while the function block actually keeps the token of the LINE_TOKEN variable the token will be released for another drive (set to 0).

COM (com)

Data type: BYTE

Interface identifier of Modbus line.

COM = 1: COM1

COM = 2: COM2

...

COM = 11: COM11 (using CM574-RS)

(COM3 = FPB, COM4 .. COM11 = COMs on CM574-RS).

Default value = 1. Minimum = 1, Maximum = 11

The COM input should not be changed while the program is running. If changed nevertheless, the new value will become effective only after a new rising edge of EN input.

SLAVE (slave)

Data type: BYTE

At input SLAVE, the address of the drive (slave) to which the connection shall be established must be specified.

Default value = 2, Minimum = 1, Maximum = 255

The function block is designed to be used with a fix SLAVE device. The SLAVE input should not be changed while the program is running. If changed nevertheless the new value will become effective only after an already running Modbus job is finished.

TIMEOUT (timeout)

Data type: WORD

The telegram timeout in milliseconds (ms) is specified at input TIMEOUT.

If no response is received within the time interval specified at TIMEOUT, the procedure is aborted and an error identifier is output.

If several drives are connected to the Modbus line and one drive cannot respond, the whole communication is waiting till the timeout is over and the Modbus procedure (job) is aborted. Afterwards the next drive can take the LINE_TOKEN signal. The TIMEOUT should not be set too long if more than one drive is connected, but also not too short for having a chance to respond within the TIMEOUT. A minimum of 100 is required.

Typical values should be between 300 ms and 2000 ms (range: minimum 100, maximum 65535).

Default value = 1000. Minimum = 100, Maximum = 65535.

DRIVE_TYPE (drive type)

Data type: INT, Default value: ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM. The input can be set either by the value directly or by using the enum.

ENUM	Value
ACS_DRIVE_ACS800	1
ACS_DRIVE_ACSM1	2
ACS_DRIVE_ACS350	3
ACS_DRIVE_ACS355	4
ACS_DRIVE_ACS310	5
ACS_DRIVE_ACS550	6
ACS_DRIVE_ACH550	7
ACS_DRIVE_ACQ810	8
ACS_DRIVE_ACS850	9
ACS_DRIVE_ACS880	10
ACS_DRIVE_ACS580	11
ACS_DRIVE_DCS800	12
ACS_DRIVE_DCS550	13
ACS_DRIVE_ACH580	14
ACS_DRIVE_ACS380	15
ACS_DRIVE_ACS480	16
ACS_DRIVE_ACQ580	17

NVAR_READ (number of variables for reading)

Data type: BYTE

With the input NVAR_READ the function block can be configured to read between 3 and 9 signals from the drive. All read data is written to the array at the READ_VALUE output. The first value is the Status Word (SW). The following values are configured in the ACS3XX / ACX550 drive with Par. 53.10 .. 53.17.

If e.g. NVAR_READ = 5 then none of the configuration parameters Par. 53.10 .. 53.13 must be 0. Then the values from READ_VALUE[1] .. READ_VALUE[5] are updated.

Default value = 3. Minimum = 3, Maximum = 9.

For ACS3XX/ACX550 drives, mapping of 53.10 and 53.11 parameters to any of the drive parameter is mandatory, otherwise function block will return error.

When NVAR READ = 3, it reads SW, 53.10 mapped parameter and 53.11 mapped parameter.

See table at description of READ_VALUE output.

LINE_TOKEN (line token)

Data type: ACS_MOD_TOKEN_TYPE

The combined input/output LINE_TOKEN must be connected to the one variable of ACS_MOD_TOKEN_TYPE of the related Modbus line. Each Modbus line must have its own LINE_TOKEN variable.

The LINE_TOKEN variable contains the token for the Modbus line and must be connected to all related ACS3XX_COM_MOD_RTU function blocks of this line (COMx).

Description:

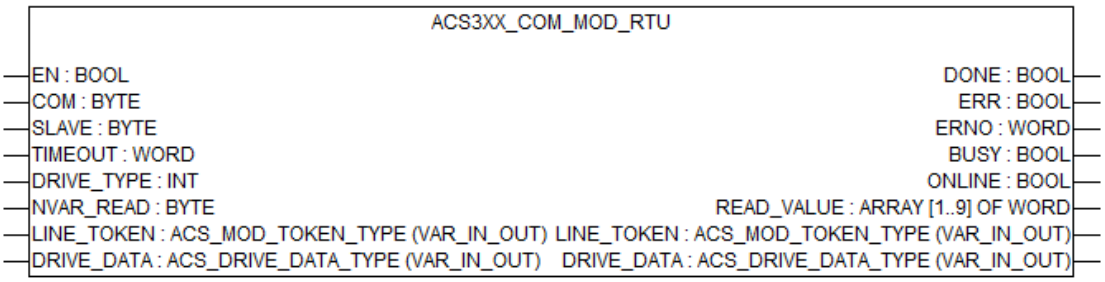
The ACS_COM_MOD_RTU_ENHANCED function block writes its SLAVE number to the LINE_TOKEN variable (takes the token) when it is 0.

If the token is already occupied it writes its SLAVE number to the next-token-request.

If all Modbus jobs of a drive are terminated, the ACS_COM_MOD_RTU_ENHANCED function block resets the token on the LINE_TOKEN variable to 0 (release the token) if the next-token-request is set (not 0).

If an ACS_COM_MOD_RTU_ENHANCED takes the token it releases the next-token-request at the same time.

Output description



LINE_TOKEN (line token)

Data type: ACS_MOD_TOKEN_TYPE

The combined input/output LINE_TOKEN must be connected to the one variable of ACS_MOD_TOKEN_TYPE of the related Modbus line. Each Modbus line must have its own LINE_TOKEN variable.

The LINE_TOKEN variable contains the token for the Modbus line and must be connected to all related ACS3XX_COM_MOD_RTU function blocks of this line (COMx).

Description:

The ACS_COM_MOD_RTU_ENHANCED function block writes its SLAVE number to the LINE_TOKEN variable (takes the token) when it is 0.

If the token is already occupied it writes its SLAVE number to the next-token-request.

If all Modbus jobs of a drive are terminated, the ACS_COM_MOD_RTU_ENHANCED function block resets the token on the LINE_TOKEN variable to 0 (release the token) if the next-token-request is set (not 0).

If an ACS_COM_MOD_RTU_ENHANCED takes the token it releases the next-token-request at the same time.

DRIVE_DATA (drive data)

Data type: ACS_DRIVE_DATA_TYPE ↬ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_RTU_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

DONE (done) Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy) Data type: BOOL

Output BUSY indicates whenever there is a communication action performed.

ONLINE (online) Data type: BOOL

After the first time input EN is set to TRUE and at least one read job and one write job is performed successfully, output ONLINE is set to TRUE.

Output ONLINE is reset to FALSE after a rising edge of EN or if an error occurs while reading the status information or writing the Control Word and Reference Values.

READ_VALUE (actual spee-darray of read values) Data type: ARRAY[1..9] OF WORD

At output READ_VALUES the values of the array are updated after the read status information job was terminated successfully (DONE = TRUE, ERR = FALSE, BUSY = FALSE).

The read status information job is requested cyclically. It reads data from the ACS drive starting at Modbus register 400051 up to the number specified at input NVAR_READ +3.

READ_VALUES contains the data as follows:

READ_VALUES[1] = <Modbus register 400054>

READ_VALUES[2] = <Modbus register 400055>

...

READ_VALUES[12] = <Modbus register 400065>.

Function call in ST:

```
ACS3XXComModRTU   (EN         := xACS3XXComModRTU_EN,
                               COM         := byACS3XXComModRTU_COM,
                               SLAVE       := byACS3XXComModRTU_SLAVE,
                               TIMEOUT     := wACS3XXComModRTU_TIMEOUT,
```

```
                                DRIVE_TYPE := eACS3XXComModRTU_DRIVE_TYPE,

                                NVAR_READ  := byACS3XXComModRTU_NVAR_READ,

                                LINE_TOKEN := tsLineToken,

                                DRIVE_DATA := tsDriveData);
xACS3XXComModRTU_DONE          := ACS3XXComModRTU.DONE;
xACS3XXComModRTU_ERR           := ACS3XXComModRTU.ERR;
wACS3XXComModRTU_ERNO          := ACS3XXComModRTU.ERNO;
xACS3XXComModRTU_BUSY          := ACS3XXComModRTU.BUSY;
xACS3XXComModRTU_ONLINE        := ACS3XXComModRTU.ONLINE;
awACS3XXComModRTU_READ_VALUE   := ACS3XXComModRTU.READ_VALUE;
```

ACS_COM_MOD_RTU communication for ACS / DCS drives via Modbus RTU

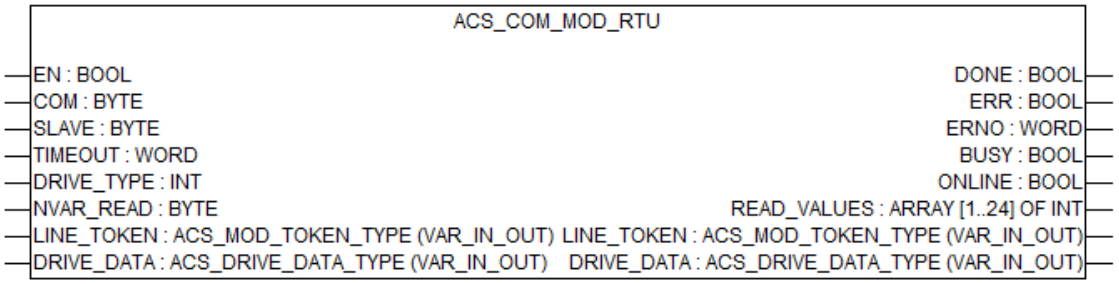


Fig. 159: Function block ACS_COM_MOD_RTU controls the Modbus RTU communication to an ACS / DCS drive and is used for the basic control of ACS / DCS drives with ABB Drives Profile.

Function block information

Available from runtime system:	V1.3.2
Included in library:	ACSDrivesComModRTU_AC500_V20.lib
Function block	with historical values

Function block ACS_COM_MOD_RTU controls the Modbus RTU communication to an ACS / DCS drive and is used for the basic control of ACS / DCS drives with ABB Drives profile. Reading Status Information from Drive The function block continuously reads data from the drive starting at Modbus register 40004. At least the Status Word (SW), Actual Value 1 (SPEED_REF), Actual Value 2 (ACT_VALUE2) are continuously read from the drive and written to the DRIVE_DATA variable.

With input NVAR_READ the function block can be configured to read in the same job between 0 .. 24 data more from the drive. These additional data is written to the array at the READ_VALUES output. These data have to be configured in the drive and are only accessible if the embedded Modbus is used. See table below for detailed information.

The following table shows the performed Modbus read job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Modbus register address in drive *)	**Mapping configuration in drive**					**Written to in AC500**		**Condition at function block**
	ACS3XX, ACX550	**ACS850, ACQ810**	**ACS580**	**ACS850, ACQ810, ACSM1, ACS880,**	**ACS800**	**DCS550, DCS800**		
Communication module	embedded fieldbus	embedded fieldbus	embedded fieldbus	FSCA-01	RMBA-01	RMBA-01		
40004	Status Word (SW)	Status Word (SW)	Par.: 58.104 = 4 - Status Word (SW)	Status Word (SW)	Status Word (SW)	Par.: 92.01=801 Status Word (SW)	DRIVE_DATA.sw	EN = TRUE
40005	Par. 53.10 (e.g.101)	Actual Value1	Par.: 58.105 = 5 – Actual Value1	Actual Value 1	Par.: 92.02 = Actual Value1 e.g. = 102 (Speed)	Par.: 92.02 = 104 Actual Value1 e.g. = 102 (Speed)	DRIVE_DATA.act-Value1	EN = TRUE
40006	Par. 53.11 (e.g.105)	Actual Value2	Par.: 58.106 = 6 – Actual Value2	Actual Value2	Par.: 92.03 = Actual Value2 e.g. = 105 (Torque) **)	92.03 = 209 Actual Value2 e.g. = 105 (Torque) **)	DRIVE_DATA.act-Value2	EN = TRUE
40007	Par. 53.12	Par. 58.35	Par.: 58.107				READ_VALUES[1]	EN = TRUE and NVAR_READ >= 1
40008	Par. 53.13	Par. 58.36	Par.: 58.108				READ_VALUES[2]	EN = TRUE and NVAR_READ >= 2
40012	Par. 53.17	Par. 58.40	Par.: 58.112				READ_VALUES[6]	EN = TRUE and NVAR_READ >= 6
40014		Par. 58.42	Par.: 58.114				READ_VALUES[8]	

Modbus register address in drive *)	Mapping configuration in drive					Written to in AC500		Condition at function block
	ACS3XX, ACX550	ACS850, ACQ810	ACS580	ACS850, ACQ810, ACSM1, ACS880,	ACS800	DCS550, DCS800		
40030		Par. 58.58					READ_VALUES[24]	EN = TRUE and NVAR_READ = 24
*) For ACS850, ACQ810 and external fieldbus adapters are having 6 digit Modbus address. Eg; ACS3XX Status Word Modbus address is 40004 and ACS850 Modbus address is 400004. **) If 51.19 .. 51.22 (Output 1 .. 4) are set to the actual values the Modbus response will be faster because those values are updated cyclically between RETA-01 and ACS800.								

If a Modbus job tries to access a register in the drive which has no valid mapping information the job is aborted with an error. Therefore in ACS3XX/ACX550 at least the Par. 53.10 and 53.11 have to be configured to the Actual Value1 and Actual Value2 e.g. 101 and 105.

If e.g. NVAR_READ = 5 the values from READ_VALUES[1 .. 5] are updated. Then all of the configured parameters Par. 53.12 ... 53.16 in the ACS3XX/ACX550 or Par. 58.35 & 58.38 in ACS850/ACQ810 drive must contain valid mapping information (not zero).

The function block checks if there are changes of the Control Word (CW), Reference Value 1 (SPEED_REF) or Reference Value 2 (REF_VALUE2) on the DRIVE_DATA variable. If there is a change a write job is requested to send these 3 values to the ACS drive starting at Modbus register 40001.

The following table shows the performed Modbus write job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Table 135: Reading status information from drive

Modbus register address in drive	Mapping configuration in drive			Taken form AC500	Condition at function block
	For all ACS drives	DCS 800 / DCS550	ACS 580		
40001	Control Word (CW)	Par.: 90.01 = 701 – Control Word (CW)	Par.: 58.101 = 1 – Control Word (CW)	DRIVE_DATA.cw	EN = TRUE
40002	Reference Value1	Par.: 90.02 = 2301 – Reference Value 1	Par.: 58.102 = 2 – Referencec Value 1	DRIVE_DATA.refValue1	EN = TRUE
40003	Reference Value2	Par.: 90.03 = 2501 – Reference Value 2	Par.: 58.103 = 3 – Referencec Value 2	DRIVE_DATA.refValue2	EN = TRUE

The requests to process other read or write Modbus jobs is transferred via the DRIVE_DATA variable at the IN_OUT variable DRIVE_DATA which can be connected to several other ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM function blocks of this drive.

If several drives are used, for each drive a communication function block such as ACS_COM_MOD_RTU must be programmed. Also every other generic slave device on the same Modbus RTU line must be programmed with it´s own ACS_COM_MOD_RTU_GEN function block. All those communication function blocks of one Modbus RTU line must be linked together via one variable of type ACS_MOD_TOKEN_TYPE, connected to the IN_OUTPUTs LINE_TOKEN. Via this variable the Modbus token is passed to the next drive / device, so only one drive / device at a time is communicating with the PLC.

Diagnosis

The output ERNO, which reflects an actual error number is only valid for one cycle if DONE and ERR output are set to TRUE.

To catch this error number an external function must be programmed.

However there are internal diagnosis variables available, which are not shown at any output, but can be accessed from the function block instance. This can be done in three ways:

- Opening the "+" sign of function block instance in the declaration part being online.
- Create an assignment in the code with <instance>.<diagnosis variable>
- Create a visualization element of the function block ACS_COM_MOD_RTU_VISU_PH.

The additional diagnosis variables are:

iWriteErrCnt:	number of errors in write jobs since EN = TRUE
wLastWriteErno:	holds the error number of the last executed write job
iReadErrCnt:	number of errors in read jobs since EN = TRUE
wLastReadErno:	holds the error number of the last executed read job

Preconditions

The function block is working with all ACS / DCS drives via Modbus RTU communication.

The data transfer to other function blocks for this drive communication to the ACS /DCSdrive is realized via the IN_OUTPUT variable DRIVE_DATA, which must be connected to the ACS_COM_MOD_RTU even if no other function block is connected.

The Modbus token is passed to other communication function blocks such as ACS_COM_MOD_RTU or ACS_COM_MOD_RTU_GEN via the IN_OUTPUT variable LINE_TOKEN which must be connected even if no other of those communication function blocks is used.

The following ACS drive parameters have to be set according the configuration for the Modbus line and the inputs of the function block.

Setting according to AC500 configuration or function block input	**ACS3XX, ACX550**	**ACS850, ACQ810**	**ACS580**	**ACS850, ACQ810, ACSM1,**	**ACS880**	**ACS800**
Communication module:	direct or FMBA-01	embedded fieldbus	embedded fieldbus	FSCA-01	FSCA-01	RMBA-01
Fieldbus activation = STD Modbus or Modbus RS-232	98.02	58.01	58.01	50.01	50.01	98.02

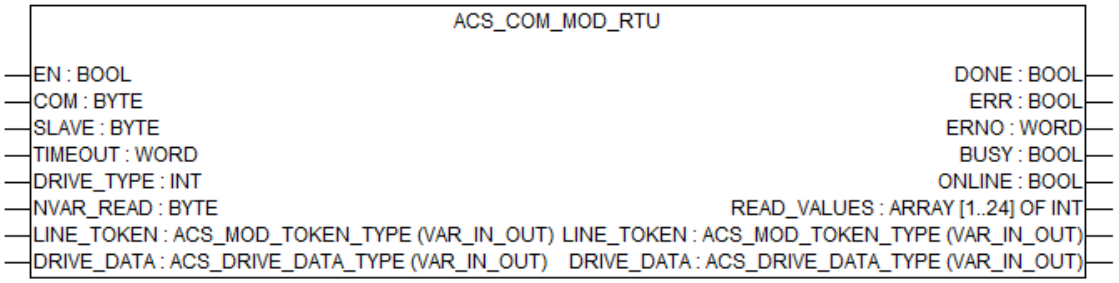
Mapping of Actual Value2 Modbus register 40006	53.11 e.g. 105	Fix	58.106	Fix	Fix	Fix
Timeout mode = None(0) or Any message(1), but not Ctrl write(2) as theses values are only written after changes.		58.08	58.15	51.07	Timeout mode	Fix monitoring of Main and Auxiliary data sets. See Manual Par.30.18.
Modbus timeout. Depending on Timeout mode. Value in 100ms.		58.07	58.16	51.06	Modbus timeout	Fix
Refresh settings in drive		58.10	58.06	51.27	51.27	

For further settings, e.g. reaction of drive at communication error, please see related drive or fieldbus adapter manual.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the block is active, the current values are available at the outputs.

After a rising edge (FALSE -> TRUE) of input EN output ONLINE is set to FALSE and parameters are read from the ACSXXX drive.

The processing of continuously read of status information from the drive (SW, ACT_VALUE1 and ACT_VALUE2) and writing of controls and Reference Values (CW, SPEED_REF, REF_VALUE2) (if they are changed) to the drive is started.

If EN is reset to FALSE while a Modbus job is performed (BUSY = TRUE), the function block will be processed until the Modbus job is terminated (DONE = TRUE for 1 cycle).

If EN is reset to FALSE while the function block actually keeps the token of the LINE_TOKEN variable, the token will be released for another drive (set to 0) as soon as no Modbus job is performed any more.

If EN = FALSE the outputs ONLINE are reset to zero, as well as the data SW, actValue1 and actValue2 on the DRIVE_DATA variable are reset to zero. The elements of the READ_VALUES array are also reset to zero.

COM (com)

Data type: BYTE

Interface identifier of Modbus line.

COM = 1: COM1

COM = 2: COM2

...

COM = 11: COM11 (using CM574-RS)

(COM3 = FPB, COM4 .. COM11 = COMs on CM574-RS).

Default value = 1. Minimum = 1, Maximum = 11

The COM input should not be changed while the program is running. If changed nevertheless, the new value will become effective only after a new rising edge of EN input.

SLAVE (slave)

Data type: BYTE

At input SLAVE, the address of the drive (slave) to which the connection shall be established must be specified.

Default value = 2, Minimum = 1, Maximum = 255

The function block is designed to be used with a fix SLAVE device. The SLAVE input should not be changed while the program is running. If changed nevertheless the new value will become effective only after an already running Modbus job is finished.

TIMEOUT (timeout)

Data type: WORD

The telegram timeout in milliseconds (ms) is specified at input TIMEOUT.

If no response is received within the time interval specified at TIMEOUT, the procedure is aborted and an error identifier is output.

If several drives are connected to the Modbus line and one drive cannot respond, the whole communication is waiting till the timeout is over and the Modbus procedure (job) is aborted. Afterwards the next drive can take the LINE_TOKEN signal. The TIMEOUT should not be set too long if more than one drive is connected, but also not too short for having a chance to respond within the TIMEOUT. A minimum of 100 is required.

Typical values should be between 300 ms and 2000 ms (range: minimum 100, maximum 65535).

Default value = 1000. Minimum = 100, Maximum = 65535.

DRIVE_TYPE (drive type)

Data type: INT, Default value: ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM. The input can be set either by the value directly or by using the enum.

ENUM	Value
ACS_DRIVE_ACS800	1
ACS_DRIVE_ACSM1	2
ACS_DRIVE_ACS350	3
ACS_DRIVE_ACS355	4
ACS_DRIVE_ACS310	5
ACS_DRIVE_ACS550	6
ACS_DRIVE_ACH550	7
ACS_DRIVE_ACQ810	8
ACS_DRIVE_ACS850	9
ACS_DRIVE_ACS880	10
ACS_DRIVE_ACS580	11
ACS_DRIVE_DCS800	12
ACS_DRIVE_DCS550	13
ACS_DRIVE_ACH580	14
ACS_DRIVE_ACS380	15
ACS_DRIVE_ACS480	16
ACS_DRIVE_ACQ580	17

NVAR_READ (number of variables for reading)

Data type: BYTE

The internal Modbus read job reads 3 + NVAR_READ words starting from Modbus register address 40004 from the drive.

Only for ACS drives using embedded fieldbus option, such as ACS3xx, ACx550, ACS850 and ACQ810 the input NVAR_READ should be set higher than 0.

With the input NVAR_READ the function block can be configured to read between 0 and 24 data more from the drive in addition to the 3 signals that are always read from Modbus registers addresses 40004 .. 40006.

If NVAR_READ input is set to e.g. 5 the internal read job addresses the Modbus registers from 40004 .. 40001.

See table *Table 135 “Reading status information from drive” on page 2303*.

The first 3 signals are always the Status Word (SW), Actual Value1 and Actual Value2 and will be written to the *“DRIVE_DATA (drive data)” on page 2309* variable.

The additional NVAR_READ data will be written to the array at the READ_VALUES output.

Example:

If e.g. NVAR_READ = 5 and all mapping Parameters, Par. 53.10 ... 53.13 for ACS3XX / ACX550 or Par. 58.35 ... 58.39 for ACS850 / ACQ810 are valid (not 0), then the values from READ_VALUES[1] to READ_VALUES[5] are updated.

Default value = 0, Minimum 0, Maximum 24.

To read/write "one" 32-bit data, the NVAR should be equal to 2. Accordingly this has to be followed if we want to read/write more than one data.

LINE_TOKEN (line token)

Data type: ACS_MOD_TOKEN_TYPE

The combined input/output LINE_TOKEN must be connected to the one variable of ACS_MOD_TOKEN_TYPE of the related Modbus line. Each Modbus line must have its own LINE_TOKEN variable.

The LINE_TOKEN variable contains the token for the Modbus line and must be connected to all related ACS3XX_COM_MOD_RTU function blocks of this line (COMx).

Description:

The ACS_COM_MOD_RTU_ENHANCED function block writes its SLAVE number to the LINE_TOKEN variable (takes the token) when it is 0.

If the token is already occupied it writes its SLAVE number to the next-token-request.

If all Modbus jobs of a drive are terminated, the ACS_COM_MOD_RTU_ENHANCED function block resets the token on the LINE_TOKEN variable to 0 (release the token) if the next-token-request is set (not 0).

If an ACS_COM_MOD_RTU_ENHANCED takes the token it releases the next-token-request at the same time.

DRIVE_DATA (drive data)

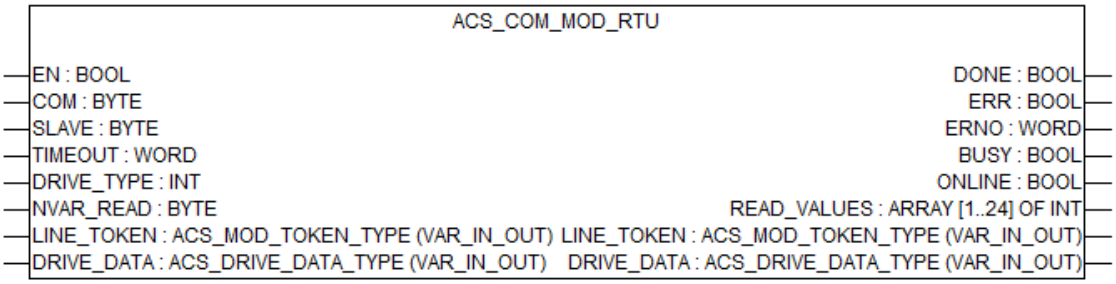
Data type: ACS_DRIVE_DATA_TYPE *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_RTU_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output description



LINE_TOKEN (line token)

Data type: ACS_MOD_TOKEN_TYPE

The combined input/output LINE_TOKEN must be connected to the one variable of ACS_MOD_TOKEN_TYPE of the related Modbus line. Each Modbus line must have its own LINE_TOKEN variable.

The LINE_TOKEN variable contains the token for the Modbus line and must be connected to all related ACS3XX_COM_MOD_RTU function blocks of this line (COMx).

Description:

The ACS_COM_MOD_RTU_ENHANCED function block writes its SLAVE number to the LINE_TOKEN variable (takes the token) when it is 0.

If the token is already occupied it writes its SLAVE number to the next-token-request.

If all Modbus jobs of a drive are terminated, the ACS_COM_MOD_RTU_ENHANCED function block resets the token on the LINE_TOKEN variable to 0 (release the token) if the next-token-request is set (not 0).

If an ACS_COM_MOD_RTU_ENHANCED takes the token it releases the next-token-request at the same time.

DRIVE_DATA (drive data)

Data type: ACS_DRIVE_DATA_TYPE ↬ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_RTU_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy)

Data type: BOOL

Output BUSY indicates whenever there is a communication action performed.

ONLINE (online)

Data type: BOOL

After the first time input EN is set to TRUE and at least one read job and one write job is performed successfully, output ONLINE is set to TRUE.

Output ONLINE is reset to FALSE after a rising edge of EN or if an error occurs while reading the status information or writing the Control Word and Reference Values.

READ_VALUES (array of read values)

Data type: ARRAY[1..12] OF INT

At output READ_VALUES the values of the array are updated after the read status information job was terminated successfully (DONE = TRUE, ERR = FALSE, BUSY = FALSE).

The read status information job is requested cyclically. It reads data from the ACS drive starting at Modbus register 400051 up to the number specified at input 3 + NVAR_READ

READ_VALUES contains the data as follows:

READ_VALUES[1] = <Modbus register 400054>

READ_VALUES[2] = <Modbus register 400055>

...

READ_VALUES[12] = <Modbus register 400065>.

Function call in ST

ACSComModRTU	(EN	= xACSComModRTU_EN,

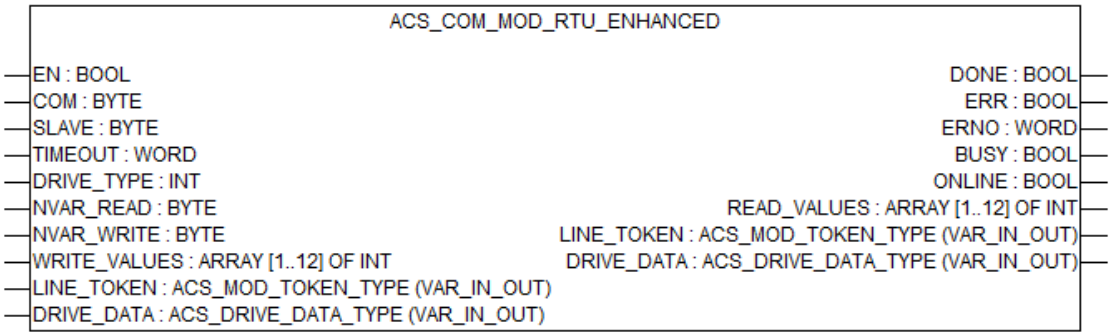
ACS_COM_MOD_RTU_ENHANCED communication for ACS drives via Modbus RTU using ABB drives profile enhanced



Function block information

Available from runtime system:	V1.3.2
Included in library:	ACSDrivesComModRTU_AC500_V20.lib
Function block	with historical values

Function block ACS_COM_MOD_RTU_ENHANCED establishes the Modbus RTU communication to an ACS drive and is used for the basic control of ACS drives with ABB Drives Profile Enhanced.

The ABB Drives Profile Enhanced communication profile provides register mapped access to the Control, Status, Reference and Actual Values of the ABB Drives Profile Enhanced. The mapping of the registers has been enhanced to allow additionally writing of up to 12 control and reading of up to 12 additionally status parameters in a single Modbus job.

The function block continuously reads data from the drive starting at Modbus register 400051. The Status Word (SW), Actual Value 1 (SPEED_REF), Actual Value 2 (ACT_VALUE2) are continuously read from the drive and written to the DRIVE_DATA variable. These values are stored in MSW, ActValue1 and ActValue2.

Apart from these three parameters there is also an option to read additional 12 more drive parameters in the same Modbus job. Using the input NVAR_READ the function block can be configured to read between 1 and 12 more parameters from the drive. All read data is then written to the array at the READ_VALUES output.

The following table shows the performed Modbus read job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Table 136: Reading status information from the drive

Modbus register address in drive	Mapping configuration in drive		Written to in AC500	Condition at function block
	ACS850, ACQ810 embedded fieldbus	**ACS850, ACQ810, ACSM1, ACS880, ACS800, ACS580**		
400051	Status Word (SW)	Status Word (SW)	DRIVE_DATA.sw	EN = TRUE
400052	Actual Value1	Actual Value1	DRIVE_DATA.act Value1	EN = TRUE
400053	Actual Value2	Actual Value2	DRIVE_DATA.act Value2	EN = TRUE
400054	Par. 58.47	FBA DATA IN 1	READ_VALUES[1]	EN = TRUE and NVAR_READ >= 1
400055	Par. 58.48	FBA DATA IN 2	READ_VALUES[2]	EN = TRUE and NVAR_READ >= 2
400065	Par. 58.58	FBA DATA IN 12	READ_VALUES[6]	EN = TRUE and NVAR_READ = 12

If a Modbus job tries to access a register in the drive which has no valid mapping information the job is aborted with an error. Therefore the drive parameters in FBA DATA IN group have to be configured according to the used NVAR_READ input number.

If 32-bit parameters are mapped to DATA IN,

- *The following field in DATA IN has to be left open (= 0) To retrieve the original 32-bit value from the drive in AC500 the HW and LW from READ_VALUES fields have to be recombined in the program.*
- *The word order of the High-Word and Low-Word can be configured in the drive. If e.g. FSCA-01 is used the configuration is done in Par.51.11.*
- *To retrieve the original 32-bit value from the drive in AC500 the HW and LW from READ_VALUES fields have to be recombined in the program.*

Function block DATA IN has to be configured in drive in the following groups see also FSCA-01 manual.

Drive	Parameter group
ACS355	FSCA-01 is not released 54.01 .. 54.10
ACS850, ACQ810, ACSM1, ACS880	52.01 .. 52.12

The function block checks if there are changes of the Control Word (CW), Reference Value 1 (SPEED_REF) or Reference Value 2 (REF_VALUE2) on the DRIVE_DATA variable. If there is a change a write job is requested to send these 3 values to the ACS drive starting at Modbus register 400001.

Apart from these three parameters there is also an option to write additional 12 more drive parameters in the same Modbus job. Using the input NVAR_WRITE the function block can be configured to write between 1 and 12 more parameters to the drive. The necessary values have to present in the array connected to WRITE_VALUES input.

The following table shows the performed Modbus write job and the needed mapping in the drive as well as the area from where the data in the AC500 is taken.

Modbus register address in drive	**Mapping configuration in drive**		**Written to in AC500**	**Condition at function block**
	ACS850, ACQ810 embedded fieldbus	**ACS850, ACQ810, ACSM1, ACS880, ACS800**		
400001	Control Word (CW)	Control Word (CW)	DRIVE_DATA.cw	EN = TRUE
400002	Reference Value1	Actual Value1	DRIVE_DATA.ref Value1	EN = TRUE
400003	Reference Value2	Actual Value2	DRIVE_DATA.ref Value2	EN = TRUE
400004	Par. 58.35	FBA DATA OUT 1	WRITE_VALUES[1]	EN = TRUE and NVAR_READ >= 1
400005	Par. 58.36	FBA DATA OUT 2	WRITE_VALUES[2]	EN = TRUE and NVAR_READ >= 2
400015	Par. 58.46	FBA DATA OUT 12	WRITE_VALUES[6]	EN = TRUE and NVAR_READ = 12

If a Modbus job tries to access a register in the drive which has no valid mapping information the job is aborted with an error. Therefore the drive parameters in FBA DATA IN group have to be configured according to the used NVAR_READ input number.

If 32-bit parameters are mapped to DATA OUT,

- *The following field in DATA OUT has to be left open (= 0)*
- *The word order of the High-Word and Low-Word can be configured in the drive. If e.g. FSCA-01 is used the configuration is done in Par.51.11.*
- *The original 32-bit value in AC500 has to be split up in HW and LW in the WRITE_VALUES array.*

Function block DATA IN has to be configured in drive in the following groups see also FSCA-01 manual.

Drive	Parameter group
ACS355	54.01 .. 54.10
ACS850, ACQ810, ACSM1, ACS880	52.01 .. 52.12

ACS drive parameters are only saved temporarily, if changed via fieldbus. To make these changes permanent in the drive the special parameter "PARAMETER SAVE" has to be set. Please see drive manuals and following table which parameter has to be set

Save valid parameters to permanent memory in drive	ACS3XX, ACX550, ACQ810, ACS850, ACSM1, ACS800	ACS880
1 = Saves the valid parameter values to permanent memory. 0 = Save completed.	Par 16.07 = 1	Par 96.07 = 1

The requests to process other read or write Modbus jobs is transferred via the DRIVE_DATA variable at the IN_OUT variable DRIVE_DATA which can be connected to several other read/ write function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM of this drive.

If several drives are used, for each drive a communication function block such as ACS_COM_MOD_RTU_ENHANCED must be programmed. Also every other generic slave device on the same Modbus RTU line must be programmed with it´s own ACS_COM_MOD_RTU_GEN function block. All those communication function blocks of one Modbus RTU line must be linked together via one variable of type ACS_MOD_TOKEN_TYPE, connected to the IN_OUTPUT LINE_TOKEN. Via this variable the Modbus token is passed to the next drive / device, so only one drive / device at a time is communicating with the PLC.

Diagnosis

The output ERNO, which reflects an actual error number is only valid for one cycle if DONE and ERR output are set to TRUE.

To catch this error number an external function must be programmed.

However there are internal diagnosis variables available, which are not shown at any output, but can be accessed from the function block instance. This can be done in three ways:

- Opening the "+" sign of function block instance in the declaration part being online.
- Create an assignment in the code with <instance>.<diagnosis variable>
- Create a visualization element of the function block.

The additional diagnosis variables are:

iWriteErrCnt:	number of errors in write jobs since EN = TRUE
wLastWriteErno:	holds the error number of the last executed write job
iReadErrCnt:	number of errors in read jobs since EN = TRUE
wLastReadErno:	holds the error number of the last executed read job

Preconditions

The function block is working with all ACS drives via Enhanced Modbus RTU communication.

The data transfer to other function blocks for this drive communication to the ACS drive is realized via the IN_OUTPUT variable DRIVE_DATA, which must be connected to ACS_COM_MOD_RTU_ENHANCED even if no other function block is connected.

The Modbus token is passed to other ACS_COM_MOD_RTU_ENHANCED function via the IN_OUTPUT variable LINE_TOKEN which must be connected even if no other ACS_COM_MOD_RTU_ENHANCED function block is used.

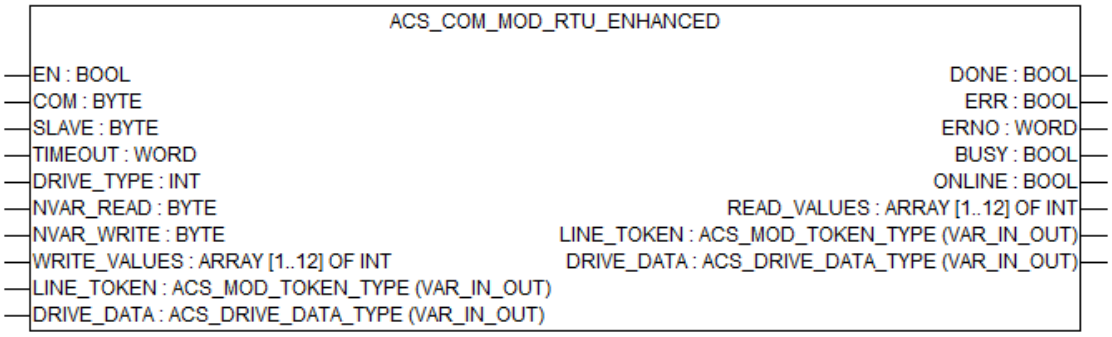
The following ACS drive parameters have to be set according to the configuration of the Modbus line and the inputs of the function block.

Setting according to AC500 configuration or function block input	**ACS355**	**ACS850, ACQ810**	**ACS850, ACQ810, ACSM1,**	**ACS880**	**ACS800**
Communication module:	FSCA-01	embedded fieldbus	FSCA-01	FSCA-01	FSCA-01
Fieldbus activation = STD Modbus or Modbus RS-232 or EXT FBA	98.02	58.01	50.01	50.01	98.02
SLAVE number	51.03	58.03	51.03	51.03	52.01
Transmission rate = AC500 Modbus configuration	51.04	58.04	51.04	51.04	52.02
Parity, Data- and Stopbits = AC500 Modbus configuration	51.05	58.05	51.05	51.05	52.03
Control profile = ABB Drives Profile Enhanced	53.05	58.06	51.02	51.02	98.07
Word order for 32-bit parameter access	No 32-bit access	58.32	51.11	51.11	51.11
Timeout mode = None(0) or Any message(1), but not Ctrl write(2) as theses values are only written after changes.	51.07	58.08	51.07	Timeout mode	Fix monitoring of Main and Auxiliary data sets. See Manual Par.30.18.

Setting according to AC500 configuration or function block input	ACS355	ACS850, ACQ810	ACS850, ACQ810, ACSM1,	ACS880	ACS800
Modbus timeout. Depending on Timeout mode. Value in 100ms.	51.06	58.07	51.06	Modbus timeout	Fix
Refresh settings in drive	51.27	58.10	51.27	51.27	

For further settings, e.g. reaction of drive at communication error, please see related drive manual.

Input descriptions



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable) Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the block is active, the current values are available at the outputs.

After a rising edge (FALSE -> TRUE) of input EN output ONLINE is set to FALSE and parameters are read from the ACS drive.

The processing of continuously read of status information from the drive (SW, ACT_VALUE1 and ACT_VALUE2) and writing of Control Word and Reference Values (CW, SPEED_REF, REF_VALUE2) (if they are changed) to the drive is started.

If EN is reset to FALSE while a Modbus job is performed (BUSY = TRUE), the function block will be processed until the Modbus job is terminated (DONE = TRUE for 1 cycle).

If EN is reset to FALSE while the function block actually keeps the token of the LINE_TOKEN variable the token will be released for another drive (set to 0) as soon as no Modbus job is performed any more.

If EN = FALSE the outputs ONLINE are reset to zero, as well as the data SW, actValue1 and actValue2 on the DRIVE_DATA variable are reset to zero. The elements of the READ_VALUES array are also reset to zero.

COM (com)

Data type: BYTE

Interface identifier of Modbus line.

COM = 1: COM1

COM = 2: COM2

...

COM = 11: COM11 (using CM574-RS)

(COM3 = FPB, COM4 .. COM11 = COMs on CM574-RS).

Default value = 1. Minimum = 1, Maximum = 11

The COM input should not be changed while the program is running. If changed nevertheless, the new value will become effective only after a new rising edge of EN input.

SLAVE (slave)

Data type: BYTE

At input SLAVE, the address of the drive (slave) to which the connection shall be established must be specified.

Default value = 2, Minimum = 1, Maximum = 255

The function block is designed to be used with a fix SLAVE device. The SLAVE input should not be changed while the program is running. If changed nevertheless the new value will become effective only after an already running Modbus job is finished.

TIMEOUT (timeout)

Data type: WORD

The telegram timeout in milliseconds (ms) is specified at input TIMEOUT.

If no response is received within the time interval specified at TIMEOUT, the procedure is aborted and an error identifier is output.

If several drives are connected to the Modbus line and one drive cannot respond, the whole communication is waiting till the timeout is over and the Modbus procedure (job) is aborted. Afterwards the next drive can take the LINE_TOKEN signal. The TIMEOUT should not be set too long if more than one drive is connected, but also not too short for having a chance to respond within the TIMEOUT. A minimum of 100 is required.

Typical values should be between 300 ms and 2000 ms (range: minimum 100, maximum 65535).

Default value = 1000. Minimum = 100, Maximum = 65535.

DRIVE_TYPE (drive type)

Data type: INT, Default value: ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM. The input can be set either by the value directly or by using the enum.

ENUM	Value
ACS_DRIVE_ACS800	1
ACS_DRIVE_ACSM1	2
ACS_DRIVE_ACS350	3
ACS_DRIVE_ACS355	4
ACS_DRIVE_ACS310	5
ACS_DRIVE_ACS550	6

ENUM	Value
ACS_DRIVE_ACH550	7
ACS_DRIVE_ACQ810	8
ACS_DRIVE_ACS850	9
ACS_DRIVE_ACS880	10
ACS_DRIVE_ACS580	11
ACS_DRIVE_DCS800	12
ACS_DRIVE_DCS550	13
ACS_DRIVE_ACH580	14
ACS_DRIVE_ACS380	15
ACS_DRIVE_ACS480	16
ACS_DRIVE_ACQ580	17

NVAR_READ (number of variables for reading)

Data type: BYTE

The internal Modbus read job reads 3 + NVAR_READ words starting from Modbus register address 400051 from the drive.

With the input NVAR_READ the function block can be configured to read between 0 and 12 data more from the drive in addition to the 3 signals that are always read from Modbus registers addresses 400051 .. 400053.

If NVAR_READ input is set to e.g. 5 the internal read job addresses the Modbus registers from 400051 .. 400058.

The first 3 signals are always the Status Word (SW), Actual Value1 and Actual Value2 and will be written to the *“DRIVE_DATA (drive data)” on page 2320* variable. The additional NVAR_READ data will be written to the array at the READ_VALUES output.

See table *Table 136 “Reading status information from the drive” on page 2313* about how to configure the drive and where the data is stored in AC500.

Default value = 0. Minimum = 0, Maximum = 12.

To read/write "one" 32-bit data, the NVAR should be equal to 2. Accordingly this has to be followed if we want to read/write more than one data.

NVAR_WRITE (number of variables for writing)

Data type: BYTE

The internal Modbus write job writes 3 + NVAR_WRITE words starting from Modbus register address 400001 to the drive, every time a change in those variables is detected.

With the input NVAR_WRITE the function block can be configured to write between 0 and 12 variables more to the drive in addition to the 3 controls (CW, ref1 and ref2). These are always written to Modbus registers addresses 400001 .. 400003 if changed.

If NVAR_WRITE input is set to e.g. 5 the internal write job addresses the Modbus registers from 400001 .. 400008.

The first 3 signals are always the Control Word (CW), Reference value1 and Reference value2 and will be taken from the DRIVE_DATA variable.

The additional NVAR_WRITE data will be taken from the array at the WRITE_VALUES input.

Default value = 0. Minimum 0, Maximum 12.

WRITE_VALUES (write values to mapped parameters in drive group DATA_OUT)

Data type: ARRAY[1..12] OF INT

The values from the array at input WRITE_VALUE will be written to Modbus registers 400004 400015 in the drive. The number of data written to the drive is specified at the input NVAR_WRITE.

See table in chapter Writing Control Word and Reference Values to the drive for information about how to configure the drive.

LINE_TOKEN (line token)

Data type: ACS_MOD_TOKEN_TYPE

The combined input/output LINE_TOKEN must be connected to the one variable of ACS_MOD_TOKEN_TYPE of the related Modbus line. Each Modbus line must have its own LINE_TOKEN variable.

The LINE_TOKEN variable contains the token for the Modbus line and must be connected to all related ACS3XX_COM_MOD_RTU function blocks of this line (COMx).

Description:

The ACS_COM_MOD_RTU_ENHANCED function block writes its SLAVE number to the LINE_TOKEN variable (takes the token) when it is 0.

If the token is already occupied it writes its SLAVE number to the next-token-request.

If all Modbus jobs of a drive are terminated, the ACS_COM_MOD_RTU_ENHANCED function block resets the token on the LINE_TOKEN variable to 0 (release the token) if the next-token-request is set (not 0).

If an ACS_COM_MOD_RTU_ENHANCED takes the token it releases the next-token-request at the same time.

DRIVE_DATA (drive data)

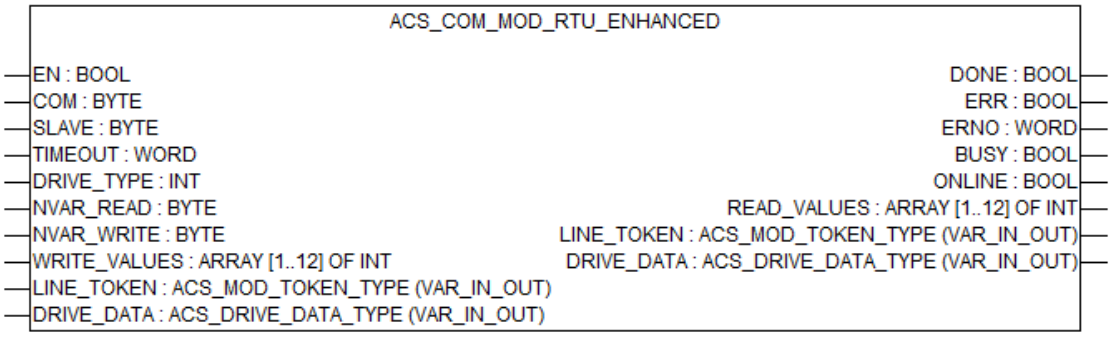
Data type: ACS_DRIVE_DATA_TYPE *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_RTU_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output descriptions



LINE_TOKEN (line token)

Data type: ACS_MOD_TOKEN_TYPE

The combined input/output LINE_TOKEN must be connected to the one variable of ACS_MOD_TOKEN_TYPE of the related Modbus line. Each Modbus line must have its own LINE_TOKEN variable.

The LINE_TOKEN variable contains the token for the Modbus line and must be connected to all related ACS3XX_COM_MOD_RTU function blocks of this line (COMx).

Description:

The ACS_COM_MOD_RTU_ENHANCED function block writes its SLAVE number to the LINE_TOKEN variable (takes the token) when it is 0.

If the token is already occupied it writes its SLAVE number to the next-token-request.

If all Modbus jobs of a drive are terminated, the ACS_COM_MOD_RTU_ENHANCED function block resets the token on the LINE_TOKEN variable to 0 (release the token) if the next-token-request is set (not 0).

If an ACS_COM_MOD_RTU_ENHANCED takes the token it releases the next-token-request at the same time.

DRIVE_DATA (drive data)

Data type: ACS_DRIVE_DATA_TYPE ↳ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_RTU_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter ↳ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy)

Data type: BOOL

Output BUSY indicates whenever there is a communication action performed.

ONLINE (online) Data type: BOOL

After the first time input EN is set to TRUE and at least one read job and one write job is performed successfully, output ONLINE is set to TRUE.

Output ONLINE is reset to FALSE after a rising edge of EN or if an error occurs while reading the status information or writing the Control Word and Reference Values.

READ_VALUES (array of read values) Data type: ARRAY[1..12] OF INT

At output READ_VALUES the values of the array are updated after the read status information job was terminated successfully (DONE = TRUE, ERR = FALSE, BUSY = FALSE).

The read status information job is requested cyclically. It reads data from the ACS drive starting at Modbus register 400051 up to the number specified at input 3 + NVAR_READ

READ_VALUES contains the data as follows:

READ_VALUES[1] = <Modbus register 400054>

READ_VALUES[2] = <Modbus register 400055>

...

READ_VALUES[12] = <Modbus register 400065>.

Function call in ST

```

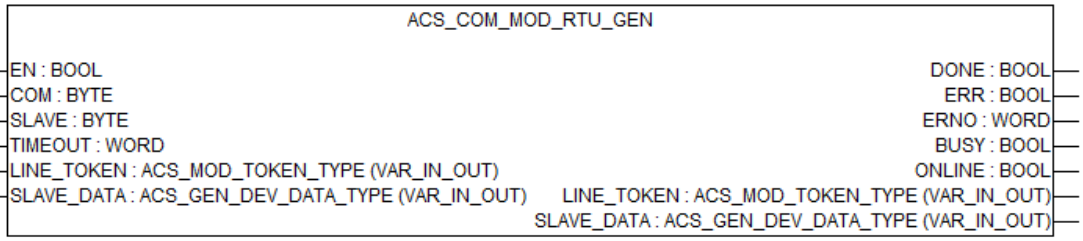
ACSComModRTUEnhanced.READ_VALUES;
```

ACS_COM_MOD_RTU_GEN communication for generic devices via Modbus RTU



Function block ACS_COM_MOD_RTU_GEN controls the Modbus RTU communication to a generic slave device. It must be used together with the function blocks ACS_COM_MOD_RTU_GEN_READ_N_PRM and/or ACS_COM_MOD_RTU_GEN_WRITE_N_PRM to exchange Modbus data. function block ACS_COM_MOD_RTU_GEN controls the Modbus RTU communication to a generic Modbus RTU server device. A generic Modbus RTU server device can be any field device which supports Modbus RTU server within it such as PLC, HMI or ABB ACS/DCS drive etc. It must be used together with the function blocks ACS_COM_MOD_RTU_GEN_READ_N_PRM and/or ACS_COM_MOD_RTU_GEN_WRITE_N_and/or ModRtuReadWrite23 to exchange Modbus data.

Block data

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesComModRTU_AC500_V20.lib
Function block	with historical values

If more devices are connected to the same Modbus RTU line, for each of them an own instance of ACS_COM_MOD_RTU_GEN or ACS_COM_MOD_RTU_ENHANCED or ACS_COM_MOD_RTU (for connection to an ABB ACS/DCS drive) function block must be used. All these function blocks must be connected to the same LineToken variable of type ACS_MOD_TOKEN_TYPE at their IN_OUT LINE_TOKEN. Via this LINE_TOKEN variable the serial access to the different devices is controlled. All these blocks must be called within the same PLC task.

At the IN_OUT SLAVE_DATA a variable of type ACS_GEN_DEV_DATA_TYPE must be connected, which inturn connected to the Modbus read/write blocks related to the same device. Via these blocks ACS_COM_MOD_RTU_GEN_READ_N_PRM and ACS_COM_MOD_RTU_GEN_WRITE_N_PRM the Modbus jobs are initiated in the order they are programmed. The requests to process these read or write Modbus jobs is transferred via the SLAVE_DATA variable to the ACS_COM_MOD_RTU_GEN block. The Modbus job will be started, when the ACS_COM_MOD_RTU_GEN block of the server has the token, and the read/write block was started before. All these blocks must be called within the same PLC task.

The input TIMEOUT sets the timeout for one Modbus job in ms. After a timeout this server will not be reconnected for the time which can be assigned at the variable SLAVA_DATA<point>reconnectPause in seconds. So a steady delay for a disconnected server can be avoided ↯ *Chapter 1.5.6.2.2 “Special characteristics of the ACS drives base library” on page 2206*.

Diagnosis: The output ERNO, which reflects an actual error number is only valid for one cycle, output ERR is set to TRUE. To capture this error number, an external function must be programmed. However there are internal diagnosis variables available, which are not shown at any output, but can be accessed from the function block instance or visualization.

The additional diagnosis variables are:

iWriteErrCnt: number of errors in write jobs since Enable = TRUE. wLastWriteErno: holds the error number of the last executed write job.

iReadErrCnt: number of errors in read jobs since Enable = TRUE. wLastReadErno: holds the error number of the last executed read job.

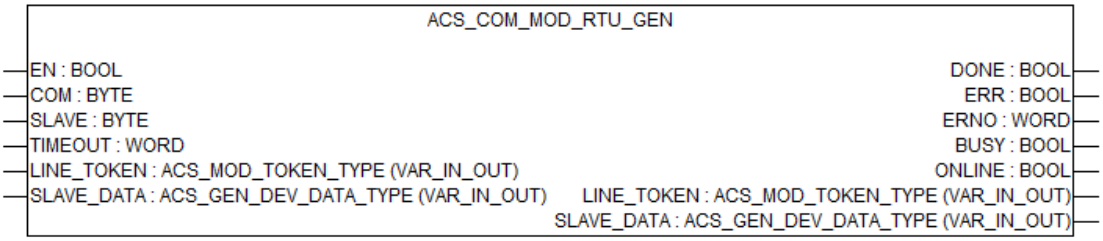
iReadWriteErrCnt: number of errors in readwrite23 with function code 23 jobs since Enable = TRUE. wLastReadWriteErno: holds the error number of the last executed readwrite23 job.

iWriteMaskErrCnt: number of errors in writemask22 with function code 22 jobs since Enable = TRUE.

wLastWriteMaskErno: holds the error number of the last executed readwrite22 job.

This function block must not be used in parallel with COM_MOD_MAST function block for the same RTU line. The function block must be used in same PLC task than other function blocks using the same variable on IN_OUT LINE_TOKEN and IN_OUT SLAVE_DATA.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the block is active, the current values are available at the outputs.

After a rising edge (FALSE -> TRUE) of input EN output ONLINE is set to FALSE.

If EN is reset to FALSE while a Modbus job is performed (BUSY = TRUE), the function block will be processed until the Modbus job is terminated (DONE = TRUE for 1 cycle).

If EN is reset to FALSE while the function block actually keeps the token of the LINE_TOKEN variable the token will be released for another device (set to 0).

COM (com)

Data type: BYTE

Interface identifier of Modbus line.

COM = 1: COM1

COM = 2: COM2

...

COM = 11: COM11 (using CM574-RS)

(COM3 = FPB, COM4 .. COM11 = COMs on CM574-RS).

Default value = 1. Minimum = 1, Maximum = 11

The COM input should not be changed while the program is running. If changed nevertheless, the new value will become effective only after a new rising edge of EN input.

SLAVE (slave)

Data type: BYTE

At input SLAVE, the address of the drive (slave) to which the connection shall be established must be specified.

Default value = 2, Minimum = 1, Maximum = 255

The function block is designed to be used with a fix SLAVE device. The SLAVE input should not be changed while the program is running. If changed nevertheless the new value will become effective only after an already running Modbus job is finished.

TIMEOUT (timeout)

Data type: WORD

The telegram timeout in milliseconds (ms) is specified at input TIMEOUT.

If no response is received within the time interval specified at TIMEOUT, the procedure is aborted and an error identifier is output.

If several drives are connected to the Modbus line and one drive cannot respond, the whole communication is waiting till the timeout is over and the Modbus procedure (job) is aborted. Afterwards the next drive can take the LINE_TOKEN signal. The TIMEOUT should not be set too long if more than one drive is connected, but also not too short for having a chance to respond within the TIMEOUT. A minimum of 100 is required.

Typical values should be between 300 ms and 2000 ms (range: minimum 100, maximum 65535).

Default value = 1000. Minimum = 100, Maximum = 65535.

LINE_TOKEN (line token)

Data type: ACS_MOD_TOKEN_TYPE

The combined input/output LINE_TOKEN must be connected to the one variable of ACS_MOD_TOKEN_TYPE of the related Modbus line. Each Modbus line must have its own LINE_TOKEN variable.

The LINE_TOKEN variable contains the token for the Modbus line and must be connected to all related ACS3XX_COM_MOD_RTU function blocks of this line (COMx).

Description:

The ACS_COM_MOD_RTU_ENHANCED function block writes its SLAVE number to the LINE_TOKEN variable (takes the token) when it is 0.

If the token is already occupied it writes its SLAVE number to the next-token-request.

If all Modbus jobs of a drive are terminated, the ACS_COM_MOD_RTU_ENHANCED function block resets the token on the LINE_TOKEN variable to 0 (release the token) if the next-token-request is set (not 0).

If an ACS_COM_MOD_RTU_ENHANCED takes the token it releases the next-token-request at the same time.

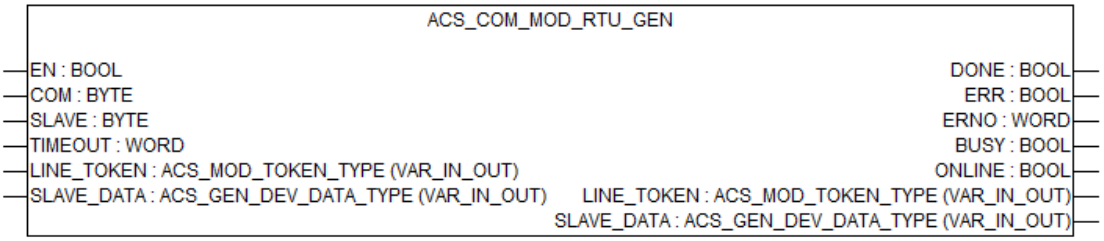
SLAVE_DATA (slave data)

Data type: ACS_DRIVE_DATA_TYPE

The combined input/output SLAVE_DATA must be connected to the variable of type ACS_GEN_DEV_DATA_TYPE of the related slave device. Each device must have its own SLAVE_DATA variable.

The SLAVE_DATA variable transfers the Modbus data from the ACS_COM_MOD_RTU_GEN_READ_N_PRM or ACS_COM_MOD_RTU_GEN_WRITE_N_PRM function blocks to the ACS_COM_MOD_RTU_GEN function block. It contains also some information about the online state of the device and must be connected to all related function blocks of this device.

Output description



DONE (done) Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy) Data type: BOOL

Output BUSY indicates whenever there is a communication action performed.

ONLINE (online) Data type: BOOL

After the first time input EN is set to TRUE and at least one read job and one write job is performed successfully, output ONLINE is set to TRUE.

Output ONLINE is reset to FALSE after a rising edge of EN or if an error occurs while reading the status information or writing the Control Word and Reference Values.

```

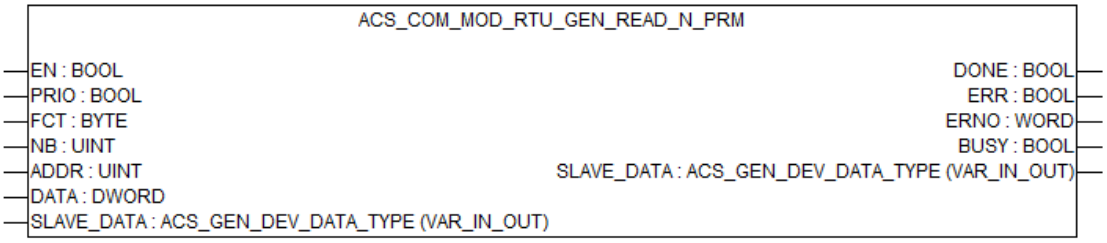
ACS_COM_MOD_RTU_GEN_READ_N_PRM read N parameters from a generic Modbus RTU device



Function block information

Available from runtime system:	V1.3.2
Included in library:	ACSDrivesComModRTU_AC500_V20.lib
Function block	with historical values

Function block ACS_COM_MOD_RTU_GEN_READ_N_PRM reads n data of the slave device. The number of data to be read is specified at the input NB. The first address is specified at the input ADDR. The values of the data is stored in the PLC memory area, defined at the input DATA. The values in the PLC memory area are updated when the read job was performed without error. This is indicated by DONE = TRUE and ERR = FALSE.

As long as the EN = TRUE a new read job is requested each time the further read job is terminated.

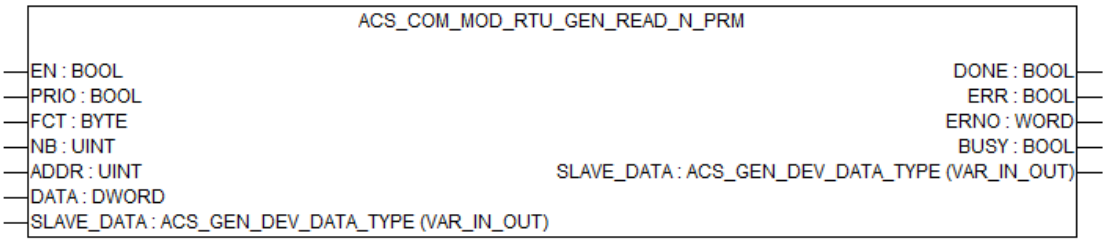
The Modbus job is started from the ACS_COM_MOD_RTU_GEN function block which is connected to the same SLAVE_DATA variable.

The slave address of the device from which the data is read is specified at this ACS_COM_MOD_RTU_GEN block.

If the input values are valid, a request to perform a Modbus RTU job is send to the ACS_COM_MOD_RTU_GEN block via the SLAVE_DATA variable.

The ACS_COM_MOD_RTU_GEN_READ_N_PRM function block does only change the values at the DATA input if the Modbus job was excecuted without errors. If the block is not enabled or the connection to the ACS_COM_MOD_RTU_GEN block is not ok these values are not updated and keep their previous values. This is also the case for the internal VALUE array. However the ACS_MOD_READ_N_PRM for drives does reset its values attached to DATA input and the VALUE array to zero in case of no connection to the related ACS_COM_MOD function block or if the block is not enabled.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type: BOOL

If a TRUE state is applied to the input EN, a request to perform a Modbus read job is set to the SLAVE_DATA variable.

All further inputs are read in.

If the state of EN stays TRUE a new read job is requested each time the previous job is terminated, indicated by the DONE = TRUE flag.

PRIO (priority)

Data type: BOOL

Input PRIO is reserved for future usage. It can be left open.

FCT (number of variables)

Data type: BYTE

The function code of the request telegram is specified at input FCT.

01 or 02	read n bits
03 or 04	read n words
05	write one bit
06	write one word
15	write n bits
16	write n words

NB (number of variables)

Data type: UINT

At input NB, the number of data to be read is specified.

The unit of NB depends on the selected function. For bit accesses the number of bits, for word and double word accesses the number of words is specified at NB.

Default: 1. Minimum 1, Maximum 96.

ADDR (address)

Data type: UINT

The operand/register address in the slave from which data should be read is specified at input ADDR.

The access to operands of AC500 devices in Modbus slave mode is defined via the Modbus cross-reference list. Only operands that are listed in the cross-reference list may be used (see Communication with Modbus RTU).

Only operands that are listed in the Modbus address list may be used. When accessing other devices, ADDR is freely selectable. The valid ranges have to be gathered from the corresponding device description.

DATA (data)

Data type: DWORD

At input DATA, the address of the first operand in the PLC is specified to which the data read by the slave should be stored.

For this purpose it is necessary that all PLC variables, which are written to the drive, have consecutive addresses. This can be obtained by declaration of each variable within the %MW0.xxx area or declaration of an array containing all variables.

Declaration of each variable has the advantage, that the types (integer or word) can be selected individually.

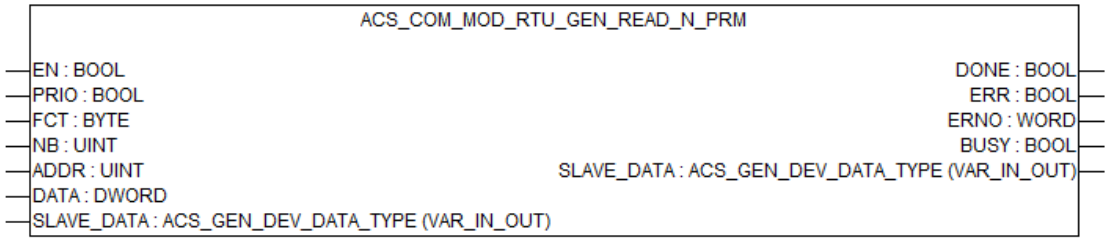
SLAVE_DATA (slave data)

Data type: ACS_DRIVE_DATA_TYPE

The combined input/output SLAVE_DATA must be connected to the variable of type ACS_GEN_DEV_DATA_TYPE of the related slave device. Each device must have its own SLAVE_DATA variable.

The SLAVE_DATA variable transfers the Modbus data from the ACS_COM_MOD_RTU_GEN_READ_N_PRM or ACS_COM_MOD_RTU_GEN_WRITE_N_PRM function blocks to the ACS_COM_MOD_RTU_GEN function block. It contains also some information about the online state of the device and must be connected to all related function blocks of this device.

Output description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy)

Data type: BOOL

Output BUSY indicates whenever there is a communication action performed.

Function call in ST

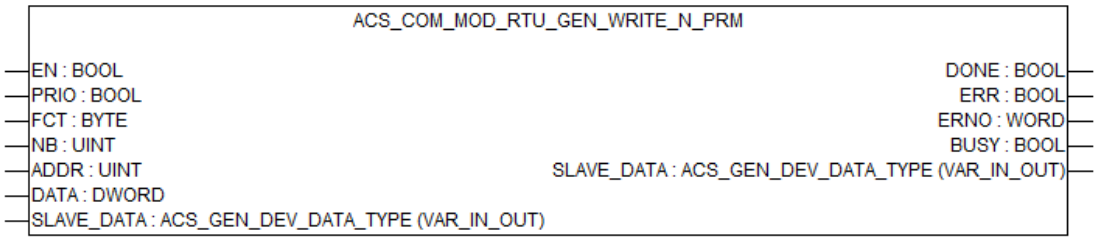
ACS_COM_MOD_RTU_GEN_WRITE_N_PRM write N parameters to a generic Modbus RTU device



Function block information

Available from runtime system:	V1.3.2
Included in library:	ACSDrivesComModRTU_AC500_V20.lib
Function block	with historical values

Function block ACS_COM_MOD_RTU_GEN_WRITE_N_PRM writes n data to the slave device. The number of data to be written is specified at the input NB. The first address is specified at the input ADDR. The values of the data that should be written must be stored in the PLC memory area, defined at the input DATA. A successful writing is indicated by DONE = TRUE and ERR = FALSE.

To initiate a write job the EN input must be given a rising edge. (FALSE -> TRUE).

After termination of this job, even if it was not successful, a next writing can once again only be started with a rising edge at EN input.

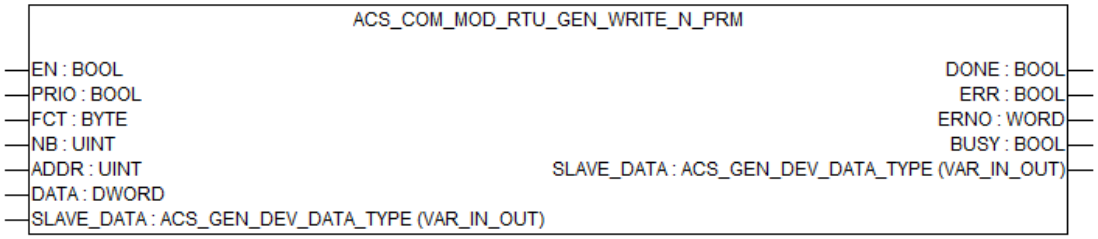
The Modbus job is started from the ACS_COM_MOD_RTU_GEN function block which is connected to the same SLAVE_DATA variable.

The slave address of the device to which the data is written is specified at this ACS_COM_MOD_RTU_GEN block.

If the input values are valid, a request to perform a Modbus RTU job is send to the ACS_COM_MOD_RTU_GEN block via the SLAVE_DATA variable.

If at least 1 input is invalid, no job is generated and the error is displayed at the outputs ERR and ERNO instead.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type: BOOL

If a FALSE -> TRUE edge is applied to input EN, all further inputs are read in (edge sensitive).

If the input values are valid, a request telegram is sent to the communication block via the DRIVE_DATA variable.

If at least 1 input is invalid, no telegram is generated and the error is displayed at the outputs ERR and ERNO instead.

The inputs are read in until the job is processed. This can be seen at the output BUSY.

PRIO (priority)

Data type: BOOL

Input PRIO is reserved for future usage. It can be left open.

FCT (number of variables)

Data type: BYTE

The function code of the request telegram is specified at input FCT.

01 or 02	read n bits
03 or 04	read n words
05	write one bit
06	write one word
15	write n bits
16	write n words

NB (number of variables)

Data type: UINT

At input NB, the number of data to be read is specified.

The unit of NB depends on the selected function. For bit accesses the number of bits, for word and double word accesses the number of words is specified at NB.

Default: 1. Minimum 1, Maximum 96.

ADDR (address)

Data type: UINT

The operand/register address in the slave from which data should be read is specified at input ADDR.

The access to operands of AC500 devices in Modbus slave mode is defined via the Modbus cross-reference list. Only operands that are listed in the cross-reference list may be used (see Communication with Modbus RTU).

Only operands that are listed in the Modbus address list may be used. When accessing other devices, ADDR is freely selectable. The valid ranges have to be gathered from the corresponding device description.

DATA (data)

Data type: DWORD

At input DATA, the address of the first operand in the PLC is specified to which the data read by the slave should be stored.

For this purpose it is necessary that all PLC variables, which are written to the drive, have consecutive addresses. This can be obtained by declaration of each variable within the %MW0.xxx area or declaration of an array containing all variables.

Declaration of each variable has the advantage, that the types (integer or word) can be selected individually.

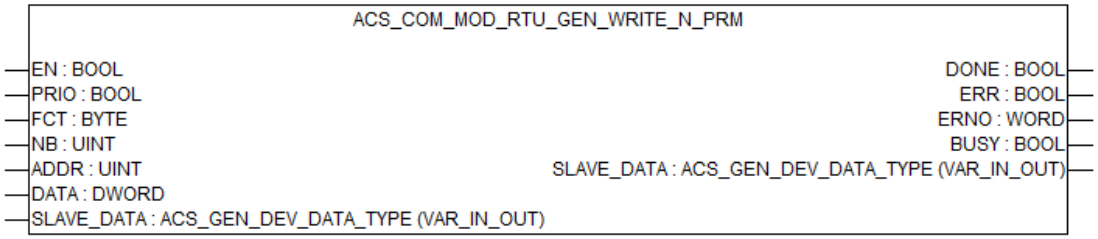
SLAVE_DATA (slave data)

Data type: ACS_DRIVE_DATA_TYPE

The combined input/output SLAVE_DATA must be connected to the variable of type ACS_GEN_DEV_DATA_TYPE of the related slave device. Each device must have its own SLAVE_DATA variable.

The SLAVE_DATA variable transfers the Modbus data from the ACS_COM_MOD_RTU_GEN_READ_N_PRM or ACS_COM_MOD_RTU_GEN_WRITE_N_PRM function blocks to the ACS_COM_MOD_RTU_GEN function block. It contains also some information about the online state of the device and must be connected to all related function blocks of this device.

Output description



> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

SLAVE_DATA (slave data)

Data type: ACS_DRIVE_DATA_TYPE

The combined input/output SLAVE_DATA must be connected to the variable of type ACS_GEN_DEV_DATA_TYPE of the related slave device. Each device must have its own SLAVE_DATA variable.

The SLAVE_DATA variable transfers the Modbus data from the ACS_COM_MOD_RTU_GEN_READ_N_PRM or ACS_COM_MOD_RTU_GEN_WRITE_N_PRM function blocks to the ACS_COM_MOD_RTU_GEN function block. It contains also some information about the online state of the device and must be connected to all related function blocks of this device.

DONE (done)

Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error)

Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number)

Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter ↬ *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy)

Data type: BOOL

Output BUSY indicates whenever there is a communication action performed.

Function call in ST

```
dwAcsComModRTUGenWriteNPrm_DATA    :=
ADR(aiAcsComModRTUGenWriteNPrm_VALUE[1]);

1.5.6.3.6 Structures

ACS_GEN_DEV_DATA_TYPE structure to exchange data between function blocks for 1 generic device

Structure ACS_GEN_DEV_DATA_TYPE is used for the SLAVE_DATA variable to exchange the data for one generic Modbus slave device.

Structure data

Available as of runtime system:	V1.3.2	Remark:
Included in library:	ACSDrivesCom-ModRTU_AC500_V20.lib	ACSDrives-Base_AC500_V20.lib is needed in addition.

Structure

Visible variable	Type	Default value	User access *)	Description
online	BOOL	FALSE	R	Connection established – set in Modbus communication function block after successfull reading and writing one Modbus job.

name	STRING(20)	Default Drive Name	R/W	Name for slave device which can be set by user directly to SLAVE_DATA variable – as information or use in visualizations.
adapterType	INT	1	R	Will be set to 100 in ACS_COM_MOD_RTU_GEN for internal checks.
*) R = read only, R/W = read and write access				

Description

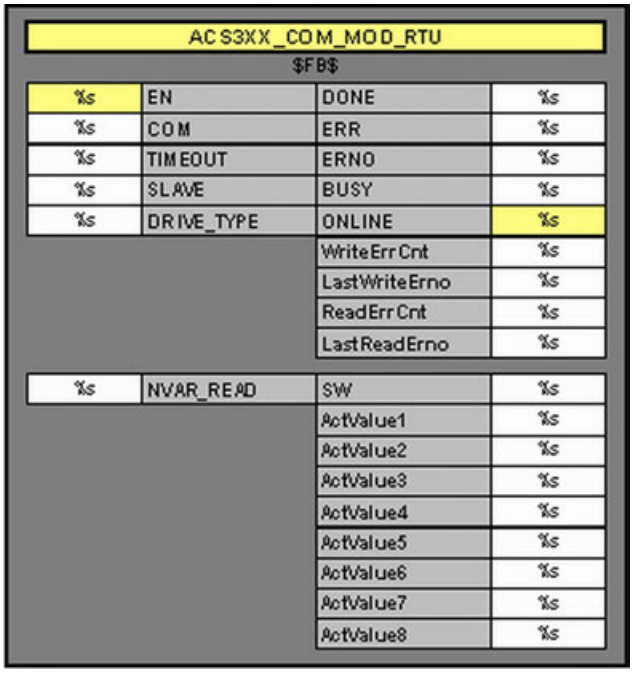
Structure ACS_GEN_DEV_DATA_TYPE is used for the SLAVE_DATA variable which must be connected to all function blocks related to the same device.

Besides the variable "name" all variables should not be written by the user directly. They are read and written within the function blocks.

The ACS_GEN_DEV_DATA_TYPE contains some more internal, invisible variables which are used for interlocks and data transfer and not meant for user access.

1.5.6.3.7 Visualizations

ACS3XX_COM_MOD_RTU_VISU_PH faceplate for the function block ACS3XX_COM_MOD_RTU



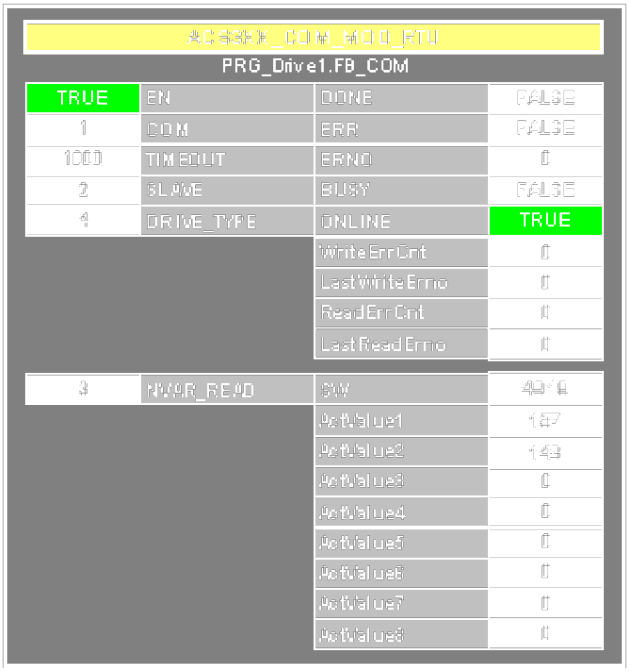


Fig. 160: Visualization offline / online mode

Visualization element ACS3XX_COM_MOD_RTU_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS3XX_COM_MOD_RTU function block which instance was used to replace the placeholder FB.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

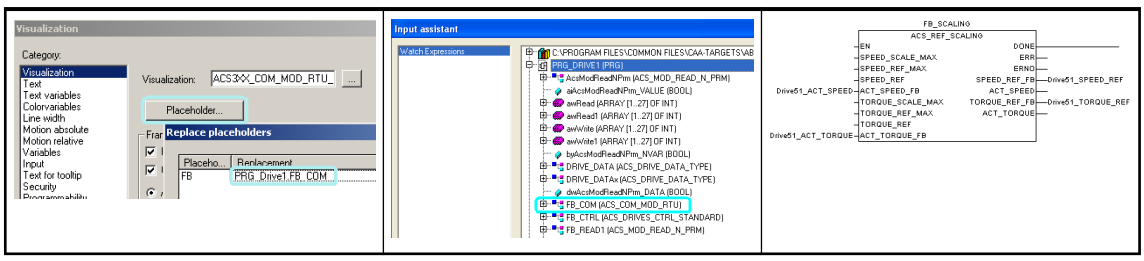
Visualization information

Available in runtime system:	V1.3.2
Included in library:	ACSDrivesComModRTU_AC500_V20_App.lib

Visualization description

Visualization element ACS3XX_COM_MOD_RTU_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS3XX_COM_MOD_RTU ↳ *Chapter 1.5.6.3.5.1 “ACS3XX_COM_MOD_RTU communication for ACS3XXwrite one bit/ACX550 drives via Modbus RTU” on page 2293* function block which instance was used to replace the placeholder FB.

All inputs of that ACS3XX_COM_MOD_RTU function block, which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.



Parameters

Access R/W

EN Access via: Toggle

Description: EN input

COM Access via: Numpad 1..10

Description: COM. After a change the program must be reset (create boot project, reset and start).

TIMEOUT Access via: Numpad min. 1

Description: TIMEOUT input

SLAVE Way of Access: Numpad 1..31

Description: SLAVE input

DRIVE_TYPE Access via: Numpad 1 ..17

Description: DRIVE_TYPE input

NVAR_READ Access via: Numpad 0 .. 12

Description: NVAR_READ input

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Drive1.FB_COM

Access R

DONE Description: DONE output.

ERR Description: ERR output.

ERNO Description: ERNO output.

WriteErrCnt Description: Numbers of write errors since EN = TRUE, is reset to 0 with rising edge of EN.

LastWriteErno Description: Error number of the last write job. See error messages of ETH_MOD_MAST function block.

ReadErrCnt Description: Numbers of read errors since EN = TRUE, is reset to 0 with rising edge of EN.

LastReadErno Description: Error number of the last read job. See error messages of COM_MOD_MAST function block.

SW_BIT13 Description: Status Word of drive, READ_VALUE[1] output

ACT_VALUE1 Description:Actual Value 1 mapped in Par. 53.10 - READ_VALUE[2] output

ACT_VALUE2 Description:Actual Value 2 mapped in Par. 53.11 - READ_VALUE[3] output

ACT_VALUE3 Description:Actual Value 3 mapped in Par. 53.12 - READ_VALUE[4] output

ACT_VALUE4 Description:Actual Value 4 mapped in Par. 53.13 - READ_VALUE[5] output

ACT_VALUE5 Description:Actual Value 5 mapped in Par. 53.14 - READ_VALUE[6] output

ACT_VALUE6 Description:Actual Value 6 mapped in Par. 53.15 - READ_VALUE[7] output

ACT_VALUE7 Description:Actual Value 7 mapped in Par. 53.16 - READ_VALUE[8] output

ACT_VALUE8 Description:Actual Value 8 mapped in Par. 53.17 - READ_VALUE[9] output

Colors

The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_COM_MOD_RTU_GEN_VISU_PH faceplate for the function block ACS_COM_MOD_RTU_GEN

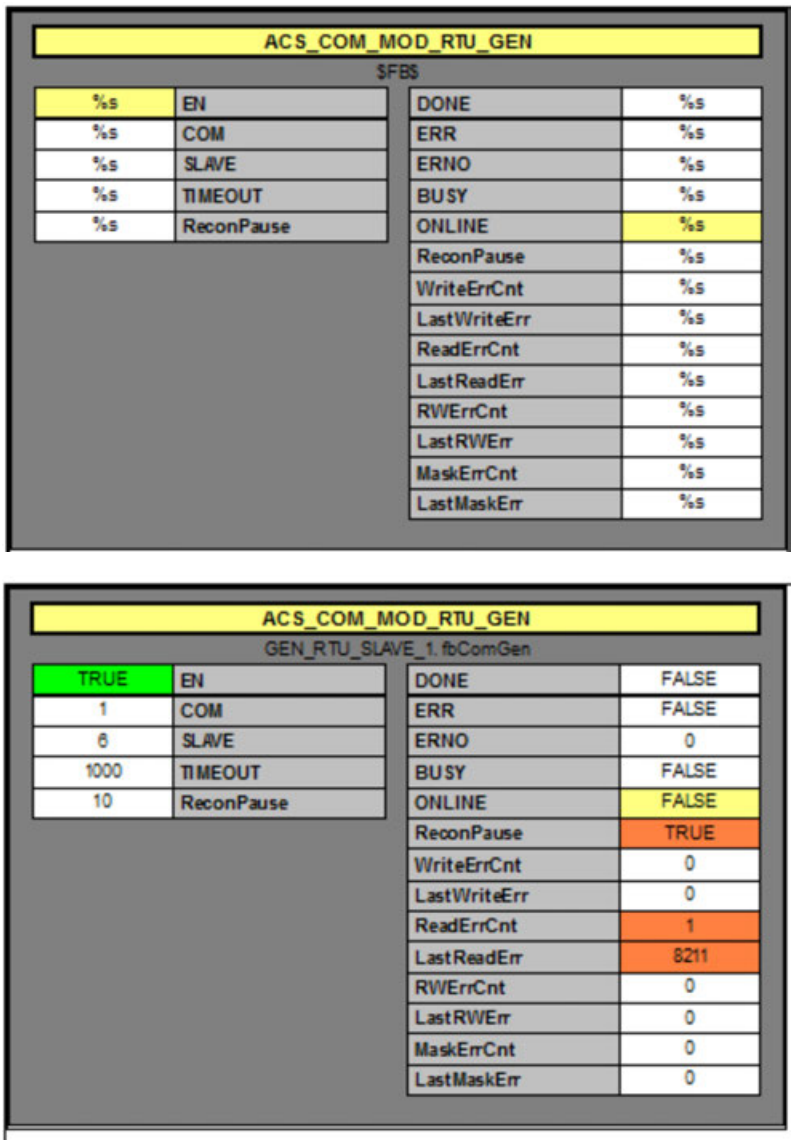

Fig. 163: Visualization offline / online mode

Visualization element ACS_COM_MOD_RTU_GEN_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_RTU_GEN ↳ *Chapter 1.5.6.3.5.4 “ACS_COM_MOD_RTU_GEN communication for generic devices via Modbus RTU ” on page 2322* function block which instance is used to replace the placeholder FB.

The visualization can also be used to control the function block by those inputs which are not connected inside the program.

Visualization data

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesComModRTU_AC500_V20.lib

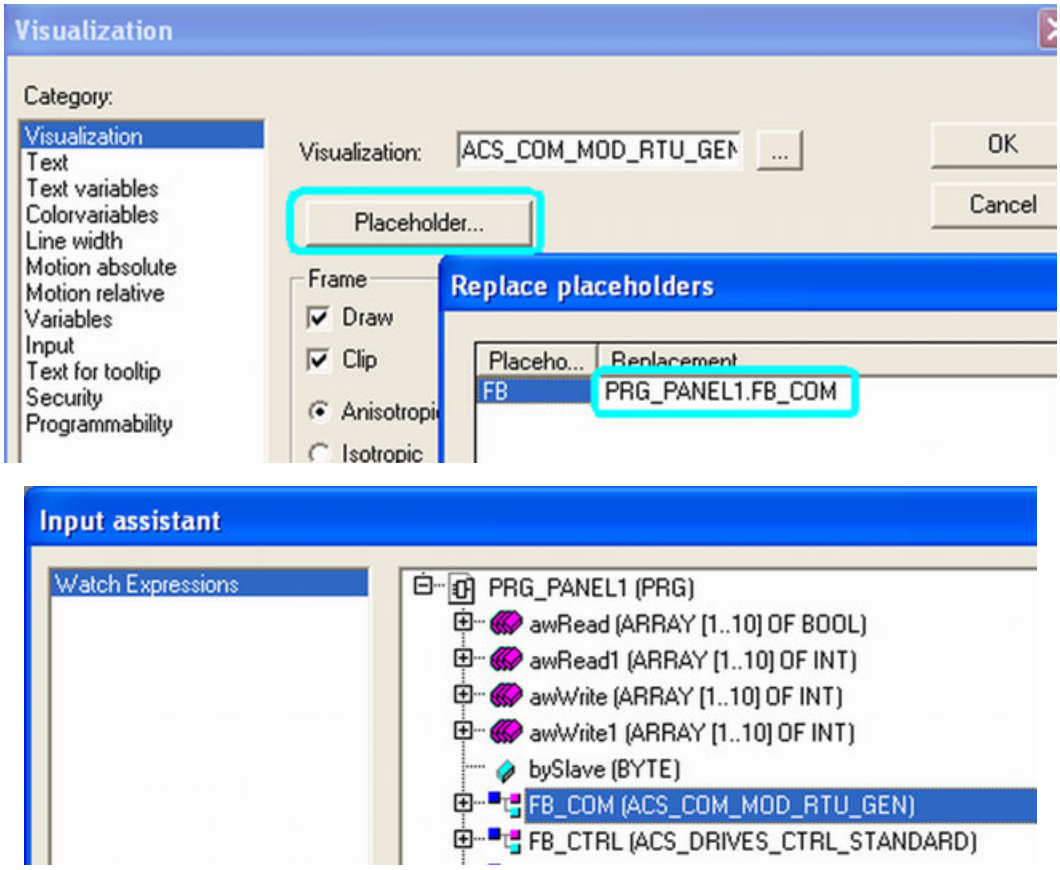
Description

Visualization element ACS_COM_MOD_RTU_GEN_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_RTU_GEN function block, which instance was used to replace the placeholder FB.

All inputs of that ACS_COM_MOD_RTU_GEN function block, which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open.

Even if most of the inputs should not be change while the program is running (COM, SLAVE and TIMEOUT), the visualization is nevertheless helpful to check the ONLINE state and additional internal variables about error count and last error numbers.

The SLAVE_DATA variable must be connected to the function block.



Parameters

Access R/W

EN

Access via: Toggle

Description: EN input

COM

Access via: Numpad 1..10

Description: COM. After a change the program must be reset (create boot project, reset and start).

SLAVE

Way of Access: Numpad 1..31

Description: SLAVE input

TIMEOUT

Access via: Numpad min. 1

Description: TIMEOUT input

ReconPause Access via: Numpad min. 0

Description: Reconnect Pause value in seconds.

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Drive1.FB_COM

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Panel1.FB_Write

Access R

DONE Description: DONE output.

ERR Description: ERR output.

ERNO Description: ERNO output.

ONLINE Description: ONLINE output

ReconPause Timeout or other SLAVE error detected and reconnection pause is active.

WriteErrCnt Description: Numbers of write errors since EN = TRUE, is reset to 0 with rising edge of EN.

LastWriteErno Description: Error number of the last write job. See error messages of ETH_MOD_MAST function block.

ReadErrCnt Description: Numbers of read errors since EN = TRUE, is reset to 0 with rising edge of EN.

LastReadErr Description: Error number of the last read job. See error messages of COM_MOD_MAST function block.

RWErrCnt Description: error count of read/Write (FCT-23) errors.

LastRWErr Description: last error code of read/Write (FCT-23) error.

MaskErrCnt Description: error count of masked (FCT-22) errors.

LastMaskErr Description: Last error code for the masked (FCT-22) error.

Colors

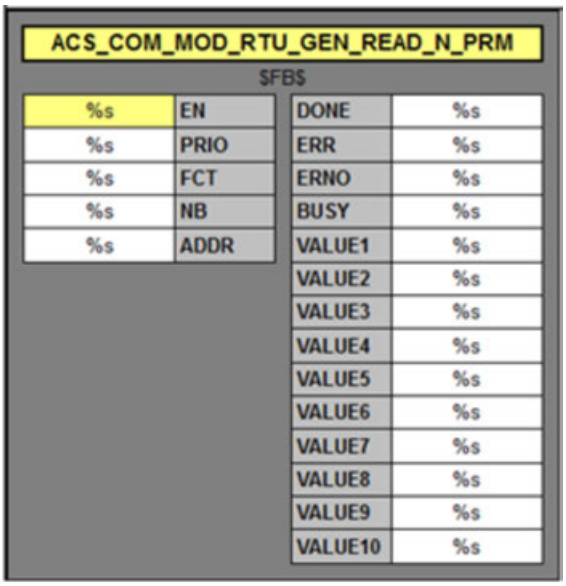
The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_COM_MOD_RTU_GEN_READ_N_PRM_VISU_PH faceplate for the function block ACS_COM_MOD_RTU_GEN_READ_N_PRM



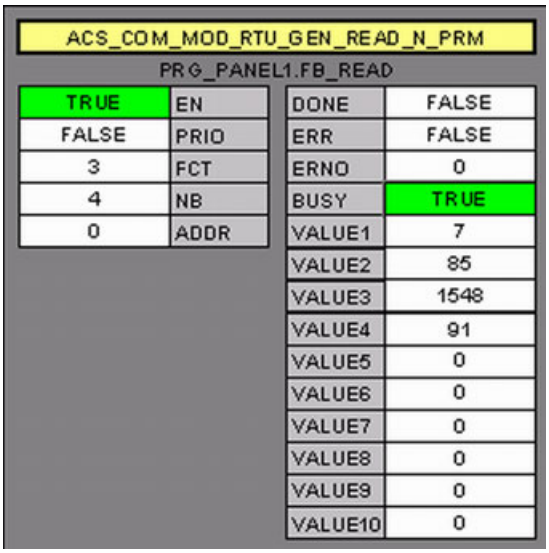


Fig. 164: Visualization offline / online mode

Visualization element ACS_COM_MOD_RTU_GEN_READ_N_PRM_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_RTU_GEN_READ_N_PRM ↳ *Chapter 1.5.6.3.5.5 "ACS_COM_MOD_RTU_GEN_READ_N_PRM read N parameters from a generic Modbus RTU device " on page 2327* function block which instance was used to replace the placeholder FB.

The visualization can also be used to control the function block by those inputs which are not connected inside the program.

Visualization data

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesComModRTU_AC500_V20.lib

Description

Visualization element ACS_COM_MOD_RTU_GEN_READ_N_PRM_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_RTU_GEN_READ_N_PRM function block which instance was used to replace the placeholder FB.

All inputs of that ACS_COM_MOD_RTU_GEN_READ_N_PRM function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.

The values to where the read data is stored to in the PLC can not be displayed with this faceplate, because they have to be accessed by the ADR operator outside the function block ACS_COM_MOD_RTU_GEN_READ_N_PRM.

Nevertheless the first 10 values are also copied to an internal array of 15 elements. The first 10 elements are displayed in this visualization.

The input DATA is not shown as it has to be connected to the address of a variable and therefore can not be set in the visualization.

SLAVE_DATA input must be connected in the program.

Parameters

Access R/W

EN

Access via: Toggle

Description: EN input

PRIO (priority) Data type: BOOL
Input PRIO is reserved for future usage. It can be left open.

VALUE2 Description: Value of 2nd read parameter, written if read job was successfully.

VALUE3 Description: Value of 3rd read parameter, written if read job was successfully.

VALUE4 Description: Value of 4th read parameter, written if read job was successfully.

VALUE5 Description: Value of 5th read parameter, written if read job was successfully.

VALUE6 Description: Value of 6th read parameter, written if read job was successfully.

VALUE7 Description: Value of 7th read parameter, written if read job was successfully.

VALUE8 Description: Value of 8th read parameter, written if read job was successfully

VALUE9 Description: Value of 9th read parameter, written if read job was successfully.

VALUE10 Description: Value of 10th read parameter, written if read job was successfully.

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Panel1.FB_Read

Colors

The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_COM_MOD_RTU_GEN_WRITE_N_PRM_VISU_PH faceplate for the function block ACS_COM_MOD_RTU_GEN_WRITE_N_PRM

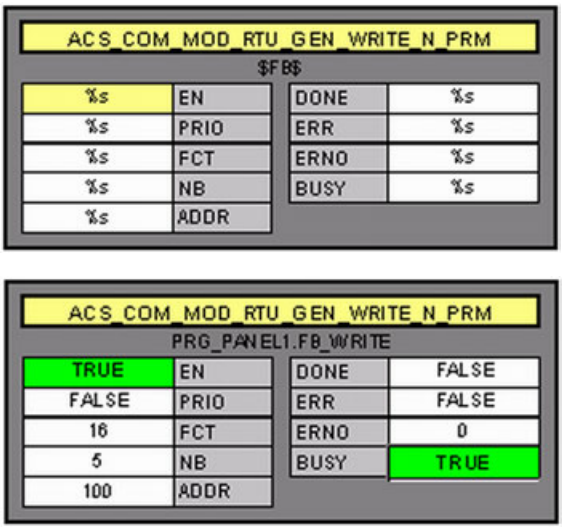

Fig. 165: Visualization offline / online mode

Visualization element ACS_COM_MOD_RTU_GEN_WRITE_N_PRM_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_RTU_GEN_WRITE_N_PRM *Chapter 1.5.6.3.5.6 “ACS_COM_MOD_RTU_GEN_WRITE_N_PRM write N parameters to a generic Modbus RTU device ” on page 2330* function block which instance was used to replace the placeholder FB.

The visualization can also be used to control the function block by those inputs which are not connected inside the program.

Visualization data

Available as of runtime system:	V1.3.2
Included in library:	ACSDrivesComModRTU_AC500_V20.lib

Description

Visualization element ACS_COM_MOD_RTU_GEN_WRITE_N_PRM_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_RTU_GEN_WRITE_N_PRM function block which instance was used to replace the placeholder FB.

All inputs of that ACS_COM_MOD_RTU_GEN_WRITE_N_PRM function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open.

The SLAVE_DATA variable must be connected to the function block.

The values to be written can not be displayed with this faceplate, because they have to be accessed by the ADR operator outside the function block ACS_COM_MOD_RTU_GEN_WRITE_N_PRM.

yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" ↳ *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" ↳ *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

1.5.6.4 ACS / DCS drives communication via Modbus TCP library

To establish the communication to an ACS / DCS drive one of the following two libraries can be used: ACSDrivesComModTCP_AC500_V22.lib or ACSDrivesComModTCP_Ext_AC500_V24.lib ↳ *Chapter 1.5.6.5 “ACS / DCS drives communication via Modbus TCP ext library” on page 2384* The ACSDrivesComModTCP_AC500_V22.lib can be used, as long as the CPU does not support more than one internal Ethernet Interface. And this library must be used, if the Firmwareversion of the CPU is less than V2.4.x.

The ACSDrivesComModTCP_Ext_AC500_V24.lib should be used for new project and if the Firmware Version of the CPU is at least V2.4.x. It must be used, if a CPU with more than one internal Ethernet Interface is used, e.g. PM595.

1.5.6.4.1 Preconditions for the use of the ACS / DCS drives communication via Modbus TCP library

The function blocks contained in the library can only be executed in RUN mode of the PLC, but not in simulation mode.

The blocks can only be used in combination with the ACSDrives-Base_AC500_V20 Library.

The library is released for the following products:

- **CPUs:** AC500 and AC500-eCo
- **Fieldbus:** Modbus TCP
- **Drives:**ACS800, ACSM1, ACS350, ACS355, ACS550, ACH550, ACQ810, ACS850, ACS880, ACS580, DCS550, DCS800
- **Modbus TCP configuration:**
  Prior to the use of the function blocks a Communication Module "Modbus_on_TCP_IP" has to be configured accordingly using Automation Builder, either at "Onboard_Ethernet" or at "CM597-ETH" module.
- **ACS_COM_MOD_TCP and ACS_COM_MOD_TCP_ENHANCED:**
  The communication function blocks are designed to be used each for one specific drive at run time. So it´s not recommended to change the COM or SLAVE inputs of the blocks while the program is running.
  There is no check in the function blocks if the maximum number of TCP/IP sockets is already reached. So the user has to take care about the number of used socket. Each ACS_COM_MOD_TCP or ACS_COM_MOD_TCP_ENHANCED function block will use one socket.

1.5.6.4.2 Components of the ACS / DCS drives communication via Modbus TCP library

Function blocks

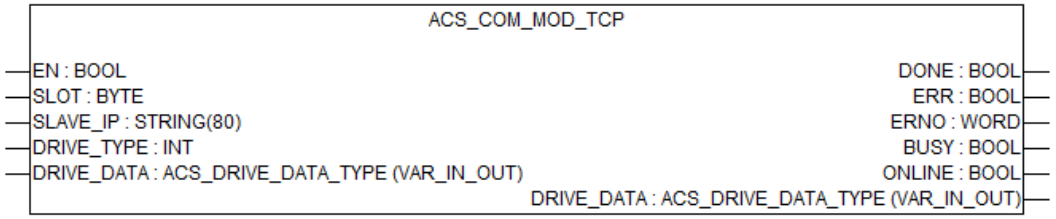
ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360*	Communication for ACS / DCS Drives via Modbus TCP
ACS_COM_MOD_TCP_ENHANCED ↳ *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367*	Communication for ACS / DCSDrives via Modbus TCP

Visualizations

ACS_COM_MOD_TCP_VISU_PH *Chapter 1.5.6.4.4.1 "ACS_COM_MOD_TCP_VISU_PH faceplate for the function block ACS_COM_MOD_TCP" on page 2376*	Faceplate for the function block
ACS_COM_MOD_TCP_ENHANCED_VISU_PH *Chapter 1.5.6.4.4.2 "ACS_COM_MOD_TCP_ENHANCED_VISU_PH faceplate for the function block ACS_COM_MOD_TCP_ENHANCED" on page 2379*	Faceplate for the function block

1.5.6.4.3 Function blocks

ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP



Function block ACS_COM_MOD_TCP controls the Modbus TCP communication to an ACS / DCS drive and is used for the basic control of ACS / DCS drives with ABB Drives profile.

Function block information

Available in runtime system:	V1.3.2
Included in library:	ACSDrivesComModTCP_AC500_V22_App.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_COM_MOD_TCP controls the Modbus TCP communication to an ACS / DCS drive and is used for the basic control of ACS / DCS drives with ABB Drives profile.

If the user changes drive profile while drive is online with PLC, function block output's may give wrong indication.

Reading Status Information from Drive

The function block continuously reads data from the drive starting at Modbus register 400004. So at least the Status Word (SW), Actual Value 1 (SPEED_REF), Actual Value 2 (ACT_VALUE2) are continuously read from the drive and written to the DRIVE_DATA variable. These values are stored in DRIVE_DATA.MSW, ActValue1 and ActValue2.

The following table shows the performed Modbus read job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

Modbus register address in drive	Mapping configuration in drive			Written to in AC500	Condition at function block
	ACS355, ACS850, ACQ810, ACSM1, ACS880	**ACS800**	**ACS550, ACH550**		
Communication module	FENA-01 / -11	RETA-01 / -02	RETA-01 / -02		
40004	Status Word (SW)	Status Word (SW) fix	Status Word 51.23 (SW) fix	DRIVE_DATA.sw	EN = TRUE
40005	Actual Value1	92.02 = Actual Value1, e.g. = 102 (Speed)	51.24 = Actual Value1 (fix)	DRIVE_DATA.actValue1	EN = TRUE
40006	Actual Value2	92.03 = Actual Value2 e.g. = 105 (Torque) *)	51.25 = Actual Value2, e.g.= 105 (Torque)	DRIVE_DATA.actValue2	EN = TRUE
*) If 51.19 .. 51.22 (Output 1 .. 4) are set to the actual values the Modbus response will be faster because those values are updated cyclically between RETA-01 and ACS800.					

Writing Control Word and Reference Values to Drive

The function block checks if there are changes of the Control Word (CW), Reference Value 1 (SPEED_REF) or Reference Value 2 (REF_VALUE2) on the DRIVE_DATA variable. If there is a change a write job is requested to send these 3 values to the ACS drive starting at Modbus register 40001.

The following table shows the performed Modbus read job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

Modbus register address in drive	Communication module		Written to in AC500	Condition at function block
	ACS355, ACS850, ACQ810, ACSM1, ACS880, ACS580	**ACS800, ACS550, ACH550, DCS550, DCS800**		
Communication module	**FENA-01 / -11**	**RETA-01 / -02**		
40001	Control Word (CW)	Control Word (CW)	DRIVE_DATA.cw	EN = TRUE
40002	Reference Value1	Reference Value1	DRIVE_DATA.ref Value1	EN = TRUE
40003	Reference Value2	Reference Value2	DRIVE_DATA.ref Value2	EN = TRUE

If a Modbus job tries to access a register in the drive which has no valid mapping information the job is aborted with an error. Therefore the drive parameters in FBA DATA OUT group have to be configured according to the used NVAR_WRITE input number.

If 32-bit parameters are mapped to DATA OUT,

- *The following field in DATA OUT has to be left open (= 0)*
- *The word order of the High-Word and Low-Word can be configured in the drive. If e.g. FENA-x1 is used the configuration is done in Par.51.22.*
- *The original 32-bit value in AC500 has to be split up in HW and LW in the WRITE_VALUES array.*

Function block DATA OUT has to be configured in drive in the following groups see also FENA-x1 manual.

Drive	Parameter group
ACS355	55.01 .. 55.10
ACS850, ACQ810, ACSM1, ACS880	53.01 .. 53.12
ACS880	53.01 .. 53.02(Fieldbus A), 56.01 .. 56.12 (Fieldbus B)

ACS drive parameters are only saved temporarily, if changed via fieldbus. To make these changes permanent in the drive the special parameter "PARAMETER SAVE" has to be set. Please see drive manuals and following table which parameter has to be set.

Save valid parameters to permanent memory in drive	ACS3XX, ACX550, ACQ810, ACS850, ACSM1, ACS800	ACS880, ACS580	DCS550, DCS800
1 = Saves the valid parameter values to permanent memory. 0 = Save completed.	Par 16.07 = 1	Par 96.07 = 1	Par 16.06 = 1

Read/Write Jobs Coming from Other Function Blocks

The requests to process other read or write Modbus jobs is transferred via the DRIVE_DATA variable at the IN_OUT variable DRIVE_DATA which can be connected to several other read/write function blocks e.g. ACS_MOD_READ_N_PRM *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212* or ACS_MOD_WRITE_N_PRM *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215* of this drive.

Communication with Several ACS Drives

If several drives are used, for each drive a communication function block such as ACS_COM_MOD_TCP or ACS_COM_MOD_TCP_ENHANCED function block must be programmed.

The function block provides the basic start/stop signals, basic diagnosis signals and the scaling of the SPEED_REF input and ACT_SPEED to the ACS fieldbus scaling range. -20000 .. +20000.

The AC500 CPU types provide different numbers of usable TCP/IP sockets. For each ACS Modbus TCP communication block (ACS_COM_MOD_TCP and ACS_COM_MOD_TCP_ENHANCED) one socket will be needed. The user has to check that the programmed number of ACS Modbus TCP communication blocks is not higher than the number of available free sockets for the used CPU.

Diagnosis

The output ERNO, which reflects an actual error number is only valid for one cycle if DONE and ERR output are set to TRUE.

To catch this error number an external function must be programmed.

However there are internal diagnosis variables available, which are not shown at any output, but can be accessed from the function block instance. This can be done in three ways:

- Opening the "+" sign of function block instance in the declaration part being online.
- Create an assignment in the code with <instance>.<diagnosis variable>.
- Create a visualization element of the function block see ACS_COM_MOD_TCP_ENHANCED_VISU_PH.

The additional diagnosis variables are:

- iWriteErrCnt: number of errors in write jobs since EN = TRUE.
- wLastWriteErno: holds the error number of the last executed write job.
- iReadErrCnt: number of errors in read jobs since EN = TRUE.
- wLastReadErno: holds the error number of the last executed read job.

Preconditions

The function block is working with all ACS / DCS drives via Modbus TCP communication with field bus adapter FENA-X1 / RETA-X1.

The data transfer to other function blocks for this drive communication to the ACS / DCS drive is realized via the IN_OUTPUT variable DRIVE_DATA, which must be connected to then ACS_COM_MOD_TCP even if no other function block is connected.

For ACS drive parameters must be set as follows:

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

Setting according to AC500 configuration or function block input	**ACS355**	**ACS850, ACQ810, ACSM1**	**ACS580, ACS880**	**ACS800, ACS550, ACH550, DCS550, DCS800**
Communication module:	FENA-01	FENA-11	FENA-11	RETA-01 / RETA-02
Fieldbus activation = EXT FBA / ENABLE	98.02	50.01	50.01	98.02

Modbus Timeout. Depending on Timeout mode. Value in 100ms.	51.20	51.20	Modbus timeout	51.17
Refresh settings in drive	51.27	51.27	51.27	51.27
**) For RETA-01/-02 IP address could also be set via hardware DIP switches. If any switch is set (192.168.0.xxx) with xxx = DIP switches setting.				

For further settings, e.g. reaction of drive at communication error, please see related drive and fieldbus manual.

Input description

EN (enable) Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the block is active, the current values are available at the outputs.

After a rising edge (FALSE -> TRUE) of input EN output ONLINE is set to FALSE and parameters are read from the ACS drive.

The processing of continuously read of status information from the drive (SW, ACT_VALUE1 and ACT_VALUE2) and writing of Control Word and Reference Values (CW, SPEED_REF, REF_VALUE2) after changes to the drive is started.

If EN is reset to FALSE while a Modbus TCP job is performed (BUSY = TRUE), the function block will be processed until the Modbus TCP job is terminated (DONE = TRUE for 1 cycle).

If EN = FALSE the outputs ONLINE are reset to zero, as well as the data SW, actValue1 and actValue2 on the DRIVE_DATA variable are reset to zero.

SLOT (slot) Data type: BYTE

At input SLOT, the Modbus interface number is specified:

SLOT = 0 ; SLOT0 (onboard Ethernet slot)

SLOT = 1 : SLOT1 (CM597-ETH)

SLOT = 2 : SLOT2 (CM597-ETH)

Default value = 0.

Maximum value = 4.

SLAVE_IP (slave IP-Address)

Data type: STRING

IP Address of the drive (slave) to which the connecton shall be established must be specified here as string. Used with 4 times 3 digits.

Default value: ‘192.168.005.003’

DRIVE_TYPE (drive type)

Data type: INT, Default value: ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM. The input can be set either by the value directly or by using the enum.

ENUM	Value
ACS_DRIVE_ACS800	1
ACS_DRIVE_ACSM1	2
ACS_DRIVE_ACS350	3
ACS_DRIVE_ACS355	4
ACS_DRIVE_ACS310	5
ACS_DRIVE_ACS550	6
ACS_DRIVE_ACH550	7
ACS_DRIVE_ACQ810	8
ACS_DRIVE_ACS850	9
ACS_DRIVE_ACS880	10
ACS_DRIVE_ACS580	11
ACS_DRIVE_DCS800	12
ACS_DRIVE_DCS550	13
ACS_DRIVE_ACH580	14
ACS_DRIVE_ACS380	15
ACS_DRIVE_ACS480	16
ACS_DRIVE_ACQ580	17

DRIVE_DATA (drive data)

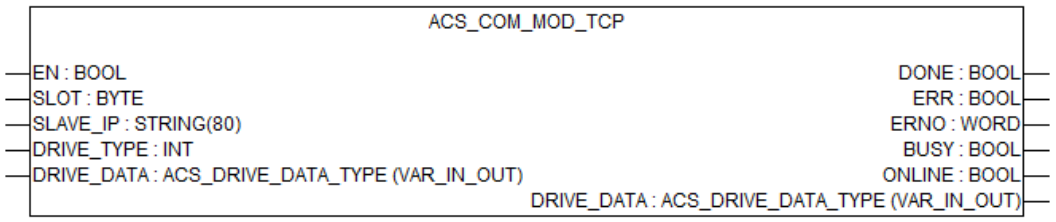
Data type: ACS_DRIVE_DATA_TYPE ↬ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS / DCS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_TCP reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus TCP jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

DONE (done) Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy) Data type: BOOL

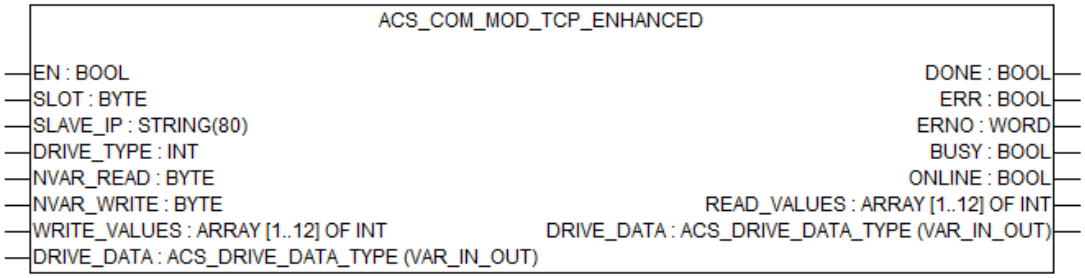
Output BUSY indicates, whenever there is a communication action performed.

ONLINE (online) Data type: BOOL

After the first time input EN is set to TRUE and at least one read job and one write job is performed successfully, output ONLINE is set to TRUE.

Output ONLINE is reset to FALSE after a rising edge of EN or if an error occurs while reading the status information or writing the Control Word and Reference Values.

ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP



Function block ACS_COM_MOD_TCP_ENHANCED establishes the Modbus TCP communication to an ACS drive. This function block is used for the basic control of the ACS drive using ABB Drives Profile Enhanced. It also reads and writes the drive parameters which are mapped in the drive.

Function block information

Available in runtime system:	V2.4
Included in library:	ACSDrivesComModTCP_AC500_V22_App.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_COM_MOD_TCP_ENHANCED establishes the Modbus TCP communication to an ACS drive and is used for the basic control of ACS drives with ABB Drives Profile Enhanced.

If the user changes drive profile while drive is online with PLC, function block output's may give wrong indication.

Reading Status Information from Drive

The function block continuously reads data from the drive starting at Modbus register 400051. So at least the Status Word (SW), Actual Value 1 (SPEED_REF), Actual Value 2 (ACT_VALUE2) are continuously read from the drive and written to the DRIVE_DATA ↳ *Chapter 1.5.6.2.6.2 "ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive" on page 2253*variable. These values are stored in DRIVE_DATA.MSW, ActValue1 and ActValue2.

Apart from these three there is also an option to read 12 additional drive parameters. Using the input NVAR_READ the function block can be configured to read between 0 and 12 parameters from the drive. All read data is then written to the array at the READ_VALUE output. Configuration in ACS drive is depending of configured parameters in group FBD DATA IN.

The following table shows the performed Modbus read job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

Modbus register address in drive	Mapping configuration in drive		Written to in AC500	Condition at function block
	ACS355	ACS850, ACQ810, ACSM1, ACS880, ACS580		
400051	Status Word (SW)	Status Word (SW)	DRIVE_DATA.sw	EN = TRUE
400052	Actual Value1	Actual Value1	DRIVE_DATA.act Value1	EN = TRUE
400053	Actual Value2	Actual Value2	DRIVE_DATA.act Value2	EN = TRUE
400054	FBA DATA IN 1	FBA DATA IN 1	READ_VALUES[1]	EN = TRUE and NVAR_READ >= 1
400055	FBA DATA IN 2	FBA DATA IN 2	READ_VALUES[2]	EN = TRUE and NVAR_READ >= 2
...	...	...	...	...
400063	FBA DATA IN 10	FBA DATA IN 10	READ_VALUES[10]	EN = TRUE and NVAR_READ >= 10
...		...	...	...
400065		FBA DATA IN 12	READ_VALUES[12]	EN = TRUE and NVAR_READ = 12

If a Modbus TCP job tries to access a register in the drive which has no valid mapping information the job is aborted with an error.

Therefore the drive parameters in FBA DATA IN group have to be configured according to the used NVAR_READ input number.

If 32-bit parameters are mapped to DATA IN,

- *The following field in DATA IN has to be left open (= 0)*
- *The word order of the High-Word and Low-Word can be configured in the drive. (using FENA-X1: Par. 51.22)*
- *To retrieve the original 32-bit value from the drive in AC500 the HW and LW from READ_VALUES fields have to be recombined in the program.*

Function block DATA IN has to be configured in drive in the following groups see also FSCA-01 manual.

Drive	Parameter group
ACS355	54.01 .. 54.10
ACS850, ACQ810, ACSM1, ACS880, ACS580	52.01 .. 52.12 52.01 .. 52.12 if installed as adapter A

Writing Control Word and Reference Values to Drive

The function block checks if there are changes of the Control Word (CW), Reference Value 1 (SPEED_REF) or Reference Value 2 (REF_VALUE2) on the DRIVE_DATA variable. If there is a change a write job is requested to send these 3 values to the ACS drive starting at Modbus register 400001.

Apart from these three parameters there is also an option to write additional 12 more drive parameters in the same Modbus job. Using the input NVAR_WRITE the function block can be configured to write between 0 and 12 more parameters to the drive. The necessary values have to present in the array connected to WRITE_VALUES input.

The following table shows the performed Modbus write job and the needed mapping in the drive as well as the area from where the data in the AC500 is taken.

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

Table 137: Writing control word and reference values to drive

Modbus register address in drive	**Mapping configuration in drive**		**Written to in AC500**	**Condition at function block**
	ACS355	ACS850, ACQ810, ACSM1, ACS880, ACS580		
400001	Control Word (CW)	Control Word (CW)	DRIVE_DATA.cw	EN = TRUE
400002	Reference Value1	Reference Value1	DRIVE_DATA.ref Value1	EN = TRUE
400003	Reference Value2	Reference Value2	DRIVE_DATA.ref Value2	EN = TRU
400004	FBA DATA OUT 1	FBA DATA OUT 1	READ_VALUES[1]	EN = TRUE and NVAR_WRITE >= 1
400005	FBA DATA OUT 2	FBA DATA OUT 2	READ_VALUES[2]	EN = TRUE and NVAR_WRITE >= 2
...	...	...	...	...
400013	FBA DATA OUT 10	FBA DATA OUT 10	READ_VALUES[10]	EN = TRUE and NVAR_WRITE >= 10
...		...	...	...
400015		FBA DATA OUT 12	READ_VALUES[12]	EN = TRUE and NVAR_WRITE >= 12

If a Modbus TCP job tries to access a register in the drive which has no valid mapping information the job is aborted with an error.

Therefore the drive parameters in FBA DATA OUT group have to be configured according to the used NVAR_WRITE input number.

If 32-bit parameters are mapped to DATA OUT,

- *The following field in DATA OUT has to be left open (= 0)*
- *The word order of the High-Word and Low-Word can be configured in the drive. (using FENA-X1: Par. 51.22)*
- *To retrieve the original 32-bit value from the drive in AC500 the HW and LW from WRITE_VALUES fields have to be recombined in the program.*

Function block DATA OUT has to be configured in drive in the following groups see also FENA-X1 manual.

Drive	Parameter group
ACS355	55.01 .. 55.10
ACS850, ACQ810, ACSM1, ACS580, ACS880	53.01 .. 53.12 53.01 .. 53.12 if installed as adapter A

ACS drive parameters are only saved temporarily, if changed via fieldbus. To make these changes permanent in the drive the special parameter "PARAMETER SAVE" has to be set.

Please see drive manuals and following table which parameter has to be set.

Save valid parameters to permanent memory in drive	ACS3XX, ACQ810, ACS850, ACSM1	ACS880, ACS580
1 = Saves the valid parameter values to permanent memory. 0 = Save completed.	Par 16.07 = 1	Par 96.07 = 1

Read/Write Jobs Coming from Other Function Blocks

The requests to process other read or write Modbus jobs is transferred via the DRIVE_DATA variable at the IN_OUT variable DRIVE_DATA which can be connected to several other read/write function blocks e.g. ACS_MOD_READ_N_PRM *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212* or ACS_MOD_WRITE_N_PRM *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215* of this drive.

Communication with several ACS Drives

If several drives are used, for each drive a communication function block such as ACS_COM_MOD_TCP_ENHANCED or ACS_COM_MOD_TCP function block must be programmed.

The function block provides the basic start/stop signals, basic diagnosis signals and the scaling of the SPEED_REF input and ACT_SPEED to the ACS fieldbus scaling range -20000 .. +20000.

The AC500 CPU types provide different numbers of usable TCP/IP sockets. For each ACS Modbus TCP communication block (ACS_COM_MOD_TCP and ACS_COM_MOD_TCP_ENHANCED) one socket will be needed.

The user has to check that the programmed number of ACS_COM_MOD_TCP or ACS_COM_MOD_TCP_ENHANCED communication blocks is not higher than the number of available free sockets for the used CPU.

Diagnosis

The output ERNO, which reflects an actual error number is only valid for one cycle if DONE and ERR output are set to TRUE.

To catch this error number an external function must be programmed.

However there are internal diagnosis variables available, which are not shown at any output, but can be accessed from the function block instance. This can be done in three ways:

- Opening the "+" sign of function block instance in the declaration part being online.
- Create an assignment in the code with <instance>.<diagnosis variable>.
- Create a visualization element of the function block see ACS_COM_MOD_TCP_ENHANCED_VISU_PH *Chapter 1.5.6.4.4.2 “ACS_COM_MOD_TCP_ENHANCED_VISU_PH faceplate for the function block ACS_COM_MOD_TCP_ENHANCED” on page 2379*.

The additional diagnosis variables are:

iWriteErrCnt:	number of errors in write jobs since EN = TRUE
wLastWriteErno:	holds the error number of the last executed write job
iReadErrCnt:	number of errors in read jobs since EN = TRUE
wLastReadErno:	holds the error number of the last executed read job

Preconditions

The function block is working with all ACS drives via Modbus TCP communication with field bus adapter FENA-X1.

The data transfer to other function blocks for this drive communication to the ACS drive is realized via the IN_OUTPUT variable DRIVE_DATA, which must be connected to ACS_COM_MOD_TCP_ENHANCED even if no other function block is connected.

The following ACS drive parameters have to be set according to the configuration of the Modbus line and the inputs of the function block.

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

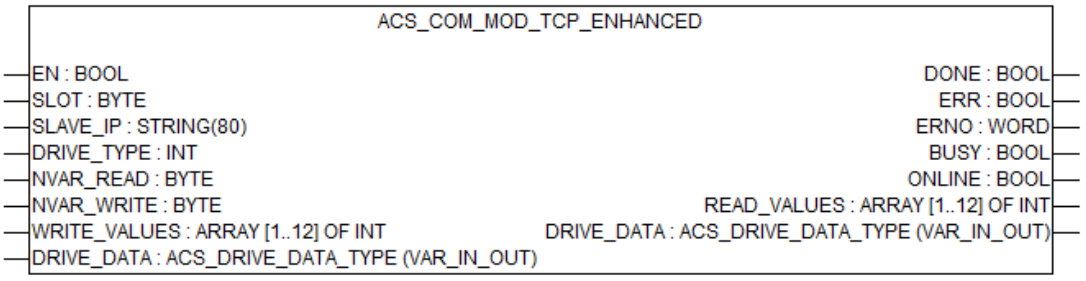
Setting according to AC500 configuration or function block input	**ACS355**	**ACS850, ACQ810, ACSM1,**	**ACS880, ACS580**	**ACX550, ACS800, DCS550, DCS800**
Communication module:	FENA-01	FENA-11	FENA-11	ENHANCED not possible with RETA-0X
Fieldbus activation = EXT FBA	98.02	50.01	50.01	
COMM RATE = Auto (0)	51.03	51.03	51.03	
IP CONFIGURATION = Static IP (0) ! not default ! Set 51.27 (Refresh) after first change to "Static IP".	51.04	51.04	51.04	
IP ADDRESS1 .. IP ADDRESS4	51.05 .. 51.08	51.05 .. 51.08	51.05 .. 51.08	
SUBNET CIDR = e.g. 255.255.255.0 = 24	51.09	51.09	51.09	

Setting according to AC500 configuration or function block input	ACS355	ACS850, ACQ810, ACSM1,	ACS880, ACS580	ACX550, ACS800, DCS550, DCS800
PROTOCOL / PROFILE = MB/TCP ABB E (ABB Drives Profile Enhanced) (1)	51.02	51.02	51.02	
Word order for 32-bit parameter access	No 32-bit access	51.22	51.22	
Timeout mode = None(0) or Any message(1), but not Ctrl write(2) as these values are only written after changes	51.21	51.21	Timeout mode	
Modbus Timeout. Depending on Timeout mode. Value in 100ms.	51.20	51.20	Modbus timeout	
Refresh settings in drive	51.27	51.27	51.27	

For further settings, e.g. reaction of drive at communication error, please see related drive and fieldbus manual.

Please refer FENA-X1 Ethernet adapter manual for more information.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable) Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the block is active, the current values are available at the outputs.

After a rising edge (FALSE -> TRUE) of input EN output ONLINE is set to FALSE and parameters are read from the ACS drive.

After successfully reading and writing of the ACS parameters, output ONLINE is set to TRUE.

The processing of continuously read of status information from the drive (SW, ACT_VALUE1 and ACT_VALUE2) and writing of Control Word and Reference Values (CW, SPEED_REF, REF_VALUE2) after changes to the drive is started.

If EN is reset to FALSE while a Modbus job is performed (BUSY = TRUE), the function block will be processed until the Modbus job is terminated (DONE = TRUE for 1 cycle).

If EN = FALSE the outputs ONLINE are reset to zero, as well as the data SW, actValue1 and actValue2 on the DRIVE_DATA variable are reset to zero. The elements of the READ_VALUES array are also reset to zero.

SLOT (slot)

Data type: BYTE

At input SLOT, the Modbus interface number is specified:

SLOT = 0 ; SLOT0 (onboard Ethernet slot)

SLOT = 1 : SLOT1 (CM597-ETH)

SLOT = 2 : SLOT2 (CM597-ETH)

Default value = 0.

Maximum value = 4.

SLAVE_IP (slave IP-Address)

Data type: STRING

IP Address of the drive (slave) to which the connecton shall be established must be specified here as string. Used with 4 times 3 digits.

Default value: ‘192.168.005.003’

DRIVE_TYPE (drive type)

Data type: INT, Default value: ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM. The input can be set either by the value directly or by using the enum.

ENUM	Value
ACS_DRIVE_ACS800	1
ACS_DRIVE_ACSM1	2
ACS_DRIVE_ACS350	3
ACS_DRIVE_ACS355	4
ACS_DRIVE_ACS310	5
ACS_DRIVE_ACS550	6
ACS_DRIVE_ACH550	7
ACS_DRIVE_ACQ810	8
ACS_DRIVE_ACS850	9
ACS_DRIVE_ACS880	10
ACS_DRIVE_ACS580	11
ACS_DRIVE_DCS800	12
ACS_DRIVE_DCS550	13
ACS_DRIVE_ACH580	14
ACS_DRIVE_ACS380	15
ACS_DRIVE_ACS480	16
ACS_DRIVE_ACQ580	17

NVAR_READ (number of variables for reading)

Data type: BYTE

With the input NVAR_READ the function block can be configured to read between 1 and 12 signals from the drive. All read data is written to the array at the READ_VALUE output. Configuration in ACS drive is depending of configured parameters in group FBD DATA IN in drive

Default value = 0. Minimum 0, Maximum 12.

To read/write "one" 32-bit data, the NVAR should be equal to 2. Accordingly this has to be followed if we want to read/write more than one data. The user has to check that the programmed number of ACS_COM_MOD_TCP or ACS_COM_MOD_TCP_ENHANCED communication blocks is not higher than the number of available free sockets for the used CPU.

NVAR_WRITE (number of variables for writing)

Data type: BYTE

The internal Modbus write job writes 3 + NVAR_WRITE words starting from Modbus register address 400001 to the drive, every time a change in those variables is detected.

With the input NVAR_WRITE the function block can be configured to write between 0 and 12 variables more to the drive in addition to the 3 controls (CW, ref1 and ref2). These are always written to Modbus registers addresses 400001 .. 400003 if changed.

If NVAR_WRITE input is set to e.g. 5 the internal write job addresses the Modbus registers from 400001 .. 400008.

The first 3 signals are always the Control Word (CW), Reference value1 and Reference value2 and will be taken from the DRIVE_DATA variable.

The additional NVAR_WRITE data will be taken from the array at the WRITE_VALUES input.

Default value = 0. Minimum 0, Maximum 12.

WRITE_VALUES (write values to mapped parameters in drive group DATA_OUT)

Data type: ARRAY[1..12] OF INT

The values from the array at input WRITE_VALUE will be written to Modbus registers 400004 400015 in the drive. The number of data written to the drive is specified at the input NVAR_WRITE.

See table in chapter Writing Control Word and Reference Values to the drive for information about how to configure the drive.

DRIVE_DATA (drive data)

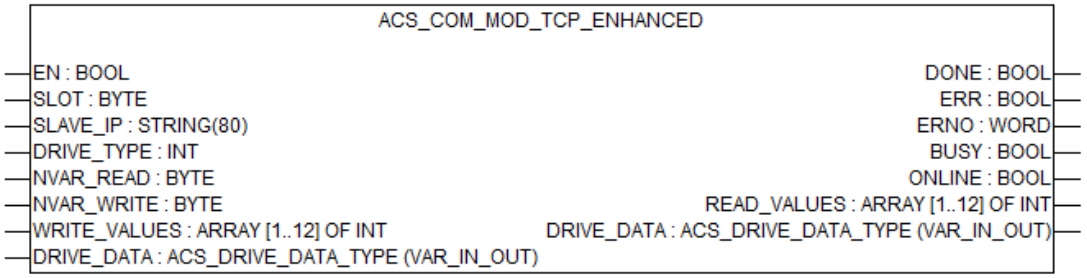
Data type: ACS_DRIVE_DATA_TYPE ↯ *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_TCP_ENHANCED reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

DONE (done) Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy) Data type: BOOL

Output BUSY indicates whenever there is a communication action performed.

ONLINE (online) Data type: BOOL

After the first time input EN is set to TRUE and at least one read job and one write job is performed successfully, output ONLINE is set to TRUE.

Output ONLINE is reset to FALSE after a rising edge of EN or if an error occurs while reading the status information or writing the Control Word and Reference Values.

READ_VALUES (array of read values) Data type: ARRAY[1..12] OF INT

At output READ_VALUES the values of the array are updated after the read status information job was terminated successfully (DONE = TRUE, ERR = FALSE, BUSY = FALSE).

The read status information job is requested cyclically. It reads data from the ACS drive starting at Modbus register 400051 up to the number specified at input 3 + NVAR_READ

READ_VALUES contains the data as follows:

READ_VALUES[1] = <Modbus register 400054>

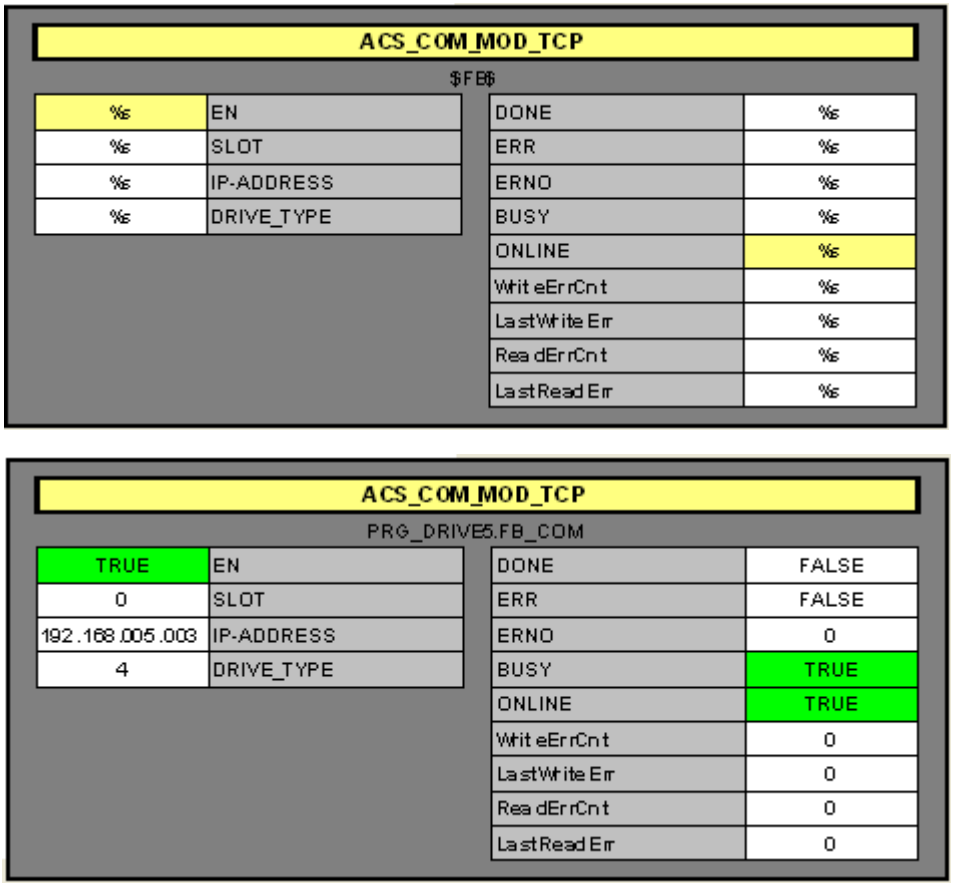
READ_VALUES[2] = <Modbus register 400055>

...

READ_VALUES[12] = <Modbus register 400065>.

1.5.6.4.4 Visualization

ACS_COM_MOD_TCP_VISU_PH faceplate for the function block ACS_COM_MOD_TCP



Visualization element ACS_COM_MOD_TCP_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_TCP ↬ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360* function block which instance was used to replace the placeholder FB.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

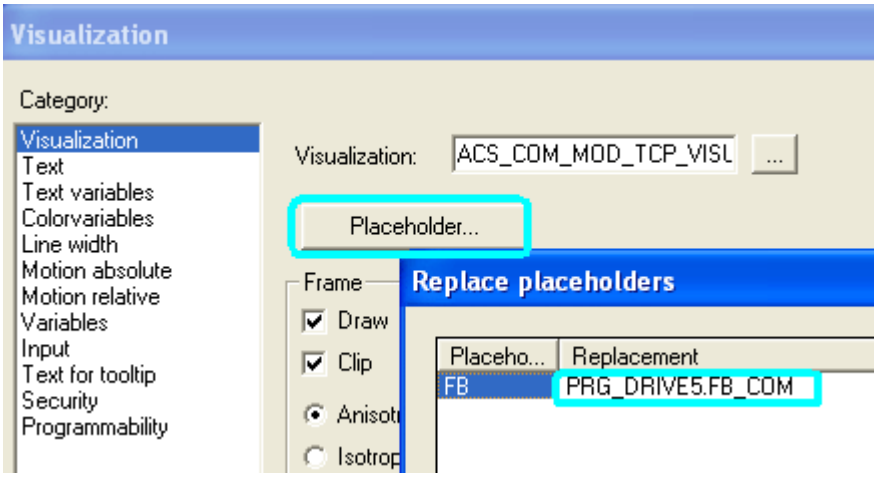
Visualization information

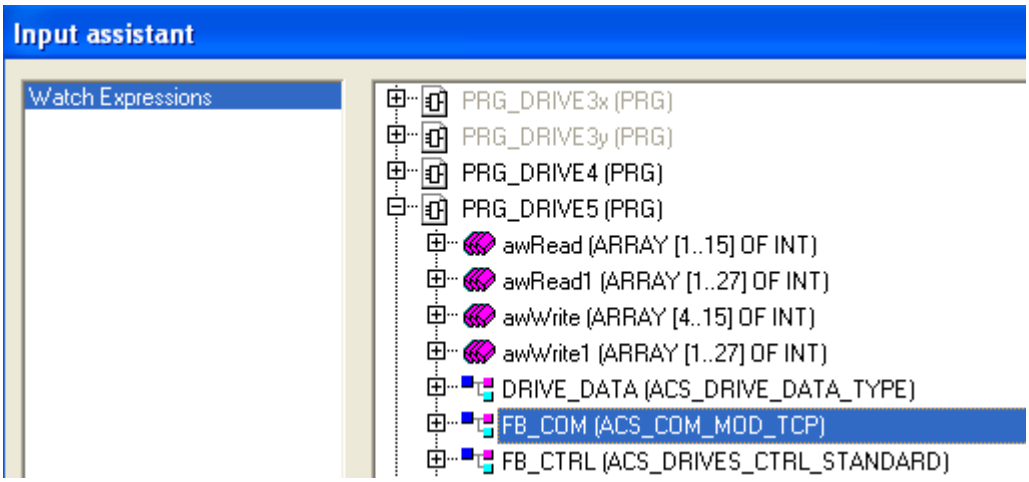
Available in runtime system:	V2.4
Included in library:	ACSDrivesComModTCP_Eth_AC500_V24.lib

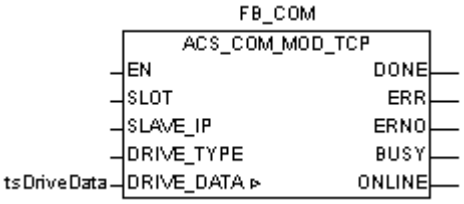
Visualization description

Visualization element ACS_COM_MOD_TCP_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_TCP ↬ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360* function block which instance was used to replace the placeholder FB.

All inputs of that ACS_COM_MOD_TCP ↳ *Chapter 1.5.6.4.3.1 “ACS_COM_MOD_TCP communication for ACS / DCS drives via Modbus TCP” on page 2360* function block which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.







Parameters

Access R/W

EN Access via: Toggle

Description: EN input

SLOT Access via: Numpad 0 .. 4

Description: SLOT (module number) of the communication module

IP_ADDRESS Access via: Text

Description: Slave address

DRIVE_TYPE Access via: Numpad 1 ..17

Description: DRIVE_TYPE input

Placeholder	Replacement	Example
FB	Instance name of the function block	PRG_Drivel.FB_COM

Access R

MCW Description: Control Word to the drive

RefValue1 Description: Reference value 1 to the drive

RefValue2 Description: Reference value 2 to the drive

DONE Description: DONE output.

ERR Description: ERR output.

ERNO Description: ERNO output.

BUSY Description: BUSY output.

ONLINE Description: ONLINE output

WriteErrCnt Description: Numbers of write errors since EN = TRUE, is reset to 0 with rising edge of EN.

LastWriteErno Description: Error number of the last write job. See error messages of ETH_MOD_MAST function block.

ReadErrCnt Description: Numbers of read errors since EN = TRUE, is reset to 0 with rising edge of EN.

LastReadErno Description: Error number of the last read job. See error messages of ETH_MOD_MAST function block.

Colors

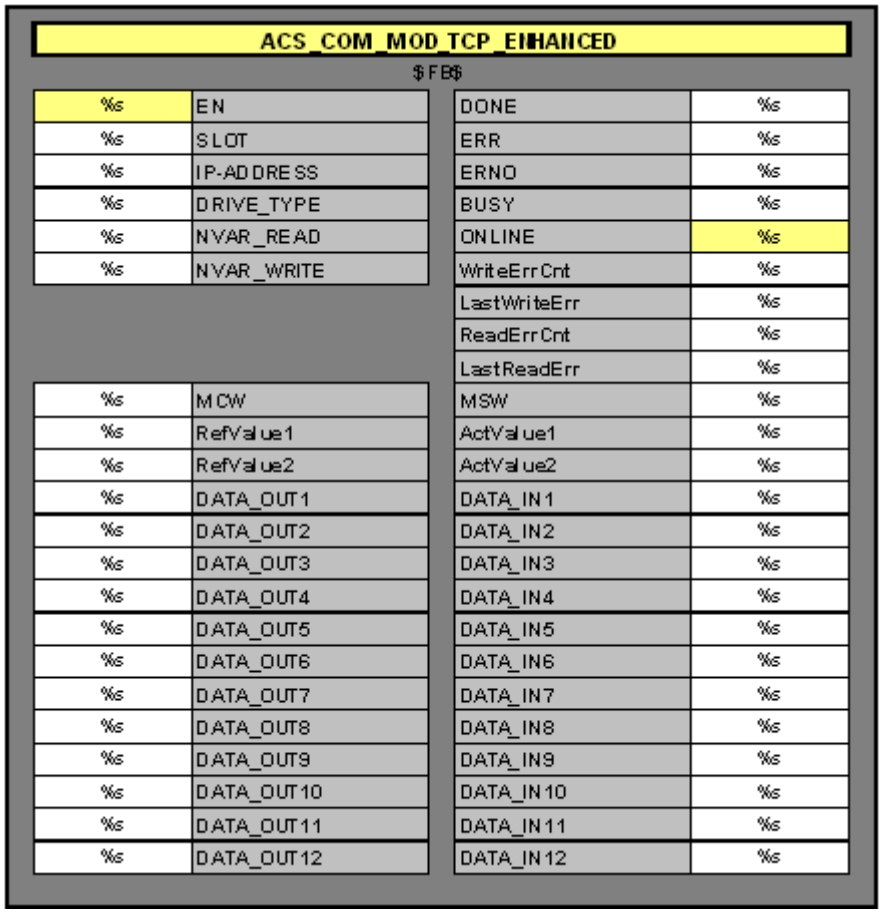
The color of the variables have the following meaning:

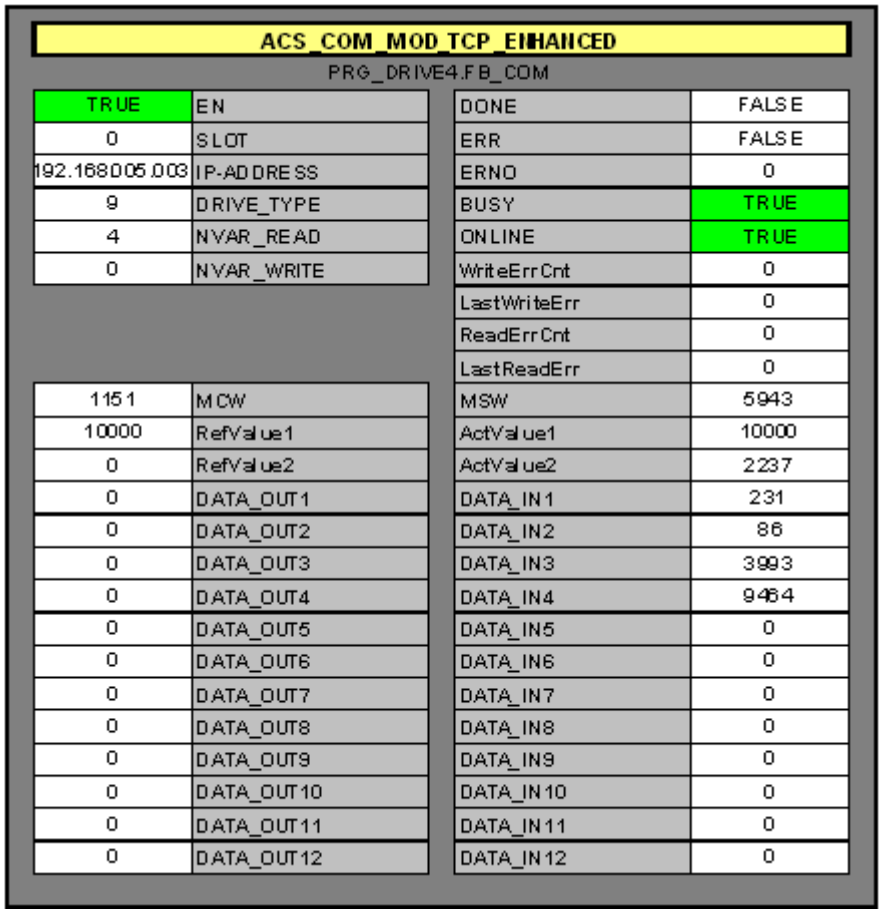
white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

ACS_COM_MOD_TCP_ENHANCED_VISU_PH faceplate for the function block ACS_COM_MOD_TCP_ENHANCED





Visualization element ACS_COM_MOD_TCP_ENHANCED_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_TCP_ENHANCED ↳ *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367* function block which instance was used to replace the placeholder FB.

The visualization could also be used to control the function block by those inputs which are not connected inside the program.

Visualization information

Available in runtime system:	V1.3.2
Included in library:	ACSDrivesComModTCP_AC500_V22_App.lib

Visualization description

Visualization element ACS_COM_MOD_TCP_ENHANCED_VISU_PH can be used to show the actual values of all inputs and outputs of the instance of an ACS_COM_MOD_TCP_ENHANCED ↳ *Chapter 1.5.6.4.3.2 “ACS_COM_MOD_TCP_ENHANCED communication for ACS / DCS drives via Modbus TCP” on page 2367* function block which instance was used to replace the placeholder FB.

All inputs of that ACS_COM_MOD_TCP_ENHANCED function block, which are not connected to a variable (left open) can be written from this faceplate. So the function block can be controlled from the visualization as long as the inputs are left open. The DRIVE_DATA variable must be connected to the function block.

The color of the variables have the following meaning:

white	Actual FALSE and should be FALSE in normal operation
green	Actual TRUE and should be TRUE in normal operation
yellow	Actual FALSE but should be TRUE in normal operation
red	Actual TRUE but should be FALSE in normal operation

The color of the background can be changed by writing a value to the global variable "dwAcsVisuBackgroundColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

The color of the title can be changed by writing a value to the global variable "dwAcsVisuTitleColor" *Chapter 1.5.6.2.7.1 “dwAcsVisuBackgroundColor and dwAcsVisuTitleColor global variables to set the background and title colors for the visualization elements” on page 2255*.

1.5.6.5 ACS / DCS drives communication via Modbus TCP ext library

To establish the communication to an ACS / DCS drive one of the following two libraries can be used: ACSDrivesComModTCP_AC500_V22.lib *Chapter 1.5.6.4 “ACS / DCS drives communication via Modbus TCP library” on page 2359* or ACSDrivesComModTCP_Ext_AC500_V24.lib The ACSDrivesComModTCP_AC500_V22.lib can be used, as long as the CPU does not support more than one internal Ethernet Interface. And this library must be used, if the Firmware-version of the CPU is less than V2.4.x.

The ACSDrivesComModTCP_Ext_AC500_V24.lib should be used for new project and if the Firmware Version of the CPU is at least V2.4.x. It must be used, if a CPU with more than one internal Ethernet Interface is used, e.g. PM595.

1.5.6.5.1 Preconditions for the use of the ACS / DCS drives communication via Modbus TCP ext library

The function blocks contained in the library can only be executed in RUN mode of the PLC, but not in simulation mode.

The blocks can only be used in combination with the ACSDrives-Base_AC500_V20 Library.

The library is released for the following products:

- **CPUs:** AC500 and AC500-eCo
- **Fieldbus:** Modbus TCP
- **Drives:**ACS800, ACSM1, ACS350, ACS355, ACS550, ACH550, ACQ810, ACS850, ACS880, ACS580, DCS550, DCS800
- **Modbus TCP configuration:**
  Prior to the use of the function blocks a Communication Module "Modbus_on_TCP_IP" has to be configured accordingly using Automation Builder, either at "Onboard_Ethernet" or at "CM597-ETH" module.
- **ACS_COM_MOD_TCPx and ACS_COM_MOD_TCPx_ENHANCED:**
  The communication function blocks are designed to be used each for one specific drive at runtime. So it´s not recommended to change the COM or SLAVE inputs of the blocks while the program is running.
  There is no check in the function blocks if the maximum number of TCP/IP sockets is already reached. So the user has to take care about the number of used socket. Each ACS_COM_MOD_TCP or ACS_COM_MOD_TCP_ENHANCED function block will use one socket.

1.5.6.5.2 Components of the ACS / DCS drives communication via Modbus TCP ext library

Function blocks

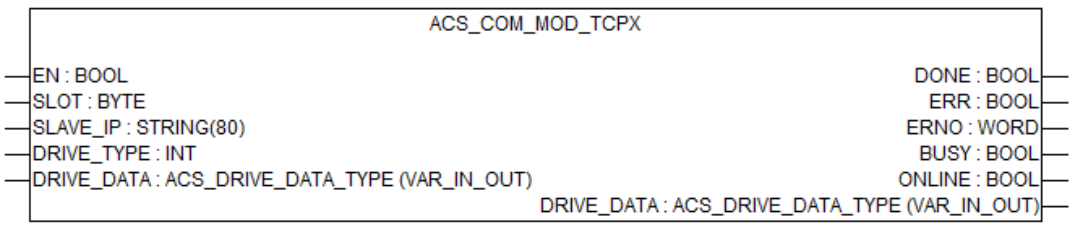
ACS_COM_MOD_TCPx ↳ *Chapter 1.5.6.5.3.1 "ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP" on page 2385*	Communication for ACS / DCS Drives via Modbus TCP
ACS_COM_MOD_TCPx_ENHANCED ↳ *Chapter 1.5.6.5.3.2 "ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP" on page 2392*	Communication for ACS / DCSDrives via Modbus TCP

Visualizations

ACS_COM_MOD_TCPx_VISU_PH ↳ *Chapter 1.5.6.5.4.1 "ACS_COM_MOD_TCPx_VISU_PH faceplate for the function block ACS_COM_MOD_TCPx" on page 2402*	Faceplate for the function block
ACS_COM_MOD_TCPx_ENHANCED_VISU_PH ↳ *Chapter 1.5.6.5.4.2 "ACS_COM_MOD_TCPx_ENHANCED_VISU_PH faceplate for the function block ACS_COM_MOD_TCPx_ENHANCED" on page 2405*	Faceplate for the function block

1.5.6.5.3 Function blocks

ACS_COM_MOD_TCPx communication for ACS / DCS drives via Modbus TCP



Function block ACS_COM_MOD_TCPx controls the Modbus TCP communication to an ACS / DCS drive and is used for the basic control of ACS / DCS drives with ABB Drives profile.

Function block information

Available in runtime system:	V2.4.x
Included in library:	ACSDrivesCom-ModTCP_Ext_AC500_V24_App.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_COM_MOD_TCPx controls the Modbus TCP communication to an ACS / DCS drive and is used for the basic control of ACS / DCS drives with ABB Drives profile.

If the user changes drive profile while drive is online with PLC, function block output's may give wrong indication.

Reading Status Information from Drive

The function block continuously reads data from the drive starting at Modbus register 400004. So at least the Status Word (SW), Actual Value 1 (SPEED_REF), Actual Value 2 (ACT_VALUE2) are continuously read from the drive and written to the DRIVE_DATA variable. These values are stored in DRIVE_DATA.MSW, ActValue1 and ActValue2.

The following table shows the performed Modbus read job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

Modbus register address in drive	**Mapping configuration in drive**			**Written to in AC500**	**Condition at function block**
	ACS355, ACS850, ACQ810, ACSM1, ACS880	**ACS800**	**ACS550, ACH550**		
Communication module	FENA-01 / -11	RETA-01 / -02	RETA-01 / -02		
40004	Status Word (SW)	Status Word (SW) fix	Status Word 51.23 (SW) fix	DRIVE_DATA.sw	EN = TRUE
40005	Actual Value1	92.02 = Actual Value1, e.g. = 102 (Speed)	51.24 = Actual Value1 (fix)	DRIVE_DATA.actValue1	EN = TRUE
40006	Actual Value2	92.03 = Actual Value2 e.g. = 105 (Torque) *)	51.25 = Actual Value2, e.g.= 105 (Torque)	DRIVE_DATA.actValue2	EN = TRUE
*) If 51.19 .. 51.22 (Output 1 .. 4) are set to the actual values the Modbus response will be faster because those values are updated cyclically between RETA-01 and ACS800.					

Writing Control Word and Reference Values to Drive

The function block checks if there are changes of the Control Word (CW), Reference Value 1 (SPEED_REF) or Reference Value 2 (REF_VALUE2) on the DRIVE_DATA variable. If there is a change a write job is requested to send these 3 values to the ACS drive starting at Modbus register 40001.

The following table shows the performed Modbus read job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

Modbus register address in drive	**Communication module**		**Written to in AC500**	**Condition at function block**
	ACS355, ACS850, ACQ810, ACSM1, ACS880, ACS580	**ACS800, ACS550, ACH550, DCS550, DCS800**		
Communication module	**FENA-01 / -11**	**RETA-01 / -02**		
40001	Control Word (CW)	Control Word (CW)	DRIVE_DATA.cw	EN = TRUE
40002	Reference Value1	Reference Value1	DRIVE_DATA.ref Value1	EN = TRUE
40003	Reference Value2	Reference Value2	DRIVE_DATA.ref Value2	EN = TRUE

If a Modbus job tries to access a register in the drive which has no valid mapping information the job is aborted with an error. Therefore the drive parameters in FBA DATA OUT group have to be configured according to the used NVAR_WRITE input number.

If 32-bit parameters are mapped to DATA OUT,

- *The following field in DATA OUT has to be left open (= 0)*
- *The word order of the High-Word and Low-Word can be configured in the drive. If e.g. FENA-x1 is used the configuration is done in Par.51.22.*
- *The original 32-bit value in AC500 has to be split up in HW and LW in the WRITE_VALUES array.*

Function block DATA OUT has to be configured in drive in the following groups see also FENA-x1 manual.

Drive	**Parameter group**
ACS355	55.01 .. 55.10
ACS850, ACQ810, ACSM1, ACS880	53.01 .. 53.12
ACS880	53.01 .. 53.02(Fieldbus A), 56.01 .. 56.12 (Fieldbus B)

ACS drive parameters are only saved temporarily, if changed via fieldbus. To make these changes permanent in the drive the special parameter "PARAMETER SAVE" has to be set. Please see drive manuals and following table which parameter has to be set.

Save valid parameters to permanent memory in drive	ACS3XX, ACX550, ACQ810, ACS850, ACSM1, ACS800	ACS880, ACS580	DCS550, DCS800
1 = Saves the valid parameter values to permanent memory. 0 = Save completed.	Par 16.07 = 1	Par 96.07 = 1	Par 16.06 = 1

Read/Write Jobs Coming from Other Function Blocks

The requests to process other read or write Modbus jobs is transferred via the DRIVE_DATA variable at the IN_OUT variable DRIVE_DATA which can be connected to several other read/write function blocks e.g. ACS_MOD_READ_N_PRM *Chapter 1.5.6.2.4.1 “ACS_MOD_READ_N_PRM” on page 2212* or ACS_MOD_WRITE_N_PRM *Chapter 1.5.6.2.4.2 “ACS_MOD_WRITE_N_PRM” on page 2215* of this drive.

Communication with Several ACS Drives

If several drives are used, for each drive a communication function block such as ACS_COM_MOD_TCPx or ACS_COM_MOD_TCPx_ENHANCED function block must be programmed.

The function block provides the basic start/stop signals, basic diagnosis signals and the scaling of the SPEED_REF input and ACT_SPEED to the ACS fieldbus scaling range. -20000 .. +20000.

The AC500 CPU types provide different numbers of usable TCP/IP sockets. For each ACS Modbus TCP communication block (ACS_COM_MOD_TCPx and ACS_COM_MOD_TCPx_ENHANCED) one socket will be needed. The user has to check that the programmed number of ACS Modbus TCP communication blocks is not higher than the number of available free sockets for the used CPU.

Diagnosis

The output ERNO, which reflects an actual error number is only valid for one cycle if DONE and ERR output are set to TRUE.

To catch this error number an external function must be programmed.

However there are internal diagnosis variables available, which are not shown at any output, but can be accessed from the function block instance. This can be done in three ways:

- Opening the "+" sign of function block instance in the declaration part being online.
- Create an assignment in the code with <instance>.<diagnosis variable>.
- Create a visualization element of the function block see ACS_COM_MOD_TCPx_VISU_PH.

The additional diagnosis variables are:

- iWriteErrCnt: number of errors in write jobs since EN = TRUE.
- wLastWriteErno: holds the error number of the last executed write job.
- iReadErrCnt: number of errors in read jobs since EN = TRUE.
- wLastReadErno: holds the error number of the last executed read job.

Preconditions

The function block is working with all ACS / DCS drives via Modbus TCP communication with field bus adapter FENA-X1 / RETA-X1.

The data transfer to other function blocks for this drive communication to the ACS / DCS drive is realized via the IN_OUTPUT variable DRIVE_DATA, which must be connected to then ACS_COM_MOD_TCPx even if no other function block is connected.

For ACS drive parameters must be set as follows:

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

Setting according to AC500 configuration or function block input	**ACS355**	**ACS850, ACQ810, ACSM1**	**ACS580, ACS880**	**ACS800, ACS550, ACH550, DCS550, DCS800**
Communication module:	FENA-01	FENA-11	FENA-11	RETA-01 / RETA-02
Fieldbus activation = EXT FBA / ENABLE	98.02	50.01	50.01	98.02
COMM RATE = Auto (0)	51.03	51.03	51.03	51.02
IP CONFIGURATION = Static IP (0) ! not default ! Set 51.27 (Refresh) after first change to "Static IP".	51.04	51.04	51.04	51.03
IP ADDRESS1 .. IP ADDRESS4	51.05 .. 51.08	51.05 .. 51.08	51.05 .. 51.08	51.04 .. 51.07 **)

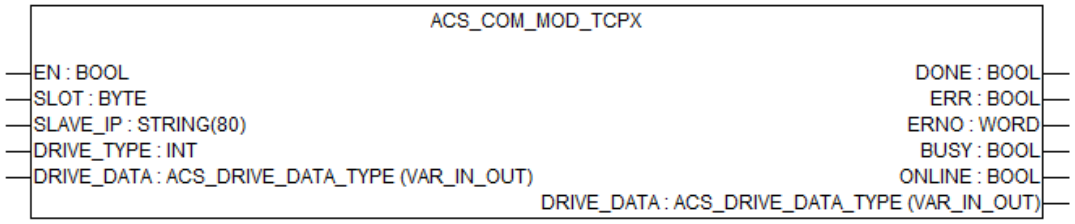
Refresh settings in drive	51.27	51.27	51.27	51.27
**) For RETA-01/-02 IP address could also be set via hardware DIP switches. If any switch is set (192.168.0.xxx) with xxx = DIP switches setting.				

For further settings, e.g. reaction of drive at communication error, please see related drive and fieldbus manual.

Input description



The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.

EN (enable)

Data type: BOOL

The function block is activated (EN = TRUE) or deactivated (EN = FALSE) via input EN.

If the block is active, the current values are available at the outputs.

After a rising edge (FALSE -> TRUE) of input EN output ONLINE is set to FALSE and parameters are read from the ACS drive.

The processing of continuously read of status information from the drive (SW, ACT_VALUE1 and ACT_VALUE2) and writing of Control Word and Reference Values (CW, SPEED_REF, REF_VALUE2) after changes to the drive is started.

If EN is reset to FALSE while a Modbus TCP job is performed (BUSY = TRUE), the function block will be processed until the Modbus TCP job is terminated (DONE = TRUE for 1 cycle).

If EN = FALSE the outputs ONLINE are reset to zero, as well as the data SW, actValue1 and actValue2 on the DRIVE_DATA variable are reset to zero.

SLOT (slot)

Data type: BYTE

At input SLOT, the Modbus interface number is specified:

SLOT = 1 : internal Ethernet communication module ETH1

SLOT = 2 : internal Ethernet communication module ETH2

SLOT = 11 : SLOT1 (CM597-ETH)

SLOT = 21 : SLOT2 (CM597-ETH)

SLOT = 31 : SLOT3 (CM597-ETH)

SLOT = 41 : SLOT4 (CM597-ETH)

Default value = 1. Valid values = 1, 2, 11, 21, 31, 41

SLAVE_IP (slave IP-Address)

Data type: STRING

IP Address of the drive (slave) to which the connecton shall be established must be specified here as string. Used with 4 times 3 digits.

Default value: ‘192.168.005.003’

DRIVE_TYPE (drive type)

Data type: INT, Default value: ACS_DRIVE_ACS355

At the input DRIVE_TYPE the type of ACS drive is specified with an ENUM. The input can be set either by the value directly or by using the enum.

ENUM	Value
ACS_DRIVE_ACS800	1
ACS_DRIVE_ACSM1	2
ACS_DRIVE_ACS350	3
ACS_DRIVE_ACS355	4
ACS_DRIVE_ACS310	5
ACS_DRIVE_ACS550	6
ACS_DRIVE_ACH550	7
ACS_DRIVE_ACQ810	8
ACS_DRIVE_ACS850	9
ACS_DRIVE_ACS880	10
ACS_DRIVE_ACS580	11
ACS_DRIVE_DCS800	12
ACS_DRIVE_DCS550	13
ACS_DRIVE_ACH580	14
ACS_DRIVE_ACS380	15
ACS_DRIVE_ACS480	16
ACS_DRIVE_ACQ580	17

DRIVE_DATA (drive data)

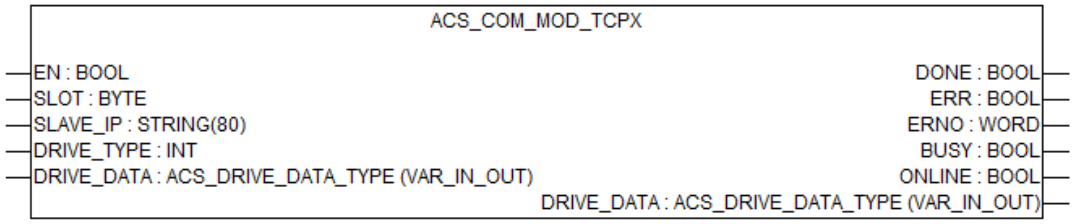
Data type: ACS_DRIVE_DATA_TYPE *Chapter 1.5.6.2.6.2 “ACS_DRIVE_DATA_TYPE structure to exchange data between function blocks for 1 Drive” on page 2253*

The combined input/output DRIVE_DATA must be connected to the variable of type ACS_DRIVE_DATA_TYPE of the related ACS drive (slave). Each drive must have its own DRIVE_DATA variable.

The DRIVE_DATA variable contains the data of the drive and must be connected to all related function blocks of this drive.

The function block ACS_COM_MOD_TCPx reads the Control Word and references (CW, SPEED_REF, REF_VALUE2) from the DRIVE_DATA variable and writes the status information (SW, ACT_SPEED, ACT-VALUE2) to the DRIVE_DATA variable. It also receives requests and data for Modbus jobs from other function blocks e.g. ACS_MOD_READ_N_PRM or ACS_MOD_WRITE_N_PRM via the DRIVE_DATA variable.

Output description



> *The inputs marked with a triangle ▷ are of the class VAR_IN_OUT (input and output variable). These inputs must be connected to a variable.*

DONE (done) Data type: BOOL

Output DONE indicates the state of the job processing. After completing or aborting the processing (due to an error), DONE is set to TRUE for one cycle. For that reason, the output always has to be considered together with output ERR. If ERR is TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERR (error) Data type: BOOL

Output ERR indicates whether an error occurred during block processing. This output always has to be considered together with output DONE. If DONE = TRUE and ERR = TRUE, an error occurred. In this case, the error number can be read at output ERNO.

ERNO (error number) Data type: WORD

Output ERNO provides an error identifier, if an invalid value was applied to an input or if an error occurred during request processing. ERNO always has to be considered together with the outputs DONE and ERR. The value output at ERNO is only valid, if DONE is TRUE and ERR is TRUE.

The encoding of the error messages output at ERNO is explained in the chapter *Chapter 1.5.3 “Error messages of the AC500 V2 function block libraries” on page 735*.

BUSY (busy) Data type: BOOL

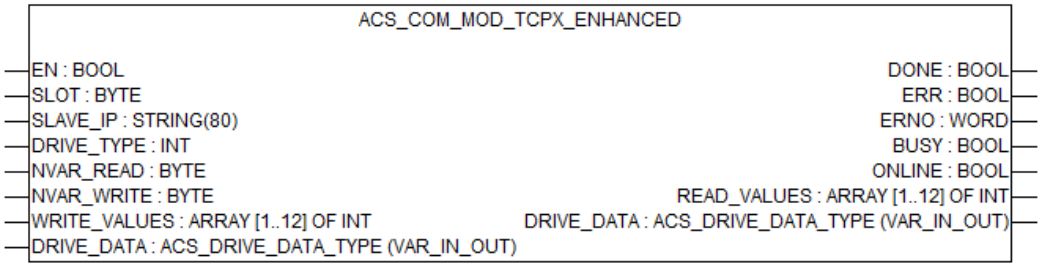
Output BUSY indicates, whenever there is a communication action performed.

ONLINE (online) Data type: BOOL

After the first time input EN is set to TRUE and at least one read job and one write job is performed successfully, output ONLINE is set to TRUE.

Output ONLINE is reset to FALSE after a rising edge of EN or if an error occurs while reading the status information or writing the Control Word and Reference Values.

ACS_COM_MOD_TCPx_ENHANCED communication for ACS / DCS drives via Modbus TCP



Function block ACS_COM_MOD_TCPx_ENHANCED establishes the Modbus TCP communication to an ACS drive. This function block is used for the basic control of the ACS drive using ABB Drives Profile Enhanced .It also reads and writes the drive parameters which are mapped in the drive.

Function block information

Available in runtime system:	V2.4x
Included in library:	ACSDrivesCom-ModTCP_Ext_AC500_V24_App.lib
Function block type:	Function block with historical values.

Block description

Function block ACS_COM_MOD_TCPx_ENHANCED establishes the Modbus TCP communication to an ACS drive and is used for the basic control of ACS drives with ABB Drives Profile Enhanced.

If the user changes drive profile while drive is online with PLC, function block output's may give wrong indication.

Reading Status Information from Drive

The function block continuously reads data from the drive starting at Modbus register 400051. So at least the Status Word (SW), Actual Value 1 (SPEED_REF), Actual Value 2 (ACT_VALUE2) are continuously read from the drive and written to the DRIVE_DATA variable. These values are stored in DRIVE_DATA.MSW, ActValue1 and ActValue2.

Apart from these three there is also an option to read 12 additional drive parameters. Using the input NVAR_READ the function block can be configured to read between 0 and 12 parameters from the drive. All read data is then written to the array at the READ_VALUE output. Configuration in ACS drive is depending of configured parameters in group FBD DATA IN.

The following table shows the performed Modbus read job and the needed mapping in the drive as well as the area where the data is stored in the AC500.

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

Modbus register address in drive	Mapping configuration in drive		Written to in AC500	Condition at function block
	ACS355	ACS850, ACQ810, ACSM1, ACS880, ACS580		
400051	Status Word (SW)	Status Word (SW)	DRIVE_DATA.sw	EN = TRUE
400052	Actual Value1	Actual Value1	DRIVE_DATA.act Value1	EN = TRUE
400053	Actual Value2	Actual Value2	DRIVE_DATA.act Value2	EN = TRUE
400054	FBA DATA IN 1	FBA DATA IN 1	READ_VALUES[1]	EN = TRUE and NVAR_READ >= 1

Modbus register address in drive	Mapping configuration in drive		Written to in AC500	Condition at function block
400055	FBA DATA IN 2	FBA DATA IN 2	READ_VALUES[2]	EN = TRUE and NVAR_READ >= 2
...	...	...	...	...
400063	FBA DATA IN 10	FBA DATA IN 10	READ_VALUES[10]	EN = TRUE and NVAR_READ >= 10
...		...	...	...
400065		FBA DATA IN 12	READ_VALUES[12]	EN = TRUE and NVAR_READ = 12

If a Modbus TCP job tries to access a register in the drive which has no valid mapping information the job is aborted with an error.

Therefore the drive parameters in FBA DATA IN group have to be configured according to the used NVAR_READ input number.

If 32-bit parameters are mapped to DATA IN,

- *The following field in DATA IN has to be left open (= 0)*
- *The word order of the High-Word and Low-Word can be configured in the drive. (using FENA-X1: Par. 51.22)*
- *To retrieve the original 32-bit value from the drive in AC500 the HW and LW from READ_VALUES fields have to be recombined in the program.*

Function block DATA IN has to be configured in drive in the following groups see also FSCA-01 manual.

Drive	Parameter group
ACS355	54.01 .. 54.10
ACS850, ACQ810, ACSM1, ACS880, ACS580	52.01 .. 52.12 52.01 .. 52.12 if installed as adapter A

Writing Control Word and Reference Values to Drive

The function block checks if there are changes of the Control Word (CW), Reference Value 1 (SPEED_REF) or Reference Value 2 (REF_VALUE2) on the DRIVE_DATA variable. If there is a change a write job is requested to send these 3 values to the ACS drive starting at Modbus register 400001.

Apart from these three parameters there is also an option to write additional 12 more drive parameters in the same Modbus job. Using the input NVAR_WRITE the function block can be configured to write between 0 and 12 more parameters to the drive. The necessary values have to present in the array connected to WRITE_VALUES input.

The following table shows the performed Modbus write job and the needed mapping in the drive as well as the area from where the data in the AC500 is taken.

Please refer the respective drives / fieldbus module manual for parameter setting, if the drive setting is not mentioned in below table.

Modbus register address in drive	Mapping configuration in drive		Written to in AC500	Condition at function block
	ACS355	ACS850, ACQ810, ACSM1, ACS880, ACS580		
400001	Control Word (CW)	Control Word (CW)	DRIVE_DATA.cw	EN = TRUE
400002	Reference Value1	Reference Value1	DRIVE_DATA.ref Value1	EN = TRUE
400003	Reference Value2	Reference Value2	DRIVE_DATA.ref Value2	EN = TRU
400004	FBA DATA OUT 1	FBA DATA OUT 1	READ_VALUES[1]	EN = TRUE and NVAR_WRITE >= 1
400005	FBA DATA OUT 2	FBA DATA OUT 2	READ_VALUES[2]	EN = TRUE and NVAR_WRITE >= 2
...	...	...	...	...
400013	FBA DATA OUT 10	FBA DATA OUT 10	READ_VALUES[10]	EN = TRUE and NVAR_WRITE >= 10
...		...	...	...
400015		FBA DATA OUT 12	READ_VALUES[12]	EN = TRUE and NVAR_WRITE >= 12

If a Modbus TCP job tries to access a register in the drive which has no valid mapping information the job is aborted with an error.

Therefore the drive parameters in FBA DATA OUT group have to be configured according to the used NVAR_WRITE input number.

If 32-bit parameters are mapped to DATA OUT,

- *The following field in DATA OUT has to be left open (= 0)*
- *The word order of the High-Word and Low-Word can be configured in the drive. (using FENA-X1: Par. 51.22)*
- *To retrieve the original 32-bit value from the drive in AC500 the HW and LW from WRITE_VALUES fields have to be recombined in the program.*

Function block DATA OUT has to be configured in drive in the following groups see also FENA-X1 manual.

Drive	Parameter group
ACS355	55.01 .. 55.10
ACS850, ACQ810, ACSM1, ACS580, ACS880	53.01 .. 53.12 53.01 .. 53.12 if installed as adapter A

ACS drive parameters are only saved temporarily, if changed via fieldbus. To make these changes permanent in the drive the special parameter "PARAMETER SAVE" has to be set.

Please see drive manuals and following table which parameter has to be set.

Save valid parameters to permanent memory in drive	ACS3XX, ACQ810, ACS850, ACSM1	ACS880, ACS580
1 = Saves the valid parameter values to permanent memory. 0 = Save completed.	Par 16.07 = 1	Par 96.07 = 1

Read/Write Jobs Coming from Other Function Blocks
